Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai
Editor-in-Chief

Editorial Board

CONTENTS

Paper 1: Development of an AI Based Failure Predictor Model to Reduce Filament Waste for a Sustainable 3D Printing Process
Authors: Noushin Mohammadian, Melissa Sofía Molina Silva, Giorgi Basiladze, Omid Fatahi Valilai
PAGE 1 – 6

Paper 2: Developing a Blockchain Based Supply Chain CO2 Footprint Tracking Framework Enabled by IoT
Authors: Mohammad Yaser Mofatteh, Roshanak Davallou, Chaida Ndahiro Ishimwe, Swaresh Suresh Divekar, Omid Fatahi Valilai
PAGE 7 – 12

Paper 3: Triggered Screen Restriction Framework: Transforming Gamified Physical Interventions
Authors: Majed Hariri, Richard Stone, Ulrike Genschel
PAGE 13 – 22

Paper 4: AI in the Detection and Prevention of Distributed Denial of Service (DDoS) Attacks
Authors: Sina Ahmadi
PAGE 23 – 29

Paper 5: A Hybrid Regression-Based Network Model for Continuous Face Recognition and Authentication
Authors: Bhanu Kiran Devisetty, Ayush Goyal, Avdesh Mishra, Mais W Nijim, David Hicks, George Toscano
PAGE 30 – 42

Paper 6: Designing Conversational Agents for Student Wellbeing
Authors: Jieyu Wang, Li Zhang, Dingfang Kang, Katherina G. Pattit
PAGE 43 – 52

Paper 7: Data Encoding with Generative AI: Towards Improved Machine Learning Performance
Authors: Abdelkrim SAOUABE, Hicham OUALLA, Imad MOURTAJI
PAGE 53 – 57

Paper 8: Cross-Modal Hash Retrieval Model for Semantic Segmentation Network for Digital Libraries
Authors: Siyu Tang, Jun Yin
PAGE 58 – 66

Paper 9: AI-Powered Waste Classification Using Convolutional Neural Networks (CNNs)
Authors: Chan Jia Yi, Chong Fong Kim
PAGE 67 – 75

Paper 10: Attention Mechanism-Based CNN-LSTM for Abusive Comments Detection and Classification in Social Media Text
Authors: BalaAnand Muthu First, Kogilavani Shanmugavadive, Veerappampalayam Easwaramoorthy Sathishkumar, Muthukumaran Maruthappa, Malliga Subramanian, Rajermani Thinakaran
PAGE 76 – 85

Paper 11: Knowledge Graph-Based Badminton Tactics Mining and Reasoning for Badminton Player Training Pattern Analysis and Optimization
Authors: Xingli Hu, Jiangtao Li, Ren Cai
PAGE 86 – 94

Paper 12: Analysis and Usability Evaluation of Virtual Reality in Cultural Landscape Promotion Platform Application
Authors: Yufang Huang, Yin Luo, Jingyu Zheng, Xunxiang Li
PAGE 95 – 103

Paper 13: Migrating from Monolithic to Microservice Architectures: A Systematic Literature Review
Authors: Hossam Hassan, Manal A. Abdel-Fattah, Wael Mohamed
PAGE 104 – 116

Paper 14: A Review on NS Beyond 5G: Techniques, Applications, Challenges and Future Research Directions
Authors: Cui Zhiyi, Azana Hafizah Mohd Aman, Faizan Qamar
PAGE 117 – 128

Paper 15: Real Time Object Detection for Sustainable Air Conditioner Energy Management System
Authors: Chang Shi Ying, C. PuiLin
PAGE 129 – 138

Paper 16: The Review of Malaysia Digital Health Service Mobile Applications' Usability Design
Authors: Kah Hao Lim, Chia Yean Lim, Anusha Achuthan, Chin Ernst Wong, Vina Phei Sean Tan
PAGE 139 – 146

Paper 17: Badminton Tracking and Motion Evaluation Model Based on Faster RCNN and Improved VGG19
Authors: Jun Ou, Chao Fu, Yanyun Cao
PAGE 147 – 158

Paper 18: Cyberbullying Detection on Social Networks Using a Hybrid Deep Learning Architecture Based on Convolutional and Recurrent Models
Authors: Aigerim Altayeva, Rustam Abdrakhmanov, Aigerim Toktarova, Abdimukhan Tolep
PAGE 159 – 167

Paper 19: Optimization with Adaptive Learning: A Better Approach for Reducing SSE to Fit Accurate Linear Regression Model for Prediction
Authors: Vijay Kumar Verma, Umesh Banodha, Kamlesh Malpani
PAGE 168 – 173

Paper 20: Efficient Remote Health Monitoring Using Deep Learning and Parallel Systems
Authors: Zakaria El Khadiri, Rachid Latif, Amine Saddik
PAGE 174 – 186

Paper 21: Smart Muni Platform: Efficient Emergency and Citizen Security Management Based on Geolocation, Technological Integration and Real Time Communication
Authors: Gerson Castro-Chucan, Hiroshi Chalco-Peñafiel, Norka Bedregal-Alpaca, Victor Cornejo-Aparicio
PAGE 187 – 195

Paper 22: Serious Games Model for Higher-Order Thinking Skills in Science Education
Authors: Siti Norliza Awang Noh, Hazura Mohamed, Nor Azan Mat Zin
PAGE 196 – 201

Paper 23: Lung CT Image Classification Algorithm Based on Improved Inception Network
Authors: Qianlan Liu
PAGE 202 – 213

Paper 24: Multilevel Characteristic Weighted Fusion Algorithm in Domestic Waste Information Classification
Authors: Min Li
PAGE 214 – 223

Paper 25: Novel Biomarkers for Colorectal Cancer Prediction
Authors: Mohamed Ashraf, M. M. El-Gayar, Eman Eldaydamony
PAGE 224 – 236

Paper 26: Environmental and Economic Benefit Analysis of Urban Construction Projects Based on Data Envelopment Analysis and Simulated Annealing Algorithm
Authors: Jie Gong
PAGE 237 – 246

Paper 27: Improving the Accuracy of Chili Leaf Disease Classification with ResNet and Fine-Tuning Strategy
Authors: Sayuti Rahman, Rahmat Arief Setyadi, Asmah Indrawati, Arnes Sembiring, Muhammad Zen
PAGE 247 – 255

Paper 28: Exploring the Impact of User Experience Elements on Virtual Reality for Emotion Regulation Through mVR-Real App
Authors: Irna Hamzah, Ely Salwana, Nilufar Baghaei
PAGE 256 – 263

Paper 29: Enhancing Emotion Regulation Through Virtual Reality Design Framework for Social-Emotional Learning (VRSEL)
Authors: Irna Hamzah, Ely Salwana, Nilufar Baghaei, Mark Billinghurst, Azhar Arsad
PAGE 264 – 272

Paper 30: Bridging the Gap: Machine Learning and Vision Neural Networks in Autonomous Vehicles for the Aging Population
Authors: Shengsheng Tan
PAGE 273 – 281

Paper 31: Machine Learning for Predicting Intradialytic Hypotension: A Survey Review
Authors: Saeed Alqahtani, Suhuai Luo, Mashhour Alanazi, Kamran Shaukat, Mohammed G Alsubaie, Mohammad Amer
PAGE 282 – 293

Paper 32: An Interactive Attention-Based Approach to Document-Level Relationship Extraction
Authors: Zhang Mei, Zhao Zhongyuan, Xu Zhitong
PAGE 294 – 301

Paper 33: Computer Modeling of the Stress-Strain State of Two Kvershlags with a Double Periodic System of Slits Weighty Elastic Transtropic Massif
Authors: Tursinbay Turymbetov, Gulmira Tugelbaeva, Baqlan Kojahmet, Bekzat Kuatbekov, Serzhan Maulenov, Bakhytzhan Turymbetov, Mukhamejan Abdibek
PAGE 302 – 308

Paper 34: Smart System for Driver Behavior Prediction
Authors: Hajar LAZAR, Zahi JARIR
PAGE 309 – 316

Paper 35: Development of Intelligent Learning Model Based on Ant Colony Optimization Algorithm
Authors: Xiaojing Guo, Xiaoying Zhu, Lei Liu

PAGE 317 – 327

Paper 36: Automated Detection of Malevolent Domains in Cyberspace Using Natural Language Processing and Machine Learning

Authors: Saleem Raja Abdul Samad, Pradeepa Ganesan, Amna Salim Al-Kaabi, Justin Rajasekaran, Singaravelan M, Peerbasha Shebbeer Basha

PAGE 328 – 341

Paper 37: Enhanced IVIFN-ExpTODIM-MABAC Technique for Multi-Attribute Group Decision-Making Under Interval-Valued Intuitionistic Fuzzy Sets

Authors: Bin Xie

PAGE 342 – 354

Paper 38: CoCoSo Framework for Management Performance Evaluation of Teaching Services in Sports Colleges and Universities with Euclidean Distance and Logarithmic Distance

Authors: Feng Li, Yuefei Wen

PAGE 355 – 364

Paper 39: Enhanced Methodology for Production-Education Integration and Quality Evaluation of Rural Vocational Education Under Rural Revitalization with 2-Tuple Linguistic Neutrosophic Numbers

Authors: Xingli Wang

PAGE 365 – 377

Paper 40: A Deep Learning Based Detection Method for Insulator Defects in High Voltage Transmission Lines

Authors: Wang Tingyu, Sun Xia, Liu Jiaxing, Zhang Yue

PAGE 378 – 384

Paper 41: A Review of Personalized Recommender System for Mental Health Interventions

Authors: Idayati Binti Mazlan, Noraswaliza Abdullah, Norashikin Ahmad, Siti Zaleha Harun

PAGE 385 – 393

Paper 42: Intelligent Service Book Sorting in University Libraries Based on Linear Discriminant Analysis Method

Authors: Changjun Wang, Fengxia You, Yu Wang

PAGE 394 – 403

Paper 43: Prediction of Booking Trends and Customer Demand in the Tourism and Hospitality Sector Using AI-Based Models

Authors: Siham Rekiek, Hakim Jebari, Kamal Reklaoui

PAGE 404 – 412

Paper 44: Optimizing Production in Reconfigurable Manufacturing Systems with Artificial Intelligence and Petri Nets

Authors: Salah Hammedi, Jalloul Elmelliani, Lotfi Nabli, Abdallah Namoun, Meshari Huwaytim Alanazi, Nasser Aljohani, Mohamed Shili, Sami Alshmrany

PAGE 413 – 425

Paper 45: TSO Algorithm and DBN-Based Comprehensive Evaluation System for University Physical Education

Authors: Yonghua Yang

PAGE 426 – 435

Paper 46: Robust Image Tampering Detection and Ownership Authentication Using Zero-Watermarking and Siamese Neural Networks

Authors: Rodrigo Eduardo Arevalo-Ancona, Manuel Cedillo-Hernandez, Francisco Javier Garcia-Ugalde

PAGE 436 – 446

Paper 47: Eating Behavior and Level of Knowledge About Healthy Eating Among Gym Users: A Multinomial Logistic Regression Study
Authors: Ana Huamani-Huaracca, Sebastián Ramos-Cosi, Michael Cieza-Terrones, Gina León-Untiveros, Alicia Alva Mantari
PAGE 447 – 455

Paper 48: Development of a Causal Model of Post-Millennials' Willingness to Disclose Information to Online Fashion Businesses (Thailand)
Authors: Apiwat Krommuang, Jinnawat Kasisuwan
PAGE 456 – 463

Paper 49: Facial Expression Classification System Using Stacked CNN
Authors: Aditya Wikan Mahastama, Edwin Mahendra, Antonius Rachmat Chrismanto, Maria Nila Anggia Rini, Andhika Galuh Prabawati
PAGE 464 – 472

Paper 50: Optimization of 3D Coverage Layout for Multi-UAV Collaborative Lighting in Emergency Rescue Operations
Authors: Dan Jiang, Rui Yan
PAGE 473 – 484

Paper 51: Analyzing the Impact of Occupancy Patterns on Indoor Air Quality in University Classrooms Using a Real-Time Monitoring System
Authors: Sri Ratna Sulitiyanti, Muhamad Komarudin, F. X Arinto Setyawan, Hery Dian Septama, Titin Yulianti, M. Farid Ammar
PAGE 485 – 492

Paper 52: Active Semi-Supervised Clustering Algorithm for Multi-Density Datasets
Authors: Walid Atwa, Abdulwahab Ali Almazroi, Eman A. Aldhahr, Nourah Fahad Janbi
PAGE 493 – 500

Paper 53: MSMA: Merged Slime Mould Algorithm for Solving Engineering Design Problems
Authors: Khaled Mohammad Alhashash, Hussein Samma, Shahrel Azmin Suandi
PAGE 501 – 516

Paper 54: Research on Credit Card Fraud Prediction Model Based on GAN-DNN Imbalance Classification Algorithm
Authors: Qin Wang, Mary Jane C.Samonte
PAGE 517 – 523

Paper 55: Impact Analysis of Informatization Means Driven by Artificial Intelligence Technology on Visual Communication
Authors: Lei Ni
PAGE 524 – 533

Paper 56: Revolutionizing Rice Leaf Disease Detection: Next-Generation SMOREF-SVM Integrating Spider Monkey Optimization and Advanced Machine Learning Techniques
Authors: Avip Kurniawan, Tri Retnaningsih Soeprobowati, Budi Warsito
PAGE 534 – 543

Paper 57: Human Dorsal Hand Vein Segmentation Method Based on GR-UNet Model
Authors: Zhike Zhao, Wen Zeng, Kunkun Wu, Xiaocan Cui
PAGE 544 – 552

Paper 58: A Proposed Batik Automatic Classification System Based on Ensemble Deep Learning and GLCM Feature Extraction Method
Authors: Luluk Elvitaria, Ezak Fadzrin Ahmad Shaubari, Noor Azah Samsudin, Shamsul Kamal Ahmad Khalid, Salamun, Zul Indra
PAGE 553 – 561

Paper 59: A Comprehensive Crucial Review of Re-Purposing DNN-Based Systems: Significance, Challenges, and Future Directions
Authors: Yaser M Al-Hamzi, Shamsul Bin Sahibuddin
PAGE 562 – 582

Paper 60: A Machine Learning Operations (MLOps) Monitoring Model Using BI-LSTM and SARSA Algorithms
Authors: Zeinab Shoieb Elgamal, Laila Elfangary, Hanan Fahmy
PAGE 583 – 593

Paper 61: Deep Learning Approach in Complex Sentiment Analysis: A Case Study on Social Problems
Authors: Bambang Nurdewanto, Kukuh Yudhistiro, Dani Yuniawan, Himawan Pramaditya, Mochammad Daffa Putra Karyudi, Yulia Natasya Farah Diba Arifin, Puput Dani Prasetyo Adi
PAGE 594 – 604

Paper 62: Evaluating the Effectiveness of the Binary PSO Method in Feature Selection to Improve the Detection of Android Botnets
Authors: Peng WANG, Zhijun WANG
PAGE 605 – 612

Paper 63: The Impact of the GQM Framework on Software Engineering Exam Outcomes
Authors: Reem Abdulaziz Alnanih
PAGE 613 – 622

Paper 64: Critical Success Factors of Microservices Architecture Implementation in the Information System Project
Authors: Mochamad Gani Amri, Teguh Raharjo, Anita Nur Fitriani, Nurman Rasyid Panusunan Hutasuhut

Development of an AI Based Failure Predictor Model to Reduce Filament Waste for a Sustainable 3D Printing Process

Noushin Mohammadian[1], Melissa Sofía Molina Silva[2], Giorgi Basiladze[3], Omid Fatahi Valilai[4]*
School of Business, Social & Decision Science, Constructor University Bremen, Campus Ring 1, 28759, Bremen, Germany

***Abstract*—This paper delves into the integration of motion tracking technology for real-time monitoring in 3D printing, with a focus on the popular fused filament fabrication (FFF) technique. Despite FFF's cost-efficiency, prevalent printing errors pose significant challenges to its commercial and environmental viability. This study proposes a solution by incorporating motion tracking nodes into the 3D printing process, tracked by cameras, enabling dynamic identification and rectification of printing failures. Addressing key research questions, the paper explores the applicability of motion tracking for failure detection, its impact on printed object quality, and the potential reduction in 3D printing waste. The proposed real-time monitoring system aims to fill a critical gap in existing 3D printing procedures, providing dynamic failure identification. The study integrates machine learning, computer vision, and motion tracking technologies, employing an inductive theoretical development strategy with active learning iterations for continuous improvement. Highlighting the revolutionary potential of 3D printing and acknowledging challenges in continuous monitoring and waste management, the suggested system pioneers real-time monitoring, striving to enhance efficiency, sustainability, and adaptability to diverse production demands. As the study progresses into implementation, it aspires to contribute significantly to the evolution of 3D printing technologies.**

Keywords*—3D printing; Fused Filament Fabrication (FFF); motion tracking; environmental sustainability; printing waste reduction

I. Introduction

Since its creation in 1971, 3D printing has come a long way. However, it has just lately gained extreme popularity due to significant price reduction in both its equipment and materials. A technique of 3D printing known as fused filament fabrication (FFF) has grown in popularity making it the most widely utilized form of 3D printing to date [1]. This preeminence can be credited to its capacity to function without a heated print environment and possessing the ability to generate internal infills yielding a lightweight structure with enough support to have a strong shell [2]. Despite FFF cost-efficiency the prevalence of printing errors remains significant, presenting challenges to the economic and environmental viability of the approach. Consequently, many endeavors have been undertaken to mitigate printing failures. Previous studies have utilized cameras and image examination to detect commonly occurring errors such as “blocked nozzle” and “incomplete print” allowing the monitoring of both the external shape of the printed object and internal structure of its layers [1], [3].

Real-time monitoring remains a feature not widely incorporated into 3D printing processes meaning that technologies and techniques for this purpose are underdeveloped. Currently, the most effective means of rectifying issues during printing involves manual adjustment of printing parameters. This process requires extensive human experience and thus is not scalable to the industrial level [2].

Motion tracking has been applied in recent years to a wide range of fields such as videogame development and medical application [4], [5], [6]. This technology uses nodes tracked by cameras to determine movement in their axes. In this paper, we explore an approach to implement real-time monitoring by integrating motion tracking nodes into the printing process. These nodes will later be tracked by cameras to identify printing failures based on the movement or misplacement of the nodes within their coordinates. Our research questions guide this exploration: Can motion tracking be applied for detection of failures in 3D printing? Does incorporating 3D motion tracking points affect the quality of the printed object? Does the utilization of motion capture technology result in a noticeable reduction in 3D printing waste produced by failures?

By addressing these questions, we aim to shed light on the potential of motion tracking technology in revolutionizing real-time monitoring for enhanced 3D printing processes.

II. Literature Review

A. Adaptive 3D Printing Error Detection

The capacity to inspect objects in motion is central to various emerging additive manufacturing (AM) applications [7]. Through this work we are providing a novel approach for the automatic detection of a prints failure to reduce waste. The core component for the autonomous detection of failure in the system is a classification model which detects whether undesirable extrusion or deviations from the original CAD model exists [8].

By identifying errors as soon as they are produced the response rate of the system reaches or even surpasses the human reaction and the model can recognize inferior quality prints that humans will have a difficult time distinguishing with high accuracy. This self-diagnostic system has the potential to

*Corresponding author

be applied to other materials and manufacturing systems without human interaction [2].

B. AI Applications for Trajectory Interpretation and Correction

This research aims to employ physical camera systems and advanced image processing models to detect and identify errors occurring during the 3D printing process. These errors encompass phenomena such as printing misalignment, over-extrusion, and filament wastage. The primary objective of this endeavor is to establish a real-time monitoring mechanism that can promptly halt the 3D printing process in response to detected anomalies. To achieve this, we intend to integrate digital markers into the digital file intended for printing. Subsequently, the camera system will be tasked with the responsibility of capturing and analyzing the printing process to discern any deviations from the specified parameters, thereby facilitating immediate intervention when errors are detected.

Similar idea was described in research of Kucukdeger & Johnson: Prior to 3D scanning, three user-defined reference points (~1 mm diameter) were placed around the perimeter of the object using a black marker to provide reference points for the 3D printing frame. The object was then scanned using a calibrated single camera-projector structured light scanning system (HP 3D Structured Light Scanner Pro S2; HP) to acquire the point cloud data following our previously reported protocols [7].

C. Literature Gap Analysis

3D printers can quickly translate 3D design data into sophisticated forms by avoiding traditional cutting tools, fixtures, and many production phases, successfully tackling the difficulty of producing complex parts. As technology progresses, 3D printing has found widespread use in a variety of industries, including consumer electronics, automotive, aerospace, healthcare, defense, geographic mapping, and creative creation. For instance, BMW adopted 3D printing technology at some of its larger dealerships to produce spare parts for classic cars [9].

Since the first 3D printer was invented by Charles Hull in 1986. After that, a great achievement has been made in 3D printing [10]. In the year 2000, ZcorpÓ, an American company in collaboration with the RilecenÓ Institute, pioneered a color 3D printer utilizing inkjet printing technology. Toward the close of that year, an Israeli firm named Object Geometries introduced the Quadra 3D printer, which merged stereolithography apparatus (SLA) with 3D inkjet technology [11]. In 2010, a significant milestone was achieved in the field of medical 3D printing when an American firm known as OrganoxoÓ collaborated with an Australian company named InvetechÓ to produce human tissues and organs using live cells.

America in 2012, products in electronic area, automobile manufacturing, medical treatment and industrial machinery industry occupy a large share [10]. In this case, the manufacturer, BMWÓ, has invested in purchasing 3D printers and developing 3D designs. As a result, they were able to shut down its regular automobile production lines, which were only utilized to produce replacement parts. As a result, BMWÓ has adopted a make-to-order strategy, in which spare parts are produced only when there is a need for them.

The manufacturing industry is experiencing a significant transformation driven by the increasing demand for personalized products. 3D printing has emerged as a powerful tool, allowing for individualized manufacturing on an unprecedented scale [12]. This technology not only enhances product personalization but also revolutionizes industries by changing traditional production methods. The adoption of 3D printing results in faster production and reduced costs, enabling consumers to have more influence on the final product's design. Additionally, manufacturing facilities utilizing 3D printing are located closer to consumers, promoting a more flexible and responsive production process with enhanced quality control. Moreover, 3D printing reduces the need for global transportation, as manufacturing sites can be closer to end destinations, and efficient distribution can be achieved through advanced tracking technologies [13]. 3D printing presents several benefits, yet it also poses challenges, including the necessity for continuous product monitoring and the management of waste generated from filament usage. These challenges hinder its adoption across sectors, as implementing this technology entails risks without a guarantee of a positive return on investment in the production system. Despite these hurdles, 3D printing continues to evolve as a flexible and powerful technique in advanced manufacturing, marking its ongoing progress in the industry [13]. The result of literature study based on the defined themes is discussed in Table I.

TABLE I. LITERATURE STUDY BASED ON THE MAIN THEMES

Research Studies	Adaptive 3D printing error detection	AI models for analysis of deviations	inclusion of sustainability analysis for 3D printing waste
[14]	Using optical images for real-time defect detection through image correlation for temperature monitoring and thermal image analysis.	Both thermal images using FLIR Thermal Studio Pro for color gradient adjustment and optical image based on feature extraction	Mention of the advantage of in-process monitoring as a part of manufacturing because it provides the possibility of intervention or repair so that the print can be salvaged in this way preventing waste.
[15]	The pharmaceutical industry can utilize the 3D printing technology to print complex shapes to later determine their effectiveness in drug profile release by analyzing their volume and surface area.	By the utilization of machine learning algorithms, they were able to determine the prediction of drug release profile of FDM printed formulations	Machine Learning provides a suitable approach to modelling the 3D printing workflow. providing accuracies as high as 93% for values in the filament hot melt extrusion process in this way reducing the number of prints needed per trial.
[16]	The printer being utilized possess a Delta 3D printing Bed. The proposed approach has been evaluated on	Utilization of sensors to collect information of different variables in both the 3-axis velocity sensors and 3-axis	This work has proposed a new method for the construction of a fault detection model for 3D printers in this way they will be able to build a

	two cases in 3D printers: fault detection of 12 different join bearings, and fault detection in 3 synchronous bands.	angle sensors for error detection to test the proposed fCGAE technique to fault detection	deep feature space from raw signals to identify flaws and prevent them from happening in future prints.
[17]	This paper proposes a data-driven fault detection framework for semi-supervised scenarios where labeled training data from the system under consideration is imbalanced, but data from a related system (the "source") is readily available.	The goal of this paper is to develop an efficient fault detection algorithm for cyber-physical systems operating in scenarios where there is imbalanced labeled training data generated by the actual plant under consideration, but where training data from a related system is readily available.	This paper presents a domain-adaptation based technique capable of leveraging a small amount of labeled data generated by the real system together with data generated by an untuned simulator. The main result shows that optimization is possible to efficiently solve defects before they happen.
[18]	Solutions for the naturally occurring under-extrusion in 3D printing resulting in mechanically weak prints as well as over-extrusion causing excess use of material with little strength gain	Utilization of deep-learning-based computer vision system to correct under- and over-extrusion issues commonly found in 3D printing technology such as the fused deposition modeling (FDM)	The implementation of this model shows that the correction of under and over-extrusion errors when they happen thanks to the application of the developed system leads to a sixfold increase in print consistency while increasing print strength by up to 200%, reducing excess print material, and saving up to 40% material cost.
[19]	Use inexpensive webcams and a single multi-head deep convolutional neural network to augment any extrusion-based 3D printer with error detection, correction, and parameter discovery for new materials.	CAXTON system for autonomous data collection A network of eight FDM 3D printers were used for data collection. Creality CR-20 Pro printers were chosen due to their low cost, preinstalled bootloader and included Z probe.	Training a multi-head neural network using images automatically labelled by deviation from optimal printing parameters. The thus trained neural network, alongside a control loop, enables real-time detection and rapid correction of diverse errors that is effective across many different 2D and 3D printers.
[20]	Use of soft sensor that was 3D printed, development of an AI-powered 3D printing system that adapts to changes and movements of target surface, and use of hydrogel-based EIT sensor to monitor lung deformations.	Combination of "offline" and "online" machine learning vision-based tracking for estimating surface deformation.	3D printing system that estimates the motion and deformation of the target surface to adapt the toolpath in real time. Therefore improving: Precision, energy efficiency, versatility and reducing waste.
[21]	SLA process uses a digital micromirror device to project a set of mask images onto the resin surface to cure layers. After solidification of each layer, the building platform moves down at a predefined amount for the next layer.	To predicting, learning, and compensating 3-D shape deviations based on data, there was proposed shape deviation generator (SDG), a data-analytical framework to facilitate the learning and prediction of 3-D printing shape accuracy.	To predict, learn, and compensate for 3-D shape deviations using shape measurement data, it was proposed a shape deviation generator (SDG) under a novel convolution formulation to facilitate the learning and prediction of 3-D printing accuracy.

The identified research gap stems from the absence of studies integrating motion tracking technology with cameras for failure detection in 3D printing processes. This void in the existing literature underscores the need for our research, as it addresses this deficiency by proposing an innovative approach that combines the application of motion tracking dots on prints that will later be analyzed by the cameras to autonomously identifying and halt a print one's failure is detected. This scientific gap demonstrates the significance of our approach to failure detection in 3D printing, showcasing a unique contribution to the field.

III. Proposed Solution for AI based Failure Detection in Sustainable 3D Printing

A. Conceptual Model of Agents, System Elements Interacting with Each Other

In the proposed solution, we foresee a dynamic interaction between many components, including 3D printer, motion tracking nodes, cameras, labeled and unlabeled data, and the monitoring system as illustrated in Fig. 1. The system's main key is the 3D printer, which leads to additive manufacturing processes. Motion tracking nodes are strategically positioned on the 3D printer and play a crucial role in tracking its motions and the behavior of the manufactured product. Cameras are used to record the real-time movement of these nodes and provide us with unlabeled data. Two types of data (labeled and non-labeled) undergo a comparison process, by projecting one date onto another and looking for deviations. The monitoring system oversees analyzing data, identifying abnormalities, and terminating a printing process in real time. During the 3D printing process, motion tracking notes continuously record the position and orientation of the printer's components during the 3D printing process. Collected information is then transmitted to the cameras, which check the movement and the position of these nodes. Therefore, the camera data is analyzed by monitoring system and compared to the predicted motion patterns. If deviations are detected, the system intervenes in real-time to stop the printing process, to assure print quality and waste reduction.

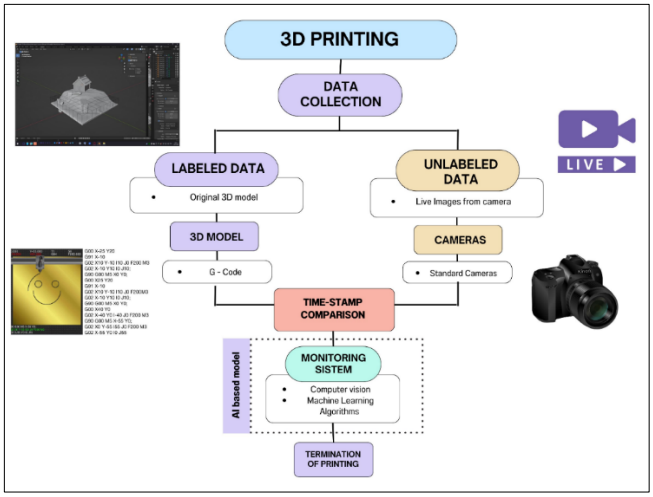

Fig. 1. The conceptual model

Our first hypothesis is that incorporating motion tracking technology into the 3D printing process can drastically improve the identification and mitigation of printing errors. Motion tracking technology, which has been used effectively in a variety of sectors, may be used to follow 3D printing in real time. It enables the detection of irregularities in the movement and location of printer components, which can serve as early warning signs of probable printing difficulties.

Our suggested solution tackles a research gap by bringing a fresh technique to 3D printing failure identification. Existing solutions frequently rely on post-print inspection or inadequate fault detection while printing. We can monitor the whole process in real time by including motion tracking nodes and cameras, recognizing problems as they occur. This novel technique makes a significant addition to the discipline by minimizing waste and improving 3D printing quality.

B. Framework for Detailed Solution

This research is based on the ontological premise that reality can be observed and measured. We think an epistemological stance that prioritizes empirical evidence and data-driven conclusions. The axiological stance cares for sustainability, efficiency, and the reduction of waste in 3D printing processes. The approach to theoretical development is essentially inductive. We will collect unlabeled data from real-world 3D printing processes, compare it with labeled data, and draw conclusions based on our findings. Additionally, we will apply a logical approach to expand on current ideas in 3D printing, motion tracking, and error detection.

The strategy is incorporating motion tracking technology into 3D printing. Data gathering with the help of motion tracking nodes and cameras, data processing using computer vision and machine learning algorithms, and the construction of real-time monitoring system are all part of the methodology. The experiment design will incorporate probability sampling methods to ensure a representative and unbiased selection of participants or data points, with the plan to print 10 test models for comprehensive evaluation.

The fusion of labeled and non-labeled data in the context of 3D printing failure detection involves a scientifically rigorous process to harness the strengths of both datasets. Our Labeled data, comprising the original 3D model, the G-code, provides explicit information about the expected finished product. Non-labeled data, acquired from cameras during the printing process, captures a broader range of real-world scenarios.

To facilitate the merging of labeled and non-labeled data detection, we propose a systematic approach. Initially, a machine learning model is trained using a labeled dataset that includes successful printing as well as varied failure occurrences. The model is then applied to unlabeled data in order to detect probable failure points.

The temporal synchronization of our labeled data, represented by the G-code, and our unlabeled data, captured by the cameras, is a pivotal aspect facilitating their seamless integration. Both datasets are equipped with time stamps, allowing for precise alignment of events during the 3D printing process. The time stamps act as temporal markers, ensuring a correspondence between the specific instructions encoded in the G-code and the corresponding visual information recorded by the cameras. This temporal alignment not only establishes a coherent chronological sequence but also enables the creation of a unified temporal framework for our data.

Active learning chooses samples with low model confidence for manual annotation, which enriches the labeled dataset. This merged dataset is utilized for model retraining, which improves the model's capacity to detect faults. Iterative self-training uses high-confidence predictions on leftover unlabeled data to extend the classified dataset. This cycling process improves the performance of the model, resulting in a continual learning loop for robust 3D printing failure verification. Regular assessment ensures that the model generalizes successfully and adjusts to new data patterns.

IV. Evaluation Scenarios

A. The Experiment Type for Your Research Project

Building upon the innovative methodology presented in [22-24], our proposed approach extends the capabilities of AI-based Computer Vision for failure detection in 3D printing. While the original work focused on identifying stringing defects during the printing process, our advancement involves the integration of labeled and non-labeled data using active learning and self-training. By incorporating time-stamped G-code information and camera feed data into our model, we enhance its capacity to detect a broader spectrum of failures in real-time.

This expansion not only allows for the identification of stringing but also facilitates the recognition of various other printing defects. Through a robust validation strategy, we aim to demonstrate improvements in both precision and recall, showcasing the efficacy of our approach in comparison to the existing model. Moreover, our proposed framework opens avenues for real-time adjustments to the printing process, enabling not only the termination of flawed prints but also corrective actions for parameters related to identified defects.

To achieve our goal of refining 3D printing failure detection, our first step will be to collect a diverse dataset comprising labeled data (G-code) and non-labeled data obtained from cameras monitoring the 3D printing process. Ensuring that both datasets possess time stamps for synchronization. After that we will preprocess the labeled data by extracting relevant features from the 3D models, for our non-labeled data, we will employ computer vision techniques to process the camera feed, extracting meaningful visual information.

Once we have our data, we will implement an active learning approach to strategically select informative instances from the non-labeled dataset for manual annotation. This iterative process optimizes the model's performance with minimal labeling effort. Moving forward we will apply self-training to iteratively improve the model's understanding by incorporating confidently predicted but initially non-labeled instances into the training process. This step enhances the model's adaptability to diverse printing scenarios. Using this information we will train a machine learning model, such as a Deep Convolutional Neural Network, using the merged dataset. We will utilize the labeled data for supervised learning and the

active learning and self-training iterations to enhance the model's performance.

In order to ensure the implementation of feature alignment techniques for compatibility between the labeled and non-labeled data we will map the feature spaces of both datasets to a common domain, facilitating seamless integration. To validate our results, we will split the dataset into training, validation, and test sets. Employing cross-validation techniques and select appropriate evaluation metrics (precision, recall, etc.) for a comprehensive assessment of the model's performance considering real-world testing to evaluate the model's robustness.

B. Validation Approach: Employing Data Augmentation and Model Evaluation in Real-Time Defect Detection

After gathering training data for the stringing defect, we implemented various Data Augmentation techniques to increase the number of training instances. Data Augmentation comprises a set of techniques applied to existing datasets to generate new synthetic data with meaningful information real, and its application was deemed necessary in this context. Specifically, for each image in the initial training set, we employed scaling to reduce the size (image resize), horizontal flipping, random cropping, 90-degree rotation, and random brightness adjustments. By applying these five data augmentation techniques to each of the 500 original training images, we expanded the dataset to a total of 2500 images.

There is a diverse selection of cutting-edge algorithms currently accessible, exhibiting differences in training speed, accuracy, and testing speed across benchmark datasets. In our case, we consider, use of cameras the necessity of striking a balance between achieving high accuracy and swift detection, given that the intended use of the model involves deployment in a real-time environment. In this investigation, the chosen model was the Single Shot Detector [22].

The Single Shot Detector running on 300 × 300 input (SSD-300), published in 2016, achieved a mean Average Precision (mAP) of 74.3% on benchmark Dataset VOC-2007 at 59 frames per second (FPS) and a mean Average Precision (mAP) of 41.2% at an Intersection over Union (IoU) of 0.5 on benchmark Dataset of Common Objects in Context (COCO test-dev2015).

V. Conclusion

In conclusion, our current study addresses critical challenges in integrating motion tracking technologies for real-time monitoring in 3D printing. While providing valuable insights, there remain opportunities for further exploration and improvement in this field.

It is imperative to thoroughly evaluate the research questions posed in this study, identifying areas that warrant additional investigation. These areas include:

- Extending the Scope of Motion Tracking: Explore the feasibility of incorporating advanced motion tracking technologies beyond the nodes-camera configuration to enhance precision and robustness in real-time monitoring.
- The Influence on Printing Speed and Efficiency: Examine how motion tracking affects the overall speed and efficiency of the 3D printing process, investigating potential impacts on printing speed and total production efficiency.
- Material Considerations: Investigate the interaction of various 3D printing materials with motion tracking systems, accounting for material differences and printing settings to assess the suggested system's flexibility across a wider range of materials.
- Human Interaction and Intervention: Examine the role of human contact and intervention when combined with real-time monitoring, considering scenarios where human operators may need to act based on monitoring system feedback, with implications for scalability in industrial settings.
- Economic and Environmental Consequences: Conduct a comprehensive examination of the economic and environmental consequences of incorporating motion tracking for real-time monitoring, comparing cost-effectiveness and sustainability to standard mistake correction approaches.
- User Acceptance and Experience: Investigate the user experiences and adoption of motion tracking-based real-time monitoring by 3D printer operators. Explore factors influencing user adoption, potential challenges, and ways to enhance user acceptability.

In summary, our study delves into the realm of 3D printing, which has evolved significantly since its inception in 1971, with fused filament fabrication (FFF) being the most widely used type today. Despite its affordability, FFF faces printing problems that threaten its commercial viability and environmental sustainability. Our proposed real-time monitoring system, utilizing motion tracking nodes and cameras, aims to address this gap by dynamically identifying and mitigating printing issues as they occur.

This research envisions a robust system for real-time intervention, ensuring print quality and waste reduction by integrating labeled G-code data with non-labeled data from cameras. The proposed framework employs an inductive theoretical development strategy, combining machine learning, computer vision, and motion tracking technologies. The experimental design includes active learning and self-training iterations, demonstrating the model's improved flaw detection over time. Our findings align with the transformative potential of 3D printing, emphasizing the need for individualized and flexible production. In conclusion, our suggested system pioneers real-time monitoring in 3D printing, utilizing motion tracking, computer vision, and machine learning. As we move into the implementation phase, we anticipate that our study will contribute to the evolution of 3D printing technologies, enhancing efficiency, sustainability, and adaptability to diverse production demands.

***Abstract*—In various industries, the convergence of the Internet of Things (IoT) and blockchain technologies has left an indelible mark on the pursuit of decarbonization. These innovations have seamlessly integrated into diverse fields, from manufacturing to logistics, offering sustainable solutions that enhance operational efficiency, transparency, and accountability. The interplay between IoT and blockchain has particularly contributed to the reduction of carbon footprints, fostering environmentally responsible practices. As industries embrace these technologies, the decentralized and transparent nature of blockchain ensures traceability in supply chains, while IoT devices facilitate real-time data monitoring. Together, they create a powerful synergy that not only streamlines processes but also drives a collective commitment to reducing environmental impact, marking a paradigm shift towards greener and more sustainable industries. Within this landscape, this research offers a comprehensive exploration of the transformative potential of blockchain in supply chain management, emphasizing its intricate connection with IoT and carbon footprint reduction. The conceptual model presented delineates the seamless integration of these elements, providing a nuanced understanding of how blockchain can revolutionize transparency and sustainability. Through practical examples and a layered diagram, it showcases the tangible benefits of this integration, highlighting its capacity to enhance data integrity and transparency in real-world supply chain scenarios. The research stands as a testament to the instrumental role that blockchain can play in fostering environmentally responsible practices within supply chains, laying the groundwork for a more sustainable future.**

Keywords*—Blockchain; IoT; supply chain; carbon footprint; sustainability

I. Introduction

The management and reduction of CO_2 emissions present a multifaceted challenge for organizations, as they grapple with diverse emission sources and the urgency of climate change mitigation [1]. Tracking CO_2 emissions across the entirety of the supply chain introduces complexity due to the global nature of supply networks, encompassing numerous suppliers and intricate logistics networks [2]. Ensuring accuracy, consistency and transparent emissions data throughout the supply chain is a formidable task, complicated by variations in reporting methodologies, data availability, and the reluctance of some stakeholders to disclose emissions information. Also, how IoT devices can communicate directly through autonomous data will be challenging because the reports and data are usually ready to use [1].

In an era of escalating environmental concerns, the logistics industry stands at the forefront of innovation, striving to reduce its carbon footprint and enhance its overall sustainability [3]. The convergence of emerging technologies, such as blockchain and the Internet of Things (IoT), holds immense promise in transforming logistics operations towards greener and more efficient practices [4], [5]. This deductive research proposal outlines an extensive investigation into the economic and environmental benefits of utilizing blockchain for managing and optimizing green logistics processes, as well as the pivotal role that blockchain plays in verifying the authenticity and accuracy of sustainability claims and certifications within the logistics industry [6]. The Internet of Things (IoT) also emerged as a powerful tool that promises not only to revolutionize the way logistics operations are managed but also to substantively contribute to global sustainability goals [7], [8].

This research is anchored by three central research questions. First, aims to elucidate the economic and environmental benefits brought about by the incorporation of blockchain technology into green logistics processes. Second, it delves into the role of blockchain in validating sustainability claims and certifications within the logistics industry, while concurrently examining the autonomous data generation capabilities of IoT devices. Lastly, it explores the mechanisms and technologies that facilitate autonomous data generation by IoT devices to support field devices in logistics operations. These questions provide the guiding framework for our research inquiry.

The initial theory posits that the integration of blockchain technology, in conjunction with the utilization of the Internet of Things (IoT), has the potential to revolutionize the green logistics industry by offering solutions to key challenges. This theory is founded on the premise that blockchain can enhance transparency, reduce costs, and improve the accuracy of sustainability claims within the logistics sector. Additionally, IoT technologies, when harnessed effectively, can autonomously generate and share data, thereby optimizing field devices' operation and decision-making processes. It is hypothesized that the synergy between blockchain and IoT, it is hypothesized, can lead to substantial economic and environmental benefits for organizations engaged in green logistics operations. Through rigorous research and analysis, the paper seeks to validate and refine this initial theory, offering valuable insights into sustainable business practices in the context of logistics and environmental responsibility.

To provide a clear roadmap for the subsequent sections of this research paper [9], it commences with an extensive review of existing literature, establishing the theoretical foundations of the study. Following that, the research methodology will be delineated, elucidating the processes of data collection, analysis, and interpretation. Mixed methodologies such as rigorous literature reviews, incisive case studies, targeted surveys, and collaborative research will be used. Subsequently, the research presents findings, addressing each research question individually [10]. Finally, it will be concluded with a comprehensive discussion, drawing connections between the research outcomes and their broader implications for green logistics, blockchain technology, and IoT applications.

II. Literature Review

A. Green Logistics

Green logistics, often referred to as environmentally sustainable logistics or eco-logistics, in the field of logistics and supply chain management, green logistics has become a crucial concept due to the rising challenges of environmental sustainability [10]. In the past, the logistics industry mainly concentrated on making operations more efficient and economical, sometimes neglecting environmental concerns. Nevertheless, as environmental problems like climate change and resource depletion became more important, there was a significant change in how logistics was perceived and carried out [11], [12].

Green logistics is a major change in how we do logistics. It's all about making sure that by moving things around, it doesn't harm the environment. This means doing things like minimizing pollution, using less energy, and not making as much waste. At the same time, it still be wanted to use resources wisely and make money [13]. This change shows that now logistics should be considered as a way to help the planet and make money, and there is a need to think about both things as the world changes.

B. Blockchain Technology

Blockchain Technology can be defined as a distributed and digital ledger technology that transparently records and verifies every step in the supply chain [14]. It offers a secure and immutable record-keeping system that enables real-time tracking of environmentally friendly practices, facilitates transparency in sustainability reporting, and helps organizations make informed decisions to minimize their carbon footprint and enhance ecological responsibility throughout their logistics operations [15]. Blockchain technology offers innovative solutions for reducing carbon footprints and fostering sustainability within supply chains. By providing end-to-end traceability and transparency, blockchain enables companies to pinpoint inefficiencies, optimize transportation routes, and select environmentally responsible suppliers [16]. Smart contracts automate eco-friendly actions, such as choosing energy-efficient shipping options [17]. The immutability of blockchain data ensures the accuracy of emissions records, preventing fraudulent sustainability claims [18]. Decentralization reduces intermediaries, cutting emissions associated with unnecessary transportation [19]. These blockchain-driven solutions empower organizations to simultaneously reduce their carbon footprint and bolster supply chain efficiency and sustainability, aligning business goals with environmental responsibility [20].

C. Literature Gap Analysis

1) Blockchain based sustainable models/applications. The pursuit of sustainable models underpinned by blockchain technology presents a transformative opportunity, particularly when coupled with the integration of IoT autonomous data. Within this context, one promising model is the "Smart contracts and emission token system" [17]. A blockchain-based sustainable model that combines smart contracts and emission tokens can significantly enhance sustainability efforts by providing a transparent, automated, and secure framework for tracking, verifying, and incentivizing emissions reductions [21].

In this innovative model for combating climate change and promoting sustainability, emissions are transformed into digital tokens, symbolizing the reduction or removal of greenhouse gases from the environment [22]. These tokens are generated based on scientifically validated emission reduction projects or actions. Crucial to this system are smart contracts, which lay out the terms and conditions of these emission reduction initiatives, specifying emission reduction goals, the methods for verification, and the issuance of emission tokens upon achieving these goals [23].

By combining smart contracts with emission tokens on a blockchain-based platform, this sustainable model enhances transparency, security, and automation in emissions tracking and reduction efforts [24]. It also encourages organizations and individuals to actively participate in sustainable practices and carbon offsetting while contributing to the global fight against climate change [25].

2) IoT and autonomous data integration with blockchain. A major change in the landscape of sustainable logistics is being brought about by the convergence of IoT, autonomous data generation, and blockchain integration [26]. The diverse potential of these technologies in solving operational and environmental concerns within supply chains has recently been highlighted.

Smart sensors used in the IoT for real-time monitoring have become popular because of their capacity to increase efficiency and transparency [27]. These strategically positioned sensors provide ongoing information on environmental conditions, safeguarding the integrity of goods and materials. Vehicle performance sensors, for instance, improve fleet management and lower carbon emissions. IoT devices, equipped with sensors and connected to networks, autonomously collect and transmit data in real-time [28]. These devices are capable of capturing environmental variables, vehicle performance metrics, and supply chain data, among others. Their ability to transmit data without manual intervention is a foundational component in achieving autonomous data communication.

Decentralized networks like blockchain play a vital role in enabling IoT devices to communicate autonomously. These networks, often peer-to-peer in nature, facilitate direct data

exchange between devices [29], [30]. This eliminates the need for intermediaries and central authorities, streamlining communication while enhancing security and efficiency also, IoT device-generated autonomous data enables data-driven decision-making for logistics operations via direct communication, the optimization of routes and predictive maintenance.

These developments are enhanced by blockchain technology, which offers a transparent and unchangeable ledger for storing data and autonomous data communication generated by IoT devices. It serves as a distributed ledger where data is securely recorded, and time stamped. This ensures data integrity and authenticity, crucial in green logistics, particularly when validating sustainability claims or ensuring compliance with environmental regulations [26]. By guaranteeing the validity of environmental data, this integration strengthens the plausibility of sustainability claims and avoids "greenwashing" [31]. The result of literature study based on the defined themes is discussed in Table I.

TABLE I. LITERATURE STUDY BASED ON THE MAIN THEMES

Research Studies	Green logistics	Blockchain Technology application	IoT and autonomous interactions
Liu and Ma [28]	New energy-saving transportation methods.		IoT application to guide warehousing operations to improve work efficiency.
Rosado Da Cruz et al. [21]	Tracing carbon footprints.	Blockchain technology for monitoring, tracking and tracing the carbon footprints of products. Smart contracts implementation.	
Tan et al. [15]	Green logistics is based on blockchain by integrating IoT and big data in logistics industry.	Applications of blockchain in logistics operations. Transforming traditional operations into blockchain based operations.	
Feroz et al. [18]	Minimizing the CO_2 emission and managing energy.	Blockchain provides prominent levels of privacy, security and traceability.	
Chelh and Ababou [32]		Potential to revolutionize supply chain management by reducing risks like fraud and data breaches while creating a resilient in green supply chain.	
Cruz [26]		Convergence of IoT-Block chain models to enhance data privacy.	
Nizetic et al. [33]			Using IoT devices to simplify process and to have efficiency, sustainability, and quality.
Ahmad [34]		Combining IoT devices and blockchain technology on Ethereum to enable secure, decentralized data exchange and automation with smart contracts in a P2P network, brings transparency.	
This research	Measuring, evaluation, and controlling of CO_2 footprint through supply chain material operations.	Application of blockchain for transparency of material data flow.	Autonomous data communication and interoperability, data privacy and security, connectivity and standardization, data driven decision making with IoT analytics.

The existing literature highlights the potential of integrating IoT autonomous data collection with blockchain technology to create sustainable and transparent supply chains. However, a significant research gap exists in the development and validation of comprehensive models and applications that can be readily adopted by organizations. These models should effectively integrate IoT autonomous data with blockchain, ensuring data accuracy, transparency, and trust throughout the supply chain [32]. To address this gap, the research will focus on bridging the divide between theory and practical application, providing adaptable, user-friendly frameworks for organizations looking to leverage IoT and blockchain for sustainable, environmentally friendly and transparent supply chains [33].

III. PROPOSED SOLUTION

The development of the frameworks should be the primary focus of this research to ensure that the promise of IoT, autonomous data, and blockchain integration is fully realized in sustainable logistics, with substantial advantages for both businesses and the environment. Fig. 1 demonstrates the conceptual model of such framework.

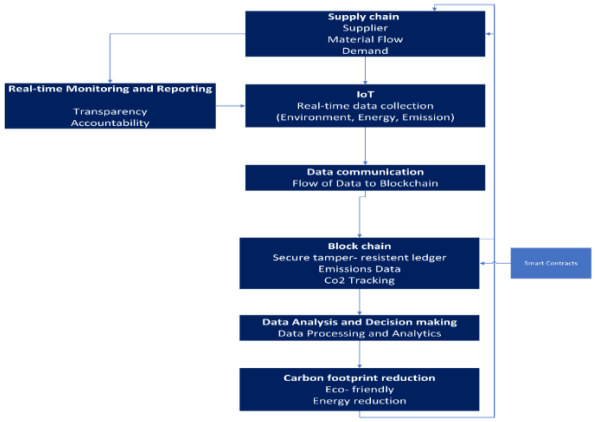

Fig. 1. Illustration of IoT, blockchain conceptual model for reducing overall CO_2 in supply chain.

A. Supply Chain Layer

The Supply Chain Layer consists of suppliers, demand and material flow. It ensures efficient sourcing, monitors material movement and forecasts demand, to enhance overall supply chain performance and sustainability [18]. This layer plays a

pivotal role in leveraging insights for informed decision-making [34].

B. Real-Time Monitoring and Reporting Layer

Throughout the process, real-time monitoring and reporting are facilitated by this layer. Stakeholders have access to emissions data, ensuring transparency and accountability [35].

C. IoT Layer

In the next layer, IoT devices are deployed throughout the supply chain. These devices autonomously collect real-time data with RFID or NFC communication methods on environmental conditions, energy consumption, and emissions [3].

D. Data Communication Layer

The data collected by IoT devices is transmitted to the Data Communication Layer. This layer manages the flow of data from the IoT devices to the blockchain [33].

E. Blockchain Layer

The data will be received and processed within the blockchain layer. The blockchain acts as a secure and tamper-resistant ledger, recording and time stamping all emissions data. Smart contracts, self-executing pieces of code on the blockchain, enforce predefined rules and automate processes. In supply chain and sustainability, smart contracts can execute actions based on the received data, such as verifying emissions compliance or triggering alerts for specific thresholds. On the other side, Emission tokens quantify a certain amount of carbon footprint emissions associated with a specific activity, process, or entity [36]. These tokens are part of the broader concept of carbon credits or carbon offset mechanisms, where organizations seek to compensate for their carbon emissions by investing in projects that reduce or capture an equivalent amount of greenhouse gases elsewhere. Emission tokens often leverage blockchain technology, providing a transparent and immutable ledger to track the generation, transfer, and retirement of these tokens. Blockchain enhances the integrity and traceability of carbon-related data [37].

F. Data Analysis and Decision Layer

The processed data is then sent to the Data Analysis and Decision Layer. Here, data analytics tools are used to gain insights into emissions patterns and identify opportunities for reducing carbon footprints [38].

G. Carbon Footprint Reduction Layer

The insights and recommendations from the Data Analysis and Decision Layer inform the actions taken in the Carbon Footprint Reduction Layer. These actions can include selecting eco-friendly transportation methods, reducing energy consumption, or adjusting sourcing practices [39].

IV. Evaluation

A. Validation Model

The validation of this research asserts the robustness and credibility of the proposed model, affirming the veracity of our claims. The focus will be mainly on the order and transport transactions as can be seen in Fig. 2.

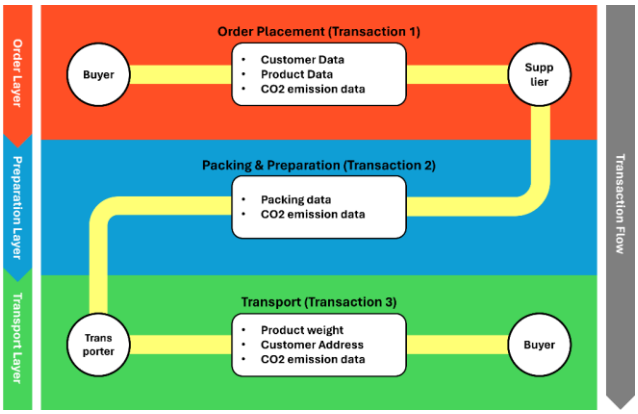

Fig. 2. Transaction and data flow of validation model for the proposed solution.

1) Order placement (Transaction 1). The initial transaction occurs when the buyer (which could be a distributor, retailer, or end consumer) places an order with the supplier. This transaction involves the transfer of order details, quantities, and specifications.

2) Packing and preparation (Transaction 2). The supplier initiates a transaction related to packing and preparing the goods for shipment. This may include generating packing lists, labeling, and preparing documentation.

3) Transport (Transaction 3). When the goods are ready for shipment, the supplier initiates a transaction to notify the transportation entity or logistics provider. This transaction includes information about the shipment, such as weight, dimensions, and the destination.

This approach has several advantages:

- Interoperability. Utilizing a general blockchain provides the advantage of fostering compatibility with diverse blockchain networks. This approach facilitates interoperability with other systems and applications that conform to prevalent blockchain standards.
- Ease of Integration. General blockchains typically feature well-established APIs and tools for network interaction. This simplifies the integration process, enabling concentration on the particular data intended to be stored in the blockchain, rather than navigating the intricacies of blockchain development.
- Security and Immutability. Leveraging an existing blockchain network assures the inherent security and immutability characteristics within blockchain technology. The decentralized and tamper-resistant nature of the blockchain ensures the integrity of the embedded information.
- Cost Efficiency. Opting for an existing blockchain network proves to be a more cost-effective choice. Creating a dedicated blockchain network can be resource-intensive, making the utilization of an established network a pragmatic alternative.

Overall, this approach not only simplifies the development process but also leverages the strengths of blockchain

technology without the need for extensive customization. It allows us to focus on the specific data and use case while benefiting from the broader blockchain ecosystem.

B. Results

The study yields a basic yet instructive blockchain implementation tailored to a supply chain context. Example transactions, such as order placement, packing, and transport, are utilized to showcase how data is structured within blocks and how blocks are sequentially linked. The creation of a genesis block and the utilization of cryptographic hashing underscore the foundational principles of blockchain technology.

The code serves as a steppingstone for comprehending more intricate blockchain frameworks and their real-world applications and highlights the importance of data integrity, decentralization, transaction transparency and key attributes of blockchain technology that contribute to its potential in optimizing supply chain management.

V. Conclusion

In this comprehensive exploration of blockchain integration in supply chain management, it is navigated through fundamental concepts and practical implementations, offering a nuanced understanding of the transformative potential of blockchain technology. The discussion commenced with the delineation of a conceptual model intricately weaving together the realms of the Internet of Things (IoT), blockchain, and carbon footprint reduction. The layers, ranging from IoT data collection to carbon footprint reduction strategies, provided a holistic perspective on how blockchain could revolutionize transparency, traceability, and sustainability within supply chain operations.

The ensuing creation and visualization of a layered diagram reinforced the intricate connections between IoT-enabled data acquisition, secure transmission through blockchain, data analysis for informed decision-making, and the imperative action layer focused on carbon footprint reduction. This conceptual model stands as a testament to the nuanced orchestration required to imbue supply chains with efficiency, accountability, and environmental responsibility. The focus on a supply chain scenario with example transactions elucidated the potential for blockchain to enhance data integrity and transparency in real-world applications. Encryption of blockchain data stands out as a crucial avenue for future research studies. Exploring robust encryption methods to restrict outsider access ensures that sensitive supply chain information remains secure and confidential. This avenue addresses growing concerns regarding data privacy and confidentiality within blockchain networks.

Triggered Screen Restriction Framework: Transforming Gamified Physical Interventions

Majed Hariri[1], Richard Stone[2], Ulrike Genschel[3]
Department HCI, Iowa State University, Ames, USA[1]
Department Industrial Engineering, Iowa State University, Ames, USA[2]
Department Statistics, Iowa State University, Ames, USA[3]

***Abstract*—This study examines the effectiveness of the Triggered Screen Restriction (TSR) framework, a novel technique to promote exercise that combines negative reinforcement with adaptive gamification elements. The study examined the TSR framework's impact on physical activity levels, addictive nature, health indicators, psychological factors, and app usability compared to a control group. A mixed experimental design was employed, with 30 participants randomly assigned to either an experimental group using a custom iOS app with the TSR framework or a control group using a similar app without TSR features. Results revealed that the TSR group demonstrated significantly higher physical activity levels ($p < .05$). The TSR framework resulted in significant increases in app usage frequency ($p < .001$). Health indicators showed a significant improvement in balance and stability through the single-leg stance test ($p < .05$), while other health metrics, including maximum jumping jacks completed in one minute, post-exercise heart rate, and body composition, exhibited no significant changes. Analysis of psychological factors revealed a significant increase in perceived competence in the TSR group ($p < .05$), with no significant changes observed in autonomy or relatedness. The TSR intervention demonstrated significantly better usability metrics, including ease of use, system reliability, and perceived usefulness, compared to the control condition (all $p < .001$). The study contributes to the expanding adoption of gamified physical interventions, showcasing the TSR framework as an effective technique for addressing physical inactivity. Future research should explore long-term effectiveness, diverse populations, and integration with wearable devices to further validate and refine the TSR approach in addressing physical inactivity.**

***Keywords*—Gamification; physical activity; negative reinforcement; triggered screen restriction framework; TSR framework; gamified physical intervention**

I. Introduction

Gamification incorporates elements from games into non-gaming settings. Its goal is to boost user engagement, motivation, and participation [1]. Increasingly, gamification is being used in physical activity interventions. Gamified interventions use game-like elements such as badges and rankings to encourage people to be more physically active [2]. Points, for instance, are awarded for task completion, symbolizing achievements. Leaderboards compare users' performances, promoting competition by ranking their achievements. Badges, earned through specific actions, visually represent achievements. Progress is marked by levels, showing advancement, and providing feedback. Challenges are set goals crafted to increase user engagement and active participation. By transforming physical activity into a game-like experience, the gamified intervention aims to increase participation and address the global decline in physical activity and its consequent rise in sedentary lifestyles [3], [4].

Gamification draws inspiration from motivational psychology and strategically employs intrinsic and extrinsic motivators to enhance user engagement in non-game contexts. By embedding some game elements, the intervention stimulates participation through the inherent desire to explore, learn, and enjoy, which indicates intrinsic motivation [5], [6]. Intrinsic motivation promotes self-regulation, as individuals are driven by personal interest instead of external rewards [7], [8]. Conversely, extrinsic motivation makes people do things for external rewards. These rewards can be money or praise from others [9]. The self-determination theory (SDT) helps us understand motivation better. SDT says that individuals have three main needs. These are the need to make choices, to feel capable, and to connect with others. Meeting these needs is key to increasing motivation and overall happiness [10], [11]. Autonomy emphasizes control over one's actions, competence pertains to the ability to navigate challenges effectively, and relatedness indicates a sense of connection with others [12], [13], [14]. Through the lens of SDT, gamification elements such as challenges and points serve as mechanisms to fulfill these innate psychological needs, thereby enhancing motivation and participation in physical activities [5], [15], [16].

A. Gamification Frameworks

The Octalysis framework identifies eight primary motivators for individuals. These motivators encourage individuals to take part in activities. The framework presents these motivators visually as an octagon [17], [18], [19]. It categorizes these motivators into white hat (positive motivations) and black hat (negative motivations) gamification, emphasizing the importance of balancing both for effective gamification.

The Mechanics, Dynamics, and Aesthetics framework encapsulates various game tactics and examination methods. It links game development, analysis, and technological investigation [20], [21], [22]. The Mechanics, Dynamics, and Aesthetics framework divides games into three main parts. Mechanics are the core elements and algorithms of the game. Dynamics refer to how the mechanics respond to player inputs in real-time. Aesthetics involve the emotional reactions of players.

The Sustainable Gamification Design framework aspires to create gamified systems with long-lasting benefits. It focuses

on three main areas. These are user activity, environmental influence, and social commitment [23], [24], [25], [26]. The Sustainable Gamification Design framework contains four key stages: Discover, Reframe, Envision, and Create, emphasizing moral and human-centered layout guides throughout the process.

The FRAGGLE framework is an agile method. The FRAGGLE framework aims to improve learning experiences through gamification. This framework aligns gamified actions with educational objectives, content, and assessment measures [27], [28], [29]. The framework has four main phases. These phases are Declaration, Creation, Execution, and Learning. The framework focuses on making gamified activities that are both engaging and educationally effective.

The growing interest in gamification for promoting physical activity presents a promising opportunity. A novel framework can be molded to encourage exercise. The novel framework can address specific needs and motivations. It can do so by using negative reinforcement. By incorporating gamification elements, this innovative approach has the prospect of boosting the acceptance of healthy habits significantly.

B. The TSR Framework

The TSR framework offers a new strategy for implementing gamification elements in exercises. It addresses the limitations of traditional methods [30]. This framework combines adaptive gamification strategies, machine learning models, and computer vision. It creates an intriguing and personalized experience to promote physical exercise. The TSR framework stands out due to its unique features. These include negative reinforcement, adaptive gamified components, and real-time action verification that respects privacy [31].

The primary technique of the TSR framework leverages individuals' Fear of Missing Out (FOMO) and employs negative reinforcement to enhance motivation. It restricts entry to social media apps based on exercise objectives. This technique harnesses people's urge to remain connected and educated. Physical activity becomes essential to access restricted venues [32]. The TSR approach also includes customized message triggers. It uses a model of computer vision to exercise recognition. The adaptive incentive system adjusts the difficulty level based on each user's established routine [31].

The TSR framework builds on existing research on gamified physical interventions. It adds new elements to overcome common limitations. We need to explore several areas to understand the TSR framework's contributions fully. These include the current landscape of gamified physical interventions, how negative reinforcement affects behavior change, and the addictive nature of electronic devices. The next section reviews related work in these areas. This process provides context for the TSR framework's unique approach and its potential to promote physical activity.

II. Related Work

A. Gamified Physical Interventions

A gamified intervention incorporating points, progress bars, challenges, and leaderboards was investigated for its effects on daily step counts. The results indicated a significant increase in steps taken by participants during the intervention period [33], [34], [35].

Researchers conducted a controlled trial study using a gamified physical intervention on overweight adults. The intervention used a fitness tracker and a smartphone app. It gave game-like feedback, helped set goals, and offered social support. The study found that during the intervention, participants took more steps. However, this increase did not last after the intervention ended [36], [37], [38].

Researchers investigated a gamification-based intervention designed to encourage walking among obese adults. The results indicated that participants who engaged with the gamified elements of the intervention increased their walking frequency [39], [40], [41].

The efficacy of gamification in enhancing physical activity was examined using a commercially available activity tracker coupled with a custom-designed mobile app. The gamified intervention, which incorporated points, leaderboards, and social interaction features, significantly increased step counts [42], [43].

A gamified intervention utilizing challenges and self-monitoring tools was designed to encourage physical activity in adults. The study identified a significant positive effect of the gamified intervention in increasing participants' daily step counts [44], [45].

The use of a gamified social media intervention delivered through WeChat was examined to promote physical activity. The intervention utilized various game mechanics, including competition, points, and social interaction, to encourage walking. The findings demonstrated that the intervention effectively increased participants' daily step counts [46].

The long-term effects of a gamified intervention on physical activity maintenance were investigated. The intervention involved points, progress bars, competition, and financial rewards, leading to a significant increase in step counts. Notably, the positive effects persisted for a two-year follow-up period, emphasizing the potential for long-term behavioral change [47], [48].

Researchers investigated a gamified intervention to increase walking in overweight and obese adults. They used the Way to Health platform. Even though the program had game-like features, it did not lead to participants walking more [49].

Researchers assessed the impact of an app with game-like features to encourage adults to be more active. The app used points, progress bars, challenges, rankings, and rewards. The study found that participants using the app became more physically active [50].

A gamified app employing points, progress bars, challenges, and social interaction elements was created to encourage physical activity. The results showed a notable rise in physical activity among users who utilized the gamified app [51].

Researchers studied the impact of the game-like features to promote exercise. The intervention used points, progress bars, and challenges. The study showed that participants who used gamified physical intervention apps exercised more [51].

A study examined the long-term impact of a gamified cycling exercise. Despite using points and progress bars, the study did not show significant long-term significance on cycling activity [52].

The related studies analyzed the prospect of gamified physical interventions. Many of the mentioned gamified physical interventions overly rely on positive reinforcement, which led to a decline in activity levels post-intervention.

B. Negative Reinforcement

Negative reinforcement makes a behavior more likely to happen again by removing unwanted provocation. Understanding how negative reinforcement affects an individual's motivation to initiate new behaviors or tasks is crucial for education, therapy, and behavior modification applications.

Reinforcement theory implies that behavior can be modified through reinforcement. Negative reinforcement is one of the four primary strategies in reinforcement theory, alongside positive reinforcement, punishment, and extinction. It is effective in increasing desired behaviors by eliminating negative conditions, but it must be carefully managed to avoid unintended results [53], [54]. Combining positive and negative reinforcement is very effective in boosting task compliance and decreasing escape-maintained damaging behavior [55], [56]. The frequency of negative reinforcement can moderately affect the persistence in completing tasks. This implies that regular use can sustain desired behaviors over time [57].

Negative reinforcement can lead to distinct emotional responses, such as increased positive affect and reduced fatigue, which may influence motivation and feedback processing in organizational settings [58]. The negative reinforcement paradigm can be effectively used in classroom settings to increase desirable behaviors and decrease undesirable ones, suggesting its potential applicability in training and development programs [59].

Teachers and therapists can use negative reinforcement effectively to increase treatment integrity and compliance with interventions. A study has demonstrated that combining performance feedback with negative reinforcement improves implementation accuracy and reduces off-task behavior among students [60]. Interventions based on negative reinforcement can be customized to fit individual needs. This customization boosts their effectiveness in behavior modification programs [61].

C. Addictive Nature of Electronic Devices

The addictive nature of electronic devices, particularly smartphones, is a growing concern. Smartphone features like infinite scroll and autoplay facilitate the perception of reinforcement rewards and promote habit formation, which together drive smartphone addiction [62]. Users often spend more time than planned on applications with infinite scrolling due to the psychological effects of the feature, leading to increased dependency on these applications [63].

FOMO greatly contributes to the addictive nature of electronic devices. FOMO is linked with the destructive effects of social media on everyday life and job performance, with various social media use disorders acting as intermediaries [64]. FOMO causes people to frequently check their phones and can predict no-mobile-phone phobia [65]. No-mobile-phone is a contemporary psychological condition marked by the fear of not having a mobile phone [66]. It also mediates between psychological needs and phubbing, strengthening the habit of constantly checking smartphones [67].

Perceived enjoyment, emotional gain, and social pressure greatly contribute to smartphone addiction. Enjoyment from using smartphones can create habitual usage, which then leads to smartphone addiction [68]. Emotional gain, which includes positive emotions and relief from negative psychological states, is a strong predictor of smartphone addiction across generations [69].

Social media interactions offer positive reinforcement (for instance, likes and comments) and negative punishment (such as social comparison). The positive and negative factors contribute to social media dependence [70]. Individuals with social anxiety and loneliness are more prone to smartphone addiction, especially when their primary use is accessing social networking sites [71].

The extensive use of smartphones for social interactions and process-related activities, such as browsing and gaming, significantly contributes to habitual and addictive smartphone behavior [72], [73]. Younger generations exhibit higher levels of smartphone addiction compared to older generations, with emotional gain and social environment pressure being strong predictors of this behavior among younger users [74], [69].

III. Objective

The study aims to thoroughly assess the TSR framework, a novel gamification framework to promote physical activity. It will compare the TSR framework with a control group that undergoes a gamified physical intervention without using the TSR framework. The study seeks to determine whether the TSR framework leads to significant improvements in physical activity levels, health metrics, and psychological aspects. Additionally, it aims to evaluate the framework's impact on app usability and its potentially addictive nature. The study examines changes in psychological aspects such as autonomy, competence, and relatedness among participants using surveys conducted before and after the intervention. Furthermore, the study evaluates participants' experiences with the gamified physical intervention, focusing on the ease of use, system reliability, and usefulness of the TSR framework in promoting physical activity.

IV. Methodology

The study employed a mixed experimental design with between-subjects and within-subjects components to assess the effectiveness of the TSR framework in enhancing physical activity and health outcomes. Participants were randomly assigned to either an experimental group using a custom iOS app with the TSR framework or a control group.

A. Participants

Following Institutional Review Board approval, 30 participants (19 to 38 years old, M = 29.56, SD = 5.25)

were recruited from Iowa State University students and residents (see Table I). Participants were healthy adults without pre-existing medical conditions that could hinder physical activity. Recruitment was conducted through campus flyers and snowball sampling. Participants were informed that their involvement was voluntary and that they could withdraw at any time without consequences.

TABLE I. PARTICIPANT DEMOGRAPHICS

Characteristic	Category	Percentage
Education	Graduate degree	53%
	Bachelor's degree	30%
	High school diploma	17%
Employment Status	Employed full-time	60%
	Unemployed	3%
	Students	37%
Used Gamified Apps Before	Yes	53%
	No	47%
Competitive Features	Yes	77%
	No	23%

B. Procedure

1) Orientation and group assignment: All participants attended an orientation session. They learned about the study's goals and steps. Then, they were split into two groups randomly. The experimental group used a custom-made iOS app with the TSR framework. The control group used the same app but without the TSR framework.

2) Intervention period: The study duration was four weeks. During the study, both groups were asked to do jumping jacks daily using the given app. The app logged the number of repetitions for each participant.

3) Data collection: Participants attended two in-person sessions at the ATHENA Lab, located at 0066 Black Engineering, ISU, for measurement of stamina and physique indicators (maximum jumping jacks in one minute, post-exercise heart rate, single-leg stance test, and body composition). Psychological factors and app usability were assessed through surveys on a secure device in the lab.

4) Data management: Data was de-identified at the point of collection, with all measures associated with assigned study ID codes rather than participant names or contact information.

5) Debriefing: All participants were fully debriefed about the true nature of the research and the importance of having a control group. In the debriefing session, participants were informed of the experiment's aim to compare the effectiveness of a gamified physical intervention with and without the TSR in boosting physical levels and improving health outcomes. The research team explained that the deception was needed to avoid potential biases and ensure the study results were valid. Participants were encouraged to ask questions and share any concerns about the deception or the study in general. The research team addressed these questions and concerns openly and honestly.

C. Apparatuses

The study utilized several apparatuses to measure participants' health metrics and facilitate the experimental procedures. Body composition, including muscle mass and fat percentage, was assessed using the eufy by Anker, Smart Scale P1. This smart scale provides accessible body composition measurements, allowing for tracking changes in muscle mass and fat percentage throughout the visits. The study used the FACEIL Pulse Oximeter Fingertip, a non-invasive device that measures heart rate and oxygen saturation levels to measure the heart rate. The pulse oximeter measured participants' heart rate immediately after the one-minute jumping jacks exercise and at one, two, three, and four minutes post-exercise to assess cardiovascular recovery. An iPhone 14 Pro was used to precisely time the one-minute jumping jacks exercise and the post-exercise heart rate measurements, ensuring consistency and accuracy in the data collection process.

D. Measurements

The study assessed various variables to measure the significance of the TSR framework:

1) Addictive nature: Number of times the app was opened by each user.

2) Physical activity metrics: Number of jumping jack repetitions.

3) Health indicators: Maximum jumping jacks in one minute, post-exercise heart rate, single-leg stance test, and body composition.

4) Psychological factors: Autonomy, competence, and relatedness.

5) App usability measures: Ease of use, system reliability, and perceived usefulness.

The surveys were administered in person at the ATHENA Lab. Participants completed the surveys on a secure device provided in the ATHENA lab. These surveys were designed to collect participant responses securely and confidentially. All the surveys had the same Likert scale. Participants fill out 5-point questionnaires varying from "Disagree" to "Agree". The surveys were adjusted to ensure no personally identifiable information (like names or email addresses) was collected with the responses.

The scales measuring psychological factors (autonomy, competence, and relatedness) were adapted from previously validated instruments, the Basic Psychological Needs in Exercise Scale (BPNES) [75]. The app usability scales were also based on established usability questionnaires, the Technology Acceptance Model (TAM), [76] [77].

In prior studies, these validated scales showed strong psychometric indicators, such as high internal consistency reliability and construct validity. By employing these validated scales, the study ensured that the psychological factors and app usability measures were reliable and valid, allowing for meaningful interpretation of the results.

The physical activity metrics and health indicators were considered objective measures. Their validity was assumed based on the accuracy of the app's logging system and the standardized protocols used for the jumping jacks test, single-leg stance test, and body composition assessment.

V. Result

All data were analyzed using JASP version 0.18.3. We employed both independent samples t-tests and repeated measures ANOVA to assess differences in our outcome measures. Independent samples t-tests were used to evaluate between-group differences, while repeated measures ANOVA was utilized to analyze changes over time and interactions between time and app mode (TSR framework vs. control). Tukey's HSD test was used for post-hoc comparisons to evaluate our hypotheses. As the results were qualitatively consistent across both parametric and non-parametric methods, we present the t-test and ANOVA results due to their familiarity to most readers and their established robustness against violations of normality and homogeneity of variance, particularly when sample sizes are equal across treatment groups, as is the case in our study [78], [79].

A. Addictive Nature

H1. The TSR framework leads to a significant increase in app usage frequency compared to a gamified physical intervention without the TSR framework.

An independent samples t-test was conducted to evaluate the impact of the TSR framework on app usage frequency. The analysis revealed a significant difference in app usage between the experimental group and the control group [$t(28) = -5.552$, $p < .001$]. Participants in the experimental group ($M = 3.112$, $SD = 1.642$) opened the app significantly more often than those in the control group ($M = 0.626$, $SD = 0.558$). These results suggest that the TSR framework significantly impacts the addictive nature of the intervention, which resulted in higher usage frequency (see Fig. 1).

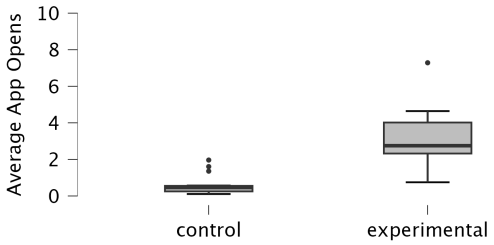

Fig. 1. Average app usage frequency by group.

B. Physical Activity Levels

H2. The TSR framework leads to a significant improvement in physical activity levels among participants compared to a control group without the TSR intervention.

An independent samples t-test was conducted to evaluate the impact of the TSR framework on physical activity levels, measured by the average number of repetitions performed. The analysis revealed a significant difference in repetitions between the experimental group and the control group [$t(28) = -2.346$, $p < .05$]. Participants in the experimental group ($M = 12.721$, $SD = 18.825$) performed significantly more repetitions on average than those in the control group ($M = 1.267$, $SD = 1.754$). These results suggest that the TSR framework significantly impacts physical activity levels (see Fig. 2).

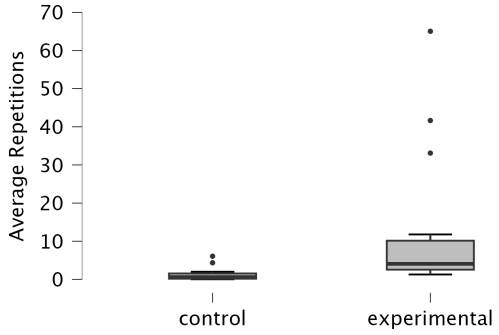

Fig. 2. Average exercise repetitions by group.

C. Health Indicators

H3. The TSR framework leads to a significant improvement in health metrics among participants compared to a control group experiencing a gamified physical intervention without the TSR framework.

Repeated measures ANOVA was performed to assess the effect of the intervention on all health metrics: maximum jumping jacks completed in one minute, post-exercise heart rate, single-leg stance test, and body composition. The analysis revealed a significant interaction between time and app mode in the within-subject effect for the Single-leg stance test [$F(1, 28) = 5.572$, $p < .05$]. The between-subjects analysis also showed a significant main effect of app mode for this test [$F(1, 28) = 7.509$, $p < .05$]. Post hoc comparisons using Tukey's HSD test revealed a significant difference between the before and after intervention scores for the experimental group (Mean Difference = -50.167, $p < .05$), while the control group showed no significant change. These results suggest that the TSR framework significantly improved balance and stability as measured by the Single-leg stance test. No significant changes were observed in the other health metrics.

D. Psychological Factors

H4. The TSR framework leads to a significant improvement in perceived psychological factors in physical activities compared to a gamified physical intervention without the TSR framework.

Repeated measures ANOVA was performed to assess the effect of the intervention on all psychological factors: autonomy, competence, and relatedness. The analysis revealed a significant main effect of time [$F(1, 28) = 7.303$, $p < .05$] and a significant interaction between time and app mode [$F(1, 28) = 4.534$, $p < .05$] for competence. Post hoc comparisons using Tukey's HSD test showed a significant increase in competence scores for the experimental group from before to after the intervention (Mean Difference = -0.656, $p < .05$), while the control group showed no significant change. These results suggest that the TSR framework significantly improved perceived competence in physical activities (see Fig. 3). No significant changes were observed for autonomy or relatedness.

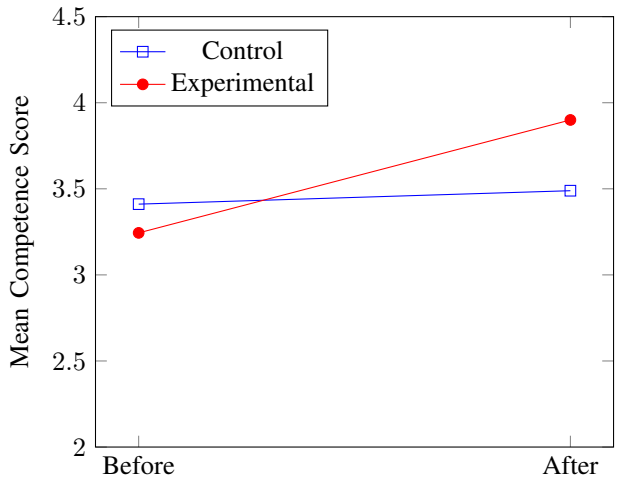

Fig. 3. Changes in competence scores before and after intervention.

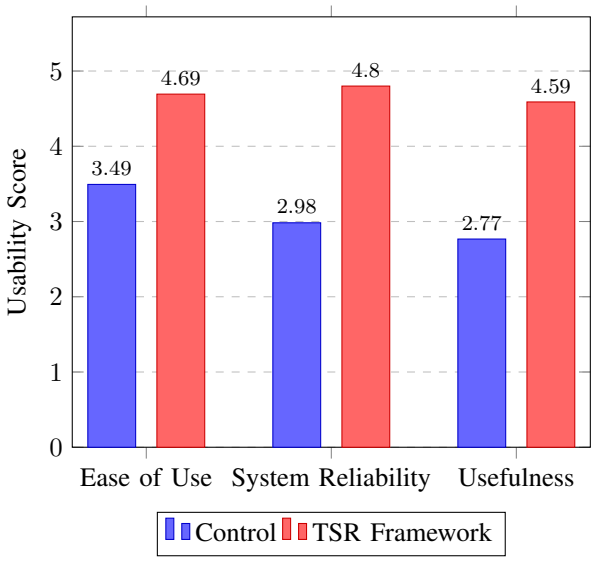

Fig. 4. Comparison of intervention usability factors between control and TSR framework groups.

E. App Usability

H5. The TSR framework leads to a significant improvement in perceived app usability compared to a gamified physical intervention without the TSR framework.

Independent samples t-tests were performed to assess the effect of the intervention on all intervention usability factors: ease of use, system reliability, and perceived usefulness. The analyses revealed significant differences between the experimental and control groups for all three factors. For perceived ease of use, a significant difference was found [t(28) = -4.372, p < .001], with the experimental group (M = 4.693, SD = 0.369) reporting higher scores than the control group (M = 3.493, SD = 0.997). Perceived system reliability also showed a significant difference [t(28) = -6.864, p < .001], with the experimental group (M = 4.800, SD = 0.330) scoring higher than the control group (M = 2.983, SD = 0.970). Similarly, perceived usefulness demonstrated a significant difference [t(28) = -5.042, p < .001], with the experimental group (M = 4.589, SD = 0.620) reporting higher scores than the control group (M = 2.767, SD = 1.255). The usability analysis shows the TSR framework intervention outperformed the control intervention in ease of use, reliability, and perceived usefulness. Participants reported it more user-friendly, reliable, and valuable for their physical activity goals, potentially boosting engagement, program commitment, and health outcomes (see Fig. 4).

VI. Discussion

This research offers important insights into the effectiveness of the TSR framework. The TSR approach to gamified physical interventions has shown promising results. The study's findings demonstrate notable improvements across several measures. However, the research also identifies specific areas that require additional investigation and refinement.

The significant increase in physical activity levels, as measured by jumping jack repetitions, in the experimental group compared to the control group aligns with previous research on gamified interventions for physical activity [33], [42], [44]. This result indicates that the TSR framework's unique approach effectively boosts users' engagement in physical exercise.

The analysis of app usage frequency revealed a significant increase in the number of times users opened the app in the experimental group compared to the control group. This finding supports the statement that through its innovative use of FoMO and negative reinforcement, the TSR framework might create an engaging and might lead to habit-forming intervention. The substantially higher usage frequency demonstrates the framework's success in leveraging addictive features to promote regular engagement with physical activities. By channeling the compelling nature of digital interactions into health-promoting behaviors, the TSR framework shows promise in transforming potentially problematic usage patterns into sustained, healthy habits.

Regarding health indicators, the significant improvement in the single-leg stance test for the experimental group is particularly noteworthy. The enhancement in balance and stability suggests that the TSR framework may offer benefits beyond just increasing activity levels, with potential implications for some physical functions. However, the lack of significant changes in other health metrics, including maximum jumping jacks completed in one minute, post-exercise heart rate, and body composition, indicates that the framework's impact on broader health outcomes may be limited, at least within the time frame of this study.

The analysis of psychological factors revealed interesting outcomes, particularly in terms of perceived competence. The significant increase in competence scores, especially evident in the experimental group, suggests that the TSR framework effectively boosts users' confidence in their ability to engage in physical activities. However, the lack of significant changes in autonomy and relatedness scores indicates that these aspects of psychological need satisfaction may require further refinement within the TSR framework.

The intervention usability measures strongly supported the

TSR framework's effectiveness in terms of user experience. Significant improvements were observed in ease of use, system reliability, and perceived usefulness compared to the control intervention. The findings highlight the importance of user experience in promoting engagement with gamified physical interventions and suggest that the TSR framework successfully addresses key aspects of technology acceptance [77].

The research findings should be interpreted with caution due to certain constraints in the study design. A key limitation was the restricted number of participants involved, which may have affected the statistical power of the analysis. Additionally, the shortness of the experimental time frame could have obscured some outcomes, particularly for health-related metrics that typically necessitate longer observation periods to manifest noticeable changes. Finally, the lack of social features and the use of machine-learning techniques may have resulted in a lack of improvement in some factors, especially autonomy and relatedness.

Nevertheless, the research offers compelling evidence for the potential of the TSR framework in promoting physical activity and improving specific health outcomes. The framework's ability to significantly increase user engagement, improve balance and stability, enhance perceived competence, and provide a superior user experience suggests that it offers a promising approach to addressing physical inactivity.

VII. Future Work

The promising results of this study on the TSR framework highlight several avenues for future research and development:

1) Long-term effectiveness: Future studies should investigate the TSR framework's ability to sustain behavior changes over extended periods. A longitudinal study lasting several months could provide valuable insights into whether the framework can maintain increased physical activity levels and the improved health indicator observed in this study. The long-term direction addresses a common challenge in health interventions and could help validate the long-term impact of the TSR approach.

2) Diverse populations: Future research should include a broader range of participants, including different age groups, fitness levels, and backgrounds. Testing the TSR framework with older adults, children, or people with specific health conditions would enhance the generalizability of the findings and potentially reveal how the framework's effectiveness varies across different demographics.

3) Varied physical activities: While the current study focused on jumping jacks, future studies should explore the framework's efficacy with a wider range of physical activities. Future studies could include aerobic exercises, strength training, or sports movements, providing insights into the versatility and broader applicability of the TSR framework across different types of physical activity.

4) Psychological factors refinement: Given the significant improvement in perceived competence but lack of change in autonomy and relatedness, future work should focus on enhancing the TSR framework to better support all aspects of psychological need satisfaction. This might involve incorporating more personalized goal-setting features or embracing social interaction elements to address autonomy and relatedness more effectively.

5) Health indicators assessment: The lack of significant changes in most health indicators, except for the single-leg stance test, suggests a need for more comprehensive and possibly longer-term health assessments. Future research could employ more sensitive measures of cardiovascular fitness, muscular strength, and body composition. Additionally, adjusting the framework's intensity and duration of physical activities might lead to more substantial health improvements.

6) Addictive nature analysis: While the increased app usage frequency demonstrates the TSR framework's effectiveness in engaging users, further research is needed to explore the long-term implications of this engagement. Studies could investigate how the framework's addictive features translate into sustained healthy behaviors over time and examine potential strategies to optimize engagement without introducing problematic usage patterns.

7) Wearable device integration: Future work could explore combining the TSR framework with popular wearable fitness devices. The integration with wearable devices could provide more accurate activity tracking and personalized feedback, potentially enhancing the framework's effectiveness and user experience even further.

VIII. Conclusion

The study provides strong evidence for the effectiveness of the TSR framework as an innovative approach to gamified physical interventions. The results demonstrate that the framework's unique features can significantly impact physical activity levels and certain health indicators. Key findings of the study include:

- A significant increase in physical activity levels in the experimental group, as measured by jumping jack repetitions, compared to the control group.
- Significantly higher app usage frequency in the TSR framework group, demonstrating the framework's success in leveraging addictive features to promote regular engagement with physical activities.
- Improved balance and stability in the TSR framework group, evidenced by significant improvements in the single-leg stance test.
- Increased perceived competence among participants using the TSR framework, while no significant changes were observed in autonomy and relatedness.
- Superior user experience with the TSR framework intervention, with significantly higher ratings in ease of use, system reliability, and perceived usefulness compared to the control intervention.

In conclusion, the TSR framework addresses several limitations of conventional gamified physical interventions by using negative reinforcement and incorporating adaptive gamification elements. The TSR approach shows promise in creating a more engaging, potentially habit-forming method for promoting physical activity. The framework offers an innovative and impactful approach to encouraging healthier,

more active lifestyles. The TSR framework has been demonstrated as an effective method for tackling physical inactivity, contributing to the broader implementation of gamified physical interventions.

AI in the Detection and Prevention of Distributed Denial of Service (DDoS) Attacks

Sina Ahmadi
National Coalition of Independent Scholars, NCIS, Seattle, USA

***Abstract*—Distributed Denial of Service (DDoS) attacks are malicious attacks that aim to disrupt the normal flow of traffic to the targeted server or network by manipulating the server's infrastructure with overflowing internet traffic. This study aims to investigate several artificial intelligence (AI) models and utilise them in the DDoS detection system. The paper examines how AI is being used to detect DDoS attacks in real-time to find the most accurate methods to improve network security. The machine learning models identified and discussed in this research include random forest, decision tree (DT), convolutional neural network (CNN), NGBoosT classifier, and stochastic gradient descent (SGD). The research findings demonstrate the effectiveness of these models in detecting DDoS attacks. The study highlights the potential for future enhancement of these technologies to enhance the security and privacy of data servers and networks in real-time. Using the qualitative research method and comparing several AI models, research results reveal that the random forest model offers the best detection accuracy (99.9974%). This finding holds significant implications for the enhancement of future DDoS detection systems.**

Keywords*—*Artificial intelligence; Distributed Denial of Service (Ddos); machine learning; detection; accuracy

I. Introduction

In today's fast-paced digital landscape, web-based services and software have seen a significant rise, with approximately 57% of the global population now using the Internet [1]. While artificial intelligence (AI) and machine learning have become powerful tools across various industries, they have also introduced a host of security challenges, particularly in maintaining the performance and security of networks. Traditional networks often struggle to keep up with the demands for efficiency and robust security, leaving businesses vulnerable to cyber threats like Distributed Denial of Service (DDoS) attacks [2]. The escalating scale and frequency of these attacks highlight a critical problem: existing network infrastructures, including those managed by software-defined networking (SDN), are increasingly incapable of providing the security required to ensure smooth business operations. SDN, which manages network traffic through software platforms rather than hardware, provides a centralised control system that enhances network flexibility and manageability [3]. However, this centralised architecture also introduces vulnerabilities, particularly at the control layer, where attackers can disrupt or manipulate network traffic through DDoS assaults. These attacks are difficult to detect, and as their intensity and frequency continue to rise, they pose significant challenges for administrators and service providers in terms of identification and mitigation [4]. Although various machine learning methods have been proposed for detecting DDoS attacks, there remains a gap in understanding which of these methods is most effective in real-time scenarios, especially within SDN environments.

This study aims to fill this gap by evaluating and comparing different AI-based detection methods to determine the most accurate technique for real-time DDoS attack mitigation in SDN. By addressing the limitations of existing detection approaches, this research seeks to provide a more effective solution for identifying and preventing DDoS attacks. The findings will offer valuable insights into how AI can enhance the security of SDN infrastructures, contributing to the broader goal of protecting businesses from network disruptions and security breaches.

Ultimately, this study's significance lies in its potential to advance current cybersecurity measures by integrating AI into SDN environments. As the intensity and sophistication of cyberattacks continue to rise, finding more accurate detection methods becomes crucial. The results of this research will be essential for administrators and service providers seeking to safeguard their networks against DDoS attacks, thus ensuring greater operational stability and data security.

II. Literature Review

This section of the paper provides a detailed understanding of existing research and guides how this research presents a different perspective in the field. Numerous researchers have investigated AI-based detection methods to understand which method is most accurate for managing detective services.

A. Performance of AI / Machine Learning in DDoS Attack Detention

Meti et al., in their experiment, observe TCP traffic from actual networks along with the number of connected devices per second as an indicator [5]. In terms of precision, accuracy, and recall levels, the results of the comparison highlight that K-Nearest Neighbour (KNN) shows the best precision and accuracy. Zekri et al. suggested that a DT is also effective in the cloud network to detect DDoS attacks [6]. Sahoo et al. present an enhanced support vector machine (SVM) model that implements genetic algorithms (GA) and kernel principal component analysis (KPCA) [7]. Bakker et al. discuss the additional costs of using AI for DDoS attack detection in SDN [8]. Another study by Polat and co-authors confirms that KNN is the most accurate method for DDoS detection and security improvements [9].

B. Use of Machine Learning for DDoS Attack Detection

Huyu et al. present techniques for optimising and creating detection models by sending real-time traffic data to an offline learning network [10]. Data is collected through routers and transmitted to the offline pipeline for data transformation and feature engineering. Optimised models combined with existing models can be used to protect networks from DDoS attacks. Chayomchai et al.'s study focuses on the impact of cybercrime and DDoS attacks on banking institutions and how these institutions are responding to these negative effects [11]. The study claims that massive malware assaults target Indian banks, resulting in the theft of private customer information and huge financial losses. It also states that poorly designed detection models that do not need annotated data to supervise DDoS attacks can be improved using latent Dirichlet allocation (LDA). Another alternative is to use an extra classification layer to remove non-attack tweets from the dataset [12]. Ashraf and Latif propose a SOM-based solution to significantly improve accuracy [13]. However, SOM principles violate SDM principles as they are built on intelligence in the data plane [14]. Peng et al. provide a detection method for anomalous SDN streams in an SDN architecture [15]. They applied the same technique to detect DDoS attacks using DPTCM-KNN as the core algorithm. The results of this study demonstrate that the deployed technique is effective; however, the detection accuracy obtained needs improvement.

C. Machine Learning Models

1) Random forest: The random forest model of machine learning refers to a method of ensemble learning that combines forecasts from different DTs. This model is used for both regression and classification. Predictions from different decision trees are combined to formulate a final forecast, and every entry in a random forest contains a different subset of the data. By deploying ensemble techniques, the individual accuracy of DTs can be improved, making them more dependable for attack detection and prevention.

2) Decision tree: A DT refers to the graphical representation of a decision-making process that separates data based on the input values into different subgroups. Each subgroup produces further branching nodes that lead to other subgroups or outcomes. In regression and classification tasks, a DT is used to generate and present predictions based on data feature values. Decision trees are simple and convenient to understand, which is why they are helpful in detecting DDoS attacks. However, the accuracy of DTs needs improvements in terms of consistency in detection.

3) *Convolutional neural network:* A CNN is used for image classification and identification. Convolutional neural networks have innumerable applications, such as face recognition, image processing, object detection, and computer vision. They are AI-powered systems that use images as input to perform. Convolutional neural networks work automatically to learn certain features that might be used for categorisation. Algorithms are adjustable to different networks in SDN, making them suitable for environments where potential attacks might occur. In terms of detecting DDoS attacks, CNNs require large amounts of labelled data that might not be available in every scenario.

4) *NGBoosT classifier*: This machine learning model is used for tasks involving data classification. NGBoosT collects different predictions from trees and evaluates those predictions to propose a final prediction. It is helpful in detecting DDoS attacks because it provides predictions about their uncertainty, which is helpful in managing unclear and uncertain situations.

5) Stochastic gradient descent: It is a straightforward and efficient method to detect DDoS attacks on networks. Stochastic Gradient Descent is used to manage complex machine learning issues commonly occurring during text categorisation and language processing tasks. This method can also be applied to different linear models and is convenient for managing different DDoS detection scenarios.

D. DDoS

Xu et al. present a technique to detect DDoS attacks in SDN. The technique mainly depends on K-FKNN and K-means++. The proposed detection system would be implemented into the controller. The experimental results of this study reveal that the implemented technique is stable and efficient [16]. However, some drawbacks that make the technique less accurate include the longer time required to detect the attack and the high load it puts on the SDN resources.

Polat et al. present an alternative method for DDoS attack detection in SDN [9]. There are two aspects to the proposed detection system. The first aspect analyses the DDoS attack traffic and normal traffic on the SDN environment dataset. Filtration wrapping and feature selection methods were deployed in the second aspect to get the most effective features for machine learning model classification. However, there is a limitation to the introduced technique: the need for further enhancement in its performance and detection accuracy.

Novaes et al. have implemented a DDoS attack and a mitigation method in SDN [17]. The whole system is called LSTM-FUZZY. The detection system comprises three stages: characterisation, detection, and mitigation. The proposed system is ineffective due to its restricted scope for addressing the vulnerabilities of other networks. In addition, the model lacks the characteristics required to test different network topologies [17].

Sarwan et al. present a space- and time-efficient DDoS attack detection technique that possesses the characteristics of identifying hosts along with the attack's origin [18]. The technique uses different traffic characteristics to identify abnormal traffic behaviour. It also uses a threshold to identify normal and compromised hosts. This DDoS detection technique is efficient as it saves time and space. However, it does have the limitation of violating SDN standards by implementing logic into switches. Thus, there is a need to improve its performance and algorithmic accuracy.

Studies reveal that DDoS attacks are often released from a single host to seize or disable access by overloading the target network or system. The degree of damage or loss depends on the strength of the attacker's resources. There are different intentions and purposes for launching a Denial-of-Service

attack, which could be personal or institutional. Attackers use botnets or zombie computers to launch a DDoS attack. These attacks are pre-planned to disrupt or destroy a target network by using land moves and targeting a specific system [19].

Existing literature covers different dimensions of the proposed research topic; however, literature about the use of AI to detect and prevent denial-of-service attacks is minimal. Artificial intelligence is evolving in every industry to automate systems and enhance network performance. Researchers must disseminate knowledge on the use of machine learning applications in different fields to protect systems from malware and security assaults. The following section of the paper defines the research problem and the significance of understanding and addressing this problem.

III. Problem Definition

Denial-of-Service (DoS) attacks happen when authorised users fail to access network data due to malicious cyber threat activities launched by third parties. These attacks, driven by various motives, are launched against emails, passwords, databases, and websites to hack the private information of individuals or organisations. Business organisations using advanced software and computing networks to perform everyday operations are prone to such attacks. For example, banks store important organisational and customer information on online databases and transform sensitive information through networks that hackers can conveniently hack and misuse. DoS attacks create enormous challenges for administrators and managers in keeping operations streamlined. Organisations with poor detection infrastructure cannot detect abnormal traffic timely, resulting in attacks and network complications. Given the technological advancements and emerging threats, the major problem lies in the timely detection of DoS attacks and the application of accurate methods to network infrastructures.

Artificial intelligence has become an essential tool for transforming business experiences. It is revolutionising every industry by redefining traditional business practices and transforming customer experiences. By using AI applications and enhancing AI-based models, defence against DoS attacks is possible. For example, AI helps reduce the surface area vulnerable to attack, thereby minimising the options available to attackers. Load balancers mitigate this issue by restricting direct Internet traffic to specific parts of the network to avoid direct attacks. Similarly, Access Control Lists (ACLs) are useful in controlling which traffic would reach applications in a given time [20].

A. DDoS Detection and Prevention

Common mechanisms for detecting and preventing DDoS include attack detection, prevention, and reaction. However, it is difficult to detect DDoS attacks in a network as it is hard to differentiate between abnormal and normal network traffic during ongoing operations. The detection of abnormal traffic in a network is the first step to detecting DDoS attacks. In addition, AI classification methods can help in identifying good and bad packets. Bed packets labelled as abnormal traffic would be dropped. The number of packets, time interval variance, average size of packets, number of bytes, size variance, and packet rate are common characteristics that help differentiate between good and bad packets.

B. Artificial Intelligence Techniques

Most relevant AI techniques include machine learning, natural language processing, and speech recognition. Machine learning algorithms are utilised in most of the settings. These techniques, including Naive Bayes, support vector machines, and neural networks, are implemented based on the nature and frequency of attacks [21].

C. Trends of DDoS Attack

In the fast-paced business world, DDoS attacks are commonplace. For instance, public networks experience frequent instances of high-intensity floods, which significantly affect the normal flow of network traffic and disrupt normal functioning. Although the security protocols of a network protect it against DDoS attacks, trends of attack vary based on the strength of the security protocols of a network. The number of organisations experiencing DDoS attacks is increasing annually, along with the growing dependence on software and databases for managing organisational processes. The integration of technology is simultaneously easing and complicating institutional processes.

D. Integration of AI Models into Networks to Prevent DDoS Attacks

Distributed Denial of Service attacks have been demonstrated to be major threats to the Internet, causing major losses to organisations and governments. With the advancement of technology, it has become convenient for attackers to launch DDoS attacks at low costs. Attackers use unknown hosts or computers to launch DDoS attacks, and it is hard to detect them without having advanced security infrastructures embedded in AI models. However, different AI models, like machine learning algorithms, are available to help detect DDoS attacks. These models vary in accuracy and performance and can be used based on network settings and requirements to prevent DDoS attacks. Fig. 1 shows a machine learning-enabled DDoS detection architecture.

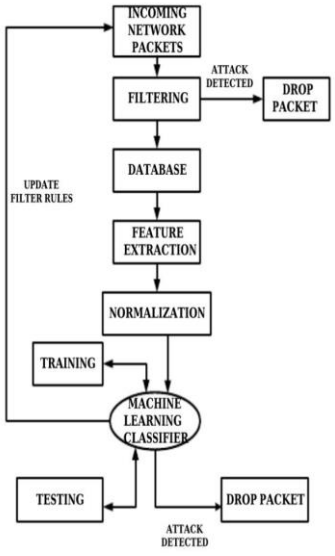

Fig. 1. DDoS attack detection architecture based on machine learning.

E. Accuracy and Adaptability

It is essential for AI-based detection models to provide accurate detection results to protect networks against unauthorised access and use. Models with the greatest accuracy rates are adaptable under certain standards. Detection models should be able to predict possible abnormalities in the network and must inform administrators to timely mitigate those abnormalities. AI-powered detection models can prevent DDoS attacks and protect networks by focusing on security and privacy [22]. The accuracy of machine learning detection models can be determined using Eq. (1).

$$Accuracy = Number\ of\ Correct\ Predictions / Total\ Number\ of\ Predictions \quad (1)$$

IV. Methodology / Approach

A. Research Design

This study uses qualitative research methodology to investigate several AI models and employ them in the DDoS detection system. Using qualitative research methodology, this study aims to explore the application of AI to detect DDoS attacks in real time in banks to find the most accurate methods to improve network security. Qualitative research methodologies encompass the use of theory and literature to explore the diverse perspectives, experiences, and behaviours of people. This approach is carefully chosen to explore and compare machine learning detection models to detect and prevent DDoS attacks. Conducting a qualitative analysis of existing literature helps in understanding the different available methods and their accuracy. This analysis may assist in determining which method is most accurate to avoid network disturbances and breaches. The objective of this study is to compare detection models based on their performance and accuracy scores and propose further improvements to enhance the security of organisational and institutional networks.

B. Research Setting and Participants

The research setting consists of private banking institutions. The participants are banks that have experienced DDoS attacks in the previous two years and used different detection and prevention techniques to prevent further attacks. They also include all researchers who presented relevant experiences regarding AI-detection methods and accuracy measures. Banks are chosen in order to study the use of AI in the detection of DDoS in real-time. Moreover, AI-powered methods are effective at detecting these attacks and maintaining security standards.

C. Data Collection

The data collection method started with the use of Google Scholar, wherein different resources were collected using several research terms such as 'Denial of Service Attacks,' 'Applications of AI in detecting network attacks,' 'network security,' and 'ML models of detection.' These search terms were chosen to retrieve relevant results from the search engine. Different articles were reviewed to collect relevant information and then compared with the observations gained from the AI detection models implemented in banks to avoid DDoS attacks. The comparison aims to understand how different models work in theory and practice as well as how they could be improved further to detect and prevent DDoS attacks in various institutional settings. Through this comparative analysis strategy, the research aimed to collect and evaluate diverse perspectives and experiences to inform its findings and conclusions. Research results would contribute to the existing literature by presenting a novel dimension of DDoS and network attacks.

D. Data Analysis

The thematic analysis approach was utilised to analyse data collected from the literature review. Resources were carefully selected and analysed to guide research problems. DDoS attacks are a wide research topic that researchers have extensively explored from different dimensions. It was ensured that the proposed research problem addressed a novel concern, and relevant literature was used to guide the research. The analysis process was detailed and comprehensive to enhance the study's credibility and guide research conclusions. Data collected from the literature review and banks using AI models to detect and prevent DDoS attacks was analysed collectively to guide discussions and the research conclusion. Three banks were randomly selected to provide e-banking services. Real-time e-banking transactions were checked to track fraudulent activities. An in-depth analysis of e-banking transaction logs was conducted. Banks employed a multi-layered security approach to prevent DDoS attacks, including the use of one-time passwords to ensure that authorised users have access to their accounts. Data from banks using AI-powered solutions to ensure their data is protected and the minimal probability of attacks was analysed. Two banks use blockchain-powered DDoS mitigation strategies and solutions to prevent DDoS attacks. Analysis of real-time e-banking transactions of banks revealed that AI and machine learning models/applications provide real-time protection to online transactions and ensure that institutional and customer data is protected from unauthorised access or breaches. The analysis of the collected data aimed to provide an in-depth understanding of Internet networks prone to DDoS attacks, the nature of attacks, causes and effects, methods to detect and prevent them, and ways in which these methods could be further improved. Furthermore, the correlation between research objectives and themes is also discussed. It highlights how information gained from these themes guides understanding of the research problem and convinces the need for improved security protocols to prevent future DDoS attacks. Thematic analysis not only summarises research findings but also contextualises these findings for readers and future researchers.

E. Ethical Considerations

Research ethics were followed throughout the research process. All resources utilised during the literature review were properly acknowledged through appropriate citations and references, giving credit to the authors. The literature analysis was presented without any personal amendments or changes. All three banks approached to investigate how AI is helpful in detecting DDoS attacks in real-time requested not to reveal their identities in the research paper. In order to respect their privacy, their identities have been concealed, and all discussions pertaining to them have been conducted anonymously. The study addresses biases and conflicts observed in research studies. It ensures that personal conflicts

and biases are avoided throughout the paper to ensure the generalisability of the results and maintain integrity throughout the research process.

V. RESULTS

A. Machine Learning Models

This research paper examined and compared five machine learning models: random forest, DT, CNN, NGBoosT classifier, and SGD. Different performance parameters were used to compare the precision and accuracy of each machine learning model. The accuracy score of each model is illustrated in Fig. 2.

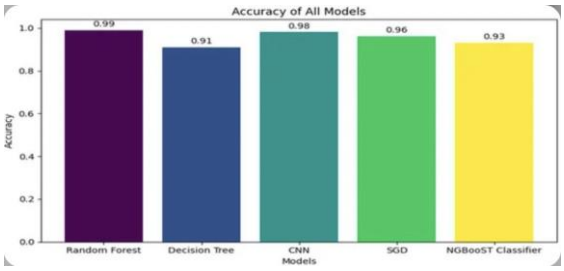

Fig. 2. Accuracy of all models.

Accuracy is a quantitative measure that quantifies the ratio of false negatives and positives to the terms present in the numerator. The numerator further specifies the sum of true negatives and true positives. Eq. (2) defines accuracy as follows:

$$Accuracy = ((TP + NP) / (FP + FN)) * 100 \quad (2)$$

The accuracy scores were used to measure the effectiveness of the five machine learning models in detecting DDoS attacks. Fig. 2 presents the ideal accuracy score of 0.99 for the random forest machine learning model. The purple bar of the random forest model shows how accurate the prediction would be compared to the rest of the four machine learning models. Similarly, CNN, SGD, NGBoosT classifier, and DT show accuracy scores of 0.98, 0.96, 0.93, and 0.91, respectively. Hence, based on the accuracy scores, the random forest machine learning model is the most effective for implementation in institutional settings, whether banks or other organisations, to detect and prevent DDoS attacks [23].

B. Comparative Analysis of Machine Learning Models

A comparative analysis of five machine learning models reveals that each model has its strengths and weaknesses. The random forest model is effective in making predictions for complex settings and is conveniently adjustable in different SDN settings compared to DT and NGBoosT classifiers. The random forest model offers flexibility in different domains compared to NGBoosT, which cancels overfitting into multiple settings. All five machine learning models differ in their approach to handling DDoS attacks in different settings. The accuracy and precision rate of each model differ, highlighting the usefulness and performance of each model in institutional settings. Each model can be individually deployed in different institutional settings based on the security requirements and infrastructure of that institution [24].

VI. DISCUSSION

A. DDoS Attack Detection and Prevention in Banking Industry

An in-depth analysis of the e-banking transaction logs of three banks reveals that AI applications are helpful in detecting and preventing DDoS attacks in real time. In banking institutions, blockchain-powered DDoS mitigation strategies are utilised to enhance security standards and protocols. Banking institutions are implementing strong security protocols and exploring new defences against DDoS attacks. They are using AI models to build strategies for identifying the origins and underlying causes of attacks. Eliminating traditional DDoS prevention approaches, banks are deploying advanced security measures to avoid financial and non-financial losses. Machine learning and AI have made it possible to automatically detect and prevent DDoS attacks [25].

Based on the analysis of existing detection and prevention models implemented by banks, some changes are proposed. With the following structure, the random forest model would provide the most accurate predictions about DDoS attacks.

The proposed changes in the DDoS detection and prevention models would yield outstanding outcomes and protect real-time customer interactions and transactions. This is depicted in Fig. 3.

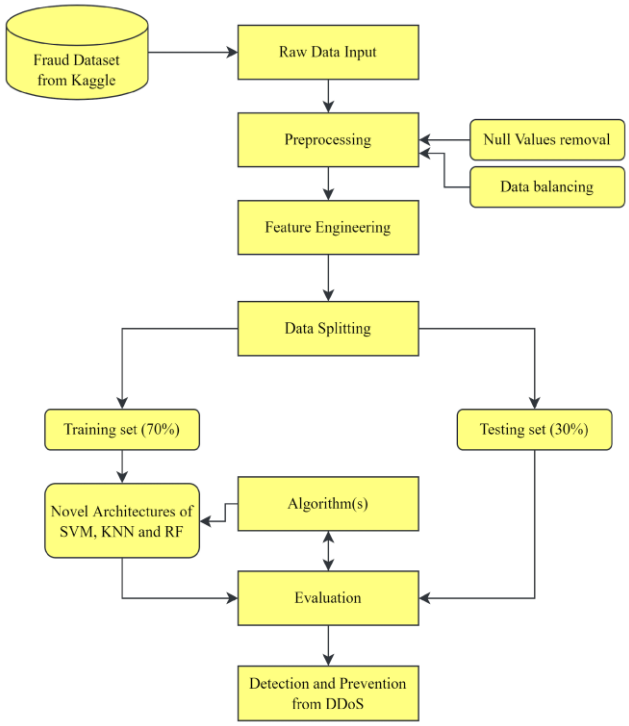

Fig. 3. Proposed machine learning model using e-banking datasets.

B. Adopting Advanced AI Solutions to Detect and Prevent DDoS Attack

In the context of cyberattacks and threats, organisations should understand the importance of advanced and updated AI models to detect and prevent DDoS attacks. Along with advancements in machine learning and AI, cyber threats are

evolving. Therefore, it is essential to timely understand the need for improved machine learning models and integrate them as needed to avoid network breaches and data thefts. Organisations and administrators can focus on evolving AI trends and models being deployed to prevent DDoS attacks. Based on the accuracy code and analysis of the machine learning models used in this study, the random forest model is most suitable for predicting DDoS attacks.

C. Privacy and Confidentiality

Banks are dealing with highly sensitive customer information that could cause major complications if breached. Banks have a paramount responsibility to protect their customers' privacy and confidentiality. This can only be achieved by using upgraded security protocols. Literature analysis reveals that corporations and organisations use different detection and prevention mechanisms to avoid financial and non-financial losses due to DDoS attacks. In dealing with customers' private information, organisations such as banks are expected to adopt ever-changing AI applications that protect network traffic and ensure no abnormalities exist. Collaborative DDoS attack detection and prevention methods can be used to detect attacks at different locations before they occur.

D. Implementation Challenges

The implementation of a machine learning model to protect organisational networks against DDoS is a challenging task. Organisations can protect their networks against these attacks by deploying advanced machine learning and AI-powered solutions and technologies. One of the biggest challenges is that machine learning and AI require a large amount of labelled data to make accurate predictions. Obtaining detailed data in any SDN setting is challenging, which limits the adaptability of these models to effectively detect and prevent DDoS attacks in every situation. Another challenge is resource allocation. The deployment of machine learning models requires heavy investments, imposing financial burdens on organisations. Moreover, not all organisations can afford the cost. In addition to purchasing and implementing machine learning models, regular updates and space requirements are also a concern. Organisations spend to mitigate cyberattacks; however, it is expensive to deploy machine learning models as they require planning from resources to training for successful deployment. To cut cyberattack costs permanently, organisations should consider and prioritise the implementation of machine learning models according to their needs and security infrastructure. This will ensure they have strong security protocols and that their assets are protected from unauthorised access and theft.

Financial institutions, such as banks, are at great risk because of the monetary value of their data. Based on our analysis, the random forest machine learning model is one of the most effective models for making accurate predictions. By enhancing its adjustability, this model can be implemented in financial organisations to timely detect and prevent DDoS attacks. The random forest model can detect abnormal traffic in a network to make predictions regarding the occurrence of a DDoS attack at a certain point. Financial institutions can effectively implement this model to avoid additional expenses associated with addressing cyberattacks and data theft [26].

VII. Conclusion

The Internet has transformed the world over the years. It has become an essential need for every institution and organisation. In this fast-paced world, the Internet is transforming lives and complicating things as well. Cyberattacks have become commonplace in the technically advanced world, wherein an unknown person can assess the private information of institutions or organisations. A DDoS attack is a form of cyberattack in which hackers take control of the central controller to disrupt or completely damage a network. Hackers can launch this attack from any server. The detection and prevention of DDoS attacks is a complicated and sometimes impossible task.

This paper aims to investigate the role of AI in the detection and prevention of DDoS attacks in real-time. To achieve this objective, data was collected and analysed from existing literature and three anonymous banks. Data analysis reveals that institutions are using attack mitigation techniques; however, these techniques are not as effective as machine learning models in defending against DDoS attacks. From the reviewed machine learning models, the random forest model is the most effective model to implement in organisational settings to detect and prevent DDoS attacks promptly. Considering the frequency of cyberattacks, researchers strongly advocate for the integration of machine learning models into the strategic planning of large organisations and institutions. This will help mitigate long-term challenges by ensuring they implement advanced security protocols. It is recommended that, with evolving technologies, organisations understand the dynamic need for security upgrades to compete efficiently in the industry.

VIII. Future Work

This research discussed five machine learning models and found that the random forest model makes more accurate predictions than the other models. Future researchers can conduct further work on the accuracy and effectiveness of the random forest model and why it is most accurate compared to other models. Future research can highlight how machine learning models are making a difference compared to traditional models in detecting and preventing DDoS attacks. Researchers can also explore how the random forest model effectively detects DDoS attacks in different network settings. The adjustability, accuracy, and precision of the random forest model can be studied in detail to justify its effectiveness in comparison to other models.

Moreover, advancements in prevention and detection techniques and mechanisms can transform organisational outcomes. Hence, by integrating and adopting advanced machine learning models to detect DDoS attacks, organisations can safeguard customers' privacy and confidentiality and streamline their everyday operations.

A Hybrid Regression-Based Network Model for Continuous Face Recognition and Authentication

Bhanu Kiran Devisetty*, Ayush Goyal, Avdesh Mishra, Mais W Nijim, David Hicks, George Toscano
Department of Electrical Engineering and Computer Science, Texas A&M University-Kingsville, Kingsville, Texas

***Abstract*—This research proposes a continuous remote biometric user authentication system implemented with a face recognition model pre-trained on face images. This work develops an algorithm combining the Hybrid Block Overlapping KT Polynomials (HBKT) and Regression-based Support Vector Machine (RSVM) methods for a face recognition-based remote user authentication system that uses a model pre-trained on the ORL, Face94 and GT datasets to recognize authorized users from face images captured through a webcam for continuous remote biometric user authentication. HBKT polynomials enhance feature extraction by capturing local and global facial patterns, while RSVM improves classification performance through efficient regression-based decision boundaries. The system can continuously capture user face images from the user's webcam for user authentication, but it can be affected by lighting variations, occlusion, and computational overhead from continuous image capture. This has been implemented in a Python program. The proposed method, when compared to previous state-of-the-art algorithms, was observed to have higher F-measure, accuracy, and speed, for most of the cases. The proposed method was observed to have accuracies of 98.82% (ORL dataset), 96.73% (GT dataset), and 95.9% (Face94 dataset).**

I. INTRODUCTION

Before allowing a user access to a secured location, resource, or system, authentication confirms the user's identity using specific credentials. Generally speaking, authentication only occurs during the user's initial interaction with the system [1]. Under these circumstances, the user is prompted with knowledge-based authentication that resembles password inquiry. The author is deemed authenticated if the user correctly replies with an example password [2]. However, one-time authentication is the standard for authentication; researchers have examined a variety of concerns, including security flaws and user dissatisfaction. For instance, when trying to unlock a smartphone with a pattern- or password-based authentication system, the user must concentrate on multiple authentication processes [3]. Driving while distracted is one concern that could arise from this for user safety. One-time authentication's lack of ability to identify attackers after the initial authentication is a significant security vulnerability [4]. For instance, if an authorized user forgets to log out or leaves their authenticated device unattended, an unauthorized user may be able to access their private resources. The above mentioned issues have prompted research into continuous authentication techniques [5]. To ensure the person who used the device to authenticate themselves the first time is still using it, these methods keep an eye on how the user interacts with it even after logging in. Simple security measures that lock users' devices and require them to re-enter their passwords after a certain amount of inactivity served as the foundation for the first attempts in this approach [6]. Though there is potential for improvement, such systems may upset people while they present a window of vulnerability. There are significant increases in the research literature on using behavior metrics, such as keystroke frequency, and biometrics, such as facial features, for continuous authentication [7]. This field has seen rapid growth, as evidenced by the numerous publications in the last ten years.

Researchers' interest in wearable medical sensors (WMSs) has grown, and these devices are beginning to be used in clinical settings. These sensors measure biological data, such as body temperature, blood pressure, and heart rate. The sales of 33 million wearable health monitoring gadgets, according to a recent Business Insider piece, are also analyzed [8]. According to the forecast, this number will rise quickly after reaching 148 million in 2019. The author proposes that such biomedical signals can also be utilized to provide authentication since they will be gathered in any case for health monitoring purposes [9]. Three factors make using biological data continuously collected for user identification and verification seem promising [10]. First, there is no need for an additional device on the body to use biological signals for authentication if WMSs are already gathering them for medical purposes. Secondly, the user is not heavily involved in collecting this data, as it is done transparently. In contrast to conventional biometrics and behavior metrics such as facial features and keyboard patterns, which may sometimes become unavailable, the biomedical signal stream obtained from wearable medical devices (WMSs) remains accessible as long as the user wears them [11] – [15]. The challenges encountered in the existing approaches are resolved using the anticipated model discussed below:

The transparent continuous authentication system H-RSVM is presented in this paper. It is based on a set of facial images provided to validate the user's authenticity. It is generally called the face recognition process. Image samples are continuously collected from the available online resources for diagnostic and therapeutic reasons. The primary distinction between a biometric characteristic and an input image is that the latter lacks the necessary discriminatory capacity to identify individuals independently. Therefore, it is doubtful that an authentication decision based solely on facial images will be adequately discriminative. Still, integrating many image samples into a single framework makes for a powerful continuous authentication mechanism. This study improves the biometric

remote authentication using HBKT polynomials integrated with RSVM, and makes it faster and more accurate than earlier studies. It affords a smooth, uninterrupted user authentication through the actual capture of images by webcams for real time and non-intrusive authentication. The proposed method is very stable and optimized for use in applications like secure remote authentication. The following sums up our primary accomplishments:

1) For the design of any continuous authentication system, this work proposes a novel H-RSVM where the features from the image datasets are analyzed and classified to have better prediction accuracy.

2) To assess the ability of prediction and to differentiate individuals, these works propose implementing a continuous authentication system known as H-RSVM and analyzing its accuracy and scalability.

3) We present a method for adaptive authorization and discuss its potential application in resolving challenges faced by users due to possible erroneous restrictions imposed by continuous authentication systems. This work outlines several potential defences against the suggested continuous authentication method and many ways to avoid them.

The work is structured as follows: Section II gives an extensive analysis of various prevailing approaches used for authentication during face recognition. Section IV delves into the problem statement. The methodology is elaborated in Section IV. The numerical outcomes are discussed in Section V, and work summarization is provided in Section VI.

II. Literature Review

It has been suggested in numerous research studies that biometrics be used for ongoing user authentication. In real-time authentication, inertial data demonstrates location, movement and device orientation concerning its surroundings [16]. Based on user activity, nonintrusive authentication techniques utilize this data to generate behavioral characteristics, such as voice, hand gestures, keyboard patterns, locomotion, touchscreen operations, and signature movements. Yu et al. [17] were the first to use a one-class distance-based classifier and build a sizable dataset for continuous authentication. They combined touchscreen, pressure, acceleration, time interval, and touch area size data with inertial data from the device's gyroscope and accelerometer. Their objective was to discern the authenticity of smartphone users, distinguishing between genuine and fraudulent individuals [18]. By generating research profiles, they achieved an Equal Error Rate (EER) of up to 3.6%, which varied depending on how each user held their device while entering their Personal Identification Number (PIN). By examining keyboard and handwriting data gathered from password submissions, Sun et al. [19] validated smartphone users in their study using deep learning techniques. The researchers categorized the images using various models, such as Naïve Bayes, Bayesian Net classifiers, and multilayer perceptrons (MLP) [20].

In a subsequent study, Menotti et al. [21] utilized a comprehensive dataset from Google's Abacus project, employing advanced techniques such as time-based deep feature extraction. Their research's main goal was to develop user authentication, and they did so by using recurrent and convolutional neural networks (CNNs and RNNs, respectively). The Google Abacus dataset, which includes 1500 people's information in their natural settings, was used for this. It is crucial to remember that this dataset is not publicly accessible. The researchers used the D-RNN model to categorize the data. Qin et al. [22] used the HMOG dataset, which included more than 27,000 samples from 10 participants, to show notable progress in the field. Wavelet, frequency, and time domain features were used to test algorithms like SVM, K-Nearest Neighbors and Hidden Markov Models. Based on an adaptation of Zhu et al. [23], speech, keyboards, touchscreens, gestures, handwriting, and mobility have all been studied in research. The requirement for user input during the whole authentication procedure is the primary disadvantage of gesture-based research [24]. It is impossible to identify an unauthorized user after the device is unlocked. However, compared to other methods, keystroke dynamics solutions are more constrained and require more data since they are impacted by fluctuations in user behavior, such as moods [25].

Moreover, changing keyboards may cause previously taught actions to become erratic. Additional research constraints conducted using touchscreens include the variability of interactions based on the device's orientation and the influence of user behavior on the level of interactivity [26]. Handwriting-based methods are seldom designed to support continuous authentication due to the smartphone's inability to detect pattern changes accurately. Speech-based authentication technologies are also hindered by background noise from the surrounding environment [27]. Furthermore, gait-based recognition, which relies on maintaining consistent positioning of the body's sensors, is vulnerable to modifications in walking patterns resulting from adjustments in clothing. Various projects have been dedicated to verifying human actions in a specific work context, such as retrieving a phone from a surface, initiating a phone call, or inputting a password [28]. While a more straightforward machine learning problem might yield better outcomes, it needs more consistency. For instance, the phone only knows how to classify various behaviors once the same activity is performed frequently once a user has been granted permission. Two different user activities are detectable by motion sensors. While the second is complex, the first is easy. Simple activities include sitting, sleeping, walking, climbing and descending stairs, and lying down [29]. In contrast, complex tasks involve riding a bike, exercising, changing clothes, and operating a vehicle. A method for determining when people are driving, biking, walking, using the bus, or utilizing the train in real time was created by Vijaya et al. [30]. This technique makes use of accelerometer and GPS data. They demonstrated that GPS data processed using principal component analysis (PCA) and recursive feature elimination (RFE) in conjunction with a random forest (RF) classifier yielded 96% accuracy. However, because GPS requires user clearance to access data and has high battery consumption, its usage in CA contexts is not practicable for real-world deployment. Support vector machine (SVM) models using accelerometer and gyroscope data were developed [30]. The model they developed was able to identify 95% of the different walking patterns, including going upwards (79%), standing (92%), sitting (94%), lying down (100%), and climbing

stairs (72%) [31] – [35]. Similar methods were used to investigate human activity detection with artificial neural networks and deep learning, yielding a 95% accuracy rate.

III. PROBLEM STATEMENT

The challenge in continuous user authentication is to create effective and non-intrusive method to distinguish between genuine and fraudulent users in various real-world conditions. Existing methods such as Gesture based, keystroke dynamics, and speech-based authentication continue to face challenges of variation, noise or changes in orientation thus producing varying results. Further, gait-based recognition is vulnerable to cloth variation or change of body posture whereas the GPS based systems though very accurate are not feasible due their high-power consumption and privacy issue. Thus, the problem is to develop a continuous authentication framework that combines multiple behavioral and biometric data and real-time authentication with minimal user input. The proposed method provides better optimal accuracy and flexibility by utilizing combined behavioral parameters and biometrics to enhance security to particular contexts of use without compromising the convenience of the end-users.

IV. METHODOLOGY

Face recognition is required in various applications, and significant progress has been identified in this research. The proposed work of remote user access with face verification consists of the following stages. Samples of face images from databases and the overall architecture are shown and discussed.

A. Dataset

The 400 grey-scale pictures in the AT&T database, once called "The ORL Database of Faces," feature 40 subjects [36-37]. Each issue has ten pictures that include every potential combination of attributes. Each subject's face samples are provided in the Portable Gray Map (PGM) format. Fig. 1 displays a variety of face samples from the databases that are utilized for training the model used in this work.

B. Pre-processing

It is the most widely utilized method for completing pre-processing. It changes the values in the image to fall between 0 and 1. Zero means and z-score normalization are the normalization techniques taken into consideration here, as stated in the equation below:

$$X_i' = \frac{X_i - mean\ (X)}{SD\ (X)} \tag{1}$$

In this case, the symbol X_i' represents data that has been normalized. The average value of the input X is represented by the mean (X), and the SD (X) represents the standard deviation. The equation below gives the expression for computing standard deviation:

$$\sigma = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N}\left(X_i - mean\ (X)\right)^2} \tag{2}$$

In this case, the provided input values' standard deviation is indicated as σ.

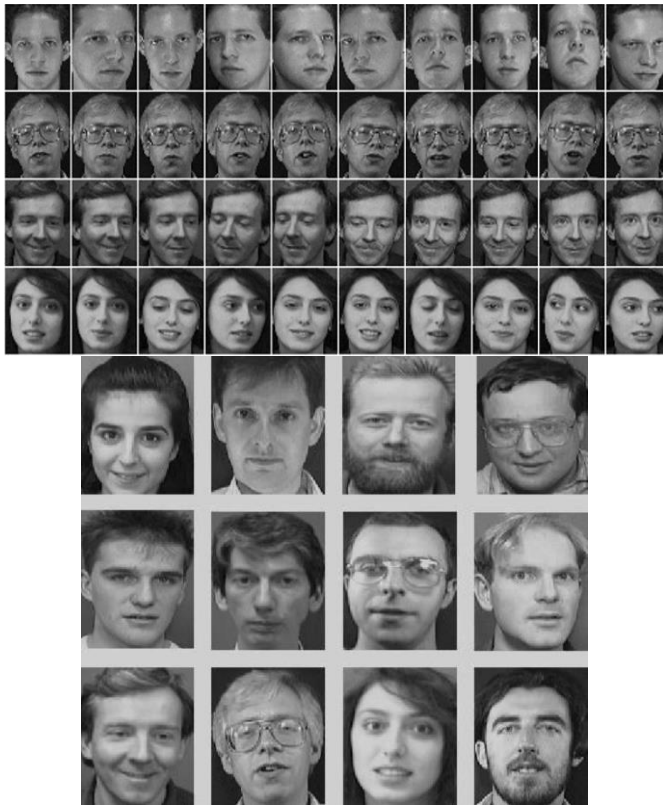

Fig. 1. Samples from the face image databases [36-37].

C. Feature Extraction

The weighted and normalized Krawtchouk polynomial's nth order is defined in the equation below as follows:

$$K_n\ (x; p, N-1) = \sqrt{\frac{\omega_K(x)}{\rho_K}}\, F_1\left(-n, -x;\ -N+1;\ \frac{1}{p}\right)$$

$$\text{where, } n, x = 0,1, \ldots, N-1;\ p \in (0,1) \tag{3}$$

Fig. 2 shows the overall architecture and functionality of the proposed work, which includes both feature extraction using HBKT polynomials and face recognition using RSVM.

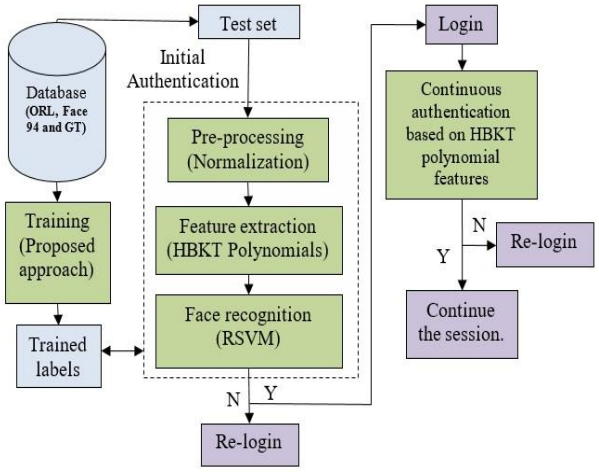

Fig. 2. Overall architecture of proposed work.

The norm and weight functions of the KP, denoted by ρ_K and ω_K, have been defined in the following manner:

$$\omega_K(x) = \binom{N-1}{x} p^x (1-p)^{N-x-1} \quad (4)$$

$$\rho_K(n) = (-1)^n \binom{1-p}{p}^n \frac{n!}{(-N+1)_n} \quad (5)$$

The three-term recurrence method is utilized to estimate KP coefficients since it is more computationally expensive to calculate KP coefficient values employing gamma and hypergeometric functions. Numerous studies have looked into this strategy. The author offered initial recurrence relation in n −direction and established recurrence relation. The recurrence relations divide the n- x plane into two regions. One of these regions has its KP coefficients computed, while the other region's coefficients are derived using a symmetry relation.

The author suggested using a dual n −direction recurrence relation involving forward and backward computations to find new KP coefficients. KP plane comprises four triangular sections for which coefficients are determined for two of the triangles. In contrast, the remaining two triangles' coefficients are derived using symmetry relation. To compute KP coefficients, a rapid recurrence relation was recently developed. As shown in Fig. 3, this entails partitioning KP space into sections designated by both primary and secondary diagonals.

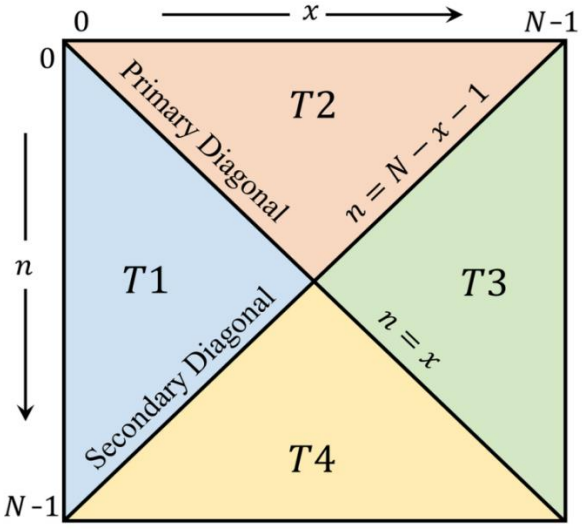

Fig. 3. KP plane.

For a wide range of parameters p, this method was better regarding computing speed, accuracy, and handling large signal quantities. In light of this rationale, the algorithm proposed is examined in this investigation. The procedure for computing the KP coefficients, denoted as $K_n(x;\ p, N-1)$ for brevity, is outlined in Fig. 4 (hereafter referred to as $K_n(x)$).

1) First, we compute $K_n(0)$ and $K_n(1)$ as follows:

$$K_n(0) = \sqrt{\frac{(N-n)p}{n(1-p)} * K_{n-1}(0)} \quad (6)$$

$$K_n(1) = \frac{-n+p(N-1)}{p(N-1)} \sqrt{\frac{(N-1)p}{(1-p)}} K_n(0) \quad (7)$$

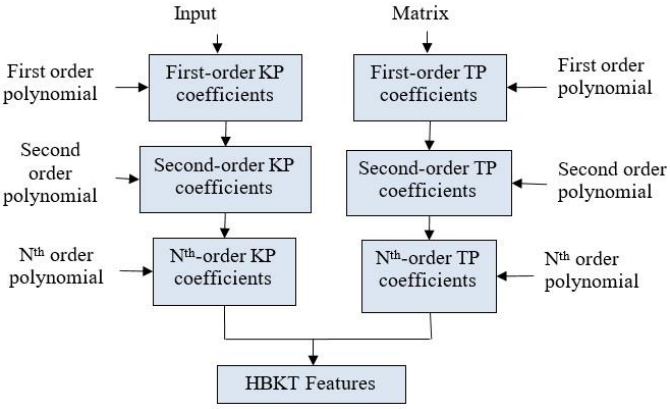

Fig. 4. HBKT feature extraction.

2) The recurrence relation in $the\ n$ direction can be used to determine KP coefficients within the temperature range T1.

$$\gamma_1 K_n(x+1) = \gamma_2 K_n(x) + \gamma_3 K_n(x-1) \quad (8)$$

$$\gamma_1 = \sqrt{p(N-x-1)(1-p)(x-1)} \quad (9)$$

$$\gamma_2 = -n + p(N-x-1) + x(1-p) \quad (10)$$

$$\gamma_3 = \sqrt{x(1-p)p(N-x)} \quad (11)$$

3) Using the symmetry connection about the main diagonal at n = x, the coefficients within the temperature range T2 can be found.

$$K_n(x) = K_x(n) \quad (12)$$

4) The symmetry relation concerning the secondary diagonal at $n = N - x - 1$ can be used to find the coefficients inside the temperature ranges T3 and T4.

$$K_{N-x-1}(x) = (-1)^{N-n-x-1} K_n(x) \quad (13)$$

5) The KP coefficients for p more significant than 0.5 values are computed using the equation below.

$$K_n(x: 1-p) = (-1)^n K_n(N-x-1; p) \quad (14)$$

D. Tchebichef Polynomial

The weighted and normalized TP's n^{th} order can be defined as follows:

$$T_n(x) = \sqrt{\frac{\omega_T(x)}{\rho_T(n)}} (1-N)_n F_2(-n, -x, 1+n; 1-N; 1), n, x = 0,1,\dots,N-1 \quad (15)$$

This formulation involves the weight function of the TP, represented as $\omega_T(x)$, and the squared norm of the TP, described as $\rho_T(n)$.

$$\omega_T(x) = 1 \quad (16)$$

$$\rho_T(n) = (2n)! \binom{N+n}{2n+1} \quad (17)$$

These are the definitions of these quantities. $\frac{a!}{b!(a-b)!}, F_2$ specifies the binomial coefficients, while $3F_2$ represents the hyper-geometric function:

$$3F_2\,(-n,-x,1+n;1,1-N;1)\;=\;\sum_{k=0}^{\infty}\frac{(-n)_k\,(-x)_k(1+n)_k}{(1)_k(1-N)_k k!} \quad (18)$$

$$(a)_k = a(a+1)(a+2).(a+k+1) \quad (19)$$

The computation of the rising factorial $(a)k$ can be determined by employing the three-term recurrence relation. This approach is precious in mitigating numerical instability and computational overload that may arise from using hyper-geometric and gamma functions for calculating TP coefficient values.

$$T_n\,(x) = \beta_1\,T_{n-1}\,(x) + \beta_2 T_{n-1}(x)$$

$$\text{Where } n = 2,3,\dots,N-1, x = 0,1,\dots,N-1 \quad (20)$$

With initial conditions:

$$T_0\,(x) = 1/\sqrt{N} \quad (21)$$

E. Krawtchouk and Tchebichef (KT) Polynomials

When features in the provided domain meet requirements for localization and EC attributes, managing elements becomes significantly easier. These capabilities greatly impact the processing stages as the signal can be described by characterizing its contents using a small number of moments. EC will reduce computational complexity because fewer moments must be computed to represent the signal fully. By identifying the region of interest (ROI), localization attribute in space provides further computational savings and facilitates feature categorization:

$$\mathbb{R}_n\,(x;N) = \sum_{j=0}^{N-1}\chi_j\,(x;p;N)\dot{y}_j(n;p,N) \quad (22)$$

$$n,x = 0,1,\dots,N-1 \quad (23)$$

To put it mathematically, the polynomial obtained by merging two OPs is also orthogonal. Combining two fundamental orthogonal polynomials, $Y_n(x;\,p,N)\;and\;X_n(x;\,p,N)$, yields the expression for the hybrid polynomial form $\mathbb{R}_n(x)$ at n^{th} order. The parameters defining these orthogonal polynomials denoted by p and N are built utilizing a particular combination level. The following are the formulas for $X_n(x;\,p,N)\;and\;Y_n(x;\,p,N)$.

$$\chi_n(x;p,N) = \sum_{i=0}^{N-1}K_i(n;p)T_j(x) \quad (24)$$

$$y_n(x;p,N) = \sum_{i=0}^{N-1}K_i(x;p)T_j(n) \quad (25)$$

$$n,x = 0,1,\dots,N-1;\; p\in(0,1)$$

The equation below can be used to express the suggested hybrid OP as follows:

$$R_n\,(x;p,N) = \sum_{i=0}^{N-1}\sum_{j=0}^{N-1}\sum_{l=0}^{N-1}K_j(i,p)T_j(x)K_l(n;p)T_l(i) \quad (26)$$

It is possible to express the equations using matrix notation. The polynomial forms of $R_n(x), X_n(x;\,p,N)$ $, Y_n(x;\,p,N), K_n(x), and\;T_n(x)$, respectively, correspond to the matrices $R, X, Y, R_k, and\;R_t$. In the equations below, it is demonstrated that the matrices KP and its transposition denoted as $R_k \equiv R_k^T$ are comparable. This significant observation highlights the symmetrical relationship between the KP coefficients along the major diagonal. Therefore, the related equations take on a particular form:

$$R = Y^T X \quad (27)$$

$$X = R_k^T R_t \quad (28)$$

$$Y = R_t^T R_k \quad (29)$$

$$R = (R_k R_t)^2 \quad (30)$$

In this context, the matrix transpose operator is denoted by $(\cdot)$. It is evident that $R_n(x)$ represents the squared expression of the sum of the Krawtchouk–Tchebichef polynomial (KP) and the Tchebichef polynomial (TP). Since the suggested set has a mathematical link with KP and TP, it can be represented by the squared Krawtchouk–Tchebichef polynomial (SKTP). Fig. 4 shows how the TP and KP modules generate the coefficients. It is noteworthy that, concerning KTP and TKP, SKTP has a notable localization characteristic and a higher EC property. Observing the SKTP coefficients symmetrically along the imaginary axis $x = (N-1)/2$ is possible. The SKTP coefficients of order $n = 127, 95, and\;64$ and those of order $n = 0, 31, and\;63$ are implied to correspond to this symmetry. In particular, $x = (N\,1)/2$ (imaginary axis), the SKTP coefficients range display symmetry are typically $n = \frac{N}{2}, \frac{N}{2}+1,\dots,N-1$. The values of $n = 0,1,\dots,N/2-1$ are included in these intervals. Moreover, the left half of the signal is associated with polynomial orders' coefficient within $n = 0,1,\dots,N/2-1$ range and the right half is related to the coefficients of polynomial orders within the range of $n = N/2, N/2+1,\dots,N-1$. Unlike TKP and KTP, where the indices of moments and signals are negatively correlated, the index of moments is linked to the indices of the signal in the signal domain. Furthermore, the SKTP basis functions for an $8*8$ block with diverse parameter p-values are shown in Fig. 3. The study reveals a gradual increase in low-frequency centre basis functions in vertical and horizontal orientations. The low frequency moves to the top left corner at a probability value of $p = 0.25$, as shown. Conversely, Fig. 3 illustrates that at a probability value of $p = 0.75$, the low frequency is displaced towards the lower right corner.

F. Regression-based Support Vector Machine (RSVM)

Support vector regression (SVR) was developed based on the support vector machine (SVM) methodology, primarily used for binary response variables. The fundamental concept behind SVR is constructing a tube with a width of ε around the data points, utilizing only residuals with absolute values more petite than a predetermined constant (referred to as ε-sensitivity). This concept is visually depicted in Fig. 5. In binary classification, two sets of points are established: those within a designated tube are not subject to penalties due to their proximity (within a predetermined threshold ε) to the predicted function. In contrast, those outside the tube are penalized based on their distance from the expected function. Support vector machines (SVMs) use a classification penalization strategy similar to this one. The methods of support vector machine learning (SVM) and support vector regression (SVR) rely on finding a hyper-plane that fits well in a feature space created by a kernel and can be efficiently generalized while maintaining the original features. Due to the scope of this book, an extensive examination of Support Vector

Regression (SVR) theory is not included. Whether SVR outperforms all other types of regression machines for continuous outcome prediction is also debatable. Because of this, we will now demonstrate how SVR is implemented in the e1071 library.

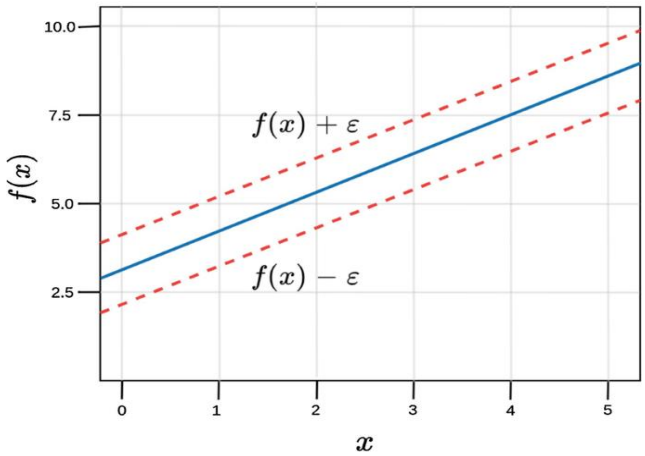

Fig. 5. Hyper-plane.

This part uses an FR system to evaluate the hybrid OP (SKTP) presented in terms of feature extraction. R-Support vector machines (SVM) are used in the facial recognition (FR) system's implementation. Fig. 5 shows the diagrammatic representation of the proposed method. The performance of KTP and TKP is evaluated against the hybrid OP, which can be generated using clear and noisy facial photographs within the FR system. The feature extraction process is the initial stage in the FR system. The image's height and width are extracted before any features are extracted using OP. We next use the given parameters, p and moment order, to generate the two polynomials, one for each dimension. Subsequently, the facial image is converted into the polynomial moment domain by applying the appropriate mathematical formula.

$$\Phi = R_1 \; if \; R_2^T \tag{31}$$

Here, R_1 and R_2 represent the produced polynomials and the face image. It is essential to highlight that the polynomial moment order determines the selection of the polynomial order. One can think of the generated moments (Φ) as a feature vector. The label of the matching face image ID is then appended to the feature vector. An array is created by combining all facial picture data in the database. The array is then normalized between -1 and 1 to guarantee that the features retain a constant dynamic range. SKTP and its hybrid versions, KP and TP, are evaluated for effectiveness and comparative analysis utilizing the AT&T facial database ORL. The database contains the faces of forty distinct persons. Each face image is 112×92 pixels in size. Ten photos of each person's face are taken at different times, with different lighting, expressions, and facial details. The RSVM model is trained using half of the face images during the training and testing phases. The moments taken from the data were used to train the RSVM model. The LIB-SVM was utilized to classify the data. RBF is employed in the RSVM model. Throughout the training phase, five-fold cross-validation was used to establish the gamma, cost and RSVM parameters. However, throughout the testing, various kinds of noise were added to every face image, making it challenging to assess SKTP's reliability. Three distinct forms of noise were employed during the degradation process: blur, salt and pepper, and Gaussian noise. Images without imperfections were utilized during the training phase exclusively. The classification accuracy is tested in the following ways to evaluate the classification's performance:

$$Accuracy = \frac{correctly\ predicted\ classes}{total\ testing\ classes} * 100\% \tag{32}$$

Ten separate testing and training images of faces were used for the testing and training stages to examine the stability of the categorization. The standard deviation and accuracy mean were computed for every ten iterations to evaluate the model's performance. Fig. 6 shows the separate training and testing phases in the face recognition system in this work.

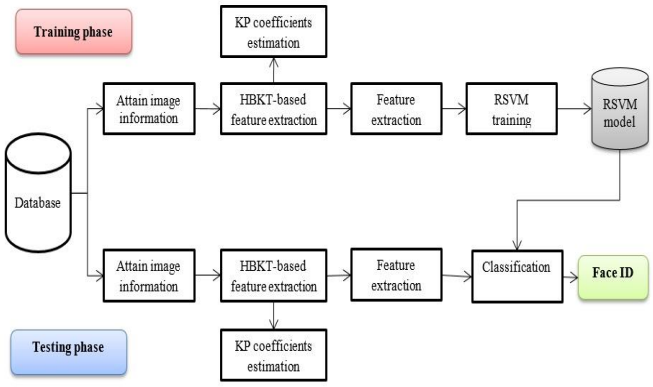

Fig. 6. Training and testing phases of the face recognition system.

G. Authentication

The evaluation of several continuous authentication systems presented in earlier research has yet to use various design criteria. A few studies consider limited requirements, such as accuracy and cost. Still, there needs to be a set of requirements for design that a continuous authentication system has to meet.

1) Passiveness: A system that is easy to operate shouldn't need constant user intervention. For instance, the user may find it very frustrating if the authentication system frequently requests that they re-enter their credentials.

2) Availability: A reliable authentication mechanism should always be available via the system. One major disadvantage of many previously suggested continuous authentication systems is that they are only sometimes available; they frequently fail because of insufficient data. In certain instances, a keyboard-centric system may erroneously decline access to a user engaged in movie viewing and not actively utilizing the keyboard.

3) High accuracy: High accuracy is, without question, the most crucial criterion for any authentication system. When a user attempts to log in as someone else, the system ought to be able to reliably and accurately identify them as imposters and deny their requests.

4) Scalability: With more users, the system should be able to manage an increasing volume of work. Its complexity in

terms of time and space should progressively increase with the number of users.

5) Efficiency: For two reasons, it is highly preferred to have a low response time or the amount of time needed to gather a test sample, analyze it, and render a conclusion. To promote user convenience, it is essential that the system rejects imposters and immediately authenticates legitimate users. Second, if there is a noticeable delay, security can also suffer. In the scenario where the authorization process requires five minutes, there is a potential vulnerability for an unauthorized individual to exploit the system and gain access to restricted resources during the on-going processing period, which lasts five minutes.

6) Low cost: The cost is a significant consideration regarding authentication methods used in low-security settings, like home computers. An authentication system should ideally be inexpensive to implement or alter in such contexts. Thus, systems without extra peripherals, like retina scanners, would often be preferred. However, expensive authentication systems could be used in highly secure areas like military bases.

7) Stability: Ideally, a feature should only slightly vary or retain its pattern for a specific time before being recorded for processing to facilitate authentication.

8) Extensibility: It should be possible for the authentication system to work on a broad range of devices independent of the underlying technology. No specific hardware should be needed for the system. One benefit of password-based authentication is its extensibility, which protects numerous methods, devices, and resources with limited system modification.

V. Results and Discussion

The proposed approach of remote user authentication based on face recognition is implemented in Python. The proposed work's environment is defined in Table I for when the face recognition based remote biometric user authentication system is implemented in real time on a login server.

After that, this work reviews five metrics employed to evaluate the suggested authentication system's accuracy. Traditionally, authentication systems are examined using the first three. To explore the precision of continuous authentication, we introduce two additional variables.

A. Metrics

The following metrics will be used in analyzing the results of applying the proposed method for face detection to perform facial user authentication in a remote biometric user authentication system:

1) False acceptance rate (FAR): The percentage of illegal users who are inadvertently approved in continuous authentication as opposed to the total number of fraudulent login attempts is known as the "False Acceptance Rate" (FAR). We use the notation $FAR_t = T_{EW}$ to describe the FAR below a given threshold, TEW. When security is the primary priority, it is advised to have a lower FAR.

2) False Rejection Rate (FRR): This indicator shows the percentage of legitimate requests mistakenly denied by users who have been granted authorized access to the system. The false rejection rate (FRR), when TEW is met, is shown by the notation $FRR_t = T_{EW}$. Because it improves user convenience, a lower FRR is preferred.

3) Rejection Rate (RR): This typically represents the total number of rejections (both legitimate and illegitimate) over the total number of attempts. In the context of authentication systems, this would mean how often access attempts are denied, regardless of whether those attempts are valid or invalid. RR Relationship to FRR (False Rejection Rate): The FRR is a subset of the RR, specifically focusing on the rate at which legitimate attempts (i.e., from authorized or genuine users) are incorrectly rejected. In contrast, RR could include all rejections, making it a broader measure. While FRR is a measure of system accuracy in identifying valid users, RR provides an overall view of the system's strictness or leniency in granting access.

4) Equal Error Rate (EER): Currently, it is noted that FAR and FRR are equivalent. However, because there is a trade-off between the two measurements, reporting FAR or FRR alone does not provide a complete picture. One rate can be lowered while permitting the other to rise. Therefore, we use EER (Equal Error Rate) rather than FAR or FRR to appropriately report the accuracy of H-RSVM (Context-Aware Behavior Analysis). This work uses $EER_t = T_{EW}$ notation to represent EER under TEW (Threshold Equal Weighting).

TABLE I. Recommended Login Server Hardware and Software Requirement

Requirements		
Sl. No	**Type**	**Specifications**
1	Processor	Intel(R) Core(TM)2 Duo CPU E8400 @ 3.00GHz 2.99 GHz processor (minimum hardware requirement)
2	Storage	195 GB (minimum storage requirement)
3	RAM	8.00 GB (minimum RAM requirement)
4	Display	Monitor resolution 1024x768 (minimum resolution requirement)
		Software Requirements
Sl. No	**Software type**	**Specification**
1	OS	Windows 10 Pro (or later)
2	S/W	Python (version 3.0 or later)

5) False Acceptance Worst-case interval (FAW): Within a specific time-frame, T, the authentication system generates accept/reject decisions as its output. Two potential output patterns can occur when an impostor attempts to authenticate in a ten-minute authentication period. Both sequences exhibit an equal number of incorrect authorizations. However, the second sequence is deemed more problematic as the impostor can exploit the system for a continuous duration of four minutes without being detected. It is a decline from the first sequence, in which the impostor was limited to one minute of system use. The most significant amount of time (minutes) that a fraudulent user could be mistakenly identified as authentic is what we refer to as FAW. FAW equals one minute in the first case and four minutes in the second.

6) False Rejection Worst-case interval (FRW): In a similar manner to the concept of a False Acceptance Window (FAW), the notion of a False Rejection Window (FRW) is introduced, denoting the maximum duration (measured in minutes) during which an authorized user may be mistakenly rejected and misidentified as an impostor.

7) Scalability metrics: The complexity of the authentication system, in terms of space and time, will experience a gradual increase as the number of users grows, as previously discussed. We use the well-known O notation to show the space and time complexity of the H-RSVM technique as a function of N, the number of individuals in the dataset, to measure the scalability of the suggested method.

We used Python to create an H-RSVM prototype to examine the authentication system's accuracy. The correctness of the model is usually assessed with a different data point set than those used to construct it. Thus, the dataset is divided into training and test sets to aid creation and assessment. However, evaluating the efficacy of a system processing time series data is unsuitable for the conventional K-fold cross-validation approach. Time series data comprises a series of measurements that frequently show local relationships between observations. Cross-validation ignores the structural characteristics introduced in the data by these dependencies. Therefore, in this work, we devised many experimental scenarios to assess the authentication system's accuracy instead of utilizing conventional cross-validation. These circumstances are discussed next.

8) Baseline: The available dataset was split into two equal portions to create the baseline scenario, which resulted in $TEW = TRW = 7h$. The model was trained over the half dataset, which comprised the first seven hours for every subject, and was tested on the second half. All bio-streams ($n = 0,1,2,..$) were used for system testing and training. R-SVM-based classification technique is used. Both linear and Radial Basis Function (RBF) kernels were used in the SVM example. Our experimental results show that the testing error diminishes and approaches the minimum while the training error decreases and approaches zero as the number of repetitions grows. As a result, we have chosen to run 40 iterations across each classifier. This work has provided the $EER_t = 7h$ value for each classifier.

9) Biased FAR_t/FRR_t: While it is simple to evaluate authentication methods using EER_t, in situations where high security is required, we may need to restrict F RRt to enhance user convenience or minimize FAR_t to prevent impostors from gaining access. A low FAR_t indicates strong security, while a low FRR_t ensures user convenience. We employ the same settings as the baseline in this experimental configuration. It is important to note that false rejection and false acceptance have different consequences. We analyze two situations: (i) measuring FRR_t and attempting to minimize FAR_t and (ii) measuring FAR_t and attempting to minimize FRR_t. The results for these two scenarios are presented in Table II. Despite a higher FRR, Table II shows that H-RSVM prevents acceptance of impostors. Table II demonstrates that H-RSVM does not negatively impact user convenience, as it correctly rejects impostors over 90% of the time without mistakenly leaving legitimate users.

10) Variable window size: This work set the training and testing window sizes to seven hours over the baseline. In this instance, we modify the testing and training window lengths as the total of the two amounts equals fourteen hours, with the training window length ranging from two to twelve hours. The average equal error rate (EER_t) for several classifiers relative to the training window size is also illustrated. When we increase the training window size from two to six hours, EER_t significantly decreases for all classifiers. After that, it stays the same until TRW approaches 11h. There are two possible reasons why EER has started to increase over this TRW. First, an over-fitting of the model is possible. Secondly, there could not be enough test points.

11) Moving training window: We tested various values for TEW and TRW. Our experiments revealed that this verification approach achieved the most favourable outcome when TEW and TRW were set to 4 hours. With 15 nodes' tree size, the classification method used was R-SVM, and the average equal error rate (EER_t) was determined to be 1.9%. The trained model must remain valid for the successive four hours to achieve maximum accuracy for TRW.

Table II provides the false acceptance rate (FAR), equal error rate (EER), accuracy, precision, recall, F-measure, and false rejection rate (FRR) metrics for the proposed RSVM method as compared to other state-of-the-art methods for the three different datasets.

Fig. 7 shows the performance comparison of the metrics such as accuracy, precision, recall, and F-measure for the proposed H-RSVM method compared with the other state-of-the-art methods when the ORL dataset is used for model training.

Fig. 8 shows the performance comparison of the metrics such as accuracy, precision, recall, and F-measure for the proposed H-RSVM method compared with the other state-of-the-art methods when the GT dataset is used for model training.

TABLE II. COMPARISON OF PROPOSED MODEL WITH EXISTING APPROACHES

Dataset	Method	FAR	EER	Accuracy	Precision	Recall	F-Measure	FRR

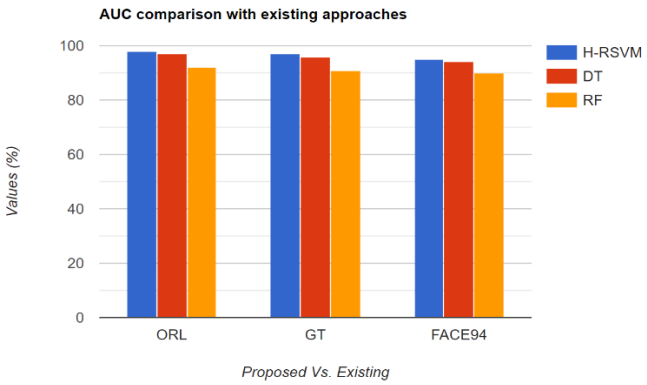

Fig. 15. AUC comparison with existing approaches.

Fig. 16 and Fig. 17 depict failed authentication and successful authentication use cases, respectively, using the proposed face-recognition-based remote authentication system. The model gives the correct prediction outcomes for both non-authorized user and authorized user with high rate of prediction accuracy. Based on the experimentation, it is proven that the anticipated model works well compared to other approaches, as discussed further below.

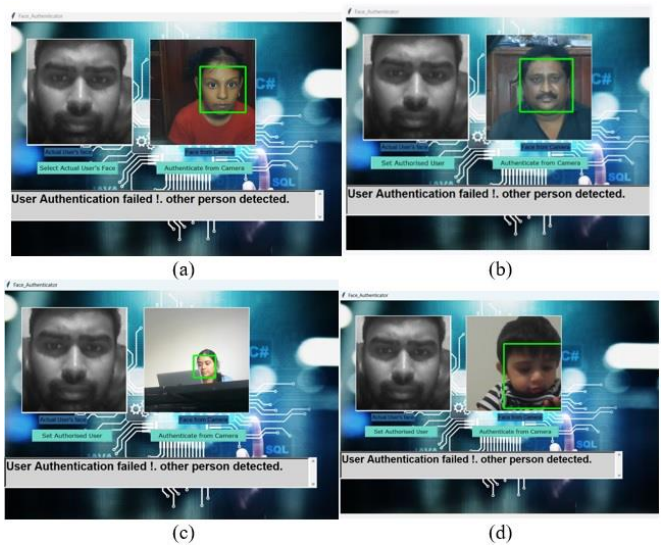

Fig. 16. Authentication outcomes for non-authorized users (a-d).

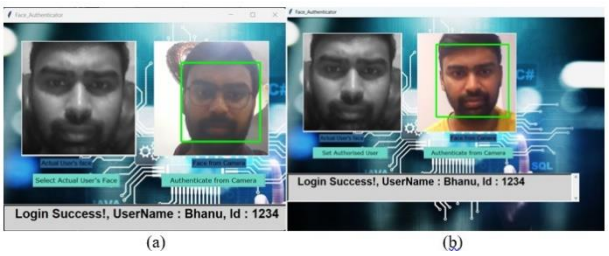

Fig. 17. Authentication outcomes for an authorized user (a-b).

Table II compares existing approaches like KNN, DT, RF and CNN. Metrics like FAR, EER, FRR, accuracy, precision, recall and F-measure are evaluated and compared. The proposed model gives 98.82% accuracy for the ORL dataset, 96.73% accuracy for the GT dataset, and 95.9% accuracy for the FACE94 dataset. The proposed model offers 98.23%, 96.16%, and 95.83% precision for the ORL, GT, and FACE94 datasets. It gives 98.19%, 96.08%, and 95.16% recall for ORL, GT, and FACE94 datasets. The proposed H-RSVM model gives 98.21%, 96.12%, and 95.49% F-measure for ORL, GT, and FACE94 datasets (see Fig. 7-12). Table III compares RR, authentication delay, and AUC evaluation with other approaches. The proposed model gives 98.04% AUC for ORL, 97% for GT, and 95% for the FACE94 dataset. The authentication delay is lesser for the proposed model, and the RR of the anticipated model is 97.19% for ORL, 94.07% for GT, and 93.15% for the FACE94 dataset, respectively (see Figures 13-15). Based on the observations, it is noted that the proposed model gives satisfying outcomes compared to other approaches.

B. Real-time Authentication

We define authorization at the outset of this section. Next, this work presents a real-time adaptive authorization (RAA) system that leverages H-RSVM's judgments to offer a tremendously flexible access control strategy. The RAA concept is not exclusive to H-RSVM. It provides a flexible model of access control that can be implemented in any authorization system that allows users to access content based on choices made by a continuous authentication method. Authorization determines whether to grant access to a system, resource, or location to a person who has already undergone authentication. Conventional authorization techniques use the user ID of an authenticated user to assign them a specific access level. However, as demonstrated by the non-zero FRR of continuous authentication systems, this simple method may unintentionally block allowed access if the authentication system cannot identify a legitimate user for a short time. Imagine a situation where a personal laptop is secured against unauthorized users using a continuous authentication method. The authentication technique authenticates the user at first. Using user ID, the authorization system establishes the user's access level. Nonetheless, the laptop can log users out if the authentication process unintentionally rejects them. The inconvenience resulting from false rejections can be reduced by using RAA techniques. These techniques continually adjust the user's access level following the authentication system's most recent determination. Here, we introduce an RAA technique with an ongoing authentication scheme.

A trust-based RAA modifies the user's access level in real-time using the trust level (TRL) parameter. Based on past choices made by the continuous authentication system, the recently established TRL metric measures our degree of confidence in a user. A higher number on the TRL scale, which ranges from 0 to 100, denotes a higher degree of trust. TRL has an initial value of 100 when a user is approved and authenticated. Following every user authentication, the trust update method continuously updates the TRL value. A simple technique for updating trust could involve increasing or decreasing TRL by a fixed amount following every accept or reject choice. The pseudo-code for this method is displayed in the trust update procedure. Two parameters, W_{accept} *and* W_{reject}, need to be set. When we are positive that a user is authentic, we should set the TRL value to 100. Otherwise, it has to be set to 0 immediately as we learn that an impostor exists. It indicates that the values of

W_{accept} *and* W_{reject} need to be chosen appropriately. In the worst-case situation, the authentication system can inadvertently deny three consecutive requests from legitimate users if, for instance, an SVM classifier with 15 nodes' tree size yields a false rejection rate of 3. The RAA approach concludes that a user is fraudulent ($TRL = 0$) if the authentication system rejects a request four times in a row. With this classifier, we can use the following formula to set the value of W_{reject}: $-100\ FRW + 1 = -100\ 4 = -25\ is\ W_{reject}.FAW = 4$ means that, in the worst situation, four successive tries would lead to mistakenly identifying an impostor as a valid user. TRL should be more prominent than 100 if the authentication system accepts five requests in a row. Therefore, the formula for setting W_{accept} is as follows: $W_{accept} = +100\ FAW + 1 = +100\ 5 = +20$. Various purposes may require different threshold levels to be specified. The work decided to restrict the threshold value for these accounts to 100 to ensure that the user can evaluate input images when the system is positive they are real. However, a lesser degree of trust might be adequate for less sensitive activities, like basic web browsing. When combined with RAA, H-RSVM can improve user-friendliness without compromising the high-security standards required for critical applications.

VI. Conclusion and Future Work

This work develops a continuous remote biometric user authentication system based on a face recognition model pre-trained on face image datasets. This research work implements an algorithm combining HB-KT Polynomials and RSVM for a face recognition based remote user authentication system that implements a model pre-trained on the ORL, Face94 and GT datasets to perform face recognition for continuous remote biometric user authentication. Comprehensive analysis has been performed to ascertain the accuracy and performance of the proposed method as compared to previous state-of-the-art algorithms. A functioning prototype has also been implemented as a Python program. The proposed model gives accuracies of 98.82% (ORL dataset), 96.73% (GT dataset), and 95.9% (Face94 dataset). Compared to other previous state-of-the-art models, the proposed model generally has been observed to have higher F-measure, accuracy, and speed. More research should be made on the use of multimodal biometric data, taken from multiple channels including face recognition, voice, and behavioral characteristics to improve the performance of continuous user authentication. Developing adaptive machine learning algorithms tailored for user interfaces that can produce personalized methods based on the particular interaction can help consider the change in behavior depending on context or mood. Privacy related issues need to be resolved, which requires storage and processing to be secure and possible solutions include decentralized approaches or homomorphic encryption. Moreover, context aware computing can adapt the authentication requirements depending on the ongoing situation context factors, usability studies are vital for the assessment of users' acceptance and interaction with the established systems, ensures both secure and usability.

Designing Conversational Agents for Student Wellbeing

An Exploratory Study of User Acceptance and Expectations

Jieyu Wang[1], Li Zhang[2], Dingfang Kang[3], Katherina G. Pattit[4]*

Office of the Provost, St. Cloud State University, St. Cloud, United States of America[4]

***Abstract*—The innovative development of AI technology provides new possibilities and new solutions to the problems that we are facing in modern society. Student well-being status has been a major concern in well-being care, especially in the post-pandemic era. The availability and quality of well-being support have limited the accessibility of well-being resources to students. Using conversational agents (CA) or chatbots to empower student well-being care is a promising solution for universities, considering the availability and cost of implementation. This research aims to explore how CAs assist students with possible well-being concerns. We invited 96 participants to fill out surveys with their demographic information and 11 short answer questions concerning their well-being and their acceptance and expectations of CAs. The results suggested the participants accepted the use of well-being CAs with ethical concerns. Upon user acceptance, the participants expressed expectations on design features such as facial expression recognition, translation, images, personalized long-term memory, etc. Based on the results this work presents a conceptual framework and chat flows for the design of a student well-being chatbot, which provides a user-centered design example for UX designers of wellbeing. Further research will introduce detailed design discoveries and a high-fidelity CA prototype to shed light on student well-being support applications. Implementing the CA will enhance the accessibility and quality of student well-being services, fostering a healthier campus environment.**

***Keywords*—Conversational agent/chatbot; wellbeing; UX design**

I. Introduction

The world is advancing with the fast development of AI chatbots. For students in schools and institutes, the expectation and stress upon them can be astounding. Student well-being has a tremendous impact on their performance in their study, work, and personal lives. Unavoidable life mishaps may cause a variety of well-being problems that require external interference. Schools have traditional ways to support their students in their physical health. However, assistance to student well-being has always been limited by the accessibility and availability of psychological and counseling resources.

Nowadays, we have more advanced artificial intelligence that empowers the work in industry and academia. Conversational agents (CAs) or chatbots, for their high availability and capability to interact with humans in natural language communication, would be a promising solution to address the shortage of resources for student well-being care.

The primary objective of this study is to ensure student well-being through the utilization of a chatbot. To achieve this goal, we sent out surveys to collect students' feedback about their acceptance and anticipation of chatbots. Based on their responses, we have developed a student well-being chatbot prototype that is embedded with information on some of the common well-being issues that students usually encounter during their education. This paper presents the design framework and chat flows of this prototype. We aim to reduce the time and confusion of students to search for relevant information online, allowing them to retrieve the needed internal university information and external resources that can be suitable and helpful to their situations.

II. Related Works

Researchers have done comprehensive examinations of CA engagement in well-being. They were able to recognize the positive impact of CAs on major mental-health symptoms for CAs that are AI-based, multimodal, highly accessible, and externally connected. They also identified the key features of CAs that would shape user experience in well-being effectiveness and controlled integration [1]. The availability of well-being CA-embedded applications in the market from January 2020 to 2023 also has been reviewed. A total of 18 applications have been selected, classified, and analyzed. Most of the applications are aimed at multiple well-being issues and have cognitive behavioral therapy implemented. The proportion of AI-based apps and rule-based apps is equal with a total of 48 behavior change techniques utilized [2]. In this related work, we reviewed the studies of CAs for student well-being at universities, CAs for well-being outside universities, chatbot design with specific features, and ethical concerns.

A. Well-being Assistants at Universities

School environments have a significant impact on the construction of student wellness. The relationship construction between students and school has been a significant factor that impacts student well-being [3]. The persistent stress students endure during their education has long been identified as a major individual well-being issue. During the pandemic, the demand for mental health assistants increased. Nelekar et al. (2022) investigated the effectiveness of using an embedded conversational agent (ECA) to assist students with their well-being. They addressed the importance of cultural context, social environment, and personal intention in their design for the ECA.

The result demonstrated a positive effect of ECA on stress reduction and student construction [4].

Aiming at the same goal, Jeong et al. (2023) imported a robot to provide therapeutic intervention as well as social tips. Their result suggested that using AI products could be a promising solution for well-being care. Follow-up interviews and analysis revealed the significant factors that should be considered during the development of a well-being caring agent, such as personality traits, underlying behaviors, and association quality between the participant and the robot [5].

Using GPT as the base, a research team with expertise in psychology has developed a conversational agent that matches real-world context. It also included the response questions that were frequently asked by students. The team evaluated the CA's performance and participant's responses. The feedback favored the approach of using GPT for well-being care and suggested GPT would require personalized features to provide better services to users [6].

Usta's (2021) study addressed the harmful stress among many undergraduate students. To discover insight into the problem, the team conducted individual interviews with participants and arranged case studies. As identified by the analysis, the stress mainly originated from maintaining a highly productive status with self-obligation. Additionally, the team was able to summarize the primary needs of the student during the stress. The case study involved the utilization of a chatbot that prompted the participants with encouragement and suggestions to increase their self-esteem. Further research was advised to consider the identified needs in this study and a different setup on the case study for a more comprehensive outcome [7].

B. The CAs for Well-being Care

CAs are also applied in mental healthcare in the general environment. To address the problem that self-help resources are not able to last long enough, Ly et al. (2017) implemented the interventions' strategies, provided solutions using a chatbot, and published it as an application to facilitate well-being care. They invited 28 participants and divided them into two groups for examination and a comparison study. The analysis of follow-up data resulted in higher achievement when compared to other intervention-implemented chatbots in related fields. This study presented self-help intervention as an effective tool for well-being care support to public health [8].

Inkster et al. (2018) conducted research aiming to address the mental health resource shortage. Their study focused on the evaluation of an AI-embedded conversational application. They invited anonymous users from a global range as participants in this study and examined the influence of the app on the participants. Evaluations were based on user feedback to evaluate the functionality of the app. Preliminary data facilitated the initial speculation. However, further research and analysis with a larger sample size were required to justify the conclusion [9].

Chatbots were also used to facilitate the well-being status of invited social groups. The participants were examined in 10 days and feedback was collected with follow-up interviews. The comparison of the experimental and controlled groups supported that the chatbot had a significant effect on improving the well-being status of the participants. Interaction with the chatbot was favored by the majority of the participants with positive feedback. Further development and research should involve the improvement of current functionality and personalization, as well as conducting a study with a larger sample size [10].

However, a study showed an insignificant impact of CA on improving students' mental well-being. An evaluation of a well-being care application has been conducted to support the increasing well-being care demand. The research team invited two groups of undergraduates and performed a study for each with randomized control. The outcome did not demonstrate the influence of the application on participants' well-being status. The insignificant result indicated the importance of appropriate CA design [11].

Aside from general well-being, some CA studies addressed specific well-being issues. Adolescence is considered a significant period in life that can easily lead to serious mental health issues if not handled properly. To support the mental health of adolescents, Gabrielli et al. (2020) introduced a chatbot as a possible resource. The study involved the design and evaluation of chatbot software that implemented CRI and CRIS coaching sessions. The result of the study favored this design with most of the participants providing positive feedback and recommendations. A follow-up investigation was required in the future to capture the effects of this design in the long-term period [12].

Because the effects of psychological interventions for cancer treatments are significant, chatbots are applied to help facilitate the process to make it more accessible and acknowledged by young adults. A study introduced the participants to a chatbot (Vivibot) to teach them psychological skills that could help them with cancer treatment and examined the effects in four weeks. The result showed a reduction in anxiety levels by using the chatbot and no other impactful effects on other well-being issues [13].

C. CA Design with Diverse Features

Emotionally sensitive chatbots have been under-explored. Ghandeharioun et al. (2019) conducted a study on an emotionally aware chatbot. They designed and evaluated the chatbot with 39 participants in two weeks. The result suggested that the participants supported the emotion detection feature. The participants' feedback has been collected and summarized into several guidelines that primarily focused on participants with positive moods. These guidelines were to be addressed in their further study [14].

Participatory design has been used to design a chatbot. A research team collected user reflections on the needs of a chatbot and summarized several guidelines for chatbot design that involved information usage and the delivery method for user-centered design. It involved the cooperation of both the evaluation and effort from the designer and mental health experts to implement these needs. Future studies would also consider possible ethical concerns and the practicality of this feature regarding the development of technologies [15].

Other than inviting users to participate in the design phase, feedback after the experiment can also be used to support CA

integration. Demirci (2018) used a conversational agent to manage interactions required for well-being care to the participants and explored the qualities of good design of CA for well-being care. They organized their results from user engagement to design qualities. They suggested that further research could repeat the process with a different user group or even a CA for a different purpose [16].

The development of conversational agents and smart speakers provides a possibility for new methods for well-being data collection. Maharjan et al. (2022) explored the feasibility of collecting self-report data with a speech-recognition CA. It presented a challenge to collect data with such a device, especially when deployed in a home context. They also conducted interviews and analyzed the data that reflected the technological limitations and appropriateness of the CA. This research provided valuable experience in using speech-recognition CA to support well-being care [17].

D. Ethical Issues

Ethical concerns in CA design are essential. Yet the appropriateness of applying them to well-being services is under-explored. Research has been done to raise awareness among researchers and developers on the advantages and downsides. A research team analyzed 120 posts regarding well-being support applications and identified the features that other researchers could pay attention to or should be avoided. The team called for the consideration of responsibility and social effects of the application [18].

Privacy and data security of users are one of the major concerns for well-being CAs. Gengoux and Roberts (2019) focused on the ethical use of user data when dealing with mental health problems in higher education [19]. Local policies are also a concern when introducing a CA to support well-being services in the context of universities. Graham et al. (2023) focused on the school's influence on the construction of wellness upon students regarding safety and internal well-being. The study was based on interviews with both the school and their students. The team identified the relationship between the school practice and well-being conditions by taking different aspects into the analysis process. These findings highlighted the significance of relationship construction of the school with students [20].

In this work, nearly one hundred university students who present common student well-being issues were recruited. They were encouraged to report well-being issues that needed to pay attention to in this research. By addressing these issues, we aim to gain a comprehensive understanding of student well-being problems and identify what assistance and resources we can provide. In the surveys, participants were asked questions to assess their perception of the necessity of a student well-being conversational agent and their expectations of the functions. The research questions of our study include the following four points:

- User well-being status: The participants were asked to identify their well-being status. This allowed them to review and pinpoint the causation related to their current well-being status, as well as areas that were presented to have a positive or negative influence on their problem.
- User acceptance: The participants were questioned about their opinions about using AI products such as CAs for student well-being support. They were encouraged to freely express their feelings toward this choice. They were welcome to express their support or disfavor with reasonable explanations. The feedback informs us where and how we can support students with our prototype.
- User expectations: The participants were asked to express their expectations on the use of conversational agents to assist them on wellbeing issues. They were encouraged to provide reasons for their responses and suggestions on specific tasks the CA would be capable of, which could be helpful and accessible to improve their well-being or support them.
- Suggestions for design and improvement: The participants were asked to provide suggestions for the prototype. This included specific features or functionalities to provide qualified services, significant issues to pay attention to and address, or user interface elements that could enhance user experience. Our team collected and evaluated these suggestions and eventually converged into several categories to provide the conceptual framework and guidelines for the design of the prototype.

By exploring the feedback from these questions, we aim to gather valuable insights from the participants to design and improve the prototype, addressing their needs and preferences to create a more user-friendly and valuable tool for student well-being support.

III. METHODOLOGY

A. Participants

The study recruited 96 students from a university located in the Midwest region of the United States. We collected and initially analyzed the demographic information to understand the participants. Our participants are students from the age of 19 up to 37 with an average of 23.34 (SD=3.35). The gender distribution contains 59% (57 participants) male and 41% (39 participants) females.

The participants were from nine diverse majors: Accounting, Economics, Education, Finance, General Business, Information Assurance, Information Systems, Management, and Marketing, Among the different majors, the participants were mainly distributed among Information Systems, Information Assurance, Finance, Marketing, and General Business. Table I contains the number of participants in different majors. Two participants did not disclose their majors.

TABLE I. PARTICIPANT BACKGROUND

MAJOR	PARTICIPANT NUMBER
Marketing	10
Accounting	6
General Business	12
Information systems	24
Management	4
Finance	15
Mathematics/Education	1
Economics	1
Information Assurance	21

Before their participation, the study received approval from the Institutional Review Board (IRB), and the students were invited to join the experiment after providing their informed consent by signing the consent forms.

B. Surveys and Data Analysis

Ninety-six participants participated in our survey studies. They provided answers to their demographic information and 11 short-answer questions concerning their well-being and their acceptance and preferences of chatbots. The collected data were analyzed using qualitative data analysis techniques that involve the open coding method (OCM). OCM allows us to uncover some of the hidden information within the participants' surveys. As we continued the process, we were able to identify the interrelationship between their answers and further categorize them into various themes.

The open coding was conducted by two researchers to identify preliminary concepts of interest. Due to the nature of the materials used, measuring inter-coder reliability was challenging. Throughout the analysis, the two researchers engaged in discussions to explore similarities and differences in the themes that emerged from the data. This iterative process allowed for a deeper understanding of the data and the development of meaningful interpretations.

IV. Results and Discussion

The study aimed to uncover insights and patterns within the collected data, facilitating a comprehensive understanding of the participants' experiences and perspectives related to the well-being CA and its usage in educational institutions.

Our open-coding analysis clarified the following design guidelines. We will center our design to address the major issues.

A. Methods to Maintain Well-being

The participants were questioned about the existence of any of the symptoms such as stress, anxiety, depression, and insomnia that they experience. The feedback from the survey indicated that the pandemic was one of the causes of the aforementioned symptoms. Further analysis of the feedback gave us a more comprehensive perspective on the problem.

Participant 4 suffered depression during the pandemic because of restricted socialization under self-quarantine. Participant 10 also experienced all the symptoms during the pandemic, especially when they were working in a hospital.

"I suffered from depression when I was in the Pandemic. The reason is that I had to self-quarantine for two weeks whenever I went back to Korea, but I once suffered from depression because I couldn't go out and meet people." (Participant 4)

"Yes I have experienced all mainly from the harsh transition to online schooling and not being able to go out and socialize as much during the pandemic and I had also worked at the Hospital during the pandemic which was stressful." (Participant 10)

Other participants showed effective self-coping ability, and socialization helped them stay mentally healthy.

Participants 34 and 57 were in a completely different situation in contrast to the previous examples. Participant 34 was not subjected to any of the symptoms and was able to keep up the good status. Participant 57 didn't experience any of the symptoms and had dependable communication channels with others. Their need for an additional release channel was much less than many other participants and less likely to suffer some well-being issues.

"Explicitly No because I tried to familiarize myself with digital transformation and got some new skills. Those skills were very helpful to utilize to get ease in my routine life. I have also organized myself regarding defining my future goals, and designing my goal scope." (Participant 34)

"No, I didn't experience any of those. I'm not someone who really goes into specifically bad moods, I'd say I'm pretty grounded when it comes to mood type of situations. If anything ever happened like that it would be hard to choose one in specific, but more than likely someone in my family…" (Participant 57)

Consequently, participants who were more willing to actively release emotions or already have a dependable release method were less likely to suffer from well-being issues. Although communication alone was not enough to support the participants, it had a positive influence.

B. User Acceptance of CAs

Based on the participants' feedback, we confirmed the possibility of using CA to support the participants and build up a reliable release channel through a CA. Before we proceed, we would like to know whether it was acceptable for the participants to use CA as a source to moderate their well-being status. It was confirmed after we analyzed the participants' feedback from the surveys. Here is some of the feedback:

In the previous theme, we noticed that Participant 8 was relatively isolated compared to other participants' feedback and preferred to be alone rather than build communication with others. Yet using AI products such as CA was acceptable to him.

"I do not contact anyone. I prefer being alone." "Yes, I would be willing to try it; I just want to keep any recording confidential/private." (Participant 8)

Another feedback was from Participant 40 who favored human contact over using AI. Participant 40 mentioned the importance of emotional exchange during communication, which could be a feature we address when we design our CA.

"No, I don't think I would seek help from AI I would rather talk to someone who I can gain their emotion from." (Participant 40)

Participant 24 expressed the same choice as Participant 40. They also preferred to communicate with real humans than with AI. But participant 24 was willing to try this method first before making a judgment.

"More likely than not I am going to turn to my mom for advice." "I wouldn't completely turn away from it without trying it out first." (Participant 24)

Unlike the previous participants, participant 77 doubted the CA's ability for complex tasks other than gathering and filtering information for the user.

"I use AI agent I think it makes our work less by searching what we need. It is better than searching in Google and picking

a website to see information about some topic. But coming to help I don't think so." (Participant 77)

Participant 78 had an accountable communication channel to release his mood and stress, but he still held a positive attitude toward AI agents. Similar to Participant 77, they expressed the same concern regarding the ability of the CA.

"I'm very close to my family. I share everything with my parents, my brother, and my friends. I talk to them daily regularly. Yes, I am willing to use an artificial agent to get some information and help. It would depend on the capabilities and functionality of the agent. Mainly, how it has been integrated with my abilities." (Participant 78)

We also received some recognition for our research. They valued this project and understood how this project could help people when they had limited medical resources to support themselves.

"I don't think it's unnecessary because some people do not like to talk to actual living people so talking to a screen would be a much better choice for them. This could help a lot for those kinds of people when they have no one to talk to." (Participant 21)

These were some of the representative responses we collected from the feedback. In general, participants were positive about using a CA or attempting to construct a release communication channel to moderate their mood and improve their state of well-being. Moreover, considering user needs, we believe we should build a student well-being CA as long as we can support students by any means in this intelligent era.

C. User Expectations of CAs

We also focused on user expectations of the CA. We investigated the role that the CA should play during the conversation according to user feedback, what kind of conversation they would prefer from the CA, and other related features that required our attention during the design process. The typical feedback was summarized as follows:

Participant 21 expected the ability of emotional support from the CA when dealing with various moods from users. Unlike emotional exchange as mentioned in the previous theme, the CA here should act more like a comforter.

"Based on the questions above, I believe that a conversational agent that helps people with their feelings or talks to people when they feel sad, mad, or emotional would be great. For those who those who do not have anyone to talk to, this would be great." (Participant 21)

The feedback of participant 37 focused more on the naturalness of the language during the conversation. In this feedback, the CA should act proactively to solve the user's problem.

"Actual conversation, the same phrases over and over do not help. They need to ask me to explain in detail what is bothering me and why I think it is." (Participant 37)

Participant 48 preferred the CA concerning data privacy and the quality of the information provided to users. He commented that the answers provided by the CA would be clear and unbiased.

"I would choose artificial intelligence. Artificial intelligence stands for privacy, it doesn't spread my ideas around. From the AI side, I would like to get more precise and objective answers." (Participant 48)

Participant 53 relied on the availability of the CA. Even though the exact functionality was not specified, she held a strong position that the CA should be a passive comforter to users.

"When everyone around me is busy it would be good to know that a conversational agent is available in difficult times when I feel like pouring my heart out (Participant 53)."

Participant 71 provided a remarkable suggestion for CA design. Instead of solving short-term tasks assigned by the user, he said the CA should also focus on how to build a long-term trustworthy relationship with users and handle long-term tasks. Well-being care was not a simple issue that could be addressed within one or two interactions, but rather a continuing process.

"It would be interesting to be linked with the conversational agent as they will analyze your thought process and may give you a rational solution. It should fulfill the user's requirements and interests and build a trustworthy relationship." (Participant 71)

The feedback from the participants further expanded the design of CA from the basic functionalities to user adaptation. It provided insight into the direction of how CAs can better fit the needs of users and maximize the support users can receive. Besides the possible roles that CAs can offer, expanding the service of CAs from short-term interaction to long-term support should be significant to the design and necessary to provide continued support to student well-being.

D. User Requests for Chatbot Design Features

The user feedback also focused on the expected features of the design. It addressed the issue related to the images used to represent CA. It mentioned the applicability of facial expression detection on student wellbeing CAs. It discussed the impact of enabling the ability to communicate in users' native language. There were also other suggestions of possible features for the CA as directions for further development.

1) Use an image to enhance user impression: The participants appeared to be diversified in their views regarding the image representing the CA.

Participant 21 suggested a customizable animated real-life person. This feature might be helpful to begin the conversation with a user and add to the impression by allowing the user to choose a figure that they feel most comfortable with.

"I think that having an image to see when talking to the conversational agent would be nice. Maybe an animated real-life person. Have different types of persons that you could choose from so that the person can choose who he/she feels like they can talk about their feelings to." (Participant 21

Not all the participants can accept human images when communicating with the CA. Participant 35 and 90 expressed their dislike toward the human image.

"I feel like a basic smile that's robotic would be nice. I would not prefer anything human-like, as I feel like it would be too creepy." (Participant 35)

"No, a conversational agent is not a human so associating it with a human face feels dishonest." (Participant 90)

The participants demonstrated a diversified opinion toward the image of CA, primarily on whether to use human images or not. It would be best to make it customizable for the user to choose the appropriate image for themselves.

2) Facial expression detection: The feedback from the participants towards a facial expression feature concentrated on the notion that facial expression detection would be useful for emotion analysis, but not sufficient. It required assistance with several other methods to function constructively. Meanwhile, some participants expressed a feeling of insecurity if emotions had been detected during the interaction with the CA.

Participant 21 shared a supportive opinion toward the expression detection feature since it could provide additional information during the conversation besides text messages.

"Yes! I think that this would make it much better because then even if the person can't say anything yet about their feelings, the conversation agent can start the conversation into their feelings based on their expressions." (Participant 21)

Another feedback that supported this feature conveyed the appreciation if the CA contained the ability of emotional exchange during the conversation.

"If a conversational agent can analyze moods I would 100% be willing to use it, why? Because if they're able to recognize emotion then it's almost the same as talking to a friend or family member which I prefer more because they're able to display emotion." (Participant 40)

Participant 24 explained a mixed feeling toward facial detection. This feedback admitted the positive effect of facial expression detection but also hesitated about this technology since it analyzes a person and collects information during the interaction.

"Yes and no I feel like that would be cool but at the same time kind of creepy. I would try it out because technology has become so advanced and interesting to me but I would be skeptical at first to the idea." (Participant 24)

There is also feedback reflecting doubt about the accuracy of facial detection. Participant 14 expressed this concern with his own experience.

"My resting face regardless of my mood oftentimes makes me look sad so I don't think this would be a great indication." (Participant 14)

We also got feedback that demonstrated a direct dislike toward this feature. Being analyzed based on their facial expression will generate an uncomfortable feeling to them during interaction.

"I don't think I would want to use it more. It honestly is uncomfortable knowing that I CA can decipher my facial expressions and mood." (Participant 45)

Our participants provided feedback on the features of facial expression detection that focused on two issues: the method of facial expression detection and its accuracy, and user acceptance of expressions analyzed during the interaction.

3) Translation: We also received some feedback on the feature of translation for the CA. Participants have been questioned whether a translation function could be added if their first language was not English.

Participant 29 gave a negative answer based on the identity of the English speaker.

"No. English is my primary language, so this would not provide any additional benefit." (Participant 29)

Participant 71 focused on the convenience for users if they could communicate with the chatbot in their native languages. When English isn't their first language, they might have limitations on expression during conversations. However, when users can communicate with CAs in their native languages, they can provide more accurate messages that improve the efficiency of communication.

"Yes, being able to communicate in your language makes it more comfortable to describe what you are feeling now. You won't be thinking much of things to say, rather you will be putting words to your emotions." (Participant 71)

Participant 53 admitted the functionality of this feature and thought it would increase the desire for people to use it since it added to the emotional connection when communicating in their native language.

"Yes, it would increase my desire to use it, as I could talk with the agent in my native language, which would make me feel that the agent is close to me and understands me well." (Participant 53)

Participant 29 provided further insight into this discussion. This participant admitted the usefulness of translation and suggested moving one step further and considering natural language processing in other languages.

"Even if I spoke a language other than English, I would be surprised if the translation was very accurate, especially with the intricacies of the English language. It would work better if the agent functioned in different languages independently of translation." (Participant 29)

Overall, the feature of translation is welcomed by most of the participants. They recognized the benefits users would receive if the conversation could be carried out in users' native languages, such as increasing communication efficiency and emotional connection. The advantage can be further expanded and probably needs tremendous work if CAs' natural language processing can understand other languages.

4) Future development: At the end of the feedback session, we organized some of the messages to generate several possible directions for further development in the design.

Participant 21 suggested chatbot personalization by memorizing previous conversations to construct a long-term association with users. This would be helpful to build a long-term connection. We could reduce data privacy concerns by users logging in with their user accounts.

"It might already be part of your ideas but maybe having the conversational agents remember the person using them and memorize all their conversations for future times. This would help a person feel connected to it." (Participant 21)

Participant 4 suggested using feedback from other users as evidence and examples to solve the user's problem with the permission of other users considering there might be data privacy concerns.

"What the other person is worried about and what is good for the other person." (Participant 4)

Participant 34 suggested implementing the feature to access human agents when CA fails to complete required tasks. This option can maximize the capability of the CA.

"If it can be possible to have an option for some experienced real agents to tackle the severe problem that conversational agent is unable to solve." (Participant 34)

Participant 24 provided valuable insight based on personal work experience that introduced how CA has been used to refer to the right resources. It triggered our consideration of task design for the CA.

"I think that they are extremely helpful when it comes to getting to the right person. Where I work, our website uses a conversational agent to answer your questions or to reroute you to someone who can help." (Participant 24)

E. Ethical Concerns

Data privacy is a concern when a user interacts with CAs. We collected some sample feedback on what the participants might be worried about when using the CA as a tool to moderate their well-being status.

Participant 10 expressed a direct concern about data disclosure to third parties, mentioning this happened to companies. Participant 20 demonstrated the situation when a user had less trust in a CA, he would only allow for limited interaction with the CA to ensure sensitive information was kept private.

"I have very strong concerns about the privacy of this agent." (Participant 10)

"I' 'm not sure I would 100% confide my worries in this conversational agent but I might be able to talk about smaller things in my life to them. (Participant 20)

Participant 22 expressed an open attitude toward the sensitive information collected during the interaction. The bottom line was no disclosure of user information to third parties. This participant was willing to try the CA to use the information for service, but this was only allowed for usage and the privacy should be respected.

"I believe that I would. I think that it's a great idea. I don't have a privacy concern unless they are trying to sell my information to people or something. It would be nice to have some privacy on these kinds of things though." (Participant 22)

This feedback focused primarily on ethical concerns of the party running the CA not selling user information to third parties and how to prevent unauthorized access to private data. To protect user data and build up trust between the user and the party that maintains the CA is crucial to the final product of this CA. In this research, we only use the data collected from the surveys and follow-up interviews before and after the interaction. The chat history between users and the CA will be anonymous and will not be recorded.

In sum, the analysis of the survey data enabled us to start our design based on users' input and provided a more detailed blueprint for the conceptual design. Therefore, we designed a conceptual framework and chat flows for the major structure in detail for our CA.

F. The Conceptual Framework and Chat Flows

We designed a student well-being chatbot prototype via the platform Juji [21, 22]. According to the framework of the prototype (Fig. 1), a user will first receive a welcome message. Then the user will be asked about his purpose. According to the participants' feedback, we designed the chat flows of depression (Fig. 2), anxiety (Fig. 3), insomnia (Fig. 4), and panic attacks (Fig. 5) based on the university's internal references and the external resources of the Mayo Clinic and the Anxiety & Depression Association of America (ADAA). The survey data suggested that these four symptoms that students usually have trouble with prevented them from achieving their best performance in their studies [23]. There are also several Q&As prepared for users to answer some quick questions.

1) Design framework (Fig. 1): When the user chooses to do a symptom examination, he or she will have to pick which one they want to check with. To distinguish each of the symptoms, definitions for each of the four are built into the Q&A. After the user selects one, the conversation will be guided to a specific topic, that is, to the specific question sets built for each symptom. After the users have finished with the questions, treatment suggestions and external links to other healthcare resources will be offered accordingly. After the chatbot offers suggestions, it will be put to wait for new tasks from the user.

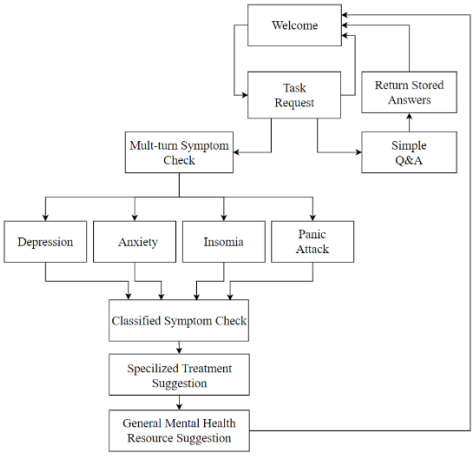

Fig. 1. Framework.

2) Depression chat flow (Fig. 2): The interaction process for depression contains a question phase and an answer phase. After the welcome message of the chatbot is presented, the user will need to select a task for the chatbot to perform. When the chatbot is asked to start an examination on depression, the conversation topic will be guided to the question phase of depression analysis. After the conversation goes through all the necessary questions, it will be guided to the suggestion phase of the chatbot. First, the specialized treatment suggestion for depression will be printed for the user. Then based on the user's location, it will suggest nearby healthcare resources and providers. Finally, it will provide general helping resources.

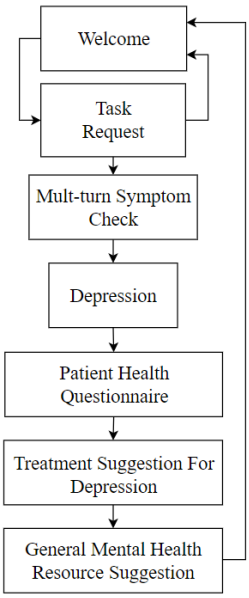

Fig. 2. Depression chat flow.

3) Anxiety chat flow (Fig. 3): We designed the general interaction sequence for the check process of Anxiety in a similar way to depression. We used the website of Mayo Client as the information source to construct our knowledge base for anxiety symptoms. The examination process for anxiety is also split into a question phase and an answer phase. When the chatbot is required for anxiety examination, it will launch the question phase of the anxiety analysis. After the conversation went through all the necessary questions, suggestions will be posted to the user. The answer contains a specialized treatment suggestion, the well-being resources to be accessed based on student location, and the generally accessible resources.

4) Insomnia (Fig. 4): The third examination process is designed for insomnia or sleep disorders. The interaction sequence for insomnia examination is split into 3 symptom checks. When the user raises a request for a checkup of this symptom, the prototype will use questions to gather the necessary information to help identify the possible result and post it to the user. The chatbot will also include a link to the information page that can help with the identified issue. At the end of the chat flow, the prototype will suggest the wellbeing resources accessible to the user based on their location, and the general accessible resources.

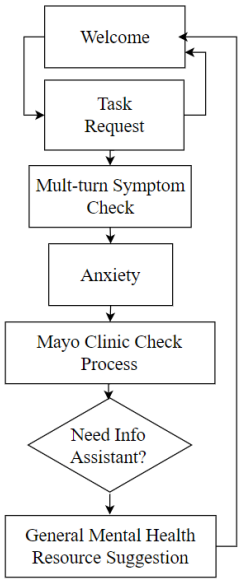

Fig. 3. Anxiety chat flow.

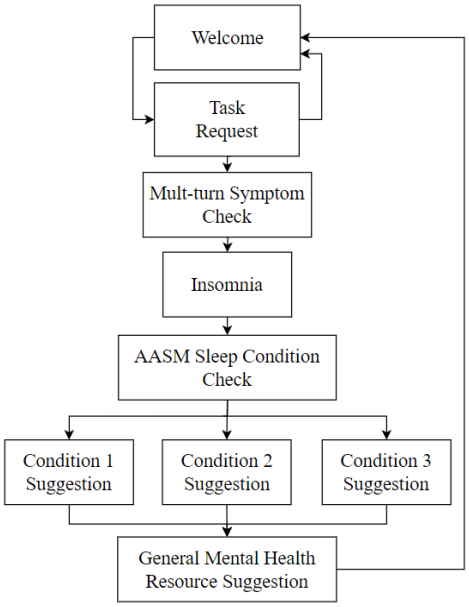

Fig. 4. Insomnia chat flow.

5) Panic attack (Fig. 5): The general interaction sequence for the examination process of panic attacks is quite similar to the design of the process for depression. When the chatbot is asked to start an examination on panic attacks, the conversation topic will be guided to the question phase of panic attack analysis. After the conversation goes through all the necessary questions, it will be guided to the suggestion phase of the chatbot. First, the specialized treatment suggestion for panic attach will be printed for the user. Then based on the user's location, the chatbot will suggest nearby healthcare resources and providers, then finally provide general helping resources such as 911.

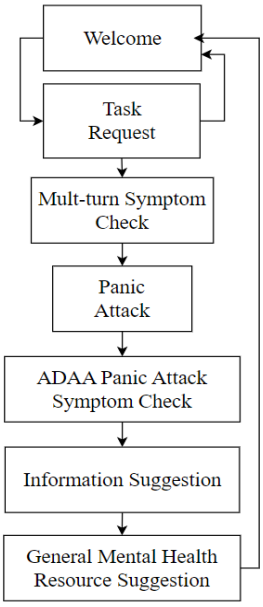

Fig. 5. Panic attack chat flow.

The work aims to provide a high-fidelity chatbot prototype for student well-being at one university, which can be a practical application once published if needed. This paper explored student acceptance and expectations for the CA via surveys and presented a framework for conceptual design and related chat flows. However, it is important to acknowledge the limitations of our study. Though the sample size of the survey could have been larger, we found numerous valuable text answers while analyzing them using the qualitative open-coding method. The qualitative results directed the framework and chat flow design, which can also be generalized and used by other UX designers who are working on well-being chatbots.

V. Conclusion

Conversational agents provide new possibilities to improve people's well-being. This work explores user acceptance and expectations of well-being CAs. The participants reported how they maintained their well-being, their acceptance of the well-being CA with privacy and security concerns, and their expectations for the CA's emotional support and availability (24/7). This work also presents a conceptual framework and chat flows for the well-being CA, which directs the further design of the chatbot.

Inviting participants into the preliminary stage of the project assisted us in the conceptual design process. User-suggested features were evaluated by feasibility and cost for project implementation. The results were used to guide our design and implementation of the CA in the next stage.

In the future, we will further design this student well-being CA into a high-fidelity prototype and evaluate it with usability testing. This high-fidelity prototype can be published into a mature app if needed. We will further look into professional evaluation recognition from experts in psychology and counseling; connect with the current healthcare system; and incorporate private information management, and ethical and legal issues when applied in the real world. We look forward to exploring how this tool can facilitate research and development in related areas.

Data Encoding with Generative AI: Towards Improved Machine Learning Performance

Abdelkrim SAOUABE, Hicham OUALLA, Imad MOURTAJI
AKKODIS Research, Paris, France

***Abstract*—This article explores the design and implementation of a Generative AI-based data encoding system aimed at enhancing human resource management processes. Addressing the complexity of HR data and the need for informed decision-making, the study introduces a novel approach that leverages Generative AI for data encoding. This approach is applied to an HR database to develop a machine learning model designed to create a salary simulator, capable of generating accurate and personalized salary estimates based on factors such as work experience, skills, geographical location, and market trends. The aim of this approach is to improve the performance of the machine learning model. Experimental results indicate that this encoding approach improves the accuracy and fairness of salary determinations. Overall, the article demonstrates how AI can revolutionize HR management by delivering innovative solutions for more equitable and strategic compensation practices.**

Keywords*—*Data encoding; Generative AI; salary simulator; human resource management; machine learning

I. Introduction

Generative AI has revolutionized many sectors, from artistic creation to complex data modeling. A crucial aspect of this technology lies in the way it encodes data, a fundamental step in machine learning. Data encoding aims to transform raw data into representations that can be exploited by learning models, directly impacting their performance. However, traditional encoding methods are not always able to fully exploit the capabilities of deep learning algorithms, particularly in applications requiring a fine-grained, contextual understanding of the data.

This article focuses on exploring the impact of using generative artificial intelligence data encoding on improving the performance of machine learning models in the field of human resources. Traditionally, classical data encoding methods in human resources rely on techniques such as one-hot encoding, ordinal encoding and the use of manually selected descriptors [1] and [2].

Although these methods are widely used, they have several significant limitations. One-hot encoding, for example, can lead to an explosion of dimensionality when the number of categories is high, making models more complex and less efficient [3]. Ordinal encoding assumes an ordered relationship between categories, which is not always relevant to HR data, where relationships between variables may be more nuanced [4].

In addition, manually selected descriptors can introduce biases and overlook important features of the data [5]. In contrast, generative AI offers an innovative approach by enabling the creation of more sophisticated and contextually relevant encodings, based on generative models trained to capture the underlying complexities and relationships in the data [6] and [7].

This approach can potentially improve the quality of encoded data, intelligently reduce dimensionality and capture subtle information that eludes traditional methods, leading to a significant improvement in the performance of machine learning models in human resource management processes, such as recruitment, talent management and forecasting staffing requirements [8], [9], [10] and [11].

In our project, we will use the coding of data related to Human Resources Management, these data are private, whose objective is to develop a salary simulator to help HR to estimate salaries for the proposed new profiles, this model relies on the encoding of data that influence the salary by methods based on AI and generative AI, such as type of occupation, region, level of education [12], [13] and [14].

II. Data

To develop the salary simulator, we used anonymous data from a French company. The data was collected and structured to meet the specific needs of our study. Among the data collected, several key columns were selected for their relevance to salary calculations.

Firstly, the 'Profession' column indicates the name of the profession according to the job reference system. This information is crucial, as each professional branch has its own salary grid, which makes it possible to differentiate pay levels for different professions [15].

Next, the ' Beginner ' column represents the employee's level of experience. This is an essential criterion, since salaries generally increase with the experience accumulated by workers in their field [16].

The 'Region ' column specifies the region of France where the job is located, allowing regional salary disparities to be considered. Indeed, salaries can vary significantly from one region to another due to the cost of living, demand for labor, and other local economic factors [17].

For example, salaries are higher in the Paris region than elsewhere. In our study, we consider the 14 regions in France:

- GRAND-EST
- PROVENCE-ALPES-CÔTE D'AZUR

- ÎLE DE France
- HAUTS-DE-France
- PAYS DE LA LOIRE
- CENTRE-VAL DE LOIRE
- OCCITANIE
- BOURGOGNE FRANCHE-COMTÉ
- AUVERGNE-RHÔNE-ALPES
- NOUVELLE AQUITAINE
- NORMANDIE
- MARTINIQUE
- BRETAGNE
- LA RÉUNION

In addition, the 'Education' column indicates the level of education required for the position. This is important, as the level of education often influences salary, as positions requiring higher qualifications are generally better paid [18]. The education levels presented in this column are: Less than Bac', ' Baccalaureate', 'Bac+2', 'Bac+3', 'Bac+5', Uninformed.

Finally, the 'Contract' column specifies the nature of the employment contract (permanent, fixed term or temporary). The nature of the contract can affect salary levels, with permanent contracts (CDI) often offering higher salaries and benefits than temporary contracts (CDD or Interim) [19]. The 'Contract' column contains three categories: CDI, CDD, Interim.

These different variables enable human resources managers to make informed and fair decisions regarding compensation while considering the multiple factors that influence salaries [20] and [21]. In fact, we will use them to develop the salary simulator, based on their encoding.

III. DATA FEATURES

To develop the salary simulator, we followed a rigorous methodological approach, incorporating advanced artificial intelligence and machine learning techniques [22] and [23].

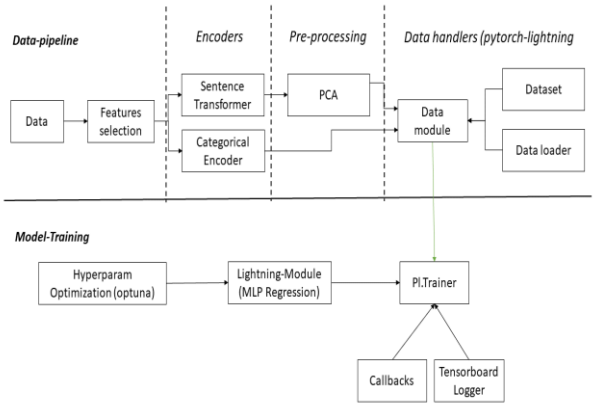

Fig. 1. Architecture of the developed model.

The first step in this process was to Clean and encode the data. This private database, which we have chosen, contains detailed information on various profession and their associated attributes. The architecture of the developed model is given in the Fig. 1.

A. Data Encoding

Data encoding in human resources management (HRM) plays an essential role in improving decision-making processes and customizing solutions, particularly in the fields of salary management, recruitments and skills development. It enables complex information to be structured, providing accurate analyses and reliable predictions, while promoting fairness in HR practices.

However, this process presents several challenges, such as the heterogeneity of data from a variety of sources, the need to protect the confidentiality of sensitive information, and the need to prevent algorithmic bias. In addition, the evolving nature of the labor market and the complexity of human factors make encoding difficult to standardize and update in real time.

The first stage in our approach is the encoding phase. To encode the columns, unique values must be extracted for each column and transmitted to the corresponding encoder to overcome the difficulties and challenges cited above. Two types of encoders are used for data encoding: categorical encoding and sentence transformers [24] and [25].

Categorical encoding is a tool used in data processing to transform categories such as colors or product types into numbers that computers can manipulate. This enables better data analysis and processing [26]. In our project, this type of encoder is used for the 'Contract', 'REGION', 'Education level' and 'Beginner' columns. ‘One Hot Encoder’ is used for normalizing numerical data and encoding categorical data respectively. All these columns are encoded as a vector of dimension equal to 27.

For the 'Profession' column, corresponding to the profession name in the database, we use the Sentence transformer. This encoding method is used because it is not possible to list all categories which contain 355 professions as Mason, Childcare Assistant, Restaurant Manager, Quality Control Technician, Pharmacy Preparer. The phrase transformer understands the meaning of the phrases and transforms them into numbers that can be used by the computer, making it easier to compare, search and analyze the phrases [27]. Encoding transforms each occupation into a numerical vector of fixed dimensions. These vectors (or embeddings) capture the semantic characteristics of the occupations, enabling mathematical operations and comparisons.

For our project, we used the generative artificial intelligence model S-BERT (Sentence-BERT), which transforms occupational titles into 768-dimensional numerical vectors. Each occupation is thus represented by a unique vector, capturing its semantic characteristics in a way that facilitates comparison and analysis. Thanks to this approach, occupations are no longer simply strings of characters, but complex mathematical representations, enabling advanced algorithmic operations such as search, classification or

prediction, while considering semantic similarities between different occupations.

The second step in our process consists in applying Principal Component Analysis (PCA) to the vectors resulting from the encoding, to simplify complex data while retaining the essential information [28]. In our project, PCA reduced the vectors in the 'Profession' column from 768 to 147 dimensions, while maintaining 92% of the variance explained. This reduction optimizes the efficiency and performance of the algorithms, while reducing the computational load.

B. Data Module

In our project, we adopted the PyTorch Lightning library to optimize the development and management of our machine learning model. PyTorch Lightning facilitates the process by structuring and organizing machine learning code, speeding up development and improving efficiency while minimizing the risk of errors. One of the library's key tools is the `DataModule` class, which encapsulates all the logic required to prepare and load data for the model [29]. This library provides a clear separation between data and model tasks, simplifying data management and making code more modular and maintainable.

IV. Model Training

A. Optimizing Hyperparameters with Optuna

Having configured the data pipeline, we now turn our attention to training the model. The first step is to optimize the hyperparameters using Optuna, a library dedicated to automatic optimization [30]. Optuna searches for ideal values for the model's hyperparameters, thus improving its overall performance. In our project, we need to optimize several key hyperparameters: the number of network layers, the number of training epochs, the number of neurons in each hidden layer, and the learning rate. This optimization allows us to fine-tune the model to obtain the best possible results.

B. Lightning Module for MLP Regression

In our project, we have opted for an MLP (Multi-Layer Perceptron) model for regression, encapsulated in a “Lightning Module”. This module is responsible for the complete definition of the neural network structure, the loss function used, and the training and evaluation logic. Using this module, we centralize and efficiently organize the essential aspects of the model, facilitating its development and management.

C. Training with PL Trainer

Having configured the Lightning module, we move on to training using the “PL Trainer”, a PyTorch Lightning class designed to simplify the model training process. The PL Trainer supports several key aspects, such as distributing tasks across multiple GPUs, managing model backups (checkpoints), and collecting performance data. By automating these tasks, the PL Trainer makes it possible to concentrate on model optimization, while ensuring efficient resource management and accurate monitoring of results [31].

D. Callbacks and Tensor Board Logger

The PL Trainer integrates callbacks and a TensorBoard logger to optimize monitoring and recording of model performance during training. Callbacks are flexible tools for carrying out specific actions at various stages of training, such as automatically saving models or dynamically adjusting the learning rate. At the same time, the TensorBoard logger provides detailed visualizations of model performance, facilitating problem diagnosis and continuous improvement of the training process. Together, these tools enable in-depth monitoring and proactive training management.

V. Evaluation Setup

The results detailed in this section focus on evaluating the performance of our MLP (Multi-Layer Perceptron) based salary prediction model for France. Performance indicators and visualizations provide an in-depth analysis of the model's accuracy and robustness, enabling a better understanding of its capabilities and limitations.

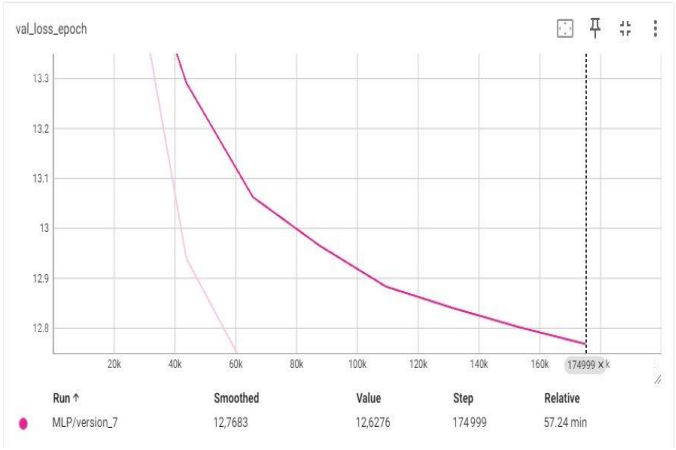

Fig. 2. The validation function (validation and test training).

The graph val_loss_epoch, presented in Fig. 2, illustrates the reduction in loss on the validation data through the training iterations. A continuous reduction in loss, as shown in the graph, indicates effective model learning. When the curve reaches a plateau, it suggests that the model is beginning to converge, and that continuing training with more iterations may not significantly improve performance.

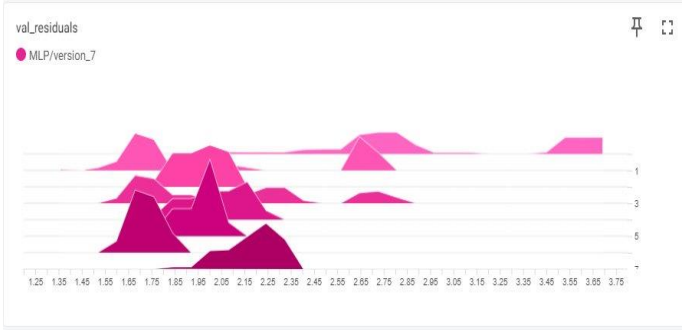

Fig. 3. Val_residuals graph.

The val_residuals graph presented in the Fig. 3, visualizes the residuals (difference between predicted and actual values) on the validation data. A narrow distribution centered around zero, as observed here, indicates that the model makes few systematic errors and that most predictions are close to the

actual values. However, peaks in certain areas may suggest areas where the model could still be improved.

These results show that the MLP model performs satisfactorily overall, with reasonably low error metrics and a steadily decreasing loss curve. Validation residuals reveal good overall accuracy, although further adjustments could be explored to refine predictions in areas where error peaks are present. These observations provide a solid basis for the continued optimization of the model and the exploration of more advanced data encoding methods to further improve its performance.

TABLE I. RESULTS OF METRICS

Test metric	Error (10^3 €)
Test_loss	16.37745475769043
Test_loss_mae	3.82299542427063
Test_loss_mse	52.06039047241211

These metrics show the model errors on the test data. The Test_loss represents the total loss on the test set, while test_loss_mae and test_loss_mse represent the mean absolute error and mean square error respectively. Lower values of MAE and MSE indicate better model performance.

VI. RESULTS AND DISCUSSION

In this section, we present the results obtained with our wage prediction model. This model was trained and tested on the previously described database. Subsequently, we developed a graphical interface to facilitate the use of this model, which we named Salary Simulator. This interface enables users to interact intuitively with the model. The following figure (see Fig. 4) illustrates the wage simulator interface.

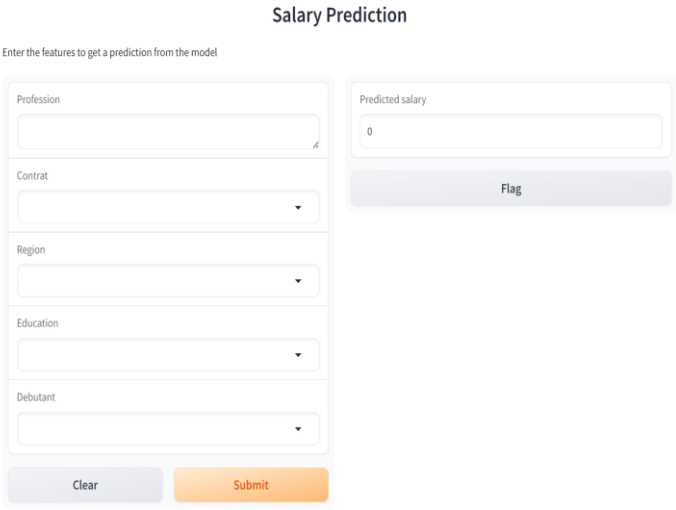

Fig. 4. Salary simulator interface.

As illustrated in the Fig. 5, the interface consists of a title at the top, “Salary Prediction”, which specifies the tool's objective. On the left, the input section allows the user to provide different information: a text field to enter the occupation, a drop-down menu to choose the type of contract, another to select the region, a field to indicate the level of education, and a last one to specify the level of experience. Two buttons at the bottom of this section allow you to reset fields with “Clear” or submit information to obtain a salary prediction with “Submit”. On the right, the output section shows the predicted salary in a field that is empty until a prediction is made and includes a “Report” button to notify any problems with the prediction.

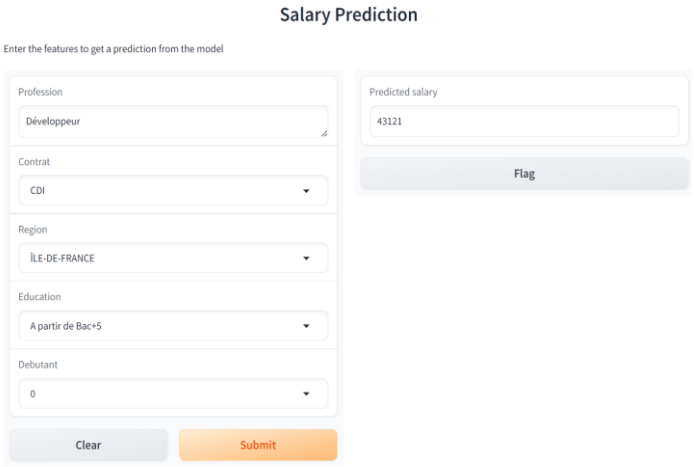

Fig. 5. Salary simulator interface with results for the test.

The result of the salary prediction shows that a Java developer with an open-ended contract working in the Paris region, with a level of education equivalent to Bac+5, with experience, can expect an annual salary of 43,545 euros. The predicted salary of 43,545 euros is in line with market standards for an experienced Java developer with Bac+5 in the Paris region, indicating that this estimate is appropriate and competitive for this region and profile.

VII. CONCLUSION

This paper highlights the significant benefits of using generative artificial intelligence data encoding in improving the performance of machine learning models applied to human resources. Unlike traditional encoding methods, such as one-hot encoding, ordinal encoding and manually selected descriptors, which are often limited by complexity constraints and potential biases, generative AI techniques enable more accurate and contextually relevant capture of the underlying subtleties and relationships of the data.

Experimental results show that models trained with generative encodings outperform those using conventional methods, both in terms of loss reduction and improved validation residuals. Metrics such as total loss, mean absolute error and root mean square error indicate improved performance, underlining the potential of these techniques for real-world applications such as recruitment, talent management and forecasting staffing requirements.

Notice that we have not found any reference work in the state of the art to make a comparison. As result, we collaborate with HR managers and professionals to validate the salary predictions generated by the model. As part of our future work, we aim to compare several alternative models utilizing other Generative AI-based encoding techniques and assess its

performance across a range of HR datasets. This will provide a more comprehensive understanding of the strengths and limitations of each approach.

Cross-Modal Hash Retrieval Model for Semantic Segmentation Network for Digital Libraries

Siyu Tang*, Jun Yin
College of Information Engineering, Shanghai Maritime University, Shanghai, 201306, China

***Abstracts*—The study optimizes the classic hash retrieval model by introducing Word2vec network and full convolutional neural network, with the goal of addressing the issues of low retrieval efficiency and poor retrieval accuracy of the traditional digital library retrieval system. The study extracts the secondary features in the graphic features and optimizes the loss function to design a cross-modal hash retrieval model based on semantic segmentation network. The experimental results indicated that the CPU utilization, memory utilization, number of concurrent operations, and operation success rate of this model were 45.4%, 36.3%, 92, and 96.7%, respectively. Its CPU utilization and memory utilization were significantly lower than other models, while the number of concurrent operations and operation success rate were significantly lower than other models. It proved its high efficiency of resource utilization and its reliability. When the amount of processed data was 100, the average response time of cross-modal hash retrieval model was 10.2s, which was significantly lower than other models, proving its high operational efficiency. The cross-modal hash retrieval model proposed in the study has better performance and provides technical support for cross-modal retrieval in digital library and also provides ideas for information retrieval in other fields.**

I. Introduction

A distributed information system that processes and stores a range of textual and graphic multimedia creations is called a digital library. It makes use of digital technology. With the aid of digital technology, it may store information resources from many carriers and geographical locations, enabling querying and distribution throughout the area and object-oriented network [1-3]. As digital technology has advanced recently, public libraries now have access to intelligent service ways. In addition, digital libraries offer tailored suggestion services to cater to the varied demands of their patrons, substantially improving their overall service experience [4]. However, book information is constantly expanding, and users face problems such as inefficiency in graphic retrieval through traditional means. Therefore, many scholars have proposed a series of methods to address this problem.

Zeng Z et al. created a visual search model based on a bag-of-words model (BWM) and various semantic associations in order to build a mobile visual search service system for digital libraries. They extracted local and global features from an image using hue, saturation, and brightness variations that are scale invariant. The results showed that the model performs better in searches [5]. A base three indexing approach based on semantic visual indexing was created by Krishnaraj N et al. to address the issue of semantic gaps between queries and disparate semantics in large-scale databases. They demonstrated that the model was accurate to 83% by using an interactive optimization model to determine the joint semantic and visual descriptor space and by combining a design model with a semantic visual joint space model [6]. Khan U A et al. designed a hybrid feature descriptor-based retrieval method in order to reduce the reliance on text annotation based digital book retrieval system. It combined genetic algorithm and support vector machine for digital book retrieval in multi-category scenarios and the results showed that the method retrieved better on four standard datasets [7]. Yu H et al. designed an image retrieval method based on typical correlation analysis and domain adaptation for the poor retrieval performance of traditional digital library retrieval methods. It transferred classifiers trained on known datasets to new datasets and combined multi-source domain data to generate classifiers on the target domain, and the findings revealed that the approach was more effective in image retrieval [8]. To achieve better cross-modal retrieval of digital libraries, He S et al. developed a cross-modal retrieval method based on category-aligned adversarial learning. By using category information to create a shared identity space, it compared samples from several modalities. The strategy outperformed other approaches on four benchmark datasets, according to the findings [9]. Wang X et al. designed a deep learning based cross-media semantic search framework for digital library to improve and enhance the multimedia retrieval system in digital library. It integrated book processing, big data and deep learning and applied them to the integration of digital library, and the results showed that the framework improved the overall search performance by 11.53% over the suboptimal method [10]. Ahmadi A et al. designed an image semantic retrieval method combining ontology and composite modeling for applying ontology to information retrieval in digital library. It was able to handle linguistic errors such as ambiguity and structural errors in digital books using semantic web organization. The results indicated that the method was able to improve the accessibility and retrieval accuracy of digital library [11]. To address the semantic gap between multimodal input text and digital library images, Rong H et al. developed a multimodal retrieval approach based on contextually relevant and irrelevant attention alignment augmentation. To capture the shared semantics across several modalities, it employed a semantic alignment augmentation approach. The approach was able to successfully capture the shared semantics between text and images, according to the results [12]. Zhen Z et al. designed a shared cloud service platform based on big data in order to effectively integrate digital book resources. It analyzed the features of digital books

and the factors affecting these features. The findings revealed that the platform was more effective in the dissemination of digital book resources [13]. To demonstrate the role of visual and verbal pre-trained models in digital book retrieval, Baldrati A et al. designed a combinatorial retrieval method based on comparative learning and task-oriented features. It integrated bimodal information by training a combiner network and provided combinatorial features for performing retrieval. The results revealed that the method outperforms existing methods [14].

In summary, scholars have obtained many results in the field of digital library graphic retrieval. Nevertheless, none of these techniques account for the potential semantic association that may exist between various graphic data, which results in inadequate retrieval accuracy. Fully convolutional neural network (FCN) is the first network for pixel-level prediction. Since its proposal, it has become the basic framework for semantic segmentation [15]. However, Word2Vec is a popular natural language processing technique that is able to represent each word as a high-dimensional vector and represent the semantic relationship between words by the similarity between the vectors [16]. In view of this, the study uses Word2Vec with FCN to optimize deep cross-modal hashing (DCMH) and considers the extraction of secondary features. Concurrently, the research enhanced the efficiency and precision of retrieval by designing an IDCMH model and optimizing the loss function. The study is novel because it combines FCN with Word2Vec, which makes full use of both the semantic vector representation of word and the pixel-level semantic information of images. This improves the model's capacity to capture the semantic link between textual and graphic data. This enhances the model's capacity to identify complex data by accounting for the extraction of secondary features.

There are four parts to the study. An overview of the digital library retrieval model's background and the state of domestic and international research are covered in Section I. The building of a multi-modal digital library retrieval system and the functional design of an associated retrieval model comprise the Section II. The proposed model's performance analysis and the practical application effect analysis make up Section III. The study's weaknesses and discussions are highlighted in Section IV. Finally, Section V concludes the paper.

II. METHODS

This section focuses on the research methodology. Section I shows the construction of multi-modal digital library retrieval system. Section II shows the function design for cross-modal hash retrieval model through semantic segmentation network. Section III shows the extraction of secondary features and the design of optimization techniques for the loss function.

A. Design of Multi-Modal Digital Library Retrieval System

Traditional libraries mainly rely on view resources such as paper books. These resources not only take up a lot of space, but also are difficult to manage and not convenient enough to use. With the arrival of the Internet era, people's reading habits have shifted and they are more willing to read on online platforms [17]. Therefore, digital library came into being. The study designs a three-tier digital library graphic retrieval system based on B/S architecture. The technical route for the realization of this three-tier architecture digital library system is shown in Fig. 1.

In Fig. 1, the system includes a representation layer (RL), a business layer (BL), and a data layer (DL). Among them, the RL is used to interact directly with the user, and it is mainly used for data entry, display, and query. The interface of this layer is realized by using the Web page, by encapsulating the user's request as an HTTP request and sending it to the BL. The BL receives the request from the RL through the API interface and performs operations such as syntactic dependency analysis, segmentation, and entity recognition. After processing the request from the RL, the data is transferred to the DL. The interface of the DL is realized using the JDBC interface, and the main functions of this layer are database connection and SQL statement execution. This layer is able to process and return requests from the BL. The overall function of the designed system is shown in Fig. 2.

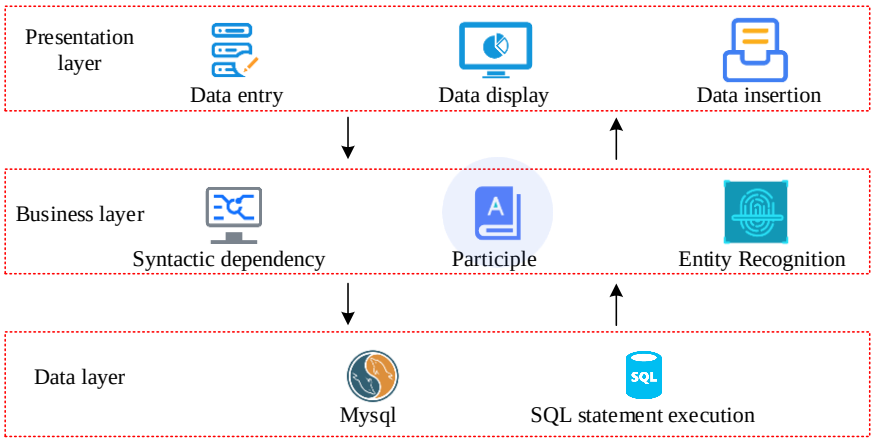

Fig. 1. Technical roadmap of three-tier architecture digital library system.

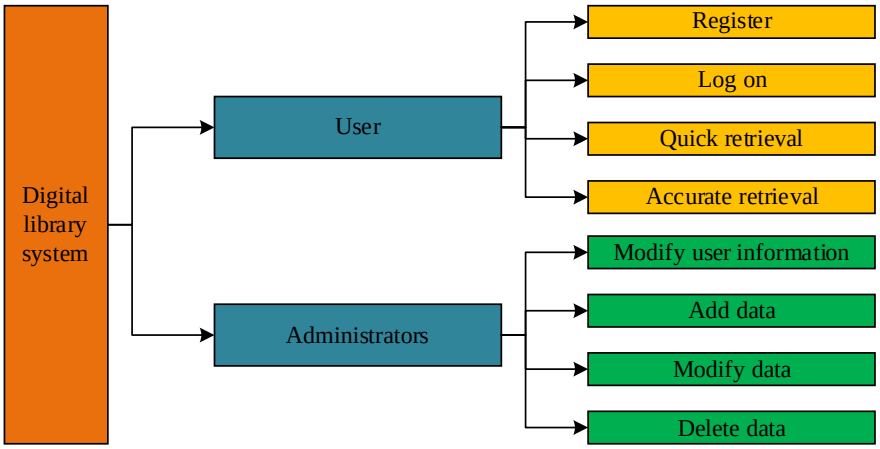

Fig. 2. Overall functionality of the designed system.

In Fig. 2, the designed digital library system mainly consists of two functional modules: user and administrator. Among them, the user module is capable of performing operations such as user registration, login, and search. When a user logs in for the first time, he/she must register an account. After that, the user must enter the correct user name and password each time he/she logs in to enter the digital library system. When the user conducts a search, each user has different needs, so the study designed two search methods, one for quick search and the other for accurate search. When a user performs a quick search, the system directly performs the search operation, while when a user performs a precise search, the system calls the algorithm module to perform the search. The administrator module can perform administrator login, user information modification, data processing and other operations. The study distinguishes between the user module and the administrator module through a User table and an Administrator table. Each table has its primary key and HTML5 role attribute is set to describe the role of different elements. When the role attribute is assigned a value of 0, it represents a user. When the role attribute is assigned to 1, it means administrator. In order to store the images and texts in the digital book, Text table and Picture table with unique primary key are created. Meanwhile, in order to store the final hash representation obtained, Text_feature table and Pic_feature table with unique primary key are created. Moreover, a foreign key is set for image feature (IF) and text feature respectively for joint query.

B. A Cross-Modal Deep Hash Model Based on Semantic Segmentation Networks

In digital library, with the explosive growth of different types of information, there is heterogeneity between the semantic features of these information. The way to measure the semantic similarity between different types of data has become the main challenge of current cross-modal retrieval in digital library [18]. Therefore, it is investigated to retrieve image and text features in digital library system through DCMH, and introduce Word2vec network with FCN to improve the DCMH algorithm. The algorithm uses Tiny_ViT as the backbone network. The data is categorized into IFs and text features based on semantic features, and the important features are extracted by an FCN IF extraction module and a Word2vec text feature extraction module. An improved deep cross-modal hashing (IDCMH) is proposed by integrating all the extracted features into the hash representation through a fully connected layer (FCL). The technical route of this algorithm implementation is shown in Fig. 3.

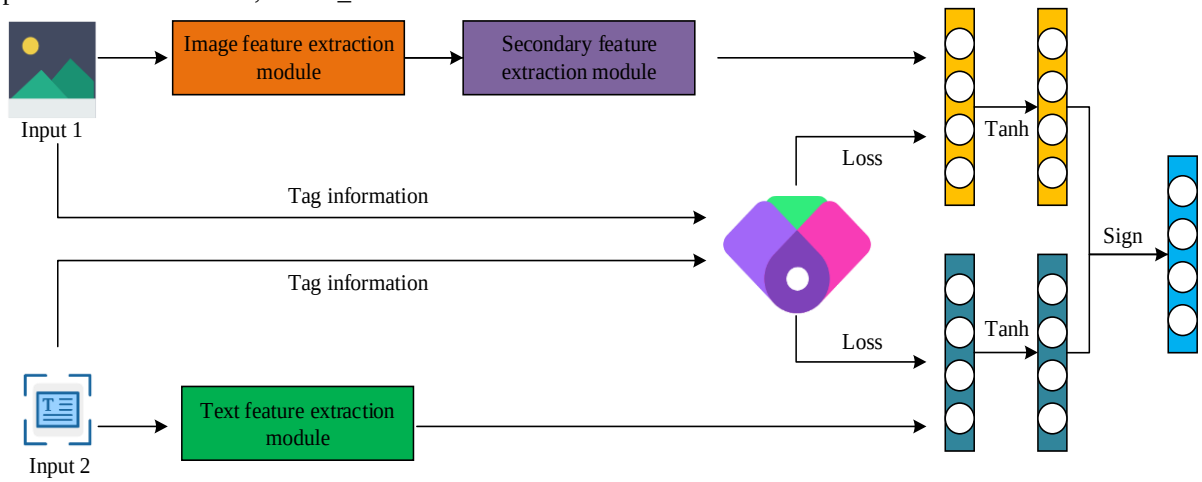

Fig. 3. Technical roadmap of cross-modal deep hashing algorithm.

The Word2vec text feature extraction module, the hash representation module, and the FCN IF extraction module comprise the three components of the IDCMH shown in Fig. 3. FCN is an end-to-end model that is able to learn mapping directly from image pixels to segmentation masks. Word2vec is a word vector model, which is able to transform words in text into real number vectors, and then perform operations such as text categorization and sentiment analysis [19-20]. The input image data and text data are pre-processed. The pre-processed data is input into FCN IF extraction module and Word2vec text feature extraction module. The training sample expressions for IFs and text features are shown in Eq. (1).

$$\begin{cases} X = \{x_i\}_{i=1}^{n} \\ Y = \{y_i\}_{i=1}^{n} \end{cases} \tag{1}$$

In Eq. (1), X represents the training samples of Ifs. Y represents the training samples of text features. i is the i th sample. n is the samples. IF extraction is performed first. Due to the different dimensions of the features in different network layers in the network, these features need to be mapped into a feature space. Therefore, the study inputs all features into a FCL and processes the features by linear transformation operations. The calculation method is shown in Eq. (2).

$$Q_t = W_q Q_m + b_q \tag{2}$$

In Eq. (2), Q_t represents the linearly transformed features. Q_m represents the secondary features. W_q is the weight of the FCL. b_q is the bias of the FCL. Then the processed features are normalized and calculated as shown in Eq. (3).

$$q_n^i = \frac{q_t^i - \mu_i}{\sqrt{\sigma_i^2 + \varepsilon}} \tag{3}$$

In Eq. (3), q_n^i is the normalized feature. μ_i is the mean of the i th feature vector. σ_i^2 is the variance of the i th feature vector. ε represents a real number to avoid a denominator of 0. The next step is to access another connectivity layer to fuse the different local features and utilize the ReLU function as an activation function. The calculation is shown in Eq. (4).

$$Q_b = \mathrm{ReLU}(W_a Q_n + b_a) \tag{4}$$

In Eq. (4), Q_b represents the fused features. ReLU(·) represents the activation function. W_a represents weights. b_a represents the bias. Fig. 4 depicts the model's flow for producing features.

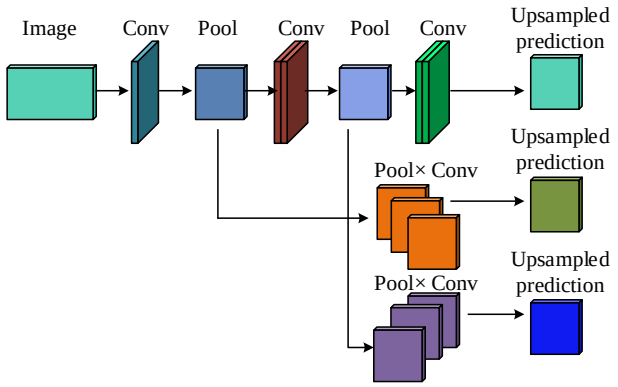

Fig. 4. The process of generating features from the model.

For text feature extraction, the continuous BWM of word2vec is used, which is able to characterize the semantic information of the words in terms of word vectors by learning the text. The continuous BWM consists of three layers: input layer, projection layer and output layer. The features to be extracted are fed into the input layer and converted into word vectors. The contextual representation of word vector is shown in Eq. (5).

$$Z = (z^{c-m}, \ldots, z^{c-1}, z^{c+1}, z^{c+m}) \tag{5}$$

In Eq. (5), Z represents the contextual representation of the word vector. m represents the number of windows. c represents the center word.

C. Improved Cross-Modal Deep Hash Model Considering Secondary Features

Since the information obtained from the digital library does not only contain important features, other secondary features that are easily ignored can also affect the performance of model extraction. Therefore, to guarantee that the extracted features are complete, a secondary feature extraction module is built. To produce the overall IF representation, the features extracted from the IF extraction module are fused with the IFs that are overlooked, which are first extracted using the secondary feature extraction module. The feature fusion process is shown in Fig. 5.

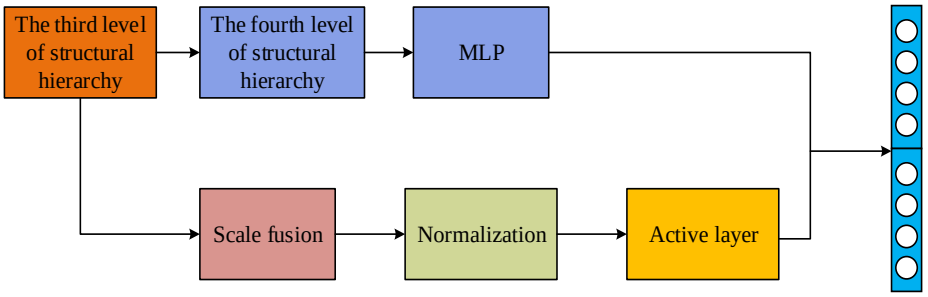

Fig. 5. Feature fusion process.

In Fig. 5, secondary features are mainly extracted by three steps including scale fusion, normalization, and feature activation. The word vector matrix is obtained by multiplying all the input word matrices with the effective coding vectors of each word, and all the word vector matrices are fused and vector averaged to represent the center word vector. The calculation is shown in Eq. (6).

$$\hat{v} = \frac{v_{c-m} + ... + v_{c+m}}{2m} \tag{6}$$

In Eq. (6), $\hat{v}$ represents the center word vector. Then it is processed using Softmax activation function and converted into probability values. The calculation is shown in Eq. (7).

$$\hat{y} = \text{Softmax}(z) \tag{7}$$

In Eq. (7), g_t represents the generated probability value. The text word vector is obtained by multiplying the obtained probability value with the input word matrix. Finally, the Ifs are hashed with the text features through the symbol function. The calculation method is shown in Eq. (8).

$$\begin{cases} F = Sign(Q_b) \\ G = Sign(\hat{y}) \end{cases} \tag{8}$$

In Eq. (8), F represents the hash code of Ifs. G represents the hash code of text features. $Sign(\cdot)$ represents the symbol function. To further deal with the heterogeneity between different features, the study is conducted by optimizing the loss function. Firstly, the smooth L1 loss function is utilized to eliminate the differences between different labels and hash representations. Eq. (9) displays the computation.

$$L(x,y) = \begin{cases} -\dfrac{0.5(x-y)^2}{\gamma}, |x-y| < \gamma \\ |x-y| - 0.5 * \gamma, |x-y| \geq \gamma \end{cases} \tag{9}$$

In Eq. (9), L represents the smooth L1 loss function. γ represents the difference between the label and the hash representation. Then cosine similarity with Jaccard coefficient is utilized to represent the semantic loss from image to text. The calculation is shown in Eq. (10).

$$J_{in} = \frac{1}{n \times n_{batchsize}} \sum_{i=1}^{n} \sum_{j=1}^{n_{batchsize}} \lambda S_{ij}^{vt}, cos\left(Q_b, \hat{y}\right)_L \tag{10}$$

In Eq. (10), J_{in} represents the semantic loss from image to text. Meanwhile, the loss function of Ifs is shown in Eq. (11).

$$J_i^v = \frac{1}{n \times n_{batchsize}} \sum_{i=1}^{n} \sum_{j=1}^{n_{batchsize}} \lambda S_{ij}^{vv}, cos\left(Q_{b_i}, Q_{b_j}\right)_L \tag{11}$$

The loss function for text features is shown in Eq. (12).

$$J_i^t = \frac{1}{n \times n_{batchsize}} \sum_{i=1}^{n} \sum_{j=1}^{n_{batchsize}} \lambda S_{ij}^{tt}, cos\left(\hat{y}_i, \hat{y}_j\right)_L \tag{12}$$

The overall loss can be obtained by IF loss and text feature loss, which is calculated as shown in Eq. (13).

$$J_O = J_i^v + J_i^t \tag{13}$$

The distance of the generated hash representation from different hash codes is minimized to quantize the hash code. The calculation is shown in Eq. (14).

$$J_q = \frac{1}{2nk}\left(\sum_{i=1}^{n}\sum_{j=1}^{k}(h_{ij} - q_{ij}) + \sum_{i=1}^{n}\sum_{j=1}^{k}(b_{ij} - \hat{y}_{ij})\right) \tag{14}$$

In Eq. (14), h_{ij} is the actual hash code. q_{ij} is the j th value of IF q_i. $\hat{y}_{ij}$ is the j th value of text feature $\hat{y}_i$. Finally, the final objective function can be obtained by synthesizing the three. Eq. (15) presents the calculating procedure.

$$\min_{B, W_v, W_t} J = J_{in} + \alpha J_O + \beta J_q \tag{15}$$

In Eq. (15), $\min_{B, W_v, W_t} J$ represents the final objective function. α and β represent the weight parameters. The above improved cross-modal hash retrieval model can quickly accomplish the retrieval of digital library. The flow is shown in Fig. 6.

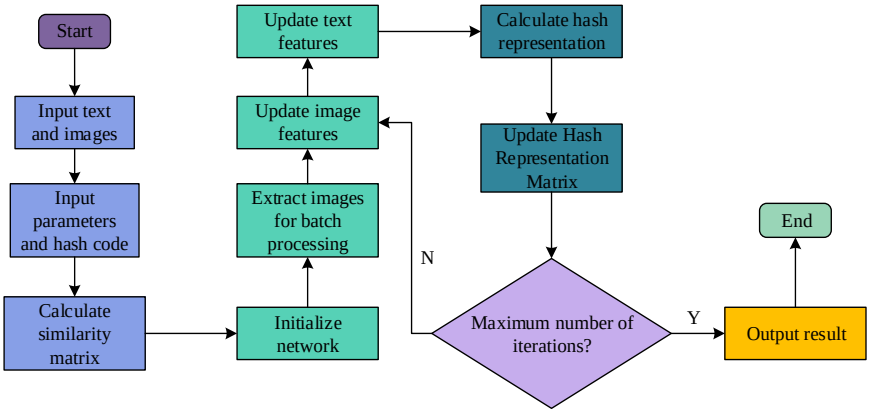

Fig. 6. Improved cross-modal hash retrieval model.

III. RESULTS

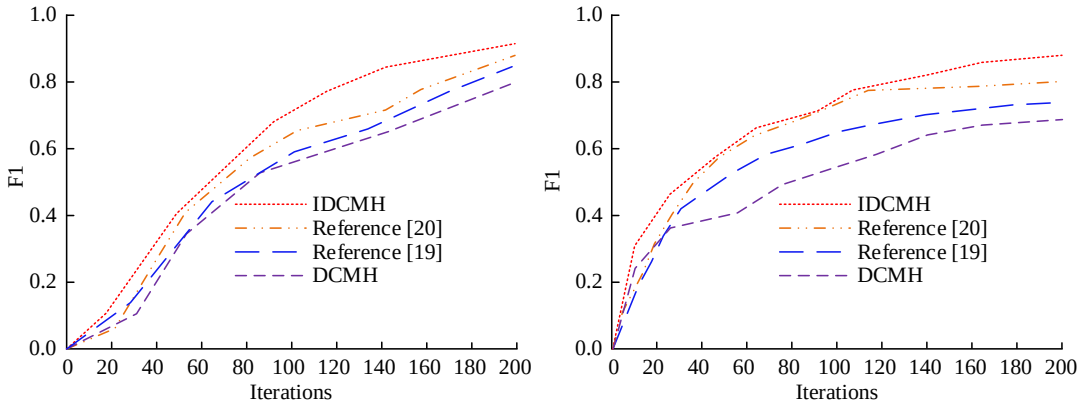
This section deals with the experimental results of the designed IDCMH retrieval model for digital library. Section I shows the performance analysis of the IDCMH retrieval model. The usefulness of the developed IDCMH retrieval model in real-world situations is examined in Section II.

A. IDCMH Model Performance Analysis

To verify the performance of the designed IDCMH model, the initial learning rate of the model is set to 0.0001, the batch size is set to 32, and the maximum iterations is 200. Firstly, the F1 metrics, the MIRFlickr dataset and the NUS-WIDE dataset are introduced, and the F1 values of the model on the different datasets are calculated respectively. Moreover, the F1 values are compared with those of the DCMH model, the model in study [19] and the model in study [20]. The MIRFlickr dataset is selected by Flickr for multimedia retrieval and contains one million images, each with text information, aesthetic quality annotations, and EXIF metadata. The NUS-WIDE dataset is an image dataset with network label annotations created by the Media Search Laboratory of the National University of Singapore, which includes 269648 images from websites with 5018 different labels. Fig. 7 presents the findings.

In Fig. 7(a), on the MIRFlickr dataset, the F1 values of all four models increase with the number of iterations. When the maximum iterations is reached, the F1 value of the DCMH model, study [19]' method, study [20]' method and IDCMH model is 0.803, 0.841, 0.887, and 0.936. In Fig. 7(b), the trend of the F1 values of the models on the NUS-WIDE dataset is the same as the trend of the F1 values on the MIRFlickr dataset with the same trend. When the maximum iterations is reached, the F1 values of the four models, DCMH, study [19], study [20] and IDCMH, are 0.682, 0.761, 0.804 and 0.877, respectively. In summary, the F1 values of the proposed IDCMH model are greater than the other three models in different datasets, which proves its better performance. It also proves its generalization ability and robustness. For validating the retrieval accuracy of the proposed IDCMH model, the study calculates the accuracy of the IDCMH model on the MIRFlickr dataset and the NUS-WIDE dataset when the hash code is 16bits, 32bits, and 64bits, respectively. The accuracy is also compared with that of DCMH, study [19], and study [20]. Table I presents the findings.

In Table I, in the MIRFlickr dataset, when the hash code is 16bits, the accuracy of the IDCMH model is 0.948. When the hash code is 32bits, the accuracy of the IDCMH model is 0.952. The IDCMH model's accuracy when the hash code is 64 bits is 0.923, which is a substantial improvement above the accuracy of other models. In the NUS-WIDE dataset, when the hash code is 16bits, 32bits, and 64bits, the accuracy of IDCMH model is 0.932, 0.936, and 0.934, respectively. It suggests that the IDCMH model offers notable performance advantages and is more efficient at executing graphic retrieval from digital libraries. Precision-recall (PR) curves for the MIRFlickr and NUS-WIDE datasets are computed for the IDCMH model, respectively, and compared to the PR curves of the other models in order to confirm the model's overall performance. Fig. 8 presents the findings.



(a) F1 values of different models on the MIRFlickr dataset

(b) F1 values of different models on the NUS-WIDE dataset

Fig. 7. F1 values of different models on the MIRFlickr and NUS-WIDE datasets.

TABLE I. PRECISION OF DIFFERENT MODELS ON MIRFLICKR DATASET AND NUS-WIDE DATASET

Model		Data set	Hash code		
			16bits	*32bits*	*64bits*
Precision	DCMH	MIRFlickr	0.702	0.618	0.622
		NUS-WIDE	0.687	0.624	0.643
	Reference [19]	MIRFlickr	0.849	0.875	0.769
		NUS-WIDE	0.837	0.831	0.853
	Reference [20]	MIRFlickr	0.871	0.883	0.887
		NUS-WIDE	0.840	0.876	0.868
	IDCMH	MIRFlickr	0.948	0.952	0.923
		NUS-WIDE	0.932	0.936	0.934

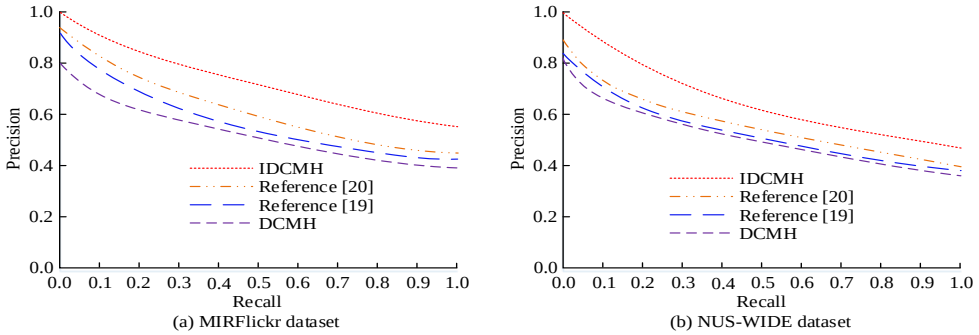


Fig. 8. PR curves of different models on MIRFlickr and NUS-WIDE datasets.

In Fig. 8(a), in the MIRFlickr dataset, the precision of all four models tends to decrease with the increase of recall. When the recall rate (RR) is 0.8, the precision of IDCMH model, study [20]' method, study [19]' method and DCMH model is 0.61, 0.47, 0.43 and 0.41. In Fig. 8(b), in the NUS-WIDE dataset, the trends of the PR curves of the four models are consistent with the trends of the PR curves in the MIRFlickr dataset. When the RR is 0.8, the RRs of the four models are 0.46, 0.40, 0.39, and 0.38, respectively. In summary, in different datasets, when the same RR is taken, the precision rate of IDCMH model is greater than that of other models. Meanwhile, it can be found that the PR curves of IDCMH model are always above the PR curves of other models, which proves that the comprehensive performance is better. In addition, it indicates that the IDCMH model has strong ability to handle large-scale datasets, proving its scalability.

B. *Practical Application Effect Analysis*

To validate the effectiveness of the designed IDCMH model in practical applications, the study is conducted in an operating environment equipped with Intel Core i9-9900k central processor, 128G running memory, 1TB hard disk, and Windows 10, and the simulation analysis is performed using Python 3.7 software. Firstly, ROUGE scores are introduced to calculate the ROUGE1 scores and ROUGE2 scores of the DCMH model in the MIRFlickr dataset, respectively. The results are also compared with the ROUGE1 score and ROUGE2 score of DCMH, study [19]' method and study [20]' method. Fig. 9 presents the findings.

In Fig. 9(a), the ROUGE1 scores of the different models increase with the number of iterations. When the maximum iterations are reached, the ROUGE1 score of IDCMH, study [20]' method, study [19]' method and DCMH is 0.85, 0.82, 0.78 and 0.76. In Fig. 9(b), the ROUGE2 scores of the models with the iteration number of the trend is consistent with the trend of the ROUGE1 score of each model. When the maximum iterations is reached, the ROUGE2 scores of the four models are 0.96, 0.90, 0.86 and 0.82, respectively. It can be found that the ROUGE1 score and ROUGE2 score of the IDCMH model are significantly larger than those of other models, which proves that it performs better in measuring the similarity of graphical features and repetition. To further validate the performance of IDCMH model, the study introduces four metrics, namely, CPU utilization, memory utilization, number of concurrent operations, and operation success rate, and calculates the metric values of different models respectively. Table II presents the findings.

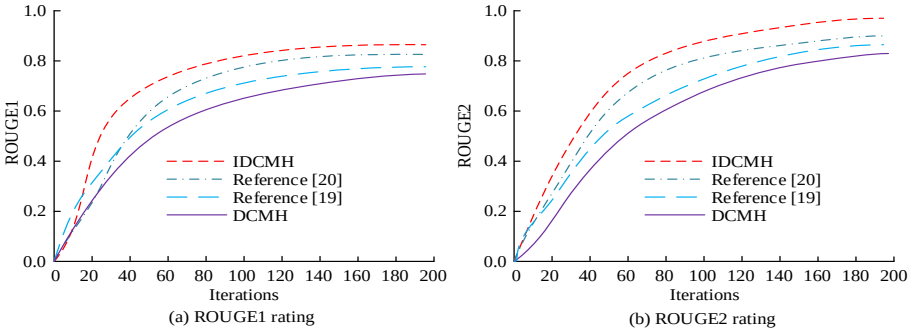

Fig. 9. ROUGE1 and ROUGE2 ratings for different models.

TABLE II. CPU UTILIZATION, MEMORY UTILIZATION, CONCURRENT OPERATIONS, AND OPERATION SUCCESS RATE OF DIFFERENT MODELS

Test indicators	Model			
	DCMH	***Reference [19]***	***Reference [20]***	***IDCMH***
Cpu utilization (%)	73.6	68.6	66.4	45.4
Memory utilization (%)	80.2	77.1	74.3	36.3
Number of concurrent operations	22	46	57	92
Operation success rate (%)	86.5	88.3	90.2	96.7

In Table II, the CPU utilization of IDCMH model is 45.4%, the memory utilization is 36.3%, the number of concurrent operations is 92, and the operation success rate is 96.7%. The analysis indicates that the CPU utilization and memory utilization of the IDCMH model are much lower than the values of the two indexes of the other models. However, the number of concurrent operations and operation success rate are significantly higher than those of the other three models. The aforementioned findings demonstrated the stability and dependability of the IDCMH model and showed that its resource utilization efficiency is excellent. Lastly, the variation of the suggested IDCMH model's response time with data amount is calculated and compared with other models' results to confirm the model's speed of operation. The results are shown in Fig. 10.

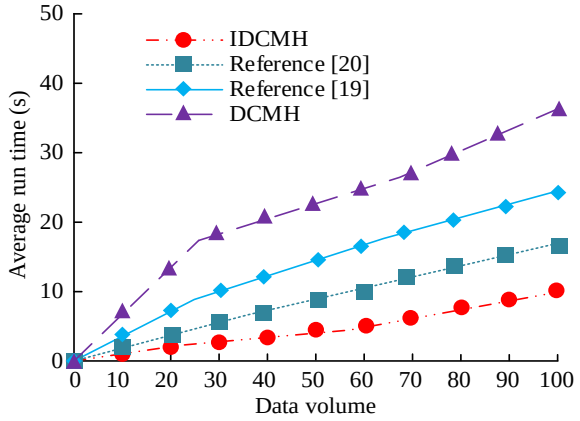

Fig. 10. The variation of response time with data volume, etc.

In Fig. 10, as the amount of processed data increases, the average response time of the proposed IDCMH model is 10.2s when the amount of processed data is 100. The average response time of the method in study [20] is 17.4s, that of the method in study [19] is 24.6s, and that of the DCMH model is 36.1s. It can be found that compared to the DCMH model, study [19] and study [20], the average response time of IDCMH model has decreased by 71.7%, 58.5% and 41.3%, respectively. It is proved that the IDCMH model runs more efficiently.

IV. Discussion

The research aims to explore a resource retrieval method for digital libraries, in order to overcome the disadvantages of slow retrieval speed and low retrieval accuracy of traditional digital library resource retrieval techniques. This research presents the development of a three-tier digital library image and text retrieval system based on the B/S architecture, utilizing Tiny_ViT as the underlying network and integrating FCN and word2vec models to enhance DCMH, culminating in the proposal of an IDCMH model. The results showed that on the MIRFlickr dataset, the F1 value of the IDCMH model reached 0.936. Moreover, on the NUS-WIDE dataset, the F1 value of the IDCMH model was 0.877, which was significantly higher than other models. It demonstrated its strong generalization ability and robustness. This was similar to the conclusion drawn by Zeng Z et al. [5]. This study proposed a visual search model based on bag of words model and multiple semantic associations that could extract local and global features of images using scale invariant feature changes and hue, saturation, and brightness, with strong generalization ability. However, compared to it, the IDCMH model was significantly better. This was because the model mainly relied on manual feature extraction and lacked understanding of deep semantics, while the IDCMH model could automatically extract deep features of images and text through FCN and Word2vec. At the same time, the IDCMH model had higher accuracy and recall than other models on different datasets, proving its good comprehensive performance and scalability. This conclusion was similar to the findings of Ahmadi A et al. [11]. The image semantic retrieval method proposed by Ahmadi A et al., which combined ontology and composite models, effectively improved retrieval accuracy. However, the construction process of the ontology was too complex, which increased the complexity of the system and leads to low scalability. The IDCMH model proposed by the research simplified the model structure and greatly enhanced scalability through optimized feature extraction and loss functions. Therefore, the IDCMH model could automatically extract deep features of images and text, and performed well in cross-modal retrieval of digital libraries, with important application value in a wider range of practical scenarios.

V. Conclusion

The rapid development of the digital era has played a good role in promoting the construction and management of digital resources in libraries. The advanced information technology can digitize the numerous digital resources, so as to maximize the contribution and utilization of information resources. Meanwhile, digital library users have increasingly high requirements for the efficiency and precision of graphic retrieval. Therefore, the research optimized the DCMH through the graphic semantic features of digital books, introduced FCN and word2vec model for semantic feature segmentation, and designed an IDCMH retrieval model. The findings showed that, on the MIRFlickr and NUS-WIDE datasets, the IDCMH retrieval model's F1 values were 0.936 and 0.877, respectively, which were significantly higher than the F1 values of the other models on the two datasets. It demonstrated the improved performance, resilience, and capacity for generalization of the model. The accuracy of IDCMH model could reach up to 0.952 on both datasets, which proved its higher accuracy. The results indicated that the IDCMH model outperformed the other models in quantifying the similarity and repetition of graphic aspects. Its ROUGE1 and ROUGE2 scores were 0.85 and 0.96, respectively. In conclusion, the proposed IDCMH model is more effective. However, the dataset used in the study contains a small amount of target data, and the calculated results may be affected to some extent. In the future, larger sources, quantities, and types of datasets will be selected to expand the variety of datasets and the richness of annotated data, providing more comprehensive data support for applying cross-modal retrieval to digital libraries and further improving the accuracy of results.

AI-Powered Waste Classification Using Convolutional Neural Networks (CNNs)

Chan Jia Yi, Chong Fong Kim
Faculty of Data Science and Information Technology, INTI International University, Nilai, Malaysia

***Abstract*—In Malaysia, approximately 70%-80% of recyclable materials end up in landfills due to low participation in Separation at Source Initiative. This is largely attributed to the public perception that waste segregation is a foreign idea, coupled with a lack of public knowledge. Around 72.19% of the residents are unsure about waste categorization and proper waste disposal. This confusion leads to apathy toward recycling efforts exacerbated by deficient environmental awareness. Existing waste classification systems mainly rely on manual entry of waste item names, leading to inaccuracies and lack of user engagement, prompting a shift towards advanced deep learning models. Moreover, current systems often fail to provide comprehensive disposal guidelines, leaving users uninformed. This project addresses the gap by specifically developing an AI-Powered Waste Classification System incorporated with Convolutional Neural Network (CNN), classifying waste technologically and providing environmentally friendly disposal guidelines. By leveraging primary and secondary waste image data, the project achieves a training accuracy of 80.66% and a validation accuracy of 77.62% in waste classification. The uniqueness of this project lies in its utilization of CNN within a user-friendly web interface that allows the user to capture or upload waste image, offering immediate waste classification results and sustainable waste disposal guidelines. It also enables users to locate recycling centers and access the dashboard. This system represents an ongoing effort to educate people and contribute to the field of waste management. It promotes Sustainability Development Goal (SDG) 12 (Responsible Consumption and Production) and SDG 13 (Climate Action), contributes zero waste, raises environmental awareness, and aligns with Malaysia's goals to increase recycling rates to 40% and reduce waste sent to landfills by 2025.**

Keywords*—Convolutional neural networks; CNN; deep learning; waste classification; recycling; zero waste; SDGs

I. Introduction

Cities around the world are struggling with a large amount of waste generation because of the rapid urbanization. According to a study by [1], the annual global waste production is projected to reach a staggering 27 billion tons by 2025. Malaysia, a country that is heavily relies on landfill disposal for waste management. It handles approximately 89% of the waste generated daily, which amounts to around 33,120 tons per day [2]. Notably, households in Malaysia are the main contributors to the waste stream, with recyclable materials constituting a substantial 70% to 80% of the landfill-bound waste [3].

To tackle the waste issue, the Malaysian government introduced "Separation at Source Initiatives" (SSI) under Act 672 starting in 2015 [4]. This plan requires households to separate their waste into recyclable and non-recyclables. Nevertheless, this plan has not been very effective because many people lack knowledge and understanding about waste segregation. Around 72% of residents are confused about waste segregation and do not know what the purpose of doing it [5]. Other efforts such as the #Asingkan campaign and KitaRecycle have also been organized, but the responses are not that active [6].

There is a widespread lack of public knowledge about proper waste disposal, recycling practices, and the environmental benefits of recycling [7]. Research conducted by [5] found that approximately 72.19% of the population is uncertain about the best waste disposal practices. This lack of awareness is often compounded by confusion about waste segregation. People are not sure which waste items belong to which categories. This confusion and lack of awareness lead to the perception that individual recycling efforts have little impact on environmental issues. As a result, people become indifferent and less motivated to recycle [8].

Moreover, the absence of well-defined policies and a sense of responsibility among Malaysians compounds the issue of limited environmental awareness [9]. A significant number of Malaysians believe that the primary responsibility for waste management lies with local authorities and municipal waste collectors. This perception creates a gap in knowledge and waste segregation practices at the household level [10]. The lack of environmental consciousness and inadequate enforcement has led to the development of a "tidak apa" (indifferent) culture among Malaysians [11].

By using the deep learning technique, the proposed system solves the issue of confusion and aligns the Malaysia 12th Pan while promoting the Sustainable Development Goals (SDGs). The proposed system aims to serve as an education platform that provides knowledge and utilizes the power of deep learning to eliminate people's confusion in waste classification, at the same time educating people about sustainable waste management practices. In short, the authors intend to influence the user positively through this system. The flow of the proposed system can be viewed in Fig. 1.

A. Problem Statement

In Malaysia, approximately 70%-80% of recyclable materials end up in landfills due to low participation in Separation at Source Initiative [3]. This is largely attributed to the public perception that waste segregation is a foreign idea, coupled with a lack of public knowledge [6]. Around 72.19% of the residents are unsure about waste categorization and

proper waste disposal [5]. Consequently, this confusion leads to apathy toward recycling efforts [7] exacerbated by deficient environmental awareness [3].

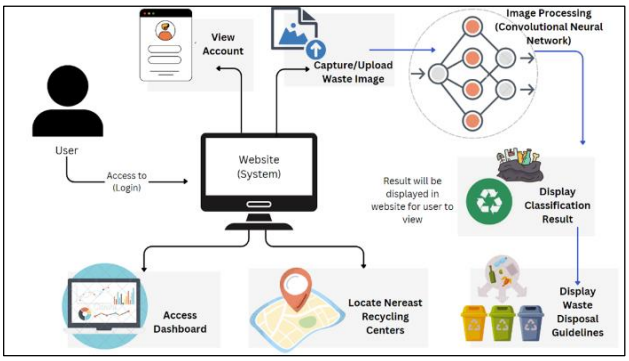

Fig. 1. System flow.

B. Research Question and Objectives

This research paper was written to fulfill the research objective via the questions stated below:

RQ1: What are the current waste management challenges?

RQ2: How effective are Convolutional Neural Networks for waste image classification?

RQ3: What features should the web-based waste classification system have to address the challenges?

RQ4: How effective is the developed system to solve the challenges?

The above research questions are to be answered through the research objectives necessary for this study.

RO1: To study the current waste management issue to recognize the challenges in terms of waste segregation and recycling.

RO2: To investigate the effectiveness of Convolutional Neural Networks in waste image classification.

RO3: To develop a web-based waste classification system.

RO4: To conduct testing and evaluation on the developed system.

This paper is organized as follows: Section II provides a comprehensive literature review, examining existing research and identifying gaps relevant to waste classification. Section III details the methodology employed in this study, outlining the processes from data collection to system development. In Section IV, the results and their implications are discussed, offering the effectiveness of the system. Finally, Section V concludes the paper by summarizing the key findings and presenting recommendations for future research in the field of waste management.

II. Literature Review

The rapid increase in waste generation in Malaysia, coupled with low recycling participation rates underscore the urgent need for effective waste management strategies. Waste classification is a key aspect of this challenge because it facilitates proper recycling and waste reduction. This section reviews current research related to waste management challenges, waste classification using CNN algorithm and the development of user-friendly systems, addressing the research objectives of this paper.

Studies indicate that waste management in Malaysia is not mature enough. The research in [4] emphasized that waste segregation and recycling are the most effective ways to reduce the waste sent to landfills. Referring to the Malaysia Solid Waste Management Policies and Plans Transformation [11], waste segregation and recycling gradually become the main objectives to target. Various organizations, both governmental and non-governmental, have made efforts to raise public awareness about the importance of these practices. One of the impressive programs is “Separation at Source Initiatives” (SSI). However, the outcome is not that positive due to a widespread lack of public knowledge and understanding about proper disposal practices, recycling guidelines, and the environmental benefits of recycling [7]. This confusion often leads individuals to feel uncertain about which waste items belong to specific categories, contributing to a perception that personal recycling efforts have minimal impact on environmental issues, as a result, many lack motivation to recycle [8]. There is a pressing need for innovative solutions to educate the public about recycling, clarify waste segregation, and raise awareness of proper disposal methods. Achieving these goals is essential for reducing waste and meeting the national target by 2025, while also promoting SDG 12 and 13.

Real-life practical applications prove that deep learning performed better than traditional machine learning in image classification tasks [12-14]. Among different deep learning models, Convolutional Neural Networks have demonstrated the highest efficiency in image classification tasks [15]. Several studies have concentrated on enhancing waste classification accuracy. The study in [16] developed the Deep Neural Network for Time Classification (DNN-TC) model using a deep transfer learning approach, achieving impressive results with 94% and 98% accuracy on Transnet and VN-trash datasets. The study in [17] focused on automatic image-based waste classification, achieving 88.66% accuracy using ResNet architecture. These studies underline the effectiveness of CNN in accurate classification of waste items. The choice of using CNN pre-trained models or using scratch depends on time and resource availability [18]. Most studies utilized pre-trained models such as Visual Geometry Group (VGG), Residual Network (ResNet), and Mobile Network (MobileNet) for image classification tasks because they performed well with the ability of the transfer learning technique to recognize a different task [18]. This research validates the use of CNNs in waste classification and directly supports the objective (RO2) to investigate the effectiveness of CNNs in waste image classification.

Upon comparing and analyzing the existing similar waste classification systems, important gaps are found. Existing systems rely only on classifying common waste and it is too general. A good waste classification system should be aligned with the country’s waste management guidelines and missions. The implementation of deep learning for waste classification systems in real-life scenarios is less as the

authors found that existing system requires the user's input to search waste items through its database such as the 101 Trash [22], which can be time-consuming. At the same time, for those systems that consist of a deep learning model for classification features such as DeepWaste [19] and EcoScan [20], it only shows the waste classification result without displaying the next step to guide users on what to do. Most studies focus primarily on the technological aspects, often neglecting the necessity of public engagement and comprehensive disposal guidelines. Furthermore, the datasets used for the existing systems are considered less, and probably this is one of the reasons that lead to inaccuracy.

To sum up, the literature outlines significant advancements in waste classification technologies but also reveals critical gaps that must be addressed. By integrating technological solutions with community engagement strategies, this research aims to develop a more effective waste classification system that enhances both efficiency and public participation.

III. Methodology

In the journey of developing the proposed system, the authors followed a structured research methodology, as shown in Fig. 2, which is a combination of the System Development Life Cycle (SDLC) and Cross-Industry Standard Process for Data Mining (CRISP-DM).

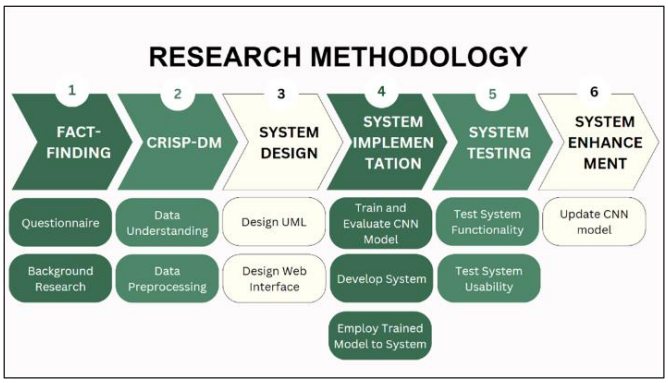

Fig. 2. Research methodology.

The research methodology used includes fact-finding, data collection, system design, system implementation, and system testing. Future enhancement would be done by regularly updating the CNN model training dataset to increase the model's accuracy and ensure that the system can classify more waste items.

A. Phase 1: Fact-Finding

The purpose of the above question is to get an overview of the waste materials commonly generated by Malaysian households. As shown in Fig. 3, plastic waste emerged as the main concern, acknowledged by 88.6% of respondents, highlighting its pervasive nature. Paper and cardboard waste were prevalent, reported by 64.8% of respondents, underlining their common use. Other categories included organic waste (55.2%), e-waste (30.5%), and clothing waste (31.4%). The high recognition of general waste, including waste such as tissue paper and masks achieved 78.1%. It reflected contemporary challenges related to pandemic-including waste. In short, the findings highlight the necessity for targeted waste management strategies, particularly for plastics and general waste, emphasizing the importance of sustainable practices such as 3R (Recycling, Reuse, Reduce) culture and public awareness.

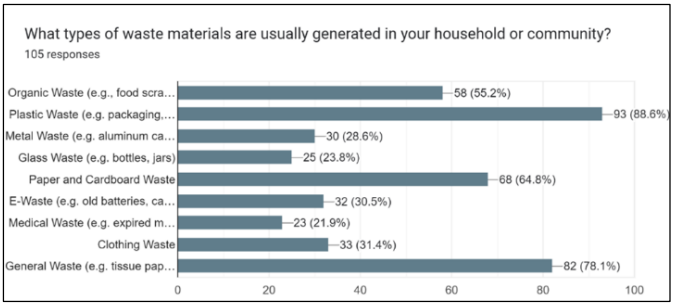

Fig. 3. Common household waste generated.

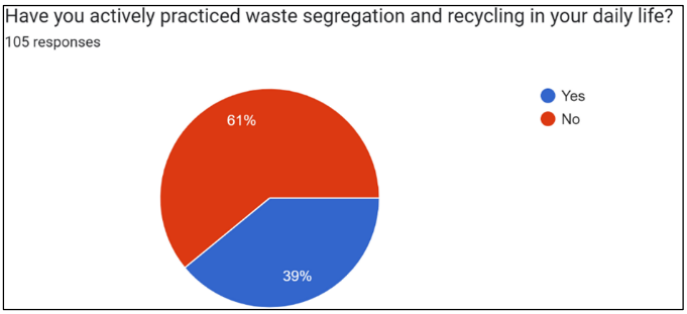

Fig. 4. Activeness in waste segregation and recycling practice.

The purpose of the above question is to understand how many respondents actively practice waste segregation and recycling in their daily lives, providing insights into their engagement with sustainable waste management. As shown in Fig. 4, only 39% of respondents actively participated in these practices. It indicates that there is a considerable portion of the population incorporating eco-friendly habits into their daily lives. Nevertheless, the majority of them, 61%, reported not actively engaging in such practices. The findings highlight a need for innovative solutions to improve community involvement in waste segregation and recycling efforts.

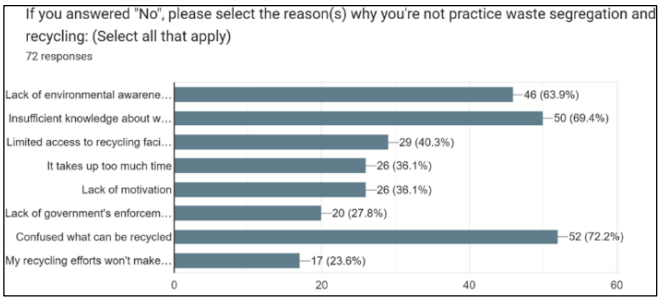

Fig. 5. Insights into the barriers that hinder sustainable waste management practices.

The main purpose above question is to figure out the reasons behind respondents not actively practicing waste segregation and recycling. It provides insights into the barriers that hinder sustainable waste management practices. As shown in Fig. 5, a significant number of respondents, about 72.2%

expressed confusion about what can be recycled. Additionally, the results indicate that the most prevalent reasons include a lack of environmental awareness (63.9%) and insufficient knowledge about waste segregation (69.4%). There are 23.6% of respondents voted for the reason that their recycling efforts would not make a significant difference to the planet. All this information is important for having educational plans and platforms to overcome specific challenges.

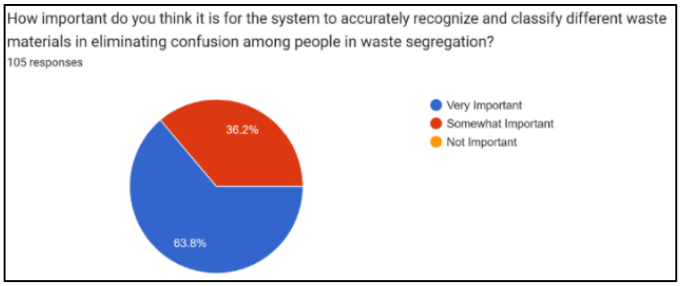

Fig. 6. How important respondents think if the system can recognize and identify waste accurately.

The purpose of asking about the importance of accurate waste material recognition and classification in the proposed system was to gain the respondents' perspective on the significance of leveraging the power of technology in addressing the issue of confusion during waste segregation. As shown in Fig. 6, 63.8% consider it "Very important", which underscores a strong consensus on the important role of technology in enhancing waste management practices. This result suggests a recognition among respondents that an AI-powered waste classification system capable of accurately classifying different waste materials could contribute to eliminating confusion during waste segregation. The positive response toward the importance of technology in waste management aligns with the objectives of the proposed system.

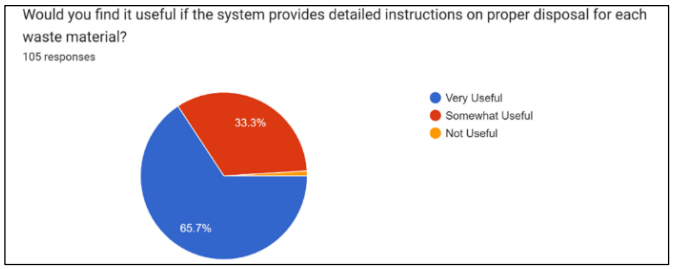

Fig. 7. How useful the system can provide instructions on waste disposal.

The purpose of including the above question in the questionnaire is to understand the users' expectations and preferences regarding the features of the proposed waste classification system. As shown in Fig. 7, the majority of respondents, 65.7%, find it "Very Useful", indicating a strong desire among respondents for a system that not only classifies waste materials but also provides comprehensive guidance on proper disposal. This result suggests that users value not only the identification aspect but also practical guidance on waste management. The demand for detailed instructions aligns with the system's goal of promoting responsible waste disposal practices. It reinforces the importance of integrating informative features within the proposed system to enhance user experience and contribute to more effective waste management habits.

B. Phase 2: CRISP-DM Framework

Following the CRISP-DM framework, the authors collected data from primary and secondary sources [21] to ensure the trained model directly reflects Malaysia's waste context. A total of 12 waste classes are labeled as shown in Fig. 8.

Fig. 8. Sample waste image from dataset for CNN model training.

Fig. 8 shows some sample waste image datasets used for CNN training. Before training, the authors removed the corrupted and low-resolution waste images to maintain the data quality. The images are pre-processed by utilizing data augmentation techniques, including rotation and flipping to improve its ability to recognize more waste variations.

C. Phase 3: System Design

The system is designed by using one of the famous UML diagrams, a use case diagram as shown in Fig. 9 to understand how each component in the system works with each other. By using a use case, the authors can easily figure out how users interact with a system. Use cases help the authors understand the system's functionality, behavior, and interactions in a structured and understandable form. They are valuable for guiding the design, development, and testing of software systems, ensuring that they meet the needs and expectations of users.

D. Phase 4: System Implementation

The authors utilized the power of Jupyter Notebook, Python Programming Language, TensorFlow, and Keras libraries to build and train the deep learning model, Convolutional Neural Network. The authors tried both methods in training the CNN model: train from scratch and train using a pre-trained model. The results from these two methods have shown a large difference.

Fig. 9. System design.

By training the CNN model from scratch, the model achieves a training accuracy of 83.82%, and a validation accuracy of 68.49% (see Fig. 10(a)). In contrast, by using a pre-trained model, which is Visual Geometry Group 16 (VGG16) as the base architecture, it achieves a training accuracy of 80.66% and an increased validation accuracy of 77.62% in waste image classification (see Fig. 10(b)). This further proves the efficacy and performance of using a pre-trained model as a base architecture, as highlighted in previous literature reviews [12] [18].

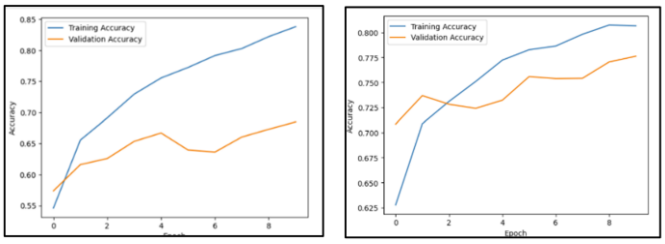

Fig. 10. (a) and (b) show the accuracy of two different methods for training the CNN model.

Transitioning to the system development, the authors used a combination of VS Code, PHP, HTML, CSS, and JavaScript to craft the user interface and system functionalities. What ties everything together is the Flask. By leveraging the Flask framework, the authors successfully integrate the trained CNN model with higher validation accuracy into the system, enabling the user to capture or upload waste images, thus getting immediate waste classification results. At this moment, users can choose to view the customized waste disposal guidelines based on their preference.

E. Phase 5: System Testing

Two main tests were conducted: unit testing and usability testing. The overall unit testing achieved a high pass rate, meaning that the majority of test cases passed successfully. Those test cases that failed will need further investigation and improvement. Some key observations are concluded. Firstly, the CNN model can classify the waste moderately well, but still, some misclassifications were detected, particularly in cases that involve complex waste images.

The result from the usability testing shows that the system consistently provides accurate waste classification results and value disposal guidance to users. Many of them expressed appreciation for the user-friendly interface for completing the tasks given. They are impressed by the power of deep learning in classifying waste images and the sustainable disposal tips provided by the system.

IV. Result and Discussion

This section presents the findings from the development and testing of the proposed waste classification system. The authors begin with system development results by displaying the interfaces, highlighting its design elements that enhance usability and facilitate efficient waste management. Next, the authors present the results of the waste classification testing, which is the main core of the system to showcase the system's accuracy and performance metrics to demonstrate its effectiveness in identifying various waste types. Finally, the authors compare the proposed system with existing solutions, illustrating its advantages in terms of classification capabilities and overall user experience. Through this discussion, the authors aim to provide a comprehensive understanding of the system's contributions to waste management practices.

A. System Development Result

The developed system consists of several features: an informative homepage, waste capture or upload, view classification results and customized disposal guidelines, locate recycling centers, and a dashboard as shown in Fig. 11, Fig. 12, Fig. 13, Fig.14 and Fig.15.

Fig. 11. Informative home page.

Fig. 11 illustrates the system's home page, which provides various useful educational resources and information. This page is designed to help users access essential content related to waste management and recycling.

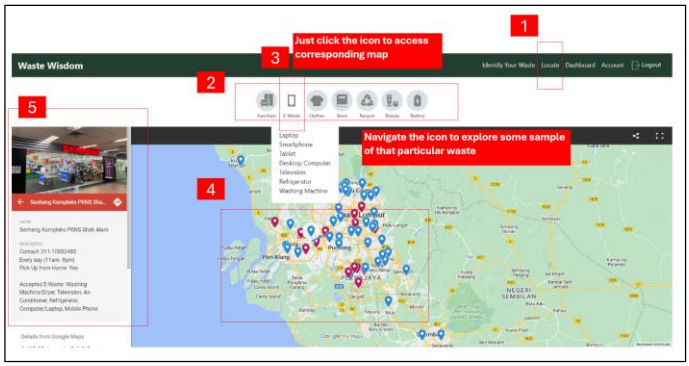

Fig. 12. Locate recycling centers.

Fig. 12 illustrates the system page where it displays the recycling center's location of each different recyclable item. Users can easily navigate through a row of clickable icons representing various items for recycling. For instance, if a user wishes to recycle furniture, they can simply click the furniture icon, and the corresponding map will be displayed.

Fig. 13. Dashboard.

Fig. 13 illustrates the dashboard, including global waste statistic, Malaysia e-waste collection centers by states, Malaysia household waste composition, recycling rate by country and Malaysia landfill status.

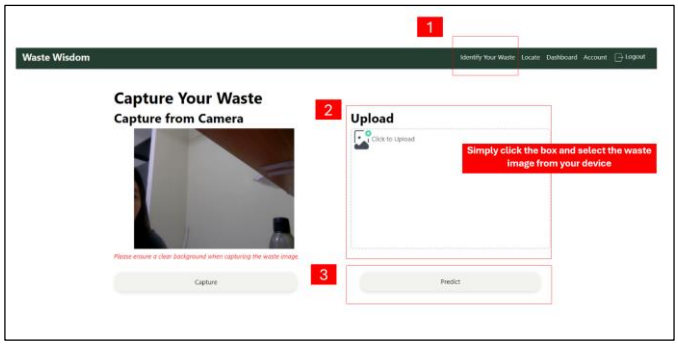

Fig. 14. Capture waste image.

Fig. 14 illustrates the system page where the user can either capture or upload the waste image.

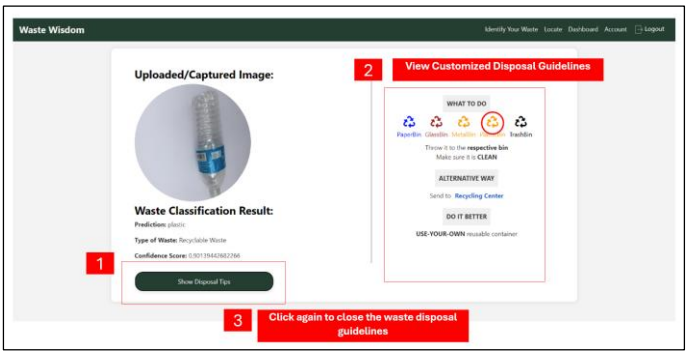

Fig. 15. Waste classification result and guidelines.

Fig. 15 illustrates the system page where the waste classification result and confidence score are displayed. Users can click the "Show Disposal Tips" button to access guidelines for classified waste.

B. Waste Classification Testing Result

This segment presents the results of the waste classification testing, detailing the accuracy and reliability of the system. The findings demonstrate the effectiveness of the classification algorithm, highlighting how well the system identifies various waste types and the confidence scores associated with each prediction.

Fig. 16. Waste items from various categories for testing.

Table I shows the predicted classifications, along with their scores, and indicates whether the model's predictions are considered a pass or fail based on the 60% threshold. The results were derived from the various waste items displayed in Fig. 16. The model correctly classifies 11 out of 12 items, showing that it performs well across a variety of waste types. Even when confidence is lower, it still makes the right prediction in most cases.

TABLE I. WASTE CLASSIFICATION TESTING RESULT

No	Expected	Predicted	Score	Pass/Fail
1	cardboard	cardboard	0.6518	Pass
2	paper	paper	0.5376	Pass
3	glass	glass	0.9991	Pass
4	organic	organic	0.6804	Pass
5	metal	metal	0.9949	Pass
6	plastic	plastic	0.8644	Pass
7	charger	glass	0.6522	Fail
8	mouse	mouse	0.5518	Pass
9	smartphone	smartphone	0.9717	Pass
10	battery	battery	0.9854	Pass
11	laptop	laptop	0.8799	Pass
12	trash	trash	0.4855	Pass

The model performed exceptionally well for categories such as Glass (0.9991), Metal (0.9949), Battery (0.9854), and Smartphone (0.9717). These high scores indicate that the model is highly confident in these predictions, likely due to clear and distinctive features that help distinguish these waste types. Predictions such as Cardboard (0.6518), Organic (0.6804), and Plastic (0.8644) also passed, with confidence scores above the 60% threshold. Although the confidence for these items is slightly lower, the model still correctly identified the waste types, demonstrating good performance overall. On the other hand, the predictions for Paper (0.5376), Mouse (0.5518), and Trash (0.4855), while below the 60% threshold, were correctly classified. The model successfully identified the correct waste category despite its lower confidence. This suggests that even in cases where the model is less sure, it can still make accurate classifications, which is a positive sign for real-world applications.

The only failure in the table is the misclassification of "Charger" as "Glass", with a confidence score of 0.6522. This is possibly due to poor image quality. Another reason might be the image itself's complexity which makes the system confused and misclassifies the waste category. Although the confidence score exceeds the threshold, the predicted output was incorrect. This indicates a specific issue in differentiating Charger from Glass. Therefore, it is important to ensure that the background is clear when capturing or uploading the waste image and further fine-tuning is needed to help the model better differentiate chargers from other materials. But overall, the trained CNN model performed reasonably well in recognizing and classifying common waste.

C. Comparison of Existing and Proposed Systems

This segment compares the proposed system with existing waste classification systems to illustrate the advantages of the proposed system. By comparing important aspects such as key features, model used, dataset, accuracy and user experience, the authors highlight how the proposed system offers enhanced capabilities and improved recycling efficiency, addressing the limitations of current solutions.

Table II shows a clear comparison of key features and models used across several waste classification systems, including DeepWaste [19], EcoScan [20], 101 Trash [22] and proposed system. The proposed system uses a larger and more diverse dataset, specifically tailored to the Malaysian waste context. Since waste generation patterns vary across countries due to cultural differences, this localized focus allows the system to better reflect the types of waste commonly found in Malaysia, enhancing its relevance and accuracy for the target region.

TABLE II. COMPARISON BETWEEN EXISTING SYSTEM AND PROPOSED SYSTEM

Aspects	Deep Waste	Eco Scan	101 Trash	Proposed System
Require Login	X	X	X	/
Model Used	Deep Learning	Not publicly disclosed	X	Deep Learning (CNN – VGG16)
Dataset Used	More than 1,200 waste images	Not publicly disclosed	101 types of trash	Primary waste images source and garbage waste dataset (15,497 images) from Kaggle
Accuracy	88.1%	X	X	77.62%
Capture Waste Image	/	/	X	/
Classification Feature	/	/	X	/
Confidence Score	/	X	X	/
Waste Disposal Guidelines Feature	X	X	/	/
Access Dashboard Feature	X	X	X	/
Locate Feature	X	X	/	/
Country-Based	X	X	/	/
Platform	Mobile	Mobile	Website	Website

[a.] / indicates the feature is present; **X** indicates the feature is absent

Although the proposed system has an accuracy of 77.62%, which is lower than Deep Waste's 88.1%, it uses the VGG-16 deep learning model. This choice provides a strong foundation for improving accuracy with further adjustments and tuning.

In terms of the classification feature, DeepWaste classifies the waste into three categories: Recycle, Trash and Compost [19], whereas EcoScan only differentiates between two categories: Paper and Glass [20]. This demonstrates the proposed system's ability to offer a more complete waste classification approach to enhance the waste segregation practice. It is believed that with more classification options, the system can improve recycling efficiency and support better waste disposal practices.

Key features such as confidence scoring, classification types, and waste disposal guidelines make the proposed system competitive and user-friendly. It also includes a dashboard and location-based functionality, ensuring its utility in local waste management. While its accuracy can be

enhanced, the proposed system's transparency, dataset size, and feature-rich design indicate its potential to outperform existing solutions with further development.

V. Conclusion and Future Work

In conclusion, the developed system is considered to reasonably effectively address the challenges outlined in the problem statement by providing a practical solution to waste classification and waste disposal technologically. The first development of this system can accurately classify common household waste.

By acting as an educational platform, the developed system aims to eliminate people's confusion about waste segregation and educate them about sustainable waste management practices, contributing to a greener environment and, at the same time promoting SDG 12 and SDG 13. By consistently using the system, it is believed that the user can influenced by the system gradually as it provides different essential knowledge about recycling practices and provides details about where they can recycle their specific waste items. Also, the dashboard info might act as an important element to raise people's awareness to start taking action to reduce waste.

In addition, future works would be done by regularly updating the CNN model training dataset and expanding the application to mobile-based. Other than that, rather than focusing on image classification tasks, waste object detection can be taken into future consideration to make it more appealing and allow for real-time processing.

Acknowledgment

I would like to express my heartfelt gratitude to my supervisor, Ms. Chong Fong Kim for her invaluable guidance, patience, encouragement, and insightful feedback during the research process. Special thanks to the Faculty of Data Science and Information Technology (FDSIT) for their support in my academic journey. Furthermore, thank you to my family and friends for their support and collaboration, which made this journey enjoyable. Lastly, I also extend my appreciation to all my educators and external contributors for their dedication to teaching and unwavering commitment to student success. Their collective wisdom and support have profoundly impacted my academic and professional journey, and for that, I am truly grateful.

***Abstract*—Human contact with one another through social networks, blogs, forums, and online news portals and communication has dramatically increased in recent years. People use these platforms to express their feelings, but sometimes hateful comments are also spread. When abusive language is used in online comments to attack individuals such as celebrities, politicians, and products, as well as groups of people associated with a given country, age, or religion, cyberbullying begins. Due to the ever-growing number of messages, it is challenging to manually recognize these abusive comments on social media platforms. This research work concentrates on a novel attention mechanism-based hybrid Convolutional Neural Network - Long Short Term Memory (CNN-LSTM) model to detect abusive comments by getting more contextual information from individual sentences. The proposed attention mechanism-based hybrid CNN-LSTM model is compared with various models on the dataset provided by the shared task on Abusive Comment Detection in Tamil – ACL 2022 which contains 9 class labels such as Misandry, Counter-speech, Xenophobia, Misogyny, Hope-speech, Homophobia, Transphobic, Not-Tamil and None-of-the-above. We obtained an accuracy of 67.14%, 68.92%, 65.35% and 68.75% on Naïve Bayes, Support Vector Machine, Logistic Regression and Random Forest respectively. Furthermore, we applied the same dataset to deep learning models like Convolutional Neural Networks (CNN), Long Short Term Memory (LSTM), Bidirectional-Long Short Term Memory (Bi-LSTM) and obtained an accuracy of 70.28%, 71.67% and 69.45%, respectively. To obtain more contextual information semantically a novel attention mechanism is applied to the hybrid CNN-LSTM model and obtained an accuracy of 75.98% which is an improvement over all the developed models as a process innovation.**

Keywords*—Attention mechanism; hybrid CNN-LSTM model; machine learning model; deep learning model; abusive comments detection

I. Introduction

The rise in web and social media interactions leads to a massive amount of information. Due to the freedom to convey everyone's opinion, sometimes the content posted on Facebook, Twitter, and YouTube may be offensive in nature [1]. Chakravarthi et al., [2] looked into the methods for recognizing several forms of abusive content, including aggressiveness, cyberbullying, hate speech, offensive language, abusive remarks, and abusive comments. Zampieri et al., [3] talked about automating the technique for detecting offensive language. The algorithms are trained using postings that have had the presence of any abusive or objectionable content noted. The entire problem was modeled as a supervised learning problem. In general, the Offensive Language Identification problem can be broadly categorized into Aggression Identification, Abusive Comments Detection, Hate Speech Identification, Offensive Language Identification and Toxic Comments Identification. The Aggression and Hate Speech Identification System classifies the given comments into Non-Aggressive, Covertly Aggressive and Overtly Aggressive. In the Abusive Comments Detection System, the class labels are Xenophobia, Misogyny, Hope-Speech, Homophobia, Transphobic, Not-Tamil, None-of-the-above categories. Toxic comments can be classified into Toxic, Severe Toxic, Obscene, Threat, Insult and Identity Hate categories.

Abuse is the act of making remarks that are hurtful to a particular person or group of people. A phrase that uses vulgar or harsh language in a discourse is referred to as abusive language either in oral form or in text form. The lack of eye contact among users of various social media platforms allows them to speak on the topic fearlessly. Therefore, it is necessary to automatically ban, discourage, or restrict users whose actions are hostile. Online abuse has contributed to issues including low self-esteem, despair, harassment, and in very extreme situations, death. Because abusive content can be communicated in a variety of ways, identifying and handling such comments is crucial and difficult. It is nearly impossible to manually find and remove abusive remarks from a large internet comment stream. Additionally, very few research has been done to identify abusive language in Dravidian languages like Tamil. The goal of this research project is to find instances of abusive language in Tamil-language YouTube comments. At the comment level, each post is tagged with nine different class labels. The data set was taken from the ACL 2022 shared task as in [4] which contains YouTube comments and Twitter posts written in Tamil language. The dataset description along with class labels are shown in Table I.

TABLE I. DATASET DESCRIPTION

Dataset	Comments	Labels
Training	2000	Misandry Counter-speech Xenophobia, Misogyny Hope-speech Homophobia Transphobic Not-Tamil None-of-the-above
Validation	240	
Testing	561	

The term "misandry" refers to established bias towards men. The term "counter-speech" refers to a strategy that presents an alternate story in place of offensive speech to combat hate speech or disinformation. The term "misogyny" refers to inherent bias against women. YouTube comments and posts with the class name "hope-speech" provide encouragement, assurance, advice, inspiration, and insight. The term "xenophobia" refers to a strong dislike of foreigners. The term "homophobia" refers to an antipathy, prejudice, or fear of homosexuals or homosexuality. The term "transphobia" is used to describe a broad spectrum of unfavorable attitudes, sentiments, or behaviors toward transgender persons. Sample comments in Tamil and their respective classes are represented in Table II.

TABLE II. COMMENTS AND CLASSES

Comments	Classes
பேச்சை எதிர்பார்த்தேன். நல்ல விளக்கம் அருமை. நியாயமான முறையில் பதிவு செய்துள்ளீர்கள். நீண்ட காலம் வாழ்வதற்கு வாழ்த்துக்கள். I was looking forward to your speech. Good description Awesome. You have registered reasonably. Congratulationson living a long life.	Hope-speech
இது பெண்மையை பயம் முறுத்தும் புரிதலற்ற பேச்சு.... This is an incomprehensible talk that scares women	Counter Speech
ராஜா நீ நாயி Raja you dog	Homophobia
கரு.நீ பெரியார் கருவா ? Are u egg of Periyar?	Misandry
சொத்து என்பதே இப்போது வந்ததுதான் அதற்கு முன்னமே ஆண்களுக்கு மட்டும் தான் சொத்து Property is what it is now and before that it was only for men	Misogyny
தமிழ் நாடு உனக்கு சோறு போடுது Tamil Nadu will give you rice	None of the above
பிச்சை பையன் எச்ச ராஜா The remnant king of the begging boy	Xenophobia
Seaman is a scumbag. Even a counselor is jealous. Waste talking fellow	Not-Tamil
அலி...நீ உழைக்கிற சாதியா Transgender …you are a working caste	Transphobic

Initial pre-processing steps like tokenization, emoji removal and label encoding are carried out. Significant features are extracted by utilizing Term Frequency-Inverse Document Frequency (TF-IDF), Count Vectorizer methods and fed into machine learning models such as Naïve Bayes (NB), Support Vector Machine (SVM), Logistic Regression (LR) and Random Forest (RF). Word embedding is a technique used by state-of-the-art deep learning models like as Convolutional Neural Networks (CNN), Long Short Term Memory (LSTM) and Bidirectional-Long Short Term Memory (Bi-LSTM) to incorporate the context or high-level meaning of each word present in the comments. Although CNN has been shown to be effective at categorizing text, its classification performance is typically hampered by the frequent omission of essential long-distance sequential data, particularly in sentences with negation and semantic transition. Similar to this, the LSTM model is capable of capturing contextual data, particularly the meaning of long text data. However, this approach is unable to concentrate on the text's most crucial passages. In this work, a hybrid deep learning framework based on an attention mechanism and a combination of CNN and LSTM is presented to identify and categorize abusive remarks in social media text. To precisely identify the abusive comments, the ACL2022 shared task dataset which contains comments in Tamil language sentences was selected as the input of the neural network. CNN layers are used in the proposed hybrid CNN-LSTM model to capture features that specify the word's local information in its context. The text is then modeled with attention signals and sequence learning is performed using LSTM layers. Finally, the input from earlier neural networks is combined and offensive remarks are detected using fully linked networks. The impact of applying feature extraction and word embedding techniques to various learned models is also examined in this research work.

All of these cutting-edge models are compared to the suggested innovative attention mechanism-based hybrid CNN-LSTM model's performance. The models must categorize the comments into one of the nine classes when the test data is given. The objectives of this research work are 1) Abusive comments detection from YouTube comments in Tamil using machine learning and deep learning models; and 2) Embedding an attention mechanism in a hybrid CNN-LSTM model.

The research work that is currently available and the tools created for abusive comment detection are described in Section II. The proposed system models are mentioned in Section III. The performance evaluation with models' comparison is represented in Section IV and Section V ends with contributions and prospects for future direction.

II. LITERATURE REVIEW

Devlin et al., [5] described an approach of detecting emotions in social media comments in various languages. The

authors employed Neural Network (NN) layers and adoptive parameters to produce different models. Sanh et al. [6] show that using information distillation, a Bidirectional Encoder Representation from Transformers (BERT) model can be made 40% smaller while preserving 97% of its language knowledge.

Vinay et al., [7] classified the comments as personal attacks and not personal attacks. They employed LSTM with word embedding, CNN with word embedding, and CNN with character embedding. Out of all the models, CNN with character-level embedding achieves the best results. A hybrid method that applies sentiment analysis to machine learning approaches was developed by Hasan et al., [8]. In their study, supervised techniques like NB and SVM were in the investigation of strategic positions.

Huang et al., [9] discovered that hierarchical LSTMs leave extensive context modeling, by allowing them to enhance sentiment categorization significantly. They used LSTMs in particular because they tackle the aforementioned vanishing gradient problem. Zhao et al. [10] used CNNs to test various feature embeddings, ranging from character to sentence level. The researchers expected that the word embedding layer would be critical for sentiment analysis since short texts have a limited quantity of contextual information. They discovered that character-level embedding worked better than other embeddings on one dataset and behaved similarly well on the other using the two datasets they utilized.

Pinkesh et al., [11] classified a tweet as racist, sexist or neither. They conduct extensive research with several deep learning architectures to learn semantic embedding. They tested on a 16K annotated tweets benchmark dataset and revealed that deep learning approaches beat machine learning algorithms. Rotaru et al., [12] discovered how essential phonetic symbols affect people's emotions. Their model's phonetic transcription feature maps show that their model performs fantastically in texts that are overly dense and filled with incorrect words. Additionally, they think that including this grammatical precedence in the sub-word design will improve the model's performance.

Sharif et al., [13] recognized aggressive texts in Bengali using a weighted ensemble strategy and developed methods such as m-BERT, Distill-BERT, Bangla-BERT, and XLM-R. These mentioned models work better than regular methods. Shreelakshmi et al., [14] worked with messages that include code-mixed data from Hindi and English that originate from multilingual consumers. Many previous methodologies omitted data from these low-resource languages.

Sentiment polarity of blended text was utilized by Sevda et al., [15] to classify sentences into those with three emotional meanings. According to this paper, shared parameters are used to translate words. They also showed a simple pre-processing technique based on clustering for gathering variations in code-mixed text. Raut et al. [16] investigated methods for extracting data from Twitter tweets. They also studied supervised learning techniques that could be utilized to identify textual tweet polarity, including SVM for Document Classification. Their conclusion suggests that SVM can recognize text features like a big feature set, or a sparse instance vector.

Cambria et al., [17] discussed new avenues for performing sentiment analysis. During the initial stage itself, a set of emotion class labels were derived from 5,553 tweets using inductive coding. Malliga et al., [18] presented an offensive language detection system using an adapter and transformer-based model. The sentimental analysis of Twitter data was carried out by Barbosa et al., [19] utilizing machine learning and deep learning techniques. They gathered test data from Twitter and examined tweets using syntactic components such as symbols, re-tweets, emoticons, tags, links, punctuation, and exclamation points. They have employed the polarity classifier and the subjectivity classifier as their two primary classifier types. A high-quality collection of Hindi-English code-switch data with 15,744 YouTube comments was produced by Ray et al., [20]. They looked at the collection's growth, the findings of trend analysis using the sample as a guide, and the consistency of the annotators.

Mathur et al., [21] developed a Hindi-English code flipped dataset into Abusive hate speech and non-offensive. A multi-label hostility detection dataset was provided by Bhardwaj et al. [22] and was divided into five categories using the BERT algorithm: fake, hate, offensive, defamatory, and non-hostile. Mulki et al., [23] classified the dataset of Twitter into abusive, hate and normal classes using the Naïve Bayes algorithm. Hassan et al., [24] used SVM and CNN+Bi-LSTM to classify offensive Arabic texts and achieved better results for the CNN+Bi-LSTM approach.

Kogilavani et al., [25] carried out sentiment analysis on Tamil code-mixed data. From the dataset, significant features are identified through a hybrid model. Leite et al. [26] reported a toxic language dataset made up of 21000 tweets that were categorized using the BERT algorithm into GBTQ+phobia, racism, insult, xenophobia, obscenity, misogyny, and non-toxic language. The brief literature review helped to realize the need to identify abusive comments that are present in the Tamil language.

Ashraf et al., [27] presented a method to detect the contextual information present in YouTube comments based on topics such as politics, religion and others. The context is identified with the help of linguistic information present in the comments. Jahan et al., [28] employed a transliterated code-mixed dataset for abusive comments detection in Bangla-English data. The result shows that the transliterated dataset does not improve the accuracy of the system.

III. Materials and Methods

Fig. 1 represents the workflow of the methodologies used in this proposed work. As the first step, pre-processing such as tokenization, emoji removal and label encoding are carried out for the dataset.

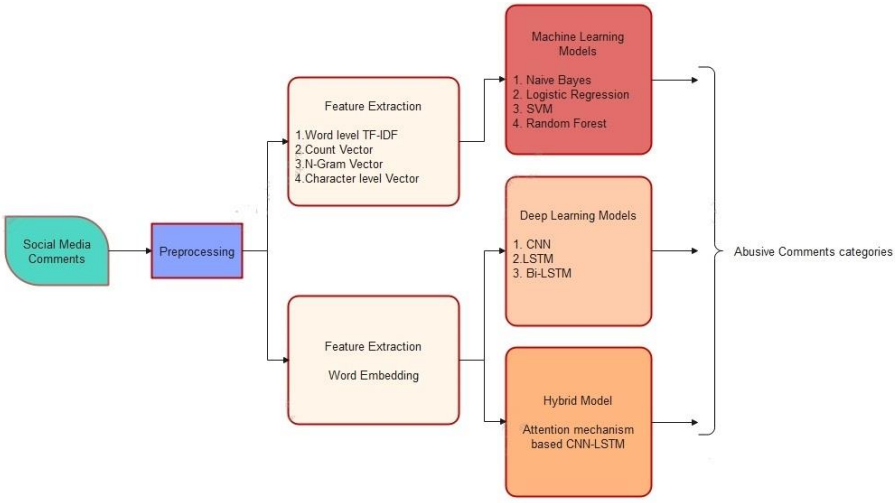

Fig. 1. Proposed system work flow.

Significant features are extracted from Tamil sentences by utilizing TF-IDF and Count Vectorizer methods. The resultant word vectors are fed into machine learning models such as NB, SVM, LR and RF. Word embedding is a technique used by deep learning models like as CNN, LSTM, and Bi-LSTM to incorporate the context or high-level meaning of each word present in the comments. Traditional approaches represent text in terms of TF, IDF, TF-IDF with sparse features. Recently deep learning models have been adopted with word embedding to extract contextual information from the text data. However, these deep learning models do not consider sequential information among the sentences. LSTM is used to capture the semantics of lengthy texts. However, this methodology is unable to focus on important textual passages. When used with text data, this restriction lowers the accuracy of deep learning models. It is necessary to concentrate on particular passages of the text, which are very similar to how people read. The goal of this research work is to suggest a hybrid CNN-LSTM model that is attention-based and can identify offensive comments. The suggested method uses a convolution layer as its first step in capturing attention signals, which reflect the local information of each word in its context. The text is then modeled using LSTM using attention signals. A word with a larger attention weight typically refers to more valuable information.

A. Feature Extraction

The process of extracting features from text input and generating numerical representations of them so that learning models can use them to produce predictions is known as feature extraction. The words or concepts that appear most frequently and have the fewest relevant data start to take precedence over the ones that appear less frequently when a vector is constructed from a text using word frequency. To avoid rating terms in papers purely on their frequency in a single text, as suggested by Sajeetha et al., [29] word frequency must be rescaled.

1) TF-IDF: With TF-IDF, words are given varying weights based on how important they are to the document. It calls attention to a particular problem that, while uncommon in our corpus, is quite crucial. Textual data has therefore been converted into real-valued vectors using TF-IDF. How frequently a word appears in a publication is referred to as term frequency. It might be compared to the likelihood of a term appearing in a document. It establishes the proportion between the frequency of a word (wi) and the overall number of words in the comment (cj). The inverse document frequency statistic can be used to assess how frequently or infrequently a phrase appears across all the documents in a corpus. By dividing the entire number of comments in the dataset by the number of comments that contain the term t, it is possible to get the logarithm of the overall term.

2) Count vector: The Count Vectorizer is used to turn a text into a vector based on how frequently each word appears in the text as a whole. This is helpful when organizing each word in a vector and working with numerous texts of this type. Each distinct word is represented by a column in a matrix created by Count Vectorizer, and each sample of text from a remark is represented by a row. The value of each field indicates how many phrases were contained in the text sample.

3) N-Gram vector: The continuous or neighboring sequence of words in a sentence is represented using the N-gram vector. After performing tokenization and stop words removal process, N-Grams from the text can be represented in vector format.

4) Character level vector: To generate a character level vector, the input sentences are decomposed into a sequence of characters including special characters. To extract morphological information from the text, this kind of character level vector is used.

5) Word embedding: Word embedding, according to Sajeetha et al., [30] is a kind of word vector that makes it possible to represent words with similar meanings. Individual words are often represented in word embedding as real-valued vectors in a predetermined vector space. Since each word is translated into a single vector and its values are learned like that of a neural network, the method is typically categorized under deep learning models. The main concept of the approach is to represent each word with dense sparse representations. A real-

valued vector with a sizable number of dimensions—often tens or hundreds—represents each word.

B. Machine Learning Models

1) Naive Bayes (NB): A group of classification methods known as NB classifiers are based on Bayes' Theorem, which states that all pairings of feature pairs are conditionally independent given the value of the class variable. Mathematically, Bayes theorem can be stated as in (1).

$$P(y|X) = \frac{P(X|y)P(y)}{P(X)} \quad (1)$$

Where y is the class variable and X is the input feature vector. NB learners and classifiers may be extremely fast in comparison to more complex algorithms. Each distribution can be estimated as a one-dimensional distribution individually since the class conditional feature distributions are separated. As a result, problems brought on by the curse of dimensionality are lessened.

2) Support Vector Machine (SVM): Both classification and regression problems can be resolved using the supervised machine learning method known as SVM. Even if categorization more closely reflects the data, regression has downsides. The SVM technique categorizes n-dimensional space by trying to find the best judgment boundary or line so that the following data points can be quickly assigned to the right category. The best choices are known as hyperplanes. When there are only two input features, the hyperplane is essentially a line. When there are three input features, the hyperplane transforms into a two-dimensional plane. Once a hyperplane is generated, it is used to make predictions or classifications by using hypothesis function *h* as in (2) where *x* is input feature, *w* is weight and *b* is bias.

$$h(x_i) = \begin{cases} +1 \; if \; w.x + b \geq 0 \\ -1 \; if \; w.x + b < 0 \end{cases} \quad (2)$$

3) Logistic Regression (LR): LR is a technique for estimating the probability of a discrete result given an input variable. LR models often yield binary outputs, such as true or false, yes or no, and so forth. It is a simple classification model that produces top-notch results and has linearly separable classes. It is a typical categorization technique used in the industrial sector. When performing classification tasks, the analytical technique of logistic regression is useful for assessing if a new sample fits into a particular category. The following equation as in (3) represents logistic regression where *x* is the input feature, *y* is the output variable, b_0 is bias and b_1 is the coefficient for input.

$$\mathrm{y} = \frac{e^{(b0+b1x)}}{1+e^{(b0+b1x)}}) \quad (3)$$

4) Random Forest (RF): The supervised machine learning algorithm RF is frequently employed to address classification and regression problems. As its name suggests, RF is made up of a sizable number of connected decision trees. The class with the highest score is chosen as our model's projection from among the predictions made by each tree in the random forest. It produces decision trees from a variety of data using regression and majority voting, respectively. One of the key characteristics of the RF algorithm was its capacity to handle data sets with both continuous and categorical variables, as in classification and regression issues. Categorization issues, yield improved outcomes.

C. Deep Learning Models

1) Convolutional Neural Network (CNN): CNN is a deep learning technique built on the Multi-Layer Perceptron (MLP). Features are retrieved and used for classification tasks in conventional algorithms. In CNN, higher concepts are created by a series of convolutional layers once these features are automatically extracted. The three main characteristics of CNN are convolution, pooling, and fully connected layers. The most fundamental part of a CNN is the convolution layer, which consists of a number of separate filters commonly referred to as masks or kernels. The input and filters are convolved to produce either an activation map or a feature map. The pooling layer comes next, and its function is to minimize the input's spatial dimensions. Its objective is to simplify the representation of intricate layers. The pooling layer's output is flattened into a single vector and sent as the fully connected layer's input. Fully linked layers, which are utilized to carry out a particular task, such as classification, are the vectors produced by a multilayer perceptron's several convolutions and pooling processes.

2) Long Short Term Memory (LSTM): LSTMs are one type of Recurrent Neural Network (RNN) that stores intermediate outcomes in LSTM networks. When linking old knowledge to fresh information in a traditional RNN, the problem of vanishing gradients usually arises. There is only one layer in the repeating module of a typical RNN. LSTM holds information in a gated cell. A cell can accumulate information and can read and write into its memory. By default, the LSTM has a propensity to retain information for a long time. The Sequential 3 model has a 20000 feature maximum, 128 embedding dimensions, a 40 sequential length, and a 196 LSTM out. The Spatial dropout1d layer receives the output of the Embedding layer, the LSTM layer receives the output of the LSTM layer, and the dense layer receives the output of the dense layer. Nine nodes in the dense layer function as sigmoid activation nodes. The categorical cross entropy loss function and Adam optimizer are used to train the LSTM.

3) Bidirectional-Long Short Term Memory (Bi-LSTM): The process of building a NN that can store sequence information both future to past and past to future is known as Bi-LSTM. Unlike a standard LSTM, a Bi-LSTM has input those flows in both directions. With a standard LSTM, we may make input flow in one way, either backward or forward. However, there is a way to maintain both the present and the future while allowing information to move both ways. In the suggested system, the values for maximum features, embedding size, sequential length, and lstm out are all set to 20,000. The spatial dropout1d layer receives the output of the embedding

layer, the dense layer receives the output of the bidirectional layer as input, and the bidirectional layer receives the output of the dense layer. Nine nodes in the dense layer employ an activation function known as a softmax. The Nadam optimizer and the categorical cross-entropy loss function are used to train the Bi-LSTM.

D. Attention Mechanism-Based Hybrid Model

By fusing CNN with LSTM, the suggested approach creates a novel hybrid model based on an attention mechanism. Through an attention mechanism, neural networks facilitate the dynamic selection of pertinent features from text data. Either the raw input or its higher level representation can receive it directly. This attention mechanism's calculations involve weighing the order of text pieces and giving more weight to pertinent text information. Mainly attention mechanism is used to capture the context between sentences so that if the sentence does not have direct abusive statements also, will be detected by this mechanism. The proposed attention mechanism-based CNN-LSTM hybrid model structure is represented in Fig. 2.

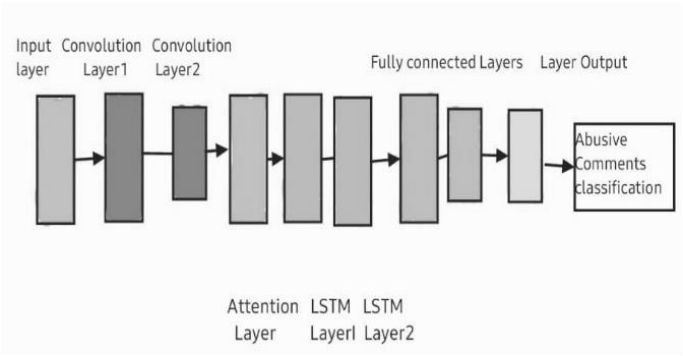

Fig. 2. Attention mechanism-based CNN-LSTM hybrid model.

To develop a CNN+LSTM hybrid model, first CNN layers are added, then attention mechanisms, LSTM layers, and Deep Layers on the output. The first LSTM layer of the LSTM+CNN model receives word vectors for each token in the sequences. This architecture can be seen as defining both the CNN Model for feature extraction and the LSTM Model for feature interpretation over time steps. The Sequential 7 model's maximum features input is set to 20,000, the embedding dimension to 128, the sequential length to 40, and the LSTM out to 196. With a pooling size of 2, a kernel size of 3, and activation functions of ReLU and sigmoid, Conv1d has 128 output filters. Text sequences are created with Conv1d. The output of the embedding layer is provided as input to the conv1d layer, the output of the conv1d layer is input to the MaxPooling1d layer, the output of the MaxPooling1d layer is input to the LSTM layer, and the output of the LSTM layer is input to the dense layer. In the dense layer, nine nodes have sigmoid activation functions. CNN+LSTM is trained using the Adam optimizer and the categorical cross entropy loss function.

IV. Performance Evaluation

Initially, the dataset is applied to word level TF-IDF, count vector, N-Gram vector and character level vector. The proposed system chooses the models based on accuracy metrics instead of loss because the model with minimum loss may not be the model with the best metric. The accuracy obtained by all these feature extraction techniques that are applied to various machine learning models is represented in Table III. The results show that, for all the models, the best accuracy is produced by the character level vector which extracts morphological features from the given text input. Among the entire machine learning models SVM model produces the highest accuracy of 0.6892.

A. Experiments

1) Precision: Precision is the proportion of positive class predictions that fall into that category. Precision values are calculated using as in (4) where TP is True Positive and FP is False Positive.

$$\text{Precision} = TP / (TP + FP) \quad (4)$$

2) Recall: Recall is a metric that indicates how well the model properly detects True Positives. The recall is determined as in (5) where FN is False Negative.

$$\text{Recall} = TP / (TP + FN) \quad (5)$$

3) F1-Score: The weighted mean of Precision and Recall is the F1 Score. This score is generated using an equation as in (6) and takes into consideration both false positives and false negatives.

$$\text{F1 Score} = 2 * (\text{Recall} * \text{Precision}) / (\text{Recall} + \text{Precision}) \quad (6)$$

The precision, recall, F1-Classification reports of machine learning models such as NB, SVM, LR and RF are presented in Table IV. The result shows that the highest precision of 0.74 is obtained for counter-speech class abusive comments by the NB model. LR produces a precision value of 0.80 for the Not-Tamil type of abusive comments. A precision value of 1.00 is produced by SVM for the Misandry type and by RF for the Not-Tamil type.

TABLE III. Accuracy Comparison of various Machine Learning Models based on Feature Extraction

Models	Word level TF-IDF	Count Vector	N-Gram Vector	Character Level Vector
Naïve Bayes	0.6312	0.6417	0.6315	0.6714
Support Vector Machine	0.6291	0.6010	0.6718	0.6892
Logistic Regression	0.6342	0.6214	0.6171	0.6535
Random Forest	0.6593	0.6432	0.6154	0.6875

TABLE IV. CLASSIFICATION REPORT OF MACHINE LEARNING MODELS

Class Label	Naïve Bayes			Support Vector Machine			Logistic Regression			Random Forest			Support
	P	R	F1-Score	P	R	F1-Score	P	R	F1-Score	P	R	F1-Score	
None-of-the-above	0.00	0.00	0.00	0.25	0.03	0.05	0.00	0.00	0.00	0.00	0.00	0.00	36
Misogyny	0.50	0.12	0.20	0.33	0.12	0.18	0.33	0.12	0.18	0.33	0.12	0.18	8
Misandry	0.00	0.00	0.00	1.00	0.09	0.17	0.67	0.18	0.29	0.75	0.27	0.40	11
Counter-speech	0.74	0.36	0.48	0.69	0.57	0.62	0.73	0.61	0.66	0.64	0.56	0.59	104
Xenophobia	0.00	0.00	0.00	0.40	0.08	0.14	0.50	0.21	0.29	0.50	0.08	0.14	24
Homophobia	0.67	0.98	0.80	0.72	0.97	0.83	0.74	0.96	0.83	0.73	0.96	0.83	346
Hope-Speech	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	1
Transphobic	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	2
Not-Tamil	0.00	0.00	0.00	0.00	0.00	0.00	0.80	0.14	0.24	1.00	0.07	0.13	29

4) Accuracy: The accuracy of classification models is one of the factors to consider while evaluating them. Informally, accuracy refers to the suggested model's proportion of correct predictions, which is determined as in (7).

$$\text{Accuracy} = (TP+FP) / \text{Total Predictions} \quad (7)$$

Fig. 3 represents the accuracy obtained by NB, LR, RF and SVM learning models. The result shows that the highest accuracy of 68.92 is obtained by SVM for the given dataset.

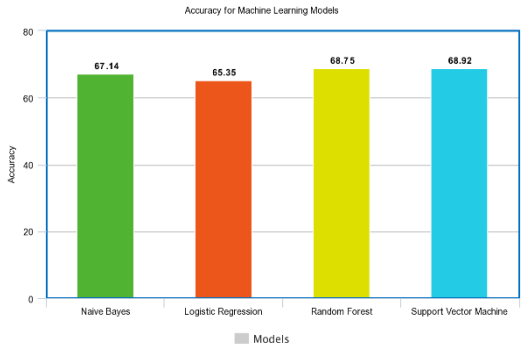

Fig. 3. Performance evaluation of machine learning models based on accuracy.

Fig. 4 denotes the accuracy of CNN, LSTM, Bi-LSTM deep learning models after extracting significant features using word embedding. The result shows that among the three mentioned models, the LSTM deep learning model performs better with an accuracy of 71.67%.

From the deep learning models, the highest accuracy obtained from two models such as CNN and LSTM are combined to generate the hybrid model. The attention mechanism is implemented in between Convolutional layers and LSTM layers in a hybrid model. The highest accuracy machine learning model such as SVM and deep learning model such as LSTM is compared with the hybrid model in Fig. 5. The result shows that the best accuracy of 75.98 is obtained by the attention mechanism-based hybrid CNN-LSTM model.

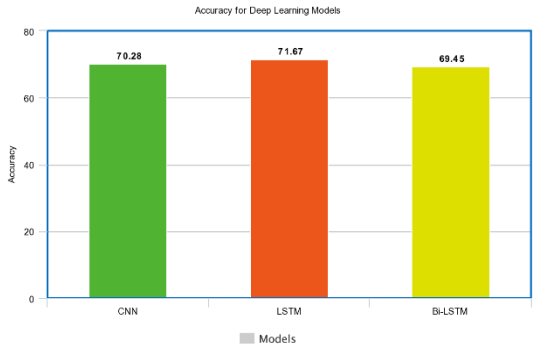

Fig. 4. Performance evaluation of deep learning models based on accuracy.

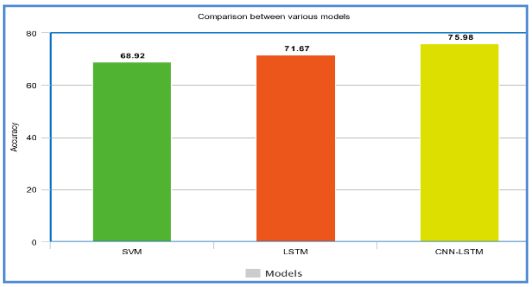

Fig. 5. Comparison of performance evaluation of machine learning, deep learning and attention mechanism-based hybrid CNN-LSTM model.

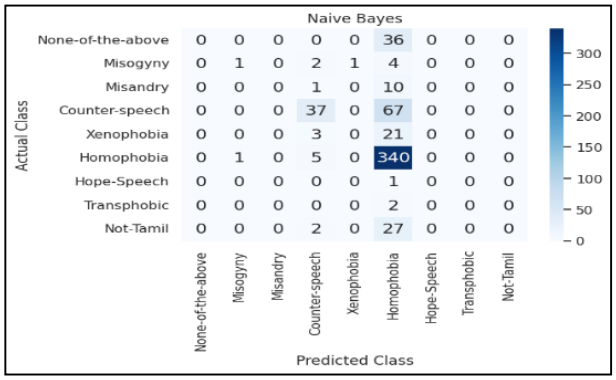
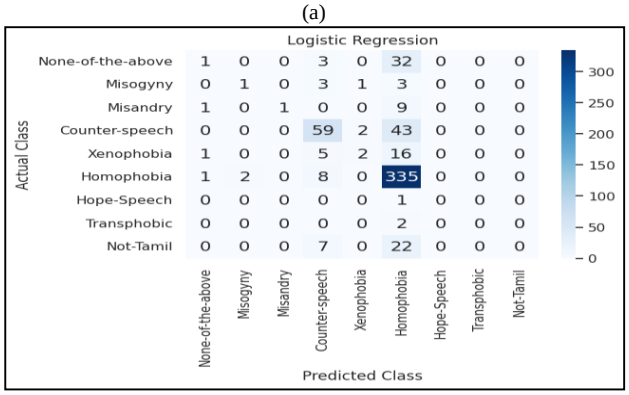
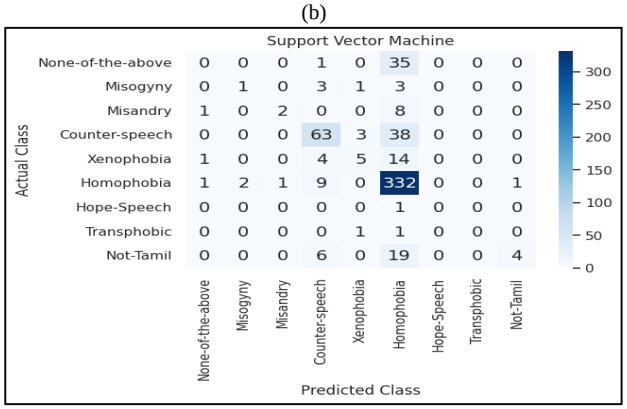
5) Confusion matrix: The confusion matrix is a useful tool for assessing classifiers' abilities to discriminate between data from different classes. In the confusion matrix form, TP and TN are displayed when the classifier is functioning well. FP and FN represent occasions where the classifier is incorrect. A confusion matrix is a table containing the given dataset's 9 classifications and dimensions of 9 x 9. Good accuracy is gained by employing the values along the confusion matrix's diagonal. The confusion matrix for machine learning algorithms like NB, SVM, LR and RF is shown in Fig. 6(a) to 6(d).



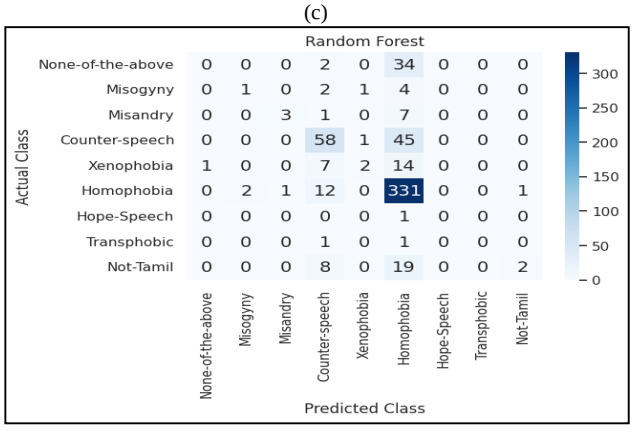
(a)



(b)



(c)

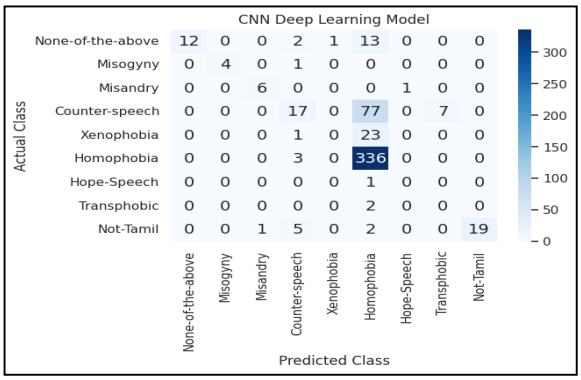


(d)

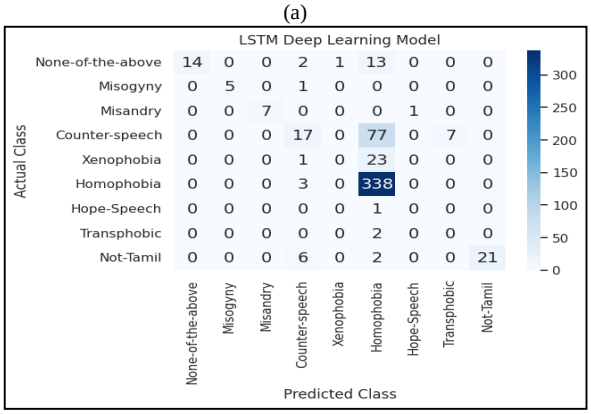
Fig. 6. (a) Confusion matrix - Naïve bayes, (b) Confusion matrix - Logistic regression, (c) Confusion matrix - Support vector machine, (d) Confusion matrix - random forest.

From the confusion matrices in Fig. 6(a) to 6(d), it is understood that out of 346 samples in Homophobia type of abusive comments, the Naïve Bayes models correctly classifies 340 comments, SVM classifies 332 comments, LR classifier 335 comments and RF classifies 331 comments. Fig. 7(a) to 7(c) represents, the confusion matrix obtained by CNN, LSTM and Bi-LSTM deep learning models.

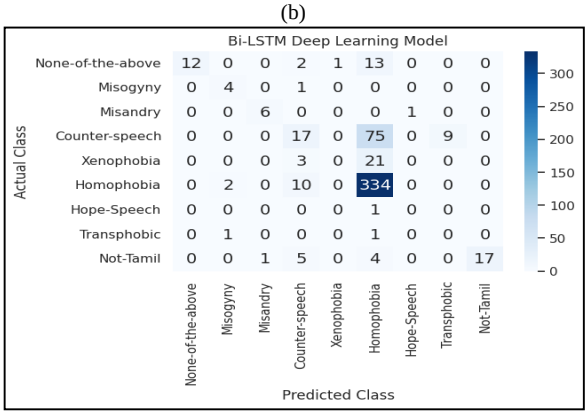
The confusion matrix in Fig. 7(a) to 7(c) shows that out of three deep learning models, the LSTM model outperforms by classifying 402 comments correctly out of 561 comments. Fig. 8 represents the confusion matrix of the proposed attention mechanism-based hybrid CNN-LSTM model. The result shows that 421 comments were correctly classified.



(a)



(b)



(c)

Fig. 7. (a) Confusion matrix - CNN Model, (b) Confusion matrix LSTM Model, (c) Confusion matrix - Bi-LSTM Model.

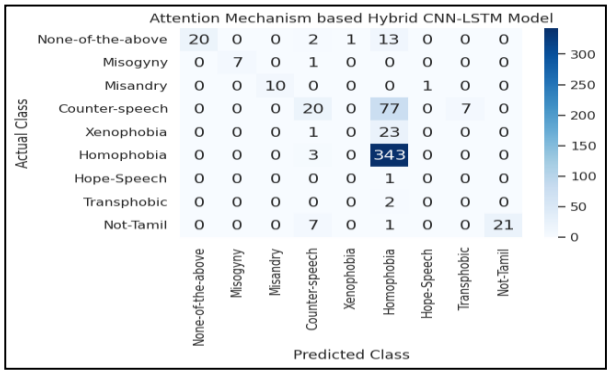


Fig. 8. Confusion matrix - Hybrid CNN-LSTM model.

6) Matthews correlation coefficient: The range of the Matthews Correlation Coefficient (MCC) is [-1,1]. The anticipated values will closely match the actual classification if the value is close to 1, which indicates that the prediction was quite accurate. There is no association between our variables if MCC is equal to 0. Values near -1 imply an inverse relationship between the true and anticipated classes. MCC is calculated using the formula specified as in Eq. (8).

$$MCC = \frac{(TP*TN-FP*FN)}{\sqrt{(TP+FP)*(TP+FN)*(TN+FP)*(TN+FN)}} \quad (8)$$

7) Cohen's Kappa: The concept of calculating the agreement between the Predicted and the True Labels—which are viewed as two random categorical variables—is the foundation of Cohen's Kappa. By creating a confusion matrix and computing the marginal rows and marginal column distributions, it is possible to compare two category variables. Kappa value is calculated using the equation as in (9) where p_o is observed probability and p_e is expected or predicted probability which is calculated from the confusion matrix.

$$Kappa = \left(\frac{p_o-p_e}{1-p_e}\right) \quad (9)$$

8) Error rate: The error rate is calculated by subtracting accuracy from 1 and it is calculated using equation as in (10). For example, the sample sentence "இது பெண்மையை பயம் முறுத்தும் புரிதலற்ற பேச்சு....(This is an incomprehensible talk that scares women ....) is the abusive comment of counter speech category. However, due to the context related to women, it is wrongly classified as a misogyny type.

$$Error\ rate = 1 - accuracy \quad (10)$$

The MCC, kappa value and error rate of all the machine learning models are represented in Table V. Out of all the mentioned machine learning models, SVM obtained the highest MCC value of 0.69 and Kappa value of 0.67. Based on accuracy, the error rate is calculated and it is less for both SVM and Random Forest.

TABLE V. MCC, KAPPA AND ERROR RATE OF MACHINE LEARNING MODELS

Machine Learning Model	MCC	Kappa	Error rate
Naïve Bayes	0.66	0.58	0.32
Support Vector Machine	0.69	0.67	0.31
Logistic Regression	0.64	0.64	0.34
Random Forest	0.67	0.64	0.31

V. CONCLUSION AND FUTURE WORK

In this research work, a hybrid CNN-LSTM model with an attention mechanism has been effectively presented to detect and categorize offensive comments into subcategories including misandry, counter-speech, xenophobia, misogyny, hope-speech, homophobia, transphobia, not-in-Tamil, and none of the above. This research work initially uses a variety of machine learning models, including NB, LR, SVM and RF along with a variety of feature extraction methods, including word level TF IDF, count vector, N-Gram vector, and character level vector. SVM with character level vector based feature extraction method achieves the best accuracy of 68.92%. Word embedding-based deep learning models including CNN, LSTM, and Bi-LSTM were applied to the dataset in order to further increase accuracy. The experimental findings demonstrated that significant features are automatically retrieved, and individual CNN, LSTM models achieve an accuracy of 70.28% and 71.69%, respectively. This result motivates us to develop a hybrid model by combining CNN with LSTM. The suggested work utilizes a novel attention mechanism between CNN and LSTM layers which is called the hybrid CNN-LSTM model to extract more pertinent features from the dataset and achieve superior accuracy of 75.98%. The proposed work detects abusive comments from code-mixed data by applying state-of-the-art machine learning, and deep learning models. Further, the accuracy is improved by applying the proposed attention mechanism-based hybrid CNN-LSTM model. In the future, transfer learning methodology for the identification and classification of abusive remarks may be utilized to improve accuracy further.

***Abstract*—As the global emphasis on sports data analysis and athlete performance optimization continues to grow, traditional badminton training methods are increasingly insufficient to meet the demands of modern high-level competitive sports. The exploration and reasoning of badminton tactics can significantly aid coaches and athletes in better comprehending game strategies, playing a vital role in the analysis and optimization of training methods. By utilizing knowledge graph-based badminton tactics mining, an approach involving heterogeneous graph splitting is employed, coupled with the incorporation of a cross-relational attention mechanism within relational graph neural networks. This mechanism assigns varying weights based on the importance of neighboring nodes across different relations, facilitating information aggregation and dissemination across multiple relationships. Furthermore, to address the challenges posed by the complexity of large-scale knowledge graphs, which feature numerous entity relationships and intricate internal structures, techniques such as training subgraph sampling, positive-negative sampling, and block-diagonal matrix decomposition are introduced. These techniques help to reduce the computational load and complexity of model training, while also enhancing the model's generalization capabilities. Finally, comparative experiments conducted on a proprietary badminton tactics dataset demonstrated the effectiveness and superiority of the proposed model improvements when reasonable parameters were applied. The case study shows that this approach holds considerable promise for the analysis and optimization of badminton players' training strategies.**

Keywords*—Badminton tactical analysis; graph neural networks; attention mechanisms; training pattern optimization; heterogeneous graph splitting; artificial intelligence

I. Introduction

As competitive sports continue to evolve, the demands on athletes to demonstrate exceptional performance in matches have become increasingly stringent. To meet these challenges, athletes need not only strong physical and psychological qualities but also advanced technical and tactical skills to identify and address their weaknesses while maximizing their strengths. Effective and scientifically sound training is crucial for enhancing athletes' competitive levels. However, the current training systems still largely rely on coaches' experience, with insufficient support from systematic data. This is particularly evident in badminton training, where the focus on technical and tactical training is relatively low, often depending on the subjective judgments of coaches and the personal feelings of athletes. This reliance on traditional methods has led to the underutilization of critical match data and a lack of scientifically based standards for evaluating technical and tactical performance.

In this context, the application of information technology is essential for improving traditional training models. However, current information technologies face significant challenges in data collection, analysis, and training optimization: data collection is often untimely, incomplete, and inaccurate, making integration difficult; data analysis lacks depth, failing to produce actionable insights; and personalized technical and tactical training programs are scarce and lack scientific backing. Additionally, the speed of information feedback does not match the fast pace of training and competition, ultimately affecting athletes' performance.

Therefore, the effective collection and utilization of training and competition data, as well as the development of personalized training programs based on this data, have become urgent tasks. With the advancement of modern database technologies and data mining techniques, these tools have increasingly been applied in the sports domain. Establishing a badminton sports database and data analysis system can significantly enhance the efficiency and depth of data collection, providing valuable insights through in-depth data analysis to inform coaches' training decisions and optimize training methods.

To fill these gaps, this paper explores how badminton tactics mining and reasoning based on knowledge graphs can assist coaches and athletes in better understanding match strategies and play a crucial role in the analysis and optimization of training methods. We propose a tactics mining approach based on heterogeneous graph decomposition, which incorporates a cross-relational attention mechanism to assign different weights in relational graph neural networks, enabling the aggregation and transmission of information across relationships. Additionally, to address the complexity challenges posed by large-scale knowledge graphs with intricate relational structures, we introduce techniques such as training subgraph sampling, positive-negative sampling, and block-diagonal matrix decomposition to reduce computational complexity and enhance model generalization. Comparative experiments conducted on a proprietary badminton tactics dataset demonstrate the effectiveness and superiority of the improvements made to our model.

II. Literature Review

This section reviews existing related work on data mining to highlight the gaps in existing research.

A. Data Mining Techniques

Data mining technology has found widespread use in the global sports arena [1]. A well-known example is the Advanced Scout system employed by teams in the American professional basketball league, which processes game data to generate key insights, such as identifying high-percentage shooting areas and determining the most effective player rotations. This system aids head coaches in developing evidence-based training plans and making real-time strategic decisions during games [2]. In the National Football League (NFL), Schatz's study of league statistics revealed a link between league averages and the performance success of players in specific offensive roles [3]. Similarly, in the National Collegiate Athletic Association (NCAA), Jay Coleman and his team analyzed historical sports data, formulating a predictive model for game outcomes that boasts an accuracy rate of 84.5% [4].

In the realm of tennis, Damien Demaj tracked the serve trajectories of opponents and, utilizing spatial and temporal data analysis techniques, discerned patterns in player movements. This allowed athletes to gain a better understanding of their opponents' technical and tactical tendencies, ultimately improving their match performance [5][6]. Additionally, Rajiv Maheswara and his team leveraged data mining and machine learning to scrutinize the movements of players, referees, and basketballs captured by high-speed cameras during NBA games. Their analysis focused on offensive scoring efficiency and defensive effectiveness, providing coaches with critical information to structure more strategic training programs for their teams [7].

B. Traditional Knowledge Reasoning

Rule-based reasoning relies on a predefined set of rules to logically derive new knowledge, directly incorporating expert domain knowledge. While this approach is effective, it is often time-consuming to create these rules, and the system's scalability is generally limited. For instance, knowledge graphs like NELL [8] and YAGO [9] use rule-based methods to expand their knowledge bases. Meanwhile, first-order probabilistic language models focus on achieving precise "local" reasoning, proving effective in tasks such as entity resolution by extending stochastic logic programs and employing PageRank variants [10] for inference. Additionally, the TensorLog system integrates knowledge graph reasoning with gradient-based deep learning [11], achieving linear computational efficiency through a tractable reasoning process.

Ontology-based reasoning, on the other hand, generates new knowledge by interpreting, reasoning, and integrating ontologies—core structures that describe entities, attributes, relationships, and concepts. For example, a semi-automatic schema construction approach [12] addresses the complex schema challenges in RDF knowledge bases, while a system based on Markov logic networks is employed to clean and refine the original knowledge base [13]. Furthermore, the method proposed by Pujara et al. [14], which uses joint inference with probabilistic soft logic [15][16], tackles issues of noise and incomplete information in large-scale knowledge graphs. The ontology path discovery algorithm OP developed by Chen et al. further enhances knowledge graphs through optimization techniques [17].

In summary, although traditional reasoning methods can be effectively applied to knowledge graphs, ontology-based methods typically offer higher accuracy, making them suitable for scenarios where precision is critical. However, these methods face challenges with large-scale knowledge instantiation, struggling with inference efficiency and recall, while noise in the raw data can lead to inference errors, limiting the scope and applicability of these traditional approaches.

C. Distributed Knowledge Reasoning Approach

Distributed representation learning centers on transforming traditional symbolic representations into numerical representations in vector space through mapping functions as a way to mitigate dimensionality catastrophe and capture implicit connections between entities and relationships. These methods are generally divided into two main categories: rule-based reasoning and ontology-based reasoning.

The TransE model [18] is a distance-based approach that embeds entities and relations in a low-dimensional vector space to model multi-relational data. It predicts links by making the sum of the head entity vector and the relation vector as close as possible to the tail entity vector. TransE has demonstrated strong performance across several knowledge bases, surpassing advanced methods of its time, and thus gained attention. While simple and fast to train, its main limitation is that it only handles one-to-one relationships. To address this, Zhen et al. [19] introduced an improved version that considers complex relationships, such as one-to-many, many-to-one, and many-to-many. The TransH model followed, performing translation on a hyperplane to better handle diverse relationships, while maintaining similar complexity to TransE. Additionally, specific strategies were introduced to mitigate incorrect negative labels, improving performance on tasks like link prediction and fact extraction in knowledge graphs like WordNet and Freebase.

The RESCAL model, proposed by Nickel et al. [20], is a tensor decomposition-based inference method that enables collective learning through its latent components and offers efficient factorization. RESCAL demonstrated significant improvements in speed and accuracy over other tensor methods. Based on RESCAL, Chang et al. [21] proposed TRESCAL, which excels in relationship extraction by leveraging entity type information, allowing faster and more accurate discovery of new relations in databases.

Inference methods based on distributed representations are more advanced than traditional methods. The TransE series, known for its simplicity and effectiveness, has become a research focus, achieving significant results despite limited further research space. The RESCAL series, favored for its interpretability and performance, holds great potential, despite higher model complexity.

D. Research Gaps

Although progress has been made in applying graph neural networks and association rule mining to knowledge graphs [22], significant gaps remain in their application to badminton tactical

reasoning and training. Current algorithms fail to fully consider dynamic player positioning, opponent adaptability, and the data requirements of input models.

1) Model adaptability and flexibility: Existing graph neural networks can simulate some aspects of badminton tactics but struggle with the complexity and real-time nature of tactical changes. These models require deeper integration of tactical theory and practical experience, and current approaches are often inefficient due to heavy reliance on data annotation and feature design.

2) Dataset standardization: The lack of unified standards for data collection and preprocessing in badminton tactics leads to inconsistencies and hinders the generalizability of different studies. Without standardized data representation, tactical reasoning methods face challenges in coherence and adaptability.

3) Complex tactical reasoning: Current techniques struggle with recognizing and reasoning about complex tactical combinations and rapidly changing scenarios. They often underperform in long-term tactical evolution and opponent strategy adaptation, requiring further optimization.

In summary, future research should focus on developing more adaptable models and standardized datasets to enhance tactical reasoning, thereby improving technical and tactical teaching and game strategy analysis in badminton.

III. Ideas for Improving Reasoning in Very Large Scale Knowledge Graphs

A. Heterogeneous Graph Splitting

Entities and relationships in a knowledge graph often exhibit diverse types and properties, creating a heterogeneous graph structure. This heterogeneity is crucial in reasoning since different types of entities and relationships may involve distinct rules, constraints, and semantics.

In this study, we employ a knowledge graph splitting approach. Heterogeneous graph splitting involves dividing a large, complex graph into smaller, more manageable subgraphs based on specific rules. This method enhances the scalability, maintainability, and processing efficiency of large knowledge graphs, particularly in distributed environments where managing smaller subgraphs is more practical.

The process of splitting a heterogeneous knowledge graph involves several key steps:

- Defining Splitting Rules: Based on the characteristics and application needs of the knowledge graph, we establish rules for splitting—such as dividing by entity types, relationship types, or attributes.
- Constructing Topologies: Using the defined rules, we construct the topology for each subgraph. This can be achieved through graph-based clustering algorithms or similarity calculations based on meta-paths.
- Performing the Split: Entities and relationships in the original graph are divided into multiple subgraphs according to the constructed topologies.
- Storing and Managing Subgraphs: Each subgraph is stored in different computing nodes or distributed storage systems, with appropriate management and maintenance.

In our study, we focus on splitting subgraphs based on relationship types. During the reasoning process, these subgraphs are embedded to better capture the distinct semantic information inherent in the heterogeneous graph structure. For example, as illustrated in Fig. 1, an original directed graph with five nodes and two types of relationships can be split into two subgraphs, each retaining the directed nature of the original structure. This allows for more precise reasoning based on the specific types of relationships in each subgraph.

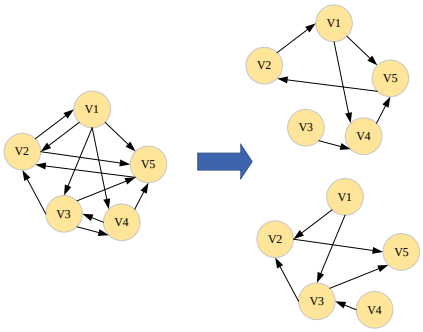

Fig. 1. Schematic diagram of knowledge graph heterogeneous graph splitting.

B. Training Subgraph Sampling

Training graph neural networks on large-scale datasets presents challenges, such as high computational complexity and issues like gradient vanishing or explosion. To address these, this study employs random sampling to generate subgraphs for training. Random sampling reduces noise by excluding irrelevant nodes and edges, thereby lowering computational and storage demands and improving training efficiency. However, tuning sampling parameters is necessary to balance subgraph size with the importance of sampled components.

Additionally, positive and negative sampling is used to preprocess training data by selecting real (positive) and non-existent (negative) edges or nodes. This approach offers several benefits:

- Addressing Data Imbalance: By balancing the number of positive and negative examples, the model avoids bias towards predicting positive instances, enhancing its overall prediction capabilities.
- Reducing Computation: Sampling limits the data used for training, cutting down on computational load and improving efficiency.
- Improving Generalization: Positive and negative sampling enables the model to learn a broader range of features, enhancing its adaptability to different graph datasets.

In summary, the introduction of positive and negative sampling in this study is crucial for addressing data imbalance, boosting computational efficiency, and enhancing the model's generalization ability.

IV. Improved Knowledge Graph Link Prediction Algorithm

In a knowledge graph, link prediction involves forecasting the relationship between two entities based on the existing graph structure, often referred to as relationship extraction. This process is crucial for expanding the knowledge graph, as manually labeling every entity and relationship is impractical given their vast number. Link prediction enables the automatic discovery of new entities and relationships from large volumes of unlabeled data, thereby enhancing the graph's scale and richness. The primary objective is to predict potential relationships between entities or to identify links between entities and relationships. This task has broad applications in fields such as information retrieval, natural language processing, recommender systems, and Q&A, where it helps to uncover correlations within the knowledge graph, thereby improving the effectiveness of these systems.

In this study, building on the concepts outlined in Fig. 1, we aim to enhance the knowledge graph link prediction algorithm by integrating key techniques such as knowledge graph embedding, data preprocessing, and graph neural networks. This approach will enable convolutional learning of entities and relationships, utilize the DistMult decoder for scoring, and apply association rule mining to select the ternary elements for evaluation. The overall architecture of the improved algorithm is depicted in Fig. 2.

A. Knowledge Graph Input to the Algorithm

Before modeling a knowledge graph, the entities and relationships within it must be converted into vector representations. This conversion is crucial because it allows us to use vector space distance and similarity measures to assess relationships between entities and infer connections between unknown entities—this process is known as knowledge graph embedding.

As illustrated in Fig. 3, the entity set in the knowledge graph is first encoded as text. These encoded entities are then mapped to corresponding sequence numbers, which typically start from 0 and increment sequentially. A dictionary is constructed to link each sequence number to an entity in the knowledge graph. During model inference, these sequence numbers are consistently used to process entity information. Additionally, a dictionary is created to map sequence numbers to vector representations, ensuring that each sequence number corresponds to a low-dimensional vector representing the final entity.

For the edge set in the knowledge graph, each edge type e_i is transformed into a relation r_i. Similar to entities, a dictionary is created to map relations to sequence numbers, and another dictionary links these sequence numbers to relation vectors. Through this process, the knowledge graph is transformed into $G = (V, \varepsilon, R)$, converting the knowledge within the graph into vector representations that can be used as inputs for subsequent algorithms.

B. Node Information Aggregation based on Node Cross-Relational Attention Mechanism

After transforming the entities and relationships in the knowledge graph into vectors, the structure of graph neural network is used to aggregate the information of the nodes to realize the task of link prediction in the existing knowledge graph. The entire knowledge graph is represented as a set of $G = (V, \varepsilon, R)$ vectors, where $\{V\} = \{1,2,3,\ldots,n\}$ is the set of all the entities in the knowledge graph, $\{\varepsilon\}$ is the set of all the edges, and $\{R\}$ is the set of relationships. Assuming that the head node of the triad is $v_i \in V$, the tail node is $v_j \in V$, and the relation between nodes is $r \in R$, then this triad can be represented as $(v_i, r, v_j) \in \varepsilon$.

In GCN, the embedding vector of a node can be computed by using the Eq. (1).

$$h^{(l+1)} = \sigma\left(\tilde{D}^{-\frac{1}{2}}\tilde{A}\tilde{D}^{-\frac{1}{2}}h^{(l)}W^{(l)}\right) \quad (1)$$

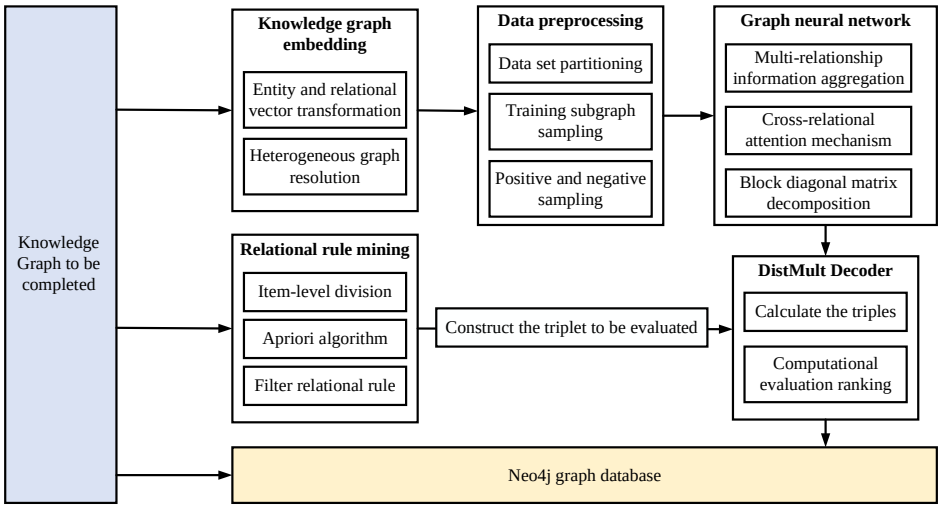

Fig. 2. Algorithm architecture diagram.

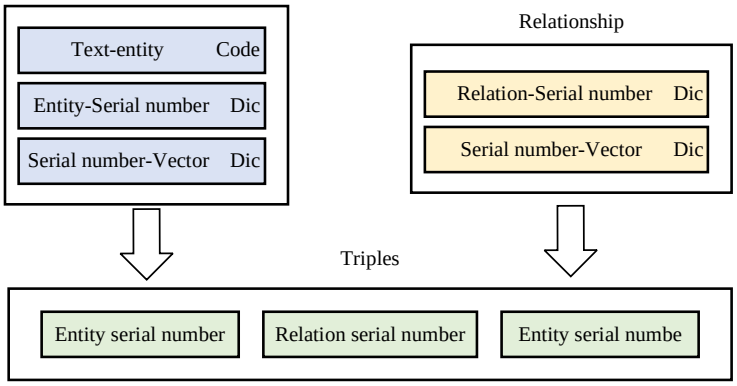

Fig. 3. Schematic of the conversion of knowledge graph triples to vectors.

where, $h^{(l)}$ is the node embedding vector of layer l, $W^{(l)}$ is the trainable weight matrix of layer l, $\tilde{A} = A + l$is the sum of the adjacency and self-connectivity matrices of the graph, $\widetilde{D}$ is the degree matrix of $\tilde{A}$, and σ is the activation function.

Based on Eq. (1), the process of GCN information aggregation can be expressed by Eq. (2).

$$h_i^{(l+1)} = \sigma\left(\sum_{j\in N_i} \frac{1}{\sqrt{d_i}d_j} h_j^{(l)} W^{(l)}\right) \quad (2)$$

where, $h_i^{(l+1)}$ denotes the embedding vector of node i at layer $l+1$, $W^{(l)}$is the trainable weight matrix, N_i is the set of neighbors of node i, $\widetilde{d}_i$ and $\widetilde{d}_j$ are the degrees of node i and node j in matrix $\tilde{A}$, respectively.

As can be seen from Eq. (2), in GCN, the information of nodes converges in different relations sharing the same weight matrix W, so GCN actually treats the graph as a homomorphic graph for processing, in this study, we will consider the heteromorphism in the knowledge graph, and we have already transformed the entities and relations in the knowledge graph into vectors in the above paper and constructed the mapping between the serial numbers and vectors of the entities and relations, using the correspondence between serial number and vector, which makes it easier to split the knowledge graph into different heteromorphic graphs for processing according to different relations, which is reflected in the fact that different relations construct different maps between entities and relations. Using the correspondence between the serial number and the vector, we can easily split the knowledge graph into different heterogeneous graphs according to different relationships, which is reflected in the construction of different weight matrices for different relationships, instead of using the same weight matrix for all relationship types as in the case of GCN.

On the basis of GCN, considering the heterogeneity of the graph, the information is aggregated for different types of edges between nodes, as shown in Eq. (3).

$$h_i^{(l+1)} = \sigma\left(\sum_{r\in R}\sum_{j\in N_i^N} \frac{1}{c_{i,r}} W_r^{(l)} h_j^{(l)} + W_0^{(l)} h_i^{(l)}\right) \quad (3)$$

Where, $h_i^{(l+1)}$ denotes the embedding of node i in the $l+1$ layer, σ is the activation function, R is the set of relations, $N_i^r$is the set of neighboring nodes of node i under relation r, $c_{i,r}$is the normalization constant, and $W_r^{(l)}$ is the weight matrix of relation r. Since the information of nodes themselves needs to be taken into account, the self-loop of nodes is introduced. The self-loop of a node can be treated as a special type of edge, and the self-loop weight matrix is denoted by $W_0^{(l)}$.

As can be seen from Eq. (3), for each relationship, a separate weight matrix W_r is computed. In large-scale knowledge graphs, due to the large number of relationships, the number of parameters in the inference process is also unusually large, which further increases the complexity of the inference process. Specifically, assuming that a graph G contains N nodes and M relationship types, each relationship type has a corresponding weight matrix W_r, size $D_l \times D_{l-1}$, where D_l is the feature dimension of the current layer of the relationship type, and D_{l-1} is the feature dimension of the previous layer. Since each node has different embedding vectors under different relation types, these weight matrices need to be computed separately at each node, resulting in an extremely large number of parameters.

In order to reduce the complexity of the model and improve the generalization performance, the diagonal decomposition of the weight matrix is performed, which transforms the complex weight matrix into a block diagonal matrix, thus reducing the number of parameters and improving the generalization performance of the model. Specifically, as shown in Eq. (4), where the size of $Q_{br}^{(l)}$ matrix is $\left(d^{(l+1)}/B\right) \times \left(d^{(l)}/B\right)$, the block diagonal decomposition of the weight matrix through a series of matrices of the summation, which greatly reduces the size of the parameters of the weight matrix and simplifies the computation process.

$$W_r^{(l)} = \bigoplus_{b=1}^{B} Q_{br}^{(l)} = diag(Q_{1r}^{(l)}, \ldots, Q_{Br}^{(l)}) \quad (4)$$

In the above node information aggregation process, each relation type uses an independent weight matrix for information transfer, and the node embedding is obtained by splicing the information of each relation type. This approach may lead to the uneven contribution of each relationship type in node embedding, and the contribution of some relationship types may be masked or weakened. To solve this problem, this study introduces the Node-level Across Relation Attention mechanism, which adjusts the weight of each relation type in the node

embedding by learning a node-level attention vector for each node.

Before calculating the node's attention mechanism, firstly, for the similarity between node i and node j under a specific relation r, the weight matrix corresponding to relation r is multiplied and spliced with node i and node j, respectively, and then multiplied with a trainable attention vector, and then the similarity between node i and node j under relation r is finally obtained by an activation function. As shown in Eq. (5), where e_{ij}^r denotes the similarity between node i and node j under relation r, $\vec{a}^r$ is a trainable attention vector, $\vec{W}_r$ is the weight matrix under relation r, and $\oplus$ denotes the vector splicing operation.

$$e_{ij}^r = \mathrm{ReLU}\left(\vec{a}^r \cdot \left[\vec{W}_r h_i^{(1)} \oplus \vec{W}_r h_j^{(1)}\right]\right) \quad (5)$$

The calculation process of attention is shown in Fig. 4. The final information aggregation process of a single node is shown in Fig. 5.

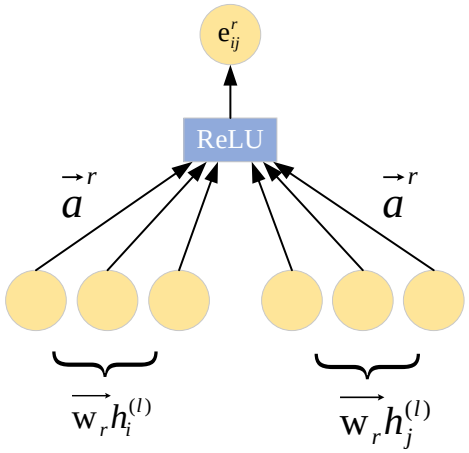

Fig. 4. Attention calculation process.

Based on Eq. (5), in the iterative process of graph neural network, each node in the knowledge graph calculates the similarity of its neighboring nodes under all the relationships, and then uses the similarity to calculate the attention of the node's neighboring nodes, and ultimately the information convergence of nodes in each layer is shown in Eq. (6). The whole information aggregation process is shown in Fig. 6, and finally the whole network outputs the embedding vector representation of nodes and relationships.

$$h_i^{(1+1)} = \sigma\left(\sum_{r\in R}\sum_{j\in N_i^r}\frac{exp\left(\mathrm{ReLU}\left(\vec{a}^r\cdot\left[\vec{W}_r h_i^{(l)}\oplus\vec{W}_r h_j^{(1)}\right]\right)\right)}{\sum_{k\in N_i^r} exp\left(\mathrm{ReLU}\left(a^r\cdot\left[\vec{W}_r^h h_i^{(l)}\oplus\vec{W}_r h_k^{(1)}\right]\right)\right)} W_r^{(l)} h_j^{(l)} + W_0^{(l)} h_i^{(l)}\right) \quad (6)$$

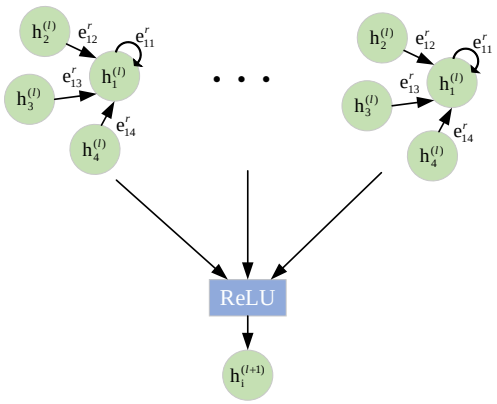

Fig. 5. Individual node final information aggregation process.

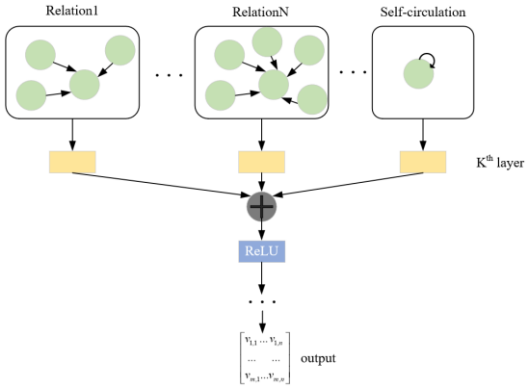

Fig. 6. Schematic diagram of node information aggregation process.

C. Training Sampling and Loss Functions

In the link prediction task, dealing with an entire knowledge graph can be challenging due to its size, often exceeding the capacity of a single GPU's memory. To address this, we sample smaller subgraphs for training. By using random sampling, we can maintain the integrity of the graph's structure while avoiding memory bottlenecks associated with processing large-scale knowledge graphs. This study employs uniform random sampling, where each node or edge is selected with equal probability. This method is straightforward, offering good randomness and repeatability, and can be executed using a random number generator.

The sampling process involves the following steps:

1) Determine the sample size: Set a hyperparameter, batch_size, to define the number of nodes or edges to sample.

2) Initialize the sample set: Create a set to store the sampled nodes or edges.

3) Random sampling: For each node or edge, generate a random number; if it falls below the sampling probability, include the node or edge in the sample set.

4) Return the sample set: Use this set for subsequent training or other tasks.

After random sampling, a training subgraph is obtained. To further enhance prediction accuracy and generalization, the study introduces positive and negative sampling. For each node pair (i, j), both positive samples (existing links) and negative samples (non-existent links) are generated. Negative samples are constructed using a random sampling strategy, with a negative sampling factor μ, where the ratio of positive to negative samples is $1:\mu$.

The loss function for the final model training is shown in Eq. (7) as follows.

$$L = -\sum_{(i,j)\in E} log\,\sigma\,(y_{(i,j)}) - \sum_{(i,j)\in \tilde{E}} log\,\sigma\,(\tilde{y}_{(i,j)}) \quad (7)$$

Where, E denotes the set of positive sample edges, E denotes the set of negative sample edges, and $y_{(i,j)}$ denotes the predicted probability of the existence of an edge between node *i* and node *j*, which can be computed by Eq. (8).

$$y_{(i,j)} = \frac{1}{k}\sum_{}^{t=1}{}^{k} \sigma(h_i^{(L)} \cdot r_i^{(L)} h_j^{(L)}) \quad (8)$$

where *k* denotes the number of negative samples sampled, $h_i^{(l)}$ and $h_j^{(l)}$ denote the embedding vectors of node *i* and node *j* in the last layer, and $r_t^{(L)}$ denotes the weight vector of relation type r_t in the Lth layer. σ denotes the sigmoid function, which is used to map the predicted values to a range between 0 and 1. The first term of the loss function is the cross-entropy loss for positive samples, indicating that the higher the probability that the model predicts the existence of positive edges, the lower the loss. The second term is the cross-entropy loss of negative samples, which means that the higher the probability that the model predicts that the negative sample edge does not exist, the lower the loss. By minimizing the loss function, it allows the model to predict the likelihood of edge existence more accurately between nodes.

V. Comparative Experiments and Analysis

This section presents comparative experiments to evaluate the model's effectiveness, focusing on the experimental environment, dataset, evaluation criteria, control group design, and final result analysis to validate the improvements made in this study.

A. Experimental Environment and Datasets

Due to the large knowledge graph dataset used in this experiment and the complexity of model computation, the experiment needs to be carried out on GPUs. The server used for the experiment is the one equipped in the lab, Windows 10 64bit system, 16GB RAM and equipped with high-computing-power GPUs. In terms of software, Python was used as the programming language for the model, PyCharm was used to compile the software, and PyTorch was used as the basic implementation library for the model.

This paper presents a custom-built knowledge graph dataset named BadmintonKG, specifically created for the badminton domain. It is designed to support applications such as tactical reasoning, match analysis, and training assistance. BadmintonKG includes 9,742 entities, 135 types of relationships, and 198,563 triples (i.e., relationships between entities). Unlike other common knowledge graph datasets, BadmintonKG focuses on the specific domain of badminton, covering various entities and relationships such as players, tactics, courts, techniques, and coaching styles. The training, validation and test sets are divided as shown in Table I.

TABLE I. BadmintonKG Data Set Delineation Table

Dataset segmentation	Entities	Relations	triples
Original dataset	9,742	135	198,563
Training set	9,742	135	176,421
Validation set	9,742	135	19,989
Test set	9,742	135	11,072

B. Evaluation Criteria and Control Group Design

MRR (Mean Reciprocal Rank) is one of the commonly used evaluation metrics in the task of knowledge graph link prediction. The core idea of MRR is to find the true tail entity *t* among all possible tail entities *t`* for each test ternary (h,r,t), and compute the inverse of its score ranking. Finally, the average of the ranked inverts of all the test triples is used as the MRR score of the model. This is calculated as shown in Eq. (9).

$$MRR = \frac{1}{|T|}\sum_{(h,r,r)\in T}\frac{1}{\text{rank}_{(hr,t)}} \quad (9)$$

In knowledge graph link prediction, Hits@ N is a commonly used evaluation metric to measure whether the algorithm can correctly predict the correct entity or relation in the test set among the first N candidate entities or relations. Specifically, assuming that the correct answer for each ternary (h,r,t) in the test set is *t*, then for each (h,r) pair, we can sort all its possible entities according to the algorithm's prediction scores in descending order and compute whether the first *N* predicted entities contain the correct answer *t*. If the correct answer is *t*, then it is called a hit. If it does, it is called a hit (hit), otherwise it is called a miss. The final hit rate is the average hit rate of all test triples among the first N candidate entities. This is shown in Eq. (10).

$$\text{Hits@}N = \frac{1}{|T|}\sum_{(h,r,t)\in T}\Pi(\text{rank}_{(h,r,t)} \le N) \quad (10)$$

To validate the effectiveness of the proposed knowledge graph inference algorithm based on graph neural networks and association rule mining, experiments will be conducted on BadmintonKG. The experimental model will be compared with three other neural network models: Graph Convolutional Network (GCN), Graph Attention Network (GAT), and Relational Graph Convolutional Network (R-GCN). The comparison will focus on the evaluation metrics MRR and Hits@N, and the impact of different training subgraph sizes on model performance will also be assessed.

Knowledge Graph Link Prediction with GCN: GCN is a graph convolutional neural network that treats the knowledge graph as a homogeneous graph, using node neighbors to perform convolution. It aggregates neighbor information with a weighted adjacency matrix, enabling it to learn node representations through multi-layer convolution. GCNs are particularly effective for graphs with similar node features.

Knowledge Graph Link Prediction with GAT: GAT extends GCN by incorporating an attention mechanism that weights the importance of each neighboring node. This allows for the aggregation of neighbor information with varying degrees, resulting in richer and more accurate node representations.

Knowledge Graph Link Prediction with R-GCN: R-GCN is designed for multi-relational graphs, using relational matrices in its convolution operations. Unlike traditional GCNs, R-GCN employs a learnable convolution kernel that adjusts to different types of relations, making it more effective for handling multi-relational data.

C. Experimental Results and Analysis

In this control group, this experimental model is compared with the other two models on two datasets, and the number of model iterations for the experiments is set to 6000, the stochastic inactivation rate is set to 0.2, the learning rate is set to 0.01, the output dimension of the hidden layer is set to 500, and the sampling mode of the training subgraphs is set to uniform. The test set evaluation results from the above training results are plotted in a table, as shown in Table II.

The above table was plotted as a line graph as shown in Fig. 7 and 8. From the above experimental data performance, the model in this study shows excellent performance on both datasets, and outperforms the other three models in all indicators.

In the BadmintonKG dataset, when the size of the training subgraph is 30000, this model outperforms the GCN, GAT, and R-GCN models in all the metrics, but the difference is relatively small, and when the size of the training subgraph is 80000, the MRR metrics of this model reaches 0.2753, which is higher than that of 0.1910 for the GCN, GAT, and R-GCN models, 0.2503 and 0.2653, which is about 40% higher than that of the GCN model, 10% higher than that of the GAT model, and 3.8% higher than that of the R-GCN model.

TABLE II. SUMMARY OF EXPERIMENTAL RESULTS

BadmintonKG	The size of the training subgraph is 30000				The size of the training subgraph is 80,000			
	MRR	Hits@1	Hits@3	Hits@10	MRR	Hits@1	Hits@3	Hits@10
Our	0.2458	0.1576	0.2677	0.4249	0.2753	0.1811	0.3066	0.4638
GCN	0.1673	0.0873	0.1927	0.3201	0.1910	0.0990	0.2283	0.3684
GAT	0.2144	0.1283	0.2373	0.3855	0.2503	0.1610	0.2695	0.4403
R-GCN	0.2412	0.1404	0.2531	0.4085	0.2653	0.1715	0.2856	0.4536

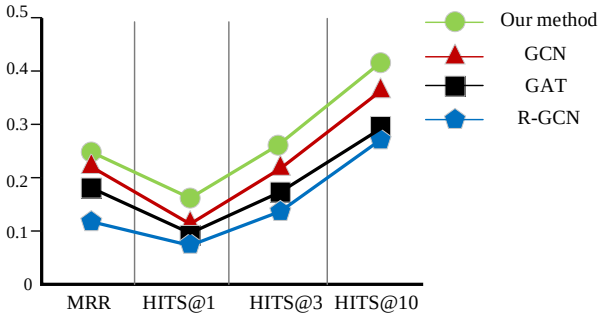

Fig. 7. BadmintonKG comparison of models (training subgraph size 30000).

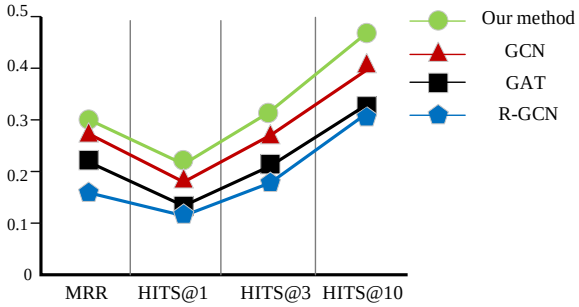

Fig. 8. BadmintonKG comparison of models (training subgraph size 80000).

Overall, the model in this study achieves better performance than the link prediction models based on GCN, GAT and R-GCN in the knowledge graph link prediction task, and shows good robustness and generalization ability, and the experimental results in this study prove the effectiveness and superiority of the proposed model in the knowledge graph link prediction task.

VI. CONCLUSION

In this study, we applied knowledge graph and graph neural network techniques to the mining and reasoning of badminton tactics, demonstrating the effectiveness of this approach in analyzing and optimizing players' training patterns. Technically, the introduction of training subgraph sampling, positive and negative sampling, and block diagonal matrix decomposition significantly reduced the computational complexity, improved the handling of large-scale knowledge graphs, and enhanced the model's generalization capabilities. These techniques not only optimized the data processing workflow but also improved the model's performance and accuracy in practical applications.

Through comparative experiments on a proprietary badminton tactics dataset, we validated the superiority of the proposed method over traditional approaches in tactical reasoning and training optimization. The results showed that our model more accurately predicted and reasoned about tactical changes in matches, offering strong scientific support for badminton training and competition. In conclusion, this study provides a novel technical approach for tactical analysis in badminton and offers a potential methodological reference for other sports.

***Abstract*—In order to improve the efficiency of analysing the application of virtual reality technology in cultural landscape promotion platform and enhance the accuracy of usability assessment, a feasibility assessment method based on MA-BiGRU for virtual reality technology cultural landscape promotion platform is proposed. Firstly, it analyses the application of virtual reality technology in cultural landscape promotion platform and designs the application feasibility assessment; secondly, it combines MA algorithm and BiGRU network, and proposes a usability assessment algorithm of virtual reality technology based on MA-BiGRU model; lastly, it analyses the feasibility and validity of the proposed method by using actual cases. The results show that, compared with other models conducted, the proposed method has a higher assessment and prediction accuracy, and it also effectively assists in completing the virtual reproduction of the cultural landscape promotion platform of Dongao Deng Village, Dongtou District, Wenzhou City, and improves the design effect of virtual reality technology in the cultural landscape promotion platform.**

Keywords*—Virtual reality technology; cultural landscape promotion platform; usability assessment algorithm; Mayfly algorithm

I. INTRODUCTION

With the continuous breakthrough of human science and technology, the visual experience of two-dimensional plane has slowly failed to meet the needs of people's life, so the three-dimensional virtual technology has gradually entered people's lives [1]. Virtual reality technology as one of the most promising technologies, with the development and improvement of hardware and software technology at this stage, has been widely used in a variety of industries, but virtual reality technology in the field of cultural landscape is lacking [2]. Currently, the main status quo of cultural landscape promotion research is reflected in the rigidity of cultural communication form, the lack of commercial profit model, combined with virtual reality technology to study the cultural landscape promotion platform not only improves the utilisation rate of cultural landscape resources, but also accelerates the speed of cultural landscape dissemination, but also realises the inheritance, innovation and development of cultural landscape [3]. The application of virtual reality technology in the cultural landscape promotion platform is mainly divided into three aspects: the application of virtual reality technology, the analysis of the application of virtual reality technology and the assessment of the usability of virtual reality technology [4].

*Corresponding Author

The application of virtual reality technology in cultural landscape promotion platform is mainly the combination of virtual reality technology and cultural landscape promotion platform design; virtual reality technology application analysis is mainly to analyse the application of virtual reality technology in cultural landscape promotion platform index mention analysis; virtual reality technology usability assessment refers to the construction of virtual reality technology in cultural landscape promotion platform application analysis and assessment model, prediction and assessment of application situation. Cai and Jin [5] studied the combination of virtual reality technology and the protection and inheritance of village and town cultural landscape, and put forward the application strategy. Li and Wang [6] studied the application of virtual reality technology in cultural theme parks, and combined the elements of jin yong's martial arts world. Mo [7] studied the method of reproducing historical and cultural landscapes based on virtual reality technology. Yang and Sun [8] addressed the problem of virtual reality display in fuzimiao, and researched the historical humanistic landscape of cultural communication and tourism business promotion strategy. Dimitar et al [9] studied the usability assessment method of virtual reality technology based on machine learning, and at the same time for the machine learning algorithms fall into the local optimal problem using intelligent optimisation algorithms to find the optimal. By analysing the above literature, although there are some research results on the combination of virtual reality technology and cultural landscape promotion platform, there are some problems: 1) the role analysis of virtual reality technology on the design of cultural landscape promotion platform is not clear enough; 2) the extraction of indicators for the analysis of the application of virtual reality technology is not comprehensive and systematic enough; 3) the accuracy of the usability assessment of virtual reality technology is low; 4) the application of virtual reality technology fails to achieve the design efficiency [10].

In view of the above problems, this paper proposes a usability assessment method for cultural landscape promotion platform of virtual reality technology based on mayfly algorithm optimised two-way gated recurrent unit neural network. Focusing on the application of virtual reality technology in the design of cultural landscape promotion platform, the application process of VR in cultural landscape promotion platform is analysed, and the relevant usability assessment indexes are extracted; for the usability assessment of the cultural landscape promotion platform based on virtual reality technology,

combining with the mayfly algorithm [11] to optimize the BiGRU neural network parameters [12], a MA-BiGRU-based feasibility assessment model of cultural landscape promotion platform based on virtual reality technology; through case study, the model proposed in this paper improves the feasibility assessment accuracy of cultural landscape promotion platform and verifies the feasibility of virtual reality technology in cultural landscape promotion platform.

This paper begins with a review of the status quo of cultural landscape promotion and how VR can address existing gaps. It then elaborates on the integration of MA and BiGRU for the usability assessment model, followed by an analysis of VR technology's impact on the design of cultural landscapes. The study incorporates actual case analysis from Dongao Ding Village, demonstrating the improved assessment and prediction accuracy of the proposed method compared to traditional models.

The paper is structured as follows:

- An overview of VR applications in cultural landscape promotion platforms.
- Explanation of the Mayfly Algorithm (MA) and the BiGRU model.
- The construction of a usability assessment method integrating MA and BiGRU.
- Application and evaluation of the proposed model using the Dongao Ding Village case.
- A discussion of results and performance improvements in the proposed approach.

II. Virtual Reality Application in Landscape Promotion

A. Virtual Reality

The use of Virtual Reality (VR) technology in cultural landscape promotion platforms is becoming more widespread, enabling users to experience cultural and tourism content in an immersive way through simulated environments.

1) VR technology: VR virtual reality technology can be regarded as a major development direction of simulation technology, which actually contains a variety of different technologies, such as human-computer interface, multimedia sensing, networking, etc. [13], as shown in Fig. 1. And the performance mode of VR virtual reality technology also contains several parts, such as environment simulation, external perception, natural skills, and sensing devices.

2) VR technology applications: According to the principle of VR technology, the application of VR technology in the cultural landscape promotion platform is mainly manifested in the following aspects [14]: 1) the construction of intelligent scenic spots; 2) the promotion of cultural and tourism virtual reality applications; 3) the digital promotion of national cultural industry parks; 4) the construction of digitally empowered cultural and tourism scenarios; and 5) the immersive tour experience of VR technology, as shown in Fig. 2.

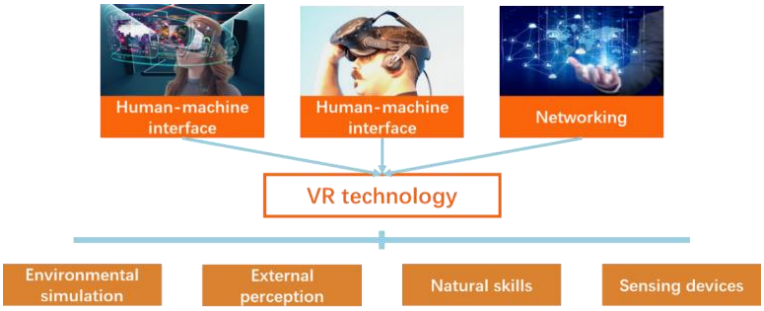

Fig. 1. Principle of VR technology.

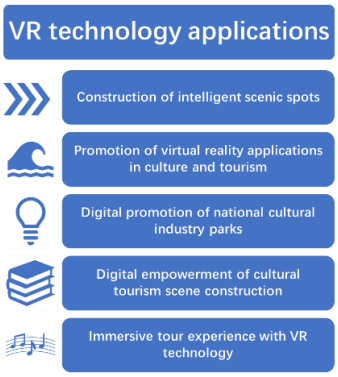

Fig. 2. Application of VR technology in the cultural landscape promotion platform.

3) Steps for the application of VR technology in cultural landscape promotion platforms: Virtual reality technology can not only bring visitors a rich and shocking visual impact, but also need to use virtual reality technology to clearly convey the information of the cultural landscape to the visitors. This paper takes the virtual reproduction of cultural landscape as a case study, based on the reality, adopts the multi-user interactive 3D modelling method of GIS, and applies the VR technology to the problem of cultural landscape reproduction [15], the specific steps are shown in Fig. 3.

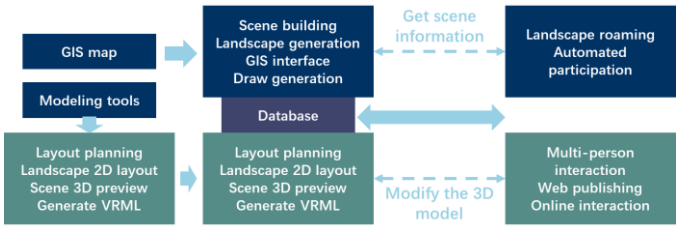

Fig. 3. Steps in reproducing the landscape virtual environment.

B. Analysis of VR Application in Cultural Landscape Promotion Platforms

According to the principles of demand, scientific, systematic and quantifiable (Fig. 4), by analysing the steps of applying VR technology in the cultural landscape promotion platform, this paper extracts the application analysis indicators from the four aspects of landscape environment, image, behaviour and spirit, as shown in Fig. 5. (1) Landscape environment includes indicators such as topography and geomorphology, climate, water bodies, flora and fauna, etc.; (2) Landscape image includes indicators such as residents, squares, historical sites, sculpture vignettes, etc.; (3) Landscape behaviour includes indicators such as daily behavioural habits, territorial construction methods, and landscape industry ideas, etc.; and (4) Landscape spirit includes feng shui, festivals and rituals, and symbolic images of the landscape, etc. [16].

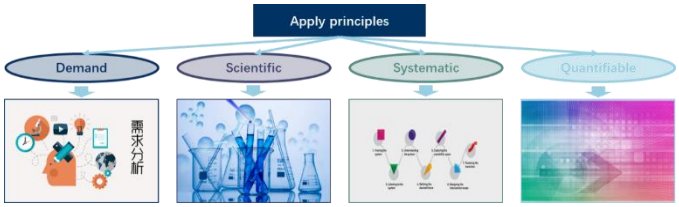

Fig. 4. Principles of application.

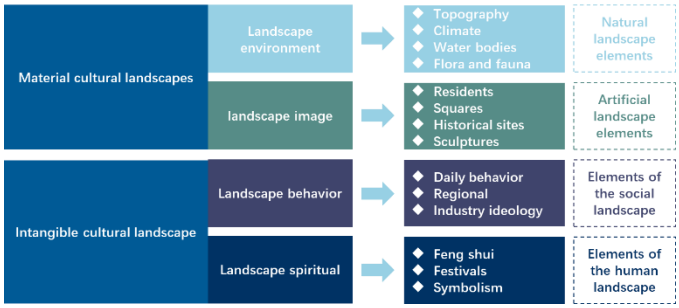

Fig. 5. Extraction of application analysis metrics.

C. Application Analysis and Feasibility Assessment Programme

By analysing the application of VR in the cultural landscape promotion platform, extracting the application analysis indexes, and after a series of data processing, the feasibility assessment model is constructed by adopting the feasibility assessment method of the cultural landscape promotion platform with improved data-driven algorithms to assess the feasibility of the application of virtual reality technology in the cultural landscape promotion platform, and the design of the scheme is specifically shown in Fig. 6. As can be seen from Fig. 6, the feasibility assessment study on the application of virtual reality technology in the cultural landscape promotion platform mainly includes key technologies such as the application analysis of VR technology, the collection of data processing, the construction of the feasibility assessment model, and performance analysis.

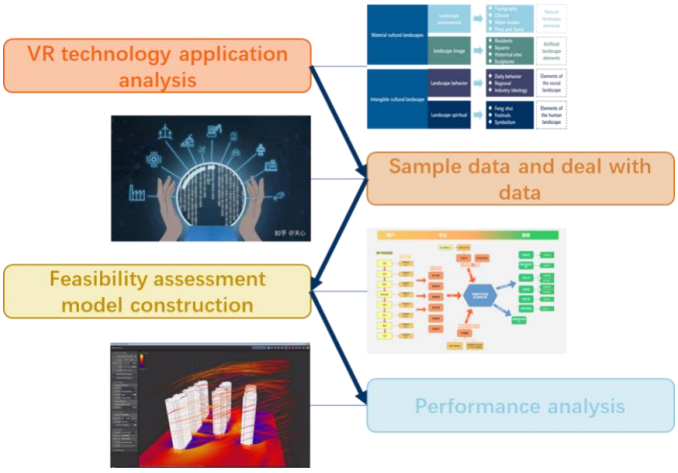

Fig. 6. Feasibility analysis assessment scenario for the application of virtual reality technology in a cultural landscape promotion platform.

III. Feasibility Assessment Algorithm for Virtual Reality Cultural Landscape Promotion Platform based on MA-BiGRU Model

A. Mayfly Algorithm

Mayfly Optimization Algorithm (MA) [17] is an optimization algorithm that mimics the flight and mating behaviour of mayflies in nature. The Mayfly Algorithm is characterised by the fact that its population is divided into two parts: male mayflies move through the global optimum and their own historical optimum positions, while female mayflies move towards a mate that is superior to them, and perform a local search on their own if the mate is weaker than them. The algorithm generates new individuals by simulating the mating process of mayflies and retains the best individuals in the group through a selection mechanism [18].

1) MA algorithm optimisation strategy: The core optimisation strategies of the MA algorithm include the following:

a) Male Mayfly movement: The position update of male mayflies relies on their own speed and the experience of neighbouring individuals, and considering the specific behaviour of mayflies on the water surface, their speed update includes the influence of cognitive and social components, as shown in the following update model:

$$x_i^{k+1} = x_i^k + v_i^{k+1} \tag{1}$$

$$v_{ij}^{k+1} = g \cdot v_{ij}^k + a_1 e^{-\beta r_p^2}\left(p_{best_{ij}} - x_{ij}^k\right) + a_2 e^{-\beta r_g^2}\left(g_{best_{ij}} - x_{ij}^k\right) \tag{2}$$

$$p_{best_{ij}} = \begin{cases} x_i^{k+1} & f\left(x_i^{k+1}\right) < f\left(p_{best_i}\right) \\ p_{best_i} & f\left(x_i^{k+1}\right) \geq f\left(p_{best_i}\right) \end{cases} \tag{3}$$

$$g_{best} = \min\left\{ f\left(p_{best1}\right), f\left(p_{best2}\right), \cdots, f\left(p_{bestN}\right)\right\} \quad (4)$$

where x_i is the position of the ith male mayfly; v_i is the velocity of the ith male mayfly; k is the number of iterations; a_1 and are positive attraction coefficients, which measure the effect of experience gained from self and society, respectively, on the behaviour; g is the coefficient of gravitational force, which decreases with the number of iterations; $p_{best_{ij}}$ is the individual optimum; $g_{best_{ij}}$ is the global optimum; N is the total number of male mayflies in the swarm; r_g is the Cartesian distance between x_i and g_{best} ; r_p is the Cartesian distance between x_i and p_{best_i} :

$$\left\| x_i - X_i \right\| = \sqrt{\sum_{j=1}^{n} \left(x_{ij} - X_{ij} \right)^2} \quad (5)$$

The best male mayflies perform a unique nuptial dance step, moving up and down at different speeds. These male mayflies have a speed of:

$$v_i^{k+1} = v_i^k + d' \times r \quad (6)$$

where d' is the wedding dance coefficient and r is a random number between 0 and 1.

b) Female Mayfly movement: Female mayflies select mates during mating, and their positional updates depend on interactions with male mayflies. The velocity update of female mayflies takes into account attractive and random wandering factors to model their movement through the air. The position of the ith female mayfly is updated as:

$$y_i^{k+1} = y_i^k + v_i^{k+1} \quad (7)$$

Female mayflies and male mayflies are attracted to each other according to the principle of equal ranking of individual fitness, the position of female mayflies changes with the position of male mayflies with the same ranking, i.e.

$$v_i^{k+1} = \begin{cases} gv_{ij}^k + a_2 e^{-\beta r_{mf}^2} \left(x_{ij}^k - y_{ij}^k \right) & f\left(y_i\right) > f\left(x_i\right) \\ gv_{ij}^k + f_{f1} \times r & f\left(y_i\right) \le f\left(x_i\right) \end{cases} \quad (8)$$

where r_{mf} is the Euclidean distance between the ith female mayfly and the ith male mayfly; and f_{f1} is a random wandering coefficient used when the female mayfly is not attracted to the male mayfly.

c) Mayfly mating: The mating process involves the selection of male and female mayflies, usually based on their respective fitness values. Mating produces offspring that replace certain individuals in the population to maintain population diversity and facilitate the search process. The position of mated offspring is calculated as follows:

$$\begin{cases} o_1 = L \cdot m_{male} + \left(1 - L\right) \cdot f_{female} \\ o_2 = L \cdot f_{female} + \left(1 - L\right) \cdot m_{male} \end{cases} \quad (9)$$

where L denotes a random value; o_1 and o_2 initial values are set to 0; m_{male} and f_{female} are the position matrices of males and females, respectively.

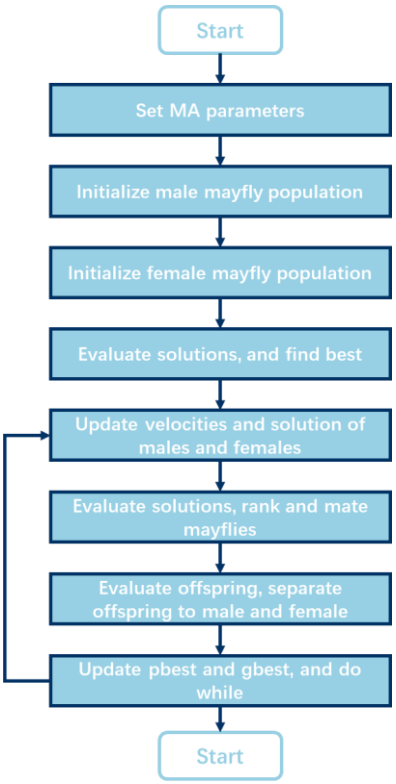

Fig. 7. Flowchart of MA algorithm.

d) Wedding dance and random wanderings: Wedding dance steps and random wandering make the algorithm search locally further, but fixed coefficients may make the mayfly iterate to a worse position later in the iteration. Therefore, make the dance step coefficients and random wandering coefficients decrease with the number of iterations, and update the arithmetic as:

$$\begin{cases} d_t = d_0 \delta \\ f_{fl_t} = f_{fl_0} \delta \end{cases} \quad (10)$$

Where, δ is a random factor with a value between 0 and 1.

e) Offspring variation: To deal with the case of premature convergence, so that the algorithm searches new regions of the space that have never been visited before, the offspring are randomly selected for the perturbed variant of the normal distribution, i.e.

$$o_n' = o_n + \sigma N_n(0,1) \tag{11}$$

where σ is the standard deviation of the normal distribution and $N_n(0,1)$ is the standard normal distribution.

2) MA algorithm flow: According to the optimisation strategy of MA algorithm, the flow of MA algorithm is shown in Fig. 7.

3) MA algorithm application: The mayfly algorithm can be applied to a wide range of optimisation problems, including engineering design [19], machine learning parameter optimisation [20], path planning [21], image segmentation [22] and other fields (Fig. 8). The strength of the algorithm lies in its ability to explore the search space efficiently and to improve search efficiency by simulating biological behaviour [19].

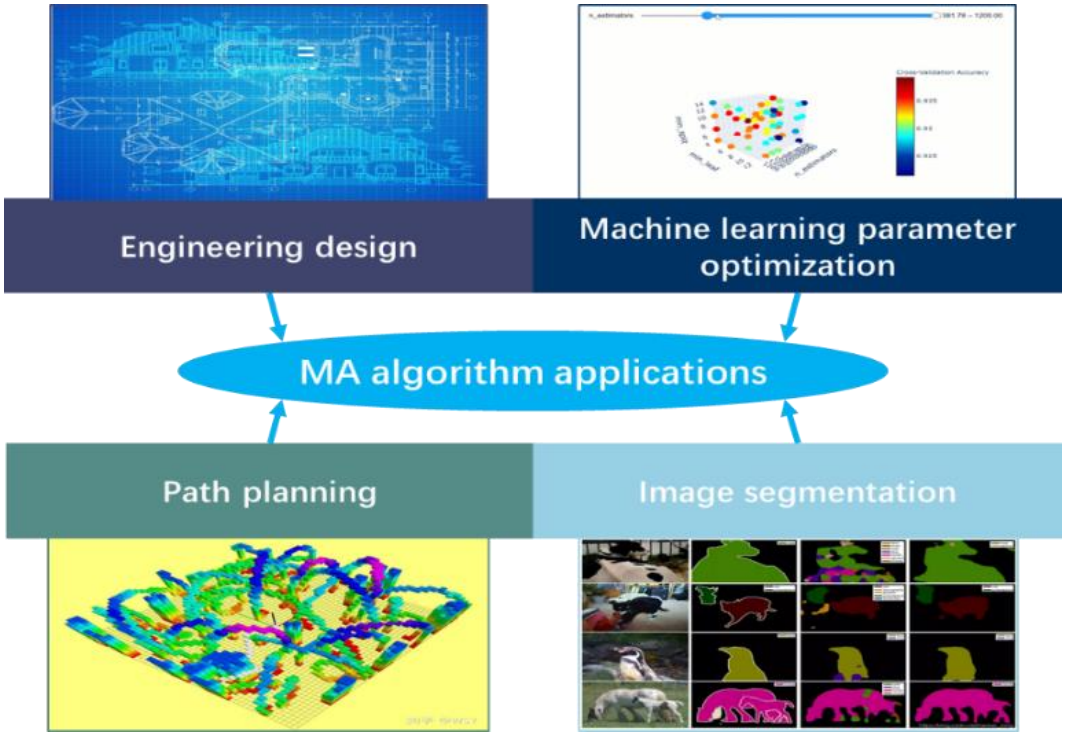

Fig. 8. Application of MA algorithm.

B. The MA-BiGRU Model

1) BiGRU network

a) BiGRU network fundamentals: BiGRU (Bidirectional Gated Recurrent Unit) network [23] is a special form of Recurrent Neural Network (RNN) that combines two directional GRU (Gated Recurrent Unit) layers to process sequence data. Compared to unidirectional RNNs, BiGRU is able to take into account both past and future information of sequence data to better understand contextual dependencies in the data, and the structure is shown in Fig. 9. The output of each time step depends not only on the information before that time point, but also on the information after, which makes BiGRU very useful in tasks such as text analysis, speech recognition, and natural language processing.

b) Characteristics of BiGRU: According to the structural principles of BiGRU network, its characteristics are as follows: i) Bidirectional structure: BiGRU consists of two GRU layers, one processing left-to-right information and the other processing right-to-left information; ii) Gating mechanism: the GRU unit contains reset gates and update gates, which control the flow of information and help the network to capture long-range dependencies; iii) Reducing the gradient vanishing problem: in comparison with the traditional RNN, GRU mitigates the gradient vanishing problem through the gating mechanism, enabling the network to learn long-distance dependencies more efficiently; iv) Parameter efficiency: although BiGRU is able to capture bi-directional information, it usually has fewer parameters than BiLSTM (Bidirectional Long Short-Term Memory), which may result in faster training speeds and lower memory requirements, as shown in Fig. 10.

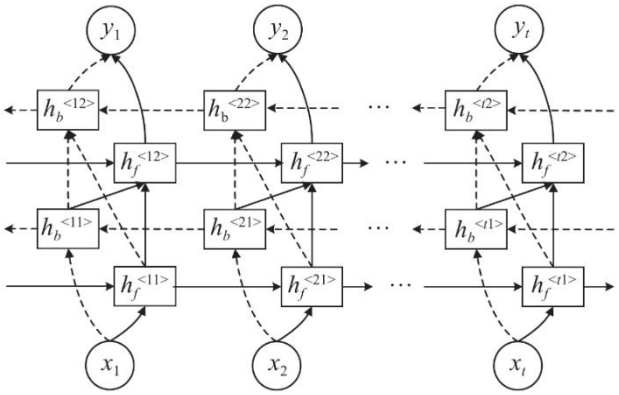

Fig. 9. Structure of the BiGRU model.

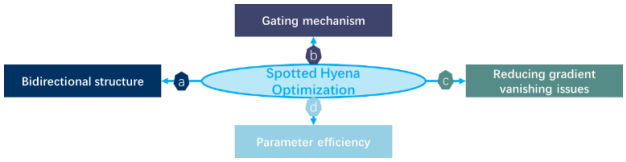

Fig. 10. BiGRU characteristics.

c) Application of BiGRU: BiGRU network is widely used in a variety of deep learning tasks due to its ability to process sequence data efficiently. For example, it can be used in natural language processing tasks such as text sentiment analysis, named entity recognition, and machine translation, as well as in the fields of time series prediction and speech recognition [24] (Fig. 11).

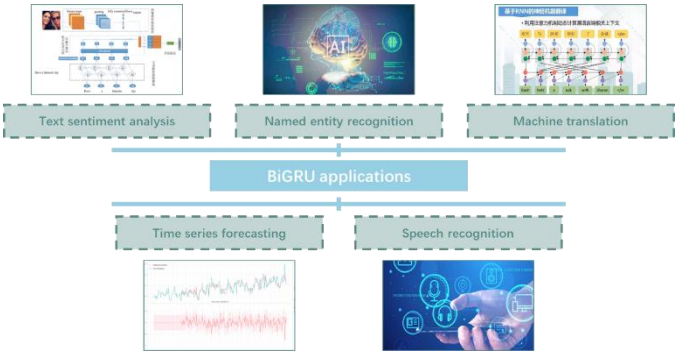

Fig. 11. BiGRU application.

2) MA-BiGRU model

a) Optimising variable coding: In the optimisation variables section, this paper uses real number coding for Update Gate, Reset Gate and Candidate State Weights and Bias of BiGRU network as shown in Fig. 12.

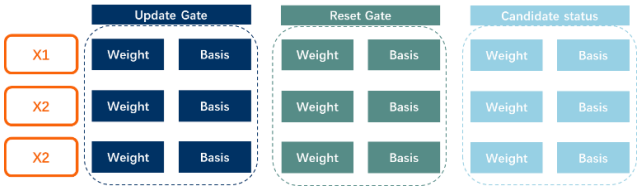

Fig. 12. Optimising the coding structure of decision variables.

b) Adaptation function setting: The MA algorithm is introduced mainly to improve the mapping accuracy of BiGRU model, so in this paper, RMSE, MAPE, MAE, R2 are selected as the fitness function in the optimisation process of MA algorithm (Fig. 13), and the specific fitness function is calculated as follows:

$$F(x) = w_1 f_{RMSE} + w_2 f_{MAPE} + w_3 f_{MAE} + w_4 (1/f_{RMSE}) \quad (12)$$

where w_1 , w_2 , w_3 and w_4 are the weights of RMSE, MAPE, MAE, and R2 , respectively.

Fig. 13. Structure of the fitness function.

c) Analysis of model steps: According to the decision variable coding and fitness function settings, the MA-BiGRU model is constructed by determining the parameters of the MA algorithm, generating the initial population, updating the update gates, reset gates, and candidate state weights and biases of the BiGRU network by using the optimisation strategy of the MA algorithm, comparing the values of the fitness function, and obtaining the optimal update gates, reset gates, and candidate state weights and biases of the BiGRU network, and thus constructing the MA-BiGRU model, and the pseudo-code is shown in Fig. 14. Fig. 15 shows the schematic diagram of SHO-LSTM structure.

Algorithm 1: BiGRU based on MA	
1	Determine optimized variables, including weights and basis;
2	Set MA algorithm parameters;
3	Encode mayfly population;
4	Calculate fitness, and update best mayfly;
5	Do While stop criteria are not met
6	Update velocities and solutions of males and females;
7	Evaluate solutions;
8	Rank the mayflies;
9	Mate the mayflies;
10	Evaluate offspring;
11	Separate offspring to male and female randomly;
12	Replace worst solutions with the best new ones;
13	Update *pbest* and *gbest*;
14	End While
15	Output best parameters of BiGRU;
16	Build MA-BiGRU model.

Fig. 14. MA-BiGRU pseudo-code.

Fig. 15. Schematic diagram of SHO-LSTM structure.

IV. Example Analyses

A. (1) Introduction of Examples

In order to verify the application of VR technology in cultural landscape promotion platform analysis and usability assessment algorithm effectiveness, this paper takes Dongao Ding Village in Dongtou District, Wenzhou City as a case study. Dongao Ding Village is located in the southeast end of Dongtou Island. Dongao Ding village coastline reefs are strange and strange, and the sandy beach is broad and soft, which has an important economic location advantage (Fig. 16).

Site location

To the east lies Senile rock、And half screen across the sea,Jingyuan has obvious advantages Dongao Ding Village is a coastal fishing village in the southeast of Dongtou Island, facing Banping Mountain across the sea. Dashatun and Xiandiengyan scenic spots are located in the village, with obvious advantages of scenic source, and are located in the important position of "Sea Garden - Hundred miles coastal style belt".

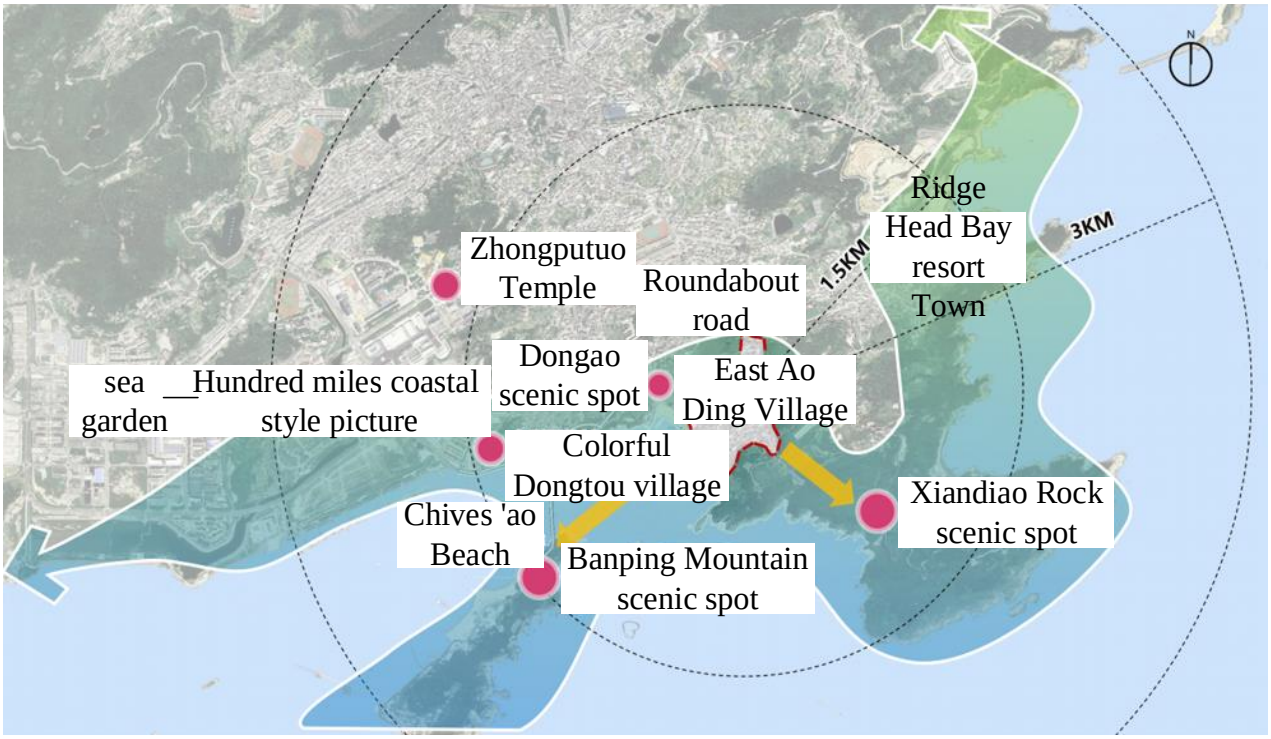

Fig. 16. Dongao Ding Village, Dongtou District, Wenzhou City, China.

In the usability evaluation algorithm experiments, this paper adopts LSTM, GRU, BiGRU, MA-BiGRU models as the analysis and comparison algorithms; LSTM, GRU, BiGRU are optimised iteratively using Adam's algorithm, the activation function is the Relu function, and the number of nodes in the hidden layer is 50; the NP of MA algorithm is set to 100, and the Max_iteration is set to 1000.

B. Example Analysis

1) Application results: Taking the landscape of Dongao Teng Village as an example, this paper uses VR technology in the cultural landscape promotion platform application analysis to extract the landscape elements of various cultural landscapes, and the specific results are shown in Fig. 17.

Fig. 17. Cultural Landscape Elements of Dongao Ding Village.

Fig. 18 gives the effect of promoting the historical and cultural landscape of Dongao Ding Village. Fig. 19 gives the effect of virtual reproduction of cultural landscape based on VR technology.

Fig. 18. Historical and Cultural Landscape Promotion Effect of Dongao Ding Village.

Fig. 19. Effect of virtual reproduction of the historical and cultural landscape of Dongao Ding Village.

2) Usability evaluation algorithm analysis: In order to test the effectiveness of the usability evaluation algorithm, this paper uses 73 samples for training and tests on samples 73-80, and the analysis results are shown in Fig. 20 and Fig. 21. Fig. 20 demonstrates the comparison of the evaluation level results of the usability evaluation algorithms based on LSTM, GRU, BiGRU, and MA-BiGRU models.

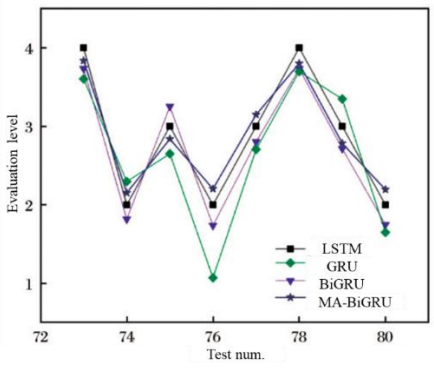

Fig. 20. Assessment level results.

The absolute errors of the usability evaluation algorithms based on LSTM, GRU, BiGRU, and MA-BiGRU models are plotted in Fig. 21. From Fig. 21, it can be seen that MA-BiGRU has the smallest absolute error.

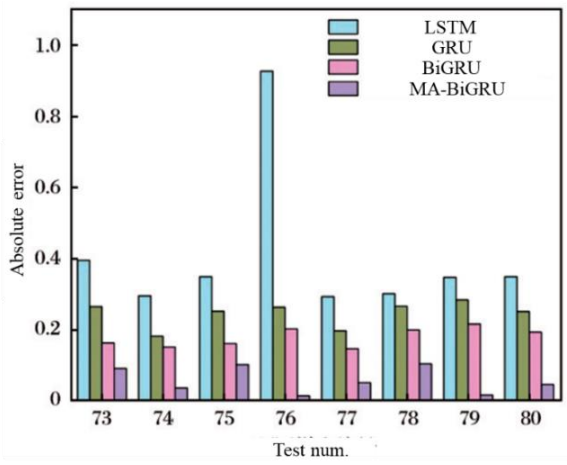

Fig. 21. Comparison of absolute error results.

V. Conclusion and Outlook

This paper proposes an application analysis and usability assessment algorithm of VR technology in cultural landscape promotion platform based on MA algorithm and BiGRU network. Taking the application of VR technology in the cultural landscape promotion platform as the research object, analysing the application situation, designing the application feasibility assessment scheme, and combining the MA algorithm and BiGRU network, an application analysis and usability assessment method based on the MA-BiGRU model is proposed. Taking Dongao Ding Village as a case study for analysis, the results show that the assessment method based on MA-BiGRU model has the best assessment and prediction accuracy and can improve the application effect.

Despite these promising results, the study has some limitations. First, the focus on a single case study limits the generalizability of the findings. Second, the computational complexity of the MA-BiGRU model may pose challenges for real-time usability in larger-scale projects.

Future research could explore three key directions: 1) Expanding the usability model to encompass a broader range of cultural landscapes across different regions. 2) Developing a more computationally efficient version of the MA-BiGRU model to facilitate real-time usability. 3) Integrating other machine learning models or algorithms to enhance the robustness and flexibility of the assessment framework. By addressing these areas, future work can further refine VR technology's role in cultural landscape promotion and its practical applications.

Migrating from Monolithic to Microservice Architectures: A Systematic Literature Review

Hossam Hassan, Manal A. Abdel-Fattah, Wael Mohamed
Information Systems Department, Helwan University, Egypt

***Abstract*—Migration from monolithic software systems to modern microservice architecture is a critical process for enhancing software systems' scalability, maintainability, and performance. This study conducted a systematic literature review to explore the various methodologies, techniques, and algorithms used in the migration of monolithic systems to modern microservice architectures. Furthermore, this study underscored the role of artificial intelligence in enhancing the efficiency and effectiveness of the migration process by examining recent literature to identify significant patterns, challenges, and optimal solutions. In addition, it emphasizes the importance of migrating monolithic systems into microservices by synthesizing various research studies that enable greater flexibility, fault tolerance, and independent scalability. The findings offer valuable insights for both researchers and practitioners in the software industry. In addition, it provides practical guidance on implementing AI-driven methodologies in software architecture evolution. Finally, we highlight future research directions in providing an automation technique for the software architecture migration.**

***Keywords*—Software migration; software evolution; monolithic architecture; microservice architecture; systematic literature review**

I. Introduction

Over the last decade, software architecture has significantly changed. Software was initially monolithic, integrating all components into a single unit. However, as software systems grew more complex, limitations in scalability, flexibility, and maintainability appeared. This encourages an investigation of intermediary architectural patterns like micro-kernel architecture and service-oriented architecture (SOA). Micro-kernel architecture has a minimal core system with only the most important functions while delegating additional functionalities to modular, user-space components, whereas SOA focuses on breaking software down into loosely coupled services. These evolutions paved the way for a new microservices architecture, which divides software into tiny, autonomous, single-need components.

Most software businesses worldwide have adopted the modern microservice architecture because of its significantly increased scalability, maintainability, flexibility, and ease of development [1], [2]. In addition, many software businesses, like Amazon, Uber, Netflix, and Spotify, are adopting this architectural approach, and the transition to microservices is well underway [3]. Microservice architecture can be represented by a collection of tiny services, each operating in its own process and interacting using lightweight protocols like HTTP (Hypertext Transfer Protocol), developed around business needs and delivered independently [2], [4].

The microservices architecture solves many monolithic system issues. Some of the major benefits of microservices include scalability, which improves resource utilization and peak performance, and flexibility, which allows development teams to pick the best tools and technologies for each service, resulting in more customized and efficient solutions, as well as fault tolerance, which prevents system failures from affecting all services, improving resilience and reliability [3].

During the migration to the microservice architecture, some software warehouses that have monolith-based systems attempt to decompose them into coherent microservice-based implementations. The purpose of this decomposition is to occasionally assist software architects in identifying microservice candidates by analyzing the application's domain, business needs, source code, and version-related information [5], [6], [7].

Nevertheless, software vendors have been exerting efforts to manually migrate from monolithic to microservice-oriented application ecosystems. Scalability, component independence, data management, service communications, deployment, and monitoring are some of the efforts [1], [8]. This migration process is subjective, requires human judgment, and is prone to errors. Expert opinions are required for this process, as is software engineers' proficiency in microservice extraction and system quality preservation [9]. Besides, extracting microservices is becoming a complex process because there is no clear or straightforward method for defining the boundaries of microservices. The first and most challenging stage in breaking down a monolithic application involves identifying microservice boundaries. Insufficient identification may lead to more complex systems with lower quality [1].

To address this gap, there is an increasing interest in using AI and ML algorithms to facilitate the migration process. AI-driven methods, such as search-based techniques and clustering algorithms, make it possible to automatically find microservice components and improve the decomposition of systems. However, the majority of the studies fail to identify relevant and potential microservices, and they struggle to determine the appropriate number of candidate microservices while also ensuring their granularity and loose coupling [10].

This paper aims to conduct a comprehensive and systematic literature review to analyze and identify the most important methods and techniques used for facilitating the migration process of software from monolithic systems to modern microservices. The review also aims to compare the results in a detailed manner through a systematic literature review (SLR),

which can serve as a foundation for developing effective solutions.

This paper's subsequent sections follow this structure: Section II encompasses the background and motivation, while Section III presents the research methodology. Section IV provides an overview of the current state of knowledge and understanding regarding the process of software migration. Section V presents the findings of this literature review. Section VI covers the conclusion of this literature review and offers suggestions for future work and improvements.

II. Background

Monolithic and microservice architectures are two different methodologies for designing and constructing software systems. A variety of factors influence the choice between them. Each architecture possesses its own advantages and disadvantages, and the determination should be made considering the particular requirements and limitations of the project. In the following subsections, we will provide additional information regarding the similarities, differences, advantages, and disadvantages of the two architectural styles.

A. Monolithic Architecture

A single deployed unit is referred to as a monolith. A monolithic system necessitates the simultaneous deployment of all functionalities. Deploying all code as a unified process, consolidating all code into a single process, characterizes a monolithic architecture [2].

The modular monolith, a new version of the single-process monolith, divides the single process into multiple distinct modules developed separately; however, deployment requires the combination of these modules. It might be an optimal solution for several enterprises and software warehouses because it defines module boundaries well, provides a significant amount of parallel work, overcomes the complexities associated with the distributed microservice architecture, and adopts a simpler deployment topology [2], [11]. Differences between monolithic and modular monolithic software architectures can be shown in Fig. 1. Shopify is an example of a company that uses this technique as a substitute for microservice deconstruction, and it appears to be quite effective for them.

Unfortunately, the monolith has recently become a symbol of avoidance and is often associated with legacy systems. However, it is actually a viable option based on the system's requirements and specifications. Some of the advantages of monolithic architecture are listed below [2], [12]:

1) Faster and rapid deployment topology: Avoids numerous distributed system issues.

2) Workflows for developers are simpler to manage.

3) Simpler monitoring and troubleshooting: End-to-end testing is simplified.

4) Code reuse is simple enough, without any duplication.

Nevertheless, an important issue with the modular monolith architecture is that the database does not have the same degree of decomposition as the code, making it difficult to separate the monolith in the future [2].

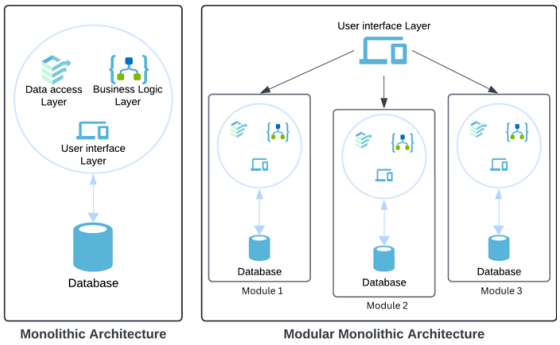

Fig. 1. Demonstrating the distinctions between monolithic and modular software architecture.

B. Microservice Architecture

Microservices are designed to be loosely coupled and independently deployable, but they may still rely on different coordination patterns to handle distributed transactions and inter-service communication, which are designed based on a specific business domain and potentially released separately. A service is a module that has specific functionality and allows other services to access it over networks. By combining these modules, the software warehouses could create more intricate and enterprise systems. Each microservice might represent a specific aspect of the system. When combined, these microservices form a complete enterprise system. In other words, they are a kind of service-oriented architecture that has a certain viewpoint on how service boundaries should be defined with the ability to deploy independently. Fig. 2 showed an example of a microservice architecture construction.

A single microservice appears as a black box. One or more network endpoints, such as a SOAP or REST API, host business functionality using appropriate protocols. Through these networked endpoints, consumers—microservices or programs—access this capability. The outer world conceals implementation elements like service technology and data storage. In most cases, microservice designs encapsulate their own databases instead of using common databases.

Microservices conceal information within their components and deliver minimal information through external interfaces. The hidden microservice implementation can be freely updated as long as the changes do not introduce incompatible modifications to the network interfaces it exposes. Changes made within a microservice boundary should not affect upstream consumers, allowing for separate functionality releases. Clear, consistent service boundaries that don't alter with internal implementation lead to looser coupling and greater cohesiveness. Some of the advantages of microservice architecture are listed below:

1) Deployability independence: Allows for modification and deployment without relying on other microservices.

2) Business domain-based model: Makes it easy to bring out new functionality and recombine microservices to provide consumers with new capabilities.

3) Owning their own state: Microservices must avoid relying on shared databases. Instead, it needs to request data from another microservice in order to access it.

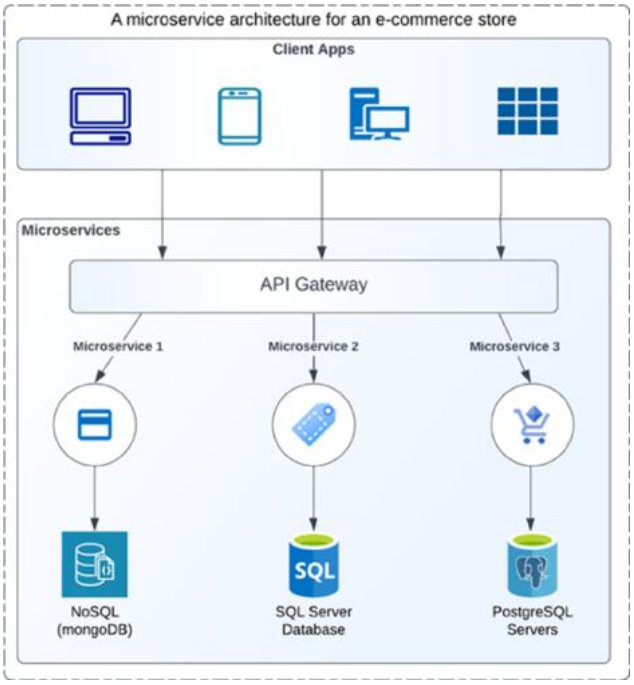

Fig. 2. A microservice architecture for an online shopping system.

III. Research Methodology

To achieve our goal of automatically migrating software architecture from monolithic to microservice, SLR was employed to analyze the migration process. This investigation encompassed the use of AI and other techniques to automate the process. SLR was chosen in this study due to its advantages over conventional literature reviews in terms of accuracy, effectiveness, and organization. It aids in the identification of our objectives, the assessment of their outcomes, and the classification of them into categories. This SLR is comprised of three primary steps, which are as follows [13], [14], and [15]:

1) Planning and preparing the review.
2) Performing the review.
3) Reporting the review.

A. Phase 1: Review Planning

Starting with these steps, this phase covers the core of SLR:

1) Clearly state questions the study will address:

RQ1: Which AI methods are effective for automated microservice architecture migration?

RQ2: What are the primary obstacles and impediments that organizations face during the migration process, and how can AI-driven solutions overcome these challenges?

RQ3: What are the criteria used to assess the effectiveness and success of AI-driven migration strategies?

2) Choose appropriate research repositories: Within the SLR, various online digital libraries were used, including but not limited to IEEE Xplore, Google Scholar, Science Direct, Springer, and MDPI.

3) Establishing research criteria: The search strings were chosen based on the SLR keywords and the alternatives to those keywords found in Software Architectural Evolution. As can be seen in Table I, these search strings were divided into two distinct categories.

4) Software Migration Process.
5) Monolithic to Microservice.

TABLE I. Search Strings for the Systematic Literature Review

GROUP	Search String
Software Migration	(“Software Migration” OR “Software Architectural Evolution” OR “Software Architecture Transformation” OR “Software Evolution” OR "Software Architecture")
	AND
monolithic to Microservice	(("Legacy", "Monolithic", "Monolithic system", "Single-layer application", "Modular Monolithic")) AND (("Microservices", "Microservices pattern", "Microservice architecture", "Service-oriented architecture (SOA)")

6) Providing clear definitions of inclusion & exclusion: The guidelines for the inclusion and exclusion criteria for this SLR were established by Kitchenhem [13].

The following criteria for inclusion were listed:

IC1: A journal publication or conference presentation are required for the research selection.

IC2: Studies should focus on software migration process, especially the migration from monolithic to microservice.

IC3: AI, ML, and other algorithms or solutions for software migration should be applied.

IC4: Studies published between 2018 and 2024. Microservices were introduced earlier, but the latest studies show the recent implementations, challenges, and innovations.

The following criteria for exclusion were listed:

EC1: Studies that failed to address the research questions.

EC2: Studies that ignored software migration process.

EC3: Studies that didn’t include microservices.

EC4: Publications published prior to 2018.

7) Establishing standards for measuring quality: This phase was significant because we compared and checked the quality of the selected studies to our objectives, research questions, and goals.

B. Phase 2: Performing the Review:

1) Primary data selection: During this stage, filtration methods were employed to apply search criteria and determine inclusion and exclusion criteria. The process of selecting the primary studies has started. The Tollgate approach was implemented to enhance the effectiveness and efficiency of the selection process in a systematic and organized manner [13].

2) Data extraction: The study selection was guided by specific criteria, including research methodology, publication

year, kind of study, and any restrictions or limitations imposed on the studies.

3) Data synthesis: The collected studies were assessed and compared with our research questions and study objectives.

C. Phase 3: Reporting the Review:

During this phase, selected studies were verified and compared against quality criteria. Fig. 3 shows the process of SLR, indicating a well-organized collection of studies available for discussion and investigation, with R representing the number of research studies in each step.

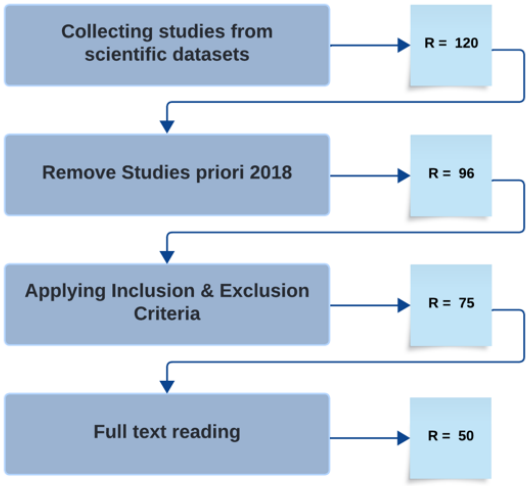

Fig. 3. The SLR selection process.

IV. State-of-the-Art

This section examined the studies selected for analysis, reviewing, and discussion.

Jin et al. [16] proposed a functionally-oriented microservice extraction (FoME) method that uses clustering of execution traces and classifies source code entities according to their functionality. The authors evaluated their method against three methods (LIMBO, WCA, and MEM) across four open-source projects. Their findings showed that FoME produces microservices with comparable cohesiveness to other methods and achieves much looser coupling. However, their method relies on high-quality test cases, with future efforts geared toward full automation of the process.

Sellami et al. [1] proposed a method called MSExtractor, which identifies microservices as multi-objective optimization problems using an indicator-based evolutionary algorithm (IBEA) while considering structural and semantic dependencies in the source code. They conducted a benchmark of seven software systems to assess the effectiveness of their method. Their findings demonstrated that MSExtractor outperformed other clustering algorithms like FoME and MEM mentioned in [16], [17]. Nevertheless, their method was limited to four web applications and lacked generalization. Future work should consider non-functional evaluation metrics.

Velepucha et al. [18] concentrated on breaking down microservice architectures. They compared different concepts, compiled a list of microservice architecture patterns as shown in Table II, and discussed the advantages and disadvantages of microservices over monolithic architectures. Future work and limitations include adapting micro-frontends, automatically migrating the decomposition process, restricting the results to an object-oriented approach, and further evaluating the literature.

TABLE II. List of Patterns used in Microservice Decomposition Process

Pattern / Description
Domain-Driven: Developing software systems focusing on business logic.
Service discovery: Addressing service interactions and communications.
Data-driven: Design systems around data behavior or structure. Data is key.
Backend for frontend: Developing services tailored to frontend clients.
Adapter microservice: Transforming microservices functionality data.
Strangler-application: Incrementally migrate to microservice.
Shared data microservice: Sharing and managing microservice data.
Aggregator microservice: Aggregate data from multiple microservices.

On the other hand, Kazanavičius et al. produced the conceptual model, which aims to migrate a monolith database into a multi-model polyglot persistence system [19]. They assessed their proof of concepts using the ISO/IEC 25012:2008 standard's definition of quality attributes. Their findings indicate that their proposed method can effectively transition data storage from a monolithic to a microservice architecture. Future direction includes the need to automate the solution and the fact that their model's adoption depends on single app.

Nordli et al. [20] focused on monolithic solution vendors; they struggle to convert monolithic products into multi-tenant cloud-native SaaS solutions because many clients, especially large enterprises, want customized products. The authors presented a proof of concept that outlines a combined approach for transforming monoliths into microservices-based, customizable cloud-native SaaS. Their findings demonstrated that a customization-driven migration approach can guide a monolith towards becoming a SaaS. Their limitations included the unavailability of datasets, the need for expert evaluation and the use of real-world systems to generalize the results, and the requirement for an automatic migration process.

Velepucha et al. [21] performed a SLR and provided a list of challenges, and benefits that arise when carrying out the migration process, as shown in Table III. Some limitations and future work include the necessity to analyze the pros and cons of each architecture, as well as automate the migration process.

TABLE III. Challenges Encountered Throughout the Software Migration

Problem/Challenges	
Utilizing an appropriate tool during the migration process.	Perform the entire microservices migration without breaking it down.
Reorganizing stakeholders is required when implementing microservices.	Challenges in identifying and designing microservices.
Desiring to transition all monolithic programs to microservices	Ensure the consistency when transitioning across databases.
Attempting to integrate new technologies into a monolithic application.	

Faustino et al. [11] performed a case study of transforming systems to microservices using a modular monolithic architecture. They discovered that a modular monolithic architecture could simplify the migration process. Additionally, it addresses issues related to performance optimization, eventual consistency, and inter-microservice communication. However, their method's limitation to a single migration case study hinders its generalizability.

Blinowski et al. [12] compared the performance and scalability of monolithic and microservice architecture by implementing a reference web application with two different technologies and architectural styles. Moreover, they selected three distinct deployment scenarios. Their findings indicated that monolithic architectures outperform microservices on a single machine, with Java handling computation-intensive tasks more efficiently than .NET. For non-computational services on machines with limited power, Azure's vertical scaling proves more cost-effective than horizontal scaling. In future studies, the authors intend to enhance the complexity of their benchmarking system, broaden its application across cloud platforms, and incorporate more performance metrics.

Bastidas Fuertes et al. [22] used Transpiler in the software architecture design model's back-end layer to automatically transform business logic from one source code to several equivalent versions. They tested the model for performance, scalability, and reliability in various scenarios and compared it with existing software design models to identify its pros and cons. Their result showed that the proposed model seeks to save costs, optimize the development process, and enhance the effectiveness of multi-programming language platforms. Nevertheless, the authors acknowledged the need for refining the model's effectiveness for generalizing the result.

Mazzara et al. [8] presented a case study to illustrate the advantages of transforming a monolithic into a microservice on scalability. The case study focuses on the FX Core system, which is critical for Danske Bank. They compared the two architectures, and the results showed that microservices have resulted in enhanced scalability and effectively resolved the significant issues posed by the monolithic. However, their findings lack insights, validation, and verification. Furthermore, the case study utilizes agile methodologies, which limits the generalizability of the results.

Assunção et al. [10] adopted an approach to redesigning features into microservices by employing search-based techniques to quantitatively assess potential redesign possibilities for monolithic features as microservices based on four criteria: coupling, cohesion, network overhead, and feature modularization. To evaluate their findings, an interview with eight monolithic system developers was conducted to get their feedback. Their findings showed that their approach demonstrates positive results and encourages more exploration. To justify configurability, future directions include generalizing results and suggesting specific criteria associated with variability.

Teguh Prasandy et al. [23] presented a method of modularizing application source code, databases, and cloud servers to identify the necessary preparations needed to make a successful transition to microservices. Their findings demonstrated that migrating to microservices can present challenges and affect stockholders, particularly system analysts and developers. Moreover, it's crucial to isolate program blocks during deployment and determine the upload time to prevent any failures. They utilized the Postman tool to assess the REST API as both a REST client and an application. Future research will include assessing the capacity of cloud servers, and evaluation is necessary to generalize the findings.

By calculating the metrics (latency, throughput, scalability, CPU usage, memory usage, and network usage) needed to compare the source and target applications, Fondazione et al. [24] developed a method to determine if migrating to microservices is beneficial. Their findings showed that monolithic works well with small to medium systems, which are typically defined by the project's overall size and complexity. The substantially higher scalability ratio of the microservice system supports the hypothesis that it performs better than a monolithic design for systems with too many concurrent users, especially when it comes to handling more traffic. Additionally, researchers conducted benchmarking experiments to evaluate their results. Future work includes testing on a real-life system, utilizing an alternative programming language, and ensuring security.

Abgaz et al. [25] conducted a SLR by examining 35 studies. Their results showed that the process of breaking down a monolith into microservices is still in its early stages, and there is a lack of techniques for integrating static, dynamic, and evolutionary data. The lack of adequate tool support is also apparent. The author conducted their SLR using Barbara Kitchenham's principles as a guide, as we illustrated in Section III. The authors suggested focusing on microservice deployment and standardizing analysis measurements.

Tapia et al. [26] assessed the performance and correlation of monolithic and microservices applications. They stress-tested their results using the same characteristics and hardware specifications. Furthermore, a mathematical model using the non-parametric regression method verified their studies' findings. Their results showed that monolithic and microservice can serve various technological situations. However, microservices improve hardware resource efficiency, cost savings, and productivity. Future directions include enhancing information security and combating cyberattacks. Moreover, automation tools for migration are required.

Kuryazov et al. [27] proposed a conceptual model for solving the issue of migrating from a monolithic architecture to microservices, especially the decomposition steps. Their conceptual model is still in its early stages and needs more evaluation and testing in a real industry. They need to develop a method for evaluating software using cohesion and coupling measurements, which will simplify the analysis of monolithic systems and estimate the migration effort. Additionally, they should create a tool that facilitates the extraction of software metadata and business logic.

Auer et al. [28] presented a decision support framework for software companies seeking to transition to microservices. Their framework is based on an examination of a set of characteristics and metrics, which they collected and reviewed through interviews with experts. Their findings provided data

and measurements that companies could use to assess microservices adoption. Future work includes validating the framework, identifying automatically applicable measures that can easily reduce decision subjectivity, and adding cloud-native technologies and micro-frontend architecture.

Daoud et al. [7] used a business process to identify needs, data, and semantics to capture dependencies between these processes, as well as a collaborative clustering technique to recommend microservices. Results showed that the approach outperformed similar ones for microservices identification and highlighted the importance of business processes. Future directions are as follows: generating new activity relationships utilizing powerful machine learning, including NLP, and evaluating various activity dependence models for microservice identification. The identification of microservices may be impacted by security concerns, which could be an intriguing development.

Hasan et al. [29] presented a collection of software architecture metrics, including coupling, complexity, cohesion, and size, to assess the maintainability of microservice architectural designs. Results showed that the suggested metrics criteria are more applicable for implementation in industrial settings. On the other hand, case studies from the real-world industrial sector need to be analyzed and applied to the suggested metrics to assess their efficacy. Furthermore, a tool-based methodology must be developed for evaluating the architectural quality of potential microservices.

Oumoussa et al. [30] performed a systematic literature review that highlighted critical areas requiring more attention, such as enhanced automated identification tools and standardized evaluation standards. Their findings showed that many techniques exist for identifying microservices; however, they often focus on particular challenges and abandon others. In addition, there is a dearth of studies that concentrate on a solution to address the migration problem.

Abdellatif et al. [31] conducted a comprehensive analysis of 41 studies. Their research aimed to identify the various inputs, processes, outputs, and usability of service identification methodologies in order to modernize monolithic software. Their findings demonstrate that the categorization aligns with the experiences of industry professionals and provides valuable assistance to practitioners in real-world industrial settings. Future directions include proposing an approach for identifying services based on their types, which enhances the potential for reusing them across several levels: application, enterprise, and business, besides generalizing their results.

Li et al. [32] proposed a technique to identify microservices by utilizing the unified model language (UML), which is derived from the source code. Then, the classes and sequence diagrams were analyzed, using them as input for clustering techniques to identify potential microservices. In addition, experiments were conducted to evaluate the proposed model and compare it to recent methods. Their findings revealed that the proposed model outperformed existing models. However, their results are not generalizable because their proposed model disregards microservice distributions and quality criteria.

The primary focus of Gomes Barbosa et al. [33] was to identify potential microservices from database procedures, specifically targeting monolithic applications developed in the 1980s and 1990s that utilized database procedures. Their proof-of-concept contributed to identifying duplicated code, improving system maintainability. For future directions, the author recommended using machine learning algorithms to fully automate the process and blackbox/whitebox testing methods to verify and validate the extracted microservices.

Al-Debagy et al. [34] decomposed monolithic into microservices architecture using a neural network model (code2vec). Their findings showed better results compared to other algorithms. Besides, authors validate their results by using quality measuring such as message level (CHM) and cohesion at domain level (CHD). Future directions may include further development and testing of the proposed model with other programming languages, as well as training.

Jin et al. [35] proposed the Functionality-oriented Service Candidate Identification (FoSCI) method, which uses a search-based functional atom grouping technique to identify service candidates from a monolithic system's execution traces. The authors assessed their method with an 8-metric service evaluation suite to analyze functionality, modularity, and evolvability. Additionally, the authors evaluated FoSCI against other methods (LIMBO, WCA, and MEM) to evaluate the impact of execution trace coverage on performance. Their results indicate that FoSCI outperforms the compared methods. However, their method prioritizes functionality over other quality attributes such as performance, security, and reliability, which could potentially benefit from future expansion.

Desai et al. [36] introduced a Graph Neural Network method for refactoring monolithic systems, termed COGCN (Clustering and Outlier-Aware Graph Convolution Net). This COGCN combines node representation, outlier detection, and clustering into a cohesive framework. To judge the quality of the clusters, four structural and desired metrics: modularity, structural modularity, non-extreme distribution (NED), and interface number (IFN) were used. Their results showed that COGCN works better than other methods like GCN, Node2Vector, and DeepWalk by improving the quality of clusters and finding outliers. Future work will include automatically determining microservice numbers and addressing procedural programming languages.

Kalia et al. [37] developed an approach called Mono2Micro. It used well-defined business use cases, spatio-temporal decomposition, and run-time call relations to functionally separate application classes. This method works better than other methods in well-defined metrics that are specific to the domain, such as FoSCI, MEM, CoGCN, and Bunch [17], [35], [36], [38] . Their tool was evaluated by using multiple criteria to verify its efficiency. Future directions focus on elaborating on the quality criteria, providing further assistance to develop effective use cases for practitioners, and generalizing the findings by supporting different programming languages.

Francisco et al. [39] performed a review of 20 papers addressing the migration process to microservices. Their results indicated that the majority of solutions rely on design

aspects, system dependency graphs, and clustering algorithms. Moreover, the majority of the studies depend on graphs and categorize them into microservices; 70% focus on web-based systems, mostly using Java as the main programming language. However, their study faces constraints due to its reliance on a single search engine and individual researcher bias. Furthermore, it advocates for a wider range of migration methodologies and database migration investigations.

Justas et al. [40] concentrated on the obstacles and approaches for migrating software to microservices by reviewing and analyzing different migration techniques; however, they didn't mention any particular evaluation metrics used to assess their review. Their results emphasized that the migration process is complex and expensive, with no one-size-fits-all solution. Future research includes a focus on developing standardized migration techniques to address the various issues posed by legacy systems.

Ren et al. [41] integrated static and dynamic analysis to examine the characteristics of monolithic systems. They employed function clustering to facilitate migration and hierarchical clustering to identify microservice candidates. They tested their method by comparing performance across four benchmark applications and validating the migration algorithm with 12 industrial and open-source applications. Their findings showed that their proposed method effectively migrates monolithic applications to microservices with high accuracy and low performance cost. However, the incomplete static analysis due to missing function invocations and user interactions may still limit the completeness of the migration.

Fritzsch et al. [42] conducted a qualitative study using semi-structured interviews in the context of migration to microservices. The authors conducted 16 comprehensive interviews with specialists from 10 software companies across 14 migration cases. Their finding indicated that the biggest motivations for migration were maintainability and scalability. Furthermore, many organizations choose a complete rebuild instead of a codebase breakdown. Principal problems included identifying the appropriate service cut and developing proficiency in emerging technologies. However, the sample procedure, which focuses only on 14 instances and individuals located in Germany, constrains their research and affects its generalizability.

Kalske et al. [43] performed a literature review focusing on architectural migration and associated challenges. Their findings indicate that organizations use microservices to mitigate complexity, enhance scalability, and resolve code ownership challenges. Nonetheless, restructuring and decoupling the tightly coupled monolith remain a significant challenge. However, their review lacks credibility and verification of their results, and there were no guidelines for conducting the review. Their future directions include understanding how various organizational structures influence the effectiveness of microservice adoption.

Vainio et al. [44] combined a case study and literature review to extract functionality from a monolithic system, then used microservices to demonstrate realistic real-world benefits and challenges for the migration process. Their findings showed significant advantages in scalability, maintainability, and the ability to use several programming languages for different services. Furthermore, the independent deployment of microservices improved system stability and performance. However, their case study did not thoroughly examine the architectural complexity and security implications of managing several microservices in extensive systems, indicating a need for additional research on these topics.

Eski et al. [45] employed a graph-based clustering methodology utilizing both static and evolutionary code coupling to derive microservices from monolithic applications. They evaluated their method by assessing two projects, which revealed an 89% success rate; however, certain services necessitated manual sub-clustering owing to their size. They planned to continue their research by adding weighted graph edges to their method, automating sub-clustering thresholds, and testing it on more projects using different algorithms.

Su et al. [46] conducted a systematic literature review by examining 32 studies to obtain insights into how software companies migrated from microservices back to monolithic architectures. Their study identified cost, complexity, scalability, performance, and organizational factors as the primary reasons for reverting. Future directions entail investigating the phenomenon across various industries and conducting empirical assessments to generalize the results.

Bandara et al. [47] developed a toolkit that utilized a fitness iterative function to identify microservices within monolithic systems. Their toolkit employed service quality metrics, including functionality, composability, self-containment, and usage. They compared the tool to manual microservice identification. Their results showed that their tool produced microservices like manual identification. Future directions include support for more programming languages and architectural patterns, machine learning models, and context knowledge to improve microservice extraction.

Michael Ayas et al. [48] examined the migration to microservices through interviews with 19 individuals from 16 organizations. Their results showed that the migration process is iterative and takes place on two levels: architectural and system-level. Moreover, they categorize key activities into four phases: designing architecture, altering the system, setting up supporting artifacts, and implementing technical artifacts. The study acknowledges the researchers' bias and the sample's representativeness. Future directions include examining more migration paths and validating results across organizations.

Taibi et al. [49] introduced a process-mining framework to aid in the decomposition of monolithic systems. Their framework identifies business processes based on log traces, clusters similar processes, and uses metrics to evaluate decomposition quality. A software architect validated their framework by comparing their results to a manual decomposition. Their framework revealed decomposition alternatives and software issues that manual analysis missed in an industrial case study. Future directions include automating the process, validating the methodology, and integrating patterns for microservices connectivity.

Silva et al. [50] conducted two case studies. These studies identified migration steps and challenges from legacy to

microservices. Their findings revealed four main issues: 1) identifying functionalities in large modules; 2) defining optimal microservice boundaries; 3) choosing features to convert into microservices; and 4) analyzing candidate microservice granularity and cohesion. Future steps include refining and supporting practical guidelines for migrating to microservice architectures, as well as surveying industry practitioners to learn more about migration challenges.

Kholy et al. [51] introduced the managing database for microservices architecture (MDMA) framework. Their framework indicates that MDMA significantly reduces execution time and data transfer size compared to a centralized approach and exhibits superior performance as the volume of requests increases. Furthermore, it improved flexibility and resilience, reducing the impact of service failures and facilitating data transfer during service deployment. Subsequent research may entail evaluating the framework in different real-world environments and broadening its applicability to various microservice architectures.

Antunes et al. [52] investigated the migration of a real-world application to a micro-frontend architecture. Results showed that micro-frontends enhance flexibility, team scalability, and incremental migration. Nonetheless, they observed increased complexity in the management of dependencies, environments, debugging, and testing. Future studies should investigate other projects and implementation methodologies, with a focus on simplifying dependency management and integration testing.

Maria et al. [53] investigated the migration towards micro-frontends. Their study demonstrates how to successfully re-implement a single-page application (SPA) using micro-frontends architecture by adopting Webpack to bundle modules and Cypress for testing. Their findings indicated improvements in team collaboration, independent deployment, and performance. Further studies include managing dependencies, enhancing integration, and evaluating performance.

Fritzsch et al. [54] used SLR to classify 10 existing approaches based on decomposition techniques. Their findings identified a lack of universally applicable approaches with adequate tool support. Future research will combine static code analysis with runtime data, create decomposition quality metrics, and automate the migration process.

Lauretis [55] presented a strategy for migrating to microservice. The author highlighted potential benefits such as improved scalability, maintainability, and evolvability for companies. Their strategy consists of five steps, including function analysis, business identification, business analysis, assigning functionalities, and creating microservices. However, their strategy is still in its early stages. Future directions include automating migration process and testing the strategy on real systems to gather performance and statistical data.

Nunes et al. [56] used transactional contexts to propose a microservices migration strategy. They used static code analysis to identify domain entities and applied a clustering algorithm to group them. Comparison with expert decompositions yields promising results. Future work will enhance the method and broaden the results, while limiting its applicability to specific frameworks and tools.

Santos et al. [57] proposed a complexity metric to measure the transition to microservices based on four similarity measures that examine entity decomposition. These measures focus on read and write sets, access sequences, and the cost of relaxing transactional consistency. Their metric was evaluated using three monolithic systems. Their complexity metric successfully identified the most complex decompositions. Future directions include using a combination of dynamic and static data, as well as further experimentation with a wider variety of systems.

Ma et al. [58] proposed Microservices Identification using Analysis for Database Access (MIADA) to account for the importance of "Database Per Service" in microservices design. Their approach facilitates clustering service endpoints for microservice identification. Two service-oriented software projects (PlanApproval and CoCoME) evaluated their results, demonstrating that MIADA can successfully recommend service endpoint clusters for microservice. Future directions include generating results and enhancing MIADA.

Ghofrani et al. [59] categorized migration challenges into inertia, anxiety, and context from 17 semi-structured expert interviews. The most significant barrier was migration anxiety, followed by inertia and context. Furthermore, they provided suggestions to overcome these obstacles. Future directions include evaluating their solutions and creating quality metrics.

Ghofrani et al. [60] conducted a survey of industry experts to identify challenges in microservices architecture. They identified critical challenges, including lack of notations, methods, and frameworks for microservices design, as well as insufficient tools for selecting third-party artifacts. In addition, they prioritized security, response time, and performance over resilience and fault tolerance. Future work includes expanding the scope and suggesting solutions for these gaps.

Razzaq et al. [61] provided a systematic mapping study on the migration towards microservices. Their review emphasized key benefits such as: including independent deployment, scalability, and lightweight mechanisms after migration. Besides, identifies migration challenges and success factors that help guide migration strategies. Future directions include, identify effective solutions for these areas, providing more in-depth research for microservice in emerging technologies.

V. RESULTS

As shown in Fig. 4, this SLR analyzed 50 studies published between 2018 and 2024 that focused on the migration process from monolithic to microservice. Furthermore, Table IV provides an overview of the findings from this literature research, covering the following topics:

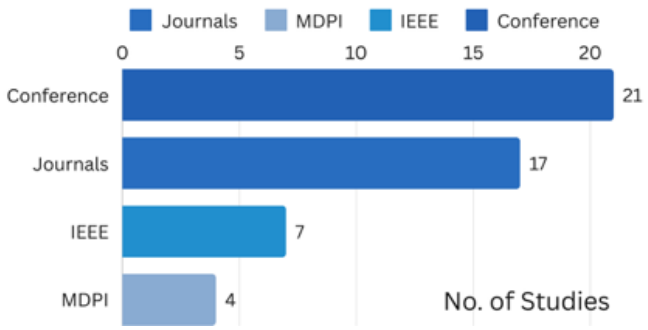

Fig. 4. Classification of studies examined in this SLR.

A. AI Algorithms and other Techniques:

Few authors emphasized providing proofs of concepts to support their ideas and provide insights for the migration process. Some studies conducted real-world industry case studies, attempting to assess and track the differences in performance, effort, scalability, and maintainability between monolithic and microservice architectures and drawing comparisons between them. Researchers are conducting extensive research on AI and other algorithmic techniques, including the indicator-based evolutionary algorithm (IBEA), neural networks, search-based algorithms, clustering algorithms, coupling, and cohesion. Additionally, some studies use SLR to improve their understanding of the microservice architecture. Fig. 5 presents the study distribution, demonstrating the use of AI and other clustering techniques in 18 studies, SLR in 13 studies, proof of concepts in 8 studies, and case studies in the remaining studies.

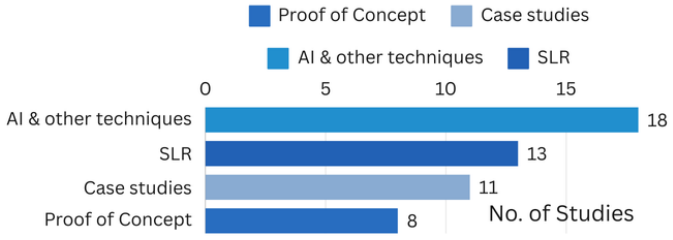

Fig. 5. Distribution of studies based on methodology.

B. Evaluation Techniques:

Major studies were evaluated and validated using a variety of techniques, including empirical assessment using a software system benchmark, the ISO/IEC 25012:2008 standard's definition of quality attributes, performance, scalability, and reliability comparisons, and architecture design comparisons. Other studies utilized cohesion at the domain level (CHD), conducted interviews with software industry experts, and utilized Postman tools for evaluation and testing. Fig. 6 presents the evaluation category.

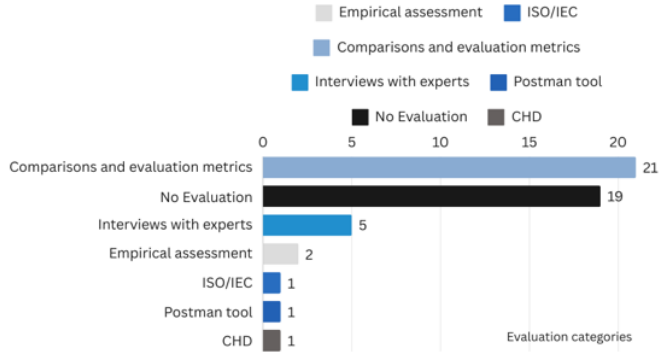

Fig. 6. Categorization of evaluations methods examined in this SLR.

C. Limitation and Future Work

Most studies in the software migration field, particularly those focusing on microservices, lack validation and verification of their models for real-world software systems, leading to a deficiency in generalizing the results of these studies. This gap emphasizes the need for further empirical research and actual implementations to test migration models in varied, real-world scenarios to ensure their robustness and reliability for wider use. The following is a list of future directions and areas for analysis and investigation:

1) Consider non-functional criteria.
2) Perspectives of software architects and developers.
3) Automated tools are needed for manual decomposition.
4) Generalizing results by testing on real-world industry.
5) The impact of cloud servers on the migration process is significant. Hyperscale's such as Azure, AWS, and GCP offer unique features like scalability options, flexible resource allocation, and Devops tools.
6) Adopt micro-frontend alongside microservices.

The subsequent discussion and answers correspond to the research questions outlined in Section III:

RQ1: There is a significant shortage of research on AI and ML methods in the software migration to microservices domain. Few studies are employing algorithms like the indicator-based evolutionary algorithm (IBEA), search-based techniques, and clustering algorithms. Other studies rely on comparisons and expert inputs to assess software quality criteria. The remaining studies offer proof-of-concepts but do not provide a comprehensive solution. A comprehensive solution would involve an automated method or algorithm that utilizes AI to simplify the transition from monolithic to microservice processes while maintaining performance, scalability, and availability. Additionally, real-world industry software systems must evaluate the solutions.

RQ2: The most significant challenges and obstacles in this domain arise from how software warehouses and architects

break down the logic and databases of software systems into dozens of interconnected microservices, which complicates the assurance of effective communication, data consistency, and the preservation of the system's overall integrity. Furthermore, it's crucial to consider the manner in which these services will interact and coordinate with each other. In addition, microservice architecture must meet non-functional criteria like performance, scalability, security, and reliability. As suggested in [7], AI can assist by using powerful ML techniques such as NLP to analyze the code, documentation, and system requirements, as well as complex clustering techniques to decompose the system logics into multiple services. To address non-functional criteria, it may be beneficial to monitor and utilize technologies, such as cloud computing and DevOps methodologies.

RQ3: The evaluation of software migration from monolithic to microservices is mostly based on comparing the two architectures and soliciting experts' opinions and recommendations. Despite this, AI models and other algorithms need to be rigorously evaluated and tested in the real industry to gather feedback from organizations and end users, enabling us to monitor performance and obtain relevant insights.

VI. Conclusion

This study conducted a systematic literature review to explore the key challenges, obstacles, and improvements in the software industry, specifically the migration from monolithic to microservice architecture. While there is growing interest in developing AI and other algorithmic techniques to facilitate this migration process, the field remains in its early stages, lacking comprehensive, end-to-end solutions that address the full complexity of the process. Most existing studies focus on theoretical frameworks, proof-of-concepts, and expert judgments rather than verifying and validating these approaches through real-world implementation.

Table IV provides a summary of this literature review, which includes a list of studies, each describing the methods used, the evaluation technologies, the results, their limitations, and future work. Section V addresses detailed answers to the three research questions. Both would assist software developers and other authors by providing the foundation for a comprehensive solution for addressing migration challenges.

The results of this literature study highlight a significant gap in the creation of effective migration tools and the validation of these solutions within the software industry. This emphasizes the need for future research to focus on the development, evaluation, and validation of automated tools in real-world environments. Furthermore, the migration process must emphasize non-functional requirements such as performance, scalability, reliability, and security. Integrating DevOps methodologies with cloud computing concepts is essential for optimizing the advantages of microservice architectures.

By identifying these gaps, this review emphasizes the importance of addressing both the theoretical and practical dimensions of the migration process, providing a roadmap for future research aimed at enhancing the efficiency, effectiveness, and scalability of software migrations. Resolving these challenges will ultimately enhance the industry's ability to migrate from monolithic systems to modern microservice-based architectures.

TABLE IV. A Concise Summary of the Research Findings from the Literature

R	Techniques used	Results	Limitations and future work
[1]	IBEA	Empirical testing showed the proposed approach is more effective.	Considering non-functional and software evaluation using.
[19]	Proof-of- concept	Migrate monolithic data storage to microservice can be applied.	Automation is needed, and the results are not generalizable.
[18]	Literature Review	Patterns for microservices. Microservices vs. monolithic pros/cons.	There is a need for evaluation, automatic decomposition.
[20]	Combined approaches	Customization-driven migration can guide monoliths into SaaS.	Generalizing results and automating the migration process.
[21]	Literature Review	List of challenges and benefits that arise in the migration process.	Analyze architectures pros and cons and automate migration.
[11]	Case Study	Modular monoliths aid migration, consistency, and communication.	Generalize and apply results to other case studies.
[12]	Case Study	Monolithic outperforms microservices, Java is better at computation.	Increase system complexity and deploy to various clouds.
[22]	Case Study	Their model optimizes development processes.	Generalizing the result required model improvement.
[8]	Case Study	Microservices improved scalability and solved the monolithic issues.	Expanding proof of concepts to generalize the results.
[10]	Search-based techniques	Promising strategy could be applied to other monolithic systems.	The model needs to be configurable and generalized.
[23]	Case Study	The migration affects stakeholders. Upload time affects deployment.	Cloud servers' application support and generalize the findings.
[24]	Case Study	Monolithic suits small-medium apps, but microservices are scalable.	Real-world testing. Ensuring security among microservices.
[25]	Literature Review	Microservices migration in its early stages, with few methods exists.	Consider deployment and microservice identification metrics.
[26]	Case Study	Microservices boost hardware efficiency, productivity, and cost.	Develop migration tools is needed and secure microservices.
[27]	Proof-of- concept	The conceptual model solve system breakdown migration steps.	Software business logic extraction tool need.

[28]	Decision framework	A complete microservices adoption measuring set for enterprises.	Validating framework and adding cloud-native technologies.
[7]	Clustering techniques	Microservices work better and stress business processes.	Using AI to identify microservices and security concerns.
[29]	Coupling and cohesion	The suggested metrics criteria are better for industrial use.	Evaluates microservice assessment using real-world case studies.
[30]	Literature Review	Emphasize automated identification and evaluation standards.	Studies focused on specific challenges and lack migration tools.
[31]	Literature Review	The study shows that categorization helps industrial professionals.	Grouping services by type may help generalize results.
[32]	Clustering techniques	Results showed the proposed model outperformed others.	Generalizing the results.
[33]	Proof-of- concept	The model found duplication and improved maintainability.	Automation using ML and black/white box for validation.
[34]	Neural network	The proposed algorithm performed better than others.	Testing the model in other languages and training on source codes.
[37]	Clustering techniques	Mono2Micro outperforms other methods.	Elaborate on the quality criteria and develop effective use cases.
[35]	Search-based techniques	FoSCI is better in service quality, functionality, and modularity.	Performance, security, and reliability are ignored.
[36]	Clustering techniques	COGCN improves cluster quality and outlier identification.	Determining microservice numbers and procedural languages.
[16]	Clustering techniques	FoME provides cohesive microservices with looser coupling.	Ensure the use of high-quality test cases and automate the process.
[39]	Literature Review	Most research used design, dependency graphs, and clustering.	Biased results and more migration methods are advocated.
[40]	Literature Review	Migration is complicated and expensive, with no single solution.	Standard migration methods to address legacy system issues.
[41]	Clustering techniques	Their microservice migration method was accurate with low cost.	Generalizing the results by adopting user interactions.
[42]	Qualitative study	Maintenance and scalability encouraged migration.	Generalizability is limited by the 14-person German sample.
[43]	Literature Review	For simplicity, scalability, and ownership, firms use microservices.	Their results lack credibility and verification.
[44]	Case Study	Microservices are scalable, maintainable, stable, and multilingual.	Security and architectural complexity need more research.
[45]	Clustering techniques	Their method revealed 89% success rate of extracted microservice.	Testing on different clustering algorithms to enhance the model.
[46]	Literature Review	Cost, complexity, and organization drive monolithic Reverting.	Examining the phenomenon across industries and generalizing.
[47]	Toolkit	Toolkit produced microservices like manual identification.	Supporting more languages, patterns, ML models, and context.
[48]	Qualitative study	Migration occurs on two levels: architectural and system-level.	Researcher bias and sample representativeness affect findings.
[49]	Process-mining	Framework outperforms manual analysis in industrial case studies.	Automating the process, validating, and integrating more patterns.
[50]	Case Study	Module's size, boundaries, features, and cohesion are challenges.	Survey industry specialists and refine microservice migration.
[51]	MDMA framework	MDMA improve runtime, data transfer, flexibility.	Testing the framework in real-world and expanding its use.
[52]	Case Study	Micro-frontends improve migration, scalability, and flexibility.	Dependencies, debugging, and testing require further research.
[53]	Case Study	SPA enhances deployment, collaboration, and performance.	Managing dependencies, enhancing integration and performance.
[54]	Literature Review	Lack of universally approaches with adequate tool support.	Automate migration with static code analysis and runtime data.
[55]	Proof-of- concept	Improved Company scalability, maintainability, and evolution.	Automating migration process and testing on real systems.
[56]	Clustering techniques	Comparison with expert decompositions yields promising results.	Improve the method and generalize the results.
[57]	Clustering techniques	Their metric successfully identified the complex decompositions.	Using dynamic and static data, along with further investigation.
[58]	Clustering techniques	MIADA can successfully recommend service endpoint clusters.	Future directions include generating results and enhancing MIADA.
[59]	Qualitative study	Anxiety, inertia, and context were the most barriers in migration.	Evaluating their proposed solutions and creating quality metrics.
[60]	Literature Review	Microservices design notations and method were critical challenges.	Expanding the scope and suggesting solutions for these gaps.
[61]	Literature Review	Emphasized independent deployment, scalability, and lightweight.	Provide research in emerging technologies to find solutions.

A Review on NS Beyond 5G: Techniques, Applications, Challenges and Future Research Directions

Cui Zhiyi, Azana Hafizah Mohd Aman, Faizan Qamar*
Center for Cyber Security-Faculty of Information Science and Technology (FTSM),
Universiti Kebangsaan Malaysia (UKM), 43600 UKM Bangi, Selangor, Malaysia

***Abstract*—With the advent of the fifth generation (5G) era, many emerging Internet of Things (IoT) applications have emerged to make life more convenient and intelligent. While the number of connected devices is growing, there are also differences in the network requirements of each device. Network slicing (NS) as an emerging technology, provides multiple logical networks for infrastructure. Each of these logical networks can provide specialized services for different needs of different applications by defining its logical topology, reliability and security level. This article provides an overview of the basic architecture, categories, and life cycle of network slicing. Then summarized two kinds of resource allocation methods and security problems based on three kinds of network slicing technologies. With the investigation of recent studies, it is found that network slicing is widely used in Industrial Internet of Things (IIoT), Internet of Medical Things (IoMT), in-vehicle systems and other applications. It improves network efficiency, improves service quality and enhances security and privacy by optimizing indicators such as latency, resource management and service quality. At the end of this study, according to the challenges faced by different research methods, the future research direction of network slicing is proposed.**

***Keywords*—5G; network slicing; resource allocation; dynamic allocation; security**

I. INTRODUCTION

5G and higher networks are predicted to have high throughput, low latency, and the power to concatenate many devices [1]. With the popularization of 5G, more and more new services appear in our lives. These different services put forward a variety of requirements for the quality of service (QoS) of the network [2]. For healthcare, autonomous industry, and smart vehicle services, networks need to offer lower latency and high reliability, security, and privacy [3]. Smart city and grid services have many applications, requiring the network to be highly scalable and provide large data sets [4]. Smart home needs safe short-distance service, and smart weather station needs long-distance communication with low bandwidth [5]. Therefore, 5G networks need to establish a more flexible and guaranteed dynamic network to meet different needs of all walks of life [6].

In this context, NS technology comes into being. NS can divide the physical network into multiple logical networks, and each logical network can formulate its own functions and characteristics to provide an independent network for a specific application [7]. However, in the highly fragmented network environment, vast demand for specific traffic leads to overload, which affects the quality of service of the network [8]. Therefore, many NS researches achieve real-time dynamic resource allocation and prediction by using artificial intelligence (AI) or machine language (ML) algorithms [9]. The algorithm predicts traffic patterns and historical data based on future demand, thereby adjusting resources ahead of time to ensure that the slice maintains stable performance during peak periods [10]. The creation of different slices, configuration updates, etc. become more complex as the number and types of slices increase. AI-driven network orchestration and autonomous management tools to adjust the lifecycle of slices, and propose automated orchestration systems and intelligent management platforms to reduce the complexity of human intervention and management [11].

In addition, NS has compatibility problems with existing network infrastructure, and operators use virtualization and software-defined networking (SDN) technologies to transfer traditional hardware functions to programmable virtual platforms to achieve flexible network control and rapid deployment [12]. This strategy not only improves the adaptability and security of the network, but also lays a technical foundation for the realization of large-scale NS in the future.

This paper introduces the architecture, function and practical application of NS. Summarizes the function and architecture of NS by reviewing the progress of research on NS in recent years. In this paper, reviews the practical applications of NS, pointes out the challenges of applying NS, and prospects the future research directions. On this basis, the major contributions of this paper are as follows:

- Introduces the architecture and life cycle of NS and classifies it according to different criteria.
- Investigate two resource allocation methods based on NS, introduce the methods in detail and summarize the test results.
- Surveys and summarizes how NS can be applied to healthcare, industrial application and in-vehicle system services.

*Corresponding Author

- Introduces the security challenges of basic functions of NS such as SDN, network functions virtualization (NFV) and their hybrid models.

This paper summarizes the development of NS and the research projects and achievements based on different methods. The remainder of this paper is as follows. Section II surveys the existing literature on NS and compares the classification from the technical point of view. Section III introduces the 5G NS architecture, classification based on different criteria, life cycle and introduces two resource allocation problems based on NS. Section IV introduces some technology based on NS. Section V introduces the security issues under the three techniques. Section VI further discusses the prior research. Section VII proposes the future research directions and challenges. Section VIII summarizes the paper.

II. Related Work

In [13], summarizes the basic concepts and analyzes implementation of NS. According to the standard given by NGMN, the network slice is divided into the infrastructure layer, network slice instance layer and service instance layer. Two categories of functional NS, Radio Access Network (RAN) subslices and core subslices, are also introduced. The authors summarize the four life cycles of NS: preparation, debugging, operation and decommissioning. The last part analyzes the application of NS in IoT and other emerging technologies such as blockchain, AI, and ML, and finds the challenges faced by each part and the direction that can be tried in the survey.

In [14], makes a summary of the six advantages of NS and their problems. The dynamic allocation of free resources among slices optimizes the scalability of the network. Use ETSI's zero-touch Network and Service Management (ZSM) to reduce human intervention and automate network operations to address scalability challenges. Or use a distributed Artificial Intelligence (DAI) approach to solve orchestration requests in the NS manager. Each slice has different network functions (NFS) and attributes to satisfy the different requirements of different applications. The reinforcement learning algorithm is used to identify slice attributes and recursion to achieve this goal. The isolation mechanism of dedicated slices can mitigate IoT security attacks. Research on design security and operational security will be expanded in the future. At the same time, it uses the verification function of the slice itself, Bayesian network, and autoencoder for intrusion detection and anomaly development, as in the case of the Application Programming Interface (API) used by the third-party tenant. Dedicated slices are assigned to each application, and isolation mechanisms and communication schemes are optimized to protect privacy. Zero-knowledge proof and argumentation tools for knowledge can optimize inter-slice communication. NS assigns each application a specific slice with sufficient resources to guarantee QoS.

In [15], the research on solving NS management in recent years is summarized. Due to the high-speed and multi-connection characteristics of 5G networks, as well as the flexibility and cost of its architecture. The authors propose that one of the challenges of NS is to completely isolate NS, in which each slice instance has its own function and is not shared between slices. But at the end of the survey, the authors put forward many shortcomings about NS. For example, the resource allocation fast mobile service cannot meet the needs of all the slicing networks, so that the compatibility of this service has drawbacks. 5G does not support inter-slice communication when performing isolation, and information propagation will be subjected to security attacks. Limited end-to-end slice orchestration also becomes an obstacle to solve this challenge simultaneously. Future work attempts to use network simulation to analyze the 5G NS architecture in different mobility scenarios, divide the 5G network into a large number of slices, and let these slices operate independently.

In [16], the scarce overview of NS's security aspects is summarized, and new security and privacy challenges based on NS are introduced for the first time. The investigation points out that when NS processes a large number of data sets because tenants use public resources, it will lead to information leakage and cause privacy security issues. The authors propose a security taxonomy based on NS, Categories include NS attack scenarios security threats, challenges and issues security solutions and trust and privacy in NS. At the same time, attack scenarios such as location tracking, impersonation attack, traditional interworking, and sealing between multiple slices are introduced. Finally, the security solutions based on AI/ML are summarized. Examples include domain isolation against DoS, authentication against identity spoofing, and access control for intrusion detection.

In [17], the author introduces some ML methods about wireless access network slice resource management. Evolutionary algorithms, supervised and unsupervised learning, reinforcement and distributed learning are used to solve the problems of slice resource sharing, dynamic management and isolation security in 5G/B5G. These ML methods are dynamic online techniques which can interact with dynamic network changes and select the most effective decision. To guarantee the QoS, the resources of a slice should be kept constant during a certain time to avoid its traffic load changes affecting other slices. Using Long Short-Term Memory (LSTM) to predict the user's demand for resources to reserve resources can reduce the number of resource reconfiguration. Many projects fixes the transmission power of user equipment, and the dynamic power allocation method combines the channel environment and interference conditions through iterative and online algorithms to optimize the drop situation and anti-interference ability. The user mobility management of slices can be optimized by predicting the user mobility to optimize the resource allocation rate and guarantee QoS. Priority queues prioritize slices to ensure service quality.

In [18], it is pointed out that the attacker attacks the network by using the NS function, which leads to the system failure. The authors divide the attacks on NS into inter-frame attacks, intra-frame attacks and lifetime attacks. At the same time, the solutions are divided into three types: RAN, core network and general solution. At this stage, NS security is mainly maintained using resource isolation, ML and encryption algorithm. This paper evaluates the performance of solving malicious attacks using open interfaces. The experimental results show that the RAN with performance isolation only needs half of the resources of the RAN without performance

isolation to achieve the same throughput. The incoming requests of mobile users were processed by first in First Out (FIFO) queue, and the statistical distribution and isolation forest were used to detect outliers. The results show that isolation forest produces more outliers. NS's end-to-end isolation can achieve security in complex systems, and blockchain can prevent data breaches and automatically manage Service Level agreements (SLAs). The existing cryptosystems cannot well protect NS from security intrusion and using quantum secure encryption method as an alternative is a future research goal.

In [19], the study explored the implementation of cloud-native NS based on SDN and multi-access Edge computing (MEC). These two approaches enable NS by virtualizing and dynamically configuring network resources. The authors discuss the design principles of cloud-native 5G core networks, how to optimize network function modularity and service chain through microservice architecture simultaneously. This paper proposes an SDN-based MEC architecture to realize low-latency and Ultra-reliable Delay Communication (URLLC) services. The feasibility of the proposed architecture in terms of NS mobility and service migration is verified through an initial evaluation in multiple edge cloud deployments in Southeast Australia. Cloud-native NS has four main challenges: federated slicing, dynamic service chaining, edge computing, and federated resource management. To address these challenges, the main goals of future research on NS are to enhance the slice federalization mechanism, optimize the dynamic service chain management, promote edge intelligent computing, and realize 4C resource joint management. Blockchain and AI technology are used to enhance resource management and isolation mechanisms. Develop more efficient dynamic service chain management algorithms in 5G architecture, and design new neural network and ML algorithms to meet low latency, high computing requirements and the management of communication, computing, caching and control resources in the joint edge environment, so as to optimize resource utilization. A summary of each literature is shown in Table I.

It is found that different methods have different advantages and disadvantages in terms of effectiveness, efficiency, scalability and applicability. For example, literature [13] focuses on the basic concept and implementation of NS, which, despite its high effectiveness, lacks in terms of scalability. The reinforcement learning method proposed in literature [14] has excellent performance in improving efficiency and scalability, but there are still security challenges. Literature in [15] presents the high efficiency and applicability of independent slices under the high connection characteristics of 5G networks. Nevertheless, the inadequate resource allocation for mobile services and the absence of end-to-end slice orchestration result in NS being unable to exert its maximum effect. Literature in [16] reveals that when NS processes a large amount of data sets, information leakage and privacy issues give rise to trust problems in information sharing between slices. The multiple machine learning methods introduced in [17] can effectively cope with dynamic resource changes, yet it is still necessary to ensure that the resource allocation among different slices does not impact QoS. Literature in [18] indicates that the RAN with performance isolation can achieve the same throughput with fewer resources, but the ability of this mechanism to counter security intrusions still requires further improvement. Literature in [19] explores the virtualization and dynamic configuration of network resources, enabling the network to possess flexibility and low-latency capabilities. In order to further improve the overall performance of network slicing, future research should focus on optimizing these aspects, especially in large-scale network deployment and cross-slicing operation scenarios, to find more efficient and secure solutions. Table II summarizes the comparison of seven articles in these aspects:

TABLE I. SUMMARY OF THE NS LITERATURE SURVEY

Reference	Summary of the Survey		
	Object	***Challenges***	***Future***
[13]	Concepts Implementation Lifecycle stages Application	Implementation complexity, interoperability, security concerns	Security exploration Efficiency Application-specific optimizations
[14]	Advantages Problems DRA Automation Configurations Security Privacy protection	Scalability Efficient resource allocation Security Privacy	Resource management with AI/ML Improved security mechanisms
[15]	Resource management Security mechanism	Ensure complete isolation Handle mobility scenarios	Simulate different mobility scenarios enhanc slice independence
[16]	Security Privacy Attack scenarios	Information leakage, securing inter-slice communication	Develop advanced AI/ML security solutions Enhance privacy protection mechanisms security solutions, enhancing privacy protection mechanisms.
[17]	Wireless access network slice resource management Dynamic resource management Isolation security	Predicting user mobility, maintaining QoS	Improving resource prediction accuracy, optimizing power allocation, enhancing mobility management
[18]	Security Attack scenarios Resource isolation	Ensuring end-to-end isolation, handling quantum security threats	Develop quantum-secure cryptographic schemes Enhance blockchain-based security measures
[19]	Cloud-native NS implementation Design principles Edge deployments	Low-latency and reliable communication, dynamic service chaining, federated resource management	Enhance slice federation Optimize service chaining Promote edge intelligent computing Integrating AI and blockchain

TABLE II. RECENT STUDIES COMPARED WITH DIFFERENT PROPERTIES

Reference	Performance Indicator			
	Effectiveness	*Efficiency*	*Scalability*	*Applicability*
[13]	High	Medium	Low	Medium
[14]	High	High	High	High
[15]	Medium	High	Medium	High
[16]	High	Medium	Medium	Low

[18]	Medium	Medium	High	Medium
[19]	High	High	High	High

NS technology has greatly optimized network resources through ML, but the current dynamic resource allocation and the isolation mechanism of dedicated slices still cannot ensure the integrity of the isolation function between NS. For example, improving interchip communication without compromising security as mentioned in [14] and [15] still lacks a comprehensive solution. In addition, as discussed in [16] and [18], applications of AI and ML in enhancing NS security have shown promise. However, the actual implementation of these solutions, especially in terms of real-time data analysis and intrusion detection, is still in the testing phase. As highlighted in [18], exploring advanced encryption methods is a promising way to address NS security vulnerabilities. In addition, although the research and development of cloud-native architecture and MEC framework for optimizing NS has begun [19], its integration with the current infrastructure is also a huge challenge to be faced.

III. NETWORK SLICING

As a novel architecture, NS can divide the physical network into multiple virtual networks. Each virtual network provides specialized services for different applications and optimizes the services continuously. NS is divided into two components, network function and Virtualized Network Function (VNF), which provide network functions for specific applications and use cases [20]. NS is supported by three main software-based network functions, namely SDN, NFV, and cloud computing[21]. When the needs of users change, cloud computing and virtualization technology can efficiently allocate shared resources to each slice of the logical network [22]. NS creates end-to-end network slices on RAN and core network to run multiple logical networks, enabling different vertical industries to run simultaneously on the same physical network infrastructure [23]. NS with complete functions can route and control packets throughout the network without being affected by other slices [24]. NS has pioneered original business conception such as Network Slicing as a Service (NSaaS) to increase revenue for mobile network operators (MNO) and hand control of networks to third parties [25].

A. Architecture

Next Generation Mobile Network (NGMN) alliance divides NS into three layers: infrastructure layer, network slice instance layer and service instance layer [26]. Fig. 1 shows the NS architecture.

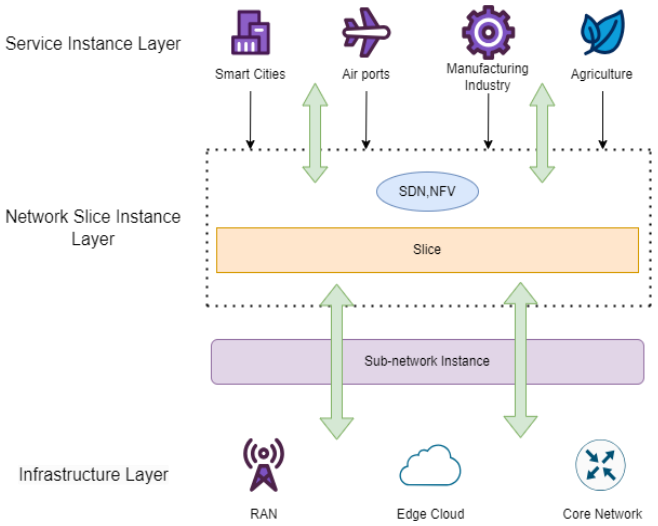

Fig. 1. NS architecture by NGMN.

1) Service instance layer: includes end-user and commercial service provided by network operators or third parties through service instances, such as applications such as virtual reality (VR), remote office, smart city, telemedicine, etc. This layer uses authentication to ensure secure access for users and devices. Distribute workloads across multiple servers to optimize resource efficiency and response time [27]. Real-time batch data processing and analysis to ensure that the data can be efficiently distributed to the terminal users. The service instance layer directly uses the network functions provided by the NS instance layer to satisfy the different needs of different applications in terms of low latency, high bandwidth, or high reliability [28]. The service instance layer includes service orchestration and management functions to ensure the running efficiency of service instances. Service orchestration manages the deployment and operation of different service instances to ensure that they cooperate. Leverage automated tools and techniques (AI/ML) to schedule resources, optimize performance, and handle failures [29].

2) Network slice instance layer: One of the core layers responsible for building virtual network instances over the top of the infrastructure layer. In this layer, each NS instance can be customized and run independently to satisfy the needs of different applications. NFV technology virtualizes the functions of traditional network devices into software modules, which optimizes the network to make it more flexible and scalable [30]. SDN and NFV are important components of the NS instance layer. SDN achieves the flexibility and dynamics of network management by separating the control plane from the data plane [31]. The control plane is managed by a centralized SDN controller. The controller communicates with network devices through an open interface to dynamically configure and manage network traffic. The data plane consists of physical and virtual network devices and performs the forwarding work of data packets. The data plane device receives the instructions issued by the control plane, and carries out the forwarding, filtering, and

processing of data packets [32]. NFV decouples the network functions and dedicated hardware devices, then runs them in the form of software on standardized hardware, thus achieving flexibility in network function deployment and management [33].

3) Infrastructure layer: Provides the physical and virtual resources required to support NS instances and service instances. This layer realizes the flexible allocation and management of resources through virtualization technology and SDN technology, which ensures the efficient operation of NS and the satisfaction of business requirements [34]. The physical hardware is the core of the infrastructure layer, with high-performance servers running VNFs and applications [35].

B. Type

NS can be classified by multiple scene: vertical and horizontal, static and dynamic, and RAN and core.

1) Classified by application scenarios: Vertical NS can establish multiple independent virtual networks can be set up on a standalone physical network infrastructure. Each slice is customized and optimized according to the different requirements of different applications. Vertical slicing allows assets to be shared between different applications and services to improve the network's service quality [36]. Each node of the network realizes the comparison capacity in a specific slice, and the traffic of different applications is isolated to complete the on-demand transmission of clients [37]. Horizontal NS distributes resources among system nodes to balance the capabilities of each node. This method provides resource isolation and edge processing [38].

2) Classified by implementation: Static NS configuration is done before the network is deployed or at an early stage of operation. Once deployed, the sliced resources will not change. The resource allocation of static slice is fixed and cannot be adjusted in real time according to the needs of applications [39]. However, its network performance and service quality are relatively stable, and its management and maintenance are also relatively simple. Therefore, it is more suitable for scenarios with stable demand such as private networks. Fixed resource allocation cannot be adjusted in real-time demand scenarios, leading to resource waste [40]. Dynamic NS can adjust resources in real time according to application requirements and network conditions, which greatly increases resource utilization and service quality [41]. It is more suitable for streaming media, healthcare, smart vehicles and other scenarios where the demand changes frequently and the flexibility and availability need to be guaranteed. However, the dynamic adjustment of resources will also bring challenges to network stability and service quality [42].

3) Classified by network architecture: RAN NS mainly manages and optimizations the resources of base station, radio spectrum, radio frequency resources and other radio access parts [43]. It can customize services for the access layer of different applications and handle mobility issues such as handover and roaming of user devices [44]. RAN NS is mostly used for some high bandwidth, low latency applications. And can connect to large-scale Internet of things like smart city sensor networks. Core NS mainly solves and optimizes the resource problems of the core network, such as data routing, session management and security control [45].

C. Lifetime

NS life cycle can be divided into four stages. The basic flow chart is shown in Fig. 2.

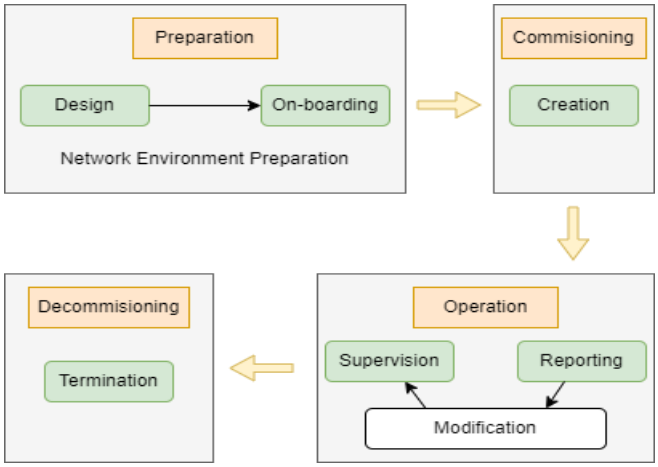

Fig. 2. NS life cycle.

1) Preparation: Network slices are planned and designed to ensure the allocation of resources and configuration. This phase needs to collect and analyze the requirements of different applications, such as bandwidth-delay reliability [46]. According to the application's requirements, the corresponding planning is made to ensure that the slice's resource allocation and service quality meet the requirements. Part of the network resources are reserved so that the dynamic allocation in the subsequent stages can proceed smoothly [47].

2) Commissioning: Setting the relevant network parameters and functions according to the specific network slice designed in the preparation phase [48]. The test verifies that the function of the slice can work properly. After ensuring that the slicing function is normal, the integration test with other services is carried out.

3) Operation: Ensure the efficient and stable operation of slices, and monitor the running status, performance indicators and service quality of slices in real-time [49]. According to the monitoring data and performance analysis results, the optimization is carried out to ensure the utilization of slice resources.

4) Decommissioning: To release the resources occupied by the network slice, clean up the data related to the deleted slice, and avoid security risks [49].

D. Resource Allocation

This section introduces two NS-based resource allocation methods.

1) An intelligent fuzzy-based system: IoT can enhance the performance of facilities which is connected by 5G. However, due to small cell sites' large-scale and unplanned deployment, switching are key issues. Due to the large number of wireless access technologies and technologies in 5G, the switching operation is complicated. In reference [50], the author proposes a fuzz-based system for 5G wireless network switching decision in view of different parameters of slicing. Two fuzzy-based switching decision models (FHDM) are constructed. In the simulation evaluation, the two models select different input parameters to see the impact on the output parameter switching decision (HD). FHDM1 selects the parameters slicing delay (SD), slicing bandwidth (SB), and slicing load (SL). FHDM2 Select Parameter slice Reliability (SR). The results show that the parameters have different influence on HD. HD values increased with the growth of SD and SL values and decreased with the increase of SB and SR values. Although FHDM2 is more complex than FHDM1, but it uses fewer input parameters, so the HD performance of FHDM2 is better. The simulation results of FHDM2 show that when the SD value is changed from 10% to 90%, and the remaining parameters are selected as 50% SR and 90% SL, the HD value increases by 50%. This suggests that when a user connects to a slice with poor service quality, switching to a better QoS is a good approach.

2) Multi-armed bandit based approach in LoRaWAN: With the increasing popularity of wireless sensor networks, LoRa WAN networks have an increasing demand for networks. Efficient resource allocation is an important difficult problem for LoRa WAN. Literature [51] introduced three schemes for how to allot the resource, and these schemes used the Multi-Armed Bandit (MAB) algorithm to maximize the packet delivery rate. UCB-MAB scheme adopts an Upper Confidence Bound (UCB) to find ways to coexist exploration and exploitation. Q-UCB-MAB scheme use Q-learning to update the Q value continuously, and it is combined with the UCB strategy to achieve deeper optimization. The third strategy of ARIMA-UCB-MAB is based on the Autoregressive Integrated Moving Average (ARIMA) model in the UCB framework to predict rewards and enhance the network's integral performance [51]. The results reveal that the three solution strategies achieve the best way to allot resource for PDR and SLA satisfaction. At the same time, with the increase of the parameters, the performance of the three schemes is optimized to a certain extent. In general, the solution strategy of ARIMA-UCB-MAB significantly outperforms the other two schemes.

IV. Technology Based on NS

Since different applications have different network requirements, NS is widely used to customize the network environment for different applications [52]. This section introduces three applications that optimize services with NS, include IoMT, IIoT and Vehicle-based system. Table III summarized technologies, existing problems and limitations of network slicing in different 5G scenarios.

A. Based on Internet of Medical Things

NS is also starting to be used in real life. With the popularity of the healthcare system, IoMT has become popular. From real-time intensive care monitoring to telemedicine, these services have highly different QoS requirements on communication networks. At present, ML/AI technology are widely used to solve these problems [53]. ML/AI analyzes data to predict patient health trends, remotely monitors patient health status, and even protects patient privacy and security. Fig. 3 shows the architecture of IoMT.

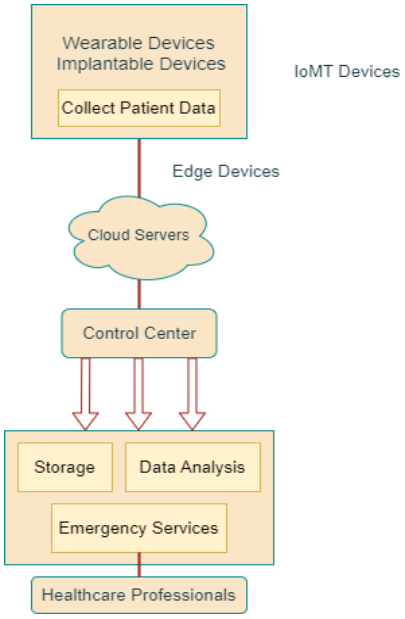

Fig. 3. IoMT architecture.

1) MT-VNE algorithm based on matching game theory: In reference [54], the authors proposed a Virtual Network Embedding solution based on two-sided matching theory (MT-VNE) to model network slices. In the NS model of medical system, each medical service is abstracted as a logical virtual network (VN), and these virtual nodes are connected by virtual links to Construct the virtual network topology. Each VN is equipped with resources that match its needs, such as processing, storage, and bandwidth resources. This innovate approach create many medical slices with different characteristics, which can be managed in one underlying network. Results show that MT-VNE performs excellently in service acceptance and resource utilization. Research will survey the impact of the underlying and virtual topology characteristics, and the future load variation of IoMT services.

2) Digital real-time health care system: During the spread of COVID-19 virus, a telemedicine system that can meet the real-time data transmission capability has become a research hotspot. But it is also a huge challenge. The authors of [55] propose an implementable architecture for digital health systems. To satisfy the needs of an end-to-end digital medical system, 5G NS is introduced to implement the system. Ensure the specificity of communication networks to satisfy the requirments for QoS in healthcare. During the architecture

design process, select an URLLC with well availability and security, guaranteed QoS, to deliver real-time patient-centered data and mobility.

The digital health systems include user plane and control plane. User plane consists of a UPF that anchors user session interconnection and traffic based on QoS which is specific. According to the data collection rules and the feasibility study of the amount of data to be deal, the dynamic slice allocation mechanism is used to accomplish this. This will ensure a commitment to patient-centered service quality. The control plane components for controlling healthcare slicing, allocating dynamic resources, and interconnecting healthcare NS with traditional telecommunications networks for voice and data communication [56]. In the future, the model will be applied to two different types of slices. Another important direction is the confidence interval of the analysis results and how to calculate the confidence interval if the analysis is integrated. The utilization of predictive advantages depends largely on the accuracy of the analysis, which also depends largely on the algorithms used to mine and process the data.

B. Based on the Industrial Internet of Things

Industrial automation is one of the most notable applications of IIoT. Many devices in the manufacturing industry require high reliability and low latency communication to ensure real-time control and monitoring of production lines [57]. Through NS, factories can create network slices dedicated to automation control, ensuring timeliness and stability of data transmission, thereby improving production efficiency and reducing downtime. Fig. 4 shows the IIoT transmission Architecture.

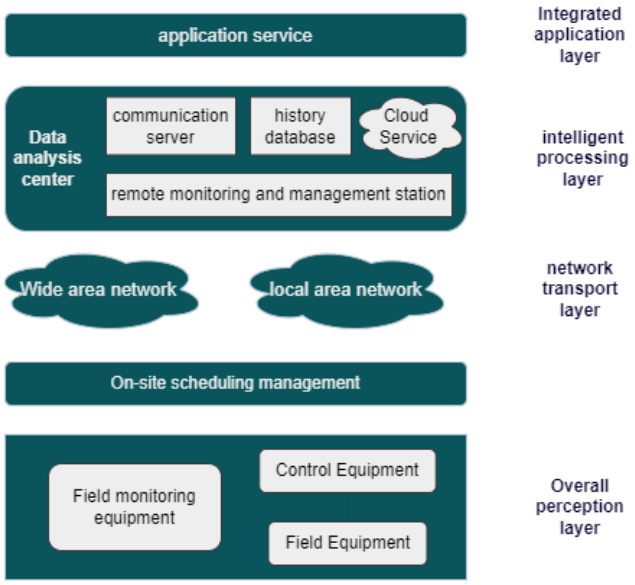

Fig. 4. IIoT architecture.

1) Resource allocation in digital siamese networks: Different services in the personalization industry place higher demands on the existing NS and resource allocation algorithms. At present, the efficiency of the algorithm is too slow and the cost is too high. In this context, the authors of [58] proposed a new network architecture in Digital Siamese Network (DTN). The architecture assists Industrial Internet of Things (IIoT) by integrating methods. The architecture is divided into three layers, three modules and two closed loops. In addition, proposes a new resource allocation system model and an solution to maximize the weighted net profit of service equilibrium. The dual-channel weighted (DCW) Critic network was introduced to realize the traffic balance and ensure the reasonable allocation of resources for personalized services. At the same time, an improved Priority Experience Replay (PER) structure was added to accelerate the convergence speed of the algorithm. This paper also proposes a PER-DCW Multi-Agent Deep Deterministic Policy Gradient (PER-DCW MADDPG) algorithm for allocating the resource in DTN-IIoT to ensure real-time operation while maintaining traffic balance.

The results show that it is necessary to ensure the service balance while dealing with the complex problem of personalized service resource allocation. The DCW network has a significant speed disadvantage, while the reliability of the network and automatic fault detection issues are also a great challenge [58]. It will continue to expand the research and use the scheme with Beyond 5G (B5G) and 6G networks. It optimizes the fault detection function of automatic network, the migration of virtual network functions and the link handover under fault conditions to make the network more reliable.

2) Non-orthogonal NS: The authors of [59] use non-orthogonal multiple access (NOMA) NS to improve the connection density of the network. In this study, the authors transformed the connectivity maximization problem into a mixed integer nonlinear programming (MINLP) problem. Subcarrier association and power allocation are jointly optimized to maximize the connectivity. The MINLP problem is first transformed into a mixed integer linear programming (MILP) problem. Then, it is further simplified into an integer linear programming (ILP) problem by formulating an effective pairing criterion. The Alternating Selection Best-Effort Pairing (AS-BEP) algorithm is used to improve the efficiency of solving the ILP problem and reduce the computational complexity. Non-orthogonal multiple access (NOMA) technology was used to share the same time-frequency resources for multiple users, and this technology improved the spectrum efficiency and network capacity.

Due to the need to support many connected devices with different service requirements, connection density and resource allocation become an important challenge. At the same time, high flexibility and high scalability are also an important requirement of industrial Internet of things for NS. In the future, simplify the complexity of MINLP algorithm to make it more suitable for real-world applications is necessary, and to continuously evaluate its feasibility and continuously optimize the algorithm in the application. Integration of NOMA and NS with other emerging technologies simultaneously, such as ML and artificial intelligence, continues to be explored to enhance decision-making processes and resource allocation strategies.

C. Vehicle-Based System

5G systems support many new things in verticals such as auto industry and power, which need more performance and cost requirements [60]. Through NS technology, vehicles can achieve real-time communication and data exchange with the cloud, to achieve intelligent navigation, remote monitoring and remote diagnosis. Fig. 5 shows the Vehicle Communication Architecture.

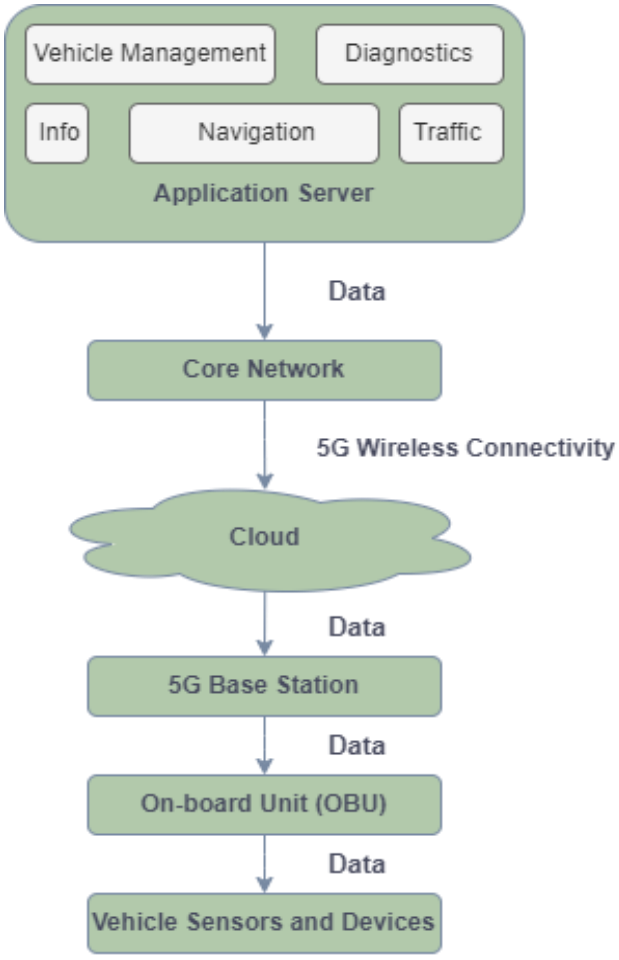

Fig. 5. Vehicle communication architecture.

1) Deep Reinforcement Learning based on Actor-Critic: A solution strategy which is appropriate for the standard 3GPP NS architecture is introduced in literature [61], which implements the Actor-Critic-based Deep Reinforcement learning (DRL) algorithm in the NS Subnet Management Function (NSSMF). The construction of this algorithm is based on the unrolling of in-vehicle applications. Because the limitation of resources, the standard slicing architecture is difficult to meet many heterogeneous service requirements without compromising the quality of service. Therefore, limited resources need to be structured in real time and efficiently to accommodate the traffic demands of different slices.

This computational approach allocates and manages resources between different generated slices in real time. In this paper, the algorithm was trained to enhance the QoS of service types in the network [61]. In the training evaluation of the computational method, the service level satisfaction of the slices is analyzed first. The results show that the satisfaction values for each slice never drop below 80% or 75%. However, the satisfaction value will decrease significantly if trained under a fixed allocation scheme. Therefore, the evaluation performance of the Actor-Critic DRL algorithm mentioned in this article is obviously better than that of the default fixed resource.

2) Vehicle-to-everything communication: A framework for V2X applications is proposed in [62]. The framework considers the coexistence of V2X communication with many other types of services to handle slice allocation. NS instances are defined within this framework. These slice instances need to interoperate and correspondence. The client instance must be configurated in each car and locked, counted, released and moved when connecting the session. The base station instance needs to accept the client request and forward it to the slice management instance; slice or slice management checks the availability of wireless resources and assigns corresponding resources to each one.

Research results show that network performance fluctuates in terms of resource consumption, switching, and blocking as the quantity of users in the region of interest changes. To provide optimal performance under a variety of network deployments and traffic conditions, resource allocation between slices must keep balanced [63].

TABLE III. NS TECHNOLOGY IN DIFFERENT APPLICATION SCENARIOS

5G Scenarios	Research Based on NS		
	Technology	***Problem***	***Limitation***
IoMT	NS ML AI	Meets different QoS require Predicts health trend of patients Monitors health status of patients remotely Protects privacy and security of patients	execution time of VNE is reduced, characteristics of underlying and virtual topology, Canges of medical service load
IIoT	NS DTN DCW PER MADDPG	Improve the reliability and low latency of real-time control and monitoring of production lines Eure service balance optisrce allocation	Resource management with AI/ML Improved security mechanisms
V2X	NS DRL MEC	Implement intelligent navigation, remote monitoring and remote diagnosis, allocates and manages resources of different slices in real time improves QoS of different service types.	Simulate different mobility scenarios enhance slice independence

V. NS Security Issues

An important part of 5G networks is to take apart network to provide different resource parts. If proper isolation is not provided for slices, the quality may be adversely impacted by flow and other factors [62]. During isolation operations, the safety of slicing becomes a central issue for most studies and studies. Softwareization using SDN and NFV in 5G networks is filling the gap in programmable control and management of network resources [64]. Table IV shows the advantages and disadvantages of each technology.

A. Software-Defined Networking

SDN technology reconstructs the traditional architecture, transforming from distributed to centralized control network architecture. SDN architecture is divided into three layers: application layer, control layer and facility layer [65]. SDN-based security threats are centered around a three-tier architecture. The first part is the data forwarding layer Switches are an important part of providing correct forwarding services for data packets at the data forward. The attacker can attach a link to one of the switch ports, threatening the end user's entry to the network [66]. The second part is the control layer translates the requirements of the SDN application layer to the SDN forwarding layer. When the controller is attacked, the whole network is affected. This is because when the switch does not receive the forwarding rule; It does not know how to forward the packet [67]. The third part is the attackers can modify the network configuration and steal network information through the application layer. This situation affects the control layer's operation and reduces the network's reliability and availability. Fig. 6 shows the SDN Security Architecture.

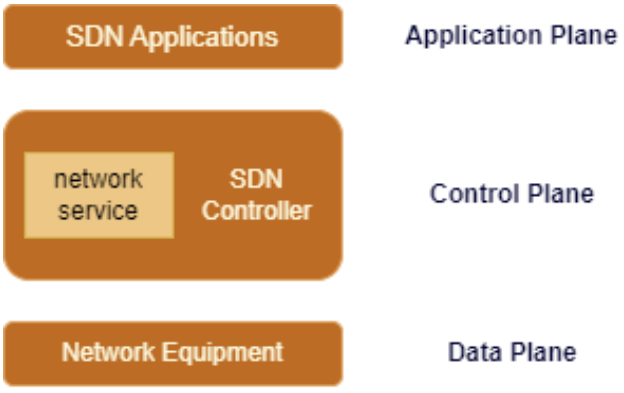

Fig. 6. SDN security architecture.

B. Network Function Virtualization

Network Function Virtualization (NFV) is a technique that virtualizes network functions using dynamic allocation to share the same facility with different functions [68]. In this technology, security problems can be caused in the following ways. When a VM allocates limited memory but unlimited resources, DoS attacks occur. Due to the complexity of integration, the integrity of the infrastructure is threatened; Resource abuse occurs when the hypervisor and scheduler fail, or when there is a lack of hypervisor isolation [69].

C. Multi-Tenant NFV/SDN

Literature [70] proposed a 5G access network security architecture supporting multi-tenant NFV/SDN. The architecture consists of security policy manager, monitoring and analysis, and Virtual Security Function (VSF). This security architecture is compatible with existing network virtualization efforts and enables fast and secure automated configuration through NFV/SDN technology. The framework mainly aims at automatic security management and VSF-based virtualization security services. The implementation of automated management relies on the service policy manager and the service monitoring and analysis policy. Virtualized security services are executed using VNS and automatically provided through the orchestrator and Virtualization Infrastructure Manager (VIM) in the NFV environment.

TABLE IV. Security Events based on different Network Slicing Technology

Technology	Research Based on NS	
	Advantage	***Limitation***
SDN	Provides centralized network control Optimized network performance Deploy applications flexibly	Controller single point of failure Complex security management Configuration challenges
NFV	Improve resource utilization Enhance infrastructure stability and resilience	High management complexity Security vulnerabilities
Hybrid NFV/SDN	Support resource sharing Improve operation and maintenance efficiency Automate security configuration	Security management and monitoring mechanism is complex Cost and resource investment are high

VI. Discussion

Through the investigation of existing research found that NS improves network efficiency and service quality by dividing logical networks, to realize the optimization of latency, resource management and security privacy. Current research trends focus on the integration of AI and ML to automate network management, resource prediction, and allocation. NS technology will enhance its application in large-scale networks by means of intelligent and automated management.

The isolation effect between slices poses a threat when resources are allocated. The defect of slice isolation will cause mutual interference between slices, which will affect the application of NS in the high movement scene of 5G. In addition, most current studies mainly rely on simulation and experimental environments, and lack the operability of resource allocation and isolation methods in complex network environments. Especially in applications such as IoMT, IIoT and in-vehicle networking, the reliability and latency of NS do not fully meet the demand. Secondly, because the challenges of 5G slicing in dynamic service chain management, edge

computing and joint resource management have not been fully solved, it is difficult to achieve efficient use of resources and continuous guarantee of service quality in practical applications.

VII. Challenges and Future Directions

NS technology faces major challenges such as efficiently and dynamically allocating resources according to demand, ensuring isolation effects, and avoiding interference. In this environment, accurate prediction of user mobility and demand to maintain quality of service and optimize resources is necessary to address these challenges [71]. Data leakage and unauthorized access in the isolation process will bring security risks to the slice information. Advanced encryption technologies such as blockchain can solve security problems such as location tracking and impersonation attacks [72]. Interoperability between different slices and integration with existing network infrastructure causes compatibility issues between vendors and carriers [73]. Developing common standards and protocols to ensure that each slice scales independently and maintains quality of service during peak load can effectively solve this problem. Orchestration and management frameworks can also be used to efficiently handle the dynamic scaling capabilities of slicing, which further optimizes low latency and reliability between services [74].

A. Challenges and Requirements

NS technology needs to allocate resources efficiently and dynamically according to demand, and ensure the isolation effect between slices [75]. This is a high requirement for predicting demand and allocating application resources. Accurately predicting user mobility and demand can also optimize the quality of service maintenance and the allocation of resources [76]. Data breaches and unauthorized access can create security issues in the isolation process.

B. Future Work

In the future, it is necessary to strengthen the application of AI/ML in resource management and develop more efficient dynamic service chain management algorithms to improve the accuracy of resource prediction [77]. Advanced security solutions are implemented using quantum secure encryption schemes and blockchain technology to enhance data protection against unauthorized access and automate SLA management [78]. Continue to explore AI/ ML-based security measures to detect and mitigate sophisticated attacks. At the same time, common NS standards and protocols are established to promote the interoperability between slicing and seamless integration with the existing network infrastructure [79]. Combine edge computing with NS to establish low-latency, efficient services, and optimize resource utilization and service delivery through AI-driven edge computing solutions [80].

VIII. Conclusion

This article explores NS technology in depth and demonstrates its strong potential for use in different 5G application scenarios. The analysis of NS architecture, resource allocation mechanism and application examples reveals the significant advantages of NS technology in the optimization of resource utilization, network latency, quality of service and security in IoMT and other fields. This research also found that the current NS technology has great challenges in cross-slice interoperability, security isolation and dynamic resource allocation. In the future, the optimization of NS architecture and the strengthening of security measures should be strengthened. Through the optimization of network slice management to improve resource utilization and network transmission performance. Use AI/ML to achieve intelligent and automated NS management, while introducing more advanced security encryption measures like blockchain and quantum encryption technology. As challenges continue to be discovered and solved, NS technology will continue to drive the digitization and intelligence of 5G applications.

Real Time Object Detection for Sustainable Air Conditioner Energy Management System

Chang Shi Ying[1], C. PuiLin[2]
Student-Faculty of Data Science and Information Technology, INTI International University, Malaysia[1]
Senior Lecturer-Faculty of Data Science and Information Technology, INTI International University, Malaysia[2]

***Abstract*—Air conditioning has become indispensable for maintaining human comfort, especially during hot weather, as people rely on it to stay cool indoors. However, the long-term and uncontrolled use of air conditioners has significantly contributed to climate change and environmental degradation. The extensive use of air conditioners releases more carbon dioxide, a greenhouse gas, into the atmosphere, exacerbating global warming and leading to adverse climate impacts. The proposed sustainable air conditioning energy management system aims to address this issue by optimising air conditioner use while minimising its environmental footprint and mitigating climate change. Current air conditioning systems in offices, buildings, and homes typically rely on fixed temperature settings, leading to excessive energy consumption and increased greenhouse gas emissions. Existing solutions, such as fixed timers, manual timer settings, and physical controllers, are ineffective as they cannot dynamically respond to changes in environmental conditions, such as room occupancy and activity levels, resulting in significant inefficiencies and environmental hazards. To overcome these limitations, the proposed system introduces an innovative solution using software engineering technology, specifically real-time object detection, to control air conditioning energy usage. This approach redefines air conditioning management by allowing the system to dynamically adapt to room occupancy, environmental factors, and activity levels, ensuring the right amount of cooling is delivered at the right time. This method represents a concrete and effective response to climate change challenges and demonstrates a commitment to creating a sustainable and environmentally responsible future.**

***Keywords*—Deep learning; energy consumption; energy efficiency; global warming; climate change; real-time object detection; Air conditioner optimization; smart meter; environmental footprint; climate action**

I. Introduction

Climate change affects every country globally, disrupting economies and impacting vulnerable populations. Climate change affects weather patterns, rising sea levels and more frequent extreme weather events. Notably, a critical concern within this context is the high energy consumption levels and carbon emissions. Sustainability has emerged as a paramount human priority in the increasingly advanced world. Taking this into account, the United Nations adopted the Sustainable Development Goals (SDGs) in 2015 to protect the planet [1].

Sustainable development and reducing energy consumption are two of the project's main objectives. Therefore, the project aligns with SDG 13, which addresses climate change, and SDG 11, which aims to achieve sustainable cities and communities. Goal 13 emphasizes the urgency of acting against climate change, while Goal 11 aims to create inclusive, safe, resilient, and sustainable cities [2]. To achieve these goals, the project sets out to develop a sustainable air conditioning system that incorporates cutting-edge software engineering technology, specifically real-time object detection.

Driven by artificial intelligence (AI) and machine learning, real-time object detection has made significant progress, especially in the field of deep learning. This advanced technology enables computers to identify and locate objects within images or live video feeds swiftly and accurately. Deep learning is a subset of machine learning using convolutional neural networks inspired by the architecture of the human brain at its core. By training these deep neural networks on extensive datasets, computers gain the ability to discern intricate patterns and features, enabling them to recognize and categorize objects in real-time scenarios.

By incorporating real-time object detection, the air conditioner energy management system adapts dynamically to the environment, optimizing energy usage with precision. Unlike traditional technology, the system can automatically adjust the temperature based on the activity levels and the number of occupants in a room. This will ensure that air conditioning energy is not wasted and protect the environment by optimizing energy use. With real-time and remote-control capabilities, the system provides users with more convenience and control. Users can easily adjust temperature settings and ensure optimal energy usage, especially when the room is unoccupied. This user-friendly solution encourages sustainable choices effortlessly.

This project aims to create innovative environmental sustainability solutions and embody buildings by solving the issue of climate change. The objective of this project is to improve existing solutions that have limited function. By optimizing energy usage, detecting human activity and occupancy, and utilizing hardware like Cameras, Smart Sensors, and Smart Remote Controllers, this project aims to use technology to build a more sustainable future.

A. Problem Statement

The current system has several problems that must be rectified. Since it controls the temperature of the air conditioner largely with an infrared remote control, its portability and accessibility may be limited as a result. Furthermore, the focus of this research is on improving user comfort rather than improving energy efficiency, which is a vital component of any smart home system. In the second article, the system's security layer is entirely made up of authentication and authorization

functions. Furthermore, it is only compatible with the Android operating system, which implies that only Android users can use it. Third, the existing air conditioner energy management system is based on an outdated algorithm known as YOLOv3 (You Only Look Once), which lacks the enhancements found in the most recent version.

Furthermore, the existing system's technique for controlling air conditioners is limited to counting the number of persons in a room and is unable to recognize individual room activities for the purpose of providing precise temperature adjustment. There is also a method known as deep learning detection, which is based on the behavior of a single resident. It is vital to consider the presence of multiple occupants to increase overall accuracy and ability. These constraints highlight the need for an improved air conditioning management system capable of overcoming these constraints while still ensuring portability, security, accessibility, and efficacy. The proposed improvements are intended to reduce air conditioner energy use for a wide variety of users, including those in homes, businesses, and buildings.

B. Research Objectives

This research paper seeks to fulfil its objectives by addressing three key questions. Firstly, it aims to study existing air conditioning systems to understand how real-time object detection and energy management can be applied within these systems. This involves a thorough analysis of current technologies and methodologies to identify opportunities for improvement. Secondly, the research focuses on designing and developing a sustainable air conditioner energy management system that not only reduces energy consumption but also promotes a more sustainable environment. Lastly, the paper will conduct rigorous testing to ensure the effectiveness of the newly developed air conditioner energy management system in real-world scenarios. This testing is crucial to validate the system's ability to optimize energy consumption, thereby contributing to a reduction in greenhouse gas emissions and fostering a more sustainable future.

II. Literature Review

The Air Conditioner (AC) system is essential for providing human comfort, yet it also contributes to the rising outdoor temperatures seen because of climate change. This creates a concerning and self-perpetuating cycle, with the CO2 emissions from AC units only exacerbating the issue. Considering this, numerous researchers have proposed solutions to reduce the contribution of AC systems to climate change. Thus, this literature review explores the approaches taken in prior research on Air Conditioner Energy Management Systems.

The current air conditioner energy management system has integrated an IoT Smart House System emphasizing the efficient management of indoor environmental conditions to enhance occupants' thermal comfort during leisure activities. It involves analyzing indoor environmental data by sensors for CO2 and particulate matter (PM) and carefully selecting measurement nodes to ensure system stability and reliability. It uses an infrared remote control to control the temperature of the air conditioner. The focus of this system is the application of IoT and user comfort [3].

Another current system, HEMS-IoT (Home Energy Management Systems-IoT), integrates big data and machine learning to manage home energy for comfort, safety, and savings. Machine learning algorithms, such as J48, are used to analyze energy consumption and user behavior patterns, while RuleML and Apache Mahout help create energy-saving recommendations based on user preferences. A case study validates HEMS-IoT's effectiveness in reducing energy consumption while maintaining home comfort. The security layer of the HEMS-IoT ensures the confidentiality and integrity of data by employing two fundamental security components, which are authentication and authorization. While at the presentation layer, HEMS-IoT is working on the Android operating system, which is a constraint to other users such as Apple iOS [4].

Another current solution for reducing energy consumption and sustainability in smart buildings is integrating deep learning and the Internet of Things (IoT). Recognizing the significance of HVAC systems in energy consumption, Elsisi et al. proposed a deep learning-based people detection system employing YOLOv3 to count occupants within specific areas of smart buildings accurately. This innovative system optimizes the operation of air conditioners based on real-time occupancy data, contributing to enhanced energy efficiency. Moreover, the IoT platform's dashboard facilitates data visualization and informed decision-making regarding energy consumption [5]. The current air conditioner energy management system relies on an outdated YOLO deep learning algorithm (YOLOv3) for object detection. However, YOLOv8, the latest version, offers enhancements such as anchor-free, improved CNN architecture, more efficient, and improved average precision score [6].

Furthermore, an existing system employs a data-driven deep learning method employing a convolutional neural network (CNN) model to detect various occupancy activities. The performance of this deep learning framework was assessed in an office space within a case study building, initially identifying activities like 'standing,' 'sitting,' 'walking,' 'napping,' and 'none,' even for detecting no occupancy. This approach achieved an average detection accuracy of 80.62% during live testing, highlighting its potential for real-time monitoring. The Deep Learning Influenced Profile (DLIP) was also evaluated in estimating sensible heat gains driven by occupancy and CO2 concentrations [7].

Machine and deep learning methods are highly effective for building energy prediction due to their advantages over traditional models, including reduced data requirements and faster model development. Machine and deep learning excel in energy forecasting, thermal comfort prediction, and occupancy detection. Deep understanding is gaining popularity in these fields thanks to increased data availability and improved algorithms. Some studies suggest combining deep and traditional machine learning techniques can further enhance application performance [8].

III. Methodology

This real-time object detection of a sustainable air conditioning energy management system will use a life cycle (SDLC) as a prototype of the research method. With this approach, the research process is considered through various

stages, each of which contributes to the development of this system. Using the SDLC framework can make research objectives more precise and more organized.

Fig. 1 shows the phase for this research. The research methodology includes requirement gathering, design system architecture, building prototype, and testing.

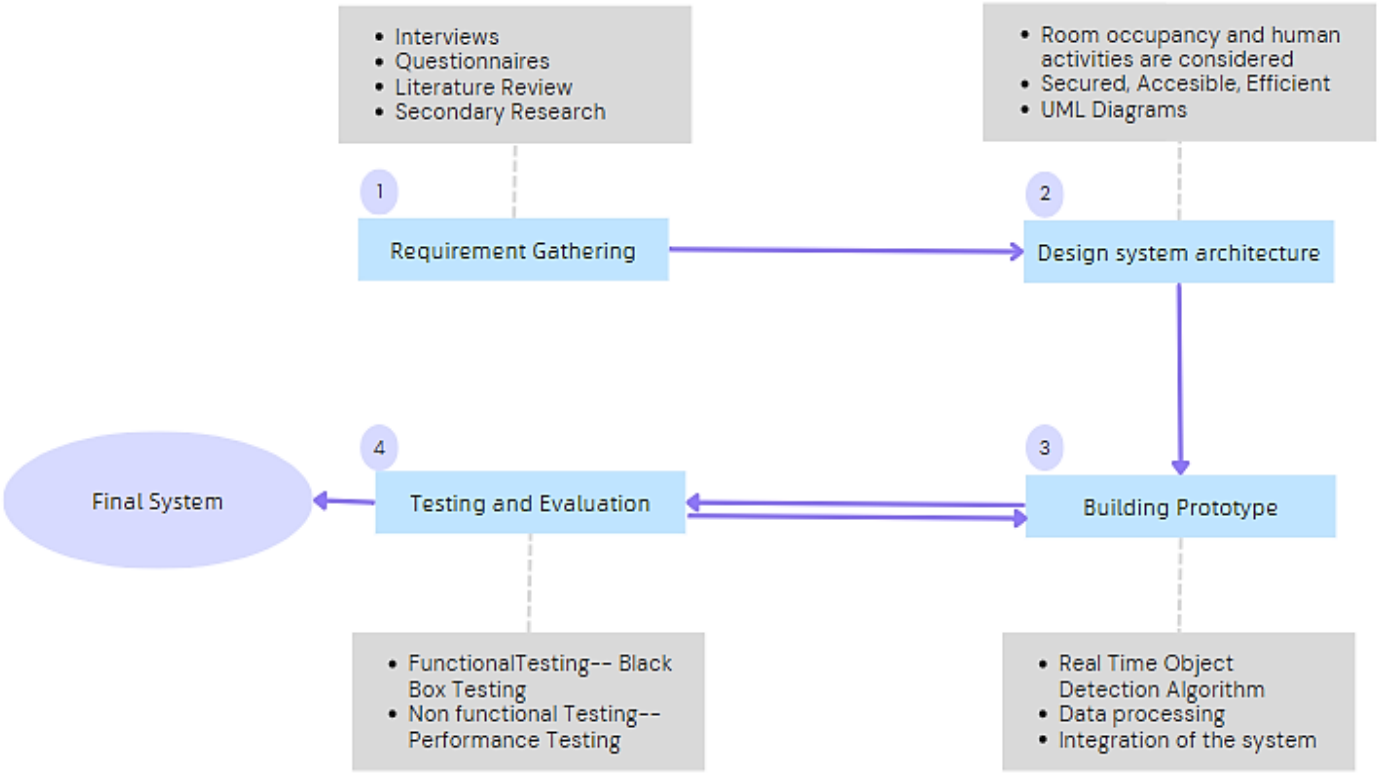

Fig. 1. SDLC prototype.

A. Phase 1: Requirements Gathering

Fig. 2 shows different preferences among respondents when adjusting air conditioner settings, preferences vary among respondents. A significant 76% prefer manual adjustments, while 39.6% use scheduled timers. Technological solutions are also employed: 14% use Wi-Fi remote control, 11% use smart thermostats, and 1% each use occupancy sensors and smartphone controls. Additionally, 2% utilize weather-based control, reflecting a blend of manual and tech-driven methods among the surveyed population.

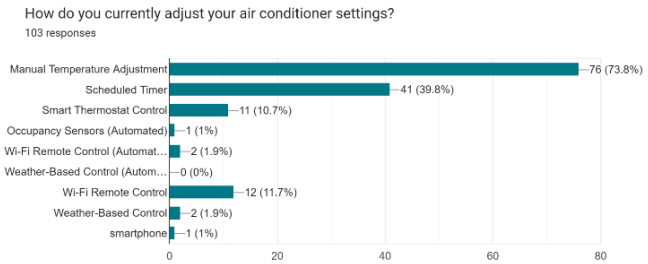

Fig. 2. Common air conditioner settings.

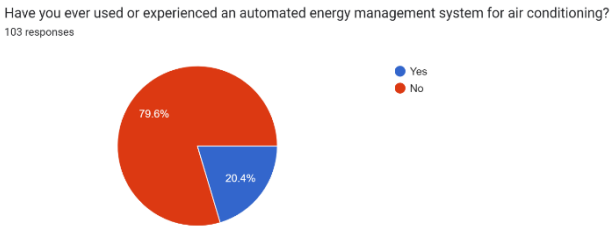

Fig. 3. Automated energy management system for air conditioning engagement report.

Fig. 3 shows that 79.6 per cent of respondents have not used or experienced an automated energy management system for air conditioning, while 20.4 per cent have reported having engaged with such automated systems. This distribution underscores that a significant majority of the surveyed population may not have had exposure to or utilized automated energy management systems in the context of air conditioning, highlighting potential opportunities for awareness and adoption of these technologies.

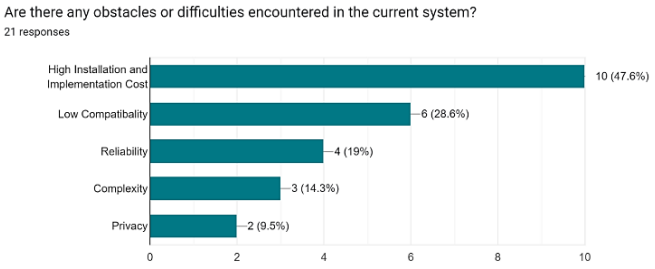

Fig. 4. Difficulties encountered in the current system report.

Fig. 4 shows that when asked about obstacles or difficulties encountered with the current air conditioning system, respondents identified several challenges. The most cited issue, chosen by 10 individuals, is the high installation and implementation cost, indicating a financial barrier that some face in adopting or maintaining their current system. Additionally, 6 respondents express concerns about low compatibility, highlighting challenges in integrating the system with other technologies or components. Four participants note reliability as an obstacle, suggesting issues with system dependability. Three respondents find complexity to be a challenge, indicating difficulties in navigating or understanding the operational intricacies of their air conditioning setup. Lastly, privacy is a concern for two individuals, suggesting a consideration of data security and personal information in the context of their air conditioning system. This diverse set of challenges provides valuable insights into the various hurdles faced by users in their experiences with current air conditioning systems.

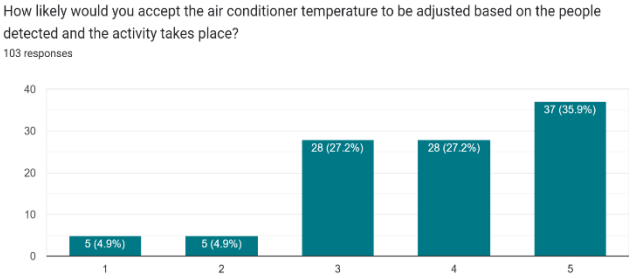

Fig. 5. Smart air conditioning acceptance rate.

Fig. 5 shows the data from respondents on their likelihood of accepting air conditioner temperature adjustments based on detected people and activities presents an interesting trend on the linear scale. A substantial 35.9 per cent expressed a high likelihood (rated 5) of accepting such adjustments, indicating a significant openness to embracing a system that adapts based on occupancy and activities. Furthermore, 27.2 per cent each chose the ratings of 3 and 4, suggesting a considerable portion with a moderate to high inclination. Meanwhile, 5 of the respondents each chose the ratings of 1 and 2, indicating a small minority expressing a lower likelihood. This data reflects a generally positive reception towards the idea of dynamically adjusting air conditioner temperature based on detected people and activities, with a notable majority leaning towards acceptance of such a system.

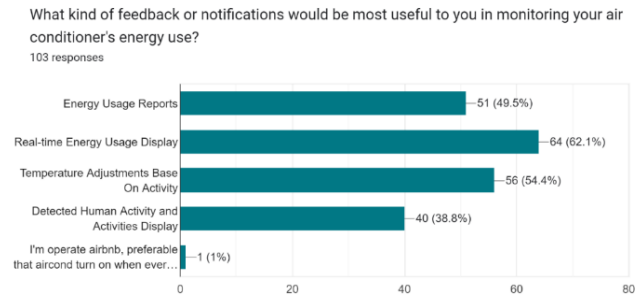

Fig. 6. Responses on preferred feedback for monitoring energy usage.

Fig. 6 shows in response to the inquiry about the most useful feedback or notifications for monitoring air conditioner energy use, most respondents, 62.1 per cent (64 individuals), express a preference for a real-time energy usage display. This indicates a strong interest in receiving immediate and transparent information about the energy consumption of their air conditioning system. Additionally, 54.4 percent (56 individuals) prioritize notifications related to temperature adjustments based on detected activities, highlighting a desire for a dynamic and responsive climate control system.

Moreover, 38.8 per cent (40 individuals) find value in notifications related to detected human activities and activities display, emphasizing the importance of understanding and being informed about the environmental conditions driving air conditioning usage. One additional response provides a unique perspective, as the respondent, operating an Airbnb, prefers the air conditioner to automatically turn on when human presence is detected and turn off when the guests leave, with the goal of optimizing energy savings. These insights collectively illustrate a strong demand for real-time information and dynamic control features that align with user preferences and enhance energy efficiency in the context of air conditioning systems.

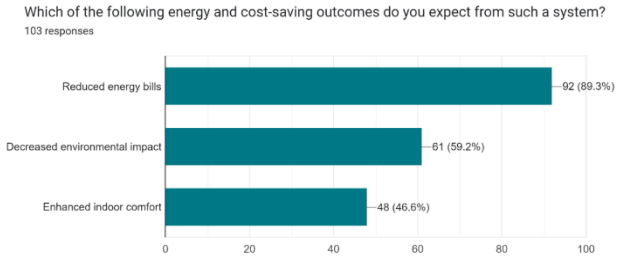

Fig. 7. Expectations of the system.

Fig. 7 shows the expectations regarding energy and cost-saving outcomes from the proposed system reveal a strong consensus among respondents. The most prominent expectation, chosen by 89.3 per cent of participants (92 individuals), is the anticipation of "Reduced energy bills." This aligns with a primary goal for many users, emphasizing the economic benefits associated with energy savings.

Additionally, 59.2 per cent of respondents (61 individuals) expressed the expectation of a "Decreased environmental impact," reflecting a heightened awareness and concern for

sustainability and environmental considerations. Furthermore, 46.6 per cent of participants (48 individuals) anticipate "Enhanced indoor comfort" as an outcome. This suggests that, beyond cost savings, respondents value the potential for improved comfort and well-being within their living or working spaces.

These expectations collectively underscore a strong interest in the practical and environmental benefits that respondents associate with the implementation of energy management systems in their air conditioning setups.

B. Phase 2: Design System Architecture

A Rich Picture is created by drawing the system with few instructions, often containing aspects such as architecture, processes, climate, people, issues stated by individuals, and conflicts. While lengthy writing is avoided, some Rich Pictures may include textual elements. The goal is to avoid mimicking organized diagrams such as Theory of Change maps while encouraging flexibility. Arrows can be used to express causal links in Rich Pictures. The analysis of a Rich Picture occurs during the process of drawing and discussing, making these diagrams a dynamic and flexible tool for understanding complex systems [9].

A Rich Picture shown in Fig. 8 is created by drawing the system with few instructions, often containing aspects such as architecture, processes, climate, people, issues stated by individuals, and conflicts. While lengthy writing is avoided, some Rich Pictures may include textual elements. The goal is to avoid mimicking organized diagrams such as Theory of Change maps while encouraging flexibility. Arrows can be used to express causal links in Rich Pictures. The analysis of a Rich Picture occurs during the process of drawing and discussing, making these diagrams a dynamic and flexible tool for understanding complex systems [9].

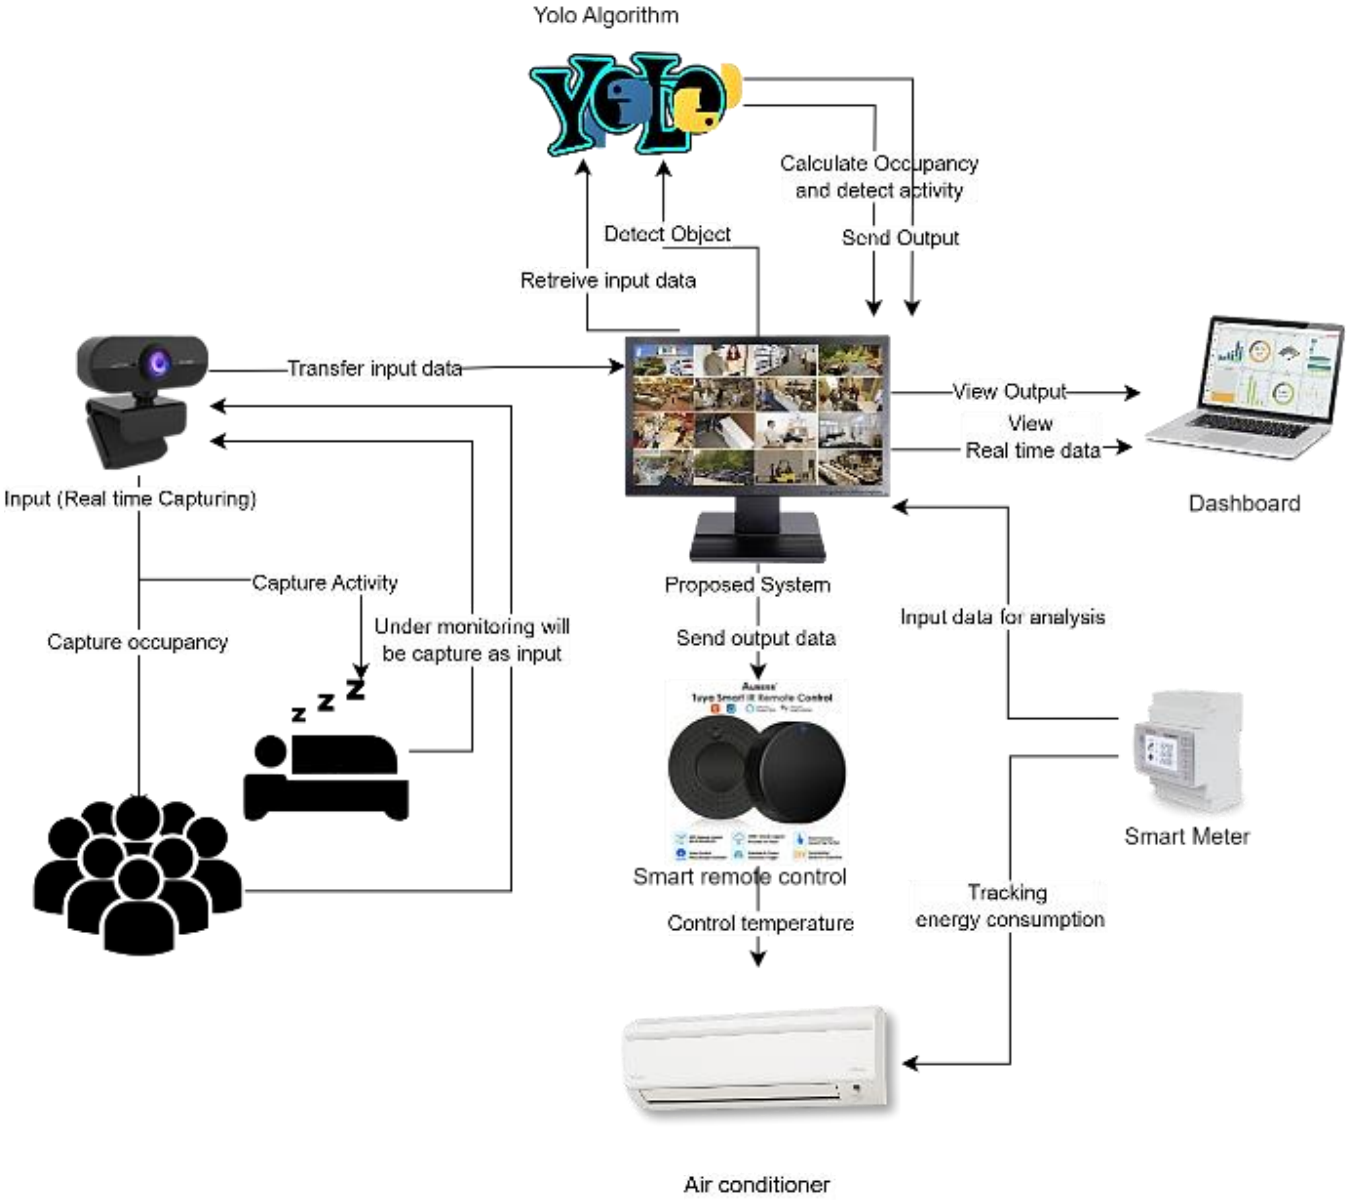

Fig. 8. Rich picture diagram.

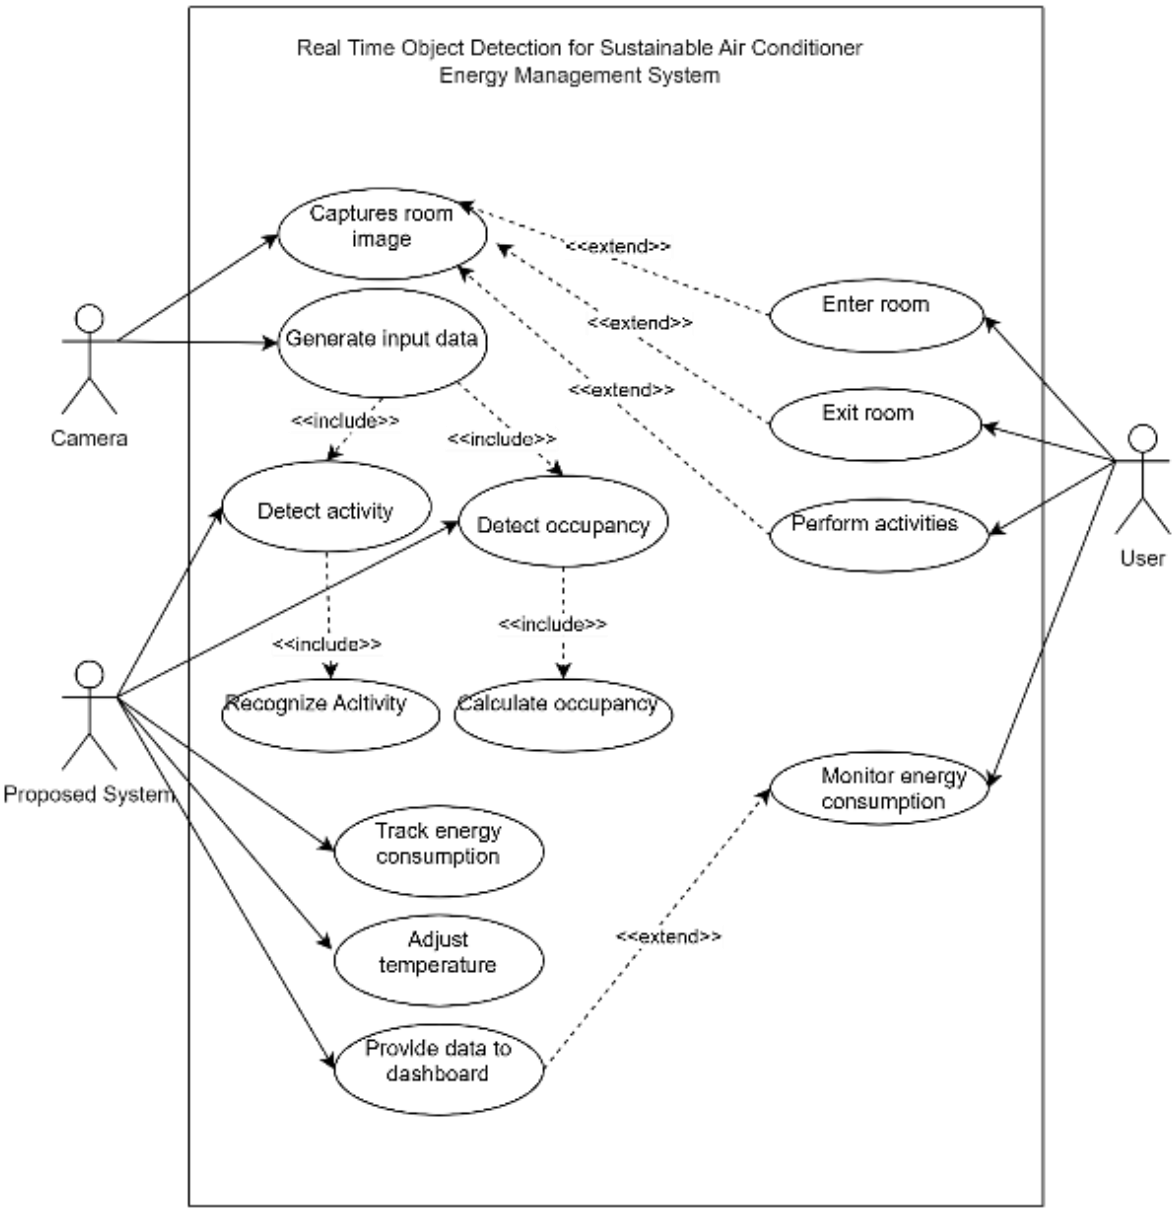

Fig. 9. Use case diagram of the proposed system.

Fig. 9 shows a use case diagram of the system. Use-case diagrams are essential UML tools for modelling system behaviour and capturing requirements. They provide a high-level overview of the system's functions, scope, and interactions with actors, illustrating what the system does without detailing underlying functions. These diagrams help define the context and requirements of the entire system or individual components. Typically created early in a project, they serve as valuable references throughout development, representing complex systems in one or multiple diagrams.

Fig. 10 shows the Class Diagram for the system comprises several distinct classes, each encapsulating specific functionalities within the overall architecture. The "Occupancy Detector" class is responsible for detecting and monitoring occupancy within the designated space, featuring attributes related to detection sensitivity and methods for processing occupancy data. The "Dashboard" class manages the graphical user interface, facilitating user interaction and real-time monitoring of system data. The "Account" class oversees user accounts, storing credentials and preferences, while the "Location" class represents spatial information tied to the physical context of the system. The "Smart Meter" class monitors and records energy consumption data, including parameters for readings. Lastly, the "Temperature Adjuster" class manages temperature settings, incorporating data related to control parameters, user preferences, and methods for adjusting temperature settings. Together, these classes define the static structure and responsibilities of key system components, providing a comprehensive overview of their interactions and collaborations. The Class Diagram serves as a visual guide to understanding the system's architecture and behaviour.

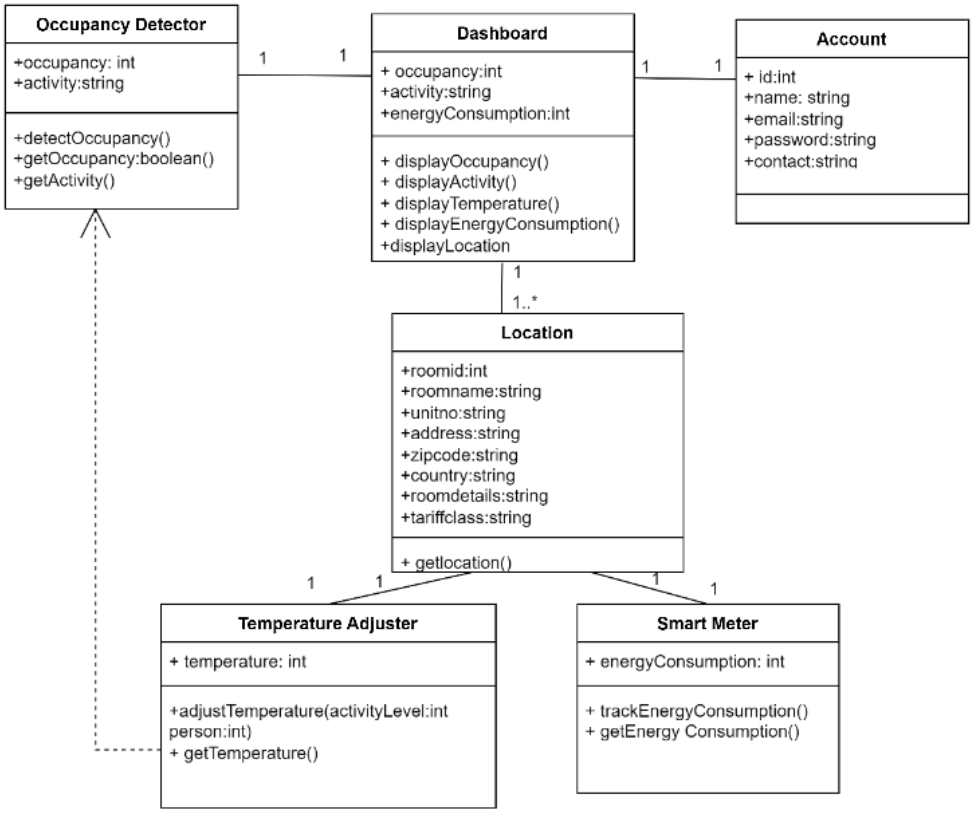

Fig. 10. Class diagram of the proposed system.

C. Phase 3: Building Prototype

Roboflow is employed to create dataset. The five classes in the dataset includes: sleeping, sitting, standing, moving, and exercising. There are a total of 2500 images and each class has an average of 250 pictures. All the images are annotated with the respective classes. 1855 (74%) images are used as train set, 448 images (18%) are used for valid set, and 197 images (8%) are used for testing purposes as shown in Fig. 11. Splitting the data into training, validation, and testing sets is important for developing an effective machine learning model.

Google Collaboratory is employed for the training of the YOLOv8 model. By leveraging Colab's infrastructure, accelerated processing capabilities are utilised, allowing for efficient training of the YOLOv8 model without the need for substantial local computational resources.

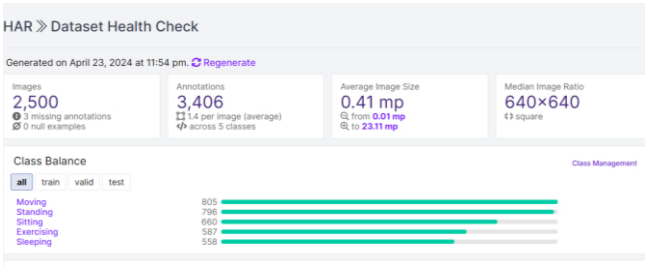

Fig. 11. Shows the health check of the dataset.

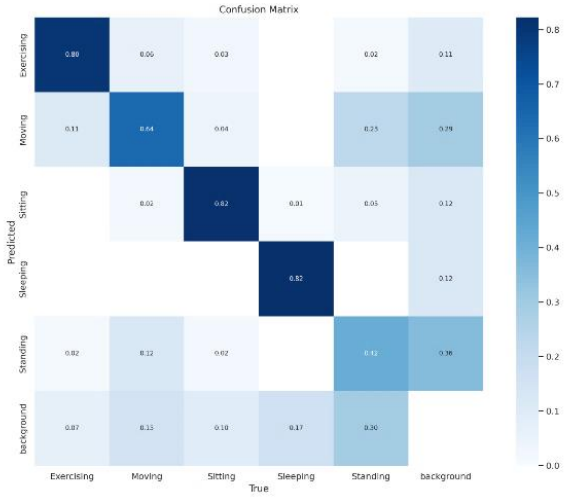

Fig. 12. YOLOv8m model confusion matrix.

As shown in Fig. 12, a high value on the diagonal 0.82 for "Sitting", 0.82 for "Sleeping" and 0.80 for "Exercising" means that the model accurately predicted that class most of the time. In contrast, lighter off-diagonal cells indicate misclassifications, such as "Standing" being incorrectly predicted as "Moving". The "background" class suggests that the model also tries to differentiate between specific activities and a lack of activity. This matrix can quickly reveal which classes are being confused by the model, guiding further improvements in its performance.

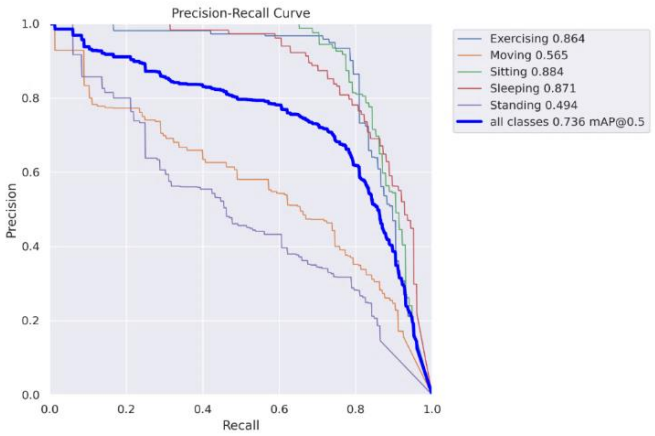

Fig. 13. YOLOv8m precision-recall curve.

The provided Precision-Recall curve in Fig. 13 evaluates a classification model's performance across five classes: “Exercising”, “Moving”, “Sitting”, “Sleeping”, and “Standing”. Precision generally decreases as Recall increases, reflecting the trade-off between accuracy and capturing all positive instances. “Sitting” exhibits the highest performance with an AUC (Area under curve) of 0.894, while “Standing” appears more challenging with a lower AUC of 0.494. The overall mAP at IoU (Intersection over Union) 0.5 is 0.736, indicating reasonable accuracy but room for enhancement, particularly in classes with less favorable Precision-Recall trade-offs.

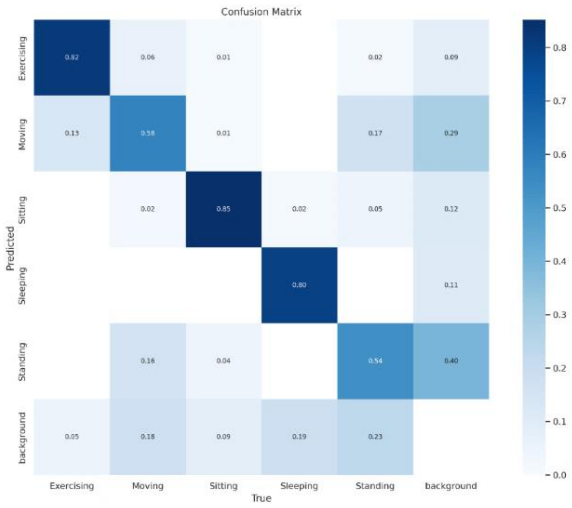

Fig. 14. YOLOv8x confusion matrix.

As shown in Fig. 14, a high value on the diagonal 0.85 for “Sitting”, 0.82 for “Exercising” and 0.80 for “Sleeping” means that the model accurately predicted that class most of the time. In contrast, lighter off-diagonal cells indicate misclassifications, such as “Standing” being incorrectly predicted as “Moving”. The “background” class suggests that the model also tries to differentiate between specific activities and a lack of activity. This matrix can quickly reveal which classes are being confused by the model, guiding further improvements in its performance.

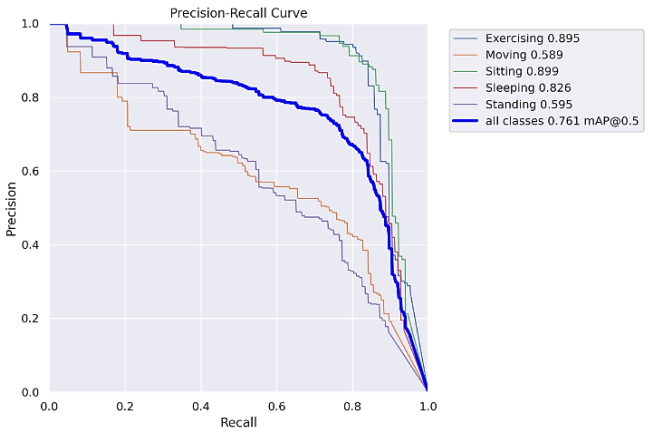

Fig. 15. YOLOv8x precision-recall curve.

The provided Precision-Recall curve in Fig. 15 evaluates a classification model's performance across five classes. Precision generally decreases as Recall increases, reflecting the trade-off between accuracy and capturing all positive instances. “Sitting” exhibits the highest performance with an AUC of 0.899, while “Moving” appears more challenging with a lower AUC of 0.589. The overall mAP at IoU 0.5 is 0.761, indicating reasonable accuracy but room for enhancement, particularly in classes with less favorable Precision-Recall trade-offs.

Based on these comparisons, the YOLOv8x model, which attained an accuracy of 76%, has been selected as the model for the Real-Time Object Detection system.

D. Phase 4: Testing and Evaluation

The testing plan encompasses both functional and non-functional aspects, including user registration, login, room management, profile editing, and system performance evaluations. Entry and exit criteria are established to ensure the proper setup and conclusion of the testing process, with a focus on achieving reliable and accurate system performance. Overall, the testing phase aims to validate the system's functionality and ensure its seamless operation in real-world scenarios, with detailed documentation provided to support the testing outcomes. The result from the usability testing shows that the system design is easy to use for the target user.

IV. DISCUSSION

The project successfully addressed the research question, “What software engineering method can be applied in the Air Conditioner Energy Management System to help reduce energy consumption?” by adopting YOLOv8 for real-time object detection and energy management. A comprehensive study of existing systems led to the development of a prototype integrating these functionalities.

To answer, “How to create a sustainable air conditioner energy management system that reduces energy consumption and contributes to a sustainable environment?” various tools were explored, system architecture was designed, and a user-friendly, efficient prototype was built as shown briefly in Fig. 16, Fig. 17, and Fig. 18.

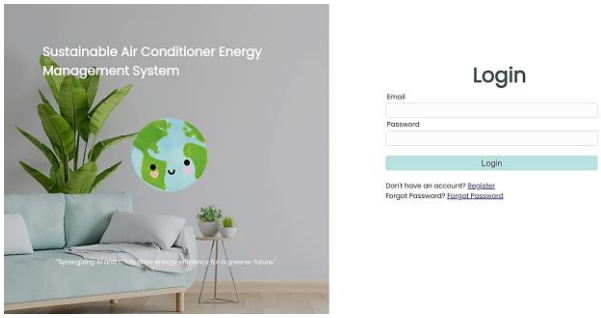

Fig. 16. Shows a screenshot of login page.

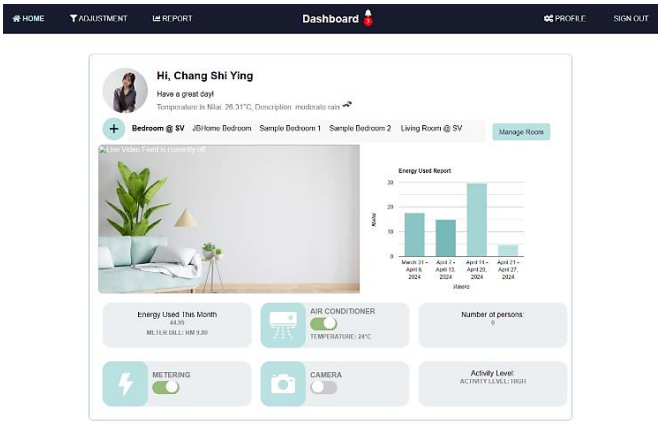

Fig. 17. Shows a screenshot of the home page (main dashboard).

Fig. 18. Shows a screenshot of the report page displaying real-world room smart meter data.

The project also evaluated the question, "How effective is the developed air conditioner energy management system in optimizing energy consumption in real-world scenarios?" by installing a smart meter to measure energy consumption before and after implementation. Testing validated the system's effectiveness and ensured seamless website functionality.

V. Results

The project successfully addressed the limitations of the existing system by adopting YOLOv8, offering significant improvements over the outdated YOLOv3 algorithm. YOLOv8 enabled more accurate real-time object detection and better tracking of room occupancy and activities, resulting in more precise temperature adjustments.

A key improvement lies in energy consumption management. The system optimized air conditioner energy usage by adjusting temperature settings based on real-time occupancy and activity data. This was a significant step forward compared to the previous system, which only counted the number of people in the room without accounting for specific activities. As a result, the new system reduced unnecessary energy consumption by avoiding overcooling or overheating the space.

The system also expanded accessibility by moving beyond Android-only compatibility, offering support for multiple operating systems and devices. Real-world testing confirmed these improvements. While no direct comparison with other systems was made due to project time limitations, the system enables users to monitor energy consumption through smart meter tracking, helping them avoid overuse. Website testing validated the seamless integration of the UI with smart home devices and common air conditioner models. The dashboard provides users with clear, actionable insights into their energy consumption, allowing for more informed energy management decisions.

However, limitations such as budget constraints impacting hardware performance, particularly in real-time object detection and dataset training, hindered optimal system performance. These challenges necessitated compromises in hardware capabilities and cloud platform usage, highlighting areas for improvement to enhance future project outcomes [10].

VI. Conclusion and Future Work

In conclusion, the developed system is deemed to effectively address the challenges outlined in the problem statement.

Enhancing the system's hardware infrastructure involves two key upgrades. First, investing in higher-performance GPUs, made possible with increased funding, accelerates model training and improves real-time object detection, boosting responsiveness and accuracy. Second, acquiring advanced cameras with superior low-light performance, faster capture speeds, and 360-degree adjustability enhances object detection, particularly in challenging lighting conditions and provides wider coverage.

Expanding the dataset and annotation process is crucial with increased resources. Additional time for dataset collection and annotation ensures a diverse range of images, improving the system's ability to accurately detect and classify objects. Including higher angle shots offers a broader perspective, further enhancing accuracy.

Strengthening system security is imperative for safeguarding user data. In addition to existing measures, implementing Secure Video Transmission, Camera Authentication, and Multi-Factor Authentication (MFA) bolsters defences against unauthorized access and cyber threats.

Integrating voice control or voice recognition based on user surveys enhances user experience and system usability. Voice commands for system functions streamline interactions, making the system more accessible and intuitive.

Future enhancements based on user feedback include refining the room selection dashboard with interactive buttons displaying meter data and editing options, integrating meter statistics directly into each room, allowing fixed temperature settings without camera detection, introducing usage limits with

notifications, and adding a leaderboard for energy-saving competition among users.

ACKNOWLEDGMENT

Acknowledgment is given to INTI International University for providing an invaluable platform for education and skill development. Special thanks are owed to the Faculty of Data Science and Information Technology for facilitating exposure to real-world challenges.

***Abstract*—Digital health services have become a trend and receive higher demand in Malaysia. However, the adoption of mobile applications to support the digital health service in the country remains low especially among older adults, contributing to low usability support of the mobile applications. This paper reviews the usability models and design factors that are relevant and applicable to support the digital health service mobile applications' design for older adults. Seven usability design factors such as efficiency, help and documentation, learnability, memorability, user-friendliness, need-base, and push-base were discovered to be most suitable to support older adult users. Subsequently, a review was conducted on the fulfilment of seven usability design factors in key Malaysian digital health service mobile applications. Findings showed that most applications supported high learnability and memorability but lacked support for another five usability factors. Lastly, a usability design framework to support the Malaysia digital health service mobile applications for older adult users would be proposed. A full exploratory study is the next step to validate the proposed framework.**

I. INTRODUCTION

Smartphones play a vital role in our daily lives by providing connection and computational power for individuals and communities. Other than the common phone functions such as making calls and sending messages, the applications in current smartphones also support various activities such as information search, travel navigation, online shopping, personal health tracking, and remote health monitoring. Currently, about 98.4% of Internet users aged 16 to 64 in Malaysia own a smartphone compared to only 7% of the same group of people who owned feature phones [1]. Although older adults have switched from using feature phones to smartphones, the interface of the existing smartphones commonly presents small font sizes and rich content that targets mainly young people and not older adults [2]. Older adults may have different smartphone usage preferences compared to younger adults. Older adults prefer browsing messages and social media posts related to news, economics, and health. They will also download applications that provide support services related to their daily chores. If mobile applications have low visibility and low learnability, it may hinder older adults from accessing information and services through mobile applications and browsers.

Digital healthcare has been gaining traction in Malaysia for the last decade. It has further accelerated rapidly since the COVID-19 pandemic period. According to Digital 2024 Malaysia [1], about a third of the population or about 10.16 million Malaysians used digital health treatment and care applications. However, the average annual value per user for digital treatment and care was only recorded at 18.72 USD in the year 2023. The first reason for the low valuation of use is related to the limited digital healthcare services offered in Malaysia such as MySejahtera, DoctorOnCall, PruBSN Navigator, Doctor2U by BP Healthcare, and GetDoc. Secondly, digital health service mobile applications are difficult to use. According to Alharbi et al. [3] and Tajudeen et al. [4], older adults faced several issues while using health service mobile applications such as a lack of understanding about the features and the know-how to complete tasks in the application such as to book a service or call for emergency help.

While the life expectancy in Malaysia for Malaysia in 2024 is 73.8 and above the average life expectancy at birth of the global population at 71 years [5], there are more elderly people in Malaysia who need digital health services accessibility. The baby boomer generation may require more assistance in using mobile applications on smartphones. Unfortunately, the mobile applications' design is not user-friendly for older adults. A limited mobile application usability study has been conducted and similarly, a limited usability design framework has been proposed to support the digital healthcare application's development for older adults. Many significant usability factors such as intuitive interfaces, personalization, and push-based support were lacking in the current digital health service mobile applications to support the older adults' needs [6], [7], [8].

This review aims to study the usability models and explore the missing factors that could be used to support older adults in Malaysia in adopting digital applications for their health and well-being. This review aims to address three research questions which are: 1) Which usability models or frameworks are applicable for digital health service mobile applications? 2) Which common usability factors are adopted in current digital mobile application studies? and 3) What are the usability factors related to older adults that should be integrated into digital health service mobile applications? This review will conclude with a proposed usability design framework to

*Corresponding Author.

support the creation of healthcare mobile applications targeted at older adults.

This review paper has five main sections. Section I highlights the importance of supporting mobile application usability for older adults. Section II describes the methodology for conducting review activities. The findings of the review are explained in Section III. Follow on, a discussion of the findings of the review is written in Section IV before the conclusion and future work of this research are given in Section V.

II. METHODOLOGY

This review focuses on three key aspects. First, the existing technology acceptance models and usability frameworks are explored to determine the usability design factors. Second, the usability theory papers, existing conferences and journal publications related to usability evaluation of mobile applications that focus on digital health service applications are collected, synthesized, and summarized. Third, the existing digital healthcare mobile applications in Malaysia are explored and analyzed to determine the coverage of usability support in the applications. The search and review were conducted using Internet searches through the Google Scholar website and Google Play store dated from the year 2016 to 2024. The review duration covered the last 8 years of publications and mobile applications. In some cases, older references which are significant and impactful were also referred to and adopted.

III. FINDINGS OF THE REVIEW

The findings are presented based on the respective research question:

A. Findings on Research Question 1: Which Usability Frameworks are Applicable for Digital Health Service Mobile Applications?

Several theoretical frameworks and models were found to be relevant for digital health service mobile applications. The Technology Acceptance Model (TAM) proposed by Davis [9] is the foundational framework for understanding user acceptance of technology. It comprises two key determinants such as perceived usefulness and perceived ease of use which influence users' attitudes and actual intention to use technology (refer to Fig. 1). Current research still adopted this TAM to study the usability and acceptance of mobile applications such as mobile banking for Islamic banks [10], mobile e-wallets in Vietnam [11], and online food delivery applications [12].

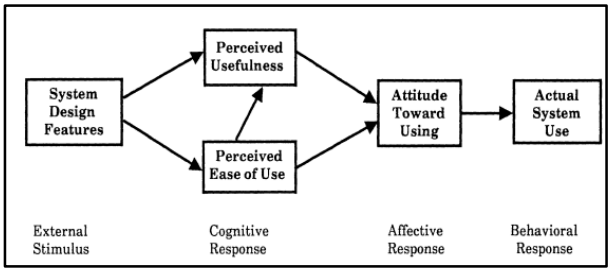

Fig. 1. Technology acceptance model (TAM) [9].

The TAM is incorporated into the Unified Theory of Acceptance and Use of Technology (UTAUT) model which was developed by Venkatesh et al. [13], together with the Theory of Reasoned Action (TRA) to provide a comprehensive understanding of the factors influencing the acceptance and usage of technology. The original UTAUT model as shown in Fig. 2, has four key determinants namely performance expectancy, effort expectancy, social influence, and facilitating conditions. Furthermore, this UTAUT model has been extended with usability attributes by Alshehri et al. [14] to cover more aspects of mobile application users' behavioural study. Besides the original four key determinants in the UTAUT model, six usability attributes namely system navigation, information quality, system learnability, visual design, system interactivity, and instructional assessment were included in the extended UTAUT model (refer to Fig. 3). The study could be moderated with demographic variables such as age, experience, gender, and willingness to use. These usability attributes were also popularly used and validated extensively in previous system evaluation studies [15], [16], [17], [18], [19]. This extended UTAUT model was adopted by Semiz & Semiz [20] who discovered that facilitating conditions attribute was the most significant factor, which affected the usage of mobile health applications.

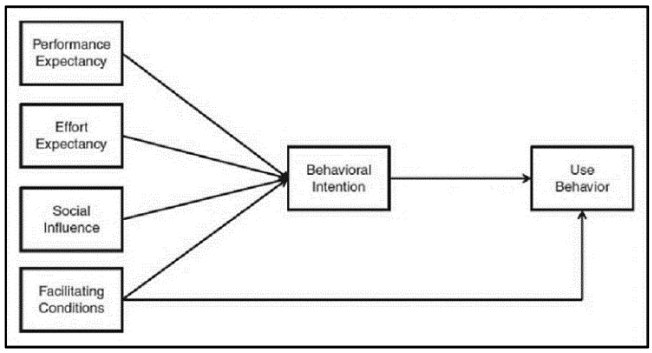

Fig. 2. UTAUT model [21].

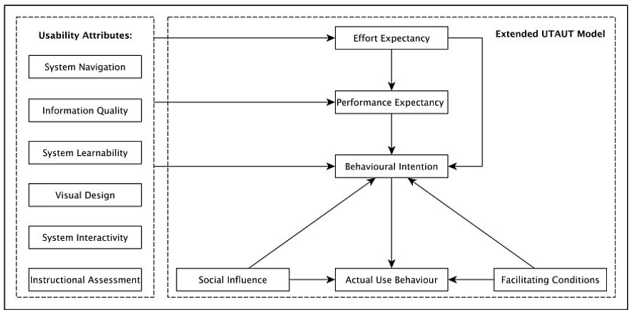

Fig. 3. UTAUT model with extended usability [14].

There are other usability theories and concepts proposed by other researchers. Nielsen proposed five quality components to support usability design [22]. The five quality components are learnability, efficiency, memorability, errors, and satisfaction. Much research was conducted and showed that the five quality components were significant in increasing the usability level of a product or system. The findings are summarized in Table I.

Nielsen also developed the Ten Principles of the Nielsen Usability Model [29]. Each principle provides insights and guidance for mobile applications, websites, and system designers to create user-friendly products to ensure that users can interact with the products efficiently and effectively. The

definition, applicability area for each of the principles, and the relevant research conducted are summarized in Table II.

TABLE I. SUMMARY OF RESEARCH FINDINGS FOR NIELSEN'S FIVE QUALITY COMPONENTS

Quality component	Definition of the Component	Supported research
Learnability	Refers to the ease of intended task accomplishment during the user's initial use of a software application	[23], [24], [25], [26], [27], [28]
Efficiency	Refers to the productivity level of using the system.	[23], [26], [27], [28]
Memorability	Refers to how easy to remember the system's functionalities and operations for users who return after having been on vacation or temporarily stopped using a program	[23], [26], [28]
Errors	Refers to any action that does not accomplish the desired goal	[23], [26], [27], [28]
Satisfaction	Refers to how pleasant the user is when using the system	[26], [27], [28]

TABLE II. OVERALL FINDINGS OF THE TEN PRINCIPLES OF NIELSEN USABILITY MODE

Principle	Definition	Applicability area	Supported research
Visibility of system	Refers to how well the system is conveyed to users	• Keep the users updated about what is going on, what is the latest status, where are the user located. • Support dynamic change of visuals and icons to highlight actions made. • Clarity of display messages.	[30]. [31]
Match between system and the real world	Refers to the natural mapping, which is easier for users to learn, use and remember how the interface and system works	• The UI element will reflect material objects similar to those objects from the real world. • Arrange the menu option and choose the color according to user's usual expectations. • The icons should convey information about their functions.	[32], [33], [34]
User control and freedom	Refers to the ability to allow users to rectify their mistake or backtrack their action such as back, cancel or undo.	• Provide browser back button. • The system "Exit" should be easy to find to let users in control when can they want to leave the system.	[34], [35]
Consistency and standards	Refers to the standardization of all the buttons and designs that exist in the system to lower the user's learning curve.	• Do not require the users to learn new interactions. • Follow established standards to make mobile interface design familiar to the users.	[31], [36], [37]
Error prevention	Refers to the effort to prevent users from making errors in the system.	• Eliminate error-prone conditions • Offer user confirmation before committing the action. • Use a placeholder and provide a range for data entry to eliminate data entry error.	[23], [34]
Recognition rather than recall	Refers to the effort to reduce the memory load of a user by making elements, actions, and options visible	• The information should be visible or easily retrieved when needed	[24], [38]
Flexibility and efficiency of use	Refers to the allowance of the user to use multiple interaction ways with the same result or task	• Allow the use of a shortcut key to reduce the number of clicks. • Define functional keys for the convenience of working with a system.	[24], [39]
Aesthetic and minimalist design	Refers to the design which consists of essential elements that support primary goals only.	• Hide rarely used or irrelevant page or module. • Encourage to use larger text and controls with lesser components in interface design.	[40], [41]
Help users recognise, diagnose, and recover from errors	Refers to the support given to help the users to recognise the errors and correct them.	• Provide meaningful error messages with plain language and not an error code. • Provide constructive suggestions to help the users to recover from the errors.	[34], [42]
Help and documentations	Refers to the availability of documentation that help users to better understand the system and know how to complete their tasks.	• Provide documents that contain a list of concrete steps that need to be carried out to complete a task. • Provide proactive help like tooltips, pop-up hints, and alert messages.	[24], [43]

Besides, the International Organization for Standardization (ISO) also created the ISO/IEC9126 matrix for information technology to evaluate their software quality in 1991 [44]. This matrix was expanded from year 2001 to 2004 to include the ISO quality model. Table III shows the five product quality characteristics in the ISO/IEC9126 matrix and their sub-characteristics. In the matrix, usability can be further explored in five aspects: understandability, learnability, operability, attractiveness, and usability compliance. Some of the sub-characteristics matched the quality components proposed by Nielsen. This matrix has been used by some researchers to investigate the system or software design efficacy towards the acceptance of users [45], [46].

TABLE III. CHARACTERISTICS OF ISO/IEC9126 MATRIX

Quality characteristic	Sub-characteristics
Functionality	• Suitability • Accuracy • Security • Interoperability • Functionality compliance
Reliability	• Maturity • Fault tolerance • Recoverability • Reliability compliance
Usability	• Understandability • Learnability • Operability • Attractiveness • Usability compliance
Efficiency	• Time behavior • Resource behavior • Efficiency compliance
Portability /Maintainability	• Analyzability • Changeability • Stability • Testability • Maintainability compliances

In conclusion, six related usability frameworks were studied and showed high applicability to be adopted in the digital health service mobile application design. Each framework proposed different variables. For example, TAM has two determinant variables; the UTAUT model has four key determinants; the extended UTAUT model has six usability attributes; Nielsen proposed five quality components as well as ten principles of the usability model; and the ISO/IEC9126 matrix comprises usability as product quality characteristic with five sub-characteristics. Each framework or model has been validated and used in various research. They are highly applicable in various types of mobile applications and web systems. Therefore, it is believed that these usability frameworks are significant and suitable for digital health service mobile application designs.

B. Findings on Research Question 2: Which Common Usability Factors are Adopted in Current Digital Mobile Application Studies?

A search was conducted on the Google Scholar website to explore the usability factors used in current digital mobile application studies. The search was conducted with keywords such as “mobile application”, “usability”, “user satisfaction”, and “user acceptance”. The search was filtered to include the recent 8 years’ research publications from 2016 to the current. The initial result returned 26,200 articles. The search results were later filtered to exclude duplicates, incomplete (pre-print, no full-text), and no usability factors as related to Research Question 1 finding, qualitative studies or studies with social science research frameworks. From the search conducted, 2006 hits were obtained and after applying filters, a total of 16 full-text articles were obtained. The mapping of 26 usability factors explored in the 16 current mobile application studies is displayed in Table IV.

The mapping in Table IV showed that efficiency, satisfaction, error, and effectiveness were the common usability factors used in existing studies. These variables were derived from Nielsen’s five quality components and ISO/IEC 9126 matrix. Other variables from TAM, UTAUT, and Nielsen’s ten principles of usability models such as learnability, ease of use, help and documentation, and visibility of system status were also adopted by the researchers. There are also some low-popularity variables such as need-base, good mapping, feedback, recognition rather than recall, consistency and standard, operability, and flexibility as displayed in Table IV.

TABLE IV. MAPPING OF USABILITY FACTORS TO CURRENT MOBILE APPLICATION STUDIES

Paper/ Variable	Need Base	Visibility of system status	Error	Consistency	Memorability	Recognition rather than recall	Ease of use	Effectiveness	Satisfaction	Learnability	Efficiency	Help and Documentation	Usefulness	Attitude or Likeability	Good conceptual Model	Good Mapping	Feedback	Security	Cognitive Load	Consistency and Standard	Privacy	Design	Accessibility	Aesthetics	Operability	Flexibility

The 16 current mobile application studies focused mainly on applications with general users of all ages. These studies did not focus on the usability considerations for older adult users. For example, variables such as need-base, feedback, and accessibility that are assumed to be more relevant to older adult users were not explored adequately nor adopted in the current studies. It may be due to the nature of mobile applications that generally do not target older adult users, or researchers and developers may have neglected this group of users.

C. Findings on Research Question 3: What are the Usability Factors Related to Older Adults that Should be Adopted in the Digital Health Service Mobile Applications?

Based on the analysis and findings from Research Questions 1 and 2 above along with other relevant studies, seven usability factors were identified to support digital health service mobile applications that targeted older adult users. The factors were presented to a professional healthcare service provider and an industry-experienced user interface & user experience (UI&UX) developer to obtain their views on the usability factors' applicability to digital health service mobile application's design. Both experts agreed that this set of usability factors is relevant and suitable in Malaysia's context. The professional healthcare service provider also proposed two new variables (need-base and push-base) to be included, which do not belong to any existing usability model or framework, but are highly important for older adult users. Based on the input provided by both experts, the rationale for including the seven usability factors in digital health service mobile applications is derived and explained in Table V.

To examine whether the current studies have adopted the proposed usability factors for older adult users' support, the previous Table IV is filtered to show the studies that supported the seven proposed usability factors. The findings are displayed in Table VI. The filtering discovered that all 16 current studies included at least one of the usability factors that support older adult users, except for the push-base factor. A few current studies such as [26], [27], [28], [47] supported up to four usability factors for older adult users. The need-base and push-base factors are rarely or not supported by the current studies.

On the other hand, the researchers also reviewed the existing Malaysia-based digital health service mobile applications on the adoption of the seven proposed usability factors as presented in Table V. The review was conducted for six mobile applications namely MySejahtera [55], DoctorOnCall [56], BookDoc [57], PruBSN navigator [58], doctor2u By BP healthCare [59], and GetDoc [60]. The findings are shown in Table VII.

The digital health service mobile application that adopted the greatest number of usability factors for older adult support is doctor2u by BP Healthcare (Table VII). The mobile application only lacked the push-base component. The most downloaded health service mobile application in Malaysia – MySejahtera also fulfilled five usability factors for older adult support. Similarly, this mobile application also did not support push-base component, as well as the need-base component. The MySejahtera was created to support Malaysia COVID-19 pandemic healthcare activities such as health monitoring and vaccination. This mobile application was mandatory to be used by citizens of all ages in Malaysia during the movement control order period. Therefore, it is justifiable that the MySejahtera application's design has a high usability level to support older adult users. On the other hand, BookDoc, which is a personalised health and wellness mobile application for enhanced well-being is more dedicated to younger users and therefore only fulfilled one usability factor of high learnability related to older adult users.

In conclusion, the evaluation of various health service mobile applications revealed the shortcomings of the usability design in different aspects for older adult users. The help and documentation, learnability, and memorability design factors are well-adopted by current health service mobile applications. Meanwhile, the efficiency and user-friendliness design factors are only adopted by half of the current mobile applications. On the other hand, the need-base and push-base factors are only adopted by one mobile application reviewed. These findings indicate that most of the current health service mobile applications in Malaysia are not older adult-friendly in design. Currently, no Malaysian mobile applications for health adopted a similar design framework also. This implies a lack of standard usability design framework for health service mobile applications, especially to support older adult users.

TABLE V. RATIONALE FOR USABILITY FACTORS INCLUSION IN DIGITAL HEALTH SERVICE MOBILE APPLICATIONS

Variable	Rationale
Efficiency	Older adult users have lower attention span due to eye tiredness. The mobile application must support fast and timely task completion.
Help and documentation	Older adults may not be familiar with mobile application's functionalities and layout, a step-by-step documentation guide or responsive help in the mobile applications will help them to use the mobile application independently.
Learnability	Older adults may not have high digital literacy skills. The mobile application operations must be easy to learn and fast to pick up by the older adult users.
Memorability	Older adults may not remember as quickly or efficiently compared to younger adults. The mobile application should reduce the need for recall on how to use the mobile application's functions for older adults
User-friendliness	The mobile application should provide user-friendly components such as bigger fonts, suitable font colors and contrast, bigger buttons, and navigation controls to allow older adult users to view, click, and navigate the mobile application contents smoothly.
Need-base	Older adults may have special needs for features such as error prompting and correction guides, automated settings, and shortcuts that may not be required by younger age users.
Push-base	Older adults may have special needs for features such as service alerts and health reminders that may not be required by normal-age users.

IV. DISCUSSION

This study discovered that the popular usability models adopted among the researchers are the Nielsen five quality components and ISO/IEC 9126 matrix. The researchers acknowledged the importance of having high usability coverage in the mobile application design to fulfil the specific users' needs and increase user satisfaction and experience. Research Questions 2 and 3 findings show different focuses on usability factors' adoption for general and health service mobile applications. It showed that the health service mobile application developers realised that the special-needs mobile application must have a unique set of usability factors to support the users. However, this awareness needs to be further strengthened to assist older adult users by considering more unique and related usability factors.

V. CONCLUSION

This study addressed three key research questions by using different approaches with reference to 43 significant research papers available in Google Scholar from the year 2016-2024. A theoretical study was conducted to identify and determine the relevant usability frameworks and models with the usability design factors to answer Research Question 1. As for Research Question 2, literature research was conducted in Google Scholar to explore the existing usability research for mobile applications in the past eight years. Studies adopted a different usability model for the mobile applications' design. It is observed that the Nielsen five quality components and ISO/IEC 9126 matrix are most adopted by researchers. Finally, to answer Research Question 3, seven usability factors were carefully selected and verified by the experts such as efficiency, help and documentation, learnability, memorability, user-friendliness, need-base, and push-base. Comparative analysis was also conducted on the existing 16 research papers and six Malaysia health service mobile applications. Overall, the fulfilment of usability factors to support older adult users was averagely low. This research identified the gap in determining the usability design framework that could be applied to mobile application design for older adults. This research is only limited to exploring the needs of older adults in the country of Malaysia as a pioneer study.

As the proposed usability design framework for older adult users is only preliminarily verified and agreed upon by two

experts, it is necessary to conduct a full exploratory study among the health service mobile application's older adult users to assess their agreement on the usability factors. The development of a health service mobile application prototype that covers the seven proposed usability factors as a proof-of-concept product for the older adult users' exploration is highly recommended. A quantitative analysis could then be conducted to measure the relationships between the seven usability factors and the acceptance or satisfaction level of health service mobile applications among older adult users. It is expected that once this future work is completed, a usability design framework to support health service mobile applications for elderly users could be proposed and adopted in Malaysia. This effort would increase Malaysian older adults' health system accessibility rate and digital healthcare value in Malaysia too.

Physical Education Institute, Xinyu University, Xinyu 338000, Jiangxi, China[1, 2]
College of Physical Education and Health, Jiangxi Science and Technology Normal University, Nanchang 330000, China[3]

***Abstract*—Badminton, as a popular sport in the field of sports, has rich information on body motions and motion trajectories. Accurately identifying the swinging motions during badminton is of great significance for badminton education, promotion, and competition. Therefore, based on the framework of Faster R-CNN multi object tracking algorithm, a new badminton tracking and motion evaluation model is proposed by introducing a VGG19 network architecture and real-time multi person pose estimation algorithm for performance optimization. The experimental results showed that the new badminton tracking and motion evaluation model achieved an average processing speed of 31.02 frames per second for five bone points in the human head, shoulder, elbow, wrist, and neck. Its accuracy in detecting the highest percentage of correct key points for the head, shoulders, elbows, wrists, and neck reached 98.05%, 98.10%, 97.89%, 97.55%, and 98.26%, respectively. The minimum values of mean square error and mean absolute error were only 0.021 and 0.026. The highest resource consumption rate was only 6.85%, and the highest accuracy of motion evaluation was 97.71%. In addition, indoor and outdoor environments had almost no impact on the performance of the model. In summary, the study aims to improve the fast region convolutional neural network and apply it to badminton tracking and motion evaluation with higher effectiveness and recognition accuracy. This study aims to demonstrate a more effective approach for the development of badminton sports.**

Keywords*—Faster RCNN; VGG19; badminton; target tracking; motion evaluation

I. Introduction

With the popularity and popularization of badminton in international sports events, its training methods have gradually become diversified [1]. In order to better track targets in badminton sports scenes, prevent injuries caused by non-standard technical motions, and promote more standardized training, it is necessary to conduct in-depth discussions on badminton tracking and motion evaluation methods. Currently, common object tracking algorithms include Visual Object Tracking (VOT), Multiple Object Tracking (MOT), and Multi-Camera Multi Object Tracking (MCMOT) [2]. The Fast Region Convolutional Neural Networks (Faster RCNN) multi object tracking algorithm based on deep learning is currently the mainstream object tracking method in the field of motion detection [3]. Numerous researchers both domestically and internationally have explored the Faster RCNN multi object tracking algorithm. For instance, J. Meza et al. developed a Faster RCNN method on the basis of transfer learning to significantly improve public transportation and achieve real-time localization in highly occluded scenes. The method could effectively shorten travel time, improve road smoothness, thereby controlling the fleet and reducing congestion [4]. T. Shimizu et al. analyzed the difficulty of target tracking in open surgeries such as plastic surgery. A method for analyzing and evaluating open surgical videos was created by combining Faster RCNN localization, Residual Network 18 (ResNet-18), and Long Short Term Memory (LSTM) modules. The experimental results showed that this method successfully detected two different open surgeries. It was superior to the commonly used two baseline methods [5]. H. Li et al. aimed to optimize the management efficiency of urban sports public services, facilitate residents to exercise, and increase their happiness index. A smart target tracking model was proposed using the Faster RCNN algorithm. The experimental results showed that Faster RCNN had good accuracy and low average time. This model could guide different populations to fully utilize public service facilities, improve quality of life, and achieve good behavior in national sports [6]. X. Yin et al. designed an image object detection method on the basis of Faster RCNN to address the incomplete image feature extraction and low classification accuracy in existing image object detection algorithms. The experimental results showed that the average accuracy was 91.04%, which had good image target detection ability [7].

Although the Faster RCNN performs well in object tracking and detection, badminton is a complex sports scene that is prone to occlusion and light interference during the motion process [8]. Therefore, to improve the accuracy of badminton target tracking and detection, and reduce the loss, it is necessary to deepen the network hierarchy of the Faster RCNN. Visual Geometry Group19 (VGG19) is an architecture in deep neural networks. It adds more convolutional layers and parameters than other architectures, which can not only better extract image features but also better process more complex image data. It has been used in various visual detection fields [9, 10]. X. Wan et al. found that traditional machine vision algorithms couldn't successfully detect defects in various steel strips. Therefore, on the basis of fast image preprocessing algorithms and transfer learning theory, a complete improved VGG19 neural network strip defect detection process was proposed. The improved VGG19 had a recognition accuracy of 97.8%. Its performance in six types of defects outperformed the baseline VGG19 [11]. R. Mohan et al. proposed a VGG19 for diagnosing various lung diseases from chest CT images on the ground of customized medical image analysis and detection networks. The experimental results showed that in multi class classification tasks, the training accuracy and

testing accuracy of VGG19 performed excellently [12]. A. Faghihi et al. analyzed the skin lesion classification using Convolutional Neural Network (CNN) technology. A pre-trained neural network application transfer learning framework was constructed using VGG19. Compared with other methods, the classification accuracy of the method reached 98.18% [13]. To develop the non-invasive diagnostic method for Obstructive Sleep Apnea Hypopnea Syndrome (OSAHS) patients, L. Ding et al. proposed a pre-trained VGG19 and LSTM fusion model to classify the snoring sounds of simple snorers and OSAHS patients. The experimental results showed that the VGG19+LSTM had the highest classification accuracy of 99.31% for simple snorers snoring and OSAHS patients snoring [14].

In summary, current target tracking and detection technologies both domestically and internationally still face many challenges in dealing with occlusions and similar object interference in complex dynamic environments. Although various studies have attempted to enhance multi-object detection in images by integrating deep learning network models with the VGG19 architecture, as well as using new algorithms such as CNN and Faster RCNN, there is still a significant gap between the current detection performance and the expectation in practical applications. These gaps are mainly reflected in insufficient robustness, making it difficult to stably track targets in environments with high occlusion or similar object interference; real-time performance has not yet met the requirements of some application scenarios, especially in sports motion analysis that requires rapid response; limited generalization ability, with poor adaptability to data under different environments and conditions; and high consumption of computing resources, which restricts the application on devices with limited resources. Therefore, an innovative badminton tracking and motion evaluation model based on Faster RCNN and improved VGG19 is proposed in the study. By combining the powerful object detection and tracking capabilities of Faster RCNN with the VGG19 feature extraction, it can solve the existing challenges in badminton tracking and motion assessment technologies and further improve the accuracy of badminton tracking and motion assessment, thus providing a more efficient and accurate motion assessment solution for the field of badminton sports. This study is divided into five sections, first being the introduction. The second section introduces how the Faster RCNN target tracking algorithm is improved and how the optimized design model is established. The third section is performance testing of the new model. The fourth section is the discussion of the results. The last section is a summary of the paper.

II. Methods and Materials

In response to the existing problems in badminton tracking and motion evaluation, such as the challenge of dealing with severe occlusion and similar appearance interference in complex sports environments, this study first introduces the basic framework of Faster RCNN algorithm from the perspective of badminton target tracking. The VGG19 architecture is introduced and significantly improved. In addition, from the perspective of evaluating the motions of badminton players, the Faster RCNN-VGG19 target tracking algorithm is used as the framework foundation, taking the real-time multi person pose estimation algorithm (OpenPose) for further optimization. Through these improvements, a new comprehensive badminton tracking and motion evaluation method is ultimately proposed, aiming to improve the accuracy and real-time performance of badminton tracking and motion evaluation.

A. Construction of 3D Object Tracking Model Based on Faster RCNN and VGG19

In order to enable athletes to master the basic motions of badminton in a standardized manner and achieve precise and real-time motion evaluation, it is necessary to quickly and accurately detect and track moving targets. The Faster RCNN is a target detection algorithm in the RCNN series, which has strong target recognition capabilities [15]. It mainly contains two parts, namely the Region Proposal Network (RPN) and the target classification network based on target feature classification [16]. The RPN network and the object classification network share weight parameters, and the two networks are trained collaboratively, which can promote the network to have good robustness and accuracy. The Faster RCNN is displayed in Fig. 1.

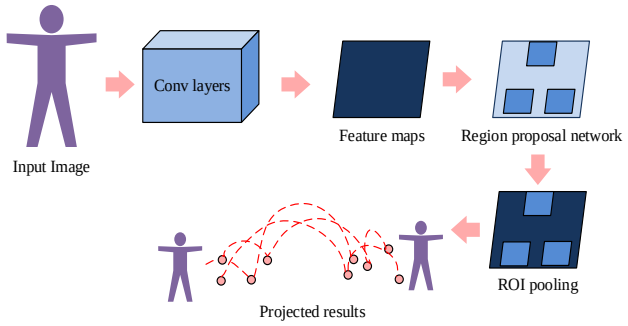

Fig. 1. Structure of the faster RCNN algorithm.

In Fig. 1, the Faster RCNN is mainly divided into three stages. Firstly, the motion image data is input into the network to obtain the corresponding feature image data. Secondly, the RPN is used to produce candidate boxes, mapping the candidate boxes generated by the RPN structure to the feature image data to obtain the relevant feature matrix. The obtained feature matrix is scaled to a size of 7×7 through the Region of Interest Pooling (ROI pooling) layer. Then, the 7×7 feature map is flattened and the final prediction result is obtained through fully connected layers. However, due to the limited appearance features of the small-sized shuttlecock, it is difficult to effectively distinguish the shuttlecock from similar small targets such as sneakers, light spots, and spectators' heads using the limited appearance features [17]. In addition, the traditional Faster RCNN uses the VGG16 framework, which cannot deepen the network hierarchy on the existing basis [18]. Therefore, in order to solve such problems, the study modifies the VGG16 framework in the Faster RCNN to the VGG19 framework. A new algorithm, namely the Faster RCNN-VGG19 object detection algorithm is proposed. The basic structure of the VGG19 framework is shown in Fig. 2.

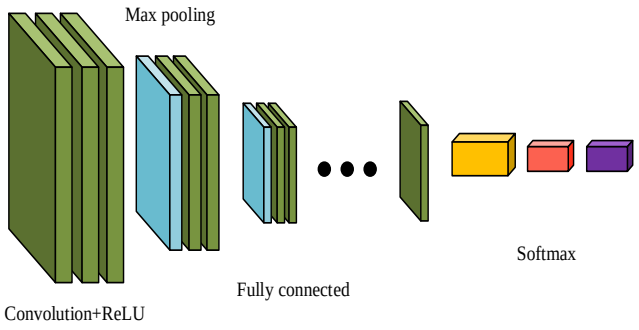

Fig. 2. Basic structure of the VGG19 framework.

In Fig. 2, the VGG19 framework mainly contains six parts: convolutional layer, batch normalization layer, ReLU activation function, maximum pooling layer, fully connected layer, and classifier [19]. The total depth of the network is 19 layers, including 16 CNN and 3 fully connected layers. The 16 CNN is further divided into 5 convolutional layers with varying numbers. The special structure of VGG19 can preserve all the features of the input image as much as possible, ensuring that the resolution of each layer's output and input is equal [20]. Batch normalization $y^{(q)}$ is shown in Eq. (1).

$$y^{(q)} = \gamma^{(q)} \frac{x^{(q)} - \mu^{(q)}}{\sqrt{(\sigma^{(q)})^2 + \varepsilon}} + \beta^{(q)} \tag{1}$$

In Eq. (1), $\gamma^{(q)}$ and $\beta^{(q)}$ represent learnable parameters. $x^{(q)}$ and $\mu^{(q)}$ represent the q-th dimensional input data and mean of the data, respectively. $\sigma^{(q)}$ represents the standard deviation. ε represents a number that prevents the denominator from being 0. Batch normalization can reduce the gradient vanishing and exploding, and accelerate the convergence speed of neural networks [21]. The ReLU is displayed in Eq. (2).

$$\mathrm{Re}\,LU(x) = \begin{cases} \max(x, 0), x \geq 0 \\ 0, x < 0 \end{cases} \tag{2}$$

In Eq. (2), x signifies the input data. When x is greater than or equal to 0, $\max(x, 0)$ is output. When x is less than 0, the output is 0. The ReLU (Rectified Linear Unit) activation function can perform a nonlinear transformation on the output of a neural network, thereby increasing the network's expressive and fitting capabilities. However, when the ReLU activation function encounters a situation where parameters need to be corrected during backpropagation, if the input is negative, the gradient becomes 0, which leads to an inability to adjust the parameters, resulting in the so-called "Dead ReLU" problem [22]. Therefore, the study introduces Leaky ReLU to address the DeadReLU of the ReLU in VGG19. The Leaky ReLU is shown in Eq. (3).

$$Leaky\,\mathrm{Re}\,LU(x) = \begin{cases} ax, x \geq 0 \\ x, x < 0 \end{cases} \tag{3}$$

In Eq. (3), a signifies the specified parameter, usually taking the smaller value. Leaky ReLU has a gradient even when the input is less than 0, and it possesses linear and non-saturating properties, which allows for fast convergence. It does not require exponential computations, making it computationally efficient and capable of addressing the issue of un-updatable weights in the standard ReLU activation function. The eigenvalue weight w_i is shown in Eq. (4).

$$w_i = \frac{e^{b_i}}{\sum_{j \in R} e^{b_j}} \tag{4}$$

In Eq. (4), b and R represent the feature map and local region, respectively. The eigenvalue weights ensure the transmission of important features, and during backpropagation, the features within the region will have a preset minimum gradient. Although the VGG19 framework can address the difficulties in tracking and recognizing small targets in the Faster-RCNN neural network algorithm, due to the effects of occlusion and lighting changes, there are still inevitable false positives and missed detections in the badminton detection results [23, 24]. Therefore, the study utilized the commonly employed triangulation algorithm from stereo vision matching to fuse the two-dimensional coordinates of the ball from multiple camera perspectives into three-dimensional coordinates, proposing a 3D target tracking model based on Faster RCNN and VGG19. The target tracking process framework of this model is shown in Fig. 3.

From Fig. 3, the target tracking process of the 3D target tracking model based on Faster RCNN and VGG19 is mainly divided into four stages: badminton 2D detection stage, badminton 2D tracking stage, badminton 3D coordinate fusion stage, and badminton 3D trajectory smoothing stage. The study first conducts badminton 2D detection in various camera perspectives based on the Faster RCNN-VGG19 object detection algorithm. Then, a 2D tracking algorithm based on Efficient Convolution Operators (ECO) is used to track the badminton balls in various camera perspectives. Secondly, the triangulation algorithm is used to effectively merge multiple 2D coordinates into one 3D coordinate. Finally, the Kalman filtering method is used to process and obtain smooth 3D badminton trajectories. The 3D coordinate point of badminton is shown in Eq. (5).

$$p_t = \frac{1}{N} \sum_{1 \leq i, j \leq n} (p_t^{ij} \left| e_t^{ij} < \tau \right.) \tag{5}$$

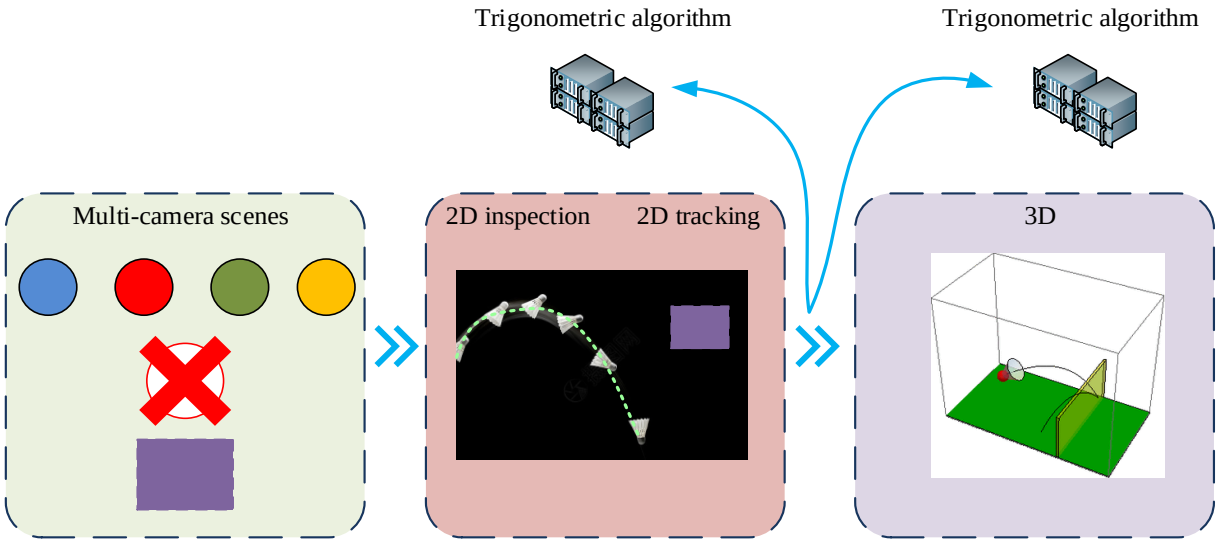

Fig. 3. Target tracking process framework for the proposed model.

In Eq. (5), p_t represents the three-dimensional coordinate fusion result of the badminton at time t. N signifies the number of camera matching pairs where the back projection error is less than the threshold τ. p_t^{ij} and e_t^{ij} represent the 3D coordinates and back projection errors calculated by the triangulation algorithm, respectively. The expression for maximizing probability $\hat{m}$ is shown in Eq. (6).

$$\hat{m} = \arg\max p(X_i^t = x_i^t, Y_i^t = Y_{j\in N(i)}^{t+1} \mid I^t) \tag{6}$$

In Eq. (6), X_i^t and x_i^t refer to whether there is badminton players or not, taking 0 or 1. Y_i^t and $Y_{j\in N(i)}^{t+1}$ represent the appearance characteristics of badminton players. The common evaluation metric for multi-object tracking algorithms is the Multiple Object Tracking Accuracy (MOTA). The study primarily takes into account three types of tracking errors — missed detections, false positives, and identity switches—for subsequent performance assessment. MOTA is shown in Eq. (7).

$$MOTA = 1 - \frac{\sum_t (c_1 \square fn_t + c_2 \square fp_t + c_3 \square idsw_t)}{\sum_t g_t} \tag{7}$$

In Eq. (7), c_1, c_2, and c_3 represent constants. g_t represents the true value. fn_t, fp_t and $idsw_t$ represent the number of missed detections, false detections, and number of identity exchanges, respectively.

B. Construction of Motion Evaluation Model Based on Faster RCNN and VGG19

After constructing a 3D object tracking model on the ground of Faster RCNN and VGG19, this study aims to address the various drawbacks of the badminton training system and attempt to optimize the model from the perspective of badminton motion evaluation. The first step in evaluating the motions of badminton players is to effectively obtain their posture information. Traditional methods for obtaining pose information often have drawbacks such as weak real-time performance, complex operation, and poor pose estimation performance [25]. The OpenPose can estimate the posture of the human body by analyzing key points in images or videos, identifying various parts of the body, and inferring the posture information. It can maintain accuracy even in complex environments [26, 27]. Therefore, OpenPose is introduced into the Faster RCNN-VGG19 object detection algorithm to analyze and process the posture information of badminton players. The basic structure of the Faster RCNN-VGG19-OpenPose pose estimation algorithm is shown in Fig. 4.

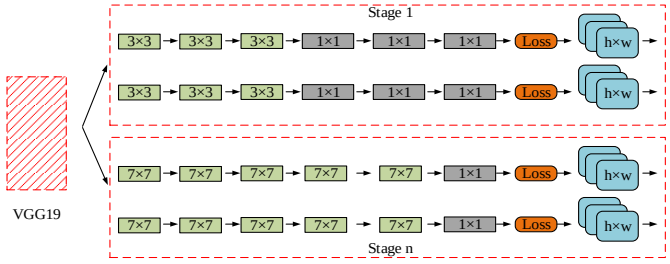

Fig. 4. The basic structure of OpenPose.

As shown in Fig. 4, the Faster RCNN-VGG19-OpenPose estimation algorithm is mainly divided into two parts, namely the limb confidence part and the site affinity vector field part. Firstly, the image is input into a parallel two branch Faster RCNN structure, and feature extraction is performed using the VGG19 architecture. Secondly, the feature maps of the image are obtained by clustering the bone points based on

initialization operation and greedy algorithm. Finally, the limb confidence prediction data and site affinity vector field prediction data are output through the limb confidence section and site affinity vector field. The predicted limb confidence data S^t and the predicted site affinity vector field data L^t are displayed in Eq. (8).

$$\begin{cases} S^t = \rho^t(F) \\ L^t = \varphi^t(F) \end{cases} \tag{8}$$

In Eq. (8), F represents the feature mapping. ρ^t and φ^t represent the CNN used for inference. In each subsequent stage, the original features and the two branch predictions generated in the previous stage are jointly input into the next stage, which can fully utilize the original features of the image to accurately predict the image in each stage. In addition, in order to successfully identify the categories of badminton swing motions, the research also cascades a fast Support Vector Machine (SVM) classifier based on the Decision Tree (DT) at the backend of OpenPose. The DT-SVM classifier can decompose nonlinear optimization problems into multiple linear SVM problems for solution, making the method simple and easy to implement. The DT structure diagram for badminton swing is shown in Fig. 5.

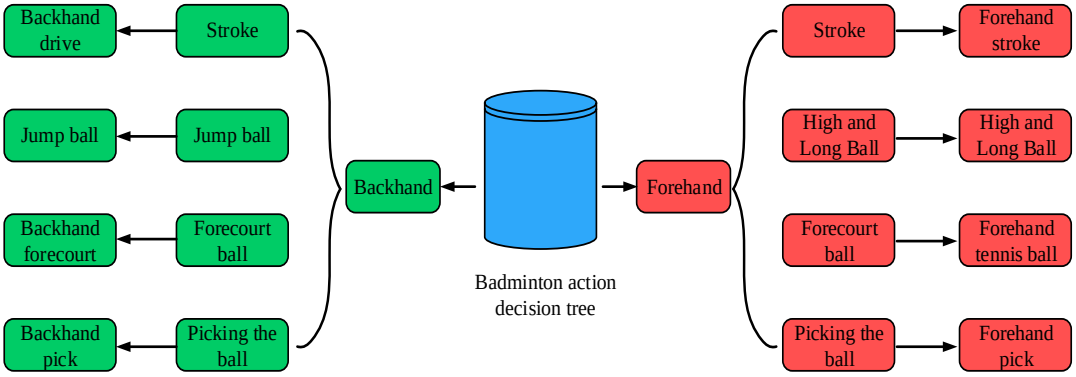

Fig. 5. Badminton swing decision tree.

From Fig. 5, the DT divides badminton swing motions into eight categories, namely high and long ball, Forehand stroke, forehand pick, Forehand tennis ball, jump ball, backhand drive, backhand pick, and backhand forecourt [28]. Firstly, the eight types of swing motions are combined to form a DT. During the classification process, each category needs to be selected before entering the next level, and unselected subtrees are deleted. This can effectively reduce the samples that need to be classified in the next step. The search step is repeated until the leaf node is reached. The final output result is obtained. However, the number of players in badminton training is generally large, and it is necessary to associate the results of the motion assessment with the target personnel; otherwise, the obtained sports assessment results will become meaningless [29]. Considering such situations, the study utilized the Particle Filter (PF) algorithm to deal with the non-Gaussianity of probability distributions in the tracking environment. The PF is shown in Eq. (9).

$$\begin{cases} x[t] = Ax[t-1] + v \\ y[t] = Cx[t] \end{cases} \tag{9}$$

In Eq. (9), $x[t]$ and $y[t]$ signify the coordinate values of the human skeletal neck. A represents the state transition matrix. v and C represent position random shift variables and diagonal matrices, respectively. The likelihood p^m of particles is shown in Eq. (10).

$$p^m = \frac{1}{\sqrt{2\pi\alpha^2}} \exp\left(-\frac{(d^m)^2}{2\alpha^2}\right) \tag{10}$$

In Eq. (10), d^m and α represent the degree difference and adjustable parameters, respectively. There are generally three annotation methods for human joint points: target instance annotation, target key point annotation, and image understanding annotation [30]. The key points of the human body during badminton motion are annotated based on target key point annotation. The annotation of key points in the human body is displayed in Fig. 6.

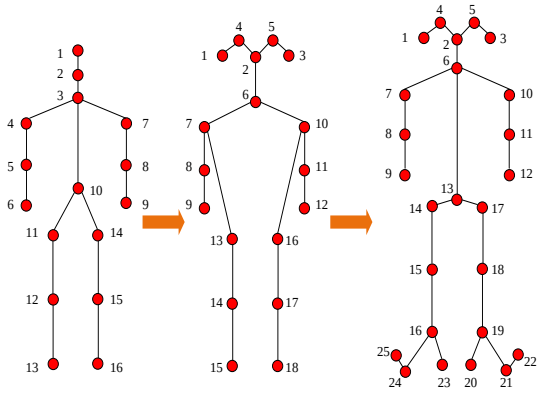

Fig. 6. Human body part key point labeling.

According to Fig. 6, there are three types of annotations for key points in the human body during badminton, namely 16 key points, 18 key points, and 25 key points. Among them, 18 key points increase facial key points compared with 16 key points, and 25 key points increase foot key points compared with 18 key points. The description of these three types of joint points can represent the skeletal information of the human body in detail, but these three methods will bring considerable computational complexity. Therefore, the study adjusts it by removing useless joints such as eyes and ears. The number of described joints is adjusted to 14. The distance $dis(x_i, x_j)$ between two joint points is shown in Eq. (11).

$$dis(x_i, x_j) = \sqrt{(x_i - x_j)^T M (x_i - x_j)} \tag{11}$$

In Eq. (11), x_i and x_j represent the positions of two joint points. M represents a symmetric positive semi-definite matrix. The rough pose representation metric is shown in Eq. (12).

$$E_{coarse}(W, B^*) = \left\| (x_n - x_n B^*)^T W_n \right\|_F^2 \tag{12}$$

In Eq. (12), B^* represents the coefficient matrix. x_n represents rough posture data, W then it represents the rank matrix of the entire column. Based on the above improvements, a motion evaluation model based on Faster RCNN and VGG19 is ultimately proposed. The motion evaluation process of this model is shown in Fig. 7.

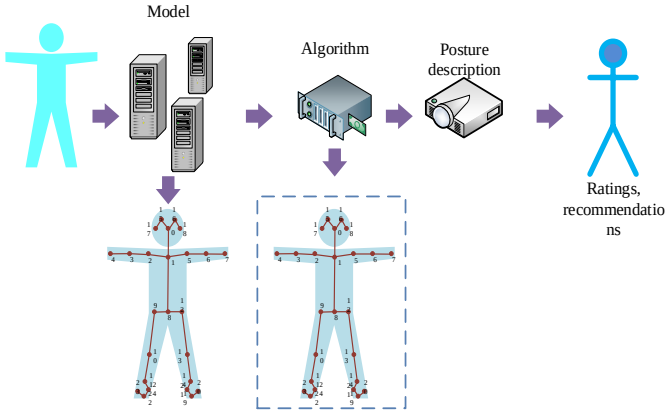

Fig. 7. The motion evaluation process of the proposed model.

From Fig. 7, the motion evaluation process mainly consists of four steps, namely the 3D target tracking model based on Faster RCNN and VGG19, posture estimation, granular posture description and scoring, and proposing motion suggestions. Firstly, a three-dimensional target tracking model based on Faster RCNN and VGG19 is used to quickly and accurately obtain the three-dimensional coordinates of badminton. Then, the position information of all human bones in the image is determined, and the prior standard parameters for each motion are obtained. Next, the posture image is described. Finally, the motion standard level is evaluated and motion suggestions are proposed.

III. Results

A. Faster RCNN-VGG19-OpenPose Algorithm Performance Testing

To verify the performance of the improved Faster RCNN-VGG19-OpenPose algorithm, a suitable experimental environment is established. The CPU is set to Intel Core i7 with a base frequency of 4.2Hz. The GPU is set to NVIDIA GeForce RTX 1660s, with 16GB of graphics memory and 16GB of memory. The Windows 10 is the operating system, Python as the algorithmic language. MPII and COCO datasets are used as the test data sources. The MPII dataset is a database of human body postures, containing approximately 25000 images and 40000 human body node information from different postures, and covering over 410 activities, all of which are sourced from YouTube videos. The COCO dataset is a dataset provided by the Microsoft team that can be used for image recognition, including various motion scenes. The study divided these datasets into training and testing sets in a ratio of 6:4, set the initial learning rate to 0.001, processed 100 frames per batch, and set the weight coefficient to 1. The study first conducts ablation tests on the Faster RCNN-VGG19-OpenPose algorithm using detection accuracy as an indicator. The test results are shown in Fig. 8.

Fig. 8(a) shows the ablation test results of each module of the Faster RCNN-VGG19-OpenPose algorithm on the training set. Fig. 8(b) shows the ablation test results of each module of the Faster RCNN-VGG19-OpenPose algorithm on the testing set. As shown in Fig. 8, with the continuous increase of iterations, the detection accuracy of each module showed an upward trend. The optimal detection accuracy of the basic Faster RCNN was 73.29%. After introducing the VGG19 architecture for optimization, the overall performance of the module improved by about 11%. The Faster RCNN-VGG19-OpenPose algorithm proposed in the study had the best performance, with the highest detection accuracy of 94.69% in the training set and a minimum of 298 iterations. The highest detection accuracy in the testing set was 93.08%, with a minimum of 243 iterations. From this, each module of the proposed algorithm has a positive effect on the overall performance, and the effect is significant. In addition, the study introduces popular target tracking algorithms for comparison, such as VOT algorithm, MOT algorithm, and MCMOT algorithm. A comparison test is conducted using tracking accuracy as an indicator, with a threshold of 200cm, as displayed in Fig. 9.

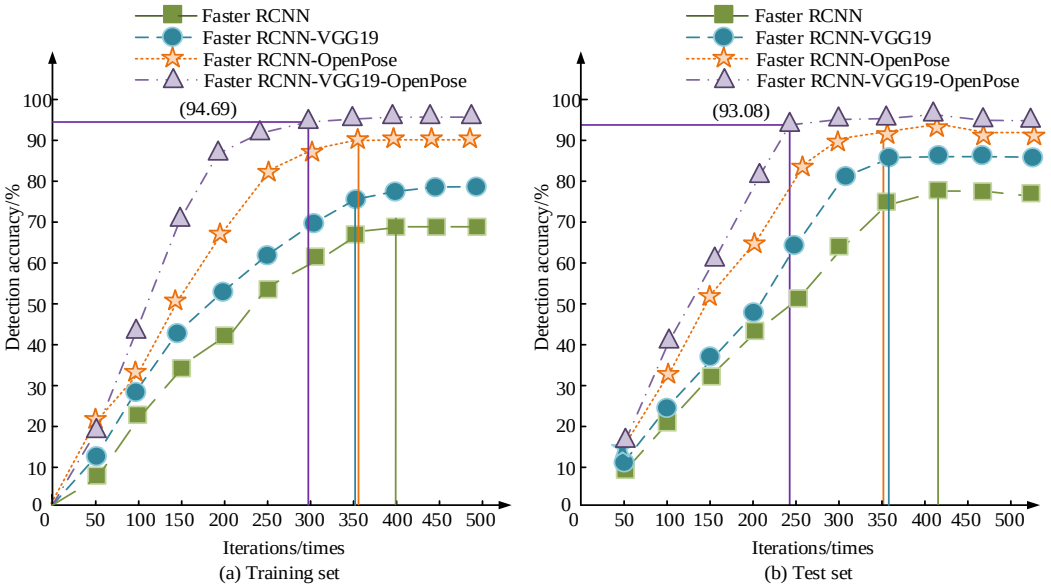

Fig. 8. Ablation test results of target tracking module with different datasets.

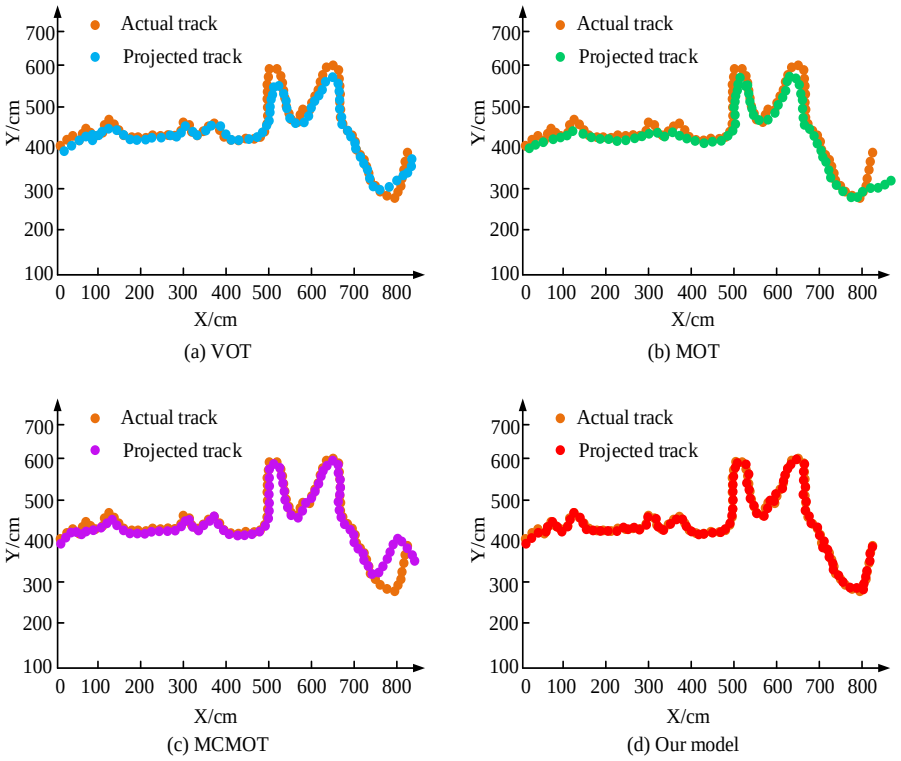

Fig. 9. Tracking accuracy of different target tracking algorithms.

Fig. 9(a) presents the comparison results of the VOT algorithm. Fig. 9(b) presents the MOT algorithm. Fig. 9(c) presents the MCMOT algorithm. Fig. 9(d) presents the Faster RCNN-VGG19-OpenPose. From Fig. 9, the Faster RCNN-VGG19-OpenPose algorithm had the highest overlap between the real trajectory and the tracked trajectory, followed by the MCMOT algorithm, and the worst overlap between the MOT algorithm and the VOT algorithm. This indicates that the proposed algorithm has strong robustness against common missed and false detections in detection. The VGG19 architecture deepens the hierarchy of Faster RCNN, alleviates tracking drift, and achieves stable tracking of badminton. The main differences between the models lie in their approaches to handling tracking problems and their adaptability to complex environments. The Faster RCNN-VGG19-OpenPose algorithm combines deep learning networks with human pose estimation technology, allowing it to more accurately capture the movement trajectory of a badminton shuttlecock, especially maintaining high tracking accuracy in situations where the shuttlecock is moving fast or there is occlusion. In

contrast, the VOT algorithm is primarily designed for tracking a single target and lacks the capability to track multiple targets, resulting in poor performance when dealing with multiple shuttlecocks or complex scenes. The MOT algorithm faces challenges in dealing with occlusions and similarities between targets, leading to a lower overlap between tracking and actual trajectories. Although the MCMOT algorithm has been improved for multi-camera environments, its performance is still not as good as the Faster RCNN-VGG19-OpenPose algorithm proposed in this study when dealing with fast-moving and complex backgrounds. To ensure the classification accuracy of the Faster RCNN-VGG19-OpenPose algorithm, the study also tests the classification accuracy of the Faster RCNN-VGG19-OpenPose algorithm for different badminton swing methods. The classification accuracy curve is shown in Fig. 10.

Fig. 10(a) presents the classification performance in the MPII. Fig. 10(b) shows the classification performance in the COCO dataset. From Fig. 10, the Faster RCNN-VGG19-OpenPose algorithm had the best classification performance in the two datasets. The best classification accuracy for badminton high and far balls, forehand strokes, forehand tennis balls, jump balls, and backhand picks reached 98.26%, 98.33%, 98.35%, 98.21%, and 97.08%, respectively, all exceeding 95%. Compared with the VOT algorithm, the Faster RCNN-VGG19-OpenPose algorithm improved the classification accuracy of high and far balls, forehand strokes, forehand tennis ball, jump balls, and backhand picks by about 18% to 25%. The above data indicates that the characteristics of the DT-SVM classifier in solving multi linear problems enable the Faster RCNN-VGG19-OpenPose algorithm to accurately classify badminton swing motions at each stage. Compared with other target tracking algorithms of the same type, it has more stable and superior recognition ability. The study also conducts multi-indicator tests on the above four algorithms using precision, recall, F1 value, and average detection time as indicators, as displayed in Table I.

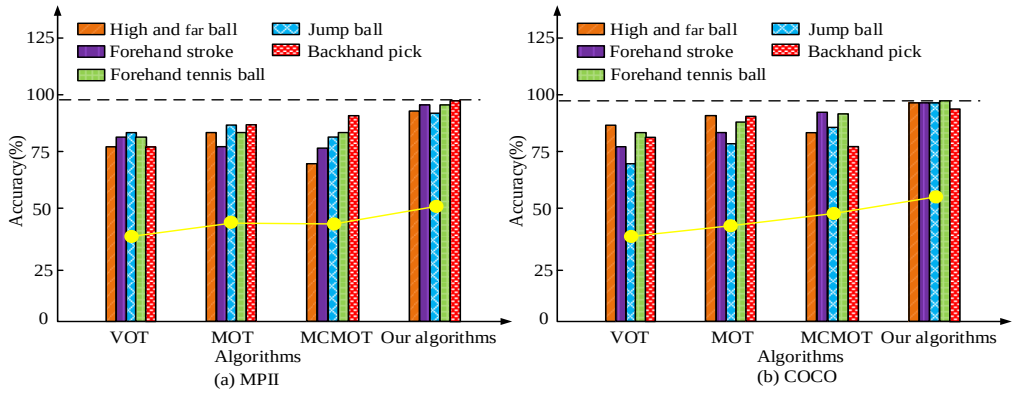

Fig. 10. Effectiveness of different algorithms in classifying badminton swing styles.

TABLE I. METRICS TEST RESULTS FOR VARIOUS ALGORITHMS

Data set	Algorithm	P/%	R/%	F1/%	Average detection time/s
MPII	VOT	88.86	87.38	88.57	5.18
	MOT	89.98	89.73	89.40	6.02
	MCMOT	91.87	88.64	90.26	5.38
	Faster RCNN-VGG19-OpenPose	95.41	94.28	95.85	2.74
COCO	VOT	89.28	88.16	88.37	4.61
	MOT	88.52	88.85	88.69	3.75
	MCMOT	91.43	90.79	91.11	3.08
	Faster RCNN-VGG19-OpenPose	95.56	93.68	95.32	2.51

According to Table I, among the four types of indicators detected, the VOT target tracking algorithm performed the worst, followed by the MOT target tracking algorithm, MCMOT target tracking algorithm, and the proposed Faster RCNN-VGG19-OpenPose algorithm. The highest P-value of the VOT target tracking algorithm was 89.28%, the highest R-value was 88.16%, the highest F1 was 88.37%, and the average detection time was 4.61s. The new Faster RCNN-VGG19-OpenPose target tracking algorithm proposed in the study had a maximum P-value of 95.56%, a maximum R-value of 93.68%, a maximum F1 value of 95.32%, and an average detection time of 2.51s. From this, the Faster RCNN-VGG19-OpenPose algorithm has relatively good performance, which is more suitable for the badminton tracking work at current stage.

B. Simulation Testing of Tracking and Motion Evaluation Model Based on Faster RCNN and VGG19

From the above test results, the Faster RCNN-VGG19-OpenPose algorithm performed excellently in badminton tracking and classification. However, this data is only feasible for the MPII and COCO datasets, and the persuasiveness and feasibility of the data results still need to

be further strengthened. The performance of the tracking and motion evaluation model based on Faster RCNN and VGG19 has not been verified yet. Therefore, the study attempts to use a self-made dataset for testing, which includes eight swing styles of badminton high and far balls, forehand strokes, forehand picks, forehand tennis ball, jump balls, backhand drives, backhand picks, and backhand forecourts. The number of videos for each badminton swing motion is 200, totaling 1400 video sequences. Each video sequence has a frame rate of 25fps, a resolution of 160x120, and an average length of 30s. At this point, the fuzzy comprehensive evaluation method is used to assign weights to the above motions. In addition, the study tracks the usage of GPU and CPU to record the time and storage space required for the model to process data. Tools such as Nsight are used to analyze resource utilization, adjust model parameters and structure to optimize efficiency, and test the long-term stability of the model in actual deployment to determine the resource consumption of each model. Table II displays the weighting results.

From Table II, the joint correlation under each motion, i.e. the weight score, was relatively reasonable and did not differ significantly from the actual physical sensation during motion. For example, in jump ball motions, there was a significant correlation between the weights of the legs, body, and knees. In forehand stroke, there is a significant correlation between the elbow, wrist, upper arm, and shoulder joints. The above motions are separately detected using confusion matrices. The same type popular motion recognition models are compared, including the LSTM model, Spatial Attention (SA), and Transformer network, as displayed in Fig. 11.

Fig. 11(a)-(d) show the confusion matrix results of LSTM, SA, Transformer, and the proposed model. From Fig. 11, the confusion matrix results for 7 different badminton swing motions under the LSTM model were poor, with only 4 groups scoring above 90 points. The same applies to the SA. There was a significant improvement in the confusion results of the Transformer, with 6 groups successfully paired for over 80 points. The confusion results of the model showed the best performance, with all 7 sets of badminton swing motions completed matching and scores above 90 points. Therefore, the designed method has certain effectiveness and performs better in similar models. In addition, to reflect the accuracy of the model in locating human skeletal points, the study also tests the model using the Percentage of Correct Key Points (PCK) and Frames Per Second (FPS) as indicators. The test results are shown in Fig. 12.

Fig. 12(a) shows the PCK performance of human bone point localization. Fig. 12(b) shows the FPS performance. As shown in Fig. 12, the proposed tracking and motion evaluation model based on Faster RCNN and VGG19 achieved an average FPS processing speed of 31.02 frames per second for five skeletal points in the human head, shoulder, elbow, wrist, and neck. Its highest PCK detection accuracy for the head, shoulder, elbow, wrist, and neck reached 98.05%, 98.10%, 97.89%, 97.55%, and 98.26%, respectively. The above data indicates that the new target tracking and motion evaluation model has unique advantages in recognizing human head, shoulder, elbow, wrist, and neck joint points. Finally, to explore the impact of the environment on the proposed model, the study also conducted comparative tests on the state-of-the-art motion assessment models under indoor and outdoor environments, using Mean Squared Error (MSE), Mean Absolute Error (MAE), resource consumption rate, and motion assessment accuracy as reference indicators. The models tested include detection methods based on the Deformable Parts Model (DFM), Tree-based Human Pose Estimation (TB-HPE), and Dual Source Deep Neural Network (DS-DNN) for human pose estimation. The test results are shown in Table III.

TABLE II. WEIGHTING VALUES FOR DIFFERENT MOTIONS AND JOINTS

Classification	High ball	Forehand stroke	Forehand pick	Forehand tennis ball	Jump ball	Backhand drive	Backhand pick	Backhand forecourt
Wrist	0.082	0.082	0.073	0.074	0.051	0.086	0.061	0.082

TABLE III. METRICS TEST RESULTS FOR DIFFERENT MODELS

Environments	Model	MSE	MAE	Resource consumption/%	Accuracy/s	References
Indoor	DFM	0.043	0.058	19.32	87.67	Lin L et al.
	TB-HPE	0.039	0.045	18.64	88.29	Gui W et al.
	DS-DNN	0.030	0.033	15.26	91.88	Xia Z et al.
	Our model	0.022	0.027	7.02	97.68	/
Outdoor	DFM	0.033	0.050	19.15	88.19	Lin L et al.
	TB-HPE	0.029	0.041	19.23	89.55	Gui W et al.
	DS-DNN	0.026	0.040	15.81	92.66	Xia Z et al.
	Our model	0.021	0.026	6.85	97.71	/

According to Table III, whether in indoor or outdoor environments, the DFM model had the worst performance in various indicators among the four models. The performance of TB-HPE, DS-DNN and the new target tracking and motion evaluation model increased from low to high. The proposed new target tracking and motion evaluation model had the lowest MSE value of 0.021, the lowest MAE value of 0.026, the lowest resource consumption rate of 6.85%, and the highest motion evaluation accuracy of 97.71%. Moreover, indoor and outdoor environments had almost no impact on the performance. In summary, the newly proposed model demonstrates the best overall performance and has more stable and superior recognition capabilities compared to the state-of-the-art motion assessment models currently available.

IV. Discussion

In the current field of sports motion target tracking and action assessment, deep learning technology, especially the application of Faster RCNN, has provided strong technical support for the automatic extraction of complex features from images. This enables algorithms to more accurately identify and track fast-moving sports targets, thereby significantly enhancing the accuracy and efficiency of target detection. However, due to the limited visual features of small-sized objects such as shuttlecocks, it is difficult for Faster RCNN to effectively distinguish them from similar small targets like sports shoes, light spots, and spectators' heads using limited visual features. In light of this, research has significantly improved Faster RCNN by introducing the VGG19 architecture, increasing the overall performance of the optimized Faster RCNN by about 11%. This indicates that the VGG19 architecture has a significant advantage in improving Faster RCNN's tracking and recognition of small targets. The result is consistent with the research findings of A Faghihi et al [13]. At the same time, in order to effectively obtain the posture information of the athletes, the study also used the improved Faster RCNN as the basic framework, and analyzed and processed the posture information of the badminton players through OpenPose and DT-SVM classifiers, finally proposing a tracking and action assessment model based on Faster RCNN and VGG19. Experimental results show that the proposed target tracking and action assessment model can achieve an average FPS processing speed of 31.02 frames per second for five key skeletal points of the human body: the head, shoulders, elbows, wrists, and neck. Moreover, its highest PCK detection accuracy rates for the head, shoulders, elbows, wrists, and neck reached 98.05%, 98.10%, 97.89%, 97.55%, and 98.26% respectively. This shows that OpenPose can process images in real-time and detect key points of multiple people, enhancing the model's joint point recognition ability. This is consistent with the research results of Chen C C et al. [31].

In summary, the research method has shown significant advantages in improving the accuracy, efficiency, and classification of badminton tracking and action assessment, which is consistent with the research conclusions of A Faghihi et al. and Chen C C et al., verifying the application potential and practical value of the method in target tracking and action assessment. Future work can further explore the integration of deep learning models, optimize algorithm efficiency, and expand the scope of applications to enhance the overall performance and applicability of sports motion analysis technology.

V. Conclusion

The research and development of sports tracking and motion evaluation have always been of great concern. The target recognition ability is crucial for athletes to achieve autonomous cooperation and optimized decision-making during the exercise process. In view of this, the Faster RCNN was used as the basic framework for target tracking. Then the VGG19 architecture and OpenPose algorithm were introduced for accuracy adjustment and pose estimation. Finally, a new badminton tracking and motion evaluation model based on Faster RCNN and improved VGG19 was proposed. Compared with other target tracking methods, the Faster RCNN-VGG19-OpenPose had the highest overlap between the real and tracking trajectories, which had good robustness, achieving stable tracking of badminton. The Faster RCNN-VGG19-OpenPose object tracking algorithm had a maximum P-value of 95.56%, R-value of 93.68%, and F1-value of 95.32%, with an average detection time of only 2.51s. It has relatively good performance, which is more suitable for the badminton tracking work at current stage. The simulation results showed that the proposed tracking and motion evaluation model based on Faster RCNN and VGG19 achieved an average FPS processing speed of 31.02 frames per second for five bone points in the human head, shoulder, elbow, wrist, and neck. Its highest PCK detection accuracy for the head, shoulder, elbow, wrist, and neck reached 98.05%, 98.10%, 97.89%, 97.55%, and 98.26%, respectively. The impact of the environment on the model was relatively small, and its overall performance was the best. Compared with similar motion recognition models, it has more stable and excellent recognition ability. In summary, the model has certain advantages and feasibility in the recognition and evaluation of badminton swing motions. However, this study only identifies a single badminton swing motion. Future research can add multiple combinations of badminton motions to improve the technical integrity. Additionally, although the study optimized the model through posture estimation technology, improving the estimation accuracy of the shoulder, elbow, and wrist joints, the estimation accuracy of other joint points has slightly decreased compared to the original model. To apply the research method to other more complex sports, future research can achieve more accurate human posture estimation by adjusting network structures, improving training strategies, or applying data augmentation techniques. At the same time, multimodal data, such as depth information or inertial sensor data, can be considered to enhance the model's ability to capture complex movements, thereby further improving the model's performance and providing more robust technical support for the rest of the sports training and assessment.

***Abstract*—This research paper explores the development and efficacy of a hybrid deep learning architecture for cyberbullying detection on social media platforms, integrating Convolutional Neural Networks (CNNs) and Long Short-Term Memory (LSTM) networks. By leveraging the strengths of both CNNs and LSTMs, the model aims to enhance the accuracy and sensitivity of detecting cyberbullying incidents. The study systematically evaluates the performance of the proposed model through a series of experiments involving a diverse dataset derived from various social media interactions, categorized by sentiment and type of bullying. Results indicate that while the model achieves high accuracy in identifying cyberbullying, challenges such as overfitting and the need for better generalization to unseen data persist. The paper also discusses ethical considerations and the potential for bias in automated monitoring systems, stressing the importance of ethical AI practices in social media governance. The findings underscore the complexity of automated cyberbullying detection and highlight the necessity for advanced machine learning techniques that are robust, scalable, and aligned with ethical standards. This study contributes to the broader discourse on the application of artificial intelligence in enhancing digital safety and advocates for a multidisciplinary approach to address the socio-technical challenges posed by cyberbullying in the digital age.**

Keywords*—*Cyberbullying detection; deep learning; CNN; LSTM; social media monitoring; sentiment analysis; digital safety

I. Introduction

Cyberbullying has emerged as a significant social problem with the rise of digital communication platforms. Unlike traditional forms of bullying, cyberbullying allows perpetrators to extend their reach beyond physical spaces, affecting victims at any time and from any location. This form of harassment is especially prevalent among adolescents and young adults and has been linked to a range of negative outcomes, including depression, anxiety, and even suicidal thoughts [1]. The anonymous and pervasive nature of online interactions complicates the detection and intervention processes, making it imperative to develop automated tools that can effectively identify and mitigate instances of cyberbullying.

Recent advancements in machine learning and natural language processing have paved the way for more sophisticated approaches to monitoring online behavior. In particular, deep learning architectures have demonstrated significant potential in text classification tasks, which are central to identifying harmful content [2]. However, the complexity of language, including the use of slang, coded messages, and context-specific references, poses unique challenges that require robust and adaptable models.

Hybrid deep learning architectures that combine convolutional neural networks (CNNs) and recurrent neural networks (RNNs) have shown promising results in various domains, such as image recognition and speech processing [3]. CNNs are adept at extracting hierarchical feature maps from spatial data, making them useful for capturing the textural patterns in language, whereas RNNs, particularly those using Long Short-Term Memory (LSTM) cells, excel in handling sequences with long-range dependencies, capturing the contextual nuances necessary for understanding the intent behind words [4].

The proposed research aims to leverage the strengths of both CNNs and LSTMs to develop a comprehensive model for cyberbullying detection on social networks. This approach is motivated by the hypothesis that a hybrid model can better accommodate the complex and dynamic nature of language used in online social platforms than models based solely on one type of network. By integrating the local feature extraction capabilities of CNNs with the sequence modeling strengths of LSTMs, the model is expected to perform with higher accuracy and sensitivity in detecting cyberbullying instances [5].

Additionally, the vast amount of data available on social networks provides a fertile ground for training deep learning models but also introduces challenges such as data imbalance, privacy concerns, and the need for models to perform well across diverse demographic groups. Addressing these challenges requires not only technical solutions but also an understanding of the social and ethical implications of deploying AI-driven monitoring tools [6].

The use of dropout layers and other regularization techniques in the architecture aims to prevent overfitting, ensuring that the model generalizes well to new, unseen data, which is critical in the ever-evolving landscape of social media language [7]. Moreover, the model's performance must be rigorously evaluated to ensure its efficacy and fairness,

preventing potential biases that could harm certain groups disproportionately [8].

This research contributes to the growing body of knowledge on AI applications in social good by providing a nuanced approach to detecting cyberbullying, which could be integrated into social networks as part of proactive measures to safeguard users. The outcome of this study has the potential to inform policies and practices not only for social media companies but also for educators and policymakers concerned with cyber welfare [9].

In summary, the increasing prevalence of cyberbullying and the limitations of current detection methodologies underscore the need for innovative solutions. This paper proposes a novel hybrid deep learning architecture that integrates the distinct advantages of CNNs and LSTMs, aiming to enhance the detection accuracy and operational efficiency of cyberbullying interventions on social platforms. By addressing both technical challenges and ethical considerations, this study seeks to contribute significantly to the safer utilization of digital spaces.

II. Related Work

The study of cyberbullying has garnered significant interest due to its profound impact on individuals and society. This section delves into the evolution of cyberbullying detection methodologies, tracing the trajectory from manual monitoring to sophisticated hybrid deep learning models. By examining past efforts and their limitations, this paper aims to underscore the novelty and necessity of the proposed approach in enhancing detection mechanisms on social media platforms [10].

A. Cyberbullying: Definitions and Impact

Cyberbullying is characterized by repeated behavior aimed at harming others using digital platforms. Definitions vary, but common elements include intent, repetition, and the use of electronic forms of contact [11]. As for its impact, studies have consistently shown that victims of cyberbullying exhibit higher levels of anxiety, depression, and even suicidal ideation, demonstrating the critical need for effective detection and prevention strategies [12].

B. Traditional Methods for Cyberbullying Detection

Initially, cyberbullying detection relied heavily on manual monitoring, where human moderators reviewed content to identify harmful behavior. However, this method is not scalable and is subject to human error and bias [13]. Subsequently, rule-based systems were developed, utilizing predefined keywords and patterns to automate detection. These systems, while faster, often failed to capture the context and complexity of human interactions, leading to high rates of false positives and negatives [14].

C. Machine Learning Approaches

The advent of machine learning heralded a new era in cyberbullying detection, with the development of sophisticated, feature-based models. Support Vector Machines (SVM) and Naive Bayes classifiers are prominent examples, employed extensively to analyze textual data. These models classify text by extracting and leveraging specific features such as word frequency and sentence structure [15]. Despite their initial success, these traditional machine learning approaches require extensive feature engineering to operate effectively. Moreover, their rigid frameworks often fail to adapt to the dynamic and evolving use of language typical of social media contexts. This limitation significantly restricts their practical applicability, as they cannot seamlessly accommodate new slang, code-switching, or emergent linguistic patterns without manual updates or retraining [16].

D. Deep Learning in Text Analysis

The limitations of traditional machine learning models led to the adoption of deep learning techniques, which can automatically learn features from data. Single-model architectures, particularly Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), have been widely used in text analysis due to their ability to extract spatial hierarchies and manage sequence dependencies, respectively [17]. CNNs are effective in extracting text patterns without the need for manual feature specification, while RNNs, especially those equipped with LSTM cells, excel in understanding context over longer text sequences [18]. However, each has limitations when used independently; CNNs can miss nuanced linguistic context, and RNNs can be computationally intensive and difficult to train on long sequences [19].

E. Hybrid Deep Learning Models

The concept of hybrid deep learning models, which integrate the strengths of CNNs and LSTMs, has started to gain traction. These models capitalize on CNNs' ability to process spatial data and LSTMs' proficiency in sequence processing, offering a robust framework for understanding complex text data. Such architectures have shown promise in fields like sentiment analysis and natural language processing, where both local features and global context are critical for accurate interpretation [20]. In the realm of cyberbullying detection, these hybrid models are proposed to enhance accuracy by effectively capturing both the textual nuances and the broader semantic context of interactions [21].

F. Challenges and Ethical Considerations

Implementing deep learning models for cyberbullying detection on social networks introduces several challenges. Data imbalance—where instances of bullying are vastly outnumbered by normal interactions—can skew model training and performance [22]. Privacy is another significant concern, as these models require access to personal data, potentially infringing on user confidentiality [23]. Moreover, the deployment of such models must be handled with care to avoid biases that could disproportionately affect certain demographics, necessitating continuous evaluation to ensure fairness and ethical integrity [24].

G. Research Gaps and Opportunities

Despite the advancements in detection technologies, several research gaps remain. Current models often fail to consider the multi-modal nature of cyberbullying, which can include text, images, and videos. Moreover, the adaptability of models to new, evolving forms of language and bullying tactics is still limited. There is a pressing need for models that can dynamically learn and adapt from incoming data streams without requiring frequent retraining [25]. Furthermore, there is a lack of comprehensive studies that integrate ethical

considerations into the model development process, an area ripe for further exploration [26-28].

III. Materials and Methods

A. Proposed Model

The proposed hybrid deep learning architecture integrates Convolutional Neural Networks (CNNs) and Long Short-Term Memory (LSTM) networks to exploit the strengths of both in detecting cyberbullying within textual data. This section elaborates on the configuration, interplay, and computational aspects of the model. Fig. 1 demonstrates the proposed model for cyberbullying detection.

The model comprises several layers, each tailored to perform specific functions critical to processing and classifying textual inputs:

Input Layer: This layer accepts pre-processed textual data, where each input unit represents a tokenized word encoded as a vector in a high-dimensional space.

Dropout Layer: Positioned immediately after the input layer, this layer randomly omits a fraction p of the input units (neurons) during training to prevent overfitting, where p is the dropout rate set to 0.5 as a starting point.

LSTM Layer: The LSTM layer processes the sequence data, preserving long-term dependencies within texts. The LSTM cells are formulated as follows:

$$i_t = \sigma\left(W_{ii}x_t + b_{ii} + W_{hi}h_{t-1} + b_{hi}\right) \quad (1)$$

$$f_t = \sigma\left(W_{if}x_t + b_{if} + W_{hf}h_{t-1} + b_{hf}\right) \quad (2)$$

$$g_t = \tanh\left(W_{ig}x_t + b_{ig} + W_{hg}h_{t-1} + b_{hg}\right) \quad (3)$$

$$o_t = \sigma\left(W_{io}x_t + b_{io} + W_{ho}h_{t-1} + b_{ho}\right) \quad (4)$$

$$c_t = f_t \otimes c_{t-1} + i_t \otimes g_t \quad (5)$$

$$h_t = o_t \otimes \tan g\left(c_t\right) \quad (6)$$

Where, I, f, g, and o are the input, forget, cell, and output gates, respectively; W and b represent weights and biases; σ denotes the sigmoid function; and ⊙ indicates element-wise multiplication.

Convolutional Layer: Following the LSTM, a convolutional layer is applied to extract local feature patterns from the output sequences of the LSTM, enhancing the model's ability to detect nuanced language patterns indicative of cyberbullying. The convolutional operation is defined as:

$$s(t) = (x * w)(t) = \sum_{a=-\infty}^{\infty} x(a)w(t-a) \quad (7)$$

where x is the input from the LSTM, w is the kernel, and s(t) is the convolved feature at time t.

Flatten Layer: This layer flattens the multi-dimensional output of the convolutional layer into a single-dimensional array for subsequent processing.

Output Layer: The final layer is a fully connected layer that maps the flattened features to the output classes, which are 'cyberbullying' and 'non-cyberbullying'. The activation function used here is the softmax function, given by:

$$Soft\max(z_i) = \frac{e^{z_i}}{\sum_j e^{z_j}} \quad (8)$$

where z_i are the inputs to the output layer from the flatten layer.

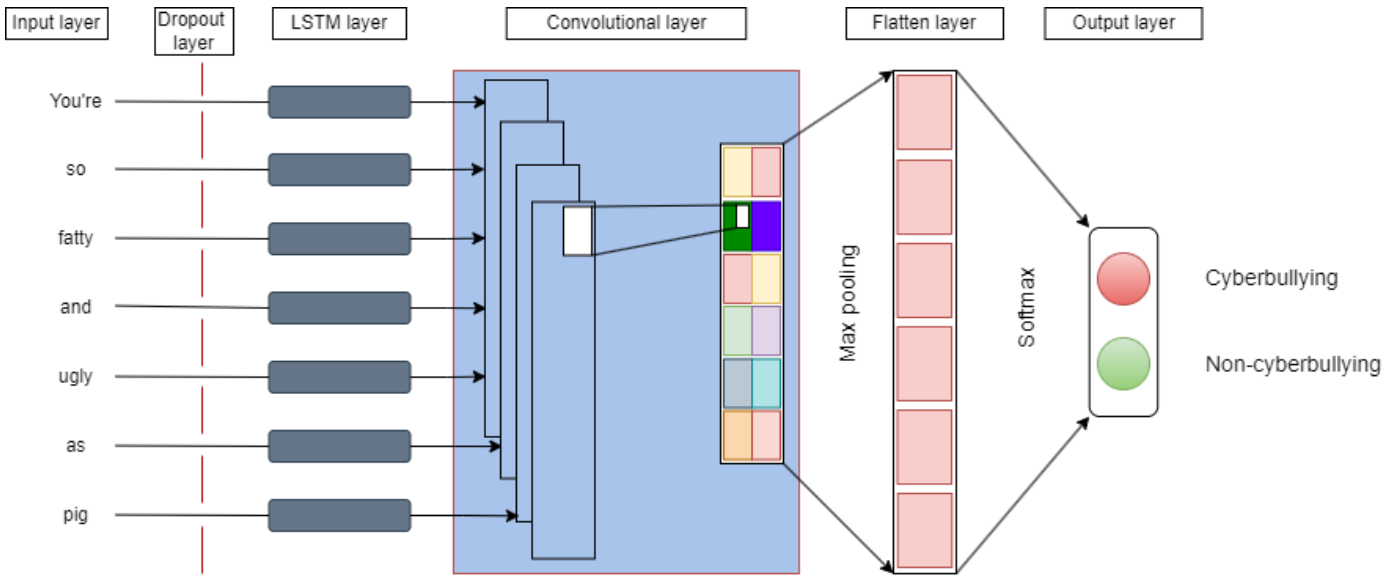

Fig. 1. Architecture of the proposed model.

The proposed model is trained using a cross-entropy loss function, which is suitable for binary classification problems like cyberbullying detection. The loss is calculated as:

$$L = -\frac{1}{N}\sum_{i=1}^{N}\left[y_i \log(\hat{y}_i) + (1-y_i)\log(1-\hat{y}_i)\right] \quad (9)$$

Where, N is the number of training samples, y_i is the actual label, and $\hat{y}_i$ is the predicted probability of the sample belonging to the 'cyberbullying' class.

By combining LSTM and CNN layers, the architecture harnesses both temporal dynamics and spatial feature extraction, making it robust against the complex variations in textual data typical of cyberbullying contexts. This model promises not only improved accuracy but also better generalizability across different social media platforms.

B. Dataset

The dataset utilized in this study is sourced from Kaggle and consists of structured data specifically tailored for cyberbullying detection tasks. This dataset is comprised of textual data collected from various social media platforms, providing a diverse representation of linguistic styles and contexts. It includes examples labeled with categories indicative of different forms of cyberbullying, facilitating the training and evaluation of machine learning models designed to identify and classify cyberbullying instances.

The data are categorized into distinct classes based on the nature and severity of the bullying behavior. This classification aids in fine-tuning the model's sensitivity to various forms of cyberbullying, from subtle to overt aggression. The dataset's structured format and comprehensive labeling make it an ideal resource for developing robust detection systems using advanced machine learning techniques such as the proposed hybrid deep learning architecture.

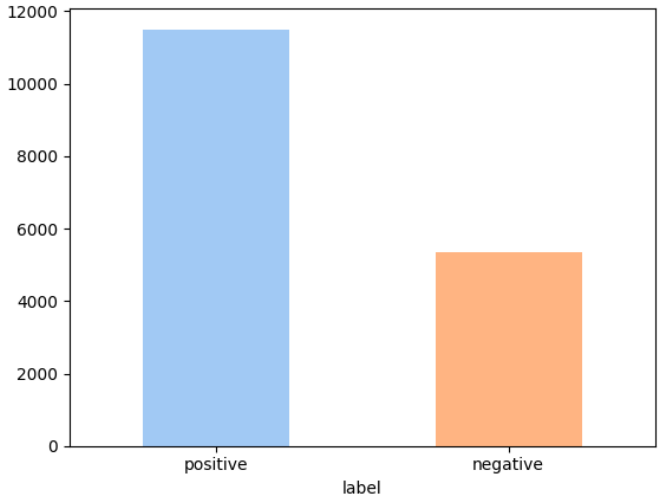

Fig. 2. Class distribution in the cyberbullying dataset.

This dataset not only enhances the model's ability to learn from real-world examples but also provides a benchmark for assessing the effectiveness of different architectural configurations and learning algorithms in accurately detecting cyberbullying across diverse digital environments.

In Fig. 2, the dataset depicted in the provided bar chart is characterized by a significant imbalance between two classes: "positive" and "negative". The "positive" class, which presumably represents instances identified as cyberbullying, substantially outnumbers the "negative" class, indicative of non-cyberbullying instances. This distribution highlights a common challenge in machine learning applications, where class imbalance can significantly impact the learning algorithm's ability to accurately generalize to new data. Such disparities necessitate the implementation of specialized techniques in data preprocessing, such as oversampling the minority class or undersampling the majority class, to ensure that the model trained on this dataset does not exhibit a bias towards the more frequently represented class. This imbalance also underscores the importance of employing robust evaluation metrics that can appropriately measure model performance in the presence of skewed class distributions.

IV. Results

A. Evaluation Parameters

In the context of this research paper on cyberbullying detection using a hybrid deep learning architecture, the evaluation of the model's performance is critical. This involves several key parameters that offer insights into the effectiveness and reliability of the model across various dimensions:

Accuracy measures the proportion of total correct predictions (both positive and negative) over all predictions made by the model. This metric is straightforward but can be misleading in datasets where class imbalance exists, as it might reflect the prevalence of the majority class rather than the model's ability to identify all classes accurately.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (10)$$

Precision assesses the correctness of positive predictions. In the context of cyberbullying, it measures the proportion of true cyberbullying instances among all instances flagged by the model as cyberbullying. High precision is crucial in this domain to minimize the number of non-bullying content mistakenly classified as bullying, which can have significant social and psychological impacts on users.

$$preision = \frac{TP}{TP + FP} \quad (11)$$

Recall, also known as sensitivity, recall quantifies the model's ability to identify all actual positives. It answers the question: "Of all the true cyberbullying instances, how many did the model correctly identify?" High recall is essential for ensuring that the model does not overlook cyberbullying instances, thus providing a safe online environment.

$$recall = \frac{TP}{TP + FN} \quad (12)$$

The F-score or F1-score is the harmonic mean of precision and recall. It is particularly useful when the balance between precision and recall is important to the application. The F-score provides a single metric that summarizes model performance in terms of both the precision and the recall, which is valuable in scenarios where both false positives and false negatives have serious implications.

$$F1 = \frac{2 \times precision \times recall}{precision + recall} \quad (13)$$

These metrics provide a comprehensive view of the model's performance, allowing for balanced optimization in scenarios where making accurate and reliable predictions is crucial. In cyberbullying detection, where the cost of false positives (non-bullying content flagged as bullying) and false negatives (failing to detect actual bullying) can be high, these measures help in fine-tuning the model to achieve optimal performance.

B. Data Preparation Results

Fig. 3 illustrates a word cloud generated from a topic modeling analysis on the cyberbullying dataset, depicting the most frequently occurring words within a specific cluster of the data labeled as "Topic 1." The prominent terms, including derogatory and offensive language, highlight the aggressive and harmful nature of the communications that are commonly identified in instances of cyberbullying. Words such as "dumb," "racist," and more severe pejorative terms point to the type of content that algorithms need to effectively identify and address. This visualization not only underscores the challenges of automatically detecting such harmful content but also serves as a stark reminder of the harsh reality faced by victims of cyberbullying. The word cloud thus provides a visual summary of the key themes and language used in cyberbullying, guiding the development of more nuanced detection mechanisms.

Fig. 3. Word cloud from cyberbullying dataset.

Fig. 4 presents the sentiment distribution across various topics derived from the cyberbullying dataset, segmented into negative, neutral, and positive sentiments. The vertical stacked bar graph illustrates a notable predominance of negative sentiments across all topics, underscoring the pervasive nature of negative expressions in discussions related to cyberbullying. Topic 0 exhibits a particularly high concentration of negative sentiment, dwarfing the other sentiments and suggesting a significant alignment with more aggressive or harmful content. In contrast, Topics 1 through 3 display a more balanced distribution but still with a visible skew towards negative sentiments. This visualization highlights the critical need for effective sentiment analysis tools in cyberbullying detection systems, as it underscores the varying emotional contexts that can pervade different discussion topics, aiding in more nuanced understanding and classification of potentially harmful content.

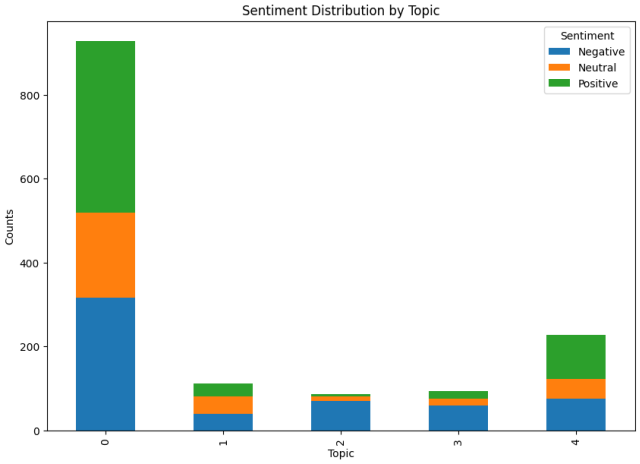

Fig. 4. Distribution of classes in the dataset.

Fig. 5 depicts the sentiment distribution across five different topics extracted from a cyberbullying dataset, with sentiments categorized as negative, neutral, and positive. The heat map highlights the count of sentiments within each topic, revealing a complex landscape of emotional expressions. Notably, Topic 0 is predominantly characterized by positive sentiments, contrasting sharply with other topics where negative sentiments prevail. This suggests that Topic 0 might encompass discussions or interactions of a different nature or context compared to the others. Topics 1 through 4 show a higher prevalence of negative sentiments, indicative of the adversarial or harmful content typically associated with cyberbullying. This distribution aids in understanding the emotional underpinnings of the topics discussed within the dataset and underscores the importance of sentiment analysis in contextualizing the interactions captured in social media data for cyberbullying detection.

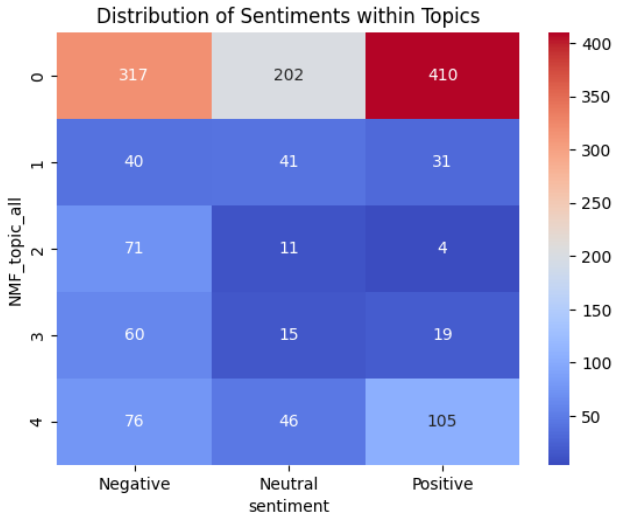

Fig. 5. Distribution of sentiments within topics.

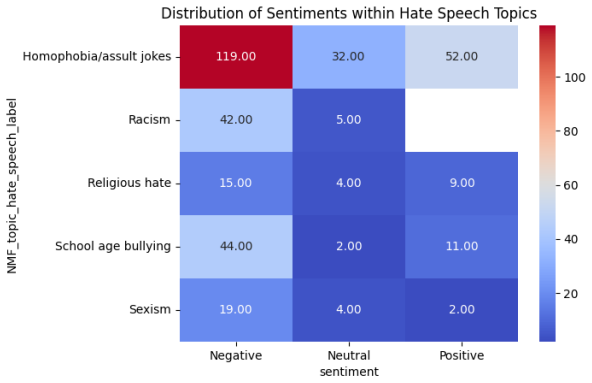

Fig. 6. Distribution of sentiments within hate speech topics.

Fig. 6 presents a heat map illustrating the distribution of sentiments categorized as negative, neutral, and positive across various hate speech topics derived from social media data. This visualization reveals that homophobia and assault jokes have a notably high incidence of positive sentiments relative to their negative sentiments, suggesting complex interactions that might include endorsements or trivialization of serious issues. In contrast, topics like racism, religious hate, school-age bullying, and sexism predominantly exhibit negative sentiments, aligning with the adversarial nature of the content. The presence of neutral sentiments across all topics indicates discussions that potentially include factual statements or undetermined stances. This detailed sentiment breakdown provides valuable insights into the nature of discussions within each hate speech category, underscoring the importance of nuanced analysis in automated detection systems to differentiate between contexts and intentions behind the words used.

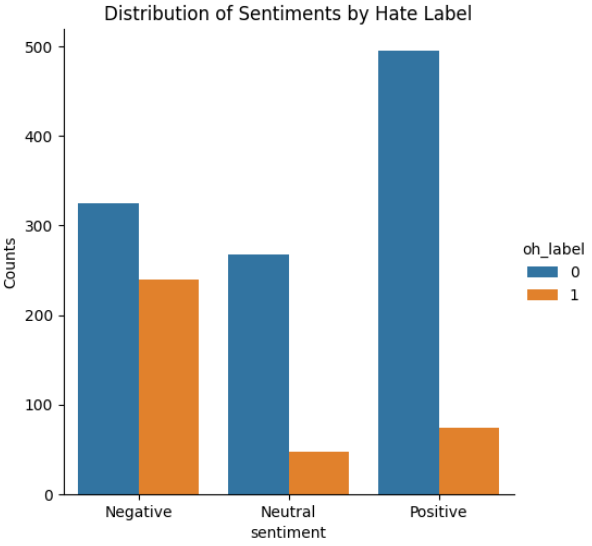

Fig. 7. Distribution of sentiments by hate label.

Fig. 7 displays a bar chart representing the distribution of sentiments categorized as negative, neutral, and positive across two distinct hate labels, identified here as "0" and "1". The labels likely denote the presence (1) or absence (0) of hate speech within the sentiments expressed. Notably, there is a predominant concentration of negative sentiments associated with the label "1", which underscores the alignment of negative sentiments with recognized hate speech. In contrast, sentiments labeled as "0", suggesting non-hate speech contexts, show a more balanced distribution among negative, neutral, and positive sentiments. This distribution highlights the complex relationship between expressed sentiments and their classification as hate speech, illustrating the challenge in distinguishing hate speech from non-hate speech based on sentiment alone. The data underscores the importance of sophisticated models that can interpret not only the sentiment but the context and intent behind expressions to effectively moderate content on social platforms.

The analysis presented in this subsection highlights the intricate relationship between sentiment and hate speech within digital communications. The visualizations and data distributions discussed reveal not only the prevalence of negative sentiments associated with confirmed instances of hate speech but also the more nuanced interplay of sentiments in texts labeled as non-hate speech. These insights underscore the challenges in deploying automated systems for the detection and moderation of hate speech, emphasizing the necessity for models that can adeptly discern context, intent, and sentiment nuances. Future research should focus on enhancing the accuracy and sensitivity of detection algorithms by incorporating multidimensional data analysis and applying advanced machine learning techniques that can better understand and process the complexities of human language and interaction in digital platforms. This approach is crucial for developing more effective and ethical tools for managing online safety and promoting positive digital communication environments.

C. Experimental Results

Fig. 8 presents a confusion matrix for a sentiment classification model applied to cyberbullying detection, displaying the numbers of true positive (TP), true negative (TN), false positive (FP), and false negative (FN) predictions. In the matrix, the horizontal axis represents the actual labels of the data ('Negative' and 'Positive'), while the vertical axis represents the predicted labels. The matrix shows that the model correctly identified 1498 negative cases and 531 positive cases as true negatives and true positives, respectively. Conversely, there were 228 cases where positive sentiments were incorrectly predicted as negative (false negatives), and 271 cases where negative sentiments were incorrectly labeled as positive.

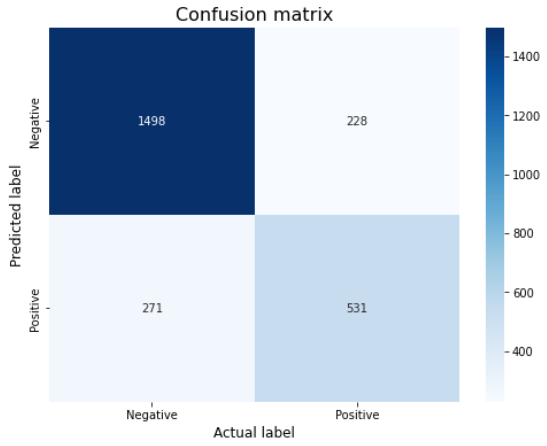

Fig. 8. Confusion matrix of sentiment classification model.

The significant number of true positives and true negatives indicates that the model is fairly effective in identifying both negative and positive sentiments accurately. However, the presence of false positives and false negatives highlights areas for potential improvement. The false negatives, in particular, are concerning because they represent instances where the model failed to detect positive sentiments, which could be crucial in contexts where affirming positive communication is as important as detecting negative or harmful content. Enhancing the model's sensitivity and specificity, possibly through more advanced feature engineering, optimization of hyperparameters, or the incorporation of context-aware algorithms, could further improve its performance. This analysis not only serves as a basis for evaluating the effectiveness of the current model but also guides future modifications and enhancements to better handle the complexities of sentiment analysis in cyberbullying contexts.

Fig. 9 displays the training and validation accuracy and loss of a deep learning model over several epochs. The left graph illustrates a steady increase in training accuracy from approximately 82.5% to 95.4% across six epochs, suggesting that the model is effectively learning from the training data. However, the validation accuracy starts around 90% and shows a declining trend to stabilize near 87.5%, indicating potential issues with overfitting as the model becomes too specialized to the training data and performs less effectively on unseen validation data. This divergence between training and validation performance is a common challenge in machine learning, highlighting the need for techniques like regularization or dropout to mitigate overfitting.

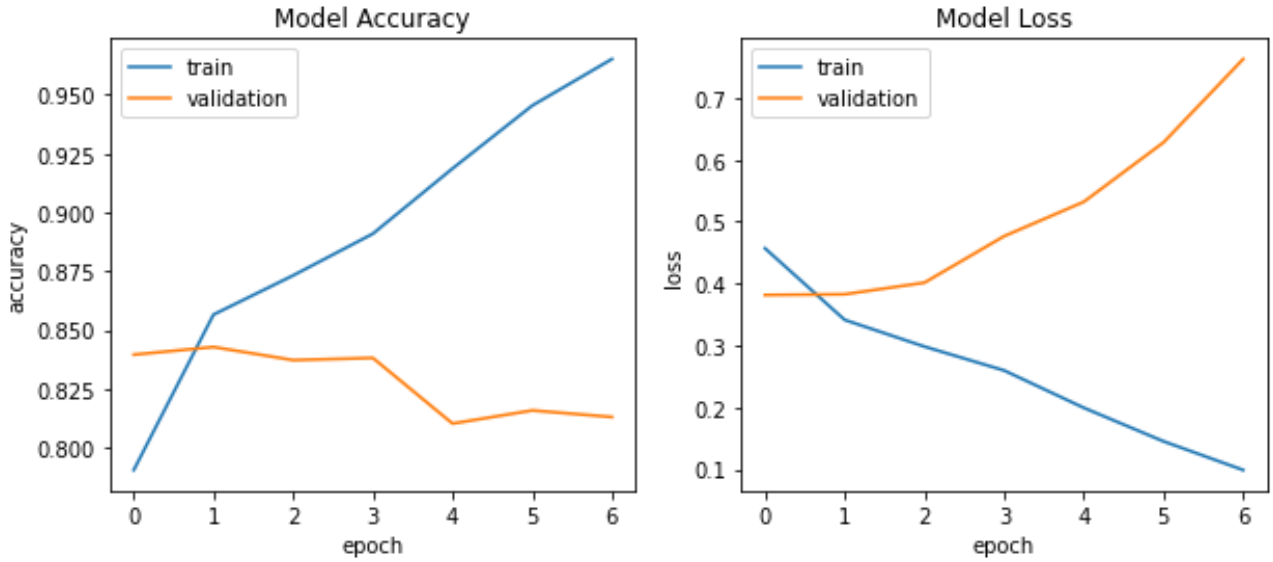

Fig. 9. Model accuracy and loss.

The right graph of model loss shows an inverse relationship to the accuracy graph. The training loss decreases sharply from about 0.7 to under 0.1, while the validation loss initially decreases but then begins to rise after the first epoch, reaching about 0.6 by the sixth epoch. This increase in validation loss alongside a decrease in validation accuracy further supports the possibility of overfitting. The early plateau and subsequent increase in validation loss could also suggest that the model's capacity is either insufficient or excessively tuned to nuances in the training data that do not generalize well. Addressing this might involve adjusting model parameters, introducing early stopping in training, or enriching the dataset to enhance the model's generalization capabilities. These adjustments are crucial for improving model robustness and ensuring reliable predictions across diverse data sets.

V. Discussion

The development and evaluation of a hybrid deep learning model to detect cyberbullying across social media platforms have yielded significant insights and highlighted several areas of concern and opportunity that warrant further discussion. The integration of Convolutional Neural Networks (CNNs) and Long Short-Term Memory (LSTM) networks in the proposed model aimed to leverage the spatial and temporal processing strengths of these architectures to enhance detection accuracy.

A. Model Performance and Overfitting

The proposed system demonstrated significant accuracy in the training and validation results, as illustrated in Fig. 9, demonstrate a clear disparity between training accuracy and validation accuracy, suggesting a tendency towards overfitting. This phenomenon, where the model performs exceptionally well on training data but less so on unseen validation data, is indicative of the model's inability to generalize beyond the training set [29-31]. Overfitting is a common challenge in machine learning, particularly in complex models such as deep neural networks. Strategies such as introducing dropout layers, increasing data augmentation, and employing regularization techniques have been recommended to mitigate this issue [32-34].

B. Sentiment and Hate Speech Analysis

The analysis of sentiments and their correlation with hate speech, as discussed through Fig. 5, 6, and 7, reveals a complex interaction between sentiment classifications and the

identification of hate speech. The prevalence of negative sentiments in recognized hate speech categories underscores the critical role of sentiment analysis in contextualizing content. However, the presence of positive and neutral sentiments within these categories also highlights the complexity of human communication, where not all harmful or aggressive communications are overtly negative [35-37].

C. Ethical Considerations and Bias

The deployment of AI in monitoring and moderating online content raises substantial ethical questions, particularly concerning privacy, consent, and the potential for bias. The model's susceptibility to biases, whether in data representation or algorithmic predilections, can lead to disproportionate flagging of content from specific demographics or linguistic groups [38-40]. It is crucial that continuous efforts be made to audit and refine these systems to ensure fairness and equity in automated content moderation [41].

D. Future Directions

Looking forward, the research highlights several pathways for improvement and further study. First, enhancing the model's generalizability through a more diverse and extensive dataset could help in reducing overfitting and improving the model's robustness across various social media contexts [42]. Second, exploring alternative hybrid architectures or newer approaches like transformer models, which have shown promise in other NLP tasks, might offer new avenues for increasing both accuracy and efficiency in processing [43-45].

Additionally, the integration of multimodal data, including images and videos alongside text, could provide a more holistic view of content, given that cyberbullying often transcends textual communication [46-47]. Finally, more nuanced understanding and classification frameworks are necessary to better differentiate between types of cyberbullying and their severities, which could aid in more targeted and effective interventions.

This research contributes to the ongoing discourse on AI's role in social media safety and the technical challenges associated with developing effective cyberbullying detection systems. While the results are promising, they also reflect the need for a cautious and considered approach to implementing such technologies. The balance between technological advancements and ethical considerations remains a critical frontier in the research and application of AI in societal contexts.

VI. Conclusion

The research undertaken in this paper has highlighted the pivotal role that hybrid deep learning architectures can play in the detection and analysis of cyberbullying across social media platforms. The integration of Convolutional Neural Networks (CNNs) and Long Short-Term Memory (LSTM) networks demonstrated potential in enhancing the accuracy of identifying harmful content by leveraging both spatial and sequential data processing capabilities. Despite this, challenges such as model overfitting and the need for greater generalization point to areas requiring further refinement. Ethical considerations around the implementation of AI in public domains, particularly concerning privacy, bias, and fairness, underscore the necessity for rigorous standards and continuous oversight in deploying such technologies. Future research directions should focus not only on improving the technical robustness of detection models through advanced machine learning techniques and diversified data sets but also on exploring the socio-technical impacts of AI interventions in human interactions. The balance between technological innovation and ethical responsibility remains a critical frontier in the application of AI, advocating for a multidisciplinary approach to ensure that advancements in AI contribute positively to societal welfare. This research contributes to a growing body of knowledge that seeks to harness the power of AI for social good, emphasizing the importance of aligning technological developments with human values and ethical standards.

***Abstract*—The Optimization provides a way through which an optimum can be achieved. It is all about designing accurate and optimal output for a given problems with using minimum available resources. It is a task which refers to minimizing an objective function f(x) parameterized by x or it is the task which refers minimizing the cost function using the model's parameters. In machine learning optimization is slightly different. Usually most of the problems, are very much aware about shape, size and type of data. Such information helps us to know where need improve. In case of machine learning optimization works perfectly when there is no knowledge about new data. The method proposed in this paper is named as Optimization with adaptive learning which is used to minimize the cost in term of number of iterations for linear regression to fit the correct line for given dataset to reduce residual error. In regression analysis a curve or line fit in such a way for the data objects, that the differences of distances between the data points and curve or line is always minimum. Proposed approach Initialize random values for parameters of linear model and calculate Error (SSE). Our objective is minimizing the values of SSE, if SSE is large, need to adjust the selected initial values. The size of the step used in each iteration is direction movement to reach the local minimum for optimal value. After performing certain repetitions of the deviation, minimum value for SSE has found and it has a stable value with no change. Real life data set have been used for expositional analysis.**

***Keywords*—Adaptive learning; regression; optimization; minimum; cost; objective; error; random**

I. Introduction

Optimization is a mathematical technique used to solve quantitative problems in a number of discipline like physics, engineering, computer science etc. Several problems be formulated and solved by combining ideas and methods with the field of optimization. In computer Science mathematical programming contains the study of the mathematical optimization and the study of the mathematical properties of these approaches [21,18]. The advances development in the optimization techniques in computer science are used to solve number of problems in operations research, game theory, and numerical analysis. The problem used for optimization have three basic components shown in Fig. 1, objective function, variables, and set of constraints. The objectives are expected as a return of costs or profits. Variables are the quantities values and can be manipulated so that to objective function can be optimized. Set of constraints for an optimization problem are restricted for values which can choose for the variables or parameters [20]. Research problem that found is how to achieve optimization is linear regression. Adaptive learning provides a way to archives optimization by using random initialization of the parameters [13,15]. Objective of the proposed work is to achieve optimization and reduce SSE for accurate prediction. The proposed work not only helps to students but as help to training institution of JEE examination, to prediction the marks and possibility for selection.

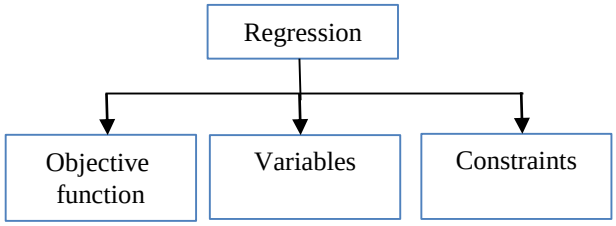

Fig. 1. Components used in regression analysis.

Regression analysis gives us number of benefits like

1) It shows important relations between variables.

2) It gives the effect of multiple explanatory variables.

II. Cost or Objective Function

The objective or cost function for analyzing regression is to find best fitted line for given inputs of x value and correct output for y value. Cost or objective function maps one or more variables on an actual instinctively representation related to predictor. ML models predict according to the new inputs [14,17].

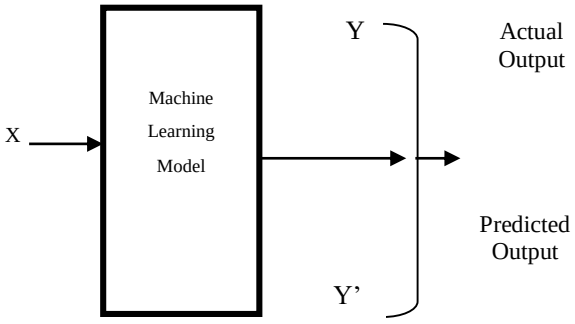

Fig. 2. Machine learning model.

The Error could be calculated by finding the difference between Predicted and Actual value:

Error = Y' (ML model Predicted value) - Y(Actual value)

A. Minimizing Error or Cost

Initial task of every ML model is to reduce cost. Minimizing value of cost functions will result to reduce error between the predicted value by ML model and actual value as shown in Fig. 2. Generally objective or cost function for linear regression is expressed in form of $\mathbf{Y = X^2}$. To minimize Objective or cost function, must find X to produce the correct Y value. The most common function required to minimize the parameters over a dataset is sum of squared error (SSE) and mean squared error (MSE). These errors ensure difference between the estimated value (prediction) and the estimator (the dataset) [16,19].

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(Y_i - \bar{Y}_i)^2$$

$$SSE = \sum_{i=1}^{n}(y_i - \bar{y})^2$$

The above equation can adjust a little to make the calculation down the track a little simpler. Squared differences have used instead using absolute, this helps to derive a regression line [22]. To discover correct line, used first deviation for cost or objective function, and it is difficult to calculate deviation for absolute values as compared to squared values.

III. Problem with Existing System

Objective of regression analysis is to discover types of relation between response and predictor to get correct value for unknown dataset. It is difficult to find most appropriate regression line that attempts to predict and best fit line for given dataset for two points [16,19]. Number of methods have already exist, but the problems is how can optimize the solution Some time it is difficult to select following variables [20,23].

- Response Variable
- Predictor Variable(s)
- Stop
- Coefficients

1) What are the techniques used that the selected model better trained or learn the past relationship?

2) Predicted error should be minimized.

3) How Hyperplane is decided that minimizes the vertical offsets?

In machine learning terminology, optimization is the task of minimizing the cost or values of objective function, function by the model's parameters has following problems:

- Criteria are not fixed for deciding the initial value for parameter.
- Find the lowest possible value of the SSE to minimize the error.

IV. Objectives

For the proposed approach our objectives are:

1) Use random initialization of the pampers, to minimize error, to get optimal output for problem.

2) Continuously apply different updated values for the coefficients, estimate and select new coefficients that have a marginally better value with reduced error.

3) The objective is to deal with real life problems and dataset.

4) Use first order derivation on data for training and check performance and validation new data.

V. Review of Related Works

Several authors have been proposed their work to improve accuracy of prediction for regression analysis and published their work in various journals. In proposed work several related papers have been studied understand the concepts and basic things. Erasmus et al. of proposed method for establishing empirical relationships using linear regression. They describe that assumptions are comparatively poor, the LR model describing a restricted expectation. Specification for model must selected carefully and it is crucial when estimates for the coefficients of interest [1]. Shen Rong et al proposed regression model used in ML. They collected forecast temperature data for one year and the sale of iced products. They created a mathematical regression model which based on theory of data mining. The proposed Linear regression model is based on the practical situation. They implemented proposed model with the latest and most popular Python3.6 [2]. Katarina Valaskova et al proposed Financial Risk Measurement and Prediction Modelling. They used financial data of an enterprises and calculate important financial ratios which is responsible for health of the company. They used important predictors for forthcoming success. Multiple regression analysis where also used and identified the important predictors [3] Darman et al proposed Grade prediction with MLR for Mathematics. They predict the students' score with used of MLR for Final Exam. Score of students used as response variable in the model and the predictor variables are the assessment for tests. They a regression model with the adding SPSS tool [4]. Gaurav Pandeya et al. proposed RM model COVID-19 for. They have collected data for a particular time periods for year 2020. They evaluated performance using 1.75 for the regression model. This was helpful Government and doctors for preparation of their plans for the next two weeks [5]. K. K. Basee et al. proposed analyzing for various Regression Models. They used linear regression, multivariate and nonlinear regression models. They developed exponential, logistic type of regression. They used mat lab software and wrote a code without using pre-defined function [6]. Ira Sharma et al. proposed Linear Regression Model for factors Related with Carbon Stock. The objective is to evaluate the factors related with carbon stock. Data have been taken from department of Forest Research and Survey (DFRS). Linear regression showed a good fit of the model [7]. Samit Ghosal et al proposed Linear Regression to predict the number of deaths due to COVID-19 in India. They trace a trend related to death counts. They interchangeably applied Multiple and

linear regression analyses. They employed auto-regression technique to improve the prediction [8]. Yujiang et al. proposed An Adaptive Learning for Regression. They clarified problem and proposed a new methodological framework to forecast targets. The framework contains neural networks, to store newly collected data [9]. M Tanveer et al. proposed LR model for evaluating models to estimate stature. They applied LR and R2 values for preferred model. 100 persona data were used for experimental [10]. Dengyuhan Dai proposed Factors Affecting the Linear Regression Model for Data Analysis. They discussed detail effects of numerous parameters on the linear fit of randomly generated data sets. They include noise, independent variables, and different sample size. They minimized the effectiveness of noise. The optimal choice of each parameter can be obtained by comparing the goodness of fit [11]. Hai-Tao Jin, Fei Wang proposed Linear Regression Analysis of Sleep Quality. Data collected from various demographic area of the participants and psychological scales. They used sample *t*-test one-way ANOVA and showed comparisons [12].

VI. Proposed Approach

Step 1: To achieve rapid optimization, apply adaptive technique, which help to getting faster results with minimum iteration and less efforts. Initialize with random small value to the parameter. Let say parameters are a(c) and b(m) were

$$(Y_{pred} = m\ X+c)$$

a is constant and b slop parameter with random values and calculate error (SSE)

Step 2: For large SSE, apply first derivation and calculate new value for parameter a and b it has very small change from their original initialized value.

$$SSE = \frac{1}{2}(Y - YP)^2$$

This provides direction for movement for what value of a and

b with SSE should minimize.

Step 3: After calculating new value for parameter apply to reach the optimal solution and again calculate new SSE**.**

$$\partial Error/\partial c = -(Y_{actual} - Y_{predicted})$$

$$\partial Error/\partial m = -(Y_{actual} - Y_{predicted}) * X$$

Here value updating in SSE by

$$SSE = \frac{1}{2}(Y_{actual} - Y_{predicted})^2 = \frac{1}{2}(Y_{actual} - (m * X + c))^2$$

Steps 4: During training after specific iterations and make sure error rate must be decreases.

Step 5: Repeat steps 2 and 3 for continuously adjustments of parameters until doesn't significantly reduce the SSE.

Step 6: Sometimes can apply 2nd order derivative which are extremely fast and accurate.

VII. Illustrate with Example using Demo Dataset

TABLE I. Demo Dataset with 10 Records

S. No	No of Hours Study 15 days (120 hours)	Predicted Score (100)
1	10	12
2	23	22
3	25	58
4	34	20
5	36	55
6	45	39
7	44	54
8	58	53
9	94	99
10	101	61

Table I shows 10 sample records. Decimal scaling is used to make calculation easy. Table II shows result after applying decimal scaling.

TABLE II. Result of Decimal Scaling (normalization)

S.No	No of Hours Study per Month (210)	Predicted Score (100)
1	0.10	0.12
2	0.23	0.22
3	0.25	0.58
4	0.34	0.20
5	0.36	0.55
6	0.45	0.39
7	0.44	0.54
8	0.58	0.53
9	0.94	1.00
10	1.01	0.61

Step 1: To better fitted a line

$$Y_{pred} = mb\ X+c,$$

Start with random values for parameter c and m and compute forecast error (SSE). Let first small random values for parameter c and m

$$c=0.46 \text{ and } m=0.74$$

Step 2: Calculate the Error w.r.t the parameters

$$\partial Error/\partial c = -(Y_{actual} - Y_{predicted})$$

$$\partial Error/\partial m = -(Y_{actual} - Y_{predicted}) * X$$

Step 3: Now update value in SSE by

$$SSE = \frac{1}{2}(Y_{actual} - Y_{predicted})^2 = \frac{1}{2}(Y_{actual} - (m * X + c))^2$$

$\partial Error/\partial c$ *and* $\partial Error/\partial m$ give the direction of the movement of c, m w.r.t to Error. Table III shows the result of first derivation and total error.

TABLE III. CALCULATING SSE WITH RANDOM VALUE

Error	$\partial Error/\partial c$	$\partial Error/\partial m$
0.102	0.45	0.00
0.076	0.39	0.09
0.001	0.05	0.01
0.126	0.50	0.17
0.017	0.18	0.07
0.077	0.39	0.18
0.031	0.24	0.11
0.063	0.35	0.20
0.09	0.14	0.13
0.175	0.59	0.59
Total (Error)=0.668	3.210	1.455

TABLE IV. CALCULATING ERROR GRADIENT WITH RESPECT TO WEIGHT

$Y_{Predicted}$ = m X+c	Error	$\partial Error/\partial c$	$\partial Error/\partial m$
0.42	0.087	0.42	0.00
`0.58	0.064	0.36	0.08
0.59	0.000	0.01	0.00
0.66	0.107	0.46	0.15
0.69	0.010	0.14	0.05
0.74	0.063	0.36	0.16
0.74	0.021	0.20	0.09
0.84	0.048	0.31	0.18
1.10	0.005	0.10	0.09
1.15	0.148	0.54	0.54
	Total (Error)=0.543	2.830	1.410

Table IV shows the reduced error with respect to weight. It is found with random values of c and m, total Error=0.668. In this situation, need to update these values.

Step 4: Adjust value of parameter with the initial random value to reach the optimal values and minimized the error.

Now, need to update parameter of c and m so that move in the direction for optimization. Now need to calculate

$$c - \partial Error/\partial c$$

$$m - \partial Error/\partial m$$

Step 5: The adaptive rules are:

$$c = c - R * \partial Error/\partial c$$

$$m = m - R * \partial Error/\partial m$$

Here, is the Adaptive rate (R) have small value which can be adjustable. In this case adaptive rate value is 0.01.

Step 6: Now use updated value of c and m for prediction are c=0.43 and m=0.72. Now again calculate Error

It is clear that new prediction, the total Error has reduced form (0.668 to 0.543). Accuracy of the prediction has been improved.

Step 7: Repeat step 3 to 5 further adjustments in the value of c and m until significantly reduce the error. At a situation when no change in the error value stop the repetition at last, got the optimal and highest prediction accuracy.

Table V shows the reduced error with updated value.

TABLE V. CALCULATING ERROR WITH RESPECT TO UPDATED VALUE

S.No	**Predicted value**	**Error**
1	0.45	0.087
2	0.62	0.064
3	0.63	0.000
4	0.70	0.107
5	0.73	0.010
6	0.78	0.063
7	0.78	0.021
8	0.88	0.048
9	1.14	0.005
10	1.20	0.148
		Total= 0.553

VIII. EXPERIMENTAL ANALYSIS AND RESULT

A. Description Bout Dataset

Performance of proposed approach were evaluated with real life dataset. Dataset has been collected from 4 JEE entrance examination preparation institute Indore M.P. (ALLEN, KALPVIKSHA, FIITJEE, NARAYANA COACHING). More 1000 students' data have been collected. Datasets contain number of hours study and score during preparation. Based on the score in preparation for JEE they got selected in final JEE examination. Dataset used number of hours students' study in 15 days and appeared in JEE test series of 100 marks. Decimal scaling is used for number of hours. Python language is used to implementation and dataset stored in CSV data.

B. Description about Implementation

Python language to implement the roped approach, pandas and matplotlib library is used for implantation. Plot regression function have created and passed three parameters x, m and c, for unknown values to predict the correct value of y with high accuracy. In a new array predicted value are appended. Another function is created for updating error and update the value of m and c by using first derivation and calculate new value of error. Scatter plot is used to show number of hours study by the student and predicted score. Data points are very close so that they are overlapped. Fig. 3 shows the positive relationship between the variables.

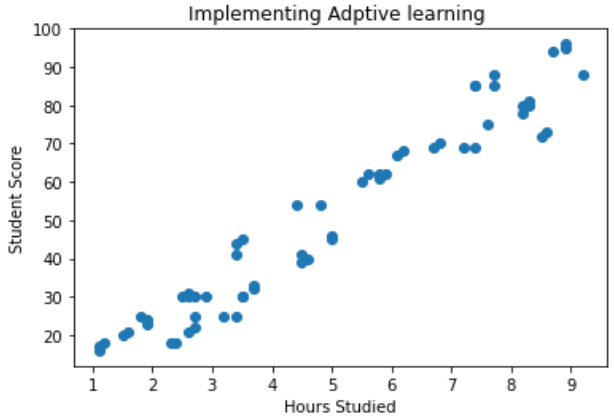

Fig. 3. Scatter plot for given dataset.

Initially the value selected for the m and c are 0.31 and 0.23, respectively. The selected valued used adaptive learning. From Fig. 4 staring with orange line and finally fitted the correct regression line for the given dataset. Fig. 4 shows the working process of adaptive learning. By the minimum number of iterations, got the best fitted line for the given dataset.

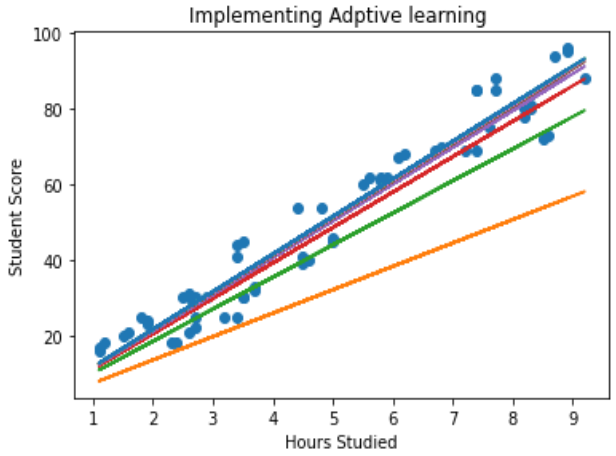

Fig. 4. Working process of adaptive learning.

In every iteration the reduced value of error has calculated. By the experimental analysis it is found that after 10 iteration the value of the error got minimized and has stable value (no minimization) at this point stop the process. Fig. 5 shows the change in value of parameters and the reduction in the error. Fig. 5 shows how the value of error gets reduced. In seconds iteration error is minimized to -5.33346109 just half of the first iteration. In the third iteration, it is minimized to -3.48410 and for fourth iteration it is minimized -2.762388. Similarly, in fifth, sixth, seventh, up to the tenth iteration the values of the error get minimized with very minor changes. So, after tenth iteration stop the process and got the best fitted line for given dataset.

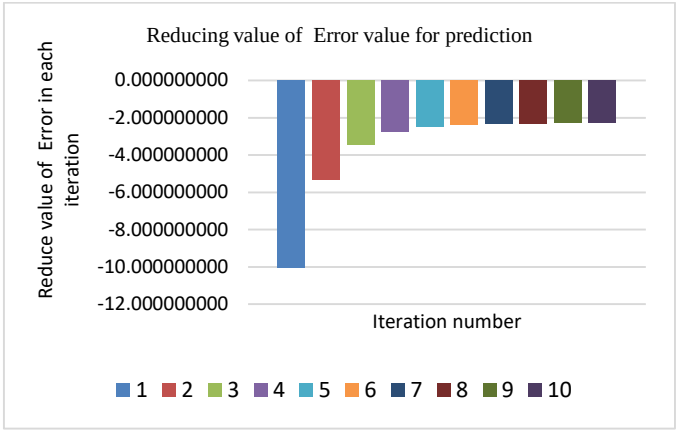

Fig. 5. Reducing error value in each iteration.

The value of the parameter m and c has been updated during each iteration. Fig. 6 shows the updated value of parameter m and c, from the Fig. 6 it is clear that after 5th iteration there are very minor changes are made in the value of m and c.

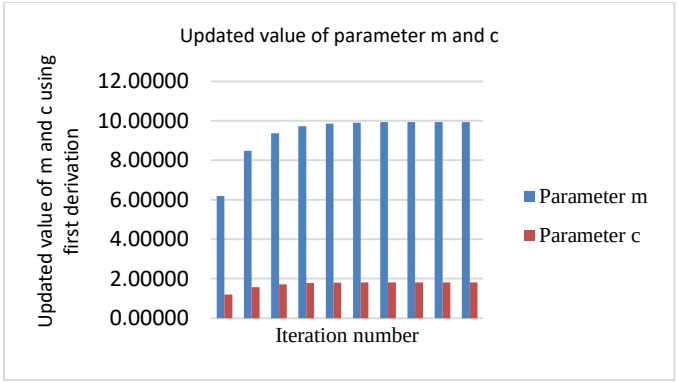

Fig. 6. Updating value of m and c during each iteration using first derivation.

So, prediction for unknown value of x the parameter has the value m=9.943 and c=1.816

C. Average prediction Error

Different number of records and calculated average prediction error have been used and found that Adaptive learning-based approach comparatively gave better prediction as other traditional approach. Table VI shows the prediction accuracy and average prediction error with number of students.

TABLE VI. PREDICTION ACCURACY AND AVERAGE PREDICTION ERROR

S No	No of Students	Prediction Accuracy	Average Prediction Error
1	890	96.31	3.69
2	2014	95.67	4.33
3	3022	97.23	2.77

Fig. 7 shows the graphical representation of number of students with prediction accuracy and average prediction error. It is also found that proposed approach is work well and proposed approach can scale up to any size of the dataset without effecting the performance.

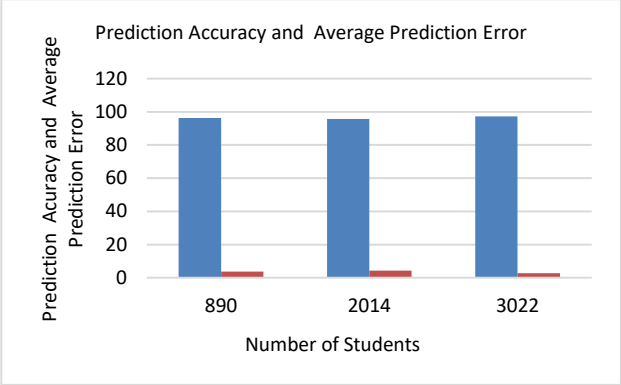

Fig. 7. Comparing prediction accuracy and average prediction error.

IX. Advantages and Limitations

The proposed approach has two advantages over the previous approach, it uses a minimum number of iterations and gives better accuracy with minimum error. The limitation of the proposed approach is that it uses only a single independent variable, there are several other parameters which can also be considered. The proposed approach is not suitable for nonlinear repression.

X. Conclusion and Future Work

Prediction is an important data analysis technique. Prediction helps us to predict what happens in future. In this paper, optimization with adaptive learning approach is proposed. Proposed approach improves accuracy of prediction by using adaptive learning and give optimal solution with minimum number of iterations. Real life data set is used for experimental analysis. Correct score can be predicted of the students based on number of studies for JEE exam. Dataset is collected from different JEE preparing centers of Indore city of Madhya Pradesh. By experimental analysis it is found that the accuracy of proposed approach for prediction is better and scalable. The proposed work helps students as well as training institution of JEE examination, to prediction the marks and possibility for selection. In future this approach can be applied for other type of regression and used for different datasets.

***Abstract*—This study presents a novel approach for non-contact extraction of physiological parameters, such as heart rate and respiratory rate, from facial images captured using RGB cameras, leveraging recent advancements in deep learning and signal processing techniques. The proposed system integrates Artifacts intelligent-driven algorithms for accurately estimating vital signs, addressing key challenges such as variations in lighting conditions, facial orientation, and noise. The system is implemented on both a naive homogeneous architecture and an optimized heterogeneous CPU-GPU system to enhance real-time performance and computational efficiency. A comparative analysis is performed to evaluate processing speed, accuracy, and resource utilization across both architectures. Results demonstrate that the optimized heterogeneous system significantly outperforms the homogeneous counterpart, achieving faster processing times while maintaining high accuracy levels. This performance boost is achieved through parallel computing frameworks such as OpenMP and OpenCL, which allow for efficient resource allocation and scalability. The research highlights the potential of heterogeneous architectures for real-time healthcare applications, including remote patient monitoring and telemedicine, providing a robust solution for future developments in non-invasive health technology.**

***Keywords*—Real-time healthcare; embedded systems; heterogeneous computing; deep learning; CPU-GPU architecture**

I. Introduction

A. Background and Motivation

In recent years, the healthcare industry has experienced a significant shift towards non-contact monitoring solutions, driven by the increasing demand for continuous and unobtrusive patient care. Traditional contact-based physiological monitoring methods, such as electrocardiograms (ECGs) and wearable biosensors, while effective in providing accurate measurements, often face several practical challenges. These challenges include patient discomfort, the need for frequent repositioning of sensors, and hygiene concerns, which can limit patient compliance and the frequency of monitoring. Moreover, the inconvenience of attaching and removing sensors can be a barrier to widespread adoption, particularly in settings that require long-term or continuous monitoring.

In response to these limitations, researchers and engineers have turned their attention to non-contact methods, specifically those leveraging facial image analysis. By utilizing standard RGB cameras, which are less intrusive and can be easily integrated into everyday environments, it is possible to monitor physiological parameters such as heart rate and respiratory rate without direct physical contact. This non-contact approach not only enhances patient comfort but also facilitates continuous and real-time monitoring, allowing for more comprehensive health assessments over time [1]-[5].

Recent advancements in deep learning and signal processing have greatly enhanced the feasibility and accuracy of extracting physiological parameters from facial images. Deep learning algorithms, particularly convolutional neural networks (CNNs) and recurrent neural networks (RNNs) have demonstrated remarkable capabilities in interpreting complex patterns within facial images, even under varying lighting conditions and different facial orientations. Signal processing techniques further refine these interpretations by analyzing subtle color changes and motion artifacts associated with physiological processes [6]-[10].

The integration of these advanced technologies into non-contact monitoring systems presents a transformative opportunity for the healthcare sector. Such systems promise not only to improve patient comfort and compliance but also to expand the reach of remote monitoring, making it possible to deliver continuous care in a variety of settings, including home environments and telemedicine platforms. This shift towards more seamless and less intrusive monitoring aligns with broader trends in healthcare innovation, aiming to enhance patient outcomes through more accessible, real-time, and data-driven approaches. As the field evolves, the development of robust, efficient, and accurate non-contact monitoring systems will play a crucial role in shaping the future of healthcare, offering new possibilities for early detection, preventive care, and personalized treatment.

B. Advances in Deep Learning and Signal Processing

Recent advances in deep learning and signal processing have brought transformative improvements to the field of non-contact physiological monitoring, particularly in analyzing facial images to extract vital signs such as heart rate and respiratory rate. Deep learning techniques, especially convolutional neural networks (CNNs), have proven to be highly effective in analyzing complex visual data. CNNs are particularly adept at detecting subtle, pixel-level changes in facial images, such as variations in skin tone caused by the underlying blood flow, a method commonly referred to as remote photoplethysmography (rPPG). These subtle changes, which are often invisible to the human eye, correlate directly with physiological parameters like heart rate, enabling precise and continuous monitoring without the need for physical contact [11]-[13].

Further advances in recurrent neural networks (RNNs), including long short-term memory networks (LSTMs), have enhanced the capability to model temporal dependencies and sequences, making them well-suited for tracking cyclic patterns such as respiratory rate. By utilizing temporal data from video sequences, RNNs can capture periodic facial movements corresponding to breathing patterns, allowing for the accurate estimation of respiratory rates. This combination of CNNs for spatial feature extraction and RNNs for temporal analysis creates a powerful framework for real-time, non-invasive physiological monitoring.

On the signal processing front, techniques such as optical flow, which detects movement by calculating changes in pixel intensities between consecutive frames, and discrete wavelet transforms (DWT), which decompose signals into multi-resolution components, have further optimized the extraction of physiological signals. These methods work in tandem with deep learning models, refining the input data and enhancing the accuracy of parameter estimation. Additionally, advanced filtering algorithms, such as bandpass filters, are often employed to remove noise and isolate the relevant physiological signal, especially under challenging conditions like varying lighting, motion artifacts, and changes in facial orientation [14]-[16].

The integration of these deep learning and signal processing techniques with heterogeneous computing platforms, such as CPU-GPU architectures, has significantly improved system performance. By distributing computational tasks across multiple processing units, such systems offer enhanced scalability, reduced latency, and faster real-time processing capabilities. This has profound implications for applications in remote health monitoring, where real-time accuracy and computational efficiency are critical. The continued refinement of these technologies promises to further elevate the feasibility of non-contact physiological monitoring for widespread use in telemedicine, smart health environments, and continuous remote patient care [17]-[20]. In the following Fig. 2, a flowchart illustrating the workflow of deep learning and signal processing techniques used in facial image analysis. The flowchart includes steps such as image acquisition, preprocessing, feature extraction, and parameter estimation.

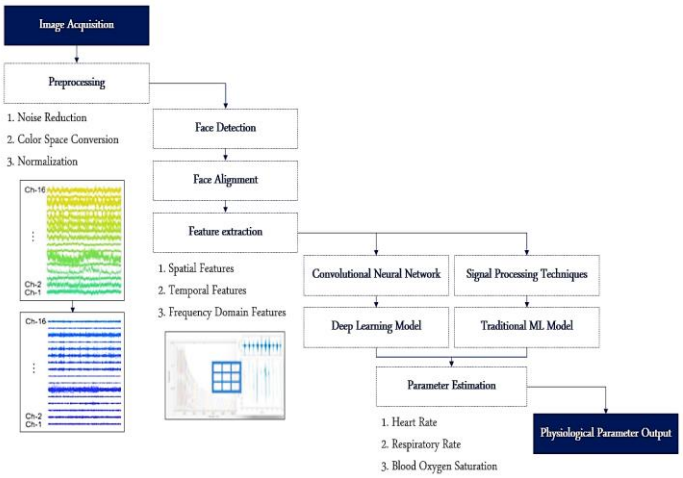

Fig. 2. Deep learning and signal processing workflow.

C. Contributions

In recent years, notable progress has been made in non-contact physiological monitoring using RGB cameras. However, many existing methods still face significant challenges. These include reduced accuracy in dynamic lighting conditions, handling diverse facial orientations, and noise in the captured signals. Additionally, although deep learning and signal processing techniques have been integrated into some systems, the real-time performance is often hindered by the high computational demands, particularly when running on homogeneous architectures such as CPU-only platforms. This creates limitations that make it difficult to deploy these systems in practical, real-time healthcare settings.

To overcome these challenges, our study introduces an optimized approach that utilizes heterogeneous architectures, specifically leveraging CPU-GPU systems, for real-time extraction of physiological parameters from facial images. This approach enhances processing speed without compromising accuracy. Furthermore, we employ advanced AI algorithms tailored to minimize the impact of noise, variations in lighting, and changes in facial orientation, thereby increasing the overall reliability and robustness of the system.

The overarching goal of this research is to design and implement a robust, non-contact system for accurately extracting physiological parameters, such as heart rate and respiratory rate, from facial images captured by RGB cameras. This system leverages state-of-the-art deep learning models and advanced signal processing techniques to address the inherent challenges in non-contact monitoring, including variations in facial orientation, changes in lighting conditions, and noise introduced by environmental factors. One of the primary contributions of this study is the development of a novel AI-driven framework that integrates convolutional neural networks (CNNs) for feature extraction with signal processing algorithms to analyze the subtle changes in facial color and movement, which correlate with vital signs. Furthermore, the

system is designed to be optimized for real-time performance by implementing it on a heterogeneous CPU-GPU architecture. This architecture enables parallel processing and efficient resource allocation, thus significantly enhancing computational efficiency. A comparative analysis is conducted between the proposed optimized heterogeneous implementation and a naive homogeneous system to evaluate improvements in processing speed, and accuracy. The research highlights that the optimized heterogeneous system achieves superior performance in real-time applications, making it well-suited for critical healthcare scenarios such as remote patient monitoring and telemedicine. Additionally, this study provides valuable insights into the advantages of parallel computing frameworks, such as OpenMP and OpenCL, in optimizing the execution of deep learning and signal processing algorithms, contributing to the broader field of non-invasive health monitoring technologies. Moreover, the following Fig. 3 is a diagram showing the overall system architecture, from facial image acquisition to physiological parameter extraction. The diagram highlights components such as the camera, processing unit, deep learning model, and output analysis.

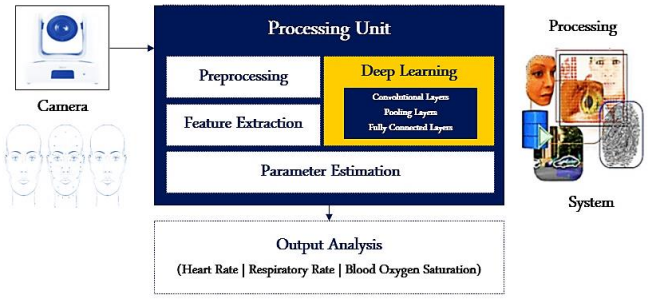

Fig. 3. System architecture and workflow.

II. State-of-the-Art: Review

A. Physiological Parameter Extraction from Facial Features

Recent advancements in non-contact physiological monitoring have enabled the extraction of vital signs, such as heart rate (HR), respiratory rate (RR), and blood oxygen levels, directly from facial images using RGB cameras. This approach leverages subtle physiological cues, primarily through techniques like Remote Photoplethysmography (rPPG), which detects minute changes in skin color caused by blood flow under the skin's surface [21]-[26]. These variations are captured as pixel intensity changes, invisible to the naked eye but detectable by advanced image processing algorithms. rPPG-based methods rely on capturing video streams of the subject's face and analyzing the temporal patterns of these pixel changes to estimate the heart rate. Similarly, respiratory rate estimation often employs optical flow algorithms that track small chest and shoulder movements associated with breathing, translating pixel displacements over time into respiration patterns. While highly effective, these techniques are sensitive to various factors such as lighting conditions, head motion, and camera quality. To mitigate these challenges, recent studies have incorporated advanced machine learning algorithms to enhance robustness, allowing for more accurate physiological measurements in real time, even under suboptimal conditions. This non-invasive approach holds tremendous promise for healthcare applications, enabling continuous monitoring without the need for physical contact, making it particularly useful for remote patient monitoring and telemedicine [27]-[33].

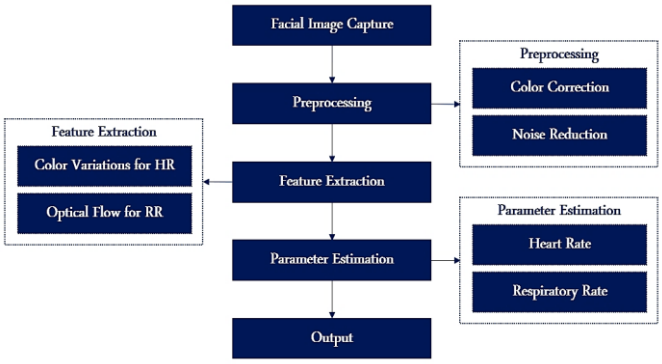

Fig. 4. Physiological parameter extraction process.

In Fig. 4, a flowchart depicting the physiological parameter extraction process, the facial image capture initiates the process, followed by preprocessing steps such as color correction and noise reduction to enhance image quality. Next, feature extraction is performed, where color variations are analyzed to estimate heart rate (HR), and optical flow techniques are used to detect respiratory rate (RR). These extracted features are then processed in the parameter estimation phase to calculate accurate values for both heart rate and respiratory rate. Finally, the system outputs these physiological parameters, providing non-contact monitoring results.

B. Image and Signal Processing Techniques

Image and signal processing techniques are fundamental in extracting physiological parameters from facial images, addressing challenges related to accuracy, robustness, and environmental variability. One of the primary techniques involves color space conversion, where facial images captured in the RGB format are transformed into alternative color spaces, such as YUV, YCbCr, or HSV. These transformations are critical as they allow the separation of luminance and chrominance components, which significantly improves the detection of subtle color variations in the skin caused by blood flow, a key indicator for heart rate estimation. Specifically, the chrominance channels (U and V in YUV, or Cb and Cr in YCbCr) are more sensitive to these physiological changes, making them ideal for accurate feature extraction [34]-[36].

An essential step in this process is skin detection, where the region of interest (ROI) is isolated to ensure that only skin pixels are analyzed. Several skin detection algorithms are employed, ranging from traditional thresholding techniques based on predefined color ranges to more sophisticated methods using machine learning models like support vector machines (SVMs) and neural networks (NN). These advanced methods adaptively classify skin regions based on training data, making the system more robust to variations in lighting and individual skin tones. Additionally, motion artifact reduction is a crucial aspect, as head movements and facial expressions can introduce noise into the signal. Techniques

such as optical flow analysis are used to track pixel displacement over time, isolating and compensating for movements unrelated to physiological signals.

In parallel, advanced signal processing methods are applied to the extracted physiological signals to enhance their clarity and improve the accuracy of parameter estimation. One widely used approach is the wavelet transform, which provides a multi-resolution analysis of the signal, capturing both time and frequency information. This method is particularly effective in isolating the periodic components corresponding to physiological processes, such as heartbeats or respiration, from background noise. Similarly, Fourier analysis is employed to transform the time-domain signal into the frequency domain, where periodic features, such as the heart rate frequency, can be more easily identified. These techniques are instrumental in filtering out high-frequency noise or low-frequency drifts that could otherwise distort the signal.

Moreover, motion-compensating filtering algorithms are often integrated into the processing pipeline to mitigate artifacts caused by slight movements of the face or background disturbances. Combined with the signal processing techniques mentioned earlier, these algorithms enhance the system's ability to produce reliable physiological parameter estimates in real-time. Overall, the synergy between image processing (such as color space conversion and skin detection) and signal processing (like wavelet transform and Fourier analysis) enables a more robust extraction of physiological parameters, ensuring that the system can operate effectively under varying conditions, such as fluctuating lighting, diverse skin tones, and slight motion disturbances. These advancements are pivotal in making non-contact physiological monitoring systems practical for real-world healthcare applications, including remote monitoring and telemedicine.

C. AI and Deep Learning in Physiological Monitoring

The incorporation of artificial intelligence (AI) and deep learning techniques has revolutionized the field of physiological monitoring from facial images, addressing key challenges such as environmental variability, facial orientation, and signal noise. Convolutional Neural Networks (CNNs) are at the forefront of feature extraction from facial images, utilizing multiple layers of convolutions to identify and learn intricate patterns related to physiological signals. CNNs excel in detecting subtle color variations and spatial features in facial skin that correlate with blood flow, enabling accurate heart rate (HR) and blood oxygen level estimation. Recurrent Neural Networks (RNNs), particularly Long Short-Term Memory (LSTM) networks, are employed to capture temporal dependencies in the data, which is crucial for analyzing dynamic physiological signals like respiratory rate (RR). LSTMs are designed to handle sequential data by retaining information over long periods, making them adept at predicting and analyzing continuous physiological variations. Furthermore, Generative Adversarial Networks (GANs) are increasingly utilized to address data quality issues by generating synthetic data that resembles real physiological signals. GANs improve signal robustness by learning from real signal distributions and correcting distortions or noise, thus enhancing the accuracy of measurements even in challenging conditions. Together, these AI-driven approaches enable sophisticated real-time physiological monitoring by providing high precision in signal extraction and analysis. The deployment of these advanced algorithms not only enhances the accuracy and reliability of non-contact health monitoring systems but also paves the way for more effective telemedicine solutions and remote patient care, showcasing the transformative impact of AI and deep learning on healthcare technology.

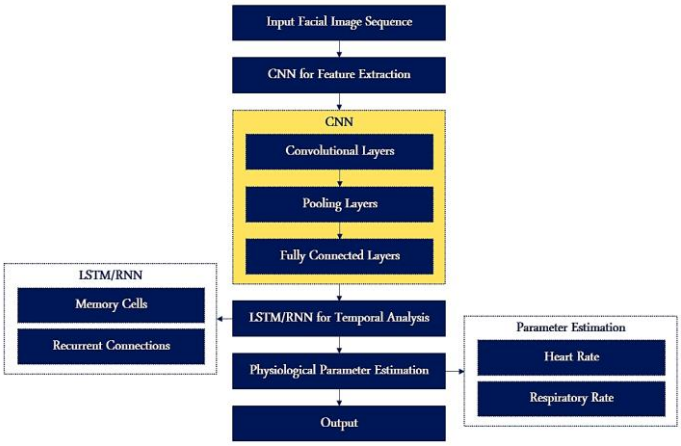

Fig. 5. AI-driven physiological monitoring.

In Fig. 5, the process begins with the input of a facial image sequence, which is then passed through a Convolutional Neural Network (CNN) for feature extraction to identify key physiological indicators from the image data. Following this, a Long Short-Term Memory (LSTM) or Recurrent Neural Network (RNN) performs temporal analysis to capture time-dependent changes in the extracted features. These changes are used to estimate physiological parameters, such as heart rate (HR) and respiratory rate (RR). The final step is the output, where the system provides the estimated physiological parameters for real-time monitoring.

D. Hardware Implementations for Physiological Monitoring

The hardware implementations for physiological monitoring systems have evolved substantially, driven by the need for real-time processing and enhanced computational capabilities. Historically, homogeneous systems relying solely on Central Processing Units (CPUs) provided a foundational approach to processing physiological data. While effective for basic tasks, these systems face limitations in handling the high computational demands associated with advanced image and signal processing algorithms, particularly those involving deep learning techniques. The limitations of homogeneous systems are primarily related to their restricted ability to perform parallel computations, which are crucial for real-time analysis of large-scale data such as facial images [37]-[39].

To overcome these constraints, heterogeneous systems have emerged, incorporating both CPUs and Graphics Processing Units (GPUs). These systems leverage the parallel processing capabilities of GPUs to handle intensive computational tasks more efficiently than traditional CPUs. For example, platforms such as the Odroid XU4 integrate a high-performance ARM Cortex-A15 CPU with an ARM Mali-T628 GPU. This combination allows for the simultaneous execution

of multiple processing threads, significantly accelerating tasks such as image pre-processing, feature extraction, and physiological parameter estimation.

The integration of heterogeneous architectures enables the utilization of parallel computing frameworks like OpenMP and OpenCL. OpenMP facilitates the efficient execution of multi-threaded applications by allowing developers to parallelize code across multiple CPU cores, thus enhancing the performance of data-intensive tasks. OpenCL, on the other hand, extends this parallelism to GPU cores, offering a robust environment for executing complex algorithms related to image and signal processing. By distributing processing workloads between CPUs and GPUs, heterogeneous systems can achieve substantial improvements in processing speed and real-time performance, which are critical for applications in remote physiological monitoring and telemedicine (Fig. 6) [40]-[42].

Despite the advantages of heterogeneous systems, several challenges persist. Optimizing these systems for energy efficiency remains a key concern, especially in mobile and embedded applications where power consumption is a critical factor. Additionally, the scalability of heterogeneous systems poses challenges as the complexity of algorithms and the volume of data increase. Future developments in hardware architecture and optimization techniques are essential to address these challenges and enhance the practicality of heterogeneous systems for broader applications in non-contact physiological monitoring.

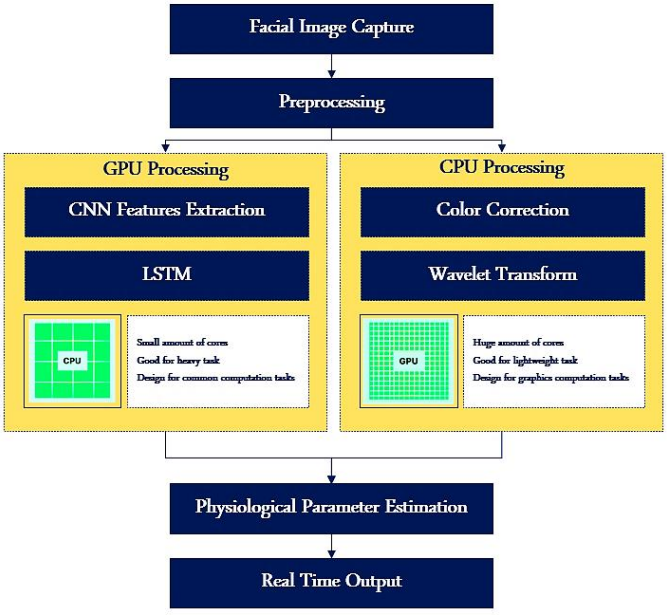

Fig. 6. Heterogeneous system architecture for physiological monitoring.

III. Proposed Methodology

A. Image and Signal Processing Algorithm

The image and signal processing algorithm for extracting physiological parameters from facial images is a multifaceted approach that integrates advanced image processing and signal analysis techniques to achieve high accuracy and robustness. Initially, high-resolution facial images are captured using a high-definition RGB camera, with the setup optimized to minimize variations in lighting conditions and facial orientation, ensuring consistent and reliable image data. The preprocessing phase involves several critical steps: first, face detection algorithms, such as Haar cascades or Multi-task Cascaded Convolutional Networks (MTCNN), are employed to precisely locate and extract the facial region from the acquired images. Subsequent normalization processes are applied to standardize image dimensions and correct for color imbalances, thereby mitigating the effects of external variables. The extracted Region of Interest (ROI) within the facial area is then subjected to detailed color analysis to detect minute variations in skin tone, which are indicative of changes in blood flow. These color fluctuations are converted into Photoplethysmographic (PPG) signals through specialized signal extraction techniques. The PPG signals, which reflect periodic variations in blood volume, are analyzed to determine heart rate and respiratory rate. Heart rate estimation is performed using Fourier Transform methods, such as Fast Fourier Transform (FFT), to identify dominant frequency components associated with cardiac activity. Respiratory rate estimation is achieved by analyzing the amplitude and frequency variations in the PPG signals, which correspond to respiratory cycles. This comprehensive algorithmic approach ensures the accurate and real-time extraction of physiological parameters, providing a solid foundation for subsequent applications in remote health monitoring and telemedicine. By combining these advanced image and signal processing techniques, the system is capable of delivering precise and actionable health insights from non-contact facial imaging.

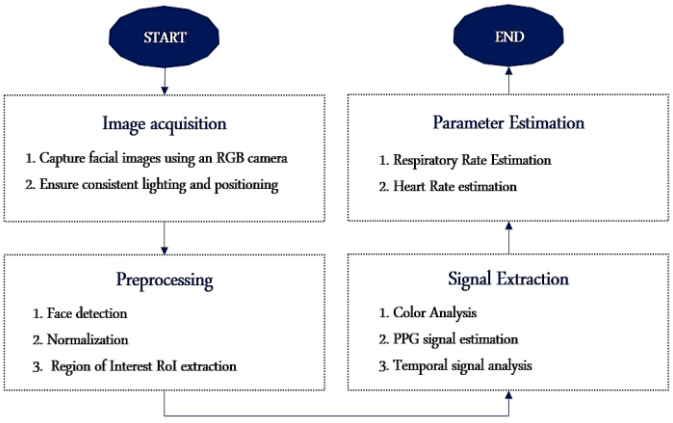

Fig. 7. Flowchart of the image and signal processing algorithm.

In Fig. 7, the image and signal processing algorithm for extracting physiological parameters from facial images involves a series of crucial steps. First, facial images are acquired using an RGB camera, capturing the necessary visual data. Next, preprocessing techniques are applied to enhance image quality and extract relevant features, such as skin tone variations. In the signal extraction phase, the algorithm analyzes subtle facial color variations to infer underlying physiological signals. Finally, parameter estimation methods are employed to process these signals and accurately derive heart rate and respiratory rate, providing non-invasive health monitoring results.

B. Deep Learning Component

The deep learning component of the proposed system is designed to significantly enhance the extraction and estimation of physiological parameters from facial images through the application of sophisticated neural network architectures. At the core of this component is the use of Convolutional Neural Networks (CNNs), which are instrumental in performing feature extraction from the raw facial images (Fig. 8). The CNN architecture comprises multiple layers, including convolutional layers that apply a series of filters to the input images to detect fundamental features such as edges and textures. These are followed by pooling layers, which reduce the dimensionality of the feature maps while preserving essential information. This hierarchical feature extraction enables the network to capture both low-level and high-level facial attributes pertinent to physiological signal analysis.

The processed features are then fed into a Recurrent Neural Network (RNN) component, specifically Long Short-Term Memory (LSTM) or Gated Recurrent Units (GRU), to address the temporal dynamics inherent in the physiological signals (Fig. 8). The RNNs are adept at capturing temporal dependencies and patterns within the time-series data extracted from the facial images, such as the periodic fluctuations in blood flow related to heart rate and respiration. By modeling these temporal relationships, the network improves the accuracy and robustness of the physiological parameter estimates.

The training of these neural networks involves using a large and diverse dataset of labeled facial images with known physiological parameters. The loss function, typically Mean Squared Error (MSE) for regression tasks, measures the discrepancy between the predicted and actual parameter values. Optimization algorithms such as Adam or Stochastic Gradient Descent (SGD) are employed to minimize this loss function by adjusting the network's weights and biases iteratively. This training process ensures that the network learns to generalize well across different individuals and conditions, enhancing its performance in real-world applications.

Furthermore, integrating these deep learning models with the signal processing pipeline is crucial for achieving real-time performance. The system benefits from parallel processing frameworks such as OpenMP and OpenCL, which are employed to optimize computational efficiency and reduce processing latency. This combined approach not only facilitates accurate and timely extraction of heart rate and respiratory rate from facial images but also ensures the system's scalability and adaptability to various deployment scenarios, including remote health monitoring and telemedicine applications. As shown in Fig. 8, the system integrates a Convolutional Neural Network (CNN) for feature extraction from facial images, utilizing convolutional layers to identify key features, pooling layers to reduce dimensionality while retaining crucial information, and fully connected layers to interpret these features for prediction. A Recurrent Neural Network (RNN), equipped with LSTM or GRU layers, processes time-series data from PPG signals to capture temporal dependencies, with an output layer predicting physiological parameters.

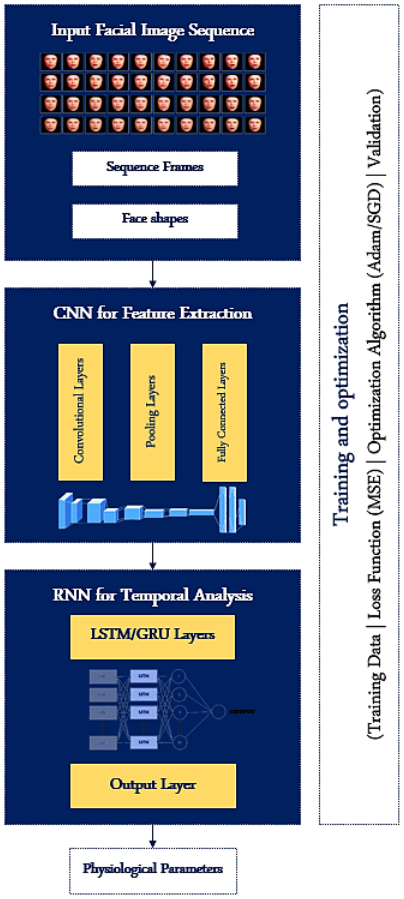

Fig. 8. Neural network architecture for physiological parameter extraction.

C. Deep Learning and AI Models

The global system architecture is meticulously designed to facilitate the efficient extraction of physiological parameters from facial images through a series of integrated modules, each performing a critical function within the overall framework. The architecture begins with the Image Acquisition Module, which utilizes high-resolution RGB cameras to capture continuous or periodic facial images under controlled lighting conditions to ensure image consistency. These images are then processed by the Preprocessing Module, which encompasses several key operations: face detection using algorithms such as Haar cascades or MTCNN, normalization of image size and color balance to mitigate variability, and extraction of the Region of Interest (ROI) where physiological signals are most prominent.

Following preprocessing, the Signal Processing Module analyzes the facial color variations within the ROI to extract photoplethysmographic (PPG) signals. This step involves sophisticated techniques to detect subtle changes in skin color due to blood flow, which are then used to derive the heart rate and respiratory rate. The extracted signals are subjected to temporal analysis to enhance accuracy.

The core of the system's analytical capabilities resides in the AI Module, which applies advanced deep learning techniques to process the extracted signals. This module incorporates Convolutional Neural Networks (CNNs) for

feature extraction from the images and Recurrent Neural Networks (RNNs), particularly Long Short-Term Memory (LSTM) or Gated Recurrent Units (GRUs), for analyzing temporal dependencies in the PPG signals. The Output Module consolidates the results, providing a user-friendly interface for displaying or transmitting the estimated physiological parameters. This module ensures that the data is presented in a format suitable for further analysis or integration with healthcare systems.

The system is implemented on both a naive homogeneous architecture and an optimized heterogeneous architecture. The homogeneous system relies solely on CPU resources, potentially limiting processing speed and efficiency. In contrast, the heterogeneous system harnesses both CPU and GPU capabilities, employing parallel computing frameworks such as OpenMP and OpenCL to enhance processing performance. The heterogeneous system allows for scalable and efficient resource allocation, significantly improving real-time processing capabilities and making it highly suitable for practical healthcare applications such as remote monitoring and telemedicine.

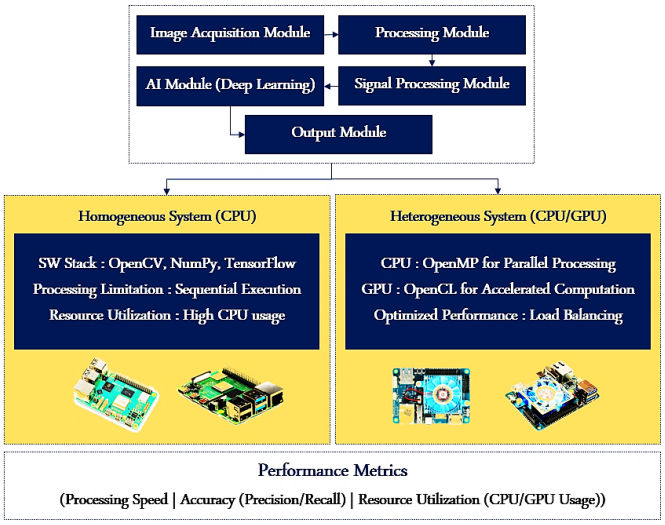

Fig. 9. System architecture diagram.

In Fig. 9 above, the system consists of several interconnected components. The image acquisition module captures facial images and sends them to the preprocessing module, which enhances image quality and extracts the region of interest (ROI) for further analysis. The signal processing module then examines color changes in the facial images, extracting photoplethysmography (PPG) signals. The AI module applies deep learning models to these signals to estimate physiological parameters such as heart rate and respiratory rate. Finally, the output module displays or transmits the extracted parameters for real-time monitoring or further processing.

IV. System Implementation

A. Homogeneous System

In the homogeneous system implementation, all computational tasks are executed on a single Central Processing Unit (CPU), which manages the entire workflow of facial image analysis for physiological parameter extraction. The process begins with the acquisition of RGB images through a standard camera setup. These images are subjected to a series of preprocessing steps to ensure uniformity and accuracy in subsequent analysis. The preprocessing phase includes facial detection using established algorithms such as Haar Cascades or Multi-task Cascaded Convolutional Networks (MTCNN). These algorithms identify and locate facial regions within the captured images, which are then cropped and normalized to mitigate variations in lighting, scale, and orientation.

Once the facial regions are isolated, the system employs remote photoplethysmography (rPPG) techniques to extract temporal signals associated with physiological parameters from these facial areas. rPPG relies on subtle variations in facial skin color that correspond to cardiovascular changes, which are indicative of heart rate and respiratory rate. Feature extraction is carried out using Convolutional Neural Networks (CNNs), which are trained to recognize patterns in the temporal signals and extract relevant features indicative of physiological states.

The extracted features are then processed through a series of signal-processing algorithms to estimate physiological parameters. This involves computing heart rate and respiratory rate from the temporal signals, with additional post-processing steps to filter out the noise and smooth the data for accurate parameter estimation. Despite its functional capability, the homogeneous system's reliance on a single CPU for all processing tasks poses constraints in terms of processing speed and real-time performance. This limitation is particularly evident when dealing with high-resolution images or when requiring rapid processing to meet real-time monitoring demands. The system's performance may be hindered by the CPU's inability to efficiently handle the computational load and parallelize tasks, leading to potential delays in parameter extraction and analysis (Table I).

TABLE I. Homogeneous System Implementation

Function	Facial image acquisition	Preprocessing	Feature extraction	Parameter estimation
Sub-Function	Capture RGB images	Face detection	Signal extraction rPPG	Signal processing
	Preprocess images	Image normalization	DL processing CNN	Post-processing
Output	Sequence of images	Normalized facial ROIs	Extracted signals & features	Estimated vital signs

B. Heterogeneous System

The optimized version of the system leverages a heterogeneous architecture, which integrates a multi-core CPU with a dedicated GPU to achieve significant improvements in both computational speed and efficiency. In this architecture, the computational tasks are strategically partitioned between the CPU and GPU to maximize resource utilization and minimize processing time. The initial steps, such as facial image acquisition and preprocessing (including face detection and normalization), are handled by the CPU. This ensures that simpler, less resource-intensive tasks are managed by the CPU,

freeing the GPU for more computationally demanding operations. Following the detection of the region of interest (ROI) in the facial image, the system offloads the critical task of signal extraction using remote photoplethysmography (rPPG) to the GPU. The GPU, with its parallel processing capabilities, efficiently handles the large datasets and intensive computations required for rPPG signal extraction and subsequent feature recognition, which is performed using advanced deep learning techniques, particularly Convolutional Neural Networks (CNNs). These CNNs are optimized for real-time processing on the GPU, significantly accelerating the analysis of facial features and the extraction of physiological signals such as heart rate and respiratory rate.

In this architecture, the GPU is not only responsible for rapid signal extraction but also for processing complex machine-learning algorithms, which are critical for the accurate estimation of physiological parameters. Parallel computing frameworks, such as OpenMP and OpenCL, are employed to further enhance system performance by enabling multi-threaded processing on both the CPU and GPU, ensuring efficient task scheduling and data handling. These frameworks allow for the dynamic allocation of resources, ensuring that bottlenecks in data transfer or processing are minimized, leading to smoother operation and faster results. Once the GPU completes the heavy computations, the CPU takes over for post-processing tasks, refining the extracted signals and performing any necessary filtering to enhance the accuracy of the physiological parameter estimations. The use of this heterogeneous architecture demonstrates a significant performance improvement over the homogeneous version, as it allows for faster processing time. The optimized system, therefore, offers a robust and efficient solution for real-time physiological monitoring, making it ideal for applications such as remote patient monitoring, telemedicine, and other non-invasive healthcare technologies where timely and accurate data processing is crucial (Table II).

TABLE II. HETEROGENEOUS SYSTEM IMPLEMENTATION

Function	Image acquisition and Preprocessing	Feature extraction	Parameter estimation
System	CPU	GPU	CPU/CPU
Sub-Function	Facial frames collecting	Signal extraction rPPG	Signal processing (GPU)
	Preprocessing	DL processing CNN	Post-processing (CPU)
Output	Preprocessed facial images	Extracted signals & features	Physiological parameter extraction

C. Performance Optimization

The performance of the proposed system was significantly enhanced through a combination of advanced optimization techniques aimed at improving both computational efficiency and real-time responsiveness. A key strategy involved leveraging parallel computing frameworks, with tasks distributed between the CPU and GPU to reduce bottlenecks and maximize resource utilization. OpenMP was employed to parallelize tasks on the CPU, enabling simultaneous execution of multiple processes, thereby reducing overall processing time. In parallel, OpenCL was utilized to harness the computational power of the GPU, particularly for tasks involving high-dimensional data processing, such as deep learning inference and signal extraction. This heterogeneous parallelism allowed the system to capitalize on the strengths of both processing units, with the CPU handling control and light processing tasks, while the GPU was responsible for more computationally intensive operations.

In addition to task distribution, memory management played a critical role in enhancing performance. To minimize data transfer overhead between the CPU and GPU, optimized memory allocation techniques were implemented, such as using pinned memory and efficient buffer management. This reduced latency associated with data movement and improved throughput. Furthermore, shared memory models were applied to accelerate data access and reduce cache misses during intensive computations.

Algorithmic optimizations were also a focus. For signal processing, advanced filtering techniques were used to accelerate the extraction of physiological parameters, while maintaining accuracy. In the deep learning component, the neural network models were optimized through pruning and quantization, reducing the model size and improving inference speed without compromising performance. These optimizations allowed the system to handle larger data inputs and deliver faster results, crucial for real-time monitoring applications.

To evaluate the impact of these optimizations, key performance metrics were assessed, including processing speed (in frames per second), accuracy of physiological parameter estimation, and resource utilization. The optimized heterogeneous system demonstrated significant improvements in processing speed compared to the naive homogeneous system, achieving real-time performance benchmarks. Resource utilization was carefully monitored to ensure efficient CPU-GPU collaboration, preventing bottlenecks and minimizing energy consumption. These optimizations not only enhanced the system's computational performance but also ensured scalability, making it suitable for deployment in real-time healthcare applications, such as remote patient monitoring and telemedicine.

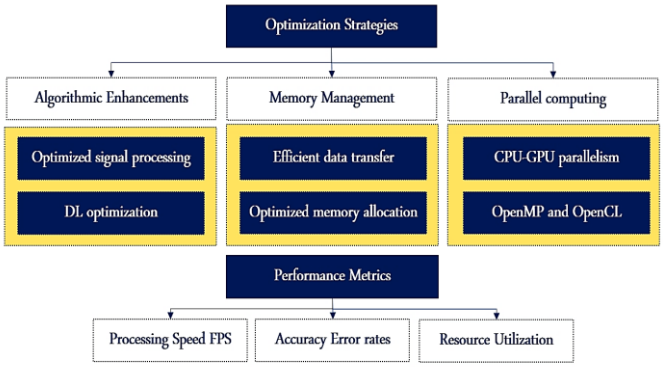

Fig. 10. Optimization strategies.

In the above Fig. 10, the optimization strategies for the system focus on enhancing performance through parallel computing, memory management, and algorithmic improvements. By distributing computational tasks between the CPU and GPU using frameworks like OpenMP and OpenCL, the system reduces bottlenecks and accelerates processing. Efficient data transfer and optimized memory allocation minimize overhead and speed up operations. Algorithmic enhancements include faster signal extraction methods and deep learning optimizations, such as model pruning and quantization, to improve inference speed. Performance metrics like processing speed (FPS), accuracy in physiological parameter estimation, and resource utilization are monitored to ensure effective and efficient operation.

V. Experimental Setup

A. Dataset and Experimental Protocol

The experimental dataset utilized in this study comprises RGB facial videos collected under various controlled and semi-controlled environmental conditions to accurately simulate real-world scenarios. These conditions include variations in ambient lighting, facial orientation, and subtle subject movements. Publicly available datasets such as UBFC-RPPG, COHFACE, or equivalent datasets were employed, each providing high-resolution facial videos paired with synchronized ground truth physiological signals, specifically heart rate and respiratory rate, obtained from reliable medical-grade sensors. Additionally, to enhance the robustness of the system and assess its performance under diverse conditions, a custom dataset was acquired using a high-definition camera (1080p resolution at 30 frames per second). In this setup, participants were positioned at a fixed distance of 1 to 2 meters from the camera, with uniform lighting to minimize external interferences.

The preprocessing phase involved converting the raw video sequences into individual frames, followed by face detection and tracking using advanced computer vision techniques, such as the Multi-task Cascaded Convolutional Networks (MTCNN) algorithm, to ensure precise extraction of the region of interest (ROI), specifically the facial area where physiological signals are most prominent. To ensure consistency across frames, facial landmarks were used to normalize the detected face, mitigating minor head movements and variations in facial orientation. For data alignment, the extracted video frames were synchronized with ground truth physiological signals through time-stamped data, ensuring accurate comparison during the validation phase. This synchronization allows for a one-to-one mapping between each frame and the corresponding physiological signal (e.g. heartbeats or respiratory cycles), which is crucial for training and testing the proposed system.

Once preprocessed, the dataset was split into training, validation, and testing subsets, ensuring a balanced distribution of conditions (e.g. lighting variations, subject movements) across all subsets. The preprocessed frames and synchronized ground truth signals were subsequently fed into the signal processing and deep learning pipelines. This comprehensive preprocessing and alignment ensured the system was rigorously tested across a variety of real-world scenarios, facilitating robust benchmarking of its performance in extracting physiological parameters such as heart rate and respiratory rate from facial images (Table III).

TABLE III. Dataset and Data Flow

Section	Subsection	Details
Dataset Overview	Dataset Composition	Facial images captured in varying conditions.
	Source	Open-source databases (e.g., UBFC-RPPG, COHFACE) or custom datasets with RGB videos.
	Custom Data Collection	- Frame rate (30 fps), resolution (1080p), distance (1-2 meters). - Description of lighting, subject movements, and position.
Experimental Protocol	Data Preprocessing	- Convert video sequences into frames for image processing. - Face detection (OpenCV, MTCNN) to extract facial regions, and normalize facial regions across frames for small movements.
	Ground Truth Alignment	- Synchronize physiological signals from wearable devices with video frames to establish ground truth.

B. Hardware and Software Setup

The experimental setup involves two distinct system configurations: a baseline homogeneous system and an optimized heterogeneous system, each designed to execute the same physiological parameter extraction tasks but under different architectural conditions. The homogeneous system, represents the naive implementation, which is typical of low-power embedded devices like the Raspberry Pi. In this configuration, all computational tasks, including image preprocessing, signal extraction, and deep learning-based prediction, are performed solely on the CPU without any hardware acceleration, thus providing a benchmark for performance evaluation. Conversely, the optimized system incorporates a heterogeneous architecture offering significant parallel processing capabilities. This architecture is employed to enhance computational efficiency by distributing workloads between the CPU and GPU. Specifically, OpenMP is used to parallelize tasks across multiple CPU cores, improving the efficiency of operations such as face detection and signal filtering, while OpenCL is utilized to offload computationally intensive tasks, such as deep learning inference and feature extraction, to the GPU. In both configurations, the software environment includes Python or C/C++ as the primary programming languages, alongside key libraries such as OpenCV for image and signal processing, TensorFlow/PyTorch for implementing deep learning models, and OpenMP/OpenCL to facilitate parallel processing. By combining these software tools with the respective hardware configurations, a comparative analysis of system performance, measured in terms of processing time, resource utilization, and overall computational efficiency, can be conducted, highlighting the advantages of heterogeneous architectures for real-time, non-contact physiological monitoring in embedded systems.

C. Signal Processing and Deep Learning Algorithm

The signal processing and deep learning algorithm for extracting physiological parameters from facial images involves a sophisticated multi-stage approach designed to enhance both accuracy and computational efficiency. The process begins with image preprocessing, where remote photoplethysmography (rPPG) techniques are employed to capture subtle, periodic color variations in the facial skin that correspond to physiological signals such as heart rate and respiration rate. This initial step involves extracting and aligning facial regions of interest from video frames using robust face detection algorithms. The extracted facial regions are then subjected to signal processing techniques to isolate the physiological signals from background noise. Specifically, a band-pass filter is applied to the raw photoplethysmographic signal to target the frequency bands associated with heart rate and respiration while filtering out high-frequency noise and low-frequency drift.

Following signal preprocessing, deep learning models are employed for advanced feature extraction and signal interpretation. Convolutional Neural Networks (CNNs) are utilized to analyze the spatial features of the facial images, enabling the system to recognize and extract features related to physiological changes. These features are then processed by Recurrent Neural Networks (RNNs), which are adept at handling time-series data and capturing temporal dependencies in the signal. The deep learning models are trained on a comprehensive dataset comprising facial images and corresponding ground truth physiological measurements, facilitating the learning of complex patterns and correlations between facial features and vital signs.

To optimize real-time performance, the system leverages heterogeneous computing architectures, integrating both CPU and GPU resources. Parallel processing frameworks, such as OpenMP, are employed to accelerate CPU-based tasks, including image preprocessing and feature extraction, while OpenCL is utilized to offload and expedite deep learning inference tasks to the GPU. This heterogeneous approach ensures efficient resource utilization and scalability, significantly reducing processing time compared to a homogeneous system. The combined use of advanced signal processing techniques and deep learning algorithms in a parallelized computing environment enables the system to achieve high accuracy in physiological parameter estimation while maintaining real-time operational capabilities, making it highly suitable for applications in remote health monitoring and telemedicine.

D. Evaluation Metrics

In evaluating the performance of the physiological parameter extraction systems, we employ a multifaceted approach that encompasses both accuracy and efficiency aspects. Accuracy Metrics focus on quantifying the precision of physiological parameters extracted from facial images. Key metrics include:

1) Mean Absolute Error (MAE): This metric measures the average magnitude of errors between the extracted and ground truth physiological parameters. It provides a straightforward indication of the system's accuracy in estimating parameters such as heart rate and respiratory rate.

2) Root Mean Square Error (RMSE): RMSE evaluates the square root of the average squared differences between extracted values and ground truth. This metric is particularly useful for assessing the impact of larger deviations and provides insight into the consistency and reliability of the parameter estimations.

Performance Metrics assess the operational efficiency and speed of the systems:

3) Processing time: This metric measures the elapsed time required for the system to process a sequence of images or video frames. It is critical for evaluating the system's capability to operate in real-time, with lower processing times indicating enhanced performance.

4) Resource utilization: This involves monitoring CPU and GPU usage during system operation. Efficient resource utilization is essential for optimizing system performance, particularly in heterogeneous systems where balancing computational load between CPU and GPU can significantly impact overall efficiency.

By analyzing these metrics, we gain comprehensive insights into both the accuracy of physiological parameter extraction and the operational efficiency of the systems. This evaluation not only highlights the strengths and limitations of the homogeneous and heterogeneous implementations but also provides a detailed understanding of their practical applicability in real-world scenarios. The comparative analysis informs decisions on optimizing system design for enhanced performance and reliability in non-invasive health monitoring applications. The following Tables IV to VI illustrate the eventual evaluation metrics overview done, and the values outlined by the MAE and the RMSE.

TABLE IV. EVALUATION METRICS OVERVIEW

Metric	Homogeneous System	Heterogeneous System
Processing Time	120ms per frame	45ms per frame
Accuracy (HR)	± from 1 to 2 bpm	
Accuracy (RR)	±from 1 to 3 breaths per minute	
Resource Utilization	High CPU usage	Balanced CPU/GPU usage

TABLE V. MEAN ABSOLUTE ERROR (MAE)

Parameter	Homogeneous System	Heterogeneous System
Heart Rate	~From 1.8 to 3.5	
Respiratory Rate	~From 0.9 to 2.1	

TABLE VI. ROOT MEAN SQUARE ERROR (RMSE)

Parameter	Homogeneous System	Heterogeneous System
Heart Rate	~From 2.0 to 4.2	
Respiratory Rate	~From 1.1 to 2.5	

VI. Results and Analysis

A. Experimental Setup and Dataset

The experimental setup for evaluating the proposed physiological parameter extraction system is meticulously designed to assess performance across different configurations. The dataset comprises a diverse set of facial images, encompassing a wide range of lighting conditions, facial expressions, and orientations. These images a captured in controlled environments to ensure variability and robustness. Each image within the dataset is meticulously annotated with ground truth values for physiological parameters such as heart rate and respiratory rate, enabling precise validation of the system's accuracy.

The experimental environment includes two distinct computing platforms: a naive homogeneous system and an optimized heterogeneous system. The homogeneous system operates on a single type of processor, serving as the baseline for performance comparison. In contrast, the heterogeneous system leverages a combination of CPU and GPU resources, utilizing parallel processing frameworks such as OpenMP and OpenCL to enhance computational efficiency and real-time processing capabilities. Detailed specifications of both systems are documented, including processor models, memory configurations, and software environments.

The experimental workflow encompasses several stages: image acquisition, preprocessing, feature extraction, and parameter estimation. Preprocessing steps involve image normalization, noise reduction, and enhancement to standardize input data. Feature extraction employs advanced signal processing techniques to isolate relevant facial features used for physiological parameter estimation. Deep learning algorithms, including convolutional neural networks (CNNs), are then applied to extract and predict the desired parameters. Diagrams illustrating the experimental setup, such as camera positioning and system architecture, are provided to represent the setup.

B. Performance Metrics

Processing time metrics are critical for understanding the system's capability to perform in real-time scenarios. Metrics such as the average processing time per image reflect the time required to process a single facial image and extract the necessary physiological parameters. The total processing time for a batch of images is also assessed to evaluate the system's efficiency in handling multiple inputs simultaneously. These metrics help in identifying potential delays and ensuring that the system can meet the real-time requirements of practical applications.

Resource utilization metrics provide insight into the efficiency with which the system uses computational resources. CPU utilization measures the percentage of processing power utilized by the central processing unit, while GPU utilization assesses the usage of the graphics processing unit, crucial for systems leveraging heterogeneous architectures. Memory usage metrics track the amount of RAM consumed during processing, which can influence the system's ability to handle large datasets or perform complex computations. Analyzing these metrics allows for the identification of resource bottlenecks and opportunities for optimization, ensuring that the system operates efficiently within the constraints of the hardware.

Together, these performance metrics offer a comprehensive evaluation of the system's ability to accurately and efficiently extract physiological parameters, highlighting areas for improvement and optimization. By systematically analyzing these metrics, the study provides a clear picture of the system's strengths and limitations, facilitating informed decisions on further enhancements and practical deployment in healthcare applications.

C. Comparative Analysis

The comparative analysis systematically evaluates the performance disparities between the naive homogeneous system and the optimized heterogeneous system, focusing on processing efficiency, accuracy, and resource utilization. In terms of processing efficiency, the optimized heterogeneous system, which utilizes a CPU-GPU architecture, demonstrates a significant reduction in image processing time. This improvement is largely attributable to the parallel processing capabilities enabled by frameworks such as OpenMP and OpenCL, which facilitate concurrent execution of computational tasks and efficient utilization of available hardware resources. The analysis also considers resource utilization, where the heterogeneous system exhibits superior efficiency in managing computational resources. CPU and GPU utilization metrics indicate that the optimized system achieves higher throughput and lower idle times.

Overall, the results highlight the tangible benefits of adopting a heterogeneous architecture for real-time physiological parameter extraction. The optimized system not only accelerates processing but also maintains higher accuracy, making it a more effective solution for demanding healthcare monitoring applications. This comparative analysis underscores the importance of leveraging advanced parallel computing techniques to achieve significant performance gains in complex real-time systems. In the following Fig. 11 illustrates the processing time achieved using the naïve version and the optimized version versus the number of frames. Also, Fig. 12 and 13 show the estimated heart and respiratory rates versus the actual ones.

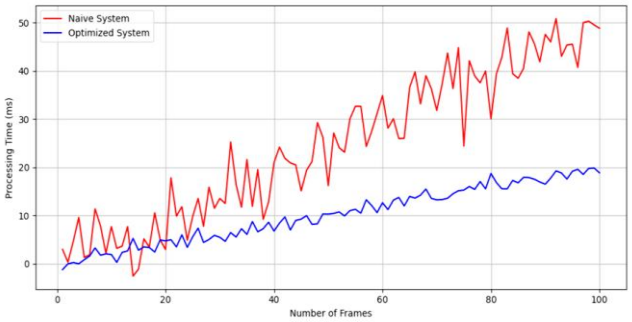

Fig. 11. Processing time vs. Number of frames.

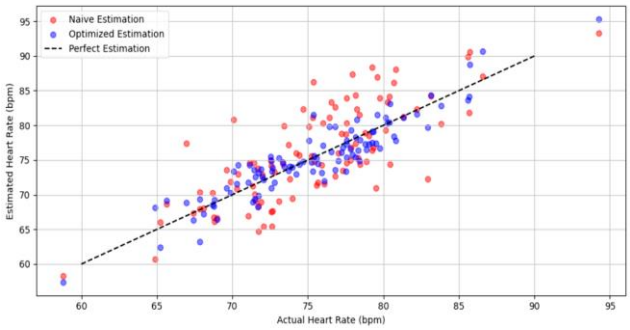

Fig. 12. Estimated HR vs. Actual HR.

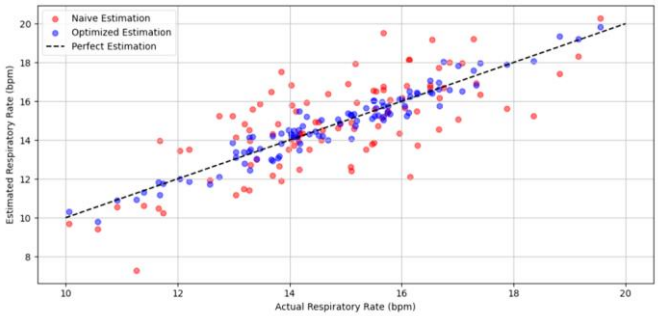

Fig. 13. Estimated RR vs. Actual RR.

VII. Conclusion

This study presents a groundbreaking approach for the non-contact extraction of physiological parameters, such as heart rate and respiratory rate, from facial images using RGB cameras, capitalizing on advanced deep learning and signal processing methodologies. The proposed system adeptly addresses several key challenges, including variations in lighting conditions, facial orientation, and background noise, through the integration of sophisticated AI-driven algorithms. A comprehensive evaluation reveals that the optimized heterogeneous architecture, employing both CPU and GPU resources, significantly outperforms the traditional homogeneous system in terms of processing speed and computational efficiency. The optimization achieved through parallel computing frameworks, notably OpenMP and OpenCL, results in marked improvements in real-time performance while preserving high accuracy levels. This advancement underscores the efficacy of heterogeneous architectures in enhancing the scalability and responsiveness of non-invasive physiological monitoring systems. The study's findings not only validate the potential of these technologies for applications in remote patient monitoring and telemedicine but also highlight the importance of continued innovation in system design and computational techniques to meet the evolving needs of healthcare technology. The successful implementation and demonstrated performance of the proposed system represent a significant step forward in the field of remote health monitoring, providing a robust platform for future research and development.

VIII. Future Work

Future work should focus on several critical aspects to advance the capabilities and practical application of non-contact physiological monitoring systems. Firstly, there is a need for continued refinement of the deep learning models and signal processing algorithms employed in the system. This includes exploring techniques such as model pruning and quantization to enhance computational efficiency and reduce latency without compromising accuracy. Additionally, integrating multi-modal sensing technologies, such as combining facial image analysis with thermal imaging or data from wearable sensors, could significantly improve the robustness and precision of physiological measurements by providing complementary data that address limitations inherent in single-modal systems. Extensive field testing across varied environments and diverse demographic groups is also essential to validate the system's performance in real-world conditions, ensuring reliability and adaptability under different lighting conditions, facial orientations, and levels of noise. Furthermore, optimizing the system for deployment on mobile and edge computing platforms would increase its accessibility and usability, making it more practical for widespread adoption. Lastly, addressing ethical and privacy concerns related to the collection and use of facial data is of utmost importance. This involves developing comprehensive guidelines and implementing advanced technologies to protect user data, ensure informed consent, and uphold privacy standards. By tackling these areas, future research can build upon the current advancements, pushing the boundaries of non-contact physiological monitoring and contributing to more effective, efficient, and ethical healthcare solutions.

Acknowledgment

We owe a debt of gratitude to the Ministry of National Education, Vocational Training, Higher Education and Scientific Research (MENFPESRS) and the National Centre for Scientific and Technical Research of Morocco (CNRST) for their financial support for the project Cov/2020/109.

Smart Muni Platform: Efficient Emergency and Citizen Security Management Based on Geolocation, Technological Integration and Real Time Communication

Gerson Castro-Chucan, Hiroshi Chalco-Peñafiel, Norka Bedregal-Alpaca, Victor Cornejo-Aparicio
Universidad Nacional de San Agustín de Arequipa, Arequipa, Perú

***Abstract*—The global increase in crime across cities has led to the development and implementation of technological solutions, such as the Smart Muni platform, designed to enhance citizen security. This platform integrates geolocation, real-time notifications, and a digital panic button to optimize emergency management and coordination between citizens and authorities. Developed using a structured approach that included requirements analysis, system design, development, testing, validation, deployment, and maintenance, the platform employs advanced technologies such as Firebase, Amazon S3, and Twilio, ensuring scalability, high availability, and seamless communication. Initially implemented in two districts with high crime rates, Smart Muni registered an average of 10 daily alerts, with peaks of up to 50 alerts in a single day. The system has proven effective in managing frequent incidents like alcoholism and domestic violence, significantly reducing response times and improving coordination. Despite its success, Smart Muni faces challenges related to optimizing its resilience against potential system failures and improving its ability to handle increased data loads. In comparison to other international systems, Smart Muni's flexible and scalable architecture stands out, though future enhancements are required to further strengthen the system's reliability and expand its features. Overall, Smart Muni has proven to be a valuable tool in improving citizen security, fostering stronger relationships between citizens and authorities, and contributing to a safer community.**

***Keywords*—Citizen security; geolocation; emergency management; cloud technology; alert platform**

I. Introduction

Citizen security refers to the protection of citizens' rights and freedoms, as well as the prevention and control of violence and crime in urban environment [1]. For García and Zambrano [2], this concept should be conceived from a broad perspective, involving both the perception of security by the population and the concrete actions carried out by the authorities to guarantee it.

Globally, many cities are experiencing rising crime rates and facing major challenges in emergency management. Rapid urbanization and increased population density in urban areas have aggravated these problems, highlighting the need for innovative solutions to ensure public safety. In large cities, the adoption of advanced technologies has proven to be effective in improving coordination and response to crime incidents and emergencies; to increase the effectiveness and efficiency of public safety operations, innovative strategies using the Global Positioning System (GPS) have been implemented. Cities such as New York and London have integrated geolocation systems and data analysis into their security strategies, allowing for a faster and more accurate response to emergencies. However, in Latin American countries, the integration of technology to promote the security of their citizens is lagging behind [3].

While several international systems, such as those implemented in New York and London, have successfully integrated geolocation and data analysis to improve emergency response, these solutions often focus on larger, well-resourced urban centers. In contrast, Latin American cities, particularly in Peru, face unique challenges such as fragmented communication infrastructures and limited access to technological resources. The existing systems also lack the ability to address the specific needs of local municipalities, which often operate under constrained budgets and require more adaptable solutions. Smart Muni fills this gap by providing a scalable, cost-effective platform tailored to the context of smaller cities in developing regions. Its integration of real-time communication, geolocation, and cloud-based technologies ensures that it can quickly adapt to the evolving needs of these communities, while also offering enhanced resilience in regions where emergency response systems are often under-resourced.

The problem of citizen security in Peru is complex and multifaceted; many Peruvian cities are experiencing an increase in crime rates, a situation that is affected by various social, economic and political factors. According to the National Strategic Programs Survey, nine out of 10 people believed that they would be victims of crime in the next 12 months [4]. Citizens and local authorities face difficulties in coordinating quick and effective actions to guarantee citizen security; there is a growing concern about acting in a timely manner to prevent crime or mitigate its consequences.

The lack of an integrated incident management system and the absence of adequate technological tools for the reception and management of security and emergency alerts compromises the authorities' ability to act in a timely manner and reduces community confidence in public safety, demonstrating the urgent need to implement an advanced technological solution to optimize emergency response and management, improve communication between citizens and authorities, and strengthen

citizen security in the region. Sarkar [5] and Samarakkody et al. [6] suggest that technological innovations enhance disaster resilience and empower citizens, creating livable communities and improving overall quality of life. Protecting a complex environment, such as a city, is a task of enormous and increasing complexity, requiring the combination of multidisciplinary techniques and tools, the availability of very diverse skills, and the ability to correlate and explore large flows of data and information [7]. Technology plays a crucial role in smart cities, supporting the optimization of urban services and improving the quality of life of their inhabitants [8].

Several research studies explore the application of geolocation and geographic information systems (GIS) to improve citizen security and tourism safety. Alvarez [9] proposes extending Ecuador's ECU 9-1-1 system to rural areas, incorporating georeferencing and monitoring cameras to enhance emergency response. In Mexico, Espinoza-Ramirez et al. [10] developed a mobile device-based system using GIS to map crime incidents, helping citizens to identify and avoid dangerous areas. However, Gonzalez [11] raises concerns about the constitutionality of citizen geolocation through mobile applications, particularly about the rights to privacy and freedom of movement. Solano Barliza [12] suggests that combining recommender systems with geolocation technologies could improve tourism safety, pointing out the lack of existing solutions specifically focused on this aspect.

The implementation of a geolocation-based software application to detect aid points when a citizen observes or suffers a crime is crucial for a rapid and coordinated response by the authorities [13], which would significantly improve communication between citizens and authorities, strengthen trust in public safety, and empower the community to actively participate in their own protection.

For their part, Jesus et al. [14] deal with the reliability and detectability of emergency management systems, emphasizing the importance of resilience to common failures. Costa et al. [15] present a review of various emergency management systems, highlighting the diversity of technologies and approaches used. Samarakkody et al. [16] investigate technological innovations that improve disaster resilience in smart cities.

In this information context, a robust and efficient platform for the management of citizen emergencies and alerts is proposed, which will significantly improve the response and coordination capacity between citizens and authorities and allow for a more direct and real-time interaction, facilitating decision making and the mobilization of resources to efficiently respond to citizens' calls for help.

II. Methodology

A. Stages

In order to develop a robust and effective platform to improve citizen security through the use of geolocated technology, a structured methodology has been followed that includes the following stages:

1) Requirements analysis: Identification of needs and definition of functionalities.

2) System design: Definition of the technical structure and design of an intuitive and accessible interface for users.

3) Development: Identification of suitable languages and frameworks for web and mobile development.

4) Testing and validation: Performing unit and integration testing to ensure that each component works correctly and the app as a whole operates smoothly, and user testing to get feedback and make necessary adjustments.

5) Deployment and maintenance: Release, monitoring and updates to improve functionality and security.

B. Implementation Context

The proposed platform was implemented in the districts of Cayma and José Luis Bustamante y Rivero, located in the region of Arequipa, Peru; districts that face a significant increase in crime. With populations of approximately 91,935 and 82,642 inhabitants, respectively, these districts have seen an increase in crimes such as robberies, vandalism, family violence and cases of alcoholism. In 2022, more than 1290 robberies and about 1038 cases of family violence were reported [17][18].

The growing concern among citizens and authorities is due to the inadequate and delayed response to emergencies, aggravated by the absence of a unified incident management system. To deal with this problem, Smart Muni was implemented, a comprehensive platform consisting of a web application, a mobile application for the sereno (municipal security officer) and a mobile application for the citizen. This solution seeks to improve coordination and efficiency in emergency attention, facilitating communication and incident management in the districts of Cayma and José Luis Bustamante y Rivero.

III. Platform Description

The direct users of the platform are citizens, serenos and municipalities (Fig. 1). Citizens use a mobile application to report incidents and emergencies, providing details such as location and multimedia information. Additionally, they receive notifications about their reports, access security information, use the panic button in emergency situations and consult the incident history.

For their part, the serenos, members of the citizen security corps, work to maintain order and security in streets and public spaces. Employed by local governments, such as provincial and district municipalities, their main function is to prevent and control risk situations, such as robberies, aggressions or disturbances. The serenos, using the corresponding mobile application, manage the incidents reported by citizens through geolocated alerts, resolving and updating them in real time, and they are monitored to ensure their location.

The municipalities use a web application to manage the platform. This web application allows attending to alerts or incidents and assigning them to the corresponding units, analyzing data in real time through advanced analysis tools to identify patterns and improve security, and sending notifications to citizens in a timely manner. Furthermore, municipalities can manage user permissions and access, integrate the system with other government and emergency entities, and continuously

monitor all activities to ensure a quick and efficient response to any incident.

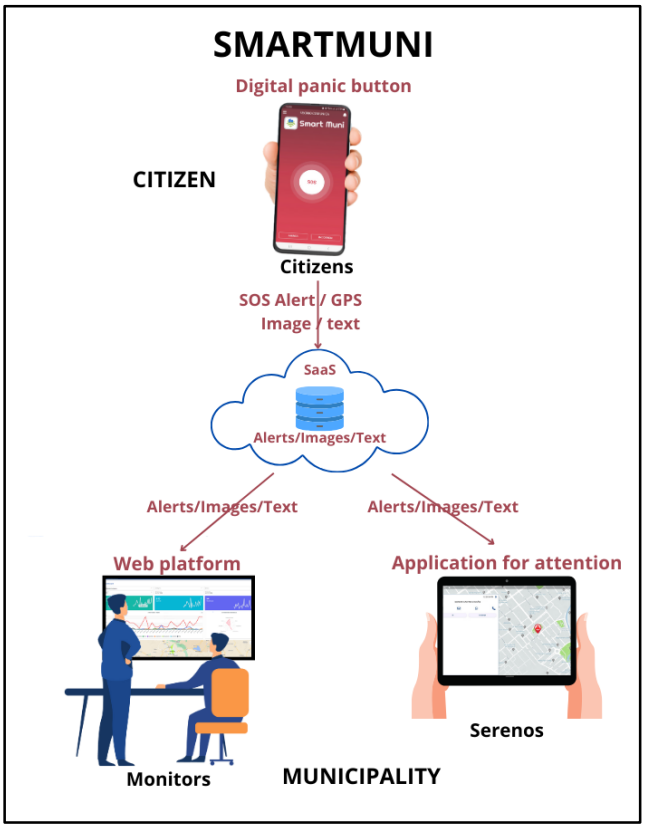

Fig. 1. Smart muni scheme.

A. Integration of Technologies

The platform architecture was designed and developed internally to ensure efficient control over the deployment and updating of the project. Fig. 2 shows the technologies employed in three key areas: data storage, message sending and deployment.

1) Data storage: For data storage, Amazon S3, PostgreSQL and Firebase Realtime Database technologies were used [19][20][21].

2) Deployment: Docker, Docker Compose and GitLab CI/CD along with GitLab Runner were used for developing, sending and executing containerized applications, facilitating continuous integration and delivery [22][23][24][25].

3) Web service providers: Web services were provided by DigitalOcean and GoDaddy, simplifying IT infrastructure and offering online tools for business [26][27].

4) Messaging: Firebase Cloud Messaging and Twilio were used for messaging and notifications, enabling communications on iOS, Android devices and web applications [28][29].

5) Development technologies: Django REST Framework, Quasar Framework and Flutter were used in the development of technologies, allowing the construction of web APIs, user interfaces and hybrid mobile applications [30][31][32].

6) Servers and middleware: Servers and middleware included Nginx, uWSGI, Let's Encrypt and Ubuntu UFW, providing high performance, security and firewall rule management on servers [33][34][35][36].

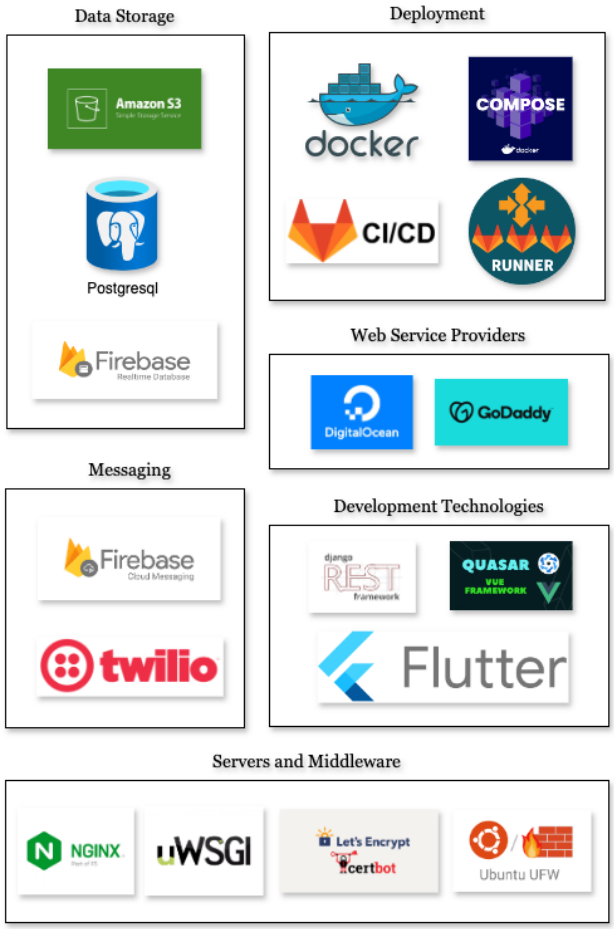

Fig. 2. Scheme of the used technologies.

B. Software Architecture

Fig. 3 shows the software architecture of the platform, integrating several external services and specialized databases.

The platform architecture is composed of the following elements:

1) Firebase services: Includes Firebase Real Time Database and Firebase Cloud Messaging for real-time storage and sending notifications to mobile devices.

2) Google service: Google Maps APIs for mapping and location functionalities.

3) Amazon service: Amazon S3 for file and data storage.

4) Twilio service: For communication and sending SMS messages.

5) GeoLite2 service: For geographic location of IP addresses.

6) PostgreSQL database: Used as the main data store.

7) Web services: This central component manages the interactions between models, controllers, views and the ORM. It is the system core that connects database and external services with the mobile applications and the website.

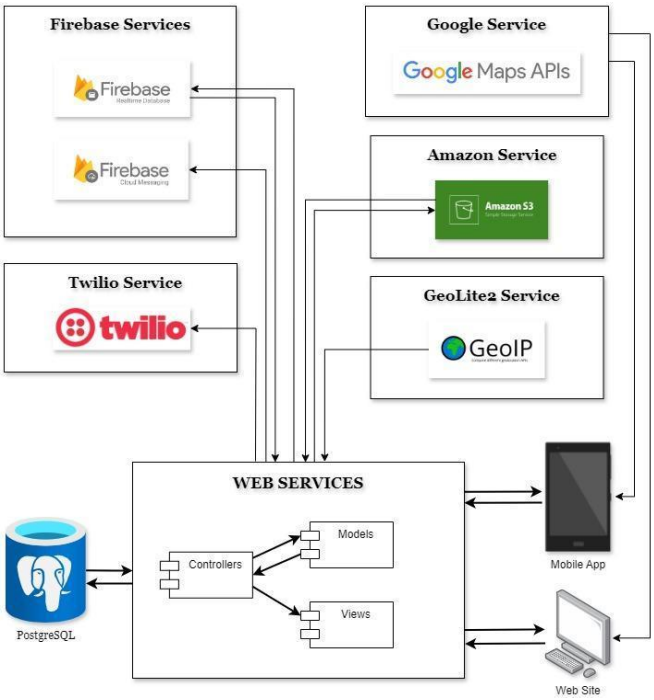

Fig. 3. Platform architecture.

This architecture allows the integration of several services and technologies providing a robust and scalable solution that supports both mobile and web applications. The web application uses Vue.js (progressive framework for building user interfaces) for client development, structured with VueRouter (library for handling navigation in Vue.js applications) for navigation and a Store (centralized solution for managing the state of an application) for state management (Fig. 4).

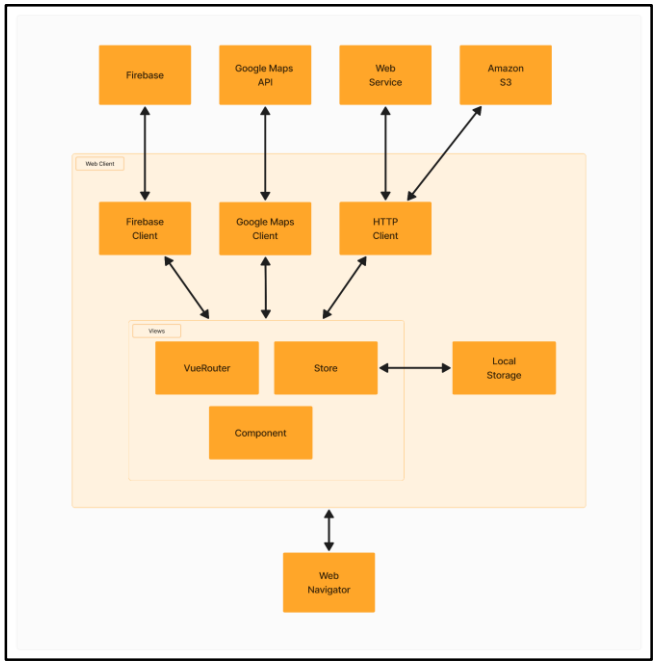

Fig. 4. Web architecture.

These components interact with Firebase for real-time databases, Google-Maps-API for maps, an API for data and Amazon S3 for file storage through specialized clients. The browser's local storage is used for session data. User interaction is performed through a web browser, communicating directly with Vue.js components for an interactive and dynamic experience.

For the mobile architecture (Fig. 5), Flutter (UI framework for creating native applications) is used with the BLoC design pattern to manage events and states. Flutter components communicate with Firebase for real-time databases, Google Maps API for maps and a web service to consume data from an API through specialized clients. The SharedPreferences library is used to persist data locally, and mobile services such as GPS and camera are integrated. The application, running on Android and iOS devices, interacts with Flutter widgets, efficiently managing resources and functionality.

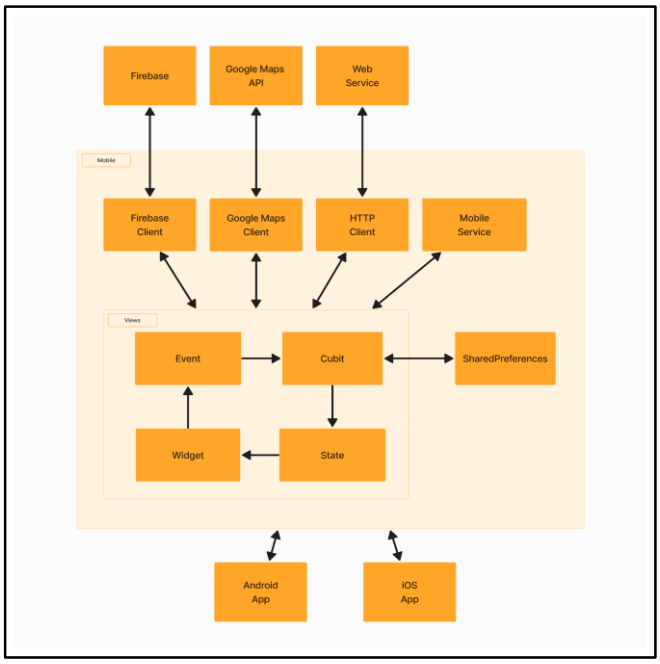

Fig. 5. Mobile architecture.

C. Navigability Diagrams

The web application allows the comprehensive management of various modules related to citizen security, including incidents, alerts, monitoring and events. Moreover, it facilitates the administration of venues, advertising, geozones and other municipal aspects, both on the part of the municipality and the administrators. The assignment of specific permissions according to account type is also considered (Fig. 6).

The mobile application for citizens (Fig. 7) allows the creation of accounts, sending alerts and generating incidents through an interactive map. Besides, configuration of profiles and the possibility of reviewing the history of alerts and incidents are also available.

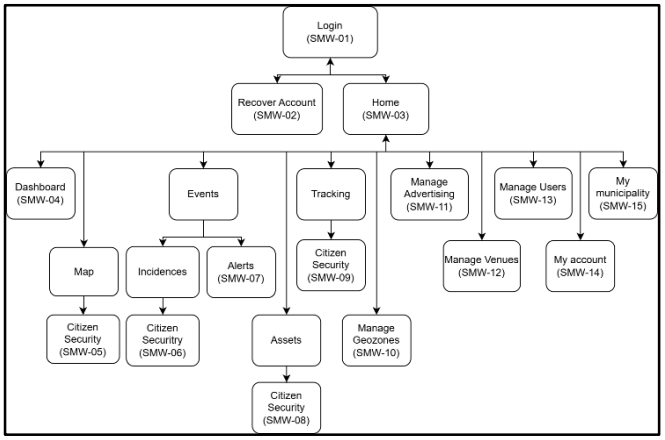

Fig. 6. Web application navigability diagram.

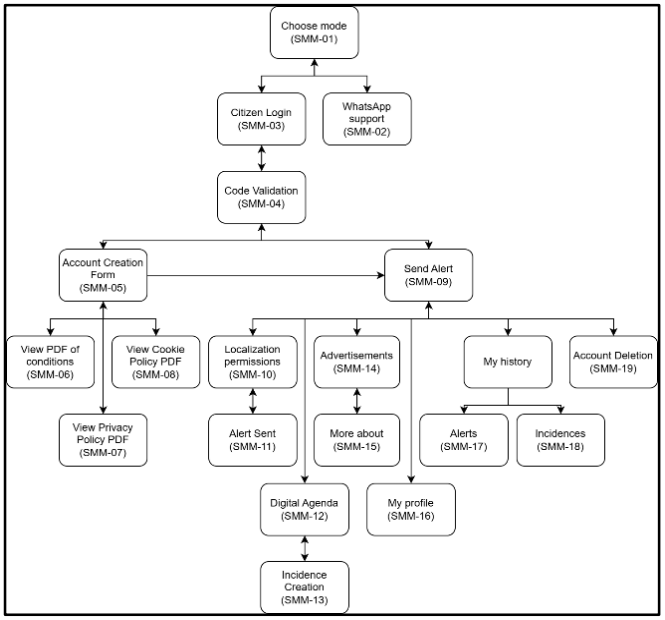

Fig. 7. Citizen's application navigability diagram.

The mobile application for serenos (Fig. 8) allows the configuration of profiles and locations, as well as the review of the history of alerts and incidents of all users. It also facilitates visualization of this information through PDF files.

D. Interfaces

The user interface is the point of human-computer interaction and communication on a device. Fig. 9 and Fig. 10 show main interfaces of the platform. Fig. 9 shows the main screen of Smart Muni web application, where an interactive map showing locations of different incidents and alerts in the city can be seen.

In this interface, alerts and incidents can be attended, as well as incidents can be filtered by their status (attended or not attended) and by type of incident (alert, family violence, alcoholism, drug addiction, robbery, vandalism, accident and others). In addition, monitoring by application is displayed, showing the number of workers, motorcycles, vans and other vehicles monitored in real time, as well as the number of cameras and sirens available.

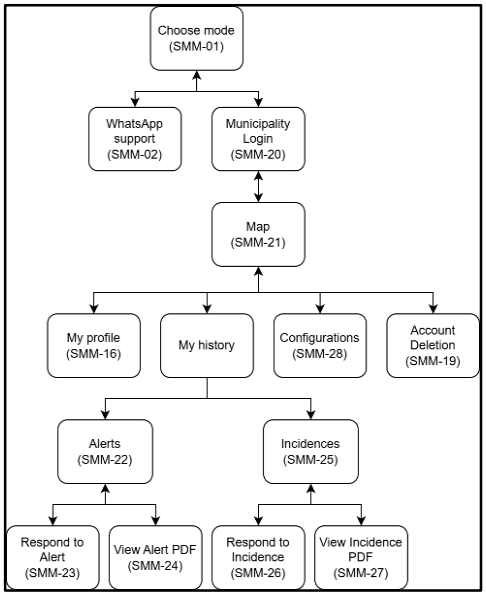

Fig. 8. Sereno's application navigability diagram.

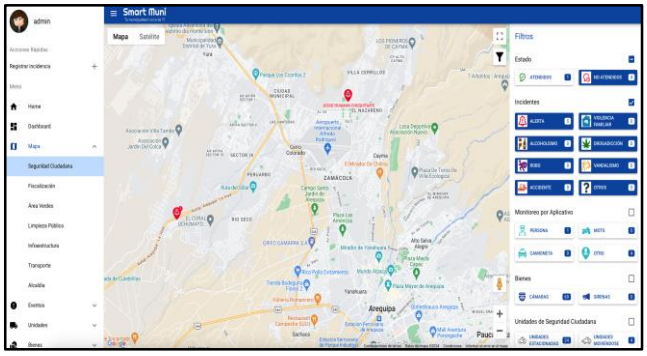

Fig. 9. Main interface of the control module and display of alerts and incidents.

Fig. 10. Mobile app sending an alert.

Detailed interfaces can be accessed by clicking on: INTERFACES.pdf

IV. RESULTS

The implementation of Smart Muni in the districts of Cayma and José Luis Bustamante y Rivero has significantly improved citizen security, demonstrating its positive impact on management of emergencies and citizen reports.

Smart Muni in the district of José Luis Bustamante has been in operation since December 20, 2023, and in the district of Cayma since June 20, 2023.

The historical record made by the application is fundamental to evaluate the accuracy and efficiency of the system compared to the manual methods previously used, methods that, since they are not adequately regulated, have not allowed access to the historical data recorded manually. Data collection through the Smart Muni platform allows for the creation of a solid base of information to be analyzed over time. This continuous recording ensures data integrity, and also facilitates identification of patterns, trends and potential improvements in the process. The historical data collected by the application over one year (Table I) are evidence of the system's impact and evolution, emphasizing its capacity to generate accurate and consistent records that contribute to informed decision making.

TABLE I. NUMBER OF ALERTS AND INCIDENCES PER MONTH

Month / Year	Cayma	José Luis Bustamante y Rivero
August 2023	145	-
September 2023	128	-
October 2023	89	-
November 2023	93	-
December 2023	117	156
January 2024	56	99
February 2024	53	48
March 2024	117	71
April 2024	139	60
May 2024	161	68
June 2024	126	32
July 2024	209	49

Heat maps are visual tools that show data density in geographic areas. In citizen security, areas with the highest frequency of incidents are indicated using a color scale. This helps the authorities to identify “hot spots” for better allocation of resources and preventive measures. Fig. 11 and Fig. 12 heat maps identified critical areas in Cayma (La Tomilla Zone B and Señorial Urbanization) and José Luis Bustamante y Rivero (Estados Unidos Avenue and Vidaurrazaga Avenue), enabling efficient targeting of resources.

Table II presents 413 incidences received, the most common were family violence and alcoholism, with 148 and 144 cases respectively, facilitating a specific preventive approach. These results demonstrate Smart Muni's effectiveness in improving community safety and well-being through effective communication and comprehensive resource management.

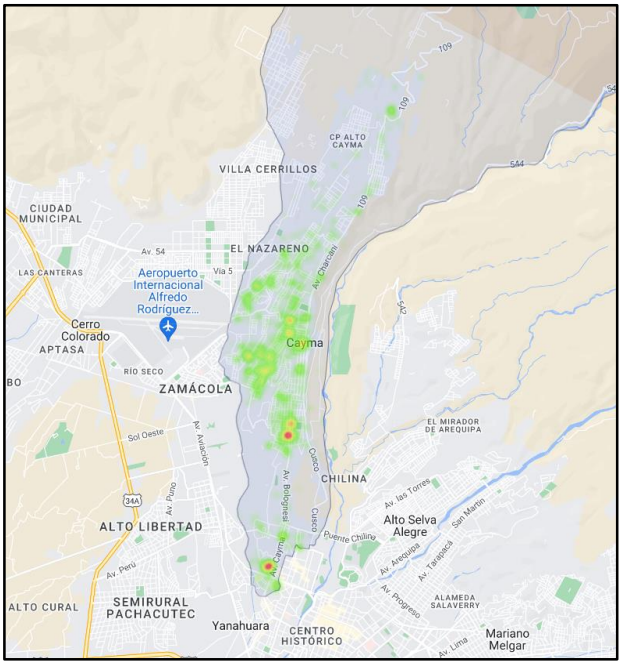

Fig. 11. Heat map of Cayma district.

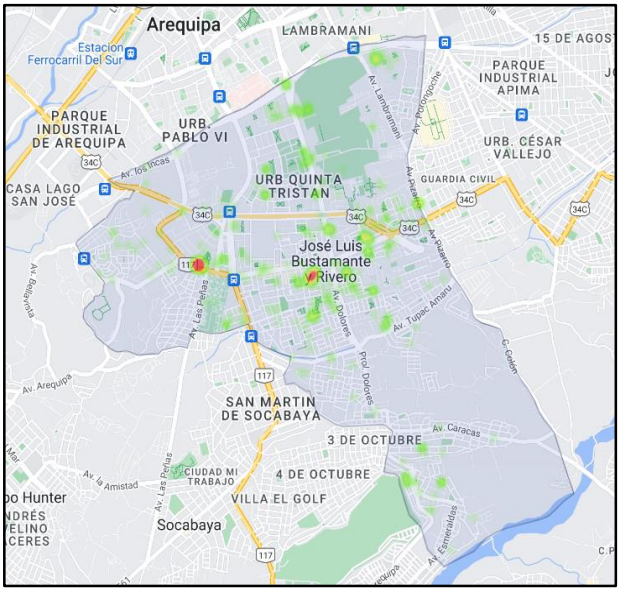

Fig. 12. Heat map of José Luis Bustamante y Rivero district.

TABLE II. NUMBER OF ALERTS AND INCIDENTS BY TYPE

Type of incident	Quantity	Percentage
Family violence	148	36%
Alcoholism	144	35%
Robbery	28	7%
Drug addiction	7	2%
Vandalism	7	2%
Accident	8	2%
Other	71	17%

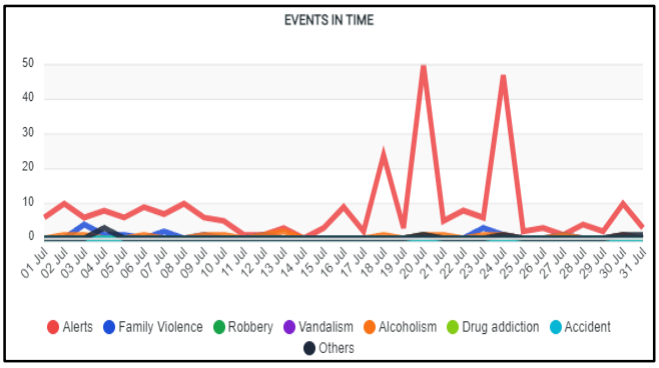

Fig. 13. Alerts and incidents graph in month with the highest activity.

Fig. 13 shows a graph illustrating the quantity of alerts and incidents recorded during the last year. The horizontal axis shows the dates, while the vertical axis shows the quantity of alerts received. Data analysis reveals the day with the highest number of recorded alerts reached a peak of 50, while the daily average number of alerts remained at 10. This graph displays trends and peaks in alert activity, providing a clear view of peak demand times and helping to plan a better response by authorities.

Fig. 14 shows a distribution graph of incident types reported through Smart Muni platform. This graph indicates that the most frequent incidence types are alcoholism and family violence, which stand out significantly over other incidence types. This information is crucial for authorities, helping to identify the areas of greatest concern and need for intervention, facilitating implementation of targeted strategies to deal more effectively with these specific problems.

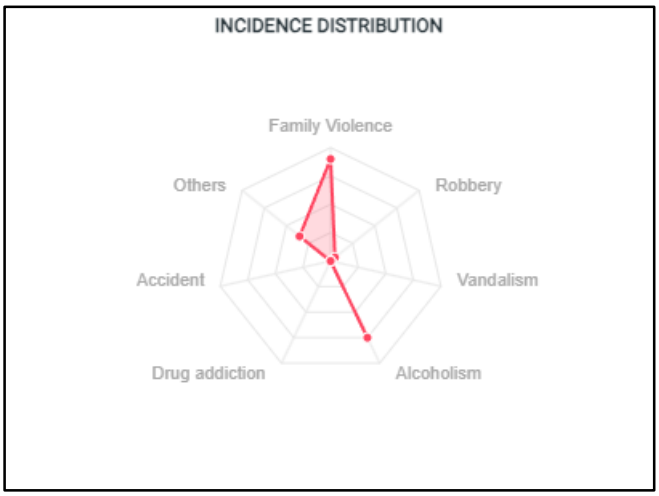

Fig. 14. Distribution of incidence types.

V. Discussion

The implementation of Smart Muni has proven to be an effective solution for emergency management and improving citizen security in the districts of Cayma and José Luis Bustamante y Rivero. The proposed platform, Smart Muni, as suggested by Liu and Li [13], uses geolocation and real-time communication technologies to enhance coordination between citizens and authorities. The implementation of tools such as the digital panic button and instant notifications has significantly reduced emergency response times, in line with recommendations of Liu and Li's study.

Smart Muni incorporates multiple layers of redundancy and uses cloud services such as Firebase and Amazon S3 to ensure data availability and reliability. Although this approach has proven to be effective, it is essential to continue to explore and improve the resilience of the system to potential failures, as suggested by Jesus et al. [14].

While Smart Muni shares similarities with several solutions reviewed by Costa et al. [15], particularly in the use of mobile applications for alert management, it offers significant advantages over existing systems. First, Smart Muni is designed to be highly scalable and flexible, making it adaptable to both large and small municipalities with varying levels of technological infrastructure. Unlike many international systems that are often cost-prohibitive for smaller cities, Smart Muni provides a cost-effective solution that is particularly suited to municipalities operating under budget constraints. Additionally, its integration of real-time communication through services such as Firebase and Twilio ensures a faster, more reliable response compared to traditional systems, which often suffer from delays due to manual processes. Moreover, the cloud-based architecture ensures high availability and data redundancy, critical for maintaining system functionality even in the face of failures, a challenge that many other systems do not adequately address. These advantages make Smart Muni an ideal solution for developing regions where emergency response systems are often underfunded and technologically underdeveloped.

One of Smart Muni's strengths is the implementation of a flexible and scalable architecture that quickly adapts to changing community needs and emerging challenges. This flexibility and adaptability are aligned with the recommendations of Samarakkody et al. [16], who emphasize the importance of dynamic and resilient systems to efficiently manage emergencies in complex urban environments.

Comparison with these previous studies has identified areas for improvement and opportunities for future research. Although Smart Muni has shown promising results in terms of efficiency and responsiveness, it is essential to continue optimizing the system's resilience to failures and exploring new technologies which can complement and enhance existing functionalities. Additionally, performing periodic evaluations and adhering to best practices identified in the literature is recommended to ensure the system remains effective and relevant.

VI. Conclusion

Smart Muni has demonstrated to be a viable and effective solution to improve citizen security through use of advanced technologies. The platform has optimized emergency management and has also strengthened the relationship between citizens and authorities, promoting a safer and more resilient community.

Smart Muni application was successfully developed and implemented, offering key functionalities such as incident reporting, geolocation, real-time notifications and digital panic button; these features have allowed for a more agile and efficient management of emergencies.

Multiple technologies were integrated, including Firebase, Amazon S3, Docker, and Twilio, among others, to guarantee a scalable and highly available system. This technological integration has permitted platform to handle large volumes of data and support fluid communication between different actors involved.

The platform has provided advanced analysis and monitoring tools, which have made it possible to identify critical areas and incidence patterns. This has facilitated a more efficient allocation of resources and implementation.

The work performed provided a solid base for future improvements and expansions of system:

1) Integration of security cameras into platform to enable real-time monitoring. This will allow authorities to view streaming cameras when a robbery is reported, ensuring a faster and more effective response.

2) Implement an option to make payments directly through the application, such as payment of municipal taxes and other municipal services. This will simplify the process for citizens and improve administrative efficiency.

3) Incorporate an intelligent chatbot to help solve users' doubts about use of application and other related issues. This will improve user experience and reduce workload for support staff.

4) Perform data analysis to evaluate security in areas within a 5 km radius, based on reports from the last 2 to 3 weeks. This will allow citizens to have a clear view of security in their area and make informed decisions.

5) Implement a function like a Facebook wall where citizens can interact anonymously, post incidents and respond to municipality publications. This will encourage greater citizen participation and improve communication between community and authorities.

6) Implement a messenger chat so the municipality can have direct communication with neighborhood councils, who are people in charge of supporting citizen security in a specific sector. This will improve coordination and response to emergency situations and security problems.

Despite its success, Smart Muni faced several challenges during its implementation. One of the main limitations was the need for continuous optimization of the system's resilience to potential failures, particularly in areas with unstable internet connectivity, which could affect real-time communication between citizens and authorities. Additionally, the platform's reliance on cloud-based services, while advantageous for scalability, also presents a challenge in terms of maintaining high availability in regions with limited infrastructure. Future improvements should focus on enhancing the system's ability to operate efficiently under these conditions and ensuring its long-term sustainability in municipalities with constrained budgets. Addressing these challenges will be critical for further expanding the platform's reach and impact in other regions.

ACKNOWLEDGMENT

The authors express their gratitude to the Universidad Nacional de San Agustin of Arequipa for the support provided in the realization of this project. The municipalities of Cayma and José Luis Bustamante y Rivero of the city of Arequipa-Peru are also thanked for their collaboration in the implementation of Smart Muni platform. Finally, acknowledgement is extended to all citizens who actively participated in testing and validation of the system.

Serious Games Model for Higher-Order Thinking Skills in Science Education

Siti Norliza Awang Noh[1], Hazura Mohamed[2], Nor Azan Mat Zin[3]
Faculty of Information Science and Technology, Universiti Kebangsaan Malaysia, 43600 Bangi Selangor, Malaysia

***Abstract*—The popularity of digital games has led to the emergence of serious games, which are developed with specific purposes beyond mere entertainment. Serious games in education represent more innovative and current pedagogical approaches. However, the existing digital games have been shown to improve critical thinking skills, although there is still a limited amount of research on science education. A preliminary study has found that digital games developed for science teaching do not incorporate all aspects of Higher-Order Thinking Skills (HOTS). This study aims to identify and validate game components and design a serious game model for HOTS in science education (PKBATDPS Model), which was validated using the Electric Circuit prototype. The study is divided into four phases: analysis, design, development and evaluation. During the analysis phase, the components of the PKBATDPS model were identified. The Electric Circuit prototype was evaluated using a quasi-experimental procedure that included pre-tests, post-tests, and learning motivation questionnaires. The experiment involved 32 elementary students; 16 in the experimental group used the serious games application prototype, whereas 16 in the control group received the traditional method. The results show that the PKBATDPS Model can be effectively used to increase students' HOTS and motivation in science education.**

***Keywords*—Serious game; Higher-Order Thinking (HOT) skills; science education; game element; learning element**

I. INTRODUCTION

Serious games are interactive digital games designed with specific purposes other than entertainment that can train and educate players [1][2]. In recent years, serious games have been developed and used in multiple fields, including the military, advertising, education, simulation, and healthcare [3][4]. In the field of education, serious games are one of the technological tools used as a teaching aid to meet the needs of the current generation. This generation is born in the age of digital technology, commonly known as the Digital Native generation, and is already familiar with technology [5]. Today's generation prefers active learning that is interactive, enjoyable, and focused on problem solving. Therefore, the use of serious games as teaching aids is in line with educational objectives, as they are designed to provide an interactive and exciting learning experience.

According to [6], serious games are a form of student-centred approach that have the potential to build students' understanding of learning. Serious games have grown significantly and widely used in many different subjects to support the learning process and provide learning experiences such as in mathematics [7], science [8], history [9] and language [10]. The use of serious games in education has been shown to have the potential to foster an engaging and interactive learning environment that cultivates critical thinking skills among students. This is because serious games involve the development of the mind and require a deeper level of thinking [6].

Hence, the integration of serious games in education should be broadened to all academic disciplines, with particular emphasis on science. It is regarded as challenging due to its abstract nature and Higher Order Thinking Skills (HOTS) presence. HOTS refers to the highest level of cognitive processing in the cognitive function hierarchy. HOTS entails receiving, storing, delivering, and synthesising new information with existing knowledge to resolve intricate problems [11]. Regarded as pivotal competencies, HOTS contribute to shaping a generation equipped with innovative thinking and the requisite abilities to confront the demands of the 21st century [12].

In Malaysia, the incorporation of thinking skills into the curriculum began in the early years of 1993, focusing on promoting critical and creative thinking skills [13][14]. In 2011, the curriculum was further enhanced to include HOTS, to stimulate students' thinking skills [13]. However, issues related to ineffective science teaching methods have hindered the successful implementation of the HOTS [15]. Traditional teaching methods, which emphasise cognitive activities such as memorisation, recall, and comprehension, have been deemed inadequate to effectively implement HOTS [12]. One-way communication learning methods, such as "note-taking and lecturing," are also viewed as teacher-centred instructional approaches. This method restricts students' ability to think critically and generate and develop their ideas, particularly in science education.

Currently, research on the design of games for science education is also being conducted. According to [16][17], serious games emerge as an effective tool that offer engaging and enjoyable experiences for enhancing learning in science. This is because serious games offer students the opportunity to engage in other alternatives to learning in simulation or experiments [18][19]. Moreover, serious games provide a more active and interactive learning experience that can stimulate interest, increase motivation [2], increase engagement [16] and improve academic achievement in science [20].

However, one of the identified issues in serious game design is the weakness in terms of learning content. In the design of games for science education, alignment with local

curriculum content is imperative to meet the requirements of the national education system and the students' needs. This necessity arises due to disparities in curriculum content, which render existing games on the market less suitable for instructional purposes within the Malaysian context [21].

Previous research has investigated digital games to enhance critical thinking skills [22], yet there remains a scarcity of studies specifically focusing on science education [23]. Preliminary investigations have revealed that digital games designed for science education often lack the integration of all components of HOTS. Additionally, the content of these digital games frequently fails to establish connections with real-life scenarios [21]. Therefore, the collaboration between game developers and subject matter experts is needed to ensure that the serious game design is in line with the learning content that emphasises the HOTS in science education. Hence, developing a model for HOTS games in science education is needed to captivate students' interest and enhance their HOTS capabilities within the subject matter.

II. METHOD

This study utilized the Design and Develop Research (DDR) approach, which encompasses four primary phases: analysis, design, development and evaluation. Data collection employed a mixed-methods approach, integrating both qualitative and quantitative research methodologies.

A. Analysis Phase

The analysis phase serves as the initial step in the study to ascertain the research requirements. During this phase, issues and problems, along with elements of the game model, were identified. The activities include a comprehensive literature review, a survey, and unstructured interviews. The literature explored students' perceptions of science education, the challenges of implementing HOTS in science education, and the design of serious games. The survey aimed to capture students' perceptions of the science subject. Unstructured interviews were conducted with a panel of eight experts, comprising six science teachers and two School Improvement Specialist Coaches Plus (SIC+) science officers, to identify HOTS implementation in science education and the role of digital games in educational settings. Fig. 1 summarizes the activities performed in this phase.

B. Design Phase

In this phase, four key activities were involved: component grouping, component mapping, low-fidelity prototype design, and initial component validation. All elements were systematically organized and mapped into different components of the PKBATDPS Model. The initial PKBATDPS Model was categorized into two primary components: learning components and game components. To illustrate the interrelationship between these components, the research model was depicted in diagram form, providing a comprehensive overview.

Subsequently, the components of the PKBATDPS Model in the low-fidelity prototype, namely the Electric Circuit storyboard, were implemented. The activities are developed based on the Standard Curriculum and Assessment Document for Year 5 Science, specifically the electric topic outlined in the Primary School Standard Curriculum. This approach ensures that the prototype is grounded in the existing educational framework and aligns with the instructional resources available to students.

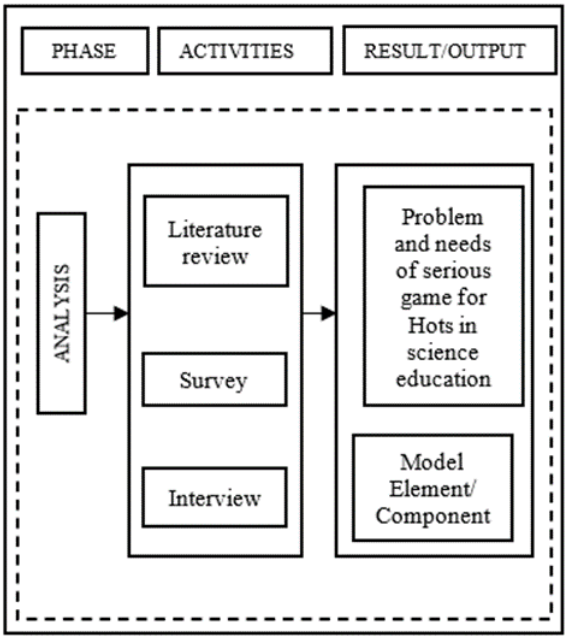

Fig. 1. The activities in the analysis phase.

The initial validation of the PKBATDPS Model components was conducted through heuristic evaluation by assessing the low-fidelity prototype. The validation of the PKBATDPS Model elements engaged two SISC+ officers from the District Education Office (DEO) and three university lecturers. The number of expert evaluators selected for this evaluation is aligned with the recommendations of [24], which advocate for a panel size of three to five individuals. The evaluators were chosen based on their expertise and experience in science education, as well as their proficiency in software and game assessment. Expert validation was conducted to ascertain the implementation of each model element in the game interface design.

The questionnaire consists of three sections: Demographic Information, Learning, and Game. Each expert evaluator responds to questions using a five-point Likert scale, where 1 indicates "Strongly Disagree", 2 “Disagree”, 3 “Neutral”, 4 “Agree” and 5 indicates "Strongly Agree". The assessment results are analysed using the Interquartile Range (IQR) to determine consensus in evaluating expert opinions [25][26]. The IQR is a measure of variability based on the distribution of data divided into three parts: the first quartile (Q1), the median or second quartile (Q2) and the third quartile (Q3). The IQR value is calculated by subtracting Q1 from Q3. Elements with an IQR value of 1 or less (≤ 1) are retained, while those with IQR value greater than (>1) are eliminated. Fig. 2 provides a summary of the activities performed in this phase.

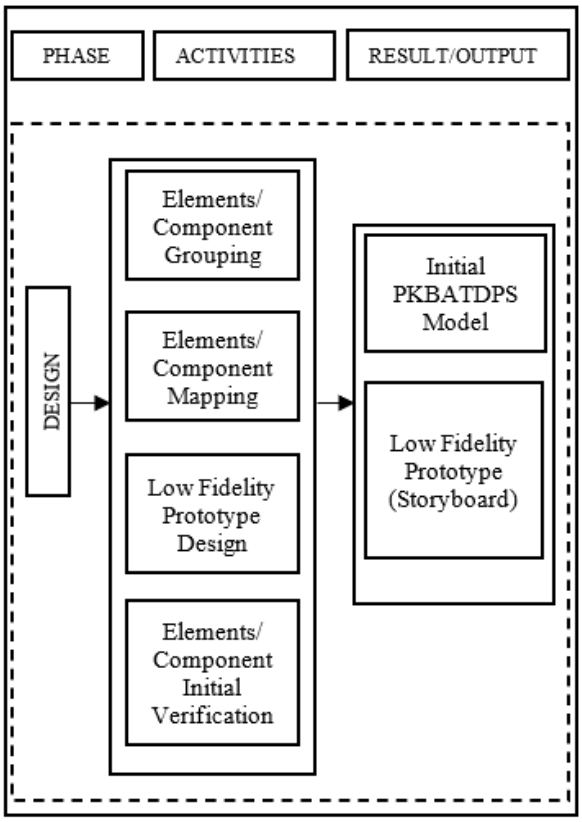

Fig. 2. The activities in the design phase.

C. Development Phase

The development phase involves the implementation of the components of the PKBATDPS Model, which have been refined based on feedback from experts, into the high-fidelity prototype, namely the Electric Circuit game prototype. The development of the Electric Circuit game prototype utilized three software applications: Adobe Photoshop, Autodesk 3D Max, and UNITY, which were employed in the process of creating the game interface. Subsequently, the development of modules, quizzes, and games was executed based on the content design established during the design phase.

The Electric Circuit game prototype is software played offline and is based on self-directed learning, allowing students to learn according to their convenience in terms of place and time.

The game prototype encompasses various subtopics, including electric power sources, complete electric circuits, and safety measures for handling electrical equipment, all presented within a narrative framework. The developmental process of the prototype unfolds progressively through different levels of the game. Advancement from one level to the next entails activities designed to cultivate HOTS, such as application, analysis, evaluation, and creation. This pedagogical approach mirrors Bloom's taxonomy (1985), which underscores the necessity for learners to master each instructional unit before progressing to subsequent ones.

Finally, a meeting was convened with the science subject teachers to provide a concise overview of the study's objectives, evaluation methods, and the prototype employed. During this session, teachers received training on the operational aspects of the Electric Circuit game prototype prior to the actual implementation and evaluation. This preparatory measure ensured that teachers were well-equipped to facilitate the learning experience and offer constructive feedback during the assessment phase, thereby enhancing the overall efficacy of the evaluation process. Fig. 3 shows the activities conducted during this phase.

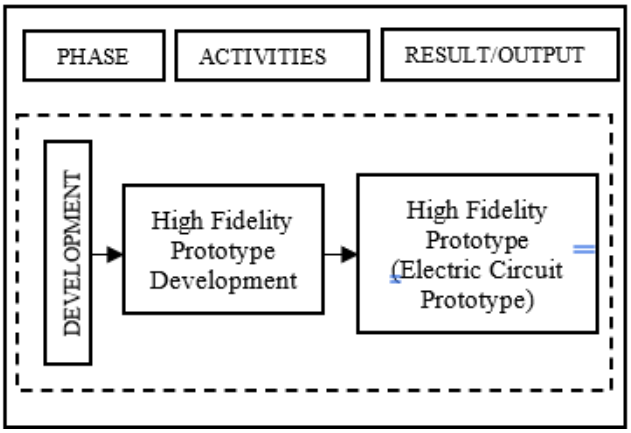

Fig. 3. The activities in the development phase.

D. Evaluation Phase

The implementation and evaluation phases involve three activities: Instrument Development, Content validation and Pilot Study, and Evaluation of the Electric Circuit game prototype. The evaluation process involves 32 fifth-grade students, divided into control and experimental groups. Participants are selected based on equivalent achievement scores from previous science assessments. This aligns with the recommendations suggesting a suitable sample size of 10 to 20 participants for comparative experimental studies [27][25]. Additionally, a minimum sample size of 15 participants is recommended for quantitative experimental research [28][29].

The independent variable in this study is the teaching method, specifically the use of serious games compared to traditional instructional methods. The dependent variables are students' scores on the science HOTS test and their motivation survey scores in science. The evaluation instrument is divided into two types: pre- and post-tests (and a motivation survey). The pre-test comprises a series of questions on the electric topic in science, generated based on the Primary School Standard Curriculum syllabus, textbooks, and reference materials for fifth-grade science. This test aims to assess students' HOTS levels in science before and after exposure to serious games.

The test instruments consist of two sections: Demographic Information and science questions which are categorised into four types. The test instruments were developed with the assistance of several teachers and subsequently reviewed by two subject-matter experts skilled in the relevant field. This expert review is essential to ensure the accuracy of the constructs and the clarity of the research instrument content, as recommended by [30].

The motivation questionnaire was then developed based on Keller's (1987) ARCS model, which includes the elements of Attention, Relevance, Confidence, and Satisfaction. This instrument was created to assess students' motivation levels before and after science learning using serious games. The questionnaire comprises two sections: Section A gathers demographic information, while Section B includes four constructs and 27 items measured using a 5-point Likert scale to evaluate student motivation in science.

A pilot study involving 15 randomly selected fifth-grade students was conducted to evaluate the reliability of a motivation questionnaire within the context of science education. The data collected were analyzed using Cronbach's alpha, following Cronbach's (1946) methodology, with IBM SPSS Statistics version 16.0. The overall reliability score of the instrument was 0.81, indicating a high level of reliability. This result suggests that the motivation questionnaire is suitable for use in actual research [31][32]. Fig. 4 illustrates the activities during the implementation and evaluation phases.

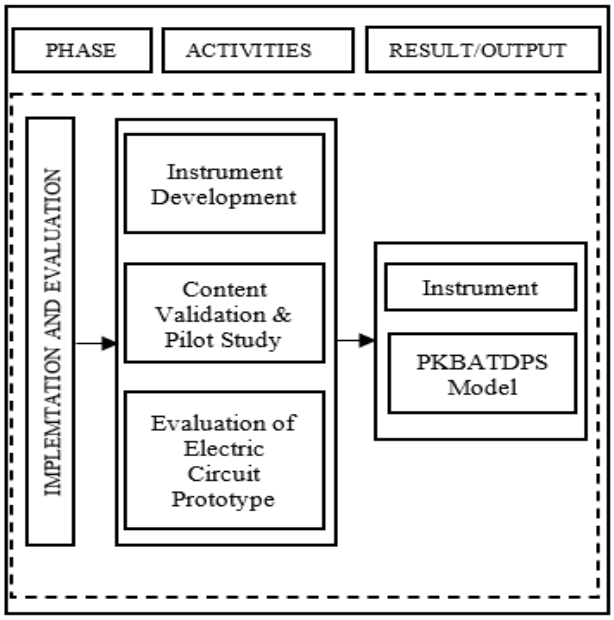

Fig. 4. The activities in the evaluation phase.

III. Results and Discussion

This study successfully identified 10 game elements categorised into two main components in the PKBATDPS Model. These ten elements consist of four learning elements and six game elements. The learning elements consist of learning objectives, constructivism learning theory, science subject content emphasising HOTS, and the ARCS motivation model. Meanwhile, the game elements consist of objectives, fantasy, challenge, feedback, control, and rule. One for both learning and game components. This indicates that the experts agreed that all assessed components of the PKBATDPS Model, as depicted in Fig. 5, were effectively implemented in this low-fidelity prototype.

Therefore, no elements needed to be eliminated or added. However, the experts provided feedback and suggestions for improving the design of the Electric Circuit prototype, particularly concerning the implementation of goal elements. They recommended that the game goal element be more clearly indicated at the end of the game to show that the game has successfully achieved the stated goal presented at the beginning. Improvements were incorporated during the development of the Electric Circuit prototype. Table I presents the learning and game elements validated by the experts, along with their IQR values.

TABLE I. PKBATDPS Model Elements Validated by Experts (IQR Value)

Bil	Learning Element	P1	P2	P3	P4	P5	Q1	Q3	IQR
1.	Learning Goal	5	5	4	5	4	4	5	1
2.	Constructivism Learning Theory	4	4	5	5	4	4	5	1
3.	Science Learning Content (Based on HOTS Element)	4	4	5	4	5	4	5	1
4.	ARCS Model Motivation	4	5	4	5	4	4	5	1
	Game Element	**P1**	**P2**	**P3**	**P4**	**P5**	**Q1**	**Q3**	**IQR**
1.	Goal	5	5	4	4	5	4	5	1
2.	Fantasy	5	4	5	4	4	4	5	1
3.	Challenge	5	5	4	4	4	4	5	1
4.	Feedback	5	5	4	4	5	4	5	1
5.	Control	5	5	4	4	5	4	5	1
6.	Rule	5	4	5	5	4	4	5	1

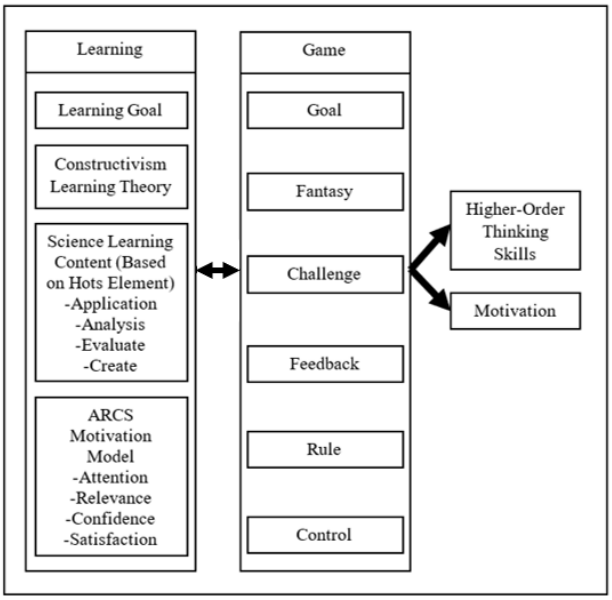

Fig. 5. PKBATDPS model.

The evaluation of the Electric Circuit prototype was conducted using a quasi-experimental method, which included pre-tests, post-tests, and learning motivation questionnaires. Two groups were involved: a control group and an experimental group.

E. Analysis of HOTS

The result revealed a significant difference in the mean scores of pre-tests and post-tests for the experimental group. Table II shows the mean score for pre-test of 16.38 and post-test of 64.63. These results indicate that there is an improvement in HOTS among students after using serious game applications in science education.

TABLE II. T-TEST RESULT OF THE PRE AND POST-TESTS FOR EXPERIMENTAL GROUP

Experiment Group	N	Mean	Standard Deviations	t	p
Pre-Test	16	16.38	9.13	16.15	0.000
Post-Test	16	64.63	9.95		

Next, the result indicated a significant difference in the mean post-test scores between the experimental and control groups. Table III shows the mean post-test score for the experimental group was 64.63, higher than the control group's mean post-test score of 29.38. These results indicated that the experiment group who engaged with the serious game application demonstrated better HOTS than the control group who received the traditional method in science.

TABLE III. T-TEST RESULT OF THE POST-TEST SCORE FOR THE EXPERIMENTAL AND THE CONTROL GROUP

Sample	Mean	Standard Deviations	t	p
Experiment Group	64.63	9.95	11.01	.000
Control Group	29.38	8.05		

F. Analysis of Motivation

The result demonstrated a significant difference in the mean scores of motivation before and after using serious game applications in science education. Table IV shows that the mean motivation score after using serious game applications was 4.45, higher than before using serious game applications. These results indicated that the students' motivation increased after using serious game applications in science education.

TABLE IV. TEST RESULT OF THE LEARNING MOTIVATION POST-QUESTIONNAIRE RATING FOR EXPERIMENTAL GROUP

Experiment Group	N	Mean	Standard Deviations	t	p
Motivation-Before	16	4.00	.30	5.39	0.000
Motivation-After	16	4.45	.28		

Then, the motivation result between the two groups indicated a significant difference in the mean motivation score. Table V shows that the mean motivation score for the experiment group was 4.45 higher compared to the control group mean score of 4.00. These results indicate that students who used the serious game application prototype in science education demonstrated higher motivation compared to those who learnt through traditional methods.

TABLE V. T-TEST RESULT OF THE LEARNING MOTIVATION POST-QUESTIONNAIRE RATING FOR EXPERIMENTAL GROUP AND CONTROL GROUP

Sample	Mean	Standard Deviations	t	p
Experiment Group	4.45	.28	3.98	.000
Control Group	3.95	.41		

Overall, these assessment results demonstrate that using the Electric Circuit prototype effectively enhances Higher-Order Thinking Skills (HOTS) and student motivation in science education. Consequently, it can be concluded that the PKBATDPS Model, as implemented in the Electric Circuit prototype, can be utilized to cultivate students' HOTS in science education. Additionally, it has the potential to increase students' motivation and interest in science education.

IV. CONCLUSION

This study successfully identified 10 elements categorised into two main components in the PKBATDPS Model and implemented in Electric Circuit prototype. The evaluation of the Electric Circuit prototype was conducted using a quasi-experimental method, which included pre-tests, post-tests, and learning motivation questionnaires. Two groups were involved: a control group and an experimental group. The experimental group participated in learning activities using the serious game application while the control group engaged in traditional learning method. The results show that students in the experiment group demonstrated a significant improvement in HOTS after using serious game applications in science education. In addition, the results reveal that the student in the experiment group who engaged with the serious game application demonstrated better HOTS than the student in the control group who received the traditional method in science. Observations showed that the students in the experimental group enjoy playing games with science. In terms of learning motivation, the result shows that the students' motivation in experiment group increased after using serious game application in science education. Furthermore, the result indicate that students who used the serious game application prototype in science education demonstrated higher motivation compared to those who learned through traditional methods. These results indicate that the implementation of serious game application in learning provides more engaging and interactive learning environment that cultivate HOTS and increase motivation in science education. Therefore, serious games can be considered a novel learning method that is more engaging, interactive, and effective in enhancing HOTS and student motivation in science education. The evaluation results of the Electric Circuit game prototype validate the proposed PKBATDPS Model suggested by this study. The results demonstrate that the objectives of the study have been achieved. However, further research can be carried out by adding learning elements and other game elements to challenge the player's level of thinking at a high level.

Lung CT Image Classification Algorithm Based on Improved Inception Network

Qianlan Liu
School of Information Engineering, Hunan University of Science and Engineering, Yongzhou, 425199, China

***Abstract*—With the continuous development of digital technology, traditional lung computed tomography medical image processing has problems such as complex images, small sample data, and similar symptoms between diseases. How to efficiently process lung computed tomography image classification has become a technical challenge. Based on this, the Inception algorithm is fused with the improved U-Net fully convolutional network to construct a lung computed tomography image classification algorithm model based on the improved Inception network. Subsequently, the Inception algorithm is compared with other algorithms for performance analysis. The results show that the proposed algorithm has the highest accuracy of 92.7% and the lowest error rate of 0.013%, which is superior to the comparison algorithm. In terms of recall comparison, the algorithm is approximately 0.121 and 0.213 higher than ResNet and GoogLeNct algorithms, respectively. In comparison with other models, the proposed model has a classification accuracy of 98.1% for viral pneumonia, with faster convergence speed and fewer required parameters. From this result, the proposed Inception network based lung computed tomography image classification algorithm model can efficiently process data information, provide technical support for lung computed tomography image classification, and thereby improve the accuracy of lung disease diagnosis.**

Keywords*—Image classification; inception; lung CT images; CNN; machine learning

I. Introduction

In recent years, the rapid development of medical technology has promoted the extensive application of computer-aided diagnosis system in the medical field, especially in the diagnosis of pulmonary diseases, where computer-aided system has shown great potential [1]. As a key link in the diagnosis of lung diseases, the accuracy of lung CT image classification directly affects the early detection and identification of diseases [2]. However, due to the complex structure and rich information of lung CT images, traditional classification methods are often difficult to effectively process, which not only limits the timely diagnosis of lung diseases, but also adversely affects the treatment effect and survival rate of patients [3]. In current studies, although deep learning has made many breakthrough achievements in the field of image classification, more refined and efficient algorithm models are still needed for specific challenges in lung CT image classification, such as high image complexity, limited sample data, and similar inter-disease symptoms [4-5]. Inception, as an important part of deep learning, can capture features of different levels through multiple branch networks and convolution nuclei of different scales, which provides the possibility to process the complex structure and rich information of lung CT images. Although the existing Inception network performs well in image classification, it still has some limitations when processing lung CT images. For example, the low degree of association between feature pixels and target pixels, as well as weak gradients of Inception module information, affect the accuracy and efficiency of classification. Therefore, this study aims to propose a lung CT image classification algorithm based on improved Inception network to enhance feature extraction and classification performance by fusing full convolutional networks (such as U-Net) to solve the problems encountered by existing algorithms in processing lung CT images. Compared with the existing research, the innovation point of this research is to integrate the improved Inception network with the full convolutional network, solve the problem of low correlation between feature pixels and target pixels by optimizing the structure of the convolutional layer and the pooling layer, and propose the combination of ResNet module and Inception module. To solve the problem of weak information gradient of Inception module. These improvements make the algorithm proposed in this study better than the existing algorithms, such as ResNet and GoogLeNet.

The research is divided into four parts. The first part analyzes the current research status of Inception algorithm and lung CT image classification models. The second part describes Inception and the CT image classification model constructed after fusion with a fully convolutional network. The third part analyzes the performance of the improved Inception algorithm and the improved Inception lung CT image classification model. The last part is a summary of the research.

II. Related Works

Imaging diagnosis of pneumonia remains a major medical challenge. Pneumonia is closely related to human life safety. The prevention and diagnosis of pneumonia are extremely important. The emergence and application of artificial intelligence provide technical support for the treatment of lung diseases. Kocks et al. proposed a machine learning algorithm tool for the diagnosis of asthma, COPD, and overlapping conditions, and compared it with primary care physicians and pulmonary specialists. The results show that the algorithm tool has excellent diagnostic performance and provides strong support for the identification of pulmonary diseases [6]. To solve the problem of inaccurate prediction of lung diseases, Annamalai's team proposed a convolutional neural network based on auction optimization algorithm. The results show that this method is superior to traditional methods in predicting performance and provides a new idea for the early diagnosis

of lung diseases [7]. Wobma et al. developed a screening algorithm for lung disease screening in patients with systemic juvenile idiopathic arthritis. The results show that the algorithm can effectively identify lung diseases in patients and improve the accuracy and efficiency of screening [8]. Zhang et al. reviewed machine learning applications for chronic obstructive pulmonary disease. The results show that machine learning has a broad application prospect in the diagnosis, treatment and management of this disease, providing strong support for clinical decision-making [9]. In order to improve the accuracy of inference for chronic obstructive pulmonary disease, Cosentino et al. proposed a deep learning model based on the original respiratory map. The results show that this method can identify new genetic loci and improve the risk model, providing a new way for the precision medicine of diseases [10].

With the improvement of medical data resources and the development of auxiliary diagnosis and treatment methods for lung diseases, lung CT medical imaging technology plays a crucial role in clinical medicine and lung disease screening. An accurate image classification model can improve the utilization rate of medical resources. To address the shortcomings of training data and its inter class similarity and variability in chest CT scans, Wang et al. proposed a two-stage deep learning strategy. It is used for invasive classification of solid nodules in chest CT images. The results show that the accuracy of the proposed binary classifier is 83.4% ± 1.4, and the AUC is 91.3% ± 2 [11]. To explore the imaging characteristics of congenital tracheal stenosis combined with left pulmonary artery suspension surgery, Fukushima team proposed a qualitative variable model based on clinical features and computed tomography imaging. After testing the model, it was found that 38 cases (86%) of bilateral lung patients has left pulmonary artery suspension surgery [12]. To determine the overall positive rate of pulmonary arteriography and the factors that affect the results of pulmonary arteriography, Aggarwal et al. conducted experiments using methods such as logistic regression analysis. The results showed that the pulmonary angiography rate in the study was 10.9%, higher than the study results with a positive rate of<2% [13]. To explore the role of preoperative CT examination results in predicting acute postoperative exacerbation in patients with gestational pneumonia and cancer, Ozawa et al. used Fisher exact test and Mann-Whitney U test. The test results show that common patterns of gestational pneumonia show 58% acute exacerbation and 73% no acute exacerbation [14]. To accurately estimate the volume of pulmonary nodules and reduce the workload of doctors, Lee proposed an intelligent method for automatically detecting and segmenting pulmonary nodules from computer tomography. The results show that the average and standard deviation of the segmentation overlap measure are 0.81 and 0.08, respectively [15].

In summary, artificial intelligence is applied to all aspects of society. In the era of data and information, people are increasingly reliant on deep neural networks. The improved concept network model is widely used in various fields such as biological component detection, adaptive learning models, and biological gene networks. With the increasing attention paid to lung health, more experts and scholars have conducted experimental research to find the optimal lung CT image classification model. However, lung CT image classification models based on improved Inception have been rarely studied. To make up for this deficiency, a lung CT image classification algorithm model based on an improved Inception network is constructed, thereby promoting the organic integration of artificial intelligence and medicine.

III. Construction of an Improved Inceptional Lung CT Image Classification Model

Nowadays, the application of artificial intelligence in medical images is also gradually increasing. Among them, convolutional neural networks have made significant contributions to medical image processing [16]. The algorithm network based on Inception can obtain deeper level data from medical images, improving the accuracy of image judgment.

A. Construction of a Lung CT Image Classification Model based on Traditional Inception

To integrate the Inception module, convolutional layers and pooling layers are fused together. The pooling layer mainly involves repairing feature images to enhance the correlation between feature pixels and target pixels [17]. This method can effectively save the central and surrounding features of the feature image, avoiding problems such as traditional maximum or average pools ignoring partial feature information [18]. The traditional maximum pooling operation is shown in Fig. 1.

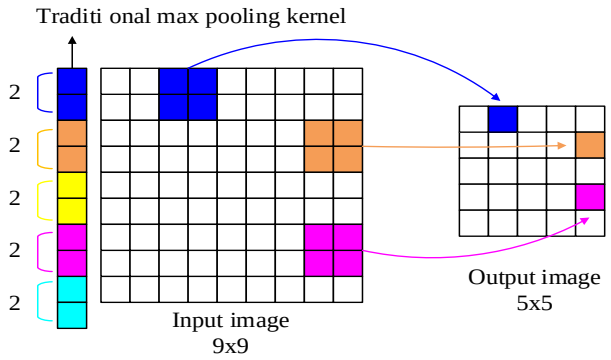

Fig. 1. Traditional maximum pooling operation.

Fig. 1 shows the traditional maximum pooling operation. The left side of Fig. 1 shows the input image. The right side shows the output image. The input image usually has a 9x9 pool core. The pool core size is uniform and fixed in distribution. The output image usually has a 5x5 pool core. The distribution of the output pool cores is uniform. The purpose of pooling layers is to reduce the dimensionality of convolutional layers and reduce the parameters during operation. Afterwards, residual modules and skip connections are used to increase the number of network layers. The calculation of the residual network is shown in Eq. (1).

$$F(x_1) = w \cdot x_1 + b \tag{1}$$

In Eq. (1), x_1 is the input value. w is the weight. b is offset. After the learning signal of the neuron is transmitted to other neurons, the activation function is used to calculate the

sum of the two branch layers. The input data is subjected to data transformation. The activation function is shown in Eq. (2).

$$y_1 = R(F) + h(x_1) \tag{2}$$

In Eq. (2), y_1 represents the input data transformation. y_1 is the sum of two branch layers. After data input and activation, perform residual module output, and the residual module output formula is shown in Eq. (3). It can effectively accelerate training speed and improve the accuracy of parameter adjustment.

$$x_{l+1} = R(y_1) \tag{3}$$

In Eq. (3), x_{l+1} is the output of the residual module. To prevent problems such as gradient dispersion, activation function is used. To enhance the propagation speed of the function, ReLU activation function is used to reduce gradient attenuation caused by deep convolution. The formula for ReLU is shown in Eq. (4).

$$R(x) = \max(0, x) \tag{4}$$

According to Eq. (4), when $x > 0$, $R(x) = x$, the derivative is 1. When $x < 0$, $R(x) = 0$, the derivative is 0. Traditional pooling cannot automatically adapt to changes in the specific location of pooling. Therefore, the Inception module adopts central pooling to preserve the central features of the patch. The central pooling operation process is shown in Fig. 2.

Fig. 2 shows the operation process of central pooling. A large pool core and a small pool core are designed in the central pool structure. The image center selects a small pool core. The image edge adopts a large pool core. This structure can eliminate many edge features. The operation steps first define the pooling area. Pooling operations are typically performed within a certain area of input data. The defined indicators are the size and shape of the area. Rectangles and circles are usually common shape features. Secondly, the total pooling value is calculated. Based on the specific pooling type, a pooling value is calculated within the pooling area. Common pooling types include maximum pooling, average pooling, and L2 pooling. Next, the summary value is output, which represents the information within the pooled area. Finally, the pooling window is moved. The pooling window is moved to the next position of input data. Afterwards, the above steps are repeated until they cover the entire input data. After the operation is completed, in order to avoid information loss during repeated down sampling and up sampling, a fusion multi-convolutional layer feature method is adopted to increase the flow ability of the data image. The specific operation is shown in Fig. 3.

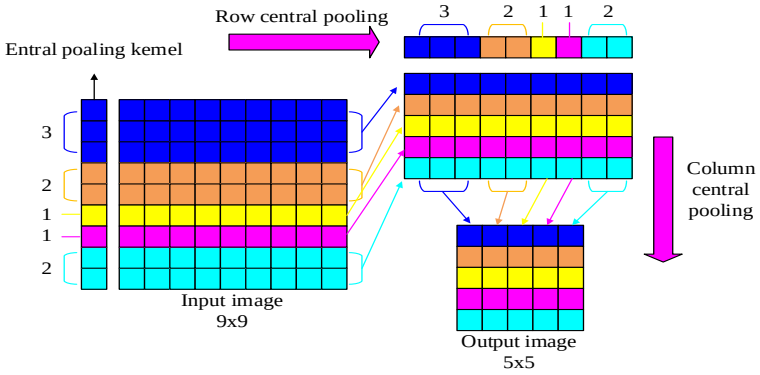

Fig. 2. Central pooling operation.

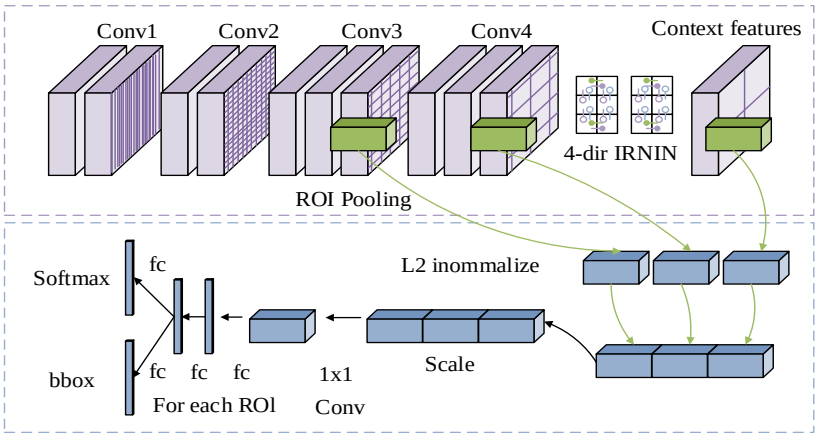

Fig. 3. Inside-outside network.

Fig. 3 shows the inner and outer network structure of the shallow convolutional layer in the Inception module using feature maps. Fig. 3 fuses multiple convolutional layers. The upper and lower features in the image are extracted and normalized in the ROI pool. After the Inception network collects features from the input image in parallel, multiple such Inception modules are first connected in series. Afterwards, all output results are concatenated into feature maps. Different sizes of convolutional kernels are beneficial for diversified feature extraction. The method of collecting signal features in parallel can effectively increase the width of the network and the adaptability to scale. This can effectively reduce information loss caused during the data sampling process, which is more conducive to machine learning.

B. *Construction of an Improved Inception Lung CT Image Classification Model*

The Inception module has four generations, namely the original version, Inception-v1, Inception-v2/v3, and Inception-v4. During the iteration process, the performance of Inception is gradually improved [19]. The traditional Inception model requires a large amount of computation. The information gradient of network backpropagation is weak. On this basis, the Inception model is improved [20-21]. Because ResNet can introduce residual connections, the network can directly transfer the features of the front layer to the back layer, thus effectively alleviating the problem of gradient disappearance. Moreover, it can enhance the feature extraction ability of the network by transmitting feature information directly. In the classification of lung CT images, the accuracy and diversity of feature extraction are very important to improve the classification performance. ResNet's structural design allows the network to more efficiently capture features at different levels in the image, which is very helpful for distinguishing subtle lung lesions. Therefore, the improved method proposed in this study is to integrate Inception with ResNet for better image classification and target detection. The improvement method is to fuse Inception with ResNet for better classification, object detection, and image segmentation. Then the corresponding information of Inception and ResNet module is overlaid. The specific algorithm is shown in Eq. (5).

$$M = \sigma(C_2\theta(C_1 \cdot x)) \tag{5}$$

In equation (5), M represents the output function. σ represents a nonlinear layer. C_2 is the scaling parameter. θ represents the activation function value. x represents the output result. In classification calculations, the loss function is used to standardize two probability distributions a and b. Then b is used to describe a. The cross entropy formula is shown in Eq. (6).

$$H(a,b) = -\sum a(x)\log b(x) \tag{6}$$

$H(a,b)$ represents the cross entropy value. $a(x)$ represents the probability distribution. $\log b(x)$ represents the probability distribution of b. Cross entropy, as a measure of the similarity between two probability distributions, is widely used in machine learning. It is mainly used to measure the difference between the predicted output of the model and the actual output. In Eq. (7), the cross entropy satisfies the probability distribution function.

$$\forall xa(X-x) \in [0,1] and \sum a(X-x) = 1 \tag{7}$$

In Eq. (7), X is the true value predicted by the model. b is the output value predicted by the model. $a(X-x)$ is the distribution function. Eq. (7) indicates that the probability of events occurring is between 1, and 0. The sum of probabilities is always 1. The improved Inception module is mainly divided into six steps to complete. The schematic diagram of the model is shown in Fig. 4.

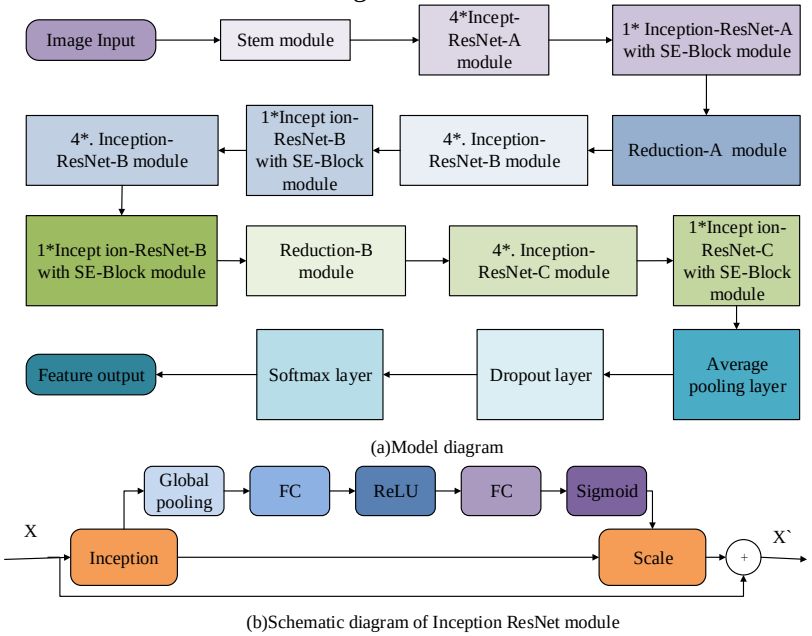

Fig. 4. Module diagram

Fig. 4(a) is a schematic diagram of the convolutional neural network architecture. Fig. 4(b) is a schematic diagram of the Inception ResNet module. Inception and ResNet network structures are combined, and sections such as Stem, SE-Block, and Reduction are added to them. To increase the running speed and deepen the network depth, the convolution size is changed in the model. The residual structures are introduced to solve the overfitting problem. Then, feature weights are added and activation functions are replaced. Finally, the number of classifications is determined. To achieve high network convergence speed in model training, all convolutional layers and inner product activation layers are used in the original U-Net network structure. The normalization formula used is shown in Eq. (8).

$$H_{ab}^{c} = \frac{H_{ab}^{c} - \mu_{ab}}{\sigma_{ab}} \tag{8}$$

In Eq. (8), σ_{ab} represents the output when a neurons in the b layer are trained to c data. μ_{ab} is the average output of a neurons in layer b. σ_{ab} represents the standard deviation of a neurons in layer b. The average output of neurons is shown in Eq. (9).

$$\mu_{ab} = \frac{1}{d}\sum_{c=1}^{d} H_{ab}^{c} \tag{9}$$

In Eq. (9), μ_{ab} is the average output of a neurons in the b layer. σ_{ab} represents the output when a neurons in layer b are trained to c data. $\frac{1}{d}$ represents the mean after summing σ_{ab}. After obtaining the mean formula of the neuron, the standard deviation of the neuron output is calculated. The standard deviation formula is shown in Eq. (10).

$$\sigma_{ab} = \sqrt{\sigma + \frac{1}{d}\sum_{c=1}^{d}(H_{ab}^{c} - \mu_{ab})^{2}} \tag{10}$$

In Eq. (10), σ_{ab} is the standard deviation of a neurons in layer b. μ_{ab} is the average output of a neurons in layer b. The values of σ and d are constants. The specification layer is placed before the activation function. The activation function of the specification layer is normalized in batches, as shown in Eq. (11).

$$y = f(BN(\sum_{a} W_a X_a)) \tag{11}$$

y represents the normalization function. $W_a X_a$ represents the connection degree between input neurons and output neurons. The bias parameter b is normalized by the system after passing through the specification layer. The main task of the BN layer is to normalize the input data values of neurons. The output values are unified within the interval of [0,1] to improve model accuracy. After building the model, the system development environment is built. In the pneumonia classification system, the B/S architecture is selected. The specific system architecture diagram is shown in Fig. 5.

Fig. 5 shows the UML sequence diagram of the pneumonia classification and prediction module. The system page includes two aspects, namely "Select File" and "Forecast". Users can click and select the corresponding test chart in the "Select File" section. The situation where there are a large number of categories in lung CT images that cannot provide classification entry points for each category can be avoided. Afterwards, the "Forecast" button is clicked to perform prediction analysis. When the user enters the platform homepage, the predicted results can be obtained. The controller calls the query interface of the experimental model to obtain CT images. The view layer posts the transmitted information on the page. Finally, the predicted results of pneumonia CT images are obtained. The corresponding probability sizes of the results are displayed in the interface. The graph cutting algorithm is used in the image, which locks and marks the target of the image. The formula is shown in Eq. (12).

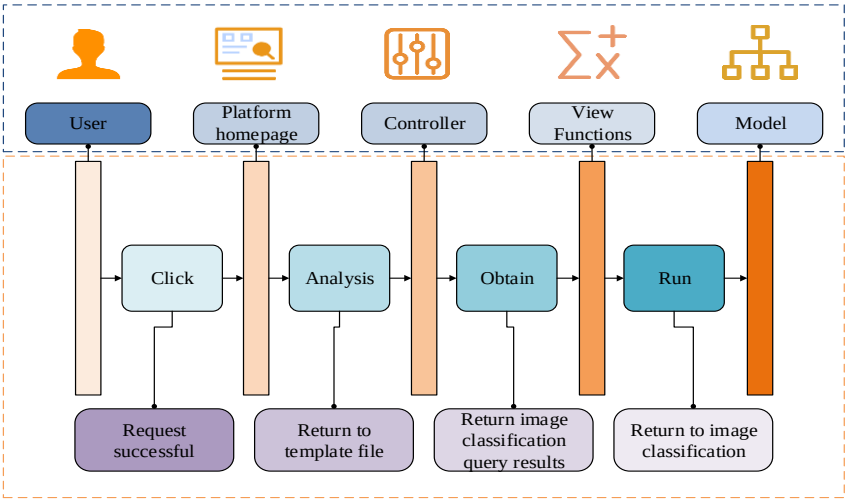

Fig. 5. UML sequence diagram of pneumonia classification and prediction module.

$$E(A) = \lambda R(A) + B(A) \tag{12}$$

In Eq. (12), A represents pixels. B represents the background pixel. $E(A)$ is the energy function. λ is the influence coefficient of the regional energy function on the total energy function. The energy function of the region term is shown in Eq. (13).

$$R(A) = \sum R_P(A_P) \tag{13}$$

In Eq. (13), $R(A)$ represents the regional energy function. R_P represents the probability of the target area. A_P represents the division of pixels. Next, the pixels are labeled as background points and front attractions. The formal expression of $R_P(A_P)$ is shown in Eq. (14).

$$R_p(O) = -\ln \Pr(I_P / O) \tag{14}$$

In Eq. (14), $\Pr$ is the target probability. R_p is the probability result. O represents the pixel of the image. After the "prediction" button is clicked, corresponding prediction analysis is performed, and then the experimental model is called using the controller. After the calculation is completed, the prediction results of the pneumonia CT image are displayed in the front interface. In summary, traditional Inception networks have low classification efficiency. It is not conducive to saving medical resources. Based on this, the traditional Inception network is improved. The improved U-Net full convolutional network image semantic segmentation is integrated into the model to improve the convergence speed of the network. This solves the segmentation speed, laying the foundation for building the optimal lung CT image classification algorithm model.

IV. Evaluation of Lung CT Image Classification Algorithm Based on Improved Inception Network

The improved Inception network lung CT image classification algorithm model can effectively enhance the accuracy of image classification. Compared to other models, the classification performance and fitting degree are superior. It requires fewer parameters. Building a system model framework on the improved U-Net is beneficial for enhancing the sensitivity of image segmentation and making the lung structure clearer.

A. Parameters Design and Evaluation of Improved Inception Network

To avoid inconsistent size and singularity in the lung CT dataset, a pneumonia CT database is constructed for abnormal pneumonia, viral pneumonia, and normal images. The specific content is shown in Table I.

TABLE I. Database

Classification	Normal CT images	Normal CT images	Abnormal CT images
Total	2300	2200	2300
Training set	1500	1300	1600
Validation set	500	500	500
Test set	600	600	600

Table I shows the pneumonia CT database constructed during this training. A total of 6800 pneumonia CT images are selected, including 4400 for training, 1500 for validation, and 1800 for testing. After preprocessing the data, 4400CT images are selected for training. The classification results of ResNet, GoogLeNct, and Inception ResNet are compared. The results are shown in Fig. 6.

Fig. 6 shows the recall rate of the classification results of the three algorithms in CP. The recall rates of ResNet, GoogLeNct, and Inception-ResNet in CP are 0.812, 0.701, and 0.953, respectively. In NCP, the recall results of the three algorithms are 0.754, 0.635, and 0.981, respectively. In the recall rate results of Normal, the Inception-ResNet algorithm is 0.121 and 0.213 higher than ResNet and GoogLeNct algorithms, respectively. From this, it can be seen that the Inception ResNet algorithm in this research has the highest recall rate in CP, NCP, and Normal. Therefore, it has the most superiority. Then, the error and specificity of the three algorithms are compared and analyzed. The results are shown in Fig. 7.

Fig. 7 shows the comparison results of error rates and specificity among the three calculations. Fig. 7(a) shows the comparison results of error rates among the three algorithms. In CP, the training error of Inception-ResNet is 0.013%, the error rate of GoogLeNct is 0.034%, and the error rate of ResNet is 0.023%. In NCP, the error rates of Inception-ResNet are 0.012% and 0.021% lower than those of ResNet and GoogLeNct algorithms. In Normal, the error rates of Inception-ResNet are 0.014% and 0.022% lower than those of ResNet and GoogLeNct algorithms. From this, the Inception-ResNet algorithm in this research has a smaller error rate compared to the other two algorithms. In Fig. 7(b), the Inception-ResNet in CP is 90.1%, which is about 31% and 42% higher than ResNet and GoogLeNct. In NCP, it is about 29.8% and 36.2% higher than ResNet and GoogLeNct. In Normal, it is about 31.2% and 34.3% higher than ResNet and GoogLeNct. From this, the Inception-ResNet algorithm has better classification performance. To further analyze the segmentation performance of Inception-ResNet algorithm in pneumonia CT images, CNN, FCN, GraphCut, region growth value, adaptive threshold and other algorithms are selected for comparison. The results are shown in Fig. 8.

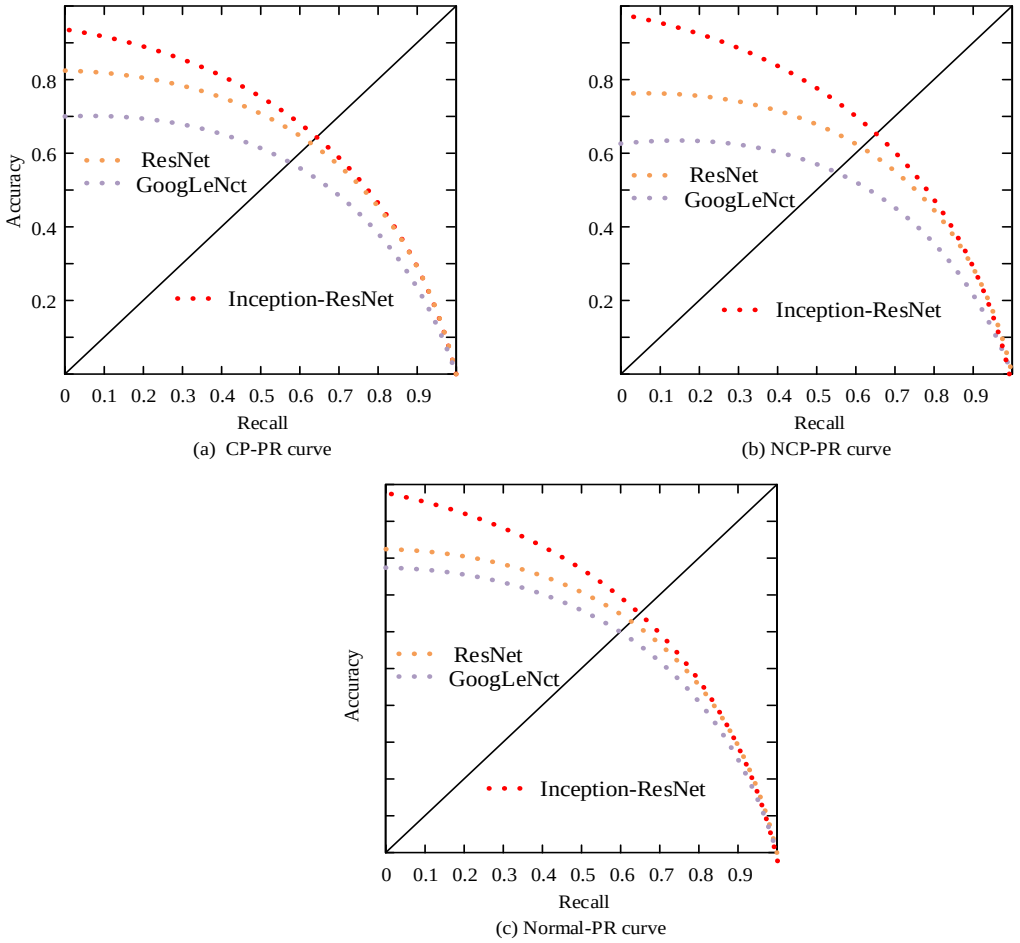

Fig. 6. Recall three algorithms.

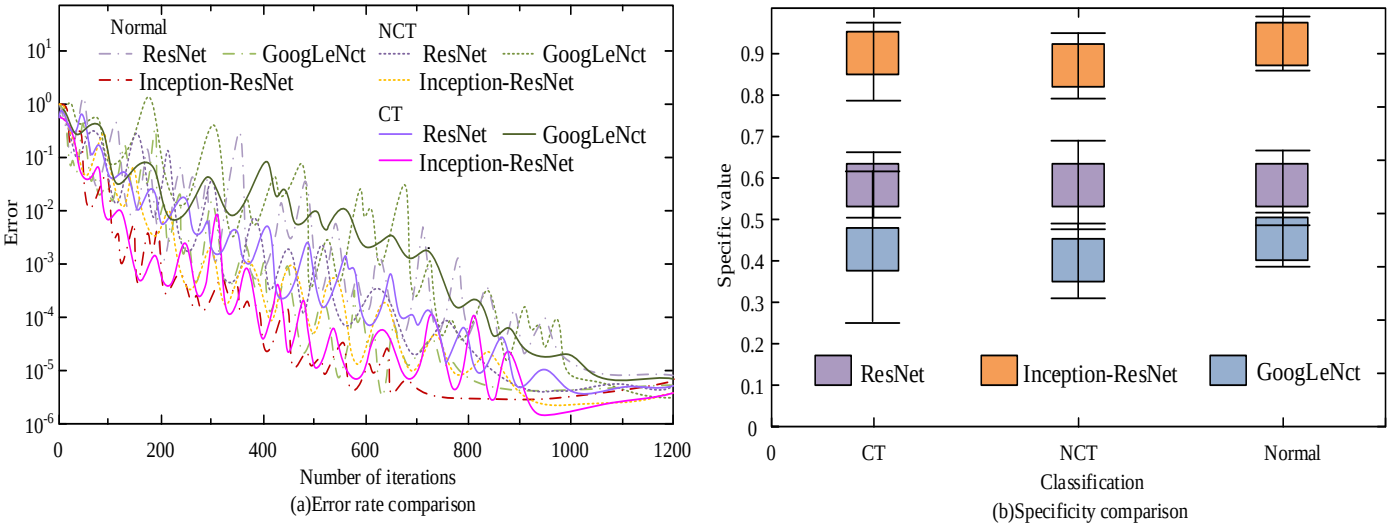

Fig. 7. Comparison of error and specificity.

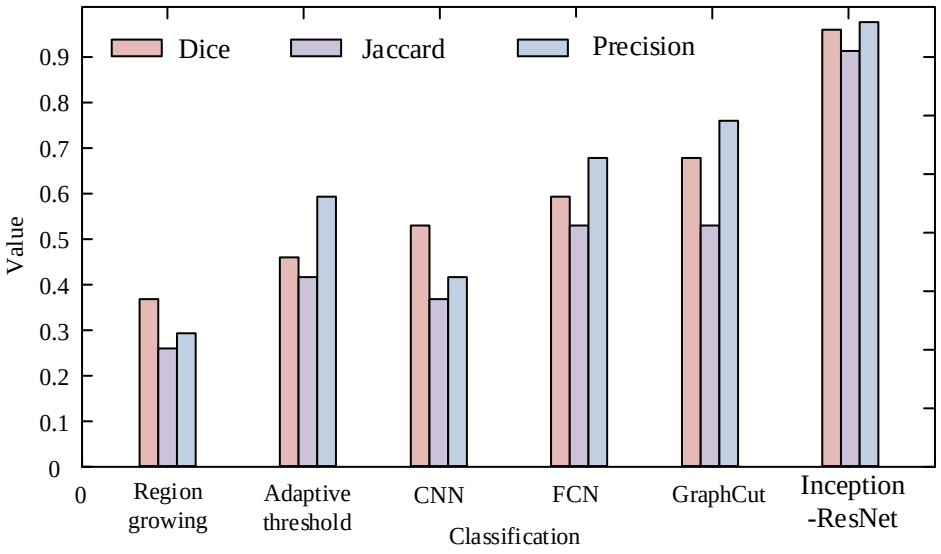

Fig. 8. Algorithm comparison histogram

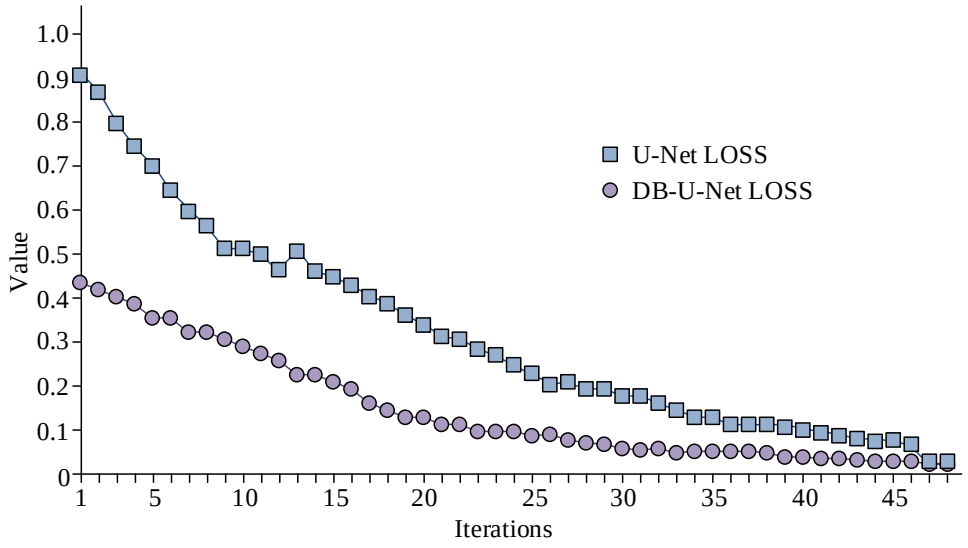
Fig. 8 shows the comparison between the Inception-ResNet algorithm and other algorithms. Compared to other algorithms, Inception-ResNet algorithm has a leading advantage in segmentation accuracy. In the comparison of Dice coefficient and Jaccard coefficient, the Inception-ResNet algorithm is about 0.25 and 0.29 higher than other algorithms, respectively. The Dice coefficient, Jaccard coefficient, and accuracy are the lowest in regional growth. The Dice coefficient, Jaccard coefficient, and accuracy values of the CNN algorithm are 0.51, 0.38, and 0.40, respectively. The Dice coefficient, Jaccard coefficient, and accuracy values of the FCN algorithm are 0.6, 0.54, and 0.68, respectively. The Dice coefficient, Jaccard coefficient, and accuracy values of the GraphCut algorithm are 0.69, 0.51, and 0.77, respectively. The Dice coefficient, Jaccard coefficient, and accuracy values of the Inception-ResNet algorithm are 0.93, 0.91, and 0.96, respectively, all exceeding 0.9. The Inception-ResNet algorithm converges faster, which is beneficial for the segmentation of lung images.

B. Performance Analysis of Improved Inception Network Model

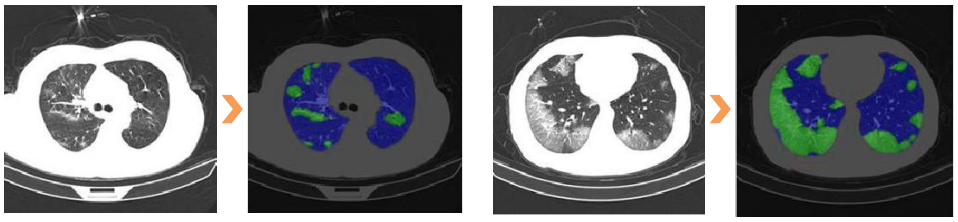
To evaluate the segmentation effect of the improved Inception network model on pneumonia CT images, segmentation experiments are conducted on the model based on image segmentation techniques. During the experiment, the loss function curve was used to represent the iterated values, and the original U-Net is compared with the improved U-Net data. The results are shown in Fig. 9(a). Afterwards, segmentation is performed on different positions of the lungs to segment the main body of the lung CT image. The final result is shown in Fig. 9(b).

Fig. 9(a) shows the loss function of the network model. In model comparison, the convergence speed of the original network model is slower than the DB-U-Net Loss model proposed in the research. When the DB-U-Net Loss model is less than 0.1, the loss function converges rapidly and reaches a minimum value around 0.18. When the number of iterations is 20, it approaches 0. The original model approaches 0 at 45 iterations. The convergence speed is relatively slow. This indicates that the improved model has better network performance. Fig. 9(b) shows the segmentation results of pneumonia images. The improved model can accurately segment lesions with pneumonia features, which has a high degree of segmentation granularity. When the segmentation model reaches the optimal level, collect the operational status of pneumonia CT images within 48 hours. The average response time, fault condition, and waiting time for the slowest response of the system are used for data comparison. The analysis results of the model performance are shown in Fig. 10.

The white screen time and first screen time in Fig. 10 reflect the response speed of the system when processing CT images of pneumonia. The white screen time refers to the time from the user's request to the system's content display, and the first screen time refers to the time from the system's content display to the completion of the main page content loading. The length of these two times directly affects the user experience, and the shorter the time, the faster the system response and the better the user experience. Fig. 10 shows the performance analysis of the model system proposed in this study. As shown in the figure, the average first screen time in the pneumonia CT image classification system is 1.01s. The average white screen time is 0.81s. The average full screen time is 1.36s. The full screen time is the longest, approximately 0.35s and 0.55s higher than the average white screen time and average first screen time, respectively. As the iteration increases, the white screen time is the most stable. The overall screen time fluctuates significantly. The first screen time fluctuates greatly when the number of iterations is 2-30. This functional test shows that the performance of each functional module and page is normal. There is no malfunction in the reaction sensitivity, and the reaction force is sensitive. Finally, the analysis is conducted using a confusion matrix approach. ResNet and GooLeNet models are compared with the Inception-ResNet model for image classification accuracy. The results are shown in Fig. 11.



(a)Iterative Network Model Loss Function



(b)Pneumonia image segmentation

Fig. 9. Loss function and image segmentation.

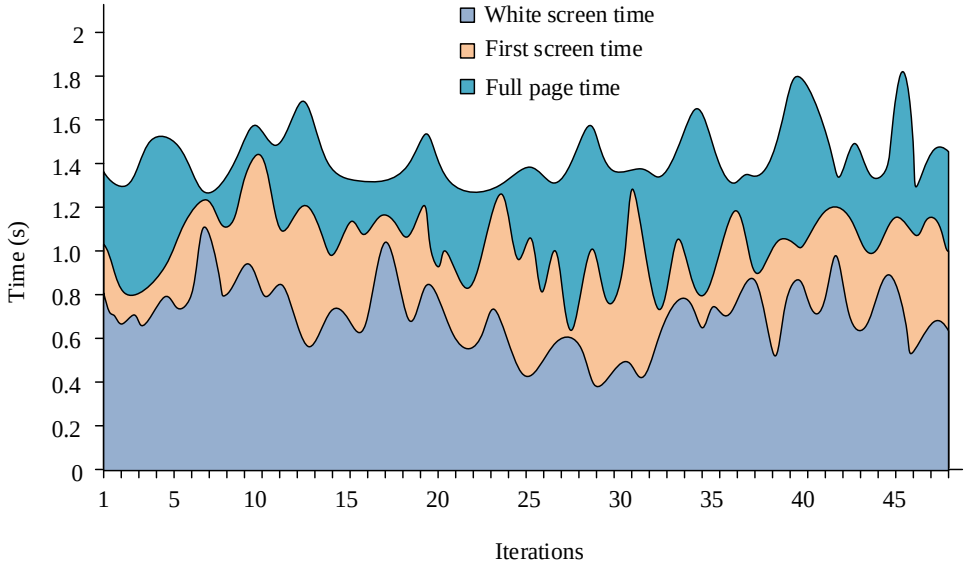


Fig. 10. Model system performance analysis.

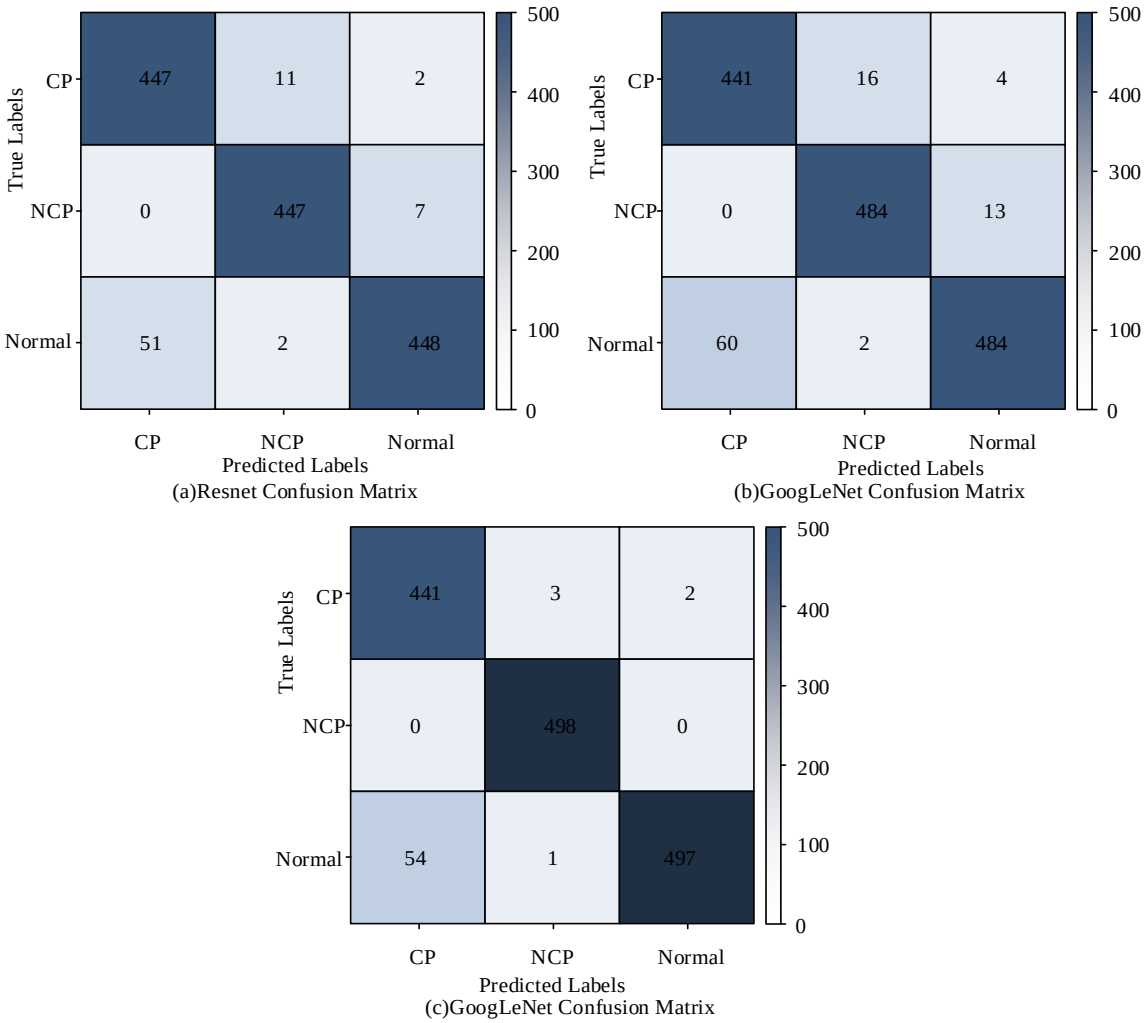

Fig. 11. Comparative analysis of confusion matrix.

Fig. 11(a) shows the confusion matrix of the ResNet model. The accuracy rate of non-severe viral classification is 89.7%. The accuracy rate in classifying abnormal pneumonia images reaches 96.3%. Fig. 11(b) shows the confusion matrix of the Google Net model. It can be seen that the classification accuracy of viral pneumonia using the Google Net model is 88.1%. The accuracy rate of classifying abnormal pneumonia is 88.7%. The classification accuracy of viral pneumonia using the Inception-ResNet model is 98.1%. The accuracy rate of classifying abnormal pneumonia is 98.7%. This method has higher classification accuracy than the other two models for pneumonia images. Compared to other convolutional neural network models, the Inception-ResNet model has higher accuracy, faster processing speed for image classification, and more mature image segmentation technology. In the performance analysis of the system model, the Inception-ResNet model exhibits a zero error rate and extremely high sensitivity. When compared with algorithms such as ResNet and GoogLeNct, the Inception-ResNet algorithm has a lower error rate and higher accuracy and specificity.

V. Discussion

In this study, a lung CT image classification algorithm model based on improved Inception network was proposed, and its performance was verified by experiments. The experimental results show that in CP, the recall rate of Inception-ResNet is 0.953, while that of ResNet and GoogLeNet are 0.812 and 0.701, respectively. In Normal, the recall rate of Inception-ResNet was also about 0.121 and 0.213 higher than the other two algorithms. This result is similar to that of Nigudgi et al. [22]. The results show that the epigenetic-RESnet algorithm has higher accuracy in identifying various types of lung CT images, which is mainly due to the advantages of integrating Inception and ResNet modules to improve the diversity and accuracy of feature extraction. In addition, from the comparison of error rate and specificity, the error rate of the initiation-Resnet algorithm in CP, NCP and Normal is lower than that of the ResNet and GoogLeNet algorithms, and the specificity is significantly higher than the other two algorithms. Especially in CP, the Inception-ResNet error rate is only 0.013%, while the specificity is as high as 90.1%, which is about 31% and 42% higher than ResNet and GoogLeNet, respectively. This

suggests that the Inception-ResNet algorithm performs better in reducing misjudgments and improving classification specificity, which helps to improve the accuracy of lung disease diagnosis.

In addition, the study is compared with CNN, FCN and GraphCut classification algorithms. The results show that the Inception-ResNet algorithm is superior to other algorithms in Dice coefficient, Jaccard coefficient and precision, especially in segmentation accuracy. This result coincides with the conclusion obtained by Sethy team [23]. This further proves the effectiveness of the Inception-ResNet algorithm in lung CT image classification. In terms of model performance analysis, the loss function of the improved Inception model rapidly converges during training and reaches the minimum value within a few iterations, which indicates that the model has high learning efficiency and stability. At the same time, in the image segmentation experiment, the improved U-Net network can segment the lesions with pneumonia characteristics more accurately, which helps doctors to judge the disease more accurately. This study further proves that the Inception-ResNet model can effectively improve the accuracy and efficiency of pulmonary CT image classification by integrating Inception and ResNet modules. In the future, the combination of more medical data and 3D imaging technology is expected to further improve the generalization ability and diagnostic accuracy of the model, and provide more powerful technical support for clinical lung disease diagnosis.

VI. Conclusion

To solve the complex images, small sample data, and similar symptoms between diseases in traditional lung CT medical image processing, the improved Inception algorithm is integrated with the improved U-Net fully convolutional network. The aim is to construct a lung CT image classification model based on an improved Inception network to improve image processing efficiency and lung disease diagnosis speed. In training, the Inception algorithm is compared and analyzed with other algorithms in terms of performance. The results show that the Inception-ResNet algorithm is approximately 0.121 and 0.213 higher than ResNet and GoogLeNct algorithms, respectively. Among CP, NCP, and Normal, this method has the highest recall rate. In the specificity comparison, the algorithm proposed in this research is 90.1% in CP. In NCP, it is about 29.8% and 36.2% higher than ResNet and GoogLeNct. In Normal, it is about 31.2% and 34.3% higher than ResNet and GoogLeNct. In the comparison of model performance, when it is less than 0.1, the improved Inception model's loss function converges rapidly and reaches a minimum value of around 0.18. When the number of iterations is 20, it approaches 0. The classification accuracy of viral pneumonia using the improved Inception model is 98.1%. The classification accuracy of abnormal pneumonia is 98.7%. In summary, the improved Inception network lung CT image classification model can accurately and efficiently process lung CT image classification, which has high practicality and feasibility. Although this research has achieved some results, the future work still needs to be deepened. On the one hand, it is necessary to continue to optimize the algorithm model and explore higher-dimensional feature extraction methods in the future to further improve the classification accuracy and efficiency. On the other hand, given that the current model is based on 2D images and cannot fully reflect the 3D structure of the lung, future research will focus on applying deep learning technology to the field of 3D imaging in order to achieve more accurate diagnosis of lung diseases. In addition, the dataset needs to be expanded to cover more types of lung diseases in the future to enhance the generalization ability and practicality of the model.

Multilevel Characteristic Weighted Fusion Algorithm in Domestic Waste Information Classification

Min Li
School of Computer and Artificial Intelligence, Henan Finance University, Zhengzhou, 451464, China

***Abstracts*—The study of domestic waste image classification holds significant significance for fields like environmental protection and smart city development. To improve the classification efficiency of household waste information, a multi-feature weighted fusion method for household waste image classification is proposed. In this research, deep learning technology was applied to develop a multi-level feature-weighted fusion network model for domestic garbage image classification. The study first analyzed the VGG-16 architecture and created a garbage image dataset for domestic garbage according to the current Shenzhen garbage classification standard. Based on this, a multi-level feature-weighted fusion model for garbage image classification was constructed using VGG-16 as the backbone network. Furthermore, it was combined with the backbone feature extraction network as well as the content-aware and boundary-aware feature extraction networks. The performance of the classification model was tested, and it was found that the highest classification accuracy of the classification model can reach 0.98, and the shortest classification time is only 3s. The multi-level feature-weighted fusion garbage image classification model constructed in this research not only has better classification performance, but also can provide a new processing idea for the urban garbage classification problem.**

Keywords*—Multi-feature; weighted fusion; image; deep learning; waste classification

I. Introduction

With urbanization accelerating, domestic waste disposal presents a growing challenge for city managers [1-2]. Waste classification (WC) can impact resource recovery, environmental protection, as well as the efficiency and quality of city operations. Successful WC entails fast, precise identification of various types of waste, a considerable challenge with the rising quantities of waste. Currently, the utilization of computer vision technology in WC is emerging as a popular research area [3-4]. Traditional garbage image classification methods rely on manually extracting features and using simple classifiers, which are limited in dealing with images that have complex backgrounds, diverse lighting, and different angles. Due to these limitations, the current garbage classification methods have the problems of low accuracy and low efficiency. Recently, convolutional neural networks (CNNs) in deep learning (DL) algorithms have displayed excellent performance for image classification tasks. However, current models encounter issues such as inadequate feature extraction and suboptimal adaptation to limited datasets [5]. In order to address the issue of low-quality garbage image classification, this study employs the VGG-16 model as the primary backbone network. A multi-feature weighted fusion image classification model of domestic waste is constructed by integrating the content and boundary perception model. Against this background, the research objective is to develop a new multi-level feature-weighted fusion network model (MFWFNM) to improve the accuracy and efficiency of domestic garbage image classification (DGIC), and to overcome the limitations of conventional models in handling complicated garbage images. The significance of this study lies in the use of this method to speed up garbage classification, facilitate users to perform garbage classification, create a good living environment, and provide certain ideas and methods for DGIC. The study comprises of six sections, first being the Introduction: Next section presents an analysis and summary of related research from other sources. The third section details the construction of the network model. The model's performance testing is covered in the fourth section, fifth section presents the discussion and the study's overall findings are presented in the last section.

II. Related Work

With the rapid pace of urbanization, the disposal of domestic waste poses a paramount challenge for urban management. Efficient waste management not only facilitates resource recovery and environmental protection, but also increases the productivity of waste disposal. In this regard, automatic classification of garbage images by computer vision technology is an important technical solution to improve the efficiency of waste management. Aiming at the shortcomings of traditional classification models, Ma et al. proposed a WC model that improves the structure of ResNet-50 network. The model was improved in two stages. First, by adding an attention module to the residual block and modifying the downsampling procedure, the input feature screening and information loss reduction were adjusted. Second, the model incorporated horizontal and vertical multi-scale feature fusion techniques to utilize the features more efficiently. The model's classification performance on tiny datasets was significantly enhanced by this restructure. The outcomes revealed that the model outperformed the original ResNet-50 model by 7.62% on the TrashNet dataset, demonstrating higher accuracy and robustness [6]. Wu et al. created a new publicly available benchmark dataset, in addition to the study a classification test was performed on this dataset using deep CNN. The results of the study showed that the created home spam image dataset was able to simulate different lighting, backgrounds, angles, and shapes, and the deep CNN was able to obtain a high classification accuracy (CA) in the data [7]. The rise of email as a means of official and personal communication has made it increasingly difficult to accurately identify and classify spam. Scholar Vivekanandam developed a novel hybrid machine

learning approach to effectively detect spam. This research was significant in safeguarding data security against unauthorized access, while also offering fresh insights and techniques for spam detection [8]. In an effort to address the issues of overfitting, inadequate convergence, and decreased recall and accuracy in conventional image recognition algorithms, Li Y et al. presented a DL-based spam image identification system. The algorithm employed the ReLU activation function to handle the gradient dissipation problem in neural network training, the Adagrad adaptive method to modify the parameters of the deep neural network, and the Dropout strategy to prevent overfitting [9].

In recent years, the use of lightweight networks is pervasive in image segmentation and face recognition due to their advantageous characteristics, including minimal resource consumption and rapid reasoning speed. The utilization of lightweight networks for the purposes of classification and image recognition has emerged as a significant area of research. For use in the facial expression picture identification task, Zou et al. introduced the multi-feature fusion CNN, a lightweight network architecture. According to experimental data, the suggested model performed better on average in terms of recognition accuracy than other compared algorithms [10]. In the face of COVID-19 epidemic, the problem of high dropout rate in catechism classes was becoming more and more prominent. Because of this, Yujiao et al. presented a dropout prediction model that combined support vector machines with feature fusion from behavioral data. The final fused features were created by applying varying weights to various behavioral features in a model that was based on Pearson's principle. The suggested model had a higher accuracy of dropout prediction, according to experimental results [11]. Zhang et al. aimed to develop an intelligent detection model for strabismus based on corneal light reflection photographs. To enhance strabismus detection performance, a multi-feature fusion model is suggested that integrates both ratio and depth features. According to the experimental data, the model successfully increased the accuracy and reliability of strabismus diagnosis, achieving an accuracy of 97.17% in strabismus identification, which was much superior to the single-feature model [12]. A unique multi-feature fusion improved transformer for the creation of image descriptions was proposed by Zhang et al. According to test results on the MSCOCO dataset, the suggested model performed better in picture description than other cutting-edge techniques [13].

In summary, numerous scholars have conducted research on junk image classification and multi-feature fusion algorithms, achieving significant results. The extant research on garbage image classification indicates that, while the results are effective, the CA and efficiency remain at a relatively low level. It is imperative to identify an effective method to enhance the classification of garbage images. Therefore, further exploration of this area appears promising. To enhance CNN's performance in solving the DGIC problem, this study utilizes a multi-feature weighted fusion DGIC model with VGG-16 as the backbone network. This model is combined with content and boundary-aware models to improve the WC model's CA and provide fresh solutions to the real-world WC problem.

III. Domestic Garbage Image Classification Method Based on Multi-Feature Weighted Fusion

To enhance the CA of domestic garbage images (DGI), this research firstly introduces the VGG-16CNN model in DL algorithm and the DGI dataset used in this research. Based on this, the boundary features and contents of the garbage images are fused, and a multilevel feature-weighted fusion algorithm model for DGIC is further proposed.

A. VGG-16 Modeling and Design of Domestic Garbage Images Dataset

The VGG-16 model of CNN is adopted in this study for domestic waste treatment. CNN belongs to the part of artificial intelligence research field, because it has a certain degree of autonomous learning, and can simulate the processing mechanism of the human brain visual nerve, so it is often used in the analysis of visual images [14]. The input layer (IL), convolutional layer (CL), pooling layer (PL), fully connected layer (FCL), and output layer make up the majority of a typical CNN. Fig. 1 depicts its overall structure.

The primary function of the CL in Fig. 1 is to extract features using the convolutional kernel. The retrieved data comes from the input of the IL, and the image features that each layer of the CL can extract are different. CNN backpropagation optimizes the weight coefficients and bias of the convolution kernel, and the size of the convolution kernel controls the complexity of the features that can be recovered from the convolution layer. The primary task of the PL is to select a large number of features to simplify the complexity of the model operation. The PL often comes after the CL. After feature extraction in the CL, a large number of image features will be sent to the PL. PL operation is generally divided into maximum pooling and average pooling, both are a large amount of feature information is divided into a number of small regions. The difference is that the former outputs the maximum value in each small region, while the latter outputs the average value of all feature information in each small region. In addition to the input and output layers, the FCL also plays an important role in CNN. The FCL, which is at the end of the CNN, is responsible for nonlinearly combining all the feature information before feeding it to the output layer. The CL and PL, on the other hand, extract and select image features, respectively.

The VGG-16 model is a popular DL network architecture named after the institution where its development team is located, i.e., the visual geometry group (VGG) at the University of Oxford. VGG-16 refers to the fact that this network structure contains 16 network layers with weights, including convolutional and FCLs. VGG-16 is a unique CNN that is often utilized in domains like image recognition and classification because of its outstanding performance and straightforward architecture. Fig. 2 depicts the VGG-16 network model's structure.

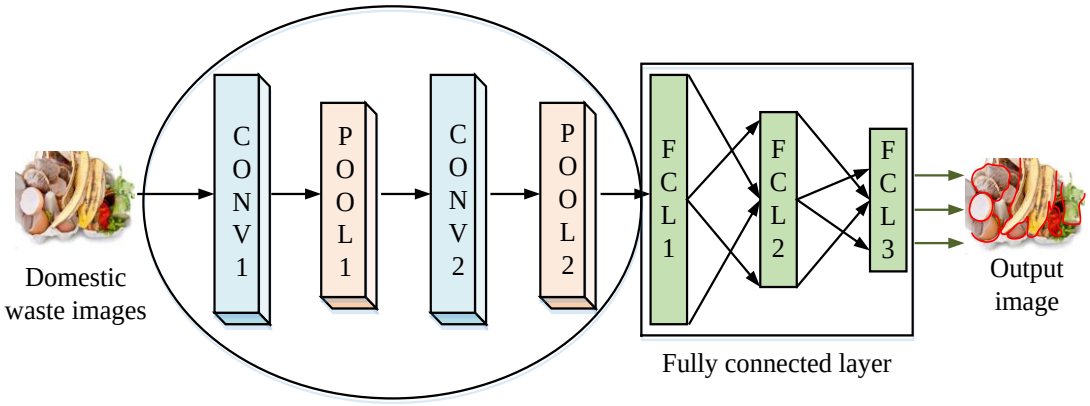

Fig. 1. Basic structure of CNN model.

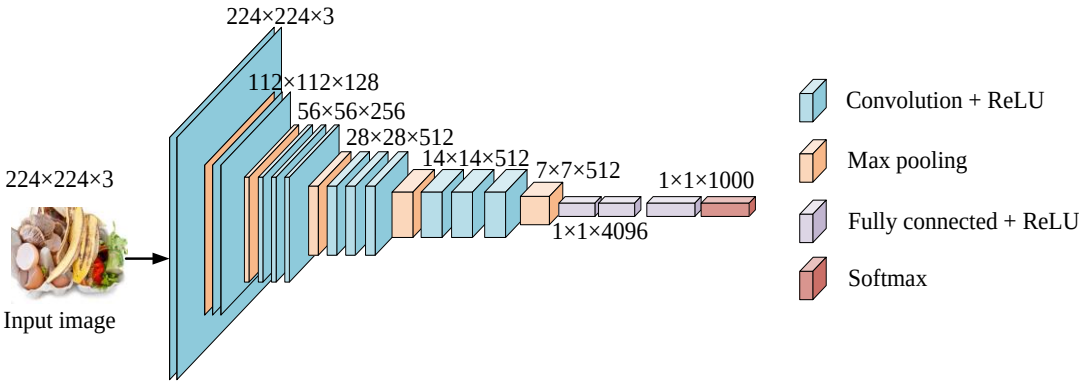

Fig. 2. VGG-16 network model structure diagram.

An FCL, a Softmax layer, an activation function, an IL, a CL, and a PL make up the entire VGG-16 network model shown in Fig. 2. The IL is a fixed-size, 224*224 RGB picture. The whole model has a total of 13 CLs, each CL has a convolutional kernel size of 3*3 with a step size of 1. Using a small convolutional kernel enables the VGG-16 network to have more weight layers, which improves the depth and complexity of the network. Each CL is followed by a ReLU activation function to increase the nonlinearity of the network. The network has a total of five PLs with a filter size of 2x2 and a step size of 2. Behind the convolutional and PLs, there are three FCLs that are connected to a Softmax layer. The Softmax layer outputs the probability values for image classification. Since the VGG-16 network model has a simple operational framework, powerful feature extraction capability and good generalization ability, this study uses the VGG-16 network as the backbone network to build a garbage image classification model.

Due to the wide variety of household garbage categories and different classification standards, the data used in this study is the DGI dataset that Huawei has previously made public in the WC Challenge Cup. This dataset contains more categories of garbage and a richer database than foreign garbage image datasets such as TrashNet and GINI, and contains a total of more than 10,000 DGIs, and the garbage in this dataset is categorized according to the WC standards of Shenzhen City. Additionally, Table I displays its classification standards.

TABLE I. CLASSIFICATION STANDARDS FOR THE DOMESTIC WASTE DATA SET

Garbage classification standards	Contains content
Hazardous waste	Batteries, expired medicines, ointments, etc.
Recyclable trash	Beverage bottles, glasses, cans, pillows, plush items, cardboard boxes, etc.
Kitchen waste	Fruit peels, tea leaves, bones, eggshells, vegetable leaves, leftovers, etc.
Other garbage	Disposable tableware, cigarette butts, toothpicks, plastic products, etc.

As shown in Table I, the waste image dataset used in this study is classified into four major categories: hazardous waste, recyclable waste, food waste, and other waste according to the WC standard of Shenzhen. Due to the large number and variety of waste images in the dataset, it is easy for the existence of similar appearance of different categories of household waste to lead to classification errors. To reduce the experimental errors, 80% of the images in the dataset are randomly and mutually exclusive divided into a training set before the experiment, leaving only 20% of the images as a test set, and the distribution of the dataset does not change during the entire experiment.

B. Design of Multi-Level Feature Weighted Fusion Network Model for Domestic Garbage Image Classification

Classifying DGIs quickly and accurately is a crucial and difficult task in the field of WC and processing nowadays.

Traditional image classification methods often face the problems of poor accuracy and lack of robustness when dealing with spam images with complex backgrounds, diverse lighting conditions and variable shapes. The utilization of multi-feature fusion methods to enhance image classification performance has become a new research trend with the development of DL and computer vision technologies. However, the effective integration of different levels of image features, such as color, shape, and texture, into beneficial information for classification remains a problem to be solved [15]. In this research, the VGG-16 network is used as the backbone network, and four different feature extraction networks are fused to design the DGIC-oriented MFWFNM. Fig. 3 displays the overall categorization model's structure.

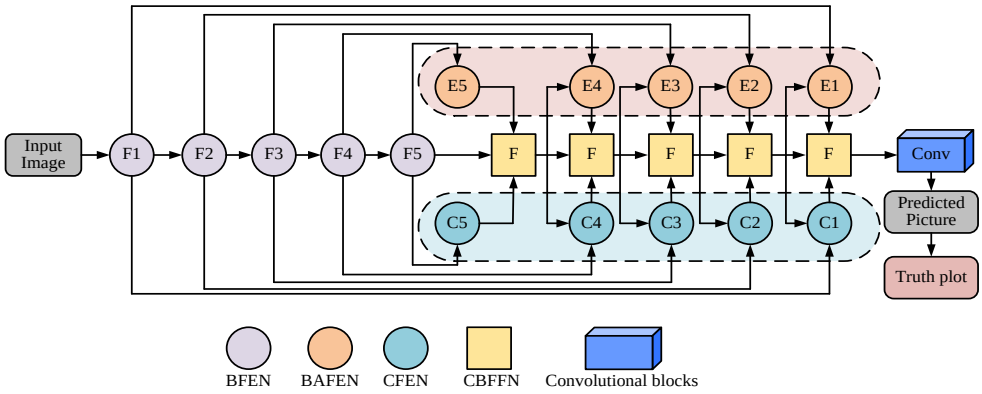

Fig. 3. Structure diagram of multi-level feature weighted fusion network model.

The multilevel feature-weighted fusion network model in Fig. 3 incorporates a total of four feature extraction networks, namely backbone feature extraction network (BFEN), boundary-aware feature extraction network (BAFEN), content-aware feature extraction network (CFEN), and content boundary feature fusion network (CBFFN). The garbage images from the domestic waste dataset are selected and input into the classification model, firstly, the multi-level features are extracted by using BFEN in VGG-16 network, then the effective content is extracted from the main features by using CFEN, and the edge information is extracted from the main features by using BAFEN. Then CBFFN is used at each stage to screen and fuse the features. Lastly, the model's ability to categorize the garbage photos is tested using a bespoke loss function. Training is stopped whenever the model is able to do so. Fig. 4 depicts the precise CFEN structure.

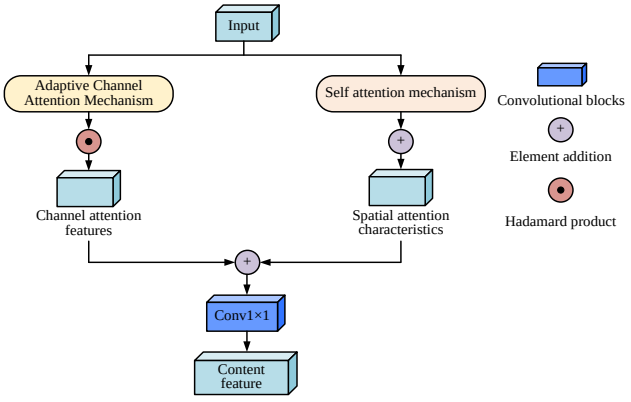

Fig. 4. CFEN structure diagram.

In Fig. 4, the CFEN is mainly composed of the channel attention feature extraction module and the spatial attention feature extraction module. For layer i, the fusion feature S_{i+1} from the previous layer of CBFFN is used as the input of CFEN, and the channel attention mechanism and spatial attention mechanism are utilized to complete the fusion of the features, so as to obtain the new features. Assuming that the feature of the output channel is F_C, the calculation equation of the channel attention feature extraction module is obtained as shown in Eq. (1).

$$F_C = S_{i+1} \text{Å} CA(S_{i+1}) \tag{1}$$

In Eq. (1), CA denotes the adaptive channel attention mechanism. Å denotes the inter-pixel addition operation. Eq. (2) displays the computational equation for the feature extraction module of spatial attention.

$$F_S = S_{i+1} \text{Å} SA(S_{i+1}) \tag{2}$$

In Eq. (2), F_S denotes the output spatial features. SA denotes the adaptive spatial attention mechanism. The extracted channel dimension and spatial dimension features in Eq. (1) and Eq. (2) are fused to obtain the equation of the fused features as shown in Eq. (3).

$$C_i = conv(F_C \text{Å} F_S) \tag{3}$$

In Eq. (3), $conv(\times)$ denotes the convolution operation and the size of the convolution kernel is 1*1. C_i denotes the content fusion feature.

In addition to using the CFEN model to fuse content features, it is also necessary to extract boundary features from garbage images. This study employs the BAFEN network to supplement edge information in order to extract more meaningful edge characteristics, therefore increasing the classification model's accuracy. Fig. 5 displays the particular structure of BAFEN.

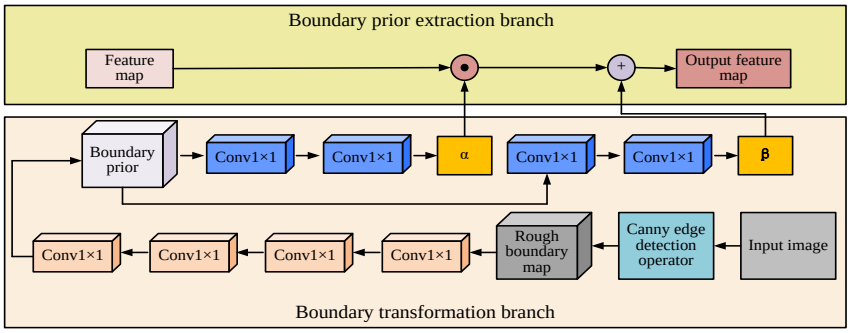

Fig. 5. BAFEN structure diagram.

In Fig. 5, the BAFEN structure mainly consists of two parts: the boundary prior extraction branch and the boundary transformation branch. Extracting features from boundary prior knowledge to serve as guidance for further processing is the primary task of the boundary prior extraction branch. The function of the boundary transformation branch is to transform the guidance information obtained from the boundary prior extraction branch into specific boundary features. First, Canny edge detection is performed on the input image, and then the detection result is used as a rough boundary map and a prior is applied to the boundary map. By extracting prior boundary knowledge and utilizing boundary transformation branches to generate the final boundary features. The mathematical calculation model of BAFEN is shown in Eq. (4).

$$BAFEN(F_i) = F_i \text{ e } a + b \tag{4}$$

In Eq. (4), F_i represents the output characteristics of the backbone network. a represents the boundary prior factor. b represents the boundary conversion factor. e represents Hadamard product. The range of values for F_i is shown in Eq. (5).

$$F = F_i \quad i \hat{I} \{1,2,3,4,5\} \tag{5}$$

In Eq. (5), F represents the set of output features. $i \hat{I} \{1,2,3,4,5\}$ represents the five CLs in BFEN. The calculation equation for a is shown in Eq. (6).

$$a = \text{Re}LU\left(Conv\left(\text{Re}LU\left(Conv\left(E_{prior}\right)\right)\right)\right) \tag{6}$$

In Eq. (6), $\text{Re}LU$ represents the activation function. E_{prior} represents the initial boundary map features. The calculation equation for b is shown in Eq. (7).

$$b = \text{Re}LU\left(Conv\left(\text{Re}LU\left(E_{prior}^{¢}\right)\right)\right) \tag{7}$$

In Eq. (7), $E_{prior}^{¢}$ represents the boundary map features after boundary transformation. By combining Eq. (6) and (7), the final boundary perception fusion feature can be obtained as shown in Eq. (8).

$$E_i = T_{conv}\left(Canny\left(F_i\right)\right) \tag{8}$$

In Eq. (8), T_{conv} represents continuous convolution operation. E_i represents boundary perception fusion features.

After obtaining fusion features and boundary perception fusion features, the study adopted a learning based approach to fuse the two features, thereby generating CBFFN. Firstly, pixel to pixel addition is used to preliminarily integrate information between C_i and E_i. Then, three CLs with 3 * 3 kernels and a step size of 1 are used for feature screening and extraction. Finally, S_{i+1} is overlaid on the output features of the last layer through residual learning to obtain a fused feature map. The calculation equation is shown in Eq. (9).

$$S_i = S_{i+1} \text{Å} T_{conv}\left(C_i \text{Å} E_i\right) \tag{9}$$

In Eq. (9), S_i represents the final fused feature map. To boost confidence, a loss function is added during the model training procedure. Eq. (10) displays the CFEN's content loss function.

$$L_C(P,T) = L_{SSIM}(P,T) + L_{IOU}(P,T) \tag{10}$$

In Eq. (10), L_C represents the content loss function of CFEN. L_{IOU} and L_{SSIM} represent the IOU loss function and SIIM loss function, respectively. P represents the classification result predicted by the model. T represents the true classification result of the model. Eq. (11) displays the BAFEN boundary loss function.

$$L_E(P,T) = L_{CBCE}(P,T_E) \tag{11}$$

In Eq. (11), L_E represents the boundary loss function of BAFEN. L_{CBCE} represents the CBCE loss function. T_E represents the boundary map of salient targets in real classification results. The fusion loss function of CBFFN is shown in Eq. (12).

$$L_F(P,T) = l_1\left(L_{IOU}(P,T) + L_{SSIM}(P,T) + l_2 L_{CBCE}(P,T)\right) \tag{12}$$

In Eq. (12), l_2 and l_1 both represent weight values. L_F represents the fusion loss function.

IV. Performance Testing and Application Analysis of Multi-level Feature Weighted Fusion Network Model for Domestic Garbage Image Classification

To verify the performance and application effectiveness of MFWFNM, this study compared three different image classification models: residual network (ResNet), faster region-based convolutional neural network (Faster R-CNN), and deformable convolutional networks (DCN). Using CA, classification error, and model iteration fitness values as performance evaluation indicators, it has been proven that the classification performance of MFWFNM is superior to other comparative models.

A. Performance Testing of Multilevel Feature Weighted Fusion Network Model

To demonstrate the benchmark performance of the model, this study chose a publicly available image dataset for simulation experiments. In order to avoid equipment errors during the experimental process, this study conducted comparative experiments in the same experimental environment. Table II displays the experimental setup and dataset details.

Table II provides the experimental environment and dataset information for this simulation experiment. Table II lists the three publicly accessible datasets that are chosen for this study's model performance testing: ImageNet, COCO, and TrashNet. Firstly, the iterative fitness changes of ResNet, Faster R-CNN, DCN, and MFWFNM are obtained as shown in Fig. 6.

In Fig. 6, the iterative fitness values of four models, ResNet, DCN, Faster R-CNN, and MFWFNM, are shown in the ImageNet, COCO, and TrashNet datasets. As shown in Fig. 6(a), ResNet, DCN, Faster R-CNN, and MFWFNM can reach a stable state by iterating 56, 44, 28, and 17 times respectively in the dataset ImageNet. As shown in Fig. 6(b), ResNet, DCN, Faster R-CNN, and MFWFNM can reach a stable state after 61, 48, 41, and 18 iterations in the dataset COCO, respectively. In Fig. 6(c), ResNet, DCN, Faster R-CNN, and MFWFNM can reach a stable state in the dataset TrashNet after 49, 25, 27, and 13 iterations, respectively. In summary, MFWFNM can quickly iterate to a stable state in all three datasets, indicating that the processing efficiency of the model is higher.

TABLE II. Experimental Environment and Data Set Information Table

Project	Composition	Configuration
Lab environment	Processor	Intel Core i9
	Graphics processor	NVIDIA RTX 3080
	Memory	32GB RAM
	Storage	1TBSSD
	Operating system	Ubuntu 20.04
	Deep learning framework	TensorFlow
	Coding software	Python 3.8
Dataset information	ImageNet	1000+ image types
	COCO	More than 80 complex scene images
	TrashNet	6 image data sets for garbage classification

Fig. 7(a), 7(b), and 7(c) show the CA values of the four models in the ImageNet, COCO, and TrashNet datasets, respectively. Fig. 7 shows that while the CA of the MFWFNM model stays above 0.9, the CA values of ResNet, DCN, and Faster R-CNN all change to some amount as the number of samples grows. In Fig. 7(a), the highest CA of ResNet, DCN, Faster R-CNN, and MFWFNM models in the ImageNet dataset is 0.77, 0.84, 0.89, and 0.96, respectively. As shown in Fig. 7(b), the highest CA of ResNet, DCN, Faster R-CNN, and MFWFNM models in the COCO dataset is 0.78, 0.82, 0.91, and 0.95, respectively. As shown in Fig. 7(c), the highest CA of ResNet, DCN, Faster R-CNN, and MFWFNM models in the TrashNet dataset is 0.77, 0.79, 0.90, and 0.98, respectively.

Fig. 8(a) and 8(b) show the mean square error (MSE) and mean absolute error (MAE) of the four models in the TrashNet dataset, respectively. In Fig. 8(a), the highest MSE values for the ResNet, DCN, Faster R-CNN, and MFWFNM models are 4.28, 3.11, 1.95, and 0.72, respectively. In Fig. 8(b), the highest MAE values for the four models ResNet, DCN, Faster R-CNN, and MFWFNM are 4.73, 3.81, 2.69, and 1.15, respectively. Overall, the MFWFNM model has better error performance when processing multi sample image data, and therefore can more accurately complete image classification tasks.

B. *Application Effect of a Multilevel Feature Weighted Fusion Network Model in Actual Waste Classification*

Using the daily WC requirements listed in Table I, this study collects over 10,000 common DGIs to further validate the good performance of the MFWFNM model in real-world WC situations. These images are then used to test the actual classification performance of different classification models. 100 images of hazardous waste, recyclable waste, kitchen waste, and other waste are selected from over 10000 datasets, and the CA and time of the four models under multiple classification tests are shown in Fig. 9.

In Fig. 9, the CA and time consumption of four models, ResNet, DCN, Faster R-CNN, and MFWFNM, in actual garbage image classification are presented. In Fig. 9(a), in the six classification tests, the ResNet classification model achieved the highest CA of 0.77 and the shortest time consumption is 22 seconds. In Fig. 9(b), in the six classification tests, the DCN classification model achieves the highest CA of 0.86 and the shortest time consumption is 13 seconds. In Fig. 9(c), in the six classification tests, the Faster R-CNN classification model achieved the highest CA of 0.95 and the shortest time consumption is six seconds. In Fig. 9(d), the CA of the MFWFNM classification model can reach up to 0.98, and the shortest time required is only three seconds. Compared to the other three WC models, the MFWFNM model can achieve better classification performance in multiple classification tests.

In Fig. 10, the evaluation scores of experts and residents for the four classification models are presented. Assuming a total of five points, the higher the score, the higher the satisfaction. Based on Fig. 10(a), (b), (c), (d), experts and users have the highest satisfaction with the classification model MFWFNM, with scores concentrated in the first quadrant. On the contrary, the satisfaction of experts and users with the other three models is relatively scattered, but overall, the Faster R-CNN model has higher satisfaction scores than the other two models.

V. Discussion

In this study, the performance of MFWFNM model was analyzed, and the application effect of MFWFNM model in garbage classification was analyzed. The experimental results showed that MFWFNM model had significant advantages in CA, MSE and MAE. In the comparison experiment of MSE values, the highest MSE values of ResNet, DCN, Faster R-CNN and MFWFNM were 4.28, 3.11, 1.95 and 0.72, respectively. Moreover, the MFWFNM model proposed in this study had lower MSE values than the comparison model. The results showed that the introduction of VGG-16 network and the combination of four backbone networks improved the computational efficiency and accuracy of the model. Wang X et al. reached a similar conclusion in the relevant research of multi-feature fusion classification model [16]. Secondly, in the comparative analysis of CA and classification time, the highest CA and shortest classification time of MFWFNM model were 0.98 and 3s, respectively, which were lower than the comparison model. This result further indicated that, the fusion of BFEN, CFEN, BAFEN and CBFFN networks and the introduction of VGG-16 network improve the computational efficiency and image CA of MFWFNM model, thus improving the accuracy of garbage classification model. This conclusion coincided with the relevant conclusion proposed by Zheng Y et al in 2023 [17]. In terms of satisfaction evaluation, experts and users expressed the highest levels of satisfaction with the MFWFNM model proposed in the study, and its satisfaction ratings were significantly higher than those of the comparison model. This result was the same as the conclusion of the image classification model proposed by Xu X team [18]. The results showed that the proposed MFWFNM model had good practical value and was helpful to improve the efficiency and quality of garbage classification. In summary, compared with relevant studies, this study proposed the VGG-16 model as the main trunk network, combined with content and boundary perception model to build a multi-feature weighted fusion DGIC model. It has higher CA and precision in processing garbage images with complex backgrounds, diverse lighting conditions and changing shapes. This model not only provides convenience for accurately determining the types of domestic garbage, but also provides a certain idea and method for the theory of garbage image classification.

VI. Conclusion

Human daily life inevitably generates waste, and effective waste sorting and recycling are currently major research topics in the field. The present study utilized the VGG-16 network as the backbone and combined it with BFEN, CFEN, BAFEN, and CBFFN to create MFWFNM for DGIC. The findings revealed that MFWFNM outperforms ResNet, DCN, and Faster R-CNN in achieving a stable state, requiring only 17, 18, and 13 iterations in ImageNet, COCO, and TrashNet datasets, respectively, compared to the other models. Notably, MFWFNM's CA in all three datasets reached up to 0.96, 0.95, and 0.98, respectively, surpassing the accuracy of the compared model. Additionally, the MFWFNM model exhibited smaller classification errors with a highest MSE value of 0.72 and a highest MAE value of 1.15, as compared to ResNet, DCN, and Faster R-CNN models with the highest MSE values of 4.28, 3.11, and 1.95, and highest MAE values of 4.73, 3.81, and 2.69, respectively. Four classification models were utilized to categorize the DGI dataset outlined in the article. The MFWFNM classification model exhibited the highest CA of 0.98, with the shortest classification time of merely three seconds, and outperformed the other three models across all metrics. In summary, the study's WC model exhibits excellent classification performance. However, it is yet to be determined whether the model can generalize to other image types. Future research should investigate the classification performance of the model in diverse settings. This study has two shortcomings. First, the number of garbage types used in the classification test is limited. In contrast, the actual environment features an increasing number of complex garbage categories. Second, although a garbage classification model has been proposed, it lacks a systematic design and implementation. On the one hand, the exploration direction of future research is to collect more image data of household garbage to increase the data set of household garbage images, and to include existing garbage types as much as possible, so as to provide data basis for training classification models. Conversely, a convenient and optimal operating system is designed in accordance with the model and user requirements, thereby facilitating convenient and expedient services for pertinent users. Moreover, a multi-feature fusion algorithm and image classification method are employed to segment and recognize medical images, thereby enabling the effective extraction of the diseased area of patients and the recognition of images. It is therefore the objective of future research to enhance the efficiency with which doctors utilize medical images for disease analysis, thereby improving the efficiency of subsequent treatment.

***Abstract*—Most researchers work on solving the important issue of identifying biomarkers linked to a certain disease, like cancer, in order to assist in the disease's diagnosis and treatment. Several research have recently suggested several methods for identifying genes linked to disease. A handful of these methods were created specifically for CRC gene prediction, though. This research presents a novel prediction technique to determine new biomarkers related to CRC that can assist in the diagnosing process. First, we preprocessed four Microarray datasets (GSE4107, GSE8671, GSE9348 and GSE32323) using RMA (Robust Multi-Array Average) method to remove local artifacts and normalize the values. Second, we used the chi-squared test for feature selection to identify some significant features from datasets. Finally, the features were fed to XGBoost (eXtreme Gradient Boosting) to diagnose various test scenarios. The proposed model achieves a high mean accuracy rate and low standard deviation. When compared to other systems, the experiment findings show promise. The predicted biomarkers are validated through a review of the literature.**

***Keywords*—Colorectal cancer (CRC); microarray; biomarkers; gene expression omnibus; feature selection; chi-squared test; XGBoost**

I. Introduction

Particularly with the current state of treatment, cancer is a complex disease [1]. Colorectal cancer is one of the leading causes of cancer-related deaths worldwide. Colorectal cancer is a type of cancer that affects the latter part of the gut intestine within the digestive system [2]. Colorectal cancer is a cancer that occurs in the last 15 centimeters of the colon that meets part of the rectal region, and these two types of cancer together call colorectal cancer [3]. In most cases, colorectal cancer begins as a small mass of non-cancer cells called adenomatous polyp, after a period of time the solids that have formed become cancer masses present in the colon. These masses may be small and accompanied by very few symptoms [4]. There may be no symptoms of colorectal cancer, especially in its early stages. Common symptoms of colorectal cancer:

- Constipation or diarrhea.
- The feeling that the intestines are not completely emptied.
- Blood in the feces.
- Frequent pain caused by gases, bloating or feeling full.
- Weight loss for no reason.
- Persistent fatigue.
- Vomiting and nausea.

Colorectal Cancer is the third most common cancer in men and the second most common in women worldwide [2]. Despite recent advances in surgical and multimodal therapies, the overall survival of advanced CRC patients remains very low. Periodic tests can significantly reduce and prevent the incidence of this disease. If colorectal cancer is detected early enough, it can mostly be treated [5].

Determining the patient's cancer kind and its biomarkers [6] is one of the biggest problems facing researchers. The biomarker is the most crucial element in cancer research since it facilitates therapy and reduces the cost and time required for diagnosis. Thus, one of the researchers' most important tasks is to identify the most relevant biomarker. Because cancer involves dynamic genetic alterations, researchers have worked hard to investigate how to diagnose and forecast the disease.

Next-generation sequencing (NGS) and microarray data [7] are two important sources of potentially helpful molecular patterns. The abundance of gene expression data [8] facilitates the discovery of disease class and cancer-related biomarkers. Microarray technology can be used to study the entire genome, proteome, and transcriptome in various cells and tissues. The ability to analyze vast amounts of data quickly is one of the advantages of microarray technology.

In the context of microarray technology, feature selection techniques [9, 10] fall into three categories: filter, embedding, and wrapper techniques. The filter approach, which is independent of the predictor and does not require the classifier, assesses and ranks the genes in relation to the class label. Gene interactions and correlations are not taken into consideration. In contrast, the wrapper approach depends on whether features are added or removed while evaluating the subgroup features using classification methods. When compared to alternative classification algorithms, the filter approach is faster but less accurate than the wrapper method. In contrast, the wrapper approach is slower computationally but yields more accurate results than the filter method. The embedded approach involves building a particular classifier but uses search methods for subsets of optimal characteristics. The merging of the filter and wrapper techniques is intended to reduce the wrapper method's computational complexity issue.

This proposed model uses the chi-squared test [11] for feature selection to identify some significant features from the datasets for colorectal cancer classification. Then, the features were fed to XGBoost (eXtreme Gradient Boosting) [12] to diagnose different test cases and identify new biomarkers related to colorectal cancer that can help in the early diagnosis

of that disease. Finally, the results were validated using SHAP algorithm to explain the importance of the proposed biomarkers in identifying colorectal cancer and expose the significant biomarkers.

The main contribution of the proposed system is the identification of new biomarkers related to CRC that can assist in the early diagnosis of the disease.

For the reader's convenience, seven sections make up the remainder of this work. The relevant literature, existing flaws, and how the suggested approach gets around them are covered in Section II. In Section III, the materials and methods are explained. Section IV introduces the datasets, assessment measures, and results. The experimental results and novel biomarkers are discussed in Section V. By applying the SHAP algorithm to validate the results, Section VI illustrates the significance of novel biomarkers. Lastly, Section VII concludes and summarizes the plans for future work. Table I lists the used abbreviations in this paper for easy reference of the reader.

II. RELATED WORK

In the field of biology, predicting genes linked to a disease is regarded as an active research topic. Genes linked to these diseases have been found and predicted by many researchers; some of these studies have focused specifically on colorectal cancer. Table II shows a summary of the current studies. For example, Ahmadieh-Yazdi et al. [13] presented an approach to predict disease-related biomarkers using the TCGA dataset [14, 15] and GEO dataset [8]. First, they used LASSO and P-SVM methods as feature selection to identify the most relevant DEGs. DEGs frequently chosen by these techniques were chosen for additional analysis. Second, they applied the Multilayer Perceptron technique in conjunction with the Artificial Neural Network (ANN) method to evaluate the effectiveness of each method's gene selection in distinguishing primary samples from metastatic malignancies.

Maurya et al. [16] proposed a novel framework to identify genes associated with CRC using the TCGA dataset and GEO dataset. They used Boruta as a features selection method to select significant genes. The most relevant genes were then utilized to create an ML-based prognostic classification model with Random Forest classifier.

Li, S et al. [17] proposed a supervised learning framework based on deep learning (DeepCSD) to identify cancer subtypes. They designed a minimalist feed-forward neural network to capture the distinct molecular features in different cancer subtypes.

Al-Rajab et al. [18] proposed a framework that provides a two-step multi-filter hybrid model to select features for the classification of colon cancer was proposed. A mixture of the Information Gain (IG) and Genetic algorithms (GA) is used in the initial stage of feature selection. In order to lower the amount of genes and acquire more relevant genes, the second stage employs the minimum Redundancy Maximum Relevance (mRMR) filter approach. Utilizing appropriate machine learning techniques for further analyzing the data is the final step. With the suggested framework model, it was discovered that the SVM, Decision Tree, Naïve Bayes, and K-Nearest Neighbor classifiers provided accurate and promising results.

According to Shuwen et al. [19], the early detection of liver metastasis is crucial for improving the prognosis of patients with colorectal adenocarcinoma (CAD), and the utilization of a single biomarker in conjunction with a classification model has greatly enhanced the ability to predict the metastasis of various cancer types. There aren't many reports on CAD, though. Thus, the purpose of this study was to determine the most appropriate classification model for CAD patients with liver metastases and, using that model, investigate the gene's metastatic process. For the purpose of identifying the CAD system with liver metastases, the CatBoost model—which was constructed using 33 feature genes—exhibited the greatest classification performance.

TABLE II. A REVIEW OF A FEW RECENT STUDIES FOR COMPARISON

Ram et al. [22]	2017	Identifying the disease-related biomarkers based on Random Forest	RF	GEO, Array Express databases

Kozuevanich et al. [20] proposed that the combination of Gene Sub-Network-based Feature Selection (GSNFS) and feature selection is very promising to identify biomarkers associated with CRC because it requires fewer subnetworks to build a classifier and provides a performance comparable to that of a full data set classifier.

Yanke et al. [21] proposed a model that used complex networks, machine learning methods and deep learning technology to look for probable genes linked to colorectal cancer in the following seven types of colorectal cancer data: LUAD, LUSC, UCEC, BRCA, COAD, HNSC, and KIRC. The signed random walk restart algorithm was employed in this suggested model to extract features. The random forest is the machine learning technique employed in this model as a colorectal cancer classifier. This model also makes use of deep learning technologies to look for putative colorectal genes and offer a novel method of diagnosing colorectal cancer.

Ram et al. [22] proposed a model that used the Random Forest algorithm to rank and select the genes needed to properly diagnose and treat cancer. While preserving its accuracy for prediction, the Random Forest method produced extremely tiny gene groups.

In conclusion, previous studies did not explore all the biomarkers associated with colorectal cancer, nor did they achieve the highest percentages in the disease classification process. To overcome the several limitations of the current studies, as mentioned above, we designed a novel prediction system that primarily identifies new biomarkers related to CRC based on microarray dataset that can assist in the diagnosing process and that is considered a very important advantage compared to previous studies. First, we preprocessed four Microarray datasets (GSE4107 [23], GSE8671 [24], GSE9348 [25] and GSE32323 [26]) using RMA (Robust Multi-Array Average) method27 to remove local artifacts and normalize the values. Second, we used the chi-squared test [11] for feature selection to identify some significant features from datasets. Finally, the features were fed to XGBoost (eXtreme Gradient Boosting) [12] to diagnose various test scenarios. The proposed model achieves a high mean accuracy rate and low standard deviation. When compared to other systems, the experiment findings show promise. The predicted biomarkers are validated through a review of the literature.

III. MATERIALS AND METHODS

The main contribution of the proposed system is the identification of new biomarkers related to CRC that can assist in the early diagnosis of the disease. Using the RMA (Robust Multi-Array Average) approach [27], we first preprocessed four Microarray datasets (GSE4107 [23], GSE8671 [24], GSE9348 [25], and GSE32323 [26]) to eliminate local artifacts and normalize the data. Secondly, we selected certain important features from datasets using the chi-squared test [11] for feature selection. XGBoost (eXtreme Gradient Boosting) [12] was then fed the features in order to diagnose several test scenarios. The model that has been suggested has a low standard deviation and a high mean accuracy rate. The experiment results show promise when compared to other systems. Based on a review of the literature, the expected biomarkers are confirmed.

The proposed prediction system is depicted in Fig. 1 with a unique four-step architecture. First, the preprocessing step comprises four steps: background correction, normalization, summarization and log2 transformation for removing local artifacts and noise. Second, the most relevant features are selected using the Chi-squared test [11] as a feature selection. Third, these proposed features are fed to the XGBoost algorithm [12] for identifying various test cases. In conclusion, we assess the proposed system's performance using five metrics, revealing encouraging outcomes in comparison to other methods. The following subsections contain more information on the suggested prediction system.

A. Preprocessing

In the preprocessing step, we prepared and improved the original dataset to feed it to the feature selection algorithm in order to improve our proposed system and obtain accurate results. The microarray datasets were preprocessed using RMA (Robust Multi-Array Average) approach [27] which involves three main steps: Background correction, Normalization, and Summarization. First, the microarray datasets were background corrected to remove local artifacts and noise so measurements aren't so affected by neighboring measurements. Second, we normalized these datasets to remove array effects so measurements from different arrays are comparable. Then, we

summarized the normalized datasets for combining probe intensities across arrays so the final measurement represents gene expression level. Finally, the log2 transformation was applied to the gene expression levels as almost all preprocessing methods return expression levels on log2 scale which is the approximately right scale.

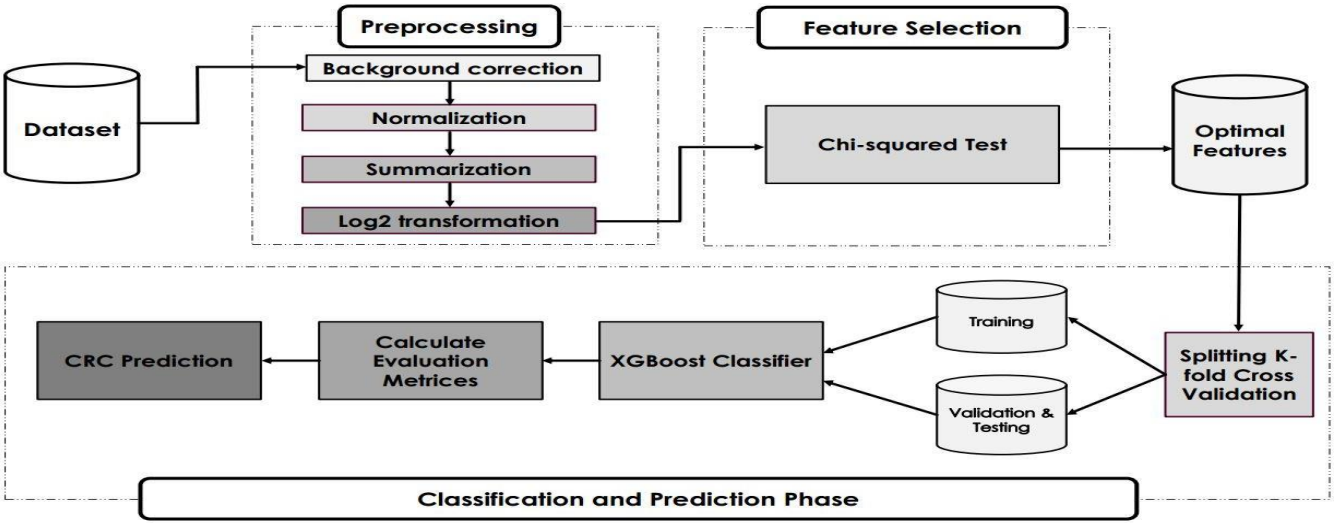

Fig. 1. The proposed prediction system.

B. Feature Selection

Feature selection stage seeks to reduce the set of features in microarray datasets by generating a new set of features from the preexisting ones. The majority of the data in the original set should be able to be summarized by these selected ones. This stage aids in lowering computation time, complexity, and model overfitting. Thus, we made an effort to narrow down the microarray datasets to the most important features. Suppose the classification algorithm receives incorrect or irrelevant features as input. In that scenario, it is unable to produce an accurate prediction because the machine learning model's performance depends heavily on the quality of the input data. As a result, we attempted to select the most notable features of most of the datasets. The selected features help us to correctly classify key genes associated with CRC. This is a crucial step in our proposed predictive model. If the features are not chosen correctly, the classification may be invalidated, impacting the predictive model.

There are three types of feature selection [9] in the microarray technology context: filter, wrapper and embedded. In the filter method, the genes are sorted and evaluated according to the class label. Correlation and gene-to-gene interactions are not considered, and it is independent of the predictor without using a learning algorithm (classifier). In contrast, the wrapper method depends on using the learning algorithm (classification algorithm) to add or remove features in order to evaluate the subset features.

This section outlines the feature selection method that produced encouraging results when compared to state-of-the-art methods: The Chi-squared test [11].

- Chi-squared test:

When large sample sizes are available, a statistical hypothesis test called a chi-squared test (also known as a chi-square [11] or X^2 test) is employed in the study of contingency tables. In layman's words, the main purpose of this test is to determine whether the two categorical variables (i.e., the two contingency table dimensions) have no effect on the test statistic. When the test statistic is chi-squared distributed under the null hypothesis, the test is considered valid. To ascertain whether there is a statistically significant discrepancy between the expected and observed frequencies in one or more categories of a contingency table, one can apply Pearson's chi-squared test. A Fisher's exact test is substituted for contingency tables with smaller sample sizes. The observations are categorized into classes that are mutually exclusive in the standard applications of this test. An X^2 frequency distribution is followed by the test statistic generated from the observations if the null hypothesis, which states that there are no differences between the classes in the population, is true. Assessing the observed frequencies' likelihood under the null hypothesis is the aim of the test. When the observations are independent, test statistics happen to follow an X^2 distribution. To verify if a pair of random variables are independent based on observations of each other, X^2 tests are also available. Datasets with categorical features are subjected to the Chi-square test. The desired number of features is determined with the optimal Chi-square scores by calculating the Chi-square between each feature and the target.

In 1900, Pearson published a paper on the X^2 test which is considered to be one of the foundations of modern statistics. In this paper, Pearson investigated a test of goodness of fit.

$$\sum_{i=1}^{k} p_i = 1 \quad (1)$$

$$\sum_{i=1}^{k} m_i = n \sum_{i=1}^{k} p_i = n \quad (2)$$

Suppose that n observations in a random sample from a population are classifed into k mutually exclusive classes with respective observed numbers of observations x_i (for i = 1,2,. . . ,k), and a null hypothesis gives the probability p_i that an observation falls into the *i*th class. So we have the expected numbers $m_i = np_i$ for all i.

$$x^2 = \sum_{i=1}^{k} \frac{(x_i - m_i)^2}{m_i} = \sum_{i=1}^{k} \frac{{x_i}^2}{m_i} - n \quad (3)$$

Pearson proposed that, under the circumstance of the null hypothesis being correct, as n → ∞ the limiting distribution of the quantity given above is the X^2 distribution as shown in Eq. (3). Pearson dealt first with the case in which the expected numbers *mi* are large enough known numbers in all cells assuming every observation *xi* may be taken as normally distributed, and reached the result that, in the limit as n becomes large, X^2 follows the X^2 distribution with *k* - 1 degrees of freedom.

To reduce the computational time and complexity for the classifier, the Chi-squared test is used to reduce the set of features and concurrently keep key features. We use Chi-squared test as feature selection to choose n features from the training model that have the highest score, based on threshold=5. After applying the Chi-squared test, we obtain 130 features instead of 54,675 features selected by Chi-squared test, as shown in Table III. As seen in Algorithm 1, we use the Chi-squared test to indicate the algorithm for the proposed feature selection after the preprocessing steps of RMA approach.

TABLE III. CHI-SQUARED FEATURE SELECTION AND THEIR NUMBERS

Dataset	# Of features before feature selection	# Of features after feature selection
GSE4107	54675	130
GSE8671	54675	130
GSE9348	54675	130
GSE32323	54675	130

Algorithm 1: The proposed preprocessing and feature Selection

Data: List of genes L_0

Result: The matrix of the most significant features F

Remove local artifacts and noise from the genes in L_0 and update it
Normalize the genes in L_0;
Represent probe intensities across arrays in L_0 as gene expression levels L_1
Transform the gene expression levels L_1 to log2 scale L_2
Initialize microarray matrix of features w
Apply the Chi-squared test for feature selection
Select the features with higher score than threshold=5 in matrix F

C. Classification

The selected features of the Chi-squared test are fed to the XGBoost classifer [12]. This classifier predicts the important genes linked to colorectal cancer (CRC) and diagnoses several test cases. Our tests demonstrate the superiority of XGBoost over state-of-the-art machine learning methods for both regression and classification tasks. XGBoost classifier is a machine learning algorithm that is applied for tabular and structured data. XGBoost is a fast and efficient implementation of gradient-boosted decision trees. XGBoost stands for extreme gradient boosting which implies that it is a large-scale machine learning technique with numerous components. XGBoost is an ensemble learning method. Relying just on the output of a single machine learning model may not always be adequate. Combining the prediction ability of several learners can be done methodically with ensemble learning [28-31]. All of the output from several models is aggregated into a single model as a result. The ensemble's models, often referred to as base learners, may come from different learning algorithms or from the same learning algorithms. The most popular ensemble learning models include bagging, boosting, stack generalization, and expert mixtures. However, two widely regarded methods for ensemble learning [28] are bagging and boosting. While these two methods can be used to a variety of statistical models, decision trees have been the most common application for them. The following is a summary of the main equations included in the XGBoost classifier:

1) Objective function: A regularized objective serves as the objective function in XGBoost and must be optimized throughout the training phase. It is composed of two terms: a regularization term that penalizes complexity to prevent overfitting, and a loss term that calculates the difference between the actual and predicted values.

$$obj(\theta) = \sum_{i=1}^{n} l(y_i, \hat{y}_i) + \sum_{k=1}^{K} (f_k) \quad (4)$$

Where:

- $l(y_i, \hat{y}_i)$ is the loss function which measures the difference between the actual target value $\hat{y}_i$.
- (f_k) is the regularization term which penalizes the complexity of the model, where represents the k-th tree.
- θ represents the model parameters.

2) Gradient and hessian tree ensemble prediction: Gradient boosting is used in XGBoost to optimize the objective function. The first and second-order derivatives of the objective function with respect to the anticipated scores must be calculated in order to carry out gradient boosting.
Where:

$$g_i = \frac{\partial}{\partial \hat{y}_i} l(y_i, \hat{y}_i) \quad (5)$$

- g_i is the first-order derivative (gradient) of the loss function.

$$h_i = \frac{\partial^2}{\partial {\hat{y}_i}^2} l(y_i, \hat{y}_i) \quad (6)$$

- h_i is the second-order derivative (Hessian) of the loss function.

3) Tree ensemble prediction: The XGBoost model's final prediction is the weighted sum of the predictions made by several trees.

$$\hat{y}_i = \sum_{k=1}^{K} f_k(x_i) \quad (7)$$

Where:

- $f_k(x_i)$ is the prediction from the k-th tree.

The XGBoost algorithm [12], which creates decision trees iteratively to minimize the above-defined objective function, is based on these equations. In numerous machine learning

applications, XGBoost provides state-of-the-art performance by optimizing the objective function. As seen in Algorithm 2, we illustrate the algorithm for the suggested classification based on the XGBoost classifier.

Algorithm 2: The proposed classification with XGBoost

Data: $D_{Train} = (x_1, y_1), (x_2, y_2), \dots, (x_N, x_N)$ $D_{Test} = (x_1, y_1), (x_2, y_2), \dots, (x_N, x_N)$
Result: Training model, and Prediction results
Use D_{Train} to train the XGBoost
Initialize the model as $h_0(x)$
For m = 1 → M do
  For i = 1 → N do
    Compute the loss function: $F(y, h_{m-1}(x_i))$
    Compute the residuals: rh,i
  End
  Fit a regression tree m_{th} to the $r_{h,i}$ values to create the terminal regions "tree leaf nodes" $R_{m,j}$, j = 1, 2, … , J; where J is the number of leaf nodes in the tree.
  For j = 1 → J do
    Get the v_m, j;
  End
  Update the weak classifier $h_m(x)$
End
Get the fnal model *H*(*x*)
Use D_{Test} to evaluate the prediction model

For s = 1 → N do
  Process XGBoost prediction model
  Get the predicted label
End
Utilizing the real and expected labels as inputs, compute the evaluation metric

IV. Experimental Results

This part includes the description of the datasets, the specifications for the hardware and software, and evaluation metrics and results. In the results subsection, first, we used the chi-squared test [11] for feature selection to identify some significant features from microarray datasets [7]. Second, the features were fed to XGBoost (eXtreme Gradient Boosting) [12] to diagnose various test scenarios. The proposed model achieves a high mean accuracy rate and low standard deviation. Third, when compared to other state-of-the-art classification algorithms, the experiment findings show promise. Finally, we use two performance measures [32] to provide some figures and tables that support a desired idea.

A. Datasets Description

Gene Expression Omnibus (GEO) [8] database served as the primary, accessible, and all-inclusive source for the gene expression raw data used in this paper when microarray data was deposited. The current study used four microarray data sets, as shown in Table IV, as follows:

- GSE4107 [23]: 22 samples and 54675 genes were included in this dataset. The data were split into two groups, each comprising 10 normal and 12 tumor samples.
- GSE8671 [24]: 64 samples and 54675 genes were included in this dataset. The data were split into two groups, each comprising 32 normal and 32 tumor samples.
- GSE9348 [25]: 82 samples and 54675 genes were included in this dataset. The data were split into two groups, each comprising 12 normal and 70 tumor samples.
- GSE32323 [26]: 34 samples and 54675 genes were included in this dataset. The data were split into two groups, each comprising 17 normal and 17 tumor samples.

TABLE IV. Description of the Datasets' Gene Expression

Dataset	Classification Type	# of Samples
GSE4107 [23]	normal	10
	tumor	12
GSE8671 [24]	normal	32
	tumor	32
GSE9348 [25]	normal	12
	tumor	70
GSE32323 [26]	normal	17
	tumor	17

B. Evaluation Metrics

This proposed work used five metrics [32] for measuring the performance of our proposed system, including accuracy (ACC), standard deviation (SD), precision, recall, and F1-Score, which are defined using Eq. (8) *to* Eq. (12).

$$ACC = \frac{TN+TP}{TN+FP+TP+FN} \quad (8)$$

$$SD = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N}(x_i - \bar{x})^2} \quad (9)$$

- x_i being the result of the i-th measurement and $\bar{x}$ being the arithmetic mean of the n results considered.

$$Precision = \frac{TP}{FP+TP} \quad (10)$$

$$Recall = SEN = TPR = \frac{TP}{FN+TP} \quad (11)$$

$$F1 - score = \frac{TP}{TP+0.5(FN+FP)} \quad (12)$$

A true positive (TP) gene is one that has been accurately predicted to be a CRC gene, and this must be made clear. Reliability of genes correctly predicted as non-CRC genes is known as true negative (TN) rate. Erroneously predicted genes as colorectal cancer (CRC) genes are known as false positives (FP). False negative (FN) is also the rate of genes that are misclassified as not being CRC genes. The percentage of accurate results over all results based on TP and TN is known as the accuracy rate, or ACC. It evaluates how accurate the proposed system is. The precision can be defined as the ratio of correctly predicted results to the total number of wrong and accurate predictions, with "results" denoting the positive genes. The rate of correctly predicted results over all correctly

predicted results is known as the SEN, recall, or TPR, where "results" refers to the negative genes.

C. Results

All of the experimental results from this investigation, together with pertinent analysis, are provided in this subsection. The comparison of feature selection, the comparison of classification techniques, and the comparison with other prediction systems comprised the three parts of the experimental results.

1) Feature selection comparison: In the feature selection stage, we attempted to select the most notable features of most of the datasets. The selected features help us to correctly classify key genes associated with CRC. This is a crucial step in our proposed predictive model. If the features are not chosen correctly, the classification may be invalidated, impacting the predictive model. We employed the Chi-squared test to identify the important features from microarray datasets in order to construct our prediction system. The features from two state-of-the-art features (PCA and LASSO) are compared with the suggested features to validate them. When compared to other systems, the experiment findings show promise. We preformed the experiments based on microarray dataset using the XGBoost classifier with 5-fold and 10-fold cross-validation technique [33]. We evaluated the results using two performance metric [32]: **ACC** and **SD**.

Microarray dataset: Table V shows the performance comparison of the proposed features based on chi-squared test and features from state-of-the-art feature selection techniques: PCA and LASSO. For 5-fold cross-validation, the proposed features achieved the following: ACC equals 93.0% and SD equals 0.13. For 10-fold cross-validation, the proposed features achieved the following: ACC equals 91.8% and SD equals 0.14. The proposed features based on chi-squared test achieve a high mean accuracy and low standard deviation as shown in Table V.

TABLE V. THE PROPOSED FEATURES' EFFECTIVENESS WAS ASSESSED USING THE CHI-SQUARED TEST AND COMPARED TO TWO OTHER METHODS, NAMELY PCA AND LASSO WITH 5- AND 10-FOLD CROSS-VALIDATION USING THE MICROARRAY DATASET

Metric	K-fold	ACC (%)	SD
PCA	5 10	86.0 90.0	0.26 0.2
LASSO	5 10	82.0 80.0	0.15 0.22
Chi-squared test (proposed)	5 10	**93.0** **92.0**	**0.13** **0.14**

As shown in Fig. 2, the proposed features based on the chi-squared test achieve a high mean accuracy (ACC).

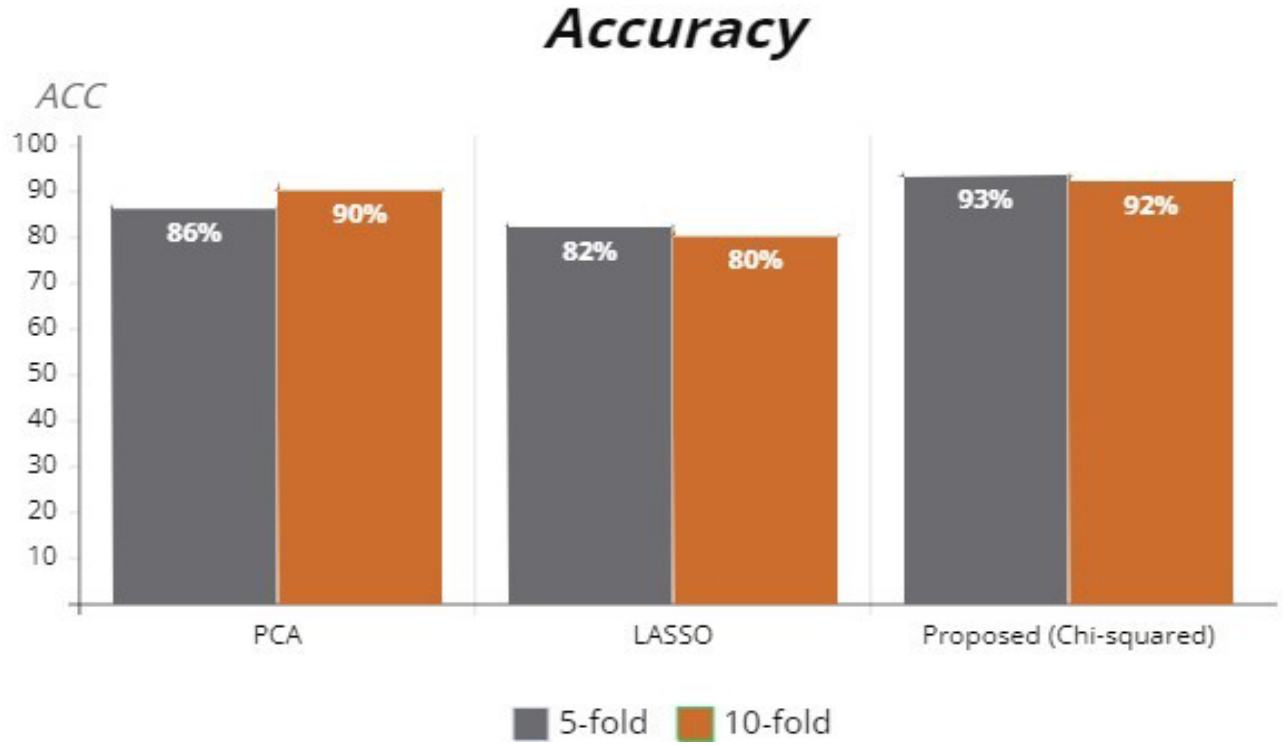

Fig. 2. The comparison between the proposed feature selection method and some state-of-the-art methods is based on accuracy.

2) Classification algorithm comparison: The selected features of the Chi-squared test are fed to the XGBoost classifier. This classifier predicts the important genes linked to colorectal cancer (CRC) and diagnoses several test cases. Our tests demonstrate the superiority of XGBoost over state-of-the-art machine learning methods for both regression and classification tasks. The results from three state-of-the-art classifiers (RF, LGBM, and LR) are compared with the XGBoost classifier to validate them. When compared to other systems, the experiment findings show promise. We

preformed the experiments based on four microarray datasets using the XGBoost classifier with 5-Fold and 10-fold cross-validation technique. We evaluated the results using five performance [32] metric: ACC, precision, recall, F1-Score and SD.

GSE4107 Microarray dataset: Table VI, shows the performance comparison of the proposed classifier based on XGBoost and classifiers from state-of-the-art techniques: LGBM, LR and RF. For 5-fold cross-validation, the proposed classifier achieved the following: ACC equals 93.0%, Precision equals 93.0%, Recall equals 100.0%, F1-score equals 96.0%, and Mean SD equals 0.085. For 10-fold cross-validation, the proposed classifier achieved the following: ACC equals 95.0%, Precision equals 90.3%, Recall equals 100.0%, F1-score equals 90.0%, and Mean SD equals 0.187. The proposed classifier based on XGBoost classifier achieved a high mean accuracy rate and low standard deviation as shown in Table VI.

As shown in Fig. 3, the proposed classifier based on XGBoost classifier achieved a high mean accuracy rate (ACC).

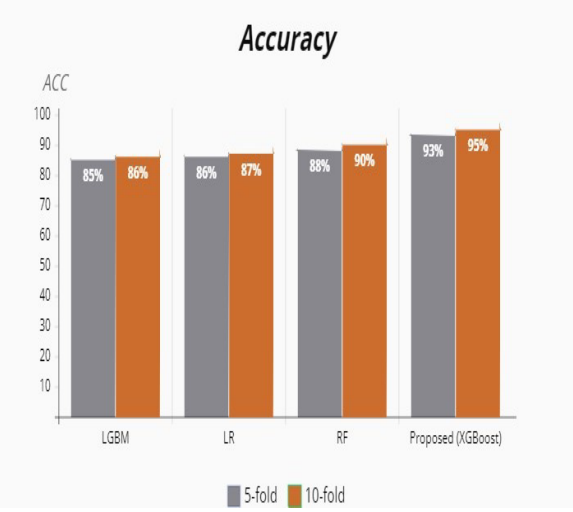

Fig. 3. The comparison between the proposed classifier and some state-of-the-art classifiers is based on accuracy using the GSE4107 dataset.

TABLE VI. USING 5-FOLD AND 10-FOLD CROSS-VALIDATION METHODS BASED ON THE 4107 DATASET, THE PROPOSED SYSTEM'S PERFORMANCE WAS EVALUATED IN COMPARISON TO STATE-OF-THE-ART CLASSIFIERS

Metric	K-fold	ACC (%)	Precision (%)	Recall (%)	F1-score (%)	SD
LGBM	5	85.4	87.2	89.5	82.4	0.180
	10	86.4	84.3	82.9	79.5	0.226
LR	5	86.2	89.6	86.3	87.4	0.155
	10	87.1	86.3	84.9	80.5	0.201
RF	5	88.9	90.2	94.5	91.4	0.120
	10	90.1	87.3	87.9	86.5	0.195
XGBoost	5	**93.0**	**93.0**	**100.0**	**96.0**	**0.085**
	10	**95.0**	**90.3**	**100.0**	**90.0**	**0.187**

GSE8671 Microarray dataset: Table VII, shows the performance comparison of the proposed classifier based on XGBoost and classifiers from state-of-the-art techniques: LGBM, LR and RF. For 5-fold cross-validation, the proposed classifier achieved the following: ACC equals 97.77%, Precision equals 96.0%, Recall equals 100.0%, F1-score equals 97.77%, and Mean SD equals 0.040. For 10-fold cross-validation, the proposed classifier achieved the following: ACC equals 98.0%, Precision equals 98.0%, Recall equals 100.0%, F1-score equals 98.88%, and Mean SD equals 0.037. The proposed classifier based on XGBoost classifier achieved a high mean accuracy rate and low standard deviation as shown in Table VII. As shown in Fig. 4, the proposed classifier based on XGBoost classifier achieved a high mean accuracy rate (ACC).

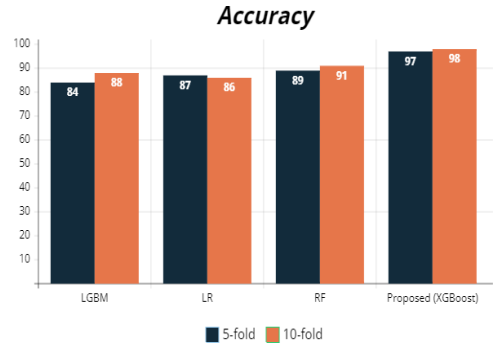

Fig. 4. The comparison between proposed classifier and some state-of-the-art classifiers based on Accuracy using GSE8671 dataset.

GSE9348 Microarray dataset: Table VIII, shows the performance comparison of the proposed classifier based on XGBoost and classifiers from state-of-the-art techniques: LGBM, LR and RF. For 5-fold cross-validation, the proposed classifier achieved the following: ACC equals 98.18%, Precision equals 100.0%, Recall equals 98.18%, F1-score equals 99.05%, and Mean SD equals 0.025. For 10-fold cross-validation, the proposed classifier achieved the following: ACC equals 91.0%, Precision equals 91.0%, Recall equals 100.0%, F1-score equals 95.05%, and Mean SD equals 0.057. The proposed classifier based on XGBoost classifier achieved a high mean accuracy rate and low standard deviation as shown in Table VIII. As shown in Fig. 5, the proposed classifier based on XGBoost classifier achieved a high mean accuracy rate (ACC).

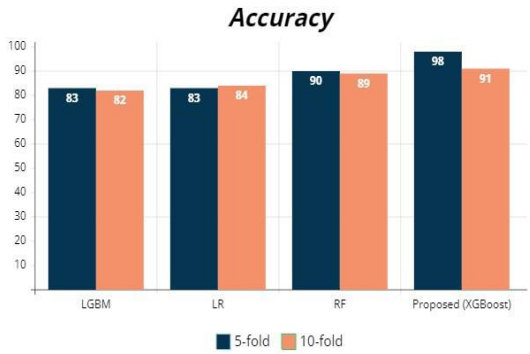

Fig. 5. The comparison between proposed classifier and some state-of-the-art classifiers based on accuracy using GSE9348 dataset.

TABLE VII. USING 5-FOLD AND 10-FOLD CROSS-VALIDATION METHODS BASED ON THE 8671 DATASET, THE PROPOSED SYSTEM'S PERFORMANCE WAS EVALUATED IN COMPARISON TO STATE-OF-THE-ART CLASSIFIERS.

Metric	K-fold	ACC (%)	Precision (%)	Recall (%)	F1-score (%)	SD
LGBM	5 10	84.2 88.5	85.4 85.6	85.5 81.4	84.1 76.4	0.190 0.236

As shown in Fig. 6, the proposed classifer based on XGBoost classifer achieved a high mean accuracy rate (ACC).

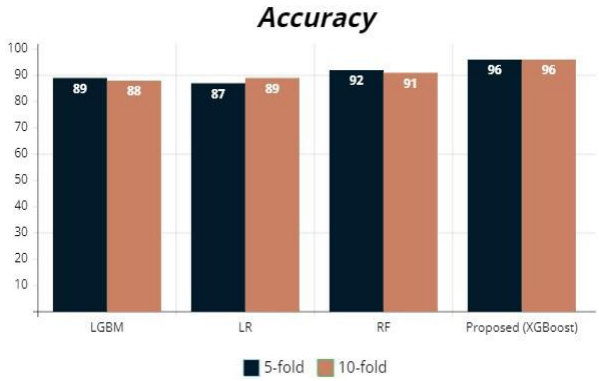

Fig. 6. The comparison between proposed classifier and some state-of-the-art classifiers based on Accuracy using GSE32323 dataset.

3) Comparison with other prediction systems: To verify how well the proposed system performs when using the XGBoost classification algorithm and the chi-squared feature selection technique. We evaluated how well the proposed system performed in comparison to state-of-the-art systems: Ahmadieh-Yazdi et al. [13], Maurya et al. [16], Li, S et al. [17], and Al-Rajab et al. [18].

The proposed system is compared to state-of-the-art systems in Table X. This comparison is based on feature selection, classification method, and performance evaluation using 10-fold cross-validation.

As shown in Fig. **7**, the proposed system achieved the highest mean accuracy rate (ACC), F1-score and Recall compared with state-of-the-art systems.

TABLE X. THE PROPOSED SYSTEM, BASED ON THE MICROARRAY DATASET, WAS COMPARED WITH THE PERFORMANCE METRICS, FEATURE SELECTION TECHNIQUES, AND CLASSIFICATION STRATEGIES EMPLOYED IN STATE-OF-THE-ART SYSTEMS

System	ACC (%)	F1-score (%)	Recall (%)	Classification Method	Feature Selection Method

V. DISCUSSION

Cancer is a complicated disease, especially in the treatment process so far. Colorectal cancer is one of the leading causes of cancer-related deaths worldwide. Colorectal Cancer is the third most common cancer in men and the second most common in women worldwide. Despite recent advances in surgical and multimodal therapies, the overall survival of advanced CRC patients remains very low. Periodic tests can significantly reduce and prevent the incidence of this disease. If colorectal cancer is detected early enough, it can mostly be treated. The biomarker is the most important component of cancer researches because it helps with the treatment process and saves cost and time in the diagnosis process. Therefore, determining the relevant biomarker is an essential task for the researchers. Researchers have made great efforts to explore an accurate diagnosis and prediction of cancer because it contains genetic changes that are dynamic. As a result, we developed our proposed prediction system to find key genes associated with colorectal cancer that can assist in the early diagnosis of the disease.

Using the RMA (Robust Multi-Array Average) approach, we first preprocessed four Microarray datasets (GSE4107, GSE8671, GSE9348, and GSE32323) to eliminate local artifacts and normalize the data. We employed 5-fold and 10-fold cross-validation methods to evaluate the proposed method. Secondly, we selected certain important features from datasets using the chi-squared test for feature selection. XGBoost (eXtreme Gradient Boosting) was then fed the features in order to diagnose several test scenarios. To verify how well the proposed system performs when using the XGBoost classification algorithm and the chi-squared feature selection technique. We evaluated how well the proposed system performed in comparison to state-of-the-art systems: Ahmadieh-Yazdi et al. [13], Maurya et al. [16], Li, S et al. [17], and Al-Rajab et al. [18]. The model that has been suggested has a low standard deviation and a high mean accuracy rate. The experiment results show promise when compared to other systems.

The results are evaluated using five performance metric: ACC, precision, recall, F1-Score and SD. For 5-fold cross-validation, the GSE4107 dataset achieved the following: ACC equals 93.0%, Precision equals 93.0%, Recall equals 100.0%, F1-score equals 96.0%, and Mean SD equals 0.085. For 10-fold cross-validation, the GSE8671 dataset achieved the following: ACC equals 98.0%, Precision equals 98.0%, Recall equals 100.0%, F1-score equals 98.88%, and Mean SD equals 0.037. For 5-fold cross-validation, the GSE9348 dataset achieved the following: ACC equals 98.18%, Precision equals 100.0%, Recall equals 98.18%, F1-score equals 99.05%, and Mean SD equals 0.025. For 5-fold cross-validation, the GSE32323 dataset achieved the following: ACC equals 96.0%, Precision equals 95.0%, Recall equals 100.0%, F1-score equals 97.14%, and Mean SD equals 0.059.

Lastly, the proposed model predicted novel CRC biomarkers that are not present in the databases [6] using the proposed prediction system. The literature review is used to verify these biomarkers. The Biomarkers that were extracted: VIP, CYR61, ADAMTS1, SLC51A, GREM1, PLN, MSI2, FOS, ADH1B, ETNK1, MEP1B, NR1H4, SYNP02, OGN, FOSB, UGT2A3, RGS1 and SERPINF1. We found out that

none of these genes had been linked to colorectal cancer (CRC) based on the literature review [6].

Table XI, show the smallest gene set for different datasets selected by XGBoost. These genes are known as colorectal cancer biomarkers and the function of each of these genes is presented in the mentioned table. The function and annotation of each selected gene were extracted from the NCBI database.

TABLE XI. THE LIST OF BIOMARKERS AND THEIR MAIN FUNCTIONS

Probe ID	Gene Symbol	Function
* "206577_*at*"	**VIP**	Encodes the vasoactive intestinal peptide (VIP) protein. VIP is a neuropeptide that has a wide range of physiological effects and is distributed widely throughout the body.
* "210764_*s_at*"	**CYR61**	Encodes a protein referred to as CCN1 (cysteine-rich protein 61),or cysteine-rich angiogenic inducer 61.
* "222162_*s_at*"	**ADAMTS1**	Encode the ADAMTS1 protein, an enzyme that is engaged in a number of biological functions, such as: Extracellular Matrix Remodeling, Angiogenesis Regulation, Cell Migration and Proliferation, and Tissue Homeostasis and Development.
* "228230_*at*"	**SLC51A**	Encodes the organic solute transporter alpha (OSTα) protein, which is a component of the heteromeric transporter complex that is involved in the transfer of bile acids.
* "218468_*s_at*"	**GREM1**	Encodes gremlin-1, a protein that belongs to the family of bone morphogenetic protein (BMP) antagonists known as DAN (differential screening-selected gene abnormal in neuroblastoma).
* "204939_*s_at*"	**PLN**	Phospholamban is essential for controlling the activity of the sarcoplasmic reticulum calcium ATPase (SERCA), a vital ion transporter.
* "1552364_*s_at*"	**MSI2**	Encodes the Musashi-2 (MSI2) protein, an RNA-binding protein belonging to the Musashi family.
* "209189_*at*"	**FOS**	Encodes the Fos protein, a member of the Fos transcription factor family.
* "209613_*s_at*"	**ADH1B**	Encodes the enzyme alcohol dehydrogenase 1B, which is essential to the liver's ethanol metabolism–the kind of alcohol present in alcoholic drinks.
* "224453_*s_at*"	**ETNK1**	Encodes the ethanolamine kinase 1 (ETNK1) enzyme, a component of the pathway responsible for phospholipid metabolism.
* "207251_*at*"	**MEP1B**	Encodes the beta subunit of meprins, zinc-dependent metalloendopeptidases composed of homo- and heterooligomers of 2 evolutionary related subunits, alpha (see MEP1A, 600388) and beta.
* "1554375_*a_at*"	**NR1H4**	Encodes a nuclear receptor called farnesoid X receptor (FXR).
* "225720_*at*"	**SYNP02**	Increases the resistance to immunotherapy and upregulates the infiltration of resting mast cells, which both contribute to the development of BLCA.
* "222722_*at*"	**OGN**	Encodes the osteoglycin protein, popularly referred to as mimecan.
"202768_*at*"	**FOSB**	Encodes the FosB protein, a member of the Fos transcription factor family.
"219948_*x_at*"	**UGT2A3**	Encodes UDP-glucuronosyltransferase 2A3, an enzyme belonging to the UGT family of enzymes.
"202988_*s_at*"	**RGS1**	Encodes the Regulator of G protein signaling 1 (RGS1) protein.
"202283_*at*"	**SERPINF1**	Encodes a protein called pigment epithelium-derived factor (PEDF), which belongs to the serpin superfamily of protease inhibitors.

VI. VALIDATION OF RESULTS

In this part, the importance of the proposed biomarkers are explained in identifying colorectal cancer by performing validation of results using SHAP algorithm [34, 35]. Model transparency, debugging, and fairness are all made possible by SHAP values, which offer a robust and theoretically valid way to understand each unique prediction of a machine learning model. Fig 8, shows the performance comparison of the proposed biomarkers based on XGBoost and other features using 4107 dataset.

Fig. 9 shows the performance comparison of the proposed biomarkers based on XGBoost and other features using 8671 dataset.

Fig. 10 shows the performance comparison of the proposed biomarkers based on XGBoost and other features using 9348 dataset.

Fig. 11 shows the performance comparison of the proposed biomarkers based on XGBoost and other features using 32323 dataset.

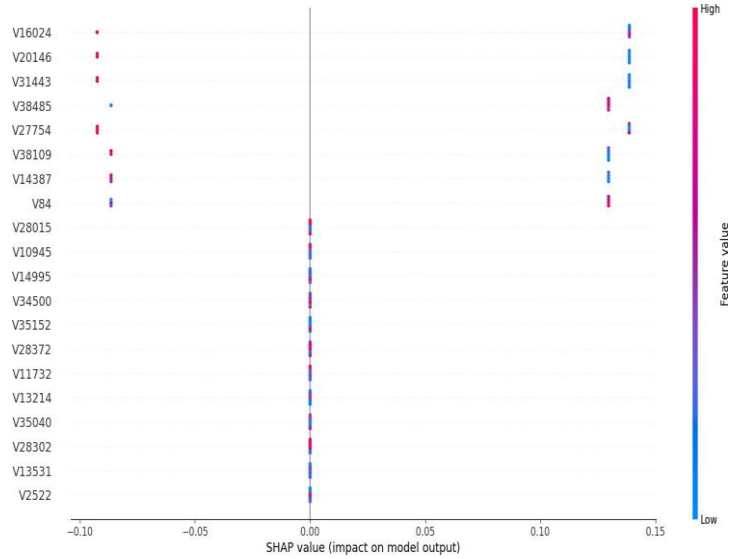

Fig. 8. The comparison between proposed biomarkers based on the 4107 dataset.

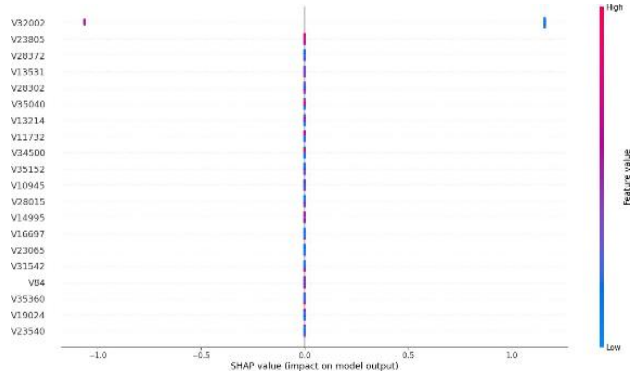

Fig. 9. The comparison between proposed biomarkers based on the 8671 dataset.

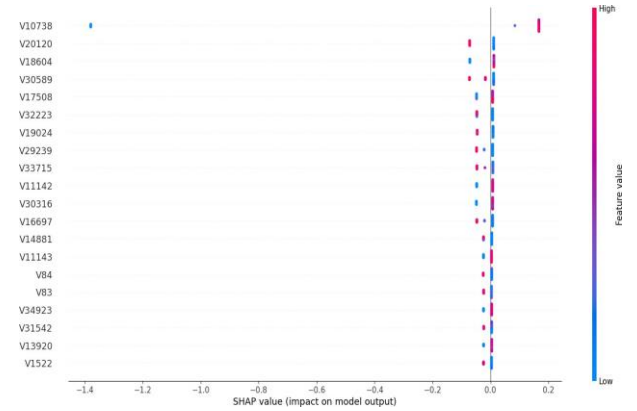

Fig. 10. The comparison between proposed biomarkers based on the 9348 dataset.

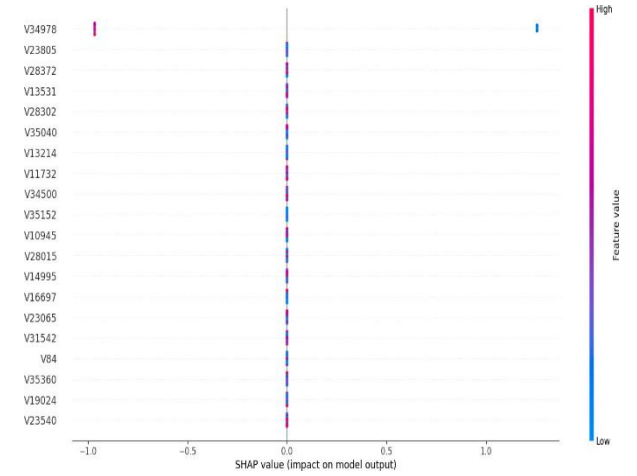

Fig. 11. The comparison between proposed biomarkers based on the 32323 dataset.

VII. Conclusion

This proposed work developed a novel prediction system to identify new biomarkers linked to CRC that can assist in an early diagnosis. The proposed model used four public microarray datasets: GSE4107, GSE8671, GSE9348 and GSE32323. The proposed prediction system comprises four steps. First, four Microarray datasets are preprocessed using the RMA (Robust Multi-Array Average) approach to eliminate local artifacts and normalize the data. Secondly, the certain important features from datasets are selected using the chi-squared test for feature selection. Then, the most relevant features were fed to XGBoost (eXtreme Gradient Boosting) to diagnose various test cases. Lastly, the results of the proposed system are assessed using five performance measures. The proposed model has a low standard deviation and a high mean accuracy rate. The experiment results show promise when compared to other systems. Based on a review of the literature, the expected biomarkers are confirmed. The future work is to find new biomarkers and gene alterations related to the different CRC grades. In the interim, the proposed system may be used to predict additional diseases that share similar genes.

VIII. Data Availability Statement

Yes, the model have research data to declare. Proposed model used four public Microarray datasets (GSE410723, GSE867124, GSE934825 and GSE3232326) downloaded from NCBI32 offcial Website.

Environmental and Economic Benefit Analysis of Urban Construction Projects Based on Data Envelopment Analysis and Simulated Annealing Algorithm

Jie Gong
School of Construction Management,
Chongqing Metropolitan College of Science and Technology, Chongqing, 402167, China

***Abstract*—With the continuous advancement of urbanization and the sustained growth of urban population, city building projects are facing severe challenges. How to analyze their environmental and economic benefits has become an urgent problem to be solved. Therefore, based on the proposed method for calculating the environmental and economic benefits of city building projects, this study uses a cross efficiency data envelopment analysis model for evaluation and solution. Then, an improved simulated annealing algorithm is used to achieve environmental and economic benefit optimization. The results showed that the improved simulated annealing algorithm tended to stabilize after 480 iterations, with maximum and minimum values of 0.86 and 0.21, respectively. The maximum F1 value was 0.988, indicating better performance. In the selected three urban construction projects, the cross efficiency data envelopment analysis model achieved high environmental and economic benefits, demonstrating the effectiveness of the model. After optimizing using the improved simulation degradation algorithm, the maximum economic benefit was increased by 850000 yuan, proving the effectiveness of the proposed method in analyzing the environmental and economic benefits of urban construction projects. It can provide more scientific decision support for construction project planning.**

Keywords*—DEA; simulated annealing algorithm; city building; environment; economics; benefit

I. INTRODUCTION

With the continuous improvement of urbanization level, China's construction industry has undergone technological innovation, and urban construction has developed rapidly [1]. During this process, many problems have arisen in the construction industry, especially sustainable development, which has had a huge impact on energy and the environment [2-3]. The reason is that urban buildings have a relatively long lifecycle, and their impact on the environment and energy consumption is also long-term, which makes it difficult for further expansion plans or existing renovations of the city to meet various requirements. Specifically, the construction unit needs to balance the impact on the surrounding environment while meeting the requirements for quantity and quality. Therefore, the analysis of environmental and economic benefits of urban construction projects has become a key research direction for many professionals. The existing analysis methods include cost-benefit analysis, life cycle assessment, regression analysis, etc. However, cost-benefit analysis is difficult to accurately quantify environmental impacts, and the evaluation of non-market factors is subjective. Although life cycle assessment methods can comprehensively consider environmental impacts, the implementation process is complex, data requirements are high, and it is difficult to provide decision support in a short period of time. Regression analysis relies on linear assumptions and is not suitable for handling nonlinear relationships. At the same time, it has high requirements for data and is easily affected by outliers. In recent years, Data Envelopment Analysis (DEA) models, Simulated Annealing (SA) algorithms, and multi-objective optimization provide theoretical and technical references for this direction [4-6]. In response to the prominent contradiction between the increase of water resources and the decrease of water supply, Wang Z et al. successfully constructed a multi-objective optimization configuration model using multi-objective programming theory. The results showed that the model had strong scientific practicality, which was of great significance for solving practical multi-objective optimization problems [7]. To solve the production demand fluctuations in unstable markets, Zhang Z et al. designed an optimized SERU model through a novel SERU production system that combined genetic algorithm and SA to achieve maximum profit increase. The results indicated that this model could effectively handle the SERU loading problem and had good robustness in solving the SERU loading model [8]. Gabi D et al. proposed a SA optimization scheme based on fruit flies to address the premature convergence of metaheuristic techniques and the imbalance between global and local searches. The scheme balanced local and global searches and was statistically analyzed using a 95% confidence interval. The results showed that the scheme could improve resource utilization by returning the minimum completion time and execution cost [9]. In response to the insufficient effectiveness and accuracy of grasshopper behavior research algorithms, Yu C et al. combined SA mechanism with original grasshopper optimization algorithm, and evaluated the relative ranking of this algorithm in CEC2017 through Friedman. The results showed that the proposed grasshopper optimization algorithm could effectively solve complex optimization problems and achieve results that meet or even exceed expectations [10]. In response to the shortcomings of previous design methods in

geothermal energy development, Liu J et al. proposed an innovative design framework that combined numerical simulation and SA, equipped with an energy lining system that generated thermal energy through circulating heat carrying fluids. The results indicated that the method still demonstrated strong processing ability under multiple factor crossover, which could guide practical applications [11]. In response to the slow convergence of existing slime mold algorithms in local search spaces, Ch L K et al. discovered the optimal solution of the objective function by mixing slime mold algorithms and SA algorithms to better change parameters. The non-convex, nonlinear, and typical engineering design difficulties were analyzed. The results showed that the mixed slime mold SA algorithm was more reasonable than other optimization techniques [12]. Camanho A S et al. conducted a literature review on the DEA of economic efficiency, including the optimization of costs, revenues, and profits. The application of different modeling methods was analyzed, providing new development directions for efficiency evaluation [13]. In response to the problem that traditional DEA cannot fully explore valuable information in big data, Zhu J focused on the development of nonlinear networks to propose corresponding DEA models. The results demonstrated the effectiveness of DEA in big data modeling [14].

By analyzing the research on DEA model and SA algorithm, both DEA model and SA algorithm have their own advantages, which are widely used in the fields of resource utilization efficiency and complex system optimization. Among them, the DEA model can effectively evaluate the relative efficiency of multiple decision-making units and is suitable for comprehensive evaluation of environmental and economic benefits. The SA algorithm can effectively search for global or approximate optimal solutions in the search space by simulating the physical annealing process. Its randomness and flexibility enable it to avoid getting stuck in local optima in complex multi-objective optimization problems. However, there is relatively little research on the combination of the two methods. Meanwhile, the economic input and output of urban construction projects have their own particularities, and the environmental impact also includes many complex factors. Therefore, starting from this point, the study combines DEA model and SA algorithm, proposes a method for calculating the environmental and economic benefits of urban construction projects, uses the cross efficiency DEA model for evaluation and solving, and combines the improved SA algorithm to optimize the environmental and economic benefits. Among them, the cross efficiency DEA model can better handle the relative efficiency evaluation between samples and reduce stability issues. The improved SA algorithm improves computational efficiency through optimization strategies and can quickly find approximate optimal solutions. The combination of these two methods can simultaneously consider economic and environmental benefits, providing a more comprehensive solution that is more suitable for the needs of complex urban construction projects.

The research content mainly includes four parts. The first part reviews the relevant research on DEA model and simulated annealing algorithm. The second part introduces the research methods. The first section analyzes the main factors in the environmental and economic benefits of urban construction projects and proposes calculation methods. The second section proposes a cross efficiency DEA model to solve multi-objective optimization problems of economic and environmental benefits. The third section proposes a combination of improved SA algorithm for optimizing economic and environmental benefits. The third part validated the performance of the improved SA algorithm and conducted empirical analysis on the environmental and economic benefits of urban construction projects. The fourth part summarizes and discusses the research results, and proposes future prospects.

II. Methods and Materials

In this chapter, the study first analyzes the main factors in the environmental and economic benefits of urban construction projects, and proposes calculation methods. Then, a combination of cross efficiency DEA model combined with improved SA algorithm is designed to optimize economic and environmental benefits.

A. Calculation of Environmental and Economic Benefits of Urban Construction Projects

The specific economic benefit indicators of urban construction projects are mainly divided into revenue indicators and cost indicators. Among them, the revenue indicators include the company's sales revenue, sales profit, and net profit. Cost indicators include material costs, labor costs, manufacturing costs, operating costs, and other aspects [15-16]. In the early stages of a construction project, costs mainly include market research, feasibility analysis, and technology development. Among them, urban buildings often face technical difficulties in the construction process. Technology research and development expenses are mainly investment related expenses for this research object. The construction cost can be divided into two parts: direct and indirect expenses. The labor, machinery, and material costs incurred during the construction project are considered direct expenses. The management fees, maintenance fees, and recycling fees of enterprises are classified as indirect expenses. Management fees refer to the property management fees incurred during the use of urban buildings, while maintenance fees are the maintenance costs incurred during the use process. The recycling cost includes the cost of dismantling components, cleaning the site, and processing fees for recycling, that is, the economic cost of dismantling, recycling, and utilization stages. In addition, the economic benefits of urban buildings include energy and resource conservation benefits, and energy conservation includes water and energy conservation. By calculating the unit electricity consumption throughout the life cycle of the building, the savings per square meter of urban buildings can be obtained, expressed as N_1. By consulting and referring to the local electricity standard P_1, the specific energy-saving benefits can be obtained, as shown in Eq. (1).

$$E_1 = N_1 * P_1 * A + S \tag{1}$$

In Eq. (1), A is the urban building area. S represents other energy saving costs. Combined with the local fixed price, the water-saving amount of urban buildings can be converted into water-saving benefits, as shown in Eq. (2).

$$E_2 = N_2 * P_2 \tag{2}$$

In Eq. (2), N_2 represents the water saving of urban construction projects. The benefits of resource conservation are mainly reflected in two aspects, namely the material saving benefits and time-saving benefits of urban construction. After comparing the differences in time efficiency between traditional and urban buildings for each floor, the time-saving benefits can be measured, as shown in Eq. (3).

$$E_3 = C * \left(\frac{D_c - D_z}{D_c} \right) \tag{3}$$

In Eq. (3), D_c and D_z represent the construction days of traditional and urban building projects, respectively. C represents the total cost of urban construction. Material saving benefits refer to the economic and environmental benefits obtained by optimizing resource utilization, improving material utilization efficiency, reducing raw material consumption and waste, and thereby reducing production costs and environmental burdens [17]. The specific calculation method is shown in Eq. (4).

$$E_4 = \sum N_i * P_i \tag{4}$$

A corresponding evaluation index system is created based on environmental benefits and costs to comprehensively assess the environmental impact and economic benefits of the model. Energy consumption includes water and electricity consumption, with water energy consumption referring to the amount of water resources used in the operation and model application of the power system. The energy consumption involves the amount of electricity consumed during model training and practical applications, including the computing resources required during model operation and the electricity consumed by equipment. Resource consumption includes the amount of wood, steel, and other resources consumed. Wood consumption involves the used wood resources in model development and system construction processes. Steel consumption includes the steel resources used in equipment manufacturing, infrastructure construction, and other aspects. The specific indicator system is shown in Fig. 1.

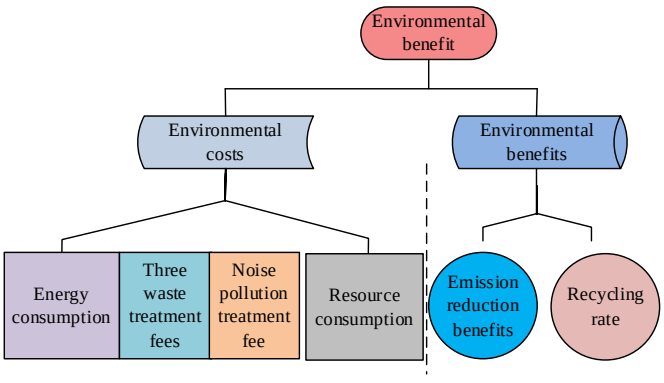

Fig. 1. Evaluation index system based on environmental benefits and environmental costs.

In order to fully evaluate the environmental impact of the project, the cost of waste treatment cannot be ignored. The cost of three wastes treatment refers to the cost of treating the wastewater, exhaust gas, noise, and solid waste generated during urban construction projects. The wastewater treatment fee covers the cost of wastewater treatment and discharge generated during construction and production processes, including the cost of wastewater collection, treatment, purification, and standard discharge. The cost of exhaust gas treatment mainly targets the exhaust gas generated during the construction process and vehicle exhaust. Usually, the exhaust emissions during the construction process do not exceed national standards, so there is less demand for treatment. The cost of solid waste disposal involves the disposal of solid waste generated during construction and production processes, such as construction waste, material residues, etc. The cost of noise pollution control includes the expenses required for implementing noise reduction measures, such as noise isolation and equipment maintenance. In the noise detection of urban buildings, the evaluation is mainly based on the relevant regulations of the urban area, as shown in Table I. The noise control can be assessed by measuring the residents' perception of noise in some areas.

TABLE I. URBAN REGIONAL NOISE ASSESSMENT STANDARDS

Adjacent	Distance/m
A type of standard applicable area	40~50
Applicable areas of Class II standards	23~35
Applicable areas of Class II standards	15~25

To reduce particulate matter emissions, the study adopts a five point sampling method, using a TH-150AH sampler to collect air samples and measure the particulate matter content in these samples. Then, the measured particulate matter content is compared with the relevant comprehensive standards. According to estimates, each square meter of dust reduction can bring 6.1 yuan in ecological benefits. Measures to reduce particulate matter not only help reduce environmental pollution, but also generate certain economic value. The specific income expression is shown in Eq. (5).

$$F = f * A * B \tag{5}$$

In equation (5), f represents the reduction of air particulate matter. B represents the ecological benefits of dust reduction in prefabricated buildings.

B. Cross Efficiency DEA Model

The study analyzed the main factors in the environmental and economic benefits of urban construction projects and proposed corresponding calculation methods. Next, it is necessary to solve the multi-objective optimization problem of economic and environmental benefits. As a non-parametric evaluation method, DEA is easy to calculate and can effectively process multi output and multi input data [18]. By creating an optimized model, it is possible to define an effective Pareto front and evaluate the efficiency of its object. In addition, the best weight combination among each decision unit can also be obtained. Therefore, when dealing with the subjective problems

caused by decision-makers' likes and dislikes in multi-objective programming, combining with multi-objective optimization solutions can be relatively easy to solve. Although traditional DEA models can effectively obtain decision units, they can only work on one decision unit, and the ranking of each decision unit depends on self-evaluation, resulting in significant errors. In response to the above two points, a method of cross evaluating its efficiency value is applied. According to the analysis, although the traditional DEA model inevitably lacks extremism, it is more suitable for dealing with practical situations [19]. In addition, traditional DEA models output decision units with many efficiency values of 1, which makes it difficult to distinguish whether they are of high quality. Cross efficiency DEA can further and hierarchically divide the decision units constructed by all efficiency values, and then obtain the rankings of all decision units. The cross efficiency DEA used in the study first calculates the negative ideal solution corresponding to the target value, including two maximization and minimization objectives. The negative ideal solutions for maximizing and minimizing the objectives are shown in Eq. (6).

$$\begin{cases} a_{ij}^{\min} = \min\left\{a_{i1}, a_{i2}, ..., a_{ij}\right\}, i = 1, 2 \\ b_{ij}^{\max} = \max\left\{a_{i1}, a_{i2}, ..., a_{ij}\right\}, i = 3, 4 \end{cases} \tag{6}$$

In Eq. (6), a_{ij} represents the maximization objective. b_{ij} represents minimization objective. Subsequently, the target values of each scheme are subtracted from the corresponding negative ideal solutions in all schemes to obtain the indicator values. The indicator value of the j-th scheme is Y_j. The conversions of a_{ij} and b_{ij} are shown in Eq. (7).

$$\begin{cases} y_{ij} = a_{ij} - a_{ij}^{\min}, i = 1, ...o \\ y_{ij} = b_{ij}^{\max} - b_{ij}, i = 3, 4, \ j = 1....o \end{cases} \tag{7}$$

After conversion, a set of homogeneous indicators can be obtained, which are then passed into the cross efficiency DEA to identify objective and effective solutions. After evaluating and analyzing the cross efficiency DEA, the efficiency ranking is then carried out. The top ranked solution is the optimal solution. For each evaluated multi-objective optimization scheme, since the objective transformation no longer involves input-output relationships, the input is usually considered as 1. Under the condition of unchanged scale benefits, applying the Charnes-Cooper transformation can obtain a linear programming model, as shown in Eq. (8).

$$\max E_{dd} = \sum_{i=1}^{4} \mu_{id} y_{id} - \delta \tag{8}$$

In Eq. (8), d is the evaluation scheme. E_{dd} is its self-evaluation relative efficiency. By solving the model, the optimal solution for scheme d is obtained. Through the evaluation and analysis of this optimal solution, the cross efficiency value of the scheme is obtained, as shown in Eq. (9).

$$E_{dj}^{*} = \frac{\sum_{i=1}^{4} \mu_{id}^{*} y_{ij}}{1 - \delta^2} (d, j = 1, ..., r) \tag{9}$$

After calculating the cross efficiency matrix, the arithmetic mean method is used to obtain the cross efficiency value, as shown in Eq. (10).

$$E_j^{*} = \frac{1}{n} \sum_{d=1}^{n} E_{dj}^{*} (n = r, j = 1, ..., r) \tag{10}$$

Among them, the higher the efficiency value, the more reasonable and excellent the solution is. By sorting efficiency values according to demand, the most effective solution can be identified, presenting decision-makers with an optimal solution that is not influenced by subjective factors. The application process of the cross efficiency DEA method is shown in Fig. 2.

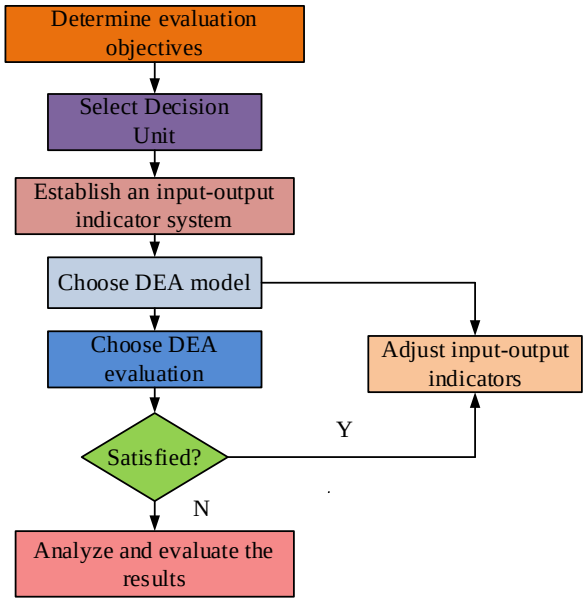

Fig. 2. Application process of cross efficiency DEA method.

C. Benefit Optimization Combined with Improved SA Algorithm

After using the cross efficiency DEA model for evaluation and solution, the study further adopts an improved simulated annealing algorithm to optimize environmental and economic benefits. SA algorithm is based on the basic principle of solid annealing and belongs to a probability-based algorithm [20-21]. Specifically, in the solid annealing, the solid is first heated to a certain degree and then slowly cooled. Due to heating, the particles inside the solid appear disordered, and the corresponding internal energy gradually increases. However, slow cooling gradually makes the particles more ordered, and equilibrium states are achieved at all temperature levels. Finally, when reaching room temperature, it becomes the ground state, and the internal energy decreases to the minimum [22]. The heating process, isothermal process, and cooling process together constitute the solid annealing process, which can actually simulate combinatorial optimization problems. That is, the solution space of the problem corresponds to the internal state of the object, the optimal solution corresponds to the lowest energy state, the objective function corresponds to the energy, and the initial temperature setting corresponds to the melting process. The Metropolis criterion optimizes the isothermal process, and the parameter controls the temperature

drop corresponding to the cooling process. The corresponding relationship is shown in Fig. 3.

The SA algorithm can escape from local optima until the global optimum is found. The calculation process is simple, making it highly applicable to combinatorial optimization problems. However, this algorithm is limited by the parameter of cooling rate, often resulting in significant time waste or the optimal solution being skipped, and has a long convergence time. Therefore, the study first introduces genetic algorithm to avoid getting stuck in local optima. A mixed mutation operator is proposed to divide the mutation process into insertion mutation, reversal mutation, and swapping mutation, reducing the randomness in the mutation process. Secondly, the Metropolis criterion is inserted to determine the entry of paternal chromosomes into the offspring population. The higher the fitness value, the greater the probability of passing. Based on these two operations, an improved SA algorithm is proposed, which can ensure the overall optimal solution results and accelerate the solving process. The improved SA algorithm first performs chromosome encoding using real number encoding. Then, real numbers in s rows and t columns that match the actual meaning are randomly obtained. Among them, t is the number of genes on the chromosome, and s is the initial population size. This generates the initial population. Afterwards, the selection operation is performed. To ensure the completeness of the optimal individual, the optimal preservation strategy, namely the elite preservation strategy, is adopted, combined with the roulette wheel method for joint screening. The elite retention strategy can enable the best individual to enter their offspring and conduct selective selection among secondary individuals, which can further place them on the offspring chromosome. Based on the roulette wheel selection method, individuals with lower fitness have a significantly increased probability of entering offspring. The individual's selection probability is shown in Eq. (11).

$$P_{selected} = \frac{fitness(a_i)}{\sum_{i=1}^{n} fitness(a_i)} \tag{11}$$

In Eq. (11), a_i represents an individual. $P_{selected}$ is the probability of being selected. $\sum_{i=1}^{n} fitness(a_i)$ is the sum of fitness values. After screening excellent paternal chromosomes, crossover operations can be carried out. In this process, it is necessary to exchange the two selected paternal chromosomes, so that offspring can inherit the excellent characteristics of the paternal chromosomes. To ensure the efficiency of the calculation, the single point crossing method is used in the study. A point on the crossing point of the parental chromosome is randomly selected, and two parental chromosomes are subjected to cleavage treatment to obtain the offspring chromosome after replacement. The effect before and after single point crossing is shown in Fig. 4.

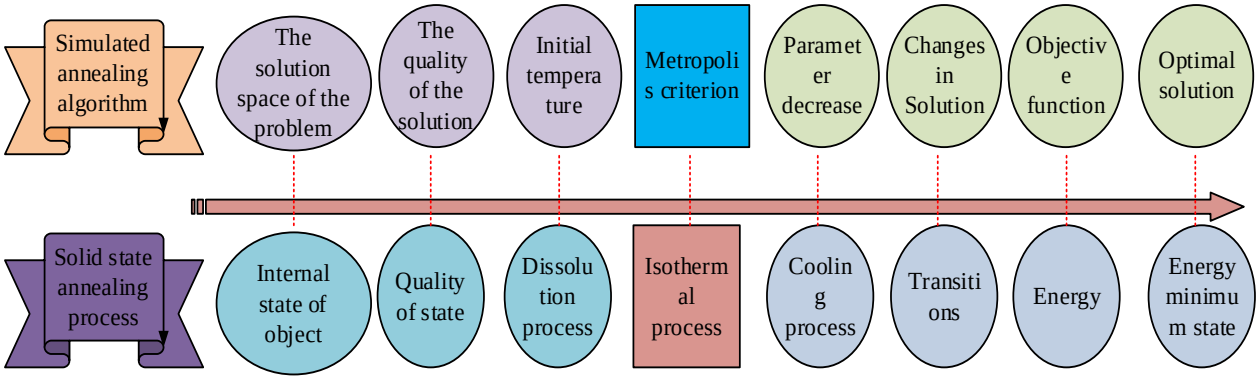

Fig. 3. The correspondence between simulated annealing algorithm and annealing process.

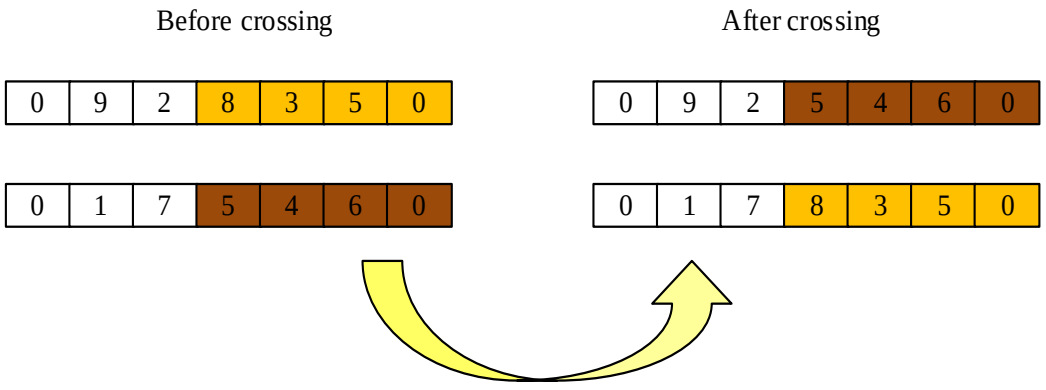

Fig. 4. Single point crossing effect before and after.

After applying crossover operations to genetic algorithms, the study improves the two-point variability theory by dividing variability into three stages: swapping, inversion, and insertion, forming a new mutation operator that avoids the local minima. After inserting the mutation, the Metropolis criterion is further introduced to determine whether the superior and inferior solutions are accepted. Firstly, the model function is solved to obtain an optimized solution, which serves as the initial value for the SA algorithm. Then, the SA algorithm is used to complete the local search in the surrounding space of the initial solution, and the local optimal solution is obtained from it. Finally, the Metropolis criterion is used to determine whether the new solution is accepted or not. When the difference between the model function of the local optimal solution and the original model function is less than 0, it can be determined as an acceptable new solution. Otherwise, it needs to be determined through Eq. (12).

$$p = \exp\left(-\frac{C_{new} - C_{old}}{T}\right) \quad (12)$$

In Eq. (12), T represents the current temperature. p represents the probability of the new solution being accepted. C_{new} represents the model function of the local optimal solution. C_{old} represents the original model function. In the probability of accepting a solution, a random number within the range of 0 to 1 is generated for comparison. When the random number is greater than p, the acceptable new solution can be retained and used as the solution of the model function. Otherwise, the new solution needs to be accepted, and the above steps need to be repeated continuously to update the annealing temperature. When the improved SA algorithm reaches the maximum number of iterations or continuously inputs the same result, the entire operation ends. Otherwise, it needs to be repeated continuously until the best result is obtained. Therefore, the operational flow of the improved SA algorithm can be presented in Fig. 5.

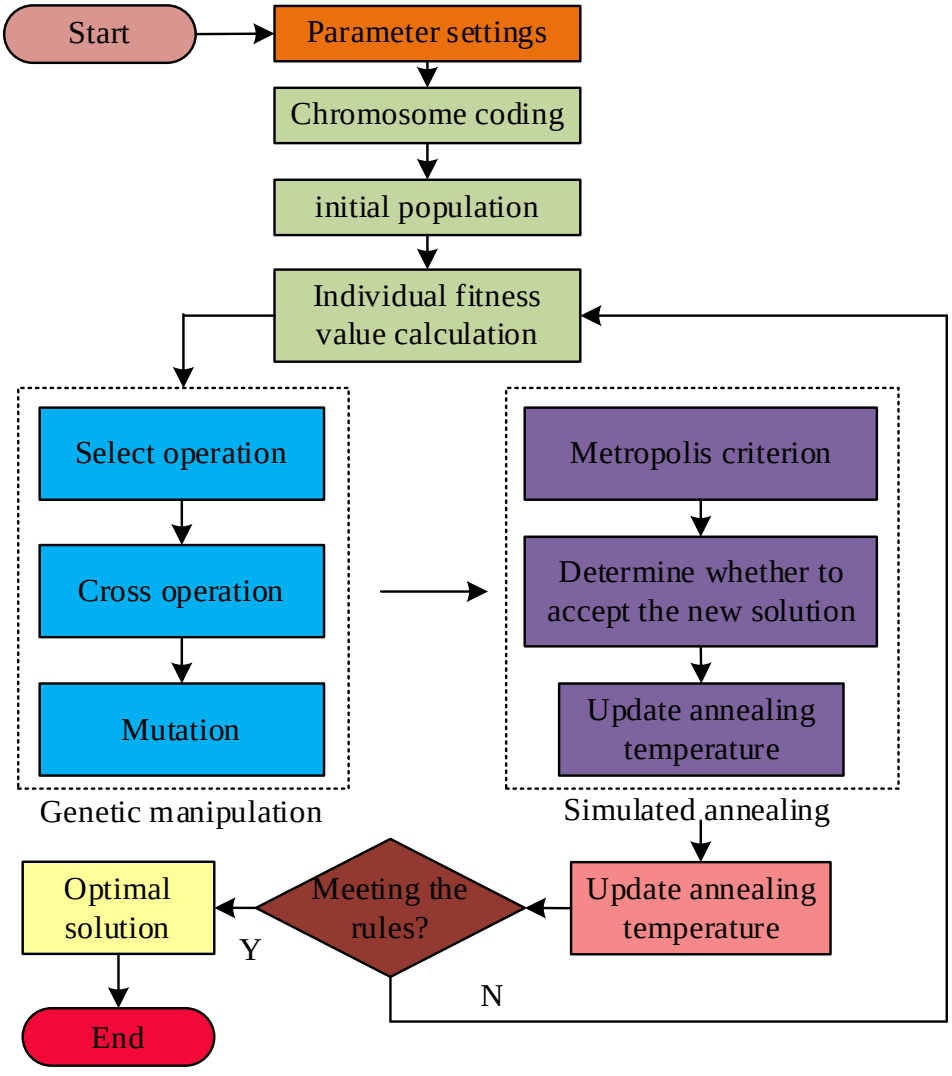

Fig. 5. The calculation process of the improved simulated annealing algorithm.

III. RESULTS

To verify the effectiveness of the proposed method for analyzing the environmental and economic benefits of urban construction projects, the study first validates the performance of the improved SA algorithm. Then, environmental and economic benefit analysis is conducted by combining cross efficiency DEA.

A. *Performance Testing of Improved Simulated Annealing Algorithm*

The performance testing of the improved SA algorithm mainly relies on Matlab 2020a simulation software, with Windows 11 operating system, 128GB of memory, and Intel Core i5-9300H central processor. During the testing process, traditional SA algorithm and SA-PSO algorithm are selected for comparison. The selected comparison indicators include fitness and F1 value, with an iteration of 2000 times. The dataset is CEC2022, which is a standard test function used to evaluate and compare the performance of optimization algorithms. This dataset can fully examine the search ability and robustness of optimization algorithms. The fitness and F1 value changes of the three methods are shown in Fig. 6.

From Fig. 6(a), during the variation of fitness values, the maximum fitness value of the improved SA was 0.86 and the minimum value was 0.21. It tended to stabilize after 480 iterations. The minimum fitness values of SA-PSO and traditional SA algorithms were 0.28 and 0.37, respectively, and both tended to stabilize after 1000 iterations, with a significantly slower convergence speed. According to Fig. 6(b), in the 5 experiments numbered A, B, C, D, and E, the maximum F1 value of the improved SA algorithm was 0.988 and the minimum value was 0.955. The average values of SA-PSO and traditional SA algorithms were 0.903 and 0.878, respectively. This proves that the improved SA algorithm has better overall performance. To further validate the performance of the improved SA algorithm, tests were conducted on two different datasets, including the Wine and Iris datasets in the UCI machine learning library. The Iris dataset is relatively small and simple, while the Wine dataset is relatively complex, and the relationships between features may be more complex, which can affect the convergence speed and stability of the algorithm. The proposed improved SA algorithm is more suitable for datasets with complex feature relationships or higher dimensions, as it can better explore and utilize the characteristics of the search space. The changes in fitness obtained are shown in Fig. 7.

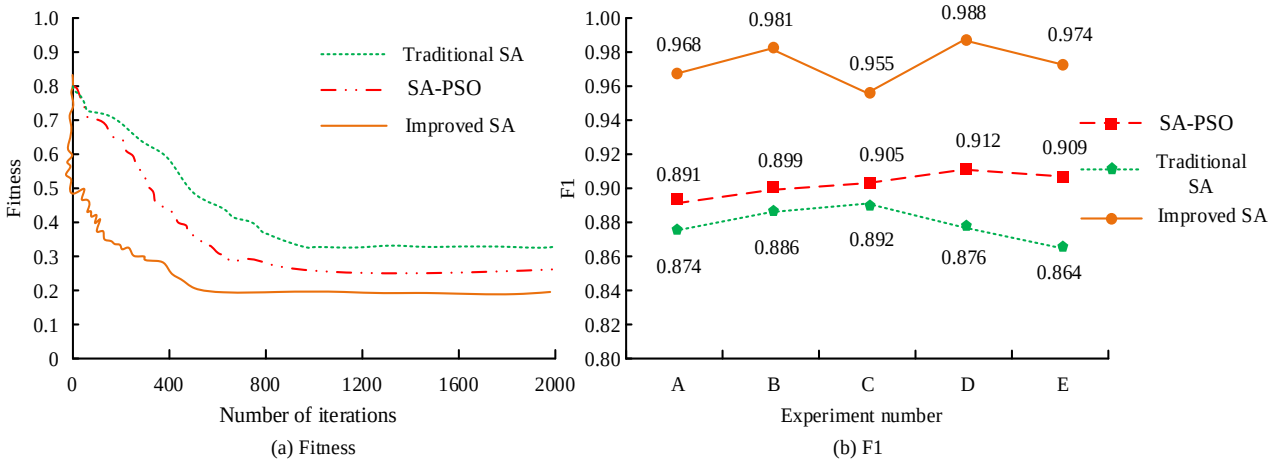

Fig. 6. The fitness and F1 value changes of three methods.

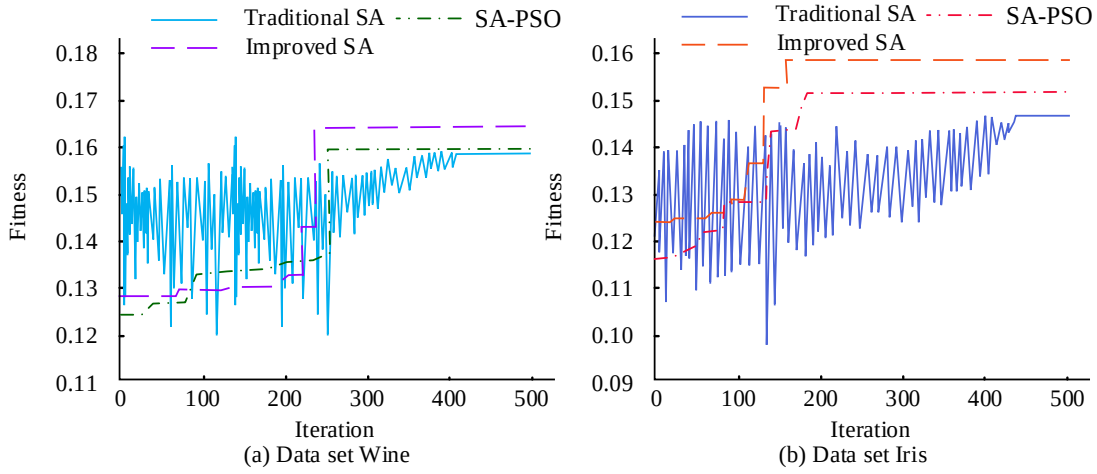

Fig. 7. Comparison of fitness values in different datasets.

From Fig. 7(a), the convergence curve of the traditional SA algorithm started with significant fluctuations and instability, and then decreased as the number of iterations increased. The algorithm eventually stabilized at 410 iterations, the fitness value was approximately 0.158. The convergence curve of the improved SA algorithm was smoother, rising in a ladder shape, and tended to stabilize at around 0.166 after 256 iterations. From Fig. 7(b), the convergence curve of the SA-PSO algorithm was relatively stable, but the improved SA algorithm still showed a ladder shape increase with a fitness value of about 0.157, indicating relatively better performance. The study continues to test the running time of the three algorithms. The results are shown in Fig. 8.

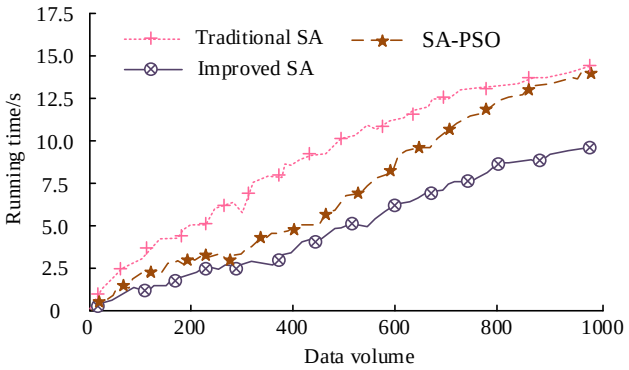

Fig. 8. The running time test results of three algorithms.

From Fig. 8, in terms of running time, with the increase of data volume, both the traditional SA algorithm and SA-PSO algorithm had a relatively fast increase in running time, with the highest being 14.2s and 14.6s, respectively. The running time curve of the improved SA algorithm always lowered than the other two algorithms, and the highest was only 9.7s, indicating significantly better running efficiency. Finally, the initial value dependency of the improved SA algorithm is validated, as shown in Table II.

From Table II, as for the improved SA algorithm, the standard deviation of the optimal value after 100 iterations was 0.00734, and the standard deviations of the optimization time and optimization iteration were 12.22352 and 3.55342, respectively. The standard deviations are relatively small, especially for the optimal value. This indicates that the stability of the optimization time and results is good, further proving the high robustness of the algorithm.

B. Empirical Analysis of Environmental and Economic Benefits of Urban Construction Projects

In order to analyze the effectiveness of the proposed method in analyzing the environmental and economic benefits of urban construction projects, three construction projects are selected from three provincial capitals in China, namely Project A, Project B, and Project C, with corresponding total construction areas of 21511m^2, 238500m^2, and 341000m^2, respectively. Firstly, the cross efficiency DEA model is used to solve the problem. The results are shown in Table III.

From Table III, the cross efficiency DEA model was effective for all three selected projects, achieving technical and scale efficiency in terms of cost and benefit, and having a high ecological efficiency. Both environmental and economic benefits were high. Based on this solution result, the improved SA algorithm is used to optimize the environment and economic benefits. The results are shown in Fig. 9.

From Fig. 9(a), in terms of environmental benefits, all three projects were improved to varying degrees, with the highest reaching 120000 yuan. From Fig. 9(b), after optimization, the economic benefits were significantly improved, with three projects increasing by 600000 yuan, 800000 yuan, and 850000 yuan respectively. From this, the proposed method can effectively improve the environmental and economic benefits of urban construction projects, and provide guidance for the implementation and later development of urban construction projects.

TABLE II. INITIAL VALUE DEPENDENCY VERIFICATION RESULTS

IV. Discussion

To accurately analyze the economic and environmental benefits of urban construction projects, a cross efficiency DEA model was studied and designed, and a hybrid mutation operator and genetic algorithm were proposed to improve the SA algorithm. Finally, performance testing and practical verification were conducted. The results show that in the CEC2022 dataset, the maximum F1 value of the improved SA algorithm is 0.988 and the minimum value is 0.955, indicating better overall performance. The test results on different Wine and Iris datasets show that the convergence curve of the improved SA algorithm is smoother, and the fitness value ultimately stabilizes at 0.166. At the same time, the fitness curve of the improved SA algorithm shows a stepwise increase, resulting in better performance. In terms of running time, with the increase of data volume, the maximum running time of the improved SA algorithm is only 9.7 seconds, and the running efficiency is significantly better than the other two methods. Liu et al. introduced the SA algorithm into the adaptive particle swarm optimization algorithm to address the multi-objective allocation problem of maximizing weapon attack effectiveness, and proposed an adaptive SA optimization algorithm. The results show that the improved SA algorithm exhibits good performance in terms of convergence speed and global optimization ability, significantly better than a single SA algorithm, and can ensure maximum attack effectiveness [23]. The improved SA algorithm outperforms the basic SA algorithm in terms of performance. The difference is that in this study, a hybrid mutation operator and genetic algorithm were used to optimize the SA algorithm. The design of the hybrid mutation operator makes it easy to adjust the type and parameters of the mutation operator according to the characteristics of different construction projects, thereby optimizing the performance of the algorithm in specific scenarios. The population mechanism of genetic algorithm enables multiple solutions to be evaluated simultaneously, thereby improving the global optimization ability of the algorithm. However, Liu S et al. used adaptive particle swarm optimization algorithm for optimization, which lacks targeted optimization ability in specific scenarios. In addition, the applicability of the cross efficiency DEA model has been demonstrated in solving urban construction projects. After optimizing using the proposed method, the economic and environmental benefits of the three projects were significantly improved, with a maximum increase of 850000 yuan and 120000 yuan respectively, once again verifying the comprehensiveness of the proposed method in considering environmental and economic benefits and providing more comprehensive information. SoltanifarM et al. used a cross efficiency DEA model to rank decision units. The results show that this method can effectively consider the mutual influence between decision units when evaluating efficiency, thereby providing a more accurate and fair efficiency ranking [24]. By calculating cross efficiency, different decision-making units can not only compare their own inputs and outputs, but also use the efficiency of other decision-making units as a benchmark. This relative evaluation method makes the results more reliable. This once again confirms the effectiveness of the cross efficiency DEA model. The research provides powerful tools for decision support in actual urban construction projects, with broad application potential, and can promote sustainable urban construction in the future.

The improved SA algorithm and cross efficiency DEA model proposed in the study have achieved good performance in the economic and environmental benefit assessment of urban construction projects, but there are still some limitations. Firstly, the parameter selection and adjustment of the model depend on specific datasets, and the lack of automated parameter tuning mechanisms may affect its universality. Secondly, the model did not consider the impact of dynamic environmental changes on the efficiency of decision-making units, which may limit its applicability in practical applications. Future research can focus on enhancing the adaptive capability of models, introducing more complex multi-objective optimization frameworks, and exploring the application of new technologies such as deep learning in the optimization process to improve the robustness and real-time decision-making ability of algorithms.

V. Conclusion

A cross efficiency DEA model was studied and designed for the economic and environmental benefit analysis of urban construction projects, and an improved SA algorithm was proposed. The results showed that in the five experiments numbered A, B, C, D, and E, the maximum F1 value of the

improved SA algorithm was 0.988 and the minimum value was 0.955. The average values of SA-PSO and traditional SA algorithms are 0.903 and 0.878, respectively. This proves that the improved SA algorithm has better overall performance. In terms of running time, with the increase of data volume, the running time of both traditional SA algorithm and SA-PSO algorithm has grown rapidly, with the highest being 14.2s and 14.6s respectively. The running time curve of the improved SA algorithm has always been lower than the other two algorithms, and the highest is only 9.7s, indicating significantly better running efficiency. In addition, the applicability of the cross efficiency DEA model has been demonstrated in solving urban construction projects. After optimizing using the proposed method, the economic and environmental benefits of the three projects have significantly improved, with a maximum increase of 850000 yuan and 120000 yuan, respectively. The method proposed by the research institute can effectively consider the environmental and economic benefits in urban construction projects. In practical applications, by optimizing the improved SA algorithm, research can quickly identify projects with excellent performance, promote the rational allocation and use of resources, and enhance the overall sustainability of the project. Further research can explore the applicability of improved algorithms in other fields and promote their application in a wider range of decision support systems.

***Abstract*—Lack of diseases detection in plants frequently results in the spread of diseases that are difficult to treat and expensive. Rapid diseases recognition enables farmers to control the diseases with appropriate treatment. This study aims to support chili farmers in identifying chili plant diseases based on leaf images. This work presents a CNN design based on several existing CNN architectures that have been fine-tuned to achieve the highest possible accuracy. The study found that the ResNet101 model with the Tanh activation function, SGD optimizer, and Reduced Learning Rate (ReduceLR) schedule, achieved a peak classification accuracy of 99.53%. This significant improvement demonstrates the potential of using advanced CNN techniques and fine-tuning strategies to enhance model accuracy in agricultural applications. The implications of this study extend to the field of precision agriculture, suggesting that the proposed model can be integrated into smart farming systems to improve the timely and efficient control of chili leaf diseases. Such advancements not only enhance crop yields but also contribute to sustainable agricultural practices and the economic stability of chili farmers.**

I. Introduction

Chili has been a flagship commodity in Indonesia's horticultural subsector, earning a solid global reputation. This finding emphasizes chili's enormous potential as a significant export commodity for Indonesia. The unique characteristics and high quality of Indonesian chili have earned global recognition, opening up significant opportunities for export growth and positively impacting the national economy [1], [2]. Chili yields a variety of products, such as fresh chili, dried chili, chili sauce, and chili oil. Dried chili is used as a spice, chili sauce is available in a variety of flavors, and chili oil, produced from chili, is utilized in the food, pharmaceutical, and cosmetic industries [3], [4].

Indonesian chili farmers face significant challenges that could affect production, welfare, and the long-term viability of their farming operations. These problems include environmental and weather fluctuations, which can have an impact on the health and growth of chili plants. In addition to changes in temperature and weather patterns, insect infestations such as thrips, caterpillars, and whiteflies, as well as diseases such as bacterial wilt and anthracnose, pose significant risks that require appropriate management measures [5]–[7]. Pest and disease attacks on chili plants are frequently detected based on the condition or appearance of the leaves, which serve as a food processing area for the plant [8] and poor chili plant development is a direct result of diseased leaves. Monitoring chili infections involves significant effort, and precise agricultural techniques are required to address this issue.

Several prior studies utilized computer vision to classify chili leaves in a variety of ways. Computer vision, which uses cameras and computational power to analyze and understand acquired images, can reliably classify diseases from chili leaves. Currently, the convolutional neural network (CNN) is the most used algorithm for computer vision problems. Transfer learning [9], fine-tuning [10], pruning [11], and new architectures [12] all have the potential to increase CNN performance and achieve high accuracy.

The aim of this study is to solve chili farmers' problems by developing a more efficient and accurate chili leaf disease detection application system utilizing CNN. The findings of this study show that by fine-tuning and optimizing the ResNet101 architecture, the accuracy of chili leaf disease classification may be greatly increased, outperforming previously classification approaches. The increased CNN accuracy attained in this work is intended to help establish a more effective and sustainable precision agriculture system. The study contributes the following:

- Analyzing how activation functions, optimization functions, and learning rate schedules improve CNN accuracy.
- Developing a fine-tuning model to increase CNN accuracy in Chili Leaf Disease Classification.
- Developing a more accurate CNN model suitable for smart farming systems.

II. Literature Review

Chili leaf classification research has advanced alongside developments in machine learning and computer vision technology. CNN has emerged as the preferred method for this purpose because of its ability to extract information from images automatically and accurately. Several methods and approaches have been investigated to increase classification accuracy, with a focus on improving network architecture and using data augmentation. Previous research has demonstrated that selecting of model and preprocessing procedures has a substantial impact on the overall system performance. Table I highlights many studies on chili leaf classification.

*Corresponding Author.

TABLE I. RELATED STUDIES

Metode	Number of Classes	Accuracy
VGGNet [13]	3	97.00%
SVM+RNN [14]	5	92.10%
GLCM+KNN [15]	2	94.00%
Fine Tuning ShuffleNet [16]	2	99.30%
Inception V3 [17]	4	93.00%

The more classes utilized in a classification system, the more diseases that affect chili leaves may be detected and classified. Thus, a more advanced and accurate system can offer more precise information for plant disease control. In this study, five classes were used to classify chili leaf diseases. According to previous studies, the accuracy achieved for the five classes was only 92.10%, showing that there is still space for development and greater accuracy.

This research focuses on enhancing the accuracy of CNNs for chili leaf disease classification by exploring various CNN architectures and optimization techniques. Techniques such as transfer learning and fine-tuning pre-trained models are expected to significantly improve model performance. Additionally, the use of more diverse data augmentation is anticipated to help mitigate overfitting and improve the model's generalization ability to new data. This study aims to contribute to the field of precision agriculture by providing more reliable and efficient solutions for plant disease detection.

III. RESEARCH METHODS

This study was conducted to evaluate several aspects of the implementation and refinement of CNN architectures, with a focus on ResNet. To achieve this goal, a series of experiments were performed, including comparing accuracy on both augmented and non-augmented data, comparing the number of layers in ResNet, and fine-tuning parameters such as activation functions, optimizers, and learning rate schedules. The research workflow began with an evaluation of the effect of data augmentation and continued with a comparison of the performance of CNN models on augmented data. Subsequently, the study investigated the effects of different ResNet layer numbers on accuracy. Experiments with different optimization functions, types of optimizers, and learning rate schedules were also part of the fine-tuning process. Finally, the best results were compared with previous studies to identify improvements achieved.

A. Fine-Tuning Strategy

Fine-tuning is performed to determine the most accurate CNN model. In this work, fine-tuning is performed on an existing CNN that has been tested and produces the highest accuracy, namely the Resnet architecture. Fine-tuning is completed in three stages: activation function tuning, optimizer tuning, and learning rate schedule. The CNN with the best activation function is saved and then fine-tuned by the optimizer. The most accurate activation function and optimizer are reported, and the learning rate schedule is adjusted accordingly. As a result, this study creates the most accurate CNN model. The fine-tuning method is illustrated in Fig. 1.

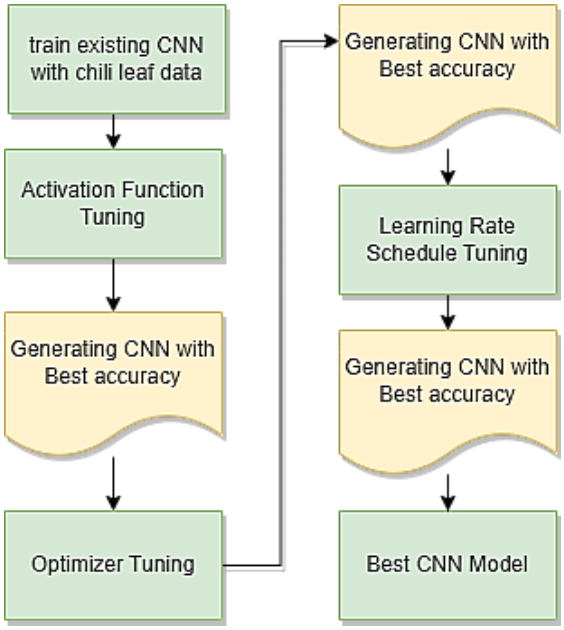

Fig. 1. Fine tuning strategy.

B. Dataset and Augmentation

The dataset used in this research consists of images of diseases affecting red chili leaves, sourced from Mendeley Data, comprising five disease classes [18]. The dataset is divided into two types: augmented and non-augmented. The dataset originally contained 531 images before augmentation, and after augmentation, the dataset expanded to 2,128 images. The details of the augmented dataset are shown in Table II below:

TABLE II. AUGMENTED DATASET

Class Name	Image	Training	Validation	Total
Powdery Mildew		486	122	608
Healthy Leaf		221	55	276
Murda Complex (mites, thrips)		342	86	428
Leaf Spot (Cercospora)		326	82	408
Nutrient Deficiency		327	81	408
Total		1702	426	2128

Table II provides information on the distribution of the augmented dataset used in this research to identify diseases in red chili leaves. This dataset consists of five different disease classes: Powdery Mildew, Healthy Leaf, Murda Complex (mites, thrips), Leaf Spot (Cercospora), and Nutrient Deficiency. Each class contains a number of images that have been divided into subsets for training and validation. The total number of images in the dataset after augmentation is 2,128, which includes 1,702 images for training and 426 images for validation. The original images that have been augmented are shown in Fig. 2.

Fig. 2. Data augmentation.

C. Activation Function

The selection of an appropriate activation function in Convolutional Neural Networks (CNNs) is crucial for improving model accuracy, particularly in classification tasks. Activation functions like ReLU, which are popular for their simplicity and effectiveness, help the network learn complex non-linear representations. However, in some cases, ReLU can lead to issues such as dead neurons, which can be mitigated by variants like Leaky ReLU or ELU that introduce a slope or non-linearity on the negative side. Other functions, such as Tanh and Sigmoid, also play important roles, particularly in regulating the output within specific ranges. Tanh maps inputs to values between -1 and 1, while Sigmoid maps inputs to values between 0 and 1. For multi-class classification, Softmax is used to convert outputs into probabilities, enabling more accurate predictions. By understanding the characteristics of these activation functions, we can optimize CNN architectures to achieve the best performance in various classification applications.

The linear activation function returns the input without any modification. It is typically used in the final layer of regression models. The equation for the linear activation function is presented in Eq. (1) [19]:

$$f(x) = a.x \tag{1}$$

ReLU (Rectified Linear Unit) is a highly popular non-linear activation function that returns the input directly if it is positive, and zero if it is negative. The equation for ReLU is shown in Eq. (2) [20].

$$f(x) = \max(0, x) \tag{2}$$

ELU (Exponential Linear Unit) is an activation function similar to ReLU but differs in how it handles negative inputs. ELU introduces non-linearity on the negative side to address the dead neuron problem associated with ReLU[21]. The equation for ELU is presented in Eq. (3).

$$f(x) = \begin{cases} x, & if\ x > 0 \\ \alpha(\exp(x) - 1), & if\ x \leq 0 \end{cases} \tag{3}$$

Leaky ReLU is a variation of ReLU that allows a small gradient when the input is negative [22]. The equation for Leaky ReLU is shown in Eq. (4).

$$f(x) = \begin{cases} x, & if\ x > 0 \\ \alpha x, & if\ x \leq 0 \end{cases} \tag{4}$$

Tanh (Hyperbolic Tangent) is an activation function that maps the input to a value between -1 and 1. It is often used in hidden layers of neural networks [23]. The equation for Tanh is given in Eq. (5):

$$f(x) = \text{Tanh}(x) \tag{5}$$

The Sigmoid activation function maps the input to a value between 0 and 1, which is commonly used in binary classification models [24]. The equation for the Sigmoid function is presented in Eq. (6):

$$f(x) = \frac{1}{1+\exp(-x)} \tag{6}$$

Softmax is an activation function typically used in the output layer for multi-class classification problems [25]. It converts the input values into probabilities. The equation for Softmax is shown in Eq. (7):

$$f(x) = \frac{\exp(x_i)}{\sum_{j=1}^{N} \exp(x_j)} \tag{7}$$

IV. Results and Discussions

A. Accuracy on Augmented and Non-Augmented Datasets

This study utilized two types of chili image datasets: one with augmented data and one without. The augmentation process involved increasing the dataset by applying horizontal flips, vertical flips, and 30-degree rotations. During model training, several key settings influenced how the model learned from the data. One of these was the number of epochs, which represents the number of times the model processes the entire dataset—set to 30 in this case. The batch size, which refers to the number of data samples processed together, was set to 32, impacting the speed and efficiency of the model's learning process. Additionally, the learning rate, fixed at 0.001, determined the magnitude of adjustments made during training to enhance the model's predictions. The momentum, set at 0.9 in the SGDM optimizer, was used to accelerate the convergence of the model. Initial experiments compared the accuracy of the ResNet101 architecture, with the results summarized in Table III.

TABLE III. ACCURACY IMPROVEMENT WITH DATASET AUGMENTATION

No	Method	Training Accuracy	Validation Accuracy
1	Non-Augmented Dataset ResNet101ResNet101	98.35%	89.72%
2	Augmented Dataset ResNet101	97.65%	98.12%

In the experiments using the ResNet101 architecture, two scenarios were compared. In the first scenario, without dataset augmentation, the model achieved a training accuracy of 98.35% and a validation accuracy of 89.72%. In the second scenario, with dataset augmentation, the model reached a training accuracy of 97.65% and a validation accuracy of 98.12%. The effect of augmentation is evident in the unusual outcome where the validation accuracy exceeded the training accuracy. However, applying dataset augmentation led to a significant improvement in the model's performance on the validation set, making it a more advantageous approach.

B. Accuracy on Existing CNNs

Based on the previous testing, it was found that data augmentation successfully improved the accuracy of CNNs in classifying chili leaf diseases. Using the augmented dataset, we tested several existing CNN architectures to determine which one would be more suitable for this classification task. The existing CNNs tested included AlexNet, GoogleNet, VGGNet, and ResNet. Table IV presents the key performance metrics obtained, including training accuracy and validation accuracy.

TABLE IV. ACCURACY OF EXISTING CNNS

No	Method	Training Accuracy	Validation Accuracy
1	AlexNet	93.9%	95.77%
2	GoogleNet	95.12%	96.95%
3	VGGNet16	95.95%	96.95%
4	ResNet 101	97.64%	98.12%

The table above shows the training accuracy and validation accuracy for several convolutional neural network methods used in the experiments. AlexNet achieved a training accuracy of 93.89% and a validation accuracy of 95.77%. GoogleNet demonstrated a training accuracy of 95.12% and a validation accuracy of 96.95%. VGGNet16 reached a training accuracy of 95.95% and a validation accuracy of 96.95%. ResNet101 achieved the highest accuracy, with a training accuracy of 97.65% and a validation accuracy of 98.12%.

C. Accuracy Comparison on ResNet

The comparison of the performance of various layers within the ResNet architecture used in this study aims to evaluate the effectiveness of each ResNet layer in the developed classification model. The comparison results are presented in Table V.

Table V presents a comparison of the training and validation accuracy of various ResNet methods used in the study. The ResNet18 method achieved a training accuracy of 96.42% and a validation accuracy of 95.77%. ResNet34 showed an improvement with a training accuracy of 97.36% and a validation accuracy of 97.18%. The ResNet50 method achieved a training accuracy of 97.83% and a validation accuracy of 97.18%. ResNet101 reached a training accuracy of 97.65% and the highest validation accuracy among the methods, at 98.12%. Finally, the ResNet152 method achieved the highest training accuracy of 98.41%, but its validation accuracy reverted to 97.18%.

D. Fine-Tuning Activation Functions for ResNet101

In an effort to enhance the performance of the ResNet101 model in classifying chili leaf diseases, fine-tuning was performed on the activation functions. Activation functions play a crucial role in determining the output of each layer in a neural network. In this section, various activation functions, such as ReLU, ELU, Leaky ReLU, Tanh, Sigmoid, and Softmax, were trained over 30 epochs. The impact of each activation function on the model's performance was then evaluated. The accuracy results for each activation function are presented in Table VI.

The model was trained using various activation methods, yielding different training and validation accuracies. The Linear method achieved a training accuracy of 97.65% and a validation accuracy of 98.12%. The ReLU method resulted in a training accuracy of 97.30% and a validation accuracy of 97.65%, while the ELU method produced a training accuracy of 97.71% and a validation accuracy of 96.95%. The Leaky ReLU method showed a training accuracy of 98.24% and a validation accuracy of 97.65%. The Tanh method achieved a training accuracy of 97.24% and the highest validation accuracy among all methods, at 99.06%. The Sigmoid method resulted in a training accuracy of 94.65% and a validation accuracy of 95.77%, while the Softmax method achieved a training accuracy of 93.89% and a validation accuracy of 96.48%. The validation results for each epoch are illustrated in Fig. 3.

TABLE V. COMPARISON OF RESNET LAYERS

No.	Method	Training Accuracy	Validation Accuracy
1	ResNet18	96.42%	95.77%
2	ResNet34	97.36%	97.18%
3	ResNet50	97.83%	97.18%
4	ResNet101	97.65%	98.12%
5	ResNet152	98.41%	97.18%

TABLE VI. ACCURACY WITH DIFFERENT ACTIVATION FUNCTIONS

No	Method	Training Accuracy	Validation Accuracy
1	Linear	97.65%	98.12%
2	ReLU	97.30%	97.65%
3	ELU	97.71%	96.95%
4	Leaky ReLU	98.24%	97.65%
5	Tanh	97.24%	99.06%
6	Sigmoid	94.65%	95.77%
7	Softmax	93.89%	96.47%

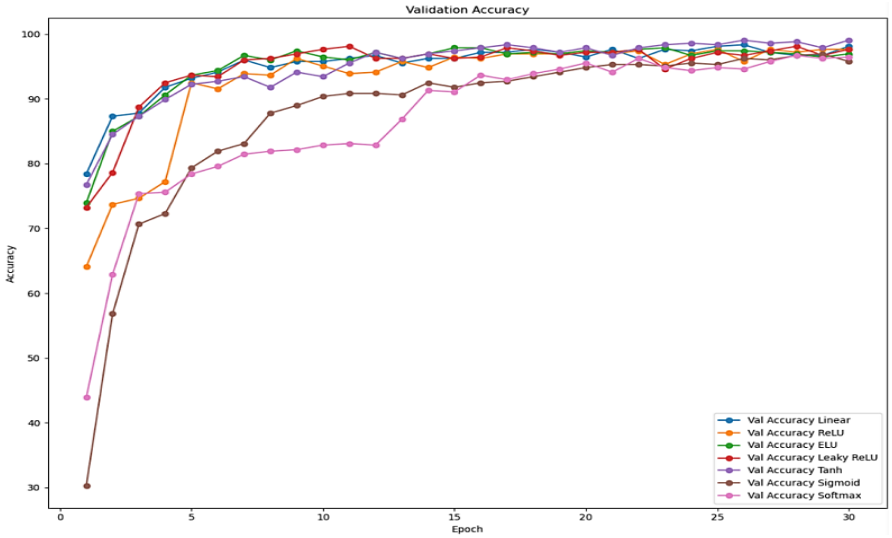

Fig. 3. Graph comparing validation accuracy with different activation functions.

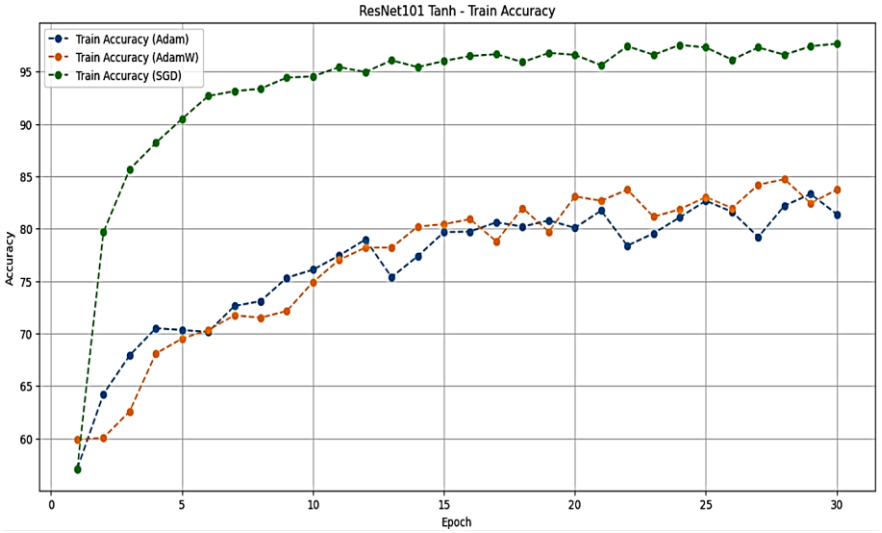

Fig. 4. Comparison of training accuracy using different optimizers.

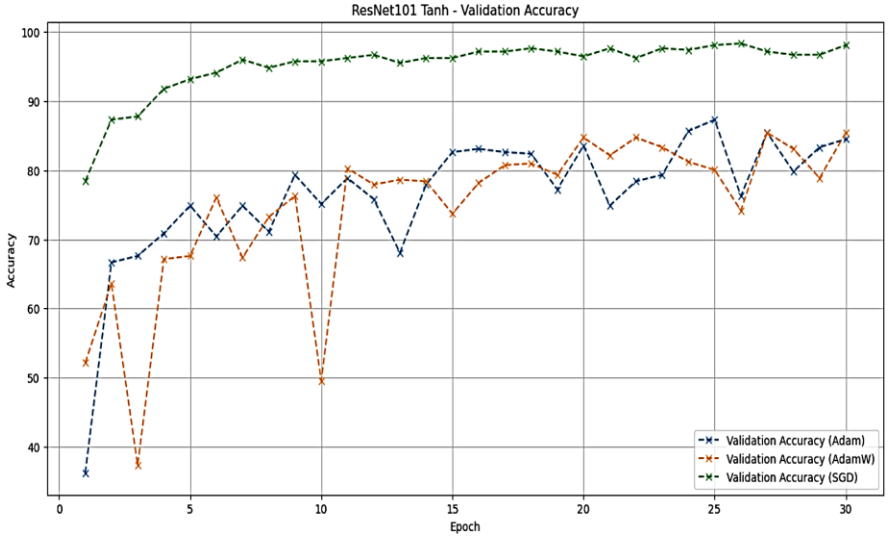

Fig. 5. Comparison of validation accuracy using different optimizers.

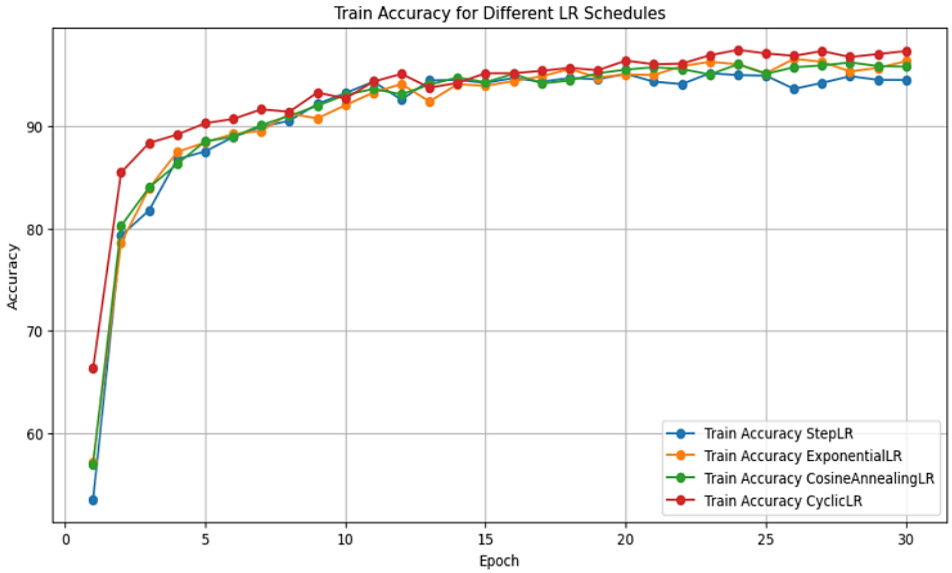

Fig. 6. Comparison of training accuracy across different learning rate schedules.

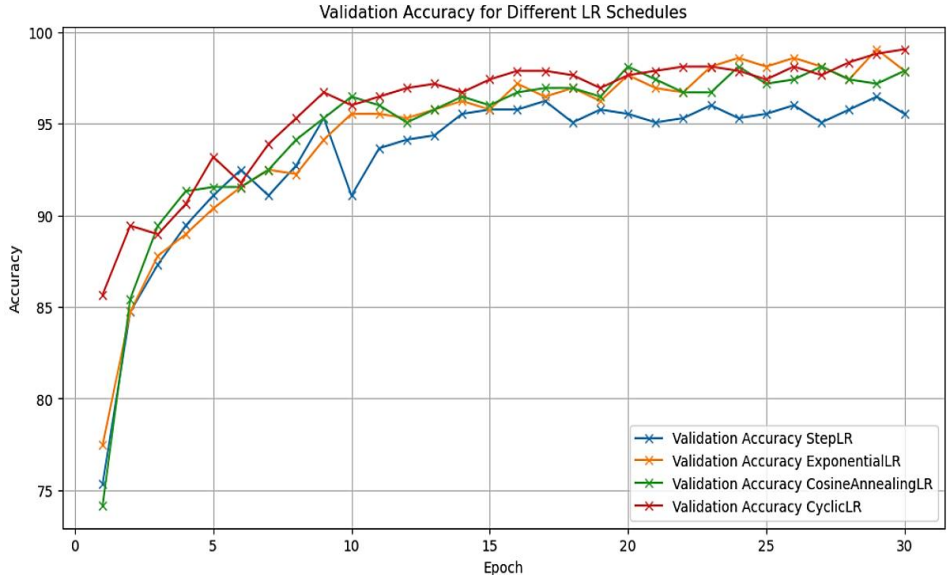

Fig. 7. Comparison of validation accuracy across different learning rate schedules.

E. Fine Tuning Optimizer ResNet101

Based on previous testing, ResNet with the Tanh activation function achieved the highest accuracy. To identify the optimal optimization function, several optimizers were tested while maintaining the Tanh activation function. The initial step involved selecting the appropriate optimizer to effectively handle the task of classifying chili leaf images. The optimizers tested included Adam, AdamW, and SGDM. The results of these tests are presented in Table VII.

Table VII shows the accuracy results of the three machine learning models tested. The different optimization functions yielded varying results. The SGDM optimizer demonstrated the best performance on both training and validation data, with accuracies of 97.24% and 99.06%, respectively. The AdamW model achieved a training accuracy of 84.72% and a validation accuracy of 85.45%, while the Adam model reached a training accuracy of 83.31% and a validation accuracy of 87.32%. Therefore, ResNet101 with the SGDM optimizer achieved the best accuracy in chili leaf classification. The accuracy comparisons for each epoch are presented in the Fig. 4 and 5.

TABLE VII. COMPARISON OF OPTIMIZERS

No	Method	Training Accuracy	Validation Accuracy
1	Adam	83.31%	87.32%
2	AdamW	84.72%	85.45%
3	**SGD**	**97.24%**	**99.06%**

F. Fine Tuning Learning Rate Schedule

In this study, five different learning rate schedules were evaluated to determine their impact on training and validation

accuracy. The results of this evaluation are presented in Table VIII below.

TABLE VIII. COMPARISON OF LEARNING RATE SCHEDULES

No	Function	Training Accuracy	Validation Accuracy
1	StepLR	95.1234	96.4789%
2	ExponentialLR	96.3572%	99.0610%
3	ConsineAnnealigLR	96.2397%	98.1221%
4	CyclicLR	97.3561%	99.0610%
5	ReduceLR	97.7673%	99.5305%

Table VIII provides a comparison of the training and validation accuracies for each learning rate schedule model tested. The StepLR model achieved a training accuracy of 95.12% and a validation accuracy of 96.48%. The ExponentialLR model, on the other hand, showed an improved training accuracy of 96.36% and a validation accuracy of 99.06%. The CosineAnnealingLR model attained a training accuracy of 96.24% and a validation accuracy of 98.12%. The CyclicLR model demonstrated further improvement with a training accuracy of 97.36% and a validation accuracy of 99.06%. Finally, the ReduceLR model exhibited the highest performance, achieving the highest training accuracy of 97.77% and the highest validation accuracy of 99.53%, making it the best-performing model among those tested.

The results indicate that different learning rate schedules can significantly affect the performance of the ResNet101 model. While StepLR provided a stable training process, models like ExponentialLR and CyclicLR demonstrated higher validation accuracies, suggesting they were better at generalizing to unseen data. The CosineAnnealingLR schedule showed a balance between training and validation accuracy, but the ReduceLR model outperformed all others by achieving both the highest training and validation accuracies. This suggests that dynamically reducing the learning rate as training progresses may be the most effective strategy for optimizing model performance in this context.

To visualize the impact of these learning rate schedules over the course of training, the accuracy for each epoch is plotted in the Fig. 6 and 7.

These figures illustrate how each learning rate schedule influenced the model's ability to learn and generalize from the data over time. As shown, the ReduceLR schedule not only maintained a high training accuracy but also led to the best validation accuracy, indicating its effectiveness in avoiding overfitting and improving model robustness.

G. Implementation

After completing the model evaluation phase on the test data, this research also implemented the model into an application. The application serves as a platform that facilitates users in classifying chili leaves to identify potential diseases. The classification page of the application is shown in Fig. 8.

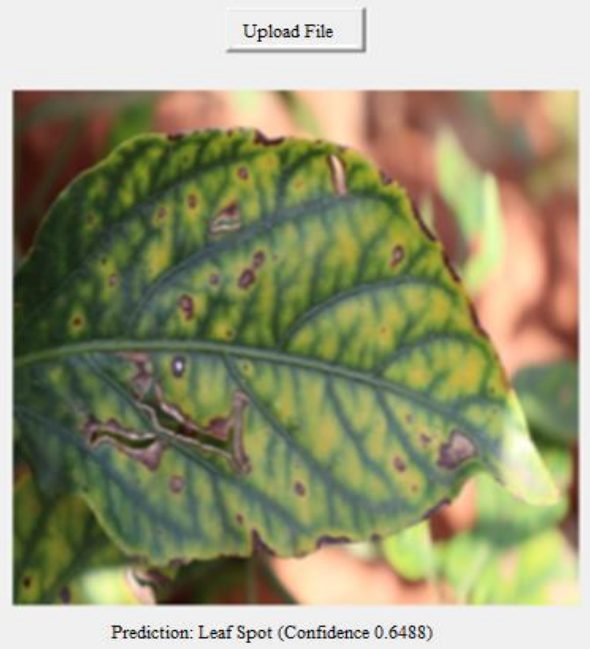

Fig. 8. Implementation of chili leaf disease classification.

Fig. 8 illustrates the classification process within the application. The image of the chili leaf, captured by a camera, is successfully classified by the ResNet101 model using the best-performing parameters. The application interface provides clear feedback to the user, indicating the identified disease, thus aiding in quick and accurate diagnosis.

H. Comparison with Previous Research

This study successfully classified chili leaf diseases with high accuracy, surpassing the accuracy achieved in previous studies. The highest accuracy was obtained with the classification of five chili leaf classes. A comparison of the accuracy from this study with that of previous research is presented in Table IX.

TABLE IX. ACCURACY COMPARISON WITH PREVIOUS RESEARCH

Methods	Number of Classes	Accuracy
VGGNet [13]	3	97.00%
SVM+RNN [14]	5	92.10%
GLCM+KNN [15]	2	94.00%
Fine Tuning ShuffleNet [16]	2	99.30%
Inception V3 [17]	4	93.00%
Xception [18]	5	79.56%
Resnet 101 (Best Parameter)	5	99.53%

According to Table IX, ResNet101 with the Tanh activation function, SGD optimizer, and ReduceLR learning rate schedule achieved an accuracy of 99.53%, accepted as the ResNet101 best parameter configuration. This best-parameter ResNet101 outperformed SVM+RNN [14], which used the same number of classes, with a 7.43% increase in accuracy. ResNet101 outperformed Xception [18], on the exactly the same dataset, with a 19.97% improvement. The best-parameter

ResNet101 also outperformed Fine Tuning ShuffleNe [16], which was only classify two chili leaf disease classifications.

V. CONCLUSION

This study successfully developed and refined a Convolutional Neural Network (CNN) model, especially ResNet101, for classifying chili leaf diseases with reliable accuracy. Through a series of experiments, including the application of multiple activation functions, optimization functions, and learning rate schedules, the model obtained an accuracy of 99.53% when diagnosing five different types of chili leaf diseases. This performance outperforms prior studies that showed the effectiveness of the ResNet101 model using the Tanh activation function, SGD optimization function, and ReduceLR learning rate schedule.

The findings demonstrated that carefully selecting and refining model parameters can greatly increase CNN accuracy in complex classification tasks. The proposed model not only outperformed previous CNN architectures such as VGGNet, Inception V3, and Xception, but it was also more effective in handling several disease classifications than other approaches such as SVM+RNN and Fine Tuning ShuffleNet.

Overall, implementing this model in a practical application-based system has the potential to help farmers and agricultural professionals in accurately diagnosing chili leaf diseases, resulting in improved disease management and crop yields. However, there are limitations to this study. Firstly, the model's performance has not been extensively tested on datasets collected from diverse environmental conditions, which may affect its generalizability in real-world scenarios. Secondly, the computational resources required for training and deploying the ResNet101 model may pose challenges for integration into low-cost, resource-constrained agricultural systems commonly found in rural areas. Further research might explore possibilities into refining the model and applying it to other agricultural fields, while addressing these limitations to enhance its practical applicability and efficiency.

ACKNOWLEDGMENT

This research was funded by the Directorate of Research, Technology, and Community Service (DRTPM), Directorate General of Higher Education, Ministry of Education and Culture of the Republic of Indonesia in 2024 under contract No. 103/E5/PG.02.00.PL/2024, with derivative contracts 020/LL1/AL.04.03/2024, and 52/P3MPI/01.3.2/VI/2024. The author would like to thank DRTPM and the Center for Research, Community Service, and International Publication (P3MPI) of Medan Area University for their support.

Exploring the Impact of User Experience Elements on Virtual Reality for Emotion Regulation Through mVR-Real App

Irna Hamzah[1], Ely Salwana[2], Nilufar Baghaei[3]
Institute of Visual Informatics, Universiti Kebangsaan Malaysia (UKM), Bangi, Selangor, Malaysia[1, 2]
School of Electrical Engineering and Computer Science, The University of Queensland, St Lucia, Australia[3]

***Abstract*—Virtual reality, a rapidly advancing technological development, has significantly evolved over the past few years, offering immersive experiences through headsets, gloves, or controllers that engage users in dynamic and captivating environments. Its applications span various fields, including video games, healthcare, education, and training simulations. However, there remains a gap in utilizing virtual reality for adolescent emotion regulation. This study explores the mVR-REAL app, designed to enhance social-emotional learning in teenagers by improving emotion regulation. Social-emotional learning is an educational approach aimed at developing essential socio-emotional skills in adolescents. Sixteen participants engaged with the mVR-REAL app through virtual scene episodes using the Meta Quest 2 headset. The emotional responses and user feedback were measured using pre and post-test questionnaires with a Likert scale such as, strongly agree, agree, neutral, disagree and strongly disagree. A numerical value was assigned to each hypothetical option on the scale. Analysis conducted with SPSS software revealed statistically significant improvements in user experience following the use of mVR-REAL. The findings suggest that mVR-REAL has the potential to enhance user experience, evoke strong emotional responses, and foster greater engagement compared to traditional applications. These insights will inform future large-scale testing of mVR-REAL, emphasizing the importance of emotional design, as well as psychological and cultural factors, in the development of virtual reality apps for emotion regulation. However, time-related challenges were identified due to the restricted duration of the VR session, highlighting the need for further research and refinement in future virtual reality app development.**

Keywords*—Virtual reality; app; user experience; emotion regulation; social-emotional learning

I. Introduction

Virtual reality (VR) is an advanced technology that creates a realistic and all-encompassing experience by simulating various settings and activities. The term "virtual reality" refers to a computer-generated simulation of a three-dimensional setting [1] or experience [2] that enables the user to interact with the simulation in a manner that is convincingly real or physical by employing specialized hardware such as a headset, gloves, or sensors. This cutting-edge technology generates sensory stimuli, serving as a transformative tool for enhancing emotion regulation (ER) practices, offering unique immersive environments that facilitate emotional experiences and coping strategies.

The study was sponsored by Malaysia's Ministry of Education under Trans-disciplinary Research Grant Scheme (TRGS/1/2020/UKM/01/4/3).

Emotion regulation (ER) encompasses the activities by which humans observe, assess, adjust, and control their emotional encounters and displays. This phenomenon can manifest in both conscious and unconscious states and involves the manipulation of emotions and expression, leveraging social-emotional learning. Social-emotional learning (SEL) refers to a process that promotes the development of essential interpersonal and affective abilities in individuals [3]. SEL has gained prominence in recent years as a vital component of education and individual development.

Over the years, there has been wide research conducted on the VR app across multiple fields involving healthcare and psychology. However, there is a limited study utilizing VR that is dedicated to the development of SEL in adolescents to enhance ER. This gap is significant because adolescents face unique emotional and social challenges during their developmental stages. Effective SEL interventions during this period are crucial for fostering resilience, empathy, and interpersonal skills [4]. If VR can demonstrably boost these skills, it may result in more engaging and meaningful educational experiences that adequately prepare adolescents for real-world interactions. Therefore, we proposed a study of an app called mVR-REAL. Mobile virtual reality to read and learn emotion regulations or mVR REAL is a VR app that is designed specifically for adolescents aged between thirteen and fourteen in the public secondary school in Malaysia. The goal of developing this app was to promote social-emotional learning in adolescents to improve emotion regulation. Focusing on adolescents is crucial as this developmental stage is marked by significant emotional and social changes. During adolescence, individuals are particularly susceptible to stressors that can impact their mental health. By utilizing VR in ER and SEL practices tailored for adolescents, educators and mental health professionals can provide targeted support that addresses the unique challenges faced during this period. Engaging adolescents through immersive experiences not only enhances their learning but also promotes a deeper understanding of their emotions and social interactions.

mVR-REAL explores the vital role of SEL in fostering good mental health by using a VR technology. SEL helps promoting self-awareness, emotional regulation, interpersonal skills, and resilience, and ultimately contributing to overall mental well-being. The findings suggest the element factors of user experience on emotion regulation are emotional and psychological.

II. Literature Review

A. Virtual Reality in Healthcare

VR has been employed in diverse contexts, encompassing therapy [5], education [6], and medical [7], to help individuals regulate their emotions in real-world situations. Studies have shown that VR can be effective in reducing negative emotions [8], such as anxiety, stress, and anger, as well as increasing positive emotions, such as empathy and relaxation. VR has the capacity to completely transform and reshape various aspects of society. Emotion regulation interventions by providing a more accessible, engaging, and personalized experience for individuals. As the technology continues to advance, VR may become a more widespread and valuable tool for improving emotional well-being. It is intended to produce an experience that is so immersive and realistic that it seems very much like either the real world or a world that the user has imagined. Virtual reality can be used for a variety of purposes, including education, training, rehabilitation, and even entertainment. A key component of virtual reality is the user's ability to interact with the virtual environment [9].

As a result, virtual reality saw explosive growth across a wide range of industries. Education [10], film [11], music [12], cultural tourism [13] and medical [14] are just a few sectors where VR has already been significantly impacted. VR is an expanding area of research that has the potential to revolutionize mental health examinations [15]. VR finds applications across various industries, including gaming, education, training, healthcare, culture [13], and entertainment, offering unique opportunities for experiential learning, skill development, and creative expression [16]. With the ongoing advancement of VR technology, there is significant potential for it to bring about a revolutionary transformation in how people perceive, interact with, and experience digital content, paving the way for new and innovative forms of storytelling and human-computer interaction. VR applications have grown into a crucial component of our everyday existence, with a variety of apps available across various platforms. However, ensuring the success of a VR app in a competitive market requires meticulous testing and refinement. Preliminary testing, a vital phase in the app development process, serves as a bridge between initial development and widespread release. This study explores the significance of experimental testing for mobile VR applications, its design, methodologies, benefits, and the impact it has on user experience.

By leveraging the established benefits of VR in healthcare, educators can develop innovative SEL and ER programs that resonate with adolescents' experiences. Despite the increasing prevalence of mental health issues among youth, the incorporation of VR into educational methodologies presents a promising opportunity to improve emotional intelligence and resilience. In summary, the mVR-REAL in healthcare not only demonstrate its capacity to influence emotional responses but also provide a robust framework for its use in promoting SEL and ER among adolescents.

B. Social-Emotional Learning and Emotion Regulation

SEL enables individuals to understand and manage their emotions, build positive relationships, demonstrate empathy and compassion, and exercise prudent judgment [3]. This educational method is comprehensive and acknowledges the importance of mental agility and social consciousness in promoting both mental health and academic achievement. An organization called CASEL has established a CASEL SEL framework for developing essential life skills [17] that revolve around recognizing and managing emotions, building healthy relationships, making responsible decisions, and cultivating resilience. It is typically integrated into curricula and educational programs to promote the emotional intelligence and mental health of individuals across all age groups [18]. SEL is an essential factor in facilitating individual development, mental health, and academic achievement. By focusing on emotional intelligence and social skills [19], SEL helps students develop resilience, cope with stress, and improve problem-solving abilities [20]. It fosters a positive school climate, reduces incidents of bullying, and enhances overall classroom engagement. Furthermore, SEL is not limited to academic settings; it has broader applications in various aspects of life, including the workplace, family dynamics, and community interactions [21]. Individuals who have strong social-emotional skills are better equipped to navigate challenges, communicate effectively, and build meaningful relationships, ultimately contributing to a more compassionate and harmonious society. SEL in adolescents is a critical component of their overall development and well-being. Teenagers is a phase characterized by profound physical, emotional, and cognitive variations, and SEL helps adolescents navigate this challenging phase successfully. SEL includes a variety of abilities and qualities that empower young individuals to comprehend and handle their emotions, establish constructive connections, make accountable choices, and cultivate a robust sense of self-worth and compassion.

The study of emotion is a central area of investigation in numerous scientific and humanistic fields [22]. Emotion regulation skills are crucial for developing better well-being in the transition from adolescence to adulthood. Silvers describes emotion regulation (ER) as a set of both implicit and explicit abilities that enable individuals to observe, assess, and adjust their emotional reactions in alignment with their objectives [23]. During adolescence, the ability to regulate emotions often undergoes significant improvement for many individuals. However, for other young people, adolescence can be a time when emotion regulation difficulties begin or develop [23]. It is widely acknowledged that the capacity to control one's emotions is a crucial component of both mental [24] and general well-being [25]. A person's ability to manage their emotions, which are dynamically used throughout everyday situations, is a form of ER.

The correlation between emotion control and mental health is crucial. Emotion management is essential to maintaining good mental health and overall wellness. Deficits in the ability to adaptively deal with challenging emotions can lead to various mental disorders such as depressive disorders, borderline personality illness and eating disorders [26]. Emotion regulation tactics like rethinking thoughts and expressive suppression are related to psychological outcomes [27], such as cognitive restructuring, which involves revising a situation to alter its emotional impact, is related to better psychological health and expressive suppression, preventing the outward expression of

emotions, is linked to decreased mental wellness [27]. Adaptive strategies like suppression are associated with these adverse effects. Lack of management of emotions can lead to reduced overall well-being that includes both pleasure-oriented and meaning-oriented elements [28]. Enhancing well-being among those with mental health issues can be attained by enhancing their emotion management abilities. In short, managing emotions is a crucial mechanism that influences mental health. Focusing on emotion regulation during therapy shows promise in reducing suffering and enhancing overall quality of life [26].

C. User Experience Elements

Twenty years of emphasis on user experience (UE) has resulted in a variety of digital devices that assist individuals in perceiving, comprehending, and communicating emotions [24]. The success of a VR app depends on the quality of the content, user experience, and technical execution. The objective of the study is to investigate the UE elements of virtual reality for ER through mVR-REAL app experimental test. Preliminary testing of research protocols, also known as pilot testing, is an essential precursor to any research undertaking. This phase allows researchers to fine-tune their procedures, detect possible complications, and improve the overall integrity of their study design.

Emotional design is a concept in user experience and product design that focuses on creating products, interfaces, or environments that elicit specific emotional responses from users. The term "ER" in psychology describes a group of both conscious and unconscious methods that humans employ to diminish, sustain, or amplify positive or negative emotions [29], which leads to promoting an individual's well-being [30]. Psychological pertains to the field of psychology and behaviour, encompassing the thinking procedures and functions that impact individual and collective experiences. This field encompasses multiple facets of mental activity, emotional awareness, enthusiasm, and interactions with others, aiming to comprehend how these factors contribute to human thought patterns and actions.

Additionally, psychology can describe anything related to the mental and emotional aspects of an individual or group, including the effects of thoughts and feelings on behaviour and well-being [31]. In the context of user experience (UE) design, psychological elements refer to aspects of human cognition, emotion, and behaviour that influence how individuals perceive and interact with a product, service, or interface. Understanding these psychological elements is crucial for creating designs that are user-friendly, engaging, and effective. Psychological principles perform an essential function in UE design by impacting how users perceive, interact with, and respond to digital products and interfaces. The element factors of user experience on emotion regulation, specifically focusing on the emotional and psychological aspects, suggest significant correlations between the UE of the app and its impact on users' emotional and psychological well-being [32]. The emotional design of a user interface, including visual elements and colour schemes plays a crucial role in influencing users' emotional states [33].

Cultural aspects in app design are critical considerations that go beyond mere aesthetics [34]. They encompass a deeper understanding and integration of cultural elements to create an inclusive and user-friendly experience for individuals from diverse backgrounds. For instance, in Malaysia uses the Malay language as the first language. In the consideration of building the app, we have selected the Malay language as the language used in the whole app representation. We can create products that resonate with a global audience, fostering positive user experiences across diverse cultural contexts through integrating these cultural considerations into the app design process.

III. METHODOLOGY

A. Participants

Participating in the study are sixteen students who are currently enrolled in secondary school in a public school in Malaysia. The subject's range in age from thirteen to fourteen years old during the study.

B. Ethics Statement

The study was conducted on March 17, 2023, comprising eight males and eight females, all fourteen-year-old secondary school students. Informed consent was obtained from all participants, and because the study involved minors, written parental consent was also secured from their parents or guardians. Participants were monitored for emotional well-being throughout the intervention, with arrangements in place to refer any identified emotional issues to the school counsellor. All data collected during the study were securely stored and maintained under strict confidentiality for the entire duration of the research. This study has earned over the Research Ethics Committee's approval, The National University of Malaysia with the ethics approval number, UKM PPI/111/8/JEP-2023-111. The Malaysian Ministry of Education has also given its permission (KPM.600-3/2/3-eras (15996)).

C. Instruments

The study involved a VR tool named Meta Quest 2 (MQ2) previously known as Oculus Quest 2. MQ2 is a virtual reality headset developed by Oculus, which is a subsidiary of Facebook which now Meta Platforms, Inc. It's a standalone VR headset that offers wireless and untethered virtual reality experiences. The MQ2 features improved hardware specifications, higher resolution displays, and enhanced processing power compared to its predecessor, the original Oculus Quest. There were three Meta Quest 2 headsets that is used by one per participant. We first pre-installed mVR-REAL apps for the pilot test. We conducted a pilot/feasibility study as an initial measure towards subsequently carrying out a comprehensive trial [35].

Participants are generally given explicit instructions on how to interact with the VR experience. There is also an initial tutorial that guide participant on how to navigate the VR space and use controllers effectively. The participants were given a briefing regarding the apps which includes a questionnaire administered before and after a test. Comparison of pre- and post-test surveys are valuable tools for assessing changes in knowledge, attitudes, behaviours, or other variables before and after an intervention.

The pre-test comprising fifteen questions on the effectiveness of the apps, and the same set of fifteen questions were handed out as a post-test questionnaire to evaluate the app's

efficacy once again after the VR session. The initial step involved conducting a systematic literature review (SLR) on VR for SEL to identify key themes, gaps, and findings in existing research related to VR applications in SEL and ER. From the SLR, specific elements that consistently emerged as crucial for effective SEL and ER interventions were identified. These included emotional awareness, coping strategies, social interactions, and empathy development. The questions were derived from a prior SLR to investigate these elements further, ensuring relevance to the study's objectives. The questionnaire conducted based on Alqahtani's method represents a valuable approach to gaining insights into various aspects of user experience [36]. Participants were given the opportunity to use the mVR-REAL after completing a pre-test questionnaire. The session took place in the school auditorium. A VR element that lasts approximately three to five minutes per scene is included in the episode. Pre and post-test questionnaires are valuable tools for assessing changes in knowledge, attitudes, behaviours, or other variables before and after an intervention.

Table I indicates a set of question for pre and post-test questionnaire. The questions are designed based on an element that found in the previous study of the systematic literature review [37]. The answer provides a multiple-choice Likert scale namely, strongly agree, agree, neutral, disagree and strongly disagree. A value in numbers was allocated to each notional choice on the scale. A Likert scale is a prevalent rating system used to measure attitudes, opinions, or perceptions [38]. It typically consists of a statement followed by a range of response options that reflect varying degrees of agreement or disagreement.

TABLE I. PRE AND POST-TEST QUESTIONNAIRE

Number	Question
1.	Sound plays a role in understanding something that is not clear
2.	Pictures make a design interesting
3.	Certain methods are required to convey information
4.	Effective interaction affects the presentation of a good story
5.	The physiology of body movement helps me act better
6.	I believe facial expressions and gestures are the result of understanding something
7.	I do not really know how to deal with stress
8.	I always hide my fear
9.	I often cannot control my anger
10.	I believe I have a wide variety of emotions
11.	I believe my behavior is influenced by my emotions
12.	I will show happiness if I feel calm
13.	I believe peace can make me happy

D. Data Analysis

The SPSS, short for Statistical Package for the Social Sciences, is a highly popular software application utilized extensively in the realm of research and data analysis. SPSS offers an interface that is easy to use and facilitates data input, manipulation, analysis, and visualization, all of which contribute to the successful discovery of insights. The acquired data was analysed using the SPSS method and paired sample t-test. The paired sample t-test was selected for this investigation because it is appropriate for comparing the means of two related groups, specifically measurements obtained from the same subjects before and after an intervention. Comparison of pre and post-test surveys provide a robust method for evaluating the impact of interventions and tracking changes in variables over time. The t-test result revealed statistically significant differences in the results users experienced after interacting with the mVR-REAL The apps enhance the user experience and facilitate participants' comprehension of emotion regulations.

IV. FINDINGS

A. User Experience Impact Based on Paired Sample T-Test

The paired samples t-test was conducted to evaluate the effectiveness of the VR intervention on SEL and ER among adolescents. The key results include the means, standard deviations, and t-values, which provide insights into the impact of the intervention. By evaluating the average scores from the pre and post-tests, a paired samples t-test was performed.

Table II shows the outcomes of the descriptive analysis using matched sample statistics on the data. The median number represents the calculated mean of the data. The desired amount might be derived over summing all the numbers provided in the data and thereafter dividing the result by the total number of variables.

TABLE II. MATCHED SAMPLE DATA

Matched Samples Data					
		Mean	N	Std. Deviation	Std. Error Mean
Pair 1	Pre-test	3.7417	15	.60774	.15692
	Post-test	3.9625	15	.44809	.11570

The mean score represents the average performance of participants on SEL and ER assessments before and after the VR intervention. The mean score in the pre-test is 3.74 and median score during the post-test is 3.96, this indicates an improvement in participants' skills.

The standard deviation measures how much individual scores deviate from the mean. A smaller standard deviation suggests that participants' scores are closely clustered around the mean, while a larger standard deviation indicates more variability in responses. For instance, the standard deviation before the intervention was .60774 and after was .44809, which suggests that participants became more consistent in their scores following the VR experience. The following demonstrates the fact that there are distinct variations in the descriptive results obtained from user experiences.

The variable N represents the quantity of information collected for every parameter. In the current study, a maximum of fifteen participants were included in the research sample, denoted by the value of N in the table. The variation of the data around the median is revealed by the typical variation. Data is considered more diverse when its standard deviation is large, and inversely. The mean is not a good indicator of the data quality if the standard variance is higher than the mean. The median value is an accurate reflection of the complete data set if

and only if the average variation value is lower than the mean value. Eq. (1) can be used to determine the average variation explicitly.

$$s = \sqrt{\frac{\sum(X_i - \bar{X})^2}{n-1}} \quad (1)$$

The symbol S represents the usual variation, $\bar{X}$ represents the median amount of the data, and n represents the number of data points. The findings indicate that the median variation among the pre-test is 0.60774 and the post-test is 0.44809. This indicates that both the variances are lower than the mean value. Hence, the mean of the pre-test and post-test may accurately portray the entire dataset. Eq. (2) provides a method to calculate the mean standard error ($s\bar{x}$) through dividing the standard deviation by the square root of the population length.

$$S\bar{x} = \frac{s}{\sqrt{n}} \quad (2)$$

The variable s represents the standard deviation, whereas the variable n represents the number of data points. The mean standard error provides a measure of how accurately the mean data across each sample can approximate the overall means for every factor.

TABLE III. PAIRED T-TEST RESULTS

Paired Sample Test								
Pair 1	Paired Changes					t	df	Sig. (2-tailed)
	Mean	Std. Deviation	Std. Error Mean	95% Confidence Break Difference				
				Lower	Upper			
Pre-test - Post-test	-.22083	.24306	.06276	-.35543	-.08623	-3.519	14	.003

Table III displays the outcomes of a paired sample t-test. The median figure of Table III is the mean of the bilateral variances generated by the variance between the median values. Test outcomes indicate that the median measurement for the variance is -.22083. The stated average variance is the total standard variation calculated from the differences between pairs. The average variation of the variance can be computed using the previously given equation [39].

The test findings indicate an average of the difference of 0.24306. The median average error is a statistical measure that provides an estimation of the normal variation over the representative standard probability for a population that is infinitely large. It is possible to determine the median error of the average variation using the formula provided. We know that the median score has a standard error of.06276. The range of certainty for the mean difference has upper and lower bounds that represent the confidence interval's confidence.

In summary, the results from the paired samples t-test reveal that participants showed significant improvements in their SEL and ER skills after engaging with the VR intervention. The mean scores increased, indicating better performance, while changes in standard deviation suggest greater consistency among participants' responses post-intervention. The statistical significance ($p < 0.05$) confirms that these improvements are unlikely to be due to chance, and a moderate effect size indicates meaningful benefits from using VR for enhancing emotional and social competencies among adolescents. This interpretation provides a clear understanding of how statistical measures reflect the effectiveness of the VR intervention without unnecessary complexity or redundancy.

This demonstrates the utilization of mVR-REAL apps has a significant influence on user experience outcomes. mVR-REAL apps are transforming the way users engage with digital content. Through an exploration of user immersion, satisfaction, and learning, this study reveals the profound impact of mVR-REAL apps on enhancing user engagement and learning in a virtual environment. The findings suggest the element factor of UE on ER are emotional and psychological. The construct will guide with the matrix on testing the mVR-REAL app.

TABLE IV. DESCRPTIVE ANALYSIS

Tests	*n*	Descriptive Statistics	Paired T-Test		
		M (Std. D)	*t*	*df*	Sig. (2-tailed)
Pre-test	15	3.74 (0.60)	-3.519	14	0.003*
Post-test	15	3.96 (0.44)			

Table IV presents a descriptive statistic. Aside from the t-value, relevance can also be inferred from the p-value or significant value seen in Table IV. The decision-making process is based on the criterion that if the significance (Sig. (2-tailed)) is below 0.05, the null hypothesis (H0) which states that there is no relationship between two paired groups, is rejected, and the alternative hypothesis (Ha) which states that there is a relationship between the two paired groups, is accepted. The paired samples t-test yielded a significance level (Sig. (2-tailed)) of 0.003, leading to the rejection of the null hypothesis (H0) and acceptance of the alternative hypothesis (Ha). Therefore, the utilization of mVR-REAL apps has a significant influence on UE outcomes which signifying an element of emotion and psychological. This displays that mVR-REAL apps are effectively used in regulating emotions among participants. The findings suggest the element factor of UE on ER are emotions and psychological. The construct will guide with the matrix on testing the mVR-REAL app.

V. DISCUSSION

The findings of this study underscore the significant potential of VR as an innovative tool for enhancing ER practices, aligning with existing literature that emphasizes the importance of immersive environments in promoting emotional well-being. Previous research has shown that VR can create a heightened sense of presence and engagement, which are critical for effective emotional interventions. This study builds on that foundation by demonstrating how specific design elements such

as aesthetics, audio, and personalization can further enhance the effectiveness of VR in supporting ER.

A. User Experience Element of Virtual Reality for Emotion Regulation

According to the findings, mVR-REAL apps positively impact the user experience. The findings propose two important UE element needed in developing a VR app to enhance ER namely emotional and psychological. In the development of a VR app aimed at enhancing emotion regulation, two crucial user experience elements are the consideration of emotional design and the incorporation of psychological principles. Both elements play significant roles in creating an immersive and effective experience for users seeking to regulate their emotions.

1) Emotional design

a) Aesthetic and visual elements: The visual aspects of a VR environment have a profound impact on users' emotions. The choice of colours, textures, and overall aesthetics can evoke specific emotional responses. For emotion regulation, calming and soothing visual elements, such as nature scenes or soft colour palettes, may be incorporated to create a positive and serene atmosphere.

b) Immersive audio: Sound and music are powerful tools for influencing emotions. Integrating immersive audio experiences that align with the desired emotional state can enhance the overall effectiveness of the app. This could involve calming ambient sounds, guided meditations, or music designed to induce relaxation.

c) Personalization: Allowing users to personalize their virtual environment can contribute to a sense of control and emotional comfort. Customizable elements, such as avatar appearance or the choice of surroundings, empower users to tailor the experience to their preferences, contributing to a more emotionally resonant interaction.

2) Psychological principles

a) Cognitive behavioural techniques: Incorporating principles from cognitive-behavioural therapy (CBT) into the VR app can provide users with practical tools for managing their emotions. This may involve interactive exercises, guided cognitive restructuring, and behaviour modification strategies that users can engage with in the VR environment. This information can be used to guide users through exercises aimed at regulating their emotional and physiological states, promoting self-awareness and control. The integration of CBT and mindfulness within VR interventions is particularly compelling due to the unique enhancements provided by the immersive nature of VR. Compared to traditional methods, VR offers several advantages that significantly bolster the effectiveness of these therapeutic techniques.

*b) Social skills***:** Implementing features that allow users to learn about their social skill to enhance the psychological impact of the app. Progress tracking, along with reflective exercises, can contribute to a sense of accomplishment and self-discovery, reinforcing positive emotional experiences.

*c) Guided mindfulness***:** Integrating mindfulness practices and relaxation techniques into the VR app such as an exercise can help users cultivate a focused and present state of mind. Guided sessions led by virtual mentors or interactive experiences that encourage mindfulness can contribute to emotional regulation by promoting a sense of calm and centeredness.

3) Cultural aspect

a) Content representation: Consideration should be given to the representation of diverse cultures of Malaysia within the mVR-REAL content. This includes incorporating scenarios, environments, and characters that are inclusive and representative of Asian cultural contexts. Users from different cultural backgrounds should feel a sense of inclusivity and relevance in the virtual experiences.

b) Language and communication: The app's language and communication should be mindful of cultural nuances. mVR-REAL involves using Malay language and ensuring that any written or spoken content is easily understandable and culturally appropriate for a Malaysian user base. Language choices should be respectful and considerate of cultural diversity. Therefore, mVR REAL chose Malay language in the whole app presentation because Malay language is close to heart of Malaysian. Emphasizing cultural representation and language in the context of VR applications is crucial for enhancing user engagement and ensuring that emotional and psychological benefits are universally accessible, particularly within the Malaysian context. Cultural relevance not only enriches the user experience but also fosters a deeper connection between the content and the users, leading to more meaningful interactions.

In summary, the findings of this study highlight the critical importance of integrating emotional, psychological, and cultural elements in the development VR applications for ER. By focusing on these aspects, developers can create immersive experiences that resonate deeply with users, enhancing engagement and therapeutic outcomes. Ultimately, mVR-REAL applications hold promise as effective tools for persons aiming to improve their emotional well-being and regulation by immersing themselves in engaging virtual environments. The findings suggest that the mVR-REAL app effectively integrates emotional, psychological, and cultural elements to enhance emotion regulation. Users experienced positive emotional effects, benefitted from cognitive-behavioural techniques, and appreciated the cultural sensitivity and inclusivity of the app, contributing to an overall positive user experience in the pursuit of improved emotional well-being. The mVR-REAL app that incorporates various elements of emotional design, psychological principles and cultural aspect has successfully impacted the user experience. This investigation has illuminated on the positive impact of various element features on user experience across a wide range of digital and physical environments involving VR apps. Furthermore, the findings from this study provide valuable insights for VR developers aiming to create applications that effectively support ER. By prioritizing emotional design and psychological principles during the early stages of development, developers can enhance user engagement and improve therapeutic outcomes.

Further research will be directed towards the concrete implementation of usability testing for the mVR-REAL project

that should focus on several key questions that emerge from the findings of this study such as how do different design elements affect user satisfaction and engagement in VR environments for ER? and what is the impact of culturally tailored content on the effectiveness of VR interventions for diverse populations?. Moreover, challenges related to time were also identified, necessitating further research on how does the duration of VR sessions influence the effectiveness of ER techniques?

In a nutshell, as the technology continues to evolve, it is imperative for developers and researchers to explore innovative ways to harness the potential of mVR-REAL apps, ultimately providing users with immersive and transformative digital experiences. The app holds the promise of reshaping how we learn, entertain, and engage with digital content in the mobile VR era. The potential long-term impact of mVR-REAL apps on the field of ER is substantial, with implications that extend beyond VR app development into broader digital health interventions. By leveraging immersive technology, these applications can transform how individuals manage their emotions, offering innovative solutions that are both engaging and effective. mVR-REAL apps can cultivate a deeper understanding of emotional states through immersive experiences that allow users to visualize and interact with their emotions in real-time. This heightened awareness can lead to improved emotional regulation skills over time, fostering resilience and adaptability in various life situations.

ACKNOWLEDGMENT

I. Hamzah expresses gratitude to the Ministry of Education, Malaysia for their crucial assistance in funding this work, provided under the Trans-disciplinary Research Grant Scheme (TRGS/1/2020/UKM/01/4/3).

***Abstract*—Virtual reality (VR) has swiftly progressed, transitioning from a niche technology primarily associated with gaming to a versatile tool with broad applications across entertainment, healthcare, education, and beyond. Social-emotional learning (SEL) is increasingly recognized for its role in enhancing individuals' social skills and emotional regulation. However, despite the growing body of research on VR, the development of specific design frameworks for integrating VR with SEL remains underexplored. This study addresses this gap by employing thematic analysis to identify the critical components necessary for a Virtual Reality Design Framework for Social-Emotional Learning (VRSEL) aimed at improving emotion regulation among Malaysian adolescents. Through qualitative data derived from expert interviews in SEL and VR, this research proposes a framework that leverages immersive VR technology to create realistic, interactive scenarios that facilitate the practice and development of social-emotional skills. The framework emphasizes key design principles, including user interface (UI), presentation layer (PL), and brain activity (BA). Our findings suggest that VRSEL is a powerful tool for SEL, offering significant potential for educational environments. However, challenges such as technical barriers, content development, and educator training must be addressed to fully realize its benefits. This research highlights the promising role of VR in advancing SEL and lays the groundwork for further exploration and refinement of VRSEL in diverse educational settings.**

Keywords*—*Virtual reality; design; framework; social-emotional learning; emotion regulation

I. Introduction

Virtual reality (VR) can be described as a computer-generated simulation technology which allows a user to interact with a computer-simulated environment [1] by employing specialized electronic apparatus [2]. Modern virtual reality (VR) technology commonly utilizes head-mounted displays (HMDs), also known as VR headsets, which allow users to immerse themselves in a virtual environment by obscuring their perception of the actual world [3]. VR offers a novel setting in users to experience being immersed. Immersion is the state where a user becomes deeply engaged in a virtual environment, leading to a detachment from the reality of time and their physical surroundings [4]. The immersive experience enables audiences to completely diverge from the actual world. Through the provision of well-defined concepts, elements, and methods, it ensures consistency, fosters collaboration, and enables the growth of design efforts. VR represents the integration of hardware and software systems to generate the accurate and immersive experience of being physically present in another dimension. VR design entails the development of immersive digital environments that can effectively and realistically engage with users. To achieve this, it is crucial to possess a comprehensive design framework.

Partelow emphasizes that, as stated by The Cambridge Dictionary, frameworks are "a structural foundation upon which something can be constructed; a set of regulations, concepts, or principles used for organizing or determining something" [5]. A design framework is a structured approach used to direct the design process throughout several stages, including software and app development and more. A design framework is a concise and visually structured system that enhances the organization of information and ideas related to an issue, resulting in improved effectiveness. Frameworks are visual or written representations of the elements, ideas, or variables of a phenomenon [6]. This framework facilitates the development process, guaranteeing that the result is captivating, operational, and easily reachable. The process of designing and developing software or any other product can be intricate. In the presence of several obstacles, we are required to have a have a well-defined framework and methodologies to effectively conceptualize, construct, evaluate, and refine optimal ideas. Through the adoption of frameworks, we can enhance their comprehension of problems and discern alternate strategies and answers that may not be immediately evident. Frameworks provide a systematic approach to organizing the process, igniting creativity, and promoting cooperation. They are fundamental components that direct the development of design solutions. Frameworks help structure the process, spark innovation, and stimulate collaboration which are essential building blocks for guiding design solutions. Several VR design frameworks are utilized in diverse fields, including healthcare [7] and education [8].

Social-emotional learning (SEL) is defined as the process through which individuals, particularly students, learn to recognize and control their emotions [9], develop empathy for others, establish positive relationships, and make responsible decisions [10]. It encompasses a set of skills that are essential

The study was funded by Malaysia's Ministry of Education under Trans-disciplinary Research Grant Scheme (TRGS/1/2020/UKM/01/4/3).

for personal and social development, including emotional awareness, emotional regulation, social awareness, relationship skills and decision making. SEL is crucial for fostering not only emotional intelligence but also academic success. Programs that effectively implement SEL strategies have been shown to improve students' social skills, enhance their academic performance, and reduce behavioural problems [11]. As SEL widens its attention to include teenage populations, it adopts the widely acknowledged theoretical framework proposed by an organization called CASEL or the Collaborative for Academic, Social, and Emotional Learning [12]. CASEL has released a framework to help spread SEL curriculum widely [13]. This framework organizes SEL competencies and helps identify well-designed, evidence-based SEL programs in a systematic manner. Schools strive to foster a nurturing atmosphere that enhances students' emotional well-being and academic performance by incorporating SEL into their educational framework. The ultimate objective is to provide students with the essential abilities and mindset to achieve outstanding academic performance and prosper in several other areas of life [13]. SEL is an essential element of education involves cultivating abilities such as empathy and emotional regulation.

Emotion regulation (ER) refers to the processes of individuals manage or control their emotional experiences and expression [14], modifying the initiation or length of emotions [15], and emotional modulation [16]. The area of emotion regulation is experiencing rapid growth within the realm of psychology [17]. Through the assistance of ER, individuals can manage their emotions, when they feel it, and how they express them. This includes both conscious and unconscious techniques. Being able to regulate one's emotions is crucial for thriving in social settings when letting one's guard down is generally frowned upon. ER is a regular and necessary process for maintaining wellbeing, and it is used flexibly in various everyday situations [18].

VR has been a rapidly developing technology with various potential applications, including in the field of psychology and mental health to treat depression and anxiety [19]. However, there is limited research that focus on enhancing emotion regulation in adolescent using VR. Therefore, the goal of this study is to develop a virtual reality design framework for social-emotional learning (VRSEL) that enhances emotion regulation in Malaysian adolescents. VR is being actively promoted as a highly promising technique for teaching and learning in various educational settings [20]. The utilization of VR offers an additional chance to effectively improve SEL through immersive educational experiences. This is accomplished by promoting improved regulation of emotions, which contributes to an individual's general state of mental health. Thematic analysis is employed to utilize qualitative data from interviews with experts in the creation of VRSEL. Thematic analysis (TA) is a systematic approach used to find, analyse, and interpret patterns of meaning or themes within qualitative data [21]. It entails a methodical procedure of analysing and reviewing data, such as transcripts of interviews or discussions in focus groups, to identify important themes that encapsulate the core of the dataset. The VRSEL framework will provide a vital guideline for other researchers to develop a specific framework in the context of emotion regulation by promoting SEL.

The aim of this study is to design a specific framework that integrate VR with SEL to enhance emotion regulation in Malaysian adolescents. This study fills this gap by utilizing thematic analysis to discern the essential elements required for VRSEL framework, applying qualitative data obtained from expert interviews in SEL and VR.

II. Literature Review

A. Virtual Reality Design Framework

Design frameworks are essential for directing the developing phase and enabling successful creation of goods or systems that prioritize the needs of the user. The application of design frameworks has been explored in various domains, including user experience design, service design, and interaction design, demonstrating their versatility and effectiveness in addressing different design challenges. The field of VR design has evolved significantly in recent years that focused on refining VR design frameworks to improve usability [22], user experience [23], and the overall effectiveness [24] of VR apps across various domains.

1) Improvement of design skills: The potential of virtual reality for strengthening design skills is rapidly being acknowledged. Studies suggest that immersive settings promote embodied experiences, leading to improved creative problem-solving and design-thinking abilities [25].

2) Consumer assessment in VR: Consumer examination of items in VR environments is another important field of study. A review has highlighted key characteristics related to how customers evaluate items in VR, indicating that VR can be a valuable platform for marketers to conduct testing and prototype development (Branca et al., 2024).

3) Skill training frameworks: An extensive analysis of VR characteristics for skill training emphasized the importance of using VR technology in specific contexts (Tusher et al., 2024). The study highlighted that the efficacy of VR in training situations relies on the congruence between VR attributes and desired learning objectives.

4) Unified adoption framework: A comprehensive investigation, including both qualitative and quantitative methodologies, has put forward a novel paradigm for the unified implementation of VR (Fares et al., 2024). This review investigates the factors that impact consumer involvement with VR technology. The primary objective of this framework is to offer a thorough comprehension of the elements that either help or impede the adoption of VR in the context of design.

In the education sector, VR frameworks aim to enhance learning experiences through immersive environments that promote engagement and retention. Educational VR applications often incorporate gamification elements to make learning more interactive and enjoyable (Lyu et al., 2023). The integration of VR in education has shown promising results in various domains, including science, history, and language learning (McGovern et al., 2020). However, its application in SEL is relatively underexplored. Prior research suggests that immersive VR experiences can significantly impact users' emotional and social skills by placing them in realistic,

emotionally charged scenarios (Marín-Morales et al., 2020). This study builds on this foundation to create a targeted framework for SEL.

B. Human Computer Interaction and Design Principle

Human-Computer Interaction (HCI) is a discipline that focuses on the optimization and efficacy of user interfaces in relation to computer systems, user-friendly input and output technology, and the psychological elements of user interfaces [26]. The domain of HCI has broadened to encompass a diverse array of devices and technologies, such as mobile devices, the Internet of Things, and virtual reality. VR technology, along with HCI, plays a crucial role in software development by minimizing errors and achieving higher levels of accuracy and quality.

This is achieved through the utilization of design principles that specifically target the user interface and presentation layer. User Interface (UI) design is a critical aspect of HCI that focuses on the look and feel, responsiveness, and interactivity of digital products. Efficient UI design guarantees that people can interact with systems effectively and provides a visually appealing presentation layer. The presentation layer (PL) of HCI refers to how information is displayed to users. UI is greatly influenced by several key components, including information architecture, visual hierarchy, and responsive design. The design of the presentation layer should prioritize the user's needs, ensuring that it is both aesthetically pleasing and practical, with a user-friendly interface. Research highlights the need of adaptive interfaces that can adjust to user context and preferences, hence improving usability and pleasure [27].

C. Social-Emotional Learning and Emotion Regulation

Twenty SEL and emotion regulation are foundational to students' academic success, school readiness, and overall well-being [28], [29]. SEL involves the process of acquiring and effectively utilizing the knowledge, attitudes, and skills necessary to understand and regulate emotions, make responsible decisions, and maintain positive social relationships (Elias & Zins, 2006; Ross & Tolan, 2018). Emotion regulation, a critical aspect of SEL, refers to the strategies and processes that individuals use to manage their emotional experiences effectively [17]. Research has consistently shown that strong emotion regulation skills are positively associated with social competence and can serve as predictors of future social functioning [31]. In collaborative learning environments, these skills are essential for managing group dynamics, maintaining positive interactions, and fostering a sense of school belonging, particularly for students with specific learning disorders. Effective emotion regulation can lead to fewer psychosocial difficulties, contributing to a more inclusive and supportive learning environment [32], [33].

The importance of integrating SEL and emotion regulation into educational curricula cannot be overstated. Emotion regulation significantly impacts mental health by shaping emotional responses and overall psychological well-being, particularly during adolescence critical period for cognitive, social, and emotional development. Recent trends indicate that adolescents are increasingly struggling to manage their emotions effectively, which raises concerns about the potential consequences on their mental health and academic performance. Educators play a pivotal role in supporting the development of these skills through various approaches, including experiential learning, mindfulness, and simulation-based exercises [34]. Frameworks such as the RULER approach and Lobczowski's model provide structured methodologies for implementing SEL and understanding emotion formation in collaborative settings [28], [35]. By embedding emotion regulation strategies into daily educational practices, educators can enhance both their own and their students' emotional intelligence, ultimately leading to improved academic outcomes and overall well-being.

D. The Role of Virtual Reality in Enhancing Social-Emotional Learning

Cultural VR has emerged as a promising tool for enhancing SEL in children and adolescents, providing immersive environments that facilitate key skills such as perspective-taking, empathy, and responsible decision-making. VR interventions have been proven effective in enhancing SEL, especially for children with autism spectrum disorders (ASD). ASD often involve challenges with social interactions, communication, and understanding social cues. VR offers a unique, controlled, and immersive environment where children with ASD can practice and develop these essential social skills in a safe, structured setting. The studies have demonstrated the effectiveness of VR interventions in promoting SEL, particularly for children with autism spectrum disorders, where it aids in the development of social skills [36], [37]. For instance, VR can simulate real-life social situations that children with ASD might find challenging, allowing them to rehearse and refine their responses in a way that is both engaging and low-risk.

These simulations can include scenarios like having a conversation, recognizing emotions, or navigating social events. By repeatedly practicing these scenarios in a VR environment, children with ASD can build confidence and competence in their social interactions, which can translate to improved social skills in real-world settings. By offering experiential learning opportunities, VR enhances student engagement and learning outcomes across various domains, including emotional regulation, cognitive skills, and social competencies (Kamei & Harriott, 2020; Murphy et al., 2021). It shows how VR's ability to create these dynamic, engaging learning experiences leads to better retention and application of skills, making it a powerful tool in education. Furthermore, the integration of VR and augmented reality tools has shown potential in developing emotional intelligence skills, benefiting both neurotypical individuals and those with autism [40]. These findings underscore VR's role as an effective pedagogical tool for promoting SEL in diverse educational settings.

E. Comparison with Other Methods

Table I presents a comparison with various models, demonstrating that the VRSEL framework excels due to its comprehensive approach to improving emotion regulation in adolescents leveraging VR technology. Through integrating immersive experiences with tailored learning pathways and secure practice environments, it mitigates numerous constraints linked to conventional educational approaches, including restricted participation and passive learning.

TABLE I. COMPARISON WITH OTHER METHODS

Methods	Advantages	Limitations
Traditional Learning	Familiarity, structured curriculum	Limited engagement, passive learning
Online Learning Platforms	Flexibility, accessibility	Lack of immersive experience, potential isolation
Role-Playing Activities	Interactive engagement, real-world application	May not fully simulate emotional scenarios
VRSEL Framework	Immersive, personalized, risk-free practice, enhanced collaboration	Requires access to technology, potential initial learning curve

Building on this foundation, immersive technologies like VR extend their potential beyond SEL to also play a significant role in emotion regulation and the induction of positive emotions. The immersive nature of VR enhances emotional experiences by increasing the sense of presence, which can boost positive emotions and arousal [41]. Moreover, VR scenarios that offer virtual social support have been found to effectively mitigate negative emotions caused by social exclusion [42]. These applications of VR in emotion regulation span various contexts, from clinical interventions to mood induction, providing dynamic opportunities to assess and intervene in emotional processes [43], [44]. While VR holds promise for facilitating transitions from negative to positive emotional states, challenges remain in accurately representing emotions and providing design guidance [45]. Future research should focus on leveraging VR's capabilities to enhance social interactions and couple experiential training with reflective moments, further expanding its applications in emotion regulation contexts.

Despite significant advancements in VR design frameworks aimed at improving usability, user experience, and effectiveness across various domains, a critical gap exists in their application for SEL and emotion regulation. While VR has shown promise in enhancing social skills and emotional intelligence, especially for individuals with autism spectrum disorders, there is limited research on how to effectively design VR environments specifically for emotion regulation. Addressing this gap is crucial as emotion regulation is a vital component of mental health and well-being, particularly in adolescents who are increasingly struggling with managing their emotions. Understanding how VR can be optimized to support emotion regulation could lead to the development of powerful tools that not only enhance SEL but also contribute to better mental health outcomes. This study is important because it seeks to create a VR design framework that specifically targets emotion regulation, offering a new avenue for educational and therapeutic interventions in this critical area.

III. METHODOLOGY

Fig. 1 shows the methodology flowchart illustrating the study's complete process, which includes six steps in the development of the VRSEL framework.

A. Research Deign

1) Objective: The study aims to develop a specialized virtual reality design framework for SEL with the goal of enhancing emotion regulation among adolescents. As part of this study, interviews were conducted to explore and understand the virtual reality components essential for creating a design framework tailored to SEL contexts.

2) *Qualitative approach:* The study utilizes qualitative methodologies, emphasizing the in-depth data gathered through interviews. The interview questions were developed based on the initial data collected during the first phase of the research, which helped shape the conceptual framework of the study.

Fig. 1. Methodology flowchart.

B. Ethical Consideration

1) Ethical approval: This study has earned over the Research Ethics Committee's approval, The National University of Malaysia with the ethics approval number, UKM PPI/111/8/JEP-2023-111. The Malaysian Ministry of Education has also given its permission (KPM.600-3/2/3-eras (15996)).

2) Confidentiality: We maintained the participant's confidentiality by anonymizing the data. All data collected during the study was securely stored and maintained under strict confidentiality for the entire duration of the research.

C. Participant

1) Data sampling: The data sampling involves six participants from two distinct domains of expertise: VR and SEL. Participants were selected based on their specialized knowledge relevant to the study.

2) Participant selection criteria: The selection of participants was based on their specialized knowledge in two critical areas namely, virtual reality (VR) and social-Emotional learning (SEL). This dual expertise is essential for providing a comprehensive evaluation of the VRSEL framework. Participants were chosen for their ability to contribute insights that align with the study's objectives:

a) VR experts: Individuals with a strong background in VR technology, design, and implementation. Their insights are crucial for understanding the technical aspects of the VRSEL framework and its effectiveness in creating immersive learning experiences.

b) SEL experts: Professionals with expertise in social-emotional learning theories, practices, and interventions. Their perspectives are vital for evaluating the framework's alignment with established SEL principles and its impact on emotional regulation.

3) Demographics: The six participants ranged in age from 30 to 65 years. The participant group included both men and women, ensuring a balanced representation that can contribute to a more comprehensive understanding of the VRSEL framework's impact across different gender perspectives.

4) Informed Consent: Informed consent was obtained from all participants, ensuring that the study adhered to ethical standards.

D. Data Collection

1) Interview procedure: We conducted the semi-structured interview both face-to-face and online.

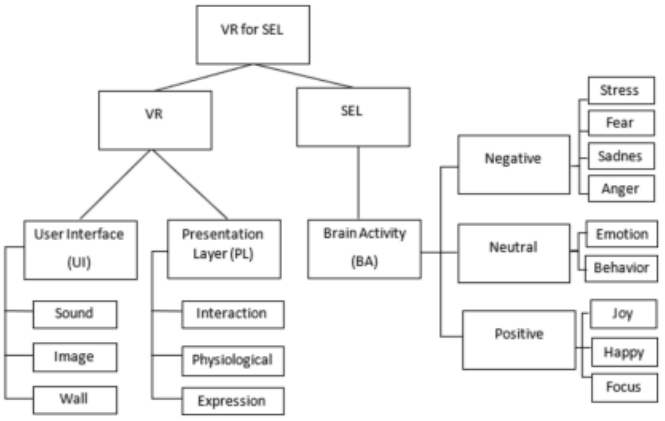

Fig. 2. Conceptual framework of VRSEL.

2) Interview guide: The preliminary data from phase one of the study, which established the study's conceptual framework [46], served as the basis for designing the interview question. Hamzah stated that it is important to have a set of requirements for making a virtual reality for social and emotional learning that could help Malaysian teens better control their feelings. Fig. 2 shows the conceptual framework of virtual reality design framework that has been designed for social-emotional knowledge developed in the earlier phase of the study by [46].

3) Recording and transcription: We recorded the interview using a voice recorder. The interview data were then transcribed using software by Google Cloud, speech-to-text, to ensure accuracy in capturing participants' responses.

E. Data Analysis

The data is analyse using thematic analysis. Thematic analysis (TA) is an adaptable method for analysing qualitative data and patterns to identify the underlying meaning. Braun and Clarke state that thematic analysis is not constrained by any one theoretical framework, rendering it a flexible instrument in qualitative research [21]. Fig. 3 displays the initial thematic map that has been produced through the process of thematic analysis. The process of TA typically involves several key steps:

1) Familiarization: The interview transcriptions were subjected to thematic analysis to ensure thorough familiarization with the data through repeated reading and examination of the transcripts.

2) Initial coding: The procedure of deriving initial codes from the data has been completed. The codes are essential since they establish the groundwork for themes.

3) Theme development: The study grouped codes into potential themes as a way of summarizing sections of the data. This involves the iterative process of reviewing themes, refining them, and ensuring they accurately represent the data. Fig. 3 represents the initial thematic map that we create at the start of data processing. The map was subsequently utilized in the development of the VRSEL framework. The theme was further examined in the discussion section of the study by providing further details on the quotation from the interview dialogue.

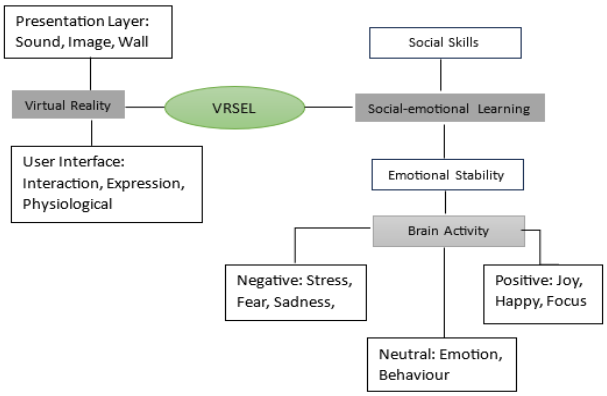

Fig. 3. Initial thematic map.

4) Reviewing themes: The themes were cross-referenced with the dataset to verify their coherence and significance.

5) Defining and naming themes: Table II indicates the definition and naming of the themes.

TABLE II. THEME DEFINITION

Themes	Sub Themes	Attributes
Virtual Reality (VR)	User Interface (UI)	Sound
		Image
		Wall
	Presentation Layer (PL)	Interaction
		Physiological
		Expression
Social-emotional Learning (SEL)	Social Skills (SS)	
	Emotional Stability (ES) Brain Activity	Stress
		Fear
		Sadness
		Anger
		Emotion
		Behavior
		Joy
		Happy
		Focus

Each theme has been delineated based on the objectives of the investigation. Subsequently, we selected the suitable titles that effectively capture the fundamental nature of the subjects. The primary focal points revolved around virtual reality and social-emotional development.

IV. FINDINGS

Fig. 4 illustrates the process of developing the VRSEL framework. The VRSEL framework is a structured approach to research that consists of four distinct stages:

Fig. 4. VRSEL framework development process.

A. Critical Literature Revie

The first stage is conducting a comprehensive examination of the current literature that is pertinent to the study area. A preliminary literature review was conducted in the initial phase of the project [46]. The study highlighted any deficiencies in knowledge, comprehending the present state of VR framework for SEL, and providing a rationale for the necessity of the study. It provides information on the research questions and objectives, which helps to drive the overall progress of the project.

B. User Requirement Data

During the second phase, data has been collected pertaining to user requirements. This entails identifying the requirements, interests, and expectations pertaining to the extent of the investigation. Method such as interviews have been utilized to gather qualitative data. This phase is crucial for guaranteeing that the framework being constructed is focused on the user and effectively tackles current issues. The utilization of theme analysis in this data analysis yields valuable insights that may be employed to tailor the research to meet the specific needs of users, hence enhancing its relevance and efficacy.

C. Framework Design

The third phase is dedicated to the development of the framework's design. This entails integrating the knowledge acquired from the literature review and user requirement data to develop a logical framework that directs the study. The framework has explicitly outlined the interconnections among different components of the study, including variables, themes, and attributes as illustrated in the Fig. 5.

1) Key themes identified: Several significant topics pertinent to the VRSEL paradigm emerged through thematic analysis:

a) Theme 1: Virtual Reality (VR): It includes subtheme of user interface (UI) and presentation layer (PL).

b) Theme 2: Social-Emotional Learning (SEL): It includes subtheme of social skills (SS) and emotional stability (ES).

D. Testing and Validation

The final phase involves the validation of the VRSEL framework and assessing the usability of the VRSEL framework in the next study. This is accomplished by utilizing experimental approaches to evaluate the efficacy and dependability of the framework for future investigations. Validation and usability testing may include pilot studies, expert review, user feedback, and VR app development based on the results obtained. Continuous testing and validation help in refining the framework, making it more robust and applicable to real-world scenarios.

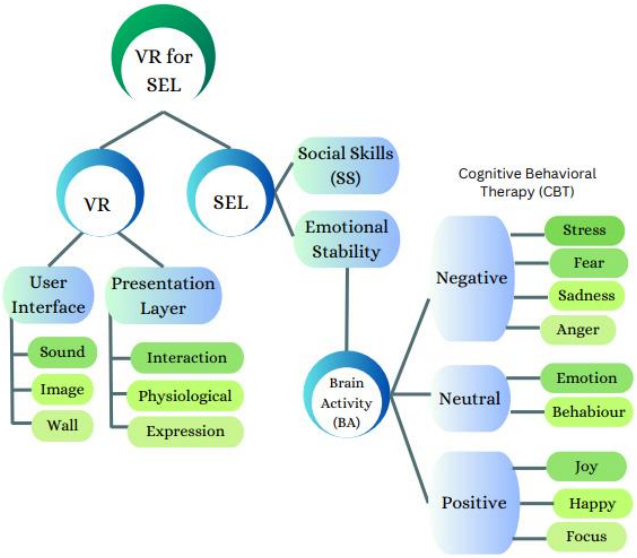

Fig. 5. VRSEL framework.

Fig. 5 highlights the primary findings of the study, which revolve around the VRSEL framework. The VRSEL framework encompasses two primary themes, specifically virtual reality (VR) and social-emotional learning (SEL). The VR theme comprises two subthemes such as user interface (UI) and presentation layer (PL). The UI features include sound, image, and wall. The characteristics of the PL encompass interaction, physiological responses, and expression. Meanwhile, the SEL theme comprises two subthemes namely, social skills (SS) and emotional stability (ES). The ES has a sub-subtheme called brain activity (BA). The BA possesses traits that can be categorized as negative, neutral, or good. The subtheme of ES is integrated with cognitive behavioural therapy (CBT).

V. DISCUSSION

A. Design Principles of the VRSEL Framework

The findings indicate that the VRSEL framework offers the necessary components for creating a targeted VR design within the context of SEL, as compared to the prior study on design framework. Table III displays the code that was produced during

the process of thematic analysis, which included interviews with all participants. Participant 3 highlight that "Social emotional development is divided into two, namely, social skills and emotional stability."

TABLE III. VRSEL INTERVIEW CODE

Codes	Interview Clip
Sound	"We need to place the sound according to the suitability of our VR application"
Image	"The objective of these computerized graphics is to get a greater impact through visuals"
Wall	"So apart from the wall, why don't we use virtual reality to visually represent avatars and other individuals?"
Interaction	"Interactive VR is one of the most important elements to get input from the user"
Physiological	"VR requires physiological movement"
Expression	"You are the virtual storyteller. You represent your own world."
Social Skill	"Social skill is an ecologically valid social skill step."
Emotional Stability	"Emotional stability is needed for someone to learn about emotions"

The VRSEL interview codes play a role in advancing the VRSEL framework. The finding highlights four fundamental design principles for its development:

1) User Interface (UI): Interaction design principles are a set of standards that assist in the creation of user interfaces that are both intuitive and engaging. These principles aim to replicate real-world social circumstances, resulting in lifelike scenarios. Sound is essential in constructing engaging and credible virtual reality settings. Sound contributes to the establishment of a feeling of being present and fully engaged in the virtual environment. The use of realistic and spatially precise audio enhances the authenticity and persuasiveness of the VR experience, immersing the user more profoundly into the scenario [47]. Creating a VR scenario needs to incorporate a diverse range of visual components, such as 360-degree image, 3D models, textured backgrounds, lighting, and interactive features [47]. Moreover, an image illustrating the concept of virtual reality, where a virtual environment may be explored using an avatar. In addition to using a virtual wall, we can enhance the immersion of virtual reality by incorporating an avatar. An avatar serves as the user's representative in the virtual world, allowing them to interact with the environment [2]. Avatars serve as digital embodiments of users, playing a vital role in creating a feeling of being present in the virtual world. Through interacting with their avatars, users could manifest their unique characteristics and personal sense of self, thereby intensifying their involvement and emotional connection to the overall experience [48].

2) Presentation Layer (PL): The presentation layer (PL) is an essential element in the design of VR, specifically in relation to interaction, physiological aspects, and user expression. It enables users to engage with virtual characters and situations to develop SEL capacities. The PL is accountable for overseeing user interactions within the VR environment. VR experiences can induce notable physiological effects on users, including symptoms such as motion sickness, eye strain, and weariness. The PL must be carefully crafted, taking into consideration these considerations, to ensure that visual elements are optimized to reduce any discomfort. The PL in social VR experiences must facilitate user expression through avatars and other virtual representations. These aspects must precisely communicate the user's movements, gestures, and facial expressions, facilitating authentic and captivating interactions with other users.

3) Social Skills (SS): Social skills are a crucial component of SEL, encompassing the abilities necessary for effective communication and building connections with others. These skills include understanding and empathizing with others, resolving conflicts in a positive manner, and demonstrating cultural humility and respect for diversity.

4) Emotional Stability (ES): Emotional stability (ES), as defined by SEL, is the capacity to skilfully control and regulate one's emotions, ensuring a harmonious emotional state in the face of diverse circumstances. This concept is closely linked to brain activity (BA) and how individuals respond to negative, neutral, and positive stimuli. BA that encompasses responses such as negative, neutral, and positive provides prompt feedback and a chance for introspection to enhance learning and incorporate cognitive brain therapy (CBT).

In Table II, SEL theme demonstrates the display of negative emotions such as stress fear, sadness, or anger. When exposed to negative stimuli, the amygdala in the brain becomes activated, resulting in intensified emotional reactions such as anxiety or wrath. Individuals who possess ES could effectively handle these responses, using techniques acquired via SEL to reduce the influence of negative feelings. Neutral stimuli, such as emotions and behaviours, typically do not elicit intense emotional reactions, enabling humans to analyse information without any prejudice. Emotional stability allows an individual to sustain concentration and lucidity in neutral circumstances, which is crucial for making decisions and resolving problems. Positive stimuli elicit the release of neurotransmitters, such as dopamine, which stimulate feelings of enjoyment and motivation such as joy happy and focus that is illustrated in Fig. 5. Individuals who possess ES can completely participate in pleasant events, which in turn improves their emotional well-being and strengthens their ability to adjust to different situations.

VI. FUTURE WORK

The results suggest that the VRSEL framework has significant potential to facilitate SEL by providing immersive and interactive experiences that foster emotional and social development. However, it is crucial to conduct thorough testing and validation of the VRSEL framework. A forthcoming phase will involve integrating the VRSEL framework into the development of a VR application for rigorous testing and validation. Implementing VR for SEL presents several challenges, including technical limitations, content development complexities, and the necessity for specialized training. From a technical perspective, VR systems demand high-performance hardware and software to deliver immersive experiences, which

can be costly and challenging to maintain, particularly in educational settings with limited resources. Additionally, creating content that is both engaging and pedagogically sound requires substantial expertise in VR technology and SEL principles. Developing realistic, interactive scenarios that effectively teach social-emotional skills necessitates close collaboration among educators, VR developers, and psychologists. Furthermore, educators and facilitators need comprehensive training not only to use VR tools but also to integrate them meaningfully into SEL curricula. This often involves a steep learning curve and ongoing support, which can hinder widespread adoption. To address these challenges, schools and institutions might consider forming partnerships with VR developers, investing in scalable training programs, and exploring cost-effective VR solutions that still offer immersive learning experiences. Additionally, ongoing research and feedback loops are essential to refining VR content and enhancing its accessibility and effectiveness across diverse educational environments.

VII. Conclusion

The VRSEL framework marks a significant advancement in integrating technology with educational practices, particularly in fostering SEL. By harnessing the immersive nature of VR, this framework creates interactive, lifelike scenarios where learners can actively engage in experiences that cultivate emotional intelligence, empathy, and other essential SEL skills among adolescents especially in Malaysia. Through virtual environments that replicate real-world social situations, VRSEL allows students to practice and enhance their emotional responses, decision-making, and interpersonal interactions in a safe, controlled setting. This experiential approach offers a deeper understanding and retention of SEL concepts compared to traditional methods.

However, the successful implementation of VRSEL in educational settings necessitates careful design and consideration of various factors. The framework's effectiveness hinges on the alignment of virtual experiences with learning objectives and the seamless integration of the technology into existing curricula. Designing these virtual environments requires a solid foundation in SEL principles and must be tailored to the diverse needs of learners, including varying learning styles and abilities. Additionally, ensuring that the content is culturally relevant and inclusive is vital for creating a positive learning experience for all students. Continued research and development are essential to fully realize the VRSEL framework's potential. While the benefits are evident, challenges such as technical limitations, content development, and the need for comprehensive educator training must be addressed. Ongoing studies are necessary to refine the framework, optimize the user experience, and assess the long-term impact of VRSEL on student outcomes. By overcoming these challenges and fostering innovation, VRSEL has the potential to transform SEL education, making it more engaging, effective, and accessible to learners worldwide.

Acknowledgment

I. Hamzah and E. Salwana expresses gratitude to the Ministry of Education, Malaysia for their crucial assistance in funding this work, provided under the Trans-disciplinary Research Grant Scheme under the code of TRGS/1/2020/UKM/01/4/3.

Bridging the Gap: Machine Learning and Vision Neural Networks in Autonomous Vehicles for the Aging Population

Shengsheng Tan
School of Science, Edith Cowan University, Joondalup, Australia

***Abstract*—As autonomous vehicles (AVs) evolve recently, it is necessary to address the unique needs of the aging population group. They can get a significant benefit from this technology. This scoping review focus the role of machine learning and vision neural networks in autonomous vehicles. A focus on enhancing safety, usability, and trust for elderly users will be mentioned as well. It systematically reviews existing literature to identify how these technologies address the cognitive and physical challenges faced by older adults. The review highlights key advancements in AV technology, such as adaptive interfaces and assistive features. That can enhance the driving experience for the elderly. Additionally, it investigates factors influencing trust and acceptance of AVs among older adults, emphasizing the importance of transparent and user-friendly design. Although, the despite notable progress has been made, the significant gaps remain in understanding how to optimize these technologies to meet the diverse needs of elderly passengers. The review identifies areas for future research, including personalized AV systems and regulatory frameworks that support designs friendly to the elderly. By addressing these gaps, the study aims to contribute to developing autonomous vehicles that are inclusive and accessible. It will make the mobility and quality of life for the aging population increased. This review underscores the importance of integrating machine learning and vision neural networks in designing AVs that cater to the unique needs of older adults. It was also offering valuable insights for researchers, policymakers, and industry stakeholders advancing autonomous vehicle technology.**

Keywords*—Autonomous vehicles; machine learning; vision neural network; human-computer interaction; aging population; artificial intelligence

I. Introduction

A. Overview of Autonomous Vehicles (AVs) and their Increasing Role in Transportation

Autonomous vehicles (AVs), also known as self-driving cars. It's capable of operating with reduced or no human input. AVs are making a revolution of the transportation landscape by offering new possibilities for mobility and accessibility [1]. These vehicles utilize a combination of sensors, cameras, and algorithms to navigate roads without human intervention [2]. The progress in vehicles' technology have accelerated the development and deployment of AVs over the past decade. The industry has positioned them as a transformative force in the automotive industry [3]. The promise of enhanced safety, efficiency, and convenience has fueled interest in AVs from governments, industry stakeholders, and consumers alike [4]. AVs offer a potential solution to reduce traffic problems as urbanization and population growth place increasing demands on transportation infrastructure. For instance, improve road safety and provide accessible transportation options for diverse populations [3].

B. Introduction to Machine Learning and Vision Neural Networks in AVs

Machine learning and vision neural networks are key technologies driving the evolution of autonomous vehicles [5]. Machine learning algorithms make AVs to learn from large datasets. This allowing them to recognize patterns, make decisions, and adapt to changing environments in different driving scenarios [6]. Vision neural networks is a subset of machine learning. They are particularly crucial for AVs as they process and interpret visual information from cameras and sensors. These networks enable AVs to detect and identify objects, interpret traffic signals, and navigate complex environments [7]. Technologies like Tesla's Full Self-Driving (FSD) system exemplify the application of vision neural networks in AVs, allowing for advanced features such as automated lane changes and obstacle avoidance [8]. The integration of these technologies enhances the capability of AVs in real-world conditions, so AVs can operate safely and efficiently on the road.

C. Importance of Addressing the Needs of the Aging Population in the Context of AV Technology

The aging population represents a significant and growing demographic, especially in Australia. Approximately 4.2 million people were aged 65 and over on 30 June 2020, this occupied 16% of Australia’s total population [9]. This group will stand to benefit greatly from autonomous vehicle technology. As the age growing, elderly may face cognitive and physical challenges that impact their ability to drive safely. Autonomous vehicles can provide a more mobility and independence ability to elderly individuals. It will reduce elder people's reliance on public transportation or family assistance [10]. However, it's essential to address the specific needs and preferences of older adults in the design and implementation of AV technology to fully meet these benefits. This includes considerations for cognitive load, ease of use, and safety features that cater to the physical limitations and cognitive changes associated with aging [11]. For example, AV technology can be developed to enhance their quality of life and promote social inclusion to focus on the unique requirements which elderly need. Additionally, understanding

and addressing the trust and acceptance factors among elderly users is critical for successful AV adoption. As this group of people continues to grow, incorporating their needs into AV design will improve accessibility and AVs can contribute positively to societal well-being at the same time [12].

II. METHODOLOGY

The methodology for this scoping review follows a structured approach to ensure comprehensive coverage of the literature related to machine learning and vision neural networks in autonomous vehicles (AVs) for the aging population. This section outlines the framework used for conducting the review, the search strategy employed to identify relevant studies, the criteria for inclusion and exclusion, and the process of data extraction and analysis.

A. Scoping Review Framework

This scoping review is conducted following the framework proposed by Arksey and O'Malley (2005), which is widely used in scoping reviews to map the existing literature and identify gaps in research. The framework of the scoping review includes of five key stages:

1) Identifying the research question: The primary research question guiding this review is: "What is the current stage of research on machine learning and vision neural networks in autonomous vehicles? How are they can help the aging population?"

2) Identifying relevant studies: A comprehensive search of academic databases was conducted to identify relevant literature. The studies published in the last four years (2020-2024) will be focused, aims to capture the most recent advancements in this field.

3) Selecting studies: The study selection process should followed by predefined inclusion and exclusion criteria, to ensure only the pertinent studies in the review inclusion.

4) Charting the data: Data from selected studies were extracted and charted to facilitate analysis and synthesis.

5) Collating, summarizing, and reporting the results: The results were collated, summarized, and reported to provide an overview of the current state of research and identify gaps and future research directions.

B. Search Strategy

The search strategy was designed to capture a comprehensive set of studies related to the use of machine learning and vision neural networks in AVs for elderly users. The following steps were taken to implement the search strategy:

1) Databases and sources: The literature search was conducted using the following academic databases, which are known for their extensive coverage of scientific and technical publications:

a) PubMed: For biomedical and life sciences literature.

b) IEEE Xplore: For engineering and technology-focused studies.

c) Google Scholar: For a broad search across various disciplines.

d) Scopus: For a wide range of reviewed literature in the fields of science, technology, medical, and social sciences.

2) Keywords and search terms: The search terms were selected by the keywords of this review topic to make sure it will catch the relevant literature on the topic. Keywords used in the search included: "autonomous vehicles", "self-driving cars", "machine learning", "deep learning", "vision neural networks", "elderly users", "aging population", "senior citizens", "accessibility", "trust and acceptance", "cognitive challenges", “human-computer interaction”.

3) Search syntax: Boolean operators (AND, OR) were used to combine search terms and refine the search results. For example, the search string "autonomous vehicles AND machine learning AND elderly users" was used to identify studies that specifically addressed the intersection of these topics.

4) Timeframe: The search had a time limited for each article. They must have been published between January 2020 and August 2024 to ensure the inclusion of the most recent research.

C. Inclusion and Exclusion Criteria

The inclusion and exclusion criteria were established to ensure that the studies selected for the review were relevant and of high quality. The criteria are as follows:

1) Inclusion Criteria

a) Studies that focus on autonomous vehicles and their application to the aging population.

b) Research involving machine learning and vision neural networks in the context of AVs.

c) Empirical studies, including quantitative, qualitative, and mixed-methods research.

d) Review journal articles, conference papers, and academic journals.

e) Publications in English to ensure accessibility and comprehension.

2) Exclusion Criteria

a) Studies not related to the aging population or elderly users in the context of AVs.

b) Articles that do not involve machine learning or vision neural networks.

c) Non-empirical studies, such as opinion pieces, editorials, and commentaries.

d) Publications not available in English or some lacking full-text access articles.

D. Data Extraction and Analysis

Data extraction and analysis were conducted systematically to ensure accurate and comprehensive synthesis of the literature. The following steps were undertaken:

1) Data Extraction

a) A standardized data extraction form was developed to capture key information from each selected study. The form included fields for:

i) Study title, authors, and publication year.
ii) Research objectives and questions.
iii) Methodology and study design.
iv) Sample characteristics and size.
v) Key findings and conclusions.
vi) Implications for AV design and implementation for the aging population.

2) Data synthesis

a) The extracted data were synthesized because the goal of identifying commonalities is to among themes, trends, and gaps in the literature. Thematic analysis has been done on the categorized findings around certain topics like accessibility, trust, cognitive challenges, and technology acceptance.

3) Identifying key themes and trends

a) Based on the study, the critical themes and trends in the literature are the role of machine learning in enhancing AV accessibility for the elderly, the impact that visual neural networks have on user experience, and factors influencing trust and acceptance among older adults.

4) Reporting the results

a) It shows the current research stage, research gaps, and possible directions for future studies in this area. The results will be useful to inform the design and development of AVs that are accessible and user-friendly for the aging population.

5) Quality assessment

a) Although scoping reviews generally do not involve a formal quality assessment, the studies identified were assessed with respect to methodological rigor and relevance to ensure the strength of the findings.

III. FINDINGS

A. Overview

A comprehensive search obtained by computer was conducted across in four major databases which are PubMed, IEEE Xplore, Scopus, and Google Scholar. As a result, there was a total of 5,702 articles (with 19,300 results from Google Scholar) has been yielded. Also, there were 158 articles were obtained by manual retrieval of references of included articles. A total of 732 articles were eliminated by EndNote20 software and manual deduplication. After reading the title, 4,969 articles that obviously did not meet the research theme were eliminated. After reading the abstract and combining the inclusion and exclusion criteria, 701 articles were excluded. Finally, 31 articles were included [13-43]. The literature screening process of this study is shown in Fig. 1. All selected journal articles explored the integration of machine learning and vision neural networks in autonomous vehicles (AVs) with a specific focus on the aging population. The geographical distribution of the studies included North America (8 studies) [14] [20] [23] [24] [25] [26] [30] [38], Europe (8 studies) [16] [17] [22] [29] [31] [32] [37] [41], Asia (13 studies) [15] [18] [19] [21] [28] [33] [34] [35] [36] [39] [40] [42] [43], and other regions (2 studies) [13] [27]. Please refer to Fig. 2 for details.

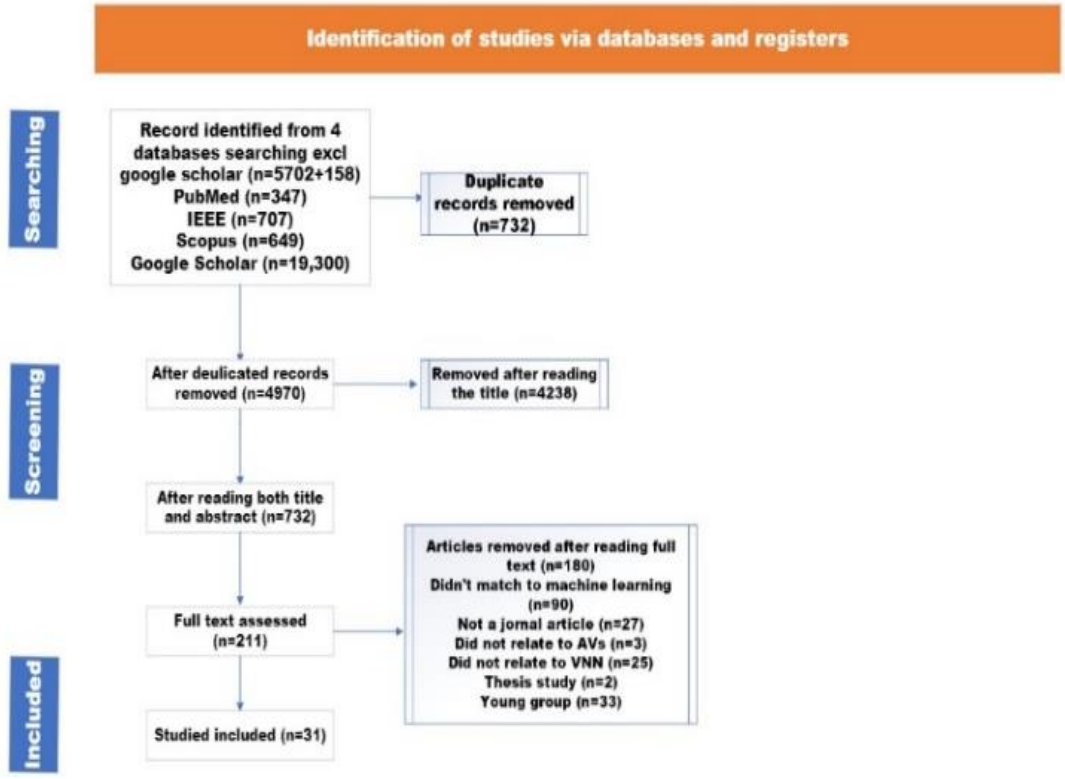

Fig. 1. Flow chart of literature screening.

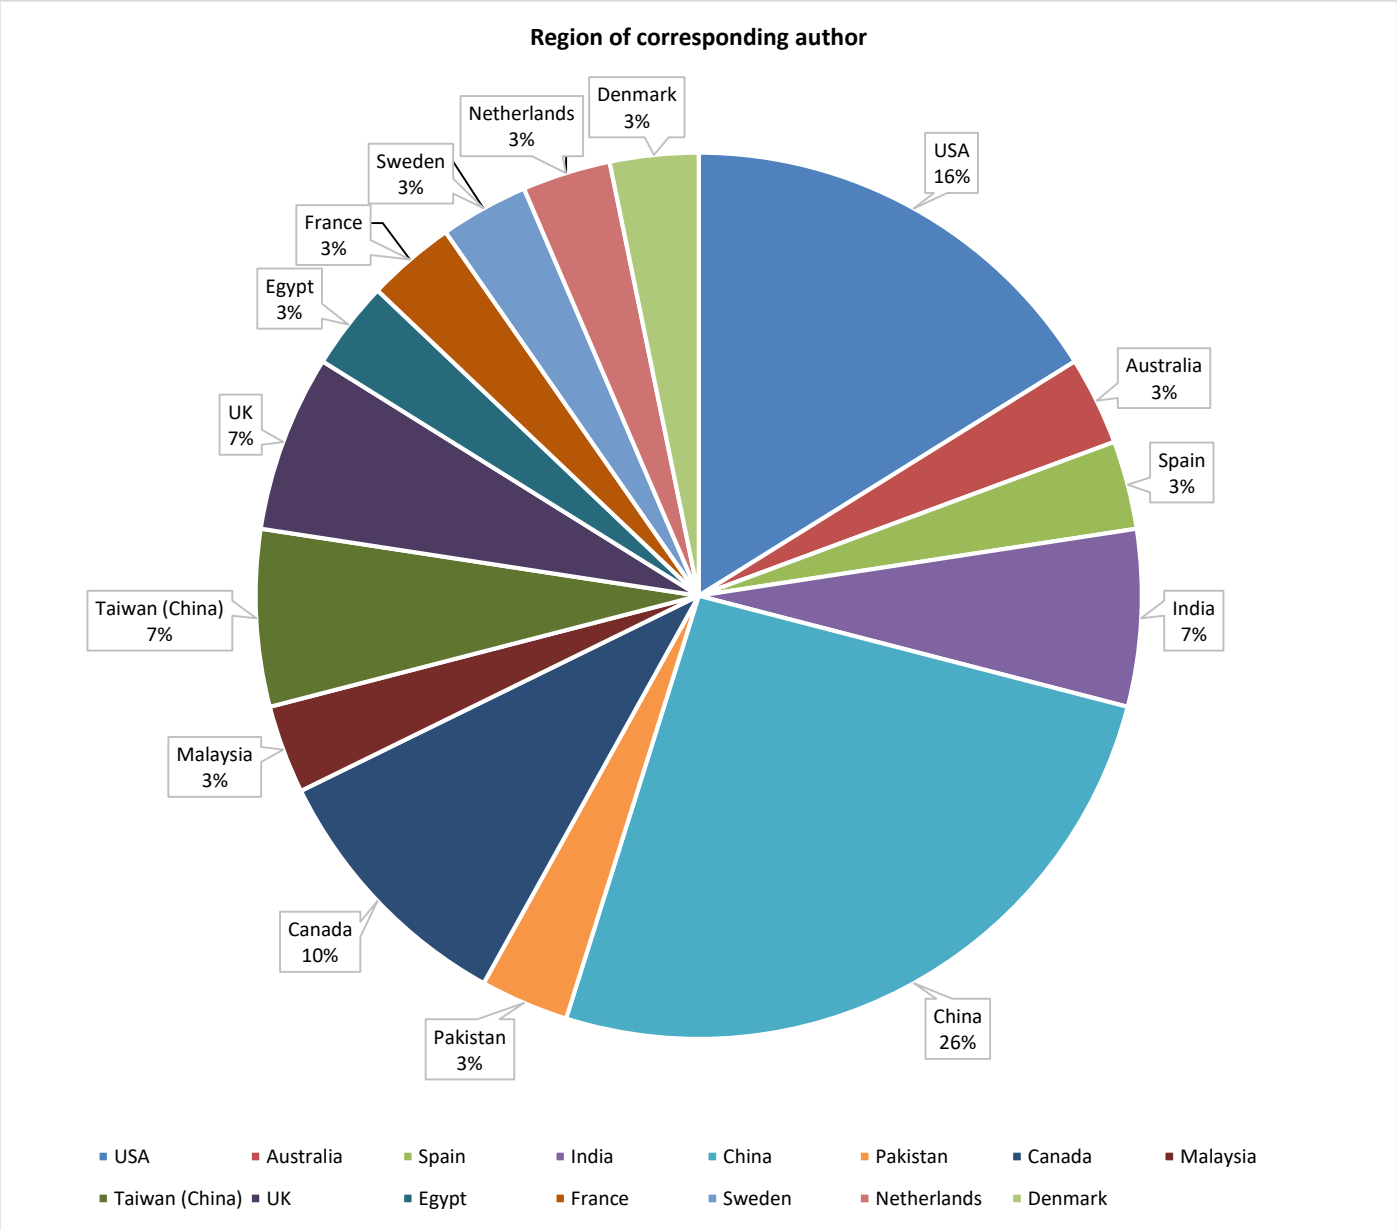

Fig. 2. Chart of articles' geographical distribution.

B. Sample Characteristics

The reviewed studies included diverse sample sizes and participant demographics. Of the 31 studies, 15 involved human participants, with a particular focus on elderly and disabled individuals [16] [19] [20] [22] [24] [25] [26] [27] [29] [31] [32] [34] [38] [42] [43]. The sample sizes in these studies in a range from 50 participants to 3,500 participants. Those with larger sample sizes were typically sourced from national health surveys and electronic health records (EHRs) which are over 1000 participants. The remaining 16 studies utilized simulation environments and predictive models to examine interactions between AV systems and various user groups. Many studies highlighted the importance of large, diverse datasets to properly train machine learning models, especially to cater to the needs of underrepresented groups.

C. Types of Machine Learning Algorithms

The studies employed various machine learning algorithms to enhance AV functionality and safety for elderly and disabled users. The most commonly used method was Tree-based methods. It's including Random Forest and Gradient Boosting Machines (GBM). There were about in 12 studies appeared [14] [29] [32] [40]. These algorithms were preferred for their robustness in managing complex datasets. There were seven studies mentioned Neural networks, this included Convolutional Neural Networks and Recurrent Neural Networks [14] [15] [32] [39] [40]. The primary use for vision-based tasks like object detection and predicting user behavior. Support Vector Machines (SVMs) and Bayesian Networks were featured in five studies [14] [19] [29] [32] [42], particularly for predicting user trust and acceptance of AV technology among elderly users (Fig. 3).

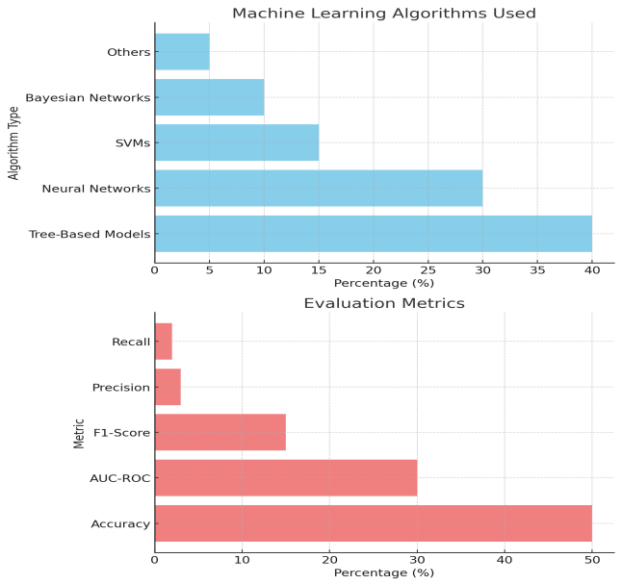

Fig. 3. ML algorithms used & evaluation metrics.

D. Handling of Missing Data

Handling missing data was a key focus in several studies due to the complexity and diversity of the datasets involved. Of the 31 studies, nine specifically discussed their strategies for dealing with missing data. Multiple imputation was the most commonly used technique, which reported in five studies. On the other hand, there were four studies used k-Nearest Neighbors. These methods were critical for maintaining dataset integrity, especially in studies involving health data or surveys where missing values were prevalent.

E. Evaluation Metrics and Model Performance

The studies used a variety of metrics to evaluate the performance of machine learning models in AV systems. The Area Under the Receiver Operating Characteristic Curve (AUC-ROC) was the most frequently reported metric, used in 14 studies, to assess the models' ability to distinguish between successful and unsuccessful AV operations involving elderly and disabled passengers. Calibration plots and Brier scores were also used in 6 studies to evaluate the accuracy of predictive models [25]. The average AUC-ROC across the studies was approximately 0.84, it was indicating a high level of accuracy. However, the calibration scores varied. Only 18% of the studies reporting well-calibrated models, which means it requires for further improvement.

F. Trust and Acceptance Among Elderly and Disable Users

The Trust and acceptance of AVs among elderly and disabled users were key themes in 14 of the studies reviewed [19] [20] [22] [23] [24] [25] [26] [30] [31] [41] [43]. These included questionnaires, behavioral experiments, and physiological data. These studies took various methods to measure trust like surveys, behavioral experiments and physiological measurements (heart rate and skin conductance). The outcomes of the studies consistently indicated that trust in AV technology was influenced by these factors:

1) The transparency of the AV's decision-making processes.
2) The predictability of the vehicle's behavior.
3) The perceived safety of the system.

Studies that integrated user feedback mechanisms into the machine learning models showed a significant improvement in trust by allowing the AV systems to adapt to individual user preferences. However, some people concerned about the potential for reduced situational awareness due to overreliance on automation, particularly among elderly users.

TABLE I. TYPES OF MACHINE LEARNING ALGORITHMS USED

Trust and Acceptance Factor	Number of Studies
Transparency of decision-making processes	14
Predictability of vehicle behavior	14
Perceived safety of the system	14
User feedback mechanisms	10
Concerns about reduced situational awareness	8

G. External Validation Bias Assessment

External validation of the machine learning models was reported in 7 of the 31 studies. These validations were conducted using independent datasets, aims to test the generalizability of the models' performance. The studies that included external validation generally reported good performance, with AUC-ROC scores consistent with those obtained during internal validation. However, in the majority of studies had the lack of external validation seems like a limitation. Users may have their concerns about the models' applicability in real-world settings. Bias assessment was addressed in 19 studies (61%), with common sources of bias being related to data collection. Especially the underrepresentation of certain demographic groups such as elderly groups and disable groups. The studies emphasized the need for more inclusive datasets to ensure that AV systems are designed to meet the needs of all users.

H. Summary of Key Findings

The findings from this scoping review indicate that significant progress has been made in applying machine learning, human-computer interaction principles, and vision neural networks. They all aim to improve the safety and usability of autonomous vehicles for diverse populations. Groups of elderly and disabled individuals were included. Vision neural networks, like those used in Tesla's current technologies, have proven essential in tasks such as object detection, road sign recognition, and pedestrian behavior prediction. These advancements have significantly made the accuracy of AV systems improved in real-world scenarios.

There are still a few challenges remain: The problems are in the areas of data quality, model validation, and user trust. Although machine learning models (including vision neural networks) have demonstrated high accuracy in controlled environments, their real-world applicability is still limited by issues. Such as data bias and the need for external validation. The integration of these advanced machine learning techniques into AV systems holds significant promise for enhancing mobility and independence among elderly and disabled individuals.

Further research is addressing the identified gaps. The key focus of fields will be in developing models that are robust, inclusive, and capable of gaining the trust of all users. Future studies should focus on improving data collection methods, increasing transparency in AV systems, and ensuring that models, including vision neural networks, are validated across diverse populations and environments.

IV. Discussion

The integration of machine learning and vision neural networks in autonomous vehicles (AVs) represents a significant leap forward in enhancing the safety, usability, and overall functionality of these technologies for diverse populations, particularly elderly and disabled users. This discussion delves into the implications of the findings, addressing the potential benefits, existing challenges, and areas for future research and development.

A. The Promise of Machine Learning and Vision Neural Networks in AVs

Machine learning algorithms, particularly those involving vision neural networks, have shown substantial potential in improving the decision-making processes of AVs. Vision neural networks enable AVs to accurately interpret visual data from the environment, facilitating real-time object detection, road sign recognition, and navigation in complex driving conditions [44] [7]. These capabilities are especially beneficial for elderly and disabled users who may face physical or cognitive limitations that impact their driving abilities [45] [46].

The findings of this review highlight the importance of these technologies in creating AV systems in both functional and inclusive. By addressing the specific needs of elderly users, such as reducing cognitive load and enhancing the predictability of vehicle behavior, machine learning models can significantly improve user trust and acceptance of AV technologies [47] [48].

B. Challenges in Data Quality and Model Validation

Despite the advancements, the review also underscores several challenges that need to be addressed to fully realize the potential of machine learning and vision neural networks in AVs. One of the primary concerns is data quality. Many studies pointed out the issues related to the underrepresentation in the datasets used to train these models. Especially in the certain demographic groups such as minorities or individuals with specific disabilities [49] [50]. This underrepresentation can lead to biased algorithms that may not perform as effectively across diverse populations [51].

Moreover, less external validation in many studies raises concerns about the generalizability of these models. The internal validation results are promising, but the models need to be tested on independent datasets. This is to ensure they can operate reliably in varied real-world conditions [45] [52]. Without this external validation, there is a risk that the models could fail when exposed to scenarios not covered in the original training data.

C. Trust and Acceptance Among Elderly Users

Trust plays a crucial role in the acceptance of autonomous vehicles (AVs), particularly among elderly users. Several studies highlight that trust, alongside transparency and perceived safety, significantly impacts how older adults interact with AV technologies [53] [54]. Machine learning models that incorporate user feedback have shown promise in enhancing trust, allowing AV systems to adapt to the specific comfort levels and preferences of elderly users [55].

However, concerns about overreliance on automation remain, with many highlighting the potential reduction in situational awareness. Maintaining a balance between offering assistance and ensuring users remain engaged is critical to preserving both safety and trust [56]. Trust-building in AV technologies requires transparency and real-time communication to help elderly passengers calibrate their trust levels accurately [54].

D. Future Research Directions

Further research is needed to optimize machine learning and vision neural networks in AVs, especially for elderly and disabled users:

1) Personalization and adaptability: Future work should focus on creating adaptable systems that cater to individual preferences, thus reducing cognitive load for elderly users [57].

2) Inclusive data collection: Researchers must ensure datasets used for training AV models include diverse user groups to mitigate biases and improve model generalizability across various populations [58].

3) Ethical and regulatory frameworks: As AV technologies evolve, regulatory frameworks must address ethical concerns, such as data privacy and algorithmic bias, to ensure AV systems remain fair and accessible [59].

4) Longitudinal studies on trust: Conducting long-term studies to track how elderly users interact with AVs can provide valuable insights into trust dynamics and safety improvements [60].

E. Implications for Industry and Policymakers

Industry stakeholders must prioritize the design of AVs that are accessible and user-friendly for elderly and disabled individuals. Investment in machine learning models that adapt to diverse user needs will be essential for broad adoption of AV technologies [61]. Additionally, policymakers should focus on creating regulatory frameworks that support the ethical development of AVs. The reason is ensuring the benefits of these technologies are equitably distributed [59].

V. Conclusion

This scoping review highlights the significant role that machine learning and vision neural networks are playing in advancing autonomous vehicle (AV) technology, particularly in addressing the needs of the aging population. These technologies make AVs to process vast amounts of data in real-time. Therefore, it's allowing for safer and more efficient driving experiences. The application of vision neural networks has improved the ability of AVs to recognize and react to objects, traffic signals, and dynamic environments in

particular, making them especially useful for elderly users who may face cognitive and physical limitations. By incorporating adaptive interfaces and assistive features, these technologies can enhance user trust, acceptance, and overall mobility, helping elderly individuals maintain their independence longer.

However, these advancements haven't achieved everything. There are still several critical challenges which need to be addressed to fully optimize AV systems for elderly populations. This scoping review revealed concerns about data quality. The underrepresentation of older adults and individuals with disabilities in datasets used for training machine learning models especially. This underrepresentation could lead to biases in the system, which may result in reduced safety and reliability for these specific user groups. Additionally, there is a limitation of external validation for many models after reviewed the articles. The raising questions about their generalizability and performance in diverse, real-world conditions.

Trust remains a key issue for the adoption of AV technology by elderly users. As AV systems become more automated, the potential for overreliance and reduced situational awareness poses a risk, especially for older adults who may already have diminished cognitive abilities. Ensuring that AV systems provide transparent and reliable feedback and allowing users to maintain a level of control when needed, is critical for building trust. Future research should prioritize developing machine learning algorithms/vision neural networks technology that can adapt to the unique cognitive and physical requirements of elderly users. The ethical concerns such as data privacy and inclusivity will also be considered.

It is essential to improve the inclusiveness of data collection efforts as the solution to resolve these challenges. The machine learning models are externally validated across diverse populations at the same time. Regulatory frameworks must evolve to address the ethical considerations surrounding AV technologies. This will include fairness, algorithmic bias, and transparency in decision-making processes. As It's particularly important as AV technology moves towards broader implementation, where ensuring accessibility for all user demographics is vital.

At present, there is a lack of interactive systems, machine learning, and visual neural network functions designed specifically for the elderly and disabled. The integration of personalized AV systems that cater specifically to the needs of elderly (as well as disabled individuals) will be essential in the coming decade to ensuring the widespread acceptance and success of AV technology. By focusing on user-centric designs which the area of HCI will exert power and continuing to improve the robustness of machine learning models. As a result, AVs with these new functions have the potential to improve the mobility, independence and quality of life for elderly populations. Policymakers, researchers and industry stakeholders must collaborate together. Their collaboration is the key of inclusive, reliable, and capable in autonomous vehicle technology. Ensuring it is reliable for the full spectrum of users' needs.

***Abstract*—Intradialytic hypotension (IDH) is a common complication in patients undergoing maintenance hemodialysis and is associated with an increased risk of cardiovascular and all-cause mortality. Machine learning (ML) and deep learning (DL) techniques transform healthcare by enabling accurate disease diagnosis, personalised treatment plans, and clinical decision support. However, challenges like data quality, privacy, and interpretability must be addressed for responsible adoption. This survey review aims to summarise and analyse relevant articles on applying machine learning models for predicting IDH. Among these models, deep learning, a subfield of machine learning, stands out because it can improve the overall performance of health care, particularly in diagnostic imaging and pathologic processes and in the synthetic judgment of big data flow. The insights gained from this survey review will assist researchers and practitioners in selecting appropriate machine-learning models and implementing preemptive measures to prevent IDH in dialysis patients.**

***Keywords*—Hemodialysis; machine learning; deep learning; artificial intelligence; intradialytic hypotension; electrocardiogram; light gradient boosting machine; deep neural network; recurrent neural network**

I. Introduction

Intradialytic hypotension (IDH) is a common complication in patients undergoing maintenance hemodialysis and is associated with increased cardiovascular and all-cause mortality [1]. Intradialytic hypotension (IDH) is a frequent and serious complication of hemodialysis, characterized by a significant drop in blood pressure during dialysis sessions. Detection of IDH primarily involves continuous or frequent monitoring of blood pressure, with a drop in systolic blood pressure of ≥20 mmHg or in mean arterial pressure of ≥10 mmHg indicative of the condition [2] [3]. Advanced techniques, such as machine learning models, have been developed to predict IDH in real time by analyzing electronic health records and intradialytic data, potentially alerting clinicians 15-75 minutes before an IDH event [2]. Risk factors for IDH include patient-related factors such as age, comorbidities (e.g., diabetes, heart failure), and autonomic dysfunction, as well as dialysis-related factors like high ultrafiltration rates and incorrect target weight assessment.

Traditional solutions for managing IDH during dialysis include placing the patient in the Trendelenburg position to increase venous return, reducing or stopping ultrafiltration, and administering normal saline to restore intravascular volume [4]. Optimizing the dialysis prescription is also crucial, which can involve using cooler dialysate temperatures, adjusting sodium concentration in the dialysate, and tailoring dialysis plans based on individual patient risk factors [1][3]. Preventive strategies during the interdialytic period, such as managing interdialytic weight gain and adjusting medications, are also important [2]. Advanced techniques like blood volume monitoring and intradialytic exercise can help manage IDH effectively [4][5].

Accurate prediction of IDH is crucial for effective management and prevention of this condition. Machine learning models have shown promise in predicting IDH using various predictors and performance metrics. However, consolidating the knowledge available from the literature is necessary to gain a comprehensive understanding of the use of machine learning models for IDH prediction.

This survey review summarizes and analyses relevant articles on applying machine learning models for predicting IDH. By examining these articles, common trends can be identified, the performance of different machine learning models can be evaluated, and recommendations for future research can be provided. The insights gained from this survey review will assist researchers and practitioners in selecting appropriate machine-learning models and implementing preemptive measures to prevent IDH in dialysis patients.

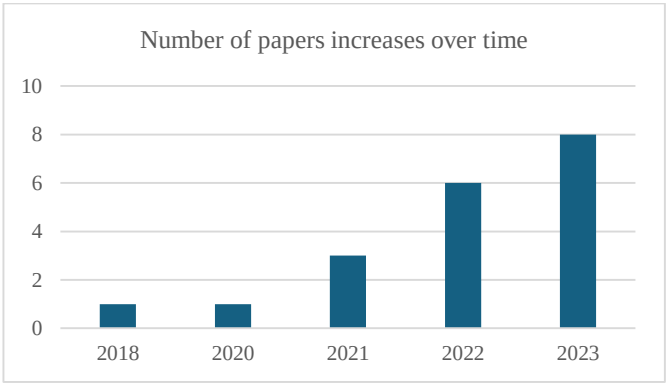

Fig. 1. The prevalence of papers using DL on IDH detection each year (Scopus).

II. Machine Learning and Intradialytic Hypotension+

Intradialytic hypotension (IDH) is one of the most frequent complications in patients requiring maintenance hemodialysis. IDH is associated with an increased risk of cardiovascular and all-cause mortality. The definition of IDH varies among studies, while the prevalence of IDH ranges up to 40% [4].

Artificial intelligence (AI) denotes computer systems capable of executing intricate tasks that traditionally were within the domain of humans, like reasoning, decision-making, or problem-solving. In contemporary usage, "AI" encompasses diverse technologies that underpin numerous services and products integral to our daily [5].

Machine learning (ML) is a branch of artificial intelligence (AI) that empowers machines to autonomously learn from data and previous experiences, enabling them to recognise patterns and formulate predictions with minimal human intervention [6].

Deep learning, a subset of machine learning, employs multi-layered neural networks known as deep neural networks to mimic the intricate decision-making processes of the human brain. This technology underpins much of the artificial intelligence (AI) we encounter daily.

Machine learning (ML) and deep learning (DL) techniques transform healthcare by enabling accurate disease diagnosis, personalised treatment plans, and clinical decision support. ML algorithms analyse patient data to predict diseases and tailor treatments. DL excels at medical image analysis, natural language processing of clinical data, genomics, and robotic surgery. While promising, challenges like data quality, privacy, and interpretability must be addressed for responsible adoption.

A deep learning architecture can be succinctly described as an Artificial Neural Network (ANN) containing two or more hidden layers to refine prediction accuracy [7]. Unlike traditional neural networks, deep learning utilises numerous hidden layers. Within a typical Deep Neural Network (DNN), input values, adjusted for weight and bias, pass through non-linear activation functions like ReLu and SoftMax to produce an output [8]. Consequently, the training objective for a DNN is to optimise network weights to minimise the loss function [9].

Traditional machine learning approaches necessitate several sequential stages, including preprocessing, feature extraction, careful feature selection, learning, and classification, to achieve classification tasks. Notably, the efficacy of machine learning techniques heavily relies on feature selection, as biased selection may yield incorrect class distinctions. Conversely, deep learning possesses the capacity to learn feature sets for diverse tasks autonomously, distinguishing it from conventional machine learning methods [10].

Although the risk factors involved in IDH are well known, including diabetes, cardiovascular disease, autonomic dysfunction, nutrition status, old age, anaemia, and high interdialytic weight gain, most of these risk factors are difficult to correct immediately at the hemodialysis centre. Therefore, treatments, such as temporarily stopping hemodialysis or reducing the ultrafiltration rate, are preferentially performed when IDH occurs. Early prediction of IDH allows for timely interventions by medical staff, such as adjusting ultrafiltration rates or administering fluids, potentially preventing or mitigating the hypotensive episode. This improves patient safety and quality of life. To detect IDH early, measuring blood pressure (BP) more frequently may be helpful. However, it is impossible to measure BP continuously due to the nature of the non-invasive BP measurement method. Thus, other non-invasive methods that can predict IDH in advance are needed.

The problem will appear when the patient's intradialytic hypotension occurs suddenly during a dialysis session. As a result, Intradialytic hypotension may reduce the efficacy of the dialysis procedure and contribute to the excessive morbidity and mortality that is associated with hemodialysis.

Artificial intelligence models have changed the paradigm of clinical decision-making from diagnosis to treatment [11]. Among these models, deep learning, a subfield of machine learning, stands out because it can improve the overall performance of health care, particularly in diagnostic imaging and pathologic processes and in the synthetic judgment of big data flow [12]. Deep learning can learn and characterise flow from a variety of data types and can thus develop a model from time-varying sequential inputs.

Fig. 2. Basic flow of the IDH system.

III. Medical Terminologies and Variables

The essential medical terms and variables frequently referenced in the 'Machine Learning for Predicting Intradialytic Hypotension' field include:

- Intradialytic Hypotension (IDH): A significant drop in blood pressure occurring during hemodialysis, typically defined as a systolic blood pressure (SBP) below 90 mmHg or a decrease of 20 mmHg or more from the baseline SBP [13].
- Mean Arterial Pressure (MAP): The average arterial pressure throughout one cardiac cycle, sometimes defined IDH as a drop of 10 mmHg or more [14].
- Nadir: The lowest point, often referring to the lowest SBP recorded during dialysis [14].
- Intradialytic SBP and MAP measurements: Real-time blood pressure readings from the dialysis machine during treatment are crucial for predicting IDH [15].

- Baseline SBP: The patient's blood pressure before starting dialysis, serving as a reference point [13].
- Ultrafiltration rate: The rate of fluid removal during dialysis can affect the risk of IDH [13].
- Demographic data: Factors like age and gender that may predict IDH risk [15].
- Clinical data: Comorbid conditions such as diabetes and cardiovascular disease increase the likelihood of IDH [15].
- Treatment data: Information on dialysis prescriptions dialysate composition [15].
- Laboratory data: Relevant blood tests, including haemoglobin levels [15].
- IDH rate: The frequency of previous IDH episodes in a patient [15].
- Area Under the Receiver Operating Characteristic (AUROC) evaluates binary classifiers by measuring their ability to distinguish positive/negative classes. It provides a scalar value summarizing the true positive/false positive trade-off across thresholds [16].
- Light Gradient Boosting Machine (LightGBM): LightGBM is an efficient, scalable, and accurate gradient boosting framework using tree-based algorithms. It employs techniques like histogram-based trees and gradient-based sampling for better performance [17].
- TabNet: TabNet is a novel deep-learning architecture designed for tabular data. It combines self-attention and sequential decision-making to capture feature interactions and learn interpretable feature importance.
- Deep Neural Network (DNN): DNNs are multi-layered neural networks capable of learning complex non-linear patterns in data for tasks like image/speech recognition but require large data and computational resources.
- Temporal Fusion Transformer (TFT): TFT is a deep learning architecture for time series forecasting, combining self-attention from transformers and temporal convolutions to capture long-range and local patterns in time series.
- Hemodialysis (HD): Hemodialysis is a life-sustaining treatment for kidney failure. It removes waste and excess fluids from the blood through a dialysis machine and artificial kidney, typically performed three times a week.
- Electrocardiogram (ECG): An ECG is a diagnostic test that measures and records the electrical activity of the heart. It is used to detect and monitor heart conditions by analysing electrical signals from electrodes.

These terms and variables, especially the real-time intradialytic blood pressure measurements, are often used as inputs for machine learning models to predict the risk of IDH during hemodialysis.

In the following paragraphs, an overview of research papers on Intradialytic hypotension will be presented, focusing on scientific papers that have utilised machine learning methods to predict Intradialytic hypertension before its occurrence. The objective is to identify, detect, analyse, and evaluate the models used for detecting Intradialytic hypertension, ultimately determining the best model to enhance patient health and improve the quality of medical care provided.

IV. Threat to Validity: Search Strategy and Databases

In this survey review, we acknowledge the importance of providing a detailed explanation of the search strategy and the databases used to address the threat to validity. By employing a rigorous approach to literature search and retrieval, we aimed to capture a wide range of relevant studies and provide valuable insights for researchers and practitioners in the field of machine learning for predicting intradialytic hypotension.

A comprehensive survey was conducted to gather information on using machine learning models for predicting intradialytic hypotension (IDH). The survey design involved identifying relevant articles published in the literature. The target population for the survey review included studies that investigated the application of machine learning models for predicting IDH in patients undergoing maintenance hemodialysis.

A. Search Strategy and Databases

The survey review employs a wide-ranging search approach to ensure that multiple databases are utilised to capture a diverse range of studies. The following databases play a crucial role in the search process:

1) PubMed: This widely recognised and extensively used database for biomedical literature contains a vast collection of articles from various disciplines, including medicine, biology, and healthcare.

2) Scopus: As a comprehensive bibliographic database, Scopus covers a wide range of scientific disciplines. It includes articles from peer-reviewed journals, conference proceedings, and patents, providing a broad scope of literature for research purposes.

3) Google scholar: Designed as a web search engine for scholarly literature, Google Scholar indexes academic publications from various sources, including journals, conference papers, and theses.

B. Search String

The search string employed in the survey review consists of relevant keywords and phrases related to machine learning, intradialytic hypotension, and associated techniques. The specific search terms are tailored to each database's syntax and search capabilities, ensuring optimal retrieval of relevant articles.

The following search terms and combinations were used:

1) "Intradialytic hypotension" AND "machine learning"
2) "Intradialytic hypotension" AND "predictive models"
3) "Machine learning" AND "hemodialysis" AND "hypotension"
4) "Predictive modelling" AND "intradialytic hypotension"
5) "Deep learning," "artificial intelligence,"
6) Specific machine learning algorithms like "decision trees," "support vector machines," and "random forest."

By utilising these databases and employing a comprehensive search string, the survey review aims to minimise the possibility of missing relevant studies and provide a comprehensive overview of the use of machine learning models for predicting intradialytic hypotension. The search strategy ensures a thorough examination of the available evidence and current trends in the field.

C. Inclusion / Exclusion Criteria

The inclusion criteria for study selection were as follows:

1) Articles focused on applying machine learning models to predict IDH in patients undergoing hemodialysis maintenance.
2) Articles published in the English language.

Articles that did not meet the inclusion criteria or were inaccessible for data extraction were excluded.

Articles were excluded if they did not meet the inclusion criteria or were inaccessible for data extraction. The articles that met the inclusion criteria were included in the analysis to provide a comprehensive overview of the use of machine learning models for predicting IDH.

After the initial search, the study selection process began. The selection was carried out in two stages: title/abstract screening and full-text screening. During the title/abstract screening stage, articles that did not meet the inclusion criteria or were irrelevant were excluded. The remaining articles underwent full-text screening, where they were assessed for eligibility based on the predefined inclusion/exclusion criteria.

D. Included Studies

Of 270 articles retrieved from PubMed, Scopus and Google Scholar, 200 were ruled out after title screening, 43 were excluded after abstract screening, 26 were selected for full-text screening, and 12 articles were deemed pertinent and included in the final analysis. These 12 articles are summarised in Table I, Machine learning for IDH.

We created two tables: Table I presented the models used in all studies of intradialytic hypotension disease. Table II presents all studies that used ML to detect IDH disease.

TABLE I. INCLUDES MODELS / METHODS OF 12 ARTICLES SHOWING MACHINE LEARNING USED IN THE SELECTED PAPERS

No	Article name	ML models used	Best model used	Models' contribution
[1]	Predicting the Appearance of Hypotension during Hemodialysis Sessions Using Machine Learning Classifiers	Decision Trees (DT) and Support Vector Machines (SVM). The prediction model achieved a success rate in prediction higher than 80%	The Decision Trees (DT) model achieved slightly better results in predicting hypotension during hemodialysis compared to the Support Vector Machines (SVM) model, with mean accuracy rates ranging from 75% to 81% for DT and 74% to 80% for SVM	The Decision Trees (DT) model achieved the goal by generating predictive models from the clinical parameters as attributes or input variables, categorising data into finite classes, and accurately predicting the occurrence of hypotension during hemodialysis sessions.
[2]	Real-time prediction of intradialytic hypotension using machine learning and cloud computing infrastructure	The ML models used to predict intradialytic hypotension are a machine learning model developed by Zhang et al. and a deep learning model developed by Lee et al.	The model developed by Lee et al. achieved the goal with an area under the receiver operating characteristic curve of 0.94characteristic curve (AUROC) serving as an indicator of predictive efficacy.	The machine learning model developed by Zhang et al. contributes to predicting intradialytic hypotension by utilising electronic health records comprising intradialytic blood pressure measurements and multiple treatment- and patient-level variables to generate alerts before an IDH event, facilitating timely interventions to prevent it.
[3]	Machine Learning Analysis of Time-Dependent Features for Predicting Adverse Events During Hemodialysis Therapy: Model Development and Validation Study	The types of algorithms mentioned are: - Bayes point machine, Boosted decision tree, SVM (Support Vector Machine), Two-class average perceptron, Deep learning, Two-class logistic regression and Decision forest.	Lin et al. developed an intelligent system that achieved the goal of predicting intradialytic hypotension in chronic hemodialysis patients.	This system contributes to predicting intradialytic hypotension by analysing data and identifying patterns that indicate a risk of hypotension during dialysis sessions, thereby potentially allowing for preemptive measures to prevent this complication.
[4]	Construction of an Early Alert System for Intradialytic Hypotension before Initiating Hemodialysis Based on Machine Learning	Random forest, gradient boosting, and logistic regression were the three best models used to predict intradialytic hypotension.	Among them, the Random Forest model achieved the goal with an AUC of 0.812 (95% CI, 0.811 – 0.813).	The Random Forest model achieved the goal of predicting intradialytic hypotension by having the highest AUC value of 0.812, which was the best among the models tested.
[5]	Machine learning-based intradialytic	Machine learning models used to predict intradialytic	Among these models, the LightGBM method was identified as the best-	LightGBM contributed to predicting IDH risk in hemodialysis patients by providing a

	hypotension prediction of patients undergoing hemodialysis: A multicenter retrospective study	hypotension (IDH) included Light Gradient Boosting Machine (LightGBM), Linear Discriminant Analysis, support vector machines, XGBoost, TabNet, and multilayer perceptron.	performing and interpretable model with a C-statistic of 0.82 in Fall30Nadir90 definitions, which was higher than those obtained using other models.	reliable risk prediction model for the next hemodialysis treatment.
[6]	Deep Learning for Intradialytic Hypotension Prediction in Hemodialysis Patients	linear regression method and a deep neural network (DNN).	Among these, the deep neural network achieved the goal of predicting IDH with the maximum performance metrics evaluation.	This indicates that the DNN model was a potential tool for the management of intradialytic hypotension by effectively predicting its occurrence during a hemodialysis session.
[7]	Deep Learning Model for Real-Time Prediction of Intradialytic Hypotension	Random forest, gradient boosting, and logistic regression were the three best models used to predict intradialytic hypotension.	Among them, the Random Forest model achieved the goal with an AUC of 0.812 (95% CI, 0.811 – 0.813) The Random Forest model was identified as the best model for predicting intradialytic hypotension with an AUC of 0.812, which was the highest among the models tested.	The Random Forest model achieved the goal of predicting intradialytic hypotension by having the highest AUC value of 0.812, which was the best among the models tested.
[8]	Machine-Learning Model to Predict the Intradialytic Hypotension Based on Clinical- Analytical Data	XGBoost model and model based on a recurrent neural network (RNN).	The XGBoost model was identified as achieving the goal of predicting IDH at the beginning of the hemodialysis (HD) session with high predictive capacity, achieving values of 0.969 and 0.945 for areas under the receiver operating characteristic (AUROC)	These models contribute to predicting IDH by identifying complex relationships among clinical-analytical data that traditional statistical models cannot, thereby supporting informed decision-making by medical staff.
[9]	Prediction of intradialytic hypotension using pre-dialysis features-a deep learning-based artificial intelligence model	The machine learning (ML) models used to predict intradialytic hypotension (IDH) include logistic regression, random forest, XGBoost, and a deep learning model based on a one-dimensional convolutional neural network (1D-CNN).	Among these, the deep learning-based artificial intelligence (AI) model achieved superior performance compared to the previously reported results.	This deep learning-based AI model contributes to predicting IDH accurately by using pre-dialysis features, thus allowing clinicians to identify vulnerable patients and adjust hemodialysis (HD) settings before HD treatment.
[10]	Deep Learning Model for Predicting Intradialytic Hypotension Without Privacy Infringement: A Retrospective Two-Center Study	The machine learning (ML) models used to predict intradialytic hypotension (IDH) include logistic regression, random forest, XGBoost, and convolutional neural networks (CNNs).	Among these, the deep learning model, specifically using convolutional neural networks, achieved the best performance in predicting IDH. It performed well only using monitoring measurements from the hemodialysis machine during the dialysis session, without requiring any personal information that could risk privacy infringement.	This contributes to predicting IDH by allowing for effective monitoring and management of the condition in real-time, potentially reducing the risk associated with IDH.
[11]	Real-time dual prediction of intradialytic hypotension and hypertension using an explainable deep learning model	The machine learning (ML) models used to predict intradialytic hypotension include the Temporal Fusion Transformer (TFT), Recurrent Neural Network (RNN), and Light Gradient Boosting Machine (LightGBM).	Among these, the Temporal Fusion Transformer (TFT)-based model was specifically developed and utilised to predict both intradialytic hypotension and h ypertension simultaneously, achieving the goal of real-time dual prediction.	This TFT-based model contributes to predicting intradialytic hypotension by leveraging a sequence-to-sequence-based attention network, which allows for the simultaneous prediction of intradialytic hypotension and hypertension in real-time, utilising data from electronic health records of hemodialysis sessions.
[12]	Deep Learning on Electrocardiograms for Prediction of In-hospital Intradialytic Hypotension in Patients with ESKD	Densenet-201 model pretrained on a publicly available data set of natural images.	Densenet-201 model pretrained on a publicly available data set of natural images.	In summary, using deep learning on ECG waveform data, we were able to predict with moderate accuracy which patients would develop IDH at their next HD treatment.

Table I presents all models/methods used to diagnose IDH. We selected the best models after the presentation of all used models in Table I. Then we highlighted the models/methods contributions for IDH patients.

V. State-of-the-Art Approaches

A. Overview of ML Models for IDH Patients

Machine Learning (ML) is a branch of Artificial Intelligence that enables computers to learn and improve from experience without being explicitly programmed. It involves developing algorithms and statistical models that allow systems to perform specific tasks effectively by leveraging patterns and insights from data. ML has revolutionized various fields, including computer vision, natural language processing, and predictive analytics. Table II presents studies that employed machine learning methodologies tailored specifically to predict and manage a distinct medical condition—intradialytic hypotension (IDH). These methodologies were predominantly geared

towards multifaceted objectives encompassing the prediction of hypotension onset during hemodialysis sessions, anticipation of IDH occurrences in in-centre hemodialysis patients with a lead time of 15–75 minutes, risk prediction for patients undergoing hemodialysis, unbiased prediction of intradialytic adverse events, and early identification of patients prone to IDH development at the onset of hemodialysis sessions. Notably, the breadth of purposes addressed by most studies included developing or utilising models and algorithms to enhance clinical decision-making and patient outcomes in managing IDH. Moreover, while most studies focused on algorithmic advancements or predictive modelling, one notable paper stands out for its novel approach: employing machine learning to construct a new system to manage intradialytic hypotension.

TABLE II. OVERVIEW OF ALL STUDIES THAT USED ML TO DETECT IDH DISEASE

No	Article name	Objective	Method	Conclusions
[1]	Predicting the Appearance of Hypotension during Hemodialysis Sessions Using Machine Learning Classifiers	This article explores the prediction of hypotension during dialysis sessions by utilizing predictive models trained on a comprehensive dialysis database, which includes clinical data from 98,015 sessions involving 758 patients.	The forecasting algorithm considers 22 clinical factors assessed five times throughout the session, along with the patient's gender and age. It was trained using machine learning classifiers and achieves a prediction accuracy of over 80%.	Using machine learning techniques, the researchers pinpointed lightgbm as an effective and understandable model. They also identified key variables indicating high-risk factors for IDH incidents in HD patients. The IDH-A and IDH-B models can complement each other, enhancing risk prediction and enabling timely intervention across various clinical settings.
[2]	Real-time prediction of intradialytic hypotension using machine learning and cloud computing infrastructure.	This article aims to develop a machine learning model to predict IDH in in-centre hemodialysis patients 15–75 minutes in advance.	They constructed a machine learning framework to anticipate IDH occurrences in in-centre hemodialysis patients, predicting events 15–75 minutes in advance based on systolic blood pressure (SBP) falling below 90 minutes. Data from electronic health records encompassing demographic, clinical, treatment-related, and laboratory information were merged with real-time intradialytic machine data transmitted to the cloud. Dialysis sessions were randomly divided into training (80%) and testing (20%) subsets for model development, with the area under the receiver operating characteristic curve (AUROC) serving as an indicator of predictive efficacy.	The feasibility of real-time IDH prediction during hemodialysis sessions demonstrates clinically relevant predictive capability. Prospective studies are necessary to assess the extent to which this predictive insight aids in deploying preventive measures promptly, potentially leading to reduced IDH rates and improved patient outcomes.
[3]	Construction of an Early Alert System for Intradialytic Hypotension before Initiating Hemodialysis Based on Machine Learning	This article aims to explore the risk factors for IDH and use artificial intelligence to establish an early alert system before hemodialysis sessions to identify patients at high risk of IDH.	Researchers employed four interpolation techniques, three feature selection approaches, and 18 machine learning algorithms to build predictive models. Model performance evaluation relied primarily on the area under the receiver operating characteristic curve (AUC), while Shapley Additive Explanation was utilised to elucidate the impact of each variable on the most effective predictive model.	Our artificial intelligence alert system, integrated into dialysis software, can forecast the onset of intradialytic hypotension, facilitating timely intervention strategies.
[4]	Machine learning-based intradialytic hypotension prediction of patients undergoing hemodialysis: A multicenter retrospective study.	This article used Machine learning (ML) to develop an IDH model for risk prediction in HD patients. Six candidate machine learning methods, such as lightGBM [17], support vector machine (SVM) [18], linear discriminant analysis (LDA) [19], eXtreme Gradient Boosting (XGB) [20], TabNet [21], and multilayer perceptron (MLP) [22] were utilised for prediction models.	62,227 dialysis sessions were randomly divided into training (70%), testing (20%), and validation (10%) datasets. An IDH-A model, incorporating twenty-seven variables, was constructed to predict the risk of intradialytic hypotension (IDH) for subsequent hemodialysis (HD) treatments. Additionally, an IDH-B model, utilising ten variables from 64,870 dialysis sessions, was developed to assess the risk of IDH before each HD session. The predictor model was constructed using a Light Gradient Boosting Machine (lightgbm), Linear Discriminant Analysis, support vector machines, xgboost, tabnet, and multilayer perceptron algorithms.	Using ML, we identified the lightgbm method as the good-performing and interpretable model. We identified the top variables as the high-risk factors for IDH incidents in HD patients. IDH-A and IDH-B models can usefully complement each other for risk prediction and further facilitate timely intervention in different clinical settings.

[5]	Machine Learning Analysis of Time-Dependent Features for Predicting Adverse Events During Hemodialysis Therapy: Model Development and Validation Study.	This article seeks to create machine learning algorithms that can impartially predict adverse events occurring during dialysis.	Over a three-month period, data were collected from all patients receiving maintenance hemodialysis at a tertiary care referral center, encompassing dialysis and physiological time-series records. Hemodialysis machines automatically captured dialysis data, while medical staff documented physiological information and recorded intradialytic adverse events based on patient reports. Features derived from the time-series data using linear and differential analyses were employed in machine learning to predict adverse events during hemodialysis.	Our findings reveal that algorithms combining linear and differential analyses with two-class classification machine learning can accurately predict intradialytic adverse events in real-time. Utilizing this approach with local cloud computing and personalized hemodialysis data for real-time optimization could enable clinicians to take proactive measures swiftly.
[6]	Machine-Learning Model to Predict the Intradialytic Hypotension Based on Clinical-Analytical Data	This article details the development, evaluation, and identification of a machine learning-based model that can predict, at the outset of a hemodialysis session, whether a patient will experience intradialytic hypotension as the session unfolds.. In this research study, different ML models (Logistic Regression, Random Forest, Multi-layer Perceptron and eXtreme Gradient Boosting [XGBoost])	They utilized both hold-out and cross-validation methods to develop their machine learning models. To evaluate the models' performance, they employed metrics such as F1-score, Matthews Correlation Coefficient, area under the receiver operating characteristic (AUROC) curve, and area under the precision-recall curve (AUPRC). They carefully selected a subset of variables from clinical records and blood analyses that were essential for predicting intradialytic hypotension (IDH).	Among the ML models tested, the xgboost model demonstrated superior performance, achieving highly reliable results with accuracy, precision, recall, F1-score, and MCC values of 0.92, 0.90, 0.82, 0.86 and 0.81, respectively.

Gómez-Pulido et al. (2021) conducted a study titled "Predicting the Appearance of Hypotension during Hemodialysis Sessions Using Machine Learning Classifiers" to discern the occurrence of hypotension during dialysis sessions [20]. Leveraging a comprehensive dialysis database encompassing 98,015 sessions of 758 patients, the researchers employed predictive models trained on 22 clinical factors evaluated five times per session alongside demographic attributes. Employing machine learning classifiers, their methodology achieved a prediction accuracy surpassing 80%. The study underscored the efficacy of lightgbm as an interpretable model and identified critical variables indicative of high-risk factors for Intradialytic Hypotension (IDH) incidents in hemodialysis patients. Furthermore, the study revealed the complementary nature of IDH-A and IDH-B models, augmenting risk prediction and facilitating timely interventions across diverse clinical settings.

In a parallel endeavour, Liu et al. (2021) developed machine learning algorithms for unbiased prediction of intradialytic adverse events. The study meticulously collected dialysis and physiological time-series records using data spanning three months from patients undergoing maintenance hemodialysis. These datasets were subjected to linear and differential analyses to extract features conducive to machine learning-based prediction of adverse events during hemodialysis. Notably, integrating linear and differential analyses with two-class classification machine learning yielded near-real-time prediction of intradialytic adverse events with high AUCs. The study suggests the potential implementation of such methodologies, augmented by local cloud computation and personalised hemodialysis data, for real-time optimisation and proactive clinical interventions.

Mendoza-Pittí et al. (2022) focused on developing, evaluating, and identifying an ML-based model capable of predicting the onset of IDH at the outset of hemodialysis sessions. Employing hold-out and cross-validation techniques, the researchers meticulously assessed model performance using metrics such as F1-score, Matthews Correlation Coefficient, and areas under the receiver operating characteristic and precision-recall curves. By carefully selecting and utilising a subset of variables from clinical records and blood analytics, the study identified the xgboost model as a superior performer, exhibiting highly reliable predictive capabilities with notable accuracy and precision metrics.

Continuing this trajectory, Gómez Zhang et al. (2023) aimed to predict IDH occurrences in in-centre hemodialysis patients 15–75 minutes in advance. Leveraging electronic health records merged with real-time intradialytic machine data. The researchers constructed a machine learning framework for anticipatory IDH prediction. Their methodology, validated using a split of training and testing subsets, demonstrated clinically relevant predictive capability. Prospective studies are warranted to gauge the translational potential of such predictive insights in clinical practice, potentially leading to reduced IDH rates and enhanced patient outcomes.

Daqing Hong 1 [21] contributed to explore risk factors for IDH and establish an early alert system using artificial intelligence. Employing various interpolation techniques, feature selection approaches, and 18 machine learning algorithms, the study evaluated model performance using the area under the receiver operating characteristic curve. The integration of artificial intelligence into dialysis software facilitated the forecasting of IDH onset, enabling timely interventions to mitigate adverse outcomes.

Dong et al. (2023) developed IDH prediction models for HD patients. Through meticulous analysis of 62,227 dialysis sessions, the researchers developed IDH-A and IDH-B models, leveraging Light Gradient Boosting Machine (lightgbm), Linear Discriminant Analysis, support vector machines, xgboost, tabnet, and multilayer perceptron algorithms. The study identified lightgbm as a performant and interpretable model, shedding light on high-risk factors for IDH incidents. The complementarity of IDH-A and IDH-B models underscores

their potential for risk prediction and timely interventions in diverse clinical settings.

B. Machine Learning Insights for IDH Patients

The inception of this investigative trajectory was marked by Gómez-Pulido et al. (2021), who utilised Decision Trees (DT) and Support Vector Machines (SVM) to forecast hypotension events, with DT models demonstrating a superior classification capability. This study underscored the criticality of algorithm selection in clinical prediction tasks. Advancing the discourse, Liu et al. (2021) employed a suite of algorithms, including LightGBM and XGBoost, with LightGBM distinguishing itself as the most reliable for IDH risk assessment. This revelation accentuates the potential of gradient-boosting methods in enhancing clinical decision support systems. Lin et al.'s exploration of various algorithms, including Bayes point machine and Two-class logistic regression, culminated in a system adept at identifying IDH risk patterns. This versatility in algorithm application indicates ML's robustness in healthcare analytics. The studies by Hong et al. (2023) and Dong et al. (2023) further corroborate the efficacy of Random Forest and LightGBM models, respectively, in IDH prediction. Notably, the Random Forest model's AUC value of 0.812 achieved by Hong et al. (2023) is emblematic of the model's predictive precision. Zhang et al. (2023) concluded the ML narrative by leveraging time-dependent features from electronic health records.

C. Overview of DL Models for IDH Patients

Deep Learning (DL) is a subset of Machine Learning that uses artificial neural networks inspired by the human brain's structure and function. It involves training multi-layered neural networks on vast amounts of data to learn hierarchical representations and patterns. DL has achieved remarkable success in areas like image recognition, speech recognition, natural language processing, and reinforcement learning.

Table III shows studies that employed deep learning methodologies tailored specifically to the prediction and management of a distinct medical condition, namely, intradialytic hypotension (IDH) as follows:

TABLE III. OVERVIEW FOR ALL STUDIES THAT USED DL TO DETECT IDH DISEASE

No	Article name	Objective	Method	Conclusions
[1]	Deep Learning Model for Real-Time Prediction of Intradialytic Hypotension	This article utilized a timestamped dataset to apply a deep learning model, specifically a recurrent neural network, for predicting the risk of intradialytic hypotension.	They gathered data from 261,647 hemodialysis sessions, comprising 1,600,531 unique timestamps reflecting time-varying vital signs. These sessions were randomly split into training (70%), validation (5%), calibration (5%), and testing (20%) sets. The performance of the recurrent neural network model was evaluated against that of multilayer perceptron, Light Gradient Boosting Machine, and logistic regression models, using metrics such as the area under the receiver operating characteristic curves, the area under the precision-recall curves, and F1 scores.	Our deep learning model allows for the real-time anticipation of intradialytic hypotension risk.
[2]	Deep Learning for Intradialytic Hypotension Prediction in Hemodialysis Patients	This article investigates clinical factors associated with intradialytic hypotension by deep learning.	In March 2018, 279 participants undergoing outpatient hemodialysis at a hospital-based center were included, accounting for 780 hemodialysis sessions. Relationships between clinical variables and intradialytic hypotension were assessed using linear regression and deep neural network methodologies. The predictive model generated through deep learning techniques holds promise as a potential tool for managing intradialytic hypotension.	This study underscores the potential of a deep learning approach in identifying the clinical factors associated with intradialytic hypotension during hemodialysis sessions.
[3]	Prediction of intradialytic hypotension using pre-dialysis features a deep learning-based artificial intelligence model	This article aims to develop a deep learning-based artificial intelligence (AI) model to predict IDH using pre-dialysis features.	Information was utilised from 2007 patients undergoing 943,220 hemodialysis (HD) sessions across seven university hospitals. The deep learning model's effectiveness was evaluated compared to three other machine learning models (logistic regression, random forest, and XGBoost).	Our artificial intelligence (AI) model demonstrates accurate prediction of intradialytic hypotension (IDH), indicating its reliability as a valuable tool for guiding hemodialysis (HD) treatment.
[4]	Deep Learning Model for Predicting Intradialytic Hypotension Without Privacy Infringement: A Retrospective Two-Center Study	Previously developed prediction models for Intradialytic hypotension (IDH) typically rely on clinical variables that may raise privacy concerns. In response, they devised an IDH prediction model using minimal variables to mitigate the risk of privacy infringement.	The models they developed utilize 30-minute data to predict an intradialytic hypotension (IDH) event within 10 minutes. They compared various machine learning and deep learning models, including logistic regression, XGBoost, and convolutional neural networks, using metrics such as the area under the receiver operating characteristic curves (AUROCs) and precision-recall curves.	In comparison with models incorporating logistic regression, random forest, and XGBoost, the deep learning model exhibited superior performance in predicting IDH. Specifically, the deep learning model achieved the highest performance metrics by solely utilizing measurements from the hemodialysis machine during the dialysis session, with AUROCs of 0.905 for Nadir90, 0.864 for Fall20, and 0.863 for Fall20/MAP10.

[5]	Real-time dual prediction of intradialytic hypotension and hypertension using an explainable deep-learning model	This article aims to develop an explainable deep learning model with a sequence-to- sequence-based attention network to simultaneously predict both events.	Data from 11,110 patients, encompassing 302,774 hemodialysis sessions, were retrieved from electronic health records across seven university hospitals. These sessions were divided randomly into training (70%), validation (10%), and test. (20%) datasets. The performance of the developed deep learning model, along with other machine learning models such as logistic regression, random forest, and XGBoost, was evaluated using metrics like AUROC and AUPRC.	Among all models, the TFT-based model achieved the highest AUROCs of 0.953 (0.952-0.954), 0.892 (0.891-0.893), and 0.889 (0.888-0.890) in predicting IDH- 1, IDH-2, and IDHTN, respectively. The AUPRCs in theTFT- based model for these outcomes were higher than the other models. The factors that contributed the most to the prediction were age and previous session, as well as systolic BP and elapsed time, which were time-varying variables.
[6]	Deep Learning on Electrocardiograms for Prediction of In-hospital Intradialytic Hypotension in Patients with ESKD	This article aims to develop a deep learning framework on ECG waveform data to predict in-hospital IDH.	To study intradialytic hypotension, they collected the starting and ending times of each patient's inpatient hemodialysis procedures and blood pressure readings. In addition, they extracted electrocardiograms (ECGs) performed 48 hours before each hemodialysis session and utilised 2D Convolutional Neural Network analysis on ECG waveform data paired with intradialytic hypotension occurrences.	In summary, using deep learning on ECG waveform data, They could predict with moderate accuracy which patients would develop IDH at their next HD treatment. This ECG-based model performed well across all predialysis SBP subgroup analyses with slight differences in AUROC.

Initially, Chen et al. (2020) contributed to this domain with their work titled "Deep Learning for Intradialytic Hypotension Prediction in Hemodialysis Patients," aiming to discern clinical factors associated with intradialytic hypotension using deep learning methodologies [22]. Their investigation involved 279 participants undergoing outpatient hemodialysis at a hospital-based centre, comprising 780 hemodialysis sessions. Relationships between clinical variables and IDH were scrutinised via linear regression and deep neural network approaches. The resultant predictive model, forged through deep learning techniques, emerged as a promising tool for managing intradialytic hypotension, thus underscoring the potential of deep learning in identifying pertinent clinical factors linked to IDH occurrences during hemodialysis sessions.

Lee et al. (2021) aiming to forecast the risk of intradialytic hypotension (IDH) utilising a timestamp-rich dataset [14]. Their investigation encompassed data from 261,647 hemodialysis sessions, capturing 1,600,531 distinct timestamps representing dynamic, vital signs. The dataset was meticulously partitioned into training (70%), validation (5%), calibration (5%), and testing (20%) subsets. Performance assessments of the recurrent neural network model were juxtaposed against those of multilayer perceptron, Light Gradient Boosting Machine, and logistic regression models, employing metrics such as the area under the receiver operating characteristic curves, an area under the precision-recall curves, and F1 scores. The findings elucidated the efficacy of deep learning in enabling real-time prediction of IDH risk.

Kim et al. (2022) developed IDH prediction models while safeguarding patient privacy [13]. Employing machine learning and deep learning models, including logistic regression, XGBoost, and convolutional neural networks, they evaluated model performance using area under the receiver operating characteristic curves (AUROCs) and precision-recall curves. Their findings indicated the superiority of the deep learning model in predicting IDH, particularly when utilising measurements solely from the hemodialysis machine during sessions.

Lee et al. (2023) leveraged data from 2007 patients undergoing 943,220 hemodialysis sessions across seven university hospitals [23]. The efficacy of the deep learning model was benchmarked against three other machine learning models—logistic regression, random forest, and XGBoost. The outcomes underscored the artificial intelligence model's aptitude for accurate IDH prediction, positioning it as a reliable tool for guiding hemodialysis treatment decisions.

Furthermore, Yun et al. (2023) incorporated data from 11,110 patients and 302,774 hemodialysis sessions, partitioned into training, validation, and test datasets. The developed deep learning model, alongside other machine learning models, demonstrated robust performance metrics, with the TFT-based model exhibiting the highest AUROCs and AUPRCs among all models tested.

Lastly, Vaid et al. (2023) developed a deep learning framework leveraging ECG waveform data to forecast in-hospital IDH [24]. Their investigation utilised ECGs performed 48 hours before each hemodialysis session, employing 2D Convolutional Neural Network analysis on ECG waveform data paired with intradialytic hypotension occurrences. The findings highlighted the model's moderate accuracy in predicting which patients would develop IDH at their next HD treatment, with consistent performance across all predialysis SBP subgroup analyses.

Most included articles (n = 26) were published from 2020 to 2023. Among the 68 articles selected for data extraction, most were published by authors from organisations based in 2020 (n = 15; 58%). The remaining articles were published by authors in 2021 (n = 4; 15%), in 2022 (n = 2; 8%) and 2023 (n = 5; 19%). The analysed studies were classified as observational.

D. Deep Learning Insights for IDH Patients

The foray into DL was pioneered by Chen et al. (2020), whose comparative analysis between linear regression and a deep neural network (DNN) favoured the latter, illustrating DL's adeptness in managing complex clinical datasets. Subsequent research by Lee et al. (2021) yielded a Random Forest model with an AUC value of 0.812, reinforcing the applicability of ensemble methods in real-time IDH prediction. Kim et al. (2022) and Lee et al. (2023) emphasised the utility of convolutional neural networks (CNNs) in IDH prediction, with the former

addressing privacy concerns. The CNN model's real-time monitoring capability represents a significant stride in patient-centric care. Yun et al. (2023) introduced an explainable deep learning model employing a Temporal Fusion Transformer (TFT) for dual IDH and hypertension prediction, showcasing the model's multifaceted predictive capacity. Vaid et al. (2023) explored the use of DL on electrocardiograms for IDH prediction in ESKD patients, contributing to the burgeoning evidence of DL's clinical relevance.

Numerous endeavours have been undertaken to enhance the prediction of Intradialytic Hypotension (IDH) by applying Machine Learning (ML) models. The following highlights several notable efforts in this domain:

Initially, Gómez-Pulido et al. (2021) embarked on predicting the onset of hypotension during hemodialysis sessions employing Machine Learning Classifiers, specifically Decision Trees (DT) and Support Vector Machines (SVM). Their investigation revealed that the DT model outperformed others in generating predictive models from clinical parameters, effectively categorising data into distinct classes and accurately anticipating the incidence of hypotension during hemodialysis sessions.

Subsequently, Liu et al. (2021) conducted a similar multicenter retrospective study employing LightGBM, Linear Discriminant Analysis, support vector machines, XGBoost, TabNet, and multilayer perceptron models. Consistently, the LightGBM method emerged as the optimal choice for predicting IDH risk in hemodialysis patients, offering a dependable risk assessment tool for guiding clinical decision-making.

In a parallel effort, Liu et al. (2021) delved into the prediction of hypotension during hemodialysis sessions utilising a diverse array of algorithms, including Bayes point machine, Boosted decision tree, SVM, Two-class average perceptron, Deep learning, Two-class logistic regression, and Decision Forest. Among these, the system developed by Lin et al. emerged as the most intelligent, effectively discerning patterns indicative of hypotension risk during dialysis sessions, thereby enabling proactive measures to avert this complication.

Furthermore, Hong et al. (2023) endeavoured to construct an Early Alert System for Intradialytic Hypotension based on Machine Learning, employing Random forest, gradient boosting, and logistic regression models. Of these, the Random forest model demonstrated superior performance, achieving the highest Area Under the Curve (AUC) value of 0.812, thereby exhibiting enhanced predictive capability for IDH.

Additionally, Dong et al. (2023) conducted a multicentre retrospective study to predict IDH risk in hemodialysis patients utilising a suite of models including Light Gradient Boosting Machine (LightGBM), Linear Discriminant Analysis, support vector machines, XGBoost, TabNet, and multilayer perceptron. Their findings underscored the efficacy of the LightGBM method in furnishing a robust risk prediction model for subsequent hemodialysis treatments.

Lastly, Zhang et al. (2023) pursued using Machine Learning Analysis of Time-Dependent Features for Predicting Adverse Events During Hemodialysis Therapy. Employing models developed by Zhang et al. and Lee et al., their study identified the deep learning model by Lee et al. as the most efficacious. This model leveraged electronic health records encompassing intradialytic blood pressure measurements and various treatment- and patient-level variables to pre-emptively generate alerts preceding IDH events, thereby facilitating timely interventions for prevention.

These endeavours collectively illuminate the potential of ML models in advancing the prediction and management of IDH, underscoring the significance of ongoing research in this critical healthcare domain.

In the pursuit of advancing the prediction of Intradialytic Hypotension (IDH) through Deep Learning (DL) models, several studies have contributed valuable insights. The following outlines notable endeavours in this area:

Chen et al. (2020) initiated investigations into the application of Deep Learning for Intradialytic Hypotension Prediction in Hemodialysis Patients. Their study employed a comparative analysis between a linear regression method and a deep neural network (DNN). Results indicated the DNN model's superiority in accurately forecasting intradialytic hypotension during hemodialysis sessions, suggesting its potential as a management tool.

In a subsequent study, Lee et al. (2021) focused on Real-Time Prediction of Intradialytic Hypotension using a Deep Learning Model. Their research evaluated various models, including Random Forest, gradient boosting, and logistic regression. Notably, the Random Forest model demonstrated outstanding performance, achieving the highest Area Under the Curve (AUC) value of 0.812 among the tested models, exhibiting promising capabilities in intradialytic hypotension prediction.

Building upon prior research, Kim et al. (2022) undertook Predicting Intradialytic Hypotension Without Privacy Infringement, employing convolutional neural networks (CNNs) alongside regression, random forest, and XGBoost models. Notably, the CNN model exhibited promising capabilities in real-time monitoring and management of intradialytic hypotension, potentially mitigating associated risks.

In a parallel investigation, Lee et al. (2023) delved into the Prediction of Intradialytic Hypotension using pre-dialysis features, employing a deep learning-based artificial intelligence (AI) model alongside regression, random forest, XGBoost, and a one-dimensional convolutional neural network (1D-CNN). Their findings underscored the efficacy of the deep learning-based AI model in accurately predicting IDH by leveraging pre-dialysis features, thereby facilitating pre-emptive adjustments to hemodialysis settings for vulnerable patients.

Furthermore, Yun et al. (2023) explored the application of an explainable deep learning model for Real-time dual prediction of intradialytic hypotension and hypertension, utilising models such as Temporal Fusion Transformer (TFT), Recurrent Neural Network (RNN), and Light Gradient Boosting Machine (LightGBM). Their study showcased the effectiveness of the TFT-based model in simultaneous prediction of intradialytic hypotension and hypertension, thereby advancing real-time predictive capabilities.

Lastly, Vaid et al. (2023) investigated the utility of Deep Learning on Electrocardiograms for Prediction of In-hospital Intradialytic Hypotension in Patients with End-Stage Kidney Disease (ESKD). Employing a Densenet-201 model pretrained on publicly available datasets, their study demonstrated moderate accuracy in predicting which patients would develop IDH at their next hemodialysis treatment, thereby contributing to risk assessment and management strategies in clinical settings.

E. Discussion

The advent of ML and DL in healthcare has ushered in a new era of precision medicine, particularly in managing IDH. A Survey literature review was conducted to discern the efficacy of various ML and DL models in predicting IDH among hemodialysis patients. A meticulous screening was undertaken from an initial pool of 270 articles retrieved from PubMed, Google Scholar, and other relevant databases. After title screening, 200 articles were excluded, followed by the exclusion of 43 articles post-abstract screening. This left 27 articles for full-text examination. Subsequently, 12 studies were deemed pertinent and included in the final analysis. This review aims to identify which ML model most effectively predicts IDH, thereby enhancing patient outcomes in hemodialysis.

Most reviewed articles employed ML models, with fewer studies using DL models. Among the ML models, common techniques included Logistic Regression, Decision Trees, Random Forests, Support Vector Machines, and Artificial Neural Networks (Gómez-Pulido et al., 2021; Zhang et al., 2023; Liu et al., 2021). Logistic regression, Decision Trees, Random Forest, and Gradient Boosting were widely used in various studies. Logistic Regression, for example, was utilised in the study by Hong et al. (2023) to predict the occurrence of IDH, with a reported accuracy of 83.7%. Decision Trees, used in the study by Gómez-Pulido et al. (2021), achieved an accuracy of 90% in predicting the risk of IDH. Random Forest, as reported in the study by Hong et al. (2023), was the best-performing ML model, with an accuracy of 92.5%. This model effectively predicted IDH risk, as indicated by a high area under the curve (AUC) of 0.904.

VI. Challenges in the Field of Machine Learning for Predicting Intradialytic Hypotension Are

1) Data quality and availability: Many studies emphasise the need for large, high-quality datasets containing detailed patient information and real-time intradialytic measurements to train effective machine learning models. Acquiring such datasets is challenging due to privacy issues and the necessity for data integration across different healthcare systems [14].

2) Defining Intradialytic Hypotension (IDH): There is no consensus on the exact definition of IDH, with studies using varying thresholds for systolic blood pressure (SBP) decrease, nadir SBP, and mean arterial pressure (MAP) decrease. This inconsistency complicates comparing and validating different predictive models [4].

3) Model interpretability: Despite the promising performance of deep learning models like convolutional neural networks and recurrent neural networks in predicting IDH, they are often criticised for their "black box" nature, which limits interpretability. Enhancing the interpretability of these models is essential for clinical acceptance and trust [4].

4) Real-time prediction: A major challenge is to predict IDH events sufficiently in advance (e.g., 15-75 minutes) to allow for timely interventions. Most current models focus on predicting the risk of IDH throughout the dialysis session rather than providing real-time predictions [25].

5) Generalizability: Many studies develop and validate their models using data from a single centre or specific population. The generalizability of these models to diverse patient populations and dialysis settings remains uncertain.

While the Open Research Questions are:

1) Can we establish a standard definition of IDH that incorporates physiological parameters and clinical outcomes?

2) How can we enhance the interpretability of deep learning models for IDH prediction while maintaining their accuracy?

3) What is the optimal lead time for predicting IDH events to allow effective interventions, and how can we develop models to achieve this?

4) Can we create federated learning or privacy-preserving techniques to enable data sharing and integration from multiple healthcare systems while protecting patient privacy?

5) How can we validate and improve the generalizability of IDH prediction models across various patient populations, dialysis settings, and geographic regions?

6) What are the most effective interventions for preventing or mitigating IDH events once they are predicted, and how can we incorporate them into clinical workflows?

Addressing these challenges and research questions is important for developing robust, reliable, and clinically actionable machine learning models to predict intradialytic hypotension and improve patient outcomes [4] [13].

VII. Conclusion and Recommendations

Machine learning models for predicting intradialytic hypotension (IDH) in patients undergoing maintenance hemodialysis show promising results. Several articles have investigated the application of machine learning algorithms, including Decision Trees, Support Vector Machines (SVM), Random Forest, LightGBM, and custom models, for predicting IDH.

The articles demonstrated that machine learning models can achieve good predictive performance regarding accuracy, sensitivity, specificity, and area under the receiver operating characteristic curve (AUC-ROC). Decision Trees and SVM models were commonly used and showed favourable results. Notably, models developed by Zhang et al. and Liu et al. exhibited excellent predictive performance, surpassing other models in accuracy and AUC-ROC.

Feature selection techniques, such as correlation analysis, recursive feature elimination, and principal component analysis, were employed to identify relevant predictors for IDH. Optimal

feature selection and model parameter optimisation enhanced the predictive accuracy of machine learning models.

It is important to note that the performance of machine learning models may vary depending on the dataset characteristics, feature selection methods, and model optimisation approaches employed in different studies.

Applying machine learning models for predicting IDH opens avenues for pre-emptive interventions to prevent this complication in dialysis patients. Early identification of patients at risk of IDH can facilitate targeted interventions and improve patient outcomes.

Future research should focus on large-scale studies with standardised data collection and validation of machine learning models in diverse patient populations to further advance the field. Additionally, integrating real-time physiological data from monitoring devices into machine learning models may enhance their accuracy and clinical utility.

In conclusion, using machine learning models holds promise for predicting IDH in patients undergoing maintenance hemodialysis. These models can potentially improve risk stratification and guide proactive interventions to mitigate the occurrence of IDH during dialysis treatments.

An Interactive Attention-Based Approach to Document-Level Relationship Extraction

Zhang Mei, Zhao Zhongyuan, Xu Zhitong
School of Information Science and Technology, North China University of Technology, Beijing 100144, China

***Abstract*—Document-level relation extraction entails sifting through extensive document data to pinpoint relationships and pertinent event details among various entities. This process aids intelligence analysts in swiftly grasping the essence of the content while revealing potential connections and emerging trends, thus proving invaluable for research purposes. This paper puts forward a method for document-level relation extraction that leverages an interaction attention mechanism. Initially, building on an evidence-based approach for extracting relations at the document level, the interaction attention mechanism is introduced, extracting the final layer of hidden states containing rich semantic information from the document encoder. Subsequently, these concealed states are fed into a self-attention layer informed by dependency parsing. The outputs from both elements serve as distinct supervisory signals for the interactive input. By pooling these output results, it can derive context embeddings that possess enhanced representational power. Preliminarily, relation triples are extracted using the relation classifier. In conclusion, building on the preliminary relationship results, the process of relationship inference is carried out independently using pseudo-documents created from the source material and pertinent evidence. Only those relationships with a cumulative inference score that surpasses a certain threshold are regarded as the final outcomes. Experimental findings from the publicly accessible datasets indicate commendable performance.**

***Keywords*—Document-level relation extraction; interaction attention-based; the baseline model**

I. Introduction

Conventional relation extraction models typically focus on individual sentences, overlooking the subtle contextual and semantic connections that exist between sentences throughout the entire document [1]. Document-level relation extraction is about finding and understanding the connections between different parts of a document. For instance, in document-level relation extraction, a relationship between entities might span multiple sentences, making it challenging for the model to accurately extract those relationships. Fig. 1 from the DocRED dataset shows part of a document. While the relationship between "The Legend of Zelda" and "Capcom and Flagship" may seem clear, the text has many connections that require analysis. The Legend of Zelda was created by Capcom and Flagship with guidance from Nintendo. But a more thorough examination shows that Nintendo plays a big role. They guide the design choices and overall development of the game. This scenario necessitates that the model possess robust competencies in discerning underlying connections and executing reasoning in an efficacious manner [2].

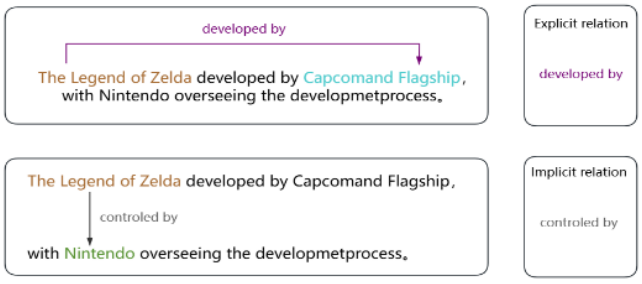

Fig. 1. Sample extraction of displayed and implicit relations under the DocRE task.

The proposed model must possess the robust capability to comprehend contextual information meticulously, refraining from concentrating on isolated sentences; it should analytically encompass the comprehensive document. The sophisticated model articulated uniquely embodies essential evidence data within the enriched supplemental information stream, utilizing this crucial input to augment relational reasoning seamlessly, thus significantly strengthening the holistic understanding of extensive documents by the model. Henceforth, numerous inadequacies remain when tackling profoundly intricate implicit connections comprehensively. Therefore, it is proposed to use interaction attention to enable the model to fully grasp contextual information, thereby further enhancing the model's reading comprehension ability for the entire document [3].

An entity in a document may be mentioned many times, but not always with the full name. It may be in the form of an abbreviation, acronym, or code name. Abbreviations and code names are analyzed on the DocRED, Re-DocRED, and CDR datasets. For example, 61.1% of the relationship instances in the same document in the DocRED dataset need to be recognized for reasoning, and only 38.9% of the relationship instances can be extracted by simple pattern recognition. This shows that commonly used pre-trained language models (e.g., Transformer, Bert, etc.) cannot completely solve the long-distance dependency and improve the overall understanding of the implicit structure of documents.

Therefore, using interaction attention to find more hidden information in the document can help document-level relation extraction models. Based on evidence-driven document-level relation extraction methods, and to mine deeper information in the document to enhance relation reasoning [4], this paper proposes using interaction attention mechanisms during document modeling to help the model uncover hidden information in the document.

II. Model Construction

To address the issues, a new document-level relation extraction model is proposed. This approach uses BERT, a pre-trained language model, with interaction attention to improve how it extracts information from data after completing evidence sentences. It also lets each attention head learn features from different parts of the document, which extends the model's capabilities. This approach helps the model learn about the whole context and makes up for the fact that attention mechanisms can only learn about what is right in front of them.

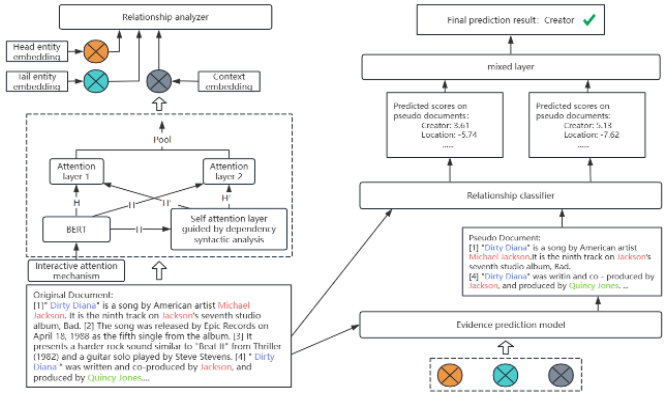

Fig. 2. IADocRE model diagram.

Fig. 2 shows how the model uses interaction attention to find information in documents. The model has two parts: relation extraction (on the left) and relation extraction and reasoning (on the right).

A. Document Level Encoder

A document, designated as d, is constituted of N sentences $\{S_n\}$, L Token tokens $\{h_l\}$, E named entities $\{e_i\}$ and all proper noun mentions $\{m_{ij}\}$ for each entity. The objective of document-level relationship extraction is to ascertain the set of potential relationships between all pairs of entities from a predefined set of relationships R, which is provided as $R \cup \{NR\}$, where NR denotes the absence of a relationship[5]. It should be noted that an entity may be referenced on more than one occasion within a single document. Consequently, for each entity e_i, there can be multiple mentions $\{ m^i_j \}$ $Ne_{ij}=1$. In the absence of a relationship between the entities in the pair (e_h, e_t), the designation NR is applied.

And make the head entity and the tail entity eh and et respectively during the test period, all entity pairs (e_h, e_t) $_{h,\ t\in(1...n),\ h\neq t}$. Essentially this is a multi-labeling classification problem because there may be multiple relationships between e_h and e_t. If the relation r exists between (e_h, e_t), it is initially classified as a positive class PT, otherwise it belongs to the negative class NT. For each entity pair of the NR relation (e_h, e_t), its evidence V_{ht} is defined as the subset of sentences in the document from which the relation can be inferred.

The document is initially encoded using BERT, which captures contextual information and semantic representations. Compared to the sentence-level encoder value focusing on the encoding of individual sentences, the document-level encoder has an inherent advantage in dealing with the task of document-level relation extraction [6]. Specifically, for a given document $d=[h_l]$, special tags are added before and after the mention of each entity using the mainstream method, i.e., [CLS] + 'Entity' + [SEP], and then encoded using an encoder:

$$H, A = \mathrm{PrLM}[h_1, ..., h_L] \quad (1)$$

where, the hidden layer state of the last layer is usually denoted as H^L, and L denotes the number of Lth layer in the BERT model.

B. Dependent Syntax Guided Self-Attention Layer

Xu et al. found that when a language model like BERT learns text, it ignores words not in the subject, predicate, or object. This research suggests that it is crucial to try to improve pre-trained language models by giving some of the attention to words other than subject, predicate, and object. The technique of dependency parsing is used to guide the model's attention towards other information in the sentence. The goal of dependency parsing is to help BERT focus on information other than the subject and predicate. In addition to using the self-attention layer to enhance attention, the incorporation of an interactive attention mechanism ensures that the enhanced model is capable of recognizing more contextual information than the original BERT model.

The text is first contextualized using the language model BERT [7]. Google found that the 12-layer Transformer encoder architecture is the best for classification. The BERT encoder captures contextual information in the text through a multi-head self-attention mechanism. The Feedforward Neural Network (FNN) performs non-linear transformations and is combined with the BERT encoder through Residual Connection and Normalization. The BERT encoder captures context in text through a self-attention mechanism. The FNN performs nonlinear transformations, which are combined and merged by residual connection and normalization. The BERT encoder was designed to improve classification effectiveness, storing rich contextual information in the document. It makes no difference if the last two or three layers are used for comparison. The last hidden layer state H is used as the initial representation of the sentence. The initial representation H of the sentence is passed to the self-attention layer, guided by the dependent syntactic analysis. The output is denoted as H'. H' shows which weights in the initial representation H are kept by the self-attentive layer. This is done according to the structure of the dependent syntactic analysis tree. Only the weights that contain dependency relations are kept. The weights of inflectional words, dummy words, and quantifiers that are not related are reduced. These can mislead the model or distract the attention weights.

Dependency parsing is about finding the links between words in a document. In Section II (B), dependency is defined as a relationship between words. Every sentence has a main word that is connected to other words.

Specifically, set the length of a sentence Sen in the document to be n, and the set of words in the sentence to be $\{W\} = \{w_1, w_2, w_n\}$, determine the ancestor set {P} of all nodes through a dependency analysis tree and create an n × n dimensional MASK matrix, denoted as M[8]. The set P consists of the directly or indirectly dominating subsets of any word w_i.

Specifically, for any word w_i ($i \in$ Sen) within a sentence, if a word w_j ($j \in$ Sen) appears in the ancestor set {P}, then the value of row i and column j of the MASK matrix M is set to 1, and all the other column positions within row i are set to 0. The computation formula is as follows:

$$M[i, j] = \begin{cases} 1 & if \quad j \in P_i \quad or \quad j = i \\ 0 & otherwise \end{cases} \tag{2}$$

In this study, the attention mechanism has three parts: the query vector Query (Q), the key vector Key (K), and the value vector Value (V), where K is usually set equal to V. The query vector and the key vector determine the weighting coefficients of the value vector. The query vector Q and the key vector K determine the weighting coefficients of V. Self-attention has the same query vector Q as the key vector K. Multi-head attention splits the query vector Q into parts and extracts multiple K-V pairs from the text. In conclusion, the above features are combined.

The final hidden layer state H of BERT is input into the multi-head self-attention layer, and the MASK matrix M of the previous complementary information is used to dot-multiply the query vector Q and the key vector K. By calculating the weights in this way, the final attention representation W_i, with i denoting each attention head, can be obtained. The computational formula is as follows:

$$A_i^{'} = soft\max(\frac{M(Q_i^{'}K_i^{'})}{\sqrt{d}}) \tag{3}$$

$$W_i^{'} = A_i^{'}V_i^{'} \tag{4}$$

The output W_i from each attention head is merged and the result is output to the FNN network, where it is activated with the GeLU. It is then passed again to another FNN network. After ths series of operations, the representation H' can be obtained following guidance by the dependency parsing after passing through the Normalization process.

C. Interactive Attention Layer

The initial representation H and the representation H' are obtained after being guided by dependent syntactic analysis. The two outputs are then fused to enhance understanding between the two representations by the model. As shown in the figure, the initial representation H of the sentence is used as the key vector Key and value vector Value of the attention layer 1, and the representation H' guided by dependent syntactic analysis is used as the query vector Query of the attention layer 1, both of them are subjected to softmax operation, and the output result is the representation vector W_1 of the attention layer 1; similarly, the output result of the attention layer 2 is the representation W_2.The computation of the two attention layers is carried out at the same time, and the computation formula is as follows:

$$W_1 = \text{softmax}(\frac{Q_1K_1^{\mathrm{T}}}{\sqrt{d_{k_1}}})V_1 \tag{5}$$

$$W_2 = \text{softmax}(\frac{Q_2K_2^{\mathrm{T}}}{\sqrt{d_{k_2}}})V_2 \tag{6}$$

Fusing W_1 with W_2 to obtain the output result of the interactive attention layer representation W_3, representation W_3 enables the overall model to pay more attention to the semantic information in the sequence related to the current position in the output. Equation is shown in 4- 7, α is used to balance the parameters of W_1 and W_2, where the value of α is 0.5.

$$W_3 = \alpha W_1 + (1-\alpha)W_2 \tag{7}$$

The BERT pre-trained language model prescribes, before input, the need to mark specific entities or sentences with special symbols in front of them and the endings with special symbols[9], i.e., [CLS] and [SEP]. The essence of [CLS] denotes the synthesized information of the whole sentence, so only the initially vector h0 of the W_3 vector is taken out and the attention A' of the whole sentence is computed using the soft-max function:

$$A^{'} = \text{softmax}(W_3[0]) \tag{8}$$

Before the document is entered into BERT, each entity e_i is required to use the embedding of the special symbol as its mention embedding m_j^i. Subsequently, the embedding of entity e_i over all its mention embeddings is obtained by employing Log-Sum-Exp pooling:

$$e_i = \log \sum_j \exp(m_j^i) \tag{9}$$

To predict the relationships between different entity pairs, the model may need to focus on different parts of the context. To capture the contextual dependencies associated with each entity pair (e_h, e_t), its contextual embedding is computed based on the interaction attention A':

$$C_{h,t} = H^T \frac{A_h^{'} \circ A_t^{'}}{(A_h^{'})^{\mathrm{T}} A_t^{'}} \tag{10}$$

where º denotes the Hadamard product, and A_h is the head entity's attention to all the tokens in the document, obtained by leveling out the mentions of the head entity. A_t is the same. Tokens that are highly attentive to both e_h and e_t must necessarily be important to both head and tail entities, and so should have more interactions on context embedding.

D. Classification of Relationships

To predict the relationship between entity pairs (e_h, e_t), the model initially computes their context-aware representations (z_h, z_t) by combining their entity embeddings (e_h, e_t) with their context embeddings $c_{h,t}$, and then utilizes a bilinear function to compute the logit of the likelihood of the existence of a relationship $r \in R$ between e_h and e_t.

$$Z_h = \tanh(W_h e_h + W_{c_h} C_{h,t}) \tag{11}$$

$$Z_t = \tanh(W_t e_t + W_{c_t} C_{h,t}) \tag{12}$$

$$y_r = Z_h W_r Z_t + b_r \tag{13}$$

where W_h, W_t, W_{ch}, W_{ct}, W_r, b_r are learnable parameters. Since the model may have different confidence levels for

different entity pairs, an adaptive threshold loss is used, which learns a virtual relationship class TH that serves as a dynamic threshold for each entity pair:

$$y_{TH} = z_h W_{TH} z_t + b_r \tag{14}$$

In the inference process, for each tuple (eh, et, r), the predicted score is obtained:

$$S_{h,r,t}^{(O)} = y_r - y_{TH} \tag{15}$$

In conclusion, the training objective for relation extraction is defined as follows:

$$L_{RE} = -\sum_{r \in P_{h,t}^T} \log\left(\frac{\exp(y_r)}{\sum_{r' \in P_{h,t}^T \cup \{TH\}} \exp(y_{r'})}\right) - \log\left(\frac{\exp(y_{TH})}{\sum_{r' \in N_{h,t}^T \cup \{TH\}} \exp(y_{r'})}\right) \tag{16}$$

Where $P_{h,t}^T$ indicates that a relationship exists between two entities and $N_{h,t}^T$ indicates that no relationship exists between entities.

E. Relational Reasoning

If the evidence sentences contain all the relevant information, there's no need to use the entire document for relationship extraction. No system can extract 100% of the evidence without omitting some sentences. Relying on extracted evidence alone may miss important information in the document, which could affect performance. The original document and the extracted evidence are combined to get the prediction results. If there are no evidence annotations, the results can be learned by the evidence prediction model from Section III or extracted by the auxiliary experiments in Section III.

Specifically, as shown in Fig. 1, a set of relationship prediction scores are initially obtained from the original document $S_{h,r,t}^{(O)}$. Then a pseudo-document d' is constructed for each entity pair by concatenating the extracted evidence sentences V_{ht} in the order in which they appear in the original document. The prediction score of the relational extraction model for the pseudo-document is recorded as $S_{h,r,t}^{(P)}$. In conclusion, fusion results are obtained by aggregating the two sets of predictions through a hybrid layer:

$$P_{Fuse(r|e_h,e_t)} = (S_{h,r,t}^{(O)} + S_{h,r,t}^{(P)} - \tau) \tag{17}$$

τ denotes the balancing parameter of the source document and the pseudo-document. The final loss function is as follows:

$$L_{Fuse} = -\sum_{r \in R} y_r \cdot P_{Fuse(r|e_h,e_t)} + (1 - y_r) \cdot \log(1 - P_{Fuse(r|e_h,e_t)}) \tag{18}$$

If $y_r = 1$ indicates that a relationship exists between the entities. Conversely, $y_r = 0$ indicates that no relationship exists between the entities.

III. Experimental Results and Analysis

The commonly used datasets for document-level relation extraction, such as DocRED, Re-DocRED, CDR, and GDA, are employed to investigate the performance differences between the model with the introduction of the interaction attention mechanism and the baseline model.

A. Data Sets

The experiments are mainly evaluated on DocRED, CDR, GDA and Re-DocRED datasets. Since CDR and GDA are relationally extracted datasets under the medical domain, since both datasets do not have annotation information such as evidence sentences, CDR and GDA are placed in the same representation for comparison [11]. Re-DocRED and DocRED tend to be generalized domain relationally extracted datasets, both containing evidence sentence information and remote supervision data, therefore CDR and GDA datasets are set in one group for comparison and DocRED and Re-DocRED are set in one group for comparison. The statistical information of the four datasets is shown in Table I.

TABLE I. Data Set Information

Statistical information	CDR	GDA	DocRED	Re-DocRED
Training Documentation	500	23353	3053	3053
verification document	500	5839	1000	1000
test document	500	1000	1000	1000
predefined relationship	2	2	97	97
Average number of entities	7.6	5.4	19.5	19.6
Average number of sentences	9.7	10.2	8.0	8.1

B. Evaluation Indicators and Parameterization

1) Evaluation indicators: As in the previous section, Precision (P), Recall (R) and F1 values were used as evaluation metrics for the experiment, which were calculated as follows:

$$P = \frac{TP}{TP + FP} \tag{19}$$

$$R = \frac{TP}{TP + FN} \tag{20}$$

$$F_1 = \frac{2 \times P \times R}{P + R} \tag{21}$$

In addition to the above commonly used evaluation metrics, there also exists the I_{gn} F_1 evaluation metric in document-level relational extraction. I_{gn} F_1 was proposed by Yao et al. The model learns relational facts existing in the training set during the training phase, which is shared with the validation set and the test set. Then if the model has learned certain relationship facts in the training set, it will inevitably affect the model's judgment in the validation or testing phase [12]. This approach obviously produces immeasurable interference in model performance evaluation, so in order to have a fairer evaluation

index, after removing the shared relationship facts in the training and validation sets and the test set, the performance evaluation of the document-level relationship extraction model is re-conducted.

2) *Parameter setting:* The IADocRE model is based on Pytorch and Huggfacing's Transformer implementation, and the model is encoded using bert as a pre-trained language model [9]. The experiments used AdamW as the optimizer in the DocRED experiments. During the self-training phase of evidence sentences, the learning rate was set to 5e-5, Warmup was set to 0.06, and the Dropout rate was set to 0.1. When running the whole model, the experiments were trained and evaluated on four RTX 3090 24GB GPUs. The specific experimental parameters are shown in Table II.

C. Main Experiment and Analysis of Results

1) Experimental results and analysis of DocRED and Re-DocRED datasets: The main results of the IADocRE model for the two datasets are shown in Table III, the IADocRE model achieved 65.54 and 63.76 on F_1 and I_{gn} F_1 of the DocRED dataset, and 79.43 and 79.05 on F_1 and I_{gn} F_1 of the Re-DocRED dataset, and the scores on the two datasets have exceeded those of the existing baseline models. The experimental results prove that the document-level relationship extraction method based on interactive attention proposed in this paper is effective. From the table of experimental results, it can be observed that among the two mainstream methods for Document-level Relation Extraction, the effect of the model based on the sequence method is usually superior to that based on the graph method.

Table III and Table IV shows that the IADocRE model is ahead of the existing baseline model level. The I_{gn} F_1 evaluation metrics are missing for some of the models in the experimental results because some of the models were not experimentally validated on the latest dataset at the time of publication, and if the model is reproduced and validated on the latest dataset, the experimental process is again affected by the initial parameter settings, the type and number of hardware devices, and the choice of optimizer strategy. Therefore, partial results on the Re-DocRED dataset are denoted by '-'.

TABLE II. OPTIMAL PARAMETER SETTINGS FOR THE EXPERIMENT

point	parameters	(be) worth
Train	Warmup	0.06
	lr	5e-5
	evi_thresh	0.2
	Dropout	0.1
	max_grad_norm	1.0
Fine-tune	Warmup	0.06
	lr	1e-6
	evi_thresh	0.2
	Dropout	0.1
	max_grad_norm	2.0

In addition to the statistics on the ternary group prediction results, the experiments also included statistics on the evidence prediction results. According to the work of Huang [6] and Xie [10] , it is known that only E2GRE and EIDER have published methods for evidence extraction results. As shown in Table IV, IADocRE's method significantly outperforms E2GRE and EIDER on BERT, the evidence sentence extraction results are improved by 5.13 and 1.56 on the validation set, and by 4.51 and 1.59 on the test set, respectively in terms of the score metrics, but, there is still a lot of room for improvement in the evidence extraction.

IADocRE-BERT (ours)	**52.27**	**52.86**

2) Experimental results and analysis of CDR and GDA datasets: The main results of the IADocRE model for the two datasets are shown in Table V. There is no concept of shared relational facts in the training and validation sets of the CDR and GDA datasets, so the evaluation metrics for both datasets are only F1.The IADocRE model achieves an F1 of 78.2 for the CDR dataset, and 87.8 for the GDA dataset. The performance on the GDA dataset has already exceeded that of existing benchmark models, but there remains a gap in performance on the CDR dataset, with the score being close to that of the SAIS model. Comparison of the two models reveals that: the SAIS model focuses more on the intermediate step of supervising and enhancing the model, which is a method that can more accurately capture the relevant context and entity-type information for the combination of the entity-type information and the evidence for achieving the effect of data enhancement. The intermediate steps of the supervised training process, such as Coreference Resolution, Entity Recognition and evidence-based retrieval, are clarified to help the model learn better.

TABLE V. EXPERIMENTAL RESULTS OF IADOCRE MODEL ON CDR AND GDA DATASETS (%)

DHG-BERT	65.9	83.1
SSAN-BERT	68.7	83.7
GLRE-BERT	68.5	-
ATLOP-BERT	69.4	83.9
SIRE-BERT	70.8	84.7
DocuNET-BERT	76.3	85.3
SAIS-BERT	**79.0**	87.1
IADocRE-BERT (ours)	78.2	**87.8**

However, the SAIS model has the issues of increased complexity, higher data and annotation requirements, and greater consumption of computational resources compared to the IADocRE model. In summary, IADocRE is able to extract more ternary information under the medical domain dataset.

D. Ablation Experiments

1) Experimental results and analysis of ablation of DocRED and Re-DocRED datasets:

a) Analysis of the impact of interactive attention mechanisms on model performance:

All other things being equal, the contribution of the interactive attention mechanism to the model is explored by conducting multiple experiments on pre-trained language models with and without the introduction of interactive attention, respectively. The results of the ablation experiments on the DocRED and Re-DocRED datasets are shown in Tables IV-VI. When the overall model removes the interactive attention mechanism and only uses the original BERT, there is a significant decrease in the extraction effect, with F_1 and I_{gn} F_1 decreasing by 1.73 and 1.86 on DocRED and the results on Re-DocRED decreasing by 1.79 and 1.49, respectively. The ablation experiments performed on the interactive attention show that the overall model metrics decrease the most, and it can be inferred that the interactive attention mechanism is very effective in enhancing the model extraction performance.

To explore the effect of the dependent syntactic bootstrap attention layer on the model in more detail, the dependent syntactic analysis was replaced with an ordinary self-attention layer [13]. The model's extraction performance showed a decrease of 0.77 in the F_1 metric and 1.57 in I_{gn} F_1 on the DocRED dataset, indicating that the IADocRE model relies heavily on the dependent syntactic analysis attention layer, especially when ignoring relational facts. The performance significantly drops when replaced with a standard attention layer.The F_1 metric on the Re-DocRED dataset decreases by 1.04 and the I_{gn} F_1 decreased by 0.89. Considering Tan et al.'s revision of the Re-DocRED dataset, which removed a large amount of shared relational facts, the observed decreases in metrics are within the normal range. In summary, the experiments demonstrate the effectiveness of using the interactive attention mechanism in the document-level relationship extraction task.

b) Analysis of the impact of source documents and pseudo-documents on model performance:

After the ablation experiments with the interactive attention mechanism, ablation experiments were also conducted on the pseudo-document and source document parts. To explore whether the presence of source documents and pseudo documents in the relational reasoning part helps the model improve the effectiveness of relational reasoning [14]. As shown in Table IV and VI, when the model retains the interactive attention mechanism and removes the pseudo-document and only retains the source document part for relational reasoning, there is a significant decrease in the effect. When the model retains the interactive attention mechanism and removes the source document for relational reasoning, the model's F_1 and I_{gn} F_1 metrics in DocRED are 0.65 and 0.7, respectively. Observing the experimental data of the source document and pseudo-

documents' ablation in the table. It can be seen that, by removing the pseudo-document, the model's F_1 and I_{gn} F_1 metrics in DocRED decrease by 1.12 and 1.32, respectively. The ablation experimental results for both the source and the pseudo-document show that: source document and pseudo-document have a significant decrease in their effectiveness. The results of the ablation experiments on source documents and pseudo-documents show that the model is more inclined to reason on pseudo-documents than on source documents, but it cannot completely rely on pseudo-documents for reasoning. Alternatively, the pseudo-document occupies a higher position in the model's reasoning.

2) Results and analysis of ablation experiments on CDR and GDA datasets:

a) Analysis of the impact of interactive attention mechanisms on model performance:

The experimental setup is the same as in the previous subsection, and the ablation experiments are conducted using the pre-trained language model with and without the introduction of the interactive attention mechanism, respectively. As shown in Table VII, using only BERT as the pre-trained language model decreases the extraction effect by 1.6 on the CDR dataset and 1.8 on the GDA dataset. The phenomenon suggests that the introduction of the interactive attention mechanism is effective in directing the model to focus on implicit expressions in biomedical documents, such as the roles of chemicals and diseases or the associations of genes with diseases, which are not always directly explicitly mentioned. Therefore, the interactive attention mechanism is effective in deepening the understanding of biomedical domain knowledge and context.

In order to explore the effect of the dependent syntactic analysis-guided attention layer on the overall model, this layer was replaced with the ordinary attention layer for experimental analysis. As shown in Tables IV- VII, the extraction effect on CDR and GDA decreased by 0.8 and 0.6, respectively, and this result indicates that the dependent syntactic analysis-guided attention layer helps the model to improve its comprehension of logical and causal relationships between sentences. In summary, the interactive attention mechanism is effective for the model's deep understanding of complex terminology and descriptive processes in biomedicine.

b) Analysis of the impact of source documents and pseudo-documents on model performance:

As can be seen in Tables IV- VII, retaining the source document for ablation experiments results in a decrease in CDR and GDA of 1.2 and 1.1, respectively. Retaining the pseudo-document for ablation experiments results in a decrease in CDR and GDA of 1.4 and 1.5, respectively. This suggests that the model reasoning partially relies more on the source document. The reason for this is that relational extraction in the biomedical domain often requires inference at multiple levels, e.g., understanding how a specific chemical can cause a change in disease state through a specific biological pathway may require inference across multiple parts of the document. If only pseudo-documents are retained for relational reasoning, there is a high risk of losing important information at other levels. Therefore, in biomedical domain datasets, the extraction performance is better when the model is capable of in-depth understanding and reasoning about the complex interactions between entities [15].

TABLE VI. RESULTS OF ABLATION EXPERIMENTS OF IADOCRE MODEL ON DOCRED AND RE-DOCRED DATASETS

Model		DocRED		Re-DocRED	
		F1	***Ign F1***	***F1***	***Ign F1***

TABLE VII. RESULTS OF ABLATION EXPERIMENTS OF THE IADOCRE MODEL ON CDR AND GDA DATASETS

Model		CDR	GDA
$IADocRE_{all}$		**78.2**	**87.8**
$IADocRE_{w/o-IA}$		76.6	86.0
$IADocRE_{w/o-DP}$		77.4	87.2
Document	-NoPseudo	77.0	86.7
	-NoOrigdo	76.8	86.3
	-all	76.6	86.2

IV. CONCLUSION

When the document-level relational extraction model fills in missing evidence information, the performance shows improvement compared to the baseline model, but there is still much room for enhancement. For example, the presence of implicit information in documents requires the model to have strong reasoning capabilities. To address this problem, the introduction of the interactive attention mechanism can help the model understand the semantic and contextual information of documents from a global perspective. By combining document information and evidence information, the model can supplement entity relationship information, thus improving the accuracy and completeness of relationship extraction. The introduction of the interactive attention mechanism helps the model to better understand the deep logical relationships, which improves the performance of the model in relational reasoning.

***Abstract*—This paper presents computer modeling of the stress-strain state of two kvershlags with a double periodic system of slits weighty elastic transtropic massif. It introduced key concepts such as 'kvershlag', a term used to describe perpendicular cavities in a layered massif, and 'weighted elastic transtropic massif', which refers to a specialized geological structure considered in the study. These terms are critical for understanding the modeling approach. Due to the complexity of the analytical solution of this class of problems, a numerical method is used. Such a mixed problem is provided to obtain a solution by bringing it to an equivalent environment. To solve such a mixed problem, it is offered to get a solution by bringing it to an equivalent climate in terms of stiffness. The finite element method was used to solve the problem. A software package has been created to solve the stress-strain state of the two kvershlags. To ensure the correctness of the software complex, it was checked using test tasks. To study the stress-strain state of kvershlags in a weighted massif. The basic systems of equations are obtained. Algorithms are constructed and the program complex FEM_3D for solving finite element method problems is compiled. Mixed problems of the stress-strain state of cavities are solved approximately. The results of complex computer calculations are systematized, analyzed, specific conclusions are drawn and recommendations for their practical application are proposed. A computer simulated the stress-strain state of two kvershlags. The numerical solution to the given problem was obtained using the software. Results demonstrate that our numerical method approach results in 0.01%.**

I. Introduction

The first results in determining the deformation modulus of rocks were obtained in laboratory conditions. Extensive research in this direction has been undertaken in engineering schools in Germany, Austria, and Switzerland. It is enough to say the works of M. Bauschinger [1], K. Bach [2], O. Graf [3], O. Müller [4], O. Fleischer [5], K. Stöcke [6], and others. Similar works have been carried out since the 1950s under the leadership of B.V. Zalesski [7], B.P. Belikov [8] at the Donetsk Polytechnic Institute, Research Institute of G.N. Kuznetsov's [9] provided. The gap in previous research lies in the limited focus on the stress-strain behavior of kvershlags in complex geological formations. Our study addresses this by applying a numerical approach based on the finite element method to model the stress-strain state of kvershlags in a weighted transtropic massif, offering new insights into their deformation behavior. Kvershlag refers to cavities that are perpendicular to the layered massif.

Difficulties in determining the deformation of rocks cannot be solved by selecting the number of limit cracks in a given homogeneous medium. This is a three-dimensional case. Due to the variety of natural conditions, it is impossible to create a general algorithm, even in an individual case. Therefore, a convenient situation is presented below to solve the problem. To investigate the stress-strain behavior of kvershlags, a mechanical-mathematical anisotropic model with reduced moduli dependent on the slit periods and physical properties of the massif is proposed. Elasticity is treated equivalently to displacements and deformation coefficients in stones. Its solution is sought through actual experiments or modeling.

Based on thorough research, it was taken the form of layers resulting from deformable slits as a function of the medium's parameters. These layers are dependent on the medium's parameters, which have been obtained analytically. It can be related to the "deformation of layered rocks" concept.

The main concepts of the effect of slits in deformable layered rock are presented in [10-28]. Displacement vectors are considered in [29] from the perspective of the mechanics of a slit homogeneous medium. From a geological point of view, a slit can be deemed to be regarded as a space between the walls of folded rocks.

A slit in a rock zone can be called a set of slits in layers. A length characterizes each slit. The slit can only be accurately measured, like longitude. The presence or absence of slit complements also distinguishes it. Accordingly, slits are

divided into open and filled. Slit fillers consist of sand, clay soils, or other components.

These layers differ in their mineral content and physical properties. The second type of complement of slits is called a latitudinal slit, which is a supplemental slit of several millimeters along the latitude.

These layers differ in their mineral content and physical properties. The second type of complement of slits is called a latitudinal slit, which is a supplemental slit of several millimeters along the latitude.

In the case of weak connection of slits, the main conclusion about slits is drawn according to the law of asymmetric distribution of the connection along the length and width.

The main contributions of this paper are as follows:

- A computer-modeled transtropic massif with doubly-periodic slit systems as a stiffness-equivalent homogeneous continuous transtropic body.
- Elastic constants are given as functions of geometric and physical parameters of rocks and slits.
- To investigate the elastic state of two kvershlags in a weighted transtropic massif, the representation of the primary systems of solving equations of the finite element method.
- We obtained multivariate calculation results on the distribution patterns of initial stresses near two shallow kvershlags in a rock massif. These patterns depend on various factors, including the parameters of the slits and other initial data.

The rest of this paper is organized as follows:

Section II presents the state of the art in studying the stress-strain state of shallow underground cavities in solid and slotted weakened massifs and discusses methods for analyzing the state of weighted rock strata with two treks—Problem Statements. Section III presents our proposed finite element approach using isoparametric computational elements. A transtropic massif with double periodic slit systems is replaced by a continuous transtropic body equivalent in stiffness to the primary medium by solving the reduction problem. In Section IV we determined the elastic constants of a transtropic body that is equivalent in stiffness to the main massif with slits. The elastic constants depend on the elastic properties of the main massif and the geometry of the slits. In the values of the initial elastic components of stresses and displacements in the transtropic massif around two kvershlags depending on the initial parameters by implementing the developed algorithms, computer program complexes, conducting multivariate calculations and analyzing the numerical results. Section V presents the experimental results, compares the performance of our proposed method with existing state-of-the-art techniques, and discusses the method with existing state-of-the-art techniques and the implications of our findings. Finally, Section VI summarizes the results and suggests directions for future research.

II. Related Works

In the last century, the works of foreign scientists mainly involved theoretical research on the stress-strain state of underground cavities in the isotropic massif. Using the symmetry of the biharmonic solutions and based on the unique properties of harmonic functions, O.Müller and K. Stocke reviewed the relevant class of problems. G.V. Kolosov, N.I. Muskhelishvili [30], in the solution of plane problems of the theory of elasticity of an isotropic body, has successfully used the method of the Complex Variable Theory. W. Wittke [31] extended the anisotropic jointed rock model (AJRM) and the corresponding analysis methods to a broader spectrum of rock types. His design approach has been applied to many tunneling, dam, and slope design projects.

The analytical function proposed by Appel considers the state of one and many related isotropic bodies with a circular hole. L.A. Filshtinsky considered orthotropic structures with a doubly periodic system of circular holes [32] and a body with elliptical holes A.S. Kosmodamiansky, M.M. Neskorodev [33]. A.S. Kosmodamiansky investigated the stress-strain state of an anisotropic elastic body with three and endless rows of holes, and based on these decisions, Zh.S. Erzhanov, K.K. Kaydarov, M.T. Tusupov [34] studied the effects of the slots on the static stress state of underground workings. Zh.S. Erzhanov, Sh.M. Aytaliev, and Zh.K. Massanov [35] proposed a computational mechanics and mathematical model of the anisotropic elastic deformation of the rock mass with doubly periodic systems slots. They solved the problem by bringing the elastic constants obtained from the transtropic body, the equivalent stiffness central massif with slots, depending on the elastic properties and the geometry of the slots. Based on this model, they studied static initial elastic states, mainly single underground cavities deep foundation of rigorous and approximate methods, and subsequent creeping cavities state-based Ǝ-Algebra Operators U.N. Rabotnov [36] and the Theory of Creep of Rocks Zh.S. Erzhanov [37].

Different types of immersed tunnels (IMT) as well as their construction methods are discussed by [38-45].

These scientists have made significant contributions to the theory of the Finite Element Method and its application to solving complex problems of statics and dynamics of solid mechanics: L. Segerlind [46], B.Z. Amusin, A.B. Fadeev [47], Zh.S. Erzhanov, T.D. Karimbaev [48], A.D. Omarov, Zh.K. Massanov, N.M.Mahmetova [49], L.B. Atymtayeva, B.E. Yagaliyeva [50] and others [51-53].

A. The Task

Investigated the static stress and strain state of two kvershlags lying in a heavy transtropic massif, depending on the degree of discontinuity, conform to small sloping layers at an angle φ. Let H denote the depth of the distance between their centers two $2L$ (Fig. 1).

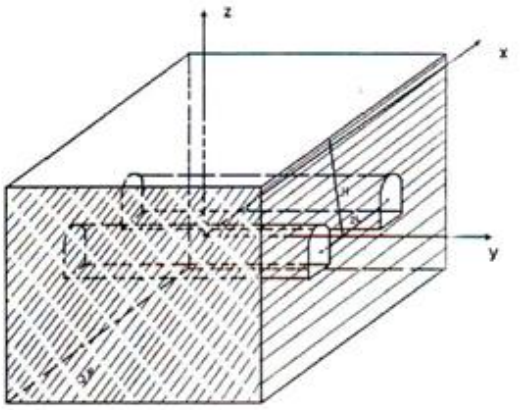

Fig. 1. Three-dimensional view.

B. The Task Explained

The plane of the cross-sectional areas with anisotropic in-plane deformation slits; efforts are at infinity (Fig. 2).

$$\sigma_x^{(\infty)} = p, \quad \sigma_z^{(\infty)} = q, \quad \tau_{xz}^{(\infty)} = r \tag{1}$$

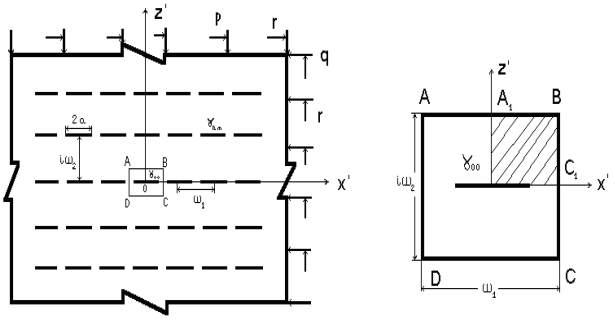

Fig. 2. Surface with a periodic system of slits.

Here γ_{00} - main crack; γ_{nm} - circuits and their length; n,m - indices, $\omega_1, i\omega_2$ - periods of slits in the directions of the axes x and z; circuits are free of external loads. E_j, ν_j, G_2 $(j=1,2)$ - elastic properties transtropic massif slots. By solving the problem of bringing to an anisotropic body with the boundary conditions (1) given elastic parameters E_i^e, ν_i^e, G_2^e, $(i=1,2)$, transtropic solid body, equivalent stiffness anisotropic massif with slits are the following formulas:

$$E_1^э = E_1, \ \nu_1^э = \nu_1, \ \nu_2^э = \nu_2,$$

$$E_2^{э^{-1}} = E_2^{-1} + 2\omega^{-1} < 2\,\mathrm{Re}\sum_{j=1}^{2} q_j \Phi_j\left(x + i\beta_j 0.5\omega, q\right) >, \tag{2}$$

$$G_2^{э^{-1}} = G_2^{-1} + 2\omega^{-1} < 2\,\mathrm{Re}\sum_{j=1}^{2}\left[p_j \Phi_j\left(x + i\beta_j 0.5\omega, r\right) + q_j \Phi_j\left(x + i\beta_j 0.5\omega, r\right)\right] >$$

Here < > - symbol averaging values, β_j – anisotropy parameters;

$$\Phi_j\left(z_j\right) = \left(B_j + iC_j\right) z_j + \sum_{k=1}^{\infty} a_{2k-1,j}\zeta_j^{-(2k-1)} + \sum_{k=1}^{\infty}\sum_{k=1}^{\infty} a_{2k-1,j} B_{jik}\left(\zeta_j^{2k-1} + \zeta_j^{-(2k-1)}\right),$$

$$B_1 = 0.5\left(p + \beta_2^2 q\right)\left(\beta_2^2 - \beta_1^2\right)^{-1} \tag{3}$$

$$B_2 = 0.5\left(p + \beta_1^2 q\right)\left(\beta_2^2 - \beta_1^2\right)^{-1}$$

$$C_1 = 0, \ C_2 = 0.5 r \beta_2^{-1};$$

III. Proposed Method

A. The Solving Problem

Hooke's law of transtropic massif with cavities with generalized plane strain relative to the Cartesian coordinate system $Oxyz$ (see Fig. 1):

$$\{\sigma\} = [\overline{D}]\{\varepsilon\}; \tag{4}$$

where $\{\sigma\} = \left(\sigma_x, \sigma_z, \tau_{yz}, \tau_{xz}, \tau_{xy}\right)^T$, $[\overline{D}] = [d_{ij}]$, $(i, j = 1,2,...,5)$; - deformation coefficients defined by the formulas [54].

Here $E_k^e, \nu_k^e, G_2^e (k=1,2)$ - effective elastic constants transtropic massif equivalent stiffness transtropic massif with slits, which depends on the elastic constants of the last and the geometry of the slits $a, \omega, i\omega$.

B. The Use of Numerical Methods

The cross-section in plane ABCD kvershlag planes of deformation using units to isoparametric calculation elements (Fig. 3).

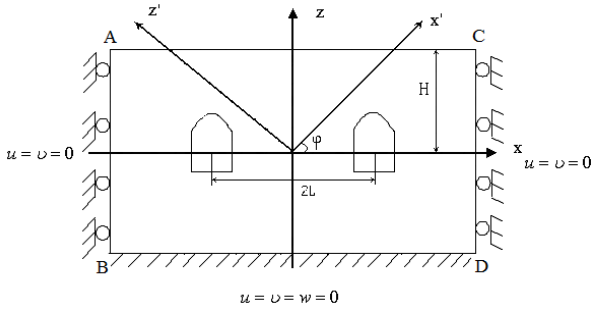

Fig. 3. Two-dimensional view.

Constitute the essential resolution of the system of algebraic equations finite element method's three $3n$-order relative to the projections of moving points, and it can be solved with the following boundary conditions [55]:

Base BD calculation area ABCD non-deformable –

$$u = v = w = 0; \tag{5}$$

Sides AB and CD under the weight of rocks moved only in the vertical direction due to a lack of influence of cavities –

$$u = v = 0, \quad w = w(z). \tag{6}$$

The study estimated the area with cavities is automatically split into isoparametric elements using the object-oriented program FEM_3D (Fig. 4).

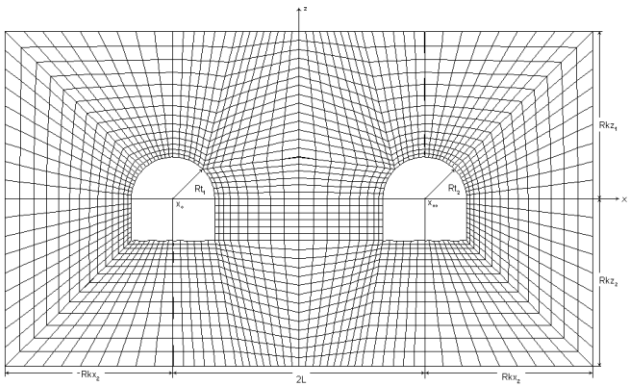

Fig. 4. A layout of the estimated area for isoparametric elements.

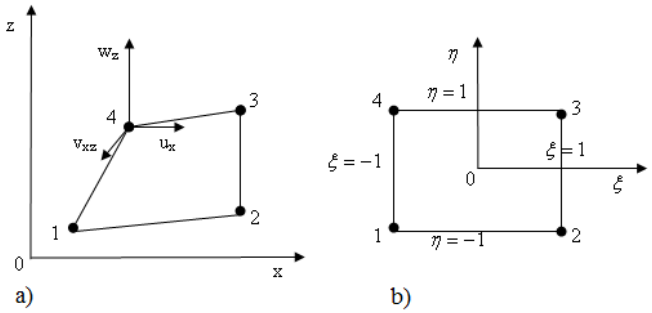
In solving the problem, we considered a generalized plane calculation algorithm for points isoparametric element (Fig. 5).



a) Cartesian coordinate system xoz;
b) Local coordinate system $\xi o \eta$;

Fig. 5. Four points isoparametric elements.

Each point acts as the vertical force of the weight:

$$f_{z_i} = -\frac{\gamma S}{4};\ (i = 1,2,3,4) \tag{6}$$

To solve the fundamental system of equations with the Finite Element Method's displacement components with the boundary conditions (5), (6) rigorous methods are complex; therefore, it can be solved in an iterative method of Gauss-Seidel-relaxation factor with a given accuracy [56]:

$$\{F\} = [K]\{U\} \tag{7}$$

here $[K] = \sum_{i=1}^{n} [k^e]_i$ – stiffness matrix of the system;

$\{U\} = (u_1,...,u_R, w_1,...,w_R, v_1,...,v_R)^T$ – displacement vector;

$\{F\} = (F_{x_1},...,F_{x_R}, F_{z_1},...,F_{z_R}, F_{y_1},...,F_{y_R})^T$ – force vector.

An attractive feature of this method is as follows: the stiffness matrix in this method is prepared only once and can be used for iterating both its own elements and the column elements of the matrix. During the first iteration, the value of the matrix is unknown, but in subsequent iterations, the value of the previous iteration is used.

IV. Experimental Results

Thus, the searched $E_1^э, E_2^э, G_2^э, \nu_1^э, \nu_2^э$ parameters describe the anisotropic medium weakened by two periodic slits according to the formulas (2) and (3). Elastic and geometrical parameters of slits shape them. It has been shown above that the equivalent homogeneous folding condition for anisotropy is realized by introducing the measure of elastic parameters. Below (Table I) is the elasticity parameter of anisotropic rocks weakened by two periodic slits [48].

Table I gives elastic parameters and their anisotropy parameters for anisotropic siltstone [35], and several cases are given by entering different values of relations of geometrical parameters.

TABLE I. Value of Equivalent Elastic Properties and Anisotropy Parameters

$\frac{\omega}{a}$	Given elastic parameters					Anisotropy parameters		
	$E_1^э \cdot 10^{-4}$ (MPa)	$E_2^э \cdot 10^{-4}$ (MPa)	$G_2^э \cdot 10^{-4}$ (MPa)	$\nu_1^э$	$\nu_2^э$	$k^э$	$n^э$	$l^э$
Anisotropic siltstone [48]								
∞	1,074	0,523	0,120	0,413	0,198	1,56	3,64	1,78
6,0	1,074	0,426	0,097	0,413	0,198	1,73	4,02	1,98
4,0	1,074	0,311	0,073	0,413	0,198	2,03	4,59	2,28
3,0	1,074	0,214	0,056	0,413	0,198	2,45	5,22	2,60
2,5	1,074	0,148	0,045	0,413	0,198	2,95	5,82	2,90

$\frac{\omega}{a} = \infty$ The given values correspond to the limit values of the layer. The first value represents the scenario with no slits, while the second value indicates that the connection between the layers is discontinuous.

Table II presents the verification of the correct operation of the developed algorithms and software systems to solve the test problem of the elastic stress state circular cavity in an anisotropic massif with the horizontal plane of isotropy in the plane strain and hydrostatic stress distribution in a pristine environment. Because of the symmetry of the problem, a quarter of the area of the cavity is divided into 342 isoparametric elements with the help of 380 points. The basic system of equations is solved in about 1140 with 1000 iterations. Unlike values of displacements at characteristic points of contour obtained by iterative and strict known methods, it is no more than 1-2%.

A. Results

In this section, we demonstrate the results that were obtained. Twelve points were obtained on the boundary of a double kvershlags in transtropic rocks weakened by weighted elastic two-period slits (Fig. 6). As a result of multivariate calculations, the change of tangential stress at the boundaries of the two kvershlags was studied. In this case, two kvershlags are located at depths of H=10M and distances between cavities of L=5M. Our findings align with recent studies (e.g., Turymbetov et al., 2020) on the stress distribution patterns in complex geological structures, but provide additional insights into the behavior of kvershlags when subjected to various stress conditions. A key difference is the extended analysis of the interaction between two closely positioned kvershlags, which has not been previously examined in detail.

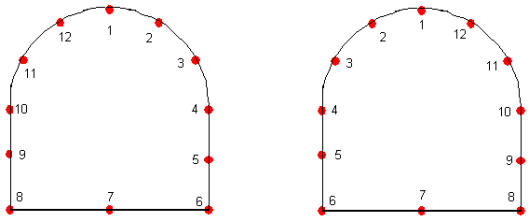

Fig. 6. Given points on the boundary of the cavity.

Tables III-V presents the variation of tangential stresses in the values w/a=∞, w/a=6, and w/a=4, the ratios of geometrical parameters.

V. DISCUSSION

Despite certain achievements in studying the state of individual deep cavities using isotropic and anisotropic elastic computational models of rock strata, there has been no systematic study of the stress-strain state of two drifts with arbitrary cross-sectional shapes and depths of location in a large inclined layered massif with a system of slits under conditions of elastic deformation of rocks.

The study of the regularity of distribution of elastic stresses and displacements in the vicinity of cavities of arbitrary depth and cross-sectional shapes depending on the inhomogeneous fractured structure is not only of theoretical interest but also has direct practical significance.

This study systematically investigates the distribution patterns of elastic stresses and displacements near two kvershlags of arbitrary profile shape and depth using the finite element method. The study is based on a homogeneous transtropic computer-modeled inclined-fine-layered massif with a double periodic system of slits, and is conducted under conditions of generalized plane deformation.

VI. CONCLUSION

Future research could focus on refining the numerical model by incorporating real-time field data, which could improve the accuracy of predictions regarding the stress-strain behavior of kvershlags in various geological settings. Additionally, the extension of this model to analyze other types of underground structures could further broaden its application.

In this paper, we presented a finite-element computational model of anisotropic rocks with a double periodic system of slits and elastic properties in the form of a transtropic body with given moduli. To ensure the generalizability and adaptability of the model, we also performed multivariate calculations.

Using an accepted model of deformation for the weighted massif, we formulated a boundary problem to determine the initial elastic stress-strain state of the kvershlag cavity. We obtained the basic equation system for solving this problem using the finite element method.

A calculation algorithm and a program complex for studying the elastic state of double kvershlags of arbitrary depth have been developed.

We conducted numerical calculations and analyzed the influence of geometric and physical parameters, as well as rock elasticity properties, on the components of stresses and displacements in the vicinity of cavities. Based on these analyses, we arrived at specific conclusions.

Our analysis revealed that as the slits approach each other, the value of displacements increases, and the value of stresses changes. Additionally, we observed that the numerical value of stresses and displacements increases as the cavity location deepens and the distance between them decreases.

Smart System for Driver Behavior Prediction

Hajar LAZAR, Zahi JARIR
Computer Science Engineering Laboratory, Cadi Ayyad University, Marrakesh, Morocco

***Abstract*—Driver behavior has recently emerged as a challenging topic in Traffic risk studies. Despite the advances in this topic, the challenges still remain. In fact, the current contribution deals with predicting at Real-time driver behavior based on machine learning techniques handling data sensing collected from smartphone sensors (accelerometer, gyroscope, GPS) and from OBD II. To ensure prediction at real time, we used a real-time architecture utilizing Atlas MongoDB service to synchronize data communication. Furthermore, we opt Random Forest model that demonstrates the highest performance compared to other models. This model has the advantage of predicting and preventing by warning a driver if his or her driving style is aggressive, moderate or slow. The proposed system aims to give more information about incidents to gain a better understanding of their causes.**

***Keywords*—Driver behavior prediction; OBD II; smartphone sensors; intelligent transport system; traffic safety**

I. Introduction

Traffic accidents have been on the rise over the past decade and have turned into a serious problem that affects the safety of people and their property. The World Health Organization report states [1] that pedestrians, cyclists, and motorcyclists are responsible for more than 50% of all road traffic deaths and, every year, road traffic crashes result in approximately 13.5 lakhs of casualties [2]. Due to its specific vehicular composition, Marrakech, a popular city in Morocco, poses a big challenge for traffic flow and safety studies. The traffic in the city is made up of roughly 40% motorcycles and 60% cars, which has a significant impact on traffic dynamics and safety patterns. The mix includes various factors, such as vehicle volumes, road conditions, and traffic control measures. The traffic system in Marrakech has a unique set of challenges because of the high number of motorcycles. In fact, Marrakech's traffic is unique and presents big challenges that have a significant impact on traffic flow and safety [3].

In recent years, there has been a proliferation of studies about traffic safety. Prediction of traffic accidents can help to prevent crashes, avoiding damage, providing drivers with warning alerts to potential risks or identifying potential causes and precautionary measures to prevent crashes from occurring [4]. The purpose of traffic risk studies is to identify crucial factors for future planning scenarios and to examine potential factors that may have adverse effects. According to research, most accidents occur due to driving behavior.

The author in study [5] identified multiple aspects of driver behavior from the same viewpoint and separated two aspects: (1) the research focused on individual psychological determinants as the basis for risky traffic behavior and its predictor, and (2) investigating the specific aspects of traffic climate that relate to social psychological determinants. In addition, they underlined the importance of focusing on studying driver behavior models: (a) The content aspect considers the limits of driver behavior and their distinctions from aggressive or dangerous driving, (b) the structural aspect involves identifying risky road behavior by examining the relationships between various behavioral manifestations of patterns in a wide social context, and (c) the dynamic aspect that identifies the behavior change in future [2].

Through various studies and research in psychology, it has come to light that rewarding desirable behavior can lead to a faster and longer-lasting change in human behavior than punishing undesirable behavior. Research has indicated that rewarding road safety behavior can be helpful, as evidenced using seatbelts and keeping driving speeds within permissible limits. However, a proper reward system is necessary for optimal effect. The authors in the study [6] proposed a system that constantly monitors drivers and uses real-time data to give them an appropriate score, provide feedback accordingly, and help punish errant drivers. They utilized different measured human factors as inputs to their smart algorithm to give an appropriate score to the driver based on their efficiency. Due to that, the major causes of road accidents and global warming are attributed to human factors. In this paper, we proposed an approach which considers human factors that can be analyzed with a smartphone sensor, a car and an OBD-II adapter. The measured human factors are given as inputs to a smart algorithm that delivers an appropriate score to the driver based on his efficiency.

The remainder of the paper is organized as follows: Section II provides an overview of the relevant literature. In Section III, we proposed our methodology in which we presented the data acquisition and data analysis. Section IV compared the different machine learning models and approved the choice of appropriate ML model. Section V covers the experimental and simulation results. Finally, Section VI summarize the paper and discusses future works.

II. Related Work

To evaluate road safety measures based on accident frequency and severity, several researchers have studied the safety effects of different road safety measures [7]. As a result, relevant techniques and methodologies have been developed to detect road accidents and identify critical factors that can cause crashes.

Nericell is a system proposed by study [8] that leverages smartphones to identify various vehicle conditions, such as braking, road bumps, honking, and stop-and-go traffic. It utilizes the smartphone's accelerometer, microphone, GSM communications, and GPS for data collection. The information gathered from multiple smartphones is aggregated on a

centralized server. The detection of such events does not involve the use of machine learning (ML) algorithms. The authors used the pattern matching and orientation calibration to detect the various vehicle situations. Similarly, the mobile sensor-platform for intelligent recognition of aggressive driving (MIROAD) is a driver behavior monitoring system developed by Johnson and Trivedi [9]. This system relies entirely on a smartphone's internal accelerometer, gyroscope, magnetometer, and GPS. They were the first to introduce a more advanced pattern recognition approach. MIROAD-equipped smartphones can detect and classify various aggressive and non-aggressive driving maneuvers using the variations of Dynamic Time Warping (DTW). The DTW is an algorithm to find similar patterns in temporal series. They don't introduce the machine learning models to classify the aggressive and non-aggressive behavior. Likewise, the system proposed by study [10] evaluates a person's driving as either safe or risky. It identifies risky events such as sudden maneuvers, turns, lane departures, braking, and acceleration using only the accelerometer, gyroscope, and magnetometer of a smartphone. It uses an endpoint detection algorithm to identify events and a DTW algorithm to compare input data with template events. Additionally, they incorporate a feature does not present in Johnson and Trivedi's system [9] which is the labeling of driver behavior. A Bayesian classifier labels the driver's behavior as safe or risky based on a calculated probability. Alternatively, the authors in study [11] developed and built a vehicle integrated system to inform drivers about the quality of their driving. They provided a safety index to each driver which indicating their ability to drive safely over prolonged periods. To reduce accidents, the safety index generated can be utilized to reward or retire the drivers. They based on the acceleration, speed and road traffic conditions parameters to indicate the Safety Index. For that, they utilized smartphones and high-end mobile devices having all the sensors to access data to develop an integrated application to track driver's performance. The machine learning models are not involved in their contribution. The authors in study [12] proposed a machine learning model based on set of rules to classify the driving maneuvers from time series data. They categorized the driver behavior as aggressive acceleration, non-aggressive, aggressive right turn, aggressive left turn, aggressive right lane change, and aggressive breaking aggressive left lane change. In fact, they utilized the accelerometer to collect the traffic data during longitudinal, lateral movement and the gyroscope for angular movement.

Recently, authors in study [13] proposed a classification model for drivers' behaviors. The dataset was built from recording OBD II (On Board Diagnostic II) parameters. The recorded data were analyzed and calculated to derived additional driving metrics such as Avg_fuel, Idle_engine, High_speed_breaking, Revv_engine, Dev_str, Vs_dev, Idle_instance, Avg_gear, Hb_instances, Avg_speed, Rev_instances. In this research, they employed the machine learning techniques, like SVM, AdaBoost, and Random Forest to classify driver behavior into ten classes: poorest, poor, bad, belong average, average, good, above average, extremely good, excellent, very good.

In our approach, we classify driving behavior into one of the following classes: aggressive, moderate or slow behavior to overcome the shortcomings of previous research that has focused only on aggressive behavior in various driving events. However, they have not addressed the other cases related to normal or slow behaviors. Additionally, we emphasize that slow driving can have a significant negative impact on urban traffic. A driver moving significantly slower than the flow of traffic may cause frustration for other drivers, leading to sudden lane changes or tailgating. Moreover, to accurately identify moderate and slow driving behaviors, it is essential to incorporate additional data features provided by OBD II adapter such as average speed, acceleration, throttle position, engine revolutions, and the vehicle's geographic location. These data features are crucial for a more comprehensive analysis of driving patterns.

Some significant points have been identified shown in Table I outlined here:

a) All papers use sensor data as input for the event detection algorithms, except [13] which used OBD II to create their dataset.

b) Some of them doesn't utilize the machine learning for classification of driver behaviors.

c) The majority of the research results in analyzing data using either mobile sensors such as accelerometer, gyroscope, magnetometer, GPS or OBD II.

TABLE I. COMPARISON BETWEEN EXISTING DRIVING BEHAVIOR STUDIES

Existing works	Types of Datasets	Machine learning models	Driver behavior Classes	Driver feedback application
[8]	smartphone's accelerometer, microphone, GSM communications, and GPS	Not considered	Not considered	Not developed
[9]	accelerometer, gyroscope, magnetometer, GPS and video	Not considered	non-aggressive and aggressive.	Not developed
[10]	accelerometer, gyroscope and the magnetometer	Bayesian classifier	safe or risky	Not developed
[11]	smartphones, high-end mobile devices and videos	Not considered	Not considered	Not developed
[12]	Accelerometer, gyroscope and the magnetometer	unsupervised learning technique using the sequential covering algorithm and classifying driving maneuvers from time-series data	aggressive acceleration, non-aggressive, aggressive right turn, aggressive left turn, aggressive right lane change, and aggressive breaking aggressive left lane change	Not developed
[13]	OBD II adapter and derived additional driving metrics	SVM, AdaBoost, and Random Forest	poorest, poor, bad, belong average, average, good, above average, extremely good, excellent, very good	Not developed

We deducted that there is no interest in combining smartphone sensors and OBD II features. By combining sensors and OBD II data systems offers more accuracy to classify driving behavior (aggressive, moderate, or slow) and capture the nuances of driver actions. This integrated approach enhances the ability to detect risky driving patterns and improves safety systems by offering a real-time, comprehensive analysis of driving habits.

The purpose of this paper is to present a system having advantage to predict and prevent by warning a driver if his or her driving style is aggressive, moderate or slow and to give information about incidents to gain a better understanding of their causes. Therefore, the proposed system determines the drivers with aggressive labels in localized areas to provide insight into where accidents are more likely to happen.

III. Methodology

Unfortunately, up to now the research involved the driving behavior factor for safety road are not widely studied in the literature. In fact, we proposed a road driving awareness system that focuses on driver behavior as a key factor in reducing road accidents and congestion problems in Morocco, particularly in Marrakesh city. Furthermore, road accidents in Morocco lead to over 4,000 deaths annually and approximately 140 million Dirhams (equivalent to about $14 million) of property damage [14]. During our analysis of the traffic road in Marrakech city, we observed that the behavior of drivers is influenced by various parameters, including infrastructure, vehicle performance, fatigue, and overspeed and we pointed out that motorcycles are the major factor that influences road accidents and congestion. Due to that, we propose a system that can predict various road problems by gathering the driver behaviour in real time. We began our system's development by collecting sensors and OBD II data, analyzing the effects of various features, and using machine learning algorithms to classify the provided data to visualize driver behavior in real-time, which led us to propose an awareness system.

A. Data Acquisition

By integrating data from smartphone sensors and OBD II adapter, driving behavior can be classified more precisely (aggressive, moderate, or slow), allowing for a deeper understanding of driver actions. This combined approach improves the detection of risky driving patterns and enhances safety systems by providing a comprehensive, and real-time analysis of driving habits. Each sensor provides unique data that, when combined, creates a more detailed and accurate picture of a driver's actions. These sensors are:

1) Accelerometer: detects rapid changes in speed, such as hard braking or sudden acceleration, key indicators of aggressive driving behavior (Fig. 1).

2) Gyroscope: measures rotational movement, helping to identify sharp turns or swerving, which can also indicate aggressive or unsafe driving (Fig. 1).

3) Magnetometer: used to determine the vehicle's orientation relative to the earth's magnetic field, aiding in directional awareness.

4) GPS: provides real-time location data, enabling the analysis of driving speed and route choice. It also helps assess whether a driver is adhering to speed limits and can indicate potential traffic conditions.

5) OBD-II: captures vehicle-specific data like throttle position, engine RPM, and fuel consumption, which provide insights into how efficiently the vehicle is being driven.

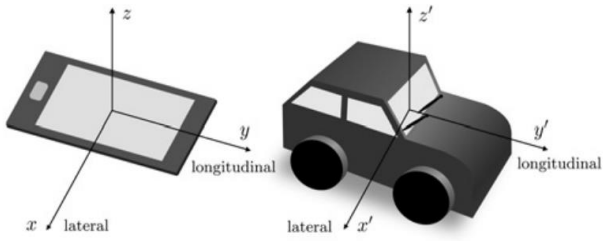

Fig. 1. Accelerometer and gyroscope sensors with vehicle coordinate system.

In our approach, we interest to label the driver behavior in three classes aggressive, moderate and slow behavior. For aggressive behavior, we collected the data set from accelerometer and gyroscope sensors to detect sudden maneuvers and sudden brakes. For moderate behavior, we need some additional features from OBD II like average speed, engine revolutions, throttle to detect average driving maneuvers. In similar way, we classify driver behavior as slow when the driver is maintaining a lower-than-average speed. To detect irregularities in the car, we must connect the OBD functions to a DLC (data link connector). The DLC is a collection of codes that make it easier to detect the work of sensors. The primary function of the OBD system is to monitor the functioning of essential engine components, such as those responsible for regulating emissions and detecting engine defects. Both hardware and firmware are crucial to extracting data from the OBD-II system. The ELM327 Bluetooth-based multi-protocol device located at the core of the system is compatible with the OBD-II protocols as shown in Fig. 2.

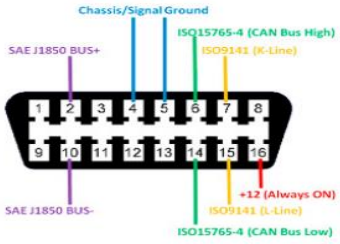

Fig. 2. OBD II system.

B. Data Analysis

To analyze the data, live vehicle data was necessary. It was collected from the Clio 4 vehicle, which was driven by same driver in Marrakesh city way. Fig. 3 illustrates the route utilized for gathering the dataset in a single direction, represented in black colored segment starting from the same point. We selected thoughtfully to simulate urban driving conditions. Therefore, we opted for a route that would enable us to collect the most relevant data possible. It was collected during crucial times, which were

chosen to reflect the different traffic conditions that are commonly observed throughout the day. The peak hours for rush are at 8:00 AM to 8:30 AM, midday from 12:00 PM to 12:30 PM, and evening from 16:30 PM to 17:00 PM. The OBD-II recorded data every second while we were driving and collected 22 features that are average fuel consumption, average speed, average speed (GPS), calculated boost, calculated instant fuel consumption, distance travelled, engine RPM x1000, fuel used, fuel used price, instant fuel power, vehicle acceleration, OBD module voltage, Calculated engine load value, engine coolant temperature, intake manifold absolute pressure, engine RPM, vehicle speed, intake air temperature, throttle position, fuel rail press, speed (GPS), altitude (GPS). At the same time, we collected the longitudinal and lateral movement from accelerometer as acc_x, acc_y, and angular movement from gyroscope gyr_z, dataset using a Samsung Galaxy A31 smartphone which is positioned at the center of a car's windshield. Table II presents the various feature categories along with their descriptions.

Fig. 3. Itinerary chosen for data collection in Marrakesh, Morocco.

TABLE II. THE OBD AND SENSORS FEATURES DESCRIPTION

Category	Features	Description
OBD II	Average speed	The average speed of the vehicle over a period of time, calculated by dividing the total distance traveled by the total time taken
	Average fuel consumption	The average rate of fuel usage, typically measured in liters per 100 kilometers (L/100 km), indicating how efficiently the vehicle uses fuel
	engine RPM x1000	The revolutions per minute of the engine, divided by 1000. It indicates how fast the engine's crankshaft is rotating.
	Distance travelled	The total distance covered by the vehicle during a trip, typically measured in kilometers
	Average speed (GPS)	The average speed of the vehicle as determined by the GPS system. It may differ from the calculated average speed due to factors like GPS signal accuracy
	vehicle acceleration	The rate at which the vehicle's speed increases, typically measured in meters per second squared (m/s²)
	OBD module voltage	The voltage level of the OBD module, typically corresponding to the vehicle's battery or alternator voltage
	Calculated engine load value	The calculated value representing the percentage of the engine's maximum capability being used. It provides an idea of how hard the engine is working
	Engine coolant temperature	The temperature of the engine's coolant, indicating how hot the engine is running.
	Intake manifold absolute pressure	The pressure inside the intake manifold, typically measured in kilopascals (kPa) or bar, used to calculate engine load and airflow
	Engine RPM	The number of revolutions per minute (RPM) at which the engine's crankshaft rotates, indicating engine speed
	Vehicle speed	The current speed of the vehicle, usually measured in kilometers per hour (km/h)
	Intake air temperature	The temperature of the air entering the engine, which can affect performance and fuel efficiency
	Throttle position	The position of the throttle valve, typically measured as a percentage from fully closed (0%) to fully open (100%), indicating how much air is being allowed into the engine
	Fuel rail press	The pressure of the fuel in the fuel rail, typically measured in kilopascals (kPa), indicating how much fuel pressure is being supplied to the injectors
	Speed (GPS)	The real-time speed of the vehicle as measured by GPS, typically more accurate than the speedometer reading
	Altitude (GPS)	The vehicle's altitude above sea level as measured by GPS, typically in meters
Accelerometer	acc_x	It measures the rate of change in velocity along the **x-axis**. This typically corresponds to motion in the left-right direction
	acc_y	It measures the acceleration along the **y-axis**, capturing vertical motion (up and down). It detects forces like gravity or upward/downward movement in space
	acc_z	It measures the acceleration along the **z-axis**, typically in the forward-backward direction. This axis is perpendicular to both the x and y axes, capturing motion like moving a device toward or away from a surface
Gyroscope	gyr_x	It measures the angular velocity around the **x-axis**. This represents the rate of rotation around the horizontal axis that runs from left to right
	gyr_y	It measures the angular velocity around the **y-axis**. This axis runs from front to back, so the gyroscope detects rotations in the left or right direction (side-to-side tilting)
	gyr_z	Measures the angular velocity around the **z-axis**. The z-axis runs vertically through the device (up-down direction), it detects rotational movements like spinning or turning the device around this vertical axis

Both datasets were merged by data acquisition module developed on mobile application and sent in real time for storing in NoSQL database. In this work, we assume that a driving behavior can be labeled into one of the classes described in the following subsections.

a) Aggressive behavior: As previously stated, we keep a gyroscope and accelerometer to recognize risky behavior. The accelerometer and gyroscope value are utilized during the trip to detect driving events like hard braking, sudden acceleration, or aggressive turning. To ensure non aggressive driving, it is recommended to use the recommended range of acceleration or deceleration values presented by [11][12][15]. For safe accelerating and braking the acc_x should be between -3 to 3 m/s². In contrast, the maneuvers such as left turn (LT), right turn (RT) influence the lateral and angular changes in a motion. Over the duration of safe LT and RT, acc_y between -1.5 to 1.5 m/s². Similarly, gyr_z perform between -0.4 to 0.4 m/s². In fact, we can identify aggressive driving, typically, when the threshold for aggressive acceleration rate greater than 2.5 to 3.0 m/s². This means a sudden increase in speed, indicating rapid acceleration. The threshold for aggressive braking rate (negative acceleration) greater than -2.5 to -3.0 m/s². In case of aggressive corning, the lateral acceleration can be greater than 1.5 m/s² and a yaw rate exceeding 15 to 20 degrees per second can indicate sharp turns. We summarized the different type of aggressiveness behavior in Table III.

TABLE III. CATEGORY OF AGGRESSIVENESS BEHAVIOR SEVERITY

Degree of Behavior aggressiveness	Type of Behavior aggressiveness
acc_x greater than -2.5 to -3.0 m/s	Braking with high speed
acc_x 2.5 to 3.0 m/s².	Sudden increase in speed
acc_y greater than 1.5 m/s and gyr_z exceed 15 to 20 degrees	Zig-zag with high speed

b) Moderate behavior: The proposed method considers a good average speed between 50 and 60 km/h. In addition, the optimal engine load indicates how much power the engine is producing relative to its maximum capacity. The normal driving rate its between 20% to 60% of maximum engine load.

c) Slow behavior: Driving the vehicle at a speed that is significantly less than the posted limits or traffic flow. Furthermore, being too cautious can result slow acceleration, early braking, and hesitancy at intersections which could lead to delays and hinder the flow of traffic.

Our research does not assume that driver behavior will remain consistent during the entire trip. Instead, we aim to detect varying actions taken by drivers during the same trip and classify them. In data analysis process, we used gradient boosting on decision trees (GBDT) models as XGBoost, Adaboost, Gradient boosting and decision tree to identify the three potential driving behavior classes. The GBDT algorithms gathers multiple weak learners, typically a decision tree, to create a stronger model that surpasses the base model. When boosting decision trees are added, they learn from the errors of previous individual trees. Each tree is connected in a series and tries to reduce the error of the previous tree. Boost algorithms may be slow to learn because of this sequential connection, but they are great at performing in the classification. In addition, we utilized random forest model which uses bagging techniques to create multiple decision trees using bootstrapped samples. The bagging method produces random samples with replacements from the input data and instructs decision trees based on the samples. A Random Forest classifier trains multiple decision trees on the same training set to enhance classification precision and combat overfitting [13][16].

IV. APPROPRIATE MACHINE LEARNING MODEL

One of the key steps is data preprocessing, which includes data clean-up and normalization. Then, we employed machine learning models for classification. We adopted in this paper XGBoost, AdaBoost, gradient boosting, decision trees, and random forests, to identify three potential driving behavior classes: aggressive, moderate, and slow. The classification techniques utilized here are outlined in the following subsections.

a) XGBoost model: XGBoost is increasingly used in the field of driver behavior analysis due to its effectiveness in handling complex, structured datasets and its ability to provide high predictive accuracy. It's a supervised algorithm that combines multiple base learners to enhance the performance of strong learners.

To analyze driver behavior, we train the model on sensors and OBD datasets $D_{sensors} = \{(X_i, y_i)\}$, $D_{obd} = \{(X_j, y_j)\}$ containing n samples and m decision variables. The driver behavior class y_i is predicted by the trained model. y_i is the target value corresponding to X_i . To understand the functions within the model, the learning objective function of XGBoost is defined as follows:

$$= \sum_{i=1}^{n} l(\hat{y}_i, y_i) + \sum_{k=1}^{K} \Omega(f_k) \quad (1)$$

where, l is a differentiable convex function that measures the discrepancy between the predicted classification value $\hat{y}_i$and the actual category y_i, this is known as the loss function. The Ω function represents the regularization term, which penalizes model complexity to help prevent overfitting.

b) AdaBoost model: AdaBoost algorithm, a widely used ensemble classifier. It works by sequentially training multiple base learners on different sets of training data. The base learners are generated sequentially. The first learner, L_1 is trained on a random subset of the data. The second learner, L_2 is trained using data where half are correctly classified by L_1 and the other half are misclassified by L_1 . The third learner, L_2 focuses on examples misclassified by both L_1 and L_2. The algorithm assigns a weight, w_1, to each training sample. In each iteration, these weights are updated, particularly increasing the weights for the misclassified samples, to help the learner focus on harder cases. The final classifier chosen in each iteration, h_r , is assigned an importance score, α_r , based on its mean squared error e_r, according to the formula:

$$\alpha_r = \frac{1}{2} \ln\left(\frac{1-e_r}{e_r}\right) \quad (2)$$

This process continues iteratively, and different base learners work together to reduce the classification error.

c) Gradient boosting model: Gradient Boosting Machine (GBM) is one of the most widely used supervised machine learning techniques. It was introduced by [17] and has been shown to be highly effective for various predictive tasks. While the training process of GBM, a function is used to distinguish between aggressive, moderate and slow driving behavior. The dataset contains O observations, each characterized by features. The training set is represented as X_i, where related labels y_i with $y_i \in \{0,1,2\}$ where 0 indicates an aggressive behavior, 1 indicates a moderate behavior and 2 indicates a slow behavior.

The goal is to minimize the aggregated loss function through multiclass function estimation. This is typically expressed as an extension of binary classification, where multiple functions are estimated, one for each class. Instead of estimating a single function, the model estimates a separate function for each class label. This is done using the following formula:

$$P(y = N|X_i) = \frac{\exp(f_N(X_i))}{\sum_{j=1}^{N} \exp(f_j(X_i))} \quad (3)$$

Where $f_N(X_i)$ is the function learned for class N at input X_i , $P(y = N|X_i)$ is the predicted probability that the instance belongs to class N, exp denotes the exponential function.

d) Random forest model: Random forest (RF) model utilizes a method called bootstrap aggregating (also known as bagging) to create multiple decision trees and enhance model performance. Bagging involves selecting random subsets of features to determine the best split points in the tree-growing process. For classification tasks, RF bases the final prediction on a majority vote across all trees. The RF predictor function is represented as:

$$f(x) = \frac{1}{K} \sum_{i=1}^{K} T(x) \quad (4)$$

where K is the number of trees, and T(x) represents the individual tree predictions. RF reduces the correlation between trees by using bagging, which creates diversity among trees by drawing different data subsets with replacement. This resampling method allows some data points to be reused multiple times, while others might not be used at all. The diversity enhances robustness to slight variations in input data.

When growing trees, RF selects the best split point from a randomly chosen subset of features at each node. This decreases the strength of individual trees but reduces their correlation, ultimately improving generalization.

e) Decision trees model: The decision tree algorithm is trained using labeled data where each driving behavior is tagged. The tree is constructed by recursively splitting the data based on the most informative features. At each node of the tree, a specific feature is used to split the data, resulting in child nodes representing subsets of the data with more homogeneous driving behaviors. This process continues until the data is sufficiently categorized, or a stopping criterion (such as maximum depth or minimum samples) is met. At each node, the best feature $X_i$and threshold θ are selected to maximize the information gain or minimize Gini impurity. The Gini impurity formula used to assess the purity of a node is:

$$Gini(T) = 1 - \sum_{i=1}^{N} p_i^2 \quad (5)$$

Where N is the number of classes (e.g., "aggressive", "moderate", "slow") and p_i is the proportion of data points in class i at node T.

To assess the efficiency of driver behavior classification, we compare the performances of XGBoost, AdaBoost, Gradient boosting, Decision tree, Random Forest using the following metrics:

- Macro Accuracy: accuracy is the ratio of correctly predicted instances (both positive and negative) over the total number of instances. In multi-class problems, macro accuracy is the overall accuracy across all classes, treating each class equally.

$$\text{Average Accuracy} = \frac{1}{N} \sum_{i=0}^{N} \frac{TP_i + TN_i}{TP_i + TN_i + FP_i + FN_i} \quad (6)$$

- Macro Precision: precision measures how many of the predicted positive instances were true positive. It's the ratio of true positives (TP) to the sum of true positives and false positives (FP). For multi-class classification, macro precision is the unweighted average precision across all classes.

$$\text{Macro Precision} = \frac{1}{N} \sum_{i=0}^{N} \frac{TP_i}{TP_i + FP_i} \quad (7)$$

- Macro recall is used to evaluate the performance of a classification model, particularly in multiclass problems. It measures the model's ability to correctly identify positive instances for each class and then averages these recalls without considering class sizes.

$$\text{Macro Recall} = \sum_{i=0}^{N} \text{Recall}_i = \frac{1}{N} \sum_{i=0}^{N} \frac{TP_i}{TP_i + FN_i} \quad (8)$$

- The macro F1-score combines the concepts of precision and recall into a single score, providing a balanced measure of a model's performance across all classes.

$$\text{Macro F1} - \text{score} = \frac{1}{N} \sum_{i=0}^{N} \frac{\text{Precision}_i \, \text{Recall}_i}{\text{Precision}_i + \text{Recall}_i} \quad (9)$$

Where N is behavior classes number which means the three classes in our study, and TP_i, FP_i, TN_i, and FN_i are the true positives, false positives, true negatives, and false negatives. Macro-averaging approach is employed to solve the problem of imbalanced data when calculating accuracy, recall, precision, and F1-score.

We divided our dataset into 70% of training and 30% of testing. Tables IV and V presented the comparison of different machine learnings algorithms based on sensors and OBD II data, respectively, using the metrics described above. We deduct that Random Forest model has achieved an accuracy of 96% and 99% in both sensors and OBD testing sets. The Random Forest

model demonstrated his efficiency in multi classification tasks. In fact, we chose it as the appropriate machine learning model to predict the three driver behavior classes already proposed.

TABLE IV. PERFORMANCE OF THE DIFFERENT MACHINE LEARNINGS MODELS USING SENSORS DATABASE

Metrics	ML models				
	XGBoost	*AdaBoost*	*Gradient Boosting*	*Decision Tree*	*Random forest*
Average Accuracy	92%	87%	88%	90%	96%
Macro Precision	91%	72%	90%	79%	97%
Macro Recall	72%	52%	54%	78%	82%
Macro F1-score	78%	51%	54%	79%	88%

TABLE V. PERFORMANCE OF THE DIFFERENT MACHINE LEARNINGS MODELS USING OBD DATABASE

Metrics	ML models				
	XGBoost	*AdaBoost*	*Gradient Boosting*	*Decision Tree*	*Random forest*
Average Accuracy	99%	96%	97%	98%	99%
Macro Precision	95%	87%	91%	80%	98%
Macro Recall	82%	84%	70%	77%	86%
Macro F1-score	88%	85%	79%	78%	92%

V. SIMULATION

Fig. 4 illustrates an overall architecture for visualizing driver behavior from data acquisition to classification and driver behavior prediction in real-time such as aggressive, moderate or slow. This architecture is based on three principal keys: (1) Sensing required data from driver's environment and context, (2) Analysing and labeling the driver's behavior class based on the gathered data, and (3) Visualizing the obtained label on driver's mobile application. These main steps are presented in more detail in the following subsections.

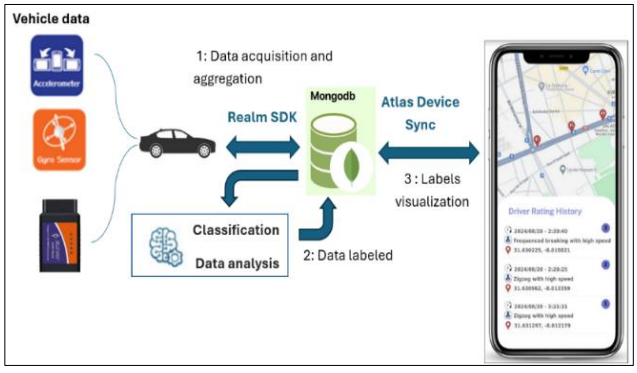

Fig. 4. Smart system for driver behavior prediction.

C. Data Acquisition and Aggregation

As mentioned earlier, the driver behavior prediction objective needs to collect various features that can help the system to categorize driver behavior into three classes: aggressive, moderate, and slow. These features are gathered both from the driver's mobile phone and from an OBDII that is connected to the driver's car and his mobile phone. The collected data related these features are concatenated in a single row json to be stored at real-time in a NoSql Mongodb database. Then the inserted data will be analysed by the chosen ML model which is Random Forest. To meet the challenge of communicating at real-time these data to Mongodb database, we used the following technologies:

- MongoDB Realm which is a lightweight database,
- Realm SDKs to synchronise in real-time these data,
- MongoDB Atlas that provides cloud-hosted managed instances of MongoDB for availability.

MongoDB Realm enables synchronisation between Realm Database and MongoDB Atlas, seamlessly stitching together the two components into an application layer for mobile application. This advantage comes from the fact that the core of Atlas MongoDB service is based on call rest API and push services.

D. Data Labeled

Once the data is stored in MongoDB database, Atlas trigger fires the module "Classification Data Analysis" implementing random forest algorithm to predict the corresponding driver behavior. The obtained label will then be updated in Mongodb database.

The random forest model read the row recently inserted in Mongodb. It analyses first the value that comes from mobile sensors to predict if the driver's behavior was aggressive or not. If the detected behaviour is aggressive, the algorithm is considered finished. Otherwise, the algorithm starts the second process by reading the OBD data to predict if the driver's behavior is moderate or slow.

Once the class is determined by the random forest model, the obtained label is then updated in MongoDB database.

The detail of the implemented algorithm is presented as follows:

Algorithm 1: Prediction Driver behavior

1. **Input**: Each Last added Row from MongoDB at real-time
2. {dataOBD, dataSensors}
3. dataOBD: Data related to OBD columns
4. dataSensors: Data related to Sensor's columns
5. **Output**: The variable "Behavior": {Agg, Slow, Moderate}
6. **Begin**
7. # **First step** – Prediction of aggressive behavior case
8. Behavior = Prediction of the behavior related to dataSensors
9. # **Second step** – Prediction of Moderate or Slow behavior cases
10. If (Behavior! = Agg)
11. Behavior = Prediction of the behavior related to dataOBD
12. # Return the result Aggressive, Moderate or Slow
13. Return Behavior
14. **End**

E. Labels Visualization

The objective of this application is not only to provide driver with valuable feedback about their driver behavior but in addition, to motivate them to be more attentive and conscious of their actions. The application was built using Flutter technology, a well-known open-source framework for designing robust and multi-platform mobile applications. Users can receive real-time updates and access to the most up-to-date information thanks to its seamless integration with APIs. Flutter technology is connected to Atlas Device Sync in order get the updated rows in MongoDB done by the classification ML model module (step 2). The map is used to display pertinent information about driver behavior in real-time using machine learning algorithms, and each color represents a different type of driver behavior. An example of driver interface is shown in the Fig. 5.

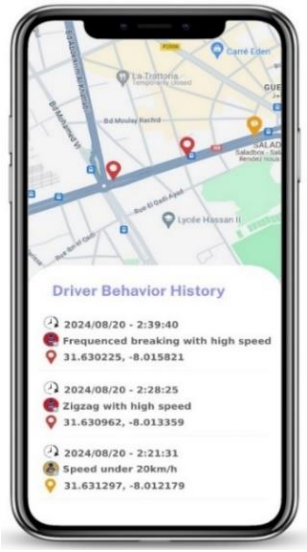

Fig. 5. Driver behavior history application.

VI. Conclusion and Future Work

Driving behavior is a crucial problem that affect the driver safety. To overcome the problem, we proposed a mobile application to aware the driver about his/her driving behavior styles. In this contribution, we developed a smart system to predict driver behavior in real-time utilizing machine learning model and the data collected from smartphone sensors and OBD II installed in a car. This system has the advantage to display on the map the relevant information about driver behavior predicted by machine learning algorithm in real time by assigning different color in which identifies a different type of driver behavior. Simulation have shown the ability of random forest model to predict three classes: aggressive, slow, moderate in both OBD and sensors data to achieve an accuracy of 92% and 88% respectively in Marrakesh city as case study. As a future work, our upcoming project involves developing a real-time recommendation system for safer routes based on driver behaviors. To establish safe routes through intersections, we propose an approach that considers the safety index of each road segment. This index will be calculated in real time, based on the safety indices of vehicles currently traveling on the respective road segment at any given moment. The safety index for each vehicle at time t will be computed in real time using the aggressiveness classification model (which distinguishes between aggressive and slow behaviors) and subsequently stored in a MongoDB repository.

College of Technology and Data, Yantai Nanshan University, Yantai 265700, China

***Abstract*—In the process of the gradual popularization of online courses, learners are increasingly dissatisfied with the recommendation mechanism of imprecise courses when faced with a large number of course choices. How to better recommend relevant courses to targeted users has become a current research hotspot. An intelligent learning model based on ant colony optimization algorithm is introduced, which can accurately calculate the similarity between courses and learners. After structured classification, the model recommends courses to learners in the optimal way. The results showed that the accuracy of this method reached 10-20 when tested in Sphere and Ellipse functions, and the optimal solution for problem Ulysses21 was 27, which was better than Advanced Sorting Ant System (ASrank), Maximum Minimum Ant System (MMAS), and Ant System (AS) based on optimization sorting. The proposed ant colony optimization algorithm had better convergence performance than ASrank, MMAS, and AS algorithms, with a shortest path of 53.5. After reaching Root Mean Square Error (RMSE) and Relative Deviation (RD) distributions of 6% and 8%, the stability of the proposed method no longer decreased with increasing RMSE. The accuracy did not vary significantly with changes in the dataset, and the reproducibility performance was better than other comparison models. In the scenarios of path Block and path Naive, the proposed algorithm had an average computation time of only 1011, which was better than the Ant Colony Optimization (ACO) and Massive Multilingual Speech (MMS) models. Therefore, the proposed algorithm improves the performance of intelligent learning models, solves the problem of local optima while enhancing the convergence efficiency of the model, and provides new solutions and directions for increasing the recommendation performance of online learning platforms.**

***Keywords*—Online courses; ant colony optimization algorithm; intelligent learning model; path planning; local optimum**

I. Introduction

With the development of the Internet, online courses have become more and more popular, which has greatly promoted the development of education in China [1-2]. The booming development of online courses has led to a rapid increase in the number of online courses. However, with the explosive growth of online courses, students are facing unprecedented information overload problems. Traditional recommendation systems often rely on simple user behavior or content features for course matching, making it difficult to accurately associate personalized student needs with corresponding courses, resulting in the dilemma of "rich information but difficult selection" [3-4]. The mismatch between students and courses not only reduces students' learning efficiency, but also restricts the further improvement of the service quality of online education platforms [5]. Therefore, there is an urgent need for an intelligent course recommendation system to solve the above problems.

To address the above challenges, more and more experts and scholars are combining machine learning with path planning, aiming to achieve more efficient personalized recommendation strategies. Liu Y and other researchers proposed a Levy-based ACO algorithm. This algorithm utilized the Levy flight model to expand its search range while searching for paths. The results indicated that its search performance was superior to existing travel agent path planning algorithms [6]. Gao W and other researchers proposed a new ACO algorithm. This algorithm utilized the combination search function to solve the problem of spatial complexity. The results showed that the algorithm outperformed existing common ant colony algorithms in terms of convergence speed and search efficiency [7]. Liu Y and other researchers proposed an ant colony algorithm based on greed and Levy flight improvement. This algorithm adopted pseudo randomness and balanced speed and space to solve the local optimal problem of path search. The results showed that the algorithm performed better than other algorithms when applied in travel sales scenarios [8]. Stodola P and other scholars proposed a car path planning algorithm based on ant colony algorithm. This algorithm used the Cordreau benchmark instance to solve the problems of other methods. The results showed that this algorithm had higher accuracy and precision than other related algorithms [9]. Zhang G et al. proposed an ACO algorithm based on genetic variation, which introduced methods such as crossover, recombination, and mutation in genetics to solve the problem of ship meteorological route planning. The results indicated that this algorithm had higher accuracy and applicability than other algorithms [10].

In recent years, many scholars have devoted themselves to building intelligent learning models to improve the existing performance of algorithms in data similarity calculation research. Intended to enhance the ability of intelligent learning models in processing large-scale complex data, improving classification accuracy, and accelerating computational efficiency. Li W and other researchers proposed a learning classification method based on intelligent optimization algorithms. This method combined operators to assign learning mechanisms to specific learning abilities, achieving analysis and classification of complex learning scenarios. As a result, this algorithm achieved better classification accuracy and reliability than other algorithms [11]. Ge Q and other scholars proposed an intelligent learning model for path

*Corresponding Author

aggregation through an efficient single source VecSim algorithm. This model used a threshold filtering algorithm to remove items with low similarity using a set threshold, and used a sampling algorithm to estimate the probability of encountering additional paths. The results indicated that the proposed method could effectively accelerate the calculation speed, with a query speed of 0.1 seconds and an error of only 10^{-4} [12]. Aggarwal K et al. developed an intelligent learning model based on artificial intelligence, machine learning, and deep learning. This model could effectively identify, analyze, and made decisions when facing large amounts of complex data, increasing the automation of data processing. The results indicated that the algorithm achieved good data analysis performance in the healthcare field [13]. Janiesch C et al. proposed an intelligent machine learning model based on neural networks, which could effectively distinguish relevant concepts in the fields of electronics and network business. The results indicated that the model outperformed traditional data analysis methods and shallow machine learning models in terms of performance. Yang K et al. proposed a federated machine learning model based on aerial computing. This model utilized multiple access channels combined with stacked waveforms to overcome the bottleneck of machine learning model aggregation. The results indicated that the model increased signal propagation strength and reduced model aggregation error [14]. Mousavinasab E et al. proposed a machine learning model based on action condition rule reasoning, which could redefine learners, classify and aggregate them. The results indicated that this method could achieve personalized learning recommendations and promote the application of learning in physics, chemistry, and clinical fields [15].

The existing models still face many challenges in dealing with the complex user behavior patterns and course features unique to online education platforms, such as the dynamic changes in user interests, the diversity of course content, and the real-time nature of recommendation results. Therefore, the study introduces the Negative Feedback Ant Colony Algorithm (NFACA) and the construction of intelligent learning models to be applied to the platform course recommendation platform, helping to improve the performance of platform recommendation algorithms. The innovation of this research lies in the development of an intelligent learning model based on NFACA mechanism, which improves the efficiency and accuracy of path planning and provides learners with more targeted course recommendations. The research contribution lies in proposing an intelligent recommendation model based on NFACA, which provides a new idea and method for course recommendation on online education platforms, solves the problems of low accuracy and efficiency of traditional recommendation algorithms, and provides reference and inspiration for future recommendation system development.

II. Methods and Materials

Firstly, an NFACA is proposed to explore the updating effects of the worst and best solutions in the negative feedback mechanism on pheromone concentration. After defining the learner, a course classification model is constructed based on the calculation method of pheromone concentration, and the intelligent learning model is optimized to improve its performance and find the optimal solution in a shorter time.

A. Design of NFACA Mechanism

Due to the rapid development of society, machine intelligence learning-related technologies have also been further improved. Introducing path planning to find the optimal solution on online learning platforms will become a new driving force for promoting educational progress. The ACO algorithm is inspired by the foraging process of ants, where food always appears randomly. Therefore, the way it selects the optimal path when searching for food has reference significance for model construction in various fields [16]. The use of the ant colony algorithm for path planning mainly solves two problems: optimal path selection and pheromone updating [17]. The selection of the optimal path involves the probability of choosing the next location from one location, as shown in Eq. (1).

$$P_{ij}^{k}(t)=\begin{cases}\dfrac{[\tau_{ij}(t)]^{\alpha}\times[\eta_{ij}(t)]^{\beta}}{\sum_{k\in allowed_k}[\tau_{ij}(t)]^{\alpha}\times[\eta_{ij}(t)]^{\beta}}, \text{if jeallowed}_k\\ 0, \text{otherwise}\end{cases} \tag{1}$$

In Eq. (1), represents the concentration of pheromones; t is the time for selecting the next location; i is the current position; j is the next selected location $\tau_{ij}(t)$ at this moment; $\eta_{ij}(t)$ is the visible range of the ant's next location selection; represents the weight of information concentration; β represents f α actors that affect information concentration; allowed_k is the total number of locations that the k th ant has not yet reached; $P_{ij}^{k}(t)$ represents the probability of ants choosing the next location at this moment. After passing through ants multiple times on a certain road, the concentration of pheromones updates as shown in Eq. (2).

$$\tau_{ij}(t+1)=(1-\rho)\times\tau_{ij}(t)+\sum_{k=1}^{m}\Delta\tau_{ij}^{k}(t) \tag{2}$$

In Eq. (2), $\tau_{ij}(t+1)$ is the pheromone concentration of the ij channel at time $\tau_{ij}(t+1)$; $\Delta\tau_{ij}^{k}(t)$ represents the concentration of pheromones left by ant k on the ij road; m represents the total number of ants passing through ij road; ρ represents the concentration of effective information. The overall process of ant colony algorithm is shown in Fig. 1 [18].

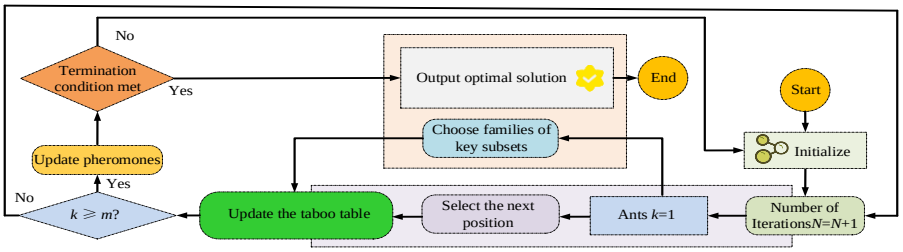

Fig. 1. General flow of ant colony algorithm.

The basic ant colony algorithm takes all the pheromones released by ants as references, which can lead to the algorithm quickly getting stuck in local optima. Therefore, the pheromones released by ants are weighted to avoid their limited field of view and see more possible paths. The weighting formula is shown in Eq. (3).

$$\tau_{ij}(t)=(1-\rho)\tau_{ij}(t)+\sum_{k=1}^{\omega-1}(\omega-k)\Delta\tau_k(i,j)+\omega\Delta\tau_b(i,j) \tag{3}$$

In Eq. (3), w represents the number of ants selected to release pheromones based on their path planning distance sorting; $\Delta\tau_b(i,j)$ represents the concentration of pheromones released by ants that have planned the optimal path; $\Delta\tau_k(i,j)$ represents the concentration of pheromones released by the total number of ants that passed through before k. Only ants that find the optimal path are selected to release pheromones, which can avoid the algorithm's "premature" mechanism in selecting the optimal path. The pheromone optimization formula is shown in Eq. (4).

$$\tau_{ij}(t)=(1-\rho)\tau_{ij}(t)+\Delta\tau_{ij}^{best} \tag{4}$$

In Eq. (4), $\Delta\tau_{ij}^{best}$ is the total concentration of pheromones on the optimal path chosen by ants. The above introduces thinking about optimal path planning from the perspective of the optimal solution, and there is also a reverse thinking entry point: the worst solution, also known as negative feedback. Negative feedback can be used to avoid falling back into the worst solution next time, just like guiding ants to the optimal solution. The formula for the negative feedback model is shown in Eq. (5).

$$\mathbf{Y}=[\delta-\varphi_{ij}(t)]^{\gamma} \tag{5}$$

In Eq. (5), δ represents the upper limit of negative feedback pheromones released on the worst planned path; $\varphi_{ij}(t)$ represents the worst path pheromone matrix; γ represents the weight of negative feedback pheromones on the path; Y represents the probability of negative feedback. The calculation steps of the negative feedback algorithm are shown in Fig. 2.

In the process of combining the worst and best solutions for path planning, different pheromones are used to select paths, and trajectories that are not within the optimal and worst ranges are updated, as shown in Eq. (6) [19].

$$\xi=\frac{L_{\text{best}}}{L_{\text{better}}} \tag{6}$$

In Eq. (6), L_{best} represents the optimal path set that conforms to the concentration of pheromones; L_{better} represents the optimal path set that conforms to the information concentration; ξ represents the relationship and similarity between the optimal and optimal paths. The paths that are not within the optimal and better range are updated, as shown in Eq. (7).

$$\chi_{ij}(t+1)=(1-\rho(t))\times\chi_{ij}(t)+\Delta\chi_{ij} \tag{7}$$

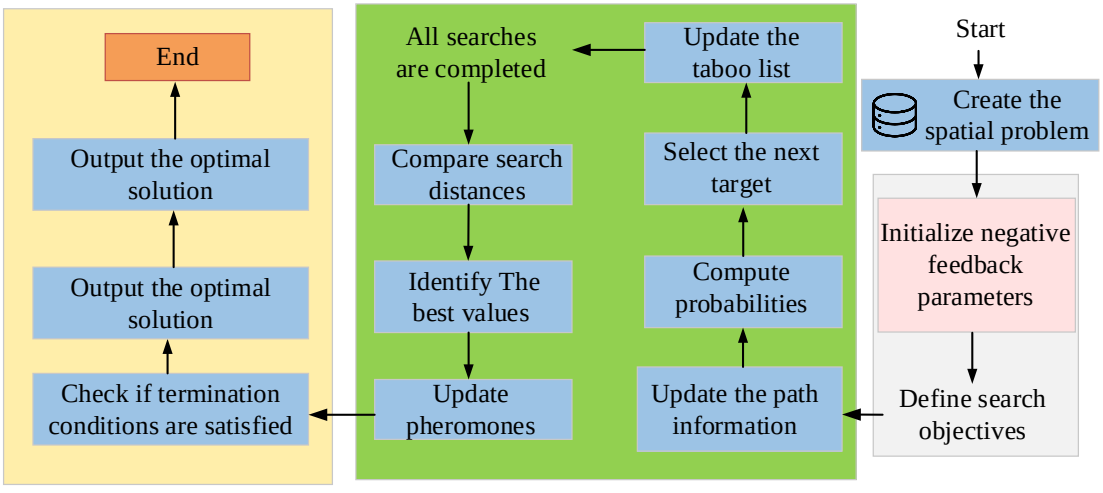

Fig. 2. Computational steps of the negative feedback algorithm.

In Eq. (7), $\chi_{ij}(t+1)$ is the total penalty amount on the channel during $t+1$ time; $\chi_{ij}(t)$ is the total amount of punishment on the ij channel within time t; $\Delta\chi_{ij}$ is the total amount of punishment that varies per unit time; $\rho(t)$ is the amount of remaining pheromone loss within time t [20].

B. Development of Intelligent Learning Path Recommendation Model Based on ACO Algorithm

The primary issue to be addressed in the construction of intelligent learning path recommendation models is the psychological burden that learners face when dealing with a large number of courses. Because a large number of unsorted or unclassified courses are directly pushed without being classified and organized by algorithms, it can cause difficulties for learners to make choices. To structurally classify massive courses and push them along the optimal path, the first step is to classify learners, which can be achieved through accurate descriptions of their learning status [21]. The description of learning state is defined based on the learner's mastery of the course, as shown in Fig. 3.

As can be seen from Fig. 3, the learner's state is divided into start, adaption, and adjustment according to its definition. After defining learners, it is necessary to clarify the calculation of pheromone concentration in ant colony algorithm, which is of great significance for the probability of selecting which path in the path recommendation process. The concentration of pheromones is calculated based on the learner's historical learning curriculum set. The concentration of pheromones on this path not only needs to divide learners into corresponding structural models based on their learning status, but also needs to divide the course into modules corresponding to learners. Therefore, the intelligent learning model requires three datasets for course recommendation: learner dataset, learning course dataset, and pheromone concentration database. The recommendation process is shown in Fig. 4.

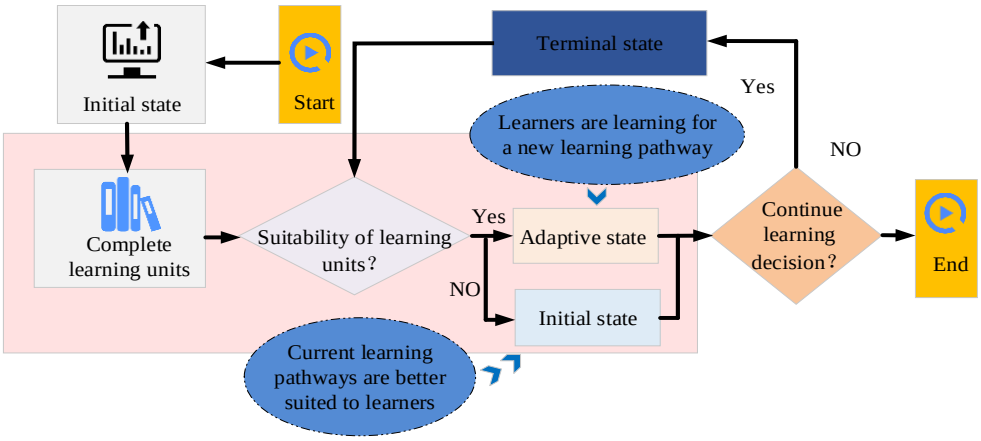

Fig. 3. The transfer diagram of learning states.

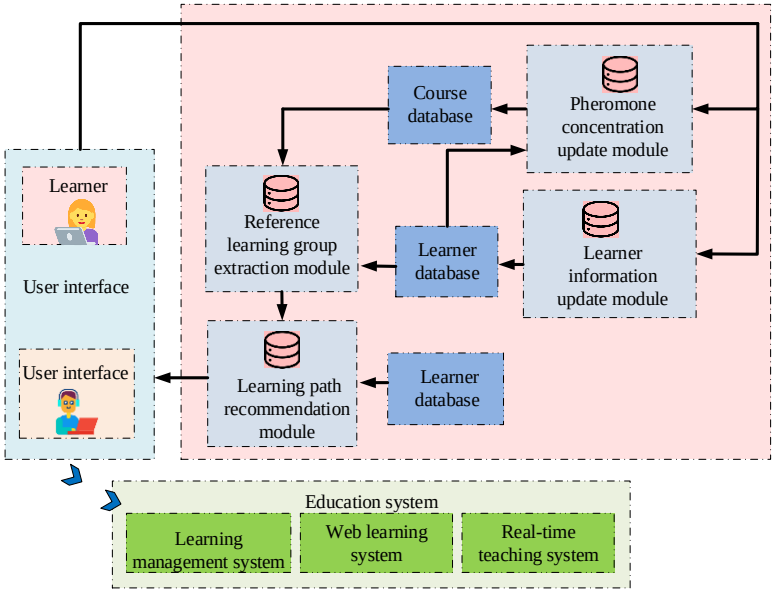

Fig. 4. Study program recommended path.

Learner data information needs to be kept updated, which is the basis for selecting the latest path based on positive and negative feedback. This ensures that each recommended path is not dependent on historical judgments and can be adaptively adjusted based on data updates. This data update requires continuous similarity calculation of learner information, as shown in Eq. (8).

$$\mathrm{Dis}\left(\mathrm{LA_i},\mathrm{LA_j}\right)=\mathrm{Dis}\left(\mathrm{LD_i},\mathrm{LD_j}\right)\times\mathrm{Dis}\left(\mathrm{E_i},\mathrm{E_j}\right) \tag{8}$$

In Eq. (8), $\mathrm{LA_i}$ and $\mathrm{LA_j}$ respectively represent two different learners; $\mathrm{LD_i}$ and $\mathrm{LD_j}$ respectively represent the areas that two different learners are interested in learning; $\mathrm{E_i}$ and $\mathrm{E_j}$ respectively represent the current level of knowledge that two different learners have in the field they are interested in learning [22]. The relationship between learners and learning domains belongs to a one-to-one correspondence, as calculated in Eq. (9).

$$\eta_{\mathrm{ik}}(\mathrm{t})=\sum_{\mathrm{LUA_j}\in\mathrm{Sim(LA_i)}}\mathrm{Dis}(\mathrm{LA_i},\mathrm{LA_j})\times\mathrm{Count}(\mathrm{LA_j},\mathrm{LUA_k}) \tag{9}$$

In Eq. (9), $\eta_{\mathrm{ik}}(\mathrm{t})$ represents similarity; $\mathrm{LUA_k}$ represents the overall learning area; $\mathrm{LUA_j}$ represents the current learning field; $\mathrm{Sim(LA_i)}$ represents the learning group. The probability that the learner has previously learned knowledge in the learning field is shown in Eq. (10) [23].

$$P_{ik}(t)=\begin{cases}\dfrac{[\eta_{ik}(t)]^{a}}{\sum\limits_{k}[\eta_{ik}(t)]^{a}}\\ 0\end{cases} \tag{10}$$

In Eq. (10), $P_{ik}(t)$ represents the probability that the learner has learned the selected learning area within time t, the probability of not learning is 0, and the probability of learning is $\dfrac{[\eta_{ik}(t)]^{a}}{\sum\limits_{k}[\eta_{ik}(t)]^{a}}$; α represents the weight of similarity; $k*$ represents the number of learners and learning domains. The similarity estimation between learning units is shown in Eq. (11) [24].

$$\Phi_{jk}=\mathrm{Dis}(\mathrm{UA_j},\mathrm{UA_k})\times\mathrm{Dis}(\mathrm{C_j},\mathrm{C_k}) \tag{11}$$

In Eq. (11), UA_j and UA_k respectively represent the number of similar contents present in the learning unit, while C_j and C_k respectively represent the degree of correlations between learning neighborhoods. The representation of pheromone concentration is the core of path planning, and the calculation method is shown in Eq. (12) [25].

$$\varepsilon=(\Delta\tau_{jk}(t)-60)/(90-60) \tag{12}$$

In Eq. (12), when $\Delta\tau_{jk}(t)$ represents the pheromone variation value, and its range is between [60, 90]. ε represents the adjustment factor. According to the change value of pheromones, learners are scored, and the current learning path is adjusted using adjustment factors. The process of judging the current level of knowledge mastery of learners is shown in Fig. 5.

When recommending learning paths based on the initial learning state of learners, due to their low or zero knowledge level and inability to rely on the calculation of the previous path or pheromone, it is necessary to choose based on the degree of matching with the course database in the model. The recommendation for learners in the initial state is shown in Eq. (13).

$$p_{oi}=\sum_{r\neq o}\lambda_{or}\cdot\theta_{ri} \tag{13}$$

In Eq. (13), p_{oi} represents the similarity between the learner in the starting learning state and the learning unit; λ_{or} is the similarity between learner S_o and learner S_r; θ_{ri} is the similarity between learner S_r and learning unit L_i. When recommending to learners who are in an adaptive state and are satisfied with the current course, it is only necessary to recommend units based on the adjustment factor, as shown in Eq. (14).

$$p_{ij}^{S_o}(t)=\begin{cases}\dfrac{\left[\eta_{ij}\right]^{\alpha^*}\times\left[\tau_{ij}(t)^*\right]^{\beta^*}}{\sum\left[\eta_{ij}\right]^{\alpha^*}\times\left[\tau_{ij}(t)^*\right]^{\beta^*}}, L_j|\ \phi_{ij},, \varepsilon\\ 0, L_j|\ \phi_{ij}>\varepsilon\end{cases} \tag{14}$$

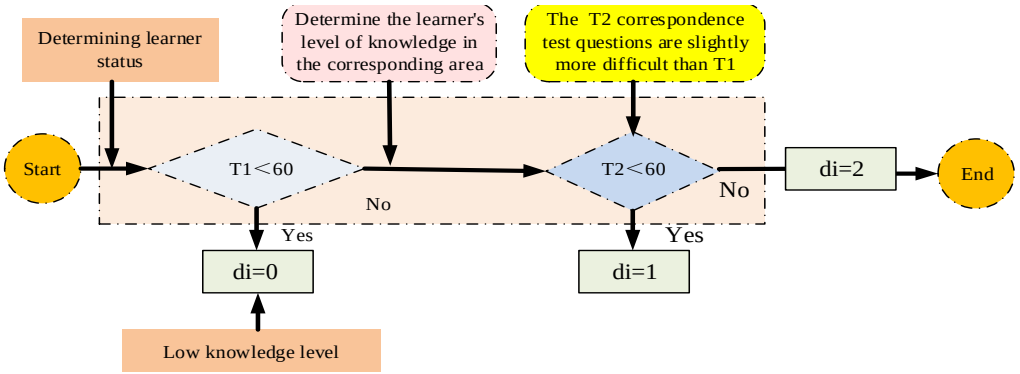

Fig. 5. Flowchart for judging the level of knowledgeable people.

In Eq. (14), $p_{ij}^{S_o}(t)$ represents the probability of S_o learners learning from L_i unit to L_j unit during t time; η_{ij} represents the pheromone between two units ij at time t; $\tau_{ij}(t)^*$ represents the pheromone density of the path connecting two units ij at t time; α^* and β^* respectively represent the influencing factors of path pheromone density and learners' level of knowledge mastery. ϕ_{ij} represents the degree of overlap between the feature values of two learning courses in ij. When recommending learners who have adjusted their status, it indicates that the learner is not satisfied with their current level of knowledge in the learning course and needs to revise their learning path, as shown in Eq. (15).

$$p_{ij}^{S_o}(t)=\begin{cases}\dfrac{\left[\eta_{ij}\right]^{\alpha^*}\times\left[\tau_{ij}(t)\right]^{\beta^*}}{\sum\left[\eta_{ij}\right]^{\alpha^*}\times\left[\tau_{ij}(t)\right]^{\beta^*}}, L_j \mid d_m^o = C_m^j \\ 0, L_j \mid d_m^o \neq C_m^j\end{cases} \quad (15)$$

In Eq. (15), d_m^o represents the degree of knowledge mastery of learner S_o in the knowledge domain n; C_m^j represents the breadth of knowledge of learning unit L_j within the knowledge domain n.

III. Results

To validate the performance of the proposed algorithm model, the dataset source and experimental platform were first introduced. Then relevant performance tests were conducted on the algorithms before and after optimization, as well as other algorithms, in different scenarios. Secondly, different functions were used to compare the proposed algorithm with other algorithms. Finally, the proposed algorithm was compared with other algorithms in terms of practical application effects.

A. Performance Testing of Intelligent Learning Model Based on ACO Algorithm

The experimental platform adopted the hardware configuration of Genuine Intel equipment ® CPU 2140 (dual core) 1.6GHz, 512MB memory. The experiment was conducted on the MATLAB 7.0 platform. The data used in the study was the TSPLIB dataset, and the related problems of this dataset achieved optimal solutions and were widely recognized. It selected relevant questions from this dataset to train and test the performance of the proposed algorithm. Combined with the comparison of three classic models in the past, the superiority of this method could be clarified. Classic algorithms included AS, MMAS, and ASrank. The study adopted the four core issues present in the TSPLIB dataset, as shown in Table I.

To verify the search capability of the proposed algorithm, four out of the seven shutdown key questions were selected for performance testing, and to compare it with three classic algorithms, the optimization results are shown in Fig. 6. From the figure, the proposed AS-N algorithm had better search ability and could search for the shortest path in a shorter time. The four algorithms ASrank, MMAS, AS, and NFACA converged to the optimal solution of problem Ulysses21 at 40, 32, 36, and 27, respectively, and the proposed results performed the best. The proposed NFACA algorithm reduced the optimal solution by 10% compared to the original AS algorithm, and reduced it by 12% and 24% compared to MMAS and ASrank. The performance of the four algorithms on datasets of four different problems is not significantly different, therefore the proposed algorithm has better reliability and convergence speed.

To verify the reliability of the proposed optimization, the actual application effects of the proposed NFACA algorithm were compared and validated with 10 dimensional test functions of ASrank, MMAS, and AS algorithms. The test functions were Sphere, Ellipse, Ackley, and Griebank, respectively. From Fig. 7, the proposed algorithm had the fastest convergence speed when tested in Sphere and Ellipse functions, with an average function value of 10-20, while the average function values of the other three algorithms were around 103. Under the influence of effective and critical subsets, its solution accuracy was higher, and when the adaptive function was estimated around 4000 times, it was already more pronounced on the average of the function than other algorithms. In the Ackley case, all four algorithms achieved good function averages, but NFACA still reached 104 before one-third of the optimization process. During the Griewankf test, only the optimized NFACA algorithm avoided the problems of "premature convergence" and getting stuck in local optima. When the number of adaptive evaluations was between 0-3000, the convergence speed was significantly faster than other algorithms.

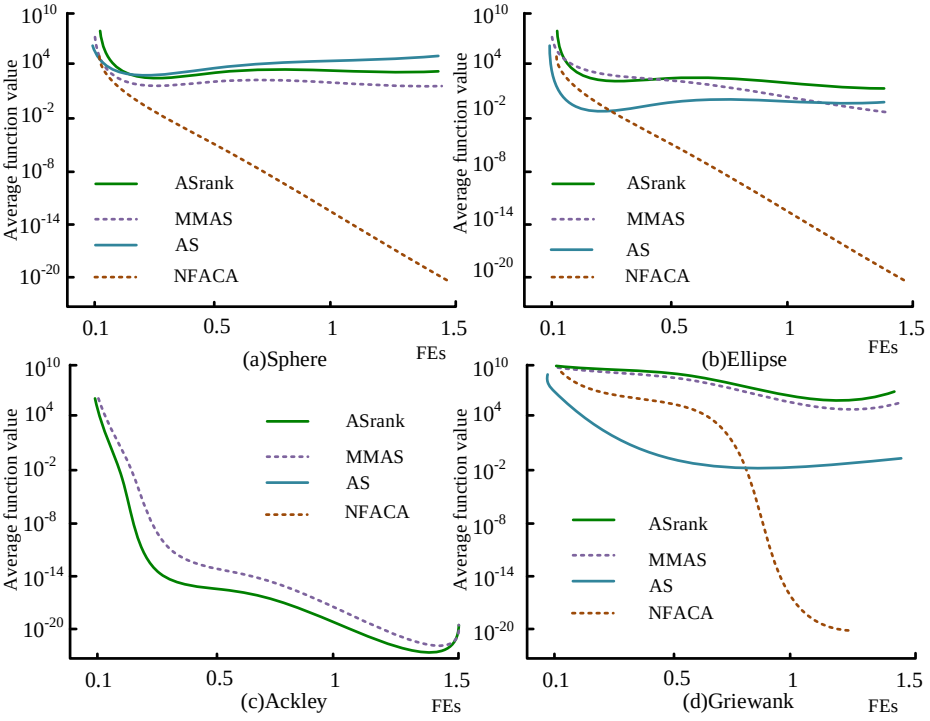

Fig. 7. Comparison of convergence curves of each algorithm in four functions.

B. *Analysis of the Actual Effect of the Intelligent Learning Model Based on the ACO Algorithm*

The convergence process curve of the proposed model with increasing iteration times was analyzed, the application effect of the model in four different real environments was evaluated, and it was compared with MMAS and AS models. From Fig. 8, all four models began to converge after more than eight searches. The ACO algorithm had a better convergence effect, with the shortest path of 53.5. The AS model had the worst convergence effect, with a difference of 5% compared to the ACO algorithm. The convergence degree of

the MMAS model and the proposed ACO algorithm was not significantly different, but they began to converge at the 6th search, showing a phenomenon of "premature convergence". The proposed algorithm achieved the best convergence effect in all four environments, indicating that it can stably and effectively search for the optimal solution in different complex environments.

To verify the stability of the constructed intelligent learning model in the application of real learning course recommendation scenarios, the stability of the proposed method, ACO and MMS algorithms were compared under different RMSE and RD. The results are shown in Fig. 9. The stability of all three methods decreased with the increase of RMSE, but when RMSE reached 6%, the stability of the proposed method no longer decreased but tended to stabilize. Among them, the ACO algorithm showed the greatest decrease, with a total decrease of 12%. The stability decline of MMS algorithm slowed down in the later stage, with a total decrease of 10%. As the absolute value of the maximum RD increased, the stability of ACO and MMS algorithms has been on a downward trend, decreasing by 12% and 15% respectively. However, the stability of the proposed algorithm was the best, and when RD increased to 8%, the stability did not continue to decrease but increases, with a total decrease of only 5%. The results indicate that the proposed method has higher stability and is more reliable for clustering classification in practical employment recommendation scenarios.

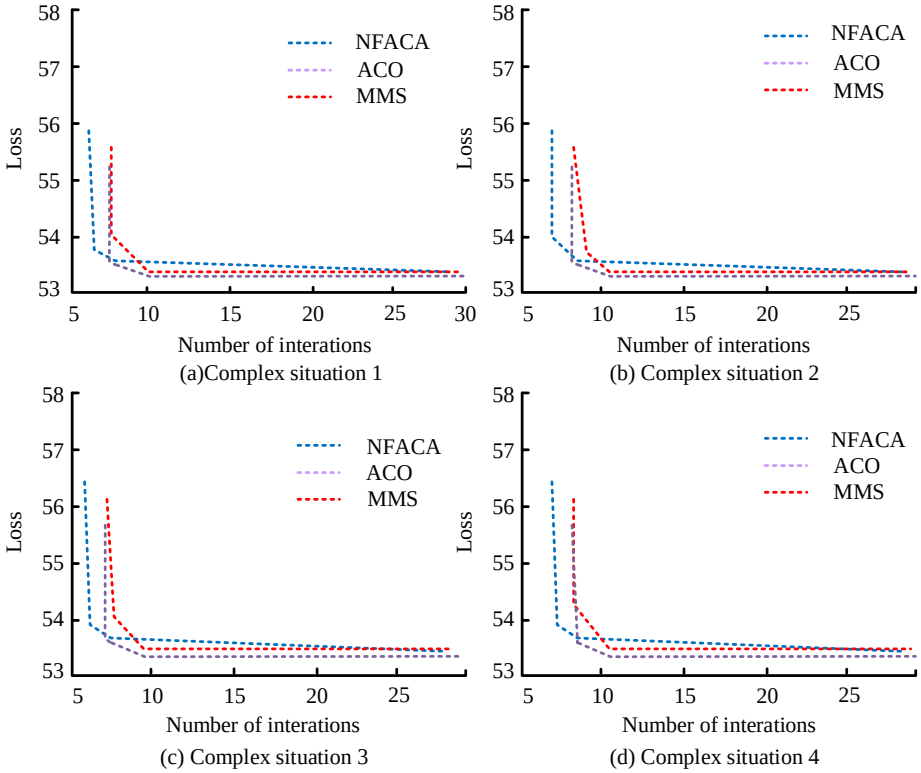

Fig. 8. Comparison of different algorithms for path search.

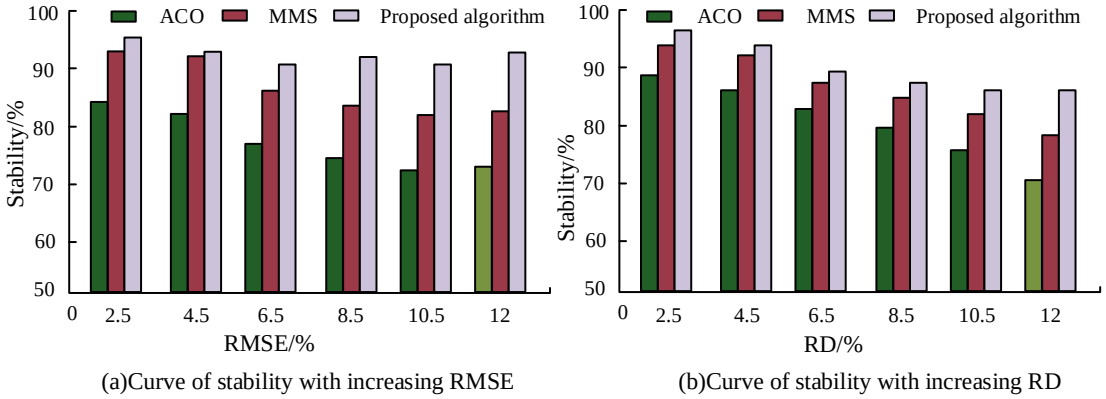

Fig. 9. Changes in stability by method.

To test the accuracy of calculating similarity between students using NFACA model, it was applied to three different university course learning platforms in real scenarios for simulation experiments, and the effects were compared using AS, TaSimRank, and RD3 algorithms. The results are shown in Fig. 10. From Fig. 10, in the datasets of the three scenarios, the accuracy of all four models increased with the increase of k. Among them, the accuracy of the proposed model achieved the best results in three scenarios, with differences within 0.2 in different datasets, and was on average 10%, 11%, and 13% higher than the accuracy of AS, TaSimRank, and RD algorithms, respectively. The RD algorithm had the lowest variation in calculation accuracy among different university datasets, ranging from 0.18 to 0.7. So, the proposed model has higher accuracy and can achieve good repeatability when applied in different course recommendation scenarios.

To test the similarity calculation efficiency of the intelligent learning model proposed by the research in recommending learning units to learners, the ACO and MMS algorithms were compared in three different university learning course recommendation scenarios under two different paths, Naive and Block. The results are shown in Fig. 11. From the figure, the proposed model used the least amount of computation time in both the path Block and path Naive scenarios. Among them, the Naive scenario took the least amount of time, with an average of only 1025s in three different scenarios, which was 16% and 23% lower than the ACO and MMS algorithms, respectively. In the path Block scenario, the proposed model still took the least amount of time, averaging only 1302 seconds, which was 12% and 19% lower than the ACO and MMS algorithms, respectively. From the results, the proposed algorithm performs the best in terms of computation time under different path comparison times. Therefore, this method is applicable in practical environments.

IV. Discussion and Conclusion

The rapid development of online learning has brought many benefits, but it is also accompanied by problems that need to be solved. In the field of course recommendation, although existing intelligent models have shown some effectiveness, they still face limitations in terms of real-time and accuracy. Liu Y and other researchers proposed a pseudo-random algorithm for path planning, which solves the problem of local optima. However, when facing large-scale datasets, there are limitations to their computational efficiency and scalability. Researchers such as Zhang G have developed an ant colony algorithm based on a genetic mutation algorithm to improve the accuracy and applicability of meteorological route planning. However, when directly applied to the field of course recommendation, the complex parameter adjustment and domain specificity issues limit its universality. Mousavinasab et al. proposed a machine learning model that better classifies learners, although it has shown good personalized recommendation performance in physics, chemistry, and clinical fields. However, how to accurately capture learners' interest changes and dynamic needs in course recommendations is still an unsolved problem. Given the limitations of the aforementioned research, an innovative intelligent learning model based on a negative feedback ant colony algorithm is proposed. Compared to traditional methods, the model proposed by the research institute has shown significant advantages in reducing the time cost for learners to choose courses, improving recommendation accuracy, and enhancing user experience.

The results showed that the proposed model achieved a convergence speed accuracy of 10^{-20} when tested in Sphere and Ellipse functions, and the optimal solution for problem Ulysses21 was 27, all of which were better than ASrank, MMAS, and AS. The NFACA mechanism had better convergence effect than ASrank, MMAS, and AS algorithms, with a shortest path of 53.5. After reaching RMSE and RD distributions of 6% and 8%, the stability of the proposed method no longer decreased with increasing RMSE. In the scenarios of path Block and path Naive, the proposed algorithm had an average computation time of only 1011, which was better than the ACO and MMS models. In the path Block scenario, the computation time of the three algorithms was slightly reduced compared to the Naive path scenario. This was because the Naive path had more comparisons, which greatly slowed down the algorithm's running speed and increased computation time. In datasets from three different university scenarios, the accuracy of all four models increased with the increase of k. Among them, the accuracy of the proposed model achieved the best results in three scenarios, and the difference in accuracy between different datasets was within 0.2, which was 10%, 11%, and 13% higher than the average accuracy of AS, TaSimRank, and RD algorithms, respectively. Therefore, the proposed method provides a new solution for path planning in the field of online course recommendation, increasing convergence speed while conducting global search, and improving the accuracy, stability, and applicability of course recommendation platform algorithms. However, there are certain limitations in the methodology, as there are multiple parameters in the negative feedback ant colony algorithm, including pheromone heuristic factor, expected heuristic factor, and pheromone evaporation coefficient. Adapting these parameters to further enhance the algorithm's ability to adaptively adjust the environment can be a future research direction. It can also be combined with a differential particle optimization algorithm to improve the diversity of solutions.

***Abstract*—Cyberattacks are intentional attacks on computer systems, networks, and devices. Malware, phishing, drive-by downloads, and injection are popular cyberattacks that can harm individuals, businesses, and organizations. Most of these attacks trick internet users by using malicious links or webpages. Malicious webpages can be used to distribute malware, steal personal information, conduct phishing attacks, or perform other malicious activities. Detecting such malicious websites is a tedious task for internet users. Therefore, locating such a website in cyberspace requires an automated detection tool. Currently, machine learning techniques are being used to detect such malicious websites. The majority of recent studies derive a limited number of features from webpages (both benign and malicious) and use machine learning (ML) algorithms to detect fraudulent webpages. However, these constrained capabilities might not use the full potential of the dataset. This study addresses this issue by identifying malicious websites using both the URL and webpage content features. To maximize detection accuracy, both ngrams and vectorization methods in natural language processing are adopted with minimum feature-set. To exploit the full potential of the dataset, the proposed approach derives the 22 common linguistic features of the URL and generates ngrams from the domain name of the URL. The textual content of the webpages was also used. The research employs seven machine learning algorithms with three vectorization methods. The outcome reveals that the proposed method outperformed the results of previous studies.**

***Keywords*—Machine learning; N-gram; linguistic features; natural language processing (NLP); malicious webpage**

I. Introduction

A malicious webpage is a website intentionally crafted to harm users or their devices, often orchestrated by hackers and cybercriminals utilizing various techniques to exploit vulnerabilities. These webpages pose significant threats, serving as conduits for malware distribution, personal information theft, phishing attacks, and other malicious activities. Cybercriminals employ common techniques like phishing, where deceptive URLs (Uniform Resource Locators) or webpages mimic legitimate sites to trick users into divulging login credentials or personal data, facilitating identity theft or financial fraud. Another tactic involves drive-by downloads, concealing malicious code within a webpage to exploit vulnerabilities in users' browsers or operating systems, and installing malware without their knowledge. Malvertising utilizes legitimate online advertising networks to redirect users to malicious pages, aiming to infect their computers with malware. Cryptojacking involves hijacking a user's computer processing power to mine cryptocurrency for attackers. Once users access a malicious webpage, they risk downloading malware, suffering personal information theft, or falling victim to various attacks. The consequences extend to severe impacts on individuals, businesses, and organizations, encompassing data theft, financial losses, reputational damage, and even physical harm.

The cost of cyber-attacks continues to rise and is a significant concern for organizations across all industries. According to IBM's 2024 Cost of a Data Breach Report, the global average cost of a breach has increased by 10% since 2023, reaching $4.88 million [1]. Global cybercrime expenditures are anticipated to increase from $3 trillion in 2015 to $10.5 trillion annually by 2025, according to Cybersecurity Ventures research [2]. Phishing attacks, which targeted 1339 brands, accounted for 36% of US data breaches in 2023. It became the second-most expensive source of compromised credentials with 5 million unique phishing sites, signaling a significant change in the dynamics of breaches across industries [3]. The financial impact of a cyber-attack depends on factors such as its severity, organizational size, and the compromised data. To mitigate these impacts, proactive measures like implementing robust security systems and conducting employee training programs are essential. While conventional security systems often rely on stored lists of URLs to block harmful links, recent attacks exploit vulnerabilities using short URLs and algorithmically generated ones, evading traditional security measures. Consequently, the necessity for an automated system employing machine learning techniques becomes increasingly critical to detect and prevent these evolving cyber threats effectively. Timely detection plays a pivotal role in ensuring a proactive defense against cyber

threats, effectively safeguarding users and their devices from various malicious activities.

Machine learning-based detection relies on feature engineering. The researcher identifies and uses six types of features for the detection of malicious webpages such as:

- Linguistic analysis of URL [3][4]: URL consists of several parts such as protocol, domain name, path, query-string, etc. Using these parts for the detection process such as a number of subdomains in the URLs, protocol used in the URL length of the path, etc.
- Information obtained Domain Name System (DNS) [3][5][6]: DNS is a critical component of the internet infrastructure, and it plays an important role in the functioning of URLs. To generate features, researchers obtain information from the DNS server such as server location, registration and expiry date of the website, etc.
- Structural information of webpage [7]: The structural information of a webpage refers to the underlying organization of the webpage's content, including its layout, formatting, and elements of the page. For malicious website detection, the researcher analyzes HTML tags, DOM objects, CSS, and JavaScript elements, and other web page components.
- Linguistic analysis of webpage contents [8]: This is the written content of the webpage, including headings, paragraphs, and other text elements. The linguistic analysis involves character and word-level analysis to find harmful websites, such as finding probable keywords, tokens, and keyword weight, etc.
- Website Reputation [9]: Website reputation or ranking refers to the perceived level of trustworthiness, authority, and relevance of a particular website, as assessed by search engines, users, and other entities. Websites with a high reputation or ranking are generally viewed as more credible and valuable and may receive more traffic and engagement as a result. Ranking of the website globally and locally is considered as a feature for malicious webpage detection.
- Visual Similarity of the Webpage [10]: Visual similarity of a webpage can be a useful tool in malicious webpage detection. Malicious actors may attempt to create webpages that are visually similar to legitimate sites to trick users into providing sensitive information or installing malware. One approach to detecting visual similarity in webpages is to use computer vision techniques such as image processing, feature extraction, and machine learning. These techniques can be used to identify and compare visual elements of webpages, such as logos, fonts, and layouts.

Among all these features, researchers preferably use the linguistic analysis of URLs because it doesn't involve any risks. Web page content, on the other hand, gets less attention due to its risky nature. However, in comparison, webpage contents are a rich source of malicious webpage detection. The majority of recent studies derive a limited number of features from the URL and use machine learning algorithms (ML) to detect fraudulent webpages. However, these constrained capabilities might not use the URL's full potential. This study addresses this issue by identifying malicious websites using both the URL and webpage content features. To maximize detection accuracy with a minimum hybrid feature set, the proposed approach uses both URL and webpage contents. To exploit the full potential of the dataset, the proposed approach derives the 22 common linguistic features of the URL and generates ngrams from the domain name of the URL. Moreover, it extracts text from the webpage's paragraph tags. In the experiment, three distinct vectorization techniques (Count vectorizer, TFIDF, and Hashing vectorizer) are used to convert text into real numbered 2-D vectors. Lastly, the vectorized features and linguistic features are integrated to generate the experimental dataset. The incorporation of vectorized contents with URL linguistic features (hybrid approach) eliminates the necessity for generating and selecting a limited number of features. This ensures the full exploitation of the dataset's potential. The research employs seven machine learning algorithms. The outcome reveals that the proposed method outperformed the results of previous studies.

Contribution of the paper:

- Both URL and Webpage contents are utilized to generate features.
- Two different feature sets are generated using URLs of the webpages namely linguistic features and character-level ngrams of the URL
- Textual contents are extracted from the paragraph tags of the webpages.
- Three different NLP methods (Count vectorizer, TFIDF, and Hashing vectorizer) are used to vectorize the textual contents such as ngrams of the URL and textual contents from the webpages.
- NLP methods are used for feature generation instead of manual feature extraction.
- A balanced dataset (malicious and benign) is used for the experiments.
- Seven machine learning algorithms are evaluated for better detection accuracy.
- Achieve higher accuracy and f1-score with minimum feature set.

The structure of this paper is organized as follows. Section I outlines the significance of the problem and an overview of the solution strategy. Existing research is presented in Section II. The NLP techniques and machine learning classifiers are presented in Section III. Section IV presents the proposed method, and Section V reports the experimental results. Section VI provides a conclusion of the paper.

II. Related Works

Malicious webpage detection is a critical component of web security, as it can help to protect users from a variety of online threats, such as malware, phishing, and other types of

malicious activity. Extensive research has been conducted in this area. Table I summarizes recent research studies in this field. Saleem et al. [7] introduced a technique for classifying malicious webpages by analyzing their content through machine learning and deep learning approaches. The presented method exclusively uses of tags, events, keywords, scripts in the website for classification. The study utilizes the Kaggle dataset. From the dataset, over 206 features are retrieved. The selectKbest approach selects the highest-scoring features for the experiment. Scores in selectKbest are based on chi-square tests. Support vector machine (SVM), random forest (RF), and convolutional neural network (CNN) are used to test the system. The results demonstrate that random forest and support vector machine obtains the accuracy of 93% and 88% respectively. Saleem et al. [11] suggested a simple technique for detecting malicious URLs. The authors note that traditional approaches to malicious URL detection, which rely on blacklists and reputation-based systems, are not effective against new or previously unseen threats. To address this, the authors propose a new approach that uses a set of lexical features, including the length of the URL, the presence of certain characters, and the number of subdomains, to train a machine learning model to detect malicious URLs. The authors evaluate their method using a UNB dataset containing over 68851 URLs, including both malicious (33473) and benign (35378) URLs. From the dataset, 27 lexical features were taken, and 20 of those features were used in the experiment. The study's findings indicate that the suggested method achieves high accuracy in detecting malicious URLs, with 99% accuracy for random forest (RF) and 98% accuracy for k-nearest neighbor (k-NN) algorithms, respectively. Malak et al. [12] evaluate different feature sets for detecting malicious URLs using machine learning and deep learning models. The authors note that existing approaches to malicious URL detection often rely on a single feature set, which may limit their effectiveness. To address this, the authors evaluate three different feature sets: lexical, network-based, and content-based. Many feature selection procedures, including correlation analysis, ANOVA, and chi-square, were utilized to select features from the dataset. Naive Bayes (NB) was shown to be the most appropriate method for identifying malicious URLs in the used dataset, with an accuracy of 96%. Kamel [13] proposes a new approach for detecting and analyzing phishing attacks on social networks, specifically on Twitter. The authors note that phishing attacks on social networks are a growing problem, and traditional approaches to detecting them, such as manual analysis or keyword-based filtering, are not effective. To address this, the authors proposed a new approach by using machine learning algorithms to identify phishing attacks on Twitter. The approach involves analyzing the content of tweets and using machine learning to classify them as either phishing or non-phishing. For this experiment, a UCI phishing, Phishtank, and MillerSmiles datasets were utilized, and roughly 25 features were retrieved from the URL, webpage, and DNS server. For the studies, LR, SVM and RF were applied, yielding 90.28%, 93.43%, and 95.51% accuracy, respectively. Lakshmanarao et. al [14] proposes a web application for detecting malicious URLs using natural language processing (NLP) and machine learning techniques. This method makes use of a count, a TFIDF, and a hashing vectorizer. The outcome demonstrates that hashing vectorizer and random forest obtained 97.5% accuracy. Machine and deep learning help detect email-delivered malicious URLs, according to Joshi et al [15]. To classify URLs, the proposed method relied on their lexical features. The experiment employed a dataset from openphish, alexa, and fire eye. The proposed method used 23 distinct lexical characteristics to distinguish between malicious and benign URLs. Combining the lexical features with 1000 trigram-based features yielded 1023-long numerical vectors to represent the URLs. To identify the most important traits, correlation and scatter matrices were used. The results show that 92% accuracy is achieved by the random forest method. Hong et al. [16] employ lexical analysis and feature quantification to identify potentially dangerous domain names. The method comprises of two stages for accurate and successful detection. A domain name is compared in the first step to a blacklist of harmful domain links. The degree to which the domain name modifications closely resemble the blacklist determines whether it is malicious or possibly malicious. In the second step, a suspected malicious domain name is assessed using the reputation value of an N-gram model. Using the N-gram approach, a collection of whitelist/blacklist substrings is extracted from the top 100,000 regular Alexa domain names. The frequency of substrings on whitelists and blacklists determines their weights. Lastly, the authenticity of the possibly dangerous domain name is determined by its reputation value. The outcome shows that the accuracy rate for the proposed method, LA-FQ, is 94.16%. Josh et al. [17] used random forest to detect algorithmically generated domains. For testing, the dataset comprised regular and algorithmically generated domain names from several malware families. Masked N-grams and other domain name data were extracted. Results show that masked N-grams provide improved performance and detection accuracy compared to state-of-the-art methods. To detect harmful web links using NLP, Saleem et al. [18] suggested an ensemble classifier. The author observed that feature generation needs effort and topic expertise. Sometimes the generated features don't maximize the data set. Hence, the suggested method generates a feature set from the URL using the NLP method and classifies using an ensemble classifier. Two datasets (D1 and D2) were used in the experiment. D1 and D2 had 91.4% and 99.1% accuracy, respectively. The phishing URL detection method used by Ozgur et al. [19] is based on machine learning and a natural language processing (NLP) feature set. URLs were broken up and features were taken from them. For the experiment, seven different machine learning algorithms were used. The author states that the proposed method is language-independent and uses a large dataset. The outcome demonstrates that random forest with NLP features has an accuracy of 97.98%.

TABLE I. SUMMARY OF THE EXISTING WORK

Author	Dataset/Data Source	Features	Accuracy	Issues
Saleem et al. [7]	Kaggle dataset	Web content-based features	SVM: 88%, RF: 93%	URL-based features and webpage textual contents were ignored.
Saleem et al. [11]	UNB Dataset	Lexical features of URL	RF:99%, KNN:98%	Limited number of features. Web content features were ignored
Malak et.al [12]	Singh & Kumar Dataset	Lexical, network-based, and content-based features	NB:96%	Limited features. The full potential of the dataset was not used.
Kamel et.al [13]	UCI phishing, Phishtank, MillerSmiles datasets	Lexical, content based and DNS server features	LR: 90.28%, SVM: 93.43%, RF: 95.51%	Limited features. The full potential of the dataset was not used.
Lakshmanarao et.al[14]	Kaggle dataset	NLP -Vectorizer Methods	Hashing vectorizer with RF: 97.5%	Potentials of web contents were not utilized.
Joshi et.al [15]	Openphish, Alexa, Fire eye	Lexical Features & N-Gram Method	RF:92%	Web content features were ignored.
Hong et al. [16]	Alexa, Anquan organization, Malwaredomains.com, Malicious domain list, Zeus Tracker, Conficker, Torping, Symmni, PhishTank	N-gram Method	LA-FQ:94.16%	Web content & Lexical URL features were ignored.
Josh et.al [17]	Alexa, Bader repo extended	N-Gram Method	RF: 98.91%	Web content & Lexical URL features were ignored.
Saleem et.al[18]	URL, UNB, Phistank dataset	NLP -Vectorizer Methods	Weighted Soft Voting Classifier: D1:91.4% , D2:99.1%	Web content & Lexical URL features were ignored.
Ozgur et.al [19]	Phistank dataset, Yandex Search API	NLP based features	RF: 97.98%	Web content and other features were ignored.

III. BACKGROUND

The URL of the webpage and the webpage's content are both valuable resources for webpage classification, particularly for the detection of malicious webpages. A URL is a string that is used as a specific identifier to find resources online. It is made up of several components as shown in Fig. 1. Due to its risk-free nature, researchers employ the URL of the webpage for detection. Two distinct methods are used to extract features from the URLs.

1) Numerical/presence measurement: check the URL for the presence of specific words or characters and count the occurrence of the specific word or character, URL/domain/path length, etc.

2) Decompose the URL string using the ngram method and identify interesting features such as the amount of 2-grams and the average length of 2-gram tokens, etc.

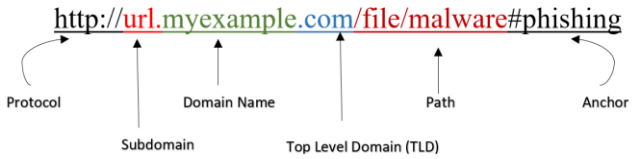

Fig. 1. Components of an URL.

Malicious websites can include a wide range of content that is intended to trick or exploit users, including fake login pages that steal login credentials, malware links that download malware onto the victim's computer, phishing forms that steal personal information, pop-up windows that direct users to phishing sites, redirect links that open phishing sites, malware scripts, fake surveys, and more. The textual content of a website serves as source for malicious activities. Generally, machine learning models operated on numerical features that are extracted from the raw dataset (list of url) and represented as 2-D array. However, in addition to a collection of URL features, this paper vectorizes URL text using natural language processing (NLP) methods. NLP has a set of vectorization methods. such as Count, Hashing, and TFIDF vectorizer. Vectorization converts text into numerical features. Then the vectorized data will be used in machine learning algorithms. Table II lists the machine learning algorithms used for the experiment.

a) Count vectorizer [20]: It works by first tokenizing the text corpus into individual words or n-grams (contiguous sequences of words). It then creates a vocabulary of unique tokens in the corpus and assigns an index to each token in the vocabulary. Finally, it counts the occurrence of each token in each document in the corpus and constructs a matrix of token counts, with one row per document and one column per token. The resulting matrix can be used as input to a machine learning algorithm for various NLP tasks.

b) TFIDF [20]: It measure the importance of each term in a document or a corpus. It considers both the frequency of a term in a document and the frequency of the term across the entire corpus. The basic idea behind TF-IDF is that a term is considered important if it appears frequently in a document but is not so common that it appears in every document in the corpus. The TF-IDF score of a term in a document is calculated by multiplying the term frequency (TF) of the term in the document by the inverse document frequency (IDF) of the term in the corpus.

The TF-IDF formula (1,2) can be expressed as follows:

$$TF(t,d) = (Number\ of\ times\ term\ t\ appears\ in\ document\ d) / (Total\ number\ of\ terms\ in\ document\ d) \quad (1)$$

$$IDF(t,D) = log\_e(Total\ number\ of\ documents\ in\ the\ corpus / Number\ of\ documents\ with\ term\ t\ in\ it)$$

$$TF-IDF(t,d,D) = TF(t,d) * IDF(t,D) \quad (2)$$

$where$:

- t: $a\ term$
- d: $a\ document$
- D: $the\ corpus$

c) Hashing vectorizer [20]: It is a technique used to convert a collection of text documents to a matrix of token occurrences. It is similar to Count-Vectorizer in that it creates a document-term matrix, but uses a hash function to convert each token to a numerical index, rather than storing the tokens as strings. This can be useful in situations where the vocabulary is very large, and the memory requirements of storing all the tokens are prohibitively high. The Hashing-Vectorizer works by mapping each token to a numerical index using a hash function. The resulting numerical index is then used as the column index in the document-term matrix. The size of the matrix is fixed in advance and depends on the number of features (i.e. the number of hashed tokens) that are required. This means that the hashing-vectorizer is a stateless transformer, and does not need to keep track of the mapping between tokens and numerical indices.

TABLE II. MACHINE LEARNING ALGORITHMS [21]

Algorithm	Explanation
Logistic Regression (LogR)	The logistic function, also referred to as the sigmoid function, is applied to a linear combination of the input variables via the logistic regression procedure. Any input value is converted by the logistic function to a probability value between 0 and 1. The method predicts the positive class (i.e., 1) if the probability is greater than a predetermined threshold (often 0.5), otherwise it predicts the negative class (i.e., 0).
Gaussian Naive Bayes (GNB)	Gaussian Naive Bayes is a variant of the Naive Bayes algorithm in machine learning that assumes that the features follow a Gaussian (normal) distribution. In Gaussian Naive Bayes, the likelihood of the features given the class is modeled as a normal distribution with mean μ and standard deviation σ for each feature and class.
Decision Tree (DT)	The Decision Tree algorithm iteratively splits data by feature or attribute value, creating a tree-like structure. At each node in the tree, the algorithm chooses the feature that delivers the best split based on some criterion, such as the Gini index or entropy. The procedure is repeated until a stopping requirement, such as a maximum depth or minimum number of samples per leaf, is fulfilled.
K Nearest Neighbors (KNN)	The number of nearest neighbors to take into account for each prediction is the initial step in the KNN algorithm's operation. The algorithm then determines the k training samples that are most similar to each new input based on a distance metric (e.g., Euclidean distance or Manhattan distance). The algorithm then calculates a forecast by averaging the target values of the k-nearest neighbors (for regression) or obtaining the majority vote (for classification).
Random Forest (RF)	Random Forest is a popular machine learning algorithm for both classification and regression tasks. It belongs to the family of ensemble learning methods, which combine multiple individual models to improve the overall predictive performance.
Gradient Boosting (GB)	Gradient Boosting is an ensemble learning method that combines weak models, usually decision trees, to generate a more accurate model. Each decision tree in the method is trained to rectify the faults of the previous tree. All tree predictions are added to make the final projection.
Extreme Gradient Boosting (XGB)	Extreme Gradient Boosting is a popular implementation of the Gradient Boosting algorithm that is optimized for speed and performance. It uses a technique called "gradient boosting with regularization," which adds a penalty term to the loss function to reduce overfitting. XGB is known for its high performance, scalability, and ability to handle large and complex data sets.

IV. PROPOSED METHOD

The proposed method utilizes both URLs and the textual contents of webpages from the raw dataset. Three distinct feature sets, ULF (URL linguistic features), CNF (Character level ngram features), and WCF (Web content features), are created.

- ULF-URL linguistic features, which include the conventional URL features.
- CNF-URL character level ngram features, which tokenize the URL's domain name using character level ngram.
- WCF-Web content features include webpage text.

Three separate NLP vectorization algorithms are employed to vectorize CNF and WCF. Subsequently, ULF, CNF, and WCF are amalgamated to form the final dataset for training and testing. The process flow of the proposed method is shown in Fig. 2.

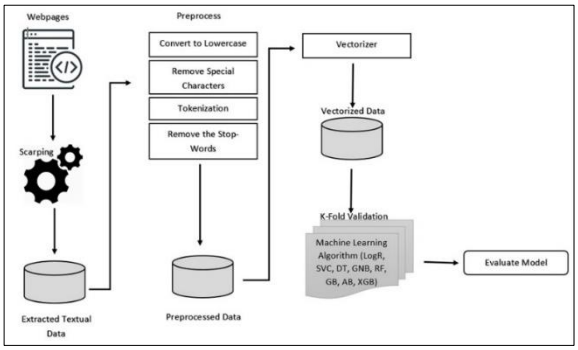

Fig. 2. Process flow.

TABLE III. URL FEATURES

No	Features	Description	No	Features	Description
1	ip_status	Presence of IP address in the URL	12	hyp_dom	Count the hyphens in domain name
2	dots_url	Count the dots in the URL.	13	at_dom	Count the @ in domain name.
3	slash_url	Count the / in the URL	14	underscr_dom	Count the underscores in the domain name
4	hyp_url	Count the hyphens in the URL	15	urllen	Length of the URL
5	hash_url	Count the # in the URL	16	num_url	Count the numbers in the URL
6	semi_url	Count the semicolons in the URL	17	alpha_url	Count the alphabet in the URL
7	and_url	Count the & in the URL	18	spl_url	Count the special symbols in the URL
8	underscr_url	Count the underscores in the URL	19	domlen	Length of domain name
9	http_url	Presence of http in the URL	20	num_dom	Count the numbers in the domain name
10	https_url	Presence of https in the URL	21	alpha_dom	Count the alphabet in the domain name
11	dots_dom	Count the dots in the domain name	22	spl_dom	Count the special symbols in the domain name
			23	url_class	Class of the URL either malicious (1)/benign (0)

A. Raw Dataset

The experiment's dataset, which contains both malicious and benign URLs, was gathered from the Kaggle URLs dataset [22]. The collection contains 450176 URLs. Classification is influenced by imbalanced datasets [23]. To prevent this problem, the experiment employs 6504 benign and 6478 malicious URLs.

B. Conventional Feature Extraction (URL Linguistic Features (ULF))

Conventional URL features include the dots in the URL, numbers in the URL, etc. Our experiments use only 23 lexical features (22 independent features and 1 dependent feature) of URLs, which are listed in Table III and saved as a separate file (conv fs.csv) as shown in Fig. 2.

C. Generating Character Level ngrams (Character level ngram features (CNF))

Character-level n-gram and word-level n-gram are two types of n-gram models used in natural language processing and machine learning. Both of these models are used for text analysis, but they operate at different levels of granularity [24]. To fully utilize the domain name of the URL, character level ngram is used in our experiment. A character-level n-gram model looks at sequences of characters in a text, regardless of the words they form. The model divides the text into n-grams, or consecutive groups of n characters called tokens, as shown in Fig. 3. Number of tokens for ngram is calculated by using the Eq. (3):

$$T_n = L - n + 1 \quad (3)$$

Where

- T_n=Total number of Tokens
- L=Length of the text
- n=Size of the ngram

For this experiment, the N value of the ngram is set between 3 and 7.

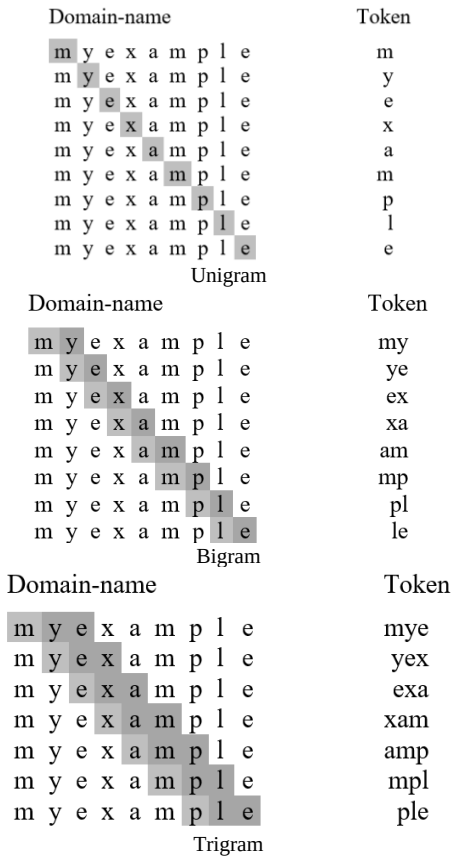

Fig. 3. Generating N-gram from the domain name.

D. Webpage Text Extraction

The process of extracting content from websites focuses on paragraph tags. The paragraph tag is a reasonable and straightforward way to organize the content of a web page because it is meant to denote a block of text that is unique from other blocks of text. After text extraction, text preprocessing begins. The preprocessing procedures are outlined in Algorithm 1.

E. Preprocess

The entire process of text vectorization is included in preprocessing. Text is cleansed by removing special characters and unnecessary components of the URL, such as the protocol, leaving only text and numbers. After text cleaning, it will be converted to lowercase, stop words will be removed, and lemmatized to reduce number of features during vectorization process. The procedures for preprocessing are summarized in Algorithm 2.

Algorithm 1: Text Extractions

```
Input: List of URLs (W)
Output: doc
Function Cont_Extraction (W, TagName)
Con=Connect(W)
Tag List = get Tag (Con, TagName)
For tag in TagList do
     doc = doc U getText(tag)
end for
                    return doc
```

The pseudo code of the method Cont_Extract () is used to extract textual contents from particular tags on the webpage. The Connect() function is used to establish the connection to the appropriate website. Following the establishment of the connection, the content of the given tag "TagName" is extracted and added to the string "doc". This "doc" will be used for preprocessing.

Algorithm 2: Data Preprocessing

```
Input: doc
Output: Corpus (T2 )
Function preProcess(doc)
Torg=read_Text(doc)
T1=clean_Text(Torg)
T1 = lower_Text(T1)
For token in T1 do
     if token is not in STOPWORDS of ENGLISH then
          T2 = T2 U Lemmatize(token)
     End if
end for
return T2
```

The pseudo-code of the preprocess() method is used to complete the preprocessing task for the given text document. The contents of the "doc" are read using the read_Text () function. The clean_Text() and lower_Text() routines convert text to uppercase and lowercase correspondingly. Stop words in a text are eliminated and lemmatized using the "for loop". The resultant corpus is to be vectorized.

F. Vectorization

Most machine learning algorithms take numeric feature vectors as input. Consequently, while working with text documents, required to convert each document into a numeric vector. This method is referred to as text vectorization. By employing various NLP techniques, such as count vectorizer, TFIDF, and hashing vectorizer, the generated tokens of text in the preprocessing and character level ngram are converted into a real-valued vector. The output of vectorization is a two-dimensional (2D) array. The vectorizer's features are set to 2500 and stored in a CSV file to limit the 2D array's size. As illustrated in Fig. 2, two files are created in our experiment, one for character level ngram tokens and another for textual content of the webpage (char level vec.csv & para text vec.csv).

G. Merging Files

After vectorization, three separate files (conv fs.csv, char level vec.csv & para text vec.csv) are combined into a single data file (combined.csv) as shown in Fig. 2. This file serves as a data file for the machine learning algorithm.

H. K-Fold Validation and Model Evaluation

The process uses a single parameter, K, to partition a data sample into k groups. When a particular number for k is selected, it may be used in place of k in the reference to the model, such as k=10 becoming 10-fold cross-validation [15]. In our experiment, a machine learning algorithm using 10-fold cross validation is fed the combined dataset (combined.csv). Four important metrics—precision, recall, accuracy, and f1-score—are used to assess the machine algorithm's performance.

V. Experimental Result

The experimental configuration consists of Windows 10, an I5 processor (3.2 GHz), and 8 GB of RAM. For programming, Python and sklearn package are utilized. Three distinct features, including URL Linguistic Features (ULF), Character-level Ngram Features (CNF), and Web Content Features (WCF), are generated for the experiments. Table II lists the seven most popular machine learning techniques used in the experiments. Each feature set and feature set combination (ULF+CNF+WCF) is examined independently for performance evaluation. Three different vectorizers were used to generate the features. A range of features between 250 and 2000 was taken for each trial. This range is known as "feature base."

1) URL linguistic feature (ULF): The features are retrieved from the URL alone by counting some characters in the URL and checking for the presence of the required pattern or characters in the URL. Table III provides the 22 features extracted from the URL. These are the most common features seen in the majority of existing research works. Fig. 2 shows the conventional feature extraction module extracting features from the Raw dataset and preparing a 2D array of values where rows represent URLs and columns represent the 22 features. The last column is the dependent feature called "class" which shows if the URL is benign (0) or malicious (1). The experiment's outcomes reveal that the random forest

achieves an accuracy of 98.31%, as depicted in both Table IV and Fig. 4. This outcome distinctly underscores the appropriateness of the selected features for the experiment.

TABLE IV. PERFORMANCE OF ULF

Type	Machine Learning Algorithm	Accuracy	Precision	Recall	F1-Score
URL Linguistic Features	LogR	95.06	99.48	90.58	94.82
	KNN	96.80	97.67	95.91	96.77
	GNB	91.19	99.44	82.82	90.36
	DT	96.66	95.76	97.84	96.74
	RF	**98.31**	**98.74**	**97.90**	**98.31**
	GB	96.83	99.06	94.55	96.74
	XGB	97.03	96.99	97.39	97.12

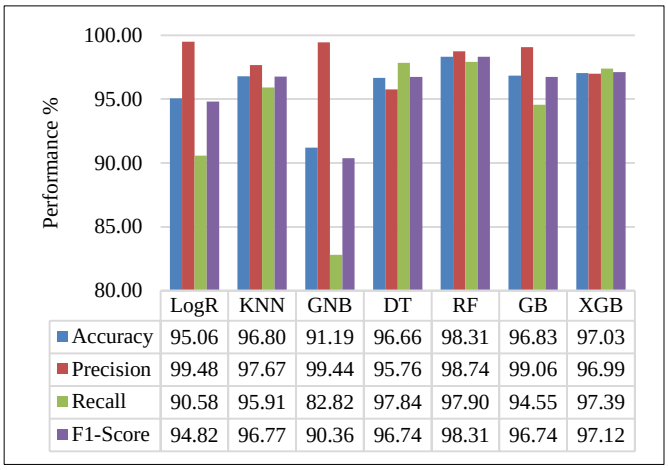

Fig. 4. Performance of ULF.

2) Character level-n-gram features (CNF): Character-level ngrams are generated by breaking a text into sequences of characters of a predetermined length. Character-level ngrams are useful for identifying patterns in text, specifically URL processing. In this experiment, character level ngram processing simply takes the URL's domain name into account. Character-level ngrams produce tokens. Following the generation of tokens, the tokens are vectorized using three distinct vectorizers for feature generation Experiments use seven machine learning algorithms to test the generated features and evaluate the performance. Tables V to VII show the outcomes of the various trials for the count, TFIDF, and hashing vectorizer, respectively. The results showed that using a 2000 feature base, count vectorizer + random forest achieves an accuracy of 90.87%, TFIDF vectorizer + random forest achieves an accuracy of 90.04%, and Hashing vectorizer + random forest achieves an accuracy of 92.95%. Fig. 5 depicts the performance comparison of three different vectorizers.

TABLE V. PERFORMANCE OF CNF WITH COUNT VECTORIZER

Feature Base	Machine Learning Algorithm	Accuracy	Precision	Recall	F1-Score
250	LogR	70.11	66.55	92.84	76.65
	KNN	68.88	70.82	69.28	69.11

	GB	71.48	67.43	94.04	77.70
	XGB	78.82	77.53	86.66	80.93

Configuring the count vectorizer with 2000 features results in an elevated accuracy of 90.87% and an F1-Score of 91.30% when applied in conjunction with the random forest algorithm. By incorporating n-grams, the count vectorizer not only captures individual words but also preserves contextual information regarding word combinations.

	GB	78.00	74.35	89.80	80.78
	XGB	87.31	83.80	93.62	88.23

Configuring the Hashing vectorizer with 2000 features yields an elevated accuracy of 92.95% and an F1-Score of 93.20% when coupled with the random forest algorithm. The incorporation of n-grams into the Hashing vectorizer enhances the representation of sequential word combinations, capturing contextual information and thereby improving the overall effectiveness of classification.

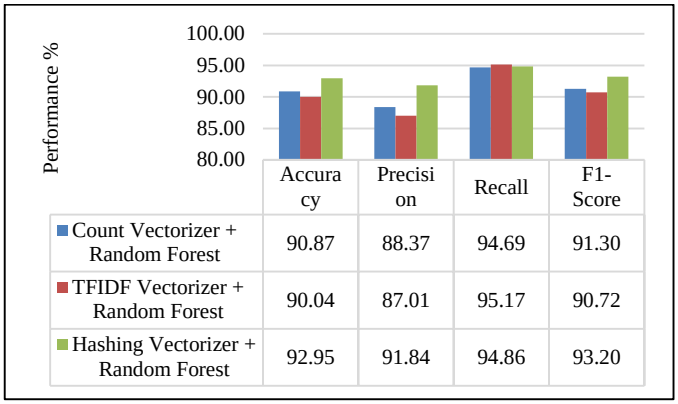

Fig. 5. Performance comparison of three vectorizers (2000 Features).

3) Web content features (WCF): The content of a webpage is the most informative option for analysis. Our experiment uses Beautiful Soup and Request in Python to analyze paragraph tag text. Text contents were preprocessed to get rid of stop words, special characters, etc. After that split the words into sentences to produce a corpus. This corpus serves as the input for the vectorizer, which produces features. To examine the generated features and assess performance, experiments utilize seven machine learning techniques. The results of the various trials for count, TFIDF, and hashing vectorizer, are displayed in Tables VIII to X. A performance comparison of three different vectorizers is shown in Fig. 6.

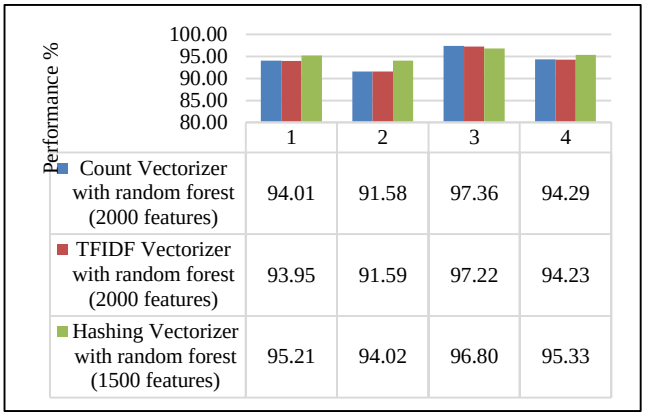

Fig. 6. Performance comparison of three vectorizers.

The findings demonstrated that when employing the 2000 feature base, the Count vectorizer with random forest achieves an accuracy of 94.01% and F1-Score of 94.29%. The TFIDF vectorizer with random forest reached an accuracy of 93.95% and an F1-score of 94.23%. However, the Hashing Vectorizer with Random Forest used a 1500 feature base and produced an accuracy of 95.21 % and an F1-score of 95.33%.

4) Combined features (CF): The combined feature set includes the features of ULF+CNF+WCF. Features are combined in row-wise. The main objective of combining feature sets is to reduce the feature set size and achieve higher accuracy. A range of features between 250 and 2000 was taken for each trial. So, the dataset for the trial is formed based on the following Eq. (4)

$$CF_n = ULF + CNF_n + WCF_n \quad (4)$$

Where n ϵ [250, 2000]

The features are merged in row-wise to create a single unified feature set. Tables XI to XIII show the outcomes of the various trials for the count, TFIDF, and hashing vectorizer, respectively. Fig. 7 depicts the performance comparison of three different vectorizers.

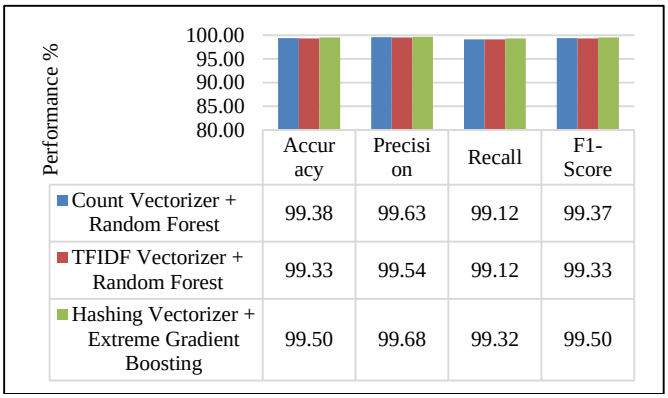

Fig. 7. Performance comparison of three vectorizers (500 Feature base).

The results showed that using a 500 features base, the Count vectorizer with random forest achieves an accuracy of 99.38% and an F1-score of 99.37%. The TFIDF vectorizer with random forest achieves an accuracy of 99.33% and an F1-score of 99.33% Hashing Vectorizer with extreme gradient boosting achieves an accuracy and F1-score of 99.50%.

All of the vectorizers employed in the experiment obtain higher accuracy and F1-score with 500 feature bases, especially the hashing vectorizer with extreme gradient boosting algorithm achieves the highest accuracy at 99.5%, as shown in Table XIV and Fig. 8. As compared to previous work, the proposed method significantly improves performance.

TABLE XIV. PERFORMANCE COMPARISON OF EXISTING AND PROPOSED METHOD

Author	Machine Learning Algorithm	Highest Accuracy
Saleem et al. [7]	Random Forest	93.0%
Saleem et al. [11]	Random Forest	99.0%
Malak et.al [12]	Naïve Bayes	96.0%
Kamel et.al [13]	Random Forest	95.51%
Lakshmanarao et.al[14]	Hashing vectorizer with Random Forest	97.50%
Joshi et.al [15]	Random Forest	92.0%
Hong et al. [16]	LA-FQ	94.16%
Josh et.al [17]	Random Forest	98.91%
Saleem et.al[18]	Weighted Soft Voting Classifier	99.10%
Ozgur et.al [19]	Random Forest	97.98%
Proposed Method	Hashing vectorizer with Extreme Gradient Boosting	99.50%

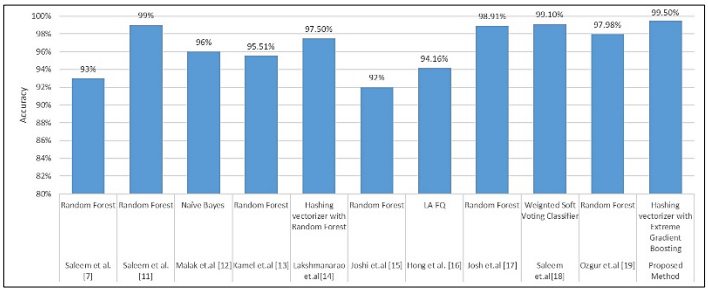

Fig. 8. Performance comparison of existing and proposed method.

VI. CONCLUSION

The majority of cybercrimes are committed using malicious links or malicious websites. Unintentionally visiting these websites or clicking on malicious links can have more serious effects, including the theft of private, sensitive information, security breaches, financial loss, and reputational damage. To find these kinds of dangerous websites on the internet, AI-based automated solutions are needed. For the detection method, this paper makes use of both URLs and web contents. Two different feature types, including ULF and CNF, are generated using URL of the webpage. Moreover, web page content is processed to generate features (WCF) for the detection procedure. Seven different machine learning methods are combined with three different vectorizers. Results of the study show that the proposed method, which combines an extreme gradient boosting algorithm with a hashing vectorizer, offers a better level of accuracy.

Enhanced IVIFN-ExpTODIM-MABAC Technique for Multi-Attribute Group Decision-Making Under Interval-Valued Intuitionistic Fuzzy Sets

Applications to College English Teaching Quality Evaluation

Bin Xie*
School of Architecture and Planning, Jiujiang University, Jiujiang, 332005, Jiangxi, China

***Abstract*—The evaluation of English teaching quality is crucial for enhancing teaching effectiveness. It helps teachers understand their teaching methods and students' learning outcomes through systematic assessment, thereby guiding teachers to adjust their teaching strategies. Additionally, the results of the evaluation provide decision-making support for educational management at schools, optimizing curriculum design and resource allocation. Regular evaluations of teaching quality motivate teachers for continuous professional development, improve teaching standards, and ensure that students achieve maximum growth and progress in their English learning journey. The assessment of college English teaching quality employs multi-attribute group decision-making (MAGDM). Techniques like Exponential TODIM (ExpTODIM) and MABAC are utilized to facilitate MAGDM. During the evaluation process, interval-valued intuitionistic fuzzy sets (IVIFSs) are utilized to handle fuzzy data. This research introduces a novel method, the interval-valued intuitionistic fuzzy number ExpTODIM-MABAC (IVIFN-ExpTODIM-MABAC) tailored for MAGDM under the framework of IVIFSs. To demonstrate its efficacy, a numerical example evaluating college English teaching quality is presented. Key contributions of this study include: (1) Extending the ExpTODIM-MABAC method to include IVIFSs with an Entropy model; (2) Utilizing Entropy to ascertain weights within IVIFSs; (3) Proposing the IVIFN-ExpTODIM-MABAC approach for MAGDM under IVIFSs; (4) Validating the approach with a numerical example and various comparative analyses of college English teaching quality.**

Keywords*—Multi-attribute group decision-making (MAGDM); interval-valued intuitionistic fuzzy sets (IVIFSs); ExpTODIM approach; MABAC approach; college English teaching quality evaluation

I. Introduction

The evaluation of English teaching quality is a critical component in educational management and pedagogical improvement. It not only focuses on the teaching skills and methods of teachers but also encompasses students' learning outcomes, the teaching environment, and curriculum content among other aspects [1]. The purpose and significance of evaluating English teaching quality are extensive and can be analyzed in the following dimensions: (1) Enhancing teaching quality. Teaching quality evaluation, through regular checks and feedback mechanisms, helps teachers recognize deficiencies in their teaching methods and techniques, thereby encouraging them to take measures for improvement. This evaluation process promotes continuous learning and self-improvement among teachers, ensuring that teaching methods stay current [2]. Additionally, teaching quality evaluations help teachers better manage course pacing and adjust teaching strategies to ensure the appropriateness and effectiveness of the content delivered. (2) Promoting student learning. Another important goal of teaching quality evaluation is to monitor and enhance students' learning outcomes [3-5]. During this process, teachers can understand students' interests, motivations, and challenges in learning English and then adopt personalized teaching approaches to meet the needs of different students [6]. For instance, for students with weaker foundations, teachers might increase tutoring time and use more interactive and visual aids to enhance their interest and efficiency in learning. (3) Optimizing curriculum design. Through the assessment of teaching quality, educational institutions can obtain direct feedback on which teaching contents and methods are most effective, which is crucial for curriculum design and textbook compilation [7, 8]. Evaluation results help education decision-makers understand changes in market and student needs, thereby optimizing the course structure, introducing new teaching contents, or eliminating outdated educational elements [9]. (4) Ensuring fairness and transparency in teaching. Regular teaching quality evaluations provide clear and fair assessment standards for all teachers and students. This standardized evaluation process helps eliminate biases and subjectivity, ensuring that every student is educated and assessed under the same standards, thus promoting fairness and transparency in educational activities [10, 11]. (5) Driving educational innovation. The results of teaching quality evaluations are a crucial basis for promoting educational innovation. Through evaluations, educational institutions can discover the effectiveness of new teaching methods and technologies, encouraging teachers to try and implement innovative teaching strategies. For example, with the development of information technology, many schools have begun experimenting with new teaching models such as blended learning and flipped classrooms. Teaching quality evaluations can effectively monitor the actual effects and adaptability of these new methods [12-14]. In conclusion, the evaluation of English teaching quality is a key tool for enhancing teaching effectiveness, ensuring educational fairness, and promoting comprehensive student development. It not only helps teachers and educational institutions understand the actual effects of

*Corresponding Author

teaching but also compels educational policies and practices to continuously adjust and improve. Therefore, establishing and maintaining a scientific and comprehensive teaching quality evaluation system is fundamental to improving educational quality and achieving educational modernization. Through such an evaluation system, we can better meet students' learning needs, enhance teachers' teaching abilities, and optimize the allocation of educational resources [15-17].

MAGDM is a collaborative decision-making process that brings together decision-makers from various backgrounds to evaluate multiple options across several attributes [18-21]. This method is prevalent in diverse sectors such as economics, management, engineering, and public policy, where complex decisions need balanced and comprehensive assessments. The essence of MAGDM lies in its ability to utilize the collective intelligence and resources of a group to pinpoint the most effective decision, considering a broad spectrum of factors. The purpose of MAGDM is multifaceted. Primarily, it aims to amalgamate diverse perspectives into a single decision-making process [22-25]. This integration is crucial in complex scenarios where no single decision-maker possesses enough information or expertise to cover all aspects of a decision comprehensively [26-28]. By involving multiple stakeholders, the decision-making process becomes more holistic and inclusive, thus enhancing the decision's quality and breadth. Moreover, MAGDM enhances the rationality and acceptance of decisions. Group discussions and evaluations increase transparency and fairness, fostering a decision-making environment where outcomes are more likely to be rational and broadly accepted. This is particularly important in settings where decisions have significant social, economic, or environmental impacts. Another critical aim of MAGDM is to optimize resource allocation. In environments where resources are scarce, this method facilitates a rational distribution based on thorough analysis and group consensus, ensuring that every decision maximizes the potential benefits from the available resources [29-32]. MAGDM also serves as a robust framework for dealing with complexity and uncertainty. By incorporating various data points and expert opinions, it provides a methodological approach to handle uncertainties inherent in dynamic environments, thereby stabilizing the decision-making process against external fluctuations [33-37]. The significance of MAGDM extends beyond just making effective decisions. It also enhances collaboration and communication among team members, who must share information and discuss options thoroughly before arriving at a consensus [38-42]. This interaction not only improves the decision outcomes but also strengthens team dynamics and cooperation. Furthermore, MAGDM promotes adaptability. As situations evolve and new information emerges, this decision-making framework can adapt, allowing decision-makers to revise their strategies promptly and efficiently [43-48]. This flexibility is vital in responding to changing conditions and maintaining the relevance and effectiveness of decisions. Lastly, the process of MAGDM increases both transparency and accountability. By documenting each decision-making step and its basis, the process ensures that all actions are traceable and decision-makers are accountable. This transparency is crucial for maintaining public trust, especially in decisions that affect broader communities or have significant public implications [38, 39, 49, 50]. In practical terms, MAGDM is seen in actions such as government policy formulation, corporate strategic planning, and new product development. For instance, in urban planning, government officials utilize MAGDM to integrate considerations like cost, public opinion, and environmental impact to devise comprehensive, sustainable urban transportation systems. In conclusion, MAGDM is more than just a decision-making tool; it is a critical process that taps into collective expertise to tackle complex problems efficiently and effectively. As the challenges in various fields grow more intricate, the role of MAGDM becomes increasingly vital, making it an indispensable element in the decision-making landscape of modern society. The evaluation of college English teaching quality involves MAGDM. IVIFSs [51] are used to represent fuzzy information during this evaluation. Various decision techniques have been proposed for MAGDM, managing the traditional ExpTODIM [52, 53] and MABAC [54, 55] techniques separately. However, there have been few or no techniques that combine the entropy model [56] with ExpTODIM [52, 53] and MABAC [54, 55] techniques under IVIFSs. Consequently, the IVIFN-ExpTODIM-MABAC technique is constructed to handle MAGDM under IVIFSs. A numerical example for evaluating college English teaching quality alongside different comparative analyses is provided to demonstrate the IVIFN-ExpTODIM-MABAC technique. The main objectives and motivations of this research include: (1) Enhancing the ExpTODIM-MABAC approach by integrating IVIFSs with the entropy framework. (2) Utilizing entropy to ascertain weights within IVIFSs. (3) Introducing the IVIFN-ExpTODIM-MABAC method for MAGDM in the context of IVIFSs. (4) Offering a numerical example and performing diverse comparative analyses to verify the IVIFN-ExpTODIM-MABAC model's effectiveness in assessing college English teaching quality.

The structure of the research is systematically organized. Section II introduces the IVIFSs. In Section III, the IVIFN-ExpTODIM-MABAC method is comprehensively proposed for MAGDM using IVIFSs. Section IV offers a numerical example that evaluates the quality of college English teaching, accompanied by comparative analyses. Section V concludes the paper with final remarks.

II. PRELIMINARIES

Atanassov [51] performed the IVIFSs.

Definition 1 [51]. The IVIFSs is introduced:

$$FI = \left\{ \left\langle FM\left(\zeta\right), FN\left(\zeta\right) \right\rangle \middle| \zeta \in X \right\} \tag{1}$$

where $FM\left(\zeta\right) \subset \left[0,1\right]$ is membership and $FN\left(\zeta\right) \subset \left[0,1\right]$ is non-membership, and $FM\left(\zeta\right), FN\left(\zeta\right)$ meet condition: $0 \le \sup FM\left(\zeta\right) + \sup FN\left(\zeta\right) \le 1$, $\forall \zeta \in X$. For convenience, $FI = \left(\left[FA, FB\right], \left[FC, FD\right]\right)$ is IVIFN.

Definition 2 [57]. Let $FI_1 = \left(\left[FA_1, FB_1\right], \left[FC_1, FD_1\right]\right)$ and $FI_2 = \left(\left[FA_2, FB_2\right], \left[FC_2, FD_2\right]\right)$ be IVIFNs, the operation laws are performed:

$$FI_1 \oplus FI_2 = \begin{pmatrix} \left[FA_1 + FA_2 - FA_1FA_2, FB_1 + FB_2 - FB_1FB_2\right], \\ \left[FC_1FC_2, FD_1FD_2\right] \end{pmatrix} \quad (2)$$

$$FI_1 \otimes FI_2 = \begin{pmatrix} \left[FA_1FA_2, FB_1FB_2\right], \\ \left[FC_1 + FC_2 - FC_1FC_2, FD_1 + FD_2 - FD_1FD_2\right] \end{pmatrix} \quad (3)$$

$$\lambda FI_1 = \left(\left[1-\left(1-FA_1\right)^{\lambda}, 1-\left(1-FB_1\right)^{\lambda}\right], \left[\left(FC_1\right)^{\lambda}, \left(FD_1\right)^{\lambda}\right]\right), \lambda > 0 \quad (4)$$

$$FI_1^{\lambda} = \left(\left[\left(FA_1\right)^{\lambda}, \left(FB_1\right)^{\lambda}\right], \left[1-\left(1-FC_1\right)^{\lambda}, 1-\left(1-FD_1\right)^{\lambda}\right]\right), \lambda > 0 \quad (5)$$

From Definition 2, several properties are established.

(1) $FI_1 \oplus FI_2 = FI_2 \oplus FI_1, FI_1 \otimes FI_2 = FI_2 \otimes FI_1, \left(\left(FI_1\right)^{\lambda_1}\right)^{\lambda_2} = \left(FI_1\right)^{\lambda_1\lambda_2}$;

(2) $\lambda\left(FI_1 \oplus FI_2\right) = \lambda FI_1 \oplus \lambda FI_2, \left(FI_1 \otimes FI_2\right)^{\lambda} = \left(FI_1\right)^{\lambda} \otimes \left(FI_2\right)^{\lambda}$;

(3) $\lambda_1 FI_1 \oplus \lambda_2 FI_1 = \left(\lambda_1 + \lambda_2\right) FI_1, \left(FI_1\right)^{\lambda_1} \otimes \left(FI_1\right)^{\lambda_2} = \left(FI_1\right)^{\left(\lambda_1 + \lambda_2\right)}$.

Definition 3 [58]. Let $FI_1 = \left(\left[FA_1, FB_1\right], \left[FC_1, FD_1\right]\right)$ and $FI_2 = \left(\left[FA_2, FB_2\right], \left[FC_2, FD_2\right]\right)$ be IVIFNs, both the score value (SV) and accuracy value (AV) of FI_1 and FI_2 are performed:

$$SV\left(FI_1\right) = \frac{FA_1 + FA_1\left(1-FA_1-FC_1\right) + FB_1 + FB_1\left(1-FB_1-FD_1\right)}{2} \quad (6)$$

$$SV\left(FI_2\right) = \frac{FA_2 + FA_2\left(1-FA_2-FC_2\right) + FB_2 + FB_2\left(1-FB_2-FD_2\right)}{2} \quad (7)$$

$$AV\left(FI_1\right) = \frac{FA_1 + FC_1 + FB_1 + FD_1}{2}, \quad (8)$$

$$AV\left(FI_2\right) = \frac{FA_2 + FC_2 + FB_2 + FD_2}{2} \quad (9)$$

For TI_1 and TI_2, from Definition 3, then

(1) *if* $SV\left(FI_1\right) < SV\left(FI_2\right)$, $FI_1 < FI_2$;

(2) *if* $SV\left(FI_1\right) > SV\left(FI_2\right), FI_1 > FI_2$;

(3) *if* $SV\left(FI_1\right) = SV\left(FI_2\right), AV\left(FI_1\right) < AV\left(FI_2\right)$, $FI_1 < FI_2$;

(4) *if* $SV\left(FI_1\right) = SV\left(FI_2\right), AV\left(FI_1\right) = AV\left(FI_2\right)$, $FI_1 = FI_2$.

Definition 4[59]. Let $FI_1 = \left(\left[FA_1, FB_1\right], \left[FC_1, FD_1\right]\right)$ and $FI_2 = \left(\left[FA_2, FB_2\right], \left[FC_2, FD_2\right]\right)$, the IVIFN Hamming distance (IVIFNHD) and IVIFN Euclidean distance (IVIFNED) are performed:

$$IVIFNHD\left(FI_1, FI_2\right) = \frac{1}{4}\begin{bmatrix} \left|FA_1 - FA_2\right| + \left|FB_1 - FB_2\right| \\ + \left|FC_1 - FC_2\right| + \left|FD_1 - FD_2\right| \end{bmatrix} \quad (10\text{-a})$$

$$IVIFNED\left(FI_1, FI_2\right) = \sqrt{\frac{1}{4}\begin{bmatrix} \left(FA_1 - FA_2\right)^2 + \left(FB_1 - FB_2\right)^2 \\ + \left(FC_1 - FC_2\right)^2 + \left(FD_1 - FD_2\right)^2 \end{bmatrix}} \quad (10\text{-b})$$

The IVIFWA and IVIFWG approach is performed [60].

Definition 5 [60]. Let $FI_j = \left(\left[FA_j, FB_j\right], \left[FC_j, FD_j\right]\right)\left(j = 1, 2, \cdots, n\right)$ be IVIFNs, the IVIFWA approach is performed:

$$IVIFWA_{f\omega}(FI_1, FI_2, \ldots, FI_n) = \bigoplus_{j=1}^{n}\left(f\omega_j FI_j\right) = \left(\left[1-\prod_{j=1}^{n}\left(1-FA_j\right)^{f\omega_j}, 1-\prod_{j=1}^{n}\left(1-FB_j\right)^{f\omega_j}\right], \left[\prod_{j=1}^{n}\left(FC_j\right)^{f\omega_j}, \prod_{j=1}^{n}\left(FD_j\right)^{f\omega_j}\right]\right) \quad (11)$$

where $f\omega=\left(f\omega_1, f\omega_2, ..., f\omega_n\right)^T$ be weight numbers of $FI_j=\left(\left[FA_j, FB_j\right], \left[FC_j, FD_j\right]\right)$, $f\omega_j>0, \sum_{j=1}^{n} f\omega_j = 1.$

Definition 6[61]. Let $FI_j=\left(\left[FA_j, FB_j\right], \left[FC_j, FD_j\right]\right)\left(j=1,2,\cdots,n\right)$ be IVIFNs, the IVIFWG approach is performed:

$$IVIFWG_{f\omega}\left(FI_1, FI_2, \ldots, FI_n\right) = \bigotimes_{j=1}^{n}\left(FI_j\right)^{f\omega_j} = \left(\left[\prod_{j=1}^{n}\left(FA_j\right)^{f\omega_j}, \prod_{j=1}^{n}\left(FB_j\right)^{f\omega_j}\right], \left[1-\prod_{j=1}^{n}\left(1-FC_j\right)^{f\omega_j}, 1-\prod_{j=1}^{n}\left(1-FD_j\right)^{f\omega_j}\right]\right) \quad (12)$$

where $f\omega=\left(f\omega_1, f\omega_2, ..., f\omega_n\right)^T$ be weight numbers of $FI_j=\left(\left[FA_j, FB_j\right], \left[FC_j, FD_j\right]\right)$, $f\omega_j>0, \sum_{j=1}^{n} f\omega_j = 1.$

III. IVIFN-ExpTODIM-MABAC Approach for MAGDM with Entropy

A. IVIFN-MAGDM Issues

Then IVIFN-ExpTODIM-MABAC approach is performed for MAGDM. Let $FA=\left\{FA_1, FA_2, \cdots, FA_m\right\}$ be alternatives and $FG=\left\{FG_1, FG_2, \cdots, FG_n\right\}$ be attributes with weight values $f\omega=\left(f\omega_1, f\omega_2, ..., f\omega_n\right)^T$, where $f\omega_j \in [0,1]$, $\sum_{j=1}^{n} f\omega_j = 1$ and experts $FE=\left\{FE_1, FE_2, \cdots, FE_q\right\}$ with weight values be $fw=\left\{fw_1, fw_2, \cdots, fw_q\right\}$. Then, IVIFN-ExpTODIM-MABAC technique is put forward for MAGDM.

Step 1. Perform the IVIFN-matrix $FR^{(t)}=\left[FR_{ij}^{(t)}\right]_{m\times n}=\left(\left[FA_{ij}^{(t)}, FB_{ij}^{(t)}\right], \left[FC_{ij}^{(t)}, FD_{ij}^{(t)}\right]\right)_{m\times n}$ and average matrix $FR=\left[FR_{ij}\right]_{m\times n}$:

$$FR^{(t)}=\left[FR_{ij}^{(t)}\right]_{m\times n}=\begin{array}{c} \\ FA_1 \\ FA_2 \\ \vdots \\ FA_m \end{array}\begin{array}{c} \begin{array}{cccc} FG_1 & FG_2 & \ldots & FG_n \end{array} \\ \begin{bmatrix} FR_{11}^{(t)} & FR_{12}^{(t)} & \ldots & FR_{1n}^{(t)} \\ FR_{21}^{(t)} & FR_{22}^{(t)} & \ldots & FR_{2n}^{(t)} \\ \vdots & \vdots & \vdots & \vdots \\ FR_{m1}^{(t)} & FR_{m2}^{(t)} & \ldots & FR_{mn}^{(t)} \end{bmatrix} \end{array} \quad (13)$$

$$FR=\left[FR_{ij}\right]_{m\times n}=\begin{array}{c} \\ FA_1 \\ FA_2 \\ \vdots \\ FA_m \end{array}\begin{array}{c} \begin{array}{cccc} FG_1 & FG_2 & \ldots & FG_n \end{array} \\ \begin{bmatrix} FR_{11} & FR_{12} & \ldots & FR_{1n} \\ FR_{21} & FR_{22} & \ldots & FR_{2n} \\ \vdots & \vdots & \vdots & \vdots \\ FR_{m1} & FR_{m2} & \ldots & FR_{mn} \end{bmatrix} \end{array} \quad (14)$$

Based on IVIFWG technique, the $FR=\left[FR_{ij}\right]_{m\times n}=\left(\left[FA_{ij}, FB_{ij}\right], \left[FC_{ij}, FD_{ij}\right]\right)_{m\times n}$ is performed in Eq. (15):

$$FR_{ij}=\left(FR_{ij}^{(t)}\right)^{fw_1}\otimes\left(FR_{ij}^{(t)}\right)^{fw_2}\otimes\cdots\otimes\left(FR_{ij}^{(t)}\right)^{fw_q} = \left(\left[\prod_{t=1}^{q}\left(FA_{ij}^{(t)}\right)^{fw_t}, \prod_{t=1}^{q}\left(FB_{ij}^{(t)}\right)^{fw_t}\right], \left[1-\prod_{t=1}^{q}\left(1-FC_{ij}^{(t)}\right)^{fw_t}, 1-\prod_{t=1}^{q}\left(1-FD_{ij}^{(t)}\right)^{fw_t}\right]\right) \quad (15)$$

Step 2. The $FR=\left[FR_{ij}\right]_{m\times n}=\left(\left[FA_{ij}, FB_{ij}\right], \left[FC_{ij}, FD_{ij}\right]\right)_{m\times n}$ is normalized to $NFR=\left[NFR_{ij}\right]_{m\times n}=\left(\left[FA_{ij}^N, FB_{ij}^N\right], \left[FC_{ij}^N, FD_{ij}^N\right]\right)_{m\times n}$ in Eq. (16, 17).

For benefit attributes:

$$NFR_{ij}=\left(\left[FA_{ij}^N, FB_{ij}^N\right], \left[FC_{ij}^N, FD_{ij}^N\right]\right) = \left(\left[FA_{ij}, FB_{ij}\right], \left[FC_{ij}, FD_{ij}\right]\right) \quad (16)$$

For cost attributes:

$$NFR_{ij}=\left(\left[FA_{ij}^N, FB_{ij}^N\right], \left[FC_{ij}^N, FD_{ij}^N\right]\right) = \left(\left[FC_{ij}, FD_{ij}\right], \left[FA_{ij}, FB_{ij}\right]\right) \quad (17)$$

B. Perform the Attributes Weight through Entropy

Step 3. The weight numbers are important for MAGDM [62-64]. Entropy technique [56] is put forward weight numbers under IVIFSs. The normalized decision matrix is performed in Eq. (18):

$$NDM_{ij}=\frac{\begin{pmatrix}SV\left(\left[FA_{ij}^{N},FB_{ij}^{N}\right],\left[FC_{ij}^{N},FD_{ij}^{N}\right]\right)\\+AV\left(\left[FA_{ij}^{N},FB_{ij}^{N}\right],\left[FC_{ij}^{N},FD_{ij}^{N}\right]\right)+0.5\end{pmatrix}}{\sum_{i=1}^{m}\left(\begin{pmatrix}SV\left(\left[FA_{ij}^{N},FB_{ij}^{N}\right],\left[FC_{ij}^{N},FD_{ij}^{N}\right]\right)\\+AV\left(\left[FA_{ij}^{N},FB_{ij}^{N}\right],\left[FC_{ij}^{N},FD_{ij}^{N}\right]\right)+0.5\end{pmatrix}\right)},\tag{18}$$

The IVIFN Shannon entropy (IVIFNSE) is produced in Eq. (19):

$$IVIFNSE_{j}=-\frac{1}{\ln m}\sum_{i=1}^{m}NDM_{ij}\ln NDM_{ij}\tag{19}$$

and $NDM_{ij}\ln NDM_{ij}=0$ if $TIVIFNDM_{ij}=0$.

The weight numbers are performed in Eq. (20):

$$f\omega_{j}=\frac{1-IVIFNSE_{j}}{\sum_{j=1}^{n}\left(1-IVIFNSE_{j}\right)}\tag{20}$$

C. IVIFN-ExpTODIM-MABAC Approach for MAGDM

The IVIFN-ExpTODIM-MABAC is performed for MAGDM.

Step 4. Perform relative weight in Eq. (21):

$$rf\omega_{j}=f\omega_{j}\Big/\max_{j}f\omega_{j},\tag{21}$$

Step 5. The IVIFN dominance degree (IVIFNDD) is performed in Eq. (22) based on two kinds of distances measures:

$$IVIFNDD_{j}\left(FA_{i},FA_{i}\right)=\begin{cases}\frac{1}{2}\left(\begin{array}{l}\frac{rf\omega_{j}\times\left(1-10^{-\rho IVIFNED\left(NFR_{ij},NFR_{ij}\right)}\right)}{\sum_{j=1}^{n}rf\omega_{j}}\\+\frac{rf\omega_{j}\times\left(1-10^{-\rho IVIFNED\left(NFR_{ij},NFR_{ij}\right)}\right)}{\sum_{j=1}^{n}rf\omega_{j}}\end{array}\right) & \text{if } SV\left(NFR_{ij}\right)>SV\left(NFR_{ij}\right)\\ 0 & \text{if } SV\left(NFR_{ij}\right)=SV\left(NFR_{ij}\right)\\ \frac{1}{2}\left(\begin{array}{l}-\frac{1}{\theta}\frac{\sum_{j=1}^{n}rt\omega_{j}\times\left(1-10^{-\rho IVIFNED\left(NTR_{ij},NTR_{ij}\right)}\right)}{rt\omega_{j}}\\-\frac{1}{\theta}\frac{\sum_{j=1}^{n}rt\omega_{j}\times\left(1-10^{-\rho IVIFNED\left(NTR_{ij},NTR_{ij}\right)}\right)}{rt\omega_{j}}\end{array}\right) & \text{if } SV\left(NFR_{ij}\right)<SV\left(NFR_{ij}\right)\end{cases}\tag{22}$$

where θ is from [65] and $\rho\in[1,5]$ [66].

The IVIFNDD under FG_{j} is performed:

$$IVIFNDD_j\left(FA_i\right)=\left[IVIFNDD_j\left(FA_i,FA_t\right)\right]_{m\times m}$$

$$=\begin{array}{c} \\ FA_1 \\ FA_2 \\ \vdots \\ FA_m \end{array}\begin{array}{c} \begin{array}{cccc} FA_1 & FA_2 & \cdots & FA_m \end{array} \\ \begin{bmatrix} 0 & IVIFNDD_j\left(FA_1,FA_2\right) & \cdots & IVIFNDD_j\left(FA_1,FA_m\right) \\ IVIFNDD_j\left(FA_2,FA_1\right) & 0 & \cdots & IVIFNDD_j\left(FA_2,FA_m\right) \\ \vdots & \vdots & \cdots & \vdots \\ IVIFNDD_j\left(FA_m,FA_1\right) & IVIFNDD_j\left(FA_m,FA_2\right) & \cdots & 0 \end{bmatrix} \end{array}$$

(3) Perform the IVIFNDD of FA_i under FG_j :

$$IVIFNDD_j\left(FA_i\right)=\sum_{t=1}^{m}IVIFNDD_j\left(FA_i,FA_t\right) \tag{23}$$

The IVIFNDD is performed:

$$IVIFNDD=\left(IVIFNDD_{ij}\right)_{m\times n}$$

$$=\begin{bmatrix} & FG_1 & FG_2 & \cdots & FG_n \\ FA_1 & \sum_{t=1}^{m}IVIFNDD_1\left(FA_1,FA_t\right) & \sum_{t=1}^{m}IVIFNDD_2\left(FA_1,FA_t\right) & \cdots & \sum_{t=1}^{m}IVIFNDD_n\left(FA_1,FA_t\right) \\ FA_2 & \sum_{t=1}^{m}IVIFNDD_1\left(FA_2,FA_t\right) & \sum_{t=1}^{m}IVIFNDD_2\left(FA_2,FA_t\right) & \cdots & \sum_{t=1}^{m}IVIFNDD_n\left(FA_2,FA_t\right) \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ FA_m & \sum_{t=1}^{m}IVIFNDD_1\left(FA_m,FA_t\right) & \sum_{t=1}^{m}IVIFNDD_2\left(FA_m,FA_t\right) & \cdots & \sum_{t=1}^{m}IVIFNDD_n\left(FA_m,FA_t\right) \end{bmatrix}$$

Step 6. Perform the IVIFNBAA (IVIFN Border Approximation Area).

$$IVIFNPIA_j=\max_{j=1}^{n}IVIFNDD_{ij},$$

$$IVIFNNIA_j=\min_{j=1}^{n}IVIFNDD_{ij} \tag{24}$$

$$NIVIFNDD_{ij}=1+\frac{IVIFNDD_{ij}-IVIFNNIA_j}{IVIFNPIA_j-IVIFNNIA_j}, \tag{25}$$

$$IVIFNBAA=\left[IVIFNBAA_j\right]_{1\times n} \tag{26}$$

$$IVIFNBAA_j=\prod_{j=1}^{n}\left(NIVIFNDD_{ij}\right)^{1/m}$$

$$=\prod_{j=1}^{n}\left(1+\frac{IVIFNDD_{ij}-IVIFNNIA_j}{IVIFNPIA_j-IVIFNNIA_j}\right)^{1/m} \tag{27}$$

Step 7. Perform the IVIFNDM (IVIFN distance measures) from IVIFNBAA:

$$IVIFNDM_{ij}=NIVIFNDD_{ij}-IVIFNBAA_j \tag{28}$$

Step 8. Perform the IVIFNWDM (IVIFN weighted distance measures) from IVIFNBAA.

$$IVIFNWDM_i=\sum_{j=1}^{n}\left(fw_j\times IVIFNDM_{ij}\right)$$

$$=\sum_{j=1}^{n}\left(fw_j\times\left(NIVIFNDD_{ij}-IVIFNBAA_j\right)\right) \tag{29}$$

Step 9. From the IVIFNWDM, the largest IVIFNWDM is the optimal choice.

IV. Numerical Example and Comparative Analysis

A. Numerical Example for College English Teaching Quality Evaluation

The evaluation of English teaching quality is a systematic process aimed at assessing the effectiveness of teaching and student learning outcomes to ensure that teaching activities effectively enhance students' English abilities. This process involves multiple aspects, including curriculum content, teaching methods, student engagement, the efficiency of learning resource use, and the teaching environment. Firstly, an essential aspect of the evaluation is the appropriateness of the curriculum content. This includes the rationality of the syllabus, the clarity of course objectives, and whether the depth and breadth of the content meet students' learning needs. Effective course design should cover all necessary language skills, such as listening, speaking, reading, and writing, and progressively enhance students' abilities through appropriate difficulty

gradients. Secondly, the innovation and diversity of teaching methods are key to the evaluation. Teachers should use various teaching strategies according to the specific needs and learning styles of students, such as cooperative learning, project-based learning, and multimedia teaching, to enhance the interactivity and interest of learning. The teacher's teaching style and abilities, such as clear expression, effective classroom management, and the timeliness and appropriateness of feedback to students, are important indicators for evaluation. Student engagement is another crucial metric for assessing teaching quality. Students' interaction in class, enthusiasm for participating in discussions, the quality and attitude toward completing assignments, and their mastery of learning materials all reflect the effectiveness of teaching. Additionally, the evaluation should also focus on students' learning motivation and self-development, including their self-assessment abilities and the achievement of learning objectives. During the evaluation process, it is also essential to fully utilize various assessment tools and technologies, such as classroom observations, student evaluations, standardized tests, and performance displays. These tools can provide direct and indirect evidence of teaching effectiveness, helping teachers and educational administrators make corresponding adjustments and improvements. Finally, the support of teaching resources and the environment is also crucial for ensuring teaching quality. Schools should provide sufficient learning materials, modern teaching facilities, and an environment conducive to learning. Moreover, continuous professional development support for teachers and resource updates are key to enhancing teaching quality. In summary, the evaluation of English teaching quality is a multi-faceted assessment process that not only focuses on teachers' teaching behaviors and students' learning outcomes but also involves curriculum design, teaching methods, student engagement, and teaching resources and environments. Through this comprehensive evaluation system, teaching quality can be effectively enhanced, ensuring students achieve the best outcomes in their English learning. The college English teaching quality evaluation is MAGDM process. Five potential English colleges $FA_i\left(i=1,2,3,4,5\right)$ are assessed with four attributes (Table I):

Five potential English colleges $FA_i\left(i=1,2,3,4,5\right)$ are assessed through linguistic scales (see Table II [67]) under experts $FE_t\left(t=1,2,3\right)$ with expert's weight $fw=\left(1/3,1/3,1/3\right)$.

TABLE I. FOUR ATTRIBUTES FOR SUSTAINABLE DEVELOPMENT EVALUATION IN HIGHER EDUCATION MANAGEMENT

Attribute	Attribute description
Student Learning Outcomes-FG_1	This indicator focuses on the specific learning achievements students gain through English instruction. It can be assessed by examining improvements in students' language skills, exam scores, and performance in simulated applications. This indicator reflects whether teaching activities can effectively enhance students' English capabilities.
Cost-effectiveness of Teaching-FG_2	The cost-related indicator primarily evaluates the relationship between input and output. In English teaching, this includes calculating the input of teaching resources (such as textbook costs, equipment investment, teacher training expenses, etc.) and comparing it with teaching outcomes. For example, the cost-effectiveness of teaching can be evaluated by analyzing the average improvement in students' scores or progression in language skills per unit cost.
Teacher Performance-FG_3	Return on educational investment is a crucial indicator of a university's economic efficiency. By assessing the returns on educational investments, universities can optimize resource allocation, enhance education quality, and improve students' employability, thereby increasing competitiveness and social impact.
Student Engagement and Feedback-FG_4	Active student participation is one of the crucial factors for successful teaching. This indicator measures through assessing students' interaction in class, homework completion, the level of activity in class discussions, and students' feedback on the teaching content. Student satisfaction with the teaching process and their suggestions can be obtained through surveys, interviews, or observations, reflecting the attractiveness and effectiveness of teaching activities.

TABLE II. LINGUISTIC SCALES AND IVIFNS

Linguistic information scale	IVIFNs
Exceedingly Bad-FEB	<[0.05,0.10], [0.85, 0.90]>
Very Bad-FVB	<[0.10,0.15], [0.75, 0.85]>
Bad-FB	<[0.15,0.20], [0.60, 0.70]>
Medium-FM	<[0.50,0.50], [0.50, 0.50]>
Good-FG	<[0.60,0.70], [0.15, 0.20]>
Very Good-FVG	<[0.75,0.85], [0.10, 0.15]>
Exceedingly Good-FEG	<[0.85,0.90], [0.05, 0.10]>

The IVIFN-ExpTODIM-MABAC is performed for college English teaching quality evaluation. $FR = \left[FR_{ij}^{(t)} \right]_{5\times4} \left(t = 1,2,3 \right)$ (Tables III to V).

Step 1. Describe the IVIFN-matrix

TABLE III. EVALUATION VALUES FOR FE_1

	FG_1	FG_2	FG_3	FG_4
FA_1	FM	FB	FVG	FVB
FA_2	FVB	FVG	FG	FM
FA_3	FVG	FG	FM	FB
FA_4	FVB	FM	FG	FVG
FA_5	FM	FVB	FVB	FVG

TABLE IV. EVALUATION INFORMATION FOR FE_2

	FG_1	FG_2	FG_3	FG_4
FA_1	FG	FVB	FVB	FM
FA_2	FG	FM	FB	FVG
FA_3	FB	FG	FVG	FVB
FA_4	FM	FM	FG	FB
FA_5	FM	FG	FVG	FB

TABLE V. EVALUATION INFORMATION FOR FE_3

	FG_1	FG_2	FG_3	FG_4
FA_1	FVG	FG	FM	FB
FA_2	FVG	FB	FVB	FM
FA_3	FM	FVG	FB	FG
FA_4	FVB	FM	FVG	FG
FA_5	FVB	FVG	FM	FG

Then, employing IVIFWG approach, the $FR = \left[FR_{ij} \right]_{5\times4}$ is performed (see Table VI).

TABLE VI. THE $FR = \left[FR_{ij} \right]_{5\times4}$

Alternatives	FG_1	FG_2
FA_1	([0.2431, 0.3410], [0.4571, 0.5589])	([0.4301, 0.4899], [0.3170, 0.3689])
FA_2	([0.1305, 0.2297], [0.7680, 0.8664])	([0.1470, 0.2459], [0.6521, 0.7503])

FA_5	([0.2233, 0.3196], [0.5778, 0.6754])	([0.4954, 0.5932], [0.3034, 0.4012])
Alternatives	FG_3	FG_5
FA_1	([0.2021, 0.3049], [0.5813, 0.6810])	([0.2568, 0.3502], [0.5350, 0.6348])
FA_2	([0.3698, 0.4691], [0.4190, 0.5172])	([0.0945, 0.1907], [0.7082, 0.8056])
FA_3	([0.0593, 0.1551], [0.7435, 0.8407])	([0.1124, 0.2086], [0.6881, 0.7879])
FA_4	([0.3925, 0.4928], [0.4057, 0.5045])	([0.0032, 0.1070], [0.8003, 0.8965])
FA_5	([0.0117, 0.1095], [0.7889, 0.8867])	([0.3058, 0.4026], [0.4942, 0.5900])

Step 3. Perform the weight numbers (Table VIII):

TABLE VIII. THE WEIGHT NUMBERS

	FG_1	FG_2	FG_3	FG_4
weight numbers	0.2599	0.3620	0.1912	0.1869

Step 4. Perform the relative weight numbers (Table IX):

TABLE IX. THE RELATIVE WEIGHT NUMBERS

	FG_1	FG_2	FG_3	FG_4
relative weight	0.7180	1.0000	0.5282	0.5163

Step 5. Perform the $IVIFNDD = \left(IVIFNDD_{ij} \right)_{5\times4}$ (see Table X):

TABLE X. THE $IVIFNDD = \left(IVIFNDD_{ij} \right)_{5\times4}$

	FG_1	FG_2	FG_3	FG_4
FA_1	1.6044	-2.5732	0.6424	-1.1950
FA_2	-0.9564	2.0414	-3.5905	0.9154
FA_3	-1.1400	-0.1256	-0.3628	1.6101
FA_4	1.1026	-0.7552	0.3485	0.5389
FA_5	-1.4750	-2.1363	-1.6255	-1.3453

Step 6. Perform the IVIFNBAA (see Tables XI to XIII).

TABLE XI. THE IVIFNPIA AND IVIFNNIA

	FG_1	FG_2	FG_3	FG_4
IVIFNPIA	1.6044	2.0414	0.6424	1.6101
IVIFNNIA	-1.4750	-2.5732	-3.5905	-1.3453

TABLE XII. THE NIVIFNDD

	FG_1	FG_2	FG_3	FG_4
FA_1	1.0000	1.2824	1.0000	1.2093
FA_2	1.3743	2.0000	2.0000	1.3730
FA_3	1.3112	1.5068	1.5253	2.0000
FA_4	1.0417	1.7260	1.6653	1.7196
FA_5	2.0000	1.0000	1.6899	1.0000

TABLE XIII. THE IVIFNBAA

	FG_1	FG_2	FG_3	FG_4
IVIFNBAA	1.3662	1.3611	1.5838	1.4345

Step 7. Perform the IVIFNDM (see Tables XIV and XV):

TABLE XIV. THE IVIFNDM

	FG_1	FG_2	FG_3	FG_4
FA_1	0.6338	-0.3611	0.4162	-0.3836
FA_2	-0.1978	0.6389	-0.5838	0.3305
FA_3	-0.2574	0.1694	0.1788	0.5655
FA_4	0.4708	0.0329	0.3468	0.2031
FA_5	-0.3662	-0.2664	-0.1195	-0.4345

TABLE XV. THE WEIGHTED IVIFNDM

	FG_1	FG_2	FG_3	FG_4
FA_1	0.1647	-0.1307	0.0796	-0.0717
FA_2	-0.0514	0.2313	-0.1116	0.0618
FA_3	-0.0669	0.0613	0.0342	0.1057
FA_4	0.1224	0.0119	0.0663	0.0380
FA_5	-0.0952	-0.0964	-0.0229	-0.0812

Step 8. Perform the IVIFNWDM (see Table XVI).

TABLE XVI. THE IVIFNWDM

	IVIFNWDM	Order
FA_1	0.0419	4
FA_2	0.1300	3
FA_3	0.1343	2
FA_4	0.2385	1
FA_5	-0.2957	5

Step 9. From the IVIFNWDIM, the order is performed: $FA_4 > FA_3 > FA_2 > FA_1 > FA_5$ and TA_4 is the best English college.

B. Comparative Analysis

Then, the IVIFN-ExpTODIM-MABAC approach is compared with IVIFWA approach [60], IVIFWG approach [61], IVIFPWA approach [68], IVIFPWG approach [68], IVIFN-MABAC approach [69], IVIFN-Taxonomy approach [70] and IVIFN-TODIM approach [71]. The comparative results are performed in Table XVII.

TABLE XVII. ORDER FOR DIFFERENT APPROACHES

Approaches	Order
IVIFWA approach [60]	$FA_4 > FA_3 > FA_2 > FA_1 > FA_5$
IVIFWG approach [61]	$FA_4 > FA_3 > FA_1 > FA_2 > FA_5$
IVIFPWA approach [68]	$FA_4 > FA_3 > FA_2 > FA_1 > FA_5$
IVIFPWG approach [68],	$FA_4 > FA_3 > FA_1 > FA_2 > FA_5$
IVIFN-MABAC approach [69]	$FA_4 > FA_3 > FA_2 > FA_1 > FA_5$
IVIFN-Taxonomy approach [70]	$FA_4 > FA_3 > FA_2 > FA_1 > FA_5$
IVIFN-TODIM approach [71]	$FA_4 > FA_3 > FA_2 > FA_1 > FA_5$
IVIFN-ExpTODIM-MABAC approach	$FA_4 > FA_3 > FA_2 > FA_1 > FA_5$

In light with RW coefficients [72], the RW coefficient between IVIFWA approach [60], IVIFWG approach [61], IVIFPWA approach [68], IVIFPWG approach [68], IVIFN-MABAC approach [69], IVIFN-Taxonomy approach [70], IVIFN-TODIM approach [71] and IVIFN-ExpTODIM-MABAC approach is 1.0000, 0.9246, 1.0000, 0. 9246, 1.0000, 1.0000, 1.0000. This verifies the IVIFN-ExpTODIM-MABAC approach is effective.

V. CONCLUSION

The purpose of evaluating the quality of English teaching is to ensure the effectiveness of teaching methods, content, and resources, and to improve the teaching skills of educators and the learning outcomes of students. Through evaluation, strengths and weaknesses in teaching can be identified, promoting the professional development of teachers and innovation in teaching methods. Moreover, this process helps in designing courses that better meet the needs of students, enhancing the overall level of teaching, and ultimately aiming to improve students' English proficiency. The evaluation of college English teaching quality involves MAGDM. Currently, the TODIM-MABAC method is utilized in MAGDM contexts, with IVIFSs used to represent fuzzy decision data during the assessment. This research introduces the IVIFN-ExpTODIM-MABAC model for MAGDM, incorporating IVIFSs. To validate the effectiveness of the IVIFN-ExpTODIM-MABAC approach, a numerical example focusing on the evaluation of college English teaching quality is presented, alongside several comparative analyses. The key contributions of this study are: (1) The expansion of the ExpTODIM-MABAC method to include IVIFSs and an entropy model. (2) The use of entropy to assign weights within the context of IVIFSs. (3) The introduction of the IVIFN-ExpTODIM-MABAC method for MAGDM using IVIFSs. (4) The provision of a numerical example and execution of various comparative analyses to confirm the applicability of the IVIFN-ExpTODIM-MABAC model in assessing college English teaching quality.

***Abstract*—Sports colleges are the highest educational level in China's higher education system to cultivate sports professionals. They shoulder the arduous task of cultivating sports talents with innovative spirit and practical ability, and contribute to the country's sports and education undertakings. Through the study of the service performance of the teaching management departments in sports colleges, it is beneficial for teaching management workers to establish the central position of teaching work more firmly in their thoughts and actions, transform their work style, enhance their ideological awareness of serving teaching work, serve teaching, teachers, and students, closely focus on teaching work to provide various services, strive to improve the level of management services, and make improving service levels and optimizing service quality an important part of improving the teaching management level in sports colleges. The management performance evaluation of teaching services in sports colleges and universities is regarded as the defined multiple-attribute decision-making (MADM). Recently, the CoCoSo and entropy technique was utilized to cope with MADM. The double-valued neutrosophic sets (DVNSs) are utilized as a technique for characterizing fuzzy information during the management performance evaluation of teaching services in sports colleges and universities. In this study, double-valued neutrosophic number CoCoSo (DVNN-CoCoSo) technique is administrated for MADM in light with DVNN Euclidean distance (DVNNED) and DVNN Logarithmic distance (DVNNLD). Finally, numerical example for management performance evaluation of teaching services in sports colleges and universities is put forward to show the DVNN-CoCoSo technique. The major contribution of this study is administrated: (1) DVNN-CoCoSo technique is administrated for MADM in light with DVNNED and DVNNLD; (2) The objective weights are considered through entropy technique; (3) numerical example for management performance evaluation of teaching services in sports colleges and universities and some comparative analysis are administrated to verify the DVNN-CoCoSo technique.**

Keywords*—Multiple-Attribute Decision-Making (MADM); Double-Valued Neutrosophic Sets (DVNSs); CoCoSo technique; management performance evaluation of teaching services

I. INTRODUCTION

Cultivating talents is the basic function and fundamental task of higher education institutions in China, and the central task of schools is often teaching work. Therefore, teaching management plays a particularly important role [1]. Sports colleges and universities have an important mission in developing the national sports industry, advancing China towards a sports powerhouse, building an innovative country, and enhancing the country's competitiveness in development [2-4]. Sports colleges have various functions such as cultivating senior specialized sports talents for national construction, conducting sports scientific research, and engaging in social services [5-7]. They actively adapt to the development needs of the national sports industry with sports as their characteristics [8-10]. Teaching management is the core function of the teaching management department, which has unique characteristics of complexity, complexity, and repetition. In the process of development, sports colleges have gradually shown a trend of expanding their scale, comprehensive professional settings, and diversified educational levels [11, 12]. The difficulty and complexity of teaching management are increasing, and with the continuous deepening of information technology in teaching management, the requirements for the quality and information acquisition ability of managers are becoming higher and higher [13, 14]. With the continuous deepening of the implementation of the credit system, the transition from the academic year system to academic year credit system, and the transformation to the credit system, the original teaching management work methods, management methods, and systems seem somewhat inadequate and difficult to adapt to. The number of disciplines and majors in sports colleges is increasing, and the number of students on campus is also increasing [15-18]. The unified management by the school appears to have a huge coverage, and it is also difficult to achieve effective management after implementing secondary college management. In the practice of teaching management, we may encounter such phenomena: the school's decision-making and work ideas cannot be well implemented. There are more discussions on teaching work than practical ones, and the problems raised during the meetings are often not solved [19, 20]. The same problems are raised year by year and occur year by year. The school's rules and regulations lack a certain degree of constraint ability; Inadequate work arrangement; The execution process is sloppy, etc. Although schools have attempted to link the implementation of their respective departments with performance, the results have been minimal.

*Corresponding Author.

Low efficiency in handling affairs, unreasonable management structure, low overall business quality of management personnel, poor channels for uploading and issuing information, and emphasis on form over connotation in goal management and management performance evaluation [21-24]. The management methods are not entirely scientific, the hierarchical and categorical distinctions in management are insufficient, the system is rigid, the response to new things is slow, and the phenomenon of habitual defense is obvious [25, 26]. Political management is too broad, administrative intervention in teaching management is too strong, the official centric ideology is severe, there are too many checkpoints, work transparency is poor, coordination is insufficient, the tendency towards government is obvious, and the rule of man is greater than the rule of law. These phenomena have been troubling many workers engaged in teaching management [27]. Sports colleges are the highest educational level in China's higher education system to cultivate sports professionals. They shoulder the arduous task of cultivating sports talents with innovative spirit and practical ability, and contribute to the country's sports and education undertakings [28-30]. The construction of teaching management performance is achieved by adopting scientific management methods, mobilizing the enthusiasm, initiative, and creativity of the majority of teaching staff in their work, correcting their service attitude, enhancing their consciousness of actively serving teaching work, thereby improving work efficiency and ability, and better implementing the school's policies and guidelines [31-33].

The management performance evaluation of teaching services in sports colleges and universities is regarded as the defined MADM. Recently, the CoCoSo [34] and entropy [35] has been used to cope with MADM. The DVNSs [36] are used as a technique for characterizing fuzzy information during the management performance evaluation of teaching services in sports colleges and universities. Furthermore, many techniques employed CoCoSo technique [34] and entropy [35] separately to manage the MADM. Until now, no or few techniques have been administrated on entropy technique [35] and CoCoSo [34] under DVNSs. Therefore, the DVNN-CoCoSo model is founded to manage the MADM. Finally, numerical example for management performance evaluation of teaching services in sports colleges and universities and comparative analysis is administrated to validate the DVNN-CoCoSo model. The major research motivation of this work is managed: (1) the novel MADM is put forward based on CoCoSo and entropy technique under DVNSs. (2) The objective weights are considered through entropy technique. (3) The new MADM technique based on DVNN-CoCoSo technique is proposed for management performance evaluation of teaching services in sports colleges and universities. (4) numerical example for management performance evaluation of teaching services in sports colleges and universities and comparative analysis are employed to prove the DVNN-CoCoSo model.

The framework of this study is administrated. Section II introduces the DVNSs. In Section III, the DVNN-CoCoSo technique is administrated for MADM. In Section IV, numerical example for blended teaching quality decision evaluation is administrated and comparative analysis is conducted. The final study ends in Section V.

II. PRELIMINARIES

Kandasamy [36] administrated the DVNSs.

Definition 1 [36]. The DVNSs RA in Θ is put forward:

$$RA=\left\{\left(\begin{matrix}\theta,RT_A(\theta),RIT_A(\theta),\\ RIF_A(\theta),RF_A(\theta)\end{matrix}\right)\middle|\theta\in\Theta\right\}. \tag{1}$$

where $RT_A(\theta)$ is truth-membership, $RIT_A(\theta)$ is indeterminacy leaning towards $RT_A(\theta)$, $RIF_A(\theta)$ is indeterminacy leaning towards $RF_A(\theta)$, $RF_A(\theta)$ is falsity-membership,

$RT_A(\theta),RIT_A(\theta),RIF_A(\theta),RF_A(\theta)\in[0,1]$,

$0\le RT_A(\theta)+RIT_A(\theta)+RIF_A(\theta)+RF_A(\theta)\le 4$.

The DVNN is expressed as $RA=(RT_A,RT_A,RIF_A,RF_A)$, where

$RT_A,RIT_A,RIF_A,RF_A\in[0,1]$

$0\le RT_A+RIT_A+RIF_A+RF_A\le 4$.

Definition 2 [36]. Let $RA=(RT_A,RT_A,RIF_A,RF_A)$ be the DVNN, the score value is administrated:

$$SV(RA)=\frac{(2+RT_A+RIT_A-RIF_A-RF_A)}{4},$$

$$SV(RA)\in[0,1] \tag{2}$$

Definition 3 [36]. Let $RA=(RT_A,RT_A,RIF_A,RF_A)$ be the DVNN, the accuracy value is administrated:

$$AV(RA)=\frac{(RT_A+RIT_A+RIF_A+RF_A)}{4},$$

$$AV(RA)\in[0,1] \tag{3}$$

The order for DVNNs is administrated.

Definition 4[36]. Let $RA=(RT_A,RT_A,RIF_A,RF_A)$ and $RB=(RT_B,RT_B,RIF_B,RF_B)$,

$$SV(RA)=\frac{(2+RT_A+RIT_A-RIF_A-RF_A)}{4},$$

$$SV(RB)=\frac{(2+RT_B+RIT_B-RIF_B-RF_B)}{4},$$

$AV\left(RA\right)=\frac{\left(RT_A+RIT_A+RIF_A+RF_A\right)}{4}$,

$AV\left(RB\right)=\frac{\left(RT_B+RIT_B+RIF_B+RF_B\right)}{4}$, if $SV\left(RA\right)<SV\left(RB\right)$, $RA<RB$; if $SV\left(RA\right)=SV\left(RB\right)$, (1)if $AV\left(RA\right)=AV\left(RB\right)$, $RA=RB$; (2) if $AV\left(RA\right)<AV\left(RB\right)$, $RA<RB$.

Definition 5 [36]. Let $RA=\left(RT_A,RT_A,RIF_A,RF_A\right)$ and $RB=\left(RT_B,RT_B,RIF_B,RF_B\right)$ be two DVNNs, the operations are administrated:

$$(1)\ RA\oplus RB=\left(RT_A+RT_B-RT_ART_B,RIT_A+RIT_B-RIT_ARIT_B,RIF_ARIF_B,RF_ARF_B\right);$$
$$(2)\ RA\otimes RB=\left(RT_ART_B,RIT_ARIT_B,RIF_A+RIF_B-RIF_ARIF_B,RF_A+RF_B-RF_ARF_B\right);$$
$$(3)\ \lambda RA=\left(1-\left(1-RT_A\right)^{\lambda},1-\left(1-RIT_A\right)^{\lambda},\left(RIF_A\right)^{\lambda},\left(RF_A\right)^{\lambda}\right),\lambda>0;$$
$$(4)\left(RA\right)^{\lambda}=\left(\left(RT_A\right)^{\lambda},\left(RIT_A\right)^{\lambda},1-\left(1-RIF_A\right)^{\lambda},1-\left(1-RF_A\right)^{\lambda}\right),\lambda>0.$$

Definition 6[36]. Let $RA=\left(RT_A,RT_A,RIF_A,RF_A\right)$ and $RB=\left(RT_B,RT_B,RIF_B,RF_B\right)$, the DVNN Euclidean distance (DVNNED) between $RA=\left(RT_A,RT_A,RIF_A,RF_A\right)$ and $RA=\left(RT_A,RT_A,RIF_A,RF_A\right)$ is:

$$ED\left(RA,RB\right)=\sqrt{\frac{1}{4}\left(\begin{array}{l}\left|RT_A-RT_B\right|^2+\left|RIT_A-RIT_B\right|^2\\+\left|RIF_A-RIF_B\right|^2+\left|RF_A-RF_B\right|^2\end{array}\right)} \quad (4)$$

Definition 7. Let $RA=\left(RT_A,RT_A,RIF_A,RF_A\right)$ and $RB=\left(RT_B,RT_B,RIF_B,RF_B\right)$, the DVNN Logarithmic distance (DVNNLD) between $RA=\left(RT_A,RT_A,RIF_A,RF_A\right)$ and $RB=\left(RT_B,RT_B,RIF_B,RF_B\right)$ is administrated:

$$DVNNLD\left(RA,RB\right)=\frac{1}{4}\left(\begin{array}{l}RT_A\log\frac{2RT_A}{RT_A+RT_B}+RT_B\log\frac{2RT_B}{RT_A+RT_B}\\+RIT_A\log\frac{2RIT_A}{RIT_A+RIT_B}+RIT_B\log\frac{2RIT_B}{RIT_A+RIT_B}\\+RIF_A\log\frac{2RIF_A}{RIF_A+RIF_B}+RIF_B\log\frac{2RIF_B}{RIF_A+RIF_B}\\+RF_A\log\frac{2RF_A}{RF_A+RF_B}+RF_B\log\frac{2RF_B}{RF_A+RF_B}\end{array}\right) \quad (5)$$

III. DVNN-CoCoSo Approach for MADM with Entropy Weight

The DVNN-CoCoSo technique is administrated for MADM. Let $RA=\left\{RA_1,RA_2,\cdots,RA_m\right\}$ be alternatives, $RG=\left\{RG_1,RG_2,\cdots,RG_n\right\}$ be attributes with weight rw, where $rw_j\in\left[0,1\right]$, $\sum_{j=1}^{n}rw_j=1$. Suppose that assessed information are DVNNs $RM=\left(RM_{ij}\right)_{m\times n}=\left(RT_{ij},RIT_{ij},RIF_{ij},RF_{ij}\right)_{m\times n}$.

Then, DVNN-CoCoSo technique is put forward MADM (see Fig. 1).

Step 1. Put forward the DVNN-matrix $RM=\left(RM_{ij}\right)_{m\times n}=\left(RT_{ij},RIT_{ij},RIF_{ij},RF_{ij}\right)_{m\times n}$

$$RM=\left[RM_{ij}\right]_{m\times n}=\begin{bmatrix}RM_{11}&RM_{12}&\cdots&RM_{1n}\\RM_{21}&RM_{22}&\cdots&RM_{2n}\\\vdots&\vdots&\vdots&\vdots\\RM_{m1}&RM_{m2}&\cdots&RM_{mn}\end{bmatrix} \quad (6)$$

$$RM_{ij}=\left(RT_{ij},RIT_{ij},RIT_{ij},RF_{ij}\right) \quad (7)$$

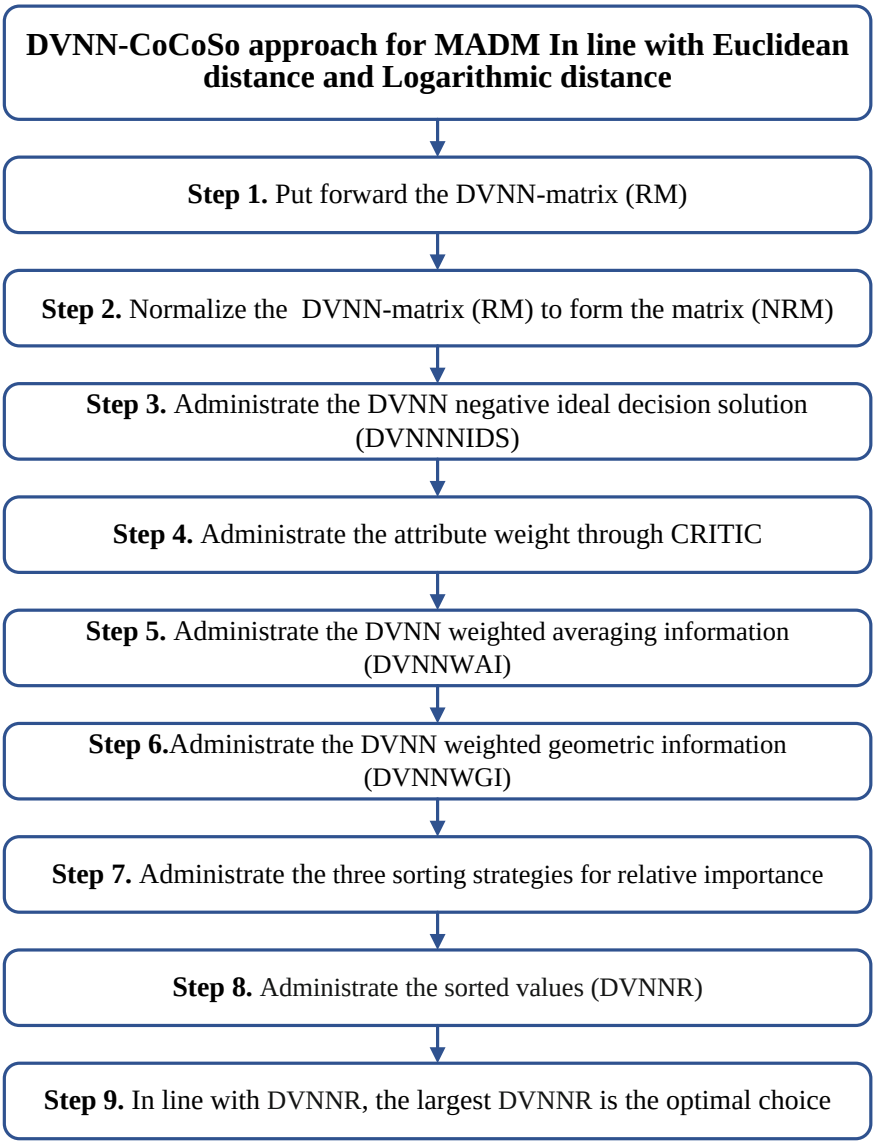

Fig. 1. DVNN-CoCoSo technique for MADM in line with Euclidean distance and Logarithmic distance.

Step 2. Normalize the

$$UR = \left(UR_{ij}\right)_{m\times n} = \left(UT_{ij}, UIT_{ij}, UIF_{ij}, UF_{ij}\right)_{m\times n}$$

into

$$NRM = \left(NRM_{ij}\right)_{m\times n} = \left(RT_{ij}^{N}, RIT_{ij}^{N}, RIF_{ij}^{N}, RF_{ij}^{N}\right)_{m\times n}$$

$$NRM_{ij} = \left(RT_{ij}^{N}, RIT_{ij}^{N}, RIF_{ij}^{N}, RF_{ij}^{N}\right) = \begin{cases} \left(RT_{ij}, RIT_{ij}, RIF_{ij}, RF_{ij}\right), & RG_j \text{ is benefit attribute} \\ \left(RF_{ij}, RIF_{ij}, RIT_{ij}, RT_{ij}\right), & RG_j \text{ is cost attribute} \end{cases} \quad (8)$$

Step 3. Administrate the DVNN negative ideal decision solution (DVNNNIDS):

$$DVNNNIDS = \begin{pmatrix} DVNNNIDS_1, DVNNNIDS_2, \\ \cdots, DVNNNIDS_n \end{pmatrix} \quad (9)$$

$$DVNNNIDS_j = \left(RT_j^{N-}, RIT_j^{N-}, RIF_j^{N-}, RF_j^{N-}\right) \quad (10)$$

$$DVNNSV\left(DVNNNIDS_j\right) = \min_i DVNNSV\left(RT_{ij}^{N}, RIT_{ij}^{N}, RIF_{ij}^{N}, RF_{ij}^{N}\right) \quad (11)$$

Step 4. Administrate the attribute weight through CRITIC.

The CRITIC [37] is administrated to obtain the objective weight.

1) Administrate the DVNNED and DVNNLD of RA_i from DVNNNIDS.

$$DVNNED\left(NRM_{ij}, DVNNNIDS_j\right) = \sqrt{\frac{1}{4}\left(\begin{array}{l}\left|RT_{ij}^{N} - RT_{j}^{N-}\right|^2 + \left|RIT_{ij}^{N} - RIT_{j}^{N-}\right|^2 \\ + \left|RIF_{ij}^{N} - RIF_{j}^{N-}\right|^2 + \left|RF_{ij}^{N} - RF_{j}^{N-}\right|^2\end{array}\right)} \quad (12)$$

$$DVNNLD\left(NRM_{ij}, DVNNNIDS_j\right) = \frac{1}{4}\left(\begin{array}{l} RT_{ij}^{N}\log\frac{2RT_{ij}^{N}}{RT_{ij}^{N}+RT_{j}^{N-}} + RT_{j}^{N-}\log\frac{2RT_{j}^{N-}}{RT_{ij}^{N}+RT_{j}^{N-}} \\ + RIT_{ij}^{N}\log\frac{2RIT_{ij}^{N}}{RIT_{ij}^{N}+RIT_{j}^{N-}} + RIT_{j}^{N-}\log\frac{2RIT_{j}^{N-}}{RIT_{ij}^{N}+RIT_{j}^{N-}} \\ + RIF_{ij}^{N}\log\frac{2RIF_{ij}^{N}}{RIF_{ij}^{N}+RIF_{j}^{N-}} + RIF_{j}^{N-}\log\frac{2RIF_{j}^{N-}}{RIF_{ij}^{N}+RIF_{j}^{N-}} \\ + RF_{ij}^{N}\log\frac{2RF_{ij}^{N}}{RF_{ij}^{N}+RF_{j}^{N-}} + RF_{j}^{N-}\log\frac{2RF_{j}^{N-}}{RF_{ij}^{N}+RF_{j}^{N-}}\end{array}\right) \quad (13)$$

$$NRMRA_j = \frac{1}{m}\sum_{i=1}^{m}\left(\frac{\left(\begin{array}{l}DVNNED\left(NRM_{ij}, DVNNNIS_j\right) \\ + DVNNLD\left(NRM_{ij}, DVNNNIDS_j\right)\end{array}\right)}{2}\right), j = 1, 2, \cdots, n. \quad (14)$$

$$NHHOA_{ij} = \frac{\left(\begin{array}{l}DVNNED\left(NRM_{ij}, DVNNNIS_j\right) \\ + DVNNLD\left(NRM_{ij}, DVNNNIDS_j\right)\end{array}\right)}{2} \quad (15)$$

2) Administrate the DVNN correlation decision coefficient (DVNNCDC):

$$DVNNCDC_{jk} = \frac{\sum_{i=1}^{m}\left(NRMRA_{ij} - NRMRA_j\right)\left(NRMRA_{ik} - NRMRA_k\right)}{\sqrt{\sum_{i=1}^{m}\left(NRMRA_{ij} - NRMRA_j\right)^2\sum_{i=1}^{m}\left(NRMRA_{ik} - NRMRA_k\right)^2}} \quad (16)$$

3) Administrate the DVNN standard deviation ($DVNNSD_j$):

$$DVNNSD_j = \sqrt{\frac{1}{m-1}\sum_{i=1}^{m}\left(NRMRA_{ij} - NRMRA_j\right)^2}, \quad (17)$$

(4) Administrate the weight numbers:

$$rw_j = \frac{DVNNSD_j\left(1 - DVNNCDC_{jk}\right)}{\sum_{k=1}^{n} DVNNSD_j\left(1 - DVNNCDC_{jk}\right)} \quad (18)$$

Step 5. Administrate the DVNN weighted averaging information (DVNNWAI).

$$DVNNWAI_i = \left(\sum_{j=1}^{n} \left(rw_j \times \begin{pmatrix} DVNNED\left(NHH_{ij}, DVNNNIS_j\right) \\ +DVNNLD\left(NRM_{ij}, DVNNNIDS_j\right) \end{pmatrix} \right) \Big/ 2 \right). \tag{19}$$

Step 6. Administrate the DVNN weighted geometric information (DVNNWGI).

$$DVNNWGI_i = \prod_{j=1}^{n} \left(\left(\begin{pmatrix} DVNNED\left(NHH_{ij}, DVNNNIS_j\right) \\ +DVNNLD\left(NRM_{ij}, DVNNNIDS_j\right) \end{pmatrix} \right) \Big/ 2 \right)^{rw_j}. \tag{20}$$

Step 7. Administrate the three sorting strategies for relative importance.

$$DVNNR_{ia} = \frac{DVNNWGI_i + DVNNWAI_i}{\sum_{i=1}^{m} \left(DVNNWGI_i + DVNNWAI_i \right)}. \tag{21}$$

$$DVNNR_{ib} = \frac{DVNNWAI_i}{\min\limits_i DVNNWAI_i} + \frac{DVNNWGI_i}{\min\limits_i DVNNWGI_i}. \tag{22}$$

$$DVNNR_{ic} = \frac{DVNNWAI_i + (1-\lambda) DVNNWGI_i}{\lambda \max\limits_i DVNNWAI_i + (1-\lambda) \max\limits_i DVNNWGI_i}, 0 \le \lambda \le 1. \tag{23}$$

where $DVNNR_{ia}$ is arithmetic average of $DVNNWAI_i, DVNNWGI$, $DVNNR_{ib}$ is relative scores of $DVNNWAI_i, DVNNWGI$, and $DVNNR_{ic}$ is balanced compromise of $DVNNWAI_i, DVNNWGI$.

Step 8. Administrate the sorted values $DVNNR_i$.

$$DVNNR_i = \begin{pmatrix} \sqrt[3]{DVNNR_{ia} DVNNR_{ib} DVNNR_{ic}} \\ +\dfrac{DVNNR_{ia} + DVNNR_{ib} + DVNNR_{ic}}{3} \end{pmatrix} \tag{24}$$

Step 9. Administrate the alternatives with $DVNNR_i \left(i = 1, 2, \cdots, m\right)$, and higher $DVNNR_i$ is better alternative.

IV. Example Study and Comparative Analysis

A. Example Study for Management Performance Evaluation of Teaching Services in Sports Colleges and Universities

The current teaching management in universities is becoming increasingly complex, and some teaching management personnel have deficiencies in concepts, professional qualities, knowledge, and mentality, which leads to a certain degree of insufficient human resources in the actual operation process of teaching management [38-40]. Collaboration and teamwork between teaching management departments are beneficial for members to overcome their own knowledge limitations, which can be achieved through rotation of teaching management positions or team work based on the time period of teaching management work. The reasonable flow of teaching management personnel within the department is an effective way for personal knowledge to be shared within the organization, which is conducive to knowledge transfer among members [41, 42]. The teaching management work of schools is mainly focused on supporting teaching work, and the nature of services is very obvious. In the practice of teaching management, teaching managers should establish the ideological consciousness of serving teaching work, serving grassroots, teaching, teachers, and students, and closely focus on providing various services around teaching work, striving to improve the level of management services [43-46]. To some extent, the process of service is the process of knowledge transfer. Teaching managers can openly express their opinions, maintain efficient communication with other managers, teachers, and students, promote the integration of various information in business relationships, and improve the behavioral paradigm of teaching managers. Continuously learning in the management process, emphasizing the learning process, summarizing the problems or advantages discovered in practice, and internalizing the correct experiences of these learning outcomes into organizational memory [47-49]. By establishing a long-term learning mechanism, a common communication channel is created for explicit and implicit knowledge within the organization, forming a shared learning system and accelerating the flow of knowledge within the organization [17, 50, 51]. We will adhere to the methods of development and reform to solve the problems in progress,

vigorously promote innovation in the teaching management system and mechanism, further improve the level of teaching management, enhance the awareness and quality of teaching management services, and achieve the goal of cultivating high-quality composite applied talents with innovative spirit and practical ability [52-55]. Education, scientific research, and training will develop comprehensively, coordinated, and sustainably. People use defensive reasoning for thinking and action in their daily lives and work because they have developed this habit for a long time in such an environment. Habitual defense is an important protective factor that prevents people from bravely facing and correcting mistakes, and hinders organizations from continuously learning and developing. In the process of teaching management reform in schools, we often encounter such problems. In the face of either new and old systems or innovation, we both face the dilemma of autonomy and control [56-58]. So, self-protection emerged, with a vague and unclear attitude towards new things, fearing that change would harm one's own interests. Establishing a creative learning environment in teaching management practice, improving the reflective learning ability of management personnel, and promoting the continuous development of teaching management [59]. The management performance evaluation of teaching services in sports colleges and universities is MADM. There are five possible sports colleges and universities $RA_i\ (i=1,2,3,4,5)$ are assessed in light with four attributes: ①RG_1 is the student feedback results; ②RG_2 is the blended teaching management costs; ③RG_3 is the blended teaching attitude; ④RG_4 is the invited peer review recognition. RG_2 is the cost. Then, the DVNN-CoCoSo model is administrated for management performance evaluation of teaching services in sports colleges and universities.

Step 1. Put forward the DVNN-matrix $RM=\left(UR_{ij}\right)_{5\times4}$ as in Table I.

TABLE I. DVNN INFORMATION

	RG_1	RG_2
RA_1	(0.35,0.64, 0.13, 0.46)	(0.42, 0.36, 0.45, 0.38)
RA_2	(0.53, 0.42,0.35, 0.54)	(0.63, 0.56, 0.37, 0.42)
RA_3	(0.46, 0.35, 0.49,0.43)	(0.29, 0.35, 0.46, 0.24)
RA_4	(0.43, 0.34, 0.37, 0.42)	(0.34, 0.53, 0.42, 0.46)

	RG_3	RG_4
RA_1	(0.49, 0.26, 0.58, 0.45)	(0.36, 0.38, 0.23, 0.43)
RA_2	(0.42, 0.31,0.52, 0.43)	(0.42, 0.57,0.16, 0.45)
RA_3	(0.25, 0.39,0.37, 0.46)	(0.49, 0.54,0.32, 0.41)
RA_4	(0.32, 0.46, 0.45, 0.39)	(0.35, 0.51,0.39, 0.42)
RA_5	(0.34, 0.48,0.42, 0.37)	(0.37, 0.64,0.15, 0.48)

Step 2. Normalize the DVNN matrix $RM=\left(UR_{ij}\right)_{5\times4}$ to $NRM=\left(NRM_{ij}\right)_{5\times4}$ (see Table II).

TABLE II. THE NORMALIZED DVNNS

	RG_1	RG_2
RA_1	(0.25, 0.39,0.37, 0.46)	(0.41, 0.32,0.54, 0.49)
RA_2	(0.32, 0.46, 0.45, 0.39)	(0.42, 0.39,0.51, 0.35)
RA_3	(0.34, 0.48,0.42, 0.37)	(0.48, 0.15,0.64, 0.37)
RA_4	(0.49, 0.26, 0.58, 0.45)	(0.43, 0.23, 0.38, 0.36)
RA_5	(0.42, 0.31,0.52, 0.43)	(0.45, 0.16,0.57, 0.42)
	RG_3	RG_4
RA_1	(0.43, 0.34, 0.37, 0.42)	(0.34, 0.53, 0.42, 0.46)
RA_2	(0.35, 0.46,0.39, 0.37)	(0.37, 0.59, 0.36, 0.29)
RA_3	(0.35,0.64, 0.13, 0.46)	(0.42, 0.36, 0.45, 0.38)
RA_4	(0.53, 0.42,0.35, 0.54)	(0.63, 0.56, 0.37, 0.42)
RA_5	(0.46, 0.35, 0.49,0.43)	(0.29, 0.35, 0.46, 0.24)

Step 3. Administrate the weight numbers (Table III).

TABLE III. THE WEIGHT NUMBERS

	RG_1	RG_2	RG_3	RG_4
weight	0.2207	0.3028	0.2504	0.2261

Step 4. Put forward the DVNNWAI (Table IV).

TABLE IV. THE DVNNWAI

	RA_1	RA_2	RA_3	RA_4	RA_5
DVNNWAI	0.8145	0.5597	0.6728	0.6984	0.4652

Step 5. Administrate the DVNNWGI (Table V).

TABLE V. THE DVNNWGI

	RA_1	RA_2	RA_3	RA_4	RA_5
DVNNWGI	0.7378	0.4613	0.5736	0.5879	0.3657

Step 6. Administrate the $DVNNR_{ia}, DVNNR_{ib}, DVNNR_{ic}$ (see Table VI).

TABLE VI. THREE DECISION STRATEGIES

	$DVNNR_{ia}$	$DVNNR_{ib}$	$DVNNR_{ic}$
RA_1	0.2615	3.7684	1.0000
RA_2	0.1720	2.4646	0.6577
RA_3	0.2099	3.0148	0.8029
RA_4	0.2167	3.1089	0.8286
RA_5	0.1400	2.0000	0.5353

Step 7. Administrate the DVNNR (see Table VII).

TABLE VII. THE DVNNR

	RA_1	RA_2	RA_3	RA_4	RA_5
DVNNR	2.6717	1.7513	2.1406	2.2081	1.4229

Step 8. According to $DVNNR_i\left(i=1,2,3,4,5\right)$, the order is $RA_1 > RA_4 > RA_3 > RA_2 > RA_5$ and the optimal sports college and university is RA_1.

B. Comparative Analysis

The DVNN-CoCoSo technique is compared with generalized double-valued neutrosophic weighted distance [36] and weighted Dice similarity measures $WD_{\mathrm{DVNS}_1}\left(RA_i, DVNNPIS\right)$, $WD_{\mathrm{DVNS}_2}\left(RA_i, DVNNPIS\right)$ and weighted generalized Dice similarity measures $WGD_{\mathrm{DVNS}_1}\left(RA_i, DVNNPIS\right)$, $WGD_{\mathrm{DVNS}_2}\left(RA_i, DVNNPIS\right)$ [60], DVNN-TODIM-VIKOR technique [61] and DVNN-ExpTODIM-GRA technique [62]. The comparative results are administrated in Table VIII.

TABLE VIII. ORDER FOR DIFFERENT TECHNIQUES

	Order
DVNN weighted Hamming distance[36]	$RA_1 > RA_4 > RA_3 > RA_2 > RA_5$
DVNN weighted Euclidean distance[36]	$RA_1 > RA_4 > RA_3 > RA_2 > RA_5$
$WD_{\mathrm{DVNS}_1}\left(RA_i, DVNNPIS\right)$ [60]	$RA_1 > RA_4 > RA_3 > RA_2 > RA_5$
$WD_{\mathrm{DVNS}_2}\left(RA_i, DVNNPIS\right)$ [60]	$RA_1 > RA_4 > RA_3 > RA_2 > RA_5$
$WGD_{\mathrm{DVNS}_1}\left(RA_i, DVNNPIS\right)$ [60]	$RA_1 > RA_4 > RA_3 > RA_2 > RA_5$
$WGD_{\mathrm{DVNS}_2}\left(RA_i, DVNNPIS\right)$ [60]	$RA_1 > RA_4 > RA_3 > RA_2 > RA_5$
DVNN-TODIM-VIKOR technique [61]	$RA_1 > RA_4 > RA_2 > RA_3 > RA_5$
DVNN-ExpTODIM-GRA technique [62]	$RA_1 > RA_4 > RA_2 > RA_3 > RA_5$
DVNN-CoCoSo technique	$RA_1 > RA_4 > RA_3 > RA_2 > RA_5$

From the above comparative analysis, the order of generalized double-valued neutrosophic weighted distance [36] and weighted Dice similarity measures $WD_{\mathrm{DVNS}_1}\left(RA_i, DVNNPIS\right)$, $WD_{\mathrm{DVNS}_2}\left(RA_i, DVNNPIS\right)$ and weighted generalized Dice similarity measures $WGD_{\mathrm{DVNS}_1}\left(RA_i, DVNNPIS\right)$, $WGD_{\mathrm{DVNS}_2}\left(RA_i, DVNNPIS\right)$ [60] is same to order of DVNN-CoCoSo technique; while order of DVNN-TODIM-VIKOR technique [61] and DVNN-ExpTODIM-GRA technique [62] is slightly different from order of DVNN-CoCoSo technique, however, several techniques have same optimal sports college and university and worst sports college and university. This verifies the effectiveness of DVNN-CoCoSo technique. Thus, the main advantages of DVNN-CoCoSo are managed: (1) DVNN-CoCoSo technique not only manages the uncertainty for MADM, but also manages three fused strategies. (2) DVNN-CoCoSo manages different behavior of CoCoSo and entropy as MADM when they are combined.

V. CONCLUSION

The service performance of the teaching management department is an important basis for measuring and evaluating the quality and operational efficiency of teaching management in higher education institutions, and is a comprehensive reflection of the school's management capabilities. Sports colleges and universities are the highest level of education in China's higher education system to cultivate sports professionals, shouldering the arduous task of cultivating sports talents with innovative spirit and practical ability, and contributing to the country's sports and education undertakings. The service performance construction of the teaching management department is achieved by adopting a scientific management approach, stimulating the enthusiasm, initiative, and creativity of teaching staff, correcting service attitudes, enhancing the consciousness of actively serving teaching work, thereby improving work efficiency and ability, and better implementing the school's policies and guidelines. The management performance evaluation of teaching services in sports colleges and universities is regarded as MADM. Consequently, the DVNN-CoCoSo technique is administrated to put forward MADM for management performance evaluation of teaching services in sports colleges and universities. The major contribution of this paper is administrated: 1) DVNN-CoCoSo technique is administrated for MADM in light with DVNNED and DVNNLD; 2) the objective weights are considered through entropy technique; 3) numerical example for management performance evaluation of teaching services in sports colleges and universities and some comparative analysis are administrated to verify the DVNN-CoCoSo technique.

There may be some possible limitations for management performance evaluation of teaching services in sports colleges and universities, which could be conducted through our future research: 1) It is a worthwhile research work to manage consensus [63-66] for management performance evaluation of teaching services in sports colleges and universities under DVNSs. 2) It is also worthwhile research to manage regret theory for management performance evaluation of teaching services in sports colleges and universities under DVNSs [67-70].

Enhanced Methodology for Production-Education Integration and Quality Evaluation of Rural Vocational Education Under Rural Revitalization with 2-Tuple Linguistic Neutrosophic Numbers

Xingli Wang*
School of Marxism, Shenzhen Polytechnic University, Shenzhen 518055, Guangdong, China

***Abstract*—Rural vocational education (RVE) plays a crucial role in nurturing practical talents for the development of rural economy and society in the new era, as well as cultivating future generations of agricultural successors. Quality evaluation serves as an essential means of ensuring educational excellence. It acts as a key element for supervision, assurance, and enhancement of educational quality. For the production-education integration (PEI) in RVE, establishing a quality evaluation system that aligns with national and rural conditions, caters to the needs of modern agricultural industry development, and reflects the characteristics of RVE is crucial. Such a system plays a vital role in leading and promoting the deep integration of industry and education in rural vocational colleges. The PEI quality evaluation in RVE under rural revitalization involves MAGDM. Currently, Exponential TODIM (ExpTODIM) approach and grey relational analysis (GRA) approach has been utilized to address MAGDM challenges. To handle uncertain information in PEI quality evaluation in RVE under rural revitalization, 2-tuple linguistic neutrosophic sets (2TLNSs) are conducted as a valuable tool. This paper introduces the implementation of the 2-tuple linguistic neutrosophic number Exponential TODIM-GRA (2TLNN-ExpTODIM-GRA) approach to effectively manage MAGDM problems using 2TLNSs. Additionally, a numerical study is conducted to validate the application of this approach for PEI quality evaluation in RVE under rural revitalization.**

Keywords*—Multiple-attribute group decision-making (MAGDM); 2TLNSs; ExpTODIM approach; GRA approach; PEI quality evaluation

I. Introduction

The adaptability of RVE to the needs of rural economic and social development in the new era is a prerequisite for RVE to fully play its inherent role and effectively serve rural economic and social development [1-3]. "Adaptability" means changing with the external environment. Under the rural revitalization strategy, development of the rural economy and society in the new era, agricultural modernization, and new urbanization construction, external development environment of RVE has undergone tremendous changes [4, 5]. This poses new tasks and requirements for RVE, requiring it to adapt to external environment changes and times demands, and timely adjust and optimize its positioning, development ideas, program offerings, and talent development goals to meet the changing external environment and the requirements of the times[6, 7]. Therefore, to assess and evaluate the adaptability of RVE to the needs of rural economic development and social development for a new era, it is necessary to examine the positioning of agricultural colleges and the positioning of talent development goals from the perspective of external demand. It is important to monitor the compatibility between the development plans of agricultural colleges and rural revitalization strategy, rural economic and social development, agricultural modernization, urbanization construction, and local agricultural development and rural development plans [8, 9]. It is necessary to observe whether the development plans are synchronized with the new era's rural economic and social development plans [10, 11]. It is crucial to observe the alignment between the professional development plans of agricultural colleges and local industries, especially the relationship between the school's advantages, distinctive programs, and leading majors, and the layout and structure of local modern agricultural industries [12, 13]. The construction of programs should closely follow the dynamic adjustment mechanism of local agricultural industry transformation and upgrading. It is essential to observe the alignment between the talent development goals of colleges and the needs of various types of rural talents and their qualifications and structure required for rural revitalization [14, 15]. The talent development goals and specifications of each major should reflect the need for compound and innovative rural talents with systematic knowledge structures and comprehensive abilities to adapt to new industries development, new formats, and new modes for rural areas [16-18].

Decision-making is a deliberate and selective process employed by humans to accomplish specific objectives [19-22]. Essentially, it involves utilizing available decision information, employing a particular method to evaluate various alternative solutions, and selecting the best solution that aligns with the decision-maker's expectations [23-27]. In our daily lives, decision-making is intertwined with various aspects such as food, clothing, housing, and transportation, where we constantly make choices [28-35]. The PEI quality evaluation of RVE under rural revitalization involves MAGDM. To address MAGDM challenges, recent approaches have utilized the ExpTODIM approach [36, 37] and GRA approach [38] approach [37]. Additionally, 2TLNSs [39] have been administrated to represent uncertain information during the PEI quality evaluation of RVE under rural revitalization. This paper introduces the ExpTODIM-GRA approach designed

specifically to manage MAGDM problems using 2TLNSs. Firstly, the basic concepts of 2TLNSs are reviewed. Then, ExpTODIM-GRA approach is administrated to address MAGDM under 2TLNSs. Finally, numerical study is administrated to validate the effectiveness of 2TLNN-ExpTODIM-GRA in the PEI quality evaluation of RVE under rural revitalization. In summary, the motivation behind this study is administrated: (1) the utilization of Entropy [39] to obtain attribute weights with 2TLNSs; (2) the implementation of the 2TLNN-ExpTODIM-GRA approach to manage the MAGDM with 2TLNSs; (3) the construction of numerical study to demonstrate the application of the administrated approach in the PEI quality evaluation of RVE under rural revitalization; and (4) the provision of comparative analyses with existing approaches.

The organization of this work is conducted: Section II introduces 2TLNSs. Section III describes the implementation of 2TLNN-ExpTODIM-GRA approach under the framework of 2TLNSs, incorporating the entropy approach. In Section IV, numerical example is presented to showcase the PEI quality evaluation in RVE under rural revitalization, accompanied by a comparative analysis. Finally, Section V offers concluding remarks to wrap up the study.

II. PRELIMINARIES

Wang et al. [39] administrated the 2TLNSs.

Definition 1[28-29]**.** Let $ds_1, ds_2, \ldots, ds_\phi$ be linguistic information and ds is administrated:

$$ds = \begin{Bmatrix} ds_0 = extremely\ poor, ds_1 = very\ poor, \\ ds_2 = poor, ds_3 = medium, ds_4 = good, \\ ds_5 = very\ good, ds_6 = extremely\ good. \end{Bmatrix}$$

Definition 2[6-7]**.** The SVNSs is administrated:

$$d\eta = \left\{ \left(\theta, \phi_\eta(\theta), \varphi_\eta(\theta), \gamma_\eta(\theta) \right) \middle| \theta \in \Theta \right\} \quad (1)$$

where $\phi_\eta(\theta), \varphi_\eta(\theta), \gamma_\eta(\theta) \in [0,1]$ is truth-membership (TM), indeterminacy-membership (IM) and falsity-membership (FM), $0 \le \phi_\eta(\theta) + \varphi_\eta(\theta) + \gamma_\eta(\theta) \le 3$.

Definition 3[39]**.** Let $d\delta_j \ (j = 1, 2, 3, \ldots, k)$ be 2TLSs. If $d\delta = \left\langle \left(ds_t, d\xi \right), \left(ds_i, d\psi \right), \left(ds_f, d\zeta \right) \right\rangle$ is administrated for $ds_t, ds_i, ds_f \in ds$, $d\xi, d\psi, d\zeta \in \left[0, 0.5 \right)$, where $\left(ds_t, d\xi \right), \left(ds_i, d\psi \right), \left(ds_f, d\zeta \right)$ is administrated for TM, IM and FM by employing 2TLSs, the 2TLNSs is administrated:

$$d\delta_j = \left\langle \left(ds_{t_j}, d\xi_j \right), \left(ds_{i_j}, d\psi_j \right), \left(ds_{f_j}, d\zeta_j \right) \right\rangle \quad (2)$$

where

$0 \le \Delta^{-1}\left(ds_{t_j}, d\xi_j \right) \le \phi, 0 \le \Delta^{-1}\left(ds_{i_j}, d\psi_j \right) \le \phi,$

$0 \le \Delta^{-1}\left(ds_{f_j}, d\zeta_j \right) \le \phi \quad , \quad 0 \le \Delta^{-1}\left(ds_{t_j}, d\xi_j \right) + \Delta^{-1}\left(ds_{i_j}, d\psi_j \right) + \Delta^{-1}\left(ds_{f_j}, d\zeta_j \right) \le 3\phi$.

Definition 4[27]. Let $d\delta = \left\langle \left(ds_t, d\xi \right), \left(ds_i, d\psi \right), \left(ds_f, d\zeta \right) \right\rangle$. The uncertain score function (USF) and uncertain accuracy function (UAF) are administrated:

$$USF\left(d\delta \right) = \frac{\begin{pmatrix} 2\phi + \Delta^{-1}\left(ds_t, d\xi \right) \\ -\Delta^{-1}\left(ds_i, d\psi \right) - \Delta^{-1}\left(ds_f, d\zeta \right) \end{pmatrix}}{3\phi},$$

$$USF\left(d\delta \right) \in \left[0,1 \right] \quad (3)$$

$$UAF(d\delta) = \frac{\phi + \Delta^{-1}\left(ds_t, d\xi \right) - \Delta^{-1}\left(ds_f, d\zeta \right)}{2\phi},$$

$$UAF(d\delta) \in \left[0,1 \right] \quad (4)$$

Definition 5[27]. Let $d\delta_1 = \left\langle \left(ds_{t_1}, d\xi_1 \right), \left(ds_{i_1}, d\psi_1 \right), \left(ds_{f_1}, d\zeta_1 \right) \right\rangle$ and $d\delta_2 = \left\langle \left(ds_{t_2}, d\xi_2 \right), \left(ds_{i_2}, d\psi_2 \right), \left(ds_{f_2}, d\zeta_2 \right) \right\rangle$, then

(1) *if* $USF\left(d\delta_1 \right) \prec USF\left(d\delta_2 \right)$, $d\delta_1 \prec d\delta_2$;

(2) *if* $USF\left(d\delta_1 \right) = USF\left(d\delta_2 \right), UAF\left(d\delta_1 \right) \prec UAF\left(d\delta_2 \right)$, $d\delta_1 \prec d\delta_2$;

(3) *if* $USF\left(d\delta_1 \right) = USF\left(d\delta_2 \right), UAF\left(d\delta_1 \right) = UAF\left(d\delta_2 \right)$, $d\delta_1 = d\delta_2$;

Definition 6[27]. Let $d\delta_1 = \left\langle \left(ds_{t_1}, d\xi_1 \right), \left(ds_{i_1}, d\psi_1 \right), \left(ds_{f_1}, d\zeta_1 \right) \right\rangle$, $d\delta_2 = \left\langle \left(ds_{t_2}, d\xi_2 \right), \left(ds_{i_2}, d\psi_2 \right), \left(ds_{f_2}, d\zeta_2 \right) \right\rangle$ and $d\delta = \left\langle \left(ds_t, d\xi \right), \left(ds_i, d\psi \right), \left(ds_f, d\zeta \right) \right\rangle$ be three 2TLNNs, then

$$d\delta_1 \oplus d\delta_2 = \left\{ \begin{array}{l} \Delta\left(\phi\left(\dfrac{\Delta^{-1}\left(ds_{t_1}, d\xi_1\right)}{\phi} + \dfrac{\Delta^{-1}\left(ds_{t_2}, d\xi_2\right)}{\phi} - \dfrac{\Delta^{-1}\left(ds_{t_1}, d\xi_1\right)}{\phi} \cdot \dfrac{\Delta^{-1}\left(ds_{t_2}, d\xi_2\right)}{\phi}\right)\right), \\ \Delta\left(\phi\left(\dfrac{\Delta^{-1}\left(ds_{i_1}, d\psi_1\right)}{\phi} \cdot \dfrac{\Delta^{-1}\left(ds_{i_2}, d\psi_2\right)}{\phi}\right)\right), \Delta\left(\phi\left(\dfrac{\Delta^{-1}\left(ds_{f_1}, d\zeta_1\right)}{\phi} \cdot \dfrac{\Delta^{-1}\left(ds_{f_2}, d\zeta_2\right)}{\phi}\right)\right) \end{array} \right\}; \tag{1}$$

$$d\delta_1 \otimes d\delta_2 = \left\{ \begin{array}{l} \Delta\left(\phi\left(\dfrac{\Delta^{-1}\left(ds_{t_1}, d\xi_1\right)}{\phi} \cdot \dfrac{\Delta^{-1}\left(ds_{t_2}, d\xi_2\right)}{\phi}\right)\right), \\ \Delta\left(\phi\left(\dfrac{\Delta^{-1}\left(ds_{i_1}, d\psi_1\right)}{\phi} + \dfrac{\Delta^{-1}\left(ds_{i_2}, d\psi_2\right)}{\phi} - \dfrac{\Delta^{-1}\left(ds_{i_1}, d\psi_1\right)}{\phi} \cdot \dfrac{\Delta^{-1}\left(ds_{i_2}, d\psi_2\right)}{\phi}\right)\right), \\ \Delta\left(\phi\left(\dfrac{\Delta^{-1}\left(ds_{f_1}, d\zeta_1\right)}{\phi} + \dfrac{\Delta^{-1}\left(ds_{f_2}, d\zeta_2\right)}{\phi} - \dfrac{\Delta^{-1}\left(ds_{f_1}, d\zeta_1\right)}{\phi} \cdot \dfrac{\Delta^{-1}\left(ds_{f_2}, d\zeta_2\right)}{\phi}\right)\right) \end{array} \right\}; \tag{2}$$

$$\xi d\delta = \left\{\Delta\left(\phi\left(1-\left(1-\frac{\Delta^{-1}\left(ds_t, d\xi\right)}{\phi}\right)^{\xi}\right)\right), \Delta\left(\phi\left(\frac{\Delta^{-1}\left(ds_i, d\psi\right)}{\phi}\right)^{\xi}\right), \Delta\left(D\left(\frac{\Delta^{-1}\left(ds_f, d\zeta\right)}{\phi}\right)^{\xi}\right)\right\}, \xi > 0; \tag{3}$$

$$d\delta^{\xi} = \left\{\Delta\left(\phi\left(\frac{\Delta^{-1}\left(ds_t, d\xi\right)}{\phi}\right)^{\xi}\right), \Delta\left(\phi\left(1-\left(1-\frac{\Delta^{-1}\left(ds_i, d\psi\right)}{\phi}\right)^{\xi}\right)\right), \Delta\left(\phi\left(1-\left(1-\frac{\Delta^{-1}\left(ds_f, d\zeta\right)}{\phi}\right)^{\xi}\right)\right)\right\}, \xi > 0. \tag{4}$$

Definition 7[40]. Let $d\delta_1 = \left\langle \left(ds_{t_1}, d\xi_1\right), \left(ds_{i_1}, d\psi_1\right), \left(ds_{f_1}, d\zeta_1\right)\right\rangle$, $d\delta_2 = \left\langle \left(ds_{t_2}, d\xi_2\right), \left(ds_{i_2}, d\psi_2\right), \left(ds_{f_2}, d\zeta_2\right)\right\rangle$, then the 2TLNN Hamming distance (2TLNNHD) is constructed:

$$2TLNNHD\left(d\delta_1, d\delta_2\right) = \frac{1}{3}\left(\begin{array}{l} \left|\dfrac{\Delta^{-1}\left(ds_{t_1}, d\xi_1\right) - \Delta^{-1}\left(ds_{t_2}, d\xi_2\right)}{\phi}\right| \\ + \left|\dfrac{\Delta^{-1}\left(ds_{i_1}, d\psi_1\right) - \Delta^{-1}\left(ds_{i_2}, d\psi_2\right)}{\phi}\right| \\ + \left|\dfrac{\Delta^{-1}\left(ds_{f_1}, d\zeta_1\right) - \Delta^{-1}\left(ds_{f_2}, d\zeta_2\right)}{\phi}\right| \end{array}\right) \tag{5}$$

The 2TLNNWA approach is administrated:

Definition 7[39]. Let $d\delta_j = \left\langle \left(ds_{t_j}, d\xi_j\right), \left(ds_{i_j}, d\psi_j\right), \left(ds_{f_j}, d\zeta_j\right)\right\rangle$, the 2TLNNWA approach is administrated:

$$2\text{TLNNWA}\left(d\delta_1, d\delta_2, \ldots, d\delta_n\right) = \overset{n}{\underset{j=1}{\oplus}} dw_j d\delta_j = \left(\begin{array}{l} \Delta\left(\phi\left(1-\prod_{j=1}^{n}\left(1-\dfrac{\Delta^{-1}\left(ds_{t_j}, d\alpha_j\right)}{\phi}\right)^{w_j}\right)\right), \\ \Delta\left(\phi\prod_{j=1}^{n}\left(\dfrac{\Delta^{-1}\left(ds_{i_j}, d\beta_j\right)}{\phi}\right)^{w_j}\right), \\ \Delta\left(\phi\prod_{j=1}^{n}\left(\dfrac{\Delta^{-1}\left(ds_{f_j}, d\chi_j\right)}{\phi}\right)^{w_j}\right) \end{array}\right) \tag{6}$$

IV. 2TLNN-EXPTODIM-GRA APPROACH FOR MAGDM WITH ENTROPY

A. 2TLNN-MAGDM Data

The 2TLNN-ExpTODIM-GRA approach is administrated for MAGDM. Let $DA=\{DA_1,DA_2,\cdots,DA_m\}$ be alternatives, and $DG=\{DG_1,DG_2,\cdots,DG_n\}$ be attributes with weight numbers $dw=(dw_1,dw_2,\cdots,dw_n)$, where $dw_j\in[0,1]$, $\sum_{j=1}^{n}dw_j=1$ and experts $DE=\{DE_1,DE_2,\cdots,DE_q\}$ with weight numbers $d\omega=(d\omega_1,d\omega_2,\cdots,d\omega_q)$ $d\omega_j\in[0,1],\sum_{j=1}^{q}d\omega_j=1.$

Then, 2TLNN-ExpTODIM-GRA approach is administrated for MAGDM.

Step 1. Build the 2TLNN-matrix $DM=\left[DM_{ij}^{(t)}\right]_{m\times n}=\left\{\begin{matrix}\left(ds_{t_{ij}}^{(t)},d\alpha_{ij}^{(t)}\right),\\ \left(ds_{i_{ij}}^{(t)},d\beta_{ij}^{(t)}\right),\left(ds_{f_{ij}}^{(t)},d\chi_{ij}^{(t)}\right)\end{matrix}\right\}_{m\times n}$ and manage the average matrix $DM=\left[DM_{ij}\right]_{m\times n}$:

$$DM^{(t)}=\left[DM_{ij}^{(t)}\right]_{m\times n}=\begin{matrix}\\DA_1\\DA_2\\\vdots\\DA_m\end{matrix}\begin{matrix}\begin{matrix}DG_1&DG_2&\cdots&DG_n\end{matrix}\\\begin{bmatrix}DM_{11}^{(t)}&DM_{12}^{(t)}&\cdots&DM_{1n}^{(t)}\\DM_{21}^{(t)}&DM_{22}^{(t)}&\cdots&DM_{2n}^{(t)}\\\vdots&\vdots&\vdots&\vdots\\DM_{m1}^{(t)}&DM_{m2}^{(t)}&\cdots&DM_{mn}^{(t)}\end{bmatrix}\end{matrix} \quad (7)$$

$$DM=\left[DM_{ij}\right]_{m\times n}=\begin{matrix}\\DA_1\\DA_2\\\vdots\\DA_m\end{matrix}\begin{matrix}\begin{matrix}DG_1&DG_2&\cdots&DG_n\end{matrix}\\\begin{bmatrix}DM_{11}&DM_{12}&\cdots&DM_{1n}\\DM_{21}&DM_{22}&\cdots&DM_{2n}\\\vdots&\vdots&\vdots&\vdots\\DM_{m1}&DM_{m2}&\cdots&DM_{mn}\end{bmatrix}\end{matrix} \quad (8)$$

In line with the 2TLNNWA approach, the $DM=\left[DM_{ij}\right]_{m\times n}=\left\{\begin{matrix}\left(ds_{t_{ij}},d\alpha_{ij}\right),\\ \left(ds_{i_{ij}},d\beta_{ij}\right),\left(ds_{f_{ij}},d\chi_{ij}\right)\end{matrix}\right\}_{m\times n}$ is:

$$DM_{ij}=d\omega_1DM_{ij}^{1}\oplus d\omega_2DM_{ij}^{2}\oplus\cdots\oplus d\omega_tDM_{ij}^{t}$$

$$=\left\{\begin{matrix}\Delta\left(\phi\left(1-\prod_{t=1}^{q}\left(1-\frac{\Delta^{-1}\left(ds_{t_{ij}}^{(t)},d\alpha_{ij}^{(t)}\right)}{\phi}\right)^{dw_t}\right)\right),\\ \Delta\left(\phi\prod_{t=1}^{q}\left(\frac{\Delta^{-1}\left(ds_{i_{ij}}^{(t)},d\beta_{ij}^{(t)}\right)}{\phi}\right)^{dw_t}\right),\\ \Delta\left(\phi\prod_{t=1}^{q}\left(\frac{\Delta^{-1}\left(ds_{f_{ij}}^{(t)},d\chi_{ij}^{(t)}\right)}{\phi}\right)^{dw_t}\right)\end{matrix}\right\} \quad (9)$$

Step 2. Administrate the normalized $NDM=\left[NDM_{ij}\right]_{m\times n}=\left\{\begin{matrix}\left(ds_{t_{ij}},d\alpha_{ij}\right),\\ \left(ds_{i_{ij}},d\beta_{ij}\right),\left(ds_{f_{ij}},d\chi_{ij}\right)\end{matrix}\right\}_{m\times n}$ in light with $DM=\left[DM_{ij}\right]_{m\times n}=\left\{\begin{matrix}\left(ds_{t_{ij}},d\alpha_{ij}\right),\\ \left(ds_{i_{ij}},d\beta_{ij}\right),\left(ds_{f_{ij}},d\chi_{ij}\right)\end{matrix}\right\}_{m\times n}$.

For beneficial attributes:

$$NDM_{ij}=DM_{ij}=\left\{\begin{matrix}\left(ds_{t_{ij}},d\alpha_{ij}\right),\\ \left(ds_{i_{ij}},d\beta_{ij}\right),\left(ds_{f_{ij}},d\chi_{ij}\right)\end{matrix}\right\} \quad (10)$$

For non-beneficial attributes:

$$NDM_{ij}=\left\{\left(ds_{t_{ij}},d\alpha_{ij}\right),\left(ds_{i_{ij}},d\beta_{ij}\right),\left(ds_{f_{ij}},d\chi_{ij}\right)\right\}$$

$$=\left\{\begin{matrix}\Delta\left(\phi-\Delta^{-1}\left(ds_{t_{ij}},d\alpha_{ij}\right)\right),\\ \Delta\left(\phi-\Delta^{-1}\left(ds_{i_{ij}},d\beta_{ij}\right)\right),\Delta\left(\phi-\Delta^{-1}\left(ds_{f_{ij}},d\chi_{ij}\right)\right)\end{matrix}\right\} \quad (11)$$

B. Administrate the Weight Numbers with Entropy

Step 3. Normalized hybrid decision matrix $NHDM_{ij}$ is administrated through Entropy [41]:

$$NHDM_{ij} = \frac{\dfrac{UAF\left\{\left(ds_{t_{ij}}, d\alpha_{ij}\right),\left(ds_{i_{ij}}, d\beta_{ij}\right),\left(ds_{f_{ij}}, d\chi_{ij}\right)\right\}}{USF\left\{\left(ds_{t_{ij}}, d\alpha_{ij}\right),\left(ds_{i_{ij}}, d\beta_{ij}\right),\left(ds_{f_{ij}}, d\chi_{ij}\right)\right\}}}{\sum_{i=1}^{m}\left(\dfrac{UAF\left\{\left(ds_{t_{ij}}, d\alpha_{ij}\right),\left(ds_{i_{ij}}, d\beta_{ij}\right),\left(ds_{f_{ij}}, d\chi_{ij}\right)\right\}}{USF\left\{\left(ds_{t_{ij}}, d\alpha_{ij}\right),\left(ds_{i_{ij}}, d\beta_{ij}\right),\left(ds_{f_{ij}}, d\chi_{ij}\right)\right\}}\right)}, \tag{12}$$

Then, the uncertain hybrid information Shannon entropy (UHISE) is administrated:

$$UHISE_j = -\frac{1}{\ln m}\sum_{i=1}^{m} NHDM_{ij} \ln NHDM_{ij} \tag{13}$$

and $NHDM_{ij} \ln NHDM_{ij} = 0$ if $NHDM_{ij} = 0$.

Then, the weights values $dw = \left(dw_1, dw_2, \cdots, dw_n\right)$ is managed:

$$dw_j = \frac{1 - UHISE_j}{\sum_{j=1}^{n}\left(1 - UHISE_j\right)} \tag{14}$$

C. 2TLNN-ExpTODIM-GRA Approach for MAGDM

2TLNN-ExpTODIM-GRA approach is administrated for MAGDM.

Step 4. Administrate relative weight:

$$rdw_j = dw_j \Big/ \max_j dw_j, \tag{15}$$

Step 5. 2TLNN dominance degree (2TLNNDD) of DA_i for DA_t under DG_j is administrated:

$$2TLNNDD_j\left(DA_i, DA_t\right) = \begin{cases} \dfrac{rdw_j \times \left(1 - 10^{-\rho 2TLNNHDHD\left(NDM_{ij}, NDM_{tj}\right)}\right)}{\sum_{j=1}^{n} rdw_j} & \text{if } SF\left(NDM_{ij}\right) > SF\left(NDM_{tj}\right) \\ 0 & \text{if } SF\left(NDM_{ij}\right) = SF\left(NDM_{tj}\right) \\ -\dfrac{1}{\theta}\dfrac{\sum_{j=1}^{n} rdw_j \times \left(1 - 10^{-\rho 2TLNNHDHD\left(NDM_{ij}, NDM_{tj}\right)}\right)}{rdw_j} & \text{if } SF\left(NDM_{ij}\right) < SF\left(NDM_{tj}\right) \end{cases} \tag{16}$$

where θ is administrated [42] and $\rho \in [1,5]$ [36].

The 2TLNNDD under DG_j is administrated:

$$2TLNNDD_j\left(DA_i\right) = \left[2TLNNDD_j\left(DA_i, DA_t\right)\right]_{m\times m}$$

$$= \begin{array}{c} \\ DA_1 \\ DA_2 \\ \vdots \\ DA_m \end{array} \begin{array}{c} \begin{array}{cccc} DA_1 & DA_2 & \cdots & DA_m \end{array} \\ \begin{bmatrix} 0 & 2TLNNDD_j\left(DA_1, DA_2\right) & \cdots & 2TLNNDD_j\left(DA_1, DA_m\right) \\ 2TLNNDD_j\left(DA_2, DA_1\right) & 0 & \cdots & 2TLNNDD_j\left(DA_2, DA_m\right) \\ \vdots & \vdots & \cdots & \vdots \\ 2TLNNDD_j\left(DA_m, DA_1\right) & 2TLNNDD_j\left(DA_m, DA_2\right) & \cdots & 0 \end{bmatrix} \end{array}$$

(3) Administrate the overall 2TLNNDD of DA_i for other alternatives under DG_j:

$$2TLNNDD_j\left(DA_i\right) = \sum_{t=1}^{m} 2TLNNDD_j\left(DA_i, DA_t\right) \tag{17}$$

The overall 2TLNNDD is administrated:

$$2TLNNDD=\left(2TLNNDD_{ij}\right)_{m\times n}$$

$$=\begin{bmatrix} & DG_1 & DG_2 & \cdots & DG_n \\ DA_1 & \sum_{t=1}^{m}2TLNNDD_1\left(DA_1,DA_t\right) & \sum_{t=1}^{m}2TLNNDD_2\left(DA_1,DA_t\right) & \cdots & \sum_{t=1}^{m}2TLNNDD_n\left(DA_1,DA_t\right) \\ DA_2 & \sum_{t=1}^{m}2TLNNDD_1\left(DA_2,DA_t\right) & \sum_{t=1}^{m}2TLNNDD_2\left(DA_2,DA_t\right) & \cdots & \sum_{t=1}^{m}2TLNNDD_n\left(DA_2,DA_t\right) \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ DA_m & \sum_{t=1}^{m}2TLNNDD_1\left(DA_m,DA_t\right) & \sum_{t=1}^{m}2TLNNDD_2\left(DA_m,DA_t\right) & \cdots & \sum_{t=1}^{m}2TLNNDD_n\left(DA_m,DA_t\right) \end{bmatrix} \quad (18)$$

Step 6. Administrate the 2TLNNPIDS (2TLNN positive ideal decision solution) and 2TLNNNIDS (2TLNN negative ideal decision solution):

$$2TLNNPIDS=\left(2TLNNPIDS_1,2TLNNPIDS_1,\cdots,2TLNNPIDS_n\right) \quad (19)$$

$$2TLNNNIDS=\left(2TLNNNIDS_1,2TLNNNIDS_1,\cdots,2TLNNNIDS_n\right) \quad (20)$$

$$2TLNNPIDS_j=\max_i\left(2TLNNDD_{ij}\right) \quad (21\text{-a})$$

$$2TLNNNIDS_j=\min_i\left(2TLNNDD_{ij}\right) \quad (21\text{-b})$$

Step 7. Administrate the 2TLNNGRC (2TLNN grey rational coefficients) from 2TLNNPIDS and 2TLNNNIDS.

$$2TLNNGRC\left(\zeta_{ij}^{+}\right)=\frac{\left(\begin{array}{l}\min\limits_{1\le i\le m}\min\limits_{1\le j\le n}\left|2TLNNDD_{ij}-2TLNNPIDS_j\right| \\ +\rho\max\limits_{1\le i\le m}\max\limits_{1\le j\le n}\left|2TLNNDD_{ij}-2TLNNPIDS_j\right|\end{array}\right)}{\left(\begin{array}{l}\left|2TLNNDD_{ij}-2TLNNPIDS_j\right| \\ +\rho\max\limits_{1\le i\le m}\max\limits_{1\le j\le n}\left|2TLNNDD_{ij}-2TLNNPIDS_j\right|\end{array}\right)} \quad (22)$$

$$2TLNNGRC\left(\zeta_{ij}^{-}\right)=\frac{\left(\begin{array}{l}\min\limits_{1\le i\le m}\min\limits_{1\le j\le n}\left|2TLNNDD_{ij}-2TLNNNIDS_j\right| \\ +\rho\max\limits_{1\le i\le m}\max\limits_{1\le j\le n}\left|2TLNNDD_{ij}-2TLNNNIDS_j\right|\end{array}\right)}{\left(\begin{array}{l}\left|2TLNNDD_{ij}-2TLNNNIDS_j\right| \\ +\rho\max\limits_{1\le i\le m}\max\limits_{1\le j\le n}\left|2TLNNDD_{ij}-2TLNNNIDS_j\right|\end{array}\right)} \quad (23)$$

Step 8. Administrate the 2TLNNGRD (2TLNN grey relation degree) from 2TLNNPIDS and 2TLNNNIDS.

$$2TLNNGRD\left(\zeta_i^{+}\right)=\sum_{j=1}^{n}dw_j\,2TLNNGRC\left(\zeta_{ij}^{+}\right) \quad (24)$$

$$2TLNNGRD\left(\zeta_i^{-}\right)=\sum_{j=1}^{n}dw_j\,2TLNNGRC\left(\zeta_{ij}^{-}\right) \quad (25)$$

Step 9. Administrate the 2TLNNRRD (2TLNN relative relational degree) from the 2TLNNPIDS.

$$2TLNNRRD\left(\zeta_i\right)=\frac{2TLNNGRD\left(\zeta_i^{+}\right)}{2TLNNGRD\left(\zeta_i^{-}\right)+2TLNNGRD\left(\zeta_i^{+}\right)}=\frac{\sum_{j=1}^{n}dw_j\,2TLNNGRC\left(\zeta_{ij}^{+}\right)}{\sum_{j=1}^{n}dw_j\,2TLNNGRC\left(\zeta_{ij}^{+}\right)+\sum_{j=1}^{n}dw_j\,2TLNNGRC\left(\zeta_{ij}^{-}\right)} \quad (26)$$

Step 10. Sort and choose the optimal alternative in line with largest 2TLNNRRD.

V. Numerical Example and Comparative Analysis

A. Numerical Example

Under the background of rural revitalization strategy and development of rural economy and society in the new era, construction of quality evaluation for PIE in rural areas needs to break free from the shackles of traditional concepts in terms of evaluation standards, evaluation orientation, evaluation mechanisms, evaluation methods, and more. It requires establishing a distinctive view of quality and a new perspective on evaluation, focusing on student-centered and comprehensive development, public governance and collaborative education, diagnostic improvement, and giving importance to the process. It is necessary to prioritize laws and policies, base standards on the highest level, emphasize individual characteristics, and prioritize systematic norms. The primary focus lies in the core elements and essential links of integrated vocational education and industry development, which aim to lead and promote deep

integration and high-quality advancement of PEI in rural areas, thereby contributing to rural revitalization. The PEI quality evaluation in RVE under rural revitalization falls under the framework of MAGDM. In this evaluation, there are five potential vocational and technical colleges $DA_i\left(i=1,2,3,4,5\right)$ to choose through four attributes [43]: DG1: Social benefit for PEI. DG2: management cost for PEI. DG3: Economic benefits for PEI. DG4: Production-education integration achievements. Five vocational and technical colleges $DA_i\left(i=1,2,3,4,5\right)$ are assessed using linguistic scales (refer to Table I [40]) under four criteria. The evaluation involves three experts $DE_t\left(t=1,2,3\right)$, each with their respective weight $d\omega=\left(1/3,1/3,1/3\right)$ in the assessment process.

TABLE I. LINGUISTIC INFORMATION SCALES AND 2TLNNS

Linguistic Terms	2TLNNs
Exceedingly Terrible-DET	$\{(ds_0,0),\ (ds_5,0),\ (ds_6,0)\}$
Very Terrible-DVT	$\{(ds_1,0),\ (ds_4,0),\ (ds_5,0)\}$
Terrible-DT	$\{(ds_2,0),\ (ds_3,0),\ (ds_4,0)\}$
Medium-DM	$\{(ds_3,0),\ (ds_3,0),\ (ds_3,0)\}$
Well-DW	$\{(ds_4,0),\ (ds_3,0),\ (ds_2,0)\}$
Very Well-DVW	$\{(ds_5,0),\ (ds_2,0),\ (ds_1,0)\}$
Exceedingly Well-DEW	$\{(ds_6,0),\ (ds_1,0),\ (ds_0,0)\}$

The PEI quality evaluation in RVE under rural revitalization is managed using the 2TLNN-ExpTODIM-GRA approach.

Step 1. Construct the 2TLNN-matrix $DM=\left[DM_{ij}^{(t)}\right]_{5\times4}\left(t=1,2,3\right)$ (Table II - IV).

Then, from 2TLNNWA approach, the $DM=\left[DM_{ij}\right]_{5\times4}$ is constructed (Table V).

Step 2. Normalize the $DM=\left[DM_{ij}\right]_{5\times4}$ into $NDM=\left[NDM_{ij}\right]_{5\times4}$ (see Table VI).

Step 3. Administrate the weight (Table VII):

Step 4. Administrate the relative weight (see Table VIII):

Step 5. Administrate the $2TLNNDD=\left(2TLNNDD_{ij}\right)_{5\times4}$ (Table IX):

Step 6. Administrate the 2TLNNPIDS and 2TLNNNIDS (Table X).

Step 7. Administrate the $2TLNNGRC\left(\zeta_{ij}^{+}\right)$ and $2TLNNGRC\left(\zeta_{ij}^{-}\right)$ (Table XI-XII).

Step 8. Establish the $2TLNNGRD\left(\zeta_{i}^{+}\right)$ and $2TLNNGRD\left(\zeta_{i}^{-}\right)$ (Table XIII).

Step 9. Establish the 2TLNNRRD (Table XIV).

$$2TLNNGRD\left(\zeta_{i}^{+}\right) \text{ AND } 2TLNNGRD\left(\zeta_{i}^{-}\right)$$

TABLE XIII. THE

Alternative	$2TLNNGRD\left(\zeta_{i}^{+}\right)$	$2TLNNGRD\left(\zeta_{i}^{-}\right)$
DA_1	0.7094	0.5136
DA_2	0.6114	0.6297
DA_3	0.5908	0.7493
DA_4	0.7308	0.5000
DA_5	0.4843	0.7204

TABLE XIV. 2TLNNRRD AND ORDER

Alternative	2TLNNRRD	Order
DA_1	0.5801	2
DA_2	0.4926	3
DA_3	0.4409	4
DA_4	0.5938	1
DA_5	0.4020	5

Thus, the order is administrated: $DA_4 > DA_1 > DA_2 > DA_3 > DA_5$ and the optimal vocational and technical college is DA_4.

B. Comparative Analysis

Then, 2TLNN-ExpTODIM-GRA approach is fully compared with 2TLNNWA approach[39], 2TLNNWG approach [39], 2TLNN-CODAS approach [44], 2TLNN-GRA approach [45], 2TLNN-CLVA approach [46] and 2TLNN-TODIM approach [40]. The comparative result is administrated in Table XV.

TABLE XV. ORDER FOR DIFFERENT APPROACHES

Approaches	Order
2TLNNWA approach [39]	$DA_4 > DA_1 > DA_2 > DA_3 > DA_5$
2TLNNWG approach [39]	$DA_4 > DA_1 > DA_3 > DA_2 > DA_5$
2TLNN-CODAS approach [44]	$DA_4 > DA_1 > DA_2 > DA_3 > DA_5$
2TLNN-GRA approach [45]	$DA_4 > DA_1 > DA_2 > DA_3 > DA_5$
2TLNN-TODIM approach [40]	$DA_4 > DA_1 > DA_2 > DA_3 > DA_5$

The comparative analysis conducted in this study confirms the reasonableness and effectiveness of the 2TLNN-ExpTODIM-GRA approach. However, it is worth highlighting that main limitations of 2TLNN-ExpTODIM-GRA approach are the lack of emphasis on consensus for MAGDM.

VI. CONCLUSION

The rural revitalization strategy is significant decision made by Party and the state, guided by the ideology of socialism with Chinese characteristics. Within this strategy, RVE serves as a crucial force in promoting self-realization among adults, breaking the cycle of poverty across generations, fostering rural industrial development, and advancing the modernization of agriculture and rural areas. Despite its importance, RVE in our country faces practical challenges such as the need to align with the accelerating agricultural modernization, the underutilization of its functional role, the transition of the rural population into employment and the corresponding lack of momentum in its development, the persistence of the "jumping off the farm gate" mindset and its deviation from the goals of RVE training, and the increasing pace of rural population aging with a delayed response from RVE. The PEI quality evaluation in RVE under the rural revitalization context involves MAGDM. In recent times, ExpTODIM approach and GRA approach was employed to manage MAGDM. To address the PEI quality evaluation in RVE under rural revitalization, the utilization of 2TLNSs proves valuable for representing uncertain information. In this study, we propose the 2TLNN-ExpTODIM-GRA approach to effectively handle MAGDM within the framework of 2TLNSs. Additionally, a numerical study is conducted to validate the implementation of this approach for the PEI quality evaluation in RVE under rural revitalization. The primary contribution of this paper lies in the development of ExpTODIM-GRA approach, specifically tailored to address MAGDM within the context of 2TLNSs, with a specific focus on the PEI quality evaluation in RVE under rural revitalization.

***Abstract*—The high-voltage transmission system is a key component of the power network, and the reliability of its insulators directly affects the safe operation of the system. Traditional insulator defect detection methods are reliant on manual inspection, which requires significant human resources and is prone to substantial subjectivity. To address this issue, this paper proposes an insulator defect recognition method based on the improved YOLOv5 algorithm. This method first collects images of insulator defects and then utilizes the YOLOv5 model for recognition training. To enhance multi-scale feature fusion capability, a bidirectional feature pyramid network (BiFPN) is introduced. During the training process, the SiUL function is used, and the SE attention mechanism has been integrated into the detection backbone network, which enhances the model's detection accuracy. Experimental results show that the model achieves a detection precision of 90.27%, a recall of 89.14%, and a mAP of 91.34% on the test set. To further enhance the model's practicality, a PyQt5-based user interface (GUI) for the inspection system is designed, enabling interactive functions such as image uploading, defect detection, and result display. In summary, the research presented in this paper provides efficient and accurate technical support for intelligent power inspection, offering a wide range of application prospects.**

***Keywords*—Insulators; insulator defect detection; improved YOLOv5; BiFPN network; PyQt5**

I. INTRODUCTION

High-voltage transmission lines are a key component of the power system, assuming the important task of transmitting electric energy, and their operational status is directly related to the stability and safety of the power system. As a key component of high-voltage transmission lines, insulators not only support and secure wires but also protect them from environmental erosion and mechanical damage. Therefore, the performance of insulators directly affects the insulation effect and service life of transmission lines. The traditional method for detecting insulator defects mainly relies on manual visual inspection, which has many problems [1]. First of all, the detection efficiency is low, manual visual inspection requires a lot of time and manpower, making it difficult to meet the needs of large-scale and rapid detection. Secondly, the misdetection rate is high; due to human factors, it is easy to miss or incorrectly detect defects, which poses potential risks to the safe operation of the power system.

With the continuous development of science and technology, deep learning-based image recognition technology shows great potential in the field of insulator defect detection. Deep learning technology can automatically extract defect features by learning from insulator images, facilitating efficient and accurate defect detection. Jia Yujin et al. (2023) proposed two lightweight enhancements to YOLOv5, combining the classical YOLOv5 with the advantages of the lightweight convolutional neural networks MobileNetV3 and GhostNet, respectively. Experimental results showed that the enhanced model reduced computational load by 49.4% while maintaining detection accuracy [2]. Ru Hongfang et al. (2023) proposed an improved YOLO x method for detecting insulator self-explosion defects, incorporating the CBAM attention mechanism into the backbone network and optimizing the IoU calculation of the loss function to EIoU, achieving a detection accuracy of 97.26% [3]. Satyajit et al. proposed an automated inspection system utilizing a six-rotor UAV and the YOLOv8n model, achieving efficient real-time monitoring by training the model with a dataset of 6020 insulator images and using image enhancement techniques to avoid overfitting. The YOLOv8n model achieved a mAP@50 of 99.4%, significantly enhancing the efficiency and accuracy of insulator detection [4]. Souza developed a Hybrid-YOLO model based on the ResNet-18 classifier, trained using 1593 grid inspection images, with a mAP of 0.99262 and an F1 score of 0.96216 for the multiclassification task, significantly improving the efficiency and accuracy of insulator detection [5]. Additionally, Yi et al. proposed the GC-YOLO model, which integrates the Ghost convolution module and CA attention mechanism in the backbone network and adds a small target detection head in the detection layer. Experimental results show that GC-YOLO achieves a recall of 89.7% and a mAP@0.5 of 94.2%, which are 7% and 6.5% higher than YOLOv5s, respectively [6]. These studies demonstrate that deep learning-based insulator defect detection techniques have significant advantages in improving detection efficiency and accuracy, showing promising application prospects.

Collectively, these studies had underscored the remarkable advantages of deep learning-based insulator defect detection technologies in enhancing detection efficiency and accuracy. However, the pursuit of further improvements in detection precision and speed remained a focal point of ongoing research. Against this backdrop, this paper proposed an insulator defect detection method for high-voltage transmission lines based on an enhanced YOLOv5 model. By incorporating the SE attention mechanism, the BiFPN module, and employing the SiLU loss function, along with the development of an insulator interaction system interface, this method aimed to achieve efficient and precise detection of insulator defects, thereby improving detection accuracy and reducing the false detection rate.

II. TESTS AND METHODS

A. Image Acquisition

In this study, the publicly available dataset of high-voltage transmission line insulators from Baidu AI Studio was used, along with insulator defect images obtained through web crawlers. Eventually, a total of 1033 insulator images were collected. Due to the limited number of insulator defect images in the original dataset, data augmentation techniques were applied to increase the dataset size and improve the model's generalization ability. After augmentation, the dataset contained 2066 images, some of which were shown in Fig. 1.

Fig. 1. Image of partial insulator defects.

B. YOLOv5 Model

The YOLOv5 model was the top-performing detection model in the YOLO family and consisted of four main modules: input, backbone network, neck, and head [7]. As shown in Fig. 2, the structure of the YOLOv5 model included techniques such as Mosaic data enhancement and adaptive anchor frame computation [8] in the input module. The backbone network employed Focus and CSPNet for feature extraction enhancement. The neck module combined different CSP modules and up-sampling techniques to obtain multi-scale contextual information. The head module was responsible for classification and regression tasks.

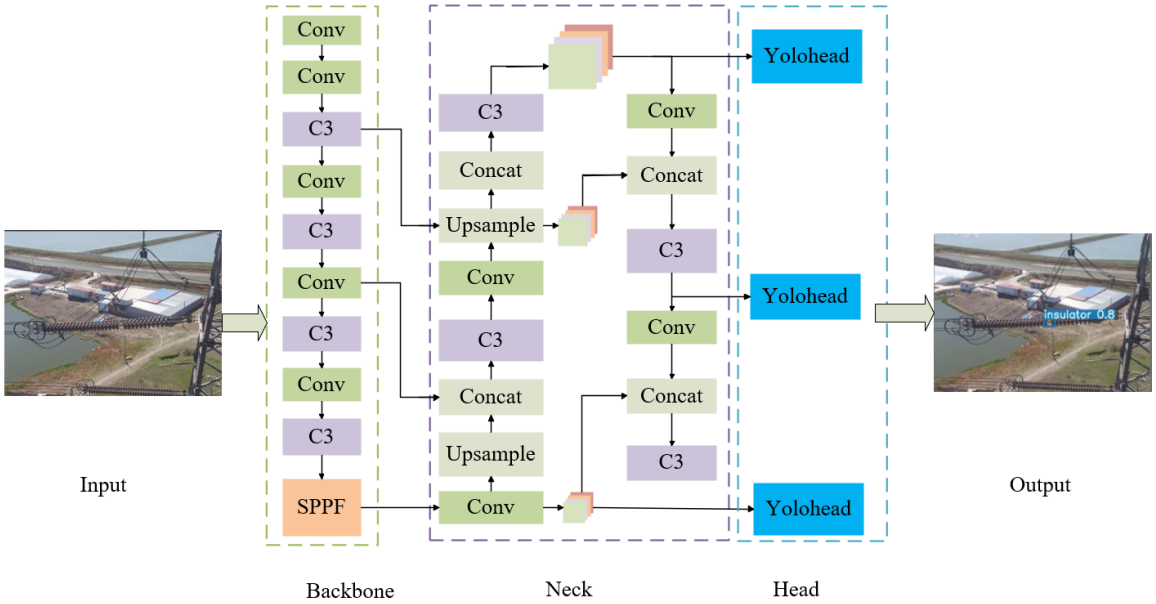

Fig. 2. YOLOv5 model structure.

C. YOLOv5 Improvements

1) SE attention mechanism: Squeeze-and-Excitation Networks (SE) [9] were implemented through two main steps: compression and excitation. As shown in Fig. 3, in the compression step, the SE module compressed the input feature map into a vector through a global average pooling operation, and then mapped it to a smaller vector through a fully connected layer. This process would be interpreted as summarizing and generalizing the overall information of the input features. In the excitation step, each element in this vector was scaled between 0 and 1 using a sigmoid function and multiplied with the original input feature map to obtain a weighted feature map [10]. This excitation operation would be understood as a recalibration of the local information of the input features. With the global averaged pooling and the excitation operations of the sigmoid function, the SE attention mechanism adapted to learn the importance of each channel, thus allowing the model to better understand the critical information in the input features and to focus on them more accurately in the output [11]. To improve the information interaction between each channel of the model and the utilization efficiency of feature information, this paper added the SE attention mechanism to the backbone network, and its specific position in the network was shown in Fig. 3.

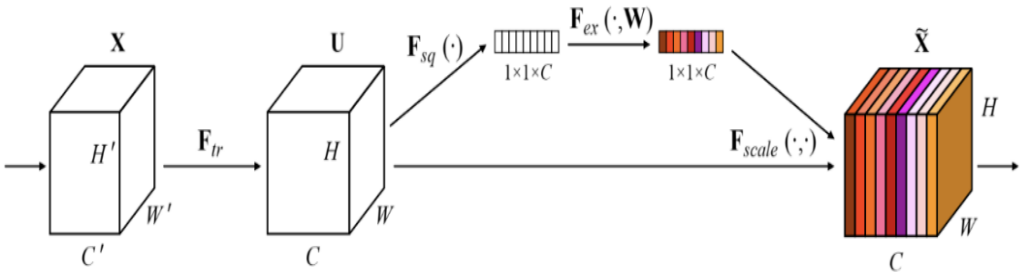

Fig. 3. Structure diagram of SE attention mechanism.

2) Bidirectional Feature Pyramid Network (BiFPN): BiFPN [12] achieved effective fusion of multi-scale features through both top-down and bottom-up pathways , with its structural diagram illustrated in Fig. 4. Its weighted feature fusion mechanism allowed the model to dynamically adjust the importance of different scale features based on task requirements, thereby enhancing feature representation accuracy. In the context of detecting insulator defects, which were typically small targets, a BiFPN module had been introduced into the model's neck section to replace the original feature pyramid network (FPN) [13]. This bi-directional feature fusion mechanism better integrated detailed information from low-level features with semantic information from high-level features, thereby improving the model's capability to detect defects across various scales.

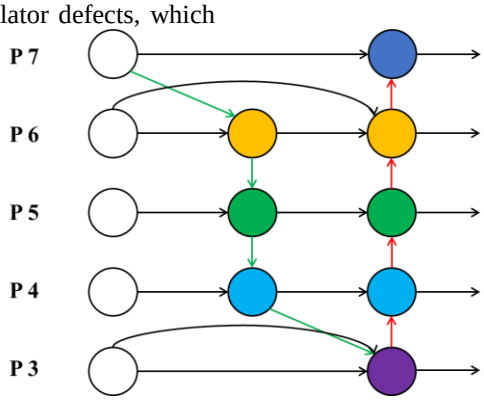

Fig. 4. Structure of bi-directional feature pyramid network.

3) SiLU activation function: In YOLOv5, the activation function introduced nonlinear factors, thereby enhancing the model's expressive power [14]. Activation functions playde a crucial role in neural networks by mapping neuron outputs to nonlinear intervals. This nonlinear mapping enabled neural networks to better adapt to complex patterns, thereby improving accuracy and performance. SiLU (Sigmoid-Weighted Linear Unit) acted as an implicit regularize with the following expression, suppressing the learning of numerous weights during training and enabling the model to focus more effectively on important features and patterns. This not only enhanced the model's generalization ability but also mitigates the risk of overfitting [15]. Additionally, due to SiLU's characteristics, the network's computational speed was improved. When the input x was large, SiLU's value was comparable to that of ReLU. Therefore, this paper adopted the SiLU activation function to enhance the overall performance of the model.

$$SiLU = x \times sigmoid(x) \quad (1)$$

$$sigmoid = \frac{1}{1+e^{-x}} \quad (2)$$

D. Interactive Interface Design for Detection Systems

In the development of an enhanced insulator defect detection system, designing an intuitive and user-friendly graphical user interface (GUI) was paramount. This section elaborated on the interactive interface design utilizing Python's PyQt5 library, as depicted in Fig. 5. The GUI aimed to streamline the interaction between users and the detection model, enhancing the system's usability and user experience.

The GUI integrated an image display area, an upload button, a detection button, and a feature for saving detection results in the backend. Users would effortlessly select an insulator image file for detection by clicking the upload button. Once loaded, the image was displayed in a designated area within the interface, facilitating user preview. Subsequently, upon clicking the detection button, the system automatically initiated the backend defect detection model, processing the image in real-time and instantly feeding back the detection results in graphical or textual form on the interface. This process not only visually showcased the detection effects but also significantly boosted detection efficiency.

To further augment the system's functionality and practicality, we had incorporated a logic for saving detection information in the backend after the detection process. Once

users confirmed the accuracy of the detection results, the information saving process was automatically triggered. The system then collected relevant detection details, including image paths, detection timestamps, defect types, locations, and severities, and leverages Python's file manipulation capabilities to save this information in a local JSON file. This step ensured the traceability and analyzability of detection results, facilitating subsequent data management and report generation.

Moreover, to guarantee a seamless user experience, meticulous optimization and testing of the GUI were conducted. By arranging interface elements logically, refining interaction logic, and incorporating error handling and user feedback mechanisms, we ensured the GUI's ease of use, stability, and reliability. Ultimately, a fully-featured, straightforward, and user-friendly GUI for the enhanced insulator defect detection system was successfully implemented, providing robust technical support for insulator inspection tasks in the power industry.

Fig. 5. Detection system interaction interface.

III. Results and Discussion

A. Test Environment

For this model training experiment, the environment was configured as follows: Python 3.8.16 served as the primary programming language with PyTorch 2.0.0 as the chosen deep learning framework. Additional software environments included Torch 2.0.0 and CUDA 11.8.0. The system ran on Windows 11, utilizing an Intel Core i7-13900HX CPU paired with an NVIDIA GeForce RTX 3060 graphics card and 16 GB of RAM. This setup ensure stable and efficient model training, guaranteeing smooth experimentation and accurate results [16].

B. Evaluative Indicators

In this study, multiple evaluative indicators were used to comprehensively assess the performance of the trained model. These indicators included precision, recall, and average precision, [17] which provided comprehensive information for evaluating different aspects of the model.

C. Optimization of Model Training and Validation Parameters

In the development of the insulator defect detection system, the optimization of parameters during the model training and validation stages represents a pivotal aspect ensuring model performance and generalization capability.

Firstly, regarding the learning rate configuration, it served as a crucial hyperparameter modulating the step size of model weight updates, significantly impacting training efficiency and stability. This system employed an initial learning rate of 0.001, coupled with a learning rate decay strategy. Specifically, as training progresses, the learning rate was automatically adjusted to 10% of its previous value every 10 epochs. This strategy aimed to balance rapid convergence during initial training phases with fine-tuning in later stages, thereby preventing the model from becoming trapped in local optima or overfitting.

Secondly, the selection of batch size needed a comprehensive consideration of hardware resource constraints and data processing efficiency. After thorough evaluation, a batch size of 32 was established in this system, ensuring efficient utilization of computational resources while maintaining the stability of the training process and mitigating noise in gradient estimations.

An initial number of 100 epochs was prescribed for training iterations, with ongoing monitoring of validation set performance to facilitate dynamic adjustments. If stagnation or a downward trend in validation set performance metrics (such as

loss or accuracy) was observed, it might indicate that the model is nearing optimality or beginning to overfit, necessitating timely termination of training.

In terms of optimizer selection, this system adopted the Adam optimizer, renowned for its adaptive learning rate adjustment capabilities, accelerating model convergence and minimizing computational resource consumption.

To further enhance model generalization, regularization techniques were integrated. Specifically, L2 regularization (weight decay) was employed, penalizing the squared sum of model weights to constrain model complexity. A weight decay coefficient of 0.0005 was set. Additionally, the Dropout strategy was implemented in select layers of the model, randomly discarding a proportion (0.3) of neuron outputs to bolster model robustness.

Through meticulous parameter optimization and effective training validation strategies, this system had successfully established a high-performance experimental environment for insulator defect detection models, laying a solid foundation for their stable performance and precise detection capabilities in practical applications.

D. Results and Analysis

1) Improved model validation analysis

a) Add SE attention mechanism analysis: To thoroughly evaluated the impact of incorporating SE attention mechanisms on the model's detection performance, this paper conducted a comparative analysis before and after their addition under identical hardware and software conditions. The specific results were presented in Table I, demonstrating that the inclusion of SE attention mechanisms notably enhances the model's accuracy in both feature extraction and classification. Specifically, precision increased by 1.3 percentage points, recall by 1.99 percentage points, and average precision by 1.79 percentage points.

TABLE I. COMPARISON OF TESTS BEFORE AND AFTER ADDING SE MODULE

Norm	Original model	After adding the SE module
Accuracy/%	88.72	90.02
Recall rate/%	86.36	88.35
Average precision/%	88.45	90.24

b) Adding Bidirectional Feature Pyramid Network (BiFPN) Analysis: To comprehensively assessed the impact of introducing a bidirectional feature pyramid network (BiFPN) on the model's detection performance, comparative experiments are conducted under identical hardware and software environments. The results, presented in Table II, demonstrate that the inclusion of BiFPN significantly enhances both the model's multi-scale feature fusion capability and its detection performance. Specifically, following the introduction of BiFPN, the precision rate increases by 1.06 percentage points, the recall rate by 2.7 percentage points, and the average precision by 1.92 percentage points.

TABLE II. COMPARISON OF TESTS BEFORE AND AFTER ADDING BIFPN

Norm	Original model	After adding BiFPN
Accuracy/%	88.72	89.78
Recall rate/%	86.36	89.06
Average precision/%	88.45	90.37

c) Analysis using the SiLU activation function: To evaluate the performance of the SiLU function, the activation function was tested before and after the enhancement of the YOLOv5 model on various datasets and models in this study. The results, presented in Table III, demonstrate that the SiLU activation function excels across all performance indicators. Specifically, the precision rate achieved 90.27%, the recall rate was 89.14%, and the average precision reached 90.34%.

TABLE III. COMPARISON OF TESTS BEFORE AND AFTER ADDING SE MODULE

Norm	Original model	SilU activation function
Accuracy/%	88.72	90.27
Recall rate/%	86.36	89.14
Average precision/%	88.45	90.34

Following the adoption of the SiLU function, the model's precision, recall, and average precision were further enhanced, underscoring SiLU's ability to optimize model parameters and improve generalization. The inclusion of the SE attention mechanism alongside the SiLU optimization function notably boost model performance. This synergy suggested that these dual enhancements effectively complement each other, resulting in improved overall model performance.

2) Comparative testing of different models: In this paper, several different models were tested against the improved YOLOv5 model. Specifically, YOLOv4, YOLOv5, and YOLOv8 were compared with the improved YOLOv5 model, and the results were shown in Table IV.

TABLE IV. TEST RESULTS OF DIFFERENT MODELS

Model	P/%	R/%	mAP/%
YOLOv4	86.35	85.26	86.88
YOLOv5	88.72	86.36	88.45
YOLOv8	90.12	88.95	90.22
This paper model	90.27	89.14	91.34

Based on the experimental results, the improved model in this study demonstrated superior performance compared to the YOLOv5, YOLOv4, and YOLOv8 models in terms of precision, recall, and average precision metrics. These findings underscored the effectiveness of the enhancement strategy proposed in this paper. Consequently, the improved model exceled across all performance metrics, affirming the efficacy of the enhancement strategy and providing robust support for future research and applications.

This paper compared and analyzed the image detection results of the YOLOv5 model on the test set before and after the

enhancement, as shown in Fig. 6. Fig. 6(a) illustrates the target detection results of the original YOLOv5 model, while Fig. 6(b) showd the target detection results of the improved YOLOv5 model proposed in this study. It was evident from the figures that the enhanced model achieved more accurate identification of insulator defects and significantly improves detection accuracy, particularly for smaller and more challenging defects. This demonstrated the effectiveness of the enhancement strategy in improving the performance of the YOLOv5 model, making it suitable for practical applications.

(a) (b)

Fig. 6. Comparison of models before and after improvement.

IV. Conclusion

This paper proposed an improved method for detecting insulator defects in high-voltage transmission lines, with a focus on intelligent identification. By incorporating a bidirectional feature pyramid network (BiFPN), the YOLOv5 model had been significantly enhanced in terms of multi-scale feature fusion. Additionally, the detection performance had been further optimized through the integration of an SE attention mechanism and the adoption of the SiLU activation function. Experimental validation had demonstrated that the improved model exhibited significant improvements in performance metrics such as precision, recall rate, and average precision, particularly in the areas of small target recognition and positional accuracy. Furthermore, the developed graphical user interface (GUI) inspection system enhances the model's usability, allowing users to easily upload images and perform defect detection operations.

However, it should be noted that this study also had potential limitations and constraints. For instance, the performance of the model might be affected by variations in lighting conditions and image quality. Future work could involve exploring more robust methods to address these challenges and further improving the model's detection capabilities.

Faculty of Computing, Universiti Teknologi Malaysia (UTM), Malaysia[4]

***Abstract*—Personalized recommender systems for mental health are becoming indispensable instruments for providing individuals with individualized resources and therapeutic interventions. This study aims to explore the application of recommender systems within the mental health domain through a systematic literature review. The research is guided by three primary questions: 1) What is a recommender system, and what techniques are available within these systems? 2) What techniques and approaches are used explicitly in recommender systems for mental health applications? 3) What are the limitations and challenges in applying recommender systems in the mental health domain? The first step in answering these questions is to give a thorough introduction to recommender systems, covering all the different methods, including content-based filtering, collaborative filtering, knowledge-based filtering, and hybrid approaches. Next, examine the specific techniques and approaches employed in the mental health context, highlighting their unique requirements for adaptation, benefits, and limitations. Ultimately, the research highlights the key limitations and challenges, including data privacy concerns, the need for tailored recommendations, and the complexities of user engagement in mental health environments. By synthesizing current knowledge, this review provides valuable insights into the potential and constraints of recommender systems in supporting mental health, offering guidance for future research and development in this critical area.**

***Keywords*—Recommender system; collaborative filtering; content-based filtering; hybrid recommender system; mental health**

I. Introduction

Recommender systems, also called information filtering support, are used to predict or suggest an item, such as products, movies, content, and others, based on machine learning algorithms that the user might be interested in. It uses content-based filtering, collaborative filtering, and a hybrid recommender system to generate recommendations based on user preferences, behavior, and other relevant data. Today, recommendation systems have become the most popular tools for personalized support, and they have the potential to personalize mental health support further and improve treatment outcomes in the digital mental health landscape.

The area of mental health treatments has seen a significant change in recent years, with a focus on acknowledging the needs, preferences, and characteristics of those who are seeking help. One in three Malaysians have a mental disease, yet half of those diagnoses are erroneously raising concerns about mental health. Numerous mental health conditions are prevalent, such as anxiety, depression, bipolar disorder, schizophrenia, and more [1]. This shows that there is cause to be concerned and emphasizes the need for mental health support and education in Malaysia. While mental health interventions are essential for addressing people's well-being, the current field mainly uses long-standing, conventional methods, including clinical diagnosis and medication intervention [2]. Even while these traditional approaches are helpful, they have many limitations. The desire for personalization—where therapies can be customized to meet the unique needs of everyone—has been sparked by the realization that there is no one-size-fits-all approach to mental health care. This change reflects a broader understanding that individuals seeking help might benefit from more engaging, effective, and ultimately transformational mental health treatment.

The need for personalization in mental health interventions is becoming increasingly acknowledged, although a severe issue still exists. The way mental health treatment is now provided does not adequately allow therapies to be adapted to each patient's specific requirements. Although helpful, traditional methods might only fully utilize personalization's potential. This issue presents a significant difficulty since it might impair user engagement and satisfaction and, more importantly, the well-being of those who are seeking mental health help. Research on the effectiveness of recommender systems specifically designed for mental health therapies remains limited. The absence of robust empirical evidence makes it difficult to determine whether these approaches are beneficial and effective.

Thus, this study aims to conduct a systematic literature review on the application of recommender systems and their core techniques—including collaborative filtering, content-based filtering, knowledge-based filtering, and hybrid approaches—focusing specifically on their use in the mental health domain. It also seeks to compare these techniques, identifying their advances, challenges, and limitations associated with their implementation in this field.

II. Research Method

This paper offers an extensive systematic literature review that critically evaluates related works that pertain to the research topic. This dissertation's literature review mainly centers on diverse recommender systems that employ various recommendation techniques. These distinctions are organized and summarized in a tabulated format to enhance

comprehension. The primary objective of this systematic literature review is to evaluate the methods available for crafting a recommender system that is ideally tailored for personalized mental health interventions.

A literature review is essential to research that comprehensively analyses existing literature on a particular topic. In the case of recommender systems, literature reviews are conducted to identify the current state of research, research trends, limitations, and opportunities. It also provides a guideline for future research in recommender systems. Hence, this part is essential to understand the current recommender systems research comprehensively. Conducting a systematic literature review (SLR) involves several key stages. Fig. 1 shows the critical stages in conducting a systematic literature review for this study.

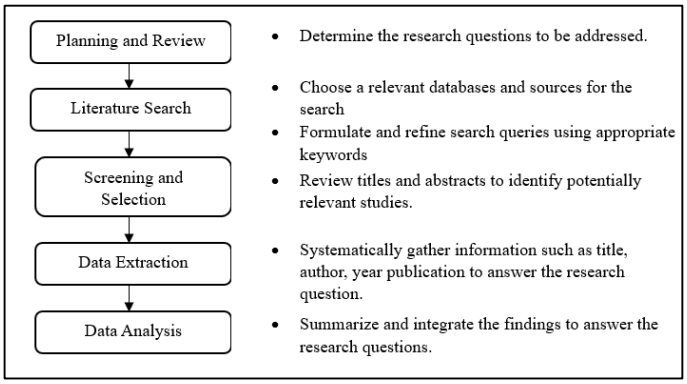

Fig. 1. Systematic literature review stage.

A. Planning and Review

This systematic review aims to understand the trends in recommender systems that can be effectively addressed, as well as the development and assessment of recommender systems. The research questions (RQ) aim to ascertain the limitations and difficulties associated with recommender systems and the evidence supporting their significance for individualized mental health. Below are the study questions that will be investigated during this comprehensive literature review:

- RQ1: What is a recommender system? What are the techniques available in the recommender system?
- RQ2: What techniques and approaches are used in recommender systems within the mental health domain?
- RQ3: What are the limitations and challenges in applying a recommender system for the mental health domain?

B. Literature Search

This section identifies relevant academic databases and sources well-regarded in personalized mental health recommender systems. Table I below shows an example of an academic database used to find relevant research in the field.

TABLE I. ACADEMIC DATABASE

Field	Academic Database
Recommender system	IEEE Xplore, ACM Digital Library, Scopus, and Google Scholar
Mental health interventions	PubMed.

The ultimate list of keywords was obtained after adding synonyms to make it longer. The search terms were defined using the research questions and the area's keywords as a guide. Table II presents examples of synonyms, and Table III presents a search query that was utilized for this study.

TABLE II. KEYWORD AND SYNONYM

Keyword	Synonym
Recommender	Suggestion, recommendation
System	Framework, mechanism, structure
Mental Health	Psychological health, emotional health, mental wellness
Intervention	Therapeutic support, support

TABLE III. SEARCH QUERY

Search ID	Search Term
S1	“Personalized recommender system” AND “mental health” AND “intervention”
S2	“Personalized recommendation for mental health” AND (“mental health intervention” OR “mental health therapeutic support”)
S3	“Customized mental health interventions” AND (“recommender system” OR “recommendation system”)
S4	(“Personalized recommendation” OR “adaptive recommendation”) AND (“mental health” OR “psychological health”) AND (“intervention” OR “support”)

C. Screening and Selection

In this activity, a few articles were selected to support the SLR. After identifying relevant papers, a quality assessment was conducted to avoid bias and internal and external validity. Incorporating the most recent research ensures that this SLR is current, comprehensive, and reflective of the state of the art in the application of recommender systems for mental health interventions. Therefore, only research published between 2019 and 2024 was chosen for this study. References were gathered, stored, and arranged using the desktop and web versions of the Mendeley software package.

About 612 results from the search were returned, comprising research articles, book chapters, proceeding papers, review articles, editorial materials, and early articles. After removing papers that were not relevant and adding relevant papers, 71) articles in total were used for this study. The flowchart below shows a detailed breakdown of the searched articles, as shown in Fig. 2.

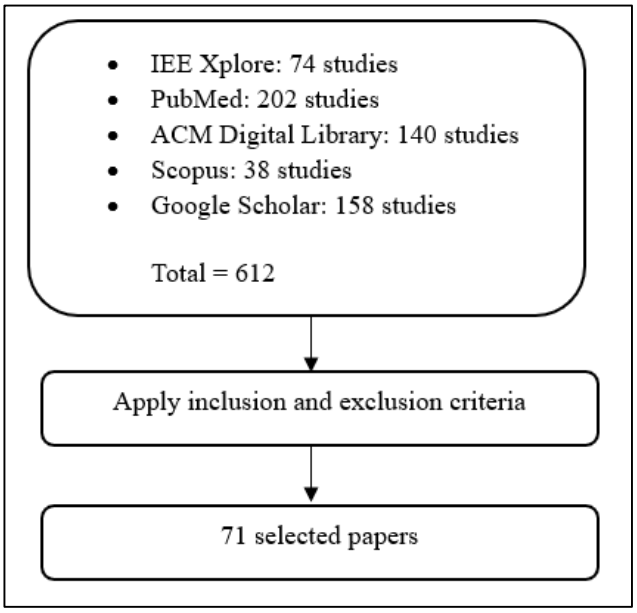

Fig. 2. Detailed breakdown of the searched articles

Explicit inclusion and exclusion criteria are necessary to guarantee that the studies are pertinent, excellent, and in line with the research goal. Table IV below shows the requirements for inclusion and exclusion.

TABLE IV. INCLUSION AND EXCLUSION

Inclusion	Exclusion
English article	Non-English article
Year published from 2019-2024	Outdated year publication
Related to the recommender system and mental health	Irrelevant to the studies
	Duplicate Literature

D. Data Extraction

Data extraction was carried out during the last phase of choosing primary research. Approaches, techniques, and application domains were among the crucial content data required to answer the research questions gathered, along with necessary metadata from the papers, such as author, title, and year of publication. Table V displays the framework for extracting data. First, a list of the extracted data is presented; next, any ambiguous data is clarified; finally, the research questions about the extracted information are explained in detail in the final column.

TABLE V. FRAMEWORK EXTRACTING DATA

Extract Data	Description	RQ
Author	Names of the authors of the study.	-
Title	Title of the study or paper	RQ1
Year of Publication	The year when the study was published	-
Journal/ Conference	Name of the journal or conference where the study was published.	-
Doi/ Link	Digital Object Identifier or URL for accessing the study	-
Application domain	Domain applied in the study	RQ2
Approach	Recommendation approach in the study	RQ3
Techniques	Technique applied in the study	RQ1

E. Data Analysis

For this review, 71 major research studies were dominated. From these studies, 23 journal articles, 26 conference papers, 4 workshop articles, 3 symposium articles, 4 handbook articles, and 11 others (website, review paper, etc.) were classified. The percentages of collated studies are presented in Fig. 3. In contrast, the total paper issued per year is presented in Fig. 4. This section presents the findings from a selection of studies that addressed each research question; these findings span several categories and include approaches, techniques, evaluation methodologies, and other crucial information.

III. REVIEW RESULT

A. Review Result Based on Research Question

1) Research question 1: What is a recommender system? What are the techniques available in the recommender system?

The rapid expansion of digital data and the growing number of internet users have led to the possibility of information overload, making it difficult for users to access relevant content on the web quickly. As a result, users often

struggle to find the information they need promptly, leading to frustration and decreased engagement with online services. This problem is particularly acute for users looking for highly specific or niche content, as they may have difficulty finding relevant items in the vast sea of available information. To address this challenge, recommender systems have been developed to help users find relevant and valuable content based on their past behaviors and preferences.

A recommender system is an information filtering system that predicts the preferences or interests of a user and recommends items that the user may like. It is widely used in e-commerce, social media, and entertainment industries to provide personalized recommendations to users [3]. Studies from [4] state that recommender systems have become more sophisticated in recent years with the development of deep learning algorithms and large datasets. Today, recommender systems are used in various applications, such as Netflix, which suggests movies based on the user's previous viewing history; YouTube recommends videos or tracks based on the user's search history; and Amazon suggests additional products based on the user's purchase history. Similarly, Facebook recommends that people befriended based on the user's social network. Traditional recommender systems use different approaches to make recommendations to users. These approaches include content-based filtering, collaborative filtering, hybrid methods, and other techniques that can be classified into more categories, such as knowledge-based filtering [4].

The area of mental health treatments has seen a significant change in recent years, focusing on acknowledging the particular needs, preferences, and characteristics of those seeking help. One in three Malaysians have a mental disease, yet half of those diagnoses are erroneously raising concerns about mental health. Numerous mental health conditions are prevalent, such as anxiety, depression, bipolar disorder, schizophrenia, and more [5]. This shows that there is cause to be concerned and emphasizes the need for mental health support and education in Malaysia. While mental health interventions are essential for addressing people's well-being, the current field mainly uses long-standing, conventional methods, including clinical diagnosis and medication intervention [2]. Even while these traditional approaches are helpful, they have a lot of limitations. The desire for personalization—where therapies can be customized to meet the unique needs of each individual—has been sparked by the realization that there is no one-size-fits-all approach to mental health care. This change reflects a broader understanding that individuals seeking help might benefit from more engaging, effective, and ultimately transformational mental health treatment.

Thus, by utilizing recommender systems, which have become valuable instruments in the more significant healthcare industry, data-driven solutions that can improve personalized treatment are provided. These systems employ user data and algorithms to offer suggestions to enhance user experiences and healthcare service delivery. While this usage offers convenience, some disadvantages need to be addressed. Therefore, this study uses a hybrid recommendation system that combines several recommendation techniques, such as content-based filtering, collaborative filtering, knowledge-based filtering, and hybrid approach, which may overcome the problems and provide more accurate and diverse recommendations.

a) Collaborative filtering approach: Recommender systems use a technique called Collaborative Filtering (CF) to forecast a user's interests based on the tastes of users who are similar to the said user [6]. It is predicated on the notion that individuals who share a joint assessment of a given item will likely do so in the future. User-based and item-based CF are the two primary categories of CF. While item-based CF suggests products comparable to those a user has previously liked, user-based CF suggests items to a user that similar users have previously liked [7].

As to [8], user-based CF is a method that forecasts the items a user would find appealing by analyzing the ratings that other users with comparable tastes have assigned to that item. This kind of recommendation system bases its product recommendations on user similarities. On e-commerce platforms, this technique is frequently used to make product recommendations to consumers based on their browsing and past purchases. To suggest movies, TV series, and songs to customers based on their viewing or listening history is also utilized by streaming services like Netflix and Spotify [9].

Item-based CF is a subset that makes recommendations to consumers based on how two comparable items are determined by utilizing user ratings. [10] states that Amazon utilized and invented it in 1998, which has been essential to the company's success. Item-based CF examines the relationship between the two items and combines the user's rated and bought items with related goods to generate a suggestion list.

Hence, CF can be classified as a powerful tool for personalizing users' experiences and increasing customer engagement and satisfaction. Table VI below shows several advantages and disadvantages of CF recommendation approaches for recommending items.

TABLE VI. ADVANTAGES AND DISADVANTAGES OF COLLABORATIVE FILTERING APPROACH

Advantage	Disadvantage
Personalization: CF provides users with personalized recommendations based on their past behavior, preferences, and activities [11].	Cold start problem: CF has a cold start problem, in which it isn't easy to make recommendations for new users or items without ratings [12].
Diversity: CF can recommend items that are not popular, which can increase the diversity of recommendations and expose users to new items [12].	Sparsity: CF can suffer from sparsity, where there are not enough ratings or data points to make accurate recommendations [12].
Scalability: CF can handle large datasets and many users, making it scalable for e-commerce platforms and other applications [11].	Over-specialization: CF can lead to over-specialization, where users are recommended items that are too similar to their past behavior, limiting their exposure to new items [12].
Adaptability: CF can adapt to user interest and preference changes over time, making it a dynamic and flexible recommendation system [11].	Popularity bias: CF can suffer from popularity bias, where popular items are recommended more frequently, leading to a need for more diversity in recommendations [11].

b) Content-based filtering approach: In recommender systems, content-based filtering (CBF) is a technique that uses the user's attributes to forecast and suggest new but comparable things [13]. The more a consumer participates, the more accurate future suggestions are generated by the CBF algorithm, which retains past user data, including clicks, reviews, and favorites, to establish a user profile. The author in [14] claims that this method does not use the data of other users when making suggestions to a single user; instead, it attempts to infer a user's features or behavior based on the item's features. Each item's unique traits must reflect its fundamental characteristics when using CBF. For example, the recommender system requires specific movie attributes, including actors and actresses, directors, the year of release, and genre, to discriminate between movies [15].

According to a [18] publication, the CBF model finds similarities between things to make suggestions based on specific criteria. These systems generate data profiles by utilizing description information, which could comprise attributes of objects or individuals. The users who previously liked, purchased, viewed, or listened to products are then suggested to them based on the developed profiles. The premise is that people may enjoy similar goods in the future if they have previously liked specific items, which is crucial to content-based filtering.

Two common approaches are typically employed in content-based filtering: Cosine distance and classification [13] [17]. In the cosine distance method, the cosine distance between the user and item vectors determines preference. For instance, the action movie vector has a positive value for a user who enjoys watching it, but the horror movie vector has a negative value for that same person. The cosine distance is used to find the similarity between the user and item vectors, and the items with the highest similarity score are recommended for use [13] [18]. The classification approach method uses a classification algorithm to predict whether a user will like an item or not based on the item's features; for example, a decision tree algorithm can be used to predict whether a user will like a movie based on its genre, director, actors, and other features. The algorithm learns from the user's past preferences and creates a model that can predict the user's future preferences [13] [18].

In summary, CBF is a method for recommender systems that uses machine learning algorithms to forecast and suggest new but comparable items based on those attributes to the user. The more a consumer participates, the more accurate future suggestions are generated by the CBF algorithm, which retains past user data, including clicks, reviews, and favorites, to establish a user profile. Rather than focusing on how an object interacts with the user, CBF approaches need additional information about its features. Table VII below shows several advantages and disadvantages of CBF recommendation approaches for recommending items.

TABLE VII. ADVANTAGES AND DISADVANTAGES OF CONTENT-BASED FILTERING

Advantage	Disadvantage
No-item cold-start problem: Content-based filtering can recommend items to new users who have yet to have any interaction [19].	Limited capacity to build upon users' current interests: The model can only provide recommendations based on the user's current interests. It is not able to build upon those interests [19].
Scalability: Since the recommendations are unique to this person, the model does not require any information about other users, simplifying scaling to many users [19].	Needs extensive domain expertise: Because the item feature representation is partially hand-engineered, this technique calls for a great deal of subject knowledge [19].
Recommendations for niche products: Based on the user's preferences, the model can identify products that only a tiny percentage of users are interested in [19].	Limited quality consideration: Content-based filtering systems mostly need to consider the quality of the items in the recommendation process [20]

c) Knowledge-based filtering approach: The knowledge-based filtering (KBF) approach is a recommendation system that does not rely on user data or ratings but instead uses domain knowledge to make recommendations. KBF systems use a set of rules or knowledge to recommend items to users based on their preferences [21][23].

According to [22], KBF systems are often used in domains where domain knowledge is readily available, such as the medical field or in recommending books. However, the quality and completeness of their domain knowledge need to be improved.

In summary, the knowledge-based filtering approach is a recommendation system that uses domain knowledge to make recommendations. It does not rely on user data or ratings, can explain its recommendations, and can handle new items. However, it is limited by the quality and completeness of its domain knowledge; it can only recommend items that match the user's known preferences and acquiring domain knowledge can take time and effort. Table VIII below shows several advantages and disadvantages of KBF recommendation approaches for recommending items.

TABLE VIII. ADVANTAGES AND DISADVANTAGES OF KNOWLEDGE-BASED FILTERING

Advantage	Disadvantage
No need for user data: Knowledge-based filtering systems do not require user data or ratings, making them useful when user data is unavailable [21][2].	Limited to domain knowledge: Knowledge-based filtering systems are limited by the quality and completeness of their domain knowledge [22].
Able to offer clarifications: Knowledge-based filtering systems can make their recommendations more visible and understandable by providing justifications for them [22].	Limited to known preferences: Knowledge-based filtering systems can only recommend items that match the user's known preferences and cannot expand on the user's interests [23].
Can handle new items: Knowledge-based filtering systems can handle new items that have yet to be rated by users [23].	Difficulty in acquiring domain knowledge: Acquiring domain knowledge can be challenging and time-consuming [22].

d) Hybrid recommender system approach: Hybrid recommender systems integrate the complementary qualities of two or more recommendation algorithms differently to benefit from the complementary qualities of two or more recommendation algorithms. Combining two or more recommendation algorithms, hybrid recommendation systems seek to give users more accurate, varied, and well-balanced recommendations. [24][25].

Developing hybrid recommender systems by fusing various methods, like content-based and collaborative filtering, is possible. While the content-based filtering component considers objects' particular characteristics and properties, the collaborative filtering component gathers the general public's knowledge [25][26]. According to an article by [24], there are various kinds of hybrid recommender systems, such as feature combination hybrid, weighted hybrid, switch hybrid, and mixed hybrid.

In summary, hybrid recommender systems leverage the complementary advantages of two or more recommendation algorithms by combining them in diverse ways. They can offer better coverage of the item space, overcome the shortcomings of individual methodologies, and deliver more precise recommendations. Nevertheless, choosing the best mix of approaches can take time and effort, and they might be more challenging to develop and maintain than single-technique systems. They also require more data. Different techniques, such as collaborative and content-based filtering, can be combined to create hybrid recommender systems. Table IX below shows several advantages and disadvantages of the hybrid recommender system approach in recommending items.

TABLE IX. ADVANTAGES AND DISADVANTAGES OF HYBRID RECOMMENDER SYSTEM

Advantage	Disadvantage
Overcoming limitations of individual techniques: Hybrid recommender systems can combine individual techniques to overcome their limitations [25].	Complexity: Hybrid recommender systems can be more complex to implement and maintain than single-technique systems [25].
Increased accuracy: Hybrid recommender systems can produce more accurate recommendations by integrating the advantages of several strategies [27].	Data requirements: Hybrid recommender systems require more data than single-technique systems [25].
Better coverage: Hybrid recommender systems can combine different techniques to provide better coverage of the item space [24].	Difficulty in selecting the right combination of techniques: Selecting the right combination of techniques can be challenging, and the hybrid system's performance depends on the quality of the individual methods [24].

2) Research question 2: What techniques and approaches are used in recommender systems within the mental health domain?

Recommender systems can improve the user experience of mental health apps by personalizing the intervention, making it more applicable to the needs of the individual user and, thus, more engaging [28] [29]. Through personalized recommendations, these systems can effectively customize the content, resources, and interventions offered by mental health apps, creating a more tailored and relevant experience for each user. According to [29], recommender systems can filter content and provide tailored mental health suggestions by leveraging individual usage data. Through meticulous analysis of user behavior, preferences, and interactions within mental health apps, these systems can discern patterns and preferences unique to each user. This insightful data analysis enables recommender systems to curate personalized content, ensuring that mental health suggestions are finely tuned to match the specific needs and interests of the individual.

Other than that, the recommender system for mental health personalization represents a transformative approach in mental health care, enabling the adaptation of treatments to the unique needs of individuals and thereby enhancing the overall care for depressive symptoms and beyond [30]. By customizing therapeutic strategies based on a person's specific circumstances, preferences, and responses, these interventions can optimize the effectiveness of treatment. According to [31], content recommendation systems are pivotal in scaling and complementing digital mental health care by offering personalized content and self-care recommendations. These systems leverage advanced algorithms to analyze user data, preferences, and behaviors, tailoring the delivery of relevant resources to individuals seeking mental health support.

Therefore, recommender systems can transform the mental health care field by personalizing interventions and better tailoring them to specific users' needs. They can be applied in various ways in mental health apps to ascertain what would be pertinent to the user. They use algorithms to forecast material or information relevant to the user.

a) Collaborative filtering for mental health: A CF Recommender System for Mental Health technology uses algorithms to provide personalized recommendations for mental health treatments or interventions. This system is designed to enhance the personalization of mental health care by recommending treatments or interventions based on the similarities between patients and their responses to different treatments. According to [22], CF algorithms, such as matrix factorization and k-nearest neighbors, have been used to improve the personalization of digital mental health therapy. These algorithms have shown a 6.5-8.3% improvement in treatment personalization.

The system uses patient ratings of treatment efficacy and demographic data to recommend treatments to new patients. Based on shared demographic and behavioral traits, it groups users into clusters. The model may suggest a treatment for a patient who is entirely new to the model or has taken depressive therapies in the past by comparing and classifying users based on specified demographic similarities and comparing treatments based on efficacy rating similarities across users [32].

Furthermore, [33] points out that CF can suggest places and activities that, according to users' prior experiences, may have a greater chance of having a favourable impact. With this, users may find tiny moments of thankfulness and joy in their daily lives. Recommended systems for digital mental health apps have some ethical concerns, especially for those that employ artificial intelligence and personal data. These include concerns

about privacy, personalization trade-offs, explainability, and the calibre of recommendations [22].

In summary, by tailoring interventions to the specific needs of each user, CF Recommender Systems for Mental Health has the potential to transform the way mental health care is provided completely. However, these systems' efficacy depends on the quantity and calibre of data available, and their application necessitates careful consideration of moral dilemmas.

b) Content-based filtering for mental health: A CBF Recommender System for Mental Health is a technology that uses algorithms to provide personalized recommendations for mental health treatments or interventions based on individual usage data. This system is designed to enhance the personalization of mental health care by recommending treatments or interventions based on the individual's past behavior and preferences. The author in [29] claim that CBF approaches have great potential for offering individualized mental health advice. Based on a user's personal information and past usage statistics, these strategies employ information filtering algorithms to provide suggestions or recommendations for appropriate material.

Therefore, by tailoring interventions and making them more relevant to the needs of specific users, CBF Recommender Systems for Mental Health have the potential to transform the way that mental health care is provided completely. However, the quality and availability of data determine how effective these systems are and using them requires careful ethical considerations [29].

Unfortunately, minimal research has been conducted in this area, possibly due to several reasons, including the sensitive nature of mental health data and the recent emergence of technology-driven solutions. It is possible that this area of study is still emerging or that research in this specific niche needs to be expanded.

c) Hybrid recommender system for mental health. A hybrid recommender system for mental health combines multiple recommendation approaches to provide individuals with personalized mental health support and resources. Research by [33] about a hybrid recommender system for mental illness detection in social media using deep learning techniques mentions that a hybrid recommender system is a sophisticated tool that combines various algorithms to analyze social media data and identify potential signs of mental illness. This system is primarily designed to optimize the detection of mental health issues, particularly depression, by analyzing patterns in social media behavior and content.

However, while hybrid recommender systems have demonstrated their potential in various domains, there is a notable lack of research specifically focused on their application in mental health. Technology plays a crucial role in mental health support, so developing hybrid recommender systems can contribute to more effective, accessible, and user-centric mental health care.

3) Research Question 3: What are the limitations and challenges in applying a recommender system for the mental health domain?

The sensitive nature of mental health data and the complexity of individual needs make the application of recommender systems in the mental health domain complex and fraught with limitations. Technological, data science, ethics, and mental health specialists must collaborate to address these issues multidisciplinary. Table X below shows the constraints and challenges in several studies on the recommender system approach using the CBF technique, CF technique, and hybrid recommender system in the mental health domain.

TABLE X. SUMMARIZATION OF RECOMMENDER SYSTEM FOR MENTAL HEALTH DOMAIN

Recommender System Approach	Studies	Limitation and challenge
CBF Technique	[29]	The lack of explainability in recommender systems used in DMH apps raises ethical concerns.
CF Technique	[27]	The analysis does not consider the cold-start scenario, in which the algorithms predict for users something they have never seen before, which is a well-known challenge for recommender systems.
	[31]	● User cold-start problem: User-user collaborative filtering relies on finding similarities in item ratings between users to make recommendations. However, a cold-start user with no item ratings cannot be given a recommendation. ● The sparsity of data: If users have rated only a few items, similarity measures between users become unreliable, affecting the accuracy of recommendations.
	[32]	There are challenges in developing engaging and personalized digital interventions, the potential of recommender systems to address these challenges, and the need for further research and empirical evaluation.
Hybrid Recommender System	[33]	Requires large labelled social media datasets, which can be difficult to obtain

IV. DISCUSSION

Specific gaps and limitations have been evident in the recommender systems literature, pointing to areas where further exploration and development are warranted. One of the primary challenges is the availability and quality of the data. Recommendation algorithms may not be as successful when dealing with sparse or noisy mental health data, such as user preferences, behavior patterns, and treatment results. To address this issue, data are collected through an online platform, which offers users the most accessible means to contribute and receive recommended interventions from the system. Experts in the field of mental health provide these intervention data. Using an online platform to collect data and incorporating the expertise of mental health professionals could

help alleviate some of the difficulties associated with limited or unreliable mental health data. However, it is essential to recognize that these approaches may not eliminate all problems. Nevertheless, they have the potential to significantly improve the quality, relevance, and effectiveness of the system's proposed mental health therapies.

Furthermore, it is crucial to acknowledge the limited research on recommender systems designed for mental health treatments. Prior research in this field often utilizes several recommendation strategies, demonstrating a wide array of methodologies. Yet, these methods have their inherent restrictions and difficulties. While hybrid recommender systems have the potential to tackle some obstacles, there is still a lack of research on their use in mental health settings. Although hybrid recommender systems have the potential to be effective in the field of mental health intervention, more research is required to evaluate their practicality, effectiveness, and implementation. The potential for synergies in hybrid recommender systems still needs to be explored. Focusing only on specific methods can make it harder to understand hybrid approaches, which could mean missing chances to improve the quality of recommendations.

Moreover, consistency in evaluating metrics across studies presents challenges in comparing and benchmarking recommender system performance. Standardized metrics and benchmarks are lacking, making it difficult to establish a common framework for evaluating recommendation quality. Addressing this requires the adoption of standardized metrics and benchmarks for more equitable comparisons.

A common challenge in recommender systems is the "cold start" problem, where recommender systems struggle to make practical recommendations for new users or items with limited data. Many studies need to adequately address this issue, which can lead to suboptimal recommendations for newcomers. Solving this problem is essential to ensure valuable recommendations for all users. In this case, combining a few techniques, which are CF, CBF, and KBF, may leverage the strengths of each approach to overcome the limitations of individual methods and handle the cold start problem more effectively.

In conclusion, it is essential to identify these holes and problems in the literature on recommender systems and take action so that the field can continue to grow and recommendation technologies improve. Future research on these areas will contribute to advancing recommender systems and their ability to serve diverse user needs and preferences.

V. Conclusion

This paper comprehensively explores recommender systems, focusing on enhancing personalization. Recommender systems are central in personalizing recommendations across various domains, improving user experiences, and guiding choices. Traditional approaches like CF and CBF are commonly used but have limitations, including the cold start problem and difficulty capturing diverse user preferences. There are challenges in delivering personalized care, including privacy concerns, the need for real-time recommendations, and limitations in cross-domain recommendations. Hence, hybrid recommender systems, which combine various recommendation techniques, hold promise for overcoming the limitations of traditional methods.

Evaluating recommender systems is essential, and standardized metrics and benchmarks are necessary for fair assessments. User and intervention data should be integrated into the evaluation of the recommendation system. Additionally, interpretability and explainability of recommendations are critical to building user trust and engagement. Privacy and ethical considerations, including data misuse and user profiling, should be considered to ensure responsible data use.

To wrap up, this review provides valuable insights into the world of recommender systems, their challenges, and the potential for improvement. The review emphasizes the importance of addressing gaps and limitations to create more effective and ethical recommendation systems that meet users' diverse needs and preferences.

VI. Future Work

Insights from the literature review suggest several promising directions for future research in recommender systems for mental health therapies. These directions are essential for overcoming current limitations and advancing the development of practical, user-friendly, and ethically sound recommendation technologies in mental health care.

Future work should prioritize addressing key challenges, including improving recommendation accuracy, mitigating cold start and data sparsity problems, and upholding ethical standards in system design and deployment. Enhancing the personalization of recommendations by integrating contextual factors such as user preferences, emotional states, and mental health history could significantly improve system performance. Moreover, innovative approaches to data utilization, such as incorporating external data sources and leveraging hybrid models, could help alleviate data-related limitations.

Research should also focus on evaluating the real-world efficacy of these systems through longitudinal studies and clinical trials to better understand their impact on mental health outcomes. Additionally, expanding the applicability of recommender systems to diverse populations is crucial for ensuring inclusivity and addressing cultural, demographic, and individual differences in mental health needs.

Exploring advanced techniques, such as deep learning, reinforcement learning, and multimodal data integration, offers further opportunities to push the boundaries of current methods. By investigating these areas, future research can significantly contribute to developing more accurate, portable recommender systems that align with ethical considerations and user needs.

Intelligent Service Book Sorting in University Libraries Based on Linear Discriminant Analysis Method

Changjun Wang*, Fengxia You, Yu Wang
Library, University of Sanya, Sanya, 572022, China

***Abstract*—The demand for intelligent services in university libraries is constantly increasing, especially in the intelligent book sorting work. The research aims to explore an intelligent classification method for university library books based on linear discriminant analysis. It is used to reduce the dimensionality of feature multidimensional data. A membership model for different categories of books is established to achieve classification. The results showed that when the training set data was reduced to two-dimensional, the feature extraction accuracy of the classification algorithm reached 64.02%, which was significantly higher than 52.48% of one-dimensional data. In addition, the membership calculation accuracy of axiomatic fuzzy sets on two-dimensional data was high, reducing the classification difficulties caused by mixed samples. After comparing and analyzing different algorithms, the proposed transfer learning linear-discriminant analysis-axiomatic fuzzy set algorithm achieved the highest accuracy of 98.67% and completed data classification in about 20s, which was superior to other commonly used classification algorithms. The practical significance of the research lies in providing an efficient and accurate book sorting algorithm, which helps to improve the work efficiency and service quality of libraries.**

Keywords*—Linear discrimination; library intelligent services; book sorting; university libraries

I. Introduction

In the digital age, rapidly advancing information technology has not only completely changed learning and working methods, but also reshaped the service model of university libraries [1]. In today's era, university libraries are no longer just storage places for physical books. It has become a digital processing factory for knowledge and an interactive platform for cultural exchange [2]. With the integrated application of big data and intelligent systems, libraries can capture readers' reading habits and preferences in real-time, thereby providing more accurate and personalized services [3]. This transformation has made book management more intelligent, simplifying the process of book classification, retrieval, and borrowing, and greatly improving the user experience [4]. As a key link in intelligent library services, the improvement of automation and intelligence levels in book sorting is particularly important [5]. The current classification of books in libraries mostly relies on manual classification, which not only has low efficiency but also cannot classify books based on their content [6]. Instead, manual classification relies more on book names, which can lead to discrepancies between book categories and actual content. At present, the intelligent book sorting model still has the problem of low classification accuracy in practical applications. The inconsistency between book content and its partition can lead to users' distrust of the library, which is not conducive to the accumulation of users in the library management. Therefore, exploring and applying new intelligent book-sorting methods has become a research hotspot for library service innovation. In order to improve the efficiency and accuracy of book classification in libraries, it is proposed to use linear discriminant analysis technology to mine and classify the feature information of book content. At the same time, a dynamic learning framework was designed to learn the characteristic information of new book types in the library, in order to expand the book classification level of the system.

The study innovatively applies LDA technology to deeply explore the characteristic information of library collections. Based on the basic characteristics of library collections, a user-friendly book sorting assistant tool is designed, which helps to improve the service efficiency of library staff. The main contribution is to develop a standardized book classification evaluation system, which is convenient for other university libraries to reference and learn from, improving the intelligent service level of the entire industry.

The main content of the research is divided into six sections. Section I is an introduction to the significance and purpose of the research. Section II is a survey of related work, which elaborates on the limitations and shortcomings of the current research direction. Section III is a study on the construction of a library book sorting model designed for research. This section is divided into two parts. The first part is the processing method of library book feature information, and the second part is the construction of a book sorting model based on kilometer fuzzy sets. Section IV of the manuscript presents the main results of the research, including training and testing of the constructed model, as well as practical application validation. Section V is a discussion of the research results, comparing the effectiveness of the proposed model with other models in the current field. Section VI is a summary of the main research content.

II. Related Works

LDA is a common statistical analysis method. Ricciardi C et al. proposed a data mining method to analyze the characteristics of patients with myocardial ischemia. 22 features were extracted. The results showed that this method

could assist clinical decision-making. The principal component analysis could reduce the number of features [7]. Ontstick L L et al. conducted a double-blind, randomized, controlled clinical trial to identify risk factors associated with mortality in Ebola patients and evaluate the predictive ability of both methods. The results showed that binary logistic regression and LDA selected the same risk factors, predicted similar mortality rates, and scored similar areas under the curve [8]. Bonati L et al. proposed descriptors to characterize these states to obtain appropriate collective variables from metastable information. Neural networks compressed information in low dimensional space and used Fisher LDA as the objective function to maximize the network's discriminative power. This method was tested on alanine dipeptides and nonlinear separable datasets. An inter-molecular aldol condensation reaction was studied [9]. Yan et al. proposed an improved LDA to address the edge classes in multi class classification. The experimental results showed that the self-weighted LDA performed better than other methods, while also having higher computational efficiency [10]. Zhou L et al. conducted a cross-sectional study to investigate the gut microbiota and metabolic function in patients with polycystic ovary syndrome, recruiting participants from different groups. The LDA could effectively count the differences and classify them [11]. Ngailo E K et al. proposed a mis-classification probability approximation algorithm based on the LDA method to solve the mis-classification approximation problem in classification problems. The approximate mis-classification probability of the unknown covariance matrix was derived. The results showed that this method improved the approximation value of mis-classification probability [12].

Intelligent services in university libraries are a necessary condition for the development of university libraries in the information age. Mohammed SH et al. used topic modeling method to solve the classification problem of Chinese text data in digital libraries. Comparing the two popular methods of Latent Dirichlet Allocation and latent semantic allocation, the former performed better. When the topics were 20, the highest coherence of the potential Dirichlet allocation was 0.592179, while the potential semantic allocation was 0.577302 [13]. Asemi A et al. used descriptive and content review methods to review articles related to robotics in libraries and information science from 2007 to 2017. The intelligent systems contributed to multiple purposes for librarians, including technical services, public services, and consultation desks. Through integration with artificial intelligence technology, current information systems had high potential for improvement [14]. Wan M et al. proposed a cloud-based product service system platform to address the challenge of urban waste issues. This platform aimed to manage solid waste management resources. Case analysis verified the feasibility of the platform [15]. Chiu CK et al. proposed a learning status management system in an intelligent classroom to improve the learning status of students. Sensor technology and image recognition technology were used to detect and collect various information from students, and Bayesian classification networks were used to infer the learning status. In addition, the system also included a feedback mechanism. Two experiments verified the accuracy and effectiveness. The learning status analysis was highly consistent with observed results. Students were more focused in class [16].

The current research on book sorting still adopts the method of classifying books based on their semantic names, which leads to significant deviations in the accuracy of book collection and sorting. Moreover, the current intelligent management platform for library management still faces problems of inability to retrieve or inaccurate retrieval results in practical applications. Aiming at the shortcomings of the current intelligent management and sorting platform for library management, this study proposes the use of LDA technology to extract feature information of key content of books and sort them based on the key content features of books. The research has changed the main sorting basis of current book sorting technology, adopting a new sorting mode to achieve the goal of improving the accuracy of book sorting.

In summary, LDA is a commonly used statistical method that has been frequently applied in various studies. Influenced by information technology, university libraries are no longer limited to collecting images and are beginning to focus on intelligent service systems. Classification management technology has rich applications in various fields. To improve the service quality, the intelligent service system of university libraries is utilized to achieve the classification management of books. Therefore, the study combines LDA with intelligent services in university libraries to conduct book-sorting research.

III. Book Sorting Model based on LDA and AFS

With the development of the information age, university libraries have also begun to develop intelligent services. Intelligent book sorting can effectively reduce library management costs and improve library classification accuracy. In Section II, LDA and AFS are used to study the book sorting methods in university libraries. A book sorting model is constructed. The research will be conducted from two aspects. The first is data dimensionality reduction based on linear discrimination, and the second is the image book sorting model based on AFS.

A. Data Dimensionality Reduction Based on Linear Discriminant

LDA is a classic statistical method widely applied in pattern recognition and machine learning. It is a supervised learning algorithm mainly used for dimensionality reduction and classification problems [17]. The core idea is to project high-dimensional data onto a low-dimensional space that best distinguishes categories. Specifically, LDA attempts to find a series of projection axes such that when data is projected onto these axes. The distance between different categories is as large as possible, and the data dispersion within the same category is as small as possible, as shown in Fig. 1 [18].

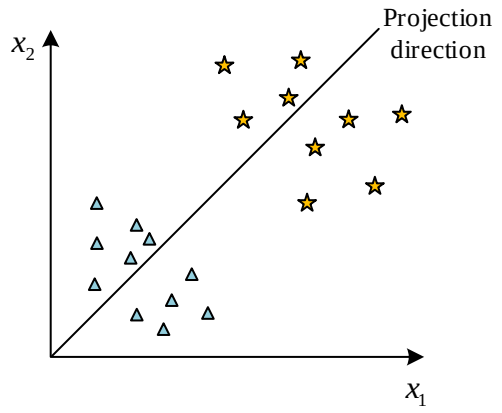

Fig. 1. LDA.

In the LDA algorithm, it is assumed that the data sample set is D. This sample set contains multiple data points. Each data point x_i can be considered as a vector in an n-dimensional space. Each component of this vector represents a feature of the data. Each data point x_i usually has an associated label category y_i, which indicates the classification to which the data point belongs. These categories are crucial for establishing classification models and making predictions in the future. In each category, it is assumed to be a classification labeled c. These classifications all have a corresponding sample size N_c. The number of samples determines the representativeness of each classification in the sample set. Generally speaking, a larger sample size indicates that the statistical characteristics of the corresponding classification are more reliable. To further analyze each category, the set of sample points for each data category is defined as X_c. For each category c, two important statistical measures can be further defined: the mean vector μ_c and the covariance matrix Σ_c. The mean vector is shown in Eq. (1) [19].

$$\mu_c = \frac{1}{N}\sum_{x\in X_c} x, c = (0,1) \tag{1}$$

The covariance matrix is shown in Eq. (2).

$$\Sigma = \sum_{x\in X_c} (x-\mu_c)(x-\mu_c)^T, c = (0,1) \tag{2}$$

A common method when dealing with binary classification problems is to find an appropriate mapping that reduces the dimensionality of high-dimensional data sample points to one-dimensional space to simplify the classification process. In mathematics, this can be achieved by defining a normal vector w, which essentially describes a vector in a one-dimensional spatial direction. Through this normal vector, the projection of each data sample point x_i on the line is represented as $w^T x_i$. Similarly, the mean values of different categories of sample points in the dataset can also be projected onto this vector to generate new mean points $w^T\mu_0$ and $w^T\mu_1$. Based on these criteria, LDA finds the optimal projection direction w through a mathematical optimization process. The original binary classification problem is transformed into a simple one-dimensional decision problem. In this way, no matter how high the dimensions of the original data are, theoretically, it can be effectively classified. The optimization objective is shown in Eq. (3).

$$MaxJ(w) = \frac{\left\|w^T\mu_0 - w^T\mu_1\right\|_2^2}{w^T\sum_0 w + w^T\sum_1 w} = \frac{w^T(\mu_0-\mu_1)(\mu_0-\mu_1)^T w}{w^T\left(\sum_0 w + w\sum_1 w\right)w} \tag{3}$$

In Eq. (3), $MaxJ(w)$ refers to the distance from the sample point to the center point. If $(\mu_0-\mu_1)(\mu_0-\mu_1)^T$ is defined as s_b and $\sum_0 w + w\sum_1 w$ is defined as s_w, then it can be expressed as Eq. (4).

$$s_w = \sum_{x\in X_c}(x-\mu_0)(x-\mu_0)^T + \sum_{x\in X_c}(x-\mu_1)(x-\mu_1)^T \tag{4}$$

By combining Eq. (4) with Eq. (3) and simplifying them, Eq. (5) can be obtained.

$$MaxJ(w) = \frac{w^T s_b w}{w^T s_w w} \tag{5}$$

Eq. (5) is the generalized Rayleigh quotient. In practical applications, most data samples are two or more categories. In this case, the optimization objective of LDA sample classification can be rewritten as Eq. (6).

$$\frac{W^T S_b W}{W^T S_w W} \tag{6}$$

In Eq. (6), S_b refers to the inter class discrete matrix of the sample points. S_w refers to the intra class discrete matrix of the data sample. S_b is shown in Eq. (7).

$$S_b = \sum_{c=1}^{k} N_c(\mu_c-\mu)(\mu_c-\mu)^T \tag{7}$$

S_w is displayed in Eq. (8).

$$S_w = \sum_{c=1}^{k}\sum_{x\in X_c}(x-\mu_c)(x-\mu_c)^T \tag{8}$$

From Eq. (7) and Eq. (8), the optimization objectives of two-class LDA cannot optimize multi-class LDA objectives. Therefore, other optimization methods are adopted to optimize multi-class LDA. The optimization objective function of multi-class LDA can be defined, as displayed in Eq. (9).

$$MaxJ(W) = \frac{\prod_{diag} W^T S_b W}{\prod_{diag} W^T S_b W} \tag{9}$$

In Eq. (9), $\prod_{diag} W^T S_b W$ refers to the diagonal element product. W represents a matrix. The optimization model for

multi-class LDA can be transformed into Eq. (10).

$$MaxJ(W) = \prod_{i-1}^{d} \frac{W_i^T S_b W_i}{W_i^T S_b W_i} \quad (10)$$

LDA is a common data dimensionality reduction method. When LDA performs data dimensionality reduction, it needs to calculate the intra class and inter class divergence matrix, and matrix $S_W^{-1}S_b$. When calculating $S_W^{-1}S_b$, a Lagrangian function needs to be introduced. The maximum eigenvalue $S_W^{-1}S_b$ and corresponding eigenvector w can be calculated. Fig. 2 displays the specific process [20].

Manifold Learning is a type of machine learning method used for dimensionality reduction, aimed at discovering and utilizing the underlying structure of the data itself to reveal its intrinsic features. These methods are based on the manifold assumption, which means that high-dimensional data is actually distributed on an unknown low-dimensional manifold. This low-dimensional manifold is implant in a high-dimensional space. The implementation of manifold learning is shown in Fig. 3 [21].

The manifold learning is applied to mine the potential structures of data in high-dimensional data spaces and obtain low-dimensional manifold representations. Then, through LDA, the low-dimensional manifold is mapped to a more discriminative space. The process of constructed Transfer Learning-LDA (TL-LDA) algorithm is shown in Fig. 4.

B. Book Sorting based on AFS

A fuzzy set is a mathematical theory used to handle uncertainty and fuzzy information, which can effectively deal with fuzzy and imprecise problems. The Membership Function (MF) of fuzzy sets can be used to describe the characteristics and attributes of fuzzy sets. AFS is a form of fuzzy set theory that satisfies a specific set of axioms and operational rules. These axioms and rules define the basic properties and operation methods of fuzzy sets, making the operations and reasoning of fuzzy sets consistent and reliable. AFS can model, represent, and process fuzzy concepts to solve real-world fuzzy problems. The research content of AFS includes membership functions of fuzzy sets, operation rules, feature descriptions, and inference methods, as shown in Fig. 5.

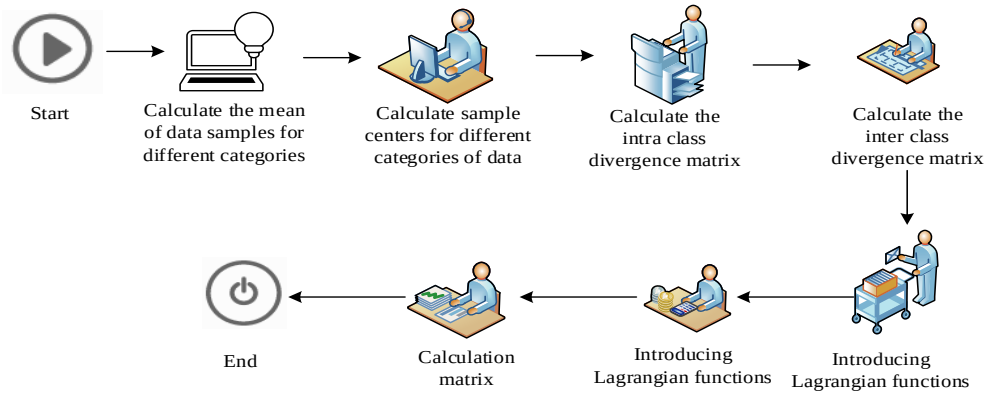

Fig. 2. LDA flow path.

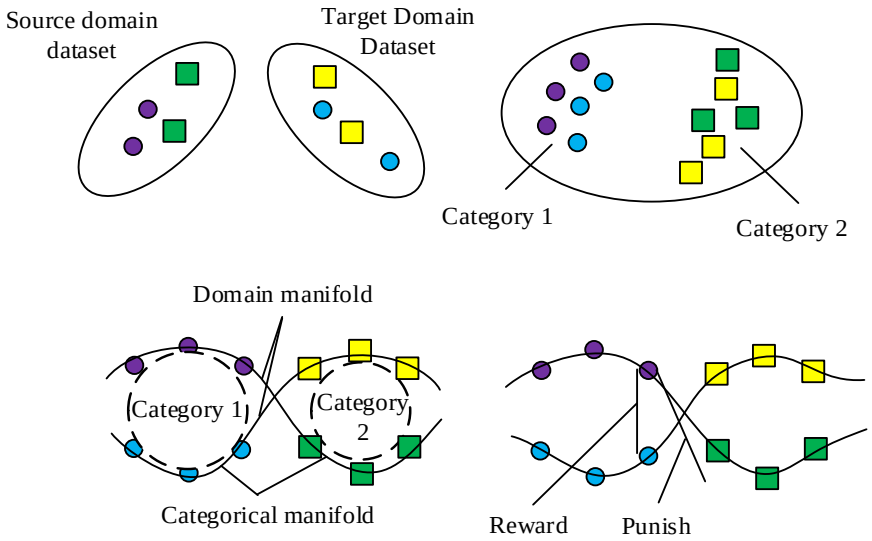

Fig. 3. The manifold learning framework.

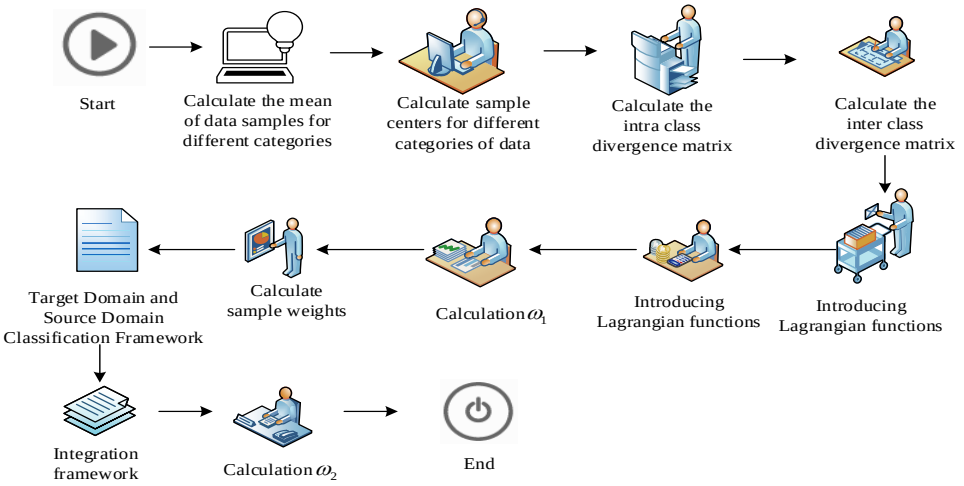

Fig. 4. Transfer learning - LDA algorithm process.

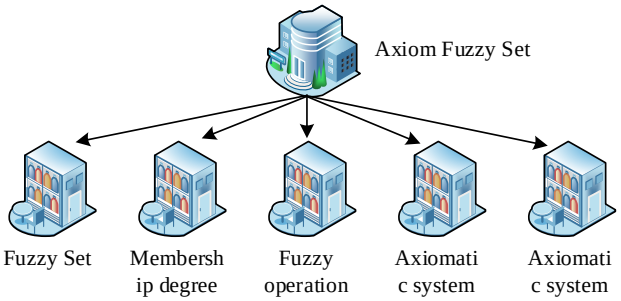

Fig. 5. Axiomatic fuzzy set of basic concepts.

Fuzzy sets refer to traditional set theory where an element either belongs to a set or not. In fuzzy set theory, the MF concept is introduced to represent the degree to which an element belongs to a certain set, which is represented by a numerical value in [0, 1]. Membership degree is the degree to which an element corresponds to a fuzzy set, reflecting the agreement between that element and the features of the fuzzy set. The MF is applied to determine the membership degree of an element in a fuzzy set. Fuzzy operations include fuzzy intersection, union and complement, which correspond to the traditional set theory. However, in their definition and operation process, the membership degree of the elements is considered. Axiom systems are designed to construct a robust fuzzy logic system. The AFS method is based on a set of strictly defined axioms that describe the basic rules that membership functions should follow, ensuring theoretical consistency and closure. Approximation reasoning refers to the reasoning process in fuzzy systems based on known information and axiomatic rules for unknown or uncertain situations. If M is assumed to be a simple set of concepts on Ω, (Ω, F, P) represents the probability measure space, and the observation dataset of (Ω, F, P) is represented as $X \subset \Omega$, (M, τ, Ω), and $(M, \tau | x, X)$. ξ is a concept that conforms to Eq. (11).

$$\xi = \sum_{i \in I} \left(\prod_{m \in A} m \right) \in EM \tag{11}$$

In Eq. (11), M represents a simple concept, which belongs to the set A. The membership function of AFS can be defined as Eq. (12).

$$\mu\xi(x) = \sup_{i \in I} \inf_{\gamma \in A_i} \frac{\sum_{u \in A_i^r} \rho_\gamma(u) N_u}{\sum_{u \in X} \rho_\gamma(u) N_u}, \forall x \in X \tag{12}$$

In Eq. (12), N_u represents the number of times sample $x \in X$ has been observed in the dataset. ρ_γ represents the weight function of a simple concept. $\rho_\gamma(x)$ is continuous on $\gamma(x)$. X is a set of randomly obtained data in probability space, and $\gamma \in M$. Then for $\forall x \in \Omega$, when $|X|$ approaches infinity, Eq. (12) can converge to Eq. (13).

$$\mu\xi(x) = \sup_{i \in I} \inf_{\gamma \in A_i} \frac{\int_{A_i^r(x)} \rho_\gamma(t) dP(t)}{\int_\Omega \rho_\gamma(t) dP(t)}, \forall x \in \Omega \tag{13}$$

After determining the membership function of the AFS structure, a book sorting model is constructed. The model uses TL-LDA to reduce the dimensionality of book data, extract the corresponding features of these data, and calculate the weight ratio of each data. AFS calculates the eligibility of each data, obtains a brief explanation, and then completes the corresponding data classification based on the brief explanation. The specific process is shown in Fig. 6.

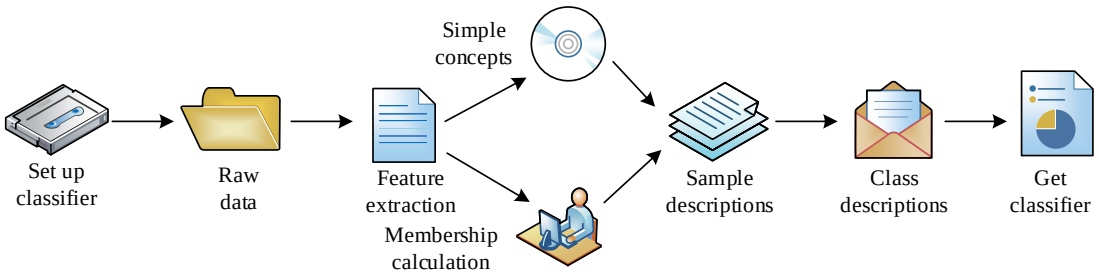

Fig. 6. Process of book sorting algorithm based on TL-LDA-AFS.

IV. Simulation Experimental Analysis of Book Sorting Model Based on LDA and AFS

In Section II, a book sorting model based on LDA and AFS is constructed. To verify the effectiveness, simulation experiments and analysis are designed on the model in Section III. Section III is divided into two parts. The first part sets the experimental environment and parameters, and the second part analyzes the simulation experiment results.

A. Experimental Environment and Parameter Settings

The experimental environment for the study is built in Python. The operating system is Windows 7 64bit, the processor is Inter (R) Core i5-12440, and the memory size is 16GB. The dataset used in the study includes the Reuters-21578 dataset, the 20 News-groups, and the Cora. Reuters-21578 is an iconic dataset in text classification, consisting of 21578 documents that provide detailed records of various major events and industry dynamics that have occurred globally. 20 The 20 News-groups is a large-scale text dataset designed specifically for research in text mining and text classification. The Cora dataset is an online document library containing approximately 37000 detailed computer science research papers in computer science research. These three datasets are used to generate 12 pairs of datasets as training and detection datasets for the model. The data ratio between the training set and the test set is 7:1, as displayed in Table I.

B. Data Dimensionality Reduction Processing Analysis

The TL-LDA performs LDA to reduce the dimensionality of the training set data. The results are shown in Fig. 7.

(a) LDA dimensionality reduction analysis

(b) One-dimensional data results

Fig. 7. LDA dimension reduction.

Fig. 7(a) shows the results of LDA dimensionality reduction on the training set data. The main data was concentrated in three regions. Fig. 7(b) shows the results of three datasets after reducing the training dataset to 1 dimension. After the data is reduced to 1 dimension, the three basic data exhibited a linear distribution. Samples of different categories may be confused within certain value ranges. The membership degree of these confused samples in specific environments is analyzed in detail to determine the MF. After the data is reduced to 1 dimension, the number of data features decreases, making it difficult for the model to distinguish these confusing samples. Therefore, reducing the dimensionality to 2D data is sufficient when performing dimensionality reduction processing. In situations with more features, more features can be applied to create fuzzy sets, which enhances classification ability. When performing discrimination, AFS can make judgments based on the membership degree on different concepts, further improving the universality and accuracy. However, it's not that having more features leads to better performance. Excessive features may lead to the curse of dimensionality in fuzzy set rules. In addition to the difficulty of model parsing, this may also consume more computing resources. Therefore, balancing the number of features is crucial for building an effective fuzzy set model. To further determine the degree of pre-processing, the accuracy between one-dimensional data and two-dimensional data is compared. The results are shown in Fig. 8.

In Fig. 8, regardless of whether the data was reduced to one-dimensional or two-dimensional, the accuracy in extracting data features continuously decreased with the increase of the ratio. When the ratio was 0.8, the accuracy of feature extraction for both dimensions decreased to the lowest. The accuracy of feature extraction for one-dimensional data was only 0.3248, while the two-dimensional data was 0.4676, which was 0.1428 higher than the one-dimensional data. When the ratio was 0.1, the accuracy of feature extraction in both dimensions increased to the highest. The accuracy of feature extraction for one-dimensional data was 0.5248, and the two-dimensional data was 0.6402, which was 0.1154 higher than that of one-dimensional data. The feature extraction accuracy of two-dimensional data was equal before the ratio was less than 0.4. The accuracy of feature extraction in one-dimensional data was always changing. When the ratio was 0.5, the accuracy of feature extraction in two-dimensional data was 0.5964, while the one-dimensional data was only 0.4856, which was 0.1008 lower than that in two-dimensional data.

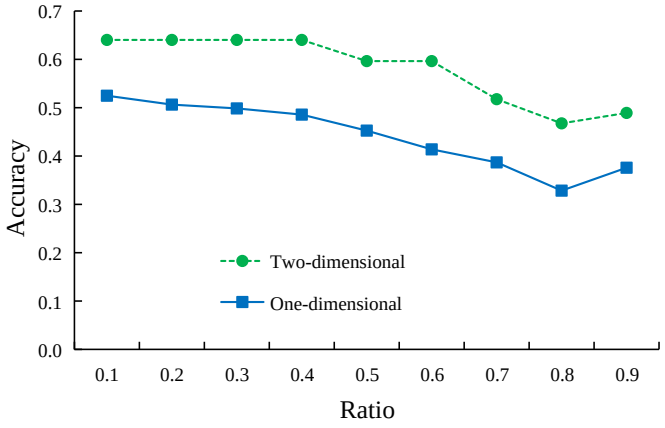

Fig. 8. Comparison of the feature extraction accuracy rate.

C. Analysis of Classification Results

After the dataset is dimensionally reduced by LDA, the membership degree is calculated using the reduced data. The results are shown in Fig. 9.

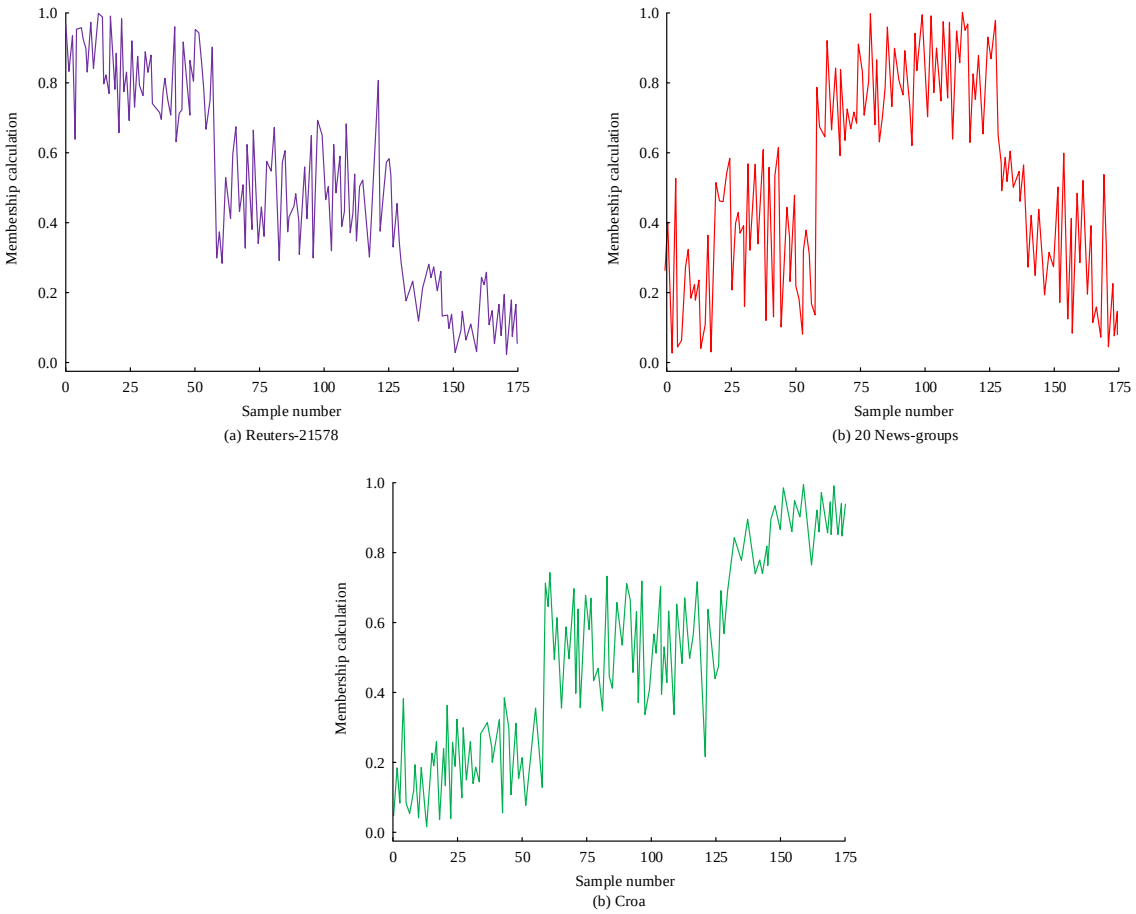

Fig. 9. Membership levels on the different datasets.

Fig. 9(a) shows the membership degree on the Reuters-21578 dataset. The membership degree of the top 50 samples was concentrated between 0.6 and 1.0. The membership degree of samples 50 to 125 was concentrated between 0.2 and 0.6. Samples 125 to 175 were concentrated between 0.0 and 0.3. Fig. 9(b) shows the membership degree on the 20 News-groups dataset. The membership degree of the top 50 samples was concentrated between 0.0 and 0.6. Samples 50 to 125 were concentrated between 0.6 and 1.0. Samples 125 to 175 were concentrated between 0.0 and 0.6. Fig. 9(c) shows the membership degree on the Cora dataset. The membership degree of the top 50 samples was concentrated between 0.0 and 0.4. Samples 50 to 125 were concentrated between 0.2 and 0.8. Samples 125 to 175 were concentrated between 0.8-1.0. The study describes the membership degrees of three datasets, as shown in Fig. 10.

Fig. 10 shows the membership degree distribution of three categories relative to all samples in the same chart. It is possible to visually observe the membership values of each category on different samples. The significant differences in membership indicate that classification decisions can be made based on these differences, thereby improving the accuracy and efficiency of classification. There are significant differences in the membership degrees of the three different datasets across all samples. Support Vector Machine (SVM), K-nearest Neighbors (KNN), Native Bayes (NB), and Logistic algorithms are commonly used classification algorithms. To verify the feasibility of TL-LDA-AFS, the accuracy and classification time of these algorithms are compared on the dataset. The results are shown in Fig. 11.

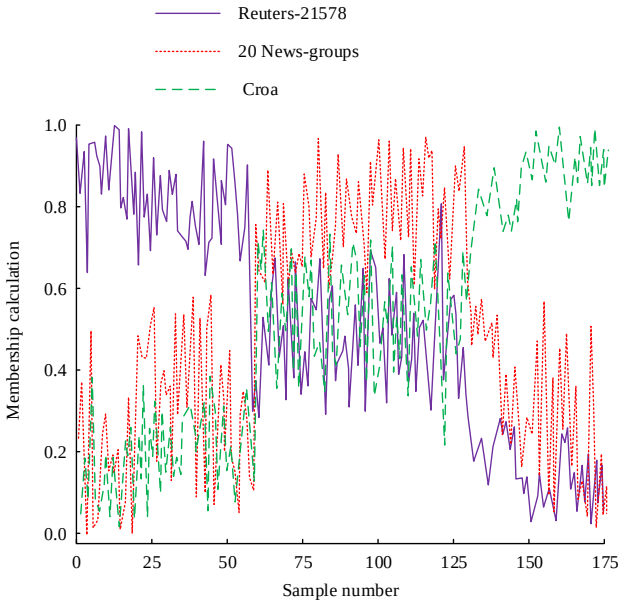

Fig. 10. Class description membership comparison.

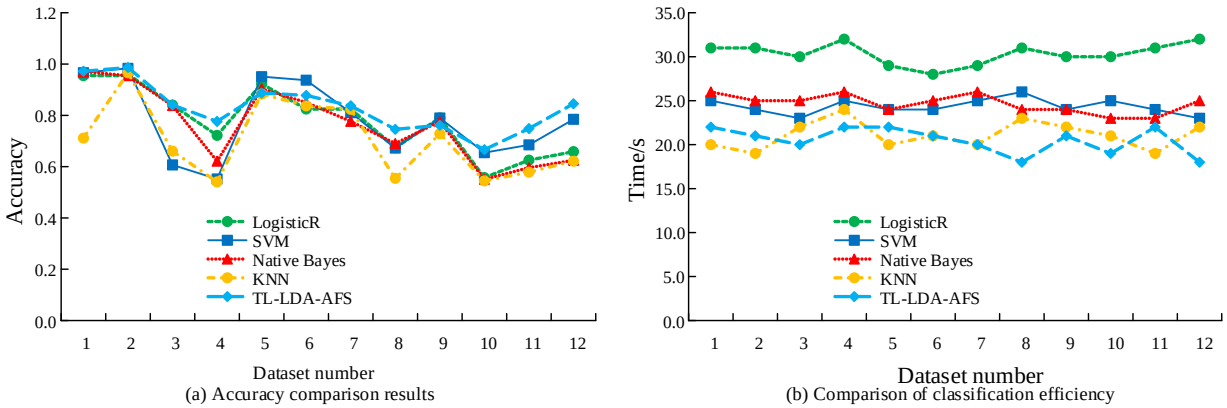

(a) Accuracy comparison results (b) Comparison of classification efficiency

Fig. 11. Model feasibility validation.

Fig. 11(a) shows the accuracy comparison. In dataset 2, all algorithms achieved the highest accuracy. The accuracy of SVM, KNN, NB, Logistic, and TL-LDA-AFS algorithms were 0.9833, 0.9660, 0.9547, 0.9600, and 0.9867, respectively. In dataset 10, all algorithms had the lowest accuracy. The accuracy of SVM, KNN, NB, Logistic, and TL-LDA-AFS algorithms were 0.6545, 0.5445, 0.5507, 0.5572, and 0.6662, respectively. Fig. 11(b) shows the algorithm time consumption. On all datasets, the TL-LDA-AFS algorithm had the lowest classification time, taking about 20s to complete the data classification. SVM, KNN, NB, and Logistic took 24s, 20 seconds, 25s, and 30s to complete data classification, respectively. Whether it is the accuracy of data classification or classification efficiency, the TL-LDA-AFS algorithm has higher accuracy. In text datasets, its performance is significantly better than other classification algorithms.

V. Discussion

A study has proposed an intelligent book classification method based on LDA and AFS to improve the efficiency and accuracy of book classification in university libraries. Asemi et al. [14] found through content review methods that intelligent systems contribute to multiple aspects of libraries. Therefore, the study adopts artificial intelligence technology to design a book sorting model. Mohammed et al. [13] used topic modeling methods to solve the classification problem of Chinese text data in digital libraries and found that latent Dirichlet allocation performed better than latent semantic allocation. Similar to the research findings, the use of artificial intelligence technology can effectively improve the level of book sorting.

The experimental results show that when the data is reduced to two-dimensional, the accuracy of feature extraction reaches 64.02%, which is significantly higher than the 52.48% of one-dimensional data. The transfer learning linear discriminant analysis axiomatic fuzzy set (TL-LDA-AFS) algorithm proposed in the study achieved the highest classification accuracy of 98.67% among all comparison algorithms, and completed data classification in approximately 20 seconds, significantly better than other commonly used classification algorithms. The intelligent book classification method based on LDA and AFS proposed in the study not only improves the accuracy and efficiency of book classification, but also provides a new intelligent solution for book management in university libraries.

VI. Conclusion

The research aims to create an intelligent book sorting system for university libraries to improve book management efficiency and user experience. Based on the LDA method, this study successfully reduces the dimensionality of multidimensional feature data to two-dimensional, making it easier to classify books more accurately. From the experimental results, when the data was reduced to 1 dimension, the three basic data exhibited a linear distribution. When the ratio was 0.8, the accuracy of feature extraction for both dimensions decreased to the lowest. The accuracy of feature extraction for one-dimensional data was only 0.3248, while the accuracy for two-dimensional data was 0.4676, which was 0.1428 higher than the one-dimensional data. The accuracy of feature extraction for LDA processed data in two-dimensional dimensionality reduction was 64.02%, which was approximately 11.54% higher than that of one-dimensional data. After comparing different classification algorithms, the TL-LDA-AFS algorithm developed in this study achieved the highest accuracy of 98.67% on dataset 2, which was the highest among all comparison algorithms. It also showed significant advantages in classification efficiency, taking only about 20s to complete classification, greatly improving the intelligence level of book sorting in university libraries. The study provides a fast and accurate intelligent book sorting algorithm for university libraries. It is expected to promote the progress of library management towards intelligence and automation, while improving the quality and efficiency of library services for teachers and students. The book sorting model designed for research has a large amount of data computation and high system load requirements when learning the feature information of different categories of books. It takes a long time to process the newly added book categories in the library, resulting in a high resource load on the book sorting system. Future research will further optimize the model's ability to learn feature information for new types of books, reduce the model's learning time for new classifications, and lower the model's burden on system resources.

Prediction of Booking Trends and Customer Demand in the Tourism and Hospitality Sector Using AI-Based Models

A Case Study of Major Hotel Chain

***Abstract*—Accurate demand forecasting is critical for optimizing operations in the tourism and hospitality sectors. This paper proposes a robust multi-algorithmic framework leveraging four advanced models of Artificial Intelligence (LSTM, Random Forest, XGBoost, and Prophet) to predict booking trends and customer demand. In contrast to traditional approaches, this study incorporates external factors such as competitors' pricing strategies, local events, and weather patterns, offering a more holistic view of demand drivers. Using a comprehensive dataset from a leading hotel chain, we systematically compare the performance of these models, providing detailed evaluations. The findings offer actionable insights for hotel managers, demonstrating how predictive analytics can inform revenue management, improve operational efficiency, and enhance marketing initiatives. These results contribute to the evolving field of demand forecasting, offering practical recommendations for data-driven decision-making in the tourism and the hospitality sector.**

***Keywords*—Artificial Intelligence; decision-making; long short-term memory; XGBoost; Random Forest; Prophet; tourism; hospitality; demand forecasting; booking trends; customer**

I. Introduction

The tourism and hospitality sector is one of the most important sectors in the world economy. The application of Artificial Intelligence has transformed this sector and other sectors [1, 2], and its support is used to enhance service quality and productivity. As more AI technologies such as machine learning, natural language processing and robotics become readily available [3], tourism and hospitality businesses can leverage them to innovate their business processes in marketing, customer service, inventory management or revenue optimization [4, 5].

Hotels, as well as other tourism service providers, face the predicament of obtaining an equilibrium between demand and supply. Overestimating the demand often lead to an overstaffing situation and waste of resources. Conversely, underestimating demand can cause a high opportunity cost of unattended customer demands and potential loss in revenue due to lack of supply. Traditional methods were designed for forecasts in those conditions where this information is close enough such as mid-term city-wide events; however, when confronted with short-term rare event related increases at a hotel caused by conferences, festivals or sudden extreme weather changes these approaches quickly outperformed given the need to incorporate variables with diverse scales as well as volatile derivatives along nonlinearity. Artificial Intelligence introduces flexible modeling that provides this improvement on classical estimation models allowing one to learn from more different sources because it can consider many exogenous factors simultaneously while capturing nonlinear relations among them.

The main problem addressed by this paper is the challenge of accurately predicting customer demand in the tourism and hospitality industry using traditional methods, which fail to account for the complexity and volatility of real-world scenarios. Hotels often experience difficulties in adjusting to sudden demand changes, leading to either overstaffing or missed revenue opportunities. The inadequacy of current forecasting approaches to include critical external factors such as competitors' pricing, local events, and unpredictable weather patterns further compounds the issue. Therefore, there is a need to develop and evaluate AI-based multi-algorithmic models capable of addressing these complexities.

This research aims to answer the following key questions:

- How can AI-based multi-algorithmic models improve the accuracy of demand forecasting in the tourism and hospitality sector?
- What is the comparative performance of advanced AI techniques such as LSTM, Random Forest, XGBoost, and Prophet in predicting booking trends?
- How do external factors, like competitors' pricing, local events, and weather conditions, influence customer demand in the hospitality industry?
- What actionable insights can hotel managers derive from AI-powered demand forecasting to optimize revenue management and operational efficiency?

The objectives of this paper are:

- To develop a comprehensive multi-algorithmic forecasting framework that combines advanced AI

models (LSTM, Random Forest, XGBoost, and Prophet) for predicting booking trends and customer demand.

- To incorporate external factors such as competitors' pricing, local events, and weather patterns into the predictive models to improve forecast accuracy.
- To systematically compare the performance of these AI models using a real-world dataset from a leading hotel chain in Morocco.
- To provide practical recommendations for hotel managers on how to use predictive analytics for better decision-making in revenue management, operational efficiency, and marketing.

The significance of this research lies in its potential to revolutionize demand forecasting in the tourism and hospitality sector through the use of AI. By developing more accurate and responsive forecasting models, this study can help hotel managers optimize their resource allocation, avoid overstaffing or under-booking, and enhance overall profitability. Furthermore, the integration of rarely considered external factors into the predictive models addresses the limitations of traditional approaches, making this research highly relevant for both academics and industry practitioners. The findings from this research can also be extended to other industries, such as retail and transportation, where demand forecasting plays a crucial role.

The paper is structured as follows: Section II provides a literature review, Section III presents the models and experimental setup, Section IV outlines the experimentation and results, Section V offers a discussion, and Section VI details future research directions, with the conclusion presented in Section VII.

II. Literature Review

A. Artificial Intelligence Technologies in Tourism and Hospitality

Artificial Intelligence technologies (machine learning, natural language processing, robotics, computer vision, augmented reality and blockchain) are increasingly employed within tourism and hospitality to produce service customer and efficient operations [5, 6]:

1) Machine learning is an algorithm able to learn from and provide recommendations or predictions depending on data is machine learning. Utilization of machine learning in tourism as well as hospitality is numerous. It can be used to predict customer preferences [7], to dynamically optimize the pricing of hotel rooms [8] as well as to optimize marketing efforts. Machine learning algorithms can analyze booking patterns and generate, based on these data, personalized travel recommendations for customers [9]. In addition, machine learning can also support inventory decision-making by demand forecasting and adjusting stocks when required [10].

2) Natural language processing is a subfield of Artificial intelligence which is focused on the interaction between computers and humans using the natural language. In tourism and hospitality, NLP is applied for chatbots and virtual assistants to answer instantly customers' questions or provide personalized recommendations [10, 11]. Furthermore, NLP helps analyzing customer feedbacks or reviews in order to extract information about customer satisfaction or points of weaknesses [12]. For instance, NLP algorithms are able to deal with huge amounts of unstructured data coming from social media or online reviews to extract trends and sentiment [13].

3) Robotics: Designing and operating machines for tasks which were previously done by humans is called robotics. Robots are used in the travel and hotel industry for chores like room cleaning, baggage handling, and check-in systems [13]. Robots may save labor expenses, improve operational efficiency, and provide visitors with an original and unforgettable experience [14, 15]. Robots with artificial intelligence, for instance, can negotiate difficult surroundings, communicate with visitors, and do highly exact jobs [16].

B. Emerging Artificial Intelligence Technologies

Beyond the well-established applications, several emerging Artificial Intelligence technologies hold promises for further transforming the tourism and hospitality sector such as Computer Vision, Voice Recognition, Augmented Reality and Blockchain:

1) Computer vision is an approach to artificial intelligence which permits machines to study and interpret visual input It is utilized in a variety of tourism-related applications. Hotels, for instance, are leveraging computer vision to ensure security by early detecting potential threats through surveillance systems [17] and facilitating automated check-ins and check-outs using facial recognition [18] as well as monitoring cleanliness and maintenance of hotel properties [19]. Computer vision is also applicable in the marketing context whereby it can capture customer demographics information as well as behaviours in retail spaces for effective product placement and promotions [20].

2) Voice recognition technology helps AI systems to understand and react to human voices. Recently, this technology is also been employed in hotel rooms. Guests can use their voice to control the room features such as lights, temperature or entertainment systems. Voice recognition promises higher convenience and guest personalization [19, 20]. Voice-activated assistants inform guests about services of the hotel, local restaurants etc., interesting spots and current weather [21]. Voice control may also help in speeding up check-in/check-out processes by reducing the time needed for filling paperwork at the front desk [22].

3) Augmented reality consists of enriching the real world with digital information. In the field of tourism, a visitor can be guided in an interactive way during his/her visit to a landmark or point of interest, or interact with virtual characters that will increase their knowledge about historic events or monuments. When booking a hotel room, customers may do a virtual tour in which they experience the look and

feel of the room through AR before taking a final decision [21, 22]. Similarly, when eating out at a restaurant, an AR system could provide a 3D visualisation of menu items and related dietary information on top of printed food menus or directly projected onto restaurant tables so as to help people make more informed choices [23]. AR has been used by destination managers to offer potential visitors immersive experiences advertising by letting them explore landscapes and other interest features without leaving home or office [24].
