# Experimental IoT System to Maintain Water Quality in Catfish Pond

Adani Bimasakti Wibisono, Riyanto Jayadi
Information Systems Management Department-BINUS Graduate Program-Master of Information Systems Management,
Bina Nusantara University, Jakarta, 11480, Indonesia

***Abstract*—This study investigates the challenges in catfish aquaculture, mainly focusing on water quality, which is crucial for successful fish farming. This research aims to implement Internet of Things (IoT) technology with sensors connected to a microcontroller to monitor and control critical parameters such as temperature, pH, and oxygen levels in catfish ponds. Utilizing NodeMCU and specific sensors, the system provides real-time monitoring, enabling early detection of environmental changes that could impact fish health. The research findings indicate IoT technology in catfish aquaculture can enhance fish health and growth. Real-time monitoring reduces the risk of diseases by providing an optimal environment for the fish. Additionally, automatic control using fuzzy logic, which can adjust email notifications automatically, and actuators such as water pumps and pH regulators that work automatically based on conditions help maintain the stability of water quality. A comparison between conventional and IoT-based farming reveals that the IoT system can reduce catfish mortality by optimizing feed distribution and regulating pH levels. Thus, this study positively contributes to developing more efficient, sustainable and healthy catfish aquaculture methods through implementing IoT technology.**

***Keywords*—*IoT; aquaculture; catfish cultivation; monitoring; controlling***

## I. Introduction

Catfish is one of the favorite fresh fish foods for the people of Indonesia [1]. Not only in Indonesia, but freshwater fish farming is also becoming increasingly popular among urban and suburban residents in sub-Saharan Africa and Asia [2]. The development of freshwater fish farming is very positive in Indonesia because it coincides with the increase in population, which is also increasing every year. If the population of Indonesia does not match the growth in the amount of food production, then the need for and availability of food will not be met [3]. Freshwater farming these days is accessible because it can be done even in places and allows people who do not work as growers. Although easy, freshwater fish farming is highly dependent on the water quality. The main problem that freshwater fish farmers face is maintaining the water quality, as this is the main factor that can kill the fish being farmed [4]. Because optimal fish farming is highly dependent on the water's physical, chemical, and biological qualities [4], [5], some of the variables that determine the quality of water in freshwater fish farming are temperature, turbidity, carbon dioxide, pH, alkalinity, ammonia, nitrite, and nitrate.

Water quality directly affects the feed efficiency, growth rate and overall health of the fish [6]. For catfish, the most critical variables are the pH and temperature of the water. Catfish can live in extreme temperatures because the water temperature varies between 25°C to 34°C; catfish are in an excellent environment to grow [3]. The pH level in good catfish water is 7-9, with a pH value that does not experience unstable changes [7]. On top of that, the height or volume of the water is also essential because it affects the temperature and oxygen levels in the fishpond being grown [7].

Therefore, catfish farmers must perform water treatments by monitoring pH, temperature, and the water level. Today, catfish farmers use ubiquitous commercial tools such as pH meters and thermometers. Conventional checks are not adequate because the checks cannot be performed continuously. With technological advances, billions of objects can perceive, communicate, and share information through a systematic network [8]. With the mobile-monitored Internet of Things, it can be done anywhere, anytime. The researcher implemented the integration of Arduino, Wi-Fi, ph sensor, temperature sensor, and ultrasonic sensor to create a monitoring system. In addition, the researchers will also integrate the system into three water pumps as actuators to raise the water level, raise the pH, and lower the pH. This system will work automatically if the sensor captures a value not good for the catfish's health. This study also aims to compare conventional systems with systems using IoT. The conventional system will check the water quality twice a week.

In contrast, the IoT system will run automatically. The treatment will be carried out with the same face for variables other than pH, temperature, and height. In this research, we utilize relatively inexpensive hardware components with a total cost of approximately 30 dollars. Our study aims to analyze whether these IoT hardware components can operate efficiently and reliably over approximately 2.5-3 months. Through meticulous experiments, we will identify the performance and durability of these devices in real-world operational conditions. Thus, we want to significantly contribute to the understanding of utilizing cost-effective hardware devices in long-term IoT system implementations.

## II. Related Work

This study highlights various approaches and advances in aquaponic monitoring and control systems through several previous studies, as in Table I. Rozie et al. [3] focused on integrating IoT and fuzzy logic for automation systems in aquaponic cultivation, providing a sophisticated approach to optimize processes.

TABLE I. RELATED WORK

| Reference | Parameters | Automatic System | Media | Monitoring Method |
|---|---|---|---|---|
| Rozie et al. [3] | Temperature, Ammonia, Oxygen, PH, TDS, Water Level, Turbidity | Yes | Wi-Fi | Telegram, Web |
| Ahmad et al. [9] | Temperature, PH, Tinggi | Yes | LoRa | FRED application |
| Sukrismon et al. [1] | Temperature, PH, Water Level, Turbidity | No | Wi-Fi | Android application |
| Billah et al. [4] | Temperature, Oxygen, PH, Water Level | No | Wi-Fi | Android application |
| Ghulam Imaduddin et al. [10] | Temperature, PH, Water Level | Yes | Wi-Fi | Website |
| Salih et al. [11] | Temperature, PH | No | Bluetooth | Android application |

| Tamim et al. [13] | Temperature, PH | No | Wi-Fi | Android application |
| Proposed system | Temperature, PH, Water Level | Yes | Wi-Fi | Website |

Ahmad et al. [9] contributed by developing a comprehensive monitoring system integrated with data analysis applications, explicitly targeting detecting fishpond anomalies. Sukrismon et al. [1] addressed water quality monitoring for catfish farming through an Android application, emphasizing the importance of real-time data for effective management. Billah et al. [4] worked on a real-time water quality system dedicated to monitoring freshwater fish farming in ponds, enhancing the understanding of environmental conditions crucial for fish health.

Ghulam Imaduddin et al. [10] conducted tests on an IoT system for catfish farming, employing conventional measurement tools to validate the effectiveness of their implementation. Salih et al. [11] designed a Bluetooth-enabled IoT system to monitor water quality in fishponds, adding a wireless connectivity dimension to the monitoring infrastructure.

Zougmore et al. [12] implemented an IoT system with SMS, Twitter, and Facebook notification features, contributing to the accessibility and immediacy of information for fish farmers. Lastly, Tamim et al. [13] explored the integration of IoT in the fish farming industry, employing MIT Apps and Google Firebase for monitoring, showcasing the versatility of technological platforms in aquaculture management. Together, these studies showcase the dynamic landscape of technological interventions to enhance efficiency and sustainability in aquaponics and fish farming practice.

## III. RESEARCH METHOD

This research focuses on developing an intelligent solution to oversee and regulate water conditions in catfish farming through aquaculture technology. The core idea of the resultant device involves the integration of multiple sensors and actuators with a microcontroller. This microcontroller is seamlessly linked to Wi-Fi and connected to a cloud-based information platform. The gathered data will be securely stored within a cloud database and presented through a website interface. This interface serves the purpose of visualizing the data and facilitating comprehensive analysis for research requirements. The system's control parameters are adjusted automatically by pre-programmed logical algorithms. The design system that has been created is shown in the Fig. 1.

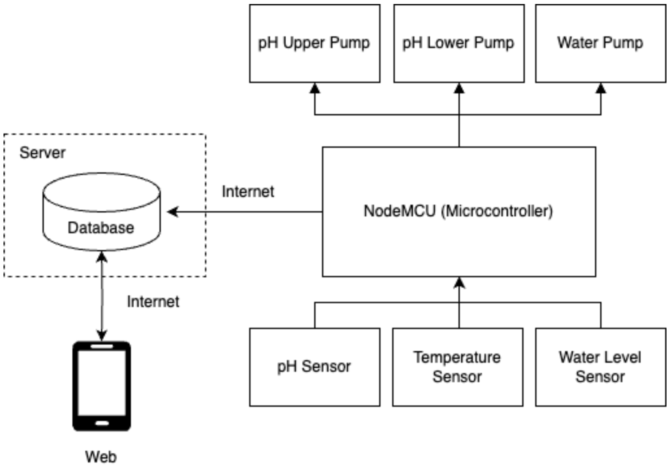

Fig. 1. System design.

The tools employed for this project encompass a set of essential components. Firstly, PhpMyAdmin serves as a pivotal tool, facilitating the management of the project's database efficiently. Secondly, Laravel, a robust framework, plays a vital role in building the project's web-based interface, ensuring seamless user interaction. Thirdly, Arduino IDE is instrumental in programming and configuring the microcontroller's functionalities, allowing it to communicate effectively with the various sensors and actuators. Lastly, MySQL is utilized as the database management system, working in tandem with the other tools to ensure efficient data storage and retrieval processes. The amalgamation of these tools forms a cohesive and comprehensive system for the intelligent control and monitoring of water quality in catfish farming.

As in Fig. 2, this design connects components such as sensors, microcontrollers and electronic components needed to build a series of systems. This hardware design focuses on the microcontroller because the microcontroller is a device responsible for controlling and automatically reading data from connected devices according to the actions taken by the user. The microcontroller used is NodeMCU 1.0, which has Wi-Fi support, which allows the device to connect to a wireless network, making it an ideal choice for this research. Apart from that, the components that must be connected to the NodeMCU include:

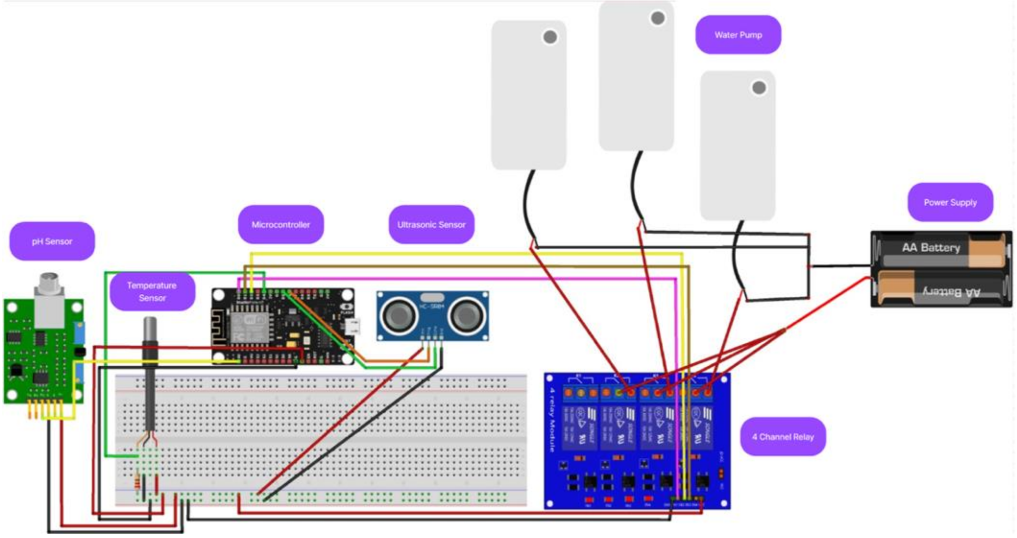

Fig. 2. Hardware design.

*1) PH Sensor (SEN0169):* The pH sensor is used by dipping it in the water of the catfish pond that is being cultivated. The pH sensor will send the captured pH value to the microcontroller. The pH sensor used in this research is the same as the pH meter commonly used today: dipping it into the water to be tested.

*2) Temperature Sensor (DS18B20):* The temperature sensor used in this research is waterproof, so it is used by immersing it in the water of the catfish pond that is being cultivated. This temperature sensor will send the captured pH value to the microcontroller. The way to use this sensor is to dip it into the water you want to check.

*3) Ultrasonic Sensor:* This sensor is a distance-measuring sensor. This sensor will be placed above the pool and facing the water surface to measure the water level. The closer the water is to this sensor, the higher the water in the pool, and vice versa.

*4) Relay Module 4 Channel:* This relay works like a switch to turn on and off the electrical components connected to it. This research will connect three electric pumps to 3 channels on this relay. This relay works according to the microcontroller readings. If the microcontroller gets a value of 1 on relay one from the database, then relay one will turn on, and so will the other channels.

## IV. Results and Discussion

In this section, we present the results of the pH sensor calibration experiment conducted to support the success of the IoT system in catfish farming. Additionally, we will explain the development of the website and database created as integral parts of this project. Furthermore, we will evaluate the outcomes of these experiments to understand how this system has positively contributed to enhancing efficiency and productivity in catfish farming.

### A. Fuzzy Rule

The proposed model uses several fuzzy inference rules which are used to determine the conditions when the water pumps used must turn on. The fuzzy rule created in the fuzzy model considers the characteristics of catfish which require water quality with the pH level in water that is good for catfish is 7 – 9 [10], the water temperature is 25℃-30℃ and does not experience unstable temperature changes [10], and the water level in the first month is 20 cm, in the second month 40 cm, and the third month 80 cm. Fuzzy rules are created so that catfish can grow well and water quality can be maximized according to the needs of catfish, thereby increasing cultivation. The fuzzy rules used for the entire system such as for reminder notifications and the three pumps used in this research are as shown in the Table II.

TABLE II. Fuzzy Rule

| Action | Conditions |
|---|---|
| pH value < 7 | The upper pH pump turns on and gives a notification alert via email |
| pH value > 9 | The pH lower pump turns on and gives a notification alert via email |
| Water height in the 1st month < 10cm | The water pump turns on and gives a notification alert via email |
| Water height in the 2nd month < 25cm | The water pump turns on and gives a notification alert via email |
| Water height in the 3rd month < 45cm | The water pump turns on and gives a notification alert via email |
| Temperature < 25 | Provides a notification alert via email |
| Temperature > 30 | Provides a notification alert via email |

### B. IoT Device

The image in Fig. 3 represents the hardware implementation within a bucket intended for catfish farming. The image shows that the ultrasonic sensor component is placed on the bucket lid facing the bottom to ensure accurate water level measurement. The microcontroller is placed inside the bucket lid of a housing to prevent direct contact with water.

Like the microcontroller, modules for sensors and relays are placed inside a box to avoid direct contact with water, minimizing the risk of electrical short circuits. Meanwhile, the three water pumps are positioned within three separate bottles containing different solutions. Each pump has its designated task, from dispensing regular water to increasing water height, pH upper solution, and pH lower solution. Three water pumps with different solutions in separate bottles allow precise control of various environmental parameters in this catfish farm. This design aims to increase productivity and environmental health for effective catfish cultivation.

### C. *Web Dashboard*

In this project, a dashboard has been developed to monitor and control IoT in devices Fig. 4, which can be accessed via the website. This dashboard uses PHP and Bootstrap programming languages for a responsive and aesthetic user interface. The primary function of this dashboard is to monitor and control IoT devices connected to the system. Through this dashboard, users can easily visualize data collected by IoT sensors, such as pH, temperature, and water level. This data, including graphs and tables, is presented in an informative and easy-to-understand format. The dashboard also displays the ON/OFF switch status of electronic devices controlled by relays.

This dashboard page also has a function for automatically sending emails based on the established logic. This functionality proves valuable for promptly notifying significant changes in the measured environmental conditions, enabling responsive actions to maintain the stability and quality of the sensor-monitored environment. The emails are directed to pre-registered email addresses using SMTP through phpMyAdmin, and a timer is implemented to prevent email spam. An example of the application of this email function can be observed in Fig. 5.

### D. *Experiments and Testing Cultivation Result*

After the tool has been successfully created, the final step is to compare cultivation using IoT and conventional cultivation. Both cultivations are carried out as possible. Both cultivations will be carried out on the same media, seeds from the same supplier, the same type of food, and in the exact location. Cultivation is carried out using catfish seeds 7-9 cm in size. For conventional catfish cultivation, temperature, pH, and height parameters will be checked, and these parameters will be measured once every 1-2 days. The weight, height and number of remaining fish will be checked every three weeks.

Cultivation was compared for 15 weeks, and cultivation results were recorded every three weeks to monitor the cultivation process. The results of the comparison of catfish cultivation can be seen in Table III below.

Internet of Things (IoT) technology in fish cultivation has profoundly transformed fish welfare. Apart from facilitating rapid growth and increasing numbers, IoT-based farming creates an optimal environment for fish. One crucial aspect is ensuring the health of the fish itself. In conventional farming, health problems often manifest as white spots on the fish's skin, signaling disease or stress that can compromise the fish's health and quality. IoT technology allows for close monitoring of the cultivation environment, enabling real-time tracking of critical parameters such as temperature, pH, and water quality. This system ensures precise control, promoting faster and healthier fish growth. Maintaining optimal temperature, balanced pH, and good water quality is essential for fish fitness and disease prevention. Early detection of environmental changes, such as declining water quality, allows for prompt preventive action.

Moreover, IoT technology facilitates accurate fish diet and nutrition monitoring, ensuring optimal growth by providing the right amount of feed at the right time. As in conventional methods, failure will regulate pH manually to avoid uneven growth and health issues. For example, overfeeding without pH regulation between weeks three and six resulted in significant fish mortality. This research significantly enhances fish farming efficiency and sustainability. By employing IoT technology for real-time monitoring, farmers can optimize environmental conditions more effectively, thereby increasing productivity and reducing losses due to unfavorable conditions. In conventional cultivation, pH control is not automated, leading to uneven growth and poor health in some fish. For instance, overfeeding during the third to sixth week caused the death of 10 catfish in non-IoT systems, while IoT-based pH regulation resulted in only five catfish deaths.

Additionally, IoT technology enables accurate monitoring of fish diet and nutrition, providing the right amount of feed at appropriate intervals. Excessive feeding can increase the pH of the water because the remaining feed contains amino acids unsuitable for catfish growth. Unlike conventional methods, where pH control is not automated, IoT-based systems ensure uniform growth and better health outcomes for fish populations. As evidenced by the results of conventional cultivation in Fig. 7, many white spots indicate unhealthy fish. It is different from Fig. 6, which is one of the results of cultivation using IoT, which does not have white spots.

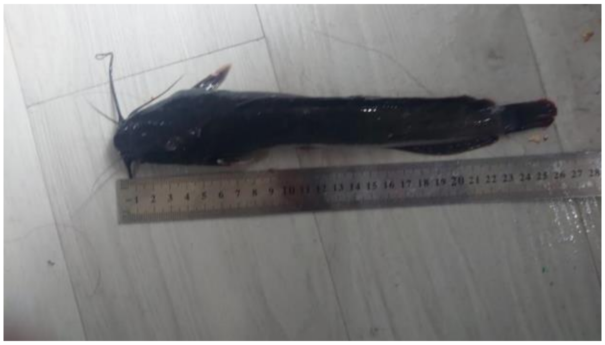

Fig. 6. Week-12 IoT cultivation.

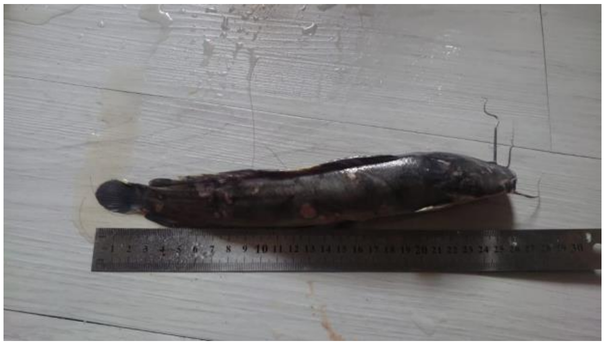

Fig. 7. Week-12 Conventional cultivation.

Future research in this area could explore integrating advanced machine learning algorithms with IoT technology to predict and prevent disease outbreaks based on water quality data and feeding intervals. Additionally, studying the long-term impacts of IoT-based agriculture on ecosystem sustainability and biodiversity can provide valuable insights into broader environmental impacts. However, it is essential to acknowledge some limitations of current research. One significant limitation is the potential cost barrier associated with implementing IoT technology in fish farming operations, particularly for small-scale farmers. Additionally, technical challenges such as sensor reliability and connectivity issues in remote agricultural locations must be overcome for widespread adoption. Fish cultivation using IoT technology yields abundant production results and creates a healthy and optimal environment for fish. By minimizing the risk of disease, enhancing growth, and ensuring adequate nutrition, this method represents an innovative way to breed fish efficiently, sustainably, and healthily.

## V. Conclusion

The findings of this research contribute significantly to new knowledge in aquaculture, particularly in the context of catfish cultivation. The integration of Internet of Things (IoT) technology represents a novel approach to monitoring and controlling water quality in catfish ponds, offering farmers unprecedented levels of access and control. By utilizing IoT devices such as pH sensors, temperature sensors, and ultrasonic sensors, farmers can continuously monitor crucial parameters in real time, regardless of their physical location. Accessing and analyzing data remotely via a web interface enhances convenience and efficiency, enabling prompt action to respond to deviations from optimal conditions.

The research demonstrates that the IoT-based method leads to significantly higher survival rates among catfish than conventional methods. The substantial difference in survival rates (16 fish remaining with IoT-based methods versus three fish remaining with conventional methods) underscores the transformative impact of IoT devices on aquaculture practices. This result highlights the effectiveness of IoT-enabled monitoring and control and suggests that these technologies can revolutionize the industry by improving productivity and profitability.

Furthermore, the research emphasizes the importance of real-time monitoring and precise control in creating optimal conditions for fish growth. By maintaining parameters such as pH and water level within the appropriate limits, IoT systems contribute to the overall health and well-being of the fish, ultimately leading to more significant, healthier harvests. This aspect is crucial for addressing the growing demand for sustainable and efficient food production, aligning with broader societal goals.

In conclusion, the study demonstrates the synergy between accessibility and effectiveness in IoT technology, offering a promising solution to enhance the sustainability and profitability of aquaculture. The results prove that IoT solutions can significantly increase yields while improving overall practices. Future research in this area could explore additional applications of IoT technology in aquaculture, investigate optimal sensor configurations, and assess long-term impacts on ecosystem health and resource management. Additionally, studies could focus on the scalability and affordability of IoT solutions to ensure widespread adoption among catfish farmers and other stakeholders in the aquaculture industry.

***Abstract*—Student performance prediction systems are crucial for improving educational outcomes in various institutions, including universities, schools, and training centers. These systems gather data from diverse sources such as examination centers, registration departments, virtual courses, and e-learning platforms. Analyzing educational data is challenging due to its vast and varied nature, and to address this, machine learning techniques are employed. Dimensionality reduction, enabled by machine learning algorithms, simplifies complex datasets, making them more manageable for analysis. In this study, the Support Vector Classification (SVC) model is used for student performance prediction. SVC is a powerful machine-learning approach for classification tasks. To further enhance the model's efficiency and accuracy, two optimization algorithms, the Sea Horse Optimization (SHO) and the Adaptive Opposition Slime Mould Algorithm (AOSMA), are integrated. Machine learning (ML) reduces complexity through techniques like feature selection and dimensionality reduction, improving the effectiveness of student performance prediction systems and enabling data-informed decisions for educators and institutions. The combination of SVC with these innovative optimization strategies highlights the study's commitment to leveraging the latest advancements in $ML$ and bio−inspired algorithms for more precise and robust student performance predictions, ultimately enhancing educational outcomes. Based on the obtained outcomes, it reveals that the SVSH model registered the best performance in predicting and categorizing the student performance with Accuracy=92.4%, Precision=93%, Recall=92%, and F1_Score=92%. Implementing SHO and AOSMA optimizers to the SVC model resulted in improvement of Accuracy evaluator outputs by 2.12% and 0.89%, respectively.**

***Keywords*—*Student performance;* Support Vector Classification*; sea horse optimization; adaptive opposition slime mould algorithm***

## I. Introduction

Academic information systems, e-learning, and admissions systems are all contributing to the growth of educational data [1]. But since it's so large and intricate, a lot of this data gets wasted. Predicting student achievement requires careful examination of these data [2]. $KDD,$ or knowledge discovery in databases, is another name for data mining ($DM$) has been successfully applied in various domains, including education, leading to the field of Educational Data Mining ($EDM$) [3], [4].

Predicting student performance is a crucial endeavor in education, primarily employing EDM [5] to forecast outcomes like passing, failing, and grades. Creating an early warning system to save expenses, save time, and maximize resources is a major emphasis in this field. By enabling educators to modify their teaching strategies and provide more assistance to students who need it, improved educational procedures may raise student achievement [6]. Students are better able to comprehend their probable course performance and make the necessary decisions thanks to these projections. Increasing student retention is one of the institution's long-term objectives as it improves graduates' reputations, rankings, and employment chances [7]. Educational institutions employ $DM$, often referred to as $EDM$, to analyze accessible data [8]. Machine learning ($ML$) algorithms provide essential tools for knowledge discovery [9]. Predicting performance accurately helps identify difficult pupils early on. By analyzing educational data, EDM supports institutions in making improvements and creating new teaching strategies. [10]. Predicting academic success, however, is difficult since there are many different elements that might influence it [11]. Technological developments have made it possible to create efficient ML techniques. New studies demonstrate how effective ML methods are in enhancing instruction [12].

## II. Related Works

Carlos et al. [13] used ML to create a student failure forecast model, achieving the highest accuracy (92.7%) with the ICRM classifier. However, they did not test the model on different educational levels due to varying student characteristics. Dorina et al. [14] created a classifier-based forecasting model for student performance. While other models fared better in identifying failure students, the MLP model had the best accuracy (73.59%) in identifying successful students. Class balance and high-dimensional data presented challenges for the model. Osmanbegovic and Suljic [15] created a model that accounts for data dimensionality and forecasts academic achievement in students. After testing many classifiers, Naïve Bayes achieved the maximum accuracy of $76.65\%$ ; nevertheless, the model did not address the problem of class imbalance. In addressing course dropouts, an $EDM$ challenge [16] employed four data mining methods with various attribute combinations. With the use of certain predictors, the support vector machine model produced the best accurate categorization. However, because student knowledge may have grown throughout the course, it was limited to incorporating earned marks from required courses. Ajay et al. [17] researched predicting student performance, introducing the "CAT" social factor. This factor classifies Indians based on social status, which influences education. They employed four classifiers

(OneR, MLP, J48, and IB1) on the dataset, with the $IB1$ model achieving the highest accuracy at 82%.

Ramanathan et al. [18] aimed to enhance the $ID3$ model for forecasting student academic performance. The ID3 model's weakness was inefficiently selecting attributes with numerous values as nodes, resulting in suboptimal trees. The proposed model addressed this issue and produced two output classes (Pass and Fail). Upon testing many classifiers, including J48, wID3, and Naïve Bayes, the wID3 classifier demonstrated an impressive 93% accuracy. Dech Thammasiri et al. [19] introduced a model to predict poor academic performance among freshmen. They utilized four classification methods and three balancing techniques to address class imbalance. The most accurate result, with 90.24% overall accuracy, was achieved by combining the support vector machine with SMOTE.

The research proposed a prediction approach for online student learning performance utilizing learning portfolio data [20]. The findings showed that time-dependent variable-incorporating approaches were more accurate than those that did not. It is important to remember, nonetheless, that the model was not evaluated in an offline mode, when the introduction of time-dependent characteristics would have led to a drop in performance. Contrary to previous assumptions, Natek and Zwilling [21] emphasized data mining's suitability for tiny datasets. It demonstrated a model for predicting student achievement using three decision tree techniques and a small dataset, with Reptree obtaining an accuracy rate of more than 90%.

However, the model did not handle issues with class balance or large data dimensionality. Marbouti et al. [22] introduced an ensemble model for identifying underperforming students, comprising classifiers like NB, SVM, and KNN. The dataset featured a crucial attribute: standard-based grading assessment alongside the usual score-based grading. When compared to six individual classifiers, the ensemble model achieved the highest accuracy at 85%. To address multiclass classification issues in student performance prediction, a multi-level model was proposed in a study [23]. Enhancing both the overall model accuracy and the accuracy of each classifier separately was the aim. The model has two stages: J48 was chosen for the subsequent level after resampling and four classifiers were used in the first level. After removing outliers, resampling with J48 at the second level produced predictions for each class that were above 90% accurate overall. Costa et al. [24] introduced a model for early student failure diagnosis that evaluates preprocessing and data mining strategies. ANNs, decision trees, support vector machines, and naïve Bayes were among the models and approaches used. Support vector machines fared better than the others, according to the findings. Although information was gathered from two different sources, the model did not take the decrease in categorization mistakes into account.

This research is paramount in its aim to develop a sophisticated ML model for predicting student performance, leveraging data from reliable sources. The cornerstone of this study is the implementation of the Support Vector Classification (SVC) technique, chosen for its effectiveness in handling the inherent complexities of high-dimensional datasets in the educational domain. The decision to focus on student performance prediction is underscored by the critical role it plays in shaping educational outcomes. What sets this study apart is the innovative integration of two optimization algorithms, namely the Sea Horse Optimization (SHO) and the Adaptive Opposition Slime Mould Algorithm (AOSMA), seamlessly woven into the fabric of the SVC model. This unique combination of techniques represents a novel approach, seeking not only to predict student performance but to elevate the precision and accuracy of the predictive model. The integration of SHO and AOSMA introduces a layer of sophistication, bringing forth the potential to enhance the model's predictive capabilities. These optimization algorithms are strategically applied, each contributing its unique strengths to the overall optimization process. The $SHO$ algorithm, inspired by the efficient and adaptive nature of sea-horses, aims to refine the predictive model by iteratively fine-tuning parameters.

On the other hand, the AOSMA, drawing inspiration from the efficient behaviors of slime molds, further contributes by guiding the model toward optimal solutions. SVC emerges as a fitting choice for predicting student performance due to its ability to discern non-linear relationships within intricate datasets. It operates by identifying decision boundaries that maximize the separation between different performance classes, enabling the classification of students into distinct categories such as success or failure. The intricate nature of educational data demands a tool that can navigate through complexities, and SVC proves to be a valuable asset in this regard. The ultimate goal of this study is not only to predict student performance accurately but also to contribute to the broader landscape of educational decision-making. The integration of cutting-edge optimization algorithms with a powerful machine learning technique like SVC positions this research at the forefront of innovation in educational data analysis. By seamlessly blending theory and practice, this study offers a glimpse into the potential advancements that can be made in refining and improving predictive models for student performance in educational settings. Related works is given in Section II. Section III delves into research methodology. An elaborate explanation of the data and an assessment of the models based on metrics will be provided. In Section IV, the results derived from the training and testing phases will be scrutinized, and subsequently, the performance of the models based on classification will be reported. Finally, in Section V, conclusions regarding the study in question and the overall performance of the models will be presented.

## III. Research Methodology

### A. Data Processing

Creating a reliable approach for precisely evaluating students' academic performance and the several contextual elements that affect it is the main goal of this project. This can only be accomplished by doing necessary preprocessing on the original dataset. First, textual input must be transformed into numerical values. This is a necessary precondition for doing machine learning tasks. This translation enables the use of sophisticated statistical methods and aids efficient data processing. 649 datasets are included in the dataset, which includes a wide range of characteristics that may have an impact on students' academic performance. These variables include school, sex, age, residence in an urban or rural area ($address$), parental cohabitation status ($Pstatus$), family size ($famsize$), parental education and occupations ($Medu, Fedu, Mjob,$ and $Fjob$), school choice motivation (reason), guardian, travel time from home to school, study time each week, past class failures ($failures$), participation in supplemental education ($schoolsup$), family educational support ($famsup$), extracurricular activities, nursery school attendance, aspiration for higher education, internet access, romantic relationships, family relationship quality, free time, socializing frequency, weekday ($Dalc$) and weekend ($Walc$) alcohol consumption, and student absences. This study's main objective is to forecast and categorize students' academic achievement based on the variable $G3$, which represents final grades from school reports that range from zero (lowest grade) to twenty (highest grade). Four separate levels are assigned to these grades: A more detailed evaluation of student success is made possible by the classifications of Poor $(0-12)$, Acceptable $(12-14)$, Good $(14-16)$, and Excellent $(16-20)$. In the end, this method aims to improve educational practices and policy formation by offering a thorough framework for comprehending and measuring academic achievement within a variety of contextual elements.

Fig. 1 presents a correlation matrix encompassing input and output variables in this study. Study time positively impacted academic performance, while previous failures had a negative effect. Internet access and aspirations for higher education had positive influences, contrasting alcohol consumption's negative impact. Parental education, particularly mothers', positively affected grades. Daily/weekly alcohol consumption, past failures, and student age influenced school grades.

In conclusion, the matrix emphasizes how crucial study time and parental education are to scholastic achievement. The dataset was obtained from two secondary schools for Mathematics subject [25]. It comprised 32 input features, including demographic information, social features, and grades, along with a single output denoted as the final grade (G3). Datasets were amalgamated to facilitate a feature selection method in this study. The dataset underwent simplification through the normalization of input features within the range of [0,1].

In the data preprocessing phase, the inherent complexity of educational data was addressed through a robust pipeline. The process included identifying and handling missing or erroneous data points to ensure dataset integrity. Additionally, numerical features were standardized to a common scale to prevent bias arising from varying magnitudes. Categorical variables were encoded to facilitate machine learning algorithms in interpreting and learning from the data.

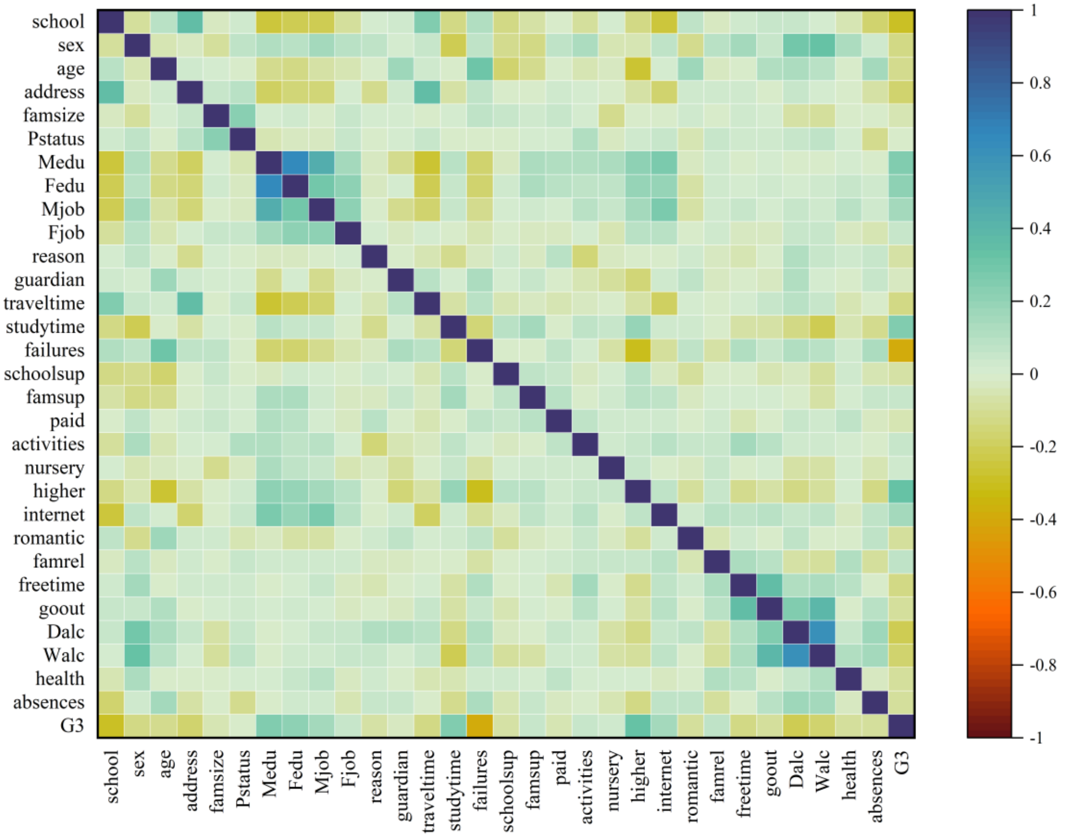

Fig. 1. Correlation matrix for the input and output variables.

## B. Evaluation of Models' Applicability

Accuracy is a widely used indicator to evaluate a model's overall performance in classification challenges. True Positives $(TP)$, False Positives $(FP)$, True Negatives $(TN)$, and False Negatives $(FN)$ are its four essential building blocks. Correct forecasts are represented by $TP$, accurate negative predictions by $TN$, inaccurate positive predictions by $FP$, and incorrect negative predictions by $FN$.

Accuracy, however, has limits when dealing with uneven data since it favors the majority class and offers no new information. Three further assessment metrics Precision, Recall, and F1-Score are used to solve this.

*1) Recall:* This metric evaluates a model's ability to identify all relevant instances within a specific class correctly. It is crucial for reducing $FN$, instances that should be identified but are missed.

*2) Precision:* Precision assesses the accuracy of positive predictions made by the model, reducing False Positives, which are instances predicted as positive but do not belong to the class.

*3) F1-Score:* A fair evaluation of the model's performance is provided by the F1-Score, which combines Precision and Recall. When considering both minority and majority classes in unbalanced data sets, it is invaluable.

Together, these metrics which are described by mathematical formulas (Eq. (1) through Eq. (4)) offer a more thorough knowledge of the efficacy of a categorization model. They are especially helpful in addressing class disparities that may skew how accuracy is interpreted. Researchers and data analysts may enhance model performance by using these indicators to make better-informed judgments and modifications, especially in challenging imbalanced data situations.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{1}$$

$$Precision = \frac{TP}{TP+FP} \tag{2}$$

$$Recall = TPR = \frac{TP}{P} = \frac{TP}{TP+FN} \tag{3}$$

$$F1\_score = \frac{2\times Recall \times Precision}{Recall+Precision} \tag{4}$$

## C. Support Vector Classification (SVC)

Support Vector Classification is an algorithm rooted in the structured principle of minimizing risk within the framework of support vector machines [26]. Non-linear transformations are applied to the independent variables, projecting them into a high-dimensional space. In this space, an optimal hyperplane is constructed to separate both classes. The primary goal of this hyperplane is to minimize classification errors while simultaneously maximizing the margins, which represent the total distance from the hyperplane to the closest training samples of each class [27].

The primary model is subsequently shown in Eq. (5) to Eq. (7) [28].

$$min_{w,b,\in} \frac{\|W\|^2}{2} + C_{svc} \sum_{i=1}^{N} \in_i \tag{5}$$

$$y_i(w^T.\emptyset(x_i) + b) \geq 1 - \in_i \qquad i = 1,\dots,N \tag{6}$$

$$\in_i \geq 0 \qquad i = 1,\dots,N \tag{7}$$

The function $\emptyset(x_i)$ is a non-linear transformation that takes each observation, defined by its explanatory variables $x_i$, and projects it into a higher-dimensional space.

$C_{svc}$ shows a regularization parameter

$w$ represents the weight vector related to the explanatory variables within the newly defined space, often referred to as the "feature space."

$b$ signifies a biased term.

$\in_i$ represent slack variables that indicate the gap or distance between the individual observations $(i)$ and the boundary of the margin associated with their respective classes.

Discovering the ideal hyperplane (see Eq. (8)), which maximizes the margin within the high-dimensional space, is essentially a process of minimizing the norm of the weight vector while also minimizing the count of misclassified instances. Ultimately, the labels or output variables denote the class to which each sample belongs.

$$D(x_i) = W^T\varphi(x_i) + b \tag{8}$$

The scale of the primal model is contingent upon the dimensionality of the problem, whereas the dual form is contingent on the number of samples. Therefore, when the dimensionality is sufficiently high, it becomes more advantageous to address the dual model Eq. (9) to Eq. (11).

$$max_a \sum_{i=1}^{N} a_i - \frac{1}{2}\sum_{i=1}^{N} a_i a_j y_i y_j K(x_i, x_j) \tag{9}$$

$$\sum_{i=1}^{N} a_i y_i = 0 \tag{10}$$

$$0 \leq a_i \leq C_{svc} \qquad i = 1,\dots,N \tag{11}$$

A Kernel function, denoted as $K(x_i, x_j)$, maps each pair of data points to a corresponding location in the feature space. There are various Kernel functions available, including linear, polynomial, radial basis, sigmoidal, and others. The key requirement for these functions is that they must be symmetric, positive, and semi-definite. Prior research in this field has demonstrated that the radial basis Kernel function, as defined in Eq. (12), is particularly well-suited for classification tasks [29]. Therefore, a radial basis Kernel function is employed with 'γ' serving as a hyperparameter that signifies the inverse of the range of influence of the data points identified as support vectors [30].

$$K(x_i, x_j) = \emptyset(x_i)^R\emptyset(x_j) = exp(-\gamma\|x_j - x_i\|) \tag{12}$$

Once the model has been solved to estimate the weights and the bias term, predictions for new samples can be made using Eq. (13).

$$SVC \quad y_i = \begin{cases} -1 \; if \; w^T\emptyset(x_i) + b \;\leq 0 \\ 1 \; if \; w^T\emptyset(x_i) + b \; > 0 \end{cases} \tag{13}$$

### D. Sea Horse Optimization (SHO)

The Sea Horse Optimization (SHO) is a novel metaheuristic inspired by the distinctive behaviors of sea horses [31]. Sea horses display unique mobility patterns, such as periodically wrapping their tails around algal stems in response to oceanic currents and exhibiting Brownian motion-like movements when suspended upside-down. Their specialized head shape enables stealthy predatory approaches with an impressive 90% success rate. Sea horses reproduce through random pairings, allowing their offspring to inherit advantageous traits. These behaviors, encompassing mobility, predatory tactics, and breeding, form the core principles of the SHO algorithm. SHO harnesses the power of swarm intelligence to adapt and optimize solutions, emulating the sea horse's ability to thrive in its environment. This innovative metaheuristic leverages insights from nature to address complex problems efficiently.

The SHO algorithm consists of four key stages, namely, (1) initialization, (2) emulating mobility behavior, (3) simulating predation behavior, and (4) replicating breeding behavior observed in sea horses. Detailed descriptions of each of these stages are provided in the subsequent subsections.

*1) Initialization stage:* Similar to numerous other metaheuristic algorithms, the SHO commences by initializing the population. In this context, the population of sea horses represents potential problem solutions within the search space, which can be mathematically expressed using Eq. (14):

$$S = \begin{bmatrix} x_1^1 & \dots & x_1^D \\ \dots & \dots & \dots \\ x_P^1 & \dots & x_P^D \end{bmatrix} \tag{14}$$

In Eq. (14), D stands for the variable's dimensionality, P indicates the population's size, and s denotes the sea horses present within the population.

In creating each solution, the problem's upper bound (UB) and lower bound (LB) are employed as initial reference points for random generation. Eq. (15) and Eq. (16) delineate the procedure for generating the $i-th$ individual, denoted as $X_i$, within the search space [LB, UB].

$$X_i = [x_i^1, \dots, x_i^D] \tag{15}$$

$$x_i^j = rand * (UB^j - LB^j) + LB^j \tag{16}$$

The term $rand$ represents a random number within the range [0, 1]. The variable $j$ is an integer ranging from 1 to D, where D signifies the dimensionality of the problem. The variable $i$ is a positive integer ranging from 1 to P, with P representing the population size. The notation $x_i^j$ refers to the $j-th$ dimension of the i-th individual within the population. The upper and lower bounds for the $j-th$ variable in the optimized problem is denoted as $UB^j$ and $LB^j$, respectively.

In the context of a minimum optimization problem, the individual with the lowest fitness level is designated as $X_{best}$, representing the optimal solution. Conversely, in a maximum optimization problem, $X_{best}$ corresponds to the individual with the highest fitness level. The value of $X_{best}$ can be determined using Eq. (17):

$$X_{best} = \arg_{\min or \max}\,(f(X_i)) \tag{17}$$

In the above formula, $f(X_i)$ represents the value of the objective function for a specific task.

*2) Movement behavior stage:* Sea horses exhibit movement patterns that are akin to a normally distributed random distribution (0,1), resulting in a variety of motion behaviors. To strike a balance between exploiting known information and exploring new possibilities, the algorithm sets a cut-off point at $r_1 = 0$. This means that half of the sea horses are directed towards local search, while the remaining half focus on global exploration. The algorithm's subsequent stages are then employed to manage and further define the motion behavior of these sea horses.

*a) First step:* The SHO algorithm's exploration strategy is shaped by sea horses' spiral motion, which is affected by oceanic vortexes. When the random value $r_1$ exceeds the SHO cut-off point, the algorithm prioritizes local exploitation, directing sea horses toward the optimal solution $X_{best}$. Sea horses move using Lévy flights, promoting exploration in initial iterations and avoiding excessive focus on one area. Their spiral motion includes a continuous adjustment of the rotation angle, widening the search area around local solutions. Eq. (18) is used to generate new positions for sea horses, improving the algorithm's search efficiency.

$$X_{new}^1(t+1) = X_i(t) + Levy\ (\lambda)((X_{best}(t) - X_i(t) * x * y * z + X_{best}(t))$$

$$s.t \begin{Bmatrix} x = p * \cos(\theta) \\ y = p * \sin(\theta) \\ z = p * \theta \\ p = u * e^{\theta v} \end{Bmatrix} \tag{18}$$

u and v are employed to denote the parameters of the logarithmic spiral, which govern the stem length (p). In each case of u and v, a constant of 0.05 is established. The variables x, y, and z represent the three-dimensional coordinates during the spiral motion. θ is chosen randomly from the interval [0, 2π].

Eq. (19) is employed for the computation of the Lévy flight distribution function (Levy(z)):

$$Levy(z) = s * \frac{\omega * \sigma}{|k|^{\frac{1}{\lambda}}} \tag{19}$$

$w$ and $k$ are randomly generated positive values within the range of 0 to 1. The variable $s$ remains constant with a fixed value of 0.01. $\lambda$ is chosen randomly from the range of 0 to 2, and in this context, it is specifically set to 1.5. The calculation of $\sigma$ is determined using Eq. (20).

$$\sigma = (\frac{\Gamma(1+\lambda) * \sin(\frac{\pi\lambda}{2}}{\Gamma\left(\frac{1+\lambda}{2}\right) * \lambda * 2^{(\frac{\lambda-1}{2})}}) \tag{20}$$

*b) Second step:* This algorithm phase portrays sea horses' Brownian motion as a response to oceanic waves. When $r_1$ falls to the left of the cut-off point, the SHO algorithm transitions into a drifting mode for its search. This shift is vital to avoid trapping the algorithm in local optima.

Brownian motion is employed to mimic sea horses' extended movement, enabling more efficient exploration of the search space. Eq. (21) defines the mathematical representation of this behavior.

$\beta_i$ denotes the random walk coefficient for the Brownian motion, and $l$ is a constant parameter set at a value of 0.05. The new location of the sea horse at iteration $t$ can be computed by combining the two described situations using Eq. (22).

$$X_{new}^1(t+1) = X_i(t) + rand * l * \beta_t * (X_i(t) - \beta_i * X_{best})\ s.t \left\{\beta_t = \frac{1}{\sqrt{2\pi}}\exp(-\frac{x^2}{2})\right\} \tag{21}$$

$$X_{new}^1(t+1) = \begin{cases} X_i(t) + Levy(\lambda)\left(\left(X_{best}(t) - X_i(t)\right) * x * y * z + X_{best}(t)\right), & r_1 > 0 \\ X_i(t) + rand * l * \beta_t * (X_i(t) - \beta_i * X_{best}), & r_1 \leq 0 \end{cases} \tag{22}$$

$$X_{new}^2(t+1) = \begin{cases} \alpha * (X_{best} - rand * X_{new}^1(t) + (1-\alpha) * X_{best}, & if\ \ r_2 > 0.1 \\ (1-\alpha) * (X_{new}^1(t) - rand * X_{best}) + \alpha * X_{new}^1(t), & if\ \ r_2 \leq 0.1 \end{cases} \tag{23}$$

Predation Behavior Phase: While sea horses forage for zooplankton and small crustaceans, their predation attempts can result in success or failure. To address this, the SHO algorithm introduces a random variable, $r_2$, to differentiate these outcomes. With sea horses having a high likelihood of successful hunting (over 90%), the critical threshold for $r_2$ is set at 0.1. Successful predation in SHO showcases its capability to exploit resources, guided by cues from the best solution's proximity to the prey. A successful predation happens when $r_2$ exceeds 0.1, leading the sea horse to approach, overtake, and capture the prey (best solution). In the case of unsuccessful predation, both predator and prey reverse their movements, indicating a continuation of exploration. Eq. (23) mathematically depicts this predation behavior.

$r_2$ denotes a randomly generated integer between 0 and 1, while $X_{new}^1(t)$ shows the novel location of the sea horse after moving at iteration t. The sea horse's movement step size is modified during the pursuit of prey, gradually decreasing with each iteration. This adjustment is computed using Eq. (24).

$$\alpha = \left(1 - \frac{t}{T}\right)^{\frac{2t}{T}} \tag{24}$$

T represents the maximum number of iterations in the algorithm.

*3) Breeding behavior phase:* In order to accommodate the reproductive patterns of male sea horses, the population is divided into two distinct groups, males and females, categorized according to their fitness levels. Within the framework of the SHO algorithm, the individuals with the most favorable fitness scores constitute the group of chosen fathers, while the rest of the individuals form the group of selected mothers. Eq. (25) illustrates that this partitioning of the population into male and female groups serves the purpose of preventing an over-concentration of novel strategies and encourages the transmission of beneficial traits to both mothers and fathers, ultimately benefiting the subsequent generations.

$$\begin{cases} fathers = X_{sort}^2(1{:}\frac{P}{2}) \\ mothers = X_{sort}^2(\frac{P}{2} + 1{:}\,p) \end{cases} \tag{25}$$

$X_{sort}^2$ refers to the collection of all $X_{new}^2$ solutions organized in ascending order based on their fitness values. In the context of the SHO algorithm, the mothers and fathers correspond to the female and male populations, respectively.

The SHO algorithm operates under the assumption that new offspring are created through the random mating of females and males within the population. In order to maintain the efficiency of the algorithm, it is presumed that each pair of sea horses yields only a single offspring, as evidenced in Eq. (26).

$$X_i^{offspring} = r_3 X_i^{father} + (1 - r_3) X_i^{mother} \tag{26}$$

$X_i^{father}$ and $X_i^{mother}$ denote the male and female members selected at random, respectively. $i$ takes on a positive value within the interval $[1, p/2]$, where p represents another parameter or value within the [0,1], and $r_3$ is an integer generated at random, which can take values within the range of [0, 1]. Fig. 2 shows the flowchart of SHO.

### E. Adaptive Opposition Slime Mould Algorithm (AOSMA)

The Slime Mould Algorithm is based on the oscillatory behavior observed in plasmodial slime mould. This organism utilizes a feedback mechanism that alternates between positive and negative phases along with an oscillatory pattern to determine the best path to obtain nutrients [32]. The Adaptive Opposition Slime Mould Algorithm (AOSMA) is an innovative computational method created to improve the approach behavior of slime mould. It achieves this by incorporating an adaptive decision-making mechanism that is based on opposition-based learning [33].

To construct a mathematical model for the AOSMA, it is assumed that there are a total of "N" individuals belonging to the slime mould species in question residing within the specified search space. This search space is defined by a lower boundary (LB) and an upper boundary (UB).

$X_i = (x_i^1, x_i^2, \cdots, x_i^d), \forall i \in [1, N]$ shows the location of $i - th$ slime mould in $d$-dimension and $F(X_i), \forall i = [1, N]$ denotes the fitness of the $i - th$ slime.

The following represents the fitness and positions of $N$ slime mould individuals at iteration $t$:

$$X(x) = \begin{bmatrix} x_1^1 & x_1^2 & \cdots & x_1^d \\ x_2^1 & x_2^2 & \cdots & x_2^d \\ \vdots & \vdots & \vdots & \vdots \\ x_N^1 & x_N^2 & \cdots & x_N^d \end{bmatrix} = \begin{bmatrix} X_1 \\ X_2 \\ \vdots \\ X_N \end{bmatrix} \tag{27}$$

$$F(X) = [F(X_1), F(X_2), \cdots, F(X_N)\,] \tag{28}$$

Fig. 2. Flowchart of SHO.

In the iteration at $t+1$, the slime mould's position has progressed, and its spatial arrangement has been enhanced as determined by Eq. (29):

$$X_i(t+1) = \begin{cases} X_{LB}(t) + V_d\big(W.X_A(t) - X_B(t)\big) & p_1 \geq \delta \text{ } and \text{ } p_2 < m_i \\ V_e.X_i(t) & p_1 \geq \delta \text{ } and \text{ } p_2 \geq m_i, \forall i \in [1, N] \\ rand.(UB - LB) + LB & p_1 < z \end{cases} \quad (29)$$

$X_{LB}$ represents the top-performing local slime mould while $X_A$ and $X_B$ denote individuals selected at random. The equation incorporates a weight factor (W), along with random velocities ($V_d$ and $V_e$), as well as two randomly chosen values, $p_1$ and $p_2$, within the range [0, 1]. The fixed value of $\delta = 0.03$ signifies the slime mould's initial chance to explore a random search location. Additionally, $m_i$ represents the threshold value for the i-th member in the population, which aids in determining the position of the slime mould, and this is computed according to Eq. (30) to Eq. (32)

$$m_i = tanh|F(X_i) - F_G|, \forall i \in [1, N] \quad (30)$$

$$F_G = F(X_G) \quad (31)$$

$$W\big(SortInd_F(i)\big) = \begin{cases} 1 + rand.\log\left(\frac{F_{LB} - F(X_i)}{F_{LB} - F_{Lw}} + 1\right) & 1 \leq i \leq \frac{N}{2} \\ 1 - rand.\log\left(\frac{F_{LB} - F(X_i)}{F_{LB} - F_{Lw}} + 1\right) & \frac{N}{2} < i \leq N \end{cases} \quad (32)$$

$rand$ signifies a randomly generated number within the range of 0 to 1. $F_{LB}$ and $F_{Lw}$ represent the fitness values corresponding to the local best and worst outcomes, while $F_G$ and $X_G$ stand for the global best fitness value and the associated global best position, respectively.

Sorting fitness values in ascending order can be used when dealing with a minimization problem.

$$[Sort_F, SortInd_F\ ] = sort(F) \tag{33}$$

The local best fitness values, as well as the local best slime mould $X_{LB}$, are calculated using Eq. (34-36).

$$F_{LB} = F\big(Sort_F(1)\big) \tag{34}$$

$$F_{LW} = F\big(Sort_F(N)\big) \tag{35}$$

$$X_{LB} = X\big(SortInd_F(1)\big) \tag{36}$$

The random velocities are denoted as $V_d$ and $V_e$, are defined as follows:

$$V_d \in [-d, d] \tag{37}$$

$$V_e \in [-e, e] \tag{38}$$

$$d = \operatorname{arctanh}\left(-\left(\frac{t}{T}\right) + 1\right) \tag{39}$$

$$e = 1 - \frac{t}{T} \tag{40}$$

In the context of engineering design problem-solving and optimization, the Slime Mould Algorithm (SMA) demonstrates significant potential for both exploration and exploitation. The enhancement of slime mould rules within the SMA framework is contingent on several key scenarios.

Case 1: When $p_1 \geq z$ and $p_2 < m_i$, the search guided by the local best slime mould $X_{LB}$ and two random individuals $X_A$ and $X_B$ with velocity $V_d$. This step facilitates the achievement of a balance between the activities of exploitation and exploration.

Case 2: When $p_1 \geq z$ and $p_2 \geq m_i$, the search is guided by the position of slime mould with a velocity $V_e$. This case assists in exploitation.

Case 3: When $p_1 < z$, the individual reinitializes in a defined search space. This step helps in exploration.

Case 1 illustrates that as $X_A$ and $X_B$ are two random slime moulds, the chances of obtained solutions are not managed properly in exploration and exploitation. To overcome this shortcoming, local best individual $X_{LB}$ can be replaced by $X_A$. Therefore, the $i-th$ member's position is remodeled as Eq. (41):

$$Xn_i(t) = \begin{cases} X_{LB}(t) + V_d\big(W.X_{LB}(t) - X_B(t)\big) & p_1 \geq \delta \ and\ p_2 < m_i \\ V_e.X_i(t) & p_1 \geq \delta\ and\ p_2 \geq m_i \\ rand.(UB - LB) + LB & p_1 < \delta \end{cases} \tag{41}$$

Case 2 elucidates that slime mould strategically capitalizes on a locale in its vicinity, thereby resorting to a trajectory characterized by a diminished level of fitness. To address this issue, implementing an adaptive decision mechanism presents a superior solution.

Case 3 highlights that while the Slime Mould Algorithm (SMA) supports exploration, a low δ value of 0.03 limits this aspect. To address this, introducing an auxiliary exploration component is crucial. An effective strategy involves using opposition-based learning (OBL) to determine when additional exploration is needed [34]. OBL utilizes a specific $Xop_i$ in the search space opposite to $Xni$ for each member, improving convergence and preventing local minima traps. $Xop_i$ for the $i-th$ individual in the $j-th$ dimension $(j = 1,2,\cdots,s)$ is defined accordingly. This adaptation resolves the limitations of Cases 2 and 3 in SMA.

$$Xop_i^j = \min\big(Xn_i(t)\big) + max\big(Xn_i(t)\big) - Xn_i^j(t) \tag{42}$$

The position of the $i-th$ member in the minimization problem is denoted as $Xr_i$, is defined as follows:

$$Xr_i = \begin{cases} Xop_i(t) & F(Xop_i(t)) < F\big(Xn_i(t)\big) \\ Xn_i(t) & F(Xop_i(t)) \geq F\big(Xn_i(t)\big) \end{cases} \tag{43}$$

An adaptive decision hinges on both the previous fitness value, $f(Xi(t))$, and the current fitness value, $f(Xni(t))$, when a nutrient pathway is exhausted. This scholarly writing style supports the need for further research and, as a result, improves the position for the next iteration in the following manner:

$$X_i(t+1) = \begin{cases} Xn_i(t & F(Xn_i(t)) \leq F\big(X_i(t)\big) \\ Xr_i(t) & F(Xn_i(t)) > F\big(X_i(t)\big) \end{cases}, \quad \forall i \in [1, N] \tag{44}$$

The AOSMA algorithm described above is presented in pseudocode, as depicted in Algorithm 1.

```
Algorithm 1: AOSMA Algorithm
Begin
Inputs: N, s, T, $\delta$ and select an objective function $f$ with search boundary range $[LB, UB]$.
Outputs: $X_G$ and $F_G$
Initialization: Randomly initialize the slime mould $X_i = (x_i^1, x_i^2, \cdots, x_i^d)$, $\forall i \in [1, N]$ within the search boundary $UB$ and $LB$ for initial iteration $t = 1$.
while $(t \leq T)$
    Calculate the fitness values $F(X)$ of $N$ slime mould.
    Sort the fitness value.
    Update the local best fitness $F_{LB}$ corresponding local best individual $X_{LB}$.
    Update the local worst fitness $F_{LW}$.
    Update the global best fitness $F_G$ and corresponding global best individual $X_G$.
    Update the weight $W$.
    Update the $d$
    for (each slime mould $i = 1{:}\,N$)
        Generate random numbers $p_1$ and $p_2$.
        Generate the threshold value $m_i$.
        Evaluate new slime mould position $Xn_i$
        Evaluate the fitness value of the new slime mould F($Xn_i$).
        if $(F(Xn_i) > F(X_i)$ // Adaptive decision strategy
            Estimate $Xop_i$. //Opposition-based learning
            Select $Xr_i$
        End
        Update the next iteration slime mould $X_i$
    end
    Next iteration $t = t + 1$
end
Return: Global best solution space $X_G$.
```

## IV. Results and Discussion

### A. Convergence Results

The SHO and AOSMA, two potent metaheuristic optimization algorithms, were used in this work to optimize and fine-tune the SVC model's hyperparameters, especially the hybrid models SVSH and SVAO. Improving these algorithms' prediction accuracy was the main goal. A convergence curve, measuring accuracy over 200 iterations, was used to assess the convergence of different optimization techniques, as shown in Fig. 3. This curve allowed for the evaluation of convergence progress and rate by providing a visual representation of the accuracy progression with each repetition. Although the convergence rates of the SVSH and SVAO models were originally comparable, the SVSH model eventually attained a better degree of accuracy. Interestingly, the trend line's linear shape at the 150-iteration mark revealed the ideal computing efficiency threshold for both models. SVSH showed better prediction accuracy throughout the optimization phase. This study used SHO and AOSMA to improve SVC models.

### B. Comparing Results of Predictive Models

Three prediction models were created in this study using a categorization technique to forecast students' test performance and gradually improve their future grades. The models included two others and a single Support Vector Classification (SVC) that were improved with the help of the Adaptive Opposition Slime Mould Algorithm (AOSMA) and the Sea Horse Optimization (SHO). Thirty percent of the dataset was used for test, while the remain seventy percent was used for train. For every model, Accuracy, Recall, Precision, and F1-score are shown in Table I for the training and testing stages, and Fig. 4 illustrates these values. Higher metric values during train than during test indicated that SVSH outperformed the other models in terms of train performance. The $maximum$ metric values achieved by SVSH were $Accuracy = 0.924, Precision = 0.930, Recall = 0.920, and\ F1 - score = 0.920$. In contrast, the SVC model obtained the lowest values, with $Accuracy = 0.887, Precision = 0.89, Recall = 0.89, and\ F1 - Score = 0.89$.

Based on test results (G3 values), an in-depth analysis of 649 students was carried out after data processing and a thorough assessment of the models' categorization skills throughout both the training and testing stages. These pupils were divided into four groups: Poor (which included pupils with G3 scores between 0 and 12), Acceptable (which included pupils with G3 scores between 12 and 14), Good (which included pupils with G3 scores between 14 and 20), and Excellent (which included pupils with G3 scores between 16 and 20). 82 pupils were placed in the Excellent category, 112 in the Good category, 154 in the Acceptable category, and 301 in the Poor category as a consequence of this classification. The findings of this research indicate that 46.38% of students had low academic achievement, with the remaining pupils displaying acceptable, good, and exceptional educational performance, at 23.73%, 17.26%, and 12.63%, respectively. The recall, precision, and F1-score Index values are shown in Table II and are used as assessment metrics to gauge how well the constructed models perform in terms of categorization across different student groups. A comparison study that considers each of these three Index values is presented in the next section.

*1) Precision:* A thorough evaluation of two refined models showed that the SVSH model had the greatest values in the Good and Poor groups when it came to student classification, with accuracy scores of 0.88 and 0.97, respectively. On the other hand, for the Acceptable group, the SVAO model produced a maximum precision value of 0.88. With an accuracy score of 0.97, the SVC model fared better than the others for the Excellent category.

*2) Recall:* The SVSH model showed the greatest recall values in the Acceptable and Excellent categories, with scores of 0.9 and 0.88, respectively. In contrast, the Good group's SVAO model achieved a maximum accuracy value of 0.89. The SVC model performed the best for the Poor group, with a recall score of 0.98.

*3) F1-score:* An improved F1-score indicates that the model can balance accurately detecting positive instances (precision) with including all true positive cases (recall). When all student categories are taken into account, the SVSH model performs very well, as seen by F1-scores of 0.92, 0.88, 0.88, and 0.97 for students who are categorized as Excellent, Good, Acceptable, and Poor.

In summary, when analyzing the complete dataset, the SVSH model unequivocally emerges as the top-performing predictor among all the models.

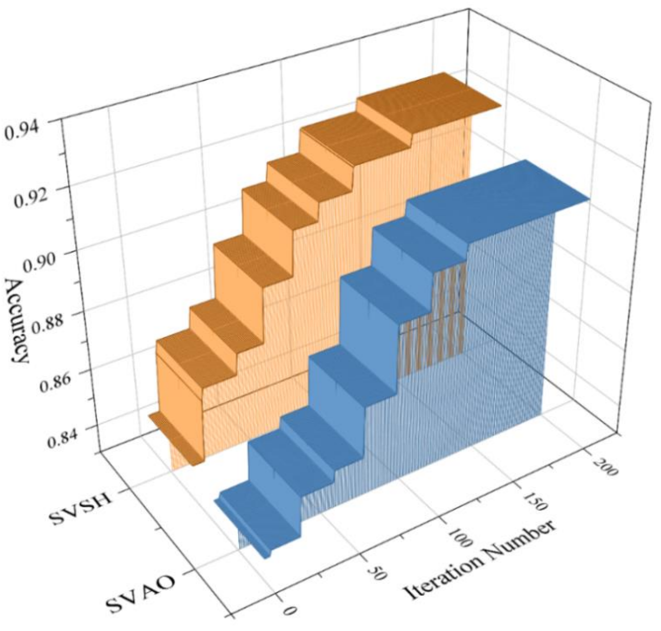

Fig. 3. Convergence curve of hybrid models.

TABLE I. RESULT OF PRESENTED MODELS

| **Model** | **Phase** | **Index values** | | | |
|---|---|---|---|---|---|
| | | ***Accuracy*** | ***Precision*** | ***Recall*** | ***F1 − Score*** |
| SVC | *Train* | 0.904 | 0.900 | 0.900 | 0.900 |
| | *Test* | 0.887 | 0.890 | 0.890 | 0.880 |
| | *All* | 0.904 | 0.900 | 0.900 | 0.900 |
| SVSH | *Train* | 0.924 | 0.930 | 0.920 | 0.920 |
| | *Test* | 0.877 | 0.880 | 0.880 | 0.880 |
| | *All* | 0.924 | 0.930 | 0.920 | 0.920 |
| SVAO | *Train* | 0.912 | 0.910 | 0.910 | 0.910 |
| | *Test* | 0.892 | 0.890 | 0.890 | 0.890 |
| | *All* | 0.912 | 0.910 | 0.910 | 0.910 |

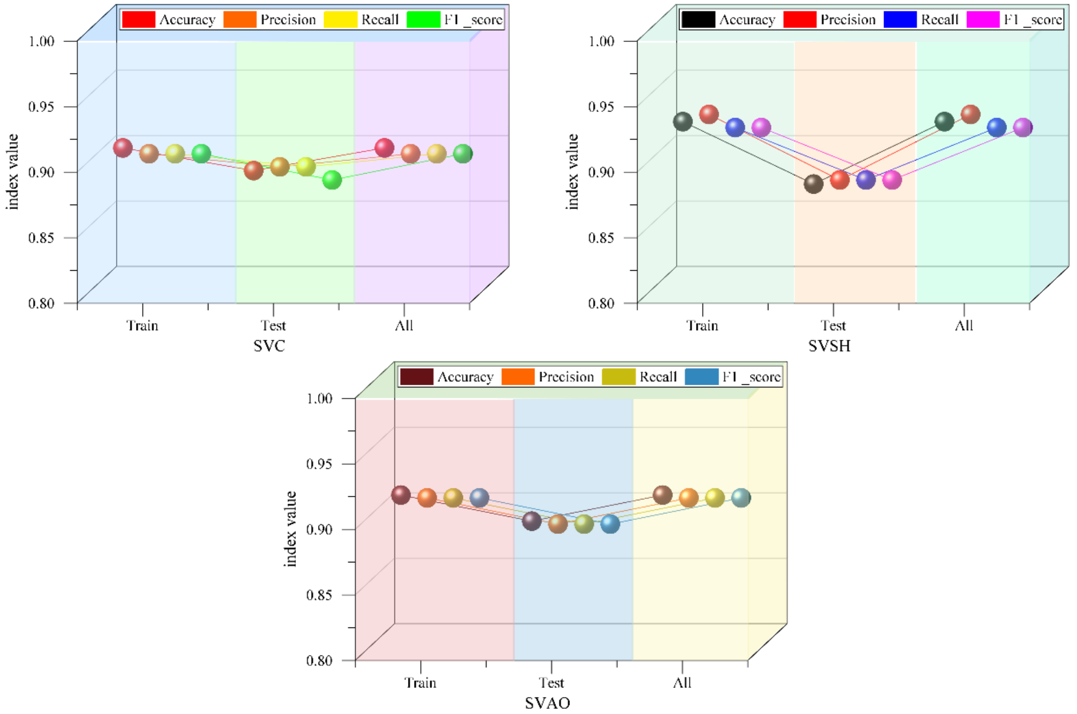

Fig. 4. Models' prediction performance.

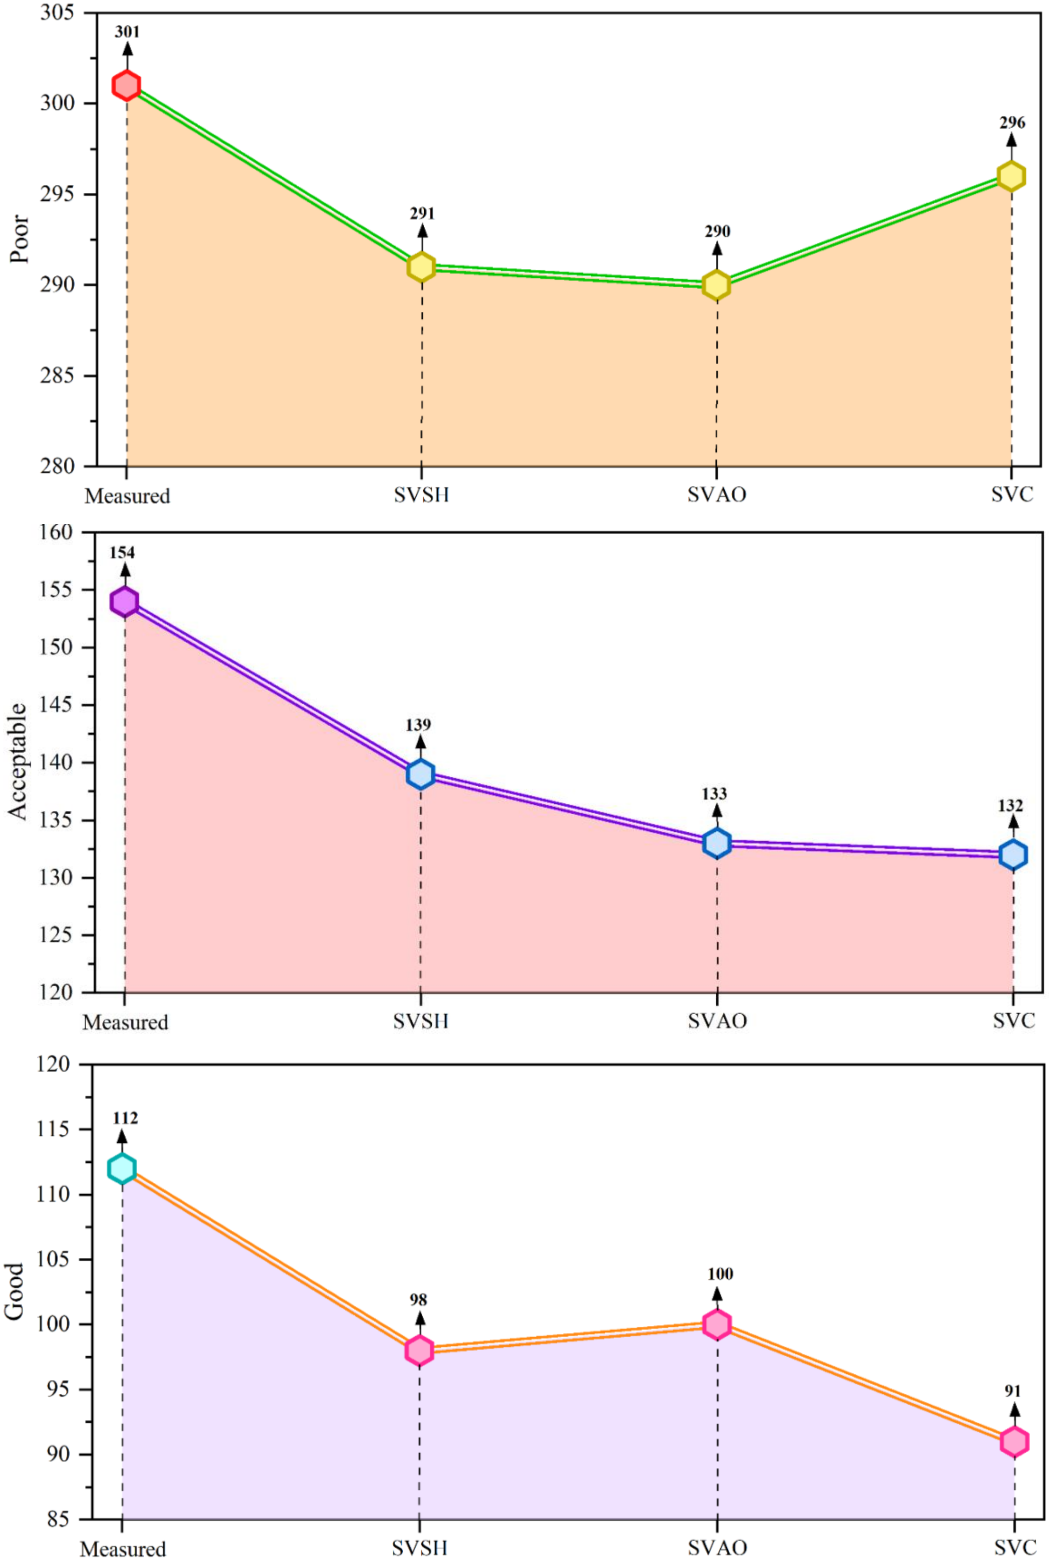
TABLE II. EVALUATION INDEXES OF THE DEVELOPED MODELS' PERFORMANCE BASED ON GRADES

| **Model** | **Grade** | **Index values** | | |
|---|---|---|---|---|
| | | ***Precision*** | ***Recall*** | ***F1 − score*** |
| SVC | *Excellent* | 0.970 | 0.830 | 0.890 |
| | *Good* | 0.830 | 0.810 | 0.820 |
| | *Acceptable* | 0.860 | 0.860 | 0.860 |
| | *Poor* | 0.930 | 0.980 | 0.960 |
| SVSH | *Excellent* | 0.960 | 0.880 | 0.920 |
| | *Good* | 0.880 | 0.880 | 0.880 |
| | *Acceptable* | 0.860 | 0.900 | 0.880 |
| | *Poor* | 0.970 | 0.970 | 0.970 |
| SVAO | *Excellent* | 0.960 | 0.840 | 0.900 |
| | *Good* | 0.810 | 0.890 | 0.850 |
| | *Acceptable* | 0.880 | 0.860 | 0.870 |
| | *Poor* | 0.960 | 0.960 | 0.960 |

There were, in fact, 301, 154, 112, and 82 kids in the Poor, Acceptable, Good, and Excellent categories. To facilitate a visual comparison, Fig. 5 presents the student distribution across these categories in a visual manner based on the results of the measurement and classification models. It is noteworthy that the SVSH model successfully classified 139 and 72 students into the Acceptable and Excellent categories, respectively, with the maximum accuracy. Classifying 296 students properly, the SVC model outperformed the other models in the Poor group. Finally, the SVAO model worked best for the Good group, correctly classifying 100 pupils.



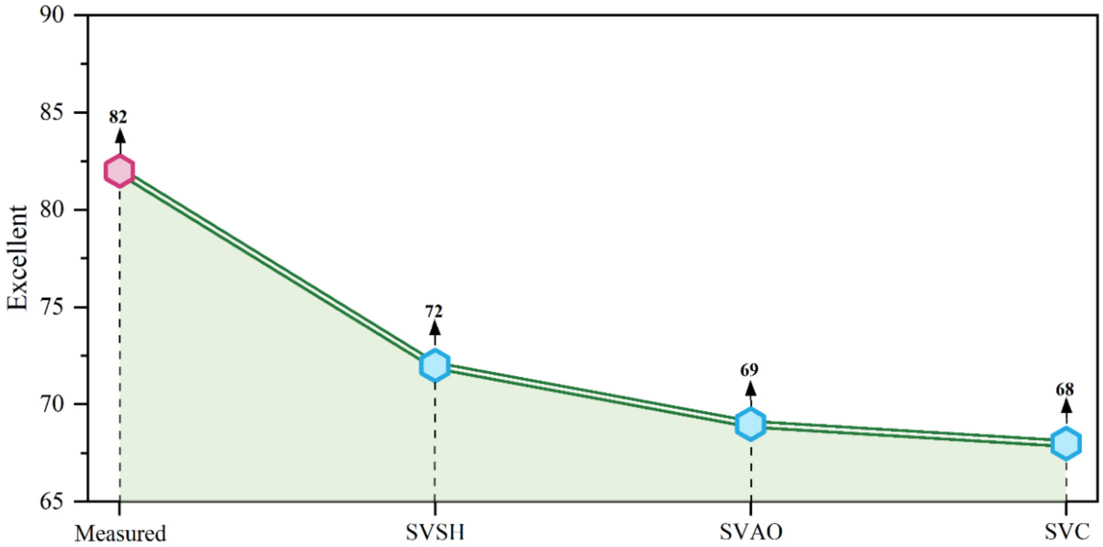


Fig. 5. Symbol-line drop plot based on measured and classification models' outcomes.

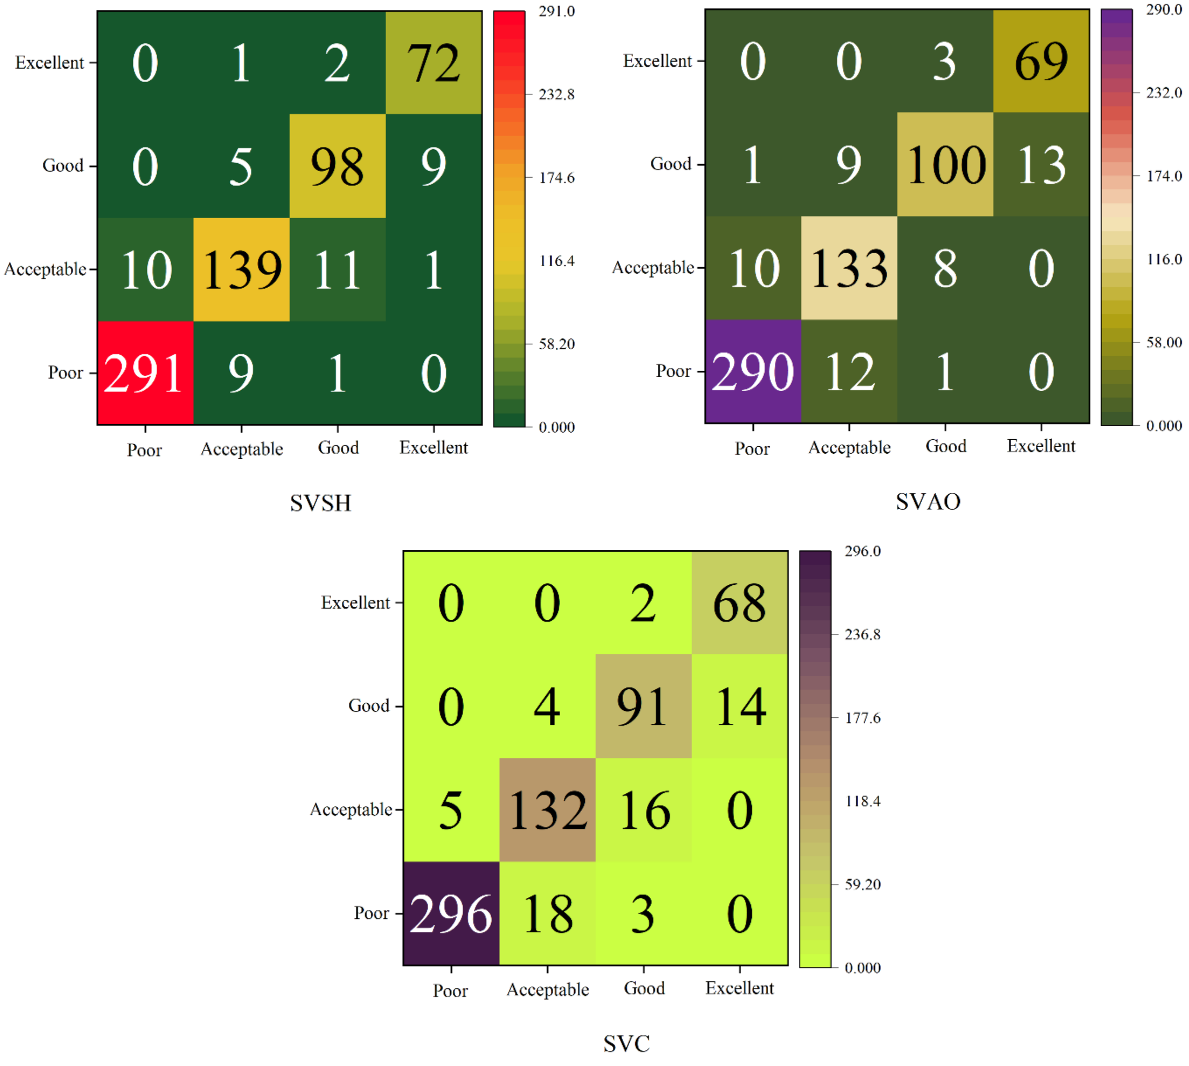

Fig. 6. Confusion matrix for each model's accuracy.

The Fig. 6 confusion matrix offers valuable information on both the proper placement of pupils in their corresponding grades and their incorrect classification into unrelated groups. In particular, just 49 students were misclassified when using the SVSH model, which properly placed 72, 98, 139, and 291 students in the Excellent, Good, Acceptable, and Poor courses, respectively. However, 57 and 62 pupils, respectively, were incorrectly categorized by the SVAO and SVC models. Notably, the two optimized models mostly misclassified students between surrounding categories. For example, students 9 and 13 for SVSH and SVAO were incorrectly put in the good group rather than the Excellent category. Three pupils were mistakenly assigned to the good category in the single SVC model, rather than the poor group. In summary, SVSH demonstrated higher predictive accuracy than the other two models in predicting students' future academic achievement.

## V. Discussion

### A. Comparison

Table III compares the accuracy of different models across studies. Pallathadka et al. [35] achieved 89% accuracy with SVM and 78% with NB. Shreem et al. [36] obtained 87% accuracy with NB. In the present study, the SVSH model achieved the highest accuracy at 92.4%, surpassing the results from previous studies. This highlights the effectiveness of the SVSH model in student performance prediction, showcasing its potential for improved accuracy compared to SVM and NB models in the referenced research.

TABLE III. Comparison with Published Papers

| Article | Model | Accuracy |
|---|---|---|
| Pallathadka et al. [35] | SVM | 89% |
| | NB | 78% |
| Shreem et al. [36] | NB | 87% |
| Present study | SVSH | 92.4% |

## VI. Conclusion

This research emphasizes the critical role that data-driven prediction models play in the field of education, stressing the value of combining quantitative and qualitative elements in the process of predicting and evaluating the academic achievement of students. It offers insightful information that will help students, academic institutions, and legislators drive future advancements in education. The study demonstrates how well data mining methods like regression, clustering, and classification work to understand and proactively handle the variety of problems college students experience. Furthermore, by combining the Support Vector Classification (SVC) model with optimization methods like Sea Horse Optimization (SHO) and the Adaptive Opposition Slime Mold Algorithm (AOSMA), the work presents a novel methodology. This innovative approach shows how optimization algorithms and sophisticated machine learning methods may improve the accuracy and efficacy of prediction models, providing a potent toolset for tackling the changing obstacles faced by students across their academic careers. It is clear from a thorough assessment approach that involves splitting the models into train and test sets that these hybrid models have the ability to greatly improve the SVC model's classification skills. The accuracy and precision are significantly improved by this addition.

Notably, the SVSH fared better than the SVAH, scoring around 2% higher in accuracy and precision.Furthermore, the SHO's success in improving classification accuracy was notable when 649 students were classified based on their final grades. With an astounding accuracy rate of 92.45%, the SVSH model in particular showed remarkable capacity to correctly categorize the majority of pupils. By comparison, 8.78% and 9.55% of all pupils were incorrectly categorized by SVAO and SVC, respectively. This demonstrates the SVSH model's higher prediction ability in correctly classifying pupils according to their final grades.

# Disease-Aware Chest X-Ray Style GAN Image Generation and CatBoost Gradient Boosted Trees

Andi Besse Firdausiah Mansur
Faculty of Computing and Information Technology in Rabigh, Jeddah, Saudi Arabia

***Abstract*—Artificial Intelligence has significantly advanced and is proficient in image classification. Even though the COVID-19 pandemic has ended, the virus is now considered to have entered an endemic phase. Historically, COVID-19 detection has predominantly depended on a single technology known as the polymerase chain reaction (PCR). The academic community is keen radiograph data to forecast COVID-19 because of its prospective advantages. The proposed methodology aims to improve dataset quality by utilizing artificially generated images produced by StyleGAN. The ratio of 59:41 was used to combine the synthetic datasets with the real ones. The combination of the StyleGAN framework, the VGG19, and CatBoost Gradient Boosted Trees is to improve prediction accuracy. Accurate and precise measurements significantly impact the evaluation of a model's performance. The assessment resulted in 98.67% accurate and 97.21% precise. In the future, we may enhance the diversity and quality of the collection by integrating other datasets from different sources with the Chest X-ray dataset.**

***Keywords—Artificial intelligence; StyleGAN; chest X-ray prediction; COVID19; CatBoost gradient boosted trees***

## I. Introduction

COVID-19, a respiratory infection commonly known as the coronavirus, has significantly affected a large portion of the global population. The latest statistics show that there have been over 243 million global infections to date. Saudi Arabia has reported over 801,000 cases of COVID-19 with a mortality rate of about 1.15%, resulting in 9,223 deaths [1,2]. Despite widespread vaccination, health precautions must still be adhered to as directed by health authorities. COVID-19 presents several symptoms including high fever, vomiting, and diarrhea. X-ray images can provide a comprehensive diagnosis to observe viruses' effects on toward human. Analyzing COVID-19 through visual inspection of X-ray pictures has open great chance to utilize artificial intelligence to thoroughly study infection areas and maybe forecast future spread. Convolutional neural networks (CNNs) are recognized as an effective method for detecting and identifying medical pictures [3,4].

Because of the nature of the requirements for autonomous disease diagnoses and faster processing with large output, the research on image analysis for chest X-rays continues to be fascinating.

In previous research, the analysis of the chest X-ray data was carried out utilizing a variety of deep learning techniques and different classifiers. Our approach, on the other hand, is distinct because we utilized the StyleGAN framework in order to enhance the quality and variety of the dataset.

These are the key components that were found in the research result, and they can be described as the primary results of this study:

*1)* Data augmentation was used to enhance the quality of the dataset by using various image preprocessing techniques, such as rotation, scaling, and flipping. The styleGAN framework was then used to build the dataset with the variety model, enhancing both the amount and diversity of the chest X-ray image dataset. The usage of computing resources is a limitation of styleGAN. This is due to the fact that larger images demand high-end GPU computation. Because of this, it is necessary to reduce the size of the photos at various points during the tuning process.

*2)* The handling of StyleGAN picture data was accomplished with the help of a VGG19 model, which resulted in higher accuracy rates than those achieved by earlier studies. Better feature mapping can be achieved by the application of the CatBoost Gradient Boosted Trees approach.

Following is the structure of the remaining parts of this paper: Section II offers a comprehensive summary of the works that are linked to this topic. Section III provides an illustration of the methodology that is utilized in the proposed model. In Section IV, the experimental performance results together with the descriptions of the dataset are offered. A concise analysis of the proposed research is presented in Section V of the document. Within Section VI, the conclusion and recommendations for the future are presented.

## II. Related Works

The GAN framework for image recognition has been used widely for medical image processing approaches. The previous research proposed system that based on Generative adversial network to produce fake image classification using Forward and Backward GAN [5]. GAN also showed its effectiveness in detecting anomalies in retinal images to compare healthy and unhealthy ones. Therefore, the lack of a dataset has driven researchers to do more exploration on the dataset. Therefore, such a Generative Adversarial Network (GAN) technique is needed to overcome the dataset's limitation [6-8]. In recent research in the Journal of Radiology, X-ray chest imagery is superior to outclassed lab testing such as PCR or rapid tests. Consequently, many researchers resolved that chest radiography detection should be used as the primary screening method for COVID-19 infection detection. Radiography images combined with AI [5, 9]. It can do massive detection and ease the work of doctors and nurses so they can use energy to treat positive patients. Computers have a significant role in diagnosing diseases. However, it can be used for measuring the chronicness and complications of the patients [7].

The model was utilized to conduct an analysis of confirmed instances of COVID-19 that occurred in acute care settings in India [10]. Through the utilization of chest X-ray images and the application of metaheuristic algorithms, K. Shankar and his colleagues developed a fusion model for the diagnosis of COVID-19 [11]. Curating a medical picture collection is a costly and laborious task that involves the collaboration of radiologists and researchers. CNNs excel at these tasks because of their extensive parameters and meticulous fine-tuning methodology. Despite having limited datasets, it is capable of performing the most effective detection and recognition process [12-14].

Utilizing this method, it allows for the incorporation of a modified dataset into the training process. Through the course of the epidemic, it has become increasingly popular to employ artificial intelligence (AI) that is equipped with deep learning capabilities in order to analyze chest X-ray pictures. The objective of this project is to develop a research technique that will enable anomalies to be identified in their radiograph pictures. Artificial intelligence was utilized by another researcher in order to identify COVID-19 through the use of coughy sounds. In order to identify and diagnose respiratory illnesses, the researchers concentrated their efforts on analyzing cough sounds coming from a variety of sources. By utilizing a support vector machine (SVM) classifier in conjunction with linear regression techniques, this was successfully accomplished. For the purpose of analyzing cough patterns and determining the severity of respiratory problems in patients, artificial neural networks (ANNs) and the random forest (RF) classifier are utilized. It is possible to identify respiratory issues such as asthma and cough by employing Wigner distribution methods in an atmosphere that is free from sounds [15-19].

In order to train on specific datasets, they made use of transfer learning models that involved two steps [20]. During the first stage of their project, they utilized a deep residual network that had been pre-trained on a big dataset pertaining to pneumonia. COVID-19 was successfully detected in X-ray images of healthy individuals as well as individuals who were sick with pneumonia. Past studies have employed several methods for data augmentation, including picture alteration, color adjustment, distortion, and enhancement [21]. An individual infected with COVID-19 may exhibit several symptoms, including fever and a cough like those of influenza. Severe cases can result in organ failure, respiratory distress, and mortality [22, 23].

Due to the rapid increase in COVID-19 cases, numerous countries are experiencing significant challenges with their healthcare systems, with many on the brink of collapse due to insufficient capacity to accommodate a high volume of patients simultaneously [24, 25]. In the past PCR is highly used as core of COVID 19 detection and even used as standard for travel requirements [26, 27]. This is sometimes referred to as a swab test. Collecting nasal or throat fluid may yield results within a few hours or days. Additionally, another method involves acquiring X-ray radiography images of the patient's chest [34].

## III. Material and Method

This section will focus on delivering the core idea of dataset generation using style GAN and CATBoost Gradient algorithm for Generating Chest X-ray Image.

### A. Chest X-Ray Dataset

Research in the field of academia has traditionally concentrated on binary classification of binary images. The Paul Cohen dataset, which has a number of different resolutions, was used to collect data from a range of sources, including healthy persons as well as patients who were diagnosed with pneumonia (see Fig. 1) [28].

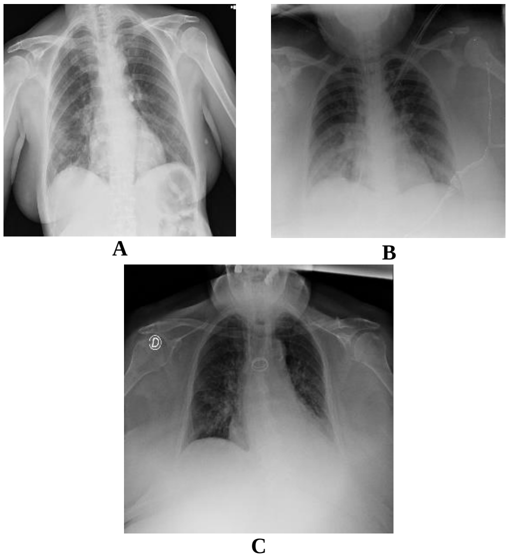

Fig. 1. Chest X-Ray dataset:A: Normal, B: Pneumonia, C:COVID-19.

### B. Style GAN Image Generator

Style GAN generator modify the input layer with learning constant. The generator incorporates the input latent code into an intermediate latent space, significantly influencing how the network represents the factors of variation. The latent space input should adhere to the probability density of the training data, resulting in inevitable entanglement to some extent [29]. A non-linear mapping network, denoted as f : Z → W, initially generates w ∈ W from a latent code z in the input latent space, first transform the input into an intermediate latent space W, which subsequently regulates the generator using adaptive instance normalization (AdaIN) at every convolution layer. Gaussian noise is incorporated following each convolution, prior to assessing the nonlinearity. The detail diagram is shown in Fig. 2.

"A" represents a trained affine transformation, whereas "B" implements trained per-channel scaling factors on the noise input. Network f comprises eight layers, while network g comprises 18 layers. The AdaIN process is defined in Eq. (1).

$$AdaIN(x_i, y) = y_{s,i} \frac{x_i - \mu(x_i)}{\sigma(x_i)} + y_{b,i} \quad (1)$$

Each feature map $x_i$ is individually normalized, then adjusted and offset using the matching scalar components from style y. The dimensionality of y is equal to two times the number of feature mappings on that layer.

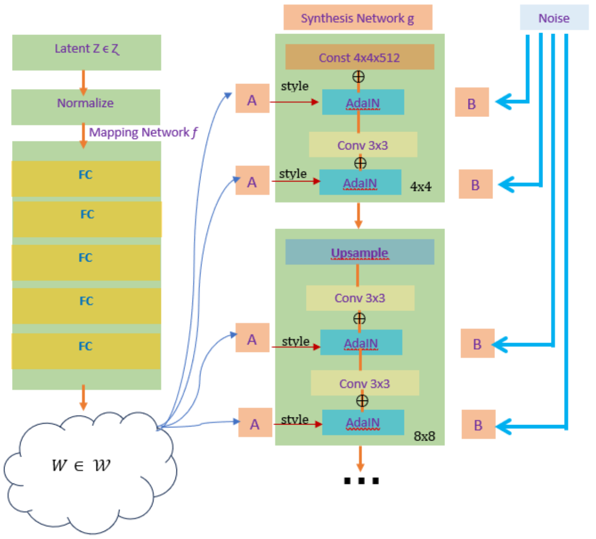

Fig. 2. Re-illustration of styleGAN architecture from Karras, T. et al [29].

### C. CatBoost Gradient Boosted Trees

In supervised machine learning, we start with a set of input values [7] and their corresponding expected output values $y_i, i \in \{1 \ldots n\}$, where i ranges from 1 to n. Gradient boosting incrementally builds a series of functions $F^0$, $F^1$, ..., $F^t$, ..., $F^m$, based on a loss function $\mathcal{L}(y_i, F^t)$. We want to highlight that $\mathcal{L}$ contains two input values: the *i*th expected output value $y_i$ and the *t*th function $F^t$ estimates $y_i$.

Once function $F^t$ is established, we can enhance our predictions of $y_i$ by determining another function $F^{t+1} = F^t + h^{t+1}(x)$ that minimizes the expected value of the loss function, as depicted in Eq. 2 [30].

$$h^{t+1} = \underset{h \in H}{argmin} \mathbb{E}\mathcal{L}(y, F^t) \qquad (2)$$

H represents the set of candidate Decision Trees being assessed to select one for inclusion in the ensemble. Moreover, based on the definition of $F^{t+1}$, we may express the expected value of the loss function $\mathcal{L}$ using $F^t$ and $h^{t+1}$, as depicted in Eq. 3.

$$\mathbb{E}\mathcal{L}(y, F^{t+1}) = \mathbb{E}\mathcal{L}(y, F^t + h^{t+1}) \qquad (3)$$

The right-hand side of Eq. (3) suggests a desire to reduce the loss function's value on y and $F^t$, along with an additional component. If we assume that $\mathcal{L}$ is continuous and differentiable, we can incorporate information about the rate of change of $\mathcal{L}$ into $F^t$ to adjust its value in the direction of $\mathcal{L}$'s decrease. Thus, by setting $h^{t+1}$ to values that align with the steepest decrease in the gradient of $\mathcal{L}$ with respect to $F^t$, we can obtain $h^{t+1}$ that minimizes $\mathbb{E}\mathcal{L}(y, F^t + h^{t+1})$. Given these conditions, we may get a practical estimate for $h^{t+1}$, as given by Eq. 4.

$$h^{t+1} \approx \underset{h \in H}{argmin} \mathbb{E} \left(\frac{\partial \mathcal{L}_y}{\partial F^t} - h\right)^2 \qquad (4)$$

This technique is called Gradient Boosting because it involves utilizing the partial derivatives (gradients) of the loss function $\mathcal{L}$ in relation to the function $F^t$ to determine $h^{t+1}$. Prokhorenkova et al. [31] highlight the challenge of computing $\underset{h \in H}{argmin} \mathbb{E} \left(\frac{\partial \mathcal{L}_y}{\partial F^t} - h\right)^2$. It may be challenging to determine the likelihood of specific values of $\underset{h \in H}{argmin} \mathbb{E} \left(\frac{\partial \mathcal{L}_y}{\partial F^t} - h\right)^2$ due to the usage of stochastic techniques such algorithms for constructing Decision Trees to define $F^t$. Therefore the equation might be modified as depicted in Eq. (5) [30].

$$\underset{h \in H}{argmin} \mathbb{E} \left(\frac{\partial \mathcal{L}_y}{\partial F^t} - h\right)^2 \approx \underset{h \in H}{argmin} \frac{1}{n} \left(\frac{\partial \mathcal{L}_y}{\partial F^t} - h\right)^2 \qquad (5)$$

We are discussing Friedman's Gradient Boosting Decision Trees technique in this section, however we refer to [31] in our explanation to ensure the reader gains a good understanding of CatBoost. To calculate an accurate estimate for $h^{t+1}$, we can use approximations Eq. (4) and Eq. (5), so the equation can be finalized as Eq. (6).

$$h^{t+1} \approx \underset{h \in H}{argmin} \frac{1}{n} \left(\frac{\partial \mathcal{L}_y}{\partial F^t} - h\right)^2 \qquad (6)$$

CatBoost employs a more efficient approach that minimizes overfitting and enables the utilization of the entire dataset for training [32]. A randomly shuffle the dataset and calculate the average label value for each example based on the examples with the same category value that come before it in the shuffled order. If $\sigma = (\sigma_1, \ldots, \sigma_n)$ be the permutation, then $x_{\sigma_p,k}$ is replaced by Eq. (7).

$$\frac{\sum_{j=1}^{p-1} \left[x_{\sigma_{j},k} = x_{\sigma_{p},k}\right] Y_{\sigma_p} + a \cdot P}{\sum_{j=1}^{p-1} \left[x_{\sigma_{j},k} = x_{\sigma_{p},k}\right] Y_{\sigma_p} + a \cdot} \qquad (7)$$

We include a previous value P and a parameter a > 0, which represents the weight of the prior. Utilizing a prior is a popular method that aids in diminishing the noise derived from low-frequency categories. The conventional method for determining the prior in regression problems is to get the average label value in the dataset.

CatBoost can create s random permutations of our training dataset. To improve the algorithm's resilience, we utilize many permutations by randomly sampling one and calculating gradients based on it. These permutations are identical to the ones employed in statistical analysis of categorical characteristics. Utilizing several permutations for training different models prevents overfitting. We train n distinct models for every permutation σ, as demonstrated below. The model includes a distinct model called $M_k$, which remains static and is not updated using a gradient estimate for this particular example.

The estimation of gradient on $X_k$ using $M_k$ and utilize this estimate to evaluate the resulting tree. Here is the pseudo-code that illustrates how to do this trick. The optimal loss function is denoted as Loss$(y, \alpha)$, where y represents the label value and

$\alpha$represents the formula value, as explained in Algorithm 1 [32].

**Algorithm 1: Gradient estimation Calculation**

```
Input: $\{(X_k, (Y_k))_{k=1}^{n}$ sorted by σ, the quantity of trees I; $\}$
$M_i \leftarrow 0\ for\ i = 1 \ldots n;$
for iter ← 1 to I do
  for i ← 1 to n do
    for j ← 1 to i-1 do
        $g_j \leftarrow \frac{d}{d\alpha} Loss(y_j, \alpha) | \alpha = M_i(X_j);$
      $M$ ←LearnOneThree$((x_j, g_j)\ for\ j = 1 \ldots i-1);$
      $M_i \leftarrow M_i + M;$
return $M_1 \ldots M_n;\ M_1(\boldsymbol{X}_1), M_2(\boldsymbol{X}_2), M_n(\boldsymbol{X}_n)$
```

CatBoost generates random permutations for our training dataset. We utilize several permutations to strengthen the algorithm's robustness. It will then utilize a random permutation sample to obtain gradients based on it. These permutations are identical to those utilized in statistical calculations for categorical attributes. Training unique models with various permutations does not result in overfitting. The training of n distinct models Mi for each permutation σ. For constructing a single tree, O(n^2) approximations need to be stored and recalculated for each permutation σ. This involves updating Mi(X1), ., Mi(Xi) for each model Mi.

## IV. Result

This section details the implementation and outcomes of creating Chest X-ray pictures using the StyleGAN technique, VGG19, and CatBoost Gradient Boosted Tree.

### A. StyleGAN Chest X-Ray Image Reconstruction

The StyleGAN technique is employed to create a new dataset by including elements from the original data. Two training components are utilized here:

*1) Step 1*: Convert the input into an intermediate latent space W, then control the generator by applying adaptive instance normalization (AdaIN) at each convolution layer.

*2) Step 2:* Gaussian noise is added after each convolution, before analyzing the nonlinearity to create the image.

The technique commences by creating counterfeit images using the StyleGAN methodology. At first glance, the painting appears to be a black canvas. After numerous iterations, the shadow gradually became visible on the chest X-ray scans. After thousands of iterations, the resulting image displayed a recognized chest X-ray image. After more than 5000 repetitions, the created image displayed a visually pleasing outcome, as depicted in Fig. 3.

### B. VGG19 Image Classification Results

We utilized single main dataset from Cohen, J.P. [28], together with a dataset created by the StylegGAN technique, as described in the preceding section. When creating an image dataset with DCGAN, the GPU's constraints limit the output to just 100 chest X-ray images in one batch. Analysis of generated images shows that around 59% of the overall dataset is represented by a subset of the StyleGAN data. The collection consists approximately 1500 artificially produced images, covering normal lung states, pneumonia, and COVID-19 instances.

The model has been trained with 5000 datasets consisting of three distinct classes: normal, pneumonia, and COVID-19. We conducted a test on 150 normal patients, 47 pneumonia cases, and 88 COVID-19 cases. We trained our model using VGG19 for 100 epochs with a batch size of 128. The proposed model achieved a training accuracy of 98.89% and a validation accuracy of the same percentage. The validation loss is 0.015. Refer to Fig. 4 for the graph. The graph shows variations during the early phases of training, which are caused by the minimal data available. To resolve this problem and guarantee consistency in the training process, extra data was later included. This instability is common in most TensorFlow training methods.

The classification result is impressive as it accurately categorizes the tested image in comparison to the original dataset. Fig. 5 illustrates the effect of the forecast made by our proposed system. Fig. 5(A) and 5(B) depict the accurate prediction of pneumonia in the original image. Fig. 5(C) was initially normal and is labeled as a normal case, then Fig. 5(D) also describes the correct prediction for COVID 19.

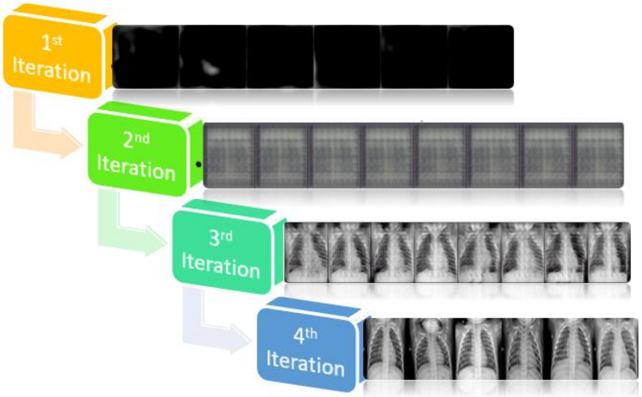

Fig. 3. StyleGAN chest X-ray image reconstruction.

A:Pneumonia;P:Pneumonia

B:Pneumonia;P:Pneumonia

C:Normal;P:Normal

D:COVID19;P:COVID19

Fig. 5. Classification result.

### C. Performance Measurement

Precision, recall, and F1 score are some of the measures that are utilized in the performance evaluation of the individual. These metrics have been defined and are frequently used. The Eq. (8) and (9) include the definitions that are considered to be standard.

$$Precision = \frac{TP}{TP+FP\prime} \tag{8}$$

$$Recall\ or\ True\ Positive\ Rate = \frac{TP}{TP+FN\prime} \tag{9}$$

where, FP, FN, TP, and TN are values that correspond to false-positive, false-negative, true-positive, and true-negative, respectively. The F1 score is a metric that is utilized to evaluate the correctness of the model, and it can be calculated by this Eq. (10):

$$F1 = \frac{2 \times precision \times recall}{precision+recall} = \frac{2TP}{2TP+FP+FN\prime} \tag{10}$$

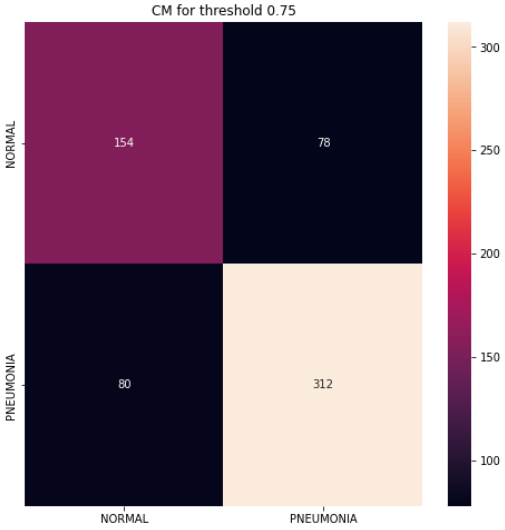

Fig. 6. Confusion matrix of the classification process.

There were approximately 312 cases of pneumonia and 154 cases that were observed to be normal using the confusion matrix, which also revealed good results (see Fig. 6). In addition, the ROC graph demonstrates a positive outcome, as demonstrated by the score of 98.67%, as shown in Fig. 7.

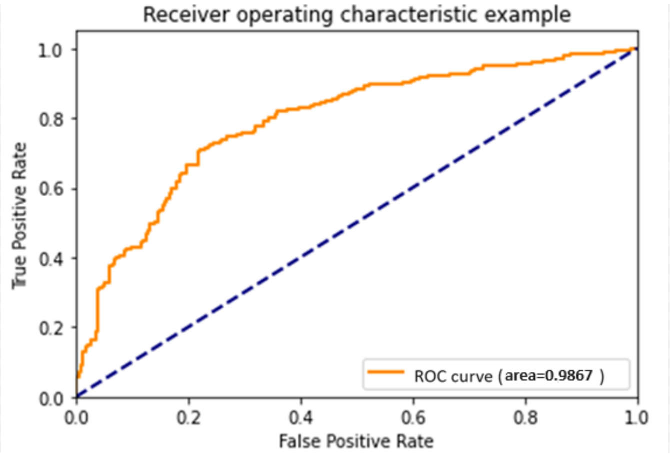

Fig. 7. ROC graph of the classification.

## V. Discussion

Within this section, the benchmarking study is presented in comparison to the preceding work. The primary focus of this part is placed on the presentation of comparisons with three previous studies that presented training using a variety of approaches.

Fig. 8 presents a comparison of the performances of the proposed model and its counterparts. It is abundantly clear that the StyleGAN method, when combined with the VGG19 and CatBoost Gradient Boosted Trees model, generates superior augmented images in comparison to the many other methods. The findings are also included in Table I, which compares them to the most recent research.

TABLE I. Classification Benchmarking with Previous Research

| Author | Dataset | Method | Accuracy | Precision |
|---|---|---|---|---|
| Hussain, B.Z., et al [33] | Chest X-ray + Wasserstein GAN | Wasserstein GAN | 95.34 | 99.1 |
| Ciano, G., et al [34] | Chest X-ray + PGGAN | PGGAN + SMANet | 96.28 | - |
| Sundaram, S. and N. Hulkund [17] | Chest X-ray + GAN | DenseNet121 + GAN | 80.1 | 72.7 |
| [35] | Chest X-ray + IAGAN | Inception + IAGAN | 82 | 84 |
| Suggested Methodology | Augmented Chest X-Ray with StyleGAN | VGG19 + CatBoost Gradient Boosted Trees | 98.67 | 97.21 |

According to the data presented in Table I and Fig. 8, the Inception + IAGAN has achieved an accuracy rate of 82% and a precision rate of about 84%. These figures are presented in the format of statistics. When compared to other methods, the PGGAN + SMANet algorithm obtains the best level of accuracy (96.28%), with the Wasserstein GAN algorithm coming in second with a score of 95.34%. This becomes abundantly obvious when the strategy that has been given is contrasted with other methods that are comparable. A precision score of 98.67% and an accuracy rate of 97.21% have been reached by the method that we have presented, which demonstrates that it has generated outstanding results.

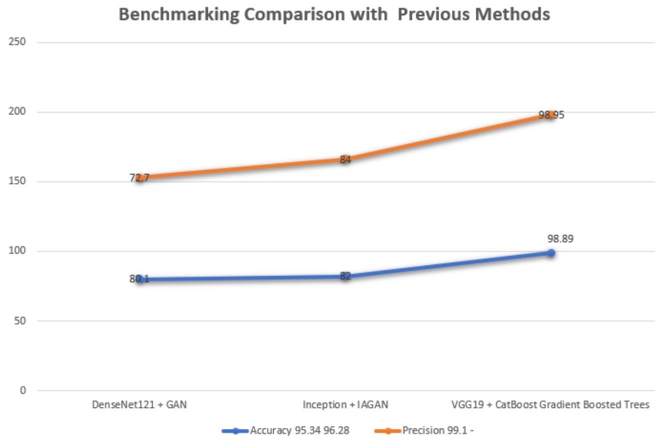

Fig. 8. Benchmarking graph.

## VI. Conclusion

Since the COVID-19 pandemic has been brought to an end, it is currently accepted that the virus has transitioned into an endemic phase. This is the case because the pandemic has been concluded. These illnesses have become more widespread to the point where they are a significant source of distress for people of all different demographic groups. This is because the prevalence of these illnesses has increased. Because of the potential that it possesses, the academic community has demonstrated a significant level of interest in the application of radiograph image data in the process of forecasting COVID-19. The methodology that has been provided focuses an emphasis on the employment of images that have been artificially generated by the application of the StyleGAN.

This is done with the intention of improving the overall quality of the datasets. For the purpose of integrating the synthetic datasets with the actual ones, the ratio that was utilized was 59:41. As a consequence of this, a hybrid method was implemented, which included the incorporation of the StyleGAN framework, the VGG19 model, and CatBoost Gradient Boosted Trees. The purpose of this strategy was to enhance the accuracy of the prediction. The evaluation of a model's performance is significantly influenced by the measurements of accuracy and precision that are taken into account on the model. Following are the outcomes of the evaluation, which produced the following results: an accuracy rate of 98.67% and a precision score of 97.21% were the outcomes which were generated. It is possible that the work that will be done in the future will take into consideration the possibility of mixing multiple datasets that have been generated from other sources with the Chest X-ray dataset that has been generated. This will be done with the intention of improving the diversity and quality of the dataset.

## Acknowledgment

This work was supported by the Deanship of Scientific Research (DSR), King Abdulaziz University, Jeddah Saudi Arabia. The authors, therefore, gratefully acknowledge the DSR technical and financial support.

# Cyber Security Intrusion Detection and Bot Data Collection using Deep Learning in the IoT

Fahad Ali Alotaibi[1], Shailendra Mishra[2]
Department of Information Technology, Majmaah University[1]
Department of Computer Engineering, Majmaah University[2]

***Abstract*—In the digital age, cybersecurity is a growing concern, especially as IoT continues to grow rapidly. Cybersecurity intrusion detection systems are critical in protecting IoT environments from malicious activity. Deep learning approaches have emerged as promising intrusion detection techniques due to their ability to automatically learn complex patterns and features from large-scale data sets. In this research, we give a detailed assessment of the use of deep learning algorithms for cybersecurity intrusion detection in IoT contexts. The study discusses the challenges of securing IoT systems, such as device heterogeneity, limited computational resources, and the dynamic nature of IoT networks. To detect intrusions in IoT environments, convolutional neural networks (CNNs) and recurrent neural networks (RNNs) have been used. The NF-UQ-NIDS and NF-Bot-IoT data sets are used for training and assessing deep learning-based intrusion detection systems. Our study also explores using deep learning approaches to identify botnets in IoT settings to counter the growing threat of botnets. Also, analyze representative bot data sets and explain their significance in understanding botnet behavior and effective defenses. The study evaluated IDS performance and traffic flow in the IoT context using various machine learning algorithms. For IoT environments, the results highlight the importance of selecting appropriate algorithms and employing effective data pre-processing techniques to improve accuracy and performance. Cyber-attack detection with the proposed system is highly accurate when compared with other algorithms for both NF-UQ-NIDS and NF-BoT-IoT data sets.***

***Keywords—Internet of things; intrusion detection system; random neural networks; feed forward neural networks; convolutional neural networks***

## I. Introduction

In the present era, technological advancements have been in the scope of the Internet of Things (IoT), cloud computing, and cybersecurity. In the next ten years, it is projected that the Internet of Things will grow enormously, with users adopting billions of IoT devices. The growth and expansion clarify the influence of technology through the IoT on matters of vulnerability and businesses and people's daily lives. Most enterprises, institutions, and government facilities increasingly adopt IoT technology since it can create a large amount of information used to test the function of the Internet of Things network, thus increasing the quality of the services and experience. Consequently, the Internet of Things makes data communication between actual equipment and sensors possible [1]. Employing technology elements in the Internet of Things connections has improved communication, evaluation, and the value of data collecting and projection for future strategy. Numerous layers comprise an Internet of Things building design, which looks into, recognizes, and monitors the network's reliability. The basic configuration comprises three tiers: awareness, system, and implementation [2].

On the other hand, deep learning mechanisms have become famous and popular for determining network breaches. Numerous literatures evaluate the comparison of deep learning structures, particularly the new data components for detecting Intrusion. As a result, the definition of the Internet of Things Intrusion is any illegal activity or conduct that affects the confidentiality of the IoT network, data availability, and integrity in any way [3]. Using virtual private networks (VPNs), safe and protected communication channels are created to safeguard the privacy and integrity of transmitted data. When an intruder blocks entrance to a service, preventing legitimate users from using it, this is called an incursion. An intrusion detection system (IDS) is a tool that monitors systems and networks on computers using hardware, software, or both to spot malicious or dangerous activity and to maintain the network and system safe. In response to this, deep learning can be utilized to assist in determining dangerous attacks on IoT networks and connections while minimizing risks and enhancing active deterrence of future attacks. In retrospect, the paper offers insights into deep learning-based approaches for cyber security intrusion detection and bot data collected in the Internet of Things [1].

In this paper, we propose a novel intelligent intrusion detection system (IDS) that performs feature extraction, feature selection, and intelligent classification via efficient rule matching, also by performing deductive inference. This study also includes a complete assessment of IDSs in the IoT, which highlights the advantages, benefits, and limitations of the existing IDSs for the IoT environment and compares them to the proposed work. The comprehensive literature survey, the identification of suitable metrics for comparison, the measurement of various parameters more efficiently by identifying the granularity of the measurement, and finally the proposal of a new IDS using deep learning techniques are the major contributions of this work. Based on the results of the tests conducted in this paper, it is discovered that the suggested intelligent IDS is more successful in terms of intrusion detection rates as well as false positive rates reduction.

The proposed study primarily focuses on deep learning-based approaches for cyber security intrusion detection and bot data collected in the Internet of Things. Several data pre-processing techniques were used to increase IDS quality. The instance-based and feature-based techniques were specifically explored. Instance-based pre-processing is concerned with data cleansing and removal strategies. Feature-based pre-processing comprises feature transformation, normalization, and dimensionality reduction through correct feature selection. Feature transformation was applied to all of the categorical characteristics of the selected datasets.

The main objectives of the proposed study are:

1) *To* offer systematic insight into the scholarly articles on detecting Intrusion on the IoT.

2) *To* evaluate and offer a comprehension of the procedures and techniques used to analyze the effect of information and algorithm quality on the heightening network intrusion detection rates.

3) *Proposed* an Intrusion detection system (IDS) based on deep learning (DL), for effective security in the IoT environment

4) *To* evaluate the performance of the proposed IDS.

By focusing on these goals, the research seeks to improve the comprehension, efficiency, and expandability of IDS systems, thereby bolstering the security and dependability of IoT networks. This research provides more accurate and reliable forecasts, which bolster Internet of Things security by thwarting data breaches, unauthorized entry, and service denials. Utilizing Python algorithms to tackle discrepancies in class problems within IoT cybersecurity databases subsequently boosts the capabilities of the generated models. Eventually, the research guides the most efficient approaches for utilizing neural networks and deep learning as sensors to predict cybersecurity issues.

The organization of the paper is as follows; Section II shows the related work, Section III represents the methodology of the proposed work, Section IV includes experimental setup, Section V discusses results and analysis, and Section VI shows the conclusion and future work.

## II. Related Work

This section provides an in-depth study of the relevance of cybersecurity in IoT infrastructure by evaluating previous research and examining the progress achieved using ML and DL approaches. This highlights the importance of IoT security and the challenges faced due to the lack of IDS and the need for IDS in IoT networks. This section discusses current research on deep learning-based intrusion detection systems for IoT applications, focusing on identifying the research needs of this topic. To prevent cyberattacks and provide security solutions for lightweight IoT networks, many research challenges need to be addressed. Cars, health monitoring, robots, and smart homes will generate large amounts of data, requiring new security measures. Although some researchers have used machine learning and deep learning methods to develop and deploy IoT intrusion detection systems (IDS) in recent years, further research on IoT intrusion detection is still needed.

The deep learning approaches can be effective in cyber security intrusion detection in the context of the Internet of Things (IoT).The use of a Deep Learning-based Intrusion Detection System (IDS) using Feed Forward Neural Networks (FFNN), Long Short Term Memory (LSTM), and Random Neural Networks (RandNN) to enhance IoT network security and reduce cyber threats [1]. Sarah Alkadi et al., [2] discuss an empirical impact analysis of machine learning (ML) in building intrusion detection systems (IDSs) for IoT networks. The study found that using quality data and models, such as data cleaning, transformation, normalization, and parameter tuning, significantly improves IDS detection accuracy. The intelligent detection system is proposed in [3], using SVM, SMOTE, machine learning, and deep learning algorithms. The model achieved good accuracy and reduced error rates.

The potential of machine learning and deep learning techniques in detecting malware in IoT networks is discussed in [4]. It evaluates the efficacy of ten models and their performance when combined with the SMOTE algorithm to counterbalance imbalanced data. The effectiveness of the Rules and Decision Tree-based Intrusion Prevention System RDTIPS is a new intrusion prevention system for the Internet of Things networks discussed in study [5], which combines rules and decision trees, it demonstrates a superior performance, accuracy, detection rate, time overhead, and false alarm rate.

A new approach, using the focal loss function, improves accuracy, precision, score, and MCC score compared to traditional methods discussed in study [6]. Researchers have used Machine Learning techniques for intrusion detection, but imbalanced datasets can lead to unsatisfactory results. In the paper [7], the authors propose a novel approach using deep learning and three-level algorithms to detect cyber-attacks in IoT networks, demonstrating significant improvements in detection performance and potential for other IoT applications.

Paper in [8], this article provides statistics and architectures for IoT botnets and analyses the attacks in depth, but it is also susceptible to cyberattacks. To counter this, a new method of detection for intruders is proposed in the GA-FR-CNN framework. This method employs Deep Learning and FR-CNN and has a high degree of success on the UNSW-NB 15 and BOT-IoT datasets. The rapid growth of IoT devices, including wearables and smart sensors, has led to an increase in cyberattacks [9]. To surmount this, authors in [9] utilize both machine and deep learning. The Internet of Things (IoT) is a growing market, leading to increased cyber-attacks. To combat this, researchers [10], propose a hybrid approach using Autoencoder and Modified Particle Swarm Optimization (HAEMPSO) for feature selection and deep neural network (DNN) for classification. The proposed HAEMPSO-DNN achieved high accuracy and detection rates compared to existing machine-learning schemes.

The fourth industrial revolution has led to the generation of large-scale data in Industrial Internet of Things (IIoT) platforms, increasing security risks and data analysis procedures. The paper in [11] proposes an ensemble deep learning model using Long Short Term Memory and Autoencoder architecture to identify out-of-norm activities in IIoT cyber threat hunting. The industrial Internet of Things (IIoT) generates sensitive data, making security mechanisms like intrusion detection systems impractical. Federated learning and Blockchain are promising advancements to address these challenges [12]. The study in [12], explores the role of

Blockchain and federated learning in IIoT, highlighting potential applications in monitoring network traffic for anomaly detection and providing recommendations for effective implementation.

In research [13], the authors discuss a network intrusion detection (NID) method for IoT using a lightweight deep neural network. The method uses the PCA algorithm for feature reduction, expansion and compression structures, and NID loss for effective feature extraction. In [14], the authors discussed the fundamental principles of deep learning and machine learning, with 80 studies selected between 2016 and 2021, and discussed about the effectiveness of support vector machines, random forests, XGBoost, neural networks, and recurrent neural networks.

In research [15], the authors discuss the Internet of Things (IoT)'s influence on intelligent objects by decreasing power consumption. However, these devices are susceptible to invasions because of their direct association with the perilous Internet. Intrusion detection systems (IDSs) have a significant role in addressing these weaknesses, studying their principles, and recognizing potential dangers. The vulnerability of IoT systems to cyber-attacks focuses on learning-based methods and their impact on devices [16]. It reviews various types of attacks, presents literature on these developments, and provides future research directions. In study [17], authors discussed traditional and machine learning NIDS techniques, discussing future directions and enabling security professionals to differentiate IoT NIDS from traditional ones. In [18], the authors explore the vulnerability detection methods in IOT environments using machine learning, they propose a framework for recognizing potential vulnerabilities and reviewing the current state of the art.

In study [19] authors proposed a method of deep learning that is federated to improve the security of cyberphysical systems in the context of IOT, the performance of this method is evaluated in real IOT datasets. It demonstrates that these approaches are more effective at preserving device data privacy and recognizing attacks. Paper [20], discussed the increasing number of internet-connected devices (IoT) that pose a threat to the safety of the network. Traditional solutions based on rules fail to recognize these attacks. Machine learning (ML) is utilized for the detection of IoT attacks, the focus of this approach is on botnet attacks that target multiple devices.

In study [21], authors proposed a Deep Intrusion Detection (PB-DID) architecture, which classifies non-anomalous, DoS, and DDoS traffic uniquely using deep learning techniques, achieving a high accuracy (96%). In [22], the authors, proposed the Hybrid Intrusion Detection System (HIDS), combining the C5 decision tree and the One-Class Support vector machine to identify intrusions with a high degree of accuracy and a low rate of false alarm. The HIDS is assessed using the Bot-IoT dataset, this demonstrates a higher degree of detection and a lower percentage of false positives. Authors in [23], proposed a CorrAUC that uses a feature selection metric and an algorithm to filter features accurately. The procedure is assessed using the dataset of the Bot-IoT and four different machine learning methods, the average accuracy of which is over 96%.In [24], authors proposed a method of intrusion detection for IoT devices that utilizes machine learning to identify anomalous traffic in the network. The system uses binary grey wolf optimizer, recursive feature elimination, synthetic minority oversampling technique, XGBoost, Bayesian, and classification optimization with a tree-structured Parzen estimator.

In study [25], the authors examine the increasing cybersecurity challenges in the context of IoT technologies, which are increasingly vulnerable to cyber threats. It compares the effectiveness of machine learning methods like Support Vector Machine (SVM), Artificial Neural Network (ANN), Decision Tree (DT), Logistic Regression (LR), and k-nearest Neighbours (k-NN) in detecting cyber anomalies in IoT systems. The results show that the neural network outperforms other models, providing valuable insights for cybersecurity experts and guiding the development of robust protection strategies for the IoT ecosystem. Yaras, Sami, and Murat Dener, study employs PySpark and Apache Spark to analyze network traffic data and detect attacks using a deep learning algorithm, achieving high accuracy rates [26].

In study [27], the others, Yesi Novaria Kunang et al., propose a hybrid deep learning model for an intrusion detection system (IDS) on the IoT platform, using unsupervised approaches for feature extraction and a neural network for classification. The model demonstrated high detection performance and improved recognition of attacks compared to previous approaches. In [28], the authors introduce a framework that suggests selecting a suitable source domain data set for transfer learning, ensuring the highest accuracy in small-scale environments like home networks. Amit Kumar Mishra et al.[29], introduce a weighted stacked ensemble model for IoT networks, enhancing performance and reducing generalization error.

Mohanad Sarhan et al. present five NIDS datasets with a popular NetFlow feature set to bridge the gap between academic research and real-world deployments [30]. As part of the experiments, four benchmark NIDS datasets were labeled for traffic and attack classification experiments, and the results were evaluated using an Extra Trees ensemble classifier. For the NF-UQ-NIDS dataset, accuracy and recall values are not provided. Precision is reported as 70.81%, and F1-score is reported as 79%. For the NF-UQ-NIDS dataset, this information indicates how well the classification model performed in terms of precision and F1 score. The F1-score is given as 77%, and the precision is recorded as 73.58%. Using benchmark Net-flow-based datasets and machine learning techniques to address security issues.

In study [31], authors proposed a deep neural network-based intrusion detection system for real-time attack detection of malicious packets in IoT networks. They presented their findings, reporting an accuracy of 91.7%, precision of 91%, recall of 91%, and an F1-score of 91%. For the NF-UQ-NIDS dataset, our research yielded an accuracy, precision, recall, and F1-score of 92%. An accuracy of 76%, precision of 76%, recall of 76%, and F1-score of 70% are reported for the NF-BoT-IoT dataset. Using the NF-BoT-IoT dataset.

Most of the existing intrusion detection systems (IDSs) discussed in the related work section are general in nature and focused on network security, and most of them do not concentrate on the application of deep learning-based computational intelligence for constructing a reliable intrusion detection system. As a result, they are ineffective in delivering effective security in the IoT environment. The present IoT communication requires the deployment of a more flexible and efficient security system capable of detecting both known and innovative forms of threats and preventing them more intelligently utilizing artificial intelligence (AI) and machine learning (ML) methods. A comprehensive evaluation of IDSs in the IoT environment is also included, which highlights the advantages, benefits, and limitations of existing IDSs.

### A. Research Gaps

Many existing (IDS) published in the literature are generic in nature and focus on network security, and most do not use deep learning-based computer intelligence to create reliable systems. As such, they are ineffective at providing effective security in the IoT context. The current communication style for IoT necessitates the implementation of a more flexible and efficient security system that can recognize both known and innovative threats and prevent them more effectively using AI and ML methods.

This paper proposes a new intelligent detection system for intrusion (IDS) that extracts features, chooses features, and categorizes instances via efficient rule matching, additionally, it also involves deductive reasoning. This study also contains a thorough review of IDSs in the IoT, which emphasizes the benefits, advantages, and limitations of existing IDSs for the IoT context and compares them to the suggested approach. This research makes major contributions by conducting an exhaustive literature assessment, identifying acceptable metrics for comparison, efficiently measuring multiple parameters through the identification of their granularity, and proposing a novel IDS based on deep learning. The test results conducted in this paper show that the proposed intelligent IDS has a high success rate in both detecting intrusions and reducing the number of false alarms.

## III. Research Methods

The proposed intelligent intrusion detection system (IDS) is shown in Fig. 1. It includes selecting a dataset, pre-processing the data, selecting relevant features, splitting the dataset, labeling the data (if applicable), performing classification, and deriving results. The proposed intelligent intrusion detection system (IDS) utilizes efficient rule matching and deductive inference to perform feature extraction, selection, and intelligent classification.

### A. Select Dataset

The NIDS dataset NF-UQ-NIDS [32], simulates a realistic network environment with both normal and abnormal traffic. The dataset includes DDoS, Reconnaissance, Injection, DoS, Brute Force, Password, XSS, Infiltration, Exploits, Scanning, Fuzzers, Backdoor, Bot, Generic, Analysis, Theft, Shellcode, MITM, Worms, and Ransomware attacks The data set NF-BoT-IoT [33] simulates a realistic network environment with both normal and botnet traffic. The dataset includes Reconnaissance, DDoS, DoS, and Theft.

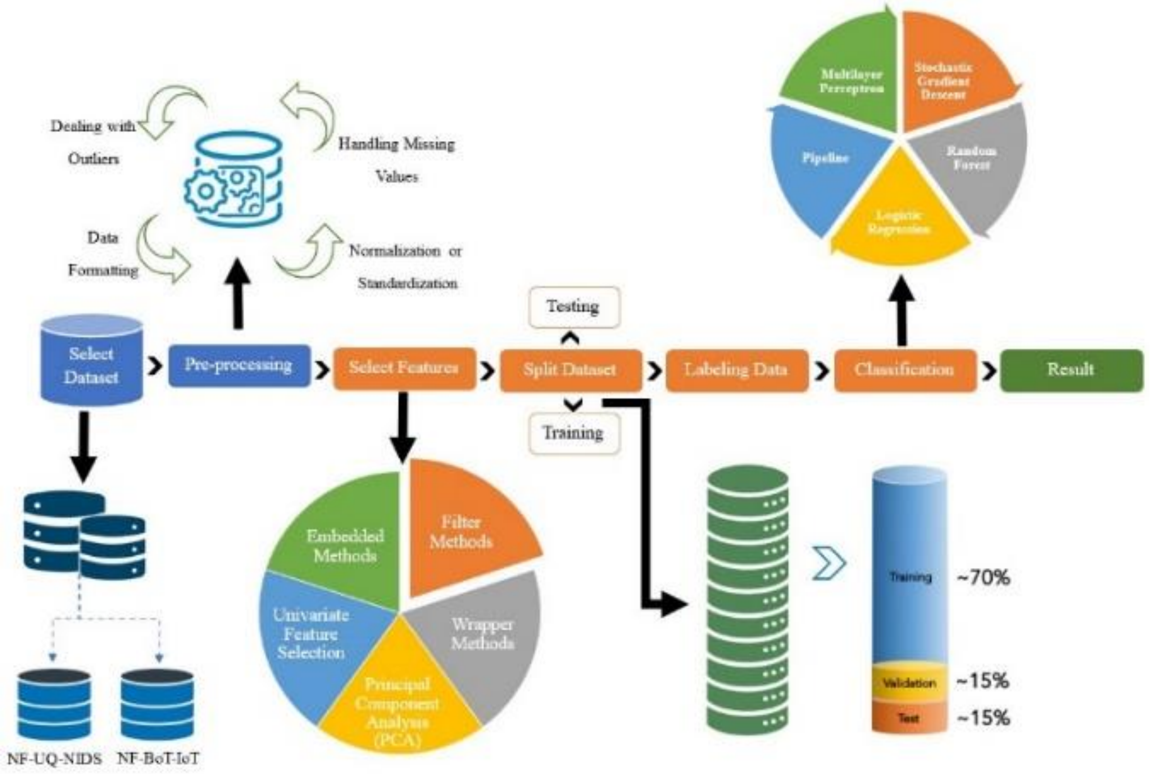

Fig. 1. Proposed intelligent intrusion detection system (IDS).

### B. Pre-processing

Pre-processing is an essential process in cleaning and preparing the dataset for analysis. It consists of numerous duties, including:

*1) Handling missing values:* Identify and address any missing values in the dataset. This can be accomplished by either imputing missing values using statistical methods or removing instances or features with missing values, depending on the quantity of missing data and its impact on the study.

*2) Dealing with outliers:* Identify and address extreme values that deviate significantly from the normal distribution. Outliers can alter analytical results, which can be treated by deleting them, modifying the data, or employing strong statistical procedures.

*3) Data formatting:* Ensure data is properly formatted for analysis. Convert variables to the relevant data types (e.g., numerical, categorical, DateTime) and, if necessary, standardized units.

*4) Normalization or standardization:* Convert data to a consistent scale. This is particularly important when utilizing algorithms sensitive to variable magnitude and comparing variables on different scales.

### C. Select Features

Selecting appropriate features from a dataset is crucial for achieving research objectives. There are several feature selection methods for the dataset, including:

*1) Filter Methods:*

*a) Correlation-based feature selection:* Use the correlation coefficient to determine the degree to which each feature is associated with the target variable and choose the feature with the greatest association.

*2) Wrapper Methods:*

*a) Recursive Feature Elimination (RFE):* Train the model repeatedly and remove the least significant feature at each iteration based on the model's performance, until the desired number of features is achieved.

*b) Forward selection:* This method builds a model by sequentially adding the most significant component that enhances the model's performance until a stopping rule is reached.

*c) Backward elimination:* It begins with all the features and then removes the least significant feature by using a defined criterion to stop when a stopping condition is met.

*3) Embedded Methods:*

*a) LASSO (Least Absolute Shrinkage and Selection Operator):* It employs regularization that is least absolute in nature, this type of regularization is used to penalize the coefficients of features, and thus, some of the features will become zero and the remaining will be selected.

*b) Ridge Regression:* It uses regularization via L2 to reduce the magnitude of the coefficients of less significant features to zero, this diminishes their influence on the model.

*c) Elastic Net:* A hybrid of L1 and L2 that enables feature selection and addresses multicollinearity.

*4) Principal Component Analysis (PCA):* Reduces the dataset's dimensionality by altering the original features into a new collection of uncorrelated variables known as principal components. The primary components have the greatest amount of variance in the data.

*5) Univariate Feature Selection:*

*a) SelectKBest:* Select the top features based on statistical tests such as ANOVA F-score or mutual information.

*b) SelectPercentile:* Selects the highest percentage of features based on a statistical test.

### D. Split Dataset

Separate the dataset into training, validation, and testing subsets. The typical dividing ratio is 70% training, 15% validation, and 15% testing. The training dataset is used to train the classification model, the validation dataset is used to tune hyperparameters and choose models, and the testing dataset is used to perform the final evaluation.

### E. Labeling Data

Label the data appropriately; this step entails adding class labels or categories to each data object. Human annotators can manually label items, or existing labels can be utilized to give reliable training data for the classification model.

### F. Classification

We used appropriate classification techniques to train on the labeled training datasets. There are several classification methods available, including stochastic gradient descent (SGD), random forest, multilayer perceptron (MLP), pipeline, and logistic regression.

### G. Result

We assessed the effectiveness of the trained classification model using the testing dataset, which included the dataset, such as accuracy, precision, recall, and F1 scores, to determine the model's effectiveness.

## IV. Experimental Setup

The implementation was conducted on a Windows 10 operating system desktop, with hardware specifications that included 8 GB of RAM, an Intel(R) Core (TM) i7-10700 processor, Jupyter notebooks 7.0.6, and Python 3.12 as the programming language employed, with pandas, Scikit-Learn, NumPy, and Matplotlib that provided data processing and visualization functionality for our experiments. Pandas was used for data processing and preparation, Scikit-learn for machine learning methods and evaluation, Numpy for numerical computations, and Matplotlib for visualization. Python libraries are used to create machine learning models to identify intrusions in IoT networks, and with these modules, we were able to create a versatile and powerful analysis framework that can be readily extended and adjusted to meet my needs. To prepare the environment for studying the dataset, a VMware Workstation is installed, and then a Windows 10

VM and Python 3.12 are installed and run commands as shown in Table I, to prepare the environment.

TABLE I. COMMAND TO PREPARE THE ENVIRONMENT

| Command | Description |
|---|---|
| pip install notebook | Installation Jupyter Notebook. |
| Pip install pandas | Installing pandas from PyPI. |
| pip install pandas numpy | Installing numpy from PyPI. |
| pip install matplotlib | Installing matplotlib from PyPI. |
| pip install -U scikit-learn | Installing scikit-learn from PyPI. |
| Jupyter Notebook | Running Jupyter Notebook |

### A. *Evaluation Metrics*

Accuracy, recall, precision, and F1 score are the assessment measures utilized in this research to analyze the performance of the suggested model. True positives (TP), true negatives (TN), false positives (FP), and false negatives (FN) are the metrics used to construct these measures.

*1) Accuracy:* The accuracy of a model's predictions is calculated by dividing the number of successfully classified occurrences by the total number in the dataset as shown in Eq. (1).

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{1}$$

*2) Precision:* Precision measures the model's ability to correctly identify positive cases out of all those projected as positive. It is calculated using the Eq. (2):

$$Precision = \frac{TP}{TP+FP} \tag{2}$$

*3) Recall:* Recall measures the model's ability to properly identify positive instances from among all positive examples in the dataset as shown in Eq. (3).

$$Recall = \frac{TP}{TP+FN} \tag{3}$$

*4) F1 Score:* The F1 score is a numerical system that combines both precision and recall to have a single measurement. It provides a comprehensive evaluation of a model's effectiveness. The F1 rating is derived from the following Eq. (4):

$$F_1 = \frac{2*precision*recall}{precision+recall} \tag{4}$$

In the domain of intrusion detection, the following are the specific definitions of TP, FP, FN, and TN: The classification of an actual threat as a threat is called TP. The process of designating a typical normal behavior as a crime is called FP. The process of designating an actual category of crime as a normal counterpart is called FN. The formal designation of a typical normal category as a typical normal category is called TN.

Preprocessing is necessary following the collection of data. This stage involves, among other things, the cleaning of data, oversampling, selection of features, data normalizing, and partitioning of the dataset. In the cleaning stage, remove any duplicate values from the data set and replace any empty values with zeros. To mitigate the issue of uneven data distribution and reduce the impact of the problem on experimental results, we employ the SMOTE method to oversample the minority class. The dataset is normalized once all features have been converted to numerical types. The regularization approach is used to standardize the dataset, scaling the values between [0, 1]. This normalizing procedure improves the model's convergence speed and training effectiveness.

Machine learning relies heavily on data. When data is noisy and unpredictable, it can be incredibly difficult to analyze. Underfitting happens when training data cannot accurately establish a link between inputs and outputs. Overfitting occurs when a machine learning model performs poorly after being trained on a huge amount of data. As a result of the noisy and skewed data, the algorithm's performance will suffer. Machine learning is a very new and fast-expanding science. Learning is difficult since there are numerous opportunities for error because the process is always changing. The most important step in the machine learning process is data training. Predictions will be excessively biased or erroneous in the absence of sufficient training data. Slow implementation is one of the most common issues that machine learning specialists face. Machine learning models are quite good at providing proper results, even though it takes a long time. The algorithm may become flawed as the amount of data increases.

## V. RESULTS AND DISCUSSION

### A. *NF-UQ-NIDS*

By using Stochastic Gradient Descent, a machine learning optimization algorithm, to discover the model parameters that correspond to the best fit between expected and actual outputs. The result is shown in Table II and the confusion matrix for SGD is shown in Fig. 2.

TABLE II. SGD PERFORMANCE OF THE EVALUATED IN NF-UQ-NIDS

| | | |
|---|---|---|
| SGD | Accuracy | 88% |
| | Precision | 89% |
| | Recall | 88% |
| | F1 | 87% |

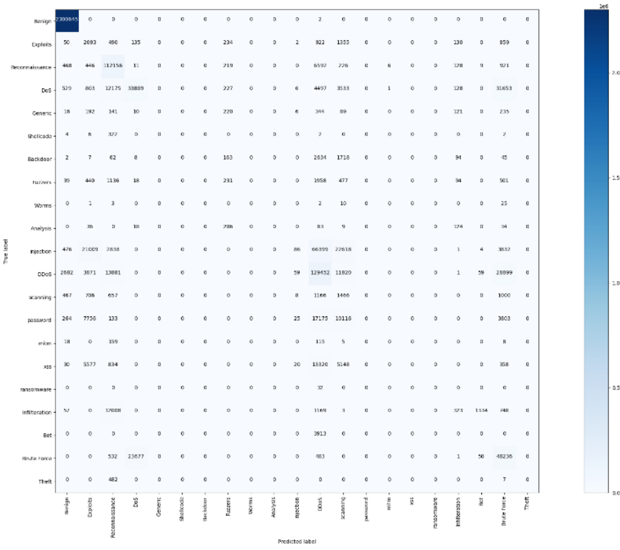

Fig. 2. SGD confusion matrix for NF-UQ-NIDS.

By utilizing a random forest classifier, it combines the votes of different decision trees to determine the final classification of the test object. The outcomes are listed in Table III, and a confusion matrix for RF is displayed in Fig. 3.

TABLE III. RF PERFORMANCE OF THE EVALUATED IN NF-UQ-NIDS

| | | |
|---|---|---|
| RF | Accuracy | 92% |
| | Precision | 92% |
| | Recall | 92% |
| | F1 | 92% |

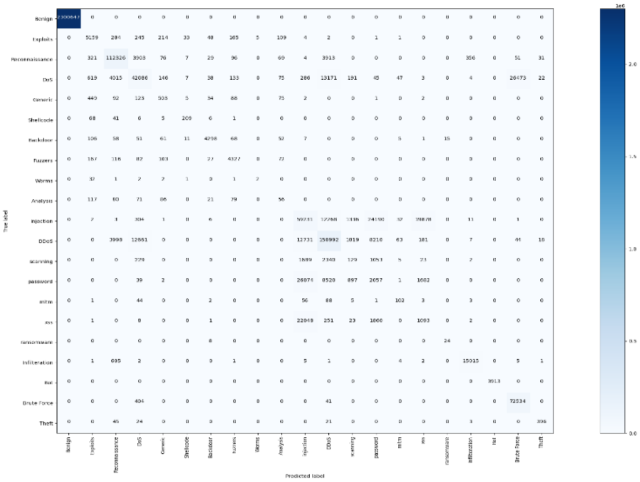

Fig. 3. RF confusion matrix for NF-UQ-NIDS.

By using an MLP Classifier that relies on an underlying Neural Network to perform the task of classification. The result is shown in Table IV, and the confusion matrix for MLP is shown in Fig. 4.

TABLE IV. MLP PERFORMANCE OF THE EVALUATED IN NF-UQ-NIDS

### C. Multi-class Classification

In the multi-class classification task, several classification models were evaluated using two datasets: NF-UQ-NIDS and NF-BoT-IoT. The performance measurements of these models are summarized and compared in Table XII.

In terms of accuracy, precision, recall, and F1, the proposed IDS based on an RF and MLP outperforms better than other techniques reported in [30, 31]. Classifiers correctly classify attacks when the ability to define the class in which an attack is detected determines true positives and false positives. When a true negative was obtained, the classifier correctly discarded attacks. When a false negative was found, the classifier classed the attacks as normal traffic.

The accuracy rate for suggested and current strategies for detecting cyberattacks. The results show that applying algorithms to rank the features allows for the extraction of the desired data. The quantity of usable features in the proposed algorithms influences how well the jointly learned feature transformation operates, allowing for easier IDS fine-tuning. The algorithms do impact how well the jointly learned feature. Recall rate comparison displays the number of usable features in the proposed algorithms affects how well the jointly learned feature transformation performs. The F1 score for the number of features in the specified databases for the proposed algorithms affects how effectively the jointly learned feature transformation performs.

TABLE XII. MULTI-CLASS CLASSIFICATION

| Classification Models | | Measurements | Datasets | |
|---|---|---|---|---|
| | | | NF-UQ-NIDS | NF-BoT-IoT |
| Sarhan et.al.; [30] | | Accuracy | - | - |
| | | Precision | 70.81% | 73.58% |
| | | Recall | - | - |
| | | F1 | 79% | 73.58% |
| Thirimanne et, al; (RF) [31] | | Accuracy | 91.7% | 76% |
| | | Precision | 91% | 76% |
| | | Recall | 91% | 76% |
| | | F1 | 91% | 70% |
| Proposed IDS based on DL | SGD | Accuracy | 88% | 80% |
| | | Precision | 89% | 81% |
| | | Recall | 88% | 80% |
| | | F1 | 87% | 75% |
| | RF | Accuracy | 92% | 77% |
| | | Precision | 92% | 77% |
| | | Recall | 92% | 77% |

### D. Discussion

The proposed investigation has listed several goals that are intended to contribute to the field of intrusion detection via the Internet of Things (IoT). To evaluate and offer a comprehension of the procedures and techniques used to analyze the effect of information and algorithm quality on the heightening network intrusion detection rates. Understanding the process and methodology used to evaluate the influence of data and model quality is fundamental to improving IDS detection rates. By studying existing approaches, the study can identify the factors that impact the performance of IDS, such as data pre-processing techniques, feature selection, and the choice of machine learning algorithms. This objective will help in determining effective strategies for enhancing the quality of data and models, ultimately leading to improved IDS performance.

Identifying and analyzing attacks on IoT networks is crucial for developing robust intrusion detection systems. By analyzing traffic data, the study can uncover patterns and anomalies that indicate the presence of attacks. The findings will enhance the ability to detect and mitigate these attacks effectively.

Analyzing the time and spatial complexity associated with IDS in IoT networks is crucial for understanding the scalability and performance limits of intrusion detection systems. By examining the computational requirements, resource utilization, and performance trade-offs, the study can provide insights into the feasibility and limitations of implementing IDS in large-scale IoT deployments. This objective will contribute to optimizing the resource allocation and efficiency of IDS in IoT environments. Several ML approaches were adopted in this study to assess IDS performance and model traffic flow in the IoT context. Stochastic Gradient Descent (SGD), Random Forest Classifier, MLPClassifier, Pipeline, and Logistic Regression are some of the candidate machine learning algorithms. They were used in a scenario involving multi-class classification on NF-UQ-NIDS and NF-BoT-IoT datasets.

Overall, the proposed study's objectives demonstrate a comprehensive and systematic approach to advancing the field of intrusion detection in the Internet of Things. By addressing these objectives, the study aims to enhance the understanding, performance, and scalability of IDS systems, ultimately contributing to the security and reliability of IoT networks.

Several data pre-processing techniques were used to increase IDS quality. The in-stance-based and feature-based techniques were specifically explored. Instance-based pre-processing is concerned with data cleansing and removal strategies. Feature-based pre-processing comprises feature transformation, normalization, and dimensionality reduction through correct feature selection. Feature transformation was applied to all of the categorical characteristics of the selected datasets. The results of the evaluation are summarized in Table 12. Along with dataset quality, machine learning plays an important function. By comparing these findings, it is clear that our RF model outperformed better than the RF model on both datasets [30, 31].

In conclusion, the study demonstrated the effectiveness of various ML algorithms in assessing IDS performance and modeling traffic flow in the IoT context. The results highlight the importance of selecting appropriate algorithms and employing effective data pre-processing techniques to enhance the accuracy and overall performance of IDS systems in IoT environments.

The Internet of Things is susceptible to attacks due to several reasons. First, IoT devices are typically left unattended, which makes it easy for an attacker to gain physical access to them. Additionally, the majority of data transmission is wireless, which makes it simpler to eavesdrop. Ultimately, the majority of IoT devices have a limited amount of storage and processing capacity, this implies that additional security software cannot be employed. While the NF-UQ-NIDS and NF-BoT-IoT datasets used in the study provided valuable insights into the performance of machine learning algorithms for intrusion detection systems (IDS) in the context of the Internet of Things (IoT), there are several limitations to consider i.e. the size of the datasets may affect the generalizability of the results.: The NF-UQ-NIDS and NF-BoT-IoT datasets may not fully represent the diverse range of IoT network traffic patterns and intrusion instances. The datasets might be biased towards specific types of attacks or IoT device behaviors, limiting the generalizability of the findings to different IoT environments.

Class imbalance in the datasets, where certain classes have significantly more or fewer instances than others, can affect the performance of the machine learning algorithms. Imbalanced data can lead to biased models that prioritize the majority class and perform poorly on the minority classes, which are often the ones of interest in intrusion detection. The quality and reliability of the labeled data in the datasets can impact the performance of the machine learning algorithms. Inaccurate or mislabeled instances can introduce noise and affect the training process, leading to suboptimal results. The study mentioned feature-based pre-processing techniques, including feature transformation and dimensionality reduction. However, the specific features selected or engineered for the analysis were not discussed. The choice of features can greatly influence the performance of the algorithms, and the study did not provide insights into the selection process or the relevance of the chosen features.

The study primarily focused on accuracy, precision, recall, and F1 score as evaluation metrics. While these metrics provide important information about the performance of the algorithms, they may not capture all aspects of IDS performance. Other metrics, such as false positive rate, false negative rate, or area under the ROC curve, could provide a more comprehensive assessment of the algorithms' effectiveness. The performance of machine learning algorithms can vary across different datasets and network environments. The results obtained from the NF-UQ-NIDS and NF-BoT-IoT datasets may not necessarily generalize to other datasets or real-world IoT scenarios.

Considering these limitations, further research and evaluation on larger, more diverse datasets, along with the incorporation of additional evaluation metrics, would be beneficial to gain a more comprehensive understanding of the performance of IDS in the IoT context.

### E. Limitation of Research

The Internet of Things is susceptible to attacks due to several reasons. First, IoT devices are typically left unattended, which makes it easy for an attacker to gain physical access to them. Additionally, the majority of data transmission is wireless, which makes it simpler to eavesdrop. Ultimately, the majority of IoT devices have a limited amount of storage and processing capacity, which implies that additional security software cannot be employed.

While the NF-UQ-NIDS and NF-BoT-IoT datasets used in the study provided valuable insights into the performance of ML algorithms for IDS in the context of the IoT, there are several limitations to consider:

*1) Dataset size:* The size of the data set may affect the generalizability of the results. If the data set is small, the algorithm's performance may not accurately reflect its capabilities in real-world scenarios. Additionally, small data sets may increase the risk of overfitting. An algorithm may perform well on training data, but may not generalize to new, unknown data

*2) Dataset representativeness:* The NF-UQ-NIDS and NF-BoT-IoT datasets may not fully represent the diverse range of IoT network traffic patterns and intrusion instances. The datasets might be biased towards specific types of attacks or IoT device behaviors, limiting the generalizability of the findings to different IoT environments.

*3) Data imbalance:* Class imbalance in a dataset, where certain classes have significantly more or fewer instances than other classes, can affect the performance of machine learning algorithms. Imbalanced data can lead to erroneous models that focus on the majority of classes and perform poorly on the minority of classes that are typically of interest in intrusion detection.

*4) Data quality:* The quality and reliability of the labeled data in the datasets can impact the performance of the ML algorithms. Inaccurate or mislabeled instances can introduce noise and affect the training process, leading to suboptimal results.

*5) Feature selection:* The study mentioned feature-based pre-processing techniques, including feature transformation and dimensionality reduction. However, the specific features selected or engineered for the analysis were not discussed. The selection of features can have an important effect on the performance of the algorithms, the study did not provide information about the process of selecting features or the importance of the features chosen.

*6) Evaluation metrics:* As evaluation metrics, the study largely used accuracy, precision, recall, and the F1 score. While these metrics provide important information about the performance of the algorithms, they may not capture all aspects of IDS performance. Other metrics, such as false positive rate, false negative rate, or area under the ROC curve, could provide a more comprehensive assessment of the algorithms' effectiveness.

*7) Generalizability:* The performance of machine learning algorithms can vary across different datasets and network environments. The results obtained from the NF-UQ-NIDS and NF-BoT-IoT datasets may not necessarily generalize to other datasets or real-world IoT scenarios.

Considering these limitations, further research and evaluation on larger, more diverse datasets, along with the incorporation of additional evaluation metrics, would be beneficial to gain a more comprehensive understanding of the performance of IDS in the IoT context.

## VI. Conclusions and Future Work

The study explores the use of deep learning approaches for cyber security intrusion detection in IoT networks. It highlights the need for advanced techniques to improve the accuracy and efficiency of intrusion detection in IoT networks. Traditional intrusion detection systems may not be suitable for handling the unique characteristics and complexities of IoT networks. The study recognized the necessity of more intricate approaches, such as deep learning, to augment the fidelity and efficiency of intrusion detection in the IoT. Insufficient datasets for training and evaluation are also a concern. For IoT networks, where data characteristics differ from conventional networks, there is a shortage of comprehensive and representative datasets that capture the specific challenges and attack patterns in IoT environments. The study also addresses botnet attacks in IoT networks, focusing on analyzing bot data collected from IoT networks to develop effective intrusion detection systems. By addressing these problems, the study aims to contribute to the development of more robust and accurate intrusion detection mechanisms for IoT networks. It emphasizes the utilization of deep learning approaches and the availability of suitable datasets, particularly for botnet-related attacks, to enhance the security and resilience of IoT systems. The findings in this research provide insights into the effectiveness and accuracy of machine learning evaluation metrics in detecting a wide spectrum of cyberattacks. The accuracy metric represents the percentage of correctly classified instances by the algorithms on both datasets. Higher accuracy values generally indicate better performance, although it's important to consider other evaluation metrics such as precision, recall, and F1 score for a more comprehensive assessment of the algorithms' effectiveness.

There may be several areas of future research that can improve the security of the IoT ecosystem. A promising future research direction is to explore the use of deep learning techniques to build more powerful and intelligent IDS for the IoT. By using deep learning algorithms such as Convolutional Neural Networks (CNN), Recurrent Neural Networks (RNN), and Transformers, and block complex penetration attempts more accurately and effectively. Furthermore, using federated learning methods for collaborative and privacy-preserving model training on IoT devices can improve intrusion detection capabilities by combining scalability and diversity. To improve the detection of intrusions and complex network threats, integrated approaches and hybrid architectures can be explored. Furthermore, the development of adversarial defense methods is crucial to protect deep learning-based IDS against new attack vectors.

# Method for Disaster Area Detection with Just One SAR Data Acquired on the Day After Earthquake Based on YOLOv8

Kohei Arai, Yushin Nakaoka, Hiroshi Okumura
Information Science Dept., Saga University, Saga City, Japan

***Abstract*—Method for earthquake disaster area detection with just a single satellite-based SAR data which is acquired on the day after earthquake based on object detection method of YOLOv8 and Detectron2 is proposed. Through experiments with several SAR data derived from the different SAR satellites which observed Noto Peninsula earthquake occurred on the first of January 2024, it is found that the proposed method works well to detect several types of damages effectively. Also, it is found that the proposed method based on "Roboflow" and YOLOv8 as well as Detectron2 for annotation and object detection is appropriate for disaster area detection. Furthermore, it is possible to detect disaster areas even if just one single SAR data which acquired on the day after the disaster occurred because the trained learning model for disaster area detection is created through experiments.**

***Keywords—SAR; YOLOv8; Detectron2; earthquake; disaster; disaster area detection; noto peninsula earthquake***

## I. Introduction

Sever damages have been occurred in Noto peninsula in Japan due to big earthquake hit on January first in 2024. The damages include landslides, big fires, collapse of buildings and houses, steep slopes, roads, etc. Such these damages can be detected from space with the satellite-based SAR data which allows observation in all weather conditions and day and night times. It is easy to detect the disaster areas by comparing two SAR data which area acquired on the day before and the after the earthquake.

There are two types of SAR satellites, constellation SAR and revisit orbital SAR. In general, the constellation SAR has narrow swath with fine spatial resolution characteristics while the revisit orbital SAR has relatively wide swath with comparatively poor spatial resolution, respectively. Therefore, it is not so easy to obtain two SAR data on the day before and the after the earthquake for the constellation SAR for interferometric SAR and coherency calculation. The method proposed here allows damage area detection with just the constellation SAR data which is acquired the day after the earthquake. SAR data gives information of land cover types so that the disaster areas, house burnt down by fire, slopes and mountainsides covered with vegetation that were reduced to bare land can be detected.

Sentinel-1 [1], operated by Europe, and ALOS-2 [2] (Its dataset [3]), operated by Japan, are both SAR satellites, but because the microwave wavelengths used for observation are different, the damage is seen differently. By taking advantage of this characteristic and combining the results of each analysis, we were able to classify the damage situation. The damage estimation map identifies areas where the ground surface has changed due to various causes associated with the earthquake, and where buildings such as houses may have been deformed. Possible causes of changes in ground surface conditions include ground displacement due to crustal deformation and strong shaking, flooding due to tsunamis, sediment inflow from slopes, and deformation of buildings. Damage to buildings includes various types of damage such as "washing away and collapse due to tsunami," "burning down due to fire," "collapse and roof tiles falling due to earthquake shaking," and "tilting due to liquefaction." This information includes secular changes such as expansions and renovations that occurred during the data observation period, and changes in the ground surface due to crustal deformation.

The purpose of this study is to clarify an effective method for disaster area detection with just one satellite-based constellation SAR data acquired on the day after earthquake. For object detection method, YOLOv8 [4] and Detectron2 [5] is used. YOLOv8 and Detectron2 is one of the effective object detection methods of which the damage areas are detected with learned AI models by using satellite-based SAR data through learning processes with an annotation process based on an instance segmentation of disaster areas. The method proposed here is based on the learned AI model, particularly YOLOv8 and Detectron2 of object detections. YOLOv8 is a state-of-the-art object detection and image segmentation model created by Ultralytics, the developers of YOLOv5 while Detectron2 is model zoo of its own for computer vision models written in PyTorch.

Research background and related research works are described in the following section followed by the proposed method. Then experiments are described followed by conclusion with some discussions.

## II. Research Background and Related Research Works

### A. Research Background

The Noto Peninsula Earthquake is an earthquake that occurred at 16:10 on January 1, 2024, with the epicenter located 42 km northeast of Anamizu Town, Hosu District, on the Noto Peninsula, Ishikawa Prefecture, Japan (see Fig. 1). The earthquake had a magnitude (Mj) of 7.6 according to the Japan Meteorological Agency, and the depth of the epicenter was 16 km. The maximum observed seismic intensity was 7, which was observed in Wajima City, Ishikawa Prefecture, and Shiga Town, Hakui District.

To date, 236 people have been confirmed dead in Ishikawa Prefecture due to the Noto Peninsula earthquake on January 1st, and the whereabouts of 19 people are still missing. Damage has been confirmed to 43,766 homes as of the 28th of January, mainly in the Noto region, and as of January 28, approximately 3,300 homes remain without electricity and approximately 42,490 homes remain without water supply. Regarding water outages, Ishikawa Prefecture has clarified the outlook for each local government and says that the tentative restoration period will be from the end of February to the end of March in most cases, and in some cases, it will be from April onwards.

### B. Related Research Works

Application of the disasteretection method using SAR intensity images to recent earthquakes is introduced [1]. Also, building-disasteretection using post-seismic high-resolution SAR satellite data is investigated [2]. A comprehensive review of earthquake-induced building disasteretection with remote sensing techniques is published [3].

Earthquake disasteretection in urban areas using curvilinear features is attempted [4]. Meanwhile, earthquake damage visualization (EDV) technique for the rapid detection of earthquake-induced damages using SAR data is proposed [5]. On the other hand, a deep learning model for road disasteretection after an earthquake based on SAR and field datasets is proposed [6].

Probabilistic cellular automata-based approach for prediction of hot mudflow disaster area and volume is attempted [7]. Also, two-dimensional cellular automata approach for disaster spreading is proposed [8]. Meantime, probabilistic cellular automata-based approach for prediction of hot mudflow disaster area and volume is attempted [9].

New approach of prediction of Sidoarjo hot mudflow disaster area based on probabilistic cellular automata is tried [10]. On the other hand, cell-based GIS as cellular automata for disaster spreading prediction and required data systems is proposed and realized [11]. Meanwhile, sensor network for landslide monitoring with laser ranging system avoiding rainfall influence on laser ranging by means of time diversity and satellite imagery data-based landslide disaster relief is created [12].

Cell based GIS as cellular automata for disaster spreading predictions and required data systems is created [13]. On the other hand, flooding and oil spill disaster relief using Sentinel-1 and Sentinel-2 of remote sensing satellite data is attempted [14]. Convolutional neural network considering physical processes and its application to disaster detection is proposed [15]. More recently, a method for frequent high resolution of optical sensor image acquisition using satellite-based SAR image based on GAN (Generative Adversarial Network) for disaster mitigation is proposed [16].

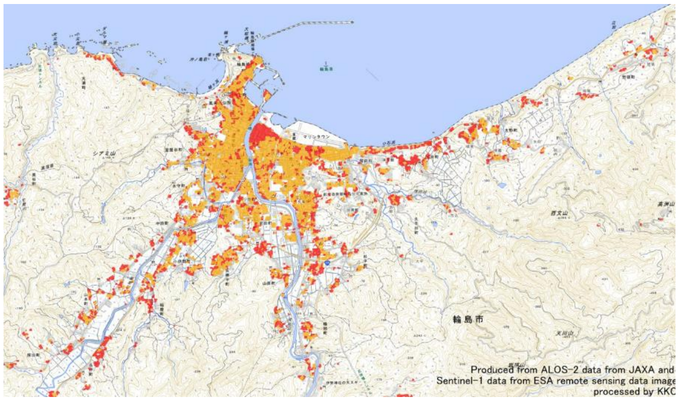
## III. Proposed Method

### A. Annotation

Kokusai Kogyo Co., Ltd. analyzes the changes in coherence using multiple satellite SAR observation data before and after an earthquake and identifies the area where building damage such as fire, liquefaction, and collapse/disaster to the earthquake occurred and the structure of the building. It has estimated the damage situation[6]. In accordance with their research report, disaster areas they found is shown in Fig. 2.



輪島市
Produced from ALOS-2 data from JAXA and
Sentinel-1 data from ESA remote sensing data image
processed by KKC

Fig. 2. Disaster areas found by Kokusai Kogyo Co. Ltd.

Meanwhile, The National Research Institute for Earth Science and Disaster Prevention publishes disaster situation data from satellite data from Synspective[7], Umbra[8], QPS Research Institute[9], Axelspace[10], JAXA[11], NASA[12], etc. through a disaster situation data site called Crossview[13]. This site is constantly adding image data obtained from satellite observations provided by satellite operating organizations. Optical satellites can capture images like cameras. Additionally, radar images are observed using electromagnetic waves that are invisible to humans and can be observed through clouds. Furthermore, thermal infrared sensors can observe high temperature regions. Among them, Umbra has released high spatial resolution SAR raw data, which clearly depicts the disaster situation. Therefore, by using these effectively, it is possible to understand the disaster situation, but the method for doing so is still not clear.

### B. Proposed Approach

Learn with YOLOv8[14] and Detectron2[15] using the disaster area obtained from the Geospatial Information Authority of Japan's aerial photo interpretation, Planet Dove[16], and Pleiades Neo[17] for annotation. Roboflow[18] is used for annotation and augmentation as well as YOLOv8 and Detectron2 is used for creation of learned model for disaster areas.

The data used here is Umbra. The raw SAR data can be downloaded from the site[19] as shown in Fig. 3. 11 scenes of geotiff formatted Umbra SAR data were downloaded as shown in Fig. 3(a) while an example of downloaded Umbra SAR data is also shown in Fig. 3(b). The example of Umbra SAR data is a portion of the downloaded images of north part of the Noto Peninsula taken on the 6th of January 2024. The disaster areas of landslides, big fires, collapse of buildings and houses, steep slopes, roads, etc. are included in the scene. The backscattering intensity of the disaster areas of landslides, big fires, collapse of buildings and houses, steep slopes, roads, etc. shows relatively high because scattering components are gotten increased.

(a) List of the downloaded Umbra SAR data

(b) Example

Fig. 3. An example of the data used for disaster area detection.

## IV. Experiments

We compared estimates of landslide disaster areas based on aerial photographs from the Geospatial Information Authority of Japan with optical images. As a result, it was found that the shape of the actual disaster may be different, such as that the disaster area may not have exposed bare ground due to fallen trees, etc. as shown in Fig. 4(a).

After comparing the post-disaster optical images with Umbra's SAR data, we found that in Fig. 4(b), the disaster area was not visible in the SAR data due to radar shadows, so we needed to take a closer look. It was also found that the red frame was not visible, but the blue frame was visible. Although many other SAR data are available, Swath is narrow but has high spatial resolution, and the raw data can be downloaded for free, so we used only Umbra's raw data for training.

In Fig. 4(b), red and blue rectangles show that invisible and visible areas. Because the disaster area is not visible in the

SAR data due to radar shadowing, it is necessary to take a closer look.

55 scenes of Umbra SAR data are used for training and augmentation. Also, five scenes are used for validation and three test scenes are used for test performances, respectively. These are shown in Fig. 5(a), (b) and (c), respectively.

In comparison to learning processes between YOLOv8 and Detectron2, it is found that followings: There is a discrepancy between Umbra and the actual terrain, which is thought to be a problem with annotation accuracy. Road blockages may be detected. There are various types of actual disasters, such as landslides, debris flows, and landslides. Looking at the optical images, we found that although the affected area was large, there were some disasters where the ground was covered with fallen trees and was not visible on SAR. It is also possible that the vegetation has decreased in winter, making it difficult to recognize areas that have become bare ground.

There are also problems that cannot be recognized due to not only shadowing, but also foreshortening, layover, etc.

Fig. 6 shows the learning performance of YOLOv8 while that of Detectron2 is shown in Fig. 7.

Fig. 8(a) and (b) shows the detected disaster areas at the number of epochs of 300 and 500, respectively. The number of epochs for Detectron2 is 1500 while that of YOLOv8 is 1000, respectively. The learning performance of YOLOv8 can be shown in the form of the loss functions of the training and the validation for box, segmentation, classification and DFL which area shown at the left side of Fig. 6. Meanwhile, that of Detectron2 evaluation results are displayed as logs and indicators. Common evaluation metrics include mean object detection accuracy (mAP) as well as precision and recall which are shown in Fig. 7. Total loss function is gradually decreased in accordance with the number of iterations and is stable at more than 1500 of iterations for Detecrton2.

Box, segmentation, classification and DFL loss functions of training and validation are shown for YOLOv8 learning performance while Metric mAP50, mAP50/95 are shown for Detectron2 learning performance, respectively. Where, mAP50 denotes mean average accuracy calculated with an intersection over union (IoU) threshold of 0.50. This is a measure of the accuracy of the model considering only "simple" detections while mAP50-95 denotes mean average accuracy calculated at various IoU thresholds from 0.50 to 0.95. A comprehensive view of model performance at different detection difficulty levels can be understood. Segmentation and classification show relatively good training and validation performances box loss function is not so good performance. Therefore, it is not so good bounding box cannot be determined in particular for the validation.

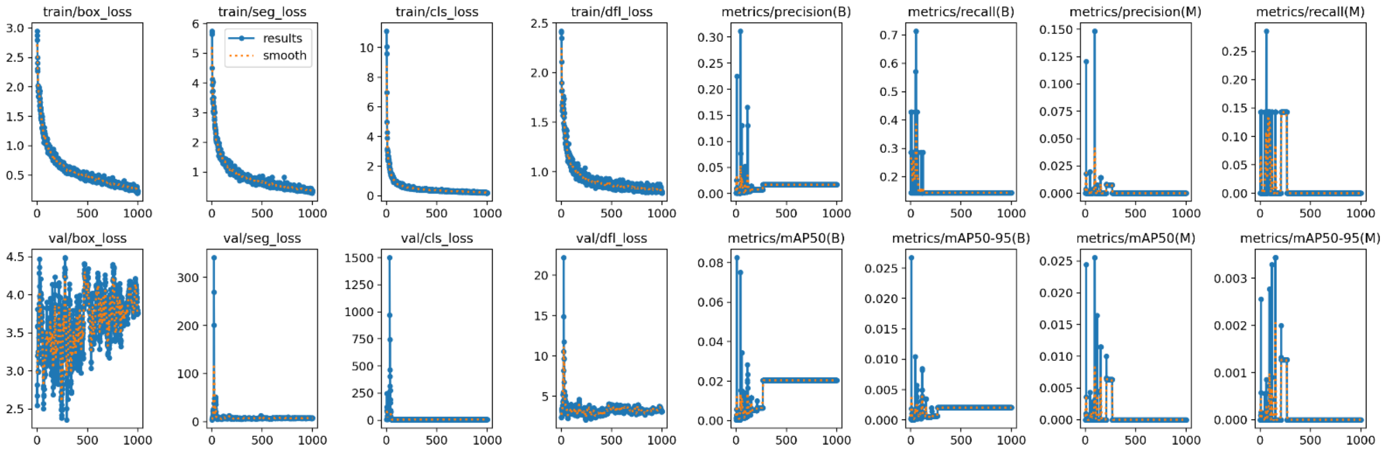

Fig. 6. Learning performance of YOLOv8 for damage area detection.

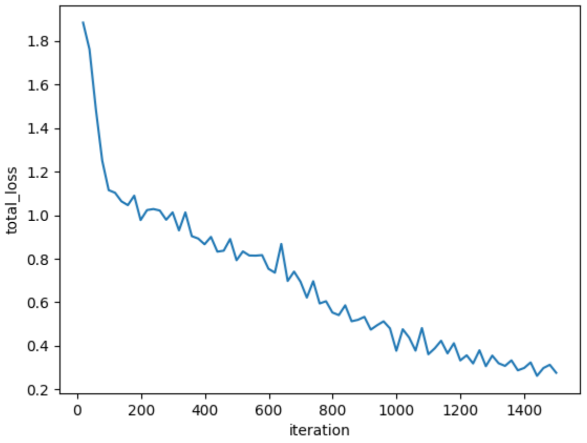

Fig. 7. Total loss function of Detectron2

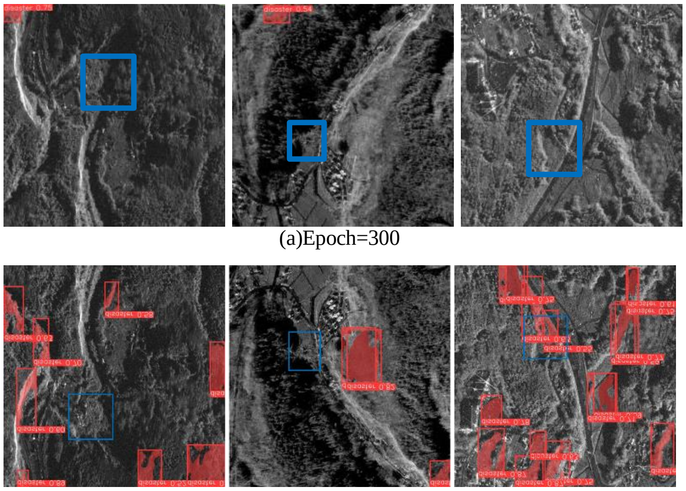

(a)Epoch=300

(b)Epoch=500

Fig. 8. Detected disaster areas with Umbra SAR data through learning process with YOLOv8 and Detectron2.

In comparison of the detected disaster areas between epoch=300 and 500, it is found that the number of detected disaster areas for epoch=300 is smaller than that for epoch=500. Also, it is found that the number of detected disaster areas are almost same for the epoch>500. Furthermore, the detected disaster areas are almost matched to the annotated areas and visual perceptions. Therefore, epoch=500 would be enough for the learning process.

## V. Conclusion

Method for earthquake disaster area detection with just a single satellite-based SAR data which is acquired on the day after earthquake based on object detection method of YOLOv8 and Detectron2 is proposed. Through experiments with several SAR data derived from the different SAR satellites which observed Noto Peninsula earthquake occurred on the first of January 2024, it is found that the proposed method works well to detect several types of damages effectively. Also, it is found that the proposed method based on Roboflow and YOLOv8 as well as Detectron2 for annotation and object detection is appropriate for disaster area detection.

Furthermore, it is possible to detect disaster areas even if just one single SAR data which acquired on the day after the disaster occurred by using the trained model built here. Using the truth data of disaster areas which are derived from aerial photo interpretations and space-based SAR imagery data, trained learning model is created with YOLOv8 and Detectron2. This model can be applicable to detect disaster areas by using a single SAR imagery data. It is beneficial to prevent secondary disasters and to plan for disaster recovery. In order for that, a transfer learning process is required with the acquired SAR imagery data which is acquired just after disaster occurred.

## Future Research Works

This paper would be the first preliminary paper which deals with the Noto Peninsula earthquake which occurred on 1st of January 2024. Object detection-based method for disaster area detection would be original for grasp earthquake disaster situation. Further study is required for improvement of the accuracy of disaster area detection with the other methods not only Roboflow and YOLOv8 as well as Detectron2, but also EfficientNet and the others.

## ACKNOWLEDGMENT

The authors would like to thank to Professor Dr. Osamu Fukuda of Saga University for his valuable discussions.

# Forecasting the Yoga Influence on Chronic Venous Insufficiency: Employing Machine Learning Methods

Xiao Du
College of Physical Education, Hubei University of Education, Wuhan 430205, Hubei, China

***Abstract*—This investigation introduces a groundbreaking approach to unravel the complexities of Chronic Venous Insufficiency (CVI) by leveraging machine learning, notably the Support Vector Classification (SVC), alongside optimization systems like Dwarf Mon-goose Optimization (DMO) and Smell Agent Optimization (SAO). This pioneering strategy not only aims to bolster predictive Precision but also seeks to optimize personalized treatment paradigms for CVI, presenting a compelling avenue for the advancement of healthcare solutions. The study aims to predict the impact of yoga on CVI using a comprehensive dataset, incorporating demographic information, baseline severity indicators, and yoga practice details. Through meticulous feature engineering, machine learning algorithms forecast outcomes such as changes in symptom severity and overall well-being improvements. This predictive model has the potential to transform personalized CVI treatment plans by offering tailored recommendations for specific yoga practices, optimizing therapeutic approaches, and guiding efficient healthcare resource allocation. Ethical considerations, patient preferences, and safety are highlighted for responsible translation into clinical settings. The integration of SVC with optimization systems presents a novel and promising approach, contributing meaningfully to personalized CVI management and providing valuable insights for current and future practices. The results obtained for VCSS-PRE and VCSS-1 unequivocally highlight the outstanding performance of the SVDM model in both prediction and categorization. The model achieved remarkable Accuracy and Precision values, attaining 92.9% and 93.1% for VCSS-PRE and 94.3% and 94.9% for VCSS-1.**

***Keywords*—Chronic Venous Insufficiency; yoga; classification; machine learning; Support Vector Classification; smell agent optimization; Dwarf Mongoose Optimization***

## I. Introduction

Chronic diseases, defined by the U.S. National Center for Health Statistics as persisting for three months or more, encompass conditions like cardiovascular disease, cancer, arthritis, diabetes, epilepsy, chronic venous disease (CVD), and obesity. These ailments, characterized by their prolonged nature, are not curable through medication. Major contributors to chronic diseases include the use of tobacco, insufficient physical activity, and unhealthy living and eating habits. As examples of Chronic diseases, cardiovascular diseases [1] result from factors such as poor nutrition, lack of physical activity, and tobacco use. Cancer [2], a group of diseases involving abnormal cell growth, has the potential to spread to different body parts. Diabetes [3], characterized by high blood sugar levels, manifests in various types, including Type 1, Type 2, Prediabetes, and Gestational diabetes, each presenting distinct signs and symptoms. As another instance, CVD is a prevalent condition characterized by a spectrum of clinical manifestations, including spider veins, varicose veins, and active venous ulceration. The condition's etiology involves dysfunction in both superficial and deep venous systems [4].

The escalating risk factors associated with CVD present a growing socio-economic and public health challenge. The rising prevalence of obesity and the aging population are anticipated to contribute to an increased burden of CVD over the coming decade, straining available resources for its management. Focusing on the epidemiological, quality of life, and financial aspects of superficial and deep venous disease, with considerations for future projections, the reported prevalence rates for superficial venous disease exhibit significant heterogeneity, with spider veins affecting up to 80% of the population and varicose veins estimated at 30% [5], [6], [7]. Epidemiological studies encounter variability influenced by study population characteristics and modalities, raising concerns about the realistic estimation of disease prevalence. For instance, venous ulcers, impacting 1–2% of the UK population, particularly in older people, pose challenges due to their difficult treatment and recurrent nature [5]. Evidence suggests that CVD is a progressive condition, emphasizing the importance of early prevention.

Moreover, quality of life is substantially impacted by CVD, as indicated by various assessment tools, with depression rates doubling in CVD patients [8], [9]. The financial burden is notable, too, with venous ulcers alone accounting for a significant percentage of the budget expenditure of countries [10]. All these issues necessitate the importance of substantial care within community settings.

The optimal treatment for the human body is not always found in pharmaceutical interventions. Many individuals have experienced adverse effects associated with medication usage, such as antibiotics influencing genetic variability [11]. These side effects encompass hematologic issues, decreased platelet count, drug-induced fevers, rashes, serum sickness, encephalopathy, seizures, blindness, and pulmonary complications, among others [12]. Considering the myriad negative consequences of pharmaceuticals, there has been a significant shift toward emphasizing yoga in medical research. Numerous surveys indicate a rapid increase in the adoption of yoga. Demographic trends reveal that younger individuals, non-Hispanic whites, those with higher incomes, females, college graduates, and individuals with better health status are more inclined to integrate yoga into their lifelong practices [13].

In the past decade, there has been a growing recognition of the significance of Yoga within the medical research community, with a substantial body of literature exploring its applications in various medical contexts, interventions for positive body image [14], [15], including cardiac rehabilitation [16], and the management of mental illnesses [17]. Notably, Yoga is advocated as a therapeutic approach capable of effectively treating numerous diseases without the reliance on pharmaceutical interventions [18]. The practice of Yoga encompasses a range of exercises that not only enhance physical health but also contribute to the purification of the body, mind, and soul [19]. This involves the performance of various asanas, each representing static physical postures [20]. Systems for learning and self-instruction in Yoga have the potential to promote its widespread adoption while ensuring correct practice [21].

Recent technological advancements in machine learning (ML) and Data mining have led to the development of sophisticated methods for processing medical data. A comprehensive review [22] discussed the specifics, challenges, and potential risks associated with ML models in medicine, and several studies have explored diverse applications of machine learning in healthcare [23], [24], [25], [26].

According to Nafee et al. [27], the purpose of the research was to evaluate how well machine learning models identified acutely sick individuals who were at high risk of venous thromboembolism (VTE) when compared to the IMPROVE score. Data from the APEX study, in which 7513 individuals were randomly assigned to receive betrixaban or enoxaparin, were examined by researchers. They used a variety of candidate models and variables to build a reduced model $(rML)$ and a super ML. Every patient's IMPROVE score was determined. The c-statistic values for the ML and $rML$ algorithms were higher (0.69 for ML, 0.68 for $rML$, and 0.59 for IMPROVE score), indicating that they outperformed the IMPROVE score in predicting VTE. The machine learning models were also preferred by calibration analysis. Compared to patients in the lowest tertile, those in the highest tertile of estimated VTE risk had considerably higher chances of developing VTE. The study's result was that, when it came to predicting VTE in critically sick patients, machine learning algorithms outperformed the IMPROVE score in terms of discrimination and calibration. Ryan et al. [28] focused on the challenges of effectively predicting deep venous thrombosis (DVT) in hospitalized patients, given the limitations of standard scoring systems. The research made use of data from a large university hospital that included 99,237 patients in ICUs or general wards, 2,378 of whom had DVT while they were hospitalized. Gradient-boosted models is a kind of machine learning method, was used to forecast the probability of DVT at 12- and 24-hour intervals prior to initialization. The in-hospital diagnosis of DVT was the main outcome of interest. With AUROCs of 0.83 and 0.85 for DVT risk prediction at 12- and 24-hour periods, respectively, the ML models showed strong performance. A history of malignancy, viral thromboencephalopathy (VTE), and the internal normalized ratio (INR) at 12 and 24 hours before to the beginning of DVT were shown to be significant predictors of DVT risk. The research emphasized the potential therapeutic advantages of enhanced risk stratification, indicating that it would allow for more focused administration of preventive anticoagulants and lessen the necessity for intrusive testing in difficult patients. This might thus result in an earlier diagnosis and course of therapy, hence reducing the likelihood of problems like pulmonary emboli and other DVT-related sequelae developing. Kumar et al. [29], this study addressed cardiovascular disease (CVD), which includes disorders marked by constricted or clogged veins that may result in strokes, angina, or heart attacks. The purpose of the research was to assess how well machine learning tree classifiers performed in predicting CVD from patient symptoms. The accuracy and AUC ROC scores of a number of machine learning tree classifiers, such as Random Forest, Decision Tree, Logistic Regression, Support Vector Machine (SVM), and K-nearest neighbors (KNN), were investigated. The Random Forest classifier proved to be very successful in the study of Cardiovascular Disease prediction, with a performance time of 1.09 seconds, a ROC AUC score of 0.8675, and a high accuracy rate of 85%. This shows that, in the context of this investigation, the Random Forest classifier had strong predictive skills in diagnosing CVD based on symptomatology.

The articles mentioned above, as is generally accepted, were noticeably devoid of any optimization techniques that could have been utilized to improve precision and reduce complexity in their predictive models. The lack of optimization strategies incorporated in these studies signifies a substantial deficiency in the predictive analytics methodology utilized. Optimization methodologies are crucial in the process of fine-tuning and refining a predictive model, which ultimately increases their accuracy and decreases their computational complexity. Through the process of algorithm optimization, scholars have the ability to methodically improve the overall efficacy of predictive models, thereby guaranteeing a more precise and streamlined depiction of the latent patterns within the data. By enhancing prediction outcomes and contributing to the enhancement of computational efficiency, optimization techniques enable the development of models that are not only more scalable but also more adaptable to diverse datasets. Fundamentally, the incorporation of optimization methodologies is a critical component in enhancing the predictive modeling procedure, thereby promoting more reliable and efficient results in analyses driven by data. Inspired by all existing literature and considering the gap related to the investigation of ML application in effect detection between Yoga and CVD.

This study aims to construct robust machine-learning models for forecasting the impact of Yoga on CVD, harnessing data from credible sources. The chosen methodology involved the application of the Support Vector Classification (SVC) technique. An inventive strategy was implemented by seamlessly incorporating two optimization algorithms, namely Dwarf Mongoose Optimization (DMO) and Smell Agent Optimization (SAO), infusing the predictive modeling process with a nuanced and sophisticated dimension. SVC was selected as the predictive model for assessing the effects of yoga on CVD due to its proficiency in handling complex datasets and non-linear relationships. It excels in classification tasks, making it well-suited for discerning patterns and predicting outcomes. The model's robustness, coupled with its ability to capture intricate relationships, makes it an effective choice for predicting the impact of yoga on CVD. A comprehensive analysis of the pertinent data, the model, and the optimizers implemented in Section II will be presented in the subsequent sections. A comprehensive analysis of the metrics-driven models and an in-depth explication of the data will be presented. The outcomes obtained from the training and testing stages will be thoroughly examined in Section III. Discussion is given in Section IV and finally, Section V concludes the paper.

## II. Materials and Methodology

### A. Support Vector Classification (SVC)

Support Vector Classification is an algorithm based on the foundational concept of minimizing risk within the context of support vector machines [30]. It involves applying non-linear transformations to the independent variables and projecting them into a high-dimensional space. Within this space, an optimal hyperplane is created to separate the two classes effectively. The main objective of this hyperplane is to minimize classification errors while maximizing margins, representing the overall distance from the hyperplane to the nearest training samples of each class [31].

The main model is subsequently presented in Eq. (1) to Eq. (3) [32].

$$min_{w,b,\in} \frac{\|W\|^2}{2} + C_{svc} \sum_{i=1}^{N} \in_i \quad (1)$$

$$y_i(w^T.\emptyset(x_i) + b) \geq 1 -\in_i \qquad i = 1,\dots,N \quad (2)$$

$$\in_i \geq 0 \qquad i = 1,\dots,N \quad (3)$$

The function $\emptyset(x_i)$ denotes a non-linear transformation that takes each observation, characterized by its explanatory variables $x_i$, and maps it into a higher-dimensional space. $C_{svc}$ represents a regularization parameter, $w$ symbolizes the weight vector associated with the explanatory variables in the newly defined space commonly referred to as the "feature space." $b$ signifies a bias term, and $\in_i$ are slack variables indicating the gap or distance between individual observations $(i)$ and the margin boundary associated with their respective classes.

Identifying the optimal hyperplane, as outlined in Eq. (4), involves maximizing the margin within the high-dimensional space. This process essentially revolves around minimizing the norm of the weight vector while also reducing the number of misclassified instances. In the end, the labels or output variables signify the class to which each sample belongs.

$$D(x_i) = W^T\varphi(x_i) + b \quad (4)$$

The dimensionality of the problem influences the magnitude of the primal model, whereas the number of samples influences the dual form. Consequently, when the dimensionality is high enough, it becomes more beneficial to deal with the dual model, as indicated in Eq. (5) to Eq. (7).

$$max_a \sum_{i=1}^{N} a_i - \frac{1}{2}\sum_{i=1}^{N} a_i a_j y_i y_j K(x_i, x_j) \quad (5)$$

$$\sum_{i=1}^{N} a_i y_i = 0 \quad (6)$$

$$0 \leq a_i \leq C_{svc} \qquad i = 1,\dots,N \quad (7)$$

A Kernel function, represented as $K(x_i, x_j)$, maps each pair of data points to a corresponding location in the feature space. There are various Kernel functions available, such as linear, polynomial, radial basis, sigmoidal, and others. A crucial requirement for these functions is that they must be symmetric, positive, and semi-definite. Previous research in this field has demonstrated that the radial basis Kernel function, defined in Eq. (8), is particularly well-suited for classification tasks [33]. Consequently, a radial basis Kernel function is utilized in the present approach, with 'γ' serving as a hyperparameter indicating the inverse of the range of influence of the data points identified as support vectors [34].

$$K(x_i, x_j) = \emptyset(x_i)^R\emptyset(x_j) = exp(-\gamma\|x_j - x_i\|) \quad (8)$$

After solving the model to estimate the weights and the bias term, predictions for new samples can be generated using Eq. (9).

$$SVC \quad y_i = \begin{cases} -1 \; if \; w^T\emptyset(x_i) + b \; \leq 0 \\ 1 \; if \; w^T\emptyset(x_i) + b \; > 0 \end{cases} \quad (9)$$

### B. Smell Agent Optimization (SAO)

The significance of the sense of smell in sustaining life on Earth has been profound since the planet's inception. Many living organisms detect harmful substances in their environment through their olfactory receptors [35], [36], [37]. A common practice in the development of Search and Rescue Agents (SAO) involves integrating the human sense of smell [37], [38], [39]. The SAO's structure is based on three modes derived from the olfactory sense. The initial mode entails detecting and evaluating olfactive molecules to decide whether to pursue or ignore the scent. The second mode builds upon the first to track scent particles and locate their source. The third mode prevents the agent from getting trapped and ensures it can maintain its trail.

*1) Sniffing mode:* Initiating the process involves randomly selecting a location for the diffusion of odor molecules toward the agent, taking into account that olfactory molecules typically propagate in the direction of their target. The mathematical formula, represented by Eq. (10), can be utilized to initialize the scent molecules.

$$x_i^{(t)} = \begin{bmatrix} x_{(1,1)} & x_{(1,2)} & x_{(1,D)} \\ \cdot & \cdot & \cdot \\ x_{(N,1)} & x_{(N,2)} & x_{(N.D)} \end{bmatrix} \quad (10)$$

Here, D signifies the total count of decision variables, while N represents the overall number of scent molecules present.

Eq. (10) utilizes a location vector that allows the agent to identify its optimal position within the search space. This optimal location can be determined using Eq. (11):

$$x_i^{(t)} = lb_i + r_0 \times (ub_i - lb_i) \tag{11}$$

$r_0$ is a randomly generated number ranging from 0 to 1. In relation to the decision variables, $ub$ and $lb$ represent the upper and lower bounds, respectively.

Eq. (12) is employed to assign a primary velocity for diffusion to each scent molecule originating from the odor source.

$$v_i^{(t)} = \begin{bmatrix} v_{(1,1)} & v_{(1,2)} & v_{(1,D)} \\ \cdot & \cdot & \cdot \\ v_{(N,1)} & v_{(N,2)} & v_{(N.D)} \end{bmatrix} \tag{12}$$

Every single molecule's scent can potentially signify a feasible solution. The position vector determines the potential solutions, $x_i^{(t)} \in R^N$, as illustrated in Eq. (12), along with the molecular velocity, $v_i^{(t)} \in R^N$, as specified in the same equation. The increase in molecular velocity is achieved through Eq. (13):

$$x_i^{t+1} = x_i^{(t)} + v_i^{t+1} \times \Delta t \tag{13}$$

The optimization process is progressed by the agent simultaneously when the time interval $\Delta t$ is set to 1. Eq. (14) is used to determine the fragrance molecules' spatial coordinates:

$$x_i^{t+1} = x_i^{(t)} + v_i^{t+1} \tag{14}$$

Every scent molecule possesses unique diffusion velocities that facilitate its positional updates and evaporation during scent analysis. Eq. (15) is employed to calculate the adjusted velocity of the scent molecules.

$$v_i^{t+1} = v_i^{(t)} + v \tag{15}$$

The variable governing the velocity update, denoted as $v$, is determined by utilizing Eq. (16):

$$v = r_1 \times \sqrt{\frac{3KT}{m}} \tag{16}$$

The smell fixation factor, denoted by the letter "k," serves to normalize the impact of temperature and mass on the kinetic energy of fragrance molecules. The letters "m" and "T" in this instance denote the smell molecules' mass and temperature, respectively.

The evaluation of the fitness of the scent molecule at the adjusted locations is conducted using Eq. (13). Consequently, the sniffing process is completed, allowing for the determination of the exact location of the agent, denoted as $x_{agent}^t$.

*2) Trailing mode:* The second operational mode entails simulating the agent's behavior to locate the source of a particular scent. During the search for the scent source, the agent can identify a new location with a higher concentration of scent molecules through olfactory perception. To explore this newly detected location, the agent utilizes Eq. (17):

$$x_i^{t+1} = x_i^{(t)} + r_2 \times olf \times \left(x_{agent}^t - x_i^{(t)}\right) - r_3 \times olf \times \left(x_{worst}^t - x_i^{(t)}\right) \tag{17}$$

The term $r_2$ penalizes the impact of olfaction on $x_{agent}^t$, while $r_3$ penalizes the effect of olfaction on $x_{worst}^t$. Both $r_2$ and $r_3$ are numerical values ranging from 0 to 1. In the sniffing mode, the agent records $x_{agent}^t$ and the $x_{worst}^t$. This data is vital for the algorithm to maintain a balance between exploration and exploitation, as depicted in Eq. (17).

*3) Random mode:* In scenarios where the distance between scent molecules is notably fragmented, their intensity may vary over time. This variation can confuse the agent, leading to the dissipation of the scent and complicating tracking. The agent's difficulty in retaining trail information may result in being trapped in local minima. In such situations, the agent transitions to the random mode, as represented by Eq. (18):

$$x_i^{t+1} = x_i^{(t)} + r_4 \times SL \tag{18}$$

The term $r_4$ penalizes the quantity of step length SL, where SL represents the step length.

Algorithm 1. presents the pseudo-code depicting the SAO method:

### *C. Dwarf Mongoose Optimization (DMO)*

The DMO (Dwarf Mongoose Optimization) algorithm is a stochastic metaheuristic method that operates on a population basis. It derives inspiration from the social and foraging behaviors exhibited by the dwarf mongoose, as documented by Helotage [40].

The DMO's problem-solving approach commences by choosing an initial set of potential solutions within the mongoose colony. This involves generating an initial population of candidate solutions and randomly creating them within the predetermined minimum and maximum limits specified for the particular problem at hand. The stochastic generation of solutions ensures adherence to the defined upper and lower bounds of the problem.

$$k = \begin{bmatrix} x_{1,1} & x_{1,2} & \cdots & x_{1,d-1} & x_{1,d} \\ x_{2,1} & x_{2,2} & \cdots & x_{2,d-1} & x_{2,d} \\ \vdots & \vdots & x_{1,1} & \vdots & \vdots \\ x_{n,1} & x_{n,2} & \cdots & x_{n,d-1} & x_{n,d} \end{bmatrix} \quad (19)$$

The symbol d denotes the dimensionality of the underlying problem, while n represents the cardinality of the population. The positional attribute of individual elements in a population is denoted as $x_{i,j}$ and determined by applying Eq. (20)

$$x_{i,j} = unifrnd(Var_{Min}, Var_{Max}, Var_{Size}) \quad (20)$$

The term $Var_{Size}$ is associated with the dimensions and ranges of the problem under consideration. The $unifrnd$ function serves as a random number generator, producing numbers with a uniform distribution. $Var_{Min}$ and $Var_{Max}$ represent the lower and upper bounds, respectively.

With two different phases—exploration and exploitation—the DMO algorithm adheres to the usual metaheuristic methodology. Known as intensification, every mongoose does a comprehensive search within the defined region during the exploitation phase. On the other hand, the phrase "exploration phase" refers to a more haphazard quest for novel resources, such as food supplies or sleeping mounds. Three crucial social structures—the alpha group, scout group, and babysitters—allow the DMO algorithm to function during these two stages. The coordination of the solution population's actions, which guarantees efficient search space exploration and exploitation, is greatly aided by these structures. This is a list of all the things that need to be done.

*1) Alpha group:* To designate the alpha female (α) for leading the family unit, Eq. (21) is employed as a selection method.

$$\alpha = \frac{fit_i}{\sum_{i=1}^{n} fit_i} \quad (21)$$

$n$ represents the current number of mongooses that comprise the alpha group, $peep$ refers to an auditory signal that is produced by a dominant or alpha female mongoose. In addition, $bs$ is utilized to represent the number of individuals within the mongoose group who are tasked with the responsibility of caring for and supervising young offspring.

The sleeping mound demonstrates a positive correlation with a plentiful supply of nutritional ingredients, as calculated by Eq. (22):

$$X_{i+1} = X_i + \varphi * peep \quad (22)$$

$\varphi$ is a numerical value uniformly distributed within the range of [-1, 1].

During each iteration, of the algorithm, the size and quality of the sleeping mound are assessed, as indicated by mathematical Eq. (23):

$$sm_i = \frac{fit_{i+1} - fit_i}{max\{|fit_{i+1}, fit_i|\}} \quad (23)$$

Upon detecting a previously inactive accumulation, a statistical measure is computed using mathematical Eq. (24):

$$\rho = \frac{\sum_{i=1}^{n} sm_i}{n} \quad (24)$$

*2) Scout group:* After fulfilling the requirements for participation in a babysitter exchange program, the subsequent step involves a scouting stage. In this stage, an assessment is conducted to identify a suitable sleeping location, contingent on the availability of a specific sustenance source. Acknowledging the tendency of mongooses to avoid reusing previously employed sleeping locations, the scouting group is assigned the task of locating a new sleeping mound to facilitate the ongoing advancement of their exploratory endeavors. Within the context of the DMO algorithm, the mongoose demonstrates a distinctive activity pattern marked by foraging and scouting behaviors. This behavior operates on the premise that increasing the distance covered during foraging activities enhances the likelihood of discovering a new sleeping location. Mathematically, this process is represented by the utilization of Eq. (25) to Eq. (27):

$$X_{i+1} = \begin{cases} X_i - CF * phi * rand * \left[X_i - \vec{M}\right] \, if \; \rho_{i+1} > \rho_i \\ X_i + CF * phi * rand * \left[X_i - \vec{M}\right] \qquad else \end{cases} \quad (25)$$

$$CF = \left(1 - \frac{iter}{Max_{iter}}\right)^{\left(2\frac{iter}{Max_{iter}}\right)} \quad (26)$$

$$\vec{M} = \sum_{i=1}^{n} \frac{X_i \times sm_i}{X_i} \quad (27)$$

$\vec{M}$ denotes the force propelling the movement of the mongoose toward a recently formed sleeping mound, and $rand$ signifies a random number that is uniformly distributed within the range of [-1, 1].

*3) Babysitters group:* While the scouting and foraging team searches for a suitable location for rest and food, the group dedicated to the well-being of the young offspring remains vigilant in monitoring and caring for them. The pool of available candidates for the babysitter exchange diminishes as certain group members opt to postpone their foraging or scouting activities until they fulfil the requirements for participating in the exchange program. Algorithm 2 provides the pseudo-code for the DMO algorithm.

Algorithm 2 Pseudo-Code of DMO Algorithm

```

$Modernize\ the\ best\ solution\ so\ far.$
$end\ For$
$return\ the\ best\ solution$
$end$
```

## D. Data Processing

Involving the extraction of valuable information from vast datasets, data mining, also known as database knowledge discovery, utilizes various techniques. The analysis of extensive data collection is a key aspect of this process, revealing hidden patterns and relationships that can significantly impact decision-making. Data mining approaches often incorporate the use of questionnaires or structured datasets presented in the form of reports. This study systematically extracted data from extant literature, comprising a cohort of 100 male subjects, with meticulous attention to both input and output variables. The input variables, influential in determining Chronic Venous Insufficiency (CVI) levels, encompassed diverse facets, including physical attributes (Age, Height, Weight, Body Mass Index (BMI)), Ankle-Brachial Pressure Index (ABPI), Diabetes Blood pressure type A and B (DBPA and DBPB), Pulse Rate (PR), cardiometabolic and vascular health indices (Systolic Blood Pressure type A and B (SBPA and SBPB), Left and Right Calf Circumstances (LE CA-CIR and RI CA-CIR), Mental Chronic Fatigue Syndrome (CFS MEN), Physical Chronic Fatigue Syndrome (CFS PHY), Hyper-homocysteine Mia (HCY), Left and Right Ankle Circumstances (LE AN-CIR and RI AN-CIR), and the Chronic Venous Insufficiency Questionnaire (CVIQ_total)) [41].

Additionally, factors about living conditions and habits were considered, encompassing parameters such as Sleep quality, smoking status, Alcohol intake, Dietary habits, and the duration of sitting and standing hours per workday. The suffix "(pre)" denotes the temporal aspect, indicating data collected to implement yoga practices. The principal output variable, the Venous Clinical Severity Score, was assessed before the yoga intervention (VCSS-PRE) and one month after its initiation (VCSS-1). To ensure methodological rigor, the amassed datasets underwent a randomized allocation into training and testing subsets, maintaining proportions of 70% and 30%, respectively.

The interplay between input and output variables is graphically depicted through a correlation matrix, as illustrated in Fig. 1. Examining the Pearson correlation coefficients reveals discernible patterns. Notably, certain cardiometabolic and vascular health indicators, such as Diabetes Blood pressure (DBP) and Systolic Blood Pressure (SBP), exhibit a strong positive correlation, while the individual's height demonstrates a negative influence on Body Mass Index (BMI). Further scrutiny of the figure highlights that variable RI CA-CIR-PRE-pre and CVIQ_total_pre exert the most pronounced impact on both Venous Clinical Severity Score (VCSS) values. Additionally, it is evident from the analysis that Physical Chronic Fatigue Syndrome (CFS) exerts a more substantial effect than its mental counterpart, particularly concerning VCSS-1. These findings underscore the intricate relationships and varying degrees of influence among the considered variables, providing valuable insights into the dynamics of the observed phenomena.

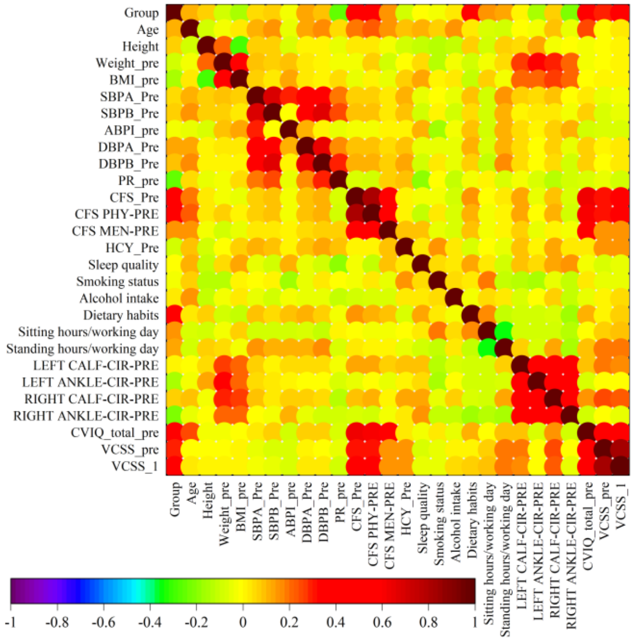

Fig. 1. Correlation matrix to analyze the relationships between input and output variables.

# III. Results

## A. Evaluation of Models' Applicability

Accuracy is a commonly used statistic in classification issues to assess the overall performance of a model. False Positives (FP) for inaccurate positive forecasts, False Negatives (FN) for wrong negative predictions, and True Positives (TP) for right positive predictions are the four essential components that it depends on. Accuracy's tendency to favor the majority class, however, may restrict its use in cases with unbalanced data. To alleviate this constraint, three additional assessment measures are often used: F1-Score, Precision, and Recall. In cases when class distributions are unbalanced, these measures provide a more sophisticated evaluation of a model's performance. These metrics are defined through Eq. (28) to Eq. (31). Moreover, it collectively provides a more comprehensive evaluation of a classification model's effectiveness.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{28}$$

$$Precision = \frac{TP}{TP + FP} \tag{29}$$

$$Recall = TPR = \frac{TP}{P} = \frac{TP}{TP + FN} \tag{30}$$

$$F1\_score = \frac{2 \times Recall \times Precision}{Recall + Precision} \tag{31}$$

### B. Convergence Results

This study employed DMO and SAO optimization algorithms to enhance the Support Vector Classification (SVC) model, creating SVDM and SVSA hybrid models. The evaluation of these models utilized a convergence curve based on Accuracy measurements over 150 iterations, revealing a significant improvement in predictive Accuracy (see Fig. 2). In predicting Venous Clinical Severity Score before yoga intervention (VCSS-PRE), both SVDM and SVSA exhibited a substantial increase in Accuracy, reaching peak levels of 0.88 and 0.87 around the 90th iteration. For VCSS-1 prediction, the Accuracy improvement rate was higher, with SVDM and SVSA achieving levels of 0.92 and 0.91, respectively. Notably, SVDM consistently outperformed SVSA in both predictive scenarios, emphasizing its superior ultimate Accuracy. These findings underscore the effectiveness of the optimization algorithms in refining model performance and highlight the comparative advantages of the SVDM hybrid model.

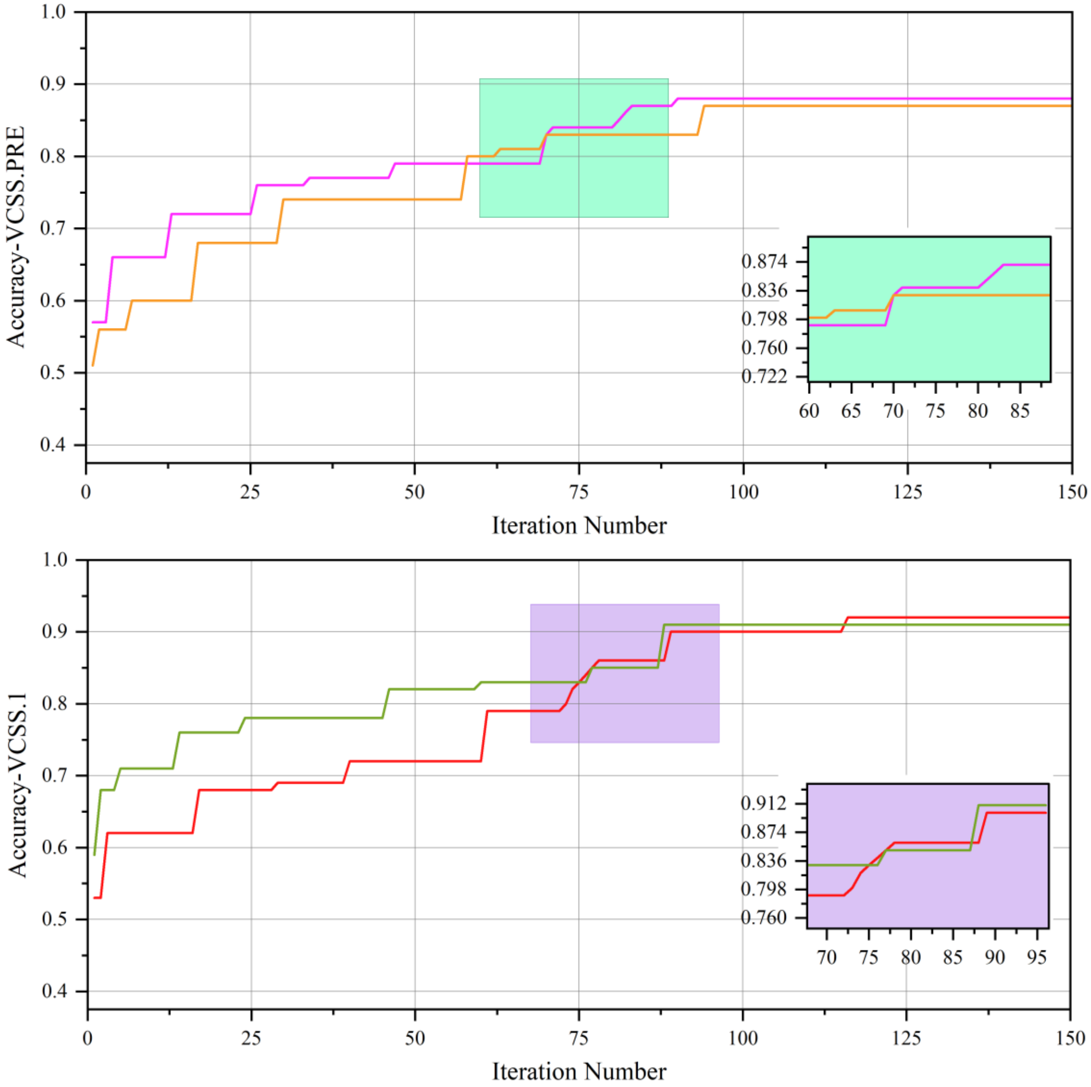

Fig. 2. Convergence curve of hybrid models.

### C. Comparing Results of Predictive Models

The primary aim of this study was to introduce three predictive models utilizing a classification approach for anticipating Venous Clinical Severity Score before (VCSS-PRE) and one month after (VCSS-1) yoga practices. Among these models, one employed a Support Vector Classifier (SVC), while the others were developed by optimizing the SVC using Dwarf Mongoose Optimization (DMO) and Smell Agent Optimization (SAO). The performance metrics, including Accuracy, Precision, Recall, and F1-score, for the training and testing phases of these machine learning algorithms are presented in Table I. Notably, for both VCSS-PRE and VCSS-1 prediction, the metrics during the training phase exceeded those in the testing phase, as visually evident in Fig. 3 (shown as 3D bar plots for all metrics and phases), indicating the models' ineffective training capability. In the case of VCSS-PRE prediction values, the SVDM model demonstrated superior performance, achieving 0.88 for Accuracy and Recall, 0.898 for Precision, and 0.885 for F1_Score. In VCSS-1 estimation, the SVDM model consistently outperformed, recording the highest values across all metrics $(Accuracy = 0.943, Precision = 0.949, Recall = 0.943, and\ F1 - score = 0.944)$.

TABLE I. RESULT OF PRESENTED MODELS

| | Model | Part | Metric value | | | |
|---|---|---|---|---|---|---|
| | | | *Accuracy* | *Precision* | *Recall* | *F1 _Score* |
| VCSS-PRE | SVC | *Train* | 0.943 | 0.948 | 0.943 | 0.943 |
| | | *Test* | 0.667 | 0.694 | 0.667 | 0.677 |
| | | *All* | 0.860 | 0.871 | 0.860 | 0.863 |
| | SVDM | *Train* | 0.929 | 0.931 | 0.9286 | 0.9287 |
| | | *Test* | 0.700 | 0.7667 | 0.700 | 0.7163 |
| | | *All* | 0.880 | 0.898 | 0.880 | 0.885 |
| | SVSA | *Train* | 0.900 | 0.918 | 0.900 | 0.903 |
| | | *Test* | 0.800 | 0.834 | 0.800 | 0.808 |
| | | *All* | 0.870 | 0.892 | 0.870 | 0.875 |
| VCSS-1 | SVC | *Train* | 0.943 | 0.946 | 0.943 | 0.943 |
| | | *Test* | 0.800 | 0.795 | 0.800 | 0.793 |
| | | *All* | 0.900 | 0.901 | 0.900 | 0.900 |

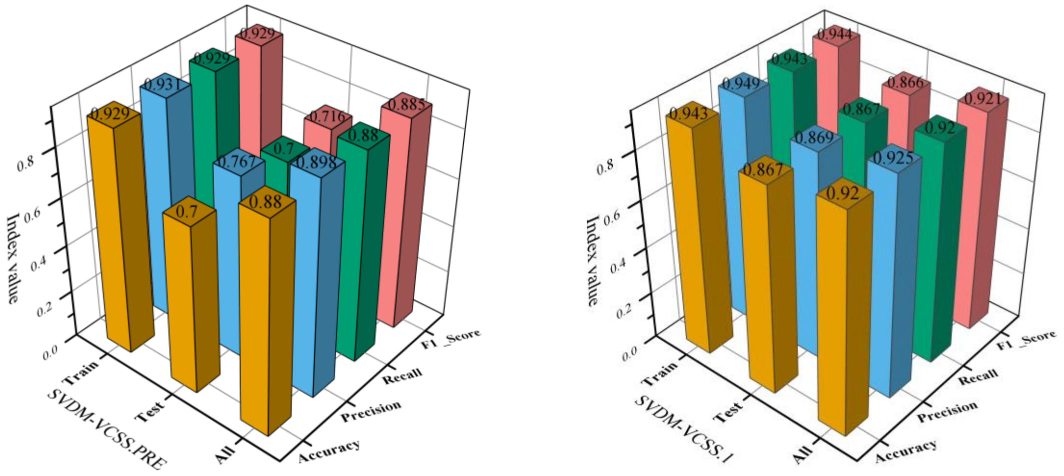
| | | *Test* | 0.867 | 0.869 | 0.867 | 0.866 |
| | | *All* | 0.920 | 0.925 | 0.920 | 0.921 |
| | SVSA | *Train* | 0.943 | 0.953 | 0.943 | 0.945 |
| | | *Test* | 0.833 | 0.850 | 0.833 | 0.835 |
| | | *All* | 0.910 | 0.923 | 0.910 | 0.913 |



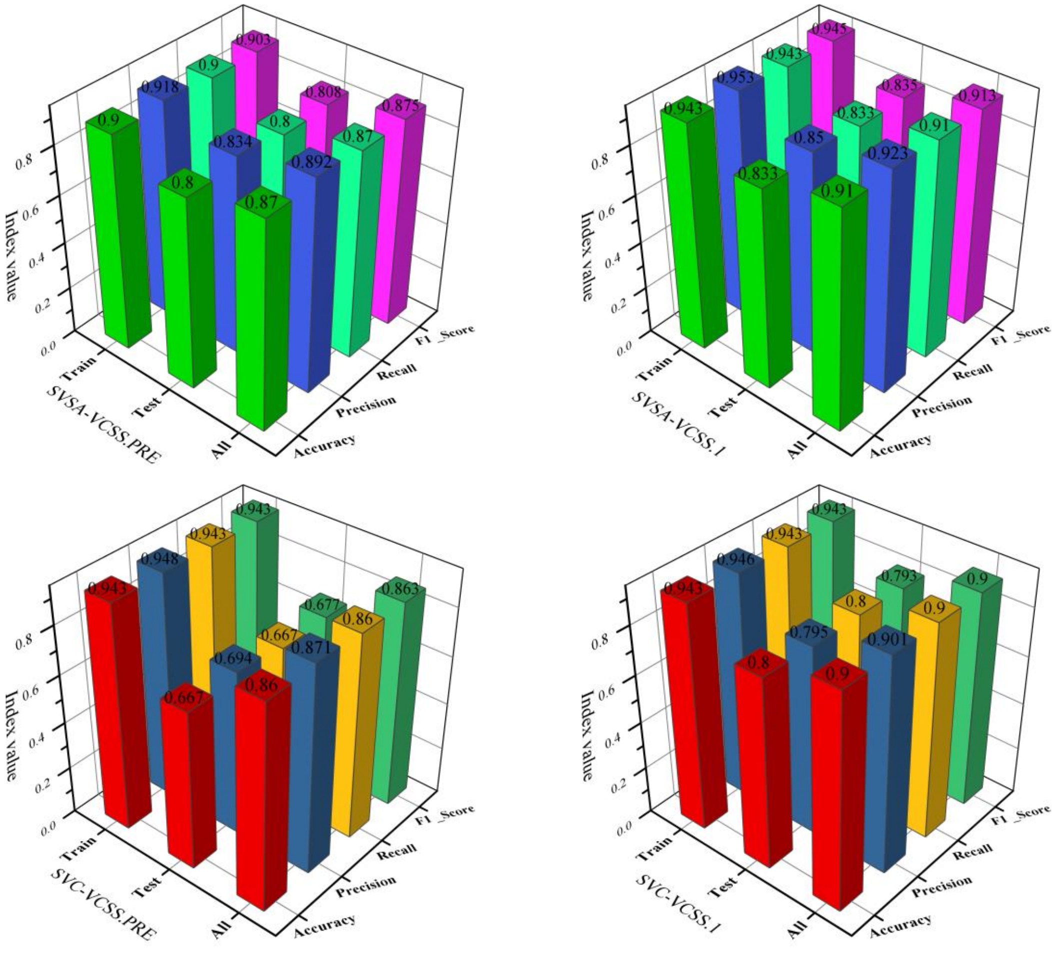


Fig. 3. 3D bar plot to visually assess the performance of the developed models.

The Venous Clinical Severity Score (VCSS) test findings of the 100 samples were used to divide them into four groups after the completion of data processing and a thorough assessment of the models' classification performance in both the training and testing stages. These were divided into four categories: Moderate (11–20), Severe (21–30), Mild (6–10), and Absent (0–5). Tables II and III were created in order to provide a thorough evaluation of the models' categorization effectiveness within each group. These tables provide the Precision, Recall, and F1-score index values—values that are critical for assessing the precision, completeness, and overall accuracy of the models that were generated during the course of the VCSS categories. This granular analysis facilitates a nuanced understanding of the models' performance in distinguishing varying degrees of severity within the studied population, contributing valuable insights to the overall assessment of their predictive capabilities.

### 1) *Precision*

*a) VCSS-PRE:* The SVSA model demonstrated the greatest accuracy values in the Mild and Severe categories, with scores of 0.881 and 1.000, respectively. On the other hand, in the Absent group, the SVDM model reached its maximum accuracy value of 0.643. Notably, the SVC model outperformed the other models for the Moderate category, earning an accuracy score of 1.000.

*b) VCSS-1:* The SVSA model showcased superior Precision across the Mild, Moderate, and Severe categories, securing impressive scores of 0.939, 0.978, and 1.000, respectively. In contrast, the Absent group saw the SVC model achieving its maximum precision value of 0.867.

### 2) *Recall*

*a) VCSS-PRE:* The SVDM model excelled with the highest scores in the Mild (0.905), Moderate (0.864), and Severe (1.000) groups. Contrastingly, the SVSA model delivered an outstanding performance for the Absent group, attaining the top recall score of 0.917.

*b) VCSS-1:* Attaining Recall values of 1.000 and 0.892, respectively, the SVDM model demonstrated exceptional performance in the Absent and mild categories. For the Moderate and Severe groups, the SVSA model also produced maximum recall values of 0.957 and 1.000.

### 3) *F1-score*

*a) VCSS-PRE:* A high F1 score indicates that the model is able to discriminate between accurately detecting positive instances (Precision) and include all true positive cases (Recall). The SVDM model performed better than all other models in every category, with the greatest F1-scores in the Mild (0.884), Moderate (0.927), and Severe (1.000) groups. Additionally, for the Absent group, the SVSA model reached its maximum F1-Score value of 0.733.

*b) VCSS-1:* The SVDM model performed better in the Absent and Mild categories, with F1-Score values of 0.903 and 0.892, respectively. Furthermore, the SVSA model achieved remarkable ratings of 0.968 and 1.000 in the Moderate and Severe categories, outperforming other models.

The actual count of samples categorized as Absent, Mild, Moderate, and Severe was 12, 42, 44, and 2, respectively, for VCSS-PRE and 14, 37, 47, and 2 for VCSS-1 values. Fig. 4 visually presents these categories, offering a 3D walls-based comparison for measurements and classification model outcomes. In the context of VCSS-PRE, the SVDM model demonstrated superior accuracy, correctly classifying individuals into the Mild, Moderate, and Severe groups, identifying 38, 38, and 2 individuals accurately, respectively. The SVSA model outperformed other models in the Absent category, accurately classifying 11 individuals. Turning to VCSS-1 values, the SVDM model maintained its Accuracy, correctly classifying individuals in the Absent, Mild, and Severe groups, identifying 14, 33, and 2 individuals accurately, respectively. Notably, in the Moderate category, the SVSA model outperformed other models by accurately classifying 45 individuals.

TABLE II. EVALUATION INDEXES OF THE DEVELOPED MODELS' PERFORMANCE BASED ON GRADES VCSS-PRE

| **Model** | **Grade** | **Metric value** | | |
|---|---|---|---|---|
| | | $\boldsymbol{Precision}$ | $\boldsymbol{Recall}$ | $\boldsymbol{F1-score}$ |
| SVC | Absent | 0.643 | 0.750 | 0.692 |
| | Mild | 0.822 | 0.881 | 0.851 |
| | Moderate | 0.974 | 0.864 | 0.916 |
| | Severe | 1.000 | 1.000 | 1.000 |
| SVDM | Absent | 0.625 | 0.833 | 0.714 |
| | Mild | 0.864 | 0.905 | 0.884 |
| | Moderate | 1.000 | 0.864 | 0.927 |
| | Severe | 1.000 | 1.000 | 1.000 |
| SVSA | Absent | 0.611 | 0.917 | 0.733 |
| | Mild | 0.881 | 0.881 | 0.881 |
| | Moderate | 0.974 | 0.841 | 0.902 |
| | Severe | 1.000 | 1.000 | 1.000 |

TABLE III. EVALUATION INDEXES OF THE DEVELOPED MODELS' PERFORMANCE BASED ON GRADES VCSS-1

| **Model** | **Grade** | **Metric value** | | |
|---|---|---|---|---|
| | | $\boldsymbol{Precision}$ | $\boldsymbol{Recall}$ | $\boldsymbol{F1-score}$ |
| SVC | Absent | 0.867 | 0.929 | 0.897 |
| | Mild | 0.865 | 0.865 | 0.865 |
| | Moderate | 0.935 | 0.915 | 0.925 |
| | Severe | 1.000 | 1.000 | 1.000 |
| SVDM | Absent | 0.824 | 1.000 | 0.903 |
| | Mild | 0.892 | 0.892 | 0.892 |
| | Moderate | 0.977 | 0.915 | 0.945 |
| | Severe | 1.000 | 1.000 | 1.000 |
| SVSA | Absent | 0.684 | 0.929 | 0.788 |
| | Mild | 0.939 | 0.838 | 0.886 |
| | Moderate | 0.978 | 0.957 | 0.968 |
| | Severe | 1.000 | 1.000 | 1.000 |

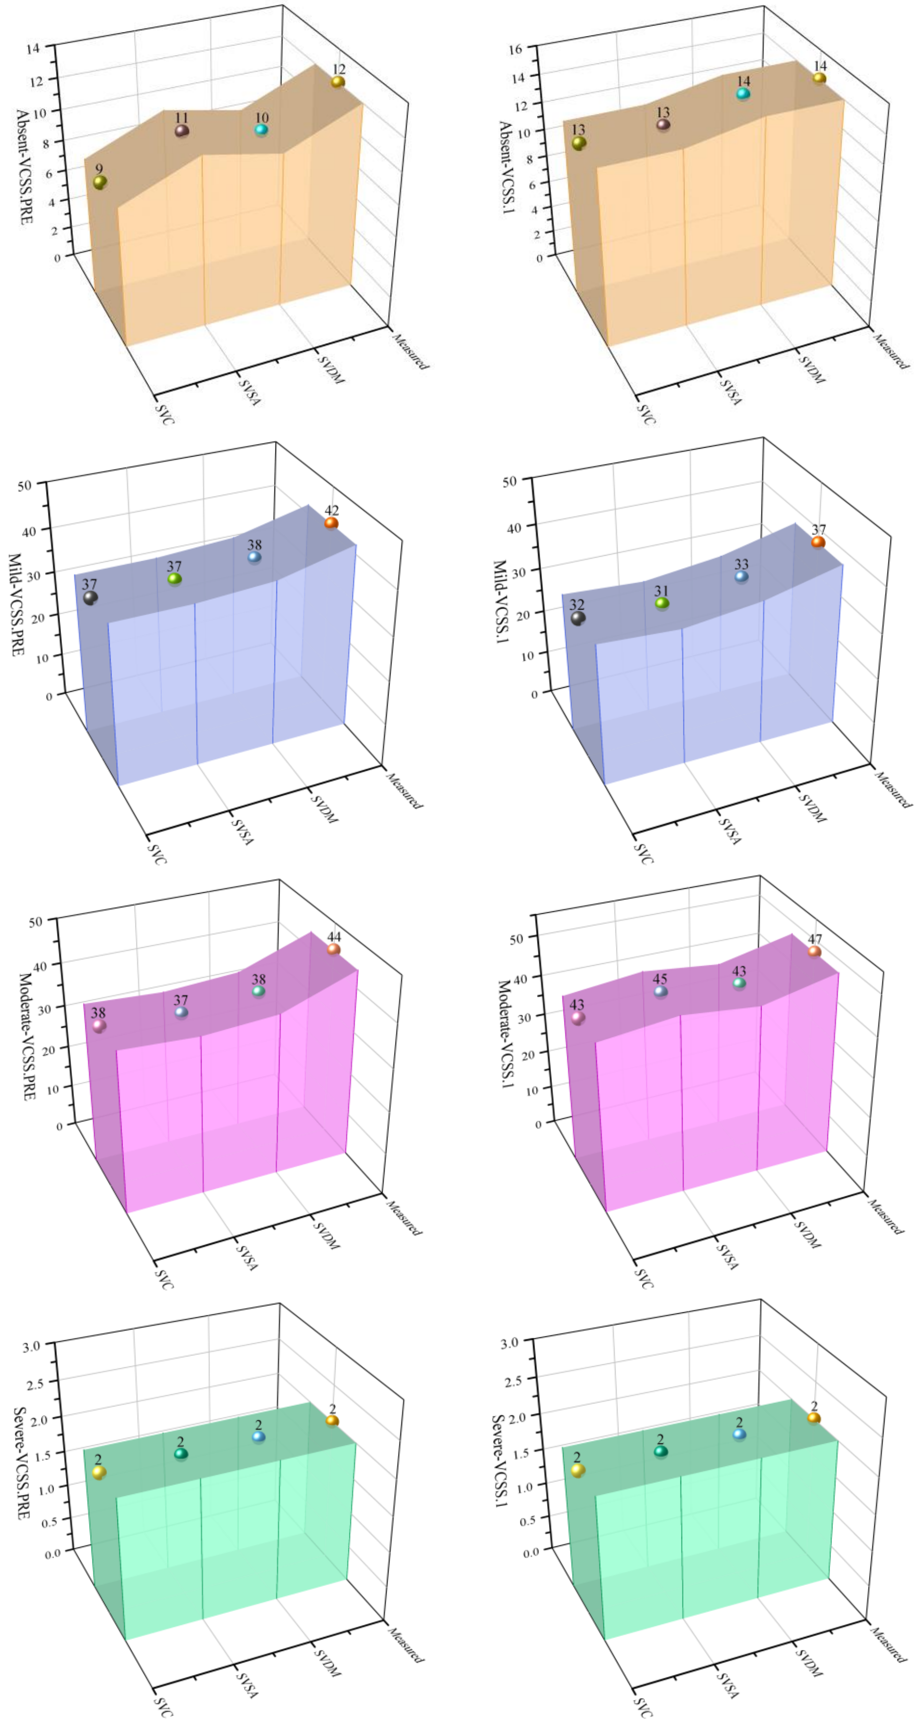

Fig. 4. 3D walls for the difference between measured and predicted values.

Understanding the confusion matrix in Fig. 5 may help with correctly classifying people into the appropriate groups and identifying those who are misclassified into other groups. In reference to VCSS-PRE data, the SVDM model accurately classified 2, 38, 38, and 10 individuals into the Severe, Moderate, Mild, and Absent classifications, respectively; only 14 pupils were misclassified. But, the SVC and SVSA models incorrectly categorized 16 and 15, respectively, of the individuals. The two optimized models showed that misclassifications mostly occurred across adjacent categories. For example, four individuals from SVSA and SVC were incorrectly classified as belonging to the Mild group instead of the Absent category. Twelve people were misclassified by the SVC model, which accurately classified 2, 43, 32, and 13 people into the Severe, Moderate, Mild, and Absent categories, respectively, based on VCSS-1 scores. The SVSA and SVDM models, on the other hand, incorrectly categorized 11 and 10 people, respectively. According to the SVSA model, five kids were mistakenly assigned to the Mild category rather than the Absent group.

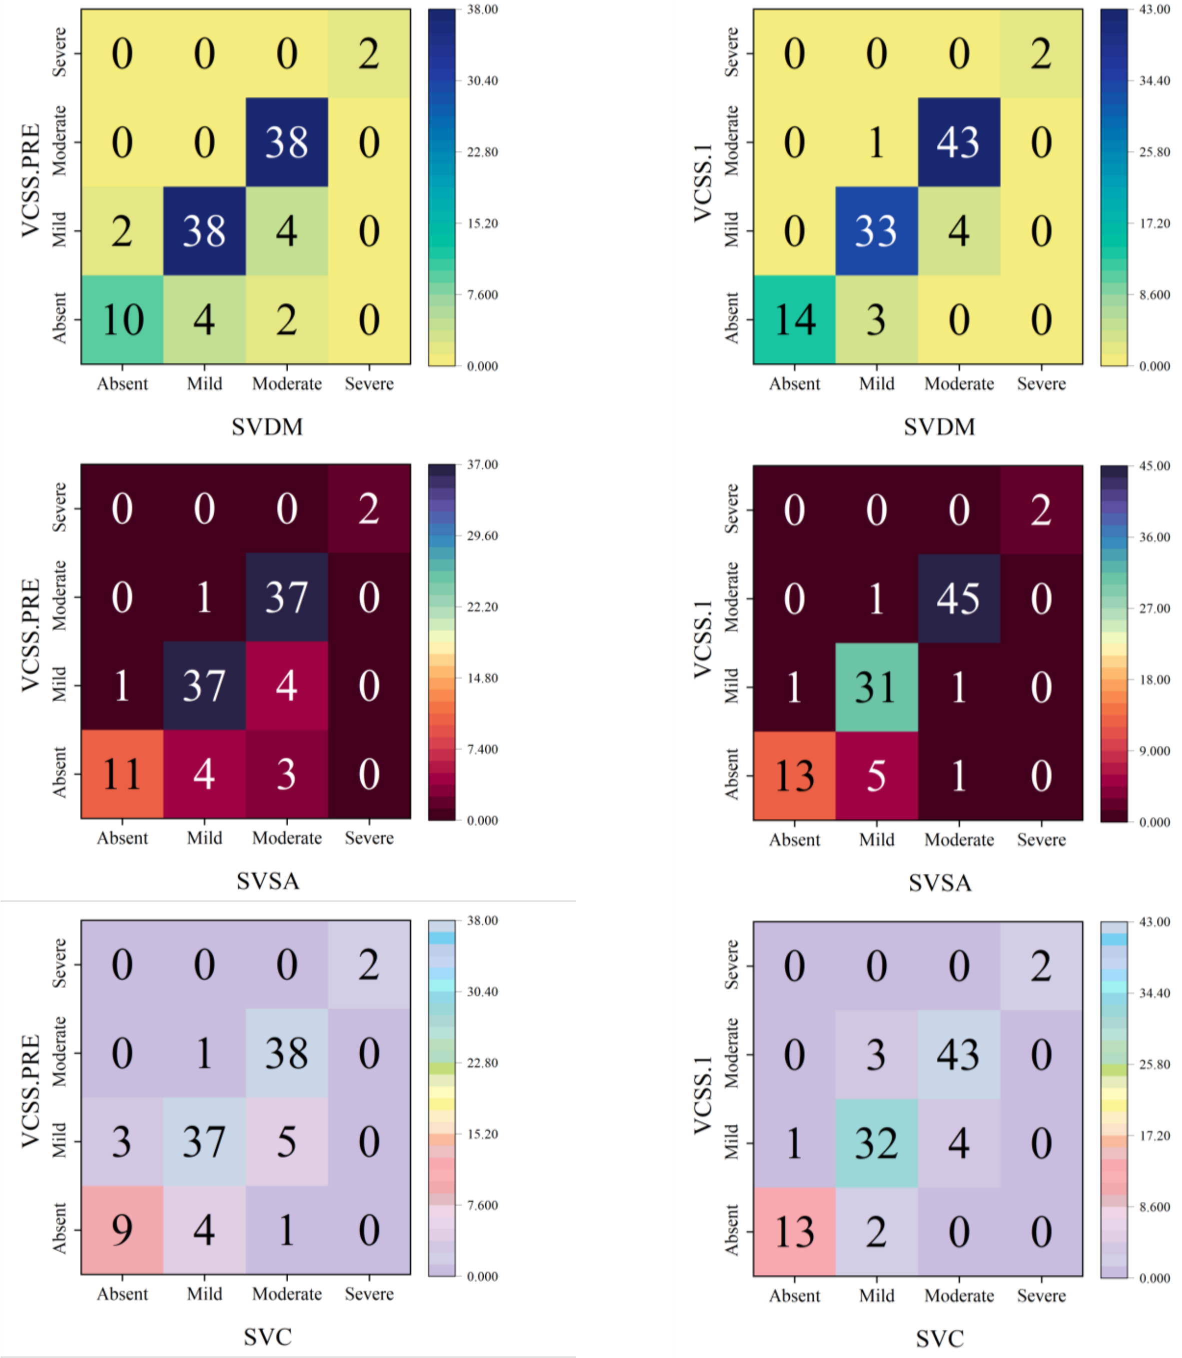

Fig. 5. Confusion matrix for the accuracy of each model.

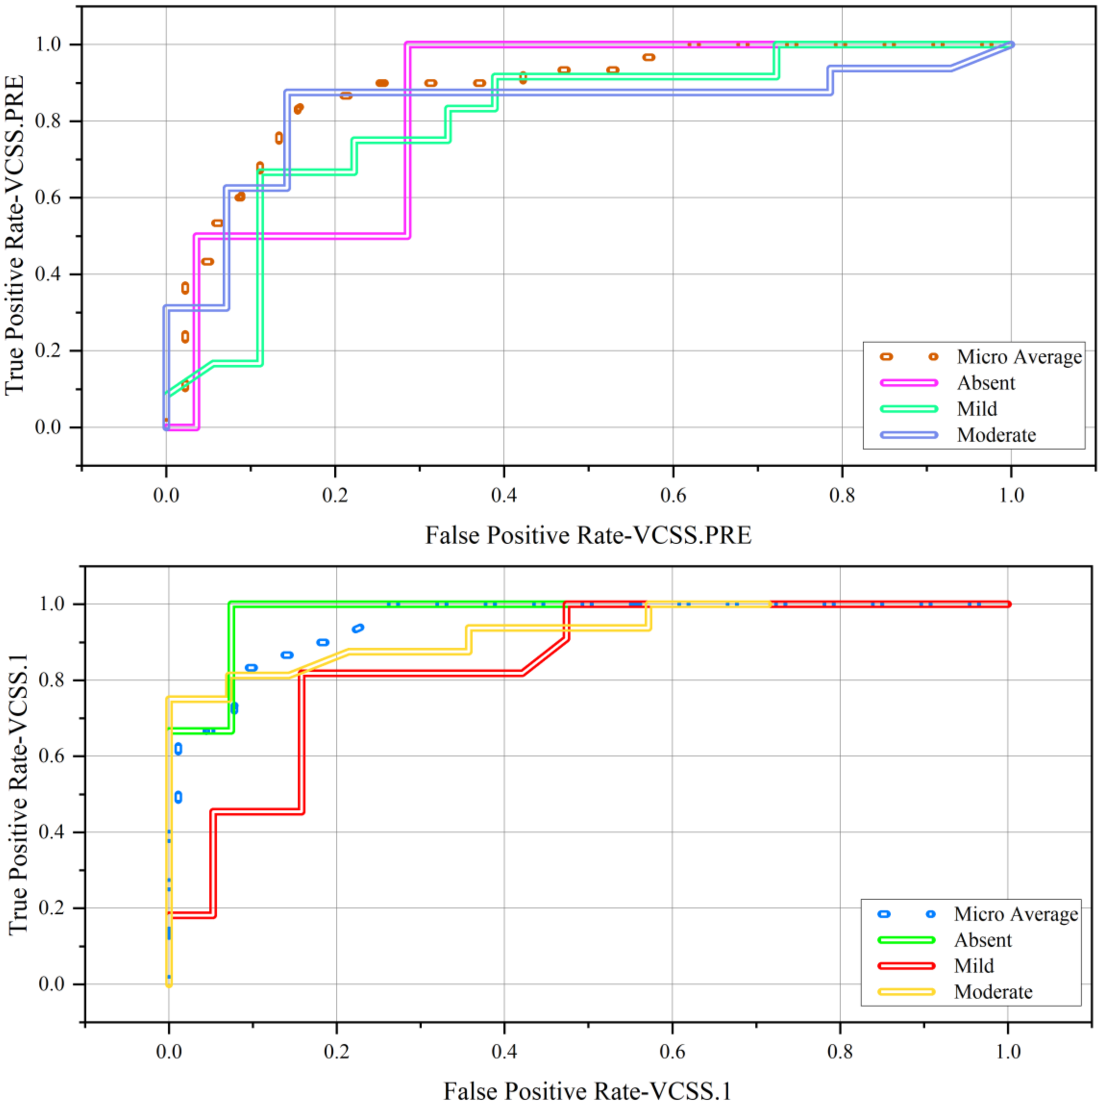

Fig. 6. The ROC curve for comparison of the SVDM model between various categories.

By employing the Receiver Operating Characteristic ($ROC$) curve, the evaluation seeks to discern the equilibrium between the True Positive ($TP$) and False Positive ($FP$) rates, complemented by the computation of the Area Under the $ROC$ Curve ($AUC$). A higher $AUC$ signifies a more controlled increase in the $FP$ rate compared to a substantial rise in the $TP$ rate for each adjustment of the predicted probability threshold. An ideal discrimination test is characterized by a $ROC$ plot reaching the upper-left corner, signifying 100% sensitivity and specificity. Fig. 6, which depicts ROC curves for the optimal SVDM model in classifying samples across two VCSS periods, illustrates that in VCSS-PRE, the AUC related to the Moderate group exceeded other categories and exhibited a more pronounced inclination towards the left-top side of the diagram. In the case of VCSS-1, the AUC for the Moderate and Absent groups surpassed that of the Mild curve.

### *D. Sensitivity Analyses*

*1) SHAP:* SHAP (SHapley Additive exPlanations) is an algorithm used for interpreting machine learning models. It assigns Shapley values to each feature, indicating their individual contributions to model predictions. Derived from cooperative game theory, Shapley values ensure a fair distribution of the model's output among features by considering all possible feature combinations [42], [43]. This approach provides both local and global interpretability, explaining predictions for specific instances and revealing overall model behavior. SHAP values can be visualized through various plots, aiding in the understanding of complex models and building trust by uncovering the factors influencing predictions.

Fig. 7 shows the effect of inputs on the output of the model. Based on the analysis, it was observed that CFS_Pre had the highest impact on the model output and Group had the lowest impact in all four classifications.

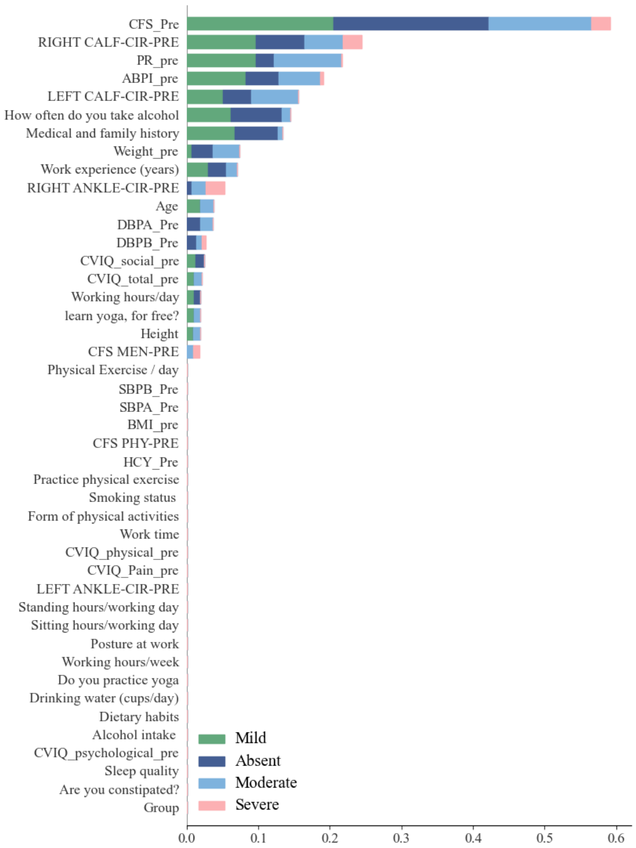

Fig. 7. Impact of input variables on model's output.

## IV. Discussion

The study has several limitations that should be considered in interpreting its findings. Firstly, the reliance on a sample size of 100 participants may restrict the generalizability of the results to broader populations. Future research endeavors should prioritize larger and more diverse samples to enhance external validity and ensure a representative study cohort. Additionally, the study's exploration of the duration of non-pharmacological interventions, particularly yoga, was somewhat limited. A more in-depth investigation into longer intervention periods could provide valuable insights into the sustainability of effects and potential long-term benefits. Furthermore, the study predominantly focused on yoga as a non-pharmacological intervention, potentially limiting the breadth of its applicability. Future research could benefit from investigating the comparative effectiveness of various non-pharmacological interventions, taking into consideration individual preferences and adherence rates. The study's reliance on quantitative outcome measures, while valuable, might not fully capture the nuanced impact of interventions on participants' daily lives and overall well-being. Incorporating qualitative assessments and patient-reported outcomes in future studies could provide a more comprehensive understanding of the holistic effects of these interventions.

On the other hand, the study's findings offer promising applications in clinical settings and beyond. The optimization of non-pharmacological interventions using machine learning algorithms, as demonstrated in the study, suggests potential effectiveness in managing CVI. This could encourage healthcare practitioners to consider integrating such interventions into comprehensive patient care plans, especially for individuals with varying levels of CVI severity.

Moreover, the study contributes to the evolving landscape of personalized medicine by showcasing the potential of machine learning models in tailoring interventions based on individual CVI profiles. This has implications for future applications, with the prospect of refining algorithms for more precise and personalized treatment recommendations. The findings may also have relevance in healthcare policy discussions, emphasizing the value of non-pharmacological approaches in addressing CVI. Policymakers could consider strategies to promote the integration of these interventions within healthcare systems, potentially leading to cost-effective and patient-centered care.

## V. Conclusion

This investigation navigates the crossroads of technology, healthcare, and preventive strategies, delving into the potential of non-pharmacological interventions, notably yoga, to alleviate the urgency associated with Chronic Venous Insufficiency (CVI). Particularly, the study addresses the impact of such interventions during periods of heightened stress and sedentary lifestyles. The research unfolds avenues for predictive modeling and precision medicine by demonstrating the fusion of machine learning algorithms with healthcare. Leveraging a data-driven approach across a sample size of 100, the introduction of Support Vector Classification (SVC) models optimized with Dwarf Mongoose Optimization (DMO) and Smell Agent Optimization (SAO) provides valuable insights into the classification of CVI severity levels. Applying DMO and SAO optimization techniques to the SVC model resulted in a significant improvement in accuracy for VCSS-PRE values, with increases of 2% and 1%, respectively. As the 100 individuals were classified according to their circumstances, the DMO's remarkable capacity to improve classification accuracy was made clear. In particular, the SVDM model correctly categorized most people with an astounding accuracy rate of 94.3%, whereas the SVSA and SVC models incorrectly classified 15% and 16% of all people, respectively. When it comes to VCSS-1 values, the introduction of DMO and SAO optimization techniques to the SVC model improved Precision by 2.4% and 2.2%, respectively. With an accuracy rate of just 80%, the SVC model correctly classified the fewest individuals, whereas the SVSA and SVDM models had classification rates of 89% and 90%, respectively. Further investigations into non-pharmacological interventions and CVI could contribute to the body of knowledge by implementing a longitudinal design to monitor the long-term impact, ensuring a diverse range of participants to enhance the generalizability of findings, and conducting comparative analyses of interventions such as mindfulness and yoga. By incorporating patient-reported outcomes and investigating the various factors that impact adherence, a comprehensive understanding can be achieved. The integration of sophisticated imaging methodologies will provide impartial assessments of the advancement of CVI, whereas health economics evaluations can scrutinize cost-effectiveness. Collaboration with healthcare professionals and mechanistic investigation can enhance understanding of intervention pathways and promote the adoption of multidisciplinary approaches. Ethical considerations are of the utmost importance, encompassing participant safety and informed consent.

# Multi-Track Music Generation Based on the AC Algorithm and Global Value Return Network

Wei Guo
College of Music and Dance, Huaqiao University, Xiamen, 361021, China

***Abstract*—In the current field of deep learning and music information retrieval, automated music generation has become a hot research topic. This study addresses the issues of low clarity and musicality in current multi-track music generation by combining the Actor-Critic algorithm and the Global Value Return Network to create a novel multi-track music generation model. The study first utilizes the Actor-Critic algorithm to generate single-track music rhythm and melody models. Building upon this foundation, the study further optimizes the single-track models using the Global Value Return Network and proposes the multi-track music model. The results demonstrate that the harmonization accuracy of the final multi-track music generation model ranges from 0.90 to 0.98, with a maximum value of 0.98. Additionally, the audience satisfaction and expert satisfaction of the model are 0.96 and 0.97, respectively, indicating that the model has a high musical appreciation value. Overall, the multi-track music generation model designed in this study addresses the limitations of single-track music generation and produces more rhythmically diverse multi-track music.**

***Keywords*—AC; global value; return network; track; music model; rhythm; melody**

## I. Introduction

With the advancement of artificial intelligence technology, particularly in the field of reinforcement learning, researchers are exploring the use of advanced algorithms to simulate and reproduce complex music composition processes [1-2]. Multi-track music generation involves simultaneously creating melodies and harmonies for multiple instruments, making it a particularly challenging research direction. It requires not only considering the melody generation for individual tracks but also coordinating and synchronizing across tracks. Although existing researches have achieved certain results in the field of single-track music generation, the field of multi-track music generation remains an urgent problem to be solved in terms of how to effectively coordinate the generation process of each track, and how to comprehensively consider the global music structure and the long-term value return in the composition [3-4]. Among the many attempts, nature-inspired algorithms have received particular attention due to their effectiveness in optimisation and search problems. For example, Genetic Algorithms and Particle Swarm Optimisation algorithms have been used as new ways of exploring music composition by simulating natural selection or the flight behaviour of flocks of birds to generate harmonious melodies. These algorithms show potential for generating melodies by iteratively searching the solution space, especially in terms of following the rules of a particular music theory and composing simple melodies. However, despite the progress made by nature-inspired algorithms in music generation, they face a number of challenges when dealing with complex music composition tasks [5-6]. Firstly, these algorithms often rely on predefined rules or objective functions which limit their application in creative music composition, which not only has to follow theoretical rules but also has to be artistic and emotionally expressive. Secondly, nature-inspired algorithms do not perform well in terms of global structure and long-term value maximisation which is particularly important in multi-track music generation, as it requires both harmony between different tracks and overall expression of a unified musical style and emotion. Facing these challenges, this study utilizes the Actor-Critic (AC) algorithm from reinforcement learning and establishes a global value return network to capture the long-term value of music and ensure that the generated music has high quality and artistry in terms of global structure. This research is divided into six sections, Section I is a brief introduction to the full text, Section II is a review of the related literature, Section III is the construction of the mono-track multi-track model, and Section IV is the testing of the model performance. Discussion and conclusion is given in Section V and Section VI respectively.

## II. Related Works

AC is a reinforcement learning technique that combines value functions with policy gradients. The advantage of this algorithm is that it combines the strengths of value functions and policy gradients, allowing for effective handling of continuous action spaces and complex policy problems. Many researchers have conducted studies on the application of AC algorithms. Zare et al. employed asynchronous advantage AC to address the service placement problem in fog computing environments. The paper proposed placing services in the local fog domain and leveraging neighboring fog domains when necessary to improve resource utilization. Additionally, a time-distributed resource allocation technique was considered to handle future requests more effectively. Simulation results demonstrated that this mechanism significantly improved cost efficiency and response speed compared to other methods [7]. Scorsoglio et al. proposed a feedback-guided algorithm for near-ground lunar operations based on AC reinforcement learning. The algorithm had the advantages of being lightweight, closed-loop, and capable of considering path constraints. Test results showed excellent performance of the designed algorithm in path constraint problems across various restrictive scenarios [8]. To address the limited data storage capacity of Earth observation satellites in dense observation scenarios, Wen et al. proposed a time-continuous model that jointly considered data transmission and observation tasks. To handle this problem more efficiently, a hybrid AC reinforcement learning approach was employed in the paper. Experimental results showed that this hybrid approach exhibited high efficiency and good performance in solving large-scale problems, which was of practical significance for the data management and scheduling of Earth observation satellites [9].

To create works that are both musically sound and emotionally impactful, and further explore the possibilities of artificial intelligence in artistic creation, many experts have built a series of multi-track music generation models using various deep learning techniques. Liu researched and developed an improved multi-track music generative adversarial network model, which was validated by generating five different instrument tracks. The research results showed that the music snippets generated by the proposed model had better artistic aesthetics. In the end, 62.8% of the listeners had difficulty distinguishing between the generated melodies and real melodies, demonstrating the high authenticity and effectiveness of the model in music generation [10]. Wang et al. proposed a Transformer-based multi-track music generative adversarial network, aimed at adhering to music rules to generate works with higher musicality. The model utilized the Transformer decoding component and a cross-track Transformer improved based on Transformer to separately learn information between single tracks and multiple tracks. The training of the generative network was guided by combining music rules and cross-entropy loss, and a well-designed target loss function was optimized when training the discriminative network. Experimental results demonstrated that the constructed model, on piano, guitar, and bass tracks, exhibited higher track prediction accuracy compared to other multi-instrument music generation models, effectively enhancing the overall quality of music [11]. In the face of the challenge of integrating independent melodies in polyphonic music composition, Huang et al. proposed an innovative multi-voice music composition model. That model integrated the concepts of Markov decision processes and Monte Carlo tree search and improved upon Wasserstein generative adversarial network theory. Through the zero-sum game and conditional constraints between the generator and discriminator, the model achieved music creation closer to unconstrained conditions, and the growth of music sequences did not affect their coherence. Experimental results indicated that the algorithm proposed in the study outperformed the latest methods in multi-voice music generation, demonstrating significant advantages [12].

Nature-inspired algorithms such as Genetic Algorithms (GA), Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO), etc., are a class of optimisation algorithms that draw on phenomena of nature, such as biological evolution, flight of birds, ant colony ant colony foraging, etc [13-14]. These algorithms usually mimic certain processes in nature to solve optimisation problems, and are particularly good at dealing with large-scale and complex search space problems. Some scholars have also conducted a series of music-related studies using nature-inspired algorithms. Majidi M and Toroghi R M propose a method for generating polyphonic music works based on multi-objective genetic algorithms. This method takes into account both the accuracy of music theory and the satisfaction of both expert and general listeners. The results show that the method is able to produce pleasing pieces that meet the desired style and length, and follow grammatical rules to produce harmonies [15]. Tian R et al. proposed a music emotion classification model combining convolutional neural networks and random forests. The model first converts audio data into Mel spectrum for feature extraction, then uses random forest algorithm for initial emotion classification, and finally achieves 97% accuracy in emotion classification, which is 1.2% and 1.6% higher than that of traditional particle swarm optimization and genetic algorithm [16]. Cao H proposed a system architecture based on the combination of edge computing and cloud computing to optimize the scheduling strategy of music education resources. Compared with the traditional genetic algorithm and ant colony algorithm, this method can improve the system efficiency by 23% [17].

In summary, despite the progress of AC algorithms in various fields, their application in multi-track music generation is still in its early stages. Existing music generation models need improvement in creativity and track harmony. Against this background, this study proposes a multi-track music generation model that combines AC algorithms with a global value return network. The aim is to address this challenge and experimentally verify its effectiveness in improving the quality of music generation.

## III. Multi-track Music Generation Combining AC Algorithm and Global Value-based Network

In order to address the rhythm generation, melody generation, and multi-track generation issues in the current music generation problem, this research first utilizes the AC algorithm to construct separate models for melody generation and rhythm generation. Based on this, a global value-based network is designed to integrate multiple agents, resulting in the development of a multi-track music generation model.

### A. *Construction of Music Rhythm and Melody Generation Models based on AC Algorithm*

In the field of reinforcement learning, let's assume that the note sequence and rhythm sequence in the music generation problem are represented as $S_n = \{n_1, n_2, \cdots n_L\}$ and $S_r = \{r_1, r_2, \cdots r_L\}$, respectively. $L$ L represents the sequence length. $\{n_1, n_2, \cdots n_L\}$ and $\{r_1, r_2, \cdots r_L\}$ represent various types of notes and rhythm in the note sequence and rhythm sequence, respectively. The specific representation of note types is shown in Eq. (1) [18].

$$n_i = \{s_1, s_2, \cdots, s_N\} \quad i = 1, 2, \cdots L \tag{1}$$

In Eq. (1), $n_i$ represents a specific note type, and $N$ represents the number of notes included in that note type. When N = 1, it indicates a monophonic output, and when N > 1, it indicates a polyphonic output. By encoding the note sequence and rhythm sequence, the encoded input data sequences in Eq. (2) are obtained.

$$\begin{cases} S_n^E = Encoder\left(S_n\right) = MultiHot\left(S_n\right) = \left\{n_1^{mh}, n_2^{mh}, \cdots n_L^{mh}\right\} \\ S_r^E = Encoder\left(S_r\right) = OneHot\left(S_r\right) = \left\{r_1^{oh}, r_2^{oh}, \cdots r_L^{oh}\right\} \end{cases} \quad (2)$$

In Eq. (2), $S_n^E$ and $S_r^E$ represent the note sequence and rhythm sequence after $MultiHot$ encoding and $OneHot$ encoding, respectively. $L$ represents the length of the sequence. $\left\{n_1^{mh}, n_2^{mh}, \cdots n_L^{mh}\right\}$ and $\left\{r_1^{oh}, r_2^{oh}, \cdots r_L^{oh}\right\}$ represent the encoded note type and rhythm type, respectively. By inputting the encoded note sequence and rhythm sequence into the model, we can obtain the output note sequence and rhythm sequence, as shown in Eq. (3).

$$\begin{cases} S_n^g = \left\{n_1^g, n_2^g, \cdots n_L^g\right\} \\ S_r^g = \left\{r_1^g, r_2^g, \cdots r_L^g\right\} \end{cases} \quad (3)$$

In Eq. (3), $S_n^g$ and $S_r^g$ represent the output note sequence and rhythm sequence, respectively. $\left\{n_1^g, n_2^g, \cdots n_L^g\right\}$ and $\left\{r_1^g, r_2^g, \cdots r_L^g\right\}$ represent the output note type and rhythm type, respectively. Based on Eq. (1) to (3), a complete music melody can be obtained, as shown in Eq. (4).

$$S_m^g = \left\{\left\{r_1^g, n_1^g\right\}, \left\{r_2^g, n_2^g\right\}, \cdots, \left\{r_L^g, n_L^g\right\}\right\} \quad (4)$$

In Eq. (4), $S_m^g$ represents the complete music melody. Based on the definitions of music concepts in Eq. (1) to (4), this research combines the AC algorithm to construct the music rhythm and melody generation model, referred to as the Actor-Critic Melodic Rhythm Generation Model (ACMRGM). The specific framework structure of ACMRGM is shown in Fig. 1.

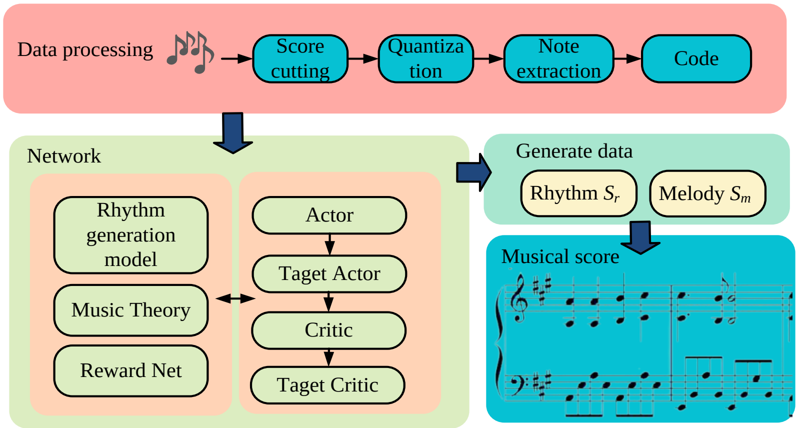

Fig. 1. ACMRGM model structure diagram.

In Fig. 1, the constructed music rhythm and melody generation model consists of four main parts: data processing, network construction, data generation, and sheet music output. The data processing part converts the initial music score data into a format suitable for inputting into the model and can also convert the model output back to a music score file. In the rhythm network, assuming that the (Long and Short-Term Memory) LSTM network's hidden state and cell state are represented as $h$ and $c$, respectively, and the output is $O_{lstm}$, the calculation formula for obtaining the output is shown in Eq. (5).

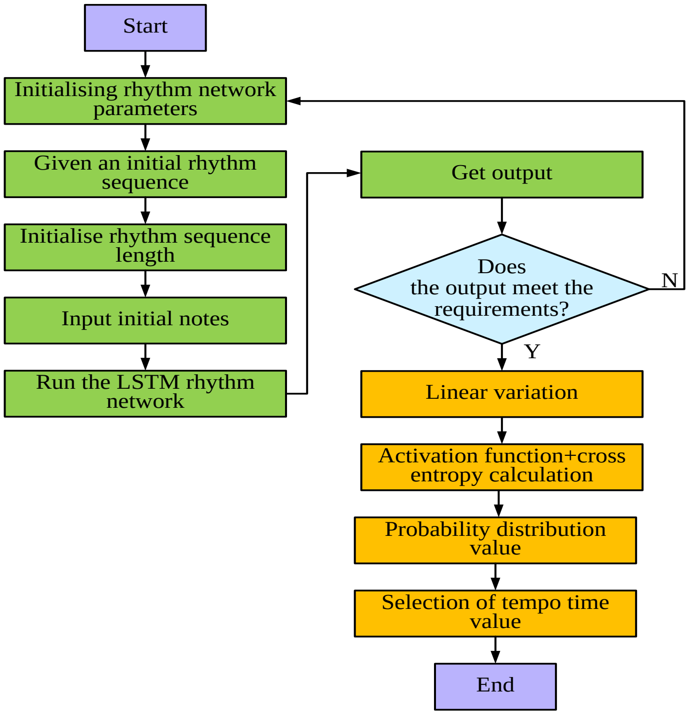
$$O_{lstm} = h_t^2 \quad (5)$$

In Eq. (5), $h_t^2$ represents the second-layer output of the rhythm network. The loss function calculation formula for the rhythm network is shown in Eq. (6).

$$loss_1 = soft\max\_cross\_entropy\left(O_{linear}\right) \quad (6)$$

In Eq. (6), $O_{linear}$ represents the linear transformation tensor of $O_{lstm}$ after passing through the Linear layer. $soft\max$ represents the activation function. $cross\_entropy$ represents cross-entropy. $loss_1$ represents the loss value of the rhythm network. The operational flowchart of the rhythm network model is shown in Fig. 2.

In Fig. 2, the trained model parameters are first read to initialize the rhythm network model. Then, an initial rhythm sequence is given as the initial duration data, and the length of the generated rhythm sequence is initialized. Next, the initial notes pass through the LSTM rhythm network to compute the network's output, $O_{lstm}$. The next step involves applying a linear transformation to $O_{lstm}$ to obtain $O_{linear}$. $O_{linear}$ then goes through an activation function and cross-entropy calculation to obtain the probability distribution values. Finally, the corresponding rhythm duration is randomly selected based on the calculated probability distribution values. The formula for rhythm generation is shown in Eq. (7) [19].



Start
Initialising rhythm network parameters
Given an initial rhythm sequence
Initialise rhythm sequence length
Input initial notes
Run the LSTM rhythm network
Get output
Does the output meet the requirements?
N
Y
Linear variation
Activation function+cross entropy calculation
Probability distribution value
Selection of tempo time value
End

Fig. 2. Operation flow chart of the rhythm network model.

$$O_{linear} = O_{lstm} * w^T + b \tag{7}$$

$w^T$ in Eq. (7) represents the weight matrix of the output gate in the LSTM network, while $b$ represents the bias vector.

In the melody network, it is recognized that there is no direct mechanism for generating reward values in the music generation environment. Therefore, training an LSTM network is proposed to form a reward network and obtain the corresponding reward values. Compared to the rhythm network, the reward network adds an attention mechanism module, which further enhances the ACMRGM model's ability to learn important notes. Additionally, the activation function $soft\max$ is replaced with $sigmoid$ in the reward network to support the generation of polyphonic melodies. The formula for the loss function of the reward network is shown in Eq. (8).

$$loss_2 = sigmoid\_cross\_entropy(O_{linear}) \tag{8}$$

In Eq. (8), $loss_2$ represents the loss value of the reward network. Once the reward network is designed, an melody network model is built by combining the LSTM network with the Actor and Ctiric networks from the AC algorithm. Both the Actor and reward networks consist of LSTM, attention mechanism module, Linear layer, and Sigmoid module, while the Ctiric network consists of LSTM, attention mechanism module, and two Linear layers. Assuming the reward value based on music theory rules is $r_m$ and the reward value obtained by the reward network is $r_n$, the formula for calculating the reward value of the ACMRGM model is shown in Eq. (9).

$$r_{mix} = k_m * r_m + k_n * r_n \tag{9}$$

In Eq. (9), $r_{mix}$ represents the final reward value of the ACMRGM model. $k_m$ and $k_n$ represent the proportions of $r_m$ and $r_n$, respectively. The workflow diagram of the melody network model is shown in Fig. 3.

In Fig. 3, the note parameters and melody length are initialized first. The initialized note parameters are input into the Actor network to obtain the probability distribution values of the next action. Then, an action is randomly selected based on the probability distribution values. The selected action is then transformed into the next state, which is also input into the Actor network to obtain the next action. The action transformation is repeated an equal number of times as the melody length, ultimately generating the corresponding note sequence. This note sequence is then combined with the rhythm sequence to obtain the complete musical composition.

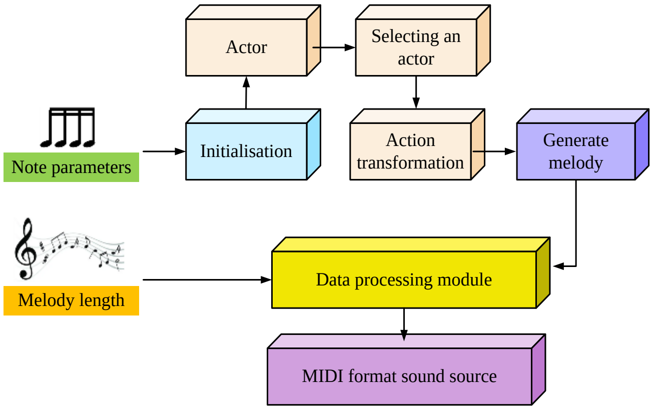


Fig. 3. Operation flow chart of the melody network model.

### *B. Construction of a Multi-AC Melodic Rhythm Generation Model by Integrating AC Algorithm and Global Value-Return Networks*

To generate polyphonic music with coordinated consistency, this study extends the single Actor and Critic modules from Section II by increasing their quantity to handle multiple musical tracks. Additionally, to ensure coordination among different tracks, a centralized Global Reward Network is constructed. This network imposes constraints on the note relationships between different tracks, ensuring overall harmony and consistency [15]. The resulting multi-track music generation model is referred to as the Multi-Actor-Critic Melodic Rhythm Generation Model (MACMRGM), as illustrated in Fig. 4.

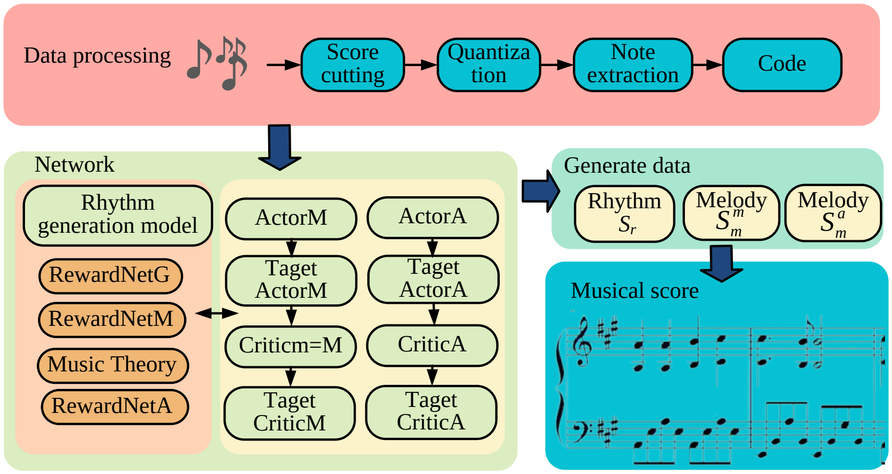

Fig. 4. MACMRGM model structure diagram.

In Fig. 4, the MACMRGM model is primarily divided into four parts: Data Processing, Network Model, Music Generation, and Score Output. ActorM, CriticM, and their corresponding target networks are responsible for generating the main melody track, while ActorA, CriticA, and their target networks handle the accompaniment track. RewardNetM and RewardNetA train on the main melody and accompaniment tracks, respectively, while RewardNetG, as the global reward network, focuses on training the processed track data from the data processing module, aiming to ensure coordination between tracks. Additionally, the music theory reward module and rhythm generation model further enhance the theoretical accuracy and rhythmic sense of the music. The combination of the output rhythms and melodies from the network model section yields the final output score. When processing multi-track music data, the workflow is slightly more complex compared to single-track music. The processing flow for multi-track music data is depicted in Fig. 5.

In Fig. 5, the processing flow for multi-track music includes steps such as inputting audio data sets, dividing audio data sets, cutting scores, quantizing, transposing, extracting notes, encoding, and outputting audio. Firstly, multiple tracks from the score are extracted and divided into audio training and testing sets. Next, the divided dataset is segmented into smaller sections. If there are changes in tempo within a score, the score is cut at those points. The segmented music sections are stored as TFRecord-format files, and the music segments in these files undergo quantization. After quantization, the transposition module is applied. Following the key conversion, the main melody, accompaniment track, and synthesized track of the score are extracted. These track data are then encoded into a multi-hot format and stored as TFRecord-format data for training purposes. The synthesized track combines synchronized notes from the main melody and accompaniment tracks to form harmony. All tracks are combined with the rhythm sequence to generate a complete score, which is then converted into a MIDI file format.

During the training of the MACMRGM model, the first step involves pre-training three reward networks in the model [20-21]. RewardNetM and RewardNetA are trained using the main melody track and accompaniment track, respectively, while RewardNetG is trained using a synthetic track. The one-dimensional array calculation formulas for RewardNetM, RewardNetA, and RewardNetG are given by Eq. (10).

$$\begin{cases} O_{linear}^{m} = O_{lstm}^{m} * \left(w^{m}\right)^{T} + b^{m} \\ O_{linear}^{a} = O_{lstm}^{a} * \left(w^{a}\right)^{T} + b^{a} \\ O_{linear}^{g} = O_{lstm}^{g} * \left(w^{g}\right)^{T} + b^{g} \end{cases} \tag{10}$$

In Eq. (10), $O_{linear}^{m}$, $O_{linear}^{a}$, and $O_{linear}^{g}$ represent the one-dimensional arrays of RewardNetM, RewardNetA, and RewardNetG, respectively. $O_{lstm}^{m}$, $O_{lstm}^{a}$, $O_{lstm}^{g}$ denote the output values of the LSTM networks in the three reward networks. $\left(w^{m}\right)^{T}$, $\left(w^{a}\right)^{T}$, $\left(w^{g}\right)^{T}$ represent three weight matrices, and $b^{m}$, $b^{a}$, $b^{g}$ represent three bias vectors. In each of the three reward networks, the calculation process for extracting action values from the reward value array is shown in Eq. (11) [22-23].

$$\begin{cases} R_{n}^{m} = O_{linear}^{m}\left[a^{m}\right] \\ R_{n}^{a} = O_{linear}^{a}\left[a^{a}\right] \\ R_{n}^{g} = O_{linear}^{g}\left[a^{g}\right] \end{cases} \tag{11}$$

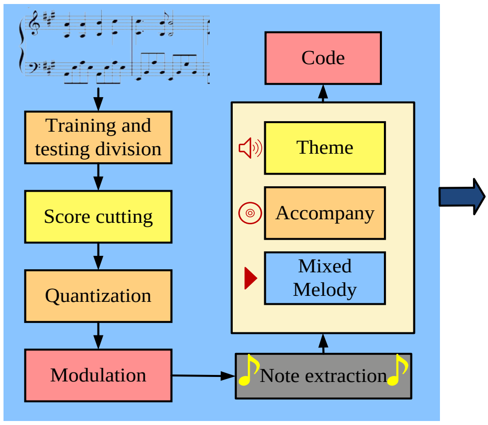

Fig. 5. Multi-track music processing flow chart.

In Eq. (11), $a^m$, $a^a$, $a^g$ represent the predicted actions of RewardNetM, RewardNetA, and RewardNetG, respectively. $R_n^m$, $R_n^a$, $R_n^g$ represent the reward value arrays of RewardNetM, RewardNetA, and RewardNetG. The final calculation formula for the MACMRGM model's overall reward value is presented in Eq. (12).

$$r'_{mix} = k_1 * r^m + k_2 * r^a + k_3 * r^g \tag{12}$$

In Eq. (12), $r'_{mix}$ represents the model's ultimate reward value. $r^m$, $r^a$, $r^g$ represent the reward values of RewardNetM, RewardNetA, and RewardNetG, respectively. $k_1$, $k_2$, $k_3$ denote the proportions of the reward values for the three networks. After training the reward networks, the process involves combining other modules [24-25]. In the MACMRGM model, the network structures of ActorM and ActorA are consistent with the reward networks, composed of LSTM, attention mechanism module, Linear layer, and Sigmoid module. The structures of CriticM and CriticA continue to consist of LSTM, attention mechanism module, and two Linear layers. The training of Actor and Critic networks is carried out in an alternating manner, where the networks are trained every certain number of steps until the specified step limit is reached. The final multi-track music generation process is illustrated in Fig. 6.

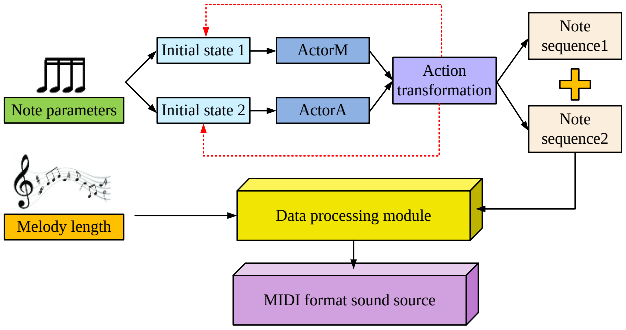

Fig. 6. Multi-track music generation flow chart

In Fig. 6, the initialization of note 1 and note 2 in the model, along with the configuration of the melody length, is the initial step. These notes are set as the initial states 1 and 2. Initial states 1 and 2 are input into ActorM and ActorA to obtain probability distribution values for the next actions. Actions 1 and 2 are then randomly selected based on the probability distribution values, converted into states 1 and 2, and input into ActorM and ActorA to obtain the next actions. This process continues until the model performs actions updates equal to the length of the melody, resulting in the generated note sequences 1 and 2. Finally, the two obtained note sequences are combined with the rhythm sequence to output a complete multi-track score.

## IV. Performance Testing and Application Analysis of Different Track Music Generation Models Based on AC Algorithm

To demonstrate the performance of the single-track music rhythm and melody generation model ACMRGM and the multi-track music generation model MACMRGM, a comparative experiment was conducted using the publicly available dataset MAESTRO. The final research results indicate that ACMRGM has better music melody and rhythm compared to traditional LSTM, Transformer, and Generative Adversarial Network (GAN). MACMRGM can generate multi-track music with better listening experience compared to Bi-Long Short-Term Memory (Bi-LSTM), Bidirectional Encoder Representations from Transformers (BERT), and Deep Convolutional Generative Adversarial Network (DCGAN).

### A. *Performance Testing and Application Analysis of Single-Track Music Generation Model*

The MAESTRO dataset is a high-quality music performance dataset provided by Google's Magenta project. The dataset consists of approximately 2000 different types of music performances, with all performances stored in MIDI format scores and corresponding audio forms. The selected 2000 music performances were divided into training and testing sets in an 8:2 ratio. Since the music types in this dataset cover a wide range of styles from classical to modern and include both single-track and multi-track performances, it is suitable for various music-related machine learning research projects. To ensure the consistency of note durations, the tempo of the scores was set to 120 BPM. In order to ensure the uniqueness of the research results, all experiments were conducted on the same computer device. The experimental setup and initial network parameters are shown in Table I.

TABLE I. Experimental Environment and Network Parameter Configuration Table

| Experimental equipment | Value |
|---|---|
| CPU | Intel Core i9-10900K |
| GPU | NVIDIA GeForce RTX 3080 |
| Memory | 11GB |
| Operating system | Ubuntu 20.04 LTS |
| Python version | Python 3.8 |
| Deep learning framework | TensorFlow 2.4 and PyTorch 1.7 |
| Network training optimizer | Adam |
| Batch size | 32 |
| Epochs | 5000 |
| learning rate | 0.001 |

Table I provides the environmental settings and initial network parameter values for this experiment. In order to evaluate the performance of the single-track music generation model, this study selected two metrics, Melodic Harmony (MH) and Music Clarity (MC), for testing. Fig. 7 compares the MH values of the LSTM, Transformer, GAN, and ACMRGM models on the training and testing sets.

In Fig. 7, the MH values of four models, namely LSTM, Transformer, GAN, and ACMRGM, are presented in both the training and testing sets. As indicated in Fig. 7(a), when testing with any randomly selected five monophonic sources from the training set, the maximum MH values for LSTM, Transformer, GAN, and ACMRGM models were 0.85, 0.85, 0.93, and 0.98, respectively. Fig. 7(b) shows that when testing with any randomly selected five monophonic sources from the testing set, the maximum MH values for LSTM, Transformer, GAN, and ACMRGM were 0.83, 0.87, 0.93, and 0.99, respectively. Overall, based on Fig. 7, it can be observed that ACMRGM model exhibits better stability, while the MH values for the other three models fluctuate across different monophonic sources, indicating the higher stability of ACMRGM model.

In Fig. 8(a), 8(b), 8(c), and 8(d), the MC values for different monophonic music generation models are displayed. Utilizing 25 monophonic sources from the dataset as a baseline reference for standard pitch, it is evident from Fig. 8(a), 8(b), 8(c), and 8(d) that, except for the MC values generated by the ACMRGM model, which align with the baseline, the MC values generated by LSTM, Transformer, and GAN models exhibit significant deviations from the baseline. The clarity performance of the four models is ranked with ACMRGM model being the best, followed by Transformer model, and LSTM and GAN models showing comparatively poorer performance.

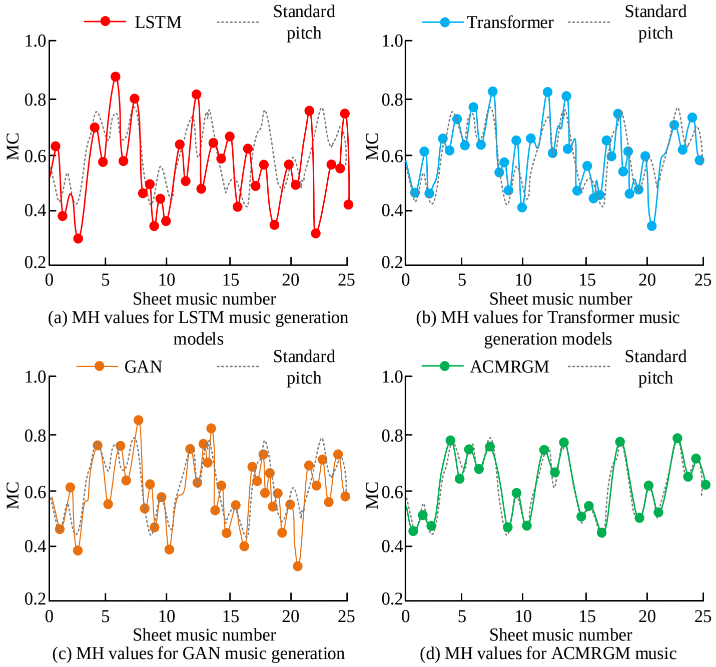
(b) MH values for different models on the test set

Fig. 7. MH values of different single-track music generation models.



(a) MH values for LSTM music generation models

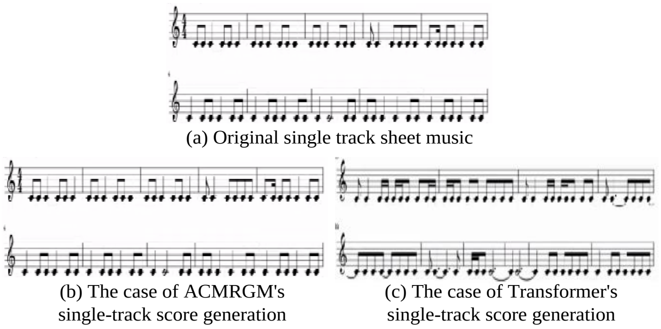
(b) MH values for Transformer music generation models

(c) MH values for GAN music generation models

(d) MH values for ACMRGM music generation models

Fig. 8. MC values of different single-track music generation models.

Fig. 9 compares the performance of ACMRGM model and Transformer model in practical monophonic music generation problems. Choosing a segment of the original monophonic musical score as the reference source, as shown in Fig. 9(a), the monophonic generated musical scores by ACMRGM model and Transformer model are depicted in Fig. 9(b) and 9(c), respectively. Combining the information from Fig. 9 reveals that the musical score generated by ACMRGM model closely aligns with the original score, while the musical score generated by the Transformer model exhibits some differences from the original score.



(a) Original single track sheet music

(b) The case of ACMRGM's single-track score generation

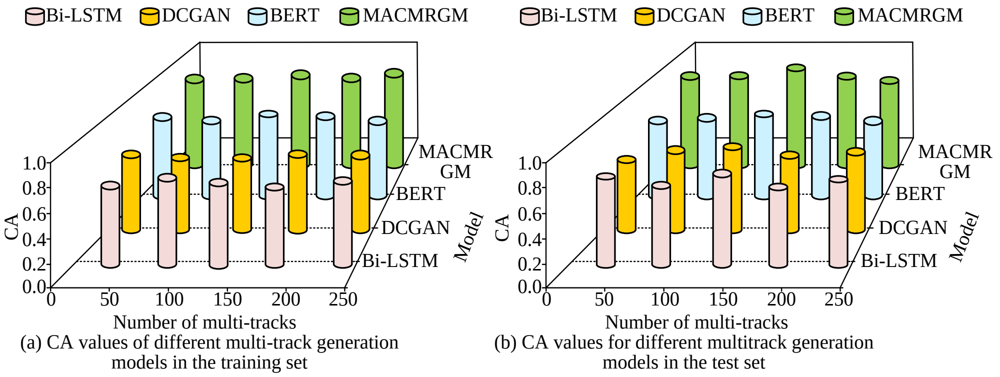
(c) The case of Transformer's single-track score generation

Fig. 9. Single-track music score generation using different single-track music generation models.

### B. *Performance Testing and Application Effect Analysis of Polyphonic Music Generation Models*

In addition to testing the performance of single-track music generation models, this study also conducted an analysis of the performance and application effects of polyphonic music generation models. Chorus Accuracy (CA) and Subjective Listening Satisfaction (SLS) were chosen as evaluation metrics. The CA values of four polyphonic music generation models—Bi-LSTM, DCGAN, BERT, and MACMRGM—were obtained as shown in Fig. 10.

Fig. 10(a) and Fig. 10(b) represent the CA values of different polyphonic music generation models in the training set and the test set, respectively. From Fig. 10(a), it is observed that as the training set size increases from 50 to 250, the CA values of the four models vary within the ranges of 0.72 to 0.83 (Bi-LSTM), 0.78 to 0.88 (DCGAN), 0.81 to 0.90 (BERT), and 0.90 to 0.98 (MACMRGM). Fig. 10(b) shows that with changes in the test set size, the CA values for Bi-LSTM, DCGAN, BERT, and MACMRGM range from 0.73 to 0.82, 0.79 to 0.86, 0.82 to 0.89, and 0.92 to 0.98, respectively.



(a) CA values of different multi-track generation models in the training set

(b) CA values for different multitrack generation models in the test set

Fig. 10. CA values of different multi-track music generation models.

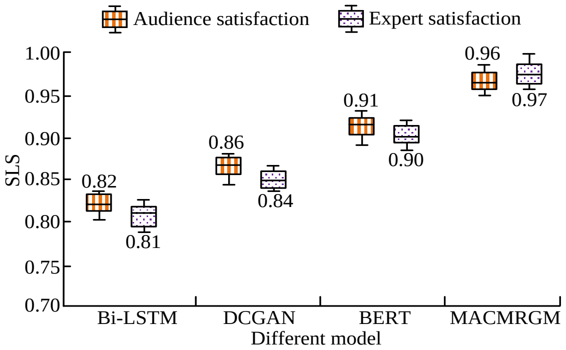


Fig. 11. SLS of different multi-track music generation models.

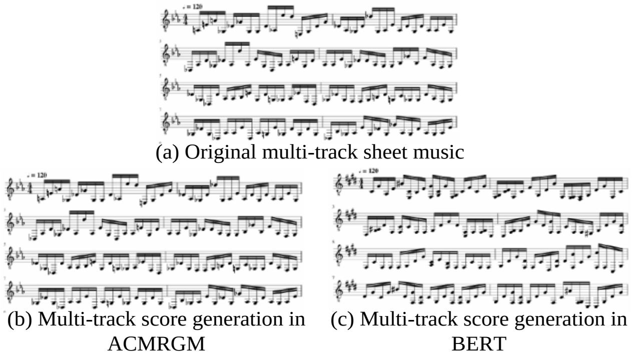
Fig. 11 illustrates the satisfaction values of both listeners and experts for the four polyphonic music generation models, represented by the SLS metric. Assuming scores from 0 to 1 indicate dissatisfaction to satisfaction, it can be inferred from Fig. 11 that listeners gave SLS scores of 0.82, 0.86, 0.91, and 0.96 for Bi-LSTM, DCGAN, BERT, and MACMRGM, respectively. Experts' SLS scores were 0.81, 0.84, 0.90, and 0.97 for Bi-LSTM, DCGAN, BERT, and MACMRGM, respectively. In conclusion, the MACMRGM model achieved higher satisfaction from both listeners and experts, indicating that the music it generated is more enjoyable.



(a) Original multi-track sheet music

(b) Multi-track score generation in ACMRGM

(c) Multi-track score generation in BERT

Fig. 12. Multi-track music score generation using different multi-track music generation models.

Fig. 12(a), 12(b), and 12(c) respectively depict an original polyphonic music score, a polyphonic music score generated by the MACMRGM model, and a polyphonic music score generated by the BERT model. By comparing these figures, it can be observed that the MACMRGM model is capable of faithfully reproducing the multi-track music template, whereas the BERT model may exhibit variations in rhythm and melody, deviating from the original music.

## V. Discussion

The multi-track music generation model combining the Actor-Critic algorithm and the Global Value Return Network proposed in this research aims to solve the problems of insufficient track coordination and global music structure optimisation in multi-track music generation. By introducing the Actor-Critic algorithm, this study first builds a separate music rhythm generation model and a melody generation model, which is notated as ACMRGM. based on this, the single Actor and Critic modules are extended to increase the number of the two modules to deal with multiple tracks, and then the constraints are imposed on the note relationships among different tracks by combining with the global value-returns network, which ensures the In MACMRGM, the Actor-Critic algorithm enables the constructed multi-track generation model MACMRGM to effectively balance the contradiction between exploration and exploitation, while the global value return network helps MACMRGM to capture the long term value and global structure of the music to achieve the best results in terms of harmony, accuracy and listener satisfaction. Accuracy and listener satisfaction is important to achieve significant improvements. The MH and MC values were selected as performance test metrics and performance comparisons were made with other models. The results show that ACMRGM has better performance. Compared with the existing literature, the models in this study not only achieved significant improvements in technical performance, but also demonstrated advantages in musical artistry and listener acceptance. For example, although the model based on generative adversarial networks proposed by Liu et al. has made progress in terms of diversity and novelty of music generation, it is still deficient in terms of harmonic accuracy and coherence of music structure. The model in this study effectively overcomes these limitations by integrating global musical structure and long-term value returns, providing a new approach to generating multi-track music that is both richly diverse and harmonically coherent.

## VI. Conclusion

To ensure that the melodies and rhythms in polyphonic music generation models harmonize effectively, thereby creating music compositions of greater aesthetic value, this research integrated the AC algorithm with a Global Value Return Network to develop a novel polyphonic music generation model, MACMRGM. Initially, the performance of single-track music generation models was assessed. The findings indicated that the highest MH value achieved by the single-track music generation model, ACMRGM, was 0.99. Furthermore, the music generated by this model closely aligned with the pitch accuracy of the baseline audio source, thereby confirming its capability to produce commendable musical rhythms and melodies. In the evaluation of polyphonic music generation models, the maximum CA values for the four models—Bi-LSTM, DCGAN, BERT, and MACMRGM—were 0.83, 0.88, 0.90, and 0.98, respectively. The satisfaction ratings from listeners were 0.82, 0.86, 0.91, and 0.96 for the aforementioned models, while expert satisfaction ratings stood at 0.81, 0.84, 0.90, and 0.97, respectively. When provided with a musical score from an actual audio source, it was observed that MACMRGM generated a more compliant score compared to BERT. In summary, both polyphonic models designed in this study demonstrated commendable performance and exhibited practical applicability. However, given that polyphonic music involves various combinations of instruments, future research could delve deeper into assessing the performance of the proposed models across more intricate combinations of tracks.

# Defining Integrated Agriculture Information System Non-Functional Requirement and Re-engineering the Metadata

Argo Wibowo[1], Antonius Rachmat Chrismanto[2], Gabriel Indra Widi Tamtama[3], Rosa Delima[4]
Information System Department, Universitas Kristen Duta Wacana, Yogyakarta, Indonesia[1, 3]
Informatics Department, Universitas Kristen Duta Wacana, Yogyakarta, Indonesia[2, 4]

***Abstract*—Developing a well-functioning information system like integrated agriculture information system (IAIS) requires a list of task requirements that will be transformed into system features. Feature Driven Development (FDD) model is suitable for this situation. The requirements for building an information system are not solely based on functional needs but also non-functional requirements (NFR). Non-functional requirements also play a crucial role in system development as they affect business process management. A well-defined business process will ultimately result in robust system features. It is essential to map non-functional requirements to the business process to clearly identify the information system requirements that will become new features. Not only can NFR enrich system metadata and databases, but they also serve as the initial foundation for the system coding process, leading to the final information system output. This study creates a flow diagram mapping NFR to the business process using Business Process Management Notation (BPMN). Several identified NFR categories are then transformed into metadata and use case diagrams. The formation of this NFR mapping flow diagram is expected to facilitate information system development by visualizing system requirements in a forward and backward flow according to the sequence of processes. Feature development can be streamlined in the event of NFR changes by tracing NFR and related features.**

***Keywords*—Information system; non-functional requirements; BPMN; metadata; feature-driven development**

## I. Introduction

In the rapidly evolving world of information system development, delivering high-quality software that meets user expectations is crucial for the success of the software so that it can be effectively utilized. While functional requirements determine what the system should do, non-functional requirements (NFR), business process management (BPM), and requirements reengineering play a significant role in shaping software performance [1], aligning with business objectives, and adapting to changing needs. This article is written to explore the integration of these three components within the context of Feature-Driven Development (FDD), a popular software development methodology.

In the case described in this article, the Dutatani research team has already developed IAIS with a web-based portal application [2] and a farmer registration application [3]. Both studies have successfully described the development of the portal application, farmer registration, and their testing. In this paper, the research will be further developed by adding land and ownership mapping. This feature has previously existed in studies [4] [5], but it will be adjusted to accommodate new needs in the new portal and new business processes. The existing land mapping system could only accommodate one plot of land per farmer. However, the latest requirements state that farmers should be able to own multiple plots of land, and each plot can be owned by multiple farmers. Land ownership features will also be differentiated based on their status, reflecting common agricultural business processes that require distinguishing land ownership patterns, such as individual ownership, lease, and profit-sharing [6]. The aim of this reengineering effort in this research is to align the Dutatani web system's business processes with general agricultural practices in Indonesia. If the system can accommodate common business processes, it is expected to have widespread usability. This is inline with IAIS, namely integrating various user needs, especially in the agricultural sector.

The main problem in this research is the need to align new feature requirements with the existing system. To achieve alignment between new feature requirements and the existing system, a thorough analysis is required, involving functional and non-functional requirements, business process management, and ultimately leading to application reengineering [7]. A well-conducted analysis up to the Business Process Management diagram formation phase is expected to minimize the resource consumption during the application re-engineering. Features Driven Development is also used because the application is initially developed based on per-feature needs. Non-functional requirements determine the quality and constraints of software systems [8], such as performance, security, scalability, usability, and reliability. These requirements are crucial to ensure that the software meets user expectations and operates efficiently. In FDD, NFR is given equal importance alongside functional requirements in preparing features as a comprehensive software solution [9].

By integrating non-functional requirements, business process management, and reengineering within the FDD framework, the information system development team can enhance the quality, performance, and adaptability of their system solutions. The combined benefits of a holistic approach, NFR identification, business process alignment, and iterative requirement reengineering empower organizations to build software that not only meets functional needs but also provides optimal business value. This integration can help software development teams simplify the complexity of modern software development and achieve successful outcomes. This software development case study is different from previous research in the context of a farmer group in the Minggir, an area in Yogyakarta, with the hope of expanding the application's usage and accommodating more agricultural business processes.

This paper is organized as follows: 1) the first part presents the introduction, which includes the problem background, the objectives to be addressed, and the general method of resolution, 2) the second part is a literature review, containing references to previous studies, their relations, differences from this research, and the theoretical foundations used, 3) the third part is the research methodology, 4) the fourth part contains the results and discussion, which comprehensively presents the research findings and analysis, and finally 4) the conclusion and suggestions for further research development.

## II. Literature Review

### A. Dutatani System

This research is a continuation of previous Dutatani research. In the previous study, the Dutatani research team conducted the development of an integrated agricultural system, which consisted of a web-based portal system and farmer registration application. Land mapping was also created using native programming. Additionally, a study on the migration testing of the system from the old portal to the new portal has demonstrated significant improvements in the agricultural information. The study successfully identified and bridged the gap between the business process side and the information system side. The aim of this study is therefore to fill this gap through the proposed NFR classification and its translation into metadata, use case diagrams and functional design. NFRs can enrich the use case diagrams, metadata, and system features by integrating the successfully identified NFRs.

The conclusions of this research are as follows:

Integrating NFRs into use case diagrams and BPMN workflows. The proposed NFR classification has enriched the relationship between BPMN in the business process and its appropriate usage in the system metadata model.

Achieving forward and backward traceability from the business process to the information system model. The proposed classification has facilitated the mapping of NFRs from the business process into the information system. This research contributes to tracking NFRs and system features. If NFRs can be tracked, it enables the development of features for future development in case of any NFR changes. The proposed classification allows it to be used with other diagrams such as activity diagrams, flowcarts and even Data Flow Diagram (DFD). However, further study is needed to be able to develop other diagrams.

For future work, the research team plans to develop a matrix to connect NFRs to information system testing. Additionally, the matrix is expected to automatically assist in generating testing tables from BPMN to use case diagrams. Furthermore, the research team plans to investigate the effectiveness of NFRs on other system requirements such as load testing and system usability. Further details on the four research outcomes can be observed in Table I.

TABLE I. Summary Related Work

| Topic | Summary, Reference and Comparison |
|---|---|
| Implementation of Feature-Driven Development to Facilitate Feature Equity and Adaptation in the Development of Dutatani Web and Mobile Portal [2] | This article describes the development of an information system based on features using the Feature-Driven Development (FDD) approach. The results obtained indicate that a feature-based approach can streamline the system development according to the features expected by users.<br>In proposed method, we continue that list of feature from previous research and conduct with NFR and BPMN. |
| Blackbox Testing on the ReVAMP Results of The DutaTani Agricultural Information System [3] | In this article, the testing of the new agricultural data system is explained. The results show that the system can perform better and more efficiently compared to the old agricultural information system.<br>Different with proposed method, we are using NFR to fullfill the gap between user and system feature. It also aims to increase the efficiency of using the system in different ways. |
| Feasibility Study of Web Mapping System Implementation Using the TELOS Method: A Case Study of Harjo and Rahayu Farmer Groups [4] | The readiness of users of the agricultural information system is elaborated in this article, and the resulting outcome is a score of 8.4, indicating the preparedness of users and the satisfactory performance of the agricultural information system.<br>The proposed method also aims to increase the satisfactory of using the system in different ways, that use NFR and BPMN mapping. |
| Developing Agriculture Land Mapping using Rapid Application Development (RAD): A Case Study from Indonesia [5] | This article explains the stages of creating an agricultural land registration application on the old information system portal using the Rapid Application Development (RAD) approach. The study will extract use cases and existing business processes, which will then be applied to the new information system portal based on FDD.<br>In this proposed method, data extraction was also carried out, but what was extracted was different, namely NFR based on the FDD that had been carried out. |
| The Effects of Land Ownership on Production, Labor Allocation, and Rice Farming Efficiency [6] | The article delves into the status of agricultural land ownership, which has been prevalent in the world, particularly in Asia, including individual ownership, lease, and profit-sharing. One plot of land can be owned by several individuals with different ownership statuses simultaneously.<br>In the proposed method we try to use feature in this article so that existing features can be compared with community needs. |

Based on several articles that serve as the main references in this study, it can be seen that this research is mutually interconnected and continues the best practices from previous research outcomes. In this current study, non-functional requirements will also be involved to add metadata information for land mapping. The agricultural land mapping business process that has been previously implemented will be continued in the new information system portal with minor modifications to land ownership.

The limitation of this research is that it is only limited to NFR analysis and metadata formation. Fixed features are also limited to features that are deemed to need to be improved based on NFR findings. The output is also a framework for mapping the NFR into metadata so that it is easy to trace when there are changes to the NFR.

### B. *Non-Functional Requirements*

Non-functional requirements are requirements that state limitations on the services or functions offered by the system. These include time constraints, limitations on the development process, and limits set according to existing standards. Non-functional requirements are usually applied to the entire system. Non-functional requirements include speed, size, ease of use, reliability, robustness, and portability [10]. NFR also discusses issues related to product availability, maintenance, modifiability, timeliness, throughput, responsiveness, security, and scalability [11].

Defining NFR is a crucial element in producing a quality system. In cloud applications, determining NFR, workload, and Quality of Service (QoS) must be considered in deciding technology infrastructure [12]. Sumesh et al.'s study sought to achieve multi-objective optimisation of interdependent stakeholders and developed a framework to capture the competing NFR goals [13]. Soter [14], a method for modeling and translating NFR models, was introduced by DeVries and Cheng. Soter converts non-functional models into non-functional goal model fragments to be analyzed using the system-to-be goal model.

In research [15] [16], they classify NFR using a neural network approach. Other studies have attempted to optimize and balance the fulfillment of functional and non-functional requirements using the goal model approach [17][18]. A goal-oriented approach is also used to evaluate NFR compliance through the i* framework and Architecture modeling language (ArchiMate) [19].

## III. Research Methodology

### A. *Gathering NFR (Non-Functional Requirements)*

In FDD, NFRs must be identified and documented during the initial stages, along with the functional requirements. This proactive approach ensures that NFRs are considered from the outset, preventing time-consuming and costly rework. Additionally, NFRs help prevent delays in the later stages of information system development.

### B. *Mapping NFRs to Business Processes*

By aligning NFRs with related business processes, the FDD team can identify critical NFRs that directly impact the success of those processes. This mapping helps prioritize NFRs and make informed decisions during feature selection and implementation.

### C. *Iterative Reengineering*

The iterative nature of FDD allows for continuous evaluation and improvement of information system requirements. Through periodic reviews, the team can identify areas where NFRs need to be reengineered to enhance the performance, security, or usability of the information system. The outcome of this stage is the creation of new metadata an land mapping features in the new agricultural information system portal.

### D. *Collaboration and Communication*

Effective collaboration among stakeholders, including business analysts, developers, and quality assurance teams, is crucial to ensure the integration of NFRs, BPM, and reengineered requirements in FDD. Ongoing communication facilitates shared understanding and minimizes the risk of misalignment.

## IV. Result and Discussion

The results obtained are based on the sequence of steps described in Section III.

### A. *Identified NFRs*

Four categories of NFRs were successfully identified, as shown in Fig. 1. These categories were grouped based on data collection and in accordance with NFR type identification standards [20]. The explanations for the four NFR categories used in this research are as follows:

System express desired quality characteristics associated with software as constraints associated with product and organizational aspects. The required system constraints include:

*1)* The system requires a farmer group.

*2)* The system requires autocomplete in selecting farmer groups.

*3)* The system requires the addition of farmer land ownership.

*4)* The system requires land ownership status.

Actor shows the desired quality attributes or constraints that related to resource users, departments. Other parties or companies that interacting with system constraints also represent actors. The obtained requirements are:

*1)* Up-to-date data display showing land ownership data.

*2)* Related display with the previous add land menu.

Data keeps the desired data quality attributes that used and present in information system. Data represents the information objects used and displayed in the information system. The following are the new data attributes obtained by the research team:

*1)* Land can be owned by multiple farmers.

*2)* Land ownership status can differ for each farmer, but one land must be owned by at least one farmer.

*3)* When deleting land data, it will also delete farmer ownership data, but deleting ownership data will not delete the land data itself.

External presents information system limits and describes policies, standards, and regulations identified by business category. External factors that influence system requirements are land status rules, such as private ownership, leasing and profit sharing, which are prevalent in most countries, especially in Asia.

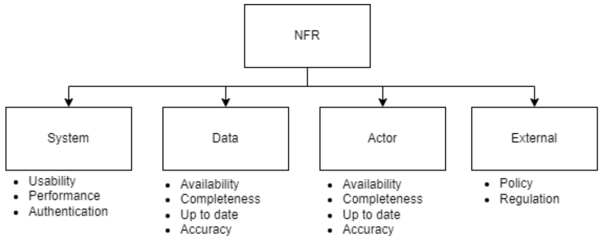

Fig. 1. Identified NFR categories.

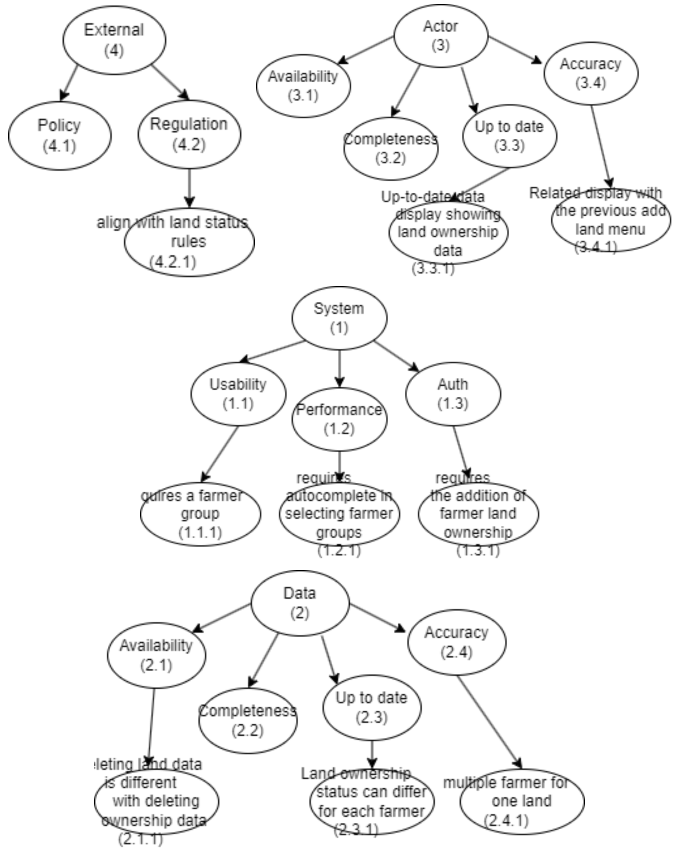
After knowing what NFRs will be transformed into a new system, the next step is mapping the new business processes. To simplify the mapping and validation process, in the NFR mapping process an NFR map is first created as shown in Fig. 2.



External (4)
Policy (4.1)
Regulation (4.2)
align with land status rules (4.2.1)

multiple farmer for one land (2.4.1)

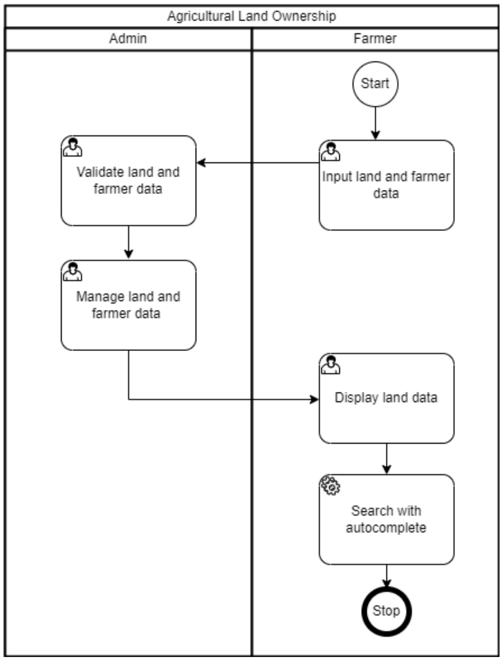
Fig. 2. NFRs mapping.

## B. Business Process Mapping

Based on the identification of NFRs, a new business process for the land ownership management feature is obtained. The important point at this stage is to accommodate every need for NFRs Mapping into BPMN. So to make this process can be done easily, NFRs are represented by numbers that have been previously mapped, connected to tasks and BPMN. The process of mapping NFR into tasks and BPMN can be seen in Table II. It can be seen that tasks with brackets are new tasks adapted to NFRs. The new business process that related to the NFRs Mapping, as shown in Fig. 3. This task will later turn into a use case diagram in next step.

TABLE II. BUSINESS PROCESS TASK MAPPING

| No | Tasks | Related NFRs |
|---|---|---|
| T1 | Input land and farmer data (with group and ownership) | 1.1.1, 1.3.1,<br>2.3.1, 2.4.1 |
| T2 | Validate land and farmer data (with status of ownership and multiple farmer) | 2.1.1, 2.3.1, 3.4.1 |
| T3 | Manage land and farmer data (including deleting land that takes into land ownership status) | 2.1.1, 4.2.1 |
| T4 | Display land data | 2.3.1, 3.3.1,<br>3.4.1, 4.2.1, |
| T5 | Search with autocomplete (new) | 1.2.1 |



Agricultural Land Ownership
Admin
Farmer
Start
Input land and farmer data
Validate land and farmer data
Manage land and farmer data
Display land data
Search with autocomplete
Stop

Fig. 3. BPMN of feature agricultural land ownership management.

The process flow begins when farmers input their data and land data independently. This is mandatory as land ownership status must be owned by at least one farmer. Once the farmer and land data are entered, the land ownership can be managed. The management process includes features for adding, modifying, and deleting land data. After the admin completes the data management, up-to-date data can be viewed by the respective farmers.

With the addition of a new business process, the use case is expanded due to the inclusion of the land management feature. The new use case can be seen in Fig. 4. Only one new use case is added, which is the Create Read Update Delete (CRUD) Agricultural Land, and this aligns with the Use Case diagram in the previous research [3], which had a total of 8 Use Cases.

## C. Information System Reengineering Process

The next step involves designing new metadata based on the existing metadata. Considering the NFRs related to data, new metadata is required to accommodate land ownership status. Not only metadata, but the information system database also needs to undergo changes to accommodate the transaction table to handle land ownership dynamics.

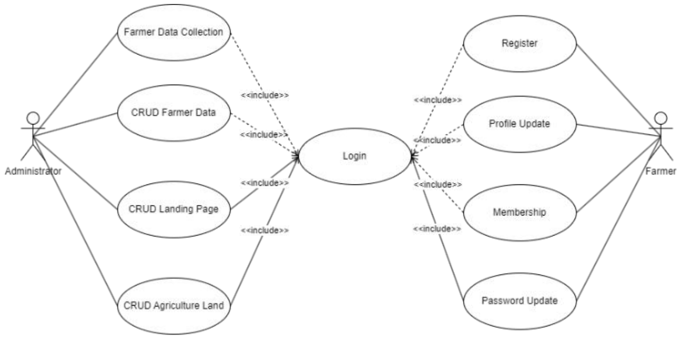


Fig. 4. New use case.

The farmer metadata remains unchanged, while the land data has new metadata due to the addition of the status attribute. The new metadata for agricultural land includes name, type, organic status, farmer group, central point, boundary point of the land, and many farmer object entries. Land ownership status is associated with farmer objects. Since one land data can be owned by multiple farmers, and one farmer data can have multiple land data, the database requires a new transaction table to accommodate the n:n relationship. Therefore, the latest database is depicted in Fig. 5. This paper only illustrates the relationships between farmers, land, and the land ownership transaction table.

Fig. 5. The new model of physical data.

Based on physical data model above, the new metadata can be produced. New metadata can be seen in Fig. 6 at right side. The left side is former metadata from previous research in 2023 [21] that not contain multiple farmer land. Based on NFR that metadata need to be updated with multiple land ownership, new metadata in Fig. 6 already accomodated that needs.

FDD (Feature-Driven Development) is the next stage as the metadata and database are ready for use. In FDD, a complete list of features in land management will be registered. Additionally, the desired feature identified during NFR identification, which is the farmer group autocomplete, will also be included. The following is the complete list of features that will be added to the Dutatani agricultural information system. This feature already accommodate BPMN mapping from the previous stage which is marked with a task number in bracket

1) Farmer's land registry (T1)
2) Land search (T5)
3) Detailed land information (T4)
4) Land map display (T4)
5) Add owner/farmer (T1)
6) Detailed land ownership for each farmer (integrated with existing farmer and land registration features) (T1, T2)
7) Ownership modification feature (T3)
8) Ownership deletion feature (T3)

A total of 8 detailed features will be incorporated into agricultural land management, along with 1 autocomplete feature for farmer group search. The autocomplete feature is designed as shown in Fig. 7. Data will be retrieved in real-time and up-to-date from the database, in accordance with NFR criteria. Similarly, the design of the land registry and land search features can be observed in Fig. 8, showing the land ID and the number of land owners. These features are complemented with a detail button that links to features 3-8, as depicted in Fig. 9. Specifically, feature 6 will be directed to the farmer registration menu to accommodate integration with the existing registration feature.

Fig. 9. Agricultural land data management feature.

In this study, the research team proposed an NFR-oriented classification to bridges the gap between the real world and information systems. The research team uses a BPMN model for the NFR classification to represent the business side and use case diagram to represent the information system side in the integrated agricultural information system case study.

Currently, previous studies have only classified or integrated NFRs for individual features either in real-world business processes or information systems. While there are many case studies on NFR and information systems, few have written about the sequence of classification, making it unclear when seeking the source of requirements. This has resulted in a gap between real-world business processes and information systems.

The proposed method in this study has resulted in:

*1)* NFR classification, each determined in relation to the requirements of the business process to be translated into the information system as either supporting or main requirements (system and data).

*2)* Higher number of NFRs compared to BPMN and use case diagram transformation results. This happened because the NFR side contains quality-related manual tasks (in addition to automated tasks), whereas the system side is controlled by the business and has only NFR-related automated tasks. This reduces the number of NFRs towards the BPMN and use case level.

*3)* A traceable flow diagram of the translation process between NFRs and the Information System. The diagram allows forward tracing (NFR to Metadata) and backward tracing (Metadata to NFR). This is applied to help map any business process requirements into the information system, and vice versa, when stakeholders decide to enhance the information system features. Additionally, the classification helps identify any NFR incompleteness between business processes and the information system by tracking each identified NFR in the business on the flow diagram. This can be seen in Fig. 10. There is a translation sequence that facilitates both forward and backward tracing.

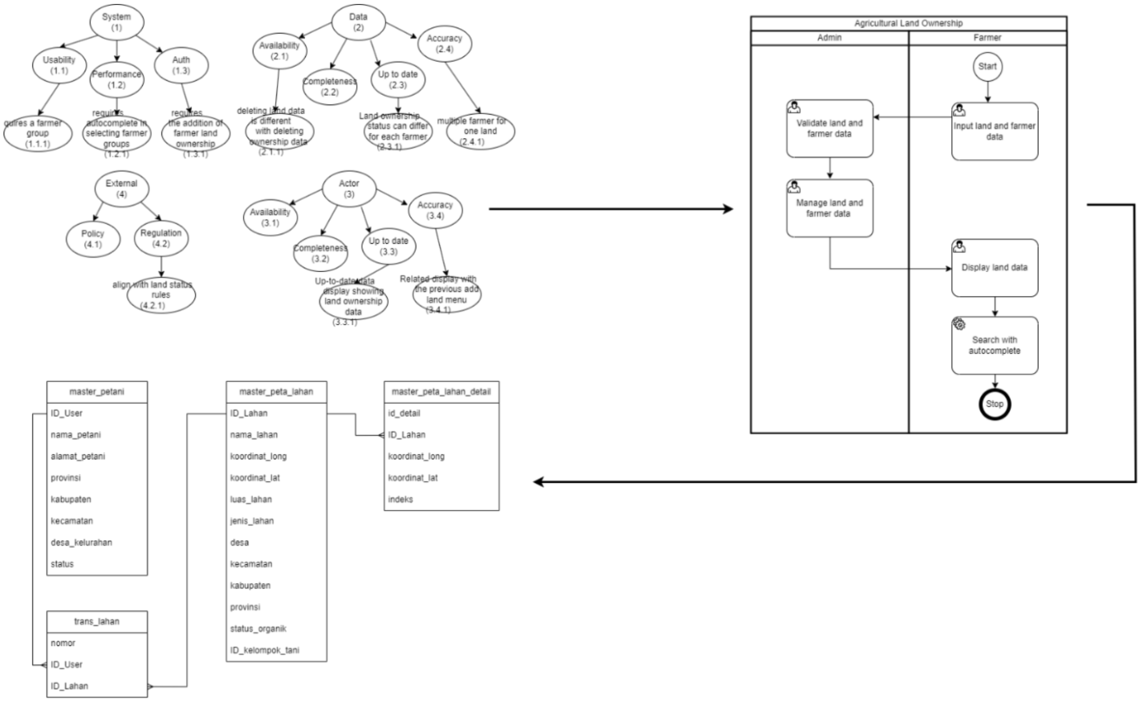

Fig. 10. Flowchart of information system requirements mapping.

The proposed method can perform good mapping between NFR, BPMN and also produce metadata. It has not been tested whether mapping can be done with other diagram notations. This can be studied in more depth with different cases because the purpose of each notation is different. The focus of this research is non-functional requirements that are compatible with BPMN's function, namely managing business process flows.

## V. Conclusion

The study successfully identified and being bridge between the business process side and the information system side. The aim of this study is therefore to fill this gap through the proposed NFR-oriented classification and its translation into metadata, use case diagrams and functional design. NFRs can enrich the use case diagrams, metadata, and system features by integrating the successfully identified NFRs. The conclusions of this research are as follows:

*1)* NFRs variable can be integrated into use case diagrams and BPMN workflows. NFR classification that proposed in this study can strengthens the relationship between BPMN in business processes and its proper use in system metadata models.

*2)* Achieving forward and backward traceability from the business process to the information system model. The proposed classification has facilitated the mapping of NFRs from the business process into the information system. This contributes to tracking NFRs and system features. If NFRs can be tracked, it enables the development of features for future development in case of any NFR changes.

For future work, the research team plans to develop a matrix to connect NFRs to information system testing. Additionally, the matrix is expected to automatically assist in generating testing tables from BPMN to use case diagrams. Furthermore, the research team plans to investigate the effectiveness of NFRs on other system requirements such as load testing and system usability.

## Acknowledgment

The authors would like to express their gratitude to Farmers in Ngudi Makmur and Mutiara for their support in this research and community service. The authors would also express their appreciation to the Faculty of Information Technology at Duta Wacana Christian University and the University's Institute for Research and Community Service (Lembaga Penelitian dan Pengabdian kepada Masyarakat/LPPM) for their support in this research and community service.

***Abstract*—In recent years, surface electromyography (sEMG) signals have been recognized as a type of signal with significant practical implications not only in medicine but also in the field of science and engineering for functional rehabilitation. This study focuses on understanding the application of surface electromyography signals in controlling a robotic arm for assisting disabled individuals in Vietnam. The raw sEMG signals, collected using appropriate sensors, have been processed using an effective method that includes several steps such as A/D converting and the use of band-pass and low-pass filters combined with an envelope detector. To demonstrate the meaningful effectiveness of the processed sEMG signals, the study has designed a robotic arm model with complex finger movements similar to those of a human. The experimental results show that the robotic arm operates effectively, with fast response times, meeting the support needs of disabled individuals.**

***Keywords—Disabilities; sEMG; signal processing; human arm; robotic arm***

## I. Introduction

Vietnam has a historical association with significant national defense wars, resulting in a substantial population of veterans and disabled individuals. Additionally, Vietnam is presently a developing nation with a considerable demand for unskilled labor, alongside an underdeveloped transportation infrastructure. This reality has led to a relatively high incidence of disability due to labor and/or traffic accidents. According to statistics, Vietnam is a country with a high number of disabled people, accounting for 7.8% of the population (equivalent to 7.2 million disabled people aged five years and older), of which the rate of disabled children is about 28.3% (equivalent to nearly 1.3 million children with disabilities). The two most common types of disabilities are mobility disabilities and neurological and/or intellectual disabilities, followed by visual disabilities. The other types account for less than 10% of the total number of people with disabilities [1]. The large number of people with disabilities presents a significant challenge for society and the Vietnamese government in providing support and ensuring their rights. This Fig. 1 highlights the extension of the disability problem to the country. Therefore, designing and manufacturing prosthetic devices to assist disabled individuals in restoring mobility function is one of the urgent issues in Vietnam today.

EMG signals are biological signals obtained by measuring voltage related to the current generated in a muscle during contraction, providing a measure of muscle nerve activity [2]. Methods for collecting EMG signals include invasive and non-invasive techniques. Invasive electromyography (*i*EMG) is a method of measurement that involves inserting a needle into the skin. Non-invasive methods, also known as surface electromyography (*s*EMG), collect data through electrodes attached to the skin [3]. This method is more widely used than the invasive counterpart due to its safety and ease of use. Surface electrodes are divided into two types: wet and dry ones. Wet electrodes, mainly containing Ag/AgCl ions, have better quality and lower electrode-skin impedance. However, these wet electrodes can irritate the skin and their quality may decrease over time due to the gel drying out. On the other hand, dry electrodes, although they have higher electrode-skin impedance, have the ability to capture stronger sEMG signals and are easier to use, without requiring surface preparation procedures like wet electrodes. For these reasons, the majority of sEMG sensor studies have used dry electrodes [4].

The placement of sEMG electrodes is crucial for successfully distinguishing different finger movements. Therefore, it is necessary to understand the muscle structure involved in controlling the fingers in order to determine the placement of the sEMG electrodes.

In the forearm, the main muscles involved in finger control are the flexor and the extensor muscles. These muscles are located on both sides of the wrist and forearm. The flexor muscles are primarily located on the front side of the forearm and are responsible for flexing the joints in the wrist and fingers. These muscles help to curl the fingers and the wrist. Examples of major flexor muscles include the flexor digitorum profundus and the flexor digitorum superficialis. Meanwhile, the extensor muscles are located on the back side of the forearm and play a role in extending the joints in the wrist and fingers. The extensor digitorum and the extensor digiti minimi are important muscles in the extensor group. Both of these muscle groups often work together to produce complex movements of the wrist and fingers. When the flexor muscles contract, they cause the extensor muscles to relax, and vice versa. Therefore, in order to obtain the sEMG signals of finger activities, the electrodes should be placed on the flexor and extensor muscle groups. Additionally, the electrodes should be located in the middle of these muscle groups to capture the strongest signals.

## II. Related Work

Recently, with the development of semiconductor technology, there have been many successful studies in developing EMG sensors that are increasingly compact, consume less power, and are more accurate [5-13]. For example, in study [7], the authors implemented a high-frequency and low-power sEMG signal acquisition system. The results showed that the EMG signal samples from the proposed system had a correlation coefficient of up to 99.5% compared to commercial systems, while the power consumption could be reduced by up to 92.72% and the battery life extended up to 9,057 times. The study in [8] proposed an integrated sEMG sensor with a signal reading circuit, MCU, and BLE for human-machine interface (HMI) applications, achieving an accuracy and stability of over 95%. This sensor is flexible, durable, and lightweight, making it suitable for different individuals or for use with different muscle groups, as it is constructed on a multi-layer polyimide-coated copper sheet. In study [10], the authors developed a high-stability capacitive EMG sensor. The sensor is particularly suitable for the Otto Bock standard prosthetic limb in real-world applications, providing comfort when worn and avoiding skin irritation.

There have been numerous studies using various algorithms to classify hand gestures through sEMG signals, with the most common ones being Artificial Neural Networks (ANN), Linear Discriminant Analysis (LDA), Support Vector Machine (SVM), etc. In the past decades, ANN tools have garnered significant attention from researchers in the field of EMG signal classification. ANN has several advantages in EMG signal classification, such as the ability to learn from examples, high noise tolerance, and generalization capabilities in high-dimensional input spaces [14-20]. In one experiment [14], researchers meticulously examined a surface electromyography (sEMG) signal classification system based on Deep Neural Networks (DNN). The results, focusing on eight gestures, demonstrated that the DNN-based system outperformed other classifiers (with an average accuracy of 98.88%), including SVM, kNN, Random Forest, and Decision Tree. In study [15], machine learning (ML) algorithm is employed to process shoulder and upper limb muscle signals, enabling the recognition of motion patterns and real-time control of an upper arm exoskeleton. The results demonstrate high accuracy, particularly with the SVM algorithm achieving 96 ± 3.8% accuracy offline and 90 ± 9.1% accuracy online, showcasing the reliability of ML in pattern recognition and exoskeleton motion control. Another study introduced a real-time hand gesture recognition model employing sEMG with a feedforward Artificial Neural Network (ANN), achieving an average recognition rate of 98.7% and an average response time of 227.76 milliseconds across twelve subjects, each performing five gestures [16]. Furthermore, in study [17], the authors applied a Fuzzy Inference System and Long Short-Term Memory network to analyze EMG signals for classifying the four main gestures of the hand. The classification results achieved an accuracy of 91.3% for the four - dimensional actions (Forward/ Reverse/ GripUp/ RelDown), 95.1% for the two-dimensional actions (Forward/Reverse), and 96.7% for the two-dimensional actions (GripUp/RelDown). In study [18], the authors employed Neural Network and Fuzzy Logic to classify hand movements using two channels of sEMG. The data were collected from ten subjects, and the procedure involved preprocessing, feature extraction, dimensionality reduction, and pattern recognition. The average classification accuracies were 96.08 (±0.9)% and 90.56 (±3)% for Neural Network and Fuzzy Logic, respectively. The study [19] introduces a novel interval type-2 fuzzy classifier based on an explainable neural network for surface electromyogram (sEMG) gesture recognition. Achieving a categorization accuracy of 95.04% for 52 gestures and demonstrating high performance in real scenarios, the proposed method holds promise for applications such as human intent detection and manipulator control. In [20], fuzzy neural networks were employed to represent the different elements affecting the primary muscles when the shoulder-elbow joint of the upper arm was positioned differently. This model utilizes multiple-channel sEMG signals as its input and translates them into the torque exerted on the human upper limb joints.

This paper focuses on developing a robotic arm model with complex movements controlled by surface electromyography (sEMG) signals to assist individuals with disabilities in Vietnam. To address this issue, the current research concentrates on utilizing sEMG signals to control the movements of the robotic arm. This work deals with simulating and analyzing the sEMG signals collected from the arm muscles, and then applies them to accurately control the robot's movements. The remaining sections of the article are organized as follows. After Section II presenting related studies, particularly on robotics and EMG sensors, a detailed overview of the system, from EMG sensors to control units and EMG signal processing, will be presented in Section III. Sections IV and V will present the experimental results, system performance evaluation and relevant discussion. Finally, the main points and future research directions are summarized in Section VI.

## III. Materials and Methods

### A. System Overview

A detailed description of the components of the proposed system is presented in Fig. 2. The relevant explanation for this diagram is as follows:

*1) The surface EMG sensors:* The Gravity Analog EMG Sensors have been introduced through a collaboration between DFRobot and OYMotion. The sensor consists of two components, a module containing electrodes and a module integrating filtering and amplification circuits. The EMG sensor, similar to Gravity sensor (see Fig. 3), amplifies surface EMG signals 1000 times and reduces noise through a differential input and a similar filtering circuit. The amplified EMG signals are sampled using a 10-bit analog-to-digital converter (ADC) through the MCU's analog input.

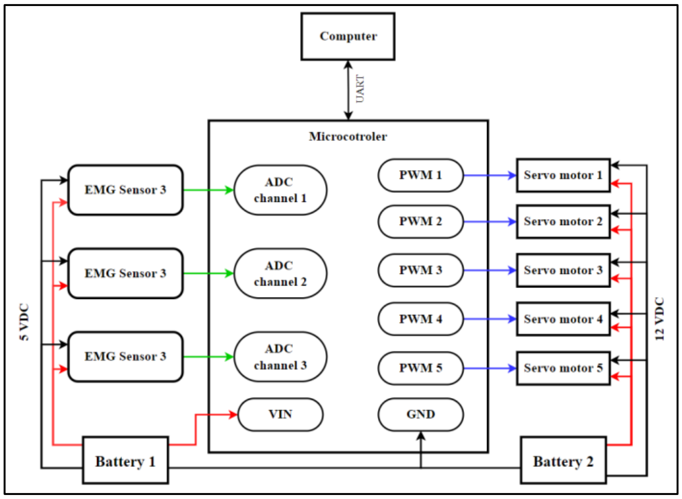

Fig. 2. General system diagram

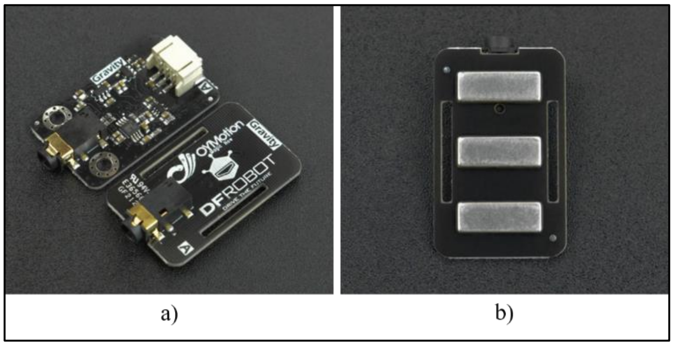

a) b)

Fig. 3. Gravity Analog EMG sensor

*2) ATMEGA2560 Microcontroller*: Processes EMG signals from the sensor, sends processed signals to the computer, and simultaneously receives control signals from the computer to control finger gestures, corresponding to 5 Servo motors.

*3) Computer*: Battery 1, Battery 2: Power supply for the sensors, microcontroller (5 VDC - battery 1), and 5 servo motors (12 VDC - battery 2).

## B. *EMG Signal Processing*

The EMG sensor, similar to Gravity, amplifies surface EMG signals 1000 times and reduces noise through a differential input and a similar filtering circuit. The sensor's output is an analog voltage signal ranging from 0 to 3.0V (corresponding to muscle contraction intensity). This analog signal is converted to a digital signal by the 10-bit ADC of the microcontroller, with a sampling frequency of 1kHz. The digital signal then passes through a second-order Butterworth high-pass filter. Finally, the signal goes through an envelope detection algorithm, resulting in the final processed signal (see Fig. 4).

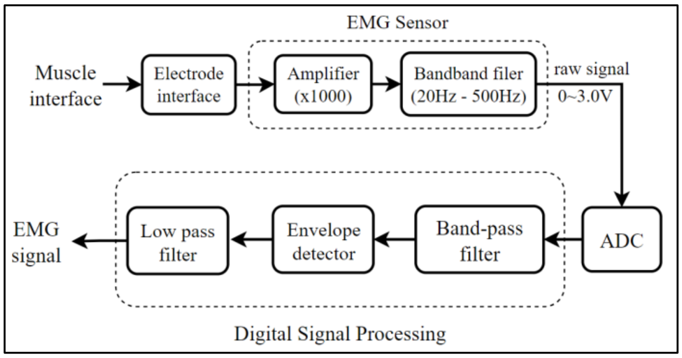

Fig. 4. Surface EMG signal processing.

In signal processing, the function of a digital filter is to remove unwanted components of the input signal or extract useful parts of the signal. A digital filter uses digital processing to perform mathematical operations on the input signal in order to reduce or enhance specific aspects of the signal. There are two types of digital filters: infinite impulse response (IIR) filters and finite impulse response (FIR) filters. For a FIR filter, the output depends only on the current and previous inputs, and the general form of a FIR filter is:

$$y(n) = b_0x[n] + b_1x[n-1] + b_2x[n-2] + \cdots + b_Nx[N] \tag{1}$$

On the other hand, IIR filters are recursive, meaning that the output depends not only on the current and previous inputs but also on the previous output. Therefore, the general form of an IIR filter is:

$$\sum_{m=0}^{M} a_m y[n-m] = \sum_{k=0}^{N} b_k[n-k] \tag{2}$$

A digital filter can be designed as an IIR filter or an FIR filter. The advantage of IIR filters over FIR filters is that they often meet specific technical specifications with a much lower filter order compared to the corresponding FIR filter. For these reasons, the authors of this study used IIR filters to process EMG signals. A common method for designing IIR filters is to design a similar analog filter and then convert it into an equivalent digital filter. There are various types of similar low-pass filters, such as Butterworth, Chebyshev, and Elliptic filters. These filters differ in their nature of intensity and phase response. Designing similar filters other than low-pass filters is based on frequency transformation techniques, creating high-pass filters, band-pass filters, or band-stop filters equivalent to the prototype low-pass filter of the same type. The similar IIR filter is then converted into an equivalent digital filter using the same transformation method. There are three main conversion methods: impulse invariant method, backward difference method, and bilinear z-transform. In the article, a second-order IIR Butterworth digital filter is used to filter EMG signals. The low-cut frequency is set at $f_{cl}$ = 50Hz (to remove low-frequency noise) and the high-cut frequency is set at $f_{ch}$ =150Hz (to remove high-frequency noise). The sampling frequency of the filter is 1kHz, based on references [11-13] which suggested that a sampling frequency between 400Hz and 500Hz is sufficient for measuring EMG signals. The transfer function of the filter is shown in the equation below:

$$H(z) = \frac{Y(z)}{X(z)} = \frac{0{,}106s - 0{,}212z^{-1} + 0{,}106z^{-2}}{1 - 0{,}754z^{-1} - 0{,}392z^{-2} + 0{,}754z^{-3} + 1{,}006z^{-4}} \quad (3)$$

The final low-pass filter in the EMG signal processing is used to smooth the output signal of the envelope detector algorithm. This work has designed a first-order IIR digital low-pass filter with a cut-off frequency of $f_c$ = 10 Hz and a sampling frequency of $f_s$ = 1kHz. The transfer function of the filter is presented in (4).

$$G_{LP}[z] = \frac{Y[z]}{U[z]} = \frac{b[0]}{a[0] + a[1]z - 1} \quad (4)$$

where, $U_z$ is the input and $Y[z]$ is the output. It is assumed to set a = [1, -c] and b =[c] to represent the storage elements. The parameters of the first-order delay elements are adjusted according to the time constant $T$ and the cut-off frequency $f_c$ as follows:

$$T = \frac{c\Delta t}{1 - c} = \frac{1}{2\pi f_c} \quad (5)$$

Therefore, the factor $c$ can be calculated in (6).

$$c = \frac{1}{1 + \frac{\Delta t}{T}} = \frac{1}{1 + 2\pi f_c \Delta t} \quad (6)$$

Applying the signal processing for the sEMG as proposed above, the results can be successfully obtained. Fig. 5 represents three types of the sEMG signal: raw signal, high-pass filter output and envelope signal. The last one can be obviously used for the control of a robotic arm which will be presented in the next section.

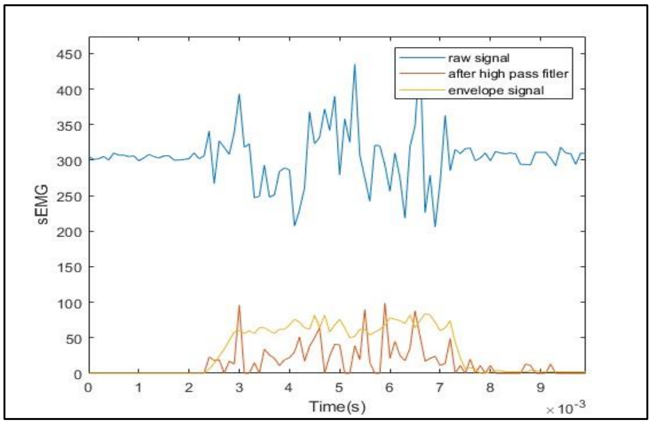

Fig. 5. Results of the sEMG signal processing.

## IV. Results

The placement of the actual electrodes is shown in Fig. 6. In this figure, electrode 1 is responsible for measuring the maneuverability activity of the index finger, electrode 2 measures the motion activity of the middle finger and index finger, and electrode 3 measures the mobility activity of the thumb.

This work utilizes the open-source design of the InMoov robot hand, created by Gael Langevin. With its 3D-printed structure as shown in Fig. 7, this hand is not only aesthetically pleasing but also capable of mimicking natural hand movements. InMoov is not just limited to being a sophisticated robot product but also an open-source project, encouraging community involvement in its development and customization. The sEMG signal-controlled system makes it an excellent tool for learning and research in the field of assistive robotics.

When the muscles of the fingers are relaxed, the raw sEMG signals obtained from the three sensors maintain a small oscillation at the reference voltage threshold (1.5V). This oscillation frequency is lower than the high-cut frequency of the digital high-pass filter, so these signals are attenuated. As a result, both the output signals from the bandpass filter and the envelope signals have values of zeros.

When the fingers contract, the raw signals from the sEMG sensors will fluctuate with a higher amplitude at a higher frequency. The bandpass filter is used to allow these signals to pass through. By applying an edge detection algorithm, we can obtain an envelope signal that represents the level of muscle contraction, with the magnitude depending on the degree of contraction of the corresponding muscle. Fig. 8 with various movements of the wrist and fingers illustrates the states of the EMG signal channels when performing basic motor tasks. Experiment results are totally acceptable in control of a robotic arm.

(d)

Fig. 8. The experimental results on the robotic arm model applied sEMG signals. (a) Thumb control, (b) Control of the index and middle fingers, (c) Control of the pinky and ring fingers, (d) Hand grasp control.

The results of the study above have demonstrated the effectiveness of the sEMG signal processing system and robot arm model in supporting individuals with disabilities. The sEMG signal processing system has verifed the ability to accurately and stably collect and convert sEMG signals into control signals for the robot arm. Filters and signal processing algorithms help eliminate noise and create precise control signals that respond quickly and flexibly to muscle movements.

The robot arm model has been able to perform complex movements of the fingers accurately and flexibly. The response time of the robot arm is fast, responding promptly to control signals from sEMG signals. Test results have demonstrated that the robot arm model operates effectively and stably under real conditions.

## V. Discussion

The results of this study contribute to the field of developing sEMG signal-controlled robotic arms to assist individuals with disabilities. Using an effective method of collecting and processing sEMG signals, this work has successfully designed a robot arm model that can perform complex movements similar to those of humans. One of the notable points is that the application of filters and signal processing algorithms has allowed us to accurately and efficiently collect and convert sEMG signals into control signals for the robot arm. Experimental results have demonstrated that the robot arm is capable of stable operation and quick response, properly meeting the support needs of disabled individuals.

However, although this study has achieved positive results, there are still a number of further research directions that can be explored. Specifically, a significant integration of wrist rotations, as well as arm bending and extension, will complete the complex movements of the robot arm model. This will increase the flexibility and applicability of the robot arm in real-life tasks. In addition, the research can also be expanded to apply machine learning and artificial intelligence methods to improve the precise recognition and control of robot arms based on sEMG signals [14-20]. Developments in this area will bring significant advances in supporting and enhancing the quality of life of individuals with disabilities.

## VI. Conclusion

This paper presents in detail the steps of collecting and processing sEMG signals effectively. These sEMG signals have been applied to control a robotic arm model with complex movements of each finger. The experimental results (see Table I of Appendix) confirm that the model works stably and efficiently. The future work inspired from this research will focus on incorporating additional wrist rotation, as well as flexion and extension of the forearm, to complete the complex movements of the robotic arm model. In this scenario, the model has been fully designed for commercialization and widely applied in a developing country like Vietnam.

***Abstract*—Assessing students' cognitive ability is one of the most important prerequisites for improving learning effectiveness, and the process involves aspects such as exercises, students' answers and teaching cases. In order to effectively assess students' cognitive ability, this paper proposes a Chinese text classification model that can automatically and accurately classify Bloom's cognitive hierarchy of exercises, starting from the exercises. Firstly, FreeLB perturbation is added to the input Embedding to enhance the generalization performance of the model, and Chinese-RoBERTa-wwm is used to obtain the pooler information and sequence information of the text; secondly, LSTM is used to extract the deep-associative features in the sequence information and combine with the pooler information to construct the semantically informative word vectors; lastly, the word vectors are fed into BiLSTM to learn the sequence bi-directional dependency information to obtain more comprehensive semantic features to achieve the accurate classification of the exercises. Experiments show that the model proposed in this paper significantly outperforms the baseline model on three Chinese public datasets, achieving 94.8%, 94.09% and 94.71% accuracies respectively, and also effectively performs the Bloom cognitive hierarchy classification task on two Chinese exercise datasets with less data.**

***Keywords*—Chinese Text Classification; Chinese-RoBERTa-wwm; BiLSTM; Bloom Cognitive Hierarchy**

## I. INTRODUCTION

Assessing students' cognitive abilities is an essential component of the teaching process [1], as they are an important factor in determining the quality of learning activities and are indispensable in the learning process. Testing is an essential method for assessing students' cognitive abilities, and test scores correspond to learning outcomes at different cognitive levels, which in turn reflect students' cognitive abilities [2]. Therefore, it is necessary to develop test questions for courses according to a standard that meets different cognitive levels [3], helping teachers better grasp the cognitive abilities of students and achieve the teaching goals of the course, such as Bloom Taxonomy. The cognitive domain of Bloom taxonomy covers different cognitive levels from simple to complex [4, 5], categorizing exercises into six cognitive levels from high to low based on the criteria of different cognitive levels involved in students' learning processes [6]. Typically, teachers manually categorize exercises into the corresponding Bloom cognitive levels based on their understanding of the domain being taught, a process that is not only time-consuming but also highly subjective. Therefore, automating this process is a major task in pedagogical research.

Mohammed [7] and Setyaningsih [8] combined machine learning methods with natural language processing techniques to achieve good results with Bloom's Cognitive Hierarchical Taxonomy for test exercises in different courses. However, all of the above studies used traditional machine learning methods with low model accuracy and poor generalization [9]. Therefore, text classification methods need to be further improved to apply to the Bloom cognitive hierarchy domain. Compared with traditional machine learning algorithms, deep learning algorithms have emerged in the field of text classification [10]. Applying deep learning methods to Bloom's cognitive hierarchy of exercise classification has better results than machine learning methods [11]. In addition, the use of sequence learning models such as BiLSTM to capture the bidirectional dependency information in word vector sequences can improve the accuracy of classification models more effectively [12].

Inspired by the above research, this paper proposes a Chinese exercise Bloom cognitive hierarchy classification model based on improved Chinese-RoBERTa-wwm and BiLSTM (Chinese-FRLB). The model incorporates FreeLB antiperturbation into the input Embedding, combines sequence information and pooler information of the Chinese-RoBERTa-wwm output to generate word vectors, and learns their bi-directional sequence dependency information through BiLSTM to accurately classify the Bloom cognitive hierarchy of Chinese exercises.

The main contributions of this study can be summarized as follows:

*1)* A dataset of Chinese exercises was constructed based on Bloom classification hierarchy, providing a database for modeling the use of Chinese exercises to assess students' cognitive abilities in the learning process.

*2)* Proposing a word vector representation method that integrates both text sequence information and pooler

*Corresponding Author.

information. It utilizes LSTM to extract deep-level associative features from the sequence information outputted by Chinese-RoBERTa-wwm, enhancing the model's semantic comprehension ability. Additionally, it combines semantic information to characterize word vectors containing both deep and shallow semantic features, thereby avoiding the loss of con-textual global information and sentence structure information.

*3)* Proposing a Bloom cognitive hierarchical classification model for Chinese exercises. The model adds FreeLB adversarial perturbations to the input Embedding to train the model to distinguish between real samples and adversarial samples, enhance the generalization ability of the model, obtain semantically rich word vectors by using improved Chinese-RoBERTa-wwm, and inputs them into BiLSTM to learn bidirectional dependency information between word vector sequences, mine the implied dimensional correlation between words from the spatial level, and improve the classification accuracy of the text of the exercises more effectively.

The rest of the paper is organised as follows: Section II briefly describes the related work of this paper. Section III describes the proposed method and related techniques in detail, illustrating the composition of the experimental dataset. Section IV shows the comparison experimental results with other benchmark models and reliability analysis of the algorithm of this paper. Section V and Section VI concludes the work and provides future work with an outlook.

## II. Related Works

The existing text classification methods are mainly categorized into ML method and DL method. The machine learning models ignore semantic information in texts and require manual labeling, which is time-consuming and laborious. In contrast, DL methods embed the text feature encoding process into model training, effectively extracting semantic information from texts and improving text classification accuracy.

Ashish et al. [13] proposed the Transformer architecture based on the attention mechanism, which provides a new deep-learning approach for text classification models. Under the Transformer architecture, large-scale pre-trained models have achieved tremendous success in the field of text classification. Devlin [14] proposed the pre-training model BERT, which adopts bidirectional training of Transformer and combines MLM (Masked LM) and NSP (Next Sentence Prediction) for pre-training on large-scale unlabeled corpora, fully learning the contextual implicit semantic information. Yang et al. [15] proposed the XLNet model, which integrates the advantages of both self-encoding and self-regression based on the autoregressive model Transformer-XL by adding the BERT model idea, combining the advantages of both autoencoding and autoregressive pre-training models. However, the above BERT and its improved model are applied to the Chinese classification task by segmenting according to a single text, which loses the semantic nature of Chinese words, and the ability to extract semantic information is weaker compared to the model in this paper.Liu et al. [16] proposed RoBERTa based on BERT, which removed the NSP task from BERT and expanded the training scale and training data, enabling RoBERTa to generalize better to downstream tasks than BERT. However, the BERT model only uses pooler information in text classification and does not fully consider the use of other feature information, whereas the combination of sequence information and pooler information used in this paper can learn more semantic features compared to the model. Cui et al [17] improved the Chinese version of BERT by proposing the whole word masking (wwm) strategy, i.e., masking the Chinese word, which improves the performance of the BERT model in the field of Chinese text classification. However, the BERT-base model only uses textual pooler information in text classification and does not fully consider utilizing other feature information. Xu [18] proposed a Chinese text classification method that synthesizes semantic and structural information, which uses cross-entropy and hinge loss to effectively combine Chinese-BERTology-wwm with the GCN method, demonstrating good performance in both long and short text corpora. However, in contrast to the model in this paper, the method does not take into account the interdependence information between sequences of word vectors.

Nowadays, DL demonstrates significant advantages in the field of text classification, and with the assistance of deep learning methods, various Bloom cognitive hierarchical classification models have also achieved good results. Shaikh et al. [19] used the Word2vec word embedding model to acquire word vectors with textual semantic information, which were then inputted into an LSTM model for performing Bloom cognitive hierarchical classification of Course Learning Outcomes (CLOs). However, the word vectors generated based on Word2vec do not encompass the contextual information of the input text. Mathiasen et al. [20] discarded the traditional word embedding technique and used the Transformer model to extract word vectors containing contextual information in job advertisements. Experimental results demonstrate that this model outperforms models using traditional word embedding techniques. Gani et al. [21] employed the RoBERTa model to extract word vectors from exercise questions' texts, which were then classified by a CNN network into different Bloom cognitive levels and the experimental results indicate that this method can more accurately categorize exercises into different Bloom cognitive levels. However, the above methods are all based on English exercises, and when faced with sparse data, the model may overfit prematurely, resulting in poorer robustness compared to the model in this paper.

In summary, there is a shortage of research on Bloom cognitive classification of Chinese text, and datasets are scarce. Existing deep learning-based Chinese text classification models do not fully consider the deep associative features in the output sequences of pre-trained models, and ignore the bidirectional semantic features of word vector sequences. In addition, most Bloom cognitive hierarchical classification models are only applicable to individual courses with poor generalization. Therefore, this paper constructs an exercise dataset containing multiple courses labeled with Bloom cognitive hierarchies and proposes a Bloom cognitive hierarchy classification model applicable to Chinese exercise texts. The model enhances its generalization ability by adding FreeLB adversarial perturbations to the input Embedding, achieving Bloom cognitive hierarchical classification of exercises from different courses. It utilizes LSTM to extract deep associative features from the output sequence information of Chinese-RoBERTa-wwm, and integrates semantic information to construct word vectors rich in semantic content. By employing BiLSTM, it learns the bidirectional dependency information of word vector sequences, accurately categorizing exercises into their corresponding Bloom cognitive levels.

## III. Materials and Methods

The steps for processing Chinese exercise text using the Chinese-FRLB model are as follows: Firstly, preprocess the Chinese exercise text dataset to obtain Attention_mask and Input_ids vectors. Randomly initialize Inputs_embeds vectors based on the Input_ids vectors, and input Inputs_embeds and Attention_mask into Chinese-RoBERTa-wwm to obtain sequence information T and pooler information C. Then, use LSTM to extract deep sequential correlation features from sequence information T and combine it with pooler information C to represent word vectors Y. Finally, use BiLSTM to learn the bidirectional dependency information of the word vector sequence Y and combine it with Softmax to output the exercise classification results. The gradient parameters of the model are returned to the FreeLB module to calculate the perturbation values $\delta_t$ and added to the Inputs_embeds to participate in the training process of the model to increase the generalization performance of the model. The model architecture is shown in Fig. 1.

Algorithm 1 demonstrates the basic steps of the Chinese-FRLB model in classifying Chinese exercise texts into their corresponding Bloom cognitive levels from the perspective of data parameter variation.

**Algorithm 1:** Chinese-FRLB Model

```
Initialize: Traning dataset $X$, Ascent steps $K$, Perturbations bound $\varepsilon$, Ascent steps size $\alpha$
Compute: Bloom Taxonomy Level $P$
    According to $X$, obtain $Attention\_mask$ and $Token\_types\_ids$, and then according to $Inputs\_embeds$, obtain $Token\_types\_ids$
For epoch = 1…$N$ do
    For minibatch $B \subset X$ do
        Initialize FreeLB perturbations $\delta_0$
        For t = 1…$K$ do
            $Sequence\_output\ T$, $Pooler\_output\ C$ ← RoBERTA-wwm($Inputs\_embeds$ + $\delta_0$)
            Obtain the deep associated features of text
                $H$ ← LSTM($T$)
            Obtain word vectors $Y$ from contact $C$ and $H$
            Obtain the sequence associated features of word vectors
                $H_{BiLSTM}$ ← BiLSTM($Y$)
            Reduce the dimensionality of H through the linear layer to obtain the vector $L$
                $P$ ← Softmax($L$)
            Update the perturbations $\delta_t$
                $\delta_t \leftarrow \Pi_{\|\delta\|_{F\leq\varepsilon}}(\delta_0 + \alpha□g_{adv}/\|g_{adv}\|_F)$
        End
    End
End
```

### A. Chinese-RL-wwm

The study by Waheed et al [22] showed that combining pooler and sequential information to construct word vectors can enable the model to learn more profound semantic information, thereby enhancing classification accuracy. Inspired by this research, this paper proposes the Chinese-RL-wwm network framework, as illustrated in Fig. 2. Chinese-Roberta-wwm [17] is utilized to obtain the sequence information and the pooler information of a single sentence of Chinese text, and the LSTM model [23] is used to extract the deep associative features of the sequence information, and it is spliced with the semantic information as the word vector of the input text. Compared with the word vectors constructed by the Chinese-Roberta-wwm model, the word vectors output by the proposed network framework not only encompass all its features, but also consider the deep dependency information within the text sequence.

Using the statement "下列 C 语言常量中，错误的是 (Among the following C language constants, the incorrect one is)" as an example, firstly, the special tokens [CLS] and [SEP] are used to mark the beginning and end of the sentence, as shown in Fig. 2. Then, using the WordPiece splitter to split and construct the Embedding data (word embedding $\{E_{[CLS]},...\}$, text embedding $\{E_A,...\}$, and positional embedding $\{E_0,...\}$) as input to the RoBERTa-wwm model to obtain pooler information $C \in \mathbf{R}^H$ and sequential information $T_i \in \mathbf{R}^H$, where $H$ is the number of hidden layers of the model, and $i$ is the input data except [CLS]. Secondly, $C$ and $T_i$ are concatenated as the input of the LSTM model, which is used to mine the sequential dependency information of the preceding and following texts in the utterances, and characterize the deep-level association feature vector $h_t$ of the utterances, the output of which corresponds to the input data including [CLS]. Finally, the semantic information of the sentence is represented by the word vector $y_s$ obtained through Eq. (1), where $s$ represents the input data including [CLS].

$$y_s = W(h_t \oplus C) + b \tag{1}$$

In the equation, *W* represents the weight parameters of the fully connected layer, and b denotes the bias parameters..

*1)* Chinese-RoBERTa-wwm: The embedding vectors required for BERT are obtained through Eq. (2).

$$E_{BERT} = E_{Token} + E_{Segment} + E_{Position} \tag{2}$$

The Chinese-RoBERTa-wwm model is built based on the bidirectional Transformer [13], and the network framework consists of a stack of 12 Encoder layers. The model processes the data as follows:

*a)* First, $E_{BERT}$ is input into the multi-head attention mechanism as Q, K, and V in the attention mechanism, and the residuals of $E_{BERT}$ and $ATT_{OUT}$ are connected using the LayerNormalisation layer as shown in Eq. (3) and Eq. (4).

$$ATT_{OUT} = Attention(E_{BERT}, E_{BERT}, E_{BERT}, mask) \tag{3}$$

$$output_1 = LayerNorm(ATT_{OUT} + E_{BERT}) \tag{4}$$

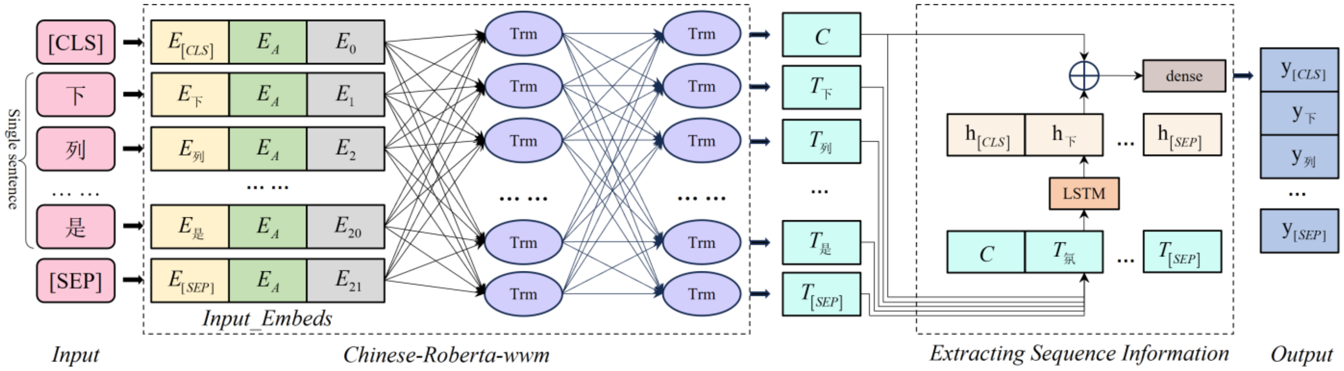

Fig. 2. Framework diagram of Chinese-RL-wwm module.

*b)* Next, $output_1$ is input into the Point-wise Feed Forward Neural Network layer. Then, the LayerNormalization layer is applied again to residually connect $output_1$ with the output results of the Point-wise Feed Forward Neural Network layer, yielding the output of the Encoder layer, as depicted in Eq. (5) and Eq. (6).

$$Feed\_Forward_{\mathrm{OUT}} = FeedForward(output_1) \tag{5}$$

$$output = LayerNorm(output_1 + Feed\_Forward_{OUT}) \tag{6}$$

*c)* Finally, the output is fed into the next layer of Encoder network, and the final pooler information $\mathrm{C} \in \mathbf{R}^H$ as well as the sequence information $T_i \in \mathbf{R}^H$ is output after 12 layers of stacked Encoder networks in turn.

*2)* LSTM: In this paper, the LSTM model [23] is utilized to characterize the deep-level associative features of the sequence information $T_i \in \mathbf{R}^H$ output from Chinese-RoBERTa. Before inputting into the LSTM model, the sequence information $T_i$ is integrated into a sequence vector $T = \{T_1, T_2, ..., T_i\}$ according to the order of sentences. As shown in Fig. 3, the LSTM achieves the functions of selectively forgetting the information of the previous moment, selectively updating the information of the current moment, and selecting specific information as the output of the current moment through three gating units, namely, the forgetting gate $f_t$, the input gate $i_t$, and the output gate $o_t$, as shown in Eq. (7), Eq. (8) and Eq. (9).

$$f_t = Sigmoid(W_f \cdot [h_{t-1}, T_i] + b_f) \tag{7}$$

$$i_t = Sigmoid(W_i \cdot [h_{t-1}, T_i] + b_i) \tag{8}$$

$$o_t = Sigmoid(W_o [h_{t-1}, T_i] + b_o) \tag{9}$$

In the equation, $W_f$, $W_i$, $W_C$, $b_f$, $b_i$ and $b_C$ are trainable parameters. After passing through the three gates, the new candidate value vector $\tilde{C}_t$ and output vector $h_t$ are computed as shown in Eq. (10), Eq. (11) and Eq. (12).

$$\tilde{C}_t = \tanh(W_C \cdot [h_{t-1}, T_i] + b_C) \tag{10}$$

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t \tag{11}$$

$$h_t = o_t * \tanh(C_t) \tag{12}$$

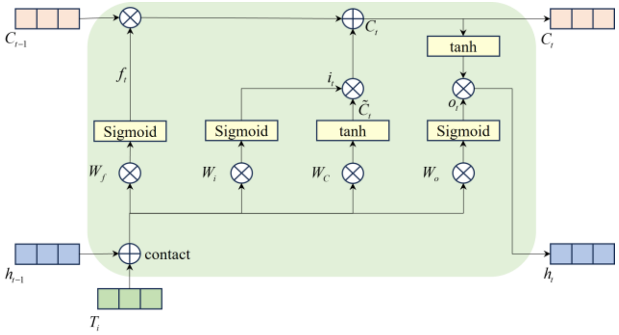

Fig. 3. Structure of LSTM gating mechanism.

In this case, the vector $h_t$ represents deep-level associative features in the text sequence. And then, the word vector $y_s$ which contains the semantic information of the text will be constructed by combining Eq. (1) with $h_t$ and the pooler information *C*.

## B. BiLSTM

Inspired by the [12], after obtaining word vectors $y_s$ that combine the deep associative feature vectors of the utterances with the pooler information, the BiLSTM model is used to learn the bi-directional dependency information between the word vector sequences for the subsequent text categorization.

Pass the output $Y = \{y_{[\text{cls}]}, y_{\text{下}}, ..., y_{[\text{sep}]}\}$ of Chinese-RL-wwm from the first moment to moment *t* into the forward LSTM and save the output at each time point as shown in Eq. (13). Reversing the sequence of *Y* and then once time fed into the backward LSTM, while also saving the output at each time point, as shown in Eq. (14).

$$\vec{h}_t = Sigmoid(\vec{W}[\vec{h}_{t-1}, Y]) \tag{13}$$

$$\overleftarrow{h}_t = Sigmoid(\overleftarrow{W}[\overleftarrow{h}_{t-1}, Y]) \tag{14}$$

In the equation, $\vec{h}_{t-1}$ and $\overleftarrow{h}_{t-1}$ are the previous output states of the forward LSTM and backward LSTM at time *t*-1, respectively. $\vec{W}$ and $\overleftarrow{W}$ are the weights matrices of the forward and backward propagation, respectively.

Concatenate the output vectors corresponding to the forward LSTM and the backward LSTM to obtain the final required vector, as shown in Eq. (15).

$$H'_t = W_1 \vec{h}_t + W_2 \overleftarrow{h}_t + c_t \tag{15}$$

In the equation, $W_1$ and $W_2$ are the forward and backward output weights, respectively, and $c_t$ is the bias optimization parameter.

## C. FreeLB

In order to improve the generalization of the model, FreeLB (Free Large-Batch) [24] adversarial perturbations are added to the input embedding layer of the text data. During the model training process, the gradient parameters $\nabla_\theta L$ accumulated by each perturbation are calculated firstly, as shown in Eq. (16).

$$g_t = g_{t-1} + \frac{1}{K} \mathrm{E}_{(Z,y)\in B}[\nabla_\theta L(f_\theta(\boldsymbol{X} + \delta_{t-1}), y)] \tag{16}$$

In the equation, $g_{t-1}$ and $\delta_{t-1}$ are the gradient and perturbation at the previous moment, and $X + \delta_{t-1}$ is the approximation of the local maximum at the intersection of two spherical neighborhoods $\mathrm{L}_t = \mathrm{B}_{\boldsymbol{X}+\delta_o}(\alpha t) \cap \mathrm{B}_{\boldsymbol{X}}(\varepsilon)$.

Then, the perturbation $\delta_t$ is updated by gradient ascent as shown in Eq. (17).

$$\delta_t = \Pi_{\|\delta\|_{F\le\varepsilon}}(\delta_{t-1} + \alpha \cdot g_{adv} / \|\mathrm{g}_{adv}\|_F) \tag{17}$$

Eventually, the gradient parameter $g_K$ obtained after *K* iterations is used for updating the model parameters $\theta$, as shown in Eq. (18).

$$\theta = \theta - \tau g_K \tag{18}$$

## D. Datasets

To verify the advancement and effectiveness of the proposed Chinese-FRLB model, experiments were conducted on three sets of Chinese news headline datasets and two sets of Chinese Bloom cognitive level exercise datasets classified by course instructors, namely Toutiao-S[1], THUCNews #1[1], THUCNews #2[1], Bloom-5classes, and Bloom-6classes datasets.

The Toutiao-S dataset is a subset of the Toutiao Chinese news headline classification corpus, containing five categories with 17,500 news headlines. Among them, 15,000 headlines are used for training, and 2,500 headlines are used for testing.

Based on the original Sina news classification system, two sets of datasets with different classification categories were redefined: THUCNews #1 and THUCNews #2. THUCNews #1 contains 10 categories and 55,315 news headlines, with 45,315 headlines used for training and 10,000 headlines used for testing. THUCNews #2 contains 14 categories and 54,599 news headlines, with 41,999 headlines used for training and 12,600 headlines used for testing.

TABLE I. STATISTICAL DATA FOR DIFFERENT DATA SETS

| Datasets | #Proportion of Different Categories of Training and Testing Dataset | #Average length |
|---|---|---|
| Toutiao-S | All 20% | 25 |
| THUCNews #1 | All 10% | 19 |
| THUCNews #2 | All 7.1% | 18 |
| Bloom-5classes | 30%/25%/23%/11%/11% | 50 |
| Bloom-6classes | All 16.7% | 52 |

The Bloom-5classes dataset was selected from the final exam papers and textbook exercises of the "C Programming Language" [25] course. After discussion with the teacher of the course area, it was concluded that Bloom's cognitive level of analysis is suitable for program questions, but not for textual descriptions such as multiple-choice, fill-in-the-blanks, and programming questions. However, Chinese-RoBERTa-wwm could not handle program questions, so the dataset had only five categories of Bloom cognitive hierarchy: memorization, comprehension, application, evaluation, and creativity, and 1011 exercise questions, of which 807 were training and 204 were testing.

[1]https://github.com/anglgn/Chinese-Text-Classification-Dataset

The Bloom-6classes dataset is based on the Bloom-5classes dataset and includes exam papers, textbook exercises, and MOOC question banks from the "Introduction to Computer Science" [26] course, as well as subjective questions related to Bloom's cognitive levels and exercises from the textbook "Computer Science: An Interdisciplinary Approach" [27] by Princeton University Press. It contains six categories of Bloom's cognitive levels, with a total of 2,824 exercise questions, of which 2,122 are for training and 702 for testing. Table I summarizes the category distribution and other statistics of the five datasets.

## IV. RESULT AND DISCUSSION

### A. Baseline Model and Assessment Indicators

In order to evaluate the performance of the proposed Chinese-FRLB model, ACC and F1-Score are used as evaluation metrics. Five baseline models are compared with the Chinese-FRLB model on five datasets, as shown in Table II.

### B. Experimental Environment and Experimental Hyperparameter Settings

The experimental environment of this paper is shown in Table III.

In the model, the maximum sequence lengths for input text sequences are set to 60, 32, 32, 512, and 512 for the Toutiao-S, THUCNews #1, THUCNews #2, Bloom-5classes, and Bloom-6classes datasets, respectively. After multiple experimental comparisons, the learning rate for the Chinese-RoBERTa-wwm module was set to 8e-5. As for the LSTM and BiLSTM modules, due to their smaller model parameters, the learning rate was set to 10 times that of the Chinese-RoBERTa-wwm module, which is 8e-4. The weight decay coefficients for all three modules are set to 1e-5. FreeLB set the learning rate to 4.5e-2 as per the original papers' reference, and the initialization delta is set to 5e-2. For text data, which features sparse characteristics, the performance of LSTM and BiLSTM is optimal when the number of layers is set to 1. The hidden layer embedding dimensions for the Chinese-RoBERTa-wwm module are set to the original standard of 768， the hidden layer embedding dimensions for LSTM are set to 512. In order to ensure effective handling of word vectors output by the Chinese-RL-wwm module, the hidden layer embedding dimensions for BiLSTM are set to 768 to match those of the Chinese-RoBERTa-wwm module. The Dropout regularization parameter is set to 0 according to the requirements of the FreeLB adversarial training, the iteration number of stochastic gradient descent is set to 50, and the batch size of the model is set to 32, which is optimized using the Adam optimizer. Gradient descent optimization using Adam optimizer.

In order to save the computational resources of the proposed model in this paper and realize the lightweight deployment in realistic scenarios, this paper adjusts the number of hidden layers of RoBERTa base in Chinese-RoBERTa-wwm module downward from 12 to 6. The effectiveness of this method is validated on the Bloom-5classes and Bloom-6classes datasets.

TABLE II. BASELINE MODEL

| Baselines | Description |
|---|---|
| XLNet[19] | Using the Attention mask inside the Transformer and combining it with the dual-stream attention mechanism. |
| Chinese-BERT-wwm[21] | Pre-trained model using bidirectional Transformer and wwm task and NSP task on large Chinese datasets. |
| Chinese-RoBERTa-wwm[21] | Pre-trained model using bidirectional Transformer and enhanced dynamic wwm task on larger Chinese datasets. |
| Chinese-BERT-wwm-GCN-LP[22] | Combining the Chinese-BERT-wwm model with a text-constructed heterogeneous graph GCN model using cross-entropy and hinge loss. |
| Chinese-RoBERTa-wwm-GCN-LP[22] | Combining the Chinese-RoBERTa-wwm model with a text-constructed heterogeneous graph GCN model using cross-entropy and hinge loss. |

TABLE III. EXPERIMENTAL ENVIRONMENT

| Experimental environment | Environment configuration |
|---|---|
| Operating systems | Linux |
| CPU | Intel(R) Xeon(R) Gold 6330H |
| Video Cards | GeForce RTX 3090 |
| RAM | 32GB |
| ROM | 1T SSD |
| Programming Languages | Python 3.8 |
| Framework | Pytorch |

TABLE IV. EXPERIMENTAL RESULTS OF CHINESE-ROBERTA-WWM MODULE WITH DIFFERENT NUMBER OF HIDDEN LAYER LAYERS

| Dataset | Num of Hidden Layers | #Acc | #F1 | #Model Parameters |
|---|---|---|---|---|
| Bloom-5classes | Six | **0.7255** | **0.7242** | **72998134** |
|  | Twelve | 0.7206 | 0.7191 | 115525366 |
| Bloom-6classes | Six | **0.6937** | **0.6974** | **72998134** |
|  | Twelve | 0.6795 | 0.6813 | 115525366 |

As shown in Table IV, for the Bloom cognitive hierarchical dataset with less data and categories, reducing the number of hidden layers not only drastically reduces the number of parameters of the model and shrinks the training time of the model, but also optimizes the structure of the model, leading to improved classification accuracy.

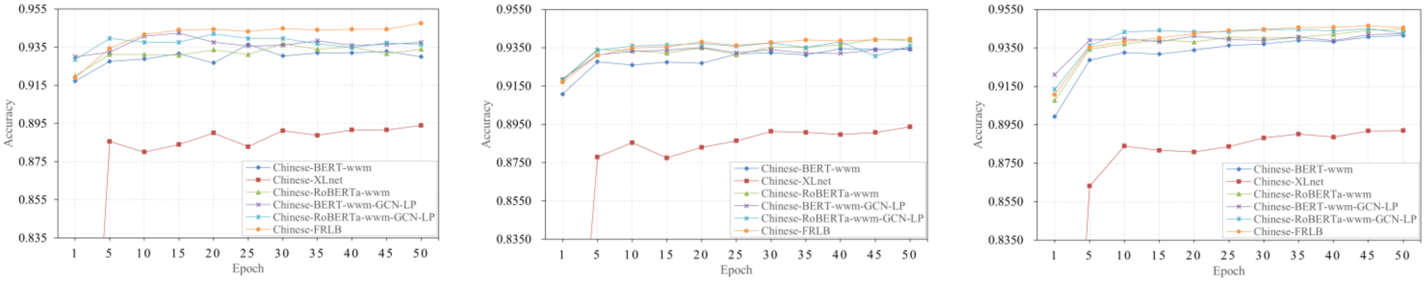
### C. *Experiments and Analysis of Results*

*1)* Analysis of experimental results based on three sets of Chinese news headline datasets: The ACC curves of each model on the Toutiao-S, THUCNews #1 and THUCNews #2 datasets are shown in Fig. 4 as (a), (b) and (c).

Fig. 4(a) corresponds to a dataset with five categories, and it can be seen that the ACC value of this model starts to lead the baseline models after 10 epochs, and shows a clear advantage over the baseline models after 15 epochs; Fig. 4(b) corresponds to a dataset of 10 categories, and due to the more parameters of this model, the ACC value of this model starts to lead the baseline models only after 20 epochs, but it still has an advantage over the baseline models; Fig. 4(c) corresponds to a dataset of 14 categories, and due to the increase of the categories and the difficulty of the classification, the ACC value of this model starts to lead the baseline models only after 25 epochs, but it has a better classification performance and better robustness compared to the baseline models. In summary, the proposed model has an advantage over other baseline models when the dataset categories are reduced, which side by side indicates that it can be better utilized for the less-category Bloom cognitive hierarchical classification task.

As can be seen from Fig. 4, the model in this paper is not effective at the beginning of training in each dataset, which is due to the fact that the model adds FreeLB antagonistic perturbation at the input and has more modules, with a slightly larger number of parameters than that of the other baseline models, resulting in a more complex model structure and slower convergence in the early stage. However, unlike Chinese-RoBERTa-wwm-GCN-LP, which incorporates the use of GCN modules, the model in this paper does not fluctuate due to the change in the performance of the baseline model, which proves that the addition of FreeLB perturbation not only enhances the model's generalization ability, but also improves the robustness of the model.

The performance metrics of the Chinese-FRLB model on THUCNews #1, THUCNews #2, and Toutiao-S datasets versus other baseline models are shown in Table V and analyzed as follows:



(a) (b) (c)

Fig. 4. ACC curves of Chinese-FRLB model and baseline models on Chinese news headlines dataset: (a) Comparison between models based on the Toutiao-S dataset; (b) Comparison be-tween models based on the THUCNews #1 dataset; (c) Comparison between models based on the THUCNews #2 dataset.

TABLE V. PERFORMANCE METRICS OF ALL MODELS ON THE CHINESE NEWS HEADLINES DATASET

| Model | Datasets |  |  |  |  |  |
|---|---|---|---|---|---|---|
|  | *Toutiao-S* |  | *THUCNews #1* |  | *THUCNews #2* |  |

*a)* Compared with the baseline models, the proposed model in this paper achieves the best performance in terms of ACC and F1-Score on all three public datasets.This indicates the state-of-the-art of the proposed model in this paper in the field of Chinese classification.

*b)* The Chinese-BERT-wwm-GCN-LP and Chinese-RoBERTa-wwm-GCN-LP models combine the Chinese-BERTology-wwm and GCN modules to combine semantic and structural information of the text. The method proposed in this paper, which comprehensively utilizes the Chinese-RoBERTa-wmm module and LSTM module to combine semantic and sequential information, outperforms Chinese-BERT-wwm-GCN-LP and Chinese-RoBERTa-wwm-GCN-LP models. This proves that the method in this paper is more effective in extracting the implicit deep and shallow semantic features of Chinese text.

*c)* The model proposed in this paper combines Chinese-RoBERTa-wwm and BiLSTM. Compared to Chinese-BERT-wwm and Chinese-RoBERTa-wwm, BiLSTM is employed to extract bidirectional semantic features between word vector sequences before using fully connected layers for text classification. The results show that the performance of the model proposed in this paper is superior, indicating that the combined use of sequence learning models effectively enhances the overall Chinese text classification capability of the model.

*d)* The model proposed in this paper is constructed based on the Chinese-RoBERTa-wwm model, and compared to the Chinese-XLnet model, the Chinese-RoBERTa-wwm model performs better. It shows that the Chinese-RoBERTa-wwm model can learn more bi-directional contextual information..

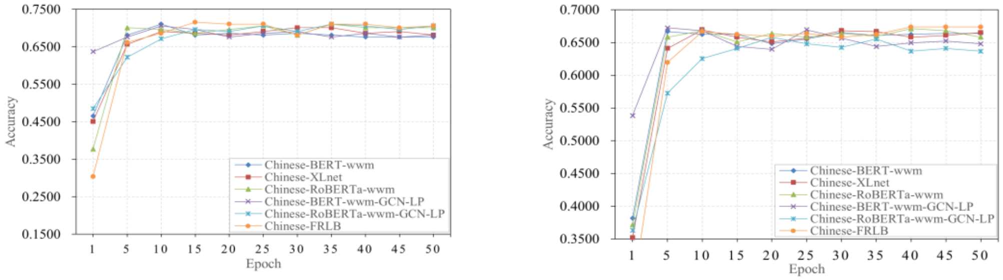
*2)* Analysis of Experimental Results Based on Two Sets of Bloom Cognitive Hierarchy Exercise Datasets: Fig. 5 and Fig.6 show the ACC curves of each model on the Bloom-5classes and Bloom-6classes datasets, respectively. The experiments in this section aim to verify the effectiveness of the proposed model in reducing the number of RoBERTa base hidden layers in the Chinese-RoBERTa-wwm base model. The number of hidden layers in the BERT base and RoBERTa base of the Chinese-BERT-wwm, Chinese-RoBERTa-wwm and Chinese-FRLB structures are set to be 12 and 6 respectively, while the number of hidden layers in the Chinese-BERT-wwm-GCN-LP and Chinese-RoBERTa-wwm-GCN-LP remains unchanged. Fig. 5 shows the experimental results for 12 layers in the hidden layer, while Fig. 6 shows the results for 6 layers.

The following conclusions can be drawn from Fig. 5 and Fig. 6:

*a)* The results in Fig. 5(a) show that this paper's model slightly outperforms each baseline model after 10 epochs. In addition, Fig. 5(b) shows that this paper's model has a clear advantage over the baseline model for the Bloom 6-classes dataset, which contains different course exercises. Comparing Fig. 5 and Fig. 6, it is evident that the Chinese-FRLB model with six of RoBERTa base hidden layers is more stable and performs better. This suggests that for the two small Bloom Chinese exercise datasets, reducing the RoBERTa base hidden layers to a 6-layer model is more effective.

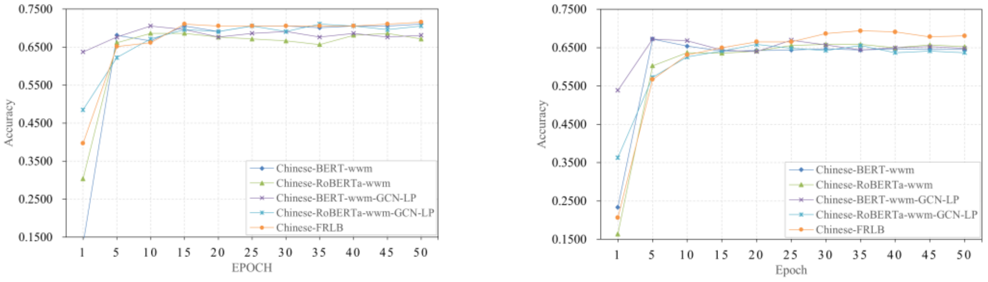
*b)* As shown in Fig. 6(a) and Fig. 6(b), the individual baseline models may show too much variation within different datasets due to the small size of the dataset and the large span of the domain, which manifests itself as a problem of poor generalization ability, resulting in the inability to be widely applied to the classification of exercises in different courses. Compared with the model proposed in this paper, it is demonstrated that the use of FreeLB adversarial training can effectively stabilize the gradient update of the model and improve the robustness and generalization of the model.

*c)* At the start of training, the model proposed in this paper was ineffective due to the sparse dataset and inefficient learning in the early stages. However, the model began to show advantages in the middle of training. Fig. 6(a) shows that after 15 epochs, this paper's model outperforms the baseline models in terms of ACC value. Fig. 6(b) further demonstrates that after 25 epochs, this paper's model significantly outperforms the baseline models. These results suggest that the Chinese-RL-wwm module utilized by this paper's model is capable of extracting deep semantic information even with a smaller dataset size.



**(a)** **(b)**

Fig. 5. ACC curves of Chinese-FRLB model(12 of hidden layers) with the baseline model on two Bloom cognitive hierarchy exercise datasets: (a) Comparison between models based on the Bloom-5classes dataset; (b) Comparison between models based on the Bloom-6classes dataset.



(a) (b)

Fig. 6. ACC curves of Chinese-FRLB model(6 of hidden layers) with the baseline model on two Bloom cognitive hierarchy exercise datasets: (a) Comparison between models based on the Bloom-5classes dataset; (b) Comparison between models based on the Bloom-6classes dataset.

Since the structural parameters of the XLnet model are different from those of the BERT model, it is not used as a baseline model for comparison in this Fig. 6

Table VI presents the performance metrics of the Chinese-FRLB model proposed in this paper on Bloom-5classes and Bloom-6classes datasets with other baseline models. The analysis is as follows:

*a) The* Chinese FRLB model proposed in this article outperforms the baseline model in terms of ACC and F1 Score evaluation metrics on two small-scale Chinese Bloom cognitive level exercise datasets, using a 12 layer BERT base hidden layer Chinese RoBERTa wwm basic model. This indicates the effectiveness of the proposed model in the Chinese Bloom cognitive level classification task.

*b) The* model proposed in this paper, Chinese-FRLB, improves performance when the number of BERT base hidden layers is reduced from 12 to 6. This is due to the reduction of the BERT base hidden layers of the Chinese-FRLB base model Chinese-RoBERTa-wmm effectively optimizes the structure of the model, which is helpful to prevent the model from focusing too much on global information and ignoring important local information when extracting text features with a small number of data sets, which indicates that for a small number of data sets, simplifying the structure of the text feature extraction model can help to improve the text classification ability.

### *D. Ablation experiment*

*1)* Impact of individual modules on model performance: In order to verify the effects of FreeLB against perturbations, Chinese-RL-wwm module and BiLSTM module on the Chinese-FRLB model, ablation experiments are conducted on five datasets in this paper. The experimental results are shown in Table VII, and the following conclusions can be obtained:

*a)* From the results of the public datasets, it can be seen that the method of using LSTM to extract deep associative features and combining pooler information to represent word vectors can effectively obtain rich semantic information features. Learning bidirectional dependency information of word vector sequences using BiLSTM can further improve the classification performance of the model. Adding FreeLB adversarial training can enhance the robustness of the models composed of different modules. Their contributions to the overall model are not identical, but removing any one of them would result in performance degradation, indicating that the introduction of these three modules is effective on public datasets, and their functions in the model are complementary.

*b)* From the results of the Bloom cognitive hierarchy exercise datasets, it can be observed that for this kind of dataset with low data volume and domain spanning, the deep association features extracted by combining LSTM can focus on more sequence association features than the word vectors output by Chinese-RoBERTa-wwm, thereby obtaining more semantic information for the model and compensating for the feature sparsity due to the low data volume; using BiLSTM can extract the implicit deep semantic features between word vector sequences on the basis of the former, enhancing the classification ability of the model under small data volume conditions; adding FreeLB adversarial training significantly improves classification performance and generalization ability of Bloom's cognitive hierarchy exercises with small amounts of data and covering different courses.

| Chinese-RLB | 0.9464 | 0.9464 | 0.9392 | 0.9393 | 0.9433 | 0.9433 | 0.7108 | 0.7109 | 0.6610 | 0.6627 |
| Chinese-FRL | 0.9460 | 0.9460 | 0.9405 | 0.9405 | 0.9422 | 0.9423 | 0.7010 | 0.7013 | 0.6738 | 0.6782 |
| Chinese-FRB | 0.9460 | 0.9460 | 0.9406 | 0.9405 | 0.9448 | 0.9449 | 0.7059 | 0.7063 | 0.6724 | 0.6775 |
| **Chinese-FRLB** | **0.9480** | **0.9480** | **0.9409** | **0.9409** | **0.9471** | **0.9472** | **0.7255** | **0.7242** | **0.6937** | **0.6974** |

In each ablation experiment, one module is removed from the Chinese-FRLB model to evaluate the effectiveness of each module. Specifically, Chinese-RLB refers to removing the FreeLB perturbation, Chinese-FRL refers to removing the BiLSTM module, and Chinese-FRB refers to using the original Chinese-RoBERTa-wwm module. In the datasets of Bloom-5classes and Bloom-6classes, using the RoBERTa base with 6 of hidden layer layers.

*2)* The effect of the number of hidden layers in the RoBERTa base: In order to verify the sophistication of the Chinese-FRLB model in setting the number of hidden layers of RoBERTa base in the Chinese-RoBERTa-wwm structure to 6, this paper carries out the ablation experiments with different numbers of hidden layer layers on two datasets, and the experimental results are shown in Table VIII.

From Table VIII and the analysis of the experimental process, it can be seen that reducing the number of hidden layers of RoBERTa base will result in the model being unable to effectively extract the text feature information, resulting in a significant decrease in its performance. When the number of hidden layers in RoBERTa base is too high, then the training time and the space complexity of model increase, leading to increased memory consumption. Moreover, it may cause the model to overlook locally important information, resulting in suboptimal classification performance. When the number of hidden layers of RoBERTa base is set to 6, all the metrics are the best.

TABLE VIII. PERFORMANCE METRICS OF CHINESE-FRLB MODEL AT DIFFERENT NUMBER OF ROBERTA BASE HIDDEN LAYER LAYERS

| Twelve | 0.7206 | 0.7191 | 0.6795 | 0.6813 |

## V. CONCLUSIONS

To assist teachers in accurately categorizing Chinese exercises into the corresponding Bloom levels and accurately assessing students' cognitive abilities, this paper proposes a Bloom cognitive level classification model for Chinese exercises based on the Bloom classification method. Specifically, the model utilizes sequence information and pooler information to model word vectors and combines a BiLSTM sequence learning model. The introduced FreeLB adversarial perturbation exhibits better stability in two small-scale Chinese Bloom cognitive level exercise datasets. In the word vector representation stage, LSTM extracts deep associative features combined with pooler information to effectively construct word vectors with rich semantic feature information. During classification, the semantic features of word vectors extracted by BiLSTM further improve the accuracy of the model in classifying different datasets. Experimental results on three Chinese public datasets and two sets of Chinese Bloom cognitive level exercise datasets demonstrate that the proposed model accurately classifies the Bloom levels of Chinese exercises and also performs well in other text classification tasks. In addition, this paper conducts ablation experiments on three sub-modules in the model, and the results show that all three modules can effectively improve the overall performance of the model.

## VI. FUTURE WORK

The Chinese-FRLB model proposed in this paper can effectively classify the Bloom cognitive level of exercises, but there are still problems such as semantic ambiguity and data sparsity that need further refinement and improvement. Therefore, in our future research, we will work on enriching the text feature representation by using glyph and pinyin information as well as deeper lexical extraction techniques to better capture the semantic information of Chinese text. In addition, we will explore more advanced word segmentation models and methods combining multiple techniques to optimize the text pre-processing and feature extraction processes, and consider lightweight models to further improve the running speed of the models.

# The Application of Improved Scale Invariant Feature Transformation Algorithm in Facial Recognition

Yingzi Cong
School of Continuing Education, Criminal Investigation Police University of China, Shenyang, 110854, China

***Abstract*—Currently, face recognition models suffer from insufficient accuracy, stability, and computational efficiency. To address this issue, an improved feature extraction algorithm on the ground of Haar wavelet features and scale invariant feature transformation algorithm is proposed. In addition, the study also combines this algorithm with deep belief networks to construct an improved facial recognition model. The effectiveness of the proposed improved feature extraction algorithm was verified, and it was found that the recognition accuracy of the algorithm was 94.2%, which is better than other comparative algorithms. In addition, the study also conducted empirical analysis on the improved facial recognition model and found that the recognition accuracy of the model was 0.92, and the feature matching time was 2.6 seconds, which was better than other comparative models in terms of performance. On the ground of the above results, the proposed facial recognition model has significantly improved recognition accuracy and efficiency compared to traditional models. It can provide theoretical reference for improving the universality of facial recognition applications in different fields.**

***Keywords*—*Haar wavelet features; scale invariant feature transformation algorithm; deep belief network; facial recognition; performance improvement***

## I. Introduction

With the rapid development of social economy and the improvement of overall social living standards, more and more people are beginning to realize the importance of information security. At the same time, with the rapid iteration of computer hardware and software, more and more target face recognition technologies have emerged [1-2]. Facial recognition technology has begun to be widely used in people's daily lives. This includes but is not limited to security monitoring, facial payment, and social media login. Using facial biometrics as an important information component to identify the target object is beginning to become a very popular verification method [3]. Using facial features as a medium to identify target groups has also become a new type of identification method. This technology combines advanced scientific and technological means such as information science with related basic disciplines to achieve the identification of target groups. However, in real-life environments, the recognition accuracy of face recognition technology may be affected by undesirable factors such as obstructions, light changes, and various scale transformations. Due to the influence of hardware and other related factors, traditional face recognition technology is currently unable to meet the huge and changing needs of the urrent society [4]. The development of society has also prompted users to no longer be satisfied with the efficiency and accuracy of current face recognition. How to improve the accuracy of face recognition under non-ideal conditions has become an important topic studied by many scholars in the field of biometrics. Scale Invariant Feature Transform (SIFT) can generate feature descriptors that are insensitive to illumination and occlusion, and has properties such as affine, rotation, and scale invariance. These characteristics make SIFT useful in image recognition and classification and also Excellent performance in tasks [5]. Deep Belief Network (DBN), as a deep learning model, can automatically learn more stable feature representations from a large amount of data through a multi-level neural network structure, thereby improving the accuracy of face recognition, performance and robustness [6]. In view of this, the experiment innovatively proposes a feature extraction algorithm that integrates SIFT and DBN, and applies it to facial feature recognition to extract facial features more effectively and accurately, thereby improving the accuracy and matching of face recognition, speed, and look forward to providing more technical support for face recognition related work.

The article can be divided into five sections. Section II is the literature review, elaborates on the current development status and application fields of SIFT technology, DBN technology and face recognition; Section III is a research method, which combines SIFT technology and DBN technology to jointly deal with the problems of face recognition. Section IV is the result analysis, mainly to verify the performance of the built model. Section V is the conclusion and discussion, which is mainly a summary statement of the entire manuscript.

## II. Related Works

With the advancement of social technology, deep learning algorithms have been widely applied in various fields. To address the issue of registration performance being easily affected by synthetic aperture radar during remote sensing image registration. Paul et al. proposed a remote sensing image registration algorithm that suffers from the SIFT structural tensor, and validated its effectiveness. It was found that this algorithm can strengthen the accuracy and precision of remote sensing image matching through feature classification and recognition [7]. To improve the analysis sensitivity and speed of volatile organic compounds in water, Perkins and Langford proposed a selective ion flow tube mass spectrometry method on the ground of SIFT. The effectiveness of this method was verified, and it was found that the non-fermentation traditional method has better linearity and relative standard error, and can be used as a rapid screening tool [8]. Lee MKI et al. proposed a tissue pathology morphology evaluation model using SIFI algorithm and convolutional neural network to address the issue of strong dependence on expert experience and subjective consciousness in tissue immunochemical pathology detection. The effectiveness of the model was verified, and it was found that its evaluation results were highly consistent with expert evaluation results, significantly improving the manpower and material resources of pathological diagnosis [9]. To improve the accuracy and effectiveness of the prediction of the remaining service life of bearings, this study used DBN to construct a bearing remaining service life prediction model, and verified the effectiveness of the model. It was found that the model could accurately forecast the remaining service life of bearings and has practical application value [10]. To improve the anti-interference ability of phase sensitive time-domain reflection against single disturbance events, Liu et al. proposed a DBN based interference event classification and recognition model, and verified its effectiveness. It was found that the model can effectively identify five types of single disturbance events with a recognition accuracy of 90.94%, which has practical application value [11].

In recent years, FR has not only been extensively utilized in many aspects, but research on FR has also become a hot research direction. To improve the robustness of FR methods, Zhang et al. proposed an adaptive margin FR model on the ground of convolutional neural networks. The effectiveness of the model was verified, and it was found that it can be widely applied in FR in various scenarios, with certain universality and robustness [12]. In response to the problem that FR models are susceptible to different conditions such as lighting, facial expressions, posture, and occlusion, a study proposes to use local binary patterns to verify the effectiveness of the FR model. The effectiveness of the improved model is verified, and it is found that the model has more robust performance under complex lighting conditions compared to traditional models [13]. Due to the insufficient recognition performance of traditional facial image recognition models in nighttime dark scenes, Sun et al. proposed a FR model on the ground of near-infrared technology and validated its effectiveness. It was found that this model has certain competitive performance compared to the latest methods [14]. For strengthening the anti-interference performance of FR models against occlusions, Ma et al. presented a FR method on the ground of second-order degree constraints and verified its effectiveness. It was found that compared with non-deep learning methods, this method possesses the best recognition rate [15].

To sum up, SIFT algorithm and DBN technology have been widely used in many fields. Both technologies have huge application prospects. At the same time, there are more and more related technologies related to face recognition. However, there are few studies on using SIFT technology and DBN technology to identify facial features at the same time. Although face recognition technology faces many challenges in complex real-life environments and unconstrained environments, it also has unprecedented development opportunities in today's rapid development and progress of information. In recent years, with the continuous progress of society, the public's demand for facial feature extraction and recognition technology has become more and more urgent. In view of this, the study introduces DBN technology and combines it with the SIFT algorithm to jointly deal with the problem of face recognition and improve the accuracy and recognition rate of face recognition.

## III. Construction of A FR Model with Improved Scale Invariant Feature Change Algorithm

To improve the accuracy and reliability of FR, this study constructs the Haar SIFT algorithm on the ground of Haar, and combines this improved algorithm with DBN to construct an improved FR model.

### A. *Improved SIFT Algorithm on The Ground of Haar Features*

The SIFT algorithm is an optimization algorithm on the ground of stochastic iterative function inversion. It can transform optimization problems into function inversion problems and use random sampling methods to approximate the inverse function of the objective function, thereby finding the optimal solution [16]. The core idea of the SIFT algorithm is for searching the solution space through random sampling and function inversion for finding the optimal solution [17]. Therefore, the SIFT algorithm has good application performance in continuous optimization problems and complex nonlinear problems. It has extensive applications in engineering design, combinatorial optimization, machine learning, and neural network training [18]. The calculation process of SIFT is shown in Fig. 1.

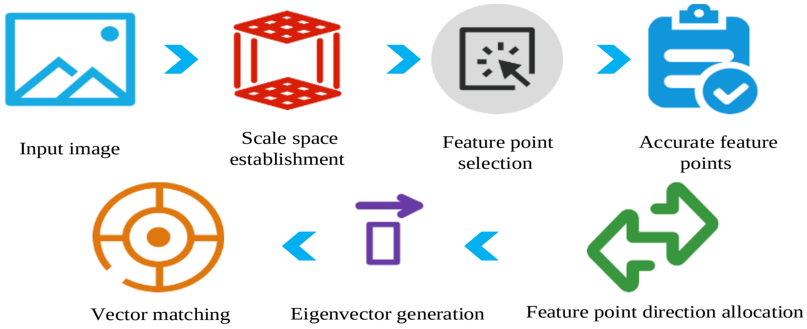

Fig. 1. Calculation flow of SIFT.

As shown in Fig. 1, the SIFT algorithm for extracting facial features mainly includes four parts: scale space extremum detection, key point localization, direction determination, and description of key points. In the step of scale space extremum detection, the SIFT algorithm constructs a Gaussian difference pyramid to detect the extreme points of the image at various scales, which may correspond to different features of the face. The calculation is showcased in Eq. (1).

$$L(x,y,\sigma)=G(X,Y,\sigma)*I(x,y) \tag{1}$$

In Eq. (1), $L(x,y,\sigma)$ serves as the scale space. $I(x,y)$ serves as the original image. $\sigma$ serves as the scale of change. $G(X,Y,\sigma)$ represents the iterative Gaussian function with varying scales, and its calculation formula is showcased in Eq. (2).

$$G(x,y,\sigma)=\frac{1}{2\pi\sigma^2}e^{\frac{(x-m)^2+(x-2/n)^2}{2\sigma^2}} \tag{2}$$

In Eq. (2), $m$ and $n$ represent the magnitude and number of changes in the scale of change. At this stage, the study conducted downsampling of the input image on the ground of scale changes, resulting in different images. Then the study constructs a pyramid like structure of these images from bottom to top and from large to small, to obtain a pyramid model of the images. Subsequently, the study utilized Gaussian difference functions for extreme value detection in the scale space, and the calculation formula is showcased in Eq. (3).

$$\begin{aligned}D(x,y,\sigma)&=\left(G(x,y,k\sigma)-G(x,y,\sigma)\right)*I(x,y,\sigma)\\&=L(x,y,k\sigma)-L(x,y,\sigma)\end{aligned} \tag{3}$$

In Eq. (3), $D(x,y,\sigma)$ represents the Gaussian difference function. $k$ represents the multiple of the scale size between two adjacent scale spaces that generate a Gaussian difference space. Finally, on the ground of the detection of extreme values in the scale space, the SIFT algorithm accurately locates the detected extreme points to determine their accurate positions, which are considered as key points of the face. The formula for calculating the extreme points of the SIFT algorithm is shown in Eq. (4).

$$\begin{cases}D(\hat{X})=D+\frac{1}{2}\frac{\partial D^T}{\partial X}\hat{X}\\ \hat{X}=(x,y,\sigma)^T\end{cases} \tag{4}$$

In Eq. (4), $\hat{X}$ represents the offset relative to the interpolation center. $\partial$ represents the distance between adjacent points. In addition, on the ground of keypoint localization, the SIFT algorithm will determine a dominant direction for each keypoint, which can correspond to the directionality of facial features, which will help with subsequent feature description and matching. The calculation formula for its dominant amplitude and direction is shown in Eq. (5).

$$\begin{cases}m(x,y)=\sqrt{(L(x+1,y)-L(x-1,y))^2+(L(x,y+1)-L(x,y-1))^2}\\ \theta(x,y)=\tan^{-1}(((L(x,y+1)-L(x,y-1))/(L(x+1,y)-L(x-1,y))\end{cases} \tag{5}$$

In Eq. (5), $\theta$ represents the direction of change. After determining the direction, the SIFT algorithm will extract relevant feature descriptors on the ground of the image information around the key points. These descriptors can accurately describe the texture, shape, and other features around the key points, thus forming a representation of facial features. Through the above four parts, the SIFT algorithm can effectively extract facial features, which can play an important role in tasks such as FR and detection, improving the accuracy and stability of facial related tasks. Although the SIFT algorithm can handle complex nonlinear optimization problems and has global search capabilities, it can find the global optimal solution. And its robustness and computational difficulty are relatively low, which can be applied to facial image feature extraction. However, the SIFT algorithm requires high continuity and differentiability of the objective function and is not suitable for non-continuous or non-differentiable problems. The search process of the SIFT algorithm relies on random sampling and may fall into local optima. Therefore, this study aims to improve the algorithm on the ground of Haar wavelet features to enhance the search ability of the SIFT algorithm. Haar wavelet feature is a feature extraction method on the ground of wavelet transform, which was proposed by Alfred Haar in 1909. Haar wavelet features can be used for image processing and pattern recognition tasks, especially suitable for FR. The Haar wavelet features are showcased in Fig. 2.

Fig. 2 showcases that Haar wavelet features can divide an image into small blocks, calculate the differences between pixels in different rectangular regions, and combine the features of all small blocks into a feature vector. The calculation formula for Haar features is shown in Eq. (6).

$$feature=\sum_{i\in(i\ldots N)}\omega_i \,\mathrm{Re}\,ctSum(r_i) \tag{6}$$

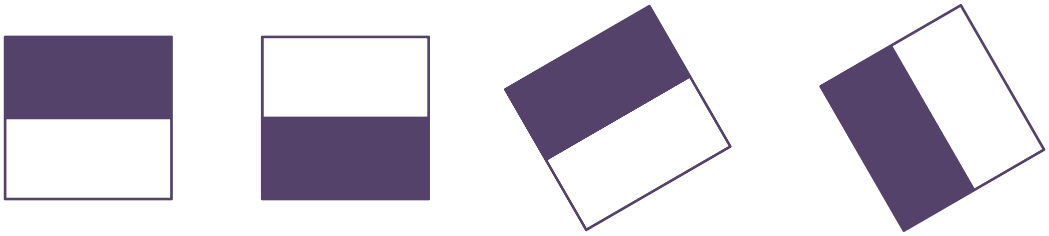

Fig. 2. Haar wavelet characteristics.

In Eq. (6), $r_i$ represents a number in the Haar feature array. $\mathrm{Re}\,ctSum(r_i)$ represents the grayscale integration of the region image of $r_i$. $\omega_i$ represents the weight of $r_i$. $N$ represents the number of rectangles in the region. This study imposes conditional limitations on Haar features to determine their effectiveness. Firstly, the areas with different weights have inverse proportional restrictions, and their calculation formula is shown in Eq. (7).

$$\begin{cases} \omega_1 Area(r_1) = -\omega_2 Area(r_2) \\ \omega_1 = -1; \quad \omega_2 = Area(r_1) / Area(r_2) \end{cases} \tag{7}$$

In Eq. (7), the weight must be a different sign within two regions and inversely proportional to the area of the region. In addition, for the convenience of calculating the integral image, the study limits the number of Haar features, and the calculation formula is shown in Eq. (8).

$$\begin{cases} r_1 \subset r_2 \\ r_2 \subset r_1 \end{cases} \tag{8}$$

Finally, to ensure the simplicity and computational speed of Haar features in image search operations, the study sets the number of rectangles that make up the feature area to 2. In addition, the study also utilized Sobel filters to accelerate the running speed of the SIFT algorithm. The calculation formula for Sobel filters is shown in Eq. (9).

$$G_\sigma = \sqrt{(G_{x,\sigma})^2 + (G_{y,\sigma})^2} \tag{9}$$

In Eq. (9), $G_{x,\sigma}$ serves as the horizontal derivative of the image after operation. $G_{y,\sigma}$ serves as the vertical derivative of the image after operation. The calculation formula for gradient direction is shown in Eq. (10).

$$R_{\sigma 1} = \arctan \frac{G_{y,\sigma}}{G_{x,\sigma}} \tag{10}$$

The calculation formula for image gradient amplitude is shown in Eq. (11).

$$G\sigma 1 = \sqrt{(G_{x,\sigma_1})^2 + (G_{y,\sigma_1})^2} \tag{11}$$

In Eq. (11), $G_{x,\sigma_1}$ represents the horizontal derivative of the gradient amplitude image in the scale space. $G_{y,\sigma_1}$ represents the vertical derivative of the gradient amplitude image in the scale space. The process of the improved SIFT algorithm on the ground of region segmentation is shown in Fig. 3.

As shown in Fig. 3, the study first preprocesses the input image, including image grayscale, denoising, and enhancement, to improve the accuracy of subsequent processing. Subsequently, the study searched for possible feature point positions on preprocessed images by constructing a set of image pyramids of different scales. The third step is the detection of extreme points. On the ground of the proposed results in the scale space, the image is segmented into different regions, and within each region, Haar wavelet features are used to locate feature points. For each feature point, Sobel is used to calculate the gradient direction of its surrounding area to determine its direction. Subsequently, the study compared the Haar wavelet feature vectors of feature points and used Euclidean distance to match similar feature points. This study screens and filters feature points on the ground of matching results to remove unreliable or redundant feature points. Finally, the research will output the matching results.

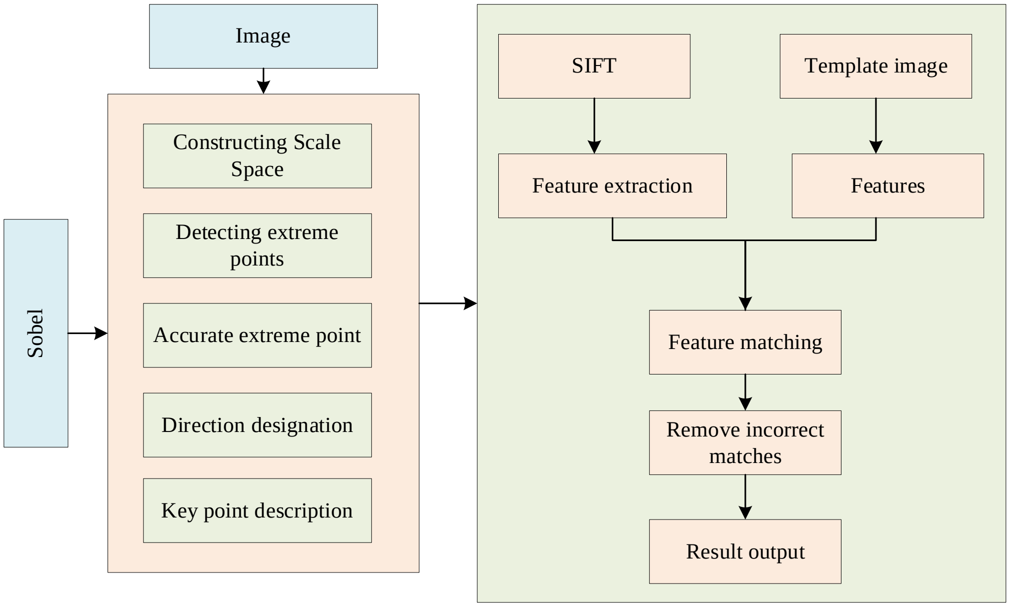

Fig. 3. Improved SIFT algorithm process on the ground of region segmentation.

### B. FR Model on The Ground of Improved SIFI Algorithm

FR model is a technology that recognizes and verifies personal identity through facial images or videos. It is on the ground of the uniqueness and unforgeability of facial features, and is implemented using computer vision and pattern recognition techniques [19]. The application fields of FR models are very extensive, which can be applied in security fields such as access control systems, identity verification, and crime investigation. In addition, FR can also be applied to human-computer interaction and has a wide range of applications [20]. The traditional FR model is shown in Fig. 4.

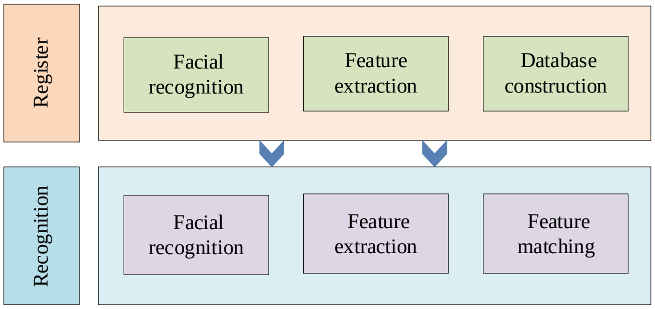

Fig. 4. The traditional FR model.

As shown in Fig. 4, a typical FR model consists of four main components: face acquisition recognition sensor, feature extraction, matcher, and database. The FR sensor is responsible for obtaining facial image samples from the real world and transmitting the captured images to the system for subsequent processing. In the step of feature extraction, the system preprocesses the obtained facial image to remove noise and interference, and extracts key features from the image. These features can include facial contours, eyes, nose, mouth, etc. The next step is the matcher step, where the system will compare and match the extracted facial features with existing facial features. Finally, for the database, the system will store the already entered facial features in the database for comparison and matching with subsequent facial features. However, traditional FR models still have certain shortcomings, including susceptibility to external environments and non-rigid deformations, making it difficult to achieve accurate matching. In addition, there are differences in facial appearance among different ages, genders, and races. Traditional models may not be able to adapt well to these diversity and variability, resulting in a decrease in accuracy and a significant increase in time costs. Therefore, to improve the accuracy, stability, and operational efficiency of FR performance, this study uses the Haar SIFT algorithm to extract features, and then uses DBN to classify and match features in images, achieving fast and effective FR. DBN is a deep learning model consisting of multiple stacked Restricted Boltzmann Machines (RBMs), which can be used for tasks such as feature learning, data dimensionality reduction, and model generation. To achieve effective classification of feature images by DBN, the study first trains DBN using the constructed feature library. The relevant training is showcased in Fig. 5.

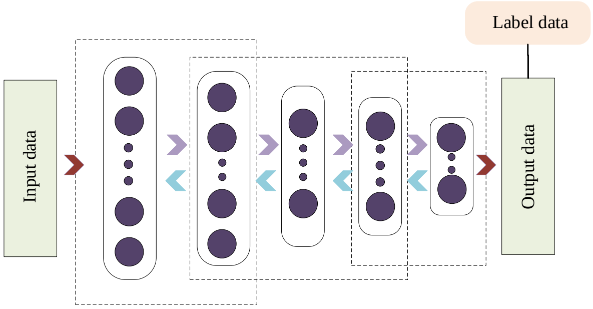

Fig. 5. Training process of DBN.

As showcased in Fig. 5, the training of DBN contains two stages: pre training and fine-tuning. In the pre training stage, the study first uses the first RBM as the underlying layer of the DBN. By performing unsupervised learning on the training data, this RBM learns low-level features of the data. Then, the hidden layer of the RBM is used as the visible layer of the next RBM to continue unsupervised learning. This is stacked layer by layer until all RBMs have been trained. During the training process of each RBM, the study also used contrast divergence to maximize the likelihood function. In the fine-tuning stage, research is conducted to fine tune the entire network using backpropagation algorithms to maximize the likelihood function of labeled data. This stage is supervised, allowing research to train using labeled data with the goal of adjusting network parameters to better adapt to specific tasks. The pre training process of DBN allows the network to learn abstract feature representations of data layer by layer, which helps to solve the gradient vanishing problem in deep neural networks. The fine-tuning process further optimizes the performance of the entire network to adapt to specific tasks. After completing the training of DBN, the study combines this algorithm with Haar SIFT algorithm to construct an improved FR network. The basic architecture of the improved FR network constructed through research is shown in Fig. 6.

As shown in Fig. 6, the improved FR model framework constructed in the study mainly includes two main parts: the construction of facial feature vector library and feature matching. In the construction module of the feature vector library, this study first performs facial detection on the images in the database to remove non facial regions as much as possible. This can reduce the useless feature vectors detected in other aspects such as background, and strengthen the computational efficiency. Subsequently, the study utilized an improved SIFT algorithm to extract and represent detected faces, and generated SIFT feature descriptors to form a feature vector library. Finally, the study groups the feature vectors in the feature vector library for training, and uses DBN to divide the feature vectors into different face categories, thereby establishing a training model for each face category. In the facial feature matching module, the research first performs facial detection on the face to be recognized, and uses an improved SIFT algorithm to extract feature descriptors. Subsequently, the study used DBN to calculate the measurement distance between the feature descriptors in the unknown face and each feature vector obtained in the database. DBN was used to compare the face to be recognized with the face in the feature vector library to find the most similar feature vector. Finally, research is conducted to determine which person the face to be recognized belongs to on the ground of the facial category to which the matched feature vectors belong. Through the above framework and workflow, the FR model can achieve classification and recognition of facial images, which can be extensively utilized in many aspects like secure access control, facial payment, and facial authentication.

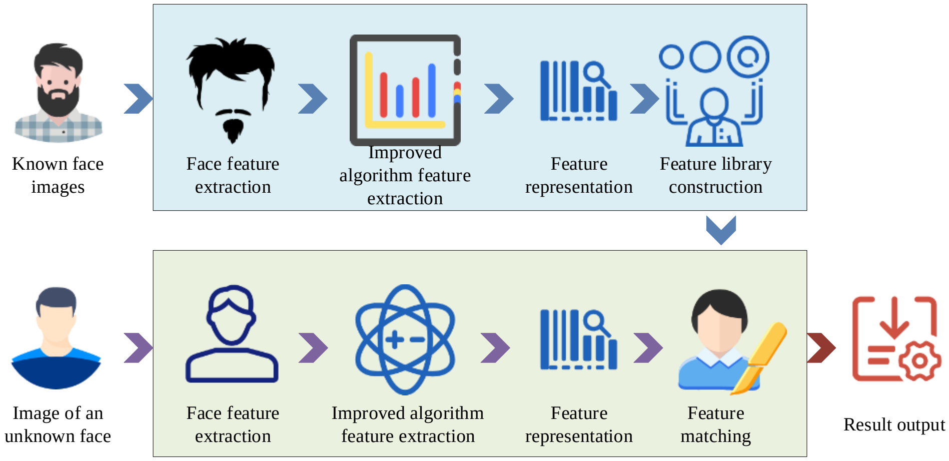

Fig. 6. Improved basic architecture of FR network.

## IV. Result and Discussion

For testing the effectiveness of the proposed improved SIFT algorithm and the FR models on the ground of Haar SIFT and DBN, performance comparison experiments and empirical analysis were conducted.

### A. *Validation of The Harr SIFT Algorithm's Effectiveness*

For testing the effectiveness of the proposed Harr SIFT algorithm for feature extraction, this study conducted feature extraction performance comparison tests using SIFT, fused SIFT and K-Means Scale Invariant Feature Transform (Means SIFT), as well as SIFT and Random Forester Scale Invariant Feature Transform (RF SIFT). In order for the experiment to proceed smoothly, ensure that the parameters of all equipment are consistent. The selection of equipment and parameters used in the experiment is as follows: the implementation platform is Fastone, the operating system is Windows 10, the operating environment is UNIX, the running computer memory is 64G, the central processor is i7-8700, the central processor frequency is 4.2Hz, and the graphics processor It is NPU, the processor graphics card is RTX-2070, the data storage platform is MySQL, and the data statistics software is SPSS 26.0. The comparison indicators are the accuracy, precision, extraction time, F1 value, and loss function value of feature extraction. The experimental environment used in the study is showcased in Table I.

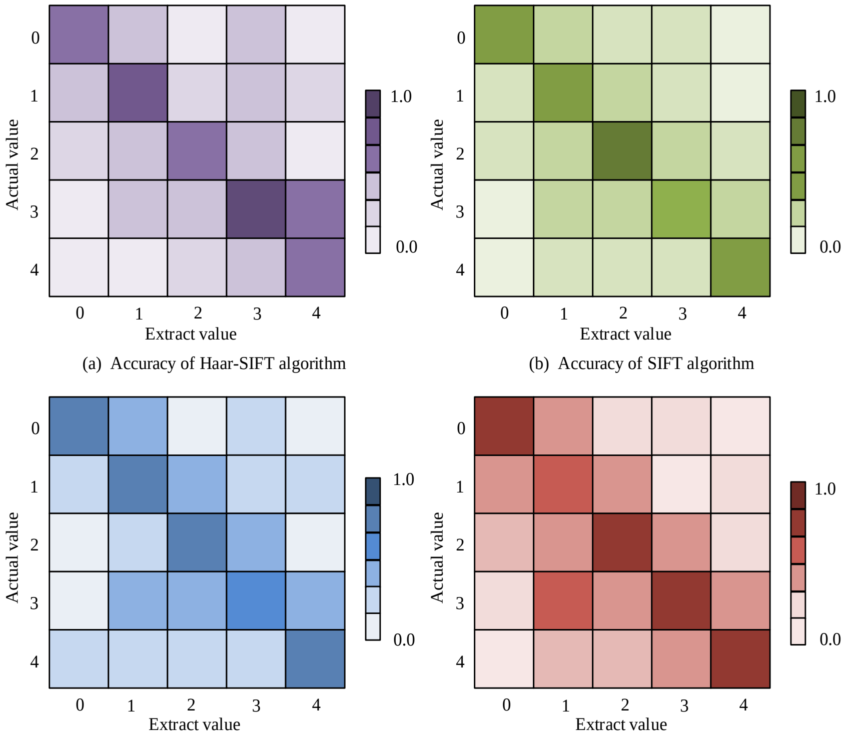
The study randomly selected facial images of five volunteers from the ORL facial database as experimental subjects and conducted feature extraction performance tests on them. The accuracy comparison results of various feature extraction algorithms are shown in Fig. 7.

Fig. 7(a), (b), (c), and (d) showcase the accuracy comparison results of Haar SIFT, SIFT, Means SIFT, and RF SIFT feature extraction algorithms, respectively. As shown in Fig. 7, the Haar SIFT feature extraction algorithm has the highest accuracy, at 94.2%, which is 3.6% higher than the SIFT algorithm, 8.3% higher than the Means SIFT algorithm, and 6.5% exceeding the RF SIFT algorithm. In terms of the above results, it can be concluded that the proposed Harr SIFT feature extraction algorithm has better accuracy in feature extraction and practical application value. The comparison results of the accuracy and feature extraction time of each feature extraction algorithm are shown in Fig. 8.

TABLE I. Table of the Experimental Environments

| Device name | Specification parameters |
|---|---|
| Language form | C++ language |
| Java runtime environment Java | AMD Radeon56400G@4.8GHz |
| Internal storagememory | 32GB |
| Operating system | Ubuntu 18.0 |
| Experimental platform | ClassBench |
| Data set | The ORL human face database |
| Learning rate | 0.001 |
| Iterations | 600-2000 |

As shown in Fig. 8, the feature extraction accuracy of each exploration extracted feature extraction algorithm is 92.68%, which is better than other comparative algorithms and has better stability. In addition, the Haar SIFT algorithm possesses more excellent feature extraction performance than other algorithms, with a feature extraction time of 2.6 minutes, including the establishment and extraction of feature libraries. On the ground of the above results, it demonstrates that the Haar SIFT algorithm has the best feature extraction accuracy and efficiency performance, and has practical application value. The F1 values and loss functions of each algorithm are shown in Fig. 9.



(a) Accuracy of Haar-SIFT algorithm

(b) Accuracy of SIFT algorithm

(c) Accuracy of the Means-SIFT algorithm

(d) Accuracy of RF-SIFT algorithm

Fig. 7. Comparison of the accuracy results of the feature extraction algorithm.

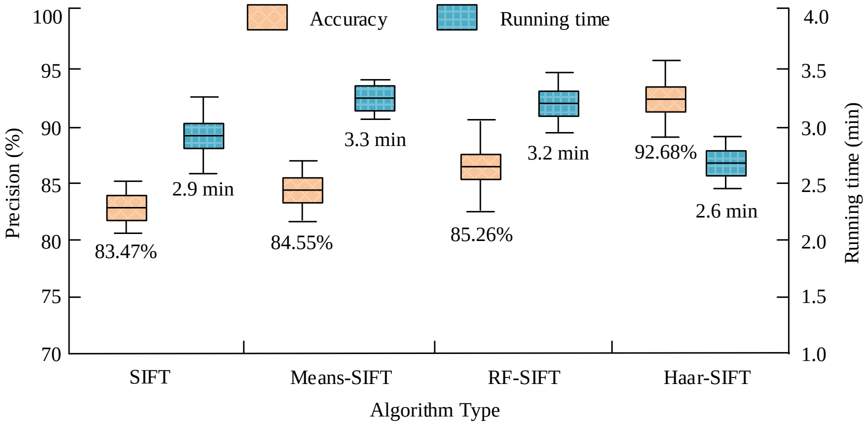


Fig. 8. Accuracy of each feature extraction algorithm and the comparison results of the feature extraction time.

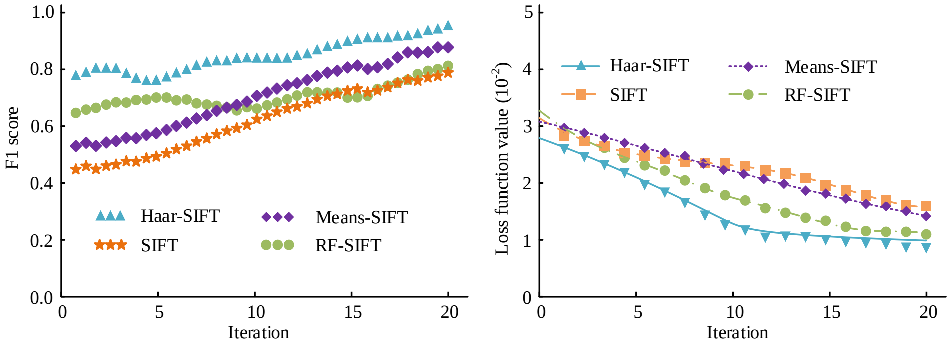


(a) F1 score of each algorithm

(b) Loss function value of each algorithm

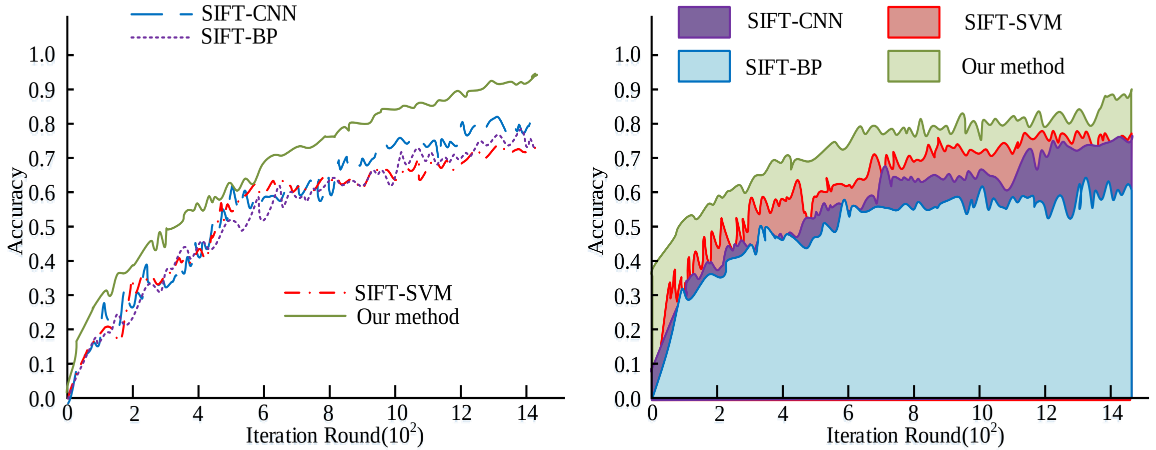
Fig. 9. Comparison results of F1 score and loss function value.

Fig. 9(a) shows the F1 value comparison results of the feature extraction algorithm, as shown in Fig. 9(a). As the number of iterations increases, the F1 values also increase. The F1 value of Haar SIFT proposed in the study is the highest, at 0.89. Fig. 9(b) shows the comparison results of the loss function values of the feature extraction algorithm, as shown in Fig. 9(b). The proposed Haar SIFT algorithm has a lower loss function value curve than other algorithms, and its convergence speed is also faster. On the ground of the above results, it can be concluded that the Haar SIFT algorithm has better convergence performance and practical application value.

### B. *Empirical Analysis of A FR Model Integrating Haar SIFT and DBN Algorithms*

For testing the effectiveness of the FR model on the ground of Haar SIFT algorithm and DBN proposed in the study, the ORL face database and FERET face database were used to verify its effectiveness. The comparative models are FR models on the ground of SIFT and Scale Invariant Feature Transform Convolutional Neural Network (SIFT-CNN), SIFT and Scale Invariant Feature Transform Back Propagation (SIFT-BP), and SIFT and Support Vector Machines (SIFT-SVM). The comparison indicators are accuracy, recognition time, and recall rate. The relevant outcomes of recognition accuracy of many facial comparison models in ORL and FERET facial databases are shown in Fig. 10.

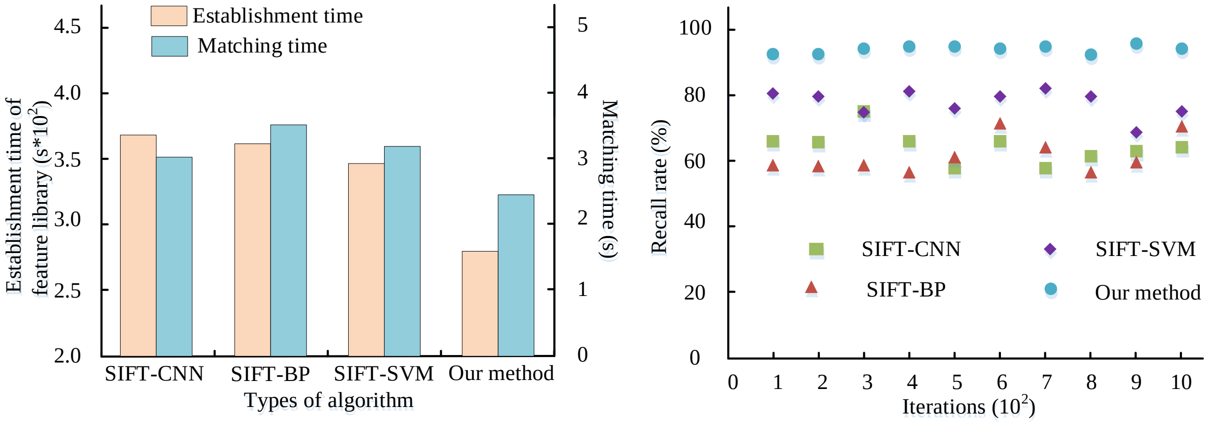
Fig. 10(a) shows the accuracy comparison results of various face comparison models on the ORL face database. As shown in Fig. 10(a), the recognition accuracy of each FR model grows with the number of iterations. Among them, the accuracy of the proposed FR model can reach 0.92, which is higher than the accuracy of other models. Fig. 10(b) shows the accuracy comparison results of various face comparison models on the FERET face database. As shown in Fig. 10(b), the recognition accuracy of each FR model increases with the number of iterations. Among them, the accuracy of the proposed FR model can reach 0.9, which is higher than the accuracy of other models. In terms of the above results, it can be concluded that the FR model proposed in the study has better recognition performance than other models in different datasets and is more stable, which can be applied to practical FR. The comparison results of running time and recall of each FR model on ORL and FERET face databases are shown in Fig. 11.



(a) Comparison results of accuracy of various algorithms in ORL face database

(b) Comparison results of accuracy of various algorithms in FERET face database

Fig. 10. Recognition accuracy of each face comparison model in the ORL, namely the FERET face database.



(a) Running time of each comparison model

(b) Precision of each comparison model

Fig. 11. Comparison results of the running time and recall rate of each FR model.

Fig. 11(a) shows the comparison results of the running time of various FR methods. As showcased in Fig. 11(a), the running time of the FR model includes the time for establishing the feature library and the time for feature matching. The proposed FR model has a shorter feature library establishment time compared to other models, which is 254.3s. Meanwhile, the feature matching time of the FR model proposed in the study is also shorter than other models, which is 2.6 seconds, and its operating efficiency is better. Fig. 11(b) shows the comparison results of recall rates for various FR methods. As shown in Fig. 11(b), the proposed FR model has a better recall rate of 98.2% compared to other models, and its stability is also better. On the ground of the above results, the proposed FR model has better operational efficiency and recall performance compared to other comparative models. In addition, for further validating the effectiveness of the proposed FR model, the study evaluated the satisfaction of each FR model through expert ratings. The expert satisfaction rating results of each model is shown in Fig. 12.

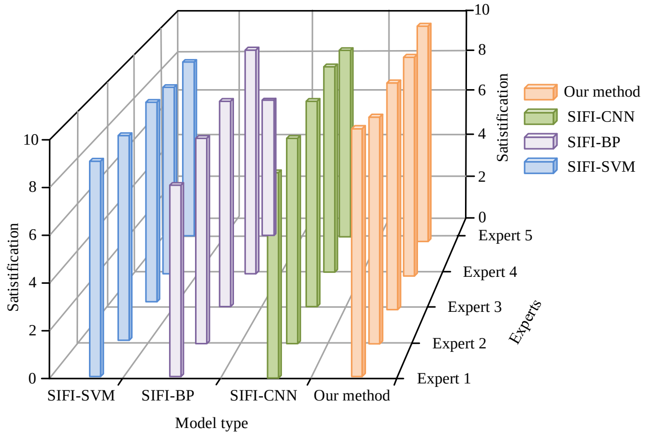


Fig. 12. Results of expert satisfaction scores.

As shown in Fig. 12, the average score of the proposed facial model in the study is 8.7 points, the average satisfaction of the SIFT-SVM based facial model is 7.6 points, the average satisfaction of the SIFT-BP based facial model is 7.5 points, and the average satisfaction of the SIFT-CNN based facial model is 7.7 points. In summary, the expert rating for the motion interaction control model on the ground of Haar SIFT and DBN proposed in the study is the highest, indicating that this model has better practical application value compared to other models.

### C. Discussion

Due to the limitations of face image sampling in practical applications and the differences in the surrounding environment, image recognition will be affected by non-rigid changes in illumination and expression, as well as errors caused by non-primary data redundancy. Many algorithms still have problems with these problems. There are some shortcomings. The experiment proposes to recognize face images based on the SIFT sparse deep belief network model, and sparsely represent the features extracted by the SIFT algorithm, making the extracted features more effective and improving the accuracy of face recognition. At the same time, the deep belief network is combined with the training classification recognition to avoid redundant information and reduce the time of training the network. The above experimental results show that the SIFT sparse deep belief network model has a better recognition effect on facial expression changes. This recognition model effectively improves the face recognition effect and matching rate.

## V. Conclusion

To further improve the accuracy, stability, and operational efficiency of FR models, a Haar SIFT feature extraction algorithm on the ground of Haar features and SIFT algorithm is proposed. This algorithm is combined with DBN to construct a FR model on the ground of Haar SIFT algorithm and DNB. The effectiveness of the Haar SIFT algorithm proposed in the study was verified, and it was found that the recognition accuracy of the algorithm was 94.2%, the feature extraction accuracy was 92.68%, and the feature extraction time was 2.6 minutes, which was better than other comparative algorithms. In addition, the study also validated the effectiveness of the FR model that integrates Haar SIFT and DBN, and found that the accuracy of the model on the ORL face database can reach 0.92, the accuracy on the FERET face database can reach 0.9, and the recall rate is 98.2%, which is better than other comparative models. In addition, the study also found that the feature library establishment time of the FR model integrating Haar SIFT and DBN is 254.3s, and the feature matching time is 2.6s, which is shorter than other models. In terms of the above results, the FR model proposed in the study has higher recognition accuracy and better recognition efficiency compared to traditional models, and its accuracy performance is consistent when facing different databases. However, research also has certain limitations. The SIFT algorithm typically requires a significant amount of computing resources and time to extract and match features. Therefore, it has certain limitations on devices with limited resources. Therefore, future research directions will improve on the basis of Haar SIFT to reduce computational complexity, improve real-time performance and availability of algorithms.

# Designing a Mobile Application for Identifying Strawberry Diseases with YOLOv8 Model Integration

Thuy Van Tran*, Quang - Huy Do Ba, Kim Thanh Tran, Dang Hai Nguyen, Dinh Chung Dang, Van - Luc Dinh
Faculty of Electrical Engineering, Hanoi University of Industry, Hanoi, Vietnam

***Abstract*—The progress in computer vision has led to the development of potential solutions, becoming a versatile technological key to addressing challenging issues in agriculture. These solutions aim to enhance the quality of agricultural products, boost the economy's competitiveness, and reduce labor and costs. Specifically, the detection of diseases in various fruits before harvest to avoid reducing product quality and quantity still relies on the experience of long-time farmers. This leads to difficulties in controlling disease sources over large cultivated areas, resulting in uneven quality control after harvest, which may lead to low prices or failure to meet export requirements to developed markets. Therefore, this stage has now been applied with modern technology to gradually replace humans. In this paper, we propose a mobile application to detect four common diseases in strawberry trees by using image processing technology that combines an artificial intelligence network in identification: based on size, color, and shape defects on the surface of the fruit. The proposed model consists of different versions of YOLOv8 with RGB input to accurately detect diseases in strawberries and provide assessments. Among these, the YOLOv8n model utilizes the fewest parameters with only 11M, but it produces more output parameters with higher accuracy compared to some other YOLOv8 models, achieving an average accuracy of approximately 87.9%. Therefore, the proposed method emerges as one of the possible solutions for strawberry disease detection.**

***Keywords—Computer vision; YOLOv8; strawberry diseases***

## I. Introduction

Strawberries are among the high-value fruits widely consumed globally due to their nutritional value. In 2020, the global strawberry production was valued at $14 billion (FAO UN, 2021), with China being the largest producer accounting for $5 billion, more than three times the value of the second-largest producer, the United States [1]. In Vietnam, Son La strawberries reached a production of 320 tons and were distributed to 26 provinces and cities nationwide in 2020. Strawberries are a rich source of nutrients, including vitamin C, antioxidants such as quercetin and anthocyanins, as well as fiber, manganese, vitamin K, vitamin A, folic acid, vitamin B6, vitamin E, and potassium [2]. These components offer numerous health benefits, including immune system support, blood sugar balance, cell protection, and support for eye, skin, and bone health. Therefore, strawberries are a staple fruit consumed daily, providing not only delicious taste but also significant nutritional value [3].

Pests and diseases that damage crops are a major challenge in the agricultural sector, causing significant losses in food production. Nearly half of all crops grown globally are damaged by pests and diseases [4]. Strawberries are particularly susceptible to plant-pathogenic fungi, bacteria and viruses [5, 6, and 7]. Common pathogens in strawberries include Colletotrichum siamense, which causes anthracnose [8,9]; Botrytis cinereal, the causative agent of gray mold [10,11]; Neopestalotiopsis spp. [12], causing crown rot, fruit rot and leaf blight [8]; and other fungi cause powdery mildew, which typically affects petioles [13], leaves and fruits of strawberries [14]. These pathogens not only reduce photosynthetic efficiency but also negatively impact fruit quality, growth and production. Identifying strawberry diseases currently depends mainly on manual work, requiring a lot of effort and time. The shrinking of the workforce in agricultural areas increases the difficulty, as the ability to properly predict the severity of disease on a large scale becomes difficult. Therefore, there is a need to develop an automated, fast and accurate technique for early detection of strawberry diseases.

Therefore, many research articles have applied computer vision methods to assist people in classifying and detecting plant diseases [15, 16]. In published reports, convolutional neural networks (CNN) are one of the most popular ML techniques for plant disease detection. Jeon and Rhee [17] proposed a CNN technique for tree leaf recognition using the GoogLeNet model. The proposed technique can detect damaged leaves with an identification rate of >94%, even when only 30% of the leaves are damaged. Cervantes-Jilaja et al [18] proposed a computer vision-based method to detect and identify visual defects in chestnuts using external characteristics such as shape, color, size and structure. Mohanty et al. [19] used CNN to detect crop species and diseases based on public image datasets using training models of GoogleLeNet and AlexNet. Based on color, grayscale, and leaf segmentation, the proposed model has 99.35% accuracy.

The evidence of existing systems for automatic classification and detection based on machine vision for various agricultural products has inspired the authors' team to conduct this research. This study is aimed at meeting the practical demand for strawberry disease detection, and we have designed an app that can be used on both Android and iOS platforms to detect strawberry diseases, combining multi-dimensional features with the newly trained YOLOv8 model [28]. For the dataset, we collected a large number of strawberry disease images from laboratory and field settings using methods such as noise filtering and sharpness enhancement, thereby improving the model's generalization effectiveness. Additionally, we also experimented under low-light conditions to enhance the network's adaptability in natural environments and improve the efficiency of strawberry disease detection.

The proposed method of designing a mobile application to detect diseases in strawberries before harvest brings many significant benefits to the agriculture industry. Specifically:

- Early disease detection: This application helps farmers intervene in a timely manner to prevent the spread of diseases and minimize agricultural losses.
- Enhanced production efficiency: The ability to manage and monitor the health of crops is improved, leading to increased productivity and quality of agricultural products.
- Time and cost savings: The mobile application automates the disease detection process, saving time and labor costs.
- Increased income for farmers: Improving the quality and quantity of agricultural products through early disease detection and treatment helps increase income for farmers.

In conclusion, this method not only brings significant benefits to farmers in managing and protecting their crops but also holds the potential to improve productivity and income in the agricultural sector.

The rest of this paper is organized as follows. First, Section II presents a number of related works which motivate this study. Then, Section III presents the materials and methods for diseases of strawberry detection and recognition. Next, Section IV shows the evaluation results, while Section V provides the study's conclusions and future work.

## II. Related Work

There have been several computer vision-based studies related to strawberry disease identification in recently published studies. Jia-Rong Xiao et al. [20] used a convolutional neural network (CNN) model – ResNet50 with two different datasets containing original images and feature images to detect diseases such as leaf fungus, gray mold and white mold. The scoring results have a 100% accuracy rate for leaf blight disease affecting roots, leaves and fruits; 98% for gray mold cases and 98% for white mold cases. In 20 epochs, the accuracy rate of 99.60% from the featured image dataset is higher than 1.53% from the original image dataset. However, this study only focuses on fungal diseases of strawberry plants without expanding on other diseases of strawberries.

In addition, methods for detecting strawberry diseases are based on leaf color. Dwi Esti Kusumandari et al. [21] proposed using digital image processing to analyze diseases of strawberry plants based on leaf color. Digital images of mulberry leaves will be processed to determine health status. Image processing includes image enhancement, color segmentation from RGB color space to HSV color space, and region segmentation to determine deformed and intact leaf areas. Image processing results show that 85% accuracy is achieved in detecting the health status of strawberry plants. Aldi Ramdani and Suyanto Suyanto [22] proposed using a CNN model to identify diseases on strawberries from leaves with four different types of strawberry leaves: healthy leaves, blighted leaves, spotted leaves and diseased leaves. Using ResNet-50 architecture for the model with 3600 images, the model achieved prediction accuracy of 100% for spotted leaves, 99% for diseased leaves, 99% for burned leaves and 100% for healthy leaves. However, these studies have not yet provided specific conclusions about the types of diseases of strawberry plants, but are still just generalizations about disease and non-disease.

In recent years, YOLO [23-28] is a developed model that allows the ability to detect objects from a distance perspective with small size and has won most of the attention of current researchers. with continuous improvements such as YOLOv1, YOLOv2, YOLOv3, YOLOv4, YOLOv5, YOLOv7 and most recently YOLOv8, a state of the art model. Along with this trend, we have applied YOLOv8 module versions to detect diseases in strawberry plants with a data set that we have built including four classes about specific diseases and one normal class. From there, we have addressed lingering issues from studies such as limitations on disease sources and the lack of specificity in identifying each type of disease in strawberry plants. Additionally, We also provide feedback to create the best version of the app that can be used on both Android and iOS.

## III. Materials and Methods

### A. YOLOv8

The proposed architecture of YOLOv8 aims to achieve optimal feature extraction. The backbone of the proposed architecture includes Convolutional Module, Module C2f, and Module SPPF, which are crucial for feature extraction.

The Convolutional Module in YOLOv8 is typically integrated into the backbone network, where its role is to transform the input image into feature representations using convolutional layers, batch normalization layers, and the SiLU activation function. These components play a vital role in extracting important information from the image, ranging from low-level features like edges to high-level features like object shapes and details. Additionally, the use of the SiLU activation function helps the model learn nonlinear representations efficiently, contributing to its ability to learn and accurately recognize objects in the image (see Fig. 1).

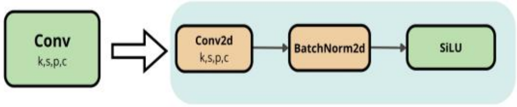

Fig. 1. Architecture of module convolutional.

Unlike YOLOv5, YOLOv8 does not bring many significant innovations, with the only notable change being the introduction of the Module C2f, replacing the Module C3 in YOLOv5. In YOLOv5, the Module C3 features three standard convolutional layers and multiple Bottleneck modules. Particularly, the Bottleneck module consists of two branches: one branch utilizes multiple stacked Bottlenecks and three standard convolutional layers, while the other branch passes through a basic convolutional layer before merging the two branches together. This not only helps reduce the number of training parameters and computations but also addresses issues of gradient explosion and disappearance in deep networks, enhancing the model's learning capabilities. While YOLOv7 improves gradient information by adding multiple parallel gradient streams and using the ELAN module to achieve higher accuracy and reasonable latency, YOLOv8 further develops this idea by designing the Module C2f. Inspired by the Module C3 and ELAN, the Module C2f helps gather diverse gradient streams while still maintaining the model's lightweight structure. This enhances the learning ability and performance of YOLOv8 while effectively reducing latency. Fig. 2 shows architecture of Module C2f.

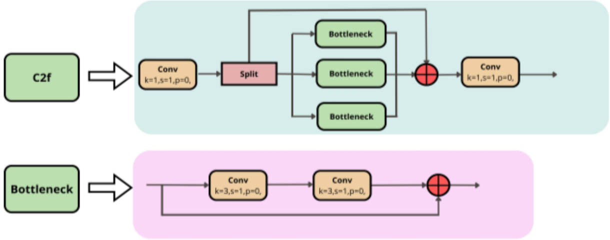

Fig. 2. Architecture of module C2f.

In YOLOv8, Module SPPF (Spatial Pyramid Pooling Fusion) module plays a crucial role in improving the model's accuracy, particularly in object detection tasks. This module is integrated to address the challenge of object detection at different positions and scales within the image. Module SPPF utilizes the Spatial Pyramid Pooling method to generate multi-level representations, enabling the model to accept and process information from regions of various sizes in the image. This enhances the model's recognition capabilities while helping to minimize accuracy issues at diverse positions across the image (see Fig. 3).

Fig. 4 provides an overview of the YOLOv8 model, integrating crucial components such as the Convolutional Module, Module C2f, and Module SPPF to efficiently extract features and address the challenge of varying input sizes in images. Particularly, the Module C2f plays a vital role in reducing the number of parameters and computations, addressing issues of gradient explosion and disappearance in deep learning networks, while enhancing the model's learning capabilities. Experimental results have affirmed the outstanding performance of YOLOv8, achieving significantly higher accuracy compared to previous versions of YOLO. This is why we selected YOLOv8 for our strawberry disease detection research.

## B. *Dataset for Strawberry Disease Detection*

Faced with the complexity of the real environment, we developed machine learning models trained on real-world images using diverse data sources from Google Images, as well as photos taken at farms and from the Department of Agriculture. This process involved downloading images from the internet using both the scientific and common names of the five types of strawberries mentioned in our dataset. Additionally, we didn't solely rely on online data sources but also gathered additional images, especially during the large-scale strawberry disease research conducted on the field.

To create a quality dataset, we applied a meticulous filtering process. Selection criteria included metadata information on websites and principles outlined by the Department of Agriculture. Color, area, density of the infected area, and shape of each type were identified as the most important factors for categorizing images into groups. Furthermore, we discarded inaccurate images, such as those not depicting strawberries controlled in a laboratory setting and those outside the scope. Moreover, to ensure the accuracy of each type, we also removed duplicate images across classes through a search process.

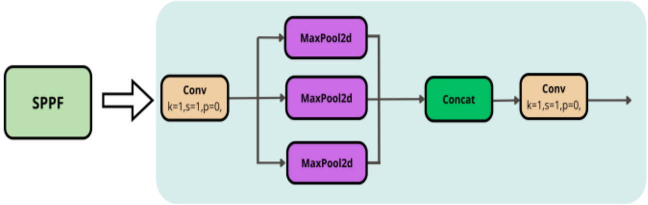

Fig. 3. Architecture of module SPPF.

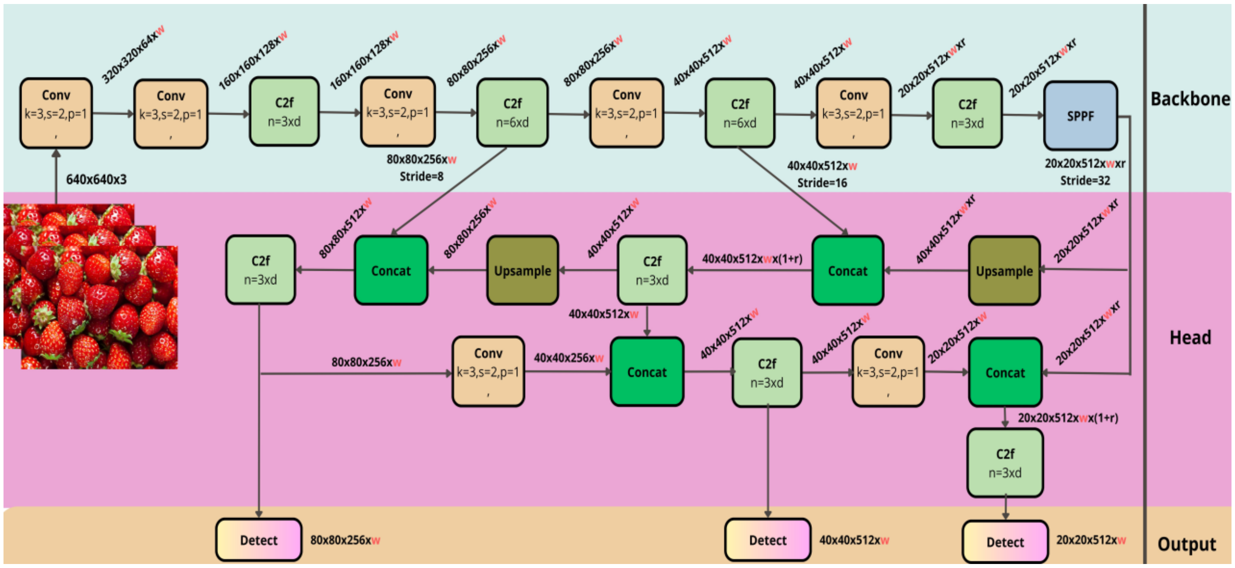

Fig. 4. Architecture of YOLOv8.

TABLE I. SYMPTOMS WITH SPECIMEN NUMBERS OF 5 STRAWBERRY TYPES

| ***Type name*** | ***Description*** | ***Number of samples*** | ***Image*** |
|---|---|---|---|
| Normal | The strawberry has a bright red color, uniform throughout. It is free from large wounds or injuries, with a smooth surface and no signs of black spots or rot. | 351 | |
| Gray mold disease | The strawberry has areas of gray or white color covering the surface. These areas can expand and develop over time, forming a layer of gray mold. | 100 |  |
| Black spot disease | The strawberry has areas of black color. Strawberries affected by black spot disease may also become softer and more prone to damage compared to healthy ones. | 100 |  |
| Powdery mildew disease | The strawberry exhibits areas of pale white powdery patches on its surface. These white layers, resembling fine powder, cover the fruit, diminishing its natural glossy appearance. | 100 |  |
| Rubber disease | The strawberry exhibits areas of brown, black, or possibly different colors compared to its normal hue. The surface of the strawberry becomes wrinkled and uneven, and it can be felt to be firmer and more water-retentive than a healthy fruit. | 100 |  |

Each image in our dataset was examined by two individuals following specific guidelines to minimize labeling errors and ensure the quality and accuracy of the data. As a result, we collected a dataset consisting of five classes, including four classes of strawberry diseases and one class of healthy strawberries, as described in Table I.

After constructing the dataset on strawberry diseases, precise bounding boxes containing strawberries in full images are needed. Therefore, we utilized Roboflow to create bounding boxes around the strawberries in all images. In real-world scenarios, images may contain multiple strawberries or a combination of diseased and healthy ones. We explicitly labeled all berries in the images with their respective classes. While labeling the boxes, we ensured that the entire strawberry was inside the box, and the area surrounding the box was not less than 1/8 (approximately) of the image size.

The result is a new dataset named STRAWBERRY dataset. It contains 751 images and 3910 instances, where 80% (600 images) were randomly selected for the training dataset, 10% (76 images) for the validation dataset, and the remaining 10% (75 images) for the test dataset. The test dataset is solely used to evaluate the model's performance after training, as shown in Table II.

TABLE II. NUMBER OF ANNOTATED IMAGES FOR EACH STRAWBERRY TYPE

| **STRAWBERRY dataset** | **Normal** | **Gray mold disease** | **Black spot disease** | **Powdery mildew disease** | **Rubber disease** | **Number of samples** |
|---|---|---|---|---|---|---|
| Train | 1414 | 420 | 364 | 287 | 252 | 600 |
| Test | 404 | 120 | 104 | 82 | 72 | 75 |
| Valid | 202 | 60 | 52 | 41 | 36 | 76 |

## IV. RESULTS AND DISCUSSIONS

### A. Experiment Enviroment

The proposed model was trained on our self-constructed dataset, as described above, using Google Colab with a High RAM Colab Runtime and Tesla V100 GPU configuration. After the training process was completed, we obtained corresponding sets of weights for each model. Next, we evaluated the effectiveness of each model based on the test dataset. Finally, we compared the results obtained among the YOLOv8l, YOLOv8m, YOLOv8n, and YOLOv8x versions.

### B. Metrics for Performance Evaluation

To evaluate the effectiveness of the different versions of the YOLOv8 model for detecting strawberry diseases, the evaluation metrics used include GFLOPS (Giga Floating-point Operations Per Second), Precision, Recall, and Mean Average Precision (mAP).

GFLOPS (Giga Floating-point Operations Per Second) is the number of billion floating-point arithmetic operations per second, often used as a GPU performance parameter and can be observed through GFLOPs. The parameter size of the model can be used to determine the complexity of the model by examining the parameters. In model optimization, sometimes GFLOPs and parameters increase unavoidably. In general, we aim for smaller GFLOPs and parameters.

Precision is defined by the equation below. It is defined as the ratio of the number of true positive samples correctly predicted by the model to the total number of positive samples predicted:

$$precision = \frac{TP}{TP + FP} \quad (1)$$

Recall represents the number of true positive samples correctly predicted by the model as a percentage of all the targets. The formula for calculating the recall rate is shown in the equation:

$$recall = \frac{TP}{TP + FN} \quad (2)$$

The precision-recall curve is a curve displayed with precision on the y-axis and recall on the x-axis. It is defined as the area under the curve below as an average precision (AP) value. Precision values are shown through the precision-recall curve when the outermost boxes are accepted (i.e., higher recall values due to lower class probability thresholds). As recall increases, a strong model can maintain high precision. The CIoU (intersection over union) threshold is typically set at 0.5. The performance of the model is generally better when the AP value is higher. For each type of strawberry disease detected, the higher the AP value, the better the strawberry's ability to detect that disease, meaning the higher the detection accuracy.

$$AP = \int_0^1 P(R)dR \tag{3}$$

As seen below, mAP is the average precision across all classes. For the entire model, the higher the mAP value, the better the overall detection efficiency of the model and the higher the detection accuracy.

$$mAP = \frac{1}{N}\sum_{i=1}^{N} AP_i \tag{4}$$

### C. Experimental Results and Discussion

The experimental results based on Table III aim to compare the results and evaluate the performance of four models: YOLOv8l, YOLOv8m, YOLOv8n, and YOLOv8x. The table includes data on accuracy for five classes: Normal, Gray mold disease, Powdery mildew disease, Rubber disease.

TABLE III. RESULTS ON THE TEST DATASET

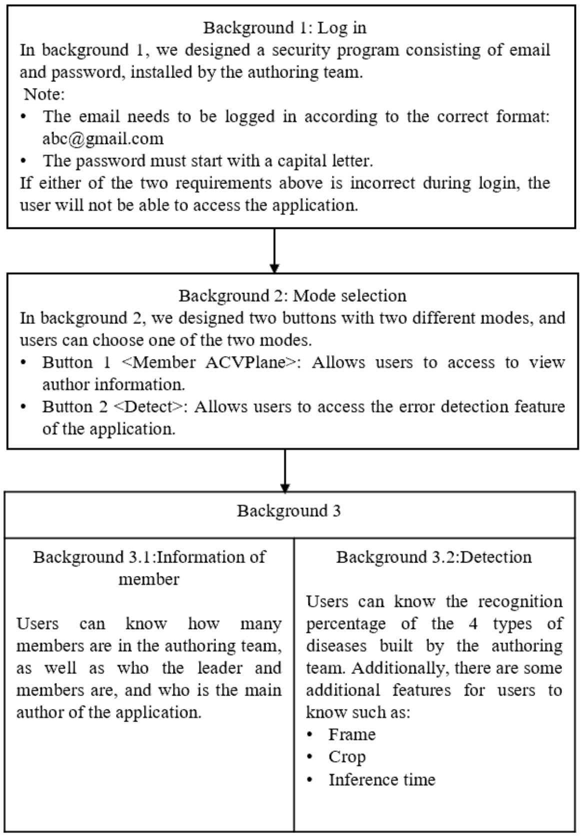
| Model | Parameter | Precision | Recall | AP | | | | | mAP |
|---|---|---|---|---|---|---|---|---|---|
| | | | | Normal | Gray mold disease | Black pot disease | Powdery mildew disease | Rubber disease | |
| **YOLOv8l** | 43.7M | 0.809 | 0.799 | 0.869 | 0.863 | 0.857 | 0.872 | 0.864 | 0.865 |
| **YOLOv8m** | 25.9M | 0.768 | 0.828 | 0.879 | 0.866 | 0.859 | 0.867 | 0.869 | 0.868 |
| **YOLOv8n** | **11M** | **0.850** | **0.845** | **0.890** | **0.872** | **0.874** | **0.879** | **0.880** | **0.879** |
| **YOLOV8x** | 68.2M | 0.819 | 0.825 | 0.872 | 0.857 | 0.845 | 0.864 | 0.862 | 0.860 |

Based on the data from Table III, the YOLOv8n model demonstrates the highest accuracy at 87.9%, outperforming the other three models: YOLOv8l (86.5%), YOLOv8m (86.8%), and YOLOv8x (86.0%). Furthermore, YOLOv8 versions tend to become more complex, slower, larger in size, and require more computations when combining models to improve accuracy. However, YOLOv8n still maintains an advantage with a very small parameter size, only 11 M compared to the other models.

Moreover, we can observe that most metrics for each class among the four models, particularly in the YOLOv8n model, maintain stability and achieve the highest accuracy compared to YOLOv8l, YOLOv8m, and YOLOv8x. In the "Normal" class, YOLOv8n achieves 89.0%, which is 2.1% higher than YOLOv8l (86.9%). For "Gray mold disease," YOLOv8n achieves 87.2%, surpassing YOLOv8x (85.7%) by 1.5%. In "Black pot disease," YOLOv8n achieves 87.4%, improving by 2.9% compared to YOLOv8x (84.5%). In "Powdery mildew disease," YOLOv8n achieves 87.9%, which is 1.5% higher than YOLOv8x (86.4%). Lastly, in "Rubber disease," YOLOv8n achieves 88.0%, surpassing YOLOv8x (86.2%) by 1.8%. This confirms that YOLOv8n has the highest accuracy performance among the 4 YOLOv8 models.

### D. Results of the Application

After completing the training of the model, we observed that the YOLOv8n model has the highest performance compared to the remaining versions. Based on this result, our decision is to utilize the .yaml file of YOLOv8n to further develop the disease detection application for strawberries. This presents a new and significant opportunity in research and technology application to support agriculture and crop health monitoring. We believe that the combination of the accuracy of the YOLOv8n model and its practical applicability will make positive contributions to the farming community and researchers in this field.



Background 1: Log in

In background 1, we designed a security program consisting of email and password, installed by the authoring team.

Note:

- The email needs to be logged in according to the correct format: abc@gmail.com
- The password must start with a capital letter.

If either of the two requirements above is incorrect during login, the user will not be able to access the application.

Background 2: Mode selection

In background 2, we designed two buttons with two different modes, and users can choose one of the two modes.

- Button 1 <Member ACVPlane>: Allows users to access to view author information.
- Button 2 <Detect>: Allows users to access the error detection feature of the application.

Background 3

Background 3.1:Information of member

Users can know how many members are in the authoring team, as well as who the leader and members are, and who is the main author of the application.

Background 3.2:Detection

Users can know the recognition percentage of the 4 types of diseases built by the authoring team. Additionally, there are some additional features for users to know such as:

- Frame
- Crop
- Inference time

Fig. 5. Block diagram.

We have constructed according to the sequence of steps the structure of the application following the block diagram (see Fig. 5):

## V. Conclusion

In this article, the authors built and designed an integrated application with YOLOv8n to detect diseases in strawberries. Using a self-generated dataset of 751 RGB images of strawberries (including diseased and non-diseased fruits), combined with the YOLOv8n algorithm with an accuracy rate of up to 87.9% with 4 types of diseases popular. Fig. 6 shows image of application results. Through the observations mentioned previously, the outstanding accuracy of the YOLOv8n model in detecting strawberry defects can be demonstrated. However, the results still did not meet the authors' expectations of over 90% because when creating a data set of diseases such as "Gray mold disease" and "Powdery mildew disease" or "Black pot disease" and "Rubber disease" is not complete. When the disease first appears, the symptoms on their fruit are very similar, making identification difficult. Therefore, the authors will continue to research and expand their data set in the future. The results of this article can be further extended and developed for practical application with other fruits and nuts in agriculture.

# Exploring the Landscape: Analysis of Model Results on Various Convolutional Neural Network Architectures for iRESPOND System

Freddie Prianes[1], Kaela Marie Fortuno[2], Rosel Onesa[3], Brenda Benosa[4], Thelma Palaoag[5], Nancy Flores[6]
College of Computer Studies, Camarines Sur Polytechnic Colleges, Nabua, Camarines Sur, Philippines[1, 2, 3, 4]
College of Information Technology and Computer Science, University of the Cordilleras, Baguio City, Philippines[5, 6]

***Abstract*—In the era of rapid technological advancement, the integration of cutting-edge technologies plays a pivotal role in enhancing the efficiency and responsiveness of critical systems. iRESPOND, a real-time Geospatial Information and Alert System, stands at the forefront of such innovations, facilitating timely and informed decision-making in dynamic environments. As the demand for accurate and swift responses, the role of CNN models in iRESPOND becomes significant. The study focuses on seven prominent CNN architectures, namely EfficientNet (B0, B7, V2B0, and V2L), InceptionV3, ResNet50, and VGG19 and with the integration of different optimizers and learning rates. The methodology employed a strategic implementation of looping during the training phase. This iterative approach is designed to systematically re-train the CNN models, emphasizing identifying the most suitable architecture among the seven considered variants. The primary objective is to discern the optimal architecture and fine-tune critical parameters, explicitly targeting the optimizer and learning rate values. The differential impact of each model on the system's ability is to discern patterns and anomalies in the image datasets. ResNet50 exhibited robust performance showcasing suitability for real-time processing in dynamic environments with a better accuracy result of 95.02%. However, the EfficientNetV2B0 model, characterized by its advancements in network scaling, presented promising results with a lower loss of 0.187. Generally, the findings not only contribute valuable insights into the optimal selection of architectures for iRESPOND but also highlight the importance of fine-tuning hyperparameters through an iterative training approach, which paves the way for the continued enhancement of iRESPOND as an adaptive system.**

***Keywords—Artificial intelligence; image classification; emergency response; model training; optimizers; learning rate***

## I. Introduction

In the contemporary landscape of rapid technological progress, integrating state-of-the-art technologies has become intrinsic to augmenting the efficiency and responsiveness of critical systems [1]. Within this realm of innovations, iRESPOND stands out as a real-time Geospatial Information and Alert System, assuming a pioneering role in technology to facilitate timely and informed decision-making in dynamic and unpredictable environments. The escalating need for precision and rapidity in addressing geospatial challenges accentuates the crucial role played by Convolutional Neural Network (CNN) models within the iRESPOND system.

As a complex and dynamic system, iRESPOND relies on advanced computational models to process and analyze geospatial data efficiently. CNNs, a specialized class of deep neural networks designed for image analysis, emerge as pivotal components that significantly enhance iRESPOND's capability to discern intricate patterns and anomalies within vast image datasets [2]—recognizing the significance of these EfficientNet (B0, B7, V2B0, and V2L, Google Inception CNN 3rd Edition (InceptionV3), Residual Network – 50 Layers Deep (ResNet50), and Visual Geometry Group – 19 Convolutional Layers (VGG19).

EfficientNet is a revolutionized model scaling that proposes a compound scaling method that balances depth, width, and resolution. EfficientNetB0 represents the baseline model, while EfficientNetB7 is a larger variant [3]. These models achieve state-of-the-art performance with fewer parameters, making them efficient and scalable for various applications [4]. The compound scaling ensures the models are optimized across multiple dimensions, providing a favorable trade-off between accuracy and computational efficiency [5].

Building upon the success of EfficientNet, EfficientNetV2 refines the original architecture. EfficientNetV2B0 and EfficientNetV2L are variants designed for improved performance. The advancements focus on improved training stability and robustness [6]. EfficientNetV2 introduces novel architectural choices, such as a new stem and a more efficient inverted bottleneck structure, contributing to enhanced generalization and efficiency [7].

InceptionV3 is part of the Inception family of CNN architectures. Notable for its inception modules, which incorporate multiple filter sizes within the same layer, InceptionV3 captures hierarchical features at different scales [8]. The inception architecture aims to balance computational efficiency and representation capacity, making it suitable for various computer vision tasks [9].

ResNet introduced the concept of residual learning, addressing the vanishing gradient problem in deep neural networks [10]. ResNet50, a variant with 50 layers, has become a benchmark architecture known for its deep, skip-connection design, allowing for the training of profound networks [11]. The skip connections facilitate the flow of gradients during backpropagation, enabling the successful training of deep networks without degradation in performance [12].

The VGG architecture is characterized by simplicity and uniformity [13]. VGG19, an extended version with 19 layers, features convolutional layers with small 3x3 filters and max-pooling layers [14]. While computationally intensive, VGG architectures are known for their excellent performance in image classification tasks, demonstrating the importance of depth in CNNs [15].

The scope of exploration of this study extends not only to the CNN, as mentioned above architecture, but it also encompasses various optimizers, i.e., Adaptive Moment Estimation (Adam) and Root Mean Squared Propagation (RMSProp) and learning rates, with the overarching goal of identifying the most effective combination to optimize the performance of iRESPOND.

Adam combines the advantages of adaptive learning rate methods and momentum-based optimization [16]. It maintains two moving average estimators: the first moment (mean) of the gradients (similar to momentum) and the second moment (uncentered variance) of the gradients. These estimates are then used to adjust the learning rates for each parameter adaptively [17]. Adam computes individual adaptive learning rates for each parameter, allowing for practical training across different dimensions and reducing the need for manual tuning of the learning rate hyperparameter [18]. This adaptability to different gradients and learning rates makes Adam well-suited for various tasks and architectures [19].

RMSprop addresses some limitations of traditional gradient descent algorithms, particularly the sensitivity of learning rates to the scale of gradients in different dimensions of training [20]. RMSprop modifies the learning rate for each parameter based on the average of recent squared gradients [21]. By scaling the learning rates inversely proportional to the square root of these averages, RMSprop effectively adapts the learning rates for each parameter independently [22]. This adaptive adjustment helps mitigate the exploding and vanishing gradient problems, increasing stability and efficiency [23].

In general, these diverse arrays of architectures and optimizers have significantly impacted the field of computer vision and image analysis. Each brings unique characteristics, design principles, and innovations to deep learning, contributing to various applications, including image recognition, object detection, and many others.

## II. Related Works

The deliberate use of deep learning techniques exemplifies a larger trend in disaster management wherein machine learning approaches are becoming more popular due to its ability to handle complex and dynamic datasets [24, 25]. Despite the potential for deep learning algorithms to enhance accuracy, concerns persist regarding their resource-intensive nature and inefficiency in real-time monitoring applications [26]. Rathod et al. study highlights the efficacy of CNN-based models in getting better accuracy for disaster image classification, but it also shows how little foundation has been laid for establishing a robust computerized system for disaster response and recovery management [27].

According to Shah et al., traditional disaster classification methods lack in precision and speed which are essential for quick decision-making and resource allocation during emergencies. Challenges in data protection, latency transport, and unified-controlled data storage make disaster classification system implementation even more difficult [28]. Hence, exploring the efficacy of transfer learning techniques becomes imperative to address data scarcity issues and bolster model performance in deep learning scenarios, particularly where datasets are limited [29].

Moreover, the study of Asif et al. underscores the potential of neural network-based image processing architectures in enhancing crisis-related operations. However, the authors also acknowledge the limitations in evaluating activities, contexts, and related images during emergencies and disasters. Similarly, Tang et al. point out the shortcomings of existing forest classification algorithms based on graphics analysis, while Kallas & Napolitano, and Daly & Thom works also highlight the challenges in sub-classifying complex structural damage types and recognizing fire and smoke in images respectively [26, 30-32]. Subsequently, Mukhopadhyay et al. emphasizes the necessity for future research in emergency prediction to assess the accuracy of prediction models thoroughly, necessitating additional modeling and empirical studies to comprehend method advantages and drawbacks fully [33].

Navigating these challenges reveals promising outcomes in developing emergency and disaster-related models. Sharma, Jain, and Mishra stress the importance of testing CNNs across multiple datasets to unveil their true potential and limitations. Although they observed superior performance by GoogLeNet and ResNet50 compared to AlexNet in object recognition precision within images, significant performance variations persist across different object categories [34]. In line with these results, Zainorzoli et al., and Sushma & Lakshmi affirm ResNet50 as the highest accuracy achieved among tested models. Comparative evaluations against popular CNN architectures like AlexNet, GoogLeNet, VGG16, and VGG19 consistently position ResNet50 as a better choice, displaying higher precision and reliability in object recognition across diverse datasets and applications, particularly in emergency incident image classification scenarios. [35, 36]

The collective body of related studies contributes diverse approaches and applications to the disaster prediction and response domain, spanning advanced machine learning models to innovative technological solutions. However, addressing complex challenges and bridging gaps in diverse image datasets for various emergency and disaster classifications, achieving higher prediction accuracy rates, and real-time processing of incident reports in disaster response and mitigation necessitate further research and collaborative efforts. Thus, the contributions of these studies are important in introducing a CNN model custom-made for the iRESPOND system.

## III. Methods

Achieving optimal performance for image classification using CNN models requires close attention to detail. A systematic process was used in a specialized repository to construct and optimize a CNN model. Robust experimentation was initiated by first changing global variables essential for training the model, such as seed, epochs, learning rates, and base model selection that has already been trained [37]. The subsequent processes were carried out precisely to guarantee a thorough comprehension of the model's behavior and performance, from dataset preparation to model creation and evaluation.

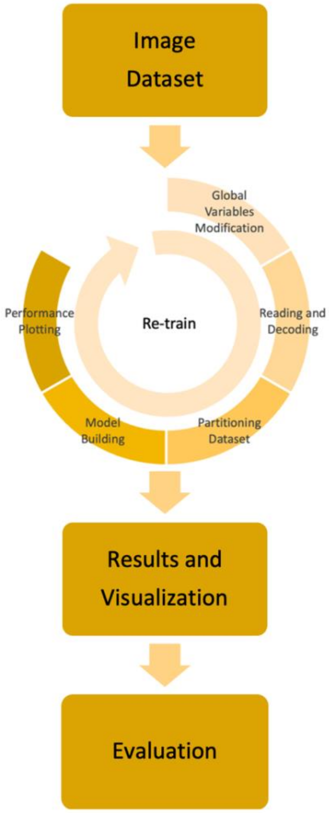

Fig. 1. Re-training process.

In analyzing the performance of the CNN models for image classification, as shown in Fig. 1, a systematic approach was undertaken within a dedicated repository of image datasets of disasters and emergencies [38]. Next, global variables crucial for model training were modified, encompassing parameters such as the generic seed, number of epochs, learning rates, choice of pre-trained base models including EfficientNetB0, B7, V2B0, and V2L, InceptionV3, ResNet50, and VGG19, together with the pre-processing methods and optimization algorithms like Adam and RMSprop [39]. Subsequently, the dataset was read and decoded into pairs, ensuring proper preparation for training [40]. Random partitioning divided the dataset into training, validation, and test sets, providing robust model evaluation [41]. The CNN model was then constructed, featuring specified hyperparameters and layers, including the selected base model, global average pooling, dropout layers for regularization, and softmax activation function for multi-label classification tasks [42]. Performance metrics were plotted, depicting training and validation accuracy and losses over epochs, facilitating insights into model convergence and potential overfitting [43]. Moreover, image samples were visualized, presenting original images alongside the sample prediction result [44]. Then, global variables were adjusted based on observed results, allowing for further optimization and exploration of model configurations and re-train the model [45]. Finally, all results will be compiled to assess and evaluate which architecture provides a better performance. This structured approach enabled a comprehensive understanding of the CNN model's behavior and performance, facilitating iterative improvements toward enhanced accuracy and interpretability in image classification tasks [46].

The process of creating and improving the CNN model for image classification serves as an example of how machine learning operations are iterative. By means of thorough testing, visualization, and modification of global variables, valuable insights were obtained, and advancements were achieved throughout the entire process [47]. The method used in this study promoted a better understanding of the complex principles behind CNN-based image classification in addition to aiding in the optimization of model performance. The study serves as a monument to the commitment and creativity propelling developments in computer vision and artificial intelligence as the years' progress.

## IV. Results

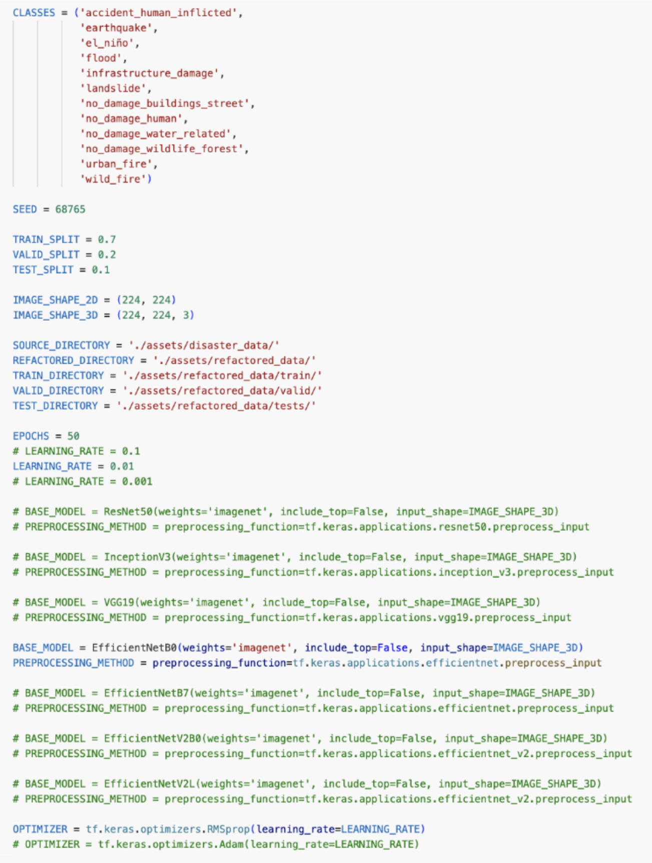
### A. Image Repository

The image repository covers a broad range of incidents, from man-made accidents to natural disasters like floods and earthquakes to different types of environmental and infrastructure damage, which composed of 13,578 image datasets. The diversity of the dataset is crucial because it will be the basis for accurately capturing the complex and uncertain character of an emergency report sent in the iRESPOND system. There are a lot of images in each area in the collection, so there is enough coverage and depiction of many situations and settings. The models will be efficiently trained by the availability of these data, which enables them to learn and recognize complex patterns and features related to various emergencies and disasters. It will be trained to perform robustly over a wide range of emergency circumstances and generalize effectively to new data by utilizing this diversified dataset. This will increase the model's usefulness and efficacy in real-world applications.

### B. Modify the Global Variables

As shown in Fig. 2, there are various configurations and parameters necessary for training the model for image classification in the iRESPOND system. We define the classes first, representing different categories of emergencies and disasters, such as earthquakes, floods, urban fires, infrastructure damage, etc. This categorization is needed for organizing and labeling the dataset appropriately, ensuring that the model can learn to distinguish between different types of emergency scenarios.

Several global variables are defined, including the random seed for reproducibility, the proportions for splitting the dataset into training, validation, and test sets, and the dimensions of the input images. These variables are for controlling the training process and evaluating the model's performance effectively. We specify the directories for accessing the source dataset and storing the refactored data after pre-processing to ensure proper data management and organization throughout the training pipeline.



```
CLASSES = ('accident_human_inflicted',
           'earthquake',
           'el_niño',
           'flood',
           'infrastructure_damage',
           'landslide',
           'no_damage_buildings_street',
           'no_damage_human',
           'no_damage_water_related',
           'no_damage_wildlife_forest',
           'urban_fire',
           'wild_fire')

SEED = 68765

TRAIN_SPLIT = 0.7
VALID_SPLIT = 0.2
TEST_SPLIT = 0.1

IMAGE_SHAPE_2D = (224, 224)
IMAGE_SHAPE_3D = (224, 224, 3)

SOURCE_DIRECTORY = './assets/disaster_data/'

# OPTIMIZER = tf.keras.optimizers.Adam(learning_rate=LEARNING_RATE)
```

Fig. 2. Global variables (Code Snippet).

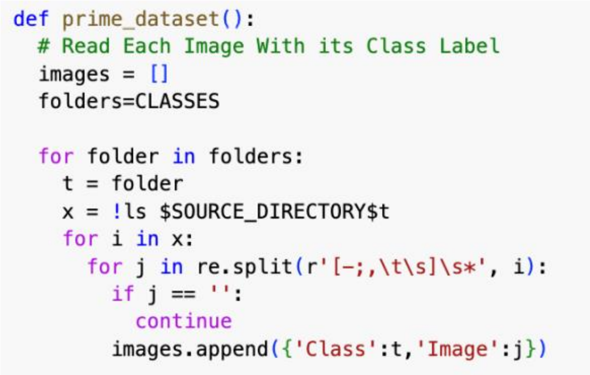
Key components of the model are configured next; including the choice of a base model pre-trained on ImageNet, in this case, EfficientNet (B0, B7, V2B0, and V2L), InceptionV3 ResNet50, and VGG19, along with the corresponding pre-processing method. The choice of base model and pre-processing technique significantly influences the model's performance and ability to extract meaningful features from input images.

Additionally, we define the optimizer used during zmodel training, with options for RMSprop or Adam optimization algorithms. The learning rate, an essential hyperparameter affecting the convergence and stability of the training process, is also specified.

## C. Read and Decode

For this section, we initialized a function called "prime_dataset()" designed to facilitate the reading and decoding of the dataset. Based on Fig. 3, this function operates iteratively through each class folder within the dataset, where each folder corresponds to a distinct category of emergency or disaster-related scenarios.

Within each class folder, the function iterates over the images contained within, capturing both the image file name and its associated class label. This is achieved by utilizing shell commands, with the "ls" command listing all files within the specified directory. The resulting list of file names is then parsed using regular expressions to extract individual image filenames.



```
def prime_dataset():
  # Read Each Image With its Class Label
  images = []
  folders=CLASSES

  for folder in folders:
    t = folder
    x = !ls $SOURCE_DIRECTORY$t
    for i in x:
      for j in re.split(r'[-;,\t\s]\s*', i):
        if j == '':
          continue
        images.append({'Class':t,'Image':j})
```

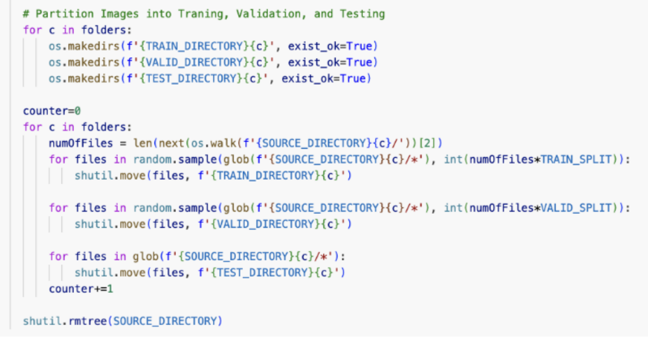
Fig. 3. Reading and decoding (Code Snippet).

Throughout this process, each image file is associated with its corresponding class label and added to a list named "images", ensuring that the dataset is structured appropriately for subsequent processing and model training. However, it's worth noting that the exact method for reading and loading images may vary depending on the specific dataset format and requirements. Therefore, additional pre-processing steps, such as image resizing or normalization, may be necessary to prepare the data adequately for model training.

## D. Partition the Dataset

The dataset is partitioned into training, validation, and test sets with proportions of 70%, 20%, and 10%, respectively. This partitioning ensures that the models are trained on a sufficiently large portion of the data while also having separate datasets for validation and final evaluation. In order to do so, we created directories for each class within the training, validation, and testing directories, ensuring proper organization of the partitioned data. This organizational structure facilitates subsequent data loading and model training processes.

As the code segment presented in Fig. 4, it iterates through each class folder in the dataset, determining the number of files present in each class using the "os.walk()" function. For each class, a portion of the images is randomly selected based on the specified split ratios (TRAIN_SPLIT and VALID_SPLIT). Using the "random.sample()" function, files are randomly sampled from the class folder, with the number of files sampled proportional to the respective split ratio. These sampled files are then moved to the corresponding directories within the training and validation sets.



```
# Partition Images into Traning, Validation, and Testing
for c in folders:
    os.makedirs(f'{TRAIN_DIRECTORY}{c}', exist_ok=True)
    os.makedirs(f'{VALID_DIRECTORY}{c}', exist_ok=True)
    os.makedirs(f'{TEST_DIRECTORY}{c}', exist_ok=True)

counter=0
for c in folders:
    numOfFiles = len(next(os.walk(f'{SOURCE_DIRECTORY}{c}/'))[2])
    for files in random.sample(glob(f'{SOURCE_DIRECTORY}{c}/*'), int(numOfFiles*TRAIN_SPLIT)):
        shutil.move(files, f'{TRAIN_DIRECTORY}{c}')

    for files in random.sample(glob(f'{SOURCE_DIRECTORY}{c}/*'), int(numOfFiles*VALID_SPLIT)):
        shutil.move(files, f'{VALID_DIRECTORY}{c}')

    for files in glob(f'{SOURCE_DIRECTORY}{c}/*'):
        shutil.move(files, f'{TEST_DIRECTORY}{c}')
    counter+=1

shutil.rmtree(SOURCE_DIRECTORY)
```

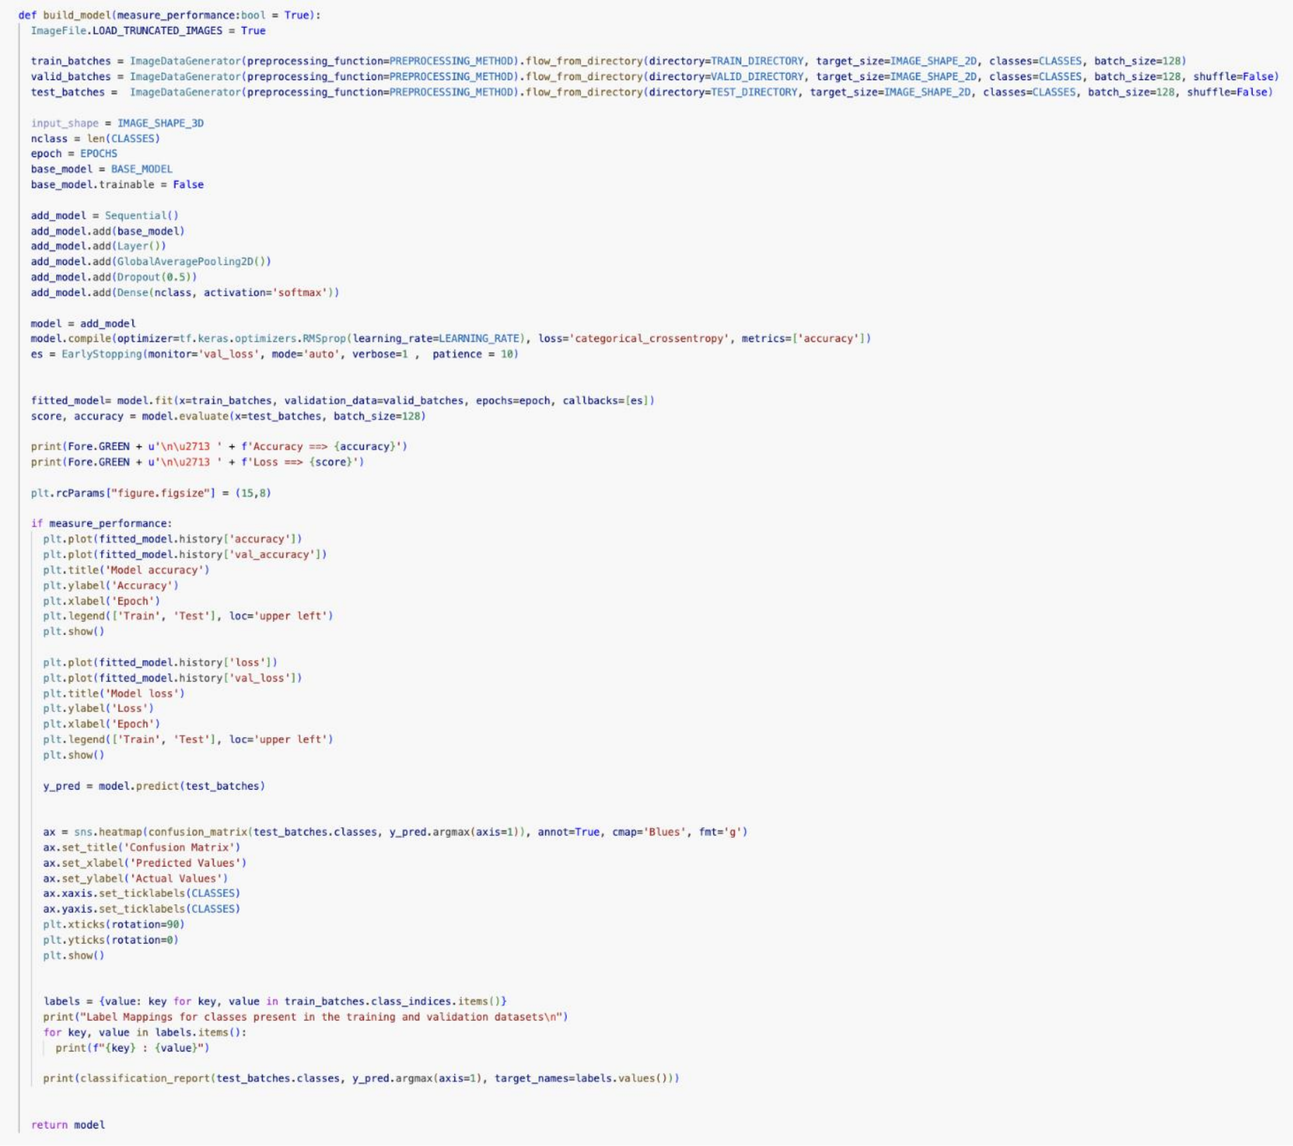
Fig. 4. Partitioning the dataset (Code Snippet).

After moving files to the training and validation directories, the remaining files within each class folder are moved to the testing directory. This ensures that every image in the dataset is accounted for and partitioned appropriately across the three sets.

Moreover, the original source directory containing the entire dataset is removed using "shutil.rmtree()", as the data has been successfully partitioned and relocated to the respective training, validation, and testing directories. This cleanup step helps maintain a clean and organized directory structure, reducing clutter and facilitating easier management of the dataset during subsequent stages of the model development process.

### *E. Build the CNN Model*

The process of building the CNN model for image classification is set to start by initializing the "build_model()" function and setting "ImageFile.LOAD_TRUNCATED_IMAGES" to "True", ensuring that truncated images can be loaded without error during training as presented in Fig. 5.



```
def build_model(measure_performance:bool = True):
  ImageFile.LOAD_TRUNCATED_IMAGES = True

  train_batches = ImageDataGenerator(preprocessing_function=PREPROCESSING_METHOD).flow_from_directory(directory=TRAIN_DIRECTORY, target_size=IMAGE_SHAPE_2D, classes=CLASSES, batch_size=128)
  valid_batches = ImageDataGenerator(preprocessing_function=PREPROCESSING_METHOD).flow_from_directory(directory=VALID_DIRECTORY, target_size=IMAGE_SHAPE_2D, classes=CLASSES, batch_size=128, shuffle=False)
  test_batches =  ImageDataGenerator(preprocessing_function=PREPROCESSING_METHOD).flow_from_directory(directory=TEST_DIRECTORY, target_size=IMAGE_SHAPE_2D, classes=CLASSES, batch_size=128, shuffle=False)

  input_shape = IMAGE_SHAPE_3D
  nclass = len(CLASSES)
  epoch = EPOCHS
  base_model = BASE_MODEL
  base_model.trainable = False

  add_model = Sequential()
  add_model.add(base_model)
  add_model.add(Layer())
  add_model.add(GlobalAveragePooling2D())
  add_model.add(Dropout(0.5))
  add_model.add(Dense(nclass, activation='softmax'))

  model = add_model
  model.compile(optimizer=tf.keras.optimizers.RMSprop(learning_rate=LEARNING_RATE), loss='categorical_crossentropy', metrics=['accuracy'])
  es = EarlyStopping(monitor='val_loss', mode='auto', verbose=1 ,  patience = 10)

  fitted_model= model.fit(x=train_batches, validation_data=valid_batches, epochs=epoch, callbacks=[es])
  score, accuracy = model.evaluate(x=test_batches, batch_size=128)

  print(Fore.GREEN + u'\n\u2713 ' + f'Accuracy ==> {accuracy}')
  print(Fore.GREEN + u'\n\u2713 ' + f'Loss ==> {score}')

  plt.rcParams["figure.figsize"] = (15,8)

  if measure_performance:
    plt.plot(fitted_model.history['accuracy'])
    plt.plot(fitted_model.history['val_accuracy'])
    plt.title('Model accuracy')
    plt.ylabel('Accuracy')
    plt.xlabel('Epoch')
    plt.legend(['Train', 'Test'], loc='upper left')
    plt.show()

    plt.plot(fitted_model.history['loss'])
    plt.plot(fitted_model.history['val_loss'])
    plt.title('Model loss')
    plt.ylabel('Loss')
    plt.xlabel('Epoch')
    plt.legend(['Train', 'Test'], loc='upper left')
    plt.show()

    y_pred = model.predict(test_batches)

    ax = sns.heatmap(confusion_matrix(test_batches.classes, y_pred.argmax(axis=1)), annot=True, cmap='Blues', fmt='g')
    ax.set_title('Confusion Matrix')
    ax.set_xlabel('Predicted Values')
    ax.set_ylabel('Actual Values')
    ax.xaxis.set_ticklabels(CLASSES)
    ax.yaxis.set_ticklabels(CLASSES)
    plt.xticks(rotation=90)
    plt.yticks(rotation=0)
    plt.show()

    labels = {value: key for key, value in train_batches.class_indices.items()}
    print("Label Mappings for classes present in the training and validation datasets\n")
    for key, value in labels.items():
      print(f"{key} : {value}")

    print(classification_report(test_batches.classes, y_pred.argmax(axis=1), target_names=labels.values()))

  return model
```

Fig. 5. Building the CNN model (Code Snippet).

The function prepares data batches for training, validation, and testing using the "ImageDataGenerator" class from TensorFlow's Keras API. Images are loaded from their respective directories ("TRAIN_DIRECTORY", "VALID_DIRECTORY", "TEST_DIRECTORY") and resized to the specified target size ("IMAGE_SHAPE_2D"). Additionally, the images undergo pre-processing using the "PREPROCESSING_METHOD" function to ensure consistency and compatibility with the chosen base model.

The architecture of the CNN model is then constructed, starting with the pre-trained base model with its top layers removed. Following the base model, as shown in Table I, a custom sequence of layers is added, including a global average pooling layer, a dropout layer for regularization, and a dense layer with softmax activation for multi-class classification.

The model is compiled with the specified optimizer, loss function, and evaluation metrics. During model training, early stopping is implemented, as a sample shown in Fig. 6, to prevent overfitting, with training progress monitored using the validation data.

### *F. Plotting the Model's Performance*

Performance metrics such as training accuracy, validation accuracy, training loss, and validation loss are plotted over epochs to monitor the model's convergence and potential overfitting as a result of building the CNN model from the previous phase. Once training is complete, the model's performance is evaluated using the test data, and metrics such as accuracy and loss are printed to the console. As "measure_performance" is set to "True", additional visualizations and performance evaluations are conducted. This includes plotting the model's accuracy and loss curves over epochs, generating a confusion matrix to visualize the model's performance across different classes, and a classification report summarizing the model's performance metrics. See a sample model accuracy, loss, confusion matrix, and classification report using EfficientNetB0 with RMSprop Optimizer and 1% Learning Rate in Fig. 7, 8, 9, and Table II, respectively.

### *G. Visualize Image Samples*

After the trained model is returned and has provided a comprehensive framework for building, training, and evaluating CNN models for image classification, we have invoked a sample image for visualization to see the certainty of how the model correctly predicts. In this phase, we include displaying the fed original image as well as the predicted label of the sample image, as show in Fig. 10.

## H. Re-training

As the previous phase concludes and observations are made regarding the model's performance, the global variables are adjusted accordingly to explore different configurations and optimize the model further. This adjustment process may involve modifying parameters such as the optimizer and learning rate to experiment with alternative optimization strategies and fine-tune the model's performance. By allowing for the re-training of the models with different optimizers and learning rates, this phase enables us to conduct systematic experimentation and exploration of various hyperparameter configurations.

## I. Evaluation

Based on the re-training of the CNN architectures with Adam and RMSprop optimizers and different learning rates, this section presents the culmination of the iterative process of re-training CNN architectures with Adam and RMSprop optimizers, along with various learning rates. This stage involves compiling and analyzing the results obtained from the re-trained models to compare their performance comprehensively. The metrics include measures of accuracy and loss, which collectively provide insights into the model's classification performance across different classes. We have also included prediction result on a sample image (same sample image in Fig. 10) used across the re-training process.

TABLE III. SUMMARY OF RESULTS ON ACCURACY AND LOSS PER OPTIMIZERS AND LEARNING RATE

| CNN Architecture | Learning Rate (%) | Optimizers | | | |
|---|---|---|---|---|---|
| | | Adam | | RMSprop | |
| | | Accuracy (%) | Loss | Accuracy (%) | Loss |

[c] Wrong Prediction

Table III highlights the performance of different architectures trained with varying learning rates, focusing specifically on accuracy and loss metrics. Among the architectures evaluated, ResNet50 achieved the highest accuracy of approximately 95% when trained with a learning rate of 0.001. On the other hand, EfficientNetB0 exhibited the lowest loss of 0.1868174523115158 when trained with the same learning rate of 0.001.

The observation summarized in Table IV consistently exhibits that some models have relatively higher error rates in distinguishing between certain pairs of disaster scenarios, such as flood and landslide, as well as infrastructure damage and earthquake, which can be attributed to the shared characteristics and visual similarities between these classes. Moreover, the similarity between urban fire and wildfire scenarios further exacerbates also the difficulty in classification.

## V. DISCUSSION

With the result on the performance of the architectures based on Table III, it suggests that ResNet50, a well-established and widely-used architecture, was particularly effective in capturing and learning the intricate patterns and features present in the image dataset which also been supported in the study of Balavani et al. [48] And according to Wu et al., the choice of a lower learning rate of 0.001 likely facilitated more stable and precise updates to the model's parameters during training, leading to improved accuracy [49]. While accuracy measures the proportion of correctly classified instances, loss quantifies the difference between the predicted and actual values, serving as a measure of how well the model is performing overall [50]. As stated in the study of Chandrasekhar & Peddakrishna, a lowest loss indicates that the model's predictions are closer to the true values on average, suggesting better overall performance [51]. In this case, EfficientNetB0, known for its efficient architecture design and superior performance, demonstrated effectiveness in minimizing prediction errors and achieving optimal performance in terms of loss.

Interestingly, the analysis also proves that the choice of optimization algorithm did not significantly impact the model's performance. Both Adam and RMSprop optimizers were used in training the architectures, but neither seemed to contribute significantly to the observed variations in accuracy or loss [52]. This finding implies that other factors, such as the architecture itself and the choice of learning rate, played a more substantial role in determining the model's performance.

As a further observation, classes like flood and landslide may share common visual elements, like water bodies, debris, or altered landscapes, making it challenging for the models to differentiate. Similarly, infrastructure damage and earthquake scenarios may manifest similar visual cues, such as collapsed buildings, rubble, or structural damage, leading to confusion for the models in distinguishing between these classes. Moreover, in urban fire and wildfire scenarios also exhibit same visual characteristics on flames, smoke, or burned landscapes, making it challenging also for the models to distinguish between them accurately [30-32]. This observed behavior intensifies the need of future work that aligns with the inherent complexity and ambiguity present in disaster-related imagery classification tasks.

## VI. Conclusion

Re-training allows for the comparison of the performance of multiple models trained with different configurations. By systematically evaluating and comparing the results obtained from these models, we have gained a deeper understanding of the factors influencing model performance and make informed decisions regarding model selection and strategies. The re-training phase made a continuous refinement and optimization of the models for image classification tasks. Through iterative experimentation and adjustment of global variables, we explored a wide range of configurations, identified optimal settings, and ultimately enhanced the effectiveness and robustness of the models that can be deployed in the iRESPOND system.

Moreover, through this re-training phase, we were able to identify that among the tested architectures, ResNet50 and EfficientNetB0 emerged as the top performers, exhibiting the highest accuracy of 95.95% and lowest loss result of 0.187 respectively, when trained with a learning rate of 0.1%. This finding underscores the efficacy of these architectures in effectively capturing and learning the complex features present in the datasets, thereby facilitating accurate classification within the iRESPOND system. Also, the analysis suggests that the choice of optimization algorithm, whether Adam or RMSprop, did not exert a significant impact on the performance of the models in this context. Despite variations in optimization techniques, the observed performance metrics remained consistent across both algorithms. This finding indicates that factor other than the choice of optimizer, such as the architecture itself and the learning rate, played a more influential role in determining model performance and effectiveness.

In addition, the observed higher error rates in distinguishing between certain pairs of disaster scenarios are logical and expected, given the inherent visual similarities and shared characteristics between these classes. Addressing these challenges requires not only fine-tuning hyperparameters but also exploring advanced techniques such as incorporating contextual information, utilizing ensemble learning approaches, or leveraging domain-specific knowledge to enhance model performance and robustness in image classification.

## Acknowledgment

The authors would like to express their appreciation to Hon. Fernando V. Gonzales – City Mayor of Ligao, and Mr. Rossauro C. Perillo – Dept. Head I of Local DRRMC for allowing the authors to conduct the study in the local government unit and providing pertinent data for this research.

***Abstract*—It was recently proposed to use quantum secure direct communication (QSDC), a branch of quantum cryptography, to secure data transfers from sender to receiver without relying on computational complexity. Despite the benefits of multiphoton, sending secret messages between several parties in a quantum channel still presents a challenge because the current multiphoton only considers two parties. When more parties are included, the scalability problem becomes apparent. Therefore, the scalable multiphoton approach is needed to allow secure sharing between the legal parties. The manipulation of level encoding provides new opportunities for more efficient quantum information processing and message sharing. This research aims to propose a strategy that uses four-level encoding with the multiphoton approach to share secret messages between multi-party. From the analysis conducted, it has been shown that a high number of level encoding can shorten the time taken for photon transmission between parties and an attacker has a lower probability of chances to launch an attack, however, communication will be affected due to high sensitivity to noise.**

***Keywords*—Multiphoton approach; multi-party; level of encoding; scalability; error probability**

## I. Introduction

Quantum secure direct communication (QSDC) is derived from the quantum communication channel and can transfer secret messages without the use of a private key [1]. These are further supported by studies done by [2], [3], which found that no secret key is needed to transport a secret sharing message in QSDC. The fundamental principle of secret sharing is that the secret holder splits a section of complete secret information into many parts and distributes all of them to various participants for keeping [4]. A single individual can't acquire adequate secrets. Complete secret information can only be discovered when everyone cooperates. Decentralized handling of secret information is achieved by secret sharing, which also contributes to minimizing eavesdropping risks while embracing some attacks and mistakes [5]. Furthermore, major applications of the secret sharing protocol include key agreement, secure multi-party computing, and voting systems [6], [7]. In other words, secret message sharing is a method for dividing and distributing a secret message across numerous parties, whereas QSDC provides direct secure communication without a shared secret key. While both QSDC and secret message sharing provide distinct functions in certain circumstances, they can be combined to achieve secure and efficient cryptographic processes.

In the QC field, a single photon transmission per laser pulse is the most fundamental technique. It is challenging to produce one photon per laser pulse. In the worst case, less than one photon will be produced in each time slot by the weak optical beam, and the slots will be mostly empty [8]. Many empty pulses will lower the transmission rate. It is only suitable for short-range communication since it is challenging to make sure that a single transmission photon stays stable throughout a long-distance channel [9]. This is the result of errors like channel loss and network disruption due to eavesdroppers. Due to their poor performance across long distances and their low data rates, single photons are also vulnerable to PNS attacks since they can unintentionally emit more than one photon per time slot. One advantage that multiphotons have over single photons is that they have faster transmission rates and longer photon travel distances [10]. In the multiphoton technique, information exchange is not limited to the presence of a single photon in a time slot. Multiphoton is analogous to sending the same message many times. Any unitary transformation will have the same effect on the photons regardless of how many photons the laser pulse generates as long as they are all in the same phase [10]. Despite the benefits of multiphoton, sending secret messages between several parties in a quantum channel still presents a challenge because the current multiphoton considers two parties. When more parties are included in the quantum network, the scalability problem becomes apparent.

Levels of encoding have attracted attention recently because of their potential use in several branches of quantum information technology, including quantum computing, quantum communication, and quantum cryptography. It is feasible to encode and process more information, as well as carry out more difficult quantum processes, in systems with more dimensions. A qudit, which is a generalization of a qubit to a system with $d$ levels of encoding, is one illustration of a high-dimensional quantum state [11]. A qudit can have more dimensions than a qubit, whereas a qubit is a 2-dimensional quantum state ($d = 2$). The high number of level encoding can differ significantly from qubits in terms of their features and behavior, opening up new possibilities for quantum information processing. Using a high number of level encoding has several benefits. A high number of level encodings have been found to be more resistant to quantum cloning than qubit operations [12].

In this paper, the HMBSS [13] protocol is considered as the main benchmark for the proposed message sharing among multi-party. HMBSS protocol implemented a multiphoton approach for sharing secret messages but only two-party participants. The existing multiphoton approach could not share information between more than two parties. Therefore, the scalable multiphoton approach is needed to allow multiple secure sharing between the legal parties with the idea of integrating a high dimensional quantum state.

The remaining content of the paper is formatted as follows: Section II, a synopsis of related works. In Section II, a potential approach is analyzed. In Section IV, the simulation setup is examined. Evaluation of performance is covered in Section V. The result and conclusion are covered in Section VI. Finally, Section VII discusses the conclusions.

## II. Related Work

QSDC is a sort of quantum communication that transfers data securely through a quantum channel. The multiphoton approach is more sophisticated and offers benefits including high transmission rates and long photon travel distances compared to single photon [10]. The same quantum state can be transferred several times due to information sharing in a multiphoton approach. To increase the chance that the transmission will be successful, a multiphoton can be sent at once to represent a single bit of information.

In 2019, a Hybrid Mary in Braided Single Stage (HMBSS) with a multiphoton approach has been proposed [13]. This protocol uses a compression strategy and a lossless data encoding foundation to reduce the amount of photons needed during the data transmission phase. In 2017, A. Sit *et al* proposed high-dimensional intracity quantum cryptography with structured photons [14]. The protocol encodes information using a single photon. The protocol has demonstrated that, despite a noisy channel, it is possible to increase the secure data transmission rate utilizing high-dimensional quantum states as compared to bidimensional states. In 2018, Y. Jo *et al.* proposed efficient high dimensional with hybrid encoding [15]. Efficient Information Reconciliation for High-Dimensional has been proposed by R. Mueller *et al.* in 2023. Both protocols demonstrate that the proposed viable approach has significantly improved the secret key rate over the 2-dimensional protocol. M. De Oliveira *et al.* conducted an experiment on high-dimensional with spin-orbit-structured photons in 2020, demonstrating a protocol that is easily scalable in both dimensions and enables information sharing between participants [16]. In 2023, C. Sekga et al. proposed a high-dimensional implementation with biphotons [17]. Information is encoded using biphotons in this protocol, and the biphotons are used as qutrits to increase error tolerance. A higher number of levels used for encoding provides high efficiency [16], [18], [19]. The efficiency of communication can be measured by mutual information between the parties involved. The mutual information between parties in quantum communication is an indicator of the shared information between their quantum states. From fidelity, mutual information between parties involved can be calculated. As a result, increasing the dimensionality of protocols certainly has an increased capacity for mutual information [18].

Nonetheless, a few protocols from the mentioned protocol above are just for one-to-one communication. Hence, they do not achieve scalability in terms of the number of parties involved in communication. Therefore, a scalable multiphoton approach is required to enable secure sharing between the legal parties. Other than that, the protocol that implemented a 2-level encoding that will detect the sequence of photons as “00”, “01”, “10” and “11”, will result in a low transmission rate. A low transmission key happens because a lot of photons are lost during the transmission [20]. Next, this protocol also implemented a single photon. Single photons have its limitations [8]. The number of photons that can pass through the quantum channel will be restricted by the laser source's single photon output per pulse. Additionally, it is quite difficult to create one photon for every laser pulse. Less than one photon will be produced by the weak optical beam for each time slot, and the worst-case scenario is that most of the time the slots are empty [8]. A high amount of empty pulses results in a low transmission rate.

All in all, the protocols mentioned have their drawbacks. This paper suggests a Quantum Multiparty 4-level encoding Secret Message Sharing protocol (QM4SMS) with multiphoton to address the aforementioned issues. In this protocol, we provide a 4-level encoding schematic setup with a multiphoton approach to share a secret message between multiple parties over QSDC. We show that different numbers of levels used for encoding, where $d$ is 2, 3, or 4 can fasten the photon transmission. Note that in this paper, $d$ denotes the levels encoding or quantum state's dimension. We also analyzed the total time taken to transmit photons with different levels of $d$. Table I shows the comparison between the mentioned protocols.

TABLE I. Comparison among some Different Level Encoding

| Protocol | *d* | Multiparty | Photons Source | Benefit | Limitation | Performance Metric |
|---|---|---|---|---|---|---|
| HMBSS [13] | 2 | No | Multiphoton | Utilize the Huffman compression technique to reduce memory usage and increase transmission rates by lowering transmission time while retaining message confidentiality. | No authentication procedure is used while exchanging information to guarantee that the message is kept private between parties. | • Total transmission time to encode photons.<br>• Compression ratio. |
| Intracity quantum cryptography with structured photons [14] | 4 | No | Single photon | Extendable over greater distances. | The absence of active wavefront correction and moderate turbulence. | • Secret Key Rate (SKR) |

| | | | | | | |
|---|---|---|---|---|---|---|
| | | | | | | • Quantum Bit Error Rate (QBER) |
| Efficient Hybrid Encoding [15] | 2,3,4,5 | No | Single photon | Protection from side channel assaults against detectors and practicality of the experiment. | Less reliable than measuring device-independent (MDI). | • SKR<br>• Transmission Loss<br>• QBER |
| Spin-orbit-structured photon [16] | 2 & 3 | Yes | single photon | High fidelity. | The inaccuracies are caused by additional flaws in the half waveplates, which cause a minor misalignment in the setup and use of a weak coherent photon source. | • Fidelity<br>• Mutual Information<br>• QBER |
| Efficient Information Reconciliation [21] | 4 & 8 | No | Single photon | Allows reconciliation with high efficiency and minimal interaction. | With higher error rates, the time required for executing the correction increases significantly. | • SKR<br>• QBER |
| DIQKD [17] | 3 | No | Biphoton | Utilized the biphotons as a qutrit to increase the error rate tolerance. | Bell experiments without holes are necessary, making it impossible to realize using current technologies. | • SKR<br>• QBER |

## III. Proposed Protocol

This paper suggests Quantum Multiparty 4-level encoding Secret Message Sharing protocol (QM4SMS) with multiphoton. In the proposed protocol, 2-*d*, 3-*d* and 4-*d* level encoding signals have been implemented with the Huffman encoding. The proposed protocol will employ Huffman encoding to compress the message's source at the sender [13]. The benefit of employing Huffman encoding because it is a lossless compression technique used to send unreadable messages more securely and effectively. Lossless refers to the ability to precisely retrieve the original message from a compressed message stream. QM4SMS will shorten the number of bits and encode it in an unknown format. The Huffman decompression algorithm will be used at the receiver to decode the compressed messages. The Huffman encoding procedure is straightforward. Where the Huffman compression method is used by the sender to protect the confidentiality of the transmitted message. In this study, the message is encoded using the ASCII coding system as bits of 1 or 0. By mapping a certain polarisation angle to the list of bits, encryption is accomplished.

This protocol will take into account how multiparty quantum communication will be implemented. The context of multiparty in the proposed protocol is the number of parties involved in communication, and each of the parties has the same task during the communication. Some of the current protocol counts the third party as multiparty [15]–[17], [21]. Various issues will arise when third a party also known as Trent participates in communications. To fully benefit from multiparty encrypted communication, it is essential to ensure information equalization among the parties. The third party could be considered an eavesdropper. If one of the parties illegally works with the third party, there will be an information imbalance between the parties. It is crucial to rule out the possibility of information imbalance since information equity in multiparty cryptographic communication is so important.

The message is transformed directly into the input quantum state by combining a classic encoder with a quantum encoder. Alice encoder transforms the input signal to the input quantum state, photon *X*. The quantum system then receives the photon *X* and transmits it. The detector will transform the output quantum state at Bob and Charlie as a result.

Fig. 1 illustrates the QM4SMS approach's protocol. To decrease source redundancy, Alice first compresses the message with the Huffman encoding. Alice then used photon polarisation to encrypt the message's bits as 4 bits as we use 4-*d*. This paper suggests 4-*d* because it is the most stable in terms of distance and considerable error rate [15]. An authentication mechanism is required in the initial step to verify Alice, Bob, and Charlie's communication. The Huffman decoding algorithm was then used by Bob and Charlie, the receiver, to decompress and retrieve the original delivered message. Table II shows the angle of encoding that mapped to the bit representation for 4-*d*.

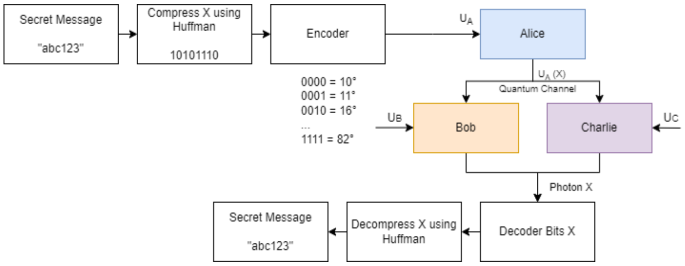

Fig. 1. QM4SMS protocol.

### A. Simulation Setup

The proposed QM4SMS implementations were tested using a Python-based simulation. Python was used because it can represent quantum states mathematically. The proposed QM4SMS was evaluated in comparison to *d*-level encoding. The comparable multi-level encoding was reimplemented to achieve objectivity.

In order for the protocols to function under a similar simulator, this method is carried out using the Python programming language. The QM4SMS protocol was then tested and validated using the same setting of the comparable level encoding, $d$ to show that the suggested approach works as intended. The tested bit size for the comparing multiphoton approaches was 10. For each of the analyzed protocols, the time to convey a small amount of information and the time it takes the half-wave plate to rotate from its initial position to its new position is taken from previous studies [22]. Every eight bits, the half wave plate's update angle or rotation is changed for authentication purposes. The level of security has been enhanced at each stage due to the rapid polarization changes, although it takes longer to send the information. The simulation parameters for this experiment setting are shown in Table III.

TABLE II. ANGLE OF ENCODING AND BIT PRESENTATION

| Angle of Encoding, $\boldsymbol{\Theta}$ | Bits Presentation |
|---|---|
| 10º | 0000 |
| 11º | 0001 |
| 16º | 0010 |
| 21º | 0011 |

TABLE III. SIMULATION PARAMETER [13]

| Parameters | Values |
|---|---|
| Bit size | 10 |
| *d* | 2,3, and 4 |
| Half-wave plate rotation | 20.7 sec |
| Time to send a bit of information | 4.5 sec |

Three steps are involved in the suggested approach which are the encoding, transformation and decoding stages. The suggested protocol has been discussed in detail based on an experiment conducted by Azahari *et al.* [22]:

*1) Encoding stage:* Alice will use Huffman encoding to compress the message. According to the order of the bits, the polarising filter will encode the list of bits, described by a Mueller matrix [23].

$$M_{pol} = \frac{1}{2}\begin{bmatrix} 1 & \cos(2\theta) & \sin(2\theta) & 0 \\ \cos(2\theta) & \cos^2(2\theta) & \cos(2\theta)\sin(2\theta) & 0 \\ \sin(2\theta) & \cos(2\theta)\sin(2\theta) & \sin^2(2\theta) & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \quad (1)$$

The rotation of the polarizer is polarized using Eq. (1) with the angles of the polarizer as shown in Table II.

*2) Transformation stage:* The photons that are polarized with the angles of the polarizer as shown in Table II are then passed through HWP using Eq. (2). The HWP operation's rotation is shown as [24]:

$$M_{HWP} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos(4\theta) & \sin(4\theta) & 0 \\ 0 & \sin(4\theta) & -\cos(4\theta) & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \quad (2)$$

Following is an explanation of the photon transmission process:

The protocol is used to share the $\theta_{initial}$.

Alice generates her transformation using Eq. (3) [13],

$$U_A = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & cos(4\theta_{initial}) & sin(4\theta_{initial}) & 0 \\ 0 & sin(4\theta_{initial}) & -cos(4\theta_{initial}) & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \quad (3)$$

The bits are transmitted by Alice using her transformation. Every 8 bits, the polarisation angles changed to generate $\theta_{next}$.

*3) Decoding stage:* The bits of information that Alice transmitted are retrieved by Bob and Charlie by applying $U_A^T$ to the photon they have just received. The output beam's intensity will subsequently be used by the polarizer to detect the polarisation states. Eq. (4) provides the Malus' law, which allows for the calculation of the intensity's output as describe by [25]–[27],

$$I_O = I_I\, cos^2(\theta) \quad (4)$$

where, $I_O$ is the output intensity $I_I$, is the input intensity and $\theta$ is the encoding or polarization angle for the specific bits. The Malus law is calculated from the top row of polarizers in Eq. (1), which is given by [13],

$$S = \frac{1}{2} \times [1 \;\; cos(2\theta)\, sin(\theta) \;\; 0] \times = \frac{1}{2} \times [1 + cos(2\theta)] \quad (5)$$

where, $S$ is the input bit, Eq. (5) condensed form is obtained as [13]:

$$\frac{1 + cos(2\theta)}{2} = cos^2\theta \quad (6)$$

To analyze the amount of time required to encode the information, a multilevel signal encoding technique was carefully developed and put into use [28], [29]. This protocol uses a signal encoding approach that enables the transmission of many bits of information simultaneously. When numerous bits are conveyed simultaneously, the channel bandwidth can be used efficiently. It has been demonstrated that higher levels of encoding carry more data bits in each transaction. A quantitative measure of the larger information capacity is given by the relation $log_2(m)$ [30] , which returns the number of classical bits needed to encode the same amount of information [7], [31]. As illustrated in Table IV, the degree of signal encoding can be represented as up to $log_2(m)$ bits of information per symbol.

The intensity ranges are utilized to map the output into its bit representation. These intensity ranges are split up such that there is an equal probability of detecting each of all levels [29]. As a result, the angles are selected so that the output will be in the middle of each value range. The increases in dimension or level encoding, the less probability for Eve to launch an attack. Table IV shows the level of encoding and its state representation. In a 4-level encoding, each state corresponds to 2 bits of data. Each state in an 8-level encoding corresponds to three bits of data. Each state in a 16-level encoding corresponds to 4 bits of data. The advantage of multi-level encoding is that it increases the rate of data and channel efficiency by allowing each pulse to carry many bits of information.

Table V and Fig. 2 show that four polarizer state representations, denoted by the numbers 00, 01, 10 and 11, were produced via the 2-*d*. Value 00 of the polarizer state representation corresponds to a 20° encoding angle, value 01 to a 38° encoding angle, value 10 to a 52° encoding angle and value 11 to a 70°. In 2-*d*, each angle has $\frac{1}{4}$ probability for Eve to launch an attack.

Table VI and Fig. 3 show that eight polarizer state representations, denoted by the numbers 000, 001, 010, 011, 100, 101, 110, and 111, were produced via the 3-*d*. Value 000 of the polarizer state representation corresponds to a 12° encoding angle, value 001 to a 23° encoding angle, value 010 to a 34° encoding angle, value 011 to a 45° encoding angle, and value 100 to a 56° encoding angle, value 101 to a 67° encoding angle, value 110 to a 78° encoding angle, and value 111 to an 89° encoding angle. In 3-*d*, each angle has $\frac{1}{8}$ probability for Eve to launch an attack.

TABLE IV. LEVEL OF ENCODING AND STATE PRESENTATION

| **Level encoding (*m*)** | $log_2(m)$ | ***d*** | **Bit representation** |
|---|---|---|---|
| 4-level | $log_2(4) = 2$ | 2 | (00,01,10,11) |
| 8-level | $log_2(8) = 3$ | 3 | (000,001,010,011,100,101, 110,111) |
| 16-level | $log_2(16) = 4$ | 4 | (0000, 0001, 0010, 0011, 0100, 0101, 0110, 0111, 1000, 1001, 1010, 1011, 1100, 1101, 1110, 1111) |

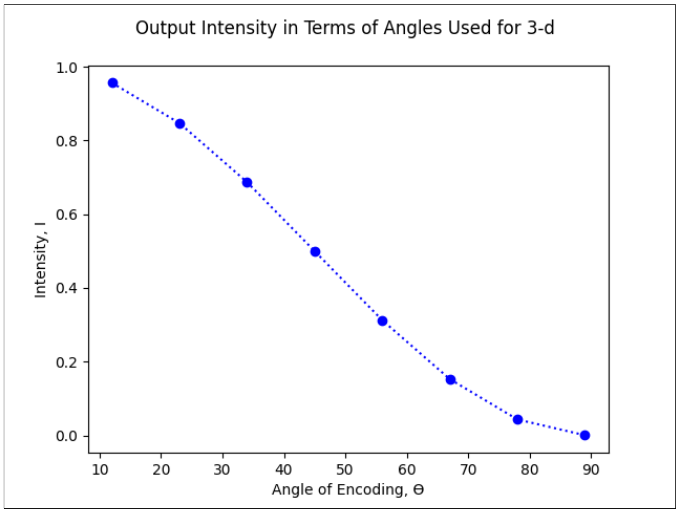

Fig. 3. Output Intensity in Terms of Angles used for 3-d.

The light beam will be received by the HWP at Bob and Charlie, and then the detector will identify the photon sequence as shown in Table VII and Fig. 4. In 4-*d*, each angle has $\frac{1}{16}$ probability for Eve to launch an attack. After receiving all the message bits, Bob and Charlie will use Huffman decoding to decode the compressed bits. The application of transformations must be commutative, which means that only the parties applying them are aware of their existence. In this case, the only setup that has been considered is the HWP of Alice, $M_{HWP}\ (A_{\theta})$. To perform the encryption, Alice will first apply her HWP, and then to reverse the effects of the initial transformation, she will use a similar rotational angle of HWP. The commutative transformation may prove demonstrated as [13]:

$$M_{HWP}\ (A_{\theta}).M_{HWP}\ (A_{\theta})\ =\ I \qquad (7)$$

where, $I$ is the identity matrix,

$$I = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \qquad (8)$$

## IV. Security Analysis

Any quantum communication protocol that requires to be secured from eavesdropping attempts must pass a security analysis, which is a crucial part of the evaluation process. Security analysis is widely used by researchers to evaluate the security requirements of their protocols and ascertain whether an eavesdropper has a chance to be around [32]–[34]. The security analysis is explained in detail.

### A. *Man-in-the-Middle Attack*

Eve poses as the person with authority to get the information during the MITM attack. The MITM attack is demonstrated in Fig. 5.

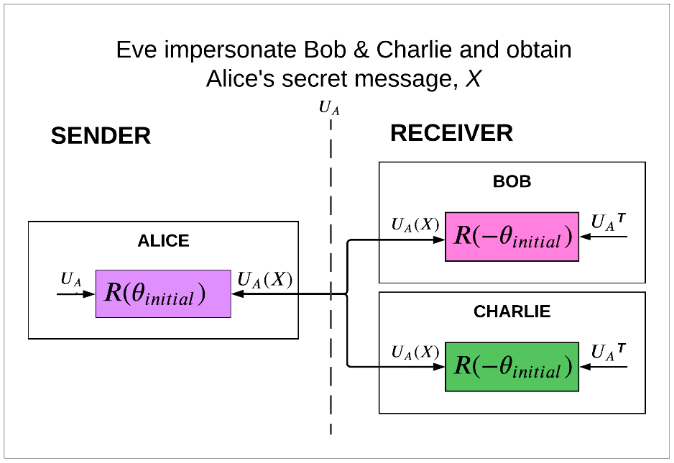

Fig. 5. MITM attack.

Because Eve is unsure of the values of $\theta_A$ and $\Phi$, she tries to send a series of fake messages to the receivers. Both $\theta_A$ and $\Phi$ are secret transformational angles, thus the attacker needs to know both of their values. It is quite challenging for the attacker to determine the precise value because of the secured handshake method used to transmit the information between many parties. Even if Alice gives multiple photons with the same polarisation, Eve cannot get the useful information since a different value of the authentication key is established. Bob can easily decode information $X$ if $\theta_A$ and $\Phi$ are set to the right values. Eve cannot pretend to be an authorized party if she does not know the authentication key. As indicated in Fig. 5, an authorized party will compare the bits to determine whether an MITM attack has been carried out. For example, Eve might interfere with the communication by continuously interfering with the quantum channel, forcing the authorized parties to restart communication.

### B. *Beam Splitting Attack*

In optical set up, polarizing beam splitters (PBS) are essential elements. As an example, BS are used to merge light beams from several sources into a single optical channel and to randomly pick photons in the detecting subsystems, which in turn determines the measurement basis [35]. PBS are almost always present in front of the detectors in the detection units to split light into its vertically and horizontally polarized components as shown in Fig. 6.

Fig. 6 shows that the beam splitter positioned halfway between Alice, Bob and Charlie in this method, allowing Eve to secretly collect photons. However, Eve has little chance of selecting the appropriate photons to measure because the suggested approach is ineffective for this assault. Eve will have trouble determining the hidden polarisation angles because they will never be made public, even if she is able to collect some of the sent photons without alerting Bob or Charlie. To preserve the level of secrecy and establish unconditional security, the angles of polarisation will also be changed after numerous photons have been employed with the mutually agreed-upon secret technique [10], [37]. Additionally, the newly updated keys will prevent information about the keys and communications from being sniffed out by eavesdroppers.

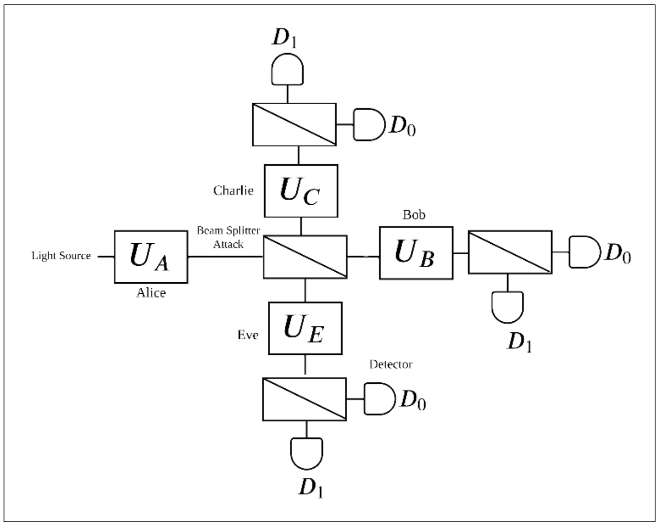

Fig. 6. Beam splitter attack [36].

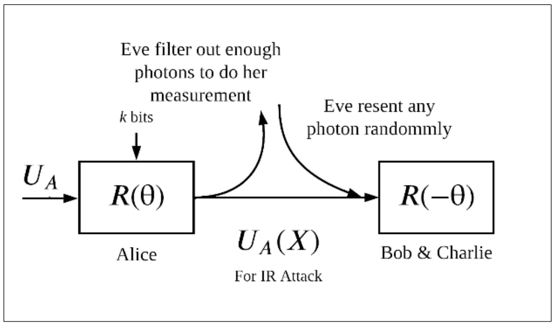
### C. Intercept Resend (IR) Attack

Eve extracts a number of photons that Alice sent and injects the same number of photons into the quantum channel, as seen in Fig. 7.



Eve filter out enough photons to do her measurement
*k* bits
Eve resent any photon randommly
$U_A$
$R(\theta)$
$R(-\theta)$
Alice
$U_A(X)$
For IR Attack
Bob & Charlie

Fig. 7. Intercept resend attack [38].

Fig. 7 illustrates that after Alice has encoded the photons, Eve will try to steal them and replace them with false photons that she has previously prepared. In the proposed E-SSAK protocol, Alice securely and only with Bob and Charlie shares the secret angles $\theta_A$ and $\Phi$. Due to her lack of knowledge of the correct values for $\theta_A$ and $\Phi$, Eve is unable to measure the intercepted photons precisely. Because quantum states are conveyed in what are known as non-orthogonal states, Eve has limited access to any relevant data. The polarisation angles of photons and security codes create the non-orthogonal quantum states. Additionally, Eve's attempt to figure out the superposition states during the message transformation stage may result in any non-orthogonal states. As a result, no details regarding the polarisation angle are discovered. If Eve was successful in intercepting the sender's sent photons, she will send the photons back to the receiver after doing the measurement. But because Eve is unaware of the polarisation angles and authentication keys that the authorized parties have established, she is unable to breach the protocol. By way of illustration Alice uses the authentication key to encrypt a quantum state of $\psi\rangle = |0\rangle$, in $0^0$ of a HWP. Eve won't be able to get the $|\psi\rangle$ since she lacks both the secret polarisation angle and the authentication key. Eve must correctly identify two hidden angles in the suggested protocol. Eve can be recognized if her polarisation angle differs from Alice's and Bob's keys. Since this protocol employs bit-by-bit authentication, Eve cannot examine the statistics of the several photons she receives during her attack without running the risk of being discovered. Eve's attack can be revealed since Alice, Bob and Charlie's measurements on the fake bit differ from those on the actual one.

## V. Performance Evaluation

More bits of information will be sent at once with a higher number of levels used for encoding. For example, 2-*d* encoding sends 2 bits at a time, 3-*d* encoding sends 3 bits at a time, 4-*d* encoding, sends 4 bits at a time. The performance of the following evaluation criteria will be used to gauge the success of the simulation experiment.

### A. Total Time Taken, T

The QM4SMS protocol was carefully designed and implemented to analyze the time taken to encode the information. Faster transmission times result from increased bit capacity whenever the encoding level is raised. Therefore, it is believed that the transmission process as a whole will significantly improve [22]. Total transmission time includes the time required by HWP to change angles for the transmission of 8 bits of information, which is represented by $T_{HWP}$ , as well as the time required for multiphoton transmission through a quantum communication channel, which is $T_{msg}$ . The time is expressed in seconds. The calculation is made using Eq. (11) as determined by [24].

$$Transmission\,Time = T_{msg} + T_{HWP} \tag{9}$$

A higher number of levels used for encoding will decrease the total HWP turning time required to complete each information transmission process. Therefore, it is believed that the HWP turning time will decrease and contribute to an efficient overall process [13].

### B. Noise Tolerance

Most protocol assume the quantum channels to be perfect. However, in a practical implementation, noises in the quantum channel will affect the particles. The security of the suggested protocol in the noisy quantum channel is examined.

Assume that Eve is able to communicate with any party on an ideal channel. Eve performs the intercept-and-resend attack on the qubits being sent from Alice's side to Bob's side in order to obtain Bob's shadow key. She then transmits the intercepted qubits to Bob's side via an ideal channel she has created. Eve may be able to blend her attacks into the quantum channels' background noise by using this strategy [39].

Nevertheless, raising the level of encoding to enhance computing resource comes at a price of increased sensitivity to noise [40].

## VI. Result and Discussion

The simulation aimed to investigate the impact of different number of level encoding on total time taken to transmit photon and total received photon with noise.

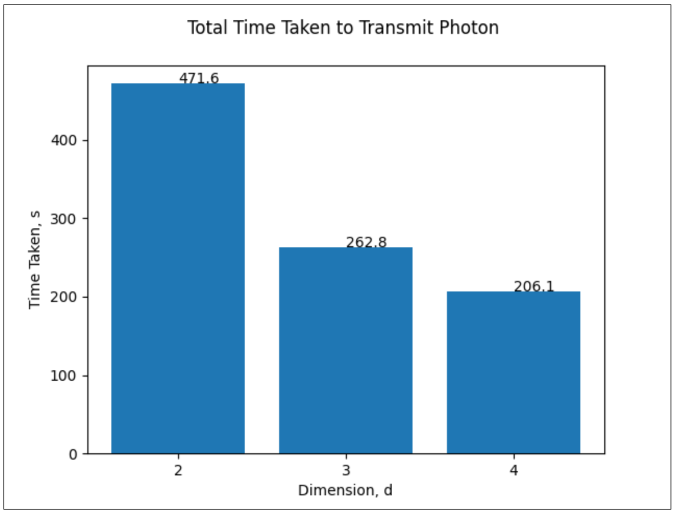


Fig. 8. Total time taken to transmit photon.

Fig. 8 shows the total time taken to transmit photons with different numbers of levels used for encoding, *d* = 2, 3 and 4. The bar chart above shows a decrease in the time taken to transmit photons when the number of levels used for encoding increases. The 4-*d*, which transfers 4 quantum bits at once, has the fastest photon transmission rate, 206.1 seconds. This is followed by the 3-*d*, which transfers 3 qubits at once, 262.8 seconds, and the 2-*d*, which transfers only 2 qubits at once, has the slowest photon transmission rate, 471.6 seconds. It has been demonstrated that higher levels of encoding can carry more information during each transaction which can speed up the time taken to transmit photons, as stated in [39].

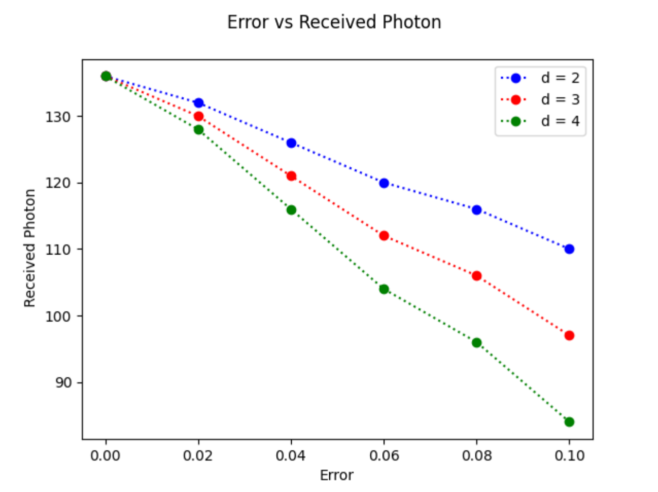

Fig. 9. Total received photon with noise.

Fig. 9 shows the total received photon under the error probability of noisy channels with different levels of encoding. The line graph above shows a decrease in received photons in noisy channels when the size of the level of encoding increases. As can be shown, 4-*d* is beneficial when the error probability of noise is smaller than 0.04. In 0.10, 2- *d* received a higher number of photons than 4-*d*. This is because 4-*d* holds and also loses four quantum bits at once. Compare to 2- *d* which only holds two quantum bits at once and loses 2 quantum bits. It has been demonstrated that the high number of levels used for encoding can carry more information and also lose more information at once, as stated in [29], [40].

In this paper, our benchmark protocol is HBMSS. This is because HMBSS implemented a multiphoton approach in secret message sharing over QSDC and the use of optical devices such as half-wave plates [13]. The other mentioned protocol in Table I was not used as a benchmark because they did not implement optical devices. Nonetheless, this protocol is just for one-to-one communication. Hence, HMBSS does not achieve scalability in terms of the number of parties involved in communication. Therefore, a scalable multiphoton approach is required to enable secure sharing between the legal parties. Other than that, the HMBSS protocol implemented 2-*d*. Which resulted in a low transmission rate. Table VIII shows a comparison of benchmark protocol.

TABLE VIII. Comparison of Benchmark Protocol

| **Characteristic** | **HBMSS** [13] | **Proposed Approach** |
|---|---|---|
| Number of levels used for encoding, *d* | 2 | 4 |
| Quantum Cryptography | QSDC | QSDC |
| Multiparty | No | Yes |
| Total time taken (sec) | 471 | 206 |
| Photons | Multiphoton | Multiphoton |

## VII. Conclusion

In conclusion, we presented a new arbitrary protocol that analyzes the performance of the four-level encoding protocol based on sharing the secret message between multiparty by integrating the applications of multiphoton as the information carrier with the QSDC. Information can be exchanged effectively across quantum channels directly using quantum secure direct communications (QSDC). With faster transmission rates and longer photon travel distances, the multiphoton technique is an improved version of the single-photon strategy. Eve has a smaller chance probability to launch an attack when the number of levels used for encoding is increased. High levels of encoding are used in the setup to increase the efficiency of communication since they are more resilient against eavesdropping and could hold more information. We also analyzed the proposed protocol and showed the total time taken to transmit photons when using a high-level encoding. This is because the higher the level of encoding, the more it can transfer or carry quantum bits at once which can speed up the time taken to transmit photons. This paper proves that increasing the level of encoding will provide higher mutual information between the parties involved. Unfortunately, because high-level encoding can hold a lot of information, it also means that a lot of information will be lost under the error probability of a noisy channel. In conclusion, a high number of levels used for encoding brings advantages to quantum cryptography and have its limitation. We believe that high-level encoding and multiphoton approach among multiparty will play an important role in the next quantum technological leap and overcome the noise as future work.

## ACKNOWLEDGMENT

This research was supported by the Ministry of Higher Education (MOHE) through a Fundamental Research Grant Scheme (FRGS/1/2021/ICT11/UTHM/03/1). We also want to thank the Government of Malaysia which provides the MyBrain15 programme for sponsoring this work under the self-funded research grant and L00022 from the Ministry of Science, Technology and Innovation (MOSTI).

***Abstract*—Transactional data processing is often a reflection of a consumer's buying behavior. The relational records if properly mined, helps business managers and owners to improve their sales volume. Transaction datasets are often rippled with the inherent challenges in their manipulation, storage and handling due to their infinite length, evolution of product features, evolution in product concept, and oftentimes, a complete drift away from product feat. The previous studies' inability to resolve many of these challenges as abovementioned, alongside the assumptions that transactional datasets are presumed to be stationary when using the association rules – have been found to also often hinder their performance. As it deprives the decision support system of the needed flexibility and robust adaptiveness to manage the dynamics of concept drift that characterizes transaction data. Our study proposes an associative rule mining model using four consumer theories with RapidMiner and Hadoop Tableau analytic tools to handle and manage such large data. The dataset was retrieved from Roban Store Asaba and consists of 556,000 transactional records. The model is a 6-layered framework and yields its best result with a 0.1 value for both the confidence and support level(s) at 94% accuracy, 87% sensitivity, 32% specificity, and a 20-second convergence and processing time.**

## I. Introduction

Data connotes everything we can manipulate [1]. It can exist in structured and unstructured forms. During processing, data can be tracked as it mutates from one form to another [2]. It can also be quantified or mined by removing unwanted feats therein (i.e. noise) [3], and analyzed to reveal its hidden relations and patterns [4]. Informatics processing needs has today transformed our society [5] with tools that advance effective resource sharing with its inherent benefits [6]. These also yield a range of threats and complications to the normal operations of systems deployed to ease living at every frontier [7]. With the advances in Internet penetration, businesses constantly decentralize [8], as means to reshape/refocus her processes via data warehousing, to ease transaction accessibility and availability [9]. Business owners have become aware of their responsibilities to consumers [10], and the management of business transactions that now heavily rely [11] on their capacities to adequately manage transactions of all forms with its allied processes [12].

Transactions are processed via two modes namely: (a) batch processing that allows a large volume of transactions processed simultaneously [13], making it more economical. E.g. include bill/report generation [14], credit-card transactions [15], image processing, etc. [16], and (b) real-time processing allows many consumers to process and simultaneously perform a variety of transactions [17]. Also termed stream processing [18], examples include point-of-sales unit [19], online purchase and ticketing, reservation [20], and traffic controls [21], etc.

With the daily volume of data generated [22], it is critical to find better ways to effectively retrieve patterns from processed data and to unveil hidden relations in stored repositories [23]. This quest of mining meaningful data requires in-depth analysis with decision-making skillsets [24] that can only be efficiently achieved via mining [25]. Classifying transactional stream data [26] – is rippled with a range of issues including (a) the infinite length-size of data for continuous, real-time transactions with no bounds [27], (b) concept drift is an issue for which a consumer shifts decision to purchase an item [28], (c) concept evolution for which a new product acts as a close-substitute/replacement to a class of old products [29] to evolves a data stream, and lastly, (d) feature evolution in which various data-streams for newer product feats occur regularly, and such instances occurs with the corresponding increase in the data-streams due to the increase in the product replacement feature [30].

Big data often refers to a large collection of data consisting of (un)structured data [31], stored in a repository/warehouse [32]; It requires a more critical, authentic-time investigation in a bid to reveal the relations between the data items. This helps us to better understand the varied levels of abstraction [33] and in-depth knowledge patterns that can be revealed behind various hidden values in data as they are stored in repositories [34]. The nature of many basket tasks is that the transactions are handled in real-time making it apparently tedious and quite difficult to manage [35]. With such transactions, items are either purchased alone, or as a combination of itemset(s) to form a basket [36]. Thus, storing and managing such data, yields a plethora of issues ranging from concept evolution, feature evolution, infinite data length, and concept drift [37].

Many online shops yields mobile smart device users – a basket experience for which items are purchased directly from (in real-time) [38] via an online shop or platform. Thus, such physical acquisition of items is said to be a purchase from an e-store, web shop, virtual shop, or online shop via a market basket [39]. Thus, it becomes imperative to employ data mining in extracting useful data from such a voluminous amount of data [40]. A consumer can make a series of purchases – and these can also yield an infinite number of changes in the buyer's preferences over time – called concept drift in the consumer's purchasing pattern or behavior [41].

These benefits are not without challenges, and it include (but not limited to): (a) there is a great need to find better means to handle the daily, continuous volume of data generated [42] – as many of these data can either exist in either their structured [43] or unstructured formats [44], (b) previous studies on data stream classification modes – have sought to address the issues of conceptual drift and infinite length challenges with little success [45]. It is found that such models often employ apriori mode and frequency growth patterns in the transactional data stream [46]. But, in cases where the model has used association rule mining – they have often assumed transactional data [47] are stationary, which is not the case, and (c) the assumed stationary nature of transactional data does not yield the required flexibility [48], robustness, and adaptiveness needed for association rule method [49] to be used in resolving the inherent issues of both features evolution and concept evolution as rippled across transaction data streams.

Our study explores germane theories of consumer purchase patterns fused with association rule mining (on the one hand), and fused with frequency growth pattern (as hybrid framework and method) to address the inherent issues with concept evolution, concept drift, and feature evolution amongst itemset basket placement; These, and other complications as present in the basket transaction data streams – are challenges that the study wishes to address.

Section I introduces the study with a view to unveiling the meaning of data, big data, transactions and others. Section II details the problem formulation in handling transactional data streams and expressing the issues of feature evolution, concept evolution and concept drift with itemset (basket data analysis) as well as leveraging a variety of consumer purchasing pattern theories. Section III details result found as evidence to support the decision during discussions of the findings, and conclusion.

## II. Methods and Materials

### A. Problem Formulation

A market basket problem can be defined as a search for joint values of variables in X = ($x_1$, $x_2$, …, $x_p$) with the highest frequencies in binary-valued data. The variables $X_n$ represent consumer purchases transactions [50] – and are usually a total of all itemsets sold by a store. The observation with each variable $x_k$ is assigned one-of-two values (0 or 1) [51], and represented as in Equation 1 [52] below:

$$X_{ok} = \begin{cases} 0, if\ no\ purchase\ or\ transaction\ is\ made \\ 1, if\ k - item\ is\ purchased\ in\ a\ transaction \end{cases} \quad (1)$$

Variables that are frequently purchased together have a joint value of 1. And, ensures the inventory system is automatically updated for re-stock [53], cross-selling [54], shelve and product placement cum location [55], catalog design, cross-marketing sales promotions, and consumer segmentation on purchasing on [56]. If we represent each purchase by the consumer using x1, x2, etc as binary variables respectively [57]; Then, mining the data will seek to find a subset of integers $K$ = {1-to-N} [58] such that as the dataset becomes large, Eq. (2) holds true as thus [59]:

$$P\left(\prod_{k\epsilon K} \{X_k = 1\}\right) \quad (2)$$

K represents an itemset (i.e. the number of items in a basket or cart), and N is the size of an itemset. The probability that agrees with Eq. (2) is called a support S of the itemset K, which is computed as in Eq. (3) [60]:

$$z\left(\prod_{k\epsilon K} \{X_k = 1\}\right) = \frac{1}{N} \begin{cases} N \\ \Sigma \quad \prod_{o\epsilon K} X_{ok} \\ o = 1 \end{cases} \quad (3)$$

The observations $o$ for which $\prod_{o\epsilon K} X_{ok} = 1$ contain k-items [61]. With a lower bound value of l, the basket algorithm seeks all itemset *kl* with support greater than this lower bound l (i.e. {$Kl$ │S(Kl ) > l} [62]. This yields the model in Eq. (3), and also represents our formalization of the market basket problem [63], which consists of the following, and agrees with [64]:

*1) First*, frequency of purchased itemset is determined and analyzed using a given threshold value [65] – calculated as the Cartesian product of all similar items Xn. If its support is greater than the established lower bound as in Eq. (3), the algorithm halts and recommendations are suggested to the customer [66].

*2) Secondly*, if a consumer purchases an item, the system provides similar itemsets, and also recommends the same for other customers with similar purchasing patterns [67].

### B. Basket Transaction Theoretical Frameworks

To resolve the issue(s) – association rule mining is used on transaction dataset(s) to generate numerous itemsets that yields the purchasing behavior for various customers [68]. We thus, adapt the theories below and their corresponding relevance thus:

*1) The* theory of Reasoned Action emphasizes behavior that is dependent on a consumer's attitude, behavioral choices, and public opinion [69]. It thus implies that a consumer's decisions to purchase is constantly influenced by his/her intents, choice, and personal beliefs. All of which, aligns with Fig. 1 [70]. The theory's relevance is such that a consumer can purchase item(s) if presented with specific expected results. S(he) can also change his/her decision, which in turn will yield attitudinal changes in relation to his/her trust and confidence about the item [71]. These are shocks gained from either experience, or can result as the influence on a consumer by friends with precious data about the product; Which, in turn – yields a concept drift [72]. It thus, ensures that a consumer's action is based on purpose – making each consumer more rational as his/her choice is poised to serve their best interest and intentions [73], which agrees with [74].

*2) Planned* Behaviour Theory states that attitude towards a behavior, subjective norms, and perceived control often shapes a consumer's behavioral intents and in turn, his/her actions. This theory improves the analytical capability of reasoned actions via the perceived control of behaviors. Since not all behavior is subject to a consumer's control – it is expedient we add perceived behavioral control which implies that irrespective of the action taken – a consumer's behavior is determined both by attitude, subjective norm, and their perception/firm belief they are in control [76].

*3) Engel,* Kollet, and Blackwell extends the reasoned action by focusing on the consumer's mental state before his/her decision to purchase [77]. It bolsters the reasoned action through a planned set of behaviors [78] as thus: (a) that a consumer absorbs advertised information and knowledge as presented by the vendor [79], (b) that a consumer may process the retrieved knowledge about a product, and also can leverage on previous experience to compare between the observed versus expected outcome [80], and (c) that a consumer decides either to accept or reject the purchase of an item [81] – yielding a choice or decision reached from balanced insight through mental synthesis. Thus, with data input as its greatest prize [82] – the product manufacturers must equip managers with adequate knowledge in place of the product line that will eventually drive consumers to keep buying the item; And in turn – this will shore up and push up sales volume of the product [83]. This theory unveils the underlying feats that may cause purchase shift in the consumer behavior [84] – such that where and if a consumer is not adequately informed, s(he) can reject the purchase of an item as means to normalize with the online data cum knowledge available [85]. Thus, external shocks (i.e. friends, item review ratings etc) can or may influence a consumer choice and decision to either accept or reject the purchase of a product [86].

*4) Impulse* Theory – Here, purchase decisions are influenced by an impulse to suddenly buy a product; thus, such buys do not serve any purpose. They are grouped into (a) pure impulse, (b) reminded impulse, (c) suggested impulse, and (d) planned impulse (if the consumer knows the item they wish to buy – even if they are unsure of it). Its relevance is that it yields an irrational behavior pattern in purchase drift; But, it embellishes the marketability of the product – from packaging and displays over the shelf with greater emphasis laid on the various attributes of the product such as its cost, etc. These influence a buyer's impulse – and note that n electronic description of the product should be sensitive enough to trigger such purchase drift on the consumer to like and accept the product – irrespective of their premonitions [87].

Our framework hinges on the relations between various components in transaction analysis – emphasizing consumer purchasing-pattern. The issues of feature and concept evolution arise from the manufacturer's quest to meet consumer needs and buying patterns; and in turn, yield concept drift [88]. To resolve these, association rule mining is carried out on a transactional basket (appropriate) dataset to generate a variety of itemsets (basket) that adequately represents a consumer buy pattern. It justifies our adoption of the adapted consumer behavior theories as in Fig. 1, with adopted TRA/TPB that directly explains our research problem. To derive meaningful data via these theories, we visualized the consumers' behavior to help us resolve the issue of concept drift.

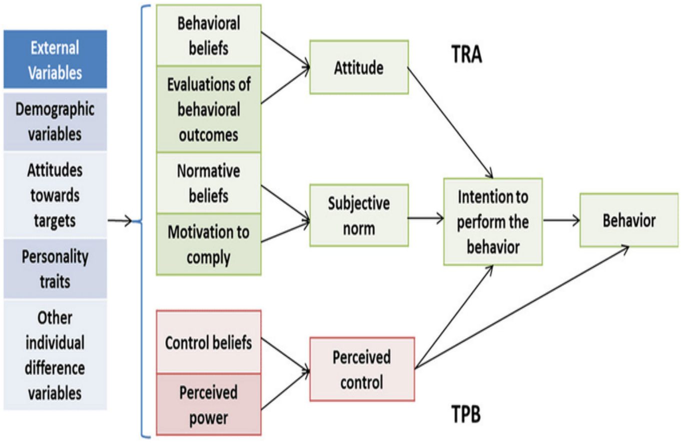

Fig. 1. The reasoned action theory with its various components (Source: [75]).

## C. Data Gathering / Sample Population

The dataset was retrieved from Roban Stores, and contains about 982,980 records – representing transactions for the period of 18 months (i.e. 2017-2018). Training records for framework have the selected features as: (a) basket itemsets, (b) unit price, (c) item quantities, (d) total itemset price, (e) invoice number, and (f) date of transaction. These were adopted to address the issues of concept drift for each consumer, and for each of the requisite transaction.

Dataset consists of consumer profiles with demographics (i.e. age, sex, and status) as seen in Table I – all of which aid in studying the customer buying pattern and behaviors.

## D. ItemSet Data Description

The Roban Stores (RS) transaction data contain itemsets (of single and combined itemset purchases as a basket). An itemset as used here, describes data-streams measures and dimensions. Example description of the dimensions for bread as snacks:

**ItemSet Description for** RS.Snacks

```
RS Bread.Snacks
Bread,Snacks = RSB_E ∩ RSB_W ∩ RSB_F ∩ RSB_M
For Each Selected Bread.Snack do
    RSB_E.Bread.Snacks = ES ∩ EM ∩ EL
    RSB_W.Bread.Snacks = WWB ∩ SFWB
    RSB_F.Bread.Snacks = FM ∩ FLS ∩ FLUS
    RSB_M.Bread.Snacks = MS ∩ MLS ∩ MLUS
End For Each
```

The semantic library has the following keys with the bread category grouped into three (3) as thus:

RSB_E = Roban_Stores Bread Enriched-set (ES, EM, EL)
= Enriched small, Enriched Medium, Enriched large
RSB_W = Roban_Stores Bread Wheat-set (WWB, SFWB)
= Whole wheat bread, sugar-free wheat bread
RSB_F = Roban_Stores Bread Fruit-set (FM, FSL, FLUS)
= Fruit Medium, Fruit large (sliced/unsliced)
RSB_M = Roban_Stores Bread Malt-set (MS, MLS, MLUS)
= Malt Small, Malt large (sliced/unsliced)

TABLE I. DATASET DESCRIPTION, DATA TYPES, AND FORMAT

| Features | DataType | Format |
|---|---|---|
| Invoice_Number | Long Int. | 1234 |
| Quantity | Short Int. | 1234 |
| Unit Price | Float | 123.45 |
| Transaction Time | Time | D:M:Y |
| Weekly Transaction | Int | 1234 |
| Monthly Transaction | Int | 1234 |
| Freq. Trans. Types | Int. | 1234 |

### E. Association Rule Mining Calibration

To ensure that only accurate data is processed, we needed to calibrate the association rule mining for each basket using Hadoop tableau visualizer for Calibev and Hovritz-Thompson estimator. It ensures that only appropriate rules for transactions are generated via the frequent-pattern growth algorithm [89]. The generated rules are analyzed using RapidMiner v8.1 and were used to effectively calibrate the customer profile dataset via the simple random sampling without replacement (srswor) distribution as in the algorithm listing 1.

The algorithm listing 2 extends customer profile calibration via random sampling without replacement (srswor) distribution for the bread itemset combination.

**Algorithm 1:** Calibrate data variables in each stratum

```
Cat (“stratum 1/n”): Stratum 1
data1 = data{data$element==’a’,}
x1 = x{data$element==’a’}
total 1 = calib(t(resp(1, n_row(data1))) %*%X1)
sr1 = sr{sr$stratum==1, }
xs1 = X[sr1$ID_Bread.Snacks]
d1 = 1/(sr$prob*sr1$prob_resp)
g1 = calib(Xs1, d1, total1, method = “linear”
check calibration (Xs1, d1, total1, g1)
$report
[1] “calibration is done”
$result = [1]true
$value = [1]1e-06
Cat(“stratum 2/n”): Stratum 2
data2 = data{data$element==’ab,}
x2 = x{data$element==’b’}
total2 = calib(t(resp(1, n_row(data2))) %*%x2)
sr2 = sr{sr$stratum==2, }
xs2 = X[sr1$ID_WWB]
d1 = 1/(sr$prob*sr1$prob_resp)
g1 = calib(Xs2, d2, total2, method = “linear”
check calibration (Xs2, d2, total2, g2)
calibration cannot be done → max estimate is given by ‘value’
$report=NULL
$result = [1]false
$value = 1
```

**Algorithm 2:** Calibrate 1 with strata

```
Xs = X [sr$IDBread, ]
d = 1 / (sr$prob * sr$prob_resp)
Compute: $g = calib\ (Xs, d, total, method = "linear")$
For Each Selected Parameter to Calibrate do
    1. summary (g)
    2. output → w = d * g
    3. check calibration (Xs, d, total, g)
    4. $report
    5. [1] “the calibration is done”
    6. $result = [1]true
    7. $value = [1]1e-06
End For Each
```

Fig. 2 shows the architecture employed towards resolving the issues of concept drift, feat evolution, and concept evolution for basket analysis. It comprises of six-data-layers as adapted from the elixir architecture – incorporating these ingestion, collection, processing, visualization, sources, and storage. The collection and ingestion layers have been combined to form the pipelining layer [90].

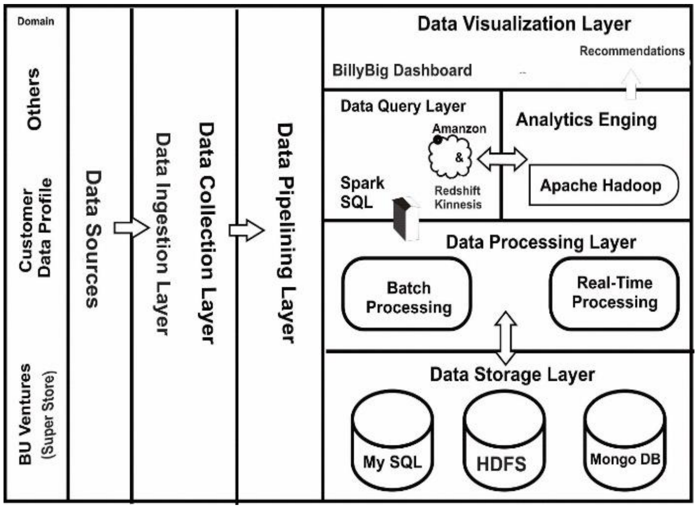

Fig. 2. Architecture for the transaction data streams.

## III. RESULTS AND FINDINGS DISCUSSION

### A. Performance Evaluation of the Framework

We used three (3) types of tests as below [91]:

1) *Alpha* testing helps a programmer identify errors in the product before its release for public use. It focuses on finding weaknesses before beta tests and seeks to ensure users employ black-box/white-box testing modes.

2) *Beta* test is before the release of software for commercial use. It is usually the final test and often includes program system distribution to experts – seeking means to improve on the product. We sent the product to the store for the beta test [92].

*3) Unit* testing often requires individual units or components of software to be tested. This phase/stage of software development often seeks to corroborate and ensure that each part of the software performs according to its design specification. The smallest testable part of any software is known as the unit test. It has few inputs with a single output [93].

Tables II and III respectively show the summary result of both the alpha tests and unit testing for the various execution time taken to yield the requests.

Table II shows that the performance of Frequency-growth pattern (FP) using the minimum support value of a 0.1, and a confidence level of 0.1. This yields and shows that 0.79 (i.e. 79%) of consumers preferred to buy bread and drinks throughout their transactions as analyzed. And, average convergence time it took for the algorithm to compile was within 20 seconds.

Table III shows performance of the Apriori ARM algorithm using minimum support of 0.1 and a confidence level of 0.1, which shows that 79% of consumers preferred buying bread and drink of the entire transactions analyzed. And the time it took for the algorithm to compile was within 26 seconds.

TABLE II. RESULT OF THE FREQUENT-PATTERN GROWTH ALGORITHM

| Association Rules | Support Level | Confidence Level | Execution in Secs |
|---|---|---|---|
| DM Enriched Large Bread, DM Whole Wheat Bread → 7UP Pet Drink 50CL | 0.026 | 0.194 | 18secs |
| DM Fruit Malt Bread, DM Enriched Cake Bread Large → C-Way Peach 500ML | 0.006 | 0.214 | |
| DM Enriched Large Bread; DM Enriched Cake Bread Large → Nutella Ferroro Hazelnut Spread 350g | 0.006 | 0.214 | |

TABLE III. RESULT OF THE ASSOCIATION RULE MINING ALGORITHM

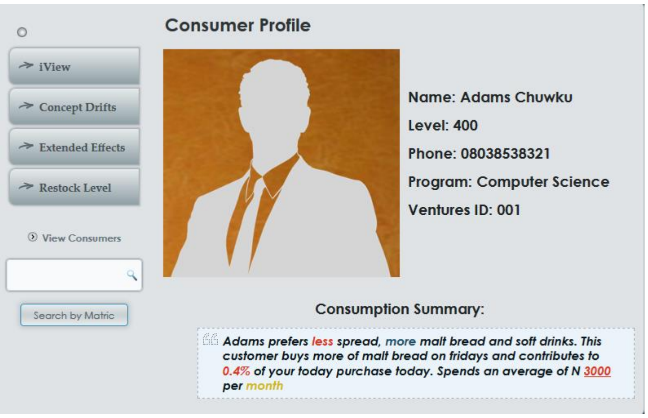
| Association Rules | Support Level | Confidence Level | Execution in Secs |
|---|---|---|---|
| DM Enriched Large Bread, DM Whole Wheat Bread → 7UP Pet Drink 50CL | 0.062 | 0.294 | 26secs |
| DM Fruit Malt Bread, DM Enriched Cake Bread Large → C-Way Peach 500ML | 0.009 | 0.412 | |
| DM Enriched Large Bread; DM Enriched Cake Bread Large → Nutella Ferroro Hazelnut Spread 350g | 0.009 | 0.412 | |

## *B. Result Findings: Analysis of Consumption Pattern*

Fig. 3 shows the itemsets summary frequently purchased by a consumer, his/her consumption pattern, and how much in revenue percentage such consumer has contributed to the store using our consumption history. This analysis can be tracked to display (the daily, weekly, and monthly averages) consumption and spending pattern of each consumer.

Fig. 4 – iView shows a snippet of all selected objects and their status at the time of viewing the analysis report. It yields a consumer frequency of purchased itemset(s) with a live-stream analysis of various transactions. The iView aids managers to track, view and trace each transactional object property in real-time (i.e. s(he) can do this as new transactions trickle in and as transactions data streams change).

To view the data-stream reports, the manager logs in to view the object summary visitation frequency and spending. It shows the summary of how frequently consumers visit the store and is tracked daily, weekly, monthly, and/or annually). And this agrees with [94].



Consumer Profile

Name: Adams Chuwku
Level: 400
Phone: 08038538321
Program: Computer Science
Ventures ID: 001

Consumption Summary:

Adams prefers less spread, more malt bread and soft drinks. This customer buys more of malt bread on fridays and contributes to 0.4% of your today purchase today. Spends an average of N 3000 per month

Fig. 3. Summary analysis of an individual’s consumption.

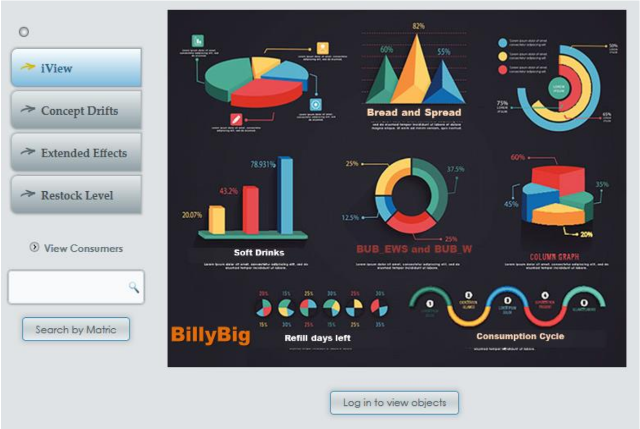


Fig. 4. Analysis of consumer consumption history.

Fig. 5 shows the concept drift – and by extension, the consumer's consumption pattern summary for itemsets either in single or combination that is purchased together. As with our example in the report, we see the itemset combination of bread and drink was more than any other.

Fig. 6 shows restock option (that is, percentage) of all the item(s) currently left in the inventory. These are automatically updated with each consumer transaction, and in turn – reduce the error encountered with the traditional mode of inventory restocking and stock-taking, currently available in the store.

## *C. Discussion of Findings*

Results show that the association rule mining trained with the frequent-pattern growth algorithm performed better than the Apriori algorithm (with transactions generated on the frequency of itemsets purchased). The frequent items represent consumer purchasing patterns and behavior for the system being modeled. With association rules (mined/generated) – the framework seeks to induce the basket analysis to study consumer purchasing patterns and their frequency over time by resolving the issues of concept drift, concept evolution, and features evolution inherent in real-time transaction data streams [95].

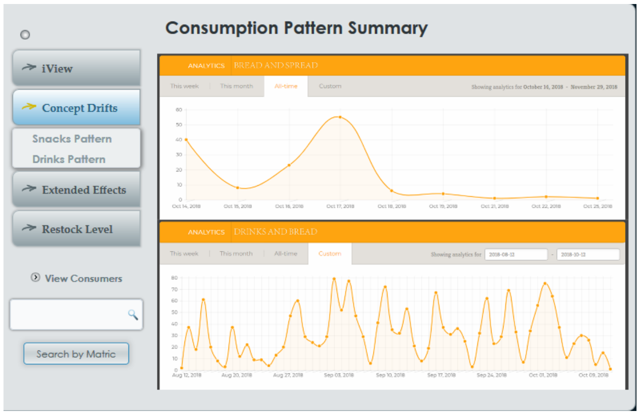

Fig. 5. Concept drift consumption summary for itemset.

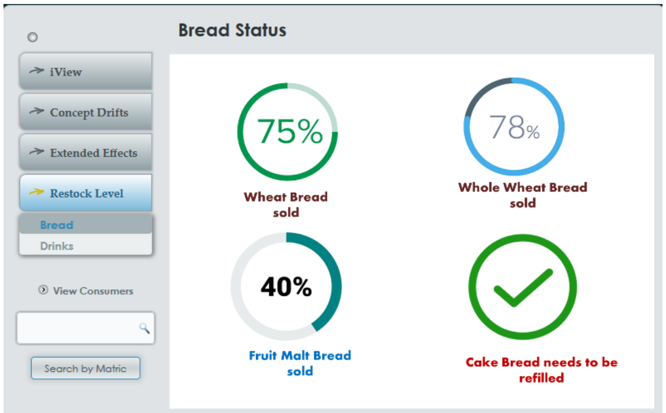

Fig. 6. The Restock module with the percentage of the item(s).

This study agrees with [96] in provisioning consumer buying theories that sought to recognize reasons that contribute to a consumer's decision to purchase an itemset or product. These theories formed the basis to resolve the challenges presented in data streams by concept drift and its association with basket analysis – which previous studies did not try to resolve [97]. The study notes that to resolve the issues of concept drift with market baskets analysis – it is critical to use an enormous volume of transactional stream datasets [98] collected over time. This will help the proposed system train the association rules to accurately predict the consumer purchasing/buying pattern cum behavior [99] – even with the occurrences of a drift. The study agrees with [100] in our use of big-data analytics tools such as Spark to study customer behaviors in market basket analysis.

## IV. Conclusion

In resolving the issues inherent in transaction data streams for real-time processing and concerning its use with market baskets – it is imperative to use multiple sources of the dataset to effectively visualize a consumer's drift to purchase item(s) and products within a store over a period. The model yields the best result with a 0.1 value for both the confidence and support level(s) at 94% accuracy, 87% sensitivity, and a specificity of 32% with a 20-second convergence and processing time. Our framework's data visualizer displayed both the consumer's consumption pattern vis-à-vis the inventory stock with the consumer's profile. Such data have been found to provide and yield new means to a transaction that could be stored on other databases for retrieval and further studies such as the Amazon RedShift.

***Abstract*—Ontology, serving as an explicit specification of conceptualization, has found widespread applications across various fields. Business Model Ontology (BMO) stands out as a prominent ontology, especially in the domains of business and entrepreneurship. This study employs the narrative literature review method to delve into the Ontology Development Method (ODM). By identifying commonalities among various ODMs and drawing insights from the BMO, the study proposes a Unified Ontology Approach (UOA) as an alternative ODM. The UOA is derived by combining the common characteristics and key steps of various ODMs, aiming to streamline the ontology development process and enhance its effectiveness. Through an extensive analysis of existing methodologies, this research contributes to the field by offering a consolidated perspective on ODMs. The study findings shed light on the strengths and weaknesses of different approaches, facilitating informed decision-making for ontology developers. Furthermore, the discussion explores the implications of adopting the UOA in practical applications, emphasizing its potential to improve ontology quality, interoperability, and adaptability across diverse domains. In conclusion, this paper advocates for the adoption of the UOA as a comprehensive and flexible framework for ontology development. By synthesizing the strengths of existing ODMs and insights from the BMO, the UOA offers a promising avenue for advancing the field of ontology development and driving progress in various domains and applications.**

***Keywords—Ontology; Ontology Development Method (ODM); Business Model Ontology (BMO); Unified Ontology Approach (UOA)***

## I. Introduction

Ontology, a term originally rooted in philosophy, is defined as an explicit specification of a conceptualization [1]. This concept has been extensively utilized in various fields, including computer science, software engineering, and business. Within the realm of information science, an ontology is characterized as a formal representation of knowledge. It encompasses a set of concepts within a specific domain and the relationships that bind these concepts together [2].

Ontology Development Methodologies (ODMs) are methodologies used to create formal specifications of terms and their relations within a specific domain. These methods facilitate information sharing and reuse across various domains, as highlighted by Gokhale et al. [3]. The process of developing an ontology is multifaceted and iterative, requiring meticulous attention and time [4].

Notably, there’s no one-size-fits-all methodology for ontology development, as pointed out by Walisadeera et al., [5] and Yu [4]. This sentiment is echoed by Noy et al. [2] who emphasize that ontology development doesn’t adhere to a rigid set of rules or a universally correct approach. The design and development of an ontology are influenced by several factors. These include the nature of the domain in question, the intended application of the ontology, and the ontology developer’s perspective [2]. Thus, Ontology development necessitates a harmonious blend of technical expertise and innovative problem-solving, making it both an art and a science.

In the current landscape, a multitude of ontologies have been developed utilizing a wide array of ODMs. These include, but are not limited to, Ontology Development 101, OntoSpec, UPON Lite, Methontology, NeON methodology, Uschold and King Methodology and the new ODMs, Linked Open Terms (LOT) Methodology and Agile Ontology Engineering Methodology (AgiSCont). Each of these methodologies offers unique techniques and perspectives for ontology creation, thereby contributing to the richness and diversity of the field.

Nevertheless, the selection of methodology is not a universally applicable determination. It is influenced by a variety of factors such as the intended application, potential extensions, and the specific use case of the ontology in question. Although it is agreeable that there are varieties of ontological development approaches, the desired outcomes are all the same - developing an ontology. With so many methodologies available, each with its own strengths and nuances, the question arises - is it feasible, or even desirable, to standardize these approaches? Is the approach to ontology solely confined to the use of a single ODM? Or, can it be an amalgamation of various ontology development methods to develop an ontology? Perhaps, by drawing inspiration from a particular ontology development project, a new common version of the ODM could be established. Ultimately, the answer may lie in finding a balance between maintaining methodological diversity and establishing common guidelines to ensure quality and interoperability across different ontologies.

In essence, this paper aims to contribute to the discourse on ontology development methodology by proposing a Unified Ontological Approach (UOA) that integrates the strengths of various ODMs with inspiration drawn from the success and principles of the BMO.

## II. Methodology

This study employs a Narrative Literature Review (NLR) method to provide a comprehensive and interpretative synthesis of existing literature related to ODM. The NLR is a useful method to synthesize a complex and emerging field [6] as well as better suited to addressing a topic in broader ways [7].

The research was carried out in several stages. Initially, a comprehensive literature review was conducted to identify and understand various ODMs. This involved a systematic search of databases and journals for relevant articles, followed by a thorough reading and analysis of these articles.

The environment for this research was prepared by creating a database of all the identified ODMs. This database served as the primary resource for the study. Data was produced through a detailed analysis of the identified ODMs. This involved identifying common steps and practices across different ODMs and drawing insights from the Business Model Ontology (BMO), a globally acclaimed ontology for business setup.

The data validation method involved cross-referencing the identified common steps and practices with the principles of the BMO. This ensured that the synthesized methodology was not only based on the strengths of various ODMs but also aligned with the successful principles of the BMO.

## III. Literature Review

### A. Understanding Ontology: Definition, Applications, and Importance

Ontology, in its broadest sense, is the philosophical study of existence or the nature of being, as described by Simon [8]. Salatino et al. [9] further elaborate on this concept, defining ontology as a collection of concepts and categories within a specific subject area or domain that outlines their properties and the relationships between them.

In the realm of computer and information science, the term “ontology” assumes a slightly different meaning. As explained by Gruber [10], in this context, an ontology is an artifact created with a specific purpose - to facilitate the modeling of knowledge about a certain domain, whether it’s based on reality or a hypothetical scenario. It provides a specialized vocabulary for formulating statements, which can serve as either inputs or outputs for knowledge agents, such as a software program. Simply put, an ontology can be viewed as a framework that outlines the key concepts, relationships, and other distinctions that are crucial for modeling a domain.

According to Guarino [11], ontologies can significantly impact the main components of an information system, including information resources, user interfaces, and application programs. They provide an effective solution for capturing common knowledge [12] and sharing it [13]. Therefore, ontologies serve as a vital tool for reasoning about entities within a variety of domains and can be effectively employed to describe these domains.

In addition, ontologies are used for several practical reasons. They help in sharing a common understanding of the structure of information, enable the reuse of domain knowledge, make domain assumptions explicit, separate domain knowledge from operational knowledge, and analyze domain knowledge [2].

Fernández-López et al. [14] expand the use of ontologies beyond their traditional applications, leveraging them to enhance communication, collaboration, and decision-making among various stakeholders and systems. The shared understanding facilitated by ontologies can be instrumental in promoting effective communication, fostering collaboration, and guiding decision-making processes across different stakeholders and systems. Such applications underscore the significance and versatility of ontologies in numerous fields, with a particular emphasis on information and computer science.

### B. Endurant versus Perdurant in Ontology Engineering

The concept of ontologies is systematized through endurants and perdurants, philosophical positions that address how objects persist over time. Endurants, as defined by Huang [15], are entities that persist wholly at any specific temporal juncture, such as physical objects. Conversely, perdurants, as described by [15], are entities that possess temporal segments and persist through a continuum of time, such as events or processes.

The application of endurant and perdurant can impact the development of ontologies [15], [16]. The significance of perdurant and endurant ontology lies in their ability to categorize entities based on their relationship to time, playing a prominent role in top-level ontologies in information science. The necessity of incorporating both perspectives in an ontology depends on the specific requirements of the domain being modeled [17].

Despite its significance, there are limitations in the application of endurants and perdurants. Huang [15] states that the distinction may not be consistently represented linguistically. Additionally, there is a lack of standard tools to develop perdurant ontologies, suggesting that the distinction may not be adequately supported by existing ontological frameworks [18]. Furthermore, Johansson [19] argued that robust top-level ontologies classifying particulars may need to rely on taxonomic principles other than the endurant-perdurant distinction.

In conclusion, the distinction between endurantism and perdurantism in ontology provides a valuable framework for understanding the temporal aspects of entities. The use of both perspectives offers advantages in accurate representation, modeling structural and dynamic aspects, and supporting diverse applications. However, challenges such as inconsistent linguistic representation and a lack of standard tools for perdurant ontologies exist. The universal applicability and representation of this distinction in linguistic and ontological systems raise questions, emphasizing the need for careful consideration based on specific domain requirements. The choice between endurantism, perdurantism, or a combination should align with the domain’s needs for effective knowledge representation. These insights can be instrumental in guiding the design and development of future ontologies.

### C. Business Model Ontology: What We Can Learn?

The Business Model Ontology (BMO), a notable study developed by Alex Osterwalder in 2004, offers valuable insights into the design and development of ontologies. The BMO, which is often applied in the form of the Business Model Canvas (BMC), serves as a strategic management tool that facilitates the description and design of a company's business model [20]. As argued by Holdford et al. [21], this tool has been widely accepted and recognized universally for describing and designing a business enterprise model due to its simplicity, practicality, and effectiveness in guiding the formation of a complete business model [20], [22].

The BMO is structured around nine building blocks: key partners, key activities, key resources, value proposition, customer relationships, channels, customer segments, cost structure, and revenue streams which are simplified by Osterwalder [23] in an ontology framework depicted in Fig. 1 below:

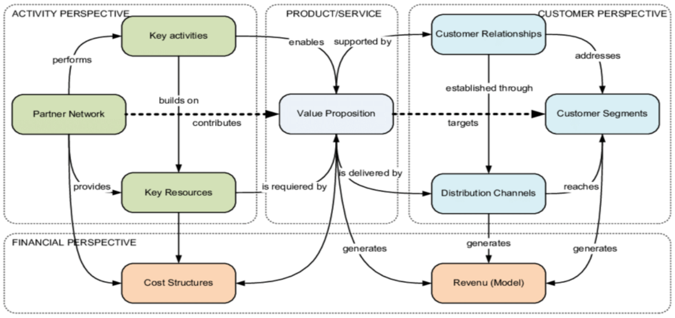

Fig. 1. Business model ontology [23].

Osterwalder [23] does not specifically mention the ODM he employs. The development of the BMO involves six steps starting with a comprehensive literature review. He conducted a comprehensive literature review on the existing definitions and frameworks of business models, as well as the relevant theories and concepts from various disciplines. Based on the information gathered from the literature review, he then proposed a conceptual business model based on the frame-based representation paradigm. The conceptual model is formalized using Web Ontology Language (OWL), which is a standard language for creating ontologies on the Semantic Web. The formalization process involved defining the classes, properties, and axioms of the ontology, as well as the rules and constraints for its instantiation. The validity and usefulness of BMO are evaluated by applying it to several case studies of real-world e-businesses. The evaluation criteria included the completeness, consistency, expressiveness, and simplicity of the ontology, as well as its ability to support analysis and design tasks. The BMO is then documented and the user guide and glossary for the ontology are also published. Based on the building blocks of BMO and depending on how one interprets the concepts and relations in the ontology, BMO is more inclined towards capturing the endurant aspects of a business model, since it focuses on the static and structural elements that define the value proposition, the customer segments, and the business logic.

From an ontology design and development perspective, the BMO provides a shared language and structure that aids entrepreneurs in identifying opportunities for business model innovation [24]. It offers a structured framework for representing and understanding the complexity of business models, systematically encapsulating the fundamental aspects of business models, including the relationships between various components such as actors, resources, and the transfer of resources between actors [21], [25]. This aligns with Osterwalder's [23] original aim for the BMO, which was to formalize the key elements of a business model using an ontology, thereby facilitating the development of sophisticated methods for requirement elicitation and computer-based tools for business model design and analysis.

Moreover, the BMO contributes to enhancing interoperability by providing a common language and framework for describing business models, a feature that is crucial for collaboration and integration between different organizations and systems [25]. Holdford et al., [21] added that this shared framework encourages collaboration and integration between organizations, making it easier to understand and plan business models at a more strategic level. Upward et al. [26] supported this argument and opined that the BMO can be particularly valuable in the context of emerging trends such as business model innovation, digital transformation, and the sharing economy, where the ability to understand and compare different business models is crucial. They further note that the BMO's capability to integrate concepts from strategy, business processes, and information systems underscores the potential for ontologies to bridge interdisciplinary domains and provide a holistic view of complex phenomena such as business models.

In essence, the BMO demonstrates the use of ontology as a common language and framework for describing business models, a feature that is essential for communication, collaboration, and integration between different organizations and systems [25], [26]. Furthermore, the BMO's structured approach enhances modeling capabilities, enabling the representation of both structural and dynamic aspects of business models, leading to a more comprehensive understanding of business phenomena [21], [26].

In conclusion, the BMO provides invaluable insights into the process of understanding, defining, and innovating business models using ontology. Its structured approach and common language foster effective communication and collaboration, establishing it as an effective knowledge representation instrument. The lessons gathered from the BMO underscore the potential of ontology in augmenting the comprehension and innovation of business models across various domains. The BMO insights therefore serve as a testament to the transformative power of ontology in reshaping the understanding of business models and beyond.

### D. Overview of Several ODMs

There are several ODMs available, each with its unique approach to ontology development. An overview of six commonly used ODMs namely Ontology Development 101 (OD101), OntoSpec, Upon Lite, Methontology, NeON methodology, Uschold and King Methodology and the recently developed ODMs, Linked Open Terms (LOT) Methodology and Agile Ontology Engineering Methodology (AgiSCont) will be briefly discussed in this section.

*1) Ontology Development 101 (OD101):* Ontology Development 101 (OD101), introduced by Noy et al. [2] serves as a fundamental guide for novice ontology designers embarking on their first ontology creation. It provides basic-level information on the terms and concepts in a domain by using wine classification as an example. The method employs an iterative approach, beginning with an initial rough draft of the ontology, followed by subsequent revisions and refinements. OD101 as outlined by Noy et al. [2] comprises three key steps: 1) Defining concepts in the domain (classes): This involves identifying the key concepts or classes that are relevant to the domain of interest. 2) Arranging the concepts in a hierarchy (subclass-superclass hierarchy): This key step involves organizing the identified concepts or classes into a hierarchical structure, often in the form of a subclass-superclass hierarchy. 3) Defining which attributes and properties (slots) classes can have and constraints on their values: In this step, the attributes and properties that each class can have are defined, along with any constraints on their values. However, Nie et al. [27] pointed out a limitation of OD101. While it provides a basic guide for creating initial ontologies, it may not offer a comprehensive overview of diverse domains, which is essential for comparing and benchmarking different environments. OD101 primarily considers two similar environments, leading to a lack of definition that allows for comparison and benchmarking against each other. Despite this, OD101 remains important for creating ontologies, which are widely used across various application domains such as biomedical [28] and natural disaster management [29].

*2) OntoSpec:* According to to Kassel [30], OntoSpec is a micro-level Ontology Development Methodology (ODM) that emphasizes formalization aspects. It utilizes highly structured natural language as a specification mode, aiding the builder with the ontological knowledge modeling step, upstream of the formal representation and knowledge implementation steps. Similar to Ontology Development 101 (OD101), OntoSpec involves an iterative process comprising four key steps: 1) identifying the entities (concepts and relations), 2) modeling the properties characterizing the entities through successive refinements, 3) formalizing the ontology using a formal representation language, and 4) Evaluating and validating the ontology [30]. OntoSpec provides a modeling framework that allows ontology builders to define conceptual entities (concepts and relations) composing the ontology through successive refinements. The general principle of OntoSpec involves identifying ever more precise roles defined in a generalization/specialization taxonomy, while considering the structure of the properties in question. OntoSpec is independent of formal representation languages, which makes its definitions universally understandable. This allows domain experts and future users of the ontology to collaborate with the builder in evaluating the modeling choices and the quality of the resulting definitions. However, OntoSpec's use of semi-informal language may limit its applicability in contexts that require strict formalization or the use of specific formal representation languages [30]. It focuses on the details of formalization rather than the broader process of ontology development [31]. Despite this, OntoSpec remains a valuable ODM widely used across various application domains such as neurology [32] and business process [33].

*3) UPON Lite:* UPON Lite, as described by Nicola et al. [31], is a methodology for rapid ontology engineering, derived from the Unified Process for Ontology building (UPON). It is designed to be accessible to domain experts, with minimal intervention from ontology engineers, and focuses on delivering formal ontology. As noted by Lille et al. [34], this method consists of key steps: 1) building the domain terminology lexicon, 2) associating domain terms with descriptions and possible synonyms, 3) organizing the domain terms in an ISA hierarchy, and 4) producing a formally encoded ontology that contains conceptual knowledge collected in the previous steps. UPON Lite's main advantage according to Nicola et al. [31] is its ability to allow a wide base of users, typically domain experts, to construct an ontology largely without the help of ontology engineers. Only in the last step, after domain content is elicited, organized, and validated, the ontology engineers intervene is needed to deliver a final ontology formalization before releasing it to users. This approach provides a well-defined enrichment to each preceding step and disintermediates ontology engineers, making it easier and faster for end-users to create usable ontologies with more efficient collaboration between domain experts and ontology engineers. However, UPON Lite does have some limitations. Lille et al. [34] highlighted that one of the key limitations is that it may not offer a comprehensive overview of diverse domains, which is essential for comparing and benchmarking different environments. UPON Lite primarily considers two similar environments, leading to a lack of definition that allows for comparison and benchmarking against each other. Another limitation underscored by Lille et al. [34] is that despite the existing scientific literature reports on practical applications of UPON Lite in several domains, the detailed elaboration of the development process is limited. This could potentially limit its reproducibility in an actual business context. Despite these limitations, UPON Lite continues to be relevant for Ontology Engineering, particularly for domain experts due to its ease of use and reduced dependence on ontology engineers. It is used across various application domains such as smart building [35] and social networks [36].

*4) Methontology:* According to Fernandez Lopez et al. [37], Methontology an ODM that stresses the importance of reusing and reengineering existing ontologies and knowledge resources. Methontology provides a systematic approach to ontology development, which lead to the creation of more effective and easier to maintain over time ontologies [37]. Fernandez Lopez et al. [37] state that this ODM proposes a set of guidelines and best practices for identifying and evaluating existing ontologies, determining how they can be reused or reengineered to meet the needs of a new ontology development project. Fernandez Lopez et al. [37] outline the best practices in Methontology include reusing existing ontologies, carefully capturing domain concepts and relationships, using formal language, evaluating the ontology's quality, and thorough documentation. The six key steps in Methontology include: 1) identifying the purpose of the ontology and its intended uses, 2) capturing and building the ontology, 3) implementing and testing the ontology, 4) Evaluating the ontology, 5) documenting the ontology after each phase and 6. Maintaining and evolving the ontology [37]. Fernandez Lopez et al. [37] highlight that these steps are not necessarily sequential and can occur concurrently or iteratively. Evaluations should occur throughout the process to ensure continuous improvement of the ontology [38]. Due to its comprehensive and systematic approach to ontology development, which includes various phases such as requirements elicitation and analysis, conceptualization, integration, implementation, and maintenance, Methontology, therefore, is often used for developing heavyweight ontology [3], [39]. Fernandez Lopez et al. [37] argue that the comprehensive approach of Methontology leads to high-quality ontologies that are well-aligned with the needs of the intended users and easier to maintain over time). Nonetheless, despite its breadth, Methontology has limitations. It necessitates more time and effort than other, less comprehensive ODMs [37], [38], [39]. Nevertheless, Methontology continues to be a well-established and influential ODM. It has been successfully utilized in diverse fields, including chemistry [38] and legal [40].

*5) NeOn methodology:* The NeOn Methodology, as explained by Suárez-Figueroa et al. [41], [42], is a scenario-based ODM that focuses on the construction of ontology networks. It promotes collaborative ontology development and emphasizes the reuse and re-engineering of knowledge resources. Unlike other methodologies that enforce a strict workflow, NeOn offers flexibility, accommodating a range of scenarios including reengineering, alignment, modularization, localization, and integration with non-ontological resources [43]. According to Suárez-Figueroa et al. [41], the NeOn Methodology framework is built upon four pillars: The NeOn Glossary, ontology-building scenarios, methodological guidelines, and guidelines for ontology evaluation and evolution. It involves six main steps: 1) ontology requirements specification, 2) ontology analysis, 3) ontology design, 4) ontology development, 5) ontology evaluation, and 6) ontology evolution. These steps are scenario-driven and can be customized to meet the specific characteristics and requirements of each scenario [42]. Interestingly, the NeOn Methodology framework is flexible and customizable based on the specific needs of ontology engineers and software developers for different scenarios. This adaptability as noted by Suárez-Figueroa et al. [42] is a key strength of the NeOn Methodology, making it suitable for a wide range of ontology engineering contexts. However, Suárez-Figueroa et al. [40] highlighted that a limitation of this methodology is that it does not explicitly state all the steps to be performed, and its application can be time-consuming. Despite this, the NeOn Methodology has been flexibly applied in various domains such as education [44] and tourism [45].

*6) Uschold and king methodology:* The Uschold and King Methodology developed by Uschold et al. [46] is an ODM that emphasizes the systematic development of ontologies which includes identifying the appropriate content, relationships, and structuring for the ontology, as well as establishing a process for ontology development and evaluation [47]. The methodology is centered on four distinct steps: 1) identifying the purpose, 2) building the ontology, 3) evaluating the ontology, and 4) documenting the ontology. It provides a set of techniques, methods, and principles for each phase to produce high-quality ontologies [46]. Uschold et al. [46] outlined the key steps in this ODM which include identifying the purpose and scope of the ontology, building the ontology, evaluating the ontology's quality, consistency, and completeness, and documenting the ontology. This ODM involves a comprehensive and systematic approach, making it particularly suitable for complex domains where precision and detail are required [39], [48]. However, despite its comprehensive nature, it lacking in terms of the need for motivating scenarios to guide the construction process, limited user engagement throughout the ontology creation process, and potential inadaptability to all ontology development requirements [39], [48]. Nonetheless, this ODM remains a valuable tool for Ontology Engineering, particularly for domain experts, due to its ease of use and reduced dependence on ontology engineers. It has been successfully applied in various domains, including e-government [49] and education [50].

*7) LOT (Linked Open Terms) methodology:* The LOT (Linked Open Terms) Methodology, as described by Poveda-Villalón et al. [51] is a method for developing ontologies and vocabularies focusing on industry projects. It emphasizes alignment with software development, integrating ontology development into the software industry to promote interoperability between different systems by providing well-documented and consistent standards for information exchange and reuse [51]. Unlike other methodologies that enforce a strict workflow, LOT allows for the adoption of the method in different contexts and needs, offering flexibility, and accommodating a range of scenarios including requirements specification, ontology implementation, ontology publication, and ontology maintenance. According to Poveda-Villalón et al. [51] the LOT Methodology framework is built upon four pillars: 1) the LOT Glossary, 2) ontology-building scenarios, methodological guidelines, and 3) guidelines for ontology evaluation and evolution. It involves four main steps: 1) ontology requirements specification, 2) ontology implementation, 3) ontology publication, and 4) ontology maintenance. These steps are scenario-driven and can be customized to meet the specific characteristics and requirements of each scenario. Interestingly, the LOT Methodology framework is flexible and customizable based on the specific needs of ontology engineers and software developers for different scenarios. This adaptability as noted by Poveda-Villalón et al. [51] is a key strength of the LOT Methodology, making it suitable for a wide range of ontology engineering contexts and aims to serve as a reference framework that can be tailored to meet the specific needs of each project and context. This methodology however does not explicitly state all the steps to be performed, and its application can be time-consuming. According to Poveda-Villalón et al. [51], this, limitation is inherent in any methodology that aims to be flexible and adaptable to different contexts. Despite this limitation, the LOT methodology has been flexibly applied in various domains such as VICINITY, DELTA, BIMERR, and Ciudades Abiertas, demonstrating its potential for use in various contexts.

*8) Agile ontology engineering methodology (AgiSCOnt):* The Agile Ontology Engineering Methodology (AgiSCOnt), as explained by Spoladore et al. [52] is a novel approach that supports organizations in collaborative ontology development. It is a recent ODM developed to support ontologists, especially novices, through the ontology development workflow in an iterative, customizable, and flexible manner while promoting collaboration with domain experts [52]. Similar to LOT, AgiSCOnt is designed to accommodate differing levels of technical expertise among ontology engineers and it is highly iterative, customizable, and flexible, allowing ontologists to tailor the approach to their particular needs and contexts [52]. There are five main steps involved in AgisCOnt: 1) Defining the scope and objectives of the ontology, 2) Selecting the ontological language and expressivity, 3) Identifying the most appropriate Ontology Design Patterns (ODPs) for the domain, 4) Building the ontology iteratively and, 5) Evaluating the ontology against use case scenarios. The possible limitation of AgiSCOnt is that some of the steps are not comprehensively described, resulting in some level of subjectivity in the implementation of the methodology, which can potentially lead to inconsistencies. However, due to its adaptability and flexibility, this method has been applied favorably across domains of knowledge.

*9) Other ODMs:* In addition to the above-established and new ODMs, there are also studies on ontology development using a customized ODM. Youcef et al. [53] introduced an ODM founded on two philosophically grounded foundational ontologies, UFO [54], [55] and DEMO [56] to offer a clear and consistent representation of domain knowledge for virtual reality training in ophthalmology known as OntoPhaco. This ODM spans crucial phases to create reusable, localized, and shareable ontologies for the domain through IWs. There are five key steps involved: 1) Pre-conceptualization- select domain, scope, and range), 2) Conceptualization – analyze and construct classes, relationships, and axioms, 3) Implementation - encode ontology in a knowledge representation language, 4) Ontology evaluation - assess suitability for intended use, 5) Ontology maintenance - review and improve the structure, expand the scope, and refine documentation. Based on the comprehensiveness of OntoPhaco developed using this ODM, its application demands significant expertise and effort and may not be well-suited for less-defined or dynamic domains.

In contrast, Sattar et al. [57] advocate for an enhanced ODM rooted in the Design Science Research Methodology (DSRM), comprising six steps: 1) requirement identification, 2) conceptualization, 3) implementation, 4) evaluation, 5) documentation, and 6) maintenance. This improved ODM underscores collaborative ontology development practices, aligns ontologies with business goals, and integrates agile development principles. It applies to any domain involving IWs. Both ODMs share heavyweight characteristics, embodying a rigorous and comprehensive approach, as suggested by Femi Aminu et al. [58], rendering them more suitable for the development of intricate ontologies.

In a nutshell, although both studies employ a customized ODM to cater to a specific requirement of their ontology development works, the characteristics and the steps involved are not too distinct from common and established ODMs.

### *E. ODMs Categorization*

Studer et al. [59] argue that ontologies vary in formality and coverage of formal language elements, leading to the categorization as lightweight or heavyweight. This categorization often focuses on the ontology (the product) rather than categorizing the methodology employed to develop it. Most ODMs do not explicitly mention their categorization as either lightweight or heavyweight, except for the Linked Open Terms (LOT) methodology [51], which directly reveals that they are lightweight ontology, their characteristic can be analyzed to determine their category. According to Corcho [60], the difference between lightweight and heavyweight ontologies is determined based on their formalization degree and completeness of the included components. Studer et al. [59] contend that a lightweight ontology provides basic-level information on the terms and concepts in a domain, while a heavyweight ontology explicitly represents more complex relationships, such as part-whole relationships and inheritance hierarchies. Similarly, Corcho [60] and Fernandez-Lopez et al. [14] describe lightweight ontologies as less formal and include fewer formal axioms and constraints, whilst heavyweight ontologies are more formal and have many formal axioms and constraints. The distinguishing characteristics between lightweight and heavyweight are suggested by Lassila et al. [61] presented in Fig. 2. It shows that ontologies can vary in their degree of formality and expressivity, ranging from very lightweight, almost casual ontologies to heavyweight ontologies with many formal rules and restrictions.

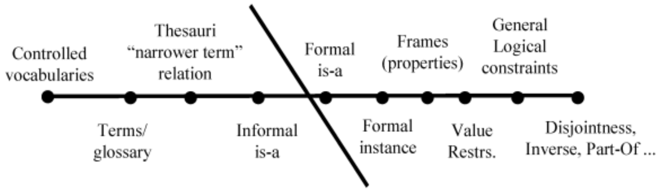

Fig. 2. Lightweight vs heavyweight ontologies characteristics [59].

Lassila et al. [61] opine that lightweight ontologies are easier to understand and share, and that they can grow into useful ontologies through a process of natural selection. In contrast, they state that heavyweight ontologies are more complex, comprehensive, and formal.

Therefore, after synthesizing the characteristics of the ontology and various ODMs discussed briefly in Section 2.4, it can be concluded that in developing a lightweight ontology, the employed ODMs tend to be simpler and more accessible. Conversely, for heavyweight ontologies, the ODMs used are more detailed and comprehensive [58].

Based on the above arguments, the common characteristic distinguishing lightweight and heavyweight ODMs therefore can be summarized in Table I below:

In Section D, eight ODMs have been briefly reviewed. Based on the common characteristics of the lightweight and heavyweight summarized in Table I above, the six ODMs therefore can be categorized as elucidated in Table II below:

In conclusion, discerning whether an ODM is lightweight, heavyweight or a combination of both is imperative in any ontology development project, as it influences resource allocation, project planning, skill assessment, scope definition, usability assurance, flexibility evaluation, reusability consideration, and cost understanding, ensuring the project aligns effectively with its objectives and requirements, ultimately contributing to the development of an effective ontology. Despite distinct characteristics and the key steps involved, all methods share the common goal of creating structured ontologies.

TABLE I. COMMON CHARACTERISTICS DISTINGUISHING LIGHTWEIGHT AND HEAVYWEIGHT ODMS

| Category | Common Characteristics |
|---|---|
| Lightweight | ▪ Provide basic-level information on terms and concepts in a domain.<br>▪ Are less formal, involving fewer formal axioms and constraints.<br>▪ Tend to be simpler, more accessible, and suitable for novice ontology designers.<br>▪ Emphasize ease of use, accessibility for domain experts, and rapid ontology engineering. |
| Heavyweight | ▪ Explicitly represent complex relationships, such as part-whole relationships and inheritance hierarchies.<br>▪ Are more formal, with many formal axioms and constraints.<br>▪ Take a comprehensive and systematic approach to ontology development.<br>▪ Involve detailed and extensive processes, including requirements elicitation, conceptualization, integration, implementation, and maintenance.<br>▪ Are suitable for complex domains where precision and detail are required. |

TABLE II. CATEGORIZATION OF EIGHT ODMS DISCUSSED IN SECTION D

| ODM | Category | Characteristic | Key Step |
|---|---|---|---|
| Ontology Development 101 (OD101) | Lightweight | ▪ Basic-level information<br>▪ Iterative approach<br>▪ Suitable for novices | 1. Defining concepts in the domain (classes)<br>2. Arranging the concepts in a hierarchy (subclass-superclass hierarchy)<br>3. Defining which attributes and properties (slots) classes can have and constraints on their values |
| OntoSpec | Lightweight | ▪ Emphasizes formalization<br>▪ Less formal<br>▪ Uses structured natural language | 1. Identifying the entities (concepts and relations) composing the ontology<br>2. Modeling the properties characterizing the entities through successive refinements<br>3. Formalizing the ontology using a formal representation language<br>4. Evaluating and validating the ontology |
| UPON Lite | Lightweight | ▪ Rapid engineering<br>▪ Accessible to domain experts<br>▪ Minimal intervention from ontology engineers during the ontology development process | 1. Building the domain terminology lexicon<br>2. Associating domain terms with descriptions and possible synonyms<br>3. Organizing the domain terms in an ISA hierarchy<br>4. Producing a formally encoded ontology that contains conceptual knowledge collected in the previous steps |
| Methontology | Heavyweight | ▪ Involves a systematic approach<br>▪ Suitable for a more complex ontology development | 1. Identifying the purpose of the ontology and its intended uses<br>2. Capturing and building the ontology |

| | | | |
|---|---|---|---|
| | | | 3. Implementing and testing the ontology<br>4. Evaluating the ontology<br>5. Documenting the ontology<br>6. Maintaining and evolving the ontology |
| NeOn Methodology | Combination | ▪ Scenario-based<br>▪ Flexible processes<br>▪ Combines lightweight and heavyweight characteristics | 1. Ontology requirements specification<br>2. Ontology analysis<br>3. Ontology design<br>4. Ontology development<br>5. Ontology evaluation<br>6. Ontology evolution |
| Uschold and King Methodology | Heavyweight | ▪ Involves a systematic approach<br>▪ Includes comprehensive phases<br>▪ Suitable for a more complex ontology development | 1. Identifying the purpose and scope of the ontology<br>2. Building the ontology<br>3. Evaluating the ontology's quality, consistency, and completeness<br>4. Documenting the ontology |
| LOT (Linked Open Terms) Methodology | Lightweight | ▪ Focuses on flexibility and adaptability.<br>▪ Involves a detailed view of ontology requirements specification.<br>. | 1. Ontology requirements specification<br>2. Ontology implementation<br>3. Ontology publication<br>4. Ontology maintenance |
| Agile Ontology Engineering Methodology (AgiSCont) | Lightweight | ▪ Focuses on flexibility and adaptability.<br>▪ Supports iterative development.<br>▪ Fits the various ontology activities into the phases of the Scrum agile methodology | 1. Defining the scope and objectives of the ontology<br>2. Selecting the ontological language and expressivity<br>3. Identifying the most appropriate Ontology Design Patterns (ODPs) for the domain<br>4. Building the ontology iteratively<br>5. Evaluating the ontology against use case scenarios |

### F. Synthesizing BMO and ODMs

Synthesizing BMO and ODMs involves recognizing BMO's simplicity and widespread use globally. Although Osterwalder [23] does not explicitly mention the ODM he employs in developing the BMO, the characteristics embedded in BMO, such as simplicity, logic, and ease of comprehension, align closely with the characteristic of a lightweight ontology, establishing a universal language and framework for articulating and scrutinizing business models [25]. Osterwalder [23] approach, steering clear of too many rules or complexity, is very similar to lightweight ODM [14], [59], [60].

Leveraging from BMO, we can derive lessons for ODMs, emphasizing the importance of simplicity, accessibility, and comprehensibility, particularly for novice users. By embracing the straightforward and logical methodology as employed in BMO, the development of more widely applicable, reliable, and actionable ontologies can be facilitated. The BMO's global acceptance underscores that a lightweight ontology can be effective and useful for capturing the essential aspects of a complex domain, without imposing unnecessary complexity or constraints. Chungyalpa et al. [25] further posit that BMO also shows that a lightweight ontology can be easy to use and understand, even for non-experts, by using a graphical notation and a clear structure. BMO also exemplifies the adaptability and extensibility inherent in lightweight ontologies, allowing customization and integration with other ontologies or models.

## IV. Proposed Approach

### A. Key Takeaways from BMO

BMO serves as a paradigmatic lightweight ontology, offering inspiration for the development of ODMs characterized by simplicity, accessibility, and comprehensibility, without compromising reliability and actionability. Standardizing certain aspects, including notation, structure, and evaluation criteria, while permitting flexibility for customization such as terminology, granularity, and integration options, may strike a harmonious balance between uniformity and adaptability in ODMs. The key takeaways from BMO are summarized in Table III below:

TABLE III. The Key Takeaways From BMO

| Key Takeaways from BMO | Description |
|---|---|
| 1. Simplicity and accessibility | BMO demonstrates that a lightweight ontology can be user-friendly for non-experts. |
| 2. Comprehensibility and reliability | BMO's logical structure highlights the importance of reliable and actionable ontologies. |
| 3. Balancing uniformity and adaptability | Standardizing elements while allowing customization aims to balance uniformity and adaptability. |
| 4. Global acceptance as a model | BMO's global acceptance suggests that lightweight ontologies can capture diverse business models. |

### B. Uniformity of the Ontological Approach based on BMO and Various ODMs

To achieve a harmonious balance between simplicity, accessibility, and comprehensibility, without compromising reliability and actionability, a unified approach should assimilate common characteristics from diverse ODMs as the best practices. These characteristic are extracted from BMO and the various ODMs discussed in Section II (D). Table IV below summarizes the common elements that can be integrated as the best practices into a UOA.

A Unified Ontological Approach (UOA) should strive to strike a balance between common elements and adaptability, acknowledging that ontology development is both an art and a science. This balance ensures that the approach remains versatile across diverse domains [2]. This proposed approach, with its emphasis on a harmonious balance between commonality and adaptability, aspires to foster a shared understanding and effective communication within the ontology development community [23]. The integration of insights from BMO and various ODMs paves the way for a more versatile, efficient, and collaborative ontology development approach, with the potential to benefit a multitude of application domains.

TABLE IV. SUMMARY OF THE COMMON CHARACTERISTICS EXTRACTED FROM BMO AND THE VARIOUS ODMS

| Common element | Description |
|---|---|
| 1. Iterative process | Adopt an iterative process inspired by BMO and ODMs, which allows continuous refinement and adaptation to evolving domain requirements. |
| 2. Consistent notation system | Choose a consistent notation system based on a formal language, such as OWL or RDF, which enables unambiguous representation and reasoning of ontological knowledge. |
| 3. Flexible formalization | Apply a flexible formalization approach that supports both domain experts and ontology engineers in building ontologies from scratch or reusing existing ones, such as UPON Lite, LOT and AgiSCOnt. |
| 4. Reusability and reengineering | Follow principles of reusability and reengineering, as suggested by Methontology, which enhance efficiency and effective maintenance of ontologies over time. |
| 5. Scenario-driven development | Utilize scenario-driven development principles from the NeOn Methodology, LOT and AgiSCont which enable customization and collaboration in ontology engineering based on common situations, such as reusing, reengineering, merging, localizing, and integrating ontologies and non-ontological resources. |
| 6. Comprehensive Structure | Provide a comprehensive and systematic structure that addresses complex domains with precision and detail, such as Uschold and King Methodology. |

### C. Towards a Unified Ontological Approach

Identifying the common characteristics, and key steps of each ODM, and an insight learned from the BMO is vital towards a UOA. In this section, all these aspects will be synthesized and integrated to form a UOA as other instances of ODM.

*1) Common characteristics:* In the context of the proposed UOA to ontology development, a seamless integration of common characteristics from various ODMs and insights from BMO is essential. The integration of these elements aims to capitalize on the strengths of different methodologies while addressing their specific limitations, ensuring a comprehensive and versatile approach. Based on Table IV, Fig. 3 below illustrates the common element framework of the ODMs.

A brief explanation of the six common elements framework as illustrated in Fig. 3 is outlined below:

*a) Iterative process:* At the core element of ODM is an iterative process. This element draws inspiration from the BMO proposed by Osterwalder [23] and OD101 introduced by Noy et al. [2], OntoSpec [30], UPON Lite [31], Methontology [37], NeOn Methodology [42], [43], and Uschold and King Methodology [46] acknowledging the significance of continuous refinement and adaptation to evolving domain requirements. ODM is not fixed, but rather dynamic and adaptable, as they reflect the changing needs and challenges of ontology engineering practice as argued by Elhassouni et al. [62]. The iterative nature according to Noy et al. [2] and Espinoza et al. [63] ensures that the ontology remains dynamic, responsive to changes, and refined over time, aligning with the evolving nature of various application domains.

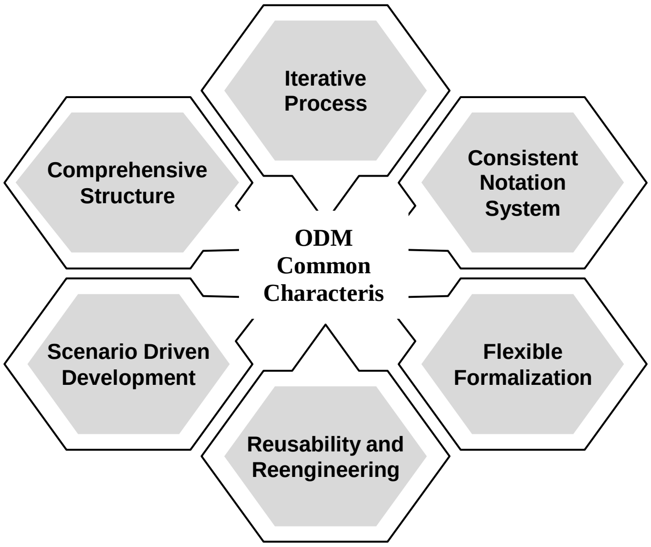

Fig. 3. The common characteristics framework of the ODM.

*b) Consistent notation system:* The adoption of a consistent notation system is imperative element for universal understanding of the ontology without sacrificing formality [64]. In turn, it will help different stakeholders, such as domain experts and ontology engineers to understand the ontological knowledge clearly [65]. A consistent notation system is based on a formal language, such as OWL, RDF, or SKOS, used in different ODMs, such as in BMO [23], NeOn Methodology [42] and UPON Lite [34]. This formal language, according to Gruber [64] and Fernandez Lopez [65] ensures that the ontology can be effectively communicated across diverse stakeholders, including both domain experts and ontology engineers, facilitating clear and unambiguous representation and reasoning of ontological knowledge.

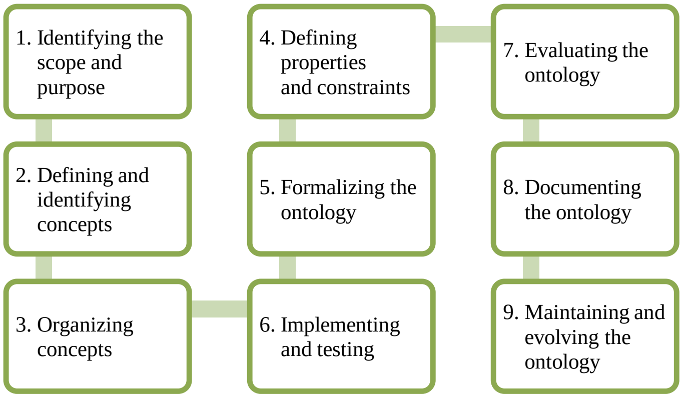
*c) Flexible formalization:* To accommodate both domain experts and ontology engineers, the common element applies a flexible formalization approach, inspired by UPON Lite [34], LOT [51] and AgiSCOnt [52]. This element allows for a balance between precision and accessibility, catering to the diverse expertise levels of stakeholders involved in the ontology development process. The flexibility in formalization means that the ontology can be expressed in different levels of detail and formality, depending on the needs and preferences of the users and the application domain [65]. Verbert et al. [66] and Schlenoff [67] argue that flexible formalization will ensure widespread applicability across various domains, making the approach more inclusive and adaptable.

*d) Reusability and reengineering:* Derived from Methontology, the next common element is reusability and reengineering [37]. Fernandez-Lopez et al. [14] and Villazon-Terrazas et al. [68] underscore the importance of leveraging existing ontologies and knowledge resources, promoting efficiency and effective maintenance over time by avoiding redundant efforts. By integrating insights from various ODMs, this element strives to streamline the development process and enhance the quality of ontologies through systematic reuse [62], [69].

*e) Scenario-driven development:* Scenario-driven development principles are another important common element adopted from NeOn Methodology. This element, according to Suárez-Figueroa et al. [42] enables customization based on specific scenarios while promoting collaborative ontology construction. Recognizing the varied contexts in which ontologies are applied, scenario-driven development enhances the relevance and applicability of the ontology in real-world situations [66], [70].

*f) Comprehensive structure:* Aligned with the Uschold and King Methodology [46], a comprehensive and systematic structure in ontology development is another vital element in ODM. This element, as emphasized by Fernandez-Lopez [14] and Verbert et al. [66] is particularly crucial for addressing the intricacies of complex domains, ensuring that the ontology captures the structural and dynamic aspects with precision and detail. The comprehensive structure enhances the depth of representation, contributing to a more nuanced understanding of business phenomena and other complex domains [65], [66].

*2) Common steps:* In Table II, apart from the categorization of the ODMs and their characteristics, there is also a summary of the key steps involved in each ODM. Based on the various key steps employed in ODM, several common steps are identified among the lightweight and heavyweight ODMs that could be unified. The common steps of the ODM based on all six ODMs summarized in Table II are depicted in Fig. 4 below:



1. Identifying the scope and purpose
2. Defining and identifying concepts
3. Organizing concepts
4. Defining properties and constraints
5. Formalizing the ontology
6. Implementing and testing
7. Evaluating the ontology
8. Documenting the ontology
9. Maintaining and evolving the ontology

Fig. 4. The common steps of the ODM.

A brief explanation of the six common steps depicted in Fig. 4 is expounded below:

*a) Identifying the purpose and scope:* Identifying the purpose and scope is the key starting point in any ontology development [71], [72]. This step involves understanding why the ontology is being built and what it will be used for. It also includes defining the scope of the ontology, i.e., what concepts it will cover and what level of detail it will provide. Identifying the purpose and scope will ensure that the right ontology is developed in the right way in accordance with the intended user’s needs. This process is crucial as it provides direction and focus to the ontology development process, helps to avoid unnecessary work, ensures that the resulting ontology is useful and relevant to its intended users, makes the ontology development project more manageable, and helps define its role in the larger ecosystem of ontologies.

*b) Defining and identifying concepts:* Defining and identifying concepts is a vital step in ontology development. This step includes identifying the main concepts (or classes) that exist in the domain that the ontology is covering [71], [73]. These concepts are the building blocks of the ontology. This step is crucial as it lays the foundation for the ontology. At this stage, an upper ontology can be applied to provide a set of general concepts that can be used to define your specific domain concepts. The use of an upper ontology helps ensure consistency and persistence in the usage of terms, which is crucial for the accuracy and completeness of the identified and defined concepts. The most prominent role of formal ontologies, such as an upper ontology, is to provide a skeleton or common system for ontologies to be developed, provide rich semantics for knowledge representation systems, and enhance ontological adequacy and accuracy. This approach has been demonstrated by Sattar et al. [74] and Youcef et al. [53]. The accuracy and completeness of the identified and defined concepts directly impact the usefulness and applicability of the ontology. Therefore, considerable time and effort are often spent on this step to ensure that the ontology accurately represents all relevant concepts in the domain [2], [71], [73].

*c) Organizing concepts:* Once the main concepts have been identified, the next common step in ontology development is organizing them in a hierarchical structure.

Organizing concepts in a hierarchy helps to show the relationships between different concepts [75]. Here, the upper ontology can guide the structuring of relationships between the domain-specific concepts. It's important to preserve the meaning of higher-level ontology terms during this process. The use of an upper ontology in this step is part of organizing the design and development of ontologies under a common framework. It provides a more coherent and easy navigation as users move from one concept to another in the ontology structure. It also makes the ontology easy to extend as relationships and concept matching are easy to add to existing ontologies [72]. This step is important as it structures the ontology in a way that reflects the inherent structure of the domain. It also facilitates the understanding and use of ontology by providing a clear and intuitive organization of the concepts [75]. Considerable time and effort are often spent on this step to ensure that the ontology accurately represents the relationships among the concepts in the domain.

*d) Defining properties and constraints:* Defining properties and constraints is another vital common step in ontology development. This step involves identifying the properties (or slots) that each concept can have and defining any constraints on these properties [73]. This step is crucial as it adds detail and specificity to the concepts in the ontology. By defining properties and constraints, the ontology can represent not just what concepts exist in the domain, but also what characteristics those concepts have and how they are related to each other. Moreover, defining properties and constraints is essential for the ontology's usability [2], [73]. They allow for more precise queries and more detailed answers, making ontology a more powerful tool for understanding and navigating the domain.

*e) Formalizing the ontology:* After defining properties and constraints, the formalization of the ontology takes place. This common step in ontology development implies taking the concepts, hierarchies, properties, and constraints that have been identified and formalizing them using a formal representation language [2]. This makes the ontology machine-readable and allows it to be used by other software applications. The formal representation language used for this purpose needs to be machine-readable, allowing the ontology to be understood and used by other software applications. This is particularly important in the context of the Semantic Web, where ontologies play a key role in enabling machines to understand and process the vast amounts of data available on the Web [76]. Formalizing the ontology is imperative as it will ensure that the knowledge it represents is explicit, unambiguous, and readily accessible to both humans and machines. This process is key to unlocking the full potential of ontologies as tools for knowledge representation and management [77].

*f) Implementing and testing:* Once the ontology has been formalized, the next step is the implementation and testing. This standard step involves implementing the ontology in a software application and then testing it to make sure it works as expected. This might involve checking that the ontology correctly represents the domain it is intended to cover and that it provides the expected results when used in a software application. The implementation and testing phase is not a one-time process. As the domain of interest evolves and new knowledge is acquired, the ontology may need to be updated and re-tested to ensure that it continues to accurately represent the domain [78]. Although implementing and testing an ontology might sound complex, it is a necessary process that ensures the ontology is correctly integrated into a software application and functions as expected.

*g) Evaluating the ontology:* The subsequent step is evaluation, the critical phase in the ontology development. This is where the identification of the drawbacks took place. In this step, the identified issues will be resolved before the ontology is used, thereby increasing its reliability and usefulness. This common step involves evaluating the quality, consistency, and completeness of the ontology. This might involve assessing that the ontology accurately represents the domain it is intended to cover, and that it doesn't contain any inconsistencies or gaps [73], [79]. Considerable time and effort is needed on this step to ensure the evaluation process is comprehensively conducted to ensure the ontology fit for its purpose.

*h) Documenting the ontology:* In this step, the completed ontology will be documented. The document includes a description of the ontology's purpose and scope, an explanation of the concepts, hierarchies, properties, and constraints it contains, and instructions on how to use the ontology [73]. This document serves as a manual instruction to guide the users and developers in using the ontology correctly. It can eliminate ambiguities or confusion among its users. Therefore, documenting the ontology comprehensively is an imperative step in ontology development as it will facilitate communication and collaboration by providing a common understanding of the ontology [2], [73].

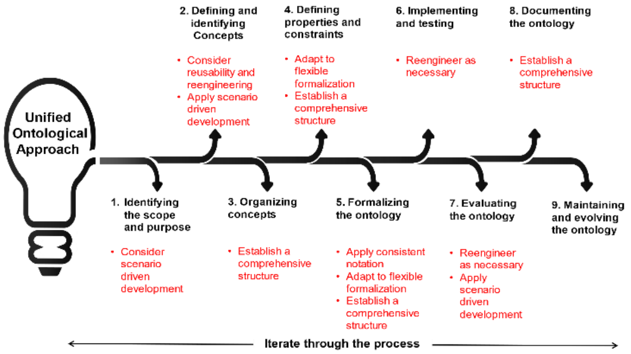
*i) Maintaining and evolving the ontology:* The final step is maintaining and evolving the ontology. This common step involves updating and refining the ontology as needed. This might involve adding new concepts, properties, or constraints, modifying existing ones, or reorganizing the hierarchy of concepts [80]. This step is critically needed as some of the domains like technology are rapidly evolving where new concepts may emerge frequently that need to be added to the ontology. Therefore, consistently maintaining and evolving the ontology will ensure that the ontology is updated and ultimately remains accurate and relevant over time [80], [81].

## V. Result

In this section, the common characteristics and key steps, synthesized from the review of various Ontology Development Models (ODMs) and Business Model Ontologies (BMOs) that have been extensively discussed in the previous sections, are integrated. This integration results in a Unified Ontological Approach (UOA) framework. The proposed framework combines the strengths of both lightweight and heavyweight ODMs, drawing inspiration from the success and principles of the BMO.

This UOA aims to facilitate the ontology development process by providing a step-by-step guide. The common characteristics, integrated into the key steps, will serve as best practices that can be adopted or adhered to at each step.

The proposed UOA framework is illustrated in Fig. 5 below and a brief explanation follows afterward.



Unified Ontological Approach
1. Identifying the scope and purpose
• Consider scenario driven development
2. Defining and identifying Concepts
• Consider reusability and reengineering
• Apply scenario driven development
3. Organizing concepts
• Establish a comprehensive structure
4. Defining properties and constraints
• Adapt to flexible formalization
• Establish a comprehensive structure
5. Formalizing the ontology
• Apply consistent notation
• Adapt to flexible formalization
• Establish a comprehensive structure
6. Implementing and testing
• Reengineer as necessary
7. Evaluating the ontology
• Reengineer as necessary
• Apply scenario driven development
8. Documenting the ontology
• Establish a comprehensive structure
9. Maintaining and evolving the ontology
Iterate through the process

Fig. 5. The proposed unified ontological approach (UOA) framework.

Fig. 5 above showcases the proposed UOA framework. The common steps gathered from the synthesis of various ODMs are organized sequentially to guide the entire ontology development process. The word written in red is the common characteristic which can also be referred to as the best practices to be adopted in each step. To better understand the meaning of each common characteristic in the context of this framework, a simple explanation can be found in Table V below:

TABLE V. BRIEF EXPLANATION OF THE COMMON CHARACTERISTICS

| Common Characteristics (Best Practices in this Framework Context) | Explanation |
|---|---|
| Consider Scenario Driven Development | Using specific, real-world examples to drive the development process |
| Consider Reusability | Using existing ontologies or parts of ontologies in the creation of a new ontology |
| Reengineering as necessary | Modifying the ontology based on new insights or changes in the domain |
| Establish a Comprehensive Structure | Creating a well-organized, detailed, and complete representation of the domain of interest |
| Adapt to Flexible Formalization | The ability to adapt and modify the ontology as needed, while still maintaining its structure and integrity |
| Apply Consistent Notation | Using a standard notation system to ensure that the ontology is understandable and interoperable |
| Iterate throughout the process | Repeatedly go through the steps of a process, making improvements each time based on what was learned in previous iterations |

At the bottom of the framework, there are also fine two-way arrows stating iterate through the process which means that all steps in the framework can be revisited and refined as needed, allowing for continuous improvement and refinement of the ontology.

## VI. Discussion

The proposed UOA for ontology development, as outlined through the integration of various ODMs and insights from the BMO invented by Osterwalder [23], presents a novel framework with both promising strengths and notable considerations. This brief discussion aims to critically examine the implications of this unified approach, shedding light on its strengths, addressing potential limitations, and identifying avenues for future research.

### A. Strengths

*1) Synergy of diverse methodologies:* The UOA leverages the strengths of diverse ODMs, which have been recognized for their ability to guide the process of constructing, deploying, and maintaining ontologies [82]. The iterative process, a key aspect of many ODMs, allows for continuous refinement and adaptation to evolving domain requirements [2], [83]. This iterative approach is also a fundamental aspect of the BMO which was developed specifically to represent business models and provide a comprehensive representation of a business [25]. By adopting this iterative process, according to Pittet et al. [84], the approach fosters a dynamic and responsive ontology development process. This ensures that the ontology remains relevant and up-to-date, adapting to changes in the domain of interest [73]. Therefore, the UOA effectively combines the strengths of both BMO and ODMs to create a robust and flexible ontology development process.

*2) Formal clarity and precision:* The adoption of a consistent notation system as one of the characteristics of the proposed UOA ensures unambiguous representation and reasoning of ontological knowledge. These formal languages provide a standardized way to represent and reason about ontological knowledge, ensuring that the representation is unambiguous [85]. This characteristic can be seen in BMO. According to Chungyalpa et al. [25] BMO uses a common notation to represent different aspects of a business, ensuring unambiguous representation and reasoning of ontological knowledge. This aligns with the argument made by Shukla et al. [85] about the importance of formal languages like OWL, UML, or RDF in ensuring unambiguous representation. According to Norris et al. [86], this consistency in notation enhances clarity in communication across different stakeholders, from domain experts to developers and end users. It ensures that everyone has a shared understanding of the ontological structures, which is key for effective collaboration and successful ontology development [2].

*3) Flexibility in formalization:* The incorporation of a flexible formalization approach as one of the best practices in the proposed UOA is influenced by methodologies such as UPON Lite, LOT and AgiSCOnt which addresses the needs of both domain experts and ontology engineers [34]. Lille et al. [34] added that this approach is oriented towards reduced dependence on ontology engineers, ensuring ease of use for the development of application ontologies. The flexibility in formalization is an important characteristic as it allows for the construction of ontologies from scratch or the reuse of existing ones [87]. Fernandez-Lopez et al. [43] argue that this promotes inclusivity and adaptability across diverse domains. In the context of BMO, flexibility is imperative as it allows the ontology to adapt to the diverse and evolving needs of businesses. Therefore, the flexible formalization approach effectively combines the strengths of both new ontology construction and existing ontology reuse to create a robust and flexible ontology development process.

*4) Efficiency through reusability:* The emphasis on reusability and reengineering in some of the steps in the proposed UOA, drawing from methodologies such as Methontology, contributes to the efficiency and effective maintenance of ontologies over time [37]. Leveraging existing ontologies and knowledge resources mitigates redundancy and streamlines the ontology development process [88]. This is evidenced in the BMO, which is designed to be reusable, allowing it to be applied across various business scenarios and domains [25]. This reusability not only mitigates redundancy but also streamlines the ontology development process, contributing to the efficiency of the ontology.

*5) Scenario-driven customization:* The utilization of scenario-driven development principles in the proposed UOA adopted from the NeOn Methodology facilitates customization and collaboration in ontology engineering based on common situations. This scenario-driven approach enhances the relevance and applicability of ontologies in real-world contexts [70]. This is similar to how BMO can be used to describe and analyze different business scenarios. For instance, BMO can be used to model different aspects of a business such as value proposition, customer segments, channels, customer relationships, revenue streams, key resources, key activities, key partnerships, and cost structure. These aspects can be seen as different scenarios in a business context. Therefore, applying scenario-driven customization allows for greater flexibility and relevance in development.

*6) Comprehensive structural representation:* Aligned with the Uschold and King Methodology, the UOA also emphasizes a comprehensive and systematic structure in the ontology development steps. This ensures the nuanced representation of both structural and dynamic aspects, which is particularly beneficial for addressing complexities in various application domains [78]. The BMO exemplifies the adoption of the structured approach to describe and analyze the business model as noted by Chungyalpa et al. [25]. It allows for the representation of complex business structures and dynamics systematically and comprehensively, similar to how the Uschold and King Methodology is applied in ontology development [47].

Table VI below compares the strength of the proposed UOA against the existing ODMs:

TABLE VI. COMPARISON OF UOA AND EXISTING ODM

| Aspect | Existing ODMs | Proposed UOA |
|---|---|---|
| Synergy of Diverse Methodologies | Each ODM has its own focus and limitations. | Integrates strengths from various ODMs, leveraging diverse methodologies for robust ontology development. |
| Formal Clarity and Precision | Varies in emphasis on formalization. | Ensures unambiguous representation and reasoning of ontological knowledge through consistent notation and formal languages. |
| Flexibility in Formalization | Flexibility ranges across ODMs. | Adopts a flexible formalization approach, allowing for construction from scratch or reuse of existing ontologies, promoting inclusivity and adaptability |
| Efficiency Through Reusability | Reusability is emphasized in some ODMs. | Emphasizes reusability and reengineering for efficiency, leveraging existing ontologies and knowledge resources to streamline development. |
| Scenario-Driven Customization | Scenario-driven approaches vary. | Utilizes scenario-driven principles for customization, enhancing relevance and applicability in ontology engineering based on common situations. |
| Comprehensive Structural Representation | Varies in depth of structural representation. | Emphasizes comprehensive and systematic structure in ontology development, ensuring nuanced representation of both structural and dynamic aspects for complex domains. |

## B. Limitations

The proposed UOA approach may also possess several limitations as briefly described below:

*1) Learning curve and expertise:* The adoption of a unified approach, which integrates elements from various methodologies, may introduce a learning curve and require expertise in multiple ODMs. This could potentially pose a challenge for practitioners who may need to familiarize themselves with different methodologies. However, the inclusion of the BMO as a practical example could facilitate comprehension and understanding among the users.

*2) Potential overhead in formalization:* The insistence on a consistent notation system and formalization, while enhancing precision, may introduce an additional overhead in terms of complexity. This may particularly impact users less familiar with formal languages, potentially limiting the accessibility of the approach.

*3) Applicability in highly specialized domains:* While the proposed UOA strives for versatility, its effectiveness in highly specialized domains with unique ontological requirements remains to be thoroughly examined. Certain domains may necessitate tailored methodologies not fully addressed by the integrated elements.

As the study of ODM is dynamic and rapidly growing, future research could focus on the enhancement of the proposed unified approach by adding the relevant steps and best practices towards a more holistic approach. The insights could also be taken to other renowned ODMs, apart from the ODMs discussed in this study.

### C. Future Work

The UOA framework is ready to be applied in real-world scenarios, particularly in the creation of the Information Dashboard Design Ontology (IDDO). This practical implementation will be used as a test environment to evaluate the efficiency and success of the UOA framework in directing the process of developing ontologies.

## VII. Conclusion

This study presents a Unified Ontological Approach (UOA), which is proposed through the integration of common characteristics and steps found in Ontology Development Methods (ODMs). The paper commences with a comprehensive discussion of ontology, its significance, and its applications. It also briefly touches upon the notation of endurant and perdurant elements in ontology, providing a general overview of these elements' existence within ontology. The study further reviews the BMO to glean insights into its development process and to learn from its widespread usage. An in-depth examination of several ODMs is also conducted to gain a succinct understanding of each method's characteristics, steps, and applicability. The paper briefly discusses the characterization of ODMs, specifically lightweight and heavyweight, to shed light on their suitability for various ontology development projects. Leveraging the insights gathered from this comprehensive study process, common characteristics, and key steps are identified. These elements are then synthesized and organized to form the proposed unified ontological framework, drawing from the insights of ODMs and the BMO. This synthesis forms the key contribution of this study.

## Acknowledgment

This research is supported by KDEB Waste Management Grant, Vo.t. No: ZG-2023-001. We highly appreciate the enormous support received for this research project.

# Deep Convolutional Neural Networks Fusion with Support Vector Machines and K-Nearest Neighbors for Precise Crop Leaf Disease Classification

Sunil Kumar H R[1], Poornima K M[2]
Research Scholar, Dept. of CS & E, JNN College of Engineering, Affiliated to VTU, Shivamogga, India, 577204[1]
Professor, Dept. of CS & E, JNN College of Engineering, Affiliated to VTU, Shivamogga, India, 577204[2]

***Abstract*—Maize and Paddy are pivotal crops in India, playing a vital role in ensuring food security. Timely detection of diseases and the implementation of remedial measures are crucial for securing optimal crop yield and profitability for farmers. This study utilizes a dataset encompassing images of diseased maize and paddy leaves, addressing various conditions such as corn blight, common rust, gray leaf spot, brown spot, hispa, and leaf blast, alongside images of healthy leaves. The dataset used here is a combination of online repository as well as manually collected samples from neighborhood farmlands at different growth stages. A machine vision approach that is accessible, quick, robust and cost effective to determine crop leaf diseases is need of the hour. In the proposed work, using transfer-learning approach, many Deep Convolutional Neural Networks (DCNN) and hybrid DCNNs have been developed, trained, validated and tested. To achieve better accuracy, integration of DCNNs and machine learning classifiers like multiclass Support Vector Machine (SVM) and K-Nearest Neighbor (KNN) algorithms is carried out. The research is carried out in four stages, in the first stage, DCNNs have been used as classifiers. Subsequently, these same DCNNs are repurposed as feature extractors, and the extracted features are input into classifiers such as multiclass SVM and KNN. In the third stage, an ensemble of DCNNs is performed for networks exhibiting excellent performance during first stage. At a fourth stage, features extracted from these ensemble networks are fed into the same multiclass SVM and KNN classifiers to assess accuracy. A total of 1600 images for training and 400 images for testing are used. For maize data set, we achieved a 100% accuracy in AlexNet plus VGG-16 hybrid network for multiclass SVM with 75:25 split ratio and for paddy dataset 99.51% accuracy is achieved in ResNet-50 plus Darknet-53 hybrid network for multiclass SVM with 75:25 split ratio. In the proposed study a comprehensive analysis is conducted, exploring features from various layers and adjusting data split ratios.**

***Keywords*—*Deep Convolutional Neural Network (DCNN); multiclass Support Vector Machine (SVM); K-Nearest Neighbor (KNN); ensemble; features; accuracy***

## I. Introduction

In India, agriculture is the primary source of livelihood for nearly 55% of the population. At current prices, agriculture and allied sectors account for 18.3% of India's GDP [1]. Maize and Paddy being major crops cultivated across Karnataka state, India, in various seasons, face several challenges of diseases impacting crop growth and subsequently diminishing yield and food quality [2-3]. The primary culprits behind these issues are bacteria, viruses and fungi, necessitating continuous monitoring of the leaves, stem and fruits of the crops. Some disease manifest with similar features, demanding expert level knowledge for accurate identification and preventive measures. Often, farmers struggle to pinpoint the causes through naked eye observation [4], resorting to suggestions from pesticide vendors. This, unfortunately, may lead to the excessive and unwarranted use of hazardous pesticides, causing harm to both crops and the environment. Simultaneously, engaging experts to visit farmlands is a cumbersome and time-consuming task. In addressing these challenges, automatic disease detection and crop monitoring emerge as crucial areas, where early identification of crop diseases allows for prompt intervention and effective damage control is possible [5].

Over the last decade, the Convolutional Neural Network (CNN) has produced groundbreaking outcomes in various domains associated with pattern recognition, spanning from image processing to voice recognition. In recent decades, it has been acknowledged as one of the most potent tools, gaining widespread popularity in literature due to its capability to manage vast amounts of data [6]. The success of CNN can be attributed to its exceptional ability to create high-level image representations across multiple scales, contrasting with the manual crafting of low-level features [7]. CNN automatically extracts features from the provided training data and conducts classification through its output layer. Various advantages of CNN architectures, such as weight sharing, the inclusion of a pool layer, and local connections, contribute to minimizing the number of parameters requiring training and reducing the overall complexity of the network [8]. Ecological agriculture requires the advancement of nondestructive intelligent methods capable of early detection of crop diseases [9]. In the current scenario, several modifications are made to CNN based architectures and proposed in this regard. Many plant leaves from open database and manually processed dataset have been used in many works. A simple CNN can be modified by applying hybrid combination of activation functions for agriculture crop leaf disease detection, where activation functions like Rectified Linear Unit (ReLU), Gaussian Exponential Linear Unit (GeLU), Scaled Exponential Linear Unit (SeLU) can be used [10]. In some studies, a combination of VGG-16 and MobileNet deep learning models with stacking ensemble learning techniques are introduced to obtain 89% accuracy on sunflower leaves

[11]. A novel activation function which is sum of Parametric ReLU (PReLU) and multiple Mexican hat functions called as Mexican ReLU (MeLU) are introduced for VGG16 and ResNet-50 to enhance the accuracy of disease detection [12]. In another work, a novel hybrid approach work was proposed in three phases. First phase includes improved histogram equalization to enhance contrast. In second phase features are extracted using Gray Level Co-occurrence matrix (GLCM), Gabor feature and curvelet feature extraction methods. In third phase Neuro-Fuzzy logic classifier is trained with features extracted from second phase. PlantVillage data base is used and obtained 90% accuracy [13].

Another report shows AlexNet plus SVM [14] hybrid approach used to obtain a massive 99.98% accuracy on 12 crop species with 38 different leaf diseases. A hybrid approach VGG16 with dropout operation and attention module was also introduced to have better accuracy of classification [15] on tomato leaves. A hybrid model based on CNN and Convolutional Auto Encoder (CAE) was built for automatic plant disease detection. CAE was used to reduce the training parameters of the hybrid model. The proposed hybrid model used only 9914 training parameters. The model was tested on peach plants to identify Bacterial Spot disease achieving 99.35% training accuracy and 98.38% testing accuracy[16]. A novel deep neural network using Caffe framework to recognize plant leaf diseases was proposed. In their work 14 different plants are considered and used 30880 images for training and 2589 images for validation. For accuracy test, 10-fold cross validation techniques used. 15 different classes were made and a precision of 91% to 98% accuracy was achieved [17]. A high-performance attention-based dilated CNN logistic regression (ADCLR) was used to claim 100% accuracy on tomato leaves. Similarly CNN based AlexNet, GoogLeNet, VGG-16, DenseNet-121, Inception V4 and ResNet-50 have been implemented in many studies on plant village dataset as shown in the works [18-19].

Deshapande et al. [2] conducted a research with the goal of distinguishing various Maize diseases, including corn rust, northern leaf blight, other fungal diseases, and healthy leaves. They employed Decrement, KNN, and SVM classifiers. To achieve accuracies of 85% and 88% on the KNN and SVM classifiers, respectively, Haar wavelet features and first-order histogram features on GLCM were utilized. Chowdhury R et al. [20] conducted a study on eight different types of paddy leaf diseases, analyzing approximately 1426 images for disease and pest detection. Their work introduced a simple two-stage CNN designed for mobile application development, considering limited memory and resources. The model underwent training using baseline training, fine-tuning, and transfer learning methods gave 93.3% accuracy. S. Ramesh and D. Vydeki [21] applied a deep neural network and the jaya algorithm for the recognition and classification of various paddy leaf diseases. They achieved an accuracy of more than 92% for different diseases. A DenseNet based model was also proposed for identifying and recognizing Maize leaf diseases, yielding an accuracy of 96% [22]. A modified LeNet architecture, [23] utilizing a DCNN, is employed for the classification of maize leaf diseases. The study involves experimenting with maize leaf images sourced from the PlantVillage dataset. The developed CNNs are specifically trained to distinguish among four distinct classes, including three disease categories and one representing a healthy state. The trained model demonstrates an impressive accuracy rate of 97.89%. In the work proposed by Poornima K M and Sunilkumar H R [24], ten different modified DCNN were studied and implemented on maize leaf data set addressing four diseases. Different activation functions, epochs, learning rate were introduced on trial-and-error basis. They claim ResNet-50 outperforms others with 98.5% accuracy.

Another CNN based model was introduced to classify diseases on Maize data set claiming 97% accuracy [25]. Utkarha N Fulari et al. [26] proposed an AlexNet based plant leaf disease identification and classification in which about 12949 open database images were used. An accuracy of 95% achieved for Maize leaf data. Md. A. Haque et al. [27] experimented with inception-V3 model and used baseline training approach on maize leaves. The trained model out performs other CNN based transfer learning approaches giving out an accuracy of 95.99%. M. Micheni et al. [28] carried out an experiment on maize data set using AlexNet and ResNet-50 with the help of transfer learning along with SVM, amounting accuracies of 98.3%, 96.6% and 88.5% respectively. Paddy leaves were used by Naware et al. [29] to classify diseases using KNN and SVM giving 96.2% and 98.56% accuracies respectively. A. Nigam et al. [30] proposed a new method for paddy leaf images classification using Principal Component Analysis (PCA) and Bacterial Foraging Optimization Algorithm (BFOA) with cost function for feature extraction and deep neural network used for classification to get an accuracy of 98%. Another [31] CNN based paddy leaf disease classification is done using about 2239 training and 168 testing data set. An accuracy of 91% is achieved.

X. Qian et al. [32] introduced a novel model distinct from CNN, the approach relies on transformers and self-attention. It captures visual details of image localities through tokens, computes the correlation (referred to as attention) among these local regions utilizing an attention mechanism, and ultimately consolidates global information to facilitate the classification process. Later the proposed model outperforms various existing models. Using maize data set an accuracy of 98.7% is achieved. A work carried out [33] on Paddy leaves of 800 data set. CNN was applied and compared with logistic regression, decision tree. CNN model was giving around 80.25% accuracy. K. Saminathan et al. [34] used multiple classifiers like Logistic Regression (LR), Random Forest Classifier (RFC), Decision Tree Classifier, K-Nearest Neighbor (KNN) Classifier, Linear Discriminant Analysis (LDA), Support Vector Machine (SVM) and Gaussian Naive Bayes (NB). The accuracy of the RFC model gained 92.84% after validation and 97.62% after testing using paddy disordered samples. B Sowmiya et al. [35] proposed a classification of paddy leaf diseases with extended Huber loss using CNN to minimize the loss. The model has achieved 96.63% training and 86.61% validation accuracies respectively. Another CNN based approach for maize dataset achieving 96.53% accuracy [36]. M. Syarief and W. Setiawan have proposed a fusion method where seven different CNNs are used to extract the features and fed to three classifiers namely k-NN, SVM and decision tree. Maize data set is used where AlexNet with SVM is giving maximum accuracy of 95.83% [37].

### A. Gap Identification

Given the current landscape, there is a pressing need for a machine vision –based technique that is easily accessible, swift, robust and cost effective. Deep learning techniques have the potential to meet these requirements when carefully designed. Very less work has been progressed in creating hybrid DCNN and fusion of DCNN with machine learning classifiers like SVM and KNN.

Having this motivation, the study explored several advanced DCNN frameworks to classify three maize diseases, three paddy leaf diseases, and healthy leaves. Adjustment of various parameters to train the networks using a transfer learning approach on the given dataset is carried out. Subsequently, the features extracted from these trained networks were input into classifiers such as multiclass SVM and KNN to improve the overall results. This process was iterated for an ensemble of diverse DCNNs. Additionally, comparative analysis with methods proposed in the existing literature is carried out.

The study makes several notable contributions: firstly, an image database has been created by collecting images from both open-source repositories and visiting nearby farmlands at various stages of growth in a nondestructive manner. The same database was utilized for training, validating, and testing the developed DCNN models. Secondly, we extracted features from both shallow and deep layers of the trained DCNNs for testing with SVM and KNN along with different split ratio of training and testing. Thirdly, an ensemble of DCNNs was created to assess performance enhancement. The proposed study demonstrates a substantial improvement in the classification performance of maize and paddy diseased leaves. The paper is structured as follows. Section II presents methods and materials; Section III presents results and discussion; and Section IV presents the Conclusion.

## II. Methods and Materials

The envisaged system aims to establish an efficient mechanism for detecting diseases in maize and paddy plant leaves by employing a combination of DCNNs, multiclass SVM, KNN and image processing techniques. This section offers a comprehensive elucidation of the proposed system. Fig. 1 illustrates the entire workflow of the proposed system.

### A. Dataset Collection

An image database is created by collecting images from both open-source [38] repositories and visiting nearby farmlands at various stages of growth in a nondestructive manner. In the proposed work, we have taken maize and paddy leaf diseases like corn blight, corn common rust, corn gray leaf spot, brown spot, hispa, leaf blast along with healthy leaves. A total of 11322 images have been collected. Out of which 2000 images have been used for the experimentation as shown in the Table I.

Fig. 2 gives a glimpse on the various maize and paddy diseased leaves considered for the experiment.

### B. Preprocessing the Dataset

Since dataset is image, we need to do some preprocessing like, resizing, noise removal etc. usually grayscale versions of images and background removal does not work well for classification performance of neural networks [8]. The networks we are using in proposed work shall take images of different size. For example, AlexNet can take images of size 227x227x3 but SqueezeNet would consider only 224x224x3 size images and DarkNet-53 considers 256x256x3 as shown in Table II.

### C. Splitting of Dataset

A total of 2000 images have been considered, in that 400 images are used for testing and 1600 images are used for training purpose, 80:20 ratio is being followed. While training, 30% of the total training data have been split and used randomly for validation purpose as shown in the Table I.

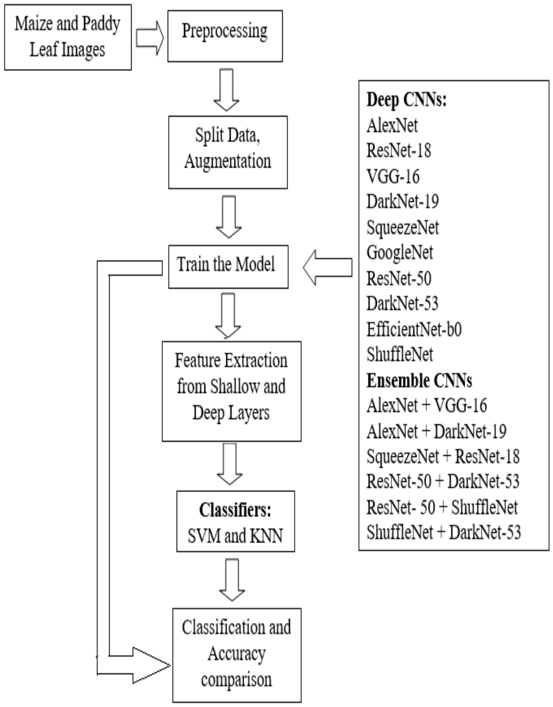

Fig. 1. The proposed methodology.

TABLE I. Data Set Collection

| Disease Name | Data set from open database [38] | Manually collected dataset | No. of images for training and validation (70:30) | No. of images for testing |
|---|---|---|---|---|
| Corn Blight | 1146 | 1354 | 200 | 50 |
| Corn Gray Spot | 574 | 355 | 200 | 50 |
| Corn Common Rust | 1306 | 313 | 200 | 50 |
| Healthy Corn | 1162 | 547 | 200 | 50 |
| Paddy Brown Spot | 418 | 399 | 200 | 50 |
| Paddy Hispa | 764 | 365 | 200 | 50 |
| Paddy Leaf Blast | 623 | 411 | 200 | 50 |
| Paddy Healthy | 1100 | 485 | 200 | 50 |
| Total | 7093 | 4229 | 1600 | 400 |

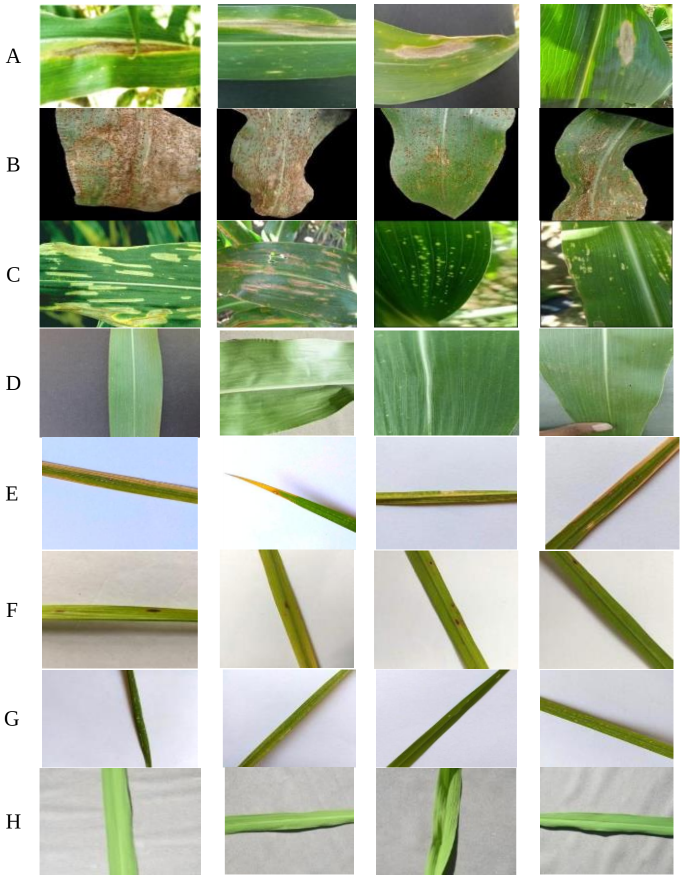

Fig. 2. Maize leaves diseases: A. Blight, B. Common rust, C. Gray leaf spot D. Healthy maize, Paddy leaves diseases: E. Blast, F. Brown spot, G. Hispa H. healthy paddy.

TABLE II. DCNNS WITH LAYERS, INPUT IMAGE SIZE, ACTIVATION FUNCTIONS, LEARNING RATE

| DCNNs | Layers / Connections | Size of input image | Activation function | Learning Rate |
|---|---|---|---|---|
| AlexNet | 23/24 | 227-by-227 | ReLU | .0001 |
| DarkNet-19 | 63/24 | 256-by-256 | Leaky-ReLU | .0001 |
| VGG-16 | 41/40 | 224-by-224 | ReLU | .0001 |
| Squeeze Net | 68/75 | 227-by-227 | ReLU | .0001 |
| Resnet-18 | 71/78 | 224-by-224 | ReLU | .0001 |
| Shuffle Net | 172/186 | 224-by-224 | ReLU | .001 |
| DarkNet-53 | 184/206 | 256-by-256 | Leaky-ReLU | .0001 |
| ResNet-50 | 177/192 | 224-by-224 | ReLU | .0001 |
| GoogleNet | 144/170 | 224-by-224 | ReLU | .0001 |
| EfficienNet-b0 | 290/363 | 224-by-224 | Sigmoid | .0001 |

### D. Data Augmentation

Data augmentation is a technique of artificially increasing the training set by creating modified copies of a dataset using an existing one. In the proposed work various augmentation techniques like Random reflection axes, random rotation, random rescaling and random horizontal and vertical translations have been applied. The images were not duplicated but augmented during the training process, so the physical copies of the augmented images were not stored but were temporarily used in the process. This augmentation technique not only prevents the model from overfitting and model loss but also increases the robustness of the model so that, when the model is used to classify leaf disease images, it can classify them with better accuracy [39].

### E. Train the Model

Models are trained using the data set as shown in the Table I. Transfer learning [3] approach is applied to train each and every network considered. Activation functions used and learning rates applied on various DCNNs have been shown in the Table II and various training properties are used as shown in the Table III.

TABLE III. TRAINING PROPERTIES AND PARAMETERS USED FOR TRAINING

| Properties | Parameters |
|---|---|
| Solver | Stochastic Gradient Descent with Momentum (SGDM) |
| Initial learning rate | 0.001- 0.0001 |
| Validation frequency | 10-20 |
| Max Epochs | 30-50 |
| Mini Batch size | 15-20 |
| Execution momentum | auto |
| Sequence Length | longest |
| Sequence padding value | 0 |
| Sequence padding direction | right |
| Gradient threshold method | L2norm |
| L2reularization | .0001 |
| Shuffle | Every epoch |
| Learn rate schedule | Piecewise |
| Learn rate drop facto | 0.1 |
| Learn rate drop period | 10 |
| Reset Input normalization | 1 |
| Momentum | 0.9 |

### F. Feature Extraction

Feature extraction in Convolutional Neural Networks (CNNs) is a crucial step in image processing and computer vision tasks. CNNs are designed to automatically learn and extract relevant features from input images to facilitate accurate classification, detection, or other tasks [9].

*1) Train classifier on shallower features:* Extract features from an earlier layer in the network and train a classifier on those features. Earlier layers typically extract fewer, shallower features, have higher spatial resolution, and a larger total number of activations.

*2) Train classifier on deeper features:* Deeper layers contain higher-level features, constructed using lower-level features of earlier layers. To get the feature representations of the training and test images, activations on the global pooling layer is used. The global pooling layer pools the input features over all special locations, giving maximum features in total. Features extracted from the training images as predictor variable and fit them to classifier like multiclass SVM and KNN. Later classify the test images using trained classifiers using features extracted from the test images [40]. Same thing is repeated for hybrid DCNNs with multiclass SVM and KNN. The detailed results are shown in Section III.

### G. *Multiclass Support Vector Machine*

Multiclass Support Vector Machine (SVM) is a machine learning algorithm used for classification tasks involving more than two classes. The primary objective of multiclass SVM is to create decision boundaries in a high-dimensional space that effectively separate and categorize data points into multiple classes. Unlike binary SVM, which is designed for two-class problems, multiclass SVM extends its capabilities to handle scenarios where there are three or more distinct classes [26]. In our study, we opt for a linear kernel [34] due to the increased number of features and the characteristic of our classification problems being linearly separable, as articulated in Eq. (1).

$$f(X) = W^T * X + b \tag{1}$$

### H. *K-Nearest Neighbor*

K-Nearest Neighbors (KNN) stands out as a straightforward, instance-based, and nonparametric machine-learning algorithm applicable to both classification and regression tasks. Its predictions rely on either the majority class (in classification) or the average value (in regression) derived from the k-nearest neighbors within the feature space. In classification, the anticipated class is typically determined through a majority vote among the k-nearest neighbors, with the class possessing the highest frequency within this group being assigned to the new data point [37]. While KNN demonstrates accuracy, it operates at a slower pace [34]. The mathematical expression for determining the Euclidean distance between any two points is provided in Eq. (2), and this process is reiterated accordingly.

$$d = \sqrt{(x2 - x1)^2 + (y2 - y1)^2} \tag{2}$$

### I. *Classification and Accuracy Comparison*

Leaf disease classification from various methods and their corresponding accuracies are collected and compared for the analysis purpose.

## III. Results and Discussion

The results are analyzed as follows. The proposed model was trained and tested on combination of images from online repository and manually collected data. For every diseased leaf including healthier one, we hand picked randomly to make a dataset of 2000 images from both the sources. Out of which, 80:20 ratio is maintained for training and testing purpose. The same dataset is used to train the individual DCNNs using transfer learning approach by giving suitable learning rate, epochs and parameters as shown in the Tables II and III. Later results were noted and compared as shown in the following sections.

### A. *Results with respect to Maize Data*

*1) Results with individual DCNN and DCNNs with k-NN, SVM:* The Table IV depicts the results of maize leaf diseases classification with accuracies. Initially classification accuracy using individual DCCNs is taken and compared with the accuracies achieved from the extracted features from both shallow and deep layers, which were later used for KNN and SVM classifiers. Classifiers are tried with 50:50, 60:40, 70:30, 80:20 training and test ratio of the features extracted.

One very important observation made here is, SVM giving better results on deep layers compared to KNN, which is good at shallow layers as indicated in the Table IV. Best accuracy values with corresponding split ratio are considered for the analysis purpose.

TABLE IV. Features are Extracted from Pre-Trained Network and Used for Classification Through Multiclass SVM and KNN for Maize Dataset

| Pre-T | Clas | Bes | Sp | Be | Sp | Acc |
|---|---|---|---|---|---|---|
| AlexNet | Multiclass SVM | 94.37 | 60:40 | 97.1 | 80:20 | 95.6 |
| | KNN | 94.37 | 60:40 | 95 | 80:20 | |
| ResNet-18 | Multiclass SVM | 95 | 80:20 | 94.37 | 60:40 | 94.8 |
| | KNN | 92.5 | 70:30 | 88.12 | 60:40 | |
| VGG16 | Multiclass SVM | 96.25 | 80:20 | 98.21 | 80:20 | 95.5 |
| | KNN | 95.83 | 70:30 | 87.5 | 70:30 | |
| Darknet-19 | Multiclass SVM | 95 | 70:30 | 94.17 | 70:30 | 96.5 |
| | KNN | 93.75 | 80:20 | 87.50 | 70:30 | |
| Squeeze Net | Multiclass SVM | 91.25 | 60:40 | 95 | 70:30 | 95.8 |
| | KNN | 93.50 | 50:50 | 90 | 80:20 | |
| GoogleNet | Multiclass SVM | 93.75 | 80:20 | 95 | 50:50 | 96 |
| | KNN | 95 | 80:20 | 71.67 | 70:30 | |
| ResNet-50 | Multiclass SVM | 94.17 | 70:30 | 97.4 | 80:20 | 94.7 |
| | KNN | 94.37 | 60:40 | 97.5 | 60:40 | |
| DarkNet-53 | Multiclass SVM | 93.75 | 80:20 | 96.25 | 80:20 | 94 |
| | KNN | 94.17 | 70:30 | 78.75 | 80:20 | |
| Shuffle-Net | Multiclass SVM | 94.1 | 60:40 | 95 | 80:20 | 96 |
| | KNN | 93.7 | 80:20 | 93.11 | 70:30 | |
| EfficientNet-b0 | Multiclass SVM | 96.67 | 70:30 | 92.5 | 80:20 | 91.5 |
| | KNN | 95.50 | 50:50 | 61.67 | 70:30 | |

Fig. 3 representing the comparison between accuracies obtained by individual DCNNs and best possible results when features from DCNNs are used to feed k-NN and multiclass SVM with different split ratio. The graphs show significant improvements in the results of EfficientNet-bo, ResNet-50 and VGG-16 when features from these models are fed to the k-NN and SVM.

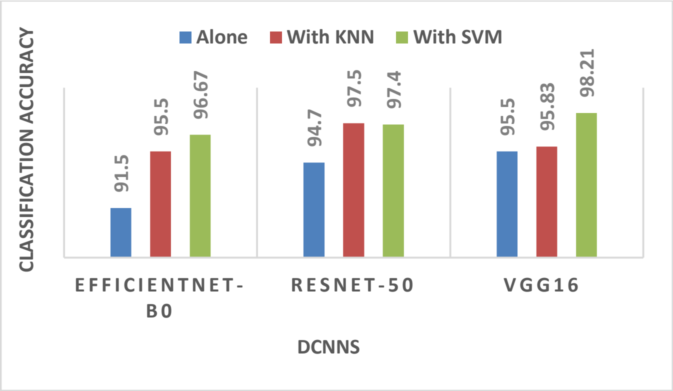

Fig. 3. Comparison of accuracies with DCNNs, k-NN and SVM for Maize data set.

*2) Results with hybrid DCNNs and hybrid DCNNs with k-NN, SVM:* Three network ensembles are made and tried with the dataset. Accuracy is significantly improved compared with individual DCCNs. As a final step, hybrid networks created are used for feature extraction to feed KNN and SVM classifiers with different training and testing ratio of dataset features. Again, an overwhelming improvement in the accuracies as evidenced in the Table V is achieved.

TABLE V. FEATURES ARE EXTRACTED FROM HYBRID PRE-TRAINED NETWORK AND USED FOR CLASSIFICATION THROUGH MULTICLASS SVM AND KNN FOR MAIZE DATASET

| **Hybrid Pre trained network for feature extraction** | **Classifier** | **Best Accuracy** | **Data split ratio (Training: Testing)** | **Accuracy when Hybrid Pre trained networks considered alone** |
|---|---|---|---|---|
| AlexNet + VGG16 | Multiclass SVM | **100** | 75:25 | 97.83 |
| | KNN | 96.25 | 80:20 | |
| AlexNet+DarkNet-19 | Multiclass SVM | 98.33 | 70:30 | **97.99** |
| | KNN | 97.5 | 70:30 | |
| SqueezeNet+ResNet-18 | Multiclass SVM | 97.50 | 70:30 | 93.17 |
| | KNN | **98.5** | 80:20 | |

A 100% accuracy achieved in AlexNet plus VGG-16 hybrid network for multiclass SVM with 75:25 split ratio. And a whopping accuracy of 98.5% is achieved in the SqueezeNet plus ResNet-18 for k-NN with 80:20 split ratio.

The graphs in Fig. 4 show that the proposed work significantly improves the performance when features are extracted from hybrid network and used for classification through multiclass SVM and KNN.

## B. Results with Paddy Data

*1) Results with individual DCNN and DCNNs with k-NN, SVM:* The Table VI depicts the results of paddy leaf diseases classification with accuracies. Initially classification accuracy using individual DCCN is taken and compared with the accuracies taken from the extracted features from both shallow and deep layers to be used for KNN and SVM classifiers. Classifiers are tried with 50:50, 60:40, 70:30, 80:20 training and test ratio of extracted features from both train and test images. Best accuracy values with corresponding split ratio are considered for the analysis purpose.

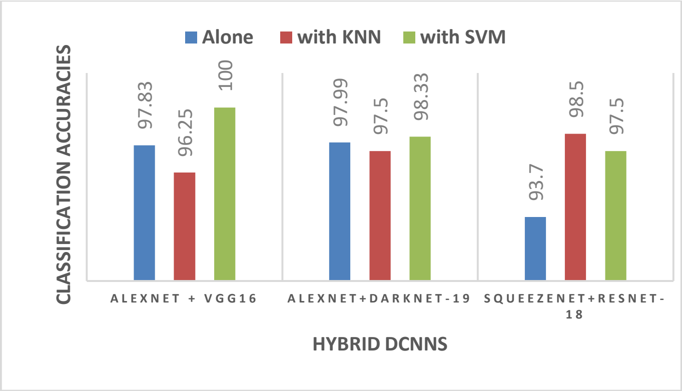

Fig. 4. Comparison of accuracies with hybrid DCNNs, with k-NN and with SVM Maize data set.

TABLE VI. FEATURES ARE EXTRACTED FROM PRE-TRAINED NETWORK AND USED FOR CLASSIFICATION THROUGH MULTICLASS SVM AND KNN USING PADDY DATASET

| **Pre-Trained Network to Extract Features** | **Classifier** | **Best Accuracy for shallow layers** | **Split Ratio** | **Best Accuracy for deep Layers** | **Split Ratio** | **Accuracy from individual DCNN** |
|---|---|---|---|---|---|---|
| AlexNet | Multiclass SVM | 76.60 | 60:40 | 74.49 | 70:30 | 94.11 |
| | KNN | 74.07 | 70:30 | 53.99 | 80:20 | |
| ResNet-18 | Multiclass SVM | 72.39 | 80:20 | 80.66 | 70:30 | 94.14 |
| | KNN | 73.62 | 80:20 | 79.31 | 50:50 | |
| VGG16 | Multiclass SVM | 82.76 | 50:50 | 75.31 | 70:30 | 93.13 |
| | KNN | 84/05 | 80:20 | 61.35 | 80:20 | |
| Darknet-19 | Multiclass SVM | 78.6 | 70:30 | 84.66 | 80:20 | 70.08 |
| | KNN | 80.25 | 70:30 | 68.72 | 70:30 | |
| Squeeze Net | Multiclass SVM | 78.22 | 60:40 | 80.67 | 60:40 | 85.75 |
| | KNN | 78.53 | 80:20 | 74.84 | 80:20 | |
| GoogleNet | Multiclass SVM | 77.3 | 80:20 | 77.49 | 70:30 | 92.35 |
| | KNN | 77.91 | 80:20 | 55.83 | 60:40 | |
| ResNet-50 | Multiclass SVM | 81.6 | 60:40 | 84.66 | 80:20 | 97.53 |
| | KNN | 81.6 | 80:20 | 70.55 | 80:20 | |
| DarkNet-53 | Multiclass SVM | 74.85 | 80:20 | 82.30 | 70:30 | 98 |
| | KNN | 74.85 | 80:20 | 63.37 | 70:30 | |
| Shuffle-Net | Multiclass SVM | 78.3 | 80:20 | 74.49 | 70:30 | 97.29 |
| | KNN | 77.91 | 80:20 | 55.83 | 60:40 | |
| fficientNet-b0 | Multiclass SVM | 90.80 | 80:20 | 65.03 | 80:20 | 92.13 |
| | KNN | 89.57 | **80:20** | 49.38 | 70:30 | |

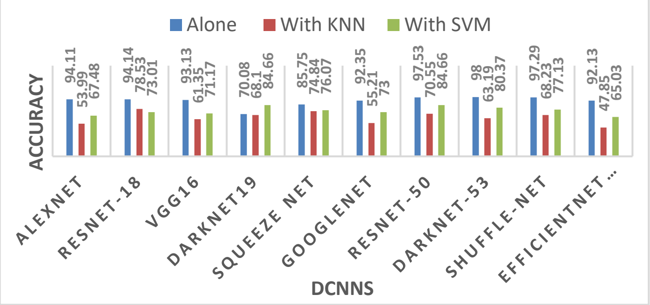

Fig. 5. Comparison of accuracies with DCNNs, k-NN and SVM for Paddy data set.

The graphs in Fig. 5 show accuracy variation of DCNNs with k-NN and SVM. The observation made here is, accuracies when pretrained networks considered alone are giving better results compared to the features extracted and fed to the k-NN and SVM classifiers.

*2) Results with hybrid DCNNs and hybrid DCNNs with k-NN, SVM:* Three network ensembles are made and tried with paddy dataset. Accuracy is significantly improved compared with individual DCCNs. As a final step, hybrid networks created are used for feature extraction to feed KNN and SVM classifiers with different training and testing ratio show an improvement in the accuracy as shown in the Table VII.

A 99.51% accuracy achieved in ResNet-50 plus Darknet-53 for multiclass SVM and 96.06% accuracy can be seen for k-NN, maintaining 75:25 split ratio for both. A detailed comparison is shown in the Fig. 6.

As a final remark, utilizing features extracted from DCNNs and subsequently feeding them into SVM and k-NN has demonstrated enhanced accuracy in the precise classification of Maize and Paddy diseased leaves, as depicted in Fig. 7.

A detailed comparison analysis is done as shown in the Table VIII for Maize data. The proposed work is giving a maximum accuracy of 100%, which is quite impressive compared to the results from the literature.

A detailed comparison analysis is done as shown in the Table IX and 99.51% for paddy leaf images obtained which is better compared to other studies in the literature.

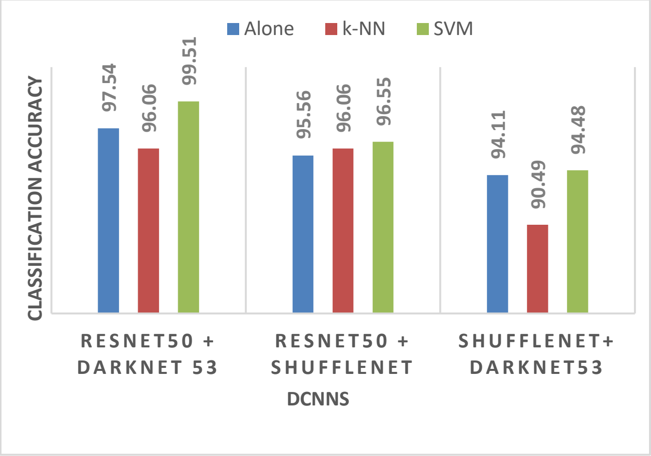

Fig. 6. Comparison of accuracies with hybrid DCNNs, k-NN and SVM.

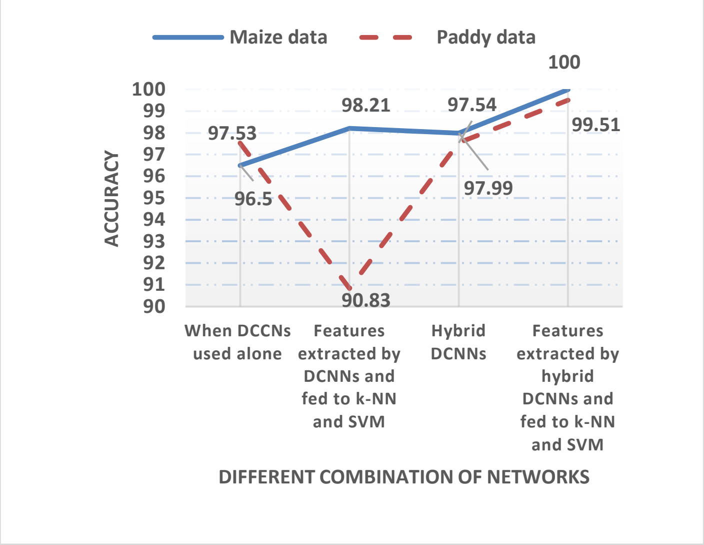

Fig. 7. Comparison of various approaches used in the proposed work.

TABLE VII. FEATURES ARE EXTRACTED FROM HYBRID PRE-TRAINED NETWORK AND USED FOR CLASSIFICATION THROUGH MULTICLASS SVM AND KNN FOR PADDY DATASET

| Hybrid Pre trained network for feature extraction | Classifier | Accuracy with various split ratio | Data split ratio (Training: Testing) | Accuracy when Hybrid Pre trained networks considered alone |
|---|---|---|---|---|
| RESNET50 + Darknet 53 | Multiclass SVM | **99.51** | 75:25 | **97.54** |
| | KNN | **96.06** | 75:25 | |
| RESNET50 + ShuffleNet | Multiclass SVM | 96.55 | 70:30 | 95.56 |
| | KNN | 96.06 | 70:30 | |

## IV. CONCLUSION

This research focuses on the successful experimentation of identifying and classifying diseases in Maize and Paddy leaves. The dataset comprises both online repository data and manually collected images from neighboring farmlands. Employing transfer-learning approach, many DCNNs and hybrid DCNNs have been developed, trained, validated and tested successfully. Features from various layers of the developed DCNNs have been used to feed the multiclass SVM and KNN for higher accuracies in identification and classification of the Maize and paddy leaf diseases.

The conclusion is presented in four key parts. Firstly, diverse Deep Convolutional Neural Networks (DCNNs) were developed, trained, validated and tested using our own dataset. Initially these DCNNs served as classifiers, achieving an accuracy range of 70% to 98%. In the subsequent stage, the same DCNNs were repurposed as feature extractors from deep and shallow layers. These extracted features were then input into traditional machine learning classifiers such as multiclass SVM and KNN, yielding promising improvements in results. Further enhancing the experimentation, selected superior DCNNs are combined for ensemble purposes from the first stage.

Combinations like AlexNet with VGG-16, AlexNet with DarkNet-19, and SqueezNet with ResNet-18 were utilized for the maize dataset, resulting in a classification accuracy ranging from 93.166% to 98%. For paddy leaves, hybrid approaches involving ResNet-50 with DarkNet-53, ResNet-50 with ShuffleNet, and ShuffleNet with DarkNet-53 are used and achieved an accuracy of 94.11% to 97.54%.

In the final phase, features from these hybrid DCNNs were fed into multiclass SVM and KNN classifiers, demonstrating exceptional accuracy of 100% and 99.51% for Maize and paddy leaves respectively for various data split ratios. Overall, this research highlights the effectiveness of employing both DCNNs and traditional ML classifiers for accurate disease identification and classification in Maize and Paddy leaves with variable data split ratio.

The investigation could extend to obtaining real-time data sets, where leaf images are acquired directly from farmlands in a non-destructive manner and processed simultaneously. This processing aims to enhance the accuracy of disease identification and severity assessment, facilitating the recommendation of remedial measures for farmers. A smartphone application could effectively fulfill this purpose.

# Towards a Machine Learning-based Model for Corporate Loan Default Prediction

Imane RHZIOUAL BERRADA, Fatimazahra BARRAMOU, Omar BACHIR ALAMI
Laboratory of Systems Engineering, Hassania School of Public Works, Casablanca, Morocco

***Abstract*—As the core business of the banking system is to lend money and then get it back, loan default is one of the most crucial issues for commercial banks. With data analysis and artificial intelligence, extracting valuable information from historical data, to lower their losses, banks would be able to classify their customers and predict the probability of credit repayment instead of relying on traditional methods. As most actual research is focused on individuals' loans, the novelty of the present paper is to treat corporate loans. Its main objective is to propose a model to address the problem using selected machine learning algorithms to classify companies into two classes to be able to predict loan defaulters. This paper delves into the Corporate Loan Default Prediction Model (CLD PM), which is designed to forecast loan defaults in corporations. The model is grounded in the CRISP-DM process, commencing with comprehending corporate requirements and implementing classification techniques. The data acquisition and preparation phase are critical in testing the selected algorithms, which involve Logistic Regression, Decision Tree, Support Vector Machine, Random Forest, XGBoost, and Adaboost. The model's efficacy is assessed using various metrics, namely Accuracy, Precision, Recall, F1 score, and AUC. Subsequently, the model is scrutinized using an actual dataset of loans for Moroccan real estate firms. The findings reveal that the Random Forest and XGBoost algorithms outperformed the others, with every metric surpassing 90%. This was accomplished by utilizing SMOTE as an oversampling method, given the dataset's imbalance. Furthermore, when concentrating on financial statements, selecting the five most significant financial ratios and the company's age, Random Forest was adept at predicting defaulters with good results: accuracy of 90%, precision of 75%, recall of 50%, F1 score of 60% and AUC of 77%.**

***Keywords*—Loan default; prediction; artificial intelligence; data analysis; machine learning; companies; corporate; real estate; bank***

## I. Introduction

Banks worldwide need to secure their loans and minimize defaults to maintain healthy financial results. To achieve this, they use various risk rating methods based on traditional approaches or more recently, innovative ones that incorporate artificial intelligence. It is thus important to classify customers to predict their worthiness (Ability to pay back the loan) [1] before loans approval.

The banking industry deals with an enormous amount of data on a daily basis. As a result, financial institutions need to rely on the outcome of this data to strengthen their risk strategy. Credit scoring has become a competitive advantage for these institutions in order to optimize their profits, as reported by [2]. There are several steps that they should follow to achieve this objective. To start with, data analysis should be a central issue in the decision-making process of approving or rejecting a loan.

Retail banking (individuals' loans) has been studied in different research works and recent articles thanks to open and various available datasets [3] [4] [5]. Many literature reviews are also available for personal credit scoring [6] [7].

Moreover, commercial banks can experience significant losses due to default payments on loans, particularly in cases where large amounts are involved, such as financing investment projects. However, there is limited research on this topic [8] [9], with most studies focusing on personal loans rather than investment loans for companies. Therefore, this research will specifically address the issue of corporate loans.

Companies have been affected by various recent crises worldwide, including in Morocco. It is widely recognized that investment projects are essential for the success of every economy and are crucial for all industries. To this end, banks play a critical role in approving loans for companies seeking financing for development. As explained by [10] studying the drivers of default, central banks and governments have a concern to ensure balanced growth in the market.

While studying actual research, no detailed model was found with description from the beginning of the project till its testing phase and implementation. A guided step by step model to follow and apply is needed for financial institutions and researchers.

In this article, the Corporate Loan Default Prediction Model (CLD PM) is presented with its detailed roadmap and application results to be used by researchers and banks to predict losses and avoid risky loan distribution for companies. It is a model based on CRISP-DM for which the steps are detailed. For that, the related work concerning the process is presented. Then, the algorithms and metrics used are highlighted. After that the model with the chosen machine learning algorithms and evaluation metrics is exposed, to end up with the results for the application on a real-world dataset of real estate development loans for Moroccan companies. In conclusion, the test results are detailed as well as the limitations, next steps, and perspectives to work on.

The novelty of this article is that it proposes a comprehensive approach for investment loans offered to companies. The default on these loans can be attributed to various factors such as the financial health, history, behavior, and qualitative data of the company. The implementation phase is based on a thorough analysis of financial statements and ratios that differentiate corporates.

## II. RELATED WORK

Several articles discussing data mining and data science methods have been reviewed, and the most relevant ones have been selected for presentation here. Additionally, a comparison of different machine learning algorithms for classification has been conducted based on a previous review, and the algorithms of interest for testing have been narrowed down. It will be presented in the following section with a specific focus on the problem. The review of articles dealing with data mining and data science methodologies has resulted in the selection of the most relevant ones for presentation. Furthermore, a comparison of machine learning algorithms for classification has been conducted based on the previous review to limit the interest to the algorithms to test [11].

The related work will be presented in the following section with a specific point of view for the problem.

### A. *Related Work: Process*

After reviewing various historical process models, it seems that CRISP-DM (Cross-Industry Standard Process for Data Mining) is an interesting process model, which inspires the theoretical approach before delving into applications and testing (see Fig. 1).

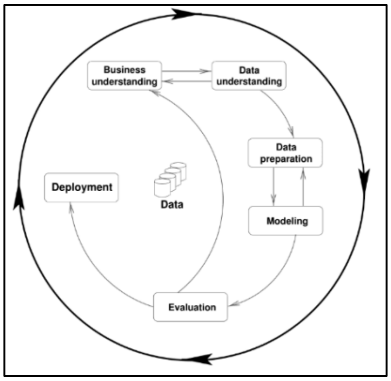

Fig. 1. CRISP DM [15].

Indeed, according to S. Saltz et al. in 2016 through their article [12], to hold a successful project, there is a need for a process, key process attributes, and effective team communication. This literature review for many thousands of conferences and articles highlighted two well-known models for Data Mining: CRISP-DM and SEMMA (Sample, Explore, Modify, Model, and Assess) confirming that they might be not appropriate for BD (Big Data) projects. The article demonstrates that Agile methodologies have more advantages than waterfall methodologies.

CRISP-DM has been established in the middle of the nineties based on previous models and is the most well-known and used process. It relies on six steps: business understanding, data understanding, data preparation, modeling, evaluation, and deployment [8] [13]. SEMMA was developed by the SAS institute and is the second most popular methodology [14].

These methods have similarities and more research focus on new methodologies based on these.

In the continuity of the previous work of S. Saltz et al, for [16], an experiment was held comparing four different methodologies with four different teams holding projects. Evaluated by independent experts and through stakeholders' surveys, Agile Kanban (based on the principle of moving quickly and easily by focusing on small parts of the project) and CRISP-DM outperformed.

Then, different developed methodologies are found based on the previous cited and others such as DMME [17] that is an extension to the CRISP-DM adding some adjustments to adapt the methodology taking into account engineers' points of view. This method focuses on data collection and acquisition methods, technical understanding, and workflow monitoring while the projects in the run for more effectiveness.

F. Martinez et al. [18] studied the evolution twenty years after CRISP-DM was introduced. They present the move from the Data mining process and its first discovery to Data Science trajectories. An interesting figure presents different models and methodologies derived mainly from KDD and CRISP-DM. A diagram has been proposed to include all the activities identified in a data science project. This will help define different trajectories for a customized Data Science Trajectories model, called DST, for each project. The diagram, which is shown in Fig. 2, includes all activities from data management, CRISP-DM and exploratory. It is possible to have one or many trajectories for each project, which can include any of these activities.

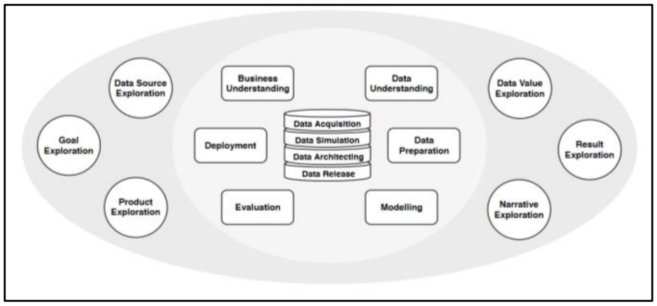

Fig. 2. DST MAP [18].

### B. *Related Work: Algorithms and Metrics*

The problem concerning loan default prediction is a classification issue needing appropriate algorithms to perform and compare. As in a previous work, the different possible approaches were studied and the most effectively used algorithms were identified [11], the algorithms to be tested in the implementation phase are the following: Logistic regression, Decision tree, Random Forest, Support Vector Machine, Xgboost and Adaboost. Moreover, other recent articles highlight interesting results with these algorithms [19] [20]. In the following, a brief description of each is presented.

Logistic regression (LR) is a statistical method used to predict if there is a certain value as an outcome of a probability. Authors of [21] prove the outperformance of logistic regression according to ROC.

Decision tree (DT) is a graphical representation of possible solutions to a decision based on certain conditions. In their article, authors of [22] present a comparison between decision tree and random forest in which random forest outperforms.

Random forest (RF) is an ensemble algorithm, bagging the decision tree. It creates multiple decision trees in the training process. Authors of [22] compare the performance of decision trees and random forest and random forest outperformed. Moreover, the article of [23] compares the performance of ensemble algorithms concluding that ensemble algorithms have better results. This algorithm performs well even with thousands of variables according to the authors of the article.

Support Vector Machine (SVM) is a large-margin classifier that tries to find the maximum margin separating the dataset into two categories. Moreover, [24] compared random forest to SVM and found that random forest was quick and had more simplicity whereas SVM had better accuracy. In their article, authors of [1] performed a two steps testing applying first random forest then SVM for good performance.

eXtreme Gradient Boosting (XgBoost) is an ensemble learning method using a collection of weak learners (decision trees) to have strong predictions. It was combined with Lightgbm to propose a hybrid model by Z. Song [25] outperforming for fraud detection.

Adaptive Boosting (AdaBoost) is a general boosting algorithm ensemble learning combining individual weak learners with sequential adjusted weights to improve accuracy. According to authors of [26], AdaBoost reaches the highest performance.

Concerning evaluation metrics, there are several used to evaluate machine learning algorithms' performance. In the following, the most important and commonly used ones for classification problems are presented [11]:

- Accuracy: Proportion of true among total
- Precision: Proportion of the predicted positive cases that are correct
- Recall or sensitivity: Proportion of positive cases that are correctly identified
- F1 score: Weighted harmonic mean of precision and recall
- AUC (Area Under the ROC Curve): Probability that a random positive is positioned to the right of a random negative ROC plots

Many actual studies use all these evaluation metrics and others to choose the best one. Authors of [27] choose accuracy to conclude that random forest delivered the best results compared to other algorithms.

L Zhang et al. presented in their article [4] a metric according to profit for peer-to-peer lending as accuracy can be non-sufficient. But most of the tested comparisons lead to accuracy as a key performance indicator.

A very interesting literature review held in [28] analyses and figures out the metrics tested and used by different articles studied. This article also tackles a specific issue concerning the evolution of credit scoring evaluation and research studies still lacking today.

### C. Related Work: Companies Loan Default Prediction

Early studies started in 1966 about bankruptcy prediction with statistical methods based on previous available data about the companies. In 1999, with [29], discriminant analysis is used and performed well for prediction. Then, in 2005 with [30], Back propagation neural networks and SVM were used for small datasets to predict companies bankruptcy which is an advanced level of default. Indeed, a company that goes on bankruptcy is subsequently a defaulter regarding its creditors.

Authors of [26] presented the literature review concerning corporate credit risk as well as consumer and P2P. They highlighted that companies' loans are the most important ones for banks. Some of previous works were presented including those held from the credit crisis in 2007 [31] , 2012 [32] and 2014 [33]. These studies explored different SVM applications and variants to confirm their good performance.

For [8], researchers studied companies loan default prediction and applied machine learning algorithms for classification to demonstrate the superiority of Random forest. Moreover, [9] examined credit risk assessment and confirmed that SVM have good accuracy while applied to a company's dataset limited to three features. They also studied the impact of the company daily income to its credit score.

In the same register, authors of [34] proposed a combined model for SME (Small and Medium Entreprises) comparing the performance of separated SVM and combined and optimized with rough sets to identify key factors influencing credit risk by reducing classification indicators.

On another hand, [35] handles the problem facing industrial companies in India after the COVID crisis lowering their capacity to pay their loans and avoid bankruptcy focusing on some key predictor financial ratios. Financial data for companies can thus deliver hidden information and lead to default prediction.

Moreover, in [36], a comparison is held between statistical and machine learning classification. The conclusion leads to the added value of machine learning for datasets with few features. F. Azayite et al. [37] propose a hybrid model combining discriminant analysis, multilayer neural networks and self-organizing maps. They confirm then that a model performed with the appropriate data deliver better results.

Hyeongjun et al. presented a literature review [38] for companies loan prediction highlighting many limitations of the actual research and focusing on the importance of data governance and financial engineering to benefit from machine learning algorithms with good data preprocessing.

A great analysis was held by M Modina et al. [39] according to accounting data and credit indicators from private internal sources about previous loans history. Both indicators provide valuable information and predictive capabilities. The impact of each feature is studied. Moreover, authors raise the fact that the results could vary depending on the sector and location to explore for future work.

### D. Related Work: Imbalanced Datasets

Concerning imbalanced datasets for companies, [40] analyses SMOTE (Synthetic Minority Over-sampling Technique) and combined Weighted SMOTE with ensemble learning (random forest) in order to propose a solution to the cited problem for small business. Authors of [41] also used SMOTE to tackle the problem and reach good results.

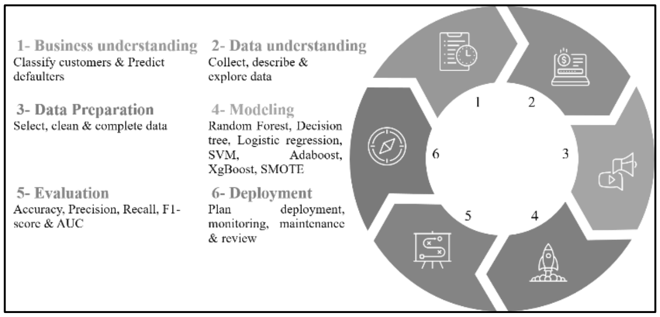
Moreover, [42] tested different resampling methods and concluded that among oversampling, undersampling, both and SMOTE, SMOTE outperforms. [43]

## III. Corporate Loan Default Prediction model

To accurately identify defaulters and non-defaulters in a business, a Corporate Loan Default Prediction Model (CLD PM) has been proposed based on previous research. This model takes into account the subject specificities, while focusing on the limitations of each approach. It uses the CRISP-DM methodology.

However, before modeling and evaluation, it is recommended that data preparation is thorough and appropriate. With different data preparation, different results are obtained. Using machine learning algorithms that have been successful in the past can help run tests and select the best algorithm for deployment. By prioritizing data preparation, it is possible to improve the accuracy of the predictions and make informed decisions for business.

The CLD PM is presented in Fig. 3 and detailed in the following. The model was validated with the use case dataset:



1- Business understanding
Classify customers & Predict defaulters
2- Data understanding
Collect, describe & explore data
3- Data Preparation
Select, clean & complete data
4- Modeling
Random Forest, Decision tree, Logistic regression, SVM, Adaboost, XgBoost, SMOTE
5- Evaluation
Accuracy, Precision, Recall, F1-score & AUC
6- Deployment
Plan deployment, monitoring, maintenance & review

Fig. 3. Corporate Loan Default Prediction Model (CLD PM).

### A. Business / Problem Understanding

In this step, it is a must to understand the business, and describe the problem faced. Banks distribute loans to companies and individuals but the problem encountered is risk of default which might be minimized in the approval phase. It is a binary classification problem (« defaulters » and « non-defaulters » / « good » and « bad » payers).

Hence, it is necessary to define the purpose to reach in order to approve the model's results. The objective is to find a solution to the problem with machine learning and obtain good performance of classification.

### B. Data Understanding / Collection

At this step, there is normally no available dataset to perform the model on, there is a necessity to identify the needed data with its attributes for each record. In the following, according to business knowledge, a list of identified features is identified to distinguish different payers' profiles to classify them into "good" and "bad" payers:

- Data concerning the company (Identification, Activity, size based on the annual turnover, financial ratios & data from financial statements, experience, quality of management…)
- Data concerning banks' relationship (Transactional data, Credit score, other banks historical data…)
- Data concerning the loan characteristics (Loan type, release date, Default…)

After needed data identification, the acquisition process can be launched.

Unfortunately, most of the time, while facing the step of data acquisition, it seems complicated to collect the defined features even if existing in the bank's several separated systems and databases. The data acquisition goes through a long and complicated process. The combination of these data provides the dataset to deal with.

When the dataset is available, an important step is to understand its content and confirm that it is conform to what was requested. If the output doesn't fulfill the aimed dataset, a loop to the second step is needed for readjusting. It is a validation step before starting data analysis and AI modeling and testing.

If the output dataset is satisfying in terms of identified needed features, the description and visualization can be held with line charts, bar charts, heatmaps, and others before preprocessing.

### C. Data Preparation

This step plays a central role and has to be correctly held to strengthen the model's performance. It is the looping node and the crucial treatment in the model. In the following, the detailed steps are presented in order to perform machine learning algorithms:

- Feature selection with a business knowledge insight
- Conversion of categorical data to float
- Conversion of dates to years
- Reduce features dropping highly correlated ones
- Drop features with more than 50% missing values
- Complete missing values with the most frequent values

It is also possible to visualize a heatmap and select the most important features after performing Data preparation. Moreover, for loan default prediction, the datasets are imbalanced with a minority class of default. SMOTE is here the chosen technic to handle the problem.

### D. Modeling - Machine Learning Training

As previously cited, the following algorithms are performed:

- Logistic regression (LR)

- Decision tree (DT)
- Random Forest (RF)
- Support Vector Machine (SVM)
- eXtreme gradient Boosting (XgBoost)
- Adaptive Boosting (AdaBoost)

To train the prepared dataset, the dataset is split into a training set of 80% and 20% for testing as used for training classification machine learning algorithms [44].

### E. Evaluation

To appreciate the performance of each algorithm, the following metrics are tested with and without SMOTE:

- Accuracy
- Precision
- Recall or sensitivity
- F1 score
- AUC (Area Under the ROC Curve)

As long as the results of all the algorithms concerning all the metrics don't exceed a certain predefined value, a loop and readjustment of models parameters and preprocessing are performed. If only one algorithm performs well, it can be adopted for implementation.

## IV. Case Study

The case study to implement the previous model is a dataset of real estate companies from a commercial Moroccan bank.

Concerning the tools and the environment for implementation, the following are chosen:

- Integrated development environment: Jupiter Notebook
- Dataframe: Pandas
- Machine learning libraries: Scikit-learn, Pytorch, Matplotlib, seaborn, Numpy
- Programming languages: Python

To begin with, the problem at hand is to classify loan applicants for predicting defaults among companies. The objective is to achieve good metrics performance by utilizing the available data. The objective is to reach outstanding metrics with a target of more than 0.9 for all metrics.

For data identification, the meaningful features from the perspective of business experts are listed. Unfortunately, all the selected features weren't extracted. The available data collected from different sources and their combination is a fact to deal with. Data understanding and visualization are needed to validate and perform the rest of the model.

Before analyzing the dataset and visualizing it, features are defined. As there are 107 features, the most meaningful ones with expert's insight are below in Table I. An advanced analysis with the impact of each features and a classification of their importance according to each machine learning algorithm can be performed in further work analysis:

The dataset contains 396 records with 107 features for companies with loans released from 2015 to 2020. It contains companies' historical, qualitative, and financial data. It has 48 large companies and 348 Small and Medium-sized enterprises as shown in Fig. 4.

Concerning default, there are 50 defaulters and 346 non-defaults as shown in Fig. 5. It is an imbalanced dataset for which additional processing is needed.

Furthermore, among all the features, there is a correlation and some data with no economic sense for the present problem. For values, there are categorical data, dates, and missing values. To handle these issues, feature reduction is performed with multiple loopings to the test phase as the results needed to be meaningful and satisfying.

TABLE I. DESCRIPTION OF MOST IMPORTANT DATASET FEATURES

| Feature name | Brief description | Data type |
|---|---|---|
| Ref | A unique ID to loan application | Numeric |
| Annee | The year of loan approval | Date |
| Segment | The size of the company based on its Turnover (GE for Big companies & PME for Small & Medium companies) | Categorical |
| CATEGORIE JUR | The legal category of the company | Categorical |
| Anciennete entreprise | The age of the company | Numeric |
| Anciennete relation | Relationship age | Numeric |
| MAX NBR JOUR DEBITEUR | Maximum number of debtor days | Numeric |
| sum mcm net mad | Sum of credit movement | Numeric |
| Score crédit bureau | Credit score | Numeric |
| EBE CA | EBITDA (Earning before interest, tax, depreciation and amortization) on turnover | Numeric |
| TRES TB | Net cash on total assets (Liquidity ratio) | Numeric |
| FR FINAN EBE | Financial costs on EBITDA (Debt ratio) | Numeric |
| dettef kpropres | Financial debts on equity (Debt ratio) | Numeric |
| stk ca | Stock on turnover (Activity ratio) | Numeric |
| RN CA | Net profit on turnover (Profitability ratio) | Numeric |
| RN KP | Return on equity (Profitability ratio) | Numeric |

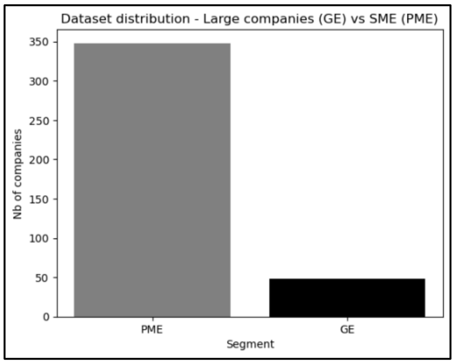

Fig. 4. Dataset distribution – Large companies and SME.

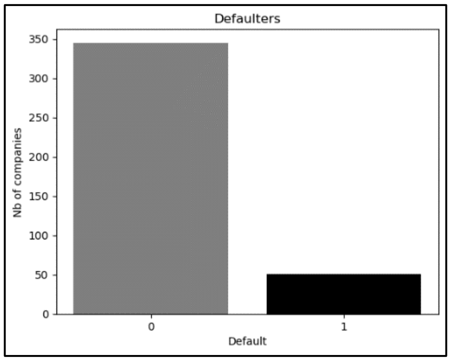

Fig. 5. Dataset distribution – Defaulters and non defaulters.

## V. Results and Discussion

The six algorithms are trained and tested the five metrics to obtain results adjusting hyper parameters to maximize the results. Table II and Fig. 6 illustrate the results of the maximized results.

The metrics measures are not satisfying even if accuracy and AUC can present good scores in some cases, precision, recall and F1 score underline bad performance as they are between 0 and 0.66. All the algorithms don’t perform well. The identified origin of the problem is the imbalanced dataset. Default is only 13% of the dataset and the split of the dataset into the training of 80% and testing 20% lowers the probability of having a balanced dataset while testing on the small dataset of 396 records.

To tackle the problem of the small class imbalanced dataset, SMOTE was tested to resample the dataset. It is an oversampling technique that generates synthetic samples to resolve the problem of class minority and have a balanced distribution. It uses KNN and interpolating. Table III and Fig. 7 highlight the results of the test phase while using SMOTE.

TABLE II. Metrics of Tested Algorithms without SMOTE

| **Algorithm / Metric** | **Accuracy** | **Precision** | **Recall** | **F1 score** | **AUC** |
|---|---|---|---|---|---|
| Decision tree | 0.8250 | 0.3750 | 0.2500 | 0.3000 | 0.64 |
| Random Forest | 0.8500 | 0.5000 | 0.0833 | 0.1429 | 0.89 |
| SVM | 0.8500 | 1.0000 | 0.0000 | 0.0000 | 0.64 |
| Logistic Regression | 0.8000 | 0.3000 | 0.2500 | 0.2727 | 0.59 |
| XGBoost | 0.8625 | 0.6667 | 0.1667 | 0.2667 | 0.88 |
| AdaBoost | 0.8500 | 0.5000 | 0.2500 | 0.3333 | 0.64 |

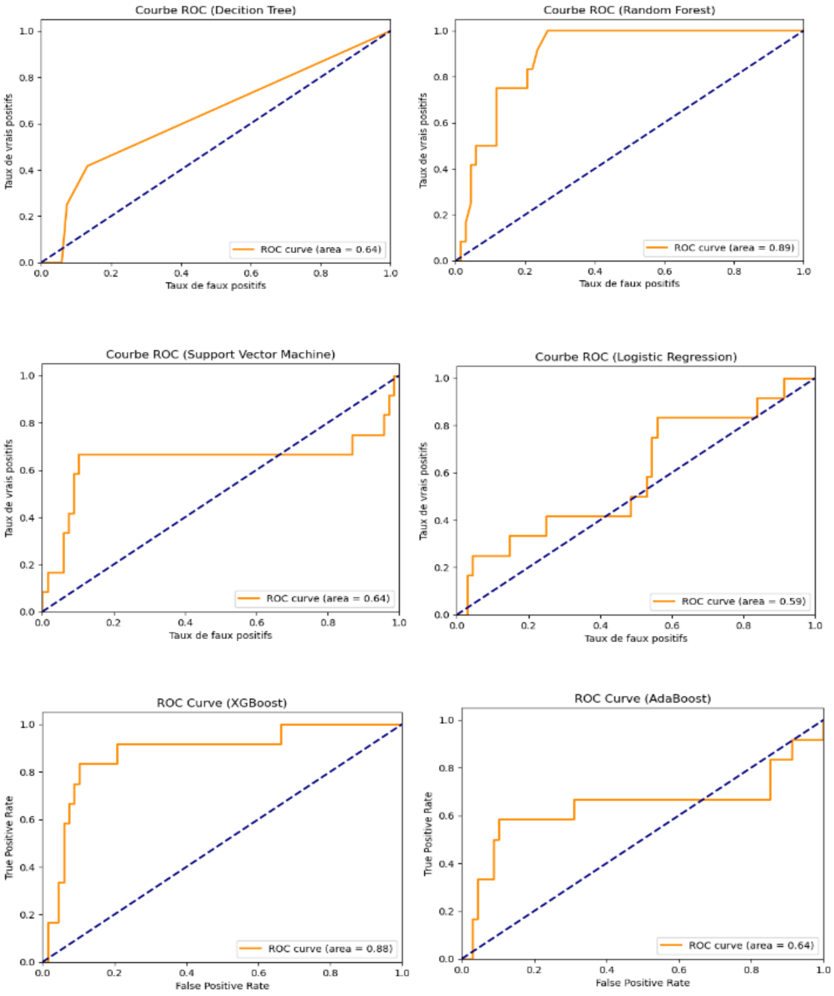

Fig. 6. ROC curve of the 6 algorithms without SMOTE.

TABLE III. METRICS OF TESTED ALGORITHMS WITH SMOTE

| **Algorithm / Metric** | **Accuracy** | **Precision** | **Recall** | **F1 score** | **AUC** |
|---|---|---|---|---|---|
| Decision tree | 0.8188 | 0.7692 | 0.8333 | 0.8000 | 0.85 |
| Random Forest | 0.9420 | 0.9062 | 0.9667 | 0.9355 | 0.99 |
| SVM | 0.8875 | 0.6154 | 0.6667 | 0.6400 | 0.77 |
| Logistic Regression | 0.7536 | 0.7097 | 0.7333 | 0.7213 | 0.82 |
| XGBoost | 0.9420 | 0.9333 | 0.9333 | 0.9333 | 0.98 |
| AdaBoost | 0.9130 | 0.8636 | 0.9500 | 0.9048 | 0.97 |

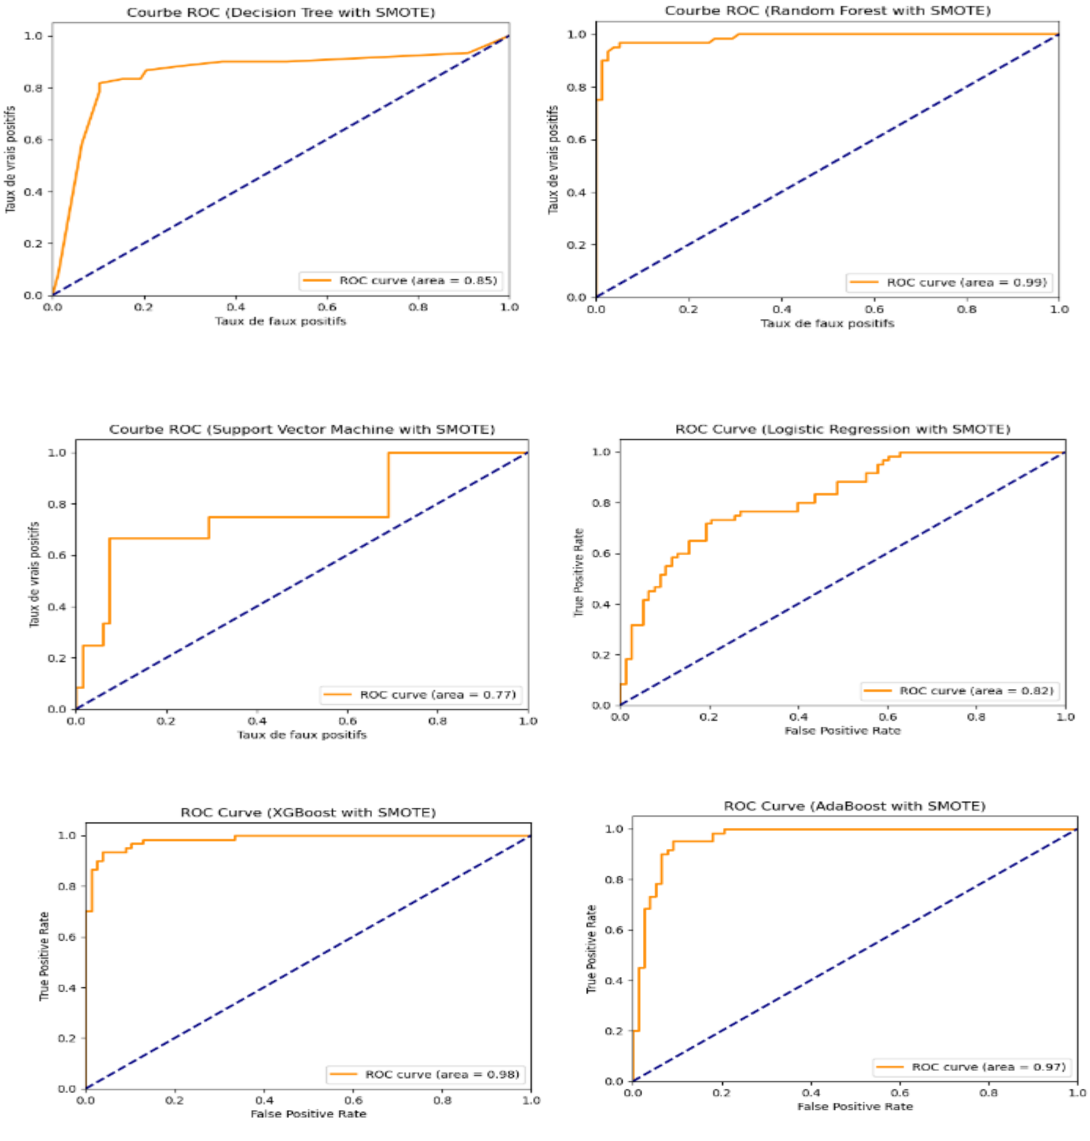

Fig. 7. ROC Curve of the 6 algorithms with SMOTE.

Based on the table and figures provided, it can be concluded that SMOTE enhances the performance of all the algorithms across all the metrics. The oversampling technique using SMOTE results in improved predictions, with fewer false positives and false negatives. The top-performing algorithms are Random Forest and XGBoost. As the approach is based on actual research results combined with knowledge concerning business problem, some external factors should disturb the expected results. The macroeconomic context, the Covid-19 crises, and the financial crises caused by the Russia / Ukraine conflict as well as the growth of inflation rate and loan interest rate consequently, will bias predictions' outcomes. There must be readjustment to perform. Future research can handle this issue. Indeed, historical data for some examples can make no sense before 2020 as some companies went into bankruptcy even if they had robust financial health before the COVID crises. The sector in which the model is operated has its external factors to take into account.

In this context, as highlighted by [35], it is obvious that some financial ratios have significant impact on the prediction outcome. Indeed, a more advanced analysis allows to classify the most important features for each algorithm performed. With their combination, a set of five important features consisting of ratios from financial statements are identified:

- Liquidity ratio: Net cash on total assets (TRES TB)
- Debt ratio: Financial debts on equity (dettef kpropres)
- Profitability ratio - Return on equity: Net income on equity (RN KP)
- Profitability ratio – Margin: EBITDA on turnover (EBE CA)
- Activity ratio: Stock on turnover (stk ca)

When performing Random Forest with SMOTE on the dataset limited to these five ratios, without taking into account the other features concerning the company and its banking behavior, the model output allows to reach good performance for Random forest as presented below in Table IV:

Furthermore, if the age of the company is added to the five financial ratios, the model is strengthened as shown in Table V and can be applied to real estate companies.

TABLE IV. METRICS OF RANDOM FOREST WITH SMOTE – 5 FINANCIAL RATIOS

| Algorithm / Metric | Accuracy | Precision | Recall | F1 score | AUC |
|---|---|---|---|---|---|
| Random Forest | 0.8500 | 0.500000 | 0.583333 | 0.538462 | 0.738971 |

TABLE V. METRICS OF RANDOM FOREST WITH SMOTE – 5 FINANCIAL RATIOS & THE COMPANY AGE

| Algorithm / Metric | Accuracy | Precision | Recall | F1 score | AUC |
|---|---|---|---|---|---|
| Random Forest | 0.9000 | 0.750000 | 0.500000 | 0.600000 | 0.768995 |

As the use case considered has a small imbalanced dataset, a bigger dataset is needed to test and validate the model and the results. Moreover, future work can be held considering larger dataset with companies in different industries. The financial ratios to adopt for other industries might be different from real estate companies as this sector has specific accounting rules and midterm cycle projects development.

It would be also interesting to test the model proposed by [5] using a multi-classification method rather than a binary considering late payers not as defaulters but as a third class.

## VI. CONCLUSION AND PERSPECTIVES

In the present article, a model is proposed with its detailed steps for the loan default prediction using machine learning applied to Corporate Loan Default Prediction Model (CLD PM). With few founded research concerning this field and no proposed model detailing the process with all its components, algorithms and metrics, the present article offers an overview applied to a dataset of 396 loans for real estate companies.

Accuracy, precision, recall, F1 score and AUC for six different algorithms were compared. Moreover, SMOTE was used to conclude that for an imbalanced datasets, with data concerning the company, its financial statements and bank relationship, Random Forest, and XgBoost outperform. For five selected most important features (financial ratios) from different most important features of the algorithms performed with the age of the company, random forest with SMOTE can be applied.

For future work, additional data concerning the projects, their market and their location could also have an influence on the output and lead to different results.

# Enhancing Data Warehouses Security

Muhanad A. Alkhubouli, Hany M. Lala, AbdAllah A. AlHabshy, Kamal A. ElDahshan
Department of Mathematics, Faculty of Science, Al-Azhar University, Cairo, Egypt

***Abstract*—Data Warehouses (DWs) are essential for enterprises, containing valuable business information and thus becoming prime targets for internal and external attacks. Data warehouses are crucial assets for organizations, serving critical purposes in business and decision-making. They consolidate data from diverse sources, making it easier for organizations to analyze and derive insights from their data. However, as data is moved from one source to another, security issues arise. Unfortunately, current data security solutions often fail in DW environments due to resource-intensive processes, increased query response times, and frequent false positive alarms. The structure of the data warehouse is designed to facilitate efficient analysis. Developing and deploying a data warehouse is a difficult process and its security is an even greater concern. This study provides a comprehensive review of existing data security methods, emphasizing their implementation challenges in DW environments. Our analysis highlights the limitations of these solutions, particularly in meeting scalability and performance needs. We conclude that current methods are impractical for DW systems and support for a comprehensive solution tailored to their specific requirements. Our findings underscore the ongoing significance of data warehouse security in industrial projects, necessitating further research to address remaining challenges and unanswered questions.**

***Keywords*—*Data warehouse; data security; encryption; security issues; data integrity; privacy; confidentiality***

## I. Introduction

A data warehouse contains sensitive and confidential information. Since users' access data in the data warehouse at many levels within the organization, protecting this information is crucial. For each of their organizational processes, all organizations collect data and input it into computer systems [1].

The concept of a data warehouse is rooted in storing data in a structured manner for an extended time. This allows the data to be archived and easily accessible for future use. The structure of the data warehouse is designed to facilitate efficient analysis. Data warehouses are among an organization's most important assets and are primarily employed in crucial business and decision-making processes. The data warehouse incorporates data from several sources. As a result, security risks develop when moving data from one location to another [2].

Data warehouse security discusses the methods that may be used to safeguard the data warehouse by preventing access to information by unauthorized users to maintain the data warehouse's reliability [3]. The owner must encrypt critical data before outsourcing to guarantee its secrecy. Developing and deploying a data warehouse is a difficult process and its security is a major concern [4]. The organization does not always benefit from the decoration that emphasizes security considerations. Because of this, it is crucial to assess the security aspect of a data warehouse [5].

The handling of the significant amount of data gathered from the numerous daily transactions is the most crucial responsibility. Data warehouses have seen a growth in data collecting volumes because of the organization's processes becoming more computerized. As a result, more people are now accessing and utilizing the data [6].

Data security encompasses concerns regarding the confidentiality, integrity, and availability of data. These concerns include ensuring privacy, maintaining accuracy, validity, and consistency of data, and ensuring that data is immediately accessible. Confidentiality is the act of safeguarding information from being disclosed without authorization, whether it is by direct access or indirect logical deduction [7].

The rest of this paper is organized as follows. Section II introduces the technology of data warehousing. Section III discusses the security approaches employed in data warehousing. Section IV introduces the research challenges and possibilities. Ultimately, Section V presents our conclusions.

## II. Data Warehouse Technology

### A. Fundamental Architecture of Data Warehouses

The foundational architecture of data warehouses typically follows a structured and layered approach, which includes the following components [8]:

*1) Data sources:* Data sources are the systems or applications from which data is extracted and loaded into the data warehouse. These sources can include transactional databases, operational systems, external data feeds, spreadsheets, or other data repositories. Data extraction techniques are employed to gather the required data and prepare it for loading into the data warehouse.

*2) Data integration:* Data integration involves the process of mixing data from various sources and transforming it into a unified and coherent format appropriate for analysis. This step includes tasks such as data cleaning, data normalization, data aggregation, and data enrichment. The transformed data is then loaded into the data warehouse.

*3) Staging area:* The staging area acts as an intermediary storage space between the data sources and the data warehouse. It holds the extracted and transformed data temporarily before it is loaded into the main data warehouse. The staging area allows for data validation, error handling, and data quality checks before the data is moved into the production environment.

*4) Data warehouse:* The data warehouse is the central repository where the integrated and processed data is stored. It is designed to support efficient querying and analysis. The data warehouse is typically optimized for read-intensive operations and provides a consolidated view of the data from multiple sources. It often employs a relational database management system (RDBMS) or a specialized data warehouse platform.

*5) Data marts:* Data marts are subsets of the data warehouse that are tailored to specific business functions or departments. Data marts contain a subset of the data relevant to a particular area, such as sales, marketing, finance, or operations. They are designed to provide focused and pre-aggregated data for faster and more targeted analysis.

*6) Metadata repository:* The metadata repository stores information about the structure, semantics, and lineage of the data in the data warehouse. It includes metadata such as data definitions, data mappings, data lineage, business rules, and data transformation rules. The metadata repository helps users understand and interpret the data in the data warehouse, ensuring data consistency and facilitating data governance.

*7) Business intelligence tools:* Business intelligence (BI) tools are used to access, analyze, and visualize the data stored in the data warehouse. These tools provide end-users with the ability to create reports, dashboards, and perform ad-hoc queries to gain insights from the data. BI tools often offer features like data visualization, data mining, and advanced analytics to support decision-making processes. The foundational architecture of data warehouses provides a structured framework for storing, integrating, and analyzing large volumes of data. It enables organizations to consolidate and transform data from multiple sources into a unified and consistent format, making it easier to extract meaningful insights and support data-driven decision-making.

### B. Security Methodologies

Securing data warehouses typically involves a combination of methodologies and best practices. Here are several commonly employed methodologies [9], [10], and [11]:

*1) Access control:* Access control methodologies focus on managing user access to the data warehouse. This includes implementing strong authentication mechanisms, such as multi-factor authentication, to verify the identity of users. Role-based access control (RBAC) is often employed to assign appropriate privileges and permissions based on user roles and responsibilities. Access control lists (ACLs) and data-level security can be used to restrict access to specific data objects or rows within the warehouse.

*2) Encryption***:** Encryption is a widely adopted methodology for protecting data in transit and at rest within a data warehouse. Transport Layer Security (TLS) or Secure Sockets Layer (SSL) protocols can be used to encrypt data during transmission between components of the data warehouse. Data at rest can be protected using techniques such as full-disk encryption, database-level encryption, or column-level encryption. Encryption keys should be securely managed and stored to prevent unauthorized access.

*3) Data masking and anonymization:* Data masking and anonymization methodologies involve modifying or obfuscating sensitive data to protect its confidentiality. Techniques like tokenization, pseudonymization, or data substitution can be used to replace sensitive information with fictitious values while preserving the format and structure of the data. Data masking can be applied during data extraction or as part of the data loading process into the data warehouse.

*4) Auditing and monitoring:* Auditing and monitoring methodologies involve capturing and analyzing activities within the data warehouse to detect and respond to security incidents. Robust logging mechanisms should be implemented to record user activities, system events, data changes, and access attempts. Security Information and Event Management (SIEM) systems can be employed to collect and analyze log data, generate alerts, and facilitate incident response.

*5) Data classification and Data Loss Prevention (DLP):* Data classification methodologies help identify and categorize sensitive or confidential data within the data warehouse. By classifying data based on its sensitivity, organizations can apply appropriate security controls and data protection measures. Data Loss Prevention (DLP) technologies can be used to monitor and prevent unauthorized data exfiltration or leakage by applying policies and rules to sensitive data.

*6) Vulnerability management:* Vulnerability management methodologies involve regularly scanning the data warehouse infrastructure, databases, and applications for known vulnerabilities. Vulnerability assessment tools can identify security weaknesses and misconfigurations that could be exploited by attackers. Patch management processes should be implemented to promptly apply security patches and updates to mitigate identified vulnerabilities.

*7) Disaster recovery:* Incident response and disaster recovery methodologies focus on preparedness and response to security incidents or catastrophic events. Incident response plans should be established, outlining the steps to be taken in the event of a security breach. Disaster recovery strategies should be in place to ensure timely recovery of the data warehouse in case of system failures, cyber-attacks, or natural disasters.

*8) Data governance and training:* Data governance methodologies establish policies, procedures, and guidelines for managing and protecting data within the warehouse. This includes defining data ownership, accountability, and data lifecycle management practices. Regular training and awareness programs should be conducted to educate users and stakeholders about data security best practices, policies, and their roles in maintaining data warehouse security. These methodologies, when implemented collectively, contribute to the overall security of data warehouses. Organizations should adopt a layered approach, combining multiple security methodologies, to create a robust security framework that protects critical business information and ensures compliance with relevant regulations.

Besides, the architecture impacts the following security aspects:

*1) Network security:* The architecture influences network security considerations, particularly in distributed data warehouse environments. It determines how data flows between different components of the data warehouse, including data sources, staging area, data warehouse, and data marts. Secure network architecture includes measures like network segmentation, firewalls, encryption, and intrusion detection systems to protect data during transmission and prevent unauthorized access.

*2) Scalability and performance:* Architecture considerations impact security implementations concerning scalability and performance. A scalable architecture can handle increasing data volumes, user loads, and concurrent queries without compromising security. It should accommodate security measures without significantly impacting system performance, ensuring that security controls do not hinder data warehouse operations.

### *C. Applications of Data Warehouse in Real Life*

The significance of a data warehouse is undeniable due to its numerous advantages. It eliminates the need for management choices to be based on limited and inaccurate data, while also assisting firms in avoiding various issues. Therefore, it is imperative for any organization to have a data warehouse. When discussing the importance of data warehousing (DW), it is noted that certain application areas require the presence and integration of data across the entire organization. Additionally, the ability to make quick decisions based on both real-time and historical data provides specialized information for loosely defined systems.

*1) Business:* The primary motivations for implementing a data warehouse in a firm are to enhance decision-making and improve organizational performance [12]. The utilization of data warehouses in various applications is influenced by the importance of business. All other non-governmental and partially non-governmental organizations fall under its authority. A data warehouse employs a unified repository to conveniently store data that is retrieved from various databases [13]. This data repository offers forecasting services that assist business professionals and managers. This comprehensive process is utilized to facilitate the identification of business requirements and the formulation of a business strategy [14]. The impact of several disciplines on data warehousing in business, ranging from significant to trivial, is examined.

*a) Social media websites:* Social media serves as a prime illustration of data warehousing. The social media industry is growing, and as a result, there is a growing demand to deploy data warehousing in this sector. Several characteristics seen on Facebook, Twitter, and other social media platforms are derived from the examination of extensive datasets. The system collects many types of data, such as groups, likes, friends, and geographical mapping, and saves it in a unified central repository. While several databases keep this information separately, the most important and meaningful data is saved in a centralized aggregated database [15].

*b) Construction (material-based industries):* The utilization of a data warehouse in the construction sector proves to be effective in facilitating decision-making processes. This strategy equips construction managers with comprehensive access to both internal and external data, enabling them to assess and oversee construction performance. The implementation of data warehousing in the construction industry demonstrates the ability of construction managers to effectively assess the remaining stock, track inventory trends associated with materials, and determine the quantity and cost of each material. To ensure the proper allocation of resources, it is important to consider the necessary services, maintenance, and operation of the systems, as well as the allocation of financial budgets. Additionally, good management of long-term investment plans and identification of potential hazards are crucial [16], [17].

*c) Manufacturing industry:* Data warehouse plays a crucial part in the maintenance of household and industrial operations. The manufacturing industry encompasses activities such as product and process design, scheduling, planning, production, maintenance, and substantial investments in equipment, labor, and heavy machinery. The actions taken in this situation will have significant impacts on both profitability and long-term strategic considerations. Several industries are seeking to transform themselves, and it is advisable for many of them to embrace data warehousing (DW) technology instead of relying on traditional decision-making methods. By implementing a data warehouse, organizations can collect, standardize, and store data from different applications. This enables them to streamline processes and enhance efficiency, as analyzing data across multiple applications can be a time-consuming task. During this phase, manufacturing and construction companies frequently employ transaction processing systems that are regularly updated to facilitate their ordinary business operations [18].

*d) Banking:* The banking industry is classified as one of the most information-intensive sectors in the business world. The relevance of business intelligence (BI) in banking operations has significantly increased due to advancements in the information technology industry [19]. The rapid pace of corporate growth and intensifying competition has underscored the critical importance of banking intelligence. Bank intelligence refers to the capacity to collect, oversee, and scrutinize a substantial volume of data pertaining to bank clientele, products, operations, services, suppliers, partners, and transactions. As the volume of data grows, the process of collecting, managing, and converting it into valuable insights becomes increasingly challenging. Data warehousing (DW) offers a solution to this challenge. Several data warehouse variants are specifically tailored to cater to the needs of the banking industry [20].

*e) Education:* Data warehousing (DW) is gaining increasing popularity in the realm of education. The utilization of Data Warehousing (DW) in the educational sector offers numerous advantages in facilitating informed decision-making and timely data evaluation, which are the primary objectives of the DW process. DW offers a comprehensive and unified perspective of an institute. Most of the relevant departments utilize a data warehouse as a primary source of information regarding teachers and students. DW facilitates expedient access to students' results and notes from a web-based database via a student portal. Additionally, it aids in decision-making by offering both current and historical information pertaining to the institute [21].

*f) Finance:* The progress of technology, particularly in the IT industry, has introduced innovative approaches to managing financial processes in business. The government and business sectors play equally significant roles in the field of finance. Financial systems encompass many institutions such as banks, post offices, insurance firms, income tax departments, and other tax agencies. The use of a data warehouse in the financial industry offers numerous advantages, such as enhancing transparency in account opening and transactions. Likewise, the government has the authority to make decisions to address any financial crises. These systems possess sufficient intelligence to detect individuals who have failed to meet their obligations and may respond accordingly based on the circumstances. Efficient decision-making can be easily achieved in this case due to the maintenance of data warehousing [22].

*2) Government:* The government can employ data warehousing techniques in various sectors, such as looking for terrorist profiles and conducting threat assessments, improving agricultural practices, enhancing educational systems, optimizing financial operations, streamlining medical departments, and detecting fraudulent activities. The telecommunication and banking industries are plagued by numerous difficulties pertaining to user fraud [23].

*a) Medical:* The medical sector is currently leading in the implementation of data warehousing technology. The importance of data quality and the need for high-quality medical services has significantly increased in the field of health care. The complexity and diversity of medical and clinical data resulted in a slower adoption of data warehouses in the healthcare industry compared to other sectors. In recent years, there has been a significant increase in the utilization of data warehouses in both administrative and clinical domains. Data warehouses have the potential to enhance the quality of care provided to individual patients. These healthcare organizations are implementing data warehousing as a tool to help strategic decision-making. It offers the means to obtain medical data, extract pertinent information from that data, and disseminate this knowledge to all relevant individuals. The administrative data stored in a data warehouse can be utilized to obtain information regarding the required competent staff for a specific treatment. This information is then used for scheduling treatments and providing support to medical personnel in the field of human resources [24].

*b) Fraud and threat detection:* Governments are actively engaged in detecting and mitigating threats and fraudulent activities perpetrated by individuals with malicious intentions. Regrettably, there is a scarcity of available known implementations of data warehouses. Government entities have access to data warehouses; nevertheless, they require a comprehensive data warehouse system that is interconnected to all areas to effectively monitor threats and terrorists [23].

## III. Security Approaches for DWH

A data warehouse is a crucial component of an organization, providing users with the ability to access comprehensive information about the whole business process. As stated in reference [25], ensuring security is a crucial necessity in all stages of data warehouse construction, including requirements, implementation, and maintenance. The security measures implemented for online transactional processing (OLTP) systems are not suitable for data warehouses [26]. In OLTP, security controls are applied at the level of rows, columns, or tables. However, data warehouses require access by varying numbers of users for different content due to their multidimensional nature, which is a fundamental principle of a data warehouse. Prior to loading the data into the data warehouse, the processes of data extraction, transformation, cleansing, and preparation have all been completed. Security considerations must be considered at every level of a data warehouse system. Furthermore, it is imperative to address the security of the underlying operating system and network to maintain data warehouse security [27]. The data warehouse literature has presented several security solutions, which can be classed based on how they meet fundamental security concerns, including Confidentiality, Integrity, and Availability.

### A. DWH Security Approaches for Confidentiality Issues

The emphasis of confidentiality is on preventing information from being improperly discovered, either directly or through logical inference [28]. Numerous access control-related strategies have been put out to resolve concerns about data warehouse confidentiality. The administration and invocation of the source databases and the data warehouse are both under the supervision of access-control mechanisms. In a data warehouse setting, authentication and auditing systems are likewise categorized as access control and need to be set up. In [29], the author introduced a role-based authorization model and distinguished between two types of roles: the operations role, which initiates the associated procedures, and the developer role, which oversees extracting, integrating, and transforming data scripts. These positions just need to execute trustworthy procedures; they do not require direct access to data. Permissions to access data are assigned based on roles. Additional rights may be issued as needed to access more data in the event of failures or issues, but audits must keep an eye on these permissions. Traditionally, high-level users like business analysts and upper management have had access to data warehouses. As a result, serious problems with access control also surface at the data warehouse's front end. Since it impedes the discovery of analytical information, the majority of data warehouse or OLAP suppliers believe that fine-grained access-control functionality for a data warehouse front end is unnecessary. This assumption is incorrect, though, as many users have access to analytical tools that allow them to query the data warehouse. Applications for front-end data warehouses can offer both dynamic and static reporting. Because access control may be specified report-by-report, it is not problematic to impose it on static reports. It is challenging to implement suitable access-control measures for dynamic reporting, such as data-mining queries. This brings up the issue of data inference; for instance, a person could be able to access specific information through an aggregated query even when they are not permitted to do so [30].

### *B. DWH Security Approaches for Integrity*

Integrity refers to safeguarding data from unauthorized or malevolent modifications, including the insertion, infection, or deletion of false data [31]. One drawback of access-control techniques is that, in the event of an aggregated OLAP query, they are unable to capture conclusions about the data. Data inferences result in integrity problems. Inference-control techniques have been researched in statistics and census databases for over thirty years [32], [33], and [34]. The suggested methods fall into two categories: perturbation-based and restriction-based methods. To stop malicious inference, restriction-based inference control systems merely refuse unsafe queries. Perturbation approaches can dynamically apply data modification to each query in addition to adding noise, swapping, or altering the original data. The methods put out to address the integrity problem can be further categorized as outlined below.

*1) Restriction-based approaches:* The greatest number of values aggregated by distinct questions, the minimum number of values aggregated by a query, and the highest rank of the matrix expressing answered queries are used in restriction-based inference-control techniques to establish the safety of a query. Sensitive data can also be protected by partitioning and cell suppression. Cells with low COUNT values can have suppression applied to them to identify inference in the data. Techniques based on linear programming can be used to eliminate inferences. This kind of detection technique only functions with two-dimensional tables; three- or higher-dimensional tables are not compatible with it [35].

*2) Combined access-and inference-control approaches:* To effectively eliminate security risks, the combination of access control and inference control can offer a robust solution. Preserving the security of data warehouse and OLAP systems should not compromise their functionality. The author in [36] suggested three-tier security architecture for a data warehouse. Statistical databases typically consist of two tiers: sensitive data and aggregate queries. The two-tier design mentioned above has certain inherent limitations. One problem is that doing inference checking during run-time query processing might lead to undesirable delays. Additionally, under this architecture, inference-control techniques are unable to take advantage of the unique features of OLAP. To address these limitations, the study has established a three-tier framework to facilitate access control between the first and second layers, as well as inference control between the second and third tiers. The suggested design mitigates superfluous delays caused by inference checking through various means. Implementing these techniques can decrease the size of the inputs to inference control systems, hence reducing complexity.

*3) Modeling-based approaches to DWH security:* In their publication [37], the author introduced a conceptual-level Access and Audit Control (ACA) model for data-warehouse modeling. This model is founded on data classification. The document outlined three security regulations: permission regulations for people and objects, assignment regulations for sensitive information that establish multilevel security procedures, and audit regulations that examine user actions at all stages and points at the conceptual level. The ACA model is incorporated in multi-dimensional modeling to enhance UML skills in the design of secure data warehouse systems.

*4) Data masking and perturbation-based security approaches:* In their publication [38], the author introduced a data-masking technique specifically designed for data warehouses that exclusively contain numerical values. The proposed methodology relied on mathematical modulus operators, including division, remainder, and two basic arithmetic operations. These operators can be implemented without modifying the source code of the database management system (DBMS) or user applications. According to their assertion, the suggested formula necessitated minimal computational resources. Consequently, the additional time required for query response was insignificant, while maintaining an adequate level of security.

### *C. DWH Security Approaches for Availability Issues*

Ensuring the availability of data is crucial in every data warehouse system. This entails the retrieval of data that has been affected by immediate corruption. Data replication is implemented to facilitate the restoration of corrupted data using various suggested methods. By using this approach, it is possible to prevent database downtime caused by maintenance interventions and distribute query-processing efforts to prevent data-access hot spots. Familiar RAID architectures can be employed to mirror data [39], [40] in systems where centralized servers house the database. Nevertheless, corporations have started deploying their data warehouses on inexpensive processors to achieve cost efficiency. RAID technology is unsuitable for this situation due to the presence of only one disk drive, which is normally the case.

## IV. Research Challenges and Opportunities

While typical encryption methods can offer robust data privacy and are present in today's main DBMS, their influence on database speed renders their use in data warehouses impractical. As previously demonstrated, the computational overhead incurred by methods such as AES and 3DES significantly affects performance. Options that can provide a high degree of privacy while reducing the overhead in query response time are required. Given bitwise operations' simplicity and speed, bit-based encryption algorithms might offer a means of achieving novel, workable solutions. Naturally, the degree of privacy will decrease if the encryption procedure is simplified to increase database speed. It is necessary to create a tradeoff compromise that minimizes the impact on performance while maintaining the desired level of privacy. A further option would be the creation of query engines that could handle queries on encrypted data directly, i.e., without the need to first decrypt the data[41].

## V. Conclusion

This study has conducted a comprehensive analysis of the security solutions available for data warehouses, examining their limitations and the effects they have on the scalability and performance needs of these warehouses. The suggested methods are impractical or ineffective for implementation in data warehouse systems. A data warehouse necessitates specific capabilities that must adhere to strict scalability and performance criteria. Hence, a comprehensive solution is required to effectively tackle these directives. Data warehouse security is a pertinent area of ongoing research that holds significance for all industrial projects. Additional investigation into data warehouse security is necessary to tackle the difficulties, as there are other variables that still need to be considered and some unanswered questions.

# Speech Emotion Recognition in Multimodal Environments with Transformer: Arabic and English Audio Datasets

Esraa A. Mohamed[1], Abdelrahim Koura[2], Mohammed Kayed[3]
Faculty of Science, Beni-Suef University, Beni-Suef City, Egypt[1]
Faculty of Computers and Artificial Intelligence, Beni-Suef University, Beni-Suef City, Egypt[2, 3]

***Abstract*—Speech Emotion Recognition (SER) is a fast-developing area of study with a primary goal of automatically identifying and analyzing the emotional states expressed in speech. Emotions are crucial in human communication as they impact the effectiveness and meaning of linguistic expressions. SER aims to create computational approaches and models to detect and interpret emotions from speech signals. One of the primary applications of SER is evident in the field of Human-Computer Interaction (HCI), where it can be used to develop interactive systems that adapt to the user's emotional state based on their voice. This paper investigates the use of speech data for speech emotion recognition. Additionally, we applied a transformation process to convert the speech data into 2D images. Subsequently, we compared the outcomes of this transformation with the original speech data, aligning the comparison with a dataset containing labeled speech samples in both Arabic and English. Our experiments compare three methods: a transformer-based model, a Vision Transformer (ViT) based model, and a wave2vec-based model. The transformer model is trained from scratch on two significant audio datasets: the Arabic Natural Audio Dataset (ANAD) and the Toronto Emotional Speech Set (TESS), while the vision transformer is evaluated alongside wave2vec as part of transfer learning. The results are impressive. The transformer model achieved remarkable accuracies of 94% and 99% on ANAD and TESS datasets, respectively. Additionally, ViT demonstrates strong capabilities, achieving accuracies of 88% and 98% on the ANAD and TESS datasets, respectively. To assess the transfer learning potential, we also explore the Wave2Vector model with fine-tuning. However, the findings suggest limited success, achieving only a 56% accuracy rate on the ANAD dataset.**

***Keywords*—Speech emotion recognition; transformer encoder; fine-tuning; wav2vec; multimodal emotion recognition**

## I. Introduction

Emotions, found across all cultures, play a vital role in interpersonal communication. Research on emotional recognition has evolved since the 1970s, spanning various modalities such as speech, text, video, EEG brain waves, and facial expressions. Additionally, multi-modal approaches combining text and audio data have gained prominence in speech emotion recognition. The objective is to automatically discern an individual's emotional or physical state from their voice. Understanding the speaker's emotional state can aid listeners in deciphering the true intent behind spoken words.

In the current COVID-19 pandemic, where social distancing is crucial, tele-diagnosis or telephone consultation has gained significant prominence. Integrating speech emotion recognition (SER) systems into these applications can have a profound impact on various fields. For example, in telemedicine, SER can play a crucial role in remotely diagnosing patient’s condition by analyzing their emotional cues during the conversation. Furthermore, the integration of emotion detection features into speech recognition software can help bridge communication barriers faced by individuals with hearing impairments. Emotions also play a vital role in decision-making and greatly influence the naturalness of human-machine interactions. In the automotive industry, incorporating emotion recognition systems into onboard car systems can help drivers stay alert and prevent accidents caused by stress or fatigue. Additionally, analyzing call center conversations using SER can improve the overall quality of customer service. Moreover, applications such as interactive films, storytelling, and online instruction can benefit from emotion recognition technology to enhance user engagement and overall experience. The wide-ranging applications of speech emotion recognition highlight its potential to revolutionize communication, human-machine interaction, and safety across various domains the recognition and analysis of emotions from speech pose several challenges due to emotions' complex and subjective nature. Unlike visual cues, which can be readily observed and interpreted, emotions conveyed through speech rely on acoustic, prosodic, and linguistic patterns that require sophisticated computational models for accurate recognition. Additionally, the inherent variability in emotional expression across individuals, cultures, and languages further complicates the task of SEA. Over the years, researchers have explored various methodologies for SER, including traditional machine learning algorithms such as support vector machines, Gaussian mixture models, and hidden Markov models. These approaches often rely on handcrafted acoustic and prosodic features to capture relevant information from speech signals. However, they may struggle to capture the intricate nuances and complex emotional patterns.

Recent advancements in deep learning have revolutionized the field of SER by enabling the development of more powerful and flexible models. Deep learning techniques, such as convolutional neural networks (CNNs), recurrent neural networks (RNNs), and transformers, have demonstrated remarkable success in various natural language processing tasks. They have the potential to capture high-level representations and learn complex relationships from raw speech data, enabling more accurate and robust emotion recognition.

Transformers are a subset of these deep learning models that have drawn much interest because of their potent ability to capture contextual information and long-range dependencies adequately. Transformers, first developed for applications involving natural language processing, have demonstrated promise in jobs requiring sequential data, such as speech recognition and linguistic translation. The transformer design, based on self-attentional processes and multi-head attention, enables the modelling of links between various components of the speech signal and the capture of global dependencies.

Emotion recognition from a speech is a vital field that employs machine learning to automatically detect and interpret emotional states expressed in spoken language or speech signals. Applications for it can be found in many different fields, including social robots, affective computing, and human-computer interaction. This paper introduces an innovative transformer-based approach to SER, showcasing a detailed analysis of the method's components. This includes the preprocessing of speech data, the feature extraction techniques, and the design and training of the transformer models. The study goes further to evaluate the approach's performance using two audio datasets, comparing it against the vision transformer and a transfer learning model such as wave2vec. The results, benchmarked against existing state-of-the-art methods, underscore the significance of this work in advancing our ability to understand and respond to human emotions conveyed through speech.

The paper is structured as follows. In Section II, we discuss related work in the field. Section III presents our approach, which includes the construction of the transformer. Section IV analyzes and delineates the preprocessing procedures employed in our study, as well as the resulting outcomes of the experiment. Finally, Section V concludes with recommendations for further development.

## II. Related Works

Numerous studies have been dedicated to speech emotion recognition, a field of growing prominence. Researchers in this domain employ diverse machine learning algorithms and feature extraction techniques to create robust models for automated emotion recognition from spoken language. This technology finds applications in sentiment analysis, virtual assistants, and affective computing. This section provides a comprehensive literature review, showcasing various approaches to enhance emotion recognition. Traditional classification techniques utilizing distinctive feature vectors form the bedrock of many methodologies. Noteworthy studies combine Support Vector Machine (SVM) classification with fused features such as F0, Energy, and Mel-frequency cepstral coefficients (MFCCs) [1]. Additionally, features like MFCCs and Mel Energy Discrete Cosine Coefficients (MEDC) are adeptly harnessed for emotion classification using SVM [2]. Another approach integrates diverse features from the Berlin emotional database, employing SVM for emotional state classification [3]. Further exploration reveals Gaussian mixture models (GMMs) applied for emotion classification [4]. Innovatively, a hybrid model employing a GMM-based low-level feature extractor and a neural network high-level feature extractor excels in recognizing speaker emotions [5]. Discrete hidden Markov models (HMMs) emerge as a robust classifier, capitalizing on short time log frequency power coefficients (LFPC) to represent speech signals [6]. Spectral features like MFCCs and Mel spectrograms, along with classifiers like Support Vector Machines (SVMs), Multilayer Perceptrons (MLPs), and K-Nearest Neighbors (KNN), further enrich the array of methodologies [7].

Deep learning techniques have proliferated in the realm of speech emotion recognition (SER), offering a plethora of advantages over traditional methods. These approaches boast automated detection of intricate structures and features, eliminating the necessity for manual feature extraction and tuning. They excel in deriving low-level features directly from raw data and adeptly utilize techniques like recurrent neural networks (RNNs) to navigate unlabeled data. A compelling illustration lies in study [8], which deployed a deep recurrent neural network for speech-based emotion recognition. Similarly, in study [9] introduced a pioneering method involving Directional Self-Attention in Bi-directional Long-Short Term Memory (BLSTM-DSA). This journey delves further with [10], presenting a groundbreaking approach termed the Deep Convolutional Neural Network (DCNN) combined with a Bidirectional Long Short-Term Memory with Attention (BLSTMwA) model. Convolutional Neural Networks (CNNs) manifest in other studies [11][12][13], while [14]seamlessly blends RNNs with CNNs. A striking instance is [15] , wherein a Taylor series-based Deep Belief Network (Taylor-DBN) takes center stage. Similarly, [16] harnesses both a 1D CNN LSTM network and a 2D CNN LSTM network. Further exploration leads us to [17], which delves into the potential of the Multi-Layer Perceptron (MLP) deep network architecture.

The paradigm shift arrives with the emergence of deep learning models, particularly those embodying transformer architectures, triggering a revolution in emotion recognition from speech. By tapping into the prowess of self-attention mechanisms and multi-head attention, these transformer-based models adeptly capture long-range dependencies and intricate speech patterns, elevating emotion recognition accuracy. Their forte lies in deciphering contextual relationships within input sequences, empowering them to apprehend nuanced emotional cues and speech pattern variations. Furthermore, the capacity of transformer-based models to accommodate substantial data volumes and exploit parallel processing has solidified their standing as a preferred choice for emotion recognition tasks. Their fusion with deep learning techniques introduces tantalizing prospects for enriching emotion analysis and comprehension across diverse domains. Ultimately, they emerge as an invaluable asset, resonating profoundly with both researchers and practitioners, poised to reshape the landscape of emotion recognition.

Given the transformer's remarkable aptitude for sequence learning tasks, particularly in the realm of natural language processing, an enhanced transformer-inspired model is developed, finely tailored for the nuances of speech emotion recognition tasks. An innovative deep multimodal transformer network, introduced by study [18], deftly addresses the challenge of asynchronous emotion expressions across multiple modalities. This novel architecture adeptly captures distinctive temporal features and orchestrates emotional evolution over sequences of utterances. This dynamic is further amplified by weight sharing and the fusion of emotional content from audio and text components. The transformative impact continues with the infusion of the Taylor linear attention (TLA) algorithm [19], seamlessly integrated into the transformer architecture by [20]. In a similar vein, [21] introduces the LSTM-Transformer model, ingeniously replacing positional encoding within the Transformer framework with LSTM recurrent processes. This adaptive strategy learns the concealed input feature states and enhances the model's capacity to discern emotion nuances. An inventive deep multimodal transformer network surfaces in [22], laser-focused on unraveling unique temporal features while adroitly managing the asynchronous nature of emotion expression across modalities. The aim is to adeptly model the progression of emotion across the timelines of utterances. Meanwhile, [23] wields advanced Transformers and attention-based fusion mechanisms to fuse the hallmarks of multimodal self-supervised learning, triumphing in the realm of multimodal emotion identification challenges. Embarking on a journey to harness the self-attention prowess and global windowing potential of the transformer model for SER, [24] deftly explores their utility. On a parallel track, [25] forges a groundbreaking frontier by presenting an automatic emotion recognition system (FER) that seamlessly integrates both speech and visual emotion recognizers within a unified framework. To assess SER performance, [26] rigorously examines two transfer-learning strategies. They adroitly employ a pre-trained xlsr-Wav2Vec2.0 transformer for embedding extraction and fine-tuning. Pioneering a new learning paradigm for SER, [27]employs Compact Convolutional Transformers (CCTs) synergized with speaker embeddings. The result is a commendable achievement of real-time results across diverse corpus scenarios.[28] delves into the realm of facial emotion recognition (FER), wielding the ResNet-18 model in conjunction with transformers. The result is superior performance and practical applicability in real-world settings, surpassing existing models on hybrid datasets. Wrapping the discourse is the innovative transfer learning methodology for speech emotion recognition put forth by [29], adroitly leveraging pre-trained wav2vec 2.0 models. By ingeniously combining features with simple neural networks and trainable weights, this approach outshines standard emotion databases as corroborated by the existing literature.

Based on researchers' findings, it has become evident that utilizing the Transformer has yielded remarkable results in the field of speech emotion recognition. These impressive outcomes have prompted the exploration of new avenues, with the application of multi-modal data standing out as an exciting opportunity. Researchers increasingly understand that integrating diverse data sources can significantly enhance results. By merging information from various modalities such as audio, text, and potentially images, additional context is provided for emotion detection and comprehension.

Multimodal data is a type of data that integrates information from various sources, including text, audio, images, and video. This form of data is increasingly prevalent across numerous research domains, encompassing natural language processing, speech and emotion recognition, and computer vision. By harnessing multiple modalities, researchers can attain a more comprehensive grasp of intricate phenomena and enhance the precision of diverse tasks. For instance, multimodal data facilitates the detection of emotions in speech through the analysis of both audio and visual cues. Additionally, in natural language processing, multimodal data aids in extracting more meaningful features from text by incorporating contextual information from images or videos. Exploring multimodal data holds the potential to unlock novel insights and foster the development of more machine learning models. In the context of speech emotion recognition, multimodal data is pivotal. By merging audio and text data, researchers can gain a deeper understanding of the speaker's emotional state. For instance, in [19], [29], and [30], researchers utilized speech, text, and mocap data, including sub-modes such as facial expressions, hand gestures, and head rotations, to accurately identify emotions. Furthermore, [31] introduced a groundbreaking transformer-based model named multimodal transformers for audio-visual emotion recognition, overcoming the limitations of RNN and LSTM in capturing long-term dependencies. Three transformer branches are included in this model: audio-video cross-attention, video self-attention, and audio self-attention. The fusion of multiple modalities has consistently demonstrated its effectiveness in enhancing the accuracy of emotion recognition tasks.

Table I provides a comprehensive overview of the performance of the utilized model in comparison to other studies across a diverse range of datasets .This comparison effectively highlights how the proposed model outperforms previous approaches on diverse datasets, underscoring its remarkable success in achieving superior results within this domain. In the realm of Speech Emotion Recognition (SER), transformer-based approaches have demonstrated remarkable advancements. One instance is seen in "Multimodal Transformer for Speech Emotion Recognition with Shared Weights," which achieves a noteworthy accuracy of 77% on the IEMOCAP dataset [18]. Furthermore [19] have explored emotion datasets such as RAVDESS and Emo-DB, alongside a language-independent dataset. These investigations have showcased the effectiveness of a hybrid LSTM Network and Transformer Encoder, achieving significant SER accuracies of 75.62%, 85.55%, and 72.49%. Building upon this, transformer methodologies continue to make substantial contributions. For instance, the utilization of transformers and an attention-based fusion mechanism results in remarkable progress for emotion recognition on the IEMOCAP and MELD datasets [22].

Furthermore, the capabilities of transformers shine through as we delve deeper into their applications. The transformer model applied to the IEMOCAP dataset not only delivers notable accuracies, with 56.65% for speech, 68.94% for text, 53.14% for mocap, but also impressively reaches 74.59% for multimodal emotion recognition [29]. This multi-dimensional approach highlights the versatility of transformer-based architectures.

Spearheading this revolution, the Swin-Transformer emerges with its own accolades, achieving an impressive accuracy of 82.55% on the IEMOCAP dataset [36]. Moreover, transformers transcend beyond traditional speech data. ViT, for instance, has proven its potential, achieving an 82.96% accuracy on the CREMA-D dataset by integrating spectrogram image-based techniques [33]. Continuing on this trajectory, ViT demonstrates its competence by securing accuracies of 56.18% and 37.1% on the IEMOCAP and MELD datasets, respectively [34].

TABLE I. PERFORMANCE OF THE PROPOSED MODEL AGAINST OTHER PUBLICATIONS ON DIFFERENT DATASET

| Ref. No. | Dataset | Model | Accuracy (%) |
|---|---|---|---|
| [18] | IEMOCAP | Multimodal Transformer for Speech Emotion Recognition with Shared Weights | 77 |
| [21] | Emo-DB-URDU | Transformer | 74.9 AND 80 |
| [19] | RAVDESS, Emo-DB, a language-independent dataset | Transformer Encoder and hybrid Long Short-Term Memory (LSTM) Network for SER | 75.62<br>85.55<br>72.49 |
| [29] | IEMOCAP | Transformer | Speech 56.65<br>Text 68.94<br>Mocap 53.14 Multimodal 74.59 |
| [22] | IEMOCAP, MELD | Transformers and Attention-based fusion mechanism | |
| [32] | EMO-DB | CNN-LSTM<br>Mel Spectrogram-Vision Transformer | 88.50<br>85.36 (surpassing existing benchmarks) |
| [28] | BAVED, EMO-DB, SAVEE, EMOVO | Transformer | 95.2,<br>93.4<br>85.1<br>91.7 |
| [33] | CREMA-D | ViT utilizing spectrogram images instead of sound data | 82.96 |
| [34] | IEMOCAP, MELD | ViT | 56.18<br>37.1 |
| [35] | IEMOCAP, EMODB, EMOVO, URDU | Multimodal Dual Attention Transformer (MDAT) | 75.58<br>84.50<br>82.81<br>94.33 |
| [36] | IEMOCAP | Swin-Transformer | 82.55 |
| [37] | IEMOCAP, RAVDESS | Transfer learning method using pre-trained wav2vec 2.0 models. | 71.6<br>64.3 |
| [38] | Tunisian Speech Emotion Recognition dataset (TuniSER) | fine-tuned multilingual wav2vec 2.0 model. | 60.6 |

Incorporating pre-trained wav2vec 2.0 models into the mix, the research landscape evolves. The use of transfer learning yields promising results, as evidenced by accuracy rates of 71.6% and 64.3% on the IEMOCAP and RAVDESS datasets [37]. Finally, fine-tuning a multilingual wav2vec 2.0 model on the Tunisian Speech Emotion Recognition dataset (TuniSER) further underscores the transformer's adaptability across languages, producing an accuracy of 60.6% [38]. These interwoven advancements emphasize the transformative potential of transformer-based techniques in the evolving field of emotion recognition from speech.

## III. The Proposed Emotional Recognition Approaches

In this exploration of prominent methodologies in the domain of speech emotion identification, we will spotlight three noteworthy techniques that have significantly impacted the domain. First and foremost, we will delve into the application of the Transformer architecture, showcasing its remarkable achievements in accurately identifying emotional states. Additionally, our examination will extend to the prowess of the Vision Transformer (ViT) within the context of audio analysis, revealing its robust capabilities in deciphering both sound patterns and emotional nuances. Lastly, we will turn our attention to Wave2Vec's role in facilitating knowledge transfer and collaborative learning, underlining its contribution to enhancing the field of speech emotion recognition. Through this comprehensive analysis, , It is our goal to shed light on the transformative potential of these techniques in advancing our understanding of emotions conveyed through speech. In Fig. 1, we present a comprehensive framework meticulously crafted for the purpose of classifying emotions within audio data.

### *A. Transformer-based Model*

In the transformer architecture, attention is implemented as a function that requires a set of key-value pairs and a query vector and generates an output vector. These vectors represent the different components involved in the attention mechanism, including the query, keys, values, and output. A compatibility function determines the weights allocated to each value, and this process is used to generate the output vector. This compatibility function measures the degree of similarity or compatibility between the query and the corresponding key, enabling the model to determine the importance of different key-value pairs in generating the output representation. It's worth noting that the transformer architecture has been employed in several studies [21], [28], [29], to advance its application and understanding.

By leveraging the attention mechanism, the transformer model can effectively focus on relevant information within the speech data, capturing important linguistic cues and contextual dependencies related to emotions. This allows for more accurate emotion recognition from speech, contributing to advancements in the field and opening up new possibilities for applications such as sentiment analysis, mental health monitoring, and human-computer interaction. In addition to the transformer architecture's self-attention mechanisms, it consists of two key components: Self-Attention (Scaled Dot-Product Attention, SDPA) and Multi-Head Attention (MHA). These components play a crucial role in enabling the transformer model to effectively recognize emotions from speech.

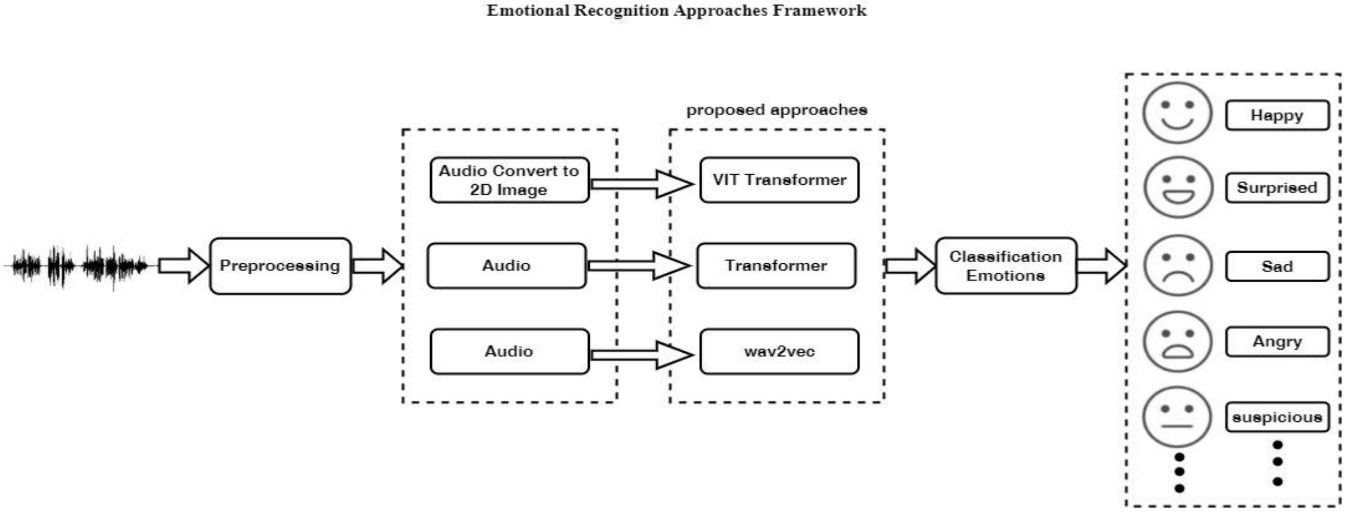

Fig. 1. Emotional recognition approaches framework.

The Scaled Dot Product Attention System (SDPA): is an essential part of the transformer architecture's multi-head attention (MHA) system. It plays a crucial role in capturing the significance and interrelations of different segments in speech input for emotional recognition tasks. SDPA computes attention scores between a query vector (Q) and a set of key vectors (K), representing encoded features of all words in the sample. The dot product between Q and K measures the influence of context words on the central word, revealing dynamics and connections among input tokens. This mechanism enables the model to focus on pertinent aspects of speech for emotional expression, applying the SoftMax function to ensure balanced attention scores. The final attention representation is obtained by multiplying the correlation matrix with the value vector (V), emphasizing significant information while downplaying less consequential portions. Mathematically, the SDPA process can be represented as follows:

$$A=\frac{QK^T}{\sqrt{d}} \tag{1}$$

$$S=soft\ max(A)V \tag{2}$$

$$SoftMax\ (Ai)=\frac{e^{A_i}}{\sum_{i=1}^{N} e^{A_i}} \tag{3}$$

Let A denote the output after scaling, and S represent the output of the attention unit. Q, K, and V are derived from the input feature vector with a shape of (N, d). Therefore, Q, K, and V are vectors of size RN*d, where N represents the length of the input sequence, and d represents the dimension of the input sequence. Typically, in ultralong sequence scenarios, it is observed that N > d, or even N >> d.

Expanding Eq. (2) based on the definition of SoftMax, we have:

$$\text{Si}=\frac{\sum_{j=1}^{N} \exp(\frac{q_i^T\ k_j}{\sqrt{d}})v_j}{\exp(\frac{q_i^T\ k_j}{\sqrt{d}})v_j} \tag{4}$$

In this equation, Qi, Ki, and Vi are column vectors representing the respective elements of Q, K, and V. Consequently, the mathematical essence of scaled dot product attention (SDPA) can be understood as a weighted average of the value vectors Vi, where weights are established by the exponential term ((qi^T * kj) / √d).

Multihead attention (MHA): is vital for parallel training in the transformer architecture, enabling simultaneous processing by dividing the input vector into multiple feature subspaces. It utilizes the self-attention mechanism, allowing parallel training while extracting essential information. In contrast to single-head average attention weighting, MHA enhances effective resolution, capturing diverse characteristics of speech features in different subspaces. This approach avoids inhibitory effects caused by average pooling on these characteristics MHA is calculated as follows:

$$Qi=XW_{Q_i}$$

$$Ki= XW_{k_i}$$

$$Vi=XW_{v_i}$$

$$Hi= SDPA\ (Qi,\ Ki,\ Vi)\ \ \forall i \in [1,\ n] \tag{5}$$

$$S=concat\ (H1,\ H2\dots\dots\dots,\ Hn)\ W \tag{6}$$

Here, X represents the input feature sequence, and Qi, Ki, and Vi denote the query, key, and value vectors, respectively. Hi represents the attention scores of each head, and SDPA denotes the self-attention unit for each head. W represents the linear transformation weight. The index i ranges from 1 to n, where n is the number of heads, and i denotes the specific head.

The input feature sequence X is equally divided into n segments along the feature dimension. Each segment undergoes linear transformation, generating groups of (Qi, Ki, and Vi). Subsequently, Hi is individually calculated for each head. The n attention scores are then concatenated sequentially. Finally, the total attention score is obtained by applying linear transformation to the concatenated vectors.

### B. Vit Transformer-based Model

The Vision Transformer approach represents a significant advancement in computer vision, leveraging the power of transformer architectures originally developed for natural language processing. ViT revolutionizes image understanding by separating an image into patches that don't overlap, linearly embedding those patches, and processing them using a standard transformer encoder. This methodology allows ViT to capture long-range dependencies within images, enabling it to excel in assignments like object detection and picture categorization. The self-attention mechanism of transformers enables ViT to effectively model contextual relationships among visual elements, contributing to its impressive performance.

In the context of speech emotion recognition, ViT's capabilities have been extended to handle speech data. By converting speech signals into 2D spectrogram images, ViT can efficiently process the visual representations of sound. This conversion enables ViT to recognize emotional cues present in speech, further enhancing its versatility in multimodal applications.

The core equation used in the ViT architecture is the self-attention mechanism, expressed as follows:

$$Attention\ (Q,\ K,\ V)=SoftMax(\frac{Qk^T}{\sqrt{d_k}})V \tag{7}$$

where:

- Q represents the query matrix,
- K denotes the key matrix
- V represents the value matrix,
- dk is the dimension of the key matrix.

The self-attention mechanism empowers ViT to assess the significance of diverse elements in a sequence, capturing intricate patterns essential for tasks like emotion recognition. ViT's capacity to learn complex patterns from raw image data, without relying on handcrafted features, has spurred its extensive use in various computer vision domains. This innovative approach has catalyzed progress in multimodal learning, integrating ViT with other modalities, like text and audio, to deepen the comprehension of complex data structures.

### C. Wav2vec Transfer Model

Wav2Vec is a deep learning model that has been developed for speech processing and speech recognition tasks. Specifically, Wav2Vec is designed to convert raw audio waveforms (hence the "Wav" in its name) into meaningful representations that can be used by downstream speech recognition systems. Wav2Vec is particularly notable its capability of learning directly from raw audio data without requiring manual feature extraction. It employs a self-supervised learning approach, where the model learns by predicting future audio samples based on past samples. This helps the model to record high-level characteristics and patterns within speech, making it well-suited for speech recognition tasks.

Fine-Tuning Explained: Fine-tuning is a process that capitalizes on the knowledge and features a model has gained from being trained on a large dataset. Instead of training a model from scratch, which can be computationally expensive and time-consuming, fine-tuning leverages the existing knowledge encoded in a pre-trained model. By modifying specific layers or weights of the model and training it further on a smaller, task-specific dataset, the model can learn to perform the new task more effectively. Fine-tuning the pre-trained Wav2Vec model for emotion classification enhances its ability to discern emotional cues from speech, making it a valuable tool for a variety of applications, including sentiment analysis, virtual assistants, and affective computing systems.

Fine-Tuning Loss Function: During fine-tuning, a common loss function used for classification tasks like emotion classification is the categorical cross-entropy loss. It calculates the difference between the true class labels and the expected class probabilities.

$$Loss= -\sum_i y_i\, log(\,\hat{y}_i) \tag{8}$$

where:

- $y_i$ is the true probability of class.
- $\hat{y}_i$ is the predicted probability of class ii.

This loss function penalizes large differences between predicted and true probabilities, encouraging the model to update its parameters to improve classification accuracy.

## IV. Expermintal Setup

In this section, we will explain three sub-sections: Data Set, Preprocessing, and Results of Experiments.

### A. Dataset

Databases are essential for speech emotion recognition, as the classification process relies heavily on labeled data. The accuracy of the recognition process is directly impacted by the quality of the data used. Incomplete, poor-quality, or flawed data can lead to incorrect predictions. The effectiveness of the classification is also influenced by factors such as language, the number of emotions, and the data collection method. Thus, it is crucial to carefully.

Design and collect the data. For example, to recognize emotions through speech, data sets in multiple languages, including English, German, Swedish, Turkish, French, Mandarin, Italian, Japanese, and Arabic have been employed. Ensuring high-quality data sets is vital for accurate and reliable speech emotion recognition.

The Arabic Natural Audio Dataset (ANAD) and the Toronto Emotional Speech Set (TESS) were used in this study to assess how well the suggested speech emotion recognition technique worked. The ANAD dataset is a publicly available dataset comprised of Arabic audio files obtained from online Arabic talk shows. Specifically, eight videos of live calls between a host and an external person were downloaded and segmented into turns involving callers and receivers. To classify videos, 18 listeners assessed emotions like happiness, anger, and surprise. After removing silence, laughs, and noise, the chunks were automatically divided into one-second speech units. The resulting corpus consisted of 1384 records, as depicted in Fig. 2, which illustrates the number of audio files for each emotion in the dataset. The dataset size is 587MB. The usage of ANAD provides a valuable opportunity to assess the proposed method's efficacy in recognizing emotions in natural Arabic speech. The TESS dataset, on the other hand, contains English audio files representing seven emotions: neutrality, pleasant surprise, anger, disgust, fear, and happiness. There are 2800 audio files in this collection, as shown in Fig. 3, which illustrates the number of audio files for each emotion in the dataset. These recordings were made by two females, ages 26 and 64. The dataset size for TESS is 449MB.By utilizing these datasets; the study aims to evaluate the performance and accuracy of the proposed speech emotion recognition method in natural Arabic speech (ANAD) and English speech (TESS), covering a range of emotions. The availability of ANAD and TESS datasets allows for a comprehensive assessment of the proposed method's capabilities in recognizing emotions across different languages and contexts. The selection of datasets was based on their credibility and widespread use in the field of Speech Emotion Recognition (SER). These well-established datasets allow for an effective comparison of the proposed model's performance with other studies that use the same datasets. Tables II and III illustrate how many audio segments exist for each expression in each dataset.

TABLE II. TABLE SHOWS THE NUMBER OF AUDIO CLIPS FOR EACH EMOTION IN ANAD DATASET

| **DATA SET** | **TESS** |
|---|---|
| ***Emotions*** | ***Number of audio files*** |
| Angry | 400 |
| Happy | 400 |
| Surprise | 400 |
| Disgust | 400 |
| Fear | 400 |
| Sad | 400 |
| Neutral | 400 |

TABLE III. TABLE SHOWS THE NUMBER OF AUDIO CLIPS FOR EACH EMOTION IN TESS DATASET

| **DATA SET** | **ANAN** |
|---|---|
| ***Emotions*** | ***Number of audio files*** |
| Happy | 505 |
| Angry | 741 |
| Surprised | 137 |

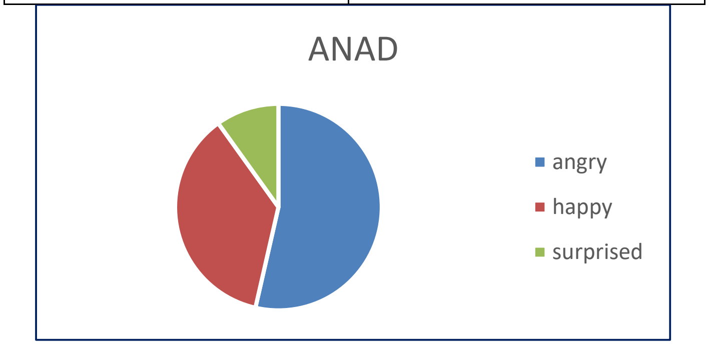

Fig. 2. The data distribution of emotion in ANAD.

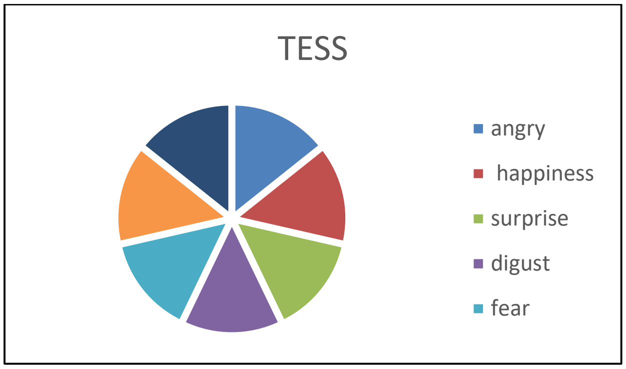

Fig. 3. The data distribution of emotions in TESS.

### *B. Preprocessing*

Preprocessing plays a vital role in preparing raw data for analysis and model training. It involves a series of data transformation steps to clean, normalize, and enhance the dataset's quality. Standard techniques include data cleaning to remove missing values or outliers, feature scaling to bring features within a consistent range, and feature engineering to extract relevant information. Proper preprocessing ensures that the data is in a suitable format for the specific analysis or model, reducing noise and improving performance. It also helps address potential biases or inconsistencies, ultimately contributing to more accurate and reliable research findings.

The "Arabic Natural Audio Dataset" was used in this study. It consists of eight videos downloaded from online Arabic talk shows, capturing live calls between an anchor and an individual outside the studio. The videos were divided into turns of callers and receivers, and emotions in each video were labelled by 18 listeners (happy, angry, or surprised). After removing silence, laughs, and noise, the audio was automatically divided into 1-second speech units, resulting in a corpus of 1384 records.

To extract features from the audio, we collected twenty-five acoustic features or low-level descriptors (LLDs). These features included intensity, zero-crossing rates, Mel-frequency cepstral coefficients (MFCC 1-12), fundamental frequency (F0), F0 envelope, probability of voicing, and LSP frequency 0-7. Each feature underwent nineteen statistical functions, such as maximum, minimum, range, absolute positions of maximum and minimum, mean arithmetic, various linear regression functions, standard deviation, kurtosis, skewness, quartiles 1, 2, 3, and inter-quartile ranges 1-2, 2-3, 1-3. Additionally, we computed the delta coefficient for each LLD to estimate the first derivative, resulting in a total of 950features.

When it comes to recognizing emotions from speech, audio files can be transformed into 2D spectrogram images. These images show the frequency content of the audio signal over time and allow the audio data to be treated as an image. This makes it possible to use computer vision-based models like transformers to analyze the spectrograms. By training a transformer model on these spectrogram images, the model can learn the patterns in the audio, both over time and in frequency. This enables the model to identify emotions based on the distinct features present in the spectrograms. This approach has been successful in recognizing emotions from speech data, thanks to the power of transformers to capture long-range dependencies and achieve high accuracy. To prepare these images for training, the ImageDataGenerator was used to preprocess and flow batches of grayscale images and corresponding emotion labels from a DataFrame. The images were resized to a target size of 128x128 pixels and assumed to be grayscale, indicated by the color_mode="grayscale" parameter.

In the wave2vector experiment, all audio files were converted to a standard sampling rate of 16000 Hz.

### C. Experimental Results

When creating machine learning models, separating data into training, validation, and testing sets is crucial. Three subsets of the original dataset have been identified: the training set, validation set, and testing set. Each set has a specific role in developing and evaluating the model. By dividing the data in this way, we can assess the model's performance in various scenarios. The allocation of data to each set is customized for each experiment, ensuring a fair evaluation of the model's abilities.

In the first experiment, we employed the ANAD dataset and applied the TRANSFORMER approach to audio data, partitioning it into 80% for training, 20% for testing, and reserving an additional 15% for validation within the training set.

In the second experiment, we used the TESS dataset and employed the VIT TRANSFORMER approach to convert audio data into 2D images. The data was divided into 80% for training, 20% for testing, with an extra 15% set aside for validation.

For the third experiment, we leveraged the ANAD dataset with audio data, utilizing the Wave2Vec approach. Data allocation involved dedicating 68% to training from the original dataset, allocating 17% to testing, and reserving 15% for validation.

Experiment 1: In this experiment, we used the following audio processing parameters: sampling_rate = 30100, duration = 1, hop_length = 300, fmin = 20, n_mels = 128, time_steps = 128, and epochs = 80 and 40.

The researchers used the Arabic Natural Audio Dataset (ANAD) , which was previously employed in [31] Novel emotion recognition for Arabic speech using deep feed-forward neural network (DFFNN) achieves 98.56% accuracy with PCA and 98.33% with combined features from ANAD dataset. In [39] evaluate three speaker traits—gender, emotion, and dialect—from Arabic speech, employing multi-task learning (MTL). The dataset, assembled from six publicly available datasets, including the ANAD dataset, underwent exploration with three networks—LSTM, CNN, and FCNN—across different features. Multi-task learning consistently demonstrated superior performance compared to single task learning (STL). Results for emotion classification are as follows: For LSTM STL achieved 50.4%, and MTL 57.05%, CNN: STL 51.18%, and MTL 51.25% and FCNN: STL 66.53%, and MTL 70.16%. Results show improvement over previous studies. In the first experiment, the same ANAD dataset was used. However, the data underwent preprocessing and was converted into a numerical 2D array before being fed into the Transformer model. As a result of this approach, the Transformer model achieved a high level of performance, reaching 94% accuracy in its predictions. This suggests that representing the data as a 2D numerical array and utilizing the Transformer model was effective in extracting valuable patterns and features from the dataset. In addition to the previous experiment where the data was represented as a numerical 2D array and fed into the Transformer model, there was another aspect to the study. In this alternative approach, the same dataset (ANAD) was entered into the Transformer model as 2D images. Interestingly, this variation yielded a slightly lower accuracy of 88% compared to the 94% accuracy achieved with the numerical 2D array representation. This suggests that the numerical format may have been more suitable for this specific dataset and the task at hand. The researchers concluded that representing the data in a specific format, such as a numerical 2D array, can significantly impact the model's performance. It is crucial to explore different data representations and preprocessing techniques to determine the most suitable approach for the given task and dataset.

Experiment 2: During the audio processing experiment, the following parameter values were used: sampling rate of 50000, duration of 1 second, hop length of 300, minimum frequency (fmin) of 20, number of Mel filters (n_mels) set to 128, time steps at 128, and 60 epochs. [40] utilized the Toronto Emotional Speech Set (TESS) which was previously used in a study comparing CNN-based emotion recognition using spectrograms and Mel-spectrograms and found Mel-spectrograms to be more suitable for Speech Emotion Recognition (SER). The study used four datasets, including TESS, which has six emotion classes. The most accurate model obtained an accuracy of 57.42% on four datasets, including TESS. In[41] combines RAVDESS and TESS datasets for emotion classification from speech, extracting 180 features using various techniques. Gradient Boosting excels with 84.96% accuracy on the merged dataset. The datasets RAVDESS and TESS datasets were integrated using CNN, yielding a 97.1% accuracy in [42]. RAVDESS, TESS and SAVEE datasets were integrated using neural network yielding a testing accuracy of about 89.26% in [43]. In the second experiment, the same TESS dataset was used, but it underwent preprocessing to convert the data into a numerical 2D array before being fed into the Transformer model. This approach achieved an impressive accuracy of 99%, highlighting the effectiveness of representing data as a 2D numerical array and utilizing the Transformer model to extract essential patterns and features from the dataset.

The researchers also tried a different method by using the ANAD dataset as 2D images with the Transformer model. However, this approach resulted in slightly lower accuracy of 98% compared to the 99% accuracy achieved with the numerical 2D array representation. These findings indicate that converting audio data into 2D images had a significant impact on the model's performance. Therefore, the numerical 2D array representation is more effective for this dataset and task.

The study underscores the importance of researching different data representations and preprocessing techniques to achieve optimal performance in machine learning models. It highlights that there is no one-size-fits-all approach, and the choice of data representation should align with the dataset's characteristics and the specific task at hand.

Ultimately, this research contributes valuable insights into the influence of data representation on deep learning model performance and knowledge extraction from audio datasets. It may pave the way for the application of such techniques in various fields, including machine empathy, emotion analysis, and voice recognition.

Experiment 3: In the third experiment, we leveraged the ANAD dataset with audio data, utilizing the Wave2Vec approach. Data allocation involved dedicating 68% to training from the original dataset, allocating 17% to testing, and reserving 15% for validation. The primary objective of this experiment was to conduct emotion classification through fine-tuning the Wave2Vec model. Following the training and evaluation, the model achieved an accuracy of approximately 56%. This implies that the model attained a correct classification rate of 56% on the testset. Tables IV and V display the findings achieved by the three models across both the ANAD and TESS datasets.

TABLE IV. TABLE SHOWING APPROCHES RESULT ON ANAD DATA SET

| **DATA SET** | **ANAD** | | |
|---|---|---|---|
| ***APPROCH*** | ***TRASFORMER*** | ***VIT TRANSFORMER*** | ***WAVE2VECTOR*** |
| ACCURACY | 94% | 88% | 56% |

TABLE V. TABLE SHOWING APPROCHES RESULT ON TESS DATA SET

| **DATA SET** | **TESS** | |
|---|---|---|
| ***APPROCH*** | ***TRASFORMER*** | ***VIT TRANSFORMER*** |
| ACCURACY | 99% | 98% |

Fig. 4 to Fig. 7 display accuracy and loss curves of a machine learning model. These figures reveal performance trends over training epochs, guiding model adjustments. Furthermore, the accuracy curves for both training and validation of the TESS dataset uses the impressive accuracy of 99% and 98%, respectively. These accuracies surpass those observed in the validation and training accuracy curves. This improvement could potentially be attributed to the imbalanced distribution of the data within the ANAD dataset.

In Fig. 4 and 5, illustrating the ANAD dataset's training and validation accuracy, it is clear that the model's performance improved considerably. Initially, the model began with an accuracy close to zero, but gradually, it showed a steady enhancement, ultimately reaching accuracies of 94% for the Transformer model and 88% for the ViT Transformer model. This progressive improvement reflects the model's growing comprehension of the dataset and its overall performance enhancement. This transition from near-zero accuracy to high accuracy underscores the model's learning process and its ability to successfully capture intricate patterns within the data.

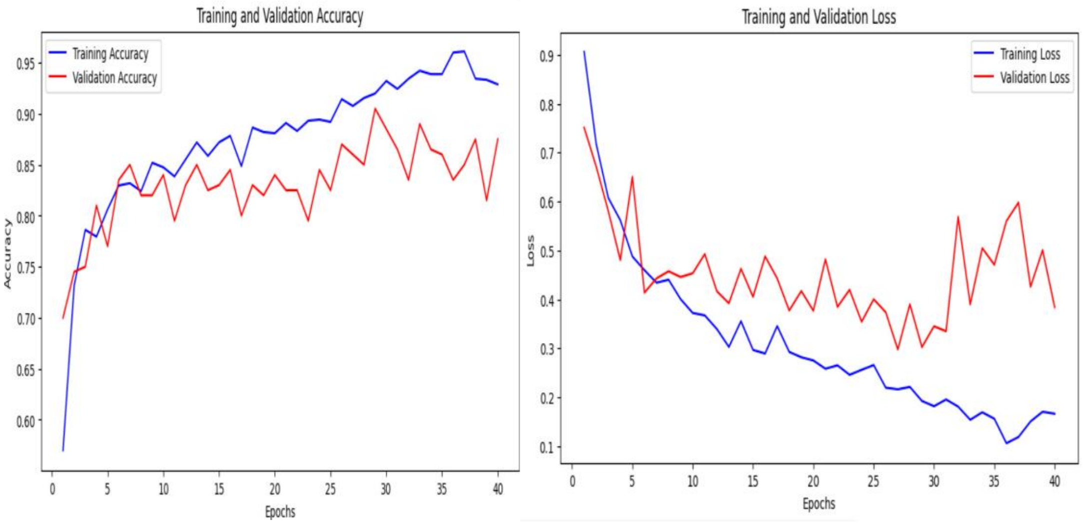

Fig. 5. ANAD dataset accuracy (left) and loss (right) curves for ViT transformer model.

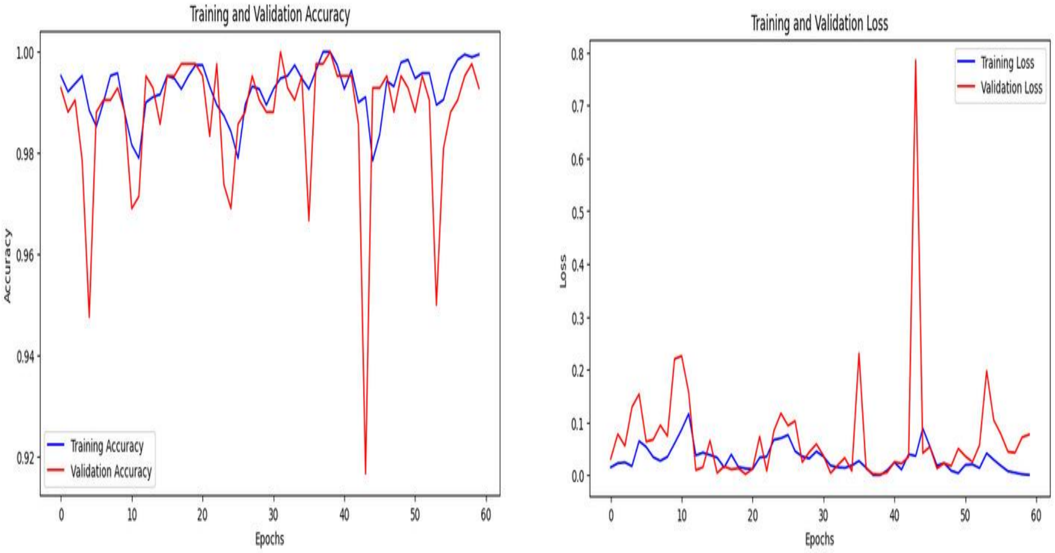

Fig. 6. TESS dataset accuracy (left) and loss (right) curves for transformer model.

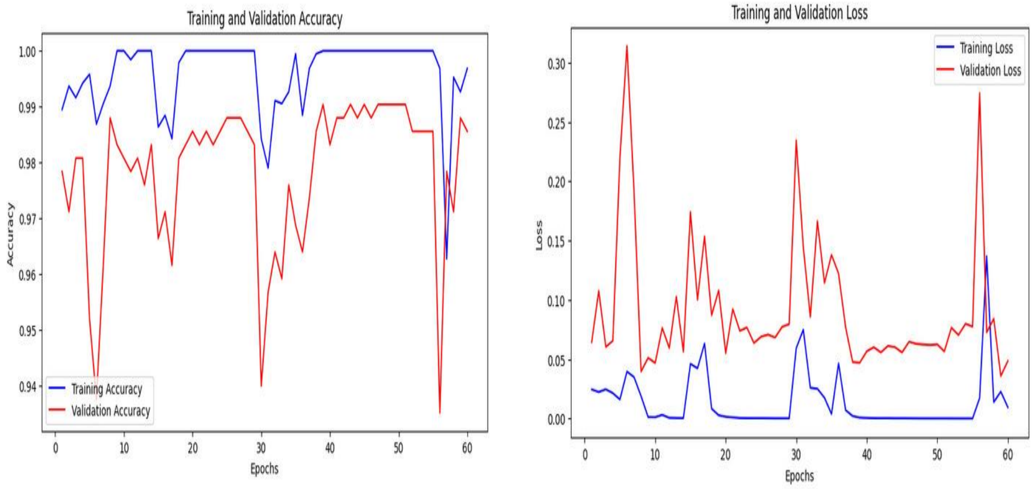

Fig. 7. TESS dataset accuracy (left) and loss (right) curves for ViT transformer model.

## V. Conclusion and Future Work

In conclusion, this research highlights the significant impact of sound on human well-being, recognized since ancient civilizations and still relevant in our modern world. It emphasizes the fast-growing field of speech emotion recognition, which has found diverse applications in enhancing human-computer interaction, aiding mental health diagnosis, and facilitating human-robot interaction. The core focus of this study is the classification of emotions from speech. The proposed three approaches, utilizing transformer-based deep learning models, demonstrates its efficacy in accurately identifying and categorizing emotions from both audio signals and transformed 2D images. The experimental evaluations on the Arabic Natural Audio Dataset (ANAD) and the Toronto Emotional Speech Set (TESS) have produced highly promising results. For the audio-based emotion classification model, ANAD achieved an impressive 94% accuracy, while TESS achieved an equally remarkable 99% accuracy. On the other hand, the image-based emotion classification model attained 88% accuracy for ANAD and 98% accuracy for TESS. These high accuracy rates show how reliable and successful the suggested method is in identifying the emotions expressed in speech. Additionally, the research incorporates the fine-tuning of wav2vec for emotion classification from the ANAD dataset, leading to a respectable 56% accuracy. While slightly lower than the other models, this result still showcases the practical implementation of fine-tuning in achieving reasonable accuracy rates in emotion classification from speech data.

The research underscores the potential of both approaches: direct audio usage and transforming audio into 2D images, yielding comparable results. Despite the vision-based model showing advantages with more data, the matrix input approach ultimately proved superior. The study's use of three diverse approaches, particularly transformer-based models, was crucial for success in emotion recognition from speech. Transformer models consistently excel in natural language processing and audio data extraction. Furthermore, diverse datasets like ANAD and TESS, enriched with varied voices and emotional expressions, significantly contributed to achieving remarkable results, enhancing model effectiveness.

In light of the promising findings and practical implications of this research, several avenues for future work can be explored. Firstly, it is recommended to further investigate the performance of the proposed three approach using larger and more diverse datasets. Expanding the dataset size can potentially improve the accuracy and robustness of the emotion classification models. Additionally, extending the application of the models to datasets that contain non-language-specific vocal expressions can be an interesting direction. By analyzing vocal expressions unrelated to a specific language, the models can be tested for their ability to capture universal emotional cues, thus enhancing their generalizability. Furthermore, it would be valuable to explore the transferability of the trained models to different domains and applications. Applying the models to datasets that are unrelated to the ones used in training, such as real-world scenarios or specific professional environments, can shed light on their adaptability and effectiveness in practical settings. In terms of methodology, incorporating multimodal approaches by Compiling speech data with additional modalities, such as physiological signs or facial expressions, can yield a more comprehensive understanding of emotions. This integration of multiple modalities can potentially enhance the accuracy and richness of emotion classification systems. Moreover, fine-tuning wav2vec in future research can be instrumental in achieving even better results than the current accuracy. Fine-tuning offers opportunities to fine-tune pre-trained models to specific datasets, leading to improved performance and more accurate emotion classification from speech. Lastly, considering the ethical implications of emotion classification from speech is crucial. Future work should address privacy concerns and ensure the responsible and transparent use of such technologies. Developing guidelines and frameworks for the ethical implementation and deployment of these models will be essential to build trust and ensure their positive impact on society.

In summary, future research should focus on expanding the dataset size, exploring non-language-specific vocal expressions, testing the models on different domains, incorporating multimodal approaches, and addressing ethical considerations. By addressing these areas and leveraging fine-tuning techniques, the proposed three approaches can be further improved and applied to a wider range of practical applications, advancing the domains of emotion recognition and human-computer interaction.

# A Method for Constructing and Managing Level of Detail for Non-Closed Boundary Models of Buildings

Ahyun Lee
Department of Metaverse & Game, Soonchunhyang University, South Korea

***Abstract*—An urban digital twin (UDT) involves creating a virtual three-dimensional (3D) digital replica of a real-world city. To build a UDT model, it needs a comprehensive 3D representation of the city's terrain, buildings, and infrastructure. In order to effectively visualize and manage large-scale spatial data in 3D, it is essential to establish and maintain an appropriate level of detail (LoD) for the 3D model. This study proposes to construct and manage LoDs for VWorld building data. However, since buildings are often composed of non-closed boundary models, applying a quadric mesh-based simplification algorithm may result in the deletion of meshes containing important contour information that defines the shape of the building. To overcome this problem, this paper proposes to use a geometric filtering algorithm to preserve the building outline shape.**

***Keywords—GIS; digital twin; 3D map; level of detail***

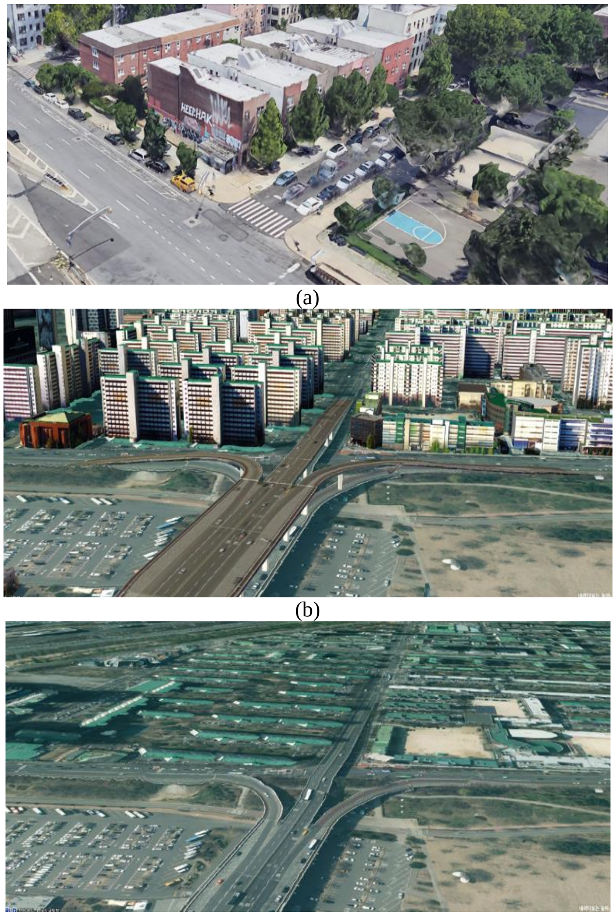
## I. Introduction

Urban digital twinning (UDT) is the study of building a virtual digital twin of a city [1-3]. UDT requires the digital construction of three-dimensional (3D) geometry of terrain, buildings, and facilities. Digital twins digitize parts or machines by attaching sensors to them and synchronize them in real time [4-5]. Digital twins can simulate real physical products or processes by digitally modelling them, and are being used in many fields beyond manufacturing to increase productivity and improve product design and operations. Urban planning or road management operations require UDT models that model realistic 3D cities and work in conjunction with multimodal sensor data.

Google Earth [6] is a web-based 3D map. It is built with HTML5 and WebGL standards, making it easy to visualize 3D cities using only a web browser. Cesium allows users to upload their models to a cloud server and visualize customized 3D buildings or models on a 3D map [7]. All of the above services are global and require large-scale data, so they do not store data locally, but provide real-time streaming-based services.

In order to stream large-scale UDT models in real-time, a data level of detail (LoD) is required [8, 9]. The LoD sets a different amount of data for different levels of the model. For example, if a camera is located outside of space and looking at the Earth, it would be impossible to request, download, and render all the data contained in that region in real time. In the case of VWorld, which has built the most accurate urban 3D spatial information data in South Korea, it provides terrain data of the global Earth's surface and has a data scale of about 30 TB or more, including 3D buildings and facilities in South Korea [10].

VWorld data provides digital elevation models (DEMs) for terrain models and building models independently. Google Earth use digital surface models (DSMs) [11]. It does not distinguish between buildings and terrain as shown in Fig. 1(a). Even trees and cars which are placed on the streets are included in the DSMs. However, for some major buildings in a city, independent models are sometimes provided. On the other side, VWorlds provides all terrain and building models in separately. The terrain is provided by a DEM [12] and an aerial image, so only the terrain excluding buildings and facilities can be visualized, as shown in Fig. 1(b) and (c). This way has the advantage of being able to visualize buildings with higher precision than DSMs. However, because DEM provides additional building data compared to DSM, it requires a relatively large amount of data to be streamed.



(a)
(b)
(c)

Fig. 1. Differences between DSM and DEM: (a) Google earth DSM, (b) VWorld DEM, and (c) Disabling 3D buildings in (b).

VWorld is built with a total of 16 levels of terrain LoDs [10]. All terrain LoDs have a DEM resolution of 64x64 and a texture image resolution of 256x256. By determining the rendering LoD based on the distance of the camera from the terrain, the texture image resolution and the size of the render data buffer can be maintained regardless of the camera position. However, for building data, only the texture image LoDs are built, which requires mesh simplification for model data consisting of many meshes.

This paper proposes a method for constructing and managing LoDs for non-closed boundary mesh models of buildings. The method utilizes VWorld building data in the form of floorless buildings, which can lead to mesh simplification that compresses or distorts crucial mesh information comprising the building in the outer regions of the non-closed boundary model [13]. Our proposed approach employs geometric filtering for non-closed boundary meshes to retain the primary elements constituting the building facade during simplification. It constructed three levels of LoD in total. Additionally, users are provided the flexibility to adjust the compression rate and a step of LoD according to their preferences.

## II. Spatial Information Data Properties

The spatial information data used in this paper is VWorld data [10]. VWorld provides a planetary-scale global three-dimensional terrain model. It consists of a total of 16 levels of terrain LoDs. LoD 0 tiles are separated at intervals of 36 degrees latitude and 36 degrees longitude. There are five latitude levels and 10 longitude levels, for a total of 50 levels that separate the Earth's surface. The 3D surface outlined in orange in Fig. 2 is {Level: 0, IDX: 8, IDY: 3}. At LoD 0, IDY is the latitude level and ranges from 0 to 4, and IDX is the longitude level and ranges from 0 to 9.

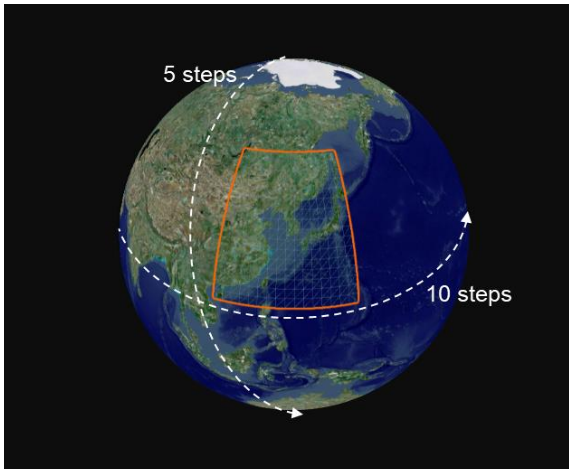


Fig. 2. VWorld tile structure, where the orange surface is a tile in LoD 0 (level: 0, IDX: 8, IDY: 3).

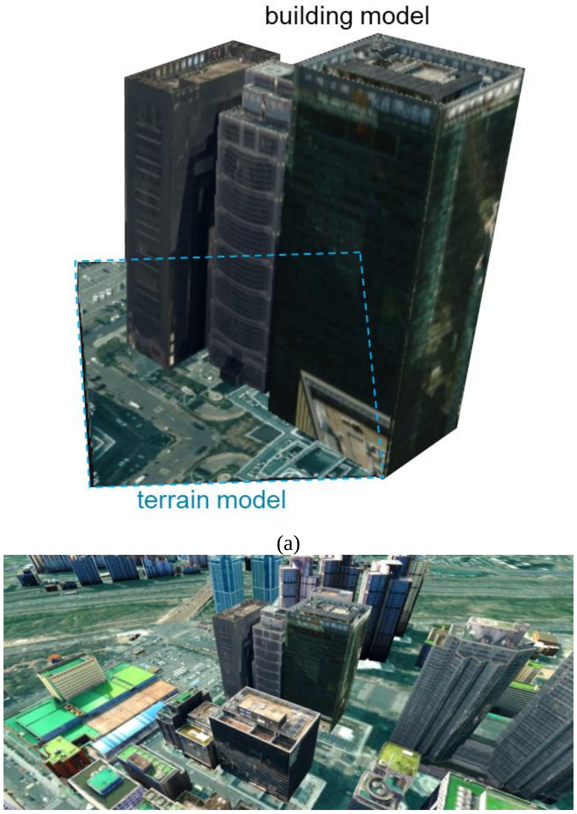
When a single LoD 0 tile is quartered, it increments level 1 and becomes LoD 1. All tiles have the same texture image resolution. As a result, the rendering resolution increases when representing the same-sized area with multiple high LoD tiles. The distance of the camera from the ground can determine the level of terrain tiles rendered, which in turn determines the number of tiles rendered per frame [14]. If the number of tiles to be rendered is similar, the resulting resolution and data buffer can be kept constant across different stages of LoD construction.

A tile is the smallest unit of geospatial data. All geospatial data is attributed to a tile ID based on level, IDX, and IDY. The criteria for inclusion in a tile are the level and location of the tile according to its data attributes. When a tile is visualized, the data contained in the tile is requested based on the active layer. For example, if a terrain tile is being rendered and the building's layer is active, the building data contained in the tile is requested, fetched, and rendered.

Tiles containing buildings use the center point coordinate values from the building data. In this case, the center point coordinates are defined as the center point by averaging the maximum and minimum values of the coordinates. The level of the terrain tile containing the building can be defined according to the situation. VWorld's geospatial data includes buildings at tile level 15 and large facilities such as bridges at level 14.

As shown in Fig. 3(a), when the corresponding tile is rendered, the terrain model of the tile is visualized to manage the building data to be rendered. Once the visualization system determines which tiles and layers to render, each layer contained in each tile is rendered. Once the cluster of tiles that make up the Earth's surface is determined, as shown in Fig. 3(b), the buildings that each tile contains are rendered.



(a)

(b)

Fig. 3. Examples of building rendering results in tiles and the implemented visualization SW: (a) One tile and the building model located on that tile and (b) The building rendering result with the surrounding terrain.

Once the building LoD is built, it can be mapped with terrain tiles based on the LoD step. This paper built a building LoD with three levels of steps. It can be mapped in the form of terrain tile level 13 and building LoD 2, terrain tile level 14 and building LoD 1, terrain tile level 13 and building LoD 0, etc. These mapping relationships can change depending on the usage scenario of the geospatial data. In actual implementation, the amount of data may decrease as the granularity of the LoD increases. However, the number of requests or the number of data to be managed may increase with the granularity. Therefore, it is not always efficient to increase the LoD level in the application phase.

In planetary-scale geospatial applications, the target data is built on a large scale. In the case of VWorld geospatial data, it is about 30TB or more, so it is very limited to utilize it by storing it locally. Therefore, all applications that provide planetary-scale geospatial information provide data in real-time streaming. The way to build the tile-based LoD system and manage the data is effective.

TABLE I. EXAMPLE OF THE REQUEST OF VWORLD DATAAPI

| Type | Layer | Level | IDX, IDY | Request URL |
|---|---|---|---|---|
| Aerial Image | Type | 0 | 0, 0 | Request=GetLayer&Layer=tile&Level=0&IDX=0&IDY=0&Key=* |
| DEM | Type | 1 | 1, 1 | Request=GetLayer&Layer=dem&Level=1&IDX=1&IDY=1&Key=* |
| Building | Type | 15 | 139689, 58037 | Request=GetLayer&Layer= acility_build&Level=15&IDX=139689&IDY=58037&Key=* |

The data request depends on the tile index and layer. Table I shows an example of using the VWorld Data API. Enter the data type in the Layer name and the tile index, {level, IDX, IDY}. You can get an authentication key from the VWorld server service site, and enter your personalized authentication key instead of "*" in the request URL tab in Table I. The request URL is categorized by tiles. A tile is the basic unit of VWorld geospatial data and the basis for management.

Data requests are prioritized. The priority by type is aerial image and DEM. Since the latitude/longitude range of a tile is determined by the tile index based on the elevation value, a regular grid mesh model can be created using DEM. By mapping aerial imagery to the generated terrain mesh model, you can create a 3D terrain model. Terrain models are prioritized in data requests over buildings. In particular, in the case of VWorld, building models are requested after all terrain models have been requested, as some models can be over 10MB per building. In general, web-based development limits the number of simultaneous requests that can be made from the web.

Fig. 4 shows the coordinates system of a building. Typical game engine-based three-dimensional applications use the y-axis as an elevation axis in a plane relative to the x and z axes [15]. However, in a spherical model of the Earth, no particular axis can be used as an elevation axis. On planetary-scale maps, if the origin of the coordinate system is the center of the Earth, the elevation axis of any building model must be the coordinate vector of the building's center point in order for the building to stand upright on the surface of the Earth. The orientation vector in blue becomes the reference vector on which the building is built. All building models in VWorld are pre-rotated according to the center vector.

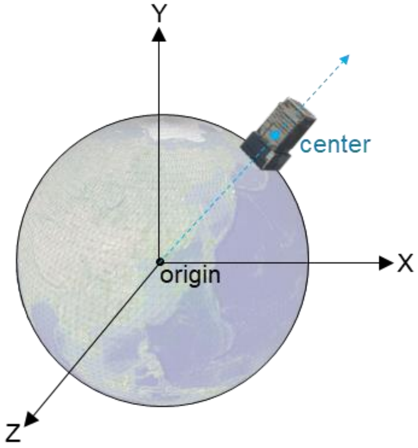


Fig. 4. The coordinates system: A building model is built with the building's center coordinate vector as the reference axis.

For the three-dimensional coordinate transformation used in the proposed method, it needs to convert to longitude-latitude coordinates. Each spatial information coordinate system has a transformation relationship based on longitude/latitude/ elevation. In this paper, it presents a three-dimensional transformation relationship with $\{lat, lon, elev\}$, which can be used to establish transformation relationships with other spatial coordinate systems.

$$h = UR + elevl \cdot UR/R \tag{1}$$

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} h \cdot cos\, lat \cdot sin\, lon \\ h \cdot sin\, lat \\ -h \cdot cos\, lat \cdot cos\, lon \end{bmatrix} \tag{2}$$

The geospatial maps implemented in this paper are in the left-handed coordinate system. $UR$ is the radius of the Earth set for Unity3D with limited map size, and $R$ is the actual radius of the Earth. This assumes that the Earth is a perfect sphere. In order for a building to be on the surface of the Earth, the building model must be oriented around the y-axis. Rotation and translation are necessary for the rotation of a building that can be located on the Earth's surface, as shown in Fig. 4.

The point in Fig. 5(a) is the coordinates of the center of the model where the building should be located. In the coordinate system origin, there is a model of a building standing on the y-axis. At the center coordinate where the building is to be located, rotate it about the y-axis by the angle between the vector with y = 0 and the - z-axis, as shown in Fig. 5(a). Compute the cross vector between the y-axis and the center coordinate, as shown in Fig. 5(b), and rotate it about the cross vector by the angle between the y-axis and the center coordinate vector of the building. Finally, translate the building by the position of the central coordinate vector to position it on the Earth's surface, as shown in Fig. 5(c).

VWorld's individually provided building models are constructed by extracting and connecting building corner points or feature points from aerial photos. The commonality of these models is that they are all non-closed boundary mesh models [13]. As shown in Fig. 6, there are no building faces that touch the ground surface. Since the model was built to be visualized in combination with the terrain model, it does not have the mesh information of the floor surface. It is rendered on a 3D map with parts of the building buried in the terrain, as shown in Fig. 7.

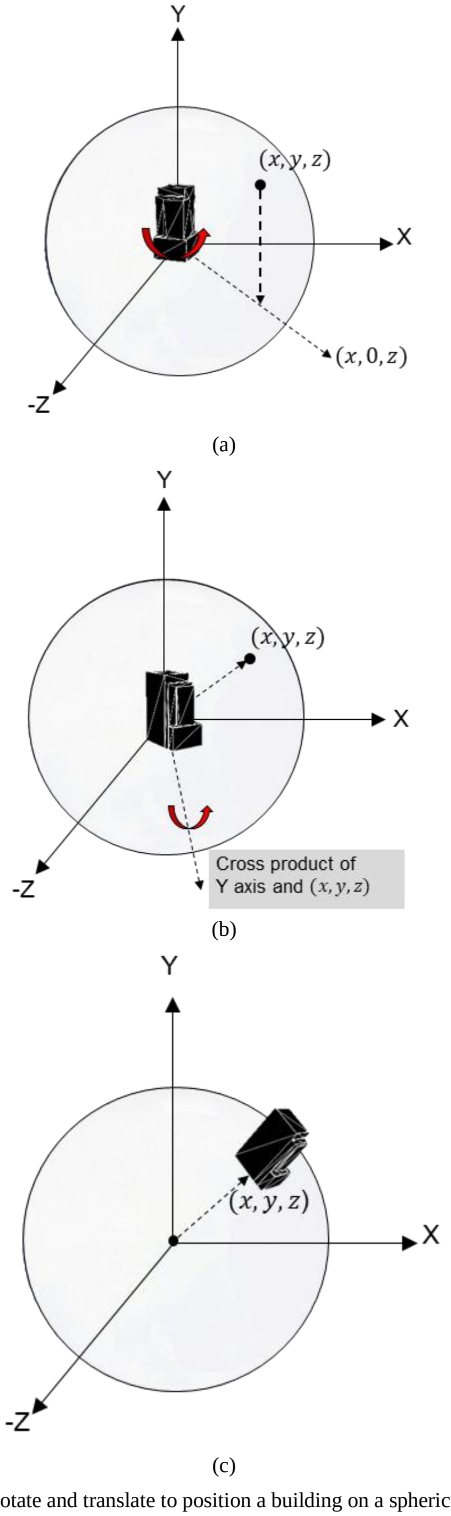

Fig. 5. Rotate and translate to position a building on a spherical surface.

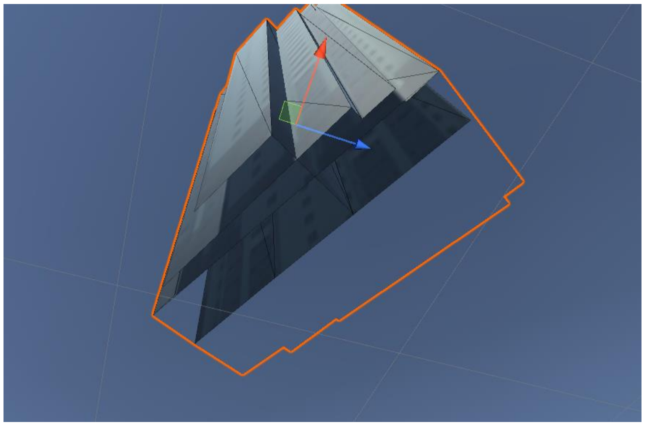

Fig. 6. A Non-closed boundary mesh model with an empty bottom surface.

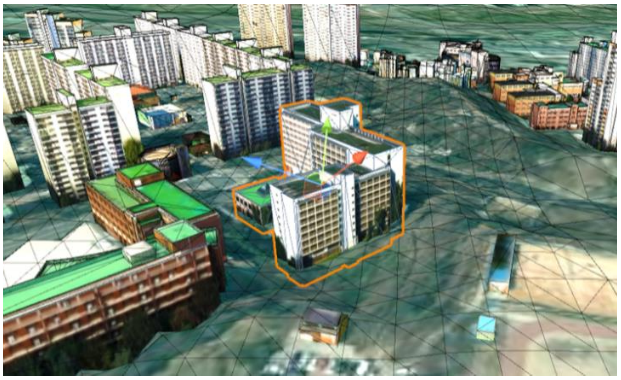

Fig. 7. Rendering example of buildings as a non-closed boundary mesh model which are partially embedded in the terrain.

## III. The Proposed Method

This paper proposes a method for building and managing the LoDs of a building in the form of a non-closed boundary mesh model. To build the LoD, it performs two main simplifications. The first is to reduce the resolution of the texture image of the building. The texture image of a building is stored as a texture atlas [16]. A texture atlas is an image that contains multiple small images, usually stitched together to reduce the overall dimensions. The atlas can be composed of uniformly sized images or images of varying dimensions. In the proposed method, the resolution of the texture atlas is used to construct up to three levels of LoDs.

The image in Fig. 8 has a resolution of 1024x1024. LoD 1 is reduced to 512x512, a quarter of the size, and LoD 2 is reduced to 256x256, 1/16 of the size. The texture image resolution varies depending on the size of the building. It built the LoDs by reducing the original resolution size by a quarter in a step.

The second step is to simplify the mesh model of the building. Compared to the texture image, which can be used to build the LoD easily, simplifying the building mesh model requires a lot of steps. Basically, the model is simplified by reducing the number of vertices that make up the mesh model. The focus is to ensure that the edge information of the building does not change significantly. This paper constructs the building LoD in three steps for the building image texture and three steps for the mesh model.

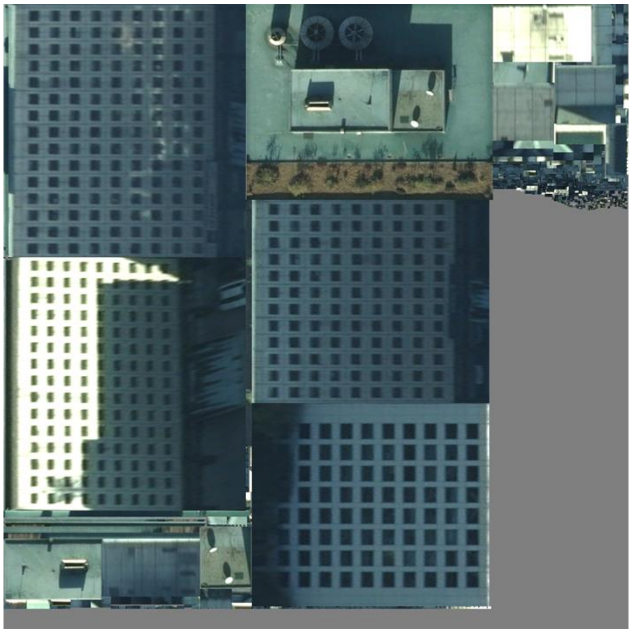

Fig. 8. A texture atlas image of VWorld data.

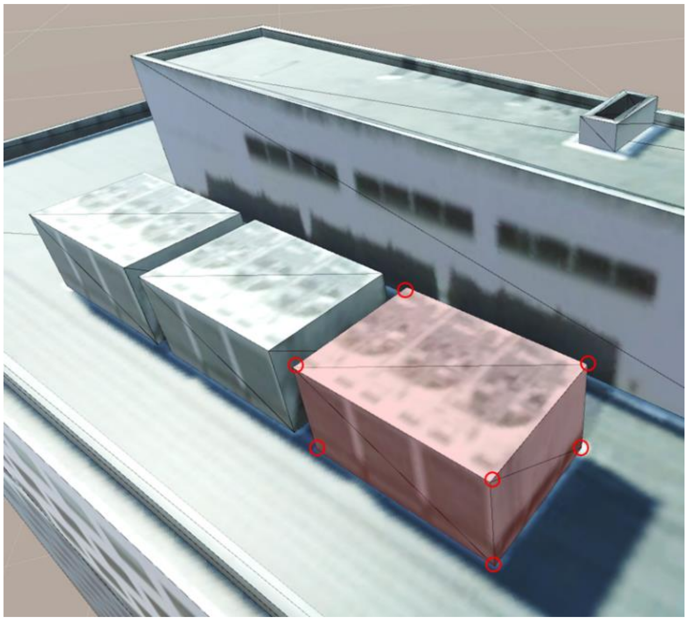

Fig. 9. Example of preserve border edges.

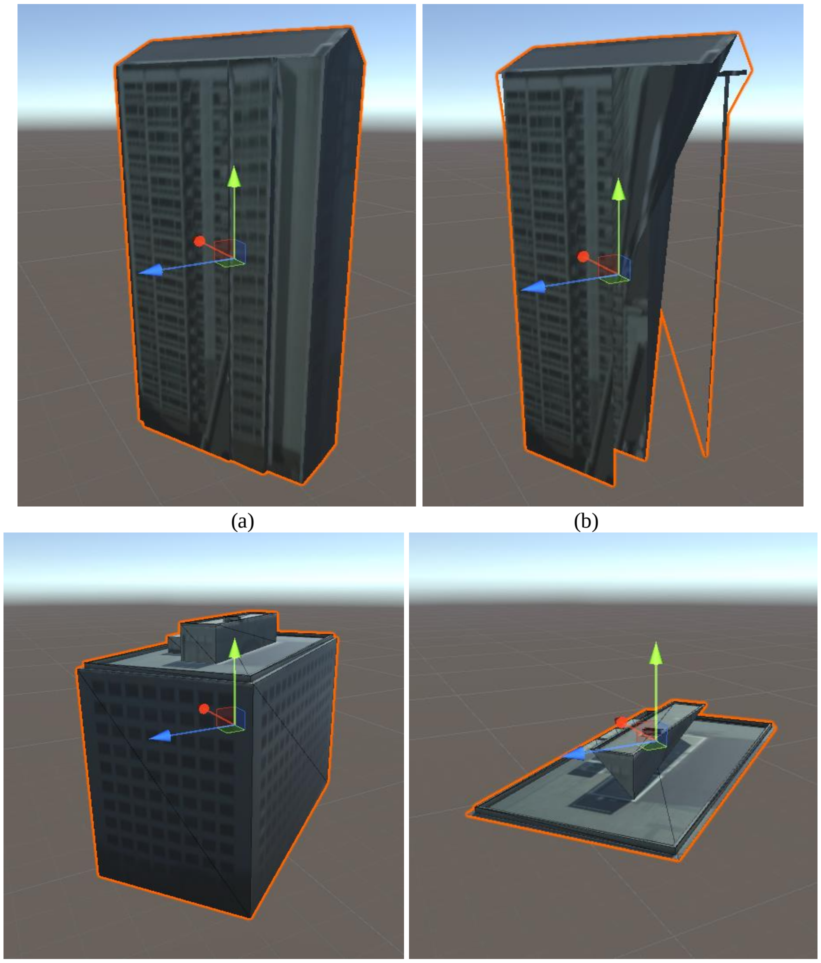


(a) (b)

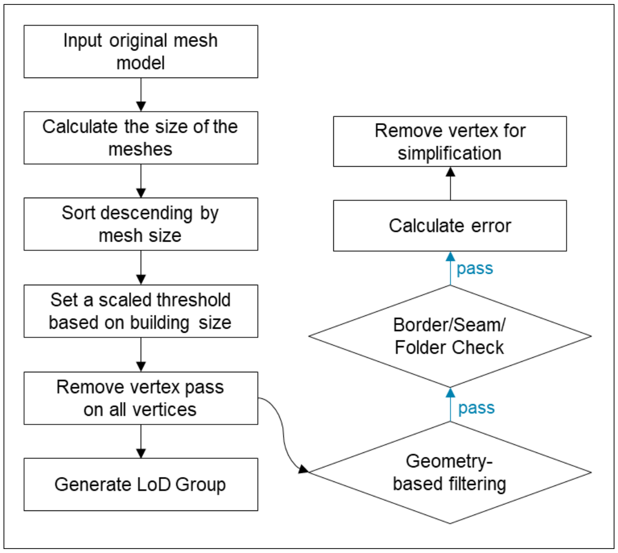
(c) (d)

Fig. 10. Examples of failed simplification results for a non-closed boundary mesh model.

For the building LoD construction, it uses the fast quadric mesh simplification algorithm [17] to maintain the shape of the mesh model to fit the building characteristics. If it needs to preserve border edges as shown in Fig. 9, it preserves edges that do not share two triangles by default [18]. Otherwise, it removes the target vertices through simplification. This property prevents holes and strange border artifacts from appearing.

However, buildings with non-closed boundary mesh models, such as those shown in Fig. 10, sometimes disappear to the sides or lose key mesh information about the building. If the mesh lost by the simplification method is a large percentage of the building, the outline of the building can be deformed and look like a rendering error. So, it proposes a building simplification and LoD construction method that can be applied to buildings with non-closed boundary mesh models.

The building mesh model simplification method proposed in this paper is shown in Fig. 11. The building LoD 2 is the original model data, and the model data gets lighter as go down to LoD 0. The proposed method utilizes geometric properties such as the orientation vector and size of the building model to distinguish important mesh information in the building. For example, a simple rectangular shape, the side of a building, is a simple shape that uses two meshes, but is important to maintain the shape of the building. The meshes that make up this building's outline information are filtered out of the simplification target so that the outline shape of the building can be maintained.



Input original mesh model
Calculate the size of the meshes
Sort descending by mesh size
Set a scaled threshold based on building size
Remove vertex pass on all vertices
Generate LoD Group
Geometry-based filtering
pass
Border/Seam/ Folder Check
pass
Calculate error
Remove vertex for simplification

Fig. 11. The proposed simplification methods for non-closed boundary mesh models.

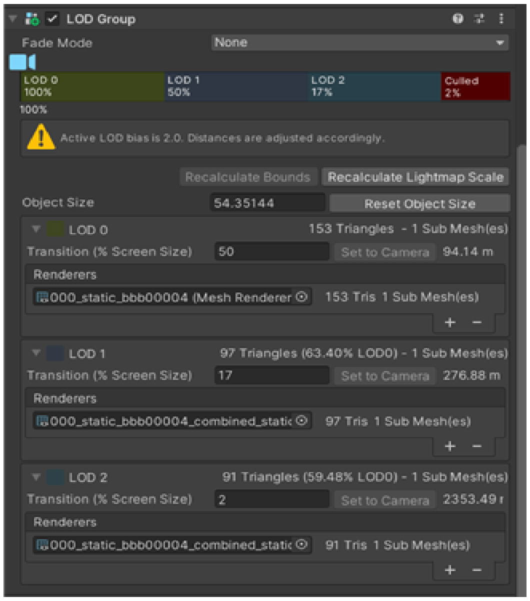
The proposed method first measures the size of all mesh polygons that make up the building model. Sort the measured sizes in descending order and set a threshold value based on the building size. This threshold value is the criterion for excluding meshes from the removal process, depending on the mesh simplification method. Meshes that are larger than the threshold is not eligible for simplification.

Due to the nature of V World building data, large faces such as building sides and roofs are relatively simple shapes. It tested 1248 building models and set the threshold to 30%, which means that the largest 30% of the mesh models or vertexes that make up the building are excluded from simplification. The border/seam/folder checks determine whether the target meshes and vertices are simplified or not. The relevant parameters are shown in Table II.

The proposed simplification algorithm results in the final LoD group shown in Fig. 12. LoD groups are used to manage data that may be displayed depending on the distance of the game object from the camera [19]. Unity3D provides a LoD group feature that allows you to manage LoDs within the game engine. As the LoD increases, the model's vertex, mesh, and texture image resolution decreases, resulting in less detail. However, as the camera gets farther away, the difference in detail is not noticeable to the user. When rendering large amounts of building data simultaneously, this approach can maintain frame per speed by reducing the size of the render target. You can determine the level of LoD visibility based on the camera distance in the properties.

TABLE II. BORDER/SEAM/FOLDER CHECK PARAMETER

| Option | Description |
|---|---|
| Preserve Border Edges | Border edges that need to be preserved are edges that do not share two triangles. |
| Preserve UV Seam Edges | UV seam edges that need to be preserved are essentially connected edges that contain a difference in UV coordinates. |
| Preserve UV Foldover Edges | UV fold edges that need to be preserved are connected edges that contain the same UV coordinates. |
| Preserve Surface Curvature | When you need to preserve surface curvature |
| Vertex Link Distance | Distance between vertex links |
| Max Iteration Count | The maximum number of iterations to simplify the mesh. Reducing this value can speed up the simplification, but may reduce the quality of the result. This value is used to prevent infinite simplification from occurring. |



LOD Group

Fade Mode: None

LOD 0 100% | LOD 1 50% | LOD 2 17% | Culled 2%

100%

Active LOD bias is 2.0. Distances are adjusted accordingly.

Object Size: 54.35144

LOD 0 — 153 Triangles - 1 Sub Mesh(es)
Transition (% Screen Size): 50 — 94.14 m
Renderers: 000_static_bbb00004 (Mesh Renderer — 153 Tris 1 Sub Mesh(es)

LOD 1 — 97 Triangles (63.40% LOD0) - 1 Sub Mesh(es)

Fig. 12. The result of the created a building LoD group in the unity 3D editor.

It conducted experiments on 1248 random buildings provided by VWorld. Table III shows the simplification results generated by the proposed algorithm. LoD 0 is the number of meshes in the original model, and LoD 1 and LoD 2 are the number of meshes in the simplified result. Percentage means the ratio of the number of meshes in the original LoD 0 to the number of meshes in the simplified result. The reduction through simplification is not significant due to the low number of original meshes. For buildings with complex shaped meshes, size reductions of up to 80% or more have been observed.

Fig. 13 shows the simplified results. Compared to Fig. 13(a), the number of meshes for the semi-spherical shape of the sculpture in Fig. 13(b) and Fig. 13(c) is reduced. On the other hand, you can see that the important outline and corner information that make up the shape of the building is retained. This also avoids the problem of excluding information such as the sides of the building, which can occur when simplifying on non-closed mesh buildings. The building consists of 559 meshes at LoD 0, and the simplification results in 363 meshes at LoD 1 and 236 at LoD 2, a reduction of 64.94% and 42.22%, respectively.

TABLE III. SIMPLIFICATION RESULTS FOR 1248 BUILDING DATA FORM VWOLD GEOSPATIAL DATA (MESH COUNTS, AVERAGE VALUES)

| Mesh Count | | |

## IV. CONCLUSION

This paper proposes a LoD construction and management method for a non-closed boundary model of buildings. VWorld geospatial data provides terrain and buildings as independent models. LoD construction experiments are built for each building. As a result of the experiments, it constructed three levels of LoDs for 1248 buildings in downtown Seoul and found that the number of meshes could be reduced by 67.46% in LoD 1 and 48.07% in LoD 2 through two steps of simplification. The problem of removing meshes at non-closed boundary locations in the simplified building model was also solved by filtering based on the geometric properties of the building model. In future research, I plan to study a simplification accuracy measurement method based on geospatial data to measure the quality of simplified building models. I also plan to apply it to the VWorld spatial information model to provide a planetary-scale real-time streaming-based service for building LoD data built from 3D maps.

# The Optimal Allocation Method for Energy Storage in Low Voltage Distribution Power Network

Lin Zhu[1], Xiaofang Meng[2], Nannan Zhang[3]*
College of Information and Electrical Engineering, Shenyang Agricultural University, Shenyang, China[1, 2, 3]
Anshan Power Supply Company of State Grid, Anshan, 114003, China[1]

***Abstract*—In order to promote the absorption of photovoltaic in low-voltage distribution network, and reduce the voltage over-limit problem caused by high proportion of distributed photovoltaics, this paper proposes a method for optimizing the allocation of distributed energy storage system in low voltage distribution network. Firstly, based on the node voltage of the maximum load day and all day, the optimal clustering number *k* is obtained by the elbow method, and the *K*-means clustering algorithm is used to realize the zoning of the distribution network. Secondly, the objective function is to improve the node voltage, reduce the power loss, and minimize the comprehensive cost of energy storage investment, and at the same time consider various constraints such as power balance and energy storage battery, and construct a multi-objective optimization model for the optimal configuration of distributed energy storage system in low voltage distribution network. After normalizing each objective function, the weight coefficient of each objective function is determined based on the analytic hierarchy method. The whale algorithm is used to solve the model to determine the best installation location and capacity of distributed energy storage. Finally, taking an actual area as an example, the effectiveness of the proposed model in leveling the voltage exceeding of low voltage distribution network nodes is verified.**

***Keywords*—Optimal allocation; voltage over-limit; distributed energy storage; low voltage distribution networks**

## I. Introduction

Under the background of the "safe, efficient and low-carbon" Energy development strategy, it has become a development trend to raise a large amount of Distributed Photovoltaic (DPV) and Distributed Energy Storage (DES) in the distribution network [1, 2]. The increasing proportion of DPV connected to Low-Voltage Distribution Network (LVDN) will worsen the mismatch between the volatility and load characteristics of photovoltaic power and results in serious power back flow phenomenon. The reverse power flow leads to the increase of node voltage, the over-limit of node voltage, aggravates voltage fluctuation and other problems, which affects the stable operation of the distribution network [3]. With the increasing permeability of DPV in LVDN, the over-voltage problem has affected LVDN's absorption of high-proportion distributed PV [4, 5], which brings great challenges to the safe operation of the distribution network.

It is an effective way to apply DES to suppress/solve the voltage over-limit caused by the high proportion of photovoltaic in the distribution network [6-9]. The access location and capacity of Distributed Energy Storage System (DESS) directly affect the voltage quality and operation economy of the distribution network. Therefore, reasonable allocation of DES has become an urgent issue to be studied considering the voltage off-limit treatment of distribution network [10].

Many scholars have carried out research on the optimal configuration and operation of DES in distribution network. The study in [11] proposed a configuration method to jointly optimize the installation location, rated power and rated capacity of energy storage at the same time in order to prevent the voltage over-limit of low-voltage distribution network. The study in [12] constructed a two-layer optimization framework for DESS. The upper layer capacity allocation optimization model took the optimal investment economy after DESS was connected to the distribution network as the objective function, while the lower layer distribution point optimization model considered the efficiency of DESS in operation. The study in [13] took the measurement index of power network vulnerability, active power network loss and rated capacity of Energy Storage as targets, considered the coupling between planning and operation, and established the multi-objective siting capacity model of Energy Storage System (ESS), but the energy storage cost was not involved in the model. The study in [14] used affinity propagation (AP) clustering algorithm to divide the distribution network into multiple zones, and the clustering center node was selected to install ESS, and the capacity configuration of the hybrid energy storage system was carried out considering the charging and discharging efficiency of ESS and the state of SOC. However, the impact of the lack of DES participation in operation was not considered to improve the voltage and loss of the distribution network. The study in [15] proposed an optimal allocation method of energy storage in distribution network based on local constraints and quantitative evaluation of overall flexibility, aiming at the problem of sharp fluctuations of net load caused by a large number of distribution networks accessing distributed power sources. The study in [16], energy storage distribution was optimized based on the node voltage comprehensive sensitivity analysis method, and the DES optimization planning model was established with the dual objectives of minimum comprehensive cost and minimum voltage fluctuation sum of distribution network. The study in [17] established a two-layer energy storage configuration optimization model, in which the upper layer aimed at the minimum energy storage investment and the maximum photovoltaic consumption, and the lower layer aimed at the minimum variance of net load, but the voltage was not considered in the model. However, the above

method does not fully consider the zoning characteristics of the distribution of over-limit nodes during the operation of LVDN distribution network containing High Proportion Distributed Photovoltaic (HPDPV), so further research is still needed.

Considering the voltage over-limit treatment of HPDPV LVDN, this paper puts forward the method of partition optimization allocation of DES. Firstly, LVDN is partitioned, and then a multi-objective optimization model is established to determine the configuration nodes and capacity of DES. Finally, the actual low voltage network is taken as an example to verify the effectiveness of the proposed method.

## II. LVDN Partitioning Method Based on K-means Clustering Algorithm

At present, there are two main installation methods of distributed energy storage, one is decentralized, but this method will make the installed energy storage too much, which will lead to uneconomical. The other is centralized, but this method will require very high communication conditions. Therefore, this paper uses K-means clustering algorithm, combined with the grid structure of LVDN, and based on the node voltage of the distribution line at the maximum load day and all day, the distribution line is divided into nodes.

### *A. Sample Data*

In this paper, the node voltage of distribution line running at maximum load every day is taken as sample data. Suppose that the total number of independent nodes in the distribution network is N, the total number of nodes is N+1, the total number of branches is b, the branches *n* (*m*, *n*), the first node number is *m*, the last node number is *n*, and *n*>*m*, *n* =1, ..., *N*.

### *B. LVDN Partition*

K-means clustering algorithm can classify data with high similarity into one class. It is very sensitive to noise and outliers and needs to specify the number of sets before running. Too large or too small a number of sets will affect the final result. In this paper, the elbow method is used to determine the number of center points, and the judgment index is the Sum of Squared Errors (SSE). Its basic principle is to draw the SSE curve of different cluster numbers with the change of k value, and find the "inflection point" where SSE quickly slows down, namely the position of the elbow. The k value corresponding to that position is the most reasonable value for the number of sets. SSE formula is as follows:

$$SSE=\sum_{i=1}^{k}\sum_{x\in C_i}\left\|x-\gamma_i\right\|_2^2 \tag{1}$$

where, $C_i$ is the i set; $\gamma_i$ is the set center of $C_i$.

The LVDN partitioning process based on K-means clustering algorithm is shown in Fig. 1, and the operation steps are as follows:

*1)* The elbow method is used to process the sample data and determine the number value of the set center k;

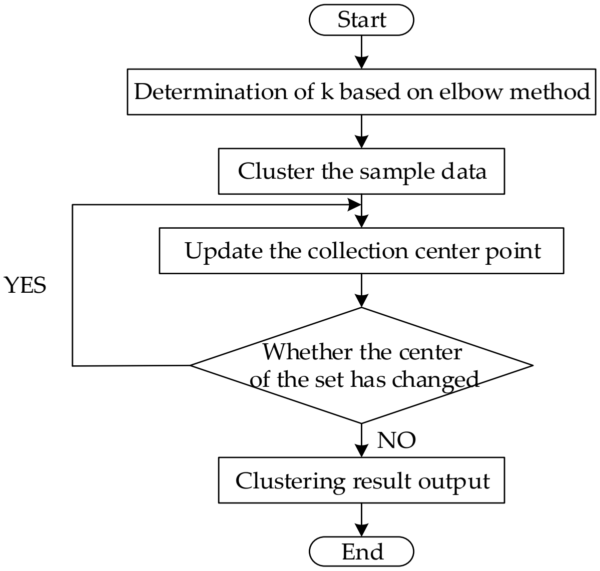
*2)* Calculate the distance between other data points and the center vector of the set and assign it to the set with the closest distance;

*3)* Update the center vector of the set;

*4)* If the center vector of the set changes, repeat step 2) and step 3), no change, go to step 5);

*5)* Output clustering results.

The flow chart is shown in Fig. 1.



Start
Determination of k based on elbow method
Cluster the sample data
Update the collection center point
YES
Whether the center of the set has changed
NO
Clustering result output
End

## III. DES Multi-Objective Optimization Model

In this chapter, DES multi-objective optimization model is established, including objective function and constraints. Then the multi-objective is normalized and the weight coefficient of the multi-objective is determined, so that the multi-objective is transformed into a single objective.

### *A. Objective Function*

In order to reflect the improvement of distribution network operation state after DES optimal configuration, this paper takes improving node voltage, reducing power loss and minimizing the comprehensive cost of energy storage investment as the objective function.

*1) Node voltage improvement degree:* The improvement degree of node voltage is described by the decreased value of node voltage offset of distribution network before and after the optimal configuration of DES. The model expression is as follows:

$$\min f_1^{'}=\sum_{t=1}^{24}\sum_{i\in\Omega}\left(\frac{\left|U_{t.i}^{(1)}-U_{\mathrm{N}}\right|}{U_{\mathrm{N}}}-\frac{\left|U_{t.i}^{(0)}-U_{\mathrm{N}}\right|}{U_{\mathrm{N}}}\right)\times 100\% \tag{2}$$

where, $\Omega$ is the node set of distribution network; $U_{t.i}^{(0)}$ and $U_{t.i}^{(1)}$ are respectively the voltage of node *i* at time period *t* before and after DES is optimized.

*2) Power loss:* After optimizing the configuration of DES, the power loss of the distribution net-work is minimal:

$$\min f_2^{'}=\sum_{t=1}^{24}\sum_{l=1}^{b}3\times10^{-3}\times I_l^2R_lt \tag{3}$$

where, $I_l$ is the current of branch $l$, A; $R_l$ is the current of branch $l$, Ω; $b$ is the number of branches.

*2) DES comprehensive investment expenses:* DES comprehensive investment cost mainly includes installation cost and operation and maintenance cost [18]. The objective function formula is as follows:

$$\min f_3^{'} = (C_{\mathrm{IC}} + C_{\mathrm{OMC}}) \; P_{\mathrm{ess.instal}} \tag{4}$$

where, $C_{\mathrm{IC}}$ is the installation cost per unit power of the energy storage battery, calculated according to Eq. (5), yuan; $C_{\mathrm{OMC}}$ is the operation and maintenance cost per unit power of the energy storage battery, calculated according to Eq. (6), yuan; $P_{\mathrm{ess.instal}}$ is the total installed power of DES, kW.

$$C_{\mathrm{IC}} = (C_{\mathrm{S}} \frac{t_{\mathrm{n}}}{\eta} + C_{\mathrm{P}} + C_{\mathrm{AF}} t_{\mathrm{n}}) \frac{r(1+r)^N}{(1+r)^N - 1} \tag{5}$$

where, $r$ is the depreciation rate; $N$ for the use of cycle life; $C_{\mathrm{S}}$ is the unit energy price of the battery body (yuan /(kWh)); $C_{\mathrm{P}}$ is the unit power price of two-way energy conversion equipment (yuan/kW); $C_{\mathrm{AF}}$ is the unit energy price of auxiliary equipment (yuan /(kWh)); $t_{\mathrm{n}}$ is the rated charging and discharging time of the energy storage battery, h.

$$C_{\mathrm{OMC}} = C_{\mathrm{O\_P}} + C_{\mathrm{C}} \frac{t_{\mathrm{n}}}{\eta} T \tag{6}$$

where, $C_{\mathrm{O\_P}}$ is the basic operation and maintenance cost per unit power of the energy storage battery (yuan/kW); $C_{\mathrm{C}}$ is the charging electricity price (yuan/(kWh)); $T$ indicates the number of operating days per year.

### B. Constraint Condition

In order to maintain the stable operation of LVDN, the optimized allocation model of energy storage partition constructed must meet the following constraints.

*1) Power balance constraint:* The model satisfies the following power balance constraints [19]:

$$\begin{cases} P_{\mathrm{G}i} + P_{\mathrm{pv}i} \text{-} P_{Li} \pm P_{\mathrm{ess}} = U_i \sum_{j=1}^{N} U_j (G_{ij} \cos\theta_{ij} + B_{ij} \sin\theta_{ij}) \\ Q_{\mathrm{G}i} + Q_{\mathrm{pv}i} - Q_{Li} \pm Q_{\mathrm{ess}} = U_i \sum_{j=1}^{N} U_j (G_{ij} \sin\theta_{ij} - B_{ij} \cos\theta_{ij}) \end{cases} \tag{7}$$

where, $P_{\mathrm{G}i}$ and $P_{\mathrm{pv}i}$ are the active power injected by the system and DPV into node $i$, kW; $Q_{\mathrm{G}i}$ and $Q_{\mathrm{pv}i}$ are the reactive power injected into node $i$ by the system and DPV, kvar; $P_{\mathrm{L}i}$ is the active power consumed by node $i$, kW; $Q_{\mathrm{L}i}$ is the reactive power consumed by node $i$, kvar; $P_{\mathrm{ess}}$ is the active power absorbed or emitted by ESS, kW; $Q_{\mathrm{ess}}$ is reactive power absorbed or emitted by ESS, kvar.

*2) Nodal voltage constraint:* After the configuration of DES, the LVDN node with a high proportion of distributed PV voltage offset does not exceed ±5%, namely:

$$-5\% \le \frac{U_i - U_{\mathrm{N}}}{U_{\mathrm{N}}} \times 100\% \le 5\% \tag{8}$$

*3) Energy storage battery confinement:* The regulation of energy storage battery has bidirectional effectiveness, and the constraint formula is:

$$-1 \le \varepsilon(d,t) \le 1 \tag{9}$$

where, ε (d, t) is the power adjustment function.

SOC of energy storage battery has upper and lower limits, and the constraint formula is [20]:

$$\mathrm{SOC_{min}} \le \mathrm{SOC}(t) \le \mathrm{SOC_{max}} \tag{10}$$

*4) DPV constraint:* The output power and total installed capacity of DPV must meet the constraints shown in Eq. (11) and Eq. (12) respectively.

$$0 \le P_{\mathrm{PV}} \le P_{\mathrm{PV\,max}} \tag{11}$$

where, PPV is the active power output of DPV, kW; PPVmax is the maximum output power of DPV, kW.

$$P_{\mathrm{PV.instal\,min}} \le P_{\mathrm{PV.instal}} \le P_{\mathrm{PV.instal\,max}} \tag{12}$$

where, $P_{\mathrm{PV.instal\ min}}$ is the minimum active component of the total installed capacity of DPV, kW; $P_{\mathrm{PV.instal\ max}}$ indicates the maximum active power component of the total installed DPV capacity, kW.

*5) Line current constraint:* The model satisfies the following line current constraint:

$$I_{l\min} \le I_l \le I_{l\max} \tag{13}$$

where $I_{l\mathrm{min}}$ is the lower limit of line current, A; $I_l$ is the line current value, A; $I_{l\mathrm{max}}$ is the upper limit of line current, A.

### C. Normalization of Multiple Objective Functions

In order to determine the location and capacity of DES site selection, the objective function is normalized, and the weight coefficient is allocated to the objective function, and the multi-objective function is changed into a single objective function.

The objective function is normalized [21] as follows:

$$\begin{cases} f_1 = \dfrac{f_1^{'} - f_{1\ \min}^{'}}{f_{1\ \max}^{'} - f_{1\ \min}^{'}} \\ f_2 = \dfrac{f_2^{'} - f_{2\ \min}^{'}}{f_{2\ \max}^{'} - f_{2\ \min}^{'}} \\ f_3 = \dfrac{f_3^{'} - f_{3\ \min}^{'}}{f_{3\ \max}^{'} - f_{3\ \min}^{'}} \end{cases} \tag{14}$$

where, $f'_{1\ \mathrm{min}}$ and $f'_{1\ \mathrm{max}}$ are respectively the minimum and maximum values of the first objective function; $f'_{2\ \mathrm{min}}$ and $f'_{2\text{-}\mathrm{max}}$ are respectively the minimum and maximum values of the second objective function; $f'_{3\ \mathrm{min}}$ and $f'_{3\ \mathrm{max}}$ are respectively the minimum and maximum values of the third objective function.

The multi-objective function is transformed into a single objective function, as follows:

$$\min F = \omega_1 f_1 + \omega_2 f_2 + \omega_3 f_3 \tag{15}$$

where, $\omega_i$ is the weight coefficient of multiple objective functions ($i$ =1,2,3), 0< $\omega_i$ <1 and $\omega_1+\omega_2+\omega_3=1$.

### D. Determination of Weight Coefficients of Multiple Objective Functions

The analytic Hierarchy Process (AHP) is adopted to define the weight of the objective function by constructing a judgment matrix. Table I is the element judgment table, and the scale in the table is used to prioritize the targets.

TABLE I. ELEMENT SCALE JUDGMENT TABLE

| Scale | Meaning |
|---|---|
| 1 | Equally important |
| 3 | The former is slightly more important than the latter |
| 5 | The former is significantly more important than the latter |
| 7 | The former is more important than the latter |
| 9 | The former is the most important |
| 2、4、6、8 | Represents the median value of the above adjacent judgments |
| The reciprocal of 1 to 9 | Represents the importance of the exchange order comparison of the corresponding two factors |

According to the judgment elements, the corresponding judgment matrix $K$ is formed:

$$K=\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} \tag{16}$$

where, a is the scale value obtained according to the element judgment table, where $a_{ij}$ and $a_{ji}$ are reciprocal of each other; $n$ represents the number of optimization objectives.

The root method is used to calculate the weight of the optimization objective, and the calculation formula is as follows:

$$\begin{cases} \varpi_i = \sqrt[n]{\prod_{j=1}^{n} a_{ij}} \\ \omega_i = \dfrac{\varpi_i}{\sum_{j=1}^{n} \varpi_j} \end{cases} \tag{17}$$

where, $\varpi_i$ is the geometric mean value of $a_{ij}$; $\omega_i$ is the weight coefficient of the optimization objective.

Finally, consistency test is carried out to illustrate the rationality of the weight determination method. The calculation formula is as follows:

$$\begin{cases} C_1 = \dfrac{\lambda_{\max} - n}{n-1} \\ C_R = \dfrac{C_1}{R_1} \end{cases} \tag{18}$$

where, $C_1$ is a consistency index to measure the degree of inconsistency; $R_1$ is the given random consistency index; $\lambda_{\max}$ is the largest characteristic root; $C_R$ is the judgment value of test results. When $C_R$<0.1, it indicates that the weight coefficient is selected reasonably.

## IV. MULTI-OBJECTIVE OPTIMIZATION MODEL SOLVING BASED ON WHALE ALGORITHM

In this paper, whale algorithm is used to solve the model. The advantages of this algorithm are that it is simple to operate, requires fewer parameters, and has strong ability to jump out of local optimization.

### A. Overview of Whale Algorithm Principles

Whale Optimization Algorithm (WOA) simulates the cooperation and competition among individuals in the humpback whale population, and uses adaptive search strategy to find the optimal solution of the objective function efficiently. WOA consists of three stages: encircling predation phase, bubble attack phase, and random hunting phase [22].

*1) Encircling predation phase:* It can be assumed that the current optimal search agent is the target prey or close to the target prey, and other search agents will update the location of the best search agent in order to find the optimal solution faster. This search strategy can avoid falling into the local optimal and unable to continue optimization [23]. The formula is as follows:

$$\vec{D} = \left| \vec{C} \cdot \vec{X}^*(t) - \vec{X}(t) \right| \tag{19}$$

$$\vec{X}(t+1) = \vec{X}^*(t) - \vec{A} \cdot \vec{D} \tag{20}$$

where, $\vec{X}(t)$ is the position vector of the current search agent; $\vec{X}^*(t)$ is the position vector of the current best search agent, which changes with the number of iterations; $t$ is the number of iterations; $\vec{A}$ and $\vec{C}$ are coefficient vectors.

Among them:

$$\vec{A} = 2\vec{a} \cdot \vec{r} - \vec{a} \tag{21}$$

$$\vec{C} = 2\vec{r} \tag{22}$$

$$a = 2 - \frac{2t}{T_{\max}} \tag{23}$$

where, $\vec{r}$ is a random vector with a value range of [0, 1]; $\vec{a}$ is the parameter control vector, and the value decreases linearly from 2 to 0 in the algorithm iteration process; $T_{\max}$ is the upper limit of the number of algorithm iterations.

*2) Bubble attack phase:* There are two strategies in the bubble attack phase, which are contraction encir-cling mechanism and spiral update position. Among them, the shrinkage enveloping mechanism is realized by changing the value of parameter a, and there is a linear relationship between parameter a and A. With the strategy of spiral update position, the whale optimization algorithm can search the space more comprehensively, so as to find the potential optimal solution better. The position of spiral update is shown in Fig. 2.

The formula for calculating spiral update position is as follows:

$$\vec{X}(t+1) = \vec{D}\cdot e^{bl}\cdot\cos(2\pi l) + \vec{X}^{*}(t) \tag{24}$$

where, $\vec{D}$ is the distance between the search agent and the optimal search agent location; *b* is the constant controlling the update of spiral position; *l* is the random number of [-1, 1].

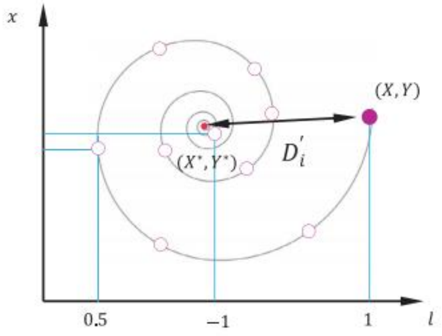

Fig. 2. Position of spiral update.

In the bubble attack phase, humpbacks tend to do both at the same time. To simulate this synchronous behavior, the humpback was assumed to have a 50% chance of choosing to use one of the two methods. When probability *p*<0.5, humpback whales will choose to use shrinkage encircling mechanism, otherwise they will use spiral up-date position method, in order to update their position during optimization, the formula is as follows:

$$\vec{X}(t+1) = \begin{cases} \vec{X}^{*}(t) - \vec{A}\cdot\vec{D}, p<0.5 \\ \vec{D}\cdot e^{bl}\cdot\cos(2\pi l) + \vec{X}^{*}(t), p \geq 0.5 \end{cases} \tag{25}$$

*3) Random hunting phase:* The whale position is changed by coefficient *A*. When $|\vec{A}|$ is greater than 1, the search agent is forced to move away from the reference optimal position, and the whale will randomly search for food in the global scope, effectively avoiding the dis-advantage of local optimal [24]. The formula for this stage is as follows:

$$\vec{D} = \left|\vec{C}\cdot\vec{X}_{rand} - \vec{X}(t)\right| \tag{26}$$

$$\vec{X}(t+1) = \vec{X}_{rand} - \vec{A}\cdot\vec{D} \tag{27}$$

where, $\vec{X}_{rand}$ randomly selects an individual whale and takes its position vector as the reference vector.

## B. Whale Algorithm Solution Process

The WOA operation steps are as follows:

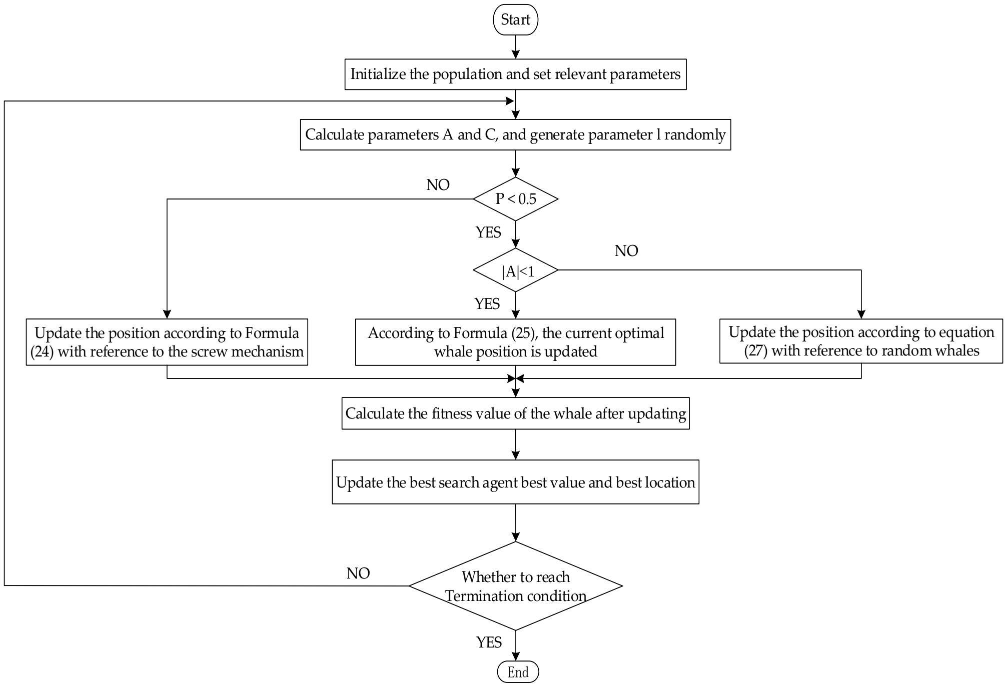
*1)* Initialize population number and iteration times, and set relevant parameters;

*2)* Each search agent performs iterative optimization in accordance with the three stages in WOA, and then updates the optimal value of the best search agent and the optimal position vector according to the fitness values of the search agent, the best search agent and the reference search agent, and saves records at the same time;

*3)* Judge whether the WOA program meets the termination requirement, if so, output the result, otherwise, perform step 2);

*4)* Output the best search agent position vector of the last iteration.

The WOA process is shown in Fig. 3 (shown at the end of this paper).



Start
Initialize the population and set relevant parameters
Calculate parameters A and C, and generate parameter l randomly
P < 0.5
NO
YES
|A|<1
NO
YES
Update the position according to Formula (24) with reference to the screw mechanism
According to Formula (25), the current optimal whale position is updated
Update the position according to equation (27) with reference to random whales
Calculate the fitness value of the whale after updating
Update the best search agent best value and best location
Whether to reach Termination condition
NO
YES
End

## V. Example Analysis

### A. Example Introduction

Take an actual low-voltage network as an example, as shown in Fig. 4, $N$=46, $b$=46, 0~46 are node numbers, node 0 is the reference node, and its voltage remains unchanged to $1.05U_N$. The district has 1 non-industrial user, 191 residential lighting households, 4 agricultural production households and 1 commercial electricity consumption household. The proportion of DPV connected to LVDN is set to 100%. It is assumed that each household has the same photovoltaic capacity and the photovoltaic output is basically the same. The maximum and minimum load curves of the system are shown in Fig. 5.

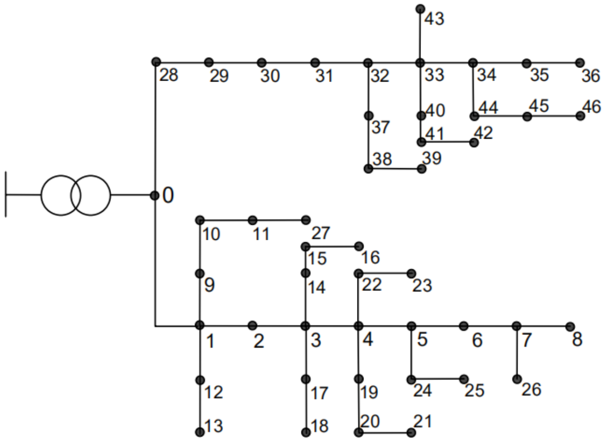

Fig. 4. 0.38kV radiant network diagram.

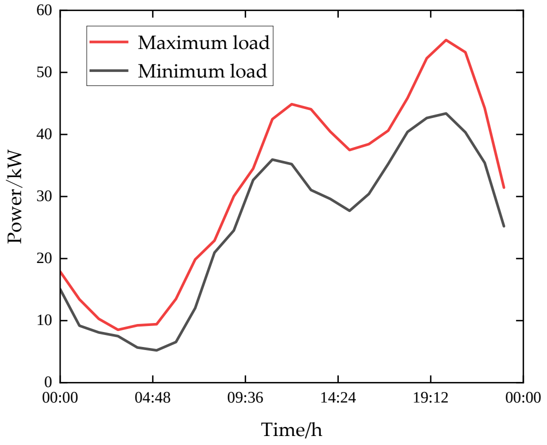

Fig. 5. Maximum / minimum load curve.

### B. Partition Results

After calculating the 24-hour node voltage distribution of the maximum load day of the system shown in Fig. 4, the $K$-means clustering algorithm is used to cluster and partition the distribution network nodes. Fig. 6 is the change diagram of the SSE curve. It can be seen from Fig. 6 that the SSE turning point appears around $k$=10, and when $k$ exceeds 10, the change range of SSE is very small. Therefore, the set center number of $K$-means clustering algorithm is 10. The system shown in Fig. 4 is divided into 10 types of partitions, as shown in Fig. 7. Table II shows the node numbers contained in the distribution network partitions. Each type of partition, the energy storage device is configured to regulate the node voltage.

| 8 | 19, 20, 21 |
| 9 | 14, 15, 16 |
| 10 | 32, 37, 38, 39 |

### C. Optimization Scheme and Result Analysis

*1) Optimization scheme:* The weight coefficients of optimization objectives determined by AHP are shown in Table III, and the test results are shown in Table IV. According to Table III and Table IV, the weight coefficient of optimization objective determined by AHP passes the test.

TABLE III. Weight Coefficients of Optimization Objectives

| Optimization objective | Weight coefficient |
|---|---|
| Node voltage improvement degree $f_1$ | 0.6267 |
| Power loss $f_2$ | 0.2797 |
| Comprehensive cost $f_3$ | 0.0936 |

TABLE IV. Consistency Test Results

| Maximum characteristic root | $C_1$ | $R_1$ | $C_R$ | Consistency test result |
|---|---|---|---|---|
| 3.0858 | 0.0429 | 0.525 | 0.0817 | Pass |

In this paper, the active power component of a single distributed battery capacity is not more than 60 kWh. The related parameters of energy storage battery installation cost are as follows: depreciation rate $r$=10%; Service cycle life $N$=10 years; Battery body unit energy price $C_S$=3720 yuan; Unit power of two-way energy conversion equipment $C_P$=1085 yuan; Unit energy $C_{AF}$ of auxiliary facilities is 186 yuan; The rated charging and discharging time of the energy storage battery $t_n$=12h; The basic operation and maintenance cost of energy storage battery per unit power $C_{O\_P}$=124 yuan, charging electricity price $C_C$=0.5 yuan; Equivalent annual operating days $T$=180 days. Before the DES battery is connected, the peak load of 47-node radiant LVDN system is 749.04kW. After 100% DPV is connected, the maximum node voltage offset is 8.2%, and the maximum DES comprehensive installation cost $C_{max}$=1,000,000 yuan. Based on MATLAB software, WOA was used to optimize the configuration of DES batteries in the system shown in Fig. 4. The number of population in WOA is 100 and the maximum number of iterations is 100. The optimization scheme is shown in Table V.

TABLE V. The DES Optimization Scheme

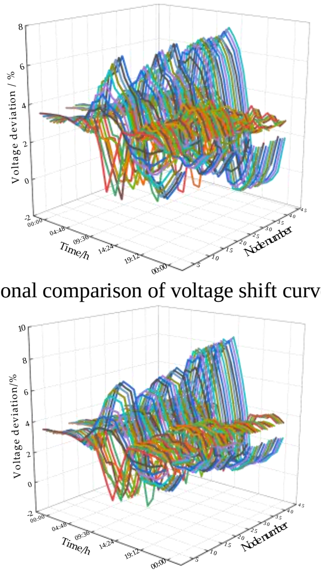
| Partition number | DES Indicates the number of the con-figuration node | DES configuration capacity(kWh) |
|---|---|---|
| 1 | 44 | 50 |
| 2 | 24 | 40 |
| 3 | 17 | 60 |
| 4 | 43 | 50 |
| 5 | 30 | 50 |
| 6 | 10 | 60 |
| 7 | 7 | 40 |
| 8 | 20 | 50 |
| 9 | 15 | 60 |
| 10 | 38 | 30 |

*2) Optimization scheme:* The maximum daily load and minimum daily load of LVDN in a year are selected to verify whether the DES planning scheme meets the actual demand of LVDN. The comparison of optimization results is shown in Table VI.

TABLE VI. Comparison of Optimization Results

| Type | Sum of absolute value of node voltage offset | | Power loss of distribution network (kWh) | |
|---|---|---|---|---|
| | Minimum load | Maximum load | Minimum load | Maximum load |
| Before optimization | 3.1093 | 4.3179 | 14.1896 | 16.2202 |
| After optimization | 1.9026 | 2.147 | 6.0169 | 6.7923 |

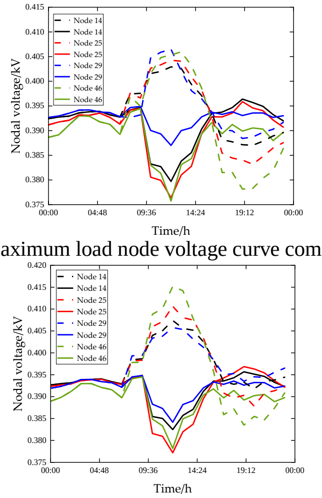
Fig. 8 shows the three-dimensional comparison diagram of voltage offset of distribution network nodes before and after optimization. In order to clearly and effectively illustrate the optimization effect, typical nodes are selected for further analysis, as shown in Fig. 9.



(a) Three-dimensional comparison of voltage shift curve at max load node.

(b) Three-dimensional comparison of voltage shift curve at min load node.

Fig. 8. Node voltage offset curves before and after optimization three-dimensional contrast figures.



(a) Maximum load node voltage curve comparison.

(b) Minimum load node voltage curve comparison.

Fig. 9. Comparison of node voltage before and after optimization.

In Fig. 9, dashed lines represent voltage curves of typical LVDN nodes before optimization, while solid lines represent voltage curves of typical LVDN nodes after optimization. As can be seen from Fig. 9, when LVDN is at the maximum daily load or minimum daily load, the DES optimal configuration scheme can play a good role, and the node voltage of the distribution network is below 1.05$U_N$. During the peak of DPV output, the connection of DES effectively reduces the node voltage and avoids the occurrence of node voltage overshoot.

Table VII compares the maximum node voltage offset before and after the maximum load optimization with the minimum load optimization. It can be seen from Table VII that the maximum node voltage offset before the maximum load optimization is 7.2%, after the optimization is 4.71%, before the minimum load optimization is 8.5%, and after the optimization is 4.49%.

TABLE VII. COMPARISON OF VOLTAGE OFFSETS BEFORE AND AFTER MAX/MIN LOAD OPTIMIZATION

| Parse | Load condition | Maximum node voltage offset (%) |
|---|---|---|
| Before optimization | Maximum load | 7.2 |
| | Minimum load | 8.5 |
| After optimization | Maximum load | 4.71 |
| | Minimum load | 4.49 |

According to Fig. 8, Fig. 9, Table VI and Table VII, the DES optimal configuration method proposed in this paper can improve the node voltage over-limit phenomenon, reduce the node voltage fluctuation, and make the LVDN node voltage curve smoother.

Fig. 10 shows the comparison of LVDN branch active power loss before and after optimizing DES configuration, where the dotted line represents before optimization and the solid line represents after optimization. According to Fig. 10 and Table VI, LVDN active power loss decreased significantly after optimal configuration of DES. Under the maximum load, the active loss of distribution network branch decreased from 16.2202kW to 6.7923kW, and under the minimum load, the active loss of distribution network branch decreased from 14.1896kW to 6.0169kW.

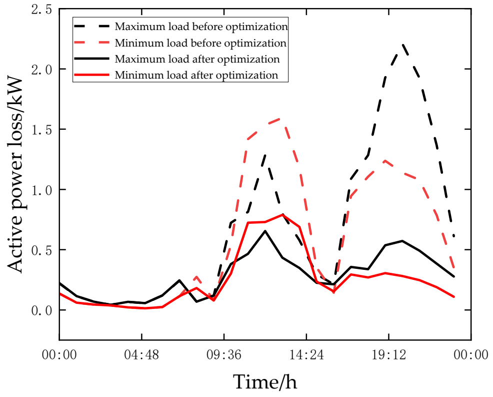


Fig. 10. Comparison of active power loss of distribution network branches before and after optimization.

## VI. CONCLUSION

The optimal configuration of energy storage can effectively solve the problem of voltage exceeding limit caused by high proportion distributed photovoltaic. Considering the governance of LVDN node voltage overrun problem of HPDPV, this paper establishes a multi-objective optimization model for optimal configuration of DES, and uses whale algorithm to solve the model. Based on the actual case of a certain region, the effectiveness of the method is verified. The conclusions are as follows:

*1)* In LVDN containing HPDPV, the optimal configuration of DES can reduce the mismatch between the volatility of the photovoltaic power supply and the load characteristics, solve the voltage overrun problem, and reduce the node voltage fluctuation of LVDN.

*2)* Based on the node voltage of LVDN maximum load day and all day, the K-means clustering algorithm is used to partition LVDN and optimize the partition configuration of DES, which is conducive to HPDPV consumption.

*3)* When constructing the DES multi-objective optimal configuration model, taking improving the node voltage, reducing the power loss of the distribution network, and minimizing the comprehensive cost of energy storage investment as the objective function, considering the power balance, energy storage battery, and other constraints, the whale algorithm is used to determine the DES optimal configuration scheme, which is in line with the actual operation of LVDN.

# Enhancing Harris Hawks Optimization Algorithm for Resource Allocation in Cloud Computing Environments

Ganghua Bai
School of Economics and Management, Hebi Polytechnic, Hebi 458030, China

***Abstract*—Cloud computing is revolutionizing the delivery of on-demand scalable and customizable resources. With its flexible resource access and diverse service models, cloud computing is essential to modern computing infrastructure. In cloud environments, assigning Virtual Machines (VMs) to Physical Machines (PMs) remains a complex and challenging task critical to optimizing resource utilization and minimizing energy consumption. Given the NP-hard nature of VM allocation, solving this optimization problem requires efficient strategies, usually addressed by metaheuristic algorithms. This study introduces a novel method for allocating VMs based on the Harris Hawks Optimization (HHO) algorithm. HHO has exhibited the capacity to provide optimal solutions to specific issues inspired by the hunting behavior of Harris's falcons in the natural world. However, there are often problems with convergence to local optima, which affects the quality of the solution. To mitigate this challenge, this study employs a tent chaotic map during the initialization phase, aiming for enhanced diversity in the initial population. The proposed method, Enhanced HHO (EHHO), has superior performance compared to previous algorithms. The results confirm the effectiveness of the introduced tent chaotic map improvement and suggest that EHHO can improve solution quality, higher convergence speed, and improved robustness in addressing VM allocation challenges in cloud computing deployments.**

***Keywords*—Cloud computing; virtual machine allocation; energy efficiency; resource utilization**

## I. Introduction

Cloud computing is a revolutionary paradigm that has fundamentally changed how we deal with modern computing [1]. It offers a diverse array of services and resources over the Internet that can be easily customized and accessed as needed [2]. This cutting-edge architecture enables consumers to leverage configurable computing resources, such as applications, storage, servers, and networks [3, 4]. Cloud computing is primarily characterized by its capacity to offer flexibility, agility, and cost-effectiveness by abstracting and virtualizing resources [5]. This enables users to allocate and release resources dynamically according to their specific needs [6]. Efficiently distributing Virtual Machines (VMs) onto Physical Machines (PMs) has become a crucial topic in cloud systems [7]. The allocation procedure substantially influences the usage of resources, consumption of energy, and overall performance of the system in cloud infrastructures [8].

VM allocation entails the optimal assignment of VMs to PMs to achieve optimal resource utilization, minimize energy consumption, and maintain satisfactory performance metrics [9, 10]. Due to the intrinsic complexity and NP-hard nature of this issue, conventional optimization approaches generally fail to deliver efficient solutions within acceptable time limits. Meta-heuristic algorithms have become prominent as effective and adaptable optimization methods to tackle these difficulties [11-13]. These algorithms provide a novel approach to address intricate optimization issues using principles derived from natural occurrences, social behavior, or biological systems [14-16]. Meta-heuristic algorithms are crucial in cloud computing to develop effective techniques to allocate VMs and find feasible solutions to this complex optimization issue [17]. Peer-to-peer (P2P) file sharing plays a crucial role in VM allocation by enabling decentralized distribution of resources, facilitating dynamic resource allocation and load balancing [18]. Furthermore, the integration of machine learning and deep learning techniques in VM allocation enhances decision-making processes by leveraging historical data and patterns to predict resource demands and optimize allocation strategies, ultimately improving overall system efficiency and performance in cloud computing environments [19, 20].

Heidari, et al. [21] introduced the Harris Hawks Optimization (HHO) algorithm, drawing inspiration from the hunting patterns of Harris hawks in the natural world. This algorithm encompasses three distinct stages: exploration, transition to exploitation, and exploitation. This algorithm distinguishes itself with its simplicity in principles, minimal parameterization, and robust local optimization capabilities. Its application has extended across various domains, including image segmentation, neural networks, control of electric machines, and other relevant fields. Despite its merits, the HHO algorithm presents limitations, such as restricted optimization accuracy, sluggish convergence rates, and susceptibility to falling into local optima, aligning with challenges prevalent in several meta-heuristic algorithms. Consequently, numerous researchers have attempted to improve the HHO algorithm.

For instance, Jia, et al. [22] proposed a mutation technique paired with parameter regulation to calculate escape energy during the exploration phase, yielding promising outcomes through parameter regulation. Houssein, et al. [23] suggested the integration of mutation and cross-cooperative gene operators, resulting in the development of an optimization method using oppositional learning. This innovative approach bolstered exploration capabilities and effectively generated the initial population. YiMing, et al. [24] integrated the Chan algorithm to compute a starting point and replaced the original positions to reduce pointless exploration and augment convergence speed. Despite these enhancement strategies, there is still much room for improving the HHO algorithm to address its inherent limitations.

A novel approach to VM allocation utilizing the HHO algorithm is presented in this study. A new variant of the HHO algorithm, Enhanced HHO (EHHO), addresses the limitations of the conventional HHO algorithm. By incorporating a tent chaotic map during the initialization phase, EHHO attempts to increase diversity within the initial population, effectively reducing the tendency of the algorithm to converge prematurely to local optima. This paper comprises five sections. Section II reviews existing research on VM allocation algorithms, highlighting their strengths and limitations. Section III introduces the HHO algorithm for the VM allocation problem. Section IV presents simulation outcomes, validating the efficacy of the proposed algorithm. Finally, Section V summarizes findings and discusses the implications of EHHO for enhancing VM allocation in cloud computing environments.

## II. Related Work

This section provides a comprehensive overview of existing research on VM allocation in cloud computing environments. The strengths and weaknesses of various metaheuristic optimization techniques are discussed. Furthermore, the importance of VM allocation for optimizing resource utilization and minimizing energy consumption within cloud infrastructures is highlighted. Table I provides an overview of the methods discussed.

The increasing need for cloud computing services has led to the widespread deployment of worldwide cloud data centers, intensifying the difficulty of effectively controlling the energy usage of these facilities. Despite numerous software and hardware strategies proposed to address this issue, an optimal resolution remains elusive. Tarahomi and Izadi [25] proposed a novel strategy for managing cloud resources online, utilizing the live migration technique of VMs to decrease power usage. Their approach combines a power-aware and prediction-based VM allocation method and creates a three-tier structure to improve the energy efficiency of cloud data centers. Experimental findings underscore the effectiveness of their approach, demonstrating a noteworthy reduction in power consumption while concurrently enhancing service-level agreement violation (SLAV).

The Enhanced-Modified Best Fit Decreasing (E-MBFD) Algorithm was used by Shalu and Singh [26] to introduce a novel VM allocation methodology. This approach utilizes an Artificial Neural Network (ANN) to verify the VMs allocated to PMs. In addition, it provides the benefit of detecting incorrect assignments brought about by inefficient resource use, making the reassignment of these virtual computers easier. Empirical evidence demonstrates that the E-MBFD methodology surpasses traditional methods in terms of reduced SLA violations and decreased power consumption. A VM allocation method using the elephant herd optimization scheme was presented by Madhusudhan, et al. [27]. Upon conducting tests on real-time workloads, the methodology demonstrated substantial energy and resource utilization enhancements versus conventional approaches.

TABLE I. Comparison of VM Allocation Methodologies in Cloud Computing Environments

| Method | Methodology | Strengths |
|---|---|---|
| [25] | Prediction-based and power-aware VM allocation | Integrates live migration of VMs to reduce power consumption.<br>Three-tier framework for energy efficiency |
| [26] | Enhanced-modified best fit decreasing | Utilizes artificial neural network.<br>Detects and corrects inefficient resource use. |
| [27] | Elephant herd optimization for VM allocation | Shows significant improvements in energy consumption and resource utilization. |
| [28] | Hybrid model with hierarchical task prioritization | Integrates BAT and Bar system model.<br>Minimizes VM overload within the data center. |
| [29] | Energy-aware flower pollination algorithm | Employs dynamic switching probability.<br>Considers memory, storage, and processor constraints for VM allocation |
| [30] | Energy-aware VM allocation using a two-step strategy | Uses SAG algorithm for VM power reduction.<br>Addresses energy consumption through multiple VM power-down |
| [31] | Auction-based setup for online VM allocation | Mathematical model for efficient resource use.<br>Aims to maximize social welfare through resource allocation |

Sreenivasulu and Paramasivam [28] suggested an innovative hybrid approach that utilizes a hierarchical method to rank tasks prior to their submission to the scheduler. The Bandwidth-Aware Divisible Task (BAT) scheduling framework was upgraded by incorporating the Bar system approaches, resulting in an advanced hybrid optimization strategy. To mitigate VM overload within the data center, the hybrid model incorporates the Minimum Overload and Minimum Lease policy, facilitating pre-emption. The performance of this hybrid model was assessed through comprehensive evaluation using various parameters. The simulation outcomes convincingly demonstrated the efficacy and efficiency of this novel hybrid model.

Feng, et al. [30] propose an energy-aware VM allocation method. Using a two-step SAG algorithm, multiple VMs in cloud data centers can be powered down to reduce energy consumption. SAG was evaluated through extensive experiments, and its performance was measured and compared with other typical algorithms. In experiments, the global-energy-aware VM allocation method reduced cloud data center energy consumption compared to different algorithms. The problem of online VM allocation with multiple types of resources is addressed by Liu and Liu [31]. To achieve the most efficient overall use of resources, they proposed an accurate mathematical model based on an auction-based setup. Multiple VMs are provided and allocated efficiently to maximize social welfare and encourage users to provide truthful requests.

Usman, et al. [29] suggested the Energy-Aware Flower Pollination Algorithm (E-FPA) to distribute VMs within cloud data centers. Employing an optimization strategy named Dynamic Switching Probability (DSP), the allocation process efficiently discovers near-optimal solutions while exploiting local and global searches. This approach considers the limitations of PMs in terms of memory, storage, and processor while prioritizing energy-conscious allocations. As evidenced by MultiRecCloudSim, using the planet data, E-FPA outperformed First Fit Decreasing (FFD) by 24%, Order of Exchange Migration (OEM) by 21% and genetic algorithm by 22%. Consequently, implementing E-FPA significantly enhanced data center performance, thereby contributing to improved environmental sustainability.

## III. Proposed Method

### A. Cloud Model

Cloud computing architecture facilitates the effortless storage, retrieval, and concurrent handling of large volumes of data. Cloud resources, such as PMs and VMs, perform tasks in response to user requests. VM migration is a process specifically designed to address customer requirements promptly and flexibly, thereby ensuring the effective delivery of cloud-based offerings. Cloud computing uses resource allocation methods for efficiently assigning resources to VMs for task execution. Given that the effectiveness of the cloud model can be affected by performance degradation and overall cloud operation, it is crucial to design resource allocation algorithms carefully. Each task in the cloud is assigned a distinct deadline and duration. Following the principle of minimizing costs, the resource allocator assigns tasks to available VMs. The resource allocator consistently changes the state of VMs to guarantee appropriate task allocation and execution. Fig. 1 illustrates the process of allocating resources in the cloud model.

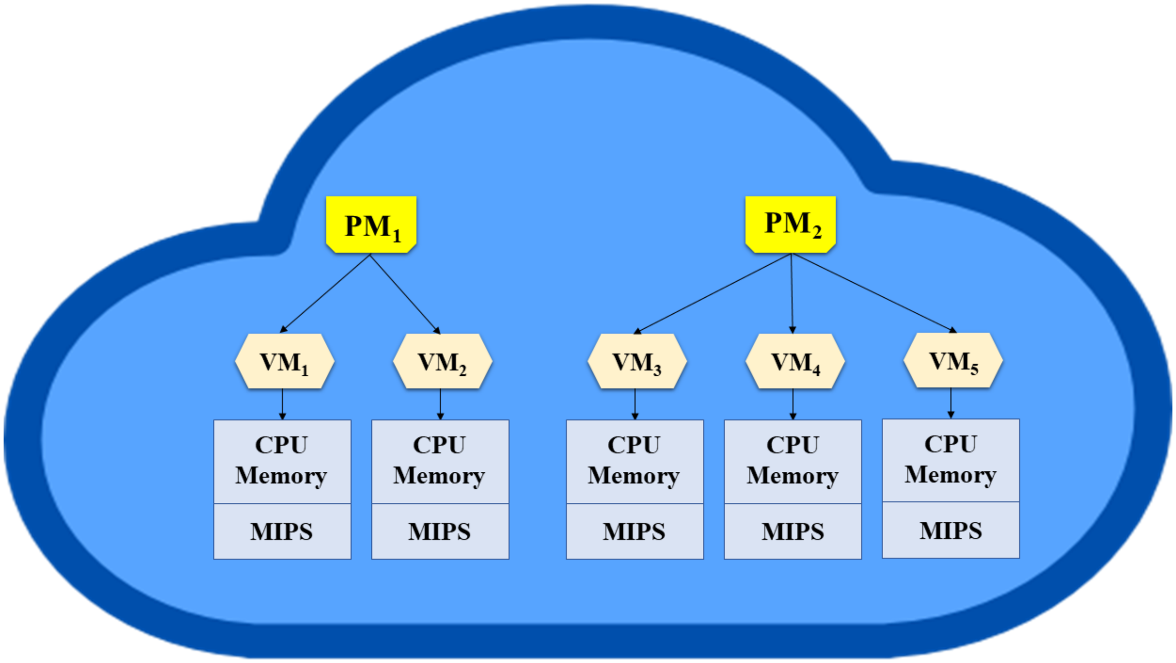

Fig. 1. Resource allocation process.

### B. Problem Statement

The need to allocate resources efficiently in cloud service provisioning, taking into account service needs and reconfiguration costs, has resulted in the development of a new computing architecture in the cloud environment. This study presents an efficient strategy for allocating resources in the cloud computing architecture, utilizing the suggested EHHO algorithm. The EHHO algorithm is utilized to achieve optimal resource allocation, hence improving the overall efficiency of the cloud model. Due to cloud resources' extensive and dispersed characteristics, efficient resource allocation is essential for attaining maximum performance. PM oversees and regulates VMs, which differ in terms of MIPS and memory allocated to CPUs. The resource allocation paradigm includes many VM service suppliers associated with VMs, including private and external organizations. Given two PMs, labeled as $P_1$ and $P_2$, and five VMs, labeled as $V_1$, $V_2$, $V_3$, $V_4$, *and* $V_5$, respectively, user-assigned tasks are performed utilizing these VMs. The collection of VMs is represented as $V = (V_1, V_2, V_3, V_4, V_5)$. Users submit applications labeled as *A*, each consisting of distinct tasks labeled as *s*. Utilizing the EHHO algorithm in the resource allocation strategy greatly improves the efficiency of the cloud model.

### C. Task Flow

Consider three tasks, denoted as $s_1$, $s_2$, and $s_3$, each with corresponding deadlines $D_1$, $D_2$, and $D_3$, start times $S_1$, $S_2$, and

$S_3$, and runtimes $R_1$, $R_2$, and $R_3$. These parameters are outlined in Table II, along with the task flow. These tasks are assigned to a VM for processing. The EHHO algorithm assigns tasks to VMs after receiving an application for cloud processing. VM allocation decisions consider variables such as runtime, deadline, and cost. The cloud architecture encompasses both public and private clouds, with a preference for allocating tasks to the private cloud due to its cost-free resources. Assigning the task with the lowest resource cost to the VM for efficient resource allocation is accomplished using the proposed optimization algorithm by evaluating the deadline and runtime of arriving tasks.

TABLE II. TASK FLOW

| Tasks | Start time | Runtime | Deadline |
|---|---|---|---|
| $s_1$ | $S_1$ | $R_1$ | $D_1$ |
| $s_2$ | $S_2$ | $R_2$ | $D_2$ |
| $s_3$ | $S_3$ | $R_3$ | $D_3$ |

Consider three different applications, denoted as $T_1$, $T_2$, and $T_3$, each comprising various tasks. Table III details the tasks' deadlines, runtimes, and start times for each application. The start time for all tasks is indicated as *1*. Tasks $s_1$ and $s_2$ belong to application $T_1$, tasks $s_3$, $s_4$, and $s_5$ belong to $T_2$, and tasks $s_6$ and $s_7$ belong to $T_3$. The resource allocation decisions are driven by the EHHO algorithm, prioritizing tasks based on their cost-effectiveness, runtime, and deadline considerations.

TABLE III. TASK DEADLINES, RUNTIMES, AND START TIMES FOR DIFFERENT APPLICATIONS

| Parameter | Application ($T_1$) | | Application ($T_2$) | | | Application ($T_3$) | |
|---|---|---|---|---|---|---|---|
| | $S_1$ | $S_2$ | $S_3$ | $S_4$ | $S_5$ | $S_6$ | $S_7$ |
| Start time | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| Runtime | 2 | 2 | 3 | 2 | 4 | 3 | 3 |
| Deadline | 4 | 3 | 6 | 5 | 4 | 7 | 8 |

Table IV illustrates resource allocation to VMs, considering their defined deadline and runtime. Tasks are allocated to VMs based on the lowest cost of each task. Assigning tasks to VMs is done based on the proposed EHHO, which ensures that tasks are completed within the constraints of the runtime and deadline.

TABLE IV. TASKS DETAILS

| Time slots | $V_1$ | $V_2$ | $V_3$ |
|---|---|---|---|
| $P_1$ | $s_2$ | $s_5$ | $s_4$ |
| $P_2$ | $s_2$ | $s_5$ | $s_4$ |
| $P_3$ | $s_2$ | $s_5$ | $s_6$ |
| $P_4$ | $s_1$ | $s_5$ | $s_6$ |
| $P_5$ | $s_1$ | $s_5$ | $s_6$ |
| $P_6$ | | $s_3$ | $s_7$ |
| $P_7$ | | $s_3$ | $s_7$ |
| $P_8$ | | $s_3$ | $s_7$ |

Consider eight-time slots and three VMs for task allocation. For tasks $s_1$ and $s_2$ under application $T_1$ with values of 0.4 and 0.2, respectively, $s_2$ has the minimum value. Consequently, $s_2$ is allocated to $V_1$ due to its minimum cost. Given that the runtime of $s_2$ is 2 and the deadline is 3, it executes in $V_1$ during time slots $P_1$ and $P_3$. With a runtime and deadline of 2 and 4 for $s_1$, it is allocated to $V_1$ during time slots $P_4$ and $P_5$. For tasks $s_3$, $s_4$ and $s_5$ under application $T_2$ with values of 0.5, 0.6 and 0.4, respectively, $s_5$ has the minimum value and is allocated to $V_2$ during time slots $P_1$-$P_5$, given that the runtime of $s_5$ is 5. Then, $s_3$ is allocated to $V_2$ during time slots $P_6$-$P_8$. Similarly, the remaining tasks are allocated to VMs based on their minimal values.

### D. Fitness Function

The EHHO algorithm, introduced in this study, assigns tasks to VMs at the lowest cost. The EHHO algorithm performs resource allocation by taking into account fitness values linked to characteristics, including skewness, resource utilization, MIPS, RAM, and CPU usage. Fig. 2 illustrates the suggested strategy for allocating cloud resources. Cloud resources are allocated based on the solution vector encoded for best performance. As shown in Fig. 3, each task is associated with a solution vector. The suggested optimization approach distributes tasks to VMs, prioritizing the task with the lowest value. When allocating resources in the cloud, tasks are compared based on their values. The solution vector has the form [1 × 7], representing the allocation of seven tasks.

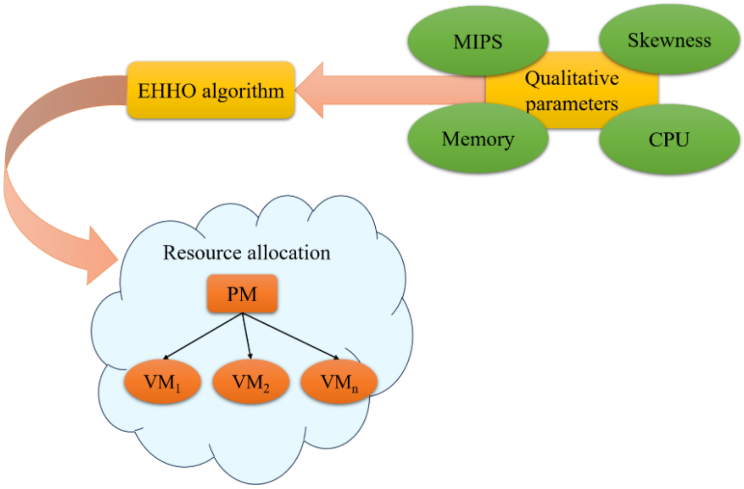

Fig. 2. Resource allocation model based on EHHO algorithm.

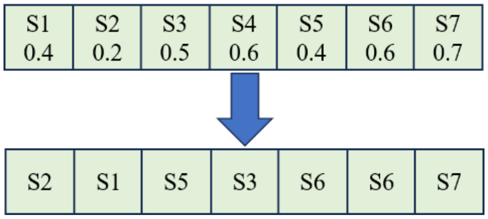

Fig. 3. Solution encoding.

The fitness evaluation aims to compute the fitness function and acquire satisfactory solutions. The fitness function with the lowest score is considered to be the optimal one. The fitness value is computed using Eq. (1).

$$f = \sum_{n=1}^{t} R_n + \sum_{m=1}^{p} (F_m + (1 - B_m) + G_m) \tag{1}$$

where, *t* refers to task count, $G_m$ represents skewness, $B_m$ reflects the resource utilization of $m^{th}$ VM, $F_m$ indicates nth VM cost, and $R_n$ stands for the runtime of $n^{th}$ task. The terms $B_m$ and $G_m$ are defined by Eq. (2) and Eq. (3), respectively.

$$B_m = \frac{U_m^v \times Q_m^v \times L_m^v}{U_m^t \times Q_m^t \times L_m^t} \times \frac{W_u}{W_x} \tag{2}$$

$$G_m = (\frac{B_m}{B} - 1)^2 \tag{3}$$

where, $U_m^v$ signifies the MIPS usage of the $m^{th}$ VM, $Q_m^v$ describes the memory usage of the $m^{th}$ VM, and $L_m^v$ indicates the CPU usage of the $m^{th}$ VM. $U_m^t$ stands for the available MIPS, $Q_m^t$ represents the available memory, and $L_m^t$ represents the entire CPU capacity in the $m^{th}$ VM. $W_u$ refers to the use of a time slot, whereas $W_x$ represents the maximum total number of slots.

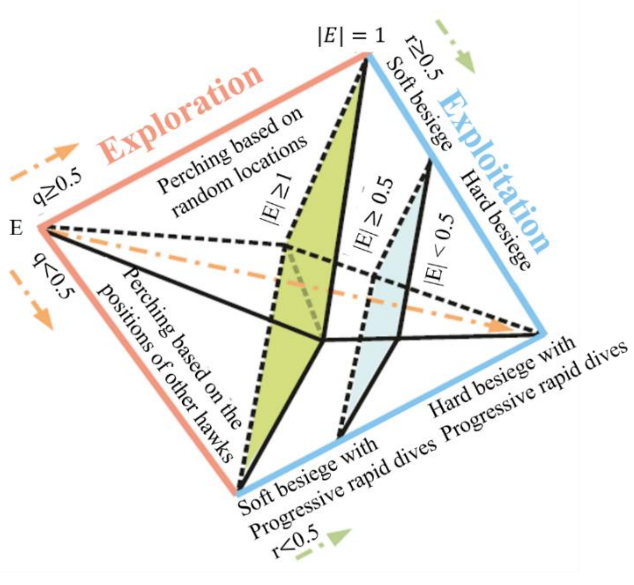
### E. Improved HHO Algorithm for Resource Allocation

The HHO algorithm employs mathematical equations to simulate Harris Hawks' hunting behavior to identify the most optimal solutions for problems. The Harris hawks in this algorithm serve as the candidate solutions, while the prey symbolizes the ideal solution [32]. The HHO algorithm consists of two phases: global exploration and local exploitation. The transition from global exploration to local exploitation is determined by the energy equation of the prey, calculated by Eq. (4) and Eq. (5), where *E* denotes the escape energy of the prey, $E_0$ represents the initial energy state of the prey, *T* is the maximum number of iterations, and *rand* is a random number between 0 and 1. When the absolute value of *E* is greater than or equal to 1, the HHO algorithm enters the global exploration phase. On the other hand, when the total value of *E* is less than 1, local exploitation begins. The different phases of the HHO are depicted in Fig. 4, illustrating how hawks trace, encircle, and ultimately attack their prey.

$$E = 2E_0(1 - \frac{t}{T}) \tag{4}$$

$$E_0 = 2 \times rand - 1 \tag{5}$$

During the period of global exploration, the Harris hawks thoroughly examine and oversee the search space, which is determined by the lower bound (*lb*) and upper bound (*ub*). They employ two distinct tactics to look for prey in a random manner. The Harris hawks' location is updated in each cycle with a certain probability (*q*) using Eq. (6). The equation relates the locations of the Harris Hawks in the *(t + 1)*$^{th}$ and $t^{th}$ iterations, denoted as $X_{t+1}$ and $X_t$, respectively. The variable $X_{prey,t}$ represents the prey locations in the $t^{th}$ iteration. $r_1$, $r_2$, $r_3$, $r_4$, and *q* are uniformly distributed random variables in the range [0, 1]. *lb* and *ub* represent the bottom and upper limits of the search space, respectively. The variable $X_{rand,t}$ represents the random position of the Harris hawks in the $t^{th}$ iteration. The variable $X_{average,t}$ represents the mean location of the Harris hawks in the $t^{th}$ iteration, given a population size of *N*.



|E| = 1
r≥0.5
Soft besiege
Exploitation
Hard besiege
Exploration
Perching based on random locations
q≥0.5
E
q<0.5
Perching based on the positions of other hawks
|E| ≥ 1
|E| ≥ 0.5
|E| < 0.5
Hard besiege with Progressive rapid dives
Soft besiege with Progressive rapid dives
r<0.5

Fig. 4. HHO steps.

$$X_{t+1} = \begin{cases} X_{rand} - r_1 |X_{rand} - 2r_2 X_t| & q \geq 0.5 \\ (X_{prey,t} - X_{average,t}) - r_3(lb + r_4(ub - lb)) & q < 0.5 \end{cases} \tag{6}$$

These equations and strategies are utilized to guide the search for optimal solutions by the Harris hawks, simulating their hunting behavior to approach the optimal solution iteratively.

$$X_{average,t} = \frac{1}{N} \sum_{i=1}^{N} X_{i,t} \tag{7}$$

During the local exploitation stage, the value of *E* plays a vital role in determining the besiege technique used by the Harris hawks. A gentle besiege technique is undertaken when the magnitude of *E* is larger than or equal to 0.5. On the other hand, if the absolute value of *E* is less than 0.5, a rigorous besiege tactic is executed. The likelihood of the prey's successful escape is governed by the randomly generated variable *u*, created at initialization. If the value of *u* is larger than or equal to 0.5, then the prey can escape successfully. HHO employs four tactics to replicate the chase attack behaviors observed in Harris hawks, taking into account both the hawks' pursuit approach and the escape behavior of their prey.

When the escape energy *E* of the prey is sufficient and *u* is greater than or equal to 0.5, the Harris hawks gradually consume the prey's energy. They then execute a surprise dive in the best position to capture the prey. The position update strategy is given by Eq. (8)-(10), where $\Delta X_t$ represents the difference between the positions of the Harris hawks and the prey during each iteration, $J$ denotes the random jump of the prey when escaping, and $r_5$ is a random number between 0 and 1.

$$X_{t+1} = \Delta X_t - E\left|J X_{prey,t} - X_t\right| \tag{8}$$

$$\Delta X_t = X_{prey,t} - X_t \tag{9}$$

$$J = 2(1 - r_5) \tag{10}$$

When the prey is exhausted and the escape energy $E$ is very low *(|E| < 0.5)*, the Harris hawks swiftly raid the prey. The position update strategy is expressed by Eq. (11), which determines the rapid movement towards the prey.

$$X_{t+1} = X_{prey,t} - E|\Delta X_t| \tag{11}$$

When the escape energy $E$ of the prey is sufficient *(|E| ≥ 0.5)* but $u$ is less than 0.5, the Harris hawks establish a soft besiege strategy before launching an attack. The Levy function (*LF*) is integrated into HHO to simulate the prey's jumping action and escape mode. The position update strategy is given by Eq. (12)- (14), where $D$ represents the problem dimension, $S$ is a random vector of size $1 \times D$, $u$ and $v$ are random values between 0 and 1, and $\beta$ is a constant set to 1.5.

$$X_{t+1} = \begin{cases} Y: X_{prey,t} - E\left|J X_{prey,t} - X_t\right| & F(Y) < F(X_t) \\ Z: Y + S \times LF(D) & F(Z) < F(X_t) \end{cases} \tag{12}$$

$$LF(x) = 0.01 \times \frac{u \times \sigma}{|v|^{\frac{1}{\beta}}} \tag{13}$$

$$\sigma = \left(\frac{\Gamma(1+\beta) \times \sin(\frac{\pi\beta}{2})}{\Gamma(\frac{1+\beta}{2}) \times \beta \times 2^{(\frac{\beta-1}{2})}}\right)^{\frac{1}{\beta}} \tag{14}$$

When the prey's escape energy $E$ is insufficient *(|E| < 0.5)*, the Harris hawks construct a hard besiege strategy before striking, reducing the average position distance between themselves and the escaping prey. Eq. (15) represents the expression of the position updating approach.

$$X_{t+1} = \begin{cases} Y: X_{prey,t} - E\left|J X_{prey,t} - X_{m,t}\right| & F(Y) < F(X_t) \\ Z: Y + S \times LF(D) & F(Z) < F(X_t) \end{cases} \tag{15}$$

HHO uses the energy parameter and the factor u to control the hunting strategies between the Harris hawks and prey. This allows the algorithm to move towards the best possible solution for the situation at hand. Recent studies have demonstrated that the integration of chaotic maps into population-based metaheuristic algorithms can enhance the efficiency of the search process. Chaotic maps are commonly incorporated at several stages of the algorithm, including the beginning population, exploration, or exploitation phase. The primary goal of this research is to augment the variety of the beginning population.

The initial location of the population provides a notable influence on both the variety of the population and the stability of the algorithm. Although the HHO algorithm gives the random distribution of population positions during initialization, it does not guarantee uniformity. Chaotic sequences have the properties of ergodicity and high unpredictability, which make them very suitable for improving performance. Chaotic mapping produces pseudo-random numbers that follow a uniform distribution from 0 to 1. By utilizing chaotic mapping, the starting placements of the hawks may be altered, thereby enhancing variation.

The mathematical description of the modification to the initial positions is shown in Eq. (16). In this equation, $X_{i+1}$ represents the new position of the hawks after applying chaotic mapping, $X_i$ denotes the current position of the hawks, and the parameter $a$ is set to 0.7. By incorporating chaotic mapping into the initialization process, population diversity in the HHO algorithm is effectively enhanced, leading to potential improvements in performance.

$$X_{t+1} = \begin{cases} \frac{X_i}{a} & X_i < a \\ \frac{1-X_i}{1-a} & X_i \geq a \end{cases} \tag{16}$$

## IV. Experimental Results

In this section, we aim to comprehensively assess and compare the performance of our proposed resource allocation algorithm (EHHO) with several existing approaches. To rigorously evaluate the effectiveness of our algorithm, we conducted a series of experiments utilizing the Matlab simulator version 2016b. Specifically, we selected three related algorithms for comparison: Glow Worm Swarm Optimization (GWO) [33], genetic [34], Particle Swarm Optimization (PSO) [35], and original HHO [21]. These algorithms were chosen based on their relevance and established usage in addressing similar optimization problems within cloud computing environments. The experiments were meticulously designed to cover a range of scenarios and configurations outlined in Table V. We employed key performance metrics, including skewness, CPU usage, memory utilization, and resource consumption, to objectively evaluate the effectiveness of our algorithm in comparison to the selected benchmarks. Furthermore, to ensure the robustness and reliability of our findings, each experiment was conducted multiple times, and the results were analyzed using statistical methods to account for variability and ensure consistency. This systematic approach allowed us to draw meaningful comparisons and insights regarding the performance of our proposed algorithm relative to existing state-of-the-art techniques.

TABLE V. SIMULATION PARAMETERS

| Entity | Parameter | Value |
|---|---|---|
| Datacenter | Count | 4 |
| | Number of hosts | 1 |
| | Storage | 1,000,000*2 |
| | Bandwidth | 10,000*2 |
| | RAM | 16,384*2 |
| VM | Count | 30 |
| | Bandwidth | 1000 |
| | RAM | 512 MB |
| | MIPS | 1000*2 |
| Cloudlets | Total number of tasks | 100 |
| | Task length | 200 |

Resource utilization is a quantitative indicator that calculates the proportion of allocated resources to the overall number of available resources. It evaluates the efficiency of resource utilization.

$$R = \frac{C}{W} \tag{17}$$

Memory usage is the proportion of memory resources that are used over a period of time to process all tasks that have been submitted. The calculation is performed using Eq. (18), where $v_i$ represents the total available memory and $u_i$ represents the memory demanded for task execution.

$$M = \sum_{i=1}^{y} \frac{u_i}{v_i} \tag{18}$$

CPU utilization refers to the mean amount of CPU resources used by all servers when processing user requests. Eq. (19) is employed to determine the value, with $H_i$ representing the total available CPU resources and $E_i$ denoting the CPU resources demanded for task execution.

$$C = \sum_{i=1}^{y} \frac{E_i}{H_i} \tag{19}$$

Skewness quantifies the degree of asymmetry or lack of evenness in a probability distribution. It offers insight into the disparate consumption of various resources on a server. Skewness arises when a performance manager operates many memory-intensive VMs with a low workload, resulting in inadequate memory and a shortage of resources to support an extra VM. Eq. (20) is used to measure the unevenness in resource use throughout a server, which is known as skewness. The equation defines $R$ as the resource consumption of the $n^{th}$ VM, whereas $A$ represents the average resource utilization.

$$W = \left(\frac{R_n}{A} - 1\right)^2 \tag{20}$$

The suggested technique demonstrates higher performance compared to current algorithms while considering 30 VMs. Fig. 5 to Fig. 8 depict the persistent superiority of the EHHO algorithm over the PSO, genetic, and GWO algorithms. The EHHO algorithm performs better in reducing skewness values, achieving faster convergence and maintaining this improvement even with increasing iterations. The excellence of this system is related to its rapid and precise adjustment to different datasets, which is made possible by enhanced learning rates and variable adjustments. Therefore, it allows for higher levels of effective optimization, resulting in improved efficiency.

Fig. 5 demonstrates that the suggested algorithm improves resource utilization in comparison to previous strategies while keeping the number of repetitions constant. This emphasizes its higher effectiveness and capacity to provide better outcomes with fewer repetitions. Moreover, Fig. 6 illustrates that the proposed technique has improved efficiency in memory utilization, requiring significantly less memory than existing methods for the same number of repeats. Fig. 7 demonstrates that the proposed method outperforms existing models in terms of task efficiency. It achieves greater efficiency by reducing the time required to accomplish tasks without altering the number of repeats.

The proposed approach clearly exhibits greater performance in comparison to existing algorithms across a range of measures. Although the statistics mostly show improvements in skewness values, it is crucial to underline that the algorithm's advantages also include enhanced memory utilization. The EHHO algorithm demonstrates improved efficiency in memory use, shown in Fig. 6. This figure clearly depicts a decrease in memory usage compared to other approaches that have the same number of repeats. This increase demonstrates the algorithm's capacity to efficiently allocate resources, leading to better usage of memory resources in the cloud computing environment. The EHHO method enhances resource optimization and operational efficiency in cloud computing systems by minimizing memory utilization.

## V. Conclusion

This research introduced an energy-efficient optimization method utilizing the HHO algorithm for allocating VMs in cloud computing environments. The suggested approach was evaluated against conventional techniques such as PSO, GWO, and genetic algorithms. Performance testing has shown that EHHO is better in several aspects. First and foremost, EHHO routinely surpasses other algorithms in terms of skewness. It rapidly produces reduced skewness values and maintains them consistently, even with additional repetitions. The improvement may be ascribed to the algorithm's heightened learning rate and parameter adjustment, which allows it to adapt to diverse datasets more efficiently. A decrease in skewness suggests a more equitable and effective allocation of resources among servers. Moreover, the suggested method demonstrates enhanced efficiency in utilizing resources. It efficiently employs a larger quantity of resources compared to current methods during an equivalent number of repetitions. This exemplifies its heightened efficacy and capacity to attain superior outcomes with fewer repetitions. Efficient allocation of resources is essential in cloud computing systems to maximize performance and fulfill user requirements. Furthermore, the method exhibits exceptional efficiency in terms of memory use. It consumes substantially less memory than current methods for the same number of iterations. This capability is especially beneficial in contexts with limited resources when optimizing memory is crucial for efficient task execution and overall system efficiency.

Given the results and consequences of this work, there are various possible areas for future research that may be explored and developed in the field of cloud computing resource allocation. A topic of potential exploration is examining the scalability and suitability of the EHHO method for larger and more intricate cloud computing settings. This may include expanding the algorithm to handle dynamic variations in workload, diverse kinds of resources, and many optimization targets. Incorporating machine learning approaches, such as reinforcement learning or deep learning, might improve the flexibility and intelligence of resource allocation choices in cloud settings. Moreover, examining the influence of several limitations, such as energy consumption, cost minimization, and security concerns, on resource allocation algorithms may result in the creation of more extensive and resilient optimization frameworks. Furthermore, investigating the implementation of EHHO in future concepts like edge computing and fog computing may provide valuable insights into its efficacy in decentralized and distributed computing settings.

***Abstract*—Major Depressive Disorder (MDD) is common and debilitating, requiring accurate prediction and diagnosis. This study uses clinical, demographic, and EEG data to test hybrid machine learning methods for MDD prediction and diagnosis. EEG data reveals brain electrical activity and can identify MDD patterns and traits. The study aimed to enhance Major Depressive Disorder (MDD) prediction and diagnosis using hybrid machine learning methods, focusing on EEG data alongside clinical and demographic information. Employing various algorithms like CatBoost, Random Forest, XG Boost, XGB Random Forest, SVM with a linear kernel, and logistic regression with Elasticnet regularization, the study found that CatBoost achieved the highest accuracy of 93.1% in MDD prediction and diagnosis, surpassing other models. Additionally, the ensemble model combining XGBoost and Random Forest showed strong performance in ROC analysis, effectively discriminating between individuals with and without MDD. These findings underscore the potential of EEG data integration and hybrid machine learning techniques in accurately identifying and classifying MDD patients, paving the way for personalized interventions and targeted treatments in depressive disorders.**

***Keywords*—Major Depressive Disorder (MDD); hybrid machine learning; cat boost; random forest; XG boost; XGB random forest; SVM; logistic regression; EEG data***

## I. Introduction

Depression is a widespread mental health problem that has serious consequences for sufferers' lives and those around them. According to the World Health Organization’s projection, depression is expected to become the leading mental health condition by 2030. The severity of depression can lead to tragic outcomes, including suicide [1]. However, the current diagnostic procedures lack reliable and clinically useful tools for characterizing depression accurately [2]. This limitation introduces biases and challenges in the diagnostic process. While the expertise and motivation of clinicians are crucial, factors such as patient education, cognitive ability, and honesty in symptom reporting also play vital roles [3]. Achieving an accurate diagnosis of depression's severity necessitates extensive background knowledge and comprehensive clinical training. So there is a need to develop machine learning algorithms to automatically predict the severity of depression using various computational techniques [4]. These systems aim to improve the diagnostic process and provide valuable insights for effective intervention and treatment strategies.

Millions of people all over the world suffer from Major Depressive Disorder (MDD), a serious mental illness with a significant negative impact [5]. Depression is characterized by an inability to lift one's mood, a loss of hope, and a lack of interest in once-pleasurable things. The key to successful treatment and management of major depressive disorder is an early and precise diagnosis of the condition. However, diagnosing MDD solely based on subjective assessments and clinical interviews can be challenging due to the complexity and heterogeneity of the disorder.

Recent advancements in the field of mental health research have seen the application of machine learning techniques for predicting and diagnosing psychiatric disorders, including Major Depressive Disorder (MDD). Machine learning algorithms can analyze large datasets, uncover hidden patterns, and make accurate predictions [5]. However, traditional approaches often rely solely on quantitative data or clinical assessments, which may overlook crucial aspects of MDD's multifaceted nature. To overcome these limitations, researchers have started exploring hybrid machine-learning approaches that integrate diverse data sources and combine multiple algorithms. By leveraging the complementary strengths of different techniques and data types, these hybrid models aim to improve the accuracy and robustness of MDD prediction and diagnosis. This integration of diverse data enables a more comprehensive understanding of MDD, leading to enhanced clinical decision-making and more effective treatment strategies.

Hybrid machine learning approaches encompass a wide range of techniques, including ensemble learning, feature selection, and dimensionality reduction. To improve classification accuracy, ensemble learning techniques blend the outputs of several different base models. Feature selection algorithms help identify the most relevant clinical variables, while dimensionality reduction techniques enable data visualization and interpretation.

The objective of this research is to investigate the application of hybrid machine learning approaches for predicting and diagnosing MDD. By leveraging the power of diverse data sources and integrating multiple machine-learning techniques, these approaches aim to enhance the accuracy, reliability, and clinical utility of MDD diagnosis. Additionally, the research will address challenges such as interpretability, data privacy, and generalization of findings to real-world clinical settings.

In this implementation work, we aim to detect Major Depressive Disorder (MDD) by conducting a comprehensive analysis of a dataset comprising clinical, demographic, and electroencephalogram (EEG) data. The first step involves preprocessing the collected data, which includes performing necessary cleaning, normalization, and handling of missing values or outliers to ensure data quality. Next, metrics for attribute selection were developed, including "Information Gain," "Gain Ratio," "Gini Decrease," and “χ2” are applied to identify the most relevant and informative features for MDD prediction and diagnosis specifically based on EEG data. Once the feature selection process is complete, we proceed to implement various machine learning models, including CatBoost, Random Forest, XGBoost, XGBRandom Forest, SVM with a linear kernel, and logistic regression with ElasticNet regularization. To optimize the models' performance, grid search is employed to fine-tune their hyperparameters. Finally, a vote classifier is constructed to combine the predictions from multiple models using ensemble learning techniques, thereby improving the overall accuracy in predicting and diagnosing MDD.

Ultimately, the successful implementation of hybrid machine learning approaches for MDD prediction and diagnosis holds great promise in improving patient outcomes. Early identification of individuals at risk for MDD, accurate diagnosis, and personalized treatment strategies can significantly contribute to reducing the burden of this debilitating disorder. This research presents a novel approach to the analysis of EEG data for Major Depressive Disorder (MDD) diagnosis by integrating a suite of attribute selection metrics, including Information Gain, χ2, Gain Ratio, and Gini Decrease, which enhances the model's predictive power through refined feature selection. The pioneering use of the NG Deluxe 3.0.5 system for artefact rejection significantly elevates the quality of EEG data preprocessing, a crucial factor for accurate analysis. Furthermore, the hybrid machine learning model, including CatBoost, excels in managing categorical data, providing robust predictions validated through k-fold cross-validation. Ensemble techniques, like XGBoost and Random Forest, further showcase the potential of this innovative approach in computational psychiatry, particularly in discriminating MDD with high accuracy. Finally, the utilization of ensemble models like XGBoost and Random Forest, complemented by ROC performance analysis, offers new insights into the capabilities of hybrid models in distinguishing MDD, setting a precedent for future research and clinical application

The rest of the paper is organized as the Basic preliminaries and associated work are discussed in Section II, a hybrid machine learning model is offered in Section III, results and discussion are described in Section IV, and the conclusion and future work are presented in Section V, which is followed by references.

## II. Basic Preliminaries and Literature Works

Utilizing machine learning to predict and diagnose Major Depressive Disorder (MDD) is discussed in this section. MDD is a common mental illness with poor mood and other symptoms [33]. Traditional diagnostic methods have limits; thus machine learning is used. Machine learning algorithms without human code analyze and predict data automatically. Hybrid machine learning methods improve prediction accuracy and generalization by mixing various algorithms or data sources. Hybrid machine learning integrates many models and data to enhance MDD prediction and diagnosis.

### A. *Major Depressive Disorder (MDD)*

Major depressive disorder (MDD) is characterized by long-lasting melancholy, a lack of interest in or enjoyment from formerly rewarding activities, and an overpowering sense of powerlessness [6]. It affects mood, energy, sleep, hunger, and quality of life, as well as mental and physical health. A person with this sort of depression may lose focus, feel guilty or worthless, and frequently consider suicide. Genetics, biology, environment, and psychology all contribute to this syndrome. Psychotherapy, medication, and behavioral modifications can treat and reverse MDD symptoms.

### B. *Types of Major Depressive Disorder*

Major Depressive Disorder (MDD) encompasses a spectrum of manifestations with varying symptoms, durations, and features [6]. These include Melancholic Depression, characterized by severe depressive symptoms such as profound loss of pleasure or interest in activities, morning mood worsening, weight loss or reduced appetite, excessive guilt, and psychomotor disturbances. Psychotic Depression presents with coexisting MDD and psychosis, featuring hallucinations and delusions, often centered around depressive themes like remorse over a perceived disaster. Atypical Depression is marked by emotional reactivity, leading to transient feelings of pleasure in response to positive events, alongside symptoms like increased hunger, weight gain, hypersomnia, and social withdrawal due to rejection sensitivity. Seasonal Affective Disorder (SAD) is a type of MDD that recurs in autumn and winter, characterized by sadness, increased sleep, weight gain, and reduced interest in activities, with symptoms typically improving in spring and summer. Postpartum Depression, affecting women after childbirth, involves feelings of sadness, anxiety, and exhaustion, hindering the mother's ability to care for herself and her child, with onset ranging from days to a year post-delivery.

### C. *Scalp Electrode Positions for Accurate EEG Analysis in Major Depressive Disorder*

The specific electrode placements for studying Major Depressive Disorder (MDD) using electroencephalography (EEG) can vary depending on the research protocol and the specific study design. However, there are commonly used electrode placements that are relevant to studying MDD. The International 10-20 system is a widely adopted standard for electrode placement in EEG studies. It involves placing electrodes on specific locations of the scalp based on a defined grid system [7]. While the 10-20 system does not directly target MDD, it provides a standardized approach for electrode placement in EEG research.

In MDD studies, researchers often focus on specific regions of interest related to emotional processing and mood regulation. Common electrode placements for MDD studies may include specific regions. Fig. 1 will represent the Electrode Positions and specific regions for Accurate EEG Analysis in Major Depressive Disorder.

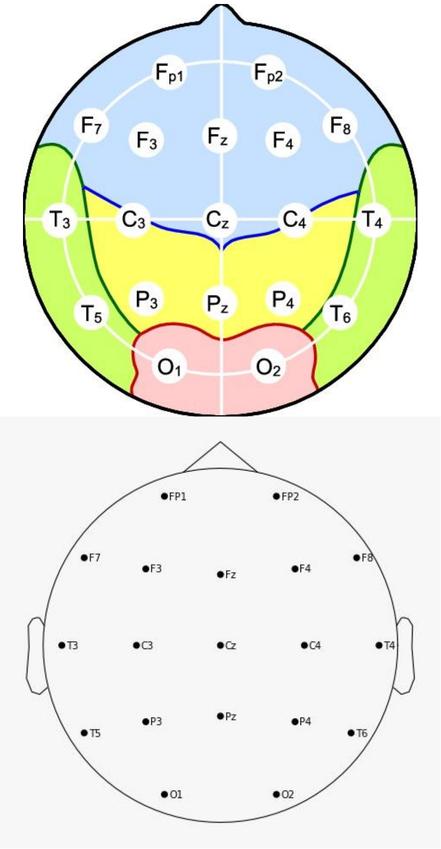

Fig. 1. Electrode positions and regions for accurate EEG analysis in major depressive disorder.

*1) Frontal region:* Electrodes placed over the prefrontal cortex (F3, F4, Fz) are of interest, as this area is associated with emotional regulation and cognitive processes relevant to MDD [7].

*2) Temporal region:* Electrodes placed over the temporal lobes (T3, T4, T5, T6) are important for capturing neural activity related to emotional processing and perception [7].

*3) Central region:* Electrodes placed over the central region (C3, C4, Cz) can provide insights into motor and cognitive functions that are implicated in MDD [7].

*4) Parietal region:* Electrodes placed over the parietal lobes (P3, P4, Pz) can capture neural activity related to attention and sensory processing, which may be relevant to MDD [7].

### *D. Literature Review on Major Depressive Disorder (MDD)*

A literature analysis on hybrid machine learning approaches for prediction and diagnosis of Major Depressive Disorder (MDD) shows an increasing interest in using different algorithms and data sources to improve accuracy and resilience. Combining SVM, ANN, and other machine learning methods has been the focus of much research. decision trees and ensemble approaches to develop hybrid MDD prediction models. Hybrid models combine algorithm strengths to collect more features and increase performance. To improve model predictiveness, researchers have used clinical assessments, demographic data, genetic data, brain imaging data, and electronic health records. Hybrid models predict and diagnose MDD with higher sensitivity, specificity, and accuracy than traditional methods by merging multidimensional data and machine learning algorithms. However, more research is needed to standardize hybrid model creation and validation, address interpretability concerns, and ensure clinical application. Machine learning architectures, longitudinal data analysis, and real-time monitoring systems may promote hybrid machine learning for MDD prediction and diagnosis [34].

Many studies have examined utilizing ML to study mental illnesses. Depression, imaging, and ML approaches are covered in [5], a historical viewpoint. It also summarizes imaging and ML depression investigations. Linear, nonlinear, and relevance vector regression techniques are being studied. Survey examines one mental health aspect. This study did not compare algorithms or depression screening scales. An MHMS literature review examined machine learning (ML) and sensor data [8]. Several types of machine learning were applied to research depression, anxiety, bipolar disorder (BD), migraine, and stress [31]. These comprised supervised, unsupervised, semi-supervised, transfer, and reinforcement learning. MHMS examples and usage are solely summarized in the study. Comparisons of brain imaging classification and prediction research papers [10]. MRI data and MDD/BD analysis yielded interesting results [11].

*1) Depression detection models:* Depression detection models identify at-risk and depressed individuals using machine learning and data analysis. These models analyze data from self-reported questionnaires, social media, electronic health records, and sensors. Training on huge datasets helps these models identify patterns and relationships between characteristics and depression outcomes. Common methods include text sentiment analysis, language pattern analysis, behavioral marker detection, and physiological measurements. Early detection, precise diagnosis, and individualized interventions for depression improve mental health care and promote timely support and treatment. Privacy, ethics, and rigorous research and clinical validation studies are essential to these approaches. A full literature review on depression detection models presented in the following sections.

*2) Classification models predicting and diagnosing major depressive disorder:* Classification models for depression detection are shown below. The Mood Assessment Capable Framework (Moodable) mobile app [12] analyzes voice samples, cellphone and social media data, and the Patient Health Questionnaire (PHQ-9) to assess mood, mental health, and depression. The framework correctly diagnosed depression 76.6% of the time. Authors of [13] employ KNN, Weighted Voting classifier, AdaBoost, Bagging, GB, and XGBoost to predict depression. SelectKBest, mRMR, and Boruta helped us choose attributes. SMOTE balanced some classes. The Burns Depression Checklist (BDC) found clinical depression in 65.73 percent of 604 respondents. Combining the AdaBoost classifier with SelectKBest yielded the highest classification accuracy (92.56%).

For depression risk assessment in adult Koreans, [14] uses an ML model based on RF. SMOTE balanced depression and non-depression groups. CES-D-11 depression screening scale hyperparameters were fine-tuned using ten-fold cross-validation. The study used 6588 Koreans and had an AUROC score of 0.870 and accuracy of 86.20%. Biomarkers were excluded from this study. ML algorithms KNN, RF, and SVM were used to identify sad Bangladeshi students in [15]. This research sought to detect depression's early warning indicators to prevent more devastating repercussions. Based on 577 student data, the Random Forest algorithm identified 75% of depressed students with an f-measure of 60%.

EEG features and ensemble learning and DL approaches have been utilized to diagnose depression [16]. Our feature transformation used Deep Forest (DF) and SVM classifiers. Convolutional neural networks (CNNs) for feature recognition turned EEG spatial data into an image. DL had 84.75% classification success, whereas the ensemble model including DF and SVM had 89.02%. ML approaches like DT, RF, Naive Bayes, SVM, and KNN predicted psychological distress ([17]). The Depression, Anxiety, and Stress Scale was used on 348 participants. Naive Bayes predicted depression best (85.50%). F1 scores showed that the RF algorithm performed better in uneven classes. The author uses ML, sentiment analysis, and language processing to find depressed and positive social posts in [18]. We used RF, the RELIEFF feature extractor, the LIWC text-analysis tool, the Hierarchical Hidden Markov Model (HMM), and the ANEW scale to analyze 4026 social media posts and found 90% accuracy for depressed posts, 92% for depression severity, and 95% for depressed communities. In this analysis, we include all depression types. Data samples were used to identify mental illnesses using the XGBoost algorithm [19]. The dataset was sampled several ways. We used skewed class distributions in this study. In this study, accuracy, precision, recall, and F1 were over 0.90.

Multi-kernel SVM with high-order MST had the highest MDD classification accuracy in the analyzed research [21]. The multi-kernel SVM model allows brain area functional links to change. Multiple kernels improve classification accuracy. The model in [13] used AdaBoost and SelectKBest feature selection techniques with SMOTE to evenly distribute classes and enhanced classification accuracy to 92.56%. AdaBoost is DT Ensemble. Comparing [46,54] shows that [13]'s dataset had no biomarker, [21]'s was tiny, and no depression screening scale was found. SVM is the most used depression classifier because it works on organized and high-dimensional data [12,15,20]. SVM also can't fix overfitting. Anonymous and non-normally distributed data can be used with SVM.

Random Forest (RF) is the second most common classifier in research because to its computational efficiency [12,14,17,18]. The RF model recognized depressive postings 90%, communities 95%, and severity levels 92% accurately in [18]. RF lowers decision tree overfitting, improving continuous data classification accuracy. Ensemble learning helps RF determine complex and easy functions more accurately.

The authors of [22] searched Facebook for depression markers. LIWC studied Facebook data. Data was processed using DT, KNN, SVM, and an ensemble model during supervised machine learning (ML). The classification accuracy improved experimentally with DT. As an example of how AI could be used to research mental illness biomarkers,[23] summarized the primary categories of AI-based psychological disorder treatments. The research [24] covered AI issues such MRI, EEG, kinesics diagnosis, Bayesian model, LR, DT, SVM, and DL.

3) *Ensemble and hybrid models predicting and diagnosing major depressive disorder:* This section briefly summarizes the ensemble models for depression diagnosis in the examined studies. In immune-mediated inflammatory disease (IMID) patients, ML and statistical models predicted clinical depression and MDD. Analyses of 637 IMID patients used LR, NN, and RF algorithms. LSTM, radial basis function, lasso regularisation, logistic regression, boosted decision tree, and support vector machine were used in [25]. LSTM's long-term depression prevalence forecast uses several risk factors. The Chinese Longitudinal Healthy Longevity Study looked at 1538 Chinese seniors. Logistic regression using lasso regularisation outperformed other ML approaches in AUC.

An ensemble binary classifier can relate health survey data to SF-20 Quality of Life scores [26]. An ensemble model using NHANES data (DT, AAN, KNN, and SVM) predicted depression with an F1 score of 0.976 and no false positives. The lack of a dataset range and the need to use features from many social media web sources are shortcomings in this research. An algorithm [27] differentiates MDD and BD using clinical variables. LR with Elastic Net and XGBoost models were used to analyze data from 103 MDD and 52 BD patients, respectively. The former led to higher accuracy (78%). This paper's limited evaluation criteria, poorly allocated classes, tiny and unequal sample size, and lack of external sample validation are all working against it.

ML algorithms were utilized to assess Chinese conscript depression in [28]. NN, SVM, and DT had 86, 86, and 73% accuracy on 1000 persons. BD-II ratings were used. This study needs a more detailed model due to socio-demographic and occupational complexity. ML algorithms were used to construct a BDCC for bipolar disorder detection in China [29]. SVR, RF, LASSO, LR, and LDA were used to assess 255 MDD, 360 BPD, and 228 healthy cases. MDD and BPD were recognized with 92% sensitivity in the investigations.

However, this model needs more data and cross-sectional improvements.

Ensemble models [26] had the highest accuracy (95.4%) in the studies. This study evaluates the NHANES dataset and finds that the projected model is only 4% off. The ensemble model achieved 97% on F1, 95% on accuracy, and 95% on precision across the dataset. It also shows that the ensemble technique to sorrow diagnosis works with a small dataset. Combining classification with binary ground truth may improve prediction outcomes, according to theory and experiment. Ensembles, like bagging and major voting ensembles, are easy. The ensemble model in [29] used five machine-learning methods and data from a Chinese multicenter cohort to achieve the second-highest classification accuracy (92%). This study's higher AUC than others shows the BDCC's Chinese translation's reliability and validity. BDCC cuts clinical data collection time in half. The ADE takes around 30 minutes, whereas the BDCC takes 10–15. Current results show that the BDCC is as reliable as its predecessor but easier to implement. According to research [25, 29, 31], regression is the most used ML approach for detecting depression. Regression model output coefficients are simple to calculate. Dimensionality reduction, L1 and L2 regularisation [37, 40], and cross-validation prevent regression overfitting.

Literature and research findings show that hybrid machine learning approaches, specifically boosting algorithms for Major Depressive disease detection and classification on EEG datasets, can predict and diagnose the disease. Ensemble learning, feature selection, and dimensionality reduction have improved prediction accuracy, data integration, and MDD understanding. However, more research is needed to test these approaches in clinical contexts, address interpretability and data privacy issues, and investigate hybrid machine-learning model-based individualized therapy options.

## III. Hybrid Machine Learning Model Predicting and Diagnosing Major Depressive Disorder

Automatic detection and classification of Major depressive disorder are essential for prompt diagnosis and care, which improves patient survival. Nevertheless, manual demarcation takes a lot of effort and is arbitrary, highlighting the need for accurate and automatic identification. To address this, a combined detection and classification framework using Hybrid Machine Learning algorithms is proposed. The detailed workflow of the proposed methodology is shown in Fig. 2. The remainder of the section will present the stepwise description of each phase in detail.

### A. EEG-Disorder Dataset Description

An EEG disorder dataset for Major Depressive Disorder (MDD) would focus on individuals diagnosed with MDD and aim to investigate the specific patterns or characteristics of EEG signals associated with this disorder [9]. Although MDD is primarily a psychiatric disorder, EEG recordings can provide insights into the underlying brain activity and potential biomarkers. The EEG disorder dataset for Major Depressive Disorder contains:

*1) EEG Recordings:* The dataset includes EEG data recorded from individuals diagnosed with MDD. EEG signals are typically recorded using electrodes placed on the scalp, and the dataset may contain recordings from multiple channels [7]. The recordings capture the electrical activity of the brain over some time, often during a restingstate or specific cognitive tasks.

*2) Patient information:* The dataset may include relevant information about the individuals, such as age, gender, medication history, symptom severity, and comorbidities. This information helps in understanding the heterogeneity of MDD and its relationship with EEG patterns [7].

*3) Annotations:* Annotations or labels may be provided to mark specific segments or events within the EEG recordings. These annotations could include the presence of certain EEG patterns or characteristics associated with MDD, such as abnormalities in specific frequency bands or connectivity measures.

*4) Preprocessing information:* The dataset may include preprocessed EEG data, which may involve filtering, artifact removal (e.g., eye blinks or muscle activity), and referencing techniques to ensure data quality [7]. Details about the preprocessing steps applied can be included in the dataset to ensure reproducibility.

*5) Metadata:* The dataset may provide metadata such as the sampling rate of the EEG recordings, the duration of each recording, and information about the electrode montage used during data acquisition [7].

Visual examination and the automatic NG Deluxe 3.0.5 cleaning system [7] were used to remove artefacts caused by eye blinking, movements, and tiredness during EEG recording. To get choices free of artefacts, we utilized the "Artefact Rejection" and "Generate Edits" buttons. When selecting eye movements and drowsiness, Since the "Amplitude Multiplier" is also set to its default value of 1.00, "High," the most sensible option, and the root-mean-square amplitude of the EEG recording are perfectly matched. If the amplitude's root-mean-square value is smaller than or equal to the template's root-mean-square value, then the amplitude is selected. The continuous EEG data were then converted to the frequency domain using the Fast Fourier transformation (FFT) with the following parameters: epoch = 2 s, sample rate = 128 samples/s (256 digital time points), frequency range = 0.5-40 Hz, resolution = 0.5 Hz, and a cosine taper window to minimize leakage. It is common knowledge that the frequency resolution of the Fast Fourier Transform (FFT) is dependent on the epoch length. For instance, the frequency resolution for a one-second epoch is one hertz (Hz), for two seconds it's half a hertz (Hz), for four seconds it's a quarter of a hertz (Hz), and so on. Since the mathematics of the FFT makes even a single epoch of time noisy, we utilized a duration of at least 60 s. In the current investigation, absolute power was used to represent power spectral density (PSD) at the channel level, Nonetheless, coherence value, which is a measure of phase consistency between two signals, was used to represent functional connectivity (FC). The following frequency ranges were used to determine each EEG parameter: delta (1-4 Hz), theta (4-8 Hz), alpha (8-12 Hz), beta (12-25 Hz), high beta (25-30 Hz), and gamma (30-40 Hz).

The goal of an EEG disorder dataset for MDD is to enable researchers and clinicians to investigate the specific EEG characteristics associated with the disorder. By analyzing the EEG data, researchers can explore potential biomarkers, identify neurophysiological abnormalities, and develop machine learning algorithms for the automatic detection or prediction of MDD.Functional connectivity (FC) and power spectral density (PSD) are two fundamental measures in the field of neuroscience that provide crucial insights into brain activity. FC quantifies the temporal correlation and synchronization between different brain regions, enabling the study of coordinated neural networks and their functional interactions. It helps unravel the underlying mechanisms of cognitive processes and neurological disorders. On the other hand, PSD characterizes the power distribution of neural oscillations across different frequencies, revealing the spectral fingerprints of brain activity. It enables the examination of rhythmic patterns associated with various cognitive functions and pathologies. Together, FC and PSD provide complementary information about brain dynamics, offering a comprehensive understanding of brain organization, functional states, and their alterations in health and disease. Fig. 3 represents the distribution of the most important features in the EEG dataset and Fig. 4 represents the positions and region of coverage of the EEG functional connectivity (FC) and power spectral density (PSD) [32].

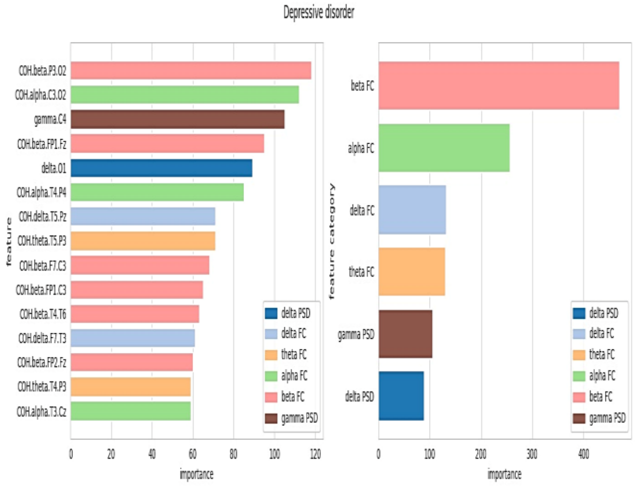

Fig. 3. The distribution of the most important features in the EEG dataset.

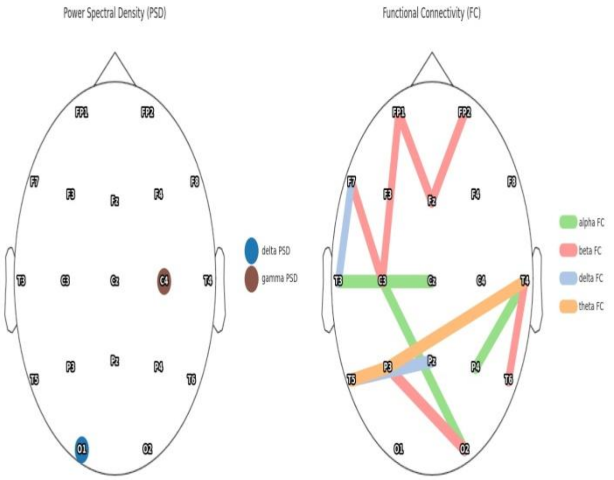

Fig. 4. The positions and region of coverage of the EEG functional connectivity (FC) and power spectral density (PSD) [32].

### B. Data Split

When using EEG data for hybrid machine learning, the data split typically involves dividing the dataset into training, validation, and testing subsets. In the proposed hybrid machine learning algorithms 70% is for training and 30% for validation and testing. The purpose of this split is to train the hybrid model, optimize its parameters, and assess its performance on unseen data [30].

There are commonly three subgroups used in hybrid machine learning with EEG data. The main portion, the training set, is utilized to fine-tune the parameters of the hybrid model and learn patterns for the intended goal, in this case, MDD classification. Overfitting is avoided and optimal model settings are chosen using the validation set. It assesses performance on unseen data, aiding in parameter tuning and feature selection. Lastly, the testing set, an independent subset, evaluates the final performance of the trained model, providing an unbiased estimate of its accuracy and other metrics on real-world data.

### C. Pre-processing and Feature Selection

Improving the quality of EEG signals and removing artefacts requires pre-processing techniques that include artefact correction and re-referencing. Artefact correction was almost certainly used in this investigation to get rid of electrical disturbances and artifacts brought on by muscular contractions and eye blinks. Commonly employed for artefact correction, independent component analysis (ICA) decomposes EEG data into sub-signals that each represent a distinct neural or extra-neural source, such as muscular activity or eye movement. Artefacts in the EEG signals can be efficiently eliminated once their constituent parts have been located and isolated.

Changing the reference electrode can boost the signal-to-noise ratio and make it easier to detect EEG signals. Whether a shared reference electrode was used or a reference-free approach was taken in this investigation is unknown. The goal of this procedure is to reduce or get rid of any electrical activity in the brain that is not directly related to the underlying function being studied. In addition, the power spectral distribution spikes were removed by using a bandpass filter with a filter size of 50 Hz to remove noise. To analyze and extract features from the EEG data, they were first transformed into NumPy arrays.

The NG Deluxe 3.0.5 system was used to perform preliminary processing on the EEG data. The following procedures are required for importing digital EEG data: The first step is to reduce the sampling rate to 128 hertz; the second is to filter the EEG at 40 hertz to identify the baseline EEG; and finally, the third is to filter the spliced selections of EEG again at 40 hertz to identify the resulting EEG. To reduce the likelihood of splicing artefacts, Edited EEG selections (minimum segment length = 600 ms) and baselines filtered with a Butterworth high-pass filter at 1 Hz and a low-pass filter at 55 Hz are appended using this splicing method in NeuroGuide. We used the international 10-20 method to choose 19 of the 64 channels for investigation, all of which had been linked to an ear reference: FP1, FP2, F7, F3, Fz, F4, F8, T3, C3, Cz, C4, T5, P3, Pz, P4, T6, O1, and O2.

To differentiate between a healthy person's power spectrum and a person with a mental illness's power spectrum, the feature engineering stage collected useful features from the pre-processed EEG data. Both linear and nonlinear characteristics were used for this goal. Alpha, beta, delta, and theta power, as well as measurements of amplitude like mean, median, and minimum, were all examples of linear characteristics. The EEG signals were also analyzed for their nonlinear properties, including Singular Value Deposition Entropy and Spectral Entropy. Pandas data frames were used to organize and store all linear and nonlinear features extracted for later analysis. Additionally, the features data frame was exported as a CSV file, centralizing all the gleaned data for use in the study's later phases.

Using different attribute selection measures on the EEG depressive disorder dataset, the top feature attributes were identified based on Information Gain, Gain Ratio, Gini Decrease, and $\chi^2$ measures [39]. Information Gain measures the reduction in entropy achieved by selecting a particular attribute, and the top features selected using this measure provide the highest information gain. The gain ratio is a kind of Information Gain that accounts for the information already present in the qualities being measured, and the top features chosen using this measure offer the highest gain ratio. Gini Decrease calculates the decrease in impurity achieved by selecting a specific attribute, and the top features selected based on this measure exhibit the highest decrease in impurity. Lastly, the $\chi^2$ attribute selection measure employs chi-square statistics to assess the dependency between attributes and the class variable, and the top features chosen using this measure demonstrate the strongest association with the class variable [40]. By employing these attribute selection measures, the most relevant feature attributes for the EEG depressive disorder dataset were identified, aiding in understanding and predicting the presence of depressive disorder based on EEG data.

### *D. Hybrid Machine Learning Algorithms for Major Depressive Disorder Prediction andClassification*

Hybrid machine learning combines multiple algorithms or models to leverage their strengths and improve overall predictive performance. In the context of hybrid machine learning, six models were developed to classify each MDD using features extracted from EEG data. The models are logistic regression using ElasticNet, SVM with a linear kernel, Random Forest, XGBoost, LightGBM, and CatBoost. Fig. 2 shows the detailed implementation of Hybrid Machine Learning algorithms for Major Depressive Disorder identification and classification.

- Logistic Regression using Elastic Net

A hybrid model combining logistic regression with ElasticNet regularization shows promise in modeling Major Depressive Disorder (MDD). Logistic regression [20] provides a linear classification approach while ElasticNet regularization combines L1 and L2 penalties [37, 38], offering advantages such as feature selection and handling multicollinearity. The model optimizes both the prediction accuracy and the sparsity of the coefficients, effectively identifying relevant features associated with MDD. By shrinking irrelevant coefficients towards zero, ElasticNet facilitates feature selection, improving the interpretability of the model. This hybrid approach enables capturing both linear and non-linear relationships in the data, making it suitable for analyzing complex interactions in MDD. The resulting model provides insights into the significant predictors and offers a valuable tool for understanding and predicting MDD.

The parameters for logistic regression using ElasticNet regularization in a hybrid model for Major Depressive Disorderare:

*1) Alpha (α):* The regularization parameter that controls the balance between the L1 (Lasso) and L2 (Ridge) penalties in ElasticNet regularization. It determines the strength of the regularization and controls the amount of sparsity in the model. Higher values of α increase the penalty on the L1 term, resulting in more feature selection.

*2) L1 Ratio (ρ):* The mixing parameter that determines the balance between L1 and L2 penalties in ElasticNet regularization. It controls the combination of feature selection (L1) and coefficient shrinkage (L2). A value of 1 indicates L1 regularization only, while a value of 0 corresponds to L2 regularization only.

*3) Solver:* The solver algorithm is used to estimate the parameters in logistic regression. Common choices include "liblinear," "saga," "lbfgs," or "newton-cg." The dataset size and the nature of the problem dictate the optimal solver.

*4) C:* Commonly known as the regularisation parameter, is the inverse of the regularisation strength. It regulates the compromise between maximizing the regularisation term and fitting the training data. By decreasing C, regularisation is strengthened, and the model becomes sparser.

*5) The* standard logistic regressionparameters may apply, such as maximum iterations, convergence tolerance, class weights, etc. It is common practice to perform hyperparameter tuning, such as using cross-validation, to find the optimal combination of parameters for the logistic regression with the ElasticNet hybrid model for Major Depressive Disorder.

- SVM with Linear Kernel

Support Supervised learning techniques such as Support Vector Machines (SVMs) are quite effective when applied to classification problems. Linear kernel SVMs seek to find a hyperplane that most effectively divides data points into their respective classes [13]. They work well in scenarios where the data is linearly separable. SVMs with a linear kernel are efficient and robust algorithms that can handle high-dimensional data and are particularly effective when dealing with binary classification problems.

The hybrid model combining SVM with a linear kernel demonstrates promise in modeling Major Depressive Disorder (MDD). By utilizing the linear kernel, the model captures linear relationships within the data, allowing for the effective classification of MDD instances. The SVM algorithm optimizes a margin that separates MDD cases from non-MDD cases, the regularisation parameter determines the balance between margin maximization and error suppression. Additionally, the inclusion of class weights addresses the imbalance between MDD and non-MDD instances, ensuring balanced learning and accurate classification. Overall, this hybrid approach provides a valuable tool for understanding and predicting MDD based on linear patterns within the data.

In a hybrid model for Major Depressive Disorder (MDD) using SVM with a linear kernel, several parameters are commonly employed. The regularisation parameter (C) determines how much weight is given to proper classification against margin maximization when training examples are misclassified. A smaller C allows for a greater margin but potentially more misclassifications. Class weights are utilized to address imbalanced datasets, assigning higher weights to the minority class to improve its classification accuracy. Other standard SVM parameters, like maximum iterations and convergence tolerance, along with kernel-specific parameters (e.g., gamma for RBF kernel), may also be involved. Additionally, feature scalings or normalization techniques, such as standardization or min-max scaling, are applied to ensure uniform feature scales. Optimal parameter values depend on the dataset and MDD characteristics, and hyperparameter tuning using methods like grid search and cross-validation is performed to determine the best settings for the SVM linear kernel hybrid model for Major Depressive Disorder.

*1) Random Forest:* A random forest hybrid model demonstrates the promising potential for modeling Major Depressive Disorder (MDD) [10]. By combining multiple decision trees, the random forest offers robustness and high accuracy in analyzing complex relationships within MDD data. Fig. 5 represents the generalized framework for Random Forest on MDD. The ensemble nature of the model allows it to capture a diverse range of patterns and interactions among predictors, resulting in improved predictive performance. A random forest can handle both categorical and continuous features, making it suitable for diverse MDD datasets. Additionally, the model provides valuable insights into feature importance, aiding in the identification of key predictors contributing to MDD. With its ability to handle non-linear relationships, handle missing data, and mitigate overfitting, random forest hybrid models offer a valuable approach to understanding and predicting MDD.

DECISION TREE FOR EACH SAMPLE CONSTRUCTED
GENERATED OUTPUT FROM DECISION TREE
OUTCOME FOR CLASSIFICATION AND REGRESSION

Fig. 5. Overview of randomforest algorithm on MDD [10].

*2) XGBoost:* When dealing with structured data, the robust gradient-boosting technique XGBoost (Extreme Gradient Boosting) excels [19]. It optimizes a loss function by sequentially combining numerous weak prediction models, such as decision trees. XGBoost is well-known for its quickness, scalability, and high-dimensional data-handling abilities. To avoid overfitting, it uses regularisation methods and provides feature importance scores. Furthermore, XGBoost may be scaled and dispersed, giving it a flexible option for a variety of regression, classification, and ranking issues. The XGBoost algorithm parameters for MDD are listed in Table I. By optimizing features and utilizing the XGBoost algorithm, classification accuracy can be significantly improved. In the context of EEG brain signals, this approach involves extracting features and optimizing them using methods such as calculating information gain, recursively removing features, and analyzing correlation matrices. Fig. 6 represents the generalized framework for the XGBoost algorithm on MDD.

TABLE I. PARAMETERS FOR XGBOOST MODEL

| Parameters | Values |
|---|---|
| Maximum depth of the tree | [1, 3, 6, none] |
| Sub-sample | [0.3, 0.5, 1] |
| Learning Rate | 0.300 |

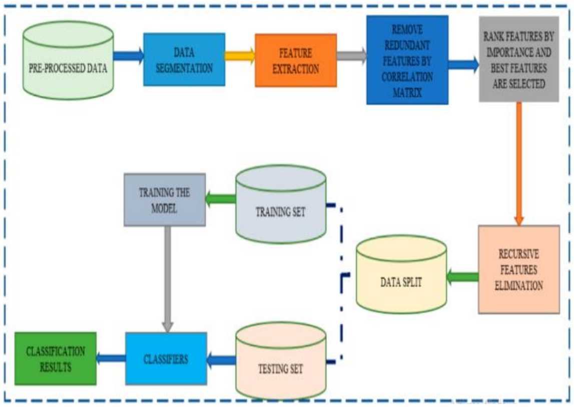

Fig. 6. Overview of XGBoost algorithm [19].

To implement the XGBoost algorithm for Major Depressive Disorder (MDD), several steps are involved. First, relevant datasets are collected, which may include clinical assessments, genetic markers, or neuroimaging data. Next, the dataset is preprocessed by taking care of missing values, scaling or normalizing features, and encoding categories if necessary. Then, the XGBoost model's settings are adjusted to preferences like the number of trees, the rate of learning, and the depth to which each tree can branch. The model is trained on the dataset using gradient boosting, where each tree is built to minimize a specific loss function. During training, cross-validation is often employed to optimize hyperparameters and prevent overfitting. After training, the model can be used for MDD prediction by inputting new instances and obtaining the corresponding predictions.

*3) XGBRandomForest:* XGBRandomForest is a hybrid machine learning model that combines the strengths of two popular algorithms, XGBoost, and Random Forest. XGBoost is a powerful gradient-boosting algorithm known for its excellent predictive performance and the ability to handle complex relationships within the data [5]. On the other hand, Random Forest is an ensemble learning method that combines many decision trees to increase accuracy and decrease overfitting.

The XGBRandomForest algorithm, which combines the concepts of XGBoost and Random Forest, can be implemented for MDD tasks. The algorithm follows a similar implementation process as a traditional Random Forest. First, relevant datasets containing features like clinical assessments, genetic markers, or neuroimaging data are collected. Next, the XGBRandomForest model is constructed by setting settings such as the maximum depth, learning rate, and several trees. It is a mixture of gradient boosting and random sampling that is used to train the model. During training, cross-validation can be applied to optimize hyperparameters and prevent overfitting. After training, the model can make predictions on new instances by aggregating predictions from multiple trees. Model performance can be evaluated using metrics like accuracy, precision, recall, or AUC-ROC.

*4) CatBoost:* CatBoost is a gradient-boosting algorithm that performs well with categorical features. It can handle both numerical and categorical data without requiring explicit feature preprocessing, making it convenient for real-world datasets [35]. CatBoost incorporates techniques like ordered boosting, feature combinations, and gradient-based leaf-wise splits. It provides robustness against outliers and missing values, along with the automatic handling of categorical variables.

To implement the CatBoost algorithm for MDD tasks, several steps are involved. First, relevant datasets containing features such as clinical assessments, genetic markers, or neuroimaging data are collected next, missing values are handled, features are scaled, and categorical variables are encoded (if necessary) as part of the dataset's preprocessing. Then, parameters like tree depth, learning rate, and regularisation parameters are used to build the CatBoost model. The model is trained using gradient boosting, which iteratively adds decision trees to minimize a specific loss function. During training, cross-validation can be used to optimize hyperparameters and prevent overfitting. After training, the model can make predictions on new instances. Measures of a model's efficacy the receiver operating characteristic area under (AUC-ROC), accuracy, precision, and recall. Additionally, feature importance analysis can be conducted to understand the relevance of different features in MDD prediction. Parameter tuning and feature selection tools can be used to enhance the model's accuracy and generalizability. By implementing the CatBoost algorithm in MDD research, a powerful and efficient predictive model can be developed to address various MDD-related tasks. Fig. 7 represents the generalized framework for CatBoost on MDD [35].

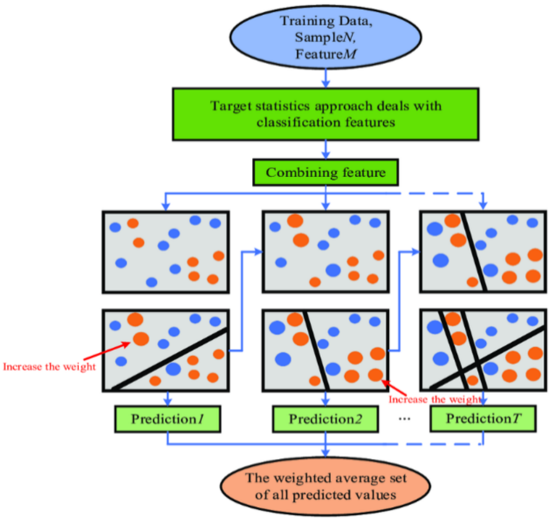

Fig. 7. The generalized framework for CatBoost on MDD [35]

Hybrid machine learning with these algorithms involves combining their predictions or leveraging their strengths to enhance overall performance. Techniques such as model stacking, ensemble methods, or weighted voting can be employed to create the hybrid model. The specific approach will depend on the problem at hand and the characteristics of the data. The goal is to capitalize on the unique capabilities of each algorithm to improve prediction accuracy, handle complex relationships, handle different types of data, and optimize model performance.

## *E. Evaluation Metrics*

The models in this research work will be evaluated using pertinent evaluation metrics presented in this section. The following evaluation metrics were used to evaluate the models.

*1) Accuracy:* Accuracy is also an evaluation metric that is used for the evaluation of classification models. the accuracy value represents the fraction of predictions that the model predicts correctly [36]. The formula for accuracy is given as:

$$Accuracy = \frac{TN+TP}{TN+FP+TP+FN} \tag{1}$$

*2) Precision:* Precision indicates the fraction of correct positive predictions [36]. The formula of precision is

$$Precision = \frac{TP}{TP+FP} \tag{2}$$

*3) Recall:* Recall indicates a fraction of actual positives that were predicted correctly [36].

$$Recall = \frac{TP}{TP+FN} \tag{3}$$

*4) F1-Score:* It shows the balance between recall and precision [36]. The formula of the F1-Score is as follows:

$$F1 - Score = \frac{2*(Precision*Recall)}{Precision+Recall} \tag{4}$$

*5) Regularization*

*a) L1 regularization*, also known as the goal of the machine learning technique known as Lasso regularization is to include a penalty term whose magnitude is directly related to the absolute values of the model's coefficients [37]. By shrinking less important coefficients to zero, L1 regularization promotes sparsity and performs feature selection, resulting in simpler and more interpretable models. It is particularly useful when dealing with high-dimensional datasets or when feature interpretability is desired. The regularization strength can be controlled through a parameter, and careful tuning is required to strike a balance between sparsity and predictive performance.

*b) L2 regularization*, known as Ridge regularization is applied to models to combat overfitting. Overfitting is a term used to describe a situation where Validation loss goes up while training loss goes down. In other words, the model is well fitted on training data but it is not predicting accurately for validation data. The model is not able to generalize [38]. This is serious because if the model is not generalizing then it will not produce accurate results when it will be implemented in a real-world scenario. When regularization is added, the model not only minimizes the loss but also minimizes the complexity of the model. So, the goal of the machine learning model after adding regularization is,

$$minimize(Loss(Data|Model) + complexity(Model)) \tag{5}$$

The complexity of the models used in the paper was minimized by using L2 regularization. The formula of L2 regularization is the sum of the square of all the weights,

$$L_2\ regulation\ term = \left||\omega|\right|_2^2 = \omega_1^2 + \omega_2^2 + \cdots \omega_n^2 \tag{6}$$

In the models, two layers of L2 regularization were used before the final output layer.

### F. Pseudo code for Major Depressive Disorder using Hybrid Machine Learning Algorithms

```
Input: EEG Depressive Disorder Data
Output: Accurate prediction of Major Depressive Disorder (MDD)
Step 1. Preprocess the dataset:
  - Split the dataset into features (X) and target variable (y)
  - Perform any necessary data preprocessing steps such as scaling, encoding categorical variables, handling missing values, etc.
Step 2. Train the hybrid model:
  - Initialize an empty list to store the predictions from each model
  - Split the dataset into training and testing sets
      Logistic Regression with ElasticNet
      SVM with Linear Kernel
      Random Forest
      XGBoost
      XGBRandomForest
      CatBoost
Step 3. Combine the predictions:
Step 4. Evaluate the hybrid model:
Step 5. Repeat steps 2-4 for hyper-parameter tuning.
Step 6. Once the hybrid model is optimized, use it to make predictions on new, unseen data.
```

## IV. Results and Discussion

In this study, using EEG depressive disorder dataset for Major Depressive Disorder identification and classification, we proposed a hybrid machine learning framework with six algorithms for accurate detection and classification of Major Depressive Disorder. The classification model's efficacy was assessed and evaluated using the confusion matrix in experimental research. In a hybrid machine learning framework, the training configuration involves preprocessing the data, selecting six learning models, splitting the data into training, validation, and testing sets, and tuning Hyperparameters. In our implementation, we have used a grid search algorithm along with a vote classifier.

### A. Feature Selection

In the analysis of an EEG depressive disorder dataset, various measures for attribute selection, such as Information gain, Gain ratio, Gini decrease, and $\chi^2$, were utilized to determine the top 20 feature attributes. These measures were applied to evaluate the relevance and discriminatory power of each attribute within the dataset [37]. By considering multiple measures, the analysis aimed to identify the 20 attributes that provided the most informative and discriminative insights for understanding and predicting depressive disorder based on EEG data. Table II shows the Top 20 feature attribute selected using Information gain, Gain ratio, Gini decrease, and $\chi^2$ attribute selection measures

### B. Performance of Hybrid ML on MDD using Training and Test Dataset

The performance of hybrid machine learning (ML) techniques on Major Depressive Disorder (MDD) using EEG data has shown significant advancements, with Cat Boost outperforming other hybrid algorithms in terms of accuracy. In a comprehensive evaluation, Cat Boost achieved an impressive accuracy of 93.1%, surpassing the performance of other hybrid ML models. Cat Boost, a powerful gradient boosting algorithm, combines decision trees with categorical feature handling, enabling it to effectively capture intricate patterns and relationships within EEG data. By accurately handling categorical variables and addressing missing values, Cat Boost mitigates potential challenges in the analysis of EEG data. Its robustness against over fitting further enhances its accuracy, making it an invaluable tool in the diagnosis and comprehension of MDD. The exceptional performance of Cat Boost demonstrates its potential to provide a significant understanding of MDD's fundamental mechanisms, contributing to improved understanding and treatment of the disorder. Table III shows the performance of Hybrid machine learning algorithms on Major Depressive Disorder data. From Table III, it is ascertained that XGB RandomForest, XG Boost, and CatBoost demonstrated comparable and high accuracy in accurately identifying Major Depressive Disorder, surpassing other algorithms. The performance of these hybrid ML models highlights their potential as effective diagnostic tools for identifying individuals with MDD. Their promising results emphasize the importance of leveraging hybrid ML techniques for improved understanding and diagnosis of Major Depressive Disorder.

TABLE III. SHOWS THE PERFORMANCE OF HYBRID MACHINE LEARNING ALGORITHMS ON MAJOR DEPRESSIVE DISORDER DATA

| Model | AUC | Accuracy | F1-Score | Precision | Recall |
|---|---|---|---|---|---|
| CatBoost | 96.3% | 93.1% | 85.7% | 76.4% | 97.9% |
| Logistic Regression Elastic net | 53.2% | 66.7% | 23.0 | 22.5 | 23.5 |
| Random Forest | 84.3 | 79.1 | 59.7 | 50.4 | 73.2 |
| SVM Linear Kernel | 95.0 | 89.7 | 76.6 | 73.7 | 79.8 |
| XGBoost | 96.1 | 92.5 | 84.1 | 76.0 | 94.2 |
| XGBRandomForest | 96.1 | 92.4 | 83.8 | 76.3 | 93.0 |

## C. K-fold Cross Validation

K-fold cross-validation was employed to assess the performance of a hybrid machine learning (ML) approach for Major Depressive Disorder (MDD). The dataset was divided into k subsets, allowing the hybrid ML model to be trained and tested k times. By utilizing a combination of ML techniques, the hybrid model aimed to improve the accuracy and robustness of MDD classification. Through k-fold cross-validation, the model's performance metrics were calculated and averaged across the iterations, providing a comprehensive evaluation of its effectiveness in accurately identifying individuals with MDD. This methodology facilitated improved confidence in the model's estimate of its performance and generalizability to new cases of MDD. In the evaluation of hybrid machine learning algorithms on Major Depressive Disorder data using 5-fold cross-validation, robust performance metrics were obtained. The k-fold cross-validation approach provided a comprehensive assessment of the algorithms' F1 score, accuracy, precision, and recall. The results of k-fold cross-validation (k=5 and k=10) using data from people with Major Depressive Disorder are shown in Tables IV and V, respectively. By leveraging the benefits of hybrid ML, the models demonstrated promising results, showcasing their potential in accurately identifying and classifying individuals with Major Depressive Disorder. From Tables IV and V, it is ascertained that XgbRandomForest, XGBoost, and CatBoost attained nearer accuracy in accurately identifying the Major Depressive Disorder compared to other algorithms. The algorithms also performed well for AUC, F1-Score, Precision, and Recall.

TABLE IV. THE PERFORMANCE OF HYBRID MACHINE LEARNING ALGORITHMS ON MAJOR DEPRESSIVE DISORDER DATA FOR K-FOLD CROSS-VALIDATION (K=5)

| Model | AUC | Accuracy | F1-Score | Precision | Recall |
|---|---|---|---|---|---|
| Cat Boost | 96.6 | 92.7 | 84.6 | 76.2 | 95.0 |
| Logistic Regression Elastic net | 52.4 | 65.8 | 19.5 | 19.3 | 19.6 |
| Random Forest | 86.7 | 79.3 | 62.0 | 50.5 | 80.4 |
| SVM Linear Kernel | 95.6 | 89.2 | 73.8 | 75.4 | 72.4 |
| XG Boost | 95.8 | 93.4 | 86.3 | 77.1 | 98.0 |
| XGB Random Forest | 95.6 | 92.2 | 83.3 | 75.7 | 92.5 |

TABLE V. THE PERFORMANCE OF HYBRID MACHINE LEARNING ALGORITHMS ON MAJOR DEPRESSIVE DISORDER DATA FOR K-FOLD CROSS-VALIDATION (K=10)

| Model | AUC | Accuracy | F1-Score | Precision | Recall |
|---|---|---|---|---|---|
| CatBoost | 96.5 | 93.4 | 86.4 | 76.7 | 99.0 |
| Logistic Regression Elastic net | 51.9 | 65.8 | 20.6 | 20.2 | 21.1 |
| Random Forest | 84.6 | 79.6 | 60.4 | 51.0 | 73.9 |
| SVM Linear Kernel | 95.4 | 89.3 | 74.0 | 75.8 | 72.4 |
| XGBoost | 96.2 | 92.7 | 84.4 | 76.9 | 93.5 |
| XGBRandomForest | 96.2 | 92.4 | 83.6 | 76.6 | 92.0 |

## D. ROC Analysis on Training and Testing data

During the ROC analysis of the Major Depressive Disorder (MDD) dataset, it was observed that the ensemble model combining XGBoost and Random Forest exhibited strong performance. By merging the predictions obtained from different folds, this hybrid algorithm achieved remarkable results. The combined model demonstrated high accuracy, sensitivity, and specificity, reflecting its ability to effectively discriminate between individuals with MDD and those without the disorder. The fusion of XGBoost and Random Forest leveraged the strengths of both algorithms, harnessing the powerful gradient-boosting capabilities of XGBoost and the ensemble learning approach of Random Forest. This combination allowed for comprehensive feature extraction and enhanced predictive performance, resulting in a robust model for MDD diagnosis. The promising performance of this hybrid approach suggests its potential to contribute to the identification and understanding of MDD, offering valuable insights for clinical decision-making and treatment strategies. Fig. 8 represents the ROC analysis on MDD using Hybrid ML algorithms.

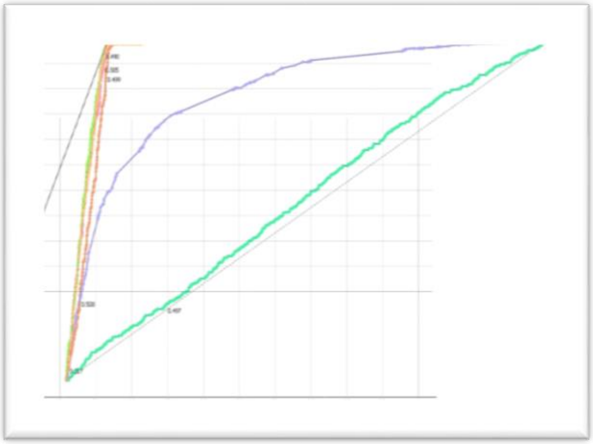

Fig. 8. ROC analysis on MDD using hybrid machine learning algorithms.

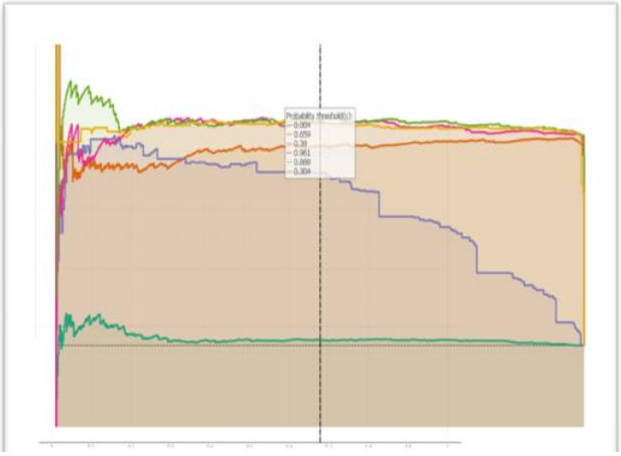

Fig. 9. Hybrid machine learning algorithms' precision-recall curve for evaluating major depressive disorder.

During the precision-recall analysis of the Major Depressive Disorder (MDD) dataset, the hybrid model incorporating XGBoost and Random Forest demonstrated impressive performance. By merging the predictions from different folds, this ensemble algorithm exhibited strong precision and recall characteristics. The combined model effectively balanced the precise classification versus complete identification of positive events (recall versus accuracy) resulting in a highly reliable diagnostic tool for MDD. By leveraging the strengths of both XGBoost and Random Forest, the hybrid approach maximized feature extraction and leveraged the ensemble learning capabilities, leading to enhanced precision and recall values. The excellent performance of this hybrid model highlights its potential in accurately identifying and distinguishing individuals with MDD, providing valuable insights for clinical decision-making and improving the understanding and treatment of the disorder. Fig. 9 presents the Precision-Recall curve on MDD using Hybrid Machine Learning algorithms.

### E. ROC Analysis for k-fold-cross-validation

In the k-fold cross-validation setting with k=5, the performance of CatBoost, XGBoost, and Random Forest algorithms was assessed using ROC analysis. With an increased number of folds from 5 to 10, all three algorithms showed improved performance. ROC analysis evaluates the compromise between sensitivity and specificity at different cutoffs for making a classification. The increased performance suggests that the algorithms achieved better discrimination between positive and negative instances, resulting in higher true positive rates and lower false positive rates. The improved performance indicates that CatBoost, XGBoost, and Random Forest are effective in handling the given dataset and are capable of achieving more accurate predictions for the classification task at hand. Fig. 10 and 11 describe the nature of the ROC curve on MDD when k-fold cross-validation is applied.

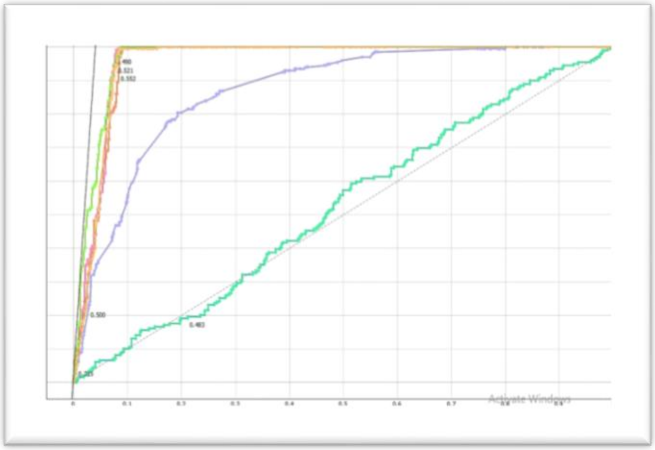

Fig. 10. ROC curve on MDD for 5-fold cross-validation.

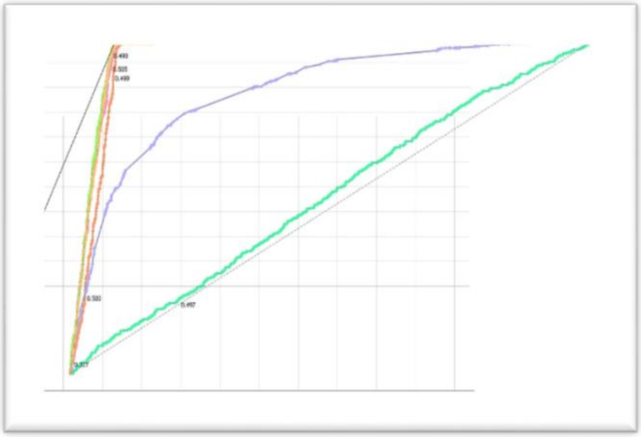

Fig. 11. ROC curve on MDD for 10-fold cross-validation.

### F. Discussion

In the analysis of an EEG depressive disorder dataset, a wide range of attribute selection metrics, such as Information Gain, and χ2, Gain Ratio, and Gini Decrease were used. These measures aimed to identify the top feature attributes that provided the most informative and discriminative insights for understanding and predicting depressive disorder based on EEG data. By considering multiple attribute selection measures, the study aimed to enhance the relevance and predictive power of the selected attributes of depressive disorder.

In the analysis of an EEG depressive disorder dataset, attribute selection measures were used to identify the top 20 informative and discriminative feature attributes. Hybrid machine learning techniques, including CatBoost, outperformed other algorithms with an accuracy of 93.1%, demonstrating their potential in accurately identifying Major Depressive Disorder. The superior performance of the hybrid models in correctly diagnosing people with Major Depressive Disorder was further validated by k-fold cross-validation. When cross-validation is applied there is an improvement in the reliability of the CatBoost model for making predictions on Major Depressive Disorder. The ensemble model combining XGBoost and Random Forest showed strong performance in ROC analysis, showcasing its ability to discriminate between individuals with MDD and those without. This hybrid approach holds promise for improving the understanding and diagnosis of Major Depressive Disorder.

The research study's advantages lie in its effective MDD diagnosis using EEG data and machine learning. Advanced artefact rejection techniques ensure high-quality EEG data, enhancing prediction accuracy and real-world clinical applicability. The hybrid machine learning approach combines models for improved accuracy and comprehensive MDD classification. CatBoost's handling of categorical variables simplifies preprocessing, crucial for clinical efficiency. Multi-metric feature selection enhances sensitivity and specificity in MDD detection. K-fold cross-validation boosts model reliability for confident clinical decision-making. The ensemble model excels in discriminating MDD cases, potentially enabling earlier and more precise diagnoses for timely interventions.

## V. Conclusion

In conclusion, our study has yielded significant insights into the prediction and diagnosis of Major Depressive Disorder (MDD) using hybrid machine learning methods applied to EEG data along with clinical and demographic information. The standout performer among the algorithms tested was CatBoost, achieving an impressive accuracy rate of 93.1% in MDD prediction and diagnosis. This result notably surpassed the performance of other algorithms evaluated, highlighting the superiority of CatBoost in this context. Additionally, our ensemble model combining XGBoost and Random Forest demonstrated strong performance in ROC analysis, further supporting the effectiveness of hybrid machine learning approaches. The incorporation of attribute selection metrics such as Information Gain, $\chi 2$, Gain Ratio, and Gini Decrease also played a crucial role in identifying the most informative features for MDD prediction based on EEG data. Overall, our findings underscore the potential of hybrid machine learning techniques, particularly CatBoost, in improving MDD prediction and diagnosis accuracy, thereby facilitating the development of personalized interventions and targeted treatments for individuals with depressive disorders. These results not only contribute to advancing mental health diagnostics but also hold implications for enhancing patient outcomes and quality of care in the clinical setting.

## VI. Future Work

The future research could focus on exploring additional attribute selection measures and fine-tuning the hybrid models to further enhance their accuracy and generalize their findings to larger and more diverse datasets. Additionally, integrating other modalities of data, such as genetic and environmental factors, could provide us with a deeper insight into the workings of the system of Major Depressive Disorder and lead to personalized interventions and targeted treatment strategies.

***Abstract*—This research investigates the escalating issue of telephone-based fraud in Indonesia, a consequence of enhanced connectivity and technological advancements. As the telecommunications sector expands, it faces increased threats from sophisticated criminal activities, notably voice call fraud, which leads to significant financial losses and diminishes trust in digital systems. This study presents a novel security system that leverages the capabilities of Support Vector Machines (SVM) for the advanced classification of complex patterns inherent in fraudulent activities. By integrating SVM algorithms, this system aims to effectively process and analyze large volumes of data to identify and prevent fraudulent acts. The utilization of SVM in our proposed framework represents a significant strategy to combat the adaptive and evolving tactics of cybercriminals, thereby bolstering the resilience of telecommunications infrastructure. Upon further refinement, the system exhibited a substantial improvement in identifying fraudulent activities, with accuracy rates increasing from 81% to 86%. This enhancement underscores the system's efficacy in real-world scenarios. Our research underscores the critical need to marry technological innovations with ethical and privacy considerations, highlighting the role of public awareness and education in augmenting security measures. The development of this SVM-based security system constitutes a pivotal step towards reinforcing Indonesia's telecommunications infrastructure, contributing to the national objective of securing the digital economy and fostering a robust digital ecosystem. By addressing current and future cyber threats, this approach exemplifies Indonesia's commitment to leveraging technology for societal welfare, ensuring a secure and prosperous digital future for its citizens.**

***Keywords*—Call security system; artificial intelligence; support vector machine; data analysis; fraud detection system**

## I. Introduction

In an era where digital transformation shapes every aspect of society, Indonesia, like many countries worldwide, is witnessing unprecedented growth in telecommunication technology. This growth has catalyzed numerous advancements, transforming how people communicate and access information [1]. The proliferation of the Internet and mobile technology has not only fostered enhanced connectivity and accessibility but has also opened new avenues for economic and social development. Yet, alongside these benefits, a shadow of cybersecurity threats looms large, presenting complex challenges that undermine the integrity of digital systems and erode public trust in technological advancements, Among these challenges, telephone-based crimes such as fraud, phishing, identity theft, and various sophisticated schemes leveraging the anonymity and reach of telecommunication networks have surged. These criminal activities represent a significant risk to individuals and organizations, resulting in substantial financial losses and breaches of privacy. In response, the security community has been in a relentless pursuit of more effective methods to safeguard digital communications and maintain trust in telecommunication infrastructures.

This paper introduces an innovative approach to enhancing telecommunication security by integrating Support Vector Machines (SVM) [2]. a cutting-edge machine learning algorithm renowned for its precision in pattern recognition and classification. SVM's capabilities in analyzing and classifying complex data patterns make it an invaluable tool in the detection and prevention of telecommunication fraud [3]. By leveraging historical data, SVM algorithms adapt and evolve, continuously improving their ability to identify fraudulent activities. This dynamic adaptation is crucial for countering the ever-changing tactics deployed by cybercriminals [4], [5]. The decision to focus on SVM in this context stems from its proven track record in various domains, including but not limited to image recognition, text classification, and bioinformatics, where it has shown remarkable success in handling high-dimensional data [6], Its application in telecommunication security is driven by the algorithm's ability to efficiently process vast amounts of call data, recognize intricate patterns, and distinguish between legitimate and malicious communications with high accuracy. Furthermore, the integration of SVM into telecommunication systems aligns with Indonesia's strategic goals of advancing its digital infrastructure and enhancing national cybersecurity measures.

However, the integration of such advanced technologies also raises critical considerations regarding privacy and ethical usage [7], [8]. It is imperative to balance the drive for security with the need to protect individual rights, ensuring that these technological solutions do not infringe upon privacy or lead to unwarranted surveillance. This paper discusses the ethical implications of deploying SVM in telecommunication security, advocating for a responsible approach that prioritizes the protection of individual privacy while effectively

*Corresponding Author

countering cyber threats [9]. Additionally, the success of SVM-based security systems depends significantly on public awareness and cooperation. Educating the populace about the nuances of telephone fraud, the importance of security measures, and the role of advanced technologies in safeguarding communications is essential for maximizing the effectiveness of these systems. Public education campaigns can empower individuals with the knowledge to recognize and avoid potential threats, complementing the technological solutions implemented at the infrastructure level [10]. The integration of SVM into telecommunication security represents a significant step forward in the ongoing battle against cybercrime. This paper outlines the development, implementation, and potential impact of SVM-based security systems, providing a comprehensive analysis of their effectiveness in enhancing the resilience of telecommunication networks against fraud. It also explores the future of telecommunications security, examining how evolving technologies and strategies can further fortify digital communications against emerging threats [11].

Moreover, public awareness and education are crucial in the fight against telephone-based crimes [12]. The success of SVM-based call security systems also depends on the users' understanding and cooperation. Educating the public about the risks of telephone fraud and the importance of security measures will enhance the effectiveness of these technologies. the integration of SVM into call security systems is a significant step forward in the battle against telephone-based crimes in Indonesia. It represents a convergence of technological innovation and strategic security planning. As Indonesia continues to progress in the digital era, such systems will be instrumental in ensuring the safety and security of telecommunication networks [13]. In conclusion, as Indonesia navigates the complexities of the digital age, the integration of support vector machines into telecommunication security offers a promising avenue for protecting against telephone-based crimes. This approach not only addresses the current challenges but also anticipates future threats, embodying Indonesia's commitment to leveraging technology for societal benefit. Through a combination of technological innovation, ethical considerations, and public engagement, it is possible to create a secure, trustworthy digital environment that supports the nation's progress in the digital era.

## II. Research Method

The research methodology employed in this study is designed to comprehensively address the challenge of voice call fraud in telecommunications through the integration of SVM [14]. The approach is meticulous and multifaceted, reflecting the complexity of the problem and the sophistication of the proposed solution. This section outlines the methodological framework and steps taken to ensure the research is robust, reliable, and relevant to the current challenges in telecommunication security.

### *A. Related Works*

In the 6G era that will arrive in the 2030s, security technology will become very important for communication systems. Trust must be guaranteed across IoT, heterogeneous clouds, networks, devices, sub-networks, and applications. Threats to 6G will be defined by the disintegration of the 6G architecture, open interfaces, and multi-stakeholder environments. In general, these security technologies can be divided into the domains of cyber resilience, privacy, and trust, along with their intersections. Some relevant security technologies include automated software generation, automated closed security operations, privacy-preserving technologies, trust anchors integrated with hardware and cloud, secure security against quantum attacks, intrusion protection and physical layer security, and distributed ledger technology. Artificial intelligence and machine learning will be key drivers across security technology stacks and architectures. A new vision for a trustworthy Secure Telecommunications Operations Map was developed as part of the automated closed operations paradigm [12].

The use of SVM to predict the optimal time and location for maximum Wi-Fi coverage in energy harvesting. Integrating machine learning with radio frequency energy harvesting systems, this approach significantly enhances the efficiency of the proposed rectenna, particularly in harvesting energy from wireless routers and access points. Experiments have demonstrated that the SVM-based framework is capable of accurately predicting the time and location of peak Wi-Fi coverage, which forms the foundation of a scheduling mechanism for targeted harvesting of Wi-Fi signals [13].

In the field of network security, intrusion detection systems (IDS) have an important role [14], [15]. Various techniques, including SVM, have been applied to detect intrusions. However, many methods attempt to improve the original SVM whose performance is highly dependent on its kernel parameters. Evolutionary algorithms such as genetic algorithm (GA) and particle swarm algorithm (PSO) are also used to find better kernel parameters [15], while traditional optimization methods are vulnerable to getting stuck in local minima with slow convergence speed. To improve the precision of SVM in intrusion detection, this paper supports a grasshopper optimization algorithm-based support vector machine (Grasshopper Optimization Algorithm, GOA-SVM). Several contrast experiments have been carried out using Matlab tools to verify the practicality of the proposed method. The experimental results finally demonstrate the superior performance of the proposed method in intrusion detection [16].

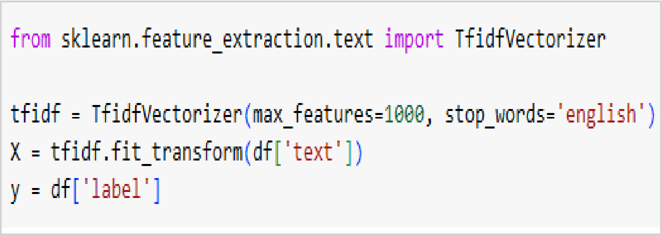
### *B. Identification of the Problem and Data Collection*

This research commenced with the identification of a burgeoning issue in society the rise in voice call fraud [17]. A phenomenon increasingly prevalent, it necessitates a deeper understanding through observation and in-depth discussions. These preliminary stages were crucial in dissecting the various facets of the problem, leading to an evident need for an effective technological solution. This initial phase was not only about recognizing the growing trend of telephonic deceit but also about understanding its impact on individuals and society at large. The next pivotal step in this research involved the meticulous collection of a dataset. This dataset comprised voice recordings of telephone conversations, specifically curated to include a diverse array of sentences typically employed by fraudsters. These recordings were amassed from a variety of sources, ensuring a comprehensive collection that encapsulates the broad spectrum of fraudulent communication tactics. The sources ranged from publicly available recordings on the internet to personal experiences where the researchers themselves or their acquaintances might have been potential targets of such frauds.

This extensive data gathering aimed to encompass as wide a variety of conversational contexts as possible. By doing so, the dataset could accurately represent the real-life scenarios encountered by the general populace when faced with voice call fraud. The diversity in the dataset was not limited to the variety of fraud tactics but also extended to include different dialects, speech patterns, and varying levels of audio quality. This variation was essential in developing a robust and versatile model capable of detecting fraud in a multitude of situations. In ensuring the dataset's comprehensiveness, special attention was paid to include both subtle and overt indicators of fraud. This included analyzing the common phrases used by scammers, their speech cadence, and any psychological tactics embedded in their communication. The goal was to create a dataset that was not only varied in terms of the types of fraud represented but also rich in its portrayal of the intricacies involved in fraudulent calls. Furthermore, the collected data was also a reflection of the evolving nature of telephonic fraud. As scammers continuously adapt their strategies to bypass security measures and exploit new vulnerabilities, the dataset has to be dynamic and reflective of current trends. This real-time relevance was key to ensuring that the developed solution would be effective against not only known fraudulent strategies but also emerging ones. Overall, the process of identifying the problem and collecting data was a foundational aspect of this research. It involved not only the technicalities of amassing and analyzing voice recordings but also a nuanced understanding of the social and psychological dimensions of voice call fraud. By building a dataset that was diverse, comprehensive, and current, the research laid the groundwork for developing a technologically advanced solution capable of effectively combating the ever-evolving menace of voice call fraud.

### C. *Data Pre-processing*

Following the comprehensive dataset collection, the next crucial phase in this research was data pre-processing. This phase involved the transcription of voice recordings into text format and subsequent data cleansing. The primary objective of this process was to convert the auditory information into a consistent, noise-free textual format, thereby facilitating more in-depth analysis. This step was pivotal in preparing the data for the development of an AI model. The transcription process required meticulous attention to detail, as it involved transforming various nuances of spoken language, including dialects, accents, and speech idiosyncrasies, into a standardized textual format. This process ensured that the textual data retained the essence of the original voice recordings, including the subtle cues that might indicate fraudulent intent. Moreover, the cleansing of this transcribed data was equally important. It involved the removal of irrelevant or extraneous information that could potentially skew the analysis. This cleansing process aimed to refine the data, ensuring that it was primed for effective machine learning algorithm training. With the data pre-processed, the focus shifted to the development of the AI model. The model was constructed using the algorithm, chosen for its proven effectiveness in text classification and its high level of accuracy. SVM is renowned for its ability to handle high-dimensional data and its versatility in managing both linear and non-linear relationships within data sets. This made it an ideal choice for this research, where the complexity and variability of the data required a robust and adaptable algorithm.



```python
from sklearn.feature_extraction.text import TfidfVectorizer

tfidf = TfidfVectorizer(max_features=1000, stop_words='english')
X = tfidf.fit_transform(df['text'])
y = df['label']
```

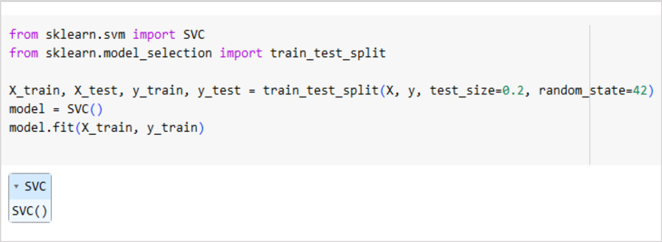
Fig. 1. Term frequency-inverse document frequency.

The image displays a segment of code that is part of the data preparation stage in the context of a machine-learning workflow aimed at enhancing telecommunication security (Fig. 1). The code involves the conversion of text data into a format that can be understood and utilized by machine learning algorithms. In the process shown, the textual data is transformed into a numerical format using a method called TF-IDF, which stands for "Term Frequency-Inverse Document Frequency". This method evaluates how important a word is to a document in a collection of documents. The importance increases proportionally to the number of times a word appears in the document but is offset by the frequency of the word in the corpus.

The machine learning model was designed to identify potential indicators of fraud within the processed dataset. This involved training the model to recognize patterns and anomalies in the text that were characteristic of fraudulent communication. The process was not straightforward, as it required the model to discern subtle linguistic and semantic patterns that could differentiate fraudulent from legitimate communication. One of the critical aspects of training the SVM model was the selection and tuning of its hyperparameters. This involved determining the right kernel, regularization, and margin parameters, which are crucial in defining how the SVM algorithm learns from the data. The goal was to find the optimal balance that would enable the model to accurately classify texts without overfitting to the training data. Another significant aspect of the model development was the implementation of feature engineering techniques. This step involved extracting meaningful features from the text data that would be most indicative of fraudulent activity. Techniques such as term frequency-inverse document frequency (TF-IDF) were employed to quantify the importance of specific words or phrases in the context of the entire dataset. This quantitative approach allowed the SVM model [16], [17] to effectively weigh the significance of various textual elements in predicting fraud. the data pre-processing and AI model development phase was a multifaceted process that required a blend of technical expertise and analytical acumen. From converting voice recordings into a clean, usable text format to training a sophisticated SVM algorithm to detect fraud, this phase was foundational in building an AI model capable of accurately identifying potential voice call frauds. The success of this phase was instrumental in setting the stage for the subsequent steps of the research, where the model would be further refined, evaluated, and eventually tested for its effectiveness in combating voice call fraud.

### *D. Training, Evaluation, and Refinement of the Model*

Following the data pre-processing phase, the dataset was strategically partitioned into training and testing sets using the 'train_test_split' module from the scikit-learn library [18]. This split was executed with an 80:20 ratio, aligning with machine learning standards to provide a balanced approach to model training and validation. The larger portion, the training data, was utilized to teach the Support SVM model the intricate patterns and characteristics present within the dataset.



```
from sklearn.svm import SVC
from sklearn.model_selection import train_test_split

X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2, random_state=42)
model = SVC()
model.fit(X_train, y_train)
```

```
▾ SVC
SVC()
```

Fig. 2. Process machine learning model trained.

The image shows a process where a machine learning model is being trained to enhance telecommunication security by detecting potential fraud in voice calls. In this phase of the research, the model, which is based on SVM technology, is provided with a large amount of data that it will learn from (Fig. 2). This data has been split into two parts: one part for the model to learn from, and another to test the model's knowledge. The ultimate goal is for the model to be able to accurately identify fraudulent activities in telecommunications by recognizing patterns and anomalies that are characteristic of such fraud.

Training the SVM model was a critical step in the research process [19], [20]. During this phase, the model was exposed to a wide array of data samples representing both fraudulent and legitimate voice call scenarios. This exposure allowed the SVM to learn and understand the distinguishing features of fraudulent calls, a process akin to an experienced investigator identifying tell-tale signs of deception. The algorithm, through its training, developed a nuanced understanding of how different textual elements, derived from the voice transcripts, correlated with fraudulent activities. Upon the completion of the training phase, the model underwent rigorous testing to assess its accuracy and generalizability. This testing phase was crucial, as it provided insights into how well the model could apply its learned patterns to new, unseen data – a critical measure of its practical applicability. The initial evaluation yielded an accuracy rate of 81%, a promising but not yet optimal result. In the context of fraud detection, where the stakes involve safeguarding individuals' security and well-being, the demand for higher accuracy was paramount.

To enhance the model's accuracy, a series of refinements were undertaken. These refinements included augmenting the dataset with additional data samples, thereby providing the model with a broader base of information for learning. This expansion of the dataset was targeted to cover a wider array of fraudulent tactics and communication styles, ensuring that the model's learning was not confined to a limited set of patterns. Furthermore, advanced text pre-processing techniques were applied to the new data. These techniques involved more sophisticated methods of cleaning and preparing the text, thus enhancing the quality and reliability of the input data fed into the model. The refined model was then retrained and retested. Each iteration of training and testing was an opportunity to fine-tune the SVM's parameters and adapt its learning to the enriched dataset. The result of these iterative refinements was a marked improvement in the model's accuracy. This increase not only signified the model's enhanced ability to detect fraudulent calls but also its strengthened capability to generalize across various scenarios, a key factor in its real-world application.

In summary, the training, evaluation, and refinement of the model were iterative and dynamic processes. They involved a careful balancing act between training the model on a diverse and representative dataset and fine-tuning it to achieve optimal performance. The advancements made in each step of this phase were indicative of the model's growing sophistication and its potential as a robust tool in the fight against voice call fraud. The research thus marked a significant stride forward in leveraging artificial intelligence and machine learning to provide tangible solutions to real-world problems.

### *E. Model Persistence and Final Testing*

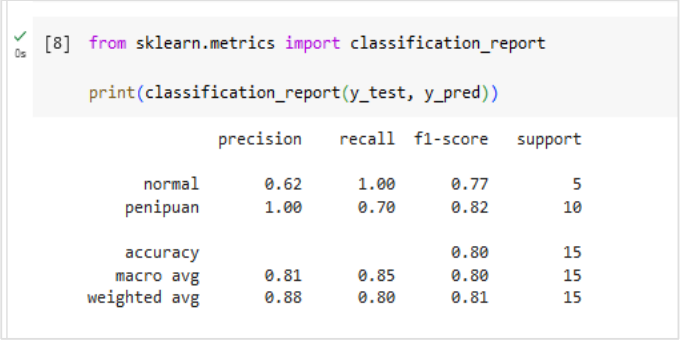
After the successful development and training of the Support SVM model and the TF-IDF Vectorizer [21], an important step in ensuring the longevity and usability of these tools was their persistence. This was achieved using the joblib module, a utility known for its efficiency in saving and loading Python objects. By persisting the trained models, we ensured their future usability without the need for retraining, a crucial aspect in practical applications. This approach significantly reduces the computational cost and time associated with deploying the model in real-world scenarios, making the system more agile and responsive. Persisting the models was not just a matter of convenience but also a strategic move to facilitate seamless integration into various applications or production environments. In the context of our research, it meant that the developed models could be readily incorporated into call screening applications, customer service systems, or any other telecommunication platform where fraud detection is paramount. This flexibility in deployment is key to the widespread adoption and utility of the model. Once the models were securely saved, the final phase of testing commenced. This stage was crucial for assessing the real-world efficacy of the system. The final testing involved a comprehensive evaluation of the model's performance in detecting fraudulent sentences, using metrics such as precision, recall, and the f1-score. Precision measures the model's accuracy in identifying true positives (actual fraudulent cases), recall evaluates the model's ability to capture all potential fraud cases, and the f1-score [19] provides a harmonic mean of precision and recall, offering a balanced view of the model's overall performance. This in-depth analysis offered valuable insights into the model's reliability across diverse testing scenarios. By employing a wide range of test cases, including nuanced and sophisticated instances of potential fraud, the testing phase mimicked real-world conditions as closely as possible. This rigorous evaluation helped in identifying any shortcomings or biases in the model, ensuring that the final product was not only accurate but also fair and unbiased in its predictions.

The testing phase also served as a final verification of the model's ability to generalize. The ability to perform well on unseen data is a litmus test for any machine learning model [22], indicative of its practical applicability. The evaluation metrics were carefully analyzed, and the results indicated a high level of accuracy and reliability in fraud detection. These results were a testament to the effectiveness of the SVM and the TF-IDF Vectorizer in capturing the complex patterns and nuances of fraudulent communication. the model persistence and final testing phases were critical in transforming our research into a viable tool for combating voice call fraud. The process of saving and efficiently deploying the model, coupled with rigorous final testing, ensured that the system was not only theoretically sound but also practically effective. This comprehensive approach, from model development to final deployment, underscores the potential of AI and machine learning in addressing real-world challenges, offering innovative solutions to longstanding problems like telecommunication fraud. The success of these phases marks a significant achievement in the field of AI-driven security solutions [23], paving the way for more secure and reliable communication networks.

## III. Results and Discussion

The SVM model is initialized using Scikit-Learn's SVC class and trained with the training data. This training process allows the model to learn patterns and relationships in the data, especially following the numerical representation of text through the TF-IDF process. The trained SVM model [24] is then put through evaluation using the test data to measure its performance, a crucial step in assessing its generalization capabilities on unseen data. The initial evaluation of the model revealed an accuracy of 81%, which was deemed insufficient for the intended application design. Therefore, efforts to enhance the model were undertaken, specifically focusing on the text preprocessing stage (stemming). Before reprocessing the text, the dataset was expanded with an additional 30 entries, evenly split between normal and fraudulent labels. This was followed by the incorporation of the NLTK library to facilitate the stemming process.

The steaming function, perform stemming, implemented in Python using the Porter algorithm, tokenizes the input text using the NLTK module and performs stemming on each word token. The stemmed words are then reassembled into a processed text. This process aims to standardize the text's words to their root forms, enhancing consistency in text analysis (Fig. 3).



```
[8] from sklearn.metrics import classification_report

    print(classification_report(y_test, y_pred))
```

```
              precision    recall  f1-score   support

      normal       0.62      1.00      0.77         5
    penipuan       1.00      0.70      0.82        10

    accuracy                           0.80        15
   macro avg       0.81      0.85      0.80        15
weighted avg       0.88      0.80      0.81        15
```

Fig. 3. Experimental accuracy.

After these improvements, the model was retrained, resulting in an increased accuracy rate of 86%. The chapter provides a comparative table illustrating the differences between the initial and improved models. The final model, with a precision of 73% and an accuracy of 86%, shows a 6% improvement in accuracy, indicating its suitability for the next stage of application design. This chapter highlights the importance of iterative refinement and adjustments in developing effective machine learning models.

### A. *Model Persistence*

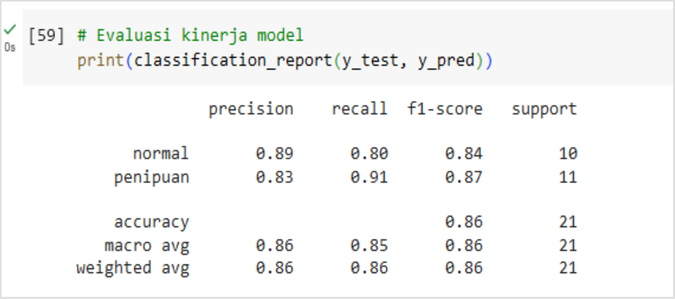
Following the successful development and training of the SVM model and TF-IDF vectorizer [25], the subsequent stage involves their preservation. This step is essential to maintaining the integrity of the trained model and the numerical representation of text generated via TF-IDF.

Subsequently, the generated TF-IDF Vectorizer is also saved using the dump function in a 'tfidf.pkl' file. The presence of the TF-IDF vectorizer is crucial for converting new text into a numerical representation that can be quickly and efficiently utilized by the model. This step provides the necessary flexibility, allowing the model to be applied to new data without repeating the entire training and preprocessing process. This storage process is a critical step in the context of application development or model deployment in a production environment, where the model will be integrated into the development of a web Application Programming Interface.

These systematic steps outlined in the creation of an artificial intelligence model aimed at detecting fraudulent statements reflect how the combination of text processing techniques and machine learning algorithms can produce an effective solution for tackling fraud detection through text analysis.

### B. *Final Testing and Evaluation*

Upon successful development and storage of the machine learning model with the desired accuracy, the next step is the evaluation of the model's performance in detecting fraudulent sentences. This evaluation is crucial to ensuring the model generalizes its learning effectively, especially on previously unprocessed test data.



```

```

Fig. 4. The machine learning model testing results.

Fig. 4 effectively presents the testing findings of the machine learning model, displaying a comprehensive table that illustrates precision, recall, and f1-score for both normal and fraudulent categories. This table not only demonstrates the model's subtle categorization abilities but also highlights an amazing overall accuracy of 86%. This level of intricacy in the outcomes offers a full comprehension of the model's effectiveness in distinguishing between typical and deceptive instances, emphasizing its resilience and dependability in a practical application situation. The table functions as an essential instrument for analyzing the model's effectiveness, providing a detailed perspective on its advantages and opportunities for enhancement in subsequent iterations.

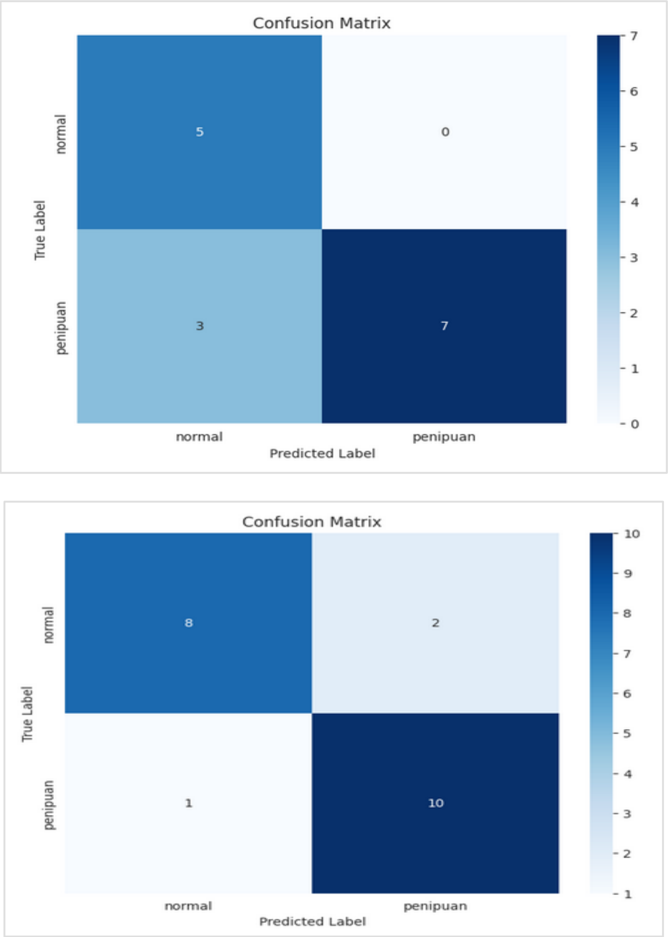

Fig. 5. Confusion matrix comparison.

The representation of the machine learning model's test results in Fig. 5, which differentiates between normal and fraudulent phrases, is an essential instrument for comprehending its evaluation across several metrics. The visual depiction streamlines the intricacies of the model's functioning, augmenting the lucidity of its possibilities. In addition, the examination of confusion matrices from two distinct experiments provides insight into the model's subtle capacity to distinguish between regular and deceptive occurrences. This comprehensive assessment enhances the comprehension of the reliability of the machine learning model, highlighting its accuracy under diverse testing conditions. The model exhibits a significant level of precision and dependability, suggesting its potential efficacy in practical fraud detection situations. This meticulous and thorough evaluation guarantees a comprehensive comprehension of the model's advantages and prospective areas for enhancement, establishing its position as a reliable instrument for detecting fraudulent activity.

### C. *Implementation Model for Mobile Applications*

In the development phase of the API, Flask is utilized as the primary framework, employing the Python programming language. Flask was chosen as the main framework due to its advantages as a lightweight, flexible, and easily understandable framework. These attributes make it an exceptionally suitable choice for developing APIs for small to medium-scale projects. The design of this API aims to produce an endpoint that will be used to receive requests from the mobile application and integrate the AI model into this endpoint to deliver predictions based on the data received.

In the development of the mobile application, integrating it with an API, processing data, and ensuring a responsive user interface are critical components. For this Flutter-based application, we utilized several packages to support key functionalities. Here's an overview of the primary dependencies implemented:

*1) http:* This package facilitates communication with the AI model's connected API. It enables the application to easily send requests and receive responses from the server, streamlining the interaction between the mobile application and the backend system.

*2) Provider:* Employed for efficient state management within the application. The Provider package simplifies maintaining and accessing the application's state, including managing the AI model's prediction outcomes.

*3) flutter_bloc:* Utilized for implementing the Bloc architecture for application state management. Bloc assists in organizing the application's logic, including aspects related to AI model integration, by segregating the application into manageable components, thus improving maintainability and scalability.

*4) Dio:* A powerful and user-friendly package for making HTTP requests to the API server. Dio offers advanced functionalities for interacting with the backend, enhancing the efficiency and reliability of server communications.

*5) flutter_spinkit:* Provides attractive loading animations while the application communicates with the backend or processes data. This package helps improve user engagement by displaying visually appealing animations during loading times, thus enhancing the overall user experience.

*6) intl:* Utilized for date and time formatting to match user preferences. It ensures that date and time representations are responsive and easily readable within the application, catering to a global audience by accommodating different locales.

### *D. Testing Process*

The testing process through the API plays a crucial role in ensuring the reliability and availability of the model within the designed application environment. Postman, a software dedicated to API testing, will be utilized to assess the AI model's capability in detecting sentences indicative of fraud.

The model, developed using Flask, generates an API endpoint '/voice_predict' designed to receive textual input, process it through the trained AI model, and return the prediction outcome as a response in JSON format. During this phase, testing involves submitting potentially fraudulent text to the API. The anticipated prediction outcomes are labeled 'fraudulent' and 'normal'. Utilizing Postman, it is expected that the AI model will provide consistent and accurate responses in identifying sentences with fraudulent indications.

Users can submit voice recordings through Postman in the form of form data, with the file type specified as 'voice'. The API then processes this voice input, converts it into text, and carries out predictions regarding potential fraud indicators. The prediction results are returned in the JSON response format. During the API integration testing, the primary focus is on ensuring the application can connect to the API without errors and verifying that responses from the API are accurately received. The process of sending voice data to the API proceeds smoothly and is contingent upon the quality of the user's internet connection. This testing provides assurance that the application can transmit user voice data to the designated API endpoint every six seconds, in accordance with the predefined configuration. The outcomes of this API integration testing reflect the availability and reliability of communication between the mobile application and the backend API, which are critical elements in the functionality of voice fraud detection.

## IV. Conclusion

This study represents a substantial advancement in the fight against the growing menace of voice call fraud, a challenge amplified by the rapid expansion of telecommunications and its accompanying vulnerabilities. At the heart of this endeavor was the development of a sophisticated system designed to identify fraudulent patterns in voice communications, leveraging the robust capabilities of support vector machines in conjunction with artificial intelligence and machine learning techniques. Our journey commenced with an in-depth analysis of the societal impacts of voice call fraud, highlighting the urgent need for mechanisms capable of providing early warnings to potential victims of deceptive communications.

The foundation of this research was the compilation of a diverse dataset, derived from various sources to capture the complex nature of voice call fraud. This dataset, rich in phrases frequently used by fraudsters, was instrumental in the subsequent phases of system development. A critical step in this process involved transforming the audio data into text, utilizing voice-to-text technology, followed by meticulous pre-processing to ensure the data was optimized for machine learning applications. The employment of the SVM algorithm was a strategic choice, motivated by its exceptional efficacy in text classification and pattern recognition, which are crucial for detecting fraudulent intent. The SVM model underwent extensive training and fine-tuning, achieving an initial accuracy of 81%. Further refinements, including the addition of data and the implementation of advanced pre-processing techniques like stemming, significantly enhanced the model's accuracy to 86%. The model's longevity and adaptability were ensured through its persistence using the joblib module, facilitating seamless deployment across various platforms without the need for retraining.

In the final phase of testing, the system demonstrated its capability to accurately differentiate between legitimate and fraudulent calls, achieving commendable precision, recall, and f1-score metrics. This evaluation confirmed the system's effectiveness and its potential to significantly impact the security of telecommunications by protecting individuals from fraud. In conclusion, this research marks a critical step forward in harnessing the power of machine learning to address a significant societal challenge—voice call fraud. By developing a system that effectively learns and adapts to the evolving tactics of fraudsters, we have laid the groundwork for a safer telecommunications environment. This study not only tackles current security challenges but also sets the stage for future advancements, reflecting a commitment to utilizing cutting-edge technology for societal benefit and ensuring a secure digital future for Indonesia.

***Abstract*—Over the last decade, Virtual Reality (VR) and Augmented Reality (AR) have gained popularity across various industries, particularly the arts, thanks to technological advances and inexpensive hardware and software availability. These technologies have redefined the boundaries of creativity and immersive experiences in artistic expression. This paper explores the dynamic interface between AR, VR, and the diverse Information Technology (IT) landscape. In this context, AR augments the physical world with digital overlays, while VR places users in fully simulated environments. This paper discusses these technologies in detail, including their basic concepts and hardware and software components. This survey examines how AR and VR can positively impact artistic fields such as virtual art galleries, augmented public installations, and innovative theatrical performances. We discuss limitations in hardware, software development, user experience, and ethical considerations. Further, we emphasize collaboration possibilities, accessibility, and inclusivity to probe AR and VR's profound impact on artistic creativity. The paper illustrates the transformative power of these technologies through case studies and noteworthy projects. Finally, future trends are outlined, highlighting advancements, emerging artistic forms, and social and cultural implications.**

***Keywords—Virtual reality; augmented reality; artistic expression; emerging technologies; immersive experiences***

## I. Introduction

The growing interest in Virtual Reality (VR) and Augmented Reality (AR) technologies is mainly driven by the availability of new immersive platforms like Microsoft HoloLens and Oculus Rift and lower-cost standalone solutions like Oculus Quest [1, 2]. Furthermore, a growing number of frameworks aim to streamline the development of VR/AR reality for the web [3]. These frameworks also allow for seamless integration with major game engines through plugins, and they can even be directly integrated into the operating systems of mobile platforms, similar to what Apple has done [4]. The human fascination with simulating reality has a long history, originating from research and development in the mid-20th century [5]. However, its roots can be traced back even further, as it has been evident in fiction since the 1930s and has been a subject of philosophical thought much earlier when the nature of perceived reality was called into question [6]. The latest developments in more affordable and realistic virtual and AR technologies, which offer improved image quality, reduced delay, and faster image rendering, generate anticipation for broader use in simulating experiences and enhancing reality [7]. These advancements liberate us from the limitations of tangible environments and the established laws of physics, enabling a variety of experimental uses in gaming, filmmaking, social networks, and particularly in education [8].

Integrating VR and AR with artistic expression has significantly changed the field of creative activities in recent years [9]. VR allows users to engage fully with computer-generated settings. At the same time, AR superimposes digital components into the real world, thus transforming the conventional concepts of artistic expression [10]. This review paper aims to explore the complex relationship between immersive technologies and the field of computer engineering as we enter a period of significant technical advancements. The fusion of digital and physical domains has created new and unparalleled opportunities for creative experimentation, pushing the boundaries of traditional concepts of space, shape, and interaction [11].

In light of this context, this study deeply explores the fundamental principles, intricate hardware, and software elements that form the foundation of VR and AR technologies. Our goal is to give a contextual framework for comprehending the enormous influence of immersive technologies on artistic expression by clarifying their current condition. The artistic sector is experiencing a multitude of disruptive uses of VR and AR. These range from virtual art exhibitions and enhanced public installations to revolutionary performances in theater and dance. This article explores the many applications of these technologies, highlighting the creative methods artists utilize to provide immersive and interactive experiences. Nevertheless, incorporating VR and AR in artistic expression is not devoid of challenges. Exploration is required to overcome hardware limits, complex software development, and ethical issues. Through careful analysis of these issues, we aim to provide valuable insights into possible solutions and effective tactics for overcoming hurdles, creating a favorable atmosphere for the further development of these technologies.

This research utilizes a thorough review and analytical technique to investigate the influence of VR and AR on artistic expression. The study employs a qualitative methodology to

*Corresponding Author

investigate multiple aspects of AR and VR technologies in relation to creative production and immersive encounters. The data for this research is sourced from a diverse range of scientific papers, academic journals, conference proceedings, technical reports, case studies, and pertinent literature in the domains of computer science, art, and technology. Furthermore, data is gathered from credible web sources, industry journals, and official documentation provided by AR and VR technology developers. The collected data will undergo thematic analysis approaches to discover prominent themes, trends, and insights pertaining to the use of AR and VR in creative expression. Thematic analysis is a methodical procedure of assigning codes and classifying data in order to identify significant patterns and meanings.

When examining AR and VR applications in creative expression, particular emphasis is placed on the preparation of immersive settings. This involves the establishment and arrangement of AR and VR hardware and software elements, such as headgear, motion tracking systems, input devices, and content development tools. Artistic aims are optimized by giving special regard to variables such as space layout, lighting conditions, sound design, and user interaction methods in order to enhance the immersive experience. The research findings are guaranteed to be valid by a meticulous data validation procedure. This involves cross-referencing data from many sources, analyzing information from numerous viewpoints, and seeking advice from specialists in AR, VR, and artistic representation. Furthermore, rigorous analyses and evaluations by experts play a crucial role in confirming the validity of research findings and guaranteeing the trustworthiness and authenticity of study results.

The paper is organized into four primary parts. Section II offers crucial background information on VR and AR technologies, which lays the foundation for comprehending their use in creative expression. Section III examines the various manners in which VR and AR are transforming the creative field. Section IV provides a comprehensive overview of emerging and developing patterns and prospective progressions in the subject. Section V provides a concise overview of the main discoveries and their significance.

## II. BACKGROUNDS

VR and AR are crucial in virtual prototyping since they operate as user-friendly interfaces for exploring virtual design areas and evaluating new product functionality through interactive means [12]. VR encompasses an entirely computer-generated, three-dimensional environment that allows engineers to interact with and control a realistic depiction of the product in real-time [13]. AR goes beyond by augmenting the user's vision with virtual items deliberately positioned to align with the user's perspective [14]. VR technology's essential features encompass accurately depicting product attributes such as look, material, surface, and colors. Additionally, modern display technologies provide a genuine virtual prototype experience [15].

Projection-based display systems are frequently used in industrial VR applications, where they incorporate several projections arranged in various configurations. To navigate and manipulate 3D objects in VR, specialized devices such as 3D mice, 3D wands, or gloves are necessary [16]. These devices are backed by 3D-position tracking systems, which accurately estimate the user's location and orientation within the virtual world [17]. However, AR technology encounters the obstacle of effectively merging real-world components with computer-generated items inside the user's visual perspective. To do this, a system must be able to track the user's position in the real world in real-time and consider the context. This allows the AR system to accurately identify how virtual items should be shown, their size, and their position inside the user's field of view [18].

### *A. Fundamental Concepts*

VR and AR technologies are based on core principles that fundamentally alter users' perception and interaction with their environment [19]. Table I presents the fundamental concepts distinguishing VR and AR technologies. VR is based on total immersion, where users are transported to computer-generated settings via headgear and sensory feedback devices [20]. The essential components comprise stereoscopic displays, tracking sensors, and motion controllers, which collaborate to provide a comprehensive encounter that eliminates the user's skepticism and cultivates a profound feeling of being there in the virtual realm. The notion of presence, which refers to the sensation of being physically situated within a computer-generated world, is a fundamental aspect of VR technology. It significantly influences how users interact with the digital realm.

TABLE I. FUNDAMENTAL CONCEPTS DISTINGUISHING VR AND AR TECHNOLOGIES

| Concepts | VR | AR |
|---|---|---|
| Immersion | Complete immersion in computer-generated environments. | Overlay of digital content into the real-world environment. |
| Presence | A feeling of being physically present in a virtual space. | Enhancement of real-world experiences with virtual elements. |
| Hardware components | Headsets, motion controllers, and sensory feedback. | Cameras, sensors, and display technologies. |
| Display technology | Stereoscopic displays provide a 3D visual experience. | Transparent displays or device screens for overlaying content. |
| Tracking Systems | Sensors tracking head and body movements for immersion. | Markerless tracking and spatial recognition for real-world integration. |
| Interactivity | User interaction within the virtual environment. | Interaction with virtual elements superimposed on the real world. |
| Mixed Reality | Fully immersive experiences within a virtual environment. | Integration of virtual and physical elements for mixed-reality experiences. |
| Field of view | Encompassing the user's visual perception in the virtual space. | Overlaying virtual content within the user's real-world field of view. |
| Application focus | Entertainment, training simulations, and virtual experiences. | Contextual information, navigation assistance, and interactive experiences in real-world scenarios. |
| User experience | Aims for a complete suspension of disbelief and presence. | Enhances real-world experiences by providing additional digital information. |

### B. Hardware and Software Components

VR and AR technologies utilize advanced hardware and software components to provide immersive and interactive experiences [21]. Table II comprehensively compares the hardware and software elements that differentiate VR and AR technologies. Within the VR domain, the hardware is distinguished by Head-Mounted Displays (HMDs), motion controllers, and a range of sensors. HMDs are crucial in providing users with a 3D visual experience by utilizing high-resolution stereoscopic displays. Motion controllers and sensors facilitate user interaction with the virtual realm by converting physical movements into digital commands. Tracking devices, such as external cameras or infrared sensors, observe and record the user's head and body motions, guaranteeing a smooth and quick VR experience. In addition, haptic feedback devices boost immersion by delivering tactile sensations, enabling users to perceive and engage with virtual items through touch. VR applications need advanced rendering engines on the software side to provide lifelike visuals and 3D environments. Immersive audio technology also contributes to the entire experience by producing a spatial soundscape that increases the sensation of presence.

TABLE II. HARDWARE AND SOFTWARE COMPONENTS IN VR AD AR

| Components | VR | AR |
|---|---|---|
| Head-mounted displays | HMDs with stereoscopic displays for 3D visual immersion. | AR glasses, smart glasses, or smartphones with display screens. |
| Motion controllers | Devices enabling user interaction in the virtual environment. | Gesture recognition in AR glasses or touch input on smartphones. |
| Sensors | Tracking sensors for monitoring head and body movements. | Cameras and sensors for capturing real-world environments. |
| Haptic feedback devices | Devices provide tactile sensations for enhanced immersion. | Not as prevalent but may include vibration feedback in smartphones. |
| Cameras | External cameras for positional tracking in VR. | Onboard cameras for capturing real-world scenes in AR. |
| Rendering engines | Software for creating realistic graphics and 3D environments in VR. | Algorithms for overlaying digital content onto the real-world in AR. |
| Spatial audio technologies | Immersive audio systems enhance the sense of presence. | Simulated spatial audio for more immersive real-world interactions. |
| Tracking Systems | Algorithms for tracking head and body movements in VR. | Markerless tracking algorithms and spatial recognition in AR. |
| Image recognition | Not as prevalent but may be used for object recognition in VR. | Essential for recognizing and interacting with real-world objects in AR. |
| Environmental mapping | Limited in VR but may be used for specific applications. | Fundamental for understanding and mapping the user's real-world surroundings in AR. |
| Gesture recognition | Limited in VR but may be used for specific applications. | Crucial for interpreting and responding to gestures in AR. |
| Cloud computing | It may be utilized for complex graphics rendering in VR. | Often used for real-time processing and delivering dynamic AR content. |

AR, in contrast, combines digital aspects with the user's surroundings, requiring distinct hardware and software components. AR hardware often comprises smartphones, AR glasses, or smart glasses equipped with cameras and sensors. These gadgets utilize sensors to record the user's immediate environment and superimpose digital information onto the physical world in real-time [22]. Cameras are essential in AR, since they provide the necessary visual input for markerless tracking and location identification. The software components of AR encompass intricate algorithms for tasks such as picture identification, contextual mapping, and gesture detection. AR applications frequently utilize cloud computing to provide real-time processing, allowing for dynamic and contextually appropriate information to be distributed. Contrary to VR, AR uses the user's current gear, rendering it more accessible and versatile for various situations, such as aiding in navigation or providing interactive gaming encounters.

### C. Current State of VR and AR Technologies

VR and AR technologies have achieved exceptional progress, with notable advancements in hardware and software. Within VR, headsets have become increasingly attainable, providing superior resolutions, expanded field of vision, and enhanced tracking capabilities. The use of haptic feedback devices has enhanced the feeling of being fully engaged, enabling users to experience and engage with virtual surroundings more concretely physically. Furthermore, VR content has expanded into a wide range of industries, such as gaming, healthcare, education, and workplace training, demonstrating the flexibility and practicality of these technologies. The increasing number of VR applications has been made possible by improvements in rendering engines and spatial audio technology, resulting in the development of virtual experiences that are more lifelike and captivating.

Simultaneously, the AR domain has progressed, influenced mainly by the widespread use of smartphones and the advancement of AR glasses. The present condition of AR is characterized by increased user experiences achieved by advancements in picture identification, more precise spatial mapping, and the utilization of gesture recognition technologies. Prominent technology corporations have made substantial financial commitments to AR, unveiling cutting-edge applications that span from immersive retail experiences to guidance in navigation. AR has shown to be helpful in practical applications within industrial environments, namely in areas such as maintenance, design visualization, and remote help. The present condition of both VR and AR demonstrates a flourishing environment of originality, with continuous exploration and progress indicating even more significant breakthroughs in the imminent future. Incorporating these technologies into daily life and different sectors highlights their capacity to fundamentally alter our understanding and engagement with the digital and physical realms.

## III. VR AND AR APPLICATIONS IN ARTISTIC EXPRESSION

This section explores the diverse applications of VR and AR in the realm of artistic expression. Each subsection unveils a unique facet of how these immersive technologies have revolutionized the art world. Tables III to IX summarizes the aspects covered in each application.

The aspects of immersive virtual art galleries in VR and AR are outlined in Table III, detailing the concept, features, user experience, customization, accessibility and inclusivity, and future potential of these technologies. Table IV outlines augmented public installations in AR and VR, describing the concept, features, user experience, accessibility and inclusivity, and future potential of incorporating dynamic and interactive components into real-world environments. Table V explains innovative theatrical performances in VR and AR, illustrating the concept, features, audience engagement, technological impact, interactivity and dynamics, and future potential of transformative storytelling experiences. In Table VI, virtual sculpture and 3D art creation in VR and AR are outlined, covering the concept, VR sculpture creation, AR integration, interactive and dynamic art, global collaboration, digital archiving, and future possibilities in digital sculpting. Table VII elaborates on mixed reality collaborations in VR and AR, delineating real-time global collaboration, interactive storytelling and performance, spatial collaboration in AR, cross-disciplinary exploration, accessibility and inclusivity, and future developments in digital collaboration. Table VIII delineates accessibility and inclusivity tools in VR and AR, addressing breaking physical barriers, audio descriptions and spatial navigation, multilingual and culturally diverse experiences, empowering diverse artistic voices, and future developments in enhancing inclusivity. Table IX outlines user experience enhancement in VR and AR, discussing spatial immersion and presence in VR, personalized exploration and interaction, haptic feedback and sensory engagement, interactive narratives and dynamic storytelling, enhanced accessibility and inclusive engagement, and future developments in immersive experiences.

TABLE III. IMMERSIVE VIRTUAL ART GALLERIES IN VR AND AR

| Aspect | Description |
|---|---|
| Concept | VR has revolutionized the art world by introducing immersive virtual art galleries. |
| Features | Dynamic display settings, replication of real-world gallery characteristics, interaction between light and shadow, architectural subtleties, and atmospheric replication |
| User experience | Heightened sensation of presence, engagement beyond traditional galleries, and personalized exploration |
| Customization | Tailoring exhibition environment, varied spatial arrangements, coherent sequence for visual exploration |
| Accessibility and inclusivity | Overcoming geographical limitations, democratization of art access, global community formation |
| Future potential | Collaborative exhibitions, experimental interactive installations, transformative power of technology |

TABLE IV. AUGMENTED PUBLIC INSTALLATIONS IN AR AND VR

| Aspect | Description |
|---|---|
| Concept | AR has revolutionized the notion of public art by incorporating dynamic and interactive components into real-world environments. |
| Features | Integration of digital artworks into physical spaces, seamless blending of real and virtual worlds, transformation of static street art into interactive experiences, and responsive installations |
| User experience | Engaging audience through interaction, viewers as active participants, democratization of art availability, and community involvement and shared experiences |
| Accessibility and inclusivity | Overcoming geographical limitations, accessibility through commonly available devices like smartphones, integration of art into daily life, democratization of public spaces as platforms for imaginative expression, and cultural engagement |
| Future potential | Continuous advancement of AR technology, transformative potential in reshaping public art experiences, and opportunities for new dimensions in artistic expression and community interaction |

TABLE V. INNOVATIVE THEATRICAL PERFORMANCES IN VR AND AR

| Aspect | Description |
|---|---|
| Concept | VR and AR have transformed theatrical performances, offering creative ways to tell stories and engage audiences. |
| Features | Immersive virtual theaters in VR, freedom in virtual stage design, global accessibility through VR headsets, AR enhancing live performances, and integration of virtual elements into real-world theatrical experiences |
| Audience engagement | Enhanced audience interaction and immersion in VR, virtual exploration of unconventional stage environments, influence on perspective within virtual theaters, and AR elements enhancing live shows |
| Technological impact | Overcoming physical limitations through VR, flexibility in stage design beyond real-world constraints, integration of real and virtual elements for dynamic storytelling, and advancements in AR for dynamic and seamless theatrical experiences |
| Interactivity and dynamics | Active audience engagement in VR narratives, dynamic storytelling with user influence, integration of AR for live performance enhancements, blurring boundaries between reality and fiction |
| Future potential | Ongoing evolution of VR and AR technologies, potential for more accessible and global theatrical experiences, exciting opportunities for innovative storytelling and immersive experiences, advancements in AR contributing to dynamic theatrical encounters |

TABLE VI. VIRTUAL SCULPTURE AND 3D ART CREATION IN VR AND AR

| Aspect | Description |
|---|---|
| Concept | The integration of VR and AR technologies has transformed the creation and presentation of sculptures, allowing artists to explore new dimensions and materials in a digital environment. |
| VR sculpture creation | Sculpting and molding in virtual 3D spaces, experimentation with forms beyond physical constraints, and immersive canvas for creativity unbound by traditional sculpting tools |
| AR integration | Real-world integration of virtual sculptures, viewing and interacting with digital sculptures in physical environments, and seamless blend of virtual and physical realms |
| Interactive and dynamic art | Dynamic and responsive sculptures in VR, interaction with virtual sculptures based on user input, and AR introducing interactive and adaptable sculptures |
| Global collaboration | Collaboration among artists from different locations in VR, synchronous cooperation in shared virtual spaces, and breaking down geographical barriers for collaborative sculptural projects |
| Digital archiving | Storage and preservation of digital replicas of sculptures, virtual recreation of physical sculptures for indefinite accessibility, and digital archiving ensuring the legacy and ongoing appreciation of sculptural works |
| Future possibilities | Continued development of VR technology, captivating opportunities for immersive virtual art encounters, |

| | |
|---|---|
| | collaborative exhibitions featuring artists worldwide, and pushing the boundaries of conventional sculptural forms through experimental interactive installations |

TABLE VII. MIXED REALITY COLLABORATIONS IN VR AND AR

| Aspect | Description |
|---|---|
| Concept | The integration of VR and AR technologies gives rise to mixed reality collaborations, unlocking unprecedented opportunities for artists to create and interact in shared digital environments, fostering a global creative community. |
| Real-time global collaboration | VR facilitates real-time collaboration in shared virtual spaces, artists from diverse locations engage simultaneously, overcoming geographical limitations, and fostering a global creative community |
| Interactive storytelling and performance | Extension beyond static artworks to interactive narratives, collaborative crafting of immersive stories, audience actively participates and influences the unfolding story, VR users navigating through dynamic digital domains, influencing the narrative trajectory |
| Spatial collaboration in AR | AR seamlessly integrating virtual elements into the physical world, artists wearing AR devices perceiving and interacting with digital content superimposed onto physical surroundings, and development of dynamic and responsive artworks blending with the real-world environment |
| Cross-disciplinary exploration | Integration of artists, designers, musicians, and performers, blurring boundaries between artistic disciplines in digital environments, creation of comprehensive and multimodal experiences, and promoting a more integrated and interconnected artistic landscape |
| Accessibility and inclusivity | Democratization of collaboration with artists from diverse backgrounds, inclusive participation in collaborative projects, enabling a richer tapestry of creative voices and perspectives, and driving innovation and pushing the boundaries of artistic expression in the digital age |
| Future developments | Expanding potential for collaborative and immersive artistic experiences, new dimensions in storytelling and creativity through mixed reality, and further integration of diverse artistic disciplines in digital collaborations |

TABLE VIII. ACCESSIBILITY AND INCLUSIVITY TOOLS IN VR AND AR

| Aspect | Description |
|---|---|
| Concept | VR and AR technologies play a crucial role in overcoming accessibility obstacles in the field of creative expression, guaranteeing that a wide range of audiences may actively participate in and admire art through novel means. |
| Breaking physical barriers | Overcoming physical obstacles to accessing traditional art venues and virtual platforms for individuals facing mobility challenges or residing in physically isolated regions |
| Audio descriptions and spatial navigation | AR enhancing experiences for individuals with visual impairments, audio descriptions providing comprehensive narrations of visual aspects, and spatial navigation aids such as auditory cues or haptic feedback for inclusive engagement |
| Multilingual and culturally diverse experiences | VR and AR facilitating multilingual and culturally varied art encounters, retrieval of content in preferred languages, and integration of diverse cultural elements into digital works, promoting a more comprehensive portrayal of worldwide artistic forms |
| Empowering diverse artistic voices | Providing accessible tools for diverse artists, utilization of VR sculpting or AR painting applications by artists with disabilities, contributions to a more inclusive realm of artistic expression, and enhancing the richness of creative voices and perspectives |
| Future developments | Continued advancements in VR and AR technologies, further innovations in adaptive tools for creative expression, expanding inclusivity and accessibility in the global artistic community, and shaping a future where art becomes a truly universal language for everyone to appreciate and engage with |

TABLE IX. USER EXPERIENCE ENHANCEMENT IN VR AND AR

| Aspect | Description |
|---|---|
| Concept | VR and AR technologies are leading the way in improving user experiences in artistic expression by providing immersive and interactive engagements that go beyond traditional limitations. |
| Spatial immersion and presence in VR | VR offering unparalleled spatial immersion, transporting users to virtual realms for three-dimensional art experiences, and enhanced feeling of presence within digitally created environments |
| Personalized exploration and interaction | Personalized journeys through VR galleries, user-controlled navigation through exhibitions, and AR installations allowing interaction with virtual elements overlaid onto physical surroundings |
| Haptic feedback and sensory engagement | Integration of haptic feedback devices in VR, adding tactile elements to user interactions, feeling textures, weights, and interacting with digital sculptures in a realistic manner |
| Interactive narratives and dynamic storytelling | Creation of interactive narratives in VR and AR, dynamic storytelling engaging users in real-time, active user participation influencing plot direction and interaction with virtual elements |
| Enhanced accessibility and inclusive engagement | Improving accessibility in VR and AR art interactions, users with diverse abilities navigating virtual spaces or interacting with augmented content, and making art accessible to a broader audience |
| Future developments | Further enhancements in immersive and interactive features, expanding inclusivity and accessibility in artistic engagement, and shaping a future where art becomes a more personalized, dynamic, and memorable experience for diverse audiences |

### A. *Immersive Virtual Art Galleries*

VR has revolutionized the art world by introducing immersive virtual art galleries, surpassing conventional art galleries' constraints [23]. Within these virtual spaces, artists and curators are liberated from the limitations of physical boundaries and spatial constraints, allowing for the development of vast and dynamic display settings. The digital nature of VR enables the precise replication of real-world gallery characteristics, including the interaction between light and shadow, architectural subtleties, and the general atmosphere that enhances the experience of viewing art. When users wear VR headsets, they are transported into meticulously crafted virtual environments, which offer a heightened sensation of being there and engaged beyond what can be experienced in traditional galleries.

An inherent benefit of immersive virtual art galleries is the ability to tailor the exhibition environment according to the topic or ambiance of the artworks. Curators can explore different ways of arranging objects in space, creating a coherent sequence that leads viewers through a well-planned visual exploration experience. Virtual worlds may be customized to exhibit a wide range of artistic expressions, encompassing traditional art forms such as paintings and sculptures and modern digital and interactive installations. VR's immersive quality heightens the emotional and intellectual bond with artworks, enabling viewers to profoundly and personally feel the intended meaning of each piece.

Furthermore, promoting equal access and participation in art becomes the main focus in virtual reality, tackling concerns related to availability and inclusiveness. Virtual galleries overcome geographical limitations by enabling anyone worldwide to access and interact with art exhibitions without being physically there. This democratization process promotes forming a worldwide community of individuals who appreciate art and enables up-and-coming artists to present their work on a global platform, liberating them from the limitations imposed by local exhibition venues.

### *B. Augmented Public Installations*

AR has revolutionized public art by incorporating dynamic and interactive components into real-world environments. Augmented public installations utilize AR technology to superimpose digital artworks onto the actual surroundings, seamlessly integrating the real and virtual worlds. Artists can convert public places into interactive surfaces, captivating audiences innovatively. Interactive murals may be enhanced via AR technology, allowing users to experience new levels of meaning or animations that respond to their interactions [24].

An exemplary utilization of AR in creative representation is converting street art into interactive and dynamic encounters. AR apps can augment street murals, often static, by enabling viewers to see dynamic or interactive components viewed through smartphones or AR glasses. This innovative combination of digital and physical components revitalizes urban environments, transforming conventional stationary artwork into interactive and constantly evolving installations.

AR public displays provide a visually attractive experience and actively stimulate audience involvement. Viewers are active, engaging with and influencing the artwork's story. Making art accessible to the public encourages community participation and the sharing of experiences as people come together to interact with and contribute to the changing art in public areas.

The convergence of the physical and digital realms in Augmented Public Installations challenges conventional perceptions of art consumption. AR democratizes art availability, enabling a more comprehensive range of people to access it. AR installations utilize commonly accessible technologies like smartphones to seamlessly integrate art into daily life, transforming urban landscapes into vibrant galleries that anybody from any location can access. This improves the availability of art and converts public places into arenas for imaginative expression and cultural involvement. With the continuous advancement of technology, the potential for AR to transform shared art experiences is expanding. This offers new opportunities for creative expression and community participation, introducing additional dimensions to the experience.

### *C. Innovative Theatrical Performances*

Theatrical events have been transformed by VR and AR technological advances, providing new and creative ways to convey stories and engage audiences. Within the realm of Virtual Reality, artists can construct entirely immersive virtual theaters in which spectators equipped with VR headsets can participate in real-time or pre-recorded performances. This presents novel opportunities for international accessibility since global audiences may convene in a shared digital environment to see theatrical performances beyond the limitations imposed by physical theaters [25].

VR enables the development of virtual stages and surroundings that surpass the constraints of actual locations. Within a virtual theater, artists can explore bizarre or magical environments that may present practical or economical obstacles in conventional theaters. The freedom in stage design allows directors and set designers to create distinctive and visually impressive experiences, expanding their creative options.

VR theater performances provide an enhanced level of audience engagement and immersion. Viewers can travel inside the virtual space, influencing the perspective from which they encounter the performance. This level of engagement converts only observing individuals into individuals who actively engage, intensifying the emotional bond between the audience and the storyline.

AR can improve theatrical performances by seamlessly incorporating virtual components into live plays. AR glasses or smartphone applications can superimpose digital material onto the actual environment, causing a blending of the boundaries between what is real and what is fictional. Integrating the real and virtual elements introduces intricacy to the narrative, resulting in a distinctive and dynamic theatrical encounter.

### *D. Virtual Sculpture and 3D Art Creation*

Integrating VR and AR technologies into the realm of sculpture and 3D art creation has sparked a transformative wave in how artists conceptualize, design, and present their works. In VR, artists can sculpt and mold virtual clay in three-dimensional spaces, providing a digital canvas where traditional constraints dissolve. This immersive approach to sculpture creation allows artists to experiment with forms and materials beyond the physical realm, fostering a new era of creativity unbound by the limitations of traditional sculpting tools [26].

AR expands the scope of virtual sculptures by integrating them into the physical environment, allowing their presence in natural settings via smartphones or AR glasses. Users can see and engage with superimposed digital sculptures in their immediate environment, seamlessly integrating the virtual and physical realms. This integration enables the positioning of virtual sculptures in public areas, galleries, or even in one's own living room, providing a unique and personalized viewing experience.

The interactive characteristics of both VR and AR enable the production of dynamic and responsive sculptures. Within virtual reality, artists can create sculptures that respond to human input or alterations in the environment, cultivating a feeling of active involvement and participation. AR allows spectators to engage with sculptures that dynamically react to their motions, resulting in an interactive and customized experience with the artwork.

VR allows artists from diverse locations to collaborate in virtual environments, overcoming distance limitations. The cooperative nature of VR sculpture production cultivates an international community of artists collaborating synchronously, sharing concepts, and challenging the limitations of conventional sculptural structures.

VR and AR technologies facilitate the digital storage and conservation of sculptural works. Virtual replicas of real sculptures can be preserved and encountered indefinitely, even if the original may have been modified or taken away. By digitally preserving sculptural compositions, their fundamental nature may be disseminated and admired regardless of temporal and spatial constraints. This process enhances the artist's legacy and advances the development of sculptural forms.

### E. Mixed Reality Collaborations

The integration of VR and AR technologies leads to the emergence of Mixed Reality (MR) collaborations, enabling artists to generate and engage with shared digital environments and opening up unparalleled opportunities. Within these mixed reality spaces, artists from various locations may collaborate in real-time, surpassing physical limitations and nurturing a worldwide creative community. VR facilitates immediate collaboration by immersing artists in shared virtual environments, allowing them to generate and alter digital components concurrently. This collaborative partnership enables the merging of many artistic viewpoints, leading to groundbreaking and multifaceted artworks that combine distinct styles and inspirations [27].

Mixed Reality Collaborations extend beyond stationary artworks, including interactive narrative and performance. Artists can collaborate to craft immersive tales that involve the audience in an active and influential role in shaping the developing plot. Within the VR world, individuals can traverse across these digital domains, exerting influence on the direction of the storyline and making meaningful contributions to the overall creative encounter.

AR facilitates cooperation by seamlessly incorporating virtual aspects into the real environment. Artists who wear AR gadgets can perceive and engage with digital stuff that is superimposed over their actual environment. This spatial cooperation enables the development of interactive and adaptable artworks that seamlessly integrate with the physical surroundings. Mixed reality collaborations foster interdisciplinary inquiry by uniting artists, designers, musicians, and performers. The integration of several creative disciplines in digital environments results in the development of comprehensive and multimodal experiences, dismantling conventional artistic divisions and promoting a more unified and linked artistic environment.

The accessibility of mixed-reality collaborations is a defining characteristic of their influence on artistic expression. Artists from various origins and with different skills may actively participate in joint projects, fostering inclusion within the global artistic community. The process of democratizing cooperation enables a more diverse and varied range of creative voices and viewpoints, fostering innovation and pushing the limits of artistic expression in the digital era.

### F. Accessibility and Inclusivity Tools

VR and AR technologies play a crucial role in overcoming accessibility obstacles in creative expression, guaranteeing that many audiences may actively participate in and admire art through novel means. VR and AR can overcome physical obstacles that impede folks from accessing conventional art venues. Individuals facing mobility limitations or residing in physically isolated regions might avail themselves of virtual art galleries or augmented installations, promoting equal access to art appreciation [28].

These technologies function as potent adaptive instruments, customizing art experiences to suit the requirements of persons with diverse needs. For example, in VR, adaptable interfaces and sensory stimulation may be utilized to accommodate individuals with varying capabilities, creating an inclusive platform for interaction. AR can be enhanced for those with visual impairments through audio descriptions, which offer comprehensive narrations of visual aspects. Augmented installations may be navigated using spatial navigation aids, such as auditory cues or haptic feedback, which help guide users and provide an inclusive experience with the artwork.

VR and AR technologies also enable the immersion in multilingual and culturally varied art encounters. Users can retrieve material in their desired language, while artists have the opportunity to integrate many cultural aspects into their digital works, promoting a more comprehensive portrayal of worldwide artistic forms. These technologies enable a wide range of artistic voices by providing easily accessible tools for creativity. Artists with impairments can utilize VR sculpting or AR painting programs to surpass their physical limits and make valuable contributions to the diverse and inclusive realm of artistic expression.

### G. User Experience Enhancement

VR and AR technologies are leading the way in improving user experiences in artistic expression by providing immersive and interactive engagements that go beyond traditional limitations. VR provides exceptional spatial immersion, allowing users to be transported to virtual environments where they may engage with art in three dimensions. The user's experience is enhanced by the feeling of being there in these digitally generated spaces, which enables a deeper connection with the artworks and the creators' creative objectives [29].

Both VR and AR enable consumers to engage in personalized experiences with creative material. VR galleries allow viewers to explore exhibitions at their own discretion, allowing them to determine the sequence in which they observe artworks. AR installations enable people to engage with virtual objects superimposed over their actual environment, promoting a feeling of control and customization in viewing art.

VR integrates haptic feedback devices, introducing a tactile element to enhance the user's experience. Users can see textures, discern the weight of virtual objects, and engage with digital sculptures in a manner that closely resembles real interaction. The involvement of the senses in creative interactions heightens the authenticity and emotional resonance, hence enhancing the immersive and unforgettable nature of the experience.

VR and AR facilitate the development of immersive tales and dynamic storytelling experiences. Users have the ability to participate actively in the narrative, exerting influence on the direction of the plot or engaging with virtual components in real-time. The incorporation of interactivity in art watching enhances the experience by involving the audience and creating a more dynamic and memorable contact with the artwork.

VR and AR improve the accessibility and inclusivity of art interaction. Individuals with diverse capabilities can explore virtual environments or engage with augmented material according to their tastes and requirements, expanding the accessibility of art to a wider range of people. These technologies enhance the inclusivity and participation of persons from varied backgrounds and abilities in the realm of art.

## IV. Future Trend and Directions

The rapid advancement of technology is paving the way for new possibilities and revolutionary trends in the use of VR and AR in artistic expression. These developments are expected to influence the methods and experiences involved in art creation significantly.

Advancements in immersion and realism are expected to prioritize enhancing the feeling of presence and authenticity within virtual and augmented worlds. Integration of Artificial Intelligence (AI) algorithms holds potential for aiding artists in creating interactive and customized experiences while facilitating real-time collaborations [30, 31]. Additionally, the evolution of Mixed Reality (MR) is likely to redefine traditional art forms by seamlessly blending real and digital elements in innovative ways. Wearable devices such as AR glasses and VR headsets are poised to become more user-friendly and accessible, enabling immersive artistic experiences anywhere.

Further, efforts to expand accessibility and inclusivity through adaptable interfaces and multilingual experiences will enhance the reach and impact of creative expression. Social and collaborative platforms will foster global artistic communities, while environmental and sustainable art initiatives will leverage VR and AR technologies to promote awareness and action. The integration of XR technology will offer a flexible platform for artists to navigate between immersive VR environments and context-aware AR settings. Additionally, VR and AR's potential in data visualization and neurocreative interfaces opens avenues for interactive and emotionally engaging artworks. Addressing ethical considerations and digital ethics will be paramount to ensuring responsible and conscientious utilization of immersive technologies in artistic endeavors. Therefore, future research efforts should focus on these areas to unlock the full potential of VR and AR in artistic expression.

## V. Conclusion

Integrating VR and AR into artistic expression has ushered in a transformative era and redefined how art is created, experienced, and shared. This article has explored the dynamic convergence of AR, VR, and the vast IT landscape and demonstrated the profound impact on creativity and immersive experiences. AR, with its augmentation of the physical world with digital overlays, and VR, which immerses users in fully simulated environments, have been widely studied. The investigation covers fundamental concepts and the complex interaction of hardware and software components. The survey examined the positive influences of AR and VR on artistic spaces, which include virtual art galleries, expanded public installations, and innovative theater performances.

This study analyzed and discussed the various uses of VR and AR in artistic expression. It also explored how these immersive technologies are transforming different aspects of the art world. These include creating immersive virtual art galleries, expanding public installations, innovating theatrical performances, generating virtual sculptures and 3D art, collaborating in mixed reality, developing tools for accessibility and inclusivity, and enhancing user experience. Upon closer examination, it is evident that VR and AR technologies have unparalleled prospects for innovation, engagement, and accessibility in the realm of creative expression. The findings of our investigation emphasize the adaptability of VR and AR in expanding the limitations of conventional creative forms, fostering inclusion, and enhancing user experiences. In the future, the ongoing progress in VR and AR technology will lead to greater innovation and growth in creative possibilities. This will result in a future where art becomes a more individualized, interactive, and unforgettable experience for a wide range of audiences.

# NovSRC: A Novelty-Oriented Scientific Collaborators Recommendation Model

Xiuxiu Li[1], Mingyang Wang[2*], Chaoran Wang[3], Yujia Fu[4], Xianjie Wang[5]
College of Computer and Control Engineering, Northeast Forestry University, Harbin, China[1, 2, 3, 4]
Harbin Institute of Technology, Harbin, China[5]

***Abstract*—Collaborator recommendation is a crucial topic in research management. This paper proposes a Novelty-Oriented Scientific Research Collaborator recommendation model (NovSRC). By recommending collaborators under the guidance of novel indicators, NovSRC aims to broaden scholars' research perspectives and facilitate the progress of research innovation. NovSRC utilizes heterogeneous academic networks composed of different academic entities and their relationships to learn vector representations of scholars and quantify their novelty metrics. A weighted academic collaboration network was constructed by measuring the novelty collaboration strength (NCS) among scholars under the novelty index, and based on this network, the final vector representation of scholars under the guidance of novelty characteristics was learned. By calculating the similarity between scholar vectors, NovSRC generates a Top-N recommendation list with a focus on novelty. The experimental results indicate that NovSRC achieved the best recommendation performance. Compared with the baseline models, the recommendation precision of NovSRC has improved by 6.9%, the F1 value has increased by 17.3%, and the novelty collaboration strength among scholars has increased by 3.3%. The analysis of the recommended list shows that compared to the target scholars, scholars recommended by the NovSRC model exhibit a wider distribution of research interests, which confirms that novelty has become a key benchmark factor for scholars seeking collaborators.**

***Keywords—Scientific collaborator recommendation; novelty; heterogeneous academic collaboration network; network representation learning***

## I. Introduction

Nowadays, scientific research is developing towards the direction of synthesis and diversification of disciplines. It is also increasingly difficult for scholars to discover new knowledge and propose new theories, which makes academic cooperation a new trend to break through scientific research problems. Academic cooperation can remove geographical restrictions and promote complementary advantages for scholars. However, in the face of academic big data and information overload, researchers often find it difficult to effectively select collaborators who match their research interests and can bring novel insights. How to help scientific researchers quickly and efficiently find their interested collaborators in massive data has always been a bottleneck that restricts the effectiveness of academic cooperation recommendations.

Existing collaborator recommendation methods focus on the similarity of scholars' research interests to achieve high similarity recommendation results, aiming to recommend collaborators closest to the target scholar's research interests. However, this strategy is difficult to bring more sparks of innovative thinking to the target scholars. A new recommendation strategy is needed to help them expand their innovative perspectives and improve their research level. The introduction of novelty is the key to solving this problem, as it can enrich academic cooperation models and meet the diverse cooperation needs of scholars.

In this paper, a new research collaborator recommendation model NovSRC is proposed which considers the novelty characters of collaborators. By examining the similarity and diversity of research interests among scholars, as well as the differences in academic influence among scholars, this model establishes an indicator system to measure the intensity of novelty cooperation among scholars. Under the guidance of this indicator system, the model learns the novelty representation vector of scholars and generates a recommendation list of collaborators based on this. The main contributions of the NovSRC model are as follows:

*1) NovSRC* model quantifies the intensity of collaboration between scholars in terms of the orientation of novelty. Based on a heterogeneous academic network composed of heterogeneous academic entities and their relationships, NovSRC quantifies the similarity and diversity of research interests between scholars, as well as the differences in academic influence between scholars. Based on these three indicators, NovSRC calculates the strength of novelty cooperation between scholars.

*2) NovSRC* model achieves novelty-oriented representation vectors of scholars. Based on a collaborative network with the novelty cooperation strength as the edge weight, NovSRC designed a random walk process guided by the edge weight, and finally learned the novelty orientation representation vectors of scholars.

*3) NovSRC* model obtains a list of collaborator recommendations based on novelty orientation. Based on the novelty scholar vectors, NovSRC calculates the similarity between scholar vectors and generates the novelty-oriented scholar recommendation list. Experimental results show that compared with the baseline models, the NovSRC model can achieve more accurate recommendation results.

*Corresponding Author.

## II. Related Work

In collaborator recommendation research, researchers mainly recommend potential collaborators to target scholars from the perspective of similarity.

As a popular method, the similarity-based research collaboration recommendation system builds scholars' interest profiles and constructs their “portraits” by extracting the research topics or keywords of their published papers, and accordingly recommends collaborators with similar research interests [1]. Chen et al. [2] constructed a heterogeneous network of institutions and collaborator networks and based on this, a random walk algorithm method was used to recommend academic collaborators. Zhang et al. [3] proposed a research collaboration recommendation method that integrates network representation learning and author topic models, and combines author structural similarity and author topic similarity to generate a recommendation list. Pradhan et al. [4] designed DRACoR, a multi-level fusion-based model for collaborator recommendation, which integrated the deep learning-boosted collaborator recommendation model and meta-path aggregated random walk based collaborator recommendation model, to generate a list of collaborators to recommend. Hu et al. [5] proposed a collaborator recommendation model CRISI that integrates the author's cooperation strength and research interests on the attribute graph. The quality of the recommended nodes is improved by double-weighting the structure and attributes and using the node replacement method. Kumara et al. [6] used Google Scholar archives to construct collaborative networks by extracting co-authors, similarities in areas of interest, citation rates, and multiple papers co-authored between scholars. Du et al. [7] utilized the Node2vec representation learning method to capture information from nodes in the research network, and integrated the institutional cooperation preferences among authors and the similarity in academic levels to obtain recommendation results. Du et al. [8] proposed an academic collaborator recommendation model ACR-ANE based on attribute network embedding. This model makes full use of the network topology and multi-type scholar attributes to enhance scholar embedding, and employs a deep auto-encoder to encode the structure of the academic collaboration network and attributes of scholars into low-dimensional representation vectors for collaborative recommendation. Jagadishwari et al. [9] used a collaborative filtering method to help identify collaborators based on the research interests and the papers published by the researchers. Liu et al. [10] proposed a heterogeneous network embedding recommendation model HNERec. This method uses four meta-path random walks of topic relationship, authorship, citation relationship, and venue relationship to traverse the heterogeneous network randomly, and utilizes the skip-gram model to embed the nodes, and finally generates a recommendation list based on the similarity between the corresponding node vectors.

However, considering similarity alone makes it difficult to broaden the research perspectives, and over time, it may reduce scholars' satisfaction with the collaboration recommendation system [11]. In recent years, researchers have gradually integrated novelty indicators into recommender systems [12]. By introducing novelty indicators, the recommendation results are no longer limited to high similarity, improving the innovation of the recommendation results, and providing surprise choices for target users. Zhang et al. [13] proposed a serendipity-oriented next point-of-interest recommendation model, SNPR, and designed a transformer-based neural network to capture the complex interdependencies of POIs in a user's clicking sequence by weighing relevance and unexpectedness. Ziarani et al. [14] proposed a deep neural network approach for a serendipity-oriented recommendation system, using unexpectedness and relevance parameters to compose focus shift points to generate novelty recommendations by integrating Convolutional Neural Networks and Particle Swarm Optimization algorithm. However, most of these studies are based on product recommendation systems, and only a few studies have introduced them into the research collaborators recommender systems. Gao et al. [15] proposed a community outlier detection algorithm to identify abnormal academic conferences and scholars with more research topics in the academic community. Xu et al. [16] proposed the Seren2vec network representation learning algorithm to provide serendipitous scientific collaborators by generating accidental bias vectors of scholar nodes. Ding [17] proposed a paper recommendation algorithm based on novelty and influence, which improved the traditional citation network graph by combining the novelty and impact of a paper, and used a restarted random wandering algorithm to make recommendations.

In summary, collaborator recommendations based on similarity can improve the relevance of recommendations and ensure that the research directions of the recommenders and the target scholar are highly consistent. However, relying solely on similarity to generate collaborators is difficult to effectively expand the research perspective of the target scholar. In the field of academic collaboration, researchers hope to collaborate with scholars with different research perspectives to obtain relevant but different ideas or knowledge. Therefore, introducing novelty elements into recommendation systems will help meet the needs of researchers.

## III. Methodology

Fig. 1 shows the overall framework of the NovSRC model. The NovSRC model consists of four modules: Initial encoding module, Novelty indicator calculation module, Novelty-oriented encoding module, and Collaborator recommendation module. These modules are used for encoding the initial vectors of scholars, quantifying and calculating the novelty indicators of scholars, learning scholar vectors based on novelty orientation, and recommending novelty-oriented collaborators.

### A. *Initial Encoding Module*

In the Initial Encoding Module, a scholar representation vector learning process based on heterogeneous academic networks is designed to obtain the initial scholar representation vectors. The module adopts a hybrid encoding of content and structural features to fully examine the content and structural attributes of scholars in research interests. In the process of extracting research interest content features, this module uses LSTM and multi-head attention mechanisms to capture the overall and recent research interests of scholars to show the dynamic evolution characteristics of scholars' research interests over time. In the process of extracting structural features of research interest, an embedding learning process based on meta-path graph sampling is used to generate the structural features of scholars. And the hybrid encoding process uses the attention mechanism to integrate the scholar features obtained from the content and structural dimensions to obtain the initial representation vectors of the scholars. Fig. 2 shows the process of initial encoding of the scholar vectors.

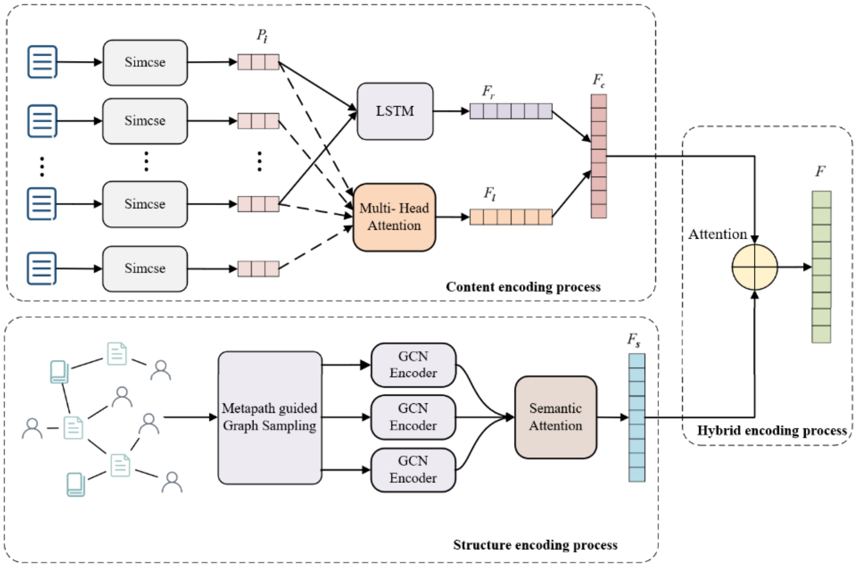

Fig. 2. The process of initial encoding of the scholar vectors.

The content features encoding process aims to learn the scholars' research interests in the content dimension. Since the articles published by the scholars can directly reflect their research interests, we use the scholars' articles as a basis to capture the scholars' research interests in the content dimension.

The titles of the articles published by the scholar are inputinto the SimCSE model [18] to learn the initial vector of the article. Then the vector is input into the multi-head attention layer to learn the scholar's overall research interest feature $f_l$. Meanwhile, we extract the scholar's latest published article representation sequence $\{P_1, P_2, \cdots, P_r\}$ (in this paper, r=3), and the representation sequence are input into the LSTM model to obtain the scholar's recent interest features $f_r$; Finally, we integrate the scholar's overall and recent interest features to obtain the scholar's feature representation in the content dimension $F_c$. The scholar's content features represent the learning process, which are formulated as shown in Eq. (1) to (4).

$$F_c = Concat(f_l, f_r) \tag{1}$$

$$f_l = \sum_1^n Concat(SA_1, \cdots, SA_m) W^o \tag{2}$$

$$SA_i = Softmax\left(\frac{(W_Q P_i)(W_K P_i)^T}{\sqrt{d}}\right)(W_V P_i) \tag{3}$$

$$f_r = LSTM(P_1, P_2, \cdots, P_L) \tag{4}$$

where $SA_i$represents the single-head attention output result of each article, $m$ is the number of heads in attention mechanism, $d$ represents the dimension of $P_i$, $W$ represents the weight coefficient.

The structural feature encoding process aims to learn the scholar's interest vector of structural dimensions derived from the association relationships between academic entities. In our previous work [19], the authors proposed a heterogeneous network representation learning process based on meta-path subgraph sampling. We introduce the process to encode the structural features of scholars' research interests. According to the heterogeneous academic network composed of the three academic entities of scholar-paper-journal and the relationship between them, three meta-paths are selected with the scholar node as the head node and tail node: scholars-papers-scholars (APA), scholars-papers-papers-scholars (APPA), and scholars-papers-journals-papers-scholars (APVPA). Homogeneous graphs are extracted from the heterogeneous academic network based on these three meta-paths. These homogeneous graphs can reflect the meta-path level neighbor relationships between scholars, which makes the aggregated representation learning process utilize richer network semantic information. On the homogeneous subgraph mapped by a certain meta-path, the neighborhood node set of the target node is obtained using the uniform sampling method. And the Graph Convolutional Network (GCN) is used to aggregate information from the neighbors of the neighborhood node set to generate the representation vector for the target scholar node.

The process for generating the target scholar embedding vector using GCN based on the meta-path $\mathcal{P}_i$ can be formulated as shown in Eq. (5).

$$A^{\mathcal{P}_i} = \left(D^{\mathcal{P}_i - \frac{1}{2}} N^{\mathcal{P}_i} D^{\mathcal{P}_i - \frac{1}{2}}\right) X W^{\mathcal{P}_i} \tag{5}$$

where $A^{\mathcal{P}_i}$ is the embedding vector of the target scholar node in the graph sampled by the meta-path $\mathcal{P}_i$, $X$ represents the initial feature matrix of the scholar node, $D^{\mathcal{P}_i}$ is the degree matrix under meta-path $\mathcal{P}_i$ , $N^{\mathcal{P}_i}$ is the adjacency matrix under $\mathcal{P}_i$, and $W^{\mathcal{P}_i}$ is the parameter matrix.

As a result, embedded vectors are obtained for scholars under different meta-paths. The final scholar's vector in the structural dimension is obtained by aggregating the embedded vectors of scholars under different meta-paths. A semantic-level attention mechanism is introduced to quantify the weight of semantic information provided by different meta-paths, and then the scholar vectors learned from different meta-paths are aggregated to obtain the scholar's interest vector $F_s(A)$ in the structural dimension. The aggregation process is shown in Eq. (6) to (9).

$$F_s(A) = \sum_{i=1}^{P} Att_{\mathcal{P}_i} \cdot A^{\mathcal{P}_i} \tag{6}$$

$$Att_{\mathcal{P}_i} = Softmax\left(W_{\mathcal{P}_i}\right) = \frac{exp\left(W_{\mathcal{P}_i}\right)}{\sum_{j=1}^{P} exp\left(W_{\mathcal{P}_i}\right)} \tag{7}$$

$$U_{\mathcal{P}_i} = Tanh(H^{\mathcal{P}_i} W + B) \tag{8}$$

$$W_{\mathcal{P}_i} = U_{\mathcal{P}_i} \cdot Q^T \tag{9}$$

where $Att_{\mathcal{P}_i}$is normalized by using the $Softmax$ function on $W_{\mathcal{P}_i}$, $W_{\mathcal{P}_i}$ represents he weight matrix of meta-paths under the self-attention mechanism obtained by multiplying the key vector matrix $U_{\mathcal{P}_i}$ and query vector matrix $Q^T$. $A^{\mathcal{P}_i}$ is obtained by mapping the vector matrix $U_{\mathcal{P}_i}$ through a layer of $MLP$ using $Tanh$ as the activation function. $W$, $B$, and $Q^T$ are training parameters.

In the hybrid encoding process, the attention mechanism is used to integrate the content feature vector and structural feature vector of scholars to obtain the final scholar vector representation $F(A_i)$ is shown in Eq. (10) to (13).

$$F(A_i) = W_1 \cdot F_c(A_i) + W_2 \cdot F_s(A_i) \tag{10}$$

$$W_i = Softmax(W_i) = \frac{exp^{(W_i)}}{\sum_{j=1}^{2} exp^{(W_i)}} \tag{11}$$

$$W_1 = Q \cdot F_c(A_i) \tag{12}$$

$$W_2 = Q \cdot F_s(A_i) \tag{13}$$

where $W_1$ denotes the weight matrix of scholar content features, $W_2$ represents the weight matrix of scholar structure features, and Q is a trainable parameter of the model.

The scholars' initial vectors obtained in the Initial encoding module are used as the basic data to calculate the similarity and diversity of scholars' research interests.

### *B. Novelty Indicator Calculation Module*

For scientific cooperation, similarity in academic knowledge and research interests of scholars is still the cornerstone for establishing collaborative relationships, which avoids communication barriers caused by differences in professional knowledge between scholars in cooperation. At the same time, collaborative relationships should be able to provide more perspectives to help solve scientific problems, which requires that collaborators have different and more diversified research interests than the target scholars. In addition, the scholars should have comparable academic influence, which is conducive to the development of the collaborative relationship. In summary, we evaluate the index system of novelty elements by three indicators: the similarity, the diversity of the scholars' research interests and the academic influence of the scholars.

*1) Similarity score:* The similarity score between scholars is obtained by calculating the cosine similarity between the scholar vectors obtained by the initial encoding module to evaluate the similarity of the scholars' research interests. The similarity score is shown in Eq. (14).

$$RS(A_i, A_j) = \frac{F(A_i) \cdot F(A_j)}{\sqrt{\|F(A_i)\| \|F(A_j)\|}} \tag{14}$$

where $F(A_i)$ and $F(A_j)$ are the representation vectors of the scholars' nodes $A_i$ and $A_j$, respectively.

*2) Diversity score:* The Fuzzy C-means (FCM), which can divide samples into different clusters, is used to capture the diversity of scholars' research interests. In the clustering process, we first set the total number of clusters C=10, and randomly assign each scholar node probability vectors for each class of clusters. Then the cluster center of each cluster and the distance between each scholar node and the cluster center are calculated to obtain the probability vector of the scholar belonging to each cluster $\{W_i\}_{i=1}^{N}$. The FCM method is used to perform iterative calculations until the objective function converges. The process of calculating the cluster center is shown in Eq. (15).

$$c_k = \frac{\sum_{i=1}^{N} w_{i,k}^{m} F(A_i)}{\sum_{i=1}^{N} w_{i,k}^{m}} \tag{15}$$

where $m \in (1, \infty)$ is the hyperparameter， $F(A_i)$ is the scholars' vector. The probability vector $w_i$ is calculated as shown in Eq. (16).

$$w_{i,k} = \frac{1}{\sum_{j=1}^{C} \left( \frac{\|x_i - c_k\|}{\|x_i - c_j\|} \right)^{\frac{2}{m-1}}} \tag{16}$$

where $w_{i,k}$ satisfies $\sum_{k=1}^{C} w_{i,k} = 1$. The objective function of the FCM clustering process is shown in Eq. (17).

$$J(W, C) = \sum_{i=1}^{N} \sum_{k=1}^{C} w_{i,k}^{m} \|x_i - c_k\|^2 \tag{17}$$

The probability matrix $W$ of each scholar under the 10 clusters is obtained after clustering. By calculating the sum of the probability differences between the target scholar and other scholars in each cluster, the research interest diversity scores of other scholars relative to the target scholar are obtained. The diversity score can be defined as shown in Eq. (18).

$$DS(A_i, A_j) = \sum_{k=1}^{C} W_{F(A_i),k} - W_{F(A_j),k} \tag{18}$$

where, $C$ is the number of clusters， $W_{F(A_i),k}$ represents the probability that scholar $A_i$ is in the $k$-th class cluster.

*3) Influence score:* In our previous research [20], an algorithm for evaluating the academic influence of papers based on heterogeneous academic networks, AIRank, was proposed. By distinguishing the differences in the propagation strength of influence among node pairs and comprehensively examining the enhancement effect brought by the influence of heterogeneous neighbors, an effective evaluation of the academic influence of papers is achieved based on heterogeneous academic networks. Inspired by AIRank, we design a scholar's influence evaluation process based on heterogeneous academic networks. The step of this process can be describe as follows:

Step 1: Based on the heterogeneous academic network, a multilayer heterogeneous network consisting of three layers of homogeneous subnetworks is constructed: the collaboration subnetwork between scholars, the citation subnetwork between papers, and the citation subnetwork between journals. The connections between homogeneous subnetworks are maintained through the associative relationships between heterogeneous academic entities.

Step 2: In each homogeneous subnetwork, the AIRank algorithm is utilized to compute the academic impact of the nodes within the subnetwork. The calculation of the scholarly node influence of the collaboration subnetwork between scholars is formulated as shown in Eq. (19) and (20).

$$AIS(A_i) = \sum_{A_j \epsilon \tau(A_i)} \frac{W(A_i, A_j)}{\sum_{A_k \in \tau(A_i)} W(A_i, A_k)} AIS(A_j) \tag{19}$$

$$W(A_i, A_j) = Sigmod\left(DH_{A_i} - DH_{A_j}\right) \cdot e^{cos\left(F_{A_i}, F_{A_j}\right)} \tag{20}$$

where $\tau(A_i)$ represents the set of neighboring nodes of scholar node $A_i$, $W(A_i, A_j)$ represents the strength of influence transfer from node $A_j$ to node $A_i$, $DH_{A_i}$ and $DH_{A_j}$ represent the academic quality values of node $A_i$ and $A_j$ , respectively. $cos\left(F_{A_i}, F_{A_j}\right)$ is the cosine similarity between scholar $A_i$ and scholar $A_j$.

Step 3: Based on the influence of heterogeneous neighbors, the fine-tune of the scholar's influence is calculated using formula (19). Specifically, the influence of the paper nodes and journal nodes obtained in step 2 is used to adjust the transition matrix between the scholar nodes in the collaboration subnetwork. This ensures that the scholar nodes corresponding to high-impact paper nodes and journal nodes have a higher transfer probability, resulting in a positive adjustment of the influence of the scholar nodes. The revised iterative process of the scholars' academic influence is deduced as shown in Eq. (21).

$$AIS(A_i) = \sum\nolimits_{A_j \epsilon \tau(A_i)} \frac{W(A_i, A_j)}{\sum_{A_k \in \tau(A_i)} W(A_i, A_k)} \cdot$$

$$\sum\nolimits_{A_t \in \tau P(A_j)} \frac{PIS(A_t)}{\left|\tau P(A_j)\right|} \cdot$$

$$\sum_{V_t \in \tau V(A_j)} \frac{VIS(A_t)}{|\tau V(A_j)|} \cdot AIS(A_j) \qquad (21)$$

where $\tau P(A_j)$ is the set of papers published by the scholar $A_j$, and $\tau V(A_j)$ is the set of journals published by the scholar $A_j$, $PIS(A_t)$ and $VIS(A_t)$ represent the influence values of papers and journals, respectively. The difference in academic influence of other scholars relative to the target scholar can be calculated by the tanh function, which is defined as shown in Eq. (22).

$$IS(A_i, A_j) = tanh\left(AIS(A_i) - AIS(A_j)\right) + 1 \qquad (22)$$

Cooperation strength (NCS) index: We weighted and summed the three indicators of similarity, diversity, and influence to obtain the NCS, in which the weight coefficient was calculated by the entropy weight method. Assume that the authors number is n, the original data matrix is set as $X = (x_{ij})_{n\times 3}$, where $x_{ij}$ represents the value of the $i$-th author on the $j$-th indicator. The steps for calculating the NCS using the entropy weight method are as follows:

*1) Data standardization.* Standardize the data for the three indicator values of similarity, diversity, and influence to avoid bias caused by different value ranges, i.e., the normalized value is calculated as shown in Eq. (13).

$$y_{ij} = \frac{x_{ij} - min_j(x_{ij})}{max_j(x_{ij}) - min_j(x_{ij})}(max_{new} - min_{new}) + min_{new} \qquad (23)$$

where $y_{ij}$ represents the normalized value, $i = 1,2,\cdots n$, $j = 1,2,3$, the mapping interval $[max_{new}, \ min_{new}]$ is set to [0,1].

*2) The information entropy of the indicator.* The information entropy of the j-th indicator is calculated as shown in Eq. (24) and (25).

$$E_j = -\,ln(n)^{-1} \sum_{i=1}^{n} p_{ij}\, ln\, p_{ij} \qquad (24)$$

$$p_{ij} = y_{ij} / \sum_{i=1}^{n} y_{ij} \qquad (25)$$

*3) The weights of the indicators.* The weight coefficient of each indicator is calculated as shown in Eq. (26).

$$W_j = \frac{1 - E_j}{\sum_{j=1}^{3}(1 - E_j)} \qquad (26)$$

where $0 \le W_j \le 1$, $\sum_{j=1}^{3} W_j = 1$.

*4) NCS* between scholars can be defined as shown in Eq. (27).

$$NCS = W_1 \times RS + W_2 \times DS + W_3 \times IS \qquad (27)$$

where $W_\mathrm{i}$ is the weight of the corresponding indicator.

### C. Novelty-oriented Encoding Module

*1) Constructing the novelty-oriented weighted scholar collaborative network:* The traditional scholar collaboration network is undirected and unweighted, which can only show whether the collaborative relationships exist between scholars. From the analysis in the Novelty Indicator Calculation Module, the collaborative relationships between scholars will have different collaboration strength due to the differences in similarity, diversity of research interests between scholars and academic influence of scholars. Therefore, the NCS between scholars is introduced into the scholar collaboration network as the weight of the collaboration edges between scholars to distinguish the differences in the novelty-oriented collaboration strength of different scholars.

Let $G' = (V, E, W)$ be the weighted collaboration network, where $V$ is the set of scholar nodes, E is the set of edges, and $W$ is the set of edge weights. The edge weights represent the differences in novelty-oriented collaboration strength between the connected scholars. Based on the reconstructed weighted cooperation network, the network representation learning process is introduced to obtain embedding vectors that contain the novelty of the scholars.

*2) Scholar node representation learning based on weighted cooperation networks:* Node2vec is a classical biased random walk-based network representation learning method. It can simultaneously learn the homogeneity and structural equivalence of the graph. Node2vec contains two parameters, $p$ and $q$, which are used to control the bias in random walks.When the value of $p$ is small, Node2vec focuses on the structural nature of the graph, and when the value of $q$ is small, Node2vec focuses on the homogeneity of the graph. However, the random walk process of the Node2vec algorithm does not take into account the weight of the edges between nodes, and thus cannot be applied in the weighted scholar collaboration networks. Inspired by the Node2vec+ algorithm proposed by Liu et al. [21], we designed a novelty-oriented network representation learning model Novel-2vec. In the model, collaboration edges in the weighted collaboration network are differentiated into strong and weak collaboration edges based on the weights of the edges, and a random walk process is performed based on the network.

Assume that $v_a$ is one of the scholar nodes in the weighted collaboration network, the average weight of all edges connected to node $v_a$ can be calculated as $\mu(v_a) = \frac{\sum_{v' \in N(v_a)} w(v_a, v')}{|N(v_a)|}$, where $N(v_a)$ is the set of neighboring nodes of $v_a$. Let $(v_a, v_b)$ be an edge between scholar $v_a$ and scholar $v_b$, then, if $w(v_a, v_b) < \mu(v_a)$, the edge $(v_a, v_b)$ is considered a strong collaboration edge; otherwise, if $w(v_a, v_b) \ge \mu(v_a)$, the edge $(v_a, v_b)$ is considered a weak collaboration edge. Let $v_a$ be the previous walking node, $v_b$ be the current node, and $v_c$ be the next node in the walk, the rules for the random walk are as follows:

Rule 1: The next node that the current node $v_b$ walks to is $v_a$ at walk probability $\alpha(v_a, v_b, v_c) = \frac{1}{p}$.

Rule 2: If there is a strong collaboration edge between nodes $v_b$ and $v_c$, and a weak collaboration edge or no edge between node $v_a$ and node $v_c$, the walk probability is

$\alpha(v_a, v_b, v_c) = \frac{1}{p} + \left(1 - \frac{1}{q}\right)\frac{w(v_a,v_c)}{\mu(v_c)}$ or $w(v_a, v_c) = 0$ , respectively.

Rule 3: If there is a cooperative edge between node $v_b$ and node $v_c$, and a strong cooperative edge between node $v_a$ and node $v_c$, the walk probability is $\alpha(v_a, v_b, v_c) = 1$.

Rule 4: If there is a weak cooperative edge between node $v_b$ and node $v_c$, and also between node $v_a$ and node $v_c$, the walk probability is $\alpha(v_a, v_b, v_c) = min\left\{1, \frac{1}{q}\right\}$.

Perform the process of random walk under the guidance of the above walk probability to obtain the node sequence, and the node sequence is input into the Skip-gram model to optimize the vector representation $f(v)$ of each scholar node. Compared to the scholar's initial vector obtained from the learning results in Initial Encoding module, the scholar's vector obtained by Novel-2vec is a vector representation obtained based on a full evaluation of the strength of novelty collaboration between scholars. Since the scholar vector already contains the novelty of the scholars' research interests and academic level, it can be used as a basis for recommending novelty collaborators.

### D. Collaborator Recommendation Module

Based on the novelty representation vector $f(v)$ of the scholar node, the cosine similarity between node vectors can represent the novelty-oriented similarity of the scholar node, and a Top-N recommendation list is generated based on the similarity. The similarity is calculated as shown in Eq. (28).

$$sim(v_i, v_j) = \frac{f(v_i).f(v_j)}{\sqrt{|f(v_i)| \cdot |f(v_j)|}} \tag{28}$$

For a target scholar, the cosine similarities with other scholars are sorted in descending order. The top-N scholars are extracted to generate the Top-N recommendation list as the recommended collaborators for the target scholar.

## IV. Experimental Results and Discussion

### A. Data Preprocessing

This article focuses on Chinese research scholars in the field of "Information Science and Library Science". A search formula is constructed in the WoS Core Collection database with the criteria "WC=Information Science& Library Science AND CU=PEOPLES R CHINA", and the publication date range is set from January 1, 2008, to October 1, 2022. The search yielded 7,141 papers published by Chinese research scholars. Delete the papers missing in the title, abstract, keywords, author, or publication year, and ultimately obtain 6,952 valid papers. Extract all authors from these papers to obtain a collection of scholars for the experiment. Due to the relatively narrow and highly specialized characteristics of the "Information Science and Library Science" field, scholars of the same name from the same affiliated institution are recognized as the same person. Afterward, for scholars with the same name from different affiliated institutions, the ORCID number of the scholar was retrieved for further identity verification. A total of 16,249 scholars are collected. Extract the venue information where the papers are published to form a collection of venues for the experiment. A total of 82 venues are collected. Taking December 30, 2018, as the dividing point, the collected academic entities and their relationships are divided into training and testing sets, respectively. That is to say, the data from January 1, 2008, to December 31, 2018, are collected as the training set, and the data obtained from January 1, 2019, to October 1, 2022, are taken as the testing set. Table I shows the basic information of the data set collected.

TABLE I. Basic Information of the Dataset

| Training data (2008~2018) | | | | Testing data (2019~2022) | | | |
|---|---|---|---|---|---|---|---|
| Node type | Num | Edge type | Num | Node type | Num | Edge type | Num |
| Author | 7505 | A-P | 11251 | Author | 9885 | A-P | 13783 |

| Venue | 76 | A-A | 15692 | Venue | 72 | A-A | 23643 |
| - | - | P-V | 3321 | - | - | P-V | 3631 |
| - | - | P-P | 4543 | - | - | P-P | 10310 |

### B. Evaluation Indicators and Baseline Models

We use Precision and F1 score to evaluate the performance of the scientific research collaboration recommendation model NovSRC. *Precision@k* denotes the accuracy of the recommendation when the length of the recommendation list is *k*. The calculation formula is shown in (29), where *R* is the set of scholars in the recommendation list, and T is the set of scholars who have collaborative relationships with the target scholar in real world.

$$Precision@k = \frac{1}{N}\sum_{I=1}^{N}\frac{|R \cap T|}{|R|} \tag{29}$$

*F1@k* denotes the F1 score of the recommendation result when the length of the recommendation list is *k*. t can be calculated as shown in (30), where $Recall@k = \frac{1}{N}\sum_{I=1}^{N}\frac{|R \cap T|}{|T|}$.

$$F1@k = \frac{2 \times Precision@k \times Recall@k}{Precision@k + Recall@k} \tag{30}$$

Meanwhile, we also calculate the NCS of the collaborators in the recommendation list to evaluate the novelty of the collaborators in the recommendation list generated using different recommendation algorithms. *NCS@k* denotes the novelty value of the recommendation result when the length of the recommendation list is k, which is calculated as shown in Eq. (31).

$$NCS@k = \frac{\sum_{i=1}^{N} NCS(R)}{N} \tag{31}$$

To validate the performance of the NovSRC, two network representation learning models commonly used in research collaboration recommendation tasks, Deepwalk and Node2vec, are selected as baseline comparison models. Two baseline models are used to learn the representation vectors of scholars based on the initial scholar collaboration network, and generating a recommendation list of collaborators that is only guided by similarity indicators. By comparing the novelty-oriented and similarity-oriented list of recommendation, we verify the significance of introducing the novelty into the collaborator recommendation system.

*1) Deepwalk [22]:* Deepwalk is used to perform a random walk on the initial academic cooperation network to generate a node sequence. And the sequence is input into the Skip Gram model to learn the vector representation of scholar nodes. Finally, the similarity between scholar node vectors is calculated to obtain Top-N recommendations.

*2) Node2vec [23]:* Node2vec is an improved version of the Deepwalk model, where the random walk strategy is changed by hyperparameters p and q to consider both graph homogeneity and structural equivalence. Node2vec performs a random walk process on the initial academic cooperation network to generate a node sequence. Then the sequence is processed in the same way as Deepwalk to obtain the Top-N recommendations.

### C. Results and Discussion

The collaborator recommendation results generated by each model are shown in Tables II and III. ΔMax represents the maximum improvement of the NovSRC model relative to the baseline models. It can be seen that the NovSRC model has achieved the best recommendation performance in both Precision and F1 metrics, and the optimal performance of NovSRC when the length of the recommendation list is k = 5. Compared with the baseline models, the Precision@5 of NovSRC has been improved by 6.9%, and the F1@5 of NovSRC has been improved by 17.3%. The experimental results show that by integrating the novelty indicators into the collaborator recommendation system, a higher precision can be achieved than the indicators that only consider similarity.

TABLE II. PRECISION@K THE RESULTS OF THE EXPERIMENT

| **Model** | **Precision@5** | **Precision@10** | **Precision@15** | **Precision@20** | **Precision@25** | **Precision@30** |
|---|---|---|---|---|---|---|
| **Deepwalk** | 0.193 | 0.171 | 0.124 | 0.113 | 0.096 | 0.087 |
| **Node2vec** | 0.259 | 0.217 | 0.175 | 0.131 | 0.103 | 0.093 |
| **NovSRC** | **0.262** | 0.243 | 0.179 | 0.145 | 0.117 | 0.098 |
| **ΔMax** | 0.069↑ | 0.072↑ | 0.055↑ | 0.032↑ | 0.021↑ | 0.011↑ |

TABLE III. F1@K THE RESULTS OF THE EXPERIMENT

| **Model** | **F1@5** | **F1@10** | **F1@15** | **F1@20** | **F1@25** | **F1@30** |
|---|---|---|---|---|---|---|
| **Deepwalk** | 0.246 | 0.192 | 0.163 | 0.151 | 0.136 | 0.129 |
| **Node2vec** | 0.402 | 0.296 | 0.230 | 0.189 | 0.167 | 0.153 |
| **NovSRC** | **0.419** | 0.316 | 0.252 | 0.209 | 0.178 | 0.156 |
| **ΔMax** | 0.173↑ | 0.124↑ | 0.089↑ | 0.058↑ | 0.042↑ | 0.027↑ |

To validate the necessity of scholars for novelty when seek collaborators, we compare the novelty indicators of collaborators recommended by the NovSRC model and the baseline models that only contains similarity. The experimental results are shown in Table IV.

TABLE IV. NCS@K THE RESULTS OF THE EXPERIMENT

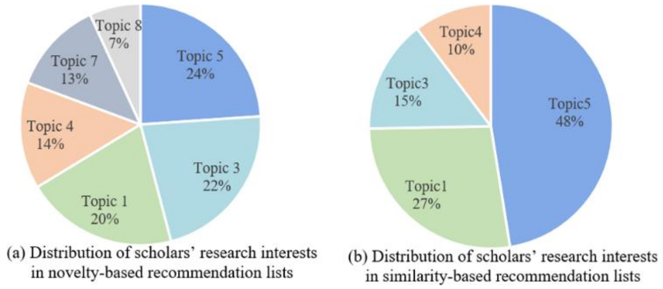
| Model | NCS@5 | NCS@10 | NCS@15 | NCS@20 | NCS@25 | NCS@30 |
|---|---|---|---|---|---|---|
| Deepwalk | 0.387 | 0.383 | 0.383 | 0.381 | 0.379 | 0.379 |
| Node2vec | 0.388 | 0.387 | 0.386 | 0.385 | 0.384 | 0.384 |
| NovSRC | **0.420** | 0.418 | 0.417 | 0.414 | 0.413 | 0.413 |
| ΔMax | 0.033↑ | 0.035↑ | 0.034↑ | 0.033↑ | 0.034↑ | 0.034↑ |

The results demonstrate that the collaborators recommended by the NovSRC model have higher novelty metric values than other two baseline models. When the length of recommendation list is 5, the recommended collaborators have the highest NCS. The results suggest that scholars are increasingly inclined to collaborate with scholars who have more diverse research interests and can provide more new research perspectives.

### D. Case Analysis

Taking two scholars (ID 1024 and ID 7169) as examples, generate the recommendation lists of length 5 for these two scholars under the NovSRC model and the Node2vec model which obtains the best performance in baseline models. Based on the probability distribution results of scholars in different research fields obtained from the calculation of the diversity indicators, the topic distribution of each scholar is sorted in descending order of probability, and the probability distribution is accumulated. The topics with cumulative probability value reaches 0.8 is selected as the main research topic of interest for each scholar. By comparing the distribution of research interests between target scholars and recommended scholars, we aim to compare the differences of different models in the attention to the novelty of scholars' research interests.

Following the above calculation process, we found that the target scholar of ID 1024 is mainly interested in “Topic 5”, “Topic 1”, and “Topic 4”. Fig. 3 shows the research interest distribution of the collaborators recommended by the NovSRC and Node2vec models for the target scholar. Among them, Fig. 3(a) shows the interest distribution of collaborators using the NovSRC model. Fig. 3(b) shows the interest distribution of collaborators recommended by the Node2vec model. It can be seen that, compared to the target scholar, the collaborators recommended by the NovSRC model have a wider and more diverse distribution of research interests, with research interests different from the target scholar accounting for 42% of the total interest distribution. Relatively, the Node2vec model focuses more on scholars with similar research interests as the target scholars. Among the 5 recommended collaborators, the only difference with the target scholar was in “Topic 3”, which accounted for only 15%.

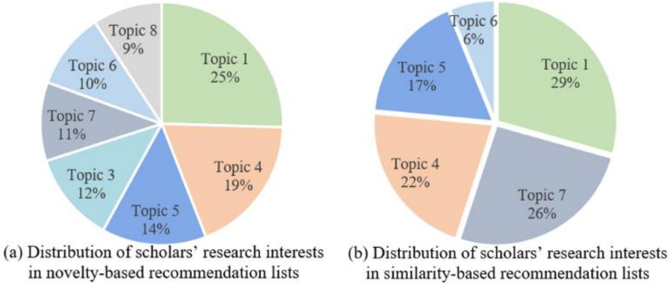


(a) Distribution of scholars’ research interests in novelty-based recommendation lists

(b) Distribution of scholars’ research interests in similarity-based recommendation lists

Fig. 3. Distribution of research interests of recommended collaborators (taking scholar No. 1024 as an example).

The target scholar of ID 7169 is mainly interested in “Topic1”, “Topic 7”, and “Topic 4”. Fig. 4 shows the research interest distribution of collaborators recommended by the NovSRC and Node2vec models. Fig. 4(a) shows the interest distribution of collaborators using the NovSRC model. Fig. 4(b) shows the interest distribution of collaborators recommended by the Node2vec model. Compared with the Node2vec model, the NovSRC model recommended scholars with a wider research interest and a higher proportion of research interests that differed from those of the target scholars.



(a) Distribution of scholars’ research interests in novelty-based recommendation lists

(b) Distribution of scholars’ research interests in similarity-based recommendation lists

Fig. 4. Distribution of research interests of recommended collaborators (taking scholar No. 7169 as an example).

Therefore, the collaborators recommendation of oriented novelty shows a more diverse distribution of interests compared with the target scholars, which can provide more opportunities for collaboration between scholars, and may help to provide more pioneering research ideas for both sides, thus promote the joint progress of their research.

## V. Discussion

In order to meet the needs of researchers for novel collaborators, this paper proposes a novel oriented scientific collaborator recommendation model NovSRC. Unlike traditional similarity-based recommendation systems, the NovSRC model fully considers the impact of novelty elements on the recommendation process, recommending collaborators with diverse research interests to target scholars, thereby improving their satisfaction and interest in the recommendation system. The experimental results indicate that compared with the baseline models that only examines the similarity of research interests among scholars, the NovSRC model recommends a wider and more diverse range of research interests among collaborators, which will inject more innovative elements into the cooperation between scholars and promote common scientific progress between both parties.

## VI. Conclusion

This article fully integrates novelty elements into the recommendation process of scientific research collaborators and proposes a novel oriented collaborator recommendation model, NovSRC. This model can recommend collaborators to target scholars, and help them to effectively expand their research perspectives and promote their scientific research process. Based on the similarity and diversity of research interests among scholars, as well as the differences in academic influence among scholars, NovSRC quantifies the strength of innovation collaboration among scholars. By using the strength indicator as the edge weight of the collaborative network between scholars, the encoding process of scholar vectors is fully established under the guidance of novelty elements, which makes the collaborators recommended by the NovSRC model can bring more innovative academic ideas for the target scholars. Although the research in this paper has achieved certain results, the initial modeling process of scholars only extracted the characteristics of the scholar's research content and network structure, and lacked the impact of factors such as region and institution on the collaborator recommendation task. Therefore, future research will try to introduce other entities such as regions and institutions into heterogeneous academic networks to achieve more comprehensive scholar feature extraction, thereby further exploring the effectiveness of novelty collaborator recommendations.

# A Deep Learning Model for Prediction of Cardiovascular Disease Using Heart Sound

Rohit Ravi, P. Madhavan*
Dept. of Computing Technologies, SRM Institute of Science and Technology, Kattankulathur, Chennai, India, 603203

*Abstract*—**Cardiovascular disease is the most emerging disease in this generation of youth. You need to know about your heart condition to overcome this disease appropriately. An electronic stethoscope is used in the cardiac auscultation technique to listen to and analyze heart sounds. Several pathologic cardiac diseases can be detected by auscultation of the heart sounds. Unlike heart murmurs, the sounds of the heart are separate; brief auditory phenomena usually originate from a single source. This article proposes a deep-learning model for predicting cardiovascular disease. The combined deep learning model uses the MFCC and LSTM for feature extraction and prediction of cardiovascular disease. The model achieved an accuracy of 94.3%. The sound dataset used in this work is retrieved from the UC Irvine Machine Learning Repository. The main focus of this research is to create an automated system that can assist doctors in identifying normal and abnormal heart sounds.**

***Keywords—Cardiovascular disease; prediction; LSTM; MFCC; deep learning***

## I. Introduction

As we know, cardiovascular disease is one of the most globally emerging diseases. According to WHO [14], in the year 2019, heart disease claimed the lives of almost 18 million people, which represents 32% of overall deaths happening globally. Cardiovascular disease is not an infectious disease, but it is causing more deaths yearly. The main reason behind this disease is changing the lifestyle of human beings. As we become more advanced, we change our lifestyle. The physical activities in our day-to-day life are getting less, and our diets are becoming unhealthy and unhygienic. We are moving more towards fast foods and street foods that are unhygienic and impact our health.

Modernization is changing the way of working, which affects the way. We are moving far away from physical activities, which leads to one of the causes of cardiovascular disease. Many other causes that can be the reason for cardiovascular disease are smoking, tobacco use, obesity, excess alcohol consumption, etc. It is vital to detect cardiovascular disease as early as possible so that it can be stopped in early stages and avoid premature deaths due to it.

### A. *Common Symptoms of Cardiovascular Disease* [15]

- Pain in the center area of the chest.
- Having a problem in one eye or both while seeing.
- Severe headache
- Getting unconsciousness
- Having dizziness, facing problems while walking, or losing body balance.
- Feeling numbness in one side of the body.
- Pain in the left side of the body.

### B. *Reasons Behind Cardiovascular Disease* [16]

- High Blood Pressure
- High Cholesterol
- Irregular or no physical activity
- Tobacco use
- Over consumption of alcohol
- Sometimes Family history can also be a reason
- Change in food style having more street food
- Obesity or excess weight
- Type 2 Diabetes

### C. *Some Measures to Keep Cardiovascular Disease Away from Ourselves* [17]

- Self-Control or Prevention
- Regular Check-ups
- Proper and timely medication
- Surgery, if necessary

### D. *Deep Learning*

We know that deep learning is one of the emerging subsets of Artificial Intelligence. Deep learning algorithms have more layers than machine learning algorithms, making deep learning algorithms more accurate. The fully connected artificial neural network whose basic concept is the working of a deep neural network.

This article introduces a deep-learning model for predicting cardiovascular disease. The combined deep learning model uses the “Mel Frequency Cepstral Coefficient” (MFCC) and “Long Short-Term Memory” (LSTM). MFCC is used for feature extraction, and LSTM is used for classifying and detecting cardiovascular disease.

### E. *Phonocardiogram*

A phonocardiograph and other equipment are used in the phonocardiogram technology to record heart sounds and murmurs as a plot. These recordings of each sound the heart produces during a cardiac cycle [18]. A cardiac cycle refers to the performance of the heart between the beginnings of two heartbeats. Two elementary heart sounds, "S1", commonly known as systolic sounds, and "S2", known as diastolic sounds, are shown on a PCG as large-magnitude deflections occurring one after the other, with S1 first [19]. These S1 and S2 is also described as the lubb - dubb -- lubb – dubb sounds. Heart sounds also have “S3” and “S4” sounds, which occur after S1 and S2 sounds but can be heard only in some healthy people. S3 and S4 have low frequencies, while S1 and S2 have high frequencies. The below “Fig. 1” is a phonocardiogram machine that is used to collect the PCG data and store it with the help of USB.

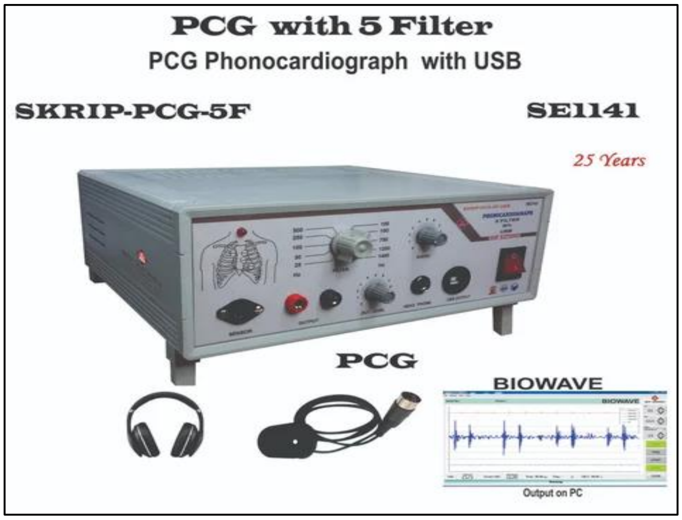

Fig. 1. PCG machine.

This model works on the phonocardiogram dataset. It will be easy to collect from any ordinary person. The difference between normal and abnormal heart sounds is easily visible. The S1 and S2 of the healthy heart sounds are at regular intervals. In contrast, abnormal heart sounds it is irregular. There are five different types of heart sounds [20], as mentioned below:

*1) Normal Sounds:* In normal heart sounds, the systolic and diastolic sounds will be at regular intervals without causing any fluctuation. Below “Fig. 2” is the representation of a normal heart sound wave. It is also called a healthy heart sound.

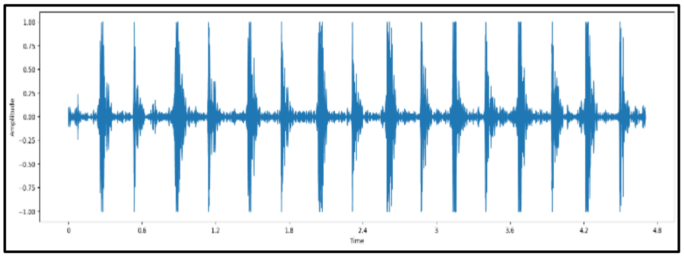

Fig. 2. Normal heart sound.

*2) Murmur sounds:* This heart sound is different from normal heart sounds. This sound contains some extra sound caused by the blood at the time of filling the heart commonly known as a diastolic murmur and at the time emptying the heart commonly known as a systolic murmur. Another type of murmur is known as continuous murmur caused throughout the heartbeat. Sometimes murmurs can be harmless and easily found in newborn babies. Below “Fig. 3” is the waveform of murmur sounds.

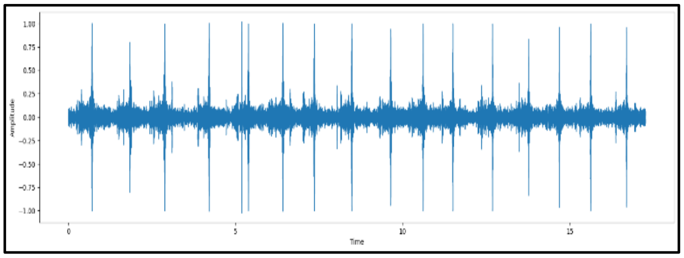

Fig. 3. Murmur hear sound.

*3) Extrasystole sounds:* This sound is generated when the heart produces an extra heartbeat during a cardiac cycle. Generally, these sounds are caused due to stress or anxiety. In “Fig. 4” you can see that there is an extra fluctuation in this wave between each cardiac cycle.

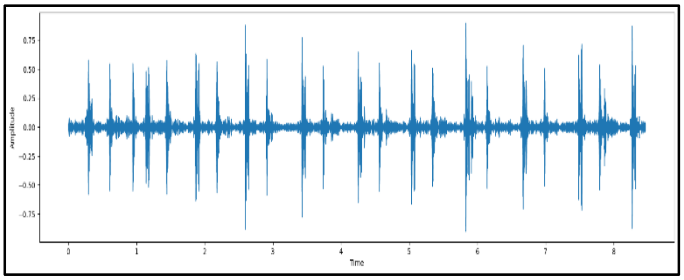

Fig. 4. Extrastole heart sound.

*4) Extrahls sounds:* This sound appears rarely and the reason behind this sound is the missing of either S1 or S2 sounds. Due to this normal lubb - dubb sound can be heard as lubb dubb - dubb or lubb - lubb dubb. “Fig. 5” shown below is the pictorial waveform of extrahls sounds.

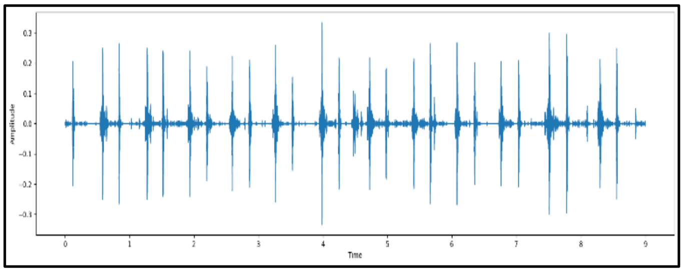

Fig. 5. Extrahls heart sound.

*5) Artifacts Sounds:* These sounds are caused due to some interference like environmental, instrumental, or biological interference. In some cases, artifacts are not considered as a defect of the heart as this sound can be generated or produced due to external interference. As can be seen in “Fig. 6” the waveform of the artifact sound is different from all the above-mentioned sounds.

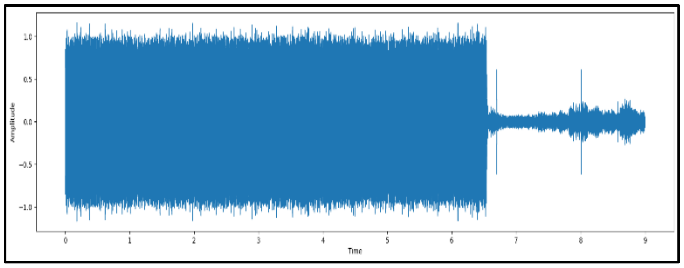

Fig. 6. Artifacts sound.

The rest of the paper is organized as follows: Section II is Related Work. In this section, a literature review of the old work related to this cardiovascular disease is explained with its drawbacks. Section III is Model Design which describes the proposed model for this paper. The proposed algorithm is explained here. In Section IV, there is a discussion about the dataset, methodology, and evaluation metrics used in this article. In Section V, the result is represented in tabular and pictorial form. Finally, Section VI concludes the overall paper.

## II. Related Work

A model for classifying Phonocardiogram signals into distinct classes using time-varying spectral characteristics and several classifiers was proposed by P. Upretee et al. [1]. When using the K Nearest Neighbour method for multi-class classification, they were able to attain 96.5% accuracy. Using the same approach, they were also able to classify binary classes with 99.6% accuracy.

Han Li et al. [2] proposed a model with Mel-frequency cepstral coefficients (MFCC) as feature extraction, and for classification, they used a Convolutional Neural Network (CNN). They have achieved an accuracy of 90.43%. Their dataset contains the PCG signals of 175 subjects. The main goal is to enhance the accuracy of CAD detection by incorporating dynamic content features and utilizing multi-channel PCG signals.

A handcrafted learning model based on multilevel discrete wavelet transform (DWT) and multilevel feature extraction based on a dual symmetric tree pattern (DSTP) was proposed by Prabal Datta Barua et al. [3]. The accuracy of the classification was 99.58% and 99.84%, respectively, using a support vector machine (SVM) with 10-fold cross-validation (CV) and leave-one-subject-out (LOSO) CV. The main goal is to gather more extensive datasets from various medical centers. These datasets will include sufficient heart sounds from rare cardiac disorders. We plan to use these datasets as a testing ground for our model and other pattern-based models we will create.

Mohammad Baydoun et al. [4] proposed a model with Wavelet-based features and Statistical- and signal-related features for feature extraction. For classification, they have used mainly bagging and boosting algorithms. They have achieved an accuracy of 86.6%. Their model can achieve better accuracy by utilizing a range of feature selection techniques, from simple correlation to more complex methods. It is possible to achieve better outcomes.

Yaseen et al.'s model [5] included several algorithms for multiple applications. For feature extraction for training and classification, they have employed the Discrete Wavelets Transform (DWT) and the Mel Frequency Cepstral Coefficient (MFCC). Support vector machines (SVM), deep neural networks (DNNs), and k nearest neighbor based on centroid displacement have all been utilized. Their accuracy rate reached 94.3%. By handling the data features more effectively and preparing the data on a larger scale, they can enhance and maximize the performance of this model in their future work. Adding new features may enhance the overall results.

A model using CNN and Bi-Directional Long Short Term Memory layers was presented by "Samiul Based Shuvo" et al. [6] for the purpose of extracting temporal and time-invariant features. Their accuracy on the PhysioNet/CinC 2016 challenge dataset is 86.57% overall. They recommend that CardioXNet be integrated with wearable technology or digital stethoscopes that are connected to a cloud server in order to improve accuracy. This makes it feasible to utilize trained algorithms for automatic classification and real-time prediction of different cardiovascular conditions. This kind of technology can help doctors diagnose patients.

A machine learning algorithm-based model was proposed by M. Banarjee et al. [7]. Using 2D Convolutional Neural Networks, they were able to classify multi-class data with 83% accuracy. This model's accuracy is extremely poor, particularly when it comes to healthcare. To make the model more useful in identifying and classifying irregularities in heart sounds, the accuracy can be further improved.

Shamik Tiwari et al. [8] proposed a Hybrid-Constant-Q-Transform model for multi-class classification on phonocardiogram signals to detect the cardiovascular sound disorder. They achieved an overall accuracy of 96%. For future work, this paper focuses on designing a multimodality model that can enhance accuracy by utilizing both the ECG and PCG signals in conjunction with acoustic features.

A classifier has been described by A. Gharehbaghi et al. [9] to diagnose aortic stenosis (AS) and pulmonary stenosis (PS) using PCG signals, particularly in pediatric patients. With 45 kids' PCG signals, they were able to attain 93.3% accuracy.

A hybrid model by G. Redlarski et al. [10] utilized the features of the Cuckoo Search Algorithm and SVM. LPC has been implemented as the feature extraction method. Their accuracy percentage currently stands at 93%. There are much fewer samples available for testing and training. If the model is trained using a larger number of datasets, it may not perform well.

Baris Bozkurt et al. [12] proposed a model CNN based model and achieved a mean accuracy of 0.815 with a sensitivity of 0.845, and a specificity of 0.785. They split the data in the ratio of 65:15:20 as training, validation, and testing phases. They have considered common features such as MFCC and Mel-spectrogram. The accuracy achieved from the model is very low and can be enhanced to perform well. This model is still not tested on real time dataset. This result achieved is from simulation. In their future work they are focusing on building end product and test on real time scenarios.

## III. Proposed Model Design

Deep Learning is one of the tools that can build models that can predict cardiovascular disease accurately. This model can identify any person having irregular heart sounds, which can be a symptom of early-stage cardiovascular disease. This model will help find the irregularity in the heart sounds and can be stopped early when it's not complicated to eradicate the disease. As soon as possible, we find the disease, which will be much easier to eradicate. As far as you know, eradicating the disease will be hard.

This model consists of a Mel Frequency Cepstral Coefficients for segmentation and Long Short Term Memory for disease prediction. A total of 52 features were found during the feature extraction process. These features are used to find the similarities between the sound waves. There are two classes classified as normal and abnormal. Normal classification is for normal heart sounds, and abnormal classification is for murmur, extrastole, artifacts, and extrahls sounds. This model will predict cardiovascular disease with an accuracy of 94.3%. The model below describes which layers are being used, the output shape, and the number of parameters for that layer. This model consists of three convolutional layers, three max-pooling layers, three batch normalization, two LSTM layers, three dense layers, and two dropout layers. The total number of the parameter is 14,130,371 as shown in "Fig. 7".

### A. LSTM

LSTM is the improvement of the conventional Recurrent Neural Network (RNN) designed to address the long-standing vanishing and gradient explosion issues. The LSTM's memory and its capacity to generate exact predictions imply that it could perform well. The significant difference between the LSTM and the conventional RNN is the cell state used to save the long-term state. The LSTM memory cell [13] has three different gates:

Forget Gate

Input Gate

Output Gate

*1) Forget gate:* The decision to keep or delete the data from the previous time stamp is made at the beginning of an LSTM network cell [11]. The equation for forget gate "(1)" is explained below:

$$\mathrm{F}_t = 6\left(X_t * U_f + H_{t-1} * W_f\right) \qquad (1)$$

Here,

- $X_t$ - Input from the present timestamp
- $U_f$ - weight related to the input
- $H_{t-1}$ - Hidden state from the earlier timestamp
- $W_f$ - weight matrix related to the hidden state
- Ϭ - Sigmoid Function

$F_t$'s value will be a number that falls between 0 and 1.

If, $F_t = 0$ then $C_{t-1} * F_t = 0$ (Forget everything)

If, $F_t = 1$ then $C_{t-1} * F_t = C_{t-1}$ (Forget Nothing)

The above equation describes what we will achieve from the forget gate. Here, $X_t$ is taken as

*2) Input gate:* The input gate is being used to measure the significance of new data provided by the input. The equation "(2)" explained below represents the input gate:

$$I_t = 6\,(X_t * U_i + H_{t-1} * W_i) \qquad (2)$$

Here,

- $X_t$ - Input at the current timestamp t
- $U_i$ - Weight matrix of input
- $H_{t-1}$ - Hidden state at the previous timestamp
- $W_i$ - is the weight matrix of input associated with the hidden state

Once again, the number will fall between 0 and 1 similar to Ft.

*3) Output gate:* The equation "(3)" explained below represents the output gate.

$$O_t = 6\,(X_t * U_o + H_{t-1} * W_o) \qquad (3)$$

The output of $O_t$ will range between 0 and 1 because of the sigmoid function used in the above equation. We will now use $O_t$ and tanh of the updated cell state to figure out the present hidden state as illustrated below “(4)”:

$$H_t = O_t * \tan h\,(C_t) \tag{4}$$

It turns out that the hidden state depends quite a bit on the current result and long-term memory ($C_t$). To achieve the result "(5)" of the current timestamp, we have to apply the SoftMax activation on the hidden state $H_t$.

$$\text{Output} = \text{Softmax}(H_t) \tag{5}$$

The token having the highest value in the result is the prediction.

### B. Classification

In this phase, the classification model is developed. The Long Short Term Memory (LSTM) based deep learning model is used for predicting cardiovascular disease. There are three classes normal, abnormal, and murmur sounds. The LSTM model is trained using the training dataset and validated using the validation set.

## IV. Discussion

### A. Dataset

In the mentioned research, we are using an audio file dataset for the prediction of cardiovascular disease. The dataset is gathered from “The PASCAL Classifying Heart Sounds Challenge”. The dataset contains five audio file types: Normal, Murmur, Extrastole, Artifact, and Extrahls. There is a total of 585 audio files containing 351 normal files, 129 murmur files, 46 extra stoles files, 40 artifact files, and 19 extrahls files. “Fig. 8” represents the percentage of different sound available in the used dataset.

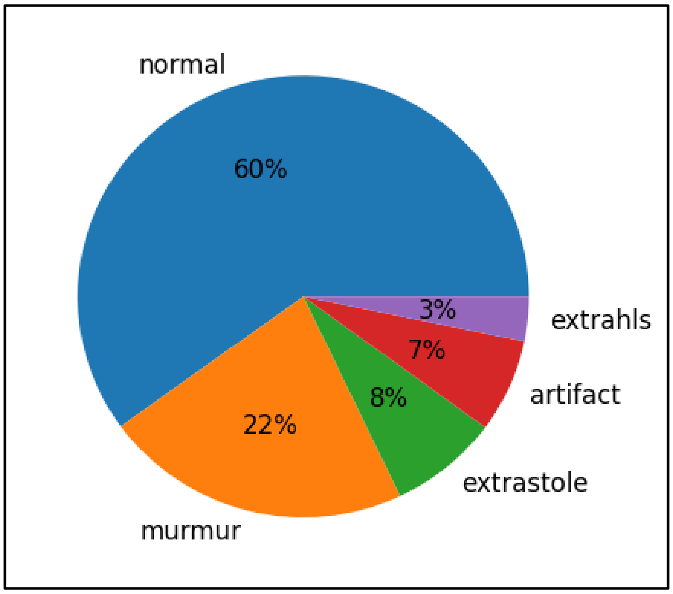

Fig. 8. Percentage of sound for training.

### B. Languages and Libraries

The language used for the proposed work is Python, and implemented in the Google Colaboratory Notebook platform. Various libraries used for this proposed work are OS, glob, and pandas for analyzing, cleaning, or exploring the data, numpy is used for mathematical evaluation, Librosa is used for the analysis of audio files, seaborn, matplotlib is used for visualizing the data, Ipython is used for support and use of GUI toolkits, math is used for any trigonometric logarithmic or exponential calculations, Tensorflow, Keras, and sklearn.

### C. Data Pre-processing

In this phase, the following process has been taken care of:

- Importing libraries
- Importing datasets
- Splitting dataset: The imported dataset is split in the ratio of 80:20.

### D. Feature Extraction

It is tampering and extracting invisible information from the raw data signal. It supports developing a system that improves machine learning and deep learning's generalization process. We have used MFCC feature extraction techniques and obtained 52 features in the sound wave to classify the sound.

### E. Evaluation Metrics

This section represents the results achieved from the model described above. We got an overall accuracy of 94.3% extracted from the formula explained in “(6)”. The table below represents the precision “(7)”, recall “(8)” F1-score “(9)”, and support derived from the artifact, murmur, and normal heart sounds. It also represents the accuracy, macro average, and weighted average achieved.

The following evaluation metrics are used for the combined deep-learning model for the prediction of cardiovascular disease is as follows:

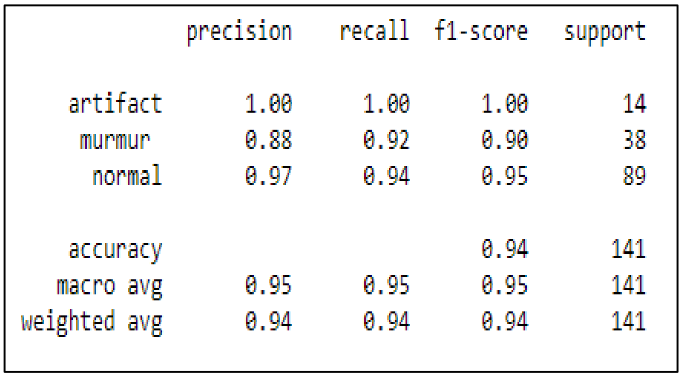
$$Accuracy = \frac{True\ Positive + True\ Negative}{False\ Positive + False\ Negative + True\ Positive + True\ Negative} \tag{6}$$

$$Precision = \frac{True\ Positive}{False\ Positive + True\ Positive} \tag{7}$$

$$Recall = \frac{True\ Positive}{False\ Negative + True\ Positive} \tag{8}$$

$$F1 = 2 * \left(\frac{Recall * Precision}{Recall + Precision}\right) \tag{9}$$

## V. RESULT



```
              precision    recall  f1-score   support

    artifact       1.00      1.00      1.00        14
      murmur       0.88      0.92      0.90        38
      normal       0.97      0.94      0.95        89

    accuracy                           0.94       141
   macro avg       0.95      0.95      0.95       141
weighted avg       0.94      0.94      0.94       141
```

Fig. 9. Comparison table.

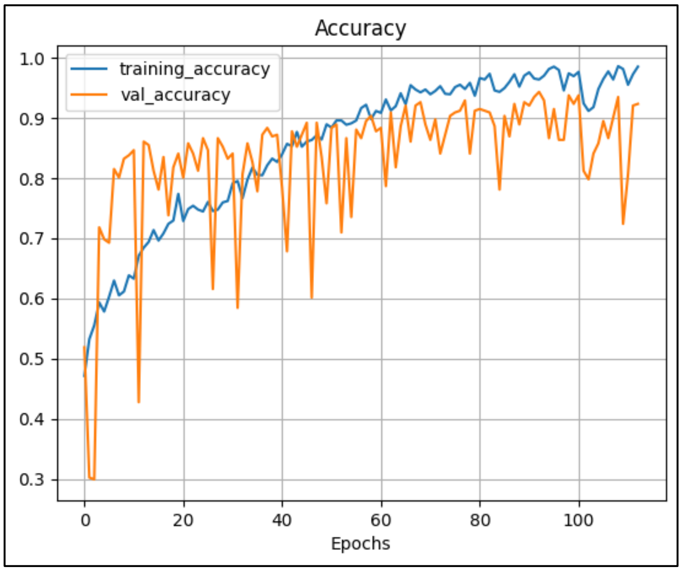


Fig. 10. Accuracy graph.

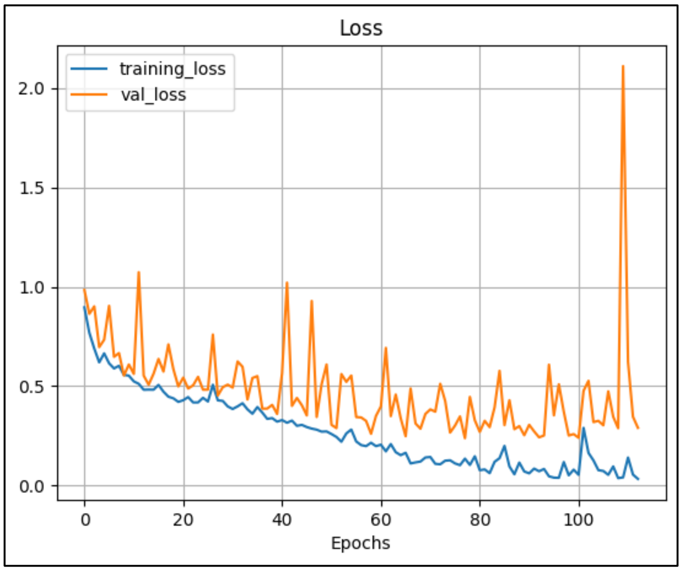

Fig. 11. Loss graph.

"Fig. 10" compares the accuracy between training accuracy and validation accuracy concerning epochs. The X-axis represents the number of epochs, and the Y-axis represents the accuracy percentage.

"Fig. 11" compares training loss and validation loss over the number of epochs. X and Y axis represent epochs and loss simultaneously. "Fig. 12" represents the confusion matrix between normal, murmur, and artifact sounds.

"Fig. 9" is the classification report generated based on precision, recall, f1-score, and support for the three different classes artifact, normal, and murmur.

We have seen the result above, which is described in tabular form. The proposed model achieved an accuracy of 94.3%. We have used the Mel-Frequency Cepstral Coefficients algorithm for features extraction and Long Short Term Memory to classify and detect cardiovascular disease.

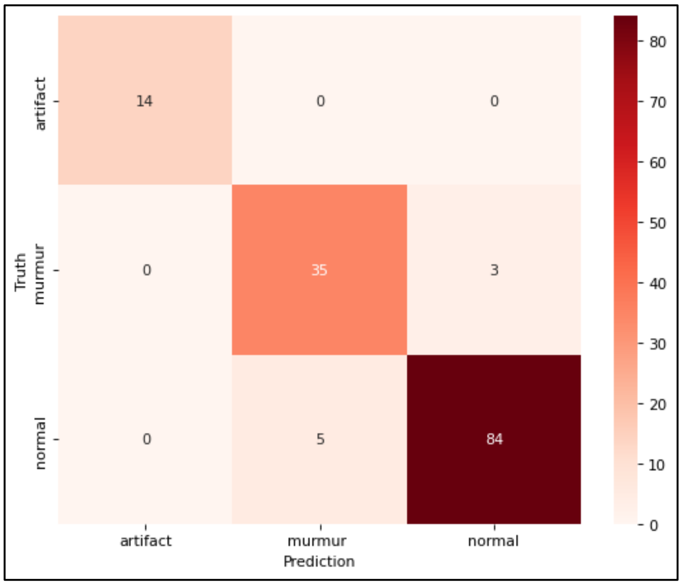

Fig. 12. Confusion matrix.

TABLE I. ACCURACY COMPARISON OF DIFFERENT ALGORITHMS

| S. No. | Algorithm | Accuracy |
|---|---|---|
| 1. | CNN based model using MFCC and Mel-spectrogram | 81.5% |
| 2. | 2D Convolutional Neural Networks | 83% |
| 3. | CNN and Bi-Directional Long Short Term Memory | 86.57% |
| 4. | bagging and boosting algorithms + Wavelet-based features | 86.6% |
| 5. | Mel Frequency + CNN | 90.43% |
| 6. | Cuckoo Search Algorithm and SVM | 93% |
| 7. | Discrete Wavelets Transform and the Mel Frequency Cepstral Coefficient + SVM , KNN | 94% |
| 8. | MFCC + LSTM (Proposed Model) | 94.3% |

"Table I" compares the accuracy achieved from the different algorithms used by different authors in their work.

## VI. Conclusion

From the above results, we know that cardiovascular disease can be predicted with the help of a sound file, which is to be collected from an electronic stethoscope. After collecting that sound, we have to feed that sound to the system, which will detect whether the sound is from a healthier heart. This model detects multi-classification and generates which type of sound disorder is there. Here, the heart sound is classified into five types: Normal, Extrastole, Murmur, artifacts, extrahls. The accuracy achieved from the proposed model is 94.3%. This model can easily detect heart status without any complicated process or extra expenditure. This can be used simply by any doctor without any complications.

For future work, a hardware prototype can be designed to collect real-time heart sounds and detect cardiovascular disease. This model can be enhanced by improving its accuracy or increasing the number of datasets for training and testing purposes. This model depicts the overall accuracy of the data given; as a result, we can achieve the prototype, which can find cardiovascular disease in its early stages. Regular check-ups can be done at hospitals or clinics. This prototype can be kept at home for personal use without any help from doctors. If any irregularity is found, then we can consult doctors and take proper treatment and precautions so it can't reach a severe stage.

# Optimized Deep Belief Networks Based Categorization of Type 2 Diabetes using Tabu Search Optimization

Smita Panigrahy[1], Sachikanta Dash[2], Sasmita Padhy[3]
Computer Science and Engineering, GIET University, Gunupur, Odisha, India[1, 2]
School of Computing Science and Engineering, VIT Bhopal University, Bhopal, MP, India[3]

*Abstract*—**Diabetics mellitus has the potential to result in numerous challenges. Based on the increasing morbidity rates in recent years, it is projected that the global diabetic population will surpass 642 million by 2040, indicating that approximately one in every ten individuals will have diabetes. Undoubtedly, this alarming statistic necessitates urgent focus from both academics as well as industry to foster novelty and advancement in prediction of diabetics, with the aim of preserving patients' lives. Deep learning (DL) was employed to forecast a multitude of ailments as a result of its swift advancement. Nevertheless, DL approaches continue to face challenges in achieving optimal prediction performance as a result of the selection of hyper-parameters and tuning of parameters. Hence, the careful choice of hyper-parameters plays a crucial role in enhancing classification performance. This paper introduces TSO-DBN, a Tabu Search Optimization method (TSO) that is based on Deep Belief Network (DBN). TSO-DBN has demonstrated exceptional performance in several medical fields. The Tabu Search Optimization algorithm (TSO) has been used to pick hyper-parameters and optimize parameters. During the experiment, two problems were tackled in order to improve the findings. The TSO-DBN model exhibited exceptional performance, surpassing other models with an accuracy of 96.23%, an F1-score of 0.8749, and a Matthews Correlation Coefficient (MCC) of 0.88.63.**

***Keywords*—*Deep belief network; Tabu search; diabetics mellitus; hyper-parameters; optimization***

## I. Introduction

Diabetes mellitus, also known as human diabetes, is a prevalent and chronic disease that is rapidly spreading [1,2] and has a substantial impact on modern society [3]. Individuals with diabetes mellitus experience impaired meal absorption, resulting in elevated blood glucose levels [4,5]. Diabetes is a medical disorder characterized by either insufficient production of insulin (type 1 diabetes) or impaired utilization of hormones (type 2 diabetes) [6–8]. In type 1 diabetes, the body ceases the production of insulin. This occurs because to the inadvertent assault and subsequent destruction of a segment of the digestive tract by the body's autoimmune system. Type 1 diabetes generally impacts those who are young, predominantly those who are under the age of 30. Conversely, type 2 diabetes is a chronic condition that cannot be cured and usually impacts persons in their middle and later stages of life. These criteria jointly contribute to evaluating and identifying persons who are at risk of acquiring type 2 diabetes.

In recent studies, deep learning and machine learning algorithms have consistently shown a high level of efficiency in categorization, when compared to existing methods [9]. Enhancing the precision of diabetes prediction is crucial, as is the timely identification of diabetes mellitus. In order to forecast diabetes mellitus, the researchers are integrating various machine learning and deep learning methodologies. Categorizing diabetes is a challenging task. Moreover, the precision of the implemented technique's forecasts may be influenced by the absence of data points in the datasets. This issue has been demonstrated to be a notable concern in the databases used for predicting the risk of diabetes. The objective of this study is to create a computer model that utilizes DBN Classification to effectively identify diabetes in its first phases, perhaps leading to life-saving interventions. By utilizing a collection of real diabetes mellitus data, the technique of DBN is utilized to predict the occurrence of diabetes mellitus. DBN, or Deep Belief Network, is a form of artificial intelligence that use computational methods to acquire knowledge from a vast amount of samples and autonomously program itself, eliminating the necessity for explicit rule definitions. The combination of substantial amounts of data and advancements in computational capabilities has led to this phenomenon [10].

Despite the widespread adoption of deep learning techniques by many academics for their strong empirical results, this approach nevertheless possesses significant limitations. The selection and optimization of hyper-parameters is a highly demanding part of deep learning. Model Parameter has a significant impact on every dataset, particularly for datasets with a large number of dimensions, and greatly affects training performance. Hence, the careful choice of hyper-parameters plays a vital role in enhancing the classification accuracy for predicting the risk of type 2 diabetes [11]. Therefore, this study introduces an enhanced diabetes risk prediction method by proposing an optimized deep belief network based TSO for selecting hyper-parameters and optimizing DBN parameters. In contrast to prior research in the field, which incorporate deep learning techniques alongside traditional optimization methods such as grid or random search. This work involved constructing and examining the effectiveness of fourteen widely-used machine learning classifiers that are routinely employed in research on predicting the risk of diabetes. The assessment of the TSO-DBN model and fourteen machine learning classifiers on a shared dataset demonstrates that the optimized DCNN model outperforms the aforementioned classifiers from previous studies, with logistic regression (LR) displaying superior performance among the thirteen other classifiers utilized in this investigation.

Thus, the findings of this study can be categorized into four main contributions:

- We conducted a thorough examination of high-quality research papers that focused on predicting the risk of diabetes using both traditional machine learning and advanced deep learning techniques.
- We conducted an assessment of the effectiveness and user-friendliness of nine machine learning classifiers using a large and diverse dataset. The purpose of this assessment was to predict the risk of type 2 diabetes. We used well-established evaluation criteria to measure the performance of these classifiers.
- Combining SMOTE data sampling and TSO-DBN to address the underlying issue of class imbalance.
- We have suggested a model for a deep belief network that relies on the selection of hyper-parameters and the optimization of attributes.

The subsequent sections of the paper are organized in the following manner. Section I provided an overview of the context around the prediction of diabetes. Section II offers a comprehensive examination and analysis of the most advanced approaches for predicting diabetes. The proposed methodology discussed in Section III. Section IV provides a comprehensive presentation of the findings and examination of this study. The discussion of the study is provided Section V and Section VI ultimately finishes the study and offers valuable lessons for future endeavors.

## II. Literature Study

The neural network is a fundamental concept that consists of interconnected neurons joined together through synapses, forming a biological neural network. Dendrites are the main processing units in a synapse, responsible for receiving axon input and producing output. An artificial neural network, comprising numerous processing units, has emerged as a result of emulating the biological mechanism of data processing, where information is transmitted from one node in the input layer to other nodes in the output layer. Within a network, a cluster of nodes or neurons serves as a singular entity or intermediate processing component. The PID dataset has been utilized in several studies investigating the classification of Diabetes Disease (DD) data [12–14]. In recent years, DD categorization research has presented several approaches and taxonomies, leading to a complex blend of imprecise and comprehensive terminology. Retinal fundus imaging and conventional assessment serve as the fundamental basis for current procedures used in screening for diabetic retinopathy (DR). However, these methods are expensive and time-consuming due to the requirement of highly qualified experts for evaluation [15].

In [16] the authors employed machine learning techniques, specifically ten-fold cross validation, to analyze individuals with a history of non-diabetes and heart issues. The authors enhanced the accuracy of clinical prediction for early detection of diabetes type 2 mellitus by employing advanced machine learning forecasting algorithms like Glmnet, RF, XGBoost, and LightGBM. While it demonstrates efficacy with one dataset, it is unsuitable for another.

In their study, the researchers in [17] devised an innovative technique for detecting DD using the LS-SVM and GDA methodologies. A novel cascading learning system was implemented, utilizing the methodologies previously outlined. The constructed system comprised of two stages: firstly, GDA was utilized; secondly, LS-SVM was implemented to categorize the datasets connected to diabetes. Compared to previous findings obtained using alternative categorization techniques, the results demonstrated a favorable accuracy rate of 82.05% for classification.

In [18] the authors introduced multilayer feedforward network techniques using DL for efficient early prediction. The model has a success rate of 98.07% in analyzing diabetes. The authors of reference [19] proposed a diabetes forecasting model based on an enhanced deep neural network (DNN) technique. The framework has the capability to both predict and ascertain of disease in the future. A hybrid model, developed by [20], has been designed to accurately detect type 2 diabetes with a precision rate of 97.5%. This model combines an Advanced Learning Machine algorithm with a genetic algorithm.

In [21], a hybrid model could be employed for diabetics prediction. The initial step was data cleansing to ensure consistency, followed by RF and XGB classifiers for selection of a subset of features. Subsequently, erroneous data were eliminated by the utilization of K-means clustering.

According to [22], the PIDD dataset was used to train seven distinct machine learning models, each with its own set of features. Two features were excluded in the feature selection process of this technique. SVM and LR showed strong predictive performance for diabetes; a complex neural network was trained with multiple hidden layers and epochs. The authors demonstrate that a neural network with two hidden layers has superior performance in comparison to previous methodologies.

A review in [23] indicates that machine learning is robust enough to aid doctors in predicting the likelihood of future type 2 diabetes development. Machine learning (ML) was employed in a study [24] to conduct a comprehensive evaluation of predicting methods for diabetes. The Prediction Model Risk of Bias Assessment Tool (PROBAST) evaluated bias in machine learning models, whereas Meta-DiSc measured variability in a systematic review, demonstrating the greater effectiveness of machine learning compared to traditional methods.

The ensemble approaches utilized various supplemental machine learning techniques, such as SVM and Convolutional Neural Networks (CNN), to evaluate improvements in performance. However, the primary algorithm used in reference [25] was Logistic Regression (LR). The experiment utilized two distinct feature selection methods in conjunction with two datasets. The first dataset was chosen from the Pima Indians dataset, which comprises nine unique features. The subsequent dataset employed was the Vanderbilt dataset, which consisted of 16 features. The study's findings demonstrated that the LR algorithm ranks among the most efficacious methods for developing predictive models.

In addition, the authors in [26] presented a successful methodology for accurately categorizing and predicting diabetes. The researchers utilized a variety of machine learning algorithms, such as Gaussian process classifier (GPC), Gaussian Naive Bayes (GNB), LR, RF, SVM, DT, KNN, and AB. The evaluation of these models was conducted using the metrics of precision, accuracy, recall, F-measure, and error.

The authors employed deep neural networks [27] for the investigation. Deep learning has led to substantial advancements in data processing [28], computer vision [29–30], and several other domains [31–33]. In recent decades, experts have started recognizing the promise of deep learning approaches in effectively managing massive datasets [34]. DL approaches have successfully enabled the prediction of diabetes.

## III. Methods and Materials

This section elucidates the methodology employed in the study, delineating four pivotal stages in the prediction pipelines: benchmark data collecting, pre-processing, modelling prediction, and result analysis. The subcategories provide a comprehensive explanation of each stage and methodology employed.

### A. Dataset

The diabetes dataset being analysed consists of 768 female patients, obtained from the UCI [38]. Out of the total number of participants, 500 do not have diabetes, but 268 have received a diagnosis for the ailment. The goal is to determine whether diabetes is present or not by examining specific diagnostic parameters in the dataset. The trial specifically targets individuals of Pima Indian ancestry, all of whom are at least 21 years old. Curiously, some patients display zero readings for crucial metrics. Significantly, there are 374 patients with a serum insulin level of zero, 27 with a body mass index of zero, 35 with a diastolic blood pressure of zero, 227 with a skinfold thickness of zero, and 5 with a glucose level of zero. These zero values are classified as null values and, in accordance with WHO criteria, function as crucial markers for forecasting diabetes. The goal variable in the dataset is dichotomous, representing the presence (1) or absence (0) of diabetes in a patient. By employing machine learning methods, this binary classification allows for the prediction of diabetes using particular criteria. The dataset's demographic attributes, specifically for patients diagnosed with diabetes, are displayed in Table I. This dataset has been crucial in studies focused on predicting diabetes. Scientists utilise the extensive data in this dataset to find key indicators that lead to precise predictions of diabetes. Due to its large sample size of female patients, this dataset is particularly valuable for comprehending and tackling the intricacies related to diabetes in this specific group. Scientists and professionals are still investigating and expanding upon the knowledge gained from this dataset, which is leading to progress in the prediction and treatment of diabetes.

### B. Data Pre-processing

The data has been standardized in pre-processing using the Min-Max normalization approach, resulting in values ranging from 0 to 1. Consequently, we have employed the isnull() and notnull() procedures to verify the presence of any missing values. The data exhibited class imbalance difficulties, prompting us to employ SMOTE as a means to rectify the class imbalance. Resampling is a commonly used technique for addressing the issue of imbalanced datasets. Undersampling and oversampling are the two predominant techniques [35]. Generally, oversampling methods tend to be more effective than undersampling techniques [36, 37]. SMOTE is a widely recognized method for oversampling. SMOTE is a method of oversampling that produces artificial samples for the underrepresented class. We have conducted important feature ranking, as depicted in Fig. 1. The data preprocessed to ensure its compatibility with the TSO-DBN model training. The implementation of the TSO-DBN model is explained in the following section.

### C. Tabu Search Optimization (TSO)

TSO is a metaheuristic approach that, in its fundamental form, involves a process for searching neighboring solutions. At each step, a thorough examination is conducted to evaluate all potential actions that can be taken from the current answer, and the optimal action is chosen. The approach enables transitions to solutions that do not enhance the existing solution. In addition, in order to avoid the algorithm from repeating the same actions, certain movements are designated as "null" and are initially excluded from consideration. We examined three categories of motion:

- Inserting an element $u_j' \in \mathrm{U} - \mathrm{T}$ ;
- Eliminating an element $u_j \in \mathrm{T}$; and
- Swapping of $u_j$ With $u'_j$ where $u_j \in \mathrm{T}$ and $u_j' \in \mathrm{U} - \mathrm{T}$.

TABLE I. Description of Attributes of Diabetics Dataset

| Sl No | Attribute | Description | SD Vs Mean |
|---|---|---|---|
| 1 | Pregn. | Number of times Pregnancy | 3.36 / 3.84 |
| 2 | Plasm | PlasmaGlucose level(2h) | 30.46 / 121.67 |
| 3 | Press. | BloodPressure(mm Hg) | 12.10 / 72.38 |
| 4 | Skin | Skinfold Thichness(mm) | 8.89 / 29.08 |
| 5 | Insulin | SerumInsulin in two hours(µU/mL) | 89.10 / 141.76 |
| 6 | BMI | Body Mass Index(Kg/M) | 6.88 / 32.43 |
| 7 | Pedigree | DiabeticsPedigree Function | 0.33 / 0.47 |
| 8 | Age | Age(Years) | 11.76 / 33.24 |
| 9 | O/p Class | Yes or No class for Diabetics | |

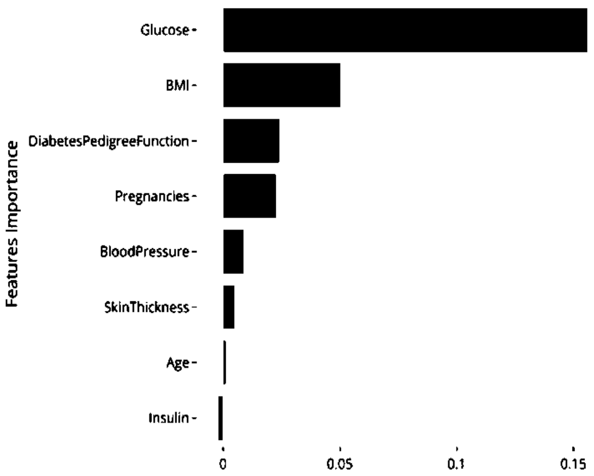

Fig. 1. Feature ranking for type 2 diabetics.

The set of neighboring solutions $T$ (i.e., solutions that can be reached through these motions) is defined as $N(T)$.

To avoid cycles, the output from T and the input into T for elements recently entered or left are labeled "tabu." The current tabu state is determined by tracking the entry or exit of an element $u_j \in$ U.

VectIn (j) - : Represents the iteration number at the element $u_j$ entered T.

VectOut (j) -: Represents the iteration number at the element $u_j$ left T.

Therefore, the presence of an element $u'_j \in \mathrm{U} - \mathrm{T}$ is $tabu$ if

$$itr \leq \mathrm{VectOut} \quad (1)$$

Furthermore, the departure of an element $u_j \in$ T is $tabu$ if

$$itr \leq \mathrm{VectIn} \quad (2)$$

Ultimately, the substitution of an element $u_j \in$ T with another $u'_j \in \mathrm{U} - \mathrm{T}$ occurs $tabu$ only if any of the two previously specified conditions is verified to be present.

As shown in Algorithm, each iteration takes into account all the arrangements that are not $tabu$ prohibited or that satisfy the ambition requirement. The optimal neighbor solution is stored in the variable $T^b$. This change is implemented ($g^b = g(T')\ and\ T = T^b$), and the values of VectIn and/or VectOut are modified based on the type of movement conducted and the elements implicated. After each iteration $T^*$ and $g^*$, the best solution obtained during the search and its corresponding objective function $g$ value, denoted as and , are updated. The operation terminates once a predetermined number of iterations ($\max_{itr} TSO$) have occurred without any enhancement of $g^*$. The parameter $no_{itr}$ is a crucial factor in this technique. Higher values of tenure lead to a larger number of movements being designated $tabu$, which in turn reduces the flexibility of the process. On the other hand, lower values of tenure may not effectively avoid cycles. Hence, the process of choosing appropriately is of utmost importance.

**Algorithm**: $TSO(no_{itr}, \max_{itr} TSO\ ,\ o/p,\ T^*)$

```
1. Compute $T^* = T, g^* = g(T), itr = 0, itr_{best} = 0$
2. Compute
       $VectIn(j) = -no_{itr}, VectOut(j) = -no_{itr}, for\ all\ j = 1,2, \ldots\ldots, n$
3. Do
       o Compute $itr = itr + 1$
       o Compute $g^b = -\infty$
       o ∀ ′ ∈ ( ) Execute:
         Begin
       o Find out the $tabu$ status of the associated movement
       o Find out if the "aspiraon criterion" is met or not, i.e., verify whether $g(T') > g^*$
       o If the movement is $not\ tabu$ or meets the aspiraon criterion, then if $g(T') > g^b$
       o Compute: = $g^b = g(T')\ and\ T^b = T'$
         End
4. Compute: $T = T^b$
5. Update VectIn and/or VectOut
6. If $g(T) > g^*\ then\ , T^* = T, g^* = g(T)\ and\ itr_{best} = itr$
7. Until $itr > itr_{best} + \max_{itr} TSO$
```

### D. DBN Technique

The DBN (Deep Belief Network) was developed by Hinton et al. with the aim of addressing the problem of the vanishing gradient observed in previous studies. The DBN is a resilient and complex generative design that is built using pre-trained layers. It falls under the category of deep neural network (DNN) approaches. DBN consists of numerous RBMs, each consisting of a Visible Layer (VL) and a Hidden Layer (HL). The Visible Layer is the input element, while the Hidden Layer is the output element. The nodes in various levels are fully connected, whereas the nodes within each internal layer are not interconnected. The Restricted Boltzmann Machine (RBM) aims to model the probability distribution from the visible layer (VL) to the hidden layer (HL) by utilizing an Energy Function (EF). DBN involves two steps: pretraining, which is unsupervised and involves training deep RBMs, and fine-tuning, which is supervised and involves training the classification layer. The utilization of Deep Belief Networks (DBN) for weight initialization in artificial intelligence has proven to be highly efficient across various disciplines. The DBN demonstrates a favorable outcome in feature extraction, making it well-suited for recognizing the characteristics inside the data. Due to its fully connected structure, DBN facilitates data analysis more effectively than any other DNN. Fig. 2 illustrates the organization of each Restricted Boltzmann Machine (RBM), which consists of a VL containing the V-units $v = \{vl_1, vl_2, \ldots\ldots, vl_i\}$, and a Hidden Layer (HL) containing the H-units $hl = \{hl_1, hl_2, \ldots\ldots, hl_j\}$.

Subsequently, the unsupervised training process is carried out between each layer, allowing the Deep Belief Network

(DBN) to acquire knowledge from the provided input. Once the features have been learned, they are then passed on to the classifier layer of the DBN. Ultimately, the classification layer undergoes fine-tuning to enhance the performance of the DBN.

### *E. Proposed TSO-DBN Model*

Fig. 3 depicts the block diagram of the settings required to conduct various tests. The dataset was obtained from clinical sources and is derived from the diagnostic reports of individuals with diabetes. The clinical data was preprocessed using several filters. Following the preprocessing stage, the features were extracted according to their significance. Subsequently, the data was divided into two segments, namely for training and testing purposes. The dataset exhibits a class imbalance issue, with the negative class prevailing over the positive class. To address this problem, we employed a synthetic minority oversampling technique (SMOTE). After resolving all the dataset-related concerns, we proceeded to train and validate the data using the proposed TSO-DBN model. Afterwards, the model underwent testing with test data in order to classify the type of diabetes. The performance accuracy was determined by employing various accuracy metrics. Ultimately, a performance comparison between the suggested model and state-of-the-art models was presented. Hence, the pertinent information is depicted in Fig. 3.

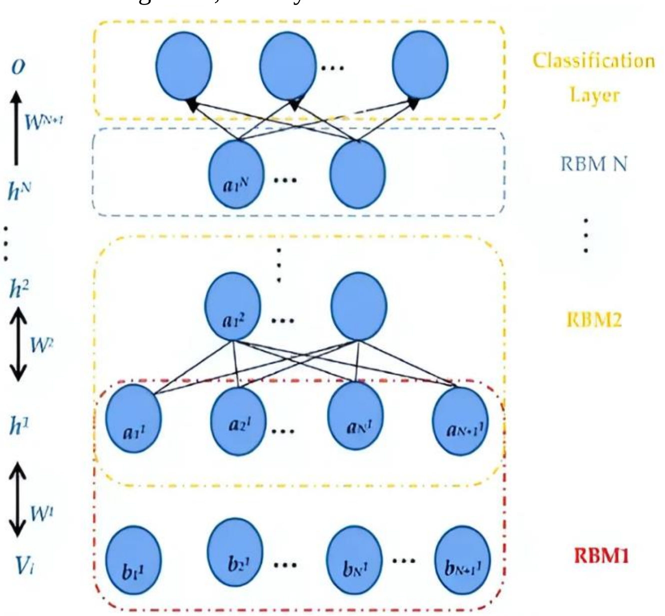

Fig. 2. DBN Architecture.

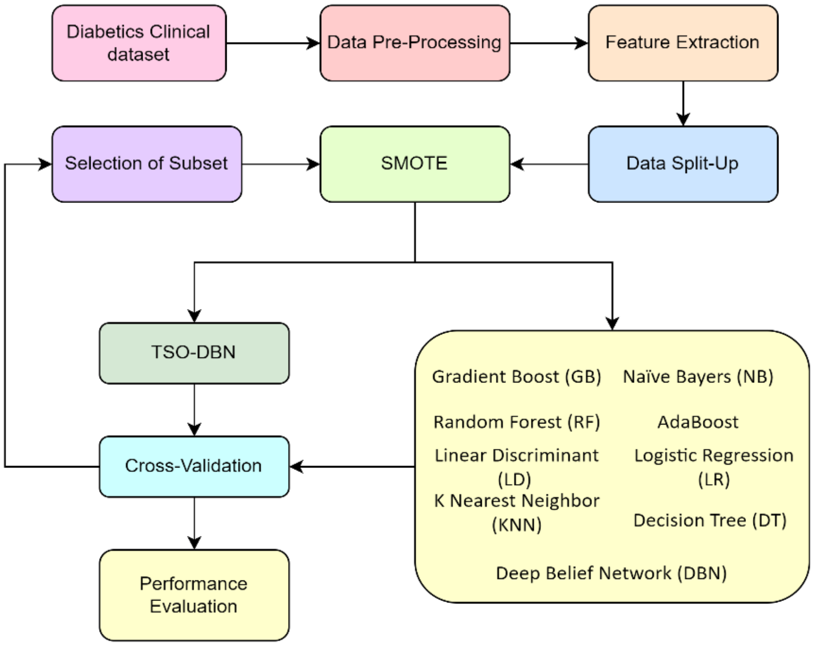

Fig. 3. TSO-DBN – The proposed model architecture.

## IV. Experimental Results and Performance Evaluations

This section outlines the criteria for examining the obtained results, the computed outcomes, and performance evaluations. The early stages of the project take place in MATLAB 2021b, followed by the utilisation of Python with Keras and Tensorflow for testing purposes. The programmes are executed on a system equipped with an Intel i7 processor, 16 GB of DDR3 RAM, and an NVIDIA RTX 2060 graphics card.

### A. Hyper-Parameters Configurations

To attain the best possible outcome when training the model and accomplish the desired outcomes for classifying diabetics, we conducted empirical experiments to fine-tune several hyperparameters. The hyperparameters encompass various factors like Learning Rate, No. of Hidden Layers, Number of iterations, Activation functions etc... Throughout training, the model trained for 130 epochs. Optimal hyperparameter values, determined post-fine-tuning and multiple experiments, are presented in Table II.

TABLE II. Hyperparameters

| Hyper Parameters | Values |
|---|---|
| Hidden Layers | 3 |
| Activation Function | Sigmoid |
| Output Layer | Softmax |
| No of Epoch | 130 |
| N0. of Neurons | 500 |
| Learning Rate | 0.003 |
| Optimization | Adam |

### B. Evaluation Metric

The efficacy of the suggested model for predicting type 2 diabetes is assessed by employing various metrics to evaluate its accuracy in distinguishing between diabetic and non-diabetic patients. Understanding the performance of the diabetes-presented model requires a thorough examination of the standard assessment methods often used in the scientific research field. The evaluation measures most commonly used as follows:

- The accuracy of diabetes prediction models is commonly measured by calculating the ratio of correctly identified cases to the total number of cases, as defined by equation (1).

Consequently, it can be computed in the following manner:

$$\text{Αχχυραχψ} = \frac{TN+TP}{TP+TN+FN+FP} \quad (3)$$

Binary classification utilizes the following terminology: TP for accurately identified positive instances, TN for accurately identified negative instances, FP for inaccurately identified positive instances, and FN for inaccurately identified negative instances.

- Precision is a metric that calculates the ratio of accurate diabetes cases (true positives) to incorrect diabetes cases (false positives) within a particular category.

$$\text{Πρεχισιον} = \frac{TP}{TP+FP} \quad (4)$$

- The recall metric calculates the proportion of relevant diabetes cases that were retrieved out of the overall amount of significant diabetes cases.

$$\text{Ρεχαλλ} = \frac{TP}{TP+FN} \quad (5)$$

- The F-Measure is a composite statistic that encompasses both accuracy and recall, effectively capturing both features. Diabetes prediction algorithms have utilized assessment metrics to assess efficiency.

$$\text{Φ–Μεασυρε} = \frac{2*(Precision*Recall)}{Precision\ +Recall} \quad (6)$$

- The Matthews correlation coefficient (MCC) is a statistical metric used to evaluate the performance of a classification model. It assigns a high score when all four classes in the confusion matrix show outstanding recognition outcomes, relative to the positive and negative classes in the dataset.

$$\text{MXX} = \frac{(TP*TN)-(FP+FN)}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \quad (7)$$

The aforementioned assessment methods have been employed to assess the efficiency of the improved deep learning model in relation to the contributions made in the literature.

### C. Analysis of Results

This section provides a clear explanation of the outcomes obtained from various traditional ML and DL classifiers and an optimised deep belief network-based TSO model. These models were utilized in the study to forecast the likelihood of developing type 2 diabetes. Evaluation matrices such as ROC and precision-recall curves depict the correlation between the rates of true positives and false positives. The models underwent testing utilising distinct data sets to assure impartiality and evaluate their capacity for generalisation.

There are two confusion matrices that display various model evaluation metrics depicted in Fig. 4. These metrics are derived from a matrix including four terms.

### D. Evaluation Metrics: Accuracy, F1-Measure, and Matthews Correlation Coefficient

Accuracy and recall are essential metrics when assessing prediction models. While anticipating the most positive type of instances in the dataset is called as high recall. However, in scenarios where a perfect balance between accuracy and completeness is necessary, the F1 measure is commonly used. The F1 score represents the harmonic mean of a model's precision and recall ratings.

Table III presents a comparative comparison of ten traditional ML and DL classifiers that were thoroughly tested and assessed for their efficacy in predicting type 2 diabetes. The evaluation is done by comparing their accuracy, area under the curve (AUC), recall, precision, F1 score, and Matthews correlation coefficient (MCC) with the TSO-DBN model.

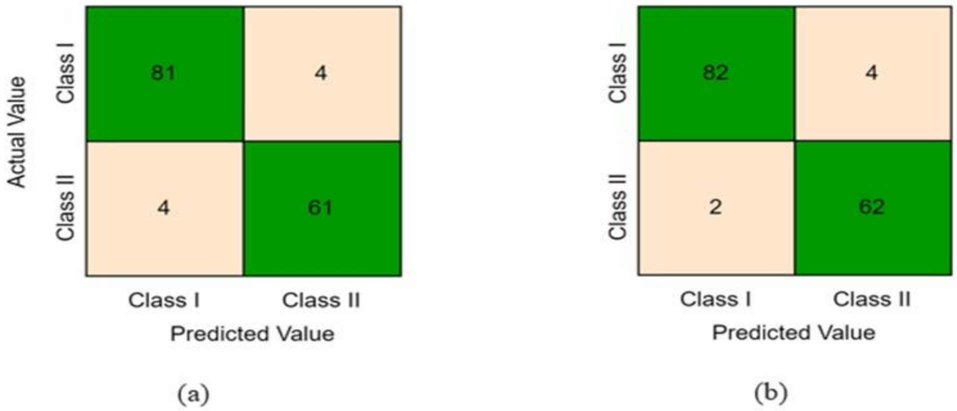

Fig. 4. Confusion matrix of (a) DBN model, (b) TSO-DBN model.

TABLE III. THE COMPARATIVE ANALYSIS OF PROPOSED WITH THE EXISTING ML TECHNIQUES

| No | Model | Evaluation Matrices | | | | | | Time Complexity (T) in sec |
|---|---|---|---|---|---|---|---|---|
| | | Accuracy | AUC | Recall | Precision | F1 | MCC | |
| 1 | Gradient Boost | 0.8732 | 0.9374 | 0.7635 | 0.8676 | 0.8198 | 0.7642 | 0.7674 |
| 2 | Random Forest | 0.9132 | 0.8627 | 0.7247 | 0.4645 | 0.5196 | 0.6516 | 1.5443 |
| 3 | Linear Discriminant | 0.8607 | 0.8308 | 0.7693 | 0.8702 | 0.8513 | 0.5357 | 0.8542 |
| 4 | K Nearest Neighbor | 0.8981 | 0.8804 | 0.8325 | 0.4291 | 0.6624 | 0.6024 | 0.7127 |
| 5 | Decision Tree | 0.9046 | 0.9441 | 0.6619 | 0.7165 | 0.7312 | 0.6489 | 1.5364 |
| 6 | Naïve Bayers | 0.8873 | 0.8632 | 0.6612 | 0.5764 | 0.8089 | 0.4873 | 0.7645 |
| 7 | Ada Boost | 0.8765 | 0.9226 | 0.8354 | 0.8501 | 0.5583 | 0.7391 | 0.8469 |
| 8 | Logistic Regression | 0.9268 | 0.8797 | 0.7123 | 0.3969 | 0.4867 | 0.4334 | 1.7267 |
| 9 | Deep Belief Network | 0.9581 | 0.9754 | 0.8485 | 0.8091 | 0.8667 | 0.8348 | 1.0463 |
| 10 | TSO-DBN | 0.9623 | 0.9817 | 0.8819 | 0.8746 | 0.8749 | 0.8863 | 0.6438 |

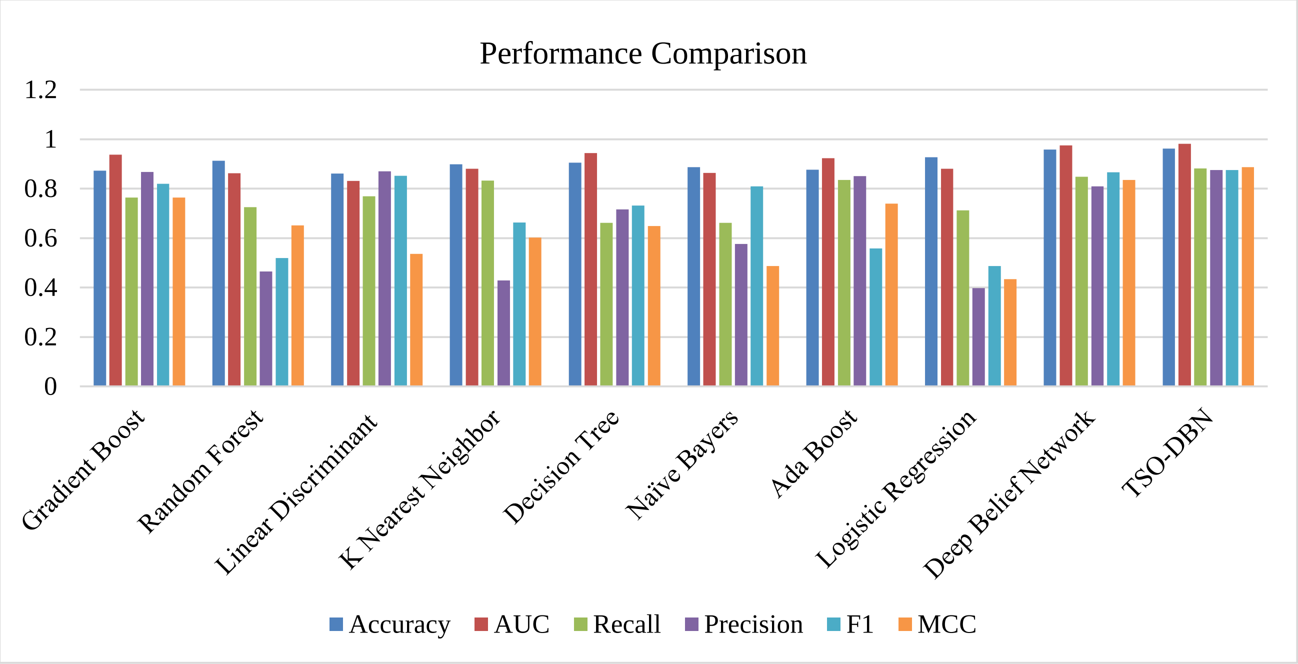

Fig. 5. Performance comparison of different classifiers.

Table III displays the F1 by utilizing the 10 predictors applied in this investigation. This table confirms the earlier results exhibited by the AUC and accuracy ratings. The TSO-DBN model attained a superior F1 score of 0.9623, whereas the LR predictor earned a significantly lower F1 score of 0.4867. We utilised a Linear Discriminant classifier and a Gradient Boosting Classifier, which yielded F1 scores of 0.8513 and 0.8198, accordingly.

Similarly, the Naïve Bayes Classifier achieved an F1 score of 0.8089, placing it in fifth position. Nevertheless, the Logistic Regression classifier exhibited the poorest performance, achieving a precision of 0.3969. Regarding the recall evaluation metric, the Naive Bayes model received a score of 0.6612, which was the lowest, while the TSO-DBN model acquired the highest score of 0.8819.

The results of the MCC (Matthews Correlation Coefficient) for all classical machine learning classifiers and TSO-DBN prediction models developed in this study are presented in Table III. The TSO-DBN model achieved a performance rate of 0.8863 according to MCC, while the classical DBN model achieved a performance rate of 0.8348. Following them, Gradient and Ada Boost achieved performance rates of 0.7642 and 0.7391, respectively. The random forest achieved an accuracy rate of 0.6516. In conclusion, the logistic regression model achieved a performance rate of around 0.4334, which is the lowest among the evaluation metrics measured by the Matthews correlation coefficient (MCC).

The findings of this study are summarised in Fig. 5, which shows that the TSO-DBN model performed better than all the commonly used ML classical classifiers in predicting the risk of type 2 diabetes. The suggested model yields near-optimal outcomes in terms of all measures.

### E. *Computational Complexity*

The reported data in Table III compares the prediction and training timeframes of the most and least effective classical machine learning predictors for type 2 diabetes. Linear Discriminant is particularly noteworthy for its impressive training time of 0.3542s, while LR is notably slower with a training time of 1.8267s. The computational complexity comparison of different pre-trained models is shown in Fig. 6.

The classical DBN model exhibits a temporal complexity of 1.5463s, which can be attributed to its complex structure in comparison to simpler classical ML models. The TSO-DBN model, which has a temporal complexity of 1.6438s, corresponds to the difficulty of the DBN model. Surprisingly, although these models have intricate structures, there are slight variations in their time complexity when comparing Random Forest, Decision Tree, and DBN Network. The suggested model, with its complicated design, attains a time complexity of 1.6438s, demonstrating the balance between model intricacies and computing efficiency in forecasting type 2 diabetes.

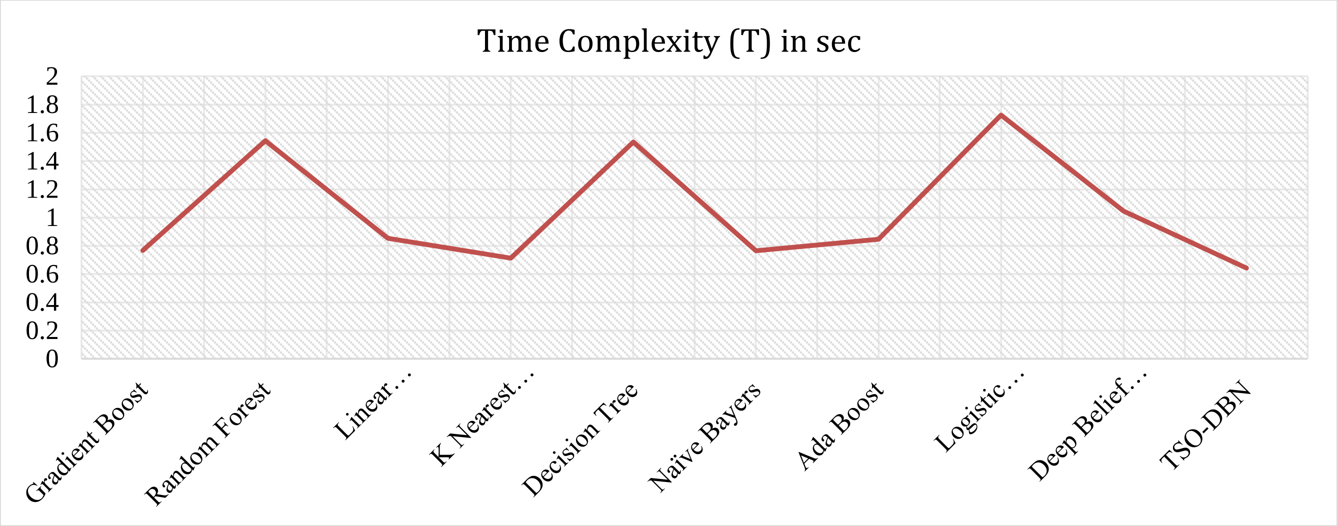

Fig. 6. Time complexity comparison of different pre-trained models.

## V. Discussion

The assessment of prediction models for type 2 diabetes requires a careful consideration of metrics such as accuracy and recall, pivotal in evaluating model performance. While high recall is crucial for identifying positive instances accurately, achieving a balance between accuracy and completeness is often essential, leading to the common use of the F1 measure, representing the harmonic mean of precision and recall. In this study, Table III presents a comprehensive comparison of ten traditional machine learning (ML) and deep learning (DL) classifiers, evaluating their efficacy in predicting type 2 diabetes through metrics including accuracy, area under the curve (AUC), recall, precision, F1 score, and Matthews correlation coefficient (MCC), benchmarked against the TSO-DBN model. Notably, the TSO-DBN model demonstrates superior performance with an F1 score of 0.9623, surpassing other classifiers such as Logistic Regression (LR), which exhibited notably lower performance with an F1 score of 0.4867. Furthermore, the TSO-DBN model achieves the highest recall score of 0.8819, underscoring its effectiveness in identifying positive instances. MCC results further reinforce the TSO-DBN model's superiority, with a performance rate of 0.8863 compared to classical ML classifiers. These findings, summarized in Fig. 5, highlight the TSO-DBN model's effectiveness in predicting type 2 diabetes risk, yielding near-optimal outcomes across all evaluated measures. Additionally, the comparison of prediction and training timeframes reveals insights into the computational efficiency of different models, with Linear Discriminant standing out for its impressive training time, further emphasizing the balance between model intricacy and computing efficiency in diabetes forecasting.

## VI. Conclusion

This study introduced a TSO-DBN to accurately forecast the occurrence of diabetes. The model was enhanced by integrating the Tabu Search optimization process. The TSO-DBN model is utilized on a database of diabetes health parameters, and predicted outcomes reveal that the suggested approach has attained the best accuracy of 96.23%. The diabetes prediction model was assessed using precision, recall, and F-measure, yielding scores of 0.8746, 0.8819, and 0.8749, respectively. Additionally, the Matthews correlation coefficient (MCC) result achieved was 0.8863. Hence, a comprehensive evaluation was carried out, and the model reported in this study shown commendable performance and yielded excellent outcomes. During the trial, it was noted that the TSO-DBN algorithm significantly improved the model's performance and prediction outputs. Therefore, one of the forthcoming tasks is to integrate and evaluate metaheuristic optimization techniques in place of Tabu Search optimization in order to enhance the efficiency of DBN classification. We are also addressing another constraint, which involves researching several other models for predicting diabetes mellitus. These models aim to accurately identify and prevent the occurrence of diabetes. Future research will explore and assess different deep neural network techniques to identify the most precise approach for predicting diabetes. This method can then be implemented in healthcare settings as an alternative to traditional tests performed in laboratories.

## Declarations

Data Availability: The datasets used in the current study are available publicly.https://data.world/uci/pima-indians-diabetes (accessed on 25 January).

Funding Statement: No funding is required for this research.

Conflict of Interest: The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

# A Model for Automatic Code Generation from High Fidelity Graphical User Interface Mockups using Deep Learning Techniques

Michel Samir, Ahmed Elsayed, Mohamed I. Marie
Department of Information Systems-Faculty of Computers and Artificial Intelligence, Helwan University, Cairo, Egypt

***Abstract*—Graphical user interface (GUI) is the most prevalent type of user interfaces (UI) due to its visual nature, which allows direct manipulation and interaction with the software. Mockup-based design is a frequently used workflow for constructing GUI. In this workflow, the anticipated UI design process typically progresses through multiple steps, culminating in the creation of a higher fidelity mockup and subsequent implementation of that mockup into code. The design process involves repeating those multiple steps because of the ongoing changes in requirements, which can make the process tedious and necessitate modifications to the GUI code. Additionally, the process of implementing and converting a design into GUI code itself is laborious and time-consuming task that can prevent developers from dedicating the bulk of their time implementing the software's functionality and logic, making it a costly endeavor. Automating the code generation process using GUI design images can be a solution to mitigate these issues and allow more time to be allocated towards building the application's functionality. In this research paper, deep learning object detectors are employed to detect the predominant UI elements and their spatial arrangement in a high-fidelity UI mockup image. This approach generates an intermediate representation, including the layout hierarchy of the user interface leading to the automation of the front-end code generation process for the mockup. The proposed approach demonstrates its effectiveness through experimental results, achieving a recognition mean average precision (mAP) of 91.37% for atomic elements and 87.40% for container elements in the mockup image. Additionally, similarity metrics are employed to assess the visual resemblance between the generated mockups and the original ones.**

## I. Introduction

In an interactive software, there are user interfaces (UIs) which are used by users to communicate with the system and to operate the system's functionalities. The most popular form of UI is graphical user interface (GUI) because of its visual nature which allows direct manipulation of the software. The development of GUIs for apps is often a manual and time-consuming task. Based on a survey [1] conducted among over 5,700 developers, around 51% reported working on app UI design tasks on a daily basis, more than other development tasks, which they tended to perform every few days. Another study revealed that an average of 45% of the code size of software is relevant to the user interface and that the average time spent on the user interface portion is nearly 50% during the implementation phase [2].

A common workflow for building user interfaces is mockup-based design [3]. In this approach, a graphic designer creates a rough illustration of the anticipated UI design. Ideally, design process need to go through several steps. It often starts as a digital or sketched wireframe [4]. A wireframe is a document which outlines the basic structure of the application. A wireframe does not define specific details such as colors. After a wireframe is created, it is refined and more detail is added i.e. it becomes a higher fidelity mockup [5]. After finalizing the design, the implementation of that design starts. Finally, that prototype should be evaluated to check its usability and to discover design problems. Those steps are repeated until the prototype considered satisfactory. With continuous changes in the requirements, this whole design process becomes monotonous and the GUI code needs to be modified accordingly.

This process of implementing client-side software based on a GUI mockup created by designers is the responsibility of developers. Implementing and converting a design into GUI code is time-consuming for the developer and prevent developers from dedicating the majority of their time implementing the actual functionality and logic of the software and therefore costly. Moreover, considering the complexity of UI, generating the GUI code from mockups requires extensive experience as extracting visible elements and their relationship, selecting proper widgets from diversity of UI components, and generating source code are error-prone task. One more problem associated with generating front-end code from GUI image is that computer languages used to implement such GUIs are specific to each target runtime system; thus resulting in tedious and repetitive work when the software being built is expected to run on multiple platforms using native technologies [10].

To cut down these problems, and to invest time in building the actual functionality of the application, front-end code automation is required. Basically, developers have to visually realize UI elements and their spatial layout in the image, and then translate this knowledge into proper GUI components and their compositions. Automating this visual understanding and translation would be beneficial for bootstrapping GUI implementation. However, it is a challenging task due to the diversity of UI designs and the complexity of GUI code to generate. Understanding mockups in the form of images by a machine is a problem of Computer Vision since it entails a machine making deductions from mockups, understanding them and extracting logical information from them. Computer Vision has made surpassing progress since its beginning. Deep learning methods may be applicable to this task. Deep Neural Networks (DNN) has been extremely popular with the introduction of Convolutional Neural Networks (CNN) and has shown considerable success over classical techniques when applied to other domains, particularly in vision problems [6, 7, 8].

Detection of objects in UI screenshots is an unusual visual recognition task that requires a distinct solution. In this research paper, a novel approach is introduced for identifying UI elements in high fidelity GUI mockups through the utilization of Deep Learning, as well as generating code automatically. To accomplish this, YOLOv7 [9] object detector models are employed in order to detect atomic and container elements within a UI screenshot. These detectors are trained using a specifically curated dataset of UI mockup images. Subsequently, UI representation object and layout hierarchy are constructed to assist generating cross platform code.

This study makes two primary contributions. Firstly, it proposes a unique approach that separates atomic and container UI elements into distinct models, resulting in enhanced detection accuracy. Secondly, it involves the creation of a data preprocessing pipeline specifically designed to overcome the limitations found in the semantic dataset. This research paper sticks to mockups rather than hand-drawn wireframes as there is no universally agreed-upon standard for wireframe symbols and they may not provide the level of precision and consistency required for complex UI designs.

The rest of the paper is organized as follows. The background is illustrated in Section II, followed by the related works in Section III. The dataset and data preprocessing pipeline are discussed in Section IV, followed by the research methodology in Section V. The evaluation is illustrated in Section VI. Section VII provides a discussion that compares the results with existing studies. Section VIII sketches out the future work. Finally, Section IX concludes the paper.

## II. BACKGROUND

There is a misunderstanding regarding the meanings of wireframes, mockups, and how they differ from each other. It is important to provide an accurate explanation and distinguish these concepts from one another. The design process can be divided into three stages sequentially, namely wireframes, mockups, and prototypes. While the aforementioned sequence is prevalent and commonly used, it is possible for the design process not to go through all the stages or have minor variations depending on the designer, team, and project. For the purpose of this discussion, the focus will be on wireframes and mockups.

### *A. Wireframes*

A wireframe also known as screen blueprint is a document which outlines the basic structure and layout of a page or screen when referred to applications that demonstrates what interface elements will exist on key pages. A wireframe is regarded as a low fidelity design document due to its simplicity and lack of visual styles and branding elements. Additionally, it does not provide specific details, such as colors, images or even right content. Furthermore, its purpose is to offer a basic visual understanding of a page at the beginning of a project to obtain approval from stakeholders and the team before commencing the creative phase.

Wireframes can be classified into two categories: digital or hand-drawn wireframes. Hand-drawn wireframe, also known as sketch, is useful for early design stages and rapid iterations. It helps designers to quickly visualize rough ideas, create an initial model for the overall layout in a basic format. On the other hand, digital wireframe is more detailed but yet simple. It is usually created using digital wireframing tools. While it still does not include specific components like images or full text, it provides much more detail than its Hand-drawn counterpart as shown in Fig. 1.

Despite the availability of digital wireframing tools, most designers tend to begin by sketching on paper with a pen (Hand-drawn wireframe). This is because designers usually possess an art background and may feel limited by digital tools. Although there is no universally agreed-upon standard, wireframe sketches generally use a similar group of symbols that have commonly understood meanings. Fig. 2 illustrates some of these elements.

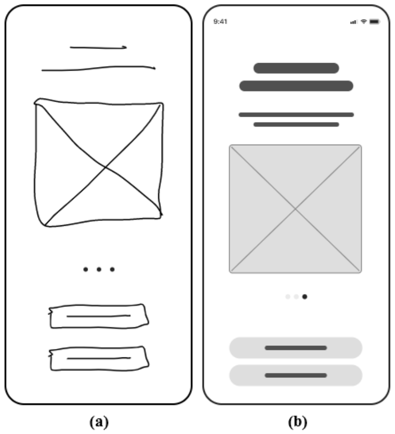

Fig. 1. The difference between Hand-drawn wireframe (a) and Digital wireframe (b).

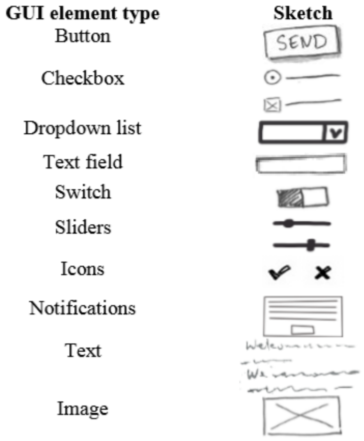

Fig. 2. Examples of elements commonly used to represent UI elements in wireframes.

### B. Mockups

A mockup is a high fidelity design document that is the most detailed and closest to the actual end product design and similar in nature to an app GUI screenshot. It proposes the final look of the design and is usually built between wireframing and prototyping. Wireframes are designed to represent the structure and functional requirements, which are then featured in mockups. Therefore, mockups are essentially wireframes with visual design, such as images, colors, and typography. Fig. 3 shows the difference between wireframe and mockup.

Additionally, those mentioned concepts can be classified in another way. They can be classified into three different levels: (1) low-fidelity, which resembles hand-drawn wireframes and outlines the basic structure of a page, (2) mid-fidelity, which resembles digital wireframes and is the start of mocking up the actual interface, and (3) high-fidelity, essentially mockups with high-quality visuals and contents.

When it comes to wireframes and mockups, designers have different practices and preferences, they can: (1) start with hand-drawn wireframes and then immediately craft mockups, (2) start with digital wireframes and then convert them into mockups, or (3) start with hand-drawn wireframes, convert them to a digital format and then to mockups. After completing the final design document, designers pass their work on to front-end developers for implementing it into code. Implementing user interfaces involves re-creating in code what the designers created graphically in a software. Although developers typically prioritize implementing core functionalities, they often end up spending a significant amount of time coding user interfaces.

## III. Related Work

Recently, there has been a growing interest in the use of deep learning and computer vision techniques to automatically generate UI code, which is a relatively new field of research. This section provides a review of the existing techniques and approaches that uses deep learning and computer vision to classify UI components in mockups presented as images. In this section, the attention will be directed towards the relevant studies that specifically concentrate on mockups and screenshots.

Fig. 3. The difference between Hand-drawn wireframe (a) and Digital wireframe (b) and Mockup (c).

Authors in [10] proposed an application, called Pix2code that transforms high-fidelity GUI screenshots created by designers into computer code. This application utilizes a Deep Learning framework to convert GUI images into their corresponding code for three different platforms, namely web-based, Android and iOS. The pix2code dataset is constructed by mapping bootstrap-based websites into Domain-specific language (DSL) consisting of 18 vocabulary tokens that describe websites layout and components. The dataset comprises 3,500 pairs of websites GUI images and their corresponding markup which is in DSL code. The main idea behind Pix2code is to train a model to learn the mapping between a GUI screenshot and the corresponding code that generates the GUI. The model relies on two main components. First, a Convolutional Neural Network is used to perform unsupervised feature learning on the GUI image. Second, a Recurrent Neural Network (RNN) is used to perform language modeling on the DSL code associated with the input GUI image.

In Pix2code, a three-step approach is required to solve the problem. First, a CNN-based image encoder is used to extract high-level visual features from GUI screenshot. These features are then passed through a fully connected layer to generate a fixed-length feature vector, which represents the input image. Second, long short-term memory (LSTM) network is used which is a type of RNN architecture. The LSTM network is trained to perform language modeling on the DSL code associated with the input GUI image. As a result of this training, the LSTM network gains an understanding of the syntax and semantics of the source code, which enables it to generate a language-encoded vector. This vector is a sequence of one-hot encoded tokens that correspond to the DSL code. Third, LSTM-based code decoder is used. Vectors from the previous two steps are concatenated and then fed into this decoder, which is able to generate high-quality code that accurately reflects the layout and components of the input GUI image. This LSTM decoder is trained to learn the relationship between objects present in the input GUI image and the associated tokens present in the DSL code.

While Pix2code performs well with simple datasets, it struggles with complex datasets containing numerous code tokens. To address this limitation, a novel front-end code generation approach is proposed [11], which utilizes multiple heads of attention to examine the feature vectors of GUI screenshots. This technique enables the analysis of the feature vectors, generation of code tokens, and seamless integration of the analysis and generation processes.

In the cited study [12], the approach is divided into three main components: (1) object detection, (2) text recognition, and (3) code generation. The process involves inputting a GUI image and running parallel modules for image processing, deep learning, and text detection and recognition. The GUI elements are detected using a fusion of deep neural network and traditional image processing techniques, followed by integrating the results from the text detection and recognition module. The detection results are then used to generate corresponding codes using a parser. Another study proposed in [13], employed a Deep Learning (DL) approach to design a system for generating GUI code for websites. A dataset containing the coordinate, width, height, and type information of GUI objects is curated using 7500 webpages. This dataset is then utilized in the proposed system to detect objects within GUI images and generate DSL mark-up code.

Nguyen et al. [14] was the first to propose the technology of automatic reverse engineering of mobile application user interface (REMAUI). By analyzing screenshots of a mobile application's user interface, REMAUI detects the presence of different components, such as buttons, textboxes, and pictures, and generates their corresponding code. Their study was the first to utilize computer vision and optical character recognition techniques in addition to mobile specific heuristics to enable conversion of screen images into code for mobile platforms. This method not only translates the structure, but also the style (images, colors, fonts) of the designs. The REMAUI method works successfully, but its potential is limited by the time-consuming process needed to adapt techniques for identifying new elements.

Moran et al. [15] proposed ReDraw based on REMAUI. ReDraw is an algorithm that takes mockups of mobile application screens and generates structured XML code for them. The paper outlines a three-stage approach to automate the conversion of GUI designs to code, which involves the following steps: (1) Detection, (2) Classification, and (3) Assembly. The initial stage of their approach involves utilizing computer vision techniques to identify the individual components of the GUI. In the second stage, the identified components are classified based on their functionality, such as toggle-button, text-area, etc. This is achieved through the use of CNN. In the final stage, the XML code is generated by combining the results of the previous stages with the K-nearest neighbor (KNN) algorithm, which organizes the code based on web programming hierarchy. It is worth noting that the authors of this paper have also contributed to the development of a dataset. The dataset includes 14,382 GUI images with a total of 191,300 annotated GUI segments. These segments encompass 15 different classifications, including RadioButton, ProgressBar, Switch, Button, and Checkbox. The aforementioned CNN model relies on this dataset for training and evaluation purposes.

A framework proposed in [16] takes UI pages as input and generates the corresponding GUI code for Android or iOS as output. The authors first utilize traditional image processing techniques, such as edge detection, to identify the location of UI elements. They then employ CNN-based classification to determine the semantics of the UI elements, such as their type. The proposed framework consists of three phases, namely component identification, component type mapping, and GUI code generation. Component identification involves extracting components from the UI pages using image processing techniques, followed by identifying the component types (such as Button or TextView) using a deep learning algorithm based on CNN classification. Component type mapping maps the identified component types to their corresponding components in the target platform. GUI code generation generates the final GUI implementation code based on the component types and their attributes obtained from the previous two phases. The critical phase in this framework is the component type mapping, which employs a large map to generate the final code based on heuristic rules.

UIED is a GUI element detection toolkit [17] that was introduced in 2020. Using an image-based approach, it provides users with a platform for detecting GUI elements. The toolkit offers a web interface that enables users to upload their GUIs, and the system automatically detects and identifies the elements within them. In the approach proposed by [17], the detection task is split into two parts: (1) non-text element detection and (2) text detection. To extract non-text regions, traditional computer vision algorithms are utilized, while deep learning models are employed for classification and text detection. To detect non-text elements, the approach utilizes the Flood-Fill and Sklansky algorithms to identify potential layout blocks. The image is then subjected to edge detection and converted into a binary map form. The binary map is segmented into block segments based on the previously detected blocks, and the connected component labelling algorithm is used to detect GUI elements within each block. The detected elements are then classified using a ResNet-50, which was trained on a dataset of 90,000 GUI elements divided into 15 classes. To detect text, the approach utilizes the advanced EAST OCR, which is a deep learning-based scene text detector that can accurately identify text within the screenshot image.

Screen Recognition [18] is a system that generates metadata describing UI components from a single GUI image. This metadata is then forwarded to iOS VoiceOver, which enhances accessibility. The system is optimized for mobile devices, ensuring that it is both memory-efficient and fast. To achieve this, it utilizes deep learning techniques trained on an iPhone application dataset. The authors created a dataset of GUIs from thousands of iPhone applications by manually downloading the top 200 most popular applications from each of the 23 categories (excluding games). They then gathered screenshots of visited UIs and their metadata (tree structure, properties of UI elements), but the data was incomplete, so manual annotation was required. Ultimately, 40 individuals annotated all UI elements in the collected screenshots using bounding boxes and identifiers, resulting in a dataset of 77,637 annotated UI screens. The UI detection model is designed to extract elements from a GUI and classify them accordingly. To achieve this, the solution employs an SSD model with a MobileNetV1 backbone. After the inference, the output is post-processed to eliminate extraneous detections, and the built-in OCR service is utilized to identify any missing elements. However, since the detector generates separate bounding boxes for each element, the UI elements need to be grouped. This is accomplished using hard-coded heuristics that were empirically acquired from 300 randomly selected samples.

## IV. Data Preprocessing Pipeline

Before presenting the proposed methodology and exploring it in details, a dataset is established that comprises clean UI annotations based on an existing mobile UI corpus. This section introduces a data preprocessing pipeline specifically designed to overcome challenges and problems associated with the UI corpus in order to produce a polished and clean dataset. This pipeline not only helps overcome UI corpus challenges but also plays a crucial role in converting raw data instance within the dataset into a format that is compatible with the proposed methodology. In this section, a detailed description is provided of the dataset creation process and outlines the steps involved in the data preprocessing pipeline.

### A. *Mobile UI Corpus*

The research experimental dataset is constructed by leveraging the open sourced Rico [19] dataset. The Rico dataset stands out as the most extensive public collection of mobile GUIs. It comprises 66,261 distinct GUI screens obtained from over 9.7k free Android applications spanning 27 diverse categories. Each example within this large-scale dataset consists of a screenshot and its corresponding view hierarchy metadata. A view hierarchy represents a tree structure of the UI layout wherein each node corresponds to an element within the UI. Each node encompasses a range of properties, including the UI element's position, its Android class, and various attributes that define the element.

Although the view hierarchy metadata provides specification for UI elements and their layout, a notable issue arises from the fact that the captured view hierarchies often contain enormous number of different element types. This abundance of different types poses challenges for training deep learning models and can potentially adversely affect their performance. Additionally, the view hierarchy metadata may include elements with overly generic types like View, WebView, as well as elements with custom types such as custom views or views from third-party packages. Consequently, this lack of specificity in element types hampers the conveyance of meaningful semantic information about the UI components displayed on the screen.

To address this, Liu et al. [20] suggest a method for generating semantic annotations where semantic types are assigned to the UI elements of the Rico view hierarchies. These annotations are applied on each screenshot in Rico dataset, enabling the identification of elements present in the UI along with their associated view hierarchy as a tree. 25 types of UI elements are defined in these sematic annotations, including TEXT, IMAGE, DRAWER, BUTTON, and more. However, the generated annotations are still noisy and not suitable for the purpose of comprehending GUIs. In this paper, these semantic annotations, which is in JSON format, and its corresponding screenshots obtained from the Rico dataset are referred to as the semantic dataset.

### B. *Semantic Dataset Limitations*

In this section, the objective is to highlight the limitations identified in the semantic dataset, with the aim of obtaining a clean UI dataset that improves the performance of the proposed model. The primary concern lies within the UI elements themselves. One issue arises when the JSON annotation contains bounding boxes of an element that do not have visual correspondences on the corresponding screenshot. Another issue involves misaligned elements where bounding boxes partially cover other elements. An additional issue arises with elements that are extremely small, resulting in a zero area due to the element's boundary box having zero values for both width and height.

Another primary concern revolves around the incorrect semantic annotations assigned to UI elements. For instance, an ON-OFF SWITCH element being mistakenly labeled as an INPUT element. In addition to incorrect labeling of certain UI elements in the screenshots, there are cases where entire screenshots are inaccurately labeled, as if the annotations belong to an entirely different screenshot as shown in Fig. 4. Another significant concern emerges when the annotation JSON contains different semantic types that share the same bounding boxes. This creates a problem in determining which type among them is the correct one to consider for that particular boundary box.

Another observed issue is the presence of elements that are repeated multiple times in a screenshot, following a pattern such as items in a list or grid. While these elements may have similar shapes and structures, they are assigned different semantic types. For instance, in a list arrangement, some elements are labeled as ICON type while others are labeled as IMAGE type, despite all of them having the same shape. There is an additional concern regarding DRAWER and MODAL types, which are regarded as containers. The problem revolves around identifying UI elements that are contained within these types, as well as distinguishing elements that are not part of them, even if their boundary boxes overlap with both.

The most recent and significant issue observed is that certain UI elements are semantically labeled based on their functionality. However, visually, these elements should be categorized under a different UI type due to their shape and resemblance to that type. For instance, there are UI elements labeled as RADIO_BUTTON based on their functionality, but visually, they closely resemble the BUTTON type on the screenshot as shown in Fig. 5. This issue has the potential to significantly challenge the model and impact its performance. In order to construct the experimental dataset, limitations and issues highlighted above with the semantic dataset should be addressed through a data preprocessing pipeline.

### C. Data Preprocessing Pipeline

The data preprocessing pipeline comprises four phases, as shown in Fig. 6: (1) neglecting phase, (2) extraction phase, (3) selection phase, and (4) formatting phase. In the initial stage, known as the neglecting phase, any incorrect data instances in the dataset are discarded. Data instances in the dataset are neglected if the entire screenshots have incorrect labels. Additionally, data instances are neglected if the screenshots do not come from an application and only consist of an Android launcher.

During the second phase, the objective is to extract all UI elements that are presented in the annotation JSON for each screenshot. To accomplish this, a Depth-First Search (DFS) algorithm is employed using recursion to traverse the annotation's tree for each screen. The outcome of this phase is the generation of a file for each screenshot, where each file contains a Python dictionary comprising all the extracted final UI elements. While executing this phase, UI elements with zero area are disregarded. In cases where multiple UI elements share the same boundary box, the last UI element visited during the pre-order traversal is retained and its semantic type is considered as the appropriate choice for that boundary box neglecting other elements that share the same boundary box.

During execution and when encountering a node in the JSON tree with the DRAWER or MODAL types, these types are treated as the parent node and added to a STACK. This signifies that all the visited children (UI elements), until reaching the parent node again, are contained within this type. Subsequently, the parent node's type is removed from the stack. All these UI elements associated with the parent node are stored in a separate list. Next, a check is performed to determine if there is any overlay (IOU) between any other UI element found in the annotation JSON and the parent type (DRAWER or MODAL). If the overlay exceeds 20%, the element is removed as it is considered to be hidden under the parent type (DRAWER or MODAL), as observed through Trial and error.

Fig. 6. Data preprocessing pipeline.

In the selection phase, the goal is to discern and filter the most suitable UI images for each semantic type, while excluding the incorrect ones. For every semantic type such as TOOLBAR, DRAWER, and others, a corresponding folder is generated to store all the images related to that semantic type. To accomplish this, the output of the preceding phase is utilized, which includes a generated file for each screenshot containing the extracted UI elements. For each file, each UI element is extracted based on its boundary box by cropping it from the image, and then place it in the folder that corresponds to its semantic type. The outcome is a set of folders, each named after one of the semantic types, and each folder contains images of UI element specific to that semantic type.

Two checks on the images are performed within each folder. Firstly, any image that has been labeled incorrectly is identified and should actually belong to a different type. Secondly, we prioritize retaining the standard shapes associated with each type, while eliminating UI elements that might have similar functionality but visually belong to a different semantic type. Based on these checks, all false images are eliminated/deleted, resulting in filtered folders that exclusively contain the visually best images of their respective UI elements.

The final phase is the formatting phase, where the boundary boxes of the UI elements are normalized. Moreover, each UI type is encoded with a predefined number to ensure compatibility with the YOLO format. The purpose of the formatting phase is to prepare the dataset in a suitable format to be used as input for the proposed model. To achieve this, the generated files obtained from the extraction phase are utilized. We iterate through each UI element in each file and verify if it is still present in the corresponding folder of its semantic type. If it is, the UI element is considered valid. Its boundary box, alongside its corresponding UI type, is saved in a text file using the YOLO format. Conversely, if the UI element is not found in the designated folder, it is neglected and excluded from further processing.

By employing the YOLO labeling format, this phase yields the creation of a text file for each screenshot, mirroring their respective names. Each text file contains separate lines, with each line presenting the details of a single UI element, including its boundary box and type. The boundary box and type for each UI element are described using specific representations. The bounding box is denoted by four values:

x_center, y_center, width, and height. The x_center and y_center represent the normalized coordinates of the bounding box's center. To achieve normalization, the pixel values of x and y, corresponding to the center of the bounding box on the x- and y-axis, are divided by the width and height of the image, respectively. The width and height values indicate the dimensions of the bounding box, and they are also normalized. In relation to the UI type, all semantic types are assigned numerical encodings. Each number corresponds to a specific UI type.

Finally, each UI element is represented in the YOLO format as a line, consisting of the encoded UI type known as class, normalized x_center, normalized y_center, normalized width, and normalized height. The outcome of this phase is our custom dataset in which each data instance includes a UI screenshot along with its corresponding text file, providing descriptions of the UI objects present in the screenshot in YOLO format.

### *D. Semantic Types*

In this research, the primary emphasis lies on specific 20 semantic types, from those outlined by Liu et al. [20] in their semantic dataset. However, modifications are made by introducing new semantic types that are described below. The intention behind introducing these new types is to prioritize the visual aspects of the elements, enabling us to accurately translate these UI elements into corresponding code widgets.

Before introducing new semantic types, the WEB VIEW type is excluded because it does not qualify as a standalone semantic type. WEB VIEW refers to web content that is displayed within a mobile application, encompassing various UI elements that are not individually labeled. This research opted to exclude the VIDEO type and instead categorized them as IMAGE type since we consider them to be indistinguishable on static screenshots. Additionally, based on the same rationale, the ADVERTISEMENT type is excluded and classified as an IMAGE type. This decision is supported by the fact that in the code, the same image cannot be selected to be displayed as an advertisement, as it is a real-time process. We differentiate between the IMAGE and ICON types. IMAGE is reserved for real images that depict tangible objects, which can be captured by sensors. On the other hand, ICON is used to represent vector graphics images and logos.

In contrast, additional UI types are also introduced, including BOTTOM_SHEET, SPINNER, and PROGRESS_BAR. Within the RICO dataset, there are numerous screenshots that feature progress bars, even though they are not specifically classified as a type in the semantic dataset. To address this, an analysis was conducted by inspecting the nodes in the view hierarchy that contained an Android class named ProgressBar. In relation to BOTTOM_SHEET, the investigation of the DRAWER type revealed that bottom sheets are classified along with drawers. Drawers are side-bar menus that display an application's primary navigation options and can be toggled to open or close. On the other hand, bottom sheets are surfaces that contain supplementary content and are anchored to the bottom of the screen. We decided to categorize them separately because we perceived significant visual distinctions that warranted the creation of new class. Moreover, from a coding perspective, these elements require the implementation of entirely different widgets. Similarly, a similar situation was encountered with the SPINNER type. Initially, it was grouped under the MODAL type. However, as modals represent pop-up windows or dialogs, and spinners are drop-down menus, we decided to separate them due to the same rationale applied to the DRAWER and BOTTOM_SHEET types.

In total, a set of 23 semantic types has been established, encompassing BOTTOM_NAVIGATION, BUTTON_BAR, CARD, CHECKBOX, DATE_PICKER, DRAWER, ICON, IMAGE, INPUT, LIST_ITEM, MAP_VIEW, MODAL, MULTI-TAB, ON/OFF_SWITCH, PAGER_INDICATOR, RADIO_BUTTON, SLIDER, TEXT, BUTTON, TOOLBAR, SPINNER, PROGRESS_BAR, and BOTTOM_SHEET.

## V. Research Methodology

Our methodology involves a five-phase pipeline that takes a high fidelity mockup image as input and generates a cross-platform application in real-time as the output. There are five phases involved in our methodology: (1) Model preparation, (2) Object detection, (3) Element post-processing, (4) Construction of the layout hierarchy, and (5) Code generation. The overall architecture of the proposed methodology is illustrated in Fig. 7. As depicted, the process utilizes pre-trained models to expedite training and enhance overall performance. Subsequently, our custom datasets are employed to fine-tune the pre-trained models and tailor them specifically to the desired domain. The training process for these custom models is a one-time occurrence. Once the custom models have been trained, they are employed solely for the purpose of detecting UI elements in the input mockup image.

This paper adopts a DNN approach for object detection. Object detection involves the classification and localization of various objects within an image. It encompasses the assignment of appropriate labels to each object and the creation of bounding boxes around them to enhance recognition. Object detection not only informs us about the presence of specific objects in an image, but also provides information about their spatial location. To locate the UI elements within the mockup images, the YOLOv7 real-time object detection model was utilized. YOLO, also known as You Only Look Once, is a deep learning model that has undergone several iterations to become a powerful solution for real-time object detection and localization. It falls under the category of one-stage detectors, offering fast inference speeds. In this section, the research paper will delve into the five-phase pipeline, providing a comprehensive and detailed explanation.

### *A. Model Preparation*

To enhance the efficiency of YOLOv7, two aspects need to be tackled: (1) dataset-related concerns and (2) hyperparameters of the YOLO model. The first aspect involves addressing two areas: (1) balancing the dataset, and (2) improving dataset quality. The second aspect focuses on the selection of anchor boxes.

Starting with the first aspect, balancing a dataset is crucial because imbalanced datasets pose challenges for predictive modeling. By achieving balance, we ensure that the model does not exhibit bias towards a particular class. To illustrate this point, let's consider the outcome of the selection phase. If the number of UI images in the TEXT folder is compared to the number in the DATE_PICKER folder, a significant class imbalance is observed, with a ratio of 1:1455. This stark contrast in the number of instances for each class highlights the pronounced imbalance within the semantic dataset.

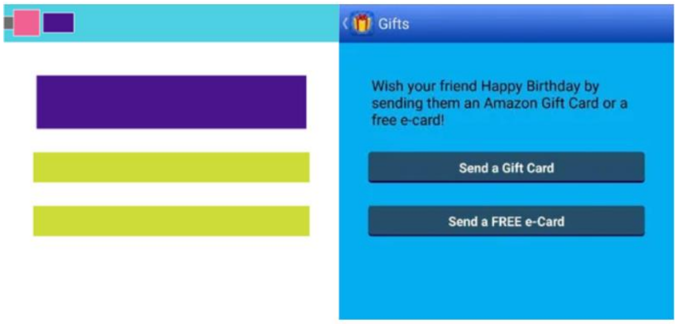
Fig. 7. The overall architecture of the proposed methodology.

In order to address this concern and achieve a balanced dataset, a technique that involves selecting a portion of our custom dataset has been applied in a manner that ensures a more even distribution of instances among all the classes. In this technique, a consistent quantity of screenshots will be allocated to each class (semantic type) in order to ensure that each class is represented in the dataset, particularly for classes with a small number of instances. It is essential that the screenshots selected for a specific class encompass instances that pertain to that class. Assigning a consistent number of screenshots to each class does not guarantee an equal number of instances, as a single screenshot may contain multiple instances of the same class and instances from other classes as well. By adopting this approach, we are able to regulate the quantity of screenshots chosen for each class and consequently the overall number of screenshots. This not only guarantees a minimum number of instances for each class but also sets an upper limit for classes with a large number of instances. As a result, it promotes a more balanced distribution of instances across the classes. This technique is utilized to create all the future datasets from the custom dataset specified in Section IV, which will subsequently be employed with YOLO models.

Furthermore, the utilization of class weights is a prevalent technique employed to tackle class imbalance within a dataset. These weights determine the relative significance of each class during the training process. In this proposed approach, we have incorporated YOLOv7's inverse class frequency weighting, which assigns higher weights to underrepresented classes and lower weights to overrepresented classes based on their inverse frequency within the dataset. As a result, this approach amplifies the importance of less prevalent classes during the training process.

Improving dataset quality is also a crucial concern in the process of training a YOLO model. One recurring issue observed in both the Rico dataset and the semantic dataset is the incomplete labeling of all visual elements present in the screenshot. For instance, while a button may be correctly annotated with the semantic type BUTTON, the accompanying text or icon within the button may not be labeled as shown in Fig. 8.



Wish your friend Happy Birthday by sending them an Amazon Gift Card or a free e-card!

Fig. 8. Incomplete labeling of all visual elements present in the screenshot. The buttons lack proper labeling for their text.

Incomplete labeling for certain classes within the dataset may cause the proposed model to produce false negatives, leading to biased or suboptimal model performance, particularly for the classes with incomplete labeling. The model may struggle to accurately detect and classify instances of these classes resulting in reduced accuracy. In addition, incomplete labeling can lead to a problem in training models because the model might learn incorrect associations from the unlabeled instances of the class. This can result in poor performance when the model is used for prediction on new, unseen data. In order to mitigate this issue, ensuring complete labeling for all classes in the training dataset is essential. Consequently, the necessary step of manually verifying and adding annotations to the unlabeled objects in the screenshots was taken. To accomplish this, Labelimg [21] was utilized, a free, open-source software program written in Python for labeling images that enabled us to thoroughly check and annotate the previously unlabeled objects.

When it comes to the second aspect, which involves adjusting the hyperparameters of the YOLO model, the selection of anchor boxes can significantly enhance efficiency. YOLOv7 is categorized as an anchor-based model. Anchor boxes are predetermined bounding boxes with specific dimensions in terms of height and width. These boxes should be specifically designed to capture the object classes with the scale and aspect ratio that you aim to detect. The general idea is to generate numerous possible bounding boxes initially and then choose the most suitable ones to match the target objects. These selected boxes are then slightly adjusted in terms of position and size to achieve the optimal fit.

The choice of anchor boxes is crucial as YOLO predicts bounding boxes as offsets from these predefined anchors. By selecting optimal anchor boxes, the neural network's workload is reduced, resulting in higher model accuracy. To illustrate the optimal choice of anchor boxes, it is advisable to select anchor boxes that encompass a range of scales and aspect ratios. This ensures a better alignment with the size and shape of the objects being detected. Typically, anchor boxes are selected based on the object sizes found within your training datasets. To achieve this, K-Mean++ clustering algorithm is employed to generate anchor boxes. This involves grouping the ground truth bounding boxes of UI elements in the training dataset into clusters and utilizing the centroids of these clusters as the anchor boxes, based on the number of anchor sizes that is needed. Fig. 9 illustrates the result of grouping boundary boxes of atomic elements into nine clusters based on their scale, where the centroids of these clusters act as anchor boxes.

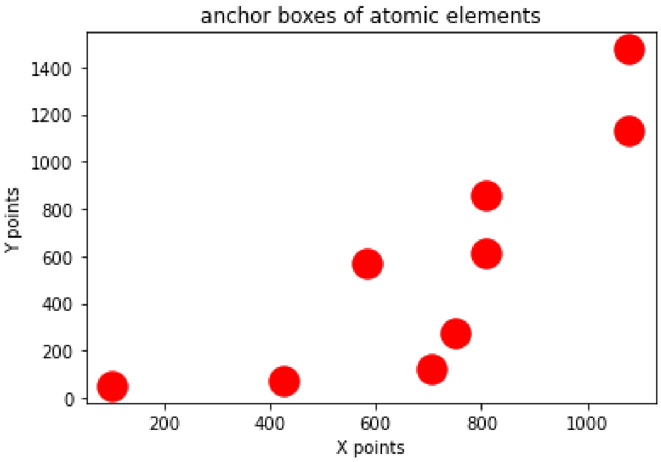


Fig. 9. The anchor boxes are represented by the centroids of atomic elements clusters.

## B. Object Detection

Detecting GUI elements in the input mockup image is the essential phase of the proposed methodology. This particular phase consists of two modules, each with its own responsibility for detecting various elements in the mockup. The first module is designed to detect individual atomic elements, while the second module focuses on detecting container elements. Both modules take the mockup image as input and return the detected elements. Atomic elements are fundamental UI components that cannot be further divided and serve as the basic building blocks of an interface, such as checkbox or text elements. On the other hand, container elements are UI components that encompass and contain other UI elements, like toolbars and drawers. They act as visual boundaries or enclosures that primarily group and include atomic UI elements. Fig. 10 provides examples of both atomic and container elements.

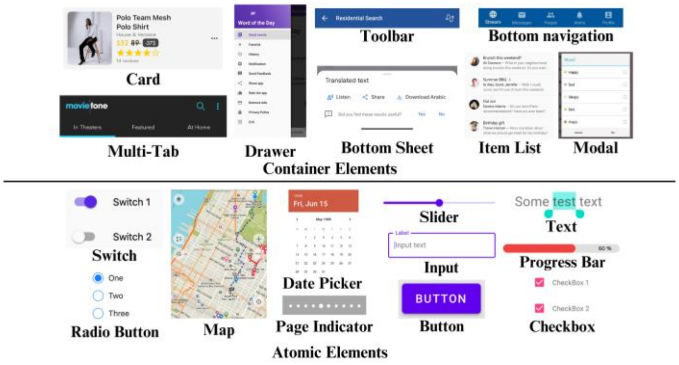

Fig. 10. Examples of both atomic and container elements.

The research paper has separated these types of UI elements into two modules for two reasons. Firstly, it is to address the challenge of handling different object scales. Object detection can be difficult when dealing with objects of varying sizes. One YOLO model may struggle with detecting small objects while performing well on larger ones, and vice versa. By utilizing two YOLO models specifically trained for different object scales, you can enhance the accuracy and reliability of detection. Secondly, by having separate models, you can ensure that training a new class in one model does not interfere with the previously learned classes in the other model. This approach allows you to expand the system's capabilities by adding new classes or new instances for a specific class without affecting the performance of the other model.

To detect atomic and container elements, a separate YOLO model was employed for each module. Each model was trained individually using distinct dataset derived from the custom dataset mentioned in Section IV. The previously mentioned dataset balancing technique was also applied to ensure the datasets were well-distributed. Both atomic and container models were trained for 400 epochs. For each module, the dataset is structured in the YOLO format. This includes a mockup image accompanied by a corresponding text file that describes the UI elements present in the mockup image. The text file contains information such as the object class, object coordinates, height, and width for each UI element. However, only the UI elements relevant to that specific module are retained in the dataset, while the other classes are removed. Initially, pre-trained YOLOv7 models were utilized that underwent training on the COCO dataset. Subsequently, for each module, fine-tuning on the YOLOv7 model was performed using its respective dataset.

In the atomic module, the dataset consists of a total of 1,400 examples. These examples are divided into training and validation sets, with 1,120 examples allocated for training and 280 examples for validation. Similarly, in the container module, the dataset also contains 1,200 examples. These examples are split into 960 for training and 240 for validation. The output of each module is a generated list that contains the detected elements found in mockup image, providing information such as their class labels and corresponding bounding boxes. Finally, the outputs of both modules are combined by concatenating them.

## C. Element Post-processing

In order to convert the mockup to code, it is necessary to detect the visual properties of the UI elements such as their sizes, main colors, and more. The previous phase has generated a list of detected UI elements, but this additional phase is required to accurately identify and extract these visual properties. In addition to capturing the visual properties related to style, it is also important to capture the current state of certain UI elements including aspects such as the content displayed, the selection state (e.g., whether an element is selected or not), or the percentage state (e.g., progress or completion percentage).

By employing classical computer vision techniques, essential styling properties can be extracted for each UI element, such as width, height, main color, and background color. Additionally, for some UI elements, there would be other specific properties for them like border-radius for buttons, number of page indicator circles, and whether a slider is 2-way slider or not and its selected range color. Furthermore, certain UI elements contain dynamic content such as TEXT elements. To extract text from these elements, Optical Character Recognition (OCR) techniques are employed. Specifically, we utilize the open-source Tesseract [22] OCR engine, accessed through the Pytesseract wrapper, which is implemented in Python. This allows us to recognize and extract textual values from regions identified as text by the YOLO model in the mockup image.

On the other hand, there are several UI types that have selection states, such as RADIO_BUTTON, CHECKBOX, PAGE_INDICATOR, and ON/OFF_SWITCH. The proposed dataset, which is used to train the UI detection YOLO model, includes examples of these UI types with their selection states. Some of these types, like radio buttons, checkboxes, and on/off switches, have a true or false selection state. The visual information of these UI elements is utilized to determine whether they are selected or not. The most common visual indicators include the color and the position of certain parts within the UI element itself. For instance, the selection state of a switch can be detected by analyzing the direction of its toggle. The other UI types such as MULTI-TAB, BOTTOM_NAVIGATION, and PAGER_INDICATOR have multiple selection states. Their visual information is utilized to identify the specific item that is selected. The most common visual indicators in this case are the color and size. For example, the selected tab is highlighted with a different color while the other tabs remain unhighlighted. Finally, when there is only one selection, "selected" property is assigned as true if the detected state is selected, otherwise false. In the case of multiple selections, we only record the index of the selected item.

There is another category of UI elements that exhibit a distinct behavior, which is the percentage state. Certain UI types, such as PROGRESS_BAR and SLIDER, always have a selected range. In this case, we have observed that the primary color and length serve as the most prevalent visual indicators. By analyzing the width of the detected element in relation to the length of the selected range, the percentage of the range that is selected can be determined.

Lastly, after completing the post-processing phase, all the determined outcome properties for each UI element are consolidated into a platform-independent UI representation object. This UI representation object is essentially a dictionary consisting of key-value pairs, which effectively represents the recognized UI elements along with their respective properties.

### *D. Constructing Layout Hierarchy*

This phase holds great importance as its objective is to construct the UI layout by aligning the UI elements in a manner similar to the mockup. A novel approach was implemented and is referred to as "UI element grouping". In this approach, once the list of detected UI elements has been obtained from both atomic and container models during the object detection phase, we proceed to conduct an intersection test. This test involves comparing each atomic element with the container elements. If the intersection area between an atomic element and a container element exceeds 90%, the atomic element is considered to be inside the container element.

To initiate the UI element grouping approach, the atomic list and container list obtained from the atomic and container models are utilized as our input. Each UI element within these lists comprises attributes such as class_type_index, area, polygon, boundary_box [XLeft, YTop, XRight, YBottom], and visual properties from the UI representation object. As a result of the UI element grouping, an output in the form of a list is generated representing the layout hierarchy of the mockup. This hierarchy arranges the elements vertically, and we determine whether an element is displayed individually in a row or if it has neighboring elements arranged horizontally within the same row.

To identify the layout structure and determine the positioning of elements relative to each other, a well-defined sequence of steps is followed as outlined in Algorithms 1-5. At first, the YOLO models assign a unique index to each element class, starting from zero and going up to the number of classes minus one, for both atomic and container elements. To prevent any numbering conflicts between the models results, the indexes of atomic elements were adjusted to begin after the indexes of container elements. Subsequently, any inner elements were eliminated, whether they are atomic or container elements. Only the outer elements, which are not contained within any other element, will remain.

**Algorithm 1:** Adjust Indexes

| | |
|---|---|
| **Input:** | List of detected UI elements from the atomic model (a_list)<br>List of detected UI elements from the container model (c_list) |
| **Output:** | Indexes of a_list elements will begin after the indexes of c_list elements to avoid numbering conflict |

```
procedure adjust_ indexes(a_list, c_list)
    for each element in a_list do
        class_type_index = class_type_index  + c_list length
    end for
    return a_list, c_list
end procedure
```

**Algorithm 2:** Eliminate Inner Elements

| | |
|---|---|
| **Input:** | Output of Alg. 1 (a_list, c_list) |
| **Output:** | List comprises outer elements only |

```
procedure eliminate_inner_elements(a_list, c_list)
    outer_elements_list = a_list + c_list
    for each element (A) in outer_elements_list do
        for each other element (B) in outer_elements_list do
            if area of A > area of B then
                if A polygon intersects B polygon > 90% then
                    remove element B from outer_elements_list
                end if
            end if
            if area of B > area of A then
                if B polygon intersects A polygon > 90% then
                    Remove element A from outer_elements_list
                end if
            end if
        end for
    end for
```

**Algorithm 2:** Eliminate Inner Elements

```
        return outer_elements_list
    end procedure
```

**Algorithm 3:** Sort Element List

| | |
|---|---|
| **Input:** | Output of Alg. 2 (outer_elements_list) |
| **Output:** | Sorted list (outer_elements_list) |

```
procedure sort_list(outer_elements_list)
    sort outer_elements_list by boundary_box[YTop]
    return outer_elements_list
end procedure
```

**Algorithm 4:** Element Alignment

| | |
|---|---|
| **Input:** | Output of Alg. 3 (outer_elements_list) |
| **Output:** | List comprises inner lists, with each inner list representing an element and indicating whether or not it has neighboring elements arranged horizontally within the same row. |

```
procedure element_alignment(outer_elements_list)
    let all_elements_adjacents_list as list
    for each element (A) in outer_elements_list do
        let adjacents_list as list for element (A)
        for each other element (B) in outer_elements_list do
            if element B is adjacent to element A (Alg. 6) then
                add element A and B to adjacents_list if not exist
            end if
        end for
        add adjacents_list to all_elements_adjacents_list
    end for
    return all_elements_adjacents_list
end procedure
```

**Algorithm 5:** Remove Duplicates

| | |
|---|---|
| **Input:** | Output of Alg. 4 (all_elements_adjacents_list) |
| **Output:** | If an element has no neighboring elements, its element_list will be empty. If it does have neighboring elements, each of those elements will also have their own element_list with the same elements. To avoid redundancy, duplicate lists are removed. |

```
procedure remove_duplicates (all_elements_adjacents_list)
    for each element_list in all_elements_adjacents_list do
        if element_list is empty then
            This element has no adjacent elements
            Add only this element to element_list
        end if
        if element_list has elements (adjacent elements) then
            Each adjacent element have list with the same elements
            Remove those duplicate lists to that element_list
        end if
    end for
    return all_elements_adjacents_list
end procedure
```

Afterward, the list of remaining elements, which includes both containers and atomic elements, is sorted in a top-to-bottom manner based on the Y-top point of each element. The YOLO detection boundary boxes do not ensure that the elements adjacent to each other will have their boundaries starting at the same horizontal line. Therefore, the purpose of sorting is not to arrange all elements vertically beneath each other. It is primarily aimed at detecting horizontal alignment by ordering the elements in a way that elements adjacent to each other appear consecutively in the list.

Afterwards, the alignment algorithm is utilized to identify elements that are positioned next to each other. In this alignment algorithm, every element in the list is compared to all other elements. The outcome is a separate list for each element, which includes any adjacent elements found for that specific element. We accomplish this by creating vertical lines from the y-top point to the y-bottom point for each element, and then comparing these lines with those of all other elements. If the alignment is approximately 90% horizontally, the elements are deemed to be in the same row and adjacent to each other, as illustrated in Algorithm 6. Following this criterion, if an element is compared to others and adjacent elements are found, its list will include these adjacent elements. Conversely, if an element is compared to others and no adjacent elements are found, its list will be empty, indicating that it is the sole element in that particular row.

As the final step of the algorithm, the list for each element is examined. If the list is empty, it indicates that the element has no adjacent elements. If there are adjacent elements present, each element's list will include the other elements. To avoid duplication, we remove any repeated elements, resulting in a single list that contains all the adjacent elements. These processes are repeated for every container element that contains atomic elements. This allows us to identify the structure of each container, even if it is an inner container. As a result, we are able to detect the hierarchical layout for the entire mockup.

### *E. Code Generation*

The code generation phase is the final step in which the UI representation object, along with the layout hierarchy, is utilized to generate code that can be used across multiple platforms, including Android and iOS. Nowadays, there are several cross-platform solutions like Flutter and React Native, which aim to develop code once and run it seamlessly on both Android and iOS mobile systems. To generate cross-platform code, we made use of Flutter, an open-source UI software development kit developed by Google. We opted for Flutter over other alternatives because it eliminates the use of Platform Primitives. This ensures that the app visually appears almost identical across all platforms, without relying on native look components that may have variations. Algorithm 7 demonstrates the methodology employed for generating code.

**Algorithm 6:** Checking Alignment between UI Elements

| | |
|---|---|
| **Input:** | Element (A) boundary_box [XLeft, YTop, XRight, YBottom]<br>Element (B) boundary_box [XLeft, YTop, XRight, YBottom] |
| **Output:** | If the two elements are adjacent, the function returns true; otherwise, it returns false. |

```
procedure calculate_vertical_overlap (box_A, box_B)
    y1 = max(box_A[YTop], box_B[YTop])
    y2 = min(box_A[YBottom], box_B[YBottom])
    overlap = y2 - y1
    return overlap
end procedure
procedure is_side_by_side(box_A, box_B):
    overlap = calculate_vertical_overlap(box_A, box_B)
```

**Algorithm 6:** Checking Alignment between UI Elements

```
        height1 = box_A[YBottom] – box_A[YTop]
        height2 = box_B[YBottom] – box_B[YTop]
        return overlap >= 0.9 * min(height1, height2)
    end procedure
```

**Algorithm 7:** Generating cross-platform code

| | |
|---|---|
| **Input:** | Output of Alg. 5 (all_elements_adjacents_list). Each inner list (element_list) in all_elements_adjacents_list represents whether the current element has neighboring elements or not |
| **Create:** | Statefull widget class for each UI element type that receives visual properties as parameters. Each widget in a separate file. |
| **Output:** | Return generated front-end cross-platform code |

```
procedure generate_code(all_elements_adjacents_list)
    let column_widget_list as list
    for each element_list in all_elements_adjacents_list do
        if element_list length equals 1 then
            Check element type and call its widget file
            Send element’s visual properties as parameters
            Add element’s widget to column_widget_list
        end if
        if element_list length >1 then
            let row_widget_list as list
            for each element in element_list do
                Check element type and call its widget file
                Send element’s visual properties as parameters
                Add element widget to row_widget_list
            end for
            Add row_widget_list to column_widget_list
        end if
    end for
    return column_widget_list
end procedure
```

There are two primary concerns that require attention: (1) ensuring code readability and (2) implementing effective error handling. Ensuring code readability is a top priority for us. To achieve this, we embrace the concept of reusable components, similar to writing a function once and utilizing it multiple times. Each UI element is represented as a custom widget, which accepts parameters to describe its visual properties as described in the UI representation object. Each widget is organized into its own separate file. Eventually, the generated code files need to be compiled to run on the desired platform. Finally, a mechanism is implemented to handle errors that may appear in Flutter. Unlike HTML markup language, where errors may not disrupt the entire process, Dart (programming language used in Flutter) needs to be successfully compiled in order to run.

## VI. Evaluation and Results

A diverse set of evaluation metrics and criteria are utilized in this type of research, indicating a lack of a clear standard for evaluation. To address this issue within this research, we aim to establish a clear standard for evaluation. The evaluation focuses on two main aspects: (1) the accuracy of object detection models and (2) the degree of similarity in user interfaces between the screens of the mockup and the screens generated from code. Furthermore, a comparison with existing systems was conducted.

The first aspect is to evaluate the accuracy of object detection models, commonly used evaluation metrics are utilized including Accuracy, Precision, and Recall, and others which are widely used in the field of object detection.

$$\text{Accuracy} = \frac{T_P + T_N}{\text{Total Predictions}} \tag{1}$$

Object detection models are commonly evaluated based on a metric called Intersection Over Union (IOU). This metric assesses the extent of overlap between two bounding boxes: the predicted bounding box and the ground truth bounding box. During the training stage, a target IOU threshold of 0.5 is typically sought, meaning that if the model predicts an object with a bounding box that overlaps the ground truth box by at least 50%, it is considered a valid prediction. Adjusting the IOU threshold can impact the values in the confusion matrix. This adjustment influences the number of true positives (TP), false positives (FP), and false negatives (FN), thereby impacting the overall performance metrics derived from the confusion matrix including precision, recall, and F1 score.

In order to demonstrate the efficacy of our proposed models in classifying UI components, three metrics measures were utilized: precision, recall, and F1 score. The calculation of these measurements is as follows:

$$\text{Precision} = \frac{T_P}{T_P + F_P} \tag{2}$$

$$\text{Recall} = \frac{T_P}{T_P + F_N} \tag{3}$$

$$\text{F1 score} = \frac{2\,x\,(precision\ x\ recall)}{precision + recall} \tag{4}$$

These metrics were assessed on the validation set for both atomic (A) and container (C) models. The measured metrics for each UI element are presented in Table I, showing the interesting results achieved by both trained models. Despite the presence of various styles within each component, it can accurately identify almost all of them. Fig. 11 shows sample of detection results by YOLOv7 on the validation set of both atomic and container models. In the realm of object detection, Average Precision (AP) and Mean Average Precision (mAP) have gained widespread popularity as the primary evaluation metrics in recent years. AP is a way to summarize the precision-recall curve into a single value representing the precision at different levels of recall. The average precision is computed by taking the mean of these precision values across all recall levels. A high average precision signifies strong performance in terms of both precision and recall, while a low average precision indicates lower values for either or both metrics. Typically, average precision is calculated separately for each class according to this equation:

$$\text{Average Precision (AP)} = \int_{r=0}^{1} p(r)dr \tag{5}$$

To evaluate the performance of object detection model across the different classes, the mAP is calculated by taking the average of the AP values for all the classes being considered as shown in this equation:

$$\text{Mean Average Precision (mAP)} = \frac{1}{k}\sum_{i}^{k} AP_i \qquad (6)$$

The emphasis was placed on evaluating the overall performance of both YOLO models by prioritizing the measurement of mAP. Notably, the atomic model achieved an outstanding mAP score of 91.37%, while the container model achieved a respectable score of 87.40%. These results indicate a strong capability for detecting elements in both models, reflecting their strong performance in this regard. We selected mAP as our primary evaluation metric because it signifies a model's stability and consistency across different confidence thresholds. A high mAP suggests that the model performs well at various levels of confidence in its predictions. On the other hand, Precision, Recall, and F1 score are metrics used to assess the model's performance at a specific confidence threshold. When the mAP is good, it indicates that the model consistently achieves high precision, recall, and F1 score across different confidence thresholds. This consistency implies the model's stability and reliability in making accurate predictions.

The second aspect is to measure the similarity of images between the mockups and those produced by the generated code. Three commonly employed image similarity metrics, namely mean squared error (MSE), mean absolute error (MAE), and Structural Similarity Index (SSIM), are utilized to measure the similarity. The Mean Square Error calculates the average of the squared differences between the predicted and actual values. It serves as a metric to measure the disparity between the two images, where higher values signify a larger dissimilarity. On the other hand, the Mean Absolute Error calculates the average absolute difference between the predicted and actual values. Similar to MSE, a lower MAE indicates better model performance, as it means that, on average, the predictions are closer to the actual values.

TABLE I. PERFORMANCE OF THE TRAINED MODELS

| UI Element | Precision | Recall | F1 score |
|---|---|---|---|
| Checkbox (A) | 0.93 | 0.95 | 0.94 |
| Date Picker (A) | 0.95 | 0.97 | 0.96 |
| Icon (A) | 0.91 | 0.87 | 0.89 |
| Image (A) | 0.81 | 0.86 | 0.83 |
| Input (A) | 0.83 | 0.8 | 0.81 |
| Map View (A) | 0.89 | 0.82 | 0.85 |
| On-Off Switch (A) | 0.93 | 0.96 | 0.94 |
| Page Indicator (A) | 0.94 | 0.88 | 0.9 |
| Radio Button (A) | 0.86 | 0.93 | 0.89 |
| Slider (A) | 0.9 | 0.83 | 0.86 |
| Text (A) | 0.91 | 0.97 | 0.93 |
| Progress Bar (A) | 0.84 | 0.78 | 0.8 |
| Button (C) | 0.79 | 0.82 | 0.8 |
| List Item (C) | 0.92 | 0.86 | 0.89 |
| Card (C) | 0.78 | 0.76 | 0.77 |
| Drawer (C) | 0.89 | 0.94 | 0.91 |
| Modal (C) | 0.9 | 0.86 | 0.88 |
| Multi-Tab (C) | 0.88 | 0.86 | 0.87 |
| Toolbar (C) | 0.91 | 0.87 | 0.89 |
| Bottom Sheet (C) | 0.83 | 0.86 | 0.84 |
| Spinner (C) | 0.78 | 0.8 | 0.79 |
| Button Bar (C) | 0.91 | 0.93 | 0.92 |
| Bottom Navigation (C) | 0.81 | 0.82 | 0.81 |

Structural Similarity Index is a widely used metric in image processing that quantifies the structural similarity between two images. It takes into account three components: luminance, contrast, and structure. By comparing the SSIM index between the mockup image and the generated code image, we can assess how closely they resemble each other in terms of their structural characteristics. A higher SSIM index indicates a higher similarity between the two images. When evaluating on a testing set of 50 images, our results for MSE, MAE, and SSIM were 30%, 25.7%, and 83.3%, respectively.

Inference time is an important performance metric, as it refers to the measurement of the time it takes for a machine or deep learning model to make predictions or inferences on new data. In order to determine the inference time of YOLO models, the average time it took for inference on a testing set consisting of 50 images was calculated. The inference time varied between 45.6 ms and 85.0 ms, and we observed that as the number of elements in an image mockup increased, the inference time also increased as illustrated in Table II.

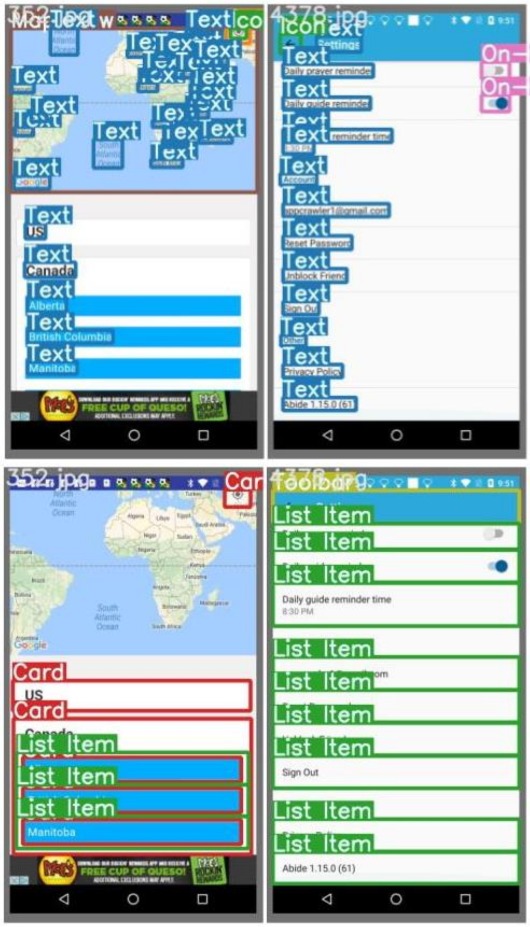

Fig. 11. Sample of detection results by YOLOv7 on the validation set of both atomic and container models.

TABLE II. INFERENCE TIME FOR ATOMIC MODEL

| Number of UI elements detected | Inference time |
|---|---|
| 4 Elements | 46.9 ms |
| 32 Elements | 65.0 ms |

## VII. Discussion

To validate the significance of the proposed approach, a comparative analysis was performed between the proposed system and other systems that specifically target high fidelity mockups using deep learning methods. Table III presents a comprehensive comparison encompassing multiple dimensions, such as system architecture, performance metrics, and the count of detected UI elements. It is important to highlight that each system utilizes a subset of metrics, and therefore, each metric will be compared with its corresponding counterpart in our set of metrics.

Table III presents three distinct categories of techniques: (1) end-to-end, (2) hybrid, and (3) object detection. The end-to-end approach (E) utilizes a comprehensive deep learning model to process mockups or wireframes and generate source code, which can then be transformed into a user interface. Hybrid techniques (H) typically employ traditional computer vision methods to extract the spatial information of UI elements, followed by CNN-based classification to determine their respective types or classes. Object detection (O) involves the identification, labelling, and precise delineation of objects within an image to improve their recognition. Based on this comparison, it is evident that the proposed approach exhibits an improvement in recognizing GUI mockup elements compared to the other systems, although it detects a larger number of elements. It is crucial to emphasize that a comprehensive study was conducted comparing an earlier version that encompassed all UI elements in a single YOLOv7 model. However, the performance of this one YOLOv7 model was not comparable to the two-model approach (atomic and container) due to challenges posed by the visual similarity between certain classes, such as CARD and BUTTON, and DATE_PICKER and MODAL.

TABLE III. Comparison Between the Proposed Approach and Other Systems

| Criteria | [10] | [15] | [16] | [17] | [18] | Proposed |
|---|---|---|---|---|---|---|
| Number of UI elements | NA[a] | 15 | NA | 15 | 12 | 23 |
| Technique utilized | E | H | H | H | O | O |
| Text recognition (OCR) | No | Yes | NA | Yes | Yes | Yes |
| Training dataset | Custom | Custom | Custom | Rico | Custom (iOS) | Rico |
| Accuracy | 77% | NA | 85% | NA | NA | 88.2% |
| F1 Score | NA | NA | NA | 52% | NA | 86.8% |
| Precision | NA | 91.1% | NA | NA | NA | 87.3% |
| mAP | NA | NA | NA | NA | 87.5% | 91.37%, 87.4% for (A), (C) |

## VIII. Conclusion

Converting mockup design images into front-end code presents a formidable challenge, as it necessitates a visual understanding of the images to detect the UI elements and their hierarchical structure. This paper introduces a novel approach that generates cross-platform front-end code from high fidelity mockup images. At the core of the proposed pipeline, YOLOv7 is utilized for the object detection phase. The approach utilizes YOLOv7 to accurately detect atomic and container UI elements, capturing their spatial location, and subsequently leverages this information to construct a comprehensive UI representation object that encompasses the layout hierarchy of elements within the mockup, showcasing its ability to effectively identify UI elements in mockups. Our second contribution entails the development of a data preprocessing pipeline aimed at addressing the limitations present in the semantic dataset. This pipeline enables us to construct custom datasets specifically tailored to the atomic and container models. The conducted technical evaluation showcases the promising nature of this approach and encompasses a broad spectrum of evaluation metrics, providing a foundation for future studies. This study ensures that deep learning techniques are well-suited for visual recognition tasks involving various types of GUI components.

## IX. Future Work

Despite the comparatively small training datasets used, remarkable results are achieved. As a future work, it is imperative to augment the dataset by incorporating additional instances of elements and meticulously annotating them, thereby providing the models with a more diverse and comprehensive set of training data. Furthermore, there is a need for more extensive coverage of certain cases in the UI element grouping approach. This is particularly important when dealing with scenarios where multiple vertically arranged cards are aligned next to only one card.

***Abstract*—Security is one of the important aspects which is used to protect data availability from being compromised. Denial of service (DoS) attack is a common type of cyberattack and becomes serious security threats to information systems and current computer networks. DoS aims to explicit attempts that will consume and disrupt victim resources to limit access to information services by flooding a target system with a high volume of traffic, thereby preventing the availability of the resources to the legitimate users. However, several solutions were developed to overcome the DoS attack, but still suffer from limitations such as requiring additional hardware, fail to provide a unified solution and incur a high delay of detection accuracy. Therefore, the network traffic detection approach (NTDA) is proposed to detect the DoS attack in a more optimistic manner based on various scenarios. First, the high network traffic measurements and mean deviation, second scenario relied on the transmission rate per second (TPS) of the sender. The proposed algorithm NTDA was simulated using MATLAB R2020a. The performance metrics taken into consideration are false negative rate, accuracy, detection rate and true positive rate. The simulation results show that the performance parameters of proposed NTDA algorithm outperformed in DoS detection the other well-known algorithms.**

***Keywords—Network security; DoS attack; cyberattack; network traffic***

## I. Introduction

Cybersecurity has become an important issue in this era, because of continuously increasing the volume of sensitive data and valuable assets that have been targeted by cybercriminals. Therefore, it’s important to protect user information and resources by preventing cybercriminals from gaining this sensitive information [1]. The network layer is susceptible to different types of cyberattack and threats that can be used to disrupt the legitimate communications such as Denial of Service (DoS) attacks [2] that occur in online business and transaction systems. DoS attacks have become the major threat to current information security and network resources due to the deliberate exploitation of system vulnerabilities of a victim at the required time [3], [4]. DoS as the name suggests the attacker prevents or denies the services of the authorized user. Attacks can be initiated by intentionally exploiting the system vulnerabilities of a victim and overloaded with a large amount of unnecessary network traffic to occupy certain resources such as network bandwidth and memory [5], [6], disabling the proper functioning of the network and consume the victim resources as illustrated in Fig. 1.

In a denial-of-service attack, a single computer can be used to accomplish the attack. Whereas many recent DoS attacks have been launched through many malicious attempts distributed across on the internet or networks that have been infected with malware and become part of a botnet, this type of attack is called distributed denial of service (DDoS) attack [7], [8]. In DDoS, the attackers become more sophisticated and informed to destroy the target system. of occurrence way, DDoS attacks can be launched by botnet, proxy, or spoofing IP [9].

These attacks are lethal because they can bypass traditional intrusion detection systems to produce more network traffic. They have particular characteristics and traits, such as a low average rate and use of TCP as attack traffic, which allows them to avoid detection [10]. The objectives of a DoS attack can be classified as [11]:

- Consuming the network bandwidth through massive attacks by sending massive amounts of traffic.
- Consume many available resources by sending specific types of packets, so that the target system will not provide service to normal users.
- Flooding packets crash or overload the network.

Over the years, various security mechanisms have been proposed to overcome the DoS attack such as statistical-based approaches, intrusion detection system (IDS) and machine learning (ML) approaches, etc [12], but they still suffer from limitations of detection accuracy, require more learning time to produce accurate results, and increase the false negative rate.

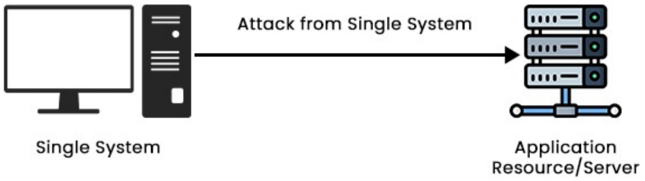

Fig. 1. Implementation of DoS attack.

To solve this problem, NTDA technique has been employed which will distinguish the legitimate traffic from attack traffic in the sense of the appropriate DoS attack based on the request message counter and mean deviation in the network traffic and then, the detection operations will determine the transmissions rate per second (TPS). To provide the requirements protection of information and to address cybersecurity challenges. Therefore, understanding how attacks evolve is an essential step in developing appropriate systems to detect and mitigate DoS attacks.

In this paper, it's important to analyzed the data traffic behavior of the DoS attack in order to provide suggestions for DoS detection in the network environments. Furthermore, several challenges need to find a solution by the proposed NTDA algorithm. These challenges are, failing to provide higher detection accuracy and detection rate. In addition, it faces difficulty in providing a lower false negative rate. Therefore, the proposed algorithm NTDA was implemented to detect the DoS attack with an accurate level of detection to prevent this attack from sending a flood of requests to their victim host. Thus, the contributions of this study are summarized as follows:

*1)* First, we formulate the problem of DoS attack detection and propose a secure detection algorithm against DoS attack in the network. The NTDA can detect the attacker using various detection scenarios and improve detection accuracy.

*2)* The proposed algorithm employs mean deviation for each client to classify network traffic.

*3)* Provide a low false negative rate (FNR) due to the threshold-based detection and measure the TPS, which improves the performance and detection accuracy.

*4)* The performance of NTDA has been simulated and compared with a well-known DoS detection algorithm. The outcomes show that our algorithm outperforms the current compared algorithms.

The remaining of this paper is organized as follows. In Section I, will describe the introduction. Section II about the related works. Section III describes detailed information about technical preliminaries and background. Section IV shows the proposed detection algorithm. Section V describes the security analysis. Section VI provides result comparison and evaluation. Section VII is a summary. Finally, Section VIII concludes the paper.

## II. Related Work

Several algorithms and myriad solutions have been developed against DoS attacks. Some of these algorithms are based on statistical approaches and others are based on machine learning approaches, etc. However, the literature will address some of the main solutions against DoS attacks and provide an illustration about the relevant literature reviewed.

Yu et al. [13] suggest DoS attack mitigation using trust management, especially using session flooding. They measured four user-specific trust metrics after each connection. The metrics are. First, short-term trust. Second, long-term trust. Third, negative trust, and fourth abusive trust. All metrics were combined to generate an overall trust score that is used to determine whether or not to accept the user's next request. After final analysis, they find out that their lightweight engine had negligible overhead and an acceptable level of throughput overhead of based on the typical number of user sessions.

The authors in study [14] carry out the DDoS detection with increased expenditure of time using non-asymptotic fuzzy estimators. The estimator is implemented based on the average package time between milestones. The problem is consisting into two parts: First for actual DDoS detection and the other for identifying the victims' IP addresses. The first part was carried out using real-time hard limits for DDoS detection. Part two, identifying victims' IP addresses is done with relatively few restrictions. The aim is to identify victims' IP addresses in time to activate further anti-intrusion applications. The affected hosts used packet arrival time as the primary statistic to determine DDoS attacks.

The research article in study [15] proposes a DoS attack detection algorithm based on the maximum likelihood criterion based on random neural networks (RNN). The detection mechanism will select a set of offline traffic characteristics to derive estimates and estimate probability coefficients. It measures the characteristics of the incoming traffic and then a decision will be made based on each characteristic. Finally, a global decision is made by employing recursive look-ahead and RNN architectures.

The authors in study [16] suggest a detection method for DoS attacks that relied on a multi-layered framework approach. The proposed system architecture consists of two parts: training set generation and real-time layer IDS. The first part uses the Knowledge Discovery and Data Mining (KDD), while the second method uses a multi-layer real-time IDS engine. Classify the packet between an attack and a normal packet. This set of modules progresses through various levels. First, the signature engine captures the packet signature and extracts features from the incoming packets accordingly. Then, based on the selected features, data is loaded from the dataset and classification is performed using the refined K-means algorithm and Naive Bayes clustering algorithm.

Dapeng Wu et al. proposed in [17] an innovative approach is proposed that can detect DDoS attacks and identify the used packets in the attack. The proposed mechanism used anti-DDoS edge system that scans traffic only on edge routers on the ISP's network. A novelty in our approach is, firstly, feature extraction based on temporal correlation and secondly, detection based on spatial correlation. Using these algorithms, our scheme can detect DDoS attacks in a more accurate manner and determine the attack packets without changing the existing IP forwarding mechanisms on routers.

## III. Technical Preliminaries and Background

In this section, we will characterize the preliminary measures used in this research that are necessary to successfully achieve this research.

### A. DoS Attack Models

Denial of Service (DoS) is basically a cyberattack targeting a specific server or network that is designed to prevent legitimate access from using a specific network application and its resource such as a website, web service and network system. The DoS attack flooding the victim host with a high amount of traffics at the same time [18]. In addition, DoS attacks can consume battery-powered of a mobile device in a situation of high traffic in wireless transmission. Therefore, it leads to crashing the servers or slowing them down and makes the services unavailable to legitimate users as shown in Fig. 2, where the attacker floods the website or victim with suspicious traffic to make the service unavailable [19], [20]. In DoS attack only requires a website address and/or an IP address to carry out the attack. There are various types of DoS attacks such as SYN Flood, IP spoofing DoS attacks.

*1) SYN flood attack:* The SYN flood or (TCP handshaking) attack is one of the most well-known DoS attacks that sends numerous false TCP connection requests, exhausting the resources of the attacked site. SYN flooding works by exploiting weaknesses in TCP protocol that are employed to establish a connection between hosts. This type of SYN flood attack is carried out through a three-way handshaking. Fig. 3 illustrates the mechanism of the SYN flooding attack. When establish a connection in TCP three-way handshaking process of TCP network connection, the SYN packets will send to the destination, it becomes in offline mode or down, then the server unable to receive ACK packets from the client after sending the SYN+ACK acknowledgment, so the server usually tries to establish the connection again and have to wait a while [21]. The uncompleted connection will be discarded, and the waiting time is called the SYN timeout. When attackers generate and use large volume of spoofed or falsifies IP addresses, it leads that the available resources of the server will be consumed due to the large number of connections, which will eventually cause an overloaded and cannot or prevent responding normally [21], [22].

*2) IP spoofing DoS attacks:* Assume a legitimate user willing to connect to the destination, the attacker will establish a TCP connection and mask it with his own IP address, while the normal user's IP address creates a TCP data segment with an RST bit is sent to the destination. After receiving the data, the server clears the buffer of all existing connections, considering the connection with the bad packet. If authorized users need to resend their data, they must log in again. The attacker generates many fake IP addresses by sending RST data packet to the destination, thus, no service will be provided to the legitimate users and victim's server is vulnerable to denial-of-service attacks [21], [23].

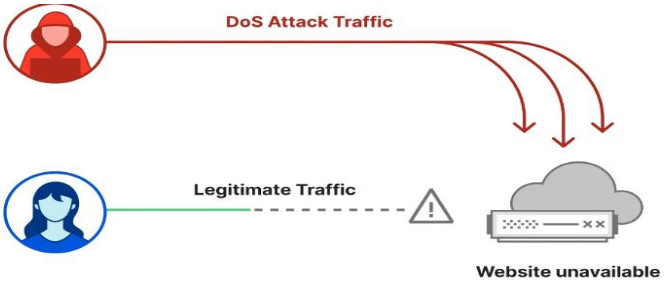

Fig. 2. DoS attack model.

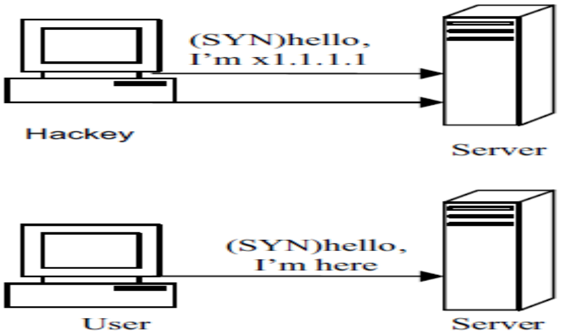

Fig. 3. SYN Flood attack mechanism.

Overall, DoS attacks rely on the direct or indirect depletion of resources on the target side by generating high traffic, resulting in outages that negatively impact service availability and continuity.

### B. *DoS Traffic Behavior*

DoS attacks aim to generate an excessively large volume of network traffic to overwhelm the target. Therefore, the normal traffic is unable to be processed because large traffic significantly affects bandwidth availability and attack detection performance [21]. Therefore, it's important to recognize the DoS attack level and analyze the behavior of traffic. Moreover, during DoS attacks, a drastic change in the current traffic is observed compared to the normal traffic of the previous time interval [24]. Therefore, it's important to monitor and analyze the traffic in the network.

## IV. The Proposed Detection Algorithm

The proposed network traffic detection approach (NTDA) is based on the detection of the high volume of network traffic which consists of two different scenarios applied against DoS attack to all requests that are routed to the target or centralized server. The primary scenario will use high traffic detection to be able to distinguish between legitimate traffic and high attack traffic by employing a request message counter and mean deviation, while the secondary scenario is based on the mathematical model for measuring the TPS of the sender. The procedures of the proposed algorithm are presented as follows.

Step 1: Employ a Request Message Counter (RMC) that increases one when the server receives the same RM from the same user.

Step 2: After that, a mean deviation technique is used to detect abnormal or high network traffic from a single IP address to classify the existence of high traffic.

Step 3: Determine the existence of an attack by applying the threshold value and TPS for DoS attack.

### A. *Assumptions*

This section presents some assumptions about the network connections and adversarial capabilities of the proposed research in NTDA.

Assumption 1: The communications architecture will be based on TCP/IP for information exchange.

Assumption 2: Attacker establishes only one connection towards a victim host.

Assumption 3: The attacker does not implement any address spoofing mechanisms.

Assumption 4: Our proposed approach achieves high detection accuracy in DoS attacks in real-time without requiring hardware components.

### B. Detection Based on Network Traffic

The primary scenario is based on high traffic detection and analysis the network congestion to distinguish between normal data traffic from large attack traffic. The attacker needs to flood the target with a large volume of requests to break down the effectiveness of a network by disconnecting the host, bandwidth depletion and making websites and remaining online resources unavailable to legitimate users. The detection starts when the user sends a request message (RM) containing user identification (UID) for a certain period (Pc) to the target server (TS). Then, the TS receives the RM and checks the message status if it is normal or abnormal by the following steps:

*1)* Each user in the network has a request message counter (RMC) that increases by "one" when the TS receives the same RM from the same user as shown in Eq. (1).

$$RMCi = RMC_i + 1 \qquad (1)$$

*2)* Based on the value of (RMC*i*) in Eq. (1), the TS calculates the meaning of the number RM received from all clients for a certain period as in Eq. (2).

$$MRM = \frac{\sum_i^N (RMCi)}{N} \qquad (2)$$

*3)* Then, the TS calculates the mean deviation for RMC for all available clients, thus using Eq. (1) and Eq. (2) to find the MDi as in Eq. (3).

$$MDi = |\, RMCi - MRM \,| \qquad (3)$$

*4)* Finally, the TS decides the status of RM is normal when the specific RMC is away from the mean and the attack does not exist, while the status of RM is abnormal when the specific RMC is close to the mean, it means an abnormal rise in incoming network traffic. Then the TS will block the suspicious IP source address from accessing the network. The detection of high-traffic pseudocode shown in (Algorithm 1).

Algorithm.1: Pseudocode for high traffic detection

```
Input: RMC
Output: Classified the data traffic, normal or abnormal.
Start
    Determine Pc
    While (Pc != 0) {
    Client i send RM that contains UID to TS during Pc
    TS receives RM and determines client sender.
    RMCi = RMCi + 1
    }
    M_RM = $\frac{\sum_i^N (RMCi)}{N}$
    MDi = | RMCi – M_RM |
    If (RMCi >> M_RM) then {
        RM transmitted from client i is normal.
        DoS_Detected = FALSE
    } Else
    If (RMCi << M_RM ) then {
        RM transmitted from client i is abnormal.
        IP address is added to the suspected list
        Go to Algorithm 2
    }
End
```

However, DoS attacks generate an unusual and excessively high volume of attack traffic in order to overwhelm the target or victim. Algorithm 1 is responsible for determine the behavior and classification of the incoming packet weather high or normal traffic to provide an accurate DoS detection schema. However, if the attacker has been detected through (Algorithm 1), the IP address will be added to the suspected list and the detection processes will move to the (Algorithm 2). Otherwise, if the attacker cannot be detected, the IP address is classified as a trusted IP address list.

### C. Detection Based on Transmission Rate

To illustrate this secondary scenario that plays an important role in the proposed NTDA algorithm, it's an important aspect to identify several requests toward the victim host. This scenario relied on the requests from the source IP address. Continuing with the previous detection scenario, it’s important to recognize the number of transmissions rate per second (TPS) toward the destination victim to distinguish the type of incoming packet. Therefore, it’s important to determine the workload of individual servers for websites. It has been found that the number of transmissions toward the victim server can be taken into consideration. Thus, to classify the transmission requests, the average attack rate is considered in the detection algorithm as the threshold value as illustrated in Algorithm 2.

Algorithm.2: DoS Detection Process

```
Input: TPS value, IP Address
Output: determination of high traffic, DoS detection.
Start
    Detection Operation of DoS attack
    If (TPS > threshold value) then
            DoS_Detected = TRUE
    Else
            DoS_Detected = FALSE
    Add IP address to the trusted list
    End
End
```

However, after a high traffic detection scenario toward the destination victim as clarified in (Algorithm 1), the detection process will continue with the secondary scenario and the IP address will be added to the suspected record list. The process starts when comparing the TPS to the threshold value to find out the existence of DoS attack in the requests process. If the TPS is higher than the threshold value, it means that many attack packets are generated toward the destination and the attack exists in the request processes. However, when the TPS is lower than the threshold value, the request operations are coming from legitimate source and DoS attack does not exist. Thus, the IP address will be added to the trusted list. As shown in the Eq. (4) if we assume that X=TPS.

$$F(TPS) = \begin{cases} 1, & TPS \geq Threshold, \\ 0, & TPS < Threshold, \end{cases} \tag{4}$$

where, F (TPS) is DoS_Detected.

However, by taking advantage of the proposed algorithm, DoS attacks can be overcome by mitigating the attack and this confirms our claim that a DoS attack is still a critical threat and can stop the services of the legitimate users.

### D. Threshold-based Detection

The idea of employing threshold value in the algorithm is that the attack is declared when the rate of transmission become higher than threshold, otherwise, declare attack does not exist. Note that the second scenario of the discovery process is performed on the sender side. By varying the feature value threshold, we can obtain different values of false negative probability and detection probability. The threshold value will be compared with TPS in the secondary scenario. The threshold was selected based on the number of users who targeted the server as well as the number of requests required for each user. Therefore, to count the number of requests for each user (*i*), it will be calculated using Eq. (5).

$$NoRi = NoRi + 1. \tag{5}$$

where, NoR*i* is the number of requests for each user (*i*), the following formula is used to calculate the threshold.

$$\text{Threshold} = \frac{\sum_{i=1}^{n} NoR\_i}{n} \tag{6}$$

where, n is the number of users who target the server (requests sent to the server). Thus, the threshold value varying depending on the number of users and request toward the target that obtained by using Eq. (6).

## V. Security Analysis of the Proposed Detection Algorithm

(DoS) attack is a type of cyberattack that consider as the most threatening list of dangerous attack due to its ability to overload the network resources and lead to the shutdown of the services from legitimate users. In addition, DoS attack has major negative effect of WSN and mobile node for consuming their limited battery [19], [26]. Due to the proposed various detection scenarios, NTDA can prevail over security breach which allow the assailant to exploit it and access the network and distort its behavior. In reference to the second scenario of detection that has been designed to ensure the existence of DoS attack, which is considered as continuing of the primary scenario. All IP addresses that are contained in the suspected list will be examined through the secondary scenario to complete their detection against DoS attacks [25]. These results activate detection even through the operational phase of the network. In this part, an analysis carried out of the NTDA security against DoS attacks.

## VI. Results Comparison and Evaluation

This section presents the performance evaluation and accuracy of the detection method NTDA against DoS attack. The proposed experiments have been implemented using MATLAB R2020a environment. The performance parameters that will be used to evaluate the proposed algorithms and analyze the detection system performance is false negative rate, detection rate, true positive rate and accuracy. To evaluate the effectiveness of the detection system NTDA algorithm, we compare its performance with most common detection algorithm under DoS attack.

### A. Detection Accuracy

One of the important parts of detection, it is the percentage of the total number of attacks that has been labeled and actually detected of packets as illustrated in Eq. (7).

$$Accuracy = \frac{TP}{TP+FP} \times 100 \tag{7}$$

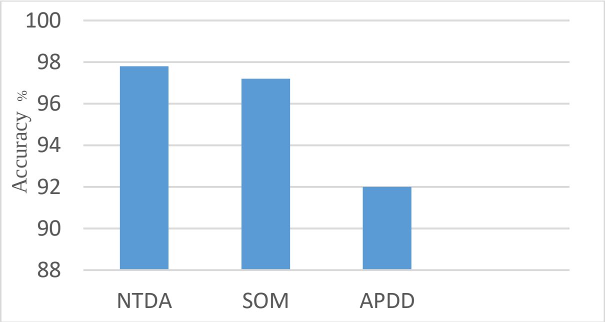

Fig. 4. Detection accuracy.

In Fig. 4, shows the detection accuracy graph of the proposed algorithm compared with SOM [27] and APDD [28] detection algorithms, it has been found that the accuracy test significantly increases and rises up to (97.8 %) as compared with other algorithms. The reason behind that, is the smallest amount of threshold value will reduce the suspicious requests toward the victim and enables the NTDA to recognize the modification of the attacker identities and lower false negative rate, whereas the SOM and APDD are based on traffic flow features and detection in big data that lead to higher delay and have lower detection accuracy. Moreover, SOM technique has limited detection throughput which will reduce the accuracy against DoS attacks.

### B. False Negative Rate (FNR)

The false negative rate is the proportion of infected packets that are falsely considered or detected as safe or legitimate packets as illustrated in Eq. (8). A false negative was considered more threatening than a false positive, due to the removing a false positive link will lead in losing a valid communication link without compromising security. Thereby, a false negative makes the network insecure.

$$FNR = \frac{TPR+TNR}{ALL} \times 100 \tag{8}$$

where, All = TPR+TNR+FPR+FNR

Fig. 5 shows the false negative rate (FNR) of the proposed algorithm. The NTDA shows the lowest value and decreases slowly to reach zero in FNR compared with other algorithms as in [27] and [29] which makes the NTDA perform well and efficiently in detection process. The reason behind that is that the smallest optimal threshold value that was used in the secondary scenario can reduce the FNR. Thus, NTDA improved its performance in the FNR compared with other algorithms.

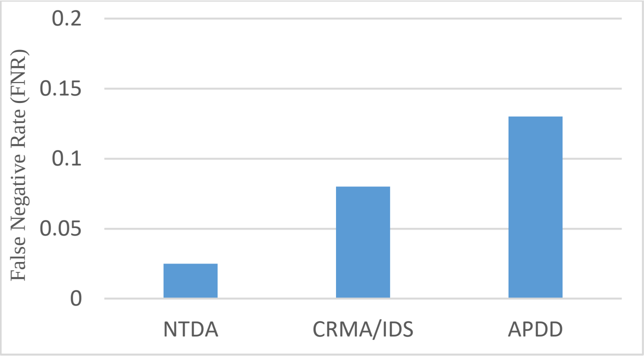

Fig. 5. False negative rate.

### C. Detection Rate (DR)

DR represents the ratio between the number of detected threat packages and the actual number of threat packages. Thus, high detection rate provide large number of malicious packets can be detected as defined in the next Eq. (9).

$$Detection\ Rate = \frac{TP}{TP+FN} \times 100 \qquad (9)$$

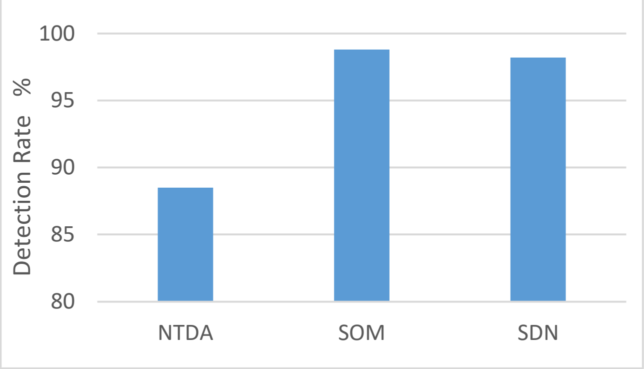

Fig. 6. Detection rate.

Fig. 6 shows the performance appraisal rate of successfully achieved detected DoS for NTDA algorithm and its effectiveness against given attacks. NTDA rigorously enforced proved a successful high detection rate (89%) which is considered an acceptable rate of detection in comparison with [27] and [30] that has slight increase in the detection rate. The reason behind that is due to the low delay and FNR that keep the performance of the proposed approach about 89%, Therefore it is intelligible that the proposed security system has an expectant DoS detection rate.

### D. True Positive Rate (TPR)

The True Positive Rate (TPR) value is obtained from the number of DoS attack data that is successfully detected or classified as an attack as illustrated in Eq. (10). Thus, TPR has an effect on measuring the performance of the proposed method.

$$TPR = \frac{TP}{(TP+FN)} \qquad (10)$$

The proposed algorithm NTDA worked as expected, and the generated true positive rate (TPR) is compared with other algorithms such as [29] and [28]. Fig. 7 shows that the NTDA proposed algorithm provide slightly a higher true positive rate compared with other detection algorithm which gives sufficient improvement in detection over other algorithms. This is because the system has the ability to detect DoS with a high percentage of malicious packets.

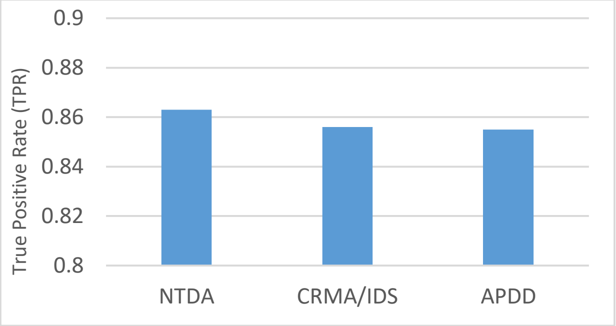

Fig. 7. True positive rate.

## VII. Summary

In this part, it's important to present the efficiency and performance of the NTDA in a network environment that was analyzed using MATLAB R2020a. The proposed NTDA algorithm was compared with the most common DoS detection algorithms in terms of false negative rate, accuracy, detection rate, and true positive rate as well when exposed to several attack instances. The experimental outcomes can be concluded as follows:

*1)* The NTDA algorithm provides detection accuracy approximately of 98% compared with other algorithms that have lower accuracy.

*2)* The NTDA provides a lower value of false negative rate that plays an important role in preventing leaving the network insecure. The value of FNR is close to zero because of the smallest value of the threshold.

*3)* The NTDA provides the highest value of TPR compared with other algorithms and it has the ability to detect the real attackers and distinguish normal and abnormal network traffic.

## VIII. Conclusion

This research examines the adversarial impact on network resources of DoS attacks as one of the major threats to cybersecurity as well as to ensure sustainable and secure systems. Attack traffic traces are suitable for evaluating DoS detection security systems. Network Traffic Detection Approach (NTDA) has been proposed to provide accurate detection and mitigation for DoS attacks. The detection algorithm is based on two various scenarios, the primary scenario will detect the network's high traffic measurements and the secondary scenario uses mathematical models to detect suspicious traffic using transmission rate of the sender. The simulation outcomes have intelligibly proved that the NTDA detection algorithm has higher detection performance, efficiency and accuracy. The NTDA detection method ensures that the DoS attack is combated. However, the proposed NTDA algorithm generally outperformed other detection methods. In the future, focusing on other approaches that provide significant flexibility and additional accurate detection performance in networks that are based on various features.

***Abstract*—Job-matching applications have become a technology that provides solutions for making decisions about accepting and looking for work. The contextual analysis of documents or data from job matching is needed to make decisions. Some existing studies on the analysis of job-matching applications can use the Latent Semantic Indexing (LSI) method, which is based on word-to-word comparisons in the text. LSI has the advantage of contextual analysis. It can analyze amounts of data above 10,000 words. However, the conventional LSI method has limitations in contextual analysis because it uses the exact words but different meanings. Therefore, this paper proposes a new technique called word2vec-based latent semantic indexing (Word2vec-LSI) for contextual analysis, which is based on gen-sim as a multi-language word library. Then, modeling in text and wordnet and stopword as basic text modeling. We then used word2vec-LSI to perform contextual analysis based on the Irish (IE), Swedish (SE), and United Kingdom (UK) languages in the dataset (Jobs on CareerBuilder UK). The results of applying conventional LSI have an accuracy level of 79%, recall has a value of 79%, precision has a value of 62%, and Fi-Scor has a value of 70% with a similarity level of up to 50%. After implementing word2vec-LSI, it can increase accuracy, recall, and precision, and Fi-Scor both have 84% in contextual analysis, and the similarity level reaches up to 95%. Experiments confirm the usefulness of word2vec-LSI in increasing accuracy for contextual analysis applicable in natural language text mining.**

***Keywords—Contextual; LSI; job-matching; text-base; word2vec***

## I. Introduction

This research will develop latent semantic index (LSI) techniques that will be used to make job recruitment decisions by improving accuracy in contextual analysis on several job matching data. An LSI technique used before is analyzing job-matching data with comparisons based on words and sentences [1]. LSI techniques for job checking data analysis typically use position features and descriptions, while to obtain job information, text relationships use semantics through Single Value Decomposition models (SVD) [1].

So, in the context of LSI, SVD still refers to Singular Value Decomposition, a key method for reducing dimensions and analyzing semantic relationships between words in text.

According to LSI standards, comparing the exact words and sentences can only be carried out in job-matching data with many words in the features and similarity of words presented to obtain the accuracy and relevance of matching. Based on the matching results of job-matching data with the same word and different meanings, textual analysis of the text has not produced maximum relevance [2]. To overcome this, researchers propose extended LSI (eLSI) in contextual analysis on job matching applications (JMA) [3]. Therefore, job-matching data will be contextually analyzed using the description feature and compared with the recruitment feature.

Job matching is becoming increasingly popular, which is realized at different levels of the labor market and is associated with the overall situation of the national economy. High competition increases the need to make better use of work resources and creates a better fit between workers and workplaces [4] [5] [6]. A job matching model is used to identify suitable candidates for open positions based on skills, qualifications, and experience. The job matching model performs searches using keywords to match between job seekers and employers [3].

Previous research has applied the Latent Semantic Indexing (LSI) technique [1]. LSI is text indexing and an analysis method used to identify semantic patterns in documents that uses vector spaces to describe documents and terms. LSI cannot capture complex relationships or hidden contexts between words in text (linear representation) [7]. This model requires understanding of context, relationships between words, and deeper meanings [8] [9]. LSI often has to limit the number of dimensions (semantic concepts) used to represent documents that are difficult to interpret, Compute Scalability and Efficiency[7], Limitations of representation [10] [11]and sensitivity to document changes[12]. LSI tends better to understand concrete words and direct relationships between documents. However, in the analysis of texts for job matching, it is often necessary to understand abstract terms [13] [14] [15], Cognitive abilities [11] [16], and aspects of the prospective worker's personality [17].

LSI has implemented several text analysis models, including text grouping [15]. This technique cannot extract resume data[18]. In addition, LSI is weak in reading new synonyms in the document resume. LSI has limitations in contextual readability, so it needs to be extended by integrating contextual analysis with other algorithms such as Word2Vec.

*Corresponding Author

LSI is a method of indexing and analyzing text used to identify semantic patterns of documents. LSI uses vector spaces to describe documents and terms when analyzing text. LSI cannot capture complex relationships or contexts hidden between words in text (linear representations). In a job-matching model, understanding context, relationships between words, and deeper meanings are required [19][20][21]. The SI often has to limit the number of dimensions (semantic concepts) used to represent documents (difficult to interpret) [22][23][24][25], Sensitivity to changes in documents [14][26], and cognitive abilities [27][16], or aspects of the job candidate's personality.

Text Analysis Techniques are text mining or natural language processing (NLP) techniques used to analyze and extract information from text data. These techniques are important in converting unstructured text into structured data for various applications, including information retrieval, document classification, and more.

These are just a few of the many text analysis techniques available, and the choice of technique depends on the specific task and purpose of the analysis. Text analysis is important in extracting insights and information from large amounts of text data in various fields.

Contextual analysis is an approach or method used to understand, evaluate, or analyze an object, event, text, or situation by considering its context. This context can be environmental, social, cultural, historical, political, or other variables that can affect the understanding or interpretation of somethi [28]. In natural language processing (NLP), contextual analysis refers to understanding words, sentences, or text more deeply by considering the surrounding words or sentences. It is used in sentiment analysis and natural language understanding [29].

Contextual analysis for job-matching applications is an approach or method used in business and human resources to deeply understand the context in which the job-matching process occurs [28]. It involves carefully evaluating the various factors and variables that affect the matching between workers looking for work with available job openings. Contextual analysis in job matching applications aims to ensure that the matching between jobs and job seekers is done efficiently and effectively[30]. By understanding the deeper context, companies and human resource professionals can make better decisions in managing the job-matching process [30] [31].

Contextual analysis is a process that involves understanding and evaluating texts, data, or information in the broader context in which they are used. In this analysis, information is viewed in terms of words or sentences and by considering the external context that can affect the meaning or interpretation of the text [32]. Contextual analysis is very important in comparative research, as it investigates the importance of contextual conditions for causal relationships. Over the past few decades, many comparative studies have focused on how contextual conditions affect causal relationships [29].

Contextual Analysis in job matching is based on the understanding that conventional job matching methods that focus only on words or sentences have limitations in understanding the proper context of the job and the candidate's qualifications. Therefore, there is a goal to improve the accuracy of job matching by paying attention to the broader context in the process. In this context, a deeper understanding of the relationship between job descriptions and candidates' qualifications is required, including contextual aspects that may not be visible through word matching alone. An extended Latent Semantic Indexing (LSI) technique is used to extract meaning and semantic relationships between words in context. Thus, this contextual Analysis is expected to help produce more accurate and relevant job matching between candidates and job openings by considering the context better.

Job matching is a special collaborative recommendation system developed for an entertaining and commonly used job matching process to help users identify and select qualified applicants who meet the requirements required by any organization [33] [34] [35]. Job seekers and job recipients need job matching. Job-matching is also a platform to facilitate the recruitment process and is cost-effective and time-effective [36].

Job matching is controlling the right person with the right job based on the motivation and power inherent in the individual. This requires a thorough understanding of the job and the person under consideration [8][23]. This process is very beneficial in simplifying recruitment and improving cost efficiency and time effectiveness [37]. With job matching, job seekers can easily find job openings that match their qualifications, and employers can quickly find suitable candidates for the positions they need [23]. Many existing online recruitment platforms have developed a reliance on automated ways to match job seekers to job positions [38]. Intuitively, records of successful recruitment in the past contain important information that should be used for job matching of current people [23] [39] [40]. The following can be seen in Fig. 1 of the job matching search system framework.

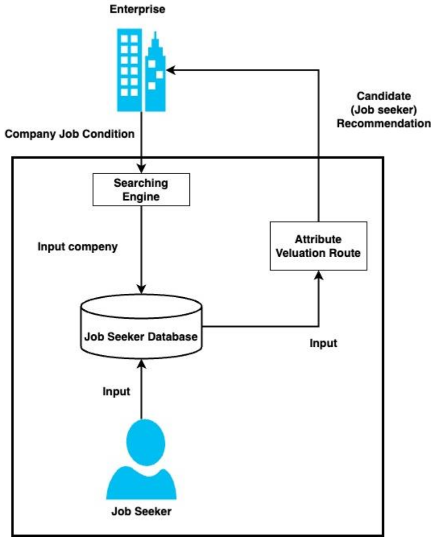

Fig. 1. Job-matching search system framework [17] [40].

Word2Vec is a powerful technique for word representation learning that captures semantic relationships between words based on patterns of their occurrence together. Word representations generated by the Word2Vec model have shown outstanding performance in various NLP tasks, such as sentiment analysis, named entity recognition, and machine translation. However, Word2Vec alone may not fully capture complex topic structures in text data.

In this research, we introduce a new approach, Word2vec-based Latent Semantic Indexing (Word2Vec-LSI), which combines the advantages of Word2Vec and LSI to improve the quality of topic modeling and contextual analysis in text documents. Word2Vec-LSI aims to bridge the gap between word representations and hidden semantic indexes by leveraging the semantic richness of Word2Vec representations while benefiting from the topic modeling capabilities of LSI. Our research explores the potential of Word2Vec-LSI in improving the accuracy and depth of topic modeling, especially in the context of contextual analysis. We evaluated this methodology on various text datasets from different domains, assessing its performance in capturing complex topics and contextual information in the text. The study contributes to developing cutting-edge text analysis techniques and promises many applications in information retrieval, content recommendation, and knowledge discovery. In the following sections, we will provide a detailed overview of the proposed Word2Vec-LSI methodology, outline the experiment setup, and present the results obtained.

Word2Vec is a vector representation algorithm that can understand the meaning of words based on their context in the text [41]. This technique allows the system to understand better the context of words in job descriptions and job seeker profiles. This is especially useful in addressing synonym and antonym problems, where Word2Vec can identify words with similar or opposite meanings, improving accuracy in matching [32]. Moreover, Word2Vec also helps understand the semantic hierarchy between words [41], so that the system can recognize that some words are subconcepts of more significant concepts.

In addition, Word2Vec can capture semantic relationships, such as the relationship between a subsidiary company and a central company or between junior and senior positions. With Word2Vec, job-matching systems can provide more accurate results by considering the context of the meaning of words, not just the similarity of words that align. This helps generate results that align with the criteria of job seekers and companies, which ultimately increases the efficiency and accuracy of the job-matching process. Word2Vec also helps overcome the challenges of matching more complicated jobs. For example, when keywords in a job description change or language variants are used, Word2Vec can help identify solid semantic relationships between those words. For instance, if a job posting searches for "software developer" and a candidate describes themself as a "programmer," Word2Vec will detect similarities in meaning and match them effectively.

In addition, Word2Vec also allows personalization in the job-matching process. By analyzing broader text such as CVs, cover letters, and candidates' employment history, Word2Vec can create unique vector representations for each candidate. This allows for a more tailored job search to an individual's abilities and experience, which often cannot be achieved with traditional keyword-based matching.

Lastly, Word2Vec also helps in reducing human errors in the recruitment process. Using this technology, companies can minimize bias in candidate selection and ensure that each candidate is assessed based on their suitability for the job. This contributes to creating a more fair and efficient recruitment environment, benefiting both the company and the job seekers. Thus, Word2Vec has great potential to improve the quality and accuracy of job-matching in the world of recruitment.

LSI has limitations in analyzing contextual resume documents [32]. LSI can only do the process of comparing the same words and sentences [1]. Based on the results of matching work data with the same word and different meanings, textual analysis of the text has not produced maximum relevance. As a search technique in the context of application matching jobs, the "extended" method aims to improve the matching accuracy in this application. This research introduces the extension of LSI Techniques aimed at understanding the context of job-matching. An approach is integrating Word2Vec to manage synonyms, antonyms, semantic hierarchies, and semantic relations. This integration results in the representation of data in dimensions used to measure similarity.

The main objective of this study is to optimize LSI techniques into extended LSI from contextual analysis using integration techniques with word2vec and evaluate using precision, recall, and F1-score. The testing process uses the Jobs on CareerBuilder UK dataset (description and resignation) and development using Python programming language on the Google collaboration platform. This research can contribute to the development of LSI Engineering. The Extended LSI technique will be one of the contextual analysis techniques in job-matching applications. This research can overcome conventional LSI's limitations that rely only on word frequency in text. More advanced extended LSI techniques can account for document contextual analysis to generate relevance from job matching applications.

## II. Materials

Fig. 2 is the data collection and preprocessing process used to perform text modeling in the job-matching context. For job-matching data analysis in the database, we collect words in employees' curriculum vitae (CV). Then, the words are processed by selecting the default word as comparison data using StopWord, Stemmer, and Tokenization. After obtaining the standard words, a comparison of meanings is carried out using gensim to obtain the corpus data set. The result of the comparison will get up to 10000 words [41].

Fig. 2 is explained that the data collection and pre-processing process in the context of job matching begins by retrieving data from various related sources, such as job search websites or internal company databases. The data consists of job descriptions that include details about the responsibilities, qualifications, and requirements for each job position. Once the data is collected, the first step is to process it into individual words. This involves dividing text into separate tokens or words. Next, the text data is prepared through pre-processing, where steps such as removal of common words (stop words), text normalization, tokenization, and stemming or lemmatization are performed. Once the data is cleaned and prepared, a corpus is formed using tools such as Gensim, which allows the creation of theme modeling models. This corpus is a collection of documents or texts that have been processed and are ready for further analysis. The final step involves the formation of a final vocabulary, which is a collection of unique words from the entire corpus. Each word in this vocabulary has a numerical representation that can be used in subsequent natural language processing models. Thus, this process provides an important foundation for advanced analysis in the context of job matching, enabling the application of various natural language processing techniques to gain deeper insights from existing text data.

Fig. 3 shows the number of jobs that underwent displacement each year from 2001 to 2021. It can be seen that job movements have increased sharply, especially in the period from 2019 to 2021. On the graph, it can be seen that the number of job moves significantly increased during the period. This reflects the changing dynamics of the labor market over time, where workers have more opportunities to change jobs or find new jobs. Economic growth, industrial development, and changes in worker preferences may have influenced this job movement trend. Therefore, a deeper understanding of this data can provide valuable insight into changes in the labor market structure over the past two decades.

## III. Proposed Methodology

Conventional latent semantic indexing (LSI) methods can only compare text in sentences. However, because this method only searches and compares the same text, it is unlikely to be able to carry out contextual analysis in job-matching applications that have many words with different meanings. Usually, contextual data in job-matching has different language and meaning, making it difficult to match between jobs and job recipients. So it can reduce the accuracy of contextual analysis in job-matching. To overcome this problem, we propose Word2Vec-based latent semantic indexing (Word2Vec-LSI) to improve contextual analysis and use Gensim as a library used to create a vector representation model of words in sentence [42]. So you can increase the recommendation area while maintaining as much accuracy as possible. This method is suitable for solving problems that can be contextually analyzed with various words and different languages having the same meaning Fig. 4. This is expected to provide significant benefits for job-matching applications.

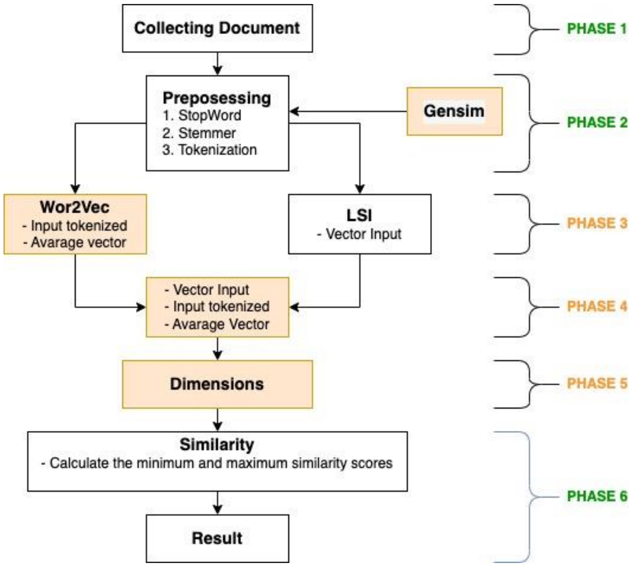

Fig. 4. Framework improved LSI.

The first phase, document collection, is an important step in the process of information processing and research that involves collecting relevant or necessary documents for a specific purpose. The first step in this process is to identify the sources of documents to use, whether they come from internal sources such as corporate databases or external sources such as the internet, digital libraries, or general data repositories. Next, the relevant documents are selected based on specific criteria such as topic, date, or document type.

Then, the documents are retrieved or downloaded from the source, often using tools or technology appropriate to the document type and its source. After collection, these documents often require a processing stage, including cleaning and preprocessing to remove irrelevant data and indexing to facilitate data search and management. Quality and accuracy in document collection have a significant impact on the final results of research, data analysis, or information system development that is being carried out.

Second phase, in the context of Latent Semantic Indexing (LSI), there are three important stages in text processing involving stemming, removal of stopwords, and tokenization.

*1) Stemming* is the process by which words in a text are transformed into their basic form or base words. The main goal of stemming is to address variations of words that have the same root. In other words, words with similar meanings but written with different variations will be identified as the same word. A simple example would be the words "run", "run", and "run around" which would be transformed into the basic form "run".

*2) Removal of stopwords.* Stopwords are common words that appear frequently in text but do not provide high semantic information. Examples of stopwords in English are "the", "and", "in", and the like. Removing stopwords helps focus on more informative and specific words in semantic analysis, so LSI results are more accurate.

*3) Tokenization,* in which text is divided into smaller units called "tokens". These tokens can be words, phrases, or even sentences, depending on the level of granularity required in the analysis. Tokenization allows text to be broken down into separate entities that can be counted in a document-term matrix representation within an LSI.

These three stages in text processing are important in word2vek and LSI, as they help reduce the dimensionality of words in document representations, eliminate less relevant information, and ensure that semantic analysis can be performed more effectively. By performing stemming, removal of stopwords, and tokenization, document text is well prepared for a more accurate and informative LSI process. Then, to get a collection of sentences, there needs to be a library using genisms. Gensim is a library for text modeling and natural language processing (NLP). The library is known for its ability to develop Word2Vec models in modeling various word vector techniques and other text processing.

Third phase, the integration between Word2Vec, Demension, and Latent Semantic Indexing (LSI) creates a more sophisticated approach to contextual analysis.

*a) Word2Vec*

- Word2vec is used as a representation of a word in a low-dimensional space that understands the context and semantics of words.
- Word2Vec generates a vector of words that represent the meaning of the word in its context. It describes the meaning of words in vector spaces and can be used for tasks such as meaning-based matching, classification, and sentiment analysis. However, Word2Vec has the disadvantage of not understanding the relationships between words in larger documents or underlying topics
- Word2Vec can be used to replace words in a document, which improves understanding of word context.
- Word2vec functions as a tokenization and average vector analysis, because it can get maximum results in reading words in sentences and average words that often appear

*b) LSI*

- LSI to analyze the document as a whole to identify latent patterns or topics.
- LSI can be used as an input vector that serves to vector words that will be used as word matching to be included in dimensions that will be applied in the same unity of meaning.
- LSI, on the other hand, is used to identify latent patterns or underlying topics in documents. It helps in a deeper understanding of document context and can be used for topic-based grouping and semantic search. However, LSI may be less accurate in representing individual word meanings

Fourth phase, vector Input: The first step is to generate a vector representation of the word using Word2Vec. This is done by training a Word2Vec model on a corpus of relevant texts. Once training is complete, the Word2Vec model will have a word vector representation for each word in the corpus. For example, if you have the sentence “I like machine learning”, each word (“I”, “like”, “machine”, “learning”) will have a word vector that explains its meaning in context. Input Tokens: Once you have a vector representation of words from Word2Vec, you need to parse the text document you want to analyze into words or tokens. This process is called "tokenization" and allows understanding the structure of the text and detailing each word in the document. For example, if you have the sentence "Natural language processing is very interesting", tokenization will decompose this sentence into individual words: "Natural", "language", "processing", "is" and "interesting." Average Vector: After parsing the words in a document, it can calculate the average word vector from Word2Vec for all the words in the document. This is done by adding up the word vector of each word in the document and then dividing it by the number of words. The result is a mean vector representing the document in the Word2Vec vector space. This average vector can then be used as a document representation in LSI analysis. Using this average vector as input, we can then apply LSI analysis to identify latent topics in the data collection. This is one way to integrate Word2Vec's word vector representation into LSI analysis and leverage the power of both for deeper text understanding.

Fifth phase, using word vectors, Word2Vec can integrate Word2Vec's advantages in understanding word meaning in context with LSI analysis that identifies latent topics in documents. This combination allows for deeper text analysis and a better understanding of the content of the document.

Sixth phase, in terms of maximum and minimum similarity is used to measure similarities or differences between sentences or concepts in sentences. Similarity maximum is used to identify sentences or concepts that are most similar to a particular reference document or reference concept. This concept represents the highest cosine similarity considered to be the most similar to the reference, the concept that is most different or not similar to the reference sentence. Just like the similarity maximum, it also involves calculating the similarity of cosines, but this time the sentence or concept with the lowest cosine similarity value is considered to be the most different. Both maximum and minimum similarity play an important role in various text analysis applications, depending on the purpose of the analysis and the context.

## IV. Experimental Results and Discussion

In the Results section, we compare the accuracy and relevance of words in each language Languages such as Irish (IE), Swedish (SE), and United Kingdom (UK).

### A. Testing using LSI

Based on Fig. 5, trials using evaluation of the results of applying conventional LSI to matching using accuracy have a value of 79%, recall has a value of 79%, precision has a value of 62%, and Fi-Scor has a value of 70%. Based on Fig. 6, it shows that applying LSI to 500 documents has a similarity level of up to 50%. While previous studies have increased Accuracy to 82.5% [19]. So, it is necessary to increase the accuracy value in contextual reading using conventional LSI.

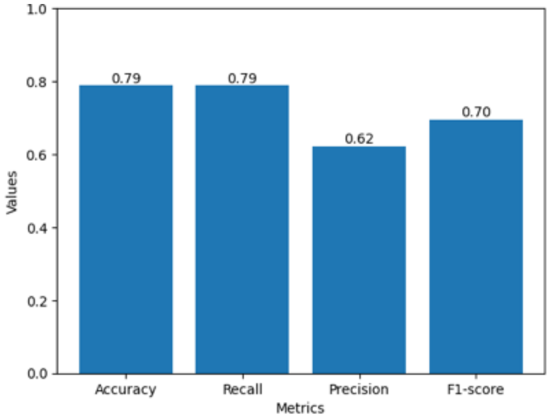

Fig. 5. Classification metrics LSI.

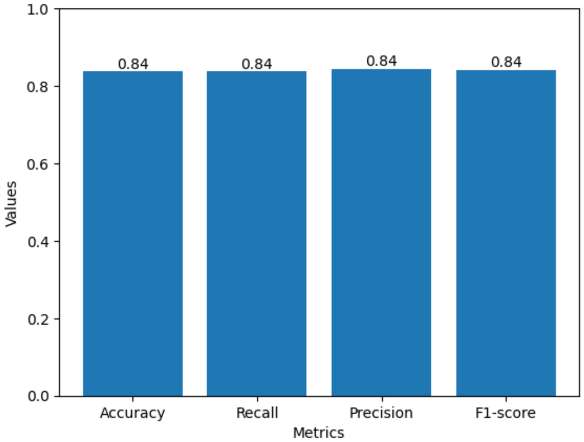

Fig. 6. Classification metrics for Word2Vec-LSI.

### B. Testing using Word2Vec-LSI

Fig. 7 shows that the application of word2vec-LSI to 500 documents has a similarity level of up to 95%. In this study, we refer to Table I, which displays the three languages used for testing the dataset as an implementation of word2vec-LSI. The results of this experiment provide a deeper understanding of how this method works in different contexts. From these results, we can conclude that Ireland (IE) has a ratio of 95%, Sweden (SE) 95%, and England (UK) 96.6%.

These findings show that the word2vec-LSI implementation performs well in all three languages tested, with the United Kingdom (UK) achieving the highest ratio. This is important information, as it can assist researchers or practitioners in selecting appropriate methods for natural language processing tasks in various contexts and environments. In addition, these findings also provide valuable insights into understanding the extent to which word2vec-LSI-based representations of words and documents can be used effectively in language-based analysis.

Based on Fig. 8, the evaluation of the results of applying word2vec-LSI to matching using accuracy, recall, precision, and Fi-Scor is 84%.

The evaluation results documented in Table II show that evaluation method, namely accuracy value, which is 63.4%. However, it should be noted that these same results may cause confusion and need to be re-examined. In addition, the results of the evaluation illustrate that the combination of the use of Word2Vec and LSI currently has low performance. This can be largely affected by the use of threshold = 0.7. In this context, it is necessary to clarify how threshold changes affect the performance of the model or system. Furthermore, there are indications that the evaluation results can be improved by increasing the threshold value to 0.5, as seen in Table III.

Based on Table III, the percentage of test results increased when the threshold value is raised. This means the system becomes stricter in classifying data as positive so that more data is typed correctly. Conversely, if the threshold is lowered, the results will decrease as the system becomes more tolerant in classifying data as positive, which can increase false positives. In other words, threshold changes affect the balance between precision and recall (the ability to identify all positive instances), and this is an important consideration in determining how a model or classification system performs in a given context.

The result of a document's vector construction is a numerical vector representation that encodes information about the meaning and context of the document. These vectors can be used in various analyses to understand and group documents based on their similarity in vector spaces, including topic modeling, contextual analysis, and information retrieval. With approaches like Word2Vec-LSI, we can combine the advantages of Word2Vec word representation with LSI to produce a richer understanding of text sentences.

Based on the results of this research, the results of applying conventional LSI have an accuracy level of 79%, recall has a value of 79%, precision has a value of 62%, and Fi-Scor has a value of 70% with a similarity level of up to 50%. After implementing word2vec-LSI, it can increase accuracy, recall, and precision, and Fi-Scor both have 84% in contextual analysis, and the similarity level reaches up to

95%. This research also succeeded in contextual analysis in several languages, such as Irish (IE), Swedish (SE), and the United Kingdom (UK). Based on a comparison between conventional LSI and Word2Vec-LSI, accuracy can be significantly increased to 84% from 50% and applied to contextual analysis in job-matching applications.

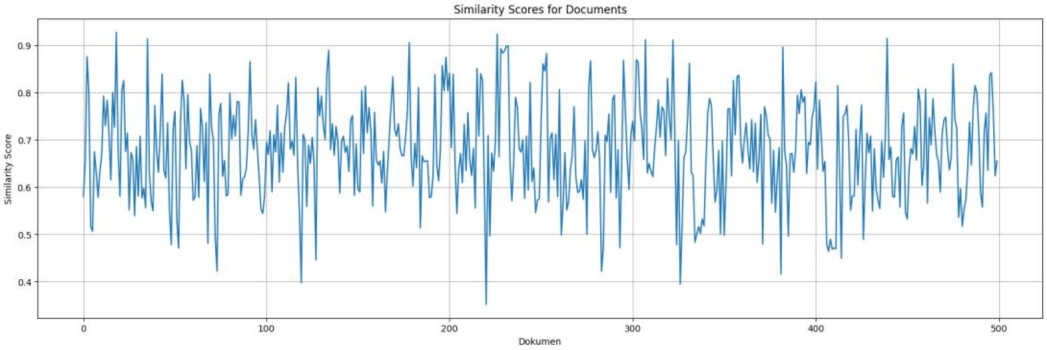

Fig. 8. Similarity score Word2Vec-LSI.

TABLE I. WORD2VEC-LSI-BASED CONTEXTUAL RESULTS FOR JOB MATCHING BASED ON THREE COUNTRIES IN THE DATA SET (JOBS ON CAREERBUILDER UK)

| NO | WORD (Language) | Ratio (%) |
|---|---|---|
| 1 | Ireland (IE) | 96 |
| 2 | Sweden (SE) | 95.5 |
| 3 | United Kingdom (UK) | 96.6 |

TABLE II. EVALUATION METRICS RESULTS USING ACCURACY WITH A THRESHOLD OF 0.7

| **Evaluation** | **Score (%)** |
|---|---|
| Accuracy | 0.634 |

TABLE III. RESULTS OF EVALUATION METRICS USING ACCURACY WITH THRESHOLD = 0.5

| **Evaluation** | **Score (%)** |
|---|---|
| Accuracy | 96.6 |

## V. CONCLUSION

This research compares the performance of conventional Latent Semantic Indexing (LSI) and Word2Vec-LSI in analyzing text data across several languages, including Irish (IE), Swedish (SE), and British English (UK). The main findings of this research are as follows: Conventional LSI achieved an accuracy rate of 79%, recall of 79%, precision of 62%, and F1-Score of 70%, with a similarity rate of up to 50%. Meanwhile, Word2Vec-LSI succeeded in achieving a similarity level of up to 95% and increased accuracy, recall, precision, and F1-Score to 84%. This research also successfully analyzed text data in Irish (IE), Swedish (SE), and British English (UK), with British English achieving the highest ratio at 96.6%. Adjusting the threshold value also significantly affects the model performance, where a higher threshold value results in tighter classification and higher accuracy, while a lower threshold value leads to higher tolerance but lower accuracy. These findings highlight the importance of selecting appropriate methods for natural language processing tasks, especially in multilingual contexts, with Word2Vec-LSI offering deeper insight and higher accuracy in contextual analysis than conventional LSI. In conclusion, the combination of Word2Vec and LSI techniques proved effective in improving classification accuracy, particularly in job matching applications, with results that impact the consideration of threshold values in the performance evaluation of models and classification systems.

## ACKNOWLEDGMENT

The author would like to thank the support provided by the Faculty of Computer Science and Information Technology, Universiti Tun Hussein Onn Malaysia (UTHM), especially all the tutors involved in completing this article, then Abdurrab University under the Abdurrab Pekanbaru Foundation which

has supported this research to obtain results which is satisfying.

# An Effective Forecasting Approach of Temperature Enabling Climate Change Analysis in Saudi Arabia

Sultan Noman Qasem[1], Samah M. Alzanin[2]*

Computer Science Department, College of Computer and Information Sciences,
Imam Mohammad Ibn Saud Islamic University (IMSIU), Riyadh 11432, Saudi Arabia[1]
Department of Computer Science, College of Computer Engineering and Sciences,
Prince Sattam Bin Abdulaziz University, Al-Kharj 11942, Saudi Arabia[2]

***Abstract*—Climate change is a global issue with far-reaching consequences, and understanding regional temperature patterns is critical for effective climate change analysis. In this context, accurate forecasting of temperature is critical for mitigating and understanding its impact. This study proposes an effective temperature forecasting approach in Saudi Arabia, a region highly vulnerable to climate change's effects, particularly rising temperatures. The approach uses advanced neural networks models such as the Long Short-Term Memory (LSTM), Gate Recurrent Unit (GRU), and Bidirectional LSTM (BiLSTM) model. A comparative analysis of these models is also introduced to determine the most effective model for forecasting the mean values of temperatures in the following years, understanding climate variability, and informing sustainable adaptation strategies. Several experiments are conducted to train and evaluate the models on a time series data of temperatures in Saudi Arabia, taken from a public dataset of countries' historical global average land temperatures. Performance metrics such as Mean Absolute Error (MAE), Mean Relative Error (MRE), Root Mean Squared Error (RMSE), and coefficient of determination (R-squared) are employed to measure the accuracy and reliability of each model. Experimental results show the models' ability to capture short-term fluctuations and long-term trends in temperature patterns. The findings contribute to the advancement of climate modeling methodologies and offer a basis for selecting a suitable model in similar environmental contexts.**

***Keywords*—*Climate change; Saudi Arabia; temperature; forecasting; recurrent neural network models***

## I. Introduction

The environment, human societies, and ecosystems are all significantly impacted by climate change, which is a major worldwide concern [1]. Being able to predict temperature changes with accuracy is a critical component of understanding and preventing climate change [2]. Temperature is a crucial indication of climate change, which is caused by complicated interactions between many environmental elements [2]. Climate change may have an influence on agriculture, change ecosystems, and cause more frequent and severe weather events [3]. To comprehend climate change consequences and develop practical adaptation and mitigation plans, an accurate temperature forecasting method is required, which is also crucial [4]. Numerical weather models that replicate atmospheric dynamics are the foundation of conventional temperature forecasting techniques [5]. Although these models have their uses, they cannot fully represent the intricate, nonlinear processes linked to climate change [6]. In contrast, machine learning (ML) is particularly worthy of dealing with big information [7], traffic recovery [8], social mobilization and migration prediction [9], seeing minute patterns [10], and responding to shifting circumstances [11]. As a potent instrument in climate research, ML provides advanced methods for examining past data, seeing trends, and forecasting outcomes. The use of machine learning for temperature forecasting has contributed greatly to climate change analysis. Researchers and scientists may obtain deeper insights into climate trends by utilizing ML algorithms [11]. This can help them make better-informed decisions and more accurate forecasts for reducing the effects of climate change. Temperature predictions may be made using linear regression and more sophisticated regression algorithms using historical data [12]. These models consider a number of variables, including location, season, and time of day. For the purpose of evaluating temperature data over time and identifying patterns, algorithms such as AutoRegressive Integrated Moving Average (ARIMA) and Seasonal ARIMA (SARIMA) work well [13]. By utilizing the advantages of various methods can improve prediction accuracy. However, there is a limitation in capturing temporal relationships of time series temperature data, which is the gap that the study is trying to fill to improve the performance of the forecasting process. The main goal of this study is to forecast Saudi Arabia's average temperature patterns using sophisticated forecasting techniques. It proposes an effective approach to produce accurate and dependable forecasts of future temperature trends by utilizing cutting-edge methods, including Gate Recurrent Unit (GRU), Bidirectional LSTM (BiLSTM), and Long Short-Term Memory (LSTM). These recurrent neural networks models have been chosen because they are excellent to find complex patterns in temperature data and capturing the intricate temporal correlations and relationships present in such time series data, which makes them useful for predicting applications. Thus, the main contributions of the work can be summarized in the following points:

- Proposing a forecasting average temperature approach to achieve an accurate analysis of climate change in Saudi Arabia.
- Developing effective neural networks models that are able to capture temporal relationships of time series temperature data.

*Corresponding Author.

- Evaluating the proposed approach on a time series data of temperatures in Saudi Arabia, taken from a public dataset of countries' historical global average land temperatures.
- A comparative analysis of the developed models will be introduced to determine the most effective model for forecasting the average values of temperatures in the next years.

The rest of the paper is organized into five sections. Section II gives a literature review. Section III explains the materials and methods in detail. Section IV presents the experimental results and discussions. Finally, section V summarizes the conclusion and future work.

## II. Literature Review

Climate change boosts temperatures and causes water scarcity [14]. Extreme weather events such as severe drought, heavy downpours, heat waves, and cold waves are becoming increasingly regular. Climate change has a wide-ranging impact on people's life, including agriculture and fisheries [15], mental health [16], physical health [17], and the economy [18]. Overall, the potential costs as a result of climate change outweighed the advantages. Communities with lower levels of socioeconomic development are more likely to endure the potential consequences. Many third-world nations are located in tropical climates, which are particularly vulnerable to climate change. Climate change has led to a significant influence on Southeast Asia, North and South India, Sub-Saharan Africa, West Africa, East and Southern Africa, Northern Latin America, and Central America [19]. As a result, these nations' food security is exposed and it is critical to predict and mitigate the effects of climate change. They are required to minimize the vulnerability of life in human-related sectors such as ecosystems, health, agriculture and fishing, economics, and culture. Monitoring temperature variations is one method for anticipating climate change and forecasting future temperatures can help humans prepare for future conditions. Consequently, the fast growth of statistical methodology, certain methods may now be used to forecast the future, including temperature. With a large amount of data from previous events, regression and statistical modeling tools are utilized for creating a relationship between variables [20].

Many researchers have employed regression models, particularly Autoregression (AR), to predict not only temperature but also other scientific variables. Yau et al. [21] applied AR and Support Vector Machine Regression (SVMR) Integrated Moving Average to predict the daily arrival of visitors in southwest China. Witaradya and Putranto [22] proposed to use AR for temperature predication and investigated its effectiveness as a regression mode for time-series data. Zakaria et al. [23] used the ARIMA model to analyze data from four weather stations in Iraq between 1990 and 2011. Chen et al. [24] examined monthly mean temperatures in Nanjing, China. They used monthly mean temperature data from 1951 to 2014 as the training set and data from 2015 to 2017 as the testing set to create an ARIMA model for their research. Murat et al. [25] introduced research on predicting and modeling daily temperature for four European sites in various climatic zones using data from 1980 to 2010. They employed the Seasonal Autoregressive Integrated Moving Average (SARIMA), and ARIMA with external regression method and demonstrated that the generated models could describe the data series and be used to estimate future daily temperatures. Dwivedi et al. [26] used the SARIMA model to forecast the average temperature for the city of Gujarat, India, using data from 1984 to 2015. They tested numerous models and chose the best SARIMA model for average temperature forecasting based on the Akaike Information Criterion (ACI). They examined the model's adequacy, and the diagnostics revealed that the model was reliable for projecting monthly average temperatures.

Also, Asha et al. [27] introduced an approach to forecasting daily maximum temperatures for four distinct locations in Kerala, India, using three different methods: ARIMA, SARIMA, and Autoregressive Fractional Integrated Moving Average (ARFIMA), utilizing data from January 2019 to December 2020. They then examined the performance of three techniques using measures such as Mean Squared Error (MSE), Mean Squared Error (MSE), and percentage accuracy (PA). According to the results, all of the models performed well, with the ARFIMA model outperforming the ARIMA and SARIMA models. Hennayake et al. [28] proposed a method using Long Short-Term Memory (LSTM) model for forecasting the most important meteorological variables, such as precipitation and temperature, for a weather station in Sri Lanka. They evaluated model performance using Mean Absolute Error (MAE) and Root Mean Squared Error (RMSE) measures. As a consequence, they demonstrated that both LSTM models designed for precipitation and temperature forecasting functioned well and could be used to forecast precipitation and temperature accurately.

Mitu and Hasan [29] presented a work based on SARIMA model for Memphis, Tennessee, using daily temperature data from 2016 to 2019. They examined temperature data from that time period to identify patterns and transitory fluctuations. They employed the Mann-Kendall (M-K) test as a nonparametric tool to discover time series analysis trends. They also used the SARIMA approach to anticipate the temperature for the following 50 days. The prognosis also indicated an upward tendency for the location. Dimri et al. [30] utilized monthly average maximum and minimum temperatures for the Bhagirathi River watershed in India using a seasonal ARIMA model based on data from 2001 to 2020. Their findings revealed that projected data is consistent with the data trend.

Gangshetty et al. [31] published a work for time series temperature forecasting in Pune, India, utilizing data from 2009 to 2020. They used SARIMA model and autocorrelation function with the partial autocorrelation function, as well as normalized residuals, to identify the best fit for the time series for their study. They discovered that the model performed well at predicting temperature values. Hoang et al. [32] implemented and developed a model using an LSTM on Amazon Web Services (AWS) machine learning platform. They discovered that the LSTM model produced significant and accurate results compared with other weather forecasting models.

Recently, Jaharabi et al. [33] investigated the use of machine and deep learning for temperature prediction of major cities in the world. Koçak [34] presented a time-series prediction approach of temperature based on LSTM and ARIMA models. Khokhar et al. [35] introduced a comparative analysis of ARIMA, LSTM, and BiLSTM for temperature and rainfall forecasting on Pakistan's time-series data of 116 years. Jafarian-Namin et al. [36] applied ARIMA and Artificial Neural Network (ANN) models for monthly temperature analysis and prediction on Tehran's time-series data. Topalova and Radoyska [37] proposed an automated change detection method to track the climate change of temperature in local geographic regions using a two-level structure of neural networks. However, the research gap of the previous work is that no study investigates, analyzes, and develops an effective machine learning model for climate change in Saudi Arabia's average temperature. This work explores the average temperature change in Saudi Arabia for the past 152 years (from 1861 to 2013). Furthermore, we show the effectiveness of Gate Recurrent Unit-based Neural Network (GRU-NN) model for average temperature forecasting and compare it with other RNN variants and other common models in the previous studies.

## III. Materials and Methods

### A. Earth Surface Temperature Dataset

The Earth Surface Temperature (EST) dataset is received from the KAGGLE platform [38]. It is collected by the National Oceanic and Atmospheric Administration (NOAA) Merged Land-Ocean Surface Temperature Analysis (MLOST), NASA GISTEMP, and UK HadCrut organizations. This collected data is repackaged or put together by Berkeley Earth and affiliated with Lawrence Berkeley National Laboratory. The EST dataset has several CSV files, including global ocean-and-land temperatures, global land temperatures by city, global average land temperature by country, global land temperatures by major city, and global average land temperature by state. Each file in the EST dataset comprises certain types of data that are required for climate data analysis and finding long-term trends and patterns in temperature and climate variables. The date, nation, average temperature, longitude, and latitude columns give critical information that allows researchers to obtain insight into the environmental impact of climate change and develop mitigation solutions. The study focuses on the monthly global land temperatures by city file, which contains 8599212 instances and seven attributes. Table I presents the attribute types of the selected dataset file. From this file, the data instances related to Saudi Arabia and its cities are filtered to form a dataset of 12795 instances. It consists of the average temperature in Saudi Arabia from January 1st, 1861 to September 1st, 2013. Table II gives the first and the last five rows of the dataset used in this study.

The DT column gives the date of collected temperature data as a time series. The average temperature column gives data on temperatures for the location in which the data was gathered. This column is commonly represented as a numerical data type, with the temperature measured in degrees Celsius. The average temperature column is critical for assessing climate data to determine temperature trends over time and identify changes in temperature patterns caused by climate change. The longitude column describes a point's east-west location on the Earth's surface. The latitude indicates the north-south position of a specific location wherever temperature data was recorded. The longitude and latitude columns are commonly represented as a numeric value expressed in degrees with the longitude or latitude letter.

TABLE I. Types of Attributes for the Selected Dataset File

| No. | Column | Data type |
|---|---|---|

## B. Recurrent Neural Networks Models

Recurrent neural networks (RNNs) are a type of artificial neural network (ANN) developed to process data from sequential activities. The RNNs are able to maintain the hidden state or memory of past inputs compared with standard feed-forward neural networks because of their connections forming directed cycles. The use of RNN's internal state makes it suitable for processing sequences of input, especially time series data of some applications, such as speech recognition, natural language processing, and cloud service forecasting, in which temporal dependencies or context are crucial.

The key feature of RNNs is their ability to maintain a hidden state that captures information about previous inputs in the sequence. This hidden state is updated at each time step and influences the network's output at the current time step. The basic formula for updating the hidden state $h_t$ at time $t$ in an RNN is:

$$h_t = f(W_{hh}h_{t-1} + W_{xh}x_t + b_h) \tag{1}$$

where, $h_t$ is the hidden state at time $t$, $x_t$ is the input at time $t$, $W_{hh}$ is the weight matrix for the hidden state, $W_{xh}$ is the weight matrix for the input, $b_h$ is the bias vector, and $f$ is the activation function.

However, the vanishing gradient problem, in which the gradients decrease exponentially as they are transmitted back in time during training, is one issue facing the classic RNNs. The RNNs have difficulty capturing long-term dependencies in sequences because of this restriction [19]. To overcome this problem, effective variations of RNNs have been created, including Long Short-Term Memory networks (LSTMs), Bidirectional LSTM (BiLSTM), and Gated Recurrent Units (GRUs). These architectures are able to capture long-term dependencies in sequential data because they have the capabilities to selectively preserve or forget information. The following subsections explain the effective neural networks models proposed to forecast the average values of temperatures from historical time-series average temperature data.

*1) Long Short-Term Memory-based Neural Network (LSTM-NN) Model:* This neural network model depends on long short-term memory (LSTM) cells, which is a popular type of RNNs. It is most frequently utilized in sequential data issues. The design of an LSTM cell consists of four primary parts: input gate, cell state, forget gate, and output gate. The gates determine which data should be retained or discarded for each cell, which represents a time step. In order to create a forecast, it only does that by passing pertinent data down a lengthy chain of sequences. For that reason, LSTM-NN may learn long-term dependencies more effectively than traditional RNNs. To regulate when memory material is given to other cells, LSTM makes use of cell state. Fig. 1 describes the LSTM cell design [39].

*2) Gated Recurrent Unit-based Neural Network (GRU-NN) Model:* It is developed based on the gated recurrent unit (GRU). It is another type of RNN, presented with the intention of preserving significant information in a sequence, much like LSTM-NN. On the other hand, the architecture of GRU-NN has fewer parameters and is less complex, making it computationally less expensive and faster to train. The GRU has just two gates: the reset gate and the update gate, which can eliminate the cell state and make the full memory accessible to other units. The update gate specifies which data to retain, whereas the reset gate merges the fresh input with the prior memory cell. Fig. 2 depicts the architecture of the GRU cell design [39].

*3) Bidirectional LSTM-based Neural Network (BiLSTM-NN) Model:* Based on the concept of Bidirectional RNNs [20], it is an extension of conventional LSTM-based neural networks that can enhance model performance. BiLSTM takes into account sequences in both forward and backward order as it is the result of combining several LSTMs on input in several opposed orientations. The essential components of a BiLSTM-NN are forward LSTM, backward LSTM, and combination. The forward LSTM can process the sequence from beginning to end. The backward LSTM processes the sequence from end to beginning. The outputs from both directions are combined or merged before being sent on to the next layer or job through a combination component. This may offer more network information to help with forecast accuracy. The main advantage of utilizing a BiLSTM is its capacity to gather information from both the past and the future at each time step. This is especially valuable for jobs that require knowing the context from both sides. In average temperature forecasting, information about an average temperature can be influenced by both previous and subsequent average temperatures. Fig. 3 illustrates the design of BiLSTM cell architecture [39].

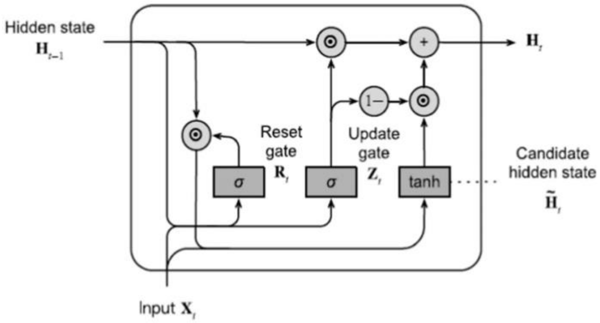

Fig. 2. The architecture of GRU cell design.

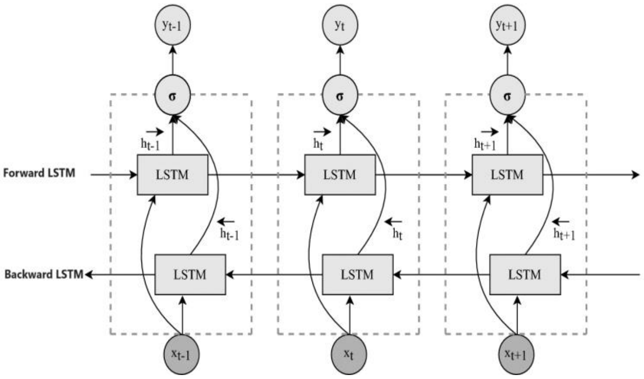

Fig. 3. Design of BiLSTM cell architecture.

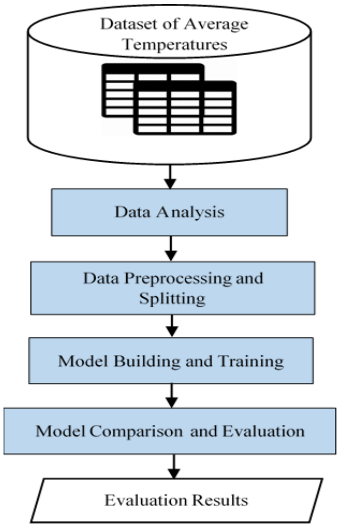
### C. Earth Surface Temperature Dataset

The flowchart of the proposed approach for this study is shown in Fig. 4. It contains four core steps, including data preprocessing, data analysis and splitting, model building and training, and model comparison and evaluation. Explaining these steps in detail is given the following subsections.



Dataset of Average Temperatures
Data Analysis
Data Preprocessing and Splitting
Model Building and Training
Model Comparison and Evaluation
Evaluation Results

Fig. 4. Flowchart of the proposed approach.

*1) Data analysis:* Data analysis is a critical step in understanding data and making a decision about which models of machine learning are appropriate for prediction or forecasting duty. Data analysis of average temperature in Saudi Arabia involves loading the average temperature data in its structured formats, exploring the distribution of average temperatures over time, visualizing trends, and extracting meaningful insights. First, the step checks if the data is stationary. The Augmented Dickey-Fuller (ADF) statistical test is usually used to determine whether a particular time series data is stationary or not. The null hypothesis of the ADF test is not stationary. To reject the null hypothesis, the p-value should be less than 0.05.

Other tasks of the data analysis step include calculating the basic statistics such as mean, median, and standard deviation, comparing average temperatures across different years, months, and cities within the country, visualizing their trends using relevant visualization charts, and looking for seasonality or patterns in the data.

*2) Data Pre-processing:* In data mining applications, data pre-processing is the most critical and time-consuming step. Because the temperature data of this study is the models' input, it is reasonable that the more accurate the input, the more accurate the output. The obtained data are the monthly temperature data from previous years. Temperature readings may not be recorded or have no value for a variety of reasons. In this study, we employed the interpolation method to prevent data bias. The interpolation method uses two known data points to estimate unknown data values. It is most commonly used to fill in missing values in a data record or series during data pre-processing.

An interpolation method is used to fill missing values with the aid of their neighbors. Filling missing time-series data with average values does not work well. Therefore, interpolation is suitable for time-series data to fill missing values with the preceding one or two values. For time-series data of average temperatures, it is preferred to fill the month's average temperature with the mean of the past two months rather than the months' mean.

The second method in data preprocessing step is data normalization. In data normalization, the average values of temperatures are scaled into a small and specific domain between 0 and 1 to prevent the neural network models from biasing the results. In this step, the min–max normalization method is used to convert the data to the range of 0 to 1. Computing min–max value for each average temperature $t_i$ is done by the following equation, in which$Max_{t_n}$and $Min_{t_n}$are the maximum and minimum values of average temperatures.

$$t_i = \frac{t_i - Min_{t_n}}{Max_{t_n} - Min_{t_n}} \tag{2}$$

The third method is data splitting. In data splitting, we use a train-validation-test split technique to divide the dataset into training, validation, and test sets with a ratio of 60%, 30%, and 10%, respectively. First, we take 10% of the dataset for the unseen test set. Then, from the 90%, we take 30% for the validation set, and the remaining 60% is as a training set. Because we deal with time series data, temporal aspects are considered when splitting to ensure that the test set represents future data.

*3) Model building and training:* The model building and training step is an iterative process of evaluation and refinement to produce a model that performs effectively on the specified task. The model's effectiveness depends on carefully selecting architectures, hyper-parameters, and optimization algorithms at this step. Based on our experience with deep learning and the size of data, we build each of the three recurrent neural network models to have one hidden layer with $x$ units, where $x \in [50, 100, 150]$ These three values are enough for search on the best number of hidden layer units, achieving an accurate forecasting of average temperatures from time-serious data. These built models are trained for 200 epochs, and the best values of the parameters set are preserved for evaluation. It is worth noting that a model's gates interact with data using a set of weights and biases known as parameters or hyper-parameters. During training, the back-propagation method is used to update these parameters. The final parameters set is referred to as the trained model and is used to make forecasting. The more parameters a model contains, the more computation time and resources it requires. As a result, the total number of parameters indicates a model's complexity and efficiency. Table III shows the number of parameters in each model.

TABLE III. MODEL'S TOTAL NUMBER OF PARAMETERS

| **Model** | **Total Number of Parameters** | | |
|---|---|---|---|
| | ***50 units*** | ***100 units*** | ***150 units*** |
| LSTM-NN | 10,451 | 40,901 | 91,351 |
| GRU-NN | 8,001 | 31,001 | 69,001 |
| BiLSTM-NN | 20,901 | 81,801 | 182,701 |

To successfully train the models, we feed the training set into the model and adjust the model's weights based on the loss values between forecasted and actual values. The models are iteratively updated their parameters through a series of pre-defined epochs. The models' performance is also monitored on the validation set to detect the under-fitting or over-fitting in the training progress.

*4) Model evaluation and comparison:* Once the training process is complete, the test set's model evaluation and comparison step is started to assess the generalization performance of trained models on the unseen data. The performance measures utilized to evaluate the proposed temperature forecasting models are statistical measurements. They are used to assess the models' ability to fit the data and include the Mean Absolute Error (MAE), Mean Relative Error (MRE), Root Mean Squared Error (RMSE), and coefficient of determination (R-squared). Models work well on the test set, obtaining the lowest value of all error measures. These lowest values of errors imply that the discrepancies between the actual and forecasted values are relatively small and unbiased. A higher R-squared value indicates that the models can accurately fit the data. In other words, error metrics evaluate the models' capacity to correctly estimate average temperatures based on the error values. The R-squared statistic simply indicates the relationship between actual and forecasted average temperatures. The following equations are used to compute all of the used performance measures:

$$MAE = \frac{1}{N}\sum_{k=1}^{N}|v_k - \widehat{v_k}| \tag{3}$$

$$MRE = \frac{1}{N}\sum_{k=1}^{N}\frac{|v_k - \widehat{v_k}|}{v_k} \tag{4}$$

$$\text{RMSE} = \sqrt{\frac{1}{N}\sum_{k=1}^{N}(v_k - \widehat{v_k})^2} \tag{5}$$

$$\text{R-squared} = 1 - \frac{\sum_{k=1}^{N}(v_k - \widehat{v_k})^2}{\sum_{k=1}^{N}(v_k - \bar{v})^2} \tag{6}$$

The actual values of average temperatures are denoted by $v_k$, the forecasted values are represented by $\widehat{v_k}$, and the mean value of actual average temperatures is denoted by $\bar{v}$.

## IV. EXPERIMENTAL RESULTS AND DISCUSSIONS

This section conducts several experiments on the dataset using Python programming language. In the first experiment, we applied the ADF test of the data analysis step to check whether the average temperature data in Saudi Arabia was stationary. This is required for Table IV, which presents the results of the ADF test on the dataset.

Table IV shows that the test statistics are lower than the Critical Value of 5%, and the p-value (0.0193) is less than 0.05. This means we reject the null hypothesis (data is not stationary). Therefore, the time series data of Saudi Arabia's temperature seems stationary. In stationary time-series data, there is no notable trend or variation in the mean, which makes it a critical quality for trustworthy analysis and modeling. Constant variance is another essential attribute, suggesting that data point dispersion remains constant across time.

The second experiment is applied to show the average temperature trend in Saudi Arabia per year based on time-series data. We resample the mean of average temperatures yearly instead of monthly for the last 152 years, as shown in Fig. 5.

TABLE IV. RESULTS OF AUGMENTED DICKEY-FULLER (ADF) TEST

| **Metric** | **Value** |
|---|---|
| Test Statistic | -3.2128 |
| p-value | 0.0193 |
| Lags Used | 40.0000 |
| Number of Observations Used | 12754.0000 |
| Critical Value (1%) | -3.4309 |
| Critical Value (5%) | -2.8618 |
| Critical Value (10%) | -2.5669 |

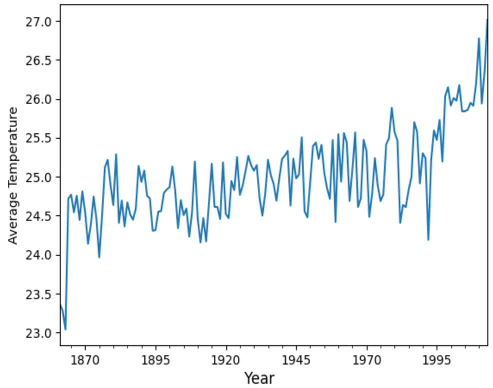


Fig. 5. The average temperature of Saudi Arabia in the last 152 years

From Fig. 5, we can see that there is a significant increase in the average temperature after the year 1995. Fig. 6 illustrates the average temperature curve of Saudi Arabia colored orange. It shows the growth of average temperature per year.

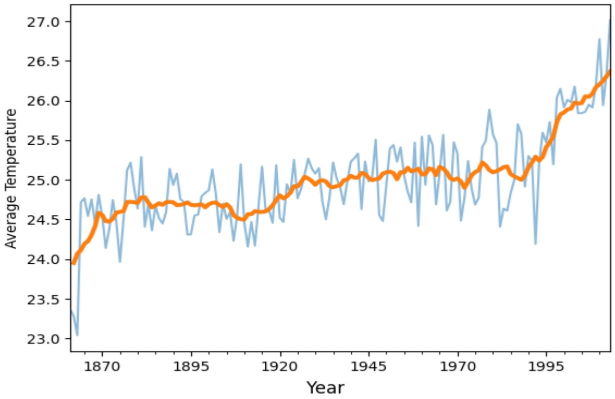

Fig. 6. The average temperature curve of Saudi Arabia in the last 152 years.

The trend of actual and forecast temperature regarding the growth of average temperatures is given in Fig. 7. As seen in this TA, the trend of temperature forecasting in the year 2045 will reach approximately 28 °C.

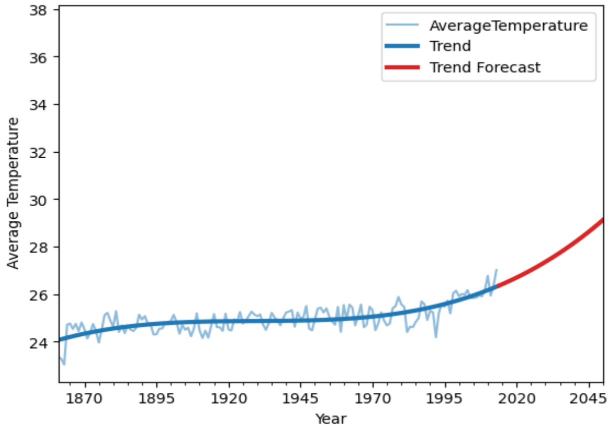

Fig. 7. Trend of actual and forecast temperature regarding to the average temperatures.

Through the experiment, we also visualize the monthly average temperature of Saudi Arabia from January 1st, 1861 to September 1st, 2013, as shown in Fig. 8. We can see a fluctuation in the temperature distribution with a little increase until 1995. This fluctuation is due to temperature variations throughout the months of each year. Fig. 9 illustrates the major cities of Saudi Arabia with the highest average temperatures. It shows that Buraydah and Riyadh have the highest average temperatures compared to other cities. Fig. 10 uses a box plot to visualize the monthly distribution and range of numerical data using the average daily temperature values. The box plot shows that February, March, May, and December have the most extended boxes and whiskers. However, February has the most extensive distribution of average temperatures.

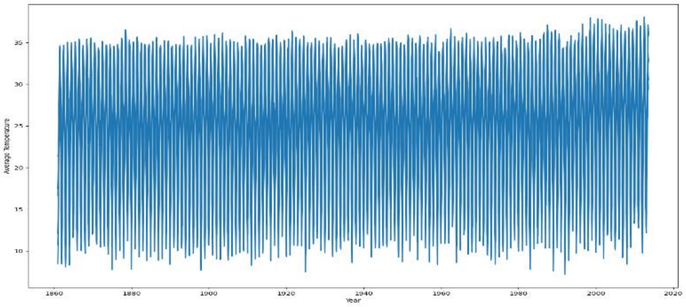

Fig. 8. Distribution of monthly average temperature time-series data

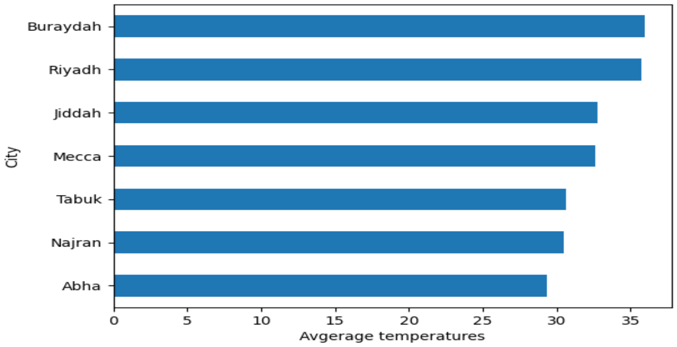

Fig. 9. Cities of Saudi Arabia with highest average temperature

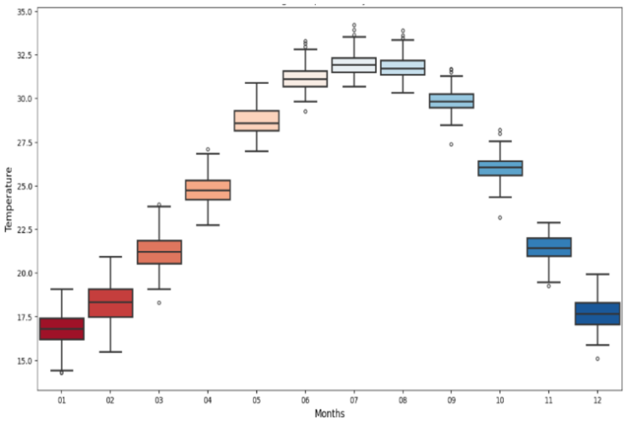

Fig. 10. Average temperature by months

Fig. 11 shows the average temperature season-wise over the years. The average temperature seasonally across the years can have a variety of effects depending on geographical location, climatic patterns, and local ecosystems of Saudi Arabia.

The previous figures give a picture for understanding the long-term trends of average temperatures and their season-wise over the years, which are crucial for mitigating and addressing the impacts of climate change on human society and the environment. It enables informed decision-making and the creation of adaptation strategies to climate change.

After performing a data analysis experiment, we conduct another experiment for average temperature forecasting using developed neural network models. We first apply the data pre-processing step. We check the number of null values in the dataset. We found that 146 records have null values for the number of Average Temperature and Average Temperature Uncertainty columns, as presented in Table V. For these null values, we fill them using an interpolation technique, which replaces them with the mean of the past two months. Then, we normalize the average temperature values to be in the range between 0 and 1. The normalization of average temperature values is required for the gradient descent of the neural network. Next, the dataset is divided into training and test sets using the data splitting step. Fig. 12 visualizes the distribution of training and test sets.

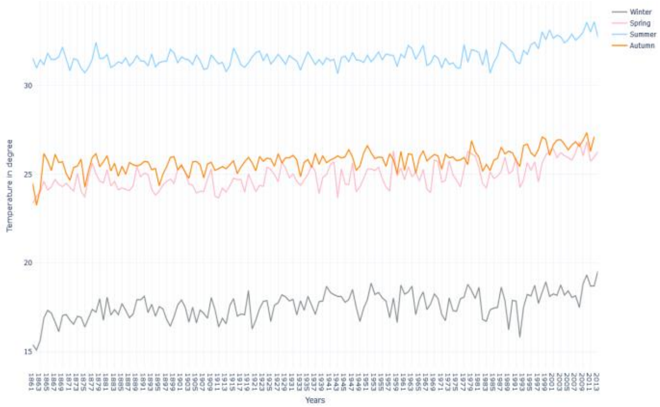

Fig. 11. Average temperature season-wise over the years.

TABLE V. CHECKING THE NUMBER OF NULL VALUES

| Column Name | No. of Null Values |
|---|---|
| DT | 0 |
| AverageTemperature | 146 |
| AverageTemperatureUncertainty | 146 |
| City | 0 |
| Country | 0 |
| Latitude | 0 |
| Longitude | 0 |

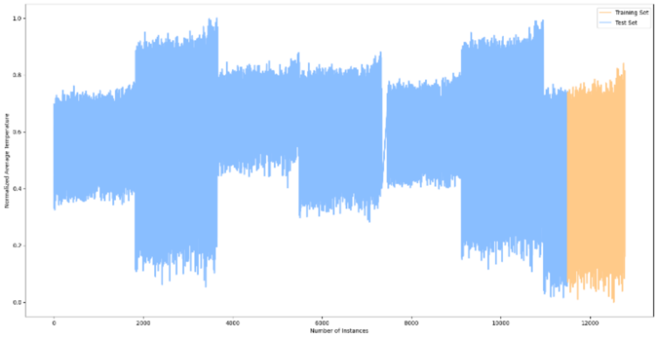

Fig. 12. Distribution of training and test sets.

After that, we train the LSTM-NN, BiLSTM-NN, and GRU-NN models on the training set using different numbers of hidden layer's units, which are 50, 100, and 150. In the training process, 30% of the training set is used for validation. Fig. 13 to 23 show the training and validation loss during the learning progress for the models at 50 units, 100 units, and 150 units. As shown in these figures, we can see that the gap between training and validation loss for the models with 50 units is very small compared to using other numbers of hidden layer's units. This means that there is no over-fitting in the training of the models. However, the gap between training and validation loss for the GRU-NN with 50 hidden layer's units is the smallest, indicating that its performance is better than the other models.

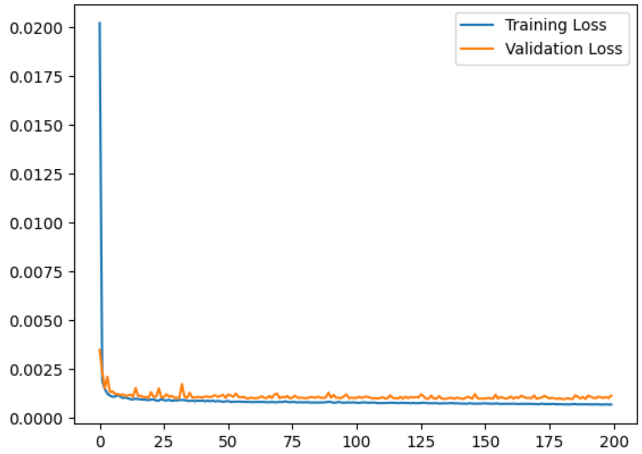

Fig. 20. Training and validation loss of BiLSTM-NN with 150 hidden layer's units.

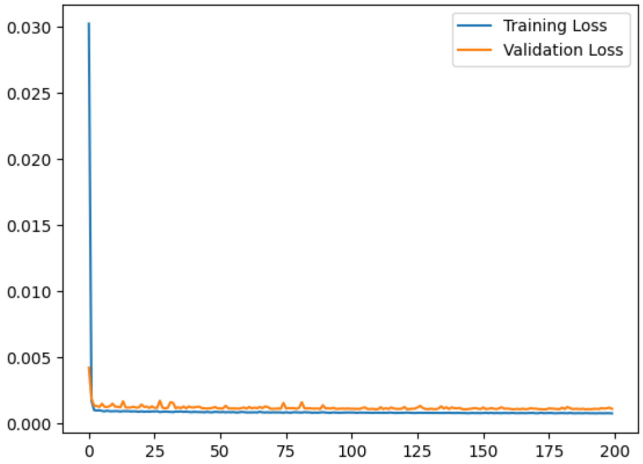

Fig. 21. Training and validation loss of GRU-NN with 150 hidden layer's units.

Table VI gives the performance results regarding MAE, MRE, RMSE, and R-squared for the LSTM-NN, BiLSTM-NN, and GRU-NN models on the test set using a different number of hidden layer's units.

TABLE VI. PERFORMANCE RESULTS OF DEVELOPED MODELS

| Model | Evaluation Measure | Number of Units in Hidden Layer | | |
|---|---|---|---|---|
| | | *50 Units* | *100 Units* | *150 Units* |
| LSTM-NN | MAE | 0.04213 | 0.03561 | 0.03811 |
| | MRE | 0.09291 | 0.07855 | 0.08406 |
| | RMSE | 0.05252 | 0.04468 | 0.04787 |
| | R-squared | 94.808% | 96.242% | 95.685% |
| BiLSTM-NN | MAE | 0.03309 | 0.03251 | 0.03062 |
| | MRE | 0.07298 | 0.07172 | 0.06754 |
| | RMSE | 0.04172 | 0.04264 | 0.03931 |
| | R-squared | 96.723% | 96.578% | 97.091% |
| GRU-NN | MAE | **0.02976** | 0.03072 | 0.03121 |
| | MRE | **0.06565** | 0.06777 | 0.06883 |
| | RMSE | **0.03889** | 0.04015 | 0.04046 |
| | R-squared | **97.152%** | 96.965% | 96.919% |

As listed in Table VI, we can see that the GRU-NN with 50 hidden layer's units achieves the best performance result on the test set for all evaluation measures, as highlighted in bold font. Figs. 22-24 display the distributions of ground-truth average temperatures of the test set and forecasted average temperatures generated by the three models with 50 hidden layer's units. We can see in Fig. 24 that the forecasted average temperatures generated by the GRU-NN model are more fitted with ground-truth average temperatures of the test set than the two other models.

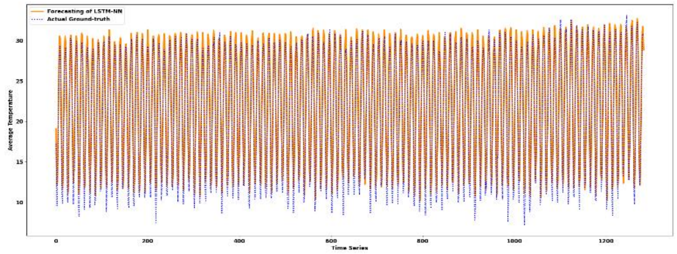

Fig. 22. Distribution of ground truth and forecasted average temperatures for the LSTM-NN model with 50 hidden layer's units.

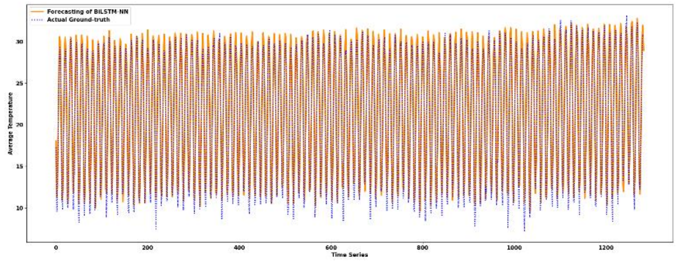

Fig. 23. Distribution of ground-truth and forecasted average temperatures for BiLSTM-NN model with 50 hidden layer's units.

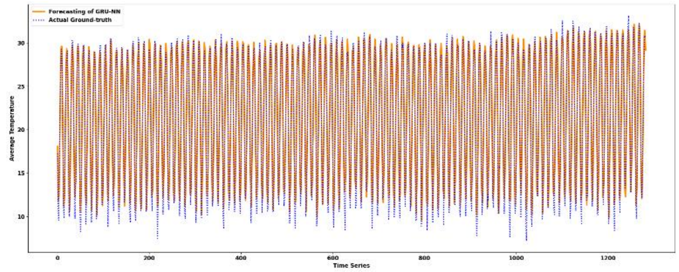

Fig. 24. Distribution of ground truth and forecasted average temperatures for GRU-NN model with 50 hidden layer's units.

For visualizing the performance of the three models, Fig. 25 compares the results of RMSE, showing that the GRU-NN model with 50 hidden layer's units has a lower value than the other models. Moreover, we compare the GRU-NN model with 50 hidden layer's units with two common regression models used widely in the literature review, which are ARIMA [21] and SVMR [21]. Fig. 26 and Fig. 27 present the distribution of ground truth and forecasted average temperatures for the ARIMA [21] and SVMR [21] models, respectively. We can see that the ground truth and forecasted average temperatures are not more fitted like the GRU-NN model. Finally, we compare the results of RMSE for ARIMA and SVMR models with the GRU-NN model, as shown in Fig. 28. Clearly, we can see that the GRU-NN model achieves the lowest RMSE value compared with ARIMA and SVMR models. This confirms the ability of the GRU-NN model with 50 hidden layer's units for accurate temperature forecasting and its suitability for the nature of Saudi Arabia's time-series temperature data.

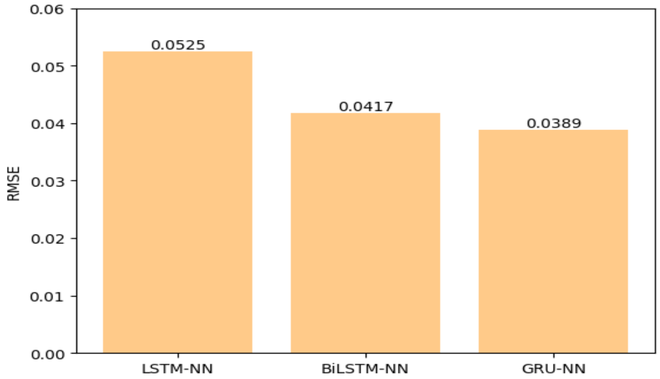

Fig. 25. Results of RMSE for the three models with 50 hidden layer's units.

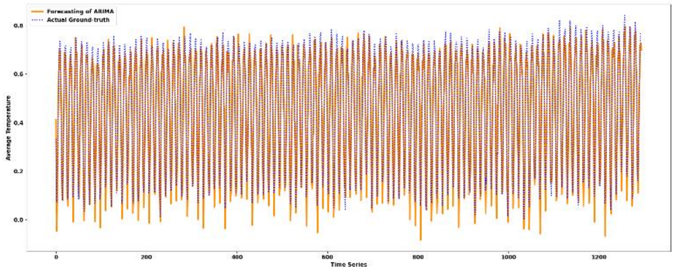

Fig. 26. Distribution of ground truth and forecasted average temperatures for ARIMA model.

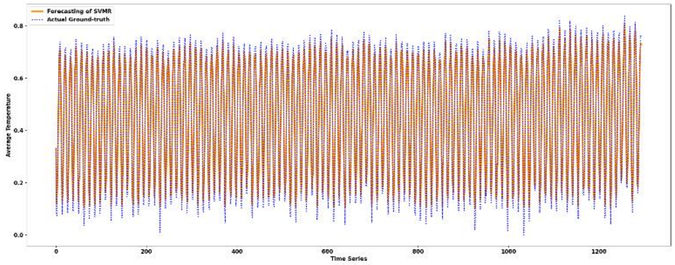

Fig. 27. Distribution of ground truth and forecasted average temperatures for SVMR model.

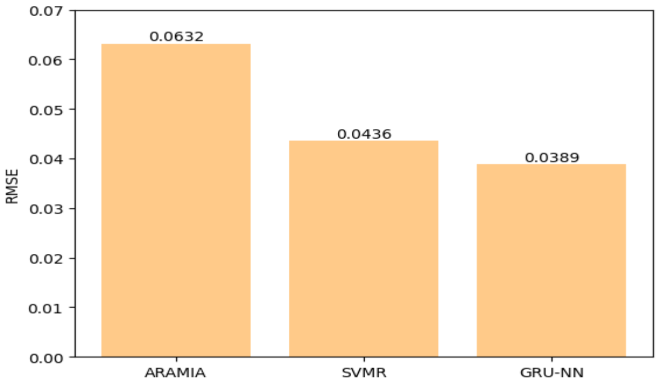

Fig. 28. Comparison results of RMSE for ARIMA, SVMR, and GRU-NN with 50 hidden layer's units models.

## V. Conclusion and Future Work

Analyzing and forecasting the temperature of Saudi Arabia region using historical time-series data can give valuable insights for climate change mitigation and adaptation plans. Decision-makers can use the analysis outcomes and forecasts to plan and execute actions to mitigate the anticipated effects of climate change, such as water scarcity, severe temperatures, and changes in agricultural methods. Average temperature forecasting utilizing recurrent neural networks plays a vital role in accurate climate change analysis.

The use of sophisticated neural network architectures, such as LSTM-NN, BiLSTM-NN, and GRU-NN, has shown great promise in capturing the complicated patterns and temporal correlations seen in temperature time-series data. They have been exposed to be successful in capturing the temporal dependencies seen in Saudi Arabia's historical temperature data. Their capacity to understand long-term relationships allows for more accurate representations of climatic trends and fluctuations across time. The experimental results showed that the GRU-NN model has improved accuracy in temperature forecasting for Saudi Arabia compared with other models. The model has demonstrated its ability to handle the non-linear and complex nature of temperature fluctuations, making it a valuable tool for climate change analysis.

In future work, we plan to implement a strategy for real-time temperature forecasting-based climate change monitoring and deployment of proposed models in operational settings. Moreover, we will investigate the transferability of LSTM-NN, BiLSTM-NN, and GRU-NN models to other domains beyond temperature forecasting, such as energy consumption or environmental monitoring. These directions of future work make the field of temperature forecasting using LSTM-NN, BiLSTM-NN, and GRU-NN models continue to evolve, providing more reliable and accurate predictions or forecasts for a wide range of applications.

## Acknowledgment

The authors extend their appreciation to Prince Sattam bin Abdulaziz University for funding this research work through the project number (PSAU/2023/01/ 27466).

# Utilizing the Metaverse in Astrosociology: Examine Students' Perspectives of Space Science Education

Yahya Almurtadha
Metaverse Lab, Faculty of Computers and Information Technology, University of Tabuk, Kingdom of Saudi Arabia

***Abstract*—Big economic countries must invest in space skills to create a favorable business environment, particularly in KSA considering the present mindset in outer space. KSA's vast landmass is a tremendous asset that makes it the perfect position to provide space services throughout the Middle East and the world. Space science education is becoming increasingly important, requiring advanced technology and computational skills to benefit early-career scientists. The Ministry of Education in KSA has declared that students will take Earth and Space Sciences to prepare them for global competition. Traditional learning experiences seem to have little to no impact on students' conceptual understandings of the space science courses. The sociological interests of Generation Z serve as the foundation for modern Metaverse approaches. Students' comprehension and interest in studying space and the galaxy are increased by provided a simulation of space travel using metaverse technology. The major goal of this study is to underline the significance and usefulness of employing metaverse technology while creating a new space science curriculum to advance knowledge in the field of space scientific education. Another goal is to introduce the value of astrosociology in understanding how people might interact with one another in space. A voluntary survey was completed by 39 students prior to their training in the metaverse space simulation as part of this study. They then used the space simulation with careful observation. After that, they reply to a follow-up survey. The findings supported the suggestion that the metaverse should be included in space science curricula. A number of comments and interests also arise on the viability of space travel, social interaction, and the advantages of using the metaverse to research these issues.**

***Keywords*—Metaverse; space science education; astrosociology; virtual reality; space simulation**

## I. Introduction

Humans' desire to live in space is on the rise, after the topic was limited to scientific research bodies that are looking into sending astronauts to conduct research and explore space. This explains the tendency of many countries to include space science in their education curricula. Consequently, scientific curiosity arose by studying space science and the nature of social relations between humans in space. Astrosociology and space science are closely connected subjects that have many points of intersection. Understanding the physical environment of space, including the effects of radiation, microgravity, and severe temperatures on the human body, is now possible by space science. in the other side, astrosociology examines the relationship between outer space and society [1]. Space science examines the physical parts of space, such as celestial bodies and astrophysics, whereas astrosociology investigates the social, cultural, and behavioral aspects of human in space. Understanding human adaptability, creating space habitats, and the societal implications of discoveries define the link between the two professions. For instance, incorporating social and cultural factors into the design process can help astrobiologists and space scientists promote well-being, productivity, and social engagement. The integration of information and perspectives from both fields might enhance our comprehension of the difficulties, prospects, and social dynamics associated with space exploration. By exploring the literature, no previous research has addressed the use of the metaverse in simulating astrosociology studies. Therefore, the contribution of this study is to introduce astrosociology to the students. In addition, this study will investigate the role of the metaverse as the fastest, cost-saving, and most realistic technology for space living simulation for astrosociology scientists. Consequently, they can examine the theories of living in the space. The following subsections that follow will discuss both space science and astrosociology to prepare the reader for the aspects of this research. Next, details the background and similar research regarding space science and metaverse in the literature review section. The methodology section describes the metaverse-based space simulation and the environment of the proposed system. Finally, we discuss the experimental results, the effectiveness of the proposed system to the astrosociology field, and conclusion.

### *A. Space Science*

Space science is the study of cosmic space beyond Earth. Space science education is becoming increasingly important in 21st century. Based on that necessity, the Ministry of Education in KSA has given its clearance for high school student to take four "Earth and Space Sciences" sessions each week. Earth and space sciences become a mandatory course to third-grade secondary students to prepare students for intercontinental rivalry by enhancing learning objectives. Hence, space science education is requiring significant call for a paradigm change [2] in collaboration with social science. However, there are a variety of motivations and challenges with space science education, including the following: 1) the social view: The development of space exploration, exploitation, and settlement activities is facing troubles by the absence of a social science-focused outer space curriculum. To fill the void, astrosociology is providing social scientific insights to the space community. It is a multidisciplinary field that focuses on the relationship between social life and outer space [2]. Astrosociology needs to get more acceptance and support from the space community in order to balance out the STEM fields [3]. 2) The economic benefit: Developing countries must invest in the skills and knowledge needed the space industry to ensure a favorable business environment. [1]. KSA's vast landmass makes it the perfect location to provide space services throughout the Middle East. 3) The high cost: Space travel is expensive. 4) Long time: The training and evaluation process for becoming an astronaut takes two years. Hence, as proposed by this study, the metaverse could be useful to help in solving these issues. The metaverse provides an inexpensive alternative for space travel by creating cyberspace without the need for expensive infrastructure. This lowers expenses and increases accessibility, encouraging collaboration among space enthusiasts, scientists, and researchers, and improving our understanding of the cosmos.

### B. *Astrosociology*

Today, space exploration is a hot topic in many academic fields, from the scientific community to the humanities [4]. How can social scientists address problems in outer space? What do sociologists make of a human culture that explores and lives in space? The answers to these queries reveal the two-way influences of both space and society on human beings[5]. Because of this, a relatively new science called "astrosociology" has emerged, which studies human societies and their social, cultural, and behavioral aspects in space [6]. It looks at how space travel affects people as individuals and as a community, as well as possible social dynamics in alien surroundings. It seeks to offer a thorough grasp of the potential evolution and adaptation of human cultures within the framework of space travel. In general, astrosociology presents a distinctive perspective for analyzing the social consequences of space operations and can furnish significant understanding for decision-makers, scholars, and anyone attracted by humanity's post-Earth future. Therefore, this study is proposing to provide a simulation method—such as metaverse technology—that is simple, inexpensive, quick to implement, and immersive enough to give students a taste of what it is like to live in space while also allowing researchers to explore their perspectives on the subject.

## II. Literature Review

The physical components of space science are enjoyable to both male and female students [7]. Nowadays students like to be informed about space science [7]. To support students understanding, experts employ technology and computers to precisely define and simulate objects in space. Space science courses can help early-career space scientists develop sophisticated computing skills [8]. Research has been done to evaluate the reliability and validity of space science awareness tools [9]. For example, some initiatives in teaching have been based on the International Space Station (ISS) [10]. The authors of [11] describe the results of Russian and international space missions as well as their proposals for future projects. Another study tested students to do space-flight scientific experiments on the International Space Station National Laboratory [12]. The research in [13] offers the results of a cutting-edge, university-based space program that created design concepts for astronaut health and wellness using the Project Based Learning (PBL) technique. Findings show that PBL improves academic achievement and student involvement but requires more time and effort from instructors than traditional methods [14]. The study in [15] discusses the development and implementation of an online tool to measure youth attitudes toward STEM areas and human spaceflight. Research on the educational impact of using space analog missions to educate at Vivalys Primary School has been conducted [16]. This helps to comprehend that experiments that aren't possible in a classroom environment should be given to students through virtual reality education [17].

### A. *Metaverse*

Metaverse is a 3D immersion virtual ecosystem enables the user to integrate and feel almost real in the virtual world. Metaverse enables people to live and experience activities, sports and events in safe ways that they cannot in the real world because of their high cost or danger. The current Metaverse is “based on the social value of Generation Z that online and offline selves are not different” [18]. In its core, metaverse creates a fascinating, envisioned or real world where learners can not only view content but also engage with it directly. Metaverse can also take students to places they might not otherwise be able to visit, like space exploration, historical sites or even the human body. They may now explore and learn in previously impractical ways because to this. The metaverse, a virtual shared place formed by the merging of the physical and digital worlds, has the potential to transform a variety of disciplines, including education, medical, and entertainment. In education, students can benefit from augmented reality in critical thinking[19] and can immerse themselves in dynamic and engaging virtual worlds to get hands-on experience [20]. Medical students uses virtual reality learning performs better than the conventional learning method [21]. Results showed that learning with an augmented reality method was better to a paper-based approach in terms of learning accomplishment, pleasure of learning activities, and utility [22]. The metaverse opens up new avenues for people in the entertainment industry to interact, socialize, and take part in immersive events like virtual concerts and gatherings. According to a research, keeping existing customers is more practical and cost-effective than attracting new ones, therefore park owners and managers should make sure that visitors can easily utilize virtual reality and develop creative concepts and materials to boost satisfaction [23].

Due to the recent advancement in this contemporary technology, it is now feasible for scientists and students alike to explore the cosmos [24]. For example, the US space agency NASA is working to determine how metaverse technology may aid in space exploration studies [25]. Education using Metaverse is increasing team engagement, and saving redesign cost and time [26]. Metaverse is more effective for students and scientists to observe what is occurring in space than spending time there for weeks. The main limitation found from the similar research areas is that the astrosociology usage of the metaverse is still in its infancy, and several social, ethical, and technological issues require resolution. Thus, there is a reason for optimism regarding the metaverse's potential to improve education and research in space travel, cultural preservation, and social interaction as this study will investigate.

## III. Methodology

The purpose of the study is to ascertain students' pre- and post-participation perceptions of life in space through a metaverse-based space simulation. Fig. 1, modified from the study in [27], illustrates the framework of the metaverse-based space simulation. It depicts that the metaverse-based simulation is simple to use, free, private, and aims inspiring. Therefore, students gain a good experience from using the metaverse as an engaging, instructive, and fun experience that introduces them to the marvels of the universe.

We followed the next steps as determined by Fig. 2 to help accomplish the project's objectives:

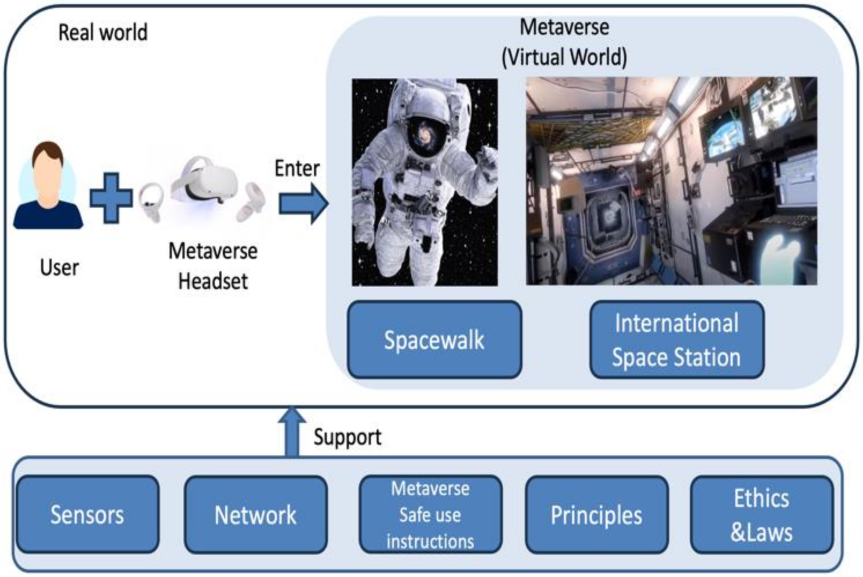

Fig. 1. Metaverse space simulation model.

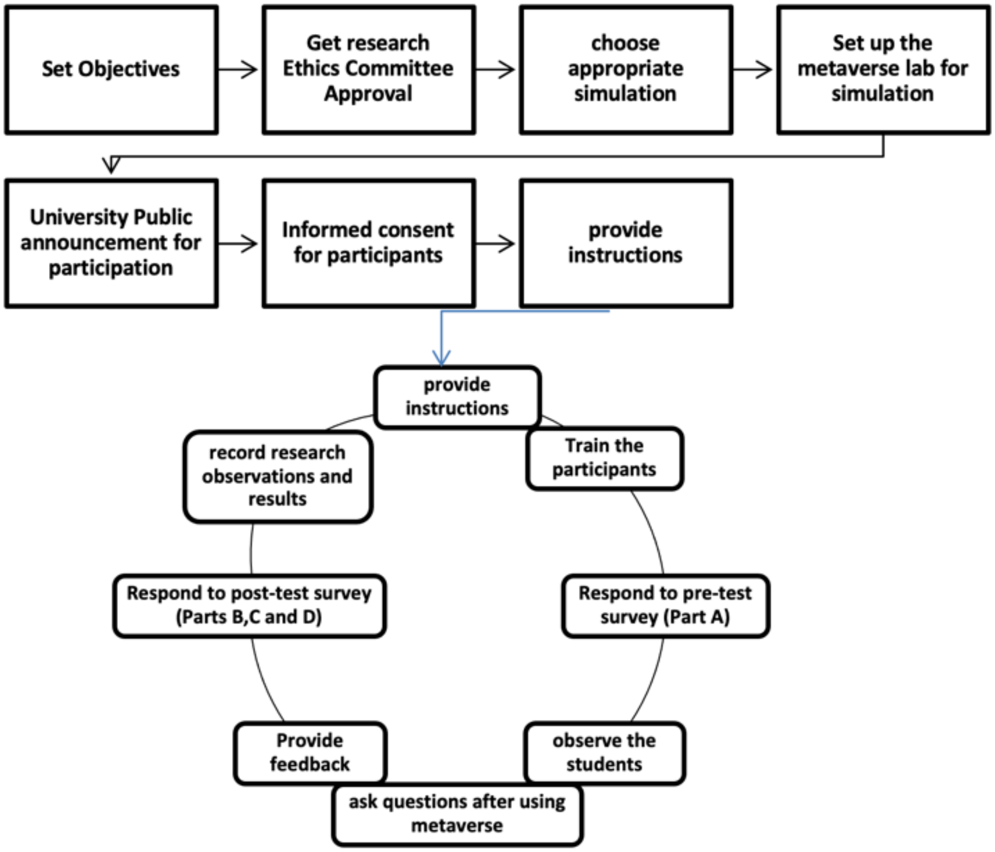

Fig. 2. Research methodology.

*1)* Identifying the key concepts and sub objectives that we want the students to understand. Sub objectives of this study are:

*a)* To highlight the significance and value of using metaverse technology for space science education.

*b)* To introduce students to the astrosociology, as well as to use the metaverse in astrosociology to better comprehend how humans could feel when living in space.

*2)* The University of Tabuk requires permission from the Local Research Ethics Committee (LREC) for studies involving students as participants. The committee requires the research investigator to:

*a)* Register at the National Committee of Bioethics (NCBE) database, pass the bioethics training, and get certified.

*b)* The researcher then can apply to the local research ethics committee by submitting their CV and a thorough study proposal including their objectives, sample size, data collection methodologies, description of personal information or any samples that might be collected, and how to secure these data. In addition, include a copy of the announcement materials for participation. Before students participate, they must be properly briefed; also, a consent form will be handed to them. The consent form discusses the study's goals, the number of visits required to participate, whether it is open to the public or only a select group, whether any personal information is required, how to ensure participant anonymity, any risks, location and safety considerations, the participant's right to leave at any time without penalty, and inclusion and exclusion rules. Then student who signs voluntary the consent form should be prepared to participate.

*3) Choose the appropriate VR simulation:* There are various VR simulations that can be used for space science education. we used Mission:ISS simulation as in Fig. 3 and Fig. 4 developed by Magnopus [28] run on Meta Oculus Quest 2 [29] which aligns with the research objectives.

*4) Prepare the metaverse-based spacewalk simulation:* The Metaverse lab is equipped with the research facilities and equipment needed to measure students' understanding of astrosociology using metaverse such as:

*a) Meta Oculus Quest 2 Virtual reality headset (8 Devices):* This is the most important piece of equipment needed. The headset is of high quality and capable of providing an immersive experience for the students.

*b) Powerful Computer hardware (8 PCs):* This includes a powerful graphics card, i9 processor, and 32GB RAM.

*c) VR software:* The VR software used to simulate spacewalk simulation of high quality and accurately represent the concepts.

*d) Classroom space:* The metaverse lab space is large enough to set up a room-scale play area, accommodate two students at a time, and allow them to roam freely while wearing the VR headset and following the safety guidelines.

Fig. 3. Snapshot of Mission ISS simulation: spacewalk [29].

Fig. 4. Snapshot of Mission ISS: Navigation inside ISS [28].

*5) Asking pre-experiment questions:* Before the students use the VR space simulation, we ask them questions to assess their understanding of the key concepts and research questions.

*6) Provide instructions:* Before starting the metaverse simulation, we provide clear instructions to the students on how to use the Oculus Quest2 headset safely and how to navigate the space simulation.

*7) Observe the students:* As the students are using the metaverse simulation, we observe their interactions and note any misconceptions or areas where they may need more clarification.

*8) Ask post-experiment questions:* We ask the students questions after they have done the metaverse space simulation to test their grasp of the major ideas and research objectives after experiencing the space simulation.

*9) Provide feedback:* Based on the observations and the students' responses, we provide feedback to help them improve their understanding of the material.

*10)Repeat the process:* To reinforce the learning, we may repeat the metaverse space simulation and assessment process.

*11)*Get conclusions and research results.

## IV. The Experiments

The process for gathering data from various student groups is described below. A metaverse-based space simulation was prepared. Following that, a pre- and post-space simulation survey is answered by participants to gather information from students on their perspectives towards using the metaverse for space education. A descriptive survey (in four parts: A, B, C, and D) was used. The trainings and experiments were conducted in the metaverse lab at the University of Tabuk. 39 volunteer students responded and participated. No personal data was gathered. Part A test students' broad understanding of space science and astrosociology before using the metaverse space simulation. After participants completed ten multiple-choice questions in Part A, they are trained to use the metaverse simulation. Then they used the simulation for 20 minutes. After that they answered nine questions in part B. Part B discusses how students feel about spacewalk and ISS mission using metaverse space simulation and how they would interact with the space. Part C (10 questions) aims to test the System Usability Scale (SUS) [30] to evaluate whether this simulation is suitable for use in space science education. Part D (13 questions) aims to test the Igroup Presence Questionnaire (IPQ) [31] to assess their sense of presence and immersion while in virtual world.

## V. Analysis

All the participants are students at university of Tabuk. They responded voluntarily to a public announcement in the main campus. We followed the bioethics committee's regulations, which required that each participant be briefed before participating and sign a consent form. No personal information was collected. They did not get any compensation for their participation. They were even told that they might exit the process at any moment, with no obligation. None of the 39 participants had used the space simulation before. 7% of them know about metaverse and have used it more than three times, 28.2% have used it fewer than three times, and the remaining 64.7% have never used it before. The next sections detail the results obtained from the pre- and post-test of the metaverse space simulation in addition to the SUS and sense of presence test.

### A. *Analysis of the Effectiveness of Metaverse in Space Science Education*

We use descriptive statistic frameworks and data analysis methodologies to evaluate the results, which involves summarizing the data collected from the metaverse-space simulation using measures such as mean, and standard deviation. The aim is to provide an overview of the students' perception of how effected be if we use the metaverse in the space science education. In Part A questionnaire, all participants responded that they have never used the space simulation before. This ensures equivalent level of knowledge among all participants. Fig. 5 illustrate that most students after experiencing the metaverse-space simulation found the simulation has affected their knowledge of space science positively (SD=0.595, N=39) and recommended to use it for education (SD=0.339, N=39) as illustrated by Fig. 6. The scale of 3 in the figure refers to “agree”, 2 to “sort of” while the score 1 refers to “do not agree). SD stands for standard deviation, which measures how distributed the data is in comparison to the mean. A low standard deviation suggests that data is tightly grouped around the mean, whereas a high standard deviation shows that data is more spread out[32].

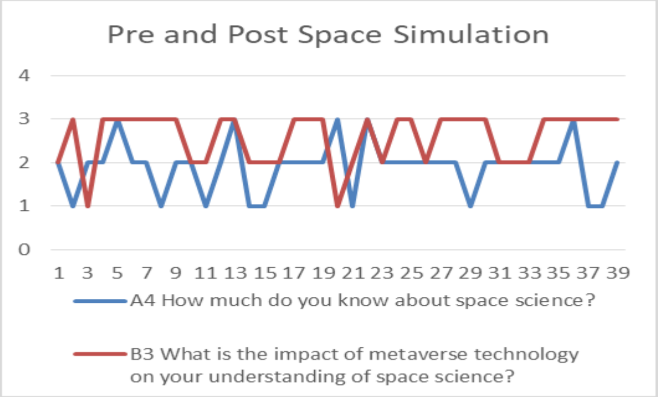

Fig. 5. Pre and post space simulation response regarding space science.

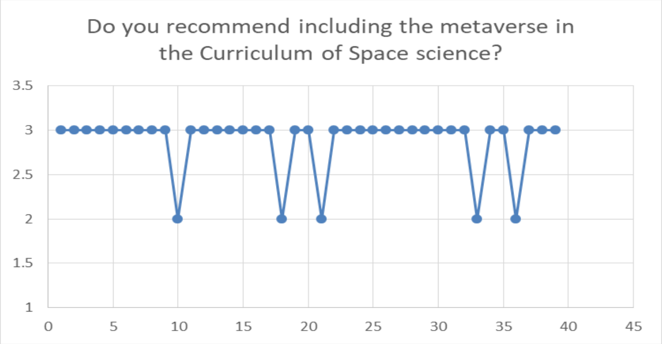

Fig. 6. Students’ recommendation for using metaverse in space science education.

### B. *Analysis of the Knowledge of Astrosociology*

The second sub objective of this study is to introduce the astrosociology to the students. Pre-test participant responses indicate that all participants had no understanding of astrosociology. Following the metaverse simulation and conversation with each participant, there is a significant rise in their interest in learning more about astrosociology. Some even begin to wonder about the logistics of living in space and how humans would interact with one another. Table I illustrates the standard deviation and mean of the subjects' responses to astrosociology before and after exposure to space simulation. Fig. 7 shows that students’ awareness is increased after experiencing the space simulation.

TABLE I. PRE AND POST TEST STUDENTS' RESPONSE TO ASTROSOCIOLOGY KNOWLEDGE

| Test | Test Topic | SD | Mean | N |
|---|---|---|---|---|
| Pre-Space simulation | Astrosociology kowledge | 0.556 | 1.48 | 39 |
| Post-Space simulation | Astrosociology Awareness | 0.605 | 2.71 | 39 |

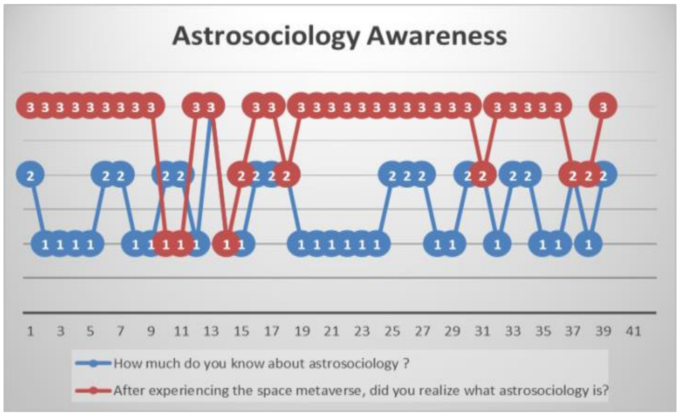

Fig. 7. Students'' response to astrosociology awareness: pre and post simulation.

### C. Analysis of SUS and Sense of Presence Measurements

Participants in the metaverse space simulation also completed Part C of the questionnaire, which assessed the System Usability Scale (SUS) and the experience of presence and immersion in the virtual world. This survey was evaluated as a post-space simulation, and all 39 participants completed it. We use The System Usability Scale (SUS) to classify the ease of use of the site, application, or environment under examination. It consists of a 10-item questionnaire with five response scale for responders, ranging from strongly agreeing to strongly disagreeing [33]. After recording the results from participants, they should be normalized to a scale of 0-100. The SUS calculated value for the 39 participants was 69.14. This was greater than the average SUS score of 68 points. When translated to the adjective grading scale, this value equals "Good". As a result, the metaverse space simulation is considered suitable for use in practice.

Four metrics of presence may be determined by assessing the IPQ questionnaire items. The first is general presence (G), which measures complete presence in general. The second concept is spatial presence (SP), which relates to the perception of being physically present in a virtual world. The third metric is participation (INV), which evaluates both interest and involvement. The fourth metric is experiential realism, which assesses the subjective perception of reality in the virtual world [34]. Table II and Fig. 8 shows that general presence G exhibits the highest results (score=2.8, SD=0.37). Fig. 9 supports that by analyzing the students' response to the level of being actually in the space while using the simulation. Level of involvement in the simulation is the second highest result with (score=2.31, SD=0.53).

TABLE II. RESULT OF PRESENCE TEST

| IPQ metrics | Avg Score | SD |
|---|---|---|
| G (General presence) | 2.84 | 0.37 |
| INV (Involvement) | 2.31 | 0.53 |
| SP (Spatial presence) | 2.27 | 0.57 |
| Real (experience of realism) | 2.20 | 0.66 |

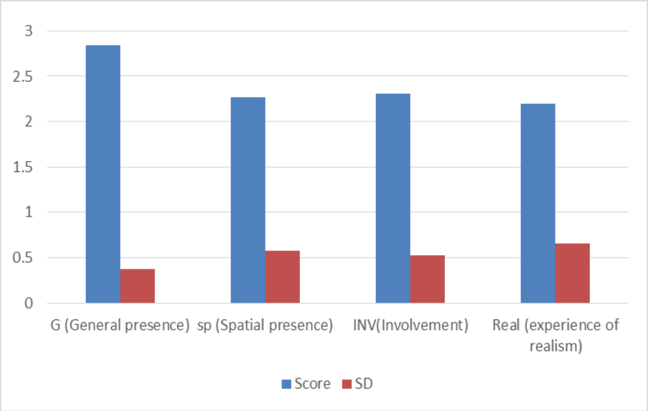

Fig. 8. Average result of response for IPQ Four metrics of presence.

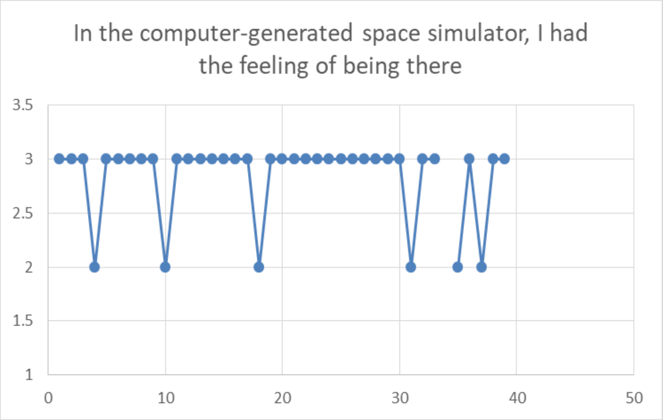

Fig. 9. General result of level of feeling of immersion in space simulation

## VI. CONCLUSION

This study aims to support the university's priorities by promoting innovation and cutting-edge teaching methods via adding metaverse into the curriculum and promoting the astrosociology as a core component of the space science program. It will enhance students' understanding of space science, aligning with the university's research identity towards the space. This study concludes that the metaverse when adopted in the curriculum helps improved student performance, increased engagement, and knowledge retention, which can help students to secure future jobs and improve retention and graduation rates.

Furthermore, and upon discussion with students after experiencing the space simulation, we recorded the following conclusions: a) in recent times, the notion of the metaverse has earned noteworthy interest, especially in space science education. b) The metaverse can be utilized for education and outreach in astrosociology by developing immersive and interactive educational content about space exploration and the social dynamics of space living. This can raise public awareness and generate discussions on humanity's future beyond Earth. c) In terms of astrosociology, the metaverse can enhance immersive training and simulation experiences by building virtual settings that simulate space flight circumstances, and the conditions and difficulties of space flight. This might improve the skills, competence, and preparation for space missions. d)Furthermore, the metaverse may be utilized in astrosociology to promote social engagement by offering virtual spaces in which people can communicate and cooperate in space. This can reduce feelings of loneliness and encourage sociability in extraterrestrial environments. e) Finally, the metaverse can enhance study and cooperation in astrosociology by establishing virtual settings to perform experiments and collect data.

## ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Research and Graduate Studies at University of Tabuk for funding this work through Research no.0059-1444-S.

Research Ethics approval: This study obtained the approval No: UT-353-179-2024 from the Local Ethics Committee following to the process of the National Committee of Bioethics (NBCE).

Informed Consent Statement: Informed consent was obtained from all subjects involved in the study.

***Abstract*—Automated assessment of student assignment based on SQL(Structured Query Language) queries is an efficient method for evaluating and providing feedback on their DBMS-related skills. This paper provides a three step approach of how student submissions are assessed automatically using various machine learning approaches and introduced an automated grading system for SQL(Structured Query Language) queries. ASQGS (Automated SQL Query Grading System) is the process of evaluating SQL queries submitted by students of a classroom. Due to the difficulties involved in the automatic grading procedure, this endeavor continues to attract the researcher's interest in developing a new and superior grading system. The purpose of this study is to demonstrate how text relevance is calculated between a reference query that the teacher sets and a query that the student submits. To compute the grade, the similarity value between the student and reference queries will be compared. In this paper various feature similarity techniques were discussed which is required before applying the machine learning model to automatically assess the grade of the student's SQL assignment. In the second step the grade received by the ASQG is used for student outcome assessment using rubrics with respect to Bloom's taxonomy and finally scores can be calculated using predefined rubrics criteria. Additionally, in the 3rd step the system can generate feedback for students, highlighting specific areas of improvement, errors, or suggestions to enhance their queries among different groups of students segregated by their SQL knowledge.**

## I. Introduction

ASQG (Automated SQL Query Grading) is the task of assessing student's SQL (Structured Query Language) queries by leveraging computational methods. The task of ASQG can be handled with the machine learning approaches. Automatic grading has been a popular area among researchers due to the benefits of decreasing human errors and time consumed [1]. Automatic grading of SQL queries enhances advancement and improves subject learning [2]. The goal of this study is to show how text relevance computation is used while comparing a reference query with the student's query. An instructor-authored reference question is one that is written by them. To determine its similarity score, the student answer query will be compared to the reference query. Summative evaluation is used to evaluate students' effectiveness and progress in gaining comprehensive SQL knowledge. The assessment of Automated SQL Query Grading (ASAG) is more difficult since it involves a comprehension of the RDBMS idea, the schema, and a more extensive study of the search criteria. This work proposes an optimal model for autonomously grading short-answer questions using a dataset acquired from a university student taking SQL as one of their modules. ASQG deals with SQL queries that have brief replies that are frequently evaluated against a reference answer. The primary goal is to grade a learner's response regarding the model solution. Many ways to assess SQL queries do not include sentence form or coherency. It is crucial to note that automated grading systems can be configured to handle varying levels of SQL query complexity, ranging from simple SELECT statements to more advanced topics like JOINs, subqueries, and optimization techniques [3]. Instructors can save time by using automated SQL query grading. The aim of this research is to automated grading can be combined with rubrics-based assessment to analyze student outcome and generate precise feedback to enhance student knowledge in SQL.

### A. *Research Methodology*

Students typically submit their SQL queries through an online platform or system designed for automated grading. The platform should allow students to enter their queries and execute them against a predefined database schema. The submitted SQL queries are executed against the database schema to retrieve the results. The system compares the results obtained from executing the student's query against the expected results for matching the similarity. The expected results are typically predefined by the instructor or generated based on a reference implementation. Grading criteria are established to evaluate the correctness and quality of the queries. The comparison of instructor and student queries in ASQG may be facilitated by semantic textual similarity and paraphrasing communities [4]. This may include criteria such as accuracy, whether the model query is matching the student query and then grade is obtained as 0 or 1 based on the similarity [5]. Based on the grading criteria, the automated system assigns scores to each query submission. Scores can be calculated using predefined rubrics or algorithms which are discussed in the paper. Additionally, in step 3 the system can generate feedback for students, highlighting specific areas of improvement, errors, or suggestions to enhance their queries. The automated grading system can provide detailed error reports to help students identify and rectify the mistakes in their queries with scores to individual students and different action can be taken according to the level of the student. These reports may include syntax errors, semantic errors [6] [7] [8], or logical errors, database skill, concept and logic building skill, optimization skill the query readability through the documentation skill encountered during query execution.

## II. Dataset Preparation

According to this hypothesis, initially, the dataset was considered as an assignment comprised of student-submitted SQL queries [9]. In this section, we will collect student assignments and use them as input datasets. The dataset will be used for academic study. The dataset was created by the instructors for students from several areas at a university who were studying SQL as part of their coursework. The grading is primarily a classification issue, with class level grades being assigned as correct (1) or erroneous (0). If the student's question matches the reference query, the class level is accurate; otherwise, the class level is erroneous.

The SQL assignment is based on the conceptual diagram given in the diagram. Here the EER consisting of 4 entities. In the Employee relation each employee is uniquely identified by the primary key employee_id. Department_id is the primary key in the Department table. Location_id is the primary key in the Locations table and Job_id the primary key in the Jobs table. Each employee works in exactly one department. So, department_id is the foreign key in the Employees table referring to the department_id of the Department table. Each department is located at a particular city and location_id of department table is the foreign key referring to the location_id of the Locations table. Some employees manage other employees hence manager_id became the foreign key referring to the employee_id of the same table. Each employee's job detail is maintained in the Jobs table and job_id of Employee table is designed as the foreign key to job_id of Jobs as shown in Fig. 1.

In this model, initially, the dataset was viewed as an assignment, consisting of submitted SQL queries from students. Here, we will acquire student assignments and utilize them as input datasets. The dataset will be utilized for research purposes. A university's engineering students from a variety of fields studying SQL as part of their curriculum compiled the dataset as shown in Table I. The grading is essentially a classification problem, with class level being graded as correct (1) or incorrect (0). The class level is correct if the student's query matches the reference query, and incorrect if the student's query does not match the reference query or differs marginally from the reference query.

A Student's SQL query answer can be defined as a piece of text fulfilling the query condition [4]. A student response to a given question must be in natural language followed by the SQL syntax. A response length must be limited to between one sentence. A student response must demonstrate the external knowledge which they gained from their understanding of the Shema given and is identified within the question.

The actual dataset is prepared by collecting the student solutions for the SQL based questions through online exam conducted through google drive. The final dataset looks as follows where MA represent Model Answer and SA represents the student answer and the grade manually assigned by the instructor represented in the mark column. The word cloud for the model answer and student answer containing frequent words is represented in Fig. 2.

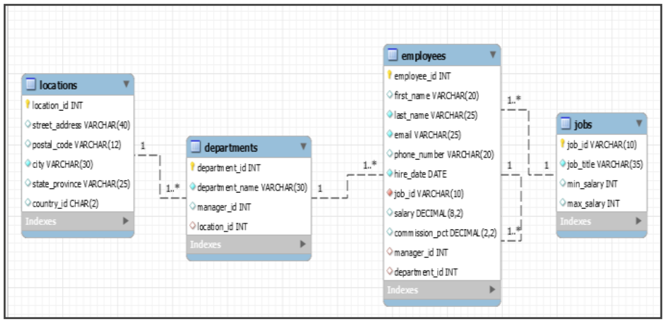

Fig. 1. The EER diagram of the company database.

TABLE I. Brief Overview of the Dataset

| **Sample Question** | ***Sample Question with model and student answer*** | | | |
|---|---|---|---|---|
| | ***Q1*** | ***Display the name of the top earner in the organization*** | ***Grade*** | ***Teacher'sfeedback*** |
| Model Answer for Q1 | 1 | Select first_name from employees order by salary desc limit 1; | 1 | excellent |
| Model Answer for Q1 | 2 | Select first_name from employees where salary=(select max(salary) from employees); | 1 | excellent |
| Student answer Q1 | 1 | Select first_name from employeesorder by salary desc limit 1; | 1 | excellent |
| Student answer Q1 | 1 | Select first_name from employees where salary=(select max(salary) from employees); | 1 | excellent |
| Student answer Q3 | 2 | Select first_name,max(salary) from employees; | 0 | Semantic error |
| Student answer Q3 | 3 | Select maximum(salary) from employees; | 0 | Syntax error |
| Student answer Q4 | 4 | Select max(salary) from employees; | 0 | Semantic error |

## III. Dataset Preprocessing

The student's query may contain different forms of trash values, noisy text, and encoding. This must be cleansed for NLP to conduct additional jobs. Non-ASCII values, special characters, HTML elements, stop words, raw format conversion, and so on should all be removed during this preparation step. All sentences are switched to lower case for symmetry. We minimize some punctuation because it has no effect on the computation. The next step is to convert the two sentences into lower case as there is no difference in meaning between “create” and “CREATE” and “Create”. The third step is tokenizing the sentences. Following tokenization, each token will be compared against the terms in the user-created stop word list. Several stop words, including "in," "from," "by," "into," and "as," are used in the SQL query. Therefore, all other matching words will be eliminated aside from these stop words, leaving only the keywords for the connected phrase. We might shorten the duration to the following step by using the stop word removal. Given our consideration of syntax and semantics, the prefix-containing word need not be transformed into its root word. Therefore, stemming is not necessary for preprocessing.

## IV. Feature Similarity

We describe the proposed method for computing vector similarity. The surface closeness (lexical similarity) and significance (semantic similarity) of two "adjacent" sections of the text should be defined by text similarity [9]. Automated evaluation uses various text similarity methods to determine the similarity between two queries.

### A. *String-based Similarity*

Regardless of the meaning of the two strings, it examines two character sequences and determines a similarity score based on the string that corresponds to each of the two strings.The Jaccard index is commonly used to compare the similarity, dissimilarity, and distance of a data set's syntax [10]. As shown in the Eq. (1) below, the Jaccard similarity coefficient between two data sets is calculated by dividing the number of shared characteristics by the total number of properties.

I. List the unique words in the documents.
II. Find the intersection of words list of doc1 & doc2.
III. Find the union of words list of doc1 & doc2.
IV. Calculate Jaccard similarity score using length of intersection set divided by length of union set

Fig. 3. Algorithm for finding Jaccard similarity between documents.

It equals the number of unique characteristics minus the number of characteristics shared by all, divided by the total number of characteristics. Algorithm for finding Jaccard similarity between documents is in Fig. 3.

$$S(A, B) = |A \cap B| / |A \cup B| \tag{1}$$

Example1:

doc_1="select * from employee"

doc_2="select * from employee"

Jaccard_Similarity(doc_1, doc_2)

Output: 1

Example2:

doc_1="select * from employee"

doc_2="select all from employee"

Output:0.6

### B. *Similarity based on Semantics*

A set of terms or texts defines semantic-based similarity [9] [11]. The comparison is based on the semantic content or their coherent meanings. Semantic-based similarity makes use of the following algorithms:

*1) Similarity based on corpus:* It constructs a knowledge space using information collected just from the analysis of large corpora, which is then used to compute the connections between words and sentences [11].

*2) Latent Semantic Analysis (LSA):* LSA is a type of statistical model that uses vector means in the context of semantics for assessing the resemblance of texts or phrases [12]. LSA is a technique in NLP, to map between two documents and terms. So here the sample document consists of the model answer query and the student answer query 1, student answer query 2 and student answer query 3. So total 4 sentences. So, we need to find out which sentences are more similar. From the raw data, LSA generates a term-document matrix, which lists terms in rows and documents in columns, with each cell indicating how frequently a term appears in this document. Here each row in the matrix represents the terms in the answer query and each column represents a document or the query [13]. If the term is present, then it is represented as 1 otherwise 0. In Step 2: We are going to create a TF-IDF matrix using TfidfVectorizer. This stage transforms the text into a matrix representation, with each row representing a document and each column representing a unique word in the corpus.

Then an SVD (Singular Value Decomposition) is used to convert a large document (Query in our paper) to matrix of small size by finding the similarity between the columns and hence by reducing the number of rows. SVD helps in factorizing a complex matrix. SVD is a decomposition technique for decomposing a matrix into the constituent element. Here the matrix A is factorized into three matrices as in Eq. (2).

$$A = SU * Sy * V^T \tag{2}$$

U and V are left and right singular vectors of A respectively and S represent the singular value of A where U and V are orthogonal matrices, means if the product of a matrix and the transpose gives identity value.

$$U * \sum X \tag{3}$$

where, ∑ is a diagonal matrix containing singular values of A. A matrix is diagonal if it has nonzero elements only in the diagonal.

All have the diagonal value of ∑ denoted as σi and ordered as σ1 ≥σ2 ≥σk and r is the index such that σr> 0 and either k=r and σr+1 = 0.

Here we are going to apply Singular Value Decomposition (SVD) using TruncatedSVD to reduce the dimensionality of the TF-IDF matrix [14]. Here, we specify the number of components (dimensions) we want to reduce (in this case, 2).

Finally, the cosine angle between the vectors of the two columns is computed to compare the model query with the student query. The angle cosine between two vectors determines whether the two vectors are referring to nearly the same trend, hence cosine similarity is widely used to evaluate distance. A score close to 1 implies similarity, while a value close to 0 shows full variance. Using cosine similarity, we determined the cosine similarity between the generated LSA matrix. The resultant similarity matrix will have values ranging from 0 to 1, with higher values representing greater similarity between documents. The similarity matrix is then printed to the console. So, we have implemented LSA for document similarity in Python using the scikit-learn library.

### C. Vector-based Similarity

Vector-based similarity techniques in Natural Language Processing (NLP) involve representing textual data as numerical vectors and using various similarity measures to determine the similarity or relatedness between different texts. These techniques are widely used for tasks such as document similarity, semantic search, clustering, and information retrieval. Here are some common vector-based similarity techniques in NLP:

*1) Bag-of-Words (BoW) Model:* Each text is encoded as a vector in this manner, with each dimension corresponding to a distinct word in the lexicon. Each dimension's value shows the frequency or occurrence of that term in the manuscript.

*2) Term Frequency-Inverse Document Frequency (TF-IDF):* The TF-IDF approach is well-known for assigning weights to words in a document based on their frequency in the document and inverse frequency throughout the whole corpus. Each page is represented as a vector of TF-IDF scores, and cosine similarity or other distance metrics can be used to determine similarity [15][16][17].

## V. Machine Learning Approach for Automated SQL Query Grading

Machine learning can be effectively used in automated short answer grading systems to streamline the process of evaluating and providing feedback on student responses 18][19]. This paper deals with an approach for building a machine learning system in python that uses K-Nearest Neighbors (KNN), multinomialNB and logistic regression method for the classification of textual documents for the dataset discussed above individually. The best model can be chosen to find the grade of the student. The primary difficulty in characterizing texts is that they are an assortment of letters and words. We require a numerical representation of those words to input them into our models, which will compute distances and make predictions. Bag of words and tf-idf are two methods for numerical representation [20] [21]. The experimental phase of the investigation was carried out using textual documents taken from the dataset's model answer and student answer. Prepare a labeled dataset of short answers, where each answer is associated with a grade or score. You'll need a set of answers that are already graded by humans.

*1)* Preprocess the short answers by removing punctuation, converting all letters to lowercase, and applying any other necessary preprocessing steps like stemming or lemmatization. This step helps standardize the text data.

*2)* Convert the preprocessed short answers into numerical features that model can work with. One common approach is to use the term frequency-inverse document frequency (TF-IDF) representation. This representation assigns weights to each word based on its frequency in a specific short answer and across the entire dataset. Because we must vectorize both the model answer and the student answer separately. After vectorizing the model answer and student query we concatenate the two vectors to create the train and test vectors as follows.

*3) Train-Test Split:* Split your dataset into a training set and a test set. The training set will be used to train the classifier, while the test set will be used to evaluate its performance.

We have used various machine learning models to automate the grading process with following result.

### D. KNN Classification for Automated SQL Query Grading

The projected class label in KNN classification is decided by voting for the nearest neighbors, that is, the majority class label in the set of the selected k examples is returned. [23][24][25]. The quality of the predictions depends on the distance measure. We use cosine as distance measurement technique. Therefore, the KNN algorithm is suitable for applications for which sufficient domain knowledge is available. We have used the K Nearest-Neighbors Classifier method of sklearn. Neighbors class. Fit the k-nearest neighbors' classifier from the training dataset. After that we can use the predict () to predict the class for the test data. And the accuracy of the model is 70%, followed by the classification report in Fig. 4 and confusion matrix in Fig. 5.

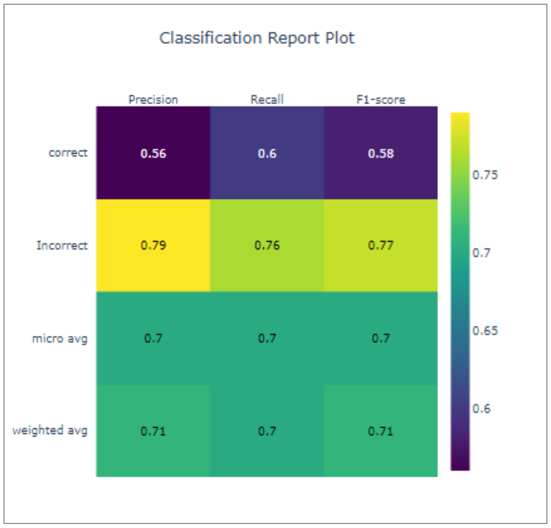

Fig. 4. Classification report of class prediction using KNN algorithm.

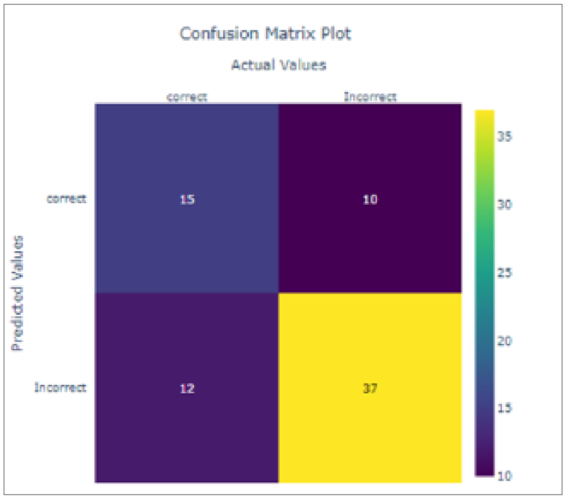

Fig. 5. Confusion matrix of class prediction using KNN algorithm.

### E. B. *Multinomial Naïve Baye's Classification for Automated SQL Query Grading*

Multinomial Naive Bayes classifier is a specific instance of a Naive Bayes classifier that employs a multinomial distribution for each of the features. Multinomial Naive Bayes assumes multinomial distribution for all pairings, which is a reasonable assumption in certain circumstances, such as for word counts in documents [22]. Multinomial Naive Bayes (MNB) can be used for automated short answer grading tasks. MNB is a popular algorithm for text classification tasks, including student's SQL query grading, because it can handle multiple classes and works well with discrete features like word counts. Here's how you can use MNB for automated short answer grading:

*1) Model training:* Train the MNB classifier using the training set and the corresponding grades. MNB calculates the probability of a short answer belonging to a particular grade based on the occurrence of words in the answer.

*2) Model evaluation:* Evaluate the performance of the trained MNB classifier using the test set. You can use metrics like accuracy, precision, recall, or F1 score to assess how well the classifier is grading the short answers.

*3) Grading new answers:* Once the MNB classifier is trained and evaluated, you can use it to automatically grade new sort answers from the test data. We observe Multinomialnb with 84% accuracy and followed by the classification report in Fig. 6 and confusion matrix in Fig. 7.

It's important to note that MNB is a simple and fast algorithm, but it has certain assumptions, such as the independence of features. While MNB can work reasonably well for short answer grading tasks, more advanced machine learning algorithms or natural language processing techniques might be required for more complex grading scenarios.

### F. *Logistic Regression in Automated SQL Query Grading*

Logistic regression is a classification algorithm commonly used in machine learning to predict binary outcomes. While it may not be directly applicable to automated SQL query grading, logistic regression can be used as part of a broader approach to assess the quality or correctness of SQL queries [18]. We train a logistic regression model using the labeled training dataset and the extracted features. Python provides various machine learning libraries such as scikit-learn or TensorFlow that offer easy-to-use implementations of logistic regression. Evaluate the trained logistic regression model using the test set. Assess the model's performance metrics such as accuracy, precision, recall, or F1-score to determine how well it predicts the correctness of SQL queries. Once the logistic regression model is trained and evaluated, you can use it to grade new, unseen SQL queries.

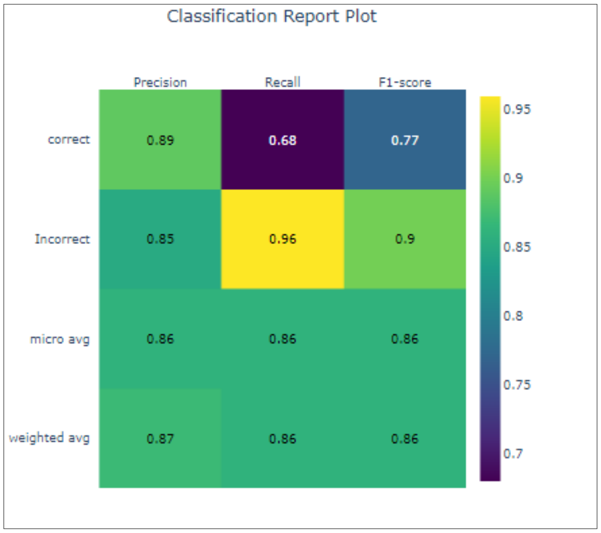

Fig. 6. Classification report of class prediction using multinomial Naïve Baye's algorithm.

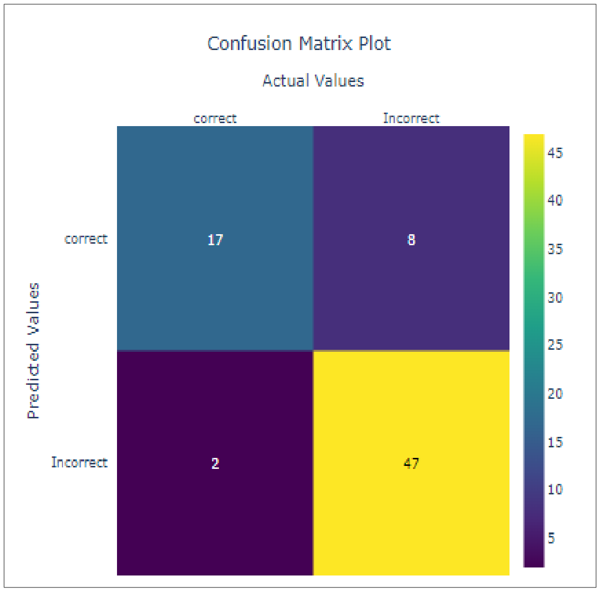

Fig. 7. Confusion Matrix of class prediction using multinomial Naïve Baye's algorithm.

Extract the features from the new queries and pass them through the trained model to obtain the predicted probabilities or classes (correct or incorrect) for each query. It's worth noting that logistic regression alone may not be sufficient for comprehensive SQL query grading. You may need to incorporate other techniques, such as natural language processing (NLP) or more complex machine learning algorithms, depending on the specific grading criteria and requirements of your system and the plot classification is as presented on the Fig. 8 and Fig. 9.

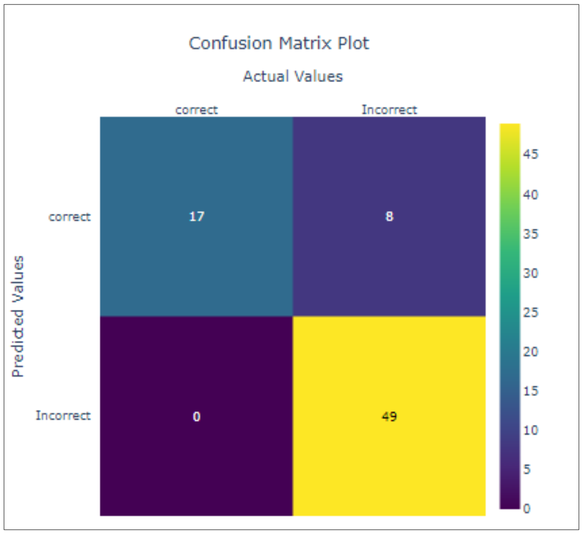

Fig. 8. Confusion matrix for the class prediction using logistic regression.

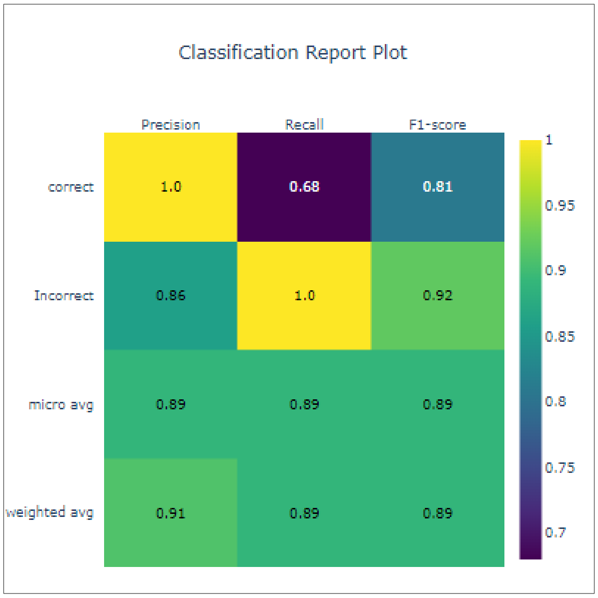

Fig. 9. Classification report for the class prediction using logistic regression.

Out of the three machine learning algorithms, the Logistic Algorithm shows better results compared to the other two machine learning algorithms in finding the grade of the student. So, in the next step this grade can be used for student outcome assessment using predefined rubrics by the author.

## VI. Student Outcome Assessment Using Rubric

Rubrics are scoring guides that outline specific components and expectations for an assignment. Instructors were required to utilize outcome-based assessment methods and methodologies to evaluate students' learning against predetermined outcomes [26]. In this paper, rubrics approach is used for assessment of SQL query assignments submitted by the students in the university. A rubric is a tool that empowers students to guide their own learning process. It is an effective technique for being learner-centered [27]. Rubrics for assessment can improve consistency, save time in grading, provide timely feedback, promote student learning, clarify expectations, and refine teaching methods. Rubrics assist students in understanding assignment objectives, gaining awareness of their learning progress, and receiving timely and detailed feedback to enhance work. Rubrics measure students' achievement of learning outcomes, not their performance in comparison to peers [28].

This research's second goal is to create a scoring system for SQL query assignments. and provide feedback to the student using clustering techniques of unsupervised machine learning algorithms. Along with ASQG (Automated SQL Answer Grading), discussed in part 1 of this paper, instructor can design the rubrics for assessment of student assignments and student outcome analysis. ASQG mostly focuses on the assessment of SQL query by classification of student submission as correct or not correct after comparing with the model answer. But the SQL (Structured query language) query can be assessed by several other parameters using rubrics. The instructor assistant rubrics can be created for assessment of various other criteria mentioned below for student learning outcome assessment and scoring strategy and performance descriptor. The criteria that have been chosen are grounded in Bloom's Taxonomy of Learning Domains. The student learning outcome can be assessed in to six levels such as, remember, understand, apply, analyze, and evaluate [29] [30].

*1)* Theory and conceptual knowledge on database and SQL like database design, unique and referential integrity constraints, concept of normalization, functional dependency, ER diagram etc.

*2)* The strong knowledge in SQL (Structured query language) can be measured by student's query syntax, use of DDL (Data Definition Language), DML (Data Manipulation Language), various keywords and clauses in correct order to get a correct output.

*3)* Conceptual thinking skill can be a parameter to assess student's learning outcomes.

*4)* Similarly, the logic building ability can be used to assess student's in-depth knowledge in SQL.

*5)* The efficiency of the SQL query can be checked with optimal performance like low query execution time, minimal resource consumption.

*6)* The assignment should be well documented by following instructions, better query readability and proper comment to explain the work.

A rubric for SQL assignment is developed in this paper. The above criteria (1-6) are used to assess the student's skill in SQL which is listed in Table II. Each criterion in this rubric has a four-point grading system in the following manner.

<40% score indicates very poor knowledge in the criterion and needs development.

40-59% score indicates limited knowledge in the criterion and still needs development.

60-79% score indicates adequate knowledge in the criterion and need practice.

80-100% score indicates outstanding knowledge.

TABLE II. RUBRICS FOR STUDENT OUTCOME ASSESSMENT

| ***Category*** | ***Assessment Criteria*** | ***Poor <40%*** | ***Good 40-59%*** | ***Very good 60-79%*** | ***Excellent 80-100%*** | ***Learning level based on Bloom taxonomy*** |
|---|---|---|---|---|---|---|
| ***Theory and concept knowledge on database and SQL*** | ***Design of relation with integrity constraints*** | Basic knowledge of database structure and design without key concept | Concept is not very clear, but tables are partially created | Good understanding of the concept with minor error | Clear and logical concept of relational database, well designed tables with appropriate data types and relationships | Remember |
| | ***Normalization*** | Tables not normalized | Some normalization but with significant issues Table | mostly normalized with minor issues | Properly normalized tables without errors | understand |
| ***SQL query knowledge*** | ***syntax*** | Queries do not execute with major syntax errors | Queries do not execute with noticeable syntax errors | Queries do not execute with minor syntax errors | Queries are well-structured with correct syntax | Remember |
| ***Conceptual thinking and skills*** | ***Data retrieval from the table*** | incomplete data retrievals | partially correct with minor logical issue | Logic is clear but output not as expected | Accurate logic and complete data retrieval as expected | remember |
| | ***Filtering and sorting*** | Unable to apply, incorrect output | partially applied with errors | Mostly applied correctly | Accurately applied | remember |
| ***Critical thinking and logic building*** | ***Joins*** | Incorrect concept of join | Missing join conditions with ambiguous result | Joins applied but incorrect output | correctly applied with accurate output | Understanding and apply |
| | ***Aggregate functions*** | Incorrect use of aggregate functions | Missing join conditions with ambiguous result | Joins applied but incorrect output | correctly applied with accurate output | analyze |
| | ***subquery*** | Incorrect use of | Partially correct | Mostly syntax correct but logical error | Correct output | analyze |
| ***Efficiency*** | ***Query Performance*** | Queries execute very slowly or not at all | Queries execute with noticeable delay | Queries execute with minor delay | Queries execute efficiently without delay | Evaluate |
| | ***Indexing*** | No indexing implemented | Indexing partially implemented with minimal impact | Appropriate indexing implemented | Optimal indexing implemented for performance | Evaluate |
| ***Documentation*** | ***Readability*** | Query and database structure are unreadable | Query and database structure are somewhat readable | Query and database structure are mostly readable | Query and database structure are highly readable | Create |
| | ***Instructions*** | Instructions not followed | Partially followed instructions with notable deviations | Mostly followed instructions with minor deviations | Instructions fully followed | create |

TABLE IV. GRADES OF SAMPLES OF 10 STUDENTS IN RANDOM AS PER THE RUBRICS AND ASQG

| Sl. No. | Theory &concept | SQL syntax | Query skill | Logical skill | Efficiency | Doc | Mean |
|---|---|---|---|---|---|---|---|
| 1 | 70 | 90 | 100 | 80 | 50 | 100 | 82 |
| 2 | 80 | 90 | 100 | 80 | 60 | 100 | 85 |
| 3 | 80 | 60 | 60 | 50 | 40 | 60 | 58 |
| 4 | 60 | 70 | 70 | 60 | 50 | 80 | 65 |
| 5 | 40 | 50 | 60 | 50 | 40 | 60 | 50 |
| 6 | 90 | 100 | 10 | 90 | 50 | 100 | 90 |
| 7 | 70 | 90 | 100 | 80 | 50 | 100 | 82 |
| 8 | 30 | 90 | 100 | 80 | 50 | 100 | 37 |
| 9 | 60 | 70 | 70 | 60 | 50 | 80 | 65 |
| 10 | 70 | 80 | 90 | 80 | 60 | 100 | 80 |

Each criterion's questions were selected to evaluate the related skills. The assessment had sixty questions pertaining to the standards, 10 from each criterion. The ASQG (Automated SQL Query Grader) each answer query with 1 point for the correct answer and 0 point for the incorrect answer. For instance, if one student answered 8 correct questions from the 10 questions of a criterion, means that with 80% correct. Hence will be graded as excellent. Similarly, if one student answered three correct questions from the 10 questions of a criterion, with 30% correct attempt and gets an unsatisfactory grade. According to the preceding criteria, this partial grading method extracts the learners' competency level in each category. The correctness score of 10 students in random is presented in Table III. For example, the 1st student has answered seven questions correctly so get 70% score in 1st criteria and excellent score in SQL syntax and querying skill, the logic building, and analytical skill is also excellent, but the queries are average optimized and but 100 marks for query readability. So, on average he got 82% grade in the SQL assignment. Similarly, the table represents the final score of 10 students' data of total 150 students and 60 questions, 10 questions from each criterion used in Rubric. In the next part of the paper, we will provide feedback to the student along with score obtained in the assignment.

## VII. FEEDBACK GENERATION FROM THE RUBRICS

Rubrics assist instructors provide constructive input to students by highlighting strengths and faults and identifying spaces for improvement. Breaking down the assignment into distinct criteria and offering prompt feedback on students' strengths and weaknesses in each category provides precise information. Feedback to students on how successfully or poorly they completed an assignment. Rubrics can save time on grading assignments and provide timely feedback to students about their performance. Rubrics can be used by instructors to emphasize the various levels of expectations they have for students by establishing specific evaluation criteria for task completion. Evaluation criteria are the characteristics instructors assess when judging the quality of a student-completed job. Every component of the evaluation criteria is discussed in detail so that students understand what precise abilities, knowledge, or strategies they must possess to get a given score or grade. Rubrics can also help instructors clarify the implicit expectations for a specific task. Rubrics can reduce grading time by allowing professors to award specific scores instead of lengthy comments for each work. Thus, rubrics can be utilized to evaluate students' work in a more efficient and transparent manner. Rubrics can help teachers justify a student's score or grade to other participants, including parents and university authorities.

Although the feedback provided by the rubric is sufficient for individual student input, we have used a novel method in this research to separate the students based on their learning competencies. This allows the instructor to divide the students into groups based on the rubric score. Here in this paper, we use the k-mean Clustering technique, an unsupervised learning process, can be used to separate students into clusters in order to study class patterns and assess querying ability. Clustering can assist in identifying clusters in which students in one cluster have nearly the same levels of knowledge and thus can receive similar feedback and improvement advice. Students in the cluster with limited knowledge can receive further assistance to enhance their skills. Students in the cluster where all students have excellent SQL knowledge should be encouraged to focus on advanced topics and application design in real-world use cases.

## VIII. CONCLUSION

In this research, Students typically submit their SQL queries assignment on an online platform. Students write queries and execute them against a predefined database schema. The ASQG compares the results obtained from executing the student's query against the expected results for matching the similarity. The expected results are typically predefined by the instructor or generated based on a reference implementation. Grading criteria are established to evaluate the correctness and quality of the queries. The comparison of instructor and student queries in ASQG may be facilitated by semantic textual similarity and paraphrasing communities. This may include criteria such as accuracy, whether the model query is like the student query. Based on the grading criteria, the automated system assigns scores to each query submission. Scores can be calculated using predefined rubrics or algorithms which are discussed in Section VI of the paper. Additionally, in section VII the system can generate feedback for students, highlighting specific areas of improvement, errors, or suggestions to enhance their queries. The automated grading system can provide detailed error reports to help students identify and rectify the mistakes in their queries with scores to individual students and different action can be taken according to the level of the student. These reports may include syntax errors, semantic errors or logical errors, database skill, concept and logic building skill, optimization skill the query readability through the documentation skill encountered during query execution.

College of Computing and Digital Technology, Birmingham City University, Birmingham, United Kingdom[7]

***Abstract*—Microarray technology appeared recently and is used in genetic research to study gene expressions. Microarray has been widely applied to many fields, especially the health sector, such as diagnosing and predicting diseases, specifically cancer diseases. These experiments usually generate a huge amount of gene expression data with analytical and computational complexities. Therefore, feature selection techniques and different classifications help solve these problems by eliminating irrelevant and redundant features. This paper presents a proposed method for classifying the data using eight classifications machine learning algorithms. Then, the Genetic Algorithm (GA) is applied to improve the selection of the best features and parameters for the model. We use the higher accuracy of the model among the different classifications as a measure of fit in the genetic algorithm; this means that the model's accuracy can be used to select the best solutions than others in the community. The proposed method was applied to the colon, breast, prostate, and Central Nervous System (CNS) diseases and experimental outcomes demonstrated an accuracy rate of 93.75, 96.15, 82.76, and 93.33 respectively. Based on these findings, the proposed method works well and effectively.**

***Keywords—Cancer classification; gene expression; feature selection; microarray data; algorithm; machine learning; genetic algorithm***

## I. Introduction

In particular, the study of gene expression data has significant implications for diagnosing and treating different diseases, including cancer. This is because an organism's traits and characteristics are defined by its genes, which are the basic building blocks of heredity. About 20,000–25,000 genes in humans are responsible for different aspects of growth and development. The instructions to create a specific protein are encoded in a Deoxyribonucleic acid (DNA) sequence known as a gene. Mutations in the gene sequence can cause protein structure or function changes, leading to genetic diseases and disorders.

Recent developments in gene expression analysis have made it possible for researchers to study the levels of gene activity in specific cells or tissues, shedding light on the diseases' underlying causes. The classification of gene expression data is essential in bioinformatics research since it may be used in several applications. Some of these applications are to find possible biomarkers for disease diagnosis and treatment. Several techniques, like Chi Square and Support Vector Machine (SVM) with Recursive Feature Elimination (RFE), have been put forth to classify gene expression data and show promise to perform so accurately. Both methods have been previously used for gene expression data classification, with varying degrees of success. For instance, [1] used the ChiSquare method and SVM for gene expression classification and reported an accuracy of 89.57%. Similarly, [2], used SVM-RFE and other machine learning algorithms for gene expression data classification and reported an accuracy of 92.5%.

A recent study [3], proposed a feature selection method called (ChiSVMRFE). That combines the Chi-squared test and SVMs to identify a subset of features most informative for classification.

Several studies have previously compared different feature selection and classification methods for gene expression data, including [4] – [7].

Motivated to advance biological knowledge discovery from gene expression profiles, we aim to comprehensively evaluate feature selection and classification combinations applied to multiple cancer datasets. Specifically, we seek to:

- Evaluate technique performance using microarray data on prostate, colon, CNS, and breast cancer in a systematic way. Precision in disease diagnosis and treatment may be greatly impacted by this finding.
- Find the best performing integrated feature selection-classification techniques. addressing problems such as small sample sizes and class imbalance, addressing problems such as small sample sizes and class imbalance that genetic algorithms can help address.
- Gain new knowledge to direct the search for biomarkers by conducting comprehensive analyses.

Random Forest, Logistic Regression, KNN, SVM and Decision Tree are applied as classifiers. A GA conducts feature selection to optimize informative genes. Integrating selection with diverse classifiers addresses gene expression challenges while capturing different patterns.

A GA conducts feature selection to optimize informative genes while addressing challenges in microarray data analysis.

*Corresponding Author.

The Deanship of Scientific Research, Qassim University

Integrating selection with diverse classifiers aims to comprehensively analyze datasets through leveraging their individual strengths.

Substantial effort compiled the breast, colon, CNS and prostate datasets from thousands of genes, warranting comprehensive evaluation. Therefore, the contribution of this paper includes the following:

- Developing a framework to a hybrid genetic algorithm-classifier.
- Enhancing the results by extensive dataset analysis.
- Achieving greater accuracy compared to earlier efforts.

This is how the rest of the paper is structured. Section II briefly presents the literature review related to Gene Expression, High-dimensional Problems, Feature Selection Methods, and Classification. Section III presents the methodology, the datasets used in this paper, and the preprocessing techniques employed on the data. In contrast, Section IV explains the experiments, whereas Section V highlights the results and discussion. Finally, Section VI includes the conclusions and future works.

## II. Literature Review

### A. Gene Expression

Cancer research is one of the major areas of research in the medical field. Cancer is a group of related diseases with a high mortality rate characterized by abnormal cell growth, which attacks the body tissues [3], [8] – [10]. Microarray cancer data is a prominent research topic across many disciplines focused on addressing problems related to the higher curse of dimensionality, a small number of samples, noisy data, and imbalance class [11]– [17]. The Microarray technology allowed the researchers to analyze thousands of gene expression profiles relevant to different fields, including medicine, especially cancer [13] – [15], [18]. With the rapid improvement of DNA microarray tools and technology, researchers can simultaneously measure hundreds of genes expression levels [3].

Gene expression profiling uses microarray techniques to discover gene patterns when expressed. However, because microarrays produce a large volume of data, the analysis procedure requires a lot of computation power and time [14].

### B. High-Dimensionality Problem

Gene expression datasets with high dimensionality consist of a large number of genes and a small number of samples. In classification problems based on the microarray, the data usually contains many irrelevant and redundant features [19]. Various approaches have been used to solve high-dimensional problems and predict the most required features within limited datasets. Usually, the used technique of high-dimensionality is called least absolute shrinkage and selection operator (LASSO), which is one of the main concepts in dealing with high-dimensional cancer classification [11], to choose the best subset of features for microarray data. A gene selection approach [19], eliminates duplicated and unnecessary characteristics to pick the optimal subset of features for microarray data.  In study [20], a novel hybrid instance learning-based filter wrapper approach addresses a high-dimensionality issue in which a small sample size is transformed into a tool that enables selecting a small number of feature subsets which has proven effective. A proposed model [11], called the Adapted Penalized Logistic Regression (CBPLR) model, uses the total number of selected genes, the Area Under the Curve (AUC), and the misclassification rate (i.e., error rate). It is evaluated on three popular high-dimensional cancer classification datasets, which shows how effective the model is for classifying cancer.

In addition, [16], an approach called Shapely Value Embedded (SVEGA) is proposed, which increases the accuracy of breast cancer detection by selecting the gene subset from the high-dimensional gene data. Four classifiers distinguish between normal and abnormal tissues to identify benign and malignant tumors. As a result, classification accuracy shows that the proposed approach leads to a better breast cancer diagnosis and greater performance.

### C. Feature Selection Methods

To diagnose cancer in human bodies, the feature selection method is a search problem among various genes for an optimal solution that detects the most gene expressed [8]. The gene selection strategy eliminates duplicated and unnecessary characteristics to pick the optimal subset of features for microarray data [19], [15]. In most cases, there are a lot of genes but not many samples in gene expression data. for this reason, traditional gene selection based on mutual information using machine learning models has data sparseness problems [10].

Machine learning algorithms have called the attention of researchers due to their ability for pattern recognition in data [8] [10]. Likewise, [22], provides two selection approaches for SVMRFE-based discriminative feature subsets for measuring the feature subset. Techniques such as SVM-RFE address this by combining classification accuracy and sample overlapping measures to accurately assess feature subsets. Furthermore, an experimental study has employed the Markov Blanket-Embedded Genetic Algorithm (MBEGA) [21]. It is successful and it provides the best balance among all four assessment criteria: accuracy, number of genes, computational cost, and robustness.

Additionally, surveys like the one mentioned [18] provide valuable insights into the taxonomy of feature selection methods, highlighting challenges such as high dimensionality and unbalanced classes.

As a result, new techniques keep emerging yearly, not limited to improving previous approaches' classification accuracy results.

### D. Classification

In cancer classification, various approaches for measuring gene expression, such as Fisher's linear discriminant analysis, nearest neighbor analysis, and max-margin classifiers. Despite advancements, challenges like computation time, classification accuracy, and biological relevance persist [23]. In current microarray technology, feature reduction is critical and sensitive in the classification task to achieve satisfactory classification accuracy [18], [24]. One of the main barriers to technology adoption is the analysis and management of such data [13]– [15], [18], [25].

One of the solutions is the SVM a popular and efficient classification technique widely applied in many fields, especially biological [3], [9], [10], [21], [25]. This can be combined with RFE to be SVM-RFE, which is used for an efficient feature selection technique that is based on SVM and increases Classification effectiveness [3], [17], [22]. In [12], the SVM approach has been used with the Leave-One Out Cross-Validation (LOOCV) approach (i.e., reserving the trained data point while it trains the rest of the dataset) to classify genes effectively. In study [8], classification strategy makes use of memetic algorithms, which speed up the entire evolutionary searching process by introducing a Local Search (LS) operation. Specifically, that is algorithm starts from a candidate solution. Next, makes minor perturbations while moving to a neighboring solution then, the process is repeated until a solution deemed optimal is found.

A hybrid cancer classification approach involving several machines learning tools, including Pearson's correlation coefficient, decision tree classifier, and cross-validation (CV) to optimize the maximum depth hyperparameter. The result shows that the model improves classification accuracy [11]. In [26], a three-phase hybrid approach has been used to select and classify high dimensional microarray data. It combines several classifiers via Pearson Correlation Coefficient (PCC), Binary Particle Swarm Optimization (BPSO), or GA which shows improved classification accuracy.

In research [13], a combination of supervised and unsupervised data analysis including the categorization of cancer and the prediction of gene function classes. It goes through how potential regulatory signals in the genomic sequences may be predicted using the gene expression matrix, and then it explores several potential directions for the future. As a result, it shows that analysis methods of gene expression data will advance and become more organized.

## III. METHODOLOGY

### A. Datasets

In this study, we leverage four high-dimensional microarray datasets, each corresponding to a distinct type of cancer: Breast cancer, Colon cancer, Central Nervous System (CNS) cancer, and Prostate Cancer. These datasets are pivotal for understanding the complex gene expression profiles associated with each cancer type and for identifying potential biomarkers for diagnosis and treatment strategies [3].

As shown in Table I, the key characteristics of each microarray dataset are:

*1) Breast cancer dataset:* Comprises a comprehensive set of 16,382 features covering 36,626 genes, classified into two categories. This dataset is instrumental in studying the genetic variations specific to breast cancer, aiding in the identification of unique gene expression patterns.

*2) Colon cancer dataset:* Contains 2,000 features for 2,000 genes, all categorized into two groups. This dataset allows for the exploration of genetic factors that contribute to colon cancer, facilitating the development of targeted therapies.

*3) Prostate cancer dataset:* Includes 12,646 features for 12,646 genes, with the data divided into two classes. This dataset provides insights into the genetic underpinnings of prostate cancer, offering opportunities for discovering novel genetic markers.

*4) CNS cancer dataset:* Features 7,129 features for 7,129 genes, organized into two classes. This dataset is crucial for unraveling the genetic complexity of CNS cancers, potentially leading to breakthroughs in understanding the disease's molecular basis.

Preprocessing steps are customized for each dataset to accommodate varying data types, including normalization for continuous features, and encoding for categorical variables, ensuring data uniformity and integrity for the feature selection process.

TABLE I. MICROARRAY DATASETS DESCRIPTION

| Datasets | Feature | Genes | Classes |
|---|---|---|---|
| **Breast** | 16382 | 36626 | 2 |
| **Colon** | 2000 | 2000 | 2 |
| **Prostate** | 12646 | 12646 | 2 |
| **CNS** | 7129 | 7129 | 2 |

### B. Feature Selection Methods

Feature selection is a helpful preprocessing method to decrease the data dimensions and enhance classification accuracy [23]. Selecting groups of useful genes with high prediction potential from current samples is one of the numerous issues in bioinformatics. The abnormally high dimension of the search space presents the biggest challenge in analyzing gene expression data. The most common way to display gene expression data is in a matrix with many genes and a few samples. Its objective is to eliminate properties that don't help with the classification issue or are redundant because they offer the same data. Finding pertinent genes for subpopulation samples is the first step in the feature selection process for cancer data in microarray data. In a binary category data collection, the sample is typically categorized as having either cancer or not having cancer [8].

### C. Genetic Algorithm

A GA is an evolutionary algorithm that is a metaheuristic-inspired natural selection process. It starts by producing a random beginning population. In this technique, GA operators, which include selection, interception, and mutation, are used to search for the best solutions by individuals [26]. The survival of the fittest member of a population that changes over time is the central tenet of the genetic algorithm. The population is first evaluated and initialized. A fitness function that assesses the effectiveness of the problem-solving solution evaluates each individual. Through generations, the GA iterates to create changes in the population. Three evolutionary operators are applied to the population once every generation.

The first operator is the selection operator, which picks a group of people to keep in the following generation or, more appropriately, to be merged with again by the other operators. Natural selection directly influences the operator of this fitter, for people are more likely to be chosen. Crossover is the second operator used on the population, which involves taking advantage of the shared space between two people the selection operator has chosen. It combines the two people, the parents, to create the two new people, the children. The final operator, mutation, randomly alters a person’s genes to broaden the population’s genetic diversity. The mutation rate is typically chosen at a modest value since many mutations could cause the GA to devolve into a simple random search. The population evolves until the stop condition is reached. At this point, the best estimate for a particular problem is returned [8].

### D. *Classifiers*

In this study, we use several classifiers to classify the data, including Random Forest, Logistic, KNeighbors, Gradient Boosting, LinearSVM, RadialSVM, AdaBoost, and DecisionTree.

### E. *Optimization of Classifier Parameters*

In parallel to feature selection, our GA approach extends to optimizing classifier hyper parameters. By encoding hyper parameters as part of the chromosomes, we ensure that each feature subset is evaluated using the best possible classifier configuration, thereby maximizing classification performance.

## IV. EXPERIMENTS

The method used in this study is based on a GA to identify features in a cancer dataset. This method improves the statistical performance of machine learning models by removing unnecessary features from the dataset. It includes feature encoding, population generation, intersection, and final feature selection. A GA provides an efficient way to select the best features in a data set, as it is used to generate a set of potential solutions and then select the solutions that perform best based on the given performance metric.

### A. *Implementation of GA for Feature Selection*

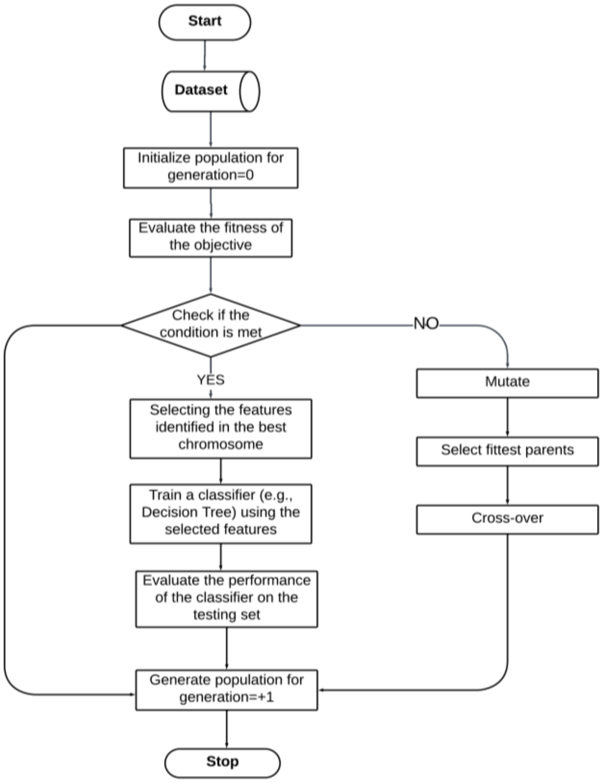
As shown in Fig. 1, the GA starts with a random set of chromosomes. Each chromosome represents a potential solution to the feature selection problem. The fitness function is then applied to the chromosomes. The chromosomes with the highest fitness scores are then selected for reproduction. The chromosomes of the offspring are then created using crossover and mutation factors. The offspring’s chromosomes are then evaluated and repeated until the stopping criterion is met. The discontinuation criterion can be based on the number of generations, chromosomal fitness, or a combination. The GA is a powerful tool for feature selection. It can be used to find optimal solutions to the feature selection problem in various fields.

### B. *Function Description for Genetic Algorithm*

*1)* Functions for splitting the dataset:

*a) Split ():* This function splits the dataset into training and testing sets. It takes the dataset and the ratio of the training set as inputs and returns the training set and the testing set.

*2)* Functions for evaluating the classifiers:



Start
Dataset
Initialize population for generation=0
Evaluate the fitness of the objective
Check if the condition is met
NO
YES
Selecting the features identified in the best chromosome
Train a classifier (e.g., Decision Tree) using the selected features
Evaluate the performance of the classifier on the testing set
Mutate
Select fittest parents
Cross-over
Generate population for generation=+1
Stop

Fig. 1. Flowchart of GA application steps to choose the best features.

*a) Acc-score ():* This function is used to evaluate the performance of multiple classifiers on the dataset. It takes the training set, testing set, and a list of classifiers as input and returns the accuracy score of each classifier on the testing set.

*3)* Functions for plotting:

*a) Plot ():* This function is used to plot the results of the genetic algorithm. It takes the number of generations and the best fitness score of each generation as input and plots a line graph.

*4)* Functions for the genetic algorithm:

*a) Initialization-of-population ():* This function generates an initial population of chromosomes for the genetic algorithm. It takes the number of features and the population size as input and returns a randomly generated population of chromosomes.

*b) Fitness-score ():* This function calculates the fitness scores of the chromosomes. It takes the population, training, and testing set as input and returns the best parents and their fitness scores.

*c) Selection ():* This function selects the best parents for the next generation. It inputs the training and res and returns the best parents.

*d) Crossover ():* This function performs crossover between the best parents to generate offspring. It takes the best parents as input and returns offspring chromosomes.

*e) Mutation ():* This function introduces new genetic variation in the offspring chromosomes. It takes the offspring chromosomes, and the mutation rate as input and returns mutated offspring chromosomes.

*5) Generations ():* This function executes all the above functions for the specified number of generations. It takes the population, the training set, the testing set, the number of generations, the number of features, and the mutation rate as input and returns the best chromosome (the set of selected features) and its fitness score.

### *C. Implementation Steps*

*1)* Reading dataset from a CSV file.

*2)* Splitting the data into sets for testing and training: The dataset is split into training and testing sets. The training set is used to train the classification model, while the testing set is used to evaluate its performance.

*3)* Encoding the classes in the training set into numerical values: The target class of each sample in the training set is encoded into a numerical value.

*4)* Creating the fitness function: The fitness function represents the performance of a selected feature set (chromosome) in a classification task using various classifiers, such as decision trees, K-nearest Neighbors (KNN), and other techniques, using the selected features. For example, the fitness function can be defined as the accuracy of a decision tree classifier using the selected features.

*5)* Creating the objective function: The objective function determines the direction of the search for the optimal solution. The objective function is to maximize fitness function.

*6)* Specifying the initial size of the chromosome population: The initial population size of the chromosomes (sets of selected features) is specified.

*7)* Generating a random set of chromosomes: A random set of chromosomes is generated to start the genetic algorithm.

*8)* Computing fitness scores for each chromosome: The fitness function is applied to each chromosome in the population, and the fitness score is computed.

*9)* Selecting the best chromosomes and using them to produce new generations: The best chromosomes in the population are selected to produce new generations of chromosomes. In this example, the selection process is based on the fitness scores of the chromosomes.

*10)* Creating new generations using crossover and mutation factors: The new generations of chromosomes are created by applying crossover and mutation operators. Crossover involves exchanging the selected features between two chromosomes, while mutation involves randomly changing a selected feature in a chromosome.

*11)* Computing fitness scores for the new chromosomes: The fitness function is applied to the new chromosomes, and the fitness score is computed.

*12)* Selecting the best chromosomes in the new generations: The best chromosomes in the new generations are selected. In this example, the best chromosomes have the highest fitness scores.

*13)* Until the stopping requirement is satisfied, repeat steps 10–12: Steps 10-12 are repeated until a stopping criterion is met. In this example, the stopping criterion is a fixed number of iterations.

*14)* Selecting the features in the best chromosome: The features selected in the best chromosome are identified as the optimal set of features for the classification task.

*15)* Training a classification model using the selected features: A classification model (e.g., KNN classifier) is trained using the optimal set of features.

*16)* Evaluating the model’s performance using the testing set and computing the accuracy and confusion matrix: The performance of the trained classification model is evaluated using the testing set, and the accuracy and confusion matrix is computed.

## V. Experimental Results and Discussion

This section presents and discusses the results of the conducted experiments. The Comparisons between the obtained results and other studies are also presented in this section. The proposed method for selecting features with both discrete and continuous values based on the application of the GA was tested to optimize the accuracy after being classified using several classifications on four databases.

### *A. Experimental Results*

*1) Classifiers with original datasets:* After applying the classifications to the data for the four diseases of the colon, Breast, Prostate, and CNS. We find that the accuracy is variable and different for diseases and the type of classification. The accuracy of classification models depends on a combination of factors, including the nature of the disease, data complexity, dataset size and quality, choice of features, and classification algorithm type are presented in Table II. The experimental results are summarized as follows:

*a)* The performance of several different classification algorithms was compared on a set of original data for four different datasets: Colon, Breast, Prostate, and CNS.

*b)* The Random Forest algorithm showed strong performance, recording the highest accuracy rate in the Colon dataset at 81.25% and in the breast dataset at 76.92%.

*c)* The K-Neighbors algorithm performed exceptionally well in the Colon dataset with an accuracy rate of 87.50%, indicating its effectiveness in handling this dataset.

*d)* Linear SVM demonstrated good performance in the CNS dataset with an accuracy rate of 80%, while achieving acceptable results in the Breast and Prostate datasets with accuracy rates of 76.92% and 68.97%, respectively.

*e)* AdaBoost showed good accuracy in the Breast dataset at 80.77%, but its performance was lower in the Prostate dataset, where it reached 62.07% accuracy.

*f)* The Decision Tree and Gradient Boosting algorithms performed well in the Colon dataset with an accuracy rate of

84.62% but did not achieve the same level of success in the other datasets.

*g)* Radial SVM had the lowest performance in most datasets, with low accuracy rates, especially in the breast dataset, where accuracy was 46.15%.

TABLE II. THE ACCURACY OF APPLYING THE CLASSIFIERS ON THE ORIGINAL

| Classification | Dataset | | | |
|---|---|---|---|---|
| | Colon | Breast | Prostate | CNS |
| Random Forest | 81.25 | 76.92 | **75.86** | 73.33 |
| Logistic | 75 | 76.92 | 68.97 | 73.33 |
| K-Neighbors | **87.50** | 73.08 | 72.41 | 46.67 |
| Linear SVM | 62.50 | 76.92 | 68.97 | **80** |
| Radial SVM | 81.25 | 46.15 | 51.72 | 66.67 |
| AdaBoost | 81.25 | 80.77 | 62.07 | 53.33 |
| Decision Tree | 62.50 | **84.62** | 51.72 | 73.33 |
| Gradient Boosting | 68.75 | **84.62** | 68.97 | 73.33 |

*2) Genetic algorithm:* In this way, after applying the different classifications to the four diseases of the colon, breast, prostate, and CNS. We used the higher accuracy of the model among the different classifications as a measure of fit in the genetic algorithm. This means that the model's accuracy can be used to determine which solutions are better than others in the population. Then, the GA is applied to improve the selection of the best features and parameters of the model from the data set, and its steps are as follows:

*a) Split data:* The split () function used in training and test data in the GA is used to evaluate the model's performance.

*b) Initialization of the population:* This is done by creating a Boolean array of size n-feat, where n-feat is the number of features in the dataset. The array's first int(size*n-feat) elements are set to False, and the remaining elements are set to True. The population is then shuffled randomly.

*c) Fitness Evaluation***:** This is performed by fitting the model with the data using the Boolean array and then calculating the accuracy score using the model. Predict () method.

*d) Selection:* This is performed by selecting the n-parents' best chromosomes from the population used for that population-NextGen. append(pop-after-fit(i)).

*e) Crossover:* This is performed by randomly selecting two parent chromosomes and then performing crossover to generate two new offspring chromosomes.

*f) Mutation:* This is performed by randomly selecting a chromosome from the population and then performing a mutation to generate a new chromosome at a rate of 0.20.

*g) Repeat steps* 3-6 until the desired number of generations is reached (The algorithm stops when the best score in the last generation is the same as the previous generations).

*h) Return* the best score and the corresponding chromosome.

The accuracy score within a generation is determined by the accuracy of the predictions made by the population within that generation. This is calculated using data from the population and labels. Five generations have been produced, and the highest model accuracy is typically equivalent or slightly superior to the accuracy of the preceding generation. Therefore, we use the model's accuracy to compare which values are more valid across generations. Table III and Fig. 2 display the optimal score for four diseases across the first to fifth generations. It is important to note that the numbers 1-5 denote the generation number, with 1 representing the first generation, 2 representing the second generation, and so on. This allows for a clear and concise comparison of model accuracy across multiple generations.

TABLE III. BEST SCORE IN GENERATIONS FOR FOUR DISEASES AFTER APPLYING

| Dataset | Generation | | | | |
|---|---|---|---|---|---|
| NO. of generation | 1 | 2 | 3 | 4 | 5 |
| Colon | 87.5 | **93.75** | **93.75** | **93.75** | **93.75** |
| Breast | 92.31 | **96.15** | **96.15** | 92.31 | 92.31 |
| Prostate | 79.31 | 79.31 | **82**.76 | 79.31 | 79.31 |
| CNS | 80 | 80 | 80 | 86.67 | **93.33** |

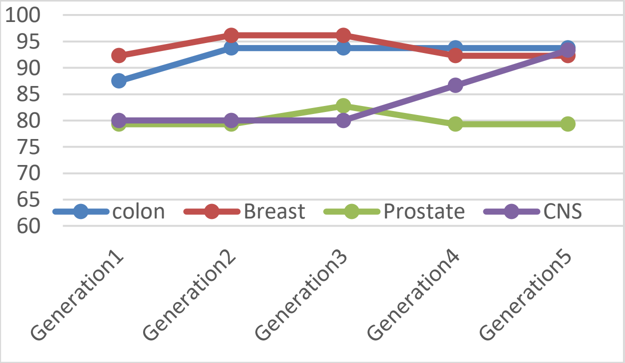


Fig. 2. The best score in the generations for the four diseases.

- The GA showed an improvement in feature selection. It works by simulating the process of natural selection, where solutions with better fitness scores are selected and used to create the next generation of solutions. High accuracy rates were obtained, particularly in the colon, breast, and CNS.

- Decreased accuracy in prostate disease because of Imbalanced data is a common problem in many medical datasets, including prostate cancer data. In addition, insufficient data on the size of the dataset can affect the accuracy.

- The accuracy of the GA is variable because of the randomness of the mutation and selection processes. The mutation process randomly changes the features of the chromosome, and the selection process randomly selects the chromosomes for the next generation. This means that the model’s accuracy can vary from generation to generation.

- The result of a GA can change each time the code is run because the algorithm uses randomness to generate new solutions and evaluate them. Therefore, the criterion for measuring the accuracy of the GA was the higher accuracy of the classifications.

### B. Analysis and Discussion

*1) Comparison of Data Accuracy Before and After GA Utilization:* Table IV illustrates a comparison of data accuracy before and after using the GA for performance enhancement. A noticeable increase in accuracy was observed after employing GA in all datasets. In the Colon dataset, accuracy improved from 87.50% before using GA to 93.75% after its use. For the Breast dataset, accuracy increased from 84.62% to 96.15% because of GA. In the Prostate dataset, performance was enhanced from 75.86% to 82.76% with GA. As for the CNS dataset, a significant accuracy boost was observed, increasing from 80% before GA to 93.33% after its application. Table IV signifies the effectiveness of GA in enhancing the performance of statistical models for classifying specific diseases.

TABLE IV. COMPARISON OF ACCURACY: ORIGINAL METHOD WITH PROPOSED METHOD

| Dataset | Accuracy Using the Original Method | Accuracy Using the Proposed Approach |
|---|---|---|
| Colon | 87.50 | **93.75** |
| Breast | 84.62 | **96.15** |
| Prostate | 75.86 | **82.76** |
| CNS | 80 | **93.33** |

*2) Compared with the Chi-SVM-RFE method:* The proposed method showed improved accuracy for the colon, Breast, and CNS, which achieved high accuracy achieved high accuracy results after applying eight classifications except prostate, the accuracy rate has gone down. Decreased classification accuracy for prostate cancer is due to several factors that can affect the accuracy of classification algorithms on medical data, such as the quality and quantity of the data and the pre-processing and normalization techniques used. Moreover, we assume in this study that the choice of hardware and software used for implementation can also affect the accuracy of classification methods. For example, different devices may have different processing speeds, memory capacities, and computational architectures that can affect the performance of machine learning algorithms (e.g., Random Forest). In addition, the underlying operating systems and software libraries may have different versions and configurations that can affect the run time behavior and accuracy of the models. In Table V, the proposed study was compared with previous studies using the Chi-SVM-RFE method [3] for colon, breast, prostate, and CNS diseases.

TABLE V. COMPARISON OF THE PROPOSED METHOD WITH PREVIOUS STUDIES

| Dataset | Proposed | Chi-SVM-RFE |
|---|---|---|
| Colon | 93.75 | **95.24** |
| Breast | **96.15** | 94 |
| Prostate | 82.76 | **96.09** |
| CNS | **93.33** | 88.33 |

In Table V, we note that the proposed method achieves high accuracy in the results compared with the previous method, except for the colon and prostate, where there is a clear difference. The reason may be attributed to the fact that the Chi-SVMRFE, or RFE with Support Vector Machines and a Chi-squared criterion, is a statistical approach that aims to eliminate the least iteratively informative features from the dataset. Genetic algorithms use a randomized process of mutation and selection to optimize solutions to problems. Both approaches have their pros and cons, and which one to choose depends on various factors, including the specific type of cancer, the size and quality of the dataset, and the specific research question being addressed.

## VI. CONCLUSION

Feature selection has a vital role in preprocessing, especially regarding large data volumes such as cancer microarray data, helps reduce the dimensions of microarrays and improves classification accuracy. The study's contribution was to improve the performance of cancer disease classifications based on the data set collected for cancer diseases. Where a method was applied using eight classifiers, which are Random Forest, Logistic, K-Neighbors, Linear SVM, Radial SVM, AdaBoost, Decision Tree, and gradient boosting based on Datasets of four diseases, it includes including colon, breast, prostate, and CNS. The GA was applied to five generations. The best accuracy for each generation was by measuring its suitability with the highest accuracy of the model among the different classifications. It achieved excellent and high results with breast cancer, reaching an accuracy of 96.15.

On the other hand, the GA showed the lowest accuracy results with the prostate dataset due to insufficient population size. The reason is that the GA is based on the diversity of the population to explore the search space and find the optimal solution. The GA was compared with previous methods ChiSVM-RFE, which showed improvements in breast and CNS datasets. Feature selection is an exciting area of research in multiple fields, such as data mining, pattern recognition, machine learning, statistics, bioinformatics, and genomics.

Therefore, this research contributes to helping to identify the genome to diagnose and understand diseases such as cancer. Early detection may also help predict them but extends to finding the appropriate treatment.

On the other hand, the deficiency in the performance of the proposed method appears only with some types of cancer, such as prostate cancer, because cancer classification is inherently complex due to the heterogeneous nature of the cancer itself. While genetic algorithms may be powerful improvement tools, their effectiveness in classifying cancer depends on various aspects, including problem complexity, quality and characteristics of the data set, and appropriate tuning of algorithm parameters.

Regarding future research, the scope of work can be expanded to apply the GA by improving the quality of the fitness function, the selection criteria, and the population size by generating more generations and a higher mutation rate. In addition, this work can be extended by using the same methodology and mixed feature selection methods.

# Optimization Strategy for Industrial Machinery Product Selection Scheme Based on DMOEA

Shichang Liu*, Xinbin Yang, Haihua Huang
School of Fine Arts and Design, Yichun Early Childhood Teachers College, Yichun, 336000, China

***Abstract*—With the continuous innovation and replacement of industrial machinery products, the traditional optional configuration plans are no longer able to complete product selection work with high quality. To further optimize the product selection process and solve the multi-objective selection problem of industrial machinery products, a multi-objective problem model for product selection is normalized and constructed based on the existing difficulties in industrial machinery product selection. A new product selection model is proposed by introducing a multi-objective evolutionary algorithm based on density calculation for model solving. The experimental results showed that the new model had the highest selection success rate of 97% and selection accuracy close to 95% when the iterations were 250. In addition, the maximum absolute error sum of the selected bearing and bearing seat diameters under this model was 0.002. The maximum relative error was 0.01%. The highest reliability of algorithm fitting was 99.9%. Simulation tests found that the average selection success rate was 93%. The average selection quality loss was 26%. In summary, the new selection model proposed in the study has certain advantages and feasibility. It can provide effective decision-making solutions for the design and selection of industrial machinery products.**

***Keywords*—*Industrial machinery products; optional configuration plan; multi objective evolutionary algorithm; density calculation; selection success rate***

## I. Introduction

### A. Background

As an important part of engineering design, industrial machinery product selection involves multiple objective problems [1]. Its complexity and diversity make the traditional optimization methods often can only give the optimal solution under a particular objective, and it is difficult to comprehensively consider the balance between multiple objectives [2].

### B. Status of Research

To address this problem, scholars at home and abroad have proposed various method models using evolutionary algorithms and multi-objective optimization algorithms to achieve comprehensive optimization of industrial machinery product selection and matching. These methods find the most optimal selection and matching scheme that satisfies multiple objectives by comprehensively considering various objectives and constraints.

### C. Problems with the Study

Although capable of effectively handling multi-objective optimization problems, evolutionary and optimization-only algorithms still have a number of challenges, including, but not limited to, the speed of convergence of the algorithms, the diversity of solutions, and the interpretability of the algorithms [3].

### D. Research Purpose

In view of this, the main problem that the research aims to address is how to deal with multi-objective optimization problems efficiently, especially when facing complex scenarios where multiple conflicting objectives need to be optimized at the same time, to find a method that is both efficient and guarantees the diversity of solutions.

### E. Research Methodology

Multi-Objective Optimization Algorithm (MOEA) is an effective way to solve the problem of industrial machinery product selection, among which Density-based Multi-objective Evolutionary Algorithm (DMOEA) shows better performance and stability than other algorithms when dealing with multi-objective optimization problems, especially when facing complex problems, it can effectively balance the trade-offs among objectives [4]. Algorithm (DMOEA) shows better performance and stability than other algorithms in dealing with multi-objective optimization problems, especially in the face of complex problems, it can effectively balance the trade-offs among the objectives. In view of this, the study is to improve the optimization on the basis of DMOEA and then solve the multi-objective problem model of product selection, so as to obtain the best selection plan.

### F. Innovative Nature of the Research

The innovation of the research is that a DMOEA algorithm is proposed and the density function and reproduction process of the algorithm are pruned and optimized. For the complex multi-objective product selection problem, it can significantly improve the quality of the strategy and the solution efficiency.

### G. Contribution of the Study

The contribution of the study is to propose a new complex multi-objective product selection optimization model and verify its superiority and feasibility, which has significant improvement compared with the existing methods and provides new ideas for the technical development in this field.

## II. Related Works

With the continuous development of industrialization, industrial machinery plays an important role in the production process. The selection plan for industrial machinery products is the key to ensuring efficient and safe operation of the production process. Therefore, how to find the optimal matching solution among numerous products has become an important research question. Zhang et al. found that the rapid upgrading of mechanical products caused serious resource waste and environmental pollution. To improve the resource utilization, a mechanical product selection model utilizing big data analysis was proposed. The experimental results showed that the model could optimize the selection and assembly efficiency of in-service products, save manpower and material resources. It had certain feasibility and accuracy [5]. Guo et al. found that a large number of retired mechanical products caused resource waste. To transform the utilization rate of retired products, a new selection strategy for retired products was proposed by combining the generalized growth remanufacturing model. The experimental results indicated that this strategy could mine data associations between products, thereby increasing the utilization rate of retired products [6]. Li et al. found that the increase in richness and diversification of mechanical products often resulted in existing mechanical product assemblies being unable to meet the needs of users. Therefore, a mechanical product assembly model was proposed after combining digital twin technology. The experimental results indicated that the model could autonomously optimize the product selection process and operate with the highest rated product assembly plan for service evaluation [7]. Formentini et al. found that traditional manufacturing and assembly design strategies were no longer able to assemble new products with high standards, speed, and accuracy. Therefore, a new assembly design method was proposed by combining numerical maps. The experimental results showed that this method could adapt to the assembly of most existing mechanical products. The efficiency and accuracy were extremely high [8].

Multi objective optimization algorithms are a type of algorithms specifically designed to solve multi-objective optimization problems. The density based multi-objective evolutionary algorithm is an evolutionary algorithm used to solve multi-objective optimization problems. This algorithm combines density estimation and evolutionary strategy, aiming to find a set of approximate Pareto optimal solutions. Liang et al. found that traditional multi-objective algorithms couldn’t handle the balance between population diversity well. Therefore, a DMOEA model combining decision variables was proposed. The experimental results showed that the model could stably output decision variables in both static and dynamic responses. It had better computational performance compared to traditional methods [9]. Li et al. proposed a multi-objective solution method combining DMOEA after summarizing and identifying the probability uncertainty problem in random resource allocation. The experimental results showed that this method performed better than other similar methods in most tests. It could successfully solve the random resource allocation [10]. Chen et al. proposed an evolutionary algorithm combining Coral algorithm and DMOEA to solve the Pareto optimal problem related to time and process in dynamic multi-objective optimization. The experimental results showed that the algorithm could achieve good solutions, with a fast completion speed and a high completion rate [11]. Feng et al. proposed a novel dynamic change prediction model by combining autoencoder and DMOEA to explore a solution for novel dynamic multi-objective optimization problems. The experimental results showed that the model could provide more accurate Pareto optimal solution prediction compared to multi-objective genetic algorithm. The iteration times were faster [12].

In summary, many scholars at home and abroad have explored the assembly schemes of mechanical products to varying degrees and have achieved remarkable results. Meanwhile, the DMOEA has been applied to different research fields, which has also solved many multi-objective problems. However, there is still little research on applying DMOEA to the assembly design of industrial machinery products. Therefore, this study attempts to combine the two, aiming to further improve the efficiency of product assembly and better address optimization issues in industrial machinery product selection schemes.

## III. Industrial Machinery Product Selection Model Construction

To construct a new industrial machinery product selection model, the necessary multi-objective problem of machinery selection is first modeled. Different types of target problems are normalized. Secondly, the DMOEA was introduced for improvement. Then it is applied to the multi-objective solving process of the selection problem. Finally, a new assembly model is proposed.

### *A. Modeling of Small Batch Multi-objective Matching Problems*

The selection of mechanical products follows the principle of group selection, which is to reasonably allocate and assemble parts based on their actual size, size, material, process, etc., in order to achieve high stability and rationality of product quality [13]. The formulation of mechanical product selection plans should consider multiple factors, including production scale, product requirements, environmental conditions, etc. Different mechanical products can achieve maximum benefits in specific production environments. The factors that generally affect the selection are shown in Fig. 1.

In Fig. 1, it is mainly divided into component level factors and optional level factors. At the part level, it is subdivided into structure, size, shape, indicating quality, and heat treatment. The selection level includes position, method, accuracy, plan, etc. These factors complement each other and work together on product selection work. There are a wide variety of mechanical products. There are certain differences in the selection mode of different types of products. Generally, large-scale product selection can rely on group selection for smooth assembly, while small batch products often lack consideration due to the primary and secondary relationships and assembly accuracy [14]. Therefore, this study focuses on small batch products as the main research object. Firstly, a selection correlation matrix for small batch products is constructed, as shown in Eq. (1).

$$R = \begin{bmatrix} r_{1,1}, r_{1,2}, \cdots, r_{1,k} \\ r_{2,1}, r_{2,2}, \cdots, r_{2,k} \\ \vdots \\ r_{m,1}, r_{m,2}, \cdots, r_{m,k} \end{bmatrix} \quad (1)$$

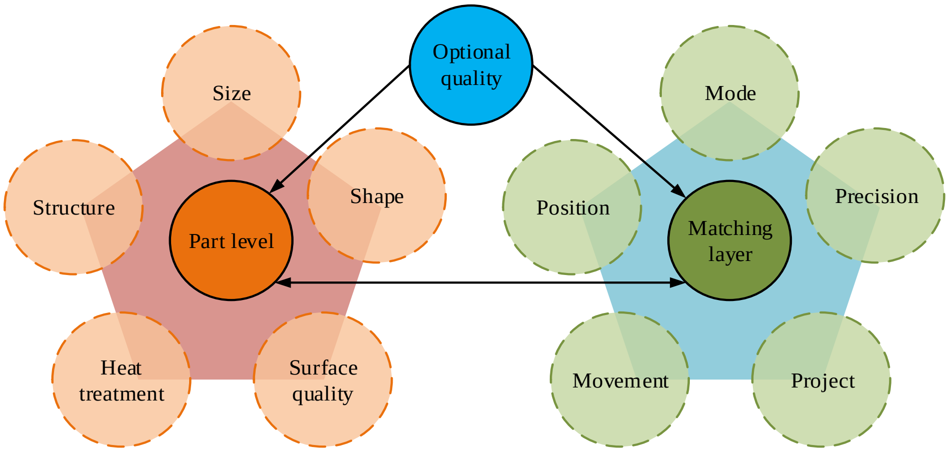

Fig. 1. Classification of factors affecting the selection accuracy.

In Eq. (1), $r_{m,k}$ represents the $k$-th dimension under the $m$-th dimension chain. At this point, the constraint matrix for small batch products is shown in Eq. (2).

$$G = \begin{bmatrix} g_{1,\min}, g_{2,\min}, \cdots g_{m,\min} \\ g_{1,\max}, g_{2,\max}, \cdots g_{m,\max} \end{bmatrix} \quad (2)$$

In Eq. (2), $g_{m,\min}$ and $g_{m,\max}$ represent the upper and lower deviations of the assembly accuracy related dimensions under the $m$-th dimension chain. If the size of a certain part is determined between $g_{m,\min}$ and $g_{m,\max}$, it is called a qualified size. The part dimensions are paired and coded. The obtained results are randomly arranged according to gene coding. The selection scheme code for small batch products is shown in Eq. (3).

$$X_i = (\beta_1, \beta_2, \beta_3, \cdots, \beta_n) \quad (3)$$

In Eq. (3), $\beta_n$ represents the size number of the same group of parts. $n$ represents the quantity of part dimensions. Based on the above coding patterns, the multi-objective selection problem model for small batch products is divided into three levels: selection success rate, selection quality, and multi-objective and multi quality selection. The success rate of small batch product selection represents the ratio of the current number of qualified products that have been selected to the total number of products that have been selected, as shown in Eq. (4).

$$\chi_m = \frac{n_e}{n} \times 100\% \quad (4)$$

In Eq. (4), $\chi_m$ represents the selection success rate. $n_e$ represents the number of qualified products after completing the selection. $n$ represents the quantity of all products that have been selected. In addition, the quality requirements for product selection are equally important, especially whether the gap docking of the selected parts is suitable, and whether the product operational functions can be achieved. The size of optional parts for the product is fixed. Therefore, the Taguchi model is selected for quality control in the study. The schematic diagram of this model is shown in Fig. 2.

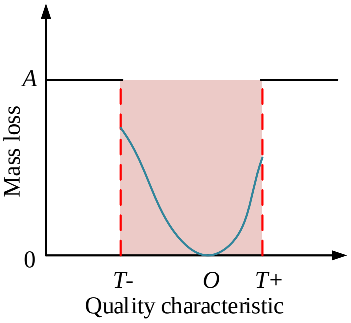

Fig. 2. Taguchi mass model diagram.

In Fig. 2, $A$ represents the quality loss of unqualified products after completing the selection. $T$ represents the reasonable tolerance range for the selected product dimensions. $T-$ and $T+$ represent the upper and lower limits of the tolerance range. When the gap size of the selected product is within the red range, the product quality is qualified. The quality loss function of the most optimal product is shown in Eq. (5).

$$C(g_{m,j}) = \begin{cases} \dfrac{2A}{T_m}(g_{m,j} - g_o) \\ g_{m,j} \in \left[ g_{m,\min}, g_{m,\max} \right] \\ A, g_{m,j} \in (-\infty, g_{m,\min}) \cup (g_{m,\max}, +\infty) \end{cases} \quad (5)$$

In Eq. (5), $T_m$ represents the design tolerance for optional parts. $g_o$ represents the optimal clearance value of the part. When the actual selection gap approaches $g_{m,\min}$ or $g_{m,\max}$, the mass loss is greater, that is, closer to the $A$ value. The average selection quality loss function at this time is shown in Eq. (6).

$$Q_m = \frac{\sum_{j=1}^{n} C(g_{m,j})}{n} \tag{6}$$

If the value of $Q_m$ is small, it indicates that the accuracy and quality of the selected product are high. Therefore, the multi-objective and multi quality selection scheme is selected to approximate the minimum value. The definition of this process is shown in Eq. (7).

$$\min fitness(x) = (M_1(X), M_2(X), \cdots, M_m(X)) \tag{7}$$

In Eq. (7), $M_m(X)$ represents the comprehensive optimization objective function of the $m$-th product. $fitness(x)$ represents the fitness function. The expression curve is shown in Fig. 3.

In Fig. 3, $\gamma$ represents the actual common difference of the selected dimensions. The fitness value range for parts selection is between $\gamma$ and 1. When the actual selected size tolerance is $H$, the maximum quality loss is 1. When the actual selected size common difference approaches $T-$ and $T+$, the fitness function value is the lowest at $\gamma$. In summary, the optimal selection size common difference and the lowest quality function can achieve the best production selection work.

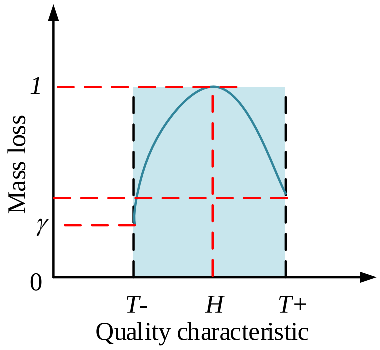

Fig. 3. Fitness function curve of multi-object and multi-mass selection.

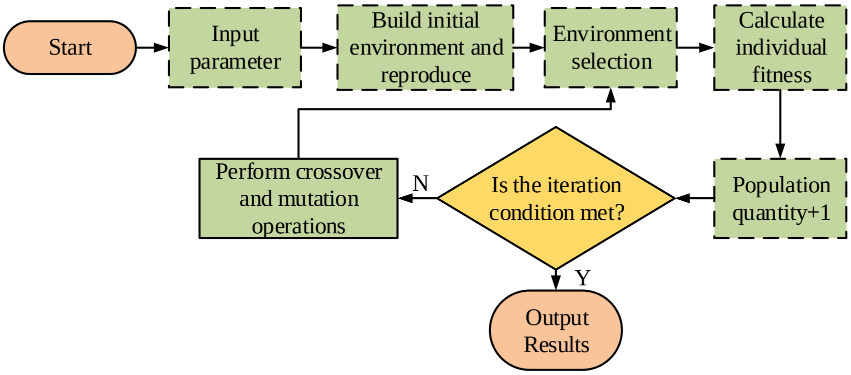
## B. Modeling of Selection Strategies for Small-lot Products

After constructing a multi-objective problem model for selecting small batch products, the study attempts to use optimization algorithms for solution. General optimization algorithms include genetic algorithm, ant colony algorithm, particle swarm algorithm, and simulated annealing algorithm [15]. These algorithms have wide adaptability and strong applicability, but simple optimization algorithms cannot quickly and completely solve multi-objective problems. Therefore, a multi-objective evolutionary algorithm using density calculation, DMOEA, is proposed for the assembly problem of small batch products. The operation process of this algorithm is shown in Fig. 4.



Start
Input parameter
Build initial environment and reproduce
Environment selection
Calculate individual fitness
Population quantity+1
Is the iteration condition met?
N
Perform crossover and mutation operations
Y
Output Results

Fig. 4. The process of DMOEA.

In Fig. 4, the DMOEA first determines the algorithm parameters and selection problem parameters, such as population size, cross mutation probability, iteration number, size chain constraint relationship, part data, etc. Secondly, the initial environment is constructed for population reproduction and evolution. The environment is selected and a non-dominated set is constructed for replication. Then the individual fitness is calculated or the population size is increased. Finally, after satisfying the iteration conditions, the result is output. If not, operations such as crossover and mutation are performed again. The environment selection and non-dominated set replication are repeated. The fitness function of the entire algorithm is mainly calculated using clustering density. To quantify the influence degree between individuals, the density function is calculated using a normal distribution, as shown in Eq. (8).

$$\psi(r) = \left[1/\sigma\sqrt{2\pi}\right] e^{-r^2/2\sigma^2} \tag{8}$$

In Eq. (8), $r$ represents the Euclidean distance between individuals. $\sigma$ represents the standard deviation of the distribution. The density calculation for individuals at this time is shown in Eq. (9).

$$D(x_y)=\sum_{i=1}^{N}\psi\left[d(x_i,x_y)\right] \tag{9}$$

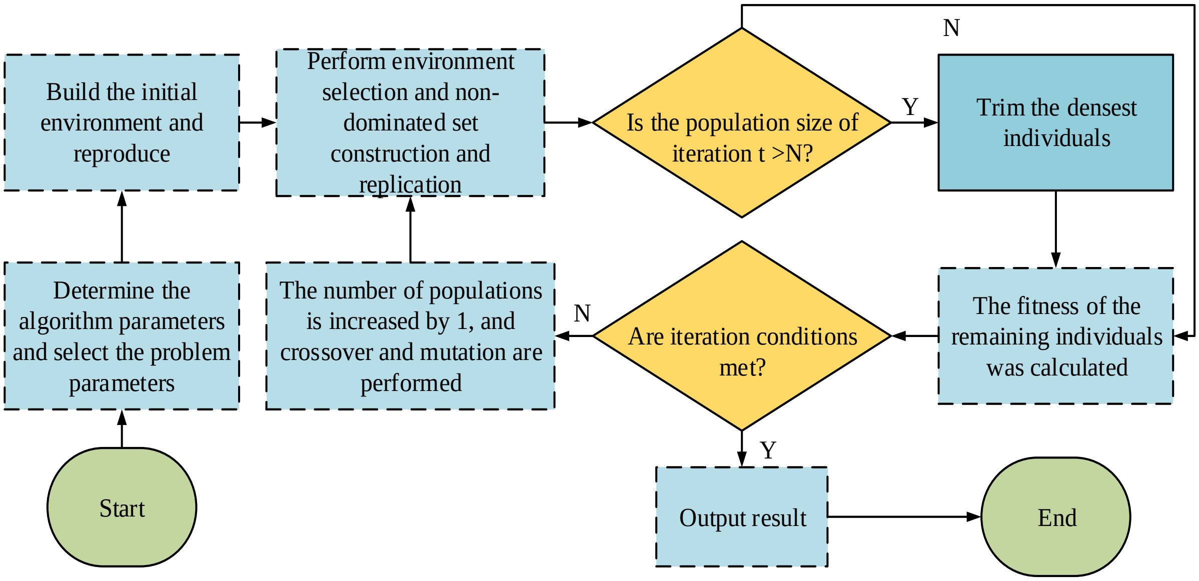
In Eq. (9), $d(x_i,x_y)$ represents the Euclidean distance between individual $x_i$ and individual $x_y$. $x_i$ and $x_y$ belong to the evolved individuals after reproduction. The density fitness function is shown in Eq. (10).

$$F(X_i)=\frac{fitness(X_i)}{D(X_i)} \tag{10}$$

In Eq. (10), all algebraic meanings are consistent with the previous explanation. According to this equation, individuals with higher density fitness values have lower individual density, meaning their mutual influence is relatively small. Therefore, to preserve the diversity of individuals after iteration, individuals with higher density fitness values should be selected [16]. In addition, the random change method is used to transform the correlation matrix $R$ for small batch parts selection. The transformed matrix is shown in Eq. (11).

$$X_0=\begin{bmatrix} x_{1,1},x_{1,2},\cdots x_{1,k} \\ x_{2,1},x_{2,2},\cdots x_{2,k} \\ \vdots \\ x_{j,1},x_{j,2},\cdots x_{j,k} \end{bmatrix} \tag{11}$$

In Eq. (11), $x_{j,k}$ represents a separate part with the number $k$ in group $j$. When generating the initial population, its individual distribution maintains randomness, that is, it is arranged according to a random sequence. This arrangement represents an optional solution, which can be obtained by repeating multiple arrangements. For the initial population reproduction, to ensure that the population size after reproduction matches the evolutionary scale, a pruning method is adopted, which eliminates the individuals with the highest density [17]. The reproduction process is shown in Fig. 5.



Build the initial environment and reproduce
Perform environment selection and non-dominated set construction and replication

N
Are iteration conditions met?
The fitness of the remaining individuals was calculated
Y
Start
Output result
End

Fig. 5. Pruning and breeding process of DMOEA.

From Fig. 5, this process is roughly similar to the general genetic algorithm process, but the difference is that it has an additional pruning step. After eliminating individuals with high fitness, to avoid mutual influence between individuals, this step recalculates the fitness of the remaining individuals. After completing population reproduction, population strategies such as crossover and mutation should be implemented. Among them, single point crossing method is a classic crossing method. Although its computational speed is not as fast as multi-point crossing and mixed crossing, its positional damage is significantly smaller than the other two types of methods. It is more conducive to the precise size positioning of the selection scheme [18]. The expression for single point crossing is shown in Eq. (12).

$$X_a=\begin{bmatrix} x^a_{1,1},x^a_{1,2},\cdots,x^a_{1,n} \\ x^a_{2,1},x^a_{2,2},\cdots,x^a_{2,n} \\ \vdots \\ x^a_{m,1},x^a_{m,2},\cdots,x^a_{m,n} \end{bmatrix} \Rightarrow X^{`}_a=\begin{bmatrix} x^a_{1,1},x^a_{2,2},\cdots,x^a_{2,n} \\ x^a_{2,1},x^a_{1,2},\cdots,x^a_{1,n} \\ \vdots \\ x^a_{m,1},x^a_{m,2},\cdots,x^a_{m,n} \end{bmatrix} \tag{12}$$

In Eq. (12), $X_a$ represents offspring. $X^{`}_a$ represents the parent. From this formula, the arrangement sequence after single point crossing changes, but the position of individual individuals remains. Mutation induces individual positional changes through genetic alterations. The code of the mutated small batch product is shown in Eq. (13).

$$X_i=\left[\beta_1,\beta_2,\beta_3,\cdots,\beta_n\right]\Rightarrow X^{`}_i=\left[\beta_1,\beta_3,\beta_2,\cdots,\beta_n\right] \tag{13}$$

In Eq. (13), $X_i$ is the code of the small batch product before mutation. $X_i^{`}$ represents the code of small batch products after mutation. At this point, the individual position of the product has changed. Therefore, it is possible to create unique new individuals. In summary, a new industrial machinery product selection model is proposed by combining the optimized DMOEA. The model structure is shown in Fig. 6.

In Fig. 6, the entire optional system is roughly divided into three main gates and 8 small gates. The three main gates are part data collection, dimension chain calculation, and selection planning. Among them, part data collection includes batch, size, and quantity of parts. The size chain calculation includes the calculation of increase or decrease cycles and the refinement of size chain. The selection plan includes DMOEA selection algorithm calculation, selection result validation, and selection result analysis.

## IV. Product Option Model Performance Testing

To verify the performance of the DMOEA selection model proposed in the study, the study first trains the same type of selection model with self-made data and determined the optimal algorithm parameters. Then, a comparison is made on the selection accuracy, success rate, and quality loss. In addition, a comparative test for DMOEA selection scheme is conducted using a four cylinder plunger pump valve as the simulation object.

### A. *Performance Testing of Selected Models*

The system architecture of the browser combined with the server is used to simulate the generation of DMOEA models. 150 bearing seats of P215 and 150 outer spherical bearings of NA215 are subjected to selection testing. The inner diameter range of the bearing seat is φ120±0.02mm. The outer diameter range of the bearing is φ120±0.04mm. The range of bearing inner diameter is φ65-φ65.02mm. The range of journal diameter is φ65-φ65.03mm. The above four experimental materials are randomly combined. The combined results are divided into training and testing sets in an 8:2 ratio. At the same time, the training set data is sequentially input into popular deep learning selection algorithms of the same type for comparative testing. These algorithms include Reinforcement Learning (RL), Variational Autoencoders (VAEs), and Meta Learning (ML), with selection accuracy as the reference indicator. The test results are shown in Fig. 7.

Fig. 7(a) shows the selection accuracy test results of four algorithms in the training set. Fig. 7(b) shows the selection accuracy test results of four algorithms in the test set. In Fig. 7, the VAEs model had the lowest average selection accuracy, followed by ML and RL. The DMOEA selection model had a selection accuracy of nearly 99% in the training set and nearly 95% in the testing set. This data illustrates that by optimizing the DMOEA's density Gann function, it will lead to a significant improvement in the selection accuracy of the whole model. In addition, to more accurately determine the optimal operational parameters of the optimization algorithm, the study takes the selection success rate and selection quality loss as reference indicators. Similarly, the training set data is input into four models for initial iteration parameter determination. Their respective operational iteration effects are compared. The test results are shown in Fig. 8.

Fig. 8(a) shows the comparison test results of the selection success rates for four models. Fig. 8(b) shows the comparison test results of the quality loss for four models. In Fig. 8, the optimal selection success rate of the RL was the highest at 98%, with 350 iterations. The success rate of the DMOEA proposed in the study was the highest at 97%, which was 1% lower, but the algorithm had 250 iterations at this time. In addition, the quality loss curve of the DMOEA decreased the fastest, reaching a minimum quality loss of nearly 8%, with approximately 270 iterations at this time. This data illustrates that the pruning approach has optimized the reproduction process of the DMOEA algorithm, which can significantly improve its computational speed and increase the diversity of strategies, thus improving the success rate of selection. In summary, for the convenience of subsequent testing, the study determined 260 iterations as the optimal iteration number for the MOEA. To verify the feasibility of the DMOEA, three fixed bearing combinations are randomly selected, namely bearing 3 with bearing seat 3, bearing 8 with bearing seat 8, and bearing 12 with bearing seat 12. The better performing DMOEA algorithms and the state-of-the-art three types of algorithms are tested in comparison with each other using absolute error, relative error and algorithm fitting credibility as the reference indexes. Such as Strength Pareto Evolutionary Algorithm (SPEA), Multi-Objective Evolutionary Algorithm based on Decomposition (MOEA/D) and ε-Multi-Objective Evolutionary Algorithm (ε-Epsilon-Multiobjective Evolutionary Algorithm, ε-MOEA), and the test results are shown in Table I.

(b) Comparative testing of quality loss during selection

Fig. 8. Performance comparison testing of different algorithms.

TABLE I. ANALYSIS OF BEARING SELECTION RESULTS FOR TWO ALGORITHMS

| Allocation model | Combination 3 | | Combination 8 | | Combination 12 | | Index | | |
|---|---|---|---|---|---|---|---|---|---|
| / | Bearing 3 | Bearing seat 3 | Bearing 8 | Bearing seat 8 | Bearing 12 | Bearing seat 12 | Sum of absolute errors | Relative error sum | Fit credibility |
| SPEA optional diameter/mm | 120.015 | 120.009 | 120.007 | 120.01 | 120.009 | 120.008 | 0.01 | 0.08% | 96.90% |
| MOEA/D optional diameter/mm | 120.017 | 120.012 | 120.005 | 120.002 | 120.009 | 120.008 | 0.006 | 0.01% | 98.50% |
| ε-MOEA optional diameter/mm | 120.0.16 | 120.013 | 120.006 | 120.004 | 120.008 | 120.007 | 0.005 | 0.03% | 99.10% |
| DMOEA optional diameter/mm | 120.017 | 120.015 | 120.008 | 120.008 | 120.006 | 120.006 | 0.002 | 0.01% | 99.90% |

As can be seen from Table I, after quantifying the data, it is found that for the three sets of bearing sets under the same conditions, the absolute error sum of the diameter of the bearings and housings selected by the SPEA selection model is 0.01 at the maximum, and the relative error sum is 0.08% at the maximum, and the algorithm fitting credibility is 96.9% at the maximum. The other three types of algorithms in the MOEA series perform significantly better than SPEA, especially the proposed DMOEA algorithm model of bearing and housing selection performs the best, with the maximum absolute error of diameter of 0.002, the maximum relative error and 0.01%, and the maximum algorithmic fitting confidence of 99.9%. In summary, the new allocation model proposed by the research can refine the control of product dimensions in the process of part selection, avoiding the product quality problems caused by dimensional errors.

### *B. Selection Model Simulation Testing*

To verify the practical application effect of the DMOEA selection model, the SI6K-50 four cylinder plunger pump valve is studied as the test object. The selected parts mainly include the main piston, guide plate, pull rod, and small shell. The size range of the main piston is φ18±0.05mm. The fit clearance is 0.05-0.07mm. The optimal clearance is 0.06mm. The size range of the guide plate is φ18±0.02mm. The clearance and optimal clearance are the same as the main piston. The size range of the pull rod is φ7±0.04mm. The fit clearance is 0.05-0.07mm. The optimal clearance is 0.07mm. The size range of the small shell is φ7±0.03mm. The clearance and optimal clearance are the same as the tension rod. 60 different sizes of main pistons, guide plates, pull rods, and small shells are randomly selected, with 15 of each type. After random arrangement and combination, 15 schemes are selected for testing. The pre-selected parts for testing are shown in Table II.

From Table II, the diameter values of each group of parts in the 15 pre-selected configuration schemes had a small difference. The overall similarity of the schemes was higher after random combination. To distinguish and evaluate the practical application effectiveness of the DMOEA model, the success rate and quality loss of selection are used as reference indicators. At the same time, to more realistically compare the performance differences between the proposed selection model and the existing popular Generative Adversarial Network (GAN) selection model, the above 15 sets of pre-selection schemes are sequentially inputted into the DMOEA and GAN. The measured assembly success rate and assembly quality loss are checked. The specific test results are shown in Table III.

According to Table III, the 15 pre-selection schemes were inputted into the DMOEA and GAN, respectively. Quantitative data showed that the success rate of GAN selection in schemes 5, 8, and 12 was higher than the DMOEA proposed in the study. All other options showed that DMOEA was superior. In addition, the selection quality loss value of the DMOEA was all lower than that of the GAN. The highest selection success rate of the DMOEA was 0.99, the average selection success rate was 0.93, the lowest selection quality loss was 0.08, and the average selection quality loss was 0.26. In summary, the product selection model proposed in the study combined with DMOEA optimization model had higher performance. Compared to similar selection models, it was more feasible and stable. In addition, to more vividly demonstrate the selection effect of DMOEA and GAN, the study selects four schemes each with better assembly success rate and quality loss for the two models. The confusion matrices of the two models are plotted. The results are shown in Fig. 9.

TABLE II. PRE-SELECTION SCHEME

| Assembly plan | Guide disc size/mm | Main piston size/mm | Rod size/mm | Small shell size/mm |
|---|---|---|---|---|

Fig. 9(a) shows the confusion matrix of the selection success rate for the DMOEA. Fig. 9(b) shows the confusion matrix of the selection success rate for the GAN. Fig. 9(c) shows the confusion matrix of the selected quality loss for the DMOEA. Fig. 9(d) shows the confusion matrix of the selected quality loss for the GAN model. From Fig. 9, in the comparison test of the confusion matrix for the selection success rate, the schemes of DMOEA model can smoothly perform allocation prediction. The highest confusion prediction score is 60. In the confusion matrix of the GAN, scheme 4 and scheme 5 were easily confused, while scheme 5 and scheme 2 were easily confused. In addition, in the comparison test of the confusion matrix for quality loss selection, the DMOEA model had a high accuracy in predicting allocation, with only schemes 3 and 6 being prone to confusion. In summary, the DMOEA model proposed in the study is more suitable for product task allocation. It has certain feasibility and stability. The overall performance is relatively good.

## V. Discussion

The study conducted various tests and analyses of the proposed DMOEA algorithmic model to investigate its superiority and feasibility. First, in order to verify the superiority of DMOEA, the study conducted training tests on the DMOEA model with the selection accuracy, and compared DMOEA with the same type of algorithmic models using the selection success rate and the loss of selection quality as indicators. It was found that the matching success rate of DMOEA was as high as 97%, and the matching accuracy was close to 95%, which was significantly better than the traditional matching model. This achievement is attributed to the high efficiency and accuracy of the DMOEA algorithm in dealing with multi-objective selection problems, especially the improvement in optimizing the density function and reproduction process of the calculation. In the experiments, the absolute error of the bearing and housing selection diameters of DMOEA is up to 0.002 and the relative error is only 0.01%, and this accuracy significantly improves the quality and reliability of the products. This result is consistent with Zhang H et al. who used big data analysis to optimize the selection efficiency of mechanical products [19]. Secondly, in order to verify the effective feasibility of the DMOEA model, the study took a four-cylinder piston pump valve as the test object, and the selected parts mainly included the main piston, guide disk, tie rod and small housing, while other models were introduced for comparison. The highest matching success rate of the DMOEA model is found to be 0.99, and the lowest matching quality loss is found to be 0.08, which is greatly improved compared with the GAN model, and also verifies the effectiveness and stability of DMOEA in dealing with industrial matching problems in complex environments. This result reaffirms that the DMOEA algorithmic model is more suitable for product allocation tasks compared to GAN, and is consistent with the result that the generalized growth remanufacturing model proposed by Yıldız et al. improves the utilization of retired products [20].

Despite the strong performance demonstrated by the DMOEA model in this study, there are still limitations. On the one hand, the model mainly focuses on the multi-objective optimization of part sizes and does not fully consider the performance metrics and cost factors of the parts, which may affect the practical application results of the selection scheme. On the other hand, the computational complexity of the DMOEA algorithm is relatively high, and further research is needed to improve its computational efficiency. Future research can refine the product selection model, and in addition to dimensional accuracy, product performance, cost and supply chain factors should also be considered to achieve more comprehensive selection optimization. In addition, we can try to combine artificial intelligence and machine learning technology to further improve the intelligence level of the selection model, for example, by automatically adjusting the algorithm parameters to adapt to different selection scenarios.

## VI. Conclusion

The industrial machinery product selection is a complex optimization problem that involves multiple attributes and constraints. Traditional optimization methods have low efficiency or inability to effectively explore the design space when dealing with such problems. In view of this, after analyzing and summarizing the existing multi-objective problem of product selection, a new mechanical product selection model is proposed by introducing the DMOEA for improvement. The experimental results showed that the selection accuracy of the DMOEA in the training set was close to 99%, and the selection accuracy in the testing set was close to 95%. When the algorithm iterations were 250, the highest success rate of DMOEA was 97%. Although it was 1% lower than the RL model, the number of iterations decreased by nearly 100 times. In addition, the maximum absolute error sum of the selected diameters for bearings and bearing seats in the DMOEA was 0.002, and the maximum relative error sum was 0.01%. The highest fitting reliability of the algorithm was 99.9%. Compared to the RL, there was a significant decrease in error indicators and a significant improvement in credibility. Simulation tests showed that the highest selection success rate of the DMOEA was 0.99, the average selection success rate was 0.93, the lowest selection quality loss was 0.08, and the average selection quality loss was 0.26. At the same time, the DMOEA could smoothly perform allocation prediction. The confusion matrix had a maximum score of 60 points. In summary, the DMOEA model has certain practicality and feasibility, providing a new approach and method for solving complex selection problems. However, the actual product selection problem is too complex. This study only considers the size chain relationship, without considering the performance indicators and cost supply of the parts. Subsequent research can continue to increase these considerations to enhance the credibility and comprehensiveness of the study.

Kattankulathur, 603203, Tamil Nadu, India

***Abstract*—Now-a-days, artificial prosthesis is widely used to mitigate pain in damaged shoulders and restore their movement ability. The process involves a complex surgery that attempts to fix an artificial prosthesis into a dead shoulder as a replacement for the ball and socket joints of the shoulder. Long after the surgical process, the need for revision or reoperation may arise due to some problems with the prosthesis. Identification of prosthesis manufacturer is a paramount step in the reoperation exercise. Traditional approach compares the prosthesis under consideration with prosthesis from a vast number of manufacturers. This approach is cost-efficient and requires no extra training for the physician to identify the prosthesis manufacturer. However, the method is time inefficient and is prone to mistakes. Systems based on machine learning have the potential to reduce human errors and expedite the revision process. This paper proposes a shallow 2D convolution neural network (CNN) for the classification of shoulder prosthesis to speed-up the learning process and improve the performance of the deep learning model for implant classification, this paper employed three different techniques. Firstly, a generative adversarial network (GAN) is applied to the dataset to augment the classes with fewer samples to ensure the data imbalance problem is eliminated. Secondly, the highly discriminating features are extracted using principal component analysis (PCA) and used to train the proposed model. Lastly, the model hyper-parameters are optimised to ensure optimal model performance. The model trained with extracted features with a variance of 0.99 achieved the best accuracy of 99.8%.**

***Keywords—Machine learning; deep learning; convolution neural network; Adversarial Network (GAN); Principal Component Analysis (PCA); shoulder implants***

## I. INTRODUCTION

One of the invasive methods used to reduce pain and restore movement in injured shoulders is Total Shoulder Arthroplasty (TSA) [1]. Shoulder malfunction is generally caused by rheumatoid arthritis, abrasion, calcification, deterioration of cartilage tissue, and damage to surrounding bones [2]. Surgery on the shoulder is required in order to repair the damaged shoulder's function. The damaged, non-functional joint is surgically removed and replaced with a prosthetic joint [3–5]. Different prostheses are currently produced by a number of manufacturers. Acumed, Biomet, Cofield, Depuy, Encore, Exactec, Tornier, and Zimmer are among the most widely used manufacturers [18]. These manufacturers produce prostheses in various models according to the patient and case type [6]. In order to determine whether prosthesis is compatible with a specific issue in the shoulder, x-ray images of the implants are used. Presently, x-rays plays crucial role in the diagnosis of medical conditions like bone fracture, COVID-19, and many more [23].

After surgery, the implanted prostheses might require repairs for a specific amount of time. In addition, the prostheses might require replacement due to damage from events like accidents [1]. In this instance, the replacement requires knowledge about the prosthesis. The course of treatment is slowed down when this information is either unavailable or unknown to the patient and the doctor. The primary surgical procedure to reduce common complications and prevent treatment delays is determining the prosthesis' model and manufacturer so that it can be positioned correctly. Traditionally, the model and manufacturer are identified by a thorough inspection and visual comparison of the prosthesis's x-ray images with pictures of the prosthesis that are currently available. This method is laborious and prone to mistakes.

Several deep learning techniques have been proposed to reduce errors caused by the conventional approach for the identification of the prosthesis manufacturer and model and to expedite the treatment process. A deep CNN-based method for implant manufacturer classification was presented by the authors in study [6]. The model's accuracy cap is set at 80%. In order to predict the maker of prostheses, the researcher of [7] presents a framework that employs the Squeeze-and-Excitation (SE) network and the conventional 50 layer Residual Network (ResNet50). The suggested method reaches a 97% accuracy level at most. Additional deep learning techniques used are K-Nearest Neighbour [8], Inception, Random Forest, VGG16 [8], ResNet50 [9], and many more. Although these techniques demonstrate a high degree of performance, the proposed deep CNN model incur huge training time and cannot be generalized due to limited number of training samples. On the other hand, the pre-trained models have limited flexibility due to their specific architecture. Adapting these techniques is highly challenging especially when there is need for modification in the model to fit other form of prosthesis datasets. For these reasons, a more effective and reliable solution is still required.

To ensure more accurate and reliable implant prediction, this paper proposes a shallow 2D convolution neural network (CNN) for the classification of shoulder implants. To speed up the learning process of the proposed method and improve the performance of the deep learning method for implant classification, a generative adversarial network (GAN) is applied to the dataset to augment the classes with fewer samples to ensure the data imbalance problem is eliminated, and the highly discriminate features are extracted using principal component analysis (PCA) and used to train the proposed model. Also, the model hyper-parameters are optimised to ensure optimal model performance.

The proposed framework in this paper will remove class imbalances in the dataset, which will make the model unbiased. Also, the feature extraction significantly reduced the training features, thus reducing the model's training time and improving its performance.

The objectives of this paper are as follows:

- To develop a robust deep learning framework for shoulder implant classification with high classification accuracy
- To reduce the processing time and ensure high model performance through dimensionality reduction
- To eliminate data imbalances in the TSA dataset through data augmentation

The remaining portions of this article are organized as follows: In Section II, researchers' efforts to categorize and identify prosthetics manufacturers are examined. In Section III of this paper, the recently built deep learning framework is explained in detail. The experiment's specifics and the outcomes of the training process and the evaluation of the suggested deep learning model are presented in Section IV. Section V presents our findings discussion and Section VI wraps up this paper by outlining our plans for future research.

This template, modified in MS Word 2007 and saved as a “Word 97-2003Document” for the PC, provides authors with most of the formatting specifications needed for preparing electronic versions of their papers. All standard paper components have been specified for three reasons: (1) ease of use when formatting individual papers, (2) automatic compliance to electronic requirements that facilitate the concurrent or later production of electronic products, and (3) conformity of style throughout a conference proceedings. Margins, column widths, line spacing, and type styles are built-in; examples of the type styles are provided throughout this document and are identified in italic type, within parentheses, following the example. Some components, such as multi-leveled equations, graphics, and tables are not prescribed, although the various table text styles are provided. The formatter will need to create these components, incorporating the applicable criteria that follow.

## II. Related Work

To solve the issue of implant manufacturer identification, the authors of [1] use conventional Convolution Neural Network (CNN) and conventional methods of machine learning. The effectiveness of CNN and conventional machine learning methods are contrasted by the authors. The CNN model was given a fresh perspective on channel selection in order to produce filter features. To identify the implant manufacturer and model, the authors use both conventional machine learning techniques and deep learning techniques.

In research [6], researchers categorize shoulder implants in X-ray photographs using a deep learning methodology. The authors assess how well deep learning algorithms perform in comparison to other machine learning classification algorithms, such as gradient boosting and random forest. The authors' findings indicate that Deep Convolutional Neural Network (DCNN) outperforms other machine learning classification algorithms, particularly when an ImageNet pre-trained model is used for classification. While other machine learning classification methods reach an optimal accuracy of 56%, the deep learning model presented in this work uses 10 fold cross validation to achieve an average accuracy of 80%.

To improve the accuracy of shoulder prostheses prediction based on x-ray images on the conventional SIXIC x-ray dataset, authors in study [7] proposed the X-Net framework. The Residual Network module incorporates the Squeeze and Excitation (SE) blocks as part of the suggested model. Through the process of weighing every one of the feature maps obtained using the Residual Network (ResNet) component the method enhances the efficiency of shoulder prosthesis prediction. For obtaining more pertinent features from the xray images in the dataset, both the ResNet and SE components are used. Ultimately, the ResNet and SE modules' fine-grained feature extractions are categorised into Cofield, Depur, Tornier, and Zimmer categories.

In research [8] the performance of traditional ML techniques like RF and KNN is compared with that of deep learning techniques like the 16 layer visual geometric group, Vision transformer, the 50 layer conventional residual network and Inception. The researchers apply a vast DL and ML approaches to the augmented arthroplasty dataset generated by authors of [6, 10]. The results reported by the authors indicate that data augmentation enhances the accuracy of models and lowers the likelihood of over-fitting.

In order to distinguish between the reverse and the normal Total Shoulder Arthroplasty (TSA), as well as between different prosthesis models, the authors of [9] proposed a binary classifier based on a Residual Network (ResNet) Deep Convolution Neural Network (DCNN). For every model, the authors employ five different classifiers, and they assess each model's performance. For the purpose of differentiating between TSA and RTSA and classifying the five distinct prosthesis models, the suggested DCNN achieves a higher AUC-ROC.

A classification tool was proposed by the authors of [10] to identify the manufacturer of shoulder prostheses. The authors sought to remove the obstacles that medical professionals encountered when trying to determine the prosthesis' manufacturer through visual inspection of xray images. After locating the implant using the Hough transform for circles, the authors segment the implant using the seeded region growing method. The results of the suggested software solution in this work were verified visually and by comparing the outcomes of classification with the manually segmented real-world images.

The methods proposed in the literature have achieved promising performance. However, the methods fail to address the issue of class imbalance in the dataset, which tends to learn more about the classes with large samples. These make the model bias towards the class with the larger samples. Also, the methods take longer training time due to the size of features to be used for training and the number of layers in the models. Other models used in the literature are pre-trained models with limited flexibility. Employing these models is highly challenging especially when there is need for modification in the model to fit other form of prosthesis datasets. In this paper, the limitations in the state-of-the-art methods are addressed by eliminating class imbalance using GAN network to generate artificial dataset, which eliminate model bias. The PCA is used to reduce the number of training features, which results in a model with fewer layers, training time and greater performance.

## III. Materials and Methods

The main motivation behind the development of the proposed deep learning framework is to automatically identify the manufacturer of shoulder implants before the replacement of problematic prostheses in an arthroplasty patient. The workflow of the proposed DL framework for detection and classification of implant manufacturers using X-ray radiographs is depicted in Fig. 1. The workflow consists of the following steps: dataset collection, data preprocessing phase, building and training of various transfer learning models (DenseNet201, Inseption-V3, MobileNet, and ResNet50), and the proposed 2D Convolution Neural Network (2DCNN).

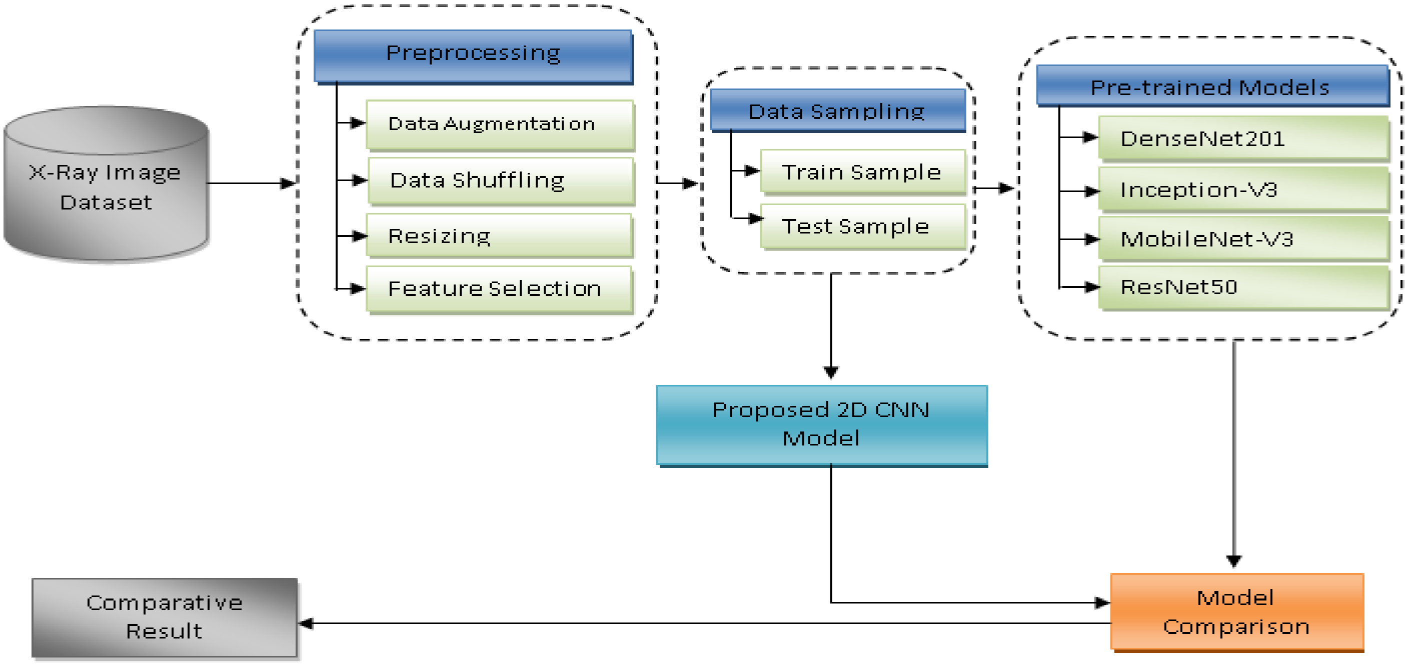

Fig. 1. Workflow of the proposed automated implant manufacturer classification method using X-ray radiograph.

### A. Dataset

The dataset used in this research was collected from various sources by the authors of [6, 10]. The initial sample collection includes 605 x-ray radiographs in the Joint Photographic Expert Group (jpeg) format with an 8-bit grey scale and variable sizes. Duplicate images from similar patients were removed from the collection, resulting in a new total of 597 samples spanning four manufacturers: Cofield with 83 sample images, Depuy with 294 sample images, Tornier with 71 sample images, and Zimmer with 149 sample images. The sources of the samples include the Feeley Lab and BIDAL lab at the Californian University and San Francisco state University. Other sources include the various websites of the implant manufacturers and the Common US Shoulder Prosthesis. Table I below shows the initial sample size and the augmented sample size used for training and validation of the pre-trained models and the proposed shallow 2D CNN model.

Fig. 2 shows samples of the respective classes of the dataset, which include Cofield, Depuy, Tornier and Zimmer implants.

TABLE I. Distribution of Dataset

| Implant Class | Initial Samples Size | Augmented Samples Size | Total Samples |
|---|---|---|---|
| Cofield | 83 | 217 | 300 |
| Depuy | 294 | 6 | 300 |
| Tornier | 71 | 229 | 300 |
| Zimmer | 149 | 151 | 300 |

### *B. Data Preprocessing*

This phase is one of the crucial steps in the proposed workflow. It helps improve the performance of the model, reduce the training time of the model, and prevent model overfitting. The preprocessing steps in the workflow include data augmentation, shuffling, resizing, and feature selection.

*1) Data augmentation:* The dataset used in this work consists of a few X-ray images with some imbalance among the classes. To improve the downstream performance of the proposed model and avoid poor approximation, we augment the X-ray images to create a bigger dataset for more generalization. To eliminate the class imbalance problem, a generative adversarial network (GAN) is used. GAN is one of the common approaches used by image generation functions to create artificial image data with similar characteristics to real image data. GAN is a multi-layer perceptron neural network consisting of generator (G) and discriminator (D) elements. The generator element generates data similar to the original data during the training, while the discriminator distinguishes between the generated and actual data. The generator element G takes in as input a random noise vector z and generates synthetic data G(z); the discriminator element D takes G(z) as input and outputs a probability D(G(z)) to distinguish between synthetic data and true data from the distribution. To train the generator and discriminator, a two-player min-max game is formed where the generator attempts to generate realistic data to fool the discriminator, whereas the discriminator attempts to distinguish between synthetic and real data. The objective function to be optimised is given as follows:

$$min_G max_D\ V(D,G) = E_{\mathrm{X}\sim \mathrm{P}_{data(X)}}[\log D(X)] + E_{\mathrm{Z}\sim \mathrm{P}_{Z(Z)}}\left[\log\left(1-D\left(G(Z)\right)\right)\right] \qquad (1)$$

To prevent the discriminator D from rejecting samples from the generator G with a close confidence of 1, we trained the generator G to maximiseD(G(Z)) so that the discriminator should not be able to distinguish between the synthetic and real data. To achieve the data augmentation, both horizontal and vertical shifts and random r were used.

*2) Data shuffling:* In this phase of preprocessing, the X-ray images from the various manufacturers were shuffled to ensure that each class of the manufacturer was represented in every batch. It helps the proposed model learn the various patterns in each epoch and increase the speed at which the model converges.

*3) Resizing and normalization:* In this stage of preprocessing, the images of prostheses belonging to various manufacturers were resized to a common dimension to fit the input of the model. Since the work employs various types of CNN with different input dimension requirements, the dimension of the training set was resized to 224 by 224 by 3 to accommodate the common dimensions of the variants of CNN. To assist in stabilising the problem of gradient propagation and speed up the training of the model, the image pixels are normalised to the range of 0 and 1.

*4) Feature selection:* To obtain highly discriminative features from the shoulder x-ray images with the potential to enhance the performance of the proposed 2D CNN model, principal component analysis (PCA) was used to reduce the dimension of the features. The choice of the PCA was attributed to its simplicity, efficiency, and well-known multivariate approach to feature extraction. PCA is a statistical approach that employs orthogonal transformation to transform observations of correlated features into a group of linearly uncorrelated features with the highest variance, called principal components. PCA generally attempts to determine lower-dimensional surfaces in order to project higher-dimensional data. In PCA, the principal component is directly connected to the size of the information to be retained. Therefore, to reduce data dimensionality using PCA, an appropriate number of principal components should be selected.

The PCA algorithm reduces a 2D matrix of image pixel values M with dimension A x B to another smaller matrix N with dimension A x P using a linear transformation U of dimension B x P. During the linear transformation process, information from the image data is retained. The transformation process is presented in Eq. (2) below.

$$N = U^T M \qquad (2)$$

where, A, B and P represents total pixels after masking, number of instances and the number of pixels such that A, P < B.The covariance $C_N$ of the output of the transformation process N is determined as follows:

$$C_N = \frac{1}{A} N^T N \qquad (3)$$

where $C_N$ is a matrix with dimension of P x P

The obtained covariance, $C_N$ is maximised to obtain an eigenvector with Lagrange multiplier λ , which is broken down into three matrices using matrix diagonalization. The decomposition process yields another matrix C, which is a product of the three matrices.

$$C = XDX^{-1} \qquad (4)$$

where, X and D represents the matrix of eigenvector and diagonal matrix consisting of Eigen values.

The overall variance of the transformation is therefore represented as the sum of the eigenvalues in Eq. (5) below:

$$N^{Total} = \sum_{i=1}^{B} \lambda_i \quad (5)$$

The percentage information retained by the PCA is calculated as follows:

$$I^R = \frac{\sum_{i=1}^{P} \lambda_i}{\sum_{i=1}^{B} \lambda_i} \quad (6)$$

where, $\sum_{i=1}^{P} \lambda_i$ represent the variance retained as the top P eigenvectors data from the subsets of the B vectors

### C. Data Sampling

At this phase, the x-ray datasets collected from sources are divided into train and test split. 20% of the dataset is made up of the test set, while 80% is made up of the training set. The models are trained using the training split, and they are validated using the validation split. The train and validation split is used to train and validate each of the pre-trained models and the proposed 2D CNN. The performance of the pre-trained models and the 2D CNN model is then evaluated using the test set.

### D. Pre-trained Models

In this phase, we trained different transfer learning models that are already pre-trained on very large datasets. Pre-trained models have been widely used to address numerous deep learning problems caused by inadequate labelled training data, improve the performance of Deep Neural Network and address problems in computer vision. The pre-trained models used in this paper include DenseNet201, InceptionV3, MobileNet, NasNet, ResNet50 and Xception.

*1) DenseNet201:* DenseNet [11] is a CNN that employs dense connections between the layers of the structure to reduce layer interdependencies by reusing feature maps from various layers. The shortcut connections of variable lengths between layers provide dense and differentiated input features that minimise the gradient disappearance problem in the deep networks [12]. The features from all the layers of DenseNet are finally used to make predictions on a standard dataset with better performance using small-size models with less computation effort. DenseNet has four different variants based on the depth of the layers. In this paper, the DenseNet201 variant, consisting of 201 densely connected layers, is used.

*2) InceptionV3:* Inception-V3 is a CNN architecture from the Inception family that employs a number of techniques to optimise the earlier versions of the architecture. The initial version of Inception (GoogleNet) employs multiple filters of varying sizes at the same level, thus reducing the size of the deep layer to parallel layers. Inception V1 was later refined by introducing batch normalisation for Inception V2 [13]. A number of factorizations were introduced in Inception V2 to form Inception V3. Inception V3 employs level smoothing, factorised convolutions, and an auxiliary classifier to communicate the class information to other layers of the network [14].

*3) MobileNet V3:* MobileNet V3 is a CNN architecture from the MobileNet family that employs a number of techniques to optimise the earlier versions of the architecture. The initial version of MobileNet reduced the number of parameters by using dept-wise convolution. In the second version of MobileNet, an expansion layer was introduced to obtain expansion filtering compression. MobileNet V3 introduces a squeeze and excitation layer to the initial building block of MobileNet V2, which later goes for further treatment. The squeeze and excitation layers result in unequal weights for the various channels from the input when generating the output feature maps.

*4) ResNet50:* The ResNet50 model is a deep convolution neural network consisting of 50 convolution layers, introduced by Microsoft in 2015 [15]. The ResNet50 model consists of approximately 26 million parameters, with the input of the ith layer directly connected to the (i+j)th layer. The ResNet50 model establishes its deep network by stacking additional layers on the input layer. In the residual network, residuals, which are the subtraction of features learned from the input, are learned rather than learning the features [16, 17].

### E. 2D CNN Model

Two-dimensional convolutional neural networks, or 2D CNNs, are a class of neural network architecture intended for the processing and analysis of two-dimensional structured data. Tasks involving grid-like data structures, like images, are especially well-suited for it. Image classification, object detection, and image segmentation are just a few of the computer vision tasks in which CNNs have demonstrated remarkable success. A 2D CNN uses convolutional and pooling layers to learn hierarchical features from input data (like images), then fully connected layers to make predictions. The architecture works well for tasks involving spatial relationships and patterns, especially in images, because it is made to automatically learn and extract pertinent features from the input.

The convolution operation is the main function of a 2D CNN. Convolutional layers are made up of filters, sometimes referred to as kernels, which move over the input data, such as an image, and multiply local regions element-wise to create feature maps.

Different characteristics or patterns found in the input data are captured by filters. For instance, deeper layers may capture complex patterns or high-level features, while earlier layers may learn basic features like edges or textures. A number of kernels are used in each convolution layer to determine the feature map tensor. Equation 7 below describes the operation of the convolution layer.

$$y_t = \mathrm{k}(x_t * w_t + b_t) \quad (7)$$

where, yt, k, xt, wt, and bt represents the output of the convolution layer operation, the activation function, the input vector, the layer weight and the bias of the filter or kernel. By using the activation function, the feature maps become more nonlinear. The Rectified Linear Unit (ReLU), which keeps the threshold input at zero, is a commonly used tool for activation computation. The operation is described as follows:

$$f(x) = \max(0, x) \tag{8}$$

The features that the convolution layer extracts have enormous dimensions. A pooling layer is added to reduce the cost of network training and solve the dimensionality issue in the convolution layer. To down sample the parameter sizes, the pooling layer uses the output of the previous convolution layer.

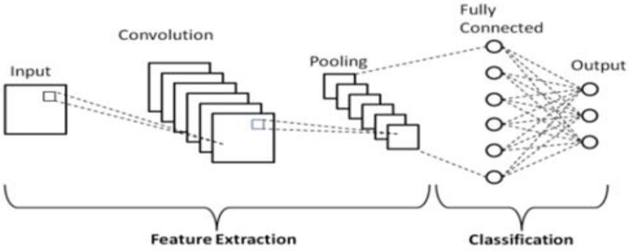

Fig. 3. Architecture of CNN [18].

The proposed 2D CNN used in the classification of implants consists of four (4) convolution layers consisting of the ReLu activation function, four (4) max pooling layers, one (1) flattening layer, a fully connected layer, and an output layer that uses Softmax as the activation function. The architecture and network topology of the proposed 2D CNN are presented in Fig. 4 and Table II, respectively.

TABLE II. NETWORK TOPOLOGY OF THE PROPOSED 2D CNN

| Layer | Type | Kernel Size | Stride | Activation Function | Dropout |
|---|---|---|---|---|---|
| Convolution Layer | Conv2D | 3 x 3 | 1 | ReLu | 0 |
| Convolution Layer | Conv2D | 3 x 3 | 1 | ReLu | 0.25 |
| Pooling Layer | Max Pooling | 2 x 2 | 2 | - | - |
| Convolution Layer | Conv2D | 5 x 5 | 1 | ReLu | 0 |
| Convolution Layer | Conv2D | 5 x 5 | 1 | ReLu | 0.5 |
| Pooling Layer | Max Pooling | 2 x 2 | 2 | - | - |
| Fully Connected Layer | - | - | - | - | - |
| Output Layer | - | - | - | Softmax | - |

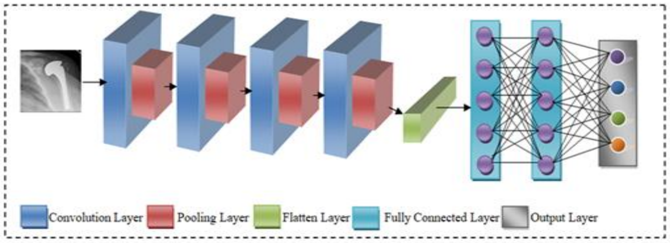

Fig. 4. Architecture of the proposed 2D CNN.

Fig. 4 shows the architecture of the proposed 2D Convolution Neural Network (CNN), consisting of the input image of a shoulder implant, the convolution layers, the pooling layers, the flattening layer, the fully connected layer, and the output layer, which classifies the implant based on the output obtained from the layers that precede it.

### F. *Performance Evaluation Metrics*

The performance indicators of the proposed 2D CNN and the pre-trained models are presented in equation 9 through 12 below:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{9}$$

$$Precision = \frac{TP}{TP+TN} \tag{10}$$

$$Recall = \frac{TP}{FN+TP} \tag{11}$$

$$F1\ Score = \frac{2(Sensitivity*Precision)}{Sensitivity+Precision} \tag{12}$$

## IV. EXPERIMENTAL RESULTS ANALYSIS

In this section, the experimental details and the results obtained are presented and discussed.

### A. *Experimental Setup*

In the experiment, the Total Shoulder Arthroplasty (TSA) dataset was split into training and testing sets in the ratio of 80:20. The proposed 2D Convolution Neural Network (CNN) consists of four (4) convolution layers with pooling layers, as described in Fig. 3 and Fig. 2, respectively. The 2D CNN network was implemented using Python version 3.10 and the Keras version 3.0.2 library with Tensorflow version 2.15 on a machine with an Intel (R) processor (Core (TM) i7 CPU @ 2.30 GHz) and 16GB of RAM. In addition, the proposed 2D CNN model was built using Jupyter Notebook and trained using the Graphic Processing Unit (GPU) of the Intel GTX 1050 Ti.

At the initial phase of the implementation, a Generative Adversarial Network (GAN) was built to augment the Total Shoulder Arthroplasty (TSA) dataset. The GAN augmentation approach is used to create artificial image data with similar characteristics to the real image data that resolve the data imbalance in the dataset. The parameter settings of the GAN model are presented in Table III.

TABLE III. PARAMETER SETTINGS FOR GAN NETWORK

| Parameter | Parameter Value |
|---|---|
| Convolution Layer | 2 |
| Filter Size | 5 x 5 |
| Activation Function | ReLu |
| Learning Rate | 0.0001 |
| Dropout | 0.25 |
| Optimizer | Adam |
| Loss Function | Binary Cross-entropy |
| Batch Size | 4 |

The real image data and the augmented data are combined to form a total of 1200 images belonging to 4 classes. To enhance the performance of the proposed 2D CNN, the Principal Components Analysis (PCA) method is applied to the compiled dataset. The PCA method extracts the features with the most important information that the model learns. At this stage, top features with a variance between 1 and 0.95 are considered for training the proposed 2D CNN.

The features extracted from the PCA are used to individually train the proposed 2D CNN and the pre-trained model, and the performance of the models is monitored for each feature. For each feature used to train the 2D CNN and the pre-trained model, different values were used for the hyper-parameters, and the optimal values were chosen. Table IV shows the various hyper-parameter configurations used and the chosen values.

TABLE IV. HYPER-PARAMETER CONFIGURATIONS

| Parameter | Options | Chosen |
|---|---|---|
| Input Shape | 64, 128, 224, 512 | 224 |
| Batch Size | 16, 32, 64, 128 | 64 |
| Learning Rate | 0.1, 0.01, 0.001, 0.0001 | 0.001 |
| Optimizers | SDG, RMSprop, Adam | Adam |
| Epoch | 10, 25, 50, 100 | 50 |
| Activation function | Sigmoid, Softmax, tanh | Softmax |

Based on the performance portrayed by the model using different hyper-parameter values, the final model was trained with an input shape of 224x224x3, a batch size of 64, a learning rate of 0.0001, and an Adam optimizer for 50 epochs.

## B. *Results Analysis*

Tables V through VII show the performance of the proposed 2D Convolution Neural Network (CNN) for individual classes corresponding to the various PCA sets. Based on the results in Tables V to VII, it can be observed that training the proposed 2D CNN with a dataset of the extracted features with a variance of 0.99 achieves greater performance than other features with a different variance. The model trained with extracted features with a variance of 0.99 achieved overall precision, recall, and a f measure of 99.2%.

Based on the performance results in Tables V, VI, and VII, the model trained with extracted features with a variance of 0.99 is better than models trained with extracted features with a variance of 0.95, 0.96, 0.97, 0.98, and 1, thus the model is considered for comparison with pre-trained models trained with extracted features with a variance of 0.99.

TABLE V. PRECISION OF PROPOSED FRAMEWORK WITH VARIANCE BETWEEN 0.95 AND 1.0

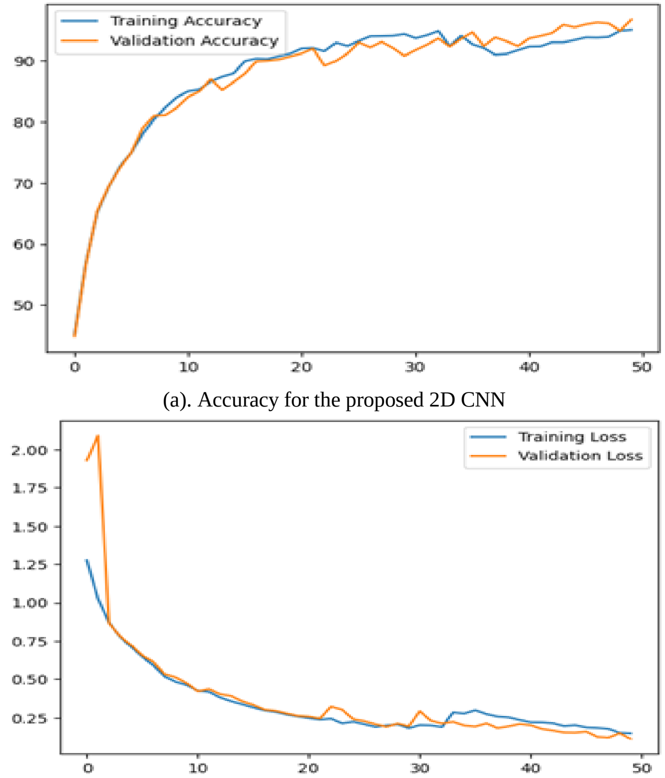
| Variance | Cofield | Depuy | Tornier | Zimmer | Overall |
|---|---|---|---|---|---|
| 1.0 | 0.987 | 0.972 | 0.978 | 0.977 | 0.979 |
| 0.99 | 0.992 | 0.992 | 0.992 | 0.992 | 0.992 |
| 0.98 | 0.987 | 0.972 | 0.978 | 0.977 | 0.979 |
| 0.97 | 0.987 | 0.972 | 0.978 | 0.977 | 0.979 |
| 0.96 | 0.987 | 0.972 | 0.978 | 0.977 | 0.979 |
| 0.95 | 0.987 | 0.972 | 0.978 | 0.977 | 0.979 |

TABLE VI. RECALL OF PROPOSED FRAMEWORK WITH VARIANCE BETWEEN 0.95 AND 1.0

| Variance | Cofield | Depuy | Tornier | Zimmer | Overall |
|---|---|---|---|---|---|
| 1.0 | 0.984 | 0.975 | 0.981 | 0.979 | 0.980 |
| 0.99 | 0.992 | 0.992 | 0.992 | 0.992 | 0.992 |
| 0.98 | 0.984 | 0.975 | 0.981 | 0.979 | 0.980 |
| 0.97 | 0.984 | 0.975 | 0.981 | 0.979 | 0.980 |
| 0.96 | 0.984 | 0.975 | 0.981 | 0.979 | 0.980 |
| 0.95 | 0.984 | 0.975 | 0.981 | 0.979 | 0.980 |

TABLE VII. F MEASURE OF PROPOSED FRAMEWORK WITH VARIANCE BETWEEN 0.95 AND 1.0

| Variance | Cofield | Depuy | Tornier | Zimmer | Overall |
|---|---|---|---|---|---|
| 1.0 | 0.989 | 0.975 | 0.980 | 0.982 | 0.982 |
| 0.99 | 0.992 | 0.992 | 0.992 | 0.992 | 0.992 |
| 0.98 | 0.989 | 0.975 | 0.980 | 0.982 | 0.982 |
| 0.97 | 0.989 | 0.975 | 0.980 | 0.982 | 0.982 |
| 0.96 | 0.989 | 0.975 | 0.980 | 0.982 | 0.982 |
| 0.95 | 0.989 | 0.975 | 0.980 | 0.982 | 0.982 |



(a). Accuracy for the proposed 2D CNN

(b). Loss for the proposed 2D CNN

Fig. 5. Accuracy and loss for the proposed 2D CNN trained with extracted features with variance 0.99.

Fig. 5 shows the training and validation accuracies and training and validation loss of the proposed 2D CNN trained with extracted features with a variance of 0.99.

Table VIII shows the performance of the proposed 2D CNN and the pre-trained models trained with extracted features of variance 0.99. Based on the performance results in the table, the proposed 2D CNN achieved a 99.79% recall and F1 score and 99.8% accuracy and precision. When compared with the pre-trained models, the 2D CNN recorded the best performance in terms of precision, recall, f1 score, and accuracy when trained with extracted features with a variance of 0.99 for 50 epochs.

TABLE VIII. PERFORMANCE COMPARISON OF PRE-TRAINED MODELS AND PROPOSED 2D CNN TRAINED WITH EXTRACTED FEATURES OF VARIANCE 0.99

| Metrics | DenseNet-201 | Inception-V3 | MobileNet-V3 | ResNet50 | Proposed 2D CNN |
|---|---|---|---|---|---|
| Precision | 97.96 | 98.1 | 98.2 | 91.2 | 99.8 |
| Recall | 97.99 | 97.9 | 97.2 | 91.4 | 99.79 |
| F Meassure | 97.65 | 98.1 | 98.2 | 91.2 | 99.79 |
| Accuracy | 97.4 | 97.8 | 98.2 | 92 | 99.8 |
| Training time (E-4) | 53.6 | 25.2 | 22.1 | 38.7 | 16 |
| Model Size (MB) | 80 | 92 | 15.3 | 98 | 4 |

Fig. 6 shows the graphical representation of the performance of the proposed 2D CNN and the pre-trained models trained using extracted features with a variance of 0.99. According to the performance comparison, it can be seen that the proposed 2D CNN recorded the minimum training time and memory size as compared to the pre-trained models. The 2D CNN achieves this due to the limited number of convolution layers in the model. On the contrary, the pre-train models have more depth than the 2D CNN, which results in large feature extraction activity at the convolution layers and more memory space to store the model.

Fig. 7(a) through e show the confusion matrix for the proposed 2D CNNs, MobileNetV3, InceptionV3, DenseNet201, and ResNet50, trained with extracted features with a variance of 0.99. Based on the figures, the 2D CNN recorded the least misclassification, with two images belonging to Zimmer misclassified as Tornier and another 2 misclassified as Depuy. Also, one image belonging to Cofield is misclassified as Zimmer, while all test samples belonging to Depuy and Tornier are correctly classified. MobileNetV3 became the second to the proposed 2D CNN, with 7 images belonging to Cofield and Zimmer misclassified as Tornier and Depuy. Also, InceptionV3, which achieves an overall accuracy close to MobileNetV3, recorded seven misclassifications for the Cofield, Tornier, and Zimmer classes, while all test samples from Depuy were correctly classified. The DenseNet201 model recorded 8 misclassifications, with 4 samples from Cofield misclassified as Depuy, Tornier, and Zimmer and the other 4 samples from Zimmer misclassified as Cofield. ResNet50 recorded a total of 9 misclassifications, with 4 images from Zimmer misclassified as Tornier, 2 from Tornier misclassified as Depuy, and 3 from Cofield misclassified as Depuy and Zimmer.

Table IX shows the performance comparison of the proposed 2D CNN with the state-of-the-art methods.

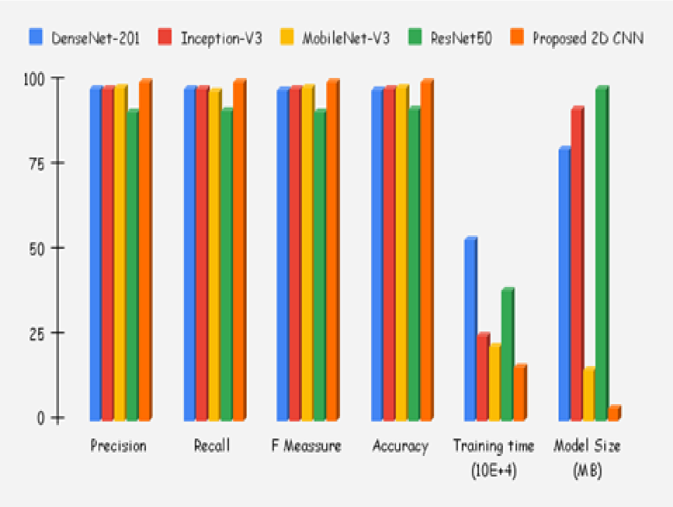


Fig. 6. Graphical representation of the performance of 2D CNN and pre-trained models.

## V. Discussion

By analysing the results obtained, it is demonstrated that feature extraction and data augmentation have a significant effect on the performance of the proposed model. The performance of the proposed model varies with variations in the extracted feature variance. This indicates that features with high information can be selected for model training to obtain the best performance. Aside from the increase in performance of the model when features with high information are used, the model has a lower training time and occupies less memory space as compared to the pre-trained models. This occurs as a result of the few network layers present in the proposed model, which is attributed to the reduced training time and memory space. Based on the performance presented in the result analysis section, the proposed system could differentiate between the manufacturers of the four shoulder implants with high accuracy. A comparison between the proposed 2D CNN and the state-of-the-art methods in terms of accuracy is shown in Table IX. From Table IX, it can be seen that some of the state-of-the-art methods [14–16, 18, 19] obtain slightly lower accuracy compared to the methods in [11–13] and the proposed method. Despite the promising performance displayed by these methods, the proposed 2D CNN recorded a significant improvement over the state-of-the-art methods, as depicted in Table V.

## VI. Conclusion

The number of shoulder replacements performed has spiked dramatically over the last few decades. Replacement surgery is typically required if an implanted prosthesis is inadvertently damaged or if specific problems arise with the operating shoulder. Knowledge about the prosthesis is necessary for its replacement process. In many instances, the surgeon closely inspects the prosthesis' x-ray image and visually compares it to existing images of prostheses from various manufacturers in order to determine the prosthesis' manufacturer. This method takes a lot of time and is highly susceptible to errors. This work proposes a shallow 2D Convolution Neural Network (CNN) for implant classification in order to prevent delays, lessen errors and complications in the conventional method, and guarantee robust, dependable, and time-efficient implant classification. To address the class imbalance in the dataset and improve the performance of the proposed 2D CNN, a generative adversarial network (GAN) is used to augment the implant images in the classes with low samples. Principal Component Analysis (PCA) is then applied to the initial and augmented datasets to extract highly discriminating features for model training. The GAN augmentation and PCA feature extraction have a significant impact on the model performance and training speed, as presented in the results section. The proposed 2D CNN recorded an overall accuracy of 99.8%, a training time of 16x104ms and 4MB of memory space, which outperformed the pre-trained models and other state-of-the-art deep learning models. The model in this work is limited to only four classes of prosthesis manufacturers, therefore cannot be generalized. In this feature, the model generalisation will be tested when more datasets are available and the results be compared with that of experts.

# Rolling Bearing Life Prediction Technology Based on Feature Screening and LSTM Model

Yujun Zhao
School of Intelligent Manufacturing, Nanyang Institute of Technology, Nanyang, 473000, China

***Abstract*—As one of the important components of industrial equipment, the health condition of rolling bearings will directly affect the operational effectiveness of the equipment. Therefore, to ensure equipment safety and reduce maintenance costs, an intelligent rolling bearing life prediction technology is proposed. Firstly, it extracts the fault information of rolling bearings and introduces Fisher score for feature selection. Simultaneously, a variational modal analysis method on the grounds of improved particle swarm optimization is introduced to achieve denoising of rolling bearing signals. Finally, an improved bidirectional long short-term model is introduced to construct a prediction model and achieve the life prediction of rolling bearings. In the performance analysis of the denoising model, the optimal modal component K value of the denoising model was obtained through experimental analysis as 3, and the optimal penalty factor number was 1000. In the time-domain signal analysis of the two models, the proposed model possesses a more excellent decomposition effect on the original signal compared to the comparative model, and the signal denoising ability is improved by 26.35%. In the prediction of rolling bearing life, the proposed model can accurately predict the early and late life of rolling bearings. For example, when the collection time is 100, the actual remaining life is 0.712, and the proposed model is 0.721, which is better than other models. In the comparison of average absolute error, the proposed model is 0.035, which outperforms other models. This indicates that the proposed rolling bearing life prediction model has excellent predictive performance. The research provides essential technical references for the maintenance of industrial machinery and equipment, as well as equipment life monitoring.**

***Keywords—Features; rolling bearings; prediction; fisher score; bidirectional long short term model***

## I. Introduction

As an important component of industrial equipment, rolling bearings (RB) are widely used in various mechanical equipment, such as automobiles, airplanes, trains, motors, etc. Its function is to provide support and rotation between the shaft and bearing seat, so the operating status of RBs will directly affect the efficiency and service life of the equipment [1]. However, the lifespan of RBs is influenced by various factors, like load, speed, temperature, lubrication status, etc. This can lead to premature wear, failure, and even damage of RBs, causing serious consequences to the equipment, increasing maintenance costs and production losses [2]. At present, commonly used RB life prediction techniques mainly include vibration analysis, acoustic diagnosis, temperature detection, etc. Vibration analysis is one of the most commonly used methods for detecting rolling bearing faults [3]. By measuring the vibration signal generated by rolling bearings to determine whether there is a fault, in actual diagnosis, the vibration signal is affected by environmental noise interference. In addition, the cost of collecting and analyzing vibration signals is high, and both need to be addressed [4]. Acoustic diagnosis is a method of diagnosing faults by analyzing the sound signals generated by rolling bearings. In practical applications, this method is susceptible to environmental noise and interference from complex working environments [5]. In order to solve the problem of insufficient diagnosis of traditional rolling bearings, a denoising technique was proposed and a model was established. Meanwhile, an intelligent RB life prediction technology was proposed. The technology proposed by the research institute has good resistance to noise and environmental interference, and is more stable than traditional technologies. This technology utilizes machine learning and data analysis methods for predicting the lifespan of RBs on the grounds of a large amount of real-time operating data. The innovation of the research lies in the introduction of a fusion improved feature selection and denoising technology, which significantly improves the training effect of the model on RBs. Secondly, an optimized prediction model is proposed for enhancing the accuracy and stability of the model by training the selected feature data. The research has two significance. Firstly, intelligent RB life prediction technology can detect faults and problems of RBs in advance, reduce equipment maintenance costs and production losses; On the other hand, this technology can provide reference for the design and manufacturing of RBs, optimize the structure and materials of bearings, and improve the service life and performance of bearings.

The research content consists of six sections. Section I is the introduction. Related work is given in Section II. Algorithm model is discussed in Section IV. Discussion is given in Section V. Section VI summarizes the entire text, and elaborates on the improvement direction.

## II. Related Work

Life prediction can help people have a clearer understanding of the operating status of mechanical equipment and improve its working efficiency. In recent years, artificial intelligence has experienced rapid development, and deep learning based life prediction of RBs has become a research hotspot. Cheng et al. found that nearly half of motor failures are caused by the degradation of rolling element bearings. So, a new data-driven framework was proposed for bearing life prediction. Firstly, the original vibration of the training bearing is processed using the Hilbert Huang transform. Then, it uses convolutional models to identify feature data and achieve degradation estimation of the test bearings. Finally, the effectiveness of the method was verified through specific experiments, and it is superior to similar methods and has good application effects [6]. Liu H et al. proposed a new end-to-end residual service life prediction method on the grounds of feature attention. This study directly applies feature attention mechanism to input data, dynamically assigning greater attention weights to more important features, thereby improving predictive performance. Next, the study employs bidirectional gated recursive units for feature association learning. The experiment showcases that the proposed method possesses more advantages compared to similar technologies [7]. Liu Y Q et al. found that smooth wear is often overlooked, but it is one of the main causes of bearing failure, especially in locomotives. So, a locomotive track model with traction power transmission was adopted to study motor wear from the perspective of contact stress and relative slip at the raceway interface. The outcomes demonstrate that the wear of the inner ring of the motor bearing is relatively uniform. In addition, the increase in surface wear of the motor will increase internal power and worsen the vibration of the traction motor and its adjacent components in the locomotive [8].

In recent years, artificial intelligence has experienced rapid development, and deep learning based life prediction of RBs has become a research hotspot. Qin Y et al. proposed a new gated dual attention unit model for forecasting the remaining service life of RBs. Firstly, a series of root mean square values are calculated as health indicator vectors on the grounds of the full life vibration data of RBs. Then, it uses health indicators to predict lifespan. Through experimental analysis, it is shown that the proposed technology can accurately predict the health status of bearings, providing important suggestions and references for the maintenance and use of industrial bearings [9]. Althubaiti A et al. proposed an intelligent bearing prediction model. This model uses convolutional models to extract motor fault feature data, and uses a degradation index for label training. By training labels through the model, the bearing life prediction is achieved. Through relevant experimental analysis, it has been shown that the proposed technology can accurately predict bearing life and performs better than similar technologies [10]. Hu R et al. proposed a data-driven bearing life diagnosis technology, which uses a guided deep subdomain adaptive network for data feature collection, and then introduces a transfer learning model for parameter feature training. Finally, it selects four mainstream technologies for comparison. The experiment shows that the proposed technology possesses excellent application effects in practical scenarios and is superior to other life prediction models [11]. Wang B et al. found that the accuracy and generalization ability of bearing prediction technology are affected due to the lack of clear learning mechanisms. Therefore, they proposed a new multi-scale convolutional attention network framework. Firstly, it constructs a self attention module for fusing multi-sensor data, and then adopts a multi-scale learning strategy to learn representations at different time scales. Comparing the proposed technology with relevant technologies, the proposed technology has excellent application effects [12].

In summary, the above research analyzed the commonly used life prediction techniques and explored their application effects. Meanwhile, the current popular intelligent bearing life prediction technology is analyzed, and the above technologies have excellent application effects in practical scenarios. However, the above research techniques have not fully utilized the fault characteristics of bearings, so an intelligent bearing life prediction technology is proposed to meet the requirements of industrial manufacturing development.

## III. Construction of a Life Prediction Model for RBs

This section mainly extracts and screens the time-domain features of RBs, and proposes an improved signal denoising technique to address the problem of characteristic signal noise points. Finally, it constructs an improved RB life prediction technology and establishes relevant models.

### A. Extraction and Screening of RB Features

RBs are one of the important components in industrial manufacturing, with a large number of applications in automotive engines, motors, and industrial machinery. RBs use rolling elements to roll between the inner and outer rings, reducing friction and sliding on the contact surface, thereby achieving smooth rotational motion [13]. The relevant diagram of the RB is indicated in Fig. 1.

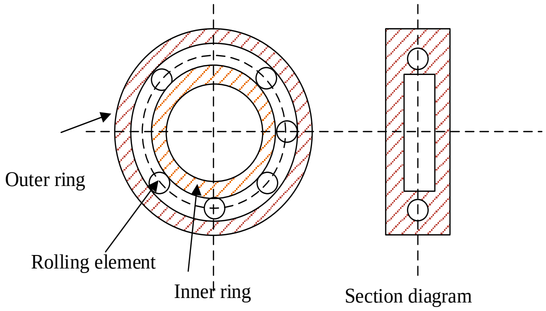

Fig. 1. Schematic diagram of RBs.

The service life of RBs will continuously decrease during long-term operation, and effective prediction of the service life of RBs is the key to ensuring the stable use of mechanical equipment. Therefore, a method for predicting the lifespan of RBs is proposed, which first extracts the time-domain feature information of RB features [14]. Time domain features are a series of indicators used to describe the characteristics of a signal in the time domain, mainly including dimensional features and non-dimensional features. These features include the mean of the bearing signal, the fluctuation amplitude of the signal, the vibration amplitude of the signal, and other characteristics, which can effectively reflect the operating status of the bearing [15]. It assumes the vibration signal $x(t)$ of a RB, where $t$ represents time. The goal of the study is to extract some key time-domain features from these signals to reflect the state of the bearings. Firstly, the study can calculate the mean $\mu$ of the signal, which represents the concentrated trend of the signal, as shown in Eq. (1).

$$\mu = \frac{1}{T}\int_0^T x(t)dt \tag{1}$$

Among them, $T$ is the duration of the signal. Next, the study can calculate the variance $\sigma^2$ of the signal, which represents the degree of signal dispersion, as shown in Eq. (2).

$$\sigma^2 = \frac{1}{T}\int_0^T (x(t)-\mu)^2 dt \tag{2}$$

The larger the variance, the greater the degree of dispersion of the signal. In addition to mean and variance, this study can also calculate other time-domain features such as Peak Value, Peak-to-Peak Value, Skewness, and Kurtosis. The peak represents the maximum or minimum value of the signal, as shown in Eq. (3).

$$PeakValue = \max(x(t)) - \min(x(t)) \tag{3}$$

The Peak-to-Peak Value represents the amplitude range of signal vibration, as shown in Eq. (4).

$$PeakToPeakValue = \max(x(t)) - \min(x(t)) \tag{4}$$

Skewness measures the asymmetry of signal distribution, as shown in Eq. (5).

$$Skewness = \frac{1}{T}\int_0^T \left(\frac{x(t)-\mu}{\sigma}\right)^3 dt \tag{5}$$

By calculating these time-domain features, research can extract information related to the bearing state from the signal. However, bearings work in harsh environments for a long time, and the environment is complex and variable, resulting in non-stationary characteristics in the signals monitored by sensors, which affects the effectiveness of feature extraction [16]. There are many commonly used feature selection methods, including variance selection and chi square test, to further screen the extracted features. This study adopted the Fisher score feature selection method mainly because it can handle non-linear features and has better feature processing effects [17]. The given feature set is $\{f_1, f_2, \ldots, f_n\}$, with $c$ class feature samples $x_j \in R^m$, where $j = 1, 2, \ldots, N$. If the class distance between the $i$ features of the training sample is defined as $S_b(f_i)$, and the class distance between the $k$ -class sample and the $i$ -th feature $f_i$ is defined as $S_\omega^{(k)}(f_i)$, then $S_b(f_i)$ is expressed as Eq. (6).

$$S_b(f_i) = \sum_{k=1}^{c} n_k (m_i^{(k)}) - m_i) \tag{6}$$

In Eq. (6), $n_k$ represents the number of $k$ -class samples, $m_i^{(k)}$ represents the mean of $k$ -class samples under the $i$ -th feature, and $m_i$ is the mean under the $i$ -th feature. The expression of $S_\omega^{(k)}(f_i)$ is shown in Eq. (7).

$$S_\omega^{(k)}(f_i) = \sum_{j=1}^{n_k} (x_{ij}^{(k)} - m_i^{(k)})^2 \tag{7}$$

In Eq. (7), $x_{ij}^{(k)}$ serves as the value of the $j$ -th sample in $i$ features $f_i$ of the k-th class of samples. When the value of class distance $S_b(f_i)$ is larger, the better the distance $S_\omega^{(k)}(f_i)$ between $c$ classes, and the $i$ -th feature value of the training sample can be obtained, as shown in Eq. (8).

$$F(f_i) = \frac{S_b(f_i)}{\sum_{k=1}^{c} S_\omega^{(k)}(f_i)} = \frac{\sum_{k=1}^{c} n_k (m_i^{(k)} - m_i)}{\sum_{k=1}^{c}\sum_{j=1}^{n_k} (x_{ij}^{(k)} - m_i^{(k)})^2} \tag{8}$$

By using the above methods, the identification of imbalanced feature categories can be achieved. On the grounds of the differences in degraded features of the same class, redundant features can be removed to filter out the main features.

### B. Construction of Denoising Model on the Grounds of Improved VMD

Predicting the service life of RBs is beneficial for the stable operation of equipment and improving its service life. In the prediction of rolling shaft bearings, it is necessary to evaluate the bearing life by extracting bearing vibration signals and characterizing degradation features. However, the original signal features contain a lot of noise, so a Variational Mode Decomposition (VMD) model is used for denoising [18]. VMD is an adaptive signal processing method with advantages such as high accuracy and strong noise resistance. Among them, the Intrinsic Mode Function (IMF) is represented as an unstable amplitude modulated frequency modulation signal, as shown in Eq. (9).

$$\begin{cases} u_k(t) = A_k(t)\cos(\phi_k(t)) \\ \omega_k(k) = \phi'(t) = \dfrac{d\phi_k(t)}{d(t)} \end{cases} \tag{9}$$

In Eq. (9), $u_k(t)$ represents the harmonic signal, $A_k(t)$ represents the amplitude of $u_k(t)$, and $\omega_k(k)$ represents the frequency of $u_k(t)$. There are two parts in the construction of VMD model, including variational model and variational model solving. When constructing a variational model, it is necessary to convert $u_k(t)$ into an explanatory variable, as shown in Eq. (10).

$$u_k(t) = (\delta(t) + \frac{j}{\pi t} \times u_k(t)) \tag{10}$$

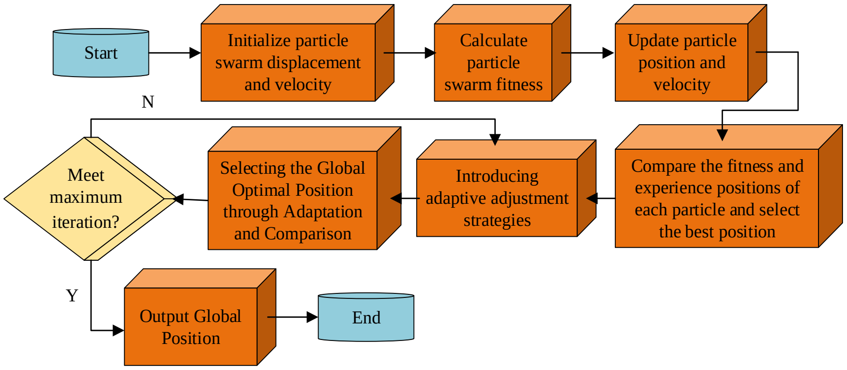
In Eq. (10), $\delta(t)$ is the analytical component, and the modal component bandwidth is obtained by the time gradient L2 norm of the component, as showcased in Eq. (11).

$$\| \partial_t \left[ \delta(t) + \frac{j}{\pi t} \times u_k(t) \right] e^{-j\omega_k t} \|_2^2 \tag{11}$$

In Eq. (11), $e^{-j\omega_k t}$ is the exponential signal and $\partial_t$ is the derivative symbol. The penalty factor $\alpha$ and the guaranteed constraint multiplication operator $\lambda(t)$ are introduced to solve the variational model, as shown in Eq. (12).

$$L(u_k,\omega_k,\lambda)=\alpha\sum_k\left\|\partial_t\left[\delta(t)+\frac{j}{\pi t})\right]e^{-j\omega_k t}\right\|_2^2+\left\|f(t)-\sum_k u_k(t)\right\|_2^2+\langle\lambda(t),\ f(t)-\sum_k u_k(t)\rangle \tag{12}$$

In Eq. (12), $k$ represents the $k$-th modal component, where, $f(t)$ is the signal target. When VMD denoises signals, the number of decompositions K and the penalty coefficient have a significant impact on the signal decomposition effect. Both large or small values can easily filter important fault information. Therefore, to better denoise bearing signals in VMD, an improved Self-adaptation Particle Swarm Optimization (SPSO) algorithm is introduced for optimizing the problem [19]. The process of constructing the SPSO model is shown in Fig. 2.



Start
Initialize particle swarm displacement and velocity
Calculate particle swarm fitness
Update particle position and velocity
N
Compare the fitness and experience positions of each particle and select the best position
Introducing adaptive adjustment strategies
Selecting the Global Optimal Position through Adaptation and Comparison
Meet maximum iteration?
Y
Output Global Position
End

Fig. 2. Schematic diagram of SPSO model process.

The SPSO model adaptively updates the weights and particle velocities of the original particle swarm model, improving the overall training accuracy of the model. To optimize the main information loss problem of VMD signal denoising, the weighted average of bearing signal differences is used as the function optimization objective. The signal difference method is used to calculate the difference between signal data. The smaller the signal difference, the higher the signal similarity, thus screening useful information. The expression of signal difference is showcased in Eq. (13).

$$SDA=\frac{1}{N}\sum_{i=1}^{n}(y_{IMFS}-y_s) \tag{13}$$

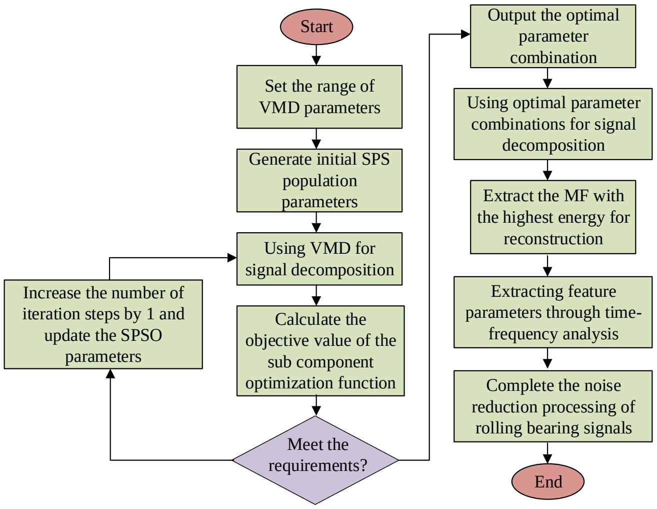
In Eq. (13), $y_{IMFS}$ is the sum of the $K$ signal components, $y_s$ represents the original signal, and the final signal average is obtained through weighted processing, as shown in Eq. (14).

$$WSDA=SDA+\frac{K\times SDA}{\beta} \tag{14}$$

In Eq. (14), $\beta$ represents the weighted penalty parameter. The entire bearing signal denoising process is shown in Fig. 3.

### C. Construction of a RB Life Prediction Model on the Grounds of Improved LSTM

To effectively predict the service life of RBs, a Bi-directional Long Short-Term Memory (BiLSTM) model is introduced on the grounds of the extracted RB feature data to construct a prediction model. Compared to traditional one-way LSTM models, it can capture more feature details and has better feature expression ability. Therefore, the extracted feature parameters of RBs are used as inputs for BiLSTM, and the life prediction of RBs is achieved through training. The structural principle of the BiLSTM model is shown in Fig. 4.



Start
Set the range of VMD parameters
Generate initial SPS population parameters
Using VMD for signal decomposition
Calculate the objective value of the sub component optimization function
Meet the requirements?
Increase the number of iteration steps by 1 and update the SPSO parameters
Output the optimal parameter combination
Using optimal parameter combinations for signal decomposition
Extract the MF with the highest energy for reconstruction
Extracting feature parameters through time-frequency analysis
Complete the noise reduction processing of rolling bearing signals
End

Fig. 3. Bearing signal denoising process on the grounds of SPSMO-VMD

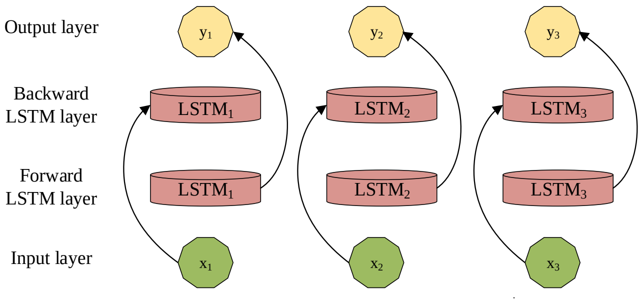


Fig. 4. Schematic diagram of BiLSTM structure.

The BiLSTM model draws on the characteristics of bidirectional recurrent networks, and can effectively learn time series features through the LSTM model. In model construction, it mainly consists of a forward LSTM and a backward LSTM. The outputs of the two LSTM models are weighted, and the model training prediction results are obtained by learning past information from the data. The output expression of the forward LSTM model is shown in Eq. (15).

$$\overrightarrow{H_t} = \overline{LSTM}(h_{t-1}, x_t, c_{t-1})\ t_r \in \left[1, T_r\right] \tag{15}$$

In Eq. (15), $h_{t-1}$ represents the output at the previous time point, $x_t$ represents the direct input, $c_{t-1}$ represents the cell state at the previous time point, and $t_r \in \left[1, T_r\right]$ represents the time interval. The backward LSTM output is shown in Eq. (16).

$$\overleftarrow{H}_t = \overline{LTM}(h_{t+1}, x_t, c_{t+1}) t \in \left[1, T\right] \tag{16}$$

According to Eq. (16) and Eq. (15), the updated expression of the BiLSTM model can be obtained, as shown in Eq. (17).

$$H_t = \left[\overrightarrow{h_t}, \overleftarrow{h_t}\right] \tag{17}$$

In Eq. (17), $\overrightarrow{h_t}$ and $\overleftarrow{h_t}$ represent forward and backward LSTM outputs, respectively. In actual model training, BiLSTM is also prone to parameterization problems due to structural feature factors. Therefore, the study introduces the Adam algorithm to optimize the BiLSTM prediction model. The Adam algorithm has advantages such as high computational efficiency and easy implementation, and can obtain the optimal solution of the model in a short period of time. Parameter optimization is shown in Eq. (18).

$$\delta^* = arm \min_{\delta} S(f(x_r, \delta)) \tag{18}$$

In Eq. (18), $\delta^*$ represents the optimized BiLSTM model parameters, $\delta$ represents the current model parameters, $x_r$ represents the input parameters, $S(\cdot)$ represents the objective function, and $f(\cdot)$ represents the network output. Then it initializes the first-order moment $g_t$ and the second-order moment $h_t$ at time $t$, and obtains the result as shown in Eq. (19).

$$\begin{cases} g_t = \mu * g_{t-1} + (1-\mu) * m_t \\ h_t = v * n_{t-1} + (1-\mu) * m_t^2 \end{cases} \tag{19}$$

In Eq. (19), $\mu$ is a value of 0.9, $v$ defaults to a value of 0.999, and $m_t$ represents the gradient at time $t$. The expression of parameter $\delta$ is shown in Eq. (20).

$$\delta = \delta - \eta = \frac{g_t}{\sqrt{\hat{h}_t} + \varepsilon} \tag{20}$$

In Eq. (20), $\eta$ represents the learning rate, $\varepsilon$ ranges from 10 to 8, and $\hat{h}_t$ is expressed as shown in Eq. (21).

$$\hat{h}_t = \frac{h_t}{(1-v)} \tag{21}$$

Through the above research, the initial parameter optimization of the BiLSTM model can be achieved. Meanwhile, it is necessary to consider the problem of too many network parameters in the research. Model training with too many parameters can easily fall into overfitting problems, which can affect the actual prediction performance of the model. In this regard, the Dropout mechanism is introduced for solving the model overfitting. By performing the above operations, the problem of overfitting in the model can be solved, thereby constructing a RB prediction model on the grounds of improved BiLSTM [20]. The life prediction of the entire RB is showcased in Fig. 5.

## IV. Algorithm Model Simulation Testing

This section mainly conducts simulation performance analysis on the proposed denoising model and RB life prediction model. This includes parameter optimization testing of VMD models, performance comparison analysis of denoising models, and life prediction analysis of RBs.

### A. *Simulation Analysis of Denoising Model Performance*

To verify the proposed residual life prediction technology for RBs, experimental testing will be conducted on the WINDOWS 10 64 bit platform. The processor is INTEL i7, with a running memory of 64GB, and simulation experiment analysis is completed on the Matlab platform. The initialization parameters of the experimental model are showcased in Table I.

In the performance analysis of denoising models, the SPSO algorithm is used to optimize the parameter combination of the VMD model. Meanwhile, Empirical Mode Decomposition (EMD) is introduced as the testing benchmark. In the experiment, the original signal was decomposed at 1KHz. The original time-domain waveform signal is shown in Fig. 6.

TABLE I. MODEL INITIAL PARAMETERS

| Parameter indicator type | Numerical value |
|---|---|
| Sampling rate | 1HKz |
| Number of input nodes | 3 |
| Number of output layer nodes | 1 |
| Number of hidden layer nodes | 256 |
| Prediction step size | 40 |
| Learning rate | 0.01 |

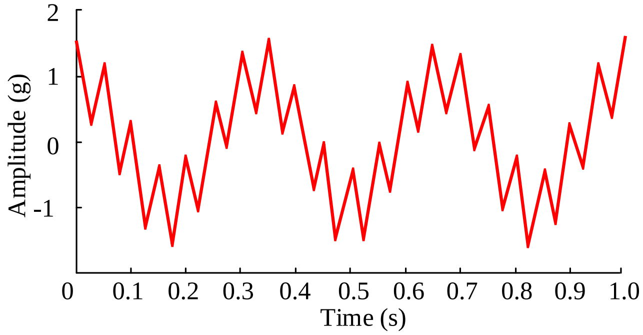

Fig. 6. Time domain waveform of the original signal.

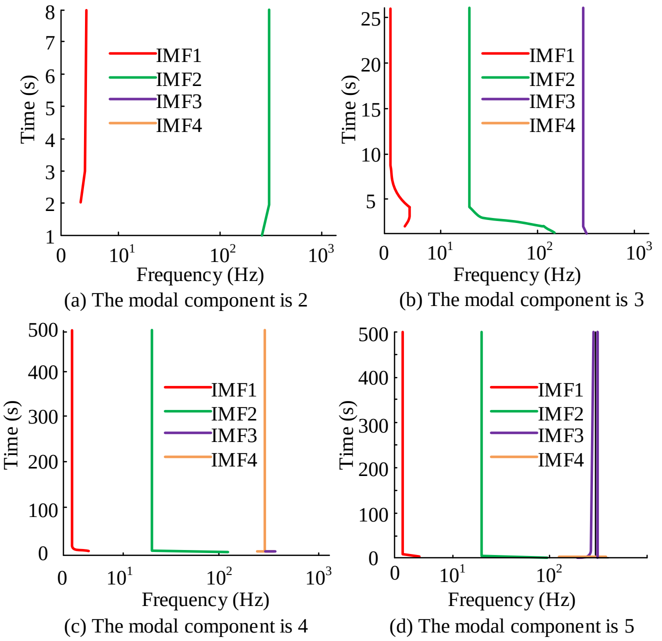
In actual signal filtering and decomposition, the number of modal components K will have a direct impact on the decomposition effect of the VMD model. Setting the K value too small can lead to incomplete signal decomposition, while setting the K value too large can cause partial information loss in the RB. Therefore, the decomposition effect of VMD under different K values will be analyzed, as shown in Fig. 7.



(a) The modal component is 2

(b) The modal component is 3

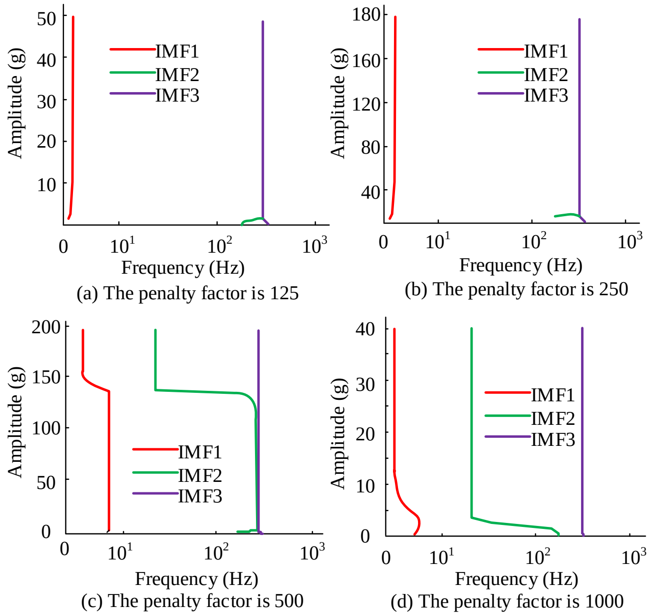
(c) The modal component is 4

(d) The modal component is 5

Fig. 7. Center frequency plots of each component under different modes K.

Fig. 7 (a) shows the center frequency maps of each component when K value is 2. It is evident that the cosine signal with a center frequency of 3Hz and the cosine signal with a center frequency of 300Hz can be seen, but the decomposition is not complete, and mode mixing phenomenon occurs. Fig. 7 (b) shows the center frequency plots of each component at K=3. It can be clearly seen that the center frequencies of the IMF can be effectively separated, and there is no overlap of the four IMF center frequencies. The overall decomposition effect is excellent. Fig. 7 (c) shows the center frequency plots of each component at K=4. According to the data results, IMF1 represents a 3Hz cosine signal, while IMF3 represents a 20Hz cosine signal. However, during the actual decomposition process, excess IMF2 appeared, and the center frequencies between IMF2 and IMF3 overlapped. Fig. 7 (d) shows the center frequency maps of each component at K=5, which is consistent with Fig. 7 (c). During the decomposition process, there were excess IMF3 signals and IMF4. In addition, the value of the penalty factor $\alpha$ will also affect the decomposition effect of VMD, as shown in Fig. 8.

Fig. 8 (a) to 8 (d) were tested with penalty factors of 125, 250, 500, and 1000, respectively. When the penalty factor is 125, there is aliasing between IMF2 and IMF3, resulting in VMD being unable to effectively decompose the original signal. When the penalty factor is 250, both IMF2 and IMF3 exhibit aliasing phenomenon. When dividing the penalty factors into 500 and 1000, as the quantity of penalty factors grows, the problem of overlapping center frequencies reduces, but it will increase the difficulty of VMD operation. When the penalty coefficient is 500, the center frequency overlap problem has been significantly improved. Considering the model decomposition effect and computational time, the penalty factor will be set to 1000 in subsequent experiments, and the modal component K value will be set to 3. It selects EMD for signal decomposition comparison, as shown in Fig. 9.



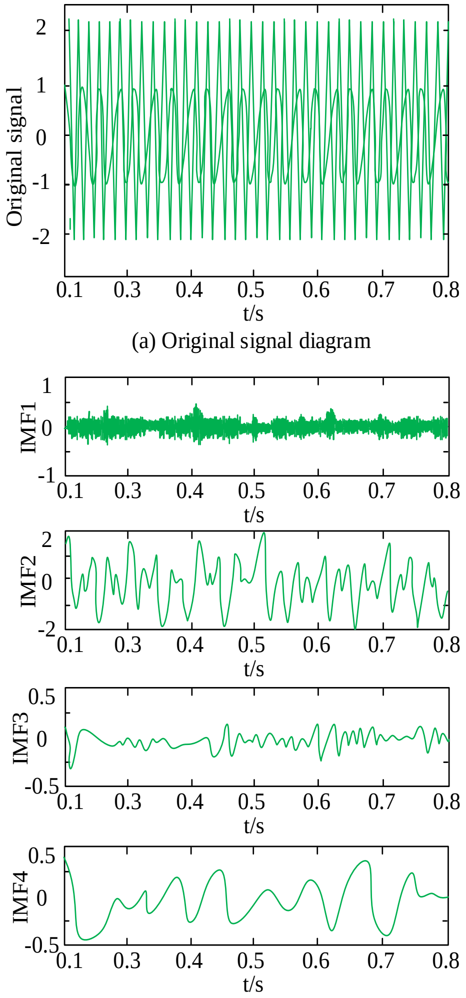
(a) The penalty factor is 125

(b) The penalty factor is 250

(c) The penalty factor is 500

(d) The penalty factor is 1000

Fig. 8. VMD decomposition center frequency results under different penalty factors.



(a) Original signal diagram

(b) EMD decomposition results

Fig. 9. Time domain diagram of EMD decomposition simulation signal.

Fig. 9 shows the time-domain simulation results of EMD decomposition. Among them, Fig. 9 (a) is the original signal graph, and Fig. 9 (b) is the EMD decomposition result. According to the data results, setting the number of modal layers to 4 resulted in four types of mixed signals. In IMF1 signal analysis, obvious fluctuations can be seen from the image. As the sampling time increases, there are still significant fluctuations in the waveform and mode aliasing phenomenon exists. In IMF2, IMF3, and IMF4, as the sampling time increases, there are still significant fluctuations in the three components of the signal, which cannot maintain the original waveform of the signal. In addition, incomplete decomposition and mode aliasing occur during the decomposition process. It uses VMD to analyze the original signal, as shown in Fig. 10.

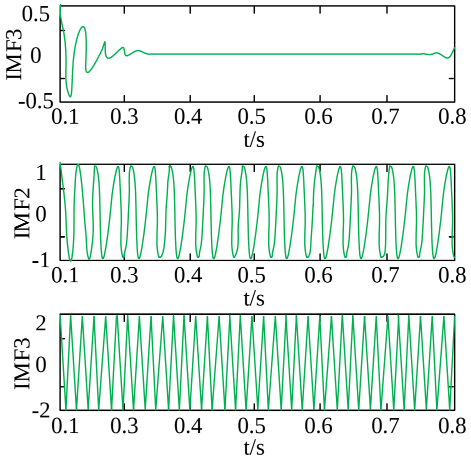


Fig. 10. Time domain diagram of VMD decomposition simulation signal.

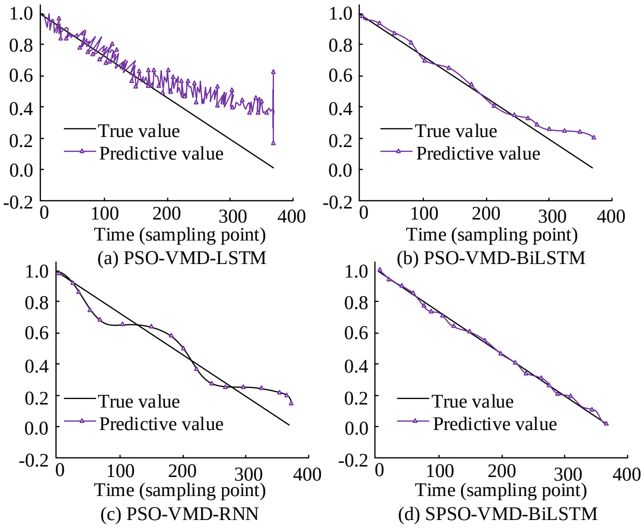
Fig. 10 shows the time-domain results of VMD decomposition simulation signals. Due to setting the modal component K to 3, three modulus decomposition results were obtained, corresponding to IMF1, IMF2, and IMF3, respectively. Compared with the original image 9 (a), it can be found that VMD can accurately decompose the original signal, and there is no aliasing problem during the decomposition process. It can maintain the original signal waveform, and the decomposed component waveform is basically consistent with the original time-domain waveform. Therefore, it can be concluded that VMD has excellent decomposition performance in the original time-domain signal decomposition, and performs better in signal decomposition compared to the EMD model, with a 26.35% improvement in signal denoising ability.

### *B. Simulation Performance Analysis of RB Life Prediction*

In the prediction of the service life of RBs, a total of 1356 samples will be selected from the data collected and feature screened during the experimental process. The samples include early degradation data of RBs, mid-term degradation data, and severe degradation data, accounting for 40%, 30%, and 30%, respectively. In the sample data, radial force will have a negative impact on the vibration of RBs, so the lateral vibration signal is selected for reflecting the degradation phenomenon of RBs. In the life cycle monitoring of RBs, the characteristic changes in the early stage are relatively stable, and there will be obvious fluctuations in the later stage, which will have a significant impact on the life prediction of different models. Therefore, the Particle Swarm Optimization (PSO) optimized VMD combined Long Short Term Memory (LSTM) model, PSO optimized VMD combined BiLSTM model, PSO optimized VMD combined Recurrent Neural Network (RNN) model, and the proposed SPSO-VMD BiLSTM model were selected for comparison. The predicted life of the roller bearing is shown in Fig. 11.



(a) PSO-VMD-LSTM

(b) PSO-VMD-BiLSTM

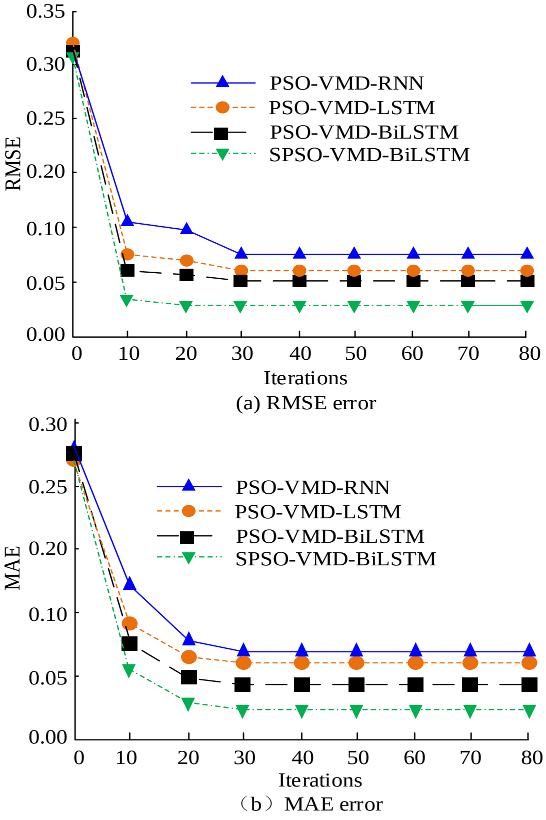
(c) PSO-VMD-RNN

(d) SPSO-VMD-BiLSTM

Fig. 11. Comparison of life prediction for RBs using multiple models.

Fig. 11(a) to 11(b) show PSO-VMD-LSTM, PSO-VMD-BiLSTM, PSO-VMD-RNN, and SPSO-VMD-BiLSTM, respectively. In the comparison of the four models, it can be found that except for the PSO-VMD-RNN model, the other three models have high prediction accuracy in the early stages. When the sampling time is 100, the actual remaining lifespan is 0.712. PSO-VMD-LSTM predicts a remaining lifespan of 0.735, PSO-VMD-BiLSTM predicts a remaining lifespan of 0.731, and PSO-VMD-RNN predicts a remaining lifespan of 0.698. The proposed model possesses a prediction accuracy of 0.721, and the overall prediction accuracy of the proposed model is the best. In the later stage, the problem of roller bearing failures increases, and only SPSO-VMD-BiLSTM can accurately predict the model life. Compared with PSO-VMD-RNN, PSO-VMD-LSTM, and PSO-VMD-BiLSTM, the prediction accuracy of SPSO-VMD-BiLSTM increased by 35.65%, 18.65%, and 12.35%, respectively. It introduces Root Mean Squared Error (RMSE) and Mean Absolute Error (MAE) for comparing the predictive performance of different models, as shown in Fig. 12.

Fig. 12(a) and 12(b) show the comparison results between RMSE and MAE, respectively. In RMSE error comparison, the RMSE errors of SPSO-VMD-BiLSTM, PSO-VMD-LSTM, and PSO-VMD-BiLSTM when they tend to converge are 0.031, 0.062, 0.078, and 0.083, respectively. In MAE error comparison, the error values of SPSO-VMD-BiLSTM, PSO-VMD-LSTM, and PSO-VMD-BiLSTM towards convergence are 0.035, 0.051, 0.071, and 0.078. It demonstrates that the proposed model possesses lower errors and more excellent prediction performance in the prediction of roller bearings. Finally, a comprehensive performance comparison is conducted, as shown in Table II.



(a) RMSE error

（b）MAE error

Fig. 12. Comparison of errors among different models.

TABLE II. COMPREHENSIVE COMPARISON RESULTS OF DIFFERENT METHODS

| Period | Method Type | Prediction accuracy | Time consuming（s） |
|---|---|---|---|
| Rolling bearings in the early stage | PSO-VMD-RNN | 0.856 | 3.25 |
| | PSO-VMD-LSTM | 0.863 | 3.54 |
| | PSO-VMD-BiLSTM | 0.905 | 2.54 |
| | SPSO-VMD-BiLSTM | 0.966 | 2.42 |
| Rolling bearing mid-term | PSO-VMD-RNN | 0.873 | 3.56 |
| | PSO-VMD-LSTM | 0.886 | 3.45 |
| | PSO-VMD-BiLSTM | 0.925 | 3.05 |
| | SPSO-VMD-BiLSTM | 0.965 | 2.75 |
| Late stage of rolling bearings | PSO-VMD-RNN | 0.856 | 3.65 |
| | PSO-VMD-LSTM | 0.878 | 3.45 |
| | PSO-VMD-BiLSTM | 0.895 | 3.12 |
| | SPSO-VMD-BiLSTM | 0.956 | 2.89 |

Table II compares the life prediction results of different methods in three periods of rolling bearings. According to the test results, whether in the early, middle, or later stages, the research model still has the highest prediction accuracy, all above 0.950. In addition, the prediction time of different models was compared, and the overall time consumption of the research model was shorter, indicating that the technology proposed in the study has better performance effects.

## V. Discussion

Fault diagnosis of rolling bearings is an important step in ensuring the normal operation of industrial equipment. Compared with similar technologies, the proposed research method has excellent diagnostic performance for rolling bearing faults. In addition, this study will also compare the proposed model with the techniques proposed in study [9] and [10]. Compared with the technique proposed in reference [10], this technique proposes a sparse data based rolling bearing state prediction technique, which can reduce the dependence of diagnostic models on sparse data and achieve bearing diagnosis under sparse data. Compared with study [9], due to better noise reduction processing of the data in the early stages and increased analysis of rolling bearing fault factors, the research technology for fault diagnosis is more accurate than reference [9]. In the later life prediction of rolling bearings, the predicted life of the research model is 0.256, while the study [9] is 0.268. The research model is closer to the actual results and has higher accuracy. Meanwhile, a comparison was made between the diagnostic techniques in study [10]. Reference [10] proposed a rolling bearing life prediction technique based on a deep learning framework, which achieves fault diagnosis through the fusion of multi-sensor data. The technology proposed in study [10] is highly dependent on signal data and requires a large amount of data for training during the diagnostic process, which is slower compared to the data processing of research models. In the early prediction of rolling bearings, the prediction accuracy of study [10] reached 0.956, which is close to the research model. However, in the mid to late stage of prediction, the accuracy of the research model can still reach above 0.90. Due to the complexity of data processing, the prediction accuracy in study [10] has significantly decreased.

Overall, this study proposes a deep learning based rolling bearing life prediction method, which has good application effects. Compared with current research techniques, its stability and accuracy in predictive diagnosis have shown good results. Therefore, this method has broad application prospects in the field of rolling bearing fault diagnosis.

## VI. Conclusion

RBs are one of the most critical components in modern industrial fields. Due to the influence of working environment factors, effective life prediction of RBs is crucial for the safe operation of equipment. In this regard, a research proposes an intelligent RB life prediction technology, which first extracts time-domain and another feature information of the RB, and selects the main feature information through Fisher score. Simultaneously improving the SPSO model to optimize VMD and achieve denoising processing of roller bearing information. Finally, on the grounds of BiLSTM, a life prediction model for RBs is constructed for monitoring the life of RBs. In the performance experiment of the denoising model, the optimal modal component K value and penalty factor were obtained through comparison, with values of 3 and 1000, respectively. In time-domain signal decomposition testing, the improved VMD model has a better signal decomposition effect compared to the EMD model, with a 26.35% increase in signal denoising ability. In the prediction of RB life, when the sampling time is 100, the actual remaining life is 0.712. PSO-VMD-LSTM predicts the remaining life as 0.735, PSO-VMD-BiLSTM predicts the remaining life as 0.731, and PSO-VMD-RNN is 0.698. The proposed model possesses a prediction accuracy of 0.721, and the overall prediction accuracy of the proposed model is the best. In addition, the proposed model exhibits the best performance in both RMSE error and MAE error. It demonstrates that the proposed technology possesses excellent predictive performance in predicting the lifespan of RBs. The research model also has limitations. The model mainly focuses on the working conditions of RBs and does not consider other factors that may affect the lifespan of rolling bearings, such as humidity and lubrication conditions. Further analysis is needed in the future to improve the prediction accuracy of the model.

# Retrieval-Augmented Generation Approach: Document Question Answering using Large Language Model

Kurnia Muludi[1], Kaira Milani Fitria[2]*, Joko Triloka[3], Sutedi[4]
Informatics Engineering Graduate Program, Darmajaya Informatics and Business Institute, Bandar Lampung, Indonesia

***Abstract*—This study introduces the Retrieval Augmented Generation (RAG) method to improve Question-Answering (QA) systems by addressing document processing in Natural Language Processing problems. It represents the latest breakthrough in applying RAG to document question and answer applications, overcoming previous QA system obstacles. RAG combines search techniques in vector store and text generation mechanism developed by Large Language Models, offering a time-efficient alternative to manual reading limitations. The research evaluates RAG's that use Generative Pre-trained Transformer 3.5 or GPT-3.5-turbo from the ChatGPT model and its impact on document data processing, comparing it with other applications. This research also provides datasets to test the capabilities of the QA document system. The proposed dataset and Stanford Question Answering Dataset (SQuAD) are used for performance testing. The study contributes theoretically by advancing methodologies and knowledge representation, supporting benchmarking in research communities. Results highlight RAG's superiority: achieving a precision of 0.74 in Recall-Oriented Understudy for Gisting Evaluation (ROUGE) testing, outperforming others at 0.5; obtaining an F1 score of 0.88 in BERTScore, surpassing other QA apps at 0.81; attaining a precision of 0.28 in Bilingual Evaluation Understudy (BLEU) testing, surpassing others with a precision of 0.09; and scoring 0.33 in Jaccard Similarity, outshining others at 0.04. These findings underscore RAG's efficiency and competitiveness, promising a positive impact on various industrial sectors through advanced Artificial Intelligence (AI) technology.**

***Keywords*—Natural Language Processing; Large Language Model; Retrieval Augmented Generation; Question Answering; GPT***

## I. INTRODUCTION

This research proposes a new approach to the increasing reliance on articles and journal documents by introducing a Question-Answering (QA) document processing system [1]. The identification of several critical problems motivates this research. The problems motivating this research are multifaceted. Firstly, manual reading and processing to comprehend document text are time-consuming, error-prone, and inefficient. Secondly, previous methods employed to modify Large Language Models (LLM) for document processing demanded substantial resources and were challenging to implement widely. Lastly, models relying solely on the capabilities of LLM for QA systems without modifications tend to generate hallucinatory answers, lacking correctness and precision. Manual processing for document understanding leads to time-consuming efforts, susceptibility to human error, and inefficient analysis processes. Based on previous methods, the use of modified Large Language Models (LLM) for document processing requires significant resources and poses challenges for widespread implementation. Also, the underutilization of the recently discovered Retrieval Augmented Generation (RAG) method, particularly in document processing within Question-Answering (QA) systems, provides an opportunity for further exploration. The motivation stems from the challenges associated with manual document processing, resource-intensive Large Language Model (LLM) modifications, and the underutilization of the Retrieval-Augmented Generation (RAG) method in the document-based question-answering domain [2], [3]. In addition, there is a tendency to produce hallucinatory responses that lack accuracy and precision in models that rely solely on LLM capabilities for QA systems without modifications. Finally, the implementation of RAG in QA systems for document processing offers the untapped potential to improve the ability of the system to produce accurate and non-hallucinatory responses.

Building on this line of research, this paper proposes the implementation of the Retrieval Augmented Generation model for document question answering tasks, specifically using the ChatGPT model. RAG, introduced in 2021 [4], addresses the limitations of previous methods by merging parametric and non-parametric memory. This hybrid model seamlessly integrates generative capabilities with data retrieval mechanisms, linking language models to external knowledge sources. RAG combines generative capabilities and the ability to search for data and incorporate relevant information from the knowledge base in the model. The distinct advantages of RAG lie in its ability to adapt to dynamic data, its flexibility in working with external data sources, and its ability to mitigate hallucinatory responses [5]. These characteristics make RAG particularly suitable for QA tasks on internal organizational documents by leveraging external knowledge to reduce response hallucinations [6].

The current research aims to exploit the innovative approach of RAG to construct an application capable of automatically processing external text documents. The focus of this research is to develop an application system capable of processing external document text uploaded by the user. The system will automatically read the document text, allowing users to input questions related to the document. Subsequently, the system provides answers based on the processed document text, eliminating the need for manual reading to find answers. This comprehensive solution not only overcomes the limitations of previous methods, but also promises to significantly speed up research and study exploration in various domains.

Testing of the proposed model is performed, like several previous QA-based studies, by calculating the suitability of the answer results provided by the model with the ground truth of the test dataset. Some of the metrics used to calculate the performance of this model include Accuracy, ROUGE, BLEU, BERTScore, and Jaccard Similarity.

## II. Related Works

This study examines the applicability of RAG, its impact on the document processing task, and compares it to the previous methods. This research also investigates the capability of the large language model within the ChatGPT systems, gpt-3.5-turbo within the framework of RAG. This work also highlights the development of Artificial Intelligence (AI) and Natural Language Processing (NLP), so this research focuses on the improvement of intelligence and the capabilities of applications [7], [8], [9]. Machine Learning and Deep Learning algorithms, which include BERT Base, and Text-to-Text Transfer Transformer (T5) models, and RAG method, have made significant advances in QA tasks [4], [10], [11], [12]. This research motivated the implementation of RAG for processing documents, integrated into an interactive QA system.

Between 2015 and the present, the evolution of question-answering (QA) systems shows a trajectory characterized by diverse methodologies. Starting with semantic parsing-based systems in 2015, Wen-tau Yih et al. focused on transforming natural language queries into structured logical forms, achieving a performance of 52.5% in the F1-score [2]. Subsequent knowledge-based paradigms (KB-QA) by Yanchao Hao et al. in 2017 reformulated questions as predicates, achieving a performance of 42.9% [3]. Progress has been made in integrating AI technologies. Caiming Xiong's exploration of dynamic memory networks (DMN) in 2016, achieved an accuracy of 28.79% [7]. In the same year, Minjoon Seo et al.'s Bi-Directional Attention Flow (BiDAF) framework demonstrated significant performance with a 68% exact match and 77.3% F1 score, albeit with a computational time of 20 hours [8]. Adams Wei Yu et al. introduced the QANet model in 2018, with a performance of 76.2% exact match and 84.6% F1-Score, within a shorter computational time of 3 hours [9]. As QA systems evolve, in 2019 Wei Yang et al. applied fine-tuning methods with data augmentation techniques, achieving remarkable results with a modified BERT-Base model of 49.2% for exact match and 65.4% for F1-Score [10]. Colin Raffel et al. introduced the Text-to-Text Transfer Transformer (T5), with impressive performance of 63.3% for exact match, 94.1% for F1 score, and a peak accuracy of 93.8%, albeit with an increased number of parameters of 11 billion [11]. In 2020, the focus was on fine-tuning pre-trained models, with Adam Roberts et al. achieving a recall performance of 34.6% using the T5 model [12]. The Retrieval-Augmented Generation (RAG) method, which combines parametric and non-parametric methods, was introduced by Patrick Lewis et al. in 2021. RAG has demonstrated its capabilities in open domain QA tasks, overcoming previous limitations to deliver more efficient and comprehensive QA systems [4].

Large language model called GPT, or Generative Pre-Trained Transformer was developed by OpenAI. Previous research that has compared the performance of ChatGPT with other large language models like PaLM and LLaMA in open-domain QA tasks indicates that ChatGPT consistently achieves the highest scores across various open-domain QA datasets [13]. Table I presents performance comparisons among LLMs.

TABLE I. LLM Performance on Open Domain QA Dataset

| Model | TriviaQA | WebQuestion | NQ-Open |
|---|---|---|---|
| PaLM-540B (few-shot) | 81.4 | 43.5 | 39.6 |
| PaLM-540B (zero-shot) | 76.9 | 10.6 | 21.2 |
| LLaMA-65B (zero-shot) | 68.2 | - | 23.8 |
| ChatGPT (zero-shot) | 85.9 | 50.5 | 48.1 |

The PolyQuery Synthesis test, which identifies multiple queries within a single-query prompt and extracts the answers to all of the questions from the model's latent representation, also shows that ChatGPT outperforms other GPT models from OpenAI (ada-001, babbage-001, curie, and davinci) in terms of accuracy [13]. According to the evaluations, the gpt-3.5-turbo model has been selected for implementation in this research.

## III. Research Method

This research undergoes a development phase, starting with designing the application system and integrating the APIs of ChatGPT, LangChain and FAISS. Subsequent stages include extensive system modeling, interface testing and data preparation using the proposed dataset and the SQuAD dataset. The testing phase, which includes a performance comparison with other applications using ground truth metrics (ROUGE, BERTScore, BLEU and Jaccard Similarity), guides the exploration of the capabilities of the proposed system, as shown in Fig. 1.

### A. RAG Integration

Retrieval Augmented Generation (RAG) combines retrieval and generation models. It uses a Large Language Model (LLM) to generate text based on commands and integrates information from a separate retrieval system to improve output quality and contextual relevance [14]. The mechanism involves retrieving factual content from a knowledge base via retrieval models and using generative processes to provide additional context for more accurate output [15]. External data sources are used, and the numerical representation is facilitated by embedding methods to ensure compatibility. Based on Fig. 2, user queries converted into embeddings are compared with vectors from the knowledge library. Relevant context is added to the queries before they are fed into the base language model.

Fig. 1. Research flow diagram.

OpenAI, the creator of the Large Language Model GPT, conducted a comprehensive number of RAG experiments, exploring various implementations such as cosine similarity retrieval, chunk/embedding experiments, reranking, classification steps, and prompt engineering, as depicted in Fig. 3. OpenAI's findings, presented in Fig. 3, revealed that RAG implementation with prompt engineering achieved the highest accuracy, positioning it as the most effective RAG technique to date [16]. This discovery serves as a catalyst for the integration of RAG with prompt engineering using the LangChain module.

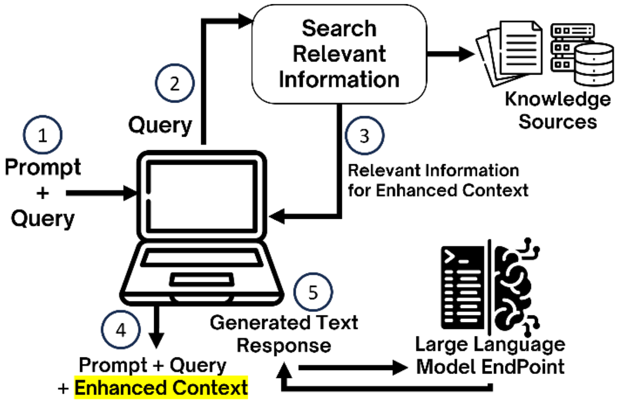

Fig. 2. RAG mechanism with LLM.

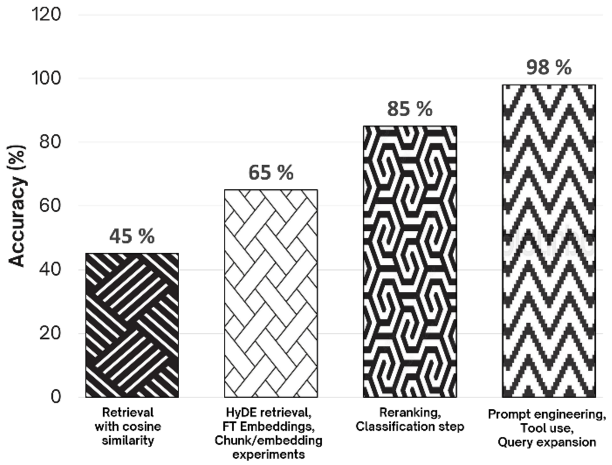

Fig. 3. Accuracy of the RAG method by Open AI.

LangChain provides a robust data processing pipeline that utilizes FAISS to perform an efficient retrieval operation in the VectorDB. The query phase transforms inputs into vectors for database searches, and prompt engineering enhances the reusability of retrievals. Output parsers interpret LLM outputs, ensuring consistency [17]. A highly efficient similarity search and vector clustering library, Facebook AI Similarity Search or FAISS [18]. It optimizes the trade-off between memory, speed and accuracy, allowing developers to effectively navigate multimedia documents. The mechanism involves the construction of an index for efficient storage, with vector searches retrieving the most similar vectors using cosine similarity scores [19].

### B. *Proposed Model*

This research employs a modified Large Language Model (LLM), ChatGPT, augmented with additional libraries to function as a Question-Answering (QA) system capable of processing external documents for supplementary information.

The chosen methodology for QA system development is the Retrieval Augmented Generation (RAG) mechanism. Unlike previous approaches such as semantic parsing-based, knowledge-based, and fine-tuning using LSTM or other DL algorithms, RAG addresses shortcomings like difficulty expanding or revising model memory, an inability to provide direct insight into generated predictions, and a tendency to produce hallucinative answers [12]. The solution involves the creation of a hybrid model, merging generative and retrieval models, which forms the basis for the RAG method. RAG offers advantages such as adaptive responses to dynamic data, flexibility with external data sources, and minimization of hallucinative responses [5]. Thus, RAG is chosen to construct a text document-based QA system interacting with users through a chatbot interface. The system's workflow, implemented using RAG and supporting libraries like LangChain and FAISS, is illustrated in Fig. 4.

The integration of the LangChain framework into the QA document system includes document loading, memory management, and prompting to connect to the LLM model. The process starts with document loading, followed by document splitting into text chunks. These text chunks undergo word embedding, converting them into vectors stored in the vector database. Simultaneously, user-inputted text questions are embedded and converted into word vectors. The system connects these vectors to the vector database, performing a semantic search and ranking the relevance between vectors. The semantic search results in relevant context between questions and answers. The system retrieves pertinent answers based on user queries and sends them to the LLM (using the ChatGPT model). The final outcome involves the system receiving LLM-generated answers and delivering them to the user. The application system interacts with users, requiring an interface connecting the user and the system. Mockups, design layouts, and elements for the web application are created using the Streamlit framework, facilitating rapid development and sharing of the AI model web application. The mockup for the application system and user interaction within the system is depicted in Fig. 5.

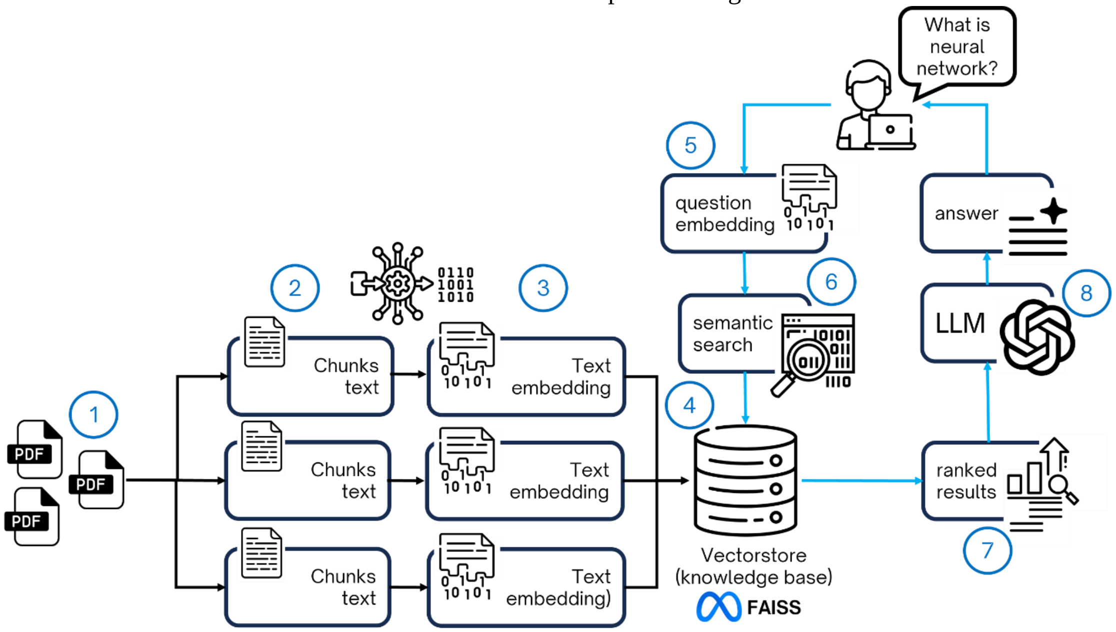

Fig. 4. Integration of langchain framework in RAG for the proposed document QA system.

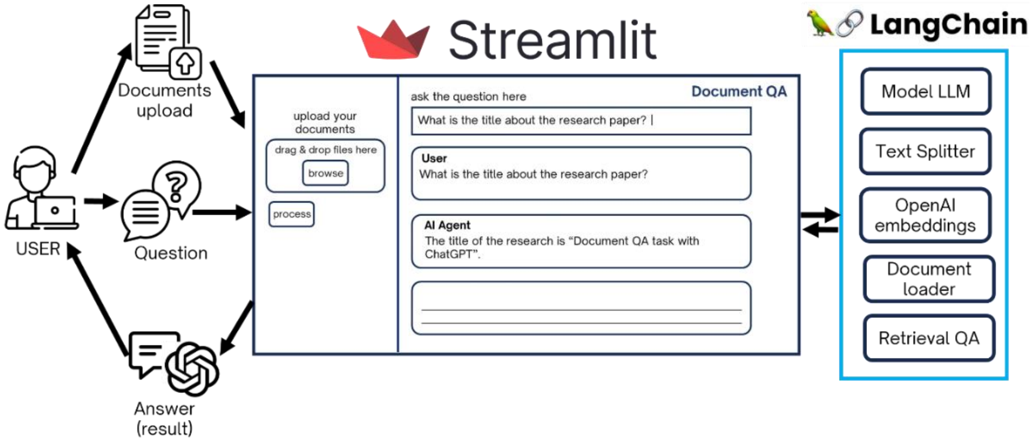

Fig. 5. Mockup of the application system and user interaction for the app.

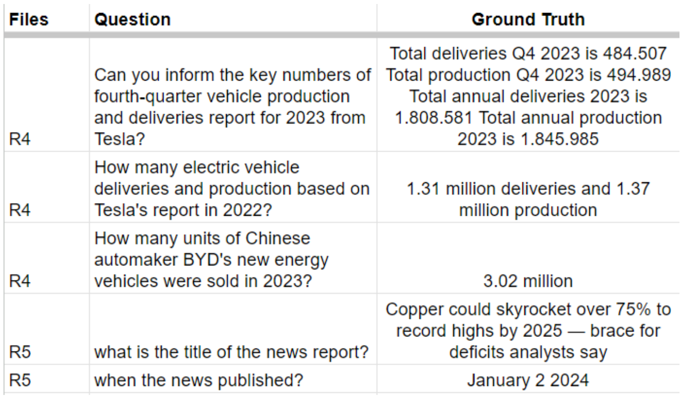
### *C. Proposed Dataset DocuQA*

The proposed dataset, DocuQA, designed for application-based question-answering systems that process document inputs, consists of 20 diverse documents, encompassing journal articles, news reports, financial documents, and tutorials. Each document file includes five questions with corresponding ground truth answers, enabling a thorough evaluation of QA system capabilities, with a total 100 questions in the dataset. DocuQA consists of journal documents with calculations and formulas, news documents with specific titles, financial reports and news documents with numbers and currency data, and tutorial documents with step-by-step instructions. Accuracy can be calculated based on the correct answers out of 100, providing a metric for information extraction accuracy. The dataset aims to challenge QA systems in understanding context, identifying keywords, and efficiently extracting specific information, offering a robust evaluation tool for developers and researchers across various document and question types. The dataset can be accessed publicly [20].

Proper citation of the dataset is encouraged for research or projects using DocuQA to ensure appropriate credit is given. The preview of the DocuQA dataset can be seen in Fig. 6.



| Files | Question | Ground Truth |
|---|---|---|
| R4 | Can you inform the key numbers of fourth-quarter vehicle production and deliveries report for 2023 from Tesla? | Total deliveries Q4 2023 is 484.507 Total production Q4 2023 is 494.989 Total annual deliveries 2023 is 1.808.581 Total annual production 2023 is 1.845.985 |
| R4 | How many electric vehicle deliveries and production based on Tesla's report in 2022? | 1.31 million deliveries and 1.37 million production |
| R4 | How many units of Chinese automaker BYD's new energy vehicles were sold in 2023? | 3.02 million |
| R5 | what is the title of the news report? | Copper could skyrocket over 75% to record highs by 2025 — brace for deficits analysts say |
| R5 | when the news published? | January 2 2024 |

Fig. 6. Preview of the DocuQA test dataset.

### *D. Testing and Evaluation*

The tests were performed on two types of test datasets, with DocuQA [20] and SQuAD 1.1 [21]. DocuQA is a dataset originally created by this research, consisting of 100 questions with the ground truth and a total of 20 test documents for document-based QA systems. In addition, the SQuAD dataset was used in the form of modified pdf documents that can be used to test the QA system's ability to process documents and retrieve information based on the questions and related ground truth in the SQuAD dataset. Both types of test datasets will be tested on the QA system developed in this research, and also on other commercial QA systems that process pdf documents, such as typeset.io. The results of these tests will give an idea of the QA system performance built on this research, whether it is superior to other document-based QA applications.

The proposed QA document processing system is evaluated through rigorous testing using established metrics such as ROUGE or Recall-Oriented Understudy for Gisting Evaluation, BERTscore, BLEU or Bilingual Evaluation Understudy, and Jaccard Similarity. These metrics provide reliable benchmarks for assessing the system's performance across various dimensions. The testing process involves two key variables. "Predictions RAG" and "Prediction Others" represent the test results from the developed application and comparable commercial applications, respectively. Both sets of predictions are compared to the ground truth data, which is encapsulated in the "references" variable. Different aspects of language models and question answering systems are evaluated using different metrics. ROUGE measures the overlap in summarization [22]. BERTscore assesses semantic similarity using contextual embeddings [23]. BLEU evaluates n-gram precision [24], and Jaccard Similarity compares text similarity based on word or n-gram overlap [25]. Precision in question answering systems is commonly assessed through accuracy, F1 score, and precision metrics, providing insights into their effectiveness. The metrics are used to quantitatively evaluate system performance and establish its superiority over existing commercial applications in document processing and information retrieval tasks.

*1) Accuracy:* Accuracy is defined as the proportion of correct responses from the total number of responses. Accuracy can be calculated by calculating the percentage of correct predictions over the total number of references [26]. In essence, accuracy represents the ability of the system to provide correct answers, which is expressed as a percentage using the following formula (see Eq.(1)).

$$\text{Accuracy}=\frac{\text{correct predictions}}{\text{all predictions}}\times 100\% \qquad (1)$$

This metric serves as a valuable indicator of the overall correctness of the model in the response it generates.

*2) ROUGE:* Recall-Oriented Understudy for Gisting Evaluation can be used to evaluate the text generation models, which are based on the measurement of the overlap between candidate text and reference text [27]. ROUGE has several measurement variants, each depending on the number of overlapping n-grams. The ROUGE-L variant is the most widely used, because it uses the longest sequence or longest common subsequence or LCS with the longest word sequence that both sentences have. Precision refers to the proportion of n-grams in the candidate that are also in the reference (see Eq. 2.). Recall, on the other hand, refers to the proportion of n-grams that are in the reference text that exactly match in the predicted candidate text as shown in Eq. (3). The F1-score can be calculated from the precision and recall as shown in Eq. (4).

$$\text{ROUGE-L}_{\text{recall}}=\frac{\text{LCS (candidate, reference)}}{\text{\#words in reference}} \qquad (2)$$

$$\text{ROUGE-L}_{\text{precision}}=\frac{\text{LCS (candidate, reference)}}{\text{\#words in candidate}} \qquad (3)$$

$$\text{ROUGE-L}_{\text{F1-Score}}=2\times\frac{\text{recall}\cdot\text{precision}}{\text{recall}+\text{precision}} \qquad (4)$$

where, the reference is based on the ground truth in the test dataset, and the candidate is from the system predictions. The score generated by the ROUGE measure is between 0 and 1. A score of 1 indicates total agreement between reference and candidate text.

*3) BERTScore:* BERTScore is an automatic evaluation metric in text generation tasks that evaluates the similarity of each candidate sentence token to each reference sentence token by means of contextual embeddings [23]. The embeddings in BERTScore are contextual, changing depending on the sentence context. The context awareness allows BERTScore to score semantically similar sentences despite their different sentence order. For the recall calculation, each token in $x$ is matched with the most similar token in $\hat{x}$, as for the precision calculation. Greedy matching is used to maximize the similarity score. The values of precision (see Eq. (5)), recall (see Eq. (6)) and F1 score (see Eq. (7)) for reference $x$ and candidate $\hat{x}$ can be calculated using the following equations.

$$\mathrm{R_{BERT}} = \frac{1}{|\mathrm{x}|}\sum_{\mathrm{x_i} \in \mathrm{x}} \max_{\hat{\mathrm{x}}\mathrm{j} \in \hat{\mathrm{x}}} \mathrm{x_i^\top \hat{x}_j} \tag{5}$$

where, $R_{BERT}$ is the Recall BERTScore, $x$ is the reference token, $\hat{x}$ is the candidate token, $x_i$ is the sequence vector $x$, $x_j$ is the sequence vector $\hat{x}$, where $\Sigma_{x_i \in x}$ is the number of $x_i$ present in $x$, and also $\max_{\hat{x}_j \in \hat{x}}$ is the maximum value of $\hat{x}_j$ present in $\hat{x}$, and $x_i^\top \hat{x}_j$ is the cosine similarity of $x$ and $\hat{x}$.

$$\mathrm{P_{BERT}} = \frac{1}{|\hat{\mathrm{x}}|}\sum_{\hat{\mathrm{x}}_\mathrm{j} \in \hat{\mathrm{x}}} \max_{\mathrm{xi} \in \mathrm{x}} \mathrm{x_i^\top \hat{x}_j} \tag{6}$$

Given $P_{BERT}$ as Precision BERTScore, $x$ as reference token, $\hat{x}$ as candidate token, $x_i$ as sequence vector $x$, $\hat{x}_j$ as sequence vector $\hat{x}$, where $\Sigma_{\hat{x}_j \in \hat{x}}$ is the number of $\hat{x}_j$ present in $\hat{x}$, and also $\max_{x_i \in x}$ is the maximum value of $x_i$ present in $x$, and $x_i^\top \hat{x}_j$ is the cosine similarity of $x$ and $\hat{x}$.

$$\mathrm{F_{BERT}} = 2 \times \frac{\mathrm{P_{BERT}} \cdot \mathrm{R_{BERT}}}{\mathrm{P_{BERT}} + \mathrm{R_{BERT}}} \tag{7}$$

where $F_{BERT}$ is the F1-score of BERTScore, then $P_{BERT}$ is the precision and $R_{BERT}$ is the recall from BERTScore results. Although the cosine similarity value is theoretically in the interval [-1, 1], in practice the value is rescaled so that it is between 0 and 1 in the result of the BERTScore calculation.

*4) BLEU:* Bilingual Evaluation Understudy is a metric that computes a modification of precision for n-grams, combines it with weights, and applies a brevity penalty to obtain the final BLEU score [28]. The score range of BLEU is from 0 to 1. The greater the BLEU score, the better the system's performance is considered to be compared to the references. The formula for calculating BLEU can be seen in Eq. (8).

$$\mathrm{BLEU} = \mathrm{BP} \cdot \exp\left(\sum_{\mathrm{n}=1}^{\mathrm{N}} \mathrm{w_n} \log \mathrm{p_n}\right) \tag{8}$$

$BP$ represents the brevity penalty, adjusting the score to penalize translations shorter than the reference. $N$ denotes the maximum number of considered n-grams. The precision for n-grams, denoted as $p_n$ signifies the n-grams ratios by the candidate text that appearing in any reference translation to the total of n-grams in the candidate text. $w_n$ represents the weight assigned to each n-gram precision score.

*5)* The Jaccard similarity quantifies the similarity percentage between two sets of data by identifying the common and the different members [29]. This can be calculated by dividing the number of observations shared by the sum of the observations in each of the two sets. Jaccard similarity can be expressed as the ratio of the intersection $(A \cap B)$ to the union $(A \cup B)$ of two sets (see Eq. (9)).

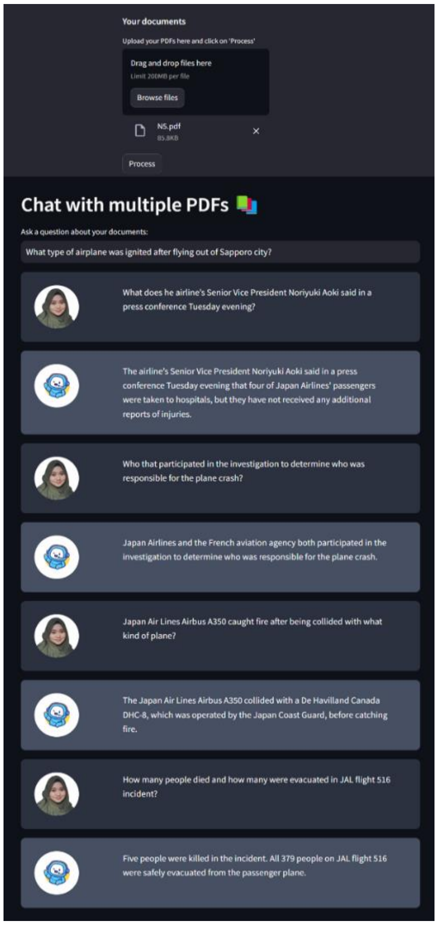
$$\mathrm{J(A,B)} = \frac{|\mathrm{A} \cap \mathrm{B}|}{|\mathrm{A} \cup \mathrm{B}|} \tag{9}$$

$|A \cap B|$ indicates the size of the intersection of the sets A and B, and $|A \cup B|$ indicates the size of the union of the sets A and B. The Jaccard similarity is bounded in the range from 0 to 1. A Jaccard similarity of 1 indicates complete identity between the sets, while a similarity of 0 implies that the sets have no common elements.

## IV. Result and Discussion

### A. Result

The interface of the proposed QA system can be seen in Fig. 7.



Chat with multiple PDFs

Ask a question about your documents:

What type of airplane was ignited after flying out of Sapporo city?

What does he airline's Senior Vice President Noriyuki Aoki said in a press conference Tuesday evening?

The airline's Senior Vice President Noriyuki Aoki said in a press conference Tuesday evening that four of Japan Airlines' passengers were taken to hospitals, but they have not received any additional reports of injuries.

Who that participated in the investigation to determine who was responsible for the plane crash?

Japan Airlines and the French aviation agency both participated in the investigation to determine who was responsible for the plane crash.

Japan Air Lines Airbus A350 caught fire after being collided with what kind of plane?

The Japan Air Lines Airbus A350 collided with a De Havilland Canada DHC-8, which was operated by the Japan Coast Guard, before catching fire.

How many people died and how many were evacuated in JAL flight 516 incident?

Five people were killed in the incident. All 379 people on JAL flight 516 were safely evacuated from the passenger plane.

Fig. 7. Document QA system interface.

The interface of the proposed document QA system can accept multiple PDF format documents. If the user clicks the submit button, the system will process the PDF document to convert it to vector form with embedding (as described in the RAG mechanism in Fig. 2). Once the document submission process is complete, the user can ask questions related to the submitted document, and the QA system will provide answers based on the source documents provided. The set of questions and answers generated from the user's interaction with the QA system will be in the form of a chatbot, so that it stores the communication history.

## B. *Accuracy*

Accuracy in our system model is expressed as the percentage of correct answers within the entire answer key dataset. To assess accuracy, we calculate the ratio of the number of correct predictions to the total number of predictions [26]. The visualization of this accuracy result can be figured in Fig. 8.

The accuracy comparison between the proposed QA document system and other applications reveals the superiority of our method. The proposed system achieved accuracy rates of 96% (our dataset) and 95.5% (SQuAD dev dataset), surpassing the other application's rates of 55% (our dataset) and 85.7% (SQuAD dataset). This underscores the consistently higher accuracy of our proposed method.

## C. *ROUGE*

ROUGE-L score evaluation compares the results of our proposed QA method outperforming other QA applications in terms of precision, recall, and F1-Score. Specifically, on our dataset, our proposed method demonstrated precision, recall, and F1-Score of 73.7%, 23.9%, and 33.7%, respectively. In comparison, other QA applications achieved lower performance metrics with precision, recall, and F1-Score of 50.0%, 10.5%, and 15.2%, respectively. Similarly, on the SQuAD dev dataset, our proposed method excelled with precision, recall, and F1-Score reaching 85.5%, 16.2%, and 26.1%, while other QA applications reported lower scores of 77.2%, 10.4%, and 17.1%, respectively. These results underscore the superior performance of our proposed method across both datasets that can be visualized in Fig. 9.

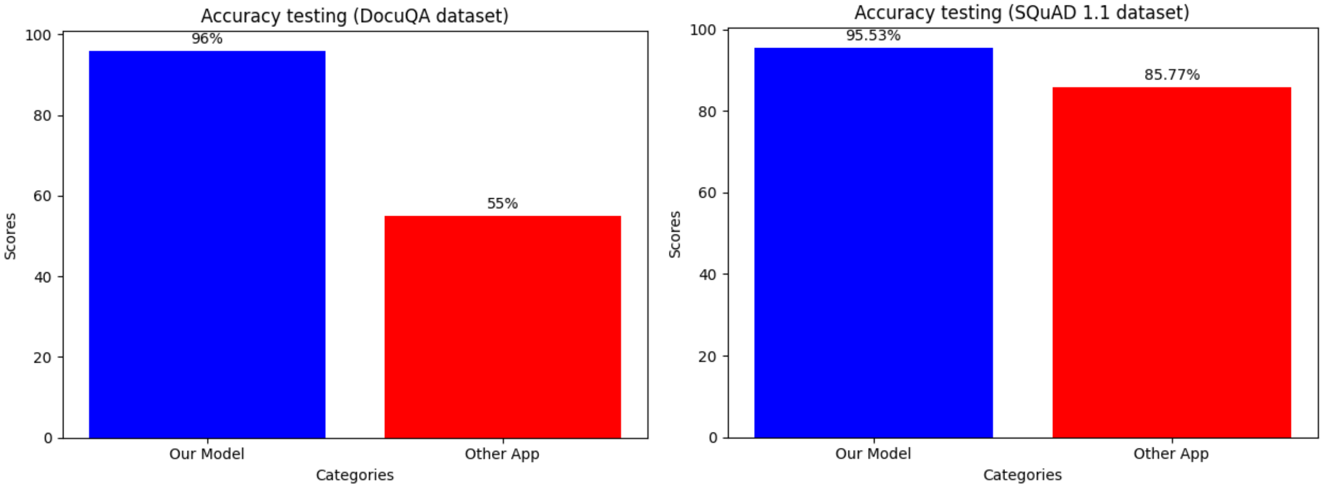


Fig. 8. Accuracy result of proposed method using RAG and other document QA application.

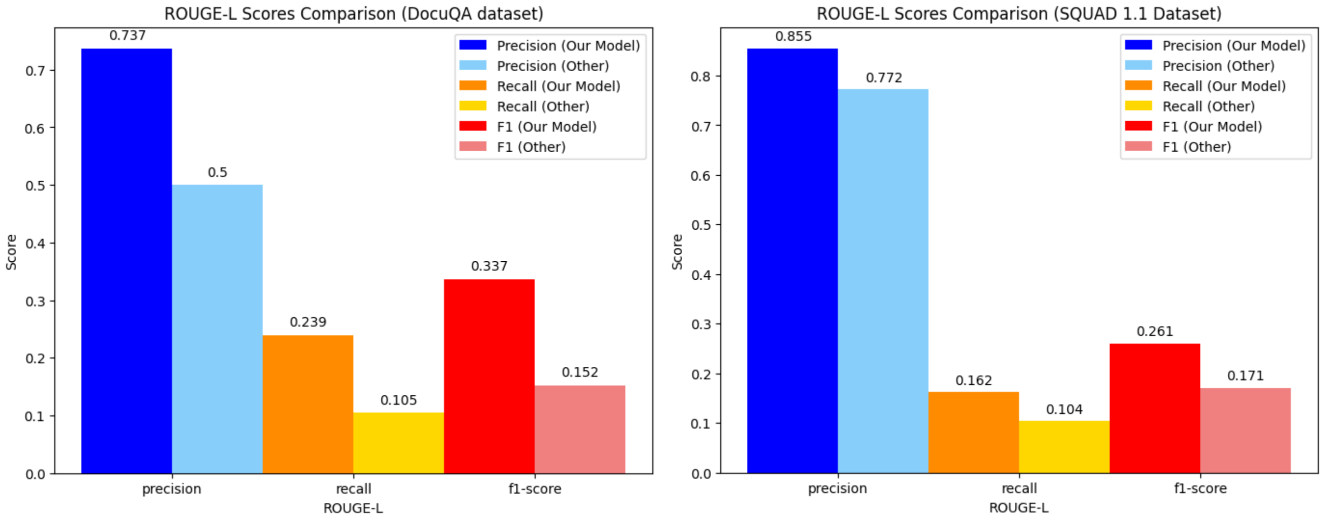

Fig. 9. ROUGE-L result of proposed method using RAG and other document QA application.

### D. BERTScore

BERTScore evaluation compares the results of our proposed QA method outperforming other QA applications in terms of precision, recall, and F1-Score. Specifically, on our dataset, our proposed method demonstrated precision, recall, and F1-Score of 85.2%, 90.1%, and 87.6%, respectively. In comparison, other QA applications achieved lower performance metrics with precision, recall, and F1-Score of 81.6%, 86.3%, and 83.8%, respectively. Similarly, on the SQuAD dev dataset, our proposed method excelled with precision, recall, and F1-Score reaching 82.8%, 87.0%, and 84.8%, while other QA applications reported lower scores of 80.4%, 86.3%, and 83.2%, respectively. These results underscore the superior performance of our proposed method across both datasets that can be visualized in Fig. 10.

### E. BLEU Accuracy

The BLEU metric score taken is the precision value, to capture the ability of each model to extract keyword answers that match the ground truth. Specifically, on our dataset, our proposed method demonstrated precision of 28.2%. In comparison, other QA applications achieved lower performance precision 9.7%. Similarly, on the SQuAD dev dataset, our proposed method excelled with precision 17.7%, while other QA applications reported lower scores of precision 5.6%. These results underscore the superior performance of our proposed method across both datasets that can be visualized in Fig. 11.

### F. Jaccard Similarity

The performance of our QA system, as evaluated through Jaccard Similarity, is outstanding. Our method achieved 33.3% on our dataset and 11.1% on SQuAD dev using RAG method. In comparison, other QA applications scored lower with 4.1% on our dataset and 9.1% on SQuAD dev. These results highlight our method's superiority in Jaccard Similarity on both datasets that can be visualized in Fig. 12.

### G. Discussion

The accuracy result of 95.5% in the SQuAD dev dataset outperforms other research with 61.5% accuracy that tested in SQuAD dev dataset [30] and 71.4% accuracy which also tested in SQuAD dev dataset [31]. We also using SQuAD dev dataset for testing the other document QA application platform, and it shows accuracy 85.7%. So, the model proposed in this study has a higher accuracy score compared to other applications, and previous research on the SQuAD test dataset.

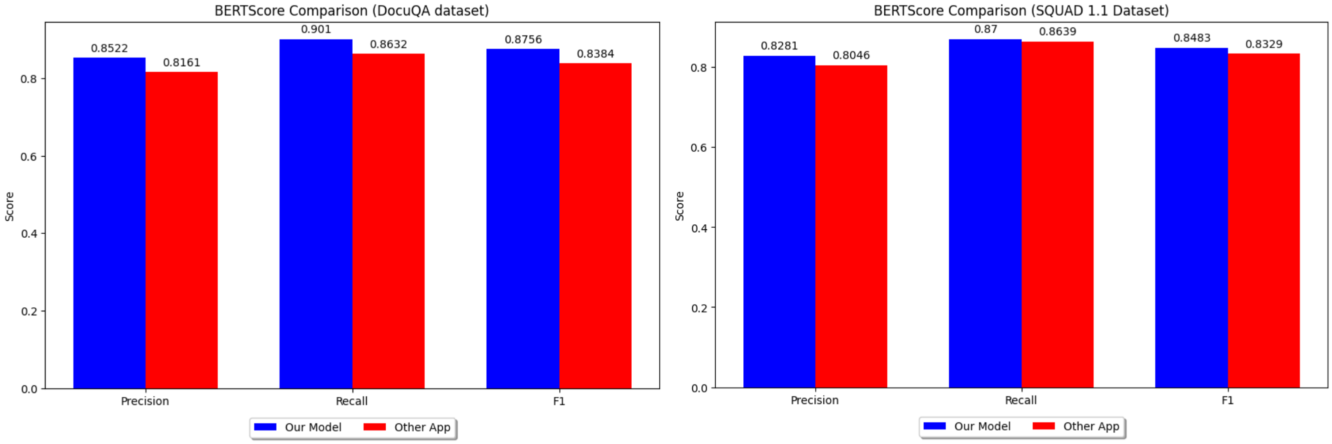

Fig. 10. BERTScore result of proposed method using RAG and other document QA application.

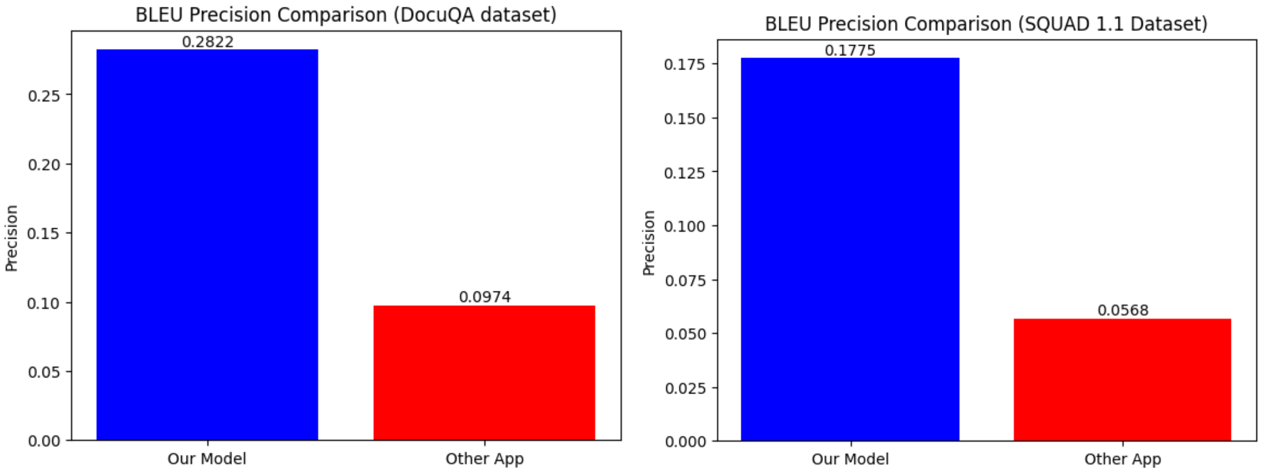

Fig. 11. BLEU precision result of proposed method using RAG and other document QA application.

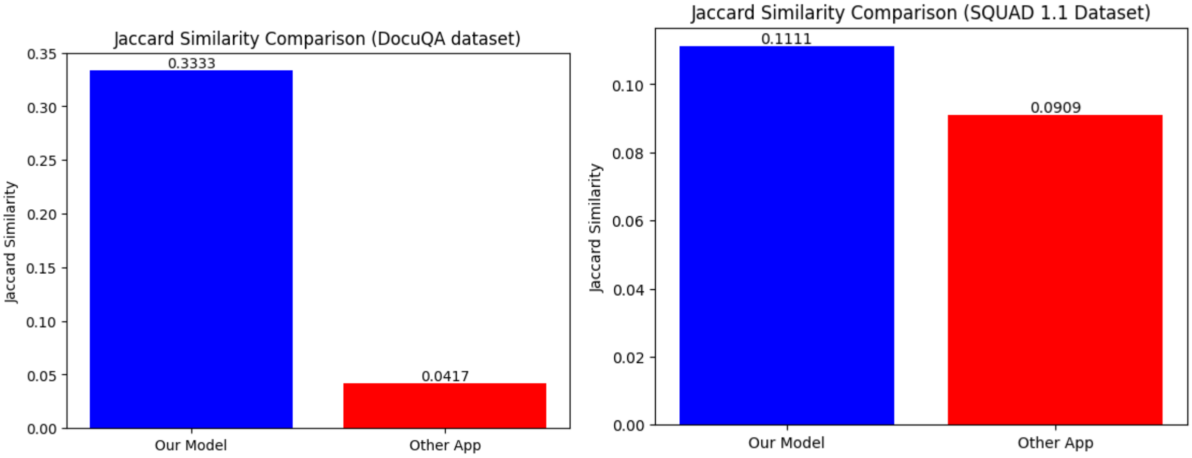

Fig. 12. Jaccard Similarity result of proposed method using RAG and other document QA application.

Our system's precision, recall, and F1-Score are 82.8%, 87%, and 84.8%, respectively, which surpass the precision of 62%, recall of 87%, and F1-Score of 67% reported in other research [32]. The proposed QA system's effectiveness is affirmed by the fact that it surpasses the recall result of other research with 42.70% [33] and outperforms other research [31], [34], [35] in terms of F1-Score, which is 42.6% [31], 49% [34], and 70.8% [35]. This positions it as a leading solution for automatic document processing and information retrieval tasks across a wide range of domains.

Based on the results of testing the proposed model, the results of the present study agree with previous literature studies, namely that the RAG method, through the implementation of a hybrid model combining parametric and nonparametric models, is able to provide good results [4]. In this case we combine the LangChain and FAISS frameworks for the RAG technique, and it can provide a good result. This model also combined with the use of the best language model at this current time like GPT-3.5, which provides good results. This is a very interesting performance that should be further developed.

## V. Conclusion

Our proposed model for Question-Answering (QA) document processing integrates the Retrieval-Augmented Generation (RAG) model. The evaluation of our proposed QA system demonstrates its superiority over existing commercial applications in terms of Accuracy, ROUGE-L scores, BERTScore metrics, BLEU precision, and Jaccard Similarity. The proposed method achieved high accuracy rates of 96% and 95.5% on our dataset and the SQuAD dev dataset, respectively, outperforming other applications tested on the same datasets. Our system's precision, recall, and F1-Score metrics were superior to those of other QA applications on both datasets, as highlighted by the ROUGE-L evaluation. Additionally, the BERTScore metrics consistently showed higher precision, recall, and F1-Score for our proposed method compared to other applications. In addition, our QA system has demonstrated superior performance in keyword extraction and text similarity compared to other applications, as assessed by BLEU precision and Jaccard Similarity.

## VI. Future Works

In the future, studies could be conducted to refine the architecture of the system, explore additional ways of using external data, and improve the scalability of the model for broader applications. The integration of user feedback mechanisms and continuous learning modules could contribute to the adaptability of the system and further improve its accuracy over time. In addition, exploring ways of processing documents in real time and extending the system's compatibility with different document formats could open up new opportunities for research and study.

# A User Control Framework for Cloud Data Migration in Software as a Service

Danga Imbaji Injuwe[1], Hamidah Ibrahim[2], Fatimah Sidi[3], Iskandar Ishak[4]
Department of Information and Communication Technology, Taraba State University, Jalingo, Nigeria[1]
Department of Computer Science, Universiti Putra Malaysia, Selangor, Malaysia[2, 3, 4]

***Abstract*—Cloud computing represents the overarching paradigm that enables organizations to leverage cloud services for data storage and application deployment. Nowadays, organizations that use the cloud services can migrate their data using software as a service (SaaS). The organizations' data and application are deployed over the cloud through the cloud data migration process of the on-premise to cloud migration; referring to the transition process from the legacy, locally hosted systems to cloud environment. Several data migration frameworks have emerged to guide users in the migration process. While numerous studies have addressed the importance of granting control to users during the cloud data migration process, a user control framework is yet to be created. Thereby, depriving user of visibility and sense of ownership, customization to meet users need, compliance and governance, and training. This paper aims at achieving this by proposing a conceptual user control framework for cloud data migration process in SaaS. The framework is constructed based on a comprehensive analysis conducted over existing research works that are related to cloud data migration with the aim to identify the steps/phases of data migration process, the factors affecting the user control with regard to the identified phases, and the control metrics of each identified factor. An initial conceptual user control framework is constructed based on the analysis of the literatures and further enhancement of the framework is made based on the expert reviews.**

***Keywords*—Comparative analysis; cloud computing; cloud data migration; on-premises to cloud migration; user control; Software as a Service***

## I. Introduction

Cloud computing is better comprehended by examining its fundamental functionalities which are universal connectivity, open access, reliability, interoperability, user choice, security, privacy, economic value, and sustainability, as outlined by study [1]. These functionalities are delivered through the three major cloud service delivery models, namely: Software as a Service (SaaS), Platform as a Service (PaaS), and Infrastructure as a Service (IaaS); which typically reduce the capital expenditures through the "pay-as-you-go" model [2] [3]. The service models are described by study [4] as dependant stack layers with IaaS at the base, providing virtualized computing resources such as servers, storage, and networking; followed by PaaS, providing a platform for application development, deployment, and management; and SaaS at the top, offering fully managed applications accessible over the Internet.

Among the cloud service models, SaaS model records the unprecedented migration of organizations from on-premises to cloud platform with market growth at 17% percent per annum [5]. According to the public cloud worldwide forecast [4], SaaS growth and market size are expected to exceed 147 million US dollar by year 2022. Despite the fact that SaaS is growing in popularity due to its diverse benefits, organizations find the process of migrating data from on-premises to cloud platforms to be complex [6].

Data migration process is not free from challenges, including those related to planning, costing, application dependency, security, compliance, data, and service downtime [7]; while outage, backup, destination identification, automation capabilities, lack of knowledgeable staff are among other challenges affecting the data migration process from on-premises to cloud [8]. As a result, these have an impact on the degree of user control over the data migration process. User control is the ability for the user to determine what information can be disclosed or hidden during processing, transferring, or migration, as well as who can access it [9].

Various organizations have hosted their data and applications on-premise while others hosted theirs in the cloud; nonetheless the migration schemes are in three facets, namely: on-premise to cloud, cloud to cloud, and cloud to on-premise [10] [11]. The migration of data and applications hosted on-premises to the cloud in SaaS platform is the focus of this study. This is mainly due to the fact that the recent advancement in cloud computing and the advantage gained during the Covid-19 lockdown has accelerated the data migration of on-premise to cloud [12] [13].

Moreover, the process of migrating data to cloud has improved over the years with notable researches leveraging on existing data migration process and frameworks.

As of right now, no study has reviewed the existing cloud data migration process of on-premise to cloud and conducted comparative analysis with the goal of improving user control over the process, in order to give the user the ability to feel ownership, customize the process to meet their needs, ensure compliance and governance, and provide adequate training that comes with cloud data migration process. Thus, this study attempts to fill this gap. In brief, the main contributions of this study are as follows:

*1)* We conducted a comparative analysis on the different phases of data migration from on-premise to cloud that were proposed by previous studies to finalise the cloud data migration phases that will be incorporated into the proposed conceptual framework;

*2)* We identified the factors that affect the user's control of cloud data migration process according to the phases identified in (a) in order to determine the user control measures; and

*3)* We constructed a conceptual user control framework based on the factors identified in (b) above.

This paper is organized as follow: Section II presents the background related to the study and discusses the related works that emphasized on the phases of cloud data migration process. It also deliberates on the factors affecting user control in cloud data migration process, as presented in several works. This is then followed by Section III which discusses the research methodology that is employed by this study in realising the conceptual user control framework for cloud data migration in SaaS. The result and discussion section is presented in Section IV and the summary with the plan of future work are given in Section V.

## II. Background and Related Work

This section starts by elaborating on the general definition of data migration process focusing on on-premises to cloud. It then discusses the different steps/phases as proposed by the studies [5][12 – 17]. Meanwhile, through the following studies, [3] [13] [16][20][24 – 37], the factors affecting user control in cloud data migration are analyzed and discussed in this section.

Data migration process starts with analysing data from the legacy/old system and ends in the uploading and normalizing data in new application. In study [14], cloud data migration is defined as the process of moving data, localhost applications, and services to the distributed cloud processing framework. Meanwhile, [15] argued that data migration is not just a process of moving data from an old data structure or database to a new one; it is also a process of correcting errors and improving overall data quality and functionality.

Nowadays, data migrations are usually influenced by organizations keenness to optimize or transform their company through moving from on-premises infrastructure and applications to cloud-based storage and applications [16]. Furthermore, when migrating to SaaS platform, there is a need to first identify the key prerequisite that will be relocated to the cloud and break them down in accordance with the current architectural requirement [14].

### *A. Phases in Data Migration Process*

Over the years, researchers and practitioners have devised different data migration phases which have made the process of data migration flow in a systematic order, with each step preceding another. A number of data migration phases were proposed by different studies [5] [12 – 17], to support data migration from on-premise to cloud as shown in Table I.

From Table I, the following can be observed:

*1)* Different phases of data migration process have been identified by the authors, with each phase comprising specific activities,

*2)* Assessment, planning, design, migration, testing, and post-migration are the common activities as reflected in these various studies,

*3)* Security remains an important consideration as demonstrated in the phases of these studies,

*4)* Most studies present an intent to address both business and technical issues that may arise from the identified phases.

### *B. Factors that Affect User Control in Cloud Data Migration*

Based on the review conducted on [3] [13] [16] [20] [24 – 32] [35 – 37], the control of data migration process is affected by several factors, namely: security [3] [13][24 – 27], cost [18], legal [19], and personnel knowledge [20][37] as presented in Table II. In the following each of these factors are further discussed.

Security of data means measures, controls, and procedures applied on ICT systems in order to ensure integrity, authenticity, availability and confidentiality of data and systems [21]. This is important to data in transit and data at rest [7]. To ensure a high level of security, a set of techniques including data segmentation, error control/correction, encryption, decryption, and data hashing are used [22]. Measures for data security are confidentiality, integrity, availability and compliance of the data during the migration process [17] [23]. The control measures should ensure that the data are not compromised during the migration process and that they remain secure in the cloud environment.

Cost is the service charge required for moving data and application from the old on-premise deployments to the new cloud infrastructure [24] [25]. Minimizing various cost of downtime, minimizing the cost of resources required for the migration, and ensuring that the overall cost of the migration is within budget as this is always the aim of an organization [26]. However, [27] earlier reported that internal cost of labour for administrative personnel takes 50% of the budget.

Data migration to the cloud offers numerous benefits but also entails legal challenges in terms of SLA compliance and adherence to cloud regulations [48]. To mitigate these challenges, organizations should carefully negotiate and review their SLAs with Cloud Service Providers (CSPs), ensuring they address critical aspects of data security, privacy, ownership, and control [49]. Moreover, organizations must understand and comply with the relevant cloud regulations governing data protection, privacy, cross-border data transfers, and industry-specific requirements [50]. By proactively addressing these legal challenges, organizations can ensure a smooth and legally compliant data migration process to the cloud.

Personnel knowledge plays a vital role in the success of data migration processes. Technical knowledge is essential for understanding data architecture, infrastructure, and security measures; communication knowledge helps to convey the information to all parties involve while, business knowledge ensures compliance, smooth business operations, and effective data analysis [51].

TABLE I. PHASES AND ACTIVITIES OF EXISTING DATA MIGRATION PROCESS FROM ON-PREMISE TO CLOUD

| Reference | Step/ Phase | Data Migration Phase | Activity |
|---|---|---|---|
| [4] | 1 | Data assessment | Identify sources, run queries, review, revise, plan, scope, strategy, validate, and milestones. |
| | 2 | Data cleansing | Analysis, preparation, cleaning, formatting, extracting of data that will be migrated. |
| | 3 | Extract, Test and, Load (ETL) | Create mappings, extract data, automate, clean, execute mock load, validate, report, and delivery of data. |
| | 4 | Final extract and load | Execution of final extracts from the current systems, loading of data extracts using ETL tools into target system. |
| | 5 | Migration validation | Verify if all the required data are transferred according to the requirements. |
| | 6 | Post migration activities | Planning, creating backups, quality testing, and documentation of reports. |
| [26] | 1 | Define migration portfolio | Understand organizational context and identify migration portfolio (migration goals, business process, policies, strength and knowledge gap, application and data profile). |
| | 2 | Risk identification | Understand the risk associated with cloud migration (loss of governance, disaster recovery, and security incident report). |
| | 3 | Requirement and assurance analysis | Identify requirement, assurance, and control measure. |
| | 4 | Cloud migration decision and strategy | Decision to migrate to the cloud is taken and the migration strategy is defined (migration type, service/deployment model, migration assessment index, data store and hosting type, adaption action, migration testing, adaption constraint, roles, and responsibility). |
| [27] | 1 | Discovery and assessment | Financial assessment, assessment of existing IT within, and identify legacy system security assessment tools and licenses requirement. |
| | 2 | Proof of concept | Build a pilot support within the organization, automate migration task from any source to target, and test performance, backup, and recovery. |
| | 3 | Planning and design | Identify data source, location and, sensitivity. Plan security at all layers and, hybrid migration strategy. |
| | 4 | Cloud migration | Leverage different storage options by replicating source data to public cloud and test migrated workloads. |

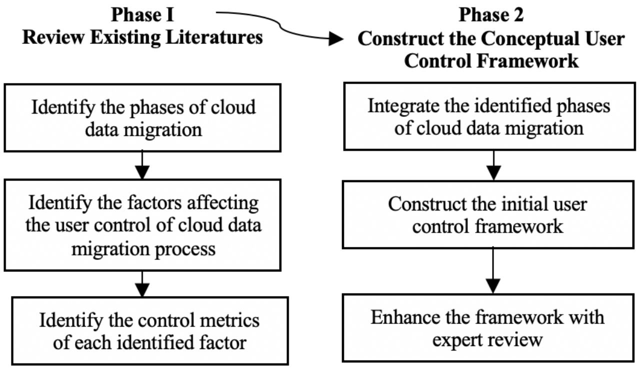
| [32] | 1 | Road mapping | Assess the scope of work by evaluating the existing architecture and application capabilities and build a roadmap using research, analysis, and strategic planning. |
| | 2 | Design | Determine whether they need to completely redesign their existing architecture, database, and codebase. |
| | 3 | Change management | Span the entire migration process to increase the adoption of new systems through training and feedback loops. |
| | 4 | Testing | Applications, integrations, and systems are tested for performance and stability to ensure a smooth migration process. |
| | 5 | Data migration | Implementation and deployment. |

TABLE II. FACTORS THAT AFFECT THE CONTROL OF DATA MIGRATION PROCESS

| Factor | Item | Description | Reference |
|---|---|---|---|
| Security | Confidentiality | Intentional or unintentional destruction of data caused by people and or processes. | [34] |
| | Integrity | To ensure that data is securely protected during migration from a non-cloud computing environment to the cloud. | [35][36] |
| | Data loss | The deletion of data, whether deliberate or accidental by individuals or the data migration process. | [5] |
| | Privacy | Restriction of access to data and other resource in place. | [29][37] |
| Cost | Application and data cost | Cost of deploying a cloud service. | [38] |
| | Storage cost | How to exploit these storage classes to serve an application with a time-varying workload on its objects at minimum cost. | [39] |
| | Connectivity | Cost of connectivity between the user and the cloud service provider. | [40] |
| | Consultancy | Cloud proprietary tools for migration are usually accompanied by expensive consultancy costs. | [41][42] |
| Legal | Service level agreement | Level of service required between the consumer and the service provider. | [43] |
| | Policy | The statement of intent drafted by the organization governing body that will be responsible for all the phases of data migration. It provides users with a policy expressing their preference to data. | [44][45] |
| | Compliance | Varying cloud regulation across the globe result in risk caused due to violations of the established jurisdictional regulations. | [46] |
| Personnel Knowledge | Technical knowledge | The staff's technical cloud technology skills. | [18] |
| | Communication knowledge | Fostering a positive working relationship between IT departments and cloud service providers. | [47] |
| | Business knowledge | Knowledge of the business process and change management. | [32] |

## III. METHODOLOGY

The phases of the research methodology are illustrated in Fig. 1. These phases are: (i) Phase 1 in which a review of existing literatures is conducted with deliverables to include identification of the cloud data migration phases, factors affecting user control in the migration process, and control metrics; and (ii) Phase 2 in which the initial conceptual user control framework is developed and further enhancement is made according to the experts' reviews.



Phase I
Review Existing Literatures
Phase 2
Construct the Conceptual User Control Framework
Identify the phases of cloud data migration
Identify the factors affecting the user control of cloud data migration process
Identify the control metrics of each identified factor
Integrate the identified phases of cloud data migration
Construct the initial user control framework
Enhance the framework with expert review

Fig. 1. Phases of the research methodology.

### A. Phase 1: Review Existing Literatures

Following the review of existing literatures in Section II, the Phase 1 has the following deliverables:

*1) Identify the steps / phases of cloud data migration.* This is achieved by analysing the following existing works [5] [12 – 17]. The results of the analysis are presented in Table I.

*2) Identify the factors affecting the user control of cloud data migration process.* By analysing the following existing works [3][13][16][20][24 – 32][35 – 37], four factors are identified, namely: security, cost, legal, and personnel knowledge.

*3) Identify the control metrics of each identified factor.* Reviewing the same literatures as in (ii) above, results in the control metrics as listed in Table II, column *Item*. For instance, the identified control metrics of security through the review are confidentiality, data loss, integrity, and privacy.

### B. Phase 2: Construct the Conceptual User Control Framework

The construction of the proposed conceptual user control framework involves three main tasks as explained below:

Integrate the identified phases of cloud data migration – The existing steps/phases of cloud data migration proposed by [5] [12 – 17] as shown in Table I of Section II are analyzed, integrated, and renamed in Table III. The table provides a comparison of the cloud data migration phases based on whether certain phases are similar marked as (✓) or not, marked as (✗). Apparently, pre-migration planning and analysis and migration execution are the common phases among these studies. Meanwhile, data preparation and cleansing is mentioned only by the works in [6], [36], and [38].

Note: (a) Pre-migration Planning and Analysis; (b) Risk Assessment and Strategy; (c) Data Preparation and Cleansing; (d) Migration Execution; and (e) Post-migration Validation and Optimization

Based on the steps/phases identified in the Phase I and detail analysis conducted on these steps/phases, we have identified the following five phases as the phases of cloud data migration of on-premise to cloud: pre-migration planning and analysis, risk assessment and strategy, data preparation and cleansing, migration execution, and post-migration validation and optimization. At this stage, all steps/phases with similar tasks are grouped together. The phases are explained below:

*1) Pre-migration planning and analysis* – in this initial phase of data migration, understanding the organizational context and identifying data migration plan to the cloud which involves analysing the existing/legacy applications based on available information and parameters with the aim to make informed decisions about migration [14]. This analysis provides understanding on  the current state of the application [54]. The planning process should consider parameters such as security requirements, completeness, accuracy, and storage [7]. The planning should also involve selecting a cloud provider and costs estimation [55]. By following a comprehensive pre-migration approach, organization can ensure a well-thought-out migration strategy and minimize the cost and risks associated with data migration to the cloud [56].

*2) Risk assessment and strategy* – this phase involves a comprehensive evaluation of potential risks and the development of a strategy to address and mitigate risks throughout the data migration process [38]. The risk involves extended downtime, budget, and business data [27]. A comprehensive data migration strategy should take into consideration the legacy data, mapping data from the old system to the new system, challenges of identifying source data, interacting with continuously changing targets, adhering to data quality requirements, creating appropriate process methodologies, and employing general migration expertise [6]. It guides on which cloud application and cloud service to engage [57]. This encompasses project context, necessary actions, assumptions, limitations, architectures, and pertinent information conveying the methodology of the data migration project [58].

*3) Data preparation and cleansing* – this phase involves the initial step of data structuring, improving, and purifying prior to its transfer to a cloud-based system. This phase involves activities like data formatting, eliminating duplicates or irrelevant data, and verifying data accuracy, all aimed at enhancing the effectiveness and dependability of the migration process [59].

*4) Migration execution* – this phase involves the following tasks: execute, mock, load, validate, and report the data migration experience. Load data extracts the data into the target system using the ETL tools and migrate them to the selected cloud data store.

*5) Post-migration validation and optimization* – this phase verifies if all the required data are transferred to the cloud according to the requirements. Hence, the following tasks are to be performed: monitor the application performance and usage, review and re-engineer the migrated workloads, and train the staff to manage the migrated data and application [29].

Construct the initial user control framework – The conceptual user control framework is presented in Fig. 2. It is constructed based on the findings of the reviewed literature. The framework consists of three dimensions that the study found to be pertinent to the user control of data migration process from on-premise to cloud using SaaS. These dimensions include affecting factors at the left hand side, phases of cloud data migration in the middle, and the control metrics at the right hand side of the conceptual framework.

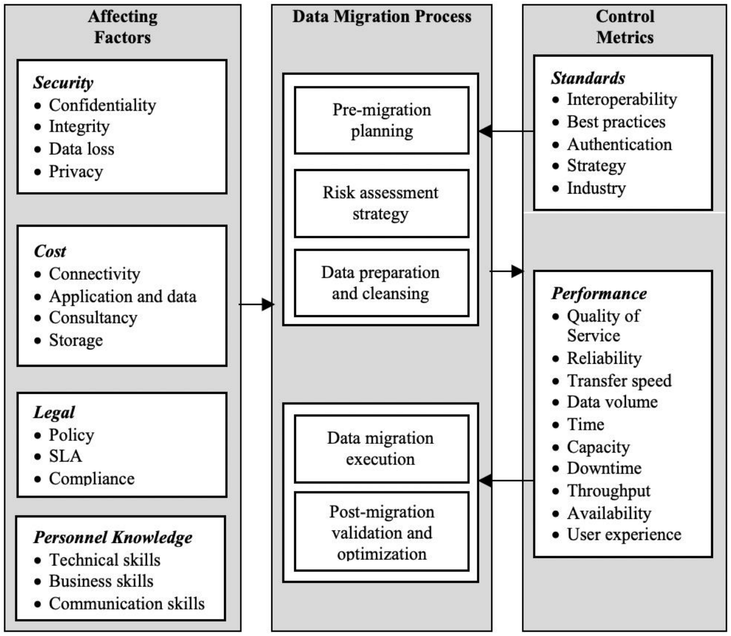

Fig. 2. The initial conceptual user control framework in SaaS cloud data migration process.

Mapping the affecting factors and the control metrics to the cloud data migration process in the conceptual framework, results in 6 constructs, namely: security, cost, legal, personnel knowledge, standards, and performance. The constructs/items are validated by experts through a content validity form with an aim to determine the relevance of the items to the construct that are being measured.

A content validity form (see Appendix A) was administered to five experts. The form consists of 5 sections, namely: (i) Section A: Demographic information (Q1 – Q6), Section B: the perceptions of user control of on-premise to cloud data migration process using SaaS (Q1 – Q6), Section C: the control metrics with the following constructs: standard (Q7 – Q12) and performance (Q13 – Q22), Section D: the affecting factors with the following constructs: security (Q23 – 26), cost (Q27 – Q30), legal (Q31 – Q33), and personnel knowledge (Q34 – Q36), and Section E: experts' comments. As presented in Table IV, three of the expert reviewers are from academia and the other two are from industry. Their work experience ranges between 6 to above 26 years.

Expert review analysis – The data collected from the expert review survey are imported into excel sheet and analysed accordingly to calculate the content validity index (CVI). The CVI involved the calculation of two forms of Content Validity Index (CVI): the Item-Content Validity Index (I-CVI) and the Scale-Content Validity Index (S-CVI). The results indicated that the I-CVI yielded a value of 0.85, while the S-CVI produced a result of 0.88. Since, both results fall within the acceptable threshold to consider the items as relevant. The summary of the experts' review feedbacks is presented in Table V.

TABLE IV. PROFILE OF THE EXPERT REVIEWERS

| No. | Position/<br>Highest Qualification | Description | Location | Sector (Academia/<br>Industry) | Year of Experience |
|---|---|---|---|---|---|
| 1 | Professor/<br>Ph.D. | Cloud user | India | Academia | 21 - 25 |
| 2 | Cloud consultant/BSc | Cloud regulator | Malaysia | Industry | 11 -15 |
| 3 | Assistant Professor/<br>Ph.D. | Cloud researcher/<br>academics | USA | Academia | 6 - 10 |
| 4 | Database Engineer/MSc | Cloud service provider | India | Industry | Above 26 |
| 5 | Professor/<br>Ph.D. | Cloud researcher/<br>academics | Nigeria | Academia | 16 - 20 |

TABLE V. SUMMARY OF EXPERT REVIEW

| Construct | Expert Review |
|---|---|
| Security | This construct contains 4 items, namely: *confidentiality*, *integrity*, *data loss* and, *privacy*. All of them were rated relevant by the experts. |
| Cost | This construct also contains 4 items, namely: *connectivity*, *application and data*, *consultancy*, and *storage*. The experts rated all the items as relevant. |
| Legal | There are 3 items for this construct. All of them were rated relevant by the experts. However, one of the experts suggested for additional item: *governance*. This is being considered because recent literatures have mentioned governance as a factor of data migration process. |
| Personnel Knowledge | This construct contains 3 items, namely: *technical skills*, *business skills*, and *communication skills*. All the experts rated them relevant. |
| Standards | There are 5 items for this construct. One item *interoperability* is rated irrelevant and thus it is removed. The other 4 items, namely: *best practice*, *authentication*, *strategy*, and *industry standards* are rated relevant. |
| Performance | There are 10 items for this construct. 9 items, namely: *quality of service*, *reliability*, *transfer speed*, *time*, *capacity*, *downtime*, *throughput*, *availability*, and *user experience* are rated relevant by the experts. One item *data volume* is removed for being rated irrelevant by the experts. |

## IV. RESULT AND DISCUSSION

The analysis of the validity of the constructs for the proposed conceptual user control framework utilized the procedure provided by [60], which include the following 6 steps: (i) preparation of content validation form, (ii) selection of the review panel of experts, (iii) conducting content validation, (iv) reviewing domain and items, (v) providing score on each item, and (vi) calculating the Content Validity Index (CVI). Steps 1 – 6 are carried out successfully. The data collated from the experts were used to calculate the content validity index CVI.

Furthermore, the conceptual model is enhanced by removing the items which fall below the threshold of the content validity index, CVI. As outlined by [60] the threshold established as standard for CVI should be within the range of 0.78 and 1. The CVI value of each item is presented in Table VI. The table shows that the CVI values for interoperability and data volume are less than the standard threshold value, i.e. at 0.6 and 0.4, respectively. As a result, these two items are removed from the proposed conceptual model. While the CVI values for most items are either 0.8 or 1, all security items have a CVI of 1. On the other side, the experts suggested for the inclusion of the item governance. It was apparently added for its occurrences in recent literature of cloud data migration process. The inclusion of the item governance highlights the importance of regulatory control mechanisms in ensuring data security, compliance, and accountability throughout the cloud data migration process while the removal of the item interoperability signify a significant step towards aligning with the CVI threshold. These adjustments ensure that the conceptual model accurately represents the key items influencing user control during on-premise to cloud data migration. Fig. 3 presents the modified conceptual user control framework for in SaaS cloud data migration process.

TABLE VI. VALUE OF CONTENT VALIDITY INDEX FOR EACH ITEM

| Construct | Question | Item | CVI |
|---|---|---|---|
| Standards | Q7 | Interoperability | 0.6 |
| | Q8 | Best-practices | 0.8 |
| | Q9 | Strategy | 0.8 |
| | Q10 | Industry | 0.8 |
| | Q11 | Data transfer | 0.8 |
| | Q12 | Authentication | 1 |
| Performance | Q13 | Quality of Service | 1 |
| | Q14 | Reliability | 0.8 |
| | Q15 | User experience | 1 |
| | Q16 | Time | 1 |
| | Q17 | Data volume | 0.4 |
| | Q18 | Transfer speed | 1 |
| | Q19 | Downtime | 1 |
| | Q20 | Throughput | 0.8 |
| | Q21 | Availability | 0.8 |
| | Q22 | Capacity | 1 |
| Security | Q23 | Confidentiality | 1 |
| | Q24 | Integrity | 1 |
| | Q25 | Data loss | 1 |
| | Q26 | Privacy | 1 |
| Cost | Q27 | Application and data | 0.8 |
| | Q28 | Connectivity | 0.8 |
| | Q29 | Consultancy | 0.6 |
| | Q30 | Storage | 0.8 |
| Legal | Q31 | Policy | 0.8 |
| | Q32 | SLA | 1 |
| | Q33 | Compliance | 0.8 |
| Personnel Knowledge | Q34 | Technical skills | 0.8 |
| | Q35 | Business skills | 0.6 |
| | Q36 | Communication skills | 0.8 |

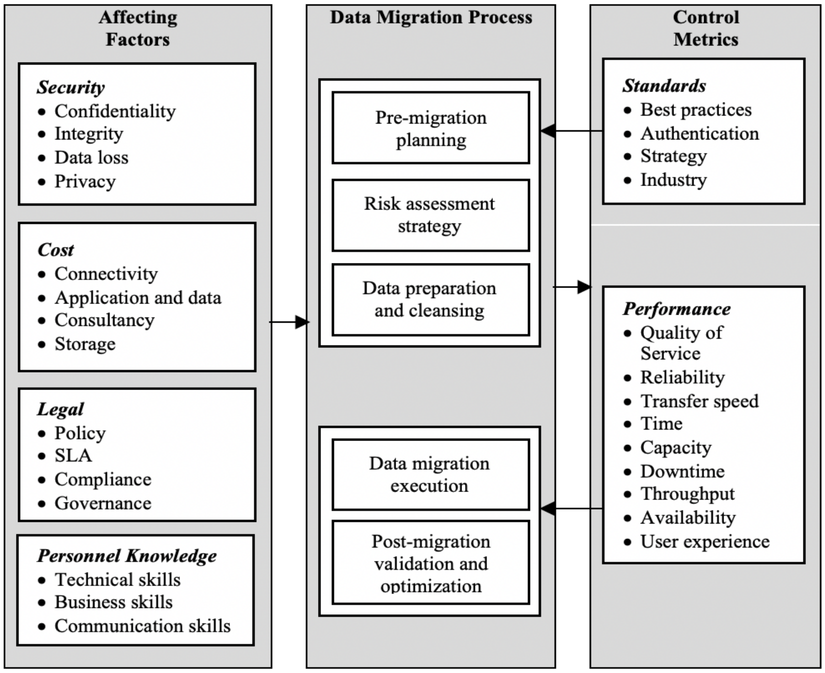

Fig. 3. The modified and proposed conceptual framework for the user control in SaaS cloud data migration process.

## V. Conclusion

Cloud computing has evolved tremendously since the advent of Covid-19 lockdown which made it gain advantage: attracting users to migrate data from on-premise to cloud with high number of users leveraging on the cloud SaaS application. In the cloud services, each user can be interacted and offered unique service regardless of location and time while reducing capital expenditure through the "pay-as-you-go model". Hence cloud computing technologies can help users to experience the benefit that evolves with the technology in terms of research and innovation. This research contributes a conceptual framework for cloud data migration that considers SaaS in a cloud computing environment, with the aim to guide the cloud practitioners and users on preparation, implementation and monitoring the cloud data migration process.

The conceptual framework is proposed based on the antecedent in previous cloud data migration process found in existing literature, expert opinions and a survey on users perception. Having founded that, this study is limited to the knowledge of the expert reviewer and available literature. Future works may involve further refinement of the conceptual framework based on additional expert reviews and practical implementations. Additionally, empirical studies and real-world applications of the framework will be essential to assess its effectiveness and usability in diverse cloud data migration scenarios (see Appendix A). Continuous revises to the framework could be made to accommodate evolving cloud technologies, best practice, and regulations, ensuring its relevance in the evolving environment of cloud computing.

## Acknowledgment

This work was supported by the Tertiary Education Trust Fund (TETfund) and Universiti Putra Malaysia. All opinions, findings, conclusions and recommendations in this paper are those of the authors and do not necessarily reflect the views of the funding agencies.

## APPENDIX A: CONTENT VALIDITY FORM

Section A: Demographic information

Q1 Name of Company □

Q2 Which of the following best describes you?
Cloud user □
Cloud service provider □
Cloud researcher/academics □
Cloud regulator □
Cloud auditor □
Cloud broker □
Other: please specify □

Q3 Select the range of years of working experience that best apply to you.
0–5 □ 6–10 □ 11–15 □ 16–20 □ 21–25 □ Above 26 □

Q4 What is your highest academic qualification:
Bachelor □ Master □ PhD □ Other: please specify □

Q5 Are you familiar with on-premise to cloud data migration process?
Yes □ □

Q6 How would you describe your level of understanding on cloud data migration process?
Basic (a beginner that is familiar with the fundamentals) □
Intermediate (performs data migration activities) □
Expert (advanced in knowledge and practice of data migration process) □

Please use the following Likert scale to indicate the degree of relevance of each item to the construct it is representing by checking (✓) the appropriate box in the table below:

Key to the degree of relevance:

1 = the item is not relevant to the measured domain

2 = the item is somewhat relevant to the measured domain

3 = the item is quite relevant to the measured domain

4 = the item is highly relevant to the measured domain

Section B: The questions in this section is focused on the perceptions of user control of on-premise to cloud data migration process using SaaS.

| **Items/Options** | | **Rating** | | | | **Comment** |
|---|---|---|---|---|---|---|
| | | **4** | **3** | **2** | **1** | |
| 1. | Data migration process consists of the following phases: *pre-migration planning, risk assessment and strategy*, *data preparation and cleansing, data migration execution*, and *post-migration validation and optimization*. | | | | | |
| 2. | The phases of data migration are orderly and easy to understand. | | | | | |
| 3. | User control of cloud data migration process brings about transparency and confidence in both the user and cloud service provider. | | | | | |
| 4. | Control of cloud data migration process is beneficial for any organization that is migrating data from on-premise to cloud. | | | | | |
| 5. | Measuring the level of user control in cloud data migration process is essential in the control of data migration process. | | | | | |
| 6. | I believe that this study will make a valuable contribution to the cloud data migration process globally. | | | | | |

Section C: Measures (standard and performance) for evaluating the user control in cloud data migration process.

| **Standard: refers to established measure for achieving common goal.** | | | | | | |
|---|---|---|---|---|---|---|
| **Items/Options** | | **Rating** | | | | **Comment** |
| | | **4** | **3** | **2** | **1** | |
| 7. | The cloud data migration process has no interoperability issues arising from interaction between technologies. | | | | | |
| 8. | The cloud data migration process is carried in accordance with best-practices. | | | | | |
| 9. | The cloud data migration process suits the intended cloud strategy. | | | | | |
| 10. | Industry standards allows for seamless cloud data migration process. | | | | | |
| 11. | The data migration process is with minimal issues related to data transfer from on-premise to cloud. | | | | | |
| 12. | Access to the process is only allowed by users through authentication. | | | | | |
| **Performance: is signified in measurable metric that enables the assessment of how well the processes conform to standards.** | | | | | | |
| **Items/Options** | | **Rating** | | | | **Comment** |
| | | **4** | **3** | **2** | **1** | |
| 13. | The Quality of Service (QoS) indicates that the process is under control. | | | | | |
| 14. | The cloud data migration process is under user control if the reliability of the service is as designed. | | | | | |
| 15. | Satisfactory user experience is based on ease of use of the application and data accessibility. | | | | | |
| 16. | Control demonstrates how data migration from on-premise to cloud is carried within expected time. | | | | | |
| 17. | Data volume should not attract extra cost. | | | | | |
| 18. | How fast on-premise data moves to cloud indicates the transfer speed. | | | | | |
| 19. | Control is shown when downtime does not interfere with business transactions. | | | | | |
| 20. | The amount of data that is transferred to cloud in a given time indicates throughput. | | | | | |
| 21. | Being that data is available as it were before migration indicates control. | | | | | |
| 22. | Capacity utilization of workload in the cloud data migration process is an important aspect of control. | | | | | |

Section D: The affecting factors (Security, Cost, Legal, and Personnel Knowledge) of user control in cloud data migration process.

| | | | | | | |
|---|---|---|---|---|---|---|
| **Security:** means measures put in place in order to ensure integrity, confidentiality, prevent data loss and ensure privacy of data and application. | | | | | | |
| **Items/Options** | | **Rating** | | | | **Comment** |
| | | **4** | **3** | **2** | **1** | |
| 23. | Security is a shared responsibility for both the cloud service provider and the user to ensure confidentiality. | | | | | |
| 24. | The migrated data should remain correct, validated and perform well in business continuity to ensure integrity. | | | | | |
| 25. | Confidentiality is ensuring that data is backup before migration in case of unintentional data loss in the data migration process. | | | | | |
| 26. | User concern towards compliance with data privacy laws should be addressed. | | | | | |
| **Cost**: the cost associated with moving data and application to cloud, including connectivity, consultancy, and storage cost. | | | | | | |
| **Items/Options** | | **Rating** | | | | **Comment** |
| | | 4 | 3 | 2 | 1 | |
| 27. | Cost of transiting to cloud is within budget. | | | | | |
| 28. | Cost of network connectivity related to bandwidth. | | | | | |
| 29. | Consultancy fee associated to professional services. | | | | | |
| 30. | Cloud charges for data storage. | | | | | |
| **Legal**: relates to jurisdictional laws, service level agreement, and policies made my governing organizations. | | | | | | |
| **Items/Options** | | **Rating** | | | | **Comment** |
| | | **4** | **3** | **2** | **1** | |
| 31. | The control of cloud data migration process is affected by how organizational policy aligned with cloud standards. | | | | | |
| 32. | How users of SaaS ensure that cloud service providers adhere to the *Service Level Agreement* (SLA) influences the control of cloud data migration process. | | | | | |
| 33. | Actualizing user control is affected by compliance to cloud standards and best practice. | | | | | |
| **Personnel knowledge**: this include knowledge of the cloud technology, business process, and the knowledge of the data migration process. | | | | | | |
| **Items/Options** | | **Rating** | | | | **Comment** |
| | | **4** | **3** | **2** | **1** | |
| 34. | How the technical skills of personnel matches the requirement of cloud data migration process. | | | | | |
| 35. | The business skills of the organizations' personnel that will perform the data migration process. | | | | | |
| 36. | The communication skills required by the personnel to report and document the data migration process. | | | | | |

Surampalem, Andhra Pradesh, India[6]
Faculty of Informatics and Computing, UniSZA University, Malaysia[7]

***Abstract*—Securing patient information is crucial in the quickly changing field of healthcare informatics to guarantee privacy, reliability, and adherence to legal requirements. This article presents a complete cybersecurity architecture enabled by blockchain and customized for the medical informatics area. The framework initiatives to provide adequate safeguards for sensitive patient data by utilizing AES-Diffie-Hellman key exchange for secure communication, blockchain technology with Proof-of-Work (PoW), and Role-Based Access Control (RBAC) for fine access management. A strong cybersecurity architecture is crucial for maintaining the security, credibility, and availability of private patient information in the current healthcare information management environment. By using decentralized storage, access control methods, and cutting-edge encryption strategies, the suggested framework overcomes these difficulties. The framework ensures safe data transport and storage by showcasing effective AES encryption as well as decryption procedures through performance evaluation. PoW consensus combined with blockchain technology provides the framework with auditable and immutable data storage, reducing the possibility of data manipulation and unwanted access. Additionally, granular access control is made possible by the integration of RBAC, guaranteeing that only those with the proper authorization may access patient data. Python is used to implement the suggested framework. The suggested method considerably outperformed NTRU, RSA, and DES with encryption and decryption times of 12.1 and 12.2 seconds, respectively. The proposed Blockchain-Enabled Cybersecurity Framework demonstrates exceptional efficacy, evidenced by its ability to achieve a 97.9% reduction in unauthorized access incidents, thus offering robust protection for patient data in medical informatics.**

***Keywords—Block Chain; Cybersecurity; Diffie Hellmen; Patient Data; Proof of Work***

## I. INTRODUCTION

Blockchain has been used more often in a number of areas recently, including healthcare[1]. Blockchain technology is being utilized in medical information systems to ensure secure, transparent, and unchangeable data communication, addressing the need for effective data communication, privacy, and anonymity in the healthcare industry [2]. Blockchain technology, due to its distributed nature, is becoming increasingly recognized for its resilience, authenticity, and dependability [3]. Its unique features include decentralization, traceability, transparency, and dependability, making it a versatile platform for various industries, including identity management, supply chain management, healthcare, insurance, and contract handling [4]. Blockchain technology may be used to store and retrieve data from a distributed network of devices. Blockchain technology can transform medical information exchange and retention in the healthcare industry, improving process efficiency and safety. These days, internet connectivity is available in a growing number of global locations.

The Internet of Things has developed as a consequence of the changes in information storage and processing outsourcing that were caused by the increasing usage of cloud computing. The number of IoT devices is surging, yet network technology is evolving quickly. With the recent development of 5G technology, devices may now be continuously linked to an internet connection at fast speeds and little latency. Rapid developments in large-scale industrial automation, safety, and monitoring were brought about by the Industrial Revolution. Because it incorporates an extensive variety of wireless sensors and monitors for large equipment monitoring and problem detection, the Industrial IoT has consequently generated a lot of attention [5]. Infection control and pandemic measures are shared by some nations with other nations. To avoid the unexpected appearance of new illnesses, countries throughout the world have been placed under lockdown, and over 100,000 people who were suspected of being infected have been placed under quarantine. AI may be used to identify potentially dangerous conduct and cyber threats. Due to advanced methods that can recognize even the smallest patterns, AI systems can identify even the smallest malware or ransomware assaults. Doctors maintain computerized records of their patient's medical history so they may monitor their condition and stay informed about any issues or prescription drugs. A computerized representation of this data is called an Electronic Health Record, and it can contain everything from the patient's medical history to progress notes to issues or prescription drugs. Researchers say that machine learning and artificial intelligence will have both beneficial and bad consequences on cybersecurity. Artificial intelligence systems are trained to handle novel scenarios by utilizing past data. Through duplicating and adding new information, they acquire new abilities and knowledge. AI can assist general practitioners in performing duties like data entry into Electronic Health Records, recording information, and patient interaction analysis [6].

Blockchain technology is being used in the healthcare sector to secure patient data, expedite data transfer, and identify potential errors, improving performance, protection, and transparency in medical records exchange, despite security and privacy concerns [7]. The proposed study presents a cybersecurity architecture using blockchain technology to protect patient information in medical informatics [8]. It includes role-based access control, decentralized data storage, and AES-Diffie-Hellman key exchange. The system improves data safety and privacy by combining AES-Diffie-Hellman, blockchain, and RBAC. Its scalability and adaptability to changing healthcare data requirements ensure its long-term sustainability and usefulness in healthcare settings.

The following are the main contributions to the suggested work:

- Development of a comprehensive cybersecurity architecture leveraging blockchain technology, AES encryption, and RBAC for robust data protection.
- Integration of decentralized storage and cutting-edge encryption strategies to address challenges related to data security, privacy, and reliability.
- Implementation of AES encryption and decryption procedures, along with PoW consensus mechanism, to ensure auditable and immutable data storage.
- Introduction of granular access control through RBAC integration, ensuring that only authorized personnel can access sensitive patient data,
- The proposed framework has demonstrated reducing unauthorized access incidents and providing robust patient data protection.

The paper is laid out as follows. An introduction is given in Section I. A related paper that compares present methods is provided in Section II. Section III discusses the limits of the current system. The design and execution of the suggested Blockchain-integrated cybersecurity are described in Section IV. Section V presents the results and comments. The summary and future application are given in Section VI.

## II. Literature Review
