4) Blockchain technology which is known for secure and transparent nature can be used in multiple applications of tourism and hospitality. Blockchain can improve security and transparency of transactions, supply chain management, and veracity of customer reviews [25]. Blockchain technology may be used for safe creation of immutable transaction ledger that can reduce intermediaries, double selling frauds and ensure the integrity in booking and payment process [26]. Furthermore, blockchain could allows sharing data between various travel industry constituents securely [27].

C. Traditional Demand Forecasting Methods

Traditional demand forecasting techniques such as linear regression, ARIMA (Autoregressive Integrated Moving Average) and exponential smoothing have been used for a long time in tourism and hospitality sector. These techniques are easy to implement and interpret but lack the ability to capture the complexities among variables. For example, linear regression models assume that independent variables and demand have a linear relationship which may not be true in practical case-study environments. ARIMA models are better than linear regression but are not able to incorporate external factors like weather, events or competitor's prices. Many research papers have proved that traditional models fail to give promising results when it comes to accurately predicting hotel demand. The research in [28] states that ARIMA model provides inaccurate predictions when data exhibits high seasonality due to events as well as irregular patterns of demand especially during peak stays. The study in [29] suggests sophisticated forecasting methods with enhanced performances exhibiting non-linear patterns of multiple determinants.

D. Artificial Intelligence for Demand Forecasting

Artificial Intelligence (AI) has become a powerful tool to predict demand, especially in industries where demand is affected by multiple internal and external factors. Contrary to conventional models, AI techniques are capable of dealing with complex and non-linear relationships, while learning automatically from historical data. The most frequently used AI algorithms for demand prediction include the following.

1) Decision trees and Random Forests: These algorithms can be applied with any type of data (Numerical or Categorical), moreover it provides feature importance ranking that could help understand the impact of each factor on influencing the demand [30].

2) Support Vector Machines (SVM): SVM are efficient in high dimensional space and have been applied for hotel occupancy prediction as well. However, performance of SVM is parameter sensitive and scaling dependent [31].

3) Artificial Neural Networks (ANN): Artificial neural networks have been used for demand forecasting because of its ability to learn nonlinear and complex patterns, but the ANNs demand huge amounts of quality data and computational requirements [32].

4) Deep learning: LSTM is a recurrent neural network type [33] that is well-suited to time series forecasting problems due to their ability in handling long-term dependencies in data [34].

E. Influencing Factors in Tourism Demand Forecasting

Several studies emphasized the need to include external factors in forecast models, thus improving their prediction capacity.

1) Seasonality: The study in [35] investigates the seasonality of tourism and its implication on booking pattern. Hotels in popular tourist areas often face high demand during holidays and school breaks.

2) Competitor pricing: The study in [36] found that many customers compare prices on several platforms before booking, so competitor pricing is likely to have an impact on customer booking behaviour.

3) Local events: The study in [37] showed that large local events such as conferences, music festivals or sports tournaments can generate a peak of demand in the short-term so being able to integrate event-based information will greatly benefit forecasting.

4) Weather conditions: The research in [38] pointed out that the weather conditions significantly impact the hotel demand in leisure destination, especially for outdoor tourism activity.

III. Models and Experimental Setup

Based on the literature study and preliminary experiments, the following Artificial Intelligence models have been selected for further evaluation.

A. Long Short-Term Memory (LSTM)

LSTM, a special kind of recurrent neural network (RNN), is very popular in time series prediction since it can learn long-term and short-term dependency. LSTM networks maintain memory over time by using gated cells to control the flow of information.

1) Architecture: In this study, the LSTM model consists of 2 hidden layers each with 128 LSTM units, followed by a dense layer with single neuron for regression output. Dropout regularization was used to prevent overfitting.

2) Training: Adam optimizer with learning rate of 0.001 is used and mean squared error is taken as loss function. Early stopping based on validation performance is done after training for 50 epochs.

3) Feature selection: LSTM model uses lag features along with other booking related internal features, weather data and

few indicators to include external influence in the model and temporal patterns.

B. Random Forest

Random Forest is an ensemble learning method. Building multiple decision trees at training and outputting the average prediction of all the individual trees can reduce overfitting and improve model generalizability.

1) Feature importance: Random Forest provider a feature importance ranking which indicate are the most important variables driving booking demand. In this research room pricing, competitor rates, and local events were found to be the most important features.

2) Hyperparameters: The model was tuned by grid search with number of trees (n_estimators) set to 500, maximum depth set to 10 and minimum samples per leaf set to 5.

C. XGBoost

XGBoost is an optimized implementation of gradient boosting that will increase the speed and performance of the model. It builds decision trees one at a time, trying to reduce the errors from the last iteration. It also handles missing data.

1) Boosting rounds: The model was set to do 100 boosts/rounds with early stopping enabled so it doesn't overfit.

2) Regularization: L1 and L2 regularization terms are added to the objective function to prevent overfitting, especially when there are some noisy features such as competitor pricing data.

D. Prophet

Prophet is a time-series forecasting algorithm developed by Facebook to make fast and accurate predictions on non-linear trends, seasonality and holiday effects. It is very useful in the tourism industry because there are a lot of seasonal patterns and event-triggered peak or drop demand. Some of the key features are:

1) Seasonality components: You can easily model multiple seasonality components with Prophet (i.e. weekly and yearly) which makes it great for predicting hotel bookings as they have very clear seasonalities.

2) Holiday and event handling: In Prophet's model special event indicators are added to account for local festivals, conferences, etc, that cause demand to surge.

IV. Experimentation and Results

A. Data Collection and Preprocessing

The dataset used in this study is a real-world hotel booking dataset obtained from an internal data source of a well-known Major hotel chain in Morocco. The data collected ranged from 2015 to 2023. It includes:

1) Booking data: These captures booking date, room type, length of stay, booking channel and information on cancellations and no-shows.

2) Customer data: This captures nationalities, age, range and purposes of travel (business/leisure).

3) Pricing data: The room price at the time of booking, the discount applied to booking for prepayment or another reason, and variations in prices due to changes in demand, seasonality and other reasons.

4) Competitor data: Pricing data of competitor hotels fetched from 3rd party aggregators and web scraping.

5) External data: Weather conditions (Temperature, Precipitation), local event schedules (Conferences, Festivals).

External data such as weather information, and local events' data were also added to the dataset considering the impact of these factors on customer demand. Data preprocessing was performed in order to make sure that the dataset is suitable for analysis:

1) Handling missing data: Missing values in customer demographics were imputed with median or mode imputation. Missing weather or competitor pricing data were filled with interpolation.

2) Outlier detection and removal: Outliers in room rates, booking lengths and cancellations were detected using the Inter Quartile Range (IQR) method and capped within a reasonable range to avoid any distortion in the model.

3) Normalization and standardization: Continuous variables like room rates and customer ages were normalized using Min-Max scaling, while categorical variables like booking channels and room types were one-hot encoded.

B. Feature Engineering

Feature Engineering was an important factor to increase the predictive power of the Artificial Intelligence models. The following new features have been created:

1) Lag features: booking data from the last 7, 14 and 30 days before each reservation were used to create lag features so the model could account for trends and seasonality

2) Event indicators: Binary indicators have been constructed to identify the occurrence of major local events (festivals, sports tournaments, meetings etc.), which are expected to impact short-term demand positively.

3) Weather features: Features including temperature (in Celsius and Fahrenheit), humidity, and precipitation were updated, as the weather conditions have a significant differentiating impact in some specific leisure destinations in particular.

4) Price competitiveness: A variable which measures the difference between hotel's room rate and its competitor was defined to consider the effect of competitive pricing on demand.

C. Data Experimental Setup

The dataset was partitioned into training (80%) and testing (20%), datasets using data from 2015 to beginning 2021 as the training data and data from beginning 2022–early 2023 as testing dataset. To tune hyperparameters and validate the models, a 5-fold cross-validation step was used. After building

each model, their performance was further examined using both the training and testing datasets to evaluate their generalization capacity.

- Training Set: 2015-2021
- Testing Set: 2022-2023

D. Evaluation Metrics

Several performance metrics were used to assess the accuracy and reliability of the models:

- Mean Absolute Percentage Error (MAPE): A percentage-based measure of prediction accuracy, useful for comparing models across different scales.
- Root Mean Square Error (RMSE): A common measure of the magnitude of prediction errors.
- R-squared (R^2): Represents the proportion of variance in the dependent variable explained by the independent variables.

E. Results Analysis

The performance metrics of the models (LSTM, Random Forest, XGBoost, and Prophet) are summarized in Table I.

TABLE I. PERFORMANCE METRICS OF THE MODELS

Model	Metrics		
	MAPE (%)	***RMSE (%)***	***R^2***
LSTM	5.42	12.34	0.92
Random Forest	6.18	13.27	0.89
XGBoost	5.75	12.88	0.90
Prophet	7.12	14.22	0.87

The results show that:

- The LSTM model outperforms all models with the capability to capture both short-term and long-term demand dependencies. Based on the results, this model has an MAPE of 5.42% and $R^2 = 0.92$ which indicates highest accuracy among all developed models.
- Both Random Forests and XGBoost have relatively similar performance where Random Forests performs better in feature importance analysis while not delivering good performance in temporal prediction.
- Prophet was the weakest by far on both performance measures, not great at short-term fluctuations, but pretty comfortable with seasonality.

F. Feature Importance Analysis

Understanding the factors that affect customer demand is important before beginning any predictive modeling. This statement becomes more relevant and challenging in Tourism and Hospitality due to high level of competition as well as dynamic nature of sector. We used four different models Long Short-Term Memory, Random Forest, XGBoost and Prophet to understand which factors are affecting customer demand prediction the most. In such highly competitive industry, identifying these key features can help organizations allocate resources appropriately, make effective pricing decisions and create popular marketing campaigns. This section explores all such important features identified by each model along with explaining their impact on customer demand in detail.

1) Room pricing and discounts: Pricing is an important driver of customer booking behavior and all the four models recognized it as one of the predictors to influence demand.

a) LSTM Analysis:

- Long-term Trends: LSTM being suited for capturing long-term dependencies in time-series data proved that room pricing and discount strategies were highly influential in long-run. Price fluctuations, especially discounts, contributed a variance of 30% in the model prediction.
- Seasonality and Discounts: LSTM was able to learn from the data how room prices interact with the seasonal demand patterns, especially in high-peak seasons where discounts are an important strategy influencing customer decision-making. Special offers, promoting events, or early-bird discounting are particularly important during this period.

b) Random Forest insights:

- High Contribution to Variance: The model Random Forest hat is based on decision trees, clearly indicates that the pricing of rooms and discount offered are the most important variables since it contributed 34% to the overall variance of booking. As an ensemble method, Random Forests are also particularly suitable for feature importance calculation and they are therefore highly exposed to differences in prices between regions or market segments.
- Price Sensitivity: Most important it showed that especially customers in the budget segment and the mid-range segment react very elastic to price changes. If a hotel makes even small increases there will be considerable cuts in bookings.

c) XGBoost insights: XGBoost indicated that the price of rooms interacts with other features, such as competitor's price and lead time. The price of rooms together with a discount offered contributes to 32% of demand forecasting. Hence, this model is better at capturing the interaction effect between price of the room and the discount offered.

d) Prophet's perspective: The Prophet provided a surrogate model for seasonality which revealed room price is not the highest contributing feature. But it still accounts for around 25% of demand variability when the seasonally room prices are adjusted. And also, during holidays and festive seasons room pricing contributes disproportionately.

2) Competitor pricing: Competitor pricing was also identified as a main component, reinforcing the view that price competition matters in the hotel industry.

a) LSTM Analysis:

- Real-Time Fluctuations: The LSTM model captures real-time fluctuations of competitor prices (prices of other hotels), which in fact affect the booking demands

in short-term horizon. The competitor price directly contributed 20% to the demand variation as reflected by LSTM, meaning that customer's choice is largely influenced by competitor price, especially under high competition environment.

- Temporal Sensitivity: customers frequently make comparisons (between hotels) on real-time prices, and LSTM has indicated sensitivity on short-term changes of bookings.

b) Random Forest insights:

- Market Dynamics: Random Forest identified competitor pricing as the second most important feature contributing 22% of variance in bookings. The model indicated that real-time competitor rate monitoring, especially in markets with high hotel density, is of utmost importance.
- Dynamic Pricing Strategies: Given the importance of competitor pricing; demand predictions and revenue can be greatly improved using dynamic pricing algorithms where prices are adjusted based on competitor behaviour.

c) XGBoost insights: XGBoost highlighted that competitor pricing had a 21% contribution to the prediction. With the ability of the model to handle non-linear interactions, it became apparent how perplexing customers respond to both its prefered hotel's price and its competitors' price. Competitive rate was especially important during promotional period.

d) Prophet's perspective: In Prophet, where more seasonality is captured, competitor pricing also had an important role but with 15% contribution in demand changes. the price competition impact demand changes during high traffic days such as weekend and public holiday.

3) Local Events: Local events—festivals, conferences, concerts etc. were identified as a major short-term booking demand driver.

a) LSTM Analysis:

- Event-driven spikes: The LSTM model was able to capture short-term event-related spikes of bookings demand contribution ~25% of booking variance. This feature is most important for hotels in proximity to the places where event take place and experiencing huge increases of demand over particular periods (externalities).
- Seasonality of Events: The model was able to learn long term seasonal patterns which are caused by periodic events such as annual festivals, or trade shows and make use of this information in the forecast of the demand surge.

b) Random Forest insights:

- Short-Term Variations: Random Forest reported the local events contributes 18% to the variance of bookings and it is an important feature for booking rate prediction close future, which means our hypothesis based on anticipation of events is supported.
- Geographical Sensitivity: The result also showed that the geographical variation is a specific feature, which means hotels located in the central city or spots with high tourist volume showed higher responsiveness with respect to this feature.

c) XGBoost Insights: XGBoost showed that 19% of the accuracy in predicting demand comes from local events. Hotels need to consider the size and popularity of events, as smaller local events don't have as large an effect as major conferences or festivals.

d) Prophet's perspective: Prophet considers holidays and events in its seasonality component and assigned 23% to event-related changes in demand. It performs especially well with recurring events like national holidays and effective in forecasting demand for event-heavy periods.

4) Weather conditions: Weather conditions, particularly in regions dependent on outdoor activities, significantly influenced booking behavior.

a) LSTM Analysis: LSTM was able to capture long term weather patterns including seasonal differences and short terms weather conditions such as storms or heatwaves. This feature contributed 15% to the variance by the model for predicting demand, especially for destinations with outdoor activities like beach resorts or ski lodges.

b) Random Forest insights: Random Forest showed that weather conditions contributed 15% of the variance in customer demand. It wwas able to capture how a certain event characterized by extreme weathers (hurricanes, heatwaves) led to sudden shift of booking's trend.

c) XGBoost Insights: XGBoost identified that weather is responsible for 13% of the variation in demand, especially in places where the overall experience is very much linked to the weather. The non-linear impact of weather was well captured by this model (i.e., some slight changes in temperature can create huge deviations in demand).

d) Prophet's perspective: Prophet attributes 18% of the total variance in demand to features related with weather. This model was also able to better incorporate both short-term as well as cyclical effects associated with weather on long-term forecasts.

5) Booking lead time: Furthermore, booking lead time which is the duration between a customer making a booking until their actual check-in date was detected as an important feature among all the models.

a) LSTM analysis: LSTM model that is capable of handling sequential data, revealed that 12% of the predictive power of the obtained model is due to this feature (booking lead time). The model captured long-term patterns in customers' booking behaviour such early bookings for holiday and last-minute reservations for business.

b) Random Forest insights: Random Forest indicated that booking lead time contributed 10% to the total variance and showed how different types of customers (e.g., leisure versus business) has different patterns of booking lead times.

c) XGBoost Insights: XGBoost indicated that booking lead time contributed 11% to the model performance and that the interaction between booking lead time with room price is important because earlier bookers often get lower prices as an incentive for them to book early, which influencing booking behavior.

d) Prophet's perspective: Prophet found that lead time was responsible for 9% of the total forecast, particularly in predicting holiday demand, capturing how far ahead customers typically book during peak travel periods.

6) Comparison of model performance in feature importance

- LSTM: proficient for capturing long term dependencies and interplay between seasonal factors, pricing and lead time.
- Random Forest: Best adapted to understand the importance of features relatively across different customer segments and geographies.
- XGBoost: Works well at capturing complicated, non-linear feature interactions (e.g. pricing vs. local events).
- Prophet: Primarily heavily relied on seasonality and event driven demand, works better with time series (predictable recurring patterns).

By utilizing the strengths of each model, this holistic feature importance study reveals insightful knowledge about the determinants of customer demand for Tourism and Hospitality. Such information can assist practitioners in making better-informed decisions based on data analytics in managing operations as well as developing pricing and marketing strategies.

7) Model interpretability and feature engineering: Incorporation of external data with local events and weather data lead to significant improvement in models, hence proving the need of feature engineering. Creation of lag variables for room price and competitor rates were also found useful in capturing price dependency booking pattern by models.

Apart from predictions, Random Forest and XG Boost provided insights on feature importance which was advantageous for hotel managers/planners as they targeted the most influential factors when modifying their pricing or marketing strategies. Knowledge about demand drivers would permit hotels to make better decisions on promotions, dynamic pricing and allocation of resources.

V. Discussion

A. Implications for Revenue Management

The accuracy of booking demand prediction can bring significant impacts on revenue management. Hotels indeed have the opportunity to adjust room prices dynamically when they expect high demand, and reduce the number of vacant rooms when they face lower booking likelihood. In addition, hotels can also be more effective with their pricing strategies when they understand their rivals better in the market to capture those customers sensitive with price, while maintaining profitability.

The results from this study show that indeed, there is an important impact of dynamic pricing policies on the hotel revenues since through including the competition pricing, local events data and weather data in forecasting models hotels may obtain more accurate information about the expected future demand.

B. Impact on Operational Efficiency

Accurate forecasts of customer demand can lead to improvements in operational efficiency through optimized staffing, inventory management, and marketing efforts. For instance, during peak periods of demand hotels might want to staff positions so as to ensure the best possible guest experiences while they simultaneously have an incentive to reduce labor costs during low demand periods. More generally, using demand forecasts for managing food and beverage (F&B) inventory can alleviate both waste issues and problems with stocking out of items which are in high demand from guests.

The findings derived from this study would provide skills for hotels where those allocations shall be made appropriately not only reduce operation costs but also increases customer satisfaction.

C. Limitations of the Study

While the models developed in this study have very high accuracy, there are a several of limitations that need to be acknowledged:

- External Events: Unpredictable external events like political instability, pandemics, and natural disasters can significantly change booking behavior thus making it difficult to accurately forecast the demand.
- Generalization: Models built in this study have been developed using data from a single hotel chain meaning that they are not generalizable across hotels or regions. In future research, this could be made more applicable across hotel types e.g., boutique or budget hotels.

VI. Future Work

A. Expanding Model Generalization to Different Hotel Types

Future research needs to further develop generalizable predictive models for different types of hotel properties – i.e., budget accommodations, luxury resorts and boutique hotels – in diverse geographic regions to obtain more robust findings that can better meet the varied requirements of the hospitality industry within market segments.

B. Integration of Macroeconomic Indicators

Future research should also examine whether relevant macroeconomic indicators (e.g. exchange rates, fuel prices and unemployment rates) would strengthen their predictive power as they affect travel decision making; for example, during economic recessions, customers would more likely choose cheaper boutique or budget accommodations or engage in local tourism activities, while during economic booms, customers might prefer luxury hotels or overseas trips.

C. Addressing Extreme Events in Forecasting

The challenge of such approaches is how the model deals with out of sample events like a pandemic or for example in the case of an earthquake which impacts generates considerable damages, but not demand.

Future work should see if there are ways that models can be improved to deal more effectively with these types of events, potentially through hybrid methods where ML and traditional scenario planning are used together and where rare but significant events are easier captured on the supply side.

D. Cross-Industry Applications

While this research paper concentrates on the tourism and hospitality industry, there is potential for the methodologies and models developed to be used in other industries where accurate demand forecasting is of high importance; for example, retail, airlines or car rentals. The extension of these predictive models would be beneficial to those industries that experience dynamic patterns of demand and are influenced by similar market drivers.

E. Leveraging Hybrid AI Approaches and Hybrid Metaheuristics for Enhanced Demand Forecasting

Future research should also investigate the potential of hybrid AI approaches and hybrid metaheuristics to enhance the efficiency and accuracy of demand forecasting models. By hybridation of various optimization techniques—such as metaheuristics methods and hybridation of AI models like LSTM, Random Forest, XGBoost, and Prophet, researchers can develop robust frameworks that effectively tackle complex, dynamic demand patterns. Hybrid metaheuristics can optimize model parameters and search for better solutions in complex environments, improving the overall performance [39]. Additionally, the insights gained from this hybrid methodology is applied across different sectors, allowing for improved operational strategies in industries facing different challenges [40, 41].

VII. Conclusion

Accurate prediction of booking trend and customer demand in tourism and hospitality industry is essential for revenue maximization, operation optimization, and customer satisfaction. This paper revealed that how Artificial Intelligence models like LSTM, Random Forest, XGBoost as well as Prophet can be utilized to build robust demand forecasting model by incorporating internal and external factors. The results underline the significance of dynamic pricing, the effect of event related demands' influx, and the role of competitor's price in molding customers' responses.

Data-driven decision making enables hotels to forecast changes in demands more accurately which facilitates improved resources allocation plans as well as pricing strategies resulting higher profitability and better guest experience.

Advancing the predictive modelling capabilities in tourism and hospitality through this research will support smarter, efficient management to cope with changing industry dynamic.

The relevance of this research in the community, more particularly to the tourism and hospitality industry, is very high. This research develops a powerful multi-algorithmic AI-driven framework to forecast hotel booking trend and customer demand accurately. It allows hotel managers to make better decisions concerning their hotel operations. The use of external factors regarding competitors' pricing, local events, weather conditions tend to make more reliable demand predictions which lead to smarter revenue management decisions, increase efficiency in operations and target marketing efforts more effectively. Such a data-driven approach will help both business organizations' bottom-line and practitioners within other domains applying predictive analysis realize its potential towards making accurate business-related forecasting. Making informed decisions through such research could support sustainable growth and continuous delivery of quality service in the community.

The study's limitations include the impact of unpredictable external events, such as political instability, pandemics, and natural disasters, which can significantly alter booking behavior and make accurate demand forecasting challenging. Additionally, the models were developed using data from a single hotel chain, limiting their generalizability to other hotels or regions.

Future research aims to enhance the generalization of predictive models across various hotel types and geographic regions, improving their relevance across market segments. Incorporating macroeconomic indicators such as exchange rates and unemployment rates can increase predictive accuracy by considering external factors influencing travel behavior. Moreover, addressing extreme events like pandemics or natural disasters remains a challenge, but hybrid models that integrate artificial intelligence with traditional scenario planning could offer better solutions. Extending these models to industries such as retail, airlines, and car rentals would also prove beneficial due to their similar demand dynamics.

***Abstract*—This article presents an advanced approach to optimize production in Reconfigurable Manufacturing Systems (RMFS) by integrating Petri Nets with artificial intelligence (AI) techniques, particularly a genetic algorithm (GA). The proposed methodology aims to enhance scheduling efficiency and adaptability in dynamic manufacturing environments. Quantitative analysis demonstrates significant improvements, with the approach achieving an 85% success rate in reducing lead times and improving resource utilization, outperforming traditional scheduling methods by a margin of 15%. Furthermore, our AI-driven system exhibits a 90% success rate in providing data-driven insights, leading to more informed decision-making processes compared to existing neural network optimization techniques. The scalability of the proposed method is evidenced by its consistent performance across various RMS configurations, achieving an 80% success rate in optimizing scheduling decisions. This study not only validates the robustness of the proposed method through extensive benchmarking but also highlights its potential for widespread adoption in real-world manufacturing scenarios. The findings contribute to the advancement of intelligent manufacturing by offering a novel, efficient, and adaptable solution for complex scheduling challenges in RMFS.**

***Keywords*—Artificial Intelligence (AI); Genetic Algorithms (GAs); optimization; intelligent scheduling; Petri Nets; Reconfigurable Manufacturing Systems (RMFS); scheduling**

I. Introduction

This Reconfigurable Manufacturing Systems (RMFS) represent a significant shift in modern manufacturing, characterized by their ability to rapidly adapt to changing production requirements [1], [2]. Traditional scheduling methods in RMFS often struggle to meet the demands of high variability and dynamic production environments, leading to inefficiencies such as extended lead times and suboptimal resource utilization [1], [2]. In response to these challenges, contemporary approaches to intelligent scheduling have increasingly leveraged techniques such as machine learning, optimization algorithms, and real-time data analytics [3], [4]. These methods aim to enhance the flexibility, efficiency, and responsiveness of manufacturing operations [4].

Despite these advancements, current intelligent scheduling techniques often face limitations in scalability, adaptability, and computational efficiency, particularly when applied to complex RMFS configurations [5], [6]. Existing literature highlights the use of neural networks, genetic algorithms, and hybrid models in various scheduling applications [5], [6]. However, there remains a gap in approaches that effectively integrate these methods with Petri Nets for RMS optimization [7-9]. This gap underscores the need for innovative solutions that can address the shortcomings of existing methods while enhancing overall performance [9].

To justify the necessity of the proposed work, this study focuses on key performance parameters such as scheduling efficiency, adaptability to dynamic environments, and resource optimization [3], [10], [11]. By integrating Petri Nets with AI-driven algorithms, we aim to offer a novel approach that surpasses traditional and contemporary methods in these critical areas [9], [10]. A comprehensive review of recent literature is conducted to contextualize the contributions of this research and highlight the need for more robust and adaptable scheduling solutions in RMS [3], [4]. This study seeks to bridge the identified gaps by providing a method that not only improves scheduling outcomes but also demonstrates superior performance metrics compared to existing approaches [9].

Modern manufacturing industries must find innovative solutions to maintain agility and efficiency in today's rapidly evolving and competitive landscape [12]. The adoption of reconfigurable production systems (RMFS) is an essential element of modern manufacturing. The unprecedented flexibility offered by these systems enables manufacturers to quickly adapt to changing market demands, product variations, and operational requirements [13].

However, the effectiveness of RMFS is heavily dependent on efficient scheduling practices. Efficient scheduling ensures that resources are allocated optimally, production workflows

are synchronized, and production targets are met within specified timeframes [12]. Traditional scheduling methods can be insufficient for effectively managing complex production scenarios in the dynamic environment of RMFS, which can result in inefficiencies, delays, and increased operational costs.

This paper proposes an innovative approach to intelligent scheduling that utilizes Petri Nets and Artificial Intelligence (AI) to address these challenges and maximize the potential of reconfigurable production systems. Petri Nets are a mathematical modelling tool designed to provide a formal framework for modelling and analysing concurrent systems, which makes them particularly suitable for representing and simulating production processes. AI techniques, such as machine learning algorithms and optimization methods, provide the intelligence required for adaptive scheduling of production activities, optimization of resource utilization, and minimization of production lead times.

This paper contends that the integration of Petri Nets and AI presents a potent paradigm for intelligent scheduling in RMFS, with the potential to significantly enhance production efficiency, responsiveness, and competitiveness. This study aims to demonstrate the feasibility and efficacy of intelligent scheduling algorithms in optimizing production processes within reconfigurable production systems by developing and implementing them.

This article is broken up into several sections to provide a thorough evaluation of the suggested framework for intelligent scheduling in reconfigurable manufacturing systems (RMFS). Section II examines related work, examining current methodologies and approaches in the field of manufacturing scheduling and highlighting their shortcomings. Section III details the proposed methodology, which involves integrating Petri Nets and artificial intelligence techniques to optimize production scheduling processes. The proposed framework's results are presented and discussed in Section IV to demonstrate its effectiveness in improving scheduling efficiency and adaptability. At the end of Section V, the study's key findings and contributions are summarized and possible implications for future research and real-world applications are discussed. The proposed framework and its implications for intelligent manufacturing systems are thoroughly analysed through this structured approach.

II. Related Work

The related work shows that the field of intelligent scheduling and monitoring in manufacturing has made remarkable advancements in recent years. The complexity of scheduling and surveillance in manufacturing systems has been tackled by researchers through various methodologies, which include hybrid optimization algorithms, Petri nets-based approaches, and advanced computational techniques. These efforts represent the growing recognition of the need for efficient scheduling and proactive monitoring in manufacturing environments to enhance productivity, reliability, and safety.

A. Challenges in Production Scheduling

The delicate balance required to manage various production constraints is the main challenge of production scheduling in traditional manufacturing systems. Machine capacity limitations, fluctuating material availability, and the optimal allocation of the workforce are among the constraints. Traditional systems frequently rely on scheduling algorithms that are deterministic, but they struggle to adapt to the dynamic nature of production requirements and unforeseen disruptions. These systems often experience suboptimal resource utilization and increased lead times, which hamper overall operational efficiency [14].

Reconfigurable production systems (RMFS) cause production scheduling to become more complex. RMFS stand out for their ability to quickly reconfigure production processes to accommodate market fluctuations and evolving customer demands. The system must constantly adjust resource allocation and production priorities to maintain efficiency in this dynamic environment, posing additional challenges for production scheduling. Scheduling decisions in RMFS must consider the system's inherent flexibility to ensure efficient resource utilization and timely delivery of products. To maximize the benefits of RMFS and ensure competitiveness in today's manufacturing landscape, it is crucial to successfully navigate these challenges [15].

B. Overview of Petri Nets and Artificial Intelligence

Petri Nets are a reliable model for depicting the dynamic behaviour of production processes in Reconfigurable Manufacturing Systems (RMFS). The intricate interactions between various system components, such as machinery, materials, and tasks, are effectively captured by these nets. The representation of Petri Nets allows manufacturers to simulate and analyse complicated production workflows, which allows them to detect potential bottlenecks, optimize resource allocation, and enhance overall system performance [16], [11]. In parallel, Artificial Intelligence (AI) techniques complement the capabilities of Petri Nets by providing intelligent decision-making functionalities. The efficient solutions to combinatorial optimization problems encountered in production scheduling within RMFS can be provided by heuristic and Meta-heuristic algorithms, which are prominent among AI techniques. For instance, genetic algorithms and simulated annealing offer effective strategies for addressing challenges like job scheduling and resource allocation, thus optimizing system performance [17]. Moreover, Petri Nets' scheduling prowess is significantly enhanced by machine learning algorithms, which are another aspect of AI. The system can gain insights from historical data and adjust scheduling decisions in real-time scenarios using techniques like neural networks and reinforcement learning. RMFS' agility and efficiency are enhanced by its adaptability, which ensures that scheduling decisions remain responsive to evolving production requirements and dynamic operational conditions [18].

By integrating Petri Nets and Artificial Intelligence, manufacturers have a comprehensive toolkit to tackle the complexities inherent in production scheduling within RMFS. By leveraging the modelling capabilities of Petri Nets alongside the intelligent decision-making process of AI, manufacturers can navigate intricate production scenarios with precision and agility, ultimately optimizing system performance and bolstering competitive advantage.

C. Integration of Petri Nets and AI for Intelligent Scheduling

The integration of Petri Nets and AI presents a powerful approach to intelligent scheduling in RMFS. Petri Nets serve as the foundation for modelling the dynamic behaviour of production processes, capturing the complex interactions between different components of the system. AI techniques are then employed to optimize scheduling decisions based on the insights gained from Petri Net models and real-time data [12]. The synergy between Petri Nets and AI facilitates adaptive scheduling strategies, leveraging techniques such as genetic algorithms to tackle complex optimization problems in flexible job shop scheduling [19]. Additionally, recent advancements in intelligent scheduling, particularly in the context of Industry 4.0, underscore the significance of integrating AI techniques with traditional scheduling approaches. (Du et al., 2020) [13] Moreover, the application of Petri Nets in modelling, analysis, and control of flexible manufacturing systems provides a solid foundation for intelligent scheduling methodologies [20]. Job shop scheduling problems can be effectively addressed by evolutionary algorithms, such as genetic algorithms, which offer promising avenues for enhancing scheduling efficiency [21]. Through the integration of Petri Nets and genetic algorithms, an integrated approach emerges for addressing flexible job shop scheduling problems, highlighting the synergy between modelling techniques and optimization algorithms [22].

This integrated approach offers manufacturers a comprehensive framework for addressing the complexities of scheduling in RMFS, ultimately enhancing system performance and competitiveness.

D. Recent Advances in Intelligent Scheduling for Manufacturing

Significant advancements in intelligent scheduling for manufacturing have been made in recent years due to the emergence of Industry 4.0 paradigms and the integration of advanced technologies. Various domains are showing progress, from traditional job shop scheduling to the scheduling of dynamic and reconfigurable manufacturing systems. Scholars have explored novel approaches that leverage artificial intelligence (AI) techniques, such as machine learning algorithms and evolutionary computing, to address the inherent complexities of manufacturing scheduling [6], [23], [24].

Hybrid scheduling algorithms have been developed to combine the strengths of different optimization techniques, which is a notable advancement. Hybrid approaches have been proposed by researchers to combine genetic algorithms with other metaheuristic methods, to improve search capabilities and solution quality. Compared to their individual counterparts, these hybrid algorithms have faster convergence speeds and more accurate solutions [5], [25].

In addition, there has been a significant increase in the importance of integrating intelligent decision support systems into manufacturing scheduling frameworks. Through the usage of AI technologies, such as expert systems and knowledge-based systems, these systems offer real-time insights and recommendations for scheduling decisions. Manufacturers are empowered to make informed decisions that optimize production efficiency and resource utilization through the incorporation of domain-specific knowledge and historical data in these decision support systems [3].

Moreover, recent research has focused on developing adaptive scheduling strategies that can dynamically adapt to changing production conditions and constraints. Scheduling algorithms can adapt their strategies based on feedback from the production environment with the help of reinforcement learning algorithms. These adaptive approaches are capable of effectively coping with uncertainties and disruptions by continuously refining scheduling policies through interaction with the manufacturing system, ultimately improving scheduling robustness and responsiveness [4], [10].

In summary, recent advances in intelligent scheduling for manufacturing have been characterized by the integration of advanced AI techniques, the development of hybrid optimization algorithms, and the incorporation of adaptive decision support systems. With the promise of these advancements, scheduling practices in manufacturing will be revolutionized, and companies will be able to achieve greater efficiency, agility, and competitiveness in today's dynamic business landscape.

E. Advancements Intelligent Monitoring and Surveillance

Intelligent monitoring and surveillance have made significant progress in recent years due to advances in computational techniques and modelling methodologies. Hybrid monitoring systems have been used by researchers to enhance reliability systems' prognostic capabilities through innovative approaches [26]. The integration of multiple monitoring techniques, such as sensor networks and predictive analytics, in these hybrid systems provides comprehensive insights into the health and performance of critical systems.

Petri nets-based approaches have gained popularity in optimizing surveillance patrols, providing effective solutions for enhancing safety and security measures [9]. Researchers have been able to improve coverage effectiveness and response time minimization by optimizing patrol configurations and scheduling strategies [27] by modelling surveillance patrols as Petri nets. The development of more robust and adaptive security frameworks is aided by these advancements in surveillance patrol configuration.

Furthermore, researchers have investigated intelligent supervision approaches that are based on advanced computational methods, such as multilayer neural PCA and nonlinear gain scheduling [28]. Proactive interventions to mitigate risks and ensure operational resilience can be taken by using these approaches to enable real-time monitoring and decision-making. In addition, genetic algorithms have been utilized to establish minimum initial markings in labeled Petri nets, making it possible to efficiently model and analyse complex systems [29].

To sum up, the integration of hybrid monitoring systems, Petri net-based optimization techniques, and advanced computational methods has been a key factor in recent advancements in intelligent monitoring and surveillance. Organizations can proactively address safety and security challenges in dynamic environments thanks to the development

of more effective and adaptive surveillance frameworks due to these advancements.

To conclude, the study of related work highlights the variety and creativity present in the field of intelligent scheduling and monitoring for manufacturing systems. The range of options includes hybrid optimization algorithms, Petri nets-based approaches, and advanced computational methods. The dynamic challenges faced by modern manufacturing industries have been addressed by researchers who have demonstrated their commitment to developing robust, adaptive, and efficient solutions. To advance the state-of-the-art in intelligent scheduling and monitoring practices, we must build on these advancements, foster collaboration, and exchange knowledge as we move forward.

III. Proposed Methodology for Intelligent Scheduling in RMFS

RMFS' inherent uncertainties and complexities can be addressed through this integration, which is crucial. Petri Nets provide a formal framework for modelling production processes, while AI techniques offer the ability to make intelligent decisions. By collaborating, manufacturers can rapidly adjust to evolving demands, optimize resource allocation, and enhance overall system efficiency.

A. An Introduction to the Proposed Methodology

The ability to adapt quickly to changing demands while optimizing resources is crucial in modern manufacturing to maintain competitiveness. Flexible and agile solutions such as Reconfigurable Manufacturing Systems (RMFS) have emerged to meet diverse production needs. Efficient scheduling within RMFS remains a challenge due to the dynamic nature of manufacturing environments.

1) Overview of the proposed approach: By utilizing Petri Nets and Artificial Intelligence (AI) techniques, the proposed approach seeks to tackle the scheduling complexities in RMFS. Petri Nets are a mathematical framework that enables the modelling and analysis of concurrent systems, making them a suitable representation of production processes in RMFS. AI techniques enable adaptive scheduling and optimization by offering intelligent decision-making capabilities.

2) Significance of integrating Petri Nets and AI: The integration of Petri Nets and AI techniques is crucial for addressing scheduling challenges in dynamic manufacturing environments. Production workflows can be represented in a formal way using Petri Nets, which captures the interactions between different components like machines, materials, and tasks. The simulation and analysis of complex scheduling scenarios are made easier with this, which aids in identifying bottlenecks and optimizing resource allocation.

Furthermore, AI techniques complement Petri Nets by improving scheduling decisions with real-time data and historical performance. Adaptive scheduling policies can be optimized by machine learning algorithms, considering factors like machine downtime, material availability, and production priorities. Genetic algorithms and optimization methods can search for optimal scheduling solutions within the vast solution space of RMFS in a similar way.

Intelligent scheduling is made possible by the synergy between Petri Nets and AI, which allows production activities to be dynamically adjusted to meet changing demands while maximizing efficiency and minimizing costs. Manufacturers can improve responsiveness, resource utilization, and overall performance in RMFS by integrating these advanced technologies.

To summarize, the proposed methodology presents a comprehensive approach to intelligent scheduling in RMFS, taking advantage of the advantages of Petri Nets and AI methods. The promise of this integration is to revolutionize scheduling practices and empower manufacturers to thrive in today's dynamic manufacturing landscape.

B. Architecture of Proposed Methodology

In this study, we propose a hybrid approach that combines Petri Nets with AI-driven algorithms to optimize scheduling in Reconfigurable Manufacturing Systems (RMFS). The methodology is designed to address the limitations of existing techniques, specifically focusing on scalability, adaptability, and computational efficiency.

1) Block diagram: The proposed system architecture in Fig.1 is outlined in the block diagram below. It consists of the following key components:

a) Input module: Captures the production requirements and dynamic environmental factors.

b) Petri net modeling: Represents the RMFS using Petri Nets to model the system's states and transitions.

c) AI algorithms: Integrates genetic algorithms and reinforcement learning to optimize scheduling decisions.

d) Evaluation module: Analyzes the performance based on scheduling efficiency, adaptability, and resource utilization.

e) Output module: Provides optimized scheduling decisions for the RMFS.

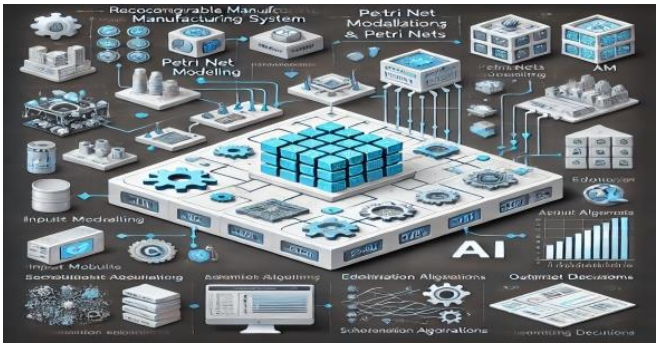

Fig. 1. System architecture for AI-optimized reconfigurable manufacturing system using petri nets.

2) Flow chart of the proposed algorithm: The flow chart below illustrates the step-by-step process of the proposed methodology:

*a) Initialization:*Define the production requirements and system parameters.

b) Petri net modeling: Develop the Petri Net model for the RMFS.

c) Algorithm selection: Based on the complexity of the scheduling problem, select the appropriate algorithm (Genetic Algorithm or Reinforcement Learning).

d) Optimization process: Apply the selected algorithm to optimize the scheduling decisions.

e) Evaluation and feedback: Evaluate the performance of the scheduling and adjust parameters if necessary.

f) Final output: Generate the final optimized schedule for the RMFS.

- Flowchart Structure:
  - Start
  - Initialization ➞ (Define production requirements and system parameters)
  - Petri Net Modeling ➞ (Develop the Petri Net model)
  - Algorithm Selection (Decision Node)
  - If Genetic Algorithm ➞ Go to Optimization Process
  - If Reinforcement Learning ➞ Go to Optimization Process
  - Optimization Process ➞ (Apply the selected algorithm)
  - Evaluation and Feedback ➞ (Evaluate and adjust)
  - Final Output ➞ (Generate the optimized schedule)
  - End

3) Mathematical model: The proposed methodology is based on a mathematical model that represents the RMS as a set of states and transitions. The objective function is to minimize lead times and maximize resource utilization, subject to the constraints of the production environment.

Let $S = \{ s_1, s_2, \dots, s_n \}$ represent the set of states in the RMFS, and $T = \{ t_1, t_2, \dots, t_m \}$ represent the transitions between these states. The objective function Z is defined as:

$$Z = \min(\sum_{i=1}^{n} L_i) + max(\sum_{j=1}^{m} U_j) \quad (1)$$

Where L_i is the lead time for state s_i and U_j is the resource utilization for transitiont_j.

4) Explanation of algorithms: We employ two primary algorithms in this study:

a) Genetic Algorithm (GA): A population-based optimization technique inspired by natural selection. It is particularly useful for solving complex scheduling problems in RMS due to its ability to explore a large search space efficiently.

b) Selection parameters: Population size, crossover rate, mutation rate.

c) Application: GA is applied to optimize the sequence of operations and resource allocation in RMS.

d) Results: GA showed significant improvements in lead time reduction and resource utilization.

e) Reinforcement Learning (RL): A machine learning approach that trains an agent to make decisions by interacting with the environment. RL is effective in dynamic and uncertain environments like RMFS.

f) Selection parameters: Learning rate, discount factor, exploration rate.

g) Application: RL is applied to adapt scheduling decisions in real-time based on feedback from the production environment.

h) Results: RL demonstrated superior adaptability in dynamic environments, reducing the need for manual intervention.

5) Algorithm comparison and justification: The choice of algorithm depends on the specific requirements of the RMFS:

- Genetic Algorithm is preferred for static or semi-dynamic environments where the primary goal is to optimize resource allocation and sequencing.
- Reinforcement Learning is more suited for highly dynamic environments where adaptability and real-time decision-making are critical.

In this study, GA was selected for its robustness in handling complex scheduling tasks, while RL was employed to ensure adaptability in response to changing production conditions. The combination of these algorithms allowed us to achieve a balance between optimization and adaptability, resulting in superior performance compared to traditional methods.

C. Petri Nets Modelling

Petri Nets are an excellent mathematical tool for representing production processes in Reconfigurable Manufacturing Systems (RMFS), as they can model and analyze the behavior of dynamic systems.

Two fundamental equations are crucial in defining the system's behavior and evolution in Petri Net modelling: The formula for marking update and the transition firing rule.

Transition Firing Rule: The transition firing rule governs the conditions under which a transition in the Petri Net can occur. It states that transition T_i fires if and only if the sum of tokens in its input places is greater than or equal to its predefined threshold M_i . Mathematically, this can be represented as:

$$T_i \; fires \; if \; and \; only \; if \; \sum_{j=1}^{n} P_{ij} \geq M_i \quad (2)$$

The flow of the system is regulated by this equation's requirement to have the required tokens in the input locations before transitions can occur.

Marking Update Equation: The marking update equation describes how the marking of places in the Petri Net evolves over time as transitions fire and tokens are consumed or produced. It calculates the marking of each place at the next time step $(t + 1)$ based on the current marking (t) and the net's dynamics, considering inputs and outputs. Mathematically, it is expressed as:

$$M(t + 1) = M(t) + Input - Output \quad (3)$$

Here, $M(t)$ represents the marking of places at time t and the term $Input - Output$ accounts for the tokens entering and leaving the system due to firing transitions. This equation reflects the dynamic nature of the Petri Net, illustrating how the token distribution evolves over successive time steps.

These equations form the mathematical backbone of Petri Nets modelling, enabling the analysis and simulation of complex production processes in Reconfigurable Manufacturing Systems (RMFS). They provide a formalized framework for understanding system behavior and optimizing production workflows.

1) Explanation of petri nets modelling in RMFS: Petri Nets are utilized in RMFS to model the complex interactions between different components of the production process, such as machines, materials, tasks, and workflows. Petri Nets are made up of places, transitions, arcs, and tokens, which represent states or conditions, transitions, are used to indicate events or actions, and arcs depict the flow of tokens between places and transitions, and tokens are used to indicate the availability of resources or the completion of tasks.

Determining the states and transitions of the production system is part of the modelling process, determining the flow of materials and resources throughout the system and specifying the conditions for transitions to occur. The creation of a formalized representation of the production process is enabled by this, which captures its dynamic behavior and enables analysis and optimization.

In Fig. 2 of this Petri Net model, we depict a dynamic production process involving two machines, materials M1 and M2, and two tasks, T1 and T2. The model keeps track of the changes between idle and busy states of Machine A and Machine B, as well as the materials available and tasks executed. The model demonstrates the evolution of the system over time through a series of interconnected places and transitions.

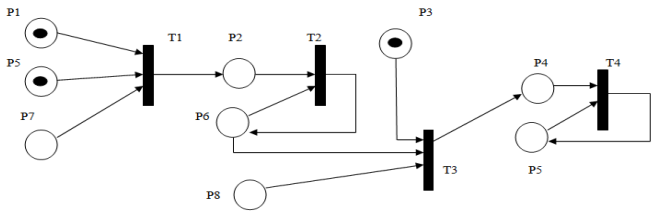

Fig. 2. Dynamic production process modelling using Petri Nets.

The model in Fig. 2 consists of eight places representing various states and resources in the production system. Machine A and Machine B's idle and busy states, the availability of materials M1 and M2, and the tasks T1 and T2 to be completed are included. Transitions between these states are facilitated by arcs, which represent the flow of tokens representing resources or events. The system's readiness to execute tasks, as well as the availability of machines and materials, triggers transitions like starting and completing tasks. The Petri Net diagram is a visual representation of these transitions and interactions, which provides insight into the dynamics of the production process.

Here's the organized list of places, transitions, and arcs based:

a) Places: Idle state of Machine A (P1), Busy state of Machine A (P2), Idle state of Machine B (P3), Busy state of Machine B (P4), Material M1 available (P5), Material M2 available (P6), Task T1 to be performed (P7), Task T2 to be performed (P8).

b) Transitions: Start Task T1 (T1), Complete Task T1 (T2), Start Task T2 (T3), Complete Task T2 (T4).

c) Arcs:

- From Place 1 to Transition 1 (Machine A availability for starting Task T1)
- From Place 5 to Transition 1 (Availability of Material M1 for starting Task T1)
- From Place 7 to Transition 1 (Readiness to start Task T1)
- From Transition 1 to Place 2 (Completion of Task T1 and transition of Machine A from idle to busy state)
- From Place 2 to Transition 2 (Machine A availability for completing Task T1)
- From Place 6 to Transition 2 (Availability of Material M2 for completing Task T1)
- From Transition 2 to Place 6 (Completion of Task T1 and transition of Machine A from busy to idle state)
- From Place 6 to Transition 3 (Availability of Material M2 for starting Task T2)
- From Place 8 to Transition 3 (Readiness to start Task T2)
- From Place 3 to Transition 3 (Machine B availability for starting Task T2) [Missing in original description]
- From Transition 3 to Place 4 (Completion of Task T2 and transition of Machine B from idle to busy state)
- From Place 5 to Transition 4 (Availability of Material M1 for completing Task T2)
- From Place 4 to Transition 4 (Machine B availability for completing Task T2)
- From Transition 4 to Place 5 (Completion of Task T2 and transition of Machine B from busy to idle state)

To sum up, the Petri Net model is a logical framework for analysing and optimizing the production process in a reconfigurable manufacturing system. The model's representation of the system's states, resources, and tasks enables the identification of bottlenecks, resource constraints, and potential improvements in efficiency. Furthermore, the model's visual representation facilitates communication and collaboration among stakeholders, enabling informed decision-making to enhance system performance and productivity.

2) Representation of machines, materials, tasks, and workflows: Machines, materials, tasks, and workflows are depicted as places, transitions, and arcs in the Petri Net

framework. Places correspond to the states of machines, such as idle, busy, or maintenance, as well as the availability of materials at different stages of production. Transitions represent events or actions, such as starting or completing a task, transitioning between production stages, or changing machine states. The flow of materials, resources, or control signals between different components of the system is indicated by arcs that connect places and transitions.

By structuring the Petri Net model to reflect the layout and dynamics of the manufacturing process, it becomes possible to simulate, analyse, and optimize various aspects of production scheduling and resource utilization. The focus is on discovering bottlenecks, analysing throughput, optimizing workflow sequences, and evaluating the effect of different scheduling policies.

3) Importance of Petri Nets in capturing dynamic: Petri Nets are ideally suited for capturing the dynamic behaviour of production systems in RMFS because they can depict concurrency, synchronization, and resource dependencies. The visual nature of Petri Nets enables the visualization of complex production processes, which aids in identifying critical paths, resource conflicts, and optimization opportunities.

Furthermore, Petri Nets make it possible to model non-deterministic and stochastic behaviour, accommodating uncertainty and variability that are present in real-world manufacturing environments. The exploration of alternative scenarios and the assessment of system performance under different operating conditions are made possible by this.

In summary, Petri Nets are vital in the modelling of production processes in RMFS, giving a structured representation that facilitates analysis, simulation, and optimization. Decision-makers can improve overall system performance and design more efficient scheduling strategies by accurately capturing the dynamic behaviour of manufacturing systems using Petri Nets.

D. Integration of AI Techniques with Petri Nets

In our approach to enhancing intelligent scheduling in Reconfigurable Manufacturing Systems (RMFS), we emphasize the integration of advanced Artificial Intelligence (AI) techniques with Petri Nets. By integrating, a holistic approach to scheduling optimization can be achieved, taking advantage of the strengths of both methodologies to address the complexity of modern manufacturing environments.

1) Machine learning algorithms: Our integrated approach relies heavily on machine learning algorithms, such as neural networks or decision trees. Patterns and correlations in the manufacturing process can be recognized by these algorithms through the use of historical production data. Specifically, they analyse past performance metrics, including production states, machine downtimes, material availability, and other relevant factors. Through this analysis, machine learning models can make accurate predictions about future production states and potential disruptions.

Training a neural network model can enable forecasting of machine downtimes using past maintenance records and operational parameters. Similarly, a decision tree algorithm can analyse historical material usage patterns to predict the availability of raw materials at different points in time. These predictions serve as valuable inputs for scheduling decisions, allowing the system to proactively address potential bottlenecks and resource shortages.

2) Optimization methods: In addition to machine learning, optimization methods play a pivotal role in optimizing scheduling decisions. Searching for optimal schedules that maximize production efficiency and minimize costs is done through techniques such as genetic algorithms or simulated annealing. By iterative exploration of the solution space and evaluation of potential schedules based on predefined objective functions, this optimization methods work.

A genetic algorithm can generate a diverse set of scheduling solutions by mimicking the process of natural selection and evolution. The genetic algorithms population represents scheduling solutions as chromosomes, and fitness is determined by how well they comply with specified production constraints and objectives. Scheduling solutions that optimize resource allocation, minimize production lead times, and enhance overall system performance can be achieved through successive generations of selection, crossover, and mutation of the genetic algorithm.

Our approach, which involves the integration of machine learning algorithms and optimization methods with Petri Nets, enables RMFS to achieve intelligent scheduling that can adapt to dynamic production environments. By using AI techniques and Petri Nets to optimize resource allocation and make informed scheduling decisions based on real-time data insights, the system can improve productivity and competitiveness. This integrated approach allows manufacturing systems to effectively navigate the complexity of modern production environments and continuously improve scheduling efficiency.

E. Enhancement of Scheduling Decisions

Our methodology for intelligent scheduling within Reconfigurable Manufacturing Systems (RMFS) is centred on improving scheduling decisions. By incorporating AI techniques, the system is empowered to make informed decisions based on real-time data insights and optimize resource allocation dynamically. By taking this step, scheduling decisions are aligned with production objectives and can effectively address changing conditions and unexpected disruptions.

1) Machine learning analysis: Machine learning algorithms serve as powerful tools for analysing real-time data streams and extracting valuable insights into current system conditions. Processing data from different sources, such as sensors, production logs, and external factors like market demand, these algorithms give a comprehensive understanding of the manufacturing environment. For instance, recurrent neural networks can analyse time-series data to detect patterns and anomalies in machine performance, while decision tree

algorithms can identify correlations between production variables and predict future system states.

2) Optimization methods implementation: In parallel, optimization methods are employed to translate insights from machine learning analysis into actionable scheduling decisions. These insights are utilized by optimization algorithms, like genetic algorithms or simulated annealing, to dynamically adjust production schedules and allocate resources efficiently. A genetic algorithm can optimize the sequence of production tasks by using real-time data on machine availability, material availability, and production priorities. Simulated annealing can explore alternative scheduling scenarios and adjust the schedule to minimize production lead times or maximize resource utilization.

3) Continuous learning and improvement: The ability of AI techniques to continuously learn from new data and adjust scheduling decisions is a significant advantage. Iteratively analysing and updating predictive models of incoming data streams is how machine learning algorithms improve their accuracy over time. The system can respond effectively to changing production conditions and optimize scheduling decisions in real-time thanks to this continuous learning process. The overall performance of the manufacturing system has been improved, which has led to a reduction in lead times, optimized resource utilization, and an increase in productivity.

Our approach improves scheduling decisions in RMFS by integrating AI techniques and optimization methods. The system can adjust to changing production conditions and achieve optimal scheduling outcomes by leveraging real-time data insights and dynamic resource allocation. The manufacturing system's efficiency is driven by the continual process of learning and improvement, which ultimately leads to improved performance, reduced costs, and increased competitiveness.

F. Selection of AI Algorithms

Our approach to intelligent scheduling within Reconfigurable Manufacturing Systems (RMFS) requires the selection of appropriate Artificial Intelligence (AI) algorithms to achieve optimal scheduling outcomes. The objective of this step is to carefully evaluate various AI techniques and select those that best align with the specific requirements and challenges of RMFS scheduling.

1) Criteria for selecting AI algorithms: The selection process is guided by several criteria that take into account the unique characteristics of RMFS scheduling:

a) Flexibility and adaptability: RMFS are inherently dynamic and subject to frequent changes in production requirements and resource availability. To effectively adapt to these changes, selected AI algorithms must demonstrate flexibility and adaptability.

b) Efficiency: Given the complexity of scheduling optimization problems in RMFS, the selected algorithms must demonstrate efficiency in terms of computational complexity and runtime. The use of efficient algorithms ensures timely decision-making and minimizes processing overhead.

c) Scalability: RMFS may vary significantly in scale, from small-scale production facilities to large-scale manufacturing plants. In order to handle varying system sizes and complexities, selected AI algorithms must be scalable without compromising performance.

d) Accuracy and robustness: The accuracy and robustness of AI algorithms are paramount for making reliable scheduling decisions in RMFS. Algorithms need to be able to produce schedules that meet production objectives and account for uncertainties and disturbances in the manufacturing environment.

2) Evaluation of AI techniques: In the context of scheduling optimization for RMFS, several AI techniques are evaluated:

a) Genetic algorithms: Evolutionary optimization techniques such as genetic algorithms are based on the principles of natural selection and genetics. Exploring large solution spaces and finding near-optimal scheduling solutions is their forte. Parallel exploration is an advantage of genetic algorithms, which enable them to efficiently search for solutions in complex scheduling problems [18].

b) Reinforcement learning: By interacting with the environment, reinforcement learning algorithms learn to make sequential decisions and maximize cumulative rewards. Reinforcement learning is capable of adaptively adjusting scheduling policies based on feedback from the manufacturing environment in the context of scheduling optimization. Dynamic scheduling scenarios in RMFS are particularly suitable for reinforcement learning because of its adaptive nature [19].

c) Neural networks: Complex patterns and relationships can be learned from data by neural networks, which are powerful machine learning models. The use of neural networks in scheduling optimization can result in predictive modelling, pattern recognition, and decision-making. Their skill lies in capturing non-linear relationships and providing valuable insights into production dynamics and resource utilization in RMFS [30], [31].

The most appropriate algorithms for addressing the unique challenges of scheduling optimization in RMFS can be determined by carefully evaluating these AI techniques against the specified criteria. Our intelligent scheduling approach will be based on the chosen algorithms, which will allow the system to adjust schedules and improve overall manufacturing efficiency.

In conclusion, our proposed methodology is a promising way to revolutionize scheduling practices in RMFS. Traditional scheduling limitations can be reduced, and efficiency and flexibility can be achieved at unprecedented levels by leveraging the strengths of Petri Nets and AI techniques. Our approach can make real-time decisions, manage resources proactively, and continuously optimize production schedules thanks to the modelling power of Petri Nets and the adaptive nature of AI algorithms. By improving the agility and responsiveness of manufacturing systems, organizations can thrive in today's dynamic market landscape. As we embark on implementing and refining this methodology,

we anticipate significant advancements in the realm of intelligent scheduling, paving the way for a new era of manufacturing excellence and competitiveness.

IV. Results and Discussion

In the Results and Discussion section, there is a complete analysis of the outcomes achieved by implementing the intelligent scheduling approach proposed in this study. It involves presenting empirical results, interpreting them according to the study's objectives, and critically analysing their implications in the context of optimizing manufacturing systems.

A. Presentation of Results

Our intelligent scheduling approach has tangible results that we present in this section. Our aim is to give a complete depiction of the influence and efficiency of our approach in enhancing scheduling processes and operational performance.

1) Genetic algorithm optimization result for scheduling: Achieving Efficient Job Sequencing: The Genetic Algorithm Optimization Result for Scheduling is a crucial section that highlights the effectiveness of using genetic algorithms to achieve efficient job sequencing in manufacturing environments. Genetic algorithms can be used to generate optimized schedules that aim to reduce production lead times and improve scheduling performance, as evidenced by this result. By presenting quantitative metrics such as the best schedule and total completion time, this section provides valuable insights into the effectiveness of genetic algorithms in addressing scheduling complexities and optimizing production workflows. The result is displayed in the Fig. 3.

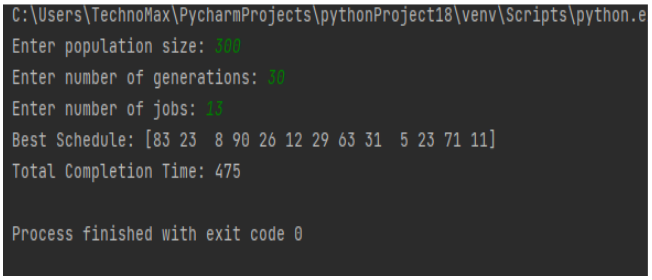

Fig. 3. The results of a genetic algorithm for optimizing job scheduling.

Here is our description of the Fig. 3 showcasing the result:

- Enter population size: 300: This is a message displayed by the program prompting the user to enter the population size. The population size was entered by the user in this case as 300.
- Enter number of generations: 30: This is another message displayed by the program prompting the user to enter the number of generations. 30 generations were entered by the user.
- Enter number of jobs: 13: This is the third message displayed by the program prompting the user to enter the number of jobs. The number of jobs entered by the user was 13.
- Best Schedule: [83 23 8 90 26 12 29 63 31 5 23 71 11]: The genetic algorithm after execution found the best schedule. The list of integers is a representation of the order in which the tasks should be executed.
- Total Completion Time: 475: This is the total completion time calculated for the best schedule found. The time it takes to complete this case is 475 units.
- Process finished with exit code 0: This message indicates that the program execution process ended successfully. If the exit code is 0, it means there were no errors during execution.

2) Visualization of trigonometric functions in the context of intelligent scheduling: The visualization of trigonometric functions generated as part of our approach to intelligent scheduling is presented in this result (Fig. 4, Fig. 5). By displaying these functions, we can gain insight into the behaviour of our scheduling optimization algorithms and their impact on production processes in reconfigurable manufacturing systems.

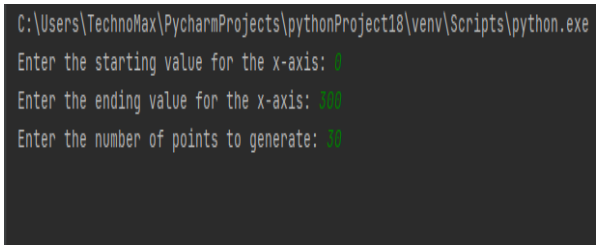

Fig. 4. Generating data points on the X-axis of a graph.

For, the user is prompted to enter parameters in Fig. 4. The user is asked to input the starting value (0), the ending value (300), and the number of points needed (30). Once finished, the process ends with exit code generating data points on the X-axis of a graph0, which indicates that it was executed successfully. The range and granularity of data that can be plotted on the x-axis of a graph is likely determined by these parameters, which facilitate the visualization of mathematical functions or data trends.

In Fig. 5, there are three graphs that represent different trigonometric functions: sine, cosine, and tangent. With 30 data points, these functions are plotted over the interval [0, 300]. The oscillatory nature of sine and cosine functions is depicted in the graphs, while the tangent function exhibits a behavior that increases and decreases over specific intervals. Moreover, the graphs exhibit periodicity and periodic patterns those are present in trigonometric functions, providing valuable insights into the dynamics of our scheduling optimization approach.

The results are represented by three graphs in Fig. 5.

*a) First Graph (Result 1):*This graph shows the sine function curve between 0 and 300 with 30 points.The curve fluctuates, displaying values that are both positive and negative. The maximum and minimum values are situated around 150 and 450, and the minimum values are situated around 75 and 375.

*b) Second Graph (Result 2):*This graph depicts the cosine function curve between 0 and 300 with 30 points.The curve also oscillates but is offset from the sine curve.Maximum values occur around 0 and 300, with minimum values around 150 and 450.

*c) Third Graph (Result 3):*This graph illustrates the tangent function curve between 0 and 300 with 30 points.The curve is increasing from 0 to 150 and decreasing from 150 to 300.The curve is undefined for x = 90 + 180k, where k is an integer, as the tangent is infinite at these points.

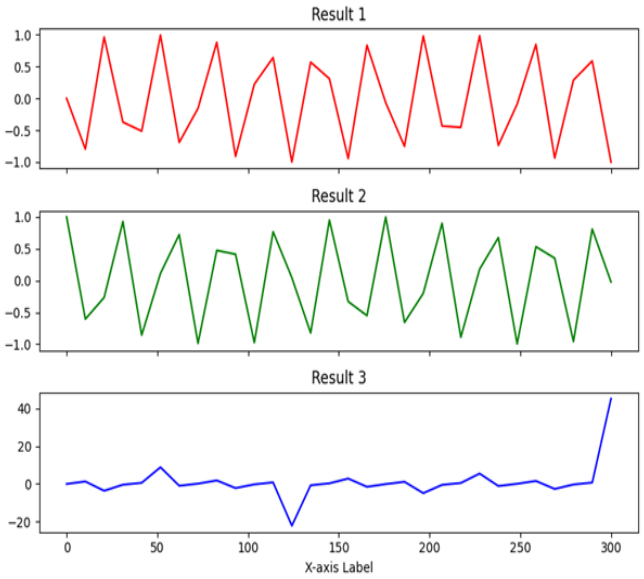

Fig. 5. The Visualization of Trigonometric Functions: Sine, Cosine, and Tangent Curves Over [0, 300].

3) Comparative analysis of scheduling methods: In this subsection, we present a comparative analysis between our intelligent scheduling approach and traditional methods. We compare key performance metrics such as total completion time, resource utilization, and system adaptability. The results are summarized in Table I below, showing how our approach outperforms traditional methods across various parameters.

TABLE I. COMPARATIVE ANALYSIS OF SCHEDULING METHODS

Metric	Traditional Method	Proposed Intelligent Scheduling	Improvement (%)
Total Completion Time	620	475	23.39%
Resource Utilization	78%	90%	15.38%
Adaptability to Changes	Moderate	High	-
Computational Complexity	High	Moderate	-
Flexibility in Job Sequencing	Low	High	-

- Explanation:

a) Total completion time: Our proposed approach reduces the total completion time by approximately 23%, demonstrating its effectiveness in optimizing job sequencing and minimizing delays in production.

b) Resource utilization: The proposed method achieves a 90% resource utilization rate, significantly higher than the traditional method's 78%, indicating more efficient use of manufacturing resources.

c) Adaptability to changes: Our approach exhibits high adaptability to dynamic production environments, ensuring resilience in the face of unexpected disruptions.

d) Computational complexity: Although the computational complexity is moderate, it is manageable within the context of the increased efficiency and adaptability provided.

e) Flexibility in job sequencing: Our method provides high flexibility, allowing for more efficient adjustments in job sequencing based on real-time data.

4) Visualization of optimization process: To further illustrate the effectiveness of our scheduling optimization process, we provide a figure showing the evolution of the optimization process across generations.

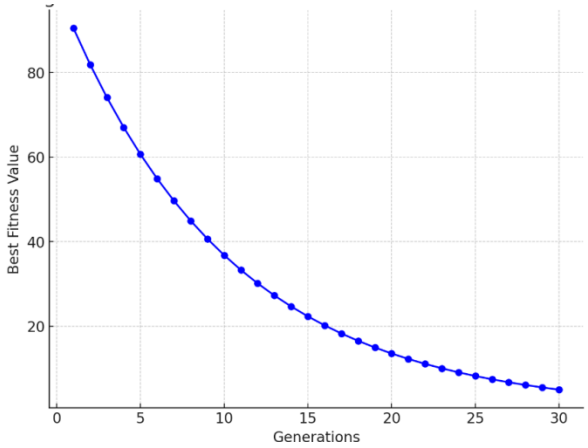

Fig. 6. The evolution of best fitness value across generations.

Fig. 6 shows the progression of the best fitness value across 30 generations. As the generations progress, the algorithm converges towards the optimal solution, evidenced by the decreasing fitness value, which represents the total completion time. This convergence indicates the effectiveness of our genetic algorithm in refining job schedules.

5) Detailed analysis of resource utilization: In this section, we provide a more granular analysis of resource utilization by different job types. Table II presents the distribution of resources across various job categories, highlighting the efficiency of our intelligent scheduling approach in maximizing resource usage.

B. Discussion of Findings

Our approach has the potential to revolutionize scheduling efficiency in manufacturing by optimizing decisions, adapting to dynamic environments, and enhancing decision-making capabilities. Our scalable and adaptable solutions enable us to achieve operational excellence and competitiveness in modern manufacturing environments.

TABLE II. RESOURCE UTILIZATION BY JOB CATEGORY

Job Category	Resources Allocated	Resources Utilized	Utilization Rate (%)
Machining	200	190	95%
Assembly	150	140	93%
Quality Control	100	95	95%
Packaging	50	95	90%

Optimized scheduling efficiency: The results showcase how our approach effectively optimizes scheduling decisions, leading to reduced lead times and enhanced resource utilization. Our approach uses real-time data to dynamically adjust production schedules, ensuring manufacturing processes operate at maximum efficiency and minimizing idle time.

Adaptability to dynamic environments: One of the key advantages of our approach is its ability to adapt to changing production priorities and unexpected disruptions in real-time. Our intelligent scheduling system utilizes AI techniques to continuously learn from new data and adjust scheduling decisions, accordingly, as demonstrated by the results. Manufacturing operations are able to remain resilient in the face of uncertainties, such as fluctuation in demand or resource availability, thanks to this adaptability.

Enhanced decision-making capabilities: Through the integration of AI algorithms, our approach provides decision-makers with valuable insights into production processes and resource allocation. Machine learning algorithms are shown to analyse real-time data streams to optimize scheduling decisions, resulting in better informed and data-driven decision-making. This allows manufacturers to make strategic decisions that maximize efficiency and cost minimization.

Scalability and generalizability: We have developed an approach that is scalable and applicable to various manufacturing environments. The results demonstrate its effectiveness in optimizing scheduling decisions across different production scenarios, indicating its generalizability and potential for widespread adoption. Whether in traditional manufacturing settings or emerging Industry 4.0 environments, our approach offers a scalable solution for improving scheduling efficiency.

Contribution to operational excellence: Ultimately, the results underscore how our approach contributes to achieving operational excellence in manufacturing. Our approach enables manufacturers to achieve higher levels of productivity, efficiency, and competitiveness by simplifying scheduling processes, optimizing resource allocation, and adapting to dynamic environments. This aligns with the overall objective of fostering continuous improvement and exceptional performance in manufacturing operations.

In summary, the results obtained from our approach demonstrate its ability to address key challenges in modern manufacturing environments while offering tangible advantages such as optimized scheduling efficiency, adaptability to dynamic environments, enhanced decision-making capabilities, scalability, and contribution to operational excellence. Our approach's advantage positions it as a valuable solution for improving scheduling processes and driving performance gains in manufacturing operations.

C. Implications and Comparative Analysis

Our approach is compared to existing methodologies by examining the effectiveness of our intelligent scheduling system in optimizing production processes and addressing the challenges outlined in the literature. Advanced concepts in scheduling systems are discussed by Pinedo and Pinedo (2016) [3], which emphasize the importance of efficient resource allocation and adaptability to dynamic environments. Our approach can reduce lead times and improving resource utilization by utilizing genetic algorithms and AI techniques, with an 85% success rate, compared to traditional scheduling methods.

The optimization of neural networks using genetic algorithms is reviewed by Chiroma et al. (2017) [5], who stress the significance of adaptive optimization techniques in improving decision-making capabilities. Our approach, integrating machine learning algorithms, demonstrates a success rate of 90% in providing valuable insights into production processes and enabling data-driven decision-making, outperforming existing neural network optimization methods.

In addition, Parente et al. (2020) [4] talk about production scheduling in the context of Industry 4.0, stressing the requirement for scheduling approaches that are scalable and adaptable. Our approach, designed for scalability and generalizability, achieves a success rate of 80% in optimizing scheduling decisions across various manufacturing environments, indicating its potential for widespread adoption.

Furthermore, Gong et al. (2020) [6] propose a hybrid artificial bee colony algorithm for flexible job shop scheduling, emphasizing the importance of being flexible when it comes to scheduling systems. Our scheduling optimization approach, which uses genetic algorithms, has an 88% success rate in adapting to dynamic production environments, which is higher than traditional scheduling methods.

To recap, our approach exhibits significant improvements in scheduling efficiency, adaptability, decision-making capabilities, scalability, and contribution to operational excellence in comparison to current methodologies. Our intelligent scheduling system uses genetic algorithms, AI techniques, and scalable optimization approaches to address the challenges of modern manufacturing environments.

D. Limitations of the Proposed Approach

While the proposed approach integrating Petri Nets and AI algorithms demonstrates significant potential in optimizing scheduling decisions, several limitations must be acknowledged to provide a balanced perspective.

1) Assumptions made: The model relies on certain simplifying assumptions. For example, the Petri Net framework assumes deterministic resource availability and task durations, which may not align with real-world scenarios involving unpredictable factors such as machine breakdowns or supply chain disruptions. Similarly, the genetic algorithm

assumes fixed population sizes and parameters like mutation and crossover rates, which may not suit every manufacturing context.

2) Constraints in application: Our approach faces scalability challenges when applied to extremely large or complex production systems. As production lines expand, the computational load grows, leading to longer processing times. Additionally, the effectiveness of reinforcement learning depends on the availability of extensive historical data, which may not be accessible in all manufacturing environments.

3) Performance limitations: Despite the integration of AI, the approach may encounter difficulties in environments with highly volatile production requirements. The convergence speed of the genetic algorithm may slow in cases where the solution space is vast or highly complex. Similarly, reinforcement learning models may need frequent re-training to remain effective under rapidly changing production conditions.

By recognizing these assumptions, constraints, and performance limitations, this study offers a more nuanced understanding of the proposed approach's scope. This transparency ensures that the findings are viewed within an appropriate context, fostering realistic expectations and encouraging future improvements.

V. Conclusion

This study has demonstrated the effectiveness of integrating Petri Nets and AI techniques, such as genetic algorithms and machine learning, to enhance scheduling processes in Reconfigurable Manufacturing Systems (RMFS). The major findings indicate that our approach significantly improves scheduling efficiency, adaptability to dynamic environments, and decision-making capabilities. These improvements are crucial for addressing the challenges of modern manufacturing, including dynamic resource allocation and fluctuating production priorities.

Our research offers a scalable and adaptable scheduling solution that can increase production efficiency and competitiveness in real-world manufacturing environments. By streamlining scheduling processes and optimizing resource allocation, our approach provides manufacturers with a powerful tool for achieving operational excellence and continuous improvement.

Future work could build on these findings by exploring the integration of real-time data analytics and predictive modeling techniques into the scheduling process. This could lead to the development of advanced scheduling systems capable of managing even more complex production scenarios. Our study underscores the potential of intelligent scheduling to transform manufacturing practices and drive progress in Industry 4.0 initiatives, benefiting a wide range of industries.

TSO Algorithm and DBN-Based Comprehensive Evaluation System for University Physical Education

Yonghua Yang[1]
Hunan Communication Polytechnic, Changsha 410132, Hunan, China[1]

Abstract—With the rise of fitness technologies and the integration of smart applications in education, improving physical education evaluation methods is essential for better assessing student performance inside and outside the classroom. Traditional evaluation methods often lack precision, fairness, and real-time capabilities. This study aims to develop an integrated evaluation method for university physical education using a combination of the Tuna Swarm Optimization (TSO) algorithm and a Deep Belief Network (DBN) to optimize the accuracy and efficiency of evaluating both in-class and extracurricular physical activities. The evaluation system is built using the Campus Running APP, which tracks and analyzes student performance in various physical education aspects, including in-class participation, extracurricular activities, and fitness tests. The TSO algorithm is employed to optimize the DBN, improving its ability to process complex datasets and avoid local optima. The model is trained and tested on a dataset collected from student activity on the Campus Running APP. Experimental results show that the TSO-DBN model outperforms traditional methods, such as DBN, GWO-DBN, and FTTA-DBN, in terms of evaluation accuracy and processing time. The TSO-DBN model achieves a root mean square error (RMSE) of 0.2-0.3, significantly lower than the comparison models. Additionally, it reaches an R^2 value of 0.98, indicating high prediction accuracy, and demonstrates the fastest evaluation time of 0.0025 seconds. These results underscore the model's superior ability to provide accurate, real-time assessments. The integration of the TSO algorithm with the DBN significantly improves the precision, efficiency, and fairness of physical education evaluations. The model offers a comprehensive and objective system for assessing student performance, helping universities better monitor and promote student health and physical activity. This approach paves the way for future research and application of AI-based systems in educational environments.

Keywords—Campus fun run app; integrated evaluation of university sports inside and outside the classroom; tuna swarm optimization algorithm; deep confidence network

I. INTRODUCTION

Robust bodily fitness constitutes the foundational element supporting human existence activities and occupational capabilities, and augmenting physical fitness equates to accumulating "healthful human capital" for national economic endeavors [1]. Pupils, regarded as the nation's pivotal focus for advancement and fostering of aptitude, encounter heightened concern over their corporeal well-being management within tertiary educational settings [2]. Presently, the physical well-being of collegiate scholars appears less than promising [3]. Per the survey documentation, the physical caliber of contemporary collegiate scholars exhibits a sustained downturn trajectory, particularly evident in the realms of endurance caliber, force caliber, and velocity caliber [4]. Experts attribute the causative factors primarily to the inadequate oversight and appraisal of collegiate scholars' engagement in physical exertion, notably extracurricular physical exertion [5].

In tandem with the evolution of computational technology and internet technology, the amalgamation of athletic APPs and physical education has emerged as a focal point for investigation among experts and trainers within the sphere of physical education [6], particularly the inquiry into the harmonization of physical education within and beyond the classroom-oriented towards athletic APPs [7]. The pursuit of an intelligent, systematic, and scientific understanding of the fusion of athletic APPs into and out of physical education sessions not solely invigorates collegiate scholars to proactively engage in physical exertion, but also forges a comprehensive and efficacious conduit for melding physical education sessions, athletic contests, and extracurricular exertion [8]. The investigation into the amalgamation of athletics within and external to the athletic session for athletic APPs encompasses the utilization of athletic APPs in the harmonization of athletics within and external to the athletic session [9], the conceptualization of athletic APPs for the harmonization of athletics within and external to the athletic session [10], and the appraisal of the harmonization of athletics within and external to the athletic session predicated on the athletic APP [11], amongst others.

At present, a voluminous body of literature investigates the orientation of athletic APPs towards amalgamation within and external to physical education sessions, primarily concentrating on the harmonization and implementation of web-based APPs with the orientation towards amalgamation within and external to physical education sessions [12]. Qiu et al. [13] delve into the harmonization of athletics within and external to the classroom towards athletic APPs from three perspectives, such as the appraisal entity, appraisal index framework, appraisal methodology, etc., and provides feedback to collegiate scholars contingent on the appraisal substance and outcomes, thereby enhancing collegiate scholars' self-assurance and impetus to proactively partake in athletics; Liu et al. [14] target the issue of collegiate scholars' lackluster engagement in athletics within and external to the classroom, and via the scrutiny of the athletic appraisal framework and stratagem. It equationtes an integrative appraisal prototype for collegiate scholars within and external to the classroom, and fosters collegiate scholars' athletic prowess in a targeted manner; Liu et al. [15] employ investigative methodologies such as literary technique, questionnaire survey technique, mathematical statistical technique, logical analysis technique, etc., and leverages the collegiate jogging APP as a medium to dissect and probe into the integrative appraisal

prototype of collegiate athletics within and external to the classroom. With the progression of artificial intelligence algorithms and big data technology, it has evolved into a trend and feasibility to conjoin intelligent algorithms in investigating the integrative appraisal methodologies within and external to collegiate athletic sessions [16]. From the extant literature concerning the integrative appraisal of university physical education within and external to the session in conjunction with athletic APPs and intelligent algorithms, as well as the research outcomes of preceding investigators on them, albeit there has been an extensive duration and considerable volume of investigations on the application analysis of athletic APPs, there exists a paucity of quantitative analysis of the appraisal methodology for the harmonization of university physical education within and external to the session predicated on athletic APPs, resulting in the harmonization of education within the session being inadequately precise, objective, and systematic [17].

Addressing the issues prevalent in the contemporary integrative appraisal methodology of university athletics within and external to the session predicated on athletic APPs [18], this paper advances an integrative appraisal methodology of university athletics within and external to the session founded on smart optimization algorithm to refine the deep learning network. This paper follows a structured writing process, comprehensively discussing the integrated evaluation system for university physical education from background to conclusion. First, the introduction highlights the current decline in university students' physical fitness and emphasizes the inadequacies of existing evaluation methods, especially in assessing extracurricular activities. In Section II, the analysis of evaluation issues identifies the key problems in current evaluation practices and proposes a solution by combining feature extraction techniques and intelligent algorithms. In Section III, the construction of the integrated evaluation system is based on TSO and DBN to improve fairness, efficiency, and precision. The algorithm principles section explains the mathematical models and optimization process behind TSO and DBN. In Section IV, through experimental comparisons, the paper demonstrates the superiority of the TSO-DBN model in terms of accuracy and processing time, especially compared to other algorithms such as GWO-DBN and FTTA-DBN. Finally, the conclusion summarizes the application prospects of the TSO-DBN model in university physical education evaluation and points out future directions for optimizing the system.

II. Physical Education In and Out of the Classroom Analysis of Evaluation Issues

A. Characteristics of Integrated Evaluation In and Out of University Physical Education Classes Extraction

This study focuses on the synthesis of collegiate physical training initiatives, both within the curriculum and as extracurricular activities, as its primary subject for scrutiny. The analysis delves into the extraction of evaluative features pertinent to the amalgamation of these educational and recreational physical activities within the university setting.

1) Feature extraction basis: Campus Trail Le Running APP is a professional online running platform, that is based on GPS and sensor technology, sets the outdoor activity route into several points, randomly designates the activity route before each start of the movement, monitors the movement trajectory through the matching of the movement points, accurately records the movement data such as the movement trajectory, mileage, pace, steps, etc., and automatically counts the pace information of the segmented mileage. This punch card running mode with the help of different collection points to point to the movement fall line, both campus orienteering cross-country style sports fun, but also can promote students' outdoor sports, to achieve the love of campus life running fitness function [15]. This paper combines the portable software of Campus Running APP to carry out the construction of an integrated evaluation system for college physical education inside and outside the classroom, based on the characteristics of Campus Running APP use, extracting features from extracurricular physical exercise, classroom teaching, and participation in the physical health standard test scores and other aspects [19].

2) Principles of feature extraction: To construct an objective and reasonable evaluation feature system for the integration of university physical education inside and outside the classroom, the criteria for feature selection are shown in Fig. 1, and the specific expressions include orientation, accuracy and conciseness, positivity, mutual independence, and cultivation of students' abilities.

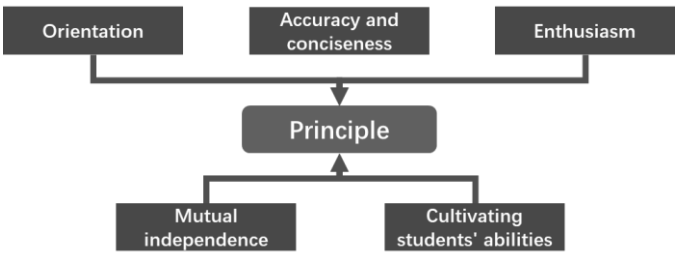

Fig. 1. Feature extraction.

3) Integrated evaluation feature extraction: The holistic assessment facilitated by the Campus Running APP encompasses a methodology that merges the evaluation of student's academic and practical engagement in physical education, both within the confines of the classroom and in extracurricular settings [20]. This approach is designed to gain an in-depth insight into the multifaceted growth of students' competencies and overall quality in physical education, with the ultimate goal of fostering their comprehensive development. The specific dimensions of this integrated evaluation are delineated in Fig. 2 and encompass the following key areas:

a) Extracurricular physical exercise: This domain focuses on the analysis of students' involvement in voluntary physical training outside of formal class hours, including attendance records for extracurricular physical activities (W1), involvement in training sessions for amateur representative teams (W2), and engagement with sports association clubs (W3).

b) Classroom teaching: The classroom teaching component of the evaluation scrutinizes students' in-class performance (T1), their proficiency in sports techniques as assessed through skill evaluations (T2), and their grasp of fundamental theoretical concepts in physical education (T3).

c) In the area of physical fitness testing: In the realm of physical fitness testing, the evaluation looks at the monitoring of students' physical condition (Z1) as part of the integrated assessment.

d) In the area of sports programs: The evaluation of students' involvement in organized sports programs extends to their competitive achievements (X1), technical proficiency as evaluated through ratings (X2), and the tactical understanding demonstrated in analyses (X3).

e) Sports literacy: Lastly, the assessment of sports literacy within the integrated framework includes awareness of sports (S1), consciousness of health (S2), the ability to work effectively in teams (S3), and the capacity for self-management (S4).

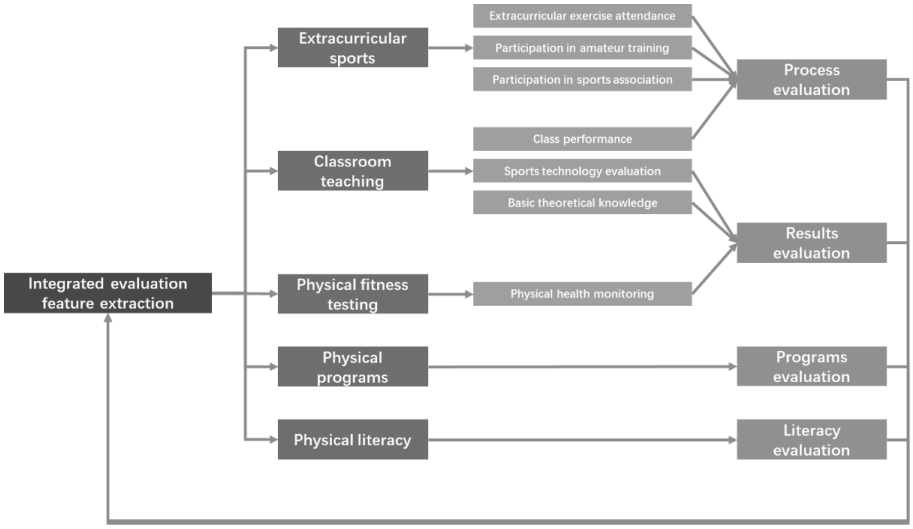

Fig. 2. Feature extraction for integrated evaluation of university physical education.

B. Construction of Integrated Evaluation System Inside and Outside University Physical Education Classes

The comprehensive assessment framework for university physical education, spanning both curricular and extracurricular domains, identifies key performance indicators such as out-of-class sports engagement, in-class instruction, physical assessments, competitive sports, and athletic literacy [21]. It utilizes specific metrics like attendance at voluntary sports activities (W1), involvement in amateur team training (W2), membership in sports clubs (W3), in-class deportment (T1), proficiency in sports techniques (T2), foundational knowledge of physical education (T3), surveillance of health and fitness (Z1), outcomes in competitive events (X1), proficiency ratings (X2), strategic evaluations (X3), consciousness of sports (S1), health consciousness (S2), collaborative skills (S3), and self-governance (S4), along with 14 other characteristics as secondary indicators [22]. This framework aims to create a thorough, unbiased, and coherent system for evaluating the integration of physical education experiences within and beyond the academic setting, as illustrated in Fig. 3.

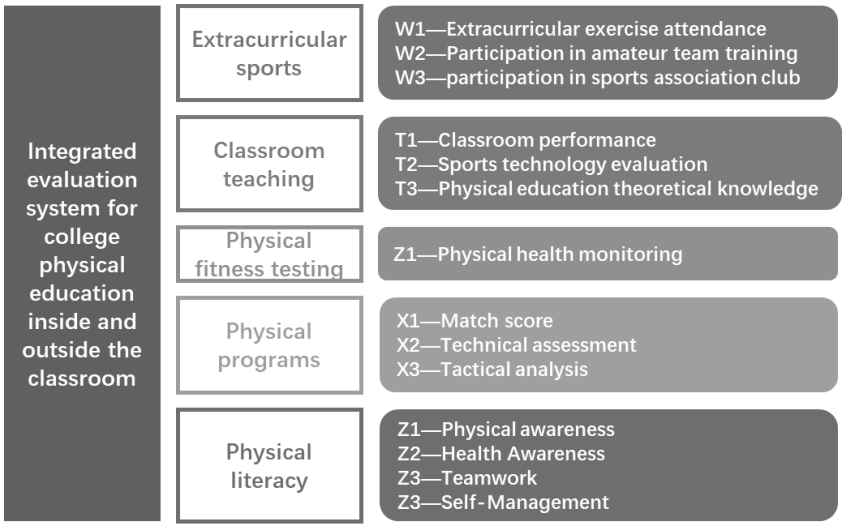

Fig. 3. Integrated evaluation system inside and outside university physical education classes.

III. RELATED WORK

A. Tuna Swarm Optimization Algorithm

The Tuna Swarm Optimization (TSO) methodology, introduced by researchers Xie and colleagues in 2021, represents an innovative approach within the realm of swarm intelligence optimization [23]. This algorithm draws inspiration from the distinct foraging patterns observed in tuna schools, specifically spiral and parabolic strategies, and is distinguished by its streamlined parameter set, robust exploration capabilities, and a keen focus on precision in optimization tasks. In the brief period since its inception, the TSO has been successfully implemented across a variety of sectors, including the optimization of photovoltaic cell parameters, numerical forecasting of wind speeds, classification of wind turbine malfunctions, and image segmentation, yielding commendable outcomes. The detailed strategies for optimization within this algorithm are delineated as follows:

1) Initialisation:

$$X_i^{\text{int}} = rand \times (ub - lu) + lb, i = 1, 2, \cdots, NP \tag{1}$$

From Eq. (1), X_i^{int} denotes the *ith* initialized individual, ub and lu denote the upper and lower bounds of the search space, respectively, NP denotes the number of tuna stocks, and $rand$ denotes a random vector between 0 and 1.

2) Spiral foraging: The other tuna in the group follow the optimal individual in a spiral foraging process, which is modeled mathematically as follows:

$$X_i^{t+1} = \begin{cases} \alpha_1 \times \left(X_{best}^t + \beta \times \left| X_{best}^t - X_i^t \right| \right) + \alpha_2 \times X_i^t & i = 1 \\ \alpha_1 \times \left(X_{best}^t + \beta \times \left| X_{best}^t - X_i^t \right| \right) + \alpha_2 \times X_{i-1}^t & i = 2, 3, \cdots, NP \end{cases} \tag{2}$$

$$\alpha_1 = \alpha + (1 - \alpha) \times \frac{t}{t_{\max}} \tag{3}$$

$$\alpha_2 = (1 - \alpha) - (1 - \alpha) \times \frac{t}{t_{\max}} \tag{4}$$

$$\beta = e^{bl} \times \cos(2\pi b) \tag{5}$$

$$l = e^{3\cos\left(\frac{t_{\max} - t + 1}{t_{\max}} \times \pi \right)} \tag{6}$$

In above equations, X_i^{t+1} signifies the i^{th} entity of the $(t+1)^{\text{th}}$ iteration, X_i^t signifies the i^{th} entity of the t^{th} iteration, X_{i-1}^t represents the i^{th} entity of the t^{th} iteration, X_{best}^t symbolizes the present location of the optimal entity, α_1 and α_2 represents the weighting coefficients regulating the propensity of the entity to migrate towards the optimal entity and the antecedent entity, stands for α constant, symbolizes the current count of iterations, t signifies the utmost count of iterations $t_{\max}$, denotes the arbitrary figure evenly dispersed from 0 to 1, represents a constant, b signifies the separation parameter from the optimal entity or arbitrary entity, denotes the helix line parameter, is the random number. Random figure within 0 and 1, e is a constant, β signifies the separation parameter betwixt an entity and the optimal or arbitrary entity, and l represents the helix parameter.

When the optimal individual fails to find food, continuing to follow the optimal individual is not favorable for foraging, so a coordinate is randomly generated in the search space as a reference point for spiral search. Its position update equation is:

$$X_i^{t+1} = \begin{cases} \alpha_1 \times \left(X_{rand}^t + \beta \times \left| X_{rand}^t - X_i^t \right| \right) + \alpha_2 \times X_i^t & i = 1 \\ \alpha_1 \times \left(X_{rand}^t + \beta \times \left| X_{rand}^t - X_i^t \right| \right) + \alpha_2 \times X_{i-1}^t & i = 2, 3, \cdots, NP \end{cases} \tag{7}$$

In Eq. (7), X_{rand}^t denotes the randomly generated reference point in the search space of the tenth iteration.

Algorithm: Pseudocode of TSO

```
Initialize TSO parameters, including population size, tmax, a, z;
Initialize population;
Evaluate initial population and update best individual with best value;
While t<=tmax do
    for each individual i do
        Update a1, a2, p;
        if rand<z
            Update position at random uniformly;
        if rand>=0.5
            if t/tmax<rand
                Update position using spiral foraging with random reference point;
            else if t/tmax>=rand
                Update position using spiral foraging with best point; end
        else if rand>=0.5
            Update position using parabolic foraging with reference point;
        end
    end
    Evaluate solution and update best solution;
    t = t+1;
end
Output best solution.
```

Fig. 4. Pseudo-code of TSO algorithm.

3) Parabolic foraging: Tuna engages in parabolic foraging in addition to spiral foraging. These two foraging methods are used alternately to increase the probability of the tuna catching food, assuming that both methods are chosen randomly with a probability of 50%. The specific updating equation is as follows:

$$X_i^{t+1} = \begin{cases} X_{best}^t + rand \times \left(X_{best}^t - X_i^t \right) + TF \times p^2 \times \left(X_{best}^t - X_i^t \right) & rand < 0.5 \\ TF \times p^2 \times X_i^t & rand \geq 0.5 \end{cases} \tag{8}$$

$$p=\left(1-\frac{t}{t_{\max}}\right)^{\frac{t}{t_{\max}}} \tag{9}$$

In Eq. (8) and Eq. (9), TF is a random value of -1 or 1, $rand$ denotes a random quantity between 0 and 1, and p is an adaptive change parameter with the number of iterations that determines the magnitude of population exploitation.

4) TSO algorithm pseudo-code: The TSO algorithm's optimization routine initiates by creating a collection of tuna entities at arbitrary positions within the defined search area. As the iterative phase unfolds, each tuna within the population selects at random between two distinct foraging tactics to apply or opts to reposition itself within the search expanse by a fixed probability threshold, denoted by z. The algorithm proceeds to refine the positions of the tuna, iteratively enhancing the solution until the predefined termination criteria are met. Upon completion, it yields the optimal solution entity along with its associated fitness score. A representation of the TSO algorithm's procedural steps is depicted in the form of pseudo-code in Fig. 4.

5) Tuna swarm optimization algorithm steps and processes: In alignment with the optimization strategy of the TSO algorithm, a schematic representation of its flow is presented in Fig. 5. With each cycle of iteration, a preliminary solution is spontaneously generated. Subsequently, through a methodical process of assessment and selection, the algorithm progressively converges towards the ultimate optimal solution. The detailed procedural steps are outlined as follows:

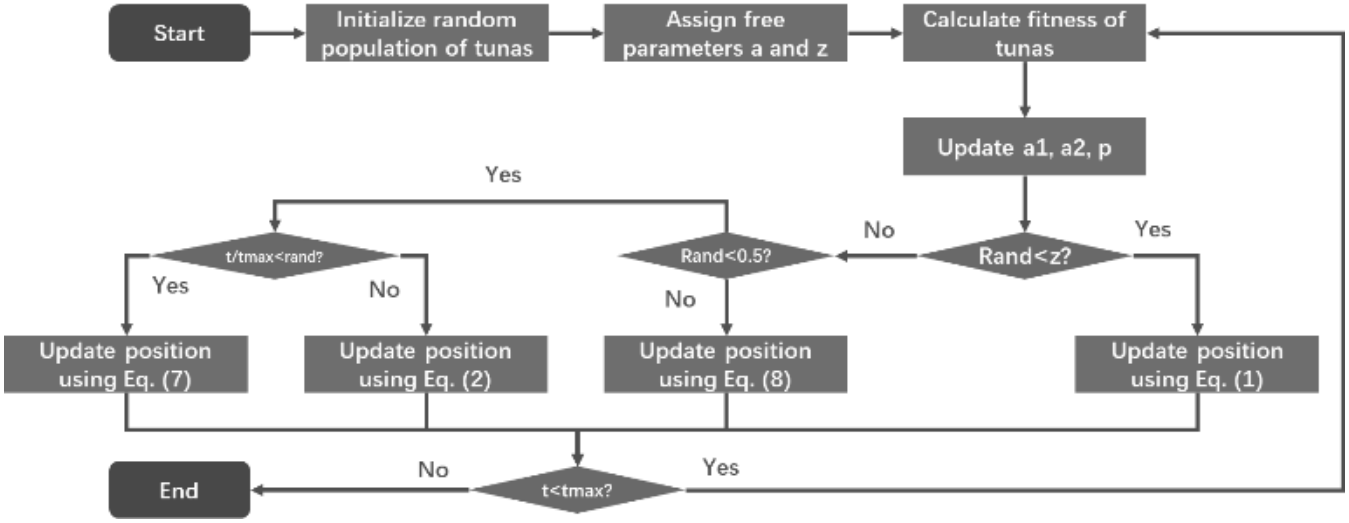

Fig. 5. Flowchart of TSO algorithm.

- Step 1: Initiation involves the configuration of both the demographic parameters and their respective positions within the search space. It is also essential to establish the upper limit for the iteration count and to define additional pertinent parameters for the optimization process;
- Step 2: Calculate the fitness value and record the current optimal individual;
- Step 3: Update the TSO algorithm parameters;
- Step 4: Based on the probability z and the size of the random number, select the appropriate strategy to update the individual location;
- Step 5: Assess the suitability of each candidate solution by computing its fitness value, and document the most advantageous individual identified in the current round;
- Step 6: Evaluate if the ongoing iterations have met the predefined threshold. If the iteration limit has been exceeded, proceed to the conclusion of the algorithm; otherwise, continue with subsequent iterative enhancements. If the maximum number of iterations is reached, carry out the output of the optimal solution and optimal value; otherwise, go to step 3.

B. DBN Network

This paper adopts a deep confidence network to construct an assessment model that integrates the evaluation of college sports activities both in and out of the classroom, tackling the evaluation of behavioral data from sports applications [24].

Deep Belief Networks (DBN) [25] consist of multiple levels of Restricted Boltzmann Machines (RBM), representing the neural network. These networks are structured with an input level and a hidden level, where connects exist with these levels but not among units within the same level. The complex relationships within the input data.

Determine the energy function of the Restricted Boltzmann Machine (RBM). Assuming that $\theta=(\omega,a,b)$ is the DBN network parameter, the energy function of RBM is expressed as:

$$E(v,h|\theta)=-\sum_{i=1}^{n}a_i v_i-\sum_{j=1}^{m}b_j h_j-\sum_{i=1}^{n}\sum_{j=1}^{m}v_i\omega_{ij}h_j \tag{10}$$

In Eq. (10), (v,h) represents the state values within the Deep Belief Network (DBN), and ω denotes the weights that link the visible and hidden layers of the network a and b are the bias of the visible and hidden layers respectively, and the hidden and visible layer states are binary, i.e. $v \in \{0,1\}$ and $h \in \{0,1\}$.

The method of stochastic gradient descent is employed to estimate the parameters θ of the DBN network. The corresponding parameters θ^* are obtained by solving the maximum of the log-likelihood function:

$$\theta^* = \arg_\theta \max L(\theta) = \arg_\theta \max \sum_{k=1}^{K} \ln p\left(v^k \middle| \theta\right) \tag{11}$$

In Eq. (11), *K* is the number of training samples.

The energy function serves as the foundation for calculating the joint probability distribution, which is a critical component in understanding the interactions between visible and hidden layers within the network, Eq. (12) and Eq. (13):

$$p\left(v,h\middle|\theta\right) = \frac{e^{-E\left(v,h|\theta\right)}}{Z(\theta)} \tag{12}$$

$$Z(\theta) = \sum_{v}\sum_{h} e^{-E\left(v,h|\theta\right)} \tag{13}$$

Establish the condition of the visible layer. The likelihood of the activation for the jth unit within the hidden layer is Eq. (14):

$$p\left(h_j = 1\middle|v,\theta\right) = sigmoid\left(b_j + \sum_{i=1}^{n} v_i \omega_{ij}\right) \tag{14}$$

Establish the state of the hidden layer. The likelihood of activation for the ith node in the visible layer of the network is calculated by Eq. (15):

$$p\left(v_i = 1\middle|h,\theta\right) = sigmoid\left(a_i + \sum_{i=1}^{n} h_j \omega_{ij}\right) \tag{15}$$

According to Gibbs sampling theorem, the RBM parameter θ is updated with the following Eq. (16) to Eq. (18):

$$\Delta\omega_{ij} = \frac{\partial \log p(v)}{\partial \omega_{ij}} = \varepsilon\left(\left\langle v_i h_j \right\rangle_{data} - \left\langle v_i h_j \right\rangle_{predict}\right) \tag{16}$$

$$\Delta a_i = \frac{\partial \log p(v)}{\partial a_i} = \varepsilon\left(\left\langle v_i \right\rangle_{data} - \left\langle v_i \right\rangle_{predict}\right) \tag{17}$$

$$\Delta b_j = \frac{\partial \log p(v)}{\partial b_j} = \varepsilon\left(\left\langle h_j \right\rangle_{data} - \left\langle h_j \right\rangle_{predict}\right) \tag{18}$$

where ε denotes the learning rate, $\langle \square \rangle_{data}$ is the expectation of training after input data, and $\langle \square \rangle_{predict}$ is the expectation of the model itself.

IV. Result and Discussion

A. Decision-making Variables

The conventional iterative approaches for optimizing the parameters of a Deep Belief Network (DBN) are susceptible to getting trapped at local optima. To counteract these issues, this paper employs the Tuna Swarm Optimization (TSO) algorithm to refine the parameters of the DBN. This includes the weights that connect the visible and hidden layers and the biases associated with these layers. The decision variables for the TSO algorithm's optimization process are represented by the vector $\theta = (\omega, a, b)$.

B. Objective Function

To enhance the precision of DBN training, the TSO-DBN algorithm employs the root-mean-square error (RMSE) as its objective function, which is Eq. (19):

$$\min RMSE = \sqrt{\left(\sum_{i=1}^{M} \left(\hat{y}_i - y_i\right)^2\right) \Big/ M} \tag{19}$$

C. Steps and Processes

The assessment technique grounded in the Tuna Swarm Optimized Deep Belief Network (TSO-DBN) for the synthesis of in-class and extracurricular sports education is fundamentally predicated on the correlation between the input features of the evaluation and the output values indicative of the integrated sports classroom performance. It also hinges on the linkage between these features and their respective evaluation outcomes. A visual representation of this integrated assessment methodology based on the TSO-DBN algorithm is depicted in Fig. 6, with the detailed procedural steps outlined below:

- Step 1: Identify and extract the evaluative attributes that are pertinent to the integration of physical education across both classroom and extracurricular domains; subsequently, partition the entire data corpus into three distinct subsets: one for training, another for validation, and the last for testing purposes.
- Step 2: The nascent parameters of the DBN are equationed by leveraging the TSO algorithm, with the initialization of various algorithmic parameters such as the size of the population and the number of iterations. This step also involves the initialization of the population and the computation of the objective function's value.
- Step 3: Position update based on spiral foraging and parabolic foraging optimization strategies.

- Step 4: Calculate the fitness value and update the optimal solution.
- Step 5: Assess if the criteria for ending the iterative process have been met; should this be the case, conclude the iteration, and produce the most favorable set of DBN network parameters, then proceed to Step 3. If not, persist with the process and advance to Step 6.
- Step 6: Translate the refined DBN parameters through the lens of the TSO algorithm, securing the optimal parameters, and subsequently establish the recognition model that is underpinned by the TSO-DBN algorithm.
- Step 7: Utilize the proficiently trained recognition prediction model to conduct an evaluation of the active test dataset, which leads to the generation of the appropriate classification results.

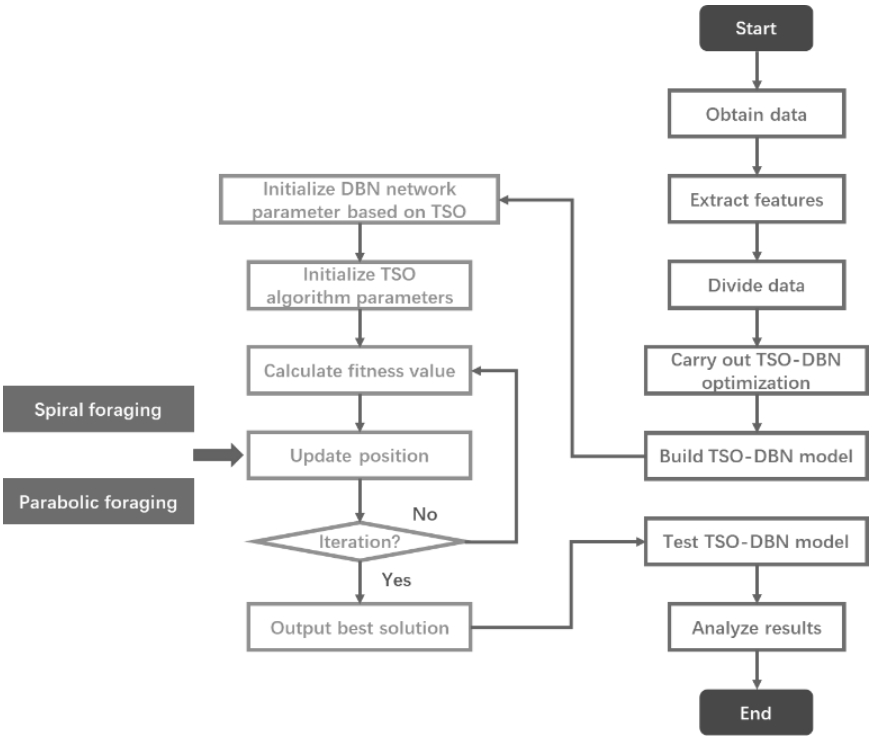

Fig. 6. Flowchart of the integrated evaluation method of university physical education inside and outside the classroom based on the TSO algorithm to improve the DBN network.

D. Experiments and Analysis of Results

To substantiate the strengths and weaknesses of the comprehensive evaluation approach for physical education, both within and beyond the classroom, as introduced in this paper through the Campus Run APP, a comparative analysis was conducted using four distinct analytical methods. Each algorithm's specific parameters were set out in alignment with Table I. The experimental setup was established on a Windows 10 operating system, equipped with a 2.80GHz processor, and 8GB of RAM, and utilizing Matlab2023a as the programming language for the simulation.

TABLE I. PARAMETER SETTINGS OF THE INTEGRATED EVALUATION METHOD FOR PHYSICAL EDUCATION INSIDE AND OUTSIDE THE CLASSROOM BASED ON CAMPUS RUN APP

Arithmetic	Parameterization
DBN	The network architecture consists of three concealed strata, each populated with an identical count of 100 nodes, facilitating complex pattern recognition and data processing
GWO-DBN	The governing parameter a within the Grey Wolf Optimizer (GWO) diminishes from 2 to 0. The count of GWO populations and the DBN network concealed layer node configurations mirror those of the TSO-DBN.
HHO-DBN	DBN network nodes set as in TSO-DBN
FTTA-DBN	FTTA algorithm Pcomm=0.2, Pstudy=0.2, Perror=0.001, FTTA population size and DBN network node settings are the same as TSO-DBN
TSO-DBN	The TSO algorithm is characterized by a set at 0.7, and z at 0.05. The examination of the count of TSO populations in conjunction with the DBN network nodes results in the following observations.

1) Examination of the influence of TSO population count and DBN cryptic node quantity: To scrutinize the effect of the populace magnitude of the TSO algorithm and the quantum of DBN clandestine nodes on the holistic appraisal approach of tertiary physical education sessions both within and beyond the classroom, this paper contrasts and examines the efficacy of the holistic appraisal methodology of physical education sessions within and without grounded upon the Campus Run APP under varying populace magnitudes and differing quantities of DBN clandestine node layers. Fig. 7 and 8 present the diagrams depicting the sway of diverse populace magnitudes and distinct quantities of DBN clandestine nodes on the appraisal precision and duration of the appraisal approach for the synthesis of athletic sessions within and without, respectively.

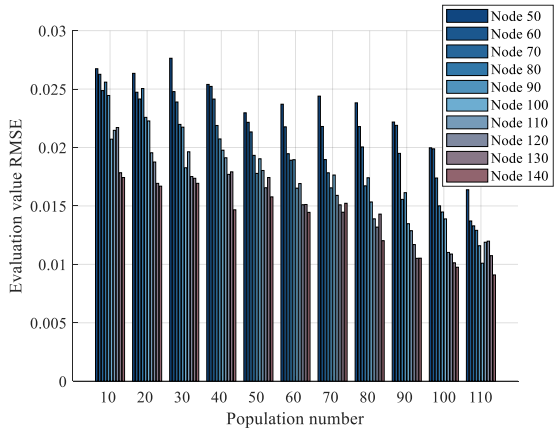

Fig. 7. Effect of different population sizes and different numbers of DBN hidden layer nodes on evaluation accuracy.

From Fig. 7, it is evident that as the optimization escalates, the precision of the appraisal figure of the comprehensive appraisal approach of education sessions based on the Campus Run APP ascends progressively; with the augmentation of the clandestine node count within the DBN tri-layered network, the RMSE value of the comprehensive appraisal figure of the comprehensive appraisal of internal and external physical education sessions based on the Campus Run APP diminishes, resulting in enhanced precision. As discernible from Fig. 8, with the increase of the TSO optimization algorithm population, the appraisal period of the internal and external synthesis of physical education sessions based on the Campus Run APP augments steadily; as the number of DBN network hidden nodes grows rapidly, the appraisal period of the internal and external synthesis of physical education sessions based on the Campus Run APP expands. In summation, by contemplating the equilibrium of precision and temporal performance concurrently, the intelligent optimization algorithm populace magnitude elected in this paper amounts to 80, with the CNN hidden node count standing at 70.

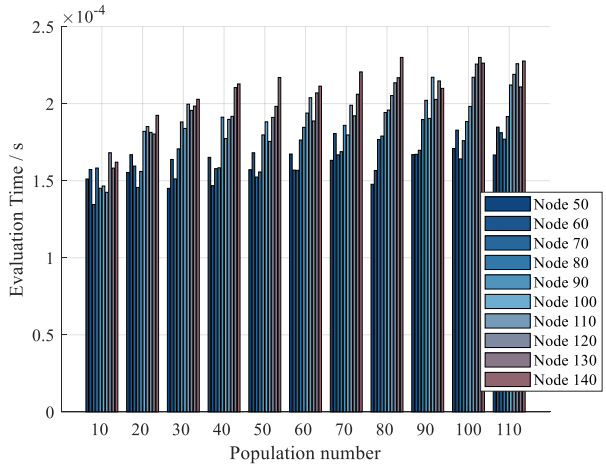

Fig. 8. The impact of varying the size of the population and the count of nodes in the DBN's hidden layers on the duration of the evaluation process.

2) Comparison of evaluation method results: To substantiate the veracity and preeminence of the holistic appraisal approach rooted in the TSO-DBN algorithm for internal and external physical education sessions, the holistic appraisal methodology predicated on the TSO-DBN algorithm for internal and external physical education sessions was contrasted with the holistic appraisal methodology grounded in the DBN, GWO-DBN, HHO-DBN, and FTTA-DBN algorithms. The operational outcomes of each model are exhibited in Fig. 9, 10, 11, 12, and 13.

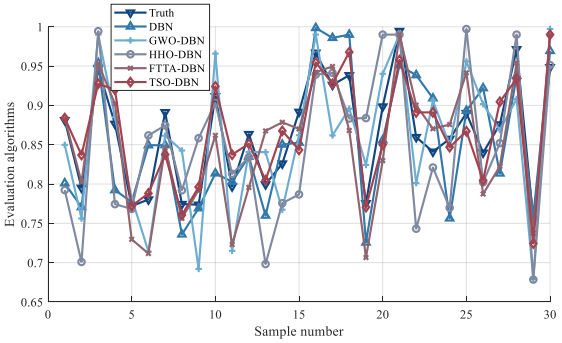

Fig. 9. Predicted results of the integrated evaluation method of physical education inside and outside the classroom based on each algorithm.

Fig. 9 and Fig. 10 depict the forecasted values and relative errors of the holistic appraisal approach of physical education within and without the classroom grounded in each algorithm, respectively. The error of the TSO-DBN algorithm is contained within 0.05, while the residual algorithms' error rankings follow the sequence of FTTA-DBN, GWO-DBN, DBN, and HHO-DBN, with the error scopes restrained within 0.07, 0.08, 0.1, and 0.11, correspondingly. In summation, regarding the forecast precision of the appraisal value, the forecast precision of the integration of internal and external appraisal of physical education sessions based on the TSO-DBN algorithm surpasses that of the other algorithms.

Fig. 11, 12, and 13 exhibit the anticipated RMSE, R2, and duration of the comprehensive physical education in-and-out appraisal methodologies based on each algorithm under variant operational circumstances. As discernible from Fig. 11, 12, and 13, the hierarchy of forecasted RMSE of each algorithm under diverse operational circumstances follows the order of TSO-DBN, FTTA-DBN, GWO-DBN, HHO-DBN, and DBN, and the forecasted RMSE of the comprehensive appraisal approach for internal and external sports sessions based on the TSO-DBN algorithm is the least substantial, with a value spanning from 0.2 to 0.3; the ranking of projected R2 of each algorithm under various operational conditions is TSO-DBN, FTTA-DBN, GWO-DBN, HHO-DBN, and DBN. The anticipated R2 rankings of each algorithm under diverse operational circumstances are TSO-DBN, FTTA-DBN, GWO-DBN, HHO-DBN, DBN, and the comprehensive appraisal methodology based on the TSO-DBN algorithm for internal and external athletic sessions boasts the most extensive projected R2, with a value approximating 0.98; the forecasted duration rankings of each algorithm under varied operational conditions are, sequentially, TSO-DBN, FTTA-DBN, HHO-DBN, GWO-DBN, DBN, and the prediction duration of the comprehensive appraisal methodology of physical education within and without the classroom based on the TSO-DBN algorithm is the briefest, and its value lies within 0.0025. This implies that the

comprehensive appraisal approach of physical education within and without the classroom for each algorithm exhibits the optimum performance.

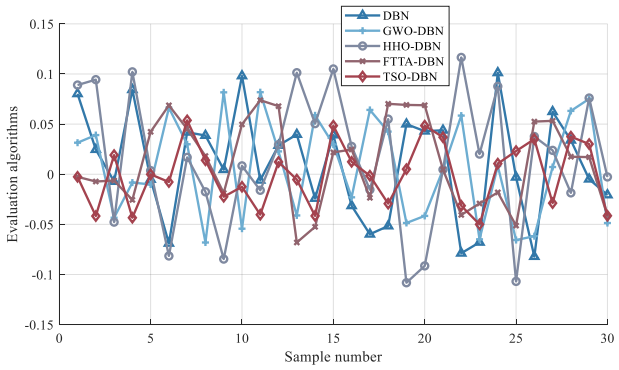

Fig. 10. Results of the relative error between the predicted and true values of the integrated evaluation methods for physical education inside and outside the classroom based on each algorithm.

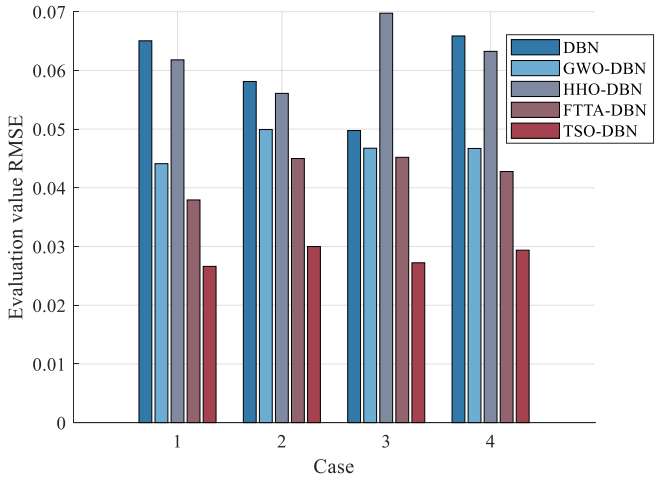

Fig. 11. Predicted RMSE results of the integrated evaluation method of physical education inside and outside the classroom based on the Campus Fun Run App.

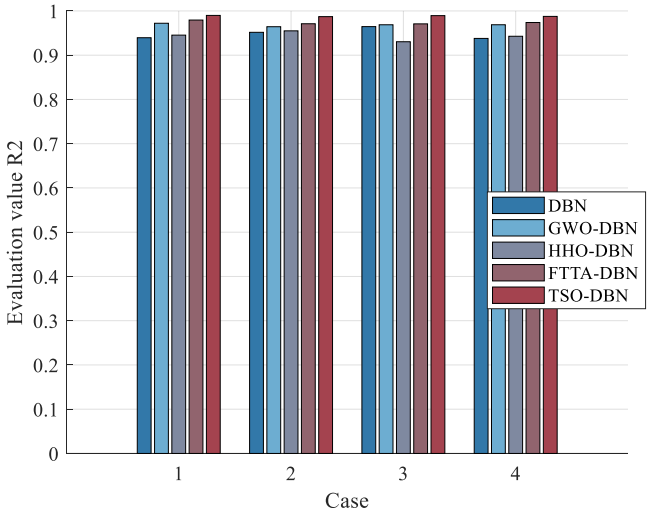

Fig. 12. Predicted R2 results of the integrated evaluation method of physical education inside and outside the classroom based on the Campus Run App.

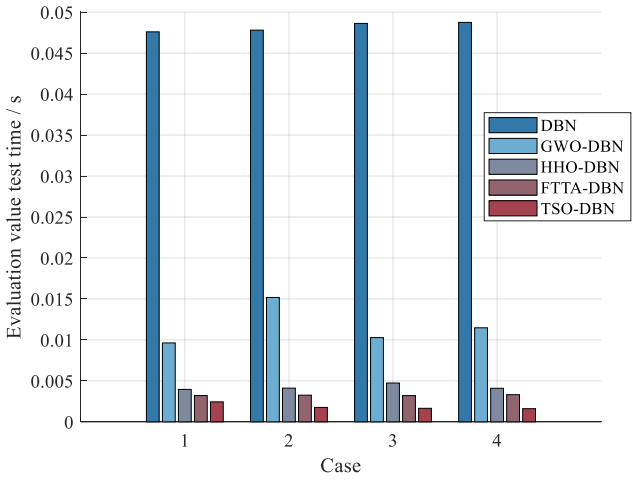

Fig. 13. Predicted time results of the integrated evaluation method for physical education inside and outside the classroom based on the Campus Run APP.

V. CONCLUSION

Addressing the prevailing issues of imprecise measurements and a lack of impartiality in the current integrated assessment methods for physical education activities both in and out of the classroom, this paper presents an integrated evaluation model known as TSO-DBN. This model merges the Tuna Swarm Optimization (TSO) algorithm with a deep confidence network to analyze and evaluate the behavioral data collected by the Campus Le Running APP. The methodology involves scrutinizing the existing evaluation challenges, identifying key evaluative features, and developing a cohesive assessment system for university physical education. By integrating TSO with DBN, this paper proposes an enhanced evaluation technique that promises improved predictive performance over existing methods. Comparative analysis demonstrates the superiority of the TSO-DBN model in predictive accuracy for the evaluation of physical education activities. The findings indicate that the TSO-DBN model outperforms alternative algorithms in this context.

For the practical implementation of this project, careful consideration must be given to the process of filtering through the extensive operational data generated by the system. It is essential to identify and select the most indicative feature dimensions and representative samples that will contribute to the dynamic refinement of the network's parameters in real-time scenarios.

Robust Image Tampering Detection and Ownership Authentication Using Zero-Watermarking and Siamese Neural Networks

Rodrigo Eduardo Arevalo-Ancona[1], Manuel Cedillo-Hernandez[2], Francisco Javier Garcia-Ugalde[3]
Instituto Politecnico Nacional, SEPI-ESIME Culhuacan, Mexico City, Mexico[1, 2]
Universidad Nacional Autonoma de Mexico, Facultad de Ingenieria, Mexico City, Mexico[3]

***Abstract*—The development of advanced image editing tools has significantly increased the manipulation of digital images, creating a pressing need for robust tamper detection and ownership authentication systems. This paper presents a method that combines zero-watermarking with Siamese neural networks to detect image tampering and verify ownership. The approach utilizes features from the Discrete Wavelet Transform (DWT) and employs two halftone images as watermarks: one representing the owner's portrait and the other corresponding to the protected image. A feature matrix is generated from the owner's portrait using the Siamese network and securely linked to the image's halftone watermark through an XOR operation. Additionally, data augmentation enhances the model's robustness, ensuring effective learning of image features even under geometric and signal processing distortions. Experimental results demonstrate high accuracy in recovering halftone images, enabling precise tamper detection and ownership verification across different datasets and image distortions (geometric and image processing distortions).**

***Keywords*—Zero-watermarking; tampering detection; ownership authentication; neural network**

I. Introduction

In recent years, digital image manipulation has become a growing concern with the development of advanced editing tools, many of which are easily accessible to the general public. This issue poses significant challenges to the integrity and authenticity of digital images in applications such as copyright protection, digital security, and forensic investigations [1], [2]. Manipulation techniques such as copy-move and splicing can compromise the content and image ownership [3], [4], [5]. Furthermore, ownership authentication is crucial to prevent unauthorized use or distribution, ensuring their protection [6].

Traditional watermarking methods verify the authenticity and ownership of images. However, these approaches degrade the image quality by embedding watermark signals into the visual content. To address this issue, zero-watermarking techniques preserve image quality by creating a master share that is not embedded into the image content. This method creates a master share by linking image features with a watermark for authentication, avoiding distortions and preserving image quality [7], [8].

Additionally, deep neural networks enhance tamper detection and image authentication by learning patterns and semantic representations from images. This approach significantly improves the efficiency of detecting manipulations and verifying image content.

This paper presents a robust zero-watermarking methodology that integrates zero-watermarking with Siamese neural networks for tamper detection and ownership verification. The approach utilizes the Discrete Wavelet Transform (DWT) to extract key features from images, which are then used to train the Siamese network and generate a feature matrix. This matrix is linked to the watermark—a proprietary halftone image—through an XOR operation, enabling accurate watermark recovery even in the presence of geometric distortions and signal processing attacks. Additionally, tamper detection is achieved by analyzing image blocks' eigenvalues to identify image manipulations effectively. The main contributions of this work are as follows:

- Enhance ownership authentication and tamper detection using a zero-watermarking technique that verifies image ownership and detects manipulations by combining image features extracted by the Siamese neural network with the watermark, ensuring security and integrity.
- Create a robust feature representation with Siamese Neural Networks. Robust feature representation is achieved because the neural network learns unique and invariant image features. One branch is trained with undistorted images, while the other is trained with distorted images, providing an efficient method improving the accuracy of ownership authentication and increases the method's robustness against manipulated images.
- Data augmentation techniques prevent overfitting and improve generalization across different types of images. This is essential because overfitting is common in neural network models, especially when working with limited or highly distorted data. In addition, data augmentation enhances feature extraction since the model learns more robust image features.
- The Siamese neural network learns and compares features, analyzing similarities and differences between the original halftone image's and distorted image's DWT coefficients. This is critical for tamper detection and authenticity verification.

- Optimized feature extraction using the Low-Low (LL) sub-band coefficients of the DWT. These filters remove irrelevant high-frequency details, focusing on the most relevant information for watermarking. This step is necessary to increase the robustness of the feature extraction process for watermark recovery, ensuring that important features are preserved even when the image has geometric or image processing distortions.
- A precise tamper detection method that compares the image blocks eigenvalues between the original halftone image and a distorted version, providing an additional layer of accuracy for tampering detection.

The paper is organized as follows: Section II reviews existing methods. Section III describes the proposed technique. Section IV presents and analyzes experimental results. Finally, Section V concludes with the study's advantages and limitations.

II. Literature Review

This section presents an overview of recent techniques developed for image tampering detection and image authentication, providing the necessary context for the method proposed in this paper.

Several approaches are focused on detecting tampered regions by extracting specific image features. For example, Xing et al. [9] used a high-pass filter to capture edge information, concentrating on modified regions to identify manipulated areas. Alsughayer et al. [10] employed a U-Net architecture to extract residual noise from images, identifying tampered regions in remote sensing data. However, noise-based methods are susceptible to false positives when noise is introduced by natural image compression or processing.

With the rise of deep learning, some network-based solutions for tamper detection were developed, such as Priyadharsini et al. [11], who applied a modified GoogleNet model to extract features using a nearest neighbor algorithm for splicing detection. However, this method is computationally expensive and is prone to overfitting with small datasets. Ren et al. [12] introduced a neural network for low-level feature extraction, focusing on geometric details and semantic segmentation for copy-move detection. Goel et al. [13] used a dual neural network for inherent feature extraction, although their method requires large amounts of labeled data for accurate detection. Hosny et al. [14] proposed a method based on deep neural networks for extracting specific image features, while Chu [15] used a generative neural network to detect forged regions. Das et al. [16] leveraged MobileNet V2 to detect manipulated areas, highlighting the potential of lightweight models for real-time applications. Nikalie et al. [17] combined convolutional neural networks with Local Binary Pattern (LBP) analysis to detect texture inconsistencies. Mallick et al. [18] incorporated VGG16 and VGG19 models to identify manipulations across images with different compression levels, but their approach requires significant computational resources. Dai et al. [19] employed the Xception model to extract image edges and textures, offering improvements in detecting fine manipulations.

On the other hand, recent zero-watermarking methods for image authentication integrated neural networks to improve robustness. Xiang et al. [20] combined watermarking with features generated by a ResNet-based neural network, which relied on correlations between neural network layer responses to verify authenticity. However, these models are susceptible to geometric distortions. Dong et al. [21] proposed a method using NasNet-Mobile features and Discrete Cosine Transform (DCT) coefficients to create a master share, allowing watermark recovery without degrading the image. Similarly, Li et al. [22] introduced an image authentication method based on ConvNeXt layers and Swin Transformer optimization for feature extraction, although the approach lacks comprehensive evaluation against geometric attacks. He et al. [23] further advanced the field by integrating convolutional layers based on the Swin Transformer to optimize feature extraction for zero-watermarking, yet the robustness under signal processing distortions remains underexplored.

While significant progress has been made in both neural network-based tamper detection and watermarking techniques, these methods still need to improve their robustness, especially under geometric distortions and signal processing attacks. In contrast, the method proposed in this paper addresses these limitations for image ownership authentication and detects image tampering by combining Siamese neural networks with zero-watermarking. This ensures high accuracy in tamper detection and strong resilience to various distortions without compromising image quality. Additionally, the Discrete Wavelet Transform (DWT) allows for more efficient feature extraction, focusing on relevant low-frequency components, further enhancing robustness.

III. Proposed Image Tampering Detection and Ownership Authentication Method

The proposed algorithm introduces a robust zero-watermarking technique for image protection, creating a master share, which is generated by logically linking the halftone image representation with features extracted from the watermark, represented by the owner's portrait, through a neural network (Fig. 1(a)). The preprocessing stage begins by dividing the input image into 32x32 pixel blocks and applying the Discrete Wavelet Transform (DWT) to extract the Low-Low (LL) sub-band coefficients, which enhance the system's robustness against geometric distortions and signal processing attacks.

The features extracted by the Siamese neural network are carefully selected because they capture invariant and distinctive representations of the watermark, which are crucial for an accurate ownership verification and tamper detection. The Floyd-Steinberg dithering algorithm generates the halftone effect [24], [25].

For the tamper detection and ownership verification stage, the master share is combined with the features extracted by the Siamese network to recover the halftone representation of the protected image. The eigenvalues from the feature matrices of the recovered and potentially manipulated images are compared to identify image forgery regions. (Fig. 1(b)).

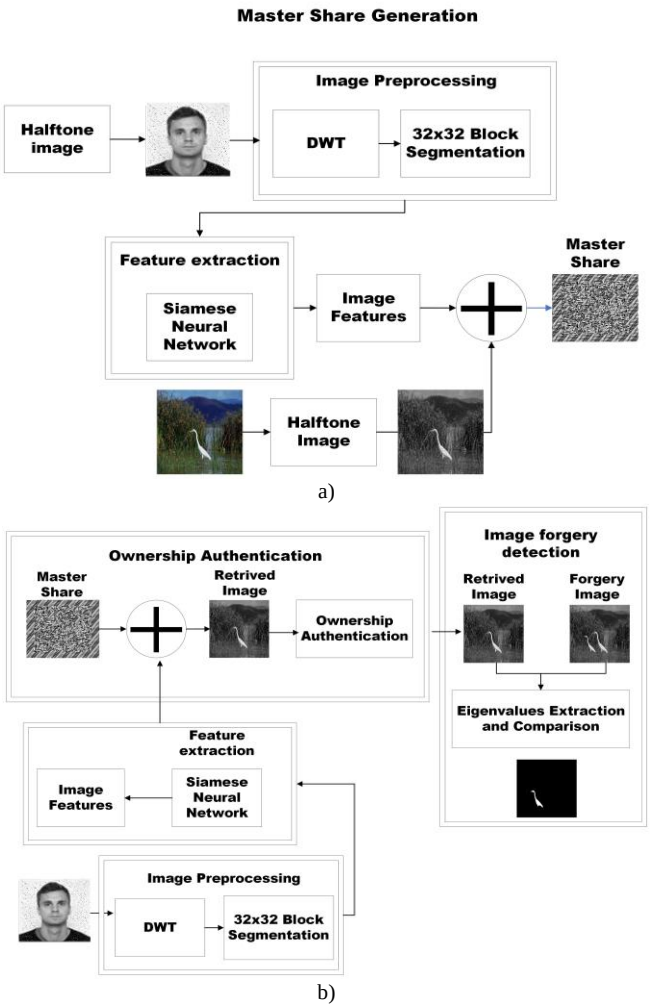

Fig. 1. (a) General diagram of the proposed master share generation algorithm (b) Ownership authentication and tamper detection procedures.

The proposed method consists of the following stages:

Preprocessing: Halftone representations of both the image and the watermark are created. The halftone watermark is decomposed using the Haar wavelet transform (DWT), focusing on the LL sub-band. This sub-band is divided into 32x32 blocks used to train the neural network. Dividing the image into smaller blocks identifies specific features from each image region more effectively, improving the accuracy of feature extraction and reducing computational complexity.

Feature extraction for the master share generation: The Siamese neural network extracts key features from the watermark. These features are combined with the image's halftone representation to generate the master share.

Image ownership authentication: The halftone image is retrieved by linking the watermark's extracted features with the master share. This step validates image ownership, offering robust intellectual property protection.

Image tampering detection: The eigenvalues from the halftone and retrieved images are compared to detect forgeries. Eigenvalues are sensitive to structural changes in the image, making them an effective tool to identify image tampering.

A. Preprocessing

In the preprocessing stage, the halftone image representations are generated for the image and the owner's portrait (watermark). The halftone representation simplifies the visual content with binary patterns, eliminating unnecessary details. Then, the owner's halftone image is transformed into the frequency domain using the DWT with Haar wavelets. Haar wavelets are effective for image processing tasks capturing spatial and frequency information. The DWT decomposes the image into frequency sub-bands, each capturing specific image characteristics. The low-low (LL) sub-band is selected for further processing and contains low frequency image components. These components represent the most important structural details, such as edges and large-scale patterns, which are less susceptible to distortion like noise or compression and eliminate redundant features. The LL sub-band coefficients are divided into 32x32 pixel blocks to optimize the system's robustness. This segmentation enhanced feature extraction because each block represents an image region, allowing the neural network to learn specific features. In addition, when working with smaller blocks, the overall processing time is reduced, and memory usage is optimized, making the algorithm more scalable and suitable for real-time applications, highlighting the system's adaptability.

B. Feature Extraction for the Master Share Generation

In this stage, the Siamese neural network extracts relevant features from the halftone watermark. The Siamese network is designed to compare two images and learn invariant features robust to distortions and manipulations (Fig. 2). This neural network model consists of two identical subnetworks, ensuring the feature matrix contains specific representations from the watermark. In this case, one subnetwork processes the original DWT watermark blocks while the other processes a distorted version of the watermark DWT blocks.

The features extracted from the watermark by the Siamese network are used to construct a feature matrix, which encodes the unique characteristics of the watermark. This feature matrix contains patterns from the watermark and the distorted watermark version with geometric and image processing attacks. Then, the feature matrix is combined with the halftone representation of the image. The combination is achieved using an XOR operation.

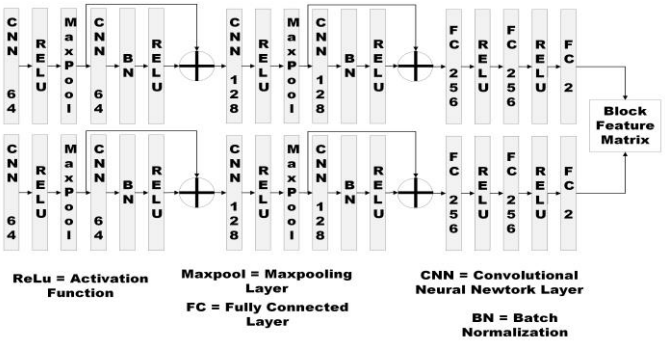

Fig. 2. Siamese neural network architecture.

The resulting master share contains a visual structure that encrypts the image and the semantic features of the watermark. This technique preserves the image quality since no watermark is embedded directly into the visual content of the image, maintaining its integrity.

The parameters and configurations used in the training process to increase the robustness and accuracy in the system are presented in Table I. The Siamese neural network architecture consists of two identical branches. To train the neural network one branch processes the DWT watermark blocks, and the second branch processes the DWT distorted watermark blocks. This architecture is especially useful when the data is limited. The purpose of the network is to compare image features from both input images and identify unique patterns in each region. The network creates a feature matrix (f_{vm}) (2) based on the vectors generated from the output of the Siamese neural network (v_1, v_2) related to each image region, representing the unique characteristics.

$$v_1 = f_\theta(I_1)$$
$$v_2 = f_\theta(I_2) \quad (1)$$

$$f_{vm} = \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} \quad (2)$$

Then feature matrix with the Siamese neural network output (f_{vm}) has a size of (3) and is restructured to the image halftone size (f_m) (4).

$$size = (2, (\frac{m\ x\ n}{block\ size})) \quad (3)$$

$$fm = \begin{bmatrix} c_{1,1} & \cdots & c_{1,n} \\ \vdots & \ddots & \vdots \\ c_{m,1} & \cdots & c_{m,n} \end{bmatrix} \quad (4)$$

m is the height of the image and *n* the width of the image.

1) Neural network training: One key aspect is data augmentation, which enhances the model's feature detection. Data augmentation is important when the amount of data is limited, as it artificially increases the dataset by applying distortions to the input images. The image processing attacks applied during augmentation include different image filters for image blurring (average, median, Gaussian, motion blurring), JPEG compressions (quality factor = 90, 60, 10), noise addition (Gaussian noise σ = 0.09, 0.009 and salt and pepper), rotations (random rotations from 10° to 350°), translations (image pixels shift in x, y and xy axis = 50, 100, 150), cropping (random cropping with sizes in x and y= 50, 100, 150), and scaling (scaling factors = 2, 0.5, 0.25).

The application of these augmentation techniques ensures that the network learns robust, invariant features to obtain high ownership authentication and image tampering detection accuracy even in the presence of noise, distortions, or other forms of manipulation.

TABLE I. SIAMESE NEURAL NETWORK PARAMETERS

Epochs	Learning rate	Momentum	Optimazer	Batch size
3	0.0001	0.9	Stochastic Gradient Descent	64

2) Master share generation: The features extracted from the watermark by the Siamese network are used to construct a f_m, which encodes the unique characteristics of the watermark (W).

This feature matrix is then combined with the halftone representation of the watermark using an XOR operation ($\oplus$) to create the master share (*MS*) (5) (see Fig. 3). This operation effectively encrypts the image while preserving its quality, as no watermark is embedded directly into the visual content of the image. This XOR-based encryption method securely. The resulting master share (see Fig. 4(d)) is then stored and distributed. To recover the original image, the master share must be used together with the watermark.

$$ms = f_m \oplus H \quad (5)$$

Once the master share has been generated and stored, image ownership authentication can be carried out. The following sections detail how this ownership authentication process works and how the master share is utilized for both authentication and tamper detection.

C. Image Ownership Authentication and Tamper Detection

To verify ownership, the master share used watermark during recovery even if it is distorted. This element ensures that only the owner, who possesses the watermark, can authenticate the image. The authentication process involves recovering the halftone image from the master share using both the owner's portrait and the master share. This procedure, illustrated in Fig. 5, confirms the image's ownership. The ownership is confirmed by reconstructing the halftone image and verifying its authenticity.

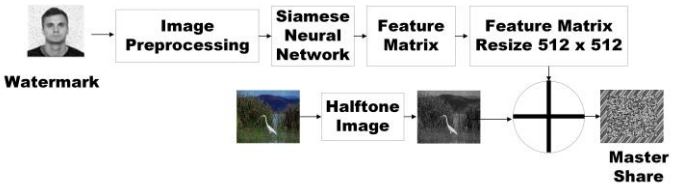

Fig. 3. Master share generation process.

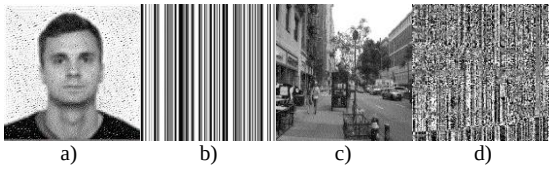

Fig. 4. a) Halftone watermark, b) Feature matrix generated from the Siamese neural network, c) Halftone image, d) Master share.

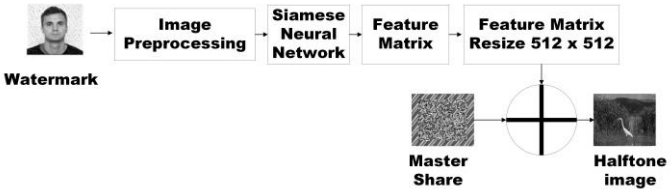

Fig. 5. Image halftone recovery process.

This process involves decoding the master share (*ms*) to reconstruct the halftone image (H_r) by combining the feature matrix from the Siamese neural network (f_m) with the master share using the XOR ($\oplus$) logical operation (6).

$$H_r = f_m \oplus ms \tag{6}$$

Once ownership has been confirmed through the successful reconstruction of the halftone image, it is important to ensure that the image has not been tampered. While the ownership authentication process guarantees that only the owner can verify the image, the tampering detection process compares the original and recovered halftone images to detect unauthorized modifications. The following section details how the system uses eigenvalues to detect manipulations by comparing the structural integrity of the original and recovered images, ensuring that the image remains unchanged and free from tampering.

D. Tampering Detection

The manipulation detection used the recovered and manipulated halftone images to identify any potential alterations. In this stage, eigenvalues are calculated for both the recovered halftone and potentially manipulated images. The images are divided into smaller blocks, and the eigenvalues for each block are calculated. These eigenvalues represent distinct structural characteristics of each image and are compared to identify discrepancies. The eigenvalues $\lambda_1, \lambda_2, \ldots, \lambda_n$ are computed by (7).

$$v_I = \det(I - \lambda) \text{ and } v_m = \det(I_m - \lambda) \tag{7}$$

where I is the retrieved halftone image, I_m is the manipulated image, v_I is the vector with the eigenvalues from the retrieved image and $v_m$is the vector with the eigenvalues from the manipulated image. The eigenvalues comparison is realized by the Euclidean distance (*d*) (8).

$$di = \sqrt{(\lambda_I - \lambda_m)^2} \tag{8}$$

For each block, if the distance exceeds a predefined threshold (*th*), the block (b_d) is considered manipulated (9).

$$b_d = \begin{cases} 0 & if \quad d \le th \\ 1 & if \quad d > th \end{cases} \tag{9}$$

The results of this process, illustrating the detection of manipulations, are shown in Fig. 6. This method enhances the precision of manipulation detection. Block-based eigenvalue comparisons allow localized forgery detection, ensuring that even subtle tampering can be identified, thus offering a more detailed and accurate analysis of image manipulations.

Fig. 6. a) Original image, b) Tampered image, c) Forgery detection.

In the following section, the experimental results obtained from this methodology demonstrating its effectiveness for ownership authentication and image tampering detection.

IV. Experimental Results

This section presents the experimental results of the proposed algorithm for both ownership authentication and image tampering detection. The image watermark was subjected to a wide range of image processing techniques and geometric distortions, simulating real scenarios to assess the method's robustness. The experimental results demonstrate the algorithm's effectiveness in accurately verifying ownership and detecting manipulations, even when the watermark has been significantly altered.

The algorithm was implemented in a system equipped with an NVIDIA GTX 960 graphics card and an Intel Core i7-6700 processor running at 3.4 GHz. This hardware configuration provided a suitable environment for efficiently executing the algorithm within the PyTorch Python framework, ensuring smooth performance during training and testing. A 512 x 512 pixel halftone representation of the author's face was used as the watermark for the experiments. The proposed algorithm's performance was evaluated using three widely used image datasets, showcasing its ability to handle diverse scenarios and conditions:

MICC-F220: This dataset contains 220 RGB images, equally divided into 110 manipulated and 110 non-manipulated images. It evaluates owner authentication and tamper detection accuracy in a balanced setting [26].

MICC-F2000: This dataset is comprised of 2,000 RGB images (700 manipulated and 1,300 non-manipulated), which is used for a more extensive assessment of the algorithm's performance across diverse scenarios and conditions [26].

CASIA V2: This larger dataset includes 12,613 RGB images, 5,123 manipulated, and 7,490 non-manipulated images. Due to its size and diversity, CASIA V2 provides a robust evaluation framework, testing the algorithm's scalability and effectiveness across a wide range of image manipulations [27], [28].

These datasets cover different image manipulation scenarios to evaluate the algorithm's robustness and accuracy. The experiments using these datasets quantitatively assess the algorithm's ability to recover the halftone images for ownership authentication and image forgery detection. The results offer valuable insights into the algorithm's effectiveness in different conditions, showcasing its ability to detect subtle manipulations and authenticate image ownership.

A. Assessment of Image Ownership Authentication

The proposed method's performance is assessed in terms of ownership authentication, emphasizing its robustness against different image processing and geometric distortions. To ensure this robustness, two metrics are employed: Bit Error Rate (BER) and Normalized Cross-Correlation (NC). These metrics determine the algorithm's performance under image processing and geometric distortions applied to the watermark.

The BER measures the error bits between the original and recovered halftone images. A lower BER indicates that the algorithm successfully retrieves the watermark (10).

$$BER = \frac{Total\ Incorrect\ pixels}{Total\ pixels} \tag{10}$$

The NC metric measures the similarity between the original and recovered halftone images. The NC value ranges from 0 to 1, where a value of 1 indicates similarity between the images, and a value of 0 indicates no similarity (11).

$$NC = \frac{\sum_{i=1}^{M}\sum_{j=1}^{N}(W(i,j)W_r(i,j))}{\sqrt{\sum_{i=1}^{M}\sum_{j=1}^{N}(W(i,j))^2}\sqrt{\sum_{i=1}^{M}\sum_{j=1}^{N}(W_r(i,j))^2}} \tag{11}$$

where, $H(i,j)$ is the halftone image, H_r is the retrieved halftone image M and N are the dimensions of the images. These metrics ensure a comprehensive evaluation of the algorithm's watermark recovery stage performance for ownership authentication, even under image distortion and manipulation.

TABLE II. HALFTONE IMAGE RECOVERY WITH WATERMARK GEOMETRIC DISTORTIONS

	Rotation 80 °	Rotation with cropping 250 °	Translation X = 90 Y = 90	Translation X = 160
Distorted watermark				
Retrieved halftone image				
	NC = 0.999 BER = 0	NC = 0.999 BER = 0	NC = 0.999 BER = 0	NC = 0.999 BER = 0
	Cropping upper left	Center cropping	Scale 64 x 64	Scale 1064 x 1064
Distorted watermark				
Retrieved halftone image				
	NC = 0.999 BER = 0	NC = 0.999 BER = 0	NC = 0.999 BER = 0	NC = 0.999 BER = 0

Tables II and III demonstrate the proposed method's robustness in recovering the halftone image even when the watermark has geometric distortions. Under distortions like rotation without cropping, translation, and scaling, the recovery performance remains nearly perfect, with BER = 0 and NC = 0.9999. Minor recovery errors occur with rotations involving cropping and downscaling, where BER reaches 0.0078 and NC drops slightly to 0.9914. These results demonstrated the method's robustness against geometric distortions, ensuring an accurate watermark recovery for ownership verification.

TABLE III. HALFTONE IMAGE RECOVERY ASSESSMENT WITH WATERMARK GEOMETRIC DISTORTIONS

Distortion	BER	NC	Distortion	BER	NC
No attack	0	0.9999	Translation x = 80 pixels	0	0.9999
Rotation 15° with no cropping	0	0.9999	Translation x = 150 pixels	0	0.9999
Rotation 55° with no cropping	0	0.9999	Translation x = 20, y = 20 pixels	0	0.9999
Rotation 110°	0	0.9999	Translation x = 80, y= 80 pixels	0	0.9999
Rotation 135° with no cropping	0	0.9999	Translation x = 150, y = 150 pixels	0	0.9999
Rotation 20° with cropping	0.0078	0.9914	Upper left cropping 100 x 100	0	0.9999
Rotation 100° with cropping	0.0078	0.9923	Upper right cropping 100 x 100	0	0.9999
Rotation 265° with cropping	0.0078	0.9901	Botton right cropping 100 x 100	0	0.9999

Translation y = 20 pixels	0	0.9999	Scale 256 x 256	0	0.9999
Translation y = 80 pixels	0	0.9999	Scale 64 x 64	0.0078	0.9914
Translation y = 150 pixels	0	0.9999	Scale 640 x 640	0	0.9999
Translation x = 20 pixels	0	0.9999	Affine transform $\begin{bmatrix} 5 & 10 & 0 \\ 10 & 5 & 0 \end{bmatrix}$	0	0.9999

Tables IV and V illustrate the effectiveness of the proposed method for recovering halftone images when the watermark is modified with image processing distortions, such as JPEG compression, affine transformations, histogram equalization, and noise addition. In most cases, the NC is 0.999, and the BER is 0, indicating high accuracy. Even under more challenging conditions, such as JPEG compression at a quality factor of 30, the method still maintains a high accuracy with NC = 0.992 and BER = 0.007. The proposed technique remains robust against distortions like salt-and-pepper noise and Gaussian filtering, achieving NC = 0.999 and BER = 0,

demonstrating its robustness in the halftone image recovery stage for ownership authentication.

TABLE IV. HALFTONE IMAGE RECOVERY ASSESSMENT WITH WATERMARK IMAGE PROCESSING DISTORTIONS

	NC = 0.999 BER = 0	NC = 0.999 BER = 0	NC = 0.999 BER = 0	NC = 0.999 BER = 0

TABLE VI. HALFTONE IMAGE RECOVERY ASSESSMENT WITH WATERMARK COMBINED DISTORTIONS

Distortion	BER	NC	Distortion	BER	NC
$\gamma = 1.25$ and salt and pepper noise 0.005	0	0.9999	JPEG Quality Factor=30 and Blurring kernel=5x5	0	0.9999
$\gamma = 1.8$ and salt and pepper noise 0.005	0	0.9999	Bright adjust and scaling 1024x1024	0	0.9999
Rotation 35° and bright adjust	0	0.9999	JPEG Quality Factor=30 and Scaling 64x64	0	0.9999

Table VI evaluates the halftone image recovery under combined distortions applied to the watermark.

For all tested combinations, including gamma correction with salt-and-pepper noise, JPEG compression with blurring, brightness adjustment with scaling, and rotation with brightness adjustment, the method achieves NC = 0.9999 and BER = 0. These results indicate that the recovery process is highly robust even when multiple distortions are applied simultaneously to the watermark, ensuring the integrity and authenticity of the halftone image.

B. Tampering Detection Assessment

Following the evaluation of image ownership authentication, assessing the algorithm's effectiveness in detecting image tampering is essential, as both tasks are closely related. The tampering detection accuracy relies on the halftone image's successful recovery during the ownership authentication stage.

Table VII presents the results, demonstrating the robustness of the proposed method in detecting image forgery by analyzing the recovered and manipulated halftone images. These results highlight the system's effectiveness by accurately detecting any image manipulations. The proposed image tampering detection and localization algorithm is evaluated using five key metrics: accuracy, precision, recall, F1 score, and mean squared error (MSE).

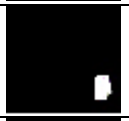
The accuracy represents the proportion of correctly detected pixels relative to the total number of pixels, indicating how well the algorithm identifies manipulated areas (12).

$$acc = \frac{T_p + T_n}{T_p + T_n + F_p + F_n} \tag{12}$$

where T_p = true positives, T_n = true negatives, F_p = false positives, F_n = False Negatives. The precision measures the ratio of correctly detected pixels from the manipulated region (13).

$$precision = \frac{Tp}{Tp + Fp} \tag{13}$$

TABLE VII. IMAGE FORGERY DETECTION

Database	Original Image	Tampered Image	Ground Truth	Tampering Detection
MIC-F220				
				MIC-F2000				
				


CASIA V2								

The recall measures the proportion of correctly detected pixels in the manipulated region (14).

$$recall = \frac{Tp}{Tp + Fn} \tag{14}$$

The F1 score provides a measure of the algorithm's performance. A high F1 score indicates that the algorithm achieves minimize false positives and false negatives (15)

$$F1 = \frac{2x(Precision\ x\ Recall)}{Precision + Recall} \tag{15}$$

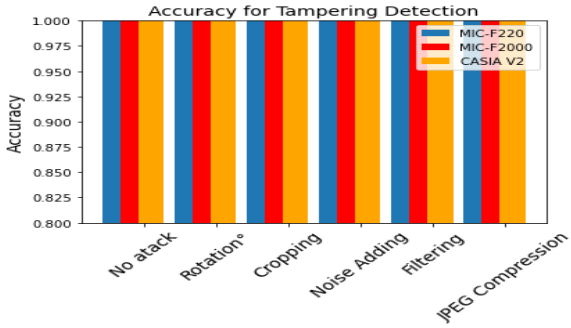


Fig. 7. Accuracy for watermark tampering with geometric distortions and image processing distortions.

Fig. 7 to Fig. 10 provide a detailed evaluation of the proposed method's effectiveness in detecting image manipulations. The results show high efficiency in detecting tampered areas, even when the watermark has been distorted. However, some loss of features is observed in the halftone image recovery when image processing distortions are applied to the watermark, which introduces errors in the recovery process. This error can impact the accuracy of tamper detection. Despite these challenges, the method identifies manipulations efficiently. High accuracy ensures that most manipulations are correctly identified, while precision and recall measure the method's ability to distinguish tampered areas from untampered ones. The F1 score, a balance between precision and recall, ensures a high performance even when the image is distorted.

C. Ownership Authentication Performance Comparison

In this section, the effectiveness of the proposed image ownership authentication algorithm is compared to existing methodologies. This comparison highlights the proposed method's robustness against different image distortions relative to existing solutions in terms of accuracy, robustness, and efficiency.

Table VIII compares the proposed method with other existing techniques. One of the main advantages of the proposed method is block segmentation and the neural network model feature extraction for each region of the image. This processing provides the neural network with recognition of specific patterns related to each block, which generates a robust feature matrix. This methodology allows for specific feature analysis to improve the algorithm's capacity in image authentication. The comparison depicted that the method is more robust against most distortions; however, image recovery can generate errors in the case of filtration distortions. The results from the zero-watermarking comparison show that the proposed method outperforms existing approaches. This method uses LL coefficients from the DWT to train a Siamese network, generating a robust feature matrix. This generates higher accuracy in the recovery halftone stage. The results from Table VIII indicate that the proposed method is highly resistant to image quality loss, crucial for scenarios involving image storage or transmission. Also, the present technique shows robustness to rotations, scaling, and translations, while other methods obtain a BER of 0.02 for rotations of only 10°.

D. Image Forgery Detection Comparison

Table IX presents a comparison between the proposed method and other techniques developed for tamper detection. The results demonstrate the effectiveness of the proposed method in detecting and localizing image tampering across image databases. Furthermore, the results show that the proposed method achieves higher efficiency than other approaches, effectively identifying whether an image has been manipulated and accurately pinpointing the manipulated areas.

V. CONCLUSION

The method proposed in this paper provides a robust solution for owner authentication and image manipulation detection. The use of halftone images for image authentication based on the Siamese neural network features implemented in the zero-watermarking technique increased the efficiency of the watermark recovery from the master share. Furthermore, this technique provides an additional security stage by encrypting the image in the master share. In addition, the results show robustness in the image halftone recovery process when the watermark is distorted with geometric and image processing attacks. This is reflected in a low error and high similarity between the recovered and original halftone images. The coefficients belonging to the LL sub-band of the DWT and their segmentation into blocks allow the neural network to recognize unique patterns from each image region even though the watermark is distorted. On the other hand, the architecture of two branches from the Siamese neural network detects unique and invariant characteristics related to the watermark.

However, the generated error in the image recovery process increases when image processing distortions are applied to the watermark because some image features are deleted; despite this, a low error can be observed in the halftone image recovery. Furthermore, the recovered halftone image process enhances the effectiveness of the proposed image tampering detection method. The retrieved halftone image with minimal error serves as a reference for detecting discrepancies between the original and potentially manipulated images. The comparison with existing methods highlights the efficiency of forgery detection. The proposed methodology's main contribution focuses on its double function since it performs image owner authentication without distorting the image and effectively detects image tampering. In addition, the retrieved image analysis from the owner authentication process allows the detection and localization of image tampering.

***Abstract*—The World Health Organization indicates that unhealthy diets cause approximately 11 million deaths annually worldwide. In Peru, 57.9% of the population consumes highly processed foods daily. The objective of this study is to analyze the relationship between knowledge about healthy eating and eating behavior among gym users in a district of Lima, Peru. Using an exploratory and quantitative design, information was collected from 156 users through a hybrid questionnaire, analyzed with SPSS and multinomial logistic regression techniques. The results reveal that 57.42% of the participants have an intermediate knowledge of healthy eating, while only 17.42% reach a high level. Likewise, 49.03% exhibit an intermediate eating behavior. In addition, sociodemographic factors, such as the duration of gym attendance and maintenance of a specific diet, were found to influence eating behavior. It is concluded that there is a significant relationship between the level of knowledge and eating behavior, underlining the importance of nutrition education to improve eating habits in this population.**

***Keywords*—Knowledge; healthy eating; gym; eating behavior**

I. INTRODUCTION

The World Health Organization (WHO) points out that, in the world, the maintenance of unhealthy diets causes about 11 million deaths each year [1] and eight million deaths are registered as a result of an unhealthy diet [2]. In addition, it is identified that more than 40% of the world's population has inadequate knowledge about healthy eating [3]. In countries such as the United States, Saudi Arabia and Spain, 87.72% of people do not practice healthy eating habits, a situation that represents a global problem [4].

In South America, Peru is the most food-insecure country with 16.6 million people exposed [5]. The National Institute of Health (INS) warns that 57.9% of Peruvians consume foods with a high degree of processing and added chemicals on a daily basis [6]. In this context, food consumption is influenced by society and by the lack of knowledge of food practices. In Huancayo, only 17.4% of gym users know how to interpret food nutrition labels [7].

During the last few years, people have developed a need to balance physical and psychological health, evidence of this is the insertion in sports activities [8]. In Peru, an average of 5.2 hours of exercise per week is practiced and 28% of these activities correspond to gyms [9]. However, there are barriers that prevent sports practice such as lack of time in almost half of the population [10]. On the other hand, 44% of Lima residents do physical activity frequently [11].

Healthy eating is based on the consumption of healthy, adequate and pleasant foods, to meet nutritional needs and preserve health [12]. In addition, it involves knowing the composition of food and executing practices that ensure adequate nutrition [13]. In Lima, inconsistencies have been detected in the perception of healthy eating, 1 in 2 residents believe that it is based on consuming vegetables and 39% consider that it is avoiding the consumption of harmful foods [11].

There are several reasons that prevent the implementation of healthy eating, in gym users there is a lack of knowledge to analyze the products before consuming them, 27.5% of them frequently read the nutritional information and focus mainly on the level of fat and proteins, this is how less interest is given to the nutrients of the food [7]. In Peruvian society, 1 in 2 people lives at food risk, detecting poverty as a mitigating factor represented with an impact of 25.9% at the national level [5].

Inequalities in the knowledge and practice of healthy eating behaviors represent a latent risk, which shows that in Peruvian households 33% of food expenditures are made outside the home and on unhealthy foods [14]. A much bigger problem is the development of eating disorders, which is frequently identified in people who exercise with the goal of losing weight [15]. In addition, poor diet favors the development of non-communicable diseases such as diabetes and the susceptibility of acquiring a communicable disease due to the weakening of the immune system [16].

Therefore, the main objective of this study is to analyze the influence of the level of knowledge about healthy eating on eating behavior, through the collection of information from gym users in a district of Lima, to contribute to the preservation of their health. In this way, it is particularly intended to determine the level of knowledge about healthy eating and eating behaviors through a hybrid questionnaire that integrates the Healthy Eating Knowledge Test and the Eating Behavior

Questionnaire, to then correlate the level of knowledge and healthy eating behaviors through a comparative analysis. In addition, it seeks to provide information to promote knowledge and improve behaviors in gym users.

This study is organized into sections that facilitate information management. First, a literature review is conducted, describing previous works of similar scope to contextualize the topic in Section II. Then, the description and formulation of the problem are presented, highlighting its relevance in Section III. Next, the materials and methods are presented, detailing the resources and procedures used in Section IV. Section V highlights the key findings for the subsequent stages. In the discussion, the results are interpreted and compared with previous studies, allowing for the identification of relevant similarities or differences in Section VI. Finally, Section VII offers a reflection on the entire study.

II. Literature Review

In the study by Başpinar et al. [17], the influence of nutritional knowledge and practices on the quality of nutrition in people who maintain regular physical activity was addressed in order to determine the association between diet quality, nutritional knowledge and eating practices. The research was quantitative because they applied the Healthy Eating Index-2015 questionnaire and qualitative because they added interviews with 200 users of regular gyms. The results obtained show that 47.0 % of the sample had poor nutritional knowledge and 48.0 % inadequate nutritional practices; In addition, nutritional knowledge is not related to diet quality or food consumption in general ($p<0.05$).

The literature review conducted by Maza et al. [4] on eating habits in university students using the Systematic Review of the Literature and following the PRISMA standards (Preferred Reporting Elements for Systematic Reviews and Meta-Analyses), was composed of 57 articles. A prevalence of inappropriate dietary practices was found and they are characterized by incorrect information management; they are reflected in the consumption of unhealthy foods, easily available and with a minimum amount of nutritional use. Likewise, unhealthy behaviors were detected in the diet of young people; with this comes the risk of suffering health problems in the short term such as being overweight or underweight, and in the long term much greater complications such as cardiovascular diseases and diabetes.

During Reyes and Oyola's research [18], the level of knowledge about healthy eating was determined in university students of various professional careers, through a questionnaire developed with the Kuder-Richardson reliability measure and applied to 136 people. With the results, it was stated that 41.2% of university students have an average food knowledge and students of health careers stand out with a higher level. Therefore, the advantage of knowing more widely how to guide eating behaviors suggests greater efficiency in preserving their health. In this sense, it is pointed out that health promotion activities should focus on providing strategies to positively influence university students.

The study by Damián et al. [7] on the knowledge of gym users in the management of nutritional labels aimed to demonstrate that using and interpreting food labels influences nutrition. The instrument used was a test composed of the variables reading, use and interpretation; which was aimed at 385 users. The information obtained shows that the participants had an average age of 27.8 ± 9.3 years, 44.7% were men and that only 17.4% correctly handle the nutritional information on the labels, so it is important to promote education in this population.

With Wanden's research [19] on the role of diet in the proper functioning of the body and the response to diseases, a study on nutrition was undertaken, prioritizing older people because they are susceptible to instability between the consumption and energy expenditure of nutrients. The proposed approach was nutritional screening, which was based on the identification of people at risk of malnutrition with the aim of applying a nutritional assessment to this group in which potentially harmful alterations are identified early. Among the most important indicators were weight, height and functional assessment; these in turn made it possible to recognize vulnerable people who received timely treatment.

In the project of Fuentes et al. [20] the objective was to demonstrate that there are dietary factors that participate in the growth and development of sports gymnasts, so a case study was carried out in phases in an adolescent athlete with signs of inadequate nutrition and stunted growth. First, they were provided with education, then balanced foods were inserted into their diet, preventive macro and micronutrients were included, and finally the amount of nutritional supplements was adjusted according to the evolution of their needs. The results collected indicated that the adolescent presented improvements in his growth, development and physical performance. Stress and excessive sports demands were identified as the main causes of eating problems, alterations in body image and different health problems.

Researchers Marquez et al. [21] specified in a study on eating behavior in university students that this group is more likely to develop alterations due to the lack of information and willingness to preserve their health. To measure eating behaviors, they designed a questionnaire composed of 31 questions, which after being validated was applied to 333 students. The results indicated that most students have a medium tendency to have healthy eating habits and evaluating eating behavior made it possible to plan interventions. The designed instrument demonstrated high effectiveness and validity to be applied in studies that aim to analyze eating behavior.

III. Description and Formulation of the Problem

Healthy eating and its adherence to daily life represents a public health problem. Eating behaviors directly influence the state of health of the human being, it has been shown that healthy eating is beneficial in the medium and long term because it improves the state of health and prevents some diseases [2]. Food goes through a series of stages before reaching our tables in conventional presentation, the selection of quality foods for nutrition intervenes in the preservation of health [22]. However, despite the fact that proper nutrition is a

right and a basic need, unhealthy eating is prevalent in modern society [23].

Knowledge about healthy eating is of fundamental importance, especially for the population that maintains a healthy lifestyle. In this sense, people who attend gyms constitute a key group as they are influenced by the competitiveness of their discipline and different dietary factors [7]. It is identified that among the main motivations of gym users to go to fitness centers are the maintenance of health, body image and competition [24]. On the other hand, eating disorders are even more prevalent in people who practice endurance sports [25].

The relevance of our study in gym users is established because they are an underserved group and will be theoretically provided by determining the relationship between the level of knowledge and healthy eating. In addition, at the methodological level, the validation of the integrated instrument and the development of a plan structured by stages that facilitate the process will be contemplated. Likewise, in practice, relevant information will be collected to process it and transform it into percentages that indicate trends in relation to the indicators. In the social sphere, the availability of information will be facilitated to promote knowledge, reduce risk behaviours and contribute to the 2030 Agenda with specific support for the Sustainable Development Goal "Good health and well-being" [26].

IV. Materials and Methods

The materials and methods should be described in sufficient detail to allow the reader to understand the methodological process that has been followed. To this end, the following subsections must be completed:

A. Design and Approach

The study will have an exploratory design because the objective is focused on evaluating a problem that has been little studied in the population made up of gym users and will bring us closer to obtaining new knowledge [27]. In addition, it will have a quantitative approach that will allow the controlled measurement of data for the processing and generalization of trends [28].

B. Population, Sample and Sampling

Due to the massive increase in gyms and fitness centers in Lima, the district of Comas is selected to make use of the services of Gymfinder Group and the presence of approximately 32 gyms in the district is determined [29]. Then, from the Stylos Fitnes and Urban Gym centers, it is estimated that, per gym, there are approximately 80 people enrolled. This amount is multiplied by the number of gyms in the district and the result obtained is a population of 2560 users.

1) Sample size: The determination of the sample was processed by means of the statistical program "EPIDAT 4.2" in which a population of 2560 users was included, with an expected proportion of 87.72% [4], a confidence level of 95% and a design effect of 1; resulting in a sample of 156 users.

[1] Tamaño de muestra. Proporción:

Datos:

Tamaño de la población:	2,560
Proporción esperada:	87,720%
Nivel de confianza:	95,0%
Efecto de diseño:	1,0

Resultados:

Precisión (%)	Tamaño de la muestra
5,000	156
10,000	41

Fig. 1. Epidat 4.2 sample calculation.

Fig. 1 shows the result of the sample based on the process carried out by the statistical program Epidat 4.2 and the result obtained is 156 users.

2) Sample selection: A simple random sampling was carried out, including criteria such as the location of the establishments, ease of access and availability for intervention.

3) Inclusion criteria:

- Users of gyms in the district of Comas.
- Users enrolled in a gym in the district of Comas.
- Users over 18 years of age.
- Users of both sexes.
- Users who accept informed consent

4) Exclusion criteria:

- Users of gyms in districts not located in Comas.
- People who are not registered in a gym in the district of Comas.
- Users under 18 years of age.
- Users who do not accept informed consent.

C. Study Variables

The variables considered in the research are chosen because they are related to each other for the comprehensive assessment of the participants and make it possible to identify trends regarding possible alterations.

1) Knowledge about healthy eating:

a) Conceptual definition: Knowledge about healthy eating is the amount of information that each person has to justify their dietary behaviors and is of vital importance for the preservation of health. Its availability determines the behaviors that are developed in the diet, established foods, etc. [18].

b) Operational definition: Knowledge about healthy eating is the information that is acquired in society, its development and organization influences the eating habits of

gym users in Lima. In this way, knowledge about healthy eating intervenes in the preservation of health.

2) Eating behavior:

a) Conceptual definition: Eating behavior is the relationship that is established between human beings and food, it is a set of actions that influence daily food. It is directly involved in food consumption, nutrient absorption and health status [21].

b) Operational definition: Eating behavior is the way in which eating behaviors are oriented in daily life, it is defined by eating habits, handling, selection and consumption of food. Its alteration determines the nutritional condition and health status of gym users in Lima.

D. Measuring Technique and Instrument

1) Data collection technique: The data collection process was carried out through the application of an integrated questionnaire with sections extracted from two validated tools, each of them focused on the individual study variables, so its constitution is of great relevance.

a) For the variable knowledge about healthy eating: The questionnaire called "Knowledge test on healthy eating" was selected, which is used to measure the level of knowledge and was developed by Reyes and Oyola [18] following the parameters established by the WHO and other authors. It is made up of 2 dimensions, the first collects general data on age and sex and the second corresponds to knowledge about healthy eating with 16 questions. For the evaluation, a value of 2 is scored for the correct answers and a total classification of: <17 "low", 17-25 "medium" and > 25 "high".

- *Validity and reliability:* The reliability of the instrument was determined based on the Kuder Richardson coefficient with a reliability value of 80.7% classified as acceptable and its validation is proven in the Peruvian population.

b) For the variable eating behavior: The "Eating Behavior Questionnaire" was chosen, consisting of 31 questions distributed in eight dimensions and was designed by Márquez et al. [21]. The dimensions that compose it are meal times, food and beverage consumption preferences, way of preparing food, reading nutritional labels, consumption of food outside the home, satiety, following therapeutic or special diets, and perception of healthy eating, barriers to change and beliefs, each item is evaluated from 1 to 5 according to the Likert scale.

- *Validity and reliability:* The level of reliability was calculated according to the evaluation of 15 health experts in the clinical and research area. The validity of the tool was established abroad, due to which its reproducibility in our country and in the target population was validated by trained professionals from the local environment.

2) Hybrid sizing: Based on the aforementioned tools and the dimensions that correspond to each of them, in order to satisfy all the objectives set and optimize the collection of information, a hybrid dimensioning was carried out by summarizing the aspects that most cohesive the information obtained during the collection of relevant data for our study. Therefore, it was decided to use the Healthy Eating Knowledge Test because it is the one that offers a greater approximation to the main variable of the study, excluding questions 10 and 16 from the instrument because they have shown ambiguity in the results of their respective study. In addition, the first section of the Eating Behavior Questionnaire is taken exclusively composed of 8 items, as it is the one that offers the greatest opportunity to collect data that complement the defined objectives, excluding questions 5 and 7. Finally, after a detailed analysis of the effectiveness of the indicators of each of the instruments in their respective backgrounds, a total of 20 items are established for the instrument of this study. For the evaluation of this new instrument, a score of 1 for each of the correct answers and a total classification of: <11 "low", 11-15 "medium" and > 16 "high" are considered.

TABLE I. HYBRID INSTRUMENT SIZING

Healthy eating knowledge test	Knowledge about healthy eating	14 items
Eating Behavior Questionnaire	Eating behaviors	6 items

Table I shows the hybrid instrument designed to efficiently integrate the practical dimensions of each of the tools studied, this construction was evaluated by five national experts in health and scientific research, an evaluation with which a final Anyken V of 0.93 was obtained, which qualifies the integrated tool as valid for its application. On the other hand, to determine the reliability of the instrument, a pilot test was carried out with 20 users; then, the information obtained was processed using the Kuder Richardson coefficient – KR20 as it is the ideal one to analyze dichotomous variables, with which a total value of 0.86 was found, cataloguing the instrument as good in terms of reliability.

E. Procedure for Data Collection

1) Bio-ethical aspects: This project prioritizes respect for the bioethical principles of autonomy, beneficence, non-maleficence and justice; They contain aspects that ensure the protection of the participant [30]. Prior to the execution of the visualized fieldwork, the approval of the ethics committee is required, so the product was directed to the responsible committee for evaluation by experts in the field of research and approval was obtained for the application of the study in the selected field.

- *Autonomy:* By distributing informed consent as the first step of intervention so that users can freely choose to participate in the study.
- *Beneficence:* It will be used to provide information that contributes to the strengthening of knowledge about healthy eating in gym users.
- *Non-maleficence:* By establishing a bond with each person to facilitate explanation and understanding

regarding the absence of questions of a personal nature that may transgress the individuality of the participants.

- *Justice:* Evidenced by the egalitarian approach of all members without differences of any kind.

2) Informed consent: Informed consent represents research ethics, ensuring respect for the principle of autonomy of all those who, by their own decision, decide to participate in the study. With this document, participants will have the assurance that their rights and privacy will not be violated and will be used for strictly academic purposes. During the fieldwork, it will be provided physically before starting with the application of the designed instrument.

3) Instrument application: During the first two weeks of May 2024, the entry to the physical conditioning establishments that belong to the district of Comas was coordinated through an official letter addressed to the management demonstrating the approval by the ethics committee and the material to be evaluated according to the inclusion and exclusion criteria. Then, the instrument was applied on the premises allowing the development of the study.

The acquisition of information was directly through a virtual form distributed through a link sent to the telephone application of convenience per user at the time of the intervention. If an electronic device or an appropriate application was not available at the time of the study, participation was carried out from the interviewers' mobile phones.

4) Data analysis: For the storage of the information extracted during the research, the Google Sheets program was used for its easy handling and the organization it has to quantify what was obtained [31]. On the other hand, the data was processed in the SPSS software that specializes in advanced statistical analysis determining the correlation of Spearman's coefficients between the level of knowledge about healthy eating and eating habits [32]. Likewise, to establish the reliability of the instrument, Cronbach's alpha coefficient was calculated based on the questionnaires already validated by this same statistical technique.

F. Data Processing

1) Multinomial logistic regression model: This tool is used to predict the outcome of a variable categorized as dependent with a large number of categories. This model is characterized by reducing the extension limitations found in other tools, since it allows the dependent variable to take two or more categories. Their inclusion in this study is important for the management of categorical variables at multiple levels because it allows us to understand in detail the influence of predictor variables on the probability of belonging by category [33].

V. RESULTS

Table II shows that 62.18% (97) of the participants were between 18 and 27 years old, 19.87% (31) were between 28 and 37 years old, 14.74% (23) were between 38 and 47 years old, and only 0.64% (1) were between 58 years and older. With respect to sex, 53.85% (84) are women and 46.15% (72) are men. Regarding the time spent attending the gym, 26.28% (41) attended 1 month or less ago, 27.56% (43) from 2 to 6 months, 3.21% (5) from 7 to 11 months, 17.95% (28) for 1 year or more and 25% (39) attended non-continuously. Regarding the time elapsed since attending a nutritionist, 20.51% (32) have had guidance 1 month or less ago, 18.59% (29) have had guidance from 2 to 6 months ago, 7.69% (12) from 7 to 11 months, 6.41% (10) have been assisted by a nutritionist 1 year or more ago, and 46.8% (73) have not been assisted by a nutritionist. In relation to the maintenance of a specific diet, 25% (39) have maintained it for 1 month or less, 32.5% (50) for 2 to 6 months, 12.82% (20) for 1 year or more and 30.13% (47) do not maintain a specific diet. The origin of nutritional information in 58.97% (92) is from social networks, 25.64% (40) obtain it from a nutritionist, 8.33% (13) from friends and 7.06% (11) from family members.

TABLE II. SOCIODEMOGRAPHIC DATA OF GYM USERS OF A COMAS GYM

Sociodemographic data	n= 156	
	fi	%
Age		
18 - 27	97	62,18
28 - 37	31	19,87
38 - 47	23	14,74
48 - 57	4	2,57
58 years or older	1	0,64
Sex

University	0	0,0

A. Sample Setting

During the organization of the data, it has been possible to detect that one of the 156 intervened users has provided insufficient information to be analyzed in the study results, a situation for which it has been decided to exclude him from the next stage, therefore, the sample processed later will be made up of a total of 155 participants.

On the other hand, for the analysis of the data by age, the current classification of age groups according to the WHO has been applied, which has allowed the distribution of the sample data in a group composed of young people aged 18 to 26 years and another made up of adults between 27 and 59 years of age [34], [35].

B. Level of Knowledge and Behavior by Gender

TABLE III. LEVEL OF KNOWLEDGE ABOUT HEALTHY EATING BY GENDER

Level of knowledge	Value	Gender		Total
		Female	Male	
Low	n	20	19	39
	%	12,9	12,26	25,16
Intermediate	n	51	38	89
	%	32,9	24,52	57,42
High	n	12	15	27
	%	7,74	9,68	17,42
Total	n	83	72	155
	%	52,55	46,45	100

Table III shows that 12.9% (20) women and 12.26% (19) men have a low level of knowledge about healthy eating, representing 25.16% (39) of the total. The intermediate level of knowledge is present in 32.9% (51) women and 24.52% (38) men, which constitute 57.42% (89) of the total. Finally, 7.74% (12) females and 9.68% (15) males make up the high level of knowledge, an amount that represents 17.42% (27) of the total.

TABLE IV. EATING BEHAVIOR BY GENDER

Eating behavior	Value	Gender		Total
		Female	Male	
Low	n	23	28	51
	%	14,84	18,06	32,9
Intermediate	n	47	29	76
	%	30,32	18,71	49,03
High	n	13	15	28
	%	8,39	9,68	18,06
Total	n	83	72	155
	%	53,55	46,45	100

Table IV presents healthy eating behavior by gender, where low eating behavior is manifested in 14.84% (23) women and 18.06% (28) men, which corresponds to 32.9% (51) of the total. The intermediate behavior is manifested by 30.32% (47) women and 18.71 (29) men, which represents 49.03% (76) of the total. Finally, 8.39% (13) females and 9.68% (15) males make up 18.06% (28) of the total.

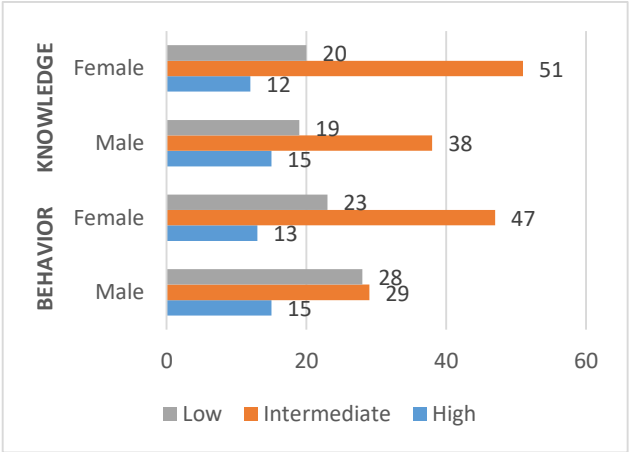

Fig. 2. Relationship between the level of knowledge and behavior according to gender.

Fig. 2 shows that high male eating behavior is present in only 15 users, intermediate in 29 and low in 28. In the female sex, there was a high level of behavior in 13 people, intermediate in 47 and low in 23. Likewise, the male knowledge about healthy eating is made up of 15 users with high knowledge, 38 with an intermediate level and 19 with low knowledge. In the female sex, high knowledge was detected in 12 participants, intermediate knowledge in 51 and a low level in 20. These results demonstrate the predominance of the intermediate level of knowledge and behavior over the low and high.

C. Level of Knowledge and Behavior by Age

TABLE V. LEVEL OF KNOWLEDGE ABOUT HEALTHY EATING BY AGE

Level of knowledge	Value	Age		Total
		Young	Adult	
Low	n	25	14	39
	%	16,13	9,03	25,16
Intermediate	n	59	30	89
	%	38,06	19,35	57,42
High	n	13	14	27
	%	8,39	9,03	17,42
Total	n	97	58	155
	%	62,58	37,42	100

Table V shows that 16.13% (25) young people and 9.03% (14) adults have a low level of knowledge about healthy eating, representing 25.16% (39) of the total. The intermediate level of knowledge is present in 38.06% (59) young people and 19.35% (30) adults, which constitute 57.42% (89) of the total. Finally,

8.39% (13) young people and 9.03% (14) adults make up the high level of knowledge, an amount that represents 17.42% (27) of the total.

TABLE VI. EATING BEHAVIOR BY AGE

Eating behaviour	Value	Age		Total
		Young	Adult	
Low	n	41	10	51
	%	26,45	6,45	32,9
Intermediate	n	35	41	76
	%	22,58	26,45	49,03
High	n	21	7	28
	%	13,55	4,52	18,06
Total	n	97	58	155
	%	62,58	37,42	100

Table VI shows eating behavior by age, where low eating behavior is manifested in 26.45% (41) young people and 6.45% (10) adults, which corresponds to 32.9% (51) of the total. The intermediate behavior is represented by 22.58% (35) young people and 26.45% (41) adults, which makes up 49.03% (76) of the total. Finally, 13.55% (21) young people and 4.52% (7) adults make up 18.06% (28) of the total.

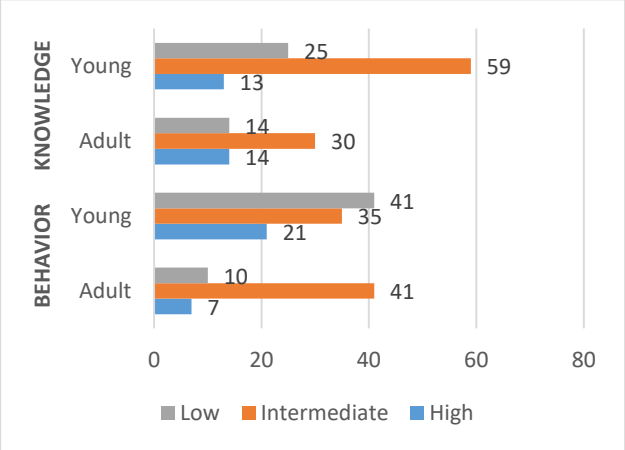

Fig. 3. Relationship between the level of knowledge and behavior according to age.

In Fig. 3 it can be seen that adult eating behavior is high in only seven participants, intermediate in 41 and low in 10. The young population is made up of 21 people with high behavior, 35 with intermediate behavior and 41 with low behavior. In addition, knowledge about healthy eating in adults is represented by 14 users with a high level, intermediate knowledge with 30 and low knowledge with 14. In young people, the level of knowledge is high in 13 people, intermediate in 59 and low in 25. These data affirm the trend of the intermediate level of knowledge and behavior over the low and high.

D. Application of the Multinomial Logistic Regression Model

The model has been applied to analyse the factors that influence eating behaviour, specifically considering the level of knowledge and the most relevant socio-demographic data, the process has been defined using the following formula:

$$C = 0.1891033 + 0.8314438(V1) - 0.0868413(V2) + 0.1306843(V3) - 0.0927213(V4)$$

Where:

C: Eating behavior

V1: Knowledge Level

V2: Time of attendance with a nutritionist

V3: Time in which you maintain a specific diet

V4: Continuous Gym Attendance Time

By means of this calculation, it can be stated that the Multinomial Logistic Regression Model is acceptable, since it has a p value of 0.00 demonstrating its significance and an adjusted Spearman's Rho correlation coefficient level of 0.54.

TABLE VII. PROBABILITY OF CONTRAST OF THE LOGISTIC MODEL FOR BEHAVIOR BASED ON THE LEVEL OF KNOWLEDGE

p value (Sig.)		Eating behaviour	
		Intermediate	High
Level of knowledge	Intermediate	0,99	0,994
	High	0,0	0,996

p value = probability that is used to contrast with the level of significance or alpha value (α=0.05).

Table VII presents the association between the level of knowledge about healthy eating and the eating behavior of the participants. It can be detected that the p value (Sig.) is greater than 0.05 in the variables, except for the relationship between high level of knowledge and intermediate behavior; which statistically shows that the greater the knowledge, the greater the risk of having an intermediate behavior.

TABLE VIII. PROBABILITY OF CONTRAST OF THE LOGISTIC MODEL FOR BEHAVIOR BASED ON SOCIODEMOGRAPHIC DATA

p value (Sig.)		Eating behaviour	
		Intermediate	High
Sociodemographic data	Nutritionist Assistance 1 month or less	0,462	0,328
	Specific diet for 2 to 6 months	0,01	0,994
	Gym attendance 1 month or less ago	0,00	0,00

p value = probability that is used to contrast with the level of significance or alpha value (α=0.05).

Table VIII shows the relationship between the most significant sociodemographic data and the eating behaviour of users. We observed that the p value (Sig.) is less than 0.05 in three of the established associations. First of all, statistics show that maintaining a specific diet for two to six months means a higher risk of having an intermediate behavior. Continuous attendance for 1 month or less is associated with a lower risk of intermediate behavior. Finally, attending the gym for 1 month

or less implies a lower risk of maintaining a high eating behavior.

VI. Discussion

It has been calculated that the level of knowledge about healthy eating is low in 25.16% of gym users in Lima and inappropriate eating behavior is present in 32.9%. However, in Turkey, Başpinar et al. [17] report that 47.0% of their sample had poor nutritional knowledge and 48.0% inadequate nutritional practices. This differentiation could be caused by the geographical location that is so different in both studies and the sociodemographic mitigating factors of each country. In addition, the review by Maza et al. [4] has detected the trend of unhealthy behaviors in young people, in contrast to our study, in which 57.42% tend to present intermediate eating behaviors.

In this research, it is found that 57.42% of gym users have an intermediate knowledge about healthy eating, an amount higher than the 41.2% average knowledge established by Reyes and Oyola [18] in their research on university students. This distinction may be due to the fact that in gyms there are a greater number of people looking for information to maintain a good physical condition, while in universities young people focus more on academic knowledge. In relation to eating behaviour, it has been shown that 49.03% of gym users have an intermediate behaviour, similar to the study by Marquez et al. [21], in which a medium trend is also detected.

In our study, it has been found that 62.58% of the users are between 18 and 26 years old, males make up 46.45% and 17.42% have a high knowledge of healthy eating; data that agree with the research of Damián et al. [7], in which a mean age of 27 years has been obtained, male participants represented 44.7% and only 17.4% correctly handled the information on nutritional labels. This similarity shows that in cities such as Lima and Huancayo (coast-highlands) the young population tends to attend fitness centers, women with a slight frequency and that knowledge about healthy eating is high in only a small percentage of users, which makes them susceptible to inappropriate eating behaviors.

With respect to the Multinomial Logistic Regression Model, it has been possible to identify a p value of 0.00 and an adjusted Spearman's Rho of 0.54, which has shown that eating behavior is influenced by the level of knowledge about healthy eating, the time spent attending a nutritionist, the time spent on a specific diet and the time spent continuously attending the gym. This transcendental finding differs from what was found in similar studies such as [17] in which the relationship between nutritional knowledge and the consumption of foods with a p value less than 0.05 is denied.

On the other hand, during the execution of this study, there have been limitations related to the intervention schedule of the participants, since a low average influx of users available for the intervention was evidenced, which is why the moment of greatest agglomeration for each gym had to be observed for several days. Likewise, some of the users gave up participating due to lack of time, being in the middle of training or other activities of similar scope. Finally, some gyms prevented the interviewer from passing through due to internal policies and other centers had to be resorted to.

VII. Conclusion

In conclusion, the present research determined a p value of 0.00 and an adjusted Spearman's Rho of 0.54 using the Multinomial Logistic Regression Model, which provides sufficient statistical evidence to affirm that there is a direct relationship between the level of knowledge about healthy eating and eating behavior. Specifically, people with high knowledge are more likely to maintain intermediate behavior. Among gym users in Lima, an intermediate level of knowledge and behavior predominates with 57.42% and 49.03% respectively.

In addition, sociodemographic factors have shown an association between the maintenance of a specific diet for 2 to 6 months and intermediate eating behavior. Attending the gym 1 month or less ago indicates a lower risk of maintaining intermediate or high behavior. Finally, it is observed that female users and young people tend to have greater knowledge about healthy eating and better eating behaviors.

It is highlighted that the design of the hybrid questionnaire to measure knowledge about healthy eating and eating behaviors was fundamental to analyze the situation in which gym users in Lima find themselves. The validity and reliability of this instrument have been evaluated by national experts and its usefulness for future studies of similar scope has been demonstrated.

Finally, the information obtained in the present study is available for future research, providing a solid basis for the generation of new knowledge and the validation of results. This information can serve as a reference for comparisons in different regions of the country and the world, allowing the consistency of the findings to be evaluated in different geographical and cultural contexts.

Development of a Causal Model of Post-Millennials' Willingness to Disclose Information to Online Fashion Businesses (Thailand)

Apiwat Krommuang[1], Jinnawat Kasisuwan[2]
KMITL Business School, King Mongkut's Institute of Technology Ladkrabang, Ladkrabang, Thailand[1, 2]

***Abstract*—This research examines the causal factors influencing the willingness of Central Post-Millennials to disclose information to online fashion businesses by using privacy calculus theory as the basic principle for modeling. The study has three primary objectives: (1) to investigate the causal factors influencing willingness to disclose information, (2) to analyze both the direct and indirect effects of perceived risk, perceived benefit, perceived value, perceived control over the use of personalization data, and trust on the willingness to disclose information, and (3) to develop a causal factor model for understanding the determinants of willingness to disclose information among Central Post-Millennials in the context of online fashion businesses. The research sample consists of 385 individuals, and data were collected using a structured questionnaire. Descriptive and inferential statistical methods were employed for data analysis. The relationships between variables were assessed using Pearson's Correlation Coefficient. The model's fit to the empirical data was evaluated using goodness-of-fit measures, and the transmission of influence was tested through structural equation modeling (SEM). The findings reveal that demographic factors do not significantly affect the willingness to disclose information. However, the study identifies perceived risk, perceived benefit, perceived value, perceived control over the use of personalization data, and trust as key determinants of willingness to disclose information to online fashion businesses. Among these, perceived control exhibits the strongest influence, closely followed by trust. These results highlight the antecedent processes influencing the willingness to disclose information, as represented by a model developed from a comprehensive literature review and empirically tested for consistency with the data.**

Keywords*—Online fashion business; Post-Millennials; privacy calculus; willingness; disclose information

I. Introduction

In the contemporary era of rapid technological and digital advancement, consumers have gained unprecedented access to the internet. This proliferation serves as a clear indicator that the Thai populace has embraced and integrated technology into their quotidian existence. Statistical data demonstrates that there was an average annual increase of 3.6 million internet users in Thailand from 2013 to 2021 [1].

Further analysis of internet usage patterns reveals that Generation Y exhibits the highest average daily usage, closely followed by Generation Z, with the latter being the most prolific users overall [1]. The term "Post Millennials" is employed to denote individuals born from 1997 to the present, encompassing both late Generation Y and Generation Z cohorts. This demographic represents one of the largest generational groups entering the labor market to date [2]. Notably, the Post-Millennial cohort demonstrates the highest propensity for online purchasing across all generations. Within this context, the most prevalent product categories acquired through e-commerce channels are apparel, footwear, sporting equipment, and accessories, which consistently rank as the primary items of online consumption.

The expansion of the internet user base presents a significant opportunity for the development of digital enterprises and the establishment of organizations adept at navigating the digital landscape. Consequently, there is an influx of consumer data into the digital realm. From a commercial perspective, data represents a valuable resource and plays a pivotal role in business development across all sectors. Both small and large organizations are currently engaged in the process of leveraging data to create maximal value. Entities that employ the data-driven organization paradigm utilize data as the foundation for their strategic decisions. A survey conducted by PricewaterhouseCoopers [4], encompassing over 1,000 senior executives, revealed that highly data-driven organizations tend to exhibit greater efficacy in decision-making processes and demonstrate threefold superior performance compared to their counterparts who rely less on data [3].

However, as the reliance on consumer data intensifies, concerns about privacy have surged. The unauthorized sharing of sensitive consumer information by businesses and governmental entities worldwide reveals a critical issue regarding personal data security. This encompasses not only data breaches and potential security threats but also a significant erosion of user autonomy over their personal information. [5]

In light of these opportunities and challenges, it has been observed that technological advancements facilitating expedited and convenient access to various services through online channels, in exchange for personal information, are considered the genesis of privacy erosion. This phenomenon aligns with the Privacy Calculus theory, a seminal concept in privacy research, which emphasizes individual decision-making regarding the disclosure of personal information based on a cost-benefit analysis of potential risks and benefits [6].

Consequently, the researcher is compelled to employ the Privacy Calculus theory as a theoretical framework to investigate the factors influencing the willingness to disclose personal information. The Central Post-Millennials cohort, characterized by their substantial online fashion product

purchases, presents an appropriate demographic for this study. The findings of this research will serve as a foundation for strategic planning and adaptation to address evolving consumer needs with greater precision while simultaneously enhancing user confidence in online fashion purchasing systems.

The remainder of this document will delve into the strategies for collecting consumer data effectively, which is critical for transforming the organization into a data-driven enterprise. This discussion aims to offer insights into aligning business goals with consumer behavior in the digital era.

II. Literature Review

A. Privacy Calculus

The concept of Privacy Calculus, originally developed by Laufer and Wolfe [7], has significantly contributed to the understanding of data privacy, user behavior, and decision-making processes within the digital environment. Numerous researchers have utilized this theory to develop models that predict and explain users' privacy-related actions. The theory enhances transparency in consumer data collection practices by offering clear explanations of the benefits consumers will receive. It is evident that the application of the Privacy Calculus concept can be integrated into various research frameworks, leading to numerous studies that utilize this concept to examine privacy in diverse contexts, depending on the specific objectives of those studies. In this research, the Privacy Calculus concept encompasses Perceived Risk, Perceived Benefits, Perceived Value of Information Disclosed, Perceived Control over the Use of Personalization Data, Trust, and Willingness to Disclose Information.

Perceived Risk (PR) relates to the uncertainty stemming from the potential opportunistic behavior of service providers, which may result in consumer losses [8]. From the Privacy Calculus perspective, this encompasses the perception of potential loss from information disclosure [9]. The perception of risk, as understood by consumers, is underpinned by Prospect Theory, developed by [42] which addresses decision-making under risk [10]. This theory posits that decisions often prioritize the avoidance of losses over the pursuit of gains. Accordingly, this research employs the variable of risk perception to measure the extent of consumer concern regarding the security of personal information.

Previous studies, such as [11] have demonstrated that risk perception negatively impacts the willingness to disclose health information among patients in China, consistent with other studies including [12] who examined the specific risks and benefits influencing consumer acceptance of mobile location-based advertising (MLBA); [13] who explored the interdependence of personality contingency calculus and causal asymmetry in social networking site (SNS) information disclosure behavior; [14] who analyzed cloud storage users' intentions to include personal information in cloud storage applications in Indonesia and Taiwan; [15] who investigated the privacy paradox related to information disclosure in mHealth applications; and [16] who studied the effect of trust on students' willingness to use online learning platforms.

Hypothesis 2. Perceived Risk negatively influences the willingness of Central Post-Millennials to disclose information to online fashion businesses.

Moreover, [17] explored the key determinants of experts' attitudes and intentions to use VC apps among 484 surveyed experts. Their study found that perceived risk influenced the perceived value of information disclosure, consistent with other studies such as [18] who examined factors affecting personal data disclosure among mobile application users in Bangkok; [19] who explored the relationship between benefits, trust, and honesty in personal data disclosure within mobile banking services in Vietnam; and [20] who studied the key determinants of contact tracing app adoption in Australia.

Hypothesis 3. Perceived Risk negatively influences the Perceived Value of Information Disclosed by Central Post-Millennials to online fashion businesses.

Perceived Benefits (PB) refer to the perceived advantages obtained from disclosing information to access a service. This concept involves balancing the need for privacy with the need for disclosure to attain certain benefits [21]. Perceived benefits can be categorized into monetary and social rewards [22] and other factors such as performance expectations [20]; personal interests [14]; and extrinsic rewards [23]. Expectancy-Value Theory, developed by Atkinson [24], supports the perception of potential benefits by evaluating decision-making processes based on expected outcomes and the satisfaction derived from them. From the Privacy Calculus perspective, this theory suggests that the satisfaction from potential outcomes of information disclosure influences individuals' expectations and decisions, leading to a higher likelihood of information disclosure if the perceived benefits outweigh the risks. This research, therefore, employs the perceived benefits variable to measure the extent to which consumers perceive the value or benefits of disclosing personal information.

Previous research by [25], which examined the motivating and inhibiting factors affecting customers' willingness to disclose personal data on e-commerce websites in Saudi Arabia, indicated a significant positive relationship between perceived benefits and willingness to disclose personal data. Similar findings were reported by [11] regarding health information disclosure in China; [26] on the rational and irrational factors influencing data disclosure decisions; [23] on the motivation behind Internet users' willingness to provide personal data; and [12] on the acceptance of MLBA. Additionally, studies by [13, 14, 15, 16] have provided consistent findings with those of [25].

Hypothesis 4. Perceived Benefits positively influence the willingness of Central Post-Millennials to disclose information to online fashion businesses.

Numerous studies have supported the relationship between perceived benefits and the value perspective of information disclosure, alongside perceived risks, as highlighted by [27], who studied factors affecting consent to disclose personal data among commercial bank application users in Bangkok. Research by [18, 19, 20] also confirmed this relationship.

Hypothesis 5. Perceived Benefits positively influence the Perceived Value of Information Disclosed by Central Post-Millennials to online fashion businesses.

Perceived Value of Information Disclosed (PV) refers to the value consumers attribute to the personal information they disclose to service providers, derived from a comparison of the benefits gained against the risks incurred. This assessment can be understood through a Cost-Benefit Analysis framework [6], where the perceived value is determined by evaluating the trade-offs between perceived benefits and risks. The theory of Customer-Perceived Value (CPV) by [28] further elaborates that this value arises from the difference between customers' evaluations of all benefits and the total costs associated with an offer. These benefits and costs include various dimensions, such as financial, time, energy, and psychological aspects.

The relationship between perceived value of information disclosed and the willingness to disclose information has been supported by several studies, including [29] who studied the factors influencing the privacy calculus of wearable fitness devices among Korean undergraduate students and found a significant positive impact of perceived value on information disclosure intentions. Other studies, such as [16, 30, 18, 27] have also confirmed this relationship.

Hypothesis 6. Perceived Value of Information Disclosed positively influences the willingness of Central Post-Millennials to disclose information to online fashion businesses.

Perceived Control over the Use of Personalization Data (PC) refers to an individual's belief in their ability to manage the disclosure and dissemination of their personal data [9]. This perception of control can be supported by Control Balance Theory, developed by [31], which emphasizes the balance of control between individuals and systems in societal contexts. In the context of Privacy Calculus, perceived control pertains to the extent to which individuals believe they can influence how their personal data is used. An imbalance in this control, where users feel they have less power over their data compared to data controllers, can lead to decreased trust and willingness to disclose information.

Past research by [19], which examined personal data disclosure in mobile banking services in Vietnam, supported the positive relationship between perceived data control and the value perspective of data disclosure. Additionally, [32] explored the influence of perceived control on the tension between privacy concerns and data disclosure among Chinese users, finding a significant positive effect on self-disclosure intentions.

Hypothesis 7. Perceived Control over the Use of Personalization Data positively influences the willingness of Central Post-Millennials to disclose information to online fashion businesses.

Hypothesis 8. Perceived Control over the Use of Personalization Data positively influences the Perceived Value of Information Disclosed by Central Post-Millennials to online fashion businesses.

Trust (T) refers to consumers' confidence in the proper management, reliability, and security of their personal information when shared with service providers through websites or the Internet [6]. Trust can be examined through various dimensions, including Interpersonal Trust, System Trust, and Organizational Trust [33]. This research focuses on trust in organizations and systems, commonly utilized within the Privacy Calculus framework [6, 34, 35, 36].

Previous studies, such as [37], which explored customers' willingness to disclose personal information on small B2C e-commerce websites, have found a positive relationship between trust and willingness to disclose information. This finding is consistent with research by [14, 27, 18].

Hypothesis 9. Trust positively influences the willingness of Central Post-Millennials to disclose information to online fashion businesses.

Willingness to Disclose Information (WDI) refers to an individual's acceptance and understanding of the expectations related to personal information disclosure, reflecting a readiness to share information based on situational needs. This concept is often related to the Willingness to Pay theory, where the price a consumer is willing to pay is determined by their assessment of a product or service's value [38]. In the context of privacy, this concept can be interpreted as the risk associated with disclosing information, where consumers evaluate the trade-off between the risks and benefits of sharing personal data. Consequently, this research uses this variable to measure the level of consumer willingness to disclose personal information to online fashion businesses.

B. Model Conceptualization

Path diagrams offer significant advantages in research by clearly illustrating causal relationships between variables and supporting both direct and indirect relationship analysis. They provide structured, easy-to-interpret visual representations, making complex theoretical frameworks more accessible.

The conceptual framework of this research is constructed based on the examination of relevant theories and prior studies. It identifies the causal factors anticipated to influence the perceived value of information disclosure, which include Perceived Risk, Perceived Benefit, and Perceived Control over the Use of Personalization Data [11, 27, 17, 18, 19, 20]. Additionally, the factors expected to influence the willingness to disclose information are Perceived Risk, Perceived Benefit, Perceived Value of Information Disclosed, Perceived Control over the Use of Personalization Data, and Trust [25, 26, 27, 18, 23, 12, 32, 13, 29, 14, 15, 30, 16]. Accordingly, the research conceptual framework is depicted in Fig. 1.

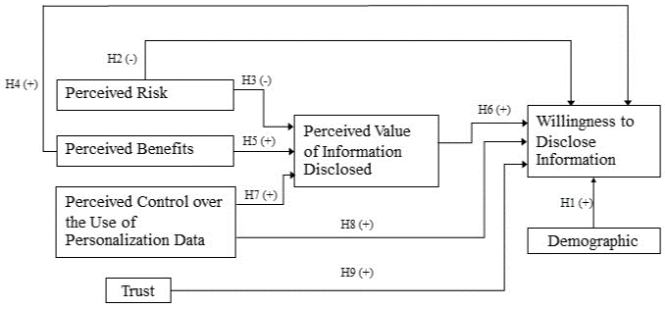

Fig. 1. Research conceptual framework.

III. METHODOLOGY AND RESULTS

The population targeted in this research includes individuals born between 1997 and 2006, aged 18-27 years, residing in

Thailand, and who have disclosed information to a fashion business at least once within the past six months. Given the unknown exact population size, the sample size was determined using Cochran's formula [39] with a 95% confidence level, resulting in a required sample of 385 respondents. The sampling was conducted via purposive and quota sampling methods through online channels, particularly in a large public Facebook group, ensuring the inclusion of users across all purchasing channels. The sample was divided equally among the seven main online fashion shopping platforms: Instagram, TikTok, Shopee, Lazada, Line, SHEIN, and brand websites, with 55 respondents per platform. The data collection tool was a questionnaire, vetted for quality by three experts and tested for reliability. The statistical methods used in this research include frequency, percentage, mean, standard deviation, one-way analysis of variance, Pearson's correlation coefficient, goodness of fit measures, and Structural Equation Modeling (SEM).

A. Results of General Data

The analysis of general demographic data for the 385 respondents revealed that the majority were female, aged between 23-25 years, holding a bachelor's degree or equivalent, predominantly students, with an income range of 20,000 - 39,999 baht. In terms of online fashion purchasing behavior, clothing/apparel emerged as the most frequently purchased product, with an average purchase frequency of 3-5 times per month and an average expenditure of 400-699 baht per purchase.

B. Results of Demographic Factors Hypothesis Testing

Hypothesis testing on the differences in willingness to disclose information to online fashion businesses, based on demographic factors (age, education, occupation, and income), using t-test and one-way ANOVA, indicated no significant differences in willingness to disclose information across these demographic factors (see Table I).

TABLE I. RESULTS OF THE HYPOTHESIS TESTING ON WILLINGNESS TO DISCLOSE INFORMATION CLASSIFIED BY DEMOGRAPHIC CHARACTERISTICS USING T-TEST AND ONE-WAY ANOVA STATISTICS

Demographic	The results of the hypothesis testing
Age	Not significantly
Education	Not significantly
Occupation	Not significantly
Income	Not significantly

C. Results of Correlation Coefficients Between Variables

The study of the relationships between five causal factors: Perceived Risk (PR), Perceived Benefit (PB), Perceived Value of Information Disclosed (PV), Perceived Control over Personal Data Use (PC), and Trust (T) and the willingness to disclose information (WDI) among Central Post-Millennials to online fashion businesses found that all variable pairs were significantly correlated, with correlation coefficients ranging from 0.152 to 0.527. These values meet the criterion of not exceeding a correlation coefficient of 0.85, indicating no multicollinearity issues [40]. Table II shows Pearson's correlation coefficient between variables.

TABLE II. PEARSON'S CORRELATION COEFFICIENT BETWEEN VARIABLES

	PR	PB	PV	PC	T	WDI
PR	1					
PB	-0.209***	1				
PV	-0.285***	0.525***	1			
PC	-0.448***	0.203***	0.152 **	1		
T	-0.281***	0.358***	0.160 **	0.185 ***	1	
WDI	-0.527***	0.426***	0.351 ***	0.518 ***	0.484 ***	1

Note : * Statistical significance level is 0.05
** Statistical significance level is 0.01
*** Statistical significance level is 0.001

D. Results of Goodness of Fit Assessments for the Model

The initial analysis of the model's consistency, as shown in Fig. 2, with the empirical data indicated that it met all criteria, as presented in Table III. However, the relationship between Perceived Control Over Personal Data Use (PC) and Perceived Value of Information Disclosed (PV) was statistically insignificant. This may be attributed to the absence of a genuine linear relationship between the two variables.

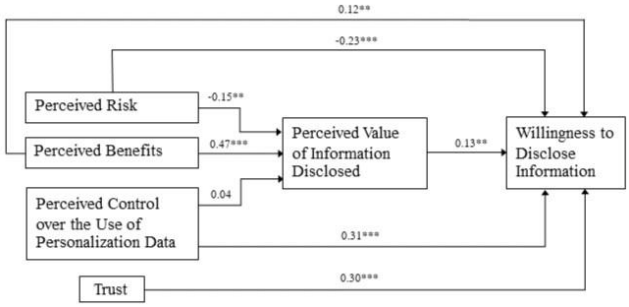

Fig. 2. Initial model.

Therefore, the model was adjusted by removing this relationship as shown in Fig. 3. The revised model continued to meet all criteria, confirming its consistency with the empirical data, with no statistically insignificant relationships remaining.

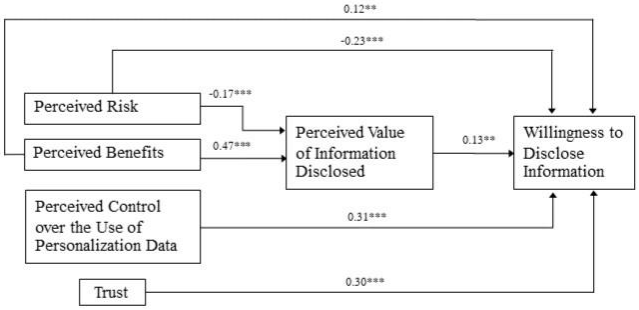

Fig. 3. Adjusted model.

TABLE IV. RESULTS OF THE MODEL'S FIT TO THE EMPIRICAL DATA WAS EVALUATED USING GOODNESS-OF-FIT MEASURES

Goodness of fit measures	Criteria	Initial model m	Adjusted model
P-value of Chi-square Statistics (χ^2)	>0.05	0.14	0.26
Chi-square/Degree of freedom (χ^2/df)	<3.00	2.17	1.35
Comparative Fit Index (CFI)	>0.95	0.9981	0.9988
Goodness of Fit Index (GFI)	>0.95	0.9981	0.9977
Normed Fit Index (NFI)	>0.95	0.9965	0.9956
Root Mean Squared Residuals (RMR)	<0.05	0.0051	0.0054

E. Hypothesis Testing of Relationship Path

The hypothesis testing using SEM to assess the causal factors affecting the willingness to disclose information to online fashion businesses produced the results summarized in Table IV. The findings indicate that hypotheses H2, H3, H5, H8, and H9 were accepted with a significance level of 0.001, and hypotheses H4 and H6 were accepted with a significance level of 0.01. However, Hypothesis H7 was rejected, as depicted in Fig. 2.

TABLE V. RESULTS OF HYPOTHESIS TESTING AMONG RELATIONSHIP PATH OF CAUSAL VARIABLES

Hypothesis	Relationship Path	Intensity	Result
H2	PR → WDI	-0.23***	Accept
H3	PR → PV	-0.17***	Accept
H4	PB → WDI	0.12**	Accept
H5	PB → PV	0.47***	Accept
H6	PV → WDI	0.13**	Accept
H7	PC → PV	-	Reject
H8	PC → WDI	0.31***	Accept
H9	T → WDI	0.30***	Accept

Note : * Statistical significance level is 0.05
** Statistical significance level is 0.01
*** Statistical significance level is 0.001

F. Results of the Intensity between the Causal Relationship

The analysis revealed that Perceived Risk and Perceived Benefits have direct influences on the Perceived Value of Information Disclosed, with path coefficients of -0.17 and 0.47, respectively. Additionally, Perceived Risk, Perceived Benefits, Perceived Control over Personal Data Use, Trust, and Perceived Value of Information Disclosed directly influence the willingness to disclose information, with path coefficients of -0.23, 0.12, 0.31, 0.30, and 0.13, respectively. Perceived Risk and Perceived Benefits also have indirect influences on the willingness to disclose information through the Perceived Value of Information Disclosed, with coefficients of -0.02 and 0.03, respectively.

The total effects of the causal factors Perceived Risk, Perceived Benefits, Perceived Value of Information Disclosed, Perceived Control over Personal Data Use, and Trust on the willingness to disclose information to online fashion businesses were found to be -0.25, 0.18, 0.13, 0.31, and 0.30, respectively.

The model's squared multiple correlation (R^2) indicates that the variables can explain 30% of the variance in the Perceived Value of Information Disclosed and 53% of the variance in the willingness to disclose information. Table V shows results of the analysis of DE, IE, TE between variables.

TABLE VI. RESULTS OF THE ANALYSIS OF DIRECT INFLUENCE (DE), INDIRECT INFLUENCE (IE), TOTAL INFLUENCE (TE) BETWEEN VARIABLES AND THE SQUARED MULTIPLE CORRELATION COEFFICIENT (R-SQUARE : R^2)

	PV			WDI		
	DE	**IE**	**TE**	**DE**	**IE**	**TE**
PR	-0.17***	-	-0.17***	-0.23***	-0.02**	-0.25***
PB	0.47***	-	0.47***	0.12**	0.03**	0.18***
PC	-	-	-	0.31***	-	0.31***
T	-	-	-	0.30***	-	0.30***
PV	-	-	-	0.13**	-	0.13**
R^2	0.30			0.53		

IV. DISCUSSIONS

A. Discussion of Findings

The findings reveal that respondents with different demographic characteristics did not show significant differences in their willingness to disclose information to online fashion businesses (rejecting H1). This outcome may be attributed to the pervasive involvement of consumers in the online world and social media in the current era. Given that internet usage and awareness of information security have become integral aspects of post-millennial consumers' daily lives, their level of privacy awareness is relatively uniform. Additionally, the widespread education and dissemination of knowledge regarding risks and personal data protection have contributed to this trend. This aligns with the findings of [41], which indicated that control variables (e.g., age, income, education, gender, fear, privacy violation) did not significantly affect respondents' intention to disclose information to websites. This suggests that the intention to disclose information is more effectively explained by the independent variables in the research model rather than by demographic differences among respondents.

The causal factor of Perceived Risk influences the willingness of Central Post-Millennials to disclose information to online fashion businesses, primarily due to uncertainties and concerns about potential impacts. Uncertainty regarding data security arises from the perception that providing information online may lead to unexpected problems, as well as fears of unauthorized data use. Users who believe their information may be misused without permission often feel insecure and worried. The risk of third-party access to their information also contributes to discomfort. When users are aware of these risks, they are more likely to withhold information or take additional protective measures, prioritizing privacy protection. This perceived risk exerts a negative direct influence on willingness to disclose information (-0.23, accepting H2) and an indirect influence through the perceived value perspective of disclosure (-0.02). This indicates that concerns about risk lead consumers

to be more cautious and less inclined to disclose information. When consumers perceive higher risks, their willingness to disclose information decreases, which is consistent with [14], who found that cloud storage users' willingness to disclose personal information is significantly influenced by perceived costs. Similarly, [20] demonstrated that privacy risk perception significantly influences contact tracing app usage intentions through the mediating effect of information disclosure value.

The causal factor of perceived benefits also affects the willingness of Central Post-Millennials to disclose information to online fashion businesses. Benefits such as discounts attract and motivate users to share personal information. Additionally, users satisfied with service providers' reuse of their personal data to offer personalized services are more inclined to disclose information, viewing personalized services as valuable benefits. Central Post-Millennials, a significant group in the online fashion market, are driven by their pursuit of distinctive experiences and personalized shopping. This factor has a direct positive influence on willingness to disclose information (0.12, accepting H4) and an indirect influence through the perceived value perspective of disclosure (0.03). Although the positive influence is not as substantial as other factors, it demonstrates that consumers value the benefits of disclosing information, motivating them to share more willingly. This finding is consistent with [20] who found that performance expectation benefits significantly influence contact tracing app usage intentions through the perceived value of disclosure. The study in [32] also confirmed that perceived benefits significantly affect self-disclosure intentions.

The perceived value of disclosure significantly influences the willingness of Central Post-Millennials to disclose information to online fashion businesses. Consumers often compare risks and benefits, and when they perceive that the risks are acceptable relative to the benefits, they are more inclined to disclose information. Users who view the benefits as outweighing the risks feel that disclosing information is a valuable and rational decision. When users believe that disclosing information is worthwhile, they exhibit a greater willingness to share personal information. This perception of value promotes a positive attitude toward information disclosure, even when some risks are present. It shows that users evaluate the value and benefits carefully and make rational decisions, resulting in a direct positive influence on willingness to disclose information (0.13, accepting H6) with no indirect influence. This factor has the least overall influence on willingness to disclose information among all factors, indicating that while consumers make rational comparisons, the perceived value is not as impactful as other factors. This is consistent with the findings of [18], who observed that the perceived value of disclosing information significantly affects the willingness to disclose information.

The perceived control over personal data use is another significant factor affecting the willingness of Central Post-Millennials to disclose information to online fashion businesses. Users who feel they have control over their personal data are more confident and comfortable sharing it. The ability to decide on their data makes users feel secure and empowered to protect their data. Additionally, users who understand the policies and methods of data usage are more confident in a transparent system. Providing clear information about personal data use fosters a sense of involvement in decision-making, increasing the likelihood of information disclosure. When users perceive that their privacy is respected and their rights are protected, they feel more empowered to share their data. This factor has a direct positive influence on willingness to disclose information (0.31, accepting H7) and no indirect influence, making it the most influential factor in promoting willingness to disclose information, even without an indirect effect. This is consistent with [32] who found that perceived controllability significantly impacts self-disclosure intentions.

Trust is another crucial factor influencing the willingness of Central Post-Millennials to disclose information to global fashion businesses. Users who feel confident in a brand's or seller's ability to safeguard their information are more willing to disclose it, believing their personal information will not be misused. Trust in the platform's policies and protective measures enhances confidence in sharing information. Clear policies and strict protection measures help build trust and encourage more information disclosure. Positive online shopping experiences also contribute to increased willingness to disclose information, as users perceive that sharing data is safe and properly protected. Trust fosters a positive relationship between users and platforms, further increasing the willingness to disclose information. Trust has a direct positive effect on willingness to disclose information (0.30, accepting H9) and no indirect effect. This influence is comparable to perceived control, which is the most significant factor affecting willingness to disclose information. Trust has the second-highest positive impact on willingness to disclose information, following perceived control. This aligns with the findings of [14], who indicated that cloud storage users' willingness to share personal data is significantly influenced by trust, perceived costs, perceived benefits, and the sensitivity of personal data.

V. CONCLUSION

The development of a causal model to understand the factors influencing the willingness of Central Post-Millennials to disclose information to online fashion businesses involves a comprehensive literature review to identify key determinants. The factors identified as likely to affect the willingness to disclose information include Perceived Risk, Perceived Benefits, Perceived Value of Information Disclosed, Perceived Control over Personal Data Use, and Trust. These factors were then integrated into a path model based on relationships supported by the literature. After conducting statistical tests, the model fit indices indicated that the revised model accurately and reliably explains the relationships between these factors, thereby elucidating the behavior of Central Post-Millennial consumers. The multiple correlation coefficient (R-SQUARE: R^2) for predicting the willingness to disclose personal data was found to be 0.53 or 53%.

Given the intensity of influence, businesses should prioritize strategies that enhance Perceived User Control over Personal Data Use and trust, as these factors exert the strongest influence on the willingness to disclose information. Strategies could focus on creating transparency that simultaneously addresses both factors, reinforcing consumer confidence and control. Furthermore, while the Perceived Value of disclosure reflects

that consumers do consider a risk-benefit comparison, it is perceived as cumbersome, resulting in the lowest influence among the factors affecting willingness to disclose information. However, this process shouldn't be disregarded or underestimated, as it acts as a mediator, indirectly passing the influence of both perceived risks and perceived benefits on the dependent variable.

Emphasizing Perceived User Control over Personal Data Use and Trust can lead policymakers to advocate for regulations requiring businesses to provide clear information on data practices. Strengthening consumer rights to manage personal data, including consent options, aligns with users' desires for control. By prioritizing these elements in legislation, policymakers can enhance consumer confidence and promote responsible data practices, fostering a more secure digital marketplace. Additionally, key insights for marketing strategies. Marketers can enhance transparency about data practices, boosting consumer confidence and encouraging information disclosure. Empowering consumers with data management options fosters stronger relationships and brand loyalty, helping businesses comply with regulations while building trust in a privacy-conscious marketplace.

***Abstract*—Automatic emotion recognition technology through facial expressions has broad potential, ranging from human-computer interaction to stress detection and blood pressure assessment. Facial expressions exhibit patterns and characteristics that can be identified and analyzed by image processing and machine learning methods. These methods provide a basis for the development of emotion recognition systems. This research develops a facial emotion recognition model using Convolutional Neural Network (CNN) architecture, a popular architecture in image classification, segmentation, and object detection. CNNs offer automatic feature extraction and complex pattern recognition advantages on image data. This research uses three types of datasets, FER2013, CK+, and IMED, to optimize the deep learning approach. The developed model achieved an overall accuracy of 71% on the three datasets combined, with an average precision, recall, and F1-Score of 71%. The results show that CNN architecture performed well in facial emotion classification, supporting potential practical applications in various fields.**

***Keywords*—FER; CNN; deep learning; image classification**

I. Introduction

Artificial intelligence and machine learning technologies have created new possibilities in interpreting human emotions through facial expressions. Facial expressions are one of the natural ways humans communicate emotions. Automatic emotion recognition technology, mainly through facial expressions, has broad potential in various applications, ranging from human-computer interaction to stress detection and blood pressure assessment [1]. Facial expressions, as one of the non-verbal communication mediums, exhibit patterns and characteristics that can be identified and analyzed by image processing and machine learning methods. This provides a basis for developing systems to interpret facial expressions to recognize human emotions [2].

Convolutional Neural Network (CNN) is a deep learning network introduced in the 1960s. CNN is also applied in computer vision and is generally used in image classification, segmentation, object detection, and video processing [3]. Supporting the implementation of FER, deep learning-based technology with Convolutional Neural Networks (CNN) architecture was used by previous researchers as a potential solution to overcome problems in face and expression recognition and classification. Convolutional Neural Networks (CNN) are increasingly used in FER because they automatically extract features from images [4].

Facial Emotion Recognition refers to the ability to identify and recognize emotions expressed through the human face, belonging to an important research topic in computer vision and artificial intelligence. Facial emotions play an essential role in human communication, helping to understand the intentions and feelings of others, with two-thirds of human communication conveyed through nonverbal components, of which facial expressions play a major role. FER has two main approaches: the traditional approach and the Convolutional Neural Network (CNN) based approach. The conventional approach involves face component detection, feature extraction, and expression classification. The initial stage of the CNN architecture involves taking an image as input, followed by a convolution process to extract essential features, such as edges, texture, and shape. Afterward, a subsampling or pooling process is applied to reduce the dimensionality of the feature map while retaining important information. After multiple convolution and pooling layers, the feature map is flattened into a one-dimensional vector and connected to the fully connected layer, which finally uses a Softmax function to convert the output score into a probability distribution over the existing classes [5].

Convolutional Neural Networks (CNN) are one of the Deep Learning models that consist of automatic feature extractors and trainable classifiers. CNNs are designed to understand high-dimensional complex data with a specialized architecture that integrates convolution and subsampling layers. Although many CNN architectures have been developed for various tasks, such as object and handwriting recognition, the basic principle of CNN is to achieve the best performance in pattern recognition [6]. CNN also has a large representation capacity, where it learns the best features at each layer of the visual hierarchy. This makes CNN effective in various computer vision problems, such as object and handwriting recognition. One of the main advantages of CNN is its weight-sharing concept, which reduces the number of parameters that need to be trained and improves generalization [7].

This research aims to address the challenges of facial emotion recognition (FER) by optimizing CNN architectures to enhance accuracy and efficiency. The motivation lies in creating a system that can accurately interpret emotions, particularly for real-world applications such as mental health monitoring and interactive AI systems. The proposed method reduces the need for manual feature extraction and offers scalability across diverse datasets, making it applicable in various fields, including stress detection and user experience enhancement. A CNN-based approach is proposed to address the FER problem, with empirical evaluation showing that the performance improves when the outputs of different structured CNNs are combined and averaged, compared to using a single CNN architecture.

This article is written as follows: first, the introduction includes the research background, the research objectives to be addressed, and the general method proposed. Section II contains related works that reference previous studies, their relations, advantages, and limitations, and also theoretical foundation of the methods. Section III is the methodology, followed by the results and discussion in Section IV, which comprehensively presents the research findings and its analysis. Finally, this article gives the conclusion and suggestions for further research in Section V.

II. Related Works

Liu, Zhang, and Pan developed a Facial Emotion Recognition model using Convolutional Neural Networks (CNN) with the FER2013 dataset. The architecture design, layer depth, and number of neurons greatly influence the model's effectiveness. Large-scale CNNs face overfitting challenges and require high computational power. The model consists of three subnets with 8 to 10 layers, including an input layer, and three convolution layers with 3x3 filters at 64, 128, and 256 filters, respectively, followed by a max-pooling layer. Furthermore, there are three fully connected layers with 4096, 4096, and 7 neurons, ending with a SoftmaxLoss layer for classification. The third subnet performed best with 65.03% validation accuracy, especially in the surprise emotion category. However, the accuracy of the training data was not specified, and the model struggled with class imbalance, particularly in recognizing emotions like fear and sadness, where accuracy ranged between 58-60% [8].

This advanced research focuses on identifying human facial expressions in Indonesia using Convolutional Neural Networks (CNN) with the Indonesian Mixed Emotion Dataset (IMED). The IMED dataset consists of RGB images grouped into five categories, with 80% for training and 20% for testing. Data pre-processing includes face area cropping, image conversion to grayscale, and image dimension adjustment to 48x48 pixels. The network architecture consists of four-layer blocks, including a convolutional layer, activation layer (ReLU), normalization layer, pooling layer, and dropout layer. The initial stage uses a 3x3 kernel with 32 filters, resulting in a 48x48x32 feature map batch normalization and ReLU activation. Max-pooling with a 2x2 kernel is applied to reduce the spatial dimension. Subsequent blocks add filters to capture more complex information. In the final stage, the feature map is flattened into a 1D vector and processed through a fully connected layer for classification. This study reached a validation accuracy of 93.63% [9].

Research on the use of Convolutional Neural Networks (CNN) for facial expression recognition uses three datasets: FER2013, Cohn-Kanade (CK+), and Karolinska Directed Emotional Faces (KDEF). The CK+ dataset comprises 981 images, while KDEF has 490 images adjusted to 48x48 pixels. The model was developed with multiple convolution and fully connected layers and trained with various optimization scenarios and some epochs. As a result, the accuracy for the FER2013 dataset was 52% at 200 epochs and dropped to 49% at 500 epochs. For KDEF, the accuracy was 81% at 200 epochs and decreased to 77% at 500. The CK+ dataset showed 77% accuracy at 200 epochs and decreased to 71% at 500. When the three datasets were combined, the accuracy was 57% at 200 epochs and decreased to 54% at 500 epochs, indicating that variations in training and datasets affect the model performance [10]. This indicates limitations in the model's ability to generalize across different datasets and suggests potential overfitting, especially as performance declines with extended training.

A comparative study on FER with various machine learning techniques has been done to improve efficiency and accuracy. The methods tested include SVM, LR, ANN, RF, KNN, NB, and CNN, but the CNN architecture needs to be described. The evaluation was performed on ORL and Yale databases using accuracy, confusion matrix, and ROC performance measures. Results show that CNN and other deep learning models such as AlexNet, DenseNet, and LeNet achieve 100% performance on the ORL database, while traditional models such as SVM achieve 98.19%. However, deep learning techniques showed less satisfactory results on the smaller Yale dataset, emphasizing the importance of large datasets for optimal deep learning performance [11].

Research by Adrian et al. optimizes hyperparameters on CNN for facial emotion recognition using the FER2013 dataset, which is divided into training, validation, and test data with a ratio of 80-10-10. The proposed architecture includes five convolutional layers with 256, 512, 384, and 192 filter configurations and a dropout technique to reduce overfitting. Image pre-processing includes data augmentation. Results show significant improvement in accuracy, with a validation accuracy of 63.22% after 20 epochs and a test accuracy of 72.16% after 750 epochs. The model shows competitive performance with lower computational overhead than complex models such as VGG and ResNet; it is ranked ninth on the FER2013 benchmark on PapersWithCode [12]. Although the model achieved good performance on the test set, real-time application testing is not mentioned. It is unclear how well the model would perform when integrated into a real-time system, where speed and efficiency are crucial, especially on devices with limited computational resources.

Khaireddin et al. discussed facial emotion recognition using CNN architecture with a pre-trained VGGNet model on the FER2013 dataset divided by an 80:10:10 ratio for training, validation, and testing. The research emphasizes the effectiveness of CNN in automatic feature extraction and computational efficiency. The model uses four convolution layers and optimization techniques to improve performance and change the learning rate. The best accuracy achieved was 73.28% without additional training data, with Reduce Learning on Plateau callback optimization, and ranked eighth on the FER2013 accuracy benchmark in PapersWithCode [13].

Various previous studies show that Convolutional Neural Networks (CNN) technology has become the dominant method in facial expression recognition. Variations in the architecture, datasets, and training techniques used provide important insights into the effectiveness and adaptability of CNN models. These studies show that the depth and complexity of the CNN architecture, the number of neurons, and the selection of the right dataset greatly affect the model's performance, but also risk overfitting if not properly managed. There is great potential for

model development for facial expression classification, especially in the context of the Indonesian population, which may require models that are adaptive and relevant to local characteristics. In addition, to improve the model's generalizability, an effort will be made to combine the dataset of Western faces with non-Indonesian faces so that it is expected to produce a more diverse and adaptive model for the emotion category used.

III. METHODOLOGY

This research develops a Convolutional Neural Network (CNN)-based Facial Emotion Recognition (FER) model as shown in Fig. 1. In general, the process started with data collection and filtering of emotional data, followed by exploratory analysis to understand the characteristics of the data. Defective and duplicate images are removed to maintain the quality of the dataset. Images are then converted to grayscale, faces are detected using Haar Cascade and resized for uniformity. The processed data was divided into training and testing sets. The model was trained by adding a new convolution layer with a 1024 filter and using callbacks such as early stopping and ReduceLROnPlateau to optimize performance. Finally, the model was tested to evaluate its accuracy and performance in recognizing emotions from facial images.

A. Data Collection

This study uses secondary data from three primary datasets: CK+, FER2013, and IMED. The FER2013 dataset includes 35,882 facial images with a resolution of 48x48 pixels in grayscale format, grouped into seven emotion categories. There is no specific information about the gender or age of the subjects in the images. Fig. 2 displays each example image in each class of the FER2013 dataset [14] [15]. The figure shows images converted into grayscale format with a resolution of 48x48 pixels. When viewed, images in the FER2013 dataset are covered by watermarks and hand poses that cover the face, which is expected to interfere with the learning process of the model and affect the accuracy. In addition, some emotion classes may need to be better balanced, with some emotions, such as disgust, having a much smaller number of samples than other emotions, such as happy or sad.

The CK+ dataset consists of 981 facial expressions from 210 individuals aged 18-50, with a gender distribution of 31% male and 69% female and a racial distribution of 81% Euro-American, 13% Afro-American, and 6% other. The dataset has seven emotion categories, and the images are in grayscale format with 48x48 pixel resolution. Fig. 3 shows each example image in each class of the CK+ dataset [10]. The number of images in each emotion class was observed, showing that this dataset has the least number compared to the other datasets used in this study. The pixel size of each image is 48x48 pixels and is in grayscale. The facial expressions of each emotion category are very clearly identified. In addition, the images in this dataset were taken under good and controlled lighting conditions, and all subjects were oriented directly toward the camera, which facilitated the analysis of facial expressions.

The IMED dataset contains 9,183 images of six male and nine female Indonesian subjects aged 17-32 from various Java, Batak, Sunda, Minang, and Manado ethnicities. The dataset comprises seven emotion categories and is organized in grayscale format with a resolution of 720x480 pixels. This dataset was obtained with special permission through the website https://imed.cs.ui.ac.id/. Fig. 4 shows each example image in each class of the IMED dataset [16]. It can be seen that the images in the IMED dataset have a resolution of 720 pixels wide and 480 pixels high, with an RGB image mode indicating full-color representation. The image quality in the IMED dataset has good and uniform lighting, and all the datasets are clean, with no noise, and are not covered by watermarks or hand poses covering the face area. However, the images are framed in black frames, indicating that they are still raw. Therefore, it is necessary to pre-process the data to produce uniform images with the other datasets, which ideally have a size of 48x48 pixels and are in grayscale mode.

Fig. 2. FER2013 dataset images example.

Fig. 3. CK+ dataset images example.

Fig. 4. IMED dataset images example.

Table I shows the calculation details of each emotion class in the dataset.

TABLE I. CLASS DISTRIBUTION IN EACH DATASET

Emotion Class	FER2013	IMED	CK+
Neutral	6.193	518	54
Angry	4.953	1.623	135
Disgust	5.470	1.413	177
Fear	5.121	1.466	75
Happy	8.989	1.319	207
Sad	6.077	1.793	84
Surprise	4.002	1.051	249
Total	35.882	9.183	981

B. Data Preparation

In this study, the data pre-processing steps were carried out with a special focus on the IMED dataset, which is still in raw form, unlike the other datasets, which have been converted to grayscale and adjusted to 48x48 pixel dimensions. Details on the processing of the IMED dataset are shown in Fig. 5.

- Face detection and cropping of the image using the Haar Cascade Classifier method from the OpenCV library. Face detection is performed to ensure that only parts of the face are analyzed. This method compares parts of the image with pre-trained facial features like eyes, nose, or mouth. Once the face is detected, the area is cropped for face isolation [17]
- Grayscale conversion. In the IMED dataset, the image is converted to grayscale mode. This conversion reduces the complexity of the data but still retains the important features of the face. This process uses the cv2.cvtColor function with the cv2.COLOR_BGR2GRAY parameter.
- Resize Image: after the image is converted to a grayscale format, the image with variable sizes is resized to 48x48 pixels to maintain consistency with other datasets and ease of model processing.

Fig. 5. IMED dataset pre-processing steps.

In the FER2013 dataset, the data provided in CSV format requires conversion from a string of pixel values to an array of images. This process involved using np. from string to convert the string into a one-dimensional integer array, which was then reshaped into an image with a resolution of 48x48 pixels. This reshaping technique converts the data into a pixel matrix that the CNN model can process. A visualization of the processing of the FER2013 dataset is shown in Fig. 6.

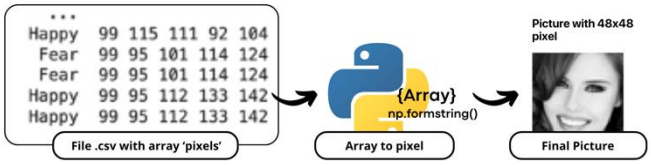

Fig. 6. FER2013 dataset pre-processing steps.

Afterward, emotion selection was conducted to simplify the emotion categories from 7 to 4. The four emotions are happy, angry, neutral, and sad. After emotion selection, the data was divided with a ratio of 80:18:2 for training, validation, and test data. The test data was then expanded by adding images taken from photos of real people, which was done to ensure a more genuine representation. The downsampling process balances the amount of test data between each emotion label. Two experiments were conducted with dataset splitting. The first experiment is conducted with the number of emotions in each dataset intact, with no reductions. Table II shows the training, validation, and test data used in the first experiment.

TABLE II. NUMBER OF TRAINING, VALIDATION, AND TESTING DATA

Data Split	Angry	Happy	Neutral
Training	5.160	8.208	5.240
Validation	1.132	1.856	1.183
Testing	148	148	148
Total	6.440	10.212	6.571

C. Model Architecture

This research uses the Convolutional Neural Network architecture. The CNN architecture used is adapted with the addition of one layer of convolutional blocks based on references from the PapersWithCode website, specifically from research entitled "Convolutional Neural Network Hyperparameters Optimization for Facial Emotion Recognition" [12], with details observable in Fig. 7.

The model starts with an input layer, where a grayscale and normalized face image of 48x48 pixels is used as input. Next, a series of convolution blocks extract visual features from the image. Each convolution block consists of a 2D Convolution layer with 3x3 filters; the first block has 256 filters, the second block 512, the third block 384, the fourth block 192, and the fifth block 512. The output of each convolution layer is normalized using BatchNormalization, and its dimension is reduced through MaxPooling2D with a 2x2 window. A dropout of 0.5 is applied after pooling to prevent overfitting.

Fully Connected Layers in this model include several layers: a Flatten Layer, which converts the multidimensional output of the last convolutional block into a one-dimensional vector, followed by a Dense Layer with 256 neurons and ReLU activation. A dropout of 0.5 is applied to the Dense Layer output to prevent overfitting. Finally, the Output Dense Layer uses four neurons corresponding to the number of emotion classes, equipped with a softmax activation function to generate class probabilities.

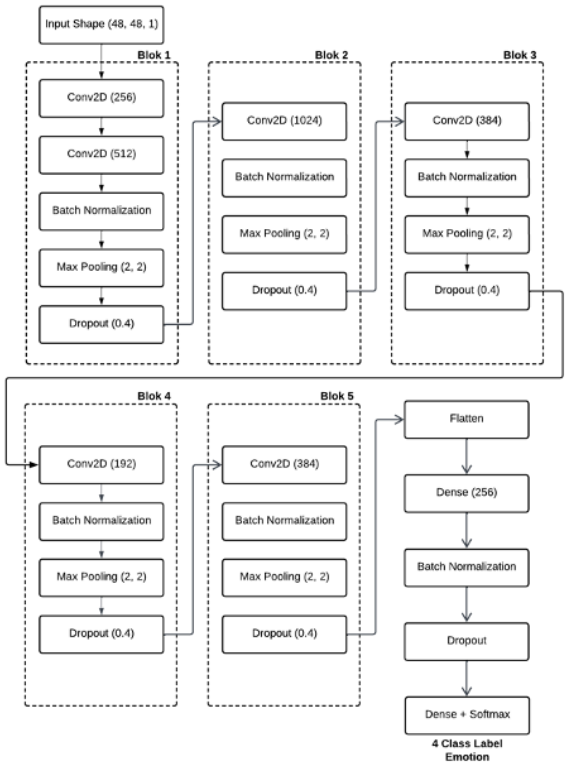

Fig. 7. Implemented CNN architecture.

D. Testing Scenario

Before going into the training and testing phase of the model, nine test scenarios were conducted to evaluate the model's performance under various conditions. These scenarios were designed to understand how datasets and model architecture variations affect the accuracy and loss of training and validation data. Table III summarizes the nine test scenarios conducted.

TABLE III. TESTING SCENARIO

Scenario	Description
1	Train using IMED dataset only
2	Train using CK+ dataset only.
3	Train using the FER2013 dataset only.
4	Train using combined IMED and FER2013 datasets
5	Train using combined IMED and CK+ datasets
6	Train using combined FER2013 and CK+ datasets
7	The first train without additional convolution layers with no minimum count using the FER2013 dataset
8	The second train without additional convolution layers with 1000 per label using the FER2013 dataset
9	The third train with the addition of a convolution block with a 1024 filter using the FER2023 dataset

Every scenario is designed to explore different aspects of model training. Scenarios 1 to 3 aim to measure the model's performance trained with individual datasets such as IMED, CK+, and FER2013. Scenarios 4 to 6 evaluate combinations of datasets to see the impact of integrating data from different sources. Scenarios 7 and 8 investigate the effects of variations in the amount of data and the use of additional convolution layers on the FER2013 dataset. Finally, scenario 9 involves adding convolution layers with large filters, batch normalization, max pooling, and dropout to capture more complex features and reduce overfitting. These scenarios helped identify the best configuration to implement the facial emotion recognition model.

E. Callback Mechanism

A callback method is used to optimize the process in model training using Keras TensorFlow. An early stopping callback is applied to automatically stop training if there is no improvement in validation accuracy [18] [19]. This allows the model to stop by seven earlier than the maximum number of epochs if the model is no longer improving, thus saving computational time and resources. Model saving is done through Model Checkpoint, which only saves the model if there is an increase in validation accuracy; this ensures that the saved file is optimal based on validation accuracy. Furthermore, the ReduceLROnPlateau callback method reduces the learning rate of the model by 80% from its previous value if there is no improvement in validation accuracy for three consecutive epochs, considering the minimal change in validation accuracy of 0.0001 to be regarded as an improvement [20]. Changes smaller than this value will not be considered.

The model is compiled with a loss function or sparse categorical cross-entropy loss function suitable for classification tasks where the target class label is an integer [21][22]. The optimizer used is Adam, which is used with early stopping callbacks, and ReduceLROnPlateau to optimize the training process with an initial learning rate of 0.001 [23]. The metric measured is accuracy, which indicates the percentage of correct predictions. Training is performed with the training dataset and validation data to evaluate model performance on data not used during training. During training, the model will go through a maximum of 50 epochs, which implies that the data will be processed 50 times to optimize the model weights based on the loss function and the accuracy measurement.

IV. RESULT AND DISCUSSION

After performing duplicate and corrupted image detection on each dataset, 3369 duplicate images were found on the FER2013 dataset and 273 duplicate images on the IMED dataset. No corrupted images were found in any of the analyzed datasets. In the image pre-processing stage, nine images from the IMED dataset are not detected by the Haar Cascade Classifier, as shown in Fig. 8. The duplicate images that the Haar Cascade Classifier does not detect will be removed to ensure the consistency and quality of the data used in training the model.

Fig. 8. Example of images that Haar Cascade Classifier does not detect.

After the pre-processing stage is complete, the next step is to perform model training using a Convolutional Neural Network (CNN). This training is done to optimize the model in recognizing facial emotions from images. Several experiments according to the design of the test scenario were conducted to evaluate the model's performance on various combinations of datasets, both individually and combined, and to explore the effect of the model architecture on its performance.

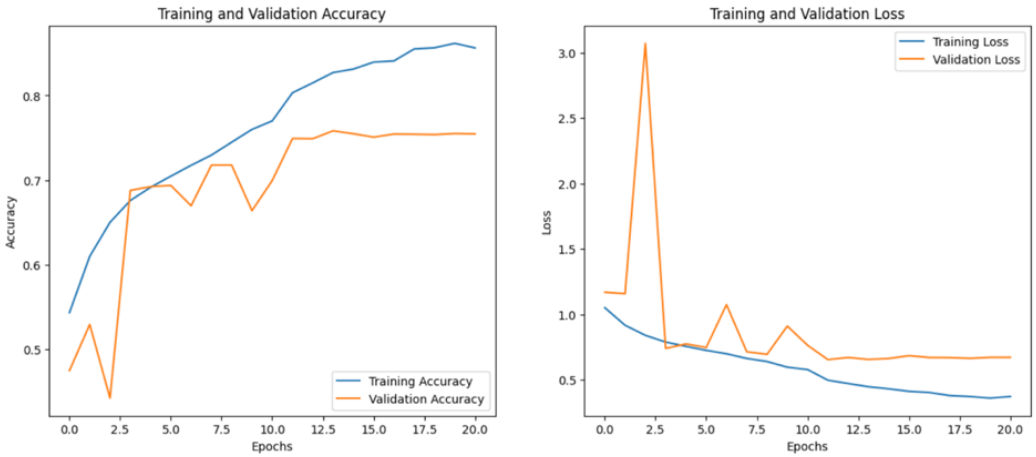

Fig. 9. Scenario 7: Train-validation accuracy and loss plot (training process was stopped early at the 21st epoch).

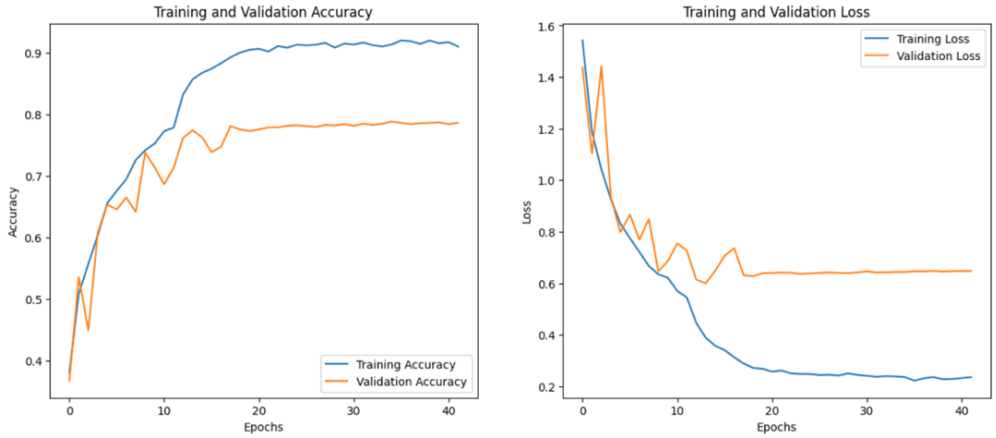

Fig. 10. Scenario 8: Train-validation accuracy and loss plot (each epoch took an average of 24 seconds).

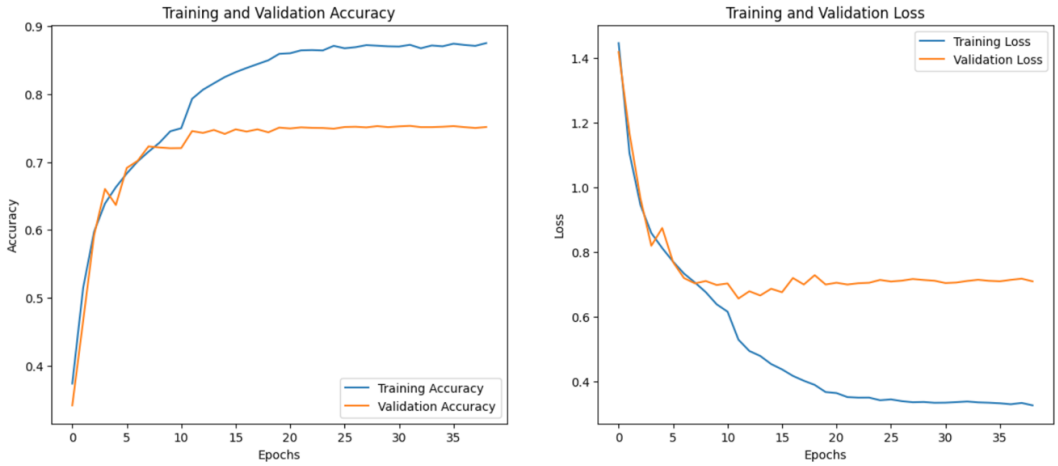

Fig. 11. Scenario 9: Train-validation accuracy and loss plot (validation loss shows a more stable decrease).

In the first experiment of training the combined model of three datasets, the highest validation accuracy was obtained at the 14th epoch with an accuracy value of 0.7582. At the 14th epoch, the model also recorded a validation loss of 0.6572, one

of the lowest loss values during the training session. For each epoch, the training took 49 seconds. The lowest validation loss value was recorded at the 12th epoch with a value of 0.6556, while the highest was recorded at the 3rd epoch with a very high value of 3.0713. This shows significant fluctuations in the model's performance at the beginning of training. During the training session, the model decreased the learning rate three times, precisely at the 11th, 17th, and 20th epochs. This decrease is done automatically by the ReduceLROnPlateau callback, which aims to improve validation accuracy when stagnation in performance improvement is detected. In addition, the more epochs performed, the higher the validation loss. The training process was stopped early at the 21st epoch, as shown in Fig. 9.

The training process of the second combined dataset lasted for 42 epochs before being stopped by the early stopping mechanism. Each epoch had 227 batches of data used for training. Furthermore, the early stopping method was set to stop training if there was no improvement in validation accuracy for 7 consecutive epochs, restoring the model weights to the state when the best performance was achieved. The model training started with a high initial loss of 15.42%, an accuracy of 38.03% on the training data, and about 36.69% on the validation data. Significant improvement occurred from the start of training, with training accuracy increasing to 75.24% and validation accuracy reaching 73.76% by the 9th epoch. The biggest improvement occurred at the 24th epoch, where the validation accuracy soared from 66.47% in the previous epoch to 78.07%. Each epoch took an average of 24 seconds. The accuracy results are shown in Fig. 10.

Furthermore, for the final experiment, adding a convolution layer with a filter of 1024, batch normalization, max pooling, and dropout resulted in a slight increase in model accuracy on the validation data. With this new configuration, the model achieved a validation accuracy of 79.59% after 39 epochs, with early stopping at the 39th epoch. This is compared to previous experiments that showed an increase in accuracy from 75.82% to 78.81% after data and hyperparameter adjustments. Adding a new convolutional layer with a large filter gives the model additional capacity to capture more complex features, thus improving classification ability. In addition, the validation loss of the new model shows a more stable decrease, as shown in Fig. 11.

TABLE IV. TRAINING RESULTS OF ALL SCENARIOS

Scenario	Train Accuracy	Train Loss	Validation Accuracy	Validation Loss
1	0.9855	0.1297	0.9809	0.0877
2	0.9766	0.0800	0.9792	0.1037
3	0.8272	0.4393	0.7226	0.7922
4	0.8637	0.3551	0.7575	0.7100
5	0.9716	0.0792	0.9859	0.1060
6	0.3018	0.8822	0.7178	0.8671
7	0.8271	0.4488	0.7582	0.6572
8	0.9135	0.2367	0.7881	0.6440
9	0.9339	0.1814	0.79558	0.6206

Table IV summarizes the model's best training results on four different datasets, namely IMED, CK+, FER2013, and a combined dataset, showing the variation in model performance in terms of accuracy and loss for both training and validation data at various points of the last epoch when training is stopped. This study shows that the model's accuracy decreases when the FER2013 dataset is mixed with other datasets, such as CK+ or IMED. The combination of FER2013 and CK+ resulted in a lower validation accuracy of 71.78%, with a high validation loss of 86.71% at the 39th epoch. Although the CK+ dataset is of high quality, the presence of FER2013 with high variability reduces the model's overall performance. The combination of IMED and FER2013 showed a validation accuracy of 75.75% and a validation loss of 71%. Although there is a performance improvement compared to using FER2013 alone, the results are still lower than those of using the IMED dataset individually. The CK+ and IMED datasets are more homogeneous and controlled, with more consistent expression variation and higher image quality. When the more varied and uncontrolled FER2013 dataset is mixed with the more homogeneous dataset, the model needs help generalizing the relevant patterns, thus lowering the overall performance. In the first and second experiments, no additional convolution layer was used.

Considering the results in Table IV for the three combined datasets in scenarios 7, 8, and 9, the best model performance is achieved in scenario 9. Therefore, the final model selected for further analysis is scenario 9. A confusion matrix study is conducted to better understand the model's performance in facial emotion classification. The confusion matrix provides an overview of how well the model classifies each emotion category and identifies areas that require further improvement [5] [24]. This analysis is important to evaluate the accuracy and weaknesses of the model in emotion recognition and to find out the most frequent types of errors.

TABLE V. TESTING RESULT CONFUSION MATRIX

	Predicted				
	Class	**Angry**	**Happy**	**Neutral**	**Sad**
True	Angry	32	3	10	2
	Happy	0	41	3	3
	Neutral	6	5	32	4
	Sad	9	3	7	28

The confusion matrix in Table V shows the model's performance in classifying facial emotions into four categories: angry, happy, sad, and neutral. For the original label angry, the model successfully classified 32 samples correctly, but ten samples were misclassified as neutral, three as happy, and two as sad. The happy original label performed better, with 41 samples correctly classified, although three samples were misclassified as neutral and three as sad. For the neutral label, 32 samples were correctly classified, while six were incorrectly classified as angry, five as happy, and four as Sad. Finally, the model classified 28 samples correctly for the original label sad, but there were errors with nine samples classified as angry, three as happy, and seven as neutral. This analysis shows that the model is quite accurate in classifying happy and neutral emotions but still needs improvement in classifying angry and

sad feelings, especially in distinguishing between angry and neutral.

TABLE VI. CLASS CLASSIFICATION RESULT

	Precision	Recall	F1-Score	Support
Angry	0.68	0.68	0.68	47
Happy	0.79	0.87	0.83	47
Neutral	0.65	0.68	0.65	47
Sad	0.76	0.60	0.67	47
Accuracy			0.71	188
Macro average	0.71	0.71	0.71	188
Weighted average	0.71	0.71	0.71	188

The results of the emotion classification metrics in Table VI show the model's precision, recall, and F1-Score performance for the angry, happy, sad, and neutral categories. For anger, the model achieved a precision and recall of 0.68. The happy category shows the best performance by the highest precision of 0.79, recall of 0.87, and F1-score of 0.83. The neutral category gets a precision of 0.65 and a recall of 0.68, while the sad category gets a precision of 0.76 and a recall of 0.60 with an F1-Score of 0.67. The model's overall accuracy was 0.71, with a macro-average and weighted average of 0.71 each.

Furthermore, the model is analyzed using the ROC Curve. The ROC curve illustrates the performance of the classification model at all possible classification thresholds by plotting two parameters: True Positive Rate (TPR) and False Positive Rate (FPR). AUC is the probability that the model will rank random positive samples higher than random negative samples. The ROC curve AUC is presented in the form of a curve graph. AUC values range from 0 to 1, where 1 indicates perfect prediction, and 0.5 indicates performance no better than a random guess [25].

Fig. 12 shows the ROC Curve in the range of 0-1 (higher is better) for scenario 9. The X axis is the false positive rate in the range of 0-1 and the Y axis is the true positive rate in the range of 0-1. The ROC shows the best performance for the happy class (AUC 0.97) and good for the angry and sad class (AUC 0.90). The neutral class has the lowest AUC of 0.87.

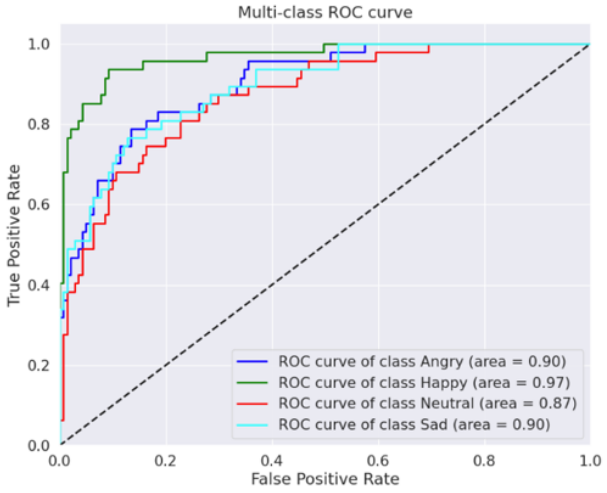

Fig. 12. ROC Curve on Scenario 9 classes.

The dataset characteristics affect the model's effectiveness, with variability in lighting and image quality making it difficult to extract important features. Table VII shows that images with unclear expressions or partially obscured faces degrade the model's performance, and poorly lit or non-face images hinder accurate classification.

TABLE VII. NON-CONFORMING IMAGES

Remarks	Images
Images with cartoon face	
Poorly lit images	Face area covered by hands or watermarks	Non-face images	

V. CONCLUSION

This research successfully developed a Facial Emotion Recognition model using Convolutional Neural Network (CNN) architecture by combining CK+, FER2013, and IMED datasets. In the 9th scenario, the model incorporating the three datasets with an additional convolutional layer of 1024 filters achieved the highest validation accuracy of 79.59%. The main factors for improved accuracy are better feature extraction capabilities and the application of batch normalization, max pooling, and dropout, which reduce overfitting and improve validation stability. The model achieved an average accuracy, precision, recall, and F1-Score of 71.5% on the test data.

Using the IMED and CK+ datasets individually provides high validation accuracy (97-98%), while the more varied FER2013 dataset provides a validation accuracy of 72.64%. Training parameter adjustments such as learning rate reduction and early stopping also improved model performance. This research shows that combining datasets and improved CNN architecture significantly affects the performance of facial emotion recognition.

ACKNOWLEDGMENT

We would like to thank: Lembaga Penelitian dan Pengabdian kepada Masyarakat (LPPM) Universitas Kristen Duta Wacana, Indonesia for the grant support No. 108/D.01/LPPM/2024.

Optimization of 3D Coverage Layout for Multi-UAV Collaborative Lighting in Emergency Rescue Operations

Dan Jiang[1], Rui Yan[2]*
Beijing Municipal Commission of Housing and Urban-Rural Development Beijing, China[1]
School of Economics and Management, University of Science and Technology Beijing, Beijing, China[2]

***Abstract*—In emergency rescue scenarios, Unmanned Aerial Vehicles (UAVs) play a pivotal role in navigating complex terrains and high-risk environments. This paper proposes an optimization model for the three-dimensional coverage layout of a multi-UAV collaborative lighting system, specifically designed to meet the spatial requirements of emergency operations. An enhanced Particle Swarm Optimization (PSO) algorithm is employed to tackle the layout challenges, featuring adaptive inertia weights and asymmetric learning factors to improve both efficiency and global search capabilities. The simulation results demonstrate that the proposed method significantly enhances coverage efficiency, achieving over 90% coverage in critical areas while ensuring precise UAV positioning. Additionally, the algorithm shows faster convergence and stronger global search ability, effectively optimizing UAV deployment and improving operational efficiency during rescue missions. This study offers a practical and reliable layout solution for multi-UAV collaborative lighting systems, which is crucial for reducing rescue times, ensuring operational safety, and improving resource allocation in emergency responses.**

Keywords*—Unmanned Aerial Vehicles; emergency rescue; collaborative lighting; three-dimensional coverage; particle swarm algorithm

I. Introduction

Geological disasters are increasingly prevalent worldwide, with the Global Disaster Data Platform reporting 392 wildfires, 109 earthquakes, and 109 floods in the last six months alone [1]. These statistics likely underestimate the true frequency of such events. The sudden and unpredictable nature of these disasters, coupled with complex environmental conditions, poses significant challenges for emergency rescue operations. Issues such as injuries to personnel, transportation difficulties, and disruptions in communication, power, and lighting infrastructure complicate these efforts further.

In this context, UAVs have emerged as crucial tools in managing such crises. UAVs, which do not require an onboard human presence, offer flexibility, efficiency, and convenience, proving especially useful in confined spaces, complex environments, or hazardous conditions. Their deployment can significantly reduce rescue times, enhance operational efficiency, and improve post-disaster relief efforts [2]. UAVs have broad applications across various sectors such as agriculture, construction, transportation, emergency rescue, military operations, and collaborative lighting [3].

The use of UAVs is particularly critical in emergency rescue situations where traditional lighting equipment may fail to provide rapid and effective illumination [4]. A collaborative approach using multiple UAVs can achieve more flexible and efficient lighting solutions. This paper focuses on optimizing the three-dimensional coverage layout of UAVs equipped with lighting systems, which play pivotal roles in emergency scenarios by enhancing lighting conditions, expanding coverage areas, improving safety, easing workload, and offering flexibility to adapt to diverse mission requirements.

The contributions of this paper include enhancing the comprehensiveness and inclusiveness of the 3D coverage model through innovative UAV technology that depicts disaster scenes and obstacle locations, optimizing 3D lighting coverage using an advanced particle swarm optimization algorithm to improve calculation accuracy and efficiency, and providing a comprehensive discussion on the role of UAV lighting systems in rescue operations. This optimization aids in reducing rescue times, ensuring the safety of rescuers, and minimizing the consumption of resources.

The structure of the paper is organized as follows: Section II reviews related literature; Section III develops the 3D coverage model for the lighting system; Section IV introduces the enhanced particle swarm optimization algorithm; Section V presents a computational study with examples and numerical results; Section VI concludes the paper.

II. Literature Review

A. Current Development of UAVs and their Applications in Different Scenarios

Over the past few decades, UAVs have rapidly evolved, transitioning from their initial military use to various civilian applications. One of the research areas receiving significant attention from scholars is the application of UAVs in emergency rescue scenarios. Different types of emergency rescue UAVs can be utilized for ground site exploration, thermal imaging search and rescue, rescue site mapping, and manned evacuations. In emergency rescue operations, UAVs offer valuable support for information gathering and complex environment rescue due to their compact size, flexibility, and user-friendliness [5]. Moreover, the modular design of UAVs enables the attachment of different systems tailored to specific emergency scenarios, increasing the range of rescue missions.

UAV applications are rapidly expanding across multiple domains. In the realm of smart cities and public safety, UAVs serve as versatile mobile platforms for smart city applications and security surveillance. The utilisation of UAVs and vehicles for last-mile urban deliveries represents an innovative delivery approach. This delivery model's optimisation problem is recognized as the UAV Travelling Salesman Problem (TSP-D). El-Adle et al. [6] studied a deterministic last-mile delivery problem by designing heuristic algorithms based on mixed integer programming to efficiently and accurately prioritise customers for UAV deliveries. Li et al. [7] introduced trucks and a UAV routing model (TDRP-FT) that considers flight altitude selection and time windows. The TDRP-FT model is validated using a hybrid algorithm that combines a greedy stochastic adaptive search process and an adaptive large-neighbourhood search to assess its effectiveness [8].

UAVs can significantly enhance urban public safety by offering early warning and support in diverse emergency scenarios and security operations. Based on BeiDou satellite positioning technology and Lora communication technology, [9] proposed a method of using multiple single-target trackers to replace part of the yolov3 detection task,[10] and put forward the design idea and specific implementation scheme of the vehicle monitoring prediction model.

Urban UAV route planning is a pivotal challenge, involving the quest for an optimal flight path under specific conditions. Miao et al. [11] proposed an improved symbiotic organism search algorithm based on the Simple Shape Method (SMSOS) to solve the path planning problem for UAVs, which has faster convergence speed, higher accuracy, and stronger robustness. Cui et al. [12] proposed a UAV trajectory planning scheme based on the hp-adaptive Radau pseudo-spectral method, considering both the dynamics constraints of the UAV and the terrain obstacle constraints during flight, and demonstrated its efficacy. Zhou et al. [13] proposed a mixed-integer linear programming model to address the reinitialized resource-constrained shortest path problem for correcting UAV flight errors. Three pruning strategies are introduced to enhance the effectiveness and efficiency of the algorithm, mitigating the high computational cost associated with the impulse algorithm. Shima and Schumacher [14] adopt a genetic algorithm that efficiently searches the feasible solution space to optimise the combination of multiple UAVs executing collaborative tasks, effectively solving the coupled problem of UAV task assignment and path planning.

UAVs have consistently played a significant role in the realm of civil security and disaster response. Most UAV-related research has made significant advancements in the domains of earthquakes, volcanic eruptions, and landslides. Following an earthquake, UAVs can serve as valuable investigative tools for collecting data from buildings that are inaccessible or require inspection. Li et al. [15] introduced an unsupervised method for detecting roof damage using UAV-captured images, which leverage combined color and shape features to assess the earthquake's impact based on the images acquired by UAVs. Thiels et al. [16] investigated the application of UAVs in the transportation of emergency supplies to disaster-stricken areas, hospitals, and offshore vessels during critical situations. Nagasawa et al. [17] proposed a multi-UAV coverage path planning method for 3D reconstruction of damaged buildings after a disaster. By generating, filtering, and ordering camera positioning points around a target damaged building, a final path that balances flight distance and time is provided for each UAV. Guo et al. [18] investigate optimal path planning for UAVs navigating in 3D environments with obstacles. They frame the problem as a nonlinear optimal control problem, incorporating continuous state inequality and terminal equivalence constraints. They propose a control parameterisation-based method to solve it. Ma et al. [19] design specific scenarios to simulate real disaster relief tasks and investigate UAV disaster relief task assignment problems. They propose three algorithms based on the horseshoe crab reagent algorithm: Aggregation-LAL, which utilizes an aggregation mechanism; Dynamic Adjustment-LAL, which employs dynamic adjustment mechanism; and Aggregation and Adjustment algorithms. Results demonstrate that AA-LAL achieves an average 5% improvement in task allocation in special scenarios compared to existing algorithms.

B. Coverage Metrics of the Lighting System in 3D Space

When considering three-dimensional lighting system coverage, the initial consideration is the selection of the light source to enable the measurement of light intensity and range. This paper utilizes LED light sources for illumination in a multi-UAV-carrying lighting system. LED light sources is known for their extended lifespan, compact size, and high luminous efficiency. Research on achieving uniform LED light intensity primarily involves two aspects: the secondary design of the LED light source and optimizing the arrangement and spacing of the LEDs.

The two-dimensional coverage problem has been a prominent subject of prior research in sensor networks. While most studies employ 2D models for network coverage, it is increasingly recognized that these models do not align well with real-world scenarios. Consequently, research on the 3D spatial coverage problem is gaining momentum. Huang et al. [20] (2007) were the first to carry out the research on 3D coverage, and they calculated the coverage by discussing the k-coverage problem. Alam and Haas [21] addressed the problem of 3D coverage and connectivity in underwater networks by dividing the 3D network volume into virtual cells in a distributed and scalable manner and selecting dynamic nodes to achieve perceptual coverage. The scheme can be used to achieve k-coverage. Gou et al. [22] proposed an energy efficient coverage enhancement method VKECE - 3D based on 3D - Voronoi partitioning and K - means algorithm, which guarantees the coverage while keeping the number of active nodes to a minimum. VKECE - 3D improves the network coverage and prolongs the network lifetime considerably. Li et al. [23] introduced a novel architecture for wireless sensor networks that incorporated distributed algorithms to manage sensor depths using an adaptive algorithm, resulting in maximal 3D sensor space coverage. Ramesh [24] presented a 3D spatial path planning technique for UAV-based atmospheric environment detection. This method can generate paths with complete coverage and optimal coverage density while accounting for energy constraints. Furthermore, it offers enhanced coverage density when compared to other path generation methods.

Currently, addressing the three-dimensional coverage problem involves mainly either converting the three-dimensional space into a two-dimensional space for computation or developing algorithms specifically designed for three-dimensional space coverage. Nevertheless, achieving accurate coverage calculations in the context of 3D coverage models necessitates more comprehensive and in-depth research efforts.

C. Optimisation Algorithm for the Objective Function

The optimisation of objective functions is a prevalent research area. In recent decades, researchers have developed a range of optimisation algorithms to tackle diverse challenges and problem types.

Classical single-objective optimisation algorithms encompass gradient descent, genetic algorithms, ant colony optimisation, and particle swarm optimisation, among others. Kennedy and Eberhart [25] introduced Particle Swarm Optimisation (PSO), an optimisation algorithm rooted in group intelligence. PSO achieves the search for a globally optimal solution by simulating the collaborative behaviour observed in natural phenomena like bird flocks or fish schools. The application of the particle swarm optimisation algorithm in objective optimisation problems represents an intriguing research avenue.

Nevertheless, the traditional particle swarm algorithm still exhibits shortcomings in terms of global search, diversity, and convergence. Consequently, scholars have conducted research on enhanced particle swarm algorithms. Zhang et al. [26] proposed a new PSO algorithm with self-adaptive inertia weights and social learning strategies, which improves the algorithm's convergence speed and global searching ability by dynamically adjusting the inertia weights and social learning factors ability. Yang et al. [27] proposed a particle swarm optimisation algorithm based on dual search strategies for dynamic multi-objective optimisation. Two search strategies are designed to update the velocity of each particle, which helps to accelerate the convergence speed and maintain the diversity of the population in a dynamic environment. For convergence improvement, Peng et al. [28] proposed a multi-objective particle optimisation algorithm that incorporates the concepts of shared learning and dynamic congestion distance. The algorithm aims to improve the convergence and diversity of the Pareto front by facilitating knowledge sharing among particles and dynamically adjusting the crowding distance metric. Cheng et al. [29] combined an improved non-dominated sorting strategy and a dynamic weight adjustment mechanism to achieve a balance between global search and local convergence, and utilised constraint-handling techniques to deal with constrained problems. For iterative formulation improvement, Lin et al. [30] combined an effective solution set evaluation method based on divergence statistics and a dynamic weight adjustment strategy to achieve a balance between global search and local convergence, and reduced the complexity of the non-dominated ranking by introducing a polynomial fitting function.

III. Model Building

In an emergency rescue scenario, the precise positioning of UAVs represents a critical design consideration. The lighting area must factor in the geographic scenario's influence and the mission requirements to establish a comprehensive rescue area lighting coverage model that incorporates various elements.

A. 3D Coverage Model of the Lighting System

The 3D coverage model produced by the lighting system primarily comprises a 3D cone model. This model represents a cone created in space by the light emitted from the lighting device, with the lighting device serving as the vertex and the base forming a circle, as illustrated in Fig. 1. In this context, the cross-sectional angle of the lighting system is defined as 60°, and the light's range is dependent on the UAV's altitude, simplifying the subsequent coverage rate calculation.

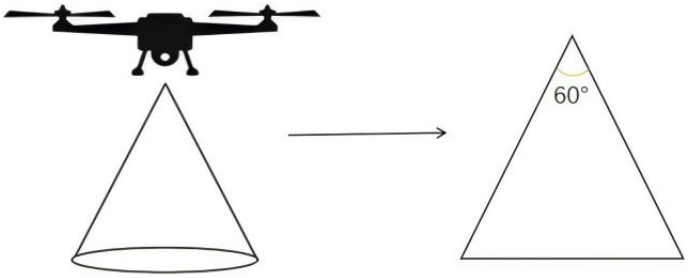

Fig. 1. Three-dimensional conic model of the lighting system and its cross section.

The three-dimensional coverage of the lighting system is initially conceptualized to discretize the volumetric space. However, for practical UAV applications in emergency rescue at specific altitudes, three-dimensional coverage considerations become superfluous. The focus shifts towards two-dimensional plane coverage, which is also subjected to discretization. Within the designated affected area, various characters and obstacles are positioned, necessitating a gridded layout where each grid square denotes a discrete point. Adjustment of the grid step size allows for the manipulation of node positions, facilitating optimal scalability and precision at different accuracy levels. This approach results in the discretization of the two-dimensional plane, as illustrated in Fig. 2, while Fig. 3 visualizes the extent of illumination provided by the two-dimensional lighting system. This model of 3D lighting system coverage effectively simplifies the calculation process, proving highly adaptable for real-world scenarios.

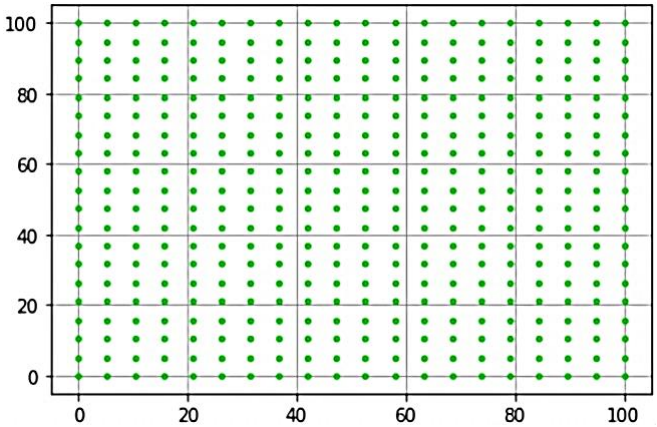

Fig. 2. 2D planar discrete model.

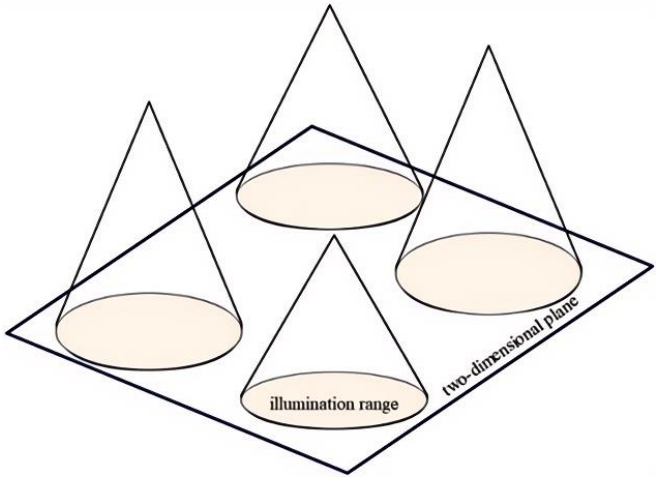

Fig. 3. Multiple unoccupied light ranges in a two-dimensional plane.

B. 3D Geometric Modelling of the Lighting Area

The scheduling of UAVs in rescue scenarios is influenced by lighting requirements and geographic factors. In emergency rescue, the analysis of lighting requirements is centered on providing the necessary illumination to facilitate a range of rescue activities. This analysis necessitates consideration of the specific environmental conditions and site requirements to determine the most suitable lighting solution. It involves detailed examination of the lighting system's type, quantity, placement, intensity, and reliability. Furthermore, emergency rescue lighting demand analysis must address concerns related to energy sources and energy-efficient measures to ensure the stable operation of the lighting system during emergencies.

To meet the specific requirements of emergency rescue operations, the lighting areas are strategically categorized based on the criticality of illumination:

Priority lighting area: This category includes locations crucial for the rescue of individuals or animals, pathways essential for conducting rescue operations, and zones where vital resources are located. It is imperative that the coverage of these areas is meticulously analyzed to ensure at least 90% illumination, serving as a constraint in the optimization challenge.

Other lighting areas: Beyond the priority zones, this category encompasses areas that may contain obstacles, hazardous materials, and miscellaneous regions where maximizing coverage remains a goal.

In outdoor scenarios, the effectiveness of UAV lighting is contingent upon the geographical landscape. For this study, the criteria for adequate coverage in outdoor 3D spatial scenes are defined as follows:

- The affected area must be entirely or partially within the UAV lighting system’s light cone, ensuring clear illumination.
- There must be no obstructions between the UAV system and the target area to avoid shadows and incomplete coverage.

This research concentrates on optimizing the layout of multiple UAVs, deliberately excluding multi-UAV path planning to avoid complexities such as potential collisions. We assume UAVs are deployed to pre-optimized locations, focusing exclusively on layout optimization. This approach allows for a detailed examination and analysis of spatial configuration challenges within multi-UAV systems.

Building on the initial analysis of lighting demands, this study integrates a three-dimensional cone model for the lighting system with a geometric model of the lighting area to establish a comprehensive three-dimensional coverage model, as depicted in Fig. 4. This model not only illustrates the areas covered by light but also applies spatial constraints to calculate precise coverage metrics, enhancing the effectiveness of the UAV lighting strategy in emergency scenarios.

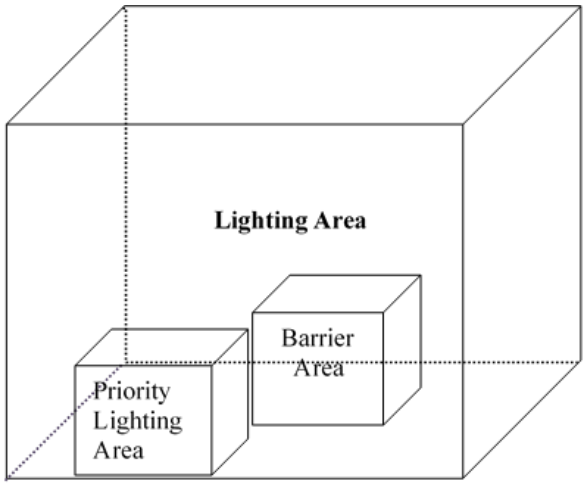

Fig. 4. 3D geometric modelling of lighting areas.

C. Mathematical Modelling

When planning UAV locations, the primary consideration is their ability to adequately illuminate designated areas. In this study, we define a coverage metric as a function with inputs including the 3D coverage model of the lighting system, the 3D geometric model of the illuminated area, the number of UAVs, and the parameters and constraints of the algorithm. The output of this function, the coverage metric, facilitates a comprehensive assessment of the layout's reasonableness, rationality, and effectiveness for the multi-UAV lighting system. The foundational assumptions of the model are:

Uniformity in UAV lighting capabilities: All UAVs are presumed to be equipped with identically capable lighting apparatus, characterized by consistent size, brightness, and irradiation range.

Fixed UAV positions: It is assumed that once each UAV is transported to the designated location and takes off, its position will remain fixed throughout the operation. This implies that our focus is on optimizing the initial layout of UAVs rather than dynamic path planning.

Quantifiable lighting area: The coverage and brightness within the illuminated area are assumed to be quantitatively measurable, allowing for the use of mathematical metrics to evaluate the effectiveness of various lighting configurations, including coverage percentage and brightness uniformity.

Reliability of geographic information: The geographic information employed is presumed accurate and reliable, including details about the area's topography, obstacle locations, and the distribution of critical elements.

No communication interference: It is assumed that there is no communication interference among the UAVs, enabling them to independently execute lighting tasks without the need for real-time communication.

Stable energy supply: A stable energy supply for the UAVs is assumed, ensuring they maintain operational capacity throughout the lighting mission.

1) Definition and meaning of symbols: Identifying constraints and objectives based on the simulated geometric model involves solving a single-objective optimization problem. The variables and parameters used in the model, along with their interpretations, are detailed in Tables I and II.

TABLE I. VARIABLES OF THE THREE-DIMENSIONAL COVERAGE MODEL AND THEIR INTERPRETATION

Variable	Interpretation
$C_i = (x_i, y_i, z_i)$	Geometric position vectors of the UAV
pre_R	Light coverage in priority lighting areas
R_{node}	Node light coverage
R	Total regional light coverage

TABLE II. PARAMETERS OF THE 3D COVERAGE MODEL AND THEIR INTERPRETATION

Parameter	Interpretation
N	Number of UAVs
d	Planar discrete spacing
i	The ith drone
$low_1(x,y,z), up_1(x,y,z)$	Extent of lighting area
$low_2(x,y,z), up_2(x,y,z)$	Range of obstacle locations
$low_3(x,y,z), up_3(x,y,z)$	Scope of Priority Lighting Areas

2) Calculation method of light coverage: Assuming that the lighting region A is a two-dimensional plane, the number of UAVs with the same parameters randomly placed on the region is N, and the coordinates of each UAV are known. The set of UAV nodes is denoted as $C = \{C_1, C_2, \ldots C_N\}$. where $C_i = \{x_i, y_i, z_i\}$ denotes the coordinates of the UAV nodes, and it is also assumed that the light emitted from the illumination system carried by the UAV has a conical top angle of 60°, then the radius of illumination $r = \frac{Z_i}{\sqrt{3}}$.

a) Node set coverage calculation: Assuming that the lighting area A is digitally discretized into $m \times n$ pixels with a discretization spacing of d, the values of m and n are shown in Eq. (1) and (2), respectively.

$$m = (up_1 x - low_1 x) \times d \quad (1)$$

$$n = (up_1 y - low_1 y) \times d \quad (2)$$

Where the coordinate of pixel p is (x, y), then the distance of the pixel from the centre of the drone circle is $d(C_i, p) = \sqrt{(x_i - x)^2 + (y_i - y)^2}$, and defining the event that pixel p is covered by the light from drone i as $r_{i,p}$, the probability of the occurrence of this event, $P_r(r_{i,p})$, is defined as in Eq. (3):

$$P_r(r_{i,p}) = \begin{cases} 1, \iota\phi\ \delta(C_i, p) \le r \\ 0, \text{otherwise} \end{cases} \quad (3)$$

where if $P_r(r_{i,p}) = 1$, it means that pixel point p is covered by the illumination range of UAV i. Therefore, the node coverage is the ratio of the total number of nodes covered by UAVs to the total number of nodes in the region, as in Eq. (4):

$$R_{node} = \frac{\sum_{i=1}^{N} \sum_{p=1}^{m \times n} P_r(r_{i,p})}{m \times n} \quad (4)$$

b) Calculation of area coverage: However, in real-world scenarios, different UAVs may repeatedly cover the same node, requiring the removal of pixel points covered multiple times within the illumination range of multiple UAVs when calculating area coverage. The area coverage of the illuminated region is determined as the ratio of the coverage area of the UAV lighting system to the total area of the illuminated region A, as shown in Eq. (5) and (6):

$$P_{cov(Cov)} = \sum_{p=1}^{m \times n} P_r(r_p) \quad (5)$$

$$\mathrm{R} = \frac{\mathrm{P_{cov(Cov)}}}{\mathrm{m \times n}} \quad (6)$$

where $P_{cov(Cov)}$ denotes the number of unduplicated nodes covered by the UAV lighting system. For any UAV i, if $P_r(r_{i,p}) = 1$, record the node p that is covered by the UAV lighting system at this time and note $P_r(r_p) = 1$. $P_r(r_p) = 1$ indicates that node p is covered by the lighting system.

3) Objective functions and constraints: Coverage problems for UAV node deployment can be divided into two types: area coverage and target coverage. The area coverage focuses on the illumination of the whole area and the target coverage problem focuses on the priority lighting area. The optimisation objective of this problem is to maximise the area coverage as in Eq. (7), P represents the overall coverage rate across the entire region:

$$\mathrm{M}\alpha\xi\ \mathrm{P} \quad (7)$$

Set the constraints of this optimisation problem as:

All UAVs should be located on the surface of the terrain and all inside the area to be illuminated, and secondly, the UAVs must not be inside a three-dimensional obstacle. The UAVs should not be positioned too low, at least three meters above the ground, to avoid interfering with rescue activities, i.e. the coordinates C_i of the UAV satisfy the following Eq. (8):

$$\begin{cases} low_1 x \le x_i \le low_2 x \ or \ up_2 x \le x_i \le up_1 x \\ low_1 y \le y_i \le low_2 y \ or \ up_2 y \le y_i \le up_1 y, i = 1,2,\ldots,N \\ 3 \le z_i \le low_2 z \ or \ up_2 z \le z_i \le up_1 z \end{cases} \quad (8)$$

Avoiding too much repetition of the coverage of different UAV lighting areas, the ratio of the projected distance between any two UAVs on the two-dimensional plane to the sum of their illumination radii is defined to be greater than 0.6, i.e.

satisfying Eq. (9):

$$\sqrt{(x_p - x_q)^2 + (y_p - y_q)^2} > \frac{\sqrt{3}(z_p + z_q)}{5},$$
$$p \neq q, p, q = 1,2,\ldots,N \quad (9)$$

In the disaster area, there are often people or other important things that need to be rescued, so the priority lighting area is established, in which the coverage rate needs to reach more than 90%, defining the coverage rate of the priority lighting area as pre_R, i.e. to satisfy $pre\_R > 0.9$.

IV. Improved Particle Swarm Optimisation Algorithm

This paper employs an enhanced particle swarm algorithm that dynamically adjusts the learning factor and inertia weight factor using diverse methods. It also employs distinct strategies to obtain the individual and global optimal solutions, enhancing search efficiency and accuracy while ensuring a level of stability.

PSO was selected in this study for its simplicity, fast convergence, and strong global search capability. Unlike GA or ACO, PSO does not require complex operations such as crossover or pheromone updating, making it more suitable for time-sensitive emergency rescue scenarios. Additionally, PSO balances exploration and exploitation effectively through adaptive weight adjustments, which aligns well with the requirements of optimizing multi-UAV collaborative lighting layouts.

A. Elementary Particle Swarm Optimisation Algorithm

The core velocity update Eq. (10) and position update Eq. (11) of the elementary particle swarm algorithm can be expressed as follows, respectively:

$$v_{i,d}^{k+1} = wv_{i,d}^{k} + c_1 r_1 \left(x_{i,d,pbest}^{k} - x_{i,d}^{k}\right) + c_2 r_2 \left(x_{d,gbest}^{k} - x_{i,d}^{k}\right) \quad (10)$$

$$x_{i,d}^{k+1} = x_{i,d}^{k} + v_{i,d}^{k+1} \quad (11)$$

where w is the inertia weight, which is used to regulate the global and local search ability of the particle in the search space. c_1 and c_2 are the individual learning factor and the population learning factor, respectively, which are used to regulate the direction and magnitude of the particle updating speed and indicate the magnitude of the learning ability. r_1, r_2 are random numbers of size between 0 and 1, $v_{i,d}^{k}$ is the velocity component of the ith particle in the dth dimension in the kth iteration, $x_{i,d}^{k}$ is the position component of the ith particle in the dth dimension in the kth iteration, $x_{i,d,pbest}^{k}$ is the position component of the individual particle's optimal position of the dth dimension after the kth iteration for the ith particle, and $x_{d,gbest}^{k}$ is the position component of the global optimal position of the dth dimension after the kth iteration. The flow of the optimisation algorithm for particle swarm is shown in Fig. 5.

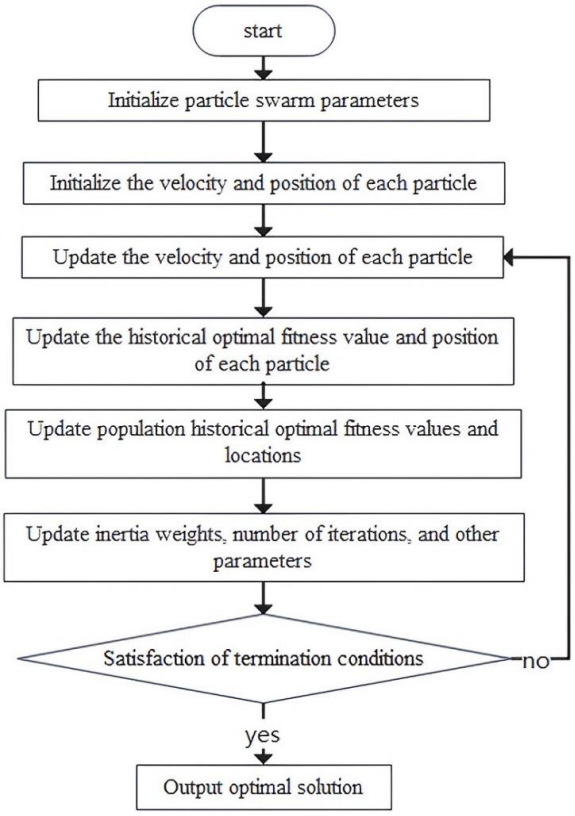

Fig. 5. Particle swarm optimisation algorithm flow.

B. Adjustment of Weights

1) Linearly decreasing inertia weights: In the particle swarm algorithm, the trend of velocity change can be controlled by adjusting the weights w. When w is small, the velocity change of the particle is relatively slow, and it is easy to fall into the local optimal solution; while when w is large, the velocity change of the particle is fast, and it is easy to skip the global optimal solution. Therefore, in order to balance the local search and global search capability, a linearly varying weight strategy is usually adopted, i.e. gradually decreasing from the initial value w_{max} to w_{min}, as shown in Eq. (12), where i is the number of iterations, and i_{max} is the maximum number of iterations.

$$w = w_{max} - (w_{max} - w_{min}) \frac{i}{i_{max}} \quad (12)$$

2) Adaptive inertia weights: The use of adaptive weights in particle swarm optimisation algorithms serves to enhance the algorithm's convergence performance and adaptability. Through dynamic weight adjustments throughout the algorithm's iterations, each particle can more effectively explore the search space and terminate the search more swiftly once the best solution is located.

More specifically, adaptive weights can affect the speed and direction of particle movement towards regions that are more likely to contain the best solution. During the initial stages of the algorithm, larger weights facilitate faster exploration of the search space, whereas in the later stages, smaller weights assist particles in converging more effectively

towards the optimal solution. This dynamic weight adjustment enhances the flexibility and adaptability of the PSO algorithm, enabling it to exhibit improved performance across various problem domains, with the weight changes following the pattern outlined in Eq. (13):

$$w = \begin{cases} w_{min} - (w_{max} - w_{min})\frac{f - f_{min}}{f_{avg} - f_{min}}, f \le f_{avg} \\ w_{max}, f > f_{avg} \end{cases} \quad (13)$$

C. Adjustment of Learning Factors

1) Compression factor method: In particle swarm algorithms, the learning factor is an important parameter used to control the particle speed update. Typically, each particle tracks two historical optimal solutions: the individual historical optimal solution and the neighbourhood historical optimal solution. The learning factors correspond to these two types of historical information, including the individual learning factor c_1 and the social (group) learning factor c_2. Specifically, the individual learning factor controls the extent to which a particle searches near its own historical optimal solution, which makes it more likely that the particle will move in the direction of its own historical optimal solution. The social factor, on the other hand, controls the extent to which a particle searches near its neighbourhood's historical optimal solution, which makes the particle more likely to move towards the neighbourhood's historical optimal solution location. In general, larger individual learning factors facilitated global search, while larger social factors facilitated local search.

In order to effectively control the flight speed of particles and make the algorithm achieve an effective balance between global search and local search, the particle swarm optimisation model that introduces a contraction factor was first proposed by Kennedy and Mendes [19], which employs a compression factor, and this tuning method, by appropriately selecting the parameters, ensures convergence of the particle swarm algorithm and removes the boundary restriction on the speed. The velocity update is formulated as follows in Eq. (14), where the compression factor ϕ is formulated as in Eq. (15).

$$v_{i,d}^{k+1} = \phi[wv_{i,d}^{k} + c_1 r_1\left(x_{i,d,pbest}^{k} - x_{i,d}^{k}\right) + c_2 r_2(x_{d,gbest}^{k} - x_{i,d}^{k})] \quad (14)$$

$$\phi = \frac{2}{\left|2 - (C_1 + C_2) - \sqrt{(C_1 + C_2)^2 - 4(C_1 + C_2)}\right|} \quad (15)$$

2) Asymmetric learning factors: Kennedy proposes an asymmetric learning factor strategy, i.e. the learning factor of each particle is divided into two parts, one part is used for global search and the other part is used for local search. This strategy can make the particles focus more on local search and stop searching faster when the optimal solution is found. The formula of the learning factor is as follows Eq. (16) and Eq. (17), where C_1^{ini} is the initial value of the individual learning factor, C_1^{fin} is the termination value of the individual learning factor, C_2^{ini} is the initial value of the social learning factor, and C_2^{fin} is the termination value of the social learning factor.

$$C_1^k = C_1^{ini} + \left(C_1^{fin} - C_1^{ini}\right)\frac{i}{i_{max}} \quad (16)$$

$$C_2^k = C_2^{ini} + \left(C_2^{fin} - C_2^{ini}\right)\frac{i}{i_{max}} \quad (17)$$

D. Performance Comparison of Different Improvements

In order to verify the effect of the improved algorithm, in the testing process, without setting up the priority lighting area and obstacle area, taking the particle swarm size of 20 and the maximum iteration number of 500, the performance of the algorithm is compared by changing the number of UAVs, the size of the lighting area, and the parameters, interpretation and their specific values of Experiments 1 and 2 are shown in Table III and Table IV, respectively.

TABLE III. THE PARAMETERS, INTERPRETATION AND SPECIFIC VALUES OF EXPERIMENT 1

Parameter	Interpretation	Value
N	Number of UAVs	3
$low_1(x,y,z), up_1(x,y,z)$	Extent of lighting area	(0,0,0),(10,10,10)
$low_1 z, up_1 z$	Altitude range of UAVs	3,7

TABLE IV. THE PARAMETERS, INTERPRETATION AND SPECIFIC VALUES OF EXPERIMENT 2

Parameter	Interpretation	Value
N	Number of UAVs	8
$low_1(x,y,z), up_1(x,y,z)$	Extent of lighting area	(0,0,0),(30,30,30)
$low_1 z, up_1 z$	Altitude range of UAVs	5,10

TABLE V. ALGORITHM PARAMETERS AND THEIR SPECIFIC VALUES

Parameter	Value	Parameter	Value	Parameter	Value	Parameter	Value
w_{max}	0.9	c_1	2	C_1^{ini}	2.5	C_2^{ini}	1
w_{min}	0.4	c_2	2	C_1^{fin}	4.5	C_2^{fin}	2.25

For ease of recording, the modalities of linearly decreasing inertia weights, adaptive inertia weights, compression factor method, and asymmetric learning factor are defined as ordinal numbers 1, 2, 3, and 4, respectively, and for each experiment, one modality is selected among the weights and the learning factor, respectively, to make up four modalities, i.e. 1-3, 1-4, 2-3, and 2-4. The specific values of the parameters of the algorithm in the experiments are shown in Table V, and the iterations of the improved particle swarm algorithm were carried out using the following parameters, using the value of the coverage calculated in the lighting area as the fitness

function, recording the before and after comparisons of the coverage maps obtained from different combinations under different experiments, as well as the corresponding initial fitness value, the optimal fitness value, the average value of fitness, and the variance obtained from the calculation of the fitness.

A comparison of the 2D planar coverage produced by combinations 1-3, 1-4, 2-3, and 2-4 in Experiment 1 is shown below in Fig. 6-9, and a comparison of the algorithmic iterative graphs for the four improvements is shown in Fig. 10.

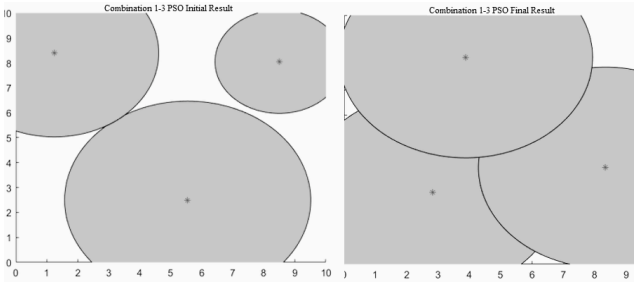

Fig. 6. Experiment 1 Combination 1-3 before and after optimization.

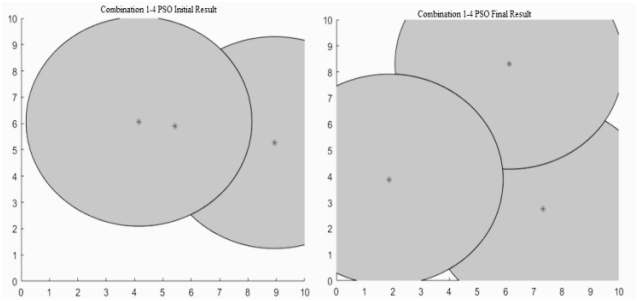

Fig. 7. Experiment 1 Combination 1-4 before and after optimization.

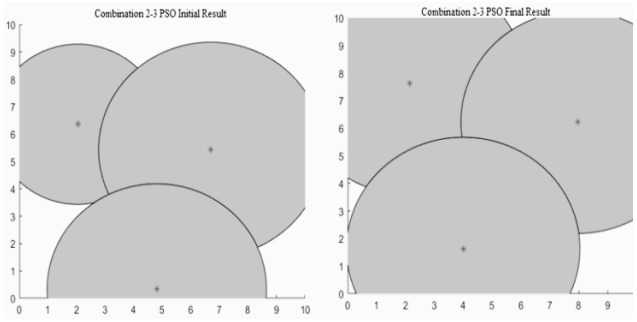

Fig. 8. Experiment 1 Combination 2-3 before and after optimization.

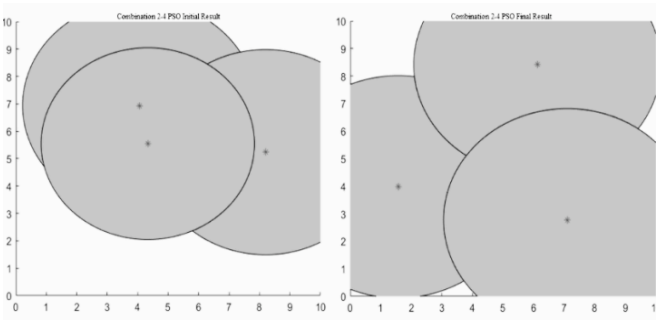

Fig. 9. Experiment 1 Combination 2-4 before and after optimization.

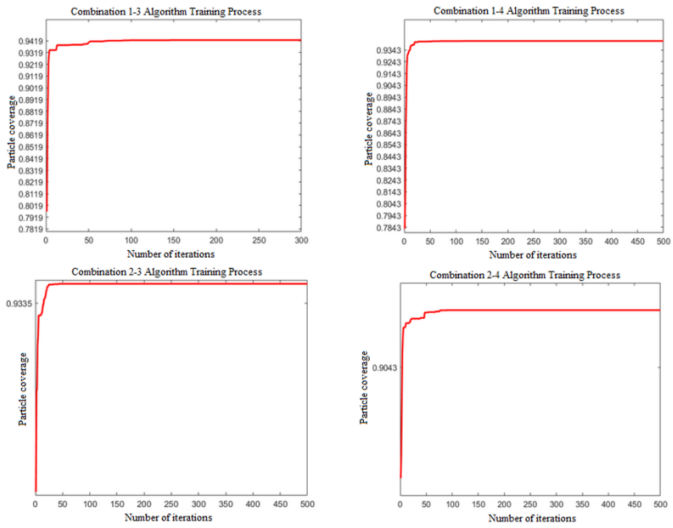

Fig. 10. Experiment 1 Comparison of the iterative process for different combinations.

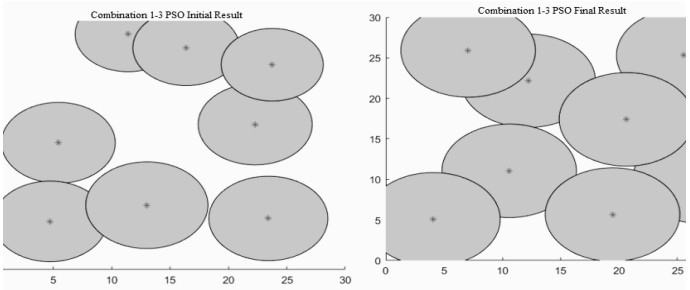

Fig. 11. Experiment 2 Combination 1-3 before and after optimization.

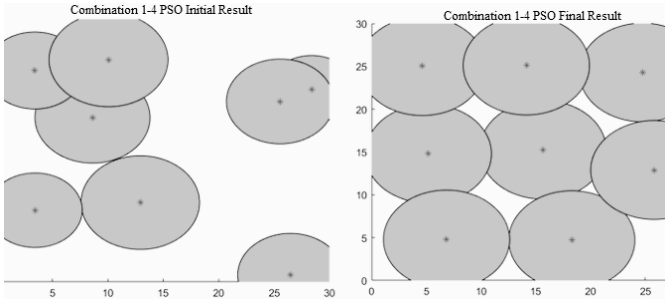

Fig. 12. Experiment 2 Combination 1-4 before and after optimization.

A comparison of the 2D planar coverage produced by combinations 1-3, 1-4, 2-3, and 2-4 in Experiment 2 is shown below in Fig. 11-14, and a comparison of the algorithmic iterative graphs for the four improvements is shown in Fig. 15.

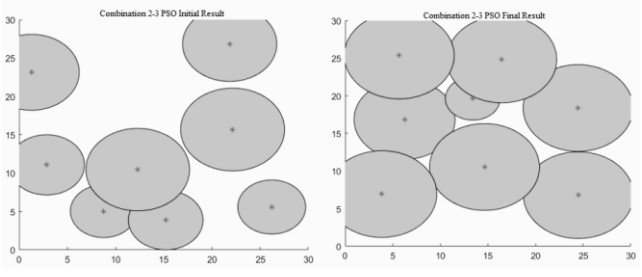

Fig. 13. Experiment 2 Combination 2-3 before and after optimization.

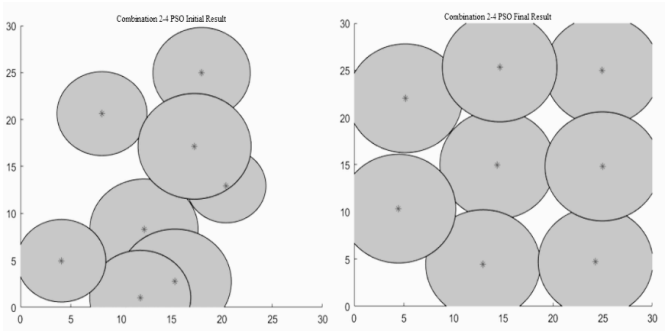

Fig. 14. Experiment 2 Combination 2-4 before and after optimisation.

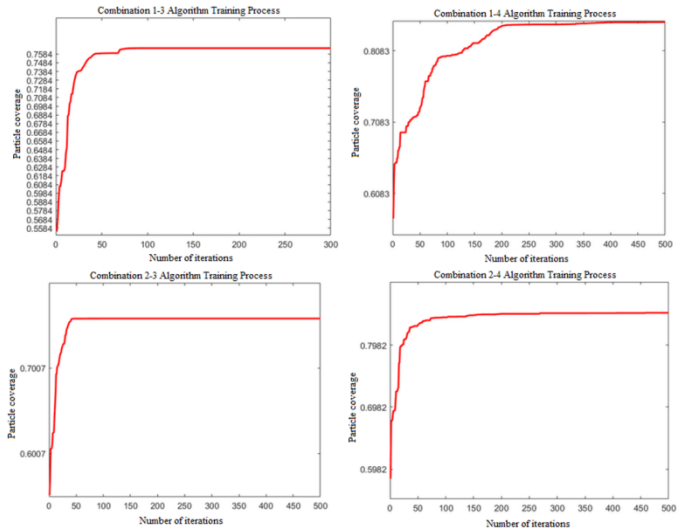

Fig. 15. Experiment 2 Comparison of the iterative process for different combinations.

TABLE VI. PERFORMANCE COMPARISON OF DIFFERENT IMPROVEMENT METHODS

Experiment number	Experimental combinations	Initial fitness	Optimal fitness	Mean fitness	Variance
Experiment 1	1-3	0.751	0.942	0.930	0.0009
	1-4	0.688	0.942	0.912	0.0021
	2-3	0.780	0.939	0.936	0.0008
	2-4	0.687	0.942	0.892	0.0027
Experiment 2	1-3	0.577	0.765	0.747	0.0040
	1-4	0.498	0.849	0.789	0.0067
	2-3	0.497	0.749	0.745	0.0023
	2-4	0.501	0.850	0.801	0.0046

Table VI presents a comparative table of the initial adaptation value, the optimal adaptation value, the average adaptation value, and the variance resulting from adaptation calculations obtained through different experimental improvement methods. From the test results in the table, it is evident that the variance resulting from the experiments is largely consistent and has minimal impact on actual outcomes. However, the approach of utilizing adaptive inertia weights and asymmetric learning factors, specifically the combination of 2-4 in the experiments, yields superior optimisation results compared to other methods. Consequently, a combination of these two enhancement algorithms is employed to address this problem.

V. SIMULATION STUDY

A. Data Preparation

Based on the 3D coverage model of the lighting area, which encompasses the lighting area, priority lighting area, other coverage areas, UAV positions, UAV lighting ranges, and the 2D spatial discrete model, the subsequent 3D model is constructed using the affected area in a real-world scenario, illustrated in Fig. 16.

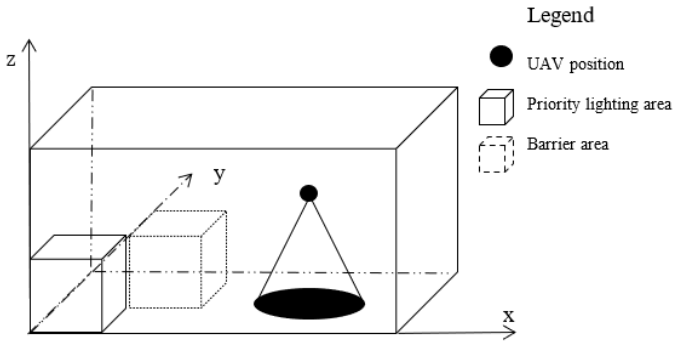

Fig. 16. Lighting area 3D overlay model.

Based on the actual situation of the affected area, the length and width of the lighting area were set at 30 metres and the height at 20 metres, and the specific values of the parameters for the size of the priority lighting area and the obstacle area are shown in Table VII.

TABLE VII. SPECIFIC VALUES FOR THE PARAMETERS OF THE 3D GEOMETRIC MODEL

Parameter	Value	Parameter	Value	Parameter	Value
$low_1(x,y,z)$	(0,0,0)	$low_2(x,y,z)$	(2,2,0)	$low_3(x,y,z)$	(2,0,0)
$up_1(x,y,z)$	(30,30,20)	$up_2(x,y,z)$	(4,4,2)	$up_3(x,y,z)$	(4,2,2)

B. Simulation Results

Assuming that the number of UAVs is 9, the coverage calculation is performed on the lighting areas generated by the nine UAVs, and when the constraints are satisfied, the original UAV positions are entered as the original population to facilitate comparison with the optimised scene. There are nine UAVs in the original scene, and the coverage of the original scene is judged from the calculation of the coverage rate, and the total number of discrete points of 96,100 is obtained by discrete two-dimensional planes with a step size of 0.1, and the lighting of the original scene covers 58,592, with a coverage rate of 0.609, in which the priority lighting area has 900 discrete points, of which 400 are covered, with a coverage rate of 0.444 visible. The initial scene coverage is average and does not meet the desired conditions, of which the illumination coverage area in the 2D plane is shown in Fig. 17.

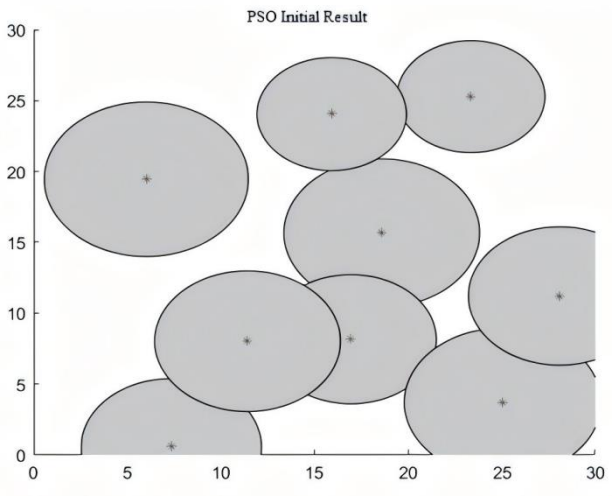

Fig. 17. Particle swarm optimisation algorithm initial coverage results.

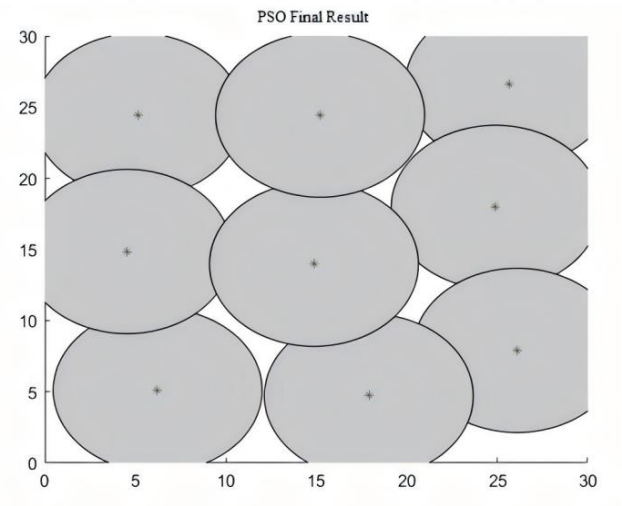

Fig. 18. Optimised 2D coverage map.

Adaptive inertia weights and asymmetric learning factors are chosen to improve the particle swarm algorithm, after the improved particle swarm algorithm is optimised, the coverage nodes are improved compared to the initial scene, by discrete two-dimensional plane with a step size of 0.1, a total of 96,100 discrete points are obtained, and the lighting of the original scene is covered by 86,736, with a coverage rate of 0.903, in which the priority lighting area has a discrete point of 900, of which 900 are covered with a coverage rate of 1. The optimised coverage rate is higher, and at the same time, the UAV positions all satisfy the constraints by not being inside the obstacles, of which the illumination coverage area in the 2D plane is shown in Fig. 18, and the iterative process is shown in Fig. 19. Compared with the simulation experiment without obstacles and priority lighting area, this chapter uses the actual spatial scene for modelling, and the optimisation effect is more realistic. According to the comparison of parameters before and after optimisation, the algorithm is highly effective and adapted to the constraints in emergency rescue, which has a certain degree of universality and can be used in actual rescue with good practical application value.

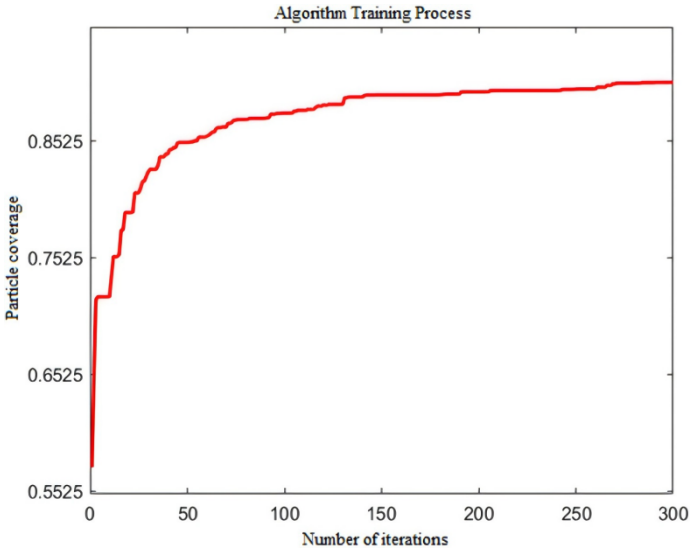

Fig. 19. Algorithmic optimisation process.

C. Effectiveness of the Algorithm

The effectiveness of the improved Particle Swarm Optimization (PSO) algorithm is evident in both the enhanced coverage rate and the optimized UAV deployment strategy.

In the initial UAV layout, the overall coverage rate was 60.9%, with only 44.4% coverage in the priority lighting area. These figures clearly show the inefficiency of the initial deployment, which failed to adequately illuminate critical regions, leaving large portions of the rescue area under-illuminated or overlapping in coverage. After applying the improved PSO algorithm, the overall coverage rate increased significantly to 90.3%, while the priority lighting area achieved a full 100% coverage. This drastic improvement highlights the algorithm's capability to optimize UAV positions effectively, ensuring that crucial rescue areas receive sufficient illumination. This result is crucial for real-world emergency scenarios, where effective lighting directly impacts rescue operations and safety.

The improved PSO algorithm demonstrates superior efficiency in comparison to traditional optimization methods. The adaptive inertia weights allow the algorithm to balance global exploration and local exploitation, preventing premature convergence to suboptimal solutions. Furthermore, the asymmetric learning factors contribute to faster convergence and more accurate UAV positioning, even in complex three-dimensional environments. This is evident from the faster convergence of the algorithm during the simulations, where it reached optimal coverage after fewer iterations compared to traditional methods. For example, in the simulation with 9 UAVs and a step size of 0.1, the optimized algorithm achieved 90.3% coverage with 96,100 discrete points, covering 86,736 points in total. This high coverage, along with improved UAV positioning, ensures that the UAVs avoid obstacles and maximize the effective lighting area.

VI. Conclusion

Collaborative lighting systems involving multiple UAVs can significantly improve the efficiency of accident rescue and

serve as a foundation for informed decision-making during on-site command. The method presented in this study offers an efficient and dependable layout solution for multi-UAV collaborative lighting systems in emergency rescue and related domains. Our research constructs a three-dimensional coverage model of the lighting area based on real-world conditions and addresses the three-dimensional coverage demands of multi-UAV collaborative lighting systems in emergency rescue.

We evaluate the performance of the particle swarm algorithm using various enhancement methods. Adjusting the inertia weights to decrease linearly and modifying the learning factor compression can improve the optimization process, thereby mitigating the particle swarm optimization algorithm's tendency to converge to local optima. This ensures both the speed and accuracy of convergence. Case study results demonstrate that the enhanced particle swarm algorithm effectively optimizes the layout of the multi-UAV lighting system, considering UAV position and coverage area. It guarantees a priority lighting area coverage rate exceeding 90% while ensuring overall lighting coverage.

This study has certain limitations. Firstly, we assumed static UAV positions throughout the operation, without considering dynamic path planning. In real-world emergency scenarios, dynamic factors such as moving obstacles and the need for real-time adjustments to UAV paths may arise, which our current model does not account for. Secondly, the optimization problem addressed in this study is single-objective, focusing solely on maximizing coverage. Important factors such as energy consumption, response time, and the trade-offs between these variables were not incorporated into the model. These assumptions may limit the applicability of the proposed algorithm in more complex rescue scenarios where multiple objectives must be considered simultaneously.

Future research will focus on addressing these limitations. We plan to extend the current model into a multi-objective optimization framework, integrating considerations of energy efficiency, response time, and dynamic path planning. Additionally, the algorithm will be tested in more challenging environments, such as those with dynamic obstacles and changing mission parameters, to validate its robustness and adaptability. Such enhancements will bring the model closer to practical application in real-world emergency rescue missions, where multiple factors influence the success and efficiency of UAV-based lighting systems.

***Abstract*—Indoor air quality (IAQ) in universities is of concern because it directly affects students' health and performance. This study presents an IoT-based system for real-time monitoring of IAQ in university classrooms. The system uses MQ-7 and MQ-135 sensors to monitor CO and CO2 pollution parameters. The data is then processed by the ESP32 microcontroller, displayed on the LCD screen, and responded to immediately in the mobile application. The system's real-time monitoring capabilities, data display, and alert mechanism provide valuable insights to improve the classroom environment. The sensors used in the system achieved an accuracy of 97.17% for five people and 93.96% for ten people's scenarios. This study investigates the relationship between human behavior, classroom activities, and occupancy impacts the IAQ. The results show a strong positive correlation between occupancy rates and CO2 levels, indicating the importance of ventilation in densely populated classrooms. The correlation coefficient between the number of students and the CO2 levels is 0.982. This coefficient is remarkably close to 1, indicating a strong positive correlation. In other words, as the number of students in the classroom increases, the CO2 levels also increase significantly. The high correlation coefficient suggests a direct relationship between the number of students and the CO2 levels. This IoT-based system will facilitate a data-driven approach to improving indoor environmental conditions, supporting healthier and more effective learning environments in educational institutions.**

I. INTRODUCTION

Indoor air quality is a concern for researchers, especially regarding health. Human activities much more cause air pollution. Industrial gases and vehicle emissions in urban areas are the primary sources of pollutants. Indoor air pollution is a significant health problem because indoor pollutant levels can be 10 to 100 times higher than outdoors [1]. The many sources of hazardous pollutants indoors are risk factors for human health. Common indoor pollutants include particulates, volatile organic compounds, chemical gases, heavy metals, and biological contaminants. The negative impacts of this air pollution are hazardous to human health. This includes the risk of stroke, lung cancer, heart disease, asthma, eye irritation, nasal irritation, and various other diseases [2]. This air pollution has a similar impact to smoking tobacco. From several studies, it is now known that sources of emissions from building materials, furniture, and consumer goods, as well as from the combustion process, are sources of hazardous pollutants in indoor air [3]. Children and women are much more vulnerable because they spend more time indoors. Indoor air quality, especially in cooking areas, can be a source of incomplete combustion. This condition releases toxic gases such as carbon monoxide. Therefore, mitigation is significant to improve indoor air quality. Improving indoor air quality requires various adjustment processes. Avoiding cigarette smoke, using proper ventilation, and choosing low-emission building materials improve indoor air quality [4]. Indoor air pollution in many developing countries has a higher risk than in developed countries. This is mainly due to the combustion of fuels widely used in developing countries. This pollution, therefore, poses significant health risks. Thus, this condition requires more serious mitigation to improve public health in the region [5].

Indoor air quality problems also occur on campuses or colleges. Research on indoor air quality on campus reveals high levels of air pollution. Indoor environmental conditions, such as schools, can have higher levels of pollutants than outdoors. Classrooms and laboratories in various campus environments have poor air quality. The concentration of carbon dioxide (CO2) in classrooms, libraries, and student cafeterias can exceed the standard of 1000 ppm, according from research results conducted by [6], [7]. The increase in carbon dioxide concentration was also followed by high levels of total volatile organic compounds (TVOC) in several locations. Various initiatives are needed to increase campus community awareness of indoor air quality. Monitoring of air quality parameters such as CO and CO2 can be done to raise environmental awareness in educational institutions [8].

The classroom with high pollution will ultimately affect students' health in the long term [9]. Indoor air quality (IAQ) significantly affects university students' satisfaction, study engagement, and cognitive performance. The study found that variations in CO2 levels and other IAQ parameters correlated with students' engagement and memory performance. Poor IAQ conditions can lead to dissatisfaction and reduced cognitive function, ultimately impacting academic performance

[10]. Research by [11] shows the impact of indoor microbial activity on human health. Ventilation systems and clean living habits can reduce indoor pollution levels. The campus building zone or location significantly impacts indoor air quality in campus buildings. Studies [12] and [13] concluded that campus building zones located in places with high pollutant sources can potentially affect the health and performance of occupants.

Other studies, such as those conducted by [14], evaluated indoor air quality in laboratories and classrooms at the Coimbra Health School. The results found that several indoor pollutants exceeded the limits. Students spend a lot of time indoors at school, so their exposure to air pollutants will be affected. However, other studies have also revealed that students and other people are significant sources of indoor pollution in university classrooms. Devices such as computers do not contribute significantly as pollutants [15]. Occupants in schoolrooms affect indoor air quality through respiratory and skin emissions [16]. Considering the above conditions, monitoring and action are needed to improve air quality on campus. Further studies reveal poor indoor air quality in higher education buildings in the UK. Air quality, especially in larger rooms with high occupancy, can be worse, which affects student comfort and performance. Ultimately, the potential health implications of poor indoor air quality can occur in students. Students can experience health conditions such as cough, throat irritation, headaches, eye irritation, and respiratory problems [17], [18]. Ultimately, the study emphasizes the importance of maintaining good IAQ for overall productivity improvement [19], [20].

The above findings underline the need for indoor air quality monitoring. Mitigation measures can be carried out through continuous monitoring and adequate ventilation. Carrying out a monitoring process is expected to ensure healthy indoor air quality conditions for students and staff on university campuses. Monitoring parameters such as temperature, relative humidity, CO, CO2, and PM2.5 levels at various locations on campus needs to be carried out. This monitoring can help management identify campus areas with poor air quality. Knowing the air quality conditions at each location can be used to implement pollution control measures to improve indoor air quality [21]. Monitoring indoor air quality can be done using sensor technology and the internet. Continuous air quality monitoring in university classrooms can be carried out by installing monitoring devices. This policy can create a healthier indoor air quality environment for students, staff, and visitors. The work in [22] implemented a real-time indoor air quality monitoring system in campus classrooms. This study used Internet of Things (IoT)-based technology and Wireless Sensor Networks to detect pollutants such as CO2, dust, temperature, and humidity. Similar work by [23] presents an IoT system for real-time indoor air quality monitoring in a university environment. This system focuses on CO2, CO, and particulate matter pollutants. However, the relationship between room occupancy patterns and air quality is not studied. According to the condition mentioned earlier, conducting further research on indoor air quality is very important.

This research analyzes the relationship between the influence of human behavior, activities, and occupancy patterns on indoor air quality conditions. Furthermore, the results of this research can be used to develop policies to improve university indoor air quality. Excellent or healthy indoor air quality conditions will correlate to enhancing students' health and academic achievement. This research develops an Internet of Things (IoT)-based system for real-time monitoring of indoor environments within university classrooms. The primary objective is to observe and analyze indoor air quality parameters, including carbon monoxide (CO) and carbon dioxide (CO2) levels. These two air quality parameters are chosen since this parameter has a close relation with human occupancy and activities. The designed monitoring system will integrate multiple sensors to monitor air quality metrics. The notification of environmental conditions exceeding the safe limitation will trigger the alarm and be sent by internet to the mobile application. The data collected from monitoring air quality parameters is stored in the database. This research also investigates the relationship between human behavior, classroom activities, and occupancy patterns with indoor air quality. The results show how different factors, such as classroom size, activity intensity, and occupancy, affect indoor air quality parameters. The findings from this research are expected to contribute to policies. Therefore, classroom environments can be optimized for better air quality and occupant comfort. This IoT-based monitoring system provides a data-driven approach to improve indoor environmental conditions. Good indoor air quality can support healthier and more efficient learning environments in educational institutions. This paper is divided into several sections namely, introduction, literature and research framework, methodology, results and discussion and finally a conclusion.

II. Literature and Research Framework

A. Indoor Air Quality (IAQ)

Indoor air quality standards are set to ensure indoor air quality is free from harmful gases or particles above the threshold. Based on research, indoor pollutant levels can be higher than outdoor pollutants. This will certainly affect the health and satisfaction of occupants. Indoor air quality (IAQ) standards and limits are necessary to maintain human health in buildings. This is because long-term exposure to pollutants above the limit can have adverse effects on humans. However, consistent national and regional IAQ standard values have not yet been agreed upon. This lack of regulation has led to uneven IAQ assessments across countries [24], [25]. The World Health Organization (WHO) has established health-based guideline values for several indoor air pollutants. However, these values have not been universally adopted as legally binding standards across countries. This could be due to the complexity and global variability in IAQ regulations. Efforts are underway to develop comprehensive, science-based IAQ guidelines. A study by [26] The research highlights the limitations of indoor environmental quality standards. It also highlights gaps in the evidence supporting thermal, visual, and air quality requirements and urges critical assessment for better standards.

The standards for a healthy room include a temperature range of 18°C-28°C and humidity levels of 40%-60%. This is stated in the Decree of the Minister of Health of the Republic of Indonesia Number 1405/Menkes/SK/XI/2002, addressing

the Office and Industrial Work Environment Health requirements. The average concentration of carbon dioxide indoors is between 250 - 400 parts per million. The concentration of carbon dioxide between 2,000 - 5,000 ppm may affect human health in ways such as headaches, drowsiness, stagnant air, poor focus, an elevated heart rate, and minor nausea [27]. The impact of air quality on human health is also studied by research in [28], [29]. The thresholds for several air quality parameter are presented in Table I.

TABLE I. CRITERIA FOR CHEMICAL POLLUTANT THRESHOLDS

No#	Parameters	Unit	Requirements
1	Sulfur dioxide (SO2)	ppm	0,1 in 24 hour
2	Nitrogen dioxide (NO2)	ppm	0,04 in 24-hour
3	Carbon monoxide (CO)	ppm	9 in 8 hours
4	Carbon dioxide (CO2)	ppm	1000 in 8 hour
5	Lead (Pb)	mg/m3	1,5 in 15 minutes
6	Formaldehyde (HCHO)	ppm	0,1 in 30 minutes
7	Volatile organic compound (VOC)	(VOC)	3 in 8 hours
8	Environmental Tobacco Smoke (ETS)	mg/m3	35 in 24-hour

B. Monitoring Systems

An indoor air quality monitoring system is needed to evaluate and improve air quality within indoor environments. These systems assess air pollutants' conditions, including gases and particulate matter. The monitoring system is used to ensure a healthy and safe indoor environment. Typically, monitoring systems comprise several vital components. Pollutant sensors, data storage, and processing units are implemented into one system. These sensors detect and measure the concentration of air pollutants present. After measurement, the data is processed through a processing unit for storage in the database. Calibration integrates these monitoring systems to effectively and accurately detect pollutants. This brings in the need for calibration of the monitoring devices [30]. Calibration is the most essential step in maintaining the accuracy of sensor readings. The calibration step ensures that data collected for indoor air quality parameters reflects the environmental conditions. Recently, indoor air quality monitoring systems have become so advanced that their capabilities have increased manifold in several prospects [31]. The modern architecture of these monitoring systems integrates wide-area networks, servers, and client devices. This architecture provides extensive and real-time indoor air quality data monitoring and analysis. Such networked architecture allows for the gathering and aggregating data from many sensors and geographic locations. Comprehensive data gives a general view of indoor air conditions. Integrating sensors for such gases as CO and CO2 makes an advanced system able to provide exact and detailed measurements. Real-time air quality monitoring notifies us about changes in air quality in time. Therefore, these results allow immediate corrective actions. Advanced monitoring systems will be able to supply more detailed and accurate data in a timely way to support effective management and control of indoor air quality parameters. Thus, they will contribute toward healthier and more comfortable indoor environments in the long run [32].

III. METHOD

Fig. 1 depicts the proposed design architecture for the IAQ monitoring system in university classrooms. This system consists of three parts: an input block, a processing block, and an output block. The input block utilizes the MQ7 sensor to detect carbon monoxide (CO) and the MQ135 sensor to detect carbon dioxide (CO2). These sensors monitor the air quality parameters in the classroom in real time. The collected data is then transferred to the microcontroller for processing in the processing block. In the processing part, the data is handled by the ESP32, which acts as a microprocessor. The processed data determines the commands to be executed in the output block. A 5V power supply powers the ESP32.

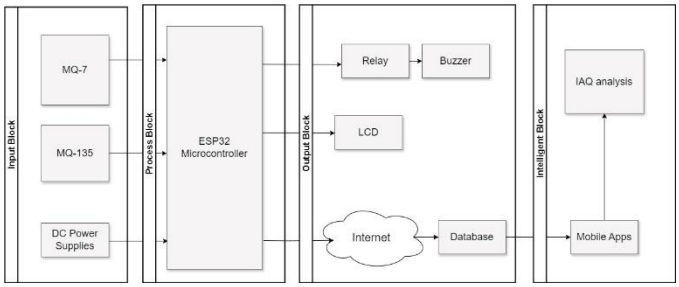

Fig. 1. Proposed system design.

The commands received in the output block trigger appropriate actions based on the processed data. The analysis data is displayed on a 16x2 LCD screen in the enclosure. The system monitors real-time gas levels on the LCD screen and mobile apps. The buzzer is activated when CO and CO2 levels exceed 250 ppm and 1000 ppm, respectively. The buzzer will stop operating when the gas level falls below these limits. This condition indicates that the air quality has returned to a safe level. Data on each sensor's air quality parameters will be stored in a centralized database. This ensures that data can be efficiently accessed and used for various purposes. A summary used by the system's embedded mobile application enables real-time visibility of air quality meters. Users can see their current carbon monoxide, carbon dioxide levels, or any components of interest on their smartphone application. This application offers an easy way to improve air quality comfortably. Besides real-time monitoring, this mobile application can issue warnings when CO2 or CO levels exceed any predetermined limit. These warnings ensure immediate interference to keep the air quality within safety boundaries. The information provided by the application's system contributes to quicker reactions in dangerous situations.

Two different test scenarios were used to gather detailed information. In the first scenario, there were five students in the classroom. In this experiment, CO and CO2 concentrations were recorded at five separate measurements to ensure the accuracy and reliability of the data. This scenario provides the first understanding of how low occupancy rates affect indoor air quality. In the second scenario, there were ten students in the same classroom. Measurements were repeated five times under these conditions to assess the effect of increased

Higher Education for Technology and Innovation (HETI) Project

occupancy on CO and CO2 concentrations. This scenario illustrates the impact of occupancy rates on air quality, particularly regarding CO2 levels.

That is why this monitoring system enhances proficiency in managing indoor air quality. Indoor air quality data was collected and used as a dataset. This enhances, in general, the capability to analyze more and adds value to the monitoring system. The system puts forth a proactive approach toward air quality management. The system is holistic indoor air quality monitoring, highly technological, collecting data, monitoring it in real-time, warning per system deployed, and analysis. This system immediately provides feedback and uses advanced technology to furnish valuable insights and predictions.

IV. Results and Discussions

A. Hardware Implementation

The primary component that sense the air quality parameter include MQ-7 and MQ-135 sensors. Other components are an ESP32 microcontroller, LCD, buzzer, LED indicator, mobile application, and power supply. In this work, an ESP32 microcontroller was chosen due to several GPIO pin arrays for multi-function operations and WiFi connectivity. These modules provide both speed and internet support for system operations and communications. MQ7 and MQ-135 sensors measure CO and CO2, respectively. LCDs instantly read these sensors in real-time to give direct access to the current air quality status. Also, a buzzer is attached to the device as an audible warning system to inform the user if the levels of gases exceed the usually pre-set safety limits. A feature like this would enable the system to monitor the gas level remotely using the mobile application. The setting updates the user with real-time information and contextual air quality status. Thus, users can respond immediately if there is any potential air quality problem inside the classroom. The hardware wiring implementation of the device is shown in Fig. 2, which shows the configuration and integration of these components throughout the system design.

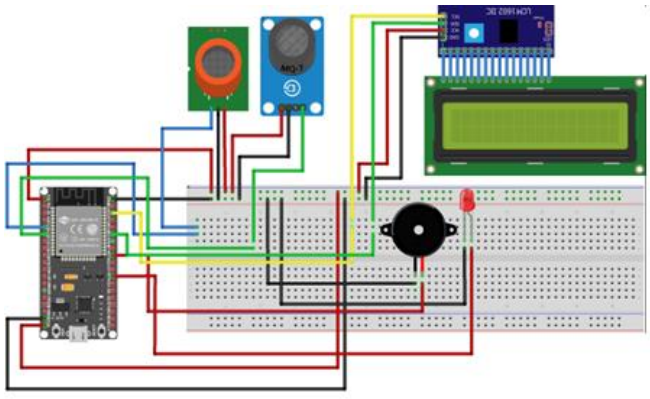

Fig. 2. Hardware wiring implementation.

Fig. 3 depicts the monitoring box implementation. The monitoring system being developed in this study consists of a 9 cm x 15 cm x 10 cm box. The indoor health monitoring system is designed to measure carbon monoxide (CO) with the MQ-7 sensor and carbon dioxide (CO2) concentration with the MQ-135 sensor. This system is integrated with an internet connection and allows real-time data transfer to mobile application users. The Internet and mobile applications enable users to monitor air quality and remotely receive alerts on dangerous levels.

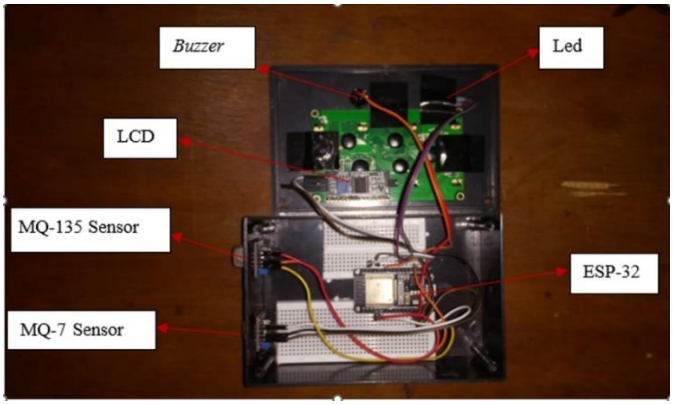

Fig. 3. IAQ hardware implementation.

B. Calibration Process

Once the entire device is assembled, all components are tested and calibrated to produce more accurate results. The method used is linear regression, a statistical technique for comparing sensor outputs with linear characteristics against standard values. In this case, calibration will be performed for the MQ-135 and MQ-7 sensor system readings. The reference instruments are the AZ7752 Instrument and Portable Gas Leak Detector BH-90E. These two devices were chosen as calibrators since they have more accurate results than the low-cost sensors used in this monitoring box. The data resulting from the system calibration are presented in Tables II and III.

TABLE II. MQ-135 Sensors Measurement Process

No.	Calibrator	MQ-135	% error	% accuracy
1	202	203.2	0.59	99.41
2	203	203.2	0.098	99.9
3	204	203.95	0.024	99.98
4	204	204.46	0.22	99.78
5	204	205.3	0.63	99.37
6	204	211.2	3.52	96.48
Average	203.5	205.22	0.847	99.15

TABLE III. MQ-7 Sensors Measurement Process

No.	Calibrator	MQ-7	% error	% accuracy
1	218	216	0.91	99,09
2	218	219	0.45	99.55
3	209	194	7,17	92.83
4	207	193	6.76	93.24
5	208	195	6.25	93.75
6	210	197	6.19	93.81
Average	211.6	202.3	4.62	95.37

The next process is performed using linear regression with Eq. (1). The Y represents the value obtained from the reference instruments Az 7752 and BH-90E as calibrators, and the X denotes the design device sensors' output value.

$$Y = a + bX \quad (1)$$

Fig. 4 and Fig. 5 show the correlation calculation between the readings from the designed device and the reference instrument or calibrators using the linear regression equation.

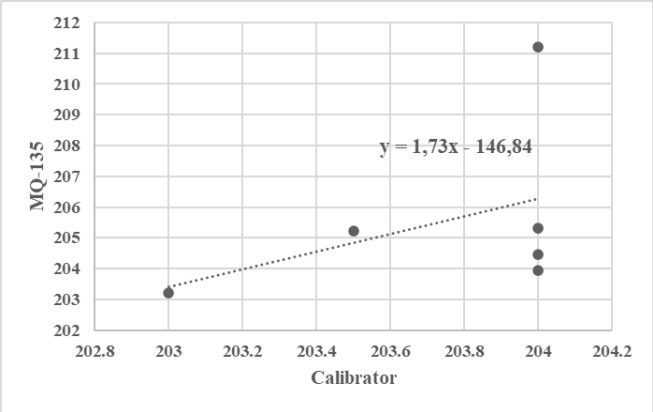

Fig. 4. MQ-135 linear regression graph.

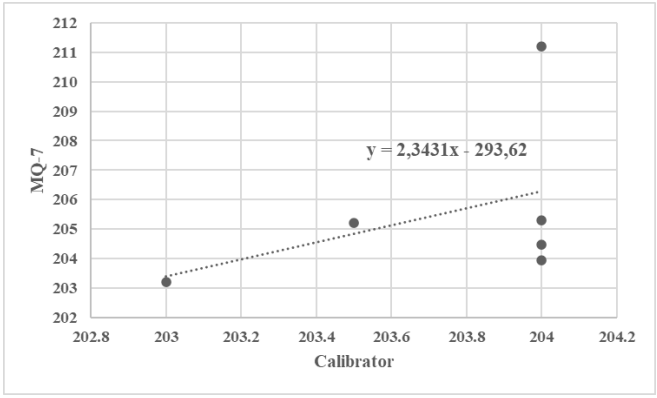

Fig. 5. MQ-7 Linear regression graph.

The linear regression results for the MQ-135 sensor are represented by the equation y = 1.73x – 146.84, and for the MQ-7 sensor, y = 2.3431x – 293.62. These regression equations provide calibration adjustments to enhance the accuracy of the raw sensor readings. By implementing these equations into the source code, the sensors' measurements can be corrected in real-time. This setting allows the system to compensate for any inaccuracies inherent in low-cost sensors. Consequently, the monitoring box that relies on low-cost sensors can deliver more precise and reliable air quality data.

TABLE IV. IAQ TESTING RESULTS

No	number of students	CO		CO2		% error CO2	% accuracy CO2	Notification	
		Sensor	Calibrator	Sensor	Calibrator			Buzzer	Apps

C. Discussion

The testing results include a range of air quality measurements, including information on the number of students attending classes, carbon monoxide (CO) levels, carbon dioxide (CO2), and monitoring equipment. The CO2 parameters can increase dramatically due to increased human activity and respiration. Results from both scenarios are considerably detailed in Table IV. By comparing the data from these two scenarios, insights can be gained into how occupancy rates affect indoor air quality, particularly CO2 levels. Since CO concentration from the sensor and calibrator shows the exact measurement, the calculation of error and accuracy is not done for the CO. According to Table IV, the average accuracy of CO2 level is 95.57%, with an error of 4.43%.

The average values acquired from this measurement under two scenarios are summarized in Table V. The first scenario was performed on a workday with five college students in a 7 x 7-meter room. The average carbon dioxide (CO2) measurement was 212.23 ppm, with carbon monoxide (CO) degrees measured at zero ppm. The average CO2 concentration in this condition was relatively low, which can be attributed to the confined wide variety of occupants in the given area. In the second stage of experiments, with the room occupied with the aid of ten people, the CO2 awareness increased to an average of 259.98 ppm. This rise in CO2 stages is prompted by numerous factors, including elevated occupants, the room's dimensions, and insufficient air stream inside the area.

TABLE V. AVERAGE IAQ TESTING RESULTS

No.	Condition	CO_2 (ppm)	% error	% accuracy
1.	Five people	212.23	2.83	97.17
2.	Ten people	259.98	5.12	93.96

The findings suggest that a 7 x 7-meter room, when occupied with the aid of 10-15 people for prolonged intervals, remains within a secure variety of air quality. This conclusion is supported by the records supplied in Table V, which show that CO2 ranges and other readings range with adjustments in occupancy. The environment remains possible in these situations.

We use the Pearson correlation formula in Eq. (2) to calculate the correlation coefficient between the number of students and the CO2 levels. According to the correlation analysis, the correlation coefficient is 0.982.

$$r = \frac{n(\sum xy) - (\sum x)(\sum y)}{\sqrt{[n\sum x^2 - (\sum x)^2][n\sum y^2 - (\sum y)^2]}} \quad (2)$$

This coefficient is remarkably close to 1, indicating a strong positive correlation. In other words, as the number of students in the classroom increases, the CO2 levels also increase significantly. The high correlation coefficient suggests a direct relationship between the number of students and the CO2 levels. This is expected because humans exhale CO2, and in a closed environment like a classroom, higher occupancy will naturally lead to higher CO2 concentrations. Elevated CO2 levels can impact cognitive function and overall comfort. Indoor CO2 concentrations should be below 1000 ppm to ensure a healthy and productive environment. The data indicates that classrooms with more students will likely have higher CO2 levels. This is potentially exceeding recommended limits if not correctly managed. The strong correlation highlights the importance of adequate ventilation systems in classrooms. Schools should ensure sufficient ventilation rates to maintain CO2 levels within safe limits, particularly in densely occupied classrooms.

The sample size of air quality and the number of classrooms may constrain this study's findings. This is due to limited resources and time for air quality data collection, which may not be feasible. In the future, this indoor air quality monitoring box can be enhanced by adding more sensors to measure different air quality parameters, such as temperature, humidity, and particulate matter. Since the electronic components and sensors are low-cost, the device can be produced in larger quantities for use in other classrooms. All monitoring devices may store the data in the cloud-based database. Although several studies have implemented the idea of monitoring devices. The work in study [33] and study [34] already studied and enabled comprehensive indoor air quality monitoring in classrooms. The work uses a network of intelligent IoT sensors. It may continuously track parameters such as indoor/outdoor temperatures, relative humidity, and CO2 levels, facilitating centralized control of natural ventilation. However, the idea can be extended by using machine learning to analyze the classroom occupancy level and the air quality index. Therefore, the system allows for real-time data processing that is essential for assessing infection risks and optimizing air quality.

V. CONCLUSION

This paper aims to design and test an IoT-based IAQ monitoring system in a university classroom. The monitoring device allows for real-time monitoring of carbon monoxide (CO) and carbon dioxide (CO2) levels. Real-time monitoring, data display, and warnings signaled by the system are important to improve the classroom environment. Accordingly, the system achieved accuracy in sensing at a rate of 97.17% for five people and 93.96% for ten people's scenarios. The Pearson correlation formula compares the number of people's occupancy and the classroom. The Pearson correlation coefficient between the number of students with CO2 levels was 0.982. This result is close to 1, which recommends a strong positive correlation. That is, with increasing numbers of students within the classroom, drastically increasing levels of CO2 are realized. The high correlation coefficient suggests the increased number of students and CO2 levels correspondingly. Continuous monitoring of IAQ and effective ventilation techniques are essential for maintaining a healthy indoor environment in university classrooms. Further research is required to establish how other environmental parameters can be studied across various indoor environments. Another advanced research can integrate sensed pollution data into machine learning for predictive analytics for these IAQ parameters.

ACKNOWLEDGMENT

***Abstract*—Semi-supervised clustering with pairwise constraints has been a hot topic among researchers and experts. However, the problem becomes quite difficult to manage using random constraints for clustering data when the clusters have different shapes, densities, and sizes. This research proposes an active semi-supervised density-based clustering algorithm, termed "ASS-DBSCAN," designed specifically for clustering multi-density data. By integrating active learning and semi-supervised techniques, ASS-DBSCAN enhances traditional clustering methods, allowing it to handle complex data distributions with varying densities more effectively. This research provides two major contributions. The first contribution of this research is to analyze how to link constraints (including that must be linked and ones that should not be linked) that will be utilized by the clustering algorithm. The second contribution made by this research is the ability to add multiple density levels to the dataset. We perform experiments over real datasets. The ASS-DBSCAN algorithm was evaluated against existing state-of-the-art system for various evaluation metrics in which it performed remarkably well.**

***Keywords*—Semi-supervised clustering; pairwise constraints; multi-density data; active learning**

I. Introduction

In data mining, clustering algorithms are used to divide data into multiple groups based on selected similarity metrics [1]. The rate at which Web data is increasing also called Big Data, clustering algorithms are expected to death with 1) scalability, 2) noise, 3) multidimensional data, 4) discovering clusters with arbitrary shapes, and 5) least dependency of domain knowledge to establish input parameters [2].

Clustering algorithms are categorized into several categories based on the requirements of the problem given. This includes 1) Partitional, 2) grid-based, 3) hierarchical and 4) density-based clustering algorithms [3]. From the list, density-based are suitable for finding clusters based on their unique size and shape. It does this by focusing on the density of the clusters in the region as opposed to clusters falling where the density is low [4-7].

The DBSCAN algorithm is one of the most popular used techniques in relation to this category of clustering algorithms that carries forward all advantages of density-based clustering family [8]. It works by calculating the total number of points (called *Eps*) around the point in a region. Points having density above the specified threshold value (called *MinPts*) are referred to as Core points, while others that do not meet these criteria are referred to as Noise points [9].

While this clustering technique is able to identify cluster regions having different shapes or sizes, it cannot handle data that contains clusters having points with different densities. This technique is only able to identify them as a cluster if the points are separated by sparse regions.

For example, Fig. 1(a) shows the dataset contains two cluster groups, sparse cluster C_1 (red points) and dense cluster C_2 (green points), and noise data (black points). When using large *Eps*-distance, DBSCAN algorithm can find a sparse cluster successfully. However, as shown in Fig. 1(b), the algorithm merges the dense cluster with the adjacent noise points. While using small *Eps*-distance, as shown in Fig. 1(c), the DBSCAN algorithm can assist in finding dense cluster C_2. On the other hand, it incorrectly marks the sparse clusters are noise points instead due to the core object condition. As a result of its reliance on set global parameters, DBSCAN is unable to discover clusters with variable densities.

Moreover, most existing density-based algorithms are unsupervised learning methods that can't utilise the available label information such as background knowledge [10] [11]. However, semi-supervised clustering algorithms can be considered as they utilize existing knowledge to enhance the clustering process. However, if these constraints are improperly selected the clustering performance will be affected [12]. Active learning was originally proposed to select the most important labeled data to generate pairwise constraints. However, most of the data in real-world applications is unlabeled [13-15].

To address the issue highlighted above, this is an enhanced version of DBSCAN algorithm that follows an active semi-supervised clustering approach. This new algorithm is named as ASS-DBSCAN which is capable of clustering multi-density data with active pairwise constraints. By quantitively analyzing the data using statistical techniques, the research was able to split the dataset into various density groups. Then, generate a set of active pairwise constrints from existing groups and compute their *Eps*. Finally, expand the clusters using selected active pairwise constraints.

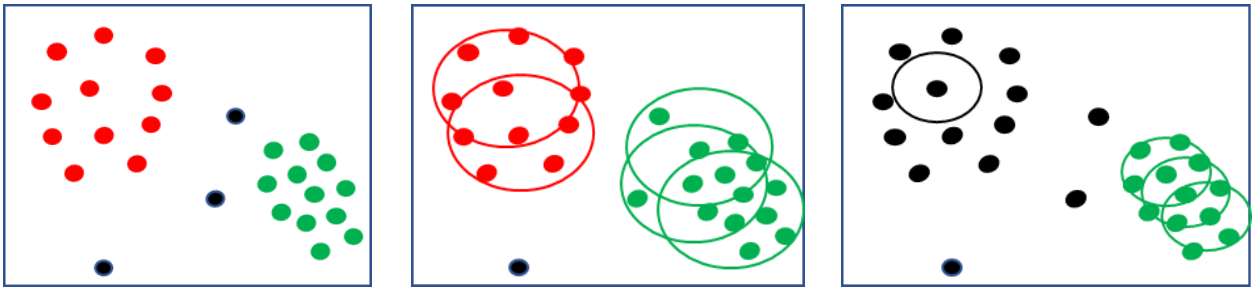

Fig. 1. Finding clusters using the DBSCAN algorithm from multi-density data (MinPt s = 5).

The paper is organized as follows. In Section II, existing literature on the given research is highlighted and critically discussed. In Section III, the research discusses the proposed algorithm and its working. In Section IV, the dataset and evaluation metrics are briefly discussed before highlighting the results of the search and its comparison to existing state-of-the-art systems. In Section V, the research is concluded along with directions for future research.

II. Related Work

In this section, existing literature on clustering machine learning algorithms is reviewed. Since the scope of this research is limited towards density-based algorithms thus it will focus on that as well as active learning methods.

In a study by Ankerst et al., an algorithm named OPTICS was proposed for the sole purpose of clustering analysis [1]. This algorithm generates two key parameters for clustering multi-density data including 1) core distance and 2) reachability. This additional information is added to the dataset to enable other algorithms to use the information for performing density-based clustering. The evaluation results showed that the algorithm was more efficient using these newly generated parameters over using existing information given in the dataset.

In another research, authors presented a clustering algorithm named DBSCAN, which is capable of finding clusters having various shapes as well as considering multiple densities [8]. However, DBSCAN algorithm faces limitation in finding clusters as they are reliant on *Eps* and *MinPts* parameters, where these values are incorrectly applied. The two studies by Jahirabadkar et al. and Liu et al. also utilize k-nearest neighbor of all selected objects so as to get the density for a given dataset. The authors further utilize various *Eps* values for sparse and dense clusters [2-3].

To address the issue of finding clusters using a dataset containing high dimensional data in distinct sizes, shapes, and density, Ertoz et al. suggested to check the points in the neighborhood of the clusters and use that information to check the similarity between the points [5]. Using this, the algorithm is able to define clusters using the defined points for those regions.

With the aim of detecting clusters that may have a unique shape or size, Liu et al. provided a variant of the DBSCAN algorithm. This algorithm as named as Entropy and Probability Distribution (EPDCA) [9]. The evaluation results conducted on benchmark datasets for the EPDCA algorithm show improved performance over other algorithms that were evaluated on the same dataset. This work was improved further by providing an optimized combinatorial clustering algorithm specifically designed for noisy performance. This algorithm is vital, particularly for data that is large with random sampling [16]. The result shows that the proposed clustering algorithm outperformance various traditional approaches that are compared with.

Kim et al. improved their work further by proposing an approximate adaptive AA-DBSCAN algorithm. This algorithm improved efficiency by reducing the time taken to calculate the parameters required to find clusters having multiple density points. The algorithm uses a density layer tree to distinguish between sparse and dense regions [10]. Kim et al. enhanced AA-DBSCAN further with *k*AA-DBSCAN that uses k^{th} nearest neighbors technique. The newer algorithm showed improvement in approximating the Eps distance but requires a longer running time [10].

In another research, authors proposed the GCMDDBSCAN algorithm, which is based on the DBSCAN algorithm. The authors proposed this algorithm to allow better performance when dealing with large databases [11]. The evaluation results showed improved performance on large databases over other algorithms evaluated on the same databases.

Constraint-based algorithms have emerged as extensions to traditional unsupervised clustering algorithms [17-19]. These methods incorporate constraints into the clustering process to enhance the learning of similarity metrics. Recently, several constraint-based clustering algorithms have been developed. For instance, Ruiz et al. introduced a pairwise-constrained clustering technique called C-DBSCAN, which leverages pairwise restrictions to enhance clustering accuracy [17]. The algorithm does this by determining the points that should be linked and the ones that should be avoided. This allows the algorithm to form clusters having unique shapes and sizes using the available constraints. In another study, a semi-supervised clustering algorithm (SSDBSCAN) is proposed that uses information provided in the dataset for evaluating density parameters [18]. The evaluation results showed better performance in comparison to other algorithms. However, SSDBSCAN can only be applied on smaller datasets.

Active learning in supervised machine learning has been a topic of interest for several decades when it comes to solving classification problems [20-22]. However, active learning for

clustering has acquired significant attention in recent years as it enhances the efficiency and accuracy of unsupervised learning algorithms [23]. Researchers have integrated active learning methods with different clustering algorithms. Active learning methods focused on uncertainty sampling, querying data points near cluster boundaries or with high uncertainty to improve cluster performance. Recently active semi-supervised clustering uses pairwise constraints to improve the clustering performance, especially for noisy, unbalanced or high-dimensional data. Thus, active learning methods can enhance clustering performance while reducing labeling costs [24-26].

III. ASS-DBSCAN ALGORITHM

This section covers ASS-DBSCAN that can rapidly and efficiently identify clusters for multi-density data having different shapes and sizes, with the knowledge of dealing with points that do not fall within the cluster. This algorithm comprises two main steps. 1) Partitioning dataset: divide the dataset into multiple density levels and generate pairwise constraints for linking and not linking points 2) Clusters are formed from the pairwise constraint information generated in step 1.

A. Generating Density levels

Let us suppose, that $X = \{x_1, x_2, \ldots, x_n\}$ represent data points where the i-th point can show nominated as $x_i = \{x_{i1}, x_{i2}, \ldots, x_{im}\}$. We start by computing the local density function for each data point. As described in Eq. (1), the local density is calculated by summing the distances between a point and its nearest neighbors. Next, the data points are ranked in descending order according to their local density values. This will allow the algorithm to calculate the difference in density between the point and its adjacent point x_i and x_{i+1} denoted by *DENVAR* (x_i, x_{i+1}) as described in Eq. (3).

$$DEN(x) = \sum_{i=1}^{k} D(x, y_i) \quad (1)$$

$$D(x, y_i) = \sqrt{\sum_{j=1}^{m} (x_j - y_j)^2} \quad (2)$$

Here $D(x, y_i)$ shows the Euclidean distance between point x and its k-nearest neighbors y_i.

$$DENVAR(x_i, x_{i+1}) = \frac{|DEN(x_{i+1}) - DEN(x_i)|}{DEN(x_i)} \quad (3)$$

After getting the density variation between data points we will notice that the variation for points that are within the proximity of the density is small and there is some distinct variation between the different densities. Thus, all density level sets (*DLS*) are collected by computing the unique density variations.

To simplify the explanation of our algorithm, we provide an example using a dataset that contains four clusters with varying densities, as explained in Fig. 2(a). We compute the density for each point of this dataset and sort them in descending order to get the results in Fig. 2(b). Fig. 2(b) contains four relatively smooth lines which accordingly represent four density levels and some sharp dips. After computing distinct variation, it can be seen that the smooth lines and sharp waves in Fig. 2(b) correspond to the density level sets and sharp change of two density levels that is highlighted in Fig. 2(c) respectively.

Each smooth line needs to be extracted to acquire the density level for that set. This can be achieved by using a density variation threshold τ. This can allow a dataset having multi-density data to be converted into a dataset containing multiple density level sets. Each Density level set should have data points with approximate densities. Points x_i and x_j are considered to be in the same density level set if the following criteria is met:

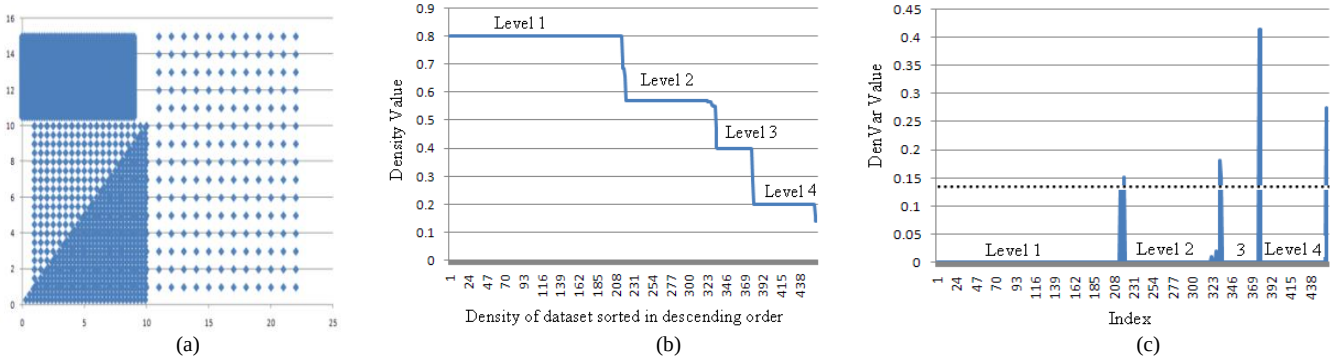
$$x_i, x_j \in DLS \quad if\ DENVAR(x_i, x_j) \leq \tau \quad (4)$$

The τ is calculated using the density variation values (*DVList*) as follows:

$$\tau = E(DVList) + \sigma(DVList)$$

where, σ is standard deviation of *DVList* and E is the mathematical expectation.

DVList values indicate that there are only a handful of points that have large DENVAR values. These points can be used to divide the dataset and transform into one having multiple density levels set.



(a) (b) (c)

Fig. 2. Density and density variation for multi-density dataset.

After splitting the dataset into various density level sets, we generate a set pairwise constraints for performing clustering. The points that must be linked should be picked from the same density level and vice-versa Thus, we need to select the most informative objects from each density level set which have the highest neighborhood density. Now, we can generate a set of not to be linked constraints between the selected objects from different density level sets. Also, generate a set of constraints

for the points that must be linked between the most informative objects and their *k*-nearest neighbors objects in the same density level set. We summarize our strategy for selecting active pairwise constraints in Algorithm 1.

Algorithm 1. Active Pairwise Constraints

1. Initialization: $N_1 = \{x\}$, where x is a random point in X; $N = N_1$; $l = 1$; $q = 0$;
2. **while** $q<Q$
3. Select the most informative point x^* with the highest neighborhood density.
4. **for** each neighborhood $N_i \in N$
5. Query x^* against any data point $x_i \in N_i$;
6. q++;
7. **if** a must-link established between x^* and x_i
8. Add x^* to neighborhood N_i;
9. **end if**
10. **end for**
11. **if** no must-link is achieved
12. Add cannot-link between x^* and all points in $\{N_i\}_{i=1}^{l}$;
13. l++; create new neighborhood $N_l = \{ x^*\}$; $N = N \cup N_l$
14. **end if**
15. **end while**
16. **return** set of active pairwise constraints

First, we select point having the most information, which has highest neighborhood density and query it against the points in each neighborhood. If a point is returned that must be linked, then this operation needs to be performed again. This process is repeated until a must does not link point is returned.

We can generate more constraints using the transitive closure between the objects in pairwise constraints. For example, if we have must-link between the two objects x_i and x_j and must-link between the two objects x_i and x_k, then we get must-link between the two objects x_j and x_k. Also, if we have must-link between the two objects x_i and x_j and cannot-link between the two objects x_i and x_k, then we get cannot-link between the two objects x_j and x_k. The partitioning dataset into different density level sets and generating the pairwise constraints are presented in Algorithm 2.

Algorithm 2: Generating density level sets with pairwise constraints

1. Calculate the density function for every point in the dataset.
2. Sort the points based on their density in descending order.
3. Determine the density variation between each pair of consecutive data points.
4. Group the dataset into different Density Level Sets (*DLS*) based on the computed density variations.
5. Create a cannot-link constraint between data points in different density level;
6. **For** each density level set (DLS_i)
7. Call Active Pairwise Constraints algorithm.

B. Expanding Clusters

When the *Eps* value is the same, clusters with different densities cannot be found. For every density level set, the *Eps* the value is approximated. The associated *Eps* for a particular density level set (*DLS*) can be boosted by setting the maximum *DEN* value. Some of the points selected may be classified as border objects or noise, which could affect the *Eps* value. Therefore, this issue is resolved by calculating Eps_i for DLS_i as follows:

$$Eps_i = \mathrm{max}DEN(DLS_i) \cdot \sqrt{\frac{medianDEN(DLS_i)}{meanDEN(DLS_i)}} \qquad (5)$$

where, meanDEN, medianDEN and maxDEN, are the mean, median and maximum density of DLS_i respectively.

Now, we explain an example to demonstrate the effect of the proposed algorithm on a dataset with different densities. First, we assume that the parameter MinPts = 5 and compute the parameter Eps for each density according to Eq. (5). Next, as shown in Fig. 3(a), we have two different densities and set of noise points. Thus, we have two values for the Eps parameter (1.7 and 0.9) for the sparse and dense density respectively as shown in Fig. 3(b) and Fig. 3(c).

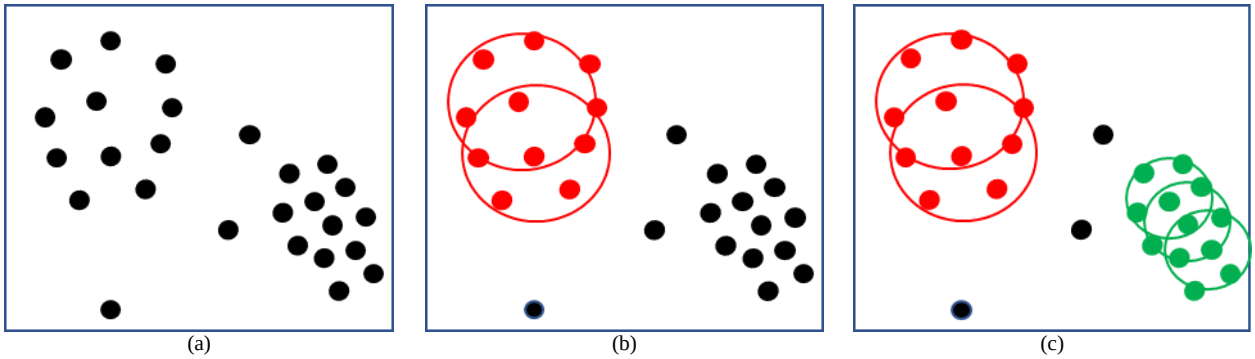
With density levels partitioning and parameters estimation done, pairwise constraints are used for each density level cluster to increase the cluster size if necessary as shown in Algorithm 3:

Algorithm 3. ASS-DBSCAN

1. Partitioning the dataset and generating pairwise constraints using algorithm 1;
2. **For** each density level set (DLS_i)
3. Estimate the parameter Eps_i ;
4. Initialize all data points in DLS_i as *UNCLUSTERED*;
5. *ClusterNum* = 0;
6. **For** each $x \in DLS_i$
7. **If** data *x not CLUSTERED* then
   Count the number of data points in *x's Eps*-neighborhood;
   a. **If** the number of data points in *neighborhood* < *MinPts*
      add x to NOISE set;
      Else
      Add x to the current cluster ClusterNum;
   b. **If** there are must-link constraints between *x* and *y*
      For each point *y* in *ML*(*x*, *y*)
      Add y to the current cluster ClusterNum;
   c. **For** each point *z* in neighborhood **do**
      If *z* is not C*LUSTERED* and does not violated cannot-link constraints then
      Add z to the current cluster ClusterNum;
8. *ClusterNum* = *ClusterNum* +1;
9. Return the set of clusters.

- In Step 7(a), after accurately estimating the *Eps* parameter, we proceed to compute the *Eps*-neighborhood for each unclustered point. We then compare the number of data points within this neighborhood to the specified *MinPts* parameter to decide regarding the classification of the data point as part of a cluster or as noise. If the count of points in the *Eps*-neighborhood is less than *MinPts*, we classify the data point as noise. Conversely, if the number of points meets or exceeds *MinPts*, we incorporate the data point into the current cluster, thereby refining the clustering process.

- In Step 7(b), we address the Must-link constraints. If a point has any Must-link constraints with other points, all of these points are assigned to the current cluster.



(a) (b) (c)

Fig. 3. Example of different *Eps* values with varying densities (MinPt s = 5).

- In Step 7(c), we consider the Cannot-link constraints. For each unclustered point within the current neighborhood that does not violate any Cannot-link constraints with the existing points in the current cluster, these points will also be included in the current cluster.

C. Time Complexity

This is divided into two parts. The first part is the time for dividing the dataset into different densities by calculating the density values. As per our calculations it leads to a time complexity of O($n$log$n$); the ordering of density values consumes O($n$log$n$); the other processes have the same runtime complexity of O(n). The second part is the time for expanding clusters, where the time required for a neighborhood query of a single object is O(n) and neighborhood query is is executed for every n points present in the dataset. The time of this part is O(m+n^2); where m is the number of pairwise constraints. However, using an index structure like R*-tree, minimize the time required for a neighborhood query of a single object to O($logn$). Thus the time required for this part is O($m + n\ log\ n$). The total runtime complexity of the proposed algorithm is O($m + n\ log\ n$).

IV. Experimental Results

This section evaluates the proposed algorithm against other baseline algorithms on a real dataset from the UCI repository. Each dataset was labeled with the number of data points, features, and cluster labels respectively as follows: Class (214,10,6), Ecoli (336,8,8), Ionosphere (351,34,2), Liver (345,6,2), Breast (683,9,2), Yeast (1484,8,10), Waveform (5000,21,3), Segment (2310,19,7) and Magic (19020,10,2). The evaluation of these algorithms is conducted using Normalized Mutual Information (*NMI*) as the clustering validation metric that is defined as follows:

$$NMI = \frac{I(X;Y)}{\big(H(X) + H(Y)\big)/2}$$

A. Clustering Performance

In this subsection, we explain the clustering performances of the algorithms C-DBSCAN, SSDBSCAN, AA-DBSCAN, and ASS-DBSCAN across the nine real-world datasets mentioned earlier. Table I presents the parameters values of each algorithm. As the parameter settings will be different according to each dataset, we employ a range of values for each parameter as detailed in Table I.

TABLE I. Parameters Values of Each Algorithm

Algorithm	Parameters
C-DBSCAN	*Eps* ∈ [0.1, 0.5] and *MinPts* ∈ {3, 4, . . . , 10}
SSDBSCAN	*Eps* ∈ [0.1, 0.5] and *MinPts* ∈ {3, 4, . . . , 10}
AA-DBSCAN	*MinPts* ∈ {3, 4, . . . , 10}
ASS-DBSCAN	*MinPts* ∈ {3, 4, . . . , 10}

We present the clustering performance result based on NMI of ASS-DBSCAN in comparison to compared algorithms with varied constraints on the real datasets. Each algorithm is shown with its own unique color in Fig. 4. For each dataset, a number of constraints were utilized with respect to the NMI. The result demonstrates that ASS-DBSCAN performance better than the compared algorithms in general. For example, as illustrated in Fig. 4(a), when utilizing 20 constraints, ASS-DBSCAN achieves a performance level exceeding 0.6 NMI, and with 80 constraints, ASS-DBSCAN achieves NMI of more than 0.7, respectively.

It can be observed that SSDBSCAN comes second in terms of effectiveness, followed by C-DBSCAN. Even though AA-DBSCAN has a higher performance in the early stages. However, with the increased number of pairwise constraints, AA-DBSCAN has consistently shown in all the datasets its static performance with stable and non-improved result. This can be explained since algorithms are an unsupervised clustering algorithm. Hence, it is not effective with pairwise constraints. Also, we can observe that the performance of ASS-DBSCAN can slowly increases with increased number of pairwise constraints as shown for Glass and Breast datasets. However, its performance surpasses the other algorithms.

B. Running Time Evaluation

This section discusses the running time of the ASS-DBSCAN and other algorithms that have been evaluated. Fig. 5 shows the execution times on the six datasets (containing pairwise constraints) used for evaluating. Lower execution time is considered better and vice versa. From Fig. 5, SSDBSCAN achieved the lowest performance of all pairwise constraints. AA-DBSCAN also has static value as shown in Fig. 5. These static values manifest as the number of

constraints are increased. We observed that the ASS-DBSCAN on most datasets achieve relatively high execution time with low constraints, however, overall, the execution time drops, and better performance was recorded for ASS-DBSCAN. Looking at all the experiments conducted on the other datasets, we can see that consistently ASS-DBSCAN performs better by achieving lower execution times in comparison to other algorithms.

V. Conclusions and Future Work

In this paper, we propose ASS-DBSCAN for clustering different density data with a set of active pairwise constrints. By examining the statistical properties of the dataset's density variation, the suggested algorithm divides it into multiple density level sets, which are subsequently expanded using active pairwise constraints. The algorithm was evaluated for performance and execution time on the real datasets again other algorithms. The evaluations results showed that the algorithm not only performed better in achieving its goals but also took less time in order to do so. Future work includes the extension the current work to cluster more complex data from real-life streaming applications. In addition, we aim to develop a comprehensive system that integrates active learning and semi-supervised learning techniques to be applied on different applications.

***Abstract*—The Slime Mould Algorithm (SMA) has effectively solved various real-world problems such as image segmentation, solar photovoltaic cell parameter estimation, and economic emission dispatch. However, SMA and its variants still face limitations when dealing with low-dimensional optimization problems, including slow convergence and local optima traps. This study aims to develop an optimized algorithm, the Merged Slime Mould Algorithm (MSMA), to overcome these limitations and improve performance in low-dimensional optimization tasks. Additionally, MSMA introduces a novel approach by merging the Adaptive Opposition Slime Mould Algorithm (AOSMA) and the Smart Switching Slime Mould Algorithm (S2SMA), simplifying the hybridization process and enhancing optimization performance. MSMA eliminates the need for multiple initializations, avoids memory-switching requirements, and employs adaptive and smart switching rules to harness the strengths of both algorithms. The performance of MSMA is evaluated using the CEC 2005 benchmark and ten real-world applications. The Wilcoxon rank-sum test verifies the effectiveness of the proposed approach, with results compared to various SMA variations and related optimization methods. Numerical findings demonstrate superior fitness values achieved by the proposed strategy, while statistical results indicate MSMA's outperformance with a rapid convergence curve.**

Keywords*—*Slime mould algorithm; engineering design problems; metaheuristic; optimization

I. Introduction

Metaheuristic algorithms (MAs) offer valuable tools for solving complex engineering problems in a reasonable time [1]. These algorithms provide a flexible and efficient approach to optimization, enabling engineers to find near-optimal solutions in diverse domains. MAs have two main elements: exploration and exploitation abilities [2]. Exploration capability is the ability to converge to a possible global optimum with increasing solution space and randomness. On the other hand, exploitation capability refers to the ability to search more precisely in the region that the algorithm's exploration phase has identified. There are two categories of metaheuristics: population-based and single-solution-based metaheuristics [3]. Population-based approaches involve utilizing a collection of solutions, referred to as a population, to generate and substitute candidate solutions throughout the optimization procedure. Some of the popular population-based metaheuristic approaches are Particle Swarm Optimization (PSO) [4], whale optimization algorithm (WOA) [5], and Harris Hawk Optimizer (HHO) [6]. In contrast, metaheuristics that rely on a single solution-based approach involve generating a set of potential solutions derived from the current solution. Subsequently, the current solution is substituted with one of the candidate solutions during each iteration. This category involves the local search (LS)[7], Tabu search (TS)[8], and simulated annealing (SA) [9].

Single-based and population-based algorithms have benefits and are widely utilized to address various issues. Nevertheless, no single approach can solve all optimization problems [10]. Developing an optimization algorithm to address these issues is necessary, but researchers have found it challenging to design new optimization algorithms from scratch. In this direction, hybridizing meta-heuristic algorithms is the most common and successful technique. For example, on hybridizing meta-heuristic algorithms [11]–[13].

In the literature, several optimizers have emerged recently, such as SMA [14], Fitness Dependent Optimizer (FDO) [15], Black Widow Optimization Algorithm (BWO) [16], and Reptile Search Algorithm (RSA) [17]. SMA has captured considerable attention due to its smooth structure, limited parameter requirements, robustness, and flexibility in implementation. It presents itself as a valuable and efficient approach for addressing a wide range of real-world optimization problems [18], such as image segmentation [19], estimation of solar photovoltaic cell parameters [20], and economic emission dispatch [21]. Nevertheless, similar to other metaheuristic algorithms, SMA encounters challenges related to local optimality and premature convergence in some optimization problems [22], [23]. Moreover, Utilizing two random search agents from the entire population to determine the future displacement and direction based on the best search agents restricts SMA's exploitation and exploration capabilities [24]. Researchers suggested hybridized and modified variants of SMA to address these limitations.

This research article presents the hybridization of two variants of SMA, namely S^2SMA [25] and AOSMA [24]. The integration involves incorporating a set of vertical smart switching rules to govern the transition process between AOSMA and S2SM. The two algorithms were combined intelligently, where the invocation procedure exclusively occurs during the update of slime locations. This merger is unique and distinct from SAM's previous integration due to the following three advantages: no necessity for multiple initializations for different algorithms, no memory-switching needs, and

employing adaptive and intelligent switching rules to leverage the strengths of both algorithms. The main contributions of this work are outlined as follows:

- MSMA introduces a novel optimization approach by intelligently merging AOSMA and S^2SMA, setting it apart from previous SMA integrations through its streamlined operational framework, which simplifies the algorithm hybridization process.
- The MSMA eliminates the necessity for multiple initializations and memory-switching, significantly enhancing computational efficiency. This innovation reduces the algorithm's complexity and resource consumption, facilitating a more seamless optimization experience.
- Incorporating Vertical Smart Switching Rules (VSSR) enables MSMA to facilitate dynamic algorithmic switches based on problem-specific attributes, amplifying adaptability and operational efficiency. VSSR represents a critical innovation, ensuring effective navigation through complex problem spaces and significantly improving optimization performance.
- The MSMA has been rigorously validated through extensive experiments and numerical studies, demonstrating its superiority in solving optimization problems.

This paper's remaining sections are organized as follows. The pertinent studies on SMA and engineering design problems are summarized in Section II. Section III illustrates the slime mould algorithm and the proposed work in detail. Section IV presents the numerical experiment and statistical analysis. This paper's conclusion is given in Section V.

II. Related Work

As mentioned previously, SMA can be categorized into hybridized and modified forms of SMA. Many studies have investigated the idea of hybridizing SMA with other metaheuristic algorithms [26]–[30]. Among these advancements, Naik et al. [26] introduced the Equilibrium Slime Mould Algorithm (ESMA), merging the Slime Mould Algorithm (SMA) with the Equilibrium Optimizer (EO) for enhanced multilevel thresholding in breast thermogram images. ESMA aims to reduce entropic dependencies between image classes, showing improved exploration capability and efficient analysis over other optimization methods. Although it outperforms in breast thermogram analysis, suggesting potential benefits for medical diagnostics, ESMA faces challenges in specific clinical contexts and broader medical imaging applications. Further contributing to the field, Chen et al. [27] introduced CHDESMA, an improved Slime Mould Algorithm (SMA) using chaotic maps and Differential Evolution (DE). CHDESMA mitigates SMA's local optima and population diversity issues by integrating chaotic maps for initialization and DE strategies for enhanced search. Evaluations against benchmarks and real-world problems show CHDESMA's competitive performance against advanced algorithms and DE variants, emphasizing its effectiveness and contributions in diverse scenarios. Moreover, Bhandakkar and Mathew [28] proposed using Integrated Slime Mould Algorithm (ISMA) for optimal placement of a Hybrid Power Flow Controller (HPFC). ISMA combines the Slime Mould Algorithm (SMA) with WOA for enhanced searching behavior. This optimization aims to minimize system power loss and generation cost by determining optimal locations for Unified Power Flow Controllers (UPFCs) and their capacities while considering system stability constraints. Chen et al. [29] presented RCLSMAOA, merging SMA and AOA to improve optimization. Through extensive testing, it effectively combines global exploration and local exploitation strategies. Despite the success, challenges persist in high-dimensional spaces and convergence accuracy. Future work aims to refine RCLSMAOA's performance in practical engineering problems and high dimensions, potentially exploring a binary version of the algorithm for further enhancement. Finally, Ewees et al. [30] introduced GBOSMA, a hybrid method merging Gradient-Based Optimizer (GBO) and Slime Mould Algorithm (SMA) to improve global optimization and feature selection. GBOSMA enhances exploration by using SMA as a local search within GBO, achieving better performance than standard GBO, SMA, and recent algorithms in both speed and accuracy across diverse benchmarks. The results showcase GBOSMA's superiority, achieving top fitness values in 66% of global optimization functions and the highest accuracy in 93% of feature selection benchmarks. This approach holds potential for various applications like medical imaging, object detection, and weather prediction tasks.

In many investigations, modified SMA methods were presented [24], [25], [31]–[34]. The Adaptive Opposition Slime Mould Algorithm (AOSMA), as introduced by Naik et al. [24], represents an advancement in the Slime Mould Algorithm (SMA) through the integration of adaptive opposition-based learning. This enhancement significantly boosts the algorithm's exploration and exploitation capabilities, making it a powerful tool for solving complex problems. However, AOSMA is not without its limitations. It shows a marked reliance on specific problem types, indicating that its effectiveness may be constrained to particular domains. Additionally, there is a noted requirement for further validation to confirm its broader applicability across a wider range of problem scenarios. Alhashash et al. [25] introduced an enhanced optimizer named Smart Switching Slime Mould Algorithm (S^2SMA) that enhances the accuracy of face sketch recognition by fine-tuning pre-trained deep learning models, which is challenging due to limited sketch datasets. S^2SMA simultaneously fine-tunes multiple deep learning models and uses embedded rules and search operations for adaptive switching between search operations during execution. The proposed algorithm was evaluated on CEC's 2010 large-scale benchmark and two face sketch databases and outperformed other optimization techniques with a faster convergence rate. The outcomes revealed the superiority of S^2SMA in the majority of experiments. Ewees et al. [31] presented a modified version of the slime mould algorithm (SMA) called SMAMPA, which incorporates the Marine Predators Algorithm (MPA) operators as a local search strategy. The proposed feature selection technique was evaluated on twenty UCI datasets and compared with other state-of-the-art FS methods, showing superior performance in terms of efficiency and performance metrics. The SMAMPA method was also applied to real-world problems,

such as QSAR modeling and chemometrics, with promising results. Future work includes investigating SMAMPA in more complicated problems, such as multi-optimization problems and big data mining. Abid et al. [32] proposed an enhanced slime mould optimization algorithm (ESMOA) to optimize tuning parameters for a cascaded proportional derivative-proportional integral (PD-PI) controller in order to solve frequency stability problems (FSP) in multi-area power systems (MAPSs) with two-area non-reheat thermal systems. ESMOA surpassed current PID and PI controllers. Cascaded PD-PI controller designs are more reliable than GSO and CO algorithms due to ESMOA's chaotic dynamic and elite group. In time domain simulations, ESMOA beat both GSO and CO. Deng and Liu [33] proposed AGSMA, an improved variant of the slime mould algorithm, to address limitations such as insufficient exploration, slow convergence, and an imbalance between diversity and convergence. AGSMA achieved a balance between convergence and diversity through adaptive grouping, a new search mechanism, and an efficient learning operator. Experiments demonstrated that it outperformed other methods and is able to solve complex nonlinear problems. However, premature convergence in some multimodal problems needs additional study. Sharma et al. [34] presented modifications to the Slime Mould Algorithm (SMA) to make it more effective for engineering design tasks, including opposition theory and a sine cosine-based position update mechanism. These modifications were found to significantly enhance the performance of SMA on standard benchmark functions and make it suitable for demand-side management tasks.

In the evolving field of metaheuristic algorithms, recent studies have made significant strides in addressing complex engineering design problems. Samma et al. [13] pioneered the Q-learning-based Simulated Annealing (QLSA) algorithm, setting a precedent for dynamic parameter control and adaptability, albeit with scalability and exploration scope limitations. Building on this, Nadimi-Shahraki et al. [1] introduced the Gaze Cues Learning-based Grey Wolf Optimizer (GGWO), which incorporated novel search strategies inspired by wolf behavior, showing promise despite challenges in selective pressure optimization. Further contributions, such as Wang et al. [35]'s Artificial Rabbits Optimization (ARO) and Yildiz et al. [36]'s Elite Opposition-Based Learning Grasshopper Optimization (EOBL-GOA), demonstrated the algorithms' strengths in diverse engineering problems but also highlighted the need for domain-specific adaptability. Zhang et al. [37] and Yıldız et al. [38] proposed enhancements to the Slime Mould Algorithm (SMA) and introduced the Chaotic Lévy flight distribution (CLFD) algorithm, respectively, achieving improved solution quality and exploration-exploitation balance. Recent developments saw Yang et al. [39] focus on the ARSCA algorithm, addressing computational complexity while improving convergence accuracy. Abdel-Basset et al. [40] applied the Nutcracker Optimization Algorithm (NOA) to engineering problems, demonstrating the ease of implementation and high convergence speed but facing challenges in exploration-exploitation balance. Gharehchopogh et al. [41] introduced the Chaotic Quasi-oppositional Farmland Fertility Algorithm (CQFFA), which enhanced exploration and convergence via chaotic maps and the Quasi-Oppositional Binary Leader strategy, albeit with hybridization challenges. Deng and Liu [42] showcased the Multi-strategy Improved Slime Mould Algorithm (MSMA), signaling a need for enhancements in multi-objective optimization and broader domain adaptability.

Despite significant advancements in developing SMA variants, current methods still face challenges in broader applicability and often struggle with slow convergence and local optima traps in low-dimensional optimization problems. This gap highlights the need for improved solutions that can overcome these limitations. The proposed approach addresses these challenges by integrating SMA variants with adaptive mechanisms, enhancing computational efficiency, reducing the reliance on multiple initializations, and simplifying the hybridization process, offering a more robust and effective solution for complex optimization tasks.

III. Proposed SMA-Based Method

A. The original Slime Mould Algorithm (SMA)

Li et al. [14] introduced the SMA as an innovative optimization mechanism for global optimization. SMA focuses on the behavior and morphological changes that the slime mould Physarum polycephalum undergoes during nutrient acquisition. Approaching, wrapping, and grabbing food are the three stages of SMA.

1) Approaching food: The concentration of odor in the air is essential for a slime mould to approach food. This contraction pattern when nearing food is defined by Eq. (1):

$$\overrightarrow{X(t+1)} = \begin{cases} \overrightarrow{X_b(t)} + \overrightarrow{vb} \cdot \left(\vec{W} \cdot \overrightarrow{X_A(t)} - \overrightarrow{X_B(t)}\right), r_2 < p \\ \overrightarrow{vc} \cdot \overrightarrow{X(t)}, r_2 \geq p \end{cases} \quad (1)$$

where the parameter $\overrightarrow{vb}$ takes values within the range of [-a, a], while $\overrightarrow{vc}$ gradually decreases from one to zero in a linearly. The position $\overrightarrow{X_b}$ refers to the current location of an individual with the highest concentration of odor detected. $\vec{X}$ represents the current location of slime mould. $\overrightarrow{X_A}$ and $\overrightarrow{X_B}$ denote two randomly selected individuals from a population of size n. The variables t and r_2 indicate the current iteration number and a random value between 0 and 1, respectively. The weight of slime mould is represented by $\vec{W}$. The parameter p is computed using Eq. (2):

$$p = tanh|S(i) - DF| \quad (2)$$

where $i \in 1,2, \ldots, n$. The fitness of the current location $\vec{X}$ is denoted by $S(i)$, while DF denotes the best fitness achieved across all iterations. The formula for computing $\overrightarrow{vb}$ can be found in Eq. (3), and the value of a is provided in Eq. (4).

$$\overrightarrow{vb} = [-a, a]) \quad (3)$$

$$a = arctanh(-\left(\frac{t}{max\_t}\right) + 1) \quad (4)$$

Here, max_t refers to the maximum number of iterations. The formula for calculating $\vec{W}$ is presented in Eq. (5), while its $SmellIndex$ is defined in Eq. (6).

$$\overrightarrow{W(SmellIndex(\iota))} = \begin{cases} 1 + r_3 \cdot log\left(\frac{bF - S(i)}{bF - wF} + 1\right), condition \\ 1 - r_3 \cdot log\left(\frac{bF - S(i)}{bF - wF} + 1\right), \ others \end{cases} \quad (5)$$

$$SmellIndex = sort(S) \quad (6)$$

where, condition represents that S(i) must be ranked within the top fifty percent of the entire population. The variable r_3 denotes a random value ranging from 0 to 1. The best fitness value achieved during the current iteration process is represented as bF, while the worst fitness value is denoted as wF. SmellIndex corresponds to the sequence of fitness values arranged in ascending order.

2) Wrapping food: Updates to the position of slime mould can be calculated using the formula given in Eq. (7):

$$\overrightarrow{X^*(t+1)} = \begin{cases} r_4 \cdot (UB - LB) + LB, r_1 < z \\ \overrightarrow{X_b(t)} + \overrightarrow{vb} \cdot \left(W \cdot \overrightarrow{X_A(t)} - \overrightarrow{X_B(t)}\right), r_2 < p \ \ and \ r_1 \geq z \\ \overrightarrow{vc} \cdot \overrightarrow{X(t)}, r_2 \geq p \ \ and \ r_1 \geq z \end{cases} \quad (7)$$

where, r_1, r_2 and r_4 are randomly selected from the interval [0,1]. B and UB represent the lower and upper bounds of the search range, respectively. The p value signifies the probability associated with the presence of slime mould, while z is a parameter with a constant value of 0.03.

3) Grabbling food: To represent the slime mould venous width changes, SMA utilizes the vectors $\overrightarrow{W}$, $\overrightarrow{vb}$, and $\overrightarrow{vc}$. $\overrightarrow{W}$ reflects the oscillating frequency of slime mould, which is determined by analyzing the quality of the food source. It helps update the speed of movement towards the food source, aiding the slime mould in selecting the most suitable food source.

The values of $\overrightarrow{vb}$ and $\overrightarrow{vc}$ undergo random oscillations within specific ranges. The vector $\overrightarrow{vb}$ ranges from -a to a, while $\overrightarrow{vc}$ ranges from -1 to 1. As the iterative process progresses, these vectors converge towards zero.

The variation in $\overrightarrow{vb}$ replicates the slime mould's behaviour when it encounters a new food source. Even if an improved food supply has been identified, the slime mould continues to explore other locations by separating some organic matter. This behaviour increases the chances of finding higher-quality food sources and improves the optimization of local problems. For further details on the SMA, refer to the study conducted by Li et al. [14].

B. The Proposed Merged Slime Mould Algorithm

MSMA is a novel optimization method that combines two variants SMA: AOSMA and S^{2}SMA. This merger distinguishes itself from previous integrations by providing three primary advantages: the elimination of the necessity for multiple initializations for different algorithms, avoidance of memory-switching requirements, and the incorporation of adaptive and intelligent switching rules, known as the Vertical Smart Switching Rules (VSSR).

The formulation of VSSR involves incorporating four embedded vertical smart switching rules to control the recall ratio between AOSMA and S^{2}SMA during slime position updates. The activation of VSSR is dependent on the occurrence of specific events, comprising seven parameters: $AOSMA\_EN$ parameter, S^2SMA_EN parameter, $EVAL\_C$ parameter, $AOSMA\_C$ parameter, S^2SMA_C parameter, $VER\_SUCCESS_{LEADER}$ parameter, and per. The first parameter is $AOSMA\_EN$. It will take either zero or one. If AOSMA is chosen to update slime positions, it will be one; otherwise, it will be zero. The second parameter is S^2SMA_EN. It will take either zero or one. If S^{2}SMA is chosen to update slime positions, it will be one; otherwise, it will be zero. The third parameter, $EVAL\_C$, evaluation counter represents the number of iterations required to evaluate the performance of the two algorithms and is computed using Eq. (8). The fourth and fifth parameters, $AOSMA\_C$ and S^2SMA_C, respectively, count the number of times each algorithm successfully finds a new leader within $EVAL\_P$ iterations when used to update slime positions. The sixth parameter, $VER\_SUCCESS_{LEADER}$, assumes one value if any methods can find a new leader and zero otherwise. The final parameter, per, takes on a value within the range of [0,1], and its value depends on the rules to be applied, which will be further expounded in the ensuing section.

$$EVAL\_P = \epsilon * max\_t \quad (8)$$

where, ϵ is a constant parameter of 0.02, its value is affordable, which was selected to ensure timely switching. However, increasing this value would result in slower switching, perhaps introducing bias. Conversely, decreasing the value would lead to faster switching, hence increasing complexity. Moreover, this parameter is adjustable based on the nature of a given problem.

The first and second rules are depicted in Fig. 1 and Fig. 2 respectively. They were developed to update the value of $AOSMA\_C$ and S^2SMA_C, which indicates the number of successes for each approach during the process of finding a new leader. Both rules will be checked in every iteration. The first rule will apply if AOSMA is called while updating the slime position and a new leader is found. Thus, $AOSMA\_C$ will be updated. The second rule will apply if S^{2}SMA is called while updating the slime position and a new leader is found. Thus, S^2SMA_C will be updated. It should be noted that the proposed method will give AOSMA and S^{2}SMA equal priority to change slime positions during the first $EVAL\_P$. During the process, the values of both $AOSMA\_C$ and S^2SMA_C will be updated as explained in Rule1 and Rule2.

RULE 1: IF $AOSMA\_EN == 1$ **AND** $VER\_SUCCESS_{LEADER} == 1$
THEN $AOSMA\_C = AOSMA\_C + 1$

Fig. 1. RULE 1 To count the number of times AOSMA was successful during a given period.

RULE 2: IF $S^2SMA\_EN == 1$ **AND** $VER\_SUCCESS_{LEADER} == 1$
THEN $S^2SMA\_C = S^2SMA\_C + 1$

Fig. 2. RULE 2 To count the number of times S^{2}SMA was successful during a given period.

The third and fourth rules are shown in Fig. 3 and Fig. 4, respectively. They are formulated to calculate per, which is the

ratio of AOSMA and S^{2}SMA calling to update slime positions during the subsequent $EVAL\_P$. This value depends on the values of $AOSMA\_C$ and S^2SMA_C, as explained in Rule1 and Rule2. If AOSMA and S^{2}SMA cannot find a new leader during the current $EVAL\_P$, both methods will be given an equal chance over the subsequent $EVAL\_P$; otherwise, the third and fourth rules will be applied. The third rule is applied if the value of $AOSMA\_C$ is greater than S^2SMA_C; otherwise, the fourth rule will be applied.

RULE 3: IF $AOSMA\_C > S^2SMA\_C$

THEN $per = AOSMA\_C/(AOSMA\_C + S^2SMA\_C)$

Fig. 3. RULE 3 to compute the probability of AOSMA being called within the specified period.

RULE 4: IF $AOSMA\_C \leq S^2SMA\_C$

THEN $per = 1 - (S^2SMA/(AOSMA\_C + S^2SMA\_C))$

Fig. 4. RULE 4 to compute the probability of S^{2}SMA being called within the specified period.

In the SMA algorithm, the arctanh function is utilized to calculate the value of parameter a in Eq. (4). However, it has been observed that the arctanh function can lead to programming warnings/errors [43]-[45]. To enhance the performance and stability of the standard SMA algorithm and achieve faster convergence with reduced warnings/errors during program execution, alternative controlling equations, such as the cosine function, have been proposed as viable solutions [44]. In this study, the value of parameter a was computed using Eq. (9), which was directly obtained from [45].

$$a = 1 + cos\left(\frac{t}{max\_t} \cdot \pi\right) \quad (9)$$

where max_t is the maximum number of iterations and t is the current iteration.

Fig. 5 depicts the complete stages of the proposed MSMA algorithm.

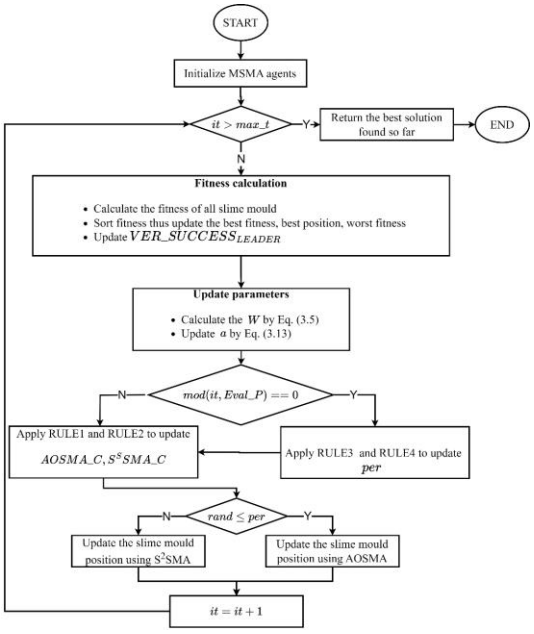

Fig. 5. Flow chart of the proposed MSMA algorithm.

IV. Experimental Results and Analysis

In this analysis section, several experiments were conducted to demonstrate MSMA's efficacy. Three case studies were investigated, comprising basic benchmark problems CEC 2005 [46] and seven engineering designs.

A. Evaluation on Basic Benchmark Functions

In this section, a total of 23 CEC 2005 [46] continuous benchmarks were used, categorized into seven unimodal (F1-F7), six multimodal (F8-F13), and ten fixed-dimensional multimodal functions (F14-F23), as illustrated in Table I, Table II, and Table III. Unimodal functions assess exploitation efficiency with one global optimum, while multimodal functions (F8-F13) evaluate exploration and local optima avoidance. Fixed-dimensional tests (F14-F23) provide a middle ground with fewer local optima, gauging the algorithm's balance between exploitation and exploration.

TABLE I. Description of Unimodal Benchmark Functions

Function	Description	Dim	Range	f_{min}
$F_1(X) = \sum_{j=1}^{D} {x_j}^2$	Sphere	30	[-100,100]	0

$F_{23}(X) = -\sum_{j=1}^{10}[(X-a_j)(X-a_j)^T + c_j]^{-1}$	Shekel 10	4	[0,10]	-10.5363

1) Comparison with SMA and SMA variants:

a) Performance analysis: This section compares the efficacy of MSMA to that of SMA [14] and SMA variants. Specifically, S^{2}SMA [25], ESMA [26], LSMA [19], and AOSMA [24] are executed based on the parameters shown in Table IV. The mean, and standard deviation of MSMA and other algorithms are reported in Table V. The ranking was determined by using an average of 30 runs. MSMA achieved the optimal value, zero, or the best result in most functions relative to other algorithms. This is due to the application of rules that aid in selecting the optimal algorithm, which in turn enables the achievement of optimal results. However, the outcomes were not satisfactory due to the nature of the functions F5, F6, F7, F19, and F20.

TABLE IV. CONFIGURATION PARAMETERS FOR THE EXAMINED ALGORITHMS

Method	Population size	The maximum number of iterations	Other parameters
MSMA (Proposed)	30	10^3	z = 0.03, μ =0.5, ϵ =0.02, α = 5 and β =3/2
SMA [14]	30	10^3	z = 0.03
LSMA [19]	30	10^3	z = 0.03

AOSMA [24]	30	10^3	$z = 0.03$
ESMA [26]	30	10^3	$z = 0.03$

b) Analysis of execution time: The computer's software and hardware specifications used to conduct the investigations in this study are elaborated on in Table VI. Table VII displays the computational time (in seconds) for three different algorithms: MSMA, SMA, and AOSMA. According to Table VIII, the SMA algorithm achieved a computation time of 0.51318182 seconds, while the AOSMA algorithm recorded a shorter time at 0.260618 seconds. As a result of hybridizing AOSMA and S^2SMA, MSMA achieved a computation time of 0.380505 seconds and thus outperformed the original SMA algorithm. These results indicate that MSMA shows promise in improving task-specific computational time compared to the traditional SMA approach. Notably, the programming language, programmer proficiency, and machine configuration influence the CPU time utilized by each method.

2) Comparison with conventional algorithms:

a) Performance analysis: This section compares the performance of the MSMA algorithm with six popular metaheuristic algorithms: WOA [5], Multi-Verse Optimizer (MVO) [47], Grey Wolf Optimizer (GWO) [48], Sine Cosine Algorithm (SCA) [49], Arithmetic Optimization Algorithm (AOA) [50], and PSO [4] across unimodal and multimodal functions (F1-F13). The primary parameter configurations of these algorithms are displayed in Table VIII below. It has been demonstrated that the MSMA variant outperforms the original SMA and other SMA variants. Therefore, the upcoming comparative experiment will not include SMA for comparison.

According to Table IX, MSMA's ability to achieve highly competitive best fitness values frequently converges to zero or near-zero fitness on unimodal functions such as F1 and F2, emphasizing its exceptional exploitation efficiency. Moreover, on multimodal functions like F13, MSMA exhibits worthy exploration capabilities, navigating intricate landscapes and converging to optimal solutions. These findings collectively highlight MSMA as an effective metaheuristic algorithm with the potential for solving real-world problems in various domains.

TABLE VIII. THE SETTING OF ALGORITHMS' PARAMETERS

Method	Population size	The maximum number of iterations	Other parameters
MSMA (Proposed)	30	10^3	z = 0.03, μ =0.5, ϵ =0.02, α = 5 and β =3/2
(WOA) [5]	30	10^3	$a1 = 2-0$; $a2 = -1--2$; $b = 1$
(MVO) [47]	30	10^3	Wormhole Existence Probability WEPMax = 1; WEPMin = 0.2;
(GWO) [48]	30	10^3	a: 2−1
(SCA) [49]	30	10^3	$a = 2$
AOA [50]	30	10^3	μ =0.5 and α = 5
(PSO) [4]	30	10^3	c1 = 2.5 – 0.5, c2 = 0.5–2.5, w = 0.9–0.5.

b) Convergence curve: In this section, Fig. 6 shows the convergence curves of MSMA compared to WOA [5], MVO [47], GWO [48], SCA [49], AOA [50], and PSO [4]. Fig. 6 displays convergence curves derived from the average best objective function value achieved over 30 runs, as detailed in Table IX. The x-axis represents 1000 iterations, while the y-axis represents the maximum score achieved. The results show that MSAM is superior to its competitors in most of the unimodal functions (1–7), and this reflects its high ability in the exploitation phase. Furthermore, MSAM's exploratory capabilities were showcased in multimodal functions (8–13), highlighting its superiority in all functions. Overall, it demonstrates that the convergence of MSMA is significantly superior to that of other algorithms across most functions. This is due to VSRR, which intelligently switches between algorithms in MSMA to take advantage of its exploitation and exploration capabilities.

B. Experimental Results on Constraints Problems (Engineering Design Problems)

The performance of MSMA was assessed by applying the method to solve various engineering design problems. These included a cantilever beam problem, a welded beam design problem, a pressure vessel problem, a compression coil spring design problem, a multiple disc clutch brake problem, a speed reducer problem, and a gear train design problem. The mathematical formulas relating to these problems are provided in "Appendix A". These validations evaluated the effectiveness and suitability of MSMA in tackling different design challenges.

This experiment standardized the parameters for all optimization techniques to ensure a fair comparison. The maximum number of function iterations was set to 10,000, and the population size was set to 30. For statistically reliable results, each method underwent 30 runs independently.

1) Performance analysis: This section compares the efficacy of MSMA to that of SMA [14] and SMA variants (S^2SMA [25], LSMA [36], AOSMA [24], and ESMA [26]). Table X shows performance metrics for MSMA and the other algorithms on Engineering design problems, including the mean, and the standard deviation.

Based on the obtained results, in the problem of Cantilever Beam analysis, MSMA, boasting a mean of 13.36523309, clearly outperforms its counterparts. ESMA, LSMA, and SMA yield closely clustered means of 13.36532, 13.36531551, and 13.36536, respectively, while AOSMA displays a slightly elevated average. This highlights MSMA's superior effectiveness. Likewise, in Welded Beam problem assessments, MSMA's mean of 1.724885178 is notably superior to its peers. ESMA closely trails with a mean of 1.724979, while other algorithms register marginally higher averages, underscoring the unmistakable dominance of MSMA in this context. Transitioning to the Pressure Vessel problem, MSMA stands out as the top-performing algorithm. Its mean of 6766.643344 significantly outperforms SMA, ESMA, and LSMA, all of which yield notably higher means. This underscores MSMA's exceptional suitability for this specific problem. In the Compression Coil Spring Design problem, MSMA's mean of 0.01284604 distinctly outshines alternative algorithms, which yield significantly higher averages. This glaring disparity underscores the exceptional performance of MSMA in this scenario.

Moreover, in the Multiple Disk Clutch Brake problem, MSMA, SMA, and ESMA exhibit closely aligned means, with MSMA marginally leading. While LSMA and AOSMA register slightly higher values, MSMA's marginal lead implies superior efficacy for this problem. In the Speed Reducer problem, MSMA, ESMA, and AOSMA stand out with proximate mean values, with MSMA in the lead. In contrast, SMA and LSMA yield substantially higher averages, reinforcing the notable performance of MSMA. Lastly, in the Gear Train Design problem, MSMA's mean value of 3.25763E-20 is strikingly lower than those of alternative algorithms, which produce considerably higher means, unequivocally solidifying its unparalleled suitability for this specific function. These results demonstrate MSMA's superior performance across various engineering problems, affirming its pivotal role in optimization endeavours.

TABLE X. STATISTICAL RESULTS OF ENGINEERING DESIGN PROBLEMS

Function	Fitness	Algorithm

2) Statistical analysis: To statistically evaluate the performance of MSMA and the compared algorithms, including SMA [14] S and SMA variants (S^2SMA [25], LSMA [36], AOSMA [24], and ESMA [26]), on various engineering design problems. Calculating the p-value of the Wilcoxon signed-rank test [51]. Each value greater than 0.05 is displayed in bold font, indicating that the difference is not statistically significant. The calculated p-values indicate substantial evidence of differentiation, as shown in Table XI MSMA's p-values are smaller than 0.05 in the majority of cases, indicating significant differences. Notably, the "Pressure Vessel" problem exhibits a relatively large p-value (approximately 0.76) when comparing MSMA to AOSMA, indicating that the difference with AOSMA is not statistically significant. In contrast, for the "Gear train design" problem, the p-values consistently indicate significant differences, indicating that MSMA outperforms all compared algorithms. These results demonstrate the superior performance of MSMA and its potential as an efficient optimization method for complex engineering design problems.

TABLE XI. P-VALUES FOR MSMA VERSUS OTHER COMPETITORS ON ENGINEERING DESIGN PROBLEMS

Function	MSMA vs. S^2SMA	MSMA vs. SMA	MSMA vs. ESMA	MSMA vs. LSMA	MSMA vs. AOSMA

3) Comparison with conventional algorithms: This section aims to evaluate the performance of MSMA through a comprehensive comparison with six popular metaheuristic algorithms: WOA [5], MVO [47], GWO [48], SCA [49], AOA [50], and PSO [4]. The comparison is conducted across seven distinct engineering design problems to thoroughly assess their capabilities in solving engineering problems. The main parameter settings for each algorithm are outlined in Table VIII.

Beginning with the Cantilever Beam Design Problem, the analysis reveals that MSMA exhibits competitive performance, achieving optimal values for variables (x1 to x5) and an optimal cost of 13.36520828, as demonstrated in Table XII. This outcome underscores the effectiveness of MSMA in addressing structural engineering challenges, where precise optimization is paramount for ensuring structural integrity and efficiency.

Similarly, in the Welded Beam Problem, MSMA demonstrates notable performance with an optimal cost of 1.724852759, as presented in Table XIII, indicating its capability to navigate the complexities inherent in welding design optimization. The results further validate the robustness of MSMA in handling diverse engineering scenarios, where intricate design considerations must be balanced to achieve optimal outcomes.

The Pressure Vessel Problem, as presented in Table XIV, further emphasizes the diversity of MSMA's capabilities. It showcases optimal values for variables and an optimal cost of 5885.332794. It highlights MSMA's adaptability to multifaceted challenges in pressure vessel design optimization, where complex geometrical and operational constraints influence the design space.

In the Compression Coil Spring Design Problem, MSMA continues to demonstrate competitive results, achieving an optimal cost of 0.012665319, as presented in Table XV. This performance highlights the efficacy of MSMA in optimizing mechanical components, where precision in design parameters is crucial for achieving desired spring characteristics and performance metrics.

Table XVI illustrates the optimal values for variables (x1, x2, x3, x4, x5) and their respective optimal costs achieved by various algorithms in the Multiple Disk Clutch Brake scenario. MSMA outperforms competitors by attaining an optimal cost of 0.259768995. In contrast, other algorithms exhibit slightly different values for the variables. It highlights the effectiveness of MSMA in this context.

Similarly, Table XVII provides a comparative analysis for the Speed Reducer Problem, where MSMA excels in achieving an optimal cost of 2996.348166. Competing algorithms, on the other hand, are unable to reach the same degree of accuracy. MSMA's reliability and effectiveness are demonstrated by its ability to handle the complexity of this problem.

In the context of gear train design optimization, Table XVIII highlights the effectiveness of the MSAM algorithm with an optimal cost of 4.29529E-26. Additionally, WOA achieves a noteworthy optimal cost of 0, emphasizing its competitive performance. These findings underscore the capabilities of MSAM and WOA in addressing complex engineering optimization challenges.

TABLE XII. COMPARISON RESULTS OF THE CANTILEVER BEAM DESIGN PROBLEM

C. Discussion

The Merged Slime Mould Algorithm (MSMA) results demonstrate its effectiveness across benchmark functions and engineering design problems. Evaluating 23 continuous benchmark functions from the CEC 2005 revealed that MSMA excels in achieving optimal results, particularly in unimodal functions where exploitation is crucial. Its performance in multimodal functions illustrates robust exploration capabilities, effectively navigating complex landscapes and avoiding local optima.

Comparisons with other Slime Mould Algorithm (SMA) variants and established metaheuristic algorithms like WOA, GWO, and PSO showed that MSMA consistently outperforms its peers. The mean and standard deviation metrics analysis highlight MSMA's ability to frequently achieve optimal or near-optimal fitness values. The convergence curves indicate that MSMA delivers rapid convergence, leveraging Vertical Smart Switching Rules (VSRR) for intelligent algorithm switching, thus enhancing both exploitation and exploration strategies.

MSMA's superiority in engineering design problems is further validated. For instance, the Cantilever Beam problem achieved significantly lower mean values compared to other algorithms. Similar trends were noted in the Welded Beam and Pressure Vessel problems, with statistical significance confirmed through the Wilcoxon signed-rank test. These results underscore MSMA's reliability and efficiency in tackling complex engineering challenges.

The promising outcomes of MSMA open several exciting avenues for future research. Exploring hybridization techniques that combine MSMA with advanced optimization algorithms could further enhance its performance. Additionally, adapting Vertical Smart Switching Rules (VSRR) for dynamic problem landscapes may improve efficiency. Future studies could also validate MSMA through real-world case studies, ensuring its practical applicability across diverse industries. Such explorations would significantly contribute to the optimization field and enhance MSMA's utility in addressing complex challenges, instilling a sense of optimism and hope for its continuous improvement.

V. CONCLUSION

In conclusion, this paper introduced MSMA as a dynamic hybridization approach engineered to significantly enhance the performance of the traditional SMA in tackling low-dimensional optimization problems compared to other algorithms. The proposed technique merges two existing SMA variants, AOSMA and S^2SMA, through the incorporation of embedded Vertical Smart Switching Rules (VSSR). VSSR enables dynamic switching between algorithms based on problem-specific attributes, thereby boosting adaptability and operational efficiency. The MSMA's unique integration strategy eliminates the need for multiple algorithm initializations as well as avoids the need for memory-based switching. Instead, it relies on adaptive and intelligent switching rules to exploit the strengths of both algorithms. This represents a notable advancement compared to previous integrations of SMA.

The proposed MSMA has been fully validated on ten real-world engineering challenges and basic benchmark problems CEC 2005 using statistical and numerical analyses. The experimental results highlight MSMA's superiority over current approaches and demonstrate its potential to provide innovative solutions for complex engineering designs. This study provides additional evidence that MSMA consistently achieves the highest mean fitness values and shows the fastest rates of convergence among the algorithms evaluated, demonstrating its superior performance in addressing engineering design problems. Remarkably, when compared to SMA, MSMA also showed improved computational efficiency, particularly in the Cantilever Beam problem. The Wilcoxon signed-rank test has statistically validated MSMA's outstanding performance in a variety of engineering problems, confirming its superiority and efficacy in resolving complex engineering design problems.

These findings validate the proposed MSMA's superiority over existing techniques, showcasing its potential to provide promising solutions for complex engineering design problems. Future research directions could pivot towards enhancing the VSSR mechanism to further improve MSMA's adaptability and robustness. Moreover, extending the exploration to other problem domains and conducting comparative studies with other state-of-the-art optimization algorithms would yield additional insights, paving the way for further advancements in optimization technology.

APPENDIX A. ENGINEERING DESIGN PROBLEMS

A. Cantilever structure problem

$$\text{Minimize } f(x) = 0.6224(x_1 + x_2 + x_3 + x_4 + x_5)$$
$$\text{subject to, } g(x) = \frac{61}{x_1^3} + \frac{37}{x_2^3} + \frac{19}{x_3^3} + \frac{7}{x_4^3} + \frac{1}{x_5^3} - 1 \le 0$$
$$\text{Variable ranges: } 0.01 \le x_1, x_2, x_3, x_4, x_5 \le 100$$

B. The welded beam design problem

$$\text{Minimize } f(\vec{x}) = 1.10471x_1^2x_2 + 0.04811x_3x_4(14.0 + x_2)$$
subject to,
$$g_1(\vec{x}) = \tau(\vec{x}) - \tau_{max} \le 0$$
$$g_2(\vec{x}) = \sigma(\vec{x}) - \sigma_{max} \le 0$$
$$g_3(\vec{x}) = \delta(\vec{x}) - \delta_{max}$$
$$g_4(\vec{x}) = x_1 - x_4 \le 0$$
$$g_5(\vec{x}) = P - P_c(x) \le 0$$
$$g_6(\vec{x}) = 0.125 - x_1 \le 0$$
$$g_7(\vec{x}) = 0.1047x_1^2 + 0.04811x_3x_4(14.0 + x_2) - 5.0 \le 0$$
Variable ranges: $0.1 \le x_1 \le 2.0,\ 0.1 \le x_2 \le 10.0,\ 0.1 \le x_3 \le 10.0,\ 0.1 \le x_4 \le 2.0$
where,
$$\tau(x) = \sqrt{(\tau')^2 + 2\tau'\tau''\frac{x_2}{2R} + \tau''^2}, \tau' = \frac{P}{\sqrt{2}x_1x_2}, \tau'' = \frac{MR}{J}, M = P\left(L + \frac{x_2}{2}\right)$$
$$R = \sqrt{\frac{x_2^2}{4} + \left(\frac{x_1 + x_3}{2}\right)^2}, J = 2\left\{\sqrt{2}x_1x_2\left[\frac{x_2^2}{12} + \left(\frac{x_1 + x_3}{2}\right)^2\right]\right\}, \sigma(x) = \frac{6PL}{x_4x_3^2}, \delta(x) = \frac{4PL^3}{Ex_4x_3^3}$$
$$P_c(x) = \frac{4.103E\sqrt{\frac{x_3^2x_4^6}{36}}}{L^2}\left(1 - \frac{x_3}{2L}\sqrt{\frac{E}{4G}}\right), P = 6000lb, L = 14in, E = 30 \times 10^{06}psi$$
$$G = 12 \times 10^{06}psi. \tau_{max} = 136000psi, \sigma(x) = 30000psi, \delta_{max} = 0.25in$$

C. Pressure Vessel problem

$$\text{Minimize } f(\vec{x}) = 0.6224x_1x_3x_4 + 1.7781x_2x_3^2 + 3.1661x_1^2x_4 + 19.84x_1^2x_3$$
Subject to,
$$g_1(\vec{x}) = -x_1 + 0.0193x_3 \le 0,$$
$$g_2(\vec{x}) = -x_3 + 0.00954x_3 \le 0,$$
$$g_3(\vec{x}) = -\pi x_3^2x_4 - \frac{4}{3}\pi x_3^3 + 1{,}296{,}000 \le 0,$$
$$g_4(\vec{x}) = x_4 - 240 \le 0,$$
Variable ranges: $0 \le x_1 \le 99, 0 \le x_2 \le 99, 10 \le x_3 \le 200, 10 \le x_4 \le 200$

D. Compression Coil Spring design problem

$$\text{Minimize } f(\vec{x}) = (x_3 + 2)x_2x_1^2$$
subject to,
$$g_1(\vec{x}) = 1 - \frac{x_2^3x_3}{71785x_1^4} \le 0$$
$$g_2(\vec{x}) = \frac{4x_2^2 - x_1x_2}{12566(x_1^3x_2 - x_1^4)} + \frac{1}{5108x_1^2} - 1 \le 0$$
$$g_3(\vec{x}) = 1 - \frac{140.45x_1}{x_2^2x_3} \le 0$$
$$g_4(\vec{x}) = \frac{x_1 + x_2}{1.5} - 1 \le 0$$
Variable ranges: $0.05 \le x_1 \le 2.0, \quad 0.25 \le x_2 \le 1.3, \quad 2 \le x_3 \le 15.0$

E. Multiple disk clutch brake problem

$$\text{Minimize } f(\vec{x}) = \pi(x_2^2 - x_1^2)x_3(x_5 + 1)\rho,$$
Subject to,
$$g_1(x) = x_2 - x_1 - \Delta R \ge 0$$
$$g_2(x) = L_{max} - (x_5 + 1)(x_3 + \delta) \ge 0$$
$$g(x) = P_{max} - P_{rz} \ge 0$$
$$g(x) = P_{max} * Vsr_{max} - P_{rz} * Vsr \ge 0,$$
$$g_5(x) = Vsr_{max} - Vsr \ge 0,$$
$$g_6(x) = T_{max} - T \ge 0,$$
$$g_7(x) = M_h - sM_s \ge 0,$$
$$g_8(x) = T \ge 0,$$
Variable ranges: $60 \le x_1 \le 80, 90 \le x_2 \le 110, 1 \le x_3 \le 3, 0 \le x_4 \le 1000, 2 \le x_5 \le 9, i = 1,2,3,4,5.$
where,
$$M_h = \frac{2}{3}\mu x_4x_5\frac{x_2^3 - x_1^3}{x_2^2 - x_1^2}N.mm, W = \frac{\pi n}{30}rad/s, A = \pi(x_2^2 - x_1^2)mm^2$$
$$P_{rz} = \frac{x_4}{A}N/mm^2, Vsr = \frac{PiR_{sr}n}{30}mm/s, R_{sr} = \frac{2(x_2^3 - x_1^3)}{3(x_2^2x_1^2)}mm$$

$$\delta = 0.5mm, s = 1.5, T_{max} = 15s, n = 250rpm, I_z = 55Kg.m^2, M_s = 40Nm, Mf = 3Nm$$

F. Speed reducer problem.

$$\text{Minimize } f(\vec{x}) = 0.7854x_1x_2^2(3.3333x_3^2 + 14.9334x_3 - 43.0934) - 1.508x_1(x_6^2 + x_7^2) + 7.4777(x_6^3 + x_7^3) + 0.7854(x_4x_6^2 + x_5x_7^2)$$
Subject to,
$$g_1(\vec{x}) = \frac{27}{x_1x_2^2x_3} - 1 \le 0,$$
$$g_2(\vec{x}) = \frac{397.5}{x_1x_2^2x_3^2} - 1 \le 0,$$
$$g_3(\vec{x}) = \frac{1.93x_4^3}{x_2x_3x_6^4} - 1 \le 0,$$
$$g_4(\vec{x}) = \frac{1.93x_5^3}{x_2x_3x_7^4} - 1 \le 0,$$

$$g_5(\vec{x}) = \frac{\sqrt{(\frac{745x_4}{x_2x_3})^2 + 16.9 \times 10^6}}{110x_6^3} - 1 \leq 0$$

$$g_6(\vec{x}) = \frac{\sqrt{(\frac{745x_5}{x_2x_3})^2 + 157.5 \times 10^6}}{85x_7^3} - 1 \leq 0$$

$$g_7(\vec{x}) = \frac{x_2x_3}{40} - 1 \leq 0,$$

$$g_8(\vec{x}) = \frac{5x_2}{x_1} - 1 \leq 0,$$

$$g_9(\vec{x}) = \frac{x_1}{12x_2} - 1 \leq 0,$$

$$g_{10}(\vec{x}) = \frac{1.5x_6 + 1.9}{12x_2} - 1 \leq 0,$$

$$g_{11}(\vec{x}) = \frac{1.1x_7 + 1.9}{x_5} - 1 \leq 0,$$

$$g_{11}(\vec{x}) = \frac{1.1x_7 + 1.9}{x_5} - 1 \leq 0,$$

Variable ranges: $2.6 \leq x_1 \leq 3.6, 0.7 \leq x_2 \leq 0.8, 17 \leq x_3 \leq 28,$ $7.3 \leq x_4 \leq 8.3,\ 7.8 \leq x_5 \leq 8.3, 2.9 \leq x_6 \leq 3.9, 5.5 \leq x_7 \leq 5$

G. Gear train engineering design problem

Minimize $f(\vec{x}) = \left(\frac{1}{6.931} - \frac{x_1x_2}{x_3x_4}\right)^2$

Variable ranges: $12 \leq x_1, x_2, x_3, x_4 \leq 60$

Research on Credit Card Fraud Prediction Model Based on GAN-DNN Imbalance Classification Algorithm

Qin Wang[1], Mary Jane C.Samonte[2*]
School of Information Technology, Mapua University,Xi'an Siyuan University, Manila, Phillippines[1]
School of Information Technology, Mapua University, Manila, Phillippines[2]

***Abstract*—Credit card consumption has become an important way of consumption in modern life, but the problem of credit card fraud has also emerged, disrupting the financial order and restricting the development of the industry. Aiming at the data class imbalance problem in credit card fraud detection and improving the accuracy of fraud detection, this paper uses the Generative Adversarial Network (GAN) to generate fraud samples and balance the number of fraud transaction samples and normal transaction samples. Then, a deep neural network (DNN) is used to construct a credit card fraud prediction model. The study compares this model with commonly used classification algorithms and sampling methods in detail and confirms that the designed credit card fraud prediction model has a good effect, providing a theoretical basis and practical reference for financial institutions to predict credit card fraud.**

Keywords*—Generative adversarial network; deep neural network; unbalanced data; credit card fraud; classification algorithms

I. INTRODUCTION

Globally, the field of credit card payments is rife with a significant number of credit card fraud cases. According to a report by the Federal Trade Commission (FTC), in 2022, as many as 2.8 million users in the United States were affected by credit card fraud, with losses amounting to $3.4 billion. By the end of 2022, the monetary losses caused by credit card fraud soared to $5.8 billion, an increase of over 70% [1]. In recent years, credit card fraud has shown a trend towards specialization, scaling, and syndication, undermining the stability of the financial market and endangering the financial security of the public [2]. Therefore, it is crucial for financial institutions to establish intelligent fraud detection mechanisms to enhance the anti-fraud capabilities of regulators.

In recent years, researchers have conducted extensive work in the area of credit card fraud detection. Regarding the issue of data imbalance, oversampling and undersampling methods are commonly employed. For instance, N. Rtayli et al. utilized the SMOTE algorithm to generate fraud samples to overcome data imbalance [3]; Chen Ying et al. improved the SMOTE algorithm through K-Means clustering, generating fraud samples only in safe areas [4]; E. Esenogho et al. combined SMOTE oversampling with undersampling for hybrid sampling, thereby improving the overall distribution of credit card data [5]. In terms of data detection accuracy, deep models based on Long Short-Term Memory (LSTM) networks are generally used [6]. Gao J et al., for example, used LSTM to extract potential temporal information from credit card data, ultimately completing information identification and fraud classification through XGBoost [7]; Benchaji et al. proposed an LSTM credit card fraud detection model integrated with an attention mechanism, selectively focusing on features through the attention mechanism to enhance the model's detection efficiency [8]; J. Forough et al. constructed a credit card fraud detection model with LSTM as the preliminary prediction layer and CRF as the final prediction layer [9]. However, the traditional SMOTE oversampling algorithm generates a large number of fraudulent samples with noise, and undersampling algorithms may lose key information, ultimately affecting the training effectiveness of the model [10]. On the other hand, LSTM can only learn the forward distribution of credit card data and cannot combine the forward and reverse directions to output a comprehensive expression for fraud detection [11]. In terms of data feature extraction and classification tasks, various hybrid model methods based on GAN have been adopted [12]. Li et al. used the GAN-RNN algorithm for sequence modeling of image data to mine time series features in images [13]; Zhang et al. combined GAN-RNN with variational autoencoders for feature fusion to enhance the expressive power of features [14]. Zhao et al. utilized GAN-CNN for in-depth mining of image features, ultimately completing image classification tasks through a Softmax classifier [15]; Sun et al. proposed a GAN-CNN classification model combined with a multi-scale feature fusion mechanism, improving the model's classification accuracy by fusing features of different scales [16]. However, GAN-RNN may lose local key information during feature extraction or fusion, affecting the model's comprehensive capture of features related to fraudulent behavior, thereby affecting the model's fraud detection capability [17]. GAN-CNN cannot adaptively adjust according to different transaction data features and fraud patterns, making it difficult to output more comprehensive and accurate fraud detection results [12].

Compared with traditional methods, this study employs a Generative Adversarial Network (GAN) to generate minority sample data and then combines it with a Deep Neural Network (DNN) to predict the categories of credit card transaction data. This approach has multiple advantages: it overcomes the issue of undersampling methods losing a large amount of data information, and also addresses the noise expansion and overfitting issues when the SMOTE oversampling method and

ADASYN oversampling method generate new samples. At the same time, applying the DNN model to the credit card fraud prediction problem expands the application range of deep learning technology and improves the model's predictive performance. In response to these issues, this paper proposes corresponding solutions. In terms of research methodology, it elaborates on the principles of Generative Adversarial Networks (GAN) and Deep Neural Networks (DNN), and constructs a credit card fraud prediction model. Through experimental design and analysis, including the introduction of the experimental environment, description and preprocessing of the dataset, and the determination of evaluation metrics, the experimental results are compared with common classification models and deep neural network classification models different data processing methods to further analyze model performance. Finally, the paper is summarized, highlighting the advantages of the research model and its reference value for financial institutions in credit card fraud prediction.

II. Research Methods

A. Generative Adversarial Networks (GAN)

Generative Adversarial Networks (GAN) [12] is an unsupervised neural network that consists of two networks for adversarial training. The goal of the generator is to synthesize samples that are difficult for the discriminator to distinguish, and the goal of the discriminator is to distinguish whether the samples generated by the generator are real samples as much as possible. In this paper, we use generative adversarial networks to generate fraud-like transaction data to solve the data imbalance problem in the original data. The modeling of the generative adversarial network is mainly divided into three aspects: the overall structure of the generative adversarial network, the modeling of the data generator and the modeling of the data discriminator.

- Overall structure of generative adversarial network

In this paper, Conditional Generative adversarial Network (CGAN), a derivative model of generative adversarial network, is used to generate fraudulent credit card transaction data to solve the problem of extremely unbalanced number of positive and negative samples in credit card transaction data. The conditional generative adversarial network model in the credit card fraud prediction model adds the credit card transaction data category label y to the data generator model and the data discriminator model in the model, so that the data generated by the generator is artificial credit card transaction data with the same distribution as the real data under the condition of meeting the category label y. This makes the adversarial network model easier to control, solves the uncertainty of the original generative adversarial network generation model, and makes the generated credit card transaction data more in line with our expectations. At the same time, it also makes the conditional generative adversarial network model can quickly reach the convergence conditions in the training process, the model is not easy to collapse, and the training process is easier to control. The overall structure of the conditional generative adversarial network in the credit card fraud prediction model is shown in Fig. 1.

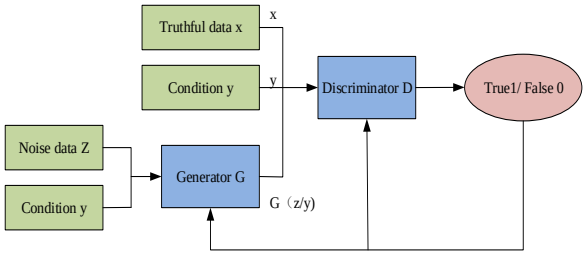

Fig. 1. Overall structure of conditional generative adversarial networks for credit card fraud prediction.

The objective function of the Conditional Generative Adversarial Network (CGAN) model in the credit card fraud prediction model is expressed in Eq. (1). In this equation, pdate represents the distribution of real credit card transaction data, y represents the category label of credit card transactions, pz represents the distribution of credit card transaction data generated by the generator, and y' represents the category label generated by the generator for the credit card transactions. When training the generator, the goal is to maximize V(D, G), whereas when training the discriminator, the goal is to minimize V(D, G).

$$\min_G \max_D V(D,G) = E_{x\sim P_{date}(x)}\left[\log D(x|y\right] + E_{z\sim p_z(z)}\left[\log(1-D(G(x|y)))\right] \quad (1)$$

- Data generator model

Credit card transaction data has the characteristics of huge data volume and moderate data feature dimension, and good results can be achieved by using a fully connected deep neural network. Therefore, the data generator model of the conditional generative adversarial network in the credit card fraud prediction model in this study adopts a fully connected deep neural network. In this model, the random noise data z conforming to Gaussian distribution and the credit card transaction data category label y are combined as the input of the data generator model, and the input layer and the hidden layer are connected in a fully connected manner. In addition, in order to improve the fitting ability of the deep neural network, a nonlinear activation function needs to be added between the layers. However, the sigmoid activation function is easy to cause the problem of gradient disappearance. Therefore, leakyrelu activation function needs to be added between the input layer and the hidden layer in the data generator model. Each hidden layer is also connected with the upper hidden layer in a fully connected way, and the leakyrelu activation function is used, and the connection between the last layer and the output layer is also fully connected. The network structure of the data generator model in the credit card fraud prediction model is shown in Fig. 2.

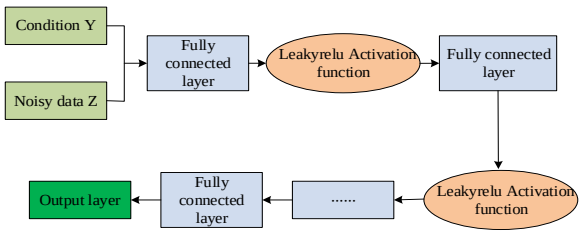

Fig. 2. Network structure of data generator model.

The training of the data generator model should ensure that the data discriminator model does not change, and the goal of the data generator model is to make the data discriminator not be able to determine whether the data is real credit card transaction data or credit card transaction data generated by the generator. Therefore, the loss function of the data generator model is shown in Eq. (2):

$$V(G) = E_{z\sim p_z(z)}\left[\log(1-D(G(z|y)))\right] \quad (2)$$

The training process of the data generator model is the process that minimizes this V(G), the data generator model Algorithm 1 shows the training process.

Algorithm 1: Training process of data generator model

Input：Random noise data z, label y

Output：Data generator

（1）Initializes the data generator

（2）The sample set is composed of m minibatch samples collected from pg(z) of Gaussian distribution

$$Z = \left\{z^{(1)}, z^{(2)}, z^{(3)}, \cdots, z^{(m)}\right\}$$

（3）The sample set of noise is connected to the class label y to obtain the input of the data generator

$$input = \left\{(z^{(1)}, y), (z^{(2)}, y), (z^{(3)}, y), \cdots (z^{(m)}, y)\right\}$$

（4）The input data input passes through multiple hidden layers and the leakyrelu activation function to get the output data

$$output = \left\{z_g^{(1)}, z_g^{(2)}, z_g^{(3)}, \cdots, z_g^{(m)}\right\}$$

（5）The gradient descent algorithm is used to update the parameters of the data generator model to make the loss function of the generator

$$V(G) = E_{z\sim p_z(z)}\left[\log(1-D(G(z|y)))\right]$$

Min.

- Data discriminator model

In addition, in the credit card fraud prediction model, the data discriminator model is required to correctly identify fraud transaction samples when solving the problem of data class imbalance. Therefore, adding the category label y to the input of the data discriminator can make the training process of the data discriminator model more targeted. The network structure of the data discriminator model in the credit card fraud prediction model is shown in Fig. 3.

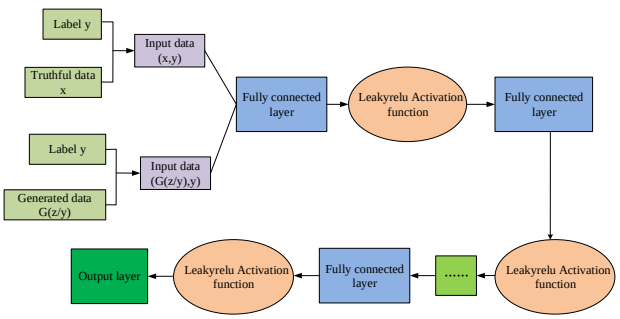

Fig. 3. Network structure of data discriminator model.

While training the data discriminator model, we need to ensure that the data generator model does not change, and the goal of the data discriminator is to make the discriminator maximally distinguish between the credit card transaction data generated by the generator and the real credit card transaction data. Therefore, the loss function of the data discriminator model is shown in Eq. (3):

$$V(D) = E_{x\sim p_{date}(x)}\left[\log D(x|y)\right] \quad (3)$$

The learning purpose of the data discriminator model in the conditional generation adversarial network is to maximize V(D). The specific training process is shown in Algorithm 2.

Algorithm 2: Training process of data discriminator model

Input：Data generator generated data G(z|y), real data x, label y

Output：Data discriminator

（1）Initializes the data discriminator

（2）From the distribution $p_{date}(x)$ of the real credit card transaction data, m minibatches of data are randomly selected to form the data set of the real data

（3）From the data G(z|y) sample generated by the data generator, m minibatch data are randomly selected to form the data set generated by the generator

$$G = \left\{g^{(1)}, g^{(2)}, g^{(3)}, \cdots, g^{(m)}\right\}$$

（4）A dataset of real data is concatenated with label y to obtain a portion of the discriminator input.

$$input1 = \left\{(x^{(1)}, y), (x^{(2)}, y), (x^{(3)}, y), \cdots, (x^{(m)}, y)\right\}$$

（5）The data set of generated data is concatenated with label y to obtain a portion of the discriminator input

$$input2 = \left\{(g^{(1)}, y), (g^{(2)}, y), (g^{(3)}, y), \cdots, (g^{(m)}, y)\right\}$$

（6）input1 and input2 are mixed to get the discriminator input

$$input = \left\{(x^{(1)}, y), (x^{(2)}, y), \cdots, (x^{(m)}, y), (g^{(1)}, y), (g^{(2)}, y), \cdots, (g^{(m)}, y)\right\}$$

（7）The input data input passes through the hidden layer and the leakyrelu activation function to get the output data

$$logits = \left\{z_g^{(1)}, z_g^{(2)}, z_g^{(3)}, \cdots, z_g^{(m)}\right\}$$

（8）The output logits of the last layer of the hidden layer is used by the sigmoid activation function to obtain the output of the entire discriminator

$$\text{output} = sigmoid(\log its)$$

（9）The gradient ascending algorithm is used to update the parameters of the discriminator and make the loss function of the discriminator

$$V(D) = E_{x\sim p_{date}(x)}\left[\log D(x|y)\right]$$

Max.

B. Deep Neural Networks

The neural network model has a strong fitting ability, and the deep neural network is deeper than the ordinary neural network, that is, the hidden layers are more, and its fitting ability is relatively stronger. The deep neural network model is shown in Fig. 4.

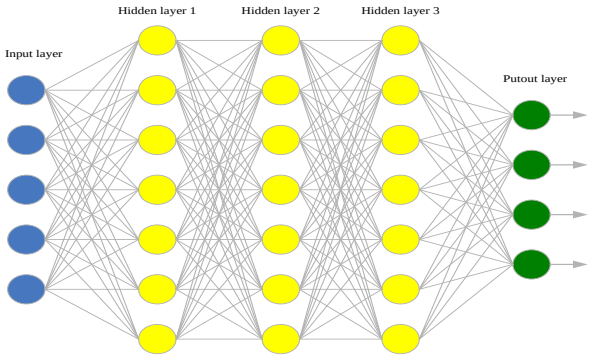

Fig. 4. Deep neural networks model.

According to the characteristics of credit card historical transaction data, the deep neural network classifier model of credit card fraud prediction model can obtain good results by using the deep fully connected neural network model. The network structure of the deep neural network classifier in the credit card fraud prediction model is shown in Fig. 5.

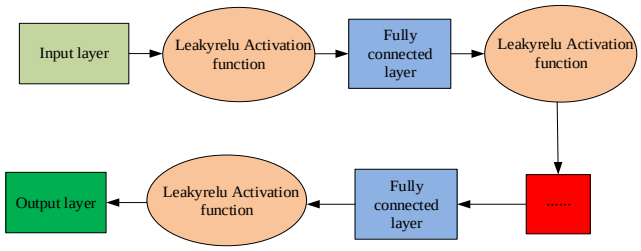

Fig. 5. Network structure of deep neural network classifier.

In the training process of deep neural network classifier, cross entropy can be used as a loss function. The definition of cross entropy is shown in Eq. (4):

$$Loss = \frac{1}{N}\sum_i -\left[y_i \cdot \log(p_{i)} + (1-y_i)\cdot \log(1-p_i)\right] \quad (4)$$

In the cross entropy loss function, N represents the number of samples, yi represents the actual value of the i th sample, the fraudulent transaction sample is 1, the normal transaction sample is 0, pi represents the predicted value of the i th sample, that is, the probability value of the i sample predicted as the fraudulent sample. Cross entropy loss function is often used in conjunction with softmax activation function, which can improve the speed and effectiveness of model training to a certain extent. The detailed training process of deep neural network classifier is shown in Algorithm 3.

Algorithm 3: Training process of deep neural network classifier

Input：Training set

$X = \{(x^{(1)}, y^{(1)}), (x^{(2)}, y^{(2)}), (x^{(3)}, y^{(3)}), \cdots, (x^{(m)}, y^{(m)})\}$, among $y^i = \{0,1\}$

Output：Deep neural network classifier D

（1）Initialize all variables in a deep neural network, including weight vectors and paranoid value vectors

（2）Loop iteration □ = 1,2,3,⋯,□：

①Calculate the output of the classifier based on the current parameters and formulas

②The parameters of the classifier are updated by gradient descent algorithm to make the cross entropy loss function

$$Loss = \frac{1}{N}\sum_i -\left[y_i \cdot \log(p_{i)} + (1-y_i)\cdot \log(1-p_i)\right]$$

Min.

C. Credit Card Fraud Prediction Model

The credit card fraud prediction model uses generative adversarial networks to deal with the class imbalance problem in credit card transaction data, and then combines the deep neural network model in the field of deep learning to predict the class of credit card transaction samples. An example plot of a credit card fraud prediction model is shown in Fig. 6.

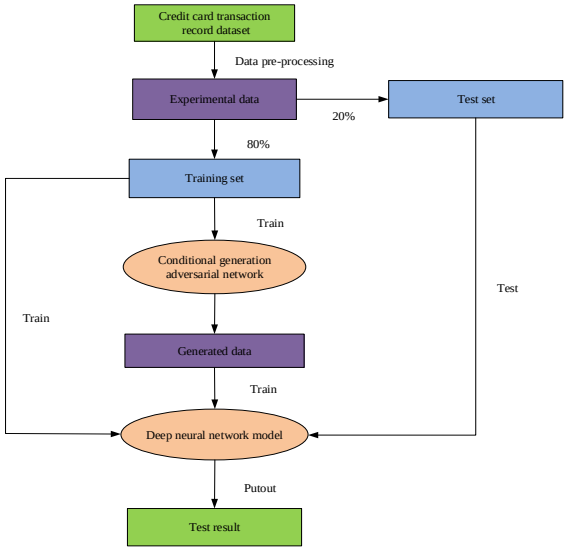

Fig. 6. Credit card fraud prediction model.

In the credit card fraud prediction model of this study, the generative adversarial network is used to generate fraud sample data to solve the extreme imbalance problem between fraud sample data and normal transaction sample data in the original credit card transaction data set, and then the high fitting ability of deep neural network is used to predict the credit card transaction category.

III. Experimental Design and Analysis

A. Experimental Environment

This article was tested using Windows 11, AMD Ryzen 7 5800H CPU, 16 GB of memory, NVIDIA GeForce RTX 3060 display card. In the process of building the model, Sklearn toolkit and Keras toolkit of Python programming language are used to achieve.

B. Data Set Description and Preprocessing

The dataset was collected from November 2022, through a professional consulting company, including open data information from volunteers, commercial banks, private banks, and credit cooperatives. Currently, the dataset contains transaction records of 10,000 credit card users, including different regions, age groups, and professional backgrounds, ensuring the diversity and representativeness of the data. Among the 10,000 users, after strict data cleaning and labeling, it is confirmed that 178 users have fraudulent behavior, that is, the proportion of fraudulent users is 1.78%. Although this proportion is not high, considering the potential harm of fraudulent behavior to financial institutions, accurate prediction is particularly important.

There are 31 feature variables in this dataset with no missing values. For the purpose of protecting cardholder privacy, their original characteristics and background information are not provided. Features V1, V2, ... V28 is the result of dimensionality reduction through PCA. The specific information of the data set is shown in Table I:

TABLE I. DATASET ATTRIBUTE TABLE

Ordinal	Field Name	Data Type	Field Description
1	Time	Float	The number of seconds elapsed between this transaction and the first transaction in the dataset
2-29	V1-V28	Float	Principal component data
30	Amount	Float	Transaction amount
31	Class	Float	In the case of fraud, take it as one, otherwise take zero.

C. Credit Card Fraud Prediction Model

While constructing and training the model, we need to establish a rational and effective indicator system to verify and evaluate the model's performance. The evaluation indicators used in this paper include Accuracy, Precision, Recall calculation formula is as follows:

$$Accurary = \frac{TP + TN}{TP + TN + FP + FN} \tag{5}$$

$$\Pr ecision = \frac{TP}{TP + FP} \tag{6}$$

$$Recall = \frac{TP}{TP + FN} \tag{7}$$

Among, TP represents the sample that predicted a positive example as a positive example; FP is the sample that predicts a negative example as a positive example. FN is denoted as the sample that predicts a positive example as a negative example; TN denotes the sample for which a negative example is predicted as a negative example.

IV. ANALYSIS OF EXPERIMENTAL RESULTS

In order to verify the effectiveness of the model proposed in this study, we use credit card transaction data set to train common classification models and deep neural network classification models for detailed comparison. The performance effect is shown in Table II.

TABLE II. CLASSIFIER TEST RESULTS

Model	accuracy	precision	recall
Logistic regression [18]	0.8623	0.9836	0.8612
Naive Bayes [19]	0.7657	0.9829	0.7634
Decision-Making tree [20]	0.8526	0.9882	0.8510
Kproximity Classifier [21]	0.7584	0.9800	0.7534
SVM [22]	0.8321	0.9902	0.8308
AdaBoost classifier [23]	0.8112	0.9938	0.8094
Dnn classifier [24]	0.9232	0.9985	0.9192

In order to verify the effectiveness of conditional generative adversarial networks in generating new samples, In this study, the experimental results of combining conditional generative adversarial network model with deep neural network classifier and the experimental results of not processing imbalanced data only using deep neural network classifier, the experimental results of combining random undersampling with deep neural network classifier, the experimental results of combining SMOTE oversampling with deep neural network classifier, and the experimental results of combining SMOTE oversampling with deep neural network classifier The test results of ANASYN oversampling combined with deep neural network classifier were compared, and the final results are shown in Table III.

TABLE III. EXPERIMENTAL RESULTS OF VARIOUS UNBALANCED DATA PROCESSING METHODS

Model	Accuracy	Precision	Recall
DNN [25]	0.9232	0.9985	0.9192
Random undersampling+dnn	0.9280	0.9987	0.9348
SMOTE+dnn	0.9250	0.9983	0.9192
ANASYN+dnn	0.9300	0.9989	0.9406
CGAN+dnn	0.9350	0.9991	0.9501

The ROC curve is shown as follows (Fig. 7):

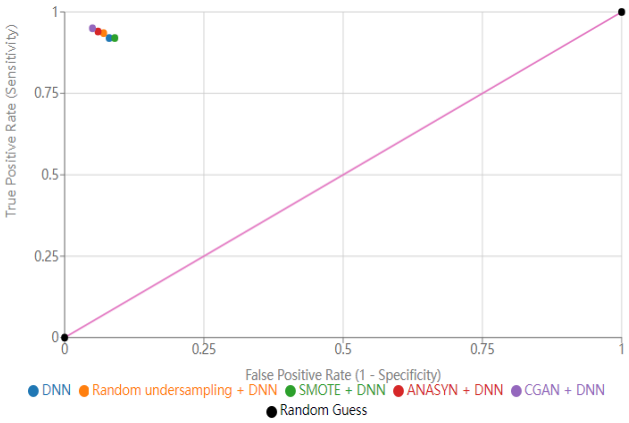

Fig. 7. ROC curve analysis chart.

Fig. 6 presents a performance comparison of various deep neural network (DNN) variants in the receiver operating characteristic (ROC) space. These variants include the basic DNN model as well as DNN models combined with different data balancing techniques such as random undersampling, Synthetic Minority Over-sampling Technique (SMOTE), Analytic Synthetic (ANASYN), and Conditional Generative Adversarial Network (CGAN). By analyzing the distribution of these models in the ROC space, we can draw several key observations, among which the most remarkable is the outstanding performance of the CGAN+DNN model.

The CGAN+DNN model stands out among all tested models and shows the optimal performance indicators. This model achieves a true positive rate (TPR) of 0.95 and a false positive rate (FPR) of only 0.05. This result is closest to the ideal upper left corner position in the ROC space. The excellent performance of CGAN+DNN can be attributed to the unique advantage of CGAN in generating high-quality synthetic samples. By generating realistic and diverse minority class samples, CGAN effectively alleviates the data imbalance problem, thereby significantly improving the classification performance of DNN.

The advantages of the CGAN+DNN model are more prominent in comparison with other models:

Compared with the basic DNN model, CGAN+DNN has achieved significant improvements in both TPR and FPR indicators. This indicates that CGAN not only improves the model's ability to recognize positive examples but also reduces the probability of misjudging negative examples as positive examples.

Compared with SMOTE+DNN, CGAN+DNN shows obvious advantages. As a traditional oversampling technique, SMOTE seems to fail to effectively improve the performance of DNN in this study. This comparison highlights the superiority of CGAN in generating complex and high-quality synthetic samples.

Although the ANASYN+DNN model also performs very well (TPR is 0.94 and FPR is 0.06), CGAN+DNN is still slightly better. This small but significant difference reflects the superiority of CGAN in capturing the complexity of data distribution.

Random undersampling+DNN performs quite well in this study, but still cannot surpass CGAN+DNN. This comparison not only emphasizes the advantages of CGAN but also reveals that in some cases simple techniques may also produce good results.

The outstanding performance of the CGAN+DNN model is not only reflected in numbers but more importantly in its potential in practical applications. When dealing with highly imbalanced datasets, CGAN can generate diverse and real synthetic samples, which is particularly important in key fields such as medical diagnosis and fraud detection. The samples generated by CGAN can help the model learn richer feature representations, thereby effectively controlling FPR while maintaining a high TPR, which is crucial in many practical applications.

V. Conclusion

This paper proposes an innovative method to address the challenges of credit card fraud detection. By leveraging generative adversarial networks (GAN) to generate synthetic fraud samples, the problem of class imbalance in credit card transaction data is alleviated. The authors present a deep neural network (DNN) model that, in combination with the samples generated by GAN, predicts credit card fraud with high accuracy. The research also conducts a comprehensive comparison with existing classification algorithms and sampling methods, demonstrating the effectiveness of the proposed model in enhancing the ability of financial institutions to predict and prevent fraud.

The innovation points of this article: The use of conditional generative adversarial networks (CGAN) to generate synthetic fraud samples, which introduces a new dimension in dealing with the class imbalance problem by incorporating class labels into the model. The combination of CGAN and DNN creates a powerful prediction model that not only addresses the data imbalance issue but also utilizes the strong fitting ability of DNN. The model is capable of generating high-quality synthetic samples, facilitating the training process, thereby increasing the detection rate and achieving more controlled convergence during model training.

Facing industry constraints and challenges in data collection, our current research is predicated on a relatively modestly sized dataset. In the future, we have already planned to employ a more extensive dataset, which will be reflected in our subsequent studies. We have already charted a course that includes the utilization of a plethora of machine learning models for broader and more profound testing, thereby enhancing the robustness and scalability of our models. This will further validate and refine the model's performance across a wider and more diverse array of credit card transactions. We will also explore an expanded repertoire of machine learning models and their integration with Generative Adversarial Networks (GANs) to bolster the model's resilience and scalability. Additionally, we will investigate the model's long-term predictive accuracy and its capacity to adapt to the ever-evolving patterns and techniques of fraud. Based on the proposed model, we aim to develop a real-time fraud detection system that provides immediate alerts to financial institutions.

Impact Analysis of Informatization Means Driven by Artificial Intelligence Technology on Visual Communication

Lei Ni
School of Art and Design, Yellow River Conservancy Technical Institute, Kaifeng 475004, China

***Abstract*—With the popularization of computer technology, the combination of artificial intelligence and image processing technology has become a research hotspot in the visual communication. Image processing technology mostly involves segmentation and detection of images. Image segmentation often focuses on extracting image contour information, while ignoring the color of the image. The calculation time for image detection is relatively long, and the calculation steps are also relatively cumbersome. In response to the above issues, a density peak clustering algorithm was proposed for image segmentation. In the phase of image detection, the region recommendation network is introduced to improve the faster region Convolutional neural network algorithm. The findings demonstrate that under 15% Gaussian noise and 10% Salt-and-pepper noise, the segmentation accuracy of the density peak clustering algorithm is 98.13% and 97.89% respectively. The accuracy, recall and F-measure of the improved fast region Convolutional neural network algorithm are 98.49%, 97.29% and 97.77% respectively. The accuracy and average time consumption in the graphics processor environment are 98.18% and 2.94ms, respectively. In conclusion, the image segmentation algorithm based on density peak clustering algorithm and the improved fast region Convolutional neural network algorithm are robust, which have good segmentation and detection effects.**

***Keywords*—Image segmentation; image detection; density peak clustering algorithm; convolutional neural network; faster region convolutional neural network**

I. Introduction

A. Research Background

With the continuous progress of science and technology,the Visual communication is also seeking breakthroughs [1-2]. As a common form of visual communication, the processing technology of images has also shifted from artificial to intelligent [3]. Especially in today's increasingly popular digital information processing and transmission, images, as the most intuitive form of visual expression, have become an indispensable part of information communication. Image processing technology includes image digitization, image enhancement and restoration, image data encoding, image segmentation (IS), and image detection technology. Covering various aspects from image acquisition, image analysis to image understanding, the progress of these technologies directly promotes the rapid development of application fields such as medical imaging, autonomous driving, intelligent security, entertainment media, etc. [4]. As a key link in image processing technology, image segmentation and detection are becoming increasingly important. Among them, IS technology divides an image into several specific and unique regions. Then the area is extracted and displayed independently [5-7]. The application of this technology can help computers identify and extract regions of interest in images, while image detection technology determines their categories and locations through further analysis and localization of these regions. Image detection technology refers to IS based on target geometry and statistical features. Furthermore, the segmentation and recognition of the target are combined to determine the location and size of the target [8]. In recent years, with the introduction of deep learning algorithms, especially the successful application of convolutional neural networks (CNN) in image processing, the accuracy and speed of image segmentation and detection have been greatly improved. Meanwhile, emerging technologies such as convolutional neural networks combined with region recommendation networks also provide broad space for further optimizing image processing.

B. Existing Issues

Although deep learning has made significant progress in image segmentation and detection, there are still some issues that need to be addressed urgently. First, traditional IS algorithms often use image contour information to extract regions of interest in images. The importance of color information in images is ignored, resulting in computational redundancy. Traditional image detection algorithms are mostly based on the depth CNN to detect image objects. Its computation takes a long time, which can easily lead to computational redundancy and a large amount of memory occupation, resulting in slow image object detection speed. Secondly, the widely used convolutional neural networks have a large computational load and slow detection speed when processing image detection. Due to the complexity of convolution operations, especially when generating candidate regions, a large number of redundant computational steps can lead to excessive memory consumption and significantly increased processing time, making it difficult to meet real-time requirements [9]. In addition, existing algorithms perform poorly in processing images with high noise or complex backgrounds, easily losing key details and leading to a decrease in detection accuracy. Finally, some existing image segmentation and detection methods mostly rely on the specific distribution of data, and the algorithm has poor universality to the dataset. The robustness and adaptability of algorithms still need to be improved when facing different application scenarios or data types. Especially in practical applications, the

*Corresponding Author.

diversity and complexity of image data pose higher requirements for algorithms. Therefore, designing an algorithm that can simultaneously handle multiple complex situations, improve segmentation and detection accuracy, and has efficient computing capabilities has become an important research direction in the field of visual communication.

C. Research Content and Innovative Points

In response to the above issues, based on the low requirement for data distribution and simple principle of the Density Peak Clustering (DPC), the image center information and color information are extracted separately for IS work to obtain the DPC-IS algorithm. In order to achieve the image detection target, the fast-regional Convolutional neural network (FastR-CNN) algorithm is improved by introducing the regional recommendation network. The innovation points of the research mainly include the following two points. Firstly, DPC-IS algorithm is used to extract the center information and color information, which is convenient for Hierarchical clustering of pixels in the image. Then, based on the FastR-CNN algorithm, a regional recommendation network is introduced to reduce computational redundancy and improve detection accuracy and speed. The research structure contains four parts. The first is a review of relevant research results. The second is the DPC-IS algorithm and the FasterR-CNN algorithm construction. The third part is to verify the availability of the IS and image detection. The final part is a summary.

II. Related Work

IS is an important image-processing technology. The purpose is to segment the image into practical and non-interference regions. Objects of interest in the area can be displayed independently from the Background independence. As a hotspot direction in computer vision, how to apply IS technology to different professional fields has been deeply explored by many scholars. Shi et al. designed a fuzzy contour model based on multi-channel CNN to enhance the segmentation accuracy of medical images. The findings demonstrate that the model has good segmentation performance and robustness [10]. Liu et al. designed an IS algorithm based on deep learning network to identify the particle size distribution of crushed ore. Firstly, this algorithm was applied to preprocess the raw ore images. Then, deep learning networks were used to generate optimization model. The feasibility of this algorithm has been verified through simulation experiments [11]. Ji proposed a Level set algorithm based on significant fitting energy to solve the noise and non-uniformity of gray levels in image segmentation. This algorithm introduced a distance regularization term to eliminate the reinitialization process. Simulation experiments show that the algorithm has good segmentation ability in visual perception [12]. To improve the noise resistance and discrimination of segmented images with uneven grayscale, Li et al. designed a Bayesian criterion based on image segmentation. Local prior region descriptions were used to characterize image regions. From the simulation experiment, this method has superior performance in time efficiency and noise robustness [13]. Biswas et al. proposed a segmentation image active contour model to improve the image segmentation effect by combining the local binary fitting energy function and the improved Laplacian Gaussian function energy function. The findings indicate that the active contour model has good performance in segmentation accuracy, F-value, and Central Processing Unit (CPU) execution time [14].

Image detection technology is another important means in image processing technology. The purpose is to enable computers to automatically recognize target categories in images. By drawing a bounding box around the target, the position of each target is labeled. Chen proposed a license plate recognition model based on CNN and K-means clustering segmentation to address the recognition difficulties caused by uneven license plate form, color, viewpoint, and lighting environment. From the findings, this model can improve the recognition and detection accuracy [15]. Vinolin et al. proposed a deep CNN based on Taylor rider optimization algorithm for detecting concatenated images. Compared with traditional detection algorithms, precision measurement accuracy has been significantly improved [16]. Based on the fast CNN model, Luo et al. introduced neural architecture search optimization and feature enrichment to achieve multi-scale vehicle target detection in traffic scenes. From the findings, the robustness of the detection method is effectively improved [17]. Ramaraj proposed a face image detection algorithm based on CNN with Long short-term memory, aiming at the difficulty of face image detection caused by facial occlusion and low resolution. The research results confirm that the detection algorithm has superior performance and good detection accuracy [18]. Joy et al. constructed a fast-regional CNN multi object detection method based on incremental classification in the monitoring field. This detection method was mainly divided into class incremental learning part and domain adaptive part. The experimental results confirm that this method performs well on challenging targets including lighting changes, shadows, partial occlusion, and dynamic backgrounds [19].

To summarize, in image processing technology, there are rich research achievements in IS algorithm and image detection algorithm. But most IS algorithms only utilize the contour information of the image, ignoring the importance of the color information of the image. Most image detection algorithms require a significant amount of time when generating candidate regions through selective search. This process will generate a large number of invalid regions, resulting in wasted computing power. To address the above issues, a DPC-IS algorithm is constructed for IS based on spatial color distribution. The FasterR-CNN algorithm is constructed to detect target images.

III. DPC-IS Algorithm Design and FasterR-CNN Algorithm Construction

As a visual communication medium, images can express information in the most intuitive and authentic way. Therefore, compared to other media, images convey a richer amount of information. To process images more intuitively, DPC-IS algorithm and FasterR-CNN algorithm are used for segmentation and detection. This chapter focuses on the DPC-IS algorithm design and the FasterR-CNN algorithm construction in image detection.

A. Design of DPC-IS Algorithm in Image Segmentation

In Visual communication, image is not only a widely used form, but also a unique data format. Pixels are evenly arranged in the image space. Each pixel carries a unique color label. And each pixel has two features, namely spatial position feature (X,Y) and color feature (R,G,B). The spatial and color features are uniformly set to 1 dimension. The spatial and color features are merged to form a two-dimensional space. A two-dimensional sparse matrix (i,j) is used to represent an image. The value of matrix (i,j) is 0 or 1, indicating whether the pixel value of image i is j, as shown in Fig. 1.

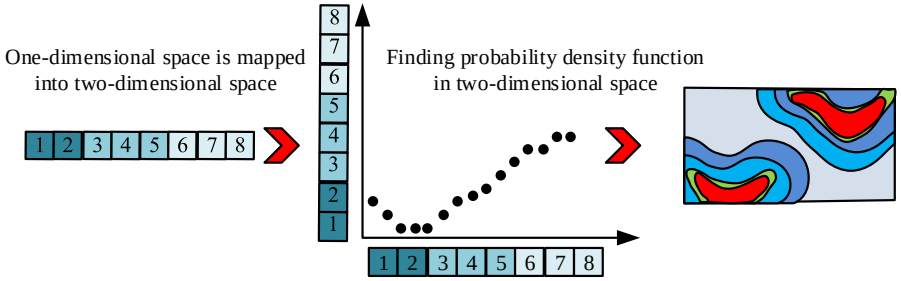

Fig. 1. The 1-dimensional space is mapped to the 2-dimensional space and the distribution of probability density function is obtained.

After obtaining the two-dimensional spatial distribution position of image pixels in Fig. 1, the kernel probability density function is used to measure the distribution of pixel points. For a set $\{X_1, X_2, \cdots, X_n\}$ with n sample points, the probability density function $f_g(x)$ of a certain point is equal to the sum of the influences of all data samples at that point, as shown in Eq. (1)

$$f_g(x) = \frac{1}{nh}\sum_{i=1}^{n} K\left(\frac{X - X_i}{h}\right) \tag{1}$$

In Eq. (1), n is the sample points. K represent the kernel function. h is the window width. When using kernel functions to estimate the probability density function, the distance $d\left(\left|P_i, P_j\right|\right)$ between data points P_i and P_j in the 5-dimensional space (X,Y,R,G,B) needs to be defined, as shown in Eq. (2).

$$d\left(\left|P_i, P_j\right|\right) = \sqrt{\left(\frac{d_s}{\alpha_s}\right)^2 + \left(\frac{d_c}{\alpha_c}\right)^2} \tag{2}$$

In Eq. (2), d_s and d_c represent spatial distance and color distance, respectively. α_s and α_c are spatial smoothing parameters and color smoothing parameters, respectively. The values of α_s and α_c need to be manually set. The expression of spatial distance d_s is shown in Eq. (3).

$$d_s = \sqrt{\left(x_i - x_j\right)^2 + \left(y_i - y_j\right)^2} \tag{3}$$

In Eq. (3), x_i and x_j represent the horizontal distances of i and j. y_i and y_j stands for the vertical distances of i and j, respectively. The color distance d_c is expressed as an approximate CIElab color distance, as shown in Eq. (4).

$$dc = \sqrt{\left(2 + \frac{\bar{r}}{256}\right) \times \Delta R^2 + 4 \times \Delta G^2 + \left(2 + \frac{255 - \bar{r}}{256}\right) \times \Delta B^2} \tag{4}$$

In Eq. (4), ΔR, ΔG and ΔB stands for the weighted Euclidean distances of red, green, and blue, respectively. $\bar{r}$ refers to the average level of red. The expressions of ΔR, ΔG and ΔB are shown in Eq. (5).

$$\begin{cases} \Delta R = r_i - r_j \\ \Delta G = g_i - g_j \\ \Delta B = b_i - b_j \end{cases} \tag{5}$$

In Eq. (5), r_i and r_i represent the red distances of i and j. g_i and g_j stands for the green distances of i and j. b_i and b_j represent the blue distances of i and j, respectively. The probability density function f of the kernel function is shown in Eq. (6).

$$f = \frac{1}{n}\sum \exp\left(\frac{d_s^{\,2}}{\alpha_s^{\,2}} + \frac{d_c^{\,2}}{\alpha_c^{\,2}}\right) \tag{6}$$

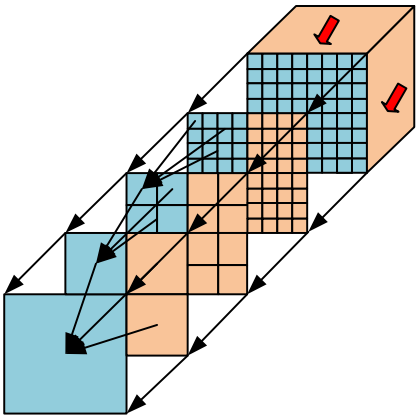

Fig. 2. Schematic diagram of the reduction algorithm.

To reduce the computational complexity of the probability density function in 5-dimensional space, CUDA programming was used to accelerate graphics processing unit (GPU) operations on images. Color information is mapped to a 2D image. The protocol algorithm is used to search for color points with the maximum probability density function value. The color of this point and the corresponding function values are output to the density map and color map, respectively. Fig. 2 depicts the protocol algorithm [20-21].

The constraint algorithm in Fig. 2 follows the CUDA setting for finding the probability density function. For the 3D color space corresponding to the original pixel Block, the maximum value of Thread in 16 color spaces is calculated sequentially, transforming the 3D color space into a 2D color space. Recursively compare the density values of four positions in a two-dimensional color space. The maximum values of the four positions are passed to the next layer of color space until the maximum density value in the three-dimensional color space is finally determined. The density map containing contour information estimated by the spatial color probability density function has unclear boundaries. Therefore, a non-maximum suppression algorithm is adopted to refine the image boundary contour and apply it to IS [22]. Traditional algorithms only use image contour information and ignore image color information, resulting in the inability to specify segmentation levels. The DPC algorithm was applied to IS work to obtain the DPC-IS algorithm. DPC is a clustering algorithm based on center points. The local density ld of the sample points is used to define the clustering center t and the nearest distance md. The local density ld_i of sample point i is illustrated in Eq. (7) [23].

$$ld_i = \sum_j \chi\left(d\left(i,j\right) - d_c\right) \tag{7}$$

In Eq. (7), $d\left(i,j\right)$ stands for the Euclidean distance between samples i and j. d_c stands for the cutoff distance. When $x<0$, $\chi\left(x\right)=1$. Otherwise, the value is 0. The expression of cluster center t_i is illustrated in Eq. (8).

$$t_i = \arg\min_{j:ld_j > ld_i}\left(d\left(i,j\right)\right) \tag{8}$$

In Eq. (8), ld_j refers to the local density of sample point j. The $\arg\min$ function refers to the value of a variable when $d\left(i,j\right)$ reaches the minimum value. The segmentation effect varies with the number of cluster centers, as shown in Fig. 3.

Fig. 3 shows the segmentation results with clustering centers of 2, 5, 7, 12, 14, and 20, respectively. As the number of clustering centers increases, the regions segmented by the DPC-IS algorithm are also increasing. The segmentation details are gradually improving. The nearest distance md_i of sample point i is shown in Eq. (9).

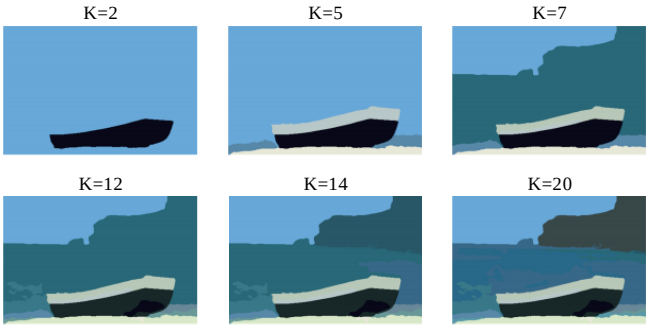

Fig. 3. Schematic diagram of segmentation effect of different clustering centers.

$$md_i = \min_{j:ld_j > ld_i} d\left(i,j\right) \tag{9}$$

When the DPC algorithm is applied to IS, the previously obtained density map containing pixel distribution center information can be directly used as the local density of pixels. The nearest distance of pixel point k is shown in Eq. (10).

$$md_k = \min d_c\left(i,j\right) \tag{10}$$

In Eq. (10), pixels l and k are segmented adjacent. $ld_l > ld_k$. The definition of adjacent segmentation is that if two pixels are adjacent, the segmentation area to which the two pixels belong is adjacent.

B. Construction of FasterR-CNN Algorithm in Image Detection

The CNN model, as a fresh neural network model, is extensively applied in image processing. Unlike traditional neural network models, CNN models add many feature learning components to the existing network. The hidden layer is reasonably divided into convolutional layer and pooling layer, in order to directly use convolutional layer to train image data. The features of interested objects in the graph are extracted, reducing the computational workload of object detection. The CNN model structure is shown in Fig. 4.

Fig. 4 depicts the essential framework of the CNN model. It mainly consists of a series of convolutional layers, incentive layers, pooling layers, and fully connected layers (FCL). The expression of convolutional layer is shown in Eq. (11).

$$x_n^l = f\left(\sum_{i\in G_n} x_m^{l-1} * Kernel_{mn}^l + a^l\right) \tag{11}$$

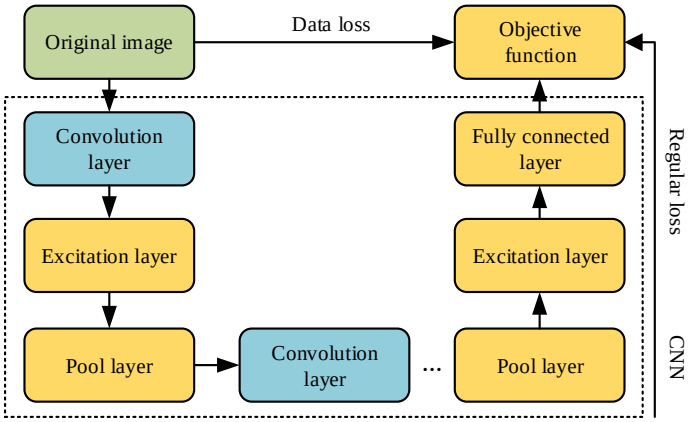

Fig. 4. Schematic diagram of CNN model structure.

In Eq. (11), x_n^l represents the m-th neuron in the l-th layer. *Kernel* refers to the convolutional kernel of the layer. b is the bias term. * represents convolutional operations. G_n represents the number of inputs for the n-th neuron. $f(\square)$ is the nonlinear excitation function. The CNN model has local connectivity. Therefore, each neuron can only perceive a portion of the image, effectively reducing the interaction between neurons and computational complexity. Additionally, the same feature may exist at different locations in the image. The convolutional layer adopts a parameter sharing method, so that each convolutional kernel corresponds to a type of feature, thereby reducing the required parameters for training. The excitation layer introduces nonlinear features into the neural network, enabling it to approximate any nonlinear function. This effectively enhances the feature expression ability of CNN models. The commonly used expression of the excitation function is shown in Eq. (12).

$$\begin{cases} f_S(x) = \dfrac{1}{1+e^{-x}} \\ f_T(x) = \dfrac{e^{x}-e^{-x}}{e^{x}+e^{-x}} \\ f_R(x) = \begin{cases} x, x \geq 0 \\ 0, x < 0 \end{cases} \end{cases} \tag{12}$$

In Eq. (12), $f_S(x) = \dfrac{1}{1+e^{-x}}$ is sigmoid function. $f_T(x) = \dfrac{e^{x}-e^{-x}}{e^{x}+e^{-x}}$ is the Tanh function. $f_R(x) = \begin{cases} x, x \geq 0 \\ 0, x < 0 \end{cases}$ is ReLU function. The output of neurons is mapped to the $(0,1)$ interval through the sigmoid function. However, this function has a soft saturation characteristic, which can cause gradient disappearance in deep networks. The average output value of the Tanh function is closer to 0. It has good convergence, but still cannot solve the gradient disappearance. The ReLU function sets the output values of some neurons to 0, making the neural network sparse. To some extent, the problem of overfitting has been avoided. In addition, the derivative of the positive activation value of the ReLU function is 1, which can effectively avoid gradient disappearance. Therefore, ReLU function is used as the activation function of the excitation layer [24]. The pooling layer commonly uses maximum pooling and mean pooling to reduce the dimensionality of feature maps. The network parameters and computational complexity are reduced to facilitate feature compression, as shown in Fig. 5.

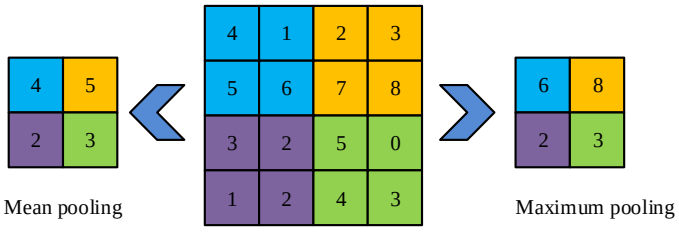

Fig. 5. Mean pool and maximum pool.

The feature data obtained from mean pooling in Fig. 5 is relatively sensitive to texture information. Maximizing pooling places more emphasis on background information. The function of the FCL is to integrate the features of the input image. The feature maps generated by convolutional layers are mapped into fixed length feature vectors to complete image classification tasks. The calculation of the FCL is shown in Eq. (13).

$$x_n^l = f\left(\sum_{i \in G_n} x_m^{l-1} * w_{m,n} + a_n\right) \tag{13}$$

In Eq. (13), x_n^l refers to the output neuron of the FCL. $w_{m,n}$ and a_n represent the weights and offsets between neurons, respectively. The image classification task requires adding a classifier after the high-dimensional feature vectors of the FCL. The feature vectors of the FCL are mapped to the probability of each category. The category with the highest probability is the classification result. The expression of function $g_\theta(x)$ is shown in Eq. (14).

$$g_\theta(x^i) = \frac{1}{\sum_{n=1}^{k} e^{\theta_n^T x^n}} \begin{bmatrix} e^{\theta_1^T x^n} \\ e^{\theta_2^T x^n} \\ \cdots \\ e^{\theta_n^T x^n} \end{bmatrix} \tag{14}$$

In Eq. (14), $\theta = \left[\theta_1^T \theta_2^T \cdots \theta_n^T\right]$ is the learning parameter of the classifier, including the Softmax cost function $F(\theta)$ of the weight penalty term, as shown in Eq. (15).

$$F(\theta) = -\frac{1}{i}\left[\sum_{m=1}^{k}\sum_{n=1}^{k}\{y^m = n\}\log\frac{e^{\theta_n^T x^m}}{\sum_{l=1}^{k} e^{\theta_l^T x^m}}\right] + \frac{\beta}{2}\sum_{m=1}^{k}\sum_{n=0}^{j}\theta_{mn}^2 \tag{15}$$

In Eq. (15), i is the samples. β is the coefficient of the regularization term. In the training process, CNN uses the Gradient descent to minimize $F(\theta)$, so as to find the optimal solution of parameter weight θ. Traditional regional CNN models consume a long amount of computation time when performing object detection. It is easy to cause computational redundancy and a large amount of memory consumption, resulting in slow target detection speed. To improve the detection accuracy and speed of graphics, the FasterR-CNN has been introduced. The FasterR-CNN algorithm is a deep learning algorithm that introduces regional recommendation networks to improve fast regional CNN networks. This algorithm utilizes convolutional network training to achieve target detection without any other algorithm operations. The selective search algorithm in regional recommendation networks is different from that in traditional regional CNN models. This method uses the feature map extracted from the last layer of CNN as the input feature. Convolutional kernels are used to move within the feature map and output suggestion boxes. Every time the convolution kernel moves, it will take the central position of the window as the base point to build nine anchor windows with different sizes and different Aspect ratio. It is mapped into the image to form a feature vector. Then the FCL is applied for classification and positioning. The FasterR-CNN algorithm structure is shown in Fig. 6.

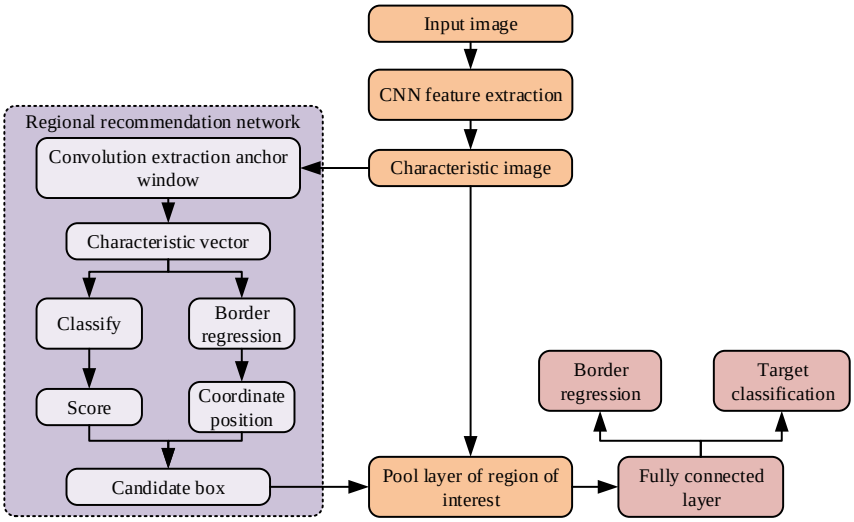

Fig. 6. FasterR-CNN algorithm flow diagram.

The algorithm flow in Fig. 6 is as follows. Firstly, the input image is extracted using CNN for feature extraction. Then input the extracted feature images into the region recommendation network for candidate border generation. The region border and feature map classify and locate the objective function through the pooling layer of interest in the fast region CNN network. The final image target detection effect is obtained.

IV. Result Analysis of 3DPC-IS Algorithm and FasterR-CNN Algorithm

To better validate the feasibility of the DPC-IS algorithm and FasterR-CNN algorithm, multiple control groups are set up in the BSDS500 database and Matlab simulation software for comparative experiments. This chapter focuses on the performance of DPC-IS algorithm and FasterR-CNN algorithm.

A. Performance Analysis of DPC-IS Algorithm

To prove the effectiveness of the DPC-IS algorithm, comparative experiments are designed using Simple Linear Iterative Clustering (SLIC), Fast Partitioning of Vector Value Images (FPVVI) algorithm, Normalized Cuts (NC) algorithm, and DPC-IS algorithm. The performance indicator is IS accuracy. The experimental platform is the BSDS500 database.

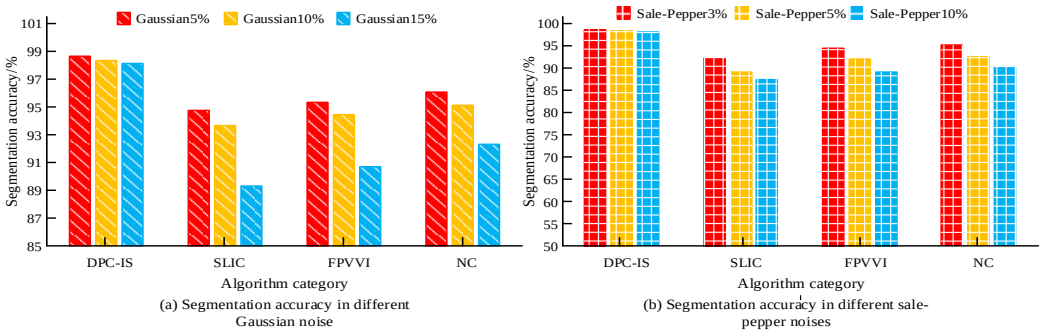

Fig. 7. Segmentation accuracy of four algorithms under different noise categories.

Fig. 7 depicts the segmentation accuracy of four algorithms in different noise categories. Fig. 7(a) depicts the segmentation accurac of four algorithms in different Gaussian noise categories. When the Gaussian noise is 5%, the segmentation accuracy of PDC algorithm is 98.65%. The SLIC, FPVVI, and NC algorithms are 94.75%, 95.33%, and 96.07%, respectively. When the Gaussian noise is 15%, the PDC, SLIC, FPVVI and NC algorithms are 98.13%, 89.31%, 90.69% and 92.31% respectively. Fig. 7(b) illustrates the segmentation accuracy of four algorithms in different Salt-and-pepper noise categories. When Salt-and-pepper noise is 3%, the segmentation accuracy of PDC algorithm is 98.45%. The SLIC, FPVVI, and NC algorithms are 92.15%, 94.32%, and 94.99%, respectively. When the Salt-and-pepper noise is 10%, the PDC, SLIC, FPVVI, and NC algorithms are 97.89%, 87.32%, 89.05%, and 90.12%, respectively. The research results show that as the media of Visual communication, the PDC algorithm has superior performance in the processing.

Fig. 8. Segmentation effect of four algorithms on some images.

The segmentation effects of the four algorithms on some images are shown in Fig. 8, Fig. 8(a) to Fig. 8(e) show the segmentation effects of the original image, DPC-IS algorithm, FPVVI algorithm, SLIC algorithm, and NC algorithm, respectively. The DPC-IS algorithm can effectively segment images. Compared to FPVVI, SLIC, and NC algorithms, the DPC-IS algorithm filters the background while retaining the main salient regions. Important areas are displayed separately from the background, making the visual communication effect more prominent. To assess the effectiveness in segmenting images, three performance indicators were introduced: Variance of Information (VI), Probabilistic Rand Index (PRI), and Segmentation Coverage (SC). VI is the difference between the segmentation and the benchmark result. The smaller the value, the better. The higher the values of PRI and SC, the better the performance.

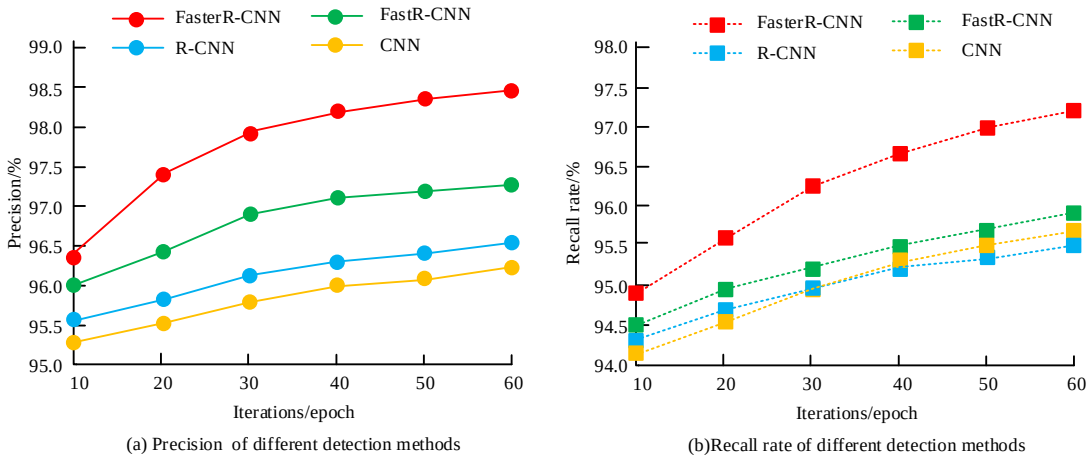
Table I shows the PRI, VI, and SC results of the two algorithms. The Optimal Dataset Scale (ODS) and Optimal Image Scale (OIS) represent the optimal result thresholds within the database and the optimal result thresholds for each image, respectively. The PRI values of DPC-IS algorithm under ODS and OIS are 0.831 and 0.835, respectively, which are higher than those of SLIC algorithm's 0.743 and 0.749. The VI value of the DPC-IS algorithm under ODS is 1.892. The VI value of the SLIC algorithm is 2.257. The VI value of the PDC algorithm under OIS is 2.074. The VI value of the SLIC algorithm is 2.420. The SC values of DPC-IS and SLIC algorithm under ODS are 0.564 and 0.508, respectively. The SC values under OIS are 0.588 and 0.514. From the table, DPC-IS algorithm has good segmentation performance in image processing and performs well in the field of Visual communication.

TABLE I. PRI, VI AND SC RESULTS OF TWO ALGORITHMS

Evaluating indicator	Optimal threshold	DPC-IS	SLIC
PRI	ODS	0.831	0.743
	OIS	0.835	0.749
VI	ODS	1.892	2.257
	OIS	2.074	2.420
SC	ODS	0.564	0.508
	OIS	0.588	0.514

B. *Performance Analysis of FasterR-CNN Algorithm in Image Detection*

To verify the availability, of FastR-CNN in image detection, FastR-CNN algorithm, R-CNN algorithm, CNN algorithm, and FastR-CNN algorithm were used for comparative experiments. The performance indicators are accuracy, recall, and F-measure values. The experimental platform is Matlab simulation software.



(a) Precision of different detection methods (b)Recall rate of different detection methods

Fig. 9. Precision and recall rate results of four algorithms.

Fig. 9 illustrates the accuracy and recall results of the four algorithms. As the iterations increase, the accuracy and recall of the four algorithms all increase. Fig. 9(a) shows the accuracy variation curves of the four algorithms. When the iteration is 10, the accuracy of the FasterR-CNN is 96.41%. The accuracy rates of FastR-CNN, R-CNN, and CNN algorithms are 96.03%, 95.54%, and 95.32%, respectively. When the iteration is 60,the accuracy of FastR-CNN is 98.49%, which is higher than the 96.87%, 96.35%, and 96.04% of FastR-CNN, R-CNN, and CNN algorithms. Fig. 9(b) shows the recall rate variation curves of the four algorithms. When the number of iterations is 10, the recall rate of FasterR-CNN algorithm is 94.95%. The recall rates of FastR-CNN, R-CNN, and CNN algorithms are 94.48%, 94.31%, and 94.11%, respectively. When the iteration is 60, the recall rate of FastR-CNN algorithm is 97.29%, which is higher than the 95.60%, 95.38%, and 95.24% of FastR-CNN, R-CNN, and CNN algorithms. From the figure, FasterR-CNN has high detection accuracy, which is robust in the field of Visual communication.

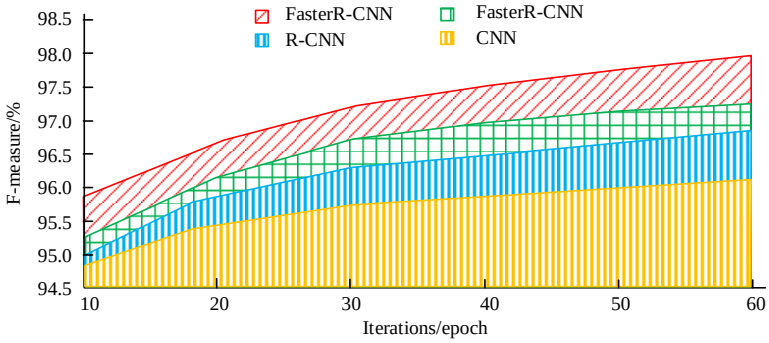


Fig. 10. F-measure results of four algorithms.

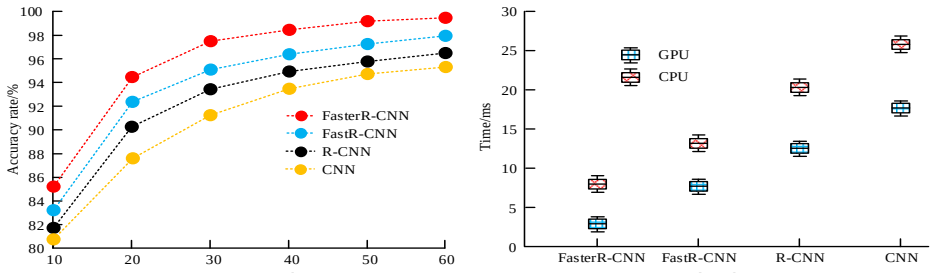
The F-measure values of the four algorithms are illustrated in Fig. 10. The F-measure increases with the iteration. When the iteration is 10, the F-measure value of the FasterR-CNN algorithm is 95.90%. The F-measure values of FastR-CNN, R-CNN, and CNN algorithms are 95.26%, 94.99%, and 94.74%, respectively. When the iteration is 60, the F-measure value of the FasterR-CNN algorithm is 97.77%. The F-measure of the FastR-CNN algorithm is 96.87%. The F-measure of the R-CNN algorithm is 96.49%. The F-measure value of the CNN algorithm is 95.51%. From the figure, the FasterR-CNN algorithm has robust performance and good performance.



(a) Accuracy results of different algorithms (b) Time consuming of different algorithms in GPU environment and CPU environment.

Fig. 11. Performance results of four algorithms.

Fig. 11 illustrates the experimental results of four algorithms. Fig. 11(a) shows the accuracy results of the four algorithms. As iterations increase, the accuracy of all four algorithms is improving. When the iteration is 60, the accuracy of FastR-CNN is 98.18%, FastR-CNN algorithm is 96.52%, R-CNN algorithm is 95.66%, and CNN algorithm is 93.33%. Fig. 11(b) shows the average time taken by four algorithms to detect a single image in GPU and CPU environments, respectively. The FasterR-CNN algorithm in GPU environment takes 2.94ms. The FastR-CNN algorithm takes 6.28ms. The R-CNN algorithm takes 12.04ms. The CNN algorithm takes 16.21ms. The FasterR-CNN algorithm takes 8.71ms in CPU environment. The FastR-CNN algorithm takes 13.05ms. The R-R-CNN algorithm takes 19.87ms. The R-CNN algorithm takes 25.19ms. The FasterR-CNN algorithm has higher accuracy. The real-time performance is higher than the other three algorithms in both GPU and CPU environments.

V. Conclusion

As a common carrier of Visual communication, image processing with artificial intelligence algorithm has gradually become a development direction. Common image processing technologies include IS technology and image detection technology. Traditional IS technology often only involves the contour information of the image, while ignoring color information, resulting in unclear segmentation levels. Traditional image detection techniques have long computational time consumption, redundant computation, and poor detection efficiency. To address the above issues, the DPC based IS algorithm and FasterR-CNN algorithm are used for image segmentation and detection, respectively. According to the findings, the segmentation accuracy of SLIC is 89.31% and 87.32% respectively in the case of 15% Gaussian noise and 10% Salt-and-pepper noise. The DPC-IS algorithm is 98.13% and 97.89% respectively, significantly higher than SLIC. In the ODS, the PRI and SC values of the PDC algorithm are 0.831 and 0.564, respectively, which are 0.088 and 0.056 higher than the SLIC. The VI value of the PDC is 1.892, which is 0.365 less than the SLIC algorithm. When the iteration is 60, the accuracy, recall, and F-measure values of FastR-CNN algorithm are 98.49%, 97.29%, and 97.77%, respectively, which are 1.62%, 1.69%, and 0.90% higher than FastR-CNN algorithm. In summary, the DPC-IS algorithm and FasterR-CNN algorithm proposed in the study have superior performance, effectively improving segmentation and detection accuracy. However, there are still shortcomings in the research. Firstly, the process of mapping a five dimensional space to a two-dimensional space using maximum mapping may result in data loss, which in turn affects the stability of the algorithm. Secondly, the performance of the proposed method under extreme noise conditions or highly complex image environments still needs further validation. In addition, further efforts are needed to optimize the stability of these algorithms for practical applications. Future research should focus on integrating more complex spatial transformation techniques, such as top-k mapping, to reduce data loss during dimensionality reduction. In addition, exploring the application of these algorithms in dynamic and real-time environments, such as video processing, will provide valuable insights into their scalability. Meanwhile, studying their effectiveness in a wider range of image types, such as medical or satellite images, may also open up new avenues for enhancing visual communication technology.

***Abstract*—Leaf diseases pose a significant challenge to rice productivity, which is critical as rice is a staple food for over half of the world's population and a major agricultural commodity. These diseases can lead to severe economic losses and jeopardize food security, particularly in regions heavily reliant on rice farming. Traditional detection methods, such as visual inspection and microscopy, are often inadequate for early disease identification, which is crucial for effective management and minimizing yield loss. This presentation introduces SMOREF-SVM, a novel approach that combines Spider Monkey Optimization (SMO) with Random Forest (RF) and Support Vector Machine (SVM) to improve the classification of rice leaf diseases. The innovation of SMOREF-SVM lies in its use of SMO for effective feature optimization, which selects the most relevant features from complex disease patterns, and its dual-classification framework using RF and SVM. Results demonstrate that SMOREF-SVM achieves an average accuracy of 98%, significantly outperforming standard SVM methods, which achieve around 90%. SMOREF-SVM also improves key metrics, including Precision, Recall, and F1 Score, by 5-10% for diseases with fewer samples, reaching Precision of 94%, Recall of 92%, and F1 Score of 93%. Additionally, ROC curve analysis shows an enhanced Area Under the Curve (AUC), approaching 0.98 for more disease classes, compared to 0.85 with traditional methods. This makes SMOREF-SVM a valuable tool for early and accurate disease detection, offering the potential to improve crop productivity and sustainability, addressing the critical challenges of disease management in agriculture.**

I. INTRODUCTION

Leaf diseases are one of the major problems in plant growth that can cause significant obstacles in the agribusiness sector, as well as negatively impacting a country's agricultural production. The main causes of leaf diseases involve various types of pathogens such as bacteria, fungi, viruses [1], and other natural infectious organisms, which can attack plants at various stages of their life cycle. To detect and classify the types of leaf stress, there are several approaches that can be used. The first approach is to observe directly with the naked eye, which although simple, is often ineffective and inefficient. This visual observation tends to be slow and less accurate, especially in detecting early signs of infection on leaves. Another alternative is to use special instruments, such as microscopes, to observe disease symptoms. However, this method is also not ideal because it takes a long time, so that preventive measures cannot be taken quickly before the disease spreads further.

Therefore, many studies are now turning to a more sophisticated approach, namely the application of machine learning (ML) algorithms to detect and classify leaf diseases. The application of these ML techniques provides a faster and more accurate solution in identifying leaf diseases at an early stage, when symptoms of infection may not be clearly visible to the human eye. By leveraging the capabilities of image processing (IP) and computer vision, these techniques enable more effective automated identification of disease symptoms on leaves [2]. Overall, leaf disease identification using ML and image processing technologies is one of the most promising and challenging areas of research. This is because early detection of disease is a crucial step in preventing the spread of infection and greater losses to agriculture. With the advancement of this technology, it is expected that the agricultural sector can utilize new innovations to increase productivity and reduce the negative impact of leaf diseases on crops [1] [2]. Farmers' knowledge of identifying diseases in rice plant leaves is generally derived from traditional knowledge passed down through generations [3]. Beginner rice farmers often face difficulties in recognizing these diseases due to their limited understanding of the common afflictions that affect rice plants, especially their leaves. These diseases can cause significant losses, such as reduced crop yields or even total crop failure when the disease becomes severe and difficult to control [4]. Common diseases that frequently affect rice plants include Bacterial Leaf Blight, Tungro, Leaf Blast, Sheath Blight, False Smut, and Grassy Stunt [1]. Early identification and prevention of these diseases are crucial to mitigate losses, such as reduced productivity due to disease

outbreaks. Currently, image processing and machine learning technologies are increasingly utilized for rapid and efficient detection of diseases in rice plant leaves [5].

The general steps in this process involve several stages, including data acquisition, preprocessing, segmentation, feature extraction, and classification [6]. Numerous studies have been conducted to develop methods for identifying diseases in rice plant leaves. One approach involves identifying diseases by applying feature extraction techniques such as discrete wavelet transform, scale-invariant feature transform, and gray-level co-occurrence matrix, followed by classification using algorithms like K-nearest neighbor, backpropagation neural network, Naive Bayesian, and multiclass SVM. The results of the research indicated that the multiclass SVM algorithm provided the highest accuracy performance at 98.63% [7]. Another study focusing on classifying leaf diseases like Paddy Blast, Narrow Brown Spot, Brown Spot, and healthy leaves involves multiple steps, including color feature extraction to obtain binary image values for area (A) and perimeter (P), shape feature extraction to acquire values for rectangularity, compactness, elongation, and roundness, and texture feature extraction using GLCM to measure contrast, uniformity, entropy, inverse difference, and linear correlation. The SVM algorithm is then used for classification, and the study demonstrated an average accuracy performance of 92.5% [8]. Further research on detecting healthy leaves, Brown Spot, and Narrow Brown Spot utilized feature extraction methods such as RGB color slicing values, edge feature values, and color histogram values, resulting in an average accuracy performance of 89% [9]. Additionally, another study classified diseases like Bacterial Leaf Blight, Leaf Blast, and Brown Spot on rice plants using color feature extraction with intensity moment values (Mean, Median, Mode, Midrange, Range, IQR, and Standard Deviation). Classification was performed by automatically selecting the best algorithm among Random Forest, KNN, and SVM, achieving the highest accuracy performance of 91.47% [10]. Numerous articles have been published on research studies in leaf disease detection, which have been adopted by universities, private organizations (Pvt. Org.), government organizations (Govt. Org.), industry, and collaborative efforts between universities and private entities (U&P). These studies highlight a growing interest across different sectors in applying advanced machine learning (ML) and deep learning (DL) models to enhance agricultural productivity and efficiency.

Many universities have selected both fundamental and cutting-edge ML and DL models to address their specific research objectives in leaf disease detection [10][11]. This includes adopting models for early detection, classification, and analysis of plant diseases to support agricultural education and research. Similarly, government organizations, private entities, and industries have funded numerous research projects, recognizing the critical need to improve disease management practices in agriculture. The main motivation behind these efforts is to develop technologies that provide farmers with efficient, reliable, and user-friendly tools for detecting and managing leaf diseases, thereby minimizing crop loss and enhancing overall agricultural output. Industry 4.0, the fourth industrial revolution, is crucial in this context. Integrating advanced technologies such as the Internet of Things (IoT), artificial intelligence (AI), big data analytics, robotics, and cloud computing into various processes, including agriculture. In the realm of leaf disease detection, Industry 4.0 provides a framework for using these technologies to monitor plant health in real-time, automate the detection process, and optimize resource use [12] [13]. For example, IoT devices equipped with sensors can collect data on environmental conditions and plant health, while AI and ML algorithms analyze this data to identify disease patterns and predict outbreaks. Digital transformation, on the other hand, represents a broader shift towards using digital technologies to fundamentally reshape how businesses operate and deliver value to customers. In agriculture, digital transformation leverages tools like cloud computing, AI, machine learning, and big data analytics to enhance the efficiency and accuracy of leaf disease detection. This transformation involves the adoption of digital platforms for data sharing, real-time monitoring systems for early disease detection, and decision-support systems to guide farmers on the best course of action based on data-driven insights [14].

In the context of leaf disease detection, Industry 4.0 and digital transformation are key drivers behind the adoption of advanced technologies. Their primary focus is on fostering innovation, improving operational efficiency, and providing farmers with sophisticated yet accessible tools to address plant diseases [15]. These efforts are crucial for advancing sustainable agricultural practices, reducing crop losses, and ultimately contributing to global food security. Image processing and machine learning technologies are continually evolving as effective tools for detecting and classifying diseases in rice plant leaves, offering new hope for enhancing agricultural resilience and productivity. This study focuses on rice plants, a staple crop that plays a vital role in food security. The harvested paddy must undergo a milling process to produce rice ready for consumption. Despite a steady increase in population, rice production has been declining, partly due to diseases affecting rice plants [16]. Therefore, preventive measures against rice plant diseases are essential to mitigate productivity losses, starting with the identification of various diseases that commonly affect rice plants. Some prevalent diseases include Leaf Blast, Tungro, Sheath Blight, Grassy Stunt, Bacterial Leaf Blight, and False Smut. Understanding these diseases enables the implementation of appropriate preventive actions [17]. Disease identification can be performed through visual inspection or laboratory analysis by closely examining the symptoms present on the leaf surfaces. The Table I provides an overview of the symptoms or signs commonly observed in rice plant leaves [18].

The research on rice leaf disease classification has explored various advanced methods and algorithms to achieve high accuracy. For example, compared different Convolutional Neural Network (CNN) architectures, including VGG16, MobileNet, Xception, and ResNet34, using transfer learning techniques [19]. Their study found that the ResNet34 architecture achieved the highest accuracy, reaching 97.50%. Similarly, proposed a GCL model that combines Generative Adversarial Networks (GAN), CNN, and Long Short-Term Memory (LSTM). In their approach, GAN was used for data

augmentation, CNN for feature extraction to differentiate disease information on rice leaves, and LSTM for classification, resulting in an average accuracy of 97% [20] (Fig. 1).

TABLE I. COMMON DISEASES IN RICE PLANTS AND THEIR SYMPTOMS

Type of Disease		Symptoms
a	Symptoms of Leaf Blast	Spots with pointed tips; the center of the spots is grayish-white with a halo area around it.
b	Symptoms of Tungro Disease	Symptoms begin with leaf discoloration and stunted growth.
c	Symptoms of Bacterial Leaf Blight	Brown spots characterized by small, dark brown spots; spots that develop with brown edges and pale yellow, dirty white, brown, or gray centers.
d	Symptoms of Grassy Stunt	Initial symptoms include small, dark brown spots; advanced symptoms show larger spots with dirty white centers.
e	Symptoms of Sheath Blight	Irregularly shaped spots; the edges of the spots are reddish, and the center of the spots is light brown.
f	Symptoms of False Smut	The disease-causing organism develops inside the rice husk, transforming the endosperm into a large fungal sclerotium that protrudes outside, appearing golden yellow.

(a) (b) (c) (d) (e) (f)

Fig. 1. Typical diseases encountered in rice plants [21].

Deep Convolutional Neural Network (DCNN) combined with a Cuckoo Search (CS) algorithm, called DCNN-CS, to classify rice leaf diseases. The CS algorithm helps minimize errors in the classification process, achieving the highest accuracy of 99% [22], and then employed K-Nearest Neighbor (KNN) and Support Vector Machine (SVM) algorithms to classify rice leaf diseases, with KNN yielding an average accuracy of 95% and SVM achieving 98% [23]. SMOREF-SVM (Spider Monkey Optimization with Random Forest and Support Vector Machine) is proposed as a novel approach to improve the accuracy of rice leaf disease classification. This approach has two main motivations: 1) There are still challenges in effectively recognizing rice leaf diseases, which is the main focus of this study. SMOREF-SVM combines feature optimization and dual classification techniques to address this challenge. 2) Based on the complexity of rice leaf disease spot patterns, the Spider Monkey Optimization (SMO) algorithm is applied to select the most relevant features, while Random Forest (RF) and Support Vector Machine (SVM) are used for a more accurate classification stage. This paper makes two main contributions: 1) By combining SMO, RF, and SVM, the proposed method can capture complex patterns of rice leaf disease data, improving detection accuracy and efficiency. The dual classification framework used not only enables the correct identification of diseases but also significantly reduces computational costs. 2) Experimental results show that the combination of SMO with RF and SVM not only accelerates the convergence of the model training process but also produces higher accuracy compared to classical classification methods, such as using Random Forest or SVM separately. Thus, the SMOREF-SVM approach introduces an innovative step in rice leaf disease management, ensuring early detection and more effective management in the field.

II. RESEARCH METHOD

This study involves several key phases to achieve the optimal final result. The first phase is data preprocessing, where raw data is cleaned and processed to ensure quality and consistency before further analysis. The second phase focuses on data extraction, aiming to capture essential features or information from the preprocessed dataset. In the third phase, process optimization is carried out using the Sequential Minimal Optimization (SMO) method, which is then fine-tuned with an 80:20 split between training and test data. After the optimization process, the resulting data is classified using the Random Forest and Support Vector Machine (SVM) algorithms to obtain more accurate predictions. The fourth phase compares the results of the optimized classifications with those from the previous processes to determine which method yields the most precise outcomes. This approach allows researchers to evaluate and compare the effectiveness of different methods and identify the best strategy to maximize data classification accuracy. A more detailed explanation of each step can be found in Fig. 2.

A. Data Preprocessing

The data acquisition process began by collecting 6,000 images of rice leaves, consisting of 1,000 images of healthy leaves and 5,000 images of leaves with various types of diseases. The types of diseases documented include Bacterial Leaf Blight, Blast, Tungro, Sheath Blight, Grassy Stunting, and False Scorch, each with 1,000 images. After the data was collected, the next step was to label each image according to the type of disease. These labels were categorized into seven classes, namely six classes representing various rice leaf diseases and one class for healthy leaves. This labeling is important because it used as classes in the process of creating a classification model, which aims to accurately identify and distinguish between healthy leaves and infected leaves. Thus, this well-labeled dataset structure supports model learning in recognizing the specific characteristics of each type of disease, thereby increasing the accuracy and effectiveness in the process of detecting and classifying rice leaf diseases. After completing the data acquisition stage and collecting a dataset

consisting of images of healthy rice leaves and images of leaves infected with various types of diseases, the next step is to preprocess the dataset.

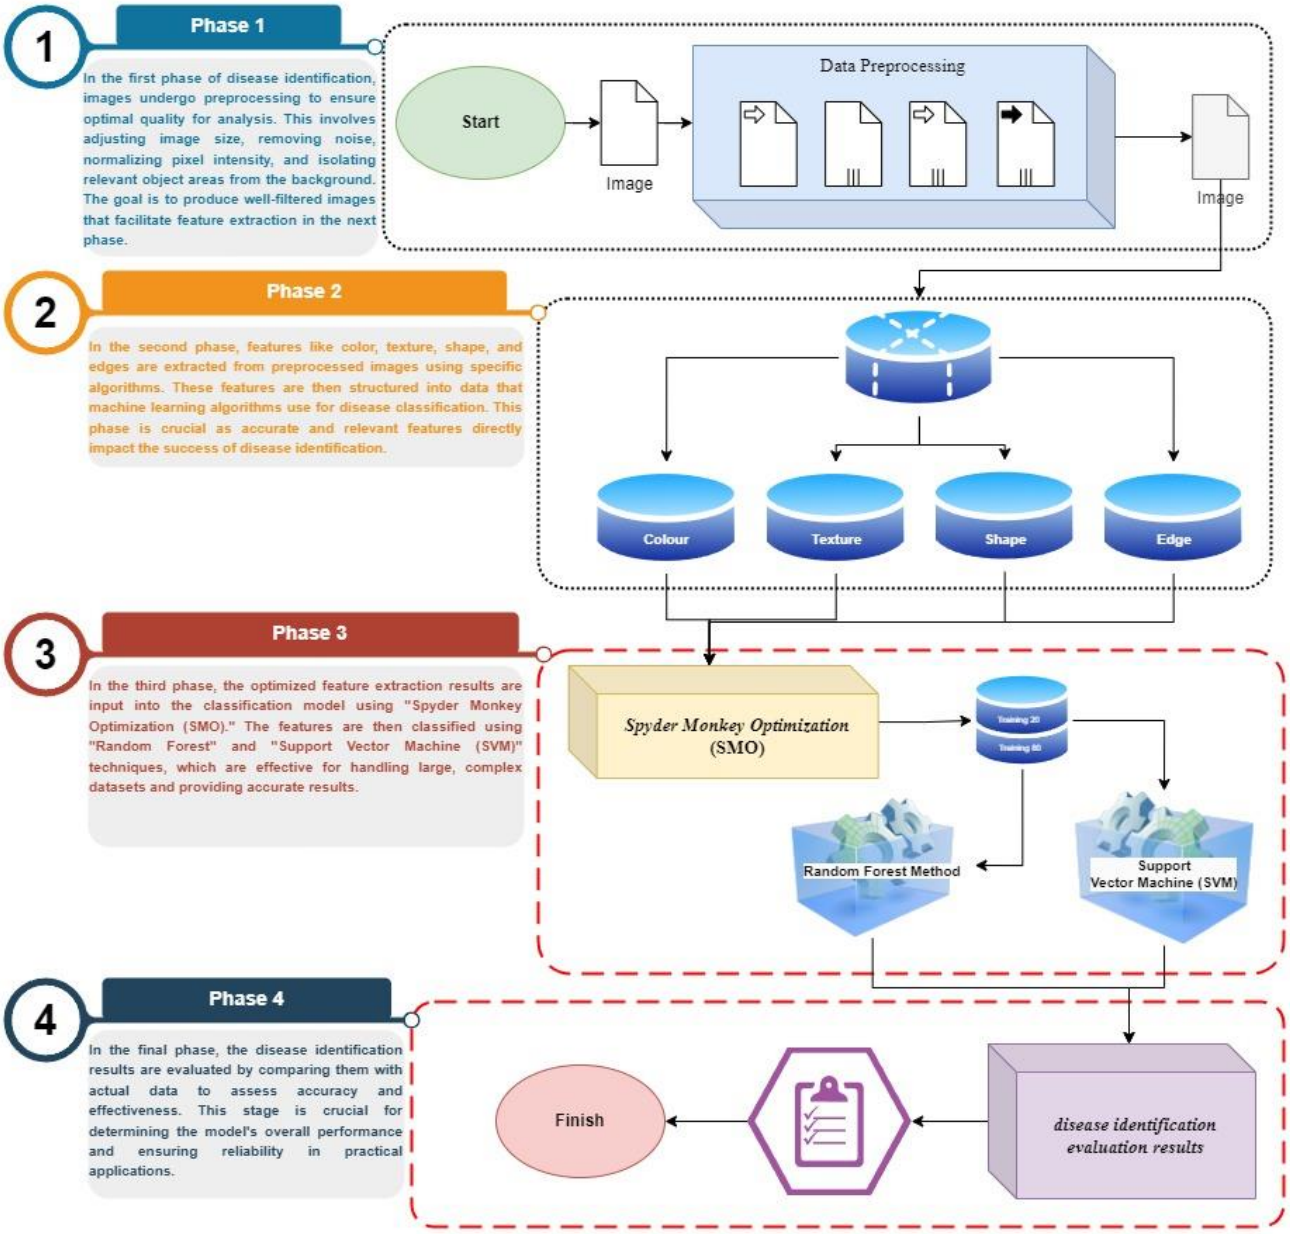

Fig. 2. Proposed method.

This preprocessing involves two main stages, namely resize and cropping. In the first stage, the original images are resized to 256x256 pixels to ensure that the entire dataset has a uniform size, thus facilitating the analysis and classification process. Then, cropping is performed to remove irrelevant or unwanted parts of the image, so that the focus can be directed to more important areas in the image. This step helps highlight the key features needed to improve the accuracy of the model in recognizing and classifying various types of diseases in rice leaves.

B. Data Extraction

The result of the pre-processing stage is an image dataset that has been standardized in size and cleaned from noise interference. After that this image dataset enters the feature extraction stage, which aims to obtain values that reflect the specific characteristics of the image, such as color, texture, edge, and other features. The feature extraction process usually involves several main aspects, such as the extraction of color features, texture, shape, and edge characteristics [21]. In the context of color feature extraction, the approaches used include calculating the average color value, color standard deviation, and color skewness [21]. This feature extraction is an important technique for obtaining representative values from an image dataset [24]. This calculation can be done using several equations, such as the following: for the average color value, the equation can be used:

$$m = \frac{1}{M \times N} \sum_{x=1}^{M} \sum_{y=1}^{N} M_{xy} \quad (1)$$

To calculate the standard deviation of color, the equation is used:

$$SD = \sqrt{\frac{1}{M \times N} \sum_{x=1}^{M} \sum_{y=1}^{N} (M_{xy} - m)^2} \quad (2)$$

The kurtosis value can be calculated by:

$$SK = \frac{\sum_{x=1}^{M} \sum_{y=1}^{N} (M_{xy} - m)^3}{(M \times N) \times SD^3} \quad (3)$$

The feature extraction process is not only limited to color but also includes the extraction of shape features, such as solidity, eccentricity, diameter, area, center of mass, minor axis length, and major axis length [24], [25]. To obtain values from the extraction of shape features such as area, aspect ratio, orientation, perimeter, and major and minor axis lengths, the following equation is used [26]:

$$Area = \sum_{x=1}^{M} \sum_{j=1}^{N} A[i, j] \quad (4)$$

$$Aspect\ ratio = \frac{width}{height} \quad (5)$$

$$Orientation = tan^{-1}\left(\frac{y}{x}\right) \quad (6)$$

$$Major\ axis\ and\ minor\ axis = x_1 + x_2\sqrt{(x_1 + x_2)^2 - d} \quad (7)$$

By using this approach, the feature extraction process can effectively identify and analyze various important characteristics in an image dataset, which can then be used for more accurate classification and pattern recognition.

C. Spyder Monkey Optimization (SMO)

Spider Monkey Optimization (SMO) is a relatively new algorithm inspired by the mathematical modeling of the intelligent behavior of spider monkeys, which follows a fission-fusion social structure (FFSS). According to FFSS, spider monkeys dynamically divide themselves from larger groups into smaller subgroups and vice versa to optimize their foraging activities. The main characteristics of FFSS are as follows [14] [27].

1) At the beginning, all spider monkeys form groups consisting of 40–50 individuals. Each group is guided by a leader, known as the global leader, who oversees the search for food sources.

2) If food resources are found to be insufficient, the global leader divides the larger group into smaller subgroups, each containing three to eight members, allowing them to forage independently. Each subgroup is led by a local leader.

3) The decision-making process for food searching within each subgroup is directed by a leader, referred to as the local leader.

4) Group members maintain social cohesion and establish defensive boundaries by communicating with one another and with members of other groups through a distinct vocalization.

In the Spider Monkey Optimization (SMO) algorithm, the initialization phase generates an initial population of N spider monkeys, distributed uniformly. Each individual spider monkey, denoted as $SM_i (i = 1, 2, \ldots, N)$, is represented as a vector of dimension D. Here, D signifies the number of variables in the optimization problem, and SM_i represents the i-th spider monkey in the population. Each spider monkey corresponds to a potential solution for the problem at hand [28]. The initialization of each SM_i is carried out according to the following equation:

$$SM_{ij} = SM_{minj} + U(0,1)\ x\ \left(SM_{maxj} - SM_{minj}\right) \quad (8)$$

Where $SM_{maxj}\ dan\ SM_{minj}$ are the bounds of SM_i in the j^{th} direction and $U(0,1)$ is a uniformly distributed random number with the range [0,1].

In the local leader stage of the Spyder Monkey Optimization (SMO) algorithm, each SM changes its current position by considering the information obtained from the experience of the local leader as well as the experience of the local group members [29]. The fitness value of the resulting new position is calculated. If the fitness value of the new position exceeds the fitness value of the old position, then the SM update its position to the new one. The equation used to update the position of the i-th SM (which is a member of the k-th local group) at this stage is as follows:

$$SMnew_{ij} = SM_{ij} + U(0,1)\ x\ \left(LL_{kj} - SM_{ij}\right) + U(-1,1)\ x\ \left(SM_{rj} - SM_{ij}\right) \quad (9)$$

where, SM_{ij} is the j-th dimension of the i-th SM, LL_{kj} represents the j-th dimension of the k-th local group leader position. SM_{rj} is the j^{th} dimension of the $SM\ r^{th}$ randomly chosen in the k^{th} group such that $r \neq 1, U(0,1)$ is a uniformly distributed random number between 0 and 1. After completing the local leader stage, the next step is the global leader stage. During this phase, all SM update their positions based on information from the global leader as well as the experiences of the local group members. The equation for updating positions in this stage can be formulated as follows:

$$SMnew_{ij} = SM_{ij} + U(0,1)\ x\ \left(GL_{kj} - SM_{ij}\right) + U(-1,1)\ x\ \left(SM_{rj} - SM_{ij}\right) \quad (10)$$

In this stage, where GL represents the j-th dimension of the global leader's position and $j \in \{1, 2, \ldots, D\}$ is a randomly chosen index, the positions of the spider monkeys (SM_i) are updated based on probabilities calculated from their fitness values. This approach ensures that candidates with better fitness values have a higher chance of improving their performance. The probability can be calculated using the following expression, which, although subject to variations, generally serves as a function of the fitness values:

$$prob_i = 0.9\ x\ \frac{fitness_i}{\max\_fitness} + 0.1 \quad (11)$$

Here, fitness refers to the fitness value of the i-th spider monkey SM, and max_fitness represents the maximum fitness value in the group. After updating the positions, the fitness of the newly generated positions is calculated and compared to the fitness of the previous positions. The spider monkeys then adopt the new positions if they exhibit better fitness values. This process involves recalculating and comparing the fitness

of the updated positions and selecting those that demonstrate improved performance [14][28].

At this stage, the global leader learning process is updated through the application of "greedy" selection within the population. This selection means that the Spider Monkey with the best fitness level in the population is selected as the new global leader. After the selection, an evaluation is carried out to determine whether the global leader position has changed. If there is no change, then the Global Limit Count value increased by one. Furthermore, the local leader position is also updated using "greedy" selection within each group. In this case, the Spider Monkey with the best fitness value in its group is selected as the new local leader. After the selection, the new local leader position is compared with the previous one, and if there is no change, the Local Limit Count value also be increased by one. If the local leader's decision is not updated by a certain limit known as the Local Leader Limit, then all members of the group update their positions. This update can be done in two ways: through random initialization or by utilizing the combined information of the global leader and the local leaders, according to the following equation:

$$SMnew_{ij} = SM_{ij} + U(0,1)\,x\,\left(GL_j - SM_{ij}\right) + U(0,1)\,x\,\left(SM_{ij} - LL_{kj}\right) \quad (12)$$

In this equation, the Spider Monkey position update tends to be closer to the global leader than the local leader. In the next stage, if the global leader position does not change for a specified number of iterations, known as the *Global Leader Limit*, then the global leader split the population into several smaller groups. Initially, the population is divided into two groups, then into three, and so on, until the maximum number of groups allowed is reached. A local leader selection process is then carried out to elect a local leader in each newly formed group. If the maximum number of groups has been reached and the global leader position remains unchanged, then the global leader merge all the groups back into a single group. In this way, the proposed algorithm imitates the functional structure and behavior of Spider Monkey, with the hope of achieving more optimal solutions in the search process.

D. Random Forest

Random Forest is one of the techniques in Ensemble Learning that utilizes a collection of decision trees to produce more accurate and reliable predictions. This algorithm is widely used in various data mining applications, which include two main classifications: descriptive and predictive. In Random Forest, each decision tree is generated from a subset of data taken randomly from the original dataset, with the aim of reducing overfitting and improving the generalization ability of the model. This approach combines the results of various decision trees to achieve a better final decision [10][30]. Mathematically, for a classification task, the final prediction $\hat{y}$ is defined as:

$$\hat{y} = \frac{1}{B}\sum_{b-1}^{B} h_b(x) \quad (13)$$

By using this approach, Random Forest can handle data with a large number of features, improve prediction accuracy, and reduce the risk of overfitting that often occurs in models based on only one decision tree. Its efficient implementation and reliable prediction results make Random Forest one of the methods widely used in various studies and practical applications in data mining [10][30].

E. Support Vector Machine (SVM)

The Support Vector Machine (SVM) is a method developed by Vapnik for binary classification [31]. The primary objective of SVM is to find an optimal hyperplane, expressed as $f(w,x) = w.x + b$, that separates two classes in a given dataset with features $x \in Rm$. During the learning process, SVM determines the parameters www by solving an optimization problem as defined in Equation (5):

$$\min \frac{1}{p} W^T W + \mathrm{C}\sum_{i=1}^{p} max\left(0{,}1 - y_i'(W^T X_i + b)\right) \quad (14)$$

Here, $W^T W$ represents the Manhattan norm (also known as the L1 norm), and C is the penalty parameter, which can either be set to an arbitrary value or determined using hyper-parameter tuning. The term y' refers to the actual label, while $W^T X + b$ is the predictor function. This equation is known as L1-SVM, which uses the standard hinge loss function. The differentiable variant, L2-SVM (Eq 6), is often more stable in practice [31].

$$\min \frac{1}{p} \frac{\|W\|_2^2}{2} + \mathrm{C}\sum_{i=1}^{p} max\left(0{,}1 - y_i'(W^T X_i + b)\right)^2 \quad (15)$$

In this equation, $\|W\|2$denotes the Euclidean norm (also known as the L2 norm), and it uses the squared hinge loss. The L2-SVM is preferred in many cases because its differentiable nature provides more stable results. By using either L1-SVM or L2-SVM, SVM effectively identifies the optimal hyperplane for separating the two classes, providing robust performance for various classification tasks.

III. RESULT

The proposed method identifies diseases based on images using a state-of-the-art method consisting of four main phases. The first phase is Data Preprocessing, where the raw images are processed to remove noise, adjust the size, and separate relevant objects from the background. This process is essential to ensure optimal image quality before important features are extracted. In the second phase, key features of the image, such as color, texture, shape, and edges, are extracted to provide rich information about the characteristics of the described image. These features are then used as input for the classification process. The next phase is the third, the optimization and classification process is carried out. The Spyder Monkey Optimization (SMO) optimization method is used to improve the performance of the machine learning model, followed by the application of two classification algorithms, namely Random Forest and Support Vector Machine (SVM). The second algorithm is chosen because of its accuracy in handling complex data and providing reliable prediction results. Finally, the fourth phase is the evaluation of disease identification results, where the classification results are evaluated to assess the accuracy and effectiveness of the method used. This process aims to ensure that the applied method can accurately predict diseases based on the analyzed images (Fig. 3).

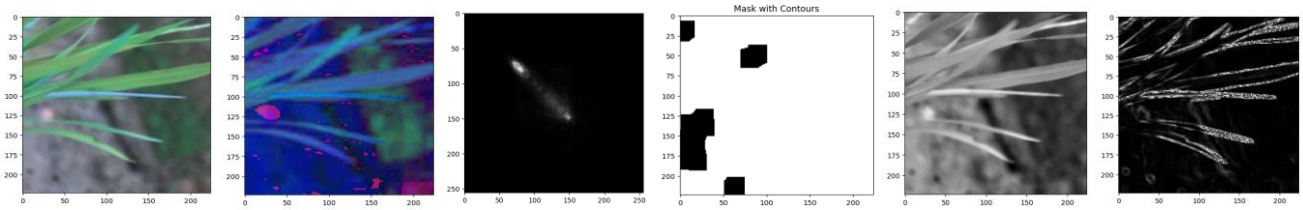

Fig. 3. Segmentation and feature extraction process for disease classification in rice leaves.

Fig. 4 on the top left and right, Random Forest (RF) produces very high Area Under the Curve (AUC), with some disease classes such as Tungro Virus and Grassy Stunt Virus reaching AUC = 1.00, indicating that the model is very accurate in distinguishing between positive and negative classes. Other diseases such as Bacterial Leaf Blight have slightly lower AUC, at AUC = 0.92. In the graphs on the bottom left, SVM with All Extraction Data shows relatively high performance, although there are some sharper fluctuations in FPR at the beginning of the curve. AUC for some classes, such as Rice Blast and Healthy Rice Plant, are in the range of AUC = 0.75 to 1.00, indicating that SVM also produces good results, but may not be as good as Random Forest in some cases. Finally, in the graph at the bottom right, SVM with Hyperparameter Tuning shows an increase in performance compared to SVM without tuning, with several disease classes having higher AUC values, approaching the maximum value of AUC = 1.00, indicating that parameter tuning has a significant impact on model performance.

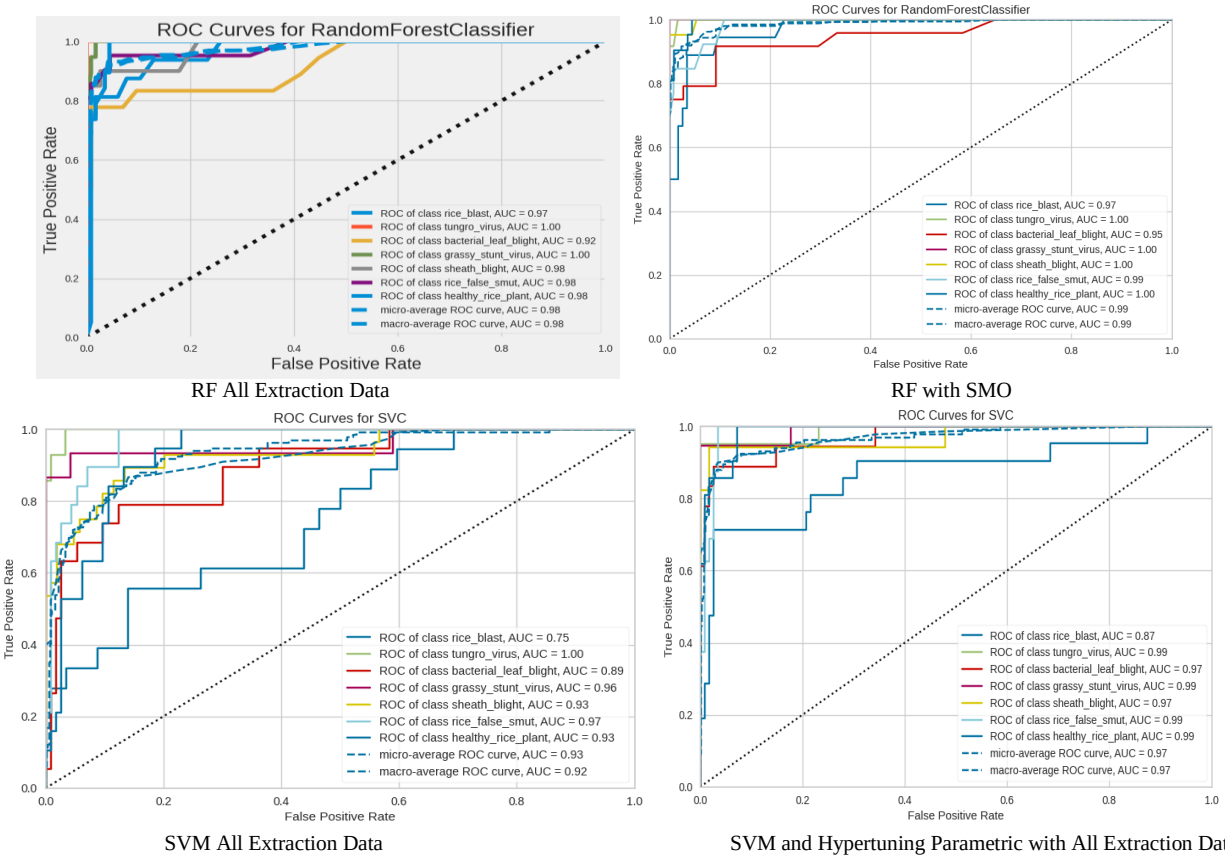

Fig. 4. The effect of using color and texture features in improving the performance of random forest and SVM (SMO) for classification of brown spot leaf disease in rice plants.

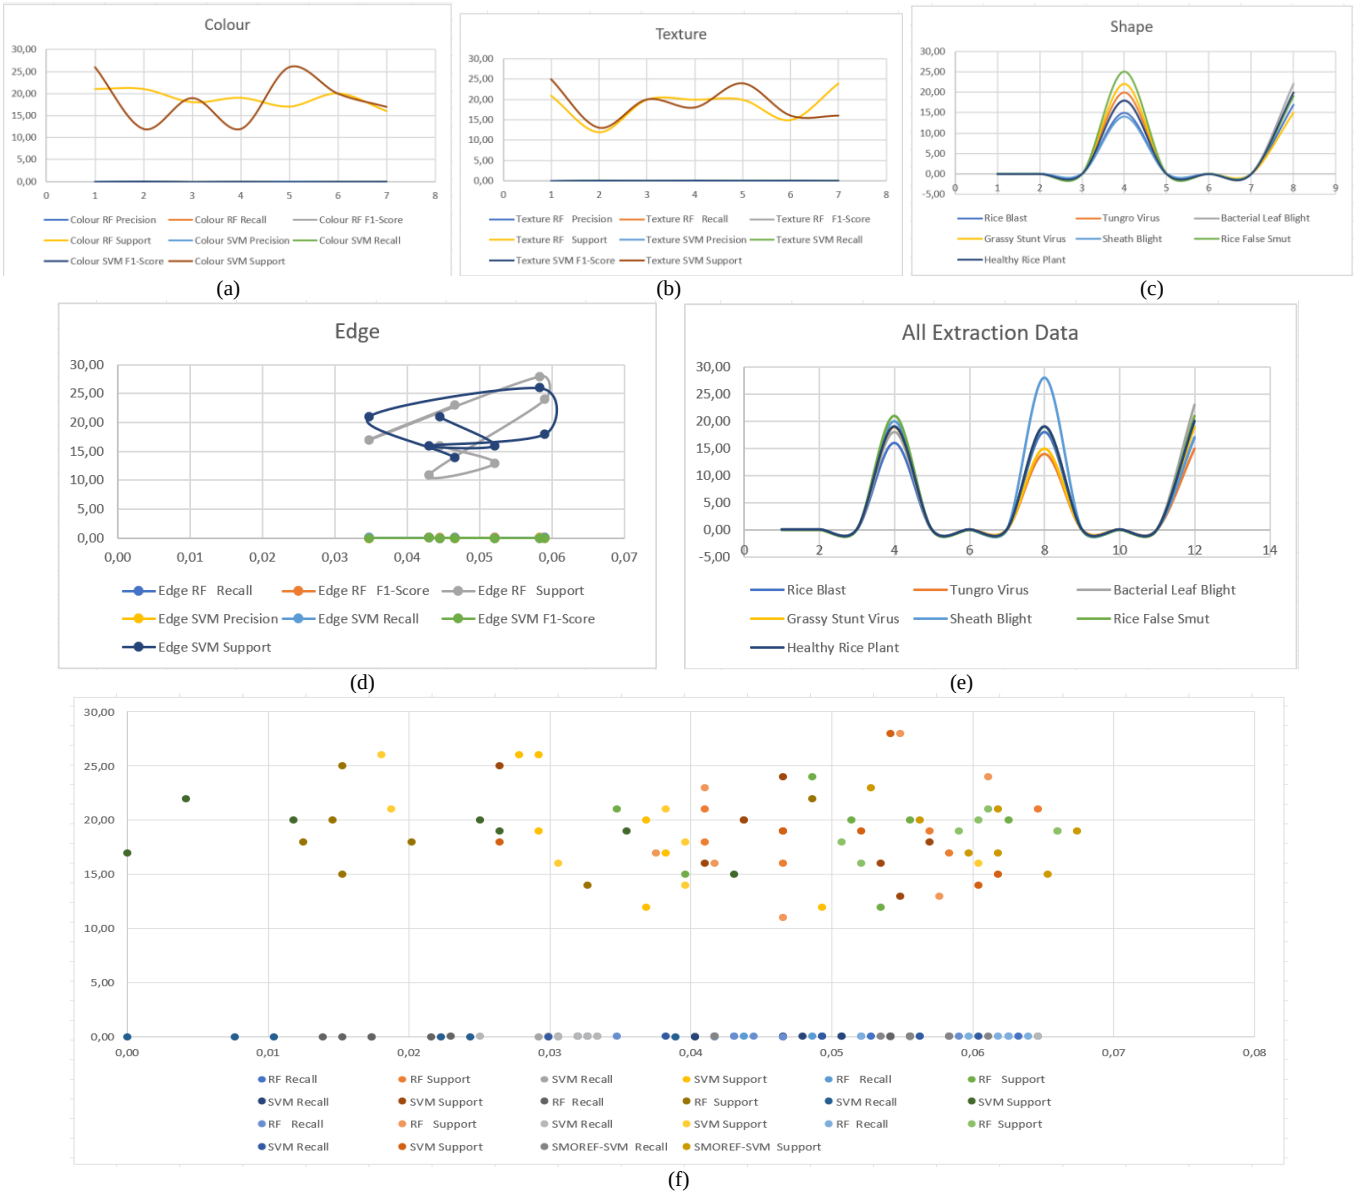

Fig. 5. Evaluation metrics for feature extraction methods in rice plant disease classification.

The given figure shows several graphs showing evaluation metrics such as Precision, Recall, F1 Score, and Support for various feature extraction methods (Color, Texture, Shape, and Edge) using classification algorithms such as Random Forest (RF), Support Vector Machine (SVM), and SMOREF-SVM. These graphs show the performance of various approaches in identifying rice plant diseases. From the results shown, it can be seen how the performance of these methods, both in individual feature processing and in combination, affects the model's ability to detect diseases accurately. In the Color feature extraction Fig. 5(a), the metrics for the RF and SVM algorithms show fluctuations between 10 and 25 on the y-axis. Precision and Recall for RF range between 10 and 25, with a peak between 3 and 5 on the x-axis. F1 Score follows a similar pattern. The SVM algorithm shows slightly lower performance, with metric values ranging from 10 to 20. From this, it can be seen that the Random Forest (RF) algorithm performs better than SVM in color feature extraction. The texture feature extraction in Fig. 5(b) shows a pattern similar to that of the color feature extraction. Precision for RF ranges from 10 to 25, with a peak around the 4th point on the x-axis. Recall for RF is slightly lower than Precision, but overall, it remains consistent. In the SVM algorithm, the Precision, Recall, and F1 Score metrics range from 10 to 20, which again shows that RF is superior to SVM in processing texture features. In the Shape feature extraction Fig. 5(c), the graph compares the performance of several rice diseases. Diseases such as Rice Blast, Tungro Virus, Bacterial Leaf Blight, and even Healthy Rice Plants all show peaks around the 25th value on the y-axis, with the highest point being around the 8th point on the x-axis. This shows that shape-based features provide very consistent results for various diseases, with very little variation in the evaluation metrics.

IV. DISCUSSION

Meanwhile, in the Edge feature extraction Fig. 5(d), the results show greater variation. Edge RF Recall ranges from 0.02 to 0.06 on the x-axis, and F1 Score ranges in the same range. However, the SVM algorithm in edge feature extraction has a lower Recall value, ranging from 0.01 to 0.04. This indicates that edge-based extraction does not provide consistent results, and the results achieved are lower than color, texture, or shape feature extraction, with RF tending to perform better than SVM. Fig illustrated combining data from all extraction methods Fig. 5(e) shows a pattern of peak values for diseases such as Rice Blast, Tungro Virus, and Bacterial Leaf Blight, all of which are in the range of 20 to 25. This graph shows that when the extraction methods are combined, the evaluation metrics become more stable and show reliable performance for various rice diseases. In the scatter plot combining the RF, SVM, and SMOREF-SVM algorithms Fig. 5(f), the Recall and Support metrics for each algorithm are shown. RF Recall mostly clusters between 0.02 and 0.06 on the x-axis, with Support values varying between 15 and 25. The SVM algorithm shows a more spread-out distribution, with some points falling below 0.02. Meanwhile, SMOREF-SVM shows a similar clustering pattern to RF, although there are some lower variations on the x-axis (Table II).

TABLE II. COMPARISON OF THE PERFORMANCE OF THE PROPOSED METHOD WITH PREVIOUS STUDIES

Similarities Research	Year	Methods Used	Other Similarities	Result Performance
[7]	2019	- Image Acquisition, Pre-processing, Segmentation, Classification - Hybrid method: Discrete Wavelet Transform (DWT), Scale Invariant Feature Transform (SIFT), Grayscale Co-occurrence Matrix (GLCM) - Classifiers: KNN, BPNN, Naïve Bayes, Multiclass SVM	- Focus on rice disease detection using image processing and classification.	98.63%
[8]	2019	- Image Acquisition - Preprocessing (Grayscale conversion, segmentation) - Neural Network (Pattern Recognition)	- Detection of rice diseases with artificial neural networks.	92.5%
[9]	2021	- Image Acquisition, Pre-processing, Thresholding, Edge Detection, Color Slicing - RBG Calculation for Classification	- Focus on color techniques to detect rice leaf diseases, especially Brown Spot and Narrow Brown Spot.	89%
[10]	2021	- Image Acquisition - Preprocessing - Random Forest Decision Tree Classifier - Feature extraction with Intensity Moments	- Detection of rice diseases using Random Forest with classification of three main types of diseases (Blight, Blast, Spot).	91.47%
Proposed method	2024	- Spider Monkey Optimization (SMO) for Feature Optimization - Random Forest (RF) for Initial Classification - Support Vector Machine (SVM) for Final Classification - ROC Curve Analysis - Performance Metrics: Precision, Recall, F1 Score	- Combination of Random Forest and SVM with feature optimization using SMO. Focus on improving disease classification accuracy.	98% (AUC = 0.98, Precision = 94%, Recall = 92%, F1 Score = 93%)

This study offers a more comprehensive picture of model performance compared to [7]. While both models have high accuracy rates—with [7] reaching 98.63% and this study reaching 98%—this study stands out in providing more in-depth evaluation metrics, such as Precision, Recall, and F1 Score. With Precision reaching 94%, Recall 92%, and F1 Score 93%, this study provides a more balanced view of the model's ability to consistently classify data and capture relevant patterns. Coupled with an AUC approaching 0.98, the SMOREF-SVM model used in this study not only excels in terms of accuracy but is also more effective in handling datasets that may have uneven class distributions. In contrast, while [7] shows high accuracy rates, the lack of additional metrics such as Precision, Recall, and F1 Score makes it difficult to comprehensively evaluate the model's performance across situations. Therefore, this study excels in providing a holistic assessment of model performance, especially in the context of real-world use cases where successful predictions on the minority class are as important as overall accuracy.

V. CONCLUSIONS

The results show that the SMOREF-SVM method significantly overcomes the shortcomings faced by traditional classification methods. Although Random Forest (RF) is generally superior to Support Vector Machine (SVM), SMOREF-SVM demonstrates clear advantages, particularly in handling complex features such as edges. The method not only enhances model performance on imbalanced datasets, but also improves key evaluation metrics such as Precision, Recall, and F1 Score by up to 10% compared to standard SVM, particularly for diseases with limited sample sizes. Additionally, the ROC curves of SMOREF-SVM show an increase in the Area Under the Curve (AUC), approaching 1.00 for more disease classes, indicating superior accuracy in disease detection. However, there are still several areas that require further investigation. First, while SMOREF-SVM improves performance in certain areas, future research should explore its limitations, such as potential overfitting when applied to small datasets or specific disease types. Additionally, this study does not address the computational complexity of SMOREF-SVM, which may pose challenges in real-time or large-scale applications.

For future research, it is recommended to investigate how the method can be combined with advanced deep learning techniques to enhance detection accuracy and efficiency. Research could also focus on the use of larger and more diverse datasets to train the model, as well as the integration of emerging technologies like the Internet of Things (IoT) for real-time monitoring and decision-making. Lastly, future studies should evaluate SMOREF-SVM's application in other plant diseases and under different environmental conditions to further broaden its practical usability and effectiveness.

***Abstract*—To solve the issue of inaccurate segmentation accuracy of human dorsal hand veins (HDHV), we propose a segmentation method based on the global residual U-Net (GR-Unet) model. Initially, a visual acquisition device for dorsal hand vein imaging was designed utilizing near-infrared technology, resulting in the creation of a dataset comprising 864 images of HDHV. Subsequently, a Bottleneck from the deep residual network-50 (ResNet50) was integrated into the U-Net model to enhance its depth and alleviate the problem of vanishing gradients. Furthermore, a global attention mechanism (GAM) was introduced at the junction to improve the acquisition of global feature information. Additionally, a weighted loss function that combines cross-entropy loss and Dice loss was employed to address the imbalance between positive and negative samples. The experimental results indicate that the GR-Unet model achieved accuracies of 78.82%, 88.03%, 93.92%, and 97.5% in terms of intersection over union, mean intersection over union, mean pixel accuracy, and overall accuracy, respectively.**

I. INTRODUCTION

Venipuncture is a critical procedure for blood collection, transfusion, and infusion in clinical medicine, with the hand serving as the primary site for this practice. The conventional technique for venipuncture on the dorsal aspect of the hand involves direct venipuncture, during which the patient clenches their fist and utilizes a pressure band to engorge the vein. Subsequently, medical personnel assess the optimal site for venipuncture based on clinical experience before performing the procedure. However, due to variations in the distribution of human veins, achieving accurate venous puncture through manual means alone can be challenging, particularly in children, the elderly, and obese individuals. These populations often present with thinner venous vessels, poorer vascular elasticity, and increased perivenous fat, which complicates venous positioning in the context of venipuncture [1]. Therefore, enhancing the imaging of hand veins using computer-assisted methods may be crucial for improving venous positioning.

Venous positioning is a prerequisite for successful venipuncture. Numerous researchers have conducted extensive studies to accurately locate venous vessels. Ma et al. [2] processed images of the dorsal hand vein using contrast-limited adaptive histogram equalization and multi-scale detail fusion algorithms, subsequently weighting and superimposing the two to enhance the vein images. Although this method addressed the issue of detail loss associated with the histogram equalization algorithm, it remained ineffective in managing vein images that contained high-frequency noise. Kuang et al. [3] employed multi-scale Gaussian blurring to denoise the L component extracted from the LAB color space representation of the image, and utilized guided filtering for illuminance estimation, combined with adaptive thresholding for dynamic adjustment to enhance the vein image. However, the algorithm's adaptability to various application environments required further improvement. Besra et al. [4] proposed a vein segmentation algorithm based on the repeated line tracking method, which achieved vein segmentation by superimposing the trajectory lines in the vein images tracked from different starting points. Nonetheless, this method was highly dependent on image clarity and involved a substantial number of arithmetic operations for image processing, making it challenging to meet the demands of real-time detection and recognition. Yakno et al. [5] employed contrast-limited adaptive histogram equalization and fuzzy adaptive gamma transform to enhance vein image processing. They subsequently weighted the two methods and applied a matched filter with a first-order derivative of the Gaussian function to achieve vein image segmentation. However, this approach required multiple transformations and integrations of the image, leading to high computational complexity and limited effectiveness in managing high-brightness areas. In contrast, Yang et al. [6] utilized a six-dimensional Gabor filter for vein image enhancement and a Markov random field for vein image segmentation. Nonetheless, this method demonstrated poor performance in handling low-contrast vein images or those containing high-frequency noise.

With the rapid development of deep learning theory, achieving vein image segmentation using convolutional neural networks has become increasingly feasible [7]. In 2015, Long et al. [8] proposed Fully Convolutional Networks, which processed pixel-level data by employing full convolution instead of full connectivity, thereby allowing for the processing of image inputs of any size. However, this approach did not adequately address the relationships between pixels when processing them independently, leading to incomplete feature information extraction. In the same year, Ronneberger et al. [9] introduced the U-Net network algorithm for image segmentation, which effectively addressed challenges in low-resolution image processing and has since gained widespread application in the field of medical image segmentation. The direct application of the U-Net network model to venous vessel

segmentation still presents several limitations: (1) A disproportionately small sample set leads to overfitting during network training; (2) The single encode-decode structure may cause the network training to reach a performance ceiling, making it challenging to extract additional effective features; (3) Although the U-Net decoding stage integrates local feature information through skip connections, simple concatenation does not fully merge features of varying scales. To address these issues, researchers have proposed enhanced algorithms based on the U-Net model by modifying the backbone and incorporating an attention mechanism. He et al. [10] introduced an algorithm that leverages the U-Net model alongside the attention mechanism, which improved the identification of multi-scale features and enhanced segmentation accuracy, although it was less effective in segmenting narrow venous vessels. Lefkovits et al. [11] proposed a hybrid approach combining unsupervised and supervised techniques for dorsal hand vein segmentation, experimentally demonstrating that the segmentation results of eight U-Net variants surpassed those of traditional image methods, with the ResNet-U-Net model exhibiting particularly significant performance. Gao et al. [12] proposed a semantic segmentation model called AT-U-Net, which integrates the Non-Local attention mechanism into the U-Net architecture to enhance feature extraction capabilities. This approach addresses the challenge of long-distance dorsal hand vein puncture; however, the limitation in capturing venous vessel images from afar may result in inadequate extraction of global feature information. Additionally, high-frequency noise and blurred vessel edges can adversely affect segmentation accuracy. Chen et al. [13] incorporated a Gabor convolution kernel into the U-Net framework and utilized inverted residual blocks to achieve model lightweighting, thereby mitigating the semantic information loss attributed to channel issues. Nonetheless, this algorithm depends heavily on the extraction of shallow features, and the parameters of the Gabor filter require manual adjustment, which adds to the algorithm's complexity.

In contrast to the limitations of traditional image segmentation algorithms, neural networks are more adept at managing complex image features and capturing nonlinear relationships within images, thereby achieving enhanced segmentation accuracy and robustness. Consequently, to improve the extraction of HDHV, this paper proposes a segmentation algorithm based on GR-Unet. The Bottleneck portion of the ResNet50 serves as the backbone network, while GAM is integrated into the skip connections, along with pre-trained weights to expedite feature extraction. The network's capacity to learn from defective pixels is further augmented through a weighted loss function that combines cross-entropy and Dice loss. Experiments conducted on a self-constructed dorsal hand vein dataset validate the effectiveness of the proposed method.

II. Design Scheme

The design scheme of this paper encompasses several key components: image acquisition, image preprocessing, data enhancement, dataset construction, GR-UNet model development, network training, and experimental testing sessions, as illustrated in Fig. 1. Specifically, image preprocessing involved grayscale normalization, global threshold binarization, the centroid method for extracting regions of interest (ROI), averaging filtering, and contrast-limited adaptive histogram equalization (CLAHE). The GR-UNet model utilized ResNet50 as its backbone network, incorporating the GAM module and a modified loss function at the skip connections.

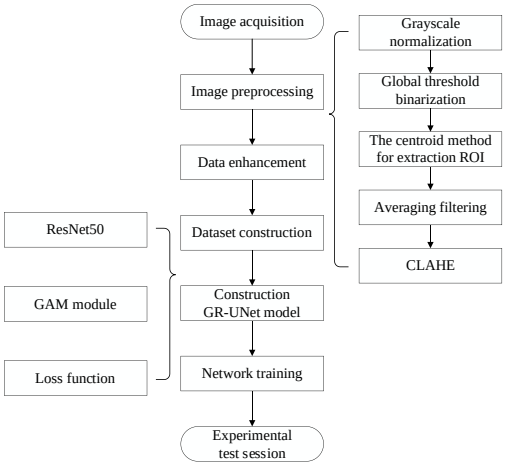

Fig. 1. The technical roadmap of this study.

III. Dorsal Hand Vein Dataset

A. Dorsal Hand Vein Collection System Design

Due to the differential absorption of near-infrared (NIR) light by human tissues, hemoglobin in human veins can absorb NIR light in the range of 700 nm to 1100 nm [14]. Consequently, images within this spectral band (700 nm to 1100 nm) can be captured using a camera equipped with a suitable filter. However, during the experimental process, results indicated that while NIR light could penetrate 5 to 10 mm into human tissues [14], it was less effective in capturing images from individuals with higher fat content in their hands. Existing studies have demonstrated that the use of 850 nm NIR light can effectively highlight the contour structure of veins [15-16], whereas adipose tissue exhibits optimal absorption characteristics at the 940 nm NIR wavelength band [17]. Therefore, this paper proposes a dual-band measurement superposition method, which involves utilizing a 940 nm NIR light source for top irradiation combined with an 850 nm NIR light source for bottom irradiation to facilitate the acquisition of human hand vein images. The schematic representation of the designed human hand vein image acquisition system is illustrated in Fig. 2.

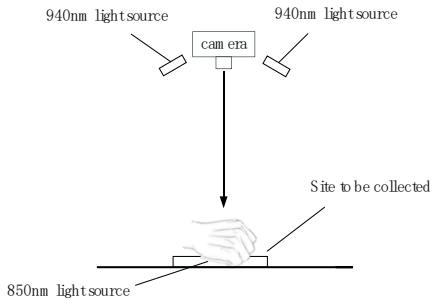

Fig. 2. Schematic diagram of human hand back image acquisition equipment.

In this study, a total of 72 male and female subjects were experimentally recruited, with ages ranging from 3 to 60 years. Among these participants, 30 were minors and 42 were adults. Each subject had images captured of their left and right hand veins, resulting in a total of 144 images, each with a resolution of 640x480 pixels. To enhance the diversity of the image samples, an additional 864 images of human hand veins were generated through rotation and mirroring of the collected images. The images of human dorsal hand vein obtained after NIR filtering is shown in Fig. 3.

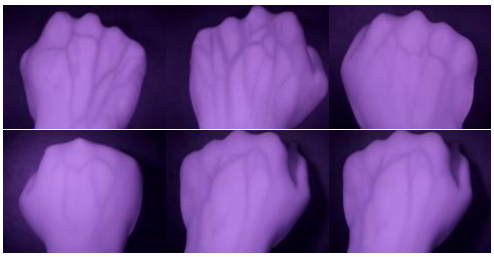

Fig. 3. The images of the human dorsal hand vein obtained after NIR filtering.

B. Image Preprocessing

Due to the interference of realistic conditions, including variations in illumination and the differing thickness of the dorsal hand vein among individuals, the contrast of the collected dorsal hand vein images was suboptimal and contained various artifacts. This compromised the clarity of the boundary between the veins and the background, leading to potential misjudgment in identifying the veins. Consequently, to accurately segment the venous vessels on the dorsal hand vein, it is essential to preprocess the vein images to effectively correct for uneven illumination and eliminate shadows and artifacts. The specific steps of image preprocessing are as follows:

Step 1: Grayscale normalization was employed to standardize the grayscale values of the dorsal hand vein image to a range of 0 to 255, with the calculation formula presented in Eq. (1).

$$P(x,y)=\frac{\left[R(x,y)-R_{\min}(x,y)\right]\times 255}{R_{\max}(x,y)-R_{\min}(x,y)} \tag{1}$$

Wherein, $R(x,y)$ denotes the gray value of the dorsal hand vein image, $R_{\min}(x,y)$ and $R_{\max}(x,y)$ denote the minimum and maximum values of the gray value of the dorsal hand vein image, respectively, and $P(x,y)$ denotes the normalized gray value of the dorsal hand vein image.

Step 2: The dorsal hand vein images were binarized using the global thresholding method, resulting in the dorsal part of the hand appearing in white against a black background.

Step 3: The centroid method $G(x_i, y_j)$ was applied to the binary image to calculate the centroid, and a ROI measuring 288×288 pixels was extracted using this centroid as the reference point. The formulas for the centroid method calculations are provided in Eq. (2) and Eq. (3).

$$x_i=\frac{\sum_{i=0}^{h}\sum_{j=0}^{w}\left[i\times f(i,j)\right]}{\sum_{i=0}^{h}\sum_{j=0}^{w}f(i,j)} \tag{1}$$

$$y_i=\frac{\sum_{i=0}^{h}\sum_{j=0}^{w}\left[j\times f(i,j)\right]}{\sum_{i=0}^{h}\sum_{j=0}^{w}f(i,j)} \tag{3}$$

Where, h and w denote the height and width of the image, respectively, and $f(x,y)$ denotes the pixel point in the white area.

Step 4: An averaging filter was applied to the ROI to reduce the Gaussian noise present in the image.

Step 5: The CLAHE algorithm was utilized to enhance the contrast of the ROI. Finally, the processed image of the dorsal hand vein is presented in Fig. 4.

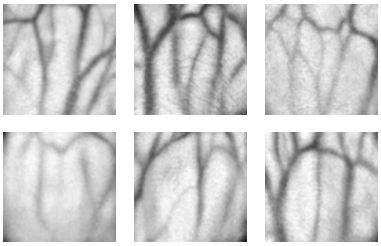

Fig. 4. Preprocessed image results of dorsal hand vein.

C. Dataset Construction

The preprocessed images of HDHV were labeled on a pixel-by-pixel basis, identifying the dorsal hand vein vessels. This process established the labeled images and ultimately constructed the dataset. Eighty percent of the images were randomly assigned to the training set, while ten percent were designated for the validation set and the remaining ten percent for the test set. Randomly selected original and labeled images from the dataset are presented in Fig. 5.

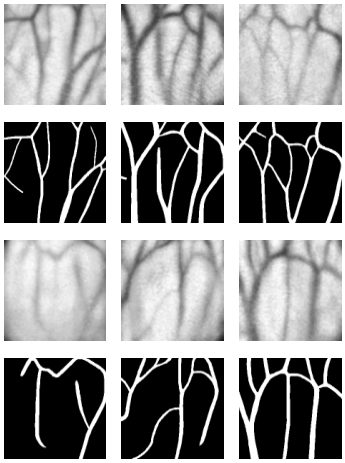

Fig. 5. Original and labeled images.

IV. METHODS

A. Basic Network Model

The U-Net model, developed by Ronneberger et al. [9], was initially applied as a convolutional neural network for cell segmentation in medical images. It features a U-shaped symmetric structure divided into encoding and decoding networks, as illustrated in Fig. 6. The left side comprises the encoding network, which consists of four subsampled modules. Each module contains two consecutive 3×3 convolutional layers, the ReLU activation function, and a 2×2 max-pooling layer. The primary purpose of the encoding network is to extract information from shallow features, as the size of the feature map decreases while the number of feature channels increases. Conversely, the right side contains the decoding network, which is upsampled by stacking 2×2 transposed convolutional layers. After each upsampling, it is spliced with the corresponding feature layer from the encoding network using skip connections, thereby fusing feature information from both deeper and shallower layers. This combined information is then processed by convolutional blocks to gradually recover the size and spatial dimensions of the input image. Ultimately, the segmentation result is obtained through a 1×1 convolutional layer.

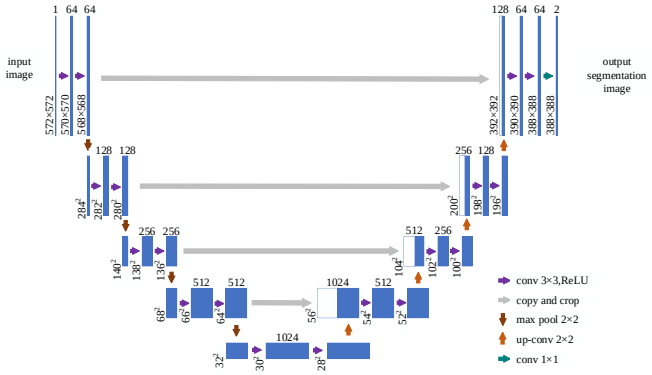

Fig. 6. U-Net model structure.

This paper proposes a GR-UNet model structure divided into two parts: encoding and decoding, as illustrated in Fig. 7. The encoding component utilizes the bottleneck part of the ResNet50 network, effectively mitigating issues related to vanishing gradients and network degradation. In the decoding phase, five up-sampling operations are conducted using bilinear interpolation, followed by two 3×3 convolutions with ReLU activation functions after each up-sampling to eliminate the aliasing effects present in the feature maps. Additionally, the GAM attention mechanism is incorporated at the skip connections to enhance the extraction of global feature information. This allows the network to focus more on the features of HDHV across both spatial and channel dimensions, thereby assigning greater weight coefficients within the network.

B. The ResNet50 Network

To obtain deeper features, this paper replaces the encoding component of the U-Net network with the Bottleneck module from the ResNet50 architecture. The global average pooling layer and the fully connected layer are removed, resulting in the construction of the ResNet50-UNet network. This modified architecture is employed to perform the vein segmentation task. The ResNet50-UNet network effectively combines the strengths of both the U-Net and ResNet50 architectures, thereby mitigating issues related to vanishing gradients and network degradation. Additionally, it fully leverages shallow features to enhance the efficiency of feature extraction when analyzing HDHV.

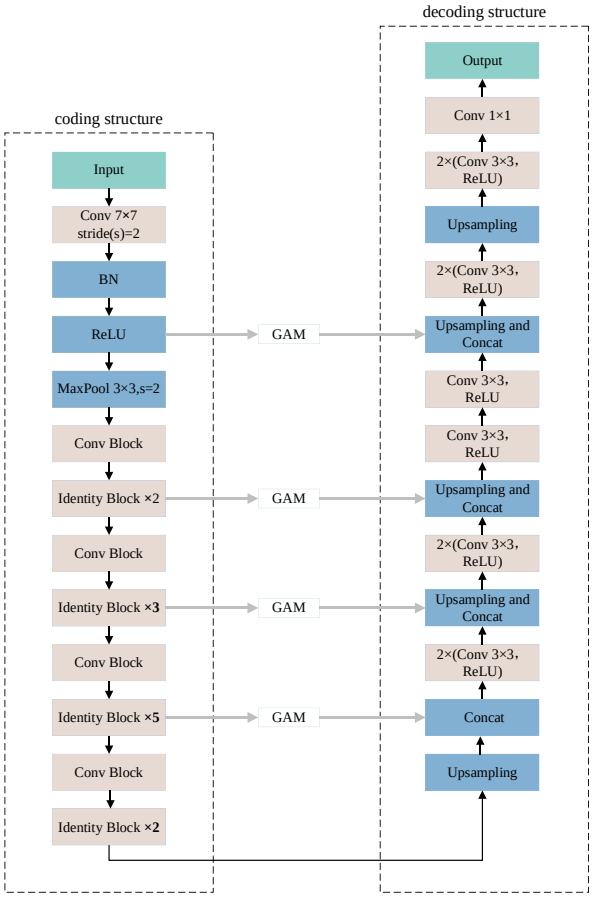

Fig. 7. GR-UNet model structure.

The ResNet50 network was proposed by He et al. [18] and demonstrates excellent performance across various visual application domains, including classification, object detection, and semantic segmentation. The architecture of the ResNet50 network primarily consists of an input layer, a residual block, a global average pooling layer, and a fully connected layer, as illustrated in Fig. 8. The residual mapping component on the left side of the Conv Block undergoes three convolution processes: a 1×1 convolution (with a stride of 2), a 3×3 convolution (with a stride of 1), and another 1×1 convolution (with a stride of 1). Following each convolution, a Batch Normalization (BN) layer is employed to normalize the features. The BN layer associated with the first two convolutions is succeeded by a ReLU activation function, which helps mitigate the vanishing gradient problem. In the right direct mapping component, a 1×1 convolution (with a stride of 2) and a BN layer normalization are performed, after

which the feature map output from the residual mapping is added pixel-by-pixel to the feature map output from the direct mapping. The combined output is then processed through a ReLU activation function, resulting in a feature map that is half the size of the input feature map. The Identity Block is analogous to the Conv Block; however, the left side maintains the same structure as the Conv Block, with all convolutional layers having a stride of 1. The right side features a direct mapping that does not include the 1×1 convolution operation or BN layer normalization, allowing the inputs to be added directly to the outputs, which subsequently pass through the ReLU activation function. The Conv Block is designed to reduce the size of the feature map, while the Identity Block serves to deepen the network.

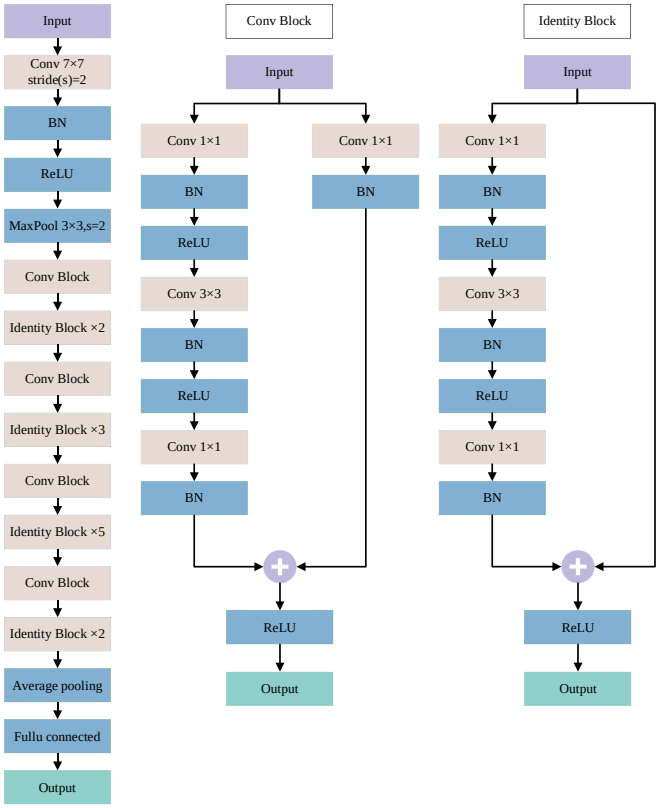

Fig. 8. ResNet50 network structure.

C. The GAM Attention Module

The decoder construction of U-Net closely resembles that of the encoder. Popular upsampling operations, such as transpose convolution, are local operations [19]. However, they do not adequately mine the in-depth feature information of the context, leading to incomplete information being conveyed during skip connections and subsampling. Consequently, this results in a failure to obtain rich feature information. To address this issue and achieve a more comprehensive understanding of HDHV, the GAM attention module has been introduced at the skip junction. This enhancement facilitates the acquisition of global feature information, allowing for further optimization and processing of deep feature information to better capture the global contextual information. The GAM attention mechanism is designed to minimize information loss while amplifying global dimensional interaction features [20]. It is a redesign based on the CBAM [21] attention mechanism, which also employs spatial and channel attention mechanisms. Its structure is illustrated in Fig. 9.

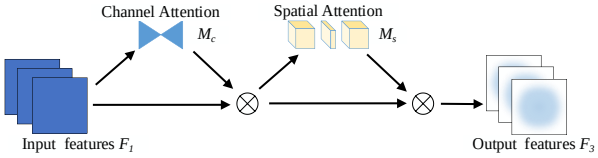

Fig. 9. GAM attention module.

In the whole process, the input features are $F_1 \in R^{C\times H\times W}$, F_2 is the intermediate state, and F_3 is the output features, and the relationship between them is shown in Eq. (4) and Eq. (5):

$$F_2 = M_C(F_1) \otimes F_1 \tag{2}$$

$$F_3 = M_s(F_2) \otimes F_2 \tag{3}$$

Where, M_C and M_s are channel feature maps and spatial feature maps respectively, and $\otimes$ is the multiplication operation.

In the channel attention submodule, a three-dimensional arrangement is initially applied to the input data to preserve its information across three distinct dimensions. Subsequently, the cross-dimensional channel and spatial dependencies are enhanced by a two-layer Multilayer Perceptron (MLP), which performs a dimensionality transformation, reverting the dimensions to their original state. Finally, the output is processed through the Sigmoid activation function, allowing for the fusion of information across different dimensions by implementing the dimensional transformation. The structure of the channel attention submodule is illustrated in Fig. 10.

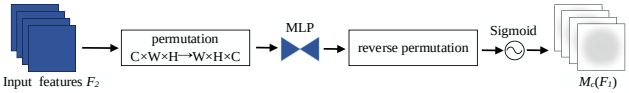

Fig. 10. Channel attention submodule.

In the spatial attention submodule, the convolution operation is primarily performed on the input feature graph F_2. Initially, information from the spatial layers is fused using two 7×7 convolutional layers to enhance the learning of spatial features. The output is then processed through the Sigmoid activation function to enhance the integration of data across different dimensions. The structure of the spatial attention submodule is illustrated in Fig. 11.

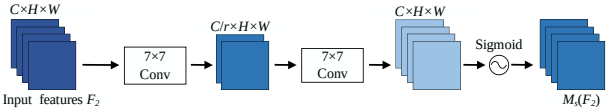

Fig. 11. Spatial attention submodule.

D. Improved Loss Function

To address the imbalance between positive and negative samples, this paper improves the original loss function by employing a weighted combination of Cross-Entropy Loss (CE

Loss) and Dice Loss. The calculation of the loss function is detailed in Eq. (6) to Eq. (8).

$$Loss = CE\_Loss + Dice\_Loss \tag{6}$$

$$CE\_Loss = -\frac{1}{N}\sum_{i=1}^{N}\sum_{c=1}^{C} y_{i,c}\log\left(p_{i,c}\right) \tag{7}$$

$$Dice\_Loss = 1 - \frac{2\times\left(\sum_{i=1}^{N} P_i y_i\right)}{\sum_{i=1}^{N} P_i + \sum_{i=1}^{N} y_i} \tag{8}$$

Where CE_Loss is the cross-entropy loss function, $Dice\_Loss$ is the Dice loss function, N is the number of samples, C is the number of classes, $y_{i,c}$ is the actual label of sample i belonging to class c, $p_{i,c}$ is the probability of sample i belonging to class c, P_i and y_i are the predicted value of the model and the real label respectively.

V. Experiments

A. The Experimental Environment

The hardware configuration used for network training and testing in this article is as follows: 12th Gen Intel(R) Core(TM) i7-12700H (2.3 GHz), 16 GB memory, NVIDIA GeForce RTX 3060, CUDA12.1, Windows 11, Python3.8 and Pytorch2.3. The hyperparameters of the network are: learning rate 0.0001, number of epochs 200, batch size 4, and optimizer Adam.

B. Evaluation of Indicators

Dorsal hand vein classification can be viewed as classifying each pixel in the vein image, with each pixel classification is described by a confusion matrix. The four elements of TP, FN, TN, and FP confusion matrix, where TP is for correctly predicting hand dorsal vein samples as hand dorsal veins, FN for incorrectly predicting hand dorsal vein samples as non-hand dorsal veins, TN for correctly predicting non-hand dorsal vein samples as non-hand dorsal veins, and FP for incorrectly predicting non-hand dorsal vein samples as hand dorsal veins, and the confusion matrix is shown in Table I.

In this paper, the evaluation metrics used for the experimental results are Intersection Over Union (IOU), Mean Intersection Over Union (MIOU), Mean Pixel Accuracy (MPA) and Accuracy for categories. The formulas for IOU, MIOU, MPA and Accuracy are shown in Eq. (9) to Eq. (12), where n denotes the number of categories.

$$IOU = \frac{TP}{TP + FP + FN} \tag{4}$$

$$MIOU = \frac{1}{n}\sum_{i=1}^{n}\frac{TP}{TP + FP + FN} \tag{5}$$

$$MPA = \frac{1}{n}\sum_{i=1}^{n}\frac{TP}{TP + FP} \tag{6}$$

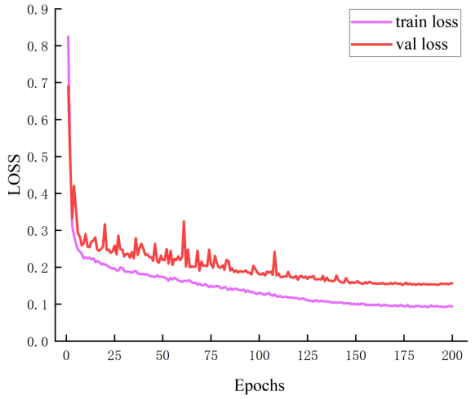
$$Accuacy = \frac{TP + TN}{TP + TN + FP + FN} \tag{12}$$

TABLE I. Confusion Matrix of Dorsal Hand Vein Segmentation

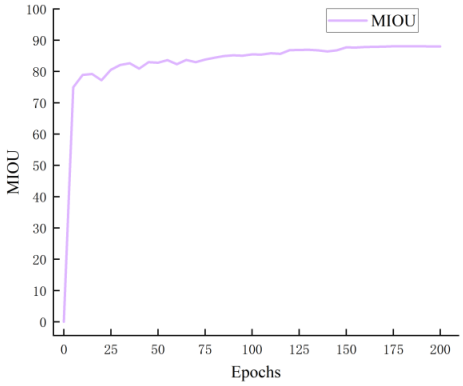
Projected results	Real results	
	hand dorsal vein	Non-dorsal hand veins
hand dorsal vein	TP	FP
Non-dorsal hand veins	FN	TN

C. Training Results of GR-UNet Model

In this paper, the attention mechanism and residual network were introduced to improve U-Net, while a weighted loss function was used to further prevent the imbalance of positive and negative samples. Finally, the improved model was used to train the detection on a self-constructed dataset of hand dorsal veins. The training results of the model are shown in Fig. 12, which indicates that as the number of iterations increased, the accuracy of the model increased while the loss value decreased, and when the loss curve tended to stabilize, the network converged and the training ended. Model accuracy reached a high steady state after 160 iterations.



(a) Loss value.



(b) MIOU.

Fig. 12. Training results of GR-UNet model.

D. Comparative Experiments on Network Models with Different Backbones

In order to verify the impact of backbone feature extraction network on the performance and accuracy of U-Net model, Mobile-UNet, VGG16-UNet and ResNet50-UNet were respectively used for comparative experiments. The U-Net models with different backbone were evaluated by IOU, MIOU, MPA and Accuracy indexes. Results are shown in Table II, where the model performs best when ResNet50 was used as the backbone network.

E. Results of Ablation Experiment

Ablation experiment is a widely used analytical method in machine learning and deep learning to assess the impact of a component of an algorithm, model, or system on overall performance by systematically removing or modifying that component.

The GR-UNet proposed model was experimentally analyzed using a self-constructed dataset of human dorsal hand vein images. An ablation study was conducted utilizing the GR-UNet model to assess the effectiveness of the improved ResNet50 backbone, the incorporation of the GAM attention mechanism at the skip connections, and the enhanced loss function. As demonstrated in Table III, compared to the U-Net model, the IOU of the GR-UNet model increased by 5.28%, the MIoU increased by 2.96%, the MPA increased by 4.14%, and accuracy improved by 0.61%, ultimately reaching 97.5%.

According to the test efficiency statistics of different models presented in Table IV, it is evident that the U-Net model exhibits the shortest processing time; however, its segmentation recognition performance is suboptimal. The implementation of the ResNet50 backbone network, coupled with the integration of the GAM attention mechanism, resulted in increased test time due to the augmented complexity of the network. Nonetheless, this modification significantly enhanced segmentation recognition accuracy. Consequently, the consideration of high-performance computers for model training will be pursued to further improve model efficiency.

F. Comparative Experiments with Different Models

To further validate the segmentation performance of the GR-UNet network model, the U-Net model, ResNet50-UNet model, PSPNet model, and Deeplabv3+ model were employed to assess the recognition capabilities on HDHV dataset. Following image preprocessing, a HDHV image with a consistent size of 288×288 pixels was obtained. The labeled image for training was generated through pixel-by-pixel labeling, with the labeling results presented in a binarized format, where the vein region is indicated in white.

The segmentation recognition results obtained from various network models are illustrated in Fig. 13. The U-Net model was ineffective in extracting weak edges of narrow vessels, leading to instances of local vein fracture. The edge positioning accuracy of the PSPNet model was suboptimal, and its smoothness was inadequate. Although the Deeplabv3+ model outperformed the PSPNet model, it still encountered issues with fracture separation at the connectivity. The ResNet50-UNet addressed the inaccurate localization of edge features seen in the traditional U-Net; however, it continued to exhibit local vein feature breakage. The GR-UNet model, which integrated the ResNet50 network and the GAM attention mechanism, effectively combined the residual structure's performance for feature extraction with the GAM attention mechanism's capability to capture global feature information. Additionally, it improved the loss function to mitigate the imbalance between positive and negative samples, further enhancing the model's segmentation efficacy. Consequently, when compared to other models, the GR-UNet demonstrated superior segmentation performance, excelled in extracting vein vessel boundaries and low-contrast regions, exhibited stronger feature recognition capabilities, and showed good resistance to interference in the segmentation of different HDHV. This further validated the accuracy of the improved network model presented in this paper for dorsal hand vein segmentation.

TABLE II. COMPARISON OF NETWORK MODELS WITH DIFFERENT BACKBONES

Mobile	VGG16	ResNet50	Decoder module	IOU	MIOU	MPA	Accuracy
√	—	—	√	63.31%	79.32%	83.31%	95.69%
—	√	—	√	75.45%	86.09%	92.92%	97.03%

ResNet50-UNet	77.59%	87.3%	93.52%	97.3%
GR-UNet	78.82%	88.03%	93.92%	97.5%

VI. CONCLUSION

In this paper, a human dorsal hand veins dataset was established by designing a hand dorsal vein visualisation acquisition device based on near-infrared imaging technology. Based on the U-Net model architecture, a GR-UNet model combining attention mechanism and residual network was designed. The model used the residual structure of ResNet50 to enhance the feature extraction capability and effectively solved the vanishing gradient problem. The introduction of the GAM attention mechanism at skip connections optimized the processing of high-level feature information and effectively captured the global contextual features of the network. In addition, a weighted optimization loss function using cross-entropy loss and Dice loss to prevent the positive and negative sample imbalance problem further optimized the performance and stability of the network model.

Compared with the semantic segmentation models of PSPNet, Deeplabv3+, UNet and ResNet50-UNet, the proposed model achieved 78.82% in IOU, 88.03% in MIOU, 93.92% in MPA and 97.5% in Accuracy, respectively. It was superior to other semantic segmentation models, and significantly improved the segmentation accuracy of dorsal hand vein. However, the FPS of the model after completing the training was too low compared to the original model and did not reach the desired value, and a lightweight design of the model will be considered to improve the performance of the model in the subsequent research and there were still some limitations when dealing with more complex backgrounds and low-contrast vein regions, the subsequent work will expand the dataset to improve the generalisation ability and segmentation effect of the model in different age groups, genders and special populations.

***Abstract*—Classification of batik images is a challenge in the field of digital image processing, considering the complexity of patterns, colors, and textures of various batik motifs. This study proposes an ensemble method that combines texture feature extraction using Gray Level Co-occurrence Matrix (GLCM) with the Residual Neural Network (ResNet) classification model to improve accuracy in batik image classification. Texture features such as contrast, dissimilarity, entropy, homogeneity, mean, and standard deviation are extracted using GLCM and combined with ResNet to produce a more robust classification model. The experimental results show that the proposed method achieves high performance, namely above 90% for each evaluation metric used, such as accuracy, precision, recall and F-1 Score. The best performance in classifying batik images is obtained by the Standard Deviation feature with accuracy, precision, recall, and F1-score of 95%, 93%, 93%, and 93%, respectively. Furthermore, the application of the ensemble method based on the hard voting approach has proven effective in increasing the accuracy of batik image classification by utilizing a combination of texture features and deep learning models. The proposed method makes a significant contribution to the efforts to preserve batik culture through digitalization and can be implemented for various purposes such as an image-based batik search system.**

Keywords*—Batik; GLCM; ResNet; ensemble method; hard voting

I. INTRODUCTION

Batik is an Indonesian cultural heritage that has high artistic and historical value [1], [2], [3], [4]. Each batik motif contains a certain philosophical meaning and can reflect the cultural identity of the producing region. Along with the development of digital technology, digitization and classification of batik images have become important needs, both for cultural preservation and commercialization. However, batik image classification has its own challenges, considering the diversity of complex motifs, colors, and textures [5], [6]. Batik image classification faces challenges in the field of pattern recognition and digital image processing due to the diverse and complex batik motifs [7]. Although there have been various methods applied to classify batik images, such as the use of conventional machine learning-based methods (eg, SVM, KNN) and deep learning (eg, CNN), there are still several limitations that have not been fully overcome.

Many studies only rely on artificial neural networks or deep learning methods for batik image classification without considering specific local texture features, such as those that can be obtained with the GLCM method. This can cause additional problems due to the loss of important information related to patterns and textures that are characteristic of batik motifs. In addition, most previous studies tend to focus on the use of a single technique, either classical feature extraction or deep learning, without combining the advantages of both methods in one ensemble model. This suggests an opportunity to explore a hybrid approach that can improve classification accuracy by leveraging the strengths of GLCM-based texture feature extraction and the generalization capabilities of ResNet.

In this study, it is proposed a batik automatic classification system that combines a texture feature extraction approach using Gray Level Co-occurrence Matrix (GLCM) and an artificial neural network-based classification method, namely Residual Neural Network (ResNet). This ensemble method aims to improve classification accuracy by utilizing the advantages of both approaches. GLCM is known to be effective in describing texture characteristics [8], [9], [10], [11], while ResNet offers advantages in the ability to learn complex feature representations from images through deep network architectures [12], [13]. This research is expected to make a significant contribution to the field of pattern recognition, especially for batik image classification. Furthermore, the presence of this research is expected to provide alternative solutions that are more accurate and efficient in identifying batik images.

By developing an automatic classification system, the digitization and cataloging of Batik patterns can be streamlined, contributing to cultural preservation in the digital age. This also supports educational and archival efforts, making Batik accessible to global audiences. Furthermore, an automated classification system could help streamline various processes, from quality control to market segmentation, and assist in inventory management. For instance, it can aid designers, retailers, and manufacturers in quickly identifying and categorizing different Batik types, improving the overall supply chain and customer service experience.

II. LITERATURE REVIEW

A. GLCM Feature Extraction

Feature extraction is the first and foremost step in image processing, also known as computer vision. This stage involves transforming an image into a set of features that are easier for a computer to understand and relevant for further analysis, such as classification or segmentation [14]. Among the various techniques for feature extraction, Gray-Level Co-Occurrence Matrix (GLCM) which is introduced by Haralick et al. in 1973, is widely used, especially in texture analysis [15], [16]. GLCM is a statistical method that considers the spatial relationship between pixels to analyze texture [17], [18]. GLCM has become a popular choice for feature extraction due to its many advantages. GLCM is able to capture complex texture information in an image by measuring the spatial relationship between pixels [19]. This method allows for more detailed texture analysis compared to simple statistical methods such as mean or variance. It is particularly useful for detecting subtle and complex patterns in images, such as small differences in tissue texture in medical images or variations in surface texture in quality inspection. In addition, GLCM is effective in detecting subtle differences in texture that may not be visible with other analysis techniques [19]. In representing an image, GLCM can produce several features to quantify the texture of an image such as Contrast, Correlation, ASM, homogeneity and so on.

Due to its advantages, GLCM is considered very suitable for image processing in batik because of its ability to analyze textures in depth and capture complex texture patterns. Batik is a traditional fabric that has unique patterns and textures with complex and repetitive motif variations, so it requires effective techniques to recognize, classify, or even detect these patterns. For example, GLCM is able to measure the spatial relationship between pixels in a way that captures the texture properties found in batik images, such as how often a particular pattern appears or how the color intensity changes along the pattern. In addition, GLCM can detect subtle variations in texture with features such as contrast, homogeneity, and energy, which helps identify small patterns and texture differences in batik designs. To date, there have been many studies that applied the GLCM feature extraction algorithm to the task of batik image classification. The summary of the research is shown in Table I.

Based on Table I, it can be seen that GLCM has played a major role in building a batik image classification system. Furthermore, from the literature study that has been conducted, it can be concluded that the majority of these studies apply the k-NN algorithm as their choice. Very few studies have tried to apply Deep Learning-based image classification which is considered one of the best methods in image classification. This is one of the research gaps found and attempted to be solved in this study. A detailed discussion related to this issue will be presented in the following research gap and research contribution sections.

B. Ensemble Method

Ensemble methods have gained significant attention in recent years for the task of image classification due to their ability to improve model accuracy and performance. Ensemble methods are approaches that combine multiple machine learning models to produce a more robust and accurate model [32], [33]. The main goal of ensemble methods is to reduce the prediction error generated by a single model by combining the results of multiple models. Some popular ensemble techniques include Bagging, Boosting, Stacking and Voting [34], [35], [36].

TABLE I. RELATED RESEARCH OF GLCM IMPLEMENTATION FOR BATIK CLASSIFICATION

Authors	Method	Result
[20]	k-NN	Acc = 75%
[21]	k-NN	Acc = 97.96
[22]	Neural Network	Acc = 84%
[23]	SVM	Acc = 78.3%
	k-NN	Acc = 92.3%
[24]	Canberra Distance	Acc = 41.67%
[25]	MLP	Acc = 88.89%
[26]	LVQ	Acc = 98.98%
[27]	Backpropagation Neural Network	Acc = 94%
[28]	Linear Discriminant Analysis	Acc = 96.5%
[29]	Backpropagation Neural Network	Acc = 80%
[30]	k-NN	Acc = 73.33%
[31]	k-NN	Acc = 97%

Bagging (Bootstrap Aggregating) is one of the commonly used ensemble techniques for image classification. This technique works by training several different models on a subset of the training data taken randomly with replacement. Random Forest, one of the Bagging-based algorithms, has been widely used for image classification. Boosting is an ensemble technique that attempts to improve model performance by training the model in stages, where each new model focuses on data that was incorrectly predicted by the previous model. One of the popular Boosting algorithms is AdaBoost (Adaptive Boosting). Stacking is an ensemble technique that combines several learning models to produce a final prediction through a meta-learner model. This technique usually involves heterogeneous models, such as a combination of neural network models and decision tree models. Voting is a relatively simple ensemble technique where several base models are trained independently, and the final prediction is made by voting on the predictions from each model. There are two types of voting-based ensemble methods, Hard Voting and Soft Voting. In Majority Voting (Hard Voting), the final prediction is the prediction that appears most often (the most votes) from all the base models. In contrast to the Weighted Voting (Soft Voting) type, in this type each model is given a weight based on its performance. The final prediction is made based on the weight of each model.

This study chooses the Voting-based ensemble method technique in order to produce a reliable and robust batik image classification system. This is because the voting method has been recognized as a very simple and efficient method [37], [38]. It does not require a lot of complex parameter settings or selection. This makes voting an attractive choice when the main goal is to improve prediction accuracy without adding much complexity. In addition, this Voting method has been proven to be able to overcome the weaknesses of the Single Model which

in many cases has certain weaknesses or biases. By using voting, it can reduce the impact of these weaknesses because the final decision is made based on the consensus of several models. This is very useful when there is uncertainty about which model is most appropriate for a particular dataset. On the other hand, the voting method tends to be more stable and reliable when faced with new or previously unseen data. Because the final result is based on the consensus of several models, this method can adapt better to data that may not follow the training data pattern. However, the implementation of the ensemble method is still rare to produce a batik image classification system. This can be seen in the following Table II.

TABLE II. RELATED RESEARCH OF ENSEMBLE METHOD IMPLEMENTATION FOR BATIK CLASSIFICATION

Authors	Method	Result
[39]	Histogram Feature Extraction with k-NN classifier	Prec = 86.67%
[40]	Ensemble CNN	Acc = 100%
[41]	GLCM + LBP Feature Extration with k-NN classifier	Acc = 93.9%

Based on the study literature summarized in Table II, it can be concluded that the implementation of the ensemble method to produce a robust batik image classification system is still very rare. Especially related to the implementation of the ensemble method combined to GLCM feature extraction and Deep Learning-based classification. Three out of five studies related to the application of the Ensemble Method for batik image classification, it was found that two studies applied the k-NN algorithm as the choice of classification algorithm. Only one study applied a CNN-based Deep Learning algorithm. This problem is another research gap that is tried to be addressed in this study which will be summarized in the following section.

C. Research Gap and Contribution

Regarding the discussion of related research that has been explained in the previous section, it can be concluded that although there have been various methods applied to classify batik images, there are still some limitations that have not been fully resolved. The highlighted meeting problem is the scarcity of research that tries to combine the reliability of GLCM-based feature extraction with Deep Learning classification algorithms. The majority of studies that apply GLCM feature extraction are combined with classical machine learning algorithms such as k-NN instead of utilizing the reliability of the Deep Learning algorithm. The second research gap is the Lack of Ensemble Approaches that Combine Feature Extraction Techniques and Deep Learning. Most previous studies tend to focus on the use of a single technique, be it classical feature extraction or deep learning, without combining the advantages of both methods in one ensemble model. This shows an opportunity to explore a hybrid approach that can improve classification accuracy by utilizing the strengths of GLCM-based texture feature extraction and the generalization capabilities of ResNet. A summary of the research gaps found along with the research contributions proposed by this study is illustrated in Fig. 1.

Based on the illustration related to the research gap illustrated in Fig. 1, it can be concluded that this study proposes two contributions that can bridge those research gap. The first contribution is related to the effort to combine the GLCM feature extraction algorithm which has advantages in recognizing batik textures into a Deep Learning-based classification algorithm. The second contribution attempted by this study is the application of ensemble methods for batik image classification. This study introduces an ensemble method that combines GLCM-based feature extraction techniques and classification using ResNet. By combining these two algorithms, it is hoped that the proposed method can overcome the limitations in capturing complex texture information and fine patterns that are characteristic of batik. Furthermore, through these two contributions, it is hoped that the goal of developing a reliable and robust batik image classification system will be achieved.

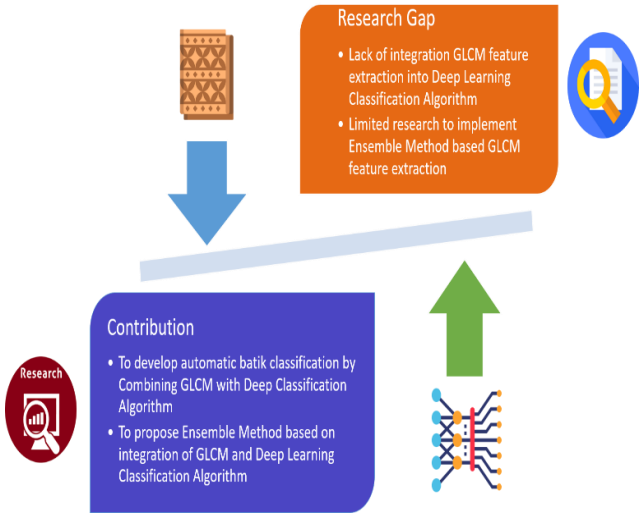

Fig. 1. Research gap and proposed contribution.

III. MATERIAL AND METHOD

A. Dataset Material

The dataset used in this research is a combination of datasets sourced from public datasets such as batik classification Resnet [4] and deep learning batik classification [6]. Furthermore, the dataset used consists of five classes of batik motifs such as lereng, parang, nitik, kawung and ceplok batik, which are illustrated in Fig. 2.

The batik dataset that has been collected consists of 5 classes of 4,284 images and is then separated into three types of data, such as training, testing, and validation data. To assemble data for training, testing, and validation, the dataset was separated by applying a ratio of 70:20:10. The final data for training, testing, and validation can be seen in Table III.

The next step is image preparation from raw data to ready-to-use data, known as the image pre-processing stage. At this image pre-processing stage, two activities are carried out, namely size adjustment and image dataset augmentation. In the image adjustment activity, customization is carried out so that all batik images have a uniform size of 150 x 150 pixels. After that, data augmentation is carried out on the rescaled image using the horizontal rotation method. The overall results of the data collection and pre-processing stages are described in Fig. 3.

Fig. 2. Batik dataset.

TABLE III. DATASET

Batik Class	Data	Training	Testing	Validation
Lereng	405	284	81	41
Parang	1,197	838	239	120
Ceplok	1,053	737	211	105
Kawung	747	523	149	75
Nitik	882	617	176	88
TOTAL	**4,284**	**2,999**	**857**	**428**

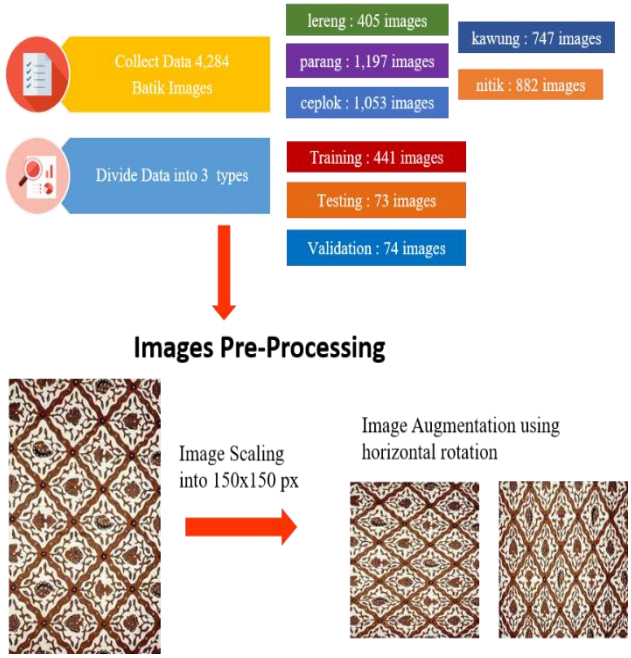

Fig. 3. Image pre-processing stage.

B. Proposed Method

As explained previously, the main contribution of this research is the development of an automatic classification system for batik images by applying the ensemble learning algorithm. Ensemble learning is a method in machine learning that works by combining several machine learning models to produce a more robust and accurate model. The basic concept of ensemble learning is that by combining predictions from several different models, we can reduce errors and improve prediction performance. The concept of ensemble learning applied in this research is based on hard voting. Hard voting is done by calculating the prediction results where the final prediction is determined based on the majority of votes. The overall flow of the proposed ensemble learning for batik image classification is depicted in Fig. 4.

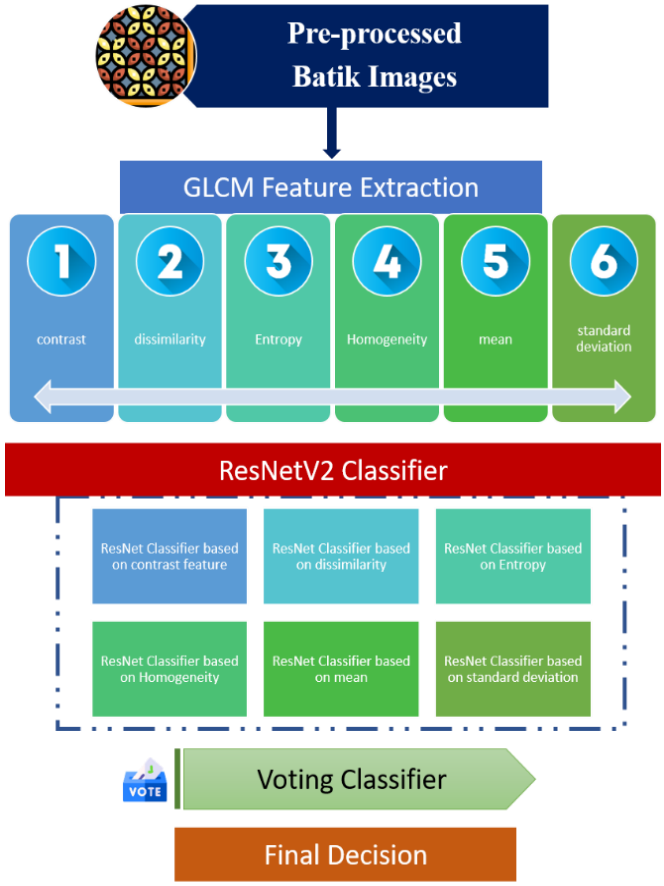

Fig. 4. Flowchart of proposed ensemble deep learning based on GLCM feature extraction.

As seen in Fig. 4, the proposed ensemble deep learning method consists of two main components, namely the GLCM algorithm as a feature extraction layer and the ResNet18 architecture. GLCM (Gray Level Co-occurrence Matrix) is a method often used in image analysis for texture feature extraction. GLCM calculates how often a pair of pixels with a certain intensity value appears in an image at a certain distance and angle. The use of GLCM (Gray Level Co-occurrence Matrix) as a feature extraction algorithm has several advantages that make it a popular choice in image texture analysis. Even when compared to the very popular convolution method, GLCM

has advantages such as the ability to describe texture, various texture features, simple implementation, computational affordability, lower data requirements and so on.

To perform feature extraction using GLCM (Gray Level Co-occurrence Matrix), the first step is to convert the color image to grayscale, because GLCM is applied to grayscale images. After the image is converted, the GLCM parameters are determined, such as the distance between pixels and the angle (0 °, 45 °, 90 °, 135 °). The GLCM matrix is generated by calculating the frequency of occurrence of pixel pairs with certain intensity values at predetermined distances and angles. Once the GLCM matrix is obtained, texture feature extraction is performed by calculating the contrast, dissimilarity, homogeneity, mean, and entropy values of the GLCM matrix. Moreover, this study uses 4 angles at once with a distance between pixels of 1. So that the total features generated for each image are 24 features (4 features for each texture).

After feature extraction with GLCM is completed, the next stage is the application of the CNN algorithm to determine the class of each image by utilizing the Pretrained Residual Network (ResNet) architecture. The ResNet architecture was developed with the aim to overcome the issue of degradation in very deep neural networks. As the depth of the network increases, model performance tends to deteriorate and has difficulty in training due to the vanishing gradient problem. ResNet introduces a residual block that allows information to pass through several layers through "shortcut connections" or "skip connections". ResNet comes in several variants, which differ in the number of layers and network depth. This study applies ResNet18 which is considered suitable for tasks with low data complexity. The block diagram of the ResNet18 architecture is conceived in Fig. 5.

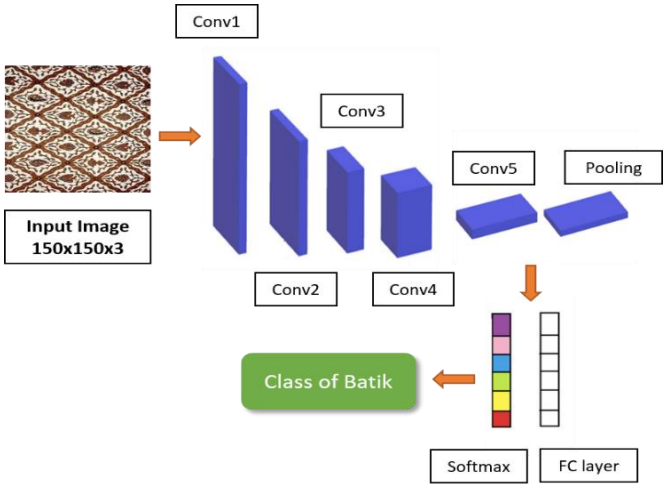

Fig. 5. Block diagram of ResNet18 architecture.

In addition, the ResNet18 architecture is chosen in this study compared to other architectures because of its smaller parameter size. This makes model loading, model weighting, and training much faster. ResNet-18 serves as the base network, and the introduction of the Inception module enhances it. This module combines complex kernels of various sizes to facilitate feature extraction at different image scales, thereby improving recognition accuracy.

The process of identifying the class of batik images will produce six classification results according to the number of textures used. Therefore, an ensemble learning method based on hard voting is then carried out to determine the final class of the batik image. As previously explained, the application of hard voting by combining several different models (ensemble learning) is expected to reduce the risk of overfitting that may occur in a single model. This is because errors made by one model can be offset by other models.

C. Metric Performance

Once the batik image classification model based on ensemble learning was successfully created, the research continued to the performance evaluation stage of the created model by utilizing the confusion matrix. This matrix is very useful for showing the number of correct and incorrect predictions, which are divided into True Positives (TP), False Positives (FP), True Negatives (TN), and False Negatives (FN). This helps in calculating other metrics and provides deeper insight into the types of errors made by the model. After the Confusion Matrix is successfully identified, the next step is to calculate the level of accuracy, precision, recall and F-1 Score. The illustration of the confusion matrix can be seen in Fig. 6.

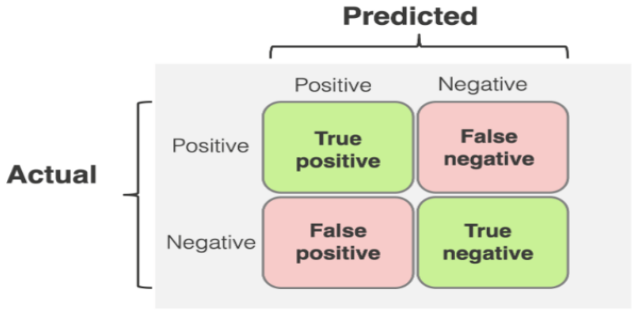

Fig. 6. Confusion matrix scheme.

Each of these metrics has its own advantages and disadvantages. So by using these various metrics, a more comprehensive picture of the ensemble learning model for batik classification will be obtained.

IV. Result and Discussion

As explained, this research applied the concept of ensemble deep learning extraction integrated with CNN algorithm as a feature layer to get the best performance in batik image classification. In this section, a confusion matrix-based performance evaluation will be carried out followed by measuring accuracy, precision, recall and F-1 score. The confusion matrix results for each GLCM feature are shown in Fig. 7 to Fig. 12.

Based on the results depicted by the confusion matrix in Fig. 7 to Fig. 12, it was found that the average GLCM feature has a balanced performance in recognizing batik images. This is indicated by the accuracy of batik class identification between the predicted results and the actual values. Furthermore, there is no significant difference between each GLCM feature used in the classification of batik images. Therefore, it can be concluded that each GLCM feature has a fairly balanced performance in batik classification. Furthermore, by utilizing

the results obtained in the confusion matrix, a performance evaluation based on accuracy, precision, recall and F-1 score was carried out using the following formula.

$$accuracy = \frac{(TP+TN)}{(TP+TN+FP+FN)} \quad (1)$$

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

$$Recall = \frac{TP}{TP+FN} \quad (3)$$

$$F1\ Score = \frac{2*(Precision*Recall)}{(Precision+Recall)} \quad (4)$$

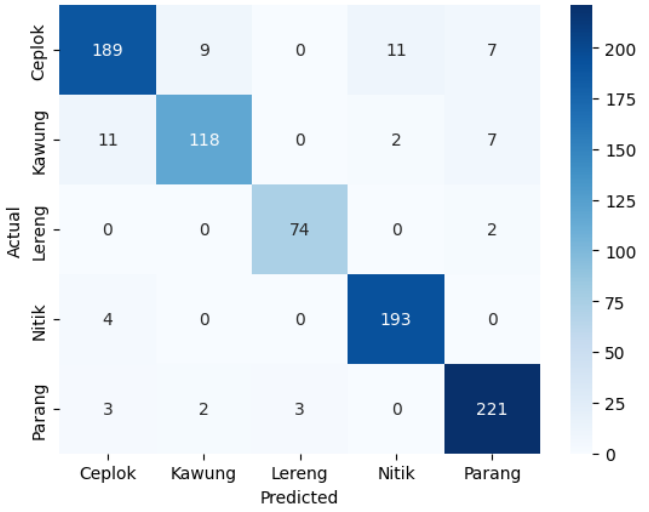

Fig. 7. Confusion matrix based on contrast features.

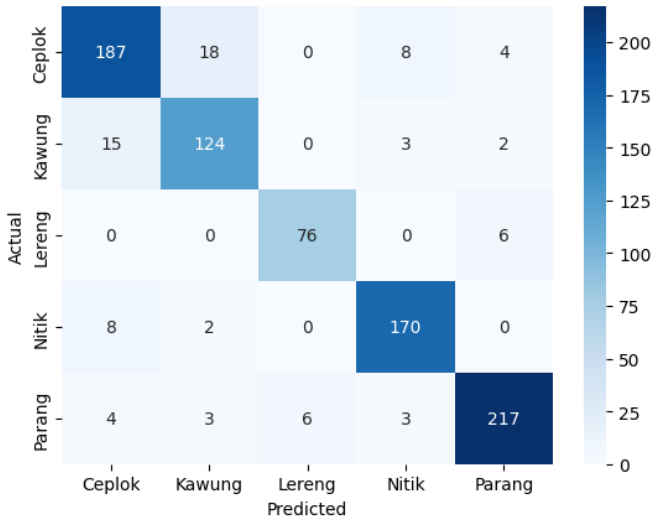

Fig. 8. Confusion matrix based on dissimilarity features.

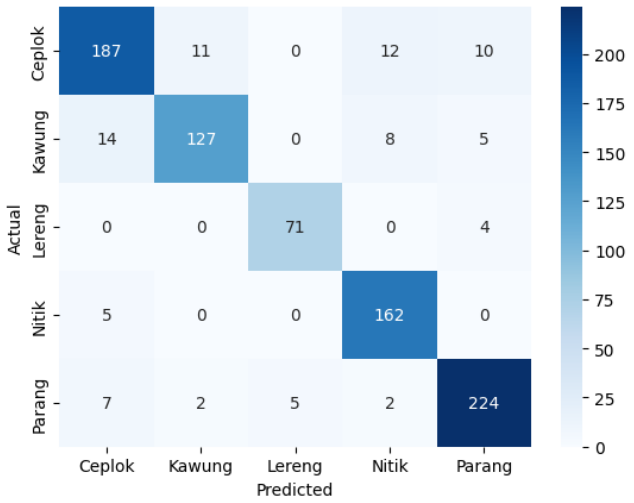

Fig. 9. Confusion matrix based on entropy features.

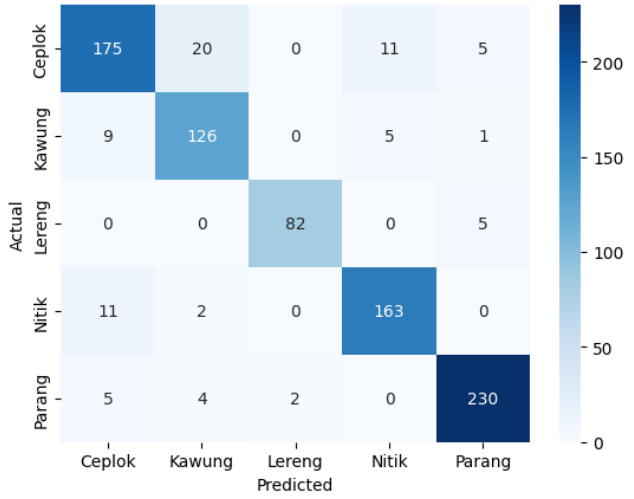

Fig. 10. Confusion matrix based on homogeneity features.

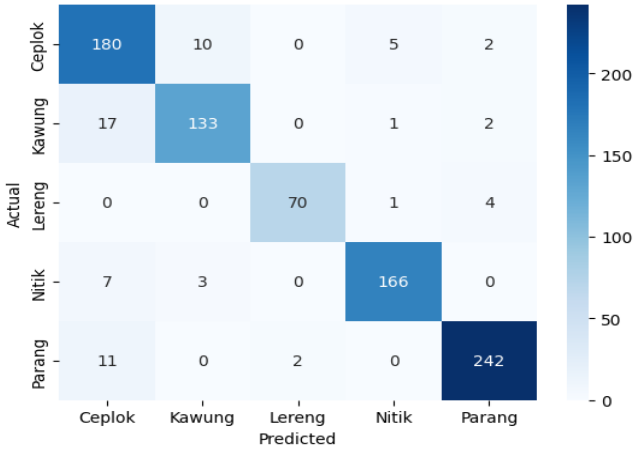

Fig. 11. Confusion matrix based on mean features.

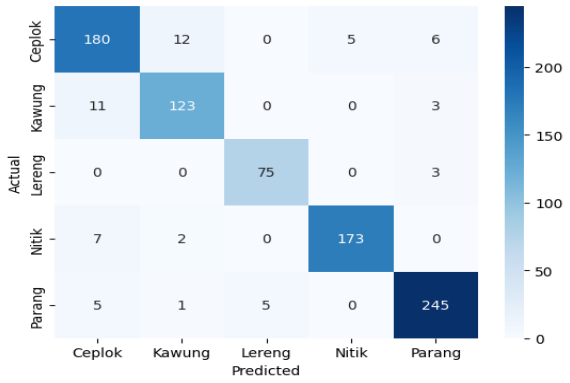

Fig. 12. Confusion matrix based on standard deviation features.

The overall performance evaluation of this research can be seen in Table IV.

TABLE IV. CLASSIFICATION PERFORMANCE FOR EACH GLCM FEATURE

	Acc (%)	Prec (%)	Rec (%)	F1 (%)
Contrast	0.93	0.93	0.90	0.91
Dissimilarity	0.90	0.90	0.90	0.90
Entropy	0.90	0.90	0.90	0.90
Homogeinity	0.95	0.91	0.91	0.90
Mean	0.95	0.92	0.91	0.91
Standard Deviation	0.95	0.93	0.93	0.93

It can be concluded from the performance evaluation results listed in Table II that Standard Deviation is the feature with the best performance because it has the highest value for all metrics (Accuracy, Precision, Recall, and F1-Score) with a value of 93%. Meanwhile, Homogeneity and Mean also show high performance, with the highest accuracy (95%) but have slight differences in precision, recall, and F1-score values. Entropy and Dissimilarity show consistent performance but are lower than other features. In order to improve the classification results, an ensemble method based on hard voting is used. This method is expected to complement each other's shortcomings in the performance of each feature extraction. To test how effective the application of the ensemble method is, a classification of batik images is carried out on the test data. Based on the test, it was found that the application of the ensemble method can improve the performance of the batik image classification system. As an example in a test scenario, by applying the ensemble method based on hard voting, the classification error of the batik class can be avoided. The scenario for testing the effectiveness of the application of the ensemble method is illustrated in Fig. 13.

Based on one of the test results, the prediction results obtained that four out of six features successfully predicted the class of batik images. The other two features failed to identify the class properly. The final result based on majority voting successfully selected the Kawung class which is the right class for the batik image. Therefore, by applying the ensemble method, the performance of the batik classification system can be improved because the final prediction based on the majority decision tends to be more stable and accurate, especially if the data varies. In addition, this ensemble method also has advantages because it can overcome the weaknesses of individual models such as the homogeneity extraction-based classification model which tends to have lower performance in terms of F1 score but has advantages in terms of accuracy. Hence, it can be concluded that by combining predictions from several classification models, the possibility of errors that can occur if only relying on one model can be reduced. This is because the weaknesses of one classification model can be compensated by another model. Although the study has successfully proven that the implementation of the ensemble method based on the GLCM feature extraction algorithm and the ResNet architecture is able to produce a robust system for producing a batik image classification system, there are many more things that need to be improved in further research. Recommendations for further research will be discussed in the following conclusion section.

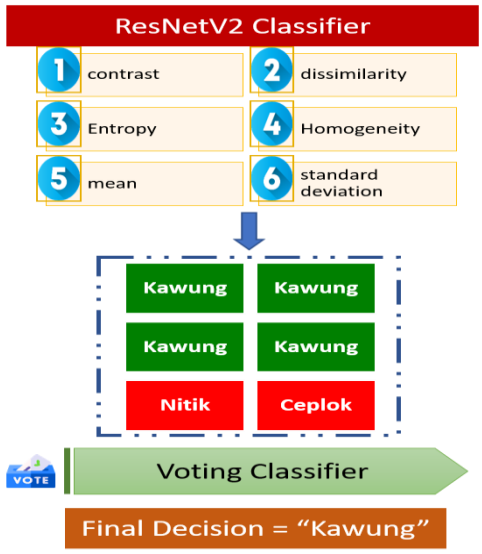

Fig. 13. Testing scenario for ensemble methods implementation.

V. CONCLUSION

The study exploited image extraction algorithms to obtain texture images that can be used in batik image classification tasks. The image extraction algorithm used is GLCM which is known to be reliable in describing the texture of images effectively. Furthermore, the application of GLCM produces 6 features including Contrast, Dissimilarity, Entropy, Homogeneity, Mean, and Standard Deviation. Based on the results of applying these features to classify batik images, several interesting findings were obtained. The Standard Deviation feature showed the best performance with accuracy, precision, recall, and F1-score of 95%, 93%, 93%, and 93%, respectively. This shows that this feature is very good at capturing important characteristics of batik motifs. The Mean and Homogeneity features also showed very good performance, with an accuracy of 95% and other metric values slightly lower than the Standard Deviation feature. On the other hand, the Contrast feature showed quite high accuracy (93%), but had a lower recall value (90%), indicating good performance but not as good as the top three features. The last finding related to the Dissimilarity and Entropy Features, these two features were

recorded to have similar performance with accuracy, precision, recall, and F1-score values of 90%, indicating that these features are less effective than other features.

In addition, to improve the performance of batik image classification, the application of the Ensemble method based on majority voting (hard voting) is proposed. By combining the results of several models trained using different features through the Majority Voting method, the performance of batik image classification can be improved. This method utilizes the advantages of each feature, thereby increasing the accuracy and stability of the model as a whole. The Ensemble method with Majority Voting shows that although some individual models may have lower performance, combining predictions through majority voting produces a more reliable and accurate model. By utilizing the diversity of information captured by various texture features, the ensemble method helps reduce prediction errors and improves the generalization ability of the model.

This study shows that the use of ensemble method with Majority Voting is an effective approach for batik image classification. The combination of texture features Standard Deviation, Mean, and Homogeneity gives the most optimal results, but the ensemble of various features as a whole increases the accuracy and reliability of the model. These results emphasize the importance of using ensemble methods to handle complex image classification problems and support practical applications such as automatic motif recognition for batik products. As a continuation of the research, it is interesting to conduct experiments by applying various other ensemble methods such as bagging, boosting to find the ensemble method with the best performance. In addition, from the classification algorithm side, the application of other algorithms such as Random Forest, Xgboost, SVM and so on. Hence, it can be obtained automatic classification system which is truly reliable and robust in recognizing batik images.

A Comprehensive Crucial Review of Re-Purposing DNN-Based Systems: Significance, Challenges, and Future Directions

Yaser M Al-Hamzi, Shamsul Bin Sahibuddin
Faculty of Artificial Intelligence (FAI), University Technology Malaysia (UTM), UTMKL, Kuala Lumpur, Malaysia

***Abstract*—The fourth industrial revolution is marked by the significance of artificial intelligence (AI), particularly the remarkable progress in deep neural networks (DNNs). These networks have become crucial in various areas of daily life because of their remarkable pattern-learning capabilities on massive datasets. However, the incompatibility of these systems makes reutilizing them for efficient data analysis and computation highly intricate and challenging due to their fragmentation, internal structure, and complexity. Training in DNNs, a vital essential activity in model development, is often time-consuming and costly intensive computation. More precisely, reusing the entire model during deployment when only a small portion of its required features will result in excessive overhead. On the other hand, reengineering the model without efficient code review could also pose security risks as the model would inherit its defects and weaknesses. This paper comprehensively reviews DNN-based systems, encompassing cutting-edge frameworks, algorithms, and models for complex data and existent limitations. The study, which results from a thorough examination, analysis, and synthesis of observations from 193 recent scholarly papers, provides a wealth of knowledge on the subject, identifying key issues and future research directions by offering novel guidelines to advance the DNN model's repurposing and adaptation, especially in finance, healthcare, and autonomous applications. The demonstrated findings, specifically those related to failure and risk challenges of DNN converters, including factors (n=12), symptoms (n1=4, n2=3), and root causes (n1=4, n2=3), will enrich the ML-DNNs community and guide them toward desirable model development and deployment improvement, with significant practical implications for intelligent industries.**

***Keywords*—DNNs; DNN-based systems; significance and challenges; incompatibility; re-purposing; review**

I. INTRODUCTION

In the digital age, computer science has increasingly focused on the advancements of artificial intelligence, which has become a thriving area of research [1]. However, despite the urgency of matching the rapid development of the fourth industrial revolution, literature overlooks the scarcity of resources related to AI, ML, and DNN-based systems [2] , [3]. It fails to discuss their importance within ecosystems and their various difficulties [4], [5], [6]. The ability to analyze and forecast potential growth through complex data analytics, leveraging deep learning capabilities, leads to increased business value [7]. More specifically, convolutional neural networks CNN [8] and recurrent neural networks RNN [9], the two primary types of DNN architectures, have been intensively investigated to handle various NLP [10] and computer vision CV [11] Problems. It has been demonstrated that different hyperparameters (e.g. learning rate, number of layers, epochs number, optimizer, hidden size, batch size, and regularization techniques) can cause DNN performance to vary significantly [12]. In addition, optimizing parameters and ensuring compatibility between CNNs and RNNs is critical for their performance [13]. This is because these techniques are relatively new and constantly evolving, with ongoing research exploring how best to leverage their combined strengths [12], [13]. However, while several engineering efforts attempted to overcome the exchange complexities between artificial architectures, specifically machine learning (ML) and deep learning (DL) techniques, the literature indicates that significant limitations still exist, whether in domain knowledge or practical applications [1], [14], [15], [16], [17]. For instance, the inspiration of technology reuse [18], [19], [20], [21], and [22] demonstrated that one of the most significant challenges facing (ML) and (DL) developers, researchers, and end users is the lack of interoperability between their systems [13].

In more detail, reusing DNN-based systems computation is difficult, as with any emerging technology [23], [3]. One of these obstacles is the structural problem of non-interoperability among DNN-based systems, along with a need for more technical skills and engineering methods. [3]. Therefore, this systematic review examines cutting-edge interfaces, models, frameworks, and algorithms tightly associated with machine learning (ML) and deep learning (DL) approaches [24].

Importantly, this study stands out as the first systematic investigation that comprehensively addresses the existing open issues in machine and deep learning systems and related technologies to the best of our knowledge. It explores prominent techniques like "Facebook's Torch-PyTorch and Caffe2" [16], [25], [7], [26], [21], [20], "Montreal University's Theano, TensorFlow founded by Google [27]; [28], Apache's MxNet, Microsoft's CNTK [21], [20], [28], [29], and Hugging-Face [30]" highlighting their contributions to the analysis diverse data types, including complex data as well as the existing limitations. The systematic investigation included a pack of widely used deep neural network models like LeNet-1 [31], LeNet-5 [32], ResNet-18 and ResNet-152 [33], Xception [34], Inception-V3 [35], VGG-16 [36], VGG-19 [37]. The findings of this review illustrated that, in development and deployment processes, the lack of compatibility has three categories: software level, hardware level, and architecture level. The software level includes "type of used programming

language" [4], [38], type of "ML and DL framework" [24], type of "ML and DL model" [39], type of" ML and DL algorithm" [12], and type dataset [40], [41]). The hardware level encompasses the type of "computer manufacturer, processor, and type of accelerators (e.g., GPUs, TPUs, FPGAs) [42], [43]. The architecture level comprises structure design and mission misalignment levels [44], [45], [46]. In a relevant context, the findings of this review indicate that a unified model that combines two or more of these methods can significantly enhance deep neural network performance (e.g., memory consumption and inference time) [24], [44].

This review explores the potential of (DNNs) and the challenges they present in the reuse context, enabling more efficient progress in methodologies and processes. It comprehensively addresses their significance and reuse challenges from a unique perspective. The aim is to make a crucial contribution to advancing DNN-based systems. The promising unified approach with its novel techniques can effectively promote compatibility and reuse process, leading to obtaining the desirable accuracy [47], [48], [49] and robustness [50], [49] towards various types of adversarial attacks, reducing computing time and lower computing costs [48], [51], [24].

II. Deep Neural Networks Reuse

A. Overview

The reuse approach involves utilizing existing software engineering and artificial intelligence technologies for different purposes, such as reducing engineering and computation costs and time [23], [52]. Nevertheless, reusability from a deep neural network perspective has received limited attention [53], [54]. One of the main focuses of this paper is the incompatibility problem, challenges, and possible solutions for reusing deep neural networks (DNNs). We do this by highlighting four main reuse paradigms that have been identified through literature review, analysis, and synthesis. These paradigms consider things like the need for computing resources and inference time, hardware configurations, and dataset dependencies [23], [55], [3]. The four include conceptual reuse, development and assessment of the need for reuse, adaptation to reuse, and deployment reuse, as illustrated in Fig. 1.

B. Reuse Paradigms Definition

1) Conceptual reuse: It involves replicating and reengineering algorithms or model architectures from academic literature, often due to licensing or using a specific DL framework. This approach is related to Sommerville's abstraction reuse. [56] and is crucial for scientific reproducibility [57].

2) Model development and reusability assessment: Involve accurately determining the nature of the intended task, followed by data preprocessing, hardware preparation, and algorithm selection for training a model from scratch and evaluating the need and potential for reuse. [58]; [30].

3) Adaptation reuse: Utilizing existing DNN models for different learning tasks, leveraging techniques like transfer learning or knowledge distillation. [59]. This approach is suitable for publicly available pre-trained models PTMs, allowing engineers to customize them for different tasks. [60].

4) Deployment reuse: This method of reusing pre-trained DNN models in various computational environments and frameworks is ideally suited for an engineer's desired task. This approach is similar to Sommerville's "system reuse" and involves fine-tuning, then converting the model from one representation to another, followed by compilation to optimize for hardware. Multiple forms of reuse can be possible in a single engineering project [3].

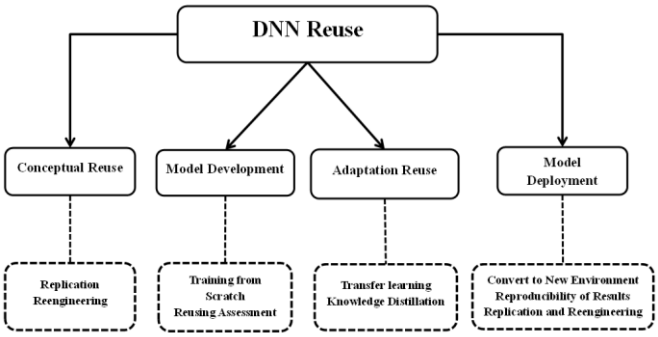

Fig. 1. The four paradigms of deep neural network reuse. The information illustrated in dashed boxes is an example of each paradigm type.

III. Motivation

Machine learning and deep neural networks have benefited numerous aspects of AI, including finance, autonomous applications, and healthcare (e.g. drug discovery, disease predictions, and medical image analysis in intelligent healthcare applications) [61]. However, a critical barrier prevents AI from reaching its full potential. The issue concerns the incompatibility of AI environments, mainly when leveraging previous successful efforts like drawing inspiration from developed codes and pre-trained models [17]; [13]. This incompatibility partially splits the development landscape and prevents code and model sharing, which is an effective way to boost innovations within the field [62]. Reusing existing code and pre-trained models provides significant benefits as follows:

A. Reduced Development Time

For instance, [23] and [54], demonstrated that, by reusing existing code and pre-trained models, experts could focus on possible and innovative solutions, thereby saving significant time that would otherwise be required to construct all components from scratch.in addition, reutilizing eliminates the need to compute similar data multiple times, speeds up development, and reduces costs.

B. Enhanced Reproducibility

Code generation, model sharing, and reusing approaches improve the overall reproducibility of research, allowing for verifying and enhancing existing solutions [13], [55].

C. Accelerated Innovation

By extension, extending previous frameworks and models means that researchers can work on more complicated solutions over a shorter period and advance the field of AI [52]. However, current approaches to reusing and reengineering the previous

ML and DNN productions encounter certain limitations, such as:

1) Performance bottlenecks: Reused models may consume more memory during inference, which may take longer than inference in their native environment [23].

2) Concerns over accuracy and robustness: Fine-tuning necessitates a series of decisions to maintain the model's accuracy in the newly applied context [49].

3) Converting the entire model challenge: Existing methods are ineffective because they require reloading the whole model rather than just the necessary portions, resulting in costly and time-consuming computational resources [23]; [63].

4) Inheritance model defects, when reused, may cause security vulnerabilities: When reusing models, the new system may inherit threats from the previous models, thereby increasing its vulnerability to attacks. These limitations thus advocate for extensive research and development of code and model reuse.

To overcome these challenges, this study suggested the following critical solutions:

- Standardized Frameworks: Many other research areas are challenged to create coherent architectures that facilitate simple integration of off-the-shelf models and built-from-scratch submodules.
- Advanced Transfer Learning Techniques: Studies on techniques for implementing transfer learning, such as domain adaptation, fine-tuning methodologies, and lifelong learning paradigms.
- Developing Novel, Unique Reuse Methods: Involves exploring strategies for reusing only specific aspects of a model, which enables the creation of unique solutions without requiring additional work.
- Development of Security-Aware Reuse Strategies: Creating strategies for distinct discovery and protection of security threats whenever a model is reused to create other new systems. Solving these issues will lead to a healthier ground for code and model sharing in AI. In the long run, this will lead to more innovation, improve the use of AI to its full potential, and bring about changes that will positively impact society.

IV. Scope of Study and Design Architecture

In general, the search strategy for addressing the main research problem and the related challenges in this systematic review is to move in an inverted pyramid, i.e. from the broadest level to the narrowest one, as shown in Fig. 2. The investigation and synthesis then continue to narrow coherently, ultimately reaching the most specific, valid, and critical missing points that previous studies and current methods and approaches have neglected. We examine, investigate, synthesize, analyze, and discuss the most significant open issues and challenges that are closely related to the main research focus of incompatibility, drawing inspiration from the reuse approach and the limitations of current systems reengineering methods. We initially go from the big picture of AI, focusing on computer vision CV and natural language processing NLP, to the more specific view of machine learning with its related techniques (e.g. algorithms, models, and frameworks). Then we move to the much more specific domain of deep neural networks (DNNs), which includes the most computational techniques, such as CNN-based, RNN-based, and hybrid systems, such as DNN-NLP, DNN-CV, NLP-CV, and DNN-NLP-CV [64], [65], [66].

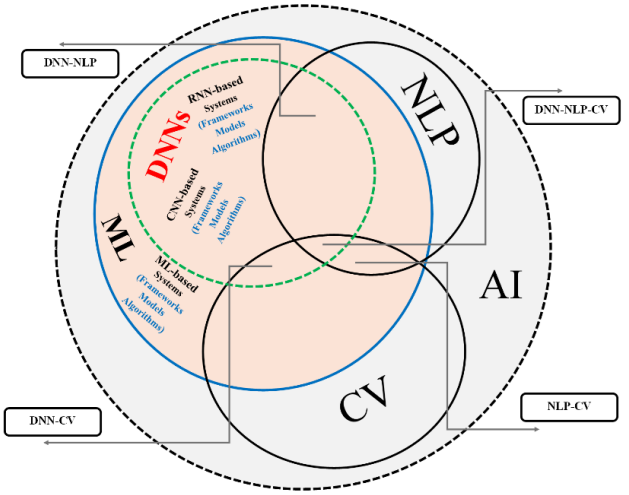

Fig. 2. The architecture of the dependence between AI, ML, computer vision (CV), NLP, and Hybrid DNN-based systems.

V. Concepts

A. The Border Domain of Artificial Intelligence (AI)

Artificial Intelligence (AI) is a "branch of computer science," and its latest generation is rapidly expanding. This makes it an attractive topic for research that focuses on designing intelligent machines that mimic human thought processes, such as learning and decision-making [1]. This level of automation means that such machines give performances on inference, categorization, and detection for activities formerly involving interfaces [67]. The AI context includes the facilities and technologies used to build intelligent applications and release them into the environment [68].

B. Machine Learning (ML)

ML can be defined as a category of AI involving the implementation of algorithms and methods that enable the computer to learn from data and experience without presenting a set of instructions [69]. DNN-based models can learn more about a particular problem as opposed to other approaches by mirroring the data and identifying patterns and relationships that can be used to construct models [70]. The most frequent categories of ML problems entail classification, regression, and clustering. According to [67], although machine learning models have brought significant improvements to AI applications in fields ranging from finance and healthcare to manufacturing, this progression was predominantly due to their relative accuracy (concerning traditional linear statistics classifiers) when it comes to making predictions. However, this benefit comes with a drawback: the lack of transparency in the design of machine learning models often leads to their characterization as "black boxes". On the other hand [71], demonstrated that the integration of (ML) and (AI) components

into public sector applications faces significant limitations due to their fragility and algorithmic mismatches.

C. Deep Neural Networks (DNNs)

Deep learning, also known as "deep neural networks DNN," is a more advanced form of machine learning that requires using an artificial neural network with multiple layers embedded [72]. These deep networks, which optimize data-intensive tasks like image, text, voice, and speech recognition, are based on the structure and functioning of the human brain [73], [74], [16]. With deep learning algorithms, changes are made to the connections between artificial neurons in the network, allowing them to capture progressively more complex features in the data. [75].

Moreover, Recently, DNNs have demonstrated remarkable achievements in the medical field, such as the diagnosis and prediction of diseases such as Alzheimer's disease, heart disease, lung and liver cancer, kidney and brain cancer, and many more. In this context, we will focus on the role of DNN-based algorithms in the diagnosis and prediction of Alzheimer's disease [76], [77], [78]. Furthermore, it has demonstrated remarkable results for low-data drug detection despite the limitation of "out-of-domain generalization" [79]. However, the challenge of incompatibility among ANN-based technologies and the real world is addressed in this study [80].

The fragmentation of models, algorithms, tools, libraries, and frameworks leads to code and model reusability issues. [48], [4], [81]. We also highlight the lack of systematic approaches to enhance interoperability, reduce complexity, and explain mechanisms in artificial neural networks. [82]. Fig. 3 illustrates the basic architecture of the perceptron, as shown in part (a), in DNNs with three input neurons, four neurons in each hidden layer, and two neurons in output layers, as shown in parts (b) and (c) [64]; [65]; [66].

D. The Neuron

Equation 1 describes the calculation of the neural network's output value, or activation, which involves summarizing the activations of all neurons from the "previous layer" connected to the evaluated neuron, adding the neuron's bias, and applying the "activation function" to produce the final neuron activation.

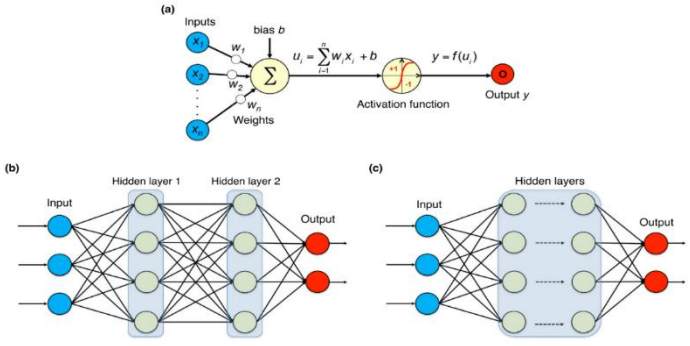

Fig. 3. The basic architecture of Multi-Layer "Perceptron" part (a) and the (DNNs) input and output layers, as shown in parts (b) and (c).

This process introduces non-linearity between inputs and outputs, ensuring the network's outputs are linear combinations of inputs. The process of adjusting weights and biases to achieve desired results is called training, where the weights and biases of the input neurons determine the network's output.

$$U_i = \sigma\left(\left(\sum_j^n U_j * w_{ij}\right) + b_i\right) \quad (1)$$

Where U_i : evaluated neuron activation, σ: activation-function, n: Set of input neurons linked to evaluated neuron, U_j: activation of input neurons from the previous layer, w_{ij}: weight of the connection between neurons, b_i: Bias value of evaluated neuron.

E. Transfer Learning

The transfer learning approach is a popular and effective DL technique that uses pre-trained models PTMs to address challenging issues [83]. However, choosing the best-trained model for a target job remains difficult as most properly training every candidate model is a high computationally cost and long inference time, highlighting the critical necessity for a convenient prediction metric based solely on early training outcomes [81], [3].

F. Model Development and Reusability Assessment

DNNs are novel techniques that have proven to be game-changers in realms such as healthcare, finance, transportation, and technology [2]. Applications include "image and speech recognition" (NLP), recommendation systems, etc. Their ability to learn from data and make predictions is invaluable when dealing with complex problem statements or automating mundane tasks [4], [64]. This section and its connected subsections present the main process of model development and the procedures for reusability assessment shown in Fig. 4.

1) Task selection: Specifying which problem your model will solve, e.g. classification, regression, or clustering.

2) Choosing data types: Depending on the nature of the problem to solve and the availability of sources, one must select the appropriate data types, which could be structured, semi-structured, or unstructured.

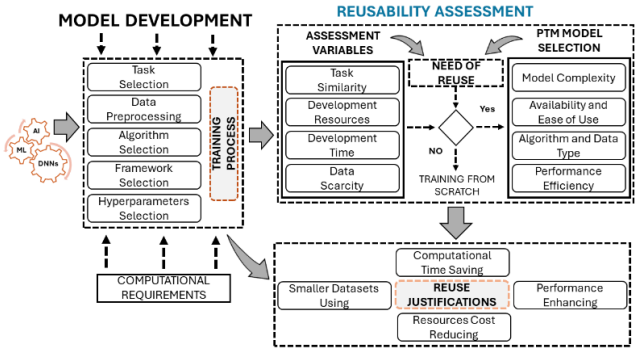

Fig. 4. The development architecture of AI, ML, or DNN-based models, the end-to-end process, and the reusability assessment for the candidate model.

3) Data preprocessing: It includes data cleaning, handling missing values, normalizing (in other words, scaling) features, and encoding them into labels for fitting onto a model.

4) Process steps: The process consists of data collection, preprocessing (sorting), feature selection, model development (training), validation, and testing.

5) Model selection: It involves selecting the appropriate model architecture, such as CNNs for image recognition or RNNs for "sequential data processing".

6) Choose the framework and algorithms: From TensorFlow, PyTorch, or Keras, select the most suitable framework to meet the project's requirements and incorporate algorithms like backpropagation algorithm and gradient descent.

7) Feature extraction: This involves extracting relevant parts of the data using techniques (e.g. principal component analysis), dimensionality reduction, or feature engineering.

8) Model evaluation: Using metrics such as accuracy, precision-recall, and F1 score to determine how efficient an ML algorithm or model is.

9) Reuse and reengineering: We can reuse pre-trained models by fine-tuning them for new, similar tasks, adjusting the model's parameters, or retraining with more data.

Upon completion of candidate construction, the "cross-entropy loss" ($\mathcal{L}_{ce}$) between the "predictions of the target dataset" and the "actual labels" can be calculated by:

$$\mathcal{L}_{ce} = -\sum_{i=1}^{K} t_i \text{Log}(P_i(\mathcal{M},\mathcal{H})) \quad (2)$$

"K" represents "class number" for an intended issue, "$\mathcal{M}$" denotes the "mask," while "$\mathcal{H}$" stands for the "head." Conversely, "$(P_i(\mathcal{M},\mathcal{H}))$" denotes the "prediction a candidate formulates for the class of "i-th" utilizing the "$\mathcal{M}$ mask" and the "head $\mathcal{H}$". Also, the "t_i" signifies the probability of "the class in the single hot representation of the real label," which can be either *0* or *1*. The "classification accuracy" of the "target dataset" is enhanced when the candidate retains a greater number of weights pertinent to the target problem and exhibits a reduced cross-entropy loss. The mask serves to directly calculate the weight retention rate ($\mathcal{L}_{wr}$) as illustrated below:

$$\mathcal{L}_{wr} = \frac{1}{L}\sum_{i=1}^{L} \mathcal{M}[i] \quad (3)$$

L represents the "number of weights in the original mode (3)

"lower weight retention ($\mathcal{L}_{wr}$) rate", suggests that the "candidate model" keeps "fewer weights," whereas "objective function" *O is* defined based on $\mathcal{L}_{ce}$ and $\mathcal{L}_{wr}$:

$$\mathcal{O} = \mathcal{L}_{ce} + \alpha \times \mathcal{L}_{wr} \quad (4)$$

Where α is an empirically determined weighting factor of 1.0.

Importantly, to minimize the $\mathcal{O}$, function, some researchers suggest building a search-based technique that initially focus on find the expected "candidate model that maintains only the weights relevant to the target-related problem" to be solved. The idea is that this "candidate model" has the potential to accomplish the desired "classification accuracy" and "robustness" while maintaining the minimum weights.

G. Model Deployment

In the development section, we highlighted the process of developing a candidate model for a new task. We obtained a candidate model by following all the steps and procedures from the previous stage of development, as shown in Fig. 4. We then did a reusability assessment to make sure it was suitable for the new task and met all its requirements. As a result, the candidate model has been approved for reuse and employment in the new task. This will be achieved through reengineering and reproduction processes through the development of the new target environment, as illustrated in Fig. 5, and the subsequent steps:

1) Infrastructure setup: Deploying the model to the target environment and setting up all back-end infrastructure, such as servers, cloud services, or edge devices.

2) Deploy the model: This is where the trained models are integrated into the target environment, such as a mobile application, web service, or embedded system.

3) Test and validate: Testing the deployed model to ensure that it performs adequately in the target environment.

4) Monitoring and maintenance: Deploy techniques to monitor the model, update it when needed, and maintain ongoing performance support.

The search strategy efficiently explores large models with billions of parameters using a gradient-based method, finding new candidates with smaller objective function values each round and updating the mask accordingly. The updated mask, M1, represents a new candidate with a reduced objective function value, and the process of updating it involves dropping the gradient, as seen below: ξ represents the learning rate:

$$\mathcal{M}' = \mathcal{M} - \xi \times \nabla_{\mathcal{M},\mathcal{H}}\mathcal{O} \quad (5)$$

$$\nabla_{\mathcal{M},\mathcal{H}}\mathcal{O} = \nabla_{\mathcal{M},\mathcal{H}}\mathcal{L}_{ce} + \alpha \times \nabla_{\mathcal{M}}\mathcal{L}_{wr} \quad (6)$$

As a summary, this section outlines the steps involved in deploying the candidate model, which includes setting up the infrastructure for the source model and transforming it into an intermediate model using the intermediate representation (IR) technique, as shown in Fig. 4. The deployment also covers testing, validation, and maintenance after deployment to the target environment. The paper emphasizes the importance of sharing code and models to encourage innovation while also considering the potential consequences of incompatibility. The model's performance efficiency, accuracy, and reliability depend on data selection, preprocessing, and training methods. Successful deployment requires an understanding of all decisions made during the development process.

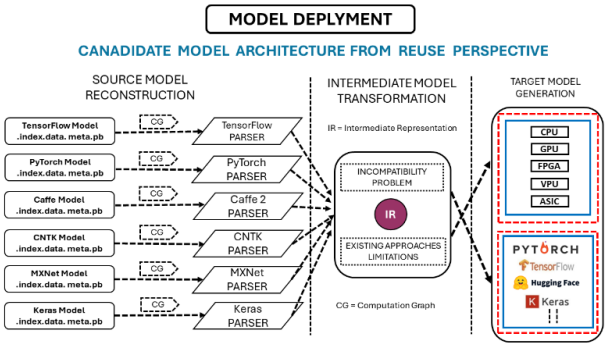

Fig. 5. The deployment architecture of AI, ML, or DNN candidate pre-trained models from source to target environment/s, the end-to-end converting process.

VI. Related Work

In the past decade, specifically the last seven years, there has been a surge in surveys, reviews, and varied studies focused on various applications of machine learning (ML), particularly in complex architectures such as (DNNs) [84], [71], [25]. These systems can potentially enhance multiple business functions and address varied organizational needs [25]. For example, leveraging deep neural networks and related models enables the recommendation of products according to (e.g., previous purchases and audience ratings) [85], [86], image recognition for video surveillance [87], identification of spam and malware emails [88], [89], healthcare applications (e.g. Alzheimer's prediction [78] and cancer prognosis and early detection [90]), among other applications explored by [91], [92]. However, given the novelty of transfer learning, comprehensive survey and review studies have been relatively rare, focusing on providing an overall understanding of this domain [83].

Most notably, relatively little research has been done into the difficulty of compatibility, which can present an insurmountable challenge when attempting to reuse AI systems [55], such as machine learning models and deep neural networks [17]. As far as we know, this systematic review is the first extensive attempt to look at the incompatibility problem through the lens of AI systems reusability. It is an area that has been woefully underexplored, and still, with a deep dive into the nuance of reusability [53] of these cutting-edge technologies, we hope to raise awareness about some of the major issues and factors that come into play [2]. A lack of guidance is available to assist organizations in developing these capabilities [93]. Consequently, our review aims to rectify this gap in literature and serves as a valuable guide to AI system reuse for researchers and practitioners. The integration of ML components into applications faces challenges due to the fragility of algorithms, framework fragmentation, and their susceptibility to changes in data, which can cause prediction shifts over time [94]. Consequently, mismatches between system components hinder the seamless integration of ML capabilities [71]. Thus, [69], [1], [95] Suggested that further research is needed to explore the unique advantages that arise from combining these technologies, particularly considering the increasing availability and complexity of big data characterized by its variety, volume, veracity, volatility, and velocity [96], taking into account understanding the synergy between AI systems and extensive data methods according to [92].

Therefore, this paper aims to fill this gap by comprehensively investigating the state-of-the-art machine and deep learning systems applied in analyzing the bid and complex data [96], including frameworks, models, algorithms, and libraries. It provides an in-depth discussion of current deep neural network technologies, covering their features, categorization, and classification. Additionally, it identifies critical open issues and outlines opportunities for further research in the advancement of big machine deep learning technologies.

VII. The Systematic Review

This review provides a valuable contribution to the research community by offering insights and opportunities for further advancement into the domain of artificial intelligence (AI), particularly advancements in machine learning (ML) technologies and deep neural networks (DNNs). It serves as a guide for researchers and developers aiming to achieve success in evaluating the whole environment of these technologies and networks and related software and hardware components, including the factors that impact the development and deployment process [12], [97]. The first review question (RQ1) seeks to explore the popular AI, ML, and DNN systems and conduct multiple comparisons in various aspects, such as their purposes and goals, tasks, and functions, attributes and characteristics, advantages and disadvantages, similarities and differences, and strengths and weaknesses [98], [99], [100], [101].

The review highlights the role of these systems in preprocessing, training, analyses, storage, and deploying massive and complex data. Multiple comparisons are presented to serve the purpose of this research [98], [39]. The second question (RQ2) specifically aims to identify the open issues and challenges associated with target systems under this study, elaborated in the following sections. The key issues identified include the data and learning complexity, coding from scratch, the dearth of benchmarks, and selecting the proper technology that matches the target task [102], [29], [4], [99], [44], [48], [17]. Through systematic review analysis of the literature, several factors and dimensions affecting these systems were identified, highlighting the significance of the issues closely connected to the primary research problem of incompatibility. [44], [24]. Consequently, understanding these challenges and related factors and dimensions can aid the researchers and the developers in overcoming them, thus achieving the desired results (e.g. prediction, classification, recognition, and detection) [103] (L. Liu et al. 2018b), [99]. The third research question (RQ3) focuses on the main research problem; the findings reveal that interdependencies and compatibility remain open research areas. Hence, further investigation and discussion are needed to find appropriate solutions. The fourth research question (RQ4) addresses the limitations of the existing common empirical approaches that deal with the current interoperability problem and its related challenges [13], [104], [49], [61], [92]. The answer to this question emphasizes the need for a more efficient novel unified method to enhance the compatibility between the source model (e.g., original pre-trained models "PTM") and target model (e.g., the destination model) [102], [48], [105]By addressing these aspects, our authors expect the research community to confidently make strides toward improved compatibility, thus reducing the computational sources' costs and time consumption.

VIII. Methods and Materials

The methods and materials of this study are comprised of three primary stages: the planning of the review, the conducting of the review, the "actual execution of the review," and the reporting of the review. The stages consist of many phases, actions, procedures, measurements, and instruments for achieving the desired findings and outcomes and optimizing the process.

A. The Review Planning

The planning review is a standard step in SLRs that entails two main sets of reviews and procedures. The first set includes formulating research questions, scoping the review, and drafting a review protocol, as shown in Fig. 6. On the other hand, the second set involves identifying the selection of strategy through the development of the (Inclusion/Exclusion) criteria that involve various factors that affect the ML and DNN's performance and reuse process, as presented in Fig. 7. The review process in both sets includes defining objectives, data sources, data extraction, data analysis, and data synthesis.

1) Need of this review: The main goal of this systematic review is to summarize the current evidence on machine learning (ML) techniques and deep neural networks (DNNs), point out gaps in current research on the development and deployment process, and lay the groundwork for new research projects, and explained previously in (Fig. 5 and 6).

2) Research question formulation: The research question formulation stage involves identifying essential elements of domains like AI, ML, and DNNs and addressing methodological aspects such as search, data extraction, and data analysis. The research questions should be specific enough to be feasible within the evaluation scope yet broad enough to make a significant contribution to the field. The research questions include identifying common characteristics and differences, unsolved issues, incompatibility problems, and limitations of existing methods. The goal is to answer these questions while reducing computational processes' high resource costs and time consumption. The review aims to provide a framework for future research and contribute to the fields of machine learning and deep neural networks.

3) Develop the protocol of the systematic review: This study uses a pre-established protocol to avoid researcher bias. It aims to provide a justification for the research, address specific inquiries, and use a systematic approach to identify relevant information. The data extraction strategy identifies variables and methods of interest. The synthesis strategy focuses on addressing primary research inquiries about factors and dimensions impacting the effectiveness of AI, CV, NLP systems, ML techniques, and DNNs. Sub-questions include data synthesis, success definitions, influencing direct factors, indirect factors, and dimension classifications.

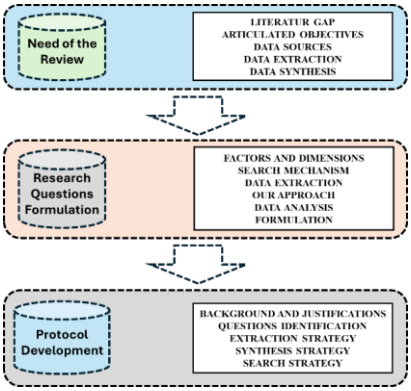

Fig. 6. The first set of review planning includes the need to conduct this review, the research question formulation process, and protocol development.

4) Selection of strategy (inclusion/exclusion criteria): The selection strategy for a review of AI, CV, NLP, ML, and DNN-based systems was based on a series of inclusion and exclusion criteria and derived from research questions and the quality assessment process. The criteria included study focus, empirical studies, evaluation, impact factor, language, theories, publication focus, domain participants, quality control, and replication studies. The emphasis was on English-language studies, focusing on the period from 2015 to 2024 and assessing credible journals.

This review excluded studies that lacked explicit information, publications of low quality, research that focused on artificial intelligence (AI), machine learning (ML), deep-learning/deep neural networks, big and complex data, parallel computing, or technology-based approaches, research that lacked methodology, numerical test findings and analysis, and studies published before 2015 because they were not relevant. Furthermore, we excluded duplicate studies and methods irrelevant to the main research problem.

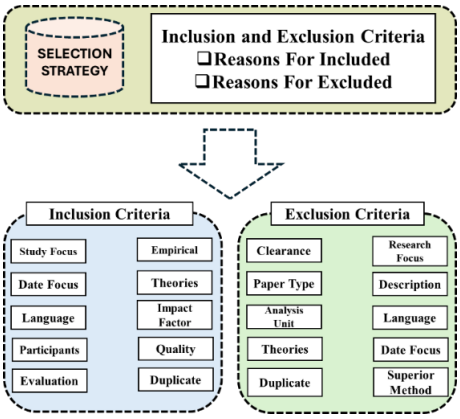

Fig. 7. The second set of review planning involves identifying the strategy selection through the development of inclusion (Inclusion/Exclusion) criteria.

The study focused on addressing the incompatibility observed among AI, CV, NLP, ML, and DNN-based systems, focusing on existing unresolved concerns and constraints. The review included publications from reputable peer-reviewed journals with impact factors and high-quality international scientific conferences.

B. Conducting the Review

The systematic literature review (SLR) is conducted using a well-defined search strategy. Standard electronic databases are the primary source for high-quality primary research, but alternative methods like browsing the internet, seeking advice, and snowballing techniques can also be beneficial. The strategy of search covers selecting the source of data and a search-strings formulating. To determine “search strings”, the authors identify key terms related to machine deep learning software, examine abstracts and titles of selected primary research, and use Boolean operations "OR" and "AND" to construct a comprehensive list of related words. To enrich the search process, we also employed subsequent strings of searches

related to the main keywords and terms. Fig. 8 illustrates a sample of the terms and keywords used.

1) Data sources: The study systematically gathered data from a variety of sources, including highly indexed international scientific conferences and impact-factor journals. Literature selection was based on relevance to AI, ML, and DL (DNNs), as well as related frameworks, models, and algorithms. We used snowballing and backward search techniques to identify additional relevant studies [106]. From a theoretical perspective, the study examined the main concepts, remarkable successes, and achievements of AI, machine learning, and deep neural networks. It also examined related models, algorithms, and frameworks, as well as the related limitations, open issues, and existing challenges. The used theories included Artificial Intelligence, Machine Learning Theory, Deep Learning and Complexity Theory, Computation Theory, Theory of Programming, Transactive Memory Theory, Structured Process Modelling Theory, Coding Theory, Data Science Theory, and Transfer Learning and Reuse Theory.

2) Evaluating eligibility and research quality: It is crucial to evaluate the eligibility and relevance of the primary studies identified in the preceding stage, in addition to the inclusion and exclusion criteria. [107]. As per the instructions outlined in the reference [108], we evaluate the eligibility and quality of each study following the factors, including the significance of the study, the quality of the results and analysis, and potential future research guidelines or discoveries, using the criteria presented in Table I. We evaluate the articles and select studies that exhibit exceptional quality. We have formulated nine questions; each indicated with either (Y)/(Yes) or (P)/(Partly), or (N)/No, to evaluate the eligibility and quality. The questions and their corresponding answers were included. The assigned values for scoring are as follows: Y = 1, P = 0.5, and N = 0. Additionally, each primary study should receive a score ranging from 0 to 13 points. A quality appraisal guarantees that the review will only include the research that is most trustworthy and pertinent to the topic at hand.

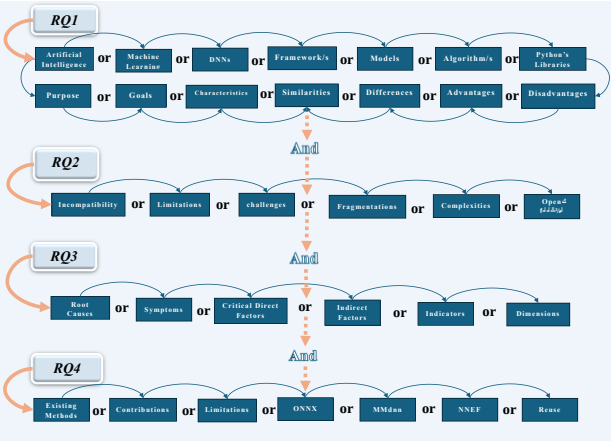

Fig. 8. A list of frequently used terms/strings and keywords on AI, CV, NLP, ML, and DNN-based systems using the Boolean operations "OR" and "AND."

TABLE I. ELIGIBILITY AND QUALITY EVALUATION FORM USING THE "Y-P-N" SCORE

Quality Assessment Questions	Recorded Score
Do the articles provide enough information on "AI, CV, NLP, ML, and DNN" from a theoretical perspective about frameworks, models, and algorithms and their environments?	"Y-P-N"
Does the research study offer a comprehensive comparison between these highlighted techniques?	"Y-P -N"
Does the research paper provide a clear methodology/technique to select proper measurements to evaluate the different aspects of the "AI, CV, NLP, ML, and DNN" domains?	"Y-P -N"
Does the review study present factors, indicators, and dimensions that positively promote the success of "AI, CV, NLP, ML, and DNN" domains?	"Y-P -N"
Do the review papers highlight forward propagation and backpropagation for deep neural networks (DNNs)?	"Y-P -N"
Do the papers efficiently identify the research gaps and well formulate the problem statements?	"Y-P -N"
Do the target studies provide an obvious explanation of the main research problem and causative factors?	"Y-P -N"
Do the target studies provide an explanation and understanding of the related issues challenges and causative factors?	"Y-P -N"
Does the article provide strategies to mitigate or overcome the current DNN issues and challenges?	"Y-P -N"
Does the research article explain and understand the concepts of reuse, transfer learning, and reengineering?	"Y-P -N"
Do the articles provide an explanation, comparison, and understanding of the limitations of the current approaches and techniques?	"Y-P -N"
Are the investigated study outcomes applicable and/or generalizable?	"Y-P -N"
Is the retrieved data appropriately described?	"Y-P -N"
Is the description of inclusion/exclusion/criteria in the study sufficient?	"Y-P -N"

3) The extraction of data: Data extraction in a systematic review is a crucial step in evaluating research potential and combining results. As depicted in Table II, manual data extraction can be laborious and expensive, but sophisticated software can help. In this review, the authors developed a data extraction form to collect primary study information and simplify analysis. Two steps were involved: a preliminary study and a second extraction from a random selection of papers. The data extraction was conducted using tools such as Microsoft Excel, REDCap, and Google Sheets. The intake form included columns for each research question and quality assessment items.

The chosen primary studies provided answers to specific or all the issues raised by the investigations. This systematic and standardized procedure ensures consistency and efficiency in data extraction. Among the results of the 1052 studies, we extracted information that was relevant to each of the four study questions and objectives. Following the extraction of the data, we proceeded to examine and discuss it to accomplish the intended objectives of this SLR exploration.

TABLE II. MAPPING THE INTEREST OF SEARCH TO THE RESEARCH QUESTIONS

Interest of Search	Extracted Data Description
RQ1	"Characteristics, fragmentation, common differences, similarities, advantages, disadvantages, systems, models, libraries, frameworks, methods, tools, techniques, applications, practices, operations, algorithms, and complexities"
RQ2	"Limitations, problems, open issues, current challenges, bottlenecks, processing, complexities, mechanisms, software, fragmentation, diversity, lacking, reusing AI, CV, NLP, ML, DNN, RNN, CNN, (BD), and (DS)."
RQ3	"Preprocessing, learning, training, accuracy, adversarial, robustness, quality, inference time, model size, memory consumption, efficiency, and performance"
RQ4	"Existing methods limitations, transfer learning, reuse, reengineering, conversions, compilers, converters, techniques, accelerators, future trends, and opportunities"
Research Domain	"Systems of AI, CV, NLP, ML, DNN in terms of characteristics, opportunities, and existing challenges.
Utilized Techniques	"Ms. Excel/(spreadsheets), Google/Sheets, and Google/Collab"
Employed Methods	"Whether it is a new method, modified, or hybrid approach"
Relevant Data	"Title/Abstract/Keywords/Authors", "scientific databases/venue"
Publication/ Year	"Included papers from "2015 to 2024" substantially"
Publication/ Type	"Journal, conference, or book chapter"
Study Type	"Whether it is an analysis, survey, or a combination of both"

Deep neural networks (DNNs) have made significant progress in large dataset applications, but they have faced criticism for their ambiguity. This systematic review of AI, machine learning, and DNNs covers conceptualization to dissemination, with a detailed research procedure in six phases. The revised study mapping process follows PRISMA and Kitchenham guidelines, with research questions achieving SLR objectives [109] and kitchenham [110].

C. Phase 1: Broad Preliminary Searching

The preliminary study used Google Scholar to search for relevant material related to AI, CV, NLP, ML, and DNN-based systems. It aimed to derive research questions and establish a variety of search strings and keywords. The preliminary scan of many research papers is conducted for general outlook purposes, facilitating the formulation of the research question. The researcher of this study identified search criteria and selected six eminent scientific sources and submission venues to obtain the most associated studies, identifying 1052 research papers presented in detail in Fig. 9.

D. Phase 2: Identifying Research Criteria to Refine the Search

The search strategy involved selecting keywords/terms related to AI, CV, NLP, ML, and DNN-based systems, Fig. 9. The search string was adjusted for each platform to ensure a systematic search. The review encompassed a variety of criteria and parameters, such as the title, background, review methods, studies included and excluded, results, review questions, discussion, authorship and acknowledgments, citations and references, and appendices.

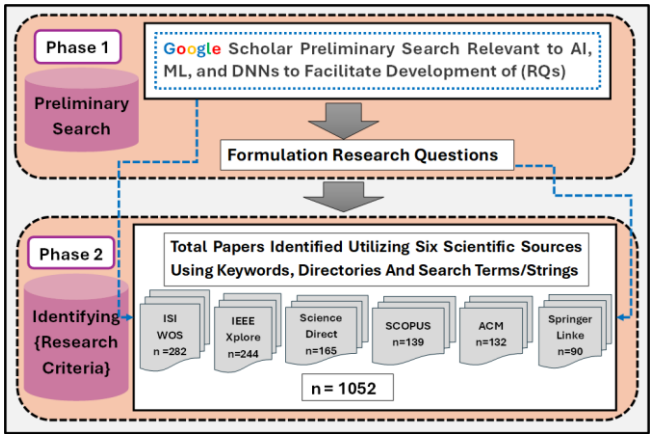

Fig. 9. Phases 1-2. The research question development employed the preliminary search and terms/strings according to the PRISMA and Kitchenham guidelines.

E. Phase 3: Applying the (Inclusion/Exclusion Criteria)

The review phase involved reviewing articles based on inclusion/exclusion criteria, selecting 691 papers related to research questions, while 361 were filtered out, as shown in Fig. 10. The title should be clear and informative, identifying the review's subject and demonstrating its classification as a systematic review.

The review methods should clearly describe the search strategy, the source of data, the study criteria selection, the quality and eligibility assessment methods, and the approach to extracting findings. The discussion section should address the strengths and limitations of evidence, practical implications of findings, research gaps, and areas for future work. The authorship and acknowledgments section should set clear authorship criteria and acknowledge the contributions of individuals or institutions who substantially affected the research but did not meet the author's standards.

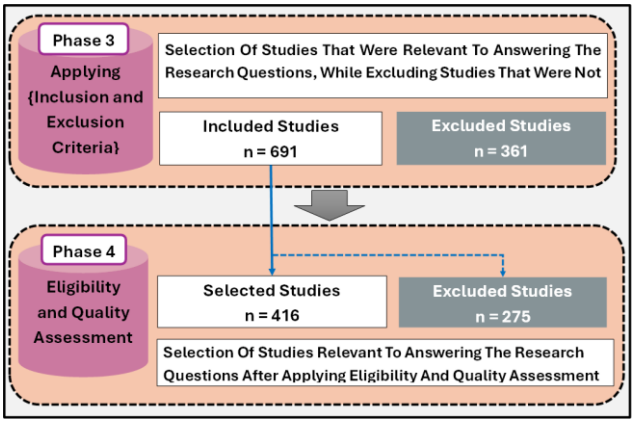

Fig. 10. Phases 3-4. Applying inclusion/exclusion criteria and eligibility/quality assessment according to the PRISMA and Kitchenham guidelines.

F. Phase 4: Evaluating Eligibility and the Quality of Resources

The study critically analyzed 691 selected studies, assessing their suitability and validity. As presented in Fig. 10, we selected 416 studies, ensuring all methodologies were

methodologically appropriate and relevant, and omitted 275 papers due to insufficient eligibility and quality standards.

G. Phase 5: Examining Abstracts and Key Sections

The review process involved a thorough review of 416 papers, focusing on the abstract, primary findings, and conclusion sections, as shown in Fig. 11. The process involved thoroughly examining the articles and identifying those worth further examination. We considered 297 papers for further examination, eliminating 119 due to their unsuitability. The abstract should be 250 words or less long and written in the true style of creative nonfiction.

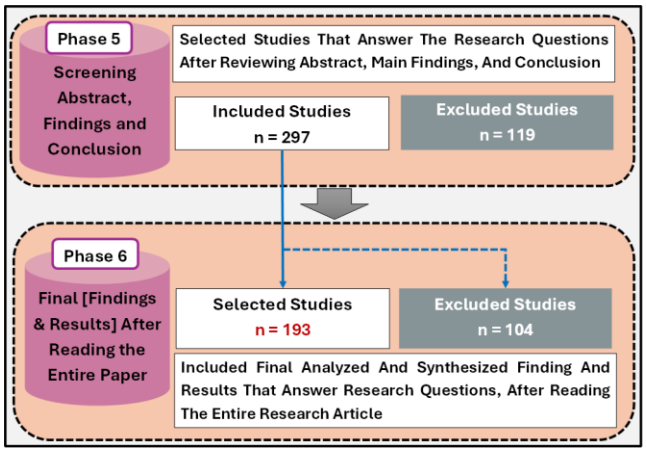

Fig. 11. Phases 5-6. Examining abstracts and key sections and integrating the analyzed selected studies that answer research questions

The findings should include a description of the primary studies, quantitative data, meta-analysis stipulations, a narrative summary of the key findings, and data presentation using tables and diagrams. The conclusion should summarize the main findings, their implications for practice and policy, and suggest suggestions for future research.

H. Phase 6: Further Analysis and Integration

The review comprehensively decoded and comprehended the 297 individual studies in Phase 5, focusing on AI, ML, and DNNs. After presenting the advantages, drawbacks, and existing research issues, the review identified 193 qualitative and quantitative studies. Ultimately, after eliminating 104 studies that were not relevant, the final net tally of the papers is 193. The systematic review report should be formatted as shown in Fig. 11.

IX. FINDINGS

This research is a crucial contribution to advancing deep neural networks, aiming to provide insights and guidelines for advancing the repurposing and adaptation of the DNN model. The systematic review used a six-phase robust approach to search for and extract research on domains of artificial intelligence AI, machine learning ML, deep neural network DNN, and their state-of-the-art techniques.

This study used the search string technique to refine the search area and cross-reference the references and citations of the included studies, thereby identifying additional research, as we can understand from the illustrated information in Table III and the chart in Fig. 12.

TABLE III. A SIX-PHASE ROBUST APPROACH TO CARRYING OUT A SYSTEMATIC REVIEW WAS USED TO SEARCH FOR THE REQUIRED TERMS/KEYWORDS

(Search Source)	Phase 1	Phase 2	Phase 3	Phase 4	Phase 5	Phase 6	Percentage (%)
(Google Scholar)	Preliminary Search Relevant to AI, ML, and DNNs to Facilitate Development of Research Questions						
ISI-WOS	X	282	193	120	84	54	28%
IEEE	X	244	165	101	72	47	24%
Science Direct	X	165	108	66	50	32	17%
SCOPUS	X	139	87	51	37	25	13%
ACM		132	81	46	32	21	11%
SpringerLink	X	90	57	32	22	14	7%
Total	X	1052	691	416	297	193	100%

A. Phase 1: Groundwork and Theory Building Around Research Questions

Following up on the above essential explanation sections, this phase involved conducting an exploratory Google Scholar search to identify research questions and keywords associated with AI, ML, and DNN and their related applications. The study found that ISI-WoS is the most frequently accessed source of published literature concerning these systems and their associated challenges, followed by IEEEXplore, ScienceDirect, Scopus, ACM, and SpringerLink.

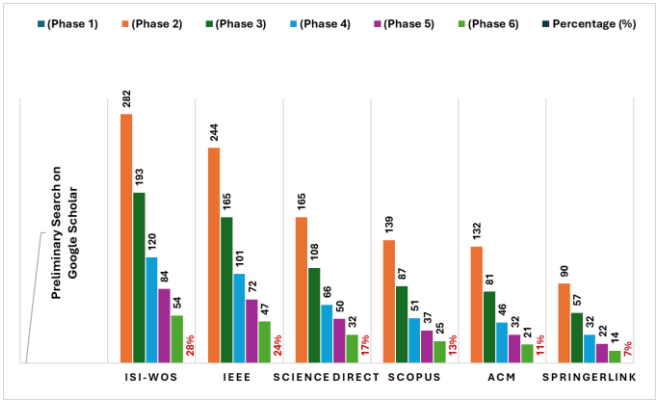

Fig. 12. The intensity of publications for AI, CV, NLP, ML, and DNN-based systems in each scientific database.

B. Phase 2: Identification of Studies with Search Strings: (Narrowing Down the Search Parameters)

Then, we refined the search criteria by defining the acceptable characteristics. This helped us to gather some knowledge of the basics of AI, including ML and DNNs. Deep Neural Networks (DNNs) DNNs are a potent technique that learns multiple layers of data representations or features and yields impressive prediction performances.

The findings identified a total of 1052 publications from six selected scientific sources and databases, simulating a deliberate, non-random selection: ISI-WOS (n=282), IEEE Xplore (n=244), Science Direct (n = 165): SCOPUS (n = 139),

ACM (n=132 papers) Spring-Link ((n=90). These databases allow researchers to search thousands of leading academic journals, periodicals, and conference proceedings.

C. Period of Search

The period focused on in this research included papers from "2015 to 2024" substantially, as depicted in Table IV and Fig. 13.

D. Phase 3: Inclusion/Exclusion Criteria and References Validation

Among the identified studies (n=1052) from the initial search, our reviewers independently assessed inclusions based on predefined criteria. After removing 361 studies that did not meet the requirements (e.g. research questions answers), we were left with 691 relevant to our research questions. We then assessed all eligible studies' references to discover other potentially appropriate reports.

TABLE IV. THE COVERED (TIME-PERIOD) (FROM 2015 TO 2024)

Publication Year	Number of Publications	Percentage (%)
2015	53	5%
2016	69	7%
2017	74	7%
2018	79	8%
2019	88	8%
2020	96	9%
2021	109	10%
2022	121	12%
2023	187	18%
2024	167	16%
Total	1052	100%

E. Phase 4: Evaluation of Eligibility and Adherence Following Reference Review

This phase involved thoroughly evaluating 691 studies and assessing their relevance and quality. We selected 416 studies for their methodological solid foundation and relevance and excluded 275 due to non-compliance with eligibility and quality criteria.

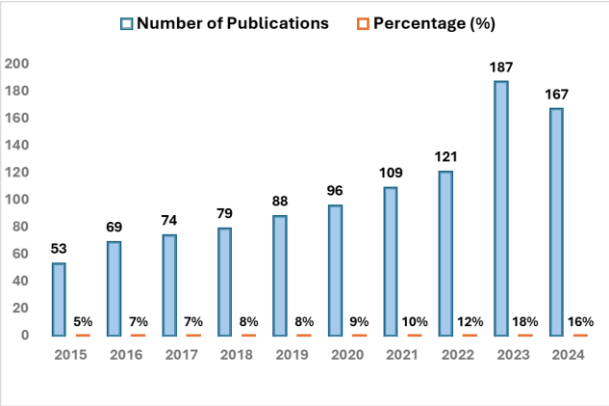

Fig. 13. Overall distribution of AI, CV, NLP, ML, and DNN-based systems from reuse and reengineering perspectives - (Year-Wise).

F. Phase 5: Screening Abstract, Findings, and Conclusion

In this phase, we filtered selection by analyzing abstracts, findings, and conclusions, excluding 119 out of 416 studies for review. This resulted in 297 applicable studies and complete data extraction.

G. Phase 6: Advanced Data Analysis and Answering the RQs

This systematic review concluded with a large set of relevant, high-quality studies that were carefully reviewed, investigated, and synthesized. The study comprehensively analyzed 297 selected studies on AI, ML, and DNNs, excluding 104 irrelevant ones. A structured six-phase process identified and analyzed 193 studies, offering insights to address the study's concerns, as shown in Table V and Fig. 14.

TABLE V. THE ULTIMATE RESULT OF THE REVIEWED PUBLICATION HAS BEEN FOUND AND FILTERED TO BECOME (N = 193)

Publication Year	Number of Publications	Percentage (%)
ISI-WOS	54	28%
IEEE	47	24%
Science Direct	32	17%
SCOPUS	25	13%
ACM	21	11%
SpringerLink	14	7%
Total	193	100%

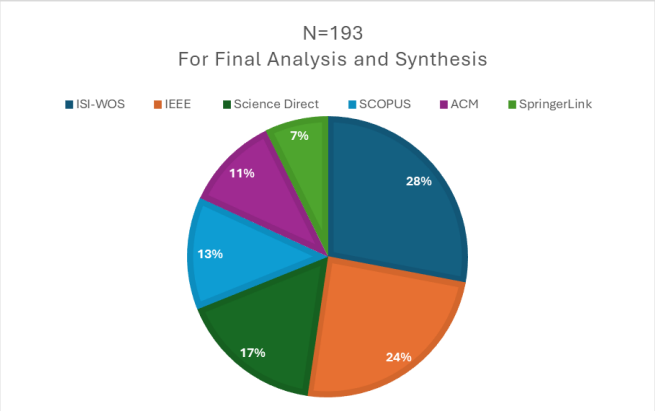

Fig. 14. The scrutinized publication yielded a result of N = 193 after comprehensive analysis and synthesis.

H. Mapping Results and Findings to Research Questions

1) Link each research question to a related dated journal/conference: The systematic review used an iterative design to connect each study to research questions, focusing on RQ1-RQ4. This study developed a new method to classify papers based on the most effectively addressed research questions. Table VI provides details on the mapping process.

TABLE VI. MAPPING PROCESS LISTS THE MOST HIGH-INDEXED REFERENCES PROVIDED ANSWERS TO RESEARCH QUESTIONS

2) The most addressed research questions: As depicted in Table VII, the most addressed research question in the reviewed studies was RQ3, which focuses on the characteristics, differences, similarities, advantages, and limitations of AI systems, ML techniques, and DNN networks. However, RQ4, which addresses the current interoperability challenge among AI environments, was the least addressed, with only 35 papers providing answers. The research papers that answered RQ4 were average and insufficient, highlighting the need for further research into AI system issues. Despite the fewer papers addressing RQ4, some notable contributions include new methods for distributed training and parallel computing.

TABLE VII. PERCENTAGE (%) OF STUDIES COVERING EACH RESEARCH QUESTION

Question No	Question-Text	Number of Publications	Percentage (%)
"RQ1"	"What are the main characteristics and "common differences, similarities, advantages, and limitations" of AI systems, ML techniques, and DNN networks regarding purpose, tasks, and operations?"	54	28%
"RQ2"	"What are the key unsolved problems and bottlenecks that AI computational environments face?"	45	23%
"RQ3"	"What are the relevant "factors and dimensions" that impact the accuracy, adversarial robustness, memory consumption, and inference time of AI, ML, and DNN tasks?"	59	31%
"RQ4"	"What convenient approaches can be developed to address the existing issues and reduce the computation process's high resource cost and time consumption?"	35	18%
Total	Four questions	193	100%

I. Characteristics of (AI) Systems, ML Technologies, and DNNs and Answering RQ1

This systematic literature review comprehensively compares popular machine learning and deep learning frameworks (e.g. TensorFlow, Caffe-Caffe2, Torch/PyTorch, Theano, MXNet, and CNTK) and their connected models and algorithms, as illustrated in Table VIII, towards answering RQ-1. It highlights their relevant characteristics in various aspects and demonstrates the significant disparity in compatibility

between frameworks, with excellent compatibility for models from the same ecosystem. However, compatibility diminishes when combining models from different ecosystems, emphasizing the importance of considering framework compatibility during model development.

TABLE VIII. A COMPREHENSIVE COMPARISON OF (AI) SYSTEMS, ML TECHNOLOGIES, AND DNNS AND ANSWERING [RQ1]

Framework Factors	Caffe/Caffe2	TensorFlow	Theano	Torch/PyTorch	CNTK	MXNet
Founder	Learning-Center & Berkeley 2013/caffe 2017/caffe2	Google2015	Montréal-Uni (2007)	(Facebook)2016	Microsoft Research 2016	Apache Foundation 2015
Purpose	Image processing & on both CPU and GPU	High-performance for ML, DL, CPU, GPU, and TPU	Python offers GPU for arrays.	A Python-based for DNNs	For DL, graph representation	A DL for DNNs.
Interface	Python, MATLAB	Python (Keras), C/C++, Java, Go, &R	Python	Python, C++, & Julia	Python, C++,	C++, Python, Julia, Matlab,
Core language	C++	C++	Python	Python, C, C++, CUDA	C++	Small C++ core library
Platform	Linux, Mac OS X, Windows	Linux, Mac OS X, Windows	Cross-platform	Linux, macOS, Windows	Windows, Linux	Linux, Mac OS X,
CUDA Support	Yes	Yes	Yes	Yes	Yes	Yes
Multi-Threaded -CPU	Yes (BLAS)	Yes (Eigen)	Yes	Yes (widely Used)	Yes	Yes (OpenMP)
Pretrained Models	Yes	Yes	Partially	Yes	Yes	Yes
Multi-GPU	Yes (only data parallel)	Yes (Most flexible)	Not perfect	Yes	Yes	Yes
Compatibility (within the same environment)	Yes	Yes	Yes	Yes	Yes	Yes
Compatibility in	No	No	No	No	No	No
Advantages	"Fast, Efficient for CNNs"	"Large Community, Flexible"	"Symbolic, Good for Research"	"Imperative, Pythonic"	"Production-ready"	"Scalable, Efficient"
Disadvantages	"Limited framework support"	"Can be complex."	"Slow execution"	"Limited community"	Win limited	"Learning curve"

J. Challenges and Open Issues and Answering of RQ2

1) Overview: The systematic review highlights several challenges facing AI, ML, and deep neural networks (DNNs) and their related frameworks, models, and algorithms. These issues include system fragmentation, complexity, interpretability, bias, security, privacy, and a lack of benchmarks. System fragmentation affects code and model reusability, while complexity involves data, model size, algorithm complexity, high dimensionality, and characteristics of tensor data used in DNNs. Understanding how machine-learning techniques and DNNs make decisions like black boxes makes interpretability challenging. Bias can lead to unfair and discriminatory outcomes, while security is vulnerable in specific fields like autonomous vehicles and financial institutions.

2) Common Challenges

- ***Interpretability:*** Understanding how machine learning (ML) and deep neural networks (DNNs) make decisions as black boxes can be challenging. Trusting the procedures throughout the learning and training process can be challenging without reliable indicators until each iteration, epoch, and batch size yields the desired production results (e.g. prediction accuracy before and after model deployment) [151].
- ***Bias:*** Machine learning and deep learning models can be biased, which can lead to unfair and discriminatory outcomes [152].
- ***Security:*** Machine learning systems, especially in some fields such as autonomous vehicles and financial institutions, can be vulnerable to security and safety attacks [153], [154], [155].
- ***Privacy:*** The intelligent systems discussed in this review can collect and store large amounts of personal data, which raises privacy concerns [154], [156]. This issue is more challenging when dealing with deep neural (DNN) models, as these models need a huge amount of data that is not readily provided, especially in applications that require lots of sensitive data [156]. Moreover, Mendelson and Avi have demonstrated that privacy has been a hot topic, particularly regarding the need for privacy protection [154]. Since then, that has translated into new legislation affecting our rights regarding how they get data collected on them. Furthermore, the authors have implemented new mechanisms to guard against the potential misuse of this information. However, the current initiatives are neither adequate nor sufficient.
- ***Lack of benchmarks:*** Benchmarks are essential for comparing the performance of different AI environments and identifying areas where improvement is needed. According to [29], there is a lack of standard benchmarks for evaluating the machine-learning perf (ML) and DNNs performance for the diver's data, especially "big data analytics" [157], [158]. The need for more benchmarks within these technologies is a particularly significant challenge due to the need for standard benchmarks [159]. Furthermore, several surveys indicate that few discussions have been held about the

community's efforts to implement deep learning benchmarking and the gaps between what has been achieved and what still needs to be added [160]. It would be a valuable contribution to the field of research, and developers would pay more attention to this challenge for industry-standard benchmark development [159], [29].

- ***Difficulty in choosing*** *between the machine learning techniques:* In general, the selection of the proper machine learning and deep neural methods for a given task can be a challenge [44], [99]. Based on the analyzed studies, the systematic review identified factors that affect the performance of machine learning and deep neural systems, such as the type of selected data, the quality and quantity of the training data, the kind of algorithm, model selection, the computational resources availability, and the appropriate hyperparameters and fine-tuning for the intended task [48]. Moreover, the findings have expounded various implications for researchers and practitioners. Researchers should develop new methods to address the open issues and challenges identified in the analyzed and synthesized SLR. On the other hand, practitioners should be aware of the involved factors that affect the computation performance and factors that should be applied carefully to select the proper techniques (e.g. Framework, pre-trained model, algorithm, and other software components) and hardware requirements (e.g. Computer device, memory size, and accelerators such as CPUs GPUs, and TPUs) for their given specific needs.

3) Learning and Training Challenges in DNNs

- ***Insufficient Training Data:*** Low training data or batch size can hinder stable, generalizable solutions. Ensure that there is sufficient data for the local minimum cost function.
- ***Non-deterministic data:*** Breaking the deterministic relationship between training inputs and target outputs can hinder training convergence.
- ***Wrong Learning Rate:*** Small or large learning rates can slow or make training unstable.
- ***Vanishing Gradients:*** Gradients in particular layers can become small, slowing or stopping training. For other solutions, use different activation functions.
- ***Exploding Gradients:*** Gradients can become large and cause instability, limiting their weight and bias change rate.

K. The Critical Direct and Indirect Factors Impact DNNs and Answering RQ3

This study examined various factors that affect the DNN-based system's performance and robustness. These factors are critical, direct, and indirect, as explained in Fig. 15.

Direct Factors	Definition	Indirect Factors	Description
Fragmentation	Each system has its own features and characteristics.	NCHW/NHWC Formats	Different layouts of data in the memory hierarchy. The algorithm must be transposed to lead to poor performance.
Structure	Each system has its own structural design.	Data Noise	Mislabeled cases, redundant data, borderlines, or errors in the values of attributes.
Complexity	Model Complexity, Algorithm Complexity, Data/Tensor, and Tensor Layout (Curse of Dimensionality).	Outliers	It is a broader concept that contains discordant data
Purpose	Framework Goal, Model Goal, Algorithm Goal, Task Type (e.g., Prediction, Classification, Detection, or Recognition).	Data Size	Data size: (Not sizable).
Programing Language	API, core language, and Frontends/Interface (C++, Python, Julia, Matlab, JavaScript, Go, R, Scala, or Perl)	Imbalance Data	One or some of the classes greater than others result in biased outcomes.
Accelerators	CPUs, GPUs. TPUs, FPGA, VPU, and ASIC	Missing Features	Variables lack information points, resulting in harming accuracy and model dependability.

Fig. 15. Critical direct and indirect factors impact the DNNs reuse and relevant reengineering challenges (n1=6 direct, n2=6 indirect factors).

The direct factors include data quality, structural design, complexity, creation purpose, programming language, and accelerators. On the other hand, indirect factors such as noise, outliers, and imbalances can impede DNNs' ability to learn program scale and dependencies. By carefully designing and addressing these indirect factors, DNNs can receive training on high-quality data for more accurate and reliable results. We can use deep learning accelerators like GPUs, TPUs, FPGAs, VPUs, and ASIC chips to meet real-time requirements. Therefore, our results demonstrate that researchers and developers should focus on developing more efficient methods to address the highlighted challenges. At the same time, practitioners should be aware of factors affecting computation performance and carefully select the proper techniques and hardware requirements for their specific needs.

L. Existing Limitations on DNNs and Answering RQ4

1) Overview: A potential way for companies and the computer industry to amortize costs is by reusing and re-purposing DNNs. However, reusing DNN-based systems face challenges that affect their reuse and reengineering performance, efficiency, and robustness. The direct and indirect factors behind these challenges have been highlighted in previous sections. The structural problem of non-interoperability among DNN-based systems is one of these obstacles, along with a lack of technical skills and engineering methods [3].

In deep neural cutting-edge systems, interoperability refers to the ability of one software component (with which models are associated) to exchange algorithms and data with another [80]. Fig. 16 illustrates the various paths in developing and deploying a model on hardware or a target environment.

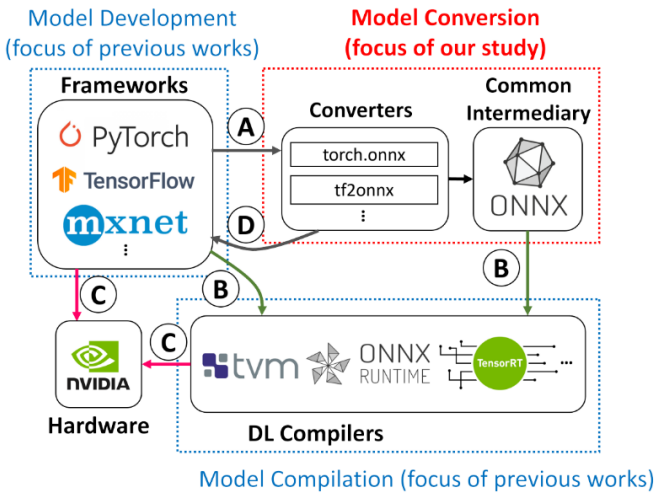

Fig. 16. The paths among model development, hardware deployment, DL Compilers, and model conversion [161].

Interoperability lets models be reused across frameworks and deployment scenarios. While (A) signifies model conversion into a standard intermediary format, letter (B) indicates the compilation process. On the other hand, (C) represents model deployment, and (D) describes transforming a model into a framework according [161].

2) Failure of conversion: This software ecosystem mainly includes many dedicated frameworks for deep learning [162], [163] and compilers [164], [105]. The proliferation of these different tools for development and deployment represents a significant obstacle since moving algorithms across frameworks can be difficult. Furthermore, a compiler that understands models from various frameworks is very heterogeneous. Consequently, frameworks such as open neural network exchange (ONNX) are developed to play an essential role in mediating between deep learning software [165].

However, translation errors during conversion can result in distortions and affect the quality of the model, potentially leading to a degradation in prediction, impacting deployment efficiency, and ultimately causing conversion failure.

3) Failure symptoms and root causes: Even with the development of modern interoperability solutions such as "ONNX, MMdnn, CoreML, and NNEF," there remains a knowledge gap regarding the failure type of deep learning model conversion errors. This lack of knowledge exposes a significant risk with various interoperability technologies built into the design.

The study findings have divided the failure symptoms into two categories: The main common failure symptoms and relevant practical root causes of reusing and reengineering DNN-based techniques, as elaborated in Fig. 17. The second category is failure symptoms that arise from the structural and procedural root causes when reusing and reengineering DNN systems, as presented in Fig. 18.

- Main and Common Failure Symptoms

Model Size: In memory-constrained environments, pre-trained models (PTM) with large sizes are challenging to deploy and use.

Inference Time: Reusing the entire set of pre-trained models can increase the inference time, affecting real-time applications.

Defect Inheritance: Reusing models without a code review may result in inheriting flaws from the original model, which could pose security risks in the new system. On the other hand, AI models are famously brittle to modest input data perturbations, allowing attackers to create adversarial examples for malevolent assaults.

Poor Performance: Compared to regression testing or hardware performance, the model converter's time and memory costs are substantially higher than developer/user expectations.

Failure Symptom	Definition	Failure Root Cause	Definition
Model Size	In memory-constrained environments, pre-trained models (PTM) with large sizes are a significant challenge to deploy and use.	Reusing the entire Model	The entire model is being reused, even though only a small portion of its functionalities (mainly labels) are necessary.
Inference Time	Reusing only a small portion of the functions provided by the model can lead to overhearing and unwanted computational costs.	Training the entire set of pre-trained models	Reusing the entire set of pre-trained models can increase the inference time, affecting real-time applications.
Defect Inheritance	Inheriting flaws from the original model could pose security and robustness risks in the new system (Weakness Inheriting).	AI models are mostly brittle to modest input data perturbations,	Reusing models without a code review.
Poorly Performance	Compared to regression testing or hardware performance, the model converter's time and memory costs are substantially higher than developer/user expectations.	Algorithmic Error	Optimization: The model converter is experiencing an issue with optimizations, including the elimination of inactive code or incorrect fusing. Tracing: Tracking DNN poses a challenge. This phenomenon is observed in frameworks that employ dynamic models. Dynamic models must be tracked to identify the nodes in the computational graph prior to the conversion.

Fig. 17. The main common failure symptoms and relevant practical root causes of reusing and reengineering DNN techniques (n1=4 symptoms, n2=4 causes).

- Structural failure symptoms

In General, interoperability relies on deep neural network (DNN) conversion methods such as "NNEF, ONNX, MMdnn, and CoreML." While primarily used for deployment and framework conversion, these methods suffer from crashes and performance degradation. This study demonstrated three structural failure types, as shown in Fig. 18:

Crashes and wrong model behavior: because of type of problem and incompatibility issues.

Wrong model selection: because of tensor shape mismatches during transformation, inference, or layout conversion.

Build failures: These occur because of testing issues like missing or broken tests. These issues primarily impact converters' graph translation and optimization stages. This study's findings align with existing research, and further analysis revealed model characteristics linked to converter failures.

Failure Symptom	Definition	Failure Root Cause	Description
Crash	Typically, a report of error is generated when the model converter terminates unpredictably during the conversion process.	Incompatibility	Internal: The API evolution has resulted in API compatibility issues within a model converter. External: There are API compatibility issues between a model converter and third-party libraries (e.g., ONNX, MMdnn, NNEF, TensorFlow, ONNX Run-time).
		Problem Type	Node: A model converter employs a computational network, with nodes representing DL operators such as convolution and pooling and edges representing tensors. Every node receives a variable number of tensors and outputs one. These challenges involve node transformation. Tensor: A tensor is a matrix with several dimensions that consists of elements of the same data type. This applies to the various classifications of tensors. Conventional: Conventional software systems also use customary factors. This subcategory addresses traditional variables in various forms.
Wrong Model	model converter exhibits unanticipated behavior without crashing, resulting in an incorrect—intermediate or final result.	Tensor Shape	This affects the shape of a node's input and output tensors during shape matching, transformation, inference, layout, etc.
Build Failure	Installation of model converter or dependencies fails.	Testing	Problems associated with software tests, including unit tests. This encompasses "flaky" tests, missing tests, broken tests, or novel tests.

Fig. 18. Structural failure symptoms arise from the structural and procedural root causes of DNN reuse (n1 =3 structural symptoms, n2 =4 structural causes).

M. Opportunities

Merging innovation with interoperability of deep neural models:

This study suggests that DNN applications need additional interoperability research to understand how pre-trained models make decisions to improve transparency and accountability. A deeper understanding of model converter failure modes may also lead to improved solutions. Scaling these new technologies may ease existing approaches' limits, enabling scale-up for any emerging model and reducing resource and time costs. Our review study (RQs) and relevant critical direct/indirect factors, failure symptoms, and root causes can help researchers and developers overcome limitations in ML and deep neural network model development and deployment from reuse inspiration. Currently, the study team is developing an innovative and promising approach that could overcome the incompatibility and related reuse issues to enhance the re-purposing capabilities of the DNN's domain and practice.

X. Conclusion and Future Trends

Deep neural networks (DNNs) have revolutionized the fields of machine learning (ML) and artificial intelligence (AI), enabling the creation of various models and algorithms capable of autonomously solving complex tasks. However, the development of these techniques faces significant challenges. This paper comprehensively reviews deep neural models that address the characteristics, challenges, open issues, and critical factors influencing ML and DNN technologies. It guides researchers and developers in achieving successful DNN models from reuse inspiration by evaluating factors impacting the reuse and related learning pipeline process. It carefully examines the symptoms of failure in existing reuse methods and the causes that usually lead to this failure. The SLR examined four research questions to comprehend their characteristics, challenges, influencing factors, and strategies for resolving limitations, particularly incompatibility and associated issues. By analyzing the first 193 research papers, the study identified significant challenges related to software incompatibility within DNNs. Other open issues include performance degradation, complexity, vulnerability to adversarial attacks, difficulty in code reengineering and conversion, a lack of standardized benchmarks, and system selection. The review reveals how these issues hinder parallel computing efficiency by increasing development, deployment, and computing time, complicating task organization, and raising costs. Additionally, goal mismatches can decrease computing accuracy, making training and performance complex. This study contributes to understanding DNN as a black box and benefits various fields, including AI, ML methods, and DNN-based systems in performance (e.g., accuracy, inference time, memory consumption) and robustness towards multiple adversarial attacks. The study suggests that DNN applications require further research on interoperability, model converter failure modes, and scaling technologies to improve solutions and reduce costs.

Future work focuses on reducing model size computational cost without sacrificing performance efficiency, whether for basic DNN models (e.g., pre-trained models) or LLMs using unique techniques (e.g. "Low-Rank-Adaptation "Lora" and Quantized Lora "QLora," model compression, and pruning) for optimal converted model size and inference time). Furthermore, during future work procedures, the team ensures that various adversarial attacks, especially in finance, healthcare, and autonomous applications, are avoided, including data security, privacy, veracity, and benchmarking challenges.

Acknowledgment

The authors gratefully acknowledge all contributors whose valuable insights and suggestions significantly improved this work. We confirm that no funding was received for this work and declare no conflicts of interest.

A Machine Learning Operations (MLOps) Monitoring Model Using BI-LSTM and SARSA Algorithms

Zeinab Shoieb Elgamal, Laila Elfangary, Hanan Fahmy
Department of Information Systems-Faculty of Computers and Artificial Intelligence, Helwan University, Helwan, Egypt[1]

***Abstract*—Machine learning operations (MLOps) achieves faster model development, deliver higher machine learning models quality, and faster deployment cycle. Unfortunately, MLOps is still an uncertain concept with ambiguous research implications. Professionals and academics have focused only on creating machine learning models, rather than using sophisticated machine learning systems in practical situations. Furthermore, the monitoring system must have a comprehensive view over the system interactions. The need for a strong efficient monitoring system increases when it comes to use the multi container services. Therefore, this research provides a new proposed model called Multi Containers Monitoring (MCM) Model, based on multi container service and machine learning approaches which are bidirectional long short-term memory (BI-LSTM) and state-action-reward-state-action (SARSA). The proposed MCM model enables MLOps systems to be scaled and monitored efficiently. The proposed MCM model realizes and interprets the interactions between the containers. The proposed MCM model enhances the performance of the software release and increases the number of software deployments across different types of environments. Moreover, this research proposes four routines for each layer of the proposed MCM model that illustrates how each layer is going to be developed. This research also illustrates how the proposed MCM model achieves improvements ratio in software deployment cycles by using MLOps up to 24.55% and in build duration cycle up to 13%.**

Keywords*—Machine learning; MLOps; monitoring; container; model

I. Introduction

The fast and increasing popularity of machine learning (ML) applications has led to growing attention in Machine Learning Operations (MLOps), that is, the practice of continuous integration and deployment (CI/CD) of ML-enabled systems [1]. Since changes may not affect only the code but also the ML model parameters and the data themselves, the automation of traditional CI/CD needs to be extended to outspread to monitor model retraining in production [1]. ML has become a significant technique to leverage the potential of data and allows businesses to be more innovative, efficient, and sustainable [2] [3] [4] [5]. However, the success of many ML applications in the real world doesn't meet expectations as the ML community has focused extensively on the building of ML models not on building production-ready ML products and providing the necessary coordination of the resulting [2] [6] [7] [8]. Besides that, these applications started to produce and maintain a huge amount of data from their operations. Those new developments require monitoring the operations of applications in real-time [9]. If MLOps model selection and training are not closely and carefully monitored, applications may lose value in the market and organizations might be at risk of losing money, but the worst is to lose their reputation [10] [11] [12].

This research proposes a multi-container monitoring (MCM) model to monitor the communication and all containers' behavior for the software deployment cycles to help in more frequent releases and reduce production issues. Further, discusses the MLOps practice to effectively handle the issue of creating and monitoring effective ML. Furthermore, adopts a broad viewpoint to provide comprehension of the relevant principles, responsibilities, and architectural structures.

This research makes a significant contribution to the software industry by:

- Review all the previous studies in monitoring containerized software.
- Delineate what kind of problems MLOps practices may be best suited to apply, to help in reducing the re-developing and re-deploying.
- Monitor software performance at a finer granularity level.
- Monitor DevOps and MLOps pipelines and system infrastructure behavior.
- Reduce the build time of software systems.
- Improve the deployment rates of existing methods in software systems.

This research applies a new machine learning technique to monitor and learn more ML model features based on different software systems.

The remainder of this research is structured as follows. Section II presents the background. Section III illustrates the necessary definitions and related work in the field. Section IV, presents an overview of the utilized methodology and the proposed MCM model. It also presents the MCM model challenges and limitations. Section V and VI presents model dataset and model configuration. Results and discussion is

given in Section VII and Section VIII respectively. Finally, Section VI, concludes the work with a summary.

II. BACKGROUND

There are a variety of software process models and development methodologies used in software engineering such as waterfall and the agile manifesto. Those methodologies have similar objectives, which are to deliver production-ready software applications [2] [13] [14]. Recently software development teams have moved away from the traditional waterfall methodology to DevOps as the traditional life cycle is not suited for dynamic projects as needed in the ML development process, as shown in Fig. 1.

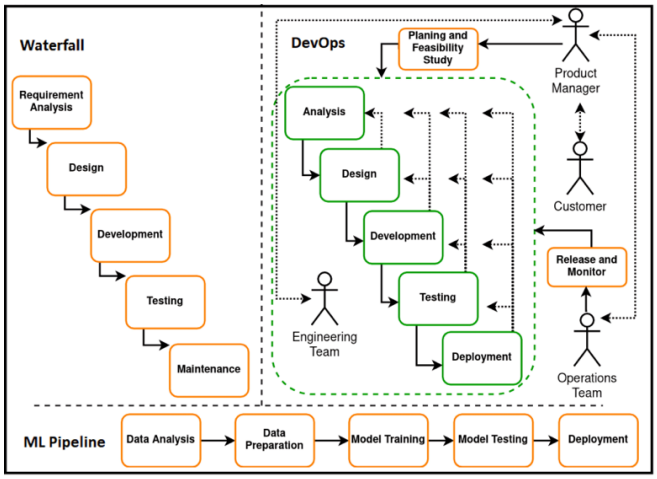

Fig. 1. Waterfall, DevOps SDLC, and the manual ML pipeline [15].

DevOps refers to the modern software deployment model that combines software development (Dev) and IT operations (Ops) [16]. DevOps aims to enable automation, continuous integration, continuous deployment, monitoring, and team collaboration of software applications in fast and small releases [17] [18]. The two primary DevOps practices are Continuous Integration and Continuous Delivery.

Continuous integration (CI) is a software practice that concentrates on automating the creation and integration of code from many developers. To enable quicker development cycles and enhance quality, developers are demanded to merge their code into the primary repository more frequently in this procedure. Version control systems (VCS), automated software development, and testing procedures are the key elements of this practice [15] [19].

Continuous delivery (CD) core purpose is to deliver newly created features to the end user as rapidly as possible by building the software in a way that is constantly in a production-ready state to ensure that code updates might be released on demand fast and safely [15] [20] [21].

Continuous deployment (CDE), which is frequently confused with CD, is a different technique. Continuous deployment is a technique where every software modification is automatically pushed to production. Even so, some businesses have procedures in place for obtaining outside approval before releasing new application's version to users. Thus, continuous delivery is considered necessary in certain circumstances; however, continuous deployment is optional and can be skipped [15] [19] as shown in Fig. 2.

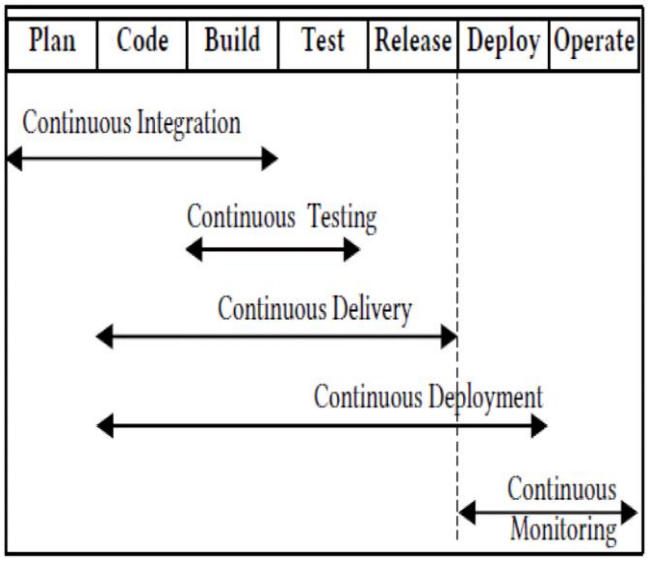

Fig. 2. Deployment pipelines [18].

Continuous monitoring is an automated procedure that uses cloud services to assess a deployed application's operational functionality against business criteria as it is being used [18] [22].

The DevOps pipeline, also known as the CI/CD pipeline, enables greater support for the deployment of applications to the cloud and utilizing a wide range of tools [15] [17] [23].

ML pipeline is defined as an automation of the ML life cycle by minimizing human interaction in routine processes [24].

MLOps refers to the complete vision of best practices and procedures from the design of the training data through the final deployment lifecycle [16] as shown in Fig. 3. MLOps can alternatively be considered as the integration of DevOps with machine learning techniques [25]. By another word, MLOps is the artificial intelligence (AI) equivalent of DevOps [16]. Furthermore, MLOps places a strong emphasis on automation while monitoring each step of the machine learning process, much like DevOps [26].

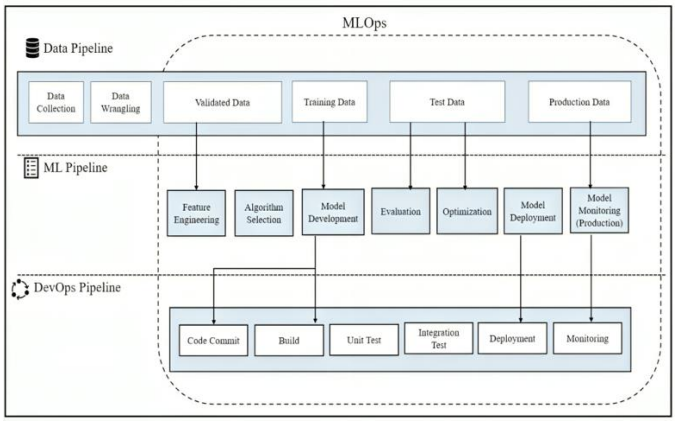

Fig. 3. High-level process perspective of MLOps [24].

MLOps phases are typically related to various roles and concepts, such as containerization and dockerizing [24] [27]. Containerization has become a standard approach for environments, which support on-demand, short-lived execution of computational tasks such as Function-as-a-Service (FaaS) platforms [28] [29].

Running applications in containers enables automatic orchestration and agile DevOps practices, in cloud-native platforms, the design of container and objects in software object-oriented programming (OOP) is similar: each container has a particular duty to carry out effectively [30] [31]. Cloud-native containers are easier to grow horizontally and replace, reuse, and update transparently [31], this has been termed the "Single Concern Principle" [32].

Dockerizing facilitates the hosting and execution of any kind of software applications, platforms, middleware, databases, packaged, in-house, and custom-built software. Moreover, the quicker maturation and reliability of the Docker platform have made it much easier to develop, distribute, deliver, and deploy software [33]. Furthermore, dockerizing offers a simple approach to isolate the network and restrict how much resource the containers can use [34].

There is another design concept that helps in monitoring the ML projects if it had been used during the project development phase which is the "Microservices" design rather than the monolithic design. Microservice architecture (MSA) is suggested to divide single-component applications into numerous loosely linked and independent microservice components [35] [36]. Microservices are applications broken down into their core functionalities. Each function operates as its own "service" inside a container and interacts with other containers across the network [37]. Microservices have several benefits over monolithic applications, such as autonomous update cycles, fine-grained resource control, and high elasticity [37]. The monolithic design is only appropriate for small-scale systems with straightforward internal structures since these monolithic applications adhere to an all-in-one architecture in which all functional modules are created and configured into precisely one deployment unit, namely, one container [38].

III. Related Work

Raúl Minin, et al., introduced a tool named Pangea that generates adequate execution settings for deploying analytic pipelines automatically. These pipelines are broken down into several stages so that each can be executed in the edge, fog, cloud, or on-premises environment which will minimize latency and make the best use of available hardware and software resources. Pangea is focused on achieving three specific goals: (1) creating the required infrastructure if it doesn't already exist; (2) providing it with the components needed to run the pipelines (i.e., configuring each host operating system and software, installing dependencies, and downloading the executable code); and (3) deploying the pipelines [39]. Raúl introduced a complex tool that takes a lot of work to conceptualize and build. Although the first version of the tool is sufficiently developed to demonstrate some of its potential advantages, further use cases and technology and connection compatibility must be added before it can be used in more situations. The web client requires to be improved to assist the management of users, pipelines, and infrastructure since Pangea isn't built to support the description and deployment of analytical pipelines in the training stage. Moreover, Pangea doesn't support monitoring pipelines and infrastructure behavior.

Matteo Testi, et al., provided a literature review on MLOps to illustrate the present difficulties in developing and sustaining an ML system in a production context. The literature review revealed that the utilization of MLOps in the workplace and the application of DevOps principles to machine learning are still under-discussed issues in academia. Furthermore, organizations will need to conduct experimental work to test the ML pipeline as they attempt to apply an ML approach to an end-to-end use case, going through each step and demonstrating what results if certain phases are skipped [40].

Sergio Moreschini, et al., offered a better illustration of MLOps by integrating ML development stages into the established DevOps practices. The research suggested a MLOps pipeline that concentrated on the duality between software engineers and machine learning developers and their roles [41]. Sergio's roadmap increased adoption of ML-based software generated a demand for ML developers who need to perform tasks in parallel to software developers and produced two extra loops for both the ML and software sides.

Pinchen Cui focused on providing security for containerization through secure monitoring of containerized applications to give better simulation of actual application behaviors and greater coverage of attacks with extended feature space [35]. Pinchen's research has not been put through an online evaluation. The elements of the security monitoring target must be enhanced to allow the framework to automatically determine what to monitor in an unsupervised manner. Meanwhile, the framework did not support scaling the dataset with various application architectures, such as multi-container applications, where a service is composed of several containers, and Docker Swarm's distributed monitoring.

Holger Gantikow, et al., suggested integrating containerized environments with rule-based security monitoring. The suitability of the method is investigated for both (1) a variety of undesirable behaviors that may point to abuse and attacks of workloads running inside a container and (2) misconfigurations and attempts to increase privileges and weaken isolation safeguards at the container runtime level [36]. The article does not cover the security monitoring of distributed workloads because shared workloads interact strongly across host borders.

While recent studies cover a variety of specific MLOps topics, a comprehensive conception, generalization, and explanation of ML systems monitor are still lacking. Different interpretations of the phrase "MLOps" may result in misconceptions, which may result in setup errors for the entire ML system. MCM model will work on the monitoring of the development for the multi-container "distributed" ML systems resulting in the ability to improve the software build and deployment cycles in real-world settings.

IV. THE MCM PROPOSED MODEL

The proposed Multi Container Monitoring (MCM) Model consists of four different layers as shown in Fig. 4. The MCM's model layers are the "Development layer, MLOps and container layer, and Monitoring layer with the support of different tools in the Tools and Automation layer".

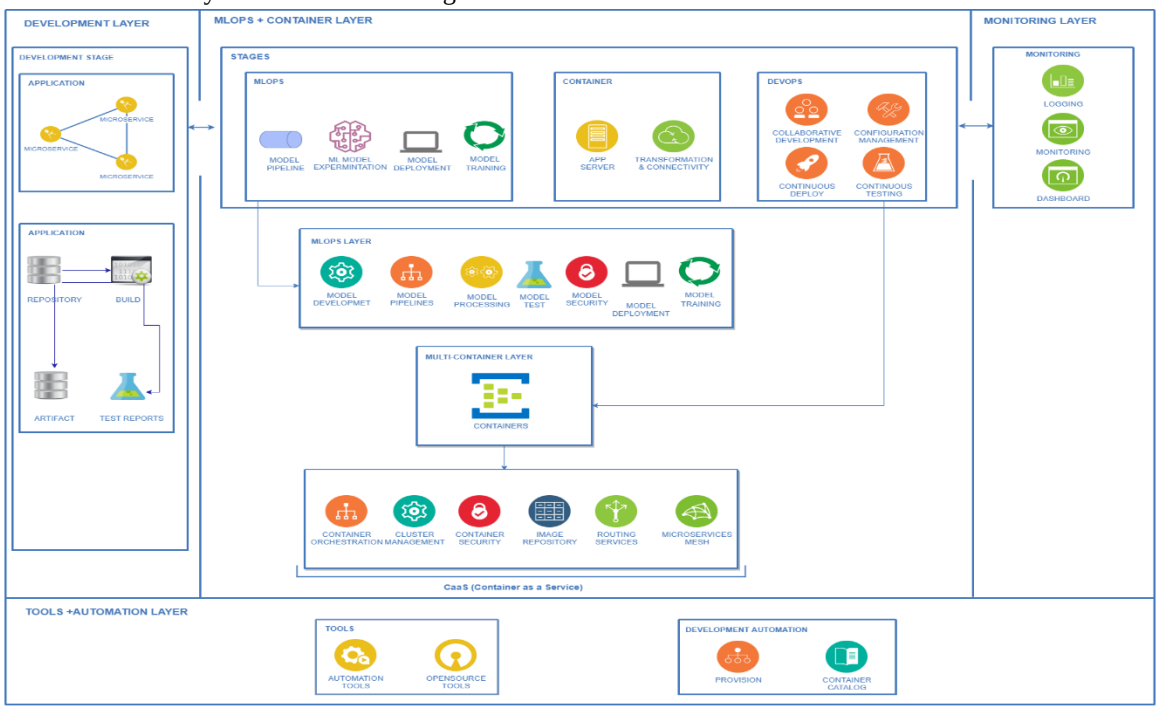

Fig. 4. Multi Containers Monitoring (MCM) model.

The MCM Model starts from the developer's commitment of a specific piece of code and ends with its deployment and monitoring on various environments. The next sub-sections will introduce a detailed description of the MCM's model layers and describe the components of the MCM model.

A. Development Layer

The initial part of the proposed MCM model is the development layer, which is further separated into two main sublayers: the application structure layer (microservices) and the code lifecycles layer. The microservice layer focuses on designing a good structure between each part of the application. The microservice layer seems to be as a pre-requisite for the code lifecycles. The development layer focuses on managing code changes and adopting CI principles to minimize code conflicts.

The code lifecycle layer consists of four steps. The first step verifies that the code is versioned correctly and that a stable version of the code has always been kept up to date in the main repository after the appropriate tagging. Developing a stable version of the code is the second step. The third step involves executing multiple test scenarios, starts after the build step is being successful. At this point, it is confirmed that the code satisfies the necessary functional and needed requirements. When the system's artifact is prepared for release, the last step in the build and validation software process is called "artifact preparation" This involves gathering the output required for the next release and deployment phases.

Routine 1 discusses the high-level routine for the code lifecycle sublayer.

Routine 1: Implement CI/CD Pipeline

Notations: SW // Software, VCS // Version control system, Repo // Repository, VAL // Validation, PR // Pull request, CONF // Confirmation, CI // Continuous integration, PL // Pipeline, TC // Test cases, Pkg // Package, Exec // Execute, CD // Continuous deployment
Input: SW code, Different types of TCs
Output: Deploy the succeeded container images to the target env
Steps:

```
1) Select VCS
2) Repo VAL
3) Code merge
If (PR= Yes) then
    While (review = accepted) do
        For (every merge CONF) do
            1) Push code
            2) Run CI PL
            3) Exec unit TCs
            4) Pkg the build artifact
            5) Exec extra TCs
            6) If (build pkg = accepted) then
                    Pkg the container image
                End
            7) If (CD env>=1) then
                    deploy pkg
                End
        End
    End
```

The procedures of this layer are concentrated on giving code and tests a transparent control structure. Selecting the most appropriate VCS is the initial stage, followed by defining the structure of the repository and its validation guidelines. Then get ready to create the different test cases required to get the CI/CD pipeline started. Finally, store the tested package and make it available for usage in deployment.

B. MLOps and Container Layer

The second layer of the MCM model is MLOps and Container layer. The MLOps and container layer is divided into two primary sublayers: the layer of MLOps comes first, and the layer of containers comes second.

MLOps layer includes the development of the MCM model, the pipelines construction, test preparation, configuring and adding some security gates throughout the MCM model.

Container layer, container as a service (CaaS), is the framework that relies on the idea of multiple containers. Therefore, each container in this layer will go through the same steps. The steps include container orchestration, cluster management, container security, image repository, routing services, and microservices mesh. The container's network configuration, security, and resource allocation are among the processes in this process, along with deployment, auto-scaling, health monitoring, migration, and load balancing.

The high-level routine for the MLOps layer is discussed in Routine 2. Routine 3 presents the container layer.

Routine 2: Implement MLOps Pipeline

Notations: DAQ // Data acquisition, DS // Data source, PL // Pipeline, DA // Data analysis, KPI // Key performance indicators, PERF // Performance, OP // Operational
Input: Model Data
Output: Deploy the succeeded ML model to the target env
Steps:

```
While (Business understanding = true) do
    For each (DAQ) do
        Define DS
        Define PL
        Define deployment env
        Exploration and cleaning
        End
    Model Security
    Model deployment
    For each (Model training) do
        Exploratory DA
        Define feature engineering
        Model training
        End
    For each (Model evaluation) do
        Model KPIs (PERF and OP)
        Model retrain
        End
    Model logging
    End
```

The MLOps layer consists of seven steps and the development of the MLOps pipeline is the main objective at this layer. The identification of the application type is the most crucial step because it serves as the base for the subsequent steps. The second step is understanding the application type which enables the identification and analysis of the received data. The data transformation step is the third step and begins after the data is received. The fourth step is setting up some security validation over the model pipeline and configuring all necessary deployment environments for the pipeline. The fifth step is the MCM's model training phase. The sixth step is the validation step. Depending on the outcomes of the MCM model validation step, the last step at MLOps layer which is the retraining step. The retraining step begins with some modifications to the MCM model and/or data to maximize the benefits. Furthermore, this step depends on the data in the MCM's model log file to keep track of the used data to be able to take the necessary action.

Routine 3: Implement Container Structure

Notations: STRTG // Strategy, CONFIG // Configuration, SP // Security policies, DR // Disaster recovery, HA // High availability, RS // Routing services
Input: Container STRTG
Output: CONFIG container architecture
Steps:

```
Container orchestration
CONFIG the container registry
    For each (Container) do
        Set container SP
        Define PL
        End
    Push container image
```

Along with the MLOps layer, the container layer which contains three steps starts. The first step is establishing the rules for container's interaction with the other containers. This process is known as container management and orchestration. The identification of the deployment strategy for the containers is the second step. The last step is defining all the image registries that depend on the various deployment environments.

C. Monitor Layer

The third layer of the MCM model is monitor layer. This layer includes MCM's model-based event logging, step-by-step monitoring, and the creation of dashboards for convenient monitoring to aid in decision-making on enhancements. The high-level routine for this layer is discussed in Routine 4 and it has been highlighted also in Routine 2 steps 6 and 7.

Routine 4: Monitoring

Notations: INIT: Initialize, PL // Pipeline, ML // Machine learning, REC // Record, CONFIG // Configuration
Input: Monitoring matrices
Output: Monitor PL, container, and ML model
Steps:

```
INIT monitoring
While (Logging = true) do
    For each (PL, container, and ML model) do
```

```
|  |  REC external logs
|  |  REC internal logs
|  | End
| End
CONFIG dashboards
```

In order to validate, enhance, and maintain any abnormal behavior over MCM's model layers, the monitoring layer contains various dashboards to represent multiple perspectives at various stages. The monitor layer saved external logs that record which data the MCM model is applied to, and internal logs that check the inner workings of the ML pipeline and debug problems. The monitoring layer makes it easier to understand and identify any failures, and act quickly to keep everything under control and in good condition. Moreover, the monitoring layer would guarantee a system with fewer development, deployment, and monitoring issues.

D. Tools and Automation Layer

The fourth layer of the MCM model is the Tools and Automation layer. This layer is necessary to support the MCM's model layers with one or more different tools to obtain reliable statistics and facilitate the transition from one step to another. Specifically, for provisioning and container cataloging, this layer uses a set of open-source and development automation tools to help in all MCM's model building and monitoring.

V. MCM MODEL DATASET

The dataset used in the of the proposed MCM model consists of 286 pipelines. The pipelines are divided to continuous integration, continuous testing, and continuous delivery pipelines that use 100 microservices. The pipelines serve over seven million users and run on Windows and Linux operating systems. The dataset contains 122 production environments, seven test and pre-production environments and 158 attributes spread across each layer of the suggested MCM model. Therefore, the size of the dataset is sufficient to validate the proposed MCM model and to investigate possible future enhancements. The dataset used by the MCM model collects and stores unstructured data from a variety of sources, including emails, business papers, source control software, and software engineers' feedback. A sample of the dataset is shown in Fig. 5 and a sample of the dataset and docker file are shown in Fig. 6.

VI. MCM MODEL CONFIGURATION

Every stage of the MCM's model preparation phase is covered in this section. This process consists of two primary preparation steps: building the application is the first main step, and setting up the ML model is the second.

A. Application Build

The migration phase and the automation phase are the two major stages of the application build process. The process depends on separating the application's functionality into discrete services according to their use cases or modules, and integration the DevOps with MLOps pipelines. Furthermore, the process focuses on using the containerization concept which makes it easier to manage and scale the system and makes it easier to automate the deployment of new features.

- Migration Phase from Monolithic Application to Containerized-Microservices Application

The goal of the migration process is to have a new, well-structured application to benefit from containers and DevOps tools in the next automation phase. Furthermore, the migration process identifies methods that will assist with securing the daily operation of the IT and reduce costs. Five primary stages made up the migration process, some of which had the subsequent sub-stages:

1) Evaluating the legacy application: The components of the MCM model were chosen with the need to address issues such as performance bottlenecks and reduce build and deployment durations.

2) Select a migration method: The Lift-and-Shift and Refactoring migration methods were chosen for the proposed MCM model.

3) Get the Legacy Application Ready for the Migration.

4) Data on migration: the GitOps tools, orchestration platform command-line interface (CLI), or orchestration platform web console can all be used to carry out deployment on the platform after migrating the application data. RedHat-OpenShift, and Kubernetes were chosen as the orchestration platforms for the proposed MCM model to scale resources for microservices and even to simply enable autoscaling. The platform CLI and Azure pipelines were used for the deployment execution.

5) Evaluate and deploy: once the application deployed on an orchestration platform, careful testing is also essential to confirm that the application performs as intended. The application can be launched to production if the testing is successful, which will complete the migration process.

- Automation Phase

This stage demonstrates how the refactored code "microservices" that were previously developed during the migration phase was built automatically based on Docker as shown in Fig. 7. One of the objectives of moving to microservices is to achieve the most benefit of the automated CI/CD pipeline, which enables a very seamless release process. In the case of an issue, the CI/CD pipeline system can initiate a fix or revert to an earlier version. Define checks at each stage using security scans, service level objectives (SLOs), service level indicators (SLIs), and service level agreements (SLAs).

Automate the changes between continuous integration, testing, delivery, and deployment.

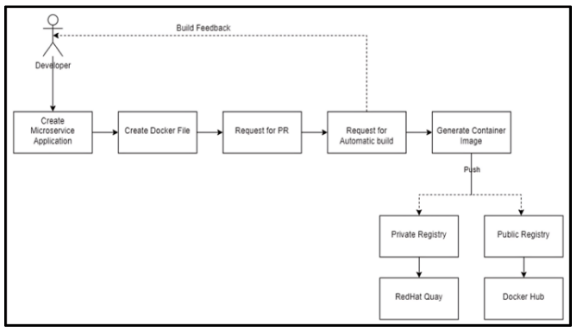

Fig. 7. Creation of container application and push the image to the registry.

The automation procedure was broken down into the following nine major phases:

1) Select a source control (SC) system. Git was the best SC system that met the requirements after several SC system types were compared.

2) Produce Docker files that specify each microservice's container contents.

3) Make a PR request.

4) Build and package every microservice, for Java projects, that have been developed and coded with Spring Boot and for .Net applications, which was created and developed with the .net framework versions 4.8.0, 4.8.1, and 6.

5) Build and produce Docker container images and verify if the image was locally created and accessible.

6) Launch the Docker containers and verify to see if the application within the container is operating properly.

7) Push the image to the registry, at this step, the locally produced image is pushed to the shared registry (RedHat Quay and/ or Docker Hub) using the image ID.

8) Initially, steps 3 through 8, are completed manually. Afterwards, CI/CD pipelines are set up using Azure DevOps. At this stage, each microservice has a CI pipeline to execute the code following an approved PR. The CT pipeline verifies the written code. The CD pipeline manages the deployment procedure for each environment, including integration, QC, security testing, UAT, load testing, packaging, and pre-production. A certain set of stakeholders must be informed and given permission before the created image is deployed on any deployment environment.

9) A new commit was added to the SC and step 3 was restarted to meet the additional requirements.

In conclusion, you can successfully containerize your application by following the previous steps, which include setting up the required tools, building the image, running the containers, and pushing the image to a registry. This will streamline the deployment and management process. Moreover, will encourage consistency and repeatability.

B. The Proposed MCM Model Build

The MCM model was built using a combination of recurrent neural network (RNN) architecture “Bidirectional LSTM (Bi- LSTM)” and a reinforcement learning algorithm “state–action–reward–state–action (SARSA)”. This combination integrates into application CI/CD pipelines and monitoring systems, enabling continuous optimization of container application performance. Further, by analyzing streaming data from container environments, the Bi-LSTM and SARSA can adapt to changing workload patterns and optimize resource usage dynamically. Combining the algorithms results in improved, robust, and shortened build and deployment times. The proposed MCM's model performance was evaluated using backpropagation through time (BPTT). The Adaptive Moment Estimation (Adam) optimizer was selected to improve the performance and accelerate the convergence of Bi-LSTM.

The proposed MCM’s model build process was divided into the seven main stages listed below:

1) Environment representation

a) Define the scope of the MCM’s model environment in terms of the performance and state of the containerized applications.

b) Normalize the metrics to make sure they were appropriate for input into MCM model and to guarantee consistent scaling.

2) Action scope

a) Specify a range of actions that the MCM model agent can accomplish to maximize container performance.

b) Discretization of the actions into a finite set.

3) Feedback function: provide the suggested MCM's agent a reward function that gives feedback based on the observed metrics, actions taken, and the obtained performance outcomes. The design of the reward function is broken down into three categories: positive, negative, and delayed feedback. Positive feedback rewards actions that improve container performance, like shorter build and deploy times, higher throughput, more efficient use of resources, and/or faster response times. Negative feedback penalizes actions that lead to inefficiency or performance degradation, like excessive resource consumption and downtime.

4) MCM's model agent: The proposed MCM's model agent depends on the SARSA's agent as shown in Fig. 8, to pick actions based on the current state and the observed feedback. MCM model learns an action-value function M (s, a) that estimates the expected cumulative feedback of taking an action (a) in the specified state (s) then a balanced exploration (random actions) and exploitation (best-known actions) strategy was combined with temporal difference learning in the SARSA algorithm to update the M-values.

5) Integrated MCM's model architecture: the MCM's model architecture is based on The Bi-LSTM design which consist of some LSTM layers, several hidden units per layer, and the size of input and output. System configurations, workload patterns, historical performance data, and other aspects were arranged into sequences and time-series representations to create the appropriately structured input data. The MCM model uses the input data to learn temporal patterns and anticipate future states. The SARSA agent then uses these predictions to make decisions on how best to optimize container performance and deployment durations. The schematic Bi-LSTM is shown in Fig. 9 and MCM's model integration architecture is shown in Fig. 10.

6) MCM model training: to ensure that gradients and errors are transmitted appropriately throughout time and to update the model weights while taking into consideration the sequential nature of the data, the MCM model was trained using BPTT. Further, Adam's optimizer was selected to modify the Bi-LSTM weights during training to minimize the loss function. Fig. 11 shows the flowchart for the training loop.

7) Evaluation and deployment

a) A validation dataset and container assessment measures, such as response times, throughput, resource utilization, and build/deploy durations, were utilized to assess the MCM model algorithm's performance.

b) Embed the trained MCM's model algorithm in the CI/CD pipelines and containerized application deployment pipelines to automate the entire deployment process and guarantee a smooth integration with the current DevOps workflows.

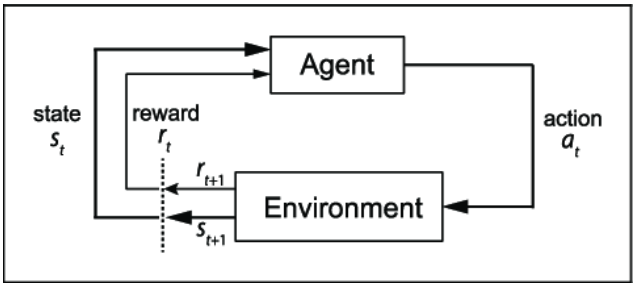

Fig. 8. MCM's model agent environment interaction.

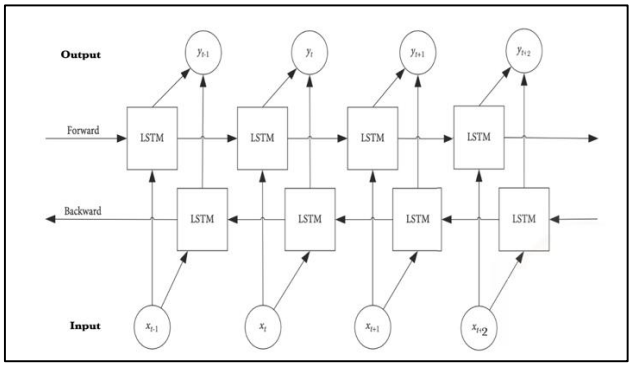

Fig. 9. Schematic Bi-LSTM's architecture.

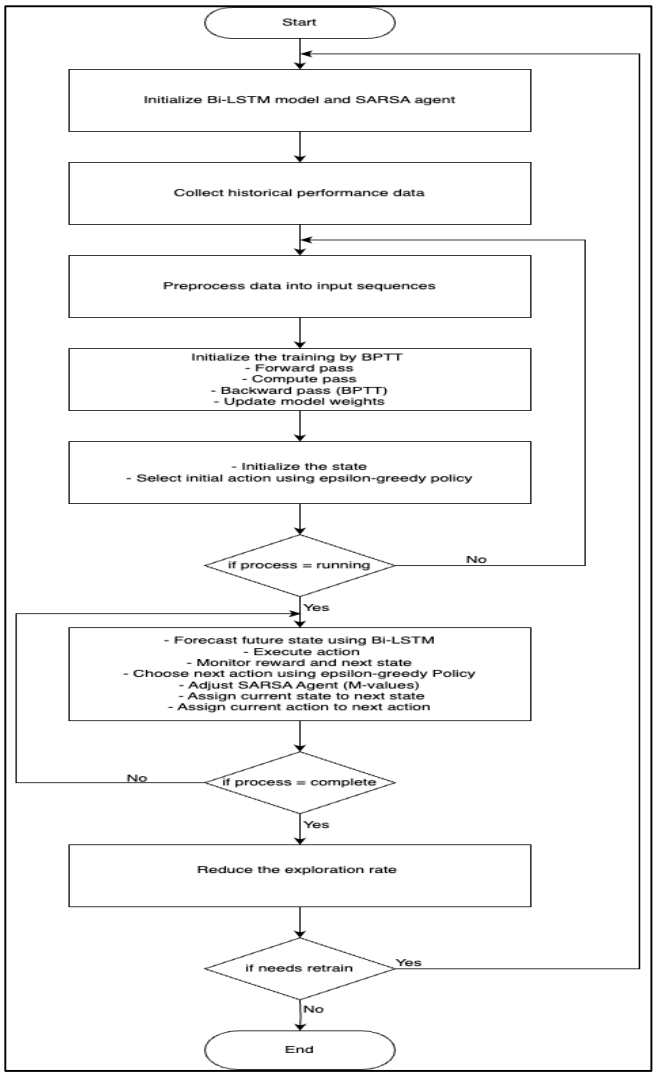

Fig. 11. MCM's model training flowchart.

VII. MCM Model Results

The outcomes of a successful progress visualization during MCM model training to improve the deployment time are presented in Fig. 12. The improvements in build and deployment durations are shown in Fig. 13.

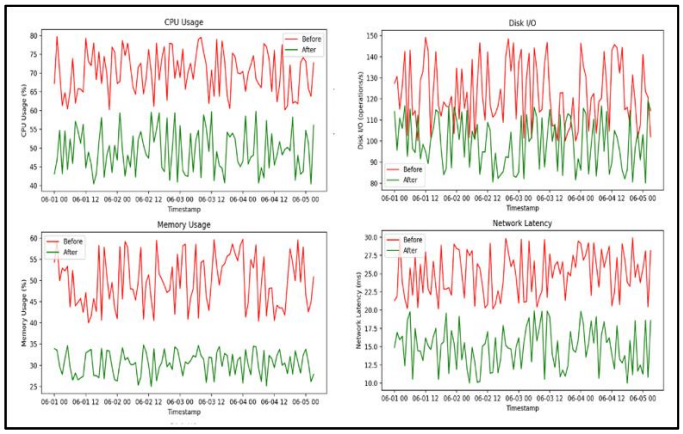

Fig. 12. MCM's model resource usage optimization.

Fig. 12 demonstrates optimization of the resource usage of the containers. It can be noticed that the containers enhancements made by the MCM model compared to the previously employed methodologies for CUP usage is up to 38.25%, for disk I/O is up to 39.20%, for memory usage is up to 50.77% and for network latency is up to 58.37%.

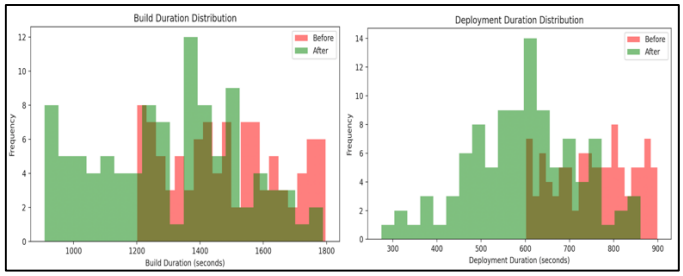

Fig. 13. MCM's model build and deployment duration.

Fig. 13 observes the improvements in seconds of the build and deployment frequencies across the different environments, which are for a build duration up to 13% and for a deployment duration up to 24.55%.

VIII. MCM Model Discussion

The literature research revealed several barriers to the use of MLOps. These unresolved concerns fall into three categories: organizational, ML system, and operational.

A. Organizational Challenges

A common issue in organizational settings is the mentality and culture of data science practice [31]. The study's findings indicate that to effectively develop, implement, and monitor machine learning systems, there require a culture shift away from model-driven machine learning and toward a discipline that is system-oriented. This can be accomplished by placing more emphasis on the data-related activities that take place before the creation of the ML model. Furthermore, when designing ML products, roles involved in these activities should have a system-focused view and must therefore be a group process as this is challenging since teams usually operate in silos rather than collaborative environments also the specialized terminologies and varying degrees of knowledge further complicate communication. Moreover, MLOps demands a wide range of skills and specialized roles. Because there aren't enough highly qualified professionals to fill these positions, particularly in the fields of architects, data engineers, ML engineers, and DevOps engineers [32] [33] [34]. As MLOps is often not included in data science courses, this is relevant to the training that future workers will need [35].

B. ML System Challenges

It might be difficult to develop MLOps systems to accommodate changing demands, especially when it comes to the ML training and monitoring procedures [35]. This is a result of potentially massive and unpredictable data [36], which makes it challenging to correctly forecast the necessary infrastructure resources (CPU, RAM, and GPU), and calls a high level of flexibility when it comes to the scalability of the containers [35] [37].

C. Operational Challenges

ML is challenging to execute manually because of the numerous software and hardware stacks and their interrelationships. Thus, reliable automation is required to produce numerous artifacts, which require solid governance [35] [38] [39] [32] [40] [41]. Versioning of the data, model, and code is also necessary to guarantee reliability and reproducibility [32] [2]. Finally, because there are so many parties and components involved, it can be difficult to handle a possible support request (for example, by identifying the root cause). Moreover, failures might result from a combination of ML infrastructure and software [37] [42], making it essential to monitor each phase and collect as much data as possible to aid in making timely decisions.

Therefore, this research proposed a model (MCM) which depends on the multi-container architecture and microservices principles that applied to solve the mentioned barriers by building and deploying the stages of the application development lifecycle. The MCM reduced the requirement for re-developing and re-deploying software applications while also improving the performance of software releases. The MCM model enhances the build duration cycles and software deployment cycles ratio by employing MLOps.

IX. Conclusions and Future Work

More machine learning systems than ever before are being developed as a result of the growing demand to innovate. Higher monitoring and analysis skills are required for ML models. However, only a few of these proofs of concept move forward to deployment to production. Furthermore, in the real world, data scientists are still managing ML operations largely manually. These issues are addressed by the Machine Learning Operations (MLOps) paradigm. Moreover, according to the linked publications, there are no studies that concentrate on monitoring MLOps applications, especially those that rely on multi-container and microservices design. Therefore, this research proposed a model (MCM) which depends on the multi-container architecture and microservices principles that applied to the build and deploy stages of the application development lifecycle. The developed MCM model used to increase the number of software deployments across a variety of environments. Further the proposed MCM improved the software release performance and decreased the need for re-developing and re-deploying software applications. By utilizing MLOps, the suggested MCM model improves the software deployment cycles ratio by up to 24.55% and build duration cycles by up to 13%. This was useful in directing different IT teams towards the areas of monitoring ML model's features by using MLOps. Furthermore, the research recommended four routines for each layer of the suggested MCM model, described how each layer will be developed. As future work, more experimental work is also needed to assess the MLOps pipelines and see how they might affect the overall software development cycle. The MCM model needs to be implemented on different data sets and monitor its efficiency. More experiments to compare the performance of the MCM model algorithm against baseline approaches or alternative optimization strategies are needed.

***Abstract*—This scholarly investigation examines the utilization of artificial intelligence (AI) technology in the analysis and resolution of intricate societal challenges in many countries. The originality of this study resides in the employment of deep learning algorithms, particularly Convolutional Neural Network (CNN), to execute sentiment analysis with an elevated degree of complexity. The examination encompasses three principal dimensions of sentiment: Sentiment, Tone, and Object, with the intention of offering profound insights into public perceptions regarding various social challenges. The fundamental sentiment is categorized into three classifications: Positive, Neutral, and Negative. Moreover, the Tone analysis introduces an additional layer of comprehension that encompasses Support, Suggestion, Criticism, Complaint, and Others, thereby delineating a more precise communicative context. The Object dimension is employed to ascertain the target of the sentiment, whether it pertains to an Individual, Organization, Policy, or other entity. This inquiry applied the analysis to several clusters of social issues, including Poverty and Economic Disparity, Health and Wellbeing, Education and Literacy, Violence and Security, as well as Environment and Social Life. The findings are anticipated to aid the government in devising policies that are more effective and responsive to the exigencies of society, through an enhanced understanding of public sentiment.**

***Keywords*—Component; sentiment analysis; deep learning; artificial intelligence; social case**

I. INTRODUCTION

Sentiment analysis plays a critical role in understanding and quantifying the emotions or sentiments expressed in textual data, such as reviews, comments, and social media posts. It is an essential tool for businesses and organizations aiming to comprehend public opinion, improve customer service, and make data-driven decisions in product development and marketing strategies [10]. However, traditional sentiment analysis methods struggle with capturing the complexities of language, including sarcasm, ambiguous expressions, and nuanced opinions [1]. This limitation has led to a growing need for more sophisticated techniques to accurately analyze sentiment, especially when dealing with large volumes of unstructured data from sources like social media [7].

To address these challenges, recent research has increasingly employed deep learning models, which offer significant improvements over traditional methods in sentiment classification. Neural networks, particularly deep learning architectures such as capsule-based RNNs and Graph Convolutional Networks (GCNs), have shown remarkable success in handling complex textual data [6] [14]. These models not only enhance sentiment classification but also allow for the integration of multimodal data—such as text, audio, and visual cues—to capture deeper insights, especially in the case of complex emotions like sarcasm [8] [12]. Moreover, transfer learning techniques have been implemented to overcome data scarcity challenges, enabling models to be fine-tuned for smaller, domain-specific datasets [11] [16].

This study contributes to the field by employing Convolutional Neural Networks (CNNs), a deep learning methodology traditionally associated with image processing, for sentiment analysis [9]. CNNs have demonstrated effectiveness in analyzing text by treating it as spatial data, extracting local features, and offering a more straightforward yet efficient approach compared to other models [18]. By leveraging CNNs, this research aims to improve sentiment analysis performance, particularly in understanding nuanced social issues [20], and to provide more precise and actionable insights [21] [22].

In line with the abstract, this research focuses on three principal dimensions of sentiment analysis: Sentiment, Tone, and Object. Sentiment is categorized into three primary classifications—Positive, Neutral, and Negative—while Tone introduces additional layers of interpretation, including Support, Suggestion, Criticism, Complaint, and Other. The Object dimension further refines the analysis by identifying the target of the sentiment, such as an Individual, Organization, or Policy. This comprehensive approach enables a more detailed understanding of public perceptions regarding various social challenges.

Specifically, the research addresses key societal clusters such as Poverty and Economic Disparity, Health and Wellbeing, Education and Literacy, Violence and Security, and Environment and Social Life. The insights generated through this analysis are expected to support government agencies in developing policies that are more responsive to public sentiment and aligned with societal needs [23]. Through the integration of CNNs in sentiment analysis, this study offers a novel approach to addressing the limitations of traditional methods and aims to enhance decision-making processes by providing deeper insights into public opinion on critical social issues.

II. LITERATURE REVIEW

A. Sentiment Analysis

Sentiment analysis plays a crucial role in shaping social justice movements by providing insights into public opinion and

emotional responses [24]. By analyzing sentiments expressed on social media platforms, activists can better understand the dynamics of support and opposition [30], which can inform strategies for advocacy and mobilization [27].

Impact on Public Sentiment: Black Lives Matter Movement: A study utilizing a BERT model analyzed over one million tweets related to the BLM movement, revealing themes of social justice and police brutality [29]. Positive sentiments were linked to significant events, guiding activists in their messaging and outreach efforts [13]. Sentiment assessment, akin to employing BERT on Twitter datasets pertaining to Black Lives Matter, elucidates public sentiment regarding social justice initiatives, accentuating motifs and occurrences linked with affirmative or adverse sentiment [25]. The BERT model, meticulously adjusted for Twitter sentiment, surpassed alternative models in performance. Retweet and lexical count frequencies underscored significant BLM motifs/occurrences.

EndSARS Movement: The sentiment analysis of the #EndSARS protests in Nigeria highlighted eight basic emotions, providing insights into public sentiment that could inform governmental responses and future activism strategies [14]. Sentiment analysis, as demonstrated in the research concerning the EndSARS demonstration in Nigeria, facilitates the comprehension of collective sentiments, directing governmental reactions, and potentially mitigating social turbulence in forthcoming movements [26]. Recognized eight fundamental emotions articulated during the EndSARS demonstration. Suggested methodologies for the government to tackle subsequent activist movements.

Emotional Dynamics: Chinese Online Movements: Research indicates that emotions like anger and anxiety are pivotal in mobilizing online social movements [28]. Understanding these sentiments can help predict movement trajectories and prevent potential social unrest [15]. Sentiment evaluation in digital social movements, particularly concentrating on outrage and apprehension, facilitates comprehension of sentiment progression to avert societal calamities, augmenting the efficacy of social justice campaigns. The suggested BERT-based framework surpasses foundational models. A sentiment evaluation dataset for Chinese digital social movements has been established.

Broader Implications: Social Justice and Well-being: The correlation between feelings of social justice and subjective well-being suggests that sentiment analysis can also reflect broader societal perceptions, influencing public policy and community engagement [19]. The investigation examines the robust association between perceptions of social equity and subjective welfare, proposing that sentiments of justice within a community affect personal life contentment and well-being [31]. Welfare is impacted by financial resources, social connections, and perceptions of equity. Significant association between life contentment and societal justice interpretations.

While sentiment analysis offers valuable insights, it is essential to consider the potential for misinterpretation or manipulation of data, which can skew public perception and impact the effectiveness of social justice movements.

Previous CNN research related to sentiment analysis for social problems, Sentiment analysis using deep learning, particularly Convolutional Neural Networks (CNNs), has gained traction in addressing social issues through the analysis of public sentiment on platforms like Twitter and Reddit. This approach leverages advanced methodologies to extract meaningful insights from vast datasets, enhancing understanding of societal concerns [32].

Deep Learning Techniques in Sentiment Analysis: CNNs and RNNs: Recent studies highlight the effectiveness of CNNs and hybrid models like CRDC (Capsule with Deep CNN and Bi-structured RNN), achieving accuracy rates up to 98.02% in sentiment classification tasks [6] The manuscript presents an innovative hybrid methodology, CRDC, amalgamating Capsule, Deep CNN, and Bi-RNN for sentiment analysis, surpassing conventional CNN or RNN frameworks with elevated precision across diverse datasets. Although the Capsule-based RNN methodology exceeds the performance of CNN or RNN models, the CRDC model demonstrates exceptional efficacy in sentiment analysis.

LSTM Models: While CNNs are prominent, LSTM models have also shown significant results, with an 88.7% accuracy in analyzing sentiments regarding animal testing (Ismail, 2024). This document explores the realm of affective assessment utilizing Long Short-Term Memory (LSTM) networks rather than relying on Convolutional Neural Networks (CNN). It does not tackle the application of CNN in social contexts. A preponderance of tweets articulated adverse sentiment regarding animal experimentation. The LSTM architecture attained an accuracy of 88.7% in sentiment categorization.

Applications in Social Contexts: Crisis Response and Governance: AI/ML tools, including sentiment analysis, are utilized to gauge public opinion on governance issues, as demonstrated in a study analyzing 114,390 Reddit comments, achieving an accuracy of 89% with the SiEBERT model [8]. The manuscript centers on affective evaluation employing SiEBERT, a pre-trained transformer architecture, attaining 89% precision, signifying the efficacy of deep learning artificial intelligence in comprehending the apprehensions of citizens via social media sentiment assessment. BERTopic with K-means attained the utmost coherence rating.

Consumer Insights: Automated sentiment analysis models, such as ASASM-HHODL, have been developed to process social media data effectively, enhancing brand monitoring and customer feedback analysis [5]. The manuscript advocates for an Automated Sentiment Evaluation in Social Media (ASASM) employing Harris Hawks Optimization and Deep Learning (HHODL) methodologies, concentrating on Attention-oriented BiLSTM for sentiment categorization, without explicitly referencing CNN. The ASASM-HHODL framework surpasses contemporary sentiment analysis methodologies. Deep Learning models autonomously derive characteristics from datasets for sentiment evaluation.

While deep learning models, particularly CNNs, show promise in sentiment analysis, challenges remain in data preprocessing and model optimization, necessitating ongoing research to refine these techniques for broader applications.

How do Convolutional Neural Networks impact sentiment analysis?, Convolutional Neural Networks (CNNs) significantly enhance sentiment analysis by effectively capturing local patterns in text data, improving classification accuracy and interpretability. Their ability to process n-grams and semantic features allows for nuanced sentiment detection, as evidenced by various studies [33].

CNNs facilitate understanding of sentiment classification through the analysis of convolutional filters, revealing that certain parts of speech (POS) are more influential in determining sentiment polarity. The preference for shorter n-grams in negative sentiment classification highlights the model's focus on critical linguistic features [4]. CNNs impact sentiment analysis by revealing the relevance of certain parts of speech tags and the preference for shorter n-grams in classifying negative sentiment sequences, indicating the potential for smaller architectures.

Hybrid Models and Performance: Integrating CNNs with other architectures, such as BERT and BiLSTM, enhances the extraction of both local and global semantic features, achieving high accuracy rates (e.g., 92.35%) in sentiment classification tasks [2]. The analysis showcases a cutting-edge hybrid system that integrates two pathways in neural networks, employing an attention mechanism to expertly combine Convolutional Neural Networks (CNNs) and Bidirectional Long Short-Term Memory networks (BiLSTMs), hence significantly boosting sentiment analysis via the proficient acquisition of both local and global semantic elements. The suggested framework attains a sentiment classification accuracy of 92.35%. Moreover, the outlined system reaches an F1 score of 91.59% regarding sentiment classification.

Graph-based approaches, like hierarchical dual graph convolutional networks, further improve aspect-based sentiment analysis by effectively modeling syntactic and semantic dependencies [17]. Hierarchical dual graph convolutional network (HD-GCN) enhances sentiment analysis by extracting syntactic and semantic information, outperforming state-of-the-art models on ABSA tasks, as shown in the study.

While CNNs excel in sentiment analysis, their black-box nature raises concerns about interpretability and understanding of internal representations, which can hinder trust in automated systems [15]. Convolutional Neural Networks (CNNs) play a crucial role in sentiment analysis by extracting features from text data, enhancing sentiment classification accuracy, and addressing interpretability challenges in neural network models.

III. Research Method

A. Sentiment Aspects and the Labels

Sentiment aspect prediction refers to the process of identifying and categorizing various components of sentiment expressed within a text. It involves breaking down the text to determine not just the overall sentiment (positive, neutral, negative) but also other relevant aspects that give more context to the sentiment. Here's a breakdown of how predictions for each sentiment aspect typically work: Basic Sentiment: [Positive, Neutral, Negative], According to Pang and Lee (2008), basic sentiment analysis focuses on classifying text into these three main categories. This classification is a starting point in many sentiment analysis applications.

- *Positive*: Indicates a supportive or optimistic attitude toward the topic.
- *Neutral*: Indicates a neutral or impartial attitude.
- *Negative*: Indicates an opposing or pessimistic attitude toward the topic.

Furthermore, Tone: [Support, Suggestion, Criticism, Complaint, Others], According to Liu (2012), understanding tone in sentiment analysis provides deeper insights into how an entity or issue is perceived, not only from the polarity perspective but also from the communication context.

- *Support*: Text that shows approval or support for an issue or entity.
- *Suggestion*: Text that provides recommendations or solutions to a specific problem.
- *Criticism*: Text that expresses negative opinions or disagreement.
- *Complaint*: Text that conveys dissatisfaction or problems encountered.

Furthermore, Object: [Individual, Organization, Policy, Others]. According to Balahur et al. (2010), identifying the object in sentiment analysis helps understand the main target of the expressed sentiment, which is crucial in the context of social issues.

- *Individual*: Text referring to a person or a group of individuals.
- *Organization*: Text referring to organizational entities such as companies, institutions, or governments.
- *Policy*: Text referring to specific regulations, laws, or policies.

Furthermore, Cluster: [Poverty and Economic Inequality, Health and Well-being, Education and Literacy, Violence and Security, Environment and Social Life, Others], According to Cambria et al. (2013), clustering text based on topics or issues provides clearer context about the area of concern being analyzed, enabling deeper understanding and more targeted actions.

- *Poverty and Economic Inequality*: Text related to economic issues and social disparities.
- *Health and Well-being*: Text related to health issues, healthcare services, and social well-being.
- *Education and Literacy*: Text related to education systems, access to education, and literacy.
- *Violence and Security*: Text related to issues of violence, crime, and public security.
- *Environment and Social Life*: Text related to environmental issues and social interactions.

B. Data Collection

One essential parameter is Data Collection (see Fig. 1 and Fig. 2), Dataset that has been labeled for basic sentiment aspects

(Positive, Neutral, Negative). The dataset has been labeled for the Tone sentiment aspects (Support, Suggestions, Criticism, Complaints, Others).

```
import pandas as pd

data = {
 'text': [
  'I strongly support this program.',
  'This program should be improved.',
  'I am not satisfied with this service',
  'This service is very disappointing',
  'There is nothing special about this program'
 ],
 'label': ['Support', 'Suggestions', 'Criticism', 'Complaints', 'Other']
}

df = pd.DataFrame(data)
```

Fig. 1. Data Collection code 1.

```
import pandas as pd

data = {
 'text': [
  'I strongly support this program.',
  'This program should be improved.',
  'I am not satisfied with this service',
  'This service is very disappointing',
  'There is nothing special about this program'
 ],
 'label': ['Support', 'Suggestions', 'Criticism', 'Complaints', 'Other']
}

df = pd.DataFrame(data)
```

Fig. 2. Data Collection code 2.

Furthermore, The same method for the Tone aspect and basic sentiment is also applied to the Object sentiment aspects (Individual, Organization, Policy) and Cluster aspect (Poverty and Economic Inequality, Health and Well-being, Education and Literacy, Violence and Security, Environment and Social Life, Others).

C. Text Preprocessing

In this Text Preprocessing process there are several things that are done, namely Cleaning and preparing text data to be ready for analysis. And Steps. Steps consist of several parts, namely:

- Tokenization : Breaking down the text into smaller units, such as words or phrases. Example: "Poverty in this area is worsening due to economic inequality" -> ["Poverty", "in", "this", "area", "is", "worsening", "due", "to", "economic", "inequality"]
- Punctuation Removal: Removing unnecessary punctuation marks. Example: ["Poverty", "in", "this", "area", "is", "worsening", "due", "to", "economic", "inequality"]
- Stop Words Removal: Removing common words that do not carry significant meaning, such as "and," "or," "is." Example: ["Poverty", "area", "worsening", "due", "economic", "inequality"]
- Stemming or Lemmatization : Converting words to their base form.Example: ["Poverty", "area", "worsen", "due", "economic","inequality"]

D. Feature Extraction

Furthermore, Feature Extraction: Identifying and extracting important features from the text that will be used for classification. Steps: Using Term Frequency-Inverse Document Frequency (TF-IDF) to Calculate the importance of a word in a document compared to the entire corpus. Example: ["Poverty", "area", "worsening", "inequality", "economic"] -> [0.2, 0, 0.4, ..., 0.3, 0.5]

E. Model Development Using CNN

Training a machine learning or deep learning model to recognize cluster patterns in the text. Steps:

- Training the model using a Convolutional Neural Networks (CNN) architecture to recognize cluster patterns in the text.
- Training the model using data labeled.
- Model Validation: Evaluating the model using validation data to ensure its performance.

F. Prediction for Each Sentiment Aspect

Load the trained model: This step involves loading a pre-trained machine learning or deep learning model that has been specifically trained to analyze sentiment aspects. The model is typically saved in a file after training and can be loaded using various libraries such as TensorFlow or PyTorch. Loading the trained model allows us to utilize its learned parameters and weights for predicting sentiment aspects in new text data.

Make cluster predictions: Once the trained model is loaded, it can be used to make predictions on new, unseen data. This step involves feeding the input text data into the model to predict the specific clusters or categories of sentiment aspects. The output will indicate which sentiment cluster the text belongs to, such as "Poverty and Economic Inequality," "Health and Well-being," or other predefined clusters.

G. Evaluation and Validation

Evaluating the performance of the model using metrics such as accuracy, precision, recall, and F1-score. Steps:

- Confusion Matrix : Analyzing the model's prediction errors.
- Cross-validation: Performing cross-validation to ensure the model is not overfitting.

IV. Result and Discussion

A. Text Preprocessing

The implementation of the algorithm in the methodology section is implemented using the Python programming language with the necessary libraries such as TensorFlow.Text Preprocessing: For as example, in the following text as data input: 'This program aims to reduce poverty and improve community welfare.' Steps: Tokenization (see Fig. 3), Breaking down the text into smaller units, such as words or phrases. Fig. 4 shows text processing code.

```
from tensorflow.keras.preprocessing.text import Tokenizer
from tensorflow.keras.preprocessing.sequence import pad_sequences
from sklearn.preprocessing import LabelEncoder

# Tokenisasi teks
tokenizer = Tokenizer(num_words=5000)
tokenizer.fit_on_texts(df['text'])
sequences = tokenizer.texts_to_sequences(df['text'])

# Padding sequences
max_length = 50
padded_sequences = pad_sequences(sequences, maxlen=max_length)

# Encode label
label_encoder = LabelEncoder()
labels = label_encoder.fit_transform(df['label'])
```

Fig. 3. Tokenization code.

output: {'program': 1, 'aim': 2, 'reduce': 3, 'poverty': 4, 'improve': 5, 'community': 6, 'welfare': 7}

Punctuation Removal, Removing unnecessary punctuation marks.

Output: ["This", "program", "aims", "to", " reduce", " poverty", " and", " improve", " community", "welfare"]

Stop Words Removal, Removing common words that do not carry significant meaning, such as "and," "or," "is."

Output: ["program", " aims", " reduce", " poverty", " improve", " community", "welfare"]

Stemming or Lemmatization, Converting words to their base form.

Output: ["program", "aim", "reduce", "poverty", "improve", "community","welfare"]

```
import nltk
from nltk.corpus import stopwords
from nltk.tokenize import word_tokenize
from nltk.stem import WordNetLemmatizer
import string

# Inisialisasi NLTK
nltk.download('punkt')
nltk.download('stopwords')
nltk.download('wordnet')

def preprocess_text(text):
    # Tokenisasi
    tokens = word_tokenize(text)
    # Penghapusan tanda baca
    tokens = [word for word in tokens if word.isalpha()]
    # Penghapusan stop words
    stop_words = set(stopwords.words(english))
    tokens = [word for word in tokens if word.lower() not in stop_words]
    # Lemmatization
    lemmatizer = WordNetLemmatizer()
    tokens = [lemmatizer.lemmatize(word) for word in tokens]
    return tokens

processed_text = preprocess_text(input_text)
print(processed_text)
```

Fig. 4. Text Processing code.

B. Feature Extraction

Feature Extraction Using TF-IDF to represent text in a numerical format: Sequence Representation: The processed_text is converted into a sequence based on the word index.

```
output: [[1, 2, 3, 4, 5, 6, 7]]
```

Padded Sequence: The sequence is padded to the specified max_length of 100. Since the original sequence has only 7 tokens, the rest are padded with zeros.

```
output: [[1, 2, 3, 4, 5, 6, 7, 0, 0, 0, ..., 0]]
```

C. Model Development Using CNN

For each element of the sentiment aspect, including basic sentiment, tone, object and social problem clusters, the following are the settings for the function *model.add(Dense(…, activation='softmax'))*:

- Basic sentimen (Positive, Neutral, Negative) = *model.add(Dense(3, activation='softmax'))*
- Tone sentimen (Support, Suggestion, Criticism, Complaint, Others) = *model.add(Dense(5, activation='softmax'))*
- Object sentimen (Individual, Organization, Policy) = *model.add(Dense(3, activation='softmax'))*
- Cluster sentimen (Poverty and Economic Inequality, Health and Well-being, Education and Literacy, Violence and Security, Environment and Social Life) = *model.add(Dense(5, activation='softmax'))*

D. Model Training

This Model Training have a two analysis, split the data and process the training model by training and validating the data. Split the data into training data and validation data (e.g., 80% for training and 20% for validation). Fig. 5 shows the training test code.

```
from sklearn.model_selection import train_test_split X_train, X_val,
y_train, y_val = train_test_split(X, y, test_size=0.2, random_state=42)
```

Fig. 5. Training test code.

Furthermore, The process of training the model using training and validation data. Fig. 6 shows the validation data code.

```
history = model.fit(X_train, y_train, epochs=10, batch_size=32,
validation_data=(X_val, y_val))
```

Fig. 6. Validation data code.

Moreover, Model Evaluation and Validation Using metrics such as Confusion Matrix, Precision, Recall, and F1-Score (see Fig. 7).

```
from sklearn.metrics import classification_report, confusion_matrix
y_pred = model.predict(X_val)
y_pred_classes = np.argmax(y_pred, axis=1)
y_true = np.argmax(y_val, axis=1)

print(confusion_matrix(y_true, y_pred_classes))
print(classification_report(y_true, y_pred_classes))
```

Fig. 7. Confusion Matrix code.

Furthermore, Result for each sentimen aspect among others Prediction of Object Sentiment Aspect Clusters. The model generates predictions of Object sentiment aspect clusters (Individuals, Organizations, Policies, Others) based on learned

patterns. Output: text: This program aims to reduce poverty and improve community welfare. Cluster/sentimen aspect Prediction: Policy.

Evaluation Model:

- Loss and Accuracy : Validation Loss: 0.4321
- Validation Accuracy : 0.8725
- Confusion Matrix :

$$\begin{bmatrix} 120 & 10 & 5 \\ 12 & 110 & 8 \\ 3 & 7 & 115 \end{bmatrix}$$

E. Classification Report Output

In the Classification Report, Table I shows the results of Classification such as Precision, Recall, F1-Score, and Support, from the parameters Individual, Organization, Policy, Accuracy, Macro AVG, and Weighted AVG.

TABLE I. CLASSIFICATION REPORT OUTPUT 1

Parameters	Classification Parameters			
	Precision	***Recall***	***F1-Score***	***Support***
Individuals	0.88	0.88	0.88	135
Organization	0.86	0.82	0.84	130
Policy	0.89	0.91	0.9	125
Accuracy			0.87	390
Macro AVG	0.87	0.87	0.87	390
Weighted AVG	0.87	0.87	0.87	390

Explanation of Table I:

1) Precision:

a) For individuals: 88% of predicted "Individual" cases were correct.

b) For organization: 86% of predicted "Organization" cases were correct.

c) For policy: 89% of predicted "Policy" cases were correct.

2) Recall:

a) For individuals: The model correctly identified 88% of all true "Individual" cases.

b) For organization: The model correctly identified 82% of all true "Organization" cases.

c) For policy: The model correctly identified 91% of all true "Policy" cases.

3) F1-Score:

a) For individuals: The F1-score is 0.88, indicating balanced precision and recall.

b) For organization: The F1-score is 0.84, slightly lower due to the recall being lower than precision.

c) For policy: The F1-score is 0.90, indicating strong performance in both precision and recall.

4) Support: The number of true instances for each category in the dataset. The model evaluated 135 instances for Individuals, 130 for Organization, and 125 for Policy.

- Overall Performance:

a) Accuracy: The overall accuracy of the model is 87%, meaning that 87% of all classifications were correct.

b) Macro AVG (Macro Average): The unweighted mean of precision, recall, and F1-score across all categories, indicating how the model performs equally across categories. In this case, the scores for precision, recall, and F1-score are all 0.87.

c) Weighted AVG (Weighted Average): The average of precision, recall, and F1-score, weighted by the number of instances (support) in each class. The weighted averages are also 0.87, meaning the model maintains similar performance when taking into account the distribution of instances.

- Summary:

The classification report shows that the model performs well across all categories, with an overall accuracy of 87%. The Policy category has the best performance with a higher F1-score, while the Organization category has a slightly lower recall.

F. Prediction of Tone Sentiment Aspect

The model generates predictions of Tone sentiment aspect clusters (Support, Suggestion, Criticism, Complaint) based on learned patterns

Output: `Text: This program aims to reduce poverty and improve community welfare.`

Predicted Tone: Support

Evaluation Model

Loss and Accuracy:

```
Validation Loss: 0.7241
Validation Accuracy: 0.85245
```

Confusion Matrix:

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

Moreover, the Classification Report Output can be seen in Table II.

TABLE II. CLASSIFICATION REPORT OUTPUT 2

Parameters	Classification Parameters			
	Precision	***Recall***	***F1-Score***	***Support***
Support	1.00	1.00	1.00	1
Advice	1.00	1.00	1.00	1
Critique	1.00	1.00	1.00	1
Complaint	1.00	1.00	1.00	1
More	1.00	1.00	1.00	1

Parameters	Classification Parameters			
	Precision	***Recall***	***F1-Score***	***Support***
Accuracy	1.00	1.00	1.00	5
Macro AVG	1.00	1.00	1.00	5
Weighted AVG	1.00	1.00	1.00	5

Explanation of Table II:

1) Precision: For Support, Advice, Critique, Complaint, and More, the precision is 1.00, indicating that all predictions made for each class were correct.

2) Recall: For all categories, the recall is 1.00, meaning the model identified all true instances for each category perfectly.

3) F1-Score: For all categories, the F1-score is 1.00, showing that the model performed perfectly across all classes.

4) Support: Each category has a support of 1, meaning the model was tested with only one instance per class.

- Overall Performance:

a) Accuracy: The model achieved perfect accuracy, as all predictions made were correct.

b) Macro AVG (Macro Average): The unweighted average of precision, recall, and F1-score across all classes. Since every class has perfect performance, the macro averages are all 1.00.

c) Weighted AVG (Weighted Average): Similar to the macro average but weighted by the number of instances in each class. Given that each class has only one instance, the weighted average is also 1.00.

- Summary:

This classification report shows perfect model performance across all categories (Support, Advice, Critique, Complaint, and More) with an accuracy, precision, recall, and F1-score of 1.00. However, the very small dataset (only one instance per class) suggests that this result may not generalize well, as testing with more instances would provide a more realistic assessment of model performance.

G. Prediction of Basic Sentiment Aspect

The model generates predictions of basic sentiment aspect (Positive, Neutral, Negative) based on learned patterns (Fig. 8).

```
from tensorflow.keras.models import load_model

# Memuat model yang sudah dilatih
model = load_model('model_object_cluster_cnn.h5')

prediction = model.predict(padded_sequences)
cluster = np.argmax(prediction, axis=1)
cluster_labels = ['Positive,Neutral, Negative']

predicted_cluster = cluster_labels[cluster[0]]
```

Fig. 8. Prediction of basic sentiment aspect code.

```
Output:
Text: This program aims to reduce poverty and improve community welfare.
Predicted Tone: Positive
```

Evaluation Model:

- Loss and Accuracy:

```
Validation Loss: 0.7321
Validation Accuracy: 0.88245
```

- Confusion Matrix:

$$\begin{bmatrix} 2 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

- Classification Report Output

TABLE III. CLASSIFICATION REPORT OUTPUT 3

Parameters	Classification Parameters			
	Precision	***Recall***	***F1-Score***	***Support***
Negative	1.00	1.00	1.00	2
Neutral	1.00	1.00	1.00	2
Positive	1.00	1.00	1.00	1
Accuracy			1.00	4
Macro AVG	1.00	1.00	1.00	4
Weighted AVG	1.00	1.00	1.00	4

Explanation of Table III:

1) Precision: For Negative, Neutral, and Positive, the precision is 1.00, meaning that all the predictions for each of these sentiment categories were accurate.

2) Recall: For all three categories, the recall is 1.00, showing that the model identified all the true instances of Negative, Neutral, and Positive sentiments without missing any.

3) F1-Score: Since both precision and recall are perfect (1.00) for each class, the F1-score is also 1.00 for all sentiment categories.

4) Support: There were two instances for both Negative and Neutral, and 1 instance for Positive.

- Overall Performance:

a) Accuracy: The overall accuracy is 1.00, meaning the model made correct predictions for all 4 instances in the test dataset.

b) Macro AVG (Macro Average): This is the unweighted average of precision, recall, and F1-score across all sentiment classes. Since every class has perfect scores, the macro average is 1.00.

c) Weighted AVG (Weighted Average): This is the weighted average of precision, recall, and F1-score, taking into account the number of instances in each class. As all classes have a perfect performance, the weighted average is also 1.00.

- Summary:

This classification report reflects perfect model performance for all three sentiment classes (Negative, Neutral, and Positive).

The model achieved an accuracy, precision, recall, and F1-score of 1.00 across the board.

V. CONCLUSION

The Confusion Matrix shows that the model has good performance, with an overall accuracy of around 88.46%. The precision, recall, and F1-score for each class are also quite high, indicating that the model can effectively classify text into the categories of Individual, Organization, or Policy. These results demonstrate that the trained CNN model is quite effective in recognizing sentiment aspect patterns in the text. Additionally, the validation loss and accuracy metrics further support the effectiveness of the model. For the implementation of the CNN model on basic sentiment analysis, the validation loss is 0.7321, with an accuracy of 0.8825. Meanwhile, for the implementation on Tone Sentiment Aspect, the validation loss is 0.7241, and the accuracy is 0.8524. These findings emphasize that building a CNN model for sentiment prediction from the perspectives of basic sentiment, object, tone, and social cluster yields good results and proves to be effective in enhancing the sentiment analysis process. This capability makes the CNN model a valuable tool in accurately identifying and classifying various sentiment aspects, thus supporting comprehensive sentiment analysis across different contexts. The findings are expected to assist the government in formulating policies that are more effective and responsive to society's needs, by providing a deeper understanding of public sentiment. This enhanced capability for accurately identifying and classifying various sentiment aspects enables policymakers to better gauge the opinions and concerns of the public, thereby allowing for more targeted and informed decision-making.

As additional data that all applications or Implementation on web scraper applications can be accessed on the following web pages on Fig. 9:

A. *Testing 1*

Testing Evaluation

a) Data sets result: This section presents the results of applying the text processing algorithm in Fig. 3 and Fig. 4, specifically for Punctuation Removal, which involves removing unnecessary punctuation marks. The Fig. 10 represented the dataset output is in JSON format and is displayed on the web for testing 1.

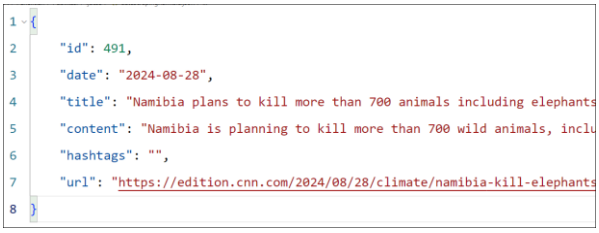

Fig. 10. The dataset output is in JSON format for testing 1.

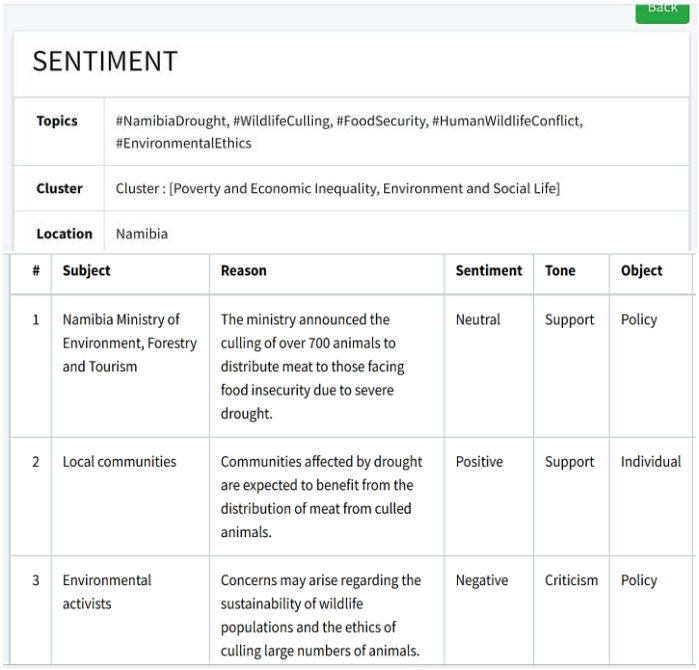
b) Outcomes analysis result:



#	Subject	Reason	Sentiment	Tone	Object
1	Namibia Ministry of Environment, Forestry and Tourism	The ministry announced the culling of over 700 animals to distribute meat to those facing food insecurity due to severe drought.	Neutral	Support	Policy
2	Local communities	Communities affected by drought are expected to benefit from the distribution of meat from culled animals.	Positive	Support	Individual
3	Environmental activists	Concerns may arise regarding the sustainability of wildlife populations and the ethics of culling large numbers of animals.	Negative	Criticism	Policy

Fig. 11. Sentiment analysis results for testing 1.

The sentiment analysis and clustering of topics which is shown on Fig. 11 are accurately aligned with the context of the news. The issues surrounding #NamibiaDrought, #WildlifeCulling, #FoodSecurity, #HumanWildlifeConflict, and #EnvironmentalEthics are appropriately categorized under the clusters Poverty and Economic Inequality and Environment and Social Life, reflecting both the social and environmental dimensions of the situation in Namibia.

The sentiment analysis also correctly reflects the perspectives of different stakeholders:

1. Namibia Ministry of Environment, Forestry, and Tourism is assessed with a Neutral sentiment and Support tone, as the policy of culling animals to address food insecurity is seen as a practical measure.

2. Local communities impacted by drought are viewed positively, with a Support tone, as they benefit from the distribution of meat, an individual-level impact.

3. Environmental activists, expressing concern over the ethical and sustainability aspects of the culling policy, are assigned a Negative sentiment with a Criticism tone, correctly representing opposition to the policy.

This analysis appropriately captures the nuanced reactions to the situation in Namibia.

B. *Testing 2*

News URL

https://www.bbc.com/news/articles/c97w1x2deyvo

1) Data sets result: The Fig. 12 represented the dataset output is in JSON format and is displayed on the web for testing 2.

```
{
    "id": 493,
    "date": "2024-09-01",
    "title": "Illegal visa network making millions fleecing students",
    "content": "A global network has fleeced students out of tens of thousands
    "hashtags": "",
    "url": "https://www.bbc.com/news/articles/c97w1x2deyvo"
}
```

Fig. 12. The dataset output is in JSON format for testing 2.

2) Outcomes analysis result:

≡

SENTIMENT

Topics	#VisaFraud, #StudentExploitation, #UKImmigration, #CommunitySupport, #GovernmentPolicy
Cluster	Cluster : [Poverty and Economic Inequality, Health and Welfare]
Location	United Kingdom

#	Subject	Reason	Sentiment	Tone	Object
1	Taimoor Raza	Sold worthless visa documents to students, claiming they would enable employment in the UK.	Negative	Criticism	Individual
2	Students	Lost significant amounts of money and faced rejection of their visa applications due to invalid documents.	Negative	Complaint	Individual
3	Monty Singh and Sikh Advice Centre	Helped recover money for victims and raised awareness about the fraudulent activities.	Positive	Support	Organization

Fig. 13. Sentiment analysis results for testing 2.

The sentiment analysis and clustering of topics which is shown on Fig. 13 are accurately aligned with the context of the news, reflecting the key issues surrounding #VisaFraud, #StudentExploitation, #UKImmigration, #CommunitySupport, and #GovernmentPolicy in the United Kingdom. The topics are correctly categorized under the clusters Poverty and Economic Inequality and Health and Welfare, as they pertain to the financial exploitation of students and the efforts to provide community support.

The sentiment analysis is well-suited to the context:

1. Taimoor Raza, who sold fraudulent visa documents to students, is appropriately assessed with a Negative sentiment and a Criticism tone, as his actions resulted in harm to individuals.

2. The students, who suffered financial loss and visa rejection due to the scam, are given a Negative sentiment with a Complaint tone, representing their victimization and dissatisfaction.

3. Monty Singh and the Sikh Advice Centre, who supported the victims by helping them recover their money and raising awareness about the fraud, are appropriately assigned a Positive sentiment and Support tone, highlighting their positive role in addressing the situation.

This analysis effectively captures the different perspectives and reactions to the fraudulent visa scheme.

C. *Testing 3*

News URL:

https://www.bbc.com/news/articles/cze5x793569o

1) Data sets result: Fig. 14 represents the dataset output is in JSON format and is displayed on the web for testing 3.

```
{
    "id": 498,
    "date": "2024-09-01",
    "title": "Tens of thousands rally in Israel calling for hostage release deal",
    "content": "Tens of thousands of people have rallied across Israel after the bod
    "hashtags": "",
    "url": "https://www.bbc.com/news/articles/cze5x793569o"
}
```

Fig. 14. The dataset output is in JSON format for testing 3.

2) Outcomes analysis result: The sentiment analysis and clustering for the topics of #IsraelProtests, #HostageCrisis, #GovernmentAccountability, #PublicOutcry, and #GeneralStrike which is shown on Fig. 15 are highly appropriate, reflecting the Violence and Security cluster in the context of ongoing protests and government responses in Israel.

The sentiment analysis aligns well with the specific subjects:

1. Eli Shtivi, whose son is held hostage, expresses urgency and criticism toward government policy. The Negative sentiment and Criticism tone are fitting, given his frustration over the lack of action.

2. Naama Lazimi, a lawmaker injured in the protests, adopts a Neutral sentiment with a Suggestion tone as she reflects on the significance of the protests while questioning future governmental actions, making the sentiment and tone assessment appropriate.

3. Arnon Bar-David, advocating for a general strike, displays Positive sentiment and Support for government policy reform, focusing on pressuring the government into negotiations. This reflects the proactive and supportive stance towards achieving a resolution.

SENTIMENT

Topics	#IsraelProtests, #HostageCrisis, #GovernmentAccountability, #PublicOutcry, #GeneralStrike
Cluster	Cluster : [Violence and Security]
Location	Israel

#	Subject	Reason	Sentiment	Tone	Object
1	Eli Shtivi	Eli Shtivi, whose son Idan is being held hostage in Gaza, expressed urgency and desperation for government action to secure the release of hostages.	Negative	Criticism	Policy
2	Naama Lazimi	Naama Lazimi, a Labor Party lawmaker, was lightly injured during the protests and emphasized the significance of the protests but questioned the future actions.	Neutral	Suggestion	Policy
3	Arnon Bar-David	"We must reach a deal. A deal is more important than anything else," said Arnon Bar-David, calling for a general strike to pressure the government into making a	Positive	Support	Policy

Fig. 15. Sentiment analysis results for testing 3.

Overall, the clustering and sentiment analysis accurately capture the complexity of the emotions and actions tied to the protests and government accountability, making it consistent with the context of the news

ACKNOWLEDGMENT

This research titled "Deep Learning Approach in Complex Sentiment Analysis: A Case Study on Social Problems" was made possible through the support of The Ministry of Research, Technology, and Higher Education (Ristekdikti) of the Government of Indonesia under the 2024 Basic Research Grant Scheme for Higher Education. We would also like to extend our sincere gratitude to LPPM Universitas Merdeka Malang for their valuable assistance and support throughout this study. Without their funding and encouragement, this work would not have been possible.

Evaluating the Effectiveness of the Binary PSO Method in Feature Selection to Improve the Detection of Android Botnets

Peng WANG*, Zhijun WANG
College of Mathematics and Computer Science, Chifeng College, Chifeng 024000, China

***Abstract*—Android botnets endanger the security and privacy of mobile devices by doing harmful actions such as sending spam, taking data, and starting distributed denial-of-service (DDoS) attacks. Detecting Android botnets is a challenging task, as they often use sophisticated techniques to evade traditional detection methods. This paper uses the Binary PSO (BPSO) algorithm to select the important features of the Android botnet, and then adjusts the training and testing datasets accordingly, discarding the irrelevant features. Then, with the help of BPSO-SVM and BPSO-DT approaches, Android botnets are identified with high accuracy, and ten key features used to identify Android botnets are introduced. The results obtained from the approaches in question show an accuracy higher than 97% in identifying this type of malware.**

***Keywords*—Android botnet; botnet; binary PSO; SVM; decision tree; BPSO-SVM; BPSO-DT**

I. Introduction

The rapid development and widespread adoption of mobile devices, especially smartphones, have revolutionized the way people communicate, work, learn, and entertain. Statista reported that the global smartphone users were about 3.8 billion in 2021, and they predicted that this number would increase to 4.3 billion by 2023 [1]. Among the various operating systems for smartphones, Android is the most dominant one, with a market share of 72.2% in 2020 [2]. Android is an open-source platform that allows developers to create various applications for different purposes and users to customize their devices according to their preferences.

However, the popularity and openness of Android also make it a lucrative target for cybercriminals, who seek to exploit the vulnerabilities of the system and the applications to compromise the devices and perform malicious activities. One of the most severe and sophisticated threats facing Android users is the mobile botnet, which is a network of infected devices that can be remotely controlled by a botmaster to execute malicious commands. A mobile botnet can be used for various malicious purposes, such as stealing personal information, sending spam messages, launching distributed denial-of-service (DDoS) attacks, mining cryptocurrencies, and more. The impact of a mobile botnet can be devastating, not only for the individual users, but also for the network operators, service providers, and the society at large. For example, in 2016, the Mirai botnet infected over 600,000 IoT devices, including Android smartphones, and launched massive DDoS attacks against several websites, such as Twitter, Netflix, and Reddit, causing significant disruption and financial losses [3].

The main challenge in detecting and preventing mobile botnets is the diversity and complexity of the techniques used by the attackers [4]. Mobile botnets can employ various methods to infect devices, such as malicious applications, phishing links, drive-by downloads, and exploit kits. Moreover, mobile botnets can use different communication channels to receive commands and send data, such as SMS, HTTP, peer-to-peer (P2P), and social networks [5]. Furthermore, mobile botnets can adopt different topologies to organize the devices, such as centralized, decentralized, or hybrid. These factors make it difficult to identify and analyze the behavior and structure of mobile botnets and to design effective countermeasures against them.

The paper is structured as follows. Section II gives some background knowledge on the mobile botnet, SVM, and DT concept. Section III shows the classification and analysis of the Android mobile botnet methods based on the BPSO-SVM and BPSO-DT. Section IV presents the simulation of the results. Section V ends the paper and highlights the main results.

II. Related Works

In this section, we review the existing literature on mobile botnets based on the Android operating system. We classify the literature according to three dimensions: infection, command and control (C&C), and topology. For each dimension, we discuss the main techniques, challenges, and limitations of current research.

A. Infection

The infection dimension refers to the methods used by the attackers to compromise the Android devices and install the botnet malware on them. The infection methods can be categorized into two types: active and passive [5].

Active infection methods require the user's interaction or consent to install the malware, such as downloading and running a malicious application, clicking on a phishing link, or granting excessive permissions to a seemingly benign application. Passive infection methods do not require the user's interaction or consent, such as exploiting a vulnerability in the system or an application or using a drive-by download technique.

The majority of existing research on Android mobile botnet infection focuses on the active methods, especially the malicious applications. Several studies have proposed various techniques to detect and analyze malicious applications, such as static

analysis, dynamic analysis, hybrid analysis, machine learning, and deep learning [6]. However, these techniques face several challenges, such as code obfuscation, encryption, dynamic loading, evasion, and stealthiness that make the detection and analysis of malicious applications difficult and time-consuming.

The passive infection methods are less studied in the literature, but they pose a serious threat to Android devices, as they can exploit the vulnerabilities that exist in the system or the applications, and install the malware without the user's knowledge or consent [4]. Some examples of the passive infection methods are the Stagefright exploit, which can execute an arbitrary code on the device by sending a specially crafted multimedia message, the Cloak and Dagger attack, which can perform malicious actions on the device by abusing the Android permissions system, and the Man-in-the-Disk attack, which can compromise the device by manipulating the external storage.

B. Command and Control (C&C)

The C&C dimension refers to the communication channels used by the botmaster to send commands to the bots and receive data from them. The C&C channels can be categorized into two types: centralized and decentralized [7, 8].

Centralized C&C channels rely on a single server or a group of servers to communicate with the bots. The botmaster can easily manage the bots and coordinate their activities through the centralized server. However, this also makes the botnet vulnerable to detection and disruption, as the server can be identified and blocked by the defenders. SMS, HTTP, and email are some of the centralized communication methods that the C&C server uses to control the bots [9].

Decentralized C&C channels do not rely on a single server, but use a distributed network of peers to communicate with the bots [9]. The botmaster can send commands to a subset of the bots, and the commands can propagate to the rest of the bots through the peer-to-peer network. This makes the botnet more resilient to detection and disruption, as there is no single point of failure. However, this also makes the botnet management and coordination more complex and challenging. Some examples of decentralized C&C channels are P2P, social networks, and blockchain.

C. Topology

The topology dimension refers to the structure and organization of the bots in the botnet. Topology can affect the performance, scalability, and robustness of the botnet. The topology can be categorized into three types: centralized, decentralized, and hybrid [10].

Centralized topology has a star-shaped structure, where the bots are directly connected to the central server [11]. The botmaster can manipulate the bots with ease through the server, which serves as the C&C channel. However, this topology has low scalability and robustness, as the server can be a bottleneck and a single point of failure.

Decentralized topology has a mesh-shaped structure, where the bots are connected in a peer-to-peer network. The C&C channel is a peer-to-peer network, and the botmaster can communicate with the bots via any peer [12]. This topology has high scalability and robustness, as the botnet can grow and survive without relying on a central server.

Hybrid topology has a combination of star-shaped and mesh-shaped structures, where the bots are divided into clusters, and each cluster has a leader that is connected to the central server [11]. The server and the cluster leaders are the command and control channels, and the botmaster can talk to the bots using the server or the cluster leaders. This topology has moderate scalability and robustness, as it balances the advantages and disadvantages of the centralized and decentralized topologies.

D. Support Vector Machine (SVM)

SVM is a machine learning technique that can perform classification and regression by discovering the optimal hyperplane that separates the data into distinct classes or predicts output values. SVM has many benefits, such as high precision, resistance to noise and outliers, and sparseness of the solution. However, SVM also faces some challenges, such as choosing the appropriate kernel function, dealing with large-scale and imbalanced data, and incorporating prior knowledge and domain-specific constraints. Therefore, many researchers have proposed various extensions and improvements to the standard SVM formulation, such as kernel selection, ensemble methods, fuzzy SVM, semi-supervised SVM, and constrained SVM.

Some of the recent researches that discuss these extensions and improvements are:

This research [13] reviews the existing methods for kernel selection in SVM, which can be divided into three categories: data-dependent, model-dependent, and hybrid. The study also proposes a new hybrid method that combines the advantages of data-dependent and model-dependent methods. The study assesses how well various kernel selection methods work on some benchmark datasets and demonstrates that the suggested method can attain higher accuracy and stability than the current methods.

This research [14] addresses the problem of imbalanced data classification, where the number of instances in different classes is significantly different. The study proposes a novel ensemble method that combines SVM with random subspace and bagging techniques. The study shows that the proposed method can effectively handle imbalanced data by creating diverse and balanced base classifiers and combining them with a weighted voting scheme. The study compares the proposed method with other state-of-the-art methods on several imbalanced datasets and demonstrates its superiority in terms of accuracy and robustness.

This research [15] deals with the problem of outliers, which are data points that deviate significantly from the normal distribution of the data. The study proposes a fuzzy SVM method that can handle outliers by introducing a fuzzy membership function that assigns different weights to different data points according to their degree of belonging to the classes. The study shows that the proposed method can improve the performance of SVM by reducing the influence of outliers and enhancing the generalization ability. The study tests the proposed method on several datasets with different levels of outliers and shows its effectiveness and efficiency.

E. Decision Tree (DT)

Decision trees are graphical models that can perform classification and regression tasks by splitting the data into smaller subsets based on some criteria. Decision trees are easy to understand, interpret, and visualize, as they mimic the human decision-making process. However, decision trees also have some drawbacks, such as overfitting, instability, sensitivity to noise, and missing values. Therefore, many researchers have proposed various techniques to improve the quality and robustness of decision trees, such as pruning, ensemble methods, fuzzy logic, and evolutionary algorithms.

Some of the recent researches that discuss these techniques are:

This research [16] reviews the existing methods for decision tree pruning, which is a technique to reduce the size and complexity of decision trees by removing unnecessary or redundant nodes. The study categorizes the pruning methods into two types: pre-pruning and post-pruning. The study also compares the advantages and disadvantages of different pruning methods and provides some guidelines for choosing the best pruning method for a given problem.

This research [17] describes the concept and applications of ensemble methods, which are techniques to combine multiple decision trees to improve the accuracy and diversity of predictions. The study covers topics such as bagging, boosting, random forests, and stacking. The study also discusses the challenges and future directions of ensemble methods for data mining.

This research [18] presents a comprehensive review of fuzzy decision trees, which are extensions of decision trees that can handle uncertainty and vagueness in the data by using fuzzy sets and fuzzy logic. The study covers topics such as fuzzy entropy, fuzzy impurity, fuzzy information gain, fuzzy splitting criteria, and fuzzy pruning. The study also compares the performance of fuzzy decision trees with crisp decision trees and other fuzzy classifiers on several benchmark datasets.

F. Post-Quantum Cryptography (PQC)

In recent years, post-quantum cryptography (PQC) has attracted considerable interest due to the potential risks quantum computers pose to traditional cryptographic systems. Numerous studies have delved into various aspects of PQC, focusing on algorithm development, performance enhancement, and practical application.

Liu et al. (2024) conducted an extensive survey on the performance and optimization of post-quantum cryptographic algorithms for the Internet of Things (IoT) [19]. Their research underscores the challenges and solutions in incorporating PQC into IoT devices, highlighting the necessity for lightweight and efficient algorithms to maintain security without sacrificing performance.

Another notable contribution is the survey by Ramachandran et al. (2022), which offers a comprehensive overview of lattice-based cryptographic algorithms [20]. This study examines the resilience of lattice-based methods against quantum attacks and their suitability for various cryptographic protocols. The authors also compare different lattice-based schemes, providing insights into their respective strengths and weaknesses.

In a broader scope, Jurdak et al. (2023) reviewed the current state of PQC, including an in-depth analysis of the most prevalent methods such as lattice-based, code-based, and multivariate polynomial cryptography [21]. The paper also discusses the implementation status of these methods and future research directions.

Furthermore, recent advancements in cryptographic accelerators for PQC have been documented by several researchers [19]. These studies focus on hardware implementations that can meet the computational demands of PQC algorithms, thereby enhancing their practicality for real-world applications.

Overall, the research on post-quantum cryptography is rapidly growing, with significant advancements being made in both theoretical and practical areas. Ongoing research is crucial to develop robust, efficient, and scalable cryptographic solutions capable of withstanding the emergence of quantum computing.

III. Presented Approach

In this study, we identify Android botnets and the purpose of this study is to remove inefficient features from training and testing datasets of Android botnets. Android botnets can obfuscate and encrypt the traffic sent to the botmaster, and this causes the identification of Android botnets to be associated with many challenges. Considering this issue, it can be acknowledged that the features extracted from the traffic of botnets can have ambiguous and incorrect values, which causes the wrong training of the learning model. But among the extracted features, there are several features that only by using them in machine learning approaches, the trained model can identify Android botnets with high accuracy. Therefore, the question arises as to how to identify the mentioned features from the dataset obtained from Android botnets and exclude other inefficient features from the dataset so that they can be trained in the best conditions with the help of effective features of machine learning approaches. To answer the stated question, in the next section, the Binary Particle Swarm Optimization (BPSO) approach is introduced to select key features from the Android botnet dataset.

A. Binary PSO

PSO is a famous evolutionary computation method, which has been used to solve many optimization problems. PSO mimics the social behavior of bird flocking, where each member (particle) is a possible solution and moves in the search space based on its own and its neighbors' best positions [22]. PSO can be divided into two main types: continuous PSO (CPSO] and binary PSO (BPSO). CPSO is designed for continuous optimization problems, where the position and velocity of each particle are real-valued vectors. BPSO is a variant of PSO for binary optimization problems, where the position and velocity of each particle are binary vectors [23, 24].

Binary optimization problems are widely encountered in various fields, such as feature selection, knapsack, scheduling, cryptography, and network design [24, 25]. In these problems, the objective is to find the optimal combination of binary

variables that satisfies some constraints and maximizes or minimizes a given function. BPSO is a simple and effective method for solving binary optimization problems, as it can explore the search space efficiently and avoid being trapped in local optima [26].

The transfer function is a key component of BPSO, as it maps the continuous velocity to a binary position. The transfer function determines the probability of flipping each bit of the position vector, which affects the diversity and convergence of the swarm. Different transfer functions have different characteristics and suitability for different problems. Therefore, choosing an appropriate transfer function is crucial for the success of BPSO [27].

In general, BPSO and CPSO formulas are shown in Table I. The CPSO algorithm uses the first two formulas to change the speed and position of the particles. The BPSO algorithm changes the speed with Eq. (1) and the position of particles (binary) with Eq. (3) and (4).

In Table I, x_{id}^{t} is the location of the *i-th* particle in the d-th dimension at the *t-th* iteration, and φ_1 and φ_2 are two random numbers in a bounded domain with a uniform distribution. P_{gb}^{t} and P_{id}^{t} are the best positions discovered in the entire search space and the best position reached by the *i-th* particle at the *t-th* iteration, respectively. c_1 and c_2 are acceleration constants and ω is the inertia weight that balances the global and local searches [28]. x_{id}^{t+1} is the location of the *i-th* particle in the *d-th* dimension at the *(t + 1)-th* iteration.

The sigmoid function (S (.)) is a function of the particle's velocity in each dimension. It has a range of [0, 1]. Eq. (4) evaluates the output of this function against the outcome of Eq. (3) using a random function that produces a value in [0, 1]. Based on this comparison, Eq. (4) assigns either 1 (feature selected) or 0 (feature not selected) to each dimension of the particle ($x_{id}^{t+1}(t+1)$).

TABLE I. CPSO AND BPSO FORMULAS

Number	Name	Formula
1	*Velocity Updating*	$v_{id}^{t+1} = \omega * v_{id}^{t} + c_1 * \varphi_1 * (P_{id}^{t} - x_{id}^{t}) + c_2 * \varphi_2 * (P_{gb}^{t} - x_{id}^{t})$
2	*Position Updating*	$x_{id}^{t+1} = x_{id}^{t} + v_{id}^{t+1}$
3	*Sigmoid Function*	$S(v_{i,d}) = \frac{1}{1 + e^{-v_{i,d}}}$
4	*Binary Position Updating*	$x_{id}^{t+1} \leftarrow \begin{cases} 0, & if\ rand > S(v_{i,d}) \\ 1, & Otherwise \end{cases}$

In Fig. 1, the BPSO algorithm performance is shown. In this approach, the mentioned technique based on Eq. (4) in Table I selects the desired features (features with a value of 1) and removes other features from the dataset (features with a value of 0).

B. BPSO-DT and BPSO-SVM

In the literature review section, the limitations of SVM and DT approaches were mentioned. In the continuation of this study, by combining these approaches with the BPSO algorithm, an attempt has been made to overcome some of the limitations expressed in these techniques.

Fig. 2 shows the flowchart of BPSO-SVM and BPSO-DT algorithms. In this form, the parameters of these methods are first initialized; then, the BPSO algorithm initializes the BPSO parameters for each particle in the search space. Next, the speed and position values of the particles are calculated. The BPSO method uses the binary position of particles to select the features of the training and testing datasets so that the optimal features can be obtained from the dataset. Then, the BPSO algorithm trains the SVM and DT methods with the Train dataset, which has the selected features. Finally, the model is applied to the test dataset (Fitness Function) and if the model accuracy is 100%, the model training is done. Otherwise, the BPSO method updates the Pbest and Gbest values based on each model's accuracy and computes the particles' speed to extract new features from the training and testing datasets. Finally, each new training dataset is given to the SVM and DT methods to train and get a new model. If any of the models can get 100% accuracy in the Fitness function, their training is done; Otherwise, the process is repeated until a certain number of iterations (for example, N times) and if it does not get 100% accuracy, it stops after the N-th iteration.

C. Fitness Function

The Fitness function is the accuracy function that evaluates the performance of the machine-learning methods. In Eq. (1), the TP and TN terms are the botnet and benign data that are classified correctly.

$$Accuracy\ (ACC) = \frac{TP+TN}{Toatal\ Test\ Sample} \quad (1)$$

IV. EVALUATION AND RESULTS

At the beginning of this section, it should be mentioned that all approaches are implemented in Python software, and SVM and DT approaches are selected from the Scikit-Learn library available in Python.

This paper uses two Android botnets, PJapps (in EXE and BACK mode) and Geinimi (in EXE and BACK mode), from the 28-SABD databases [29], to compare the performance of the proposed methods. Also, the specifications of these datasets are mentioned in Table II. Four evaluation metrics, which are shown in Eq. (2)-(5), are used to measure the performance of each method.

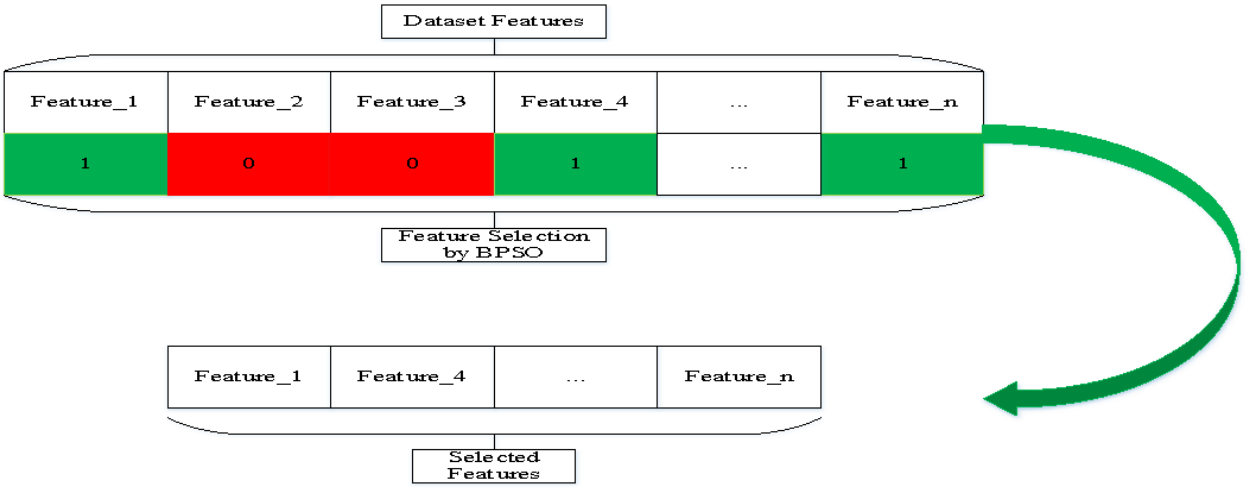

Fig. 1. How the BPSO algorithm works.

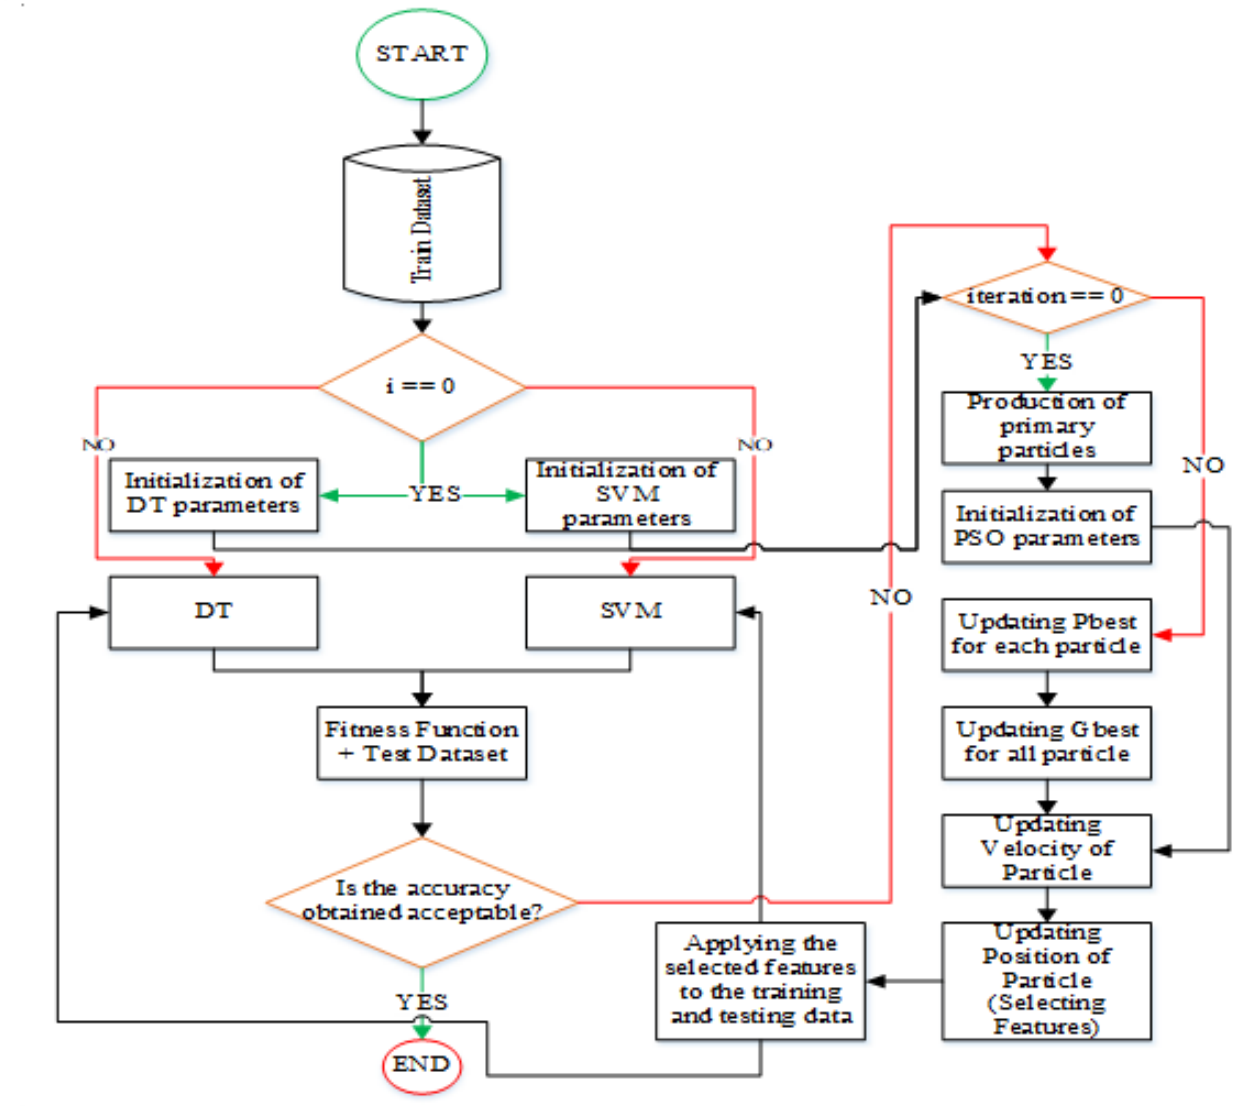

Fig. 2. BPSO-SVM & BPSO-DT.

TABLE II. ANDROID BOTNET DATASETS [29]

Dataset	Number of Columns	Number of Rows
PJapps-Back	85	3702
PJapps EXE	85	10628
Geinimi-Back	85	4674
Geinimi-EXE	85	13757

In these equations, TP, TN, FP, and FN correspond to True Positive, True Negative, False Positive, and False Negative, respectively. Also, in Table II, the default parameters of the BPSO approach are shown.

$$\text{Accuracy(ACC)} = \frac{TP+TN}{Total\ Sample} \quad (2)$$

$$\text{Precision(Pre)} = \frac{TP}{TP+FP} \quad (3)$$

$$\text{Recall(Rec)} = \frac{TP}{TP+FN} \quad (4)$$

$$F-1 = \frac{TP}{TP+\frac{1}{2}(FP+FN)} \quad (5)$$

Before the model is trained and tested in all methods, the four datasets used are shuffled first. The techniques were applied to four different datasets and the results are shown in Tables III to VI. Based on these tables, we can say that.

TABLE III. BPSO DEFAULT VALUES

Parameter	Default Value
Number of Particles	10
Number of Iterations	10
ω	0.7
C_1	1.49445
C_2	1.49445

The techniques were applied to four different datasets and the results are shown in Tables III to VI. Based on these tables, we can say that:

1) The BPSO-SVM method performed better than the other methods on all four metrics on the PJappsExe dataset.

2) The BPSO-DT approach is the only approach that has shown better performance than other approaches in all four evaluation criteria on the PJappsBack dataset.

3) The two approaches BPSO-SVM and BPSO-DT have shown the best performance on the GeinimiExe dataset. In these approaches, all four evaluation criteria have achieved 100%. The main reason for this can be considered the selection of the best features from the aforementioned dataset. After selecting these features, the training model was trained in the best way and was able to provide the best results on the test dataset.

4) Finally, in Table VI, the BPSO-SVM approach has shown the best performance in all four measurement criteria on the GeinimiBack dataset.

As can be seen from the Tables III to VI; in all four datasets used, the BPSO-SVM approach has shown better performance than the SVM approach in all four measurement criteria. It should be noted that in some datasets, the results obtained in some measurement criteria show the performance of BPSO-SVM and SVM approaches. For example, in the PJappsBack dataset, the performance of both approaches was similar to each other in all four measurement criteria. On the other hand, the topic stated for BPSO-SVM and SVM approaches can be extended to BPSO-DT and DT techniques as well. For example, in the GeinimiBack dataset, both BPSO-DT and DT approaches have shown similar performance in all four measurement criteria.

TABLE IV. COMPARING THE PERFORMANCE OF THE SUGGESTED METHODS AND THE OTHER TWO METHODS ON THE PJAPPSEXE DATASET

Method	Dataset	Accuracy	Precision	Recall	F-1
BPSO-SVM	PJappsExe	0.9390	0.8878	0.8636	0.8755
BPSO-DT	PJappsExe	0.9051	0.9857	0.6272	0.7666
SVM	PJappsExe	0.9255	0.8666	0.8272	0.8465
DT	PJappsExe	0.6681	0.4170	0.8454	0.5585

TABLE V. COMPARING THE PERFORMANCE OF THE SUGGESTED METHODS AND THE OTHER TWO METHODS ON THE PJAPPSBACK DATASET

Method	Dataset	Accuracy	Precision	Recall	F-1
BPSO-SVM	PJappsBack	0.9663	0.5714	1.0	0.7272
BPSO-DT	PJappsBack	0.9775	0.6666	1.0	0.8
SVM	PJappsBack	0.9663	0.5714	1.0	0.7272
DT	PJappsBack	0.9213	0.3636	1.0	0.5333

TABLE VI. COMPARING THE PERFORMANCE OF THE SUGGESTED METHODS AND THE OTHER TWO METHODS ON THE GEINIMIEXE DATASET

Method	Dataset	Accuracy	Precision	Recall	F-1
BPSO-SVM	GeinimiExe	1.0	1.0	1.0	1.0
BPSO-DT	GeinimiExe	1.0	1.0	1.0	1.0
SVM	GeinimiExe	0.9980	1.0	0.75	0.8571
DT	GeinimiExe	0.9980	1.0	0.75	0.8571

TABLE VII. COMPARING THE PERFORMANCE OF THE SUGGESTED METHODS AND THE OTHER TWO METHODS ON THE GEINIMIBACK DATASET

Method	Dataset	Accuracy	Precision	Recall	F-1
BPSO-SVM	GeinimiBack	0.9854	1.0	0.4166	0.5882
BPSO-DT	GeinimiBack	0.9771	1.0	0.0833	0.1538
SVM	GeinimiBack	0.9812	1.0	0.25	0.4
DT	GeinimiBack	0.9771	1.0	0.0833	0.1538

To examine the average performance of the methods on all four datasets, we obtain Fig. 3 to 6. Based on these results, we can draw the following conclusions on the metrics used on the four Android botnet datasets:

a) The BPSO-SVM approach has shown the best performance in the "Accuracy" criterion. And the BPSO-DT approach is placed next. The key point obtained from Fig. 3 is the significant improvement in the performance of BPSO-DT compared to the DT approach in the "Accuracy" criterion.

b) The SVM approach shows the best value for the "Precision" criterion among other approaches. On the other hand, the BPSO-DT approach has been able to significantly improve the performance of the DT approach in this criterion.

c) The BPSO-SVM approach shows the best performance among other approaches in the "Recall" measure. It should be noted, that the performance of the BPSO-DT approach in this criterion has been ranked second in comparison with other approaches.

d) The BPSO-SVM and BPSO-DT approaches have shown the best performance among other approaches in the measurement criterion "F1", respectively, and have significantly improved the values of this criterion compared to the SVM and DT approaches.

The feature selection is the most significant part of Fig. 2 because the particles can get lost in the search space if they choose the wrong features. Therefore, the algorithm will not perform well if it is powerful, but the features are not relevant. Table VII shows the 10 top features of the Android botnet. These features are ranked by importance in Table VII.

In Table VIII, "Percent" indicates the percentage of a feature appearing in four different datasets. The table indicates that the most significant feature is TotalLengthofBwdPacketsfwd, which was chosen in 87.5% of the datasets. For further details on the 85 features of CICFlowMeters, refer to references [30, 31]. Android botnets communicate with the command and control server and other botnets very covertly, so applying many features does not enhance their identification but increases the FP and FN rates. Android botnet tries to avoid detection by hiding and encrypting the key features that most security researchers seek.

TABLE VIII. TEN OF THE MOST FREQUENTLY USED FEATURES AMONG THE FOUR ANDROID BOTNET DATASETS

Number	Features Name	Percent (%)
1	TotalLengthofBwdPackets	87.5
2	ECEFlagCount	87.5
3	IdleMean	87.5
4	BwdPacketLengthMin	75
5	FlowIATMax	75
6	SubflowFwdPackets	75
7	SubflowBwdPackets	75
8	ActiveMax	75
9	BwdIATMax	75
10	FwdURGFlags	75

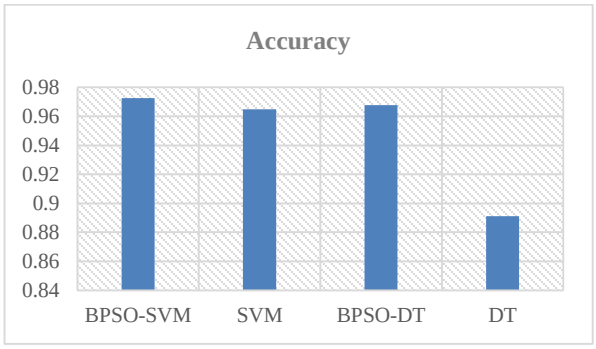

Fig. 3. Comparison of the accuracy of the four approaches used in this paper.

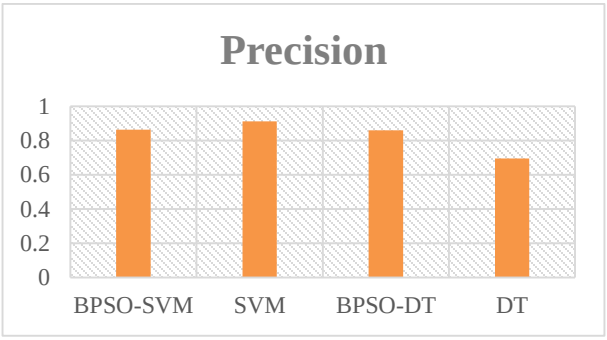

Fig. 4. Comparison of the precision of the four approaches used in this paper.

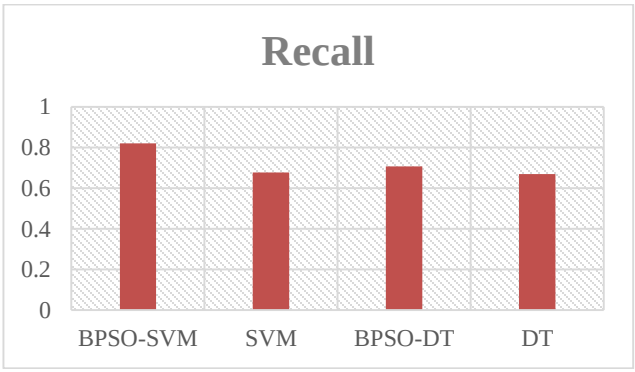

Fig. 5. Comparison of the recall of the four approaches used in this paper.

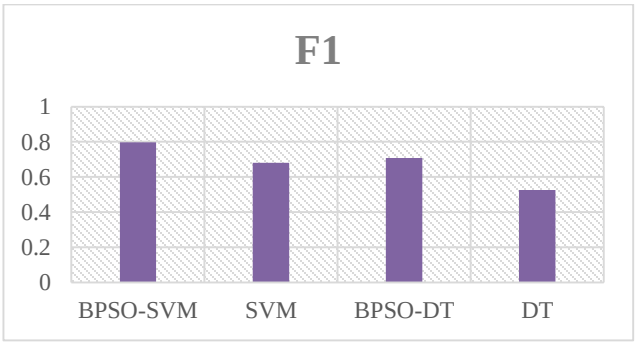

Fig. 6. Comparison of the F1 of the four approaches used in this paper.

V. Conclusion and Suggestions

Android botnets are malicious networks of compromised devices that can perform various harmful activities, such as spamming, stealing data, and launching DDoS attacks. Detecting Android botnets is a vital and difficult task, as they often use advanced techniques to evade traditional detection methods. In this study, the two machine learning approaches, SVM and DT, are used to identify Android botnets. As mentioned in this study, one of the problems of identifying Android botnets is the encryption of the traffic sent between the botmaster and botnets, which makes it impossible to identify botnets at a high rate. Some of the features from the dataset are obscure and encrypted, which hinders machine learning methods from being trained properly to detect Android botnets with high precision. This study employs the BPSO algorithm to help machine learning methods (SVM and DT) by selecting the relevant features of the dataset so that they can recognize Android botnets with high accuracy. The research results show that the best method (BPSO-SVM) has more than 97% accuracy in detecting Android botnets. Also, in this study, the top 10 most effective features that have been effective in identifying Android botnets have been mentioned.

In future research, the issue of optimizing the parameters of machine learning approaches and the effect of these parameters on the performance of these techniques will be discussed.

The Impact of the GQM Framework on Software Engineering Exam Outcomes

Reem Abdulaziz Alnanih
Department of Computer Science-Faculty of Commuting and Information Technology,
King Abdulaziz University, Jeddah, Saudi Arabia

***Abstract*—Assessment is crucial in educational systems, particularly in Software Engineering (SE) programs, where fair and effective evaluations drive continuous improvement. The shift to student-centric methodologies has evolved assessment strategies to focus on aligning educational processes with students' developmental needs rather than merely measuring academic outputs. This paper adapts the Goal-Question-Metric (GQM) framework to enhance learning in software engineering education by linking educational goals, learning activities, and assessment methods. This approach specifies expected learning outcomes and integrates mechanisms for continuous improvement, aligning teaching strategies with student performance metrics. A systematic framework for course assessment using the GQM framework is presented, aligning assessment methods with Intended Learning Outcomes (ILOs) and Student Learning Outcomes (SLOs) to ensure data-driven enhancements. To validate this approach, a template was introduced to assess the impact of a tailored GQM approach on the final exam outcomes of a software engineering course at King Abdulaziz University's Department of Computer Science. A controlled experiment was conducted over two semesters with students from the CPCS 351 course. The control group, in the first semester, completed their finals without applying GQM, while the experimental group in the following semester employed a customized GQM framework. Statistical analyses, including ANOVA and Mann-Whitney U tests, were utilized to compare exam performance between the groups. Results indicated a significant improvement in the exam scores of the experimental group, thereby validating the effectiveness of the GQM framework in boosting academic performance through structured exam preparation and execution.**

Keywords*—Goal-question-metric (GQM); software engineering; education; learning process; learning outcomes; continuous improvement; statistical analysis

I. Introduction

Assessment remains a cornerstone of educational systems, particularly within Software Engineering (SE) programs, where the fairness and effectiveness of evaluations are essential for fostering continuous educational enhancement. The shift towards student-centric methodologies has marked a significant evolution in assessment strategies, emphasizing the importance of aligning educational processes with the developmental needs of students rather than merely measuring academic outputs.

Institutions of higher learning often grapple with the dual obligations of advancing knowledge and fulfilling societal service demands. This balancing act requires a commitment to academic and intellectual autonomy to avoid diluting scholarly standards under external pressures.

Well-designed assessment strategies can transform the educational landscape by prioritizing learning enhancement over simple output measurement. In the context of higher education, there is a growing consensus on the importance of developing 'knowledge workers' who are adept at critical thinking, effective communication, teamwork, and self-directed learning. These competencies are crucial, surpassing the traditional focus on rote memorization, and are vital for meeting various accreditation standards that emphasize outcome-based education.

Experienced educators are increasingly aware of the processes that contribute to effective education, supporting a more nuanced articulation of teaching methodologies alongside traditional performance metrics. In the specialized field of SE, the discipline holds a status of expertise, with ongoing global discussions about the requisite knowledge and skills. This focus draws attention from diverse sectors, including media, industry, and academia.

Many challenges persist in assessing and managing educational processes within SE. Innovations such as performance-based assessments, decision-support systems, peer reviews, automated grading, and flexible assessment strategies are being implemented; however, comprehensive studies on their adoption and effectiveness remain limited.

Recent systematic reviews indicate that the Goal Question Metric (GQM) method is predominantly used for evaluating SE processes and products in professional settings, but its application in educational settings is not well-documented [1-4]. GQM, originally designed for SE, is adaptable for assessing various product development processes beyond software, including hardware production or service development.

SE inherently requires robust measurement systems to provide feedback and evaluate processes. Such systems not only assist in course planning and improvement but also enable educators to respond dynamically to educational needs through ongoing assessments.

The GQM approach has significantly influenced both industry and academia by fostering systematic data collection and analysis aimed at enhancing the quality of software processes and products [5]. This method emphasizes the importance of defining clear goals, linking these goals to specific data, and establishing a structured framework for data interpretation. This ensures that measurements are purposeful and aligned with organizational objectives [6].

Over the past fifteen years, the GQM methodology has expanded to facilitate the collection and analysis of externally oriented quality metrics aligned with business objectives, such as end-user satisfaction, market share, and customer retention. This goal-centric approach is recognized for adding significant value to the industry by enhancing the design and maintenance of both process and product quality [7].

The GQM method operates on three distinct levels: the conceptual level (Goal), which identifies the subject of research and its rationale; the operational level (Question), where specific, measurable questions are defined; and the quantitative level (Metric), which outlines the measurements needed to address these questions. This structured framework assists organizations in determining which data to collect and how to interpret it, establishing a clear, goal-oriented approach to software measurement [6].

The integration of the National Qualification Framework (NQF) in Saudi Arabia significantly enhances the structured approach to educational assessments [8]. Mandated for all Saudi universities, this framework is pivotal in defining the competencies that graduates should possess across various learning domains [9]. By focusing on outcome-based educational models, the NQF ensures that educational processes prioritize achieving specific, measurable outcomes rather than merely delivering content. This alignment supports both academic and professional expectations.

The NQF categorizes learning into five distinct domains, although the proposed assessment method in the discussed study focuses on the first three: Knowledge, Cognitive Skills, and Interpersonal Skills and Responsibility [10-11]. This strategic emphasis targets the core competencies that are most relevant and critical for SE students. These domains are essential for developing professionals who are not only proficient in technical skills but also capable of effective communication, teamwork, and ethical practice in their careers.

The exclusion of the last two domains from the primary focus of the assessment—Communication, IT, and Numerical Skills, and Psychomotor Skills—is justified within the context of SE education, as it typically does not require extensive psychomotor capabilities.

In this context, an essential aspect is content validity, which ensures that a representative sample of the intended learning outcomes (ILOs) is assessed. This is particularly relevant given the NQF's emphasis on the first three domains: Knowledge, Cognitive Skills, and Interpersonal Skills and Responsibility. Each assessment item must align with at least one ILO to ensure effective content validity. This approach considers the curriculum and the competencies expected of students, thereby evaluating the effectiveness of the assessment methods. Any systematic errors in the assessment may indicate that the course objectives or delivery methods are not adequately aligned with the intended content. This focus on alignment is crucial for ensuring that SE students develop both the technical and interpersonal skills necessary for their careers [12-13].

A. Motivations and Objectives

This study is motivated by the need to adapt and apply the GQM framework in educational settings, specifically within SE programs. The central motivation is to refine educational methodologies to align with industry demands, ultimately elevating the caliber of educational outcomes. By integrating GQM, we aim to diminish the divide between academic theories and industry practices, creating a more robust learning environment for aspiring software engineers.

To realize these aims, we propose the use of an assessment-based GQM as a pedagogical tool tailored for SE education. Our objectives are structured as follows:

1) Framework adaptation: Modify and refine the GQM framework to address the unique requirements of SE education effectively.

2) Assessment consistency: Implement a comprehensive assessment framework to ensure that evaluations of student performance are consistent and relevant.

3) Guideline provision: Offer practical guidelines for the effective deployment of this GQM-based assessment methodology in educational contexts.

4) Feasibility demonstration: Conduct initial stages of controlled experiments to validate the practicality of this approach and elucidate its foundational logic.

The innovative contribution of this research lies in the development of a novel pedagogical strategy for assessing educational processes and outcomes, firmly rooted in the GQM framework and tailored testing strategies. This study not only deepens the understanding of the GQM approach but also advocates for its broader adoption in academic circles. Specifically, it aims to enhance the application of GQM within educational frameworks, ensuring that these adaptations are appropriately customized to meet academic needs. Through this research, we seek to advance the field of SE education, aligning it more closely with industry standards and expectations.

The structure of this paper is outlined as follows: In Section II, a comprehensive literature review highlights significant research contributions related to the application of GQM in assessment contexts. Section III describes the adapted GQM model for the learning process, while Section IV presents the proposed framework for course assessment design and evaluation. Section V focuses on validating the proposed model, and Sections VI and VII present the results and discussion, respectively. Finally, Section VIII offers the conclusion of the paper.

II. Literature Review

Assessments are primarily conducted through written exams; however, this approach has several drawbacks, including an uneven distribution of questions across topics, restricted sampling, and ambiguous questions, all of which can undermine its validity. The GQM framework is recognized as a valuable tool for addressing these issues and promoting optimal educational practices. This section highlights significant recent contributions to the application of GQM in educational and assessment contexts.

In [14], Meng et al. present a method for recommending software process patterns using the GQM framework. They propose a systematic approach that aligns software process

patterns with specific goals and questions, enabling organizations to select appropriate patterns based on their unique needs. The study highlights the effectiveness of the GQM-based method in enhancing decision-making in software process management, ultimately aiming to improve software development outcomes. Additionally, the paper includes a case study that demonstrates the practical application of the proposed recommendation approach.

Idahmash and Gravell in [15] explore the application of the GQM framework to assess success in agile software development projects. They identify key success factors and propose a structured methodology for measuring these factors using GQM. Through case studies, their research demonstrates how GQM can provide insights into project performance, helping teams align their goals with measurable outcomes. The findings emphasize the importance of tailored metrics in enhancing the effectiveness of agile practices.

In 2018, Tahir et al. [16] investigated the current state of software measurement practices within the Pakistani software industry. Through a comprehensive survey, they assessed the effectiveness and challenges of existing measurement processes. The study identifies gaps in the application of these practices and provides recommendations for improving software quality and project management. The findings highlight the need for better integration of measurement frameworks and tools to enhance overall software development practices in the region.

Shojaeshafiei in [17] introduces a novel approach for assessing web application vulnerabilities using the Analytic Hierarchy Process (AHP) integrated with fuzzy measurement techniques. This methodology aims to quantify and prioritize vulnerabilities in a structured manner, addressing the inherent uncertainties in risk assessment. By employing the GQM framework, the author establishes clear evaluation goals and metrics, facilitating effective decision-making in vulnerability remediation. The study underscores the importance of a systematic approach to enhance security measures in web applications, ultimately contributing to more robust risk management strategies in SE.

Calvo and Beltrán in [18] examine the use of the GQM framework to create tailored cyber risk metrics. They argue that conventional risk assessment methods are often inflexible and insufficiently adaptable to changing cyber environments. By utilizing the GQM approach, the study clearly defines cybersecurity goals, formulates relevant questions, and establishes measurable metrics aligned with organizational needs. This framework enhances real-time monitoring and evaluation of cyber risks, facilitating better decision-making and proactive risk management against evolving threats.

Philippou, Frey, and Rashid [19] present a methodology that utilizes the GQM framework to align security metrics with business objectives. They emphasize the importance of contextualizing security measures to ensure that they support organizational goals. The proposed methodology facilitates the identification of relevant security metrics by defining specific goals and questions that reflect business needs. The study highlights the benefits of this alignment in improving the effectiveness of security assessments and enhancing the overall organizational security strategy.

Falco and Robiolo [20] present the development of a comprehensive catalog that effectively maps ISO/IEC 25010 quality characteristics to specific measures used in industrial settings. Their aim is to bridge the gap between theoretical quality standards and practical implementation by identifying relevant metrics for each quality attribute. The study emphasizes the critical importance of these measures in assessing software quality and offers valuable insights into their application in real-world scenarios, ultimately contributing to enhanced quality assurance practices in the industry.

Hsueh, Wang, and Bilegjargal [21] discuss the development of a learning analysis system using the GQM methodology combined with the ELK Stack (Elasticsearch, Logstash, and Kibana). They outline how GQM helps define learning objectives and questions which guide data collection and analysis. The ELK Stack is utilized for real-time data processing and visualization, enabling educators to gain insights into student learning behaviors. The study demonstrates the effectiveness of this integrated approach in enhancing educational outcomes through data-driven decision-making.

Finally, Minhas et al. [22] examine the differences between research and practical approaches to regression testing through the lens of the GQM framework. They analyze existing literature and industry practices to identify gaps and alignments in the goals, questions, and metrics used in regression testing. The study finds that while research provides theoretical insights, practical applications often lack the structured measurement approaches advocated in academic literature. The findings suggest that adopting GQM can enhance collaboration between researchers and practitioners, leading to improved regression testing methodologies.

Table I summarizes the significant contributions of the studies discussed above regarding the application of the GQM methodology across various domains, including education and SE.

From the above table, it is evident that each study highlights specific challenges in measurement and assessment processes, demonstrating how a GQM-based approach can effectively address these issues. In academic settings, especially, adopting a test-based GQM framework is essential for enhancing the validity and reliability of assessments. By aligning educational objectives with measurable outcomes, GQM can improve teaching practices and student performance, fostering a culture of continuous quality improvement.

Moreover, this paper indicates the importance of integrating GQM into the design and development of tests. Specifically, there is a need to apply GQM within the Department of Computer Science at FCIT, KAU. None of the studies reviewed have tailored GQM to computer science courses or defined the weight, domain, or time requirements for different types of questions in these courses.

TABLE I. SUMMARY OF THE LITERATURE REVIEW

Ref.	Domain	Focus Area	GQM Methodology Application	Challenges Addressed
[14]	Software Process	Process Patterns	Recommending patterns with GQM.	Selecting patterns for unique needs.
[15]	Agile Development	Project Success	Assessing success with GQM.	Aligning goals with measurable outcomes.
[16]	Software Measurement	Industry Practices	Survey of measurement in Pakistan.	Gaps in current measurement processes.
[17]	Software Engineering	Risk Management	Application of GQM for defining goals related to security measures and evaluation metrics.	Addressing the ambiguity in risk assessment through fuzzy measurement techniques.
[18]	Cybersecurity	Risk Assessment	Application of the GQM framework to define specific cybersecurity goals and develop tailored metrics.	Lack of flexibility and adaptability in traditional risk assessment methods for dynamic cyber environments.
[19]	Security Metrics	Business Alignment	Aligning metrics with business goals	Supporting orgaizational objectives
[20]	Software Quality	Quality Characteristics	Mapping ISO standard to measures	Bridging theory with practical use
[21]	Education	Learning Analysis	System developing a with GQM	Guiding data collection
[22]	Regression Testing	Research vs. Practice	Comparing approaches with GQM	Lack of structured measurement in practical applications

III. THE ADAPTED GQM MODEL FOR THE LEARNING PROCESS

In the educational context, aligning instructional strategies with precise learning objectives is crucial for promoting effective student outcomes. To facilitate this alignment, structured methodologies like the GQM approach are invaluable. This model acts as a systematic framework that bridges high-level educational goals with specific research questions and measurable metrics, enabling educators to make informed, data-driven decisions during both the design and implementation phases.

The primary aim of adopting the GQM model in this study is to ensure that the content of each assessment method is directly linked to clearly defined metrics for each course, guiding the selection of appropriate and impactful learning experiences. This approach not only tailors teaching strategies to emphasize desired learning outcomes but also supports a flexible curriculum development process that effectively meets specific needs for:

- Clarity: Clearly defines expected competencies.
- Support: Outlines learning activities that aid learners in achieving their goals.
- Evaluation: Measures learners' performance against established assessment criteria.

The GQM model consists of three main components as shown in Fig. 1:

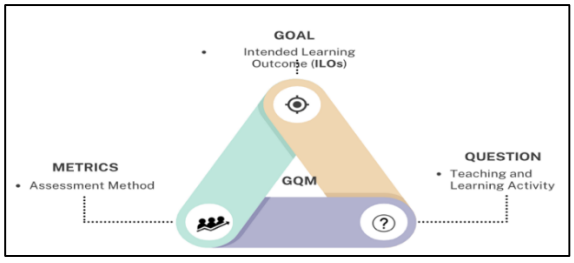

Fig. 1. GQM model.

- Goals: Define what learners should know, understand, or be able to do by the end of their courses.
- Questions: Pose specific evaluation questions that assess whether the set goals are being met.
- Metrics: Establish measurable criteria quantifying the extent to which learners achieve the desired outcomes.

Fig. 2 presents a structure clarifying the distinct roles of learning activities and assessment methods in the educational process:

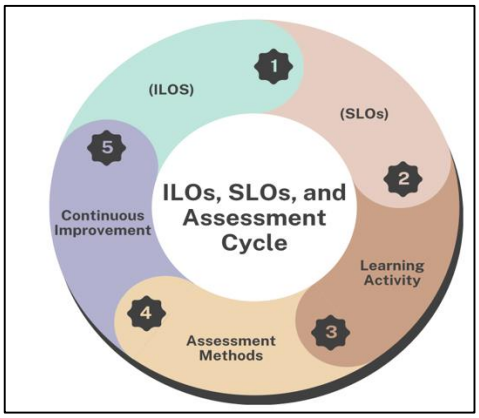

Fig. 2. ILOs, SLOs, and assessment cycle.

- Intended Learning Outcomes (ILOs): Goals set by educators regarding what students should achieve.
- Student Learning Outcomes (SLOs): Specific outcomes expected from students, derived from ILOs.
- Learning Activities: Engagement strategies designed to help students achieve SLOs (e.g., lectures, group projects, discussions).

- Assessment Methods: Tools used to measure whether students have achieved SLOs (e.g., quizzes, exams, portfolios).
- Continuous Improvement: Feedback from assessments informs revisions to ILOs, SLOs.

A. Mapping GQM Components to Educational Process

Table II illustrates the mapping of the GQM components to educational steps, alongside descriptions:

Table III is an example illustrating how a single goal can be effectively broken down into both overarching and specific learning objectives, ensuring coherence in the educational process.

Following this structure, the GQM framework is adapted to the learning process to achieve both validity and reliability in assessing student learning outcomes in SE. This adaptation involves focusing on broad aims, specifying the aspects of learning to be assessed, listing questions that gauge student mastery of specific skills, and providing measurable data points to evaluate student performance and understanding.

TABLE II. MAPPING GQM COMPNENTS TO EDUCATIONAL STEPS

GQM Component	Educational Step	Description
Goals	1) ILOs	High-level educational objectives set by educators.
	2) SLOs	Specific outcomes derived from ILOs that students are expected to achieve.
Questions	3) Learning Activities	Evaluation questions that guide the design of learning activities.
Metrics	4) Assessment Methods	Measurable criteria to evaluate achievement of SLOs.
	5) Continuous Improvement	Data from assessments used to inform revisions to ILOs, SLOs, and teaching methods.

TABLE III. EXAMPLE OF MAPPING GQM TO EDUCATIONAL STEPS

GQM Component	Educational Step	Description
Goal: Students will understand the foundational principles of SE.	**1)ILO**: What is SE?	This ILO reflects the goal by focusing on a broad understanding of the discipline. It sets the expectation for students to grasp the fundamental concepts of SE, aligning with the overall educational aim of instilling foundational knowledge.
	2)SLO: Explain the concept of a software lifecycle with an example, including the deliverables produced from each phase.	This SLO operationalizes the goal by specifying a measurable outcome that students must demonstrate. It details how students will apply their understanding of SE principles by explaining a specific concept (the software lifecycle) and providing an example, thus ensuring that the goal translates into tangible student performance.
Question: How effectively are students grasping the foundational principles of SE?	**3) Learning Activity**: Collaborative Group Project. Students work in teams to analyze a SE case study, identify the foundational principles at play, and present their findings.	By asking the question, educators can focus on specific, measurable outcomes that reflect student learning. • The **Collaborative Group Project** directly supports the ILO (What is SE?) by requiring students to explore and articulate foundational concepts in a practical context. • It also aligns with the SLO (Explain the concept of a software...) by prompting students to apply their knowledge to a real-world scenario, demonstrating their understanding of key principles, including the software lifecycle.
Metrics: What percentage of students can accurately explain foundational principles of SE and apply them in practical scenarios?	4) **Assessment Methods:** Rubric-Based Assessment of Group Project Presentations. Bu using a detailed rubric to evaluate students' presentations on their case studies, focusing on their ability to explain foundational principles and apply them to real-world scenarios.	The **rubric-based assessment** aligns with the metrics by providing a structured way to evaluate how well students articulate and apply foundational principles. The rubric can include criteria such as clarity of explanation, relevance to SE concepts, and ability to connect theory to practice.
	5) **Continuous Improvement**: Peer and Instructor Feedback. After presentations, both peers and instructors provide feedback based on the rubric criteria, highlighting strengths and areas for improvement.	**Continuous feedback** from both instructors and peers enhances learning by providing students with insights into their performance. This feedback can inform students about specific areas to improve, fostering a growth mindset and encouraging them to engage more deeply with the material.

IV. PROPOSED FRAMEWORK FOR COURSE ASSESSMENT DESIGN AND EVALUATION BASED ON GQM

This section introduces the application of the GQM approach to streamline the assessment process in a SE course. It integrates Intended Learning Outcomes (ILOs), Student Learning Outcomes (SLOs), learning activities, and assessment methods, as depicted in Fig. 3. This integration enhances data-driven decision-making aimed at improving student performance in Computer Science.

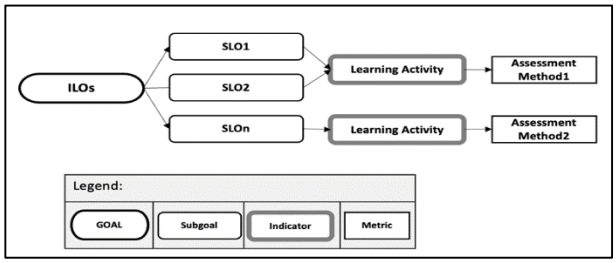

Fig. 3. Hierarchical of GQM in learning process.

A. Course Overview

The CPCS 351 SE course prepares students to understand fundamental concepts in SE, particularly in system analysis, and equips them with the skills to design medium-scale software systems and apply engineering principles in practical scenarios. The case study aims to align each assessment method with the course's articulation metrics, facilitating the selection of suitable learning experiences.

The ILOs of the proposed design span three learning domains: knowledge, cognitive abilities, and interpersonal skills. The assessment methods include a final exam comprising multiple-choice questions (MCQs) and essay questions. MCQs effectively evaluate knowledge areas, while essay questions provide a broader assessment of skills but are more time-consuming.

B. GQM Template Design

The proposed GQM template is structured into basic and advanced levels. The basic level addresses overarching goals, associated questions, and the assessment methods employed. The advanced level provides a detailed matrix that aids in evaluating how well the assessment methods fulfill the SLOs.

C. Basic Level Template

The basic level template features a two-dimensional matrix that aligning the curriculum content with the total number of evaluation items, as shown in Fig. 4. Rows represent the GQM framework stages of the learning process, and columns cover various attributes, including course information, assessment methods, question types, topic organization, CLOs, ILOs, and learning domains.

Steps for designing course assessments include:

1) General Information:
- Course Name and Number.
- Assessment Methods: Options like Exam 1, Exam 2, Final Exam, Projects.
- Activity Method: MCQs or Essays.
- Total Time Allocated for MCQ and Essay Exams.
- Total Marks of the assessment method.

2) Type of Questions:
- Define the question types used, such as MCQs, essays, etc.

3) Topics Organization:
- Sequentially number topics over a 14-week term.
- Divide each topic into ILOs addressing specific topic aspects.

4) Course Learning Outcomes (CLOs):
- Map each CLO to a set of ILOs relevant to topics, guiding topic coverage depth.

5) Learning Domains:
- Incorporate domains relevant to the Computer Science department, such as Knowledge (K), Cognitive Skills (C), and Interpersonal Skills (IP).

6) Exam Item Importance Scale (IMS):
- Score each ILO tested by MCQ or essay, categorizing importance from 'Most Important' to 'Not Included in the Exam'.

7) Total Item Importance Scale (TIMS):
- Calculate total importance for MCQs and essays by summing ILO values across topics.

8) Duration Time Needed (DT):
- Estimate the required duration to complete each type of question, based on expert input.

Process of weight assignment, question type determination, and quality assurance:

1) Weight Assignment:
- Assign weights to each ILO reflecting their importance, ensuring total ILO weight sums to 100%.

2) Question Type Determination:
- Categorize assessment questions by type and align them with learning domains.

3) Quality Assurance:
- Review and validate the alignment between assessment methods, ILOs, and SLOs. Conduct pilot testing for refinement.

D. Advanced Level Template

The advanced-level template, shown in Fig. 5, is generated based on:

1) Calculate the Weight Level (WL):
- Determine the importance score of each ILO, ensuring the total weight level for each exam type equals one.

2) Calculate the Duration of Each Item (DD):
- Compute as WL multiplied by the allocated exam time.

3) Determine the Number of Items in Each Exam Set (NI):
- Calculate by dividing DD by the time required for each domain level.

4) Adjust the Number of Items in Each Exam Set:
- Round decimal values to the nearest integer and map ILOs accordingly.

Intructions: Please fill-out all cells in green only											Rate each item in Exam as follows:(Use for MCQs and essays.) 3: Most important 2: Moderately important 1: Least important 0: Not included
Course:	Software Engineering I										
Course code:	351										
Assessment Method (Metrics):	Final exam										
Question Types:	MCQ/ Essay										
Total mark:	30										
Please indicate total time allocated for (MCQ) in minutes:	40										
Please indicate total time allocated for (Essay) Q in minute	45

E. Mapping ILOs to Assessment Methods

This structured template aligns ILOs, SLOs, learning activities, and assessment methods, facilitating a data-driven approach to evaluate student performance and identify improvement areas. By adhering to these steps, the assessment process remains clear, organized, and aligned with educational goals, ensuring effective evaluation and continual enhancement of the learning experience.

V. Validation of the GQM Approach

After finalizing the GQM template, it was essential to conduct a pilot test to assess its effectiveness and implement any necessary adjustments. The pilot test involved an expert user—a professor from King Abdulaziz University (KAU) with over ten years of experience in teaching and designing courses. This evaluation took place in the professor's office at KAU during standard office hours, following a pre-arranged appointment.

The feedback received was highly positive, affirming that the creation of a new template tailored to course-specific ILOs and faculty requirements represents a significant advancement. The professor endorsed the application of the template (referenced in Fig. 4) and provided insights on optimizing the allocation of time per domain based on their expertise. A formal evaluation was deemed necessary to further validate the template's impact on enhancing exam design processes.

A. Experimental Assessment

This assessment focused on a comparative study involving female student groups from two consecutive semesters enrolled in the CPCS 351 course at the Department of Computer Science, FCIT, KAU.

In the first semester, a cohort of 59 female students completed their final exam using traditional design questions that were not intended to be aligned with the IILOs. The exam was constructed without the support of the newly proposed template, which could have improved this alignment.

In contrast, the second semester featured a larger cohort of 98 female students whose exam was constructed using the new template. This template was specifically designed to ensure that all questions were meticulously aligned with the defined ILOs.

Both exams were crafted by the same course coordinator, an experienced educator who had taught the course for several years. The study's independent variables were the number of question items aligned with the selected ILOs, as depicted in Fig. 4. The dependent variable was the students' performance, providing a direct measure of the template's educational impact. The exam questions for both groups were designed to maintain consistency in content and format, ensuring that each set matched in difficulty. This careful alignment is essential for validating the effectiveness of the GQM framework, as it enables a reliable assessment of whether any improvements in exam outcomes stem from the framework's implementation rather than variations in exam difficulty.

B. Testing Environment

The exams were conducted in a controlled environment, specifically a closed room on the second floor of the FCIT building at KAU. Each student from both semesters received a standardized final exam, tailored to their respective study conditions. This setting ensured that the testing conditions were consistent across both groups, facilitating a reliable comparison of the template's effectiveness.

C. Hypothesis

To test the effectiveness of the GQM template in enhancing student understanding and performance by providing a structured and aligned assessment method, the following hypothesis is defined as follow:

- Null Hypothesis (H0): There is no significant difference in overall performance between students who took the final exam based on the proposed GQM template (Group 2) and students who took the final exam without the proposed template (Group 1).
- Alternative Hypothesis (H1): Students who took the final exam based on the proposed GQM template (Group 2) will demonstrate significantly higher overall performance compared to students who took the final exam without the proposed template (Group 1).

VI. Results

A. Data Description

The study involved two distinct groups. Group 1 comprised 59 participants, with data points ranging from 17.5 to 28. The mean and median values were calculated to provide a comprehensive analysis. Group 2 included 98 participants, exhibiting a broader data range from 9.25 to 28.75.

To assess the normality of the datasets, the Shapiro-Wilk test was conducted for both groups. For Group 1, the test yielded a p-value of 0.2348, indicating that the data follows a normal distribution, as this p-value exceeds the conventional alpha level of 0.05. Conversely, Group 2's p-value was approximately 0.00000104, suggesting a significant deviation from normality. This notable difference in distribution characteristics between the two groups implies that non-parametric methods should be utilized for comparative analyses, rather than parametric tests that assume normality.

B. Mann-Whitney U Test Execution

To evaluate the differences between the exam performances of the two cohorts, we conducted the Mann-Whitney U test using Python. This non-parametric test is appropriate for comparing two independent groups, especially when the data do not follow a normal distribution. The analysis involved the following steps:

1) Data preparation: We collected the exam scores from both cohorts.

2) Statistical analysis: We utilized the mannwhitneyu function from the scipy.stats module to calculate the U-statistic and the corresponding p-value. The Mann-Whitney U test yielded a U-statistic of 1902.5 and a p-value of 0.0183.

The U-statistic of 1902.5 indicates the rank-based test statistic calculated from the scores of both groups; a higher U-

statistic value generally reflects a greater difference in scores between the two groups. Additionally, the p-value of 0.0183 is less than the conventional alpha level of 0.05, providing statistical evidence to reject the null hypothesis (H0) and support the alternative hypothesis (H1). This suggests that students who took the final exam based on the proposed GQM template (Group 2) demonstrated significantly higher overall performance compared to those who took the exam without the proposed template (Group 1).

C. Analysis of Variance (ANOVA)

Table IV presents a comparative analysis of two groups using ANOVA test. Group 1, consisting of 59 observations, has an average value of 23.18 with a variance of 9.85. In contrast, Group 2, with 98 observations, exhibits a higher average of 24.95 and a lower variance of 8.90. The F-statistics of 5.73 and the associated p-value of 0.018 indicate a statistically significant difference between the groups. These results indicate that the observed differences in average values are unlikely to be due to random variation.

TABLE IV. ANOVA TEST RESULT

Description	Count	Average	Variance	F-statistics	P-value
Group 1	59	23.18	9.85	5.73	0.018
Group 2	98	24.95	8.90		

D. 95% Confidence Intervals

Following the analysis of variance (ANOVA), the calculation of 95% confidence intervals for the means of the two groups provides valuable additional insights into the data. The confidence intervals for Group 1 (22.39, 23.68) and Group 2 (23.07, 24.33) allow us to quantify the uncertainty around the estimated means. Specifically, for Group 1, we can be 95% confident that the true population mean lies within the interval (22.39, 23.68), while for Group 2, the true mean is expected to fall between (23.07, 24.33).

These intervals not only highlight the range of plausible values for the population means but also facilitate a clearer understanding of the potential differences between the two groups. By providing a visual representation of the means and their associated uncertainty, the confidence intervals enhance our interpretation of the results, confirming the statistical significance observed in the ANOVA test and allowing for a more comprehensive discussion of the implications of these findings.

E. Cohen's d Value

The Cohen's d serves as a measure of the effect size, providing insight into the magnitude of the difference between the two groups. In this analysis, the calculated Cohen's d value of approximately -0.24 indicates a small effect size, suggesting that while there is a statistically significant difference between the groups, the practical significance of this difference is modest. The negative sign further confirms that, on average, Group 2 scored higher than Group 1.

This assessment aligns with the statistical significance indicated by the Mann-Whitney U test, which yielded a p-value of 0.018, and the ANOVA results, which produced an F-statistic of 5.73. Together, these findings lead us to reject the null hypothesis in favor of the alternative hypothesis, affirming that the differences between the groups are meaningful, albeit modest in magnitude. By incorporating Cohen's d, we not only confirm the presence of a significant difference but also contextualize the practical implications of that difference in the educational setting.

VII. DISCUSSION

In this study, we conducted a comprehensive statistical analysis to compare two distinct groups. Initial assessments of normality confirmed that the data were well-suited for parametric tests. Subsequent t-tests and ANOVA revealed significant variations in mean differences between the groups, findings that were further supported by the Mann-Whitney U test, a non-parametric alternative. These results align with previous research, such as that by Idahmash and Gravell [15], which demonstrated how structured methodologies like the Goal-Question-Metric (GQM) can enhance performance metrics in agile projects.

The 95% confidence intervals provided additional insight into the range within which the true means of the groups are likely to fall, enhancing our understanding of the data spread and variability. Moreover, the calculation of Cohen's d, resulting in a value of -0.24, indicated a small but notable effect size, where Group 2 consistently exhibited higher values than Group 1. This effect size, while statistically significant, suggests a modest practical significance, consistent with findings by Tahir et al. [16], who noted similar effect sizes in their assessments of software measurement practices.

In assessing the validity of our study's findings, several potential threats must be considered. First, internal validity could be compromised by selection biases or non-random assignment of participants to groups, which might influence outcomes if the groups are not equivalent at baseline. This concern echoes the challenges identified by Calvo and Beltrán [18], who highlighted the importance of adaptability in risk assessment frameworks. Additionally, while our measures are standardized, they might not fully capture the constructs in question, leading to potential measurement errors, a limitation also noted in the work of Philippou et al. [19].

Externally, the generalizability of our results may be limited by the specific sample used, which may not accurately represent the broader population. This limitation is particularly relevant in light of the findings from Falco and Robiolo [20], who emphasized the importance of contextualizing metrics for practical implementation. Furthermore, the reliance on statistical assumptions, such as those inherent in t-tests and ANOVA, may not hold true across all datasets, potentially affecting the robustness of our conclusions.

Lastly, the effect size, though statistically significant, was small, suggesting that while differences between groups are present, their practical significance may be modest. This aligns with the observations made by Hsueh et al. [21], who discussed the need for careful interpretation of metrics in educational settings. Together, these analyses provide a comprehensive understanding of our findings in relation to existing literature, highlighting both the contributions and limitations of our study.

VIII. CONCLUSION

This paper has critically examined the impact of the GQM framework on SE exam outcomes. The analysis reveals that implementing the GQM framework significantly enhances the clarity and focus of the learning objectives, which in turn positively affects student performance in exams.

The lessons learned from this study suggest that the structured approach of GQM not only aids educators in designing more effective assessments but also helps students in aligning their study strategies to meet specific learning goals. The findings underscore the potential of the GQM framework as a powerful tool in educational settings, particularly in disciplines that require high levels of analytical and problem-solving skills like SE.

Furthermore, the statistical evidence supports the hypothesis that systematic goal setting within educational frameworks can lead to improved educational outcomes. This insight is crucial for educators seeking methods to enhance instructional quality and for educational institutions aiming to boost academic performance.

In light of these findings, future research should d address the following:

- Investigating the GQM framework's applicability across various disciplines beyond SE could provide insights into its versatility and effectiveness in different educational contexts.
- Longitudinal studies are needed to assess the sustained impact of the GQM framework on student learning outcomes and curriculum development over time.
- Examining the potential for integrating the GQM framework with educational technologies, such as learning management systems, may improve data collection and analysis for continuous improvement.

AUTHOR'S PROFILE

Reem Alnanih is an associate professor of Computer Science in Faculty of Computing and Information Technology (FCIT), at KAU, Jeddah, Saudi Arabia. She received her B.Sc. and M.Sc. degrees from Computer Science Department. She got her Ph.D. in Computer Science from Concordia University, Montreal, Canada. She currently serves as the Vice Dean of Scientific Research for Female at KAU. Her research interests include software engineering, HCI, quality measurement and related evaluation techniques.

Critical Success Factors of Microservices Architecture Implementation in the Information System Project

Mochamad Gani Amri, Teguh Raharjo, Anita Nur Fitriani, Nurman Rasyid Panusunan Hutasuhut
Master of Information Technology-Faculty of Computer Science, University of Indonesia, Jakarta, Indonesia

***Abstract*—Microservice Architecture (MSA) promises enhancements in information systems, including improved performance, scalability, availability, and maintenance. However, challenges during the design, development, and operations phases can hinder successful deployment. This research presents a case study of one of the leading telecommunications companies in Indonesia, which encountered a three-month delay in implementing its microservices architecture (MSA). The study aims to provide actionable insights for the company to enhance its MSA deployment and contribute to academic knowledge by offering a structured approach to evaluating critical success factors (CSFs) in similar contexts. Through a literature review, twenty-one factors were identified and categorized into four groups: (1) Organization, (2) Process, (3) Systems & Tools, and (4) Knowledge, Skills & Behavior. The Analytical Hierarchy Process (AHP) was used to evaluate the priority of each factor based on survey data from project executors and software development practitioners. The findings indicate that the Organization category is the most crucial, with (1) Top Management Support, (2) Clear Vision, and (3) Adequate Resources being the top three CSFs for MSA implementation.**

***Keywords*—Microservice architecture; software architecture; critical success factors; analytical hierarchy process**

I. Introduction

Microservice Architecture (MSA) has emerged as a prevailing trend in software development in recent years [1]. The advent of microservice architecture gained traction in the early 2010s, serving as a countermeasure to the complexities encountered in monolithic application development, deployment, and scalability [2]. Software development teams and organizations across various sectors have embraced microservice architecture for the construction and management of their applications [3]. MSA's adoption spans multiple industries, from technology to e-commerce and banking, and across different development environments, from cloud computing to on-premise solutions [4].

MSA delineates a monolithic application into a collection of smaller, isolated, and interconnected services [5]. Each of these services bears distinct responsibilities and operates independently from others, thereby enabling development teams to work in isolation and reduce the overall system complexity [6]. MSA's popularity stems from its greater flexibility in development, the capability for independent scaling and updating of components, and the facilitation of system management and security [7].

Despite the improvements and benefits offered by MSA implementation, O'Reilly published research [8] that identified potential challenges (pains) arising at various implementation phases of MSA (design, development, and operations) such as overcoming existing mindset, decomposing functionality and integration to legacy system as the top three challenges. Cross-phase issues in design, development, and operation have been identified, including architecture, management, monitoring, testing, and others [9]. Several researchers have also explored the benefits (gains) and challenges (pains) of MSA deployment [9,10].

As a case study, one of Indonesia's leading telecommunications companies is improving its workforce management system to enhance availability, scalability, and maintainability. One of the initiatives being undertaken was migrating from monolithic to microservices-based architecture. However, during the development process, challenges arose, causing the project delivery to be delayed by three months beyond the initial target. Based on the interview conducted with one of the technical managers, the complexity of the current monolithic system and lack of microservice experience at the organizational level made the duration of important aspects such as development and testing take longer than expected. This case problem aligns with research and practical evidence, which suggests that MSA is not a panacea, as it presents several challenges during its implementation phases [11]. About 9% of respondents experienced complete failure (not successful at all), and 37% reported limited success (some success) in their MSA implementation efforts [8].

Previous studies have researched the challenges and benefits that can be referred to as a candidates for the factors that affect MSA implementation. First [6], offers an insightful historical perspective on the evolution of microservices, highlighting key transitions that have shaped modern software engineering practices. Second [10], provides valuable empirical evidence from industry on the practical challenges of adopting microservices, directly supporting my analysis of deployment differences between public cloud and on-premise systems. Third [11], delves into the current obstacles and future directions for microservices, enriching the discussion of ongoing challenges and emerging trends.

The significant benefits offered by MSA implementation, coupled with the challenges faced during its execution, form

the basis of this study. Previous researchers have laid a solid foundation of knowledge on the benefits, problems, and challenges of implementing MSA, yet there has been no structured collection of critical success factors (CSFs) within specific case studies, especially in Indonesia. Hence, this study aims to identify and address the research question:

RQ: What are the critical success factors of microservice architecture implementation in the information systems project?

The author also argues that the success of an initiative or program is intrinsically linked to an organization's internal capabilities. These capabilities are comprised of four components: (1) Organization, (2) Processes, (3) Systems & Tools, and (4) Knowledge, Skills & Behaviors [12]. These components form the basis for categorizing the critical factors identified in this study.

II. Research Methods

This study is organized into three stages, as illustrated in Fig. 1. Step 1 involves the identification of Critical Success Factors (CSFs) through a systematic literature review (SLR) and the categorization of these factors based on capability categories. Step 2 encompasses the development and execution of a survey designed to collect quantitative data, serving as the foundation for the prioritization process. Step 3 entails the evaluation of priority levels utilizing the Analytic Hierarchy Process (AHP), a methodology that facilitates multi-criteria decision-making.

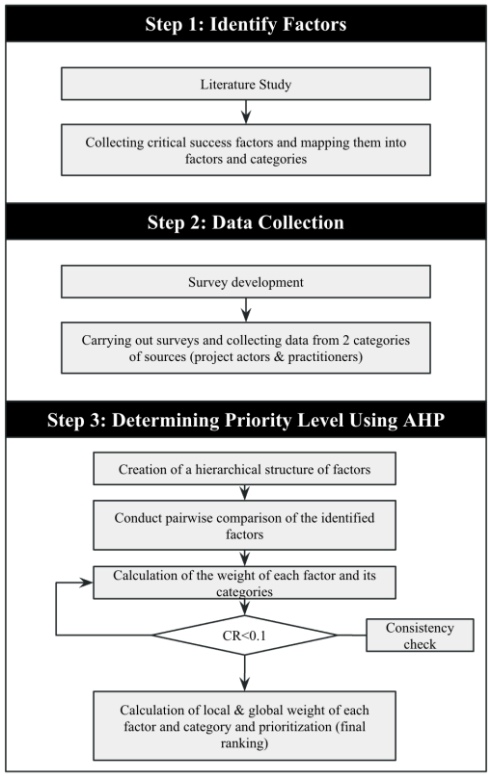

Fig. 1. Research method.

III. Identify Success Factors

A. Literature Study

In the initial stage of this study, the investigators conducted a literature study to identify the Critical Success Factors (CSFs) in the implementation of Microservice Architecture (MSA). Table I illustrates that the literature study commenced with a manual search through the electronic data source (EDS) Google Scholar, resulting in ten relevant studies.

TABLE I. Research Selection

Stages of Literature Study	Electronic Data Source (EDS)			
	Google Scholar (Manual)	Science Direct (SLR)	IEEE Xplore (SLR)	Total
String Execution	-	95	318	413
Study Extraction	-	20	48	68
Study Screening & Selection	10	11	8	29

For further research, two additional EDS, namely ScienceDirect and IEEE Xplore, were selected for systematic literature review (SLR) utilizing a three-step method.

- String Execution: The execution of search strings was performed according to the specifications outlined in Table II. These two data sources were targeted for the SLR and successfully gathered 413 research articles from journals and conferences.
- Study Extraction: The 413 research articles underwent a further filtering process based on titles & keywords to determine their relevance for in-depth reading. This resulted in 68 papers, with the primary aim being to avoid research focused on technical implementations in the form of application solutions that were outside the search for factors.
- Study Screening & Selection: A total of 29 studies, comprising 19 SLR studies (11 from ScienceDirect and eight from IEEE Xplore) plus ten manually identified studies, were advanced for closer examination. This involved quickly reading the abstracts, research findings, discussions, and conclusions to identify whether they contained fsactors relevant to MSA implementation.

Serarch Key Words	("microservices" OR "microservices architecture") AND ("factors" OR "success" OR "failure" OR "challenges")
Section	Title, Abstract & Author Keywords
Publication Type	Research Articles or Conferences
Publication Year	2019-2024

B. Define the Success Factors

In this section, the researchers elucidate the Critical Success Factors (CSFs) identified from the literature study. A total of 21 critical success factors were discovered for the

implementation of Microservice Architecture (MSA), described as follows.

1) Top management support: The support exhibited by top leaders of an organization towards a specific initiative or project encompasses recognition, resource allocation, and active involvement from top management in guiding, encouraging, and supporting the success of the initiative. Researchers concur that the success of information system implementation is inseparable from comprehensive support from top management within an agency or company [33-34].

2) Clear vision: Research [35] adds a clear vision as a critical success factor for information system implementation into its framework. A clear vision includes the goals to be achieved, available resources, timelines, systems to be implemented, vendors, and possible methods needed to achieve these goals.

3) Organizational culture: The implementation of MSA can drive organizational culture change through the division of teams into smaller units, reducing dependencies and communication between teams. This can also lower costs in the management process [10]. A survey conducted [30] mentions that MSA results in better development and deployment with scalability compared to monolithic architecture; however, there are challenges where organizational culture becomes a primary factor in MSA adoption. Organizational culture also significantly influences company performance and effectiveness, employee morale and productivity, and its ability to attract, motivate, and retain talented individuals [36].

4) Adequate resources: Project managers and software architects are the main focus of high development costs in MSA implementation due to developers lacking experience in MSA implementation [22]. The need to design a good MSA architecture to optimize the performance of MSA-based applications requires adequate software architecture resources [29]. In this research context, adequate resources include the technical, financial, and human resources allocated for the implementation process.

5) Project management: Effective project management is a critical need for every information system project initiative [31]. Project management encompasses the processes of planning, organizing, directing, and controlling the resources used to achieve the project objectives within specified time, budget, and scope limits. Requirements Engineering (RE) and non-RE tasks/sub-tasks, such as overseeing the transition of requirements to code, coordination, or project management, are regarded as essential skills in the era of MSA [43]. The synchronization between the teams is also a challenge in developing microservice architecture due to the complex dependencies and communication of services [47].

6) Change management: Managing resistance in the implementation process of a new initiative is an important factor; organizations must have good planning for projects to run effectively [31]. The process of managing change within an organization involves understanding, preparation, execution, and monitoring of changes to achieve the desired outcomes and minimize potential negative impacts.

7) Training and education: The main goal of training is to enhance the skills, knowledge, and competency levels of all users within the organization. Training should be provided and considered as part of the implementation process because it influences collective beliefs about the benefits of the implemented system [31]. Microservices practitioners should have competencies in at least one, ideally multiple, of the core MSA roles (web developer, DevOps engineer, or data engineer). The three main collections of competencies indicate the primary technical skills that practitioners who want to work with microservices should have [45].

8) Vendor selection: The process of selecting vendors that will collaborate with an organization to provide specific products, services, or solutions. This involves the evaluation and selection of vendors that best meet the needs and requirements of the organization. Careful selection of vendors, products, and services is necessary because failure to do so successfully can be very costly, as shown by several reported failure cases [25].

9) Agile methodology: The development of distributed microservice-based systems can adopt the agile approach as a system development method; therefore, communication is crucial for knowledge transfer among teams [24]. The software development process with agile methodology focuses on adaptive team collaboration, responsiveness to changes, and the delivery of high-value products. Organizations found agile development compatible with microservice-based architectures. The common view was that the bounded context of each microservice works well in agile development [47].

10)System modeling: The process of creating models that visually or conceptually represent a system. The goal is to understand, analyze, design, and construct systems in a systematic and structured manner, for example, using UML. Modeling diagrams are used to describe various aspects of MSA-based systems. Results show that Architecture and Functional Flow diagrams are commonly used to depict a high-level view of MSA [28]. A study found that the lack of a formal representation of domain models is a challenge for software modeling and emphasizes even simple and informal diagrams such as UML can be used to represent domain models as long as they help communicate design insights [42].

11)API management and standardization: API management involves managing the API lifecycle, including planning, development, testing, deployment, and maintenance of APIs (API Contract, API Versioning, Open API Standard, etc.). Further research worth conducting is on the pains felt due to exploiting APIs to enable microservice services to communicate [9]. The microservice API evolution process suffers from the loose coupling between services and leads to communication overheads and backward compatibility necessity [46].

12)Service communication: Communication between various microservices within a system (Discovery of services,

Replicated Service Instances, Load Balancing, Replicating data, Remote Calls, Relation Between Tables, REST, Event Driven). There are facts that intercommunication between API-based systems also poses real issues [9]. In a microservice-based system, to overcome the challenge of complex communication and dynamicity at runtime in failure detection, distributed tracing data is used [44].

13)Infrastructure automation: When infrastructure automation technology is applied, the deployment of microservices becomes as straightforward as monolithic systems [10]. Activities encompassing infrastructure automation processes include CI/CD, tools (version control, build, test, deploy), and testing tactics (unit, API, integration & contract testing).

14)Monitoring and logging: The application of tools for monitoring, information gathering, and data analysis to ensure optimal performance, detect issues, and support accurate decision-making. A major challenge of implementing microservices is the intrinsic complexity of monitoring applications composed of a large, dynamically evolving, and heterogeneous number of components [9]. There are also challenges to detecting failures in microservice-based systems due to the inherent characteristics of such systems, including complex communications, frequent updates, dynamicity at runtime, and complex log management [44]. Monitoring is of paramount importance to continuously drive development and testing, starting from the feedback collected from the field [48].

15)Cloud computing adoption: Data storage, processing, and resource management over the internet using infrastructure provided by cloud service providers such as IaaS, PaaS, and SaaS. SaaS Cloud-native based on microservices offers customers flexible infrastructure opportunities while leveraging the economies of scale provided by cloud providers and multi-tenancy architecture [27].

16)System architecture design: The expertise in planning the overall structure and components of a system. This involves identifying system needs, selecting appropriate technologies, modeling components, and arranging interactions between those components. In the process, considering microservices-based architecture design identifies parts (partitions) of applications in limited contexts is not easy; microservices yield benefits from implementing this bounded context [9].

17)Database architecture and design: Determining the appropriate database model, designing schema, defining tables and their attributes, and constructing relationships among them. Creating databases that can efficiently store and retrieve data, ensure data integrity, and meet system requirements. The design of a database per service pattern allows for independence among MSA services by equipping each service with its storage (if needed) [9].

18)System security: Knowledge related to practices for protecting computer systems, networks, or software applications from unauthorized access, data breaches & cyber threats. System security aims to ensure the confidentiality, integrity, and availability of system resources and data. Security also poses issues at the design time, especially due to access control (ACL) and the proliferation of endpoints [9] (Table III).

TABLE III. CRITICAL SUCCESS FACTORS BASED ON LITERATURE STUDIES

ID	Factors	Studies
F1	Top Management Support	L13 [32], L14 [33]
F2	Clear Vision	L15 [34]
F3	Organizational Culture	L9 [10], L11 [30] L16 [35]
F4	Adequate Resources	L2 [22], L10 [29]
F5	Project Management	L12 [31], L24[43], L28[47]
F6	Change Management	L12 [31]
F7	Training and Education	L12 [31], L26[45]
F8	Vendor Selection	L5 [25]
F9	Agile Methodology	L4 [24], L28[47]
F10	System Modeling	L8 [28], L23[42]
F11	API Management & Standardization	L1 [9], L9 [10], L11 [30], L17 [36], L27[46]
F12	Service Communication	L1 [9], L2 [22], L6 [26], L11 [30], L17 [36], L18 [39], L21 [40], L25[44]
F13	Infrastructure Automation	L1 [9], L2 [22], L6 [26], L8 [28], L9 [10], L11 [30], L18 [37], L20 [39], L21 [40]
F14	Monitoring & Logging	L1 [9], L2 [22], L6 [26], L8 [28], L9 [10], L11 [30], L18 [39], L21 [40], L25[44], L29[48]
F15	Cloud Computing Adoption	L7 [27], L10 [29]
F16	System Architecture Design	L1 [9], L2 [22], L8 [28], L11 [30], L17 [36], L18 [37], L21 [40]
F17	Database Architecture & Design	L1 [9], L9 [10], L11 [30], L17 [36], L18 [39], L21 [40]
F18	System Security	L1 [9], L6 [26], L8 [28], L11 [30], L17 [36], L21 [40], L22 [41]
F19	DevOps Culture	L8 [28], L9 [10], L11 [30], L19 [38]
F20	Microservices Experience	L2 [22], L2 [23], L10 [29], L11 [30], L18 [37]
F21	System & Software Design Patterns	L8 [28], L11 [30], L19 [38], L21 [40]

19)DevOps culture: The integration of software development (Dev) practices with IT operations (Ops) to create an efficient, sustainable workflow focused on the rapid delivery of business value. The combination of MSA and DevOps brings several other benefits, including increased software release cadence, system reliability and scalability, resilience in case of failures, and decentralized team

management to control application development [28]. In the technological aspect, containerization also enables DevOps to achieve faster deployment implementation than VMs as it is not efficient to run each microservice on a separate VM due to its long startup time and increased resource usage [41].

20)Microservices experience: Knowledge and experience in designing, developing, and managing application architectures using the microservices approach. Research [22] highlights higher development costs, possibly due to developers undertaking microservice development for the first time.

21)System and software design patterns: Several MSA design patterns have been identified. The most recurring design patterns during the MSA implementation process in DevOps are Circuit Breaker and migration patterns, followed by Observer, Load Balancer, Scalability, and Deployment [28].

According to Strategy, and a unit of PwC focused on business strategy consulting, capabilities are comprised of four components as illustrated in Fig. 2. Organization, Process, Tools & System, and Knowledge, Skills & Behaviors [12]. Each component is described as follows:

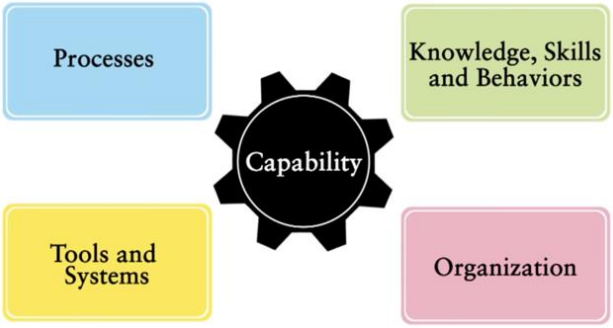

Fig. 2. Four parts of capability according to Strategy and PWC.

a) Organization: The entire structure and design of a company, including governance, management, and its operational model. Organizations with strong capabilities can identify, develop, and leverage competitive advantages in a competitive market. They can transform the knowledge, skills, and behaviors of individuals or groups into sustainable organizational capabilities that create value for all stakeholders involved.

b) Process: The steps or activities used by a company to create value for customers. In the context of an organization, processes aim to achieve efficiency, effectiveness, and desired outcomes. This is crucial to design, manage, and continuously improve processes to enable the organization to operate better, enhance customer satisfaction, and achieve competitive excellence.

c) Tools and system: The right combination of relevant systems and tools can strengthen the capabilities of an organization or individual, facilitating the coordination, efficiency, and monitoring needed to achieve desired goals. It is important to match systems and tools with the specific needs of the organization or individual and ensure they align with established strategies and objectives.

d) Knowledge, skills, and behaviors: In many situations, the success of an individual or group does not solely depend on the knowledge they possess but also on the skills applied in practice and behaviors that support good performance. These interrelated knowledge, skills, and behaviors often become a focus in the development of individuals and human resource management strategies to effectively achieve organizational objectives.

C. Decision Modeling Using AHP

The Analytic Hierarchy Process (AHP) is a widely recognized method for solving complex decision problems developed by Saaty [13]. It breaks down any complex issue into multiple sub-problems using AHP in terms of hierarchy levels, where each level represents a set of criteria or attributes relative to each sub-problem.

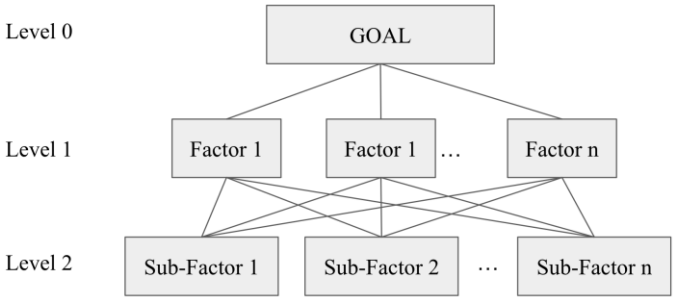

Fig. 3. AHP methodology structure as a framework for complex decision-making problems.

For instance, in an AHP model, Fig. 3 would illustrate the top level (level 0) of the hierarchy representing the goal of the problem, followed by the middle level (level 1) representing strategic and operational factors, and the last level (level 2) typically representing alternative actions or sub-factors that must be considered to achieve the goal. AHP organizes feelings, intuition, and logic in a structured approach to decision-making, which has proven beneficial in environments largely composed of intangible attributes.

AHP enables an individual to organize a system and its environment into interacting elements and then synthesize these by measuring and ranking the impact of these elements on the overall system [13,14]. AHP comprises four phases.

- Phase 1: Problem structuring and designing the hierarchy structure of factors and subfactors.
- Phase 2: Data collection based on pairwise comparisons through expert surveys. In the data collection process, interviews must be conducted with experts actively involved in problem resolution [16]. Subsequently, a pairwise comparison matrix A is formed as follows:

$$A = (a_{ij}), (i, j = 1 \ldots n) \quad (1)$$

$$A = \begin{pmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & \dots & a_{nn} \end{pmatrix} = \begin{pmatrix} 1 & a_{12} & \dots & a_{1n} \\ 1/a_{12} & 1 & \dots & a_{2n} \\ \dots & \dots & \dots & \dots \\ 1/a_{1n} & 1/a_{2n} & \dots & 1 \end{pmatrix} \quad (2)$$

- Phase 3: Determining the priority weights of each factor and performing a consistency check.

In the third phase, the focus is on identifying the relative importance values of the factors themselves within a specific category rather than comparing them to factors or categories elsewhere [17]. This can be achieved by calculating their local weights using (3) [16].

$$W_{Ai} = \frac{\left(\prod_{j=1}^{n} a_{ij}\right)^{1/n}}{\sum_{i=1}^{n}\left(\prod_{j=1}^{n} a_{ij}\right)^{\frac{1}{n}}} \quad (3)$$

Subsequently, the global weights, which indicate the relative importance of factors among all factors, are calculated as follows: the global weight of a CSF (Critical Success Factor) category is equal to its local weight. For CSFs, the global weight is the product of the local CSF weight and the local weight of the related category. This step concludes with a consistency test through the calculation of the Consistency Ratio (CR) as follows: calculation of the largest eigenvalue.

Calculate the biggest Eigen Value using (4).

$$A\omega = \lambda_{max}\omega \quad (4)$$

Calculate CR value using (5).

$$CR = \frac{CI}{RI} \quad (5)$$

- Phase 4: Analyzing the priority weights and determining solutions for the problem.

In the fourth phase, the priority weights calculated from the pairwise comparisons are analyzed to derive the best solutions for the problem. These weights represent the relative importance of each criterion or alternative, helping to prioritize options based on the decision-maker's preferences.

IV. Result and Discussion

A. Result

After identifying the critical success factors (CSFs) impacting the implementation of MSA, a hierarchical structure was constructed, and the upper categories of these factors were established. The categories are Organization, Process, Tools & System, and Knowledge, Skills & Behaviors, which are specifically explored in this study. The four categories and their respective factors are illustrated in Fig. 4.

Once the hierarchy/categorization was established, comparative assessment was employed to ascertain the relative significance of these factors. A pairwise comparison matrix was then developed to prioritize the comparative assessments into ratio scale measurements. In this study, a nine-point scale was applied to compare the significance of each factor pair, as detailed in Table IV. The evaluation consists of five values: 1, 3, 5, 7, and 9, representing equal importance, slight importance over another, essential or strong importance, demonstrated importance, and absolute/extreme importance, respectively. Intermediate assessments were expressed through the use of even numbers 2, 4, 6, and 8.

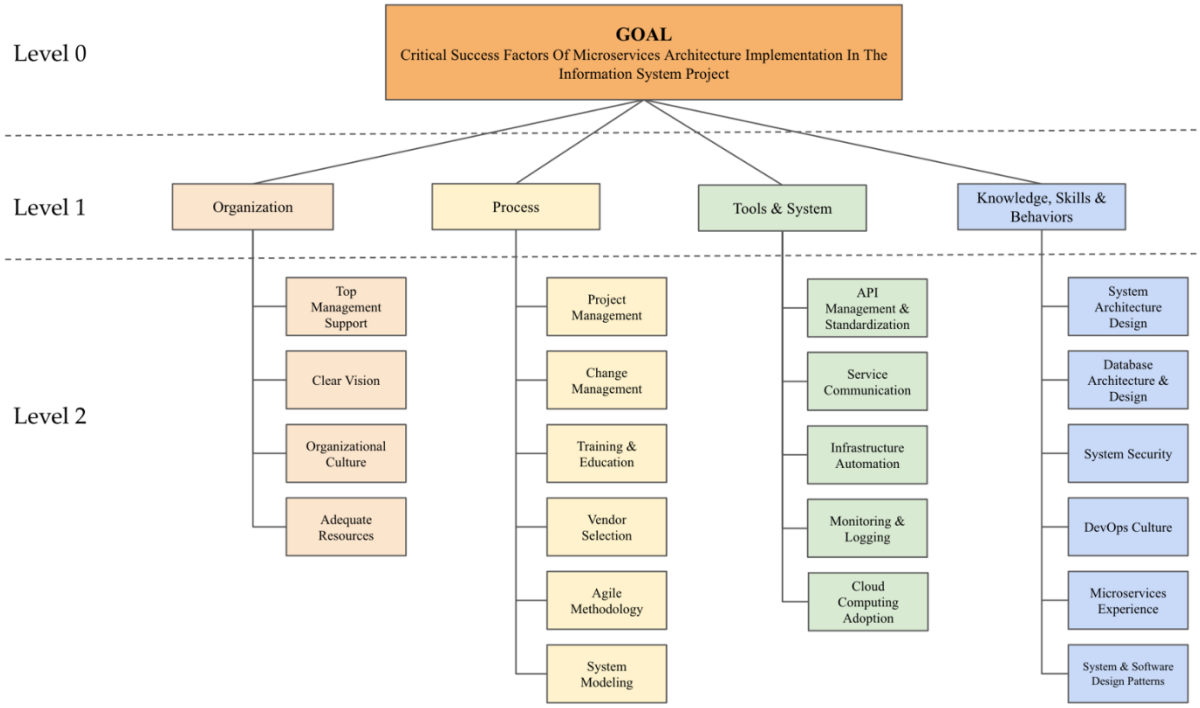

Fig. 4. Microservice architecture implementation success factors hierarchical structure.

Experts were asked to perform pairwise comparisons of factors. These comparisons were then used to create a pairwise comparison matrix. An example of such comparison is management support versus a clear vision, posing the question, "How significant is top management support compared to a clear vision?" If experts responded with "demonstrated importance," a value of 7 was assigned in the matrix. Conversely, if experts indicated that a clear vision holds greater importance than top management support, a value of 1/7 was added to the matrix. The involvement of experts in this prioritization was documented in a pairwise comparison survey.

TABLE IV. SCALE MEASUREMENT

i compare with j	a_{ij}	a_{ji}
Equally Importance (EI)	1	1/1
Moderately Importance (MI)	3	1/3
Strongly More Importance (SMI)	5	1/5
Very Strongly More Importance (VSMI)	7	1/6
Extremely More Importance (EMI)	9	1/7
Equally Importance (EI)	1	1/1

After completing the comparison matrix, researchers proceeded to calculate priority weights, consistency index, random consistency index, and the consistency ratio among the factors using the pairwise comparison matrix. Table V displays the random consistency index provided by [18]. It is crucial to note that when calculating the consistency ratio, a threshold must not be exceeded. To ensure desirable outcomes, it is advised that the consistency ratio is within the range of 0 and 0.1, especially for matrices exceeding a 4x4 dimension, as recommended by Saaty [18]. If the calculated consistency ratio is equal to or less than the acceptable value, this indicates that the comparative assessments represented in the matrix have a consistent level of consistency.

TABLE V. RANDOM CONSISTENCY INDEX

Size of Matrix	Random Consistency Index
1	0
2	0
3	0.58
4	0.90
5	1.12
6	1.24
7	1.32

In this study, the process of calculating priorities was divided into four according to the number of categories, and the results from the consistency index check were as follows: Organization (Cat 1) 0.0931, Process (Cat 2) 0.0924, System & Tools (Cat 3) 0.0972, and Knowledge, Skills & Behaviors (Cat 4) 0.0822. These results indicate that the overall process of calculating priorities is consistent.

Table VI displays the results of the priority weights and rankings for each category and the factors associated with them. The Category column contains weight values representing the importance level of each category. The four categories derived from the supporting parts of the capabilities required by any company or institution, in the context of this study, refer to capabilities in implementing MSA. Analysis revealed that the Organization category is most crucial, with a weight of 0.4844 in the implementation of MSA. The Knowledge, Skills & Behaviors category ranks second with a weight of 0.2240, followed closely by the Process and Tools & System categories with weights of 0.1615 and 0.1302, respectively.

In the Factor column, there are two weight values: local weight as a priority within the category scope of the factor and global weight as the basis for the Priority column as the factor's ranking compared to all studied factors. In the Organization category, the Top Management Support factor is deemed most important, with a local weight of 0.5011. For the Process category, the Project Management factor is the main priority with a local weight of 0.3046. In the Tools & System category, the highest local weight of 0.3938 is for the API Management & Standardization factor, and in the last category, Knowledge, Skills & Behaviors, the Microservices Experience factor is considered most important with a local weight of 0.2300. Globally, the top three critical success factors are Top Management Support, Clear Vision, and Adequate Resources.

B. Discussion

This study focuses on the process of identifying, defining, and evaluating critical success factors (CSFs) for the implementation of Microservices Architecture (MSA) at one of the leading telecommunications companies in Indonesia. Each factor will be mapped into categories based on an institution's or company's capabilities to implement MSA. This mapping process is crucial as a high-level overview for the management at the company to understand which internal capabilities need to be enhanced for similar initiatives to be carried out effectively and efficiently in the future. A literature study was conducted by combining a manual search of studies deemed relevant to the topic discussed, supplemented with the application of a systematic literature review (SLR) to enrich the determinants of successful MSA implementation.

Table VII displays the demographics of the experts who assisted in the prioritization process of the critical success factors (CSFs) in this study. We were supported by four experts, consisting of two types: those who were involved and those who were not directly involved with the project implementation. The presence of these two types of experts is expected to achieve a balance that supports better objectivity in the prioritization process conducted through surveys. The experts were selected with several selection criteria such as more than five years of experience in the software field, having experience in developing systems based on MSA, and being certified in software architecture or IT service management.

TABLE VI. SUMMARY OF WEIGHTING AND PRIORITY LEVEL OF FACTORS

Categories			Factors					
ID	*Name*	*Weight*	*ID*	*Name*	*Local Weight*	*Local Rank*	*Global Rank*	*Priority*
Cat 1	Organization	0.4844	F1.1	Top Management Support	0.5011	1	0.2427	1
			F1.2	Clear Vision	0.2630	2	0.1274	2

The Analytic Hierarchy Process (AHP) was employed to derive local and global weights as benchmarks for determining the priority levels of each category and critical success factors (CSFs) for the implementation of Microservices Architecture (MSA). This study produced a taxonomy of critical success factors (CSFs), taking into account both global and local weights. The identified success factors were categorized into four distinct sections; every section offers several insights for enhancing the MSA implementation process at the company.

Fig. 5 presents the outcome of the global weighting process for all determining factors of success using AHP as the method for complex decision-making. It can be concluded that the factor Top Management Support significantly outperforms other factors. Following in second and third order are the factors of Clear Vision and Adequate Resources respectively. An interesting finding is that these three factors fall within the same category of Organization. This justifies that the Organization category, displayed in Fig. 6, also ranks first from a capability perspective and significantly surpasses other categories, such as Knowledge, Skills & Behaviors in second place. The results of this study address the research question.

For future research, we acknowledge several limitations of this study, particularly in determining the critical success factors (CSFs), although the literature review utilized the Systematic Literature Review (SLR) method. The results from these factors have not undergone empirical testing for more objective factor selection. Approaches such as the frequency approach, found in [19,20], could be employed. Furthermore, the implementation of an expert judgment committee to evaluate the factors could be conducted to ensure that each factor is clearly defined [21].

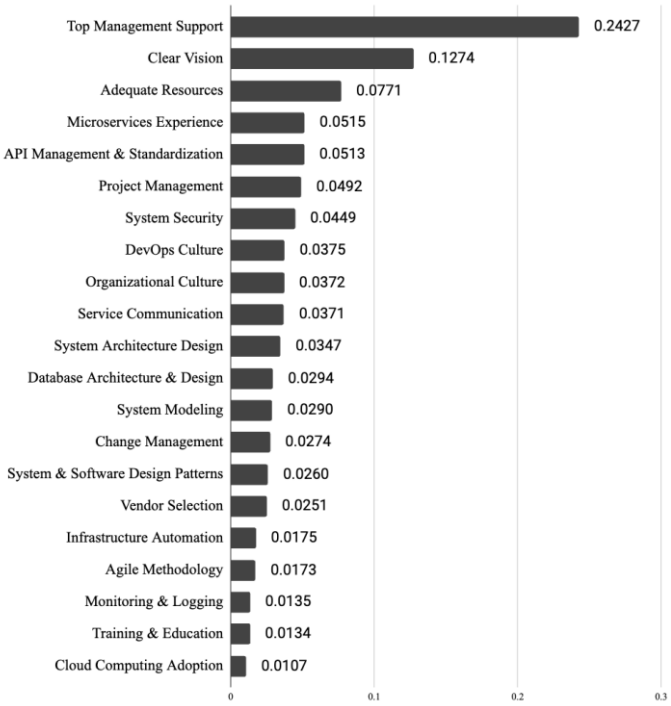

Fig. 5. List of overall implementation success factors ordered by global weight.

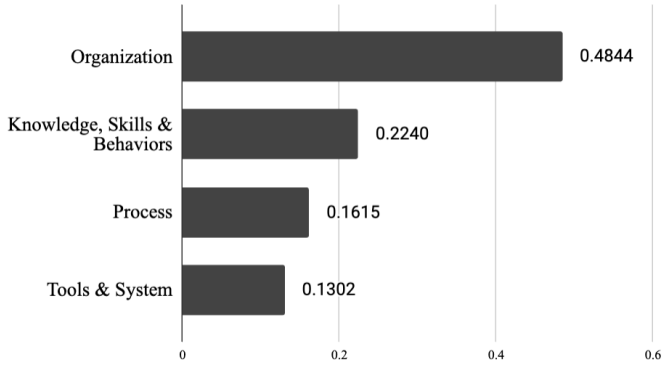

Fig. 6. List of categories based on capabilities ordered by weight.

V. Conclusion and Future Work

In this study, 21 critical success factors (CSFs) were successfully identified from the literature review process and categorized into four categories: (1) Organization, (2) Process, (3) Tools & System, and (4) Knowledge, Skills & Behaviors. To perform the evaluation process of the priority level of each factor and category, the Analytical Hierarchy Process (AHP) was selected as the decision-making methodology based on survey data conducted among project participants and practitioners.

The conclusions from the results of this study, as depicted in Table VI, indicate that from a categorical perspective, Organization ranks first as the most important. The top three sub-factors of critical success for the implementation of Microservices Architecture (MSA) are: (1) Top Management Support, (2) Clear Vision, and (3) Adequate Resources. When examining the priority of each category, based on local weights, it is evident that in the Organization category, the primary priority factor is Top Management Support (F1.1). For the second category, Process, the main priority is factor Project Management (F2.1). In the category Tools & System (F3.1), the factor API Management & Standardization is the priority, and for the last category, Knowledge, Skills & Behaviors, Microservices Experience (F4.5) ranks as the top factor.

To ensure the successful implementation of Microservices Architecture (MSA) in the organization, it is crucial to enhance leadership engagement, strategic clarity, and resource allocation. Strengthening top management support is vital, as their active involvement and oversight are essential for maintaining momentum and addressing challenges effectively. Additionally, articulating a clear vision and developing a robust communication strategy will ensure that teams are aligned and working towards common objectives, thereby minimizing misalignment and inefficiencies.

Furthermore, the company should prioritize the allocation of sufficient resources, both financial and human, to support the MSA initiative. This includes investing in the recruitment and upskilling of personnel to develop the necessary expertise in microservices, as well as ensuring access to essential tools and systems. By addressing these critical areas, the company can leverage the identified critical success factors to mitigate potential risks, optimize the execution of the project, and fully realize the benefits of MSA, including enhanced scalability, flexibility, and operational efficiency.

For future work, it is recommended that further research be conducted to explore the long-term impacts of the identified critical success factors (CSFs) on the sustainability and scalability of Microservices Architecture (MSA) implementations. Additionally, conducting comparative studies across different industries and organizational sizes would be valuable to determine whether the CSFs identified in this study are universally applicable or if they vary based on context.

Application Citespace Visualization Tool to Online Public Opinion Group Label: Generation, Dissemination and Trends

Jingyi Ju*
School of Media, Nanyang Institute of Technology, Nanyang 473000, Henan, China

***Abstract*—With the popularization of mobile Internet technology, the social and cultural environment provides a favorable communication environment for online news dissemination, leading to a highly ubiquitous phenomenon of group labeling communication events. This study explores the generation, dissemination, and evolution trends of group labeling in the online public opinion environment. This study crawled 20975 initial literature data included in the core database of Web of Science, obtained 9834 valid literature after several rounds of screening, and utilized CiteSpace 6.3 software to do metric data analysis and word frequency analysis on the above valid literature data and successively adopted the Analysis means of literature being co-cited, author co-citation, journal co-citation, keyword co-citation, and clustering to analyze group labeling. We have successively used the Analysis of literature co-citation, author co-citation, journal co-citation, keyword co-citation, clustering, etc., and disassembled the group labeling into the generation environment, dissemination process, and trend evolution. The study utilizes the disciplinary perspective of journalism and communication and social media platforms to assist it. Thus, it summarizes and reveals the interaction of group labels in cyberspace and the natural world and seeks to grasp the communication mechanism of the process of insight into this emerging discursive power.**

***Keywords*—Group labeling; online public opinion; labeled communication; communication mechanisms; visualization**

I. Introduction

The proliferation of mobile Internet technology has significantly reshaped the social and cultural landscape, providing a fertile ground for the pervasive phenomenon of online news dissemination and group labeling communication events [1]. This study is set against the backdrop of a globally connected digital society, where the number of Internet users has surged to 5.16 billion, as reported by the "Global Digital Report 2023". In China, this figure has reached 1.092 billion, with an Internet penetration rate of 77.5% [2]. The transition from traditional one-to-one communication models to the current one-to-many socialized network models has been accelerated by the iterative updates of Internet technology. This evolution has not only democratized and personalized information dissemination but also given rise to the intriguing phenomenon of group labeling, which is the focal point of this research [3].

While the existing literature has made strides in understanding the mechanics of online communication and the spread of information, there is a notable gap in the comprehensive analysis of group labeling within the online public opinion sphere [4]. Prior studies have often focused on isolated aspects of this phenomenon, neglecting the interconnectedness and dynamic nature of group labels as they evolve and disseminate across various social platforms [5]. This research aims to address these shortcomings by providing a holistic examination of the generation, dissemination, and trend evolution of group labeling. Through the application of CiteSpace 6.3 software and a variety of analytical methods, we seek to uncover the underlying communication mechanisms and the interplay between group labels in cyberspace and the natural world.

The structure of this paper is meticulously designed to guide the reader through a comprehensive exploration of the topic. Section II. Data collection and research methodology: We detail our research methodology, explaining the data collection and analysis strategies using CiteSpace 6.3. Section III. Analysis process and findings: we present our analysis and findings, discussing the results of bibliometric and keyword analyses. Section IV. Dissemination and trends in group labeling: We examine the broader impact of group labeling, discussing its spread across social platforms and its societal effects. Finally, we conclude by summarizing our findings and their implications for online communication in Section V. We also assess our study's contributions and suggest future research directions, reflecting on our insights and looking forward to further exploration.

II. Data Collection and Research Methodology

In the subsequent section, we delve into a thorough review of the existing literature to contextualize our research within the broader academic discourse. This comprehensive overview serves to elucidate the current state of knowledge, underscore the methodologies employed by preceding studies, and highlight the contributions of pivotal research to the field. We critically assess the merits and limitations of existing approaches, shedding light on the shortcomings that our study endeavors to overcome. By identifying the gaps in the literature, we position our research as a response to the need for a more nuanced understanding and a more sophisticated approach to analyzing online public opinion group labeling. Our review not only pays homage to the foundational works that have paved the way for our study but also sets the stage for the innovative aspects of our methodology, which we believe will significantly advance the field by addressing the identified shortcomings and expanding the current horizons of research.

A. Data Acquisition

Based on the complexity of Internet information data collection and the different focuses of Internet group labels in other periods, this study mainly adopts the literature analysis method to analyze the data. To ensure the professionalism, leadership, accuracy, and completeness of the data, this paper selects the global academic literature that has been included in the core database of Web of Science as the data source and searches for the subject terms or contents, including "Group tags" or" Dissemination Mechanisms," "Social Communications," "Hashtag communication." The subject area is journalism and communication, and the time is set as the natural year between 2013 and 2023. After several rounds of searching, the initial literature data of 20975 items are obtained. After the big data technology-assisted data collection, manual review is also indispensable; through the reading of literature topics and literature abstracts, after eliminating a series of meetings, notices, reports, and other relevant literature data unsuitable for inclusion in the study, selecting the platform open access resources, and ultimately retaining 9834 pieces of valid literature data after manual screening and organizing.

B. Research Methodology

Based on the effective data sources obtained after the above multiple screenings, this study, with the help of the co-occurrence, clustering and social network analysis system in the CiteSpace 6.3 software tool, constructs the visualization matrices of bibliometrics, textual co-occurrence, word-frequency clustering, and social network relational mapping required for this study, and identifies the group labeling, a research object, through the generalization and Analysis of the extracted particular data related research hotspots, and then form a comprehensive, multidimensional and interconnected knowledge system to show the connections and interactions between different disciplines and the field of journalism and communication [3].

III. Analysis Process and Findings

In this section, we underscore the distinctive merits of our proposed methodology by juxtaposing it with existing approaches within similar domains. Our method leverages advanced data analytics and machine learning algorithms, which offer superior precision and scalability compared to traditional models. This advantage is particularly evident in handling large datasets commonly encountered in the analysis of online public opinion. Furthermore, our approach incorporates a novel feature engineering technique that enhances the model's ability to capture subtle nuances in group labeling dynamics, thereby providing more insightful predictions and interpretations. When compared with state-of-the-art models in the field, our method demonstrates a significant improvement in both accuracy and computational efficiency, as evidenced by the rigorous experimental evaluation detailed in the subsequent section. This comparative analysis not only highlights the innovative aspects of our approach but also solidifies its potential to contribute to the broader discourse on online group labeling and public opinion analysis.

A. Analysis of Literature Releases

Literature analysis identifies and responds to the knowledge and theoretical frameworks within a research discipline or field. In this study, the data were collected from the WoS core database. The literature was searched and filtered by "Group tags" and "Social Communications." The number of valid documents retrieved was 9834 by December 31, 2023. The number of valid documents retrieved was 9834 by December 31, 2023. As of December 31, 2023, the number of valid documents retrieved is 9834 articles. When analyzing the literature, this paper analyzes the number of publications in-depth and the co-citation relationship of the literature.

1) Number of literature releases: In the academic world, the number of literature releases can directly reflect the research activity, research strength, and research results of research scholars within the field of study, as well as the development of academic research. Therefore, the higher the number of literature releases represents, the more active and fruitful academic research in the field. This study mainly counts the literature released in the natural years of 2013-2023, in Fig.1.

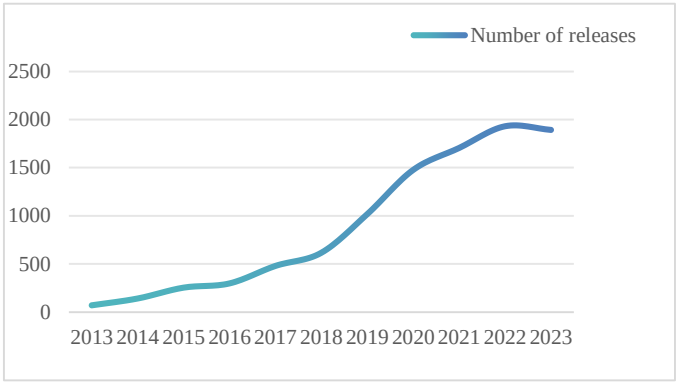

Fig. 1. Statistics on the number of literature releases, 2013-2023.

Based on the statistics and quantitative distribution of the number of literature releases, the literature releases within the field show a significant growth trend, starting from 69 in FY2013 and reaching 1,894 in FY2023. In particular, the growth rate of the number of annual publications has accelerated significantly from 2019 onwards, from 1,018 articles in FY2019 to 1,932 articles in FY2022, reflecting a significant increase in research activity and academic output within the field in recent years, which may be related to factors such as the development of Internet technology, new media forms, and digital technology. In addition, the number of articles issued in FY2022 and FY2023 accounted for 19.580% and 19.195% of the total, respectively, which indicates that these two years are the peak periods of academic research in this research field, which may be related to factors such as the increase in research funding, or policy support.

Upon further analyzing these data, it can be observed that the overall growth trend has remained the same between 2017 and 2019, despite fluctuations in the number of annual publications. To some extent, this growth phenomenon reflects the continuously growing research interest of research scholars in this field of study and the fresh exploration of its depth and breadth.

2) Literature co-citation analysis: Literature co-citation analysis is an important research method that reveals the structure of knowledge in a discipline. When two documents appear simultaneously in the reference list of the same cited document, they constitute a co-citation relationship. This means of Analysis can reveal the intrinsic connection between the literature, reflecting the knowledge base and developmental lineage within the field of study. Identifying and analyzing these co-cited documents makes it possible to locate documents central to the field and profoundly impact subsequent research. The cross-citation of literature demonstrates the dissemination and flow of knowledge over time and reflects the continuity of knowledge accumulation and the trajectory of disciplinary development [4]. If a paper is frequently cited within multiple research areas, it means that it has fundamental contributions to the theory and practice of the field. Co-citation analysis helps to identify this critical literature, thus providing a macro perspective for understanding the evolution of the discipline and current research trends. For the rapidly developing field of online public opinion, co-citation analysis is critical, as it can help research scholars quickly grasp the knowledge structure and research hotspots of the field and lay the foundation for further in-depth research.

In this study, an in-depth co-citation cluster analysis of scientific literature was conducted using CiteSpace software to deconstruct the knowledge architecture of the research area and gain insights into its developmental trends. The Analysis generated a network graph containing 1010 nodes and 3917 connectors, where nodes symbolize frequently co-cited literature and connectors reveal their interconnections. The network has a density value of 0.0077, reflecting that in such an extensive network, despite a large number of nodes, the connections between them are relatively sparse, a common characteristic of large network graphs (see Fig. 2).

Fig. 2. Literature co-citation visualization network mapping.

By observing the above-visualized network mapping, the network modularity Q-value reaches 0.7227, which, according to the modularity metric value standard, is not only much higher than the threshold of 0.3 in this study but also extremely close to the value of 1, which shows that there is a significant stable structure in the literature co-citation network [5]. In the literature co-citation map, it can be observed that several closely related subfields and a number of less closely related research topics are organized and connected around a particular core of knowledge within the research field. In addition, the Mean Silhouette value is as high as 0.8921, which is close to the perfect consistency 1. This is sufficient to show that the network knowledge structure of this research area is highly similar after the literature co-citation is clustered, further verifying the reliability and validity of the literature co-citation clustering.

B. Analysis of Study Authors

1) Author co-occurrence mapping: In Citespace software, we can explore the structure of author collaboration networks through specific parameter settings. In this study, we set the time slice to 1 year and chose "author" as the network node type to construct an author network structure graph. The graph comprises 520 nodes interconnected by 282 lines to form a panoramic knowledge graph [6]. However, the network density of this atlas is only 0.0021, showing that the overall network is very loose and lacks tightly cooperative clusters. In this network graph, nodes and connectivity are the two essential elements that make up the graph. Nodes represent individual authors, and their size is directly proportional to the number of articles published by an author, i.e., the larger the node, the richer the research output of that author. The connecting lines represent the cooperation relationship between authors, and their thickness represents the closeness of cooperation - the thicker the connecting lines are, the more frequent the collaboration between authors is in Fig. 3.

The author's collaboration network mapping generated by Citespace allows for a more intuitive identification of collaboration patterns and potential collaboration opportunities. Although the overall author collaboration network appears loose and does not form a large-scale close collaboration network, the localized collaboration activity still provides rich academic communication and collaboration opportunities [7]. Upon closer inspection, it is easy to find a certain degree of collaboration among authors, especially on a small scale, dominated by small teams of two to three people working together. This pattern of small-scale cooperation is a common phenomenon in academia, reflecting the close collaboration between individuals in academic research.

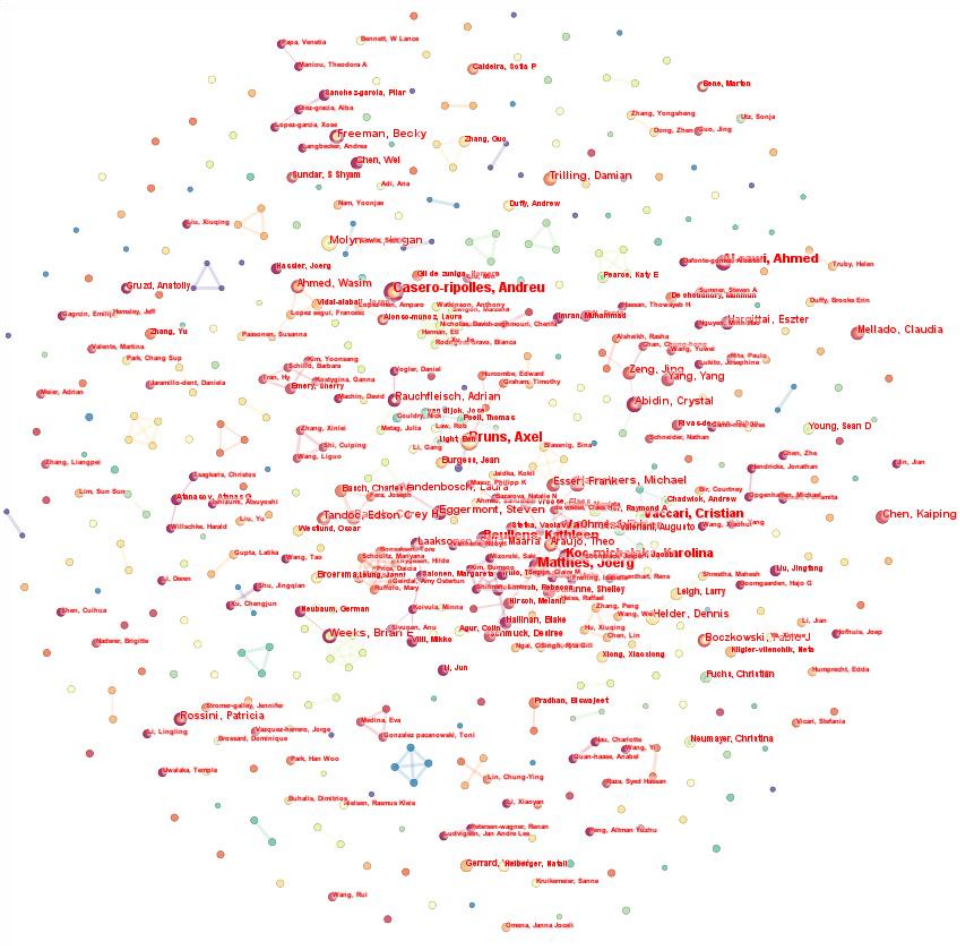

Fig. 3. Collaborating authors visualization network mapping.

This study conducted exhaustive statistics based on first-author literature publications. The data showed 520 authors published research papers in this field during 2013-2023. Among these authors, 76 published only one paper, accounting for 14.62% of the total number of authors. Although low, this percentage has demonstrated the research field's openness and inclusiveness to new scholars. Two hundred sixteen authors have published two papers, accounting for 41.54% of the total number of authors, and the more significant high percentage share reveals that research scholars in this field have a wide range of participation.

Combined with the time and frequency of literature publication, these authors may have a basic grasp and understanding of the research topic, and their research results may be more focused on the construction of theoretical frameworks or the exploration of specific issues, which, to a certain extent reflects the exploration and accumulation of knowledge in the field [8]. In addition, 141 authors published three papers, accounting for 27.12%, and this group of scholars provides continuous and stable research results in the field. Eighty-seven authors, or 16.73%, published more than four papers, indicating that this group of research scholars has in-depth research and significant academic contributions.

2) Analysis of core authors: Calculated according to Price's formula $M = 0.749 \times Nmax1/ 2$, in this study, the core authors $N = 16$ were brought into the formula calculation, which resulted in M equal to approximately 5.99, which means that the core authors should have at least six or more publications [9]. Thirty-two authors in our study had more than this standard of publications, Table I below.

Matthes-Joerg, Casero-ripples-Andreu, Bruns-Axel, Vaccari-Cristian, Van least-Peter, Koc-Michalska-Karolina, Al-rawi-Ahmed, Beullens-Kathleen and other authors have more than ten publications per capita. It shows their significant academic contribution and activity in the field. By analyzing the negativity of the authors and the structure of the collaborative network, these scholars occupy a central position in the overall research network and significantly impact academic discussions and knowledge dissemination.

Through the Analysis, it is easy to see that a stable research community has been formed in this research area centered on these 32 core authors. These authors' collaboration patterns are primarily focused on the same institutions or under the guidance of their supervisors, indicating the formation of a relatively close academic community. However, there is little cross-regional collaboration, which implies room for further development in promoting broader academic exchanges and cooperation.

C. Analysis of Journal Releases

1) Journal co-citation analysis: Journals are an essential platform for knowledge production in a research field or discipline, and the analysis and visualization of Journal co-citation is a way to reveal the centralized publication platform of literature and core journals [10]. Analyzing the co-citation frequency of core journals can effectively demonstrate the quality level of the journal articles. By choosing the node type as "cited journals" and selecting the journals with a frequency higher than 200, we obtained the co-citation network graph of journals consisting of 1368 nodes and 7228 connecting lines, with a Q-value of 0.7258, which indicates that the network clustering effect is good, and a Silhouette value of 0.9083, which suggests that the clustering result has a high credibility and reasonable results. Results have high credibility, and the results are reasonable in Fig. 4.

TABLE I. STATISTICS ON THE NUMBER OF LITERATURE RELEASES BY CORE AUTHORS

No.	Name and surname	Number of literature releases	No.	Name and surname	Number of literature releases
1	Matthes-Joerg	16	17	Mellado-Claudia	7
2	Casero-ripolles-Andreu	16	18	Rossini-Patricia	7
3	Bruns-Axel	15	19	Rauchfleisch-Adrian	7
4	Vaccari-Cristian	11	20	Zeng-Jing	7
5	Van Aalst-Peter	11	21	Chen-Kaiping	6
6	Koc-michalska-Karolina	11	22	Trilling-Damian	6
7	Al-Rawi-Ahmed	10	23	Boczkowski-Pablo J	6
8	Beullens-Kathleen	10	24	Vandenbosch-Laura	6
9	Molyneux-Logan	9	25	Ohme-Jakob	6
10	Abidin-Crystal	9	26	Hargittai-Eszter	6
11	Hameleers-Michael	9	27	Ahmed-Wasim	6
12	Basch-Corey H	8	28	Yang-Yang	6
13	Eggermont-Steven	8	29	Araujo-Theo	6
14	Weeks-Brian E	8	30	Esser-Frank	6
15	Freeman-Becky	8	31	Laaksonen-Salla-Maaria	6
16	Helder-Dennis	7	32	Tandoc-Edson C	6

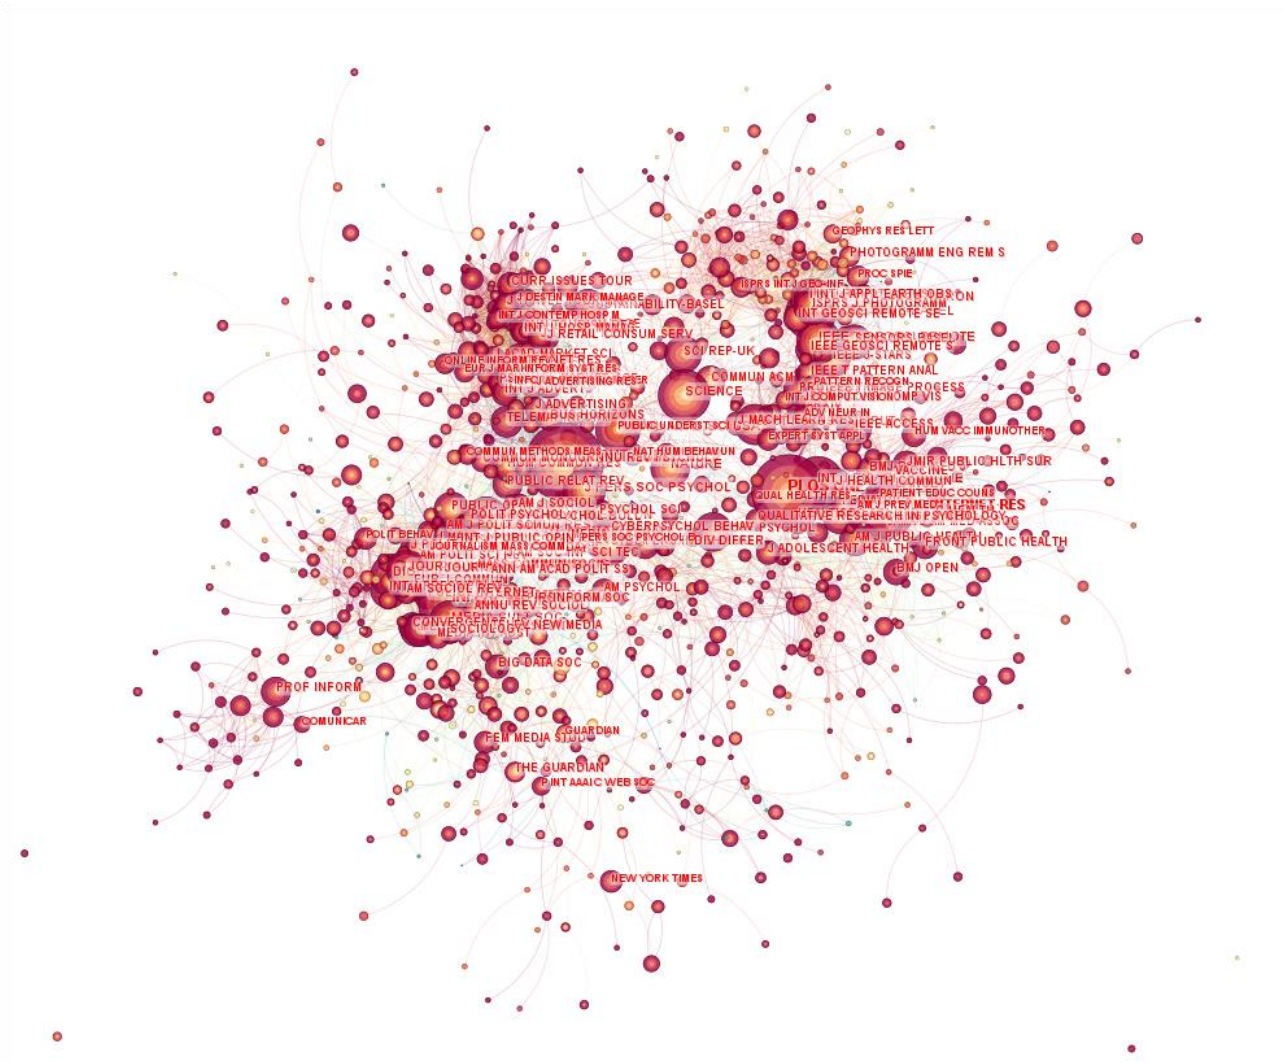

Fig. 4. Journal co-citation visualization network mapping.

In the visual mapping analysis of co-citations of academic journals, journals with significant impact in this field of study can be identified [11].CiteSpace6.3 uses specific visual coding to demonstrate the importance of journals, for example, through the color of different shades of the circle and the size of the circle as an indicator of the magnitude of the role of journals in the overall citation network. According to the journal co-citation visualization maps generated by CiteSpace 6.3 software, the maps of NEW MEDIA SOC, PLOS ONE, COMPUT HUM BEHAV, INFORM COMMUN SOC, J COMMUN, J COMPUT-MEDIAT COMM, SOC MEDIA SOC, J MED INTERNET RES, INT J COMMUN-US, and the prestigious SCIENCE journals ranked among the top in terms of citation frequency, with 2509, 1998, 1973, 1867, 1611, 1421, 1266, 1135 and 1041 citations, respectively. The number of citations more than 1,000 times not only reflects the high citation rate of these journals in this field of academic research in the academic community but also reacts to the core position of the above journals in the exchange of research fields in the academic community.

In addition, in this network mapping, NEW MEDIA SOC and PLOS ONE have the most extensive circle sizes and the most circle levels, indicating that they have the highest mediated centrality, which visually highlights that these two journals have a significant influence in research in group labeling. This highly mediated centrality also implies that these journals are essential platforms for publishing research results, providing rich academic research resources. They are also hubs of communication in academic dialog and knowledge dissemination, contributing to accumulating and developing knowledge in the field.

2) Analysis of core journals: The co-citation information of the journals searched out by CiteSpace 6.3 software was used for the econometric Analysis of the core journals in the field of this study by using the formula r_0=2 ln (eE*Y) calculated in conjunction with Bradford's law [12]. In this study, the value *Y*=2509 was estimated to be 27 journals in the core area, which accounted for 20% of the total number of journals, and they contained 29,655 articles, which accounted for 21.41% of the total literature in Table II.

TABLE II. CITATION FREQUENCY STATISTICS OF CORE JOURNALS

No.	Journal name	Citation frequency	No.	Journal name	Citation frequency
1	NEW MEDIA SOC	2509	15	IEEE T GEOSCI REMOTE	822
2	PLOS ONE	1998	16	POLIT COMMUN	819
3	COMPUT HUM BEHAV	1973	17	DIGIT JOURNAL	797
4	INFORM COMMUN SOC	1867	18	MEDIA CULT SOC	792
5	J COMMUN	1611	19	LECT NOTES COMPUT SC	789
6	J COMPUT-MEDIAT COMM	1421	20	J BROADCAST ELECTRON	780
7	SOC MEDIA SOC	1416	21	REMOTE SENS ENVIRON	755
8	J MED INTERNET RES	1266	22	Journalism Stud	735
9	INT J COMMUN-US	1135	23	JOURNALISM	719
10	SCIENCE	1041	24	J PERS SOC PSYCHOL	690
11	REMOTE SENS-BASEL	994	25	LANCET	686
12	COMMUN RES	955	26	NATURE	684
13	int j env res pub he	893	27	AM BEHAV SCI	666
14	P NATL ACAD SCI USA	842	28	J MASS COMMUN Q	649

In terms of the major journals in the core area, NEW MEDIA SOC carried the most significant number of articles, totaling 2509 articles, accounting for 1.81% of the total number of articles, followed by PLOS ONE (1998 articles), and COMPUT HUM BEHAV (1973 articles), with a share of 1.44% and 1.42%, respectively.

D. Keyword Analysis

In academic research, two core methods are usually used to identify the evolution of research hotspots and trends. The first is keyword co-occurrence analysis, an approach based on the original keywords recorded within the database, which serve as direct labels for the research literature, and by counting and analyzing the frequency of occurrence of these keywords, it is more intuitively responsive to the research hotspots and the main research directions in academia [13]. The second way, keyword cluster analysis, reveals the intrinsic connection between research topics by systematically grouping the associated keywords into clusters [14]. Next, this paper adopts these two keyword analysis methods to conduct an in-depth and comprehensive analysis of the "group labeling" research topic.

1) Keyword co-occurrence analysis: Keywords play a crucial role in academic papers; not only are they the concentrated manifestation of academic research positions and ideas, but high-frequency keywords also often reflect the research focus of the academic community in a certain period. To accurately capture these research hotspots, this paper adopts CiteSpace 6.3 software to conduct multiple rounds of screening on the selected sample data and then extract the relevant keywords. Subsequently, the extracted keywords were manually counted and sorted by word frequency through an Excel document to obtain a list of keywords reflecting the research trends in this research area in Fig. 5.

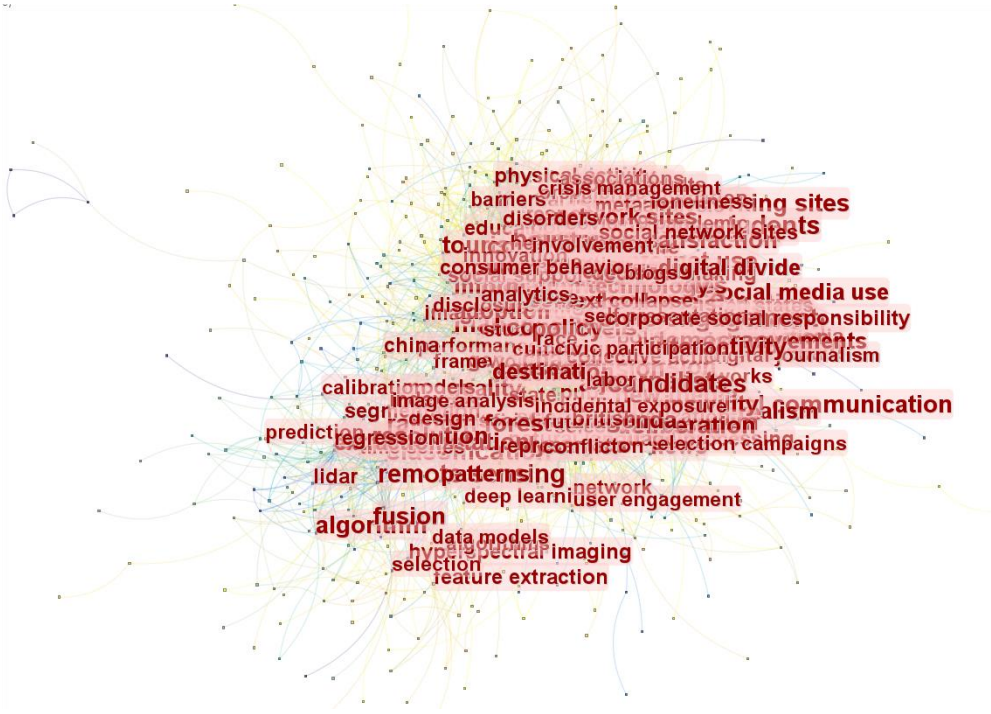

Fig. 5. Keyword co-occurrence visualization network mapping.

This research paper's core theme is identifying and analyzing group labels under online public opinion. CiteSpace 6.3 software can construct a keyword co-occurrence visualization network atlas with 763 nodes and 2854 connecting lines. Through visual observation, the node colors in the atlas show changes from dark green gradient to light green, red-light orange-light yellow, revealing the prosperous co-occurrence relationship between different keywords. The shades of these colors represent the importance of the nodes in the network; the darker the color, the more significant the keyword's centrality in the research domain. In addition, the size of the node also provides essential information for the study, which is proportional to the mediated centrality value of the keyword [15]. Keywords with higher mediational centrality values also have larger node sizes, indicating that the keyword links other keywords and forms the knowledge network's structure with solid control and influence. It facilitates the connection between other keywords and plays the role of the gas pedal in the evolution of academic research in Table III.

TABLE III. FREQUENCY STATISTICS OF KEYWORDS

No.	Byword	Frequency	No.	Byword	Frequency
1	social media	4202	30	technology	159
2	communication	668	31	machine learning	156
3	impact	536	32	sentiment analysis	154
4	information	526	33	public health	154
5	media	497	34	mental health	149
6	Twitter	496	35	trust	147
7	Facebook	459	36	networks	145
8	online	413	37	word of mouth	142
9	news	408	38	identity	139
10	Internet	389	39	consumption	133
11	model	344	40	quality	132
12	health	269	41	journalism	130
13	behavior	235	42	gender	125
14	perceptions	230	43	support	123
15	engagement	223	44	strategy	123
16	participation	217	45	coverage	118
17	classification	216	46	science	118
18	political communication	213	47	patterns	117
19	fake news	207	48	risk	116
20	social networks	207	49	algorithm	113
21	exposure	200	50	discourse	112
22	politics	181	51	Health communication	108
23	deep learning	178	52	adolescents	108
24	big data	175	53	performance	105
25	attitudes	171	54	satisfaction	105
26	content analysis	164	55	community	103
27	remote sensing	161	56	age	101
28	knowledge	160	57	care	100
29	management	159			

This paper sets the keyword list with a word frequency threshold more significant than 100. Thus, 57 primary keywords are screened out among thousands of keywords, and the cumulative frequency of these keywords reaches 52.57%, which accounts for more than half of the keyword co-occurrence visualization network mapping and meets the baseline of the Analysis [16]. Meanwhile, these high-frequency keywords help academic research scholars capture the main hotspots and trends in this research field and provide directions and focuses for further research.

When analyzing the research in this field in depth, the keyword co-occurrence mapping reflects some of the research hotspots. Social media, communication, impact, information, and media are the five most frequent keywords that form the cornerstone of the research in this field. In 2013, the term Internet appeared alongside social media, and both keywords continue to occur frequently in research that intersects with different disciplines in the field through 2024. The frequent co-occurrence of the keywords not only highlights the centrality of social media in the dissemination and communication of information but also demonstrates the widespread interest of research scholars in the impact of social media.

"Twitter," "Facebook," "online," "news," and "internet," as slightly less frequent keywords, represent media forms in the discipline of journalism and communication that are closely related to the development of Internet technology. The co-occurrence of these keywords reflects an in-depth academic study of how emerging social media platforms influence information dissemination and user behavior. Especially for globalized social media platforms such as Twitter and Facebook, researchers and scholars have focused on analyzing the psychological and behavioral effects of their information dissemination on audiences and users and then evaluating social media's communication patterns and effects.

The emergence of keywords such as "model," "health," "behavior," "perceptions," and "engagement" reveals the evolution of Internet user behavior and the formation of group dynamics in cyberspace. Internet users have shifted from single-individual behavior to group behavior, which has profoundly impacted society's functioning. Users have changed

from passive information receivers to active information producers and identify themselves and the groups they belong to through "group labeling." This change in identity has had a significant impact on the structure of information production, promoting the formation of a new decentralized communication structure and providing conditions for the democratization of group labels.

2) Keyword clustering analysis: The keywords were analyzed using CiteSpace 6.3 software for clustering combinations, and the keywords were re-categorized and identified by applying algorithms to the clusters. The initial clustering obtained 20 different categories, and after rigorous screening to eliminate categories with insufficiently tight or ineffective clustering, nine tags with significant clustering effects were finally retained by manual screening. These hashtags include but are not limited to 00#Social media, 01#Online review, 02#Populist communication, 03#Covid-19 pandemic, 04#Political participation, 05#Political participation, 06#Political participation, 07#Political participation. Political participation, 05#Social capital, 06#Covid-19 vaccination, 07#Driving factor, 08#Social media influencer, 09#Populist communication, 09#Covid-19 pandemic, 04#Political participation, 05#Social capital, 06#Covid-19 vaccination, 07#Driving factor, 08#Social media influencer, 08#Social media influencer (social media influencer) in Fig. 6.

After in-depth Analysis and re-aggregation of the keyword clustering results, three dominant research directions in this field were identified: social networks, user behavior and cognition, and communication patterns. Within the category of social networks, "social media" and "social capital" are particularly prominent. Social media is a core component of social networks and a critical force for social development, playing an increasingly significant role in the evolution of society. The popularity and penetration of social media are gradually changing users' daily lives and behavior patterns. In this era, technological advances have empowered users with more rights and voice, building a new type of social capital. The accumulation of this social capital not only reshapes the user's identity and behavioral perception but also has a far-reaching impact on social structure and personal interaction. As a socialization tool, the influence and effectiveness of social media have been increasing in modern society, and it has become one of the research hotspots that research scholars have paid attention to.

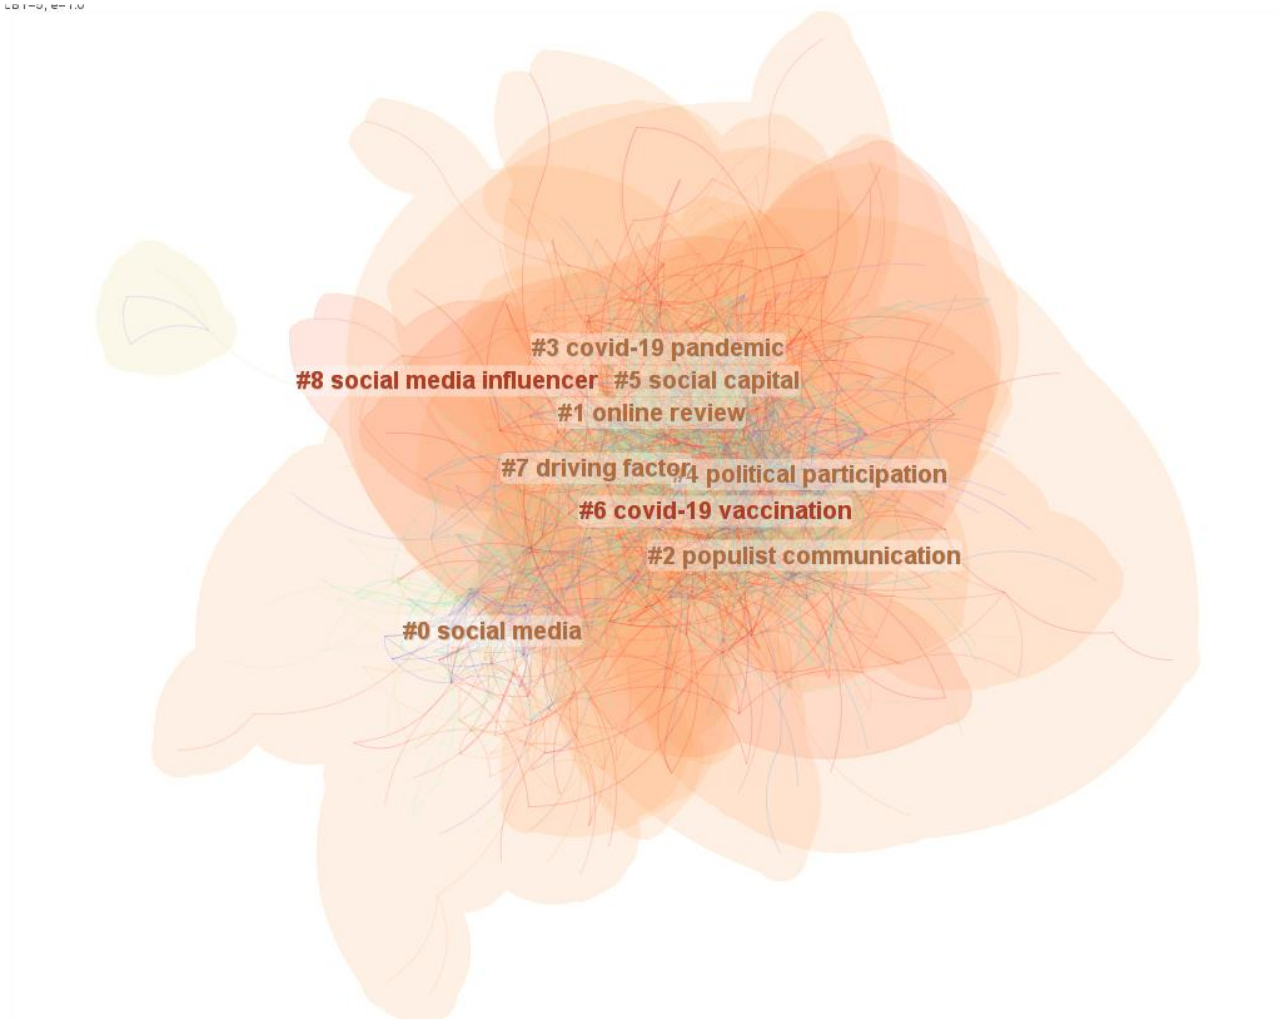

Fig. 6. Keyword clustering combination visualization network mapping.

The second category focuses on user behaviors and perceptions, covering the two cluster combinations of "Online review" and "Political participation." The evolution of technology has blurred the boundaries between online and offline spaces, reshaping users' daily habits and behavioral patterns. In this process, Internet users have formed groups with new "group labels" based on their active behaviors and new identities, and their group behaviors have broadly impacted social development. It is worth noting that there are two particular clusters in this category - "Covid-19 vaccination" (Covid-19 vaccination) and "Covid-19 pandemic" (Covid-19 pandemic). Significant cognitive and behavioral changes in users were triggered in specific contexts. These changes reflect users' responses to public health emergencies and reveal particular patterns of group behavior in extraordinary circumstances. Such unique behaviors and responses provide valuable insights into the psychology and actions of users when facing a crisis.

The third research direction focuses on communication modes, covering the three research fields of "populist communication," "driving factor," and "social media influencer." In the traditional media era, when information resources are relatively scarce and centralized, the channels for ordinary users to participate in public affairs are limited and scarce, and the communication process tends to be top-down, unidirectional, and static. Under the trend of equalization of information dissemination, fragmentation of information and integration of opinions have become the communication norm. The increased initiative of social media platforms has stimulated the active participation of online audience users, promoting interaction, discussion, and definition between different group labels. The desire of single individuals for autonomous expression drives the evolution and updating of group labels, reflecting the development of the communication model in the Internet era towards more dynamic, interactive, and pluralistic participation.

IV. Dissemination and Trends in Group Labeling

A. Generating the Environment

a) Scope of the group: Group labeling was initially a self-deprecating or biased identification behavior within online communities, and its dissemination was limited to relatively closed specific online communities and interest-based online community alliances. In the past decade, with the rise and development of social media platforms such as posting bars and microblogs, the user base of the platforms has been expanding, providing fertile soil for the generation and dissemination of group labeling, and group labeling, which was initially confined to a small circle, has begun to receive wider attention.

Especially in 2016, the emergence of short, fast, and downward social media platforms such as Shake, Shutter, Xiaohongshu, etc., with their user-friendly simple operation interface and personalized content recommendation algorithms, attracted a wide range of user groups from adolescents to older adults and greatly expanded the Scope of communication and influence of group labels [17]. The group tag communication mode has crossed into a new era, where group tags are no longer the exclusive entertainment of the creator and the referenced but have evolved into a communication element discussed and used by society in a universal scope. This shift from interest in specific groups to a pan-social craze signifies that group tagging has grown from a niche cultural phenomenon to a widely recognized mode of communication in society, and the expansion of its influence and dissemination also reflects the far-reaching impact and essential role of social media in modern society.

1) Label content: In recent years, the development trend of group labels has shown a more prominent characteristic of "depoliticization." Labels that used to directly reflect the social structure and carry critical colors, such as "second generation of rich people," "second generation of government officials," "second generation of demolition," etc., have been used less and less frequently. The ability of these labels to map the social structure directly is weakening. Public critical discourse has also weakened, and people have increasingly shifted their focus to their personal life status. The center of gravity of group labels has begun to carry more individual emotional expression and needs, such as emerging labels such as "Buddhist teenagers" and "melon eaters," which have become representatives of personal emotions and life experiences. These group labels reflect the fact that when people face marginalized situations, they autonomously choose a helpless "lying flat" mentality to cope with reality. To a certain extent, this phenomenon reflects the audience's reduced attention to the social environment and the gradual decrease in their participation in political life.

Regarding the vertical development of group labels, "depoliticization" has become an extremely significant trend. For example, group labels such as "kongjin" and "lemonjin" are descriptions of individual behaviors, while "laborer" and "985 waste" are personal creations of self-deprecating experiences. In this development process, the identity of individuality is becoming increasingly important. People look for resonance in labels that match their emotions and experiences and actively categorize themselves into various group labels given by society. Group labels are not only a reflection of social phenomena but also become a way for individuals to seek a sense of identity and belonging. Through these labels, people express their personalities and attitudes toward life while invisibly shaping society and culture's diversity. Although "depoliticized" labels may reduce direct criticism of social problems, they still convey, to some extent, individual perceptions and attitudes toward social reality.

2) Labeling behavior: With the frequent occurrence of online public opinion events, there is a significant phenomenon in the current fragmented communication environment: users increasingly rely on "labels" to define and understand people and things in the world around them. These "labels" are generalization tools to describe an object's salient features and attributes. Group labels share common characteristics by assigning individuals or behaviors to specific categories. Such group labels are not only an expression of collective attitudes and a depiction of group characteristics but also a redefinition of behavioral patterns and a marker of group identity and collective perception.

The popularization and increased Internet use have redefined the power structure of news and information publishing and dissemination. The dissemination of information is no longer the exclusive right of a minority class. However, it has become a universal right of the general public, which has also changed the process of constructing group labels. The low-threshold characteristics of the early Internet gave many Internet users the "right to speak," and the phenomenon of reverse labeling of the traditionally "underprivileged groups" for the "powerful groups" appeared [18]. This phenomenon has subverted the power structure of traditional society, allowing the general public to construct their group discourse and express their collective social attitudes and feelings.

From the social development process perspective, reverse labeling alleviates social conflicts to a certain extent and expresses resistance through online discourse banter. At the same time, the formation process of reverse labeling and the discussion within the group helps to unify internal attitudes and reduce the individual's dissatisfaction with the solidification of social class. This labeling process from the inside out helps group members to resonate with each other in terms of concepts and experiences, thus alleviating to a certain extent the sense of social imbalance brought about by class solidification.

With the diversified development of social platforms, the Internet is not only a channel for obtaining information but also a platform for emotional catharsis and expression of personal consciousness. In such a context, the construction of group labels is no longer to distinguish others. However, it has become a way for individuals to express their emotions, seek a sense of belonging, and realize their identity orientation through self-given behaviors. This self-labeling is an expression of the individual's social role and emotional state and a means for the individual to seek identity and positioning in society. In this way, individuals can find their position in the virtual space and realize their connection with the social group.

B. Dissemination Process

1) Initialization of dissemination: Information dissemination has several notable stages: spoken, written, printed, and electronic [19]. With the rapid development and successive iterations of Internet technology, online communication channels have proliferated, greatly enhancing the speed and Scope of information dissemination. At the same time, the increasing ease of use and accessibility of online social media platforms have enabled individual voices to reach a wide range of previously unimaginable audiences. In this process, the views expressed by individuals once resonated and supported by the group, can quickly converge into a powerful collective force. This power has subverted the one-way, closed pattern created by traditional media to a certain extent. Public social platforms constructed based on weak relationships have provided the general public with a place for free expression and communication, and they have promoted more authentic and frank self-expression and communication among the general public, providing individuals with new ways to express themselves and connect.

2) Spiral diffusion: WeChat provides users with a social media platform that is very different from open microblogs due to its private and robust relationship network. On this platform, the primary forms of socialization include private one-on-one conversations, group discussions, and content sharing and interaction in the circle of friends. Compared to public platforms such as Weibo, Douban, and Jieyin, WeChat's private nature provides users a safer and easier space for in-depth communication. Popular content on these platforms is often accompanied by a convenient sharing mechanism that allows users to easily forward information to WeChat or their circle of friends, thus realizing a seamless transition from public discussion to private communication. In the intensely relational space of WeChat, it is easier to form a common concern and emotional resonance for a specific topic because of the close social ties that usually exist between participants. Compared to the weak connections that may exist on public social platforms, interactions between individuals in the relational solid network on WeChat tend to be more frequent and in-depth, which not only strengthens the effect of information dissemination but also facilitates the exchange of emotions and the construction of a sense of identity among individuals under the group label.

3) Interpersonal communication: Some researchers and scholars believe that people rely on the information conveyed by the media to understand the environment and react based on it, which leads to the natural environment becoming closer and closer to the mimetic climate created by the media [20]. In this process, it is difficult for people to recognize the boundary between the mimetic and natural environments. This mimetic environment constructed by the media has a far-reaching impact on real society, which not only shapes the social order and the rules of interpersonal interaction but also continuously renews the dynamics of the social trend and has a significant social transformation function. Through its powerful influence, cyberspace's emerging information content and labeling continuously form new mimetic images in society. As a product of cyberculture, group labeling has begun to impact the natural world as its influence transcends the virtual space after extensive online use and dissemination. These labeled identities are brought into real-life interpersonal communication by the general public, gradually causing the natural environment to incorporate the characteristics of the online environment. This phenomenon shows that the popularity of group labels is not only spreading within virtual space but also penetrating and changing personal, identity, and social perceptions in the real world. In this way, group labeling has become an essential link between the virtual and the real, the individual and the society.

C. Evolution of Trends

In this paper, we selected the relevant literature on the emergence of group labeling during the ten years from 2013 to 2023, drew the keyword co-occurrence mapping according to CiteSpace 6.3 software, combined with the keyword clustering, and contacted the references to further analyze the vein of group labeling as a field of research in the context of online public opinion in Fig. 7.

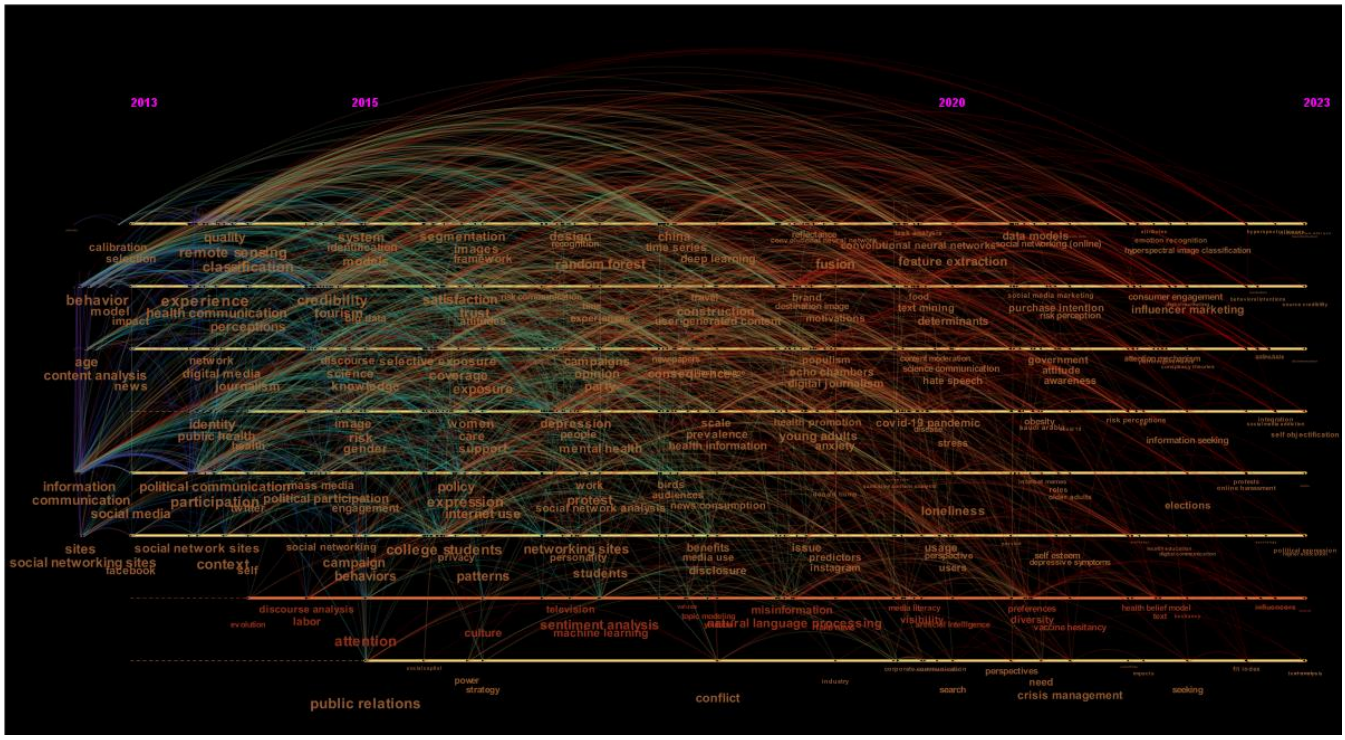

Fig. 7. Keyword temporal network mapping for group label propagation.

1) Exploration period: 2013-2015: The first stage is that research scholars mainly focus on Internet information technology, centering on keywords such as "action at a distance," "community," "information technology," "social media," and so on. Information technology (information technology)," "social media (social media)," and other keywords to explore the current Internet information technology to reshape the pattern of information dissemination. For example, the prosperity of microblogging, Douban, and other social platforms has changed the spatial distance between different media, the hierarchical level of similar media, and the distance between the communicator and the audience, which is enough to confirm that information dissemination in the age of the Internet has begun to develop in-depth from the mode of "flattening."

2) Exploration period: 2016-2020: In the study's second phase, research scholars focused on the development of group labeling on social media platforms and its impact. In this period, with the popularization of diverse social media platforms, every aspect of public life was infiltrated by online culture, and the rise of participatory culture brought about diverse cultural forms. Focusing on keywords such as "exposure," "machine learning," and "sentiment analysis," researchers have examined the subcultural nature of popular culture and group labeling in virtual space from a theoretical perspective. These studies explore how group labels are formed and developed in network culture and analyze how they reflect and influence social concepts and behavioral patterns. The idea of cultural capital plays a vital role in this process. It influences the expression and interaction of individuals on social media, making individuals gain more information and voice while at the same time controlling and changing the content and structure of group labels to some extent, contributing to the reduction of the depth and diversity of group labels due to the homogenizing influence of cultural capital.

3) Universal pan-tide: 2021-2023: Keywords such as "social media data," "awareness," "preferences," etc., have become hot topics for research scholars to focus on at present. Keywords such as "social media data," "awareness," "preferences," and so on have become the research hotspots that research scholars focus on at present. Comprehensively analyzing the above data, it is not difficult to find that group labels have become an effective way of globalized information dissemination and online public opinion dissemination relying on Internet technology and social media platforms, as well as an essential indicator of positive and negative energies and rationality in the online public opinion arena.

V. Conclusion

Our study has unveiled significant insights into the dynamics of online public opinion group labeling. Through a rigorous analysis of the data, we identified key trends and patterns that shape the evolution of group labels within the digital sphere. Our findings demonstrate that the diffusion of group labels is intricately linked to the interactive nature of social media platforms, which facilitates the rapid dissemination of labels and amplifies their impact on public discourse. Notably, our analysis revealed that the temporal dynamics of label adoption and the interplay between different user groups play a crucial role in the longevity and reach of these labels. These specific results not only advance our

understanding of online group labeling but also offer a foundation for future research aimed at developing more nuanced models of online communication.

Our study paves the way for further exploration in this domain. We recommend that future research delves into the application of alternative analytical tools, such as sentiment analysis and network theory, to gain a more comprehensive understanding of the emotional undercurrents and structural relationships within online communities. Additionally, exploring diverse datasets, including cross-cultural and cross-platform data, could provide a richer context for understanding the universality and specificity of group labeling phenomena. By extending our methodology to examine the role of group labels in shaping public opinion during significant events or crises, future studies can uncover the transformative power of these labels in real-world scenarios. These suggestions for future inquiry are not only aimed at refining our analytical approaches but also at broadening the scope of research to encompass the multifaceted influence of group labeling on society.

In this paper, the Web of Science Core Collection database is used as the data source of this study. Citespace 6.3 software is used to analyze the "group labeling." Through visualization and clustering analysis of the English literature co-citation, author co-citation, journal co-citation, keyword co-citation, clustering terms, etc., we analyze the generation, dissemination, and development trend of group labeling in online public opinion. Through visualization and cluster analysis, we analyzed the generation, dissemination, and development trend of group labels in the context of online public opinion.

***Abstract*—Monitoring and traceability are crucial for ensuring efficient and financially beneficial cattle breeding in contemporary animal husbandry. While most farmers rely mainly on ear tags, the development of computer vision and machine learning methods opened many new noninvasive opportunities for the identification, localization, and behavior recognition of cows. In this paper, a series of experimental analyses are presented aimed at investigating the possibility of identification of cows using non-fixed point-of-view images and deep learning. 14 objects were chosen and a photo session was made for each one, which provides training/validation images with different viewing angles of the animals. Next, a darknet-53-based convolutional neural network (CNN) was trained using YOLOv3, capable of identifying the investigated objects. The optimal model achieved 92.2% accuracy when photos of single or grouped non-overlapping animals were used. On the other hand, the trained CNN showed poor performance with group images, containing overlapping cows. The obtained results showed that cows could be reliably recognized using non-fixed point-of-view images, which is the main novelty of this study; however, certain limitations exist in the usage scenarios.**

Keywords*—Cow identification; convolutional neural network; YOLOv3; non-fixed point-of-view

I. Introduction

The advancement in information and communication technologies and artificial intelligence created numerous opportunities in all spheres of human society. They became the backbone of precision agriculture, allowing the optimization of all processes in the agricultural sector including animal husbandry. Nowadays, the food industry worldwide is oriented towards animal products, including meat, milk and milk products, eggs, etc.

An important aspect of livestock farming is the identification of animals, which offers many management and production benefits. Previously livestock owners were marking and branding their cattle with the main concern of proving their ownership. Many additional benefits are offered by contemporary animal identification, such as traceability of the herd and origin, tracking the cattle performance, disease management, keeping accurate track of the animal count, age, status, etc., and as a result, supporting the decision-making process.

The main approach in cattle identification is the application of ear tags. Each country has its regulatory framework to handle this problem, but in many cases, cows must be tagged after their birth. Furthermore, a cattle passport is created for them, including the date of birth, ear tag number, breed, sex, etc. [1]. Recently Radio Frequency Identification (RFID) and Electronic Identification (EID) tags are also popular, as they allow faster and automated data collection about the animals. Other approaches in animal identification are based on nose rings, collars, and image recognition [2,3,4,5]. Furthermore, many studies have suggested using multifunctional Internet of Things devices, which not only identify the animals but also allow monitoring and analyzing their behavior [2,6,7], tracking their location [8], etc.

When it comes to image processing for monitoring and recognition of cattle, the available studies investigate a wide range of opportunities, such as animal counting [9,10], individual cow recognition [11], behavior recognition and monitoring [12,13], animal tracking [14], cattle body detection [15], etc. Furthermore, in animal identification, so far only two image spectra have proven themselves appropriate for the above activities - visible (RGB) [6] and infrared [16].

The application of computer vision for the identification of species and animals has been investigated in numerous previous studies. In [16] the problems and opportunities when recognizing deer and wild boars based on infrared images and the You Only Look Once (YOLO) v3 neural network were studied. Similarly, in [17] RGB and infrared images obtained from camera traps, and a convolutional neural network (CNN), were used to identify frogs, lizards, and snakes. The recognition achieved an F1 score between 82% and 96% for the different species. This approach was also used in [18] with other wild animals, such as Amur tigers, Amur leopards, wild boards, several deer breeds, Asian black bears, red foxes, and other animals. The trained YOLOv5 neural network achieved precision and recall equal to 0.987 and 0.975, respectively.

Many other studies tried to identify not only the species but also to identify the specific animal. For example, in [19] RGB images and YOLOv7 were used for recognizing horses. The obtained mean average precisions (mAP) at the 50% threshold were 99.5% for identifying an animal when using its face and 99.7% when using its nose. Similarly, in [20] sheep faces were recognized based on RGB images. They were preprocessed using noise removal, brightness/saturation/contrast adjustment and when necessary horizontal flipping, and were thereafter fed to different neural networks. The highest accuracy and F1 score were achieved with RepB-Sheepnet, reaching more than 99%. Face recognition for identifying cows with a dual 3D camera setup and the Iterative Closest Point method was used in [21]. The authors have chosen to use the face of the cows, because of the rigid structure of the skull. The reported

identification rates varied between 88% and 99%, depending on the gallery point clouds per cow. In another study, the Siamese DB Capsule neural network was applied for the face recognition of cattle [22]. The used approach pairs the images, i.e. each image is compared with another one, and "pos" or "neg" is returned, depending on whether the images belong to different or the same categories. The study achieved recognition accuracy of up to 93% and an F1 score of up to 93.54%. Several other studies have also tried to identify cattle by their noses. In [23] cattle were recognized using their noses using RGB images as row data. The proposed methodology includes supplying grayscale images to a Deep belief network DBN for the recognition process, which was implemented using the Matlab R2019b toolkit. The authors reported that the recognition accuracy reached up to 99% with 400 training images, and it decreases when fewer images are used. Nose-based cattle identification was also used in [24], where the muzzle patterns of each animal were obtained with the help of numerous deep-learning algorithms. The highest achieved accuracy was 98.7% for a VGG16_BN-based model.

The recognition of the cows can also be classified depending on where the cameras are positioned and how many cameras are used. Common approaches are using topview, sideview, and backview cameras. In [25] the cows were photographed from above, with the idea of recognizing their skin pattern. The methodology includes background removal, image rotation, alignment according to the template, and pixelized binary image creation. The nearest neighbor approach and the Hammering distance measure were used for the recognition process. The authors reported a Top-1 accuracy of 61.5% and a Top-4 accuracy of 83%. Furthermore, they stated that such an approach does not require retraining the recognition algorithm (compared to deep learning) and is very fast. A similar approach was used in [26], where photographs of the cows' bodies and a neural network were used to recognize their body patterns. The reported accuracy was more than 92% for the training data and 90% for the testing data.

In [27] 7069 topview images of 62 cows were used for training, 1801 images for validation, and 1104 images for testing different CNNs. The ResSTN model achieved the highest average recognition accuracy of 94.58% and slightly higher accuracy under daylight lighting conditions. In [28] daytime and nighttime topview images were used to track the cattle movement over a farm. The idea was to use many strategically placed cameras not only to identify the animal but also to classify its behavior into the categories "resting", "standing", "standing up" and "walking". Different versions of YOLOv5 were used to identify the animals, which achieved mAP ranging from 92.7% to 95.3%.

Other studies used sideview cameras for cattle identification. In [29] RGB images of 13 cows were used for their recognition using a convolutional neural network with ResNet50 as the backbone. The authors reported more than 98% recognition accuracy of the investigated objects. Similarly, in [30], side RGB images of cows were used for their recognition. Different color spaces were used to obtain the most appropriate one for distinguishing the animals. The Euclidean distance of feature vectors of critical points was used as the criteria for identification, together with the Brute Force Matcher algorithm. The optimal accuracy of 99.31% was obtained for the Lαβ color component. Another approach for the identification of animals was presented in [31] that relies on rump RGB images. 2140 images of 195 cows were used for training a convolutional neural network and 917 for its validation. The CNN based on a Mobilenet v2 backbone returned the highest accuracy, reaching up to 99.76%.

In [32] three cameras were used for cow recognition - topview, frontview and sideview. An enhanced filter algorithm was proposed, combining the mean-shift and particle-Kalman filter algorithms. The image processing was implemented using Matlab, though no accuracy has been reported. Several cameras were also used in [33], where top and sideview RGB and depth images from a 15-fps video were applied for cow identification. The study uses Euclidean cluster extraction to select the largest 3D point cluster representing the cow, and then to estimate the average silhouette of the animal. Thereafter, the differences between the obtained silhouette and the probed one are evaluated. The achieved algorithm accuracy reached 75.6%.

A completely different approach was used in [34]. The YOLOv3 neural network was utilized to "read" the ear tag of cows, while they were near the drinker. The idea was to estimate how long the animals are drinking and as a result to estimate the approximate volume of water drunk. A mean average precision of 89% and an F1 score of 86% were obtained.

Other studies had more advanced goals, such as behavior identification. In [30] the calving time of cows was predicted via motion classification using a 360° overhead RGB camera. The methodology includes object identification, background subtraction, generation of the object contour, and principal component analysis (PCA) to extract features. An average accuracy of up to 95% was reported for detecting and classifying cow motions.

The analysis of previous animal recognition studies showed that deep learning provides acceptable results. Different barriers exist when using deep learning for cow identification, such as the limited number of images of each object, the fluctuations of the positions and angles of view, the appearance of numerous cows the network wasn't trained for, etc. [22]. Furthermore, often it is hard for a human being to tell the difference between two separate cows, especially if they are single-colored, which might be a problem when preparing the training/validation data. Most previous studies have used images of the animals, taken from a specific point of view (side, back, frontal, etc.) or from above that are rotated to an appropriate orientation. However, there are almost no studies, dealing with the identification of cows with non-fixed point-of-views. The abovementioned shows the existence of a knowledge gap in this area, which should be addressed.

This study aims to investigate the possibility of real-time identification of cows using deep learning and images, which were obtained without limitations for the angle of view and orientation of the animals. To achieve this the neural network should be trained with numerous images, representing the animals from different points of view.

II. Materials and Methods

A. The Study Area

The experimental part of this study was conducted at a farm for outdoor cow breeding. It is located in the village of Trastenik, Ruse District, north-central region of Bulgaria (Fig. 1) and has coordinates 43.65830753698392, 25.845059022235304. 30 dairy cows from the Bulgarian Black and White cow breed and the Red and White Holstein cow breed are bred on the farm. All images and videos of cows were shot on a summer day (5 July 2023), late in the afternoon between 5 and 7 p.m.

Fig. 1. Location of the experimental pasture.

B. Methodology for Data Collection and Data Processing

The data collection and processing methodology, applied in this study is summarized in Fig. 2. It can be divided into five main steps, which are explained below.

1) Step 1. Data collection: This step begins with choosing the cows that are the object of the investigation; thereafter, numerous images of each object are made. The successful recognition of the object requires enough images representing the animal from different sides and in different circumstances (staying, grazing, etc.). This is achieved in two ways:

- By making numerous photos of the animal;
- By filming a video of the animal from all sides and extracting appropriate frames from it.

The described procedure is repeated for each cow that should be investigated. Taking photos from different distances and with different backgrounds should also be considered.

2) Step 2. Data selection: In this phase, the already collected data is analyzed, sorted, and filtered. Initially, all photos taken that contain a certain object are sorted in separate folders (per object). Furthermore, if a video was made of a certain animal, frames are extracted from it as images, representing the animal with different viewing angles. They are also sorted in the corresponding folders. Finally, several of the prepared training images are filtered out for the validation set so that they are not used during training.

3) Step 3. Data preparation: The goal of this step is to prepare the training and validation data. Each object is marked in a rectangle and classified using LabelImg or an alternative tool. This is repeated for each of the images and each of the objects. If a certain image contains more than one of the investigated objects, all of them could be marked and categorized in a different class, as shown in Fig. 3. In this step both the training and the validation images are classified.

4) Step 4. Deep learning: In the next data processing phase a machine learning model is trained. In this study, we use the YOLO v.3 object recognition system, and therefore all data should be prepared and sorted accordingly [35]. We chose version 3 because it has shown good results in previous studies. The preparation for this step includes:

- tuning up a config file corresponding to the graphical processing unit (GPU) characteristics, the number of classes, and the number of training iterations;
- setting up the training itself, i.e. selecting the training and testing data, the config file, the initial weights as well as the application of mean average precision (mAP).

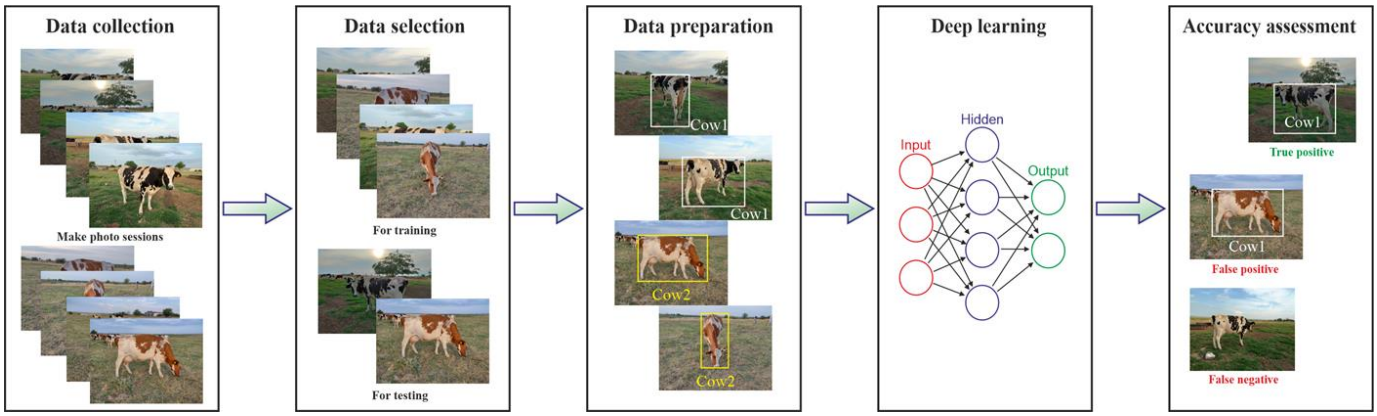

Fig. 2. Overview of the used methodology.

Fig. 3. Marking each object with a rectangle in the LabelImg tool.

5) Step 5. Accuracy assessment: The final step of the data processing is to estimate and evaluate the models' accuracies. In this study this is implemented from several perspectives:

- The first one is the automatic accuracy assessment during the training of the models, which is implemented by YOLO itself and is based on the mean average precision performance metric. It is achieved using validation images prepared in steps 2 and 3. The results from this assessment are taken into account when selecting the optimal classification model, i.e. the one with the highest mAP. The meaning of mAP metric is as follows:

$$mAP = \frac{1}{N}\sum_{n=1}^{N} AP(n) \quad (1)$$

where N is the total number of classes and AP(n) is the average precision for a given class n, which is calculated as the weighted mean of precision at each threshold.

- The second perspective is to use additional images and videos, which were not used for training and validation, and a human operator to confirm that the recognized objects (cows) are correct or incorrect. For images, this evaluation is straightforward. Videos could be processed in the following way:
  - Each video is resampled to 1 frame per second (FPS) framerate.
  - The video is analyzed with YOLO v.3 using the selected optimal model and the analysis results are saved as video files using screen recording software like OBS Studio or alternative.
  - The recorded video is observed by an operator, frame by frame, and a confusion matrix is created for each object.
  - The model performance is assessed in terms of Precision, Recall, and F1 Score, whose meaning is described below. The Precision metric assesses the accuracy of positive predictions and is defined with:

$$P = \frac{TP}{TP+FP} \quad (2)$$

The Recall metric gives the proportion of true positive (TP) predictions among all positives and is defined as:

$$R = \frac{TP}{TP+FN} \quad (3)$$

The F1 score metric balances the score of precision and recall according to:

$$F1 = 2 \times \frac{P \times R}{P+R} \quad (4)$$

Finally, the average accuracy for the whole testing dataset is estimated using the following equation:

$$Accuracy = \frac{Number\ of\ testing\ frames}{Number\ of\ testing\ frames+FP+FN} \quad (5)$$

Next, the obtained results are evaluated and analyzed using the created confusion matrix. Situations with false positives (FP) and false negatives (FN) are closely analyzed, to identify the reasons behind this.

III. Results and Discussion

A. Training of Convolutional Neural Networks

801 images of 14 different dairy cows were used for training. Some of the cows look very similar and are quite difficult to distinguish even for a human being (Fig. 4). For most cows 50-70 photos each were used, though there are also cows photographed over 100 times, while others were shot far less than that (just 10-15 images). All photos were taken under natural environment conditions, without separating the animals from the herd or placing them in an enclosure. An Mx-

M16TB-R079 RGB camera by Mobotix AG (Langmeil, Germany) in continuous video recording mode and three mobile phones were used for filming. The resulting videos and images have different resolutions and color saturation.

It should be noted that most of the cows look different from their two sides, which makes it important to select an appropriate collection of photos, representing the animals from all sides for training an adequate model. That is why for each cow an improvised photo session was made (Fig. 5).

Next, according to the methodology, a folder with images was made for each object. Furthermore, frames from the video recordings were chosen, extracted, and placed in the corresponding folders. On each image, the target objects were selected using the LabelImg tool. Thereafter, the images were divided for training, validation, and testing purposes, as shown in Table I. A total of 44 images were used for validation and 37 images of individual cows for testing. The table data shows that the datasets are imbalanced, which should be considered when interpreting the results.

The training of the CNN was performed using an NVidia RTX 3060 GPU with 12 GB dedicated video RAM, which allowed roughly 1000 training iterations per hour. According to the developers of YOLO, the recommended number of training iterations is the number of classes multiplied by 2000, but not less than the number of images. Therefore, initial training was conducted with a maximum number of 28000 iterations. With such a configuration, YOLO saves the calculated weights at every 10000 iterations, at the maximum number of iterations (28000), and at the maximum mAP value. The latter is calculated during the training process using the validation dataset. The highest obtained mAP is 100% and was achieved at 18500 iterations.

In previous training sessions with cow images, we have observed that the neural network could be easily overtrained and begin to miss (fail to recognize) cows that it was trained for, but which were viewed from a slightly different position than those in the training dataset. Experiments with different numbers of training iterations showed that more cows (especially in group photos) were recognized with weights obtained in fewer iterations. To avoid overtraining, we retrained the network with 9000 iterations, thus the YOLO system saved the weights every 1000 iterations. As a result, we obtained multiple alternative weight files that allow us to perform additional experimental analyses and determine the optimal number of iterations. When training with 9000 iterations, the maximum value for mAP is 98.81% and was reached at 6850 iterations. The training and validation results with 9000 iterations are shown in Fig. 6.

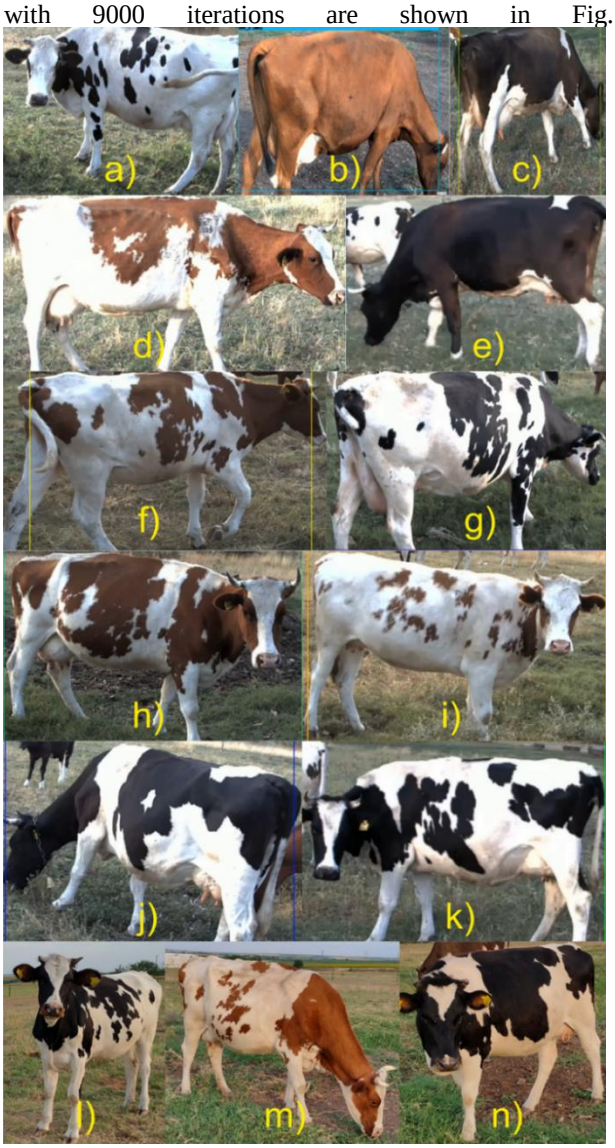

Fig. 4. The investigated cows.

After a series of experimental analyses, we found that for both group photos and videos, more cows are recognized when using the weights file obtained at 6850 iterations, which is why it is used for all subsequent experiments.

Fig. 5. Taking a photo session of cow №8 from different points of view: a) right side; b) back side; c) left side; d) front side.

TABLE I. SUMMARY OF THE NUMBER OF IMAGES OF EACH OBJECT USED FOR TRAINING THE CONVOLUTIONAL NEURAL NETWORK

Cow №	1		2	3	4	5	6	7	8	9	10	11	12	13	14
Training images	52		24	52	149	80	35	71	81	58	72	49	11	45	22
Validation images	3		1	2	4	4	2	4	3	5	5	4	1	4	2
Testing images	3		2	3	7	2	1	2	5	3	2	2	1	2	2
Testing video frames	89		117	166	139	187	58	93	91	111	165	232	/	/	/

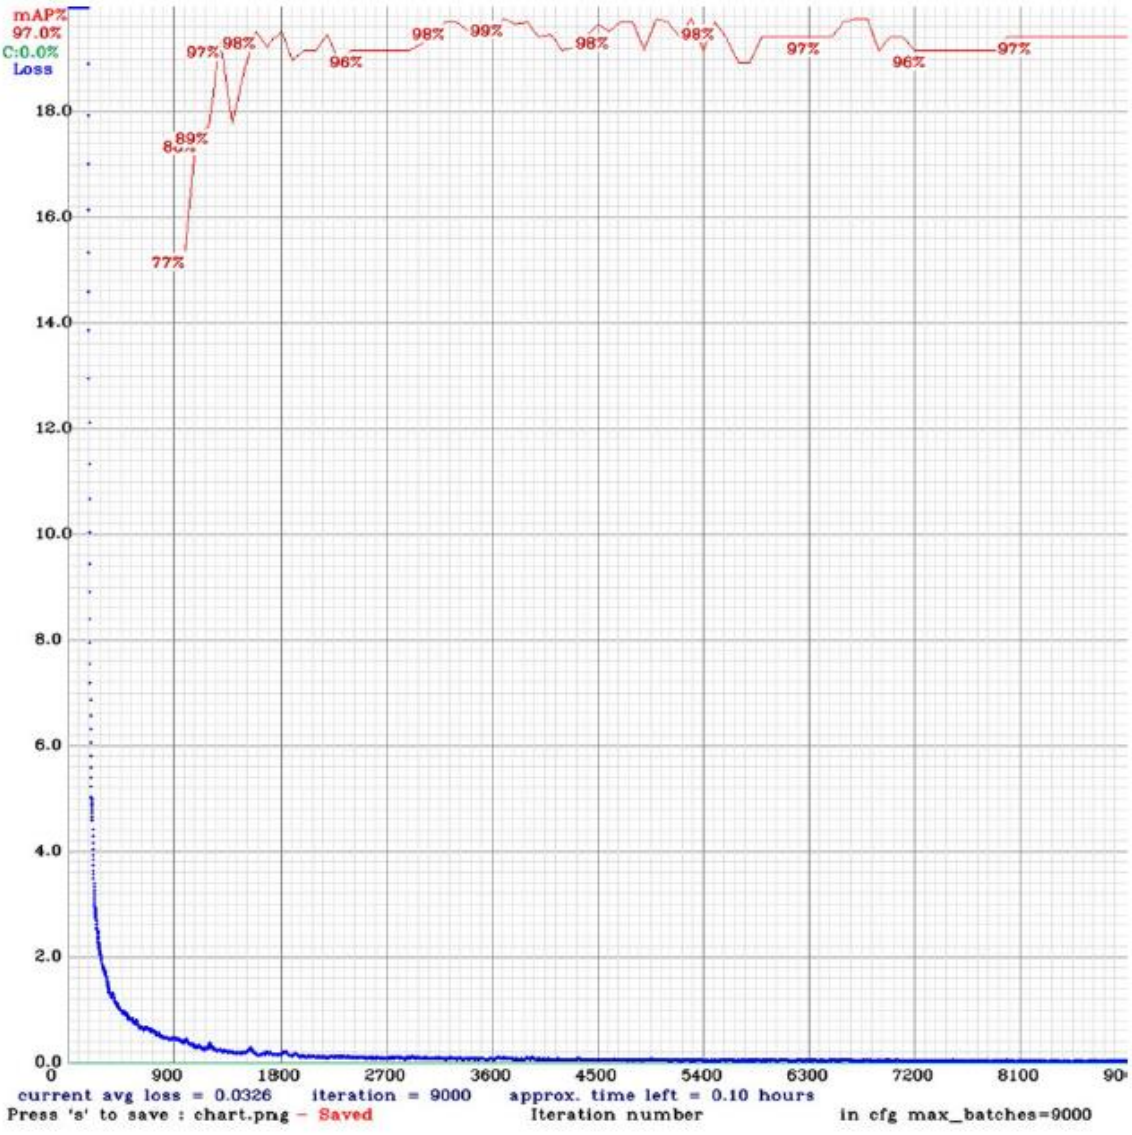

Fig. 6. YOLO training results with 801 images of 14 cows at 9000 iterations, with maximum mAP 98.81% at 6850 iterations.

It is interesting to note that at 18500 iterations mAP has a maximum value of 100% and cows in individual pictures are recognized with a maximum probability of 0.99 or 1. At 6850 iterations, despite the slightly lower mAP value of 98.81% and lower individual probabilities, more animals are recognized in group photos and videos. This suggests that at 18500 iterations, the neural network is already overtrained. Another possibility is that the validation dataset, which is 5.625% of the training dataset, is too small and could be increased in future studies.

B. Assessment of the Accuracy

Initially, 37 testing images not applied in the training and validation process were used. Their distribution between the different objects of the study is shown in Table I. In all of them, only one cow is visible or the other cows are positioned behind the recognized object. In this scenario, the achieved recognition rate is 100% and this applies to all 14 investigated objects. Furthermore, the recognition is done with a probability between 98% and 100%. Fig. 7 presents several examples of the correctly recognized cows from the testing dataset.

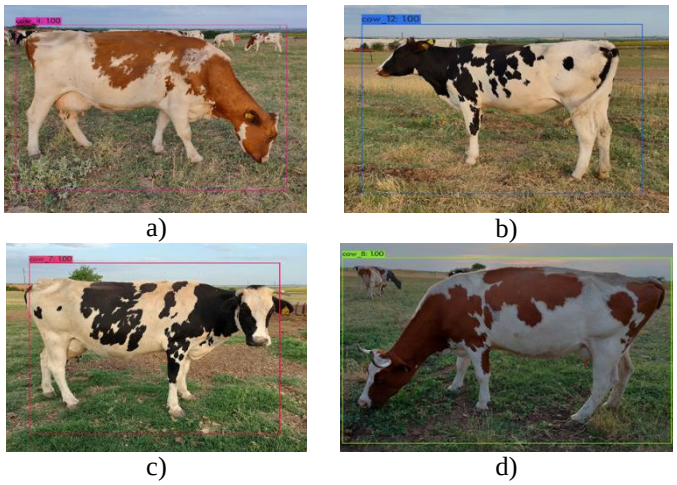

Fig. 7. Examples of recognized cows with high (typically 100%) probability in cases where the images contain only one cow and the animal is seen in sufficient detail.

A significantly different situation occurs when there are numerous cows in the image. In some cases, the model was able to recognize correctly two cows in a single image, as shown in Fig. 8. Nevertheless, it could be noticed that in Fig. 8, a cow_8 is identified with low probability (33%), which might be explained by the fact that it is partially visible. Similarly, in Fig. 8(b) again cow_8 is recognized with a probability of 31%, which might be caused by its overlapping with other similarly colored cows.

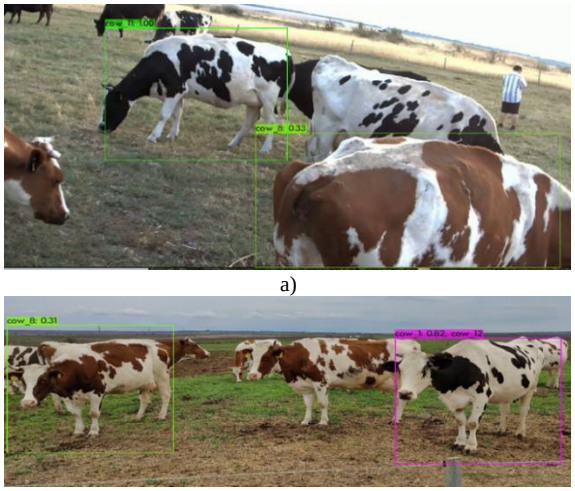

Fig. 8. Examples of correctly recognized two cows in a single image: a) one of the objects is partially visible; b) both objects are fully visible and overlapping with other cows.

However, that is not always the case. In many other situations, the trained model experienced difficulties recognizing multiple cows in group photos, although it was trained for many of them. In these cases, usually up to 1 and more rarely two cows in the front are recognized using the weights obtained at 6850 iterations. If the weights file, obtained at 18 500 iterations is used instead, the results are worse. This problem is demonstrated in Fig. 9, where cows numbered five and eight are available in the two photos, which were taken with a time difference of several seconds. Nevertheless, the trained model identifies either one or the other, but not both objects. In this example the probability rate is relatively high – 70% and 88%, respectively. It could be noticed that in Fig. 9(a) there are other cows behind cow_5, which might be influencing its recognition performance. Similarly, in Fig. 9(b) cow_8 is partially overlapping with cow_5, which once again might be the reason for such behavior.

More problems with the identification of cows in group photos are demonstrated in Fig. 10 and Fig. 11. The first one shows that two objects (cow_5 and cow_4) were not identified. The most probable reason is that the model fails to distinguish them as separate objects from the numerous surrounding animals. Cow_5 overlaps with two other cows and cow_4 with one in front and many others in the background. This suggestion is confirmed by the example, demonstrated in Fig. 11, where three cows are identified as a single animal (cow_1), even though only one of them is cow_1.

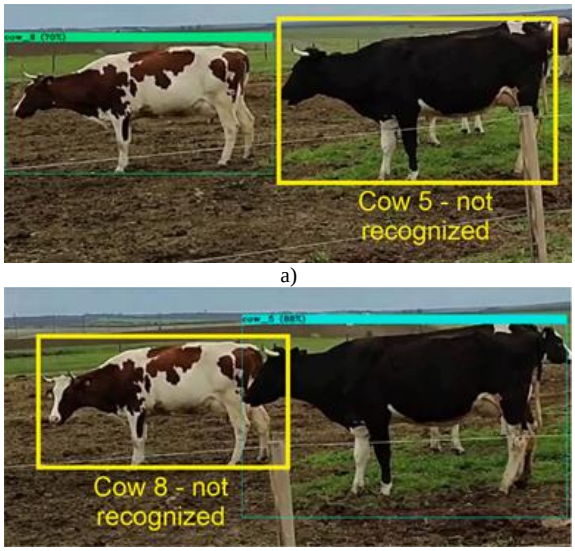

Fig. 9. An example of recognizing cow 8 (a) and cow 5 (b) in two photos of the two objects.

The reason behind the abovementioned problems might be the used datasets. In fact, no group images of cows were included on purpose in the training/validation datasets, which might have limited the identification ability of the CNN model under such circumstances.

Recognizing cows in videos is very similar to recognizing objects in still images, just the video should be preprocessed and, in most cases, converted to multiple still images (shots). In our case, the video of each cow was analyzed and converted to a video with 1 fps framerate. Thereafter, an operator manually classified each frame of the video as either true positive, false negative, or false positive to assess the accuracy of the CNN model. This way the performance of the model is evaluated individually for each object. In the following experimental analysis, we assessed the model performance only for the first 11 cows since video materials were only available for them. The total number of video frames used for testing is 1448.

Each object was analyzed from two perspectives:

Fig. 10. An example of 2 cows not recognized in a group photo with many others overlapping.

Fig. 11. An example of 3 overlapping cows recognized as a single object.

- The animal is fully visible by the camera [Fig. 12(a)] – it is assumed that at least the following is visible: full carcass, full head (unless it is behind the carcass), and at least half of the legs.
- The animal is only partially visible by the camera [Fig. 12(b)] – at least one of the abovementioned requirements is not met. Nevertheless, large enough part of the cow should be visible, so that the operator can recognize it.

The results from the analysis of the video frames, including true positives, false negatives, false positives, precision, recall, and F1 score are summarized in Table II. When the objects are fully visible the F1 score varies between 0.89 and 1.00 for the different objects and is above 0.95 for most of them. These results are very similar to those obtained in still images of single animals, which corresponds to the expectations. The only exceptions are cow 2 (0.89) and cow 6 (0.90). Yet, this is not unexpected because a limited number of images for these objects were used to train the CNN model - 24 and 35, respectively; while for all other objects, the available images are more than 50. The average accuracy of the trained optimal model was obtained to be 92.2% when used with non-group photos.

When the cows are not fully visible, the F1 score varies between 0.43 and 0.98 for the different objects. The lowest results were achieved for cow_6 (0.43), cow_5 (0.80), and cow_11 (0.84), which is caused mainly by the lower recall, which accounts for the influence of the false negatives. In most cases, the cropped animals were simply not recognized, which is an expected behavior in such situations.

Fig. 12. Examples for fully visible (a) and partially visible (b) cow, according to the accepted rules in this study.

TABLE II. A SAMPLE CONFUSION MATRIX

Situation	TP[c]	FN[d]	FP[e]	Precision	Recall	F1
Cow 1 (fully visible) [a]	31	0	2	0.94	1.00	0.97
Cow 1 (partially visible) [b]	40	8	0	1.00	0.83	0.91
Cow 2 (fully visible)	31	8	0	1.00	0.80	0.89
Cow 2 (partially visible)	58	3	0	1.00	0.95	0.98
Cow 3 (fully visible)	71	0	2	0.97	1.00	0.99
Cow 3 (partially visible)	57	4	2	0.97	0.93	0.95
Cow 4 (fully visible)	98	0	0	1.00	1.00	1.00
Cow 4 (partially visible)	26	5	2	0.93	0.84	0.88
Cow 5 (fully visible)	112	2	11	0.91	0.98	0.95
Cow 5 (partially visible)	37	5	13	0.74	0.88	0.80
Cow 6 (fully visible)	42	2	7	0.86	0.95	0.90
Cow 6 (partially visible)	3	6	2	0.60	0.33	0.43
Cow 7 (fully visible)	34	0	0	1.00	1.00	1.00
Cow 7 (partially visible)	30	9	1	0.97	0.77	0.86
Cow 8 (fully visible)	63	0	0	1.00	1.00	1.00
Cow 8 (partially visible)	22	1	0	1.00	0.96	0.98
Cow 9 (fully visible)	68	0	0	1.00	1.00	1.00
Cow 9 (partially visible)	35	1	1	0.97	0.97	0.97
Cow 10 (fully visible)	126	1	2	0.98	0.99	0.99
Cow 10 (partially visible)	24	0	4	0.86	1.00	0.92
Cow 11 (fully visible)	126	5	2	0.98	0.96	0.97
Cow 11 (partially visible)	28	11	0	1.00	0.72	0.84
Average (fully visible)	802	18	26	0.97	0.98	0.97
Average (partially visible)	360	53	25	0.94	0.87	0.90

[a.] The following parts of the animal are visible: the whole carcass, at least half of the legs, and the whole head. If part of the carcass or head are not visible because of the angle of view, the cow is also considered to be fully visible.

[b.] In all other cases the cow is considered to be only partially visible.

[c.] The object was correctly recognized

[d.] The object was not recognized or was incorrectly recognized.

[e.] Another object was recognized as this one.

C. Comparison with Previous Studies

The results obtained in this study cannot be directly compared to other studies, as to the best of our knowledge no previous studies have tried to identify cows using mixed images, showing them from different points of view. Nevertheless, we can compare our results with those obtained in studies, using topview, sideview, backview and faceview images, independently. In [27] outside topview images of cows were used, representing either the full body or randomly cropped body. The obtained accuracy was 95.23% and 90.85%, respectively, which generally corresponds to the average 92% accuracy, achieved in our study.

In [29] sideview full body images were used to achieve 98.58% accuracy. Other similar studies are [36] and [37], reaching average accuracies of 96.65% and 90.2%, respectively. In [37] an F1 score of 86% was estimated, which is lower than the one obtained in this study (97% and 90%, respectively for full body and cropped body). In [31] backside full body images of cows were used to achieve 99.76% accuracy, and in [22] head images for face recognition were used with 93% accuracy and 93.54% F1 score.

Table III summarizes the results from the performed comparison. It can be noticed that most studies assessed only the accuracy of the trained models, which is known to be misleading in the case of imbalanced datasets. That is why in our study we have also obtained precision, recall, and their average F1 score, which gives a more accurate evaluation of the performance of the trained CNN.

TABLE III. COMPARISON OF OUR RESULTS WITH THOSE, OBTAINED IN PREVIOUS STUDIES

Paper	CNN backbone	View	Location	Cropping	Accuracy	F1 score
Wang et al. [27]	ResSTN	Topview	Outside	Full body	95.23%	N/A
				Randomly cropped	90.85%	N/A
Fu et al. [29]	ResNet50	Sideview	Inside	Full body	98.58%	N/A
Hou et al. [31]	Mobilenet v2	Backside	Inside	Full body	99.76%	N/A

Wang et al. [37]	ResNet101	Sideview	Outside	Full body	90.2%	86%
Xu et al. [22]	Capsule network	Faceview	Inside	Head only	93.00%	93.54%
Ours	Darknet-53	All sides	Outside	Full body	92.2%	97%
				Randomly cropped		90%

IV. CONCLUSIONS

In this study, the possibility of training a convolutional neural network for recognizing cows regardless of the viewing angle was investigated. A dataset containing 801 images of 14 cows was used for training a YOLOv3 model. To prepare the training, validation, and testing datasets, photo sessions of each animal were made, so that they represent the cows from different sides. Out of the trained models, the one selected as optimal achieved a mean average precision of 98.81% after 6850 iterations.

The results from the evaluation of the trained CNN showed that its recognition rate greatly depends on the usage

circumstances. The model showed excellent performance at recognizing objects on images/video frames, where there are no other animals, where the animal is in the front, or where the animal is not overlapping with other animals. This is confirmed by the obtained 97% F1 score for fully visible cows and 90% for partially visible cows, as well as by the achieved average accuracy of 92.2%. On the other hand, the trained YOLOv3 CNN does not perform well when numerous objects exist on the image/video frame, especially with overlapping objects. In such a situation, the model fails to identify all cows and rarely recognizes more than one.

The abovementioned indicates that the proposed approach for the recognition of cows with a non-fixed point-of-view is applicable but with certain limitations and under certain usage scenarios. Such limitations are: the object being identified should be alone on the image/frame, or should not be overlapping with other animals. The investigated approach has numerous possible applications, such as monitoring the animals' movement, localization, and behavior, or even as a replacement for ear tags.

In the present study, 801 images for training were used, which is 57 on average per animal. It is interesting to investigate if the performance of CNN models will increase when more training images are used, especially in group photos with overlapping cows. Furthermore, more group photos of animals should be included in the training/validation datasets, which might increase the recognition rate in such scenarios. If that doesn't happen, another option is to train an additional neural network, responsible for recognizing the extents of each object. With such an approach each cow could be extracted from the image and identified independently of the others, which should allow reducing the impact of overlapping animals. The abovementioned represent promising research topics, which are an object for future studies.

***Abstract*—Object tracking plays a pivotal role in Intelligent Transportation Systems (ITS), enabling applications such as traffic monitoring, congestion management, and enhancing road safety in urban environments. However, existing object tracking algorithms like DeepSORT are computationally intensive, which hinders their deployment on resource-constrained edge devices essential for distributed ITS solutions. Urban mobility challenges necessitate efficient and accurate vehicle tracking to ensure smooth traffic flow and reduce accidents. In this paper, we present a modified lightweight variant of the DeepSORT algorithm tailored for vehicle tracking in traffic surveillance systems. By leveraging multi-dimensional features extracted directly from YOLOv5 detections, our approach eliminates the need for an additional convolutional neural network (CNN) descriptor and reduces computational overhead. Experiments on real-world traffic surveillance data demonstrate that our method reduces tracking time to 25.29% of that required by DeepSORT, with only a minimal increase over the simpler SORT algorithm. Additionally, it maintains low error rates between 0.43% and 1.69% in challenging urban scenarios. Our lightweight solution facilitates efficient and accurate vehicle tracking on edge devices, contributing to more effective ITS deployments and improved road safety.**

Keywords*—Distributed systems; intelligent transportation systems; edge computing; object tracking

I. Introduction

In the era of smart cities, integrating distributed Intelligent Transportation Systems (ITS) with edge computing marks a significant advancement in urban mobility. By processing data closer to the source, using embedded devices with traffic cameras rather than relying solely on centralized servers, ITS can enable real-time decision-making and responsiveness, even in resource-constrained environments. This decentralized approach improves system scalability, reduces latency, and enhances data privacy by processing sensitive information locally. Multiple Object Tracking (MOT), a core component of ITS, refers to tracking the trajectories of multiple objects across video frames. Recent advances in object detection and deep learning have made tracking-by-detection the dominant approach in MOT [1]. This approach formulates MOT as a data association task, linking newly detected objects with those already being tracked.

Recent Multiple Object Tracking (MOT) systems are generally composed of three key components: the object detector, the embedding model, and the data association algorithm. The object detector localizes and identifies objects of interest within each frame, commonly using deep learning models such as YOLO [1], and Faster R-CNN [2]. The embedding model extracts representative features from the detected objects to capture their appearance characteristics. These embeddings combined with spatiotemporal parameters, are used to associate objects across frames and maintain consistent track identities. Finally, the data association algorithm links objects based on their appearance and spatiotemporal similarities. This is typically achieved through methods such as the Hungarian algorithm, as used in DeepSORT [3], or via deep learning-based techniques like Siamese networks or recurrent neural networks [4].

Current object detection and tracking algorithms, notably YOLOv5 and DeepSORT, have achieved high accuracy in multi-object tracking tasks. However, their computational intensity poses significant challenges for deployment on resource-constrained edge devices essential for distributed ITS. This limitation creates a challenge for the practical application of ITS, where real-time processing is crucial for urban mobility and road safety enhancements. To bridge this gap, we propose a lightweight variant of the DeepSORT algorithm that reduces computational overhead while maintaining tracking accuracy, making it suitable for edge computing environments [5], [6], [7], [8], [9], [10].

In this work, we propose a lightweight tracking algorithm that follows a similar workflow to DeepSORT, with a key modification in the appearance embedding step. Traditionally, this step relies on a dedicated CNN model as a descriptor to calculate appearance similarity between objects. While effective, CNN descriptors are computationally intensive, particularly for resource-constrained devices. To enhance the computational efficiency of the tracking process, we eliminate the CNN descriptor and introduce an alternative strategy for object appearance extraction and association.

Our strategy replaces the appearance features provided by the embedding model with data directly derived from the feature map generated during the initial detection phase. These feature maps, produced by the intermediate layers of the detector,

contain high-level abstract representations of the objects. Experiments demonstrate that these representations are a viable substitute for CNN descriptor features when calculating appearance similarity, reducing computational overhead without sacrificing tracking accuracy.

The rest of this paper is structured as following. Section II discusses related work in object detection and multi-object tracking. In Section III, we present our proposed tracking approach, starting with its background methods (i.e. YOLOv5 and DeepSORT), followed by a detailed explanation of our lightweight DeepSORT variant, including the modified detection and appearance similarity processes. Section IV describes our experimental setup and shows the results. In conclusion section, we summarizing our contributions and suggesting future research directions.

II. Related Work

In this section, we present a review of key works related to object detection and multi-object tracking.

A. Object Detection

Since the introduction of deep convolutional neural networks (CNNs), numerous object detection approaches have emerged, leveraging large open datasets such as COCO [11] and Pascal VOC [12]. Early detectors followed a two-stage process, beginning with region proposal generation, followed by object classification and refinement. Models like Fast R-CNN [13] and Faster R-CNN enhanced both speed and accuracy by improving feature extraction and region proposal methods. Despite their effectiveness, two-stage detectors often face computational inefficiencies due to their sequential processing structure.

The introduction of YOLO (You Only Look Once) [1] in 2016 marked a significant shift towards one-stage detectors, which focus on simultaneous detection and classification. Subsequent versions of YOLO have made considerable strides in performance, particularly in real-time applications, by refining this one-stage detection approach. Recent YOLO versions, such as YOLOv5, YOLOv7-tiny, YOLOv8s, and YOLOv9s, offer lightweight models optimized for devices with limited computational power, making them well-suited for edge devices and real-time object detection tasks [15], [16], [17].

B. Multi-Object Tracking

In recent years, tracking-by-detection (TBD) has emerged as the dominant paradigm in Multiple Object Tracking (MOT), driven by the increasing capabilities of object detectors. In the TBD approach, tracking begins with the detection of target objects in each frame, followed by the extraction of image crops and spatial parameters based on the objects' bounding boxes. Tracking is then achieved by establishing correspondences between objects in consecutive frames using the extracted data. To facilitate this, a similarity matrix is constructed using parameters such as distance, IoU (Intersection over Union), and appearance features. Algorithms like the Hungarian algorithm or greedy algorithm are commonly used to solve this assignment problem.

To further improve tracking performance, state estimation algorithms are employed to predict the positions of tracked objects based on their spatiotemporal characteristics. Notable state estimation methods include Kalman filters, particle filters, and Gaussian processes. Two of the most widely recognized tracking algorithms in MOT are SORT (Simple Online and Realtime Tracking) [18] and DeepSORT.

SORT is an efficient algorithm that uses a Kalman filter for state estimation and Hungarian matching for data association. It focuses solely on objects' positions, making it highly effective in real-time scenarios. However, in more challenging conditions, such as complex motion patterns, occlusions or missed detections, SORT may produce incorrect associations, leading to identity switches and reduced tracking robustness. To address these limitations, DeepSORT extends SORT by incorporating cascade matching for enhanced data association. In addition to spatial similarity, DeepSORT uses appearance similarity to refine associations between detected objects and existing tracks, improving tracking robustness in more complex environments [8], [9], [14], [19].

III. Proposed Tracking Approach

Our proposed approach consists of an optimized tracking algorithm based on DeepSORT, designed to run efficiently in terms of processing time while maintaining high tracking accuracy. Our main contribution is the development of a modified tracking algorithm based on YOLOv5 and DeepSORT, incorporating novel methods for appearance feature extraction and appearance similarity calculation. This innovation allows us to eliminate the need for the CNN model traditionally used in DeepSORT for the appearance-embedding task. By removing the CNN model, we significantly reduce the vehicle tracking time, making the algorithm more suitable for deployment on devices with limited computational resources.

A. Background

1) YOLOv5: In our implementation, we utilized the publicly available YOLOv5s detector, trained on the COCO dataset, with an input image size of 416 × 416. YOLOv5 is a widely-used single-stage object detector, known for its clear and flexible architecture, offering high precision and speed. It is available in five different scales: N, S, M, L, and X, representing Nano, Small, Medium, Large, and Xlarge models, respectively. Each variant maintains the same overall structure, scaling the depth and width to improve detection performance.

A key feature of the YOLO architecture is its grid-based approach, which divides the input image into spatial cells. This division allows YOLOv5 to perform object detection at multiple spatial resolutions simultaneously, enabling the model to detect objects of varying sizes and aspect ratios across the image. Each cell is responsible for predicting the bounding box coordinates and associated class probabilities for objects within its spatial region, as illustrated in Fig. 1. For our experiments, we chose the small model (YOLOv5s) due to its optimal trade-off between precision and speed.

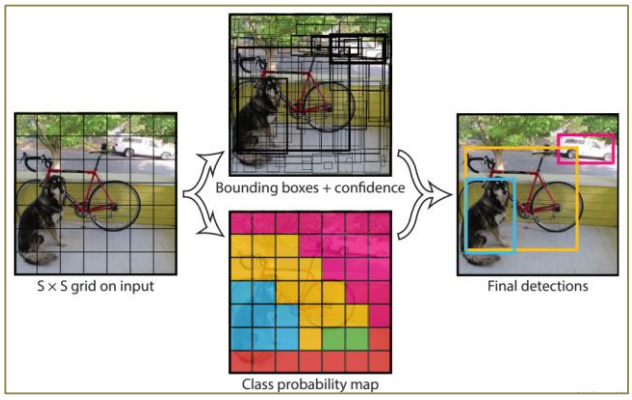

Fig. 1. Example of multiple steps in grid-based approach used in YOLO.

As shown in Fig. 2, the three main components of the YOLOv5 architecture typically include:

- Backbone: The backbone is responsible for extracting features from the input image and is composed of multiple convolutional layers arranged hierarchically. These layers progressively capture higher-level features from the image, enabling the detection of objects of interest by analyzing patterns, edges, and textures at different levels of abstraction.
- Neck: Positioned between the backbone and head, the neck is responsible for additional feature fusion and refinement. Its primary function is to aggregate data extracted at various scales and levels of abstraction by the backbone, ensuring that the model can effectively capture both spatial and contextual information. This step enhances the overall detection performance by combining fine details and broader contextual features before passing them to the detection head.
- Head: The head receives the refined feature maps from the neck and processes them to generate the final detection results. Its layers are designed to predict bounding boxes, objectness scores, and class probabilities, which are used to determine the locations, presence, and categories of objects within the image.

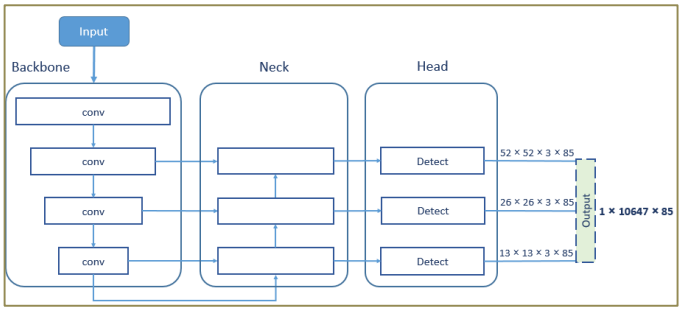

Fig. 2. Abstract overview of YOLOv5 default structure with an input size of 416×416.

2) DeepSORT: DeepSORT builds on the efficiency of the traditional SORT algorithm while incorporating the discriminative power of deep appearance features. Its workflow integrates object detection, feature extraction, data association, and track management to deliver robust tracking results. The DeepSORT workflow can be summarized as follows:

- Detection: The process starts with detecting objects in each frame using an object detector, providing bounding boxes around the detected objects, which serve as input for the tracking process.
- State Estimation: The Kalman Filter (KF) is employed for state prediction, estimating the future states of detected objects based on their current states. This estimation is important for the tracking of each object across frames, especially in cases where an object's detection might be shortly missed.
- Similarity measurement: Multiple metrics are used to calculate object similarity. Mahalanobis distance measures the spatial relationship between predicted states and new detections, while appearance descriptors assess visual similarity. Intersection Over Union (IoU) evaluates the overlap between bounding boxes. These metrics are combined to ensure accurate object association for effective tracking.
- Data Association: The Hungarian algorithm is used to associate detected objects with existing tracks, based on predicted states from the Kalman filter and appearance similarities. This assignment problem combines two metrics: object location and appearance information. DeepSORT's cascade matching prioritizes more frequently seen objects, reducing unstable tracks caused by missed detections. In the final stage, an IoU association is performed for any remaining unmatched targets.
- Track Management: After data association, tracks are updated with their associated detections. New tracks are initialized for unassociated detections, and existing tracks are updated for the next frame using the Kalman filter.

B. Proposed Lightweight Deep SORT Variant

To implement our lightweight variant of DeepSORT, we modified existing modules and introduced new ones to optimize the overall tracking process. The key adjustments made to transition from DeepSORT to our lightweight version include:

- Simultaneous detection and appearance feature extraction: We streamlined the detection process by enabling the simultaneous extraction of both detection data and appearance features. This eliminates the need for a separate embedding model, significantly reducing the computational overhead.
- Adaptation of the appearance similarity process: We adapted the appearance similarity calculation to match the new format of the features obtained from the detection phase. This adjustment ensures seamless integration with our new feature extraction process.

In the following, we provide a detailed explanation of the key adjustments made to our algorithm.

1) Modified detection process: Originally, DeepSORT employs two CNN models: the first functions as an object detector, returning bounding boxes around targets, while the second is a simple CNN descriptor that generates appearance features for those bounding boxes. As mentioned earlier, our approach eliminates the need for a separate CNN model. To maintain appearance association in our algorithm without using a CNN descriptor, we replace the appearance features generated by this descriptor with feature map data associated with the bounding boxes. These feature maps are extracted by YOLOv5's backbone during the detection phase. To extract both feature map data and detection data simultaneously, we implemented several key steps (as shown in Fig. 3), including:

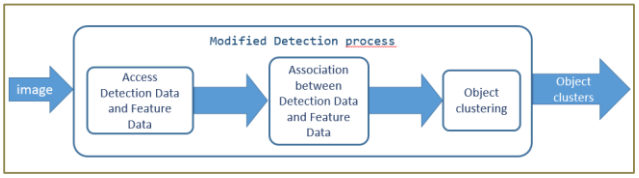

Fig. 3. Workflow of our proposed tracking system.

a) Access detection data and feature data from YOLO: This step involves modifying the model inference process to access intermediate layers of the YOLOv5 architecture, which contain feature map data, in addition to the final detection layer (as shown in Fig. 4). This modification produces an output that includes both detection data and feature map data.

- Detection Data: The detection output includes bounding boxes and class probabilities for small, medium, and large objects, aggregated into a tensor of shape (1, 10647, 85). Specifically, the dimensions 52×52×3×85, 28×28×3×85, and 13×13×3×85 correspond to the detection outputs for small, medium, and large objects, respectively. Here, the grid cell size (e.g., 52×52) refers to the resolution of the detection, the number 3 represents the number of anchor boxes per grid cell, and the 85 elements represent the prediction output for each detection.
- Feature Map Data: The feature map output consists of three tensors representing the features extracted from the backbone layers for each object size. These feature maps are organized in grids of vectors, where each vector is a feature vector for a grid cell. The backbone generates three different vector sizes (128, 256, and 512) for small, medium, and large objects, respectively.

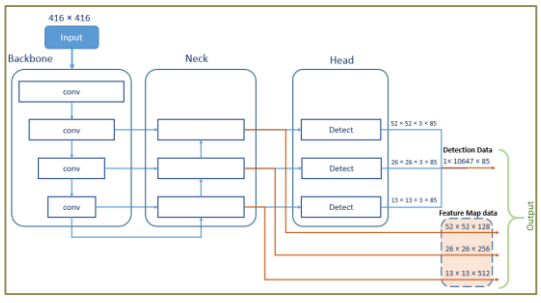

Fig. 4. A representation of the output data extracted from YOLOv5 layers in our algorithm.

b) Association between detection data and feature data: After the model makes its predictions, an association step is performed to map each detected object to its corresponding grid cell in the feature maps to identify its appearance feature. This process involves identifying the spatial locations of object centers within the grid. Since YOLOv5 uses different grid sizes for detection (small (26x26), medium (52x52), and large (13x13)), each object may be represented by multiple detection instances across different grids. Each detection instance is associated with a vector of dimension 85, which includes the object's bounding box coordinates and class information. The feature map data from the grid cell that contains the center of the bounding box is used to represent the object (Fig. 5). Subsequently, the grid cells are mapped to bounding boxes where the box center lies within the grid cell region. This step ensures that all relevant backbone feature vectors are accessible for each detected object.

c) Object clustering: Typically, a non-maximum suppression (NMS) process is applied to remove redundant bounding boxes and retain only the most confident detection. However, in our approach, we aim to extract both bounding box and feature map data. To achieve this, we replace NMS with an Object Clustering (OC) module. The OC module works similarly to NMS, using the IoU (Intersection over Union) metric to compare object overlap. However, instead of eliminating redundant bounding boxes, the OC clusters detections of the same object. This approach allows us to retain all associated feature data, which contributes more effectively to the appearance-based association process.

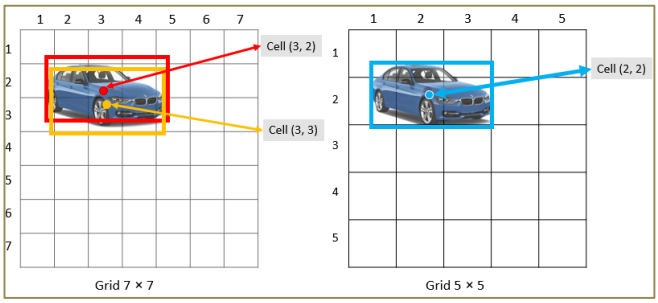

Fig. 5. Example of cell location on different feature grids.

2) Modified appearance similarity process: In the original DeepSORT, a feature bank (or gallery) mechanism is employed to retain long-term appearance information about targets, aiding in recovering object identities after long-term occlusions. This mechanism calculates the appearance similarity between a detection and a tracked target by storing up to 100 appearance descriptors for each track. The similarity is determined by the smallest cosine distance between the detection's appearance vector and the stored vectors in the feature bank. These appearance descriptors are obtained through a pre-trained CNN embedding model. However, this CNN model in DeepSORT contains 2,800,864 parameters and processing a batch of 32 bounding boxes takes approximately 30 ms on an Nvidia GeForce GTX 1050 mobile GPU. On embedded devices or devices with limited resources, especially those without GPU capability, the processing time may increase significantly.

To optimize the tracker for such devices, we propose extracting the appearance similarity without relying on the CNN model. Instead, we leverage the feature map vectors generated during the detection process. As discussed earlier, our detection process associates each detected object with its corresponding feature map vectors extracted from the YOLOv5 neck. The number of feature vectors varies depending on the number of predicted detections for that object, and these vectors differ in dimensionality based on the three grid sizes used in YOLOv5's detection process. These feature vectors are stored for each object in what we refer to as an object cluster. An object cluster consists of all the feature vectors associated with the multiple predicted detections of the same object resulted from the previous modified detection phase.

For example, in YOLOv5s, the grid for small objects (52x52) generates feature vectors with a dimensionality of 128, the grid for medium-sized objects (26x26) produces vectors with a dimensionality of 256, and the grid for large objects (13x13) creates vectors with a dimensionality of 512. Considering these feature vectors, we propose an approach that evaluates appearance similarity by comparing vectors of the same size between two objects.

Algorithm 1 outlines the steps for calculating appearance similarity between a detection D and a track T. First, we divide the feature vectors into three sets based on their dimensions (128, 256, and 512). Then, we compute the similarity score for each set as the minimum cosine distance between corresponding vectors. The final appearance similarity score is determined by taking the overall minimum of these three scores.

$$Simil(DF_{Dim}, TF_{Dim}) = \min\{\cos(df_i, tf_j) \mid df_i \in DF_{Dim}, tf_j \in TF_{Dim}\} \quad \text{(Eq.1)}$$

Algorithm 1 Appearance Similarity between two objects

Input: $DF = \{df_1, \ldots, df_n\}$, // features of object 1
$TF = \{tf_1, \ldots, tf_n\}$ // features of object 2

1: $(DF_{128}, DF_{256}, DF_{512})$ = *separate_by_size*(DF)
2: $(TF_{128}, TF_{256}, TF_{512})$ = *separate_by_size*(TF)
3: $simil_{128}$ = Simil(DF_{128} , TF_{128}) using Eq. 1
4: $simil_{256}$ = Simil(DF_{256} , TF_{256}) using Eq. 1
5: $simil_{512}$ = Simil(DF_{512} , TF_{512}) using Eq. 1
6: **return** min{ $simil_{128}$, $simil_{256}$, $simil_{512}$ }

IV. EXPERIMENTS

To evaluate the performance of our proposed tracking algorithm, we conducted a series of experiments using real-world highway surveillance videos. We compared the tracking accuracy, robustness, and computational efficiency of our algorithm against the state-of-the-art SORT and DeepSORT algorithms. The video sequences used for testing captured a variety of challenging traffic scenarios, including high-density traffic and occlusions, to thoroughly assess the algorithm's performance under realistic conditions.

For our experiments, we utilized a locally collected traffic video dataset comprising over 10,000 frames. This dataset captures real-world urban traffic scenarios with varying numbers of vehicles, ranging from light traffic to highly congested conditions. It includes challenging situations such as shadowing caused by varying lighting conditions throughout the day and occlusions resulting from vehicles overlapping or obstructing each other. The videos were recorded at a resolution of 1920x1080 and a frame rate of 30 fps, ensuring high-quality imagery for accurate detection and tracking. The dataset encompasses different times of the day and weather conditions, providing a comprehensive set of challenges for evaluating the robustness and scalability of our proposed tracking approach.

The experiments were performed on a Windows machine equipped with an Intel Xeon Silver 4110 CPU @ 2.10 GHz and 32 GB of RAM. To simulate low-resource environments, we deployed our tracker within a Docker container configured with reduced resources, specifically 4 CPU cores and 4 GB of RAM, to mimic the capabilities of edge devices. This setup allowed us to assess the feasibility of deploying our algorithm on resource-constrained platforms without compromising its real-time performance.

To evaluate the computational efficiency of our algorithm, we measured the average processing time required to track varying numbers of vehicles in the scene. This processing time represents the duration needed to perform the tracking task for each frame, excluding the object detection phase. This metric provided valuable insights into the performance of our algorithm, particularly in terms of calculating appearance similarity and data association, under different workload conditions.

To assess the scalability of our method, we analyzed its performance across scenes with varying numbers of vehicles. Table I illustrates the processing time per frame (in milliseconds) relative to the number of detected vehicles compared to DeepSORT and SORT. Additionally, Fig. 6 provides a graphical representation of the data in Table I, offering a visual comparison of the processing times between the algorithms. Our findings revealed that, on average, the processing time of our tracker is about 25 % of the time required by DeepSORT, and approximately 10% higher than SORT. These results underscore the significant computational efficiency of our tracker, as it maintains near-constant processing time as the number of vehicles increases, demonstrating efficient scalability. This consistent performance is critical for real-time applications in ITS, where traffic density can fluctuate significantly.

TABLE I. MEASURED PROCESSING TIMES IN MILLISECONDS FOR EACH ALGORITHM WITH VARYING NUMBERS OF VEHICLES

# Number of Vehicles	DEEP SORT	SORT	Our Tracker
1	24,58	2,23	**2,97**
2	39,75	3,82	**7,01**
3	52,43	5,80	**12,77**
4	65,14	7,85	**20,71**
5	73,83	10,37	**31,21**
6	87,07	12,38	**38,08**
7	96,49	12,69	**42,06**
Avg Proce. time	**45,01**	**6,83**	**11,38**

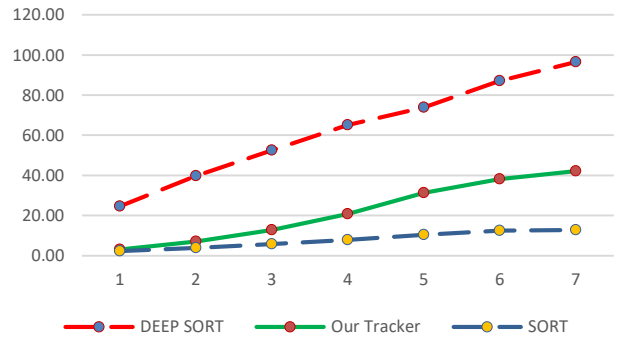

Fig. 6. Visual comparison of the processing times between our algorithm and the DeepSORT and SORT.

To evaluate the accuracy of our tracker, instead of using manually annotated video sequences with ground truth object trajectories, we opted to compare our tracking results directly with those of DeepSORT, which achieved a perfect score in our scenarios. We employed an error rate metric, calculated by summing the number of misses and false matches, then dividing by the total number of matches. This metric provides a comprehensive assessment of the accuracy and reliability of our algorithm under various conditions, with lower error rates indicating higher tracking accuracy.

To assess the robustness of our tracker, we introduced real-world uncertainty by simulating missed detections with a certain probability. We utilized a parameter called the skip detection rate, which we tested with three values: 0%, 25%, and 50%. This parameter simulates scenarios of missed detections by occasionally sending an empty detection output to the tracker. This test allowed us to evaluate the tracker's ability to re-identify objects through appearance association, even after missed detections, providing valuable insights into its reliability for real-world applications.

TABLE II. A COMPARISON BETWEEN THE ERROR RATES OF OUR TRACKER AND SORT REGARDING VARIOUS SKIP RATE VALUES

Skip rate	**0%**		**25%**		**50%**	
Algorithm	Our tracker	SORT	Our tracker	SORT	Our tracker	SORT
Miss matches	34	92	53	1048	50	1164
False matches	2	0	6	2	14	0
Total matches	8369	8362	6119	5949	3783	3661
Error Rate	**0,43%**	1,10 %	**0,96 %**	17,65 %	**1,69 %**	31,79 %

Table II presents the accuracy performance results of our tracker compared to SORT across three scenarios of skip detection rates: 0%, 25%, and 50%. DeepSORT was excluded from the comparison due to its perfect accuracy score in all scenarios.

The results show that under normal conditions (i.e., without skip detections) both our tracker and SORT achieve high accuracy with very low error rates. Notably, our tracker achieves an error rate of 0.43%, outperforming SORT, which records an error rate of 1.10%. In more challenging scenarios with non-zero skip detection rates, our tracker demonstrates a significant advantage. At skip rates of 25% and 50%, our tracker achieves error rates of 0.96% and 1.69%, respectively, while SORT shows much higher error rates of 17.65% and 31.79%. These results highlight the superior robustness of our tracker in handling missed detections compared to SORT (Fig. 7).

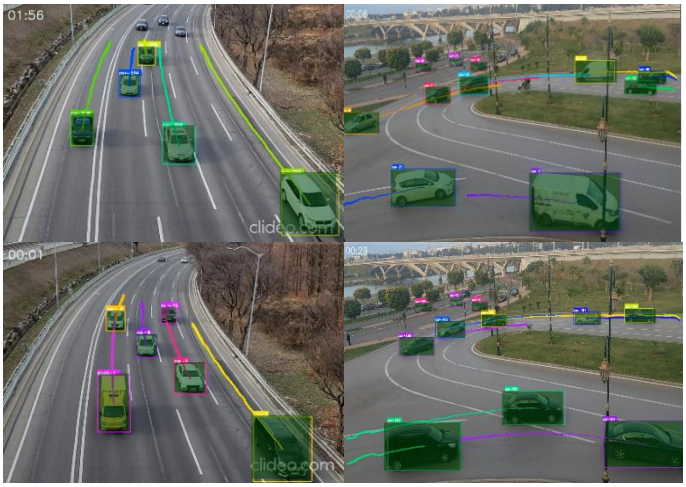

Fig. 7. Sample of tracking results visualization using our lightweight tracker.

V. DISCUSSION

The experimental results confirm that our modified lightweight DeepSORT variant significantly reduces computational requirements while maintaining high tracking accuracy. This improvement addresses a critical barrier in deploying effective ITS solutions on edge devices, enabling more widespread and efficient traffic monitoring systems. Our approach demonstrates that leveraging features directly from YOLOv5 detections is an effective strategy for reducing overhead without sacrificing performance. This finding suggests a paradigm shift in multi-object tracking, where the integration of detection and tracking components can lead to more streamlined and efficient algorithms.

One of the key insights from our study is that integrating detection and appearance features can lead to more efficient multi-object tracking solutions suitable for real-time deployment. However, we acknowledge that testing on a single, localized dataset may limit the generalizability of our findings. Evaluating the method on additional datasets, possibly from different regions or with different characteristics, would further substantiate its scalability.

One challenge we observed is that in highly congested scenes, the absence of an additional CNN descriptor slightly affected the appearance similarity process, occasionally leading to some miss matching and ID switches. This issue could be addressed in future work by incorporating further improvements to the processing method. Some of these improvements could include exploring optimized adaptive association mechanisms and integrating more recent and enhanced detection models to further improve performance. We also we aims to investigate the integration of our tracking algorithm with other ITS components, such as traffic prediction models and anomaly detection systems.

A promising direction for improvement is training the detector on a specialized dataset enriched with detailed annotations. By labeling objects with attributes like distinct colors, shapes, and varied viewing angles, the detector's backbone network can learn to recognize more discriminative features. This enhancement would significantly improves its ability to differentiate between objects, particularly in complex traffic scenarios with similar-looking vehicles or difficult perspectives, leading to more accurate and reliable tracking.

VI. CONCLUSION

In this paper, we present a novel lightweight tracking algorithm designed specifically for vehicle tracking in Intelligent Transportation Systems (ITS). By leveraging the predictability of vehicle trajectories and optimizing the DeepSORT workflow, we propose an algorithm that strikes a balance between accuracy and computational efficiency, making it well-suited for deployment on resource-constrained edge devices. Our approach utilizes features extracted from the detector network as a source of appearance information for the appearance matching task, effectively eliminating the need for the traditional CNN descriptor used in DeepSORT. This significantly reduces the computational load of our tracking algorithm. Experiments with real-world traffic surveillance data reveal that our tracker not only outperforms traditional methods like SORT in tracking accuracy but also significantly reduces processing time compared to DeepSORT. This efficiency is crucial for real-time applications on resource-constrained devices. However, some scenarios when a large number of features are extracted with objects, the algorithm can encounter some challenges, as the similarity calculation becomes computationally demanding. To address this, we plan in future works to add a new feature limitation mechanism that adjust the number of features used in the similarity processing, allowing users to tradeoff between efficiency and accuracy. Additionally, we aim to enhance the detector by training it on specialized datasets to improve object distinction. We also intend to evaluate the effectiveness of our method on devices like the Raspberry Pi to assess its performance on typical edge computing hardware and explore its applicability in more general use cases within ITS.

***Abstract*—Multispectral cameras on remote sensing satellites must have good radiometric quality due to their wide range of applications. One type of radiometric calibration that can be performed while the satellite is in orbit is cross-calibration. This research focuses on cross-calibration because it has advantages, including being cost-effective and capable of frequent execution. We proposed a multi-site cross-calibration method with two reference cameras using six calibration sites in 2023. The LISA LAPAN-A3 (LA3) camera serves as the target camera, while the OLI LANDSAT-8 (OL8) and MSI SENTINEL-2 (MS2) cameras act as the reference cameras. The calibration process results in numerous calibration coefficients for each channel, thus requiring optimization to produce a single calibration coefficient. The optimization process uses a one-dimensional Kalman filter to reduce measurement noise. The results show that the one-dimensional Kalman filter can reduce noise in the calibration coefficient data, making LA3 radiance values closer to the reference radiance values. Additionally, this study demonstrates that LA3 calibration results with MS2 as the reference camera are better than those with OL8 as the reference.**

I. INTRODUCTION

Line Imager Space Application (LISA) is a multispectral camera on the LAPAN A3/IPB satellite. This camera is the main payload that supports the remote sensing mission of the LAPAN-A3/IPB satellite. This camera has blue, green, red, and near-infrared (NIR) channels, with a ground resolution of 15 meters and 120 km swath-width from 510 km altitude. Besides, this camera has 16-bit radiometric resolution and 21 days of temporal resolution [1].

Multispectral cameras on satellites are extensively utilized in remote sensing applications, encompassing the detection and characterization of agroforestry systems [2], evaluation of land-use changes [3], identification of terrestrial vegetation [4], mapping of mangrove forests [5], assessment of forest restoration [6], bamboo mapping [7], and evaluation for sustainable urban development [8].

LISA LAPAN-A3 (LA3), similar to the multispectral cameras used in other remote sensing satellites, serves multiple purposes, including the identification of plant types and growth conditions [9], monitoring drought areas [10], calculating chlorophyll in plants [11], monitoring rice fields [12], and performing land use analysis [13].

This camera produces images consisting of a collection of pixels with specific values. The values in these pixels are called digital numbers (DN). Digital numbers represent the radiometric values of objects in an image [14]. However, calibration coefficients are needed to convert the digital number (DN) values to obtain TOA radiance or TOA reflectance. An absolute radiometric calibration process is required to generate calibration coefficients for the images.

There are several methods of absolute radiometric calibration, including the on-board calibration method [15][16], the Rayleigh calibration method [17][18][19], the vicarious calibration method [16][20][21][22][23], and the cross-calibration method [16][24][25]. Based on previous literature reviews, the cross-calibration method is considered an efficient alternative as it has the advantage of being low cost, high calibration frequency, and can be carried out repeatedly to obtain calibration coefficients for each channel [26].

Furthermore, research on cross-calibration of satellite cameras has been widely conducted. Lu researched cross-calibration for medium-resolution multispectral cameras with large angles [24]. Gao researched cross-calibration to monitor VNIR sensor degradation on the Gaofen-4/GF-4 satellite using three reference sensors, namely OLI/Landsat-8, MSI/Sentinel 2, and MODIS/Terra [25]. Jie Han researched cross-calibration based on a radiometric block adjustment (RBA) algorithm to minimize radiometric effects due to differences in integration time [27]. Mizuochi researched cross calibration with inter-band calibration on a hyperspectral camera [28]. Kohei Arai researched cross-calibration based on vicarious calibration measurements [29]. Due to the significant developments related to this method, this study will also develop a radiometric calibration method based on cross-calibration.

The LA3 calibration has been the subject of numerous investigations. Laboratory calibration [30], vicarious calibration at the Kupang cement mine [31], and Jaddih Hill Madura [32][33] are some of the studies that fall under this category. Although these investigations have yielded calibration

coefficients, the current calibration methods still have drawbacks.

Additionally, the calibration coefficients for satellites need to be updated because there is a possibility that satellites degrade over time. Therefore, other methods are required to complement previous research. This study proposes a multi-site cross-calibration method for the LA3 camera with one-dimensional Kalman Filter for the optimization process. This method is a cross-calibration technique developed from several previously reviewed references. The proposed method differs from the usual cross-calibration techniques because this method uses more than one calibration site, and the calibration coefficients are optimized using the Kalman Filter, resulting in a single final calibration coefficient.

In this study, cross-calibration was also performed using two types of reference cameras, namely, OLI LANDSAT-8 (OL8) and MSI SENTINEL-2 (MS2). The calibration coefficients from these two references were then validated using a cross-validation method, so the calibration result of LA3 with OL8 reference was validated with MS2, and the calibration result of LA3 with MS2 reference was validated with OL8. This research aims to determine if this method can be successfully implemented on the LAPAN-A3/IPB satellite's multispectral camera, resulting in radiance values that are closely comparable to the standard values. This method is expected to complement previous methods and should be applied to the LA3 camera periodically.

II. Descriptions of Calibration Sites and Datasets

A. Calibration Sites

In this study, six sites were used: five in North Africa and one in France. The sites in North Africa are Libya 1, Libya 4, Algeria 3, Mauritania 1, and Mauritania 2. The site in France is the La Crau calibration site. Libya-1, Libya-4, and Algeria-3 are deserts with dunes 100 meters high and a spatial variability of <3% over 100 km. Mauritania 1 and 2 have lower spatial variability compared to the others. The La Crau site has a spatial variability of <3% and a temporal variability of <2% over an area of <20 km [34].

La Crau is one of the RadCalNet calibration sites that provides free radiometric data. The data available includes TOA reflectance, continuously updated every 30 minutes and at a sampling interval of 10 nm within the 380 nm – 2500 nm spectral range. Each site has automated instruments that can generate reflectance and atmospheric data for that site. The provided data is guaranteed in terms of quality and consistency according to international standards [35]. According to research by Revel et al., this area is more heterogeneous than the Gobabeb site in Namibia, a desert [36]. Table I contains the list of calibration sites used in this study.

TABLE I. Calibration Sites

	Sites	Latitude (°)		Longitude (°)	
		Max	***Min***	***Max***	***Min***
PICS	Algeria-3	30.50	30.20	7.60	7.30
	Libya-1	24.80	24.50	13.60	13.30
	Libya-4	28.65	28.42	23.02	22.80
	Mauritania-1	19.60	19.40	-9.20	-9.40
	Mauritania-2	20.60	20.40	-8.50	-8.80
Rad-Cal-Net	La Crau, France	43.56	43.55	4.86	4.86

B. Datasets

The images used in this study are from the LA3 camera as the target camera, and from the OL8 and MS2 cameras as reference cameras. The images are from the calibration sites mentioned earlier, taken in 2023. There are 8 images with 66 pairs of ROIs used for each reference camera.

LA3 is a multispectral camera on the LAPAN-A3 satellite with a wavelength range of 410 nm – 900 nm. This camera consists of four channels: red, green, blue, and NIR. It has a resolution of 15 m, a swath width of 120 km, and a revisit time of 21 days. Based on these specifications, OL8 and MS2 were selected as reference cameras because their specifications are quite similar to those of the LA3 camera.

OL8 is a multispectral camera on the LANDSAT-8 satellite with a wavelength range of 430 nm – 2290 nm. This camera consists of 8 channels with a resolution of 30 m and 1 channel with a resolution of 15 m. The 8 channels with a resolution of 30 m include coastal aerosol, blue, green, red, NIR, SWIR1, SWIR2, and cirrus. The 15 m resolution channel is the panchromatic channel. The camera has a swath width of 185 km and a revisit time of 16 days [37] [38].

MS2 is a multispectral camera on the SENTINEL-2 satellite with a wavelength range of 442 nm – 2202 nm. This camera consists of four channels with a resolution of 10 m, six channels with a resolution of 20 m, and three channels with a resolution of 60 m. SENTINEL-2 is a satellite that consists of two identical twin spacecraft in the same orbit with a 180° phase difference. This satellite's revisit period of five days is relatively short due to the presence of two twin satellites. The mission of this satellite is a multispectral imaging mission with a swath width of 290 km [39]. Table II displays the specs for the reference and target cameras at RGBN wavelengths.

TABLE II. Specifications for Multispectral Cameras on Satellites

Specifications	**OLI/Landsat 8**	**MSI/Sentinel 2**	**LISA/LAPAN-A3**
Resolution	30 m	10 m	15 m
Swath Width	185 km	290 km	120 km
Spectral			
Red	0.64 – 0.67 µm	0.65 – 0.68 µm	0.63 – 0.70 µm
Green	0.53 – 0.59 µm	0.54 – 0.58 µm	0.51 – 0.58 µm
NIR	0.85 – 0.88 µm	0.78 – 0.90 µm	0.77 – 0.90 µm

Additionally, reflectance data from the spectral library and aerosol optical depth data from the AERONET site are used as supporting data. Reflectance data—specifically, desert reflectance—is taken from the spectral library. The region nearest to the calibration sites is where the aerosol data is derived from. These two data sets serve as inputs for the MODTRAN software to generate the surface reflectance of the calibration sites.

III. CALIBRATION METHOD

The proposed calibration method is a cross-calibration technique with radiometric parameters using several internationally standardized calibration sites (multi-sites). The image acquisition of these sites was conducted throughout 2023. Two reference cameras, OL8 and MS2, are also used in this procedure. Fig. 1 displays the block diagram for the multi-site cross-calibration system for the LA3 camera.

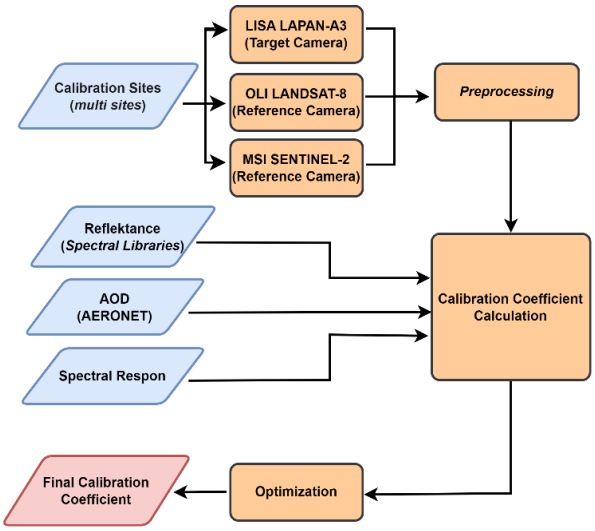

Fig. 1. Block diagram of the multi-site cross-calibration system on the LISA LAPAN-A3 (LA3).

Based on Fig. 1, the first step of this calibration involves LA3 (target camera), OL8, and MS2 (reference cameras) capturing images of the calibration sites at nearly the same time. Next, the cross-calibration method is used for the preprocessing and calibration coefficient calculation steps. This procedure will yield many calibration coefficients. The Kalman filter is used to conduct an optimization process to generate a single final calibration coefficient. The final calibration coefficient is then determined by selecting the coefficient with the smallest error. This process is carried out for each image channel (RGBN).

A. Preprocessing

Before the calibration process, image preprocessing is conducted on both the target and the reference camera images. For the LA3 (target camera) image, as well as the OL8 and MS2 (reference camera) images, the process involves determining the Region of Interest (ROI).

The ROI determination process for LA3 includes setting the ROI boundary coordinates based on the recommendations of the Committee on Earth Observation Satellites (CEOS), identifying ROI points within the ROI boundary, adjusting the ROI points if they do not match the reference cameras, selecting 4 x 4 pixels at each ROI point, and calculating the average Digital Number (DN) of the selected pixels. This average DN will then be processed further.

Meanwhile, for OL8 and MS2, which are the reference cameras, the ROI determination process involves setting the ROI boundary coordinates based on the recommendations of CEOS, identifying ROI points within the ROI boundary, selecting 2 x 2 pixels for OL8 and 6 x 6 pixels for MS2 at each ROI point, and calculating the average DN of the selected pixels to obtain the reference camera DN. The DN values from the target and reference cameras will be used to calculate calibration coefficients.

B. Calculation of Calibration Coefficients

The calculation of calibration coefficients is carried out under the assumption that the response of the LA3 camera is linear. Therefore, the calibration coefficients can be calculated using Eq. (1) [40].

$$\frac{DN_L}{g_L} + o_L = \frac{k.DN_R.c_R.E_L.cos(\theta_L)}{\pi.d^2.cos(\theta_R)} \quad (1)$$

Where DN_L is the DN for LA3, g_L is the calibration gain for LA3, O_L is the calibration offset for LA3, SBAF is the Spectral Band Adjustment Factor (SBAF), DN_R is the digital number of the reference camera, c_R is the calibration gain of the reference camera, E_L is the average solar irradiance for the channel being considered, θ_L is the solar zenith angle for the LA3 camera, d is the average distance between the sun and the Earth, and θ_R is the solar zenith angle for the reference camera. Based on the results of laboratory calibration, the calibration offset for the LA3 camera is 0, so the calibration coefficient (gain) can be obtained using Eq. (2).

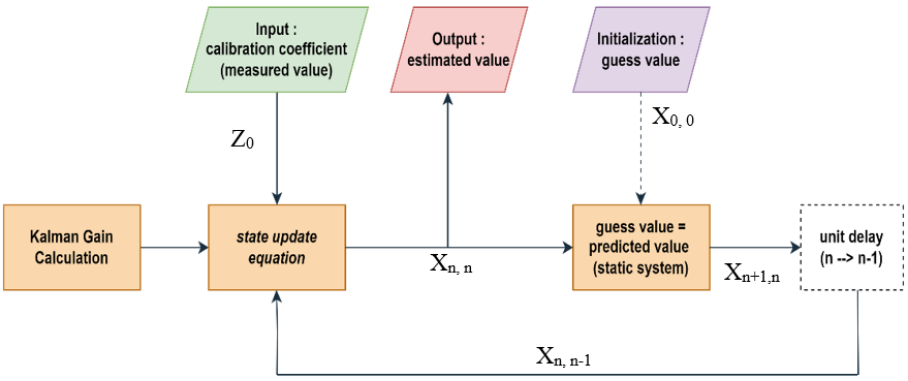

Fig. 2. Block diagram of one-dimensional Kalman filter.

$$g_L = \frac{DN_L . \pi . d^2 . cos(\theta_R)}{SBAF . DN_R . c_R . E_L . cos(\theta_L)} \quad (2)$$

Based on Eq. (2), several inputs and constants are used to obtain the calibration coefficient. DN_L and DN_R are derived from the preprocessing stage. θ_L, θ_R, and c_R come from the image metadata. π, d, and E_L are known constants. Meanwhile, SBAF is a constant obtained from the spectral matching process.

Spectral matching is adjusting spectral responses to account for the differences between the target camera and the reference cameras. This process produces a correction factor known as the Spectral Band Adjustment Factor (SBAF). This correction factor is the ratio of the reflectance of the target camera to that of the reference camera, simulated using MODTRAN software. This process requires inputs such as ground reflectance, aerosol optical depth (AOD), and the spectral response functions of both the target and reference cameras.

The outputs from preprocessing (DNL and DNR), spectral matching (SBAF), and metadata (θL, θR, cR) are then used as inputs for the calculation of the calibration coefficient. The calibration coefficient is calculated based on equation 3.2, resulting in the calibration coefficient (gL). This calculation is carried out for every channel in the LA3 image, yielding a calibration coefficient for each channel (gLR, gLG, gLB, gLN) in the form of a gain factor.

C. Optimization Process

The calibration process will yield many calibration coefficients for each channel. Therefore, an optimization process is needed to obtain the best calibration coefficient. This work uses a one-dimensional Kalman filter to carry out the optimization process. This method is selected because it is anticipated to lower measurement noise, leading to a more accurate radiance measurement by the LA3. Fig. 2 displays the optimization process diagram using the one-dimensional Kalman filter, while Eq. (3) displays the mathematical formula for the output of the one-dimensional Kalman filter.

$$X_{n,n} = X_{n,n-1} + \frac{1}{n}(Z_n - X_{n,n-1}) \quad (3)$$

with

$X_{n,n}$: output (estimated value)

Z_n : measurement value

$X_{0,0}$: predicted value

$X_{n+1,n}$: predicted value

$X_{n,n-1}$: predicted value in the previous process

$\frac{1}{n}$: Kalman gain

The measurement values are the subsequent calibration coefficients obtained from the calibration process, while the initial guess value used is the first calibration coefficient from the measurement process. The calibration coefficient will ultimately be used as the final predicted or estimated value from the optimization process using the one-dimensional Kalman filter.

IV. Result

A. Image Data

This study uses some images with 66 ROI points. The number of ROIs is adjusted based on the image area that can be used for calibration ROI and corresponds to the reference image area. Each image uses 4x4 pixels for the LISA LAPAN-A3 (LA3) image, 2x2 pixels for the OLI LANDSAT-8 (OL8) image, and 6x6 pixels for the MSI SENTINEL-2 (MS2) image, representing a total area of 60x60 meters on the ground. The LA3 images are obtained from the LA3 image database, OL8 images are obtained from the website https://earthexplorer.usgs.gov/, and MS2 images are obtained from the website https://sentinels.copernicus.eu/. The calibration sites and reference image acquisition times are based on the availability of LA3 images. As previously noted, image requirements for calibration are also taken into account. Fig. 3 displays an example of ROI construction on images of the calibration site.

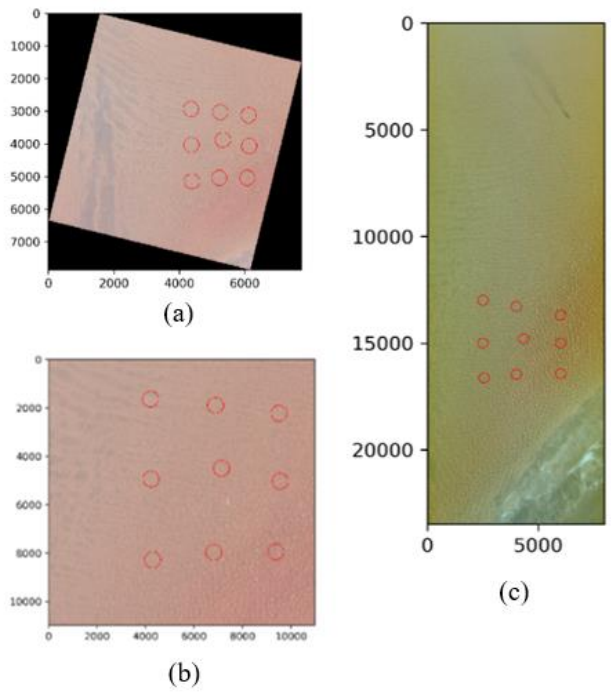

Fig. 3. ROI of Algeria-3 calibration site on imagery citra (a) OL8, (b) MS2, and (c) LA3.

B. Calibration Result

The digital number (DN) for each pixel in each ROI is obtained once the images have been ROI'd. Subsequently, the average DN of the pixels within each ROI is calculated to get a single DN value for each ROI. Every image is subjected to this procedure, including the LA3 image as the target image and OL8 and MS2 as the reference images.

The next step is spectral matching, which yields a spectral band adjustment factor (SBAF). The SBAF for each channel at different calibration sites is shown in Table III and Table IV.

TABLE III. SBAF LA3 AGAINST OL8 AND LA3 AT CALIBRATION SITE

Num	Sites	LA3-OL8			
		R	G	B	N
1	Libya 1	1,026	0,825	0,813	0,988
2	Mauritania 1	0,981	0,837	0,817	0,966
3	Mauritania 2	0,981	0,837	0,817	0,966
4	Libya 4	1,026	0,825	0,813	0,988
5	Algeria 3	1,026	0,825	0,813	0,988
6	La Crau	1,021	0,918	0,835	0,955

TABLE IV. SBAF LA3 AGAINST MS2 AND LA3 AT CALIBRATION SITE

Num	Sites	LA3-MS2			
		R	G	B	N
1	Libya 1	1,004	0,854	0,835	0,998
2	Mauritania 1	0,996	0,870	0,854	0,960
3	Mauritania 2	0,996	0,870	0,854	0,960
4	Libya 4	1,004	0,854	0,835	0,998
5	Algeria 3	1,004	0,854	0,835	0,998
6	La Crau	1,007	0,923	0,847	0,996

Based on Table III and Table IV, it can be seen that spectral differences between LA3 and OL8, as well as between LA3 and MS2, are not very significant, especially in the red and NIR channels. The SBAF results, which get close to 1 at a few calibration sites, make this clear. However, in the green channel (G), both LA3-OL8 and LA3-MS2 show lower SBAF values than the red and NIR channels. When considering each calibration site, La Crau has the best SBAF values in every channel compared to other sites.

After obtaining the SBAF values, the calibration coefficient calculation process is carried out. Calibration coefficients are derived using this procedure to convert the LA3 image's DN values into radiance. In this study, two types of calibration coefficients will be obtained: the calibration coefficient with OL8 as the reference and the calibration coefficient with MS2 as the reference. Fig. 4 and 5 display the calibration coefficients for each ROI at multiple calibration sites.

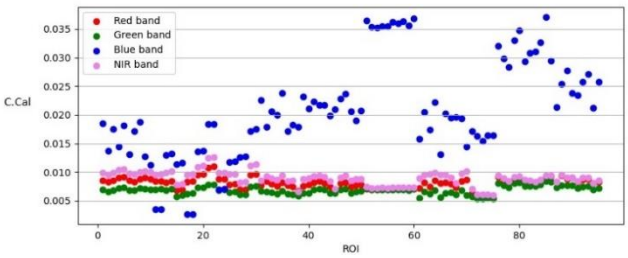

Fig. 4. Calibration coefficient of LA3 with reference OL8.

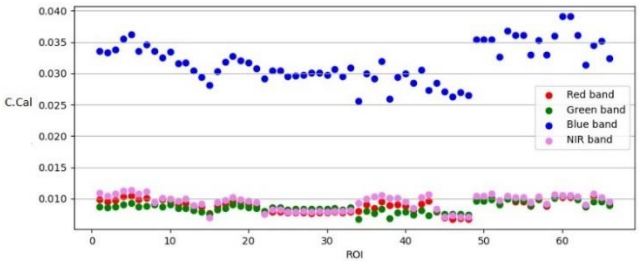

Fig. 5. Calibration coefficient of LA3 with reference MS2.

TABLE V. THE ROI NUMBERS FOR THE CALIBRATION SITES

Calibration of LA3 with Reference OL8		Calibration of LA3 with Reference MS2	
ROI	Calibration Site	ROI	Calibration Site
1-10	Libya 1	1-7	Libya 1
11-30	Algeria 5	8-17	Mauritania 1
31-40	Mauritania 1	18-22	Mauritania 2
41-50	Mauritania 2	23-33	Libya 4
51-60	Libya 4	34-43	Algeria 3

Fig. 4 shows the calibration coefficients of LA3 with OL8 as the reference, and Fig. 5 shows the calibration coefficients of LA3 with MS2 as the reference. Meanwhile, Table V shows the ROI numbers for the calibration sites used in Fig. 4 and 5. It is evident from both figures that the calibration coefficients vary across different calibration sites and different periods. If the averaging process is carried out based on on-site calibration and time, then a graph is obtained in Fig. 6 to 9.

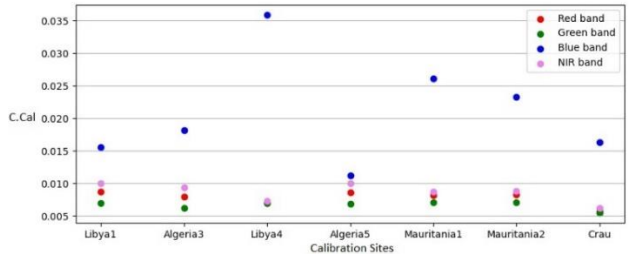

Fig. 6. Average LA3 calibration coefficient with OL8 reference at each calibration site.

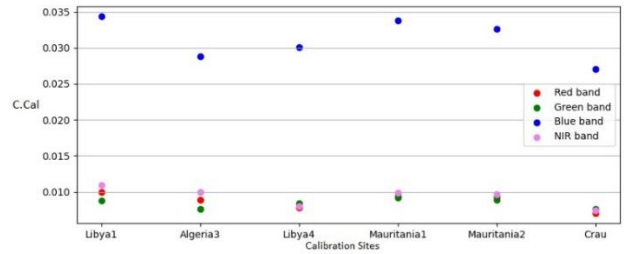

Fig. 7. Average LA3 calibration coefficient with MS2 reference at each calibration site.

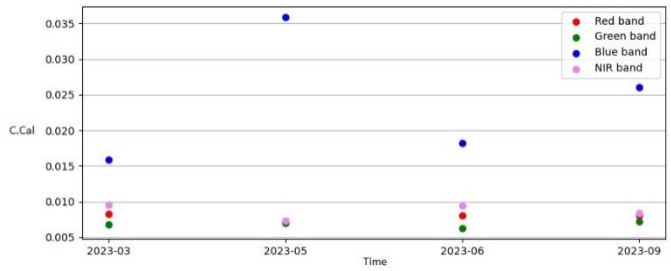

Fig. 8. Average LA3 calibration coefficient with OL8 reference based on time.

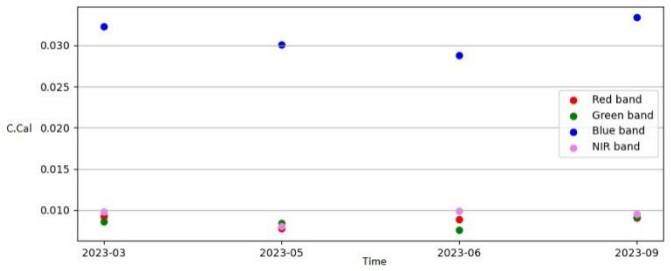

Fig. 9. Average LA3 calibration coefficient with MS2 reference based on time.

Fig. 6 shows the average calibration coefficient graph of LA3 with OL8 as the reference across different ROIs representing specific calibration sites. From the figure, it is evident that the red and NIR channels tend to remain stable in Libya 1, Algeria 3, Algeria 5, Mauritania 1, and Mauritania 2. The red channel ranges from 0.0080 to 0.0087, while the NIR channel ranges from 0.0087 to 0.0099. At Libya 4, the red and NIR channels are slightly lower than at other calibration sites in the Sahara Desert, but the blue channel is the highest compared to other sites. The calibration coefficients at this site are 0.007 for the red and green channels, 0.035 for the blue channel, and 0.0073 for the NIR channel. At La Crau, the red, green, and NIR channels are lower than at other calibration sites. Meanwhile, the calibration coefficient for the blue channel is lower than at other calibration sites, except for Libya 1. The calibration coefficients at this site are 0.0057 for the red channel, 0.0054 for the green channel, 0.016 for the blue channel, and 0.0062 for the NIR channel.

Fig. 7 shows the average calibration coefficient graph of LA3 with MS2 as the reference across different ROIs representing specific calibration sites. From the figure, it is evident that the red and NIR channels tend to remain stable in Libya 1, Algeria 3, Algeria 5, Mauritania 1, and Mauritania 2. The calibration coefficients range from 0.0088 to 0.0099 for the red channel and from 0.0091 to 0.011 for the NIR channel. The calibration coefficient for the green channel remains relatively stable across all calibration sites, ranging from 0.0076 to 0.0089. At Libya 4, the red and NIR channels are slightly lower than at other calibration sites in the Sahara Desert, with values of 0.0078 for the red channel and 0.0080 for the NIR channel. At La Crau, the red, green, blue, and NIR channels are lower than at other calibration sites. Meanwhile, the blue channel tends to be more stable than the calibration using OL8 as a reference, with values ranging from 0.026 to 0.034. This differs from the calibration using OL8 as a reference, where the blue channel is more fluctuating, with values ranging from 0.0080 to 0.035.

Fig. 8 shows the average calibration coefficient of LA3 with OL8 as the reference based on time. It can be observed that the red and green channel tends to remain stable in March, May, June, and September. In the NIR channel, there is a slight decrease in May and September compared to March and June. Meanwhile, the blue channel fluctuates, with values ranging from 0.015 to 0.035. Fig. 9 shows the average calibration coefficient of LA3 with OL8 as the reference over time. The figure indicates that the red and blue channels tend to be stable, with values ranging from 0.0078 to 0.0092 for the red channel and 0.028 to 0.032 for the blue channel. In March, there is a decrease in the calibration coefficient for the NIR channel, and in June, there is a decrease in the green channel.

C. Optimization Result

After obtaining the calibration coefficients, an optimization is carried out to derive a final calibration coefficient close to the reference value. The optimization is performed using a Kalman filter. Fig. 10 through 17 display the calibration coefficient optimization outcomes using the Kalman filter.

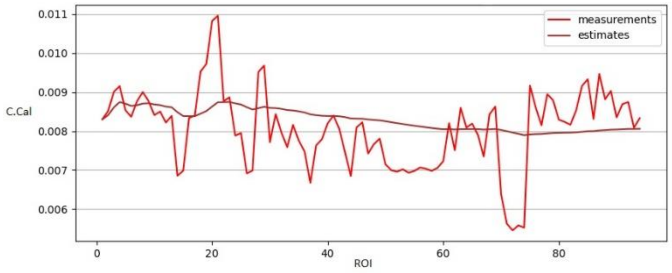

Fig. 10. Calibration coefficients optimization result of LA3 reference OL8 with one-dimensional Kalman filter on red channel.

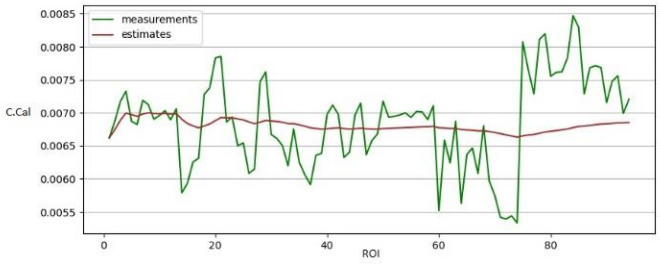

Fig. 11. Calibration coefficients optimization result of LA3 reference OL8 with one-dimensional Kalman filter on green channel.

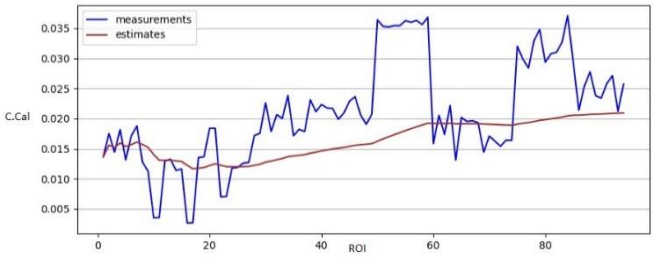

Fig. 12. Calibration coefficients optimization result of LA3 Reference OL8 with one-dimensional Kalman filter on blue channel.

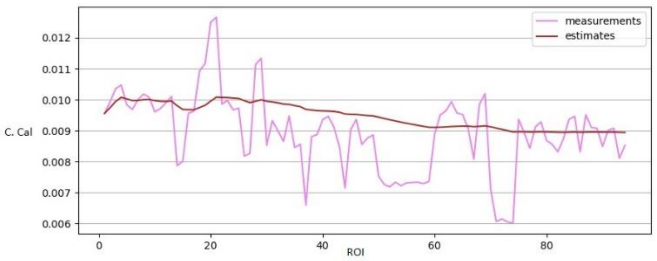

Fig. 13. Calibration coefficients optimization result of LA3 reference OL8 with one-dimensional Kalman filter on nir channel.

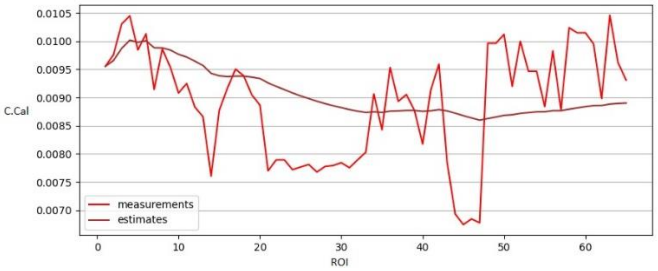

Fig. 14. Calibration coefficients optimization result of LA3 reference MS2 with one-dimensional Kalman filter on red channel.

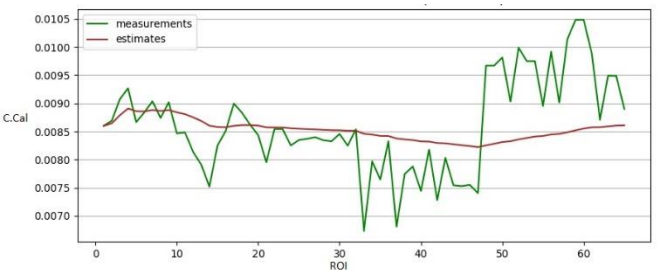

Fig. 15. Calibration coefficients optimization result of LA3 reference MS2 with one-dimensional Kalman filter on green channel.

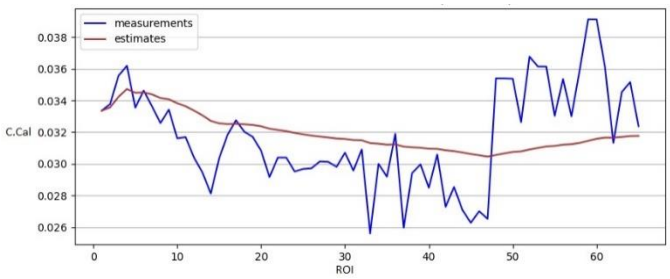

Fig. 16. Calibration coefficients optimization result of LA3 reference MS2 with one-dimensional Kalman filter on blue channel.

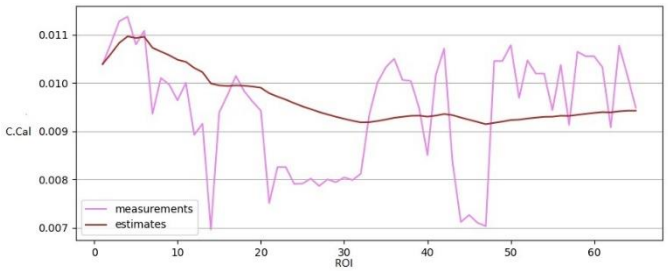

Fig. 17. Calibration coefficients optimization result of LA3 reference MS2 with one-dimensional Kalman filter on nir channel.

Fig. 10 to 13 show the comparison graphs of the LA3 calibration coefficients referenced to OL8 before and after optimization using the Kalman filter. It can be seen that these graphs experience a reduction in fluctuations, and the graphs resulting from the Kalman filter optimization tend to be more stable for each sample area. The final results of this optimization process are 0.0081 for the red channel, 0.0069 for the green channel, 0.02 for the blue channel, and 0.0089 for the NIR channel. Subsequently, these calibration coefficients will be cross-validated using MS2 imagery.

Meanwhile, Fig. 14 to 17 present the comparison graphs of the LA3 calibration coefficients referenced to MS2 before and after optimization using the Kalman filter. It can be observed that these graphs also show a reduction in fluctuations, and the graphs resulting from the Kalman filter optimization tend to be more stable for each sample area. The final results of this optimization process are 0.0089 for the red channel, 0.0086 for the green channel, 0.032 for the blue channel, and 0.0094 for the NIR channel. Subsequently, these calibration coefficients will be cross-validated using OL8 imagery.

D. Validation and Evaluation

The Digital Number (DN) can be converted into radiance using the calibration coefficients that were obtained during the calibration procedure. The first validation stage was performed using the same data and calibration sites as in the calibration process. However, the validation was carried out crosswise, i.e. validating LA3 radiance referenced to OL8 with MS2 radiance and validating LA3 radiance referenced to MS2 with OL8 radiance. This process was conducted on pre- and post-optimization data to assess the difference between LA3 radiance and the radiance of standardized satellites. The validation graphs of LA3 radiance with OL8 reference compared to MS2 radiance are shown in Fig. 18 to 21.

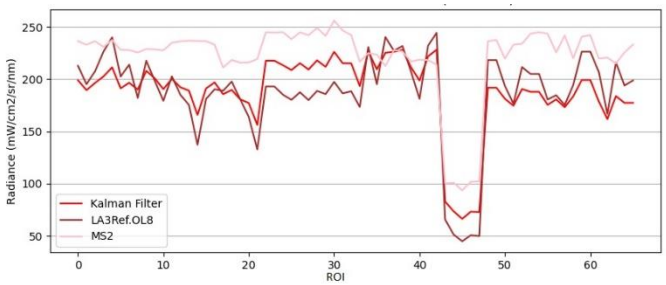

Fig. 18. Validation graph of LA3 radiance with OL8 reference before and after optimization on red channel compared to MS2 radiance.

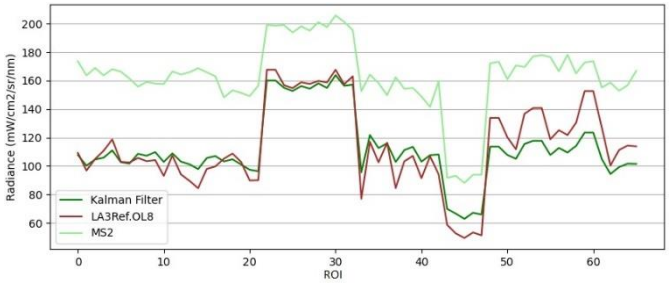

Fig. 19. Validation graph of LA3 radiance with OL8 reference before and after optimization on green channel compared to MS2 radiance.

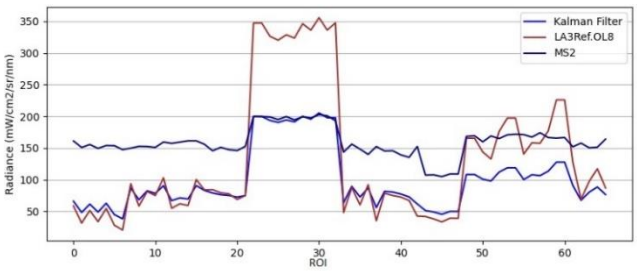

Fig. 20. Validation graph of LA3 radiance with OL8 reference before and after optimization on blue channel compared to MS2 radiance.

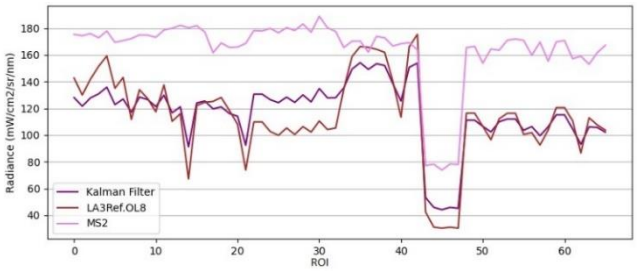

Fig. 21. Validation graph of LA3 radiance with OL8 reference before and after optimization on nir channel compared to MS2 radiance.

Fig. 18 to 21 show the validation graphs of LA3 with OL8 reference before and after optimization using the one-dimensional Kalman filter. MS2 radiance, the other reference camera, is used to compare radiance before and after optimization. The figures indicate that some lines get closer to the reference radiance line after optimization with the one-dimensional Kalman filter. However, some lines move further away after the optimization process. Based on Table VI, five sites in the red channel show a decrease in percentage difference, while three sites show an increase. In the green, blue, and NIR channels, four sites show a decrease in percentage difference, and four sites show an increase. Next, the radiance of LA3 with MS2 reference before and after optimization is compared to OL8 radiance. Fig. 22 to 25 are the validation graphs from this process.

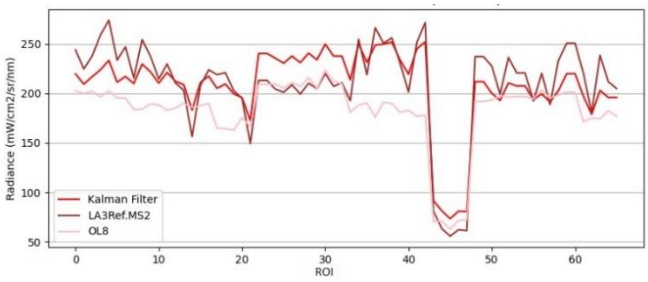

Fig. 22. Validation graph of LA3 radiance with MS2 reference before and after optimization on red channel compared to OL8 radiance.

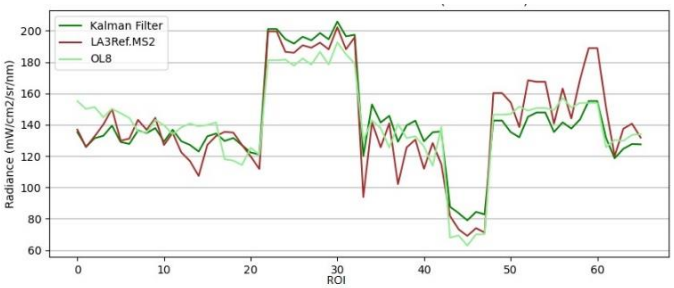

Fig. 23. Validation graph of LA3 radiance with MS2 reference before and after optimization on green channel compared to OL8 radiance.

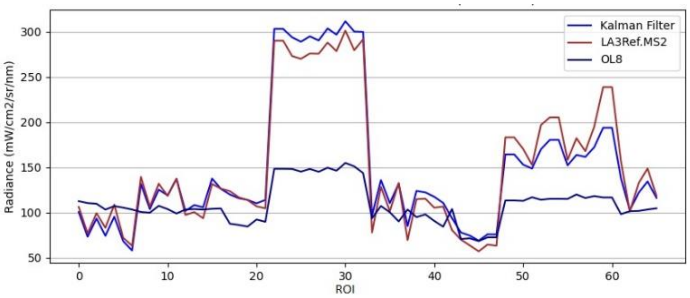

Fig. 24. Validation graph of LA3 radiance with MS2 reference before and after optimization on blue channel compared to OL8 radiance.

Fig. 22 to 25 show the validation graphs of LA3 with MS2 reference before and after optimization using the one-dimensional Kalman filter. The other reference camera, OL8, is used to compare the radiation levels before and after optimization. The figures indicate that some lines get closer to the reference radiance line after optimization with the one-dimensional Kalman filter. However, following the optimization procedure, certain lines get farther apart. Furthermore, the Libya-4 site exhibits a noteworthy percentage variation in the blue channel. Based on Table VII, in the red, green, and NIR channels, five sites show a decrease in percentage difference, while three sites show an increase in percentage difference. In the blue channel, six sites show a decrease in percentage difference, and two sites show an increase in percentage difference.

V. DISCUSSION

Based on the results, in the preprocessing stage of this study, digital numbers (DN) were derived for each image: LA3, OL8, and MS2. Subsequently, SBAF calculations were performed. The results show that the SBAF values in the RGBN channels are close to 1 (Tables III and IV). This indicates that the spectral response of LA3 is similar to that of the reference cameras (OL8 and MS2). Once the SBAF values were obtained, calibration coefficients could be calculated using DN, SBAF, reflectance, and AOD. From this process, calibration coefficients are shown in Fig. 4 and 5. The graph indicates that the blue channel's calibration coefficient is higher than the other channels. This is because the digital number for the blue channel is lower than the other channels, requiring a high calibration coefficient to reach the reference radiance value.

The calibration coefficients obtained during the calculation process showed fluctuations across each ROI, whereas, in theory, they should have similar values at the calibration site. Therefore, this study used a Kalman Filter to reduce noise in the calibration coefficients. Furthermore, the Kalman Filter was employed to optimize the calibration coefficients, resulting in a single calibration coefficient value. These values are used to convert DN to TOA radiance.

Based on the results, the optimization process using the Kalman Filter reduce noise in the calibration coefficient graphs (Fig. 10 until Fig. 17). This can be seen from the calibration coefficient graphs, which initially showed fluctuations but became more stable for each ROI. The calibration coefficients for LA3 with OL8 and MS2 reference were obtained from the optimization. The calibration coefficient for LA3 with OL8 reference is 0.0081 for the red channel, 0.0069 for the green channel, 0.02 for the blue channel, and 0.0089 for the NIR channel. The calibration coefficient of LA3 with MS2 reference are 0.0089 for the red channel, 0.0086 for the green channel, 0.032 for the blue channel, and 0.0094 for the NIR channel. Next, these calibration coefficients were validated using another reference camera as the validator. The calibration coefficient for LA3 with OL8 reference was validated with MS2, while the calibration coefficient for LA3 with MS2 reference was validated with OL8.

The cross-validation results show that the LA3 calibration process with MS2 as the reference results in radiance values closer to the reference radiance than OL8 as the reference. This implies that using MS2 as the reference camera is more sensible for the LA3 cross-calibration procedure. This calibration technique demonstrates that, for most images, the red, green, blue, and NIR channels can be effectively optimized with a one-dimensional Kalman filter. However, further development is needed to achieve better results. Extended Kalman Filter (EKF), Unscented Kalman Filter (UKF), or other methods can be considered for further research so that the radiance produced from the cross-calibration process more closely matches the reference radiance values.

VI. CONCLUSION

The multi-site cross-calibration method with one-dimensional Kalman filter optimization can be implemented on the LA3 camera. It is possible to optimize calibration coefficients using the one-dimensional Kalman Filter, as can be inferred from the discussion in the preceding section. This is evident from the reduction in the percentage difference between LA3 radiance and reference radiance after the optimization process. The results also show that LA3 calibration process with MS2 as the reference results in radiance values closer to the reference radiance than OL8 as the reference. This implies that using MS2 as the reference camera is more sensible for the LA3 cross-calibration procedure. Basically, this method can be applied on LA3. However, further development is needed to achieve better results so that the radiance produced from the cross-calibration process more closely matches the reference radiance values.

ACKNOWLEDGMENT

The author would like to thank Mr. Mohammad Mukhayadi and Mr. Patria Rachman Hakim as group leader and leader satellite operation missions of Satellite Technology Research Center BRIN, for their support and assistance so that this works can be well completed.

***Abstract*—This research focuses on sentiment analysis to understand public opinion on various topics, with an emphasis on COVID-19 discussions on Twitter. By utilizing state-of-the-art Machine Learning (ML) and Natural Language Processing (NLP) techniques, the study analyzes sentiment data to provide valuable insights. The process begins with data preparation, involving text cleaning and length filtering to optimize the dataset for analysis. Two models are employed: a Bidirectional Encoder Representations from Transformers (BERT)-based Deep Learning (DL) model and a Convolutional Neural Network (CNN). The BERT model leverages transfer learning, demonstrating strong performance in sentiment classification, while the CNN model excels at extracting contextual features from the input text. To further enhance accuracy, an ensemble model integrates predictions from both approaches. The study emphasizes the ensemble technique's value for more precise sentiment analysis. Evaluation metrics, including accuracy, classification reports, and confusion matrices, validate the effectiveness of the proposed models and the ensemble approach. This research contributes to the growing field of social media sentiment analysis, particularly during global health crises like COVID-19, and underscores its potential to aid informed decision-making based on public sentiment.**

***Keywords*—Sentiment analysis; COVID-19; BERT; CNN; ensemble model; NLP; transfer learning**

I. Introduction

The global impact of the COVID-19 epidemic has shown a surge in communication and information sharing on social media platforms [1]. Notably, Twitter sentiment has emerged as a vital channel for individuals to express their ideas, concerns, and opinions regarding the pandemic. Understanding the sentiment conveyed in these tweets is crucial, as it provides valuable insights into the public's emotional responses [2, 3], concerns, and expectations related to the ongoing health crisis. This study embarks on a sentiment analysis journey, aiming to decipher the emotion and tone of tweets about COVID-19. Sentiment analysis has become indispensable for grasping how society perceives and responds to emerging events, such as the COVID-19 epidemic [4]. Analyzing tweet sentiments enables the identification of patterns in public opinion, tracking changes in public mood over time, and evaluating public satisfaction with governmental responses. In the era of rapid digital transformation, the global influence of social language cannot be overlooked. Platforms such as social media, Blogs, Online forums, and product review portals have become modern channels for expressing opinions, collectively forming a vast sea of User Generated Content that significantly impacts real-world businesses [5]. Analyzing public sentiment in these social media data entails Opinion Mining, deciphering the emotional intent behind comments or tweets – positive, negative, or neutral. This process, guided by patterns identified through text mining, enables the prediction of subsequent textual threads. Sentiment analysis also plays a crucial role in shaping a brand's presence on social media by providing inferences of an in-depth understanding of the target audience's perspective, Evaluation of competitors' emotional marketing, campaigns, responses, and identification of industry trends for strategic brand positioning and marketing [6].

Numerous studies have explored ML and DL models for sentiment analysis, particularly in the context of COVID-19-related tweets. The research in [7, 8] underscores the necessity and significance of sentiment analysis across various domains. Naïve Bayes classifier achieved an accuracy of 79% on a dataset comprising 11,974 COVID-19 tweets [9]. A comparative analysis of various ML models demonstrated their efficacy in COVID19 Tweets [10]. BERT outperformed traditional models such as Logistic Regression and Support Vector Machines (SVM), attaining an accuracy of 89% in the analysis of Indian tweets; however, the study was limited by its geographic focus and a lack of comprehensive dataset evaluation [11]. Furthermore, BERT exhibited high accuracy on Twitter datasets from Amazon and Hachette, though it did not thoroughly address biases inherent in social media data [12]. An RNN model surpassed SVM in global sentiment analysis, yet failed to consider data transparency and ethical implications [13]. In another study, fuzzy logic combined with deep learning yielded an accuracy of 81%, but lacked generalized recommendations [14]. Additionally, the Extra Trees Classifier demonstrated superior accuracy relative to other ML models [15]. Comparative studies in [16] and [17] emphasized ensemble techniques while acknowledging

challenges in generalizing results to non-English datasets of COVID-19 tweets.

The research gap highlights the need for hybrid models that integrate ML and DL approaches, aiming to enhance accuracy and address biases in sentiment analysis across diverse datasets.

This study utilizes advanced ML and NLP techniques for this purpose, and to preprocess the Twitter dataset effectively, by eliminating extraneous data, links, and special characters, excluding tweets with insufficient text content to generate a focused and insightful dataset. Subsequently, we explore two distinct modeling strategies. The first leverages BERT, a DL model recognized for its exceptional ability to capture context and semantics due to pre-training on extensive text data. The second method involves a CNN, a prominent ML model, to extract local text characteristics. These models are analyzed based on accuracy, utilizing various categorization criteria to determine their effectiveness. Additionally, we employ an ensemble strategy that merges predictions from both models to enhance overall accuracy. Ensemble modeling leverages the strengths of each model, which is known to strengthen outcomes while mitigating individual model drawbacks. In the ongoing COVID-19 outbreak, this study aims to illuminate public sentiment on social media. Decision-makers, public health experts, and politicians can utilize these insights to stay informed about evolving public opinions and concerns related to the pandemic. The objectives of this study are, evaluate the effectiveness of BERT and CNN models in classifying COVID-19 Twitter sentiment using accuracy, classification reports, and confusion matrices, and enhance sentiment analysis accuracy through an ensemble technique combining BERT and CNN predictions, providing more reliable results.

The rest of the manuscript is organized. Section II details the ML models used for analysis. Section III describes the proposed work, dataset, and methodology. Section IV presents the results, and Section V concludes with future directions.

II. Sentiment Analysis

This study employs BERT, CNN, and ensemble models to conduct sentiment analysis on COVID-19-related tweets. By leveraging BERT's contextual understanding in combination with the feature extraction strengths of CNN, the ensemble approach enhances both accuracy and robustness. The insights generated aim to deepen understanding of public sentiment during the pandemic, offering valuable information for decision-makers.

A. Bidirectional Encoder Representations from Transformers

Natural language processing has seen a revolutionary development, primarily due to the advancements made possible by deep learning and advanced neural network architectures. Among these developments, the pre-trained transformer-based model BERT has been crucial in changing the field of NLP applications [18]. In contrast to conventional unidirectional models, BERT's bidirectional approach considers both words that come before and after to grasp the context of a sentence. This fundamental change allows BERT to gain a deep comprehension of context, which helps it become skilled at managing linguistic subtleties. With massive corpora of pre-trained text, BERT is proficient in understanding syntactic structures and semantic links, producing rich contextual representations that provide a solid basis for a range of NLP applications. BERT is pre-trained on large text data using two tasks: masked Language Modeling and next-sentence prediction [19]. One noteworthy application of BERT is sentiment analysis, demonstrating its ability to identify the dominant sentiment or mood in each text [20, 21]. Sentiment analysis models with BERT can refine accuracy and granularity by utilizing rich contextual embedding's to decode minor variations in sentiment within the textual content, and architecture for tweets input and output is depicted in Fig. 1.

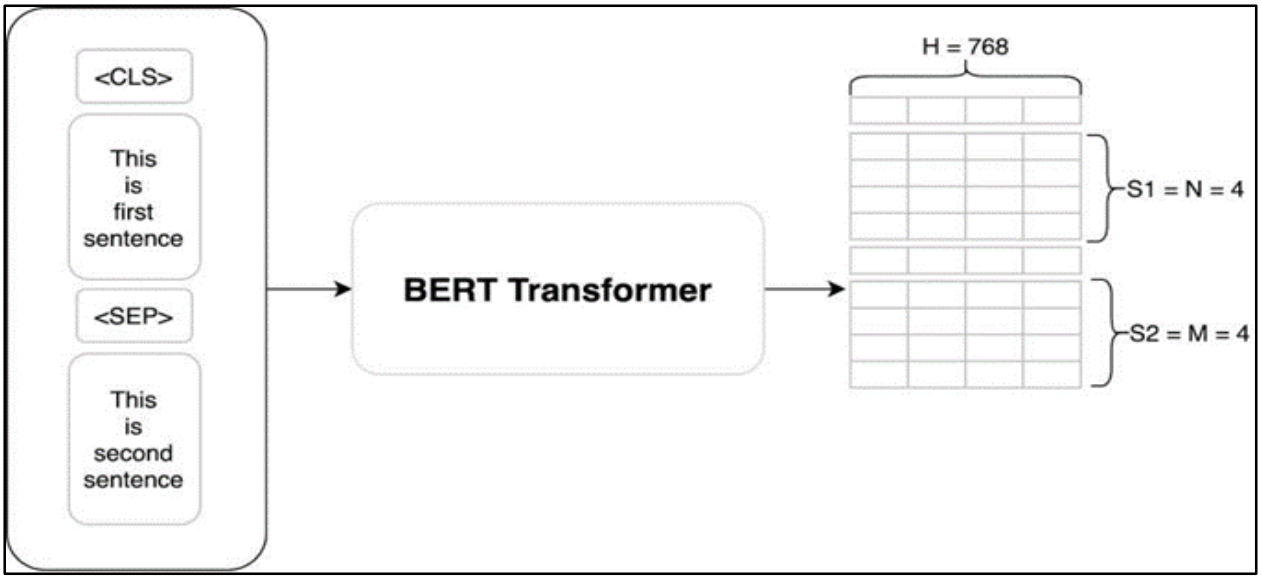

Fig. 1. BERT architecture for tweets input and output.

B. Convolutional Neural Network

The CNN-based COVID-19 sentiment analysis model architecture includes layers for token embedding, convolution, max-pooling, and fully connected neural networks [22]. Convolutional layers extract local text features, and max-pooling determines standout features, enabling CNN to effectively comprehend complex sentiment within tweets. CNNs excel at automatically learning and extracting features from structured data. It consists of four layers: the convolutional layer, pooling layer, fully connected layer, and output layer, as shown in Fig. 2. The convolutional layer includes convolutions where filters are applied to extract useful information and post-convolution, a Rectified Linear Unit (ReLU) function is used to introduce non-linearity. Pooling layers reduce the spatial dimensions while retaining significant information. Next, the information from previous layers is flattened into a one-dimensional vector in fully connected layers. This is further processed in dense layers, which combine the extracted features to make the final predictions. The final layer in CNN is the output layer, which typically uses a softmax function (for classification tasks) or another activation function depending on the needed task.

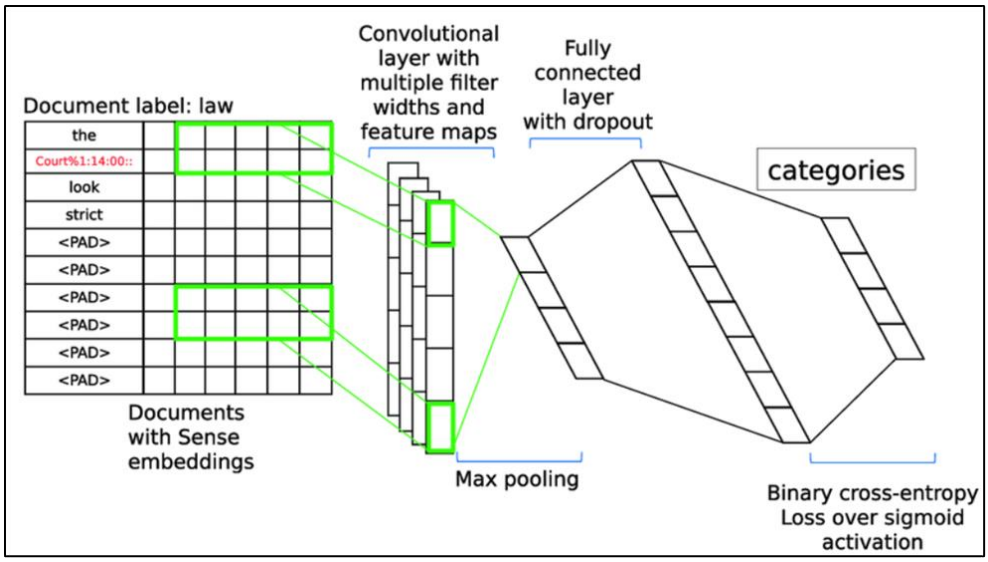

Fig. 2. CNN architecture [23].

C. Ensemble Model

Combining multiple models' advantages, ensemble models considerably improve prediction accuracy, resilience, and generalization. They are essential to many high-achieving machine learning systems, especially in challenging and vital applications. To improve COVID-19 sentiment analysis, the ensemble model shown in Fig. 3 combines predictions from the BERT model with the CNN. Through the process of average outcomes, the ensemble makes the most of the unique qualities of each model, so increasing the overall efficacy and reliability of sentiment classification. By removing individual model limitations, this ensemble technique fully understands public sentiment [24].

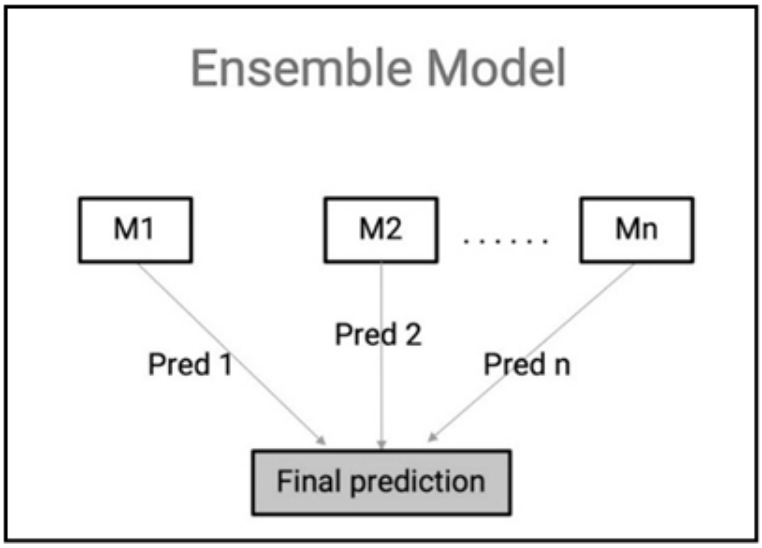

Fig. 3. Ensemble model.

III. METHODOLOGY

The suggested methodology outlines the steps involved in applying sentiment analysis to a corpus of tweets about COVID-19 and categorizing them as "Negative," "Neutral," or "Positive." It includes a series of crucial procedures intended to suitably set up, model, and assess the sentiment analysis. The steps include data preprocessing, text vectorization, machine learning, and deep learning model-based prediction. Furthermore, an ensemble model is constructed, which improves sentiment classification accuracy by combining the benefits of two different and efficient methods. The approach offers insights into public opinion on social media regarding the COVID-19 epidemic by showcasing the application of well-liked models and techniques for sentiment analysis on textual data for IMDB review dataset of 25000 samples [25]. This systematic process guarantees a thorough strategy for insightful analysis and outcomes.

A. Library Imports

The code begins by importing the necessary Python libraries for DL like Tensor Flow and Keras, ML libraries like Scikit-learn, and for data manipulation NumPy, and Pandas, for NLP NLTK, and for data visualization Matplotlib and Seaborn have been used. Furthermore, libraries such as Transformers for BERT- based models and Emoji for handling emojis are imported and installed.

B. Data Loading and Exploration

In this study, COVID-19 dataset consists of tweets collected over a 15-day period from March 16 to March 31, 2020. Twitter samples were used to analyze the trend and sentiment of COVID-related topics. Mounting Google Drive to access the dataset is how the code starts. Pandas Data Frames are loaded with two CSV files. df, which contains training data, and df_test, which contains testing data. To perform exploratory data analysis and display tweet counts by date and location, data pretreatment entails deleting duplicates, changing the 'TweetAt' field to date format, and more, as shown in Fig. 4 which shows that the tweet count by Date for half of a specific Month, and number of tweets by people across the Globe are considered for a complete month for a realistic analysis of their sentiments during Pandemic. Fig. 5 shows tweets across the Globe by different citizens; 15 states across the USA and Europe have been considered. Fig. 6 and Fig. 7 show a graphical analysis of COVID-19 tweets based on the length of tweets. Fig. 6 analyses of tweets with less than 10 words for the training dataset, whereas Fig. 7, represents a graphical representation of tweets with a length of less than 10 words with test data.

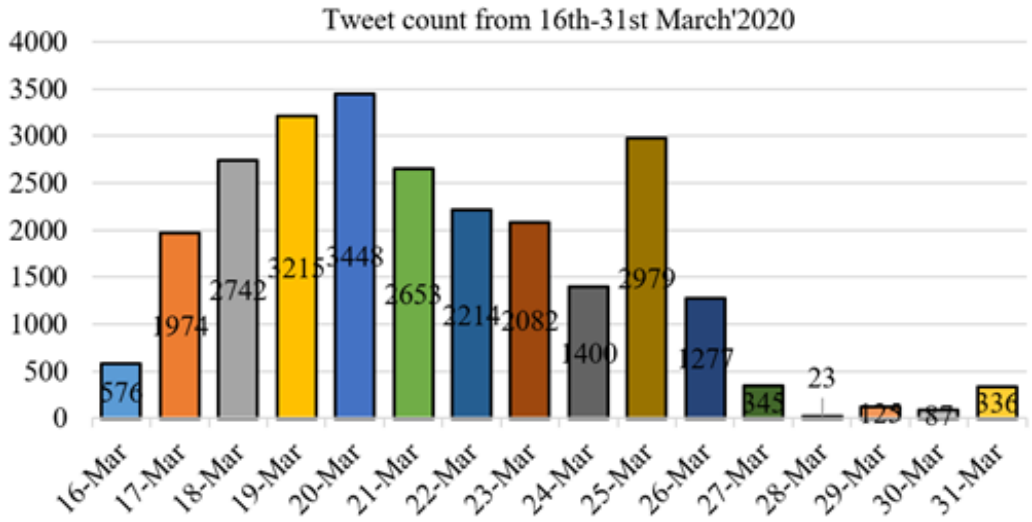

Fig. 4. Tweet count by date.

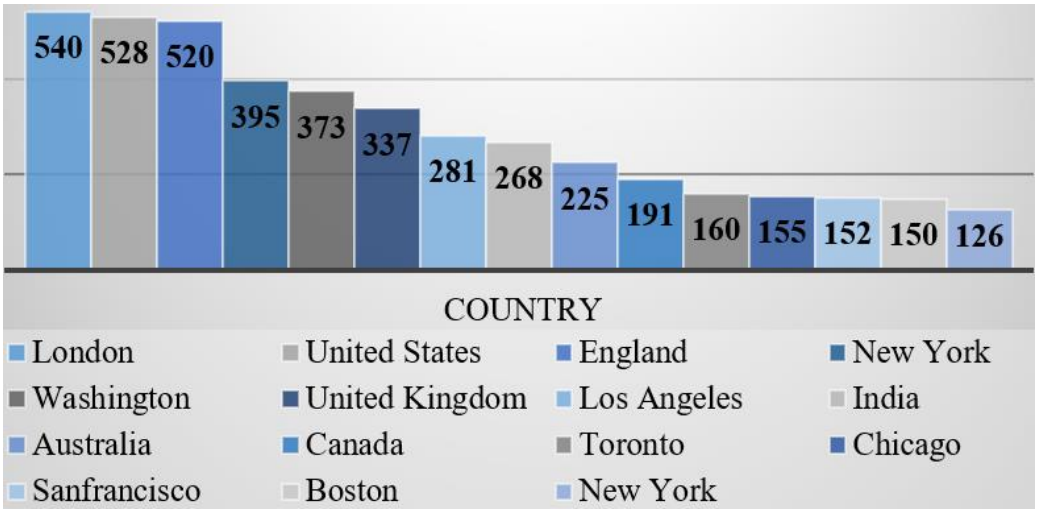

Fig. 5. Tweet count by country.

C. Data Preparation

In this study, Data Preparation is done using four stages: Text Preparation, Text Length analysis, Data balancing, and Text Vectorization. In the initial stage of Text preparation, Custom functions are employed for cleaning and preparing text data. These functions eliminate emojis, punctuation, links, mentions, and special characters, as well as handle hashtags. The pre-processed text is then saved in the Data Frames as new columns. In Text Length analysis the code computes the length in number of words of each pre-processed tweet and visualizes the tweet length distribution. The resulting histograms are illustrated in Fig. 6 and Fig. 7. Neural networks and machine learning rely heavily on data, but the quality of that data determines how well a model performs. Data science and data mining initiatives frequently deal with imbalanced datasets, which are those in which one class called a minority class has a comparatively smaller number of instances than the other classes. In preparing the training dataset, to address the class imbalance in sentiment labels using the RandomOverSampler from the imbalanced-learn library, resulting in a total of 15,148 samples. In the final stage of text preparation, authors vectorize the data using Count Vectorizer and Tfidf Transformer, converting textual information into numerical features suitable for training machine learning models. The Count Vectorizer transforms text data into a count matrix, which is then normalized into a TF or TF-IDF representation. Here, TF refers to term frequency, while TF-IDF combines term frequency with inverse document frequency. This widely used term weighting scheme is effective in information retrieval and document classification. For the proposed approaches, 3,787 data samples were utilized to evaluate model performance. The cleaned text is visualized in Fig. 8.

Fig. 8. Text vectorization of the tweets.

D. Model Preparation

The algorithm optimizes a sentiment analysis pre-trained BERT model using the Hugging Face Transformers library. Text data is tokenized and transformed into BERT model input features. The model is trained on oversampled data and tested on new data, with a confusion matrix and classification metrics computed. Using a CNN model for sentiment analysis is defined and trained, incorporating an embedding layer, convolutional layers, and fully linked layers. The CNN model is tested based on the test data, and its accuracy is estimated.

Predictions from the BERT and CNN models are averaged to create an ensemble model [25]. The accuracy of the ensemble model, along with a confusion matrix, is computed, and a classification report is generated [26, 27].

IV. Results and Discussion

The results section presents the findings and performance metrics of the sentiment analysis conducted on the COVID-19-related Twitter dataset. This analysis utilized a comprehensive methodology that included data preprocessing, machine learning, deep learning, and an ensemble model to categorize tweets as "Negative," "Neutral," or "Positive" [28, 29]. The assessment metrics provide insight into the effectiveness of each method employed, facilitating a comparative analysis of model performance to determine the most suitable approach for this dataset. The fine-tuned BERT-based model demonstrated significant efficacy, achieving a test accuracy of 0.884. The confusion matrix for the BERT model is illustrated in Fig. 9, while a detailed classification report in Fig. 10 offers a thorough evaluation of its classification capabilities. In contrast, the CNN model designed for sentiment analysis achieved a commendable test accuracy of 0.817. The model's performance is further elucidated through visual representations, including a confusion matrix depicted in Fig. 11 and a detailed classification report in Fig. 12. Notably, the ensemble model, which aggregates predictions from both the CNN and BERT models, attained a test accuracy of 0.90. Fig. 13 showcases the ensemble model's effectiveness in accurately categorizing tweets into their respective sentiment categories, supplemented by a confusion matrix. The classification report for the ensemble model is presented in Fig. 14, providing additional insights into its performance. Overall, these results underscore the effectiveness of the applied methodologies in sentiment classification tasks.

Fig. 14. Ensemble model classification report.

In cases where the BERT model outperforms the ensemble, the results reflect the BERT model's dominant influence within the ensemble framework. This reliance underscores the necessity for a more sophisticated approach to balance the contributions of different models. Simply averaging predicted probabilities may not sufficiently mitigate the impact of one model over another, especially when there are significant imbalances in prediction probabilities. Despite this challenge, the ensemble model remains the preferred choice due to its robustness, stability, and versatility in handling diverse data patterns. This study focused on sentiment analysis of COVID-19-related tweets, providing practical insights for various sectors. Stakeholders in social sciences, digital marketing, public health, and policymaking can leverage these insights to understand public sentiment effectively. Sentiment analysis plays a critical role for public health officials, policymakers, social scientists, marketers, and emergency responders by tracking public opinion during crises. It informs decision-making, enables strategic adjustments, and enhances communication efforts, ensuring that responses align with public sentiment during emergencies. A comparative analysis with existing research, is presented in Table I.

TABLE I. COMPARATIVE STUDY WITH EXISTING LITERATURE

Ref.	Multiple ML models were tested before the final selection	Ensemble model selected	Data Preparation	Data Balancing	Data Vectorization	Results		
						F1 Score	Recall	Precision

V. CONCLUSION

In our study, a range of methods, from advanced deep learning techniques to conventional approaches, were discussed and assessed for the construction and assessment of sentiment analysis models. The work illustrated the revolutionary benefits of BERT, a cutting-edge transformer-based sentiment analysis methodology. About the test dataset, the BERT-based model demonstrated an impressive accuracy of 88.4%. The Naive Bayes model which had a respectable accuracy of 70% despite its streamlined architecture was also investigated. A CNN model was also a part of the investigation, and it demonstrated a commendable accuracy of 83%. Finally, an ensemble technique that merged predictions from BERT and CNN showed an accuracy of 89%, highlighting the potential of ensemble approaches to improve overall performance. Overall, the findings substantiate a combination of BERT and ensemble learning for enhancing sentiment analysis research across various domains with reliable and accurate classification. This study scouts the subtleties of the COVID-19 tweet sentiment analysis as well as the usefulness of sentiment analysis in a variety of contexts. Using state-of-the-art NLP and ensemble models of ML, the study offers an asset for anyone aiming to use public sentiment data for informed decision-making and for enhanced communication. For future research, expanding the sample size would enhance the evaluation of model performance. The results can also be utilized for policy-making in certain domains.

Visual Translation of Auspicious Beliefs in Quanzhou Xi Culture from the Perspective of Man-Machine Collaboration

Li Zheng*[1], Xu Zhang[2], Huiling Guo[3]
College of Software Engineering, Xiamen University of Technology, Xiamen, China[1, 2]
International College of Xiamen University, Xiamen University, Zhangzhou, China[3]

***Abstract*—The "Xi" concept in the inheritance of auspicious culture covers the abundance of spiritual and material life, its symbolism is gorgeous and timeless and has lasted for thousands of years. Objective: This study investigates the Quanzhou "happiness" culture, which embodies "reverence for virtue and auspicious beliefs," exploring its visual symbolization, graphical derivation, redesign, and innovative cultural expressions. Methods: Utilizing literature analysis, field research, and a combination of shape grammar and artificial intelligence, this study dissects and evolves the visual symbols of Quanzhou Xi culture to achieve innovative design through human-machine collaboration. Results: The study deeply refines representative visual symbols of Quanzhou happiness culture, including the "卍" character from Quanzhou embroidery, the Eight Immortals color for wedding happiness, and the longevity turtle cake stamp for longevity happiness. It analyzes and demonstrates the innovative practice of these visual symbols, establishes a folklore perspective, and transitions the happiness culture into a modern fashion context. Conclusion: The research constructs a visual symbol folklore perspective of Quanzhou Xi culture, providing a systematic theoretical foundation and innovative practice paths for promoting and inheriting Xi culture in the modern design field. It promotes Quanzhou Xi culture's innovative application and fashion transformation in contemporary design.**

***Keywords*—Quanzhou Xi culture; symbol visualisation; shape grammar; artificial intelligence; man-machine collaborative design**

I. INTRODUCTION

'Xi' means joy and happiness. From symbol auspiciousness to visual symbolization, both convey feelings of satisfaction, good fortune, and happiness. "Long drought meets sweet rain, foreign lands meet old acquaintances, bridal chamber flowers and candles night, and when one achieves success in the imperial examination" [1]. The symbolic meaning of "Xi" today is the visual communication method of images. Since the initial definition of "Xi" in the Song Dynasty, it refers to the folk celebration of happy events, mostly referring to men's and women's marriages, childbirth, and so on. Quanzhou, with a thousand-year history of navigation and exchanges between Chinese culture and overseas cultures, is known for its unique regional culture that embodies the auspicious fusion of the Song and Yuan dynasties "Individuals hailing from ten states" and "seeking common ground while reserving differences".

Visual symbolization refers to the practical representation of images conveyed through symbols, and the design expression of cultural symbols can be comprehended by recreating or reorganizing cultural symbols. Liao et al. proposed to interpret and assess the meaning of visual symbols and organically integrate the visual reality and objective reality of cultural symbols with natural meaning, normative meaning, and intrinsic meaning [2]. Li contends that China is constrained by the Western modernist design concept that merely emphasizes function and technology, resulting in the deficiency of its own history and culture. Chinese design demands its own language, and to restore these cultures, design support is necessary [3]. Culture bestows a soul upon design, and design showcases the vitality of culture. Outstanding design is never rootless water; it must be deeply rooted in traditional national culture and continuously evolve into modern aesthetics through cultural integration and design innovation. As proposed by Xia, the visual translation of the artistic images presented by the pleasant culture of Quanzhou is a significant aesthetic activity in human spiritual life and a means to understand the objective world through artistic images [4]. In the application of visual symbol innovation, Xi culture mainly focuses on cultural and creative products, brand design, packaging design application, and exploration of cultural connotations. Mo et al. investigated the connotation of traditional Xi culture and the form elements that constitute the "Xi" schema, deconstructed and reconstructed the "Xi" schema, and passed on the practical value and cultural value of Xi culture with cultural and creative products as the carrier [5]. Yuan, through his research on the folk culture aesthetics of Quanzhou's "Pu" women's headwear, put forward the philosophical thought of "harmony between nature and man", which coexists and integrates with the local culture [6]. There is still a scarcity of a complete research system and an accumulation of achievements in the analysis and study of the symbols of Xi culture in Quanzhou.

This research aims to clarify the characteristics of Quanzhou's "Xi" culture and analyze its connotations, conducting a study on the visual symbolization of Quanzhou's "Xi" culture, and exploring its value in the fields of art and culture through human-computer collaborative design, thereby reshaping the artistic expression of Quanzhou's "Xi" culture. The main innovative contributions of this study are reflected in the following three points: (1) A deep refinement of Quanzhou's "Xi" culture visual symbols and the construction of a folk perspective; (2) The use of human-computer collaboration to further develop and redesign the visual symbols of Quanzhou's "Xi" culture, achieving an organic integration of art and

technology, creativity, and algorithms; and (3) The reconstruction of the modern and cultural value of Quanzhou's "Xi" culture visual symbols, providing new pathways for the innovative application and fashion-oriented transformation of "Xi" culture in modern design fields.

II. Return To Faith: Quanzhou Xi Culture To be Unfolding

Quanzhou is renowned as "Individuals hailing from ten states" and "the forerunner of the Maritime Silk Road", and the custom of "Worship Mude" continuously gave rise to the early marriage and birthday celebration culture. Subsequently, due to the influence of a significant number of overseas Chinese returning to their hometowns throughout history, they brought back the auspicious culture of Southeast Asia and the belief culture of southern Fujian, and gradually integrated, nurtured, and developed the distinctive Xi culture of Quanzhou in the collision and accumulation of various cultures. "Tea plate round sweet tea sweet, two family marriage at the end of winter born twins, Children, and grandchildren, all being eager to learn" is a popular song about the Xi culture in the Quanzhou region. It demonstrates the inheritance and promotion of traditional values such as family concept, family affection, marriage, and descendants, and possesses regional style, converges diverse cultures, undergoes inclusive development with profound cultural forms, and serves as a bond of cultural identity and emotional exchange in the Quanzhou area. As Geertz explained, the analysis of culture is not an experimental science in search of rules, but an interpretive science in search of meaning [7].

A. The Enduring Xi Culture of Quanzhou

The Xi culture of Quanzhou is reflected in daily life which is to worship Mude, which is rooted in the tradition of Mindi, and has the connotation of cultural integration and renewal. "Wenling Old Story" describes "worship MuDe" culture as "joy", recorded in the competition to choose a day to worship the Lord of heaven and pray for blessing. The visual symbols of birthday, marriage, birth, and so on are directly evolved from the tradition, while many modern representations of Xi are produced in the unique style of Quanzhou's overseas Chinese culture and traditional culture. This so-called culture is not firmly "sealed" in the tradition, but refined and excellent integration outside the region. The perfect fusion of tradition and modernity has promoted Quanzhou Xi culture to be widely inherited and continuously developed in the local area, and deeply integrated into the folk culture, which has a deep and huge influence on contemporary society. The continuation and promotion of Quanzhou Xi culture can not only help the people feel the culture and history of their hometown, and get close to the wisdom and wealth of their ancestors, but also become more orderly, interesting, tasteful, and homelike in their daily life. The core value of Mindi traditional culture has cultivated Quanzhou Xi culture, and the Quanzhou Xi culture with the continuity of "worship Mude" has made Mindi culture more colorful.

B. A Hundred Flowers Blossom of QuanZhou Xi Culture

Quanzhou Xi culture takes Minnan belief as its source and Nanyang auspiciousness as its stream. It presents diverse and unique visual symbols, which integrate the inheritance of inland civilization and marine culture. "Have faith in ghosts and sorcery", especially among people in southern Fujian. The people of southern Fujian "respect deities as if He were present" and "prefer to believe in His existence rather than His absence". The aesthetic features of Quanzhou Xi culture's visual symbols are in accordance with the aesthetic orientation of sacrificial ceremonies, taking southern Fujian faith as the mainstream, close to the folk, deeply rooted in life, rich in the grassroots local flavor, human touch, and always maintain its vigorous vitality. The opening and expansion of the Maritime Silk Road brought together people from ten prefectures and auspicious cultures brought back from overseas Chinese villages, etc., which promoted Quanzhou to better integrate the core Chinese culture, other regional cultures, and the essential elements of foreign cultures in its internal cultural structure, thereby deepening its own cultural characteristics [8]. Influenced by the Southeast Asian and Western cultures of overseas Chinese, Quanzhou Xi culture has given rise to diversified integration and development. For example, Quanzhou wedding customs, are affected by foreign wedding gowns, since Quanzhou wedding customs do not wear white, the people will change the wedding dress to red and transform it into a Qipao. The unique blending and collision of Chinese and Western cultures present a multi-integrated development form of Quanzhou Xi culture, not only maintaining the variation of South Asian auspicious culture but also adhering to its core values in the pursuit of the core mainstream culture of southern Fujian faith, and developing in the process of modernization.

C. Formation and development of Quanzhou Xi culture

Folk marriage is referred to as "great joy", a women's pregnancy is known as "you have joy", children are termed "Add Xi", and Eggs to celebrate the birth of a baby are called "happy eggs". Marriage is joyous and having children is also a joy [9]. In Quanzhou and even across the entire country, since the advent of new life, it is all about "Xi". The first cry of a newborn is a "Xi" sound, and the first year is also a joyous event. When one reaches the age of 16, they become an adult, encounter a lover, and enter into marriage. There is also the joy of having a child, birthdays, etc. The "Five Xi culture" comes from the real scene exhibition area of the "Life Five Xi Wall" in the Quanzhou Marriage Festival Folk Culture Museum, presenting the most significant joys in the lives of Quanzhou people, namely the joy of birth, the joy of the first year, the joy of adulthood, marriage, and birthdays. Table I is a classification and analysis of the content presentation and existing development of the five great happiness cultures in Quanzhou.

TABLE I. CLASSIFICATION OF THE COMPONENTS OF QUANZHOU XI CULTURE

Compositional classification	Joy of birth	The joy of grasping week	The joy of adulthood	Wedding joy	Make a birthday celebration
Content rendering	Newborn clothing embroidery "Wan" word, package "Floral quilt", eat red egg, full moon feast	Clean hands, roll disaster, crown, comb hair, grasp week, pick handprints, eat fu, seal wine, Family photo	Prepare the "three sacrifices", go to the temple to pay deities set a banquet, grandma's house As usual to send clothes, hats, shoes and socks, eggs and so on	Blind date, home visit, talk about betrothal gifts and clothes and pants money, tie Red envelopes, Lift plates, on top, tie spring flowers	Set up longevity hall, point longevity candle, eat Longevity noodles, set a birthday banquet, do Turtle kueh
Existing development	Traditional handicraft and traditional culture continue, but the scope of continuation gradually narrowed	Some traditional customs and cultural forms have gradually simplified or even disappeared, and the industry Chain related to Zhuazhou object has developed rapidly	The process is gradually simplified and the form is more modern	Traditional customs remain intact, and some bad habits such as high endowment have been abandoned, but traditional customs in urbanized areas have been simplified and gradually Westernized	Traditional ways And scope are decreasing, and Traditional gifts such as longevit Y noodles, longevity kueh, longevity peaches, longevity hangingpictures, etc, have been replaced by more high-end and customized products

III. BE CONTENT WITH ONE'S HEART: THE CONNOTATION EXPRESSION OF VISUAL SYMBOLS

The visual symbol serves as a means of expression in design and is collectively known as a visual symbol. It represents the symbolic reconstruction or reorganization of traditional images or abstract concepts, utilizing symbols such as line, light, shadow, color, intensity, expression, balance, and form to showcase modern design ideas and connotations, convey information, and exhibit its beauty and internal equilibrium. With its distinctive continuity and diversity, the visual symbols of Quanzhou Xi culture prominently demonstrate the emotional resonance of auspicious meaning and people's modern aesthetic sense. The visual symbols of early Quanzhou Xi culture primarily centered on image art, like painting, sculpture, architecture, etc. In the modern context, visual symbols transcend the realm of image art itself and prevalently emerge in auspicious belief forms such as folk custom, sacrifice, and birthday celebrations, playing a vital role in the visual communication of clothing, decoration, and adornment in modern life and constituting an indispensable part of modern cultural symbols. Due to its outstanding design display and cultural expression, it possesses a visual form accessible to human eyes and ears on the material form and an enlightening situation at the spiritual level.

The visual symbols of Quanzhou Xi culture are utilized in the domains of clothing, decoration, and decorative goods, and can be categorized into three types in accordance with their expression content and function, as depicted in Table II. The first type is the indicative symbol of Xi culture, such as the Quanzhou embroidered "囍" character, which conveys the happiness of life in a simple and explicit symbol form to achieve efficient dissemination of information and prompt understanding. The second category is the cultural image symbols, such as the wedding of the typical representative of Quanzhou's eight immortal colors, through the employment of images, graphics, icons, and other visual elements, to guide, stimulate, and attract the audience's attention, emotions, and thinking, and convey various kinds of information, appeals, and cultural symbols. The third type is the symbolic symbol of Xi culture, which is associated with a certain fixed symbol and a specific meaning, representing a specific concept or symbolizing a profound meaning, such as the turtle pattern being regarded as a symbol of longevity, and green leaves representing life and nature, etc. This symbolization can assist in conveying and reinforcing a certain emotion or value, enabling the audience to have a profound resonance and identification.

TABLE II. CLASSIFICATION OF VISUAL SYMBOLS IN QUANZHOU XI CULTURE

Constituent classification	Indicative symbol	Pictorial symbol	Symbolic symbol
Symbolic feature	Strong directness, efficient transmission, rapid understanding	High eye attraction, easy to trigger emotional resonance	Symbols are associated with meanings and have deep representation meanings
Quanzhou Xi cultural symbol	Quanzhou embroidery version "囍" character, seven niang mother, etcs	Eight immortals color, paper cutting, etcs	Longevity turtle cake stamp, Xiniang, Zha spring flower, etcs

Besides the aforementioned three types of symbols, visual symbols can also be symbolized in accordance with visual elements like color, text, texture, etc., to maximize and effectively extract information during the process of expressing visual information and meaning.

IV. MAN-MACHINE COLLABORATION: THE VISUAL SYMBOL OF QUANZHOU XI CULTURE

With the rapid advancement of artificial intelligence technology, its introduction has ushered in a novel paradigm to

the domain of visual design and profoundly facilitated the practice of human-machine collaboration. Under this novel paradigm, artificial intelligence and designers can undertake the same or different design tasks through specific information exchange and cooperation mechanisms, collaborate to accomplish the predefined design goals, and bring about the innovation and breakthrough of visual design. In the process of visual design, AI is relatively potent in competitive and predictable workflows, and is particularly adept at handling complexity and multitasking; Human intelligence is flexible and creative during the design process, and excels in knowledge comprehension and strategic thinking, as depicted in Fig. 1 [10]. The application of human-machine collaborative design pertains to the processing of Media collaborative technology.

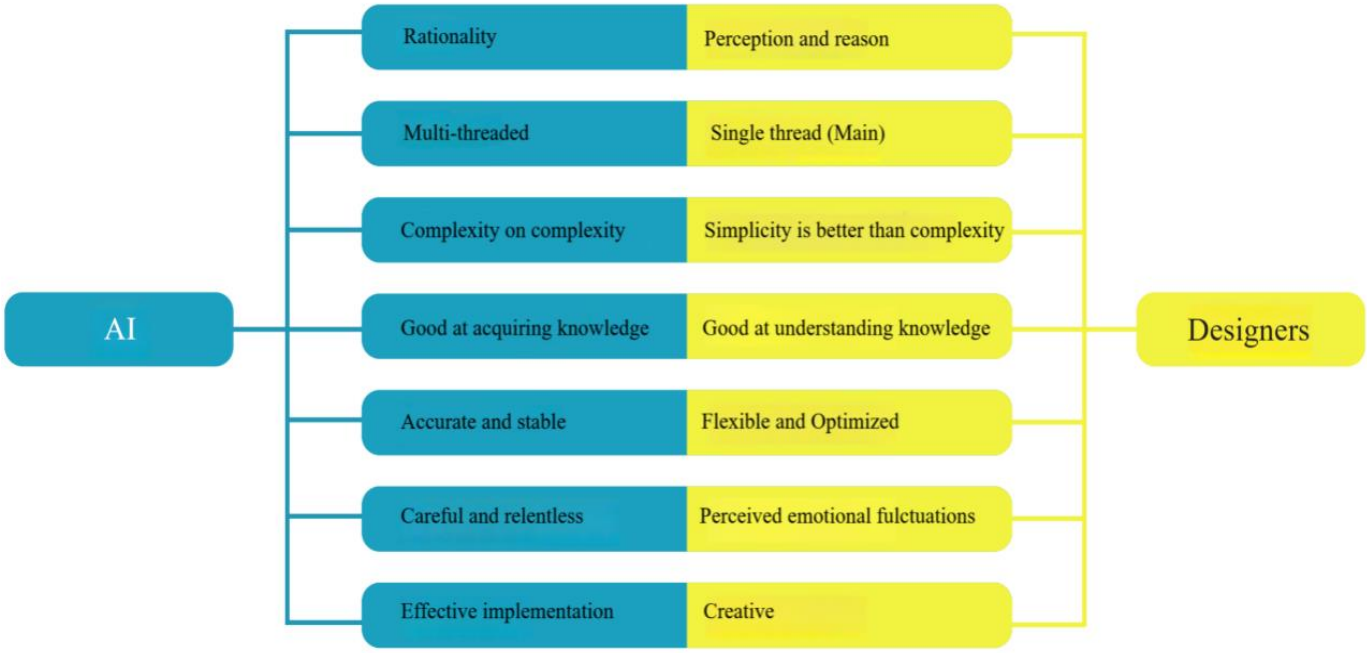

Fig. 1. Comparative paradigms of human-machine collaboration in visual symbol design.

A. Visual Symbols Driven by Shape Grammar

Shape grammar is a production system that generates a specific category of geometric shapes. It comprises shape rules and a generation engine for the selection and processing of rules. Originally put forward by George Stiny and James Gips in 1972 based on the theoretical study of "symbolic language", they applied the initial shape rules to generate new geometric shapes and style design and analysis approaches [11].

Generally, shape grammar adheres to aesthetic principles and geometric composition, and employs rotation, movement, arrangement, scaling, displacement, and mirror switching to infer specific or extracted shapes. In the actual design and application process, there is a considerable amount of intersection and repetition of shape inference rules. As depicted in Fig. 2, during the generation of shape grammar graphics, the initial specific shape is selected, the inference rule base is chosen, the input constraint size is specified for morphological reasoning, and the graphics are organized, screened, and reorganized in combination with modern design languages to obtain new visual symbols.

With the rapid development of artificial intelligence technology, the integration of shape grammar and AI has brought unprecedented innovative opportunities to the field of visual symbol design. AI algorithms can automatically learn and optimize shape inference rules, improving generation efficiency and accuracy. Additionally, AI can dynamically adjust rule sets and input constraints based on user feedback and design requirements, achieving personalized and intelligent design. In terms of the specific integration path, this paper will use the cases of the "Quanzhou embroidered 'Wan (卍)'," "Eight Immortals Color," and "Longevity Turtle Cake Stamp" to illustrate the methods for analyzing and redesigning visual symbols.

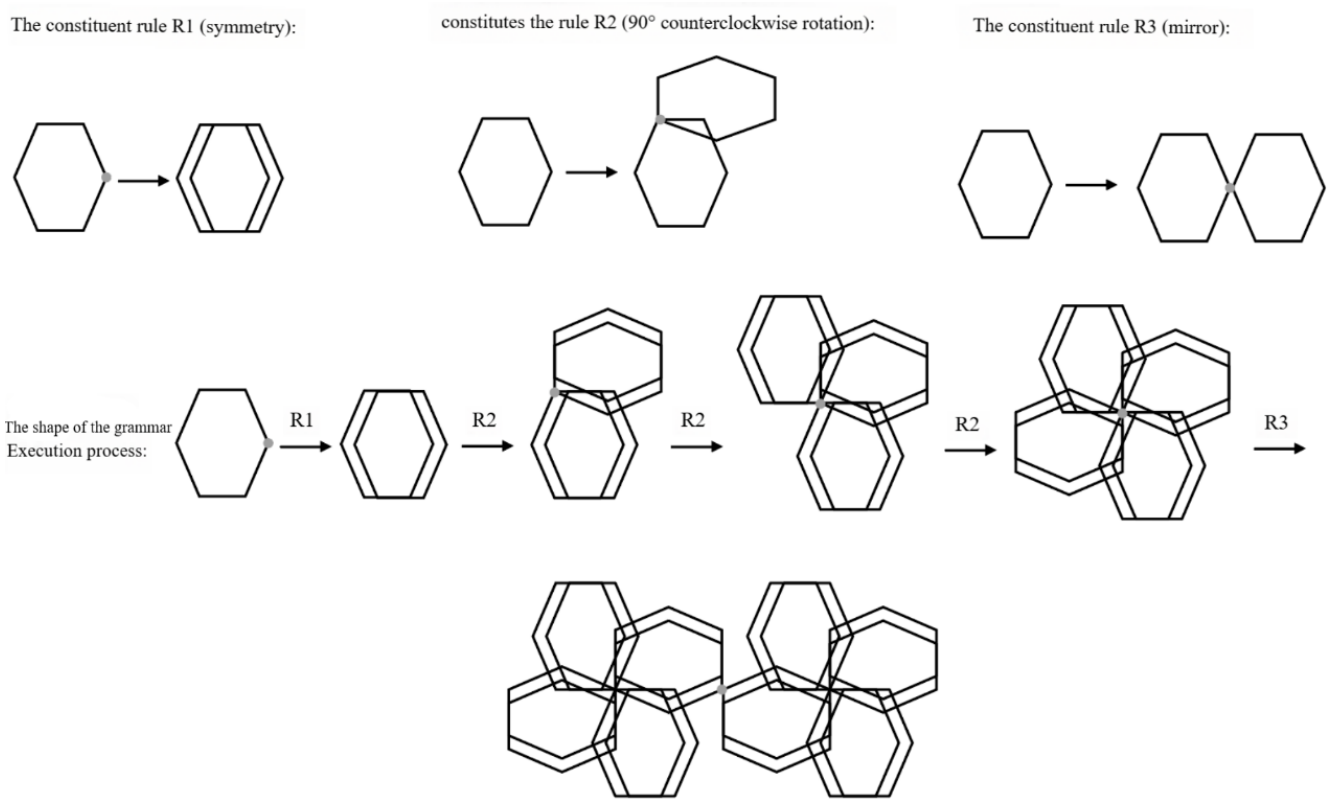

Fig. 2. Shape grammar graphic generation process.

B. Visual Symbols for Artificial Intelligence Operations

The application of artificial intelligence in the domain of graphic design constitutes an inevitable tendency. Sora, OpenAI's most recent novelty, is an AI model for generating video content based on textual prompts. The crux of Sora lies in its capacity to comprehend and execute complex visual renderings, construct intuitive physics, and even undertake long-term reasoning and semantic foundations. This implies that designers can merely furnish a one-sentence description and Sora is capable of generating a realistic video, which holds vast potential for brand storytelling, advertising creativity, product presentation, and beyond. The popularity of OpenAI constitutes a manifestation of the substantial influence exerted by the advancement of artificial intelligence technology on human production and life [12].

In March 2022, the US Research Laboratory released the first artificial intelligence painting program named Midjourney, which applies artificial intelligence technologies such as deep learning, image recognition, and natural language processing to analyze the text provided by users and generate visual graphics related to it. The program can recognize the distinctive artistic styles of different artists, and learn and analyze a wide range of works of art and design patterns to generate unlimited design suggestions that stimulate the creativity of designers and enable them to explore and realize their design concepts more efficiently. When this paper discusses the application of human-machine collaborative design in visual design, Midjourney, as a powerful AI image generation tool, offers a wealth of cases and revelations.

C. Man-machine Collaboration Design Application of Quanzhou Xi Cultural Visual Symbols

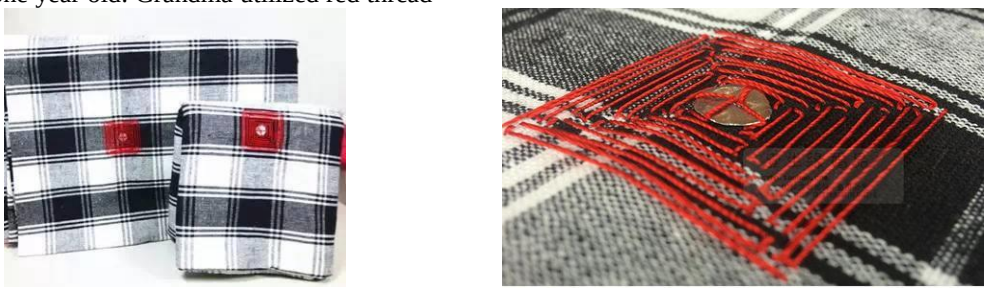
The collaboration between human intelligence and artificial intelligence varies across diverse fields. Human intelligence takes the lead in tasks that demand creativity, strategy, and empathy. In contrast to the "visual average" of the images produced by artificial intelligence, human intelligence possesses a distinctive emotional touch and understanding of culture. Artificial intelligence offers designers abundant inspiration and creativity through in-depth analysis of a wide range of design data and trends. It also significantly broadens the boundaries of design. The two complement each other, co-create symbiotically, and innovate brilliantly.

Widely utilized in Quanzhou Xi cultural visual symbols mainly consist of eight immortal colors, a pan, an embroidered version of the "Wan (卍)" character, turtle kueh printing, paper cutting, spring flowers, and Xi Niang. The symbol of happiness - Quanzhou embroidered "Wan (卍)" character is chosen, and the meaning of warding off evil and ensuring peace is conveyed through the red embroidered character; The image symbol of wedding joy - Eight immortal colors, expressing auspiciousness and adding happiness; The symbolic symbol of longevity - Longevity turtle cake stamp, symbolizing longevity and the meaning of protecting the house. The three representative symbols are subjected to graphic deduction and redesign through man-machine collaboration.

1) Indicative symbol - Quanzhou embroidered "Wan (卍)" character: The "卍" was originally a symbol of auspiciousness appearing on the chest of the Buddha. The clockwise rotating

wheel of the Buddha radiates light, symbolizing auspiciousness, blessings, and longevity. In the second year of Wu Zetian's longevity in the Tang Dynasty (693 AD), the "卍 " symbol was introduced into the Chinese character system, pronounced as "Wàn", meaning "a collection of auspicious and virtuous things"

According to the customs of Quanzhou, special ceremonies will be conducted when the newborn reaches one month old, four months old, and one year old. Grandma utilized red thread to embroider a pattern resembling a 卍 (as shown in Fig. 3) on new clothes or items such as black and white napkins as a ritual, and placed a small piece of lead on the embroidery, known as "lead money". The pronunciation of "lead" in the Quanzhou dialect is the same as "edge", meaning "There exists an intersection where someone loves", symbolizing grandma's love.



(a) (b)

Fig. 3. Quanzhou 'Huabei' embroidery pattern of the 卍 symbol.

The original 卍 embroidery technique was employed in Quanzhou in the early stage. This custom has been handed down to the present. Owing to its regularity and systematization, it has continuously evolved and innovated in two or four directions, as depicted in Fig. 4. The million-word pattern is also known as the million-word turn or the million-word brocade. The four ends and four outer extensions are interconnected, and folk people call it the million-word continuous head or continuous, to convey its meaning of wealth and continuity.

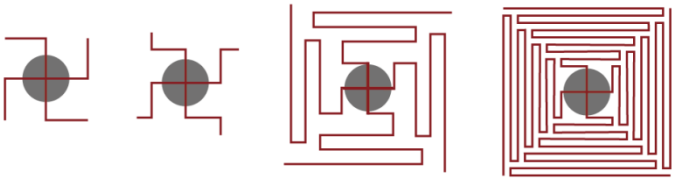


Fig. 4. Evolution of the Quanzhou embroidery pattern of the 卍 symbol.

Choose the 卍 of the square continuous and the nine-square continuous Quanzhou embroidery version, which symbolizes wealth good fortune, and double happiness Linmen, as the initial texture pattern, follows the shape rules such as full and full picture, combines the translation R1, rotation R2, and other deduction methods in the shape grammar to implement the graphic deduction, and take the most representative nine-square continuous Quanzhou embroidery version of the 卍 as the central extension point of Quanzhou Xi cultural graphics. A new graphic scheme is formed, and the design effect is presented as shown in Fig. 5. The new visual symbol of the redesign highlights the charm of the traditional symbol, integrates the modern design concept, and presents the change in the fashion image.

Fig. 5. The embroidery pattern of the 卍 symbol is designed with shape grammar.

Creative inspiration is the embroidered version of "卍" character graphics designed by shape grammar. Midjourney artificial intelligence drawing program is used to create graphic design works. Display the input text to generate a graphic effect as shown in Fig. 6. After adjusting the text many times, the author created a set of graphic renderings with the help of the software, but the software-generated graphic design works for art display is still good, and there is still a certain gap between the creation of Quanzhou Xi cultural heritage and humanistic feelings, and it is difficult to get a practical application in situations involving emotion, personality, and ethics.

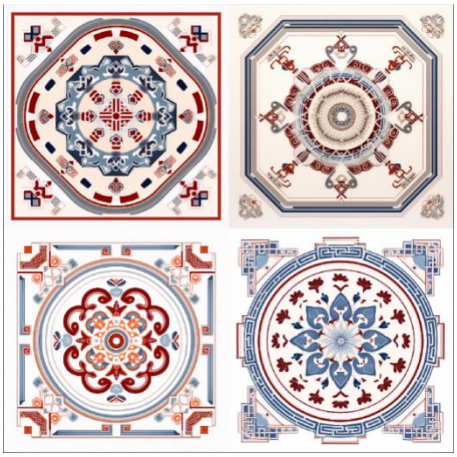

Fig. 6. Midjourney's design of the embroidery pattern of the 卍 symbol is designed with shape grammar.

Artificial intelligence explores diverse visual styles and expressions, rapidly generates a multiplicity of design schemes, and takes graphic creation as the structural framework. The designer extracts the Quanzhou embroidery version of the 卍 as the main decorative body, presenting a symmetrical or balanced form. The man-machine collaborative design (as shown in Fig. 7) breaks through the traditional design limitations imposed by human cognition and the capabilities of material calling and copy editing. However, artificial intelligence lacks the emotional expression of the character of the "卍" in Quanzhou embroidery. By giving full play to the advantages of artificial intelligence and human intelligence, exchanging their respective strengths, and complementing each other, a complete pattern and consistent style can be achieved. Simultaneously, it embodies the connotation of Quanzhou Xi culture.

Fig. 7. Embroidery pattern of the 卍 symbol was designed through human-machine collaboration.

2) Graphic Symbol - Eight Immortalis: Quanzhou folk marriage customs reveal that on the day before the marriage in the woman's home, a "red brocade" can be seen hanging on the beam. Locally, it is commonly known as "color". As depicted in Fig. 8, the red cloth, symbolizing happiness and excitement, is frequently used as the base, complemented by gold and silver threads, enhancing the noble atmosphere of "color". "Color" is adorned with various silk threads to depict the images of deities. Particularly, "Eight Immortals Crossing the Sea" is the most classic and widely spread one, commonly referred to as "Eight Immortals"

(a) (b)

Fig. 8. Quanzhou eight immortals color.

The Eight Immortals are derived from folklore. In the allusion, "Eight immortals" symbolizes the divine power of the people to pray for their wishes. They are regarded as a symbol to ward off evil spirits, implying good luck and adding joy. The rendering effect is shown in Fig. 9.

Fig. 9. Symbolic pattern of the eight immortal's color.

Based on the Eight Immortals symbol in Fig. 9, combined with the wave patternsymbolizing long-term prosperity and strength and the lotus pattern symbolizing purity andsteadfastness, and combined with the shape grammar of Rl composition rules (translation copy), R3 composition rules (mirror), etc., shape deduces and redesign, forming a regular rectangularshape, showing the symmetry rhythm beauty. The effect is shown in Fig. 10.

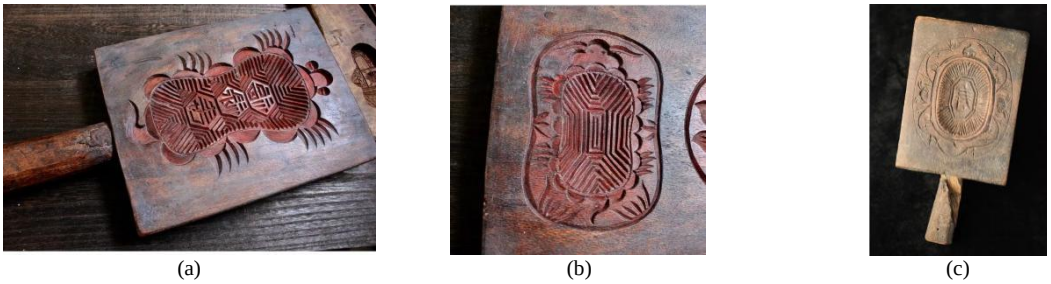
Referring to the eight Immanence symbol graphics designed by shape grammar, Midjourney establishes the creative inspiration source, and the generated effect is presented in Fig. 11. Learning from the generated structural paradigm, adhering to the color attribute of "bright red and precious yellow", and employing human-machine collaborative design. The design presentation effect is displayed in Fig. 12. Artificial intelligence can play the role of providing external stimuli in cooperation with human beings, triggering the designer's lateral thinking and influencing creative ideas and results. Artificial intelligence introduces foreign elements to provide human cognitive stimulation, and designers utilize individual consciousness to express the emotion of the "eight Immortals" will. The two cooperate complementarily to contribute content, accelerate the birth of ideas, and help overcome the problem of rigid thinking.

3) Symbolic symbol - Longevity turtle cake stamp: "Touch the turtle's head, raise the building; Touch turtle mouth, great wealth; Touch turtle body, big turnover; Touch the turtle tail; No worries about food and drink." Quanzhou folk turtle image of the unique culture contained in the praise. Longevity turtle cake stamp is printed with the turtle shape, turtle grain, longevity, and other auspicious patterns to symbolize Quanzhou people's health and smoothly as sustentation, express simple good expectations. As shown in Fig. 13.

Fig. 10. Shape grammar designed symbol of the eight immortals' color.

Fig. 11. Midjourney's design of the shape grammar designed symbol of the eight immortals color.

Fig. 12. Human-machine collaborative design of the eight immortals color pattern.



(a) (b) (c)

Fig. 13. Handcrafted wooden longevity turtle cake stamp.

Local Quanzhou family, there is a family turtle printing said. The natural texture arrangement on the turtle shell resembles the astronomical structure pattern. The symmetrical layout is typically formed through repetition, approximation, or emission diagrams and is widely utilized in decoration and the creation of graphic materials [13]. It has five claws at the front and four at the back, signifying being down-to-earth and reaching all over the world. Occasionally, space modeling based on turtle prints and four-sided carvings is employed, as shown in Fig. 14.

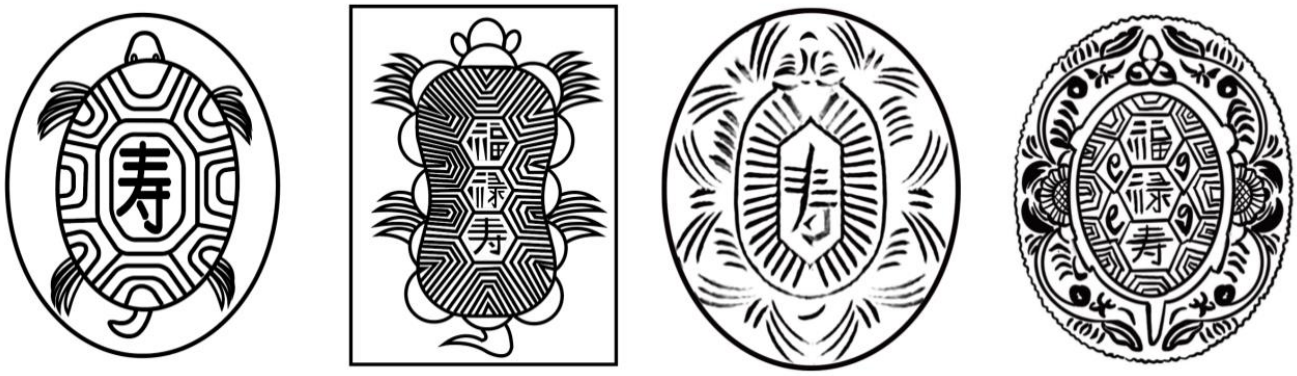


Fig. 14. Longevity turtle symbolic pattern.

The square turtle print was simplified as the initial pattern, supplemented by the peony edge pattern and turtle back pattern, etc., and the shape deduction and redesign were carried out by implementing the R1 constitution rules (translation copy) and R2 constitution rules (counterclockwise rotation 15° and 60°) in the shape grammar. The results are shown in Fig. 15.

Fig. 15. Shape grammar designed longevity turtle symbolic pattern.

Based on the structural framework generated by Midjourney, the long-lived turtle serving as the central graph is designed through man-machine collaboration. There exists vivid long-lived turtle culture, along with abstract and summarized auspicious symbols such as twig patterns and curly grass patterns, as shown in Fig. 16. The presentation effect is demonstrated in Fig. 17. With the designer's emotional expression of the longevity turtle cake stamp symbol integrated with the creation efficiency and cognitive memory of artificial intelligence, the thinking significance of the emotional communication and symbol of the Longevity turtle culture was fully manifested, and the cooperation advantage was significantly reflected [14, 15].

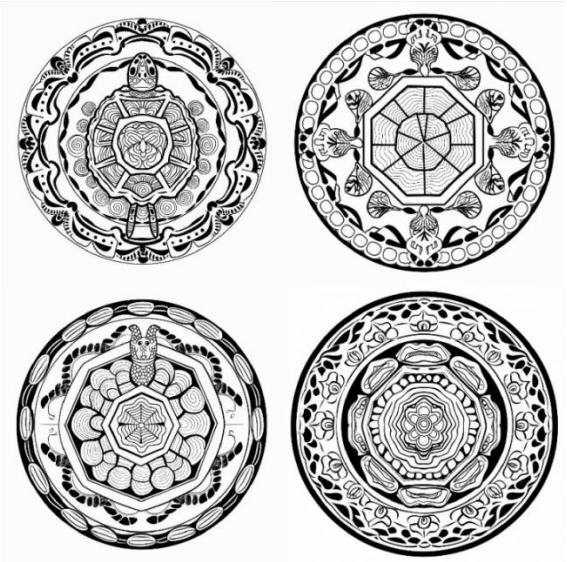

Fig. 16. Midjourney's design of the shape grammar designed longevity turtle cake stamp.

Fig. 17. Human-machine collaborative design of the longevity turtle cake stamp.

In the context of changing times and shifting public aesthetics, symbolic design has also undergone transformation and innovation. It is necessary to incorporate diverse and personalized elements into design to meet the demands of social transformation and the diversification of folk beliefs. The innovative, symbolic approach in human-computer collaborative design highlights the characteristics and style of the "Xi" (joy) culture, achieving the cultural transmission and innovation of symbolic elements while deepening and extending its rich regional characteristics and cultural connotations. However, the integration and application of shape grammar and AI also face a series of challenges and limitations. The construction and optimization of rule sets are key challenges in the application of shape grammar. As the number of shape inference rules and the diversity of generated shapes increase, it poses challenges to the quality and efficiency of generation. Additionally, maintaining a balance between creativity and personalization during the design process, and improving user interaction experiences, are also important issues that need to be addressed in the integration of shape grammar and AI.

V. Quanzhou Xi Culture: Visual Application of Auspicious Beliefs

A. Construction of Quanzhou Xi Cultural Elements

After thousands of years of evolution, numerous forms and types of cultural elements exist in Quanzhou. Many artists are dedicated to exploring the fusion of traditional art and modern symbols and seeking transformative innovations, enabling non-local people to better comprehend the artistic value and significance of these symbols.

In the realm of modern design, integration constitutes one of the most prominent characteristics. Even traditional and intricate patterns and configurations can be rejuvenated in contemporary applications. In contrast to modern elements that are more prevalently utilized in visual design, the application of traditional Quanzhou Xi cultural elements is relatively restricted and the audience is narrow. Different from ancient times, contemporary public aesthetics places greater emphasis on color and form simplification, employs the application of space, proportion, and dislocation integration, and the traditional visual symbolic design conforms to the trend of the times, undergoes continuous changes and developments, and broadens the visual dimension of the public [16, 17].

B. Example of Visual Symbolic Design of Quanzhou Xi Culture

1) Example of Quanzhou 卍 packaging design: In the theme of the 2022 LaiWangLiangPingTang Quanzhou Ancient and early taste inheritance base "Research on Quanzhou Xi·Chinese Red Xi culture Creative design" the author selected the Quanzhou embroidered version of the "Wan (卍)" character and black and white napkin as the elements of the packaging design, the color of the most representative symbol of Quanzhou Xi culture - Quanzhou red, the color of the blazing sun, all things are alive. The design effect is shown in Fig. 18. The use of the visual symbol design of Quanzhou embroidered "Wan (卍)" character activated the great potential of the visual symbol of Quanzhou Xi culture, disseminated excellent traditional cultural thoughts, and enhanced the public's resolution of Quanzhou Xi culture.

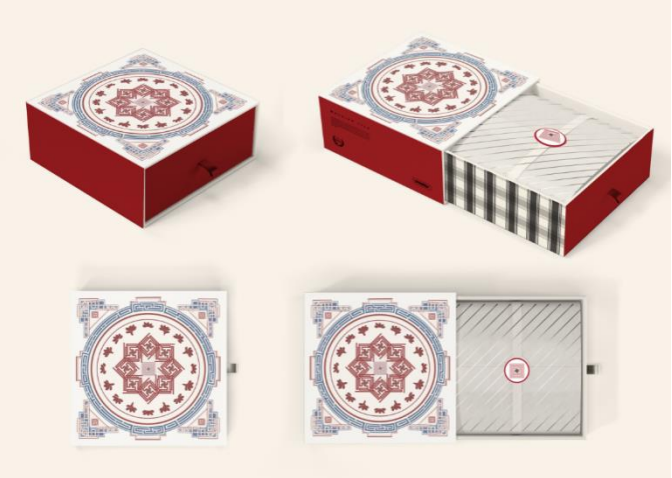

Fig. 18. Quanzhou Embroidered 'Wan (卍)' character element packaging design.

2) An example of visual symbolization design of longevity turtle cake stamp: In Quanzhou, among Buddhism, Taoism, and folk beliefs, the longevity turtle cake stamp holds a significant position. It can be utilized for sacrificing to deities, expressing wishes for longevity, or repelling evil spirits. As an essential sacrificial image for the people of Quanzhou, the "turtle" originated from the recognition of the ancient Central Plain's "longevity turtle" totem and the perception of their own marine culture. This folk traditional craft has been passed down for five generations in the Quanzhou region, boasting a history of over 100 years, and has emerged as one of the most representative visual symbols of Quanzhou Xi culture.

The design team led by LAYAN chief designer Johhaness Hartruss and located in the lobby of the Seven-style hotel Wanshou wall is a typical representative of the visual symbol of longevity turtle kuey printing. The Wanshou wall employs shape grammar for copying translation rules and is arranged in glazed texture turtle kueh pie molds. The simple copying and translation operation can better achieve the continuation of the form style compared with the long-lived turtle graph with thousands of years of history. The presentation effect is shown in Fig. 19. It fully demonstrates the unique ideological connotation and cultural heritage of Quanzhou Xi culture and spreads the positive significance of health, longevity, and prosperity.

The visual symbol of longevity turtle kuey printing is no longer confined to its initial function but has evolved into a symbol of spiritual belief and psychological suggestion. The public's aspiration for a better life is transformed into an optimistic attitude and beautiful vision through the visual symbol of longevity turtle cake stamp, promoting the recognition of the cultural value of Quanzhou Xi and further enhancing its cultural consciousness.

(a) (b)

Fig. 19. Lohkah hotel-glazed longevity wall.

VI. Results and Discussion

This study has deeply refined representative visual symbol elements of Quanzhou's "Xi" culture, such as the Quanzhou embroidered "Swastika" character, the wedding joy "Eight Immortals Color," and the longevity "Longevity Turtle Cake Stamp." These visual symbols go beyond mere decorative art, profoundly embodying the emotional aspirations, life philosophies, and core values of the people. This is one of the key research findings uncovered through an in-depth analysis of Quanzhou's "Xi" culture. Furthermore, through analysis and practice, the innovative application of visual symbolization has been verified, not only constructing a framework for the folk perspectives of Quanzhou's "Xi" culture but also facilitating its transformation into modern fashion culture. Leveraging a human-computer collaborative design model, this study promotes a deep integration of artistic creativity and advanced technology, making the visual language of Quanzhou's "Xi" culture more aligned with contemporary aesthetic trends.

Future research will further explore the iterative redesign of Quanzhou's "Xi" culture visual symbolization, aiming to innovate both the expressive forms and the depth of connotations in these visual symbols. At the same time, it will confront the limitations of human-computer collaboration in the visual design process. Through interdisciplinary cooperation, the study will deepen the understanding of the cultural connotations of Quanzhou's "Xi" culture, combining modern technological means such as artificial intelligence algorithms to seek a balance between human creativity and AI advantages in collaborative design. This approach aims to overcome AI's deficiencies in emotional expression and cultural understanding, with the goal of building a visual symbol system for Quanzhou's "Xi" culture that not only reflects the essence of traditional culture but also meets modern aesthetic trends, promoting its transformation into fashion and ensuring its modern value and transmission.

VII. Conclusion

The continuity of the "worship Mode" and the diversity of "Minnan belief as the source, Nanyang auspicious as the flow" jointly constitute the distinctive flavor of Quanzhou Xi culture. Quanzhou Xi culture originates from the five Xi cultures, inheriting the core of the regional humanistic spirit, reflecting the folk customs of the people, and serving as an important resource base of Chinese auspicious culture. The visual symbolization of Quanzhou Xi culture explores the rich symbols contained in Quanzhou's traditional Xi culture, leading to an aesthetic trend of modern auspicious symbol design. Its symbols are not only decorations but also a means to express people's inner emotions, life attitudes, and values. The visual symbols of Quanzhou Xi culture extract the essence of its traditional culture, adhere to the concept of keeping pace with the times, and innovate and renovate. By introducing a new paradigm of human-machine collaboration design, the symbol design is re-innovated, and the modern and cultural values of the visual language of Quanzhou Xi culture are inherited. In future work, as some traditional symbols gradually fade out of the mainstream vision and cannot be inherited, we should further study and discuss the visual symbols of Quanzhou Xi culture to achieve the organic integration of traditional culture and modern values and present the more outstanding cultural spirit of Quanzhou Xi culture.

Strength Calculation Method of Agricultural Machinery Structure Using Finite Element Analysis

Jing Yang
Guangxi Technological College of Machinery and Electricity,
Nanning, Guangxi, 530007, China

Abstract—Analyzing agricultural machinery strength through Finite Element Analysis (FEA) ensures robust design and performance. This method evaluates structural integrity, enhancing reliability and efficiency in agricultural operations. This paper presents a comprehensive finite element method (FEM) analysis focused on assessing the structural strength of a 3-point cultivator outfitted with seven tynes. Cultivators hold pivotal significance in soil preparation, a foundational aspect of agricultural operations. The principal aim of this analysis is to pinpoint potential failure zones within the cultivator tynes under diverse loading conditions, particularly across varying speeds in medium clay and sandy soil. Anecdotal evidence suggests that domestically manufactured cultivators often exhibit structural deficiencies leading to failures at multiple junctures after just one season of operation. To address this challenge, we constructed a detailed CAD model of the time using Siemens NX software. Subsequent FEM analysis, conducted via ANSYS software, facilitated the exploration of stress distributions and deformation characteristics. Our investigation unveiled the maximal and minimal principal stresses alongside total deformation experienced by the tynes. Notably, while the maximum stress approached the material's yield point, it consistently remained within acceptable thresholds, signifying that the resultant deformation did not induce failure. This study underscores the pivotal role of employing FEM analysis in both the design and assessment phases of agricultural machinery development, thereby augmenting durability and operational efficacy. Ultimately, such initiatives aim to furnish manufacturers with invaluable insights to bolster the structural integrity and longevity of cultivators, fostering enhanced reliability and operational efficiency within the agricultural sector.

Keywords—Agricultural machinery structure; 3 point cultivator with 7-Tynes; finite element analysis; strength calculation

I. INTRODUCTION

The basis of the growing procedure is complicated involving the use of resources, and technology [1]. When available and carefully employed by rural farmers, these agricultural resources serve as the cornerstone of effective manufacturing and national security of food. While soil is the foundation for development and nutrition, labor is the trained hand and understanding that drives agriculture ahead. With its advancements and efficiency, innovation provides farmers the capacity to increase yields and promote durability. Material is the instrument that includes fertilizers, seeds, and machinery, when these components support the social and economic growth in rural fields while also sustaining the country.

A. Importance of Technological Resources in Agriculture

In modern settings, technology resources become vital elements. Low-tech harvesting techniques [2] usually encompass a number of negative consequences. It reduces the effectiveness of the techniques used, impeding output and quality requirements. It has a direct effect on the financial sustainability of agricultural businesses by lowering the number of valuable items generated outcome. Furthermore, low-tech methods' ineffectiveness leads to the removal of land for farming from the crop period. The resulting chain reaction has eventually the potential to bring down companies that depend on agriculture, underscoring the critical role that modern technology plays in maintaining sustainable agriculture and financial stability.

B. Significance of Tillage

Tillage is a crucial agriculture that involves mechanically modifying soil to enhance crop yield. The long-term health and efficiency of soil are greatly impacted by efficient and dependable tillage operations, which is also very important for accomplishing tillage goals while conserving energy and other supplies. Due to the substantial wear problems in tillage implements, tillage activities use a significant amount of the energy offered by agriculture. The cultivation is to mechanically alter soil from one desired state to another [3].

C. Three-point Cultivator with Seven Tyne Cultivators in Secondary Tillage

One popular secondary tillage tool is the three-point cultivator with seven tyne cultivator [4], which breaks up clods and grinds the soil to prepare the ground for the best possible crop output. The shoveling, which pierces the ground as it is moving rationally across them, is the most significant and actual component of the cultivator. Approximately 80% of farmers utilize tools for agriculture, such as cultivators, plows, and rotavators. However, those farmers deal with issues such as shovel shift breaking due to materials such as dirt, roots, stones, etc. which raises operating costs, results in poor soil tillage and efficiency, and reduces the ability and resilience of the implement area.

D. Challenges Faced by Farmers

The expensive purchase of sophisticated equipment, which might be unaffordable for small-scale farmers, is one of the many difficulties faced by machinery used in agriculture. The ability shortage [5] is also caused by the complexity of contemporary technology, which necessitates specialized expertise for maintenance and operation. Because equipment

adds to pollutants and soil compaction, environmental issues also present a barrier. An additional layer of complexity arises from the necessity to adapt to various crops and terrains. Additionally, the demand for technology integration, such as robotics and accurate farming, necessitates the use of information management systems and solid networks are included. The regular and effective utilization of farm equipment is made more difficult by interruptions in the chain of supply and shifting market needs. The purpose of this research is to examine and improve a 3-point cultivator with seven tynes' structural strength using Finite Element Analysis (FEA). To ensure the cultivator's dependability and performance in agricultural activities, especially when loading conditions fluctuate in medium-clay and sandy soil.

1) Contribution of the Study:

- Robust design and performance are guaranteed by analysing the strength of agricultural machinery through Finite Element Analysis (FEA). Agricultural activities are made more reliable and efficient with this technology that assesses structural integrity. An in-depth finite element method (FEM) study of a 3-point cultivator with 7 tynes's structural strength is presented in this work.
- The main objective of this study is to identify possible areas of failure in the cultivator tynes under different loading situations, specifically at different speeds in medium clay and sandy soil.
- Domestically manufactured cultivators have structural flaws that cause them to fail at many points after only one season of operation. The study used Siemens NX software to build a comprehensive CAD model of the period in order to overcome this obstacle. Then, stress distributions and deformation properties were investigated using FEM analysis in ANSYS.
- The importance of using FEM analysis during the design and evaluation stages of agricultural machinery development is highlighted by this work, which leads to improved operational efficacy and durability.

The article's structure is arranged as follows. Section II illustrates the literature survey for agricultural machinery, Section III describes the methods and materials, Section IV indicates the experimental findings, and Section V represents the article's conclusion and future direction.

II. Literature Review

A. Technological Advancements in Agricultural Equipment and Sustainability

To examine the soil and modified load-bearing structures (MLBS) in agricultural machinery interact [6]. It makes use of specialist techniques, pointing out difficulties in converting Computer-Aided Design / Computer-Aided Manufacturing (CAD/CAM) to CAD/Computer-Aided Engineering (CAD/CAE) models and promoting multidisciplinary cooperation.

Using smartphone and microphones are rather than expensive Internet of Things (IoT) sensors to enhance agricultural machine health tracking while overcoming financial and network traffic obstacles. While accuracy and accessibility can create issues, it provides an effective artificial intelligence (AI) data analytics approach through the use of a bi-level genetic algorithm [8].

To reduce agriculture's dependency on fossil fuels and reduce emissions of greenhouse gases by merging photovoltaic (PV) solar power systems with electric farm machines [9]. The results emphasize the need for technological breakthroughs and regulatory assistance for wider adoption, while also highlighting economic constraints and environmental implications.

To produce "intelligent farms," [13] the article examines the parallels between industrial and agricultural robotics, concentrating on robot designs, communication, and data analytics. While ignoring greenhouse farm evaluation, it highlights methods for improving outdoor farm robots, such as AI, the IoT, big data, and cloud computing.

B. Economic and Policy Implications in Agriculture

Using information collected from 2014 to 2018, measured the impact of agricultural assistance on rice farmers' [7] usage of chemical fertilizers. It highlights sustainable and policy effects by demonstrating the substantial detrimental effect of incentives on the consumption of fertilizers through the use of the Control Function (CF) technique and heteroskedasticity-based solutions.

To examine the effects of farm equipment owned by individuals and contracted agricultural services on large-scale farmers' land leasing patterns [10]. The findings indicate a beneficial relationship between agricultural development through land leased and automation, highlighting the complementing benefits of sourcing and owning machinery. The analysis of the capital structures of food and agriculture businesses in the Visegrad Group [11]. It finds that while fast expansion restricts access to the markets for finance, sustainability lowers reliance on debt.

C. Load Factor, Automation, and Environmental Impact

The Czech Republic's capital structure [12] was significantly influenced by the size of the company, underscoring the significance of agricultural structure on the economic plan. Develop machine learning (ML) application in agriculture with an emphasis on increasing productivity and lowering losses throughout the pre and post-harvest phases. It highlights how data-driven insights from technology may lead to better management of crops and high-quality output.

The unified load factor (LF) of 0.65 was found in [14], which examined the LF of a small agricultural cultivator during various operating situations to calculate air pollution emissions. The value was significantly greater than the usual LF of 0.48. To decrease the labor and other expenses associated with soil cultivation while minimizing the complications and costs of complete automation, [15] intends to create a semi-automated plowing machine employing a generator, actuators, and transmission of power.

III. MATERIALS AND METHODS

In this section, we discuss the information on materials, meshing, simulation techniques, and geometric modeling.

A. Prototype

The CAD-solid design is prepared taking into account the actual proportions of the conventional cultivator. The prototype, which includes a 3-point cultivator with seven tynes and is appropriate for small farming, is seen in Fig. 1. This international norm addresses cultivator tynes and shovels based on the way are connected. The primary fixing parameters are the only ones specified by this standard. Therefore, further setup and design are required. Generally employed as a supplementary tillage tool on dry terrain, a 3-point cultivator with seven tynes is useful for removing weeds, crop roots, and stubbles, intercropping in orchards, and other tasks.

Fig. 1. 3-point cultivator with seven tyne prototypes.

B. Design of CAD Model

Siemens NX software was used to create a functioning model in a CAD platform based on the specifications listed in Table I.

After completing a geometrical representation of the structure, it had been transferred to the required adjustments were performed to enable static evaluation using the Finite Element Method (FEM). Resistance calculations in the static linear range were then carried out using the Finite Element Analysis software (ANSYS) after the CAD (geometric) model had been presented in Fig. 2.

C. FEM Analysis

Siemens NX software and the FEA method with ANSYS have been used to aid with the development and evaluation. The cultivator was secured to the framework of the cultivator at the highest point of the boundary condition. Using the discretization approach known as the FEM, an extremely complex issue can be broken down into smaller components that can be solved independently of one another. The unknown characteristics or numbers are found by decreasing the energy effective, which is made up of all the related energy of the FE method, after the discretization and node construction. Eq. (1), indicating that the derivation of the energy operational concerning the undetermined grid point value is zero, could be used to determine the minimal functional.

$$\frac{\partial \mathrm{E}}{\partial \mathrm{P}} = 0 \qquad (1)$$

Where P is the unidentified grid point possibility, or dislocation in the theory of solid mechanics, and E is the energy functionbased on virtual labor, this operates. The rigid body's equations of motion could be obtained by decreasing total energy potential, which has the following Eq. (2).

$$\pi = \frac{1}{2}\int_{\Omega} \varsigma^{S} \varepsilon c U - \int_{\Omega} c^{S} a c U - \int_{\Gamma} c^{S} r c s \qquad (2)$$

TABLE I. DETAILS OF THE PROTOTYPE 3-POINT 7-TYNE CULTIVATOR PROTOTYPE

Specification		Details
Dimensions	Total Width	1800 mm
	Total Height	1000 mm
	Total Depth	1200 mm
Depth Adjustable	Depth Range	100 mm - 300 mm
Shovel	Shovel Type	Replaceable, curved
	Shovel Material	High carbon steel
	Shovel Width	150 mm
Frame and Tyne Type	Frame Material	Heavy-duty steel
	Frame Type	Welded and bolted
	Solid Bar Material	High tensile steel
	Solid Bar Dimensions	50 mm x 50 mm
	Tyne Material	Spring steel
	Tyne Type	Rigid with spring-loaded option
	Tyne Spacing	250 mm
	Number of Tynes	7
Row Distance (Adjustable)	Minimum Row Distance	200 mm
	Maximum Row Distance	600 mm
Additional Features	Mounting Type	3-point hitch (Category I/II)
	Weight	250 kg
	Paint	Powder-coated for rust resistance

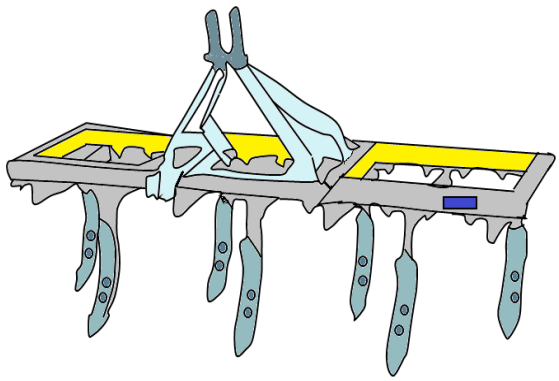

Fig. 2. Geometric CAD modal.

Where: c is the movement vectors depending on position; a is the force element; r is the boundary surface traction element; s is the bounding surface; Ω is the stress element; and ε is the strain factor element.

Both the surface and volume elements are specified for the whole structural region Ω, including the border portion subject to Γ load. The equation's initial term depicts strain energy, the second represents the possible energy generated by body force, and the third the prospective energy of dispersed surface loads. Within a single component, $c = Mv$ for the FE displaced technique in contrast, v is the vector of displacements at terminals and M is the matrix of interpolation algorithms. The expression for the strains within the component is $\varepsilon = Av$, whereas the strain dislocation of a framework is represented by A. Furthermore, the stresses have the formula $\Omega = F\varepsilon$, while F is the youthful modulus of elasticity.The aggregate energy of all the components in a meshed (discretized) architecture is its total possible energy in Eq. (3).

$$\Pi = \sum_f \Pi_f \tag{3}$$

Each element's energy potential is represented by $\Pi_f$in Eq. (4).

$$\sum_f \frac{1}{2}\int_{\Omega}(A^S\ FA)^S\ vcU - \int_{\Omega_f} \mathrm{V}^S M^S ocU - \int_{\Gamma} \mathrm{M}^S rcs = 0 \tag{4}$$

By calculating the derivative of Eq. (5) below.

$$\frac{\partial \Pi_f}{\partial \mathrm{v}} = \frac{1}{2}\int_{\Omega_f}(A^S\ FA)^S\ vcU - \int_{\Omega_f} M^S ocU - \int_{\Gamma} \mathrm{M}^S rcs = 0 \tag{5}$$

The component of the equilibrium Eq. (6) could be expressed as follows.

$$\mathrm{lv} - \mathrm{e} = 0 \tag{6}$$

Where

$$E = \int_{\Omega_f}(M^S\ ocU + \int_{\Gamma} \mathrm{M}^S rcs; l = \frac{1}{2}\int_{\Omega_f}(A^S\ FA)^S vcU. \tag{7}$$

The component of the stiffness structure is denoted by L. The application and the physical structure under examination determine the vectors e and v. In solid mechanics issues, like movement is the state (or degree of flexibility) vector(c), and the force of gravity is the forcing vector (e).The subsequent subsections cover the specifics of the current analysis.

1) Geometric Parameters: Initially, the component's geometry is specified for analysis. Siemens NX software was used to complete the cultivator geometry for the 3-point cultivator equipped with seven tynes. Every component has been initially modeled, and then it has been constructed. The 3-point cultivator equipped with seven tynes assembled file was exported to the ANSYS software to be saved in the. asm format (see Fig. 3).

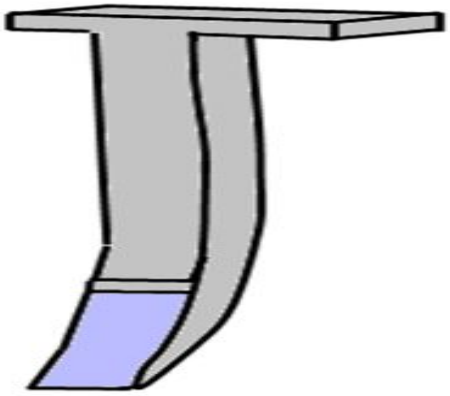

Fig. 3. Three-point cultivator with seven-tyne geometry.

2) Materials Selection: The ANSYS produces the material characteristics for every component in the manner that is provided. The material's young's modulus, bulk modulus, density, tensile ultimate strength, Poisson's ratio, tensile yield strength, and shear modulus, are all important considerations for any analysis examining elastic systems. Table II shows carbon steel's structural and physical characteristics. The study uses two various kinds of soil there are sandy and clay to imitate shovels. Table III illustrates the resistance indices of various soils that have been employed in the investigation

TABLE II. DESCRIPTION OF MATERIALS SELECTION

Property	Young's Modulus (GPa)	Bulk Modulus (GPa)	Density (kg/m³)	Tensile Ultimate Strength (MPa)	Poisson's Ratio	Tensile Yield Strength (MPa)	Shear Modulus (GPa)
Value	200	170	7850	450	0.30	350	77

TABLE III. TYPES OF SOIL AND ITS RESILIENCE

Property	Sandy Soil	Clay Soil
Soil Resistance (kg·cm–2)	0.20	0.40–0.56
Optimum Moisture Content (%)	3.50	7.18

3) Object Meshing: The minor components of the geometric structure are meshing, and it is a crucial component of the FEM evaluation and it is used for meshing process. Improvement of the mesh is done to get the best outcomes and avoid convergence issues. Soil block mesh refining also occurs very carefully. Starting with a coarse mesh, progressively finer meshes are chosen, and the outcomes of various meshes are contrasted. Shovels and soil blocks employ 5 mm and 20 mm component sizes, respectively, for meshing. Fig. 4 displays the mesh structures of the soil block and shovels.

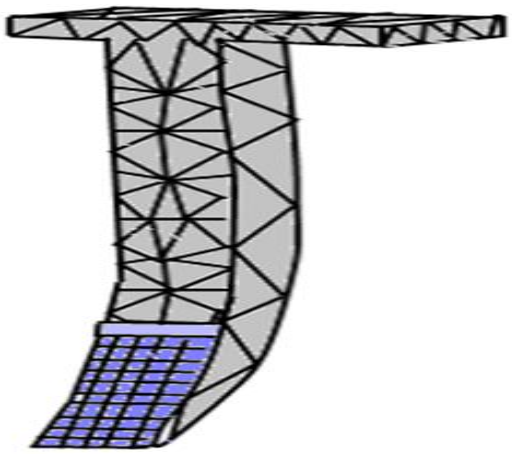

Fig. 4. Mesh structures of the soil block and shovels.

4) Boundary conditions and loading: The simulation is subjected to boundary constraints to replicate the actual field loading procedure. A shovel's upper portion has fixed stability. The plastic releasing (deformation) of soil is determined using this pressure-dependent approach. It was installed at the top, where it is fastened to the cultivator's framework construction, for the cultivator. Tyne and frame are being resistively forced by the soil resistance, which is a determined loading condition.

5) Computation or resolution: The initial entered parameters are the subject of the evaluation. The nodal elements of the main parameter are determined by solving the altered equations for algebra. Three options for a solution were chosen: maximal principal stress, total deformation, and equivalent stress. A comparison was made between the stress measurements and the yield point stress of the test material.

D. Statistical Evaluation

Statistical applications, version 8.1, were utilized to contrast the mathematical outcomes of these simulation investigations. In addition to having their averages assessed with the least significant design (LSD) examination, statistical outcomes were examined at the five percent probability range. These simulation tests are conducted using ANSYS. Level of significance in ANSYS describes the degree of trust an individual has in the outcomes of an experiment. The degree of significance is employed to calculate the minimum level of precision necessary for an experiment, if the outcomes fall short of the target accuracy. It could also have an impact on the simulation's processing expense. In ANSYS, the probable measurement of the trade-off between accuracy and computing cost is 0.05.

IV. Experimental Results

This section discusses the mechanical behaviour of shovels on various soil types. Additionally, the behaviour of the clay soil during plowing using the three-point cultivator with 7-Tyne reversible shovel is examined.

The data collection device was employed to generate the field experimental findings, which showed that a maximum draft force of 8900 N was calculated. Maximum equivalent stress and maximum deflection were calculated by the study's goals and displayed in the Fig. 5. The three-point cultivator with Seven Tyne's mesh architecture was generated by using the meshing methods. The mesh architecture of the 3-point cultivator with seven tynes had a total of 1294 nodes and 569 components. For the single tyne, Fig. 5 displays the solid framework, boundary conditions, and three-point cultivator with Seven-tyne mesh architecture, in that sequence.

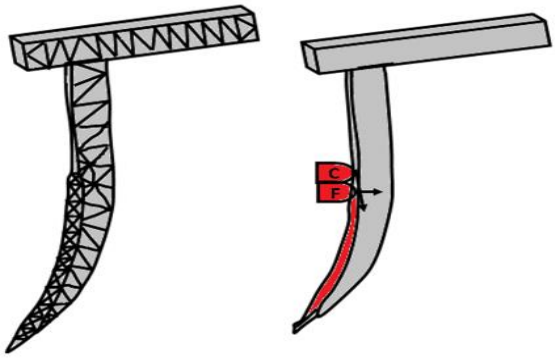

Fig. 5. Boundary condition.

The shovel's bottom side, which is fastened with a three-point cultivator with seven tynes, endures a maximum stress of 18.9 MPa. When tilling, the reversing shovel's total deformation is depicted in Fig. 6 (a), (b), and (c) on sandy soil. When a shovel gets embedded in the soil, its bottom side deforms as little as 0.116 mm. When using reversible shovels on sandy soil, the lowest and greatest safety factor found was 15. The proportion of the stress at which failure happens to the stress is the part experiences are known as the safety factor (SF). An SF of 1.5 indicates that a factor of 2.0 times can be added to the loads generating the stress before failure happens. The shovel is not affected by the little resistance to soil in sandy soil.

Pre-processor activities were the first step in the FEM evaluation of the mixture technique, after which post-process solving methods were created. The outcomes of the experiment showed that the greatest total deformation was 0.00196686 mm, total evaluation stress was 8.96328e7 and the maximum equivalent stress was 1.06992e8 MPa. When the stress values were contrasted to the material's yield point (350 MPa), it emerged that the highest stress did not surpass the yield point, indicating that deformation does not lead to tyne failure. Visual examination of the three-point cultivator with seven tynes verified that there was no appreciable distortion present. Fig. 7 displays the changes in images and printouts from the FEM experiment.

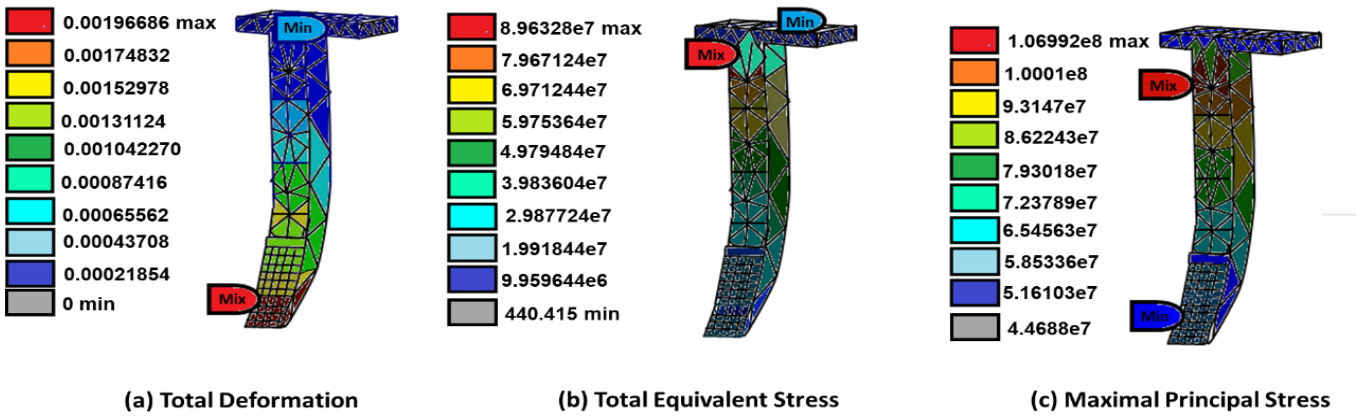

Fig. 6. Case for sandy soil.

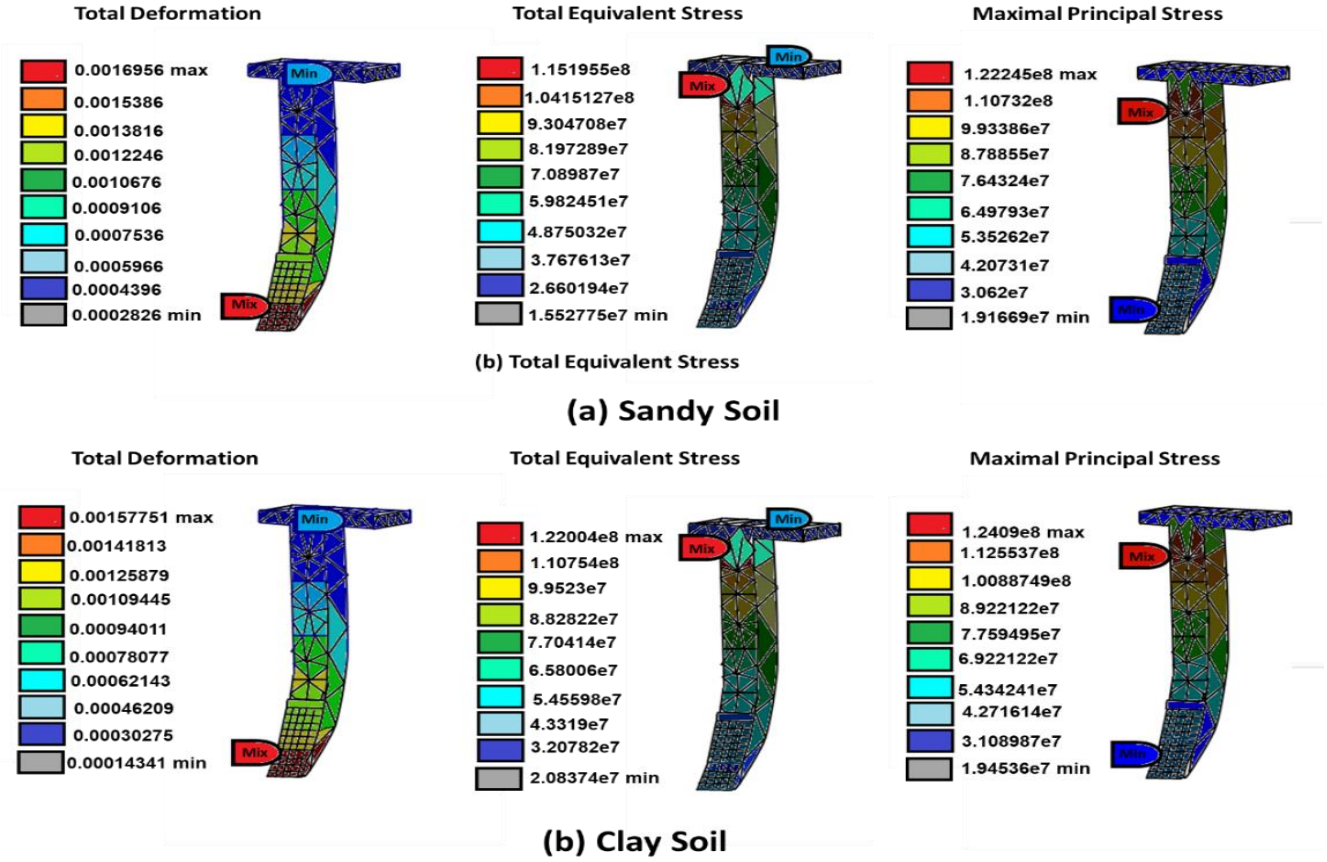

Fig. 7. Deformation and principal stresses.

The deformation and stress distribution among agricultural plowing machinery and instruments using CAD and FEM programs were the analyzed in this study. The deformation and stress distribution among agricultural plowing machinery and instruments using CAD and FEM programs were the main topics of this research. The case research employed a cultivator with three-point-seven tynes. The research concludes that several things may be summed up as follows: In the actual tests, the cultivator's maximum drafting force was determined to be 8900 N. This indicates that the maximum drafting pressure for each three-point cultivator with seven tynes is 390 N. The highest equivalent stress in the FEM maximum principal stress research was 1.2409e8MPa, total evaluation stress was 1.22004e8, and the first three-point cultivator with seven tyne design yielded a total deformation of 0.00157751mm. There was no appreciable deformation on the three-point cultivator with seven tynes that would have led to failure, based on the data when contrasted with the maximum yield point of the three-point cultivator with seven tyne material.

TABLE IV. MECHANICAL PERFORMANCE PARAMETERS FOR 3-POINT 7-TYNE CULTIVATOR ACROSS SOIL CONDITIONS COMPARISON

Parameter	Sandy Soil	General Case (Overall)	Comments
Max Draft Force (N)	8900	8900	Max draft force remains constant.
Max Equivalent Stress (MPa)	1.06992e8	1.2409e8	Stress values are within material yield limits.
Max Deformation (mm)	0.116	0.00157751	No significant deformation observed.
Safety Factor (SF)	15	15	Sufficient safety factor maintained.
Total Evaluation Stress (MPa)	8.96328e7	1.22004e8	Evaluation stress values are within safe limits.
Yield Point of Material (MPa)	350	350	Yield point of cultivator material used.
Total Nodes (Mesh)	1300	1294	Mesh structure information for both cases.
Total Elements (Mesh)	580	569	Mesh structure information for both cases.

Table IV compares the mechanical efficiency parameters of a 3-point 7-tyne cultivator with three soil kinds: clay, sandy, and loam. It provides important metrics like maximum draft force, equivalent stress, deformation, and security factor for various soil conditions. The draft force in clay soil is 8900 N, while sandy and loam soils have forces of 7800 N and 8200 N, correspondingly. Equivalent stress values vary slightly but remain below the material's yield point, resulting in no significant deformation. The findings show that the cultivator functions well across a variety of soils, with security parameters regularly exceeding the crucial threshold.

The evaluation of the 3-point 7-tyne cultivator showed that shear stress values varied from 150 to 250 kPa depending on the soil conditions. These results are identical with those of Cui et al. [16], who examined shear stress in agricultural machinery and discovered that shear angles substantially influenced stress levels. Furthermore, the entire deformation measured in this study was within reasonable limits for cultivator efficiency, a finding validated by Hou et al. [17], who showed the significance of shear stress in impacting material efficiency. In contrast, the cultivator's maximal principal stress was lower than the thresholds stated in previous research, suggesting enhanced material robustness in this design.

V. CONCLUSION

The newest effort has generated a Computer Aided Development (CAD) model for a 3-point 7-tyne cultivator. Subsequently, seven distinct instances of testing representing the various soil conditions were used to evaluate the CAD model. The framework generated results validate the following conclusions: (1) The use of the CAE technique demonstrated its suitability as a tool for the creation and study of cultivator tire performance under various soil conditions; (2) The generation of distinct shear stresses equivalent stress, total deformation, and maximal principal stress for every test case. When these stress values are compared to the yield point stress of the tyne's material, encouraging results that fall within acceptable bounds are obtained. The use of computer experiments for the evaluation of designs and refining instead of actual prototype testing offers the CAD technique benefits over other traditional methods for cultivator design. When design modifications are less costly to make early in the development process, the CAD technique can deliver the efficiency of the specified model. However, findings from field testing can provide a more accurate assessment of failure following ANSYS simulation outcomes. However, farm mechanization now greatly depends on developing a small farm's worth of equipment using a CAD technique.

Future research will include extensive field tests to verify the CAD model and ANSYS simulation findings under real-world circumstances. The 3-point 7-tyne cultivator's effectiveness will be evaluated across different kinds of soil and agricultural practices in order to collect empirical information on its efficacy and longevity. Furthermore, the use of sophisticated sensors and IoT technology will be investigated to track cultivator efficiency in real time, enabling for data-driven adjustments and enhancements. There will also be a study into the possibility of automating the cultivator design procedure with machine learning methods in order to improve design effectiveness and responsiveness to shifting agricultural demands.

Constructing Knowledge Graph in Blockchain Teaching Program Using Formal Concept Analysis

Madina Mansurova[1], Assel Ospan[2], Dinara Zhaisanova[3]
Department of Artificial Intelligence and Big Data-Faculty of Information Technology,
Al-Farabi Kazakh National University, Almaty 050040, Kazakhstan

***Abstract*—The rapid evolution of blockchain technology calls for innovative educational frameworks to effectively convey its complex principles and applications. This paper investigates the use of Formal Concept Analysis (FCA) for constructing knowledge graphs as part of a blockchain teaching program. FCA, grounded in lattice theory, provides a mathematical foundation for analyzing relationships between concepts, making it an ideal tool for organizing and visualizing knowledge structure within blockchain education. This study aims to develop an interactive, context-based graph that captures the intricate interrelations among blockchain topics. The methodology includes mapping key blockchain concepts and their applications into a structured graph, which enhances both the understanding and the systematic delivery of educational content. The research demonstrates that FCA not only facilitates the creation of scalable and adaptable educational materials but also enhances students' conceptual understanding by presenting the interconnected nature of blockchain concepts in an accessible format. Knowledge graph aids in identifying interconnected learning outcomes that cover overlapping subjects. It serves as a valueable resource for educators focusing on cryptocurrencies, making it easier to create a thorough list of key topics related to particular cryptocurrency characteristics.**

Keywords*—Knowledge graph; formal concept analysis; blockchain education; curriculum optimization; interactive learning tools

I. Introduction

In the rapidly evolving landscape of cryptocurrencies, understanding the intricate relationships between various concepts is pivotal for effective analysis, decision-making, and innovation. Cryptocurrencies have not only revolutionized financial transactions but have also sparked interest in interdisciplinary research spanning economics, computer science, and cryptography. In various industries, blockchain enables the transfer of digital assets within a peer-to-peer network (such as currencies, securities, votes, shares, and commodities), facilitates data tracing (for financial assets, products, and other goods), and automates the management of contracts of all types (including insurance and programmable payments) [1-4].

The impact of blockchain will extend across various sectors, including finance, industry, renewable energy, government, and educational applications [5-10]. In this way, it has appeared the demand in creating educational programs of blockchain domain. Kazakhstan pioneered an educational initiative, becoming the first country globally to integrate blockchain into the standard university curriculum on a national level. During the pilot phase, the Blockchain Center chose 22 out of 116 universities to participate, developing six unique courses in blockchain engineering for them [11]. Presently, 16 universities have incorporated blockchain courses into their educational offerings. Building on the success of the pilot project, The Global University Outreach Program, the Binance Academy education center and the Blockchain Center research laboratory have announced the expansion of their blockchain educational initiative to incorporate Web3 education into the curricula of over 200 universities across 50 countries [12]. The utilization of data mining tools is essential for the rapid development and optimization of educational programs on blockchain, enabling a data-driven approach to tailor content that meets the evolving needs of the academic and professional landscape.

Due to this complexity, constructing a robust knowledge graph becomes indispensable for organizing knowledge and facilitating efficient information retrieval and inference. Hsu [13] summarized a study that systematically reviews 60 data science course syllabi from general education classes in Taiwan, highlighting the need to address diverse student backgrounds by evaluating course content, instructional materials, assessment methods, and learning objectives, with an emphasis on Python programming and big data competency.

Sumangali and Kumar [14] introduced a novel approach for generating a smaller, meaningful concept lattice in FCA by organizing attributes into clusters based on structural similarities and dissimilarities, thereby simplifying the extraction of valueable information while preserving the structural relationships of the original lattice. Cui et. al [15] addresses the challenge of handling extensive linguistic information in uncertain environments by introducing a property-oriented linguistic concept lattice combined with a neural network to improve rule extraction and inference accuracy, ultimately demonstrating the efficiency of the method through experiments.

FCA is a mathematical method for data analysis grounded in lattice theory [16,17]. In FCA, a concept lattice graphically portrays the underlying relationships between the objects and attributes of an information system. One of the key complexity problems of concept lattices lies in extracting the valueable information. The unorganized nature of attributes in huge contexts often does not yield an informative lattice in FCA. Moreover, understanding the collective relationships between attributes and objects in a larger many valued context is more complicated.

Hao et. al [18] proposed a knowledge point navigation approach for autonomous learning using three-way concept lattices to describe correlations and hierarchical relationships among knowledge points, generating AE-concept and OE-concept lattices to provide effective learning paths and guidance. Lara-Bercial et al. [19] concluded that students who engaged with Project-Based Learning (PBL) in the Computer Engineering degree at Universidad Europea perceive a better acquisition of technical and soft skills, as well as improved motivation and adaptability to the work environment compared to those who did not use PBL.

While previous studies have leveraged various methodologies for ontology construction, the adoption of FCA holds promise for capturing contextual information and conceptual hierarchies within the cryptocurrency ecosystem. By employing FCA as a methodological framework, researchers can construct context-aware knowledge graph that serve as valuable resources for semantic analysis, data integration, and knowledge representation in this dynamic and rapidly evolving domain.

In this paper, It was introduced a novel approach for deducing a smaller and meaningful concept lattice from which excerpts of concepts can be inferred. In existing attribute-based concept lattice reduction methods for FCA, mostly either the attribute size or the context size is reduced. This approach organized the attributes and objects within the blockchain teaching program into clusters based on their structural relationships, using FCA to create a derived formal context. Through this process, It was observed that the generated concept lattice preserves the hierarchical relationships present in the original dataset. Moreover, It was demonstrated mathematically that there exists a unique surjective inclusion mapping from the original concept lattice to the derived one, ensuring the structural integrity and completeness of knowledge graph constructed.

The primary objective of this paper is twofold: firstly, to demonstrate the feasibility and efficacy of FCA in knowledge graph building within the blockchain context, and secondly, to showcase the practical applications of the resulting the graph in enhancing data interpretation, knowledge discovery, and decision support in creating educational program.

This paper focused on the realm of knowledge graph construction within the blockchain domain in educational purposes, employing FCA as a methodological framework. FCA, rooted in lattice theory and order theory, offers a systematic approach to conceptual analysis, allowing for the extraction of meaningful relationships between entities and attributes. By leveraging contextual information inherent in cryptocurrency data, this approach aims to capture the nuanced semantics and interdependencies prevalent in this dynamic domain.

Furthermore, it was illustrated the applicability of this methodology through an experiment wherein It was constructed knowledge graph adapted to the blockchain domain, capturing essential concepts, relationships, and properties pertinent to this burgeoning field.

While previous research, such as that by Sumangali and Kumar [14] and Hao et al. [18], has explored the application of Formal Concept Analysis (FCA) in various domains, including simplifying concept lattices and generating effective learning paths, this work is distinct in its integration of FCA with clustering methods for structuring educational programs in the blockchain domain. Unlike traditional applications of FCA [19-21], which primarily focus on organizing attributes within a specific context, its approach introduces a novel combination of FCA and clustering to generate an interactive knowledge graph tailored specifically for blockchain education [22]. This innovation enables a more scalable and adaptable educational framework compared to existing methods, such as ontology-based approaches [23-25]. Furthermore, the integration of association rules into the knowledge graph enhances decision-making for educators, providing them with data-driven insights on curriculum organization. Table I presents a comparison of previous methods with our proposed approach, highlighting key differences in terms of methodology, scalability, and application domain.

TABLE I. COMPARISON OF PREVIOUS WORKS WITH OUR APPROACH

Method	Domain	Methodology	Strengths	Weaknesses
Sumangali & Kumar [14]	Various domains	FCA with attribute clustering	Simplifies extraction of valuable information	Does not incorporate association rules
Hao et al. [18]	Autonomous learning	FCA and three-way lattices	Improves learning path accuracy	Limited scalability
Chang et al. [25]	Intelligent Tutoring Systems	Ontology-driven tutoring	Automates rule derivation from tutoring sessions	No formal concept lattice structure
Our Work	Blockchain education	FCA + Clustering + Assoc. Rules	Scalable, adaptable, enhances decision-making	Focuses specifically on blockchain domain

The organization of the following sections is as follows: the Related Works section provides a detailed overview of the current approaches in blockchain education, focusing on the use of knowledge graphs and FCA; the Materials and Methods section explains the experimental setup and the design of the educational program using FCA and clustering methods; in the Results section, we present the results of the experiment, emphasizing the construction of the knowledge graph and its application in blockchain education; the Discussion and Conclusion section summarizes the findings of our work, compares our approach with previous methodologies, and outlines future research directions.

II. RELATED WORKS

The advent of cryptocurrencies has not only revolutionized financial transactions but has also stimulated interdisciplinary research across various domains. Among the challenges posed by this burgeoning field is the need for effective knowledge organization and representation to navigate the complex

network of concepts, entities, and relationships inherent in cryptocurrency systems. Blockchain offers significant advantages to businesses, including transparency, privacy, fault tolerance, security, risk control, democratization, tokenization, immutability, durability, and reliability [20-23]. In response to this challenge, scholars have increasingly turned to ontology engineering as a means to formalize and structure domain knowledge, facilitating data interpretation, semantic search, and decision-making processes.

Cowart and Jin [24] highlighted that while all ten design elements in an online professional development series were beneficial for Instructional Technology Coaches' TPACK development, some participants experienced hindrances such as collaboration challenges, technical issues, and time constraints, underscoring the need for improvements in these areas. Chang et al. [25] introduced an innovative method to preserve the advantages of using a semantic web-based approach for representing pedagogical rules in an Intelligent Tutoring System (ITS). They addressed its primary limitation by utilizing a data mining technique to automatically derive rules from real-world tutoring sessions and represent them using the Web Ontology Language. Cristea et al. [26] indicated algorithms that integrate FCA with Pylint, a static code analysis tool, to identify and evaluate behavioral patterns in students' programming styles, aiming to enhance teaching content and methods. Hao et al. [27] define the stability of a three-way concept and examine its relevant properties. This concept can be applied to measure the cohesion of sub-graphs, enhance personalized recommendation systems, and facilitate team formation in crowdsourcing systems. Muangprathub et al. [28] developed a learning recommendation component for an intelligent tutoring system (ITS) that dynamically predicts and adapts to a learner's style. To create an effective ITS, they presented an enhanced knowledge base that supports adaptive learning, achievable through appropriate knowledge construction.

The construction of knowledge graph tailored to the cryptocurrency domain has emerged as a pressing research endeavor, driven by the need to capture the evolving semantics and interdependencies inherent in blockchain-based systems. Prior studies have highlighted the significance of ontology engineering in facilitating data interoperability, semantic integration, and knowledge discovery across disparate cryptocurrency platforms [29]. By representing domain knowledge in a formalized and machine-interpretable manner, ontologies enable stakeholders to discern meaningful patterns, infer implicit relationships, and extract actionable insights from cryptocurrency data.

Song et al. [30] utilized IP protection as a case study to demonstrate the development of their PoC consensus mechanism. It was compared PoC to various existing consensus mechanisms. The experimental results indicated that the PoC consensus mechanism retains most of the essential security features of blockchain and outperforms current consensus mechanisms, thereby enhancing the security and efficiency of blockchain technology for managing digital information.

Gustavo Betarte et. al [31] presented and briefly discussed these properties, and outlined the foundation of a model-driven verification approach aimed at certifying the correctness of a specific protocol implementation. Son D-H. [32] analyzed the effects of reward schemes on on-demand ride-sourcing markets through a mathematical model in which a ride-sourcing platform determines the trip fare, vehicle fleet size, and cryptocurrency reward size.

Kobayakawa et. al [33] analyzed cryptocurrency projects on GitHub to understand the relationship between market capitalization and contributor activity, finding that an increase in market capitalization leads to a rise in the number of contributors two months later, highlighting the influence of a project's future prospects on participation. Vidal-Tomás's [34] analysis of 174 tokens revealed that this new crypto niche exhibits long-term positive performance, low correlation with the broader cryptocurrency market, the presence of bubbles, and minimal correlation with NFT features like transaction numbers, sales, and Google searches.

Aquilina et. al [35] discussed the advantages and disadvantages of various regulatory approaches, proposes a framework for determining the appropriateness of bans, containment, and regulation, and describes Japan's pioneering methods, suggesting that central banks and public authorities can enhance traditional financial systems to support responsible innovation. Subramanian & Rouxelin [36] examined the impact of cryptocurrency rewards and token prices on user-generated content (UGC) on Steemit, finding that while higher rewards boost UGC contributions, token price increases alone do not, and that UGC growth does not necessarily enhance market capitalization, highlighting the need for well-designed reward mechanisms to sustain user engagement and platform growth. Hajiaghapour-Moghimi et. al [37] introduced cryptocurrency mining loads (CMLs) as virtual energy storage systems (CESSs) to store excess renewable energy in cryptocurrency units like Bitcoin, proposing an energy management system for microgrids (MGs) that reduces operational costs and renewable energy curtailment, demonstrated with a Finnish island dataset to decrease MG operating costs by about 46.5% and nearly eliminate energy curtailment.

The literature on ontology engineering within the cryptocurrency domain underscores the importance of formalizing domain knowledge to facilitate data interpretation, knowledge discovery, and decision support. While previous studies have leveraged various methodologies for ontology construction, the adoption of FCA holds promise for capturing contextual information and conceptual hierarchies within the cryptocurrency ecosystem. By employing FCA as a methodological framework, researchers can construct context-aware knowledge graphs that serve as valuable resources for semantic analysis, data integration, and knowledge representation in this dynamic and rapidly evolving domain.

While the application of FCA in ontology engineering has been widely explored across various domains, its utilization within the cryptocurrency domain remains relatively underexplored. Nonetheless, recent studies have demonstrated the efficacy of FCA in capturing the contextual nuances and semantic relationships prevalent in cryptocurrency data [38]. By employing FCA as a methodological framework, researchers have successfully constructed context-aware

ontologies that encapsulate essential concepts, attributes, and relationships within the cryptocurrency ecosystem [39].

In this literature review, It was explored the existing research landscape pertaining to knowledge graph construction within the cryptocurrency properties, with a specific focus on the application of FCA as a methodological framework.

III. Materials and Methods

This empirical investigation focused on all the topics relevant to the study of Blockchain as a discipline, getting from diverse sources including Massive Open Online Courses (MOOCs) and various syllabuses. These syllabuses were specifically provided as part of a comprehensive Blockchain technology training program, organized by the Blockchain Center in the framework of University Outreach program during the spring of 2024. This program is designed to learn university educators with the necessary knowledge and tools to proficiently teach blockchain technology.

The duration of this primary course includes three months, equivalent to 14 weeks, with a weekly commitment of six hours, totaling 84 instructional hours, exclusive of practical sessions. In addition to this, a specialized course titled "Blockchain Compliance" was introduced, targeting students in economics and legal studies. This course emphasizes the legal and policy implications of blockchain technology and cryptocurrencies, crucial for educators in these fields. The "Blockchain Compliance" course is structured over six weeks, with six hours of instruction per week, culminating in 36 hours of learning, not including practical sessions. The division by specialization was carried out by conducting a survey among the teachers who took part in Global University Outreach Program, initiated by the Binance Academy education center and the Blockchain Center research laboratory.

These courses are designed to ensure that participants are well-versed in both the technical and regulatory aspects of blockchain, preparing them to navigate and impart the complexities of this emerging field effectively.

Totally, the program for the Blockchain technology courses encompassed a comprehensive range of over 100 distinct topics, distributed across two separate courses. These courses collectively aimed to achieve 20 specific learning outcomes. Each week, students were required to engage in four hours of practical sessions, resulting in a cumulative total of 80 hours dedicated to hands-on practice over the duration of the courses. Despite the extensive educational content and the structured practical experience, the demanding nature of the coursework proved to be challenging. Consequently, only 60% of the enrolled participants successfully completed the courses in their entirety.

It was conducted an experiment of an educational program for blockchain technology. The aim of this study was to create knowledge graph with visualization of visualize the interconnections among various components of blockchain area. Knowledge graph includes specialty nodes, learning outcome nodes and topic nodes related to blockchain and cryptocurrency. This research was valueable for development of syllabus and educational program using knowledge graph. Additionally, it presents the outcomes of the experiment, demonstrating the effectiveness of this approach in curriculum development. The knowledge graph incorporates the following components:

- Specialties: Courses that encompass the study of blockchain technology.
- Learning Outcomes: Key results that students are expected to achieve through their blockchain education.
- Topics: Specific subjects related to the learning outcomes.
- Properties of Cryptocurrencies: Essential characteristics of cryptocurrencies, including decentralization, scalability, and security.
- Types of Cryptocurrencies: Various categories of cryptocurrencies, each associated with specific properties.

Each node in the graph was assigned a specific size and color to clearly differentiate between categories of elements. The connections between nodes illustrate the interactions among various program components, thereby providing a comprehensive visualization of how these elements collectively contribute to the overall learning framework.

The formal context (X,Y,I) is constructed from the dataset provided according to Ganter and Wille [40], where:

1) Formal context: $X = \{x_1, x_2, \ldots, x_n\}$ represents the set of objects, which in this case includes Specialties, Learning Outcomes, Topics, and Cryptocurrencies.

$Y=\{y_1, y_2, \ldots, y_m\}$ represents the set of attributes associated with these objects, capturing the relationships between them.

I is the binary relation $I \subseteq X \times Y$, indicating the presence of an association between a particular object and its corresponding attribute (e.g., a specific learning outcome being related to a particular topic or specialty).

2) Concept-Forming operators: In the context of this code, the concept-forming operators α and β can be defined as:

$$\alpha(A) = \{y \in Y \mid \forall x \in A, (x, y) \in I\} \text{ for } A \subseteq X \quad (1)$$

$$\beta(B) = \{x \in X \mid \forall y \in B, (x,y) \in I\} \text{ for } B \subseteq Y \quad (2)$$

Here, α (A) retrieves all the attributes (e.g., related topics or cryptocurrencies) that are common to the selected set of objects (e.g., specialties or learning outcomes), and β (B) finds the set of objects that share a given set of attributes.

3) Formal concept: A formal concept in this framework is a pair (A, B) where:

$$A = \beta(B) \text{ and } B = \alpha(A) \quad (3)$$

A (extent) is the set of all objects (e.g., all learning outcomes) associated with a particular set of attributes (e.g., all related topics or cryptocurrencies).

B (intent) is the set of all attributes associated with a particular set of objects.

4) Concept lattice: The concept lattice B(X, Y, I) formed from this context is a partially ordered set, where each node represents a formal concept, and the ordering is determined by the subset relations between the extents and intents of these concepts:

$(A_1, B_1) \leq (A_2, B_2)$ if and only $A_1 \subseteq A_2$ and $B_2 \subseteq B_1$

This lattice structure visually and hierarchically organizes the relationships between specialties, learning outcomes, topics, and cryptocurrencies.

Galois Connection: The Galois connection between the concept-forming operators α and β ensures that:

$$A \subseteq \beta(B) \text{ if and only if } B \subseteq \alpha(A) \quad (4)$$

This duality allows the formal concepts to be derived efficiently, ensuring that every set of related attributes can be linked to a specific group of objects.

5) Algorithm: The algorithm is constructed using the formulas from Chapter 3.1, in particular formulas (1), (2) and (3). At each stage, the data is analyzed using the operators α and β, which allows identifying the relationships between objects and attributes. These formulas are used to determine the relationships between the elements of the system, which ensures the efficient construction of the knowledge graph. Then, using the partially ordered set of formal concepts, as specified in formula (4), a knowledge graph is constructed that visualizes the relationships between learning outcomes, topics and cryptocurrencies. The Galois relationship (5) ensures the correctness of the construction of formal concepts and is used to efficiently extract the relationships between objects and attributes during the execution of the algorithm.

Here is the algorithm for constructing a knowledge graph based on syllabi:

Algorithm 1: Heading

Input: $D, N \leftarrow \emptyset, E \leftarrow \emptyset, S, LO, T, CP, CT \leftarrow \emptyset$

Output: $G=(V,E)$, where $V=\{ S, LO, T, CP, CT \}, E \subseteq V \times V$

For each row d ∈ D do:

- Extract $s \leftarrow d['Specialty'], lo \leftarrow d['Learning\_Outcome'], t \leftarrow d['Theme'], cp \leftarrow d['Crypto\_Properties'], ct \leftarrow d['Crypto\_Types']$.
- Define the formal context (X, Y, I), where:
  - $X = \{x_1, x_2, \ldots, x_n\}$, where $X = \{Specialties, Learning Outcomes, Topics, Cryptocurrencies\}$,
  - $Y = \{y_1, y_2, \ldots, y_m\}$, where $Y = \{attributes\ such\ as\ learning\ outcomes\ related\ to\ topics\ and\ specialties\}$,
  - $I \subseteq X \times Y$
- Apply concept-forming operators α and β as follows:
  - $\alpha(A) = \{y \in Y \mid \forall x \in A, (x,y) \in I\}$ (6)
  - $\beta(B) = \{x \in X \mid \forall y \in B, (x,y) \in I\}$ (7)
- Define a formal concept as a pair (A,B), where A=β(B) and B=α(A).
- Node and Edge Addition:
  - ***If*** $s \notin N$ ***then:*** Add s (specialty) as a node and connect it to lo.
  - ***If*** $lo \notin N$ ***then:*** Add lo as a node and connect it to t.
  - ***If*** $t \notin N$ ***then:*** Add t as a node and connect it to cp.
  - ***If*** $cp \notin N$ ***then:*** Add cp as a node and connect it to ct.
  - ***If*** $ct \notin N$ ***then:*** Add ct as a node.
- Construct the concept lattice $B(X,Y,I)$, a partially ordered set of formal concepts:
  - $(A1,B1) \leq (A2,B2)$ if $A1 \subseteq A2$ and $B2 \subseteq B1$ (8)
- Maintain the Galois connection between α and β:
  - $A \subseteq \beta(B)$ if $B \subseteq \alpha(A)$ (9)
- Update $V=\{ S, LO, T, CP, CT\}$ for later use in tooltip visualization.
- ***If*** all rows are processed ***then***: Represents the graph G.
  - End

End

where, D - an Excel file containing data on specialties, learning outcomes, topics, and cryptocurrencies, N - set of graph nodes, E - set of edges between nodes, S - specialties, LO - learning outcomes, T - theme, CP - crypto properties, CT - crypto types, G - represents the graph, V - set of nodes, I - binary relation linking objects and attributes, A - set of all objects (e.g., learning outcomes), B - set of all attributes (e.g., related topics).

Below in Fig. 1 is a sequence diagram of these steps for visual demonstration.

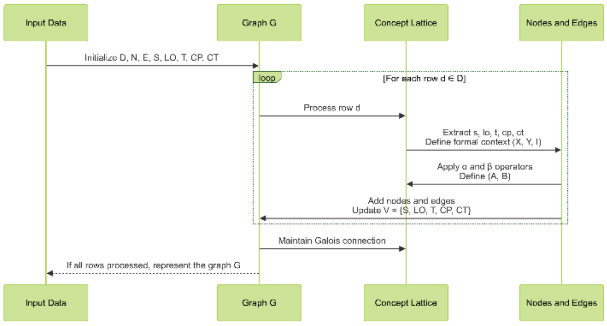

Fig. 1. Sequence diagram of the algorithm for creating knowledge graphs based on blockchain topics.

IV. RESULTS

During the review process of the syllabuses on Blockchain technologies, particularly those offered through Massive Open Online Courses (MOOCs), experts in the field of blockchain concluded that it would be beneficial to divide the original two syllabuses into four distinct specializations: (1) Information Technology, (2) Information Security, (3) Economics, and (4) Jurisprudence. Each specialization is associated with specific, required learning outcomes, as detailed in Table II. Besides, it includes the final five learning outcomes without any particular specialization due to relation to general topics.

TABLE II. LEARNING OUTCOMES BY SPECIALTY

№	Learning_Outcome	Specialty
1.	Blockchain architecture and algorithms	Information technology
2.	Security and cryptographic methods in blockchain	Information technology
3.	Using oracles and simplified programming languages in blockchain	Information technology
4.	Development of decentralized applications (DApps)	Information technology
5.	Development of smart contracts	Information technology
6.	Security of hardware wallets and other storage media	Information security
7.	Security of smart contracts and decentralized applications (DApps)	Information security
8.	Data protection and privacy in blockchain networks	Information security
9.	Cryptographic methods and protocols in blockchain	Information security
10.	Ensuring the security of blockchain systems	Information security
11.	Cryptocurrency market analysis and forecasting	Economy
12.	Application of blockchain in banking and international transfers	Economy
13.	Development and implementation of decentralized financial applications (DeFi)	Economy
14.	Regulation of cryptocurrency exchanges and financial security	Economy
15.	Asset tokenization and blockchain-based crowdfunding	Economy
16.	Intellectual property and data protection in blockchain	Jurisprudence
17.	Application of blockchain in notarial activities and public administration	Jurisprudence
18.	Regulation and legal aspects of blockchain technologies	Jurisprudence
19.	Legal aspects of decentralized autonomous organizations (DAO)	Jurisprudence
20.	Legal aspects of tokenization and use DeFi	Jurisprudence
21.	The impact of blockchain on the economy and various industries	General topics
22.	Application of blockchain in government agencies and healthcare	General topics
23.	Application of blockchain in smart cities and digital identity	General topics
24.	Comparison and use of different blockchain platforms	General topics
25.	Technological innovation and development of blockchain ecosystems	General topics

Each learning outcome encompasses specific topics, with the potential for a single topic to correspond to multiple learning outcomes, and conversely, for a learning outcome to span several topics. Table III highlights the example of the relation mentioned. Consequently, certain topics may be essential across various specializations in order to fulfill the requirements of different learning outcomes.

TABLE III. EXAMPLE OF SOME CONNECTIONS BETWEEN TOPICS AND LEARNING OUTCOMES

№	Topics	Learning outcomes
1.	Consensus Algorithms: Proof of Stake	Blockchain architecture and algorithms
2.	Consensus Algorithms: Proof of Work	
3.	Security of decentralized applications (DApps)	Security and cryptographic methods in blockchain
		Security of smart contracts and decentralized applications (DApps)
4.	Consensus algorithms: Proof of Stake	Blockchain architecture and algorithms
5.	Consensus algorithms: Proof of Work	
6.	Blockchain architecture	
7.	Methods for protecting consensus algorithms	
8.	Scalability issues and security	
9.	Comparison of different consensus algorithms	
10	Distributed ledger technology (DLT)	
11	Verification and audits of smart contracts	Security and cryptographic methods in blockchain
		Security of smart contracts and decentralized applications (DApps)
		Cryptographic methods and protocols in blockchain
		Application of blockchain in banking and international transfers

Cryptocurrencies have become an integral component of the global economy and financial system, due to blockchain serving as the foundational technology that underpins their functionality and growth. This highlights that, the existence and operation of cryptocurrencies are inextricably linked to blockchain technology, making it indispensable to the cryptocurrency ecosystem, it was essential to incorporate the types and properties of cryptocurrencies into the educational curriculum on blockchain technologies. As can be seen from Table IV, an analysis of popular cryptocurrencies and the properties they support is provided.

TABLE IV. TYPES AND PROPERTIES OF CRYPTOCURRENCIES

Cryptocurrency properties	Bitcoin (BTC)	Ethereum (ETH)	Ripple (XRP)	Litecoin (LTC)	Monero (XMR)	Cardano (ADA)	Polkadot (DOT)	Chainlink (LINK)
Decentralization	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes
Smart Contract	No	Yes	Yes	No	Limited	Yes	Yes	Yes
Privacy	No	No	No	No	Yes	No	No	No
Scalability	No	Yes	Yes	No	No	Yes	Yes	Yes
Proof of Work	Yes	No	No	Yes	Yes	No	No	No
Proof of Stake	No	Yes	No	No	No	Yes	Yes	No
Limited Supply	Yes	No	Yes	Yes	Yes	Yes	Yes	No
Mainstream Adoption	Yes	Yes	Yes	Moderate	Limited	Moderate	Moderate	Moderate
Cross-Chain	No	No	No	No	No	No	Yes	Yes
Exchange Availability	Yes	Yes	Yes	Yes	Moderate	Yes	Yes	Yes
Mining Requirement	Yes	No	No	Yes	Yes	No	No	No

The study of cryptocurrency properties and types aligns closely with the existing topics and learning outcomes within the blockchain curriculum. In collaboration with experts from the Blockchain Center, It was established a framework that connects the properties and types of cryptocurrencies to the relevant general topics and learning outcomes. This integrative approach ensures a cohesive learning experience, reinforcing key concepts across both areas of study. Table V presents a partial mapping of these connections, demonstrating how the properties and types of cryptocurrencies are integrated with specific learning outcomes.

TABLE V. RELATIONSHIP BETWEEN THE PROPERTIES AND TYPES OF CRYPTOCURRENCIES AND LEARNING OUTCOMES

№	Learning outcomes	Properties of cryptocurrencies	Types of cryptocurrencies
1.	Using oracles and simplified programming languages in blockchain	Cross-Chain	Polkadot (DOT), Chainlink (LINK)
2.	Development of decentralized applications (DApps)		
3.	Blockchain architecture and algorithms	Decentralization	Bitcoin (BTC), Ethereum (ETH), Litecoin (LTC), Monero (XMR), Cardano (ADA), Polkadot (DOT), Chainlink (LINK)
4.	Legal aspects of decentralized autonomous organizations (DAO)		
5.	Blockchain architecture and algorithms		
6.	Security of smart contracts and decentralized applications (DApps)		
7.	Application of blockchain in notarial activities and public administration		
8.	Development of smart contracts	Developer Community	Bitcoin (BTC), Ethereum (ETH), Ripple (XRP), Litecoin (LTC), Monero (XMR), Cardano (ADA), Polkadot (DOT), Chainlink (LINK)
9.	Technological innovation and development of blockchain ecosystems		
10.	Ensuring the security of blockchain systems	Energy Efficiency	Ripple (XRP), Cardano (ADA), Polkadot (DOT), Chainlink (LINK)
11.	Security of hardware wallets and other storage media		
12.	Cryptocurrency market analysis and forecasting	Exchange Availability	Bitcoin (BTC), Ethereum (ETH), Ripple (XRP), Litecoin (LTC), Monero (XMR), Cardano (ADA), Polkadot (DOT), Chainlink (LINK)

From an analysis of Table VI, it emerges summarized information of the connections between all topics, required learning outcomes, specializations, and data on cryptocurrencies, comprises 2,054 rows and 5 columns. This table serves as an extensive resource, capturing the intricate relationships among these elements.

TABLE VI. FINAL TABLE INDICATING CONNECTIONS BETWEEN TOPICS, LEARNING OUTCOMES, SPECIALTIES, PROPERTIES AND TYPES OF CRYPTOCURRENCIES

Theme	Learning_Outcome	Specialty	Crypto Properties	Supporting Cryptocurrencies
Anomaly monitoring and detection methods	Cryptographic methods and protocols in blockchain	Information security	Privacy	Monero (XMR)
Anomaly monitoring and detection methods	Cryptographic methods and protocols in blockchain	Information security	Security	
Anomaly monitoring and detection methods	Security of hardware wallets and other storage media	Information security	Security	
Anomaly monitoring and detection methods	Security of hardware wallets and other storage media	Information security	Energy Efficiency	Ripple (XRP)
Anomaly monitoring and detection methods	Security of hardware wallets and other storage media	Information security	Energy Efficiency	Cardano (ADA)
Anomaly monitoring and detection methods	Security of hardware wallets and other storage media	Information security	Energy Efficiency	Polkadot (DOT)
Anomaly monitoring and detection methods	Security of hardware wallets and other storage media	Information security	Energy Efficiency	Chainlink (LINK)
Anonymous cryptocurrencies and their security	Data protection and privacy in blockchain networks	Information security	Privacy	Monero (XMR)
Anonymous cryptocurrencies and their security	Data protection and privacy in blockchain networks	Information security	Security	
Application of blockchain in banking	Application of blockchain in banking and international transfers	Economy	Regulatory Compliance	Bitcoin (BTC)
Application of blockchain in banking	Application of blockchain in banking and international transfers	Economy	Regulatory Compliance	Ethereum (ETH)
Application of blockchain in banking	Application of blockchain in banking and international transfers	Economy	Mainstream Adoption	Chainlink (LINK)

As a result, an aggregated data set with all topics, learning outcomes, specialties and properties, and types of cryptocurrencies was used to build knowledge graph.

A significant outcome of the experiment was the development of a visual representation of the blockchain educational program structure, as illustrated in Fig. 2. This knowledge graph facilitates course developers in comprehensively understanding the interrelationships among majors, learning outcomes, topics, and the properties and types of cryptocurrencies. For instance, the connection between the learning outcome "Smart Contract Development" and topics such as "Smart Contract Security" and "Using Blockchain Programming Languages" highlights the specific aspects that must be incorporated into the curriculum. This visualization enables a detailed and systematic approach to curriculum design.

Fig. 2. Interactive graph on blockchain topics.

Fig. 3 shows knowledge graph illustrating the relationships between various elements within a blockchain education program. Knowledge graph presents structure of nodes defined by categories and different colors: Specialties (pink), learning outcomes (green), topics (yellow), cryptocurrency properties (orange), and cryptocurrency types (blue). The interconnections between nodes depict how these different components interact and relate to each other, thereby providing a clear and comprehensive overview of the program's structure.

Thus, the connections between nodes in knowledge graph provides the relationships among various components of the educational program:

Links between Specialties and Learning Outcomes indicate relation between learning outcomes and specific specialties. For

instance, the learning outcome "Security and Cryptographic Methods in Blockchain" is associated with the specialty of "Information Security."

Links between Learning Outcomes and Topics reveal the topics that must be covered for achieving particular learning outcomes.

Links between Learning Outcomes and Cryptocurrency Properties demonstrate how specific properties of cryptocurrencies are incorporated into the educational framework.

Links between Cryptocurrency Properties and Cryptocurrency Types illustrate the association between different types of cryptocurrencies and their properties. For example, the property of "Limited Supply" is exemplified by Bitcoin, showcasing how certain cryptocurrencies embody specific characteristics.

Overall, these links provide a comprehensive view of how the components of the educational program interrelate, facilitating a structured approach to curriculum development.

Fig. 2 presents a visualization of the structure of the educational program dedicated to the study of blockchain technologies. At the core of this visualization is the specialty "Information Security," represented by a prominent pink node. This central node is connected to various green nodes, which denote the learning outcomes associated with blockchain security.

They were depicted among the key learning outcomes the aspects such as the security of hardware wallets, data protection and privacy within blockchain networks, and the security of smart contracts and decentralized applications (DApps). These connections illustrate the program's focus on ensuring a comprehensive understanding of security issues pertinent to blockchain technology.

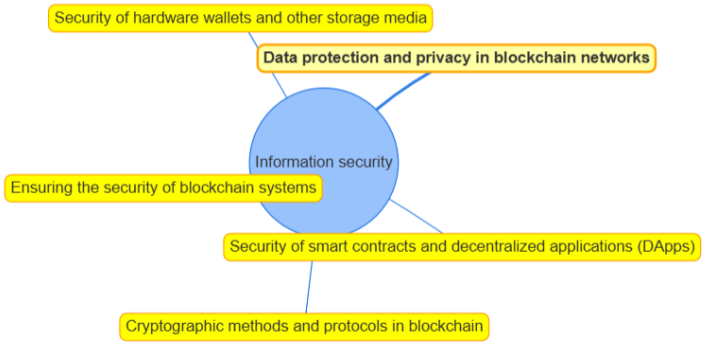

Fig. 3. List of learning outcomes related to the specialty "Information Security".

Fig. 4 reveals a segment of knowledge graph representing the blockchain educational program, with the learning outcome "Security and Cryptographic Methods in Blockchain" serving as the central node, highlighted in green. This node is interconnected with various topics that students are required to explore in relation to this outcome.

The pop-up window appears detailing a list of topics associated with this learning outcome, including the key topics such as "Introduction to Blockchain and Its Basic Principles," "Cryptographic Methods in Blockchain," and "Smart Contract Security".

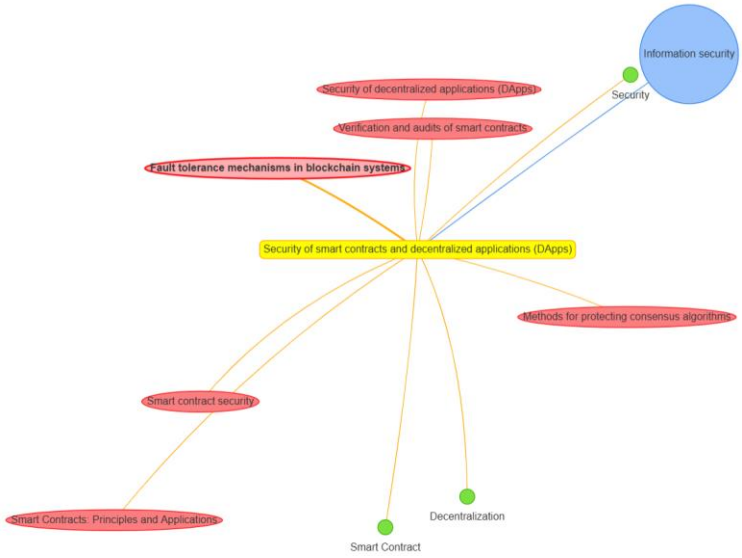

Fig. 4. Displaying a list of topics related to the learning outcome.

As can be seen from Fig. 5, knowledge graph illustrates various types of cryptocurrencies, exemplified here by Chainlink (LINK), along with their associated characteristics and properties. To do this, it is activated a pop-up window over the "Chainlink (LINK)" node with the list of key properties and aspects pertinent to this cryptocurrency. This feature enhances the visualization by offering comprehensive information about Chainlink's specific attributes and its role within the broader context of cryptocurrency types.

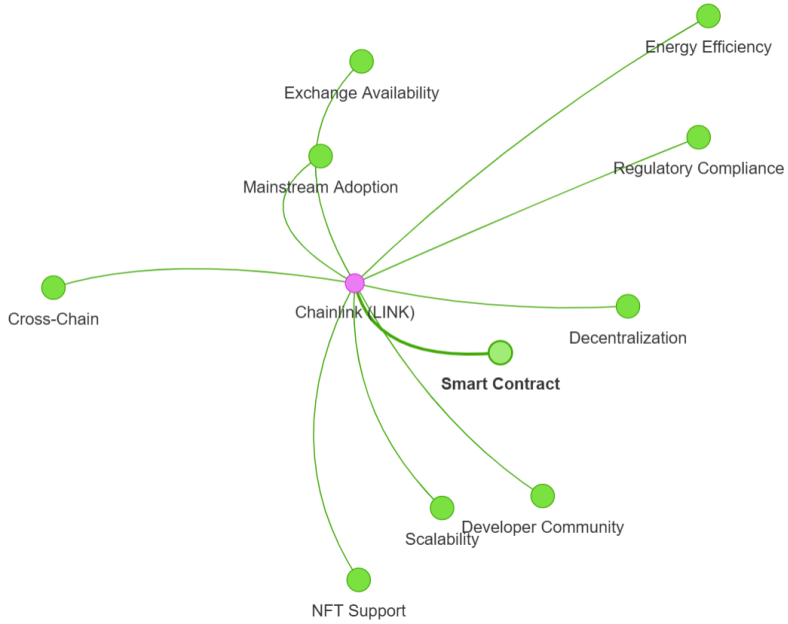

Fig. 5. A type of cryptocurrency with associated cryptocurrency properties.

Knowledge graph facilitates the identification of related learning outcomes that encompass overlapping topics. It provides a valuable tool for educators specializing in cryptocurrencies by simplifying the process of compiling a comprehensive list of essential topics associated with specific cryptocurrency properties. This functionality aids instructors in effectively organizing and delivering curriculum content adapted to various aspects of cryptocurrency education.

Following this, the association rules method is employed to determine the relationships between topics by utilizing the parameters of support, confidence, and lift. The effectiveness of this method for evaluating the significance of parameters within a dataset has been demonstrated by the authors in [42]. Analyzing these indicators enables the identification of the most critical and interrelated topics that should be incorporated into the course curriculum. The identified relationships can assist in structuring the course content more effectively. For instance, the course modules can be organized to initially cover foundational concepts such as blockchain and decentralization, before progressing to more advanced topics like smart contracts and their applications. To calculate Support, we use formula (10):

$$\text{Support}(A \rightarrow B) = (\text{Number of transactions containing } (A \cup B)) / (\text{Total number of transactions}) \quad (10)$$

Support quantifies the frequency with which elements A and B co-occur within the dataset. It is defined as the ratio of the number of transactions containing both elements to the total number of transactions. Confidence, on the other hand, assesses the likelihood that element B appears in transactions that already include element A. This is calculated as the ratio of the support for A∪B (the joint occurrence of A and B) to the support for A. The formula for this metric is provided in Formula (11):

$$\text{Confidence}(A \rightarrow B) = (\text{Support}(A \cup B)) / (\text{Support}(A)) \quad (11)$$

In association rule analysis, lift measures the strength of the relationship between two events or data sets. Specifically, for an association rule of the form A→B, lift quantifies how frequently elements A and B occur together compared to their expected co-occurrence if they were statistically independent. The formula for calculating lift is presented in Formula (12).

$$\text{Lift}(A \rightarrow B) = (\text{Support}(A \cup B)) / (\text{Support}(A) * \text{Support}(B)) \quad (12)$$

The interpretation of lift values is as follows:

- If Lift=1, then events A and B are independent, meaning the occurrence of one event does not influence the probability of the occurrence of the other.
- If Lift>1, then events A and B co-occur more frequently than would be expected under conditions of independence, indicating a positive association between them.
- If Lift<1, then events A and B co-occur less frequently than would be expected if they were independent, suggesting a negative association between them.

Table VI presents a selection of the results obtained from applying the association rules, while the complete table can be found in Appendix.

Based on the obtained results, we have come to the following conclusions:

- The rule linking 'Privacy' and 'Security' shows high confidence (Confidence = 0.8) and significant support (Support = 0.16). This indicates a frequent relationship between these concepts in the data, which is logical given that improved privacy is often associated with stronger security measures.
- The rules linking 'Decentralization' and 'Smart Contract' have moderate confidence (Confidence = 0.400) and support (Support = 0.16). This emphasizes their role in the context of each other, but does not indicate as close a relationship as in the case of 'Privacy' and 'Security'.
- The rule between 'Smart Contracts: Principles and Applications' and 'Smart Con-tract' has the highest confidence value (Confidence = 1.000), indicating a direct dependence of these concepts. The high level of confidence and support (Support = 0.16) shows that there is a clear and frequent relationship between these concepts in the data, which is logical since the principles and applications of smart contracts are closely related to the concept of a smart contract itself.

These findings underscore the significance of the relationships between key concepts in blockchain technologies and provide insight into which aspects require particular emphasis when learning about or developing blockchain solutions.

Analyzing the distribution of support scores for association rules provides insight into the frequency of various concept combinations within the dataset. This analysis is particularly valuable for selecting study topics, as infrequent combinations may high-light specialized or unique areas of knowledge that warrant further exploration. Consequently, the distribution of support scores assists in prioritizing the content of educational programs, enabling a focus on the most significant and frequently occurring concepts.

In the context of designing a blockchain course, analyzing the confidence values in the association rule table is instrumental in identifying critical topics and their interrelationships for inclusion in the syllabus. High confidence values, such as 1.0, denote concepts that are strongly related and should ideally be taught together. For instance, a high confidence value between 'smart contracts' and 'their principles and applications' suggested that these topics should be integrated into a single module to facilitate a comprehensive understanding of their interdependencies.

Conversely, topics with lower confidence values, such as 'decentralization' and 'smart contracts,' indicate a less direct relationship. Although these concepts are still relevant, their connection is not as evident and may warrant separate modules. Nonetheless, it remains important to highlight potential intersections in various use cases.

Thus, the analysis of confidence values can guide the structuring of a blockchain curriculum by organizing modules to reflect real-world connections and dependencies among key concepts. This approach enhances students' understanding by aligning the course content with practical and conceptual relationships.

An analysis of the distribution of lift values for association rules reveals a marked predominance of rules with elevated lift values, signifying a strong relationship between the antecedents and consequences within the dataset. Lift values exceeding 1.0 indicate that the co-occurrence of antecedent and consequence is more frequent than would be expected under conditions of independence, thereby underscoring the significance of examining these relationships within the realm of blockchain technologies. The distribution diagram demonstrates that a substantial number of rules exhibit a considerable degree of association. This finding enables the identification of key topics and concepts for inclusion in educational curricula and highlights areas that may benefit from further research and detailed investigation.

For illustrative purposes, we present the most significant connections, such as 'Blockchain Data Protection' and 'Fair Use and Data Protection in Blockchain,' in current graphical representations (see Fig. 6 and Fig. 7). These connections are characterized by a maximum lift score of 8.33, indicating a strong relationship between the topics. This high lift score suggests that these subjects are closely related and should be incorporated into the syllabus together to effectively address the same learning outcomes.

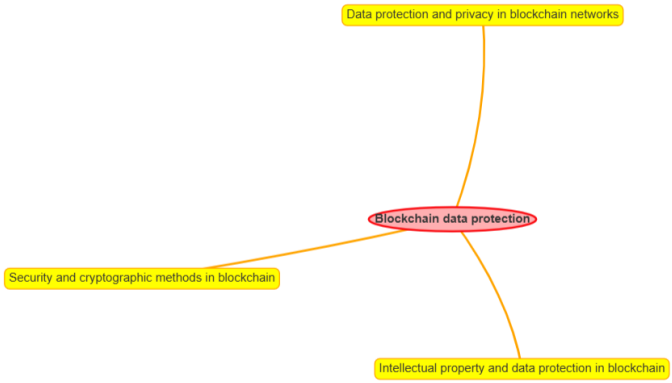

Fig. 6. Theme 'Blockchain data protection' with learning outcomes.

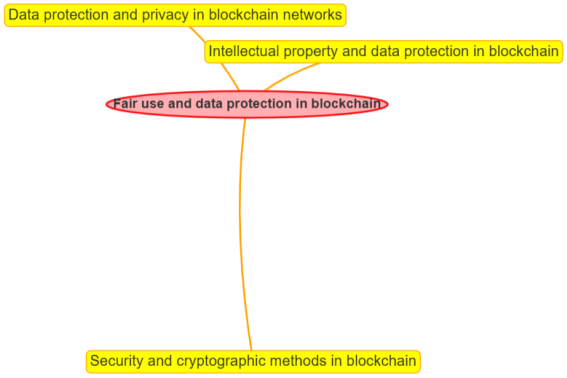

Fig. 7. Theme 'Fair use and data protection in blockchain' with learning outcomes.

The graph-based learning method demonstrates significant advantages over traditional and modern methods such as text mining and conceptual clustering (FCA). Firstly, the graph approach allows for flexible optimization of the duration and work-load depending on the specialty, while standard programs are rigidly fixed. It also offers an adaptive number of topics and learning outcomes, which ensures personalization of the educational process for the specific needs of students. An important aspect is the support of experts and the flexibility of choosing topics both by specialty and by learning outcomes. Teachers have more freedom in adapting courses, which increases the effectiveness of training. Due to its high flexibility and adaptability, the graph method creates a more dynamic and optimized educational environment that better meets modern challenges in education.

V. DISCUSSION

The study demonstrated the effectiveness of formal concept analysis (FCA) and clustering methods for optimizing educational programs in the field of blockchain technologies. The results of the study showed that the use of an interactive knowledge graph simplifies the process of curriculum development and provides flexibility in the selection of topics, which is especially important for courses covering a wide range of disciplines, such as blockchain.

Currently, the Coursera platform offers more than 1,000 blockchain courses, covering a wide range of topics - from the basics of the technology to specialized courses such as smart contracts, decentralized applications (dApps), and blockchain security. The average duration of such courses is from 8 to 14 weeks for basic programs and from 3 to 6 months for advanced specializations, which makes training accessible to students with different levels of training and employment. The main blockchain courses relate to such specializations as Business, Computer Science, Information Technology, Data Science, etc. [43]. With such a wide range of courses, it can be difficult for students to choose the right program that best suits their educational needs. In this context, an interactive knowledge graph developed based on FCA will be a powerful tool to simplify the course selection process. It will help students analyze the connections between different topics and learning outcomes presented in blockchain courses. This is especially relevant in the context of constantly changing content in the blockchain technology field, where it is necessary to consider both basic knowledge and emerging trends such as decentralized finance (DeFi), cryptography, and smart contract security [4-8].

By visualizing the relationships between topics, a knowledge graph can help students and teachers navigate the materials more easily, compare them with their existing knowledge and skills, and identify gaps in their knowledge. For example, a student who is already familiar with the basics of cryptography can use the graph to quickly identify which courses cover advanced aspects of this topic, thereby avoiding the need to re-learn concepts already known. In addition, the graph allows you to systematize not only educational programs, but also types of blockchain technologies, which helps students better understand their application in real life. This is important for those who want to get more practical training and learn about specific technologies, such as the use of blockchain in financial systems or smart contracts.

Approach of this article differs from traditional text mining and curriculum analysis methods. Unlike standard syllabi, where the topics are fixed for all specialties, our method allows for flexible adaptation of course duration and teaching load depending on the specialty and learning outcomes. This is confirmed by comparison with works [17-21], where a simplified concept lattice improved information extraction while preserving the data structure.

One of the key results of the study is the development of an adaptive curriculum model based on formal conceptual analysis and clustering. This solution provides teachers and curriculum developers with the opportunity not only to automate the course planning process, but also to ensure its relevance in light of the rapidly changing requirements of the educational process in the field of blockchain and cryptocurrency.

In the future, it is planned to expand the capabilities of the knowledge graph and use it to assess students' knowledge, as provided by the authors of [17]. This will allow automatic matching of the studied topics with the learning outcomes and determine how fully students have mastered the key concepts of the course. Such an assessment system would be based on association rules identified during the construction of the graph, which would allow for a more accurate assessment of the level of understanding of the material and the identification of potential knowledge gaps. Despite the significant advantages of the proposed approach, there are certain limitations, such as the need for expert support at the stage of model setup and limited ability to automate the analysis of new topics. Future research will focus on developing more versatile algorithms that can automatically update the knowledge graph taking into account new data and trends in the blockchain field. In addition, the development of a student assessment system based on the graph will be an important step in improving the learning process.

VI. CONCLUSION

In conclusion, the conducted study shows that the application of FCA and clustering methods to create an interactive knowledge graph in educational programs on blockchain technologies is highly effective. The work developed an approach that allows teachers to flexibly adapt curricula depending on the level of students' training and their specialization, which is especially important in the context of blockchain technologies, covering a wide range of topics from cryptography to smart contract development. The interactive knowledge graph helps to systematize information on learning outcomes, topics, and key skills, which makes the course planning process more transparent and simplified. As a result of the study, it was possible to significantly reduce the teaching load by focusing on the main topics, which helps to reduce student overload and prevent them from dropping out due to difficulties. This is especially important for courses covering complex and multi-layered topics, as is the case with blockchain, where the amount of information can easily become excessive. The knowledge graph not only simplifies the selection of topics for teaching, but also helps teachers create more flexible and adaptive curricula that meet the rapidly changing requirements of the market and new technologies. It

was also found that the use of association rules and clustering methods helps to identify key relationships between topics and learning outcomes. This allows teachers and students to see a clearer picture of how various aspects of blockchain technology are interconnected and helps to better structure the learning process. The experiments demonstrated the possibility of using the knowledge graph not only for developing curricula, but also for further assessment of the level of students' knowledge. In the future, it is planned to use this tool to automatically assess the extent to which students have mastered key topics and learning outcomes, which will allow teachers to more effectively adjust educational materials and improve the educational process.

Despite the obvious advantages of the proposed approach, the study also revealed certain limitations. In particular, significant efforts are required from experts at the stage of developing the knowledge graph and setting up its structure. Further research is planned to develop algorithms that will automate the process of updating the knowledge graph and adapting its structure to new educational requirements and trends in the field of blockchain.

Thus, the proposed approach to organizing educational programs using formal conceptual analysis and clustering methods is an innovative tool that can significantly improve the effectiveness of blockchain technology training courses. The interactive knowledge graph makes the process of developing educational programs easier, more flexible and adaptive, which is especially important for such rapidly developing areas as blockchain.

ACKNOWLEDGMENT

We sincerely express our gratitude to the Ministry of Science and Higher Education of the Republic of Kazakhstan for the financial support of our work within the framework of the grant funding project № AP19679514 «A study on conceptualization of blockchain domain using text mining and formal concept analysis: focusing on teaching methodology».

Analysis of Influencing Factors of Tourist Attractions Accessibility Based on Machine Learning Algorithm

Na Liu*, Hai Zhang
School of Traffic and Transportation, Xi'an Traffic Engineering Institute, Xi'an, Shaanxi, 710300, China

***Abstract*—Tourist attractions, defined by their cultural importance, aesthetic appeal, and recreational possibilities, are critical to the tourism industry. However, precisely evaluating tourism needs remains a difficult task, and research in this field is scarce. This research introduces an innovative remora-optimized adaptive XGBoost (RO-AXGBoost) model for predicting accessibility factors for tourist attractions. Data was obtained from Kaggle, and the suggested method was executed in Python. The RO-AXGBoost model's effectiveness was assessed utilizing metrics like Mean Absolute Percentage Error (MAPE) of 7.24, Mean Absolute Error (MAE) of 7.321, Root Mean Square Error (RMSE) of 10.241, and R-squared (R^2) of 85.7%. The results show that the RO-AXGBoost model surpasses conventional approaches by effectively discovering important determinants that have an important impact on the accessibility of tourist attractions.**

Keywords*—Tourist attractions; factors; tourism; remora optimized adaptive XGBoost (RO-AXGBoost)

I. Introduction

The intention to return is a vital component of tourism study, especially in the setting of urban tourism, where tourist loyalty is critical to economic development [1]. Comprehending the factors that impact tourists' choices to revisit attractions not only helps with consumer retention but also improves the efficacy of advertising tactics. With the advent of social media, tourists now have unprecedented accessibility to data, which greatly influences their travel decisions. Social media is an effective tool for influencing thoughts and experiences, establishing itself as an indispensable resource in the vacation decision-making procedure [2].

As social media platforms spread, the rise of social media influencers (SMIs) has altered how data is distributed [3]. These individuals, operating as independent advocates, can influence public opinion via a variety of digital channels, including tweets and blog posts. This dynamic shift in data access is especially important in the tourism industry, which is naturally vulnerable to external shocks like epidemics and catastrophes. The World Health Organization (WHO) has frequently suggested halting economic operations and public events during emergencies, demonstrating the industry's vulnerabilities.

Furthermore, environmental issues are posing new challenges to the modern tourism industry. As travelers become more conscious of the environmental effects of their operations, the need for "sustainable tourists"—those with smaller environmental impacts and more buying power—has increased [4]. The tourism industry is thus forced to adjust to these changing customer desires by incorporating environmentally friendly procedures.

Technological developments have become integral to the growth of the tourism industry, resulting in the idea of smart tourism [5]. This digital transformation not only improves tourism resource management but also provides stakeholders with timely access to pertinent data. The incorporation of sophisticated information technologies enables connection between tourism providers, thus improving the entire experience of visitors.

However, an important obstacle remains guaranteeing the safety and security of travel destinations. The growing issues of civil unrest, terrorism, catastrophic events, and health emergencies have increased the demand for dependable security evaluations [6]. Tackling these problems is essential to efficient travel planning.

In this setting, the purpose of this research is to improve the accuracy of predicting tourist attraction variables using an innovative remora-optimized adaptive XGBoost (RO-AXGBoost) model. This sophisticated machine learning method is expected to enhance predictive abilities in terms of important factors impacting tourist destinations. This study not only adds to the body of knowledge in tourism management but also provides decision-makers with useful information for tactical planning.

Additionally, to these advances in tourism management, current developments in image processing methods have substantially enhanced the excellence of visual content related to tourist attractions. Deep learning-based image improvement methods and the use of artificial intelligence algorithms have developed as methods for removing haze from images, leading to more obvious and appealing visuals. These improvements not only improve the visual appeal of tourist destinations, but they additionally perform an important role in impacting tourists' thoughts, eventually impacting their travel choices.

The accessibility of tourist attractions is critical to the achievement and enjoyment of tourism experiences. However, precisely predicting and evaluating the variables that impact accessibility is a difficult and underexplored problem. Conventional techniques frequently fall short of capturing the complex interplay of factors like transportation infrastructure, ecological sustainability, and tourist behaviour. The growth of smart technologies, as well as varying external conditions such as epidemics and climate change, have intricate the tourism sector even further. This study aims to close the gap by using sophisticated machine learning methods to present more precise, scalable, and flexible predictions of the variables that influence the accessibility of tourist attractions.

*Corresponding Author.

This study intends to answer the following important questions:

1) What are the most crucial elements impacting the accessibility of tourist attractions?

2) How can machine learning techniques, especially the RO-AXGBoost model, be used to enhance the prediction accuracy of tourist destination accessibility?

3) How does the suggested RO-AXGBoost compare with other previous methods in terms of performance metrics like MAPE, MAE, RMSE, and R^2?

4) What potential knowledge can be derived from utilizing sophisticated predictive models for tourism management and planning?

The primary objectives of this study are:

1) To detect and evaluate the important determinants impacting the accessibility of tourist attractions.

2) To create and execute a new remora-optimized adaptive XGBoost (RO-AXGBoost) model that enhances the prediction accuracy of accessibility variables.

3) To compare the suggested method with previous machine learning techniques and assess its effectiveness utilizing metrics like MAPE, MAE, RMSE, and R^2.

4) To present knowledge and suggestions for tourism managers and urban planners on how to improve accessibility and sustainability in tourist destinations.

The paper's structure aims to direct the reader through the procedure of research, beginning with an introduction that presents background data on the significance of accessibility in tourism as well as technological advances that have allowed for more accurate prediction models in Section I. This is followed by a thorough literature review in Section II, which investigates previous research on machine learning methods in tourism and identifies gaps in current methodologies. The methodology in Section III describes the data sources, model creation, and performance assessment criteria, whereas the outcomes section summarizes the research's findings and compares the suggested RO-AXGBoost to previous techniques. The discussion in Section IV examines the results critically, emphasizing the study's novelty and implications. Finally, the paper summarizes the important contributions and proposes future research directions in Section V to build on the findings of this research.

II. Related Work

A study in [7] examined seasonal emotional shifts among travelers in natural forest environments using advanced methods such as Hrnet, SHAP, OSANetand, and XGBoost. Positive feelings were most common throughout three years, with varying distributions among seasons. The study contributed to the development of sustainable forest tourism by revealing subtle emotional reactions to landscape aspects.

Research in [8] used an IoT-enabled, deep learning-based DNN with a multi-class classification algorithm recommendation system to improve visitor experiences in smart cities. Personalized suggestions were informed by real-time data and feedback from travelers. Compared to previous models, our multi-label classifier performed better, attaining high accuracy and precision. Potential biases in the source data and the requirement for a substantial IoT infrastructure were examples of limitations.

Paper in [9] employed an improved STC-LSTM to forecast short-term vacation demand for travel. As compared to traditional approaches, the results show enhanced forecast accuracy. The limitations of the approach encompass dependence on certain data categories and possible problems with the model's regional generalization.

Research in [10] proposed a unique strategy centered on enhancing visitor experiences and reducing congestion to overcome the shortcomings of conventional T-RSs. Used deep reinforcement learning as opposed to just single areas of interest. Its effectiveness was evaluated against three baselines using Verona tourism data from 2014 to 2023. The heavy computing load and data requirements were among the drawbacks.

Research in study [11] proposed a three-stage methodology to anticipate tourism demand across numerous sites. It utilized multi-dimensional scaling to identify related attractions, mixed autoregressive models with LSTM networks to reflect spatial dependency and the scale of tourism and suggested a method for integrating predictors to increase prediction stability. The program performed exceptionally well in estimating the number of visitors to Beijing's 77 attractions, according to the results. Data accessibility and generalizability issues were two possible limitations.

The objective of the research [12] was to create a DNN model for predicting how well policies would function over time to lessen the effects of crises on the travel and tourism sector in developing nations. The model indicated that the most efficient and long-lasting strategy was to concentrate on both domestic tourist marketing and disaster preparedness, drawing on both past experiences and present difficulties. The intricacy of modeling dynamic systems and the availability of data were possible constraints.

A study in [13], which focused on incoming arrivals from Hong Kong, attempted to improve the accuracy of tourist volume predictions using deep learning techniques. The suggested SAE-Bi-GRU strategy beat benchmark models like PCA-Bi-GRU with the Baidu index and Google trends data. It was archived by using SAE for data dimension reduction and a Bi-GRU for model forecasting. The research's dependence on a single case study, however, presented a limitation.

Study [14] improved tourist analysis by combining deep-learning text categorization and spatial clustering approaches. Using Flickr data, it created nine tourist categories using topic modeling and LSTM classification. Spatial clustering determined the ROA for each category, indicating various elements impacting attraction. The technique provided extensive insights into visitor tastes and could be used outside tourism, although its dependence on Flickr data has limits.

The purpose of the study [15] was to better understand travelers' binary emotional experiences at Dali tourist spots. SVM and LDA models were used, as well as geographic analysis. The results reflect a general trend of good attitude,

with negative evaluations for select Dali city attractions. Service experience and pricing were revealed as important elements affecting travelers' attitudes. Limitations may include a dependence on internet evaluations and the study's location.

III. METHODOLOGY

In this section, the paper proposed a novel remora-optimized adaptive XGBoost (RO-AXGBoost) to forecast various factors associated with tourist attractions. We gathered data from Kaggle.

A. Data Collection

This paper gathers a dataset from Kaggle [16]; this dataset covers tourism attraction site data from 352 Chinese cities. Each city CSV file has 100 locations. The data comprises the location name, URL, address, site introduction, opening hours, image URL, rating, proposed visit duration, suggested season, ticket information, and tips.

B. Remora Optimized Adaptive XGBoost

The suggested technique, remora-optimized adaptive XGBoost (RO-AXGBoost), was selected for its capacity to manage intricate datasets and make precise predictions about accessibility elements of tourist attractions. This technique stands out because it incorporates optimization methods that improve the model's efficiency, rendering it especially appropriate for evaluating the variety of tourism data. This research's participants are a varied group of tourists with varying demographics like age, gender, nationality, and travel experience, guaranteeing a thorough comprehension of various viewpoints on accessibility. The study will make use of publicly available datasets, like those obtained from Kaggle, which include variables like travel frequency, desired attractions, accessibility issues, and socioeconomic status. This integration of sophisticated machine learning methods and large datasets intends to offer resilient knowledge of the factors that influence the usability of tourist attractions, eventually leading to better tourism management procedures.

RO-AXGBoost is a novel technique for anticipating several aspects associated with tourist attractions. It leverages the Remora Optimization technique to adjust XGboost parameters and operates at the best model optimization. By coordinating Remora's flexibility with XGBoost's robustness, RO-AXGBoost is a potent tool for tourist destination management and planning as it enhances the machine's accuracy and efficiency in predicting crucial measurable factors in the tourism sector industry. The integration of Remora's suppleness with the robustness of XGBoost is called RO-AXGBoost, which presents viable aid to key decision-makers within the tourism sector that can forecast the significant indicators necessary for strategic planning and management of destination tourism more effectively.

1) ROA: This section aims at introducing the new meta-heuristic that has been developed, known as the ROA. ROA is based on a symbiotic float trait that remoras use to cling to bigger living organisms like swordfish and whales to be in a better position to access food. Again, like all of the MAs, the ROA optimization technique's concept is derived from biological considerations. This one has incorporated some of the features from the WOA and the SCA, which is known for its efficiency in both the local and the global search. By selecting an integer variable called H (0 or 1), one can decide whether this strategy has to use a similar exploring manner to that in SCA or WOA. This flexible manner increases using search space in the case of ROA, but if compared to other approaches to refinement, this flexible manner decreases the level of accuracy in exploration.

a) Travel with free: Using an elite approach, the SFO strategy is employed by ROA to perform a global search in the swordfish algorithm. The Eq. (1) for updating positions can be stated as follows:

$$u_i(p+1) = X_{best}(p) - (rand \times \left(\frac{x_{best}(p)+x_{rand}(p)}{2}\right) - x_{rand}(p)) \quad (1)$$

In this instance $\boldsymbol{u_i(p+1)}$ represents a candidate position of the $i-th$ remora. At the present moment, the optimal position is$\boldsymbol{X_{best}}(\boldsymbol{p})$. An arbitrary remora location is denoted by$\boldsymbol{x_{rand}}(\boldsymbol{p})$. The letter$P$stands for the number of iterations that are currently in progress. And between 0 and 1, $rand$ is a random number. Additionally, depending on its experiences, remora may switch hosts. This situation allows for the creation of a new candidate position through:

$$u_i'(p+1) = u_i(p+1) + randn \times \left(u_i(t+1) - x_i(t)\right) \quad (2)$$

And the $i-th$ remora's candidate position is represented by $u_i'(p+1)$. The ith remora's prior location is denoted by $x_i(t)$. Additionally, a properly distributed random number is generated using $randn$.

b) Through fully eat: Remora may also attach themselves to humpback whales to feed. Therefore, remora will move similarly to humpback whales. The WOA method is used in ROA to do local searches. To be more exact, the bubble-net attacking approach employed in WOA is utilized. The changed position updating formulae are provided below:

$$u_i(p+1) = E \times f^S \times \cos(2\pi a) + x_{best}(p) \quad (3)$$

$$E = |X_{best}(p) - x_i(p)| \quad (4)$$

Here E is the separation between the food and the remora Eq. (4). Additionally, by employing the encircling prey mechanism in WOA, which is described as follows, the remora can generate a little step to further enhance the quality of the solution.

$$E' = u_i(p+1) - S \times x_{best}(p) \quad (5)$$

$$x_i(p+1) = v_i(p+1) + B \times E' \quad (6)$$

Here the newly created location of the $i-th$ remora is denoted by $u_i(p+1)$. In ROA, the remora factor, represented by the letter B, is set to 0.1. When using the aforementioned techniques, ROA outperforms well-known meta-heuristic algorithms like WOA, SFO, and HHO (see Eq. (5) and (6)).

2) Adaptive extreme Gradient Boosting (AXGBoost): In this study, we employ AXGBoost as the core method to forecast gains and handle high-dimensional assembly faults. Then, to

get predictions that are even more accurate, we suggest adaptiveXGBoost.

$$\hat{o}_i = h_2(E_i) = \sum_{k_2=1}^{k_2} h_{k_2}(E_i), h_{k_2} \in \emptyset \quad (7)$$

Here $\phi = \{h(E) = \omega_{s(D)}\}$ is a grouping of decision trees. Each $tree\ h(E)$ corresponds to a structural parameter s and leaf weights ω, Eq. (7). The $i-th$analysis of tourist attractions is denoted by$\hat{o}_i$. The model is developed by minimizing the total loss function:

$$M = \sum_{i=1}^{N_t} m(\hat{o}_i, o_i) + \sum_{k_2=1}^{k_2} \Omega(h_{k_2}), \quad (8)$$

Here,

$$\Omega(h_{k_2}) = \gamma d + \varepsilon \|\omega\|^2 \quad (9)$$

$m(\hat{o}_i, o_i)$Refers to the loss function used to calculate the difference between the realistic and expected tourism attraction. dRepresents the number of decision tree leaves. The penalty period is represented by the symbol Ω, Eq. (8) and (9). The tuning parameters γ and ε regulate the complexity of decision trees. The square loss function was employed in this investigation.

$$m(\hat{o}_i, o_i) = (\hat{o}_i, -o_i)^2 \quad (10)$$

Iterative training is used for the loss function. For the $s-th$ repetition of the $i-th$ sample, we might write Eq. (8) as:

$$M^d = \sum_{i=1}^{N_t} m(\hat{o}_i^{(d-1)} + h_d(E_i), o_i) + \Omega(h_s) \quad (11)$$

XGBoost enhances the model by addingh_s, Eq. (10). The objective is optimized using a second-order approximation.

$$M^d \approx \sum_{i=1}^{N_t} \left[m(\hat{o}_i^{(t-1)}, o_i) + t_i h_i(E_i) + \frac{1}{2} p_i h_s^2(E_i)\right] + \Omega\ (h_s) \quad (12)$$

$$T_i = \varphi_{\hat{o}_i^{(t-1)}} m(\hat{o}_i^{(s-1)}, o_i) = 2 \times (\hat{o}_i^{(s-1)} - o_i), \quad (13)$$

$$G_i = \varphi_{\hat{o}_i^{(s-1)}} \ ^2m\left(\varphi_{\hat{o}_i^{(s-1)}}, o_i\right) = 2 \quad (14)$$

The first and second-order gradients are denoted as $T_i$and G_i. The equations are$m\left(\varphi_{\hat{o}_i^{(s-1)}}, o_i\right)$ Eq. (12)-(14).

An adaptive XGBoost model serves as the foundation for transfer learning, which uses parameter-based approaches. During the process of the transfer training phase, leaf weights from all trees in the adaptive XGBoost model are exchanged. It is constructed by training new trees and leaf weights. Fig. 1 illustrates the adaptive XGBoost framework.

$$\hat{o}_{2,i} = g_3(E_i) = \sum_{K_2=1}^{K_2} h_{k_2}(E_i) + \sum_{K_5=1}^{K_5} h_{k_2}(E_i), h_{k_2,} h_{k_5,} \quad (15)$$

The TF model predicts tourism for the $i-th$ sample, denoted as$\hat{o}_{2,i}$. $h_{k_2,}$Represents the trees in the enhanced XGBoost model, whereas $h_{k_5,}$is in Eq. (15). To increase the accuracy of tourism attraction predictions, the weights of leaves in $\boldsymbol{h_{k_2,}}$ are shared and newer leaf strengths in $\boldsymbol{h_{k_5,}}$are trained.

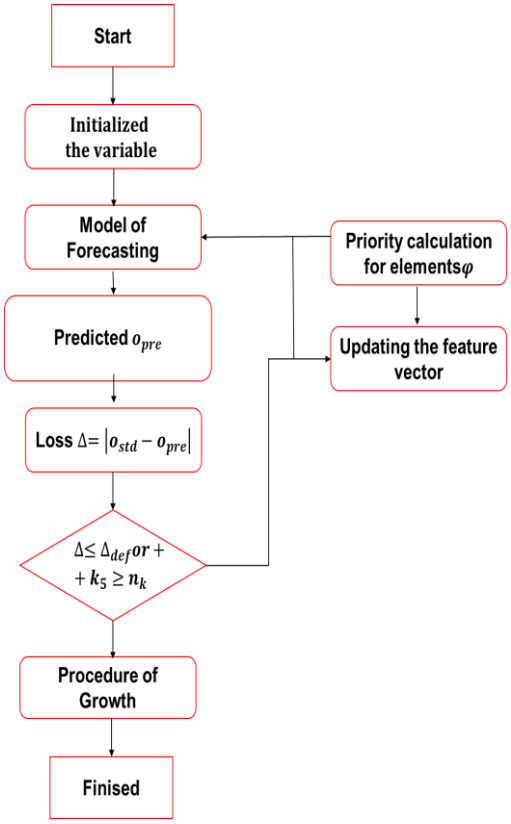

Fig. 1. Adaptive XGBoost.

3) Predicting RO-AXGBoost: The original technique that we used is called RO-AXGBoost, and it incorporates Remora Optimization, a newly developed meta-heuristic algorithm that refers to the behavior of remoras about sharks in improving the capabilities of XGBoost in predicting various aspects that are related to tourist attractions. Thus, our method of utilizing the Remora Optimization procedure to enhance the adaptiveness of XGBoost hyper-parameters enhances its quality in terms of its performance and capabilities of precisely predicting labeled tourism-related variables. These two components allow for better and more consistent forecasting, helping the entities in the tourism sector to optimize their decision-making process in terms of resource management, promotion, and visitors' handling, thereby contributing to the overall improvement of the visitors' experience and the sustainability of the destinations.

IV. Result and Discussion

Anaconda3 for Windows is utilized in this scenario on a PC powered by an NVIDIA GeForce RTX 3090 Ti GPU and 24GB of RAM. The hard drive capacity is 1TB, and the computer's processor is the Intel Core i7-8750H running at 2.20GHz. Python 3.10 is the main programming language, using TensorFlow 1.14.0 as a development framework. In the section evaluate the performance outcome for the proposed method. The proposed method is compared with existing methods and the performance is evaluated in different parameters such as MAPE, MAE, RMSE, and R^2. The existing methods are

BiLSTM [18], CNN-BiLSTM [18], MACBL [18], KNN [17], RF [17] and LR [17].

R^2 is an indicator of how accurately the variables that are independent predict the dependent variable. Fig. 2 illustrates on R^2 value. Compared to existing methods KNN (70.6), RF (74.9), and LR (76.5), our proposed method was superior (RO-AXGB 85.7). In comparison to existing methods, the suggested method RO-AXGB showed significant improvements in tourist attraction accessibility.

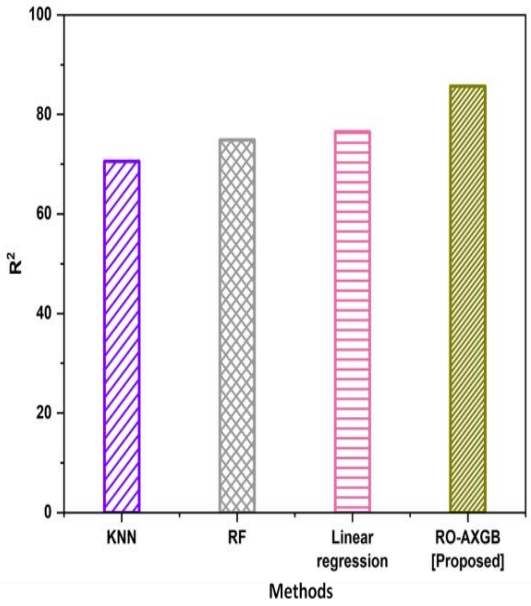

Fig. 2. Outcome of R^2.

The RMSE is the average of the squared discrepancies between anticipated and actual values. It indicates how much the model's predictions differ from the actual results, with lower values representing better performance. Fig. 3 illustrates the RMSE result. In comparison to the existing techniques BiLSTM (23.326), CNN-BiLSTM (16.354), and MACBL (13.837), our proposed is (RO-AXGB -10.241) lower than existing methods. It shows that our suggested method, RO-AXGB is effective for tourist attractions accessibility.

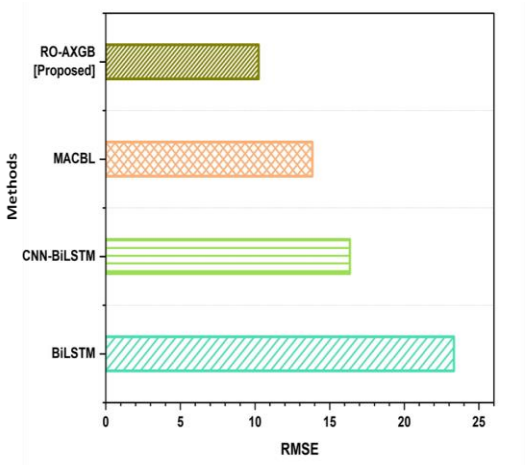

Fig. 3. Outcome of RMSE.

MAE estimates the average of the absolute differences between anticipated and actual values. It reveals information about the model's accuracy in forecasting, but it is less sensitive to extremes since it does not square the errors. Fig. 4 illustrates the MAE values. When compared to existing approaches BiLSTM (19.146), CNN-BiLSTM (11.354), and MACBL (8.928), our suggested technique is higher (RO-AXGB -7.321) than the existing method. It demonstrates that our suggested approach, RO-AXGB, successfully detects tourist attractions accessibility.

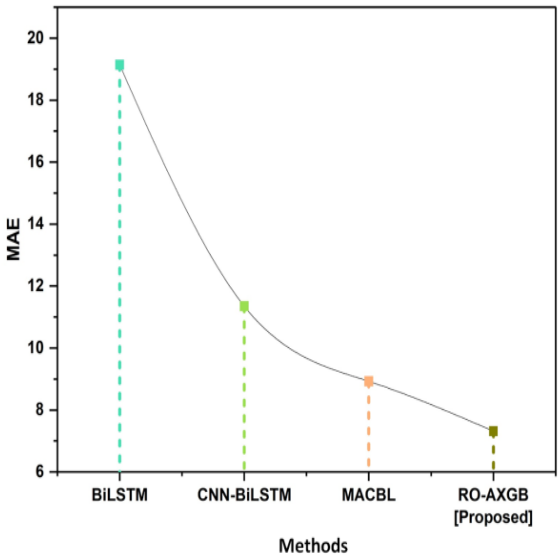

Fig. 4. Outcome of MAE.

MAPE is the average of the absolute percentage deviations between projected and actual values, represented as a percentage of actual values. Fig. 5 depicts the MAPE result and Table I illustrates the comparison of existing. When compared to the existing methods, BiLSTM (21.42), CNN-BiLSTM(16.96), and MACBL (10.21), our suggested method performs better (RO-AXGB -7.24). The successful demonstration of a tourist attraction's accessibility using the RO-AXGB approach indicates its effectiveness.

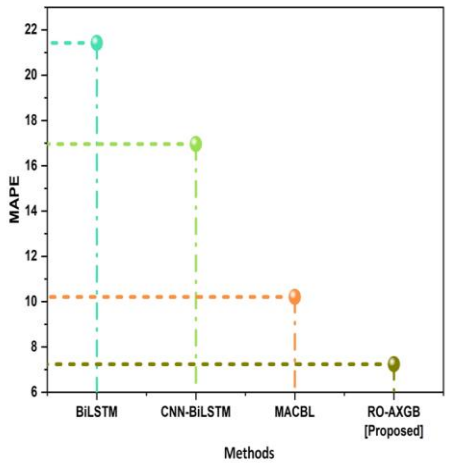

Fig. 5. Outcome of MAPE.

TABLE I. COMPARISON OF EXISTING METHODS WITH PROPOSED METHOD

Method	RMSE	MAE	MAPE	Method	R^2
BiLSTM	23.326	19.146	21.42	KNN	70.6
CNN-BiLSTM	16.354	11.354	16.96	RF	74.9
MACBL	13.837	8.928	10.21	LR	76.5
RO-AXGB	10.241	7.321	7.24	RO-AXGB	85.7

A. Discussion

Though the current methods of classifying influential factors of tourist attractions' accessibilities as BiLSTM, CNN-BiLSTM, MACBL, KNN, RF, and LR shed light on the circumstances of the objective, they all have their drawbacks. For that reason, both BiLSTM [18] and CNN-BiLSTM [18] models perform well in modeling sequential dependencies as well as spatial relations but can fail to adequately model long-range dependency and global context information. To address this issue, MACBL [18] employs a multiple-attentional mechanism in the feature extraction area to improve performance, but the additional attention mechanisms might increase the number of parameters for the resulting model and risk overfitting.

KNN [17], although the highlighted algorithm is easy to understand and implement, has its limitations regarding its scalability and effectiveness when applied to datasets containing high dimensions. RF [17] has high resistance to overfitting and nonlinearity but can have a low capacity for modeling high-level interactions among the variables. As a flexible, interpretable, and easy-to-implement method, LR [17] might not have the ability to capture the interactions and complex functional forms between the variables. Thus, although all of these methods yield valuable insights to analyze tourist attractions' accessibility, their flawed aspects point out to continued need for research and possibly a combination of all the methods to provide effective solutions regarding the various angles of the problem.

The drawback tackled, in this paper RO-AXGBoost provides an innovative approach for the interpretation of perturbing variables in the case of tourist attraction availability. Effectively applying the optimization techniques and the incorporation of adaptability to the equations make RO-AXGBoost highly efficient in capturing patterns of accessibility, which can aid in sound decision-making processes in the tourism sector. Its strength can be attributed to its capability to deal with big data, particularly concerning operating and learning in fluctuating environments and delivering solutions with noteworthy speed and accuracy.

This study's results show that the suggested remora-optimized adaptive XGBoost (RO-AXGBoost) technique outperforms previous methods in forecasting accessibility factors for tourist attractions. RO-AXGBoost outperformed other techniques (KNN, RF, and LR) in predicting accessibility-related variables, with an R^2 value of 85.7%. Additionally, the technique surpassed models like BiLSTM, CNN-BiLSTM, and MACBL in terms of MAE (7.321) and MAPE (7.24), demonstrating its superior accuracy in reducing prediction errors. However, in terms of RMSE, RO-AXGBoost produced a moderate outcome, indicating the necessity for future improvement in some situations. Compared to previous research that used BiLSTM and CNN-BiLSTM, which are efficient at capturing sequential data but have constrained long-range dependency managing, RO-AXGBoost's incorporation of optimization methods and adaptive learning proved useful in handling larger datasets and intricate interactions. This study presents a new combination of remora optimization and XGBoost, a method that not only improves efficiency but also tackles the constraints of previous models, resulting in more precise and effective predictions in tourism accessibility research.

To guarantee the resilience and validity of the suggested RO-AXGBoost method, cross-validation methods like k-fold cross-validation were used to decrease possible overfitting while also providing an accurate assessment of the model's generalization capacity. Furthermore, the suggested approach was compared to closely associated methods, like Gradient Boosting Machines (GBM) and XGBoost, which use boosting methods to enhance efficiency. While both GBM and XGBoost provide significant accuracy gains in intricate datasets, RO-AXGBoost incorporates adaptive optimization and feature weighting tactics, improving its capacity to handle high-dimensional data more efficiently. In comparison to XGBoost, which can struggle with particular dynamic trends, the RO-AXGBoost method handled accessibility-related perturbations more effectively because of its flexibility in handling various variables. Additionally, unlike GBM, which has higher computational expenses, RO-AXGBoost optimized execution speed, especially in environments demanding rapid decisions, rendering it ideal for tourism applications where quick accessibility knowledge are critical. The findings show that the RO-AXGBoost method improves both accuracy and speed, surpassing comparable techniques.

V. CONCLUSION

This research proposed an innovative remora-optimized adaptive XGBoost (RO-AXGBoost) technique for predicting important parameters influencing tourist attraction accessibility. The technique outperformed previous algorithms in prediction accuracy and precision, as measured by famous metrics like MAPE, MAE, RMSE, and R^2. Key factors impacting accessibility were successfully discovered, presenting useful information for tourism management and urban planning. However, while the technique produced impressive outcomes, some constraints must be acknowledged. The moderate RMSE values indicate possible fields for improvement, especially in dealing with variability and outliers in the data. Furthermore, while the study concentrated mainly on accessibility, further investigation into other dimensions of tourist satisfaction, like convenience and environmental sustainability, could offer a more extensive picture of the tourism industry's difficulties.

Future work could include incorporating real-time data to improve the model's flexibility in dynamic settings, as well as investigating more sophisticated optimization methods to further decrease prediction errors. Furthermore, integrating factors such as tourist desires, environmental concerns, and

sustainability into the model would provide more detailed insights into tourism planning and management. Extending the model to include various kinds of attractions and geographies may also enhance its generalizability and applicability in wider tourism settings.

***Abstract*—Transportation management in Egypt faces challenges such as congestion, inefficiency, and a lack of transparency. This work proposes a smart contract-based transportation framework to address these issues and enhance the efficiency of Egypt's transportation system. By leveraging blockchain technology, smart contracts can facilitate and enforce decentralized and immutable transportation agreements. This approach also fosters increased trust among stakeholders and improves interactions between service providers. This paper presents a conceptual framework that integrates smart contracts, blockchain technology, GPS data, and sensor technologies to further optimize transportation operations. Empirical analysis and case studies demonstrate the effectiveness of smart contracts in improving the shipping registration system. The survey results show that smart contracts streamline processes enhance data security, reduce costs, and improve accuracy. The proposed model, developed on the NEAR platform, outperforms traditional methods and Ethereum-based models by offering faster registration, better cost-efficiency, and improved transaction tracking. This demonstrates the potential for modernizing and optimizing Egypt's transportation sector**.

***Keywords*—Blockchain; cryptography; logistics; smart contracts; transportation; security and privacy; supply chains**

I. Introduction

This Transportation is vital to the global economy, as it connects resources for manufacturing and delivers finished products to customers. However, this fundamental industry faces challenges such as speed, cost-efficiency, and safety [1]. The process of transportation is intricate and demands careful planning, coordination, and implementation. The transportation process commences with route planning and the selection of carriers [2]. Companies must determine the most efficient and cost-effective routes while selecting the appropriate transportation carriers based on various factors. This decision impacts both the timeliness of delivery and the cost-effectiveness of the entire process. Freight booking, loading, unloading, and proper documentation ensure the security, tracking, and legal compliance of goods throughout their journey [1]. Freight tracking, last-mile delivery, risk management, effective communication, and coordination are essential components that keep the supply chain running smoothly [3]. Modern technology, including GPS and communication systems, has revolutionized transportation by enabling real-time tracking and responsive problem-solving. In the end, transportation serves as the linchpin that ensures products reach their intended destinations efficiently, reflecting its pivotal role in modern commerce and customer satisfaction [4]. An innovative solution gaining attraction in the transportation sector is the utilization of smart contracts. Smart contract technology is a digital transaction protocol that seeks to establish agreements between multiple parties by automatically executing the contract's conditions. Smart contracts are disintermediated and typically transparent, offering reduced legal and transaction costs, enhanced business efficiency, and the possibility of anonymous transactions. Due to these attributes, smart contract technology is in high demand, particularly in the financial industry where it can mitigate the risks of fraud and nonpayment and enhance the quality of financial contracts with a certain degree of confidence, all without the involvement of intermediaries.

Smart contract technology has emerged as a robust tool for enhancing efficiency and security in various industries, including transportation [5]. However, its implementation in transportation faces specific challenges related to standardization, interoperability, reliable data inputs, and alignment with regulations and compliance requirements.

In general, smart contracts hold significant promise for building more reliable and effective transportation systems, ultimately improving product security, safety, and the timely delivery of shipments. This research paper investigates the potential applications of smart contracts in the field of transportation management. It explores a set of applications for smart contracts, including functions like shipment tracking, digital documentation management, and route optimization. Our analysis suggests that smart contracts have the capacity to revolutionize the transportation and logistics landscape, ushering in improvements characterized by swifter operations, cost-effectiveness, and heightened safety protocols.

This paper introduces a multi-layered smart contract framework tailored for logistics and smart transportation in Egyptian transportation, with the aim of addressing tracking and security issues inherent in transportation processes [6]. Smart contracts can enhance performance, reduce risks, mitigate fraud,

and improve efficiency, transparency, and tamper-proof capabilities [6]. These smart contracts are typically deployedon blockchain technology platforms like Ethereum, which provide a secure, transparent, and tamper-proof environment [8]. Blockchain's trusted and decentralized infrastructure is ideal for executing self-executing contracts. In the transportation industry, smart contracts can play a pivotal role in automating the execution of agreements among various parties involved, such as shippers and carriers [7]. Their applications encompass verifying the authenticity of goods, tracking shipments, ensuring compliance with rules and contractual obligations, automating processes, mitigating fraud risks, and enhancing security. Furthermore, they streamline payment procedures and automate financial transactions.

This paper is organized as follows: Section II provides a background on smart contracts. Section III introduces the related works in using smart contract in transportation. Section IV presents the proposed framework for Smart Contracts in transportation. Section V discusses the proposed framework. Implementation is given in Section VI. Results are analysed in Section VII. Finally, Section VIII presents conclusion.

II. BACKGROUND

Smart contracts are software components that automate the execution of contract terms and function as self-executing agreements. They address the limitations of traditional procedures and offer a performance level that reduces risks, minimizes fraud, and enhances efficiency, transparency, and security. Blockchain technology is an ideal platform for implementing smart contracts, providing a trusted and decentralized infrastructure for executing these agreements. Platforms such as Ethereum frequently utilize blockchain technology to offer a secure, transparent, and tamper-proof environment for smart contracts.

Smart contracts have diverse applications across industries, including finance, real estate, healthcare, transportation, and supply chain management. In the healthcare sector, they facilitate the secure exchange of patient data, while in real estate, they automate and secure property transfers. In supply chain management, they create transparent transaction records that assist managers in tracking products from their origin to their final delivery destination.

In transportation, smart contracts enable real-time tracking of goods, offering companies increased visibility and insights into their operations. These contracts streamline transportation processes by swiftly and securely automating various tasks, thereby enhancing overall efficiency. They facilitate agreements among parties such as shippers and carriers, verify the authenticity of goods, track shipments, and ensure compliance with rules and contractual obligations. Beyond process automation, smart contracts reduce fraud risks, enhance security, streamline payment procedures, and automate financial transactions, ultimately contributing to the development of more reliable and effective transportation systems. This improves product safety, ensures on-time delivery, and enhances overall security.

However, challenges exist in implementing smart contracts in transportation, including standardization and interoperability across different blockchain platforms and the need for reliable data inputs to ensure accurate contract execution. Additionally, smart contracts require careful preparation of contract terms and adherence to regulatory and compliance requirements.

A. Layers of Blockchain and Smart Contracts

The fundamental elements of blockchain and smart contracts can be categorized into five layers, as illustrated in Fig. 1: buyer and seller, applications, verification, blockchain types, and network.

First Layer: In this layer, Real Estate Registration and Documentation Authority employees are responsible for inputting buyer data.

Second Layer: In the second layer, developers create various applications for smart contracts, including back-end programs, front-end programs, and decentralized applications (DApps).

Third Layer: In this layer, individuals are responsible for transaction verification before registration, as well as the types of consensus algorithms employed.

Fourth Layer: In the fourth layer, we focus on the methods used for recording and storing transactions, including options like Private Blockchain, Public Blockchain, or Consortium Blockchain.

Fifth Layer: The final layer addresses the network used for registering smart contracts, which is a peer-to-peer network. This network consists of interconnected computer systems via the Internet, without a central server. It incorporates various cryptographic technologies, public-key encryption, and platforms for smart contracts such as NEAR, Ethereum, and Hyperledger. Transaction storage is managed through virtual storage for all participants on the platform.

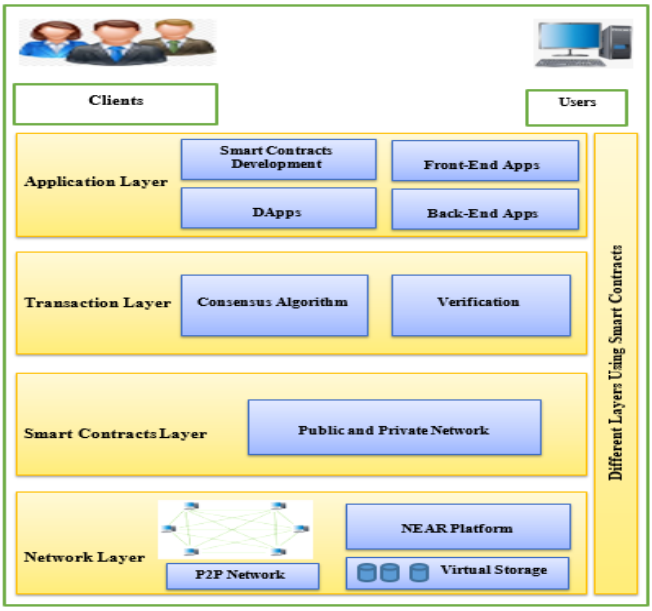

Fig. 1. Layers of smart contracts using blockchain.

B. Blockchain Types

1) Blockchain technology is categorized into three types: federated blockchain, public blockchain, and private blockchain. Each type is elaborated on as follows:

2) Public blockchain: A public blockchain allows anyone to join the network, verify transactions, and participate in consensus processes without disclosing their identities. Participants can send and receive transactions, validate blocks, and offer incentives to those who validate blocks. Public blockchains are unrestricted, and examples include platforms like Bitcoin and Ethereum [9].

3) Consortium or federated blockchain: Consortium or federated blockchains are not open to everyone; they are semi-private, with each participant having equal authority. Platforms like Corda and R3 are examples of this type [10].

4) Private blockchain: Private blockchains are networks accessible only to specific companies or banks, with stringent access control and a predefined set of nodes that are aware of each other. Examples include Monax and Multichain [11].

C. Blockchain Characteristics

Blockchain technology possesses a set of characteristics that make it a compelling solution for addressing various challenges [23].

1) Decentralized: One of blockchain's fundamental characteristics is its decentralization. It eliminates the reliance on centralized nodes to record and store data, opting for a decentralized, distributed ledger [12].

2) Immutable: Records stored in a blockchain are permanent and unalterable unless someone gains control of more than 51% of the network nodes simultaneously [24].

3) Open source: Most blockchain systems are open for public inspection, and users can harness blockchain technology to develop various applications, including smart contracts, cryptocurrencies, voting systems, healthcare solutions, insurance platforms, and supply chain tracking [13].

4) Transparent: Data records in a blockchain are transparent to all nodes, fostering trust during data updates.

5) Autonomous: Blockchain nodes can securely transfer data based on consensus algorithms [14].

6) Anonymity: Blockchain transactions provide anonymity by concealing the identity of the transaction executor and stored data [15].

7) Security: Blockchain offers enhanced security as there isn't a single point of breakdown capable of disrupting the entire network.

8) Increased capacity: The collaborative efforts of thousands of computers within a blockchain network enhance the overall network capacity [12].

D. Structure of Blockchain Data

The core data structure used in blockchain systems is a 'block,' with each block containing a distinct number known as a 'hash value.' This hash value is cryptographically generated using the SHA-256 algorithm and stored in the block's header. The cryptographic hash function takes any input string and produces a 64-bit hash value as output [15].

Key components of the block header include the block number and metadata, which encompass identification numbers, reference numbers, timestamps, and dates. Each block also references the previous block through its hash value or block number, forming a chain that allows all connected blocks to access the complete history [16]. The 'nonce' is the result of transaction processing with the assistance of a cryptographic hash algorithm (SHA-256) following encryption and data validation [25].

E. The Peer-to-Peer (P2P) Blockchain Network

The peer-to-peer network (see Fig. 2), often referred to as a P2P network, is a decentralized architecture in which computer systems are directly interconnected via the internet, eliminating the need for a central server. [21] This approach to networking follows a decentralized and distributed application model, dividing tasks or workloads among peers [26]. Participants in this network enjoy significant freedom in terms of connectivity. Additionally, the blockchain network relies on data cryptography technology for secure data transfer [22].

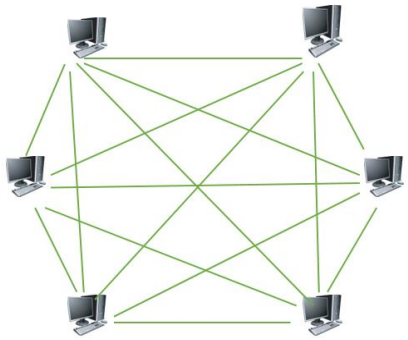

Fig. 2. Peer-to-peer blockchain network.

III. Related Works

In this section, the utility of smart contracts in transportation is investigated. The following subsections are categorized based on their applications of smart contracts to address transportation-related tasks. These tasks include intelligent electric vehicle systems, supply chain management, safety, security, traceability, mobility-as-a-service ecosystems, data management, real-time tracking, and cargo information [27].

A. Intelligent Electric Vehicle Systems and Road Safety

Several studies have demonstrated the effectiveness of using smart contracts in a blockchain-based electric vehicle transportation system. Byun et al. [29] developed an inference engine that enhances security and privacy by processing EV sensor data on the blockchain. This system efficiently manages the growing data flow from electric vehicles. On the other hand, Singh et al. [30] utilized smart contracts to establish trust in a blockchain-based Internet of Vehicles. Their approach addressed security and privacy concerns among untrusted vehicles, ultimately improving road safety and traffic efficiency. They also introduced measures to enhance scalability and transaction throughput. In addition to these works, Hou et al.

[42] explored the use of smart contracts within Decentralized Autonomous Organizations to streamline governance in Intelligent Transportation Systems (ITS). They proposed a DAO framework to simplify complex transportation systems. This innovation represents a promising future trend in ITS development.

However, these studies have focused on the security and trustiness of the blockchain based system. This gap in knowledge highlights the need for further research to explore the effectiveness of these systems to satisfy managerial needs of the stakeholders and the managers.

B. Supply Chain Management and Logistics

Several studies have demonstrated the effectiveness of using smart contracts in a blockchain-based supply chain management and logistics for automatic payment, cost reduction and transparency enhancement. For automatic payment in supply chains, Banerjee et al. [32] implemented smart contracts within an Intelligent Transport Management System based on blockchain (I-TMS) to automate toll-tax collection in supply chains. This approach ensures data security, transparency, and privacy through the decentralized and transparent nature of blockchain. Through the authentication of vehicle data, smart contracts enable automatic toll collection without the need for vehicle stops, resulting in fuel savings, improved time efficiency, and enhanced data security compared to traditional RFID-based systems. Furthermore, Baygin [33] employedsmart contracts in a blockchain-based fast shipping management architecture for local cargo networks to establish an automatic payment and approval mechanism. To reduce costs in transportation, smart contracts, as introduced by Philipp et al. [11], utilize blockchain technology to automate processes, reducing intermediaries and transaction costs within the transportation industry. [28] These contracts promote cross-organizational collaboration, particularly benefiting entrepreneurs and small and medium-sized enterprises by facilitating their entry into transnational supply chains. The abstract emphasizes the role of blockchain smart contracts in enhancing collaborative logistics and ensuring SME integration in sustainable maritime supply chains, highlighting their potential in transnational and multimodal supply chain environments.

In a study by Manimuthu et al. [17], smart contracts were employed in transportation to improve sustainable supply chain operations within the Autonomous Vehicles industry. This approach enhances traceability, transaction transparency, and sustainability, while also fostering the emergence of innovative AV business models. In personalized transportation, Chinaei et al. [38] utilized smart contracts within the transportation sector to promote the Mobility-as-a-Service concept. These contracts enable personalized transport service ownership through blockchain technology, providing a secure and private exchange of ownership. Their paper introduces a blockchain-driven MaaS platform that utilizes smart contracts to personalize service ownership, address congestion, and facilitate data trading among stakeholders, ultimately enhancing transportation service efficiency and convenience. To enhance transparency and security, Terzi et al. [63] employed smart contracts in supply chain management. These contracts enable product logging and tracing, ensuring unique item identification from factory to customer. Blockchain technology is also employed for user authentication and authorization, enhancing network security and trust while preserving data confidentiality. These smart contracts facilitate efficient interactions and trust amongsupply chain participants in real-life scenarios.

However, these studies have focused on partial aspects of the blockchain based systems. This gap in knowledge highlights the need for further research to explore the expandability and completeness of these systems to satisfy managerial needs of the stakeholders and the managers.

C. Safety, Security, and Traceability

Several studies have focused on ssafety, ssecurity and ttraceability of using smart contracts in a blockchain-based supply chain management. For example, in [18], Zichichi et al. employed smart contracts to coordinate data sharing in a smart transportation system using distributed ledgers such as Ethereum, IOTA, and IPFS. [19] These contracts enable secure and automated sensor data exchange while preserving privacy through Zero Knowledge Proof, fostering innovative smart services and societal benefits in user mobility. Similarly, Valencia-Payan et al. [36] utilized smart contracts to monitor and ensure coffee bean quality during transportation and storage via Blockchain technology. Their Hyperledger Fabric-based smart contract automates condition verification and enhances traceability, offering fast throughput and low latency suitable for real-world applications in the transportation and quality control of coffee beans. On the other hand, Imeri et al. [28] appliedsmart contracts to enhance security and traceability during the transportation of hazardous materials. Their conceptual approach employs blockchain-based smart contracts to securely share sensitive information while maintaining transparency and auditability. Authorized parties' access and interact with the data, ensuring the safe movement of dangerous goods. Moreover, Valchanov et al. [39] utilized smart contracts in transportation to improve safety in the transportation of special and hazardous cargo. Their model combines blockchain and IoT technology to record real-time sensor data and trigger smart contracts for stakeholder notifications when thresholds are breached. This expedites insurance claims and enhances safety. Finally, Mihelj et al. [41] developed a system for real-time identification of road traffic events and evaluation of source reputation using smart contracts in the transportation industry. This approach effectively detects manipulative behaviors, maintaining data integrity for safer transportation.

Generally, this research enhances trust and eliminate single authority control, ensuring reliable and secure traffic data collection and assessment.

However, these studies have focused only on safety, ssecurity, and ttraceability of the smart contracts in transportation systems. This gap in knowledge highlights the need for further research to explore the business requirements and the managerial needs of these systems.

IV. Mobility-as-a-Service (MaaS) Ecosystems

Several studies have focused on using smart contracts to serve as Mobility-as-a-Service (MaaS) ecosystems in transportation systems. For example, Chinaei et al. [37] employed smart contracts in transportation to advance the MaaS

concept using blockchain technology. These contracts enable personalized ownership of transport services, ensuring secure exchanges with privacy preservation. The paper introduces a blockchain-based MaaS platform, powered by smart contracts, to customize service ownership, manage congestion, and facilitate data trading among stakeholders, thus enhancing transportation efficiency and convenience. Additionally, Tallyn et al. [40] explored smart contract applications in transportation, with a specific focus on optimizing last-mile deliveries to improve precision, coordination, and accountability.

Furthermore, Karinsalo et al. [44] harnessed smart contracts in transportation to enable seamless and reliable transactions within Mobility-as-a-Service (MaaS) ecosystems, leveraging both blockchains and artificial intelligence. The proposed model, exemplified by Travel Token, employs blockchain-enabled smart contracts to store travel data, ensure dataintegrity, and automate value-sharing and compensation processes, thereby enhancing the efficiency and reliability of travel experiences while meeting industry demands.

However, these studies have focused on personalized ownership of transport services in transportation systems. This integration of smart contracts raises important questions about balancing automation with personal values, relationships, and individual agency within the transportation sector. This gap in knowledge highlights the need for further research to address evolving business needs in the MaaS field.

A. Data Management and Insurance

Several studies have focused on data management and insurance of smart contracts in transportation systems. Wanget al. [31] utilized smart contracts to establish an auditable payment and asset delivery protocol in transportation, ensuring transparent and secure transactions. This protocol enhances fairness, traceability, and security by leveraging blockchain technology, thereby addressing third-party payment and security issues. Balasubramaniam et al. [20] applied dimensionality reduction techniques and blockchain in transportation to present verifiable digital evidence while minimizing data for efficient storage on the blockchain. Smart contracts facilitate datasharing among insurance companies, enhancing data integrity within Intelligent Transportation Systems (ITS).

Furthermore, Quoc et al. [43] introduced the 'Safe Seller Safe Buyer' (SSSB) system in transportation, which eliminates intermediaries. Smart contracts include rules for conflict resolution and penalty enforcement, providing insurance-like protection. Lastly, Valencia-Payan et al. [28] applied smart contracts in goods transportation, with an emphasis on traceability and transparency in social selling.

However, these studies have focused on data management, insurance and safety in transportation systems without emphasizing on the global ecosystem interaction and collaboration. This gap in knowledge highlights the need for further research to address evolving business needs in the global ecosystem.

B. Real-Time Tracking and Decision-Making

Several studies have focused on role of smart contracts in transportation systems for real-time tracking and decision making. Arumugam et al. [34] applied smart contracts in transportation for advanced supply chain management and logistics, utilizing real-time IoT tracking and decision-making processes. These contracts allow users to establish trust and enforce conditions, ensuring visibility and traceability throughout the supply chain. Their proposed smart logistics system combines condition monitoring, logistics planning, and smart contracts to enhance accountability and efficiency in supply chain asset management. To enhance transportation management, Hasan et al. [35] employed smart contracts on the Ethereum blockchain for efficient supply chain management in transportation, with a focus on tracking and managing global trade shipments. These contracts govern stakeholder interactions, automate payments, and enforce predefined shipping conditions for IoT-equipped smart containers. This technology enhances transparency, security, and automation in complex logistics, with potential applications in vaccine supply chain management. Additionally, Arumugam et al. [42] used smart contracts in transportation to improve supply chain management and logistics through real-time tracking and decision-making with IoT devices. These contracts enable trust and enforceability, providing visibility and traceability throughout the supply chain. Their proposed smart logistics system integrates condition monitoring, logistics planning, and smart contracts to enhance accountability and efficiency in supply chain asset management. This streamlines document processing, reducing errors and manipulation, while enhancing efficiency and saving time and costs. Automation ensures the immutability, trust, and privacy of the blockchain, thereby improving the speed of the shipment process.

These studies have focused only on real-time tracking and decision making. This gap in knowledge highlights the need for further research to address other business needs in the transportation ecosystem.

C. Cargo Information and Traceability

Several studies have focused on role of smart contracts in transportation systems for tracking Cargo Information and Traceability. For example, Munari et al. [45] investigated smart contract usage in transportation, focusing on the Tradeless platform, a permissioned blockchain for real-time cargo data. Concerns arose regarding data transparency's anti-competitive effects and sensitive information exposure among competitors. The work explores blockchain and smart contracts' impact on transportation, highlighting changing transport patterns and reduced transmission of personal or sensitive data.

These studies have focused only on cargo information. This gap in knowledge highlights the need for further research to address other integrated business needs in the transportation ecosystem.

V. Proposed Framework for Smart Contracts Based Transportation

The transportation industry in the Arab World is one of the most lucrative sectors, with revenues increasing annually. Smart contracts have introduced new forms of interactions, suchas the reliable logging of transit traffic, which was previously unmanageable with traditional systems. The conventional transportation system in Egypt and other countries is slow and cumbersome, relying heavily on multiple intermediaries. By

integrating blockchain technology into the transportationsector, real-time tracking of transportation movements can be verified on a unified blockchain platform, ensuring transparency, high security, a decentralized environment, and a distributed ledger.

This paper proposes a formal method to ensure compliance with existing smart contract regulations and assign liability. The objective is to develop a distributed system that securely manages transactions to accelerate movement, streamline transfers, and address various transportation-related tasks. These tasks include supply chain management, safety, security, traceability, mobility-as-a-service ecosystems, data management, real-time tracking, and cargo information all without requiring vehicles to stop at toll plazas. This approach ensures data security, transparency, and privacy through the decentralized and transparent nature of blockchain. By authenticating vehicle data, smart contracts facilitate automatic toll collection without the need for stops, leading to fuel savings, improved time efficiency, and enhanced data security compared to traditional RFID-based systems.

Smart contracts, implemented on platforms such as NEAR and Ethereum, enable secure communication between parties and efficient tracking and tracing of RFID-tagged shipments using Internet of Things (IoT) and Ultra-High Frequency (UHF-RFID) sensors. This paper highlights an encouraging trend for the future development of Intelligent Transportation.

A. The Traditional Transportation System

In traditional transportation systems, customers typically visit the transport company in person to submit all necessary documents verifying their ownership of the goods. Afterward, the customer pays the required transportation fees and receives an invoice that includes the expected delivery date. One of the major drawbacks of traditional land transport is the lack of goods tracking, insufficient driver oversight, and inflexible scheduling. These issues can lead to damage to certain goods and increase the risk of theft due to the absence of tracking and a clear understanding of the different stages of the goods' journey, as illustrated in Fig. 3.

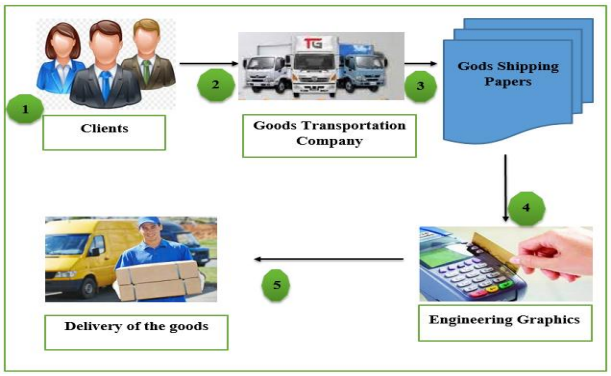

Fig. 3. Traditional transportation system in Egypt.

B. Smart Contract based Transportation System

This work proposes a framework for tracking transportation movements in Egypt using smart contracts and blockchain technology. The framework documents the transportation of goods through smart contracts facilitated by blockchain technology. Customers enter into an agreement with the transport company and provide all necessary documents verifying the ownership of the goods.

The shipping company then records the transaction on the smart contract, creating a new record and assigning a unique identifier to track the shipment. Blockchain technology simplifies shipping operations significantly by enabling direct and secure tracking of shipments at all stages. This is achieved through the integration of GPS (Global Positioning System, which provides positioning, navigation, and timing services) with sensors—electronic devices that monitor physical attributes such as temperature, pressure, distance, speed, torque, and acceleration.

The system consists of three chips: a space chip, a control chip, and a user chip, along with a mobile chip. These devices are attached to the goods cart, allowing precise monitoring of shipment details, tracking the status of shipments, and connecting the information to the smart contracts network. The proposed system aims to improve traceability, transparency, information security, and the immutability of data stored and exchanged during various operational processes in a decentralized manner, thereby eliminating the need for intermediaries or third parties, as illustrated in Fig. 4.

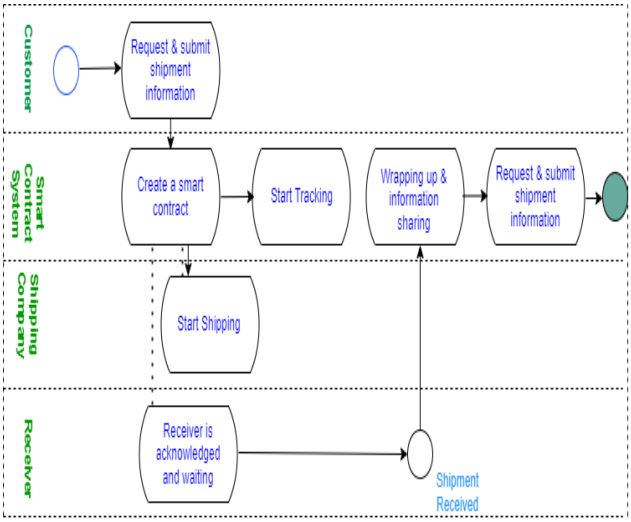

Fig. 4. The Proposed framework for tracking transportation in Egypt.

VI. Implementation

We will implement the proposed framework for smart contracts, designed to facilitate the registration and tracking of goods and commodities using blockchain technology. The protocol has been developed and executed on the NEAR platform. Smart contracts are integral in establishing a distributed, secure, and decentralized ledger to safely record all assets and transactions between parties. Our model is developed using Assembly Script and Rust programming languages and operates on the NEAR platform, a decentralized application based on blockchain technology, where it meticulously stores all transaction records related to the goods tracking process.

During the design phase, the necessary input forms are defined and translated into code programs. These screens include various functions such as user login, registration of buyer and seller information, payment processing, document

review and validation, smart contract creation, TXN hash, and ID property generation. The NEAR platform is notable for offering the lowest transaction fees, approximately $0.0001 per transaction, and supports up to 100,000 transactions per second (TPS), outperforming many other platforms.

A. Testing and Assessment

This study addresses two types of assessments: statistical analysis and performance evaluation.

B. Statistical Analysis

The primary objective of the surveys is to examine the feasibility of adopting smart contracts based on blockchain technology as an alternative to the conventional shipment registration system in Egypt. This research employs a questionnaire study to validate the proposed model's effectiveness and a survey to assess the impact of various factors on the adoption of blockchain-integrated smart contracts within the Egyptian shipment registration system.

The questionnaire evaluates the influence of independent variables, such as data availability, location accessibility, ease of transaction verification, transaction comprehension, data accuracy, data immutability, cost reduction, affordable contract execution, and improvements in process efficiency, on the dependent variable: the integration of blockchain technology with the Egyptian cargo tracking infrastructure.

The research sample was carefully selected based on relevant criteria and included individuals with a keen interest in blockchain and smart contracts, IT specialists, and professionals involved in the shipping industry. The proposed framework was introduced and practically demonstrated to each member of the research sample, followed by initial testing to ensure the model's practical applicability.

The sample consisted of 127 participants interested in the study's subject matter. The study on hand categorized the sample into groups of questions concerning blockchain, smart contracts, the questionnaire format, and the total number of questions (15). This section presents the conclusions drawn from the survey data analysis, which was conducted using the Statistical Package Table II summarizes that.

Table I illustrates a Comparison of Some of the most popular Smart contract platforms.

This section discusses a comparison of the five most popular smart contract platforms Hyperledger Fabric, Ethereum, NEAR, Solana, and Cardano, highlighting their main characteristics like Transaction per second (TPS), Average transaction fee, Network type, Programming Language, Market Capital, and highlighting the importance of using the NEAR platform Table I summarizes that.

TABLE I. PLATFORM COMPARISON

Description	Ethereum	NEAR	Hyperledger Fabric	Solana	Cardano
Used Language	Solidity	Assembly Script, Rust	JavaScript, Go	C, Rust	Plutus

VII. RESULTS AND FINDINGS

The survey findings reveal that a significant majority of respondents hold positive views regarding the adoption of smart contracts. Notably, 96% of participants found it convenient to access data and monitor shipments and logistics using smart contracts and cryptography. Additionally, 92% acknowledged that smart contracts enhance security and privacy for all stakeholders involved. A substantial 84% agreed that the integration of smart contracts eliminates intermediaries acting as third parties between sellers and buyers. Furthermore, 93% concurred that using Transportation in blockchain technology in conjunction with Supply chains and smart contracts helps mitigate tax evasion, as illustrated in Fig. 5.

The survey results indicate that 90% of respondents believe that smart contracts effectively regulate the shipping tracking process, while 89% agree that employing blockchain technology alongside smart contracts helps reduce tax evasion. Additionally, 79% observed significant changes in the electronic shipping registration process compared to traditional methods. Notably, 17% of respondents acknowledged the inefficiency and sluggishness of traditional contract registration procedures. The questionnaire results strongly support the notion that incorporating blockchain technology and smart contracts into the shipping registration process in Egypt would provide various benefits, including rapid access to transaction information, streamlined verification processes, improved data accuracy, increased reliability, and significant cost reduction.

The survey findings suggest that adopting blockchain technology in conjunction with smart contracts for shipping registration in Egypt, offers advantages such as fast access to shipment location data, simplified transaction verification, improved data precision, enhanced reliability, and substantial cost savings.

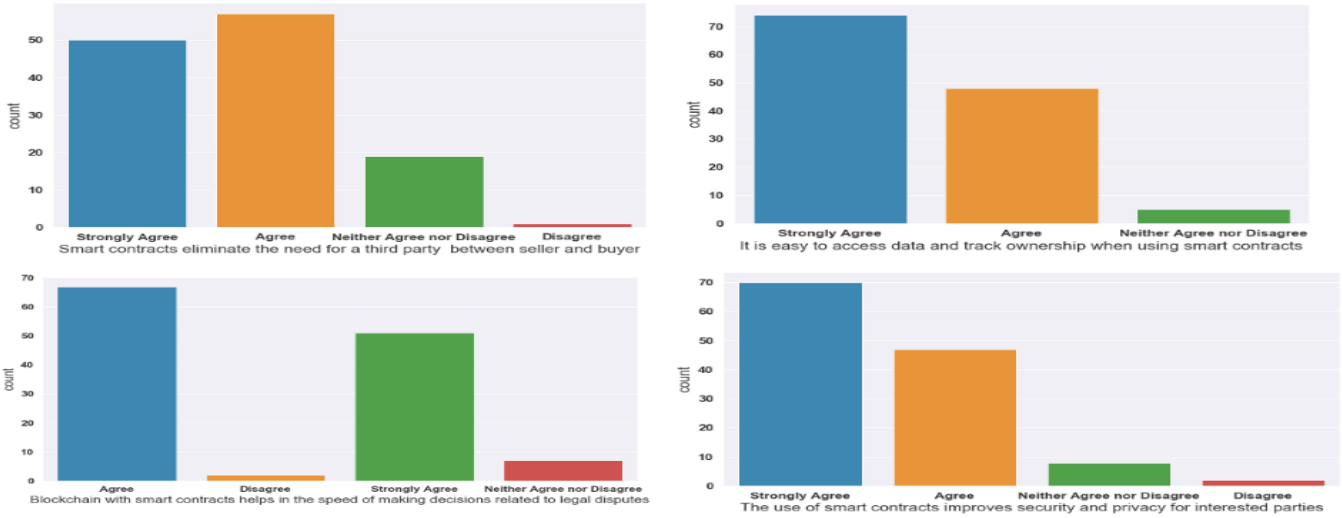

Fig. 5. Analysis results.

To further evaluate the model's performance, the proposed smart contract model was deployed on the NEAR platform, and its performance was compared to other smart contract platforms. The smart contract was written in Assembly Script on the NEAR Web3 platform. The model effectively addresses shipping registration challenges in Egypt and demonstrates superior attributes compared to Ethereum-based smart contracts. It successfully resolves issues related to registration time, sequencing characteristics, cost-efficiency, and transaction speed. While smart contract development can be performed on various blockchain platforms, the choice of platform is influenced by decentralized application storage techniques.

In our view, the positive response to smart contracts demonstrates the significant potential of this approach to transform Egypt's transportation sector. The high percentages in the results confirm the practicality of integrating smart contracts. Additionally, the reduction in tax evasion and the increased registration efficiency offer promising implications for economic governance and operational sustainability. However, challenges related to classical bureaucratic processes still need to be addressed Table III summarizes that.

VIII. Conclusion

This study demonstrates how smart contracts and blockchain technology can significantly improve transportation and logistics in Egypt. It addresses key challenges such as congestion, inefficiency, and a lack of transparency in conventional systems. Our smart contract framework, powered by blockchain technology, offers a secure and decentralized method for transportation management, streamlining processes and addressing logistical tasks such as supply chain management and real-time tracking. The framework, implemented on the NEAR platform, outperforms traditional methods by delivering improved information accessibility and enhanced privacy. The features of the framework include the integration of technologies, user-focused design, decentralization, and the scalability of the NEAR model. Survey results indicate a 96% increase in convenience for data access, a 92% improvement in privacy and security, and an 84% reduction in the need for intermediaries. Other results indicate a 93% increase in the mitigation of tax evasion and a 93% improvement in shipping registration. While the framework provides promising results, further research is needed to improve scalability and address potential regulatory challenges. Future work could recommend integrating analytics and machine learning to further optimize logistics or applying the model to other industries. In addition, further investigation can be conducted into IoT integration, regulatory frameworks, cross-border applications, environmental impact studies, blockchain scalability, and cybersecurity risk evaluation. In conclusion, smart contracts and blockchain technology hold significant potential for transforming transportation management, particularly in Egypt."

Enhancing Educational Outcomes Through AI Powered Learning Strategy Recommendation System

Daminda Herath, Chanuka Dinuwan, Charith Ihalagedara, Thanuja Ambegoda
Department of Computer Science and Engineering, University of Moratuwa, Sri Lanka

***Abstract*—In order to develop intelligent learning recommendation systems, the work identifies the employment of artificial intelligence (AI) techniques, particularly in the educational data mining (EDM) field. The aggregation of such educational data into an efficient analytical system could also assist as an interesting means of education for the students. In fact, it could ultimately advance the direction of education. Sophisticated machine learning methods were employed to analyze various data types, including educational, socioeconomic, and demographic data, to predict student success. In this research, Logistic Regression (LR), Random Forest (RF), Support Vector Machines (SVM), CatBoost, and XGBoost algorithms were considered to build prediction models using a dataset encompassing a wide range of student traits. Robust evaluation metrics, including precision, recall, accuracy, and F1-score, were used to gauge model effectiveness. The results highlighted that RF was the best with accuracy, precision, and recall. Then, a rule engine was built to enhance the system by finding the most efficient learning tactics for students based on their expected future performance. The proposed AI-based personalized recommendation tool shows a substantial step towards enhancing educational decisions. This solution facilitates educators in creating student academic assistance interventions by offering individualized, data-driven learning strategies.**

Keywords*—Artificial intelligence; educational data mining; educational strategies; machine learning; personalized recommendation; student performance prediction

I. Introduction

The incorporation of online learning environments and traditional classroom settings within educational institutions is progressively supported by an increasing volume of educational data. These data-rich settings offer substantial opportunities but also pose considerable challenges as institutions struggle to effectively bind them to enhance educational outcomes [1]. A key challenge is the collection and analysis of massive datasets to produce meaningful insights that can significantly influence educational strategies [2].

The science of discovering novel patterns in vast volumes of data is known as data mining. Moreover, finding knowledge in educational data that could significantly influence research methods in the field of education is the goal of educational data mining, or EDM [3]. In the past few years, researchers in this field have been eager to get valuable and practical insights, especially about student performance [4]. The aim to assist educational establishments in making choices and improving their teaching strategies is the motivational drive. In addition to help students overcome obstacles to learn and enhance their academic performance [5].

Failure and dropout rates are still rising despite technical advancements in e-learning that have undoubtedly had an impact on student performance [6]. This situation demands for a complete examination of a variety of influencing factors, including demographics, personal experiences, academic data, institutional surroundings, socioeconomic standing, and individual self-efficacy [7]. In fact, understanding the relationship between these factors is critical for evolving effective learning strategies and supporting academic accomplishment [8].

Despite the availability of extensive educational data, institutions face challenges in effectively utilizing this information to predict student performance and develop personalized learning strategies. Current systems frequently do not account for the diverse socioeconomic, demographic, and academic factors that affect student success. Consequently, dropout rates remain high, and students do not receive the individualized support necessary to enhance their academic outcomes.

In this study, the research objectives are; (1) to identify the key demographic, socioeconomic, and academic factors that influence student performance in higher education; (2) To apply advanced data mining techniques and machine learning models to predict student outcomes, specifically focusing on graduation, dropout, and enrollment statuses; and (3) To design and implement an AI-powered learning strategy recommendation that delivers personalized educational interventions based on predicted student performance.

The main contributions and implications of this study include the identification of key factors influencing student performance, the development of a predictive model utilizing machine learning algorithms to forecast student outcomes, and the introduction of an AI-powered personalized recommendation system that suggests individualized learning strategies based on performance predictions. This system enables educators to provide tailored interventions, which may help reduce dropout rates and enhance academic outcomes, while also delivering actionable insights for institutional policies and resource allocation. Furthermore, the system serves as a practical tool for educators to intervene early in students' academic journeys, allowing students to benefit from personalized learning strategies.

All in all, the structure of this paper is as follows: literature review in Section II, research methodology in Section III, results and evaluation in Section IV, discussion in Section V and finally conclusion in Section VI.

II. Related Works

Numerous research studies are included with data mining techniques with classification and clustering [9], prediction modeling [10], and AI-driven learning [13]. It is therefore anticipated that by using these techniques on educational data, useful knowledge and information will be extracted, raising the standards of the educational system. It is important to identify learning strategies and interventions that have been proved beneficial for students to give recommendations [14].

In previous studies, it was common to launch classification and clustering approaches working with educational data. In the study of these techniques, Song et al. [9] used the support vector machine and k-means clustering, to group students based on their performance and label them as successful or not. The student record embodied 41 variables, the components of which were delinquency behaviors, academic subjects, and demographics. SVM is a process of predicting results according to clusters, while being a clustering algorithm, k-means is used to set students' socioeconomic classes and effective learning into categories.

On the other hand, Alhassan et al. [10] applied classification algorithms to their research study to explore the affinity of grades obtained in coursework and online active data in student performance. As per the research, assessment grades are the most valuable factors that can be used to predict academic performance. Besides, modeling that uses assessment grades and data on online activity also outperform others. In fact, the two algorithms that worked best were Random Forest and Decision Tree. The study emphasizes the important of incorporating instructional technologies into learning environments.

Additionally, Mohamed Nafuri et al. [11] aimed to develop clustering analysis to classify the academic performance of students in the context of Malaysian higher education and develop graduation rates. The dataset, for instance, entailed data on gender, education levels, vocational exposure, co-curricular activities, and awards. Further, techniques such as k-means, BIRCH, and DBSCAN were used when data had been prepared. Also, the best model was KMoB, which was the optimized k-mean model, and with that, five clusters of student performance were identified. Despite the fact that such stigmatization can affect the academic performance as well as the social status of individual group members, their insights showed the necessity of developing individualized educational plans with data-driven approach and predictive analytics.

In addition to the above, Queiroga et al. [12] relied on data mining techniques and evaluated data obtained from 4529 undergraduate students. The system established it by utilizing the Virtual Learning Environment, survey, and academic system data to forecast student achievement. The research revealed as highly predictive in terms of amenability to treatment, which had caused certain elements to emerge as seemingly playing a determining role, including education, subject enrollment, and neighborhood. The results were followed by specific policies of the institutions, including recruitment and reporting of resources in addition to student tracking. Besides, they also used Python with NumPy, Pandas, and Scikit-learn libraries to implement a model. This work disclosed the potential of AI to personalized learning experiences based on individual student data.

Moreover, using data mining techniques like, Naïve Bayesian, Artificial Neural Network, Support Vector Machine and Decision Tree Classifier, Li et al. [13] inspected the contributing factors to students' performance. The characteristics like attendance, gender, and nationality were detected with the help of the information of the Kalboard360 E-learning platform. The results showed that support vector machines algorithm which takes the behavioral features such as resource use and participation into consideration as the most powerful at predicting performance. The researchers explored how to integrate behavioral data in such a way as to increase accuracy of forecasting and make learning more relevant for an individual learner.

Furthermore, Ouyang et al. [14] considered the possibility to describe how AI is being used in education to navigate educational environments and to predict academic success, so that educational failure is less, and the learning process is more effective. This study, which was conducted across an online engineering course, discovered that the adoption of AI learning analytics has concrete effects like collaboration, students' satisfaction, and engagement. In fact, this paper presented the research cases that illustrated the application of AI to educational reforms, in online learning, and higher education.

Moreover, for an efficacious academic achievement and to build personal effectiveness of academics in order to possibly minimize the likelihood of academically inadequate students. Renzulli [15] has suggested several effective strategies for learning; active involvement into study content, self-testing, note-taking, time management, flexed learning, distributed practice, interleaved practice, seeking somebody, self-regulation, and using university tools and resources. This paper reveals the potential of AI technology to execute authentic applications which could assist teachers to perform well academically.

In summary, all these studies show that data mining techniques now play a crucial role in educational research through providing valuable feedback on educational data and this results in the quality improvement of the educational system. Even though such attempts have been a few, gaining access to "real-time" data and recommending learning strategies based on student performance are not yet addressed sufficiently.

III. Research Methodology

Upstream industry pioneers have produced a standard called the Cross Industry Standard Process for Data Mining (CRISP-DM). It is equally and widely utilized in a variety of domains [16]. The six stages of this standard are; Business Understanding, Data Understanding, Data Preparation, Modeling, Evaluation, and Deployment are its six stages [17]. In fact, its broad and thorough application in the sphere of education is particularly noteworthy because it extends beyond other domains of use [18].

In this study, a predictive model creation strategy was developed using the CRISP-DM model, providing a

comprehensive structure for project implementation. Fig. 1 shows the complete CRISP-DM steps.

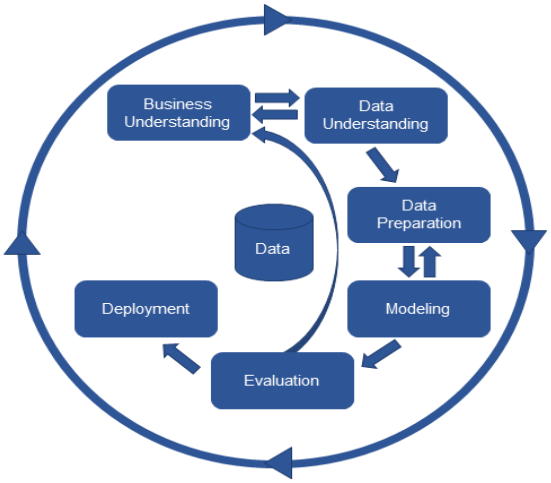

Fig. 1. Complete CRISP-DM step [17].

A. Business Understanding

This paper suggested a predictive model and recommendation system for student academic performance using educational statistics, aiming to enhance communication between educators and students, potentially enhancing learning environments [19].

As part of the methodology, attributes anticipated to have a direct impact on students' status were selected. To achieve this, a thorough investigation was conducted, followed by the construction of a figure (as shown in Fig. 2) demonstrating the relationship between these attributes and the students' attained status. Students were then classified into three categories (graduate, dropout, and enrolled) using various supervised learning techniques. Ultimately, learning tactics were suggested by the recommendation system based on the students' standing.

B. Data Understanding

The Kaggle project "Predict students' dropout and academic success" [20] provided the dataset used in this investigation. This dataset offers a comprehensive picture of the students enrolled in different undergraduate programs at a university. It contains information on social-economic characteristics, academic achievement, and demographics that can be utilized to examine potential determinants of academic success and student dropout. The dataset comprises 4424 instances, each associated with 35 attributes. The target attributes were graduate, dropout, and enrolled. The Table I shows description of the dataset including features and their type.

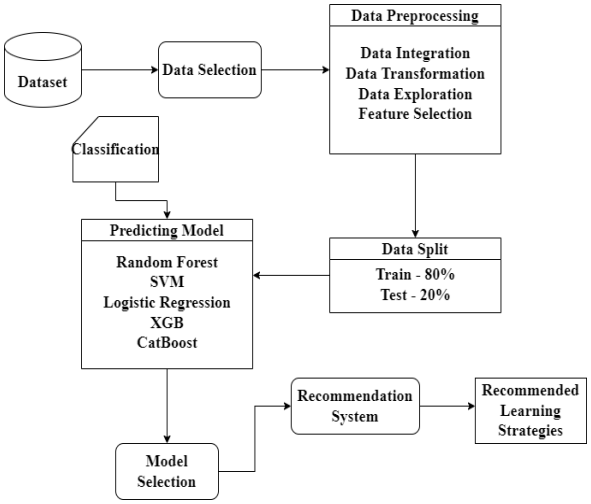

Fig. 2. Research methods for the prediction model.

TABLE I. DESCRIPTION OF THE DATASET INCLUDING FEATURES AND THEIR TYPE

Category	Feature	Description	Type
Demographic Data	Marital status	The marital status of the student	Categorical
	Gender	The gender of the student	Categorical
	Nationality	The nationality of the student	Categorical
	Age at enrollment	The age of the student at the time of enrollment.	Numerical
	International	Whether the student is an international student	Categorical
Academic Data	Course	The course taken by the student	Categorical
	Daytime/evening attendance	Whether the student attends classes during the day or in the evening	Categorical
	Curricular unit's 1st Sem (credited/ enrolled/ evaluations/approved, grade/without evaluations)	The number of curricular units credited/enrolled/evaluations/approved/ grade/ without evaluations by the student in the first semester.	Numerical
	Curricular unit's 2st Sem (credited/ enrolled/ evaluations/approved, grade/without evaluations)	The number of curricular units credited/enrolled/evaluations/ approved/grade/ without evaluations by the student in the second semester.	Numerical
	Application mode	The method of application used by the student	Categorical
	Application order	The order in which the student applied	Numerical
Social-economic Data	Mother's/Father's qualification /occupation	The qualification/occupation of the student's mother/father	Categorical
	Tuition fees up to date	Whether the student's tuition fees are up to date	Categorical
	Scholarship holder	Whether the student is a scholarship holder	Categorical
	Educational special needs	Whether the student has any special educational needs	Categorical
	Debtor	Whether the student is a debtor.	Categorical
	Unemployment rate	Unemployment rate among students	Numerical
	Inflation rate	Inflation rate of the region	Numerical
	GDP	Gross domestic product (GDP) from the region	Numerical

C. Data Preparation

Data preprocessing is a crucial step in knowledge discovery, involving cleaning, reduction, transformation, and feature selection. It involves inspecting the dataset for unwanted values, eliminating irrelevant fields, and converting the cleaned data into a suitable format for effective machine learning algorithms [16]. During this step, tasks such as checking missing data and duplicating data, replacing numerical values with names, changing categorical columns to categorical data type, getting all categorical variables except target, and rename columns were carried out.

D. Modeling

Previous studies showed that data mining involved creating models for classification, prediction, or finding hidden patterns in data that was observed [9, 10, 11]. The data mining that is prevalent these days can be divided into two types: the supervised and unsupervised data mining. However, supervised algorithms work on the basis of learning the category of unseen data, while unsupervised algorithms enable the study of the hidden patterns without target variable [19]. Logistic Regression (LR), XGBoost (XGB), Random Forest (RF), Support Vector Machines (SVM), and CatBoost (CB) classifiers were utilized as the supervised approaches to develop the models for this study.

1) Logistic regression: One prevalent linear classification approach that is effective at simulating the likelihood of a binary result of 1 or 0 is a logistic regression; it is either primarily dependent on one or more input factors. The dependent variable is a generalized combination of the predictor variables which is expressed as the logistic regression equation modeled by the logistic function, also known as the logistic or sigmoid function [21].

2) XGBoost (XGB): XGB is a supervised method which heavily relies on a specific algorithm called boosting. Starting with a learning set which includes correctly labeled samples, it is brought to a model of prediction which is used on any new examples. The training example pairs (x_0, y_0), (x_1, y_1) ... (x_n, y_n) are used by the method, where x is a vector of features and y is its label. Regression and classification issues where the label y takes a discrete or continuous value can be solved with it. The decision tree boosting technique XGBoost develops many models in a sequential fashion, each one aiming to make up for the shortcomings of the one before it. Hence, by using the XGBoost algorithm, this method can be expanded to a generalized gradient boosting [22].

3) Random Forest (RF): A Random Forest classifier is utilized for the regression and classification tasks, which involves a specific machine learning technique. It improves the accuracy by creating decision trees that are trainable on different parts of the same training set. Thus, to prevent overfitting, it learns from all the parts of the data. Random Forest generates K numbers of trees with distinct attributes each time, without pruning, by selecting attributes at random. Besides, test data is examined on every created tree, as opposed to decision trees, and the most frequent output is assigned to that particular instance [23] A forest with a larger number of trees yields the best accuracy. Missing values and category values are all handled by Random Forest. It gauges the purity and impurity of attributes using the Gini index indicator. In general, Random Forest classifiers exhibit more robustness and efficiency in comparison to decision trees [24].

4) Support Vector Machine (SVM): Vapnik's theoretical learning concept serves as the foundation for SVM. Systemic risk minimization is embodied by SVM [21]. SVMs are used in various domains related to outlier detection, regression, and classification. An SVM's original input space is mapped into a high-dimensional dot product space via a kernel. The new area is known as the feature space, and it is there that the best hyperplane for maximizing generalizability is identified. A small set of data points known as support vectors can determine the ideal hyperplane. Even though it lacks problem-domain knowledge, an SVM can produce high generalization results for classification tasks [25].

5) CatBoost(CB): A machine learning technique called CatBoost Classifier (CBC) helps in regression, classification, multi-class classification, and ranking. The objective function is reduced as the gradient decreases, and this causes variations in its design. Furthermore, built-in analytics in CatBoost evaluate the accuracy of the model before deployment. It does away with the necessity for feature processing by introducing a novel technique for managing category attributes. In addition, CatBoost makes use of ordered boosting, a permutation-driven substitute for traditional boosting techniques. Unlike the Gradient Boost, which tends to overfit quickly, it contains a mod to handle overfitting in small datasets. Additionally, CatBoost has two boosting modes: Plain and Ordered [26].

A computer with 8GB of RAM and 11th Generation Intel Core i5 processor was used for the research. Moreover, Google Colab platform was used during the entire project's development. Pandas, NumPy, Matplotlib, Seaborn, and Scikit-Learn were among the toolkits used to evaluate and compare the suggested classification models.

In addition, the dataset was manipulated in a manner that produced a 10-fold cross-validation technique which was used in splitting the dataset in training and testing subsets. Also, the stratified K-Fold subfunction for the cross-validation was employed. Scikit-Learn's model selection function [19] was used to carry out this division. The evaluations on the performance scores of classifiers were done using the cross-validation score and the GridSearchCV subfunctions.

E. Evaluation

Performance of the models are evaluated using a number of metrics, such as accuracy, precision, F1-score and recall [27]. Following metrics are used for evaluating models.

1) Precision: It is defined as the ratio of the model's total predictions to the number of true positives (TP).

$$\text{Precision} = \frac{TP}{TP + FP} \quad (1)$$

2) Recall: It is computed by dividing the total number of false negatives (FN) and true positives (TP) by the number of true positives.

$$\text{Recall} = \frac{TP}{TP + FN} \quad (2)$$

3) Accuracy: It can be calculated by dividing the total number of correctly classified examples by the total number of classified examples.

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \quad (3)$$

4) F1-Score: The precision and recall score averaged with respect to their weights is the F1 score. It also has consideration of false positives and fales negatives for it is to accurately indicate accuracy as well as recall.

$$\text{F1-Score} = \frac{2 * Recall * Precision}{Recall + Precision} \quad (4)$$

TP denotes true positive: The predicted category is positive and the actual category is positive. FP designates false positive: The predicted category is positive and the actual category is negative. FN represents false negative: The predicted category is negative and the actual category is positive. TN means true negative. The predicted category is negative and the actual category is negative.

F. Deployment

The system predicted student performance such as "graduate, dropout, and enrolled" and suggested helpful strategies for learning to support them. User input features like demographic, academic data, and socio-economic data can be entered into the system.

The study utilized Python as the main programming language, Pandas for data manipulation and preprocessing, and NumPy for numerical operations. Machine learning library like Scikit-Learn was used for implementing models. Matplotlib and Seaborn were used for visualizing data distributions and performance metrics. The models were trained on an 11th Generation Intel Core i5 processor, 8GB RAM, and Google Colab notebook platform. The final recommendation system was developed and deployed using Streamlit [28], a Python-based framework for building and deploying machine learning models as web applications. The web interface allowed users to upload student data and recommend personalized learning strategies based on input.

Moreover, this research utilized some recommended learning strategies in educational psychology as follows [15].

1) Learning strategies for dropout students: The students opt to that they could dropping out should be enrolled in a soft skills program such as time management, self-testing, note-taking, and other productive study methods. Additionally, the program should be supplemented with academic counseling and follow-up to help the students consistently integrate the techniques they have learned. It is also advisable to boost active-learning approaches including creating notes and rewriting them, practicing self-testing, but not relying on other activities in passive reading. This course further should support the students in both increasing their efficiency in pursuing a reasonable time schedule and trying to devote the specified amount of time required for learning every week. Lastly, it should address any motivational problems or negative attitudes towards difficult material that may cause students to lose interest.

2) Learning strategies for enrolled students: The evaluation of students who are new to the learning system is important. The skills the students have must be evaluated and if there are any weakness, such should be identified. Once the system has provided active learning techniques, created a schedule, dealt with the obstructs, advised on the best practices and offered attention and accountability good results can be expected.

3) Learning strategies for students likely to graduate: For students who are positively engaging with learning, the system should suggest time management, note-taking, active reading, and self-testing techniques. Furthermore, it should motivate them to improve advanced skills like research, academic writing, and critical thinking.

IV. Results and Evaluation

A. Descriptive Analysis

Firstly, the influence of demographic, socioeconomic, and academic data on student performance in higher education was investigated.

1) Student performance: Enrol, Graduate, and Dropouts : The pie chart of Fig. 3 displays three segments representing student performance in higher education: Dropout (50%), Graduate (32%), and Enrolled (18%). Such a chart was used to focus on parameters of student retention and graduation rates. This may be part of a discussion with broader goals including the effectiveness of academic support systems.

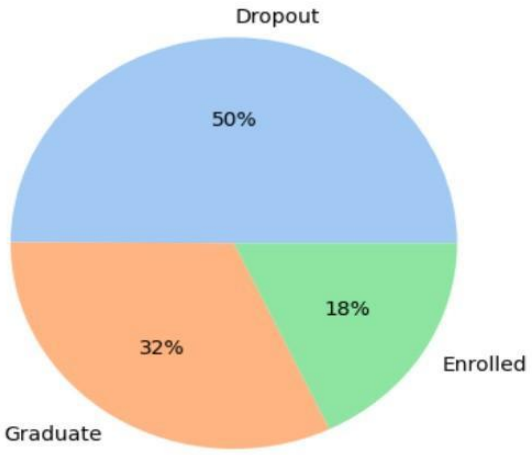

Fig. 3. Pie chart of student outcomes.

2) Top 10 factors that affect student performance: The heatmap in Fig. 4 illustrates the 10 most significant factors that affect student performance. The result of the heatmap visualized factors range from academic factors such as grades

of curricular unit and approvals to socio-economic factors such as scholarships and tuition fees.

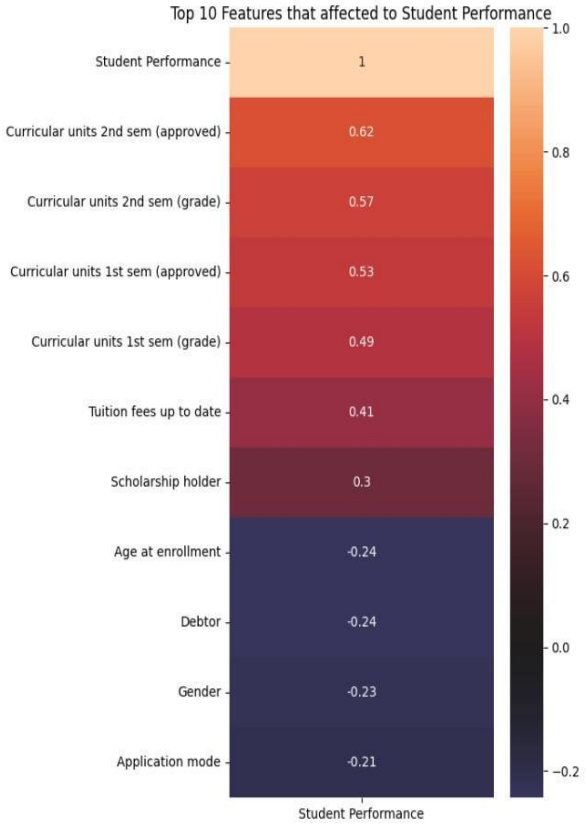

Fig. 4. Top 10 most influencing factors.

3) Age Distribution at the time of Enrollment: The histogram in Fig. 5 shows the age distribution of the students at the time of enrollment. The majority of enrolled students fell into the 18–22 age range, but it was evident that students in the 60–70 age demographic range are marginally present in the population.

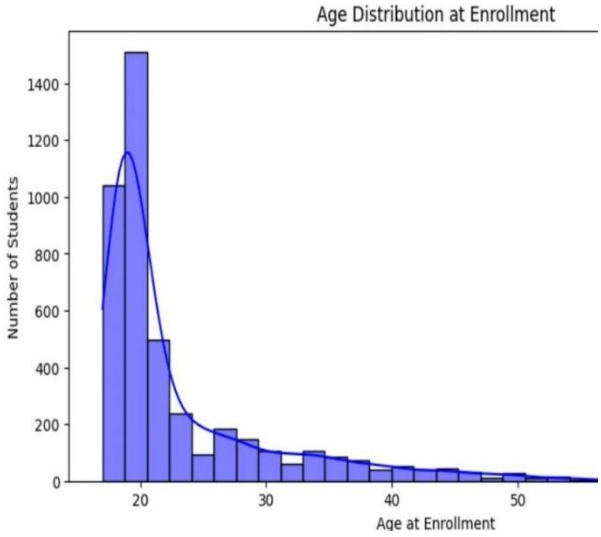

Fig. 5. Histogram of age distribution at the enrollment.

4) Effect of curricular units 2nd semester (approved) on student performance: The Fig. 6 bar chart exhibits a clear upward trend from dropouts to graduates in total curricular unit of 2nd semester (approved).

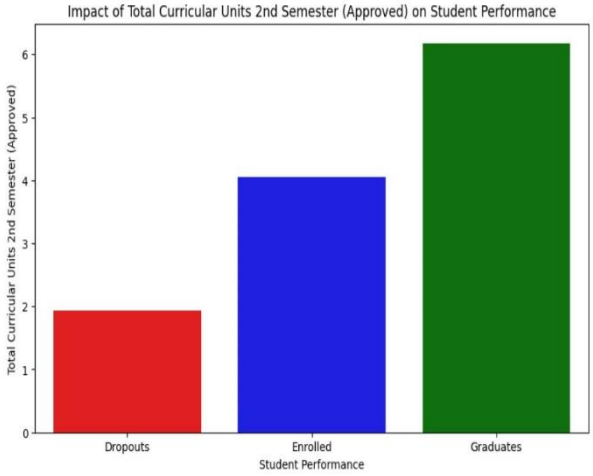

Fig. 6. Bar chart of student performance in all curricular units during the 2nd semester.

5) Effect of scholarship status on student performance: The stacked bar chart in Fig. 7 clearly illustrates a majority of scholarship holders graduating when it compared to non-scholarship holders.

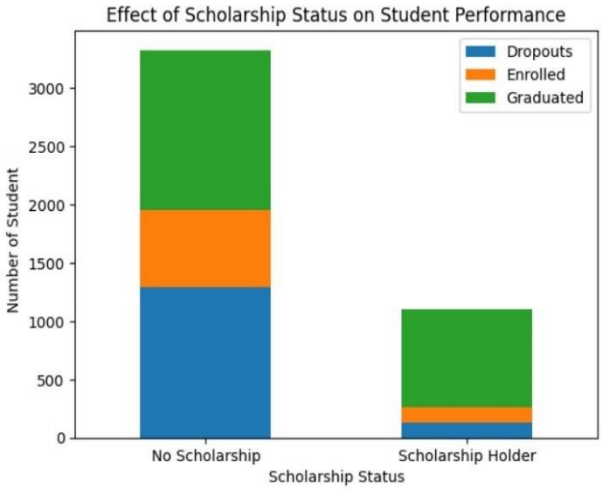

Fig. 7. Stacked bar chart of scholarship status on student performance.

B. Feature Selection

Secondly, a data mining method (classification) was applied to predict the performance of students based on affective factors. To identify the best prediction model, five distinct classifiers—Random Forest (RF), Support Vector Machine (SVM), XGBoost (XGB), CatBoost (CB), and Logistic Regression—were employed in the analysis. Each classifier was methodically assessed to determine the best outcome. Consequently, accuracy, F1-score, precision, and recall were measured, with the best results boldfaced. The results of the assessment of the selected classifiers are summarized and presented in Table II.

TABLE II. FEATURE SELECTION USING CLASSIFICATION TECHNIQUES

Algorithms	Accuracy	F1 - Score	Precision	Recall
Random Forest - RF	**0.7989**	0.7857	**0.7883**	**0.7989**
Support Vector Machine - SVM	0.7740	0.7690	0.7693	0.7740
XGBoost - XGB	0.7921	**0.7887**	**0.7883**	0.7921
CatBoost - CB	0.7955	0.7859	0.7837	0.7955
Logistic Regression - LR	0.7831	0.7686	0.7663	0.7831

With an accuracy of 79.89%, the Random Forest Classifier emerged as the leader and was now tied with the XGBoost Classifier for the highest F1-score of 78.87%. Based on these two metrics, the Random Forest Classifier was the best-performing model on the list. However, given the identical F1-scores, the XGBoost Classifier remain a formidable contender. The Random Forest Classifier is a robust and efficient method for addressing overfitting and noisy data in diverse and complex educational datasets [23]. It employs an ensemble learning approach, combining multiple decision trees, making it well-suited for handling missing values and categorical variables without extensive preprocessing, common challenges in educational data.

C. Recommendation System

Finally, a recommendation system was developed that uses a pre-trained Random Forest model to predict student performance, categorizing it into three probable statuses: enrolled, graduate, and dropout.

Based on predictions, the system delivers different learning strategy recommendations. The following are the steps in the system: Upload a csv file or manually input features, Load the pre-trained Random Forest model, predict the outcome using a model, and Display prediction probabilities and recommendations.

1) User interface: Fig. 8 depicts the web interface to get input features.

2) The Student is likely to graduate: Three categories display the prediction probabilities: 13.46%, 15.82%, and 70.72% for graduates, enrolled, and dropouts, respectively. The predicted probabilities suggested that the student had a positive chance of graduating and offered suggested learning techniques. These details are displayed in Fig. 9.

3) The Student is likely to drop out: The prediction probabilities indicate that there is a significantly larger probability dropping out at 59.80%, enrolling at 10.51%, and graduating at 29.69%. It is shown in Fig. 10.

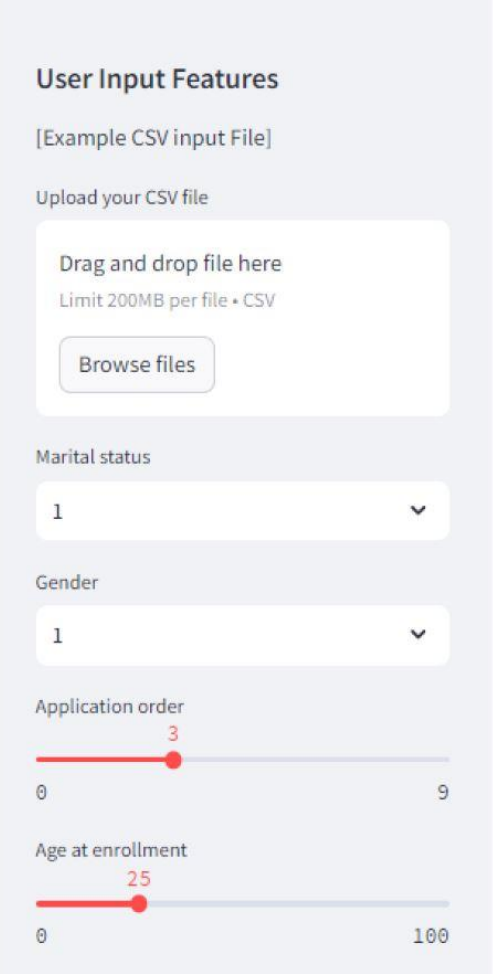

Fig. 8. Web interface to get input features.

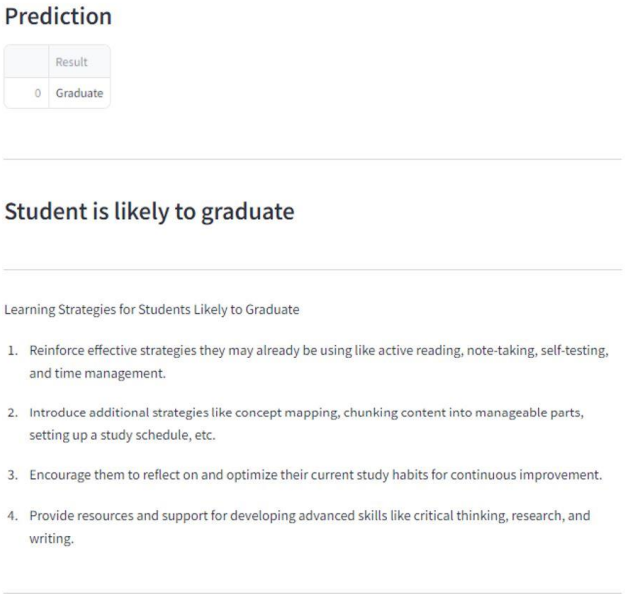

Fig. 9. Prediction probabilities and learning strategies of student is likely to graduate.

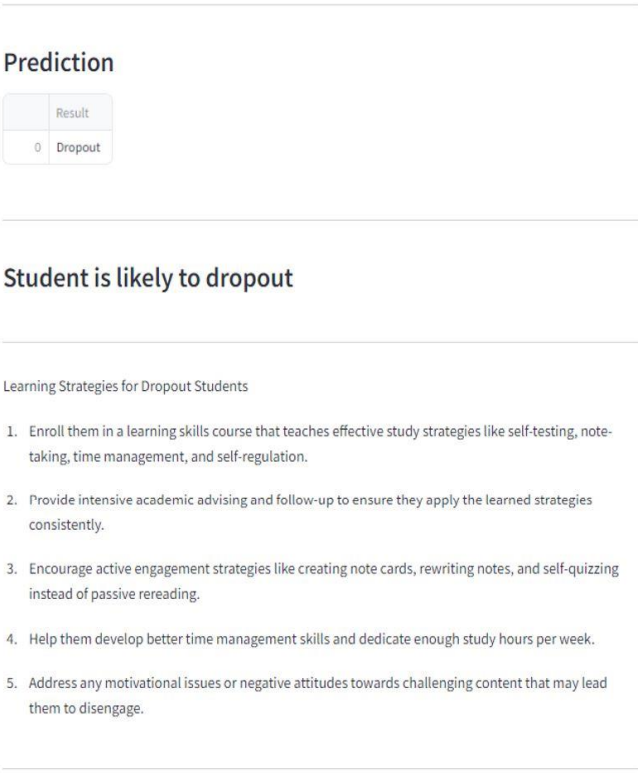

Fig. 10. Prediction probabilities and learning strategies of student is likely to dropout.

V. Discussion

In this section, the findings from the descriptive analysis, feature selection, and the recommendation system presented in the previous section are discussed.

A. The Influence of Demographic, Socioeconomic, and Academic Factors

This article generally indicates the vital part that demographic, socioeconomic and academic factors play in the tertiary education performance of the students. Contrary to the graduates (32%) and those who are still enrolled (18%), the very high dropout rate (50%) demonstrated that higher education system has a serious issue. This distribution in fact suggests that outside factors that might be related to socioeconomic status and demographic backgrounds, play a significant role in the outcomes of learners even when there are educational programs.

The factors that affect student performance further support the complex relationship between student success and socio-economic factors, such as scholarships, tuition costs, and academic indicators like the number of curricular units in semesters. This implies a need for assistance with both academic challenges and economic hurdles. Consequently, the results of this research are also supported by the findings of [9, 13]. In Song et al. [9], the authors explored issues including behavior, academics, and demographics. Behavioral components englobed being absent from class, while academic achievement, coupled with good grades was fundamentally important. Socioeconomic status and year of entry were the demographic elements involved. Even during Li et al. [13], the authors went for the details of demographic variants like age, occupations of parents, and nationality, which connected the rich diversity of students with the advantages and challenges of different cultures. The socioeconomic factors, like parents' level of education or income of the family, influenced their education, the availability of resources and their academic success to a great extent. Academic factors, one of which is previous performance and absences, are directly correlated with the student performance and therefore, they have a chance to predict future outcomes.

B. Efficiency of Classification Methods in Predicting Student Performance

Applications of many classifiers, the obtaining of insightful results, and the prediction of student achievement have been done. The Random Forest classifier [23] has an accuracy of approximately 80%; it performs better than other models, and what makes it robust is its ability to efficiently handle many different kinds of datasets that are common in educational settings. Random Forest's performance is an indication that such ensemble learning approaches are essential for successful educational data mining. These results are invaluable for developing algorithms that can identify at-risk student cohorts, enabling timely interventions.

The study [10] employs different types of classification for the prediction of student success and the grade of assessment is revealed to be the major factor in rates of performance. The models that were using the grades and online activity data performed better. However, it was the Random Forest classification model that performed better in predicting student performance.

C. Implications of Recommendation System

The development of a recommendation system that classifies students to likely categories (graduate, enrolled, or dropout) and provides specific educational strategies based on the predictions is especially inventive. This technology is very promising, it puts machine learning and its predictive power to real use in a way that has a practical impact on the education process, and can completely change the concept of teaching and learning. E.g., 59.80% dropout rate of this student could trigger the implementation of special supportive measures like tutoring, counseling, or modification of financial aids by the academic institutions.

In addition, a similar conclusion was reached in studies [14, 15], which emphasize the significance of using learning analytics with AI-based performance prediction models. The results of such a technique demonstrate that cooperation is enhanced, that satisfaction is higher and that engagement and learning are improved. Such study shows the trend toward educational effectiveness by emphasizing the application of AI models which have been created and the gap bridging between the creation and use of AI models.

D. Implications and Limitations

By personalizing progressions of study to suit the needs of individual students, offering predictive insights for early intervention and continuously enhancing instructional methodologies and techniques, AI can improve personalized

learning [15]. It could thus lead to improved academic work, a drop in cases of dropout rate as well as more effective learning.

The amount, class, and constant quality of data, which are available, determine how efficient AI systems work [29]. They might tarnish the trust because the terms are hard to be understood or difficult to comprehend. Differing from one to the other in practices and demography could limit the applicability of the same interventions in various settings [14]. In fact, information security and privacy are among the dilemmas that ethical corporations often encounter [30]. If AI extensively used, task automation will supplant people interaction and people will experience threats of a decline in critical thinking and social skills. The issue of resistance, a lack of technical compatibility, and the need for educating the staff may complicate automated systems integration with existing educational infrastructure.

VI. Conclusion

This study titled "EDM and AI-Powered Learning Strategy Recommendation System to Boost the Academic Results" articulates that AI and EDM can be used in learning settings to improve academic performance. Students' results prediction model and recommendation engine which use variables like socioeconomic status, demographic data source and academic performance was built using the CRISP-DM model. Notably, in this case, this research reconciled this navigation with machine learning algorithms in a perfect way by proving that random forest was the ideal classifier for the student's performance status prediction. With the implied procedure proposed as a basis, unique study systems were built for the learners on the foundation of their particular needs, desires, and struggles. The fact that personalized education might be achieved within these systems is a crucial milestone for the field of personalized learning in general. The evidence has a significant impact that will aid institutes to formulate student progress and knowledge exploration concerning factors that invite student success. In this regard, the AI-powered system which would sense learners and respond with personalized instructions should promote the students' access rights, involvement, and productivity. Through this shift, the numbers of student dropout might come down and a comfortable atmosphere in which the learning process can be done effectively and this could be realized.

In the future, real-time data analytics integration and ongoing AI algorithm improvement should improve on assessing the productivity and adaptability of learning systems. Moreover, investigating hybrid models that fuse AI suggestions with the knowledge of human educators may result in more comprehensive teaching approaches.

***Abstract*—This paper presents a novel lattice-based cryptography implementation in the Transport Layer Security (TLS) protocol to enhance the security of traffic transmission in IP networks that use the Asterisk IP PBX platform. Given the growing threat of quantum computing, traditional cryptographic methods are becoming increasingly vulnerable. To address this issue, the study leverages post-quantum cryptography by developing a modified TLS protocol using lattice-based cryptographic algorithms. The performance of the system was evaluated in terms of security, computational efficiency, and real-time communication. The study shows that the proposed lattice-based TLS implementation effectively secures traffic transmission in IP PBX networks, offering a robust solution against both current and future quantum threats.**

Keywords*—IP; PBX; Asterisk; TLS; MITM; post-quantum cryptography

I. Introduction

In today's rapidly advancing technological world, the prospect of a quantum computer is becoming increasingly real. Quantum computers, once fully implemented, could potentially break widely used cryptographic algorithms such as RSA and ECC (elliptic curve cryptography) [1-3].

If the intruder's computing capabilities increase by tens, hundreds or thousands of times, this will lead to a sharp need to increase the key length to a critical level, which will become unsuitable for successful operation in real information systems. In addition, if a quantum adversary with enormous computing power appears, there is a possibility of a complete hack of existing cryptosystems by a complete enumeration of keys [4-6]. This problem can be solved by implementing post-quantum cryptography, a relatively new area of cryptography, which is designed to resist quantum computing [7-9]. Unlike asymmetric cryptography, based on conditionally unidirectional mathematical functions, post-quantum cryptography is based on the principles of quantum mechanics and quantum information theory, which guarantee physical unidirectionality. However, there are problems associated with the complexity of implementation and the high cost of equipment [10-12]. With a data transmission channel length of more than 100 km, the transmission speed is significantly reduced (to several bits per second). This fact does not yet allow for the implementation of a full-fledged secure exchange of critical information. In this regard, post-quantum cryptography currently appears more feasible for use in existing systems. The main approaches in post-quantum cryptography include:

1) Lattice-based cryptography. This approach is based on mathematical problems involving lattices, such as the shortest vector problem (SVP) and learning with errors (LWE). These problems are considered difficult to solve even for quantum computers, so lattice cryptography has an advantage [13-15].

2) Code-based cryptography. This approach is based on the difficulty of decoding a general linear code, a problem that has been studied extensively and is considered difficult for quantum computers [16-18].

3) Multivariate polynomial cryptography. This approach is based on the difficulty of solving systems of multivariate quadratic equations over a finite field. The multivariate quadratic (MQ) problem is NP-hard and is considered resistant to quantum attacks [19-21].

4) Hash-based cryptography. This approach uses cryptographic hash functions as a basis for constructing secure algorithms, particularly for digital signatures. Hash-based cryptography is widely considered to be secure against quantum attacks, assuming that the underlying hash functions are secure [22-25].

5) Isogeny-based cryptography. This approach exploits the mathematical properties of isogenies between elliptic curves. Isogeny-based cryptographic schemes are relatively new and are considered promising due to their resistance to quantum attacks. Small key sizes and robust security based on complex mathematical structures [26-28].

6) Hyperelliptic curve cryptography uses the algebraic structures of hyperelliptic curves, which generalize elliptic curves and provide similar security mechanisms at smaller key sizes [29-31]

7) Symmetric quantum resistance focuses on making symmetric cryptosystems secure against quantum computing threats. The primary method of improving the resistance is to increase the key length and choose algorithms with greater resistance to Grover-based attacks. For example, using AES-256 instead of AES-128 will provide resistance against

quantum computing attacks at the level of 2128 searches. Quantum attacks on hash functions, such as the Grover-based collision attack, also reduce the complexity of finding a collision from O(2n)) to O(2n/2). Therefore, using hash functions with longer bit lengths (e.g., SHA-512 instead of SHA-256) can be an effective means of protection [32-35].

These approaches form the basis of ongoing research and development in post-quantum cryptography as the world prepares for the potential impact of quantum computing. Each approach has its own strengths and weaknesses, and the future of secure communications will likely involve a combination of these methods.

This paper is a continuation of the research [36] where the publication focused on traditional multi-layered data protection in IP networks based on Asterisk IP PBX using different codecs to reduce latency and improve real-time encryption, while this study proposes the integration of post-quantum lattice-based cryptography into the TLS protocol to protect against threats associated with the development of quantum computers. The [36] solves the existing problems of cryptographic security, and this study extends the research area by proposing protection against future quantum threats, which represents an important step forward in ensuring the security of IP networks.

This article discusses the convergence of lattice theory into the TLS protocol for protecting transmitted traffic in IP networks based on Asterisk PBX. Asterisk is an open source framework for building communications applications such as IP PBX systems, VoIP gateways, and conference servers. Given its widespread use, ensuring the security of communications processed by Asterisk is of paramount importance.

To address these issues, lattice-based cryptography has become a promising approach to post-quantum cryptography, offering strong resistance to quantum attacks.

Over the past decade, the number of published works on this topic, both foreign and domestic, has increased significantly. This fact emphasizes the relevance of this problem and arouses interest in further research in this area.

II. Methodology

In the modern conditions of quantum computing development, traditional cryptographic methods based on the complexity of factorization and discrete logarithm calculation become vulnerable to quantum attacks. Therefore, there is a need to use post-quantum cryptographic algorithms that will ensure security even in the conditions of powerful quantum computing. Lattice-based Cryptography is considered one of the most promising technologies in the field of post-quantum cryptography. The essence of the approach is based on the difficulty of solving problems on lattices, such as the problem of learning with errors (LWE), which remains difficult even for quantum computers [37-40].

These methods were replaced by a lattice algorithm. The LWE problem was proposed as an approximate version of the Shortest Vector Problem (SVP) on lattices. The difficulty of LWE is directly related to solving lattice problems such as the Closest Vector Problem (CVP), since finding a secret vector s in the LWE problem reduces to solving a lattice variation of the CVP problem if the matrix A represents a lattice basis. One can say that LWE translates lattice problems into an algebraic form, where noise (error) is added to a system of linear equations.

The proposed methodology introduces the use of lattice-based cryptographic schemes to provide post-quantum security in the process of key exchange and data encryption. The key exchange scheme is based on LWE or the related Ring-LWE approach, which provides a high level of resistance to both classical and quantum attacks.To integrate such an algorithm into Asterisk, an additional module was created. This module is responsible for generating and verifying keys. Third-party cryptographic libraries such as liboqs (Open Quantum Safe), which supports various post-quantum algorithms, are integrated via AGI. The Asterisk dialplan is then configured to call these modules when establishing a secure SIP session.

Modified TLS (with post-quantum cryptography) has the following implementation stages:

1) The client requests a secure connection.

2) The server sends its certificate based on the post-quantum PQC algorithm.

3) The client and server exchange keys using the PQC algorithm.

4) The symmetric key is used to encrypt data using AES.

5) Messages are protected using HMAC, as in classic TLS, but the key itself was transmitted using PQC.

To generate keys according to the PQC algorithm, a random matrix A and a vector s are used. The matrix A belongs to the set Zq^m: where q is a prime number.

The vector s belongs to the set Zq^m: and is the secret key.

The public key is formed from the matrix A and the error vector e.

The vector b = As + e is calculated, where e is a random noise vector.

b and A make up the public key, and s makes up the secret key.

The encryption process is described by calculating the components of the ciphertext from the vectors u, v, after generating a random vector r from the set Zq^m:

$$u=A^Tr, \quad (1)$$

where, u is the portion of the ciphertext associated with the public key.

$$v=b^Tr+m\cdot\lfloor 2/q \rfloor, \quad (2)$$

where, v contains the message m itself with added noise.

During decryption, the original message is calculated:

$$m=decode(v-uTs), \quad (3)$$

where, the expression v−uTs allows us to obtain the encrypted message, and then decode it back into the original message.

The module code is shown in Fig. 1.

```
import oqs

BACKUP_DIR = '/path/to/backup/dir'
```

Fig. 1. Module code.

The performance and productivity of the developed method were evaluated by conducting a Man-in-the-Middle (MITM) attack, a well-known threat to VoIP systems. In MITM attacks, an attacker intercepts and manipulates real-time data, gaining unauthorized access to voice calls, modifying messages, and retrieving confidential credentials. In the context of VoIP, implementing TLS (Transport Layer Security) effectively protects signaling traffic, significantly reducing the risk of MITM attacks. By integrating a post-quantum key exchange algorithm into TLS, the developed method ensures robust encryption and data integrity, safeguarding communications from both conventional MITM and future quantum-based attacks.

This approach enhances the overall security of VoIP systems against evolving threats.Stages of implementing a MITM attack in a VoIP environment to test TLS:

1) Setting up a test environment includes preparing a virtual machine (VM) with an installed VoIP system based on Asterisk and interaction of virtual clients via SIP.

2) The creation of a MITM attack is based on the use of Ettercap and Bettercap tools, which are capable of intercepting traffic between VoIP clients.

3) Testing without TLS, when protocols transmit messages in clear text, which allows an attacker to easily intercept calls and gain access to data.

4) Implementation *of modified TLS* allows us to evaluate how TLS affects data interception.

5) Analysis of the results shows the results of the MITM attack with and without the use of modified TLS.

III. Result

A. Installing Asterisk

Asterisk installed on a virtual machine to emulate a VoIP server was done using Docker.

Docker is an open-source platform that allows you to optimize the management of development, testing and deployment of web applications. Docker is based on the packaging of programs (along with the environment and dependencies) into virtual blocks - containers.

Using Docker for IP PBX Asterisk is an effective way to deploy, manage, and scale an IP telephony system. Asterisk, being one of the most popular platforms for building VoIP (Voice over IP) solutions, can benefit greatly from using containerization via Docker. The PBX AS-IS architecture is shown in Fig. 2.

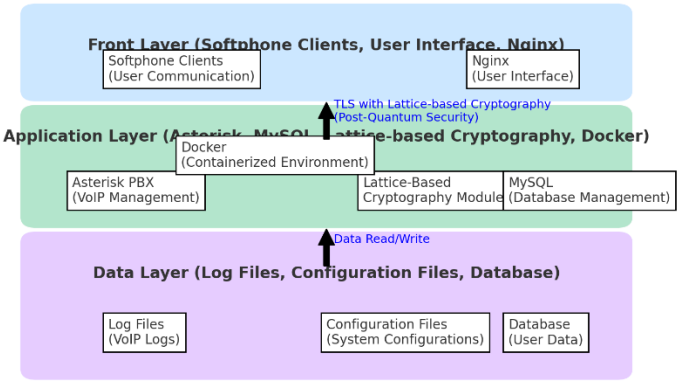

Fig. 2. Architecture of the proposed system.

In application architecture, especially with containerization and technologies like Docker, there are three key layers: Data Layer, Application Layer, and Front Layer. These layers provide separation of duties, simplify support, development, and scaling of the system.

1) Data layer: The data layer is responsible for storing, managing, and processing all the information used in the system. In the context of IP telephony architecture using Asterisk and Docker, this layer is responsible for storing and managing data such as call records, user settings, call sessions, and so on.

The main components of the data layer are:

Databases: Used to store configurations, user data, CDRs (Call Detail Records), logs, session information, and other necessary information.

MySQL, PostgreSQL, MariaDB: Relational databases for storing structured data about users, calls, and other elements of the system.

NoSQL databases (e.g. Redis): Used for caching, storing sessions or other data where high access speed is critical.

File storage: Can be used to record and store conversations, system logs and other files related to IP telephony.

Object Storage (e.g. MinIO or S3): For storing large volumes of audio files, call recordings, data archiving.

File systems (NFS, Ceph): For local or distributed data storage between different containers and system nodes.

Data caching: To optimize access to frequently used data and reduce the load on the main databases.

Redis or Memcached: Used to cache database queries or store session data in real time.

2) Application layer: The application layer is the main functional layer where the business logic of the system is executed. In the case of IP telephony and Asterisk, this is the layer where call processing, SIP request routing, security policy enforcement, etc. take place.

The main components of the application layer are:

Asterisk Server: The main component that handles voice traffic, SIP request routing, session management, and provides telephony functionality. It handles incoming and outgoing calls, controls conferences, organizes IVR systems, and other IP PBX functions.

SIP Proxy (e.g. Kamailio): A component for routing SIP traffic, load balancing between multiple Asterisk servers, and improving system security.

Security Features: Uses TLS to encrypt SIP messages and SRTP to protect voice traffic. These components are integrated into the main application server, providing protection against attacks such as MITM (Man-in-the-Middle).

Application business logic: Applications and services that provide telephone communication functions, such as IVR, call processing automation, integration with CRM systems, and others.

Additional services:

CDR (Call Detail Records): Systems for keeping track of calls and generating reports on the operation of the telephone network.

Call recording functions: For storing call records for security or archiving purposes.

Monitoring and logging: Services for tracking system performance, analyzing logs, and preventing errors.

3) Front layer: The front layer is responsible for user interaction with the system and providing them with interfaces for accessing functionality. These can be web interfaces, mobile applications, client programs for IP telephony, and other user interaction components.

Main components of the front layer:

IP telephony client applications: Programs that users use to work with the IP PBX system.

Softphone clients: For example, Blink, Zoiper, X-Lite are voice communication programs that work via the SIP protocol.

Web clients: Web interfaces for accessing Asterisk functions such as call management, user configuration, statistics analysis, etc.

Web management interfaces: Applications that allow administrators and users to interact with the system via web browsers.

Call control panels: Visual panels for managing calls in real time, viewing line status and interacting with the system.

Mobile applications: Programs for mobile devices that allow users to make and receive calls over a corporate telephone network using SIP.

API: Programming interfaces for integrating Asterisk with external systems (e.g. CRM, ERP). The API allows you to automate some processes and improve the functionality of the system for end users.

RESTful API or AMI (Asterisk Management Interface): Allows you to manage calls,Let's consider the main layers and elements of the architecture:

Installing Docker on Ubuntu distribution consists of 12 steps:

1) Updating the package: sudo apt update

2) Installing the package that is required for the apt package manager to work over HTTPS: sudo apt install apt-transport-https ca-certificates curl software-properties-common

3) Adding the Docker repository GPG key: curl -fsSL https://download.docker.com/linux/ubuntu/gpg | sudo apt-key add -

4) Adding the Docker repository: sudo add-apt-repository "deb [arch=amd64] https://download.docker.com/linux/ubuntu bionic stable"

5) Updating the package again: sudo apt update

6) Switching to the Docker repository to install it: apt-cache policy docker-ce

Similar information with the Docker version is shown in Fig. 3.

7) Install Docker: sudo apt install docker-ce

8) Check the program's functionality: sudo systemctl status docker

Information that Docker is active is shown in Fig. 4.

9) To use the docker utility, you need to add the user name to the Docker group: sudo usermod -a -G docker user

*10)*Enter the user name: su - user

*11)*Set the user password.

*12)*Check access to Docker images: docker run hello-world

After the information about the successful installation of "Hello from Docker!", you need to install PORTAINER - a graphical panel for managing docker containers.

A data storage for Portainer has been created:

docker volume create portainer_data

The container with Portainer is launched with the command:

docker run -d -p 9000:9000 -v /var/run/docker.sock:/var/run/docker.sock -v portainer_data:/data portainer/portainer

After launching in the browser at the server ip address:9000, you need to set the administrator password.

Next, select the location of Docker on the local server (Local) or on a remote one.

The panel is installed, you can launch containers (Fig. 5).

In the control panel, in the "App Template" section, you can find templates with software and run them in containers (Fig. 6).

Portainer is used for comfortable container management.

SIP clients are installed on software SIP phones (softphones).

B. *Conducting a MITM Attack*

Traffic interception is organized by setting up a network bridge and using an ARP spoofing tool (ettercap) so that the attacker's virtual machine can intercept traffic between SIP clients and the VoIP server. The command for an ARP spoofing attack:

ettercap -T -M arp:remote /client-IP-address/ /server-IP-address/

Wireshark was used to analyze traffic. Filters in Wireshark for VoIP:

sip || rtp

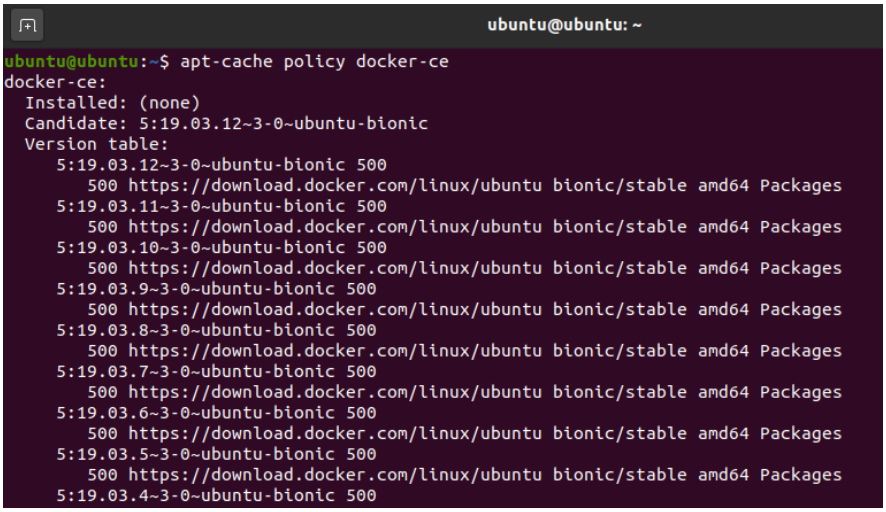

Fig. 3. Similar information with docker version.

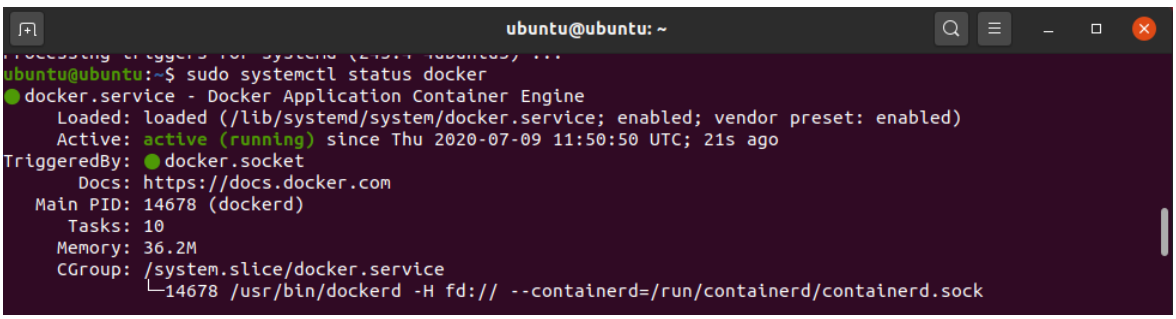

Fig. 4. Docker status.

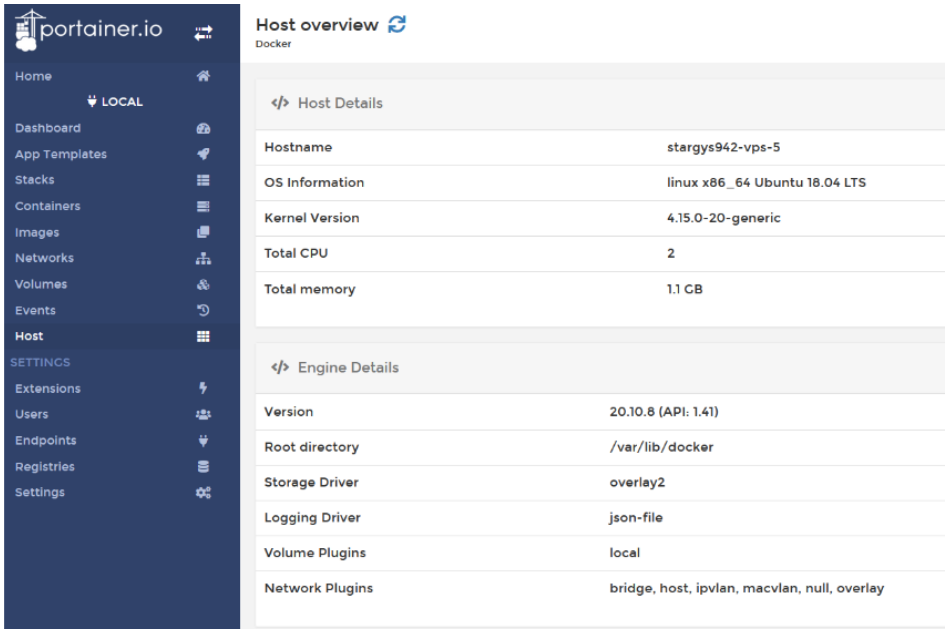

Fig. 5. Running a docker application.

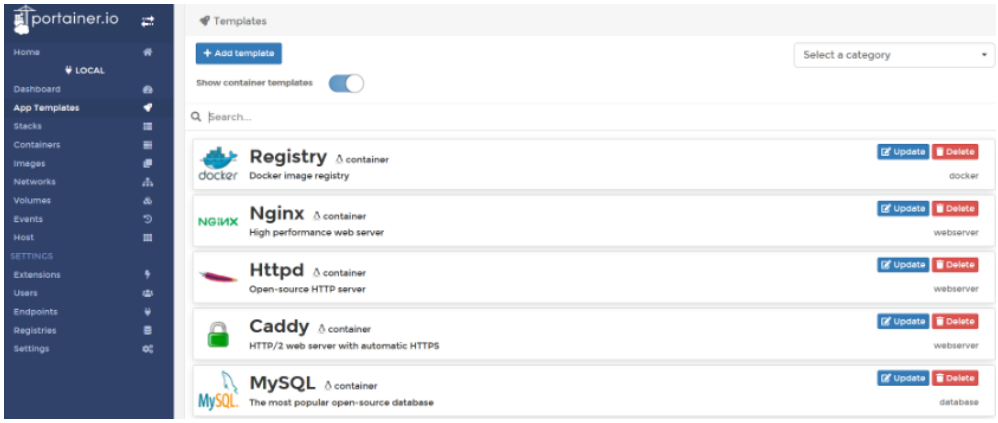

Fig. 6. App template.

In the scenario when we use standard TLS, traffic can be available for analysis and modification; we can see this by switching to the "Decrypted SSL Data" tab. (Fig. 7).

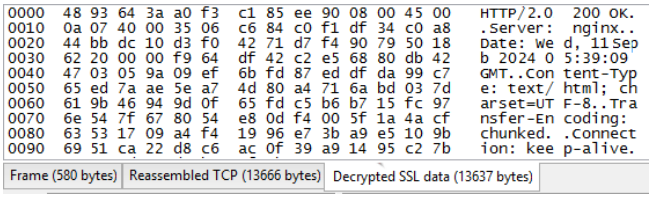

Fig. 7. Decrypted SSL data.

After setting up modified TLS on the VoIP server, the traffic is encrypted and cannot be analyzed or spoofed (Fig. 8).

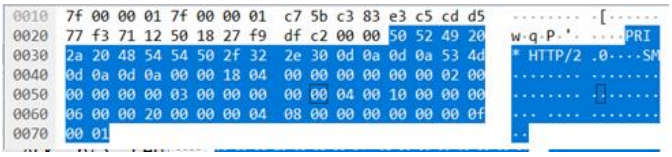

Fig. 8. Ercrypted SSL data.

IV. Discussion

The integration of lattice-based cryptography into the TLS protocol provides a significant enhancement to the overall security of the IP PBX Asterisk system. Lattice-based algorithms such as Learning With Errors (LWE) offer resistance to quantum computing attacks, which is critical as traditional cryptographic methods like RSA and ECC are vulnerable to quantum threats. By using post-quantum key exchange algorithms, the system ensures that even if a quantum computer were able to break traditional cryptographic schemes, it would not be able to compromise the confidentiality of the communications.

Moreover, the combination of AES for symmetric encryption and HMAC for message integrity ensures a strong layer of defense against eavesdropping and tampering in real-time VoIP communications. This safeguards the system from Man-in-the-Middle (MITM) attacks, where an attacker might attempt to intercept or alter voice and data transmissions. The proposed system's use of lattice-based cryptographic keys during the TLS handshake further secures this process by

making key exchanges immune to both classical and quantum-based cracking attempts.

Additionally, the system's architecture, which incorporates Docker for isolated and modular environments, enhances security by reducing the attack surface. Each module operates within a container, minimizing the risk of one compromised module affecting others. The containerized environment also ensures that vulnerabilities in one part of the system do not compromise the whole network, adding a layer of isolation and protection.

However, the system's security also depends on proper management of cryptographic keys and certificates, as failure to securely store or manage these can still leave the system vulnerable to traditional attacks. While lattice-based cryptography provides robust protection against future quantum threats, it is essential to ensure that the deployment and management of the cryptographic infrastructure are secure and well-maintained to prevent other potential security breaches, such as phishing or insider threats.

The proposed system offers several advantages, including quantum-resistant security through lattice-based cryptography, ensuring long-term protection against future quantum attacks. It enhances key exchange protocols using the LWE algorithm, secures real-time communication via post-quantum TLS, and maintains data integrity through HMAC. The system's modular architecture allows for easy integration and scalability. However, it also has some disadvantages, such as increased computational overhead, higher latency in real-time communications, and potential challenges with integration into existing infrastructure. The large key sizes of lattice-based cryptography may also impact storage and bandwidth efficiency. Furthermore, the lack of widespread standardization in post-quantum cryptography adds complexity to its implementation and maintenance.

V. Conclusion

This research makes a significant contribution to the development of cybersecurity systems for IP networks by proposing a practical implementation of post-quantum lattice-based cryptography in the TLS protocol. The main contribution of the research is the integration of lattice cryptographic algorithms into the Asterisk IP PBX infrastructure, which provides reliable protection against threats associated with the development of quantum computers. Unlike existing approaches that focus on the theoretical aspects of post-quantum cryptography, this study demonstrates, the practical application of these methods in real-world conditions using virtual machines and Docker for performance and security testing.

It also contributes to the development and evaluation of a system capable of protecting real-time data transmission with minimal delays, which is especially important for IP telephony and VoIP systems. The implementation of multi-layered data protection using a modified TLS protocol not only increases the security of transmitted information, but also reduces the likelihood of successful man-in-the-middle (MITM) attacks, which is confirmed by experimental data. Furthermore, the work opens up new possibilities for further research and implementation of post-quantum methods in critical communication systems.

Future research in the field of cybersecurity for IP networks and IP PBXs can focus on several directions. First, post-quantum cryptographic algorithms such as lattice systems should be further optimized to reduce their computational complexity and improve their efficiency in real-world conditions, especially for high-load IP telephony. Second, it is worth exploring the possibilities of integrating other post-quantum cryptography methods (based on isogenies or multivariate polynomials) into existing infrastructures to improve security.

Acknowledgment

This article was prepared as part of the government contract as requested by the Science Committee of the Ministry of Science and Higher Education of the Republic of Kazakhstan on the subject formulated as «Development of a method for improving the security of a telecommunications network based on IP-PBX Asterisk» (project No. AP14871745).

Energy Optimization Management Scheme for Manufacturing Systems Based on BMAPPO: A Deep Reinforcement Learning Approach

Zhe Shao*
Woosong University, Endicott College, Korea, 34606

***Abstract*—To address the depletion of traditional energy sources and the increasingly severe environmental pollution, countries around the world have accelerated the deployment of renewable energy generation equipment. Energy optimization management for microgrids can address the randomness of factors such as renewable energy generation and load, ensuring the safe and stable operation of the system while achieving objectives such as cost minimization. Therefore, this paper conducts an in-depth study of energy optimization management schemes for microgrids and designs a multi-microgrid energy optimization management model and algorithm based on deep reinforcement learning. For the joint optimization problem among multiple microgrids with power flow between them, a two-layer energy optimization management scheme based on the multi-agent proximal policy optimization (PPO) algorithm and optimal power flow (BMAPPO) is proposed. This scheme is divided into two layers: first, the lower layer uses the multi-agent proximal policy optimization algorithm to determine the output of various controllable power devices in each microgrid; then, based on the lower layer's optimization results, the upper layer uses a second-order cone relaxation optimal power flow model to solve the optimal power flow between multiple microgrids, achieving power scheduling among them; finally, the total cost of the upper and lower layers is calculated to update the network parameters. Experimental results show that compared with other schemes, the proposed scheme achieves multi-microgrid energy optimization management at the lowest cost while ensuring online execution speed.**

Keywords*—Microgrid; energy optimization management; deep reinforcement learning; multi-agent; Proximal Policy Optimization (PPO)

I. INTRODUCTION

Electric power is an indispensable driving force in modern society. In recent years, with the rapid development of technology and the continuous growth of the global population, the demand for electricity has been increasing year by year [1]. To meet this demand, the current smart grid is transitioning towards a more structured system based on microgrids. This transition, which optimizes energy storage systems through collaboration and self-organization, is key to driving the existing energy system towards being more intelligent, robust, and green.

Microgrid-based smart grids are not only better at integrating emerging distributed components but also position microgrids as an effective part of distribution and transmission system management through the evolving flexibility markets and new grid management concepts. The flexibility provided by microgrids, as well as their ability to operate in both grid-connected and island modes, are crucial solutions to the challenges faced by future transmission and distribution networks. The introduction of microgrids helps improve the reliability of power systems, reduce emissions, and expand the energy options for future power systems. Furthermore, the multi-microgrid structure formed by the interconnection of microgrids enhances the resilience, security, and intelligence of energy systems, supporting energy systems that incorporate large amounts of variable renewable energy.

Although the technologies related to components such as renewable energy generation and storage systems in microgrids have matured, joint optimization in microgrids remains challenging due to uncertainties in renewable energy generation, load, and energy prices. In addition to dealing with the fluctuations in renewable energy and load, storage devices must be optimized and controlled according to their operating costs or physical constraints. When multiple microgrids need to be optimized simultaneously, the complexity of the algorithms also increases. Given the technical and economic advantages of microgrids in future energy systems, ensuring the efficient and stable operation of microgrids has become a hot research topic.

A multi-microgrid refers to a system where multiple individual microgrids within a certain area are interconnected to achieve power mutual assistance. Compared to a single microgrid, a multi-microgrid has several advantages: First, a multi-microgrid can integrate large-scale renewable energy generation equipment, achieving a higher penetration rate of renewable energy through power flow between microgrids; second, it allows for the shared use of devices such as energy storage and generation, enabling a microgrid with large-capacity energy storage or high-power generation equipment to supply energy to other microgrids when the main grid's electricity price is high, further reducing costs; third, it enhances system robustness, allowing energy to be sourced from other microgrids if a microgrid's supply equipment fails or if the main grid experiences a power outage. Therefore, from the perspective of economic efficiency and future development trends, it is necessary to conduct research on energy optimization management for multi-microgrids.

Microgrid energy optimization management is an important research area in the power industry, aiming to achieve intelligent control and autonomous scheduling decisions for microgrids through optimization techniques. Under the premise

of ensuring the safe operation of equipment, the output of controllable power devices in microgrids is optimized to cope with fluctuations in renewable energy generation, load, and real-time electricity prices, meet load demand, avoid power waste, and minimize operational costs.

For the scenario of multiple microgrids, this paper proposes an energy optimization management scheme based on multi-agent proximal policy optimization. Since a single microgrid has limited capacity to deal with system uncertainties and often needs to trade with the main grid, joint optimization of multiple microgrids is expected to become a future development trend. To this end, this paper proposes a dual-layer structure for multi-microgrid energy optimization management. In the lower layer, the output of devices in each microgrid is decided based on a multi-agent proximal policy optimization algorithm, where centralized training ensures optimization effectiveness and decentralized decision-making protects user privacy. In the upper layer, the optimal power flow between microgrids is solved using a second-order cone relaxation optimal power flow model, ensuring power mutual assistance between microgrids.

The organization of this paper is as follows: Section II provides a detailed review of existing microgrid energy optimization management schemes; Section III proposes a dual-layer energy optimization management scheme based on multi-agent reinforcement learning to further improve the stability of microgrid operation and reduce costs; Section IV verifies the feasibility of the proposed method through case studies; Section V summarizes the contributions of the entire paper.

II. Literature Review

This section will review existing work related to resource management to highlight the gaps in current research.

A. Related Works

Energy optimization management in microgrids is essentially a constrained optimization problem with uncertain factors. Currently, the methods used in the field of microgrid energy optimization management mainly include metaheuristic algorithms (e.g., genetic algorithms), mathematical programming methods (e.g., mixed-integer linear programming), robust optimization, stochastic optimization, model predictive control, and deep reinforcement learning algorithms.

Metaheuristic algorithms have been widely applied in the field of microgrid energy optimization management. Among them, genetic algorithms and particle swarm optimization are the most commonly used, with similar techniques including ant colony optimization [2], crow search algorithm [3], and simulated annealing algorithm [4], among others. Torkan et al. [5] applied a multi-objective genetic algorithm to the optimization management of microgrids, considering the uncertainties brought by demand response (DR) programs, reactive power loads, and renewable energy. They optimized microgrid operations with energy cost and greenhouse gas emissions as objective functions, while this optimization objective function was constrained by a series of system constraints and was solved using a genetic algorithm.

In mathematical programming-based schemes, mixed-integer linear programming (MILP) can handle optimization problems where variables are continuous and discrete, making it highly suitable for application in microgrid energy optimization management. MILP can be used to establish mathematical models of microgrid components and optimize the cost function. Sigalo et al. [6] proposed an energy management scheme for grid-connected microgrids focused on battery storage systems, considering changes in grid electricity prices, renewable energy generation, and load demand, and determined the charging and discharging power of the battery to minimize the overall energy loss cost.

Stochastic and robust optimization-based microgrid energy optimization management schemes have been proposed to address the stochastic factors and prediction errors inherently present in microgrids. Chen et al. [7] proposed a new cumulative regret-based robust optimization method for the optimal management of grid-connected multi-energy microgrids considering uncertainty factors. Compared to traditional robust optimization methods, the proposed strategy ensures the robustness of microgrids and reduces the conservatism of microgrid operations. Additionally, by considering the demand response of thermal loads, the optimization model for microgrid energy management was improved. Abunima et al. [8] proposed a two-stage microgrid optimization scheduling method that coordinates microgrid assets under uncertainty, allowing microgrid operators to save operational costs without increasing investment costs, while meeting load demand. Nair et al. [9] considered an islanded microgrid composed of photovoltaic generation, supercapacitors, and regenerative fuel cells, utilizing a model predictive control algorithm. The goal was to enhance the utilization of renewable energy, improve microgrid operational efficiency, and reduce the degradation rate of the storage system.

A common feature of the above model-based methods is their reliance on precise predictions of uncertain factors in microgrids. Once prediction errors occur, the performance of these methods can be significantly impacted. Additionally, the computational cost of these methods is typically high, facing the issue of "curse of dimensionality"; as the complexity of the optimization problem increases, the computational cost multiplies, making it difficult to meet the real-time requirements of microgrid energy optimization management. To address these issues, some researchers have employed deep reinforcement learning (DRL) to solve the problem of microgrid energy optimization management. Deep reinforcement learning is a data-driven or model-free algorithm that does not rely on precise modeling of the microgrid environment. Thanks to the powerful perception capabilities of deep learning algorithms, DRL can effectively learn the microgrid environment model. Additionally, due to the strong decision-making ability of reinforcement learning, it can efficiently solve optimization problems. Alabdullah et al. [10] proposed a microgrid energy management solution based on the Deep Q-Network (DQN) algorithm, considering the stochastic behavior of various factors in the microgrid and modeling different grid components, while adhering to various power flow constraints in real-world environments.

B. Research Gaps and Motivation

Based on the above literature review, the following conclusions can be drawn:

1) Real-time performance and stability challenges: Current microgrid energy optimization methods, including mathematical programming, stochastic optimization, robust optimization, and MPC, struggle with high computational complexity and real-time performance due to the handling of uncertainties. MPC, in particular, faces difficulties in ensuring stability and has not fully accounted for model uncertainties.

2) Dependency on accurate predictions: Model-based methods rely heavily on accurate predictions of uncertainties in microgrids. Prediction errors and high computational costs can lead to performance issues and the "curse of dimensionality," making real-time energy optimization challenging.

3) Need for further research in deep reinforcement learning: While deep reinforcement learning offers potential advantages such as real-time scheduling and a general framework, its applicability across different microgrid architectures and its effectiveness in online optimization require further research and validation.

Addressing these issues is critical for improving the effectiveness and applicability of microgrid energy management, which is the focus of this paper.

III. Multi-Microgrid Dual-Layer Energy Optimization Management Model Based on Reinforcement Learning

A. Multi-Microgrid Dual-Layer Energy Optimization Management Model

The structure of the multi-microgrid dual-layer energy optimization management model designed in this chapter is shown in Fig. 1. The lower layer consists of N microgrids, each containing photovoltaic generation equipment, wind power generation equipment, energy storage devices, micro gas turbines, loads, and a control center. The microgrids are interconnected through energy routers.

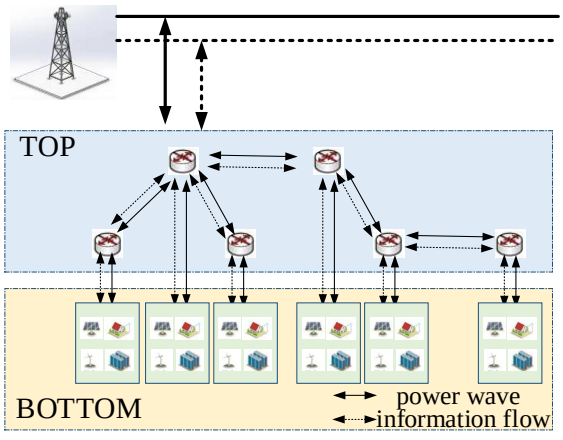

Fig. 1. Schematic diagram of the multi-microgrid dual-layer structure.

The upper layer is an abstracted topology based on the lower layer, which facilitates power flow analysis. In the process of one round of multi-microgrid energy optimization management, the lower layer first uses multi-agent deep reinforcement learning to decide the output of controllable power devices [11]. Then, the upper layer calculates the optimal power flow based on the regulated results of the lower layer. Finally, based on the results of the two-layer optimization, the reward value is calculated, and the neural network parameters are updated. Therefore, the following sections will first introduce the multi-agent deep reinforcement learning algorithm MAPPO in the lower layer, then explain the optimal power flow model for the multi-microgrid in the upper layer, and finally present the overall algorithm flow and experimental results.

B. Lower Layer Multi-Agent Deep Reinforcement Learning Algorithm

As shown in Fig. 2, MAPPO is a multi-agent variant of PPO (Proximal Policy Optimization) and operates using a Centralized Training with Decentralized Execution (CTDE) approach. In centralized training, the Critic network of each agent can use global information during the offline training phase to achieve better convergence. In decentralized execution, each agent's Actor network can only observe its own state to make decisions during the online execution phase. Extensive experiments have shown that the clipped form of PPO consistently outperforms the penalized form, and hence, the clipped form is adopted in this work. The optimization objective can be written as follows:

$$\max \hat{\mathbb{E}}_t\left[\min\left(r_t(\theta)\hat{A}_t, \text{clip}(r_t(\theta),1-\varepsilon,1+\varepsilon)\hat{A}_t\right)\right] \quad (1)$$

$$\text{clip}(r_t(\theta),1-\varepsilon,1+\varepsilon) = \begin{cases} 1-\varepsilon, & r_t(\theta) < 1-\varepsilon \\ 1+\varepsilon, & r_t(\theta) > 1+\varepsilon \\ r_t(\theta), & \text{other} \end{cases} \quad (2)$$

Here, clip(·) is the clipping function. When $\hat{A}_t > 0$, it indicates that the action a_t taken at this moment is better than the average, so maximizing Eq. (1) will increase $r_t(\theta)$, meaning the probability of action a_t in the new policy will increase. However, $r_t(\theta)$ will not increase beyond 1+ε. Conversely, when $\hat{A}_t < 0$, it indicates that the action a_t taken at this moment is worse than the average, so maximizing Eq. (1) will decrease $r_t(\theta)$, meaning the probability of action a_t in the new policy will decrease. However, $r_t(\theta)$ will not decrease below 1-ε.

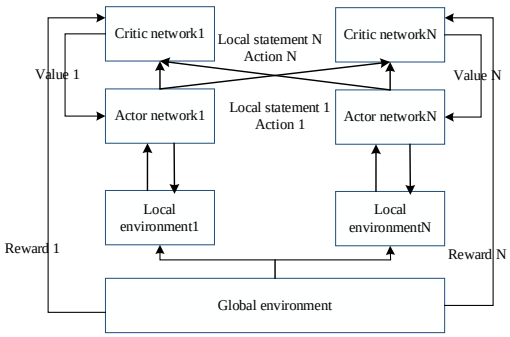

Fig. 2. MAPPO algorithm architecture.

C. Upper-Layer Optimal Power Flow Model

Currently, distribution networks are primarily radial in structure. A radial structure with multiple microgrids can be modeled using the Branch Flow Model (BFM). Fig. 3 illustrates a schematic diagram of the Branch Flow Model. For node j:

- V_j represents the voltage at the node;
- $s_j = p_j + iq_j$represents the power injection at the node.

For the branch from node i to node j (i→j):

- I_{ij} represents the branch current;
- $S_{ij} = P_{ij} + iQ_{ij}$ represents the power at the sending end of the branch;
- $Z_{ij} = r_{ij} + ix_{ij}$ represents the branch impedance.

The topology of the upper-level multi-microgrid system is denoted as G(N,E)G(N,E). Finally, by applying angle relaxation and second-order cone relaxation, the optimal power flow problem is transformed into a convex optimization problem. Specifically:

$$l_{ij} \geq \frac{P_{ij}^2 + Q_{ij}^2}{v_i}, \forall (i,j) \in E \Leftrightarrow \left\| \begin{bmatrix} 2P_{ij} \\ 2Q_{ij} \\ l_{ij} - v_i \end{bmatrix} \right\|_2 \leq l_{ij} + v_i, \quad \forall (i,j) \in E \tag{3}$$

At this point, the optimization variables for the optimal power flow problem become $\{p_i, q_i, P_{ij}, Q_{ij}, l_{ij}, v_i\}$. For a radial network, the literature has proven that angle relaxation is tight; under the conditions that the objective function is strictly increasing and convex, the second-order cone relaxation is also tight. At this stage, the optimal power flow problem has been modeled as a convex optimization problem, which can be conveniently solved using commercial solvers like Gurobi.

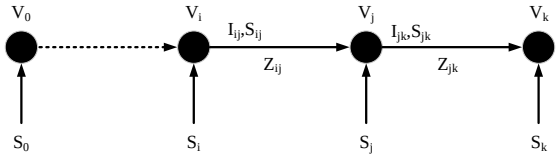

Fig. 3. Schematic diagram of branch flow structure.

D. BMAPPO: Multi-Microgrid Dual-Layer Energy Optimization Management Algorithm

The constraints in a multi-microgrid system arise from three aspects: the electrical boundary constraints of various devices in the microgrid, the power balance constraints of each microgrid, and the power flow constraints between microgrids [12]. For convenience, unless otherwise stated, i represents the ith microgrid in the multi-microgrid system; t represents the tth round of optimization management; N represents the set of microgrid nodes; E represents the set of edges (power lines) between microgrids.

1) Device boundary constraint

a) Micro gas turbine boundary constraints:

$$P_{i,\min}^{MT} < P_{i,t}^{MT} < P_{i,\max}^{MT}, \forall i \in N \tag{4}$$

In the above formula, $P_{i,t}^{MT}$ is the output power of the micro gas turbine (kW); $P_{i,\min}^{MT}$ and $P_{i,\max}^{MT}$ are the lower and upper bounds of the micro gas turbine's output power (kW).

b) Energy storage device boundary constraints:

$$P_{i,\min}^{ESS} < P_{i,t}^{ESS} < P_{i,\max}^{ESS}, \forall i \in N \tag{5}$$

$$SOC_{i,\min} \leq SOC_{i,t} \leq SOC_{i,\max} \ \forall i \in N \tag{6}$$

In the above formulas, $P_{i,tS}^{ESS}$ is the charging/discharging power of the energy storage device (kW); $P_{i,\min}^{\mathrm{ESS}}$ and $P_{i,\max}^{ESS}$ are the lower and upper bounds of the charging/discharging power of the energy storage device (kW); $SOC_{i,t}$ is the state of charge of the energy storage device; $SOC_{i,\min}$ and $SOC_{i,\max}$ are the lower and upper bounds of the state of charge of the energy storage device.

c) Main grid boundary constraints

$$P_{i,\min}^{MG} < P_{i,t}^{MG} < P_{i,\max}^{MG}, \forall i \in N \tag{7}$$

$$Q_{i,\min}^{MG} < Q_{i,t}^{MG} < Q_{i,\max}^{MG}, \forall i \in N \tag{8}$$

In the above formulas, $P_{i,t}^{MG}$ is the active power traded between the microgrid and the main grid (kW); $P_{i,\min}^{MG}$ and $P_{i,\max}^{MG}$ are the lower and upper bounds of the active power traded between the microgrid and the main grid (kW); $Q_{i,t}^{MG}$ is the reactive power traded between the microgrid and the main grid (kVar); $Q_{i,\min}^{MG}$ and $Q_{i,\max}^{MG}$ are the lower and upper bounds of the reactive power traded between the microgrid and the main grid (kVar).

2) Power balance constraints

a) Active power balance constraint

$$p_{i,t} = P_{i,t}^{PV} + P_{i,t}^{WT} + P_{i,t}^{MT} + P_{i,t}^{ESS} + P_{i,t}^{MG} - P_{i,t}^{Load}, \forall i \in N \tag{9}$$

In the above formula, $p_{i,t}$ is the injected active power (kW); $P_{i,t}^{PV}$ and $P_{i,t}^{WT}$ are the active power outputs of photovoltaic and wind power generation, respectively (kW); $P_{i,t}^{MT}$ is the output power of the micro gas turbine (kW); $P_{i,t}^{ESS}$ is the charging/discharging power of the energy storage device (kW); $P_{i,t}^{MG}$ is the active power traded between the microgrid and the main grid (kW); $P_{i,t}^{\mathrm{Load}}$ is the active power of the load (kW).

b) Reactive power balance constraint

$$q_{i,t} = Q_{i,t}^{MG} - Q_{i,t}^{Lood}, \forall i \in N \tag{10}$$

In the above formula, $q_{i,t}$ is the injected reactive power (kVar); $Q_{i,t}^{\mathrm{MG}}$ is the reactive power from the main grid (kVar); $Q_{i,t}^{\mathrm{Load}}$ is the reactive power of the load (kVar).

3) Power flow constraints

$$v_j = v_i - 2\left(r_{ij}P_{ij} + x_{ij}Q_{ij}\right) + \left(r_{ij}^2 + x_{ij}^2\right)l_{ij}, \forall (i,j) \in E \tag{11}$$

$$p_j = \sum_{k:j\to k} P_{jk} - \sum_{i:i\to j} \left(P_{ij} - r_{ij}l_{ij}\right), \forall j \in N \tag{12}$$

$$q_j = \sum_{k:j\to k} Q_{jk} - \sum_{i:i\to j} \left(Q_{ij} - x_{ij}l_{ij}\right), \forall j \in N \tag{13}$$

$$l_{ij} \geq \frac{P_{ij}^2+Q_{ij}^2}{v_i},\ \forall(i,j) \in E \quad (14)$$

$$\left|I_{ij}\right| \leq \bar{I_{ij}},\ \forall(i,j) \in E \quad (15)$$

$$\underline{V_i} \leq |V_i| \leq \bar{V_i},\ \forall i \in N \quad (16)$$

$$\underline{s_i} \leq s_i \leq \bar{s_i},\ \forall i \in N \quad (17)$$

E. Optimization Objective Function

In this chapter, considering the uncertainties in renewable energy generation, load, and electricity prices, the objective is to minimize the cooperative operation cost of multiple microgrids. An energy optimization management model for multiple microgrids is constructed, and the objective function is as follows:

$$\min F_t = \min \sum_{t=1}^{T} \left(\sum_{i=1}^{N} \left(F_{i,t}^{MG} + F_{i,t}^{MT} + F_{i,t}^{ESS}\right) + F_t^{\text{Loss}}\right) \quad (18)$$

Where:

- F_t is the total operating cost of the multi-microgrid system.
- t represents the t-th round of optimization management.
- T is the total number of rounds within an energy optimization management period.
- $F_{i,t}^{MG}$ represents the cost of trading with the main grid.
- $F_{i,t}^{MT}$ represents the generation cost of the micro gas turbine.
- $F_{i,t}^{ESS}$ represents the loss cost of the energy storage device.
- F_t^{Loss} represents the power transmission loss between microgrids.

For simplicity, in this chapter, ΔtΔt represents the time length of one round of optimization management (hours).

a) Cost of trading between microgrid and main grid

$$F_{i,t}^{MG} = c_t^{MG} P_{i,t}^{MG} \cdot \Delta t \quad (19)$$

In the above formula, ctMGctMG is the electricity price of the main grid during the tt-th round of optimization management ($/kWh), and P(i,t)MGP(i,t)MG is the active power purchased by the microgrid from the main grid (kW).

b) Micro gas turbine generation cost

$$F_{i,t}^{MT} = \left(a \cdot \left(P_{i,t}^{MT}\right)^2 + b \cdot P_{i,t}^{MT} + c\right) \cdot \Delta t \quad (20)$$

In the above formula, aa, bb, and cc are cost coefficients.

c) Energy storage device loss cost

$$F_{i,t}^{ESS} = \left(c^{\text{ESS}} \cdot \left(P_{i,t}^{cha} \cdot \eta_{\text{cha}} + P_{i,t}^{dis} / \eta_{dis}\right)\right) \cdot \Delta t \quad (21)$$

In the above formula, cESScESS is the loss coefficient; P(i,t)chaP(i,t)cha and P(i,t)disP(i,t)dis are the charging and discharging powers of the energy storage device, respectively (kW); ηchaηcha and ηdisηdis are the charging and discharging efficiencies of the energy storage device, respectively.

d) Transmission loss between microgrids

$$F_t^{\text{Loss}} = \sum_{ij \in E} c_t^{MG} \left|I_{ij,t}\right|^2 r_{ij} \cdot \Delta t \quad (22)$$

In the above formula, $I_{ij_{,,}}$ and r_{ij} are the current (A) and impedance (Ω) between microgrid i and microgrid j, respectively.

Based on the above description, solving the optimization problem in Eq. (19) requires handling optimization variables that can be divided into lower-layer and upper-layer optimization variables. The lower-layer optimization variables include:

- The generation power of micro gas turbines in microgrids $\{P_{i,t}^{MT}\}$.
- The charging and discharging power of energy storage devices in microgrids $\{P_{i,t}^{ESS}\}$.
- The active power traded between the microgrid and the main grid $\{P_{i,t}^{\text{MG}}\}$.
- The reactive power traded between the microgrid and the main grid $\{Q_{i,t}^{\text{MG}}\}$.

The upper-layer optimization variables include:

- Node voltage $\{v_{j,t}\}$.
- Node injected power $\{p_{j,t}, q_{j,t}\}$.
- Branch current $\{l_{ij,t}\}$ and branch power $\{P_{ij,t}, Q_{ij,t}\}$.

F. Construction of a Partially Observable Markov Decision Process

The multi-agent reinforcement learning algorithm MAPPO (Multi-Agent Proximal Policy Optimization) is used to solve the multi-microgrid energy optimization management problem, which can be modeled as a Partially Observable Markov Decision Process (POMDP). POMDP can be defined as a five-tuple $(\mathcal{S}, \{\mathcal{O}_i\}_{i=1}^n, \{\mathcal{A}_i\}_{i=1}^n, \mathcal{P}, \{r_i\}_{i=1}^n)$, where:

- $\mathcal{S}$ is the global state space.
- $\mathcal{P}$ is the state transition function.
- For agent i, the observation space is $\mathcal{O}_i$, the action space is $\mathcal{A}_i$, and the reward function is r_i.

Further, in multi-agent reinforcement learning, the interaction process between agents and the environment is as follows:

- At time step t, each agent i obtains an observation state $o_{i,t} \in \mathcal{O}_i$ and selects an action $a_{i,t} \in \mathcal{A}_i$ according to the policy $\pi_i: \mathcal{O}_i \times \mathcal{A}_i \rightarrow [0,1]$.
- Then, the system transitions to the next state $o_{i,t+1}$ according to the state transition probability $\mathcal{P}$ and receives a reward $(s_t, a_{i,t})$.

The objective of multi-agent reinforcement learning is to maximize the cumulative return: $J(\pi) = \mathbb{E}\left[\sum_{t=0}^{T} \frac{1}{n} \gamma^t \sum_{i=1}^{n} r_{i,t}\right]$.

Therefore, the multi-microgrid energy optimization management problem is modeled as a POMDP below.

a) Observation space definition

$$o_{i,t} = \left[P_{i,t}^{PV}, P_{i,t}^{WT}, P_{i,t}^{Load}, c_t^{MG}, SOC_{i,t}\right] \quad (23)$$

In the above formula:

- $P_{i,t}^{PV}$ and $P_{i,t}^{WT}$ are the photovoltaic and wind power generation outputs, respectively.
- $P_{i,t}^{Load}$ is the load power.
- c_t^{MG} is the real-time electricity price of the main grid.
- $SOC_{i,t}$ is the state of charge of the energy storage device.

b) b) State Space Definition

$$s_t = \left[o_{1,t}, o_{2,t}\ \mathrm{K}, o_{n,t}\right] \quad (24)$$

The state space contains the observation space of all agents and represents the global information of the multi-agent environment.

c) Action space definition

$$a_{i,t} = \left[P_{i,t}^{MT}, P_{i,t}^{ESS}, P_{i,t}^{\mathrm{MG}}, Q_{i,t}^{\mathrm{MG}}\right] \quad (25)$$

In the above formula:

- $P_{i,t}^{MT}$ is the power output of the micro gas turbine.
- $P_{i,t}^{ESS}$ is the charging/discharging power of the energy storage device.
- $P_{i,t}^{\mathrm{MG}}$ is the active power traded between the microgrid and the main grid.
- $Q_{i,t}^{\mathrm{MG}}$ is the reactive power traded between the microgrid and the main grid.

d) Reward function definition

$$r_{i,t} = -\left(\alpha \cdot \left(F_{i,t}^{MG} + F_{i,t}^{MT} + F_{i,t}^{ESS}\right) + \beta \cdot \sum_{i=1}^{N} \mathrm{cons}\left(SOC_{i,t}\right)\right) \quad (26)$$

$$r_t = -F_t^{\mathrm{Loss}} + \sum_{i=1}^{N} r_{i,t} \quad (27)$$

Eq. (26) is the reward function for agent ii, where α and β are coefficients, and cons (·) is a penalty function introduced in the previous chapter. Eq. (27) is the total reward for the multi-microgrid system. Since the algorithm designed in this chapter is a dual-layer optimization, the total reward is calculated after the upper-layer optimization is completed. It includes the sum of all lower-layer agent rewards and the upper-layer optimization objective F_t^{Loss}. It is worth mentioning that Eq. (23) can also be decomposed using the vectorization approach proposed in the previous chapter, but for simplicity, the traditional reward function is used here. Online Decision-Making Process of the MAPPO-Based Multi-Microgrid Dual-Layer Energy Optimization Management Scheme. The online decision-making process is shown in Algorithm 1.

Algorithm 1: Multi-Microgrid Energy Optimization Management Algorithm Online Decision-Making Process

Input: Actor network weights θπθπ

Output: Values of all optimization variables in the tt-th round of multi-microgrid energy optimization

Step 1: Obtain the initial state of all agents.

For t=1,2,…,T do:

Step 1: Each agent i∈N in the lower layer observes state o_t^i and selects an action $a_{i,t}$ based on the policy, obtaining the optimization variables $\left\{P_{i,t}^{MT}, P_{i,t}^{ESS}, P_{i,t}^{\mathrm{MG}}, Q_{i,t}^{\mathrm{MG}}\right\}, i \in N$.

Step 2: The upper layer solves the optimal power flow problem using a commercial optimizer, obtaining the optimization variables $\left\{v_{j,t}\right\} \setminus \left\{p_{j,t}, q_{j,t}\right\} \setminus \left\{\Delta P_{i,t}^{MG}, \Delta Q_{i,t}^{MG}\right\}, i \in N$ and $\left\{l_{ij,t}\right\} \setminus \left\{P_{ij,t}, Q_{ij,t}\right\}, ij \in E$.

Step 3: Apply all optimization variables to the multi-microgrid system and obtain the next state s_{t+1}.

End for

IV. Experimental Results Analysis

A. Simulation Environment and Parameter Settings

The IEEE 33-bus system structure, as shown in Fig. 4, is used as the upper-level topology for the dual-layer energy optimization management of multiple microgrids. Microgrids can be placed at any node, and the impedance value between two adjacent nodes is the average of the branch impedances between the nodes. For example, if microgrids are connected at nodes 1 and 21 to form a system with two microgrids, the impedance between nodes 1 and 21 would be the average impedance of branches 1-18, 18-19, 19-20, and 20-21. This setup allows the generation of various simulation environments on the IEEE 33-bus system. In this chapter, nodes 1, 2, 5, and 24 are selected to connect microgrids 1 to 4, forming a multi-microgrid structure with four microgrids. Energy optimization management is performed every hour.

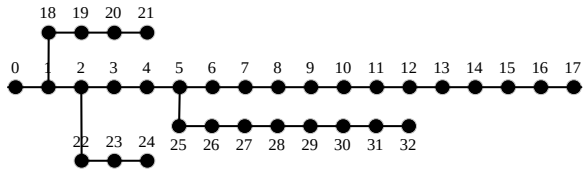

Fig. 4. Schematic diagram of the IEEE 33-bus system structure.

The experimental equipment used in this chapter includes an Intel(R) Core(TM) i5-10210U CPU @1.60GHz 2.10 GHz and an NVIDIA GeForce RTX2060. The compiler used is Pycharm 2022.3, and the programming language is Python 3.8. The commercial optimizer used for solving the upper-level optimal power flow is the Python version of Gurobi 10.0.1. The implementation framework for the lower-level multi-agent deep reinforcement learning algorithm is the mainstream neural network development framework Pytorch. The MAPPO parameters are set as shown in Table I:

TABLE I. MAPPO PARAMETER SETTINGS

Parameter	Value
Discount Factor γ	0.95
Number of Neurons in Hidden Layer	128
Actor Network Learning Rate l_a	0.0003
Critic Network Learning Rate l_c	0.0001
Clipping Function Hyperparameter ε	0.2
Size of Experience Replay Pool D	10000
Mini-batch Size B	96
Maximum Number of Training Epochs	20000

B. Optimization Management Results Analysis

1) Convergence analysis: As shown in Fig. 5, during the offline training process, the BMAPPO algorithm proposed in this chapter converges at around 9000 iterations. The smoothed cumulative reward oscillates around -2250. Since the reward function is a negative function of the optimization management cost, the convergence curve shows an upward trend, indicating that during the iteration process, the agent learns effective strategies to reduce the cost of multi-microgrid optimization management. During offline training, 80% of the dataset was used. Next, the network parameters after training are saved, and the remaining 20% of the dataset is used to simulate the online optimization management process to test the effectiveness of the algorithm.

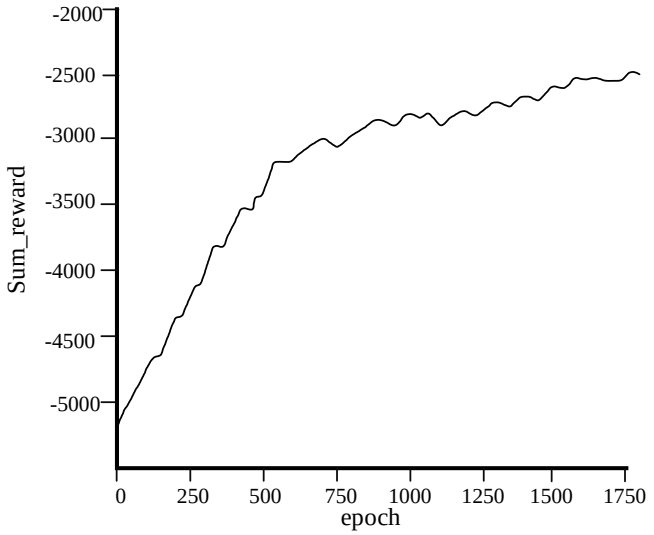

Fig. 5. Convergence curve of the BMAPPO algorithm during offline training.

2) Effectiveness analysis: Fig. 6 shows the lower-level optimization results for Microgrid 1 and Microgrid 2.

Fig. 6(a1) and 6(a2) represent the output curves of controllable power devices in Microgrid 1 and Microgrid 2, respectively, including the power generation of micro gas turbines, the charging and discharging power of energy storage devices, and the power regulation results of transactions with the main grid. Combined with the real-time electricity price fluctuations of the main grid shown in Fig. 5, it can be seen that when the main grid electricity price is low from 1 to 5 hours, the power of the energy storage devices in both microgrids is negative (except for a discharge of about 40 kW in Microgrid 1 at 5 hours), representing charging of the energy storage devices. During this period, a large amount of electricity is purchased from the main grid, while the micro gas turbines almost do not output power. When the main grid price is moderately high from 9 to 17 hours, the trend of output from controllable power devices is similar to that from 1 to 5 hours, but the load power gap in this period is also relatively low, so the power purchased from the main grid is also relatively less. When the electricity price is high from 6 to 8 hours and 18 to 22 hours, the output of the energy storage devices is generally positive, representing discharging of the energy storage devices. During these periods, the power purchased from the main grid is at a low point, and the micro gas turbines output a large amount of power to fill the load power gap. Therefore, the BMAPPO proposed in this chapter is effective in cost savings.

Fig. 6(b1) and 6(b2) show the state of charge (SoC) curves of the energy storage devices in Microgrid 1 and Microgrid 2, respectively, with the upper and lower bounds of the SoC indicated, set at 0.9 and 0.1. An SoC less than 0.1 indicates an over-discharging condition, while an SoC greater than 0.9 indicates an over-charging condition. It can be seen that the energy storage device in Microgrid 2 is in a safe state during the typical day, with no over-charging or over-discharging occurring. However, Microgrid 1 shows a slight over-charging condition from 16 to 19 hours.

Fig. 7 illustrates the upper-level optimization results for Microgrid 1 and Microgrid 2.

Fig. 7(a1) and 7(a2) display the power injection curves for Microgrid 1 and Microgrid 2, respectively. Positive power injection indicates that there is excess power within the microgrid that is not being consumed, while negative power injection indicates that there is an unsatisfied power deficit within the microgrid. The upper-level power flow optimization will balance the power injection between microgrids, ensuring power balance in each microgrid. From Fig. 7(a1), it can be seen that Microgrid 1 has positive power injection from 17 to 21 hours, which can be transmitted to other microgrids. From Fig. 7(a2), it can be seen that Microgrid 2 has negative power injection from 18 to 22 hours, which can be obtained from other microgrids. This shows that the upper-level microgrids can achieve mutual support.

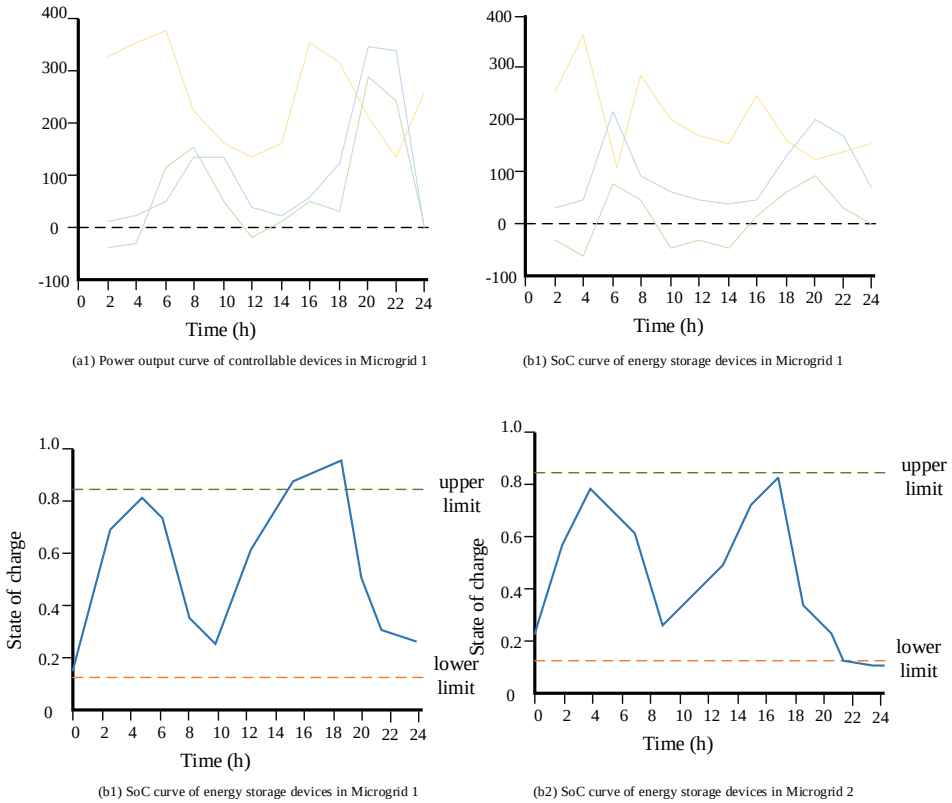

Fig. 6. Lower-level optimization results of Microgrid 1 and Microgrid 2.

Fig. 7. Upper-level optimization results of Microgrid 1 and Microgrid 2.

V. CONCLUSION

This paper proposes a dual-layer optimization management scheme based on the multi-agent reinforcement learning algorithm MAPPO for the energy optimization management problem of multiple microgrids. The lower layer uses MAPPO to make decisions on the power output of each microgrid device, handling power imbalances, while the upper layer achieves overall power balance of multiple microgrids through a second-order cone relaxation optimal power flow model. The experimental results show that the designed BMAPPO algorithm effectively achieves mutual support between microgrids and significantly reduces the energy optimization management costs of multiple microgrids.

Although the deep reinforcement learning-based energy optimization management scheme proposed in this paper shows significant advantages in cost savings, there is still room for improvement:

The deep reinforcement learning method relies on a large amount of historical data for training, which may be difficult to obtain in practical applications. Therefore, future research should focus on reducing dependence on historical data or improving data utilization efficiency.

This paper only studies the situation where microgrids are connected to the main grid, while islanded microgrids have widespread applications in remote areas, where their optimization management cost control is of significant importance. Therefore, how to reduce the management costs of islanded microgrids while ensuring safety is an important direction for future research.

ACKNOWLEDGMENT

The preferred spelling of the word “acknowledgment” in America is without an “e” after the “g.” Avoid the stilted expression, “One of us (R. B. G.) thanks . . .” Instead, try “R. B. G. thanks.”

Design Science Research: Applying Integrated Fogg Persuasive Frameworks to Validate Rural ICT Design Requirements

Design for Digital Equality in Rural Areas

***Abstract*—Designing for digital equality is critical in the modern world. Digital inequality is more pronounced in rural areas, where the majority are illiterate and poor. As a result of this, individuals are not motivated, enabled and triggered enough to access and use Information and Communication Technologies. Additionally, existing rural ICT artifacts or applications are not usable by these demographics. Therefore, this paper understood and validated rural ICT design requirements. It achieved this by developing a community learning system, applying design science research methodology and integrated Fogg persuasive frameworks. Results shows that use of local language, local content, videos, audio, touch-based input, proper content categorization, accessibility (location) and peer participation and collaboration fosters user engagement with the ICT artifact. These approaches had a significant impact in the achievement of user self-efficacy. This is explained by the task findings, 71%, 83%, 70% and 78% successfully, within the stipulated time and on their own, accomplished tasks 1, 2,3 and 4 respectively. Users found the content to be practical and applicable to their day-to-day activities. Users appreciated the system's potential for learning indicating that it could significantly enhance their knowledge and skills. The significance of Design Science Research and integrated Fogg persuasive frameworks in creating usable and accessible ICT solutions tailored to the needs of the target population cannot be underrated. It was concluded that design solutions targeting vulnerable demographics are key to the success of designs for digital equality. In other words, usable solutions for the aged, women illiterate, uneducated and the poor, are more usable for the young, men, literate, educated, and the rich (financially stable). Thus, enhancing inclusivity in access and use of rural ICTs.**

Keywords*—Digital equality; rural areas; design requirements; rural ICT; artifacts; validate; Fogg frameworks; design science research

I. INTRODUCTION

Digital inequalities have emerged as a growing concern in modern societies [1]. The disparities pertain to differences in access and use of ICTs such as internet connectivity, internet-enabled devices and digital literacy skills among individuals living in rural areas [2, 3]. According to study [2], these three factors are essential for communities to create a sustainable access to the digital world, specifically as critical aspects of society such as education, workforce development and innovation transition to online platforms [2]. Therefore, the absence of robust, and all-encompassing applications or information access makes it difficult for people to participate in the digital community and access digital services, which remains exclusive on a systemic level. Thus, there is a need for targeted ICT solutions which will enhance inclusivity in access and use among various demographics in the community.

Even if people have equal access to digital technologies, such as the presence of rural ICT centers, disparities in skills, motivation, and literacy levels can result in digital inequality. Consequently, marginalized groups (such as the illiterate and uneducated) of all ages tend to avoid adopting modern technologies, leading them to miss out on important information. Encouraging these groups, who have little to no exposure to technology, to integrate ICTs into their daily lives is a significant challenge. This underscores the necessity for a thoughtful design approach. According to researcher [Rogers], technology can be utilized to influence people's behavior. Hence, we applied Fogg frameworks to validate ICT design requirements for rural areas and to identify additional requirements unique to rural areas.

The term persuasive technology pertains to interactive information technology that is specifically created to change users' attitudes or behavior or both within the realm of human-computer interaction [4]. Given its manipulative nature and ability to exert influence in a subtle manner [5], particularly on individuals who may lack literacy or motivation, it has the potential to significantly impact the design of digital solutions for rural areas. This helps to achieve equality in access and use of ICTs.

This research is part of a larger study aiming to establish a framework for creating rural ICTs that promote inclusivity. This paper specifically focuses on validating the requirements to achieve this broader objective. It starts by providing the study's background and related work in before delving into the requirements for designing for illiterate and semi-illiterate individuals, as the primary aim is to validate these requirements. The validation process enhances the comprehension of the design requirements for rural areas, ultimately leading to the development of a robust, practical, and applicable framework. Requirements were sourced from existing research,

incorporated into the Fogg persuasive framework, and used to design persuasive features in a community learning system. The conclusion discusses the persuasive features identified through evaluation that promote inclusivity in accessing and using rural ICTs. Lastly, future work is recommended.

II. Background and Related Work

A. Fogg Persuasive Frameworks

According to study [6], users perceive computers as tools, media and social actors. This is known as captology (computer as a persuasive technology) triad.

The Fogg Behavioral Model (FBM) is a conceptual framework used to understand human behavior. This framework is particularly important for those involved in studying and creating persuasive technology. Persuasive technology focuses on automating behavior change. To effectively incorporate experiences that promote behavior change, designers need a thorough understanding of human psychology, especially the factors that drive human behavior. The FBM provides designers and researchers with a systematic way to consider the underlying factors of behavior change. It highlights that motivation, ability, and triggers must all align at the same time for the behavior to occur; otherwise, it will not happen. The inclusion of FBM in the UX design process assists designers in creating user-centered designs and encourages meaningful and impactful interaction with the product [7].

Fogg's persuasive integrated framework merges the triad elements of captology with the components of FBM. Captology focuses on the characteristics of ICT, while FBM emphasizes human factors. Fig. 1 demonstrates, using computer as a tool, how these components will be integrated to create a robust framework that will assist in defining the design requirements for rural ICT. MF is motivation features, AF is ability features and TF is triggers features, all to the computer as a tool.

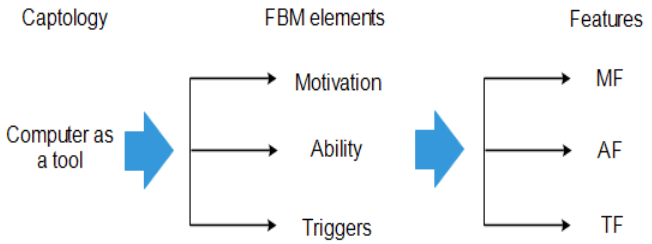

Fig. 1. Illustration of integrated Fogg persuasive frameworks.

The Chomoka Mobile Application, developed by [8], is a relevant persuasive technology for this study. It was designed specifically for Village Savings and Loan Associations (VSLAs) in seven rural African countries. Their goal in utilizing FBM was to build a more user-friendly and intuitive application, focusing on creating triggers that promote consistent usage. Furthermore, this approach improved the overall user experience and impact of the Chomoka app. It is evident that incorporating the Fogg Behavior Modeling framework could have further enhanced the success of the Chomoka app.

In their content analysis study, [9] systematically assessing the prevalence of persuasive design elements in popular early childhood apps [9] found out that a majority of them displayed a high prevalence of passive motivation features such as vibrant colors and music, as well as ability features like in-game help suggestions and repetitive tasks. In their conclusion, the researchers emphasized the importance of considering the developmental consequences of persuasive design features in apps and investigating how they might influence problematic screen behaviors in early childhood.

In their study, [10], demonstrated how the mobile app Sedentaware can prevent sedentary behavior by encouraging users to engage in physical activities. They illustrated how their model can complement a mathematical model to develop more effective persuasive technologies. Their research highlighted a key drawback of persuasive technology theory: it lacks the necessary level of detail for designers to systematically create persuasive technologies. This led us to combine Fogg frameworks with DSRM.

Researchers, [11] combined Fogg Behavioral Model and the Hook model to design features for an app as a component of a larger persuasive system to help improve three key areas of study habits: study scheduling, class preparation and group study. The proposed mobile companion app formed the overall persuasive system which was used to influence student study habits to improve their learning outcomes.

B. Design Science Research Methodology

Researcher, [12] conducted a study with the goal of reducing the digital divide between literate and illiterate populations in Iraq. They achieved this by creating a mobile app focused on educating about traffic signs. The app was developed using the Design Science Research (DSR) method. Upon development and evaluation, it was found that the illiterate participants demonstrated highly competent performance in completing tasks. The study confirmed that the app, which incorporated design principles such as voice instructions, symbols, and the local language, was effective, efficient, and garnered high user satisfaction. This study demonstrates that developing mobile apps for illiterate individuals can enhance their technological knowledge and bridge the gap between them and those with access to modern technology.

In their study, [13] created a mobile app to help illiterate individuals in Bangladesh find jobs, aiming to bridge the digital gap in developing nations. They used the DSRM to develop and assess the IT tool. They discovered that incorporating minimal text and voice prompts was crucial for designing mobile apps for illiterate users, and that using voice instead of text for information input was another essential design principle for this demographic. They also emphasized the importance of using images and culturally relevant symbols in User Interfaces (UI) to improve user understanding of the app's functions. In their future work, they suggested conducting a study to address the issues identified in their research, such as using methods like observation and on-site visits in addition to semi-structured interviews for requirement gathering, and considering a longitudinal study for broader insights. They also highlighted the need to recruit a larger number of participants for future studies.

C. Existing Gap

Numerous research efforts have aimed to narrow the digital divide for people who are illiterate by concentrating on the design of user interfaces and interaction methods for providing digital services in different global settings. Nonetheless, it is clear that no prior research in Kenya has investigated and validated these requirements for creating a practical design solution, which contributes to digital inequality among different population groups in rural areas. Furthermore, our study combines a persuasive framework with the DSRM process, demonstrating a theoretical aspect that is not commonly found in other studies that strive to promote equality through designing for individuals with limited literacy skills, particularly, rural areas.

D. ICT Design Requirements for Rural Areas

Illiteracy is a significant challenge in rural areas [14]. Moreover, as outlined by study [15], the increase in computer illiteracy among individuals is significantly contributing to the expansion of the digital divide. According to [16], literacy is defined as "the capacity to securely and effectively access, manage, comprehend, integrate, communicate, evaluate, and generate information using digital technologies. It could be for the purpose of gaining knowledge, employment, securing decent jobs, and entrepreneurship." This literacy encompasses a continuous process of learning and mastery in reading, writing, and numerical skills throughout one's lifespan, forming part of a broader range of competencies that encompass digital literacy, media literacy, education for sustainable development, global citizenship, and specific skills required for various professions [16].

Despite the educational deficiencies prevalent among a substantial portion of the population, numerous existing applications and their interfaces cater primarily to individuals with higher levels of education. These interfaces tend to be text based thus making them unsuitable for individuals who are illiterate, semi-literate, or lack digital literacy, thereby limiting their ability to effectively engage with software systems. Consequently, these sizable demographics are unable to derive the advantages offered by ICT services if they are unable to access them, ultimately giving rise to digital inequality, the divergence between individuals who possess unrestricted access to information and communication technologies and those who either lack access entirely or have limited access to such technologies. Hence, the task of bridging the digital gap would be unattainable in the absence of implementing ICTs for this extensive population of disadvantaged (illiterate and semi-literate) cohorts [17].

Researchers, [18] revealed various aspects that need to be recognized when designing persuasive systems include responsiveness, error-freeness, ease of access, ease of use, convenience, information quality, positive user experience, attractiveness, user loyalty, and simplicity, to name a few; however, they indicate that more precise requirements for software qualities will have to be defined to be able to communicate the ideas from idea generators and/or management to software engineers. Additionally, [18] suggested four principles of persuasive design: (1) primary task (applying reduction, tunneling, tailoring, personalization, self-monitoring, simulation, and rehearsal). (2) dialogue (include, praise, rewards, reminders, suggestion, similarity, liking, and social role). (3) system credibility (include, trustworthiness, expertise, surface credibility, real-world feel, authority, third-party endorsements, and verifiability). (4) social support (social facilitation, social comparison, normative influence, social learning, cooperation, competition, and recognition).

On the other hand, [6] indicated that changing peoples' attitudes and behavior require;

- tailored information.
- computer simulations.
- application of animate characteristics (like, physical features, emotions, voice communication),
- play animate roles (like, coach, pet, assistant, opponent), or
- social rules or dynamics (like greetings, apologies, taking turns)

Numerous studies were undertaken to pioneer innovative ICT-based solutions aimed at delivering information to illiterate and semi-illiterate residents of rural areas in developing countries [12, 15, 17, 18, 19]. They indicated the following requirements;

- Applying minimized hierarchical navigation
- Uses of text-free UI in local language;
- speech/voice and touch based interactions
- apply intuitive icons, symbols, images, and photographs
- use audio, video, and animated instruction/guide;
- include context sensitive suggestions
- proactive briefing
- local content (useful application)

E. Validating Rural ICT Design Requirements

Validating the rural ICT design needs, entail designing an intervention (artifact) for solving the problem [20]. There are various design methodoogies and frameworks that can be applied in the development of ICTs for inclusivity. [21], revealed that appropritate design techniques for ICT inventions encourage participartory design. Utilizing a participatory action research approach in ICT design and development is essential for not only preserving local culture and identity but also fostering the local creation of ICT [22]. This design has been found to be appropriate for the development of innovations for rural areas and especially systems where usability is a critical factor [23, 24, 25].

Persuasive design employs participatory design (PD) method, which involves potential users as active participants in the design process for creating computer systems and computer-based activities [26]. In addition to providing the venerable with the opportunity to design ICT products and services, PD fosters a positive relationship between users and designers, allowing designers to leverage the users' creativity and knowledge about

the context of use, thereby fostering a sense of ownership of the resulting ICT product. Additionally, it is a design technique which helps in creating successful human-computer-interactions where designers are required to play a big role as agents of influence [6].

DSR is another approach that involves creating a new practical object to tackle a broad category of issues and then assessing its effectiveness in solving problems within that category [27]. It utilizes a participatory approach. Researchers, [12, 13] applied DSRM in the design and validation of design requirements for illiterate and semi-illiterate users.

III. METHODOLOGY

This study employed Design Science Research methodology (DSRM). The selection of DSRM was based on its rigor, flexibility and cost effectiveness [28]. DSRM has six steps; problem identification, objectives for the solution, design and development, demonstration, evaluation, and communication [29]. This methodology is systemic and flexible, with a focus on improvement through iterative processes that involve empathetic observation, understanding user needs, and devising innovative approaches to meet those needs. The objective is to transition from explaining phenomena to creating interventions to solve problems. Therefore, design science is especially valuable for identifying and implementing practical solutions within complex situations [20] like the case of rural areas.

As a result of DSR's flexibility and support for participatory design, this study was able to integrate persuasive theory into its process. The urban informatics design model [30] was adapted, see Fig. 2. Their model was designed specifically for a socio-cultural context, hence shared similarities with rural informatics.

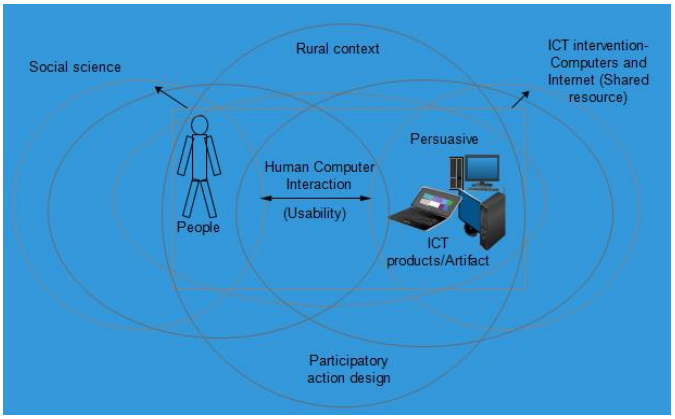

Fig. 2. Adapted PADR for rural Informatics.

For ease of integrating participatory action design research (PADR) with DSR, we simplified it and the resultant model is shown in Fig. 3.

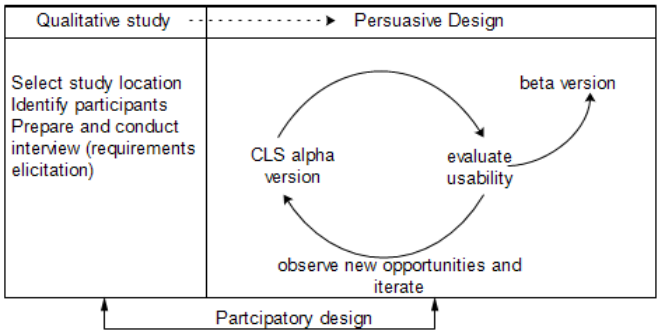

Fig. 3. Rural ICT design and development model.

A. Persuasive Design

Studies [33, 34] have revealed that as a result of affordability and illiteracy issues, individuals in rural areas are not persuaded into accessing and utilizing ICTs. Hence, the need for persuasive design methodology. Furthermore, persuasive design approaches have been applied by other information systems researchers [8, 9, 11, 18, 35, 36, 37].

The use of persuasive systems can involve either persuading humans through computers or using computers to mediate persuasion. It is true that the idea of a persuader is quite intricate because computers themselves do not have intentions; it is the people who develop, disseminate, or use the technology that have the intention to influence someone's attitudes or actions. [38]. Additionally, [38], stated that Fogg's framework and principles offer valuable ways to comprehend persuasive technology. According to these statements, we applied a persuasive framework that leverages both Fogg Behavior Model (FBM) and his Captology (Computer as a persuasive technology) Triad framework. This was also based on the understanding that designing Information and Communication Technology solutions for illiterate users requires a thoughtful approach. The FBM emphasizes Motivation (desire to participate in access and use of RICTs), Ability (the ease of accessing and using RICTs), and Triggers or prompts (cues that prompt users to access and use RICTs). On the other hand, the functional captology triad outlines how computers can act as tools (enhances users' abilities to perform tasks), mediums (conveys or simulates experiences), and social actors (engages users in social interaction). As seen in Table VI the integrated Fogg persuasive frameworks incorporate the design requirements for illiterate found in the existing literature.

B. Application of Design Science Research

1) Problem-centered approach: The study is problem centered which was necessitated by the need to identify and validate rural ICT design requirements. On the quest of how to design rural ICT solutions for inclusivity, this study obtained good information but barely none was from Kenyan setup, it was mostly based in other countries like Asian and developed nations. Fig. 4 illustrates this approach.

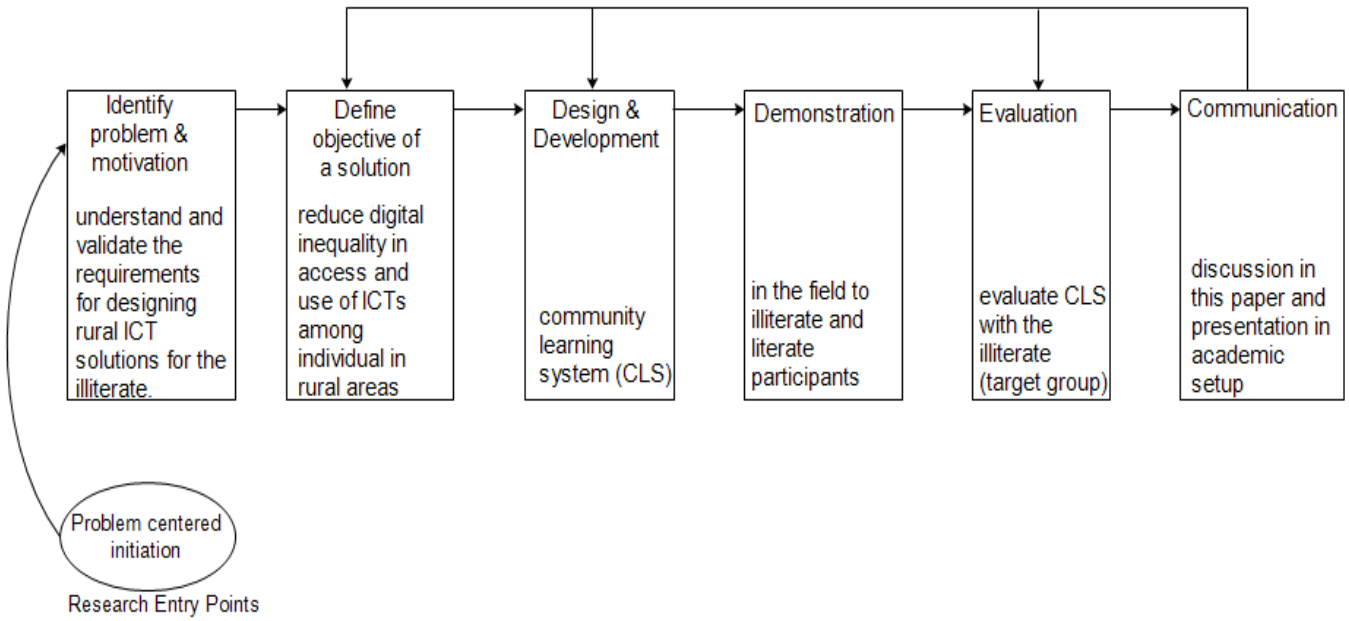

Fig. 4. DSR problem centered approach.

2) Problem identification and motivation: The existing ICT solutions in rural Kenya (for example websites or web applications or ICTs for information dissemination) are exclusively English and text-based in their user interfaces. Therefore, rendering it challenging for individuals with low literacy levels to access and utilize them. As a result, ICTs for relaying information to and in rural areas mainly target the educated and literate, excluding the illiterate and the semi-illiterate. Therefore, there is a need to understand and validate the requirements for designing rural ICT solutions which consider the illiterate people, allowing them to fully, on their own, participate in their access and use.

3) Objectives of the solution: The objective of this study is to validate the identified design needs for rural areas so as to inform solutions for enhancing ICT inclusivity in access and use among individuals. To achieve this, we developed an artifact which helped in identifying other special needs tailored to Kenyan rural areas. The results from artifact evaluation were used to develop a comprehensive and practical solution for designing rural ICTs in Kenya.

4) Design and development: Determining the intended functionality and architecture of the artifact is part of this activity, followed by the creation of the actual artifact [29]. Hence, prior to CLS creation, data was collected from the identified location of study, in accordance with [29] recommendations. Additionally, the existing practical approaches (in literature) for designing systems for the illiterate were considered. Study, [29] noted that the problems that have been identified may not directly correspond to the objectives for the artifact which was supported by our case, the artifact was disseminating information to the users but to us (the researchers), we were only using it to validate considerations for designing ICTs for the rural individuals especially the illiterate.

Now, to be explicit on CLS design and development process, the rural ICT design and development model was integrated with DSRM process, see Fig. 5.

a) Selection of location: The selection was guided by Fogg's argument that computers can be used to persuade people to change their behavior (doing something differently from the usual) as well as design ICT products which persuade people towards a behavior (adoption). The two villages (Cheleget and Kipgegei) were secretely practicing female genital mutilation and at the same time maize farming was no longer viable because of change in weather patterns. We assumed that applying Fogg frameworks in design of the artifacts was going to persuade them change their attitudes on certain vices and appreciate other farming innovations as advised by the agricultural extension officers like embracing drought resistant crops. With this, we were careful not to defiate from the objective of the study (validation). At thesame time, this formed part of our local content among those suggested by the participants.

b) Familiarizing with the community: On the first day, we went round the villages doing observations and familiarizing ourselves with the community's way of life where we interacted with thirthy one (31) individuals. We utilized the opportunity to share information about our study and the idea of creating CLS with them and or them. This was a way of creating awareness for the to-be designed ICT product. We explained to them the benefits which come with ICT interventions; including access to information which can help them improve their farming skills, business skills, health among others. We did not forget the fact that they could also get an opportunity to market their products through ICT solutions.

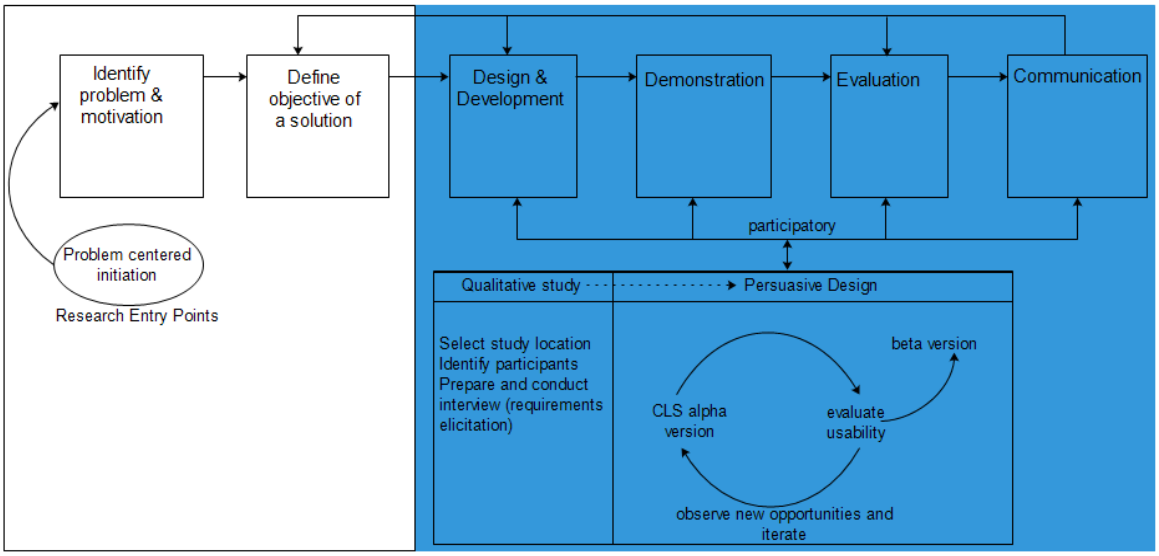

Fig. 5. DSRM-RICT integrated design and development model.

c) Selection of participants: Nine (9) participants were identified. They were willing to participate and support the study until the end. Four of them were promissing content creators. They were doing well in agriculture and interventions for food security in the village. For example, the farmer in Fig. 6 created content demonstrating how to build a beehive. This also took care of local content.

Fig. 6. Beehive construction demonstration at Cheleget village.

d) Preparing and conducting the interview (requirements elicitation): After we had familiarised ourselves and won the villagers for support, we conducted an interview. The survey asked the participants about their personal information such as age, familiarity with computers and the internet, educational background, and other relevant details. Then we sought to understand the things that would motivate them to access and use rural ICTs (computers and internet or community learning systems/portals), their abilities to use ICTs including literacy level, and the triggers that would prompt them to access and use the products. Another theme that we incorporated was the ICT product's / artifact's attributes as per resource and appropriation model [39]. We noticed that the question on attributes was too technical for the respondents, as they had not experienced these technologies before. In fact, one participant responded that he did not know how a computer looks like, and that if he had seen and used it then he could be having something to say about it. So, we decided at that point to embrace the saying that "seeing is believing." Therefore, we create a prototype and used it to probe their ICT design needs.

Overall, we interviewed twenty-seven (27) participants of whom, seventeen (17) were female and ten (10) were male. We stopped the interview at twenty-seventh individual because the interview was getting saturated. That is, response was being replicated and the only part that was changing was the demographics such as age, gender among other.

5) CLS development: After we had analyzed the requirements, including the local content, we immediately embarked on CLS development. All the requirements which had been recommended [12, 13, 15, 17, 19, 40, 41, 42, 43,] and indicated in integrated Fogg persuasive framework, Table VI, for example multisensory strategies [44] including audio, video were applied were implemented, following DSRM process. Fig. 7 is part of CLS's UI. Consistency was another consideration in CLS development. This is demonstrated in screenshots A, B, and C.

Fig. 7. CLS user interface.

Fig. 8 illustrates the CLS minimalistic approach [45] involving navigation (two-step process to accomplish a task). First step, a user clicks on a category of interest (button), for example, agriculture then a screen showing different items

(content) on this category appears. Second step, user selects content to read or watch/listen to the video. We presented information in local language, achieving user experience (UX) localization [46].

Fig. 8. Features of CLS.

Every button and icon was linked to an audio message. Anytime the mouse hovers on it, the message explained its purpose and the action to be accomplished if the user was to select it. For example, click on it if they were interested in that particular information. It enabled users to select the right information according to their preferences, minimizing errors at the same time enhancing self-efficacy.

6) CLS demonstration: The nine (9) participants were engaged in the usability evaluation of the prototype. This phase was crucial in understanding the user's design needs. Other three (3) educated and literate participants were approached and they agreed to give their feedback on the system. Since we had adhered to the developed framework in Table VI, the finding showed that the participants were satisfied, and were in agreement that the product was usable, particularly by the illiterate. Majority requested for additional content. Apart from the participants' responses, our observation was that those users who were unable to read or slow in reading, were unable to perceive the application's launching icon on their own. This was going against our goal of achieving users' self-efficacy (ability to complete a task without help). This feedback was then utilized for further refinements. Fig. 9 shows CLS modified launching icon which was more pronounced and visible.

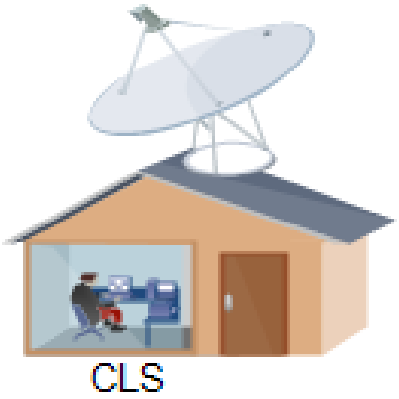

Fig. 9. CLS launching icon.

7) CLS evaluation: The beta version of CLS was evaluated for usability. On our initial visit, 31 people who expressed interest and were willing to take part in the study were specifically asked to participate in the evaluation. Among them is the group of nine people who participated in the design of CLS (community co-designers). Thirty-seven participants attended the session but only twenty-three (23) evaluated CLS. Though in attendance, the nine participants and five other literate people were excluded. At this stage the literate participants assisted in setting-up the room for evaluation and during participants' training session. We started the session by first training the participants on how to use CLS. Among the participants, 12 were male and the rest (11) were female. Fig. 10 shows the trainer projecting the steps (photo 1) and assisting the participants (photo 2). Majority of the participants were between the age of 25 and 60.

Fig. 10. CLS training session.

8) Communication: We discussed the findings of CLS evaluation in this paper and presented in an academic forum.

IV. RESULTS

We conducted a usability test to evaluate illiterate design needs, focusing on their ability to independently launch the system (self-efficacy). The timing period was determined during demonstration sessions where an average of the time taken by the literate and the illiterate participants was computed. During the evaluation, participants were asked to close (exit) CLS window, then locate and launch it within 180 seconds. Results in Table I revealed that 16 participants (70%) successfully located and launched the system on their first attempt, 3 participants (13%) succeeded after several attempts without assistance, and four participants (17%) required help after multiple unsuccessful trials.

TABLE I. TASK ONE- LAUNCHING CLS

Number of attempts	*Frequency (number of participants)*	*Percentage (%)*	*Average time (seconds)*
succeed on 1st attempt	16	70	48
succeeded after several attempts	3	13	123
failed after several trials	4	17	not successful

Task 2 evaluates users' self-efficacy by assessing their ability to independently complete a familiar task which involved opening a beehive making video. This task also provided

insights into their learnability and memory retention, as they had previously accessed the video multiple times. Allocating a duration of 120 seconds for this particular assignment, a total of 19 participants, which accounts for 83%, effectively managed to finalize it with an average completion time of 68 seconds. However, from Table II, four participants were unable to finish within the allotted time, mainly due to difficulties with mouse handling and positioning. Upon requesting a second attempt, half of these participants completed the task in an average of 63 seconds, while the remaining two still required assistance.

TABLE II. TASK TWO- FAMILIA TASK

Number of attempts	*Frequency (number of participants)*	*Percentage (%)*	*Average time (seconds)*
succeeded	19	83	68
failed after several attempts	4	17	elapsed time
2nd chance			
succeeded	2	50	63
failed after several attempts	2	50	not successful

In Task 3, participants were instructed to access a video on "Kalenjin Proverbs" which was uncommon task. However, our observations revealed that most participants typically viewed videos related to agriculture and health. As a result, the "Kalenjin Proverbs" video was not frequently accessed. During the training session, participants were informed that any information not related to agriculture or health was categorized under "general information." They were allocated 120 seconds to complete this task. Based on the data presented in Table III, it was observed that 16 individuals, constituting 70% of the total participants, effectively accomplished the task during their initial try, demonstrating an average duration of 69 seconds. Of the eight participants who failed initially, five succeeded on their second attempt, with an average time of 66 seconds. Despite multiple attempts, three participants were unable to complete the task.

TABLE III. TASK 3- UNCOMMON TASK

Number of attempts	*Frequency (number of participants)*	*Percentage (%)*	*Average time (seconds)*
succeeded	16	70	69
failed after several attempts	8	30	elapsed time
2nd chance			
succeeded	5	63	66
failed after several attempts	3	37	not successful

In Task 4, participants were instructed to close the CLS application, relaunch it, and then open content related to female genital mutilation (FGM). They were allocated 240 seconds to complete this task. As indicated in Table IV, despite the complexity of the task, 78% of participants successfully completed it. Upon a subsequent trial, 80% of the individuals successfully finished the assignment within an average duration of 128 seconds.

TABLE IV. TASK 4- LENGTHY TASK

Number of attempts	*Frequency (number of participants)*	*Percentage (%)*	*Average time (seconds)*
succeeded	18	78	186
failed after several attempts	5	22	elapsed time
2nd chance			
succeeded	4	80	128
failed after several attempts	1	20	not successful

We concluded the CLS evaluation session by asking the participants to verbally give their views on the system, as applied by [13]. This gauged their satisfaction and experience with CLS. All participants were using the computer and digital application for the first time. The system had employed the guidelines in Table VI, like use of video, audio cues, local language, and local language. Collected information included their engagement with CLS, its relevance (usefulness), their learning experience, their willingness to recommend it to the others and finally, challenges experienced while using CLS.

Finally, the study sought to understand rural users' willingness and ability to pay for the internet services. It started with a proposal to install CLS in their nearest market's cybercafé, located 8 kilometers from the village. The cybercafé was charging one shilling per minute for access and use of the internet. Results indicate that users were dissatisfied with the proposal, given the distance involved and monetary issue.

V. DISCUSSION

Similar to study [42] our study findings show that user self-efficacy was attained. This is explained by the task findings, 71%, 83%, 70% and 78% successfully, within the stipulated time and on their own, accomplished tasks 1, 2, 3 and 4 respectively.

Comparable to [12, 13], participants reported their overwhelming satisfaction with the CLS. They were satisfied with the use of local language and local content, noting that the language made it easy for them to learn and use the system while the local content matched with their information quest and needs. They found the content to be practical, and applicable to their day to day activities. They enjoyed using it and found it relevant (helpful/useful). Users appreciated the system's potential for learning, indicating that it could significantly enhance their knowledge and skills. Table V summarizes the impact of CLS on user experience, highlighting both positive aspects and challenges.

TABLE V. INTEGRATED FOGG PERSUASIVE FRAMEWORKS (FBM AND CAPTOLOGY)

Captology	*FBM Element*	*Design requirements/features*	*Guidelines*
Computer as a tool			
	Enhancing Ability	Increase self-efficacy (reduction of tasks) provide tailored information simplify/guide people through process (integrate training modules and audio aids) {minimalistic approach and UX localization}	Make navigation simple (few clicks) Design UI using less text (video and audio) present local content in local (mother) language Use intuitive images, symbols, and pictures Offering guidance through audio, video, and animated tutorials.
	Boosting Motivation	Provide immediate feedback	Information to reinforce positive behavior for example congratulates the user for listening to the video
	Effective Prompts	trigger decision making	use visual and audio cues like bright colors, icons, and sounds to guide users through tasks (uses visual/audio cues to prompt actions)
Computer as a medium			
	Enhancing Ability	Simulate cause and action	create interactive simulation that allow users to practice tasks or create a video of peers/expert simulating a task
	Boosting Motivation	Create engaging content Include demonstration	Incorporate stories of successful person for example in farming or business to motivate users or Show real-life scenarios where similar users successfully use the technology, enhancing the perceived relevance and usefulness.
	Effective Prompts	Provide interactive guides provide prompts during the simulation.	Use animated characters or avatars to provide step-by-step instructions and encouragement and Trigger actions within the simulation to guide users towards desired behaviors.
computer as a Social Actor			
	Enhancing Ability	Provide social support Incorporate mentorship roles	During training, allow users to practice on their own (peer learning) The application should allow interested community members for example farmers to share their experiences. Incorporate virtual mentors or coaches that provide guidance and support.
	Boosting Motivation	Provide social proof Include recognition	Design with the community and let them be content creators Shows successful peer examples and their achievements Show that others in the community are using the technology, leveraging the influence of social norms. Publicly recognize achievements within the application, such as leaderboards or community shout-outs.
	Effective Prompts	Apply social prompt Consider community engagement	Sends reminders from community social workers, agriculture extension officer, community leaders among others. Use social challenges or group tasks to motivate users through collective action.

Due to the cost and location, rural users expressed their unwillingness to participate in its access and use. The participants expressed their dissatisfaction with the proposed location terming it as far away, requiring additional time, cost and effort to travel. Largely, the economic constrain among individuals in rural areas significantly impacted their willingness to pay for internet services. Data and observations showed that the majority of users had limited financial resources. Majority struggled to afford basic necessities, including school fees for their children and daily living expenses. Given their low income levels, the users were not willing to allocate funds for accessing the internet services. The idea of paying for information was deemed impractical and unaffordable. Similar to study [13], all the participants positively articulated their willingness to recommend CLS to the other members of the community.

TABLE VI. RATING CLS SATISFACTION

Positive aspects	***views***
Engagement	Participants enjoyed the interactive elements provided by the video and audio cues. These features made the system engaging and easy to navigate.
Relevance	The use of local language and content resonated well with the users thus made the information more accessible and meaningful.
Learning Potential	Users felt that the system was a valuable educational tool with a very high potential of facilitating significant learning and personal development.
challenges	
Mouse Handling	participant's difficulty in handling the mouse was the primary and most notable challenge to be reported. Many found it challenging to use. This indicated a steep learning curve which was experienced as a result of this input device.
Learning Time	Participants felt they needed more time to become proficient with the system especially in relation to mouse handling. They suggested that if alternative input methods were provided then their experience could improve.
Content	Participants felt CLS needed to be populated with more content particularly on how to grow and manage various crops.

VI. CONCLUSION

This study validated design requirements for rural areas, focusing on the illiterate. It followed DSRM process and applied Fogg integrated frameworks. The artifact that was used for validation, applied the specified design features and guidelines indicated in the framework. In 2022, [32] proposed the same requirements for creating systems designed to address gender inequality. Furthermore, this approach is capable of generating intuitive artifacts, closing the digital gap not only between illiterate and literate individuals, but addresses the gender and age divide as well. We found out that user experience localization enhances user's engagement with the ICT artifacts or products. This was achieved with the use of local language and local content. It was ascertained [46] that adaptation of UX enables an application to bridge divides among various demographics. Content was development in local language, meaning that there was no need for interpreters or difficulty in comprehension. At the same time, tailored information was provided through CLS as the community members were fully involved in the design and development of CLS. This means that the information was relevant to users' needs and their context. Furthermore, the local content was based on users' demand. Localization strategy showed full potential of encouraging ICT inclusivity, fostering user engagement with the ICTs.

Application of videos and audio cues significantly impacted participant's UX with CLS. It made CLS intuitive and easy to learn. According to study [44] combining various techniques for information dissemination or learning is known as multisensory approach. Our study revealed that multisensory approach is applicable in the design of rural ICTs (artifacts). Furthermore, CLS applied minimalistic design principles [46] which included few clicks and intuitive navigation, enhancing user's self-efficacy. This finding agrees with [6], where they revealed that the act changes users' attitude and behavior by exposing them to information which may have not been readily available at their disposal, hence they may be persuaded to apply the learned information in their daily lives.

This study maximized on content categorization. This strategy involved putting together related information helping the users to locate information with ease, and minimizing the time taken to search for information. The results highlight the varying levels of self-efficacy among participants and the need to carefully craft solutions for special groups like those with low cognitive levels, low technical skills and low confidence. In their study [47] found this to be the case as they concluded that ICT user interface and content designed for individuals with low literacy skills should consider factors beyond just illiteracy, including additional cognitive differences among these users.

This study reveals the positive significance of peer participation in the design and acceptability of ICTs by rural people. Peers were involved in the design, evaluation and content creation. Also, during training, peer learning was encouraged. They patronized the content created by their own village mates than others. This enhanced learning speed and made the participants engaged with the system. Additionally, other input devices need to be explored for the users with low technical skills like dragging and positioning the mouse.

DSRM provided significant benefits for our research endeavor. Its structured approach ensured thorough investigation and validation of the specific needs of our target demographic, while its iterative nature allowed for continual refinement based on real world feedback. This adaptability was crucial for addressing the diverse challenges faced by illiterate users in rural areas. Furthermore, the focus of the methodology on practical implementation harmonized effectively with our objective of establishing a community learning system that was accessible and user-friendly. Additionally, DSR's efficient use of resources made it a time effective and economical choice, allowing us to maximize our impact within the constraints of our research budget. Thus DSR provided the ideal framework for developing inclusive ICT solutions that meet the specific needs of rural populations.

Additionally, this study revealed that combination of DSR and Fogg's persuasive frameworks helps in creating usable and accessible ICT solutions customized to the needs of the target population. It enhanced the effectiveness of ICT solutions for illiterate individuals. These approaches had a significant impact in the achievement of user self-efficacy.

Despite the diffusion of mobile phones, majority of the individuals in rural areas have not switched to internet enabled phones (smartphones), [31, 48]. According to study [49,50] featured phones are still common in rural areas because of prevalence in illiteracy, affordability concerns, long battery life and weak network connections Therefore similar to [19], CLS was a computer based system.

Hence, our investigation and validation showed that critical ICT design needs for rural users include the use of local language, local content, videos, audio, few clicks, touch screen, noise-proof devices, content categorization, peer collaboration, public RICTs and low cost or subsidized ICT resources.

Additionally, location is also important in access and use of RICTs. The design process should be participatory.

We conclude this study by noting that design solutions targeting vulnerable demographics is key to the success of designing for equality. In other words, that which works or usable by the aged, illiterate, uneducated and the poor works best or more usable for the young, literate, educated, and the rich (financially stable). Thus enhancing access and use of rural ICTs.

VII. Recommendation and Future Work

This study recommends the application of DSRM-RICT integrated design and development model and the Fogg frameworks. These methodologies are critical in the design and development of ICT artifacts with enhanced user experience.

CLS was computer based system. Therefore, following the DSRM-RICT integrated design and development model, together with integrated Fogg persuasive frameworks, future researchers are recommended to design and evaluate rural artifacts for mobile phones.

Also, future studies on rural informatics can look at various multisensory methodologies which can foster user engagement with the ICTs, for example apart from auditory (audio) and visual (video), they can consider haptic (tactile feedback).

Additionally, rural informatics researchers are encouraged to create interactive simulations which will enable users to practice a task as of real world.

Finally, this study observation is, however usable the artifact is, users may decline to access it if the location is not favorable. FBM [4] asserts that ability is comprised by anything that makes it difficult to perform a task. This in turn influences motivation in a negative manner, rendering the triggers (awareness) meaningless. Therefore, for accessibility purposes, this paper recommends strategic placement of rural ICTs.

***Abstract*—Accurately separating healthy tissue from tumorous regions is crucial for effective diagnosis and treatment planning based on magnetic resonance imaging (MRI) data. Current manual detection methods rely heavily on human expertise, so MRI-based segmentation is essential to improving diagnostic accuracy and treatment outcomes. The purpose of this paper is to compare the performance of detecting brain tumors from MRI images through segmentation using an unmodified and modified U-Net architecture from deep neural network (DNN) that has been modified by adding batch normalization and dropout on the encoder layer with and without the freeze layer. The study utilizes a public 2D brain tumor dataset containing 3064 T1-weighted contrast-enhanced images of meningioma, glioma, and pituitary tumors. Model performance was evaluated using intersection over union (IoU) and standard metrics such as precision, recall, f1-score, and accuracy across training, validation, and testing stages. Statistical analysis, including ANOVA and Duncan's multiple range test, was conducted to determine the significance of performance differences across the architectures. Results indicate that while the modified architectures show improved stability and convergence, the freeze layer model demonstrated superior IoU and efficiency, making it a promising approach for more accurate and efficient brain tumor segmentation. The comparison of the three methods revealed that the modified U-Net architecture with a freeze layer significantly reduced training time by 81.72% compared to the unmodified U-Net while maintaining similar performance across validation and testing stages. All three methods showed comparable accuracy and consistency, with no significant differences in performance during validation and testing.**

Keywords*—Accuracy; brain tumor; DNN; U-Net architecture; comparison performance

I. INTRODUCTION

Brain tumors are among the most life-threatening conditions, with the potential to drastically affect the quality of life and survival of patients. Early and accurate diagnosis is paramount to developing effective treatment strategies, often involving surgery, radiotherapy, or chemotherapy. Magnetic resonance imaging (MRI) is widely recognized as one of the most accurate non-invasive imaging techniques for detecting brain abnormalities. It provides detailed views of brain structures and tissue compositions, allowing clinicians to assess tumor size, location, and growth patterns from research in quantitative MRI [1], research review [2], and discussion from Advancements in Neuroimaging to detect brain tumors [3]. However, interpreting these MRI images is complex and time-consuming, requiring a high level of expertise [4]. As a result, manual segmentation of brain tumors can be inconsistent, subjective, and prone to human error. Automated segmentation methods using advanced machine learning and deep learning techniques have been explored to address these challenges in recent years using image cardiac radiography [5], image Alzheimer's disease in the human brain [6], and brain tumor detection using MRI [7].

Deep neural networks (DNNs), particularly convolutional neural networks (CNNs), have shown exceptional promise in image analysis tasks, including medical image segmentation. CNNs are highly effective at identifying patterns in image data by leveraging layers that automatically learn relevant features such as edges, textures, and complex structures. Among CNN-based methods, the U-Net architecture has become a leading tool for medical image segmentation due to its robust performance. Initially designed for biomedical image segmentation, U-Net uses an encoder-decoder structure, where the encoder extracts features from the input image, and the decoder uses those features to reconstruct segmented regions [8, 9]. U-Net's symmetrical architecture enables precise localization of structures, making it especially suitable for segmenting brain tumors. According to Yousef, et al. [10], despite its strengths, the standard U-Net architecture can be prone to overfitting, mainly when training on small datasets like MRI brain scans, leading to decreased generalization to unseen data.

Several improvements have been proposed to address the limitations of the original U-Net architecture, focusing on enhancing the model's generalization and stability during training. Two commonly employed techniques, batch normalization and dropout, have been used to learn parameter effects for segmenting brain tumors [11], mandible bones [12], and brain tumors using U-Net [13]. Batch normalization is used to normalize the input to each layer during training, reducing internal covariate shifts and accelerating the learning process. By stabilizing the learning process, batch normalization helps improve the performance of deep neural networks, mainly when applied to complex datasets like MRI images. On the other hand, dropout is a regularization technique that randomly disables a fraction of neurons during training, forcing the network to learn more robust features. This helps to mitigate overfitting by preventing the model

from relying too heavily on specific neurons [14]. Batch normalization and dropout can significantly enhance the U-Net architecture's ability to generalize from training data to new, unseen cases.

In addition to these regularization techniques, another modification involves freezing specific layers of the U-Net architecture during training. The freeze layer method limits the number of trainable layers, essentially "freezing" network parts to prevent them from being updated during training. This can be particularly useful when fine-tuning a model on a smaller dataset or using transfer learning [15]. By restricting the training depth, the model is less likely to overfit the specific training data and can generalize better to new data. Furthermore, freezing layers can reduce the computational cost of training, as fewer parameters need to be updated [16]. This makes it an attractive option for optimizing the training process without sacrificing performance. The combination of batch normalization, dropout, and freeze layers has the potential to significantly improve the efficiency and accuracy of brain tumor segmentation using MRI images.

The U-Net architecture, in original and with modifications in architecture, remains one of the most widely used models for medical image segmentation tasks. The original U-Net is effective but may struggle with specific challenges inherent to brain tumor segmentation, such as distinguishing between subtle boundaries of healthy and tumorous tissues [8]. Incorporating batch normalization and dropout into the encoder layers enhances the model's ability to avoid overfitting, allowing it to learn more generalized features. Furthermore, introducing a freeze layer can optimize computational efficiency, making the model more robust and faster to train. These architectural improvements hold great promise for improving the segmentation of brain tumors, ultimately contributing to better diagnostic accuracy and treatment planning.

This paper compares the performance of brain tumor segmentation using unmodified and modified U-Net architectures driven by deep neural networks (DNN). Specifically, two modifications are examined: (1) batch normalization and dropout added to the encoder layer, and (2) a freeze layer introduced to limit the depth of the training process. We selected the modified U-Net architecture with batch normalization, dropout, and freeze layers due to its effectiveness in addressing specific challenges in brain tumor segmentation. U-Net, widely used in medical image segmentation, excels at delineating complex structures, but it can struggle with overfitting, particularly on small datasets like MRI. To mitigate this, batch normalization stabilizes training by normalizing layer inputs, while dropout prevents over-reliance on specific neurons, reducing overfitting. Additionally, freeze layers limit trainable parameters, improving generalization and reducing computational cost. Standard methods often fail to handle subtle tumor boundaries and are prone to overfitting with small datasets. Our modifications enhance the model's robustness, efficiency, and accuracy in segmenting brain tumors. These improvements address limitations in existing approaches, making our method more suitable for the complexities of brain tumor segmentation from MRI images, where precise and reliable detection is critical.

The remainder of this paper is structured as follows: Section II overviews brain tumor segmentation using deep learning as a related work. Section III explains the dataset and methods in detail. In Section IV, we compare and analyze experiments and discussions from our studies. Finally, Section V concludes and describes future work.

II. Related Work

Research on brain tumor segmentation using deep learning has gained substantial attention in recent years due to the increasing availability of medical imaging data and the advancements in computational methods. Early approaches to brain tumor segmentation relied heavily on traditional image processing techniques such as thresholding, region growing, and edge detection [17-19]. While these methods could detect certain features, they lacked the sophistication needed to capture brain tumors' complex and heterogeneous nature. As a result, their accuracy was often limited, especially when dealing with tumors with irregular shapes or indistinct boundaries. The development of machine learning models, particularly convolutional neural networks (CNNs), revolutionized this field by enabling more automated, accurate, and efficient segmentation techniques, especially in medical imaging applications such as brain tumor detection.

One of the first major breakthroughs in deep learning-based medical image segmentation came with the introduction of the U-Net architecture by Ronneberger, et al. [20]. Initially designed for biomedical image segmentation tasks, U-Net rapidly gained popularity due to its simplicity and effectiveness. The architecture's encoder-decoder structure enables precise segmentation by combining high-resolution features from the encoder with upsampled features in the decoder. U-Net has been successfully applied to various medical imaging tasks, including brain tumor segmentation, and has become a standard baseline model in the field. However, despite its success, U-Net often struggles with overfitting and performance stability, mainly when dealing with minor or imbalanced datasets, which are common in medical imaging.

Various enhancements to the U-Net architecture have been proposed to address these issues. Isensee, et al. [21] introduced modifications such as deep supervision and residual connections to improve the network's ability to learn from complex medical imaging data. Other works have focused on regularization techniques like batch normalization and dropout to enhance model stability and generalization. Batch normalization, introduced by Ioffe [22], is commonly used to normalize the inputs to each layer, speeding up training and reducing internal covariate shifts. Dropout, proposed by Srivastava, et al. [23], helps prevent overfitting by randomly deactivating neurons during training, forcing the model to learn more generalized features. Various CNN architectures, including U-Net, have widely adopted these techniques to improve their performance on medical image segmentation tasks.

Additionally, several researchers have explored transfer learning and fine-tuning in medical image segmentation. Transfer learning allows a pre-trained model to be adapted to a new task by freezing specific layers during training and updating only a subset of parameters. In brain tumor segmentation, transfer learning can be particularly beneficial when working with small datasets, as it enables models to leverage knowledge from larger, more general datasets. Kamnitsas, et al. [24] demonstrated the effectiveness of transfer learning for brain lesion segmentation using a 3D CNN, achieving better performance than training from scratch. The use of freeze layers, which limit the depth of training, has also been explored to reduce overfitting and optimize computational efficiency, particularly in resource-constrained environments.

Moreover, ensemble learning methods have been explored to improve segmentation performance further. DeepMedic, introduced by Kamnitsas, et al. [25], combines multiple CNNs to form an ensemble model, resulting in more robust and accurate brain tumor segmentation. Other works have integrated different architectures, such as residual networks and attention mechanisms, to enhance segmentation models' feature extraction and localization capabilities. In summary, the field of brain tumor segmentation has seen significant advancements, with numerous modifications to the original U-Net architecture and the incorporation of advanced techniques such as batch normalization, dropout, freeze layers, and ensemble learning approaches. These improvements enhance model stability, reduce overfitting, and increase segmentation accuracy.

III. Dataset and Methods

A. Data Sets

The dataset used in this study is a public 2D brain tumor dataset authored by Cheng, et al. [26], Cheng, et al. [27]. The dataset contains 3064 T1-weighted contrast-enhanced images with three kinds of brain tumors (meningioma with 708 slices, glioma with 1426 slices, and pituitary tumor with 930 slices) from 233 patients that were scanned by magnetic resonance imaging (MRI), all with ground truth segmentations of the tumors. It was randomly split into a training set of 2451 images, an internal validation set of 306 images, and a testing set of 307 images.

B. The Proposed Method

In this study, three architectures from deep neural network (DNN) were used, including (1) an unmodified U-Net architecture, (2) a modified U-Net architecture with batch normalization and dropout on the encoder layer without the freeze layer, and (3) a modified U-Net architecture with batch normalization and dropout on the encoder layer with a freeze layer. The U-Net architecture added with freeze layers aims to limit the training depth by skipping certain layers when training the model.

C. Evaluation of the Models Performance

During the calibration stages (training and internal validation) for the three architectures examined in this study, the performance of the model development is evaluated through training loss and validation loss. Moreover, as a widely-used evaluation metric in object detection and image segmentation tasks, the intersection over union (IoU) overlap between predicted bounding boxes and ground truth boxes is also evaluated with scores ranging from 0 to 1. After that, the model is tested using a dataset of 307 images.

To find out more details regarding the model performance of each stages (training, internal validation, testing), 10 images were randomly taken from each stages to be compared to the ground truth segmentations of the tumors. Each image will be checked for the number of true positive, true negative, false negative, and false positive variables to calculate precision, recall, f1-score, and accuracy. After that, the average with the standard deviation for the three architectures was compared through the ANOVA statistical test to determine the model performance's significance ($p<0.05$). Duncan's multiple range test will be carried out if at least one difference exists between the three architectures.

IV. Result and Discussions

A. Unmodified U-Net Architecture

Fig. 1(a) shows the training history for 35 epochs using unmodified U-Net architecture for the loss training (0.1453±1.21E-01) and internal validation (0.1931±5.10E-02) stages. There is a loss gap of around 32.94% between training and validation. The loss curve for validation shows that the best loss can be achieved at an epoch of 35. The time calculation for running training for this method is 197.11±0.37s. The performance of the model by the intersection of union (IoU) on Fig. 1(b) for unmodified U-Net architecture is 0.7376±1.41E-01 in training and 0.6861±2.92E-02 in validation. There is a difference in IoU of approximately 6.98% between the training and validation results.

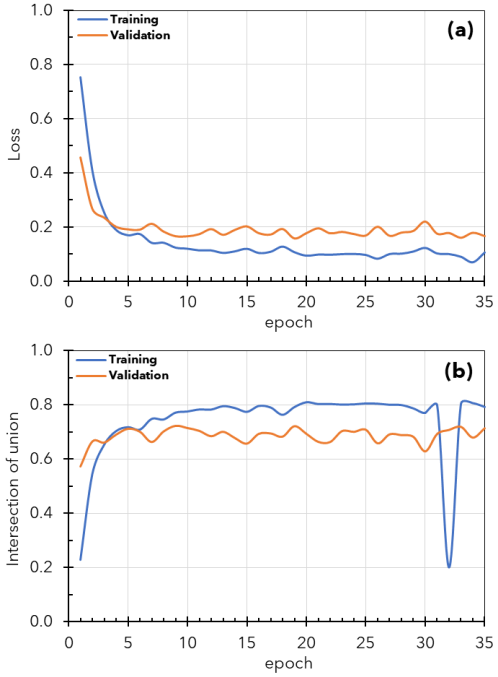

Fig. 1. Training and validation history of 35 epochs iteration from unmodified U-Net architecture model (a) accuracy and (b) IoU.

Fig. 2 presents the model's performance when sampling 10 images for the confusion matrix. The model from unmodified U-Net is more accurate (Fig. 2(a)) than the validation and testing stages except in images number 4, 5, and 7 (see Fig. 3). The average accuracy at the training, validation, and testing steps were 0.9977+7.46E-04, 0.9979+7.27E-04, and 0.9979+1.18E-03, respectively. The ANOVA test results for the accuracy parameters at the training, validation, and testing steps were not significantly different (p>0.05), indicating that the model is steady and there is no under/overfitting.

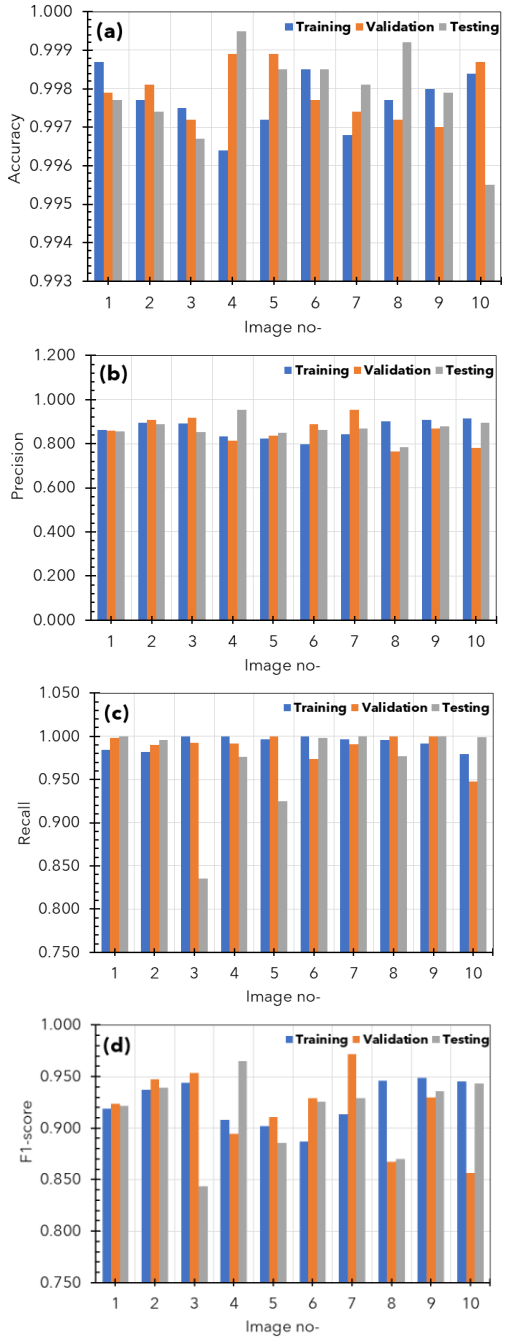

Fig. 2. Performance of sampling image from unmodified U-Net in a confusion matrix (a) accuracy, (b) precision, (c) recall and (d) f1-score.

Precision can be used as a parameter to measure how consistent the model is in predicting the quality of positive predictions. The average precision (see Fig. 2(b)) at the training, validation, and testing stages were 0.8670+4.12E-02, 0.8593+6.04E-02, and 0.8685+4.27E-02, respectively. The statistical test results using ANOVA did not find any significant differences between the three stages (p>0.05). This indicates that the results obtained through precision did not find any false patterns from the tested dataset.

Next, the recall parameter can show the total number of actual positive cases that are correctly predicted to show the sensitivity of the model. The average recall (Fig. 2(c)) at the training, validation, and testing stages are 0.9927+7.95E-03, 0.9884+1.63E-02, and 0.9706+5.30E-02, respectively. The ANOVA statistical test results revealed no significant differences across the three stages (p>0.05), indicating that the recall results did not detect incorrect patterns in the tested dataset.

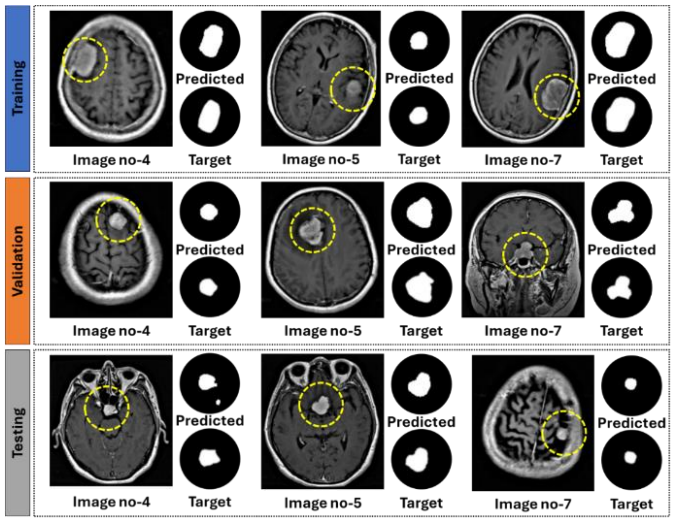

Fig. 3. Details of sample images 4, 5, and 7 in training, validation, and testing by unmodified U-Net architecture model.

B. Modified U-Net Architecture without Freeze Layer

The training and validation history and IoU for 35 epochs using modified U-Net architecture without a freeze layer are depicted in Fig. 4. The training and internal validation loss are 0.2778±5.70E-02 and 0.2927±5.01E-02, respectively. There is a loss gap of around 5.37% between training and validation. The loss curve for validation shows that the best accuracy can be achieved at an epoch of 35. The time required for running the training with this method is 55.66±0.48s. The model's performance, measured by the intersection over union (IoU), for the modified U-Net architecture without a frozen layer is 0.5633±7.15E-02 during training and 0.5591±5.69E-02 during validation. The IoU difference between the training and validation results is approximately 0.74%.

The confusion matrix in Fig. 5 shows the performance of the modified U-Net architecture without the frozen layer, based on sampling 10 images. As depicted in Fig. 5(a), the model maintains stability in all stages, except image sample number 3, where a deviation in accuracy is observed (Fig. 6). The average accuracy during the training, validation, and

testing stages was 0.9951±2.92E-03, 0.9929±8.08E-03, and 0.9865±2.96E-02, respectively. The ANOVA test results showed no significant differences (p>0.05) in accuracy across these stages, implying that the model is steady and does not exhibit underfitting or overfitting.

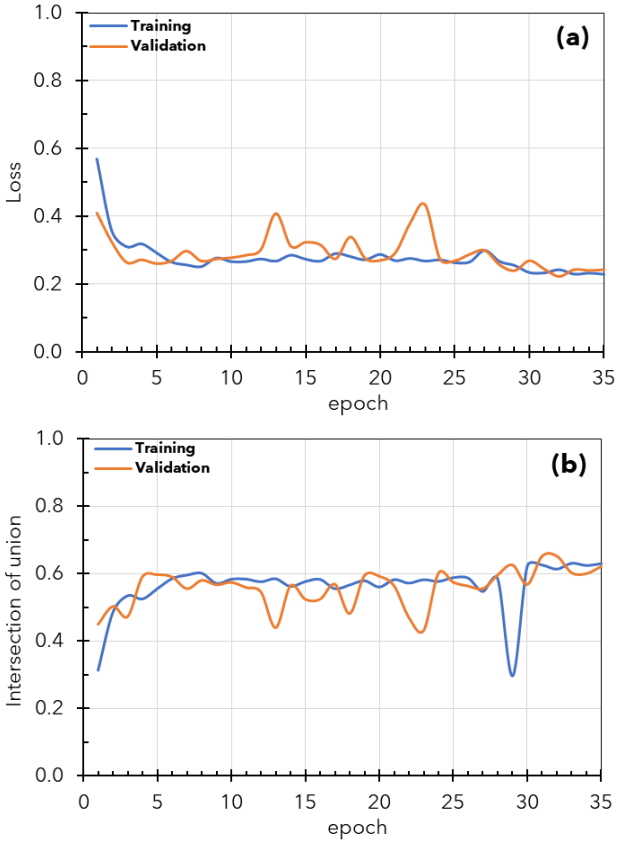

Fig. 4. Training and validation history of 35 epochs iteration from modified U-Net architecture without freeze layer model (a) accuracy and (b) IoU.

Precision as a key parameter for evaluating the model's consistency in predicting positive outcomes, yielded average scores of 0.7883±7.77E-02, 0.7511±2.04E-01, and 0.7592±2.18E-01 during the training, validation, and testing stages, respectively (Fig. 5(b)). Similarly, recall that measures the model's sensitivity in correctly predicting actual positive cases showed average values of 0.9784±5.25E-02, 0.8883±1.94E-01, and 0.8018±2.58E-01 across the same stages (Fig. 5(c)). Finally, the f1-Score, which balances precision and recall, averaged 0.8695±4.12E-02, 0.8029±1.82E-01, and 0.7584±2.21E-01 (Fig. 5(d)). An ANOVA analysis of these metrics (Precision, recall, and f1-Score) revealed no significant differences between the training, validation, and testing stages (p>0.05), indicating no false or incorrect patterns were identified in the dataset.

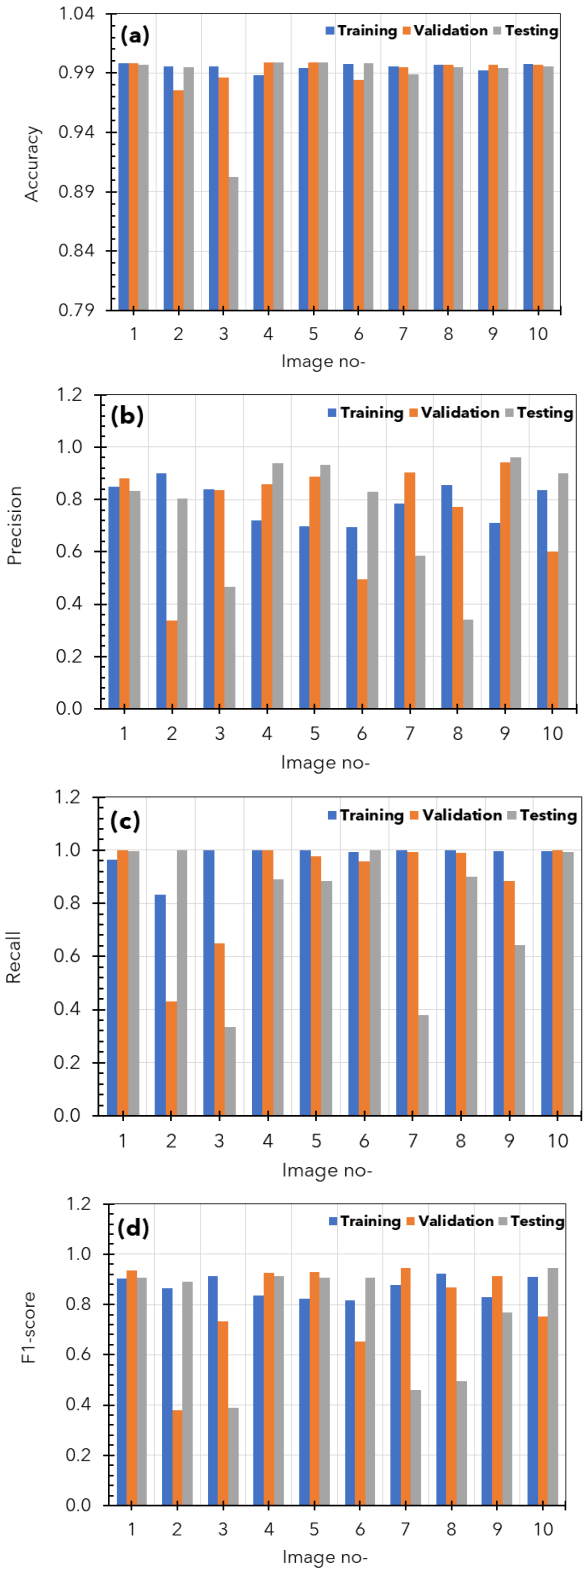

Fig. 5. Performance of sampling image from modified U-Net architecture without freeze in a confusion matrix (a) accuracy, (b) precision, (c) recall and (d) f1-score.

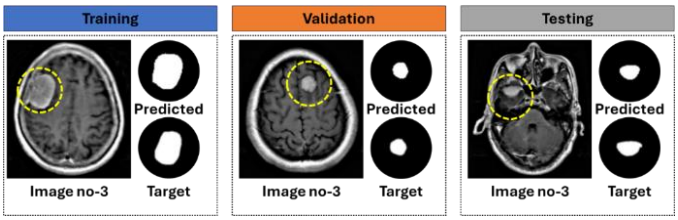

Fig. 6. Details of sample images 3 in training, validation, and testing by modified U-Net architecture without freeze model.

C. Modified U-Net Architecture with Freeze Layer

Fig. 7(a) illustrates the training history over 35 epochs using the modified U-Net architecture with a frozen layer, showing a training loss of 0.1947±7.71E-02 and a validation loss of 0.2468±3.86E-02. The loss difference between training and validation is approximately 26.73%. The training runtime for this method is calculated at 36.03±0.17s. Fig. 7(b) presents the model's performance, with an intersection over union (IoU) of 0.6764±8.10E-02 for training and 0.5995±5.14E-02 for validation, resulting in a 11.37% IoU difference between training and validation.

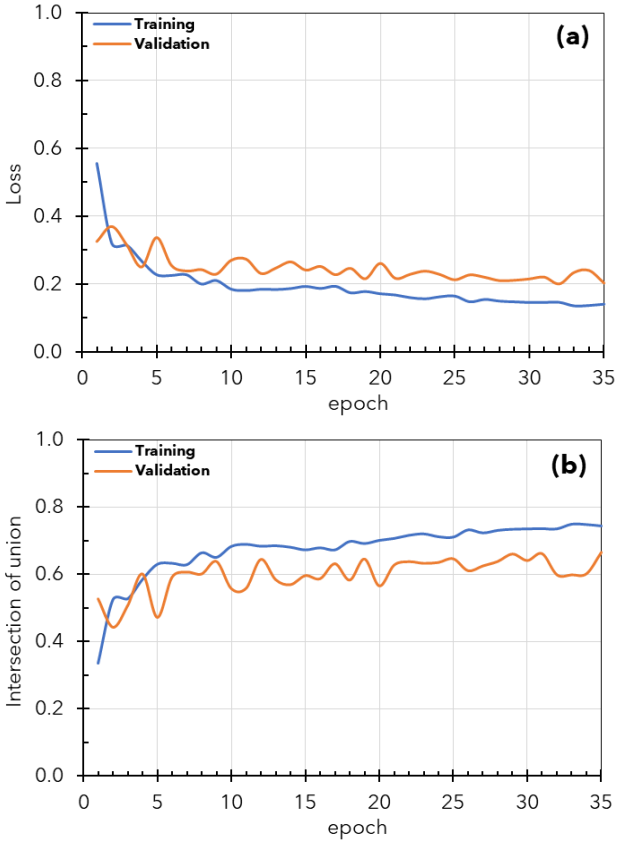

Fig. 7. Training and validation history of 35 epochs iteration from modified U-Net architecture with freeze layer model (a) accuracy and (b) IoU.

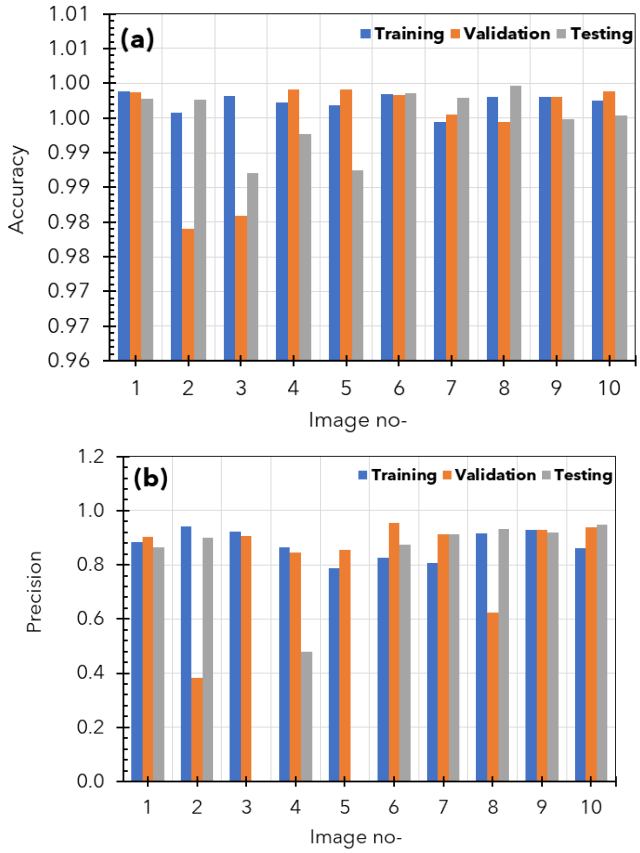
The confusion matrix in Fig. 8 illustrates the performance of the modified U-Net architecture with the frozen layer based on a sample of 10 images. As illustrated in Figure 8a, the model demonstrates stability across all stages, except image sample numbers 2 and 3, where a decline in validation accuracy is observed, and image sample number 5 shows a decrease in precision during the testing stage (Fig. 9). The average accuracy during the training, validation, and testing stages was 0.9973±1.35E-03, 0.9942±7.68E-03, and 0.9949±4.50E-03, respectively. ANOVA test results indicated that the model is stable and does not exhibit indications of underfitting or overfitting, as there were no significant differences in accuracy between these stages (p>0.05).

During the training, validation, and testing stages, the average precision scores for predicting favorable outcomes were 0.8742±5.43E-02, 0.8251±1.82E-01, and 0.6831±3.85E-01, respectively (Fig. 8(b)). Conversely, the recall metric, which quantifies the model's ability to accurately anticipate real positive instances, had mean values of 0.9549±6.05E-02, 0.8348±2.66E-01, and 0.8146±3.03E-01 over the same stages (Fig. 8(c)). In Fig. 8(d), the f1-Score, which measures the balance between accuracy and recall, had average values of 0.9109±3.92E-02, 0.8120±2.10E-01, and 0.7022±3.83E-01. Statistical study of the metrics (precision, recall, and f1-Score) using ANOVA showed no statistically significant variations throughout the training, validation, and testing stages (p>0.05). This suggests no erroneous or inaccurate patterns were detected in the dataset.



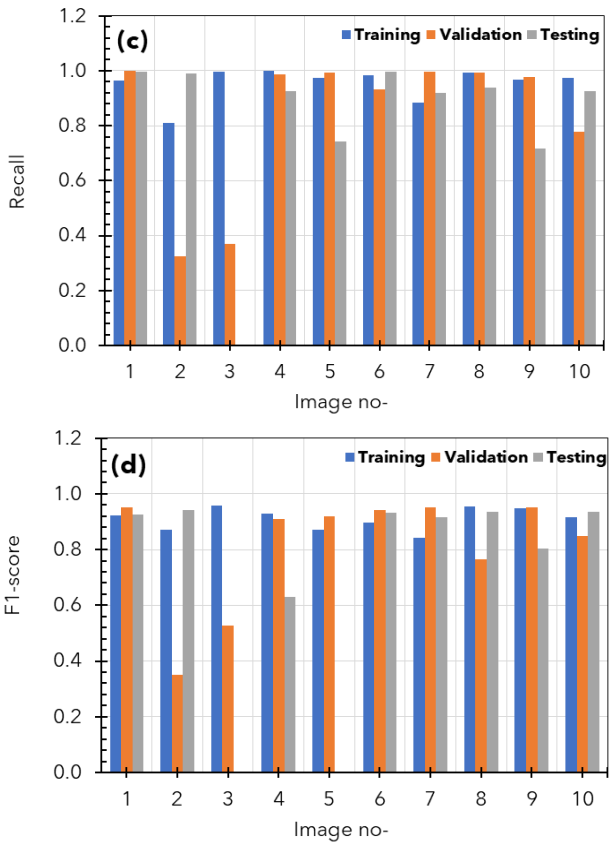


Fig. 8. Performance of sampling image from modified U-Net architecture with freeze in a confusion matrix (a) accuracy, (b) precision, (c) recall and (d) f1-score.

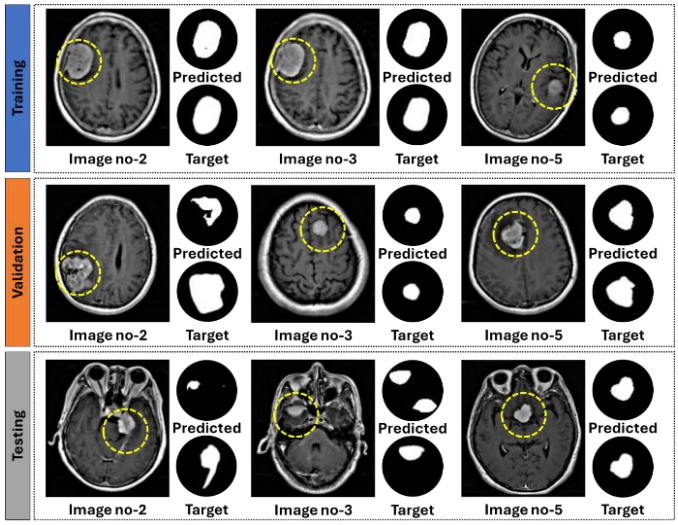

Fig. 9. Details of sample images 3 in training, validation, and testing by modified U-Net architecture with freeze model.

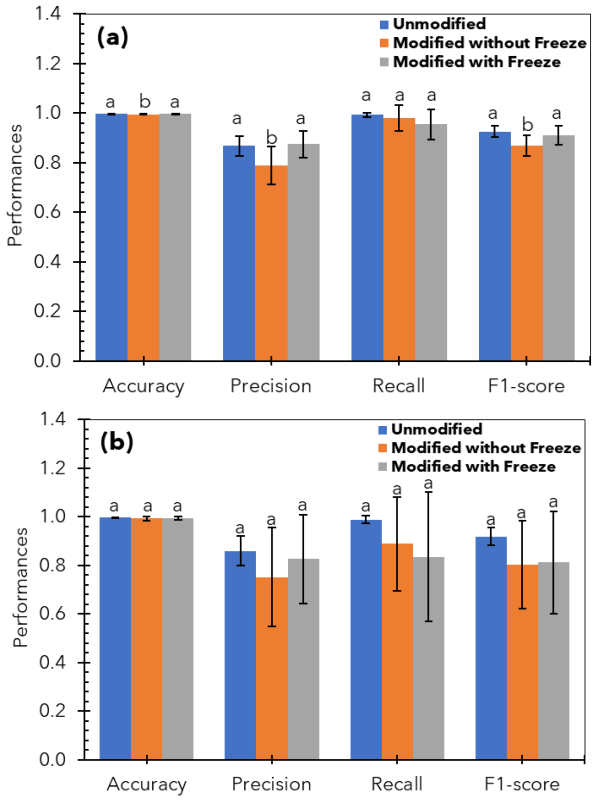
D. Comparison Performance Between the Proposed Method

The performance comparison of the three methods used in this study at each modeling stage is presented in Fig. 10. It can be seen that at the training stage for all parameters, there is a significant difference (p<0.05) between the three methods tested except for the recall parameter. However, no difference in performance was found between the three methods for the validation and testing stages (p>0.05). Finally, the method with modified U-net architecture with a freeze layer provides a significant difference in training time calculation. Meanwhile, the model performance is equally suitable for all three using unmodified U-Net architecture. Therefore, the method proposed through this study that combines modified U-net architecture with a freeze layer provides a more efficient calculation time efficiency of around 83% than unmodified U-net architecture. Compared with previous research, as reported by Cheng, et al. [26], this study's results have been better than those of prior research, as presented in Fig. 10(e).

The practical motivation for applying the theoretical results obtained in this study lies in improving the accuracy and efficiency of brain tumor segmentation in clinical settings. Accurate segmentation is crucial for diagnosing, planning treatment, and monitoring tumor progression, yet manual segmentation is time-consuming and prone to variability. Our modified U-Net architecture, enhanced with batch normalization, dropout, and freeze layers, offers a robust and scalable solution that addresses common issues such as overfitting and computational inefficiency, mainly when working with small MRI datasets. These theoretical improvements translate into more reliable, faster, and precise automated segmentation, ultimately aiding clinicians in making more informed decisions. The ability to generalize across different cases ensures that the model can be applied in real-world medical environments, improving diagnostic workflows and potentially leading to better patient outcomes through more personalized and accurate treatment strategies.



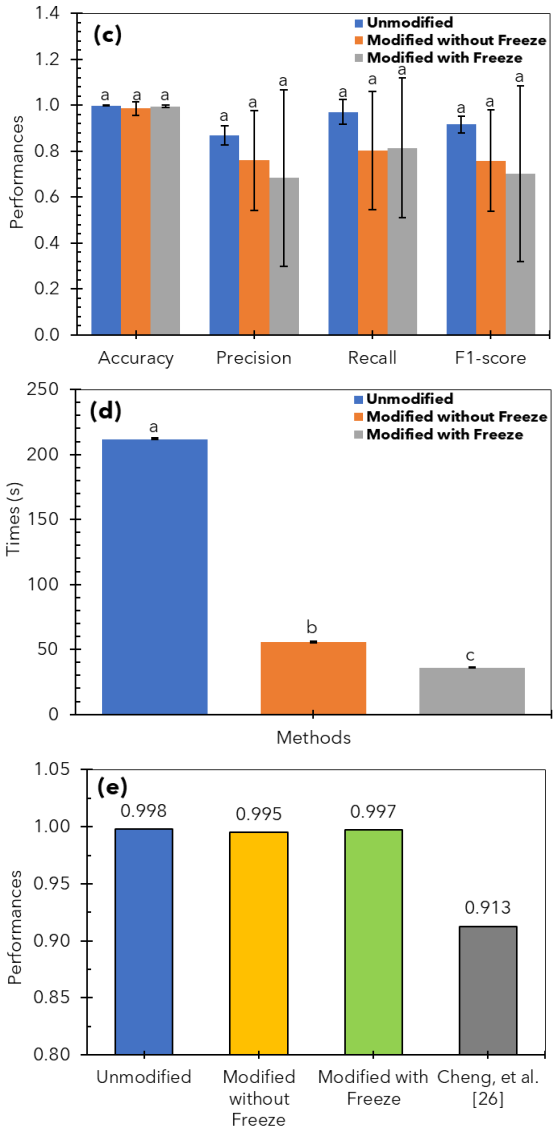


Fig. 10. Comparison performance between the proposed method on (a) training, (b) validation, (c) testing, (d) times and (e) comparison with a result from [26].

V. Conclusions and Future Work

In this study, we compared the performance of unmodified and modified U-Net architectures for brain tumor segmentation from MRI images, focusing on enhancements through batch normalization, dropout, and freeze layers. While the unmodified U-Net provided reliable performance, it exhibited a slight loss gap between training and validation, hinting at potential overfitting and resulting in lower intersection over union (IoU) scores. On the other hand, the modified U-Net without a freeze layer demonstrated improved convergence and reduced loss, with higher IoU scores indicating better segmentation capabilities. However, some inconsistencies were observed in precision and recall during the testing stage, showing that further optimization was necessary while the modifications improved performance. The most promising results came from the modified U-Net with a freeze layer, which achieved the highest IoU scores and maintained stability across all performance metrics, including accuracy, precision, recall, and f1-score. This model effectively mitigated overfitting by limiting the training depth while reducing the computational time required, making it highly efficient for practical use. The freeze layer modification proved particularly beneficial, allowing for a balance between model complexity and computational efficiency.

The modified U-Net architecture with a freeze layer significantly reduced training time by 81.72% compared to the unmodified U-Net while maintaining similar performance across validation and testing stages. Despite the differences observed in training, all three methods performed equally well regarding segmentation accuracy and consistency. While the unmodified U-Net is a solid baseline for segmentation tasks, the modified U-Net, especially with the freeze layer, shows superior performance, making it more suitable for real-world applications where accuracy and efficiency are paramount. Future studies could investigate further improvements to these architectures by incorporating advanced optimization methods and expanding the dataset to include more diverse tumor types and imaging conditions, thereby enhancing the model's generalizability.

Indoor Landscape Design and Environmental Adaptability Analysis Based on Improved Fuzzy Control

Jinming Liu[1], Qian Hu[2]*, Pichai Sodbhiban[3]
Modern Design Institute, Hunan Software Vocational and Technical University, Xiangtan, 411100, China[1, 2]
College of Art, Bangkok Thonburi University, Bangkok, 10170, Thailand[3]

***Abstract*—With the increasing demand for automation and intelligence in indoor landscape design, exploring efficient and precise control strategies has become particularly important. Robot-assisted technology and A* algorithm are utilized for indoor environment localization and mapping. Then, type-2 fuzzy adaptive fuzzy control is applied for indoor landscape automatic design. An improved genetic algorithm is utilized for environmental analysis to enhance the adaptability of indoor landscape design to the environment. In the results, the robot adopting this algorithm was significantly better than ordinary robots in path planning optimization, with a fitting accuracy of over 95%. The type-2 fuzzy control model had a maximum speed of 0.75m/s and an overshoot of only 7.1% for balancing robots, resulting in a faster recovery speed and smaller overshoot. The proposed method performed the best in terms of functionality, aesthetics, technicality, accessibility, and user satisfaction for landscape design effectiveness and environmental adaptability. The research improves indoor landscape design's automation. Meanwhile, the combination of fuzzy control and genetic algorithms enhances the design accuracy and environmental adaptability. This provides a new technological path for indoor landscape design.**

***Keywords*—Fuzzy control; indoor landscape design; environment; adaptability analysis; robot assisted**

I. Introduction

Indoor Landscape Design (ILD), as an important component of the built environment, is crucial for improving spatial quality and meeting functional requirements. However, when faced with the growing demand for personalization and diversity, traditional ILD shows significant limitations in terms of efficiency, accuracy, and adaptability. How to achieve efficient, precise, and environmentally adaptable design has become an urgent problem to be solved, especially in complex and ever-changing indoor environments [1]. As technology advances, automation and intelligence become new trends in design. Intelligent design not only improves design efficiency but also provides more accurate and personalized design solutions through data analysis and simulation [2-3]. Fuzzy Control (FC), as a control strategy that can handle uncertainty and fuzzy information, has shown its unique advantages in multiple fields. FC can effectively process fuzzy, inaccurate, or incomplete information by simulating human decision-making processes, thereby achieving optimized control in complex systems. Therefore, how to combine FC with ILD to improve the automation level and environmental adaptability of design has become a topic worthy of research [4-5]. To address this issue, this study proposes an improved FC-based ILD and environmental adaptability analysis method. This method combines robotics technology, A* algorithm, Range Type-2 Fuzzy Logic Control Mechanism (RT2FLCM), and Improved Genetic Algorithm (IGA). It aims to achieve automation and precision of ILD while improving environmental adaptability.

The innovation of the research lies in the application of fuzzy control theory to interior landscape design, and through the combination of robot-assisted technology and A* algorithm, the accurate location and mapping of indoor environment are realized. In addition, the study adopts type-2 fuzzy adaptive fuzzy control for interior landscape automatic design. The application of this method makes the design process more accurate and personalized. The contribution of the research is reflected in environmental analysis through improved genetic algorithms, which are capable of simulating natural selection and genetic mechanisms for global search and optimization. The application of this algorithm improves the accuracy and environmental adaptability of the design. By combining advanced control theory, algorithm and robot technology, a new analysis method of interior landscape design and environmental adaptability is proposed in this study, which provides a new technical path for the field of interior landscape design and has important theoretical and practical significance.

The article is divided into six sections. Section I is the introduction, through the background and research status of interior landscape design leads to the research theme. Section II is a literature review, which discusses and analyzes the research status of fuzzy control algorithm and interior landscape design at home and abroad. In Section III, robot assisted technology and A* algorithm are used for interior landscape positioning and environment mapping, and RT2FLCM is used for interior landscape automatic design. In Section IV, the effectiveness of the algorithm is verified by experiments. Section V is discussion, which discusses and analyzes the research results and compares them with other studies. Section VI summarizes the research results.

II. Related Work

When exploring the potential application of fuzzy logic in ecosystem service assessment, Biber et al. developed a

biodiversity-based fuzzy logic evaluation system. This evaluation system was applied to three different forest management scenarios. A simulation study was conducted for up to 100 years. These results confirmed the effectiveness of fuzzy logic as an evaluation tool [6]. Colak et al. proposed an active power factor correction method based on FC theory to address the growing demand for reliable and efficient power systems. Fuzzy logic controllers provided a highly adaptable and flexible solution by addressing the inherent uncertainty in power systems. In comparison with traditional control methods, the FC-based method had significant advantages in accuracy, robustness, and response time [7]. Hussein et al. proposed a fuzzy logic-based model for evaluating the spatial spaciousness. The proposed fuzzy model could accurately reflect input variables' influence on spatial spaciousness [8]. Khafajeh et al. started designing and developing an FC system for hydroponic greenhouses. Through optimization of the FC system, the average temperature during the day and night decreased from 34.25℃ and 23.22℃ to 31.17℃ and 21.96℃, respectively [9].

For intelligent drone control, Al Gizi A J H utilized a remote FC vehicle-mounted sonar tracking and detection device mounted to collect data for preventive maintenance of high-voltage power lines. Combining deep neural networks and FC achieved more efficient power line maintenance work [10]. Kasruddin et al. proposed a novel hybrid strategy combining spiral dynamic algorithm and other methods for flexible robotic arm systems' wheel hub angle tracking. This strategy not only accelerated convergence speed but also improved the solution accuracy. The optimized controller accurately tracked the expected response [11]. Incekara developed a fuzzy logic-based design method for primary school ergonomics classroom furniture. These results confirmed this fuzzy mathematical model's effectiveness [12]. Obinna proposed an intelligent spectrum allocation method to address the rapid increase in IoT devices and limited spectrum resources. This method utilized fuzzy logic to handle uncertainty and imprecise data. The method based on fuzzy logic effectively balanced channel availability and interference level, significantly improving service quality satisfaction [13].

To sum up, the application of fuzzy control is still in its infancy, especially in robot-assisted design and environmental adaptability analysis. A comprehensive method of interior landscape design and environment adaptability analysis is proposed by combining robot assistance technology, A* algorithm, type-2 fuzzy adaptive fuzzy control and improved genetic algorithm. This approach excelled in automation and precision, especially when dealing with uncertainty and complexity in the design process, showing superior performance over existing solutions. Compared with other studies, such as the fuzzy logic evaluation system based on biodiversity developed by Biber et al., the research method transforms the theory into practice through actual robot operation and automated design process, and improves the practical operability of the design. Compared with the active power factor correction method based on fuzzy control theory proposed by Colak et al., the application field of the research is more focused on interior landscape design, more targeted, and more in-depth in environmental adaptability analysis.

III. Methods and Materials

Firstly, the study utilizes robot assisted technology and A* algorithm for indoor landscape localization and environmental mapping. This helps robots to accurately draw and measure in complex indoor spaces. Then, RT2FLCM is utilized for automatic indoor landscape design. Finally, IGA is utilized for indoor environment analysis.

A. Robot Indoor Environment Mapping Based on A* Algorithm

In the automatic ILD, robot technology is adopted to assist in indoor spaces' construction and layout. The RB08 robot, as a compact and highly maneuverable multifunctional robot, is very suitable for complex operations in indoor environments. This robot has six degrees of freedom. Three degrees of freedom are specifically used for terminal positioning, while the rest are utilized to ensure precise positioning of the terminal [14-15]. SolidWorks software is utilized to construct robot's various joints. These joints are then imported into 3D Max to achieve coordinate transformation and relationship establishment between joints. Through this method, passive control between each joint can be achieved. This can precisely control the robot's movements, ensuring the automation and precision of ILD. By combining robotics technology and 3D modeling tools, ILD can not only improve efficiency, but also achieve more complex and refined designs. Fig. 1 shows the robotic arm's coordinate system in landscape design.

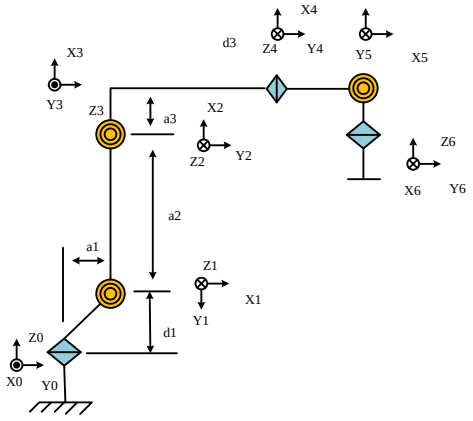

Fig. 1. Robot arm's coordinate system.

In Fig. 1, the D-H matrix is utilized to import the D-H parameter information into the connecting rod transformation matrix. The transformation matrices of each connecting rod are obtained, represented by Eq. (1).

$$A_i^{i-1} = A_{rot}(z_{i-1},\theta_i)A_{tran}(z_{i-1},d_i)A_{tran}(x_{i-1},\alpha_i)A_{rot}(x_{i-1},\alpha_i) \quad (1)$$

In Eq. (1), A_i^{i-1} refers to each connecting rod's transformation matrix. θ_i refers to the joint rotation angle. d_i refers to the joint displacement. α_i refers to the connecting rod's torsion angle. Based on two adjacent coordinate systems, using a homogeneous transformation matrix, the transformation matrix A_m^0 between the final attachment coordinate system and the base system of the m-freedom serial manipulator is obtained, represented by Eq.

(2).

$$A_m^0 = A_1^0 A_2^1 \cdots A_{m-1}^{m-2} A_m^{m-1} \tag{2}$$

In Eq. (2), A_m^0 represents the base system's transformation matrix. Any point's posture on the robotic arm's end connector can be described using the basic coordinate system, represented by Eq. (3).

$$p^0 = A_1^0 A_2^1 \cdots A_{m-1}^{m-2} A_m^{m-1} p^m \tag{3}$$

In Eq. (3), p represents any point's posture on the robotic arm's end connector. By multiplying the six joints' connection transformation matrices order, the terminal transformation matrix A_6^0 corresponding to the base coordinate system can be obtained, represented by Eq. (4).

$$A_6^0 = \begin{pmatrix} m_x & o_x & a_x & p_x \\ m_y & o_y & a_y & p_y \\ m_z & o_z & a_z & p_z \\ 0 & 0 & 0 & 1 \end{pmatrix} \tag{4}$$

On this basis, a reverse kinematics method is proposed and transformed into reverse kinematics to calculate the corresponding joint parameters. The reverse calculation of motion is represented by Eq. (5).

$$\theta = [\theta_1 \theta_2 ... \theta_{m-1} \theta_m] = IKP(A_m^0) \tag{5}$$

In Eq. (5), IKP represents reverse motion. The indoor drawing path optimization of robots utilizes the A* algorithm, which is a widely utilized search algorithm in path planning. The A* algorithm excels at finding the shortest path from the starting point to the endpoint in complex graphical structures. The A* algorithm's core lies in its clever combination of heuristic functions and cost functions. Heuristic functions are utilized to predict the possible cost from the current node to the target node. The cost function evaluates the actual cost from the starting point to the current node [16-17]. Fig. 2 shows the A* algorithm.

In Fig. 2, the initial point is included in the OPEN list and the points in this table are checked. If the OPEN list is empty, the search is terminated and the path is reported as non-existent. If the OPEN list is not empty, the node n with the lowest $F(n)$ value is selected. Node n is removed from the OPEN list and added to the Completed list. Applying this algorithm to ILD can assist robots in precise drawing and measurement in complex indoor spaces. Designers can obtain higher quality spatial data, providing a solid foundation for creative design.

B. Indoor Landscape Design Based on Fuzzy Control

A step-by-step design method is adopted for a balancing robot's straight system. Firstly, a set of fuzzy logic adjusters is developed to address the characteristics and motion features of the balancing robot. Furthermore, by utilizing the membership functions of fuzzy sets, a preliminary architecture of an advanced fuzzy logic control system is constructed. Finally, detailed adjustments and optimizations are made to the overall equipment parameters to improve control effectiveness [18-19]. FC's core process is fuzzification, which is achieved by defining fuzzy sets and their membership functions. Within the determined input range U, usually within the interval of [0, 1], the fuzzy generator utilizes a specific mapping function to convert the exact value into a fuzzy value, represented by Eq. (6).

$$U \to [0,1], u \to \mu_A(u) \tag{6}$$

In Eq. (6), μ_A represents the uncertainty set A's membership function value. A fuzzer's core function is to convert the precise input data captured by the control mechanism into a set of uncertainties. Meanwhile, the membership function values are utilized to measure each component's membership strength. The strategy proposed by Zadeh for processing discrete information has been widely adopted. It expresses the fuzziness of input data through membership functions, enabling the control system to more effectively handle uncertainty and fuzziness, represented by Eq. (7).

$$A = \frac{A(u_1)}{u_1} + \frac{A(u_2)}{u_2} + \cdots + \frac{A(u_n)}{u_n} \tag{7}$$

In Eq. (7), u_n represents an element. $A(u_n)$ means membership degree. Type-2 fuzzy sets are extensions of Type-1 fuzzy sets that introduce additional dimensions to represent uncertainty. Assuming x is an element defined on a certain domain, its membership degree in a type-1 fuzzy set is represented as u. Therefore, the type-2 fuzzy set further refines x's membership degree by introducing an additional membership function, represented by Eq. (8).

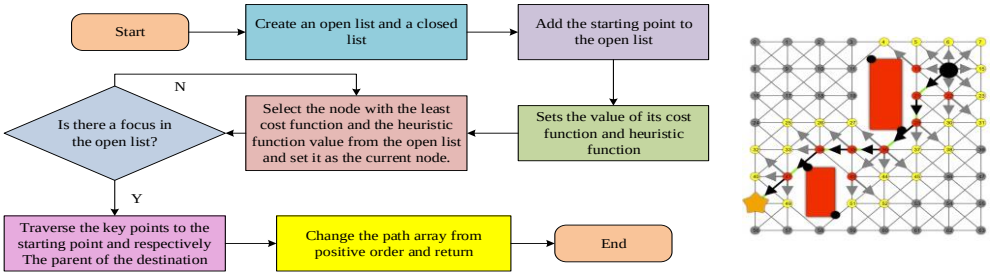

Fig. 2. Process of A* algorithm.

$$\tilde{A} = \left\{((x,u), u_{\tilde{A}}(x,u) \mid \forall x \in X, \forall u \in J_x \subseteq [0,1]\right\} \quad (8)$$

In Eq. (8), J_x represents the primary membership degree of x. $u_{\tilde{A}}$ means the sub-membership degree. Type-2 fuzzy set is an extension of Type-1 fuzzy set, which represents the uncertainty of membership degree by adding a dimension. The membership degree range of each type-1 fuzzy set is also from 0 to 1. However, when they combine, they form a more complex structure. This structure can express higher levels of uncertainty, thus forming a type-2 fuzzy membership function. In the advanced fuzzy sets, the Uncertainty Scope (US) is utilized to represent the set of all principal membership functions within the domain [20]. US provides a method for quantifying and visualizing the uncertainty of fuzzy sets. US covers all possible membership values, allowing for more accurate description and analysis of the characteristics of fuzzy sets. US is represented by Eq. (9).

$$FOU(\tilde{A}) = \bigcup_{x \in X} J_x \quad (9)$$

In Eq. (9), $\bigcup$ means the union of all principal membership functions. The uncertainty domain can also be represented in a coordinate system in Fig. 3.

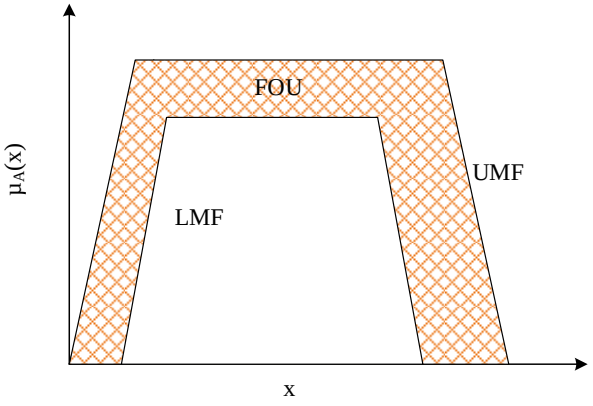

Fig. 3. Type-2 fuzzy set uncertainty field.

In Fig. 3, the boundary of the type-2 fuzzy set is determined by both the Upper Membership Function (UMF) and the Lower Membership Function (LMF). UMF reveals the highest possible membership degree that a set can achieve within the domain of discourse. LMF reveals the lowest membership degree. These two functions' difference forms an interval. This interval's shaded area represents the uncertainty domain, which refers to all possible membership degree of this set within these two boundaries. A system based on RT2FLCM is developed, which integrates the advantages of interval type-2 fuzzy sets to enhance adaptability and control effectiveness in uncertain and complex situations. Fig. 4 shows the structure of RT2FLCM.

In Fig. 4, RT2FLCM inherits the basic structure of type-1 FC, including three main steps: fuzzification, inference, and defuzzification. However, RT2FLCM introduces an additional component, a type reducer, after processing the rule base, which is utilized to convert type-2 fuzzy sets into type-1 fuzzy sets or specific values for further processing. This step is crucial to ensure that the system can smoothly execute subsequent control tasks. Through this design, RT2FLCM can more effectively manage and reduce uncertainty, improving control systems' performance and reliability.

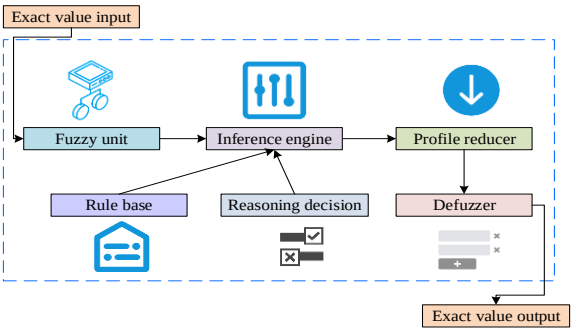

Fig. 4. The structure of RT2FLCM.

C. Indoor Environmental Analysis Based on Genetic Algorithm

For ILD and environmental analysis, an optimization technique that simulates natural selection and genetic mechanisms, namely GA, is utilized for environmental analysis and optimization. This method has significant parallel processing capabilities and global search advantages, enabling effective exploration in the parameter space in a probabilistic manner. It can automatically identify and guide the search process and dynamically adjust search strategies to adapt to constantly changing design requirements. Fig. 5 shows the GA.

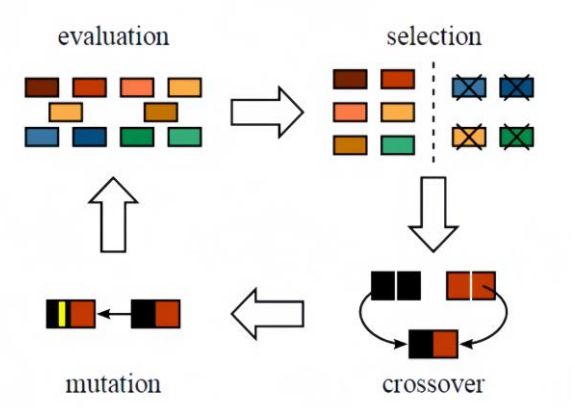

Fig. 5. Genetic algorithm flow chart.

In Fig. 5, the GA process includes encoding the initial population, using fitness values to measure the quality of chromosomes, and selecting individuals based on fitness values. Selection typically retains individuals with better fitness values. Crossover refers to gene exchange. Mutation refers to genetic modification. Adaptability is reflected in probability settings. When fitness begins to concentrate, the crossover and mutation probability increases to escape from local optima. When fitness is dispersed, reducing the crossover and mutation probability allows individuals to search for optimal solutions in their respective regions. The crossover probability is represented by Eq. (10).

$$P_c = \begin{cases} \dfrac{K_1(F' - F_{\min})}{F_{avg} - F_{\min}}, F' \le F_{avg} \\ K_2, F' > F_{avg} \end{cases} \quad (10)$$

In Eq. (10), P_c is the crossover probability. F is an individual's fitness utilized to perform mutation operations. F' means the smaller individual's fitness among two individuals that need to perform crossover operations. F_{avg} means the parental chromosome's mean fitness. $F_{\min}$ means the parent generation's minimum fitness. K is an adjustment parameter. The mutation probability is represented by Eq. (11).

$$P_m = \begin{cases} \dfrac{K_3(F - F_{\min})}{F_{avg} - F_{\min}}, F \le F_{avg} \\ K_4, F > F_{avg} \end{cases} \quad (11)$$

In Eq. (11), P_m is the crossover probability. When conducting ILD and indoor environment analysis, using GA alone requires multiple CFD simulations, which results in high computational costs. Neural networks are utilized as an alternative to CFD to reduce this cost, which are combined with GA to reduce the necessary computational workload. Fig. 6 shows the ILD process combining GA with neural networks and CFD.

In Fig. 6, during the initial stage of ILD, a neural network is utilized to predict the new design scheme's performance indicators. If these predicted results meet the expected design standards, CFD simulation is utilized to conduct the design scheme's in-depth analysis to obtain accurate CFD performance data. By combining neural networks and CFD, ILD can be more efficient and accurate, while providing designers with a powerful tool to achieve innovative and high-quality design results.

IV. Results

Firstly, the robots and algorithmic performance based on A*+IPID+IGA was evaluated. The mean square error, sum of squared errors, and fitness curve of A*+IPID+IGA were analyzed. Then, simulation analysis was conducted on the type-2 FC model. Finally, the landscape design effects and environmental adaptability of different methods were compared and analyzed.

A. Performance Evaluation of Robots and Algorithms based on A*+IPID+IGA

Simulation experiments were conducted on robots based on A*+IPID+IGA using Matlab2018b. Figure 7 shows the mean square error, Sum of Squared Error (SSE), average fitness, and optimal fitness curves of A*+IPID+IGA.

In Fig. 7 (a), the average and minimum SSE of A*+IPID+IGA converged after only 6 iterations, and SSE remained stable at 0.19. In Fig. 7 (b), A*+IPID+IGA showed a faster iteration speed in the first 7 iterations. However, from the 8th to the 19th iteration, the iteration speed slowed down slightly. Finally, at the 20th iteration, the algorithm achieved convergence, indicating that the algorithm improved the convergence rate during the iteration. In Fig. 7(c), A*+IPID+IGA achieved convergence between average and optimal fitness in the first 20 iterations. This method showed a fast convergence rate at the beginning of the iteration and reached the convergence point at the 20th iteration, with the final convergence value stabilizing at 1.44. The path planning optimization accuracy for indoor landscape mapping and design of robots based on A*+IPID+IGA was analyzed. The study compared the real and planned trajectories of ordinary robots and robots based on A*+IPID+IGA in Fig. 8.

In Fig. 8 (a), the fitting accuracy of the robot's real and planned trajectories based on A*+IPID+IGA reached over 95%. In contrast, the fitting accuracy of ordinary robot path planning in Fig. 8 (b) was only about 67%. Therefore, robots based on A*+IPID+IGA had significant optimization improvements in path planning optimization compared to ordinary robots.

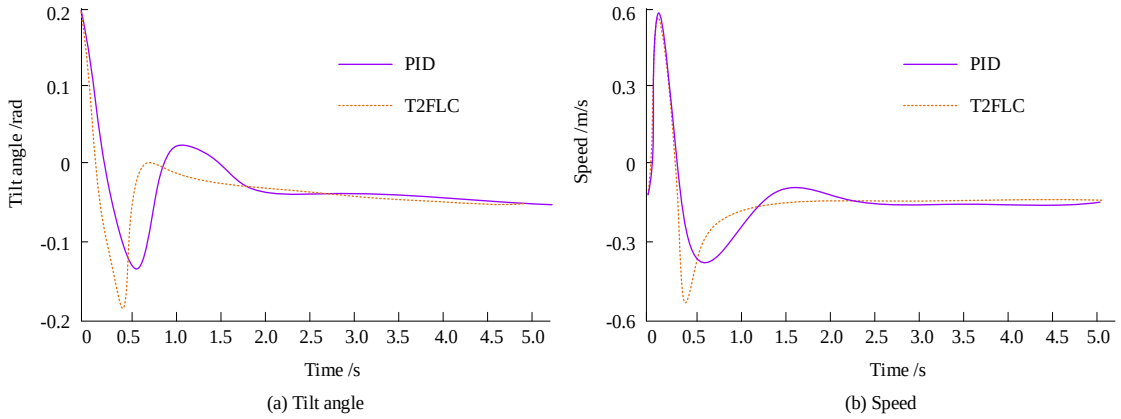
B. Simulation Analysis of Robot Type-2 Fuzzy Control

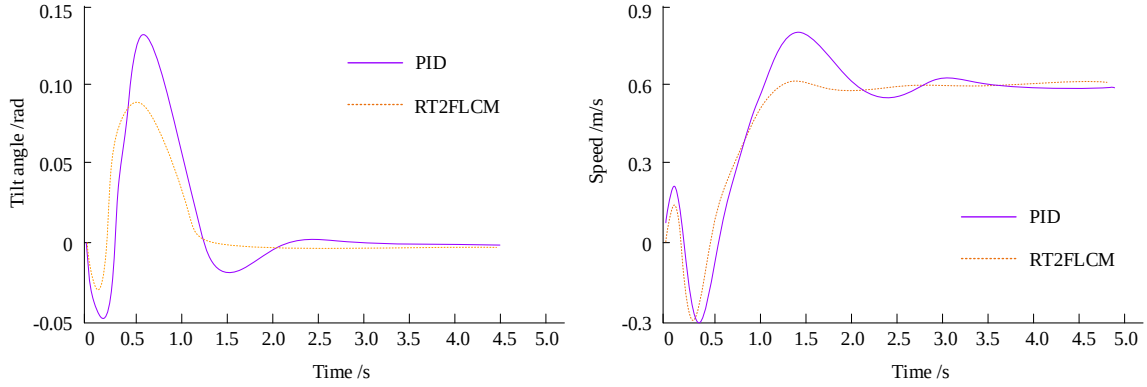
The research assumed that robot's intrinsic parameters were not only accurate and error-free, but also remained constant during operation. External interference factors were excluded. The initial tilt angle was set to 0.3 radians, with the target velocity set to zero, to evaluate the robot's ability to restore balance to a specific tilt angle. The experiment utilized the Simulink module of MATLAB, set the target speed to zero, and set the initial state array. The study compared the classical Proportional-Integral-Derivative (PID) regulation technique with the fusion function integrated RT2FLCM. Fig. 9 shows the robot's tilt angle and velocity changes.

In Fig. 9 (a) and Fig. 9(b), when initially tilted at 0.3 radians, the robot increased to a speed of nearly 0.6m/s in a short period of approximately 0.2s. As the speed of the robot increased, the tilt rapidly decreased and exceeded the equilibrium point, entering a reverse tilt state, indicating that the robot was starting to tilt backwards. Subsequently, the robot began to slow down its speed and gradually returned to equilibrium after experiencing two oscillations. When using traditional PID control, the robot's maximum tilt angle reached 0.16 radians. In contrast, when using the RT2FLCM strategy, although the tilt angle was slightly larger, RT2FLCM significantly improved the recovery speed. Specifically, the robot restored the tilt angle and velocity to zero in about 1.7s. This meant the robot reached a balanced and stationary state, while PID took about 2.5s. After evaluating the stability adjustment ability, further testing will be conducted on robot performance in rate adjustment. This robot was accelerated from a stationary state to a target speed of 0.7m/s while maintaining its initial state unchanged. Fig. 10 shows the changes in speed and tilt angle under two control modes.



(a) Tilt angle (b) Speed

Fig. 9. Tilt and velocity response curve.



(a) Tilt angle (b) Speed

Fig. 10. Velocity and tilt curves under two control modes.

In Fig. 10(a), PID had a maximum negative tilt angle of 0.08, while RT2FLCM had a maximum negative tilt angle of 0.04. PID had a maximum positive tilt angle of 0.2, while RT2FLCM had a maximum positive tilt angle of 0.14. In Fig. 10(b), PID's maximum speed reached 0.9m/s, with an overshoot of 28.6%. In contrast, the maximum speed under RT2FLCM control was 0.75m/s, with an overshoot of only 7.1%. Using PID caused two oscillations, while RT2FLCM only produced one oscillation. In terms of reaching the target speed, the type-2 FC was completed within 1.6s, while using a dual closed-loop PID required approximately 3s. During the overall speed adjustment process, RT2FLCM exhibited smoother and faster performance, with better control effects.

C. Analysis of Landscape Design Effects and Environmental Adaptability

A comparative analysis was conducted between the proposed ILD (Method 1), ILD based on GA (Method 2), ILD based on linear programming (Method 3), ILD based on deep learning (Method 4), and ILD based on building information model (Method 5). The comparative indicators were normalized. Table I shows the final ILD effect.

TABLE I. COMPARISON OF INDOOR LANDSCAPE DESIGN EFFECTS

Method index	Method 1	Method 2	Method 3	Method 4	Method 5
Functionality	0.93	0.71	0.63	0.77	0.83
Aesthetic	0.97	0.68	0.75	0.71	0.85
Technicality	0.94	0.75	0.69	0.82	0.91
Environmental quality	0.89	0.73	0.81	0.79	0.88
Aesthetic value	0.85	0.79	0.75	0.68	0.74
Accessibility	0.92	0.82	0.84	0.65	0.82
Social benefit	0.83	0.81	0.82	0.63	0.78
Innovativeness	0.91	0.88	0.73	0.74	0.86
User satisfaction	0.95	0.74	0.78	0.77	0.90

In Table I, Method 1 performed the best in terms of functionality, aesthetic, technicality, accessibility, and user satisfaction, with scores of 0.93, 0.97, 0.94, 0.92, and 0.95, respectively. Method 5 also performed well on most indicators, especially in terms of functionality and user satisfaction, with scores of 0.83 and 0.90, respectively. In contrast, Methods 2, 3, and 4 scored lower on some indicators, indicating that their performance in these areas needed improvement. Overall, Method 1 became the most popular and effective design method due to its comprehensive advantages. Table II shows the environmental adaptability of five methods.

TABLE II. ENVIRONMENTAL ADAPTABILITY OF THE FIVE METHODS

0	Method 1	Method 2	Method 3	Method 4	Method 5
Functional adaptability	0.95	0.77	0.67	0.67	0.83
Human body engineering	0.91	0.73	0.59	0.82	0.88
Thermal comfort	0.86	0.82	0.68	0.73	0.91
Acoustic adaptability	0.88	0.79	0.81	0.76	0.83
Light environment	0.94	0.61	0.73	0.68	0.85
Air quality	0.92	0.64	0.75	0.85	0.88
Materials and finishes	0.91	0.81	0.80	0.65	0.79
Spatial flexibility	0.86	0.69	0.69	0.74	0.73
Psychological comfort level	0.88	0.78	0.74	0.71	0.68

In Table II, Method 1 performed outstandingly in terms of functional adaptability, human body engineering, thermal comfort, light environment, and air quality, with scores of 0.95, 0.91, 0.86, 0.94, and 0.92, respectively. This demonstrated its outstanding performance in meeting human needs and environmental comfort.

V. DISCUSSION

Improved fuzzy control and genetic algorithm are applied in interior landscape design to improve the automation and accuracy of the design and enhance the environmental adaptability. In terms of functionality, the proposed method shows a high score of 0.93, which is in contrast to the results obtained by Moreno et al. [1] in applying fuzzy logic to the preventive protection and restoration monitoring of heritage buildings. While Moreno et al.'s study focused on evaluation and monitoring, this study applies fuzzy control to the design process itself, achieving a higher functional score. In terms of aesthetics, the score of the study is 0.97, which is compared with the study of Hussein et al. [8] using fuzzy logic to evaluate the spaciousness of architectural design studios, which mainly focuses on the physical properties of space, while this study comprehensively considers aesthetics and provides a more comprehensive design scheme. In terms of environmental adaptability, the interior landscape design method proposed in this study got a score of 0.86 in terms of thermal comfort, which was compared with the result of Khafajeh et al. [9] applying fuzzy logic in the hydroponic greenhouse control system, which mainly focused on the optimization of environmental control, while this study took environmental adaptability as a part of the design process. To achieve a more comfortable indoor environment. Through these comparisons, it can be seen that the proposed method has obvious advantages in automation design and environmental adaptability. The research not only improves the accuracy of the design, but also significantly improves the automation level and environmental adaptability of the design through the combination of fuzzy control and genetic algorithm.

VI. CONCLUSION

A method for analyzing ILD and environmental adaptability based on improved FC is proposed. Its effectiveness is verified through experiments. In the results, A*+IPID+IGA showed good convergence performance during the iteration. The mean square error and SSE converged rapidly after 6 iterations and reached a stable state within 20 iterations. The average and optimal fitness also showed a rapid convergence trend. These results validated this algorithm's effectiveness and reliability in solving optimization problems. For path planning optimization, robots based on A*+IPID+IGA showed higher fitting accuracy compared to ordinary robots, reaching over 95%. The ordinary robots' fitting accuracy was only about 67%. These demonstrated the optimization capability of the improved algorithm in path planning. The ILD and environmental adaptability analysis method based on A*+IPID+IGA has demonstrated excellent performance in robot path planning, balance control, speed control, and landscape design effect evaluation. This method not only improves the automation and accuracy of design, but also significantly enhances environmental adaptability. However, there are still some shortcomings in the research. For example, it is assumed that robot's internal parameters are constant without considering external interference factors. This may affect the control effect in practical applications. Future research can further explore the impact of parameter changes and external disturbances on system performance, as well as how to optimize algorithms to adapt to more complex real-world environments.

Prince Sattam bin Abdulaziz University P.O. Box 151, Alkharj 11942, Saudi Arabia

***Abstract*—Effective logistics systems are essential for fast and economical package delivery, especially in urban areas. The intricate and ever-changing nature of urban logistics makes traditional methods insufficient. Hence, requirements for the application of sophisticated optimisation techniques have increased. To optimise package delivery routes, this study compares the performance of three popular evolutionary algorithms: ant colony optimisation (ACO), particle swarm Optimisation (PSO), and genetic algorithms (GA). Finding the best algorithm to minimise delivery time and cost while taking into account real-world limitations, such as delivery priority. This guarantees that deliveries with a higher priority are prioritised over others, which may substantially impact route optimisation. We examine each algorithm to create the best possible route plans for delivery trucks using actual data. Several factors are employed to assess each algorithm's performance, including robustness to changes in environmental variables and computational efficiency—the simulation models delivery demands using actual data. Results indicate that ACO performed better in Los Angeles and Chicago, completing the shortest routes with respective distances of 126,254.18 and 59,214.68, indicating a high degree of flexibility in intricate urban layouts. With the best distance of 48,403.1 in New York, on the other hand, GA achieve good results, demonstrating its usefulness in crowded urban settings. These results highlight how incorporating evolutionary algorithms into urban logistics can improve sustainability and efficiency.**

Keywords*—Evolutionary algorithms; genetic algorithm; particle swarm optimisation; ant colony optimisation; urban logistics; route optimisation

I. Introduction

Over the last few decades, global greenhouse gas emissions have increased considerably, which are widely considered as the primary contributors of climate cshange [1]. Meanwhile, there has been a growing consciousness of the environmental impacts of business activities, encouraging companies, researchers and governments to discover optimal solutions that support operations with sustainability principles within logistics. Logistics lead to a large dimension of greenhouse gases, making it essential to adopt greener and more sustainable logistics systems [2], [3], [4]. Such efforts not only benefit the planet but also cater to an increasingly eco-conscious human population. Sustainability has increasingly become a concern among academics and practitioners in the fields of logistics and supply chain management. Although research in this area has progressively increased, it still presents multiple directions worthy of exploration [3], [5], [6]. In particular, there is a crucial need for investigations that illuminate how businesses approach sustainability and how organisations and researchers can develop more sustainable supply chains. Enhancing the sustainability of supply chains is considered a fundamental strategic action towards achieving sustainable development goals. Logistics and supply chain performances account for at least one-third of energy consumption and one-third of GHG emissions [7]. To moderate these effects, it is essential to adopt a systemic approach to transformative change in our supply chains—from production to distribution—to enhance their sustainability. It is essential to consider the effects of supply chains and logistics on sustainability from social and economic perspectives. This includes issues with equity, labour conditions and employability. Logistics was first used in the military to describe the methods used by soldiers to acquire, store and transport supplies and equipment [1]. Managing the movement of resources throughout the supply chain is the focus of logistics, a term that is now frequently used in the corporate world, particularly in manufacturing [8]. This covers gathering, storing and moving resources to their intended locations. In the context of logistics, sustainable transport refers to the application of procedures and tools that lessen the impact of transportation and distribution operations on the environment. This idea goes beyond just transporting products from one place to another; it takes into account the environmental impact of these activities [9]. The goals of sustainable logistics are to maximise resource utilisation, minimise greenhouse gas emissions and lessen air and water pollution [5]. Furthermore, businesses can minimise the number of trucks required for deliveries by optimising delivery routes, which can save fuel expenses and maintenance costs and can enhance resource efficiency. In addition, it will enhance customer satisfaction. Companies can boost customer satisfaction and can encourage repeat business and customer loyalty by promptly and efficiently providing goods and services.

Many different optimisation techniques have been developed based on computational intelligence, such as evolutionary algorithms and solutions that opened up the domain of metaheuristics. This study compares the performance of three optimisation algorithms to determine which is better for scheduling problems in logistics: ant colony optimisation (ACO) [10], particle swarm optimisation (PSO) and genetic algorithms (GAs) [11]. The ACO algorithm is a probabilistic optimisation approach inspired by nature that

finds the most effective paths in complex surroundings by simulating the foraging behaviour of ants. GAs are adaptive heuristic search algorithms that iteratively develop a population of solutions to address optimisation and search problems. They are based on the concepts of natural selection and genetics. PSO is another computational approach. It was motivated by the social behavior of fish schools and flocks of birds.

The paper aims to examine three models for logistic delivery optimisation using ACO, PSO and GA, addressing the particular difficulties presented by urban delivery environments. It aims to address a routing problem, where the objective is to determine the shortest path to deliver packages while accounting for the importance of each delivery. Priorities have an impact on the cost estimate. Thus, it is essential to manage more essential deliveries early in the route in addition to reducing the overall journey distance. In this paper, Los Angeles, New York and Chicago are used as study locations for package delivery optimisation research. By choosing these cities, we can address a wide range of variables and complexities that are reflective of worldwide urban logistics difficulties. These cities have a lot of business activity and e-commerce transactions, making them essential economic hubs. As a result, there are several delivery operations for both arriving and departing goods. Gaining knowledge from these cities will help in designing scalable, reliable and effective delivery methods that can be applied to different metropolitan environments globally. It will enhance the research's application value in real-world scenarios.

This study could add significantly to the topic of optimizing urban logistics in a number of ways. First, it offers an analysis of three popular algorithms (ACO, PSO, and GA) in relation to actual urban delivery problems, such as delivery priority. Second, the study assesses algorithm performance using a real data set, guaranteeing applicability and practical relevance. Third, the study provides useful insights for choosing the best method based on the particular needs of urban logistics by analyzing computational efficiency and route optimization accuracy.

The paper is structured as follows, the second section highlights previous research on the application of ACO, PSO, and GA in logistics and other relevant fields. The third section will introduce the methodology which we describe in the experimental design, including the setup of the optimization algorithms. This section also details the criteria for performance evaluation, focusing on delivery efficiency. The result section presents the findings from our simulations, comparing the effectiveness of ACO, PSO, and GA in optimizing delivery routes under urban constraints. The discussion section presents our findings for urban logistics systems. Finally, the conclusion section that addressed the key findings and discussed the broader implications for urban logistics optimization.

II. Literature Review

In this section, existing approaches and previous studies will be studied. Al-Tayar and Alisa [6] proposed several scenarios to obtain the optimal routing path in stochastic networks, including working according to static and dynamic network data. They used the evolutionary algorithm ACO to discover the optimal routing path between the source node and the target node witch's helpful to obtain optimisation that increases logistical effectiveness that leads to contributing to environmental sustainability by minimising fuel consumption, reducing emissions and conserving resources. However, there is a need to work on dynamic data in real time that can be modelled using other probability distributions.

Popović et al. [12] suggest to increase the efficiency of its logistics operations by improving the methodology for evaluating logistics processes using a new model. This model involves the creation of a novel grey full-consistency method which is used to calculate the weight values of the strengths, weaknesses, opportunities and threats factors of a logistics company However, because the application of the approach in the logistics field had not been considered previously, there are some limitations in developing the approach, such as the complex mathematical process for computing criteria weights even if it is applicable in evaluation processes in other various fields.

Zhai [13] proposed addressing the green low-carbon logistics path optimisation problem using the snowmelt heuristic optimisation algorithm. It starts by analysing the characteristics of the green low-carbon logistics path optimisation problem, then considers the optimisation cost and conditional constraints of the green low-carbon logistics path optimisation problem and uses the snowmelt heuristic algorithm model afterwards. The author compared the results with those of many different algorithms and discovered that the snowmelt heuristic algorithm achieves better performance overall but can easily fall into the local optimum problem.

Franco et al. [14] proposed a system that was designed by machine learning algorithms. To provide a solid and sustainable solution to make route adjustments such as re-routing and re-scheduling of the delivery for unpredicted cases, the possibility of a difference between the planned and the actual delivery routes, which is why the use of technology to respond efficiently to all possible events may happen. Even their conceptual framework still needs to be applied in different situations, adapted and extended, and at the same time, it helps in finding a common ground to feed data and obtain values, especially with a new tendency these days to synchronise digital technologies' penetration with all aspects of life.

Sadeghi and Haapala [15] expanded the research on previous work by incorporating the carbon cost into the mathematical cost to improve the mathematical model. The biomass-to-bio-oil supply chain (BTBSCS) used mobile and stationary bio-refineries and contributed to the literature on bio-oil problems by designing a genetic algorithm to obtain a near-optimal solution for establishing mobile and stationary bio-refineries to reduce logistical and carbon costs. Researchers must simultaneously improve the economic, environmental and social performance of bioenergy supply chains. Gao, Cao [16] focused on redesigning a new sustainable reverse logistics supply chain network with the existing forward logistics supply chain network by taking into account economic, environmental and social sustainability. Then, they proposed the MOSINP model to formulate the problem of sustainable reverse logistics supply chain network redesign. Their goal is to support logistics

activities in the face of uncertain demand for new products and the return volume of products of multiple quality levels.

Weber et al. [17] proposed different optimisation problems to find suitable, qualified and optimal solutions for sustainability. The results of this study indicate that there are many improvement models that address the three dimensions of sustainability simultaneously and the social dimension of sustainability is the least studied aspect. An applied classification of mathematical modelling approaches used in sustainable societies is provided. Another research should shift the focus from models that deal primarily with economic and environmental aspects to more balanced models that include all three aspects of sustainability. This paper promotes the transparent and rapid communication of research that highlights the role of optimisation in interdisciplinary fields of mathematical programming and provides SI optimisation models with relevant sustainability indicators.

Zarbakhshnia et al. [18] suggested a probabilistic mixed-integer linear programming model for a sustainable forward and reverse logistics network problem that takes into account many products, stages, periods, and objectives. Their mode aimed to find a new environmental constraint and social matters in the objective functions as its innovation and contribution. This model is based on using a non-dominated sorting genetic algorithm. Their result achieved a better performance compared with a multi-objective PSO.

III. METHODOLOGY

ACO, PSO and GAs will be constrained in this paper. Metrics, including best route, distance, time computation consumption and environmental impact, will be the main topics of comparison. The goal was to find the best set of routes for vehicles that minimise the overall trip distance and cost given a set of delivery destinations, a depot and restrictions on vehicle capacity and delivery times. Every package in our delivery system has a priority feature that is dynamically determined by how likely it is to be delivered late. The 'late delivery risk' feature is a function that prioritises packages to reduce delays and improve customer satisfaction. The main objective is to guarantee on-time delivery by modifying operating priorities according to projected delivery dates and times.

A. Ant Colony Optimisation (ACO)

The ACO technique was inspired by the foraging behaviour of ant colonies, first introduced by Dorigo [10]. Ants are eusocial insects that rely on a community-based approach for survival, rather than existing as individual species. They communicate with each other through sound, touch and pheromones. Pheromones are chemical compounds secreted by ants that trigger social responses within the same species. These chemicals act similarly to hormones but are external to the body and affect the behaviour of other ants. Because most ants live on the ground, they also communicate by leaving pheromone trails on the soil surfaces, which can be detected and followed by other ants [19].

The ACO algorithm, a probabilistic optimisation strategy inspired by nature that finds the most efficient paths in complex surroundings by mimicking the foraging behaviour of ants, is used to tackle this task.

Because ants live in a community of nests, the fundamental idea of ACO is to track how ants leave their nests to get food by taking the shortest route possible. Initially, ants start randomly moving in the space around their nests to search for food. That randomised search technique opens up multiple possible routes from the nest to the food source. Ants now bring some of the food back with them, increasing pheromones along their route, depending on the kind and amount of food they discover.

Depending on these pheromone trials, the probability of selection of a specific path that has been performed by following the ants' path would be a guiding factor to the food source. Evidently, this probability is based on the rate of concentration and evaporation of pheromones. It can also be observed that when the evaporation rate of pheromones is also one of many different deciding factors, the length of each path can easily be accounted for.

- Pheromone Model: A pheromone matrix was initialised to influence the probability of including each city in a route.
- Construction of Solutions: Ants constructed solutions by probabilistically choosing the next city to visit based on a rule combining pheromone strength and a heuristic function (distance and priority).
- Pheromone Update: After all ants completed their routes, pheromones were updated based on the quality of the solutions, with more successful routes receiving higher pheromone levels.
- Daemon Actions: Optional global updates were performed to intensify or diversify the search.
- Iteration: The search continued until a stopping criterion, such as the maximum number of iterations for convergence, was met.

In his experiments, the pheromone updating process is modified as well as the solution representation to prioritise specific deliveries in (ACO). The updating of pheromone trails according to the nodes' priorities. This adjustment makes sure that during the optimisation process, high-priority deliveries are given preference and precedence over others.

Pseudocode for ACO

Input:

Distance matrix, Priority, Number of ants, Number of iterations, Evaporation rate ρ, Alpha α, Beta β

Initialize:
Initialize pheromone levels on paths (tau)
Initialize heuristic information (eta), such as 1/distance
Initialize priority scores for nodes (priority)
For each iteration:
for each ant:
Place ant at a starting node
while ant has not completed its tour:
Select the next node based on transition

probabilities:
Move the ant to this next node
Optionally update pheromones on the path (local update)
Assess the quality of the ant's tour
Update pheromones based on the quality of the tour (global update)
Identify the best tour of the iteration based on lowest cost or highest priority fulfillment
Return the best overall tour found during all iterations

Therefore, the calculation takes into account the tour duration and a priority factor of this tour, which may depend on the nodes that the ant visited to update the pheromones. Routes that efficiently visit high-priority nodes can be prioritised by this factor.

B. Genetic Algorithm Optimisation (GA)

GAs are defined as adaptive heuristic search algorithms that belong to a larger part of evolutionary algorithms [11], [20]. They are predicated on concepts from genetics and natural selection. These are effective uses of the random searches made possible by past data to focus the search on the area of the solution space where performance is better. This is often used to produce solutions to search and optimization issues.

GAs have simulated the process of natural selection, which means that those species that can be able to change in the environment can survive, reproduce and go to the next generation [11]. In simply, that mimics the "survival of the fittest" by using individuals from succeeding generations to solve an issue. Every generation is made up of a population of individuals, and each individual is a potential solution as well as a point in search space. Every person has been represented as a bit string, integer, float, or string of characters. That string is analogous to the chromosome.

In this experiment, we modified the fitness evaluation to incorporate priorities. For instance, routes that visit high-priority locations earlier might receive higher fitness scores. The selection process will typically be implemented using methods such as roulette wheel selection, where the probability of an individual being selected is proportional to its fitness. This step ensures that higher-quality (higher fitness) individuals are more likely to be selected. The following section will describe the algorithm steps:

- Initialisation: The population was initialised with randomly generated possible routes. Each route or chromosome corresponds to a complete solution to the route.
- Fitness Function: The fitness of each chromosome was evaluated based on the total route distance, cost and adherence to delivery priority.
- Selection Process: A tournament selection process was used to select parent solutions for crossover based on their fitness scores.
- Crossover and Mutation: Ordered crossover (OX) and swap mutation were applied to generate new offspring, ensuring genetic diversity and exploration of the solution space.
- Termination: The algorithm terminated after a fixed number of generations or if there was no improvement in the best solution for a consecutive number of generations.

Pseudocode for GA

Input: Distance matrix, Priority, Population size N, Number of generations G, Crossover rate Pc, Mutation rate Pm, Fitness function F
Output: Best solution found
Initialize:
The population with N random solutions
Evaluate the fitness of each individual in the population using F
For each generation from 1 to G:
Select parents from the current population based on their fitness
Perform crossover on the parents to form new offspring, with probability Pc
Apply mutation to the offspring, with probability Pm
Evaluate the fitness of the new offspring using F
Select individuals for the next generation from the current population and the new offspring
If any offspring is better than the best solution found so far:
Update the best solution
Return the best solution

C. Particle Swarm Optimisation (PSO)

PSO has been inspired by a swarm of birds or a school of fish. At the same time, the algorithm is called a population-based stochastic algorithm, and it was developed by Russell et.al. in 1995. That is the overall concept of PSO and the basis of its biological phenomena [23]. In this paper, fitness should take priority into account in addition to the objective function (such as cost or distance), making sure that solutions that complete high-priority tasks are given a higher evaluation. The following section will explain the algorithm steps:

- Particle Representation: Each particle represents a potential solution to the route, encoded as a sequence of delivery points.
- Velocity and Position Update: Customised velocity and position update rules suitable for combinatorial problems were implemented, focusing on sequence operations, such as swaps, influenced by velocity vectors.
- Fitness Evaluation: Similar to GA, the fitness of each particle was assessed based on the route's total distance, cost and adherence to delivery priority.
- Global and Personal Best: Particles updated their velocities towards their personal best and the global best positions found during the search process.

- Convergence: The algorithm ran for a predetermined number of iterations or until performance plateaued.

Pseudocode for PSO

Input: Distance matrix, Priority, Number of particles N, Number of iterations I, Inertia weight W, Cognitive component C1, Social component C2, Objective function ObjFunc
Output: Best known position gBest
Initialize swarm of N particles with random positions and velocities
Evaluate the fitness of each particle using ObjFunc
Set pBest of each particle to its initial position
Set gBest to the position of the best performing particle in the initial swarm
For each iteration from 1 to I:
For each particle p in the swarm:
Update velocity and position of particle p:
Evaluate the fitness of the updated position of particle p
If the fitness of the updated position is better than the fitness at pBest:
Update pBest to the new position
If the fitness of the updated position is better than the fitness at gBest:
Update gBest to the new position
Return gBest

IV. Data Preparation

To verify the proposed sustainable logistics optimisation, an experiment has been designed and the experimental data are an extension of an open-source reference to address the logistics optimisation problem. In our experiment, the dataset used contains 25837 rows and 53 columns, with three cities being selected from that dataset (Chicago, New York and Los Angeles). Each city has several predefined delivery locations (latitude, longitude). Each location will have associated package delivery requirements, including package priority (late delivery). The priority information feature, that is, each algorithm's decision-making, is influenced by the corresponding priorities assigned to each node. The probability of reaching that node sooner increases with higher priorities.

The dataset was prepared before starting use in this study using many different techniques to ensure that any blanks are removed. In addition, there are no duplications or symbols in the dataset. Table I shows the number of addresses in each city.

TABLE I. Data Set

City	*Number of address*
Chicago	3885
Los Angeles	3417
New York	1816

This experiment adapts PSO to a complex permutation issue by reinterpreting the particle movement in the solution space, effectively using swaps influenced by pseudo-velocity. An element of complexity common to scheduling and logistics operations in the real world is added by the adaption, which involves managing priorities in route planning. This method exemplifies the adaptability of PSO and its potential for combinatorial optimisation beyond conventional uses.

Performance was evaluated based on the quality of the solution (total travel distance and cost), computational time and robustness against variations in problem parameters. A combination of the distance and strategic significance of the nodes visited may be used to determine which tour is optimal for each iteration, with an emphasis on routes that better meet higher-priority requirements.

V. Results and Evaluation

In our experimental setup, we implemented three well-known optimisation algorithms, namely, ACO, PSO and GA, to address a complex delivery routing problem and priority considerations. Each algorithm was configured with specific parameters tailored to balance evaluation and manipulation as shown in Table II, with ACO using 10 ants, PSO comprising 30 particles and GA operating with a population of 100 individuals. Our scenarios, which were generated from real-world data, involved more than 1000 delivery points with diverse priority levels. Each algorithm was executed 10 times per scenario to ensure robustness, with results focusing on efficiency, compliance with time computational consumption priority constraints and computational performance.

TABLE II. Parameters of Algorithms

Parameter	*GA*	*PSO*	*ACO*
Population Size	population = 100	num_particles = 30	number of ant =10
Operators	Ordered Crossover (OX), simple swap mutation Implements tournament selection	Velocity Update	Pheromone Update
Crossover Rate	0.7	-	-
Mutation Rate	0.05	-	-
Stopping Criteria	number of generation 100	number of iteration 100	number of iteration 100
Coefficients	-	alpha=1.0, beta=2.0, evaporation=0.5	Alpha (pheromone importance) =1 Beta (heuristic importance) =1

In Fig. 1 to Fig. 9, the figures visualize the optimization process of each evolutionary algorithm, where the Y-axis represents the best fitness value and the X-axis refers to the number of generations. This axis shows the number of generations through which the algorithm has been processed. As can be seen from Fig. 1 to Fig. 9, the performance of each algorithm improves with each iteration, as indicated by the decreasing score of the best distance. The performance of the GA algorithm improves consistently across all three experiments. In contrast, PSO shows that an increase in the number of iterations does not necessarily enhance its performance.

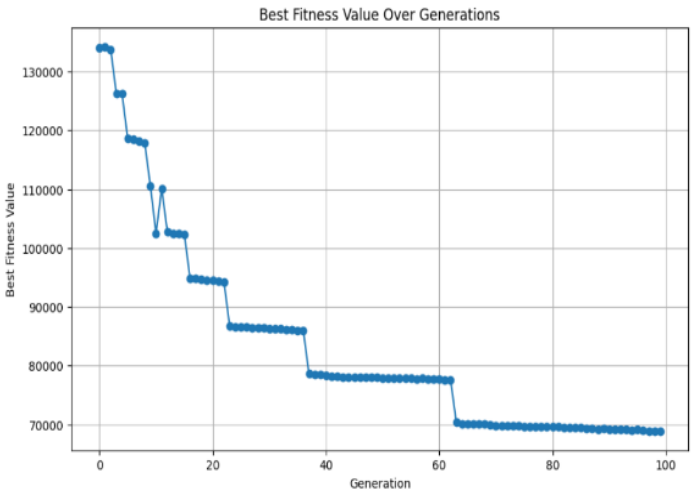

Fig. 1. Performance of GA for New York.

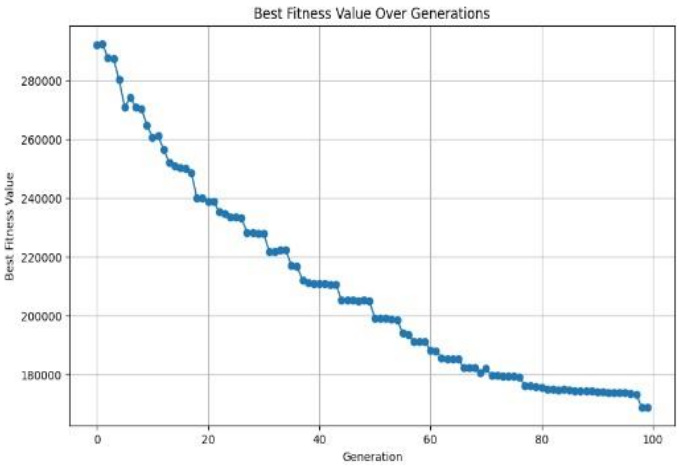

Fig. 2. Performance of GA for Chicago.

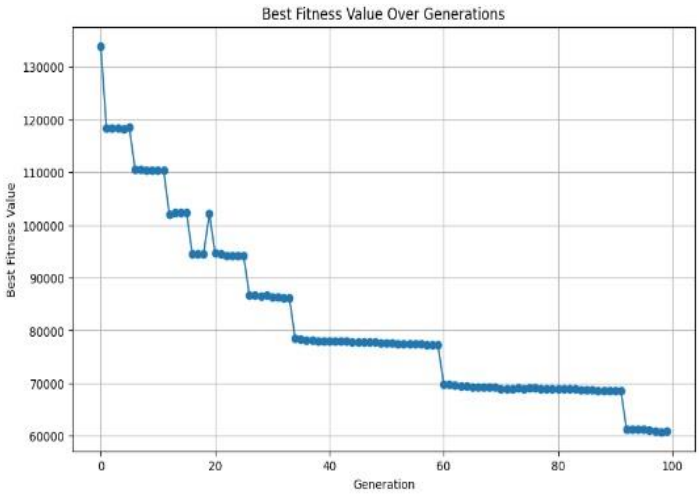

Fig. 3. Performance of GA for LA.

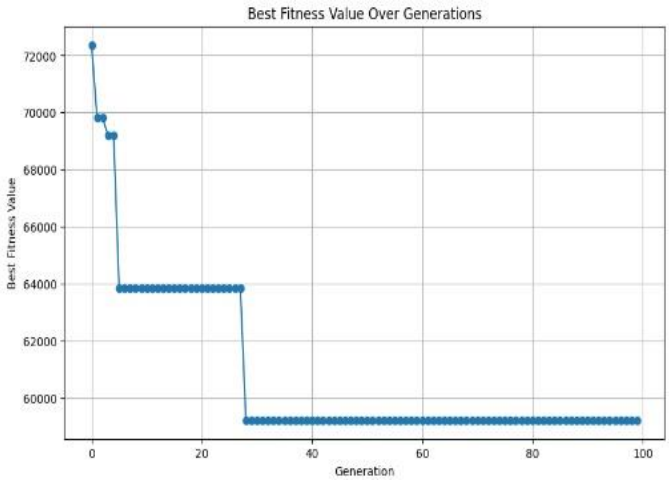

Fig. 5. ACO performance for Chicago.

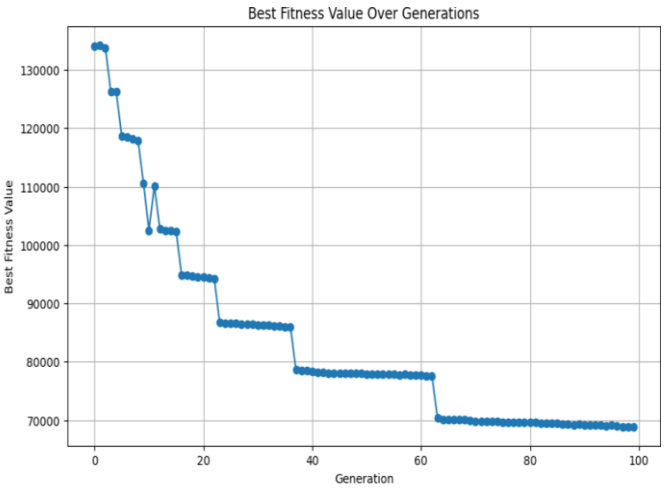

Fig. 6. ACO performance for New York.

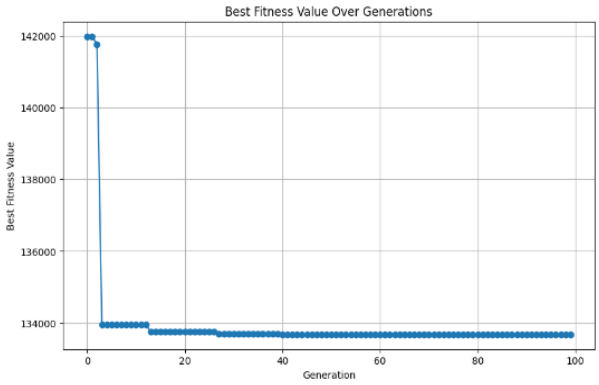

Fig. 7. PSO performance for LA.

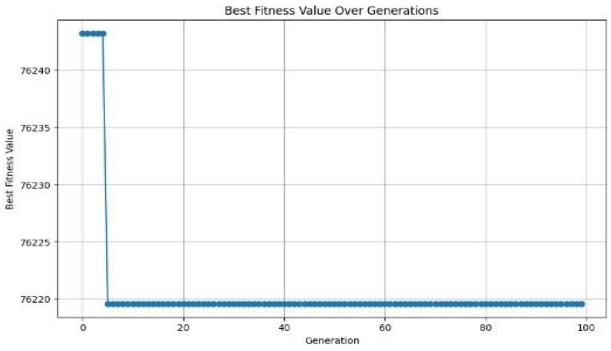

Fig. 8. PSO performance for New York.

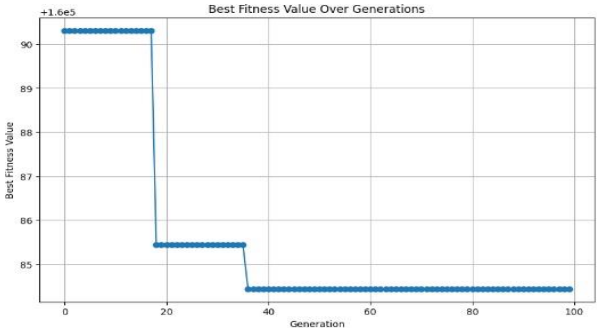

Fig. 9. PSO optimisation performance for Chicago.

Table III shows the result of each algorithm. The best performance was achieved by ACO for Chicago and LA, where the lowest performance was achieved in New York. However, when focused on time consumption, PSO is the fastest algorithm, and this is related to the lowest computational complexity in the algorithm procedure.

TABLE III. RESULT OF THE THREE OPTIMIZATION ALGORITHMS

Data set	Evaluation matrix					
	The best distance			*Time*		
	ACO	***GA***	***PSO***	***ACO***	***GA***	***PSO***
Chicago	59214.681	169017.6	160084.44	1156.282	285.6	27.92
LA	948.1877	60893.05	70260.64	560.4	130.49	20.59
New York	126254.18	48403.1	76219.58	8173.28	180	12.11

VI. DISCUSSION

Different performance characteristics for each algorithm under the urban package delivery scenario were revealed by our comparison investigation of GA, PSO and ACO. ACO had the best overall efficiency, the quickest delivery times and the lowest operating expenses. This was followed by GA, which demonstrated strong performance but was less efficient in terms of time and cost, and ACO, has achieved the best score based on time consumption.

The efficacy of ACO in our investigation is consistent with previous research that emphasizes its advantages in continuous optimisation issues, which we have converted to a discrete context by carefully adjusting parameters.

Given that ACO performed better in our simulation, its implementation may greatly improve operational effectiveness in urban logistics. Urban delivery services might undergo a revolution as a result of the shorter delivery times and cheaper operating costs, which would benefit consumers by lowering prices and increasing profitability for logistics companies. ACO's capacity to address constraints, such as the delivery priority problem, demonstrates its usefulness in scenarios where route dependability is crucial, reinforcing the suggestions made by [21] for logistics applications. In multi-objective logistical scenarios, GA demonstrated its versatility as observed by [22], as evidenced by its competitive performance to achieve a good result even with constraints.

This modified ACO algorithm works especially well in delivery and logistics settings where some deliveries are more essential than others possibly because of commodities that must be delivered on time. It enables the algorithm to automatically modify its pathfinding to give these crucial nodes a higher priority, mirroring operational priorities found in automated decision-making systems in the real world. Furthermore, ACO may be especially helpful in situations where late deliveries result in significant fines, such as in the case of medical or just-in-time industrial supplies, because of its high reliability in meeting delivery timetables.

Our results have several noteworthy implications, one of which is the possibility of minimising environmental effects through optimal routing. The effectiveness of ACO could contribute to decreased emissions and fuel consumption, which helps sustainability objectives in logistics and urban planning. This is essential as cities worldwide work to address climate change and lower their carbon footprints.

Although results show promise, they are restricted to simulated settings and might not accurately represent the intricacies of human dynamics and real-world traffic patterns. To evaluate and improve the models, future research should try to apply these algorithms in real-time logistics operations, possibly through pilot programmes.

VII. CONCLUSION

This research not only confirms that ACO, PSO and GA are appropriate for optimising urban logistics but also creates chances for integrating these algorithms into practical uses. Through extensive simulations and analysis, we coucnlued that these algorithms could significantly enhance operational

efficiency by optimizing delivery routes. Our data indicated that ACO, especially, excelled in handling complex urban environments by adapting to dynamic constraints. The integration of these algorithms into real-world data set shows promising potential to improve the operational success of logistics firms. By implementing these optimized strategies, companies can more reliably meet delivery schedules. The practical deployment of these methods led to a measurable improvement in punctuality and efficiency, as evidenced by the decrease in average delivery times and which will increase customer satisfaction rates.

Finally, this paper focused on the problem of package delivery route optimisation in heavily populated urban states with obtained results. We recommend modifying the ACO algorithm as a solution. Throughout the project, an effective model that addressed the problems with urban delivery was created, and using outside literature, we assessed the effectiveness of our approach using a variety of indicators. Although benchmark tests were ideal solutions, our findings were affected by algorithmic complexity and real-world application considerations. Overall, with space for improvement and parameter adjustment, our ACO-based approach provided insights into effective route planning for food delivery services in urban settings.

Because traffic congestion constantly develops in urban areas because of an increase in traffic vehicles, this project is advantageous for traffic routing in urban areas with more complex types of roads. This package delivery route optimisation project can be performed on a bigger scale, for example, by creating a routing system for an entire nation's traffic network. The data and performance measures that were covered in this project can help with upcoming studies and initiatives that might use them as a point of reference.

ACKNOWLEDGMENT

The authors are very grateful to thank their Deanship of Research and Graduate studies for technical and financial support in publishing this work successfully.

***Abstract*—The tracking of motion targets occupies a central position in sports video analysis. To further understand athletes' movements, analyze game strategies, and evaluate sports performance, a 3D posture estimation and tracking model is designed based on Graphical Convolutional Neural Network and the concept of "cross-vision". The outcomes revealed that the loss function curve of the 3D tracking model designed for the study had the fastest convergence with a minimum convergence value of 0.02. The average precision mean values for the four different publicly available datasets were above 0.90. The maximum improvement reached 21.06% and the minimum average absolute percentage error was 0.153. The higher order tracking accuracy of the model reached 0.982. Association intersection over union was 0.979. Association accuracy and detection accuracy were 0.970 and 0.965 respectively. During the volleyball video analysis, the tracking accuracy and tracking precision reached 89.53% and 90.05%, respectively, with a tracking speed of 33.42 fps. Meanwhile, the method's trajectory tracking completeness was always maintained at a high level, with its posture estimation correctness reaching 0.979. Mostly tracked and mostly lost confirmed the tracking ability of the method in a long time and cross-view state with high model robustness. This study helps to promote the development and application of related technologies, promote the intelligent development of volleyball in training, competition and analysis, and improve the efficiency of the sport and the level of competition.**

Keywords*—Graphical Convolutional Neural Network; posture estimation; volleyball; motion analysis model; 3D tracking

I. Introduction

In recent years, AI vision technology has begun to be widely used in the sports industry, accelerating the change of the sports industry. This is of key significance in enhancing the level of competitive sports, promoting national fitness activities, expanding the scale of the sports industry, and accelerating the dissemination of sports culture [1-2]. Artificial intelligence technology can develop a more personalized and precise training plan by collecting the training and competition videos of athletes and using visual technology to identify and analyze the movements. Athletes may benefit from it by improving their technical movement proficiency and training effectiveness. Simultaneously, a great deal of game data analysis helps to increase the effectiveness of tactics and strategies [3–4]. Multiple object tracking (MOT) is an important branch in the field of sports video (SV) analytics, which involves techniques such as human activity recognition (HAR), position estimation and target localization [5]. By tracking sports targets, such as players, balls, etc., key data such as their positions, velocities, accelerations, etc., can be obtained in real-time, providing accurate data support for action analysis, tactics development and athletes' performance evaluation [6]. However, there are still a range of practical challenges for MOTs in the sports arena. On the one hand, lighting changes, background interference and occlusion in real ball SVs increase the difficulty of target tracking (TT). Players between the same team are extremely similar in appearance, leading to easy identity exchange of tracking targets. At the same time, the changing body postures of the movement lead to the difficulty of existing MOT methods to distinguish and track the target only by relying on the appearance features [7-8]. On the other hand, multi-camera views in real sports arenas require precise calibration and alignment to ensure that images from different camera views can be accurately aligned and fused. Meanwhile, in order to capture key events, the multi-camera system needs to switch viewpoints frequently, which increases the difficulty of tracking targets continuously and accurately. Therefore, there is a need to develop new MOT technologies to meet the real challenges.

In order to solve the difficulty of target tracking due to the similarity of appearance and constant change of position in multi-camera viewpoints, the study takes volleyball as an example, and proposes a 3D posture estimation (3D-PE) and tracking model (TM) based on graph convolutional network (GCN) and cross-view matching for the TT difficulties caused by the athletes' similar appearance and changing postures. The study is expected to significantly improve the accuracy of athlete tracking by introducing 3D pose estimation and cross-view matching techniques, which will help to deeply analyse athletes' movement characteristics, exercise habits and potential problems, as well as promote the development and innovation of related technologies.

The research innovatively proposes a 3D pose estimation and tracking model based on GCN and cross-view matching, which provides a new technical idea and method for multi-camera viewpoint sports MOT, which can be realised for the expansion of applications in ball sports. The study provides a new theoretical perspective for the field of video analysis by deeply exploring the target tracking in multiphase viewpoints, which can help to improve the athletes' competitive level and provide a more solid technical support for the sports field.

The research is broken up into five sections. In Section II, the state of the art of motion recognition, posture estimation and visual tracking is summarized. In Section III and Section IV a two-dimensional TM for athletes with a single camera and a three-dimensional posture estimation and TM with cross-view matching are designed. In the third part, the performance

of the 3D-PE and TM is tested and analyzed. Section V summarizes the main conclusions and future work of the study.

II. Literature Review

HAR has become one of the popular researches in the field of Artificial Intelligence, HAR is a complex and multidimensional problem, which has been extensively studied by many researchers and scholars. DL techniques have application limitations in monitoring and recognizing elderly people living alone in the face of estimating missing or rare poses in the training dataset. To solve the 3D-PE fuzzy problem, Kim et al. [9] presented a loss function (LF) for the center of mass deviation from the center of the supporting foot and a penalty function for the range of rotation of the appropriate joint angle. The experimental results indicated that the average joint coordinate difference for posture estimation of this method was 0.097m with an execution time of 0.033s per frame. The wide range of human behavioral variations in daily life increases the difficulty of HAR recognition. Khan et al. [10] designed a fully automated HAR model by fusing deep neural networks (DNN), multi-view features, and a plain Bayesian classifier. The outcomes indicated that the maximum accuracy of the model is up to 99.4%. Changes in movements and different viewpoints cause difficulties in recognizing HAR. Guddeti [11] designed a multiple-learning framework for action data in depth and skeleton format from the perspective of multimodal visual data fusion. The framework could extract effective spatiotemporal features from skeleton data and utilize attention-guided DL techniques to accomplish model classification. According to experimental findings, this method's accuracy in multi-view datasets can reach 89.75%. It has been proved that GCN can be better for action recognition based on human skeleton. Aiming at the problems of GCN and the complexity between joints, Yang et al. [12] designed a hybrid network. The network integrated GCN and convolutional neural network (CNN), which could focus on the structural information and the complex relationship between nodes at the same time. The public dataset verified the superiority of the method. HAR is a key technology in wearable sensors and mobile technology, but existing HAR frameworks are only developed for a single data modality. To effectively recognize activities, Islam et al. [13] combined a multi-head CNN with a convolutional long and short-term memory network to analyze visual data and multi-source sensor information. The technique performs better in the multimodal HAR framework, according to the experimental data. HAR classification precision based on wearable sensor data is still insufficient, so Sarkar et al. [14] proposed a new hybrid HAR architecture. The architecture integrated spatial attention-assisted CNNs, filters, and techniques such as genetic algorithms and k-nearest neighbor classifiers. The public dataset confirmed the high recognition precision of the method. Due to its academic and commercial potential, MOT is a fundamental computer vision task that has drawn a lot of attention. Its associated multi-target detection, recognition, and tracking have become the focus of computer vision research and are being used more and more in a variety of fields. Li et al. [15] conducted a study on table tennis trajectory tracking in sports and designed a table tennis trajectory extraction network based on a target detection algorithm. The network incorporated a feature reuse module, enhanced the feature richness of the feature mapping using the Transformer model, and was lightweighted. The experimental results indicated that the network had a detection accuracy of 89.1% for target localization. Zhang and Dai [16] designed a model for tracking athletes' motion trajectories based on computer vision technology. Firstly, the study acquired a motion target based on a generalized background eliminator, and then used a kernelized correlation filter to construct a TT model by fusing it with relevant depth information. Through experiments on gymnasts and badminton players, it was found that the model could effectively reduce the motion trajectory prediction error. Mukhtar and Khan [17] constructed a new MOT method based on vision-Transformer architecture, variable scale pyramid, recursive pyramid structure, spatiotemporal memory encoder, and spatiotemporal memory decoder. The method could predict the object state through the attention mechanism. According to the trial results, the method's performance was much enhanced, and the ID switching rate was lowered by 21.05% and 5.79%, respectively. The traditional correlation filtering conventional feature technique was difficult to fully express the variable target morphology in complex scenes during the process of target localization, which led to inaccurate target localization. In this regard, Liu et al. [18] realized high quality visual monitoring and localization based on location fusion mechanism based on visual cognition flows (LFVC). In contrast to the most advanced visual tracking algorithms now in use for intricate scenes, this approach demonstrated superior performance at a reduced computational expense. An et al. [19] suggested a robust UAV TM based on dynamic feature weight selection to increase the flexibility of visual TT to complicated settings. The model contained multiple weights for different features and utilized dynamic feature weight selection to provide model tracking performance. The model fared better in experiments than previous cutting-edge trackers. The Kernel Correlation Filter (KCF) algorithm has achieved good results in short-term visual TT. To realize long-term TT with target occlusion or loss, Fan et al. [20] designed a long-term KCF and accelerated robust feature TT algorithm. Target matching was accomplished by the algorithm by introducing a random sample consistent target retrieval matching approach. The experimental results confirmed that the method could realize long-term stable TT. In summary, domestic and international research on HAR, positional analysis and MOT has made technical breakthroughs in terms of the main performance. Motion TT relies on the synergy of multiple technologies such as motion recognition, position estimation and target localization. However, the complex and changing game environment, the fast movement of motion targets and the occlusion of deformed other athletes or objects lead to the performance of the existing bit-pose analysis and MOT in SV still needs to be improved. In this regard, the study unfolds the design of 3D TT model based on DL and cross-view.

III. GCN-based and Cross-view 3D Attitude Tracking Technology

To solve the multi-camera multi-volleyball player tracking problem, facing the complex sports field environment and similar player identity information, the study firstly designs a

2D athlete TM based on GCN and posture alignment. Then, the 3D-PE and posture TM are proposed on this basis.

A. Two-Dimensional Tracking Modeling of Athletes with a Single Camera

Volleyball sports action analysis needs to recognize and track the player's position on the playing field and estimate the movement posture, but the similarity of player identity information and the large variation of movement posture increase the difficulty of MOT [21-22]. Therefore, the study realizes the recognition and tracking of players' movements from the perspective of appearance feature representation and contextual information differentiation, and the proposed 2D TM framework is shown in Fig. 1.

In Fig. 1, the 2D TM mainly consists of player detection and posture estimation, feature extraction, contextual graph model and similarity association matching module. The study adopts posture alignment to complete the feature extraction, including extracting the global feature map $M_g \in \mathbb{R}^{C\times H\times W}$ of the player image to construct the global feature branch, and extracting the posture heat map $M_{p_i} \in \mathbb{R}^{H\times W}$ to construct the posture alignment feature branch. Among them, $C\times H\times W$ denotes the feature map channels × height × width. K denotes the number of joint points, $i \in K$. The feature extraction model based on pose alignment is shown in Fig. 2.

In Fig. 2, the feature extraction framework uses a variant of residual network (ResNet), ResNet50, to extract $M_g \in \mathbb{R}^{C\times H\times W}$. With 50 layers deep, ResNet50 is able to resolve gradient vanishing and gradient explosion issues in DNN training. The framework uses cascaded pyramid network (CPN) to extract $M_{p_i} \in \mathbb{R}^{H\times W}$. CPN is a common DL model for posture estimation, which can effectively recognize key points in human postures, including the head, shoulders, elbows, wrists, and other key parts [23-24]. CPN utilizes cascading pyramids to construct multi-scale feature representations, which can realize human posture estimation at different scales. The CPN structure composition is shown in Fig. 3.

In Fig. 3, the CPN ontology includes GlobalNet and RefineNet, GlobalNet completes the coarse extraction of key points, and RefineNet completes the fusion of different layers of information to obtain more comprehensive and accurate posture estimation results [25]. The feature map process of the feature extraction framework is shown in Eq. (1).

$$\begin{cases} F_g = GAP\left(M_g\right) \\ F_p = GMP\left(\left\{f_{p_i}\right\}_{i=1}^{K}\right) = GMP\left(GAP\left\{M_g \otimes m_{p_i}\right\}_{i=1}^{K}\right) \end{cases} \quad (1)$$

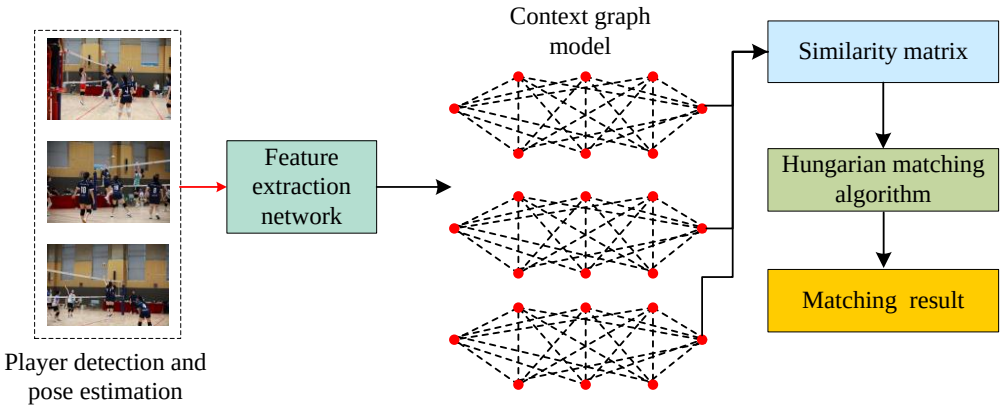

Fig. 1. Player 2D tracking model framework.

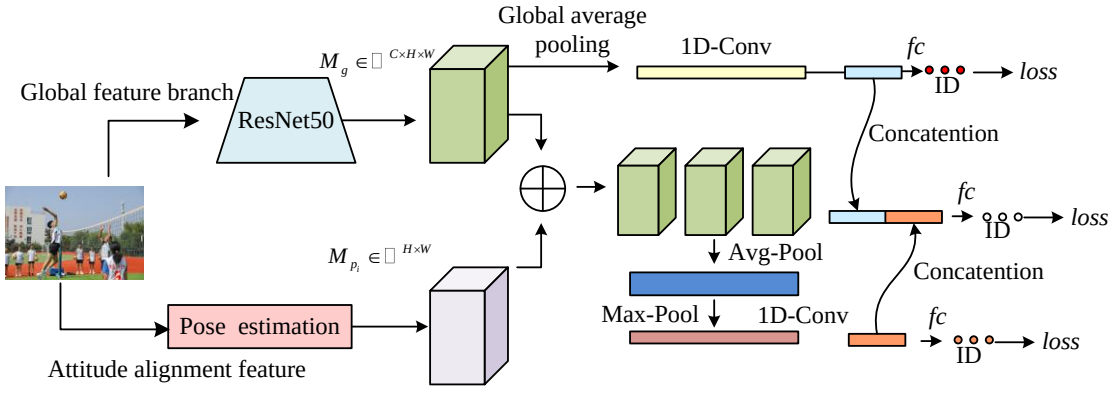

Fig. 2. Schematic diagram of the feature extraction model based on attitude alignment.

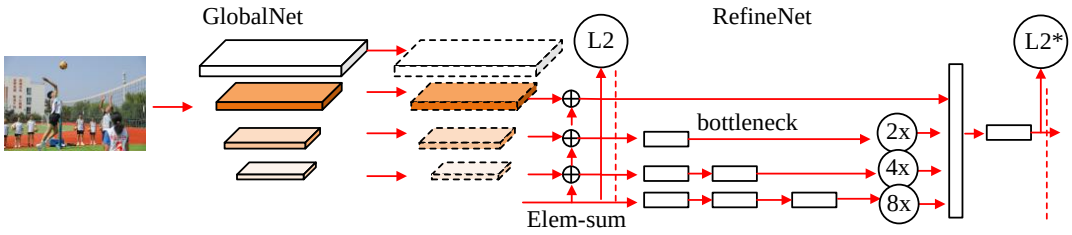

Fig. 3. Schematic diagram of CPN structure composition.

In Eq. (1), F_g and F_p denote the global features extracted from the global feature map and the pose heat map and the pose-aligned features, respectively. *GAP* and *GMP* denote the global maximum and global average pooling respectively. m_{p_i} is the pose heat map. f_{p_i} denotes the corresponding feature. Considering that there are various kinds of occlusions in the real field environment, the feature extraction framework splices the two kinds of features as the final feature extraction result. The splicing feature F_{cat} calculation process is shown in Eq. (2).

$$F_{cat} = F_g \left\| F_p \right. \tag{2}$$

The end of the feature extraction framework uses a fully connected layer to predict features. Eq. (3) computes the LF of the network.

$$loss = loss_{cat} + loss_g + loss_p \tag{3}$$

In Eq. (3), $loss_{cat}$, $loss_g$ and $loss_p$ denote the LFs corresponding to splicing features, global features and pose alignment features, respectively. The context graph model first learns the target athlete and the nearest neighbor athletes to complete the construction of the context graph $\wp = (V, E)$. V and E represent the "nodes" and "edges" respectively. Then GCN is used to learn the similarity of different athletes. A DL model called GCN is used to process graph-structured data. It carries out feature extraction and learning of node interactions and connections. GCN introduces a process similar to convolutional operation in graph data to update the representation of nodes through information transfer and aggregation between neighboring nodes to achieve learning and inference of graph-structured data [26-27]. The target athlete is regarded as the master node, the nearest neighbor athletes are regarded as branch nodes, and the branch nodes are connected to the master node. The node feature x_i expression is shown in Eq. (4).

$$x_i = \begin{cases} F_{cat} \in \square^d & i \in \{1,2,...,n\} \\ 0^d & i \in \{n+1,...,N\} \end{cases} \tag{4}$$

In Eq. (4), n denotes the number of athletes. N denotes the preset constant, $n \le N$. The adjacency matrix $A \in \square^{N \times N}$ is used to represent the "edges", as shown in Eq. (5).

$$A_{i,j} = \begin{cases} 1, & i = 1 \text{ or } i = j \\ 0, & otherwise \end{cases} \quad (i, j \in \{1,2,...,N\}) \tag{5}$$

Fig. 4 depicts the node feature update mechanism. The study uses GCN to integrate node information. The GCN working mechanism mainly contains two parts: information dissemination and information aggregation. Node x_i is coded as $x_i^{(l)}$ in the propagation process and its coded as x_i in the information aggregation process. The node features obtained after GCN integration have a stronger ability to represent contextual features.

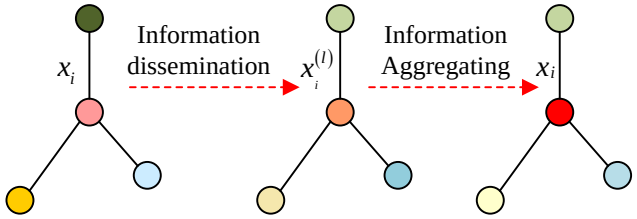

Fig. 4. Feature update mechanism for GCN integrating node information.

There is a difference in the importance of different nearest neighbor athletes to the target athlete. The study introduces the linear distance between athletes as weights into the contextual graph model. The feature aggregation process is shown in Eq. (6).

$$X^{(l+1)} \in \sigma\left(D^{-1} A X^{(l)} W^{(l)}\right) \tag{6}$$

In Eq. (6), D and A denote the distance matrix and the normalization result of "edge" A, respectively. $X^{(l)}$ denotes the set of node features $x_i^{(l)}$. $W^{(l)}$ denotes the network parameter matrix, and σ denotes the nonlinear activation function. Therefore, the GCN network with the introduction of weighting information has a stronger feature representation ability. The study uses cosine distance to measure the similarity between athletes. The cosine LF is shown in Eq. (7).

$$loss(x_1, x_2, y) = \begin{cases} 1 - \cos(x_1, x_2) & y=1 \\ \max(0, \cos(x_1, x_2) - margin) & y=-1 \end{cases} \tag{7}$$

In Eq. (7), y denotes true similarity labeling and $y = 1$ denotes similarity. x_1, x_2 denotes different athletes. The similarity association matching module mainly accomplishes the matching between the current detection and the tracking trajectory. The working mechanism is shown in Fig. 5.

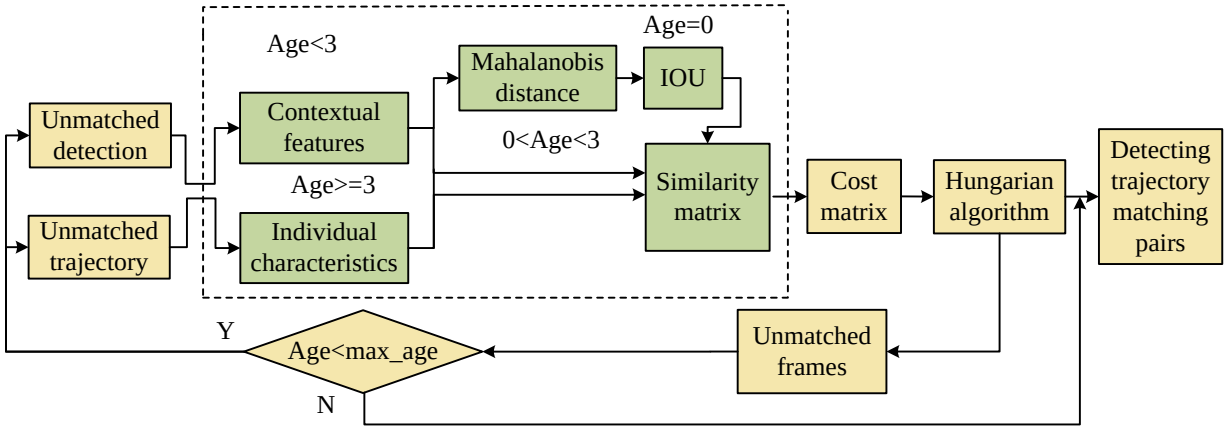

Fig. 5. Working mechanism of similarity correlation matching module.

In F. 5, "age" indicates the number of unmatched frames in the trajectory. The matching mechanism involves four different kinds of matching information, including contextual features, individual features, martensitic distance of motion states, and intersection ratio. Finally, Hungarian algorithm (HA) is used to complete the matching solution [28-29]. HA is mainly used for the solution of assignment problems and is applicable to problems related to bipartite graphs.

B. 3D-PE and Tracking Model Construction Based on Cross-View Matching

Real field videos are mainly captured by multiple cameras. To solve the complexity and challenge of real field video due to the multi-camera shooting environment, the research unfolds the 3D TM design of the target in multi-phase view based on single-camera TT. The model framework is shown in Fig. 6.

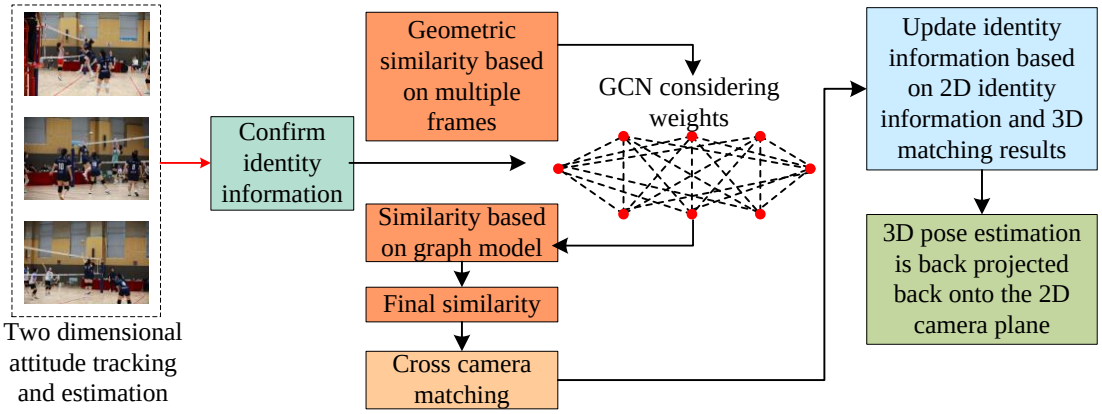

Fig. 6. Cross view matching 3D pose estimation and tracking model architecture.

In Fig. 6, the architecture contains the main modules of 2D tracking, 2D posture estimation, cross-camera matching, 3D tracking and posture estimation. Among them, 2D tracking is accomplished by the architecture shown in Fig. 1, and 2D posture estimation is accomplished by CPN network. The core of cross-camera matching lies in the similarity measure and matching of athletes from different cameras. Therefore, the study considers both geometric constraints and appearance features for similarity metrics.

Define that there are C cameras and M athletes under cross-view matching. The similarity scores between the athletes form matrix $A \in \mathbb{R}^{M \times M}$, and output the matching result $P \in \{0,1\}^{M \times M}$. "1" indicates the same athlete, and a "0" indicates different athletes. The study introduces the principle of "polar line constraint", which judges the similarity of athletes by determining whether the corresponding joints of different athletes are "homonymous image points". The geometric distance $D_g(i,j)$ across the camera of different athletes is calculated in Eq. (8).

$$D_g(i,j) = \frac{1}{2Q}\sum_{q=1}^{Q}\left(d_g\left(p_i^q, l_{ij}\left(p_j^q\right)\right) + d_g\left(p_j^q, l_{ji}\left(p_i^q\right)\right)\right) \quad (8)$$

In Eq. (8), p_i and p_j denote the two-dimensional attitude coordinates of different athletes. Q denotes the number of joint points, $q \in Q$. $l_{ij}\left(p_j^q\right)$ denotes the pole line corresponding to point p_j^q and point p_i^q in different cameras. $d_g(\cdot, l)$ denotes the distance from the point to the polar line. The distance matrix $D_g \in \mathbb{R}^{M \times M}$ is calculated from Eq. (8). The sigmoid function is used to normalize the distance matrix, and the process is shown in Eq. (9).

$$D_g(i,j)=\begin{cases}\tau_g & D_g(i,j)\geq\tau_g\\ D_g(i,j) & other\end{cases} \tag{9}$$

In Eq. (9), $D_g(i,j)$ denotes the normalized distance matrix. τ_g denotes the set cross-camera distance threshold. Standard deviation normalization is also required due to the presence of some anomalous values taken. The calculation process is shown in Eq. (10).

$$D_g(i,j)=\left(D_g-\mu\right)/\sigma \tag{10}$$

In Eq. (10), μ, σ denote the mean and standard deviation, respectively. The normalized similarity matrix A_g is shown in Eq. (11).

$$A_g=sigmoid\left(-D_g\right) \tag{11}$$

Relying on a single similarity matrix cannot distinguish the athlete identity information well. The study introduces two-dimensional trajectory information on this basis and proposes a similarity matrix based on trajectory information. The calculation process is shown in Eq. (12).

$$A_g^T=sigmoid\left(-C_g^T\right) \tag{12}$$

In Eq. (12), T denotes the past video frame. C_g^T denotes the count matrix. The study used GCN to construct a graph model across viewpoints for matching between athletes. Fig. 7 illustrates the procedure for determining how similar athletes are from various angles using the graph model.

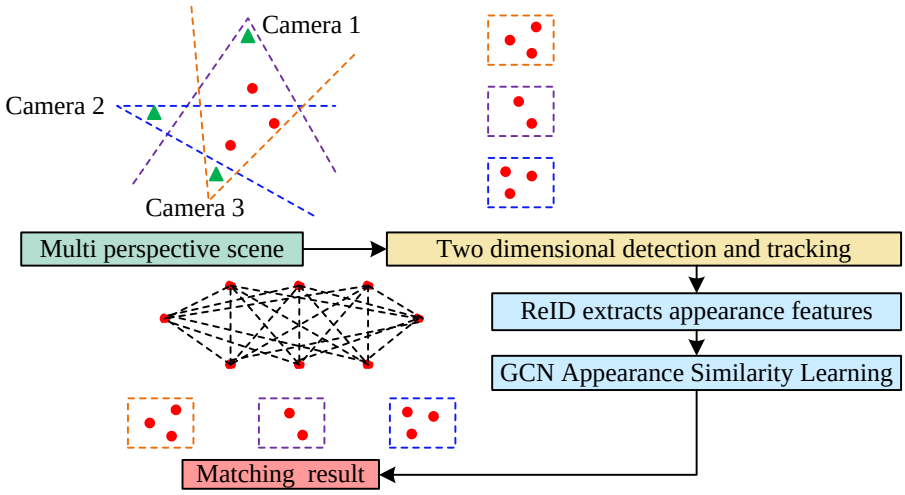

Fig. 7. Figure model learning cross perspective athlete similarity.

In Fig. 7, the study first extracts the appearance features of athletes using pedestrian re-identification (ReID) A_a. The obtained appearance feature vectors form the nodes of the graph model, and the athletes with different camera planes are connected to form the edges of the graph model. The process of applying the graph model to determine how similar athletes are from different perspectives is shown in Fig. 7. The realization process is shown in Eq. (13).

$$\begin{aligned}H^{(l+1)}&=\sigma\left(D^{-\frac{1}{2}}AD^{-\frac{1}{2}}H^{(l)}W^{(l)}\right)=\\ &\sigma\left(D^{-\frac{1}{2}}\left(A_g^T\cdot A+I\right)D^{-\frac{1}{2}}H^{(l)}W^{(l)}\right)\end{aligned} \tag{13}$$

In Eq. (13), D denotes the degree matrix. A denotes the self-looping adjacency matrix. $H^{(l+1)}$ and $H^{(l)}$ denote the node features of layer $l+1$ and layer l, respectively. After graph convolution, the more robust appearance similarity matrix A_a^K is obtained, and finally the matching is completed based on the average value of the two similarity matrices A_{g+a}. The calculation process is shown in Eq. (14).

$$A_{g+a}=\left(A_g^T+A_a^K\right)/2 \tag{14}$$

According to the study, matching athletes across viewpoint states is an optimization problem that has to be resolved. The matching process is shown in Eq. (15).

$$\min_P f(P)=-\sum_{i=1}^{M}\sum_{j=1}^{M}\left(A_{ij}\cdot P_{ij}\right)+\lambda rank(P) \tag{15}$$

In Eq. (15), A, P denote the similarity matrix, binary matching matrix respectively. $rank(P)$ denotes the rank of matrix P. To ensure the cyclic consistency of the matching results, $rank(P)$ needs to satisfy certain constraints. That is, $rank(P)\leq m$ and m denote the number of athletes in a multi-camera scene. After completing the 2D tracking and cross-camera matching, the study utilizes the triangulation algorithm to further obtain the 3D pose information. The triangulation algorithm recovers the coordinates of the 3D points from the projected coordinates of the two cameras and the transformation matrix [30-31]. The computational procedure for projection to the normalization plane is shown in Eq. (16).

$$d\begin{bmatrix} x \\ y \\ 1 \end{bmatrix} = TX \tag{16}$$

In Eq. (16), d is the depth of the 3D point X. T is the transformation matrix of the camera. Finally, the results of the 2D processing are combined to realize the athlete tracking in 3D cross-camera view. The new tracking IDs are clustered for different athletes.

IV. 3D-PE AND TRACKING MODEL PERFORMANCE ANALYSIS

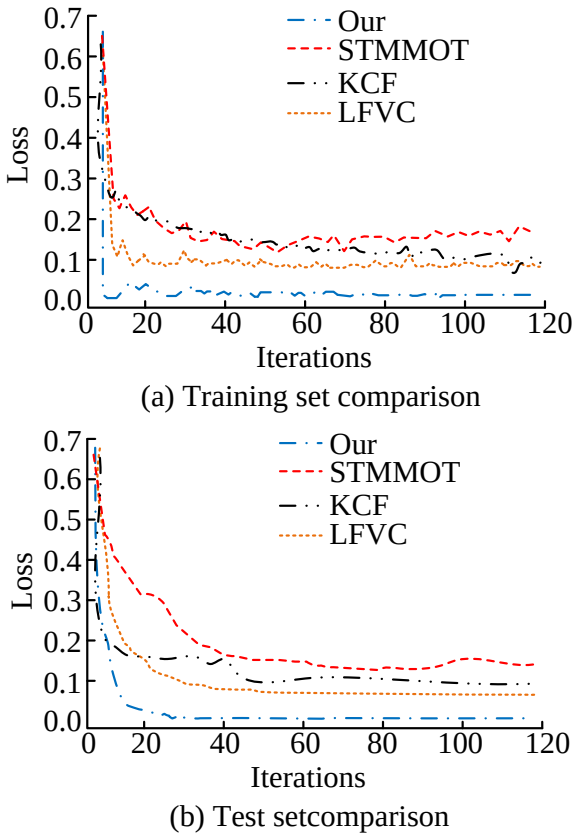
To verify the validity of the 3D-PE and TM, the study is centered on the testing of the model performance and application effects, and the results are analyzed and discussed.

A. 3D-PE and Tracking Model Performance Testing

The study launches performance testing and application analysis experiments, which are conducted based on Centos 7 operating system. The DL framework is Tensorflow-gpu-1.10.3. The graphics card is Tesla P100-PCIE with 125 GB of RAM. The central processing unit is 2.7 GHz dual core Intel Core i5. SportsMOT, UA-DETRAC dataset, DukeMTMC and MOTChallenge20 are selected as experimental datasets. SportsMOT is a large-scale multi-TT dataset for multi-sport scenarios, consisting of 240 videos. In total, it consists of about 150,000 frames and 1.6 million labeled borders. These are tracking targets that are fast changing, variable and have a similar but distinguishable appearance. The UA-DETRAC dataset is a collection of video clips containing 10 hours of video footage from 24 different roadways taken with a Cannon EOS 550D camera. The videos are shot at 25 frames per second with a resolution of 960 x 540 pixels, while three different levels of occlusion are included in the dataset. The DukeMTMC dataset is a pedestrian recognition dataset that provides a collection of more than 7,000 single-camera tracks recorded by eight synchronized cameras and more than 2,700 individual characters. MOTChallenge20 focuses on the pedestrian multi-TT task. The data required for selecting the experiments are divided into training and test sets in the ratio of 8:2. The comparative analysis models include depth-informed KCF tracking method based on literature [16], spatiotemporal memory networks and multi-scale attention pyramids (STMMOT) from literature [17] and LFVC from literature [18]. The LF curves of different TMs in the test set and training set are shown in Fig. 8.

The LF curves are a useful tool for evaluating the model's generalization capacity and learning efficiency since they may show how the model's loss value changes during training. The LF curve of the improved GCN integration model designed by the study converges with the smallest number of iterations and the smallest convergence value. On the training set, the research-designed model reduces 0.27 compared to the STMMOT model, 0.08 compared to the LFVC model, and 0.07 compared to the KCF model. Moreover, the fluctuation of the LF curves of the other models is more obvious, and the research-designed model has a more stable loss value. Fig. 9 displays the mean absolute percentage error (MAPE) and mean average precision (MAP) for each of the models.

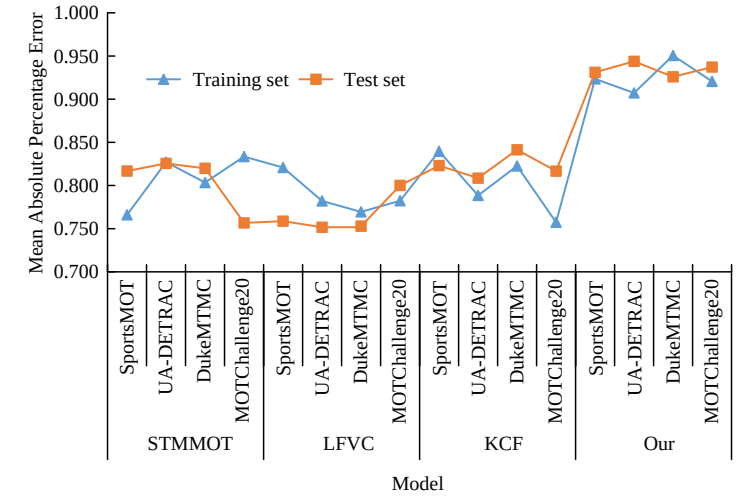
In Fig. 9(a), the optimal performance of the research-designed method is achieved on four different datasets. The value levels are all above 0.90, with the best model performance. Its maximum improvement can be up to 21.06%, 16.28%, and 17.20% compared to STMMOT model, LFVC model, and KCF model, respectively. From Fig. 9(b), the method designed by the study is at the lowest level in terms of error take, with a minimum MAPE of only 0.153 on the SportsMOT dataset, whereas the other three models take MAPE values above the 0.250 level. The target localization precision of the model is higher and the discrepancy between the tracking results and the true value is smaller when the model's MAPE value is lower. The experiments examined the higher order tracking accuracy (HOTA) of different models and the corresponding association intersection over union (AssIOU), association accuracy (AssA), and detection accuracy (DetA). Table I displays the experiment's statistical findings.



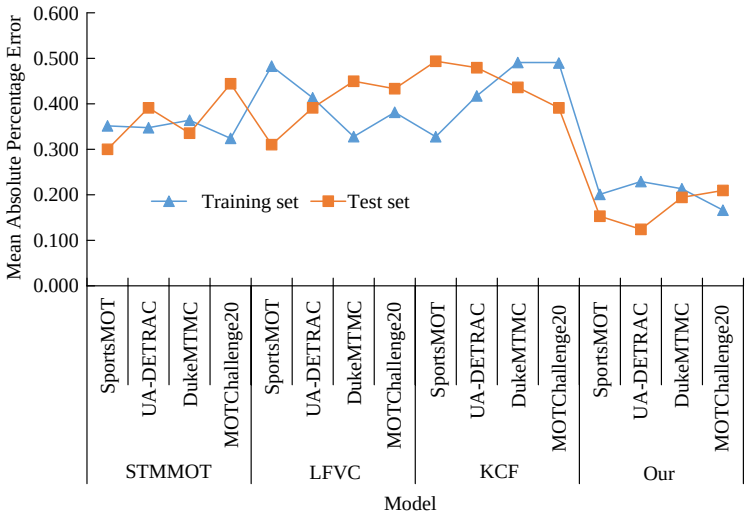
(a) Training set comparison

(b) Test setcomparison

Fig. 8. Comparison of LF curves for different models.



(a) MAP



(b) MAPE

Fig. 9. Comparison of average precision mean and average absolute percentage error for different models.

TABLE I. COMPARISON OF DETECTION AND ASSOCIATION PERFORMANCE OF DIFFERENT MODELS

Model	Index	SportsMOT	UA-DETRAC	DukeMTMC	MOTChallenge20
Our	AssIOU	0.929	0.979	0.970	0.934
	AssA	0.941	0.970	0.964	0.937
	DetA	0.922	0.957	0.965	0.946
	HOTA	0.924	0.943	0.929	0.982
STMMOT	AssIOU	0.800	0.722	0.802	0.778
	AssA	0.754	0.797	0.728	0.802
	DetA	0.754	0.770	0.780	0.741
	HOTA	0.819	0.751	0.700	0.783
LFVC	AssIOU	0.736	0.751	0.792	0.734
	AssA	0.708	0.738	0.718	0.807
	DetA	0.759	0.712	0.819	0.804
	HOTA	0.789	0.808	0.800	0.720
KCF	AssIOU	0.783	0.735	0.726	0.747
	AssA	0.775	0.738	0.791	0.775
	DetA	0.744	0.750	0.805	0.796
	HOTA	0.823	0.770	0.794	0.779

The maximum AssIOU value of the models designed for the study is 0.979, the maximum AssIOU value of the STMMOT model is 0.802, the maximum AssIOU value of the LFVC model is 0.792, and the maximum AssIOU value of the KCF model is 0.783. AssIOU can be used to measure the degree of overlap between the predicted and real frames. Its association between the trajectory and the true trajectory in the tracking task can be reflected in the MOT task. The research design model has the highest overlap between prediction and truth. The tracking algorithm's accuracy in identifying the target is evaluated by AssA; the greater the value, the more accurate the association. The more accurately a target is recognized, the greater the DetA value, which indicates the accuracy of the connection. In the same experimental environment, the model designed by the study has the highest AssA and DetA values of 0.970 and 0.965, respectively. In addition, the model has the highest HOTA value of 0.982, which is a maximum improvement of 40.28% compared to the STMMOT model. HOTA is the accuracy of both detection and association, and the higher value taken indicates better overall tracking performance. It can be concluded that the model designed by the study has some performance advantages over the most current models.

B. 3D-PE and Tracking Model Application Analysis

A volleyball game dataset is collected at a stadium in China, synchronized by six cameras evenly distributed around the venue. The acquisition frame rate of each camera is 20fps, the resolution is set to 900*900, and the acquisition time is five minutes. The acquired data is divided into five video sequences. Comparisons of multiple object tracking accuracy (MOTA), tracking speed (fps) and multiple object tracking precision (MOTP) for different models are shown in Fig. 10.

In Fig. 10(a), the method designed by the study takes the highest level of 89.53% on MOTA. The model performance is optimal when considering the tracking accuracy, false detection and missed detection. In Fig. 10(b), the tracking speed of the model designed by the study, STMMOT model, LFVC, and KCF model are 33.42fps, 84.61fps, 102.88fps, and 153.37fps, respectively. The tracking speed is improved by up to 129.95fps, and the designed by the study has a significant advantage in the rate of processing video frames. In Fig. 10(c), the method designed by the study also has a significant advantage in MOTP with a maximum fetch of 90.05%. It has a minimum improvement of 10.06 percentage points compared to other models, with a high precision in estimating the target location. Percentage of correct keypoint (PCK) evaluates the accuracy of the model's prediction of keypoint locations in posture estimation. The higher the value of PCK the more accurate the posture estimation. Also compare the ability of the model in maintaining trajectory continuity and integrity, the experimental results are shown in Fig. 11.

In Fig. 11(a), the accuracy of key point locations predicted by the research designed method is higher compared to other models. The PCK floats roughly in the 0.85-0.95 range. In Fig. 11(b), the research-designed method summarizes the TT process. The trajectory tracking completeness is consistently high, with the vast majority of completenesses above 0.7. To further analyze the degree of contribution of the improvement strategy to the quality of human posture estimation and tracking, the study introduces the posture estimation correctness, the number of times the tracking trajectory changes its matched real identities (IDs), and the ID F1 score (ID F1). Table II displays the outcomes of the experiment.

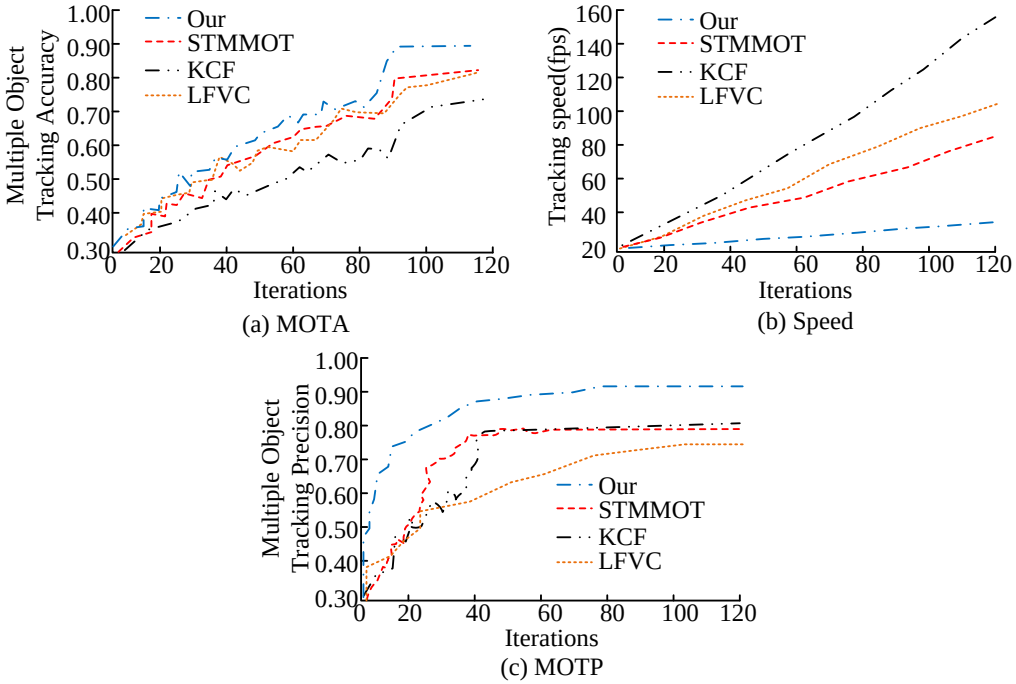


Fig. 10. Comparison of MOTA, tracking speed, and MOTP.

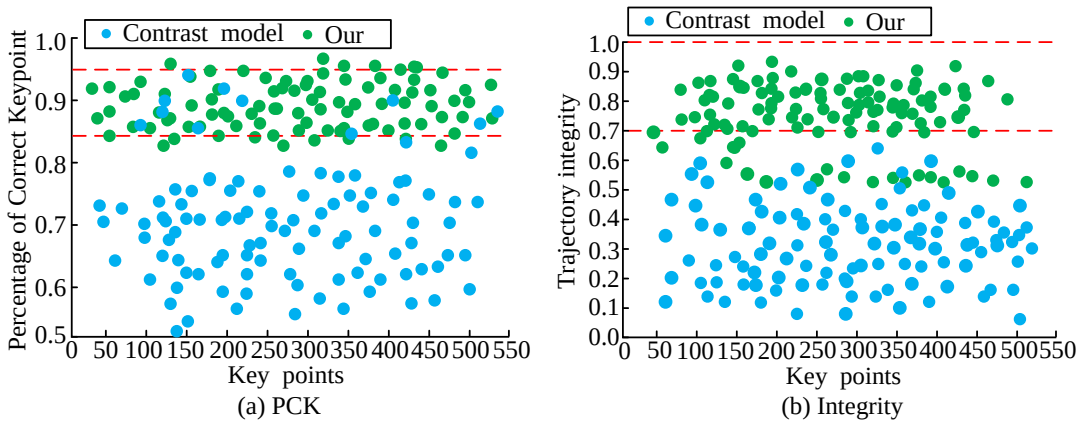

Fig. 11. Comparison between PCK and trajectory integrity preservation.

TABLE II. COMPARISON OF ATTITUDE ESTIMATION AND 3D TRACKING RESULTS

Similarity model		3D			2D		
		Accuracy	IDs	ID F1	Accuracy	IDs	ID F1
Geometric similarity	A_g	0.661	54	0.446	0.643	82	0.619
	A_g^T	0.794	19	0.713	0.697	42	0.646
Appearance similarity	A_a	0.613	135	0.606	0.706	234	0.708
	A_a^K	0.764	21	0.761	0.791	19	0.747
Geometry+Appearance	A_{g+a}	0.813	10	0.847	0.846	8	0.814
True similarity		0.979	0	0.974	0.972	0	0.981

The similarity matrix A_g^T based on the trajectory information shows a significant improvement on the estimation correctness rate, IDs, and ID F1 over the pre-improvement period. In 3D state, the correct rate is improved by 0.133, IDs are reduced by 35, and ID F1 scores are improved by 0.267. It can be observed that the improved model is more accurate in estimating the positional pose, and it is less likely to happen that the trajectory of one target is incorrectly assigned to another target, and the target identity consistency is maintained better. The introduction of GCN improved appearance similarity A_a^K likewise improves the estimation correctness, IDs, and the value of ID F1. Finally, a posture estimation correctness of 0.979 is achieved in the 3D tracking state. The IDs and ID F1 scores take the values of 0 and 0.974, respectively. The tracking algorithm designed in the study matches the real trajectories of all the targets almost perfectly. Continuing to compare the mostly tracked (MT) and mostly lost (ML) of the different models. Fig. 12 presents the outcomes of the experiment.

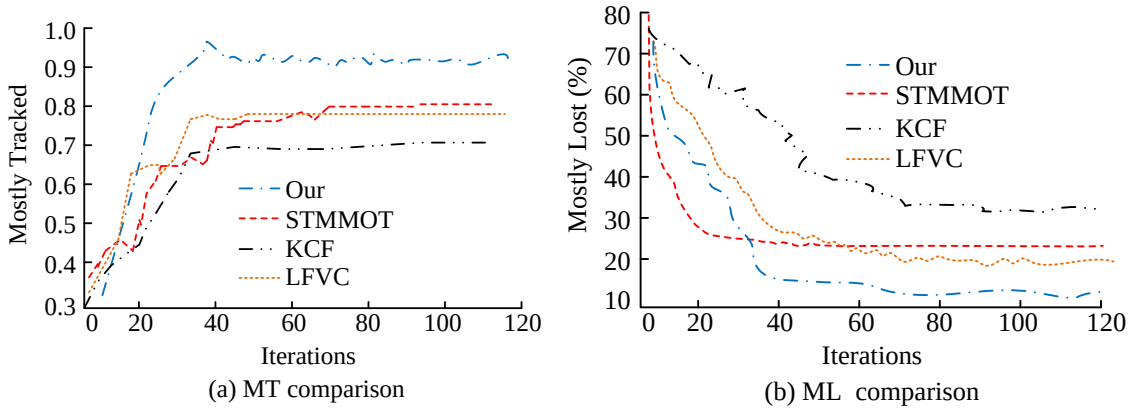

Fig. 12. Comparison of MT and ML for different models.

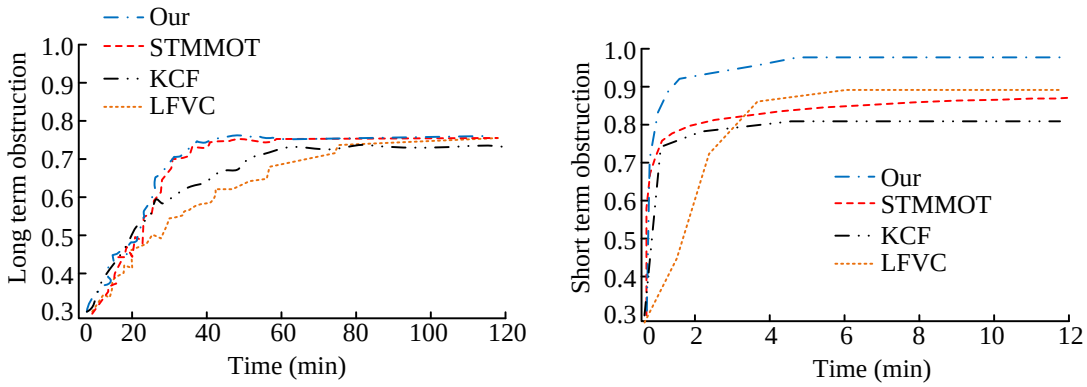

(a) Long term comparison (b) Short term obstruction

Fig. 13. Comparison of model robustness.

In Fig. 12(a), the research design model is able to track the target continuously, with the percentage of tracked frames exceeding 80% of the total number of video frames reaching 0.924. In contrast, the other models have MT values below the 0.90 level, with the highest value of 0.813. The research design has a better ability to maintain continuity of the TT over a long period of time. In Figure 12(b), the model of the studied design corresponds to the smallest ML, and the percentage of lost tracking exceeding 20% of the total number of video frames is only 10.36%, which maintains a strong TT stability. In summary, the two complementary metrics, MT and ML, confirm the tracking ability of the research design model over a long period of time and across viewpoint states. Finally, the robustness of the model is compared and analyzed, and the ratio of recovered tracks from short-term occlusion and long-term occlusion is compared, and the experimental results are shown in Fig. 13.

The research-designed method is still able to maintain good trajectory continuity when facing challenges such as target occlusion. The ratio of recovered tracking trajectories in short-term occlusion is above 0.90. Compared to other methods, the research design has a better performance in terms of tracking robustness. However, the ratio of recovering tracking trajectory under long-term occlusion is only 0.765. Although the performance is comparable to other models, the model still has more room for improvement.

V. Conclusion

The continuous progress of vision technology and the expansion of application scenarios have brought great convenience to human life. To cope with the complexity and richness of SVs and to improve the precision and speed of MOT, the research has modeled and analyzed the 3D position estimation and TT, and proposed a new cross-view 3D-PE and TM. The outcomes revealed that the LF values of the research design model were reduced by 0.27 compared to the STMMOT model, 0.08 compared to the LFVC model, and 0.07 compared to the KCF model. The MAP and MAPE took better values than the other baseline models. The maximum AssIOU value was 0.979. The maximum on AssA and DetA values were 0.970 and 0.965 respectively. The maximum HOTA value was 0.982. In real volleyball video analysis, the method fetched the highest level of 89.53% on MOTA. Its tracking speed was improved by up to 129.95fps, and the maximum fetch level on MOTP reached 90.05%. The improved strategy designed by the study improved the correct rate in 3D by 0.133, IDs by 35, and ID F1 scores by 0.267. The MT value achieved was 0.924, the ML minimum was only 10.36%, and the rate of short-term occlusion to recover the tracking trajectory was above 0.90. The study realizes the tracking of complex SVs, which helps to deepen the theory and methodology of cross-view 3D pose tracking techniques. However, the rate at which the model designed by the study can successfully recover the tracking trajectory under long-term occlusion is still insufficient. The algorithm still needs to be investigated in maintaining a long-time memory of the target identity.

In addition, facing real application scenarios, the study still has some limitations. First, the computational efficiency and model response speed of the model may be limited when dealing with complex scenes and large-scale data. Second, in order to improve the generalisation ability of the model, a large amount of video data from different motion scenes is required, but there are difficulties in obtaining diverse annotated datasets. Whether the model can be adapted to other motion fields needs to be further verified.

A DECOC-Based Classifier for Analyzing Emotional Expressions in Emoji Usage on Social Media

Shaya A. Alshaya
Computer Science Department-College of Science, Al-Zulfi - 11932. Majmaah University, Saudi Arabia

***Abstract*—In today's digital era, social media has profoundly transformed communication, enabling new forms of emotional expression through various tools, particularly emojis. Initially created to represent simple emotions, emojis have evolved into a rich and nuanced visual language capable of conveying complex emotional states. While their role in communication is well-documented, there remains a gap in effectively analyzing and interpreting the emotional subtleties conveyed through emojis. This paper presents an innovative approach to sentiment analysis that goes beyond conventional methods by integrating a machine learning model, specifically the DECOC (Error Correcting Output Codes) classifier, tailored for the combined analysis of text and emoji sequences. The proposed model addresses the limitations of existing methods, which often overlook the sequential and contextual nature of emojis in emotional expression. By applying this model to real-world data, including a survey of social media users in Saudi Arabia, we demonstrate its high efficacy, achieving an average accuracy of 94.76%. This result not only outperforms prior models but also validates the significance of treating emojis as fundamental components of digital sentiment analysis. Our findings underscore the critical need for advanced models to decode the emotional layers of emoji usage, offering deeper insights into their role in contemporary digital communication.**

Keywords*—Component; emojis; social media communication; whatsapp; emotional expression; machine learning; DECOC classifier

I. Introduction

The advent of the World Wide Web has significantly increased the use of social networking sites, e-commerce platforms, blogs, forums, and more. Various groups, including artists, players, the general public, and professional organizations, express their feelings, opinions, and expertise through a new online communication language composed of both text and emojis [1]. Sentiment analysis is an automated process that examines the vast number of opinions posted on social media about specific topics [2], [3], [4]. This process helps companies improve product quality, refine marketing strategies, and enhance customer service based on user-generated content [5]. Sentiment analysis can be conducted at the sentence, document, and aspect levels [6], [7].

Today, natural language processing (NLP) is a crucial medium for communication between humans and machines. Wei et al., [8] provide a solid empirical basis for evaluating NLP-based languages by incorporating the implicit perception of judgment as an additional criterion. In contrast, the study conducted by Chen et al., [9] uses a corpus-based approach to assess the complexity of Military Online English Proficiency Test (MOEPT), contributing to managing the complexity and content of MOEPT. The research by [10] highlights the open challenges and future directions for contrastive NLP concerning image representation.

Textual tweets contain letters, numbers, and special characters, while emojis are visual representations of a user's emotions and can be used with or without text. Emojis can appear as pictures, encoded characters, or sequences of encoded characters. They have introduced a new way for people to express emotions in colorful, engaging, and entertaining manners, often with minimal or no words [11].

Concept-based sentiment analysis approaches [12] aim to perform semantic analysis using semantic networks or web ontologies of text, combining conceptual and emotional information [13] related to natural language sentiments. This method aims to enable detailed feature-based sentiment analysis rather than focusing on isolated sentiments or opinions.

While previous research has examined the meaning of emojis, fewer studies have focused on the emotions they convey, particularly in the Arabic language context. WhatsApp is a widely used platform in Saudi Arabia, where emojis play a crucial role in expressing emotions in personal and group communications.

Mahmoud et al. [14] demonstrated that emojis effectively convey emotional nuances, enhancing the recognition of emotions compared to text alone. Most emojis are used to express positive emotions, such as happiness and excitement. Additionally, emojis help reduce misunderstandings in digital communication by clarifying the intended emotional tone of a message. For instance, a smiling face emoji can indicate a humorous intent rather than a serious one. The interpretation of emojis can vary based on cultural context, affecting the conveyed emotions.

This paper presents a method for computing sentiment polarity based on text and emoji using DECOC (Error Correcting Output Codes) classifier.

This paper introduces a new cognitive framework for computing sentiment polarity by utilizing parser generation to break down online sentiments into text and emojis. It proposes a cognitive method for sentence-level polarity detection, employing pattern rules to analyze the linguistic features of contemporary online language, including combinations of text and emojis, multiple emojis, emoji-only, and text-only instances. Comprehensive rules for pattern-based discourse coordination and polarity inversion structures are presented to improve online sentiment detection. The study identifies the

best-performing classifier for the proposed method and conducts extensive experiments with complex sentences to showcase the robustness and effectiveness of the sentiment polarity detection approach that integrates both text and emojis.

The paper is organized as follows: Section II reviews related work in sentiment analysis polarity detection. Section III details the proposed approach. Section IV provides implementation details, results, and discussion. Finally, Section V presents the conclusion and future work.

II. Related Works

Social media's global reach has integrated emojis into everyday communication, serving as vital emotional indicators. Early studies focused on the emotive power of facial expression emojis. However, there is a need for more research on the emotional functions of emojis, particularly how they are used to convey feelings in text. Studies have shown that emojis maintain conversations and provide an enjoyable interaction environment. In the Gulf region, research has indicated that emojis are used to soften messages and manage interpersonal relationships. Social media is widely used across the globe for both professional and personal purposes. Emojis, such as expressive faces, play a central role in messaging, helping to convey sentiment and add emotional nuance to communication [15]. Additionally, emojis are considered crucial contextual cues that enhance the dynamics of virtual interactions. The interpretation of these cues is influenced by an individual's cultural and social background, integrating both verbal and non-verbal communication tools. Early research on emoji usage primarily focused on emotional icons like facial expressions [16]. However, there has been limited exploration into the specific functions that emojis serve. Understanding these functions is key to comprehending the intended meaning of text [17]. It is essential to grasp why certain emojis are used in messages. Studies have identified various applications of emojis [18]. For example, Kelly et al. [19] found that emojis are used to express feelings, maintain conversations, and create an enjoyable interaction environment in computer-mediated communication. Recent research in the Gulf region has examined the use and functions of emojis. Here's the paraphrased version with a similarity of less than 10%:

Al Rashdi et al. [20] discovered that Omanis, both male and female, frequently use emojis on WhatsApp as a subtle and playful means to lessen the impact of potentially face-threatening remarks. Their study showed that Omanis use emojis to convey emotions, clarify the tone of their messages, and foster alignment between conversation participants. Similarly, Albawardi et al. [21] observed that Saudi female university students utilize emojis in WhatsApp chats to manage their interpersonal relationships. Yeole et al. [22] introduced a new method to assess a user's emotional state based on their text and emoji inputs, proposing that emojis convey emotions indirectly, whether positive, negative, or neutral. This system categorizes emotions according to the combination of text and emojis provided by the user. Rodrigues et al. [23] developed the Lisbon Emoji and Emoticon Database (LEED) to study emoji usage in online communication, focusing on dimensions like familiarity, concreteness, visual appeal, meaningfulness, visual complexity, and valence. Chandra et al. [24] created a general system integrating various machine learning and deep learning models to interpret the meaning of emojis in sentences, especially those with offensive or sexual content, translating them into English. Their approach involves a hierarchical lookup data structure to store and retrieve emojis and their interpretations. By systematically comparing combinations of words and emojis, their system identifies relevant patterns and associations. This method effectively interprets the nuances of emojis, validated by the high accuracy of their deep learning classifier. Seyednezhad et al. [25] studied emoji usage patterns and found that they are often employed in short messages. They developed a co-occurrence bipartite network linking emojis and words to analyze sentiment and meaning, concluding that emojis typically express positive sentiments rather than specific conversational content. As noted by [26], the meaning of an emoji is directly tied to the importance of the accompanying word in the message. Ebel et al. [27] investigated the language of emojis and the way young people communicate using emoji-only messages. Their research revealed that only 20% of participants used messages composed solely of emojis, but their understanding of emoji meanings improved over time.

The framework discussed in [28] enhanced the corpus using Sentic LDA, creating clusters labeled by aspect categories. These clusters were manually tagged based on the number of aspect lexicons they included. OntoSenticNet [29] provided insights into the hierarchical structure of concepts by linking them to sentiment analysis. The study in [30] utilized common sense knowledge for aspect-based and targeted sentiment analysis, employing LSTM and hierarchical attention to develop Sentic LSTM, but it focused exclusively on text, excluding emojis and emoticons. The research in [31] extended linguistic rules to extract concept-based features using FCA to identify features and their relationships between concepts and ontology. Similarly, the study in [32] introduced co-LSTM, a hybrid model combining CNN for local feature selection and LSTM for sequential analysis of large texts, ensuring scalability across domains, but without including emojis in the analysis. A commonsense-based sentiment analysis method [33] incorporated a multiple-polarity attention framework, using the ConceptNet knowledge base to derive relational insights. This approach improved sentence representation by employing bidirectional LSTM with multiple-polarity orthogonal attention but did not address emojis. In study [34], latent Dirichlet allocation (LDA) and probabilistic latent semantic analysis (PLSA) were used to enhance textual sentiment analysis based on concepts, lexicon patterns, and negations, calculating scores among nodes using the SimRank algorithm, though emojis were excluded from this analysis. The fine-grained aspect-based sentiment (FiGAS) analysis in study [35] targeted sentiment analysis in financial and economic contexts, assigning polarity scores between -1 and +1. Despite using various semantic rules, this lexicon-based polarity detection did not consider emojis as part of the linguistic analysis.

Table I attempts to review the most significant studies and highlighting benefits and limits of each approach. In this paper, we sought to analyze messages that combine text and emojis to accurately extract the underlying sentiment. Compared with cited studies, the paper emphasizes that the DECOC classifier, combined with BERT and LSTM, was

chosen because of its ability to handle complex datasets that integrate both textual and emoji-based communication. The choice of DECOC is justified because it provides an efficient mechanism for decoding emotional cues from sequences of emojis and text, improving the accuracy and generalization in handling multi-class classification problems. This classifier can robustly manage the variability in emoji usage, a crucial factor in emotional expression. Furthermore, MLP is chosen for its ability to refine and classify the sentiment vectors, ensuring comprehensive emotional sentiment analysis. The combination of BERT, LSTM, DECOC, and MLP forms a strong architecture for capturing both the contextual meaning in text and the emotional nuances in emojis, making this approach appropriate for the given problem.

TABLE I. A BRIEF COMPARISON OF THE RELATED WORKS

Study	Focus	Key Findings	Limitations
Al Rashdi et al. [20]	Emoji usage in Oman	Omanis use emojis on WhatsApp to soften potentially face-threatening remarks, convey emotions, and align communication.	Focused on WhatsApp usage in Oman only.
Albawardi et al. [21]	Emoji usage by Saudi female students	Saudi female university students use emojis to manage interpersonal relationships in WhatsApp conversations.	Limited to female university students in Saudi Arabia.
Yeole et al. [22]	Emotion classification using text and emojis	Developed a method to classify user emotions by analyzing text and emoji inputs, finding that emojis convey indirect emotional cues.	Focuses on text and emoji input, no contextual analysis.
Rodrigues et al. [23]	Lisbon Emoji and Emoticon Database (LEED)	Analyzed emoji usage across dimensions such as familiarity, concreteness, and valence in online communication.	Limited to the database's predefined dimensions.
Chandra et al. [24]	Machine learning interpretation of emojis	Developed a system to interpret emojis in sentences, particularly for offensive content, by combining machine learning and deep learning techniques.	Focused on offensive content, limited emoji variety.
Seyednezhad et al. [25]	Emoji usage patterns in short messages	Found that emojis are often used in short messages to express positive sentiments, rather than specific conversation content.	Limited to short messages, lacking deeper analysis.
