# Editorial Preface

## *From the Desk of Managing Editor…*

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

**Thank you for Sharing Wisdom!**

# Network Intrusion Detection in Cloud Environments: A Comparative Analysis of Approaches

Sina Ahmadi
National Coalition of Independent Scholars (NCIS), Seattle, WA, USA

***Abstract*—This research study comprehensively analyzes network intrusion detection in cloud environments by examining several approaches. These approaches have been explored and compared to determine the optimal and appropriate choice based on specific conditions. This research study employs a qualitative approach, specifically conducting a thematic literature analysis from 2020 to 2024. The research material has been exclusively obtained via Google Scholar. The traditional approaches identified in this research include anomaly-based and signature-based detection, along with innovative technologies and methods such as user behavior monitoring and machine learning. The findings of these studies demonstrate the effectiveness of conventional methods in known threat detection. They also struggle to identify novel attacks and understand the need for hybrid approaches that integrate the strengths of both. In this research study, the authors have addressed challenges such as privacy compliance, performance scalability, and false positives, highlighting the importance of continuous monitoring, privacy-preserving technologies, and real-time threat intelligence integration. This study also highlights the importance of stakeholder buy-in and staff training for the successful implementation of a network intrusion detection system (NIDS), especially when determining the evolving nature of cyber threats. This study concludes by defining a balanced approach combining new and old methodologies to offer an effective defense against diverse cyber threats in cloud environments. The future scope of NIDS in cloud environments has also been discussed, including enhancing privacy compliance capabilities and integrating AI-driven anomaly detection to meet emerging threats and regulatory requirements.**

***Keywords—Cloud networking; cloud security; firewall; intrusion detection; NIDS***

## I. Introduction

In the changing landscape of cloud computing, the attraction of rapid development, scalability, and cost savings is undeniable. However, shared resources and a dynamic environment exacerbate the weaknesses of this system. Traditional security measures must avoid the ever-evolving attack landscape. Therefore, the robust and adaptable NIDS plays a vital role in the defense system, which protects critical infrastructure and sensitive data [1]. The article presents a detailed analysis of various customized NIDS approaches, especially for the cloud environment. The complexities of anomaly-based, signature-based, and behavior-based detection systems are carefully examined in an organized manner, analyzing their effectiveness in finding and reducing threats within the dynamic cloud environment. The primary objective of this analysis is to gain a comprehensive understanding of the merits and drawbacks of each approach by incorporating and utilizing the latest advancements in the field, as well as recent research and industry best practices.

This systematic and detailed examination provides a detailed overview of anomaly-based, signature-based, and behavior-based NIDS approaches in the cloud system. Furthermore, a comprehensive analysis is conducted to identify the strengths, weaknesses, and perfect cyber threat scenarios for every approach in a systematic manner. Furthermore, organizations carefully examine emerging trends and predict the potential future direction of threats in cloud systems. This article also aims to provide a practical direction for applying and optimizing this system within the cloud environment. By integrating our relative analysis with real-world case research and best practices, readers will acquire practical insights into implementing effective breach detection strategies customized to their cloud architecture and security needs. This article explores the concepts of scalability, resource optimization, and integration with existing security systems. This will aid individuals utilizing cloud services to stay protected from new threats and ensure the resilience of their systems in the face of evolving cyber risks.

## II. Literature Review

### A. *Evaluating the Effectiveness of NIDS Approaches*

Network intrusion detection systems have become very common in cloud environments. It is a detection system that is installed on a virtual switch. Additionally, NIDS primarily analyzes and monitors network traffic to detect unauthorized access or unusual activity. The effectiveness of such systems has been researched in prior studies [3]. According to the researchers, NIDS mainly works by detecting data packets for particular behaviors and patterns indicative of an attack. It can also identify and alert network administrations to attacks, including unauthorized access, viruses, and port scanning. Fig. 1 depicts a typical network intrusion detection system.

A prior study [4] shows that NIDS can effectively ensure cloud security. It helps prevent network attacks and detect vulnerabilities within the cloud, such as unsecured networks or outdated software. Another benefit is its ability to protect a company’s essential data through its alert system. Real-time monitoring can also be done using NIDS, and security personnel can quickly respond to cloud attacks. Lastly, NIDS helps companies comply with network security regulations like GDPR or HIPAA. Fig. 2 shows the effectiveness of NIDS.

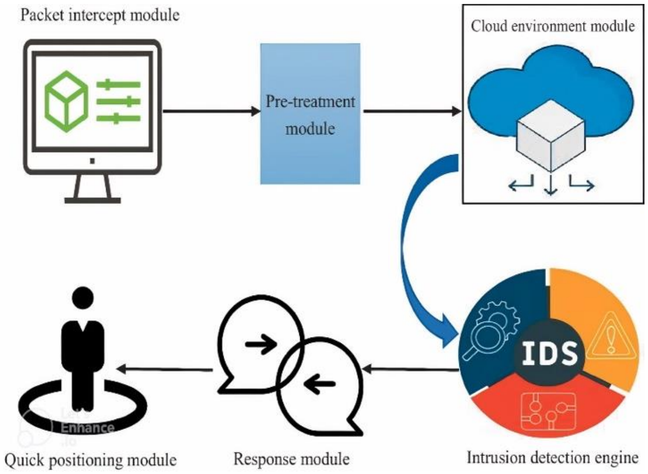

Fig. 1. Network intrusion detection system [2].

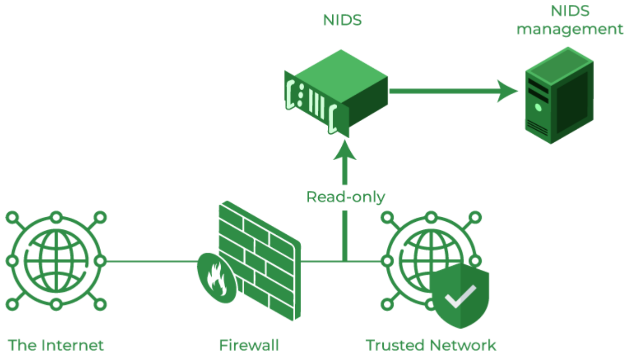

Fig. 2. Effectiveness of NIDS [5].

### B. Implementing NIDS Solutions in Cloud Environments

Network intrusion detection system solutions can be implemented in cloud environments using different detection methods. For example, signature-based detection is a common technique in this regard. According to study [6], signature-based detection compares traffic passing throughout the network against attack patterns or already known signatures. These patterns are predefined and linked with different attacks. When the incoming traffic matches a pattern of attack, it is detected instantly, and an alert is sent to the network administrator. However, this method is effective only in the case of detecting known attacks.

Another method is centered on anomaly-based detection. This approach detects anomalous network traffic that deviates from the usual network behavior. An alert is sent to the network administrator when any activity is outside the expected range. This method is very beneficial in detecting known and unknown attacks. However, it can also give false positives. Hybrid detection is another method that combines anomaly-based and signature-based detection. According to a prior study [7], this approach uses both methods to detect the attacks and has high levels of accuracy.

### C. Exploring Emerging Trends in Cloud-Native NIDS Technologies

Many new trends are emerging in intrusion detection in cloud environments. These trends are improving how companies approach cloud security. The most common trend is using artificial intelligence (AI) to enhance the capabilities of NIDS technologies. According to study [8], AI helps NIDS evaluate large network traffic data. This way, threats and attacks are detected more efficiently and accurately. Machine learning is also being used in this area to improve a company's NIDS and reduce the level of false positives.

Another trend is the use of microservice architectures and containerization in NIDS. They mainly help companies improve the security of their cloud-based environments. According to study [9], companies utilize advanced NIDS to match the current infrastructure when microservices and containers are used. Real-time detection of threats is carried out with the help of these techniques. Thus, mitigating risks is done more quickly while ensuring highly granular security controls for companies.

### D. Integration Matters: Leveraging Cloud Platforms for Enhanced NIDS

Integrating a cloud environment with NIDS provides many advantages to a company's security system [10]. Cloud platforms mainly offer improved services and infrastructure that will enhance the abilities of traditional NIDS. The primary advantage is using cloud-based techniques and services to improve threat detection. In this case, advanced analytics enhance the accuracy of intrusion detection. These analytics can assist companies greatly in improving the effectiveness of their NIDS without using any updated hardware.

Cloud platforms also offer easy integration with different security systems. This provides the ease of implementing an improved security system in companies. According to study [11], the system improves if security information and event management (SIEM) is used in NIDS. It enhances its ability to detect attacks. The IT infrastructure of the company is also improved in this way. The use of third-party solutions and APIs also enhances network security. Companies can develop new strategies with the help of these solutions and improve their cloud-based NIDS.

### E. Protecting Data and Meeting Regulations: Balancing Privacy and Compliance in Cloud-based NIDS

Complying with regulatory regulations is crucial when it comes to cloud-based NIDS. Companies need to ensure compliance with relevant regulations to overcome privacy issues. Cloud-based NIDS mainly analyzes and processes network traffic data, including private data. Thus, it is essential to use strong security measures for data protection. According to [12], different regulations, such as CCPA, HIPAA, and GDPR, can be implemented in this case. These regulations require companies to implement strong security practices to protect the cloud environment.

The use of data encryption and anonymization is also another robust approach. By anonymizing and encrypting an individual's personal information using solid passwords, companies can reduce the risk of external attacks. According to [13], these encryption protocols can help a company manage its security measures while meeting regulatory requirements. The use of data handling procedures is also essential in this case. When a company uses cloud-based NIDS, it is necessary to understand how the traffic data is processed and stored. Gaining consent from users is also required in this case. These specific rules ensure the utmost protection of the data.

### *F. Future Directions and Challenges for NIDS in Cloud Environments*

Various innovative methodologies are emerging in cloud computing and its associated NIDS. For example, the needs of companies are changing, and advanced technologies are being developed accordingly. According to study [14], one primary future direction is using machine learning and AI techniques in NIDS to improve its ability to detect threats. Since cybersecurity attacks are becoming very common these days, these technologies can help companies monitor their security systems in real time.

Furthermore, several challenges are linked to the use of advanced NIDS. According to study [15], the primary concern is to ensure the high levels of efficiency of the NIDS. This is due to the high volume of traffic in cloud systems, which poses challenges in their management. It is essential to ensure high-performance optimization and scalability levels to overcome the challenges of using NIDS. Thus, using advanced technologies and intelligent tactics can significantly help a company.

### *G. Identified Gaps*

While the literature review thoroughly examines cloud-based NIDS techniques, there are several notable gaps worth addressing. First, a deeper analysis of the specific challenges and limitations of each NIDS approach would provide valuable insights into their practical implementation and effectiveness in real-world cloud environments, especially considering the ever-evolving nature of cyber threats. Additionally, the review lacks discussion on the potential impacts of emerging technologies, such as quantum computing, on the efficacy of NIDS systems. Understanding how these advancements may influence threat detection and mitigation strategies is crucial for ensuring the long-term security of cloud-based systems. Furthermore, there is a notable absence of emphasis on the socio-technical aspects of NIDS implementation, including user acceptance, organizational culture, and the human element in cybersecurity operations. Exploring these aspects would offer a more comprehensive understanding of the challenges and opportunities associated with deploying NIDS in cloud environments, ultimately informing more effective security strategies.

## III. Problem Definition

In the unique landscape of cloud computing, the assimilation of NIDS creates complex challenges. Organizations encounter an intricate interplay of factors that affect the security of their sensitive data and infrastructure when they transition their systems to a cloud environment. Given the changing threats and technological advancements, the main problem lies in recognizing and applying practical NIDS approaches customized for cloud environments.

### *A. Complexity of Cloud Environments*

Cloud networks show unquiet characteristics, including various network topologies, fluctuating workloads, and shared resources in study [16]. The traditional NIDS is designed for fixed on-site setups, which may need to be revised to adjust to the unique nature of the cloud system. As a result, this difference often leads to problems in an organization’s ability to detect and address problems effectively. The constant changes in cloud setups make it difficult to use traditional NIDS. Thus, novel solutions that can adequately adjust to these changes are needed. In addition, the rapid growth and distribution of resources in cloud setups make it even harder for traditional NIDS systems to keep up. For instance, if organizations want to solve these challenges, they would need a revolution towards NIDS solutions that can smoothly combine with cloud systems while maintaining high detection efficiency and responsiveness.

### *B. Diverse Threat Landscape*

The different threat systems present a significant challenge to the effectiveness of NIDS in cloud systems [17]. Cyber threats range from well-known attacks with a signature that is easily accessible to new and unknown viruses and attacks that constantly change their appearance, continuously evolving and posing further risks. Network intrusion detection systems detect known and unknown attacks while reducing false positives and negatives to zero. Maintaining this balance is essential to avoid consuming the security teams with false alarms while confirming that the main threats are solved. Thus, NIDS solutions customized for cloud environments must be quick and sophisticated, accurately differentiating between normal network activities and dangerous behavior to enhance overall threat detection capabilities and effectively reduce security risks. When comparing the performance of signature-based, anomaly-based, and hybrid detection methods (see Table I), it becomes evident that the hybrid approach demonstrates the highest true positive rate at 95%. This indicates its superior capability in accurately identifying intrusions while maintaining a low false positive rate, making it a promising option for enhancing network security.

Table I shows NIDS detection rates.

TABLE I. NIDS Detection Rates

| **Methodology** | **True Positive Rate (%)** | **False Positive Rate (%)** |
|---|---|---|
| Signature-based | 90 | 5 |
| Anomaly-based | 85 | 8 |
| Hybrid Detection | 95 | 3 |

### *C. Adaptability and Scalability*

In cloud setups, it is essential for NIDS to have the capability to adapt and scale up [18]. These systems must handle different amounts of work and changes to how the network is set up. They should be able to identify and address security threats and adapt to the cloud setup changes, which is significant for keeping security strong without impeding performance or causing problems. As the cloud system has changed significantly, NI and DS must adjust quickly and adequately to secure data. Moreover, the cost of a cloud setup is irrelevant.

### D. Integration with Cloud-Native Technologies

Connecting the NIDS with cloud-native technologies is very important to identify and stop the challenges in cloud setups. This entails utilizing cloud-based APIs to enhance the capabilities of the NIDS in terms of monitoring and protecting network traffic. However, these tools can be complex to make NIDS perform effectively because each cloud platform performs differently. In addition, continuously monitoring network traffic in containers increases the challenges. To deal with these challenges, organizations must engage in proactive thinking over effective strategies and ensure the implementation of robust security measures. Connecting NIDS with cloud-native technologies is complex; however, it is also essential for ensuring security against online threats in cloud setups.

### E. Privacy and Compliance

It is essential to ensure that the NIDS is good at identifying the challenges and problems in the system while following the rules correctly [19]. Additionally, NIDS needs to be able to monitor network traffic and identify threats without breaking the laws and regulations. This means using techniques to hide sensitive data while still identifying threats. It is essential to work according to the laws. Organizations must understand privacy laws and rules and set up robust NIDS systems to protect data privacy and network security. They can reduce risks and protect their network by focusing on data privacy and security. Privacy protection score can be determined using Eq. (1).

$$Privacy\ Protection\ Score = \frac{Data\ Encryption\ Level\ x\ Compliance\ Adherence}{Data\ Sensitivity} \quad (1)$$

## IV. Methodology / Approach

### A. Research Design

This study used qualitative research methodology to obtain positive and accurate outcomes and to explore and compare different approaches regarding network intrusion detection in cloud-based networks. Qualitative research methodology can be defined as a research methodology that integrates social sciences and other disciplines to understand and explore diverse perceptions, behaviors, and experiences of different people and groups. This approach helps understand the benefits and complexities of the NIDS methodologies in a cloud network. The objective of this study was to gain valuable insights into the research conducted by different authors using qualitative research methods to enable a comparative analysis of different NIDS approaches.

### B. Research Setting and Participants

The research setting encompassed different cloud environments, such as hybrid, private, and public clouds. The included participants are researchers who conducted a study on network intrusion detection in cloud environments and the different approaches they used. All the researchers are highly qualified experts who have conducted in-depth research on this topic. The majority of participants consisted of IT professionals, cloud architects, and cybersecurity experts who possessed comprehensive knowledge about cloud environments, their complexities, and their benefits.

### C. Data Collection

The study's data collection process began with a systematic search on Google Scholar, using keywords such as "network intrusion detection," "NIDS in cloud environments," and "cloud-based network security." These keywords were meticulously chosen to retrieve scholarly articles, reports, and publications pertinent to network NIDS within cloud environments. By employing this approach, the study aimed to capture a wide array of literature covering various aspects of NIDS methodologies within cloud networks. The selection of specific search terms and their variations ensured a thorough exploration of relevant research material, facilitating a comprehensive understanding of the topic. Through this systematic search strategy, the study aimed to gather diverse perspectives and insights to inform its analysis and conclusions effectively. This rigorous approach to data collection contributes to the study's credibility and enhances its potential to yield valuable insights into NIDS approaches in cloud environments.

### D. Data Analysis

To conduct data analysis for this research study, thematic analysis was employed to analyze the qualitative data obtained from the literature review. The data was categorized systematically to identify relevant patterns, themes, and insights regarding emerging trends and challenges related to NIDS approaches within cloud networks. The key findings and data were explored regarding the comparative analysis of different NIDS methodologies in cloud environments. Moreover, thematic analysis played an integral role in identifying discrepancies and commonalities among the findings from the literature review. The analysis process was iterative, ensuring a comprehensive examination and enhancing the reliability and credibility of the study's conclusion. The thematic analysis of qualitative data obtained from the literature review on NIDS approaches within cloud networks bolstered a comprehensive explanation of the identified themes and their direct relevance to the study's aims. Each theme was carefully elucidated with detailed descriptions, supported by specific examples and evidence from the literature. By delving deeper into the nuances of each theme, the analysis aims to offer a nuanced understanding of the challenges, emerging trends, and best practices in NIDS methodologies within cloud environments. Furthermore, the relevance of each theme to the overarching research objectives was explicitly discussed, highlighting how insights derived from these themes contribute to addressing the research questions and advancing knowledge in the field of cloud security. This approach ensures that the analysis not only identifies key findings but also contextualizes them within the broader scope of the study, enhancing the overall quality and significance of the research.

### E. Ethical Considerations

The ethical considerations in this research study during the literature review evaluation were centered on the use of academic materials and ethical sourcing. All papers selected from Google Scholar followed the ethical standards, which ensured the acknowledgment of the author's work and the appropriate citation. Biases and conflicts in the literature chosen were also accounted for and acknowledged in the analysis. Moreover, efforts were made to represent the selected research studies' findings accurately and maintain the integrity of this research.

## V. Results and Discussion

### A. Traditional Approaches Effectiveness

The traditional NIDS techniques, including signature-based and anomaly-based detection, have presented the changing effectiveness of cloud systems [20]. Signature-based detection, which is very efficient in detecting attacks, has faced limitations in finding zero-day threats due to its fixed nature. On the other hand, anomaly-based detection shows the promise to identify the contrasts from normal behavior but often suffers from high false positives, particularly in dynamic cloud environments. Hybrid detection approaches, which combine the advantages of both signature-based and anomaly-based methods, offer enhanced range and reduce false positives compared to conventional approaches. Studies have shown that the hybrid detection system can accomplish accurate favorable rates of almost 95% or higher while maintaining lower false positives, which makes it a practical choice for cloud system breach detection.

### B. Challenges and Opportunities in Emerging Approaches

New techniques to detect cloud system breaches are emerging, like machine learning, tracking user behavior, and cloud-specific technologies. Machine learning, especially LSTM networks, has accurately spotted dangerous threats [21]. However, it takes time to understand how these methods work, and in certain situations, additional data is needed before they can be used. Monitoring user behavior can help in detecting anomalous activities performed by individuals within the system. Conversely, it is complex to set up since it needs a lot of user information. Although cloud-specific technologies use aspects of cloud systems to detect breaches, there is a need for enhanced regulations and mechanisms to govern access privileges. Combining the new methods can make the cloud system safer by identifying the recent changes in the system that may jeopardize the integrity of the data. Even though there are challenges, such as understanding how these methods work, new approaches to identifying breaches can help protect the cloud system from potential threats? Thus, it is imperative that we consistently research and enhance these methods to make them even better at safeguarding cloud systems.

### C. Comparative Analysis of NIDS Approaches

Comparing old and new approaches to detecting violations shows which is good or bad. Traditional methods work effectively in dealing with known information; however, attacks can be missed nowadays, leading to sensitive data loss. New techniques, such as using intelligent algorithms or observing user behavior, can detect more types of attacks. However, these procedures require meticulous setup and necessitate assistance in comprehending user perspectives and safeguarding data confidentiality [22]. Combining old and new methods can create a favorable balance that detects more threats while minimizing errors. It is also important to consider the dynamic nature of threats and evaluate the effectiveness of the measures in ensuring data security. Traditional approaches might require increased speed to detect emerging attacks; however, innovative methods can adapt and evolve in response to evolving threats. Combining old and new methods strengthens organizations against different cyber threats. Organizations can use the latest technology to stay ahead and keep their data and systems safe from threats.

### D. Adapting to an Evolving Threat Landscape

In the context of evolving threats, NIDS must understand the importance of adaptability to changing tactics and emerging attack vectors. Cyber threats are evolving; thus, their complexity also keeps growing, making it imperative for NIDS to stay proactive and vigilant when identifying and mitigating potential risks. Moreover, it is necessary to continuously monitor emerging threats and update the threat intelligence feeds and configurations of NIDS. This is the best way to develop innovative attack methods and vulnerabilities. The effectiveness and agility of NIDS in cloud-based networks can be enhanced by implementing automated systems and integrating real-time threat intelligence for instant threat detection and response.

### E. Addressing False Positives

As cloud environments advance, it is essential to minimize false positives to maintain effective intrusion detection [23]. False alarms can easily be mitigated by using SIEM solutions, integrating real-time threat intelligence feeds, and using NIDS parameters. Threat intelligence and detection thresholds are essential in filtering out known benign activities, helping organizations reduce the impact of false positives on organizational operations. Therefore, organizations can focus on ongoing monitoring and analysis of false positive incidents to extract valuable insights and refine NIDS configurations. It is also helpful in improving the overall detection accuracy.

### F. Ensuring Performance and Scalability

Suppose an organization wants a high level of performance and scalability in cloud-based networks. In that case, it needs to optimize NIDS configurations and focus on using distributed detection architectures. Organizations can also distribute detection workloads in multiple instances or nodes to efficiently manage workloads without affecting detection efficacy at any cost. Thus, integrating cloud-based technologies and optimizing detection algorithms can enhance the scalability and performance of network intrusion detection strategies.

In addition, the performance of NIDS in cloud environments can be enhanced by focusing on resource allocation and effective capacity planning. Performance bottlenecks may arise from fulfilling future workload demands and concentrating on the overall growth of these strategies. Thus, performance and scalability can be enhanced by implementing auto-scaling mechanisms based on predefined thresholds to adjust resource allocation due to workload patterns and network traffic changes. Undoubtedly, performance testing is crucial for obtaining valuable insights regarding the effectiveness of NIDS configurations and identifying areas for optimization. Table II details resource allocation in various cloud services and their costs, aiding organizations in understanding usage patterns and budgeting. For instance, $50 for 1000 GB storage shows storage needs, $100 for 500 GB computing reflects computational demands, and $20 for 100 GB network bandwidth stresses connectivity significance.

TABLE II. RESOURCE ALLOCATION

| Cloud Service | Resource Allocation (GB) | Cost ($) |
|---|---|---|
| Storage | 1000 | 50 |
| Computing | 500 | 100 |
| Network Bandwidth | 100 | 20 |

### G. Privacy and Compliance Considerations

Regulatory compliance standards and data privacy are paramount in cloud-based intrusion detection [24]. In this case, the primary anonymization techniques, such as tokenization and encryption, help protect the sensitive information of organizations and their associated users. Thus, these techniques effectively aid in detecting intrusion. It is also necessary for organizations to ensure compliance with regulations such as PCI DSS, HIPAA, and GDPR, which implement strict data security and privacy requirements. Identity and access management (IAM) systems are implemented to enhance data privacy and limit access to organizational data by granting permissions to specific and authorized users only. Moreover, employees must be educated regarding data privacy policies and regulations, and security awareness practices must be promoted to handle sensitive information. Regular audits must be conducted to ensure ongoing compliance with regulatory requirements. Table III outlines compliance costs for GDPR, HIPAA, and PCI DSS, emphasizing the financial commitment required for regulatory adherence. For instance, $10,000 for GDPR signifies investments in data protection, $15,000 for HIPAA reflects patient information security, and $12,000 for PCI DSS highlights payment data protection expenditures, aiding resource allocation and compliance prioritization.

TABLE III. COMPLIANCE COSTS

| Regulation | Compliance Cost ($) |
|---|---|
| GDPR | 10,000 |
| HIPAA | 15,000 |
| PCI DSS | 12,000 |

### H. Hybrid Approach Advantages

A hybrid approach combines both traditional and innovative NIDS methodologies, enabling it to combine the advantages of both methods for intrusion detection in cloud environments [25]. By combining anomaly-based and signature-based detection strengths, hybrid systems can achieve higher detection accuracy while minimizing false positives. Additionally, integrating adaptive and self-learning hybrid systems with machine learning and AI technologies results in enhanced accuracy and efficiency that can be improved over time. The hybrid approaches have several advantages, such as flexibility and scalability, allowing them to adjust their intrusion detection systems to meet the specific cloud environment. This ability will enable organizations to adjust detection strategies based on workload demands and emerging threats. Eq. (2) can help in calculating detection accuracy.

$$\frac{True\ Positives+True\ Negatives}{True\ Positives+True\ Negatives+False\ Positives+False\ Negatives}\ x\ 100\% \tag{2}$$

### I. Organizational Implementation Challenges

The implementation of NIDS in a cloud system can result in several challenges [26]. Organizations must overcome these challenges to deploy and manage NIDS successfully. The biggest challenges are the complications of cloud architecture and the varied range of available platforms and services. Careful management and planning are required for NIDS's compatible and active implementation in multiple cloud environments. Organizations also face resource allocation challenges, including allocating storage spaces for the placement of NIDS without affecting the system and adequate allocation of computing resources. Additionally, the implementation and management of NIDS are greatly influenced by factors such as staff training and skill development. Thus, it is beneficial for organizations to invest in training programs, considering the constantly changing nature of cyber threats and the difficulty of NIDS technologies. It will help organizations ensure that the workers have the skills to accurately monitor, configure, and respond to any security incident. Getting stakeholder buy-in and support is essential to overcome the resistance hindering progress and ensure the proper implementation of NIDS. Collaboration and alignment of aims can be boosted during the implementation process by reaching stakeholders from different levels and departments within the organization.

## VI. CONCLUSION

Cloud computing is the most used system nowadays; however, data security in cloud computing is one of the most critical concerns. The rising reliance of organizations on cloud environments for communication, storage, and data computation has led to a growing demand for a robust security system such as NIDS. The main focus of this article is to examine NIDS mechanisms explicitly created for security in a cloud environment. In a time where cloud computing offers scalability, cost-effectiveness, and agility, the shared responsibility model focuses on providing active steps to secure data from breaches. In the constantly changing cloud architecture, old-style security models must be more robust to tackle security threats. For this reason, it has become essential to use anomaly-based, signature-based, and emerging behavior-based threat detection systems, as they help organizations boost their data security in the cloud. Considering information from recent studies, the article seeks to equip stakeholders with a concise overview of limitations, strengths, and future predictions about different NIDS methodologies. Organizations can quickly detect the difficulties in cloud security with the help of this comparative analysis. The findings of this study will also help them boost strong defenses in this constantly changing threat landscape. Moreover, technologies are evolving continuously, necessitating a corresponding adaptation in strategies to protect data confidentiality.

## VII. Future Scope

The future scope of NIDS in cloud environments includes the potential for further innovations and advancements to address emerging challenges quickly and effectively. A significant future development is using machine learning and AI in NIDS frameworks. With these technologies, the abilities of NIDS can be enhanced to detect and respond to different types of threats in real-time, which, in turn, improves the network's overall security. Furthermore, AI-driven anomaly detection mechanisms can be integrated into the future to enhance organizations' visibility into their cloud networks. The future of NIDS in cloud environments also includes exploring innovative approaches to enhance compliance and privacy capabilities. As technology evolves, the associated threats also increase, necessitating an increase in NIDS solutions. For this purpose, privacy-preserving technologies like homomorphic encryption can be incorporated by organizations in the future. The future scope of NIDS also includes exploring advanced threat intelligence integration and collaboration mechanisms. Moreover, NIDS can access various threat intelligence sources by building solid relationships and information-sharing initiatives with industry fellows, cybersecurity organizations, and government agencies.

Additionally, advancements in cloud computing infrastructure and networking technologies offer opportunities for NIDS to evolve further. The integration of software-defined networking (SDN) and network functions virtualization (NFV) can enable more agile and dynamic intrusion detection mechanisms. However, the adoption of edge computing and fog computing paradigms presents new challenges and possibilities for NIDS deployment and management at the network edge. Thus, by leveraging these emerging technologies, NIDS can adapt to the changing landscape of cloud environments, providing enhanced security and resilience against evolving cyber threats. Future research and development in these areas promises to shape the future of NIDS in safeguarding cloud-based systems.

***Abstract*—In recent decades, mobile devices have evolved in potential and prevalence significantly while advancements in security have stagnated. As smartphones now hold unprecedented amounts of sensitive data, there is an increasing need to resolve this gap in security. To address this issue, researchers have experimented with biometric-based authentication methods to improve smartphone security. Following a comprehensive review, it was found that gait-based mobile authentication is under-researched compared to other behavioral biometrics. This study aims to contribute to the knowledge of biometric and gait-based authentication through the analysis of recent gait datasets and their potential with machine learning algorithms. Two recently published gait datasets were used with algorithms such as Random Forest, Decision Tree, and XGBoost to successfully differentiate users based on their respective walking features. Throughout this paper, the datasets, methodology, algorithms, experimental results, and goals for future work will be described.**

***Keywords—Machine learning; machine learning algorithms; behavioral biometrics; gait dynamics; motion sensors***

## I. INTRODUCTION

The demand for mobile device performance continues to increase as society and industry becomes more technology oriented. Nowadays, smartphones are used for an ever-expanding array of problems including navigation, calculations, photography, and socialization. The ability to combine solutions to multiple daily functionalities into the applications of a smart device is expected by today's mobile device users. Recently, the use of mobile financial transaction options and the holding of sensitive card data such as Apple Pay, Apple Wallet, PayPal, and Venmo have become popular. In the United States, 59% of in-person stores, restaurants, and other services allow for apple pay, only superseded by 70% in the U.K. [1]. While only needing to bring a phone into a store to complete transactions is appealing to consumers, financial security consequences arise if devices are stolen and broken into. Losing a phone can now have a similar impact to losing a wallet. With these advancements, it has been necessary to find secure ways to protect the sensitive data smart devices hold.

In response to these concerns, researchers have been investigating the potential of novel authentication methods to improve mobile device security. The two current most common methods of authentication for devices are knowledge-based and physiological-based. In knowledge-based authentication, information that is known only to the owner is used to secure the device. This method can be deployed as a sequence of characters and numbers, or as a graphical pattern. While knowledge-based authentication is widely popular and easy to use, it is also prone to security risks if this information is leaked or stolen by an adversary [2]. Physiological biometrics uses physical traits of the user for authentication, such as facial, fingerprint, palm or ocular characteristics scanned by the device. These methods have become more popular in recent years and have become implemented in phones and other devices. Unfortunately, physiological methods have found to be less accurate and more costly than expected, sometimes requiring additional hardware to accurately scan the user's features [3]. Researchers have found an alternative solution in the form of behavioral biometrics. Behavioral biometrics uses an individual's unique behavioral characteristics to secure a device. They are cost effective, as they collect data with low-cost sensors already within the device such as motion sensors and the touch screen [2]. It is also notable that while knowledge-based and physiological methods are generally used as a one-time authentication strategy, behavioral biometrics methods can continuously authenticate the device while it is being used. This strategy analyzes user behavior repeatedly to secure the device in the case that an initial one-time authentication has failed, and the device has already been accessed [4].

There are many different behavioral strategies used to secure a device with the innate sensors, including touch dynamics, keystroke dynamics, and motion dynamics. Motion dynamics utilize the motion sensors in a device, including the accelerometer, gyroscope, and magnetometer sensors. Motion dynamics can be captured anytime the device is being used where motion is involved. One subset is known as gait dynamics, where the device records data from the motion sensors while the user walks to capture their gait characteristics. As of late, these behavioral biometrics methods have been found to be effective in securing mobile devices when used with machine learning and deep learning algorithms with high accuracy metrics and low error rates [5].

This paper aims to further research into this field of study with these contributions:

- Expand knowledge into behavioral biometrics authentication with the comparison of two recently published gait datasets [6, 7].
- Develop Machine Learning models (Random Forest, Decision Tree, XGBoost) to evaluate the efficiency of gait biometric authentication and compare classifier results.

## II. Background and Related Work

The direction of this study was inspired by the findings of a past work, reviewing the use of Machine Learning (ML) and Deep Learning (DL) algorithms with biometrics-based mobile authentication systems [5]. This review examined 66 of the latest experimental studies on behavioral biometrics with touch dynamics, keystroke dynamics, motion dynamics and gait dynamics with a focus on how they performed with various algorithms. It was found that studies on the usage of AI algorithms with biometrics have become popular in recent years as the increase in number and quality of public training datasets has allowed for the construction of better performing and more accurate models. Of the dynamics listed, touch dynamics and motion dynamics were the most popular, with 24 and 18 studies cited respectively. Despite having decent performance metrics in comparison, gait dynamics were found to be under-researched, numbering at 11 cited studies, the lowest of the four dynamics. Therefore, this study has sought to breach this gap by analyzing the performance of recently published gait datasets with AI algorithms.

In previous reviews [5, 8], it was established that to continue progress in the investigation of behavioral biometrics mobile authentication systems, it is worthwhile to focus on how systems can be advanced past previous boundaries and ensure models can hold up against real world contexts. One way to do this is to ensure datasets have larger sample sizes that can properly represent a population and effectively train a ML/DL model. In recent years, many high-quality biometrics datasets with larger sample sizes have been published for public use, allowing us to advance model quality. One example in gait dynamics would be the IDNet dataset, published in 2018 [9]. This dataset has since been cited in over 200 papers with a majority published after the year 2020. The IDNet dataset consists of accelerometer and gyroscope data collected from 50 subjects over a six-month period and was collected to classify gait cycles regardless of device orientation. Of the reviewed studies, [10], [11], and [12] used the IDNet dataset to evaluate various LSTM-based models and resulted in accuracy metrics ranging from 96-99%. Another notable dataset would be the WhuGait dataset, published in 2020 [13]. This dataset contained gait motion sensor data from 118 individuals collected in an unrestrained “wild” environment. Their presenting study analyzed the dataset performance with a hybrid Convolutional Neural Network (CNN) and Long-Short Term Memory (LSTM) model, resulting in an accuracy performance of 93.75%.

Mobile gait authentication studies typically rely on the use of motion sensors within the phone such as accelerometer, gyroscope, and magnetometer to capture an individual’s gait cycle characteristics. Of the motion dynamics studies reviewed, pairing accelerometer and gyroscope sensor data was the most popular [5]. Within gait studies, a similar pattern was seen with studies preferring either accelerometer data alone or a pairing of accelerometer and gyroscope data. In the WhuGait study [13], accelerometer and gyroscope data were collected. Results from this study found that individually, accelerometer data performed better than gyroscope, but using both was complementary.

Overall, recent studies in mobile gait authentication favored hybrid Deep Learning (DL) models. Of the gait studies reviewed, architectures using CNN feature extraction with LSTM classification numbered half of the cited papers with accuracy metrics ranging from 90.00-99.99% [5]. Within some of these studies, the hybrid models were also compared to ML algorithms in performance. In all the studies, DL algorithms outperformed ML algorithms, but in some the ML algorithms performed at adequate levels comparatively. In the IDNet paper, a model with CNN feature extraction and One-Class Support Vector Machine (OC-SVM) classification was tested on their data with a performance of < 0.15 False Acceptance Rate (FAR) and False Rejection Rate (FRR) [9]. In another study [14], a CNN model was proposed for gait authentication and evaluated with a large public dataset. Their model was compared with the performance of Random Forest (RF) and K-Nearest Neighbors (KNN) algorithms. CNN had the best performance with 0.9882 accuracy, but RF did not lag too far behind with an accuracy of 0.9551. In a third study [15], walking data from a small dataset was tested on LSTM, CNN, Support Vector Machine (SVM) and Multi-Layer Perceptron (MLP) in two scenarios. In the binary classification scenario using training data from both the target user and other users, SVM had the best performance compared to MLP with 98.42% accuracy. In a scenario where the training data only included the target user’s data, LSTM significantly outperformed SVM with 90.24% accuracy. Overall, DL algorithms have proved to dominate current gait mobile authentication studies with high accuracy rates and low error rates, but it has been noted in some comparison studies that ML algorithms such as RF and SVM remain effective in certain scenarios. This can prove useful if one is attempting to build a smaller security system with less data than is required for advanced DL models.

Studies most recently published demonstrating the continued relevance of gait dynamics mobile authentication research include [16], and [17]. In study [16], researchers collected accelerometer and angular velocity sensor readings from 10 individuals in pocket and hand-hold positions over periods of around 90 seconds. They trained a CNN model with the data, producing an average accuracy of 0.9175. The study concluded that gait data collected over short periods of time can be successfully used for authentication. In study [17], researchers proposed IRGA, their implicit real-time gait authentication system using a hybrid CNN+LSTM model. They collected accelerometer, gyroscope, and magnetometer sensor readings from 16 individuals in varying positions and walking styles, analyzing the impact of constrained vs unconstrained environments. They concluded that authentication based on gait characteristics is feasible despite limitations. Their model was tested on multiple datasets, achieving a highest average accuracy of 99.4% with the ZJU-GaitAcc dataset.

## III. Methodology

### A. Datasets

Two datasets were chosen to compare algorithm performance. They were each chosen for their similarities as well as their relatively recent publishing dates bearing a limited number of citations. The first, BB-MAS, is a large dataset comprising of swiping, keystroke, and gait data collected from desktop, tablet, and mobile phone devices [2]. It was published in 2019 by Belman et al. The dataset demographic consists of 117 individuals, 72 male and 45 female, of which the majority spoke English and was right hand dominant. The data collection process consisted of a sequence of events each individual performed to complete all dynamics activities. First, the individual would start the desktop and touch dynamics activities before walking down a corridor with their mobile device, passing through a stairwell, walking down another corridor, and returning along the same path. The files were split between device used and sensor collected from as well as device position. Gait accelerometer and gyroscope data was collected from a mobile device at a 50Hz sampling rate in two positions; one where the device was held in the hand, and one where the device was placed in the pocket. The X, Y, and Z axis values were recorded for each sensor. Gait data collection time for each individual ranged around 5-10 minutes. The mobile devices used in the study were Samsung-S6 and HTC-One phones. Timestamps were included along with each user file folder to differentiate between corridor walking and stair climbing. Only data in which the individual was performing walking movements along a corridor with a mobile device was used.

The second dataset, MMUISD, was published in 2020 by Permatasari et al [3]. The MMUISD dataset originally consisted of data from 322 undergraduate students (246 male and 76 female) which was cut down to 120 for the publicly available dataset. The data collection process was simple, requiring individuals to walk down a 15-meter corridor with their device. An android application was downloaded onto each device and used to collect accelerometer and gyroscope data at a 50Hz fixed sampling rate. X, Y and Z axis values were recorded for both accelerometer and gyroscope. There were six different device positions in the study, of which only the hand and pocket positions were used. Users were instructed to walk naturally without restraints in three different speeds: slow, normal, and fast. User file data was differentiated based on speed and position. Data collection time ranged from 5-8 minutes for each individual to complete all speeds. Due to time constraints, the number of individual users per speed and position in the public dataset differed between 65 and 99 individuals as can be seen in Table I.

TABLE I. MMUISD PARTICIPANTS

| Position / Speed | # of Participants |
|---|---|
| Left H slow | 65 |
| Left H Normal | 99 |
| Left H Fast | 96 |
| Right H Slow | 79 |
| Right H Normal | 80 |
| Right H Fast | 76 |
| Left P Slow | 90 |
| Left P Normal | 74 |
| Left P Fast | 97 |
| Right P Slow | 96 |
| Right P Normal | 75 |
| Right P Fast | 75 |

## B. Data Cleaning and Preprocessing

Before feature extraction, it is important to properly preprocess and clean the data to prevent avoidable errors. The pandas python library and PyCharm environment were used to facilitate these steps. Both datasets selected had clear signals without significant outliers, so it was not needed to take many steps in the initial cleaning process. The null values in all rows were replaced with 0 for all user files in each dataset.

The preprocessing steps were unique to each dataset since the organization of the user files and data signals differed slightly. The MMUISD dataset was straightforward, as both the gyroscope and accelerometer sensor readings were compiled in the same file for each user and only recorded walking data. BB-MAS instead separated gyroscope and accelerometer readings into different files. Due to how the data was collected, stair climbing and walking were recorded on the same files and required given timestamps to differentiate the two. Taking extra steps to preprocess the BB-MAS files was necessary to properly compare both datasets. First, the timestamp file matching the current user file being preprocessed was extracted and the checkpoints corresponding to the walking segments were identified. Then, the accelerometer and gyroscope signal files were merged based on the recording times. Using the checkpoints, walking sequence data was separated and concatenated into a new Data Frame to be used in the feature extraction process.

## C. Feature Extraction

In time series analysis problems, time domain features are typically extracted from sequences of the recorded data. The sequence lengths were chosen by visualizing the mean of

$$m = \sqrt{x^2 + y^2 + z^2} \quad (1)$$

From the x, y, and z axis of each signal with respect to the time. An example of this visualization is provided by Fig. 1. For the MMUISD dataset, a sequence length of 10 was chosen. The BB-MAS dataset has a greater amount of datapoints, thus a sequence length of 20 was found to be optimal.

The same feature sets were chosen for both datasets for comparison purposes. Eight different statistical features were extracted from the x, y, z axes and m of both the accelerometer and gyroscope signal. In total, 64 features were extracted from each user file. The features were selected based on previous studies as well as the recommendations of the chosen datasets. In the BB-MAS readme document, Mean, Standard deviation, Band Power, Energy, Median Frequency, Interquartile Range, Range, Signal to Noise Ratio, Dynamic Time Warping Distance, Mutual Information and Correlation were suggested as possible gait features. Other gait authentication studies reviewed commonly included features such as Mean, Standard Deviation, Band Power, Median Frequency, Interquartile Range, Range, Dynamic Time Warping Distance, Average Max and Min, Root Mean Square, and Average Absolute Difference [9, 18, 19]. For the final feature set, the Mean, Standard Deviation, Average Min and Max, Interquartile Range, Range, Root Mean Square, and Absolute Deviation from x, y, z and m were extracted.

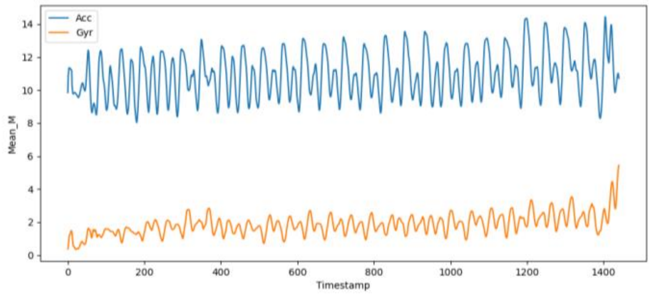

Fig. 1. Visualization of the mean m of the accelerometer and gyroscope signals from a user in the MMUISD dataset.

### D. Training and Testing

Data from each user was split with 80% used for training the models and 20% used for testing. This 80/20 split was chosen as 80/20 and 70/30 splits for training and testing sets have been found by empirical research studies to be optimal for statistical model performance [20]. The authentic user data and imposter data was then concatenated together for the final training and testing sets. For the testing set, the user data was concatenated with a 40% random sample of the imposter data to prevent overfitting and bias. To enable the model to properly differentiate an authentic user from an imposter within the training data, each data point included a class label with a 0 or 1. A 0 represented an authentic user and while a 1 was an imposter. During the testing process, these labels were used to determine how accurate the classifier’s decision making was. For data normalization, Standard Scaler was used for the Random Forest and Decision Tree Models, while Simple Imputer was used with the XGBoost model.

During the initial testing process, the parameters of each ML model were fine tuned to produce the best classification results with the datasets. The Random Forest model comprised of a parameter set with 100 estimators, a max depth of 20, a minimum sample split of 2, a minimum number of trees of 1, 7 jobs to run in parallel, and class weights determined by the number of positive and negative samples. The Decision Tree model included Gini Impurity function, a max depth of 10, and class weights determined by the number of positive and negative samples. The XGBoost model required more manipulation than the previous models, producing higher levels of overfitting. To combat this, the feature set was cut down to around 15 by evaluating feature importance with a basic binary logistic XGBoost model. Feature importance was visualized with a pyplot bar graph, and features that produced an importance level of less than 0.2 were removed. Features that produced high levels of feature importance in both datasets included Min and Max, Mean, Root Mean Square, and Range. The final XGBoost model parameters included binary logistic objective, a learning rate of 1.5 and a scale pos weight determined by class balance.

## IV. Results

This study intends to evaluate the efficiency of gait characteristics for differentiating mobile users by comparing the classification performance of ML algorithms with two recent gait datasets. For classification analysis, high performance binary classifiers were selected such as Random Forest, Decision Tree, and XGBoost. The classifiers were trained and evaluated as specified in the previous section on all users.

To properly evaluate the performance of the models on the datasets, the following statistical evaluation metrics were included in the results for each user in each dataset:

- The Accuracy (ACC): Rate of correctly predicted results.
- F-Score (F1): Measure of the harmonic mean of precision and recall.
- False Positive Rate (FPR): Rate of incorrectly identified authentic users.
- False Negative Rate (FNR): Rate of incorrectly identified imposters.
- Equal Error Rate (ERR): Threshold where FPR and FNR are equal.

When observing these metrics, lower EER, FPR and FNR rates are desired over higher ones, as they represent how well a model can differentiate between authentic users and imposters. The accuracy metric is helpful for measuring overall model performance accuracy. Similarly, a larger F1 score is indicative of strong overall model performance.

Table II shows the results from training the models with the MMUISD dataset. Random Forest had the best overall classification performance using MMUISD with an average accuracy of 98.90% and an average EER of 4.18%. Random Forest achieved the highest accuracy in the right pocket position at slow speed with 99.18% and a lowest EER of 2.76% in the right pocket at fast speed. While the XGBoost model achieved a higher average accuracy than Random Forest with 98.98%, it also had higher average error rates of 18.94%. DT had a lowest error rate with 3.69% but had a smaller overall average accuracy than Random Forest. The XGBoost model had tended to overfit to the user, resulting in higher and more varied error rates after tuning.

BB-MAS results are shown in Table III. Random Forest had the best performance with an overall accuracy of 99.03% and an EER of 1.04%. Decision Tree and XGBoost had similar differences in performances with Decision Tree achieving lower accuracy scores but a similar EER score. XGBoost again achieved the highest accuracy score but with higher EER scores due to a tendency to overfit the data.

Table IV compares the performance of the two datasets. In both datasets, Random Forest had the best overall performance. The Pocket Phone position achieved the best accuracy and EER results in both datasets as well. One noticeable difference is that Decision Tree achieved a better accuracy in the hand position with the MMUISD dataset, with a score of 95.41% compared to 88.98% with the BB-MAS dataset. It is also notable that the pocket position achieved better error results with the BB-MAS dataset compared to the MMUISD dataset, with an average EER of 1.04% compared to 3.37% when evaluated with the Random Forest model.

## V. DISCUSSION AND ANALYSIS

The three chosen algorithms had very similar classification performance between the two datasets with slight differences in EER regarding device positioning. The performance of the models did not differ between the between positions and speeds with relation to the number of participants that collected in each position as described in Table I. Between both datasets, Random Forest was found to be the best performing algorithm overall with high accuracy rates paired with lower EER rates.

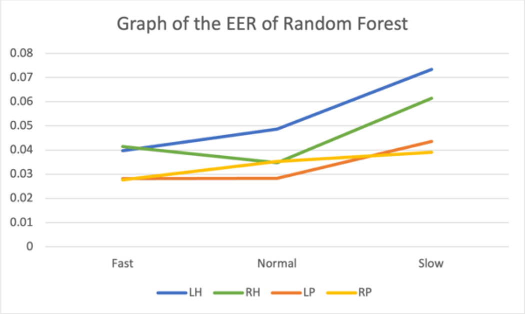

Fig. 2. Visualization difference in EER performance of Random Forest between different phone positions.

The results for the MMUISD dataset have interesting implications on the effect of position and speed on model performance. As shown in Fig. 2, Random Forest EER generally increased as the user's speed became slower. This could imply more variation in the data as the walk speed decreases, as opposed to a fast speed with a lower EER rate. A similar pattern was found in the Decision Tree model. The XGBoost did not follow this pattern as it had more varied error rates. The pocket position achieved generally better results overall compared to the hand position with all algorithms. This could imply that keeping the device closer to the body results in more stability and less variation and noise in the signal compared to holding the device in the hand. The difference in performance was seen more prominently with Random Forest and XGBoost compared to Decision Tree. For Random Forest, the EER was 3.37 % in the pocket compared to 4.99% in the hand. Model accuracy and F1 score did not differ significantly between the right and left positions but EER increased slightly with the left-hand position.

The BB-MAS dataset had nearly identical results to MMUISD as shown in Table IV. Once again, Pocket Phone position achieved better accuracy scores and EER values with all algorithms compared to the hand phone position, emphasizing the possibility that having the device closer to the body provides a more stable and predictable signal for the models. Compared to the MMUISD dataset, with BB-MAS the pocket position had better error results with an average of 1.04% EER with Random Forest.

In Table V, results with the MMUISD and BB-MAS datasets have been compared with recent reviewed studies utilizing datasets of similar participant size [10, 11, 12, 13, 14]. The comparative studies utilized well-known public datasets such as IDNet and WhuGait with various LSTM models. It was observed that the produced results outperformed in average accuracy rates with Random Forest. Most notably, Random Forest trained on MMUISD dataset achieved one of the highest accuracies overall of 0.9911 on similar and higher levels than comparative studies using high performance DL models such as LSTM and CNN. The accuracies with RF were also achieved with suitably low error rates. This is indicative that ML models still have the potential to meet and even exceed the authentication performance of DL models with careful selection of parameters and quality datasets.

TABLE V. COMPARATIVE ANALYSIS

| **Dataset** | MMUISD | | BB-MAS | | IDNet | | | WhuGait | | Kaggle | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| **Model** | RF | DT | RF | DT | ContAuth LSTM [10] | CNN+LSTM [11] | HDLN LSTM [12] | HDLN LSTM [12] | CNN+LSTM [13] | CNN [14] | RF [14] |

## VI. LIMITATIONS AND FUTURE WORK

While gait authentication demonstrates potential as a form of behavioral biometrics authentication for mobile devices, it faces limitations that prevent it from logically being used as a sole security method. Gait authentication has a downside in that it requires an individual to move to collect samples. It also faces various obstacles in behavioral variation related to the surrounding environment, such as stairs, hills, and user health [4]. Thus, it is recommended that current gait dynamics authentication methods are used in low security applications as a supporting security method in a multimodal system [4].

One limitation acknowledged in this study would be that the model training strategy utilized is a simplified version that uses only time-domain features extracted directly from the accelerometer and gyroscope sensors and segmented with fixed time intervals. Nowadays, many gait studies are using more advanced methods of characterizing an individual's gait walking pattern [2]. For example, in study [19], the signal was segmented according to the gait cycle instead of a fixed time interval. This was done by using an autocorrelation algorithm to detect the points in the signal at which a heel touch can be identified with the Z-axis signal magnitude. Then, the signal was segmented based on these points. In study [20], a similar strategy was used in which gait cycle segmentation was performed by identifying accelerometer signal change points with autocorrelation coefficients and segmenting based on the identified patterns. From there, a feature vector was extracted from each pattern in time and frequency domains. Due to complexity and time constraints, this study did not utilize these strategies. In the future, it could be beneficial to the expansion of research in gait dynamics authentication if the code for some of these strategies was documented and made accessible for public use and analysis.

Another limitation in this study would be the construction of the XGBoost model. Despite attempts at parameter manipulation and feature analysis, the XGBoost model remained somewhat overfit, resulting in high accuracy at the expense of suitable EER rates. For future research, the XGBoost is not recommended for use with these datasets unless further steps are taken to properly avoid overfitting.

For today's ML and DL models, it is considered best practice to produce a model that can properly represent a diverse population. The datasets chosen for this study, while including a greater number of individuals than used in previous datasets historically, still included bias towards certain groups. For example, both datasets included a larger number of male participants than female. While this study did not test for how gender bias affected model performance on different individuals, this could be analyzed in future work. Another possible form of bias could be the balance of right-handed and left-handed individuals. In the demographic file of the BB-MAS dataset it can be found that nearly all participants are listed as right-handed.

As established in the background section of this paper, while ML models have been found to perform well with gait dynamics authentication, DL models generally outperform by great margins in both accuracy and error rates. With the results of this study, it was found that ML models such as Random Forest can still match and exceed the performance accuracy of recent studies using DL algorithms while maintaining acceptable error rates. For future work, the next direction of study would be to analyze and compare the performance of DL models such as CNN or LSTM with ML models, using the selected or similar gait datasets. Current trends in research have expanded from ML into the potentials of DL, thus it is encouraged that gait authentication should be further investigated with DL algorithms to advance potential for security. As devices have progressively become mobile in nature, it is necessary to take advantage of motion-sensing in security applications and pursue study in their advancements with both ML and DL algorithms.

## VII. Conclusion

From the results of this study, it can be concluded that both datasets perform well with machine learning algorithms to classify gait walking characteristics. The MMUISD dataset may be preferable in a study that aims to observe the effects of different speeds or positions on gait classification performance. The BB-MAS dataset could also be preferable in a study that aims to identify a broader context for behavioral biometrics security including movement and touch interactions across different devices and environments.

After analyzing classifier performance, Random Forest was recognized as an optimal ML classifier for gait dynamics classification capable of achieving similar results to DL models. While XGBoost achieved the highest average accuracy and Decision Tree achieved the lowest average EER rates between datasets, Random Forest resulted in the best overall metrics balancing both categories. In the pocket position, Random Forest had an average accuracy of 99.03% with the BB-MAS dataset and 99.11% with the MMUISD dataset. Random Forest also achieved optimal EER rates below 5% with 1.04% in the pocket position. XGBoost could possibly be manipulated further to combat overfitting and achieve lower error rates.

Through compared analysis of the performance in different scenarios, it has been observed that position and speed can influence classifier performance. In both datasets and all algorithms, placing the device in the pocket position had better accuracy and EER scores compared to the hand position. This could imply that keeping the mobile device in a position closer and secured to the body results in motion signals with more stability and less variation. It was also observed that as the walking speed increased, EER rates increased as well. This could suggest that slower walking speeds can result in more variation in the gait cycle signal, resulting in less favorable algorithm performance. While noticeable, these differences did not differ too significantly, demonstrating the potential for gait dynamics authentication in real world scenarios.

Regardless of these results, in the real world, an individual will not be confined to a set walking speed or corridor. It is recommended that future studies endeavor to build datasets with more variation in position and activity to allow for the construction of feasible gait authentication models in real world contexts. It is hoped that this study can provide worthwhile information to contribute to the advancement of behavioral biometrics mobile authentication models.

## Acknowledgment

The funding for this project has been provided by the University of Wisconsin-Eau Claire’s Blugold Fellowship and the University of Wisconsin-Eau Claire Computer Science Department’s Karlgaard Scholarship.

# Privacy-Aware Decision Making: The Effect of Privacy Nudges on Privacy Awareness and the Monetary Assessment of Personal Information

Vera Schmitt[1], James Nicholson[2], Sebastian Möller[3]
Quality and Usability Lab, Technische Universität Berlin, Berlin, Germany[1,3]
Department of Computer and Information Sciences, Northumbria University, Newcastle, United Kingdom[2]

*Abstract*—**Nowadays, smartphones are equipped with various sensors collecting a huge amount of sensitive personal information about their users. However, for smartphone users, it remains hidden, and sensitive information is accessed by used applications and data requesters. Moreover, governmental institutions have no means to verify if applications requesting sensitive information are compliant with the General Data Protection Directive (GDPR), as it is infeasible to check the technical details and data requested by applications that are on the market. Thus, this research aims to shed light on the compliance analysis of applications with the GDPR. Therefore, a multidimensional analysis is applied to analyzing the permission requests of applications and empirically test if the information provided about potentially dangerous permissions influences the privacy awareness and their willingness to pay or sell personal data of users. The use case of Google Maps has been chosen to examine privacy awareness and the monetary assessment of data in a concrete scenario. The information about the multidimensional analysis of the permission requests of Google Maps and the privacy consent form is used to design privacy nudges to inform users about potentially harmful permission requests that are not in line with the GDPR. The privacy nudges are evaluated in two crowdsourcing experiments with overall 426 participants, showing that information about harmful data collection practices increases privacy awareness and also the willingness to pay for the protection of personal data.**

## I. Introduction

Smartphone applications (apps) are nowadays considered an indispensable part of our lives due to the wide range of services and utilities they provide, such as digital contact tracing, public transport, navigation, education, and many others. Many business strategies depend on continuous data collection to earn revenue by leveraging personal data. Firms such as Google and Facebook require users to continuously provide personal information as a precondition for accessing their services. This enables them to profit through detailed targeting and advertising [1], [2], [3]. Additionally, a growing number of firms and institutions are engaging in the exchange of users' personal data, often navigating ambiguous legal areas while handling the earnings from these transactions [4]. However, the continuous data sharing from many applications on smartphones, which monitor, collect, and transmit data about the daily lifestyle of their owners, can reveal sensitive information, such as camera feeds, messages, moving patterns, voice commands, physiological data, and much more [5]. However, it is not a trivial task for the users to verify whether applications might induce a potential privacy threat. Due to the mobile nature and use of wireless communication protocols, applications are able to access, use, and transmit sensitive information to remote servers without user interactions [6]. Often it remains unclear to users what data is being transferred and how to turn continuous data sharing off. The complexity and length of privacy consent forms and the lack of technical knowledge are obstacles hindering the user from making privacy-conscious decisions [7]. Cases of mishandling and misuse of personal information have heightened government awareness about the necessity of creating regulatory structures to protect personal data on the internet. The General Data Protection Regulation (GDPR) of the European Union and the California Consumer Privacy Act (CCPA) exemplify this, setting standard data privacy regulations and enhancing individuals' authority over their personal information [8]. While the industry has attributed economic value to personal data, utilizing it across various businesses from social media and advertising to the enhancement of personalized products, the assessment of the monetary worth of the data from the viewpoint of the user remains a largely unexplored area of study [8], [9], [10], [3], [11]. To assess the monetary value of specific goods from the users' perspective, the metrics employed are the Willingness to Pay (WTP) for a particular item and the Willingness to Accept (WTA) compensation in exchange for that same item [11].

Therefore, a detailed analysis is presented in the following to shed light on regulatory compliance issues, inappropriate design and development strategies, and severe privacy issues applications might have. The analysis follows a similar structure as proposed in [6], [12] to evaluate potential GDPR compliance issues of a sensitive domain such as location tracking applications. Moreover, different privacy nudges are designed based on the results of a multistage analysis to examine effective means of informing users about potentially harmful privacy practices. Additionally, we examine whether users have higher WTP and WTA ratings to protect their personal information on a monthly basis when presented with information about what data is collected continuously.

Thus, this analysis aims to answer the following research questions:
**RQ1:** Do privacy nudges about potentially harmful privacy practices increase the awareness of users?
**RQ2:** Do information about potentially harmful permission requests change users' privacy awareness and willingness to

pay for the protection of personal data?

Our analysis comprises two main phases. The *Phase I* consists of three steps: (1) we analyze the apps' permission requests within their Android manifests to provide an overview of the most prominent permission requests and their potential privacy and security implications; (2) we inspect statements made by app providers in their privacy policies with respect to the fulfillment of legal requirements enforced by the data protection legislation; and (3) we explores the apps' run-time permission accesses to investigate if apps access any sensitive resources without users being aware of it. In *Phase II* the results from *Phase I* are used to design privacy nudges to be incorporated in crowdsourcing studies. The privacy nudges are examined if they increase privacy awareness and facilitate privacy-aware decision-making. In sum, the contributions of this work are the following: (1) detailed compliance analysis of privacy policies of surveillance and behavior analysis of location tracking apps' permission access patterns at run-time; (2) Design of privacy nudges based on the findings to inform users about potentially harmful permission requests; (3) and evaluation of whether information about potentially harmful permission requests not in line with the GDPR influence users' privacy awareness and monetary assessment of their personal data. This paper is organized as follows: first, an overview of related work is given in Section II. In Section III the privacy nudges are described which are designed based on the results from the GDPR compliance analysis. In Section IV the methodological background for privacy awareness, privacy nudges, WTP and WTA, and the experimental workflow are described and Section V empirically examines if information about potentially harmful permission requests changes the privacy awareness and monetary assessment of personal data. Finally, Section VI discusses the multidimensional analysis of applications GDPR compliance, privacy nudges, and their influence on privacy awareness and monetary assessment and concludes this paper and indicates future research directions.

## II. Related Work

After the GDPR was enforced in 2018, it can be expected that service providers and app developers have adapted to the GDPR by either improving their privacy statements or through the improvement of software design and consideration of GDPR principles in the development phase [13]. The empirical verification, if principles of the GDPR, such as *transparency*, *data minimization*, or *data protection* have been considered in the design of services and applications has not yet been enforced by the European Commission or any other official authority. Previous studies have shown that there is still a vast amount of data requested from users of mobile applications, where there is no comprehensive approach for users to verify if the app's privacy consent form is compliant with the GDPR requirements and also if the app itself does comply with the own privacy consent form and the GDPR alike [14], [15]. Therefore, the assessment of privacy risks associated with various applications suffers from a general shortage of empirical evidence [16], [13]. Some approaches have been proposed for assessing the privacy of apps by monitoring sensitive permissions, such as location information, contacts, of camera access [17], [18]. Other approaches such as FAIR [19] propose a privacy risk assessment of Android apps by monitoring the behavior with regards to monitoring the access to sensitive personal information. Further research has been done by developing an automatic framework, called *Trust4App* to assess the trustworthiness of mobile applications [20]. While these approaches focus on the risk assessment of mobile applications, there are only a few approaches that integrate the privacy policies in their assessment, such as [6]. Not much information can be found in the literature, which reveals a comprehensive analysis concerning the GDPR compliance of mobile applications [13]. Therefore, more research needs to be done to shed more light on transparently verifying GDPR compliance of online services and mobile applications, especially where sensitive data is shared continuously. Especially in context-sensitive digital ecosystems, there is a high risk of privacy violations [21]. Many business models are built on the ongoing acquisition of data to profit from the personal information of individuals. Major technology firms, like Google and Facebook, necessitate the constant sharing of personal data by users in return for their services, deriving revenue through targeted advertising and profiling techniques [1], [2]. The GDPR is designed to increase control over personal data shared online, yet it frequently results in intricate rules and settings that might not align well with the specific needs of individual users. However, users typically show limited capacity in evaluating the pros and cons of data exchange scenarios and might consent to enduring privacy risks for immediate benefits [22]. Moreover, a fundamental issue concerning privacy regulations and settings is whether users place importance on and value their privacy and are aware of potentially harmful data-sharing practices [8].

Previous studies highlight usability issues in mobile app permissions, impacting user comprehension and control, leading to inadequate privacy risk assessments and decision-making. Research indicates a general deficit in privacy literacy and awareness among mobile users, complicating their ability to navigate privacy concerns effectively. Despite some flexibility in iOS permission settings, both Android and iOS platforms fall short in offering clear explanations about permission functionalities, data access, and usage scope, thus obscuring the implications of permission settings for personal data security [23], [24], [25], [26], [27], [28], [29], [30], [31], [32], [15], [33]. Recent research has focused on enhancing privacy permission interfaces, aiming to better inform user decision-making. These interfaces have been refined to highlight apps' potentially invasive privacy practices and incorporate warning indicators, as well as clearly listing the data apps collect and do not collect [23], [26], [25]. Studies, such as the one by Kelley et al. [34], demonstrate that such interfaces can significantly raise users' awareness of privacy risks, leading to more informed choices. The emphasis has largely been on delivering explicit information regarding data usage, thereby fostering transparent user engagement. Additionally, there's a growing trend towards employing soft paternalistic strategies like privacy nudges to subtly guide users towards safer privacy practices without compromising their autonomy [25], [33], [35], [36]. Efforts in research have aimed at creating privacy nudges tailored to the permission requests of diverse apps, yielding mixed results. These variations are attributed to factors like the context of data sharing [35], the type of device used [30], and the app's functional domain [37]. Notably, the impact of privacy nudges seems negligible on users' awareness of video-call and messenger applications, yet significant for weather or fitness apps [38]. Additionally, some nudges are designed to enhance user understanding by comparing the number of permissions an app requests against similar apps, thereby aiding users in grasping the implications of the permissions sought [36], [39], [37], [38], [23]. However, the relation between enhanced privacy awareness through privacy nudges and the relation to monetary assessment of personal information has not been systematically covered by the previous literature.

Therefore, this analysis aims to shed light on privacy assessment concerning personal data sharing and GDPR compliance of apps with access to very sensitive data. Previous research has shown that privacy nudges have the potential to support privacy-aware decision-making of users [40], [7], [36], [41], [42], [37]. Thus, the GDPR compliance analysis is used to design privacy nudges to support the decision-making process of users. Different types of privacy nudges are then empirically examined in two user experiments concerning privacy awareness and their influence on the monetary assessment of privacy.

## III. Analysis Design and Methodology

Assessing the privacy risks associated with different smartphone apps is challenging for users. Due to their dependence on wireless communication, these apps can independently access, use, and send sensitive information to remote servers [6]. The details of how data is transferred are usually not clear to the user, including the methods to stop ongoing data sharing. Furthermore, the complexity and excessive length of privacy policies, coupled with a lack of technical knowledge, hinder users from making knowledgeable choices about their privacy [7]. Therefore, privacy nudges or framing techniques are frequently employed to alert users to privacy dangers. For the following analysis, different privacy nudges have been designed to examine their influence on privacy awareness and the monetary assessment of personal data. Hereby, the procedure of analyzing permission requests, the permission manifest, and the privacy policy of applications is followed which has been introduced by [3], [43], [6], [25].

In the analysis that follows, two kinds of privacy nudges are utilized to demonstrate the effect of informational and visual nudges on both privacy on privacy awareness and monetary assessment. This research on privacy awareness includes an in-depth examination designed to emphasize the difficulties associated with adhering to regulations like the GDPR, limitations in design and development approaches, and critical privacy concerns that could affect surveillance applications. Often, users remain unaware of the specific data being shared and the methods to stop continuous data transmission. The complexity and lengthiness of privacy consent forms, along with a lack of technical knowledge, create obstacles that hinder individuals from making educated choices about their privacy [7]. Past research has demonstrated that users often express surprise and discomfort upon learning the extent of information collected by smartphone applications [35], [11]. Therefore, the purpose of privacy nudges and framing effects is to aid users in making decisions that are aware of privacy concerns and to highlight the potential risks associated with sharing sensitive personal information.

The examination of legal compliance is organized based on the proposed framework introduced in [6], [43], [44], specifically designed to evaluate the GDPR conformity of widely used and renowned applications. The analysis of technical and legal compliance is divided into three primary phases. In *Phase I*, the analysis focuses on the permissions requested in the applications' Android manifests, providing an overview of the most critical permission requests and their potential impacts on privacy and security. *Phase II* assesses the claims made by app developers in their privacy policies about adherence to data protection regulations. Finally, *Phase III* investigates the runtime permissions used by the apps to ascertain if they access sensitive information without the users' knowledge. Drawing on the insights from the three stages of the analysis, the outcomes have been leveraged to create visual and informational nudges for some well-recognized applications. The privacy nudges were developed using the insights from the analysis across all three phases. These nudges integrate design principles from existing studies [45], [37] by incorporating clear, short, and relevant information summarized from the analysis of permission requests and privacy policies of chosen applications. The purpose of the nudges is to decrease *information asymmetry* and *cognitive load*, helping users to swiftly evaluate which information an application can access and whether this complies with legal requirements in the EU.

### A. Analyzing Permission Requests and Privacy Policy

*1) Permission requests analysis:* The device's resources can be accessed by apps through permissions in Android. Consent from users is sometimes required depending on the source type. Android defines three types of permissions [12]: *install-time*, *run-time*, and *special*. *Install-time* permissions are automatically granted to an app when the user installs it. Android defines two sub-types of install-time permissions, including *normal* and *signature* permissions. *Normal* permissions allow access to resources that are considered low-risk, and they are granted during the installation of any apps requesting them. Only when the app that aims to access specific permissions is signed by the same certificate as the app that defines the permission, so-called *signature* level permissions are granted at install-time [12]. In fact, the system grants permission to one app at install time only if the app is requesting signature permission that another app has defined and if they are both signed by the same developer.

The *run-time* permissions, also known as dangerous permissions, grant access to resources that are considered to be high-risk [12]. In such cases, users are asked to explicitly grant permission to these requests. *Special* permissions correspond to particular app operations. Only the platform and the Original Equipment Manufacturer (OEM) can define special permissions. Every app has an `AndroidManifest.xml` file that contains information about that particular app (e.g., its name, author, icon, and description) and permissions that grant access to data such as location, SMS messages, or camera on the device.

*2) Privacy policy analysis:* For the privacy policy analysis, we explore the compliance of Google Maps with fundamental legal requirements. For this, we rely on the EU GDPR benchmarking conducted in [46] that resulted in the identification of 12 privacy policy principles.

(a) Baseline nudge control group

Google Maps

„Google Maps“ darf auf die folgenden Bereiche Ihres Smartphone zugreifen, obwohl dies nicht für die Grundfunktionalität der App erforderlich wäre.

WLAN-Verbindungs-informationen

Die App kann WLAN-Verbindungen sehen, die auf Ihrem Handy gespeichert sind. Dadurch können **Standort-Informationen** gesammelt werden, zum Beispiel wo Sie sind und wo Sie waren.

Telefon, Geräte-ID & Anrufinformationen

Die App kann Ihren Telefonstatus, Ihre Anrufliste und die **Identität** Ihres Handys abrufen oder verändern. Dadurch können Informationen über Ihre Identität (wer Sie sind) und über Ihre **Kommunikation**, (z.B. mit wem Sie wann, wie lange kommuniziert haben), gesammelt werden.

SMS

Die App kann SMS lesen, empfangen und senden. Dadurch können Informationen über Ihre **Kommunikation** (z.B. mit wem Sie wann kommuniziert haben), Ihre **Identität** (wer und wie Sie sind), Ihre sozialen Netzwerke (z.B. Freunde, Familie), sowie **demografische Informationen** (z.B. Beruf, Wohngebiet) gesammelt werden.

Geräte- und App-Verlauf

Die App kann Ihre aktiven Apps abrufen. Dadurch können ähnliche Informationen über Sie gesammelt werden wie durch Ihr Web-Browsing, z.B. Informationen zu Ihrer **Identität** (wer und wie Sie sind). In diesem Fall kann die App statt Ihres Browser—Verlaufs Ihren **App-Verlauf** einsehen.

(c) Visual nudge experimental group

Fig. 1. Example of privacy nudges designed containing the plain nudge for the control group in Fig. 1(a), the information nudge in Fig. 1(b), and the visual nudge containing a classification of privacy nudges in the traffic light metaphor. The privacy nudges are designed based on the permission request analysis.

The privacy policy of an app is a statement or a legal document that gives information about the ways an app provider collects, uses, discloses, and manages users' data. By law, data collectors (including app providers) are required to be transparent about their data collection, sharing, and processing practices and specify how they comply with legal principles [46]. Based on keyword- and semantic-based search techniques, a data protection expert went through each privacy policy to analyze the compliance of these apps concerning the following principles which are summarized and used similarly in [12] and [6].

*a) Data collection:* The legal foundation is defined in Art. 5 (1) GDPR, which states the general principles of processing personal data. Also, Art. 6 in the GDPR indicates when processing is lawful, which includes when consent is given by a user of a service or application. Moreover, both articles address the question of when consent is necessary for the performance of a contract or compliance with legal obligations when the vital interests of the user or another natural person need to be protected, and when a task is carried out for the public or legitimate interest pursued by the controller or by a third party. Nevertheless, this applies only if such interests do not conflict with fundamental rights and also the freedom of a user. Hereby, e.g. advertising is not classified as a necessary interest and thus, needs to be analyzed based on other legal foundations [47], [12], [6].

*b) Children protection:* Personal data which is related to children needs to be treated with special attention. As defined in Rec. 38 in the GDPR children "may be less aware of the risks, consequences, and safeguards concerned and their rights in relation to the processing of personal data". Service providers need to provide information in a very clear and comprehensive language so that also children are able to understand it easily (Rec. 58 GDPR). Moreover, the processing of children's data is strictly regulated and data can only be processed on a lawful basis if the child is at least 16 years old (Art. 8 GDPR). In case the child is younger, processing of children's data is only lawful when a parent or also legal guardian has given consent [12], [6].

*c) Third-Party sharing:* Third-party tracking is one of the most common approaches to collecting personal information through various apps. Hereby, it is legally regulated by Art. 13 in the GDPR, where it is defined that the recipients or categories of recipients of personal information must be declared to the users [12], [6].

*d) Third-Country sharing:* The legal requirements for third-country sharing are described in *Chapter 5* in the GDPR. Hereby, personal data can only be transferred to other countries when a similar level of protection is enforced. This means that the protection of personal data travels also across borders when personal data is transferred to servers outside of the EU. Furthermore, the privacy policy must state its procedures when personal data is shared with other countries outside of the EU [12], [6].

*e) Data protection:* Technical and organizational measures to ensure the appropriate security of personal information must be ensured by the data controller as stated in Art. 32 in the GDPR. Especially in the smartphone ecosystem, this has major implications, as they are usually linked to huge amounts of data transfer. Moreover, the components of data protection are closely interrelated with privacy-by-design principles [48], [12], [6].

*f) Data retention:* The principle of data minimization and storage limitation is described in Art. 13 (2), and 14 (2) in the GDPR. Hereby, the data controller has the obligation to inform users how long personal data is retained. Especially for "the right to be forgotten" (Art. 17) this is crucial as personal data can only be stored for a limited time [12], [6].

*g) User's control:* Further user rights are defined in *Chapter 3* of the GDPR, which contains the right to information and access to personal data; the right to rectification;

the right to erasure; the right to restriction of processing; the right to data portability; and the right to object and automated individual decision-making. IN Art. 13 (2), and 14 (2) it is defined that service or app providers are required to provide these rights to users to ensure fair and transparent data processing [12], [6].

*h) Privacy policy changes:* In Art. 12 of the GDPR app or service providers have the obligation to inform users about privacy policy changes in a transparent and comprehensive way. This should further ensure lawful, fair, and transparent processing of personal information [12], [6].

*i) Privacy breach notification:* In Art. 34 of the GDPR it is defined that in case a data breach occurs that might result in a risk to the rights and freedoms of users, the data controller or service provider must inform the users asap. Also, the information that needs to be provided in the data breach notification is regulated by this article. Thus, a data breach notification must name the data protection officer and mention the likely consequences of the data breach. Furthermore, measures must be mentioned how to mitigate the effects of the data breach. Moreover, the supervisory authority must be informed not later than 72 hours after the detection of the data breach [12], [6].

*j) App-Focused:* Often, the privacy policy is not exclusively formulated for only one application, but shared among multiple services that are provided by the same data controller or app developer [49]. This principle is incorporated in the principle of lawfulness, fairness, and transparency [12], [6].

*k) Purpose specification:* Data collection must be specified by service providers or data controllers according to Art.

13 (1c), and 14 (1c) in the GDPR. The principle of purpose limitation is relevant to preventing the exploitation of personal data for other use cases. It is also closely related to the data collection principle but refers rather to a clear statement and explanation of data collection purposes [12], [6].

*l) Contact information:* Users have the right to be informed about the identity of service providers and data controllers, which includes the name of service providers, also legal representation, legal status, and postal address (Art. 13 (1a), and 14 (1a) in the GDPR). The principle of contact information is closely interrelated with the principle of lawfulness, fairness, and transparency. Providing such information is relevant to give users the option to also file a formal compliance [12], [6].

We conducted a user study to better understand how users behave when informed of these digressions by apps. Specifically, we selected the Google Maps app due to its popularity ($>500$ Mio downloads) and has access to sensitive information.

## IV. Empirical Examination of Permission Requests in Terms of Privacy Nudges

The analysis of permission requests can serve as an automatic tool to monitor whether applications available in the app store are compliant with GDPR at a technical level. While this kind of monitoring has not been established yet, it offers a promising strategy to assist developers in adhering to GDPR guidelines and inform users if the respective applications are privacy-preserving.

### A. Nudge Design and Monetary Valuation

According to Almuhimedi et al. [36], users are mostly unaware of data collection practices, and when information is provided users are motivated to adjust their app settings [36]. According to Shih et al. [50], the purpose for data access was the main factor affecting the users' choices, e.g., if the purpose is vaguely formulated, participants became privacy-aware and were less willing to disclose information. The traffic light metaphor thus serves as a useful tool for users to efficiently oversee valid and invalid permission requests in compliance with GDPR [51]. To investigate the impact of information about permission requests and access to sensitive data on privacy awareness, the aforementioned procedure is applied to track permission requests from the popular Google Maps app. Google Maps was selected for its widespread usage, in contrast to more niche applications like specific security camera apps. The permission requests of the Google Maps app were monitored for one week, and the privacy policy was analyzed to classify these requests according to the traffic light metaphor as either valid (green), critical (orange) or invalid (red).

In Fig. 1, the privacy nudges are displayed for the example of Google Maps. Hereby, the nudge for the control group is displayed in Fig. 1 A providing only plain details on the types of information collected while using Google Maps. In a crowdsourced study, these nudges were evaluated by randomly allocating 100 participants to an experimental group and another 100 participants to a control group. The study is designed to investigate whether privacy nudges increase privacy awareness among the experimental group. Thus, questions measuring privacy awareness were included in the survey both before and after the presentation of the privacy nudges. Another approach has been chosen, where information about potential risks of sharing information or benefits when protecting personal data is directly incorporated in the monetary assessment of the experiment. Hereby, the privacy nudges are positively associated by using the *green* color of traffic light metaphor for the WTP scenario, where participants are requested to indicate how much they would pay for protecting the personal data collected by Google Maps as displayed in Fig. 2. For the WTA scenario, the privacy nudges use the *red* color to indicate the potential risk when sharing the information with Google Maps as displayed in Fig. 3. For the second privacy nudge design approach another crowdsourcing study was conducted, where 112 participants were randomly assigned to the control group and 114 to the experimental group. Additionally, the WTP and WTA questionnaire was customized for the privacy nudge scenarios. Participants were queried about their readiness to pay for data protection to avoid sharing the shown information with the data requester, and conversely, how much compensation they would require to allow their data, collected by the applications used in the experiment, to be shared. For measuring the WTP and WTA discrete choice surveys have been incorporated to measure the individual monetary value preferences following the study design of [8] and [9].

Moreover, privacy awareness is assessed through five dimensions derived from prior studies [52], including (1) the perceived sensitivity of personal information, (2) the awareness of being surveilled, (3) the feeling of intrusion, (4) the sense of control over one's personal information, and (5) the perception of secondary use of personal information. Responses to these questions are captured on a 7-point Likert Scale, where 1 signifies "strongly disagree" and 7 represents "strongly agree."

### B. Experiment Workflow

A crowdsourcing experiment was prepared to test the influence of privacy nudges on privacy awareness and the monetary assessment of privacy. To empirically assess whether privacy nudges affect users' privacy awareness, we adopted a privacy awareness questionnaire from prior research [29], [53], [40], including also items about privacy concerns, and perceived control as subdimensions for privacy awareness. Moreover, the influence of privacy nudges is further examined on WTP and WTA for the protection of personal data collected by the Google Maps app. WTP and WTA are measured by using the Discrete Choice Experimental design method [9] particularly useful for assessing the impact on non-market goods, for which value cannot be determined using revealed preference methods that depend on observing actual behavioral choices. Here the participants can rate how much they would pay on a monthly basis for using the Google Maps app, but not sharing their personal information. Both experiments contain three survey parts and two experimental parts. First, the participants are asked to fill out a questionnaire about their privacy awareness. Afterward, the participants were randomly assigned to the experimental or control group. The use case of the Google Maps app is explained to the participants. They receive the respective privacy nudges depending on the control or experimental group. Afterward, the participants are required

to fill out the privacy awareness questionnaire again, before starting with the monetary evaluation, if they would be willing to pay or accept money for their personal data related to the privacy nudges for the Google Maps app use case. In Fig. 4, a visual depiction of the experimental workflow is shown. Overall, 426 participants took part in the two experiments where the participants were randomly assigned to either the control or experimental group. For the first experiment containing the information and visual nudge the average age of the participants was 33.5, 81 participants were male, 118 female, and 1 reported to be of *other* gender. For the second experiment containing the privacy nudges incorporated in the monetary valuation the average age was 32.4, 104 were male, 106 were female, and six participants reported *other* gender.

## V. Results

The two experiments with 426 participants have been conducted through the crowdsourcing platform Crowdee[1], to examine the influence of the privacy nudges for German participants who use the Google Maps app[2]. In the following, the results from the two experiments are described in more detail.

### A. First Experiment

Fig. 5 illustrates the changes in awareness ratings for the experimental group, comparing their responses before and after being exposed to the privacy nudges. A slight increase in privacy awareness can be identified after the nudge has been presented (mean 4.86) in comparison to the privacy assessment before the nudge (mean 4.74). After the presentation of the nudge in the first experiment, a modest rise in privacy awareness is observed, with the mean score increasing to 4.86 from a pre-nudge mean privacy awareness of 4.74. Nonetheless, upon performing a Wilcoxon signed-rank test to compare the two related samples, the increase in privacy awareness was found to be statistically insignificant ($W$=2390.5, *p-value* = .76)[3]. In the comparison of the WTP and WTA between the control and experimental group, the experimental group showed a marginally higher WTP (mean .41) relative to the control group (mean .38), although the difference is not statistically significant.

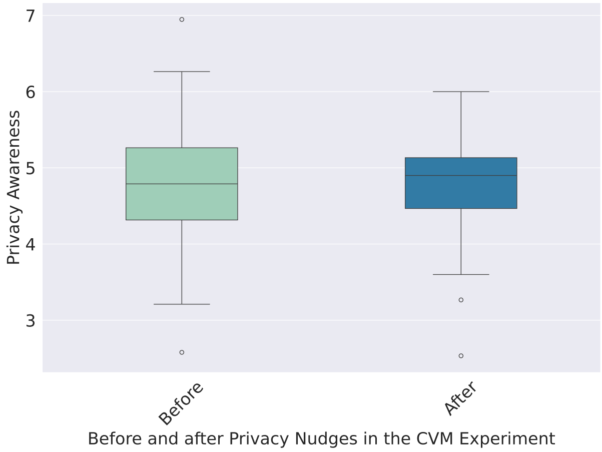

Fig. 5. Comparison of PA for the visual and information privacy nudges ($W$=2390.5, *p-value* = .76).

Remarkably, the control group exhibited a higher willingness to accept after exposure to the privacy nudges, with a mean of .91, compared to the experimental group, which had a mean of .84. Yet, when a Mann-Whitney U test was applied for the between-group comparison, the differences were found to be not statistically significant ($U$ = 4573, *p-value*= .19). The findings from the first experiment including the information and visual privacy nudges indicate a minor trend towards heightened privacy awareness and a greater WTP for personal data protection. Nonetheless, these results do not allow for final conclusions due to the absence of significant differences, which could be attributed to random variations in the data. Additionally, since the privacy nudges were introduced prior to the monetary valuation of data types, participants noted difficulties in recalling the details presented in the privacy nudges.

### B. Second Experiment

In the second experiment, the information is deliberately concise to avoid *information overload*, drawing upon the analysis of permission requests described earlier. In relation to the approach of the first study, the visual nudge employs the *traffic light metaphor* to underscore the risks associated with information sharing. In the WTA scenario, where participants

[1] https://www.crowdee.com/

[2] The participants received 6€ for on average participating 15 minutes in the experiment. General information about the study was given, but the experimental group and control group setup has not been mentioned beforehand.

[3] All *p-values* were corrected using the Benjamini-Hochberg procedure to mitigate the risk of *alpha* accumulation errors.

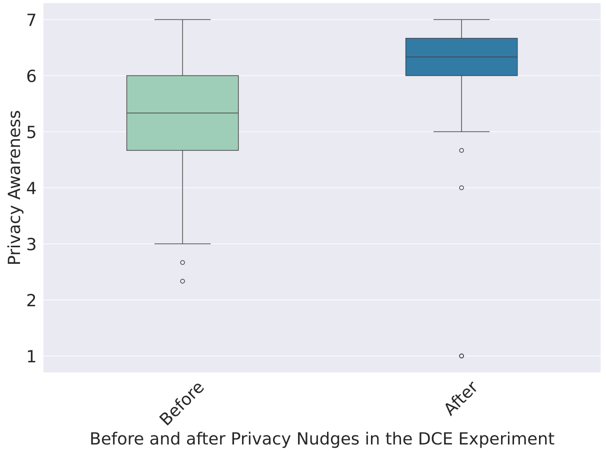

Fig. 6. Comparison of PA for the privacy nudges used DCE test paradigm ($W$=3095.5, *p-value*=$<$ .01, Cohen´s D = .76).

are asked to set a price for selling their information to a data requester, the color *red* is utilized, whereas *green* is applied in the WTP scenario to highlight the benefits of safeguarding specific types of information, making these advantages clearer to the participants (see Fig. 3 and Fig. 2). A comparison of privacy awareness (PA) assessments before and after the presentation of privacy nudges (see Fig. 6) reveals a significant increase in PA ($W$=3095.5, *p-value*$<$ .01, Cohen's D = .76) for the experimental group post-nudges (mean = 6.1) compared to pre-nudges (mean = 5.2). In analyzing the impact of privacy nudges on the monetary valuation, specifically WTP and WTA, noticeable differences emerge. A Mann Whitney-U test comparing WTP shows significant differences ($U$= 52662, *p-value*=.01, Cohen's D = .44), with the WTP valuation significantly higher in the experimental group (mean = .40) than in the control group (mean = .36). Similarly, significant disparities are found in WTA between the experimental and control groups ($U$= 55055, *p-value*$<$ .01, Cohen's D = .42), with the experimental group's WTA valuation also significantly higher (mean = .45) compared to the control group (mean = .42). The results from the modified privacy nudge design in the second study suggest a substantial impact (Cohen's D = .76) on privacy awareness (PA) and notably elevate the WTP and WTA evaluations relative to the control group. Therefore, when potential risks associated with selling personal data are clearly communicated and visually emphasized, participants tend to assign higher WTA values. Likewise, when information on the advantages of safeguarding specific data types is provided, participants demonstrate a significantly increased willingness to pay for the protection of their personal information.

Overall, the results from the user study show that when informed about valid, critical, and invalid permission requests according to the GDPR, users have a higher privacy awareness and are willing to pay to protect their personal information. We also highlight that future research can further explore the users' privacy awareness aspects concerning the integration of different types of privacy nudges into people's daily lives and activities. Users may not be fully aware of the negative consequences that such apps could potentially have on their privacy. We also note that the developers and providers of these apps should carefully address privacy threats discussed in this paper and make sure their app design and the development life cycle respect privacy by design.

## VI. Discussion and Conclusion

In this paper, we first presented a multidimensional analysis to showcase potential GDPR compliance issues of Google Maps. In particular, we focused on the system permission requests of Google Maps for Android, their privacy policies, and adherence to existing regulations defined in the GDPR. Finally, we analyzed the run-time permission requests to identify potential privacy and security issues associated with this application. The analysis shows that this app accesses sensitive data from the users' devices while also embedding trackers to transfer this sensitive data to external servers. The findings show that further mechanisms are necessary to enforce data protection regulations, such as the GDPR. Secondly, we evaluated in an experiment if information about the requested permissions and the potential infringements of personal data protection outlined in the GDPR influence users' privacy awareness and WTP and WTA for protecting personal information. We found that, when users are presented with more information about potentially harmful permission requests, they show significantly higher privacy awareness, in comparison to the control group, not receiving detailed information about potentially harmful permission requests. Furthermore, when presented with visual and information nudges no significant differences have been observed for protecting personal information. When integrating the privacy nudges in the experimental setup when examining the monetary assessment of personal data in comparison to showing privacy nudges beforehand, significant differences can be observed between the privacy awareness before and after the privacy nudges are displayed. Moreover, the WTP and WTA ratings also significantly increased for the experimental group in the second experiment, indicating that privacy-aware decision-making is facilitated when the information is incorporated directly into the decision-making process, and not beforehand.

Overall, the findings of the permission request analysis of the first part, and the human evaluation of privacy nudges designed to empirically evaluate the permission request analysis show that procedures need to be developed to more closely monitor applications not only in the legal domain but also through technical analysis, e.g. analyzing permission requests and embedded trackers. Thus, an approach to automatize the analysis of technical dimensions is necessary, to enable the enforcement of data protection regulations also on a technical level and detect possible pitfalls and areas where adjustment or further clarification of the regulation is necessary.

# User Experience and Behavioural Adaptation Based on Repeated Usage of Vehicle Automation: Online Survey

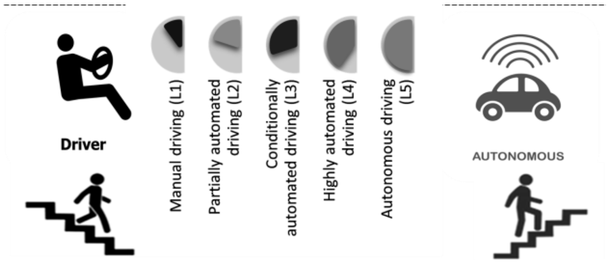
Naomi Y. Mbelekani, Klaus Bengler
Chair of Ergonomics, School of Engineering and Design, Technical University of Munich, Munich, Germany

***Abstract*—For years, Level 2 vehicle automation systems (VAS) have been commercially available, yet the extent to which users comprehend their capabilities and limitations remains largely unclear. This study aimed to evaluate user knowledge regarding Level 2 VAS and explore the correlation between user experiences (UX), behavioural adaptations, trust, and acceptance. By using an online survey, we sought to deepen understanding of how UX, trust, and acceptance of Level 2 automated vehicles (AVs) evolve with prolonged use in urban traffic. The survey, comprising demographic data and knowledge inquiries (automated driving experience and timeframes, vehicle operation competency, driving skills over long-term use of automation, the learning process, automation-induced effects, trust in automation, and ADS researchers and manufacturers), was completed by various drivers (N=16). This investigation focused on users' long-term experiences with automation in urban traffic. Consequently, we offer user-centric transformative insights into users' experiences with driving automation in urban traffic settings. Results revealed that users' knowledge of automation exhibits their learning patterns, trust and acceptance. Moreover, users' attitudes trust, and acceptance varies across different user profiles. What we have also learned about UX and the changing nature of user behaviours towards automation is that, automated driving changes influence the safety and risk conditions in which users and AVs interact. These findings can inform the development of interaction design strategies and policy aimed at enhancing UX of AV users.**

***Keywords*—*Automated vehicles; automation effects; user experience (UX); trust; acceptance; behavioural adaptations***

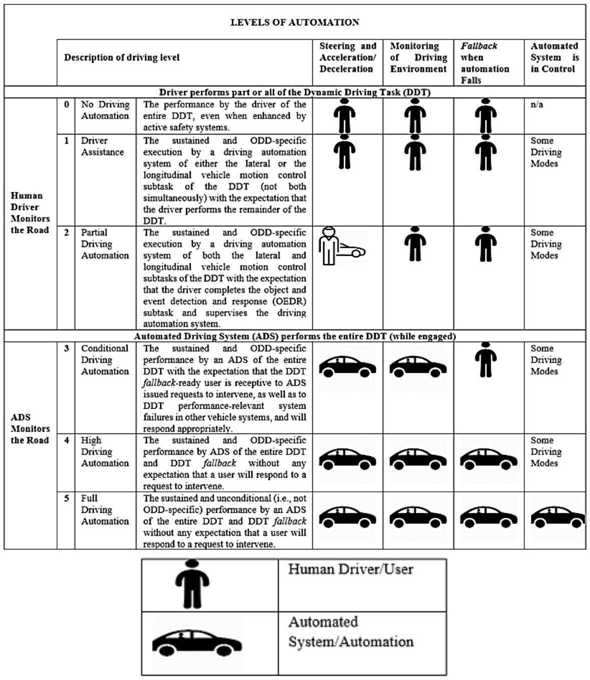
## I. Introduction

Automation, characterised by its ability to actively select data, transform information, make decisions, or control processes, offers immense potential to enhance human performance and safety [1]. Within the context of driving, automation is described using different levels of task responsibility and human involvement. The International Organization for Standardization (ISO) provides simplified descriptions of what constitutes levels of automation (LOA). However, different original equipment manufacturers (OEMs) develop their vehicle automation systems (VAS) or automated vehicle (AV) systems to suite their brand identity (marketing, brand personality, brand product standards, legal reasons, etc.). They tend to subscribe different names to their systems (for example, as representative Level 2 automation: Tesla Autopilot, Super-Cruise, Blue-Cruise, Pilot Assist, etc.), even though they may fall under the same LOA description under ISO (SAE J3016). With transitional LOA, such as 'partially' as well as 'conditionally' automated, and 'highly automated', which we used to derive a graphical representation, as shown in Fig. 1 and 2. For instance, some OEMs have been known to categorise their VAS based on different marketing strategies. Either with a cool factor, comfort factor, or active safety factor, for example. In a sense, it is quite common for some of these systems to be known by different appellations. Nonetheless, some of the automation systems remain the same as they in effect functions in the same way, for example, driving support systems.



Driver
Manual driving (L1)
Partially automated driving (L2)
Conditionally automated driving (L3)
Highly automated driving (L4)
Autonomous driving (L5)
AUTONOMOUS

Fig. 1. LOA for AVs, from manual driving to autonomous.



| LEVELS OF AUTOMATION | | | | | | | |
|---|---|---|---|---|---|---|---|
| | Description of driving level | | | Steering and Acceleration/ Deceleration | Monitoring of Driving Environment | *Fallback* when automation Falls | Automated System is in Control |
| Driver performs part or all of the Dynamic Driving Task (DDT) | | | | | | | |
| Human Driver Monitors the Road | 0 | No Driving Automation | The performance by the driver of the entire DDT, even when enhanced by active safety systems. | 👤 | 👤 | 👤 | n/a |
| | 1 | Driver Assistance | The sustained and ODD-specific execution by a driving automation system of either the lateral or the longitudinal vehicle motion control subtask of the DDT (not both simultaneously) with the expectation that the driver performs the remainder of the DDT. | 👤 | 👤 | 👤 | Some Driving Modes |
| | 2 | Partial Driving Automation | The sustained and ODD-specific execution by a driving automation system of both the lateral and longitudinal vehicle motion control subtasks of the DDT with the expectation that the driver completes the object and event detection and response (OEDR) subtask and supervises the driving automation system. | 👤🚗 | 👤 | 👤 | Some Driving Modes |
| Automated Driving System (ADS) performs the entire DDT (while engaged) | | | | | | | |
| ADS Monitors the Road | 3 | Conditional Driving Automation | The sustained and ODD-specific performance by an ADS of the entire DDT with the expectation that the DDT *fallback*-ready user is receptive to ADS issued requests to intervene, as well as to DDT performance-relevant system failures in other vehicle systems, and will respond appropriately. | 🚗 | 🚗 | 👤 | Some Driving Modes |
| | 4 | High Driving Automation | The sustained and ODD-specific performance by ADS of the entire DDT and DDT *fallback* without any expectation that a user will respond to a request to intervene. | 🚗 | 🚗 | 🚗 | Some Driving Modes |
| | 5 | Full Driving Automation | The sustained and unconditional (i.e., not ODD-specific) performance by an ADS of the entire DDT and DDT *fallback* without any expectation that a user will respond to a request to intervene. | 🚗 | 🚗 | 🚗 | 🚗 |

| | |

Fig. 2. VAS spectrum (adapted from SAE J3016).

It is important to discriminate how different AV-LOA have an effect on UX and behaviour towards automation. For instances, different in-vehicle intelligent transport systems (ITS), advanced driver assistance system (ADAS) or automated driving systems (ADS), as well as in-vehicle information and communication systems (IVIS) or in-vehicle information architecture systems (IAS). Additionally, future in-vehicle artificial intelligent (AI) systems and human-machine interfaces (HMIs) or user interfaces (UIs), as well as Adaptive Integrated Driver-vehicle Interface (AIDE). These vehicle computerised systems are designed to support the user in keeping the AV on the road and in avoiding collisions with obstacles, other vehicles and other road users or vulnerable road users (VRUs). However, recent on road risk-based conditions have highlighted that their advantages are not universally guaranteed.

### A. Problem Statement and Study Significance

As automated driving technology evolves, it significantly impacts the UX and behaviours of road users, disrupting the environment in which they have traditionally operated. The following are some key insights into the changing dynamics:

*1) Change in user behaviour:* With the introduction of AV systems, users may become less engaged in the driving task. They may rely more on the AV's capabilities, resulting in changes in their behaviour. For example, such as reduced vigilance and slower response times.

*2) BAC:* Users may exhibit BAC in response to AVs. This could include changes in driving habits, skills, preferences for AV systems, and changes in risk perception and decision-making processes.

*3) Trust and acceptance:* As AV technology advances, users' trust in and acceptance of AV systems become critical. In essence, users may exhibit distrust and caution or over trust and incaution towards AV features. However, with positive UX and improved reliability, trust may improve over time.

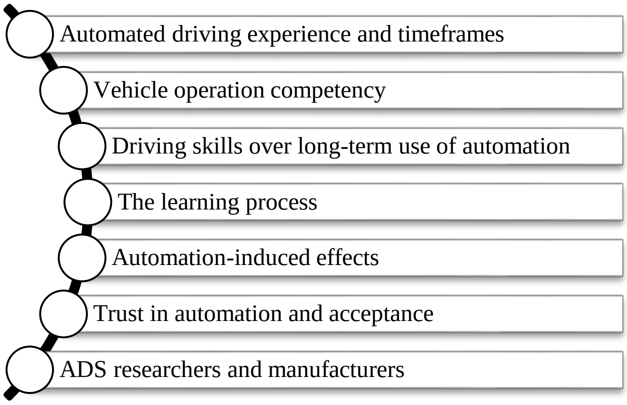
*4) Adaptation to new HMI/UIs:* AV systems introduce new HMIs and interaction modalities within AVs. Users need to adapt to these interfaces to effectively control and interact with AVs. In order to avoid mode confusion and induce mode awareness. This adaptation may involve learning new control mechanisms, understanding AV system feedback, and evoking to new ways of interacting with the AVs.

*5) Reconsideration of user roles:* As AVs take on more driving functions, users' roles and responsibilities in the driving process undergo significant changes. Users may transition from active drivers to passive passengers, requiring them to redefine their roles, participation in NDRT, responsibilities, and expectations concerning AV operation and safety.

*6) Impact on road design and environment:* The integration of AV technology reshapes the on road experience and driving environment, influencing traffic flow, road infrastructure and design, road users/VRUs, and regulatory frameworks. AV users must adapt to these changes, including new traffic patterns, infrastructure requirements for automated driving operation, and updated regulations governing AVs.

Generally, the changeover to automated driving brings about significant shifts in UX and BA for road users. Understanding these changes is crucial for ensuring safe adoption and assimilation of AVs into the transportation ecosystem.

In this study, we specifically consider levels of UX based on L2 AVs. In order to conceptualise L2 AVs and their usefulness with respect to the user, we consider behavioural adaptation (BA) and change (BC) or BAC based on repeated usage and sequences of effects [2]. Moreover, considering how UX, trust, and acceptance of L2 AV functionalities (e.g. longitudinal and lateral driver support systems) change with long-term repeated usage in urban traffic. Furthermore, it is highly influential to assess usability by emphasising the concept of Learnability in Automated Driving (LiAD) [3], which considers learning effects of automation on user behaviour. Thus, proposes a comparison between users 'learning to misuse' and 'learning to responsibly use' automation, relative to the operation of AV on road traffic. The study explores the relevance of UX, trust and acceptance based on prolonged usage of L2 AVs, by considering users knowledge on the following inquiries, as illustrated by Fig. 3.



Automated driving experience and timeframes
Vehicle operation competency
Driving skills over long-term use of automation
The learning process
Automation-induced effects
Trust in automation and acceptance
ADS researchers and manufacturers

Fig. 3. Study knowledge inquiries.

UX research has become a critical element in creating successful human-automation interactions (HAI) and AVs for future use cases and user journeys. It has become a crucial topic for the future of AV induced quality experiences, particularly with the introduction of super intelligent automation, artificial intelligence (AI) and generative AI. This is because of its direct impact on user behaviour, and as a way of safeguarding in-vehicle AI-UX vision of the future. Thus, it is essential to consider UX that is expedient and self-serving based on human factors and quality-based interaction design strategies. Essentially, developing augmented and super automation intelligence enables AVs that induce safe decisions, as well as active, proactive or reactive (responsive) safety based behaviours in traffic situations also the ability to perform driving actions completely safe in the future.

Depending on user types, context of use, and environmental situation, the knowledge attained from this study opens up the prospect for UX on road that is more efficient, organic/natural, safe and predictive. This opens up a multitude of new research questions based on users experiencing learning, trust, and acceptance over long-term automation exposure. This knowledge helps with formulating resilient interaction design strategies that stand the test of time, and progressive multimodal learning strategies between the user and AV.

## II. Related Works

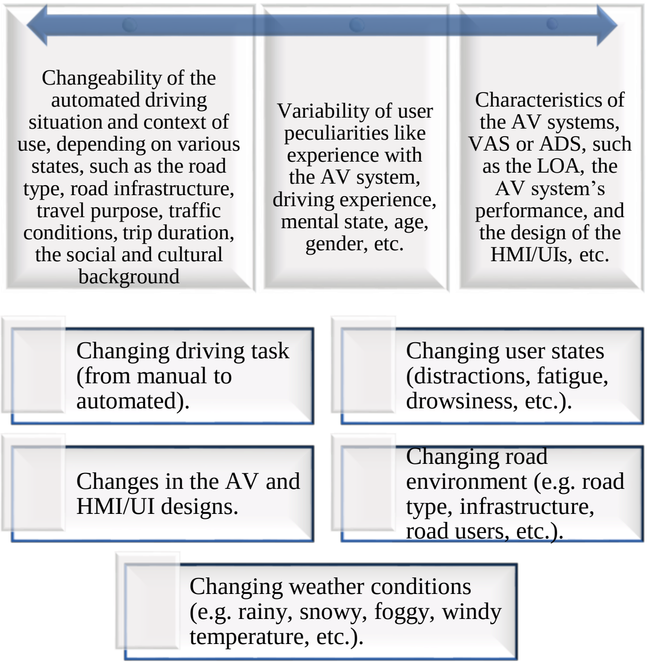
Numerous researchers have aimed to investigate UX and BA of L2 (see [4-5]) and L3-4 (see [6, 7, 8]) AVs. In an automated highway system, study in [9] investigated the effects driving performance after an extended period of travel. The researchers concluded that human factors play a pivotal role in how AV systems are experienced [9]. The study in [10] emphasised challenges induced by L2 automated driving. This type of research has become a trend, as other researchers aim to identify L3 automated driving [11] due to the L3 AV introduced on public roads. The study in [12] examined the effect of automation use, misuse, disuse, and abuse, which has inspired more research on the topic of BA [2] as automation changes and evolves.

Moreover, researchers have also considered the process of automation acceptance on road traffic, as seen in the lens of the Multi-level model on Automated Vehicle Acceptance (MAVA) [13]. The impact of most of AV features (from fully manual to fully automated) have been discussed by different researchers, as we see with [14, 15, 16]. This also considers a future direction of research and development towards benchmarking Highly Automated Vehicles (HAV) vision boards, considering trust and acceptance. According to some OEMs, we should already have been able to choose to be chauffeured by AVs instead of driving them, the vision for tomorrow where pressing one button will turn AVs into L5 autonomous driving. However, the current reality is that human users are still required to pay attention and be situationally aware during L2-3 automated driving.

In order for users to be able to operate their L2-3 AVs to their fullest capabilities, they are required to familiarise themselves with a myriad of knowledge processes, functionalities, acronyms, controls, and symbols, to name a few. The user-vehicle interfaces (or HMIs) form a significant part on how AV systems are understood and operated. Including the type of information displayed to facilitate mode awareness. Distinguishing, recognising and knowing symbols is, consequently, essential for users to safely operate AVs equipped with different functionalities. It is thus important to explore how HMI/UI design may influence BA over long-term exposure.

The Organisation for Economic Cooperation and Development (OECD) defined BA as “those behaviours which might occur following the introduction of changes to the road-vehicle-user system and which were not intended by the initiators of the change [...]. They create a continuum of effects ranging from a positive increase in safety to a decrease in safety” [2]. As a result, users are able to adapt to the exposed vehicle automation situation (including its limitations and capabilities). Fundamentally, behavioural evolutionism is seen as an applicable theory. In this context, ‘behavioural evolutionism’ pertains to the examination of how user behaviours related to AVs changes over time, incorporating concepts such as learnability, trustability, and acceptability. It considers various factors such as user states, system design, and environmental influences in shaping these behaviours.

As an illustration, the evolution of automated driving (AVs as societal innovations) can be viewed as subject to environmental factors, serving as the mechanisms by which human users adjust to their altered on road traffic circumstances. This adaptation is prompted by both physical alterations in road infrastructure and social changes. Essentially, the process of BAC is considered as the evolution and manifestation of new behaviour towards AV. Users are confronted with changing driving situations that they have to adapt to, constantly. This occurs at changed UXs, resulting in ‘AV user modifications’ due to long-term automation exposure. In a general context, ‘AV user modifications’ is used to depict users experiencing changes or transformations throughout their automated driving experiences. These changes are activated due to users’ interaction with AV systems in various changing situation, and they evolve from the complex interplay of different factors, as illustrated by Fig. 4.



Changeability of the automated driving situation and context of use, depending on various states, such as the road type, road infrastructure, travel purpose, traffic conditions, trip duration, the social and cultural background
Variability of user peculiarities like experience with the AV system, driving experience, mental state, age, gender, etc.
Characteristics of the AV systems, VAS or ADS, such as the LOA, the AV system’s performance, and the design of the HMI/UIs, etc.
Changing driving task (from manual to automated).
Changing user states (distractions, fatigue, drowsiness, etc.).
Changes in the AV and HMI/UI designs.
Changing road environment (e.g. road type, infrastructure, road users, etc.).
Changing weather conditions (e.g. rainy, snowy, foggy, windy temperature, etc.).

Fig. 4. Changing situations and UX factors.

The ‘power law of learning’ and ‘power law of practice’ is important to consider, as users take possession of the purpose, working principles, and expected performance of the AV over time. This has an indirect and/or direct effect on the usage process; especially, as users are exposed and use the AV system, long-term. Concerning the temporal factors affecting BAC and two main phases, the following have been profoundly argued in literature and are therefore considered.

- Learning and appropriation phase: The user discovers the AV system, learns how it operates, and identifies its capabilities and limitations. This learning process is assumed crucial for the user’s mental model of the AV system, the confidence the user has in it and its optimal use.

- Integration phase: The user, through experienced using the AV system in different road situations, reorganises their activity by integrating the AV system in the management of the overall driving task.

Thorough examination of the ‘learning and appropriation’ phase is essential as the progression and duration of this phase directly influence the evolution of users’ behaviour over time. As the ‘learning and appropriation’ phase unfolds, users may gain crucial elements necessary for constructing mental models pertaining to the AV system. Informed by these mental models, users may make decisions, whether consciously or unconsciously—regarding when to safely operate the AV and when to engage non-driving related tasks (NDRTs). Furthermore, mental models play a crucial role in determining the level of trust to invest in the automation and its incorporation into their daily routines. These decision-making processes have consequences on the manifestation of either positive or negative BA to AVs, and are further explored by study [3]. Thus, when researching BA, it is important to consider mental models. It is essential to discover factors that might cause BA to AV systems (considering longitudinal driver support systems, lateral driver support systems, and driver performance monitoring and support systems). In addition, the users’ mental model in relation to the AV-LOA and the trust in automation should be considered.

Research on BA has primarily cantered around various AV systems. However, there is a need to expand understanding to encompass BA to the context of HMI and UI designs. Adaptive Cruise Control (ACC) and Lane-Keeping Assistance (LKA) systems deal with longitudinal and lateral controls of a vehicle. When referring to AV-HMI induced effects to BA, both ACC and LKA have distinctive symbols. These symbols play a significant role in facilitating users’ comprehension and swift recognition.

- ACC: “a system which accelerates or decelerates the vehicle to automatically maintain a driver pre-set speed and driver pre-set gap distance from the vehicle in front” (ISO 7000-2580).

- LKA: a “system to keep a vehicle between lane markings” (ISO 7000-3128).

The following AV functionalities (see Fig. 5) are able to imitate human driver abilities, such as logical decision-making processes and reasoning on road traffic.

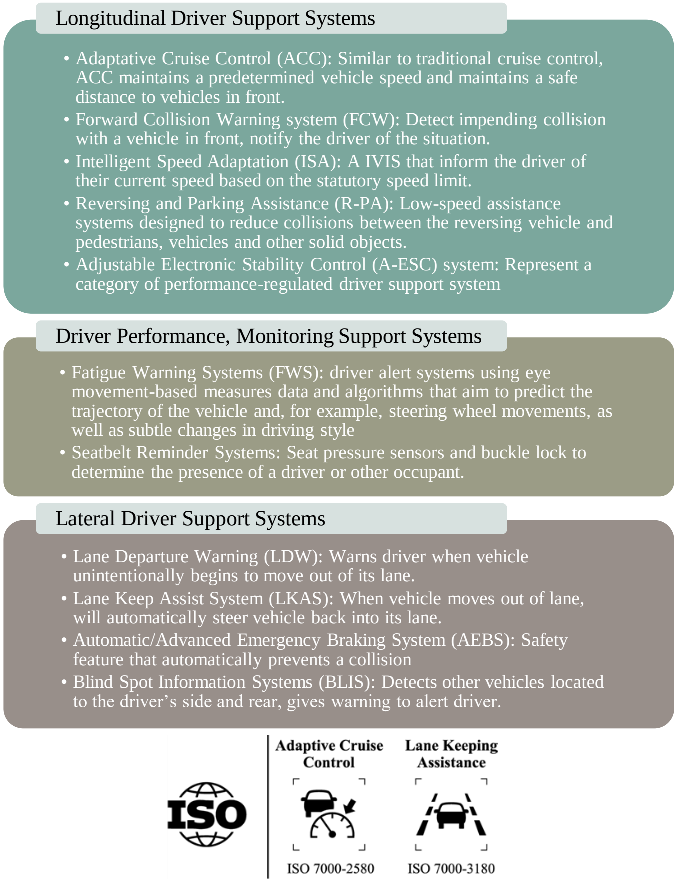
*A. Synergies of effects and BAC perspectives*

Synergies of effects refer to the combined or compounded impacts or benefits that arise from the interaction or coordination of multiple factors or elements due to long-term repeated automation exposure such as trust, reliance, situational awareness (SA), or skills, to name a few. These synergies may result in outcomes that are greater than what would be expected from each individual factor acting alone. For example,

- In trust, synergies of effects may occur when different factors associated with trust in automation influence the AV user to behave in a specific manner. As a result of either over trust, mistrust or distrust.

- In SA, synergies of effects may occur when multiple variables interact to produce a more pronounced or unexpected result. As a result of either distraction, fatigue, drowsiness, concentration (attentiveness), etc.

- In skills, synergies of effects may occur, for example, as a result of deskilling, upskilling, or reskilling.



Longitudinal Driver Support Systems

- Adaptative Cruise Control (ACC): Similar to traditional cruise control, ACC maintains a predetermined vehicle speed and maintains a safe distance to vehicles in front.
- Forward Collision Warning system (FCW): Detect impending collision with a vehicle in front, notify the driver of the situation.
- Intelligent Speed Adaptation (ISA): A IVIS that inform the driver of their current speed based on the statutory speed limit.
- Reversing and Parking Assistance (R-PA): Low-speed assistance systems designed to reduce collisions between the reversing vehicle and pedestrians, vehicles and other solid objects.
- Adjustable Electronic Stability Control (A-ESC) system: Represent a category of performance-regulated driver support system

Driver Performance, Monitoring Support Systems

- Fatigue Warning Systems (FWS): driver alert systems using eye movement-based measures data and algorithms that aim to predict the trajectory of the vehicle and, for example, steering wheel movements, as well as subtle changes in driving style
- Seatbelt Reminder Systems: Seat pressure sensors and buckle lock to determine the presence of a driver or other occupant.

Lateral Driver Support Systems

- Lane Departure Warning (LDW): Warns driver when vehicle unintentionally begins to move out of its lane.
- Lane Keep Assist System (LKAS): When vehicle moves out of lane, will automatically steer vehicle back into its lane.
- Automatic/Advanced Emergency Braking System (AEBS): Safety feature that automatically prevents a collision
- Blind Spot Information Systems (BLIS): Detects other vehicles located to the driver’s side and rear, gives warning to alert driver.

Fig. 5. LOA functionalities and example ISO symbols for ACC/LKA.

These effects may result in either constructive (positive) or destructive (negative) impacts, such as increased efficiency or inefficiency, safety or risk, misuse or responsible use, satisfaction or dissatisfaction, acceptance or rejection, etc. Overall, synergies of effects highlight the interconnectedness and potential amplification of HAI and long-term automation exposure outcomes that can arise from the combined influence of different UX factors.

AV-based BA refers to behavioural analysis conducted in the context of repeated AV systems usage or exposure. This involves analysing various aspects such as human behaviour towards the AV system, AV system performance, potential benefits, drawbacks, and impacts on safety and user experience associated with AV technology. This analysis aims to understand how AV systems (see Fig. 6, 7, 8) impact on road traffic and driving dynamics, traffic flow, safety and overall driving experience. As well as, how they align with industry objectives and regulatory requirements.

*1) BA* perspectives on Longitudinal Driver Support Systems *a) ACC-based B:* ACC employs sensors such as radar and laser to automatically adjust the distance to the vehicles ahead and provide the driver with road-related information. This includes parameters like the speed and proximity to other vehicles and VRUs. These variables are constantly monitored to maintain safe distances and mitigate risks. The system can assume control of the vehicle's speed, decelerating or accelerating as needed based on traffic conditions. In cases of emergency, such as a driver failing to respond to visual or auditory warnings, the ACC with emergency braking (EB) system can initiate evasive actions like braking, reducing engine power, or bringing the vehicle to a stop. ACC operates at speeds above 30 km/h, but there are also variants like 'stop and go' ACC or low-speed following (LSF) systems designed for lower speeds [14].

Driver Performance Monitoring and Support Systems
Fatigue warning systems (FWS)
Driver Monitoring Systems (DMS)
Seatbelt Reminder Systems

Fig. 8. Myriad of BA for driver performance monitoring and support.

From a BA perspective, among other considerations, studies have considered effects of ACC on BA (see [4, 17]). For example, examine driver behaviour in response to ACC, along with its potential advantages and disadvantages. Studies have delved into driving styles, particularly focusing on speed (driving fast) and attention (the ability to ignore distractions), for example. Findings indicate that ACC-based BA result in higher speeds, smaller minimum time headways, and increased brake force [17]. Furthermore, safety has an impact on BA. While most drivers assess ACC positively, they also note undesirable BA emphasising the need for caution concerning potential safety implications of such systems. Other studies investigated the learning phase of ACC over a month, using various data acquisition methods. For example, [4] noted, "as ACC primarily affects the guidance level, the duration of the learning phase and its impact on driver behaviour might differ." Moreover, drivers familiarised themselves with the operation of ACC controls and display elements after two weeks [4]. A few drivers felt confident with takeover situations. Ref. [4] revealed significant BC during the initial two weeks. The impact on trust in ACC and acceptance of ACC is important to consider, long-term.

*b) FCW-based BA:* Collision mitigation systems, like FCW systems, alert drivers, either visually or audibly, about the likelihood of a collision by continuously monitoring the road and nearby vehicles [14]. There are two types of FCW systems: non-adaptive and adaptive. The adaptive FCW adjusts the timing of its alerts based on individual driver reaction times. However, FCW systems do not have the capability to control vehicle speed. They can only warn the driver when entities, such as VRUs, are detected within a predefined threshold based on predicted time to collision (TTC). Many FCW systems rely on the driver to take manual action to control the vehicle and avoid a collision, as they do not initiate automatic actions. The effectiveness of warning algorithms in maintaining drivers' UX and BA to collision over time is crucial to investigate.

From a BA perspective, research indicates that extended use (>6000 km) of FCW systems can lead to a regression in drivers' following behaviour to pre-trial levels once the system is deactivated. Additionally, the impact on trust and acceptance of FCW has been highlighted in various studies. The study in [18] evaluated FCW systems based on different driver profiles, distinguishing between non-aggressive drivers (low sensation seeking, long followers) and aggressive drivers (high sensation seeking, short followers). It was noted in [18] that, if the timing of warning presentations is perceived as inaccurate, trust in the system diminishes, leading to reduced likelihood of appropriate driver responses. High-quality FCW design is considered crucial for achieving high acceptance rates and actual usage of the system. The study in [19] explored the likelihood of drivers performing avoidance manoeuvres based on driver characteristics (such as age, gender) and study location. Essentially, in [19] observed that drivers aged 40 years and older were more inclined to use both braking and steering to avoid rear-end collisions, while drivers from coastal urban areas were less likely to solely rely on braking when responding to FCW alerts. Conversely, younger drivers and those in rural settings were more prone to opt for braking alone, potentially due to their familiarity with less congested traffic conditions. These findings shed light on the human factors and environmental factors influencing the adoption of different avoidance strategies by driver types.

The research in [20] investigated how FCW technology impacts driving behaviour and safety, specifically examining how these effects vary across different pre-crash scenarios. They discovered that both the FCW system and the specific scenario influenced driver behaviour leading up to imminent rear-end collisions [20]. The study argued that "various types of drivers experienced different advantages from the FCW in each scenario." Extensive research has investigated the impact of the FCW system on drivers' adaptability, including their response times in releasing the throttle or initiating braking, as well as its safety benefits, such as reducing collision rates and improving safety metrics like time-to-collision. This comprehensive body of research highlights the effectiveness of the FCW system in enhancing driving safety. These discoveries provide valuable insights for developing next-generation vehicle collision warning systems, especially with the incorporation of augmented reality (AR) and artificial intelligence (AI) technologies.

*c) ISA-based BA:* ISA systems are largely viewed as IVIS designed to alert drivers about their speed concerning the prescribed speed limit for a given road, thereby enhancing overall road safety. According to study [21], "driver perceptions of ISA systems contribute to the effectiveness of speeding reduction." This is influenced by several factors, including system capabilities, human factors, user demographics, and trip attributes.

From a BA perspective, ISA systems are generally considered to be well-developed and sufficiently accurate for dependable usage. However, statutory speed limits, such as those set for urban and rural areas, are often established with somewhat rudimentary intervals dictated by lawmakers rather than being based on specific road features, local infrastructure, and relevant parameters like camber, curve radius, and gradient in [14]. Furthermore, researchers have asserted that accidents related to speed persist, particularly on curved road sections. Additionally, it has been argued that simply providing speed limit (PSL) information along vertical and horizontal curves is insufficient to shield drivers from the risks associated with prevailing conditions [22]. The study in [21] investigated driver BA concerning the influence of operating vehicles equipped with ISA systems. The study examined three distinct IVIS-HMI functionalities: informative, warning, and intervening. The researchers explored perceived effects on drivers to discern their attitudes towards the systems and potential connections between anticipated and observed behaviour. The study in [21] concluded that the use of ISA systems led to "the adoption of vehicle speeds that are likely to enhance road safety" and promoted improved driver behaviour. However, it was also uncovered that "drivers may misuse ISA systems, potentially leading to adverse road safety outcomes."

The research in [22] investigated the influence of V-ISA on driving performance, a system with the capability to estimate the dynamic (real-time) speed limit based on current visibility conditions and stopping distance. Additionally, the researchers assessed drivers' acceptance and usability of three V-ISA functionalities. V-ISA operates in three modes: it can (i) provide visual information (V-ISA Information), (ii) alert the driver with a warning sound (V-ISA Warning), and/or (iii) directly intervene to adjust and control vehicle speed (V-ISA Intervening). The study revealed that "V-ISA effectively reduced the risks associated with speeding, with relatively high levels of acceptance and perceived usability" [22]. Moreover, the study found that V-ISA can have positive effects on road safety by aiding drivers in regulating their driving speed.

*d) R-PA-based BA:* Low-speed driver assistance systems, like reversing or backing systems, are intended to minimize collisions involving the reversing vehicle, VRUs, and entities that might be obscured from the driver's view [14]. These systems typically utilize short-distance radar along with audio feedback (beeps) and/or video feedback (displayed on a screen visible to the driver), providing visual feedback and sometimes audio cues when the vehicle is in reverse. Regardless of the warning medium used (audio or video), reversing systems appear to reduce collisions, with video-based systems demonstrating greater effectiveness. Over time, OEMs have integrated in-vehicle technologies for parking assistance. As an example, Volkswagen offers Park Assist, while Mercedes provides various parking assistance systems such as Parking Assistance System, Active Parking Assist, and Remote Parking Assist, which includes a Digital Extra feature accessible via a smartphone app. BMW offers a range of systems including Self-Parking System, Parking Assist, and Parking Assist Plus. Additionally, Valeo offers the Parking Slot Measurement System, Siemens provides Park-Mate, and Volvo offers the Evolve system for parking assistance.

From a BA perspective, [23] presents a parking assistance system that utilizes dense motion-stereo to generate real-time depth maps of the surrounding environment. This system has various applications, including automatic parking slot detection, collision warnings for door pivoting ranges, augmented parking, and an image-based rendering technique to visualize the area surrounding the host vehicle [23]. The study acknowledges challenges such as shearing effects when utilizing rolling shutter cameras, smearing with global shutter, and misalignments associated with interlaced images. Ref. [24] evaluated the impacts of rear parking sensors, rear-view cameras, and rear automatic braking systems on backing crashes. They used negative binomial regression to compare reported instances of backing crash involvement per insured vehicle among General Motors AV equipped with various combination of systems [24].

Research findings indicate that while rear-view cameras and rear parking sensors are contributing to a decrease in backing crashes, their effectiveness could be constrained by drivers' insufficient use or reaction to the systems. Moreover, revealed that rear automatic braking, as it does not solely depend on drivers' appropriate responses, enhances the efficiency of these safety systems [24]. Ref. [25] stressed the preference among drivers for AVs that can locate suitable parking spots and autonomously manoeuvre into them, minimizing the need for driver intervention and reducing parking stress. The importance of ultrasonic sensors in achieving heightened safety levels was also emphasised. These insights are valuable for informing the design of future automated parking and unparking technologies. The impact of automation in digitalized automatic parking.

*e) A-ESC-based BA*: The algorithm or model used by the ESC system is determined by the OEM, and its sensitivity varies depending on the vehicle's make, model, and year. For many drivers, the activation of ESC during normal driving is a rare occurrence, which can be considered one of the primary advantages of ESC systems. Equally, A-ESC (Adaptive ESC) systems and S-ESC (Standard ESC) represent a type of support system regulated by performance standards. S-ESC functions to counteract over-steering or under-steering by comparing the actual vertical rotation of the vehicle (measured by the yaw sensor) to the expected rotation based on the steering wheel angle sensor. The relevance of S-ESC or F-

ESC (Fixed ESC) is typically low for most drivers in terms of their perceived functionality [14].

A-ESC poses more intriguing considerations from a BA perspective, as it raises questions about system relevance and the potential for BA. The study in [26] examined traffic safety performance concerning active safety systems, with a specific focus on the Antilock Braking System (ABS) and Electronic Stability Control (ESC). This included evaluations of driver behaviour and the impact on traffic safety. In assessing the effect of ESC through physical testing, the researchers identified several test methods. Moreover, estimated driver behaviour effects [26].

### 2) *BA* perspective on Lateral Driver Support Systems

*a) LDW/LKA-based BA:* LDW systems are designed to alert drivers when their vehicle unintentionally drifts out of its lane. These systems typically rely on video sensors positioned in the front of the AV or infrared sensors mounted behind the windshield, which process images from the road ahead [14]. They issue warnings to the driver through visual cues, audible alerts, and/or haptic feedback. Similarly, LKA systems operate on the same principles as LDW. However, if the driver fails to heed the warnings, LKA intervenes to ensure the AV avoids unintended lane departures. LKS systems utilise a digital camera mounted on the windshield to identify lane markers and determine the AV's position on the road. These systems provide haptic feedback, often in the form of vibrations in the steering wheel, to alert the driver of lane deviation.

From a BA perspective, for instance, if persistent drifting occurs, indicating driver drowsiness, the system's warning lamps will alert the driver to stop and rest. In cases where the driver is inattentive to the LDW and drifts out of the lane, the steering system will intervene to guide the vehicle back into the lane. The study in [28] observed that "drivers must familiarise themselves with various symbols to correctly identify and activate the system they wish to be using," as OEMs often replace standard graphical symbols with their own preferences. Therefore, it is crucial to consider the learning, trust, and acceptance of AV systems for the continuous development and evaluation of UX and BA over time.

*b) BLIS-based BA:* Similarly to most in-vehicle ITS or ADAS, BLIS is perceived as an additional safety feature. BLIS comprises a sensor that detects AVs located to the driver's side and rear. When the turn indicator is not activated, it issues alerts (visual or auditory) to drivers. For instance, higher levels of warning intensity indicate an increased potential for hazardous lane changes [14]. BLIS utilises either a camera to visually detect vehicles or side radar for enhanced performance in warning of rapidly approaching vehicles entering the blind spot.

From a BA perspective on BLIS, consist of the possibility of drivers becoming complacent and relying on the system rather than consistently checking their rear-view mirrors over the long term [14]. The study in [29] highlighted that both ACC and BLIS have the capability to reduce driving task discomfort and risks while enhancing driving comfort and promoting safer journeys. However, studies have also cautioned about the potential for users to exhibit negative BA, which could lead to adverse effects on safety. Concerning BA, we consider that, for ACC, research on BA yields conflicting results, particularly regarding lane keeping, following distance, speed adjustment, and reaction to critical events. Consequently, no unanimous conclusions have been reached in this area of study [29]. For BLIS, there is a notable scarcity of studies focused specifically on BA, highlighting a gap in the existing research. Therefore, there is a clear necessity for further investigation and exploration in this area to better understand its implications and effects [29].

### 3) *BA* perspective on Driver Performance Monitoring and Support Systems

*a) FWS-based BA:* Fatigue can be defined as the subjective sensation of tiredness accompanied by a reluctance or disinclination to continue engaging in a task. Studies examining the impact effects of driver fatigue on driving commonly employ measures such as vehicle control and psychophysiological indicators to assess driver drowsiness. The timing of the day has a more pronounced effect on driver fatigue compared to the duration of the task itself [27]. Driver impairment due to drowsiness is cited as a significant cause of both single and multiple vehicle collisions [27]. It is noted that, "drowsiness and inattention may contribute to approximately one million collisions annually in the U.S., representing one-sixth of reported collisions" [27]. Research indicates that 31% of drivers who experience drowsiness are initially unaware of its onset [27]. FWS are recognized as countermeasures designed to mitigate collisions linked to driver fatigue. They act as countermeasures that help alert drivers that they are drowsy. These driver alert systems utilise eye movement-based measurements and algorithms to anticipate the AV's trajectory. This includes analysing steering wheel movements and subtle changes in driving behaviour, with detection techniques incorporating lane departure, steering wheel activity, and ocular and facial characteristics.

From a BA perspective, the study in [27] noted that, "driver impairment due to fatigue induced drowsiness is a significant cause of vehicle collisions". The study in [27] evaluated driver BA to a FWS, and provided behavioural results on objective and subjective driver fatigue, driving time, number of breaks or on break duration. The research revealed that taking 30-minute breaks is ineffective in countering drowsiness [27]. Moreover, their findings suggest that FWS might not substantially decrease collisions resulting from fatigue [27].

*b) Seatbelt reminder systems:* Seatbelt Reminder Systems utilize visual and audible reminders, incorporating pressure sensors in the seat and buckle locks to detect vehicle occupants [14]. If an occupant is detected without their seatbelt fastened, the system intensifies signalling, such as flashing lights or audible beeping, to emphasize the urgency of the warning. Certain vehicle models are equipped with systems that monitor all available seats for occupants.

## III. Methods

The study was conducted using lime survey, with a focus on L2 AV usage and UX. As the study was an online study, no control elements were emphasised. The survey instrument was designed using information pertaining the project objectives. From an in-depth industry expert interview study, knowledge obtained from this study was used in deriving the survey instrument. The aim was to gauge a general understanding of UX based on repeated/long-term automation usage in urban traffic streams, specifically from a user-centric perspective.

### A. *Procedure*

Upon opening the survey, participants were informed about the study procedure and what is expected of them. A brief description of what driving automation means was provided. This is because, as non-experts in the field, users are sometimes not able to discriminate the difference between LOA, ITS, ADAS, ADS, as well as IVIS and IAS. This is due to different OEM brand positioning, for example. In addition, they were informed about the length of the survey and each section theme. The survey was a one-time procedure. The average duration between the first and last input was max = 60 days.

### B. *Sample*

The study was conducted with N = 16 drivers. The mean = 2.56, Std. Dev. = 1.031. About half of the sample (50%) was male and another half was female (50%). Concerning the participants age, 16 to 25 (6.3%), 26 to 39 (50.0%), 40 to 59 (18.8%), 60+ (25.0%). In addition, 37.5% held a driving license for less than five (5) years, and 62.5% for more than five (5) years. When asked about their preferences, 25.0% noted they prefer to manually drive their vehicles, while 75.0% noted preference towards driving automation.

Regarding their driving experience (mileage), 37.5% had less than 10000 miles, 18.8% had 10000 to 100000 miles, and 43.8% had 100000 plus miles during the time of the study. When asked, how often do you drive? 43.8% stated 1-3 days per week, 37.5% stated 3-6 days per week, and 18.8% stated 7 days per week. The decision to select the sample of the study, was based on the need to understanding real world users' long-term repeated experiences with L2 automated driving features.

### C. *Data Analysis*

The survey was based on different information themes, for which this paper was derived. To analyse the data, we used descriptive analysis and content analysis for qualitative data. The following themes were analysed: automated driving experience and timeframes, vehicle operation competency, driving skills over long-term use, learning process, automation-induced effects, trust in automation, and remarks. The steps taken to analyse the data, were reviewing and transcription, data familiarisation, theme selection, reviewing, and categorisation, overall data integration, and reporting of results.

## IV. Results

### A. *Automated Driving Experience and Timeframes*

Participants where ask to provide their automated driving experience, and timeframe of usage. A period of either "1-13 weeks" was noted by four (4) participants, "3-6 months" was noted by two (2) participants, "6-12 months" was noted by three (3) participants, and "more than 1 ≤ year" was noted by seven (7) participants. When asked about the timeframe of usage, considering short-term or long-term. The participants quantified short-term based on hours to days (with 30 days being the highest timeframe), while long-term was quantified based on months to years (with three years being the highest timeframe).

### B. *Vehicle Operation Competency*

Participants where ask to provide information pertaining to their competence based on long-term automated driving. When asked, "Do you know '*how*' to use all of the driving automation functions installed in the vehicle that you drive?" Ten (10) participants selected 'No' and six (6) participants selected 'Yes', as shown on Fig. 9. Understanding '*how*' to use all the driving automation functions installed in the vehicle that participants drive indicates possessing comprehensive knowledge and proficiency in operating these AV features. This understanding encompasses familiarity with the activation, deactivation, and adjustment of various vehicle automation functions, as well as awareness of their specific functionalities and limitations. This suggests that participants are equipped with the necessary skills and know-how to effectively use these vehicle automation systems to enhance driving safety and convenience.

When asked, "Do you know '*when*' to use all the driving automation functions installed in the vehicle that you drive?" Fourteen (14) participants selected 'No' and two (2) participants selected 'Yes', as shown on Fig. 9. Understanding '*when*' to use all the driving automation functions installed in the vehicle that participants drive involves recognising the appropriate circumstances and conditions for activating these AV systems or features. This comprehension includes awareness of situations (SA) where driving automation functions such as ACC, LKA, and AEB systems can be beneficial and enhance driving safety and efficiency. It also entails understanding the limitations of these AV systems and knowing when manual intervention may be necessary, such as in certain weather conditions, complex driving scenarios, or low visibility situations. Essentially, knowing '*when*' to use driving automation functions involves a nuanced understanding of both the capabilities of AV systems and the context of the driving environment.

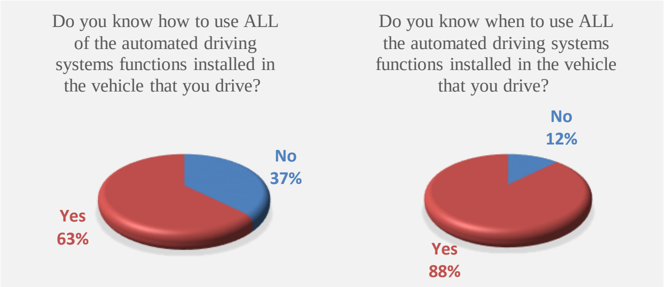

Fig. 9. Use factors: How to use (left) and when to use (right).

When asked, "Are you '*proficient*' in using the driving automation functions installed in the vehicle that you drive during any weather condition?" As shown on Fig. 10, two (2) participants chose 'No' and fourteen (14) participants chose 'Yes'. For participants to state that they are '*proficient*' in using the driving automation functions installed in their L2 AV during any weather condition means that they possess a high level of skill and competence in using AV features, regardless of the weather conditions. This proficiency implies that participants are capable of effectively navigating and controlling the AV's ADAS/ADS, such as ACC, LKA, AEB, and others, even when faced with challenging weather conditions: rain, snow, fog, or extreme temperatures.

Being proficient in using these L2 AV features suggests that. To some degree, participants understand their capabilities and limitations, know how to activate and deactivate them as needed, and can make informed decisions to ensure safe and efficient driving under various weather scenarios. It also implies that participants are familiar with any specific adjustments or considerations required for optimal performance of the driving automation functions in different weather conditions. Overall, claiming proficiency in using driving automation functions in any weather condition indicates a high level of skill, experience, and confidence in using AV systems to enhance driving safety and convenience across a range of environmental circumstances.

When asked, "Do you feel '*comfortable*' using driving automation functions in your vehicle?" As shown in Fig. 10, one (1) participant selected 'No' and fifteen (15) participants selected 'Yes'. Feeling '*comfortable*' with the driving automation functions in the vehicle indicates a sense of ease, confidence, and familiarity with using these AV features. This level of comfort suggests that participants are at ease with operating the vehicle automation functions and have a good understanding of their capabilities and limitations. It implies that participant feel relaxed and confident while engaging these AV features during their daily driving experiences.

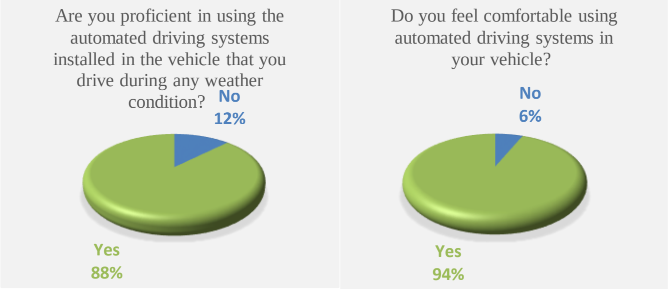

Fig. 10. Proficiency (left) and comfortability (right) factors.

When asked, "Do you know the difference between '*hands-off*' and '*hands-on*' driving automation functions protocols?" Three (3) participants selected 'No' and thirteen (13) participants selected 'Yes', as shown on Fig. 11 (left figure). The distinction between '*hands-off*' and '*hands-on*' driving automation protocols relates to the degree of manual engagement required from the driver during AV operation:

*1) Hands-off driving automation:* In this mode, the AV system can manage most driving tasks independently, with minimal or no physical input from the driver. It encompasses advanced automated systems where the AV can steer, accelerate, and brake within pre-set parameters. However, the driver must remain attentive and ready to intervene if necessary.

*2) Hands-on driving automation:* This protocol necessitates the driver to maintain continuous contact with the steering wheel and be prepared to take control of the AV when required. While automation systems like ACC or LKA may be active, the driver remains responsible for monitoring the driving environment and intervening as needed. Hands-on automation offers assistance but does not fully relieve the driver of their driving responsibilities.

In essence, hands-off automation grants more autonomy to the vehicle, while hands-on automation mandates ongoing driver involvement and supervision, even with automation in operation. When asked, "Do you understand the difference between *automated mode* and *manual mode* in critical situations?" One (1) participant selected 'No' and fifteen (15) participants selected 'Yes', as shown on Fig. 11 (right figure). Understanding the difference between automated and manual driving modes in critical situations involves drivers grasping how each mode functions and the driver's role within them. In automated mode, the AV systems primarily handle driving tasks, using sensors and algorithms to make decisions regarding steering, acceleration, and braking. During critical moments such as sudden obstacles or emergencies, the ADS is expected to respond promptly, although driver intervention may be necessary if prompted or if the situation demands it. Conversely, in manual mode, the driver assumes direct control over driving functions, especially in complex or unpredictable scenarios where the ADS may struggle. The driver's ability to make quick decisions and navigate effectively becomes crucial for ensuring safety. Thus, participants understanding these modes entail recognising the balance between automated assistance and human control in critical driving situations.

When asked, "Do you know in which situations you need to take over control of the vehicle when driving automated?" One (1) participant chose 'No' and fifteen (15) participants chose 'Yes' as illustrated by Fig. 11 (bottom). Participants understanding the instances necessitating driver intervention to assume control of the AV while driving in automated mode involve identifying various scenarios where human oversight becomes crucial for safety. These include emergencies, such as, sudden obstacles or hazards, AV system technical malfunctions, adverse weather conditions impairing sensor efficacy, navigating complex or ambiguous traffic situations, and adapting to changes in road infrastructure like construction zones. Recognising when to intervene underscores the importance of acknowledging the AV system's limitations and being prepared to step in when human judgment and decision-making are vital for safe navigation.

When asked, "Where do you usually use automation when driving?" As shown on Fig. 12, for highways: three (3) participants chose 'No' and thirteen (13) participants chose 'Yes', for inner cities: three (3) participants chose 'No' and thirteen (13) participants chose 'Yes', and for rural roads: eleven (11) participants chose 'No' and five (5) participants chose 'Yes'. Participants typically use automation features while driving in various scenarios, including highway driving, navigating heavy traffic, and cruising on roads. Driving automation finds its usefulness in a range of contexts, including highway cruising, navigating heavy traffic, and managing long-distance journeys. It is seen as particularly advantageous in scenarios such as highway driving, where traffic patterns are more predictable, as well as during stop-and-go traffic situations, where systems like ACC can alleviate driver fatigue. Moreover, driving automation is seen to prove beneficial during routine commuting, assisting drivers on familiar routes, and in city driving, where systems like AEB enhance safety amidst complex urban environments. Additionally, VAS can support in adverse weather conditions by providing traction control and stability assistance. However, it is crucial for drivers to remain attentive and prepared to take control when necessary, as VASs may not be equipped to handle all driving scenarios effectively.

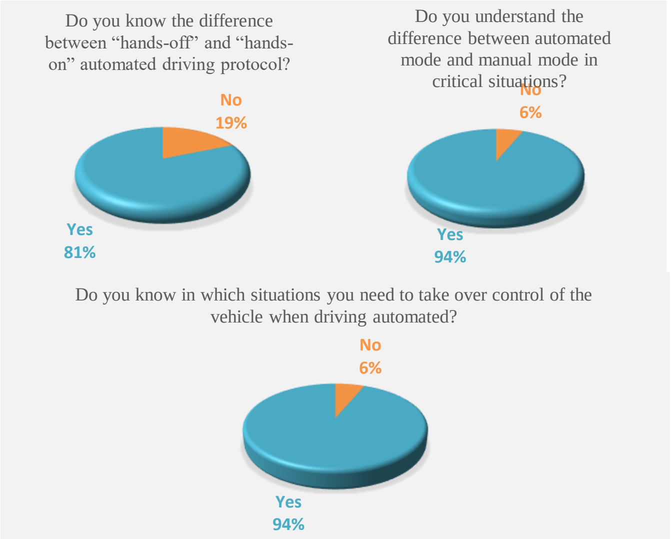

Fig. 11. Hands on/off (left), automated/manual mode (right), and context of use (bottom) factors.

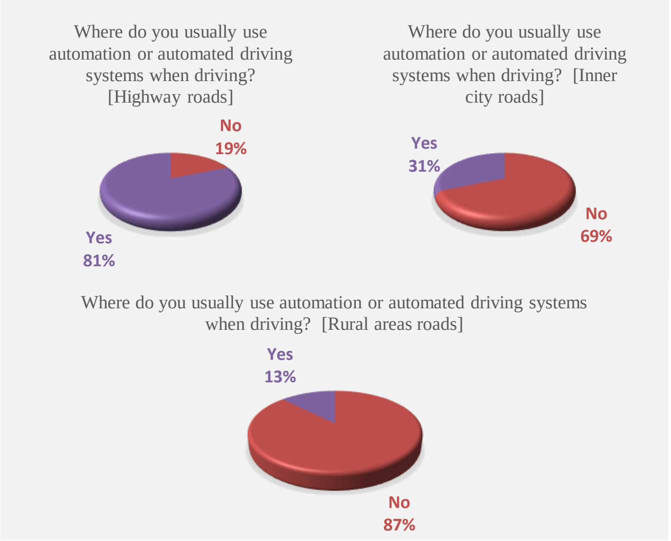

Fig. 12. Where to use factors: Highway (left), inner city (right), and rural roads (bottom).

### C. *Driving Skills Over Long-Term Use of Automation*

Participants where ask to provide information concerning their driving skills based on long-term usage of driving automation features. Proficiency in driving, developed through extensive use of driving automation features, is characterised by a deep understanding of the AV's capabilities and limitations. Over time, drivers become adept at seamlessly incorporating systems like ACC and LKA into their driving routines to enhance safety and convenience. Experienced users of these AV systems demonstrate heightened SA, making informed decisions about when to use VAS based on road conditions and traffic flow. Moreover, these users develop discerning judgment in assessing the reliability of VAS and intervening when necessary to ensure safe driving. Through continuous practice (based on the power law of practice), drivers refine their skills to strike a balance between leveraging automation benefits and maintaining vigilance on the road. With 1 (Strongly Agree), 2 (Agree), 3 (Disagree), 4 (Strongly Disagree). When provided the statements:

1) *"Long-term use of automation has an effect on humans' driving skills":* As shown on Fig. 13 (top figure), nine (9) participants chose 'Strongly Agree', two (2) participants chose 'Disagree', and five (5) participants chose 'Agree'. This reveals that extended reliance on automation has an impact on human driving abilities.

2) *"Using automation for a long period of time has an effect on people's manual driving style":* As shown on Fig. 13 (middle figure), six (6) participants chose 'Strongly Agree', three (3) participants chose 'Disagree', and seven (7) participants chose 'Agree'. This shows that prolonged dependence on automation alters individual users' manual driving behaviours.

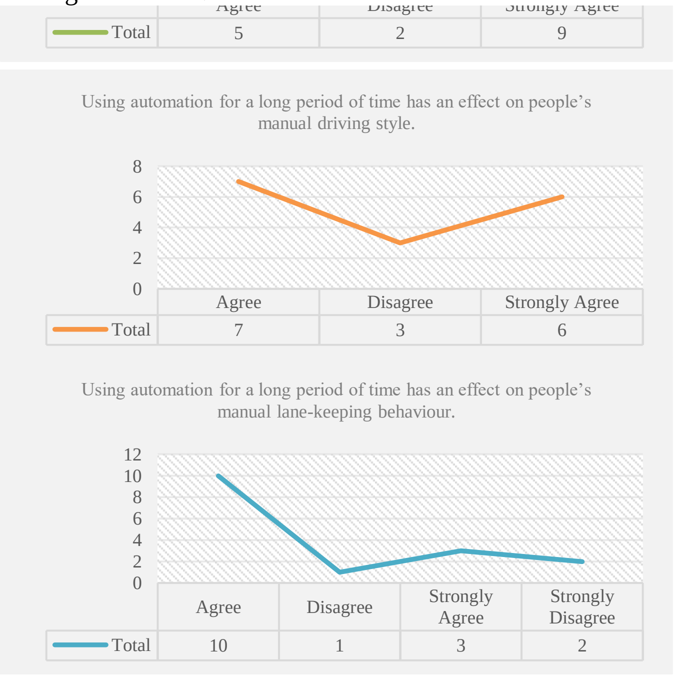

Fig. 13. Effects factors: Driving skills (top Fig), manual skills (middle Fig), and manual lane keeping (bottom Fig).

1) *Using automation for a long period of time has an effect on people's manual lane-keeping behaviour":* As shown on Fig. 13 (bottom figure), ten (10) participants chose 'Agree', one (1) participants chose 'Disagree', three (3) participants

chose ‘Strongly Agree’, and two (2) participants chose ‘Strongly Disagree’. This highlights that extended use of automation significantly influences individual user’s manual lane-keeping behaviour over time.

*2) “Using automation for a long period of time has an effect on people’s manual steering behaviour*”: As shown on Fig. 14 (top figure), nine (9) participants chose ‘Strongly Agree’, two (2) participants chose ‘Disagree’, and five (5) participants chose ‘Agree’. This reveals that long-term reliance on automation affects individual users’ manual steering behaviour.

*3) “Using automation for a long period of time has an effect on people’s manual braking behaviour”:* As shown on Fig. 14 (middle figure), seven (7) participants chose ‘Strongly Agree’, two (2) participants chose ‘Disagree’, and seven (7) participants chose ‘Agree’. This highlights that extended use of automation has an impact on individual users’ manual braking behaviour over time.

*4) “Using automation for a long period of time has an effect on peoples’ gaze behaviour”:* As shown on Fig 14 (bottom figure), two (2) participants chose ‘Strongly Agree’, two (2) participants chose ‘Disagree’, and twelve (12) participants chose ‘Agree’. This shows that extended reliance on automation alters individual users’ gaze behavior over time.

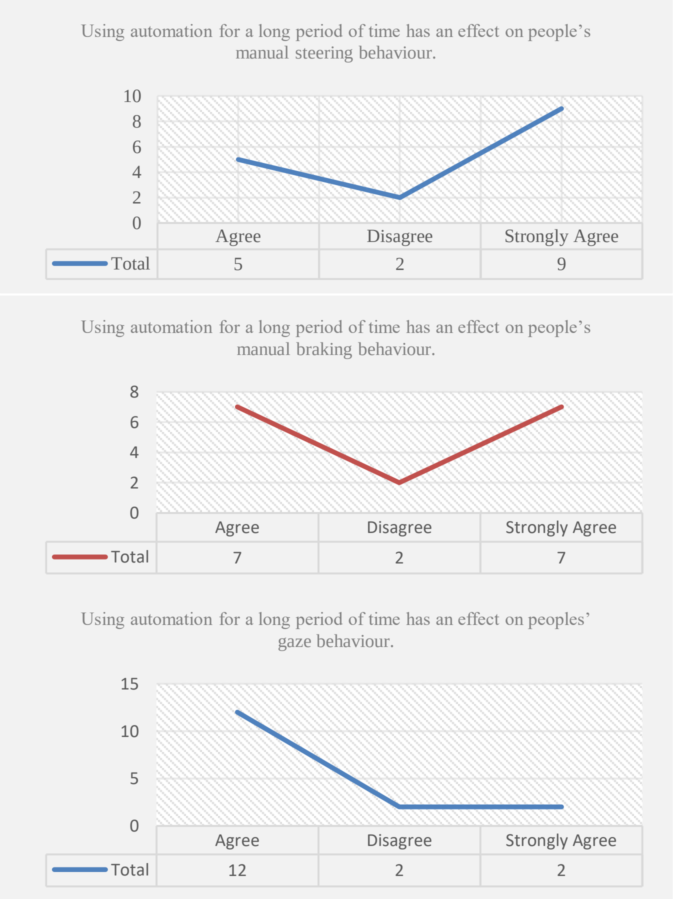

Fig. 14. Effects factors: Manual steering (top Fig), braking (middle Fig), and gaze behaviour (bottom Fig).

*5) “Using automation for a long period of time has an effect on people’s temperament (e.g. impatience, frustration, irritation, aggressiveness, calmness, rage, etc.) behaviour when driving manually”:* As shown on Fig. 15 (top figure), eight (8) participants chose ‘Agree’, six (6) participants chose ‘Disagree’, one (1) participants chose ‘Strongly Agree’, and one (1) participants chose ‘Strongly Disagree’. This highlights that prolonged use of automation can influence individual users’ temperament over time.

*6) “Using automation for a long period of time has an effect on people’s cognitive reasoning or decision-making process when driving manually”:* As shown on Fig. 15 (bottom figure), two (2) participants chose ‘Strongly Agree’, two (2) participants chose ‘Disagree’, and twelve (12) participants chose ‘Agree’. This highlights that extended use of automation can impact individual users’ cognitive reasoning or decision-making processes when driving manually.

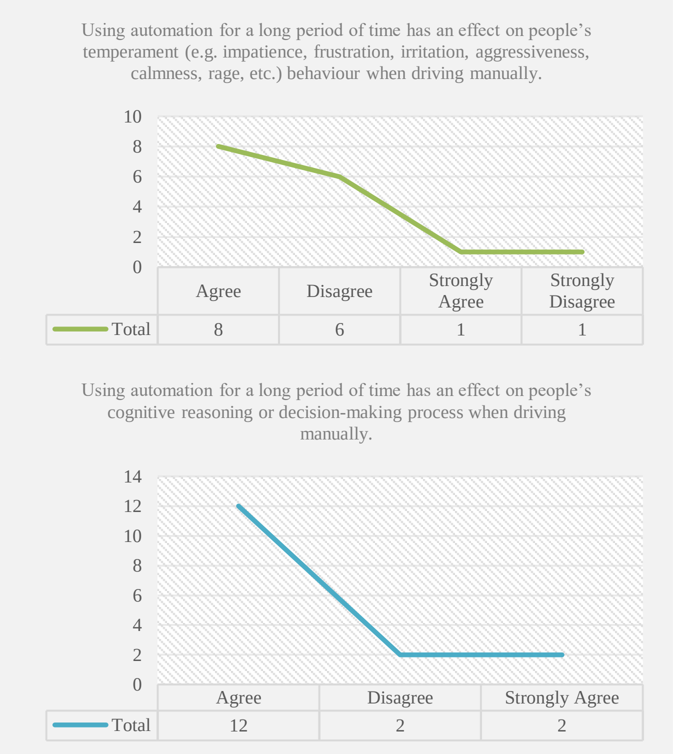

Fig. 15. Effects factors: Temperament (top) and cognitive reasoning (bottom).

## *D. The Learning Process*

Participants were asked to provide information concerning how they learned to use driving automation features in their vehicles. When asked, “Do you think it is important to receive training on how to use driving automation systems?” As shown on Fig 16, Five (5) participants chose ‘No’ and eleven (11) chose ‘Yes’. Thus, this stresses that receiving training on how to use driving automation systems is crucial, especially in different scenarios.

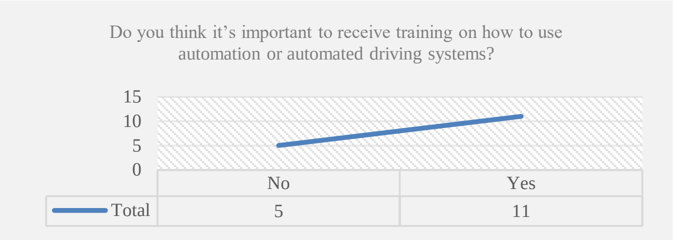

Fig. 16. Learning effects factors.

Participants were thereafter asked to provide a remark for receiving training, at which the following reasons were given:

When asked, "How did you learn to use the automated driving systems in the vehicle(s) that you drive?" with 1 being Social media (YouTube, Facebook, etc.), 2 being Social networks (Family and friends), 3 being Learned by myself, 4 being Driving School, 5 being Vehicle brand website, and 6 being 'Other'. As shown on Fig. 17 (top figure), most participants selected 2, which is 'Social networks (Family and friends)', and only 1 participant selected 1, which is 'Social media (YouTube, Facebook, etc.)'. This shows that participants familiarised themselves with using the AV systems in the vehicles they drive through a combination of reading the user manual, receiving hands-on instruction from dealership staff or certified trainers, and experimenting with the ADSs during their driving experiences. When asked, "How easy was it to learn to use the automated driving features in the vehicle(s) that you drive?" As shown on Fig. 17 (bottom figure), four (4) participants chose 'Challenging', five (5) participants chose 'Easy', one (1) participant chose 'Very challenging', and six (6) participants chose 'Very easy'. This show learning to use AV system depends on individual characteristics, AV system design, as well as context of use and exposure.

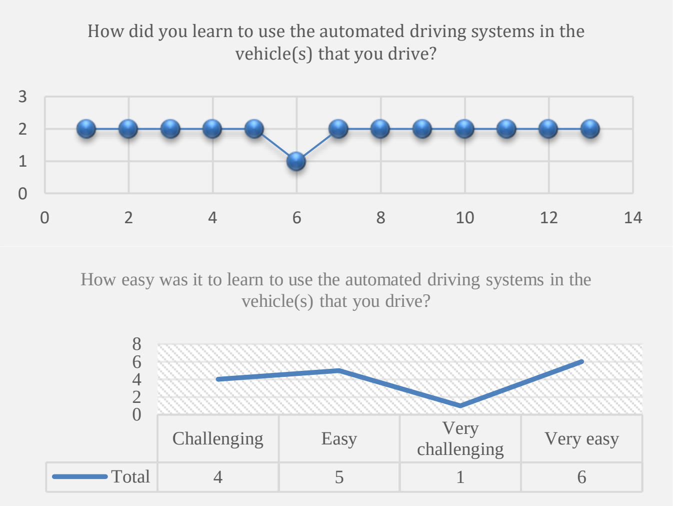

Fig. 17. Learning process (top) and easiness to learning (bottom).

## E. *Automation-induced Effects*

Participants were asked to provide information pertaining to their understanding of automation-induced effects. Information regarding participants' understanding of the effects induced by vehicle automation typically encompasses drivers' awareness of how vehicle automation impacts various aspects of driving behaviour, cognitive processes, and overall driving experience. This understanding may include knowledge about changes in manual driving habits, alterations in attentional focus or gaze behaviour, shifts in decision-making processes, and potential changes in overall driving temperament. Moreover, it may involve awareness of the benefits and limitations of vehicle automation, as well as the importance of maintaining vigilance and readiness to intervene when necessary. Inclusively, an understanding of automation-induced effects is crucial for ensuring safe and effective integration of AV technology into the driving environment. When asked,

- "Do you think there are risks in using driving automation systems long-term?" As shown on Fig. 18 (left figure), eight (8) participants chose 'Yes', five (5) participants chose 'No', and three (3) participants chose not to answer. This shows that using driving automation systems over long term poses certain risks that should be considered.
- "Do you think there are safety benefits in using driving automation systems long-term?" As shown on Fig. 18 (right figure), eleven (11) participants chose 'Yes', two (2) participants chose 'No', and three (3) participants chose not to answer. This shows that there are safety benefits associated with using driving automation systems over long term.

TABLE I. LEARNING EFFECTS REMARKS

| Participants | Learning Effects Remarks |
|---|---|
| | Remarks |
| "These vehicle automated systems can be complex because every car brand has its own different systems and HMIs. So training especially for first-time users is important." | |
| "Training and learning by doing is important." | |
| "Short introduction is needed." | |
| "You experience it and at first you are a little suspicious or doubt the features. And while monitoring it quite strictly, you get to learn how capable the system really is." | |
| "Some people don't know how to use automated cars." | |
| "These automated systems are still new and not a lot of people know exactly how to use them and when to use them, as well as where to use them. So training is important, not necessarily on how to use but also on educating people to know what they are there for." | |

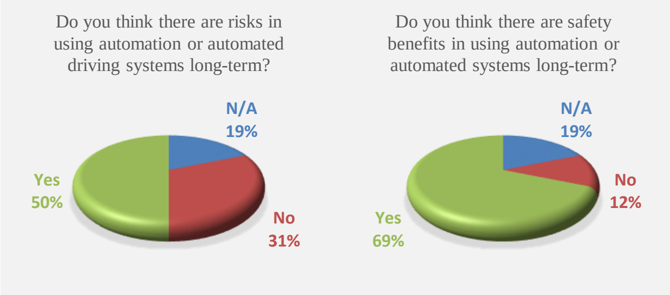

Fig. 18. Risks and safety effects factors.

Participants were further asked to name some risks and safety benefits of using driving automation systems. The following reasons were given (see Table II).

TABLE II. RISKS /BENEFITS OF USING AV

<table>
<tr><th rowspan="2">Participants</th><th colspan="2">Risks /Benefits of Using AV</th></tr>
<tr><th>Risks</th><th>Benefits</th></tr>
<tr><td colspan="2">Risks include paying less attention to the road and other vehicles, being overly confident in automation to do all the driving tasks, over trusting the automation in complex situations, loss of driving skills, etc. Inexperienced and insecure drivers pose a hazard.</td><td>Safety benefits include automation systems helping with the driving tasks, being able to perform other tasks, more safer driving with automation as my co-driver, the system helping me when I lose control of the car, etc.</td></tr>
<tr><td colspan="2">With curvy roads, I sometimes don’t trust in automation; its confusing.</td><td>Less congestion, safer on highway.</td></tr>
<tr><td colspan="2">Drivers forget how to drive independently and control the vehicle themselves in critical situations.</td><td>Safe automatic braking, adjustable distance, automatic speed limitation.</td></tr>
<tr><td colspan="2">Rely on systems too much. Forget or stop monitoring surroundings.</td><td>As long as used correctly, the system reacts faster and more reliable than a human does.</td></tr>
<tr><td colspan="2">You get bored while driving automated, or even tired. You focus on other things you should not.</td><td>System applies to the legal limits and regulations.</td></tr>
<tr><td colspan="2">You lose skills, need training.</td><td>System does not get tired.</td></tr>
<tr><td colspan="2">You are out of the loop, if a critical situation comes up.</td><td>System might be able to adapt to the user's behaviour.</td></tr>
<tr><td colspan="2">Getting the attention back to driving might take longer after a long period of automation.</td><td>System is usually safe, instead of a nervous or aggressive driver type.</td></tr>
<tr><td colspan="2">Risks when you experience a problem with your car and u cannot fix it because it is an automated car.</td><td>System monitors the driver's behaviour and keeps it at a safe level. Faster ROI.</td></tr>
<tr><td colspan="2">People become lazy, they forget to drive, they rely heavily on the automation, they neglect their roles, the automation is not 100% safe, and it could fail.</td><td>It is good for when you lose control of the car, it can be your co-driver, and it helps with taking off extra stress of driving the car.</td></tr>
<tr><td colspan="2">Risks can be system malfunctions. Over trust in automation.</td><td>Smaller environmental footprint. Easy integration.</td></tr>
<tr><td colspan="2">You cannot change the speed.</td><td></td></tr>
</table>

The constraints of AV systems involve their incapacity to completely emulate human decision-making and flexibility in intricate or unforeseeable driving scenarios, as well as their dependence on sensors that could be influenced by adverse weather or environmental conditions. Moreover, these AV systems might encounter challenges in accurately interpreting specific road markings or signage, potentially leading to navigation errors. Additionally, AV systems may not consistently detect all road obstacles or hazards, raising the possibility of accidents or collisions. In essence, while AV systems offer various advantages, it's crucial for users to recognize their limitations and maintain attentiveness during driving. When asked, “Do you understand the limitations of driving automation systems?” As shown on Fig 19 (left figure), eleven (11) participants chose ‘Yes’, two (2) participants chose ‘No’, and three (3) participants chose not to answer.

The capabilities and functionalities of AV systems include assisting with tasks like maintaining speed and distance from other vehicles, staying within lanes, and offering alerts or interventions in specific driving scenarios. These AV systems can feature advanced elements like ACC, LKA, AEB, and semi-autonomous driving modes. Additionally, certain AV systems provide convenience features like parking assistance and traffic jam assist. Ultimately, these capabilities aim to improve driving safety, comfort, and convenience by lessening the driver’s workload and addressing risks on the road. When asked, “Do you understand the capabilities of driving automation systems?” As shown on Fig. 19 (right figure), eleven (11) participants chose ‘Yes’, two (2) participants chose ‘No’, and three (3) participants chose not to answer.

Participants were further asked to name/list limitations and capabilities of driving automation systems (see Table III).

Participants were further asked to list examples of how using driving automation systems over time has negative effects and positive effects on users (see Table IV).

## F. Trust in Automation

Participants were asked to describe the level of trust they have in driving automation systems. When asked, “Do you trust automation to safely drive you to your destination without you constantly supervising it?” As shown on Fig. 20 (left figure), Six (6) participants chose ‘Yes’, six (6) participants chose ‘No’, and four (4) participants chose not to answer. Participants in the study express varying levels of confidence in driving automation systems, ranging from complete trust to scepticism or caution.

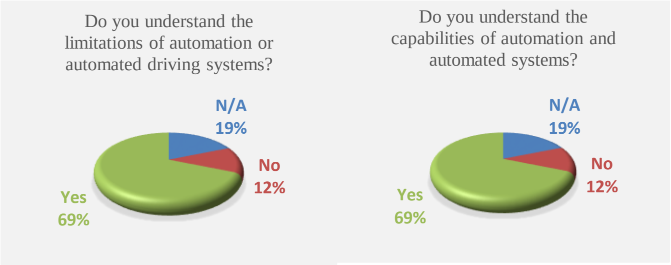

Fig. 19. Limitations and capabilities factors.

TABLE III. LIMITATIONS / CAPABILITIES OF AV

<table>
<tr><th rowspan="2">Participants</th><th colspan="2">Limitations/Capabilities of AV</th></tr>
<tr><th>Limitations</th><th>Capabilities</th></tr>
<tr><td colspan="2">It is a machine, so it cannot be better than a human.</td><td>It is a good co-driver partner</td></tr>
<tr><td colspan="2">All limitations are in the manual. May sometimes fail to detect risk situation.</td><td>Can handle most of the regular driving scenarios.</td></tr>
<tr><td colspan="2">Rush hour traffic is sometimes too much for automation, even on highways.</td><td>Shows good performance on well-marked roads, with non-rush hour traffic, at speed range from 50 to 140 km/hr.</td></tr>
<tr><td colspan="2">In construction areas and on roads without road-marking automation does not work.</td><td>Allows relaxed driving. It limits the speed correctly.</td></tr>
<tr><td colspan="2">Automation is not made for increased speed.</td><td>It is good in keeping the selected distance to cars in front.</td></tr>
<tr><td colspan="2">Limitations during bad weather, and bad road marking.</td><td>It is holding the lane exactly. It warns the driver to be alert.</td></tr>
<tr><td colspan="2">Limits during weather conditions. Sensor blindness and limits/width.</td><td>Reproduction of known and common behaviours.</td></tr>
<tr><td colspan="2">New situations are hard to handle, system is unable to interpret unknown situations.</td><td>Driving without changing gears several times.</td></tr>
<tr><td colspan="2">It has specific speed limit. It is not fully functional yet, it has errors, and it causes people to be negligent when driving.</td><td>It is good for driving under the influence, it helps people to not crash.</td></tr>
<tr><td colspan="2">Limits to using full capabilities or functions due to pre-programming that cannot be over ridded. Limit on ODDs</td><td>It keeps people safe, and it helps with driving so that people can do other stuff.</td></tr>
</table>

TABLE IV. NEGATIVE / POSITIVE EFFECTS OF USING AV

| Participants | Negative/Positive Effects of Using AV | |
|---|---|---|
| | **Negative Effects** | **Positive Effects** |
| It may be flawed, prone to error, and people can over trust in situations they should not. | | People can perform other personal tasks and use their time on the road more usefully like reading, rest, eat, nap and catch up on family time, etc. |
| Humans may pay less attention and neglect risks. When the ADS fails, it could be dangerous. | | Relaxing during a drive, save time for other things, e.g. reading, working in the car. |
| Sometimes driver loses attention. Visual and acoustic warning confuses or frightens driver. | | Automated long distance driving is relaxing. Automated driving provides a kind of safety. |
| Drivers forget how to park themselves, drivers forget how to assess risks, they forget how to drive smoothly and quickly. | | Time while driving for other tasks. Arrive more relaxed. Tendency to drive safer and more relaxed. |
| You lose your skills and experience, rely too much on the systems, tend to trust too much, stop monitoring properly. | | It makes driving easier for human beings. They are so quick to understand, and you do not get tired. |
| You will not know how to manual drive, unable to drive manually. | | Reduce workload, consistency, saves time. |
| They forget how to drive, they become over trusting on automation, they misjudge it. Less focus. | | People can use their time for other things, they can catch up with friends and family, work, can relax, and they can be safe and enjoy travelling. |
| You will get into a comfort zone whereby you dependent on it. | | It is simple. Less accidents and less road rage. |

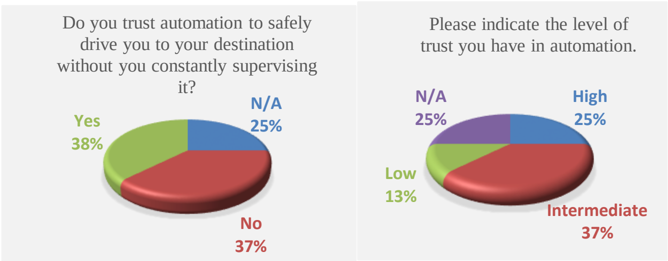

Fig. 20. Trust factors (left) and level of trust factors (right).

Participants were further asked to indicate the level of trust they have in automation, Low, Medium, or High. As shown on Fig. 20 (right figure), Four (4) participants chose 'High', six (6) participants chose 'Medium', two (2) participants chose 'Low', and four (4) participants chose not to answer. They generally indicate their level of trust in automation as low, medium, or high, depending on their experiences and perceptions. Participants provided remarks, such as, "it is not yet error-free", "driver attention is needed", "in the long term, automation for monitoring is needed, traffic violations should be recorded", and "depends entirely on the situation." Participants were asked to list views on trust over long-term use. For example, describe causes to trust, distrust/mistrust, over trust in automation.

. Participants were asked to list examples of NDRTs that people do while driving (e.g. answering text messages, emails, checking social media, etc.), which are illustrated by Table V.

It is shown that, causes for trusting vehicle automation include consistent positive experiences, reliable performance, and clear communication of AV system capabilities and limitations. Conversely, causes for distrust or mistrust may arise from instances of system failure, inconsistent performance, or unclear communication about system reliability. Moreover, overtrust in automation may stem from a lack of understanding of its limitations, complacency due to extended periods of successful use, or misplaced confidence in the AV system's abilities.

Concerning examples of automation misuses, participants mentioned the following, which are illustrated by Table VI.

It is shown that, causes of vehicle automation misuse can stem from various factors, including overreliance on automation, lack of understanding of AV system limitations, complacency due to prolonged successful use, and failure to maintain vigilance and readiness to intervene when necessary. Furthermore, misuses may occur due to misinterpretation of AV system response or information, as well as intentional misuse or disregard for safety guidelines. Furthermore, inadequate training or improper implementation of AV systems can contribute to their misuse.

TABLE V. CAUSES OF TRUST IN AUTOMATION

| Participants | Table Column Head | |
|---|---|---|
| | **Trust in Automation** | |
| **Trust** | **Mistrust/Distrust** | **Over Trust** |
| It has disadvantages and advantages. People may overly trust it over time, which can have negative consequences, as these systems are not yet error-free. In situations where people are afraid of technology, its important for it to prove that its trustworthy in order to use it for a longer time. | Because of media that shows that automation can be dangerous, people fear the unknown, fear that machines will overtake human life, etc. No or minimal practice. | Because they believe it is designed to help people, it's more intelligent than humans, it does the job more efficiently, etc. |
| It depends on the developed type of vehicle automation. | The capability of perception and planning is not developed enough for safe driving. | Don't understand how AV work, and may think it is very safe. |
| I trust automation if conditions on the road are not crowded and if the road itself is well marked and not too curvy. | Sudden braking on highways or rural roads with speed limits. Automation inaccuracy. | Blind trust in new technology. Not aware of risk circumstances (weather ...). |
| In the longterm, automation for monitoring is used. | System failure, monitoring of driving behaviour. | Because it is easier to use. Product quality. |
| Depend on performance - it might get higher. If you do not struggle so much to drive a car, it is much easier to use. | Bad behaviour and false actions (e.g. following falsely detected lanes on highway). Get scared or disappointed by car while driving long distance. | Because of misconceptions that it's more intelligent and skilful than humans. |
| People trust automation but not over trust it. Because technology does not always work and cannot replace humans. Maybe over time you get used to the idea of automation, so trust level will increase. This will increase over time. | Because it is a struggle when it does not function. Because of the sci-fi movies and social media that show how its not good, can become redundant. When not comfortable with automation, a sense of mistrust kicks in. | Lack of education on what exactly it is and how it's designed.<br>Repeated usage without incidents.<br>Automation accuracy. |

TABLE VI. NDRT THAT PEOPLE DO WHILE DRIVING AND MISUSES

| **Participants** | **NDRT and Misuses** | |
|---|---|---|
| | **NDRTs while driving** | **Misuses** |
| Phone calls, drinking, texting, sending messages and emails, chatting. Picking up phones, answering text messages. Searching radio channels or music, searching phone numbers, checking the map, calling phone, answering. Answering text messages, emails, checking social media. Text, eat, read papers or books, listening to podcasts, check mails, answer phone calls, get dressed. Texting while driving, making calls. text chatting. checking emails, answering calls, videos calls, and texting, eating, and taking a rest. Google, using social networking. Answering e.g. WhatsApp, Facebook and YouTube. Phone usage, looking outside, talking with other passengers. | | Giving too many responsibilities to the automation to carry out the whole task without their full attention. WhatsApp, e-mails or Mobile phone usage while driving.<br>Not paying attention to the driving. Driving or holding the steer wheel with one hand. Stop monitoring, willingly trick the steering detection (not really grabbing the wheel), and ignore warnings. Not putting a seat belt. Making calls while driving. Giving all the driving responsibilities to the car, not being alert on the road, doing other stuff while driving, and drinking alcohol in the car. Answering calls while driving. Using on curvy roads with relatively high speed. |

Participants were further asked to give remarks (see Table VII) concerning ADSs, concerning what researchers and manufacturers should emphasis on.

TABLE VII. RESEARCHERS / OEMS' ADS FOCUS POINTS

| **Participants** | **ADS Researchers and Manufacturers** |
|---|---|
| | **Researchers/OEMs ADS Focus Points** |
| Researchers/manufacturers should give more focus to designing and developing automated systems that are efficient and safe. | |
| The car interfaces should be more efficient, as well as designed for different people, for example, colour blindness, older people with eye issues, etc. | |
| The interfaces should not only be in a physical mode but also a nonphysical mode of communication. People do not always want to look at the interface for information; they also want to hear it, feel it or sense its presence. | |
| Evaluate the ability of the automated driving while increasing trust of the automated driving. Not only visual und acoustic warning, but also a verbal assistance and warning interface. Easy operation with voice commands. | |
| Make clearer when and how the system works. And stress more on when it won't be able to work. Look more into situations that might cause problems. For example, tesla's wrong detection of cycles drawn on tracks, reaction to white tracks or walls, etc. | |
| They should make sure that, some parts are easier to use. More physical buttons. AV system affordability, reliability and education. | |
| Educational purposes because people sometimes forget. More simplified systems and easy to use functions. Young and old people education. | |
| Developer should understand that not everyone has a technical background, so people may not understand it and know how to use it correctly. | |

It can be argued that, researchers and manufacturers should prioritise several key areas to ensure the safe and effective use of AVs. These include educating users about AV system capabilities and limitations, improving HAI through intuitive interfaces, enhancing AV system reliability and performance through rigorous testing and repeated measures, implementing continuous monitoring and prolonged evaluation processes, collaborating with regulatory authorities to establish clear standards and policy science, and addressing ethical considerations such as irresponsibleness and accountability. By focusing on human factors aspects, they can promote responsible development and deployment of vehicle automation technologies, fostering trust, safety resilience, and usability among user types.

## V. DISCUSSION

Based on the findings, we advocate for further research to gain a comprehensive understanding of the context of automated driving experiences and BA, as well as UX safety architectures over extended periods of automation usage. Although users express satisfaction with AVs, there are concerns stemming from their reactions to safety-critical situations with automation activated, as well as their incomplete understanding of the AV system's functionality, particularly regarding awareness of potential critical situations when automation is engaged. Therefore, it's crucial to investigate BAC over prolonged use or exposure to AV systems. When developing Interaction Design Systems (IxDS) for safety-based use cases, it is essential to consider key parameters related to the human user (see Table VIII), the AV system (see Table IX), and the interaction design factors (see Table X).

TABLE VIII. AUTOMATED DRIVING EXPERIENCE CONSIDERING HUMAN FACTORS

| **Fundamental Aspects of Human Factors** | | |
|---|---|---|
| **Aspects** | **Categories** | **Description** |
| User ability | User ability | Attention allocation, problem recognition, decision making processes, action implementation, skills and competences, etc. |
| | User variations | Beliefs, emotions, distraction, stress, fatigues, mental state, personality type, drowsy, etc. |
| | Reasoning efficacy | Mental models, SA, workload distribution, trust, and learning patterns, etc. |
| | Behaviour adaptation | Changes in use context, use/misuse and abuse automation, trust/distrust, accept/reject, etc. |

TABLE IX. AUTOMATED DRIVING EXPERIENCE CONSIDERING AV FACTORS

| **Fundamental Aspects of AV Factors** | | |
|---|---|---|
| **Aspects** | **Categories** | **Description** |
| AV ability | Degree of autonomy | The level at which the automation can operate the vehicle and the degree of autonomy that it is able to make decisions and enforce action, etc. |
| | AV system morphology | Behavioural components, e.g. anthropomorphic (human-like behaviour), zoomorphic (animal-like), robotic (machine-like), etc. |
| | HMI/UI | Nature of information, transparency, cleaner design language, terminology and symbols, visually comfortable design, distractive design. |
| | Adaptation | Automation adaption to user types, etc. |
| | AV ability | Capabilities and limitations, error-proneness, robustness, awareness, and learning, etc. |

The findings reveal that when assessing the overall evaluation of vehicle operation competency and driving skills over long-term use, users' understanding of vehicle automation is limited. As automation technology advances, developers must implement improved mechanisms to transparently communicate the purposes of various Vehicle Automation Systems (VAS) and provide guidance on their usage, taking into account the varying levels of difficulty among different user types. Additionally, there should be a focus on enhancing

Human-Automation Skilfulness (HAS) to facilitate the development of driving skills, as well as considering future needs for reskilling and upskilling in Human-Automation Interaction (HAI) [30].

Learning is a multifaceted process that can be categorized into three aspects of UX performance: cognitive, affective, and psychomotor, which also includes factors such as acuity (range of vision) [2]. Through repeated exposure to vehicle automation, users undergo continuous development of their mental models and changes in their brain architecture. This occurs due to the various ways in which humans receive, process, connect, categorize, and utilise information, as well as discard it over the long term. With repeated use of automation, there is a notable evolution in UX, trust, and acceptance, driven by users' ongoing learning processes and patterns as they encounter diverse situations.

TABLE X. AUTOMATED DRIVING EXPERIENCE CONSIDERING INTERACTION DESIGN FACTORS

| **Fundamental Aspects of Interaction Design Factors** | | |
|---|---|---|
| **Aspects** | **Categories** | **Description** |
| IxDS | Suave design | Configurations of humans and AV systems, co-corporative designs, structure of teaming (the interaction can be synchronous or asynchronous), etc. |
| | Multi-road user | Designed for multi-driver, driver-driver, driver-pedestrian, driver-motorcyclist situations, etc. |
| | Roles | Supervisor, operator, mechanic/programmer, peer, bystander, mentor, information consumer, synchronous or asynchronous, etc. |
| | Decision support | Type of info for decision support categorised according to pre-processing, available sensor info, device, type of sensor fusion, etc. |
| | Design configuration | Homogeneous (singular OEM-based IxD of the same system), heterogeneous (several OEM-based IxD of different systems). |
| Task ability | Task type | Task specified from an operation classification point of view, performance parameters, task shaping, goal-directed process, analysis, etc. |
| | Task criticality | Importance of the task to be performed. E.g., an AV could fail to detect human or risky situations |
| Setting and State context | Environmental | Degree of environmental distractions. E.g. the weather, road type, traffic density, signs, etc. |
| | Composition | Homogeneous (several vehicles of the same LOA) or heterogeneous (several vehicles of different LOA) operating on the same space. |
| | Journey pain points | Road design factors that influence user journey, curvy roads, modes of physical proximity to other road users, such as avoiding, passing, following, approaching, and touching, etc. |

In regards to automation-induced effects and trust in automation, users often perceive trust as a sense of entrapment. There are observable learning effects stemming from repeated usage, which influence both the levels and patterns of trust over time. As users gain more experience with VAS, they may feel less inclined to monitor the system closely, leading to reduced SA and potentially poorer performance, especially as automation advances to higher levels (e.g., L3). Various NDRTs that users engage in while driving in automated mode are prevalent. While users generally demonstrate a level of trust in automation, they also express safety concerns. Drivers frequently report instances of distrust, along with feelings of risk, discomfort, stress, and encountering demanding situations.

Furthermore, it is essential to recognize that the same user will perceive the same VAS differently depending on various factors such as the situation, setting, weather conditions, and mental state (e.g., fatigue, distraction). Similarly, different users may interpret the same automated driving event in distinct ways and experience trust differently, leading to a context-specific understanding. As UX engineers or researchers, the goal is to strive for a consistent and satisfactory UX based on safety criteria over prolonged use. The results highlight the importance of obtaining a clear understanding of user types for designing AV experiences, particularly as AVs redefine people's lifestyles. Conducting user-centered research helps to gain insights into different user types, their typical behaviours, encountered challenges, and points of discomfort, allowing for the development of IxDS that withstand the test of time. Consequently, this facilitates the creation of AV systems and HMI/UI designs that effectively resonate with diverse users, enhancing driving engagement, pleasure, and satisfaction.

The initial step involves defining various levels of UX and deriving specifications regarding the relationship between UX and BA. These levels of UX encompass novice, advanced beginner, competent, proficient, and expert levels. Additionally, it is crucial to consider how the effects of automation transfer between different levels of knowledge, such as from novice to competent or across various AV designs. This distinction is characterised by the transition from operational explicit knowledge at different levels to more strategic tacit knowledge over time. We can argue that, learned patterns are established through prolonged experiences with automation, resulting in the development of models of information patterns. Models representing different levels of UX should be utilised to shape long-term user behaviour data, providing a comprehensive understanding of both current and future states of in-vehicle UX. The gathered data contributes to a cohesive understanding, which can further inform the determination of the magnitude and type of IxDS required. The following are some lessons learned on inspiring safe adoption of automation and risk-free adaptable user behaviours.

1) *Effective* communication and proactive engagement are essential for influencing user behaviour positively. It is crucial to clearly communicate the effects of automation and provide appealing alternatives.

2) *Bridging* the gap between belief bias, attitude and behaviour requires collaborative efforts from diverse stakeholders, including policymakers, the AV industry, non-governmental organizations, and academia.

3) *Achieving* collaboration among stakeholders necessitates effective transparent communication and mutual understanding. This ensures that all relevant parties are aligned towards promoting safety and responsible behaviour in AV usage, over time.

Additionally, longitudinal data threads are essential for examining various aspects of BA at different levels of UX. Moreover, importance is given towards long-term studies to understand the learning curve, for both learning patterns of incorrect uses (misuses) and correct uses. The research in [4] emphasised the importance of long-term experiments to understand the duration of the learning phase, which necessitates field operational tests. However, field tests are influenced by multiple uncontrollable factors, requiring the integration of various examination methods to obtain reliable information. To advance research in this area, KLEAR (Knowledge discovery on Long-term Exposure of Automation Research) based mixed methods can be employed to assess both negative and positive BA towards AV systems and HMIs. Sequentially, pre-post in-depth interviews (IDI) or focus group discussions, naturalistic Field Operational Tests (nFOT), and/or driving simulator approaches can be conducted with users.

## VI. Conclusion

The aim of this study was to gather knowledge on L2 automated features that are already in the market and used by a wide range of people, globally. It is thus important to evaluate how these automated features are experienced over long-term use. It is important to acknowledge UX and BA based on real world automation usage. We aimed at examining possible use consequences in automated driving, coupled with IxD design effects on human-automation symbiosis. We explored UX, learning, trust, and acceptance over time, in order to visualise automation effects and UX aspects on user behaviour. As part of our synthesis on understanding UX, we have considered possible ‘user discomfort points’ and ‘user comfort points’ to communicate the diverse nature or topics under the umbrella of automated driving in urban traffic streams. Equally, we find that, there is a contentious issue concerning policy reforms to mitigate misuses, AV design, the ‘do not harm’ or laissez-faire (i.e., ‘let them do’) approach, and training protocols seen among software developers, OEMs, and different stakeholders in the field. And this has been argued by many scholars over years.

The objective of this study was to gather insights into L2 AV features that are currently available in the market and widely used by individuals globally. It is crucial to assess how these AV systems are experienced over prolonged use, considering UX and BA based on real-world automation usage. Our aim was to investigate potential consequences of use in automated driving on road traffic, as well as the synergies of effects on human-automation symbiosis. We examined UX, learning, trust, and acceptance over time to predict the effects of automation and UX aspects on user behaviour. As part of our synthesis in understanding UX, we have identified potential ‘user discomfort points’ and ‘user comfort points’ to encompass the diverse nature of topics related to automated driving on road urban traffic scenarios. Furthermore, we have observed a contentious issue surrounding policy science aimed at mitigating risks, as well as considerations about AV design and the approach taken by software developers, OEMs, and various stakeholders in the field, ranging from a ‘do not harm’ stance to a laissez-faire approach (‘let them do’). This issue has been a subject of consideration among scholars for many years.

Furthermore, there is a lack of facilitation of resilient human factors requirements. Additionally, it is crucial to derive specific safety-oriented Interaction Design (IxD) parameters to facilitate the harmonisation of AVs and HMI terminology, levels of difficulty, limitations, capabilities, context of use, and timeframe of exposure. Moreover, consider different user types and variations. Undoubtedly, there exists a delicate balance between unnecessarily constraining innovative designs and ensuring that AV systems remain understandable for average users, thereby sustaining behavioural-based safety over time. It is for this reason that we emphasise the indispensability of long-term data based on automation effects, ranging from short-term to long-term impacts, as well as behaviour and mental models.

***Abstract*—Stock market simulations are widely used to create synthetic environments for testing trading strategies before deploying them to real-time markets. However, the weak realism often found in these simulations presents a significant challenge. Improving the quality of stock market simulations could be facilitated by the availability of rich and granular real Limit Order Books (LOB) data. Unfortunately, access to LOB data is typically very limited. To address this issue, a framework based on Generative Adversarial Networks (GAN) is proposed to generate synthetic realistic LOB data. This generated data can then be utilized for simulating downstream decision-making tasks, such as testing trading strategies, conducting stress tests, and performing prediction tasks. To effectively tackle challenges related to the temporal and local dependencies inherent in LOB structures and to generate highly realistic data, the framework relies on a specific data representation and preprocessing scheme, transformers, and conditional Wasserstein GAN with gradient penalty. The framework is trained using the FI-2010 benchmark dataset and an ablation study is conducted to demonstrate the importance of each component of the proposed framework. Moreover, qualitative and quantitative metrics are proposed to assess the quality of the generated data. Experimental results indicate that the framework outperforms existing benchmarks in simulating realistic market conditions, thus demonstrating its effectiveness in generating synthetic LOB data for diverse downstream tasks.**

***Keywords*—Limit order book simulations; transformers; wasserstein GAN with gradient penalty; FI-2010 benchmark dataset**

## I. Introduction

Stock markets are complex systems, with underlying dynamics that remain largely unknown. Modeling such environments using traditional approaches poses unique challenges, including selecting appropriate hand-crafted features and verifying market assumptions. Leveraging the advancements in machine learning and deep learning techniques, numerous studies have sought to model market behaviors utilizing these innovative tools [1]-[4].

The dynamics of markets are influenced by interactions among multiple agents. These interactions are documented in the Limit Order Book (LOB) through buy and sell orders, providing rich insights into the market microstructure [5]. Such data is invaluable to traders, investors, regulators, and researchers. Unfortunately, the granular details within the LOB are not publicly accessible, with only aggregated daily summaries of price changes being made available. One potential solution involves adopting an agnostic approach toward the unknown underlying dynamics and embracing solutions capable of extracting crucial characteristics from the actual data.

Generative Adversarial Networks (GANs) [6] offer an intriguing solution for modeling the LOB data due to their exceptional ability to generate data from complex distributions. Recent breakthroughs in GANs have accelerated their adoption across various domains, including image generation [7], [8], text generation [9], and audio generation [10].

In finance, numerous studies have leveraged GANs to model financial data, demonstrating their competitiveness compared to other deep learning techniques [11–16]. While GANs exhibit promising attributes for producing realistic simulations, their application as a data generation technique for stock market data remains relatively nascent [17]. Furthermore, only a handful of studies have explored the potential of GANs for stock market simulation [18, 19]. This work aims to bridge this gap.

In this work, the aim is to develop a solution capable of simulating the LOB by generating synthetic data that closely resemble real data, capturing key statistical properties and mimicking the behavior of stock order dynamics realistically. The output of the framework is synthetic yet realistic LOB data. The practical implications of this endeavor are manifold. The generated data can be utilized for training forecasting models, calibrating trading strategies, conducting stress tests, performing backtests, and detecting anomalies. Additionally, the proposed procedure helps address data access limitations by creating synthetic data.

The main contribution of this study is a new framework based on GANs models for generating synthetic Limit Order Book data to simulate stock market behaviors. The proposed solution relies on a specific data representation and preprocessing scheme, along with conditional Wasserstein GAN with a gradient penalty for model training. An assessment methodology is proposed to evaluate the quality and realism of the generated LOB data, and a comparison with state-of-the-art models is provided.

The paper is organized as follows: a review of related works is presented in Section II. The developed framework is detailed in Section III. Subsequently, experimental settings and results are presented and discussed in Sections IV and V, respectively. Finally, Section VI provides conclusions and outlines possible future avenues of research.

## II. Related Works

In this section, an overview of the LOB and GANs basics is provided, along with a review of works that have simulated LOB data using various techniques.

### A. Limit Order Book Background and Simulation

The LOB serves as a comprehensive record of all orders submitted to an exchange system, providing a detailed snapshot of market activities at a microstructure level. At any given moment, the LOB includes active orders organized by price levels. An active order is an order that is still unmatched or uncancelled. Orders are categorized as either asks or bids, and they can be modified or cancelled until they are executed. An execution, or trade, occurs when there is a match between ask and bid prices. Orders may be market orders, executed immediately at the best available price, or limit orders, executed only when there is a matching sell (buy) order at the desired price. Fig. 1 presents a simplified visualization of an LOB. The LOB undergoes continuous updates due to the arrival of new orders, cancellations, and executions, altering the current state of the market.

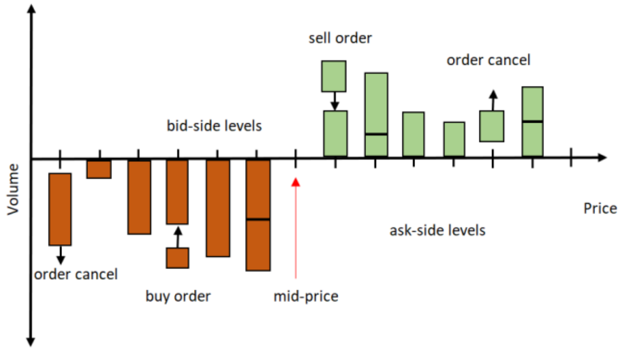

Fig. 1. Simplified graphical representation of the LOB showing the bid and ask sides prices structure and the impact of different order types on the LOB's price levels.

The deployment of new algorithms or trading strategies in real environments necessitates extensive testing under various market scenarios. These tests are typically conducted within a simulation framework that mimics the states of the LOB. The LOB, being a dynamic and complex system, poses a challenge for both market practitioners and researchers. Explicitly expressing the LOB as a function is often infeasible due to the hidden complexity of its underlying dynamics.

Furthermore, despite the increasing use of GANs in various stock market applications, their application for LOB simulation remains relatively understudied. Only a few studies have explored certain aspects of GANs for stock market simulation, with other works focusing solely on generating individual stock price time series. This section reviews related works pertaining to the aforementioned aspects of LOB simulation (see Table I).

The multi-agent approach is widely adopted as a technique for market generation, simulating interactions among agents in the market. It involves emulating multiple types of traders with diverse trading strategies and testing the performance of new experimental trading strategies by simulating market responses to modifications of agent archetypes within the simulation.

The authors of [21] proposed an Agent-Based Interactive Discrete Event Simulation (ABIDES) environment, which provides the capability to simulate interactions among various types of trading agents. This simulation occurs within a continuous double-auction mechanism, with an exchange agent, utilizing a Limit Order Book (LOB) featuring price-then-FIFO matching rules. Additionally, ABIDES incorporates a simulation kernel responsible for managing the flow of time and facilitating all inter-agent communication. The objective of ABIDES is to replicate a realistic financial market environment by simulating the characteristics observed in real financial markets.

TABLE I. Market Simulation Techniques

| Ref. | Objective | Technique |
|---|---|---|
| [17] | Generation of financial time series | Generative adversarial networks (GANs) |
| [19] | Simulating market orders | Conditional GAN |
| [18] | Simulating market orders | Conditional Wasserstein GAN with<br>Gradient Penalty. |
| [20] | Simulating market orders | Conditional GAN |
| [21] | Simulating agents interactions | ABIDES |
| [22] | Simulating orders execution | Reinforcement learning (RL) |
| [23] | Calibration of multi-agent simulation | GAN with self-attention |
| [24] | Simulating multi-agent systems | Reinforcement learning |
| [25] | Simulating multi-agent systems | Model generating transactions |
| [26] | Simulation of the order flow | Sequence Generative Adversarial Network (SeqGAN) |
| [27] | Simulating order optimal execution | ABIDES and Re-inforcement learning |
| [28] | Generation of financial time series | Wasserstein GAN |

Furthermore, in study [27] the authors proposed a multi-agent LOB simulation environment for the training of RL execution agents within ABIDES. By comparing the LOB stylized facts on simulations using their method with the ones of a market-replay simulation using real LOB data, they showed the realism of their simulations.

In study [22], an approach is deployed to model order execution decisions based on signals derived from LOB knowledge by a Markov Decision Process; and train an execution agent in a LOB simulator, which simulates multi-agent interaction.

The reference in [23] introduced a method, for the calibration of multiagent simulators, that can distinguish between "real" and "fake" price and volume time series as a part of GAN with self-attention, and then utilize it within an optimization framework to tune the parameters of a simulator model with known agent archetypes to represent market scenarios.

In study [24], the authors designed a multi-agent stock market simulator, in which each agent learns to trade autonomously via reinforcement learning. The authors showed that the proposed simulator can reproduce key market microstructure metrics, such as various price autocorrelation scalars over multiple time intervals.

Lastly, in study [25] a simulative model of a financial market, based on the LOB data is presented. The traders' heterogeneity is characterized by their trading rules, and by introducing a behavioral individual risk aversion and a learning ability.

The aforementioned works depend on explicit hand-crafted rules and intricate assumptions to tailor simulations to desired specifications. These simulations are influenced by numerous hyperparameters, including the selection of agent types, the variety and quantity of permissible orders, and other factors. While this approach provides considerable flexibility in generating diverse simulated scenarios, it may lead to shortcomings in simulating market dynamics realistically, particularly when compared to real market conditions.

### *B. Generative Adversarial Networks Background*

GANs are frameworks for training generative models [6]. A GAN has two components: a Generator G which learns to produce synthetic examples looking like the real ones and, a Discriminator D which tries to discriminate between real and synthetic examples. To train a GAN, a vector of noise Z~$P_Z$ is fed to Generator G which tries to map this vector to real data. The adversarial learning process corresponds to the following Minmax function:

$$min_G max_D\ E_{x\sim p_{data(x)}}[logD(x)] + E_{z\sim p_{z(z)}}\left[\log(1 - D\big(G(Z)\big))\right] \quad (1)$$

In practice, GANs with the Minmax function are hard to train due to the mode collapse challenge [29]. Ref. [30] proposed a solution to fix this issue, namely the Wasserstein GAN (WSGAN).

Even if, the WSGAN shows smooth training, [31] explained that vanishing or exploding gradients can always occur. They proposed a solution, the WGAN-GP, which adds a gradient penalty to the objective WSGAN function:

$$min_G max_D\ E_{x\sim p_{data(x)}}[D(x)] - E_{z\sim p_{z(z)}}\left[D\big(G(Z)\big)\right] - \lambda E_{\hat{x}\sim p_{\hat{x}}(\hat{x})}[(\|\nabla_{\hat{x}} D(\hat{x})\|_2 - 1\,)^2\,] \quad (2)$$

$\lambda$ is the gradient penalty coefficient. Gradients are calculated in linear interpolation $\hat{x}\sim p_{\hat{x}}(\hat{x})$ between real and synthetic examples, $p_{\hat{x}}$ is the sampling distribution of those linear interpolations. WGAN-GP is the actual state of the art in many domains: image field [32], airfoil shapes simulation [33], and text processing [34].

*1) GAN for Time-series generation:* In study [17] the authors proposed a generative adversarial network for financial time-series modeling. The model relies on a generator with a multilayer perceptron (MLP), convolutional neural networks (CNNs), and the combination of these two neural networks (MLP-CNNs), the same architecture is used for the discriminator. The proposed approach is assessed regarding the ability to reproduce some major stylized facts of the studied data. They showed that the proposed model produces a time series that recovers the statistical properties of financial time series.

In study [26] the authors used the Sequence Generative Adversarial Network (SeqGAN) for modeling the order flow to simulate the intraday price variation. To assess the performance of the proposed framework a comparison is made between the generated data and the real ones regarding the returns distribution tails and the volatility of the mid-price time series. The experimental results showed that their method reproduces the statistics of real data better than the benchmark.

Authors in study [28] used Wasserstein GAN for data augmentation to generate stock market order time series. Using data from Tokyo Stock Exchange, they showed that the probability distribution of synthetic order events generated by the GAN was close to reality.

The aforementioned approaches aim to enhance stock market prediction accuracy by augmenting training datasets with synthetic examples. While the application of GANs in this context shows promise in improving stock market modeling, it primarily addresses aspects related to price variation. However, market simulation presents a more complex challenge, as it seeks to model the microstructure dynamics of the stock market at the order level.

*2) GAN for stock market simulation:* In study [19] the authors proposed an approach to generate stock market orders based on conditional GANs. The adopted architecture relies on LSTM and convolutional layers for the generator and discriminator. The generator considers, in addition to historical data, handcrafted features that approximate market mechanisms. This work includes an ablation study to assess the importance of each component of the proposed architecture and provides a set of assessment metrics to evaluate the quality of generated data. For comparison purposes, two baseline models are used: Variational auto-encoder and Deep Convolutional Generative Adversarial Network (DCGAN). The proposed method showed better results than the benchmarks.

In study [20], a conditional GAN was used to build a framework called LOB-GAN to simulate the market ordering behavior. They used the LOB-GAN to help a reinforcement learning-based trading portfolio agent to make better generalizations. Their experimental results suggest that the framework improves out-of-sample portfolio performance by 4%.

Authors in study [18] proposed a market generator to simulate synthetic market orders. The quality of generated data is assessed in terms of stylized facts. The adopted architecture relies on a Conditional Wasserstein Generative Adversarial Network with Gradient Penalty. The generator and discriminator use long short-term memory (LSTM) and convolutional layers. The output of the proposed approach is a single order to feed to the exchange given the current state of the market. This work does not provide an ablation study to assess the contribution of each component in the proposed framework.

Authors in study [35] surveyed the metrics to assess the robustness and realism of the market simulation. This work proposes a catalog of known stylized facts regarding LOB microstructure behavior: return distributions, volumes, and order flow, non-stationary patterns, order market impact, and, cross-asset correlations.

Although the studies mentioned earlier show promise, they are not without significant challenges and limitations. These include reliance on manually engineered features, limitations in simulating individual orders rather than entire market dynamics, and the complexity inherent in the models utilized. These factors may hinder the scalability and accuracy of the simulations, thus impacting their effectiveness in capturing real-world market behavior.

## III. The Proposed Framework

The objective is to simulate the dynamics of the Limit Order Book (LOB) by generating synthetic data. To achieve this goal, a generative framework has been developed. This section provides a detailed exposition of the principal components constituting the proposed framework.

### A. Overview of the Frameworks

Fig. 2 offers an overview of the main steps of the proposed framework. Initially, raw Limit Order Book (LOB) data undergo preprocessing, adopting a spatial-temporal representation conducive to machine learning tasks. To capture the spatial-temporal dependencies inherent in market data, a transformer-based temporal model is selected for the generator, while a convolutional neural network serves as the discriminator. Additionally, both a condition vector and a noise vector are inputted into the generator, enhancing its capability to effectively capture local and temporal correlations.

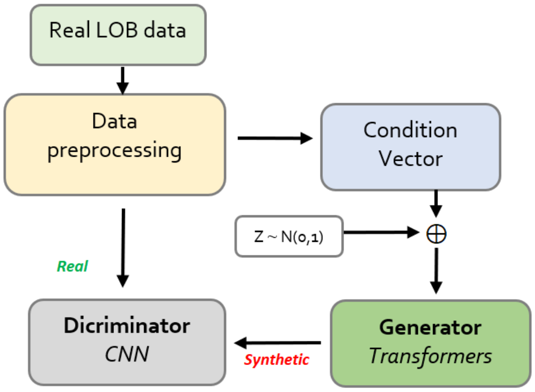

Fig. 2. The principal components of the proposed framework are depicted as a data flow pipeline. Real data undergo preprocessing before being passed to the Generator and the Discriminator, operating within an adversarial scheme.

### B. Data Representation and Preprocessing

The commonly-used representation of the LOB consists of a time series of multiple levels of orders. It's a series of timely indexed snapshots with a local structure of the ask and bid orders organized by price levels as illustrated in Fig. 3.

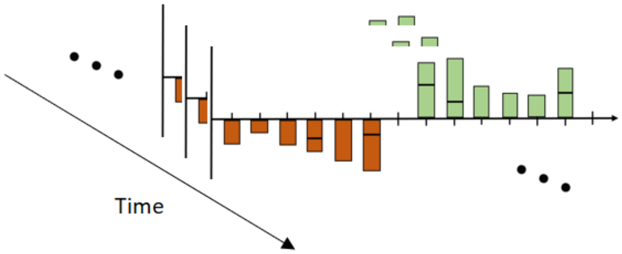

Fig. 3. Representation of the LOB as time-indexed consecutive snapshots. A snapshot represents the state of the price level structure of the LOB at a given moment.

Each input data point in the LOB can be expressed as $\vec{x} \in \mathbb{R}^{T\times 4L}$. Where T is the history of the stock snapshots reflecting the evolution of the LOB after each event such as execution, modification, or cancellation. L is the number of price levels on each side of the LOB. The snapshot is a spatial representation of the LOB in terms of the price level. Let's $i$ in $[1, L]$, the snapshot is a vector $x_t = \{p_a^i(t), v_a^i(t), p_b^i(t), v_b^i(t)\}_{i=1}^{L}$ the $p_a^i(t)$ and $p_b^i(t)$ are the ask and bid prices and $v_a^i(t)$ and $v_b^i(t)$ are the ask and bid volumes. Hence, the 4L representation expresses the length of each snapshot in the LOB at time t.

The spatial-temporal representation of the LOB implies many challenges from a machine-learning point of view. The prices-levels representation does not yield local smoothness of the LOB features. As an illustration, let's consider a LOB with only three levels of prices on each side. Fig. 4 shows the initial state of the LOB at t=i. Each side contains active orders at the price levels 95, 97, and 99 for the bid side and 101, 103, and 106 for the ask side. This state will be perturbed by a bid at the price of 98 and ask at price of 102.

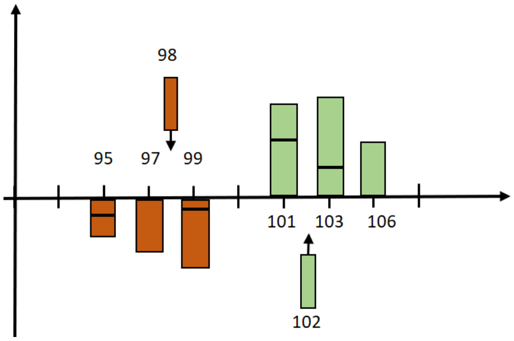

Fig. 4. LOB's snapshot at time t=i with price levels ranging from 95 to 106 and an upcoming new ask and bid orders at prices 102 and 98.

The new state of the LOB resulting from these two orders is depicted in Fig. 5. It is evident that the new price levels on each side have undergone a complete transformation, as price levels 95 and 106 are no longer visible in this LOB with 3 price levels. Instead, the bid side now consists of price levels 97, 98, and 99, while the ask side comprises levels 101, 102, and 103. This illustration highlights how even a minor perturbation can induce a substantial shift in the data structure. Put differently, any slight perturbation of the LOB due to changes in price level values causes a significant alteration in the LOB snapshots. Such variability poses a challenge to model robustness, as consecutive LOB snapshots can exhibit entirely different data structures. To address this challenge, a modification in data representation is adopted by employing "mid-price-centered moving windows" as introduced by [36].

In LOB simulation, the mid-price data is a region of particular interest since it is generally where the stock price is formed by the matching of the bid and ask order. The "mid-price-centered moving windows" representation [36] consists of a two-dimensional window around the mid-price for a time point, it contains N LOB history and 2W + 1 continuous price levels stepped by the tick size Δp. This representation gives a view of the LOB within a history of N time point and a price range [p(t) − WΔp,p(t) + WΔp].

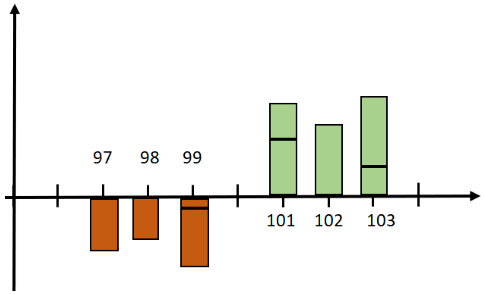

Fig. 5. LOB’s snapshot structure at time t=i+1 following the processing of the new ask and bid orders with price levels ranging from 97 to 103 instead of 95 to 106.

In this new two-dimensional LOB’s representation x ∈ RN×2W+1, each element xn,i, n = 1,...,N, i = 0,...,2W of the moving window representation indicates the volume of limit orders at price level p(t)−WΔp+i and at LOB snapshot t − N + n The ask side is marked by xn,i > 0 and the bid side by xn,i < 0 and |xn,i| for volume size. Fig. 6 illustrates this 2-dimensional representation of the first 200 LOB snapshots from the FI-2010 dataset [37].

This data representation provides an efficient data structuration around the mid-price region and data are summarised in a spatial-temporal presentation of the ask and bid volume. The extent of this region [p(t)−WΔp,p(t)+WΔp] is a hyperparameter to be determined during the training process.

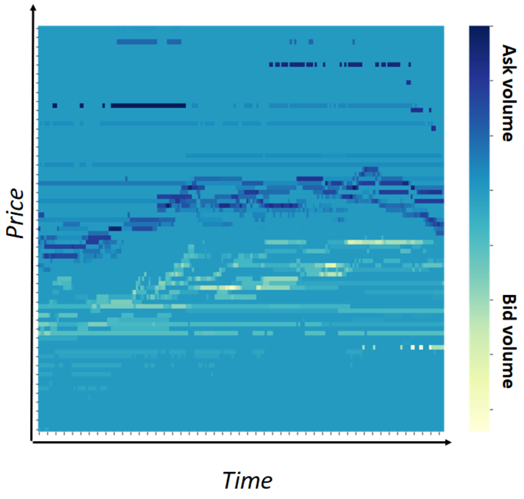

Fig. 6. Mid-price-centered moving windows of the LOB snapshots.

While providing a harmonious data view, the mid-price-centered moving windows are a sparse presentation of the LOB data. To overcome this limitation, [36] proposes an interesting variation namely the accumulated moving window representation. Each element xn,i becomes the sum of total volumes up to the corresponding price level on each side in the n-th snapshot. Fig. 7 illustrates the accumulated moving window representation of the first 200 LOB snapshots from the FI-2010 dataset.

After the aforementioned preprocessing steps, the input data are in the form of x ∈ RN×2W+1. For the FI-2010 dataset used for this study, we consider N = 50 and W = 20.

### C. The Generator

The choice of a Transformer [38] to model LOB data is motivated by its ability to efficiently capture interactions and long-range dependencies in sequential data. In addition, Transformer offers a great computational performance due to its parallel matrix multiplication operations since it has no recurrence.

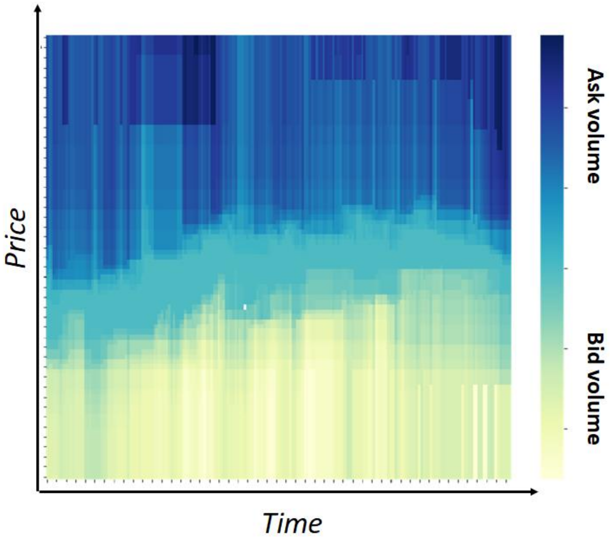

Fig. 7. The accumulated moving windows of the LOB snapshots.

The Transformer model relies on a self-attention mechanism that learns regions of interest by considering all past snapshots in the LOB history. In particular, it is expected from the Transformer Generator to efficiently capture the dynamic around the mid-price region.

The Transformer is composed of an Encoder-Decoder structure. In the Encoder, we find two sublayers: self-attention followed by a position-wise feed-forward layer. The Decoder has three sublayers: self-attention, cross attention, and position-wise feed-forward layer. To prevent information loss, the Transformer uses residual connections between sublayers. Self-attention sublayers employ multiple attention heads that learn different sets of attention projections.

The attention used by the Transformer is given by:

$$Attention(\boldsymbol{Q},\boldsymbol{K},\boldsymbol{V}) = softmax(\frac{QK^T}{\sqrt{D_k}}) \quad (3)$$

where, $\boldsymbol{Q} \in \mathbb{R}^{N\times D_k}$ are queries, $\boldsymbol{K} \in \mathbb{R}^{M\times D_k}$ are keys, $\boldsymbol{V} \in \mathbb{R}^{M\times D_v}$ and $N, M$ are the lengths for queries and keys (or values). $D_k, D_v$ for keys (or queries) and values dimensions.

In the LOB context, the next snapshot is highly influenced by the past ones. Hence, for the positional encoding, a relative positional encoding [39] is opted for, as it is believed that the relative positions or distances between snapshots are a key element in LOB simulation.

### D. The Transformer

The task of the discriminator (or the Critic when using WGAN-GP) is to accurately distinguish between real and synthetic data. In our context, the discriminator task is a classification between real and synthetic snapshots. Convolutional Neural Networks (CNN) are known for their good performance in images and natural language processing. Since snapshots have spatial-temporal structures, it's believed that the use of a Convolutional Neural Network (CNN) as a discriminator is a good choice. Within the GAN settings, to get a well trained discriminator the generator is expected to produce a wide variety of diverse examples.

The CNN is composed mainly of two components: a convolution layer and a pooling layer. The convolution layer applies several filters to the input data which extract the key features of the input data. The number of convolution filters and layers is a hyperparameter to be determined. The pooling layer downsamples the feature map while preserving most information to ensure a more robust representation regarding the location change of the feature map produced by the convolution filters. To perform classification, the extracted features are connected to a linear layer followed by a sigmoid function.

### E. The Condition Vector

To further enhance the capacity of the generator to efficiently capture the past snapshots dynamic and produce a "contextualized" output, a conditional GAN architecture [40] is adopted. To do so, the generator relies on random vectors as well as a condition vector to produce synthetic examples. As a condition, a vector of the last 20 snapshots is used. Under these settings, the produced samples ( $\hat{x}$ ) by the Generator can be interpreted as a conditional distribution of $x$ given Y : $\hat{x} \sim \mathbb{P}_G(x \mid Y)$**.** The random vector size is set to 100.

### F. Training and Hyperparameters

The proposed framework includes several essential hyperparameters that require precise tuning to achieve consistent outcomes. Extensive experimentation with the FI2010 dataset revealed optimal parameter values, as detailed in Tables II and III, which yielded the most favorable results.

TABLE II. GENERATOR HYPERPARAMETERS

| Hyperparameter | Value |
|---|---|
| Batch size | 64 |
| Number of heads | 5 |
| Number of blocks | 2 |

TABLE III. DISCRIMINATOR HYPERPARAMETERS

| *Hyperparameter* | *Value* |
|---|---|
| Convolution layers | 2 |
| Filter size | 5 |
| Convolution activation function | tanh |
| Pooling size | 2 |
| Pooling activation function | ReLu |

A dropout layer with a rate of 0.2 is applied before the final linear layer of the generator.

The choice of the aforementioned hyperparameters is adjusted regarding a trade-off between the computational complexity and the output quality.

The model is trained with the WGAN-GP loss using the Adam Optimiser. The learning rate for the generator and critic is 2 × 10−4 and the maximum epoch number is 100.

### G. Baselines and Evaluation Procedure

The evaluation of GANs models poses a significant challenge due to their inherent complexity and the multitude of factors influencing their performance. In order to determine the effectiveness of the framework in generating realistic LOB data, a comprehensive approach is imperative. Hence, the following strategy is meticulously devised to assess the fidelity and quality of the generated data:

*1) Baselines:* For comparison purposes, three state-of-the-art benchmarks are used:

*a)* A framework for market simulation based on a Conditional GAN (CGAN) as in [18, 19].

*b)* A Recurrent Variational Autoencoder (VAE) [39].

*c)* And a Deep Convolutional Generative Adversarial Network (DCGAN) [41].

*2) Qualitative assessment:* To evaluate the framework, qualitative and quantitative approaches are employed. The qualitative approach involves visual comparisons between the distributions of real and synthetic data. While it is acknowledged that this evaluation is not definitive, it is considered to provide valuable intuition regarding the output quality.

*3) Quantitative assessment:* To quantitatively assess the performance of the framework, the two-sample Kolmogorov-Smirnov test is employed. In this context, the null hypothesis (H0) posits that "the synthetic and the real data are drawn from the same distribution.

*4) Ablation study:* To explore the individual contributions of each component within the framework towards generating realistic data, an ablation study is conducted. This rigorous analysis aims to systematically examine the effects of each component, providing insights into their respective influences on the quality of the generated data.

## IV. The Experimental Settings

The framework is trained and tested on the FI-2010 dataset [37] which is the new benchmark dataset for LOB modeling [36]. The FI-210 records the LOB, for ten days, for five instruments from the Nasdaq Nordic stock market (Helsinki Stock Exchange). The FI-210 consists of 10 orders on each side of the LOB. The F-210 can be downloaded from: « https://etsin.fairdata.fi ».

The proposed methods of this study were implemented using Python programming language. Keras library was used to implement the GAN-based framework. Experiments were conducted on a computer running the Windows 10 operating system with the configuration of Intel(R) Core (TM) i5-8250U CPU @ 1.60GHz (8 CPUs), 1.8GHz, 8 GB RAM, and 500 Gigabytes hard disk drive.

## V. Results and Discussion

As previously outlined, with the adoption of the 2-dimensional LOB representation, the input data are predominantly distributed around the mid-price. Therefore, the primary assessment objective is to evaluate the framework's ability to generate mid-price data that closely approximates real-world observations.

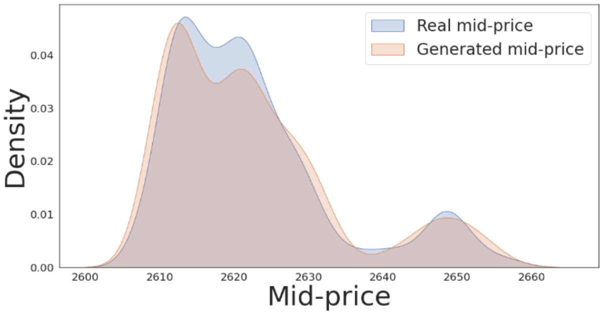

Fig. 8. Mid-price distributions.

Fig. 8 depicts a notable similarity between the generated mid-price data and the real counterparts. Both distributions exhibit similar characteristics, notably in terms of their multi-mode attributes, suggesting a strong correspondence between the simulated and actual data.

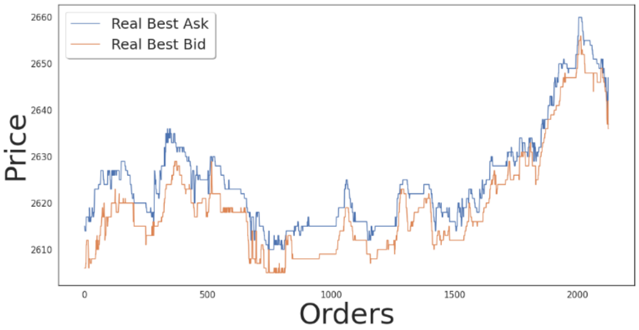

Fig. 9. Real ask and bid of consecutive orders.

One critical aspect that cannot be overlooked is the temporal correlation inherent in the distributions of the best ask and bid data (see Fig. 9). The framework must generate these data with attributes similar to those observed in real market conditions.

Fig. 10 provides insight into the coherence of temporal correlations exhibited in the generated distributions. This aspect is crucial for capturing the dynamic nature of market data over time. The effectiveness of maintaining such coherence largely hinges on the self-attention mechanism employed by the generator, highlighting its pivotal role in ensuring the fidelity and accuracy of the generated data.

Another crucial aspect to consider is the distributions of the best ask and bid data. It is essential for the framework to generate best ask and bid data that exhibit similar attributes to those observed in real market conditions. Thus, ensuring consistency in these distributions is imperative for the fidelity of the generated data.

Fig. 11 and Fig. 12 visually confirm the close resemblance between the generated best ask and bid data and their real counterparts, showcasing the framework's ability to accurately capture essential market dynamics.

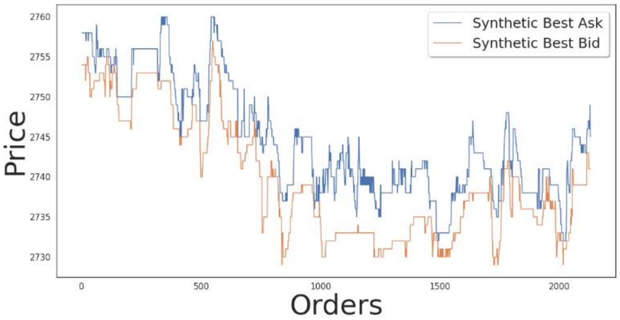

Fig. 10. Synthetic ask and bid distribution.

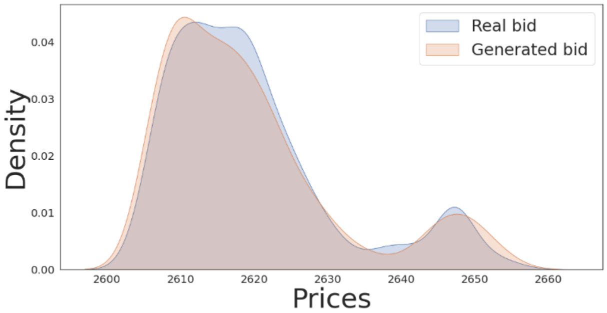

Fig. 11. The bid distributions.

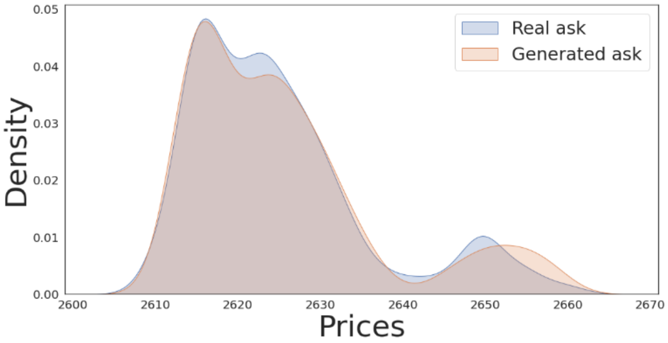

Fig. 12. The ask distributions.

To quantitatively evaluate the proximity and similarity of the generated data to the real ones, a Kolmogorov-Smirnov (K-S) test is conducted. This statistical analysis allows for a comprehensive assessment of the degree of correspondence between the distributions of the generated and real data sets, providing valuable insights into the fidelity and accuracy of the simulated data.

TABLE IV. K-S DISTANCES

| | *Mid-price* | *Best ask* | *Best bid* |
|---|---|---|---|
| Real vs Our framework | 0.23 | 0.32 | 0.11 |
| Real vs CGAN | 0.22 | 0.39 | 0.25 |
| Real vs VAE | 0.61 | 0.67 | 0.72 |
| Real vs DCGAN | 0.42 | 0.45 | 0.51 |

These results, presented in Table IV, underscore the framework's performance in generating synthetic data relative to other models, as indicated by the Kolmogorov-Smirnov (K-S) distances. The framework demonstrates superior performance compared to CGAN, particularly in replicating the distributions of best ask and best bid data. While CGAN shows slightly lower K-S distances for mid-price, the framework consistently outperforms across all metrics. Furthermore, when compared to the VAE and DCGAN models, the framework exhibits superior performance. The lower K-S distances achieved by the framework underscore its capability to generate synthetic data that closely resembles real market observations.

To thoroughly assess the contributions of each framework component, an ablation studyis conducted. This analysis enables us to systematically evaluate the impact of individual elements on overall performance, aiding in the optimization and refinement of the framework's design for generating synthetic data.

Table V presents the results of the ablation study, showcasing the impact on the framework's performance, measured by the K-S distances, when key components are removed. When the data representation component is omitted from the framework (using the original data structure instead), there is a noticeable increase in the K-S distances across all metrics. Similarly, removing the condition from the framework leads to a moderate increase in the K-S distances. Furthermore, omitting the Wasserstein Gradient Penalty (WGAN-GP) results in a discernible rise in the K-S distances, indicating a significant contribution of this component to the framework's performance. Similarly, when the Transformer component is replaced with LSTM, there is a notable increase in the K-S distances, highlighting the importance of Transformers in capturing essential temporal dependencies. Moreover, removing the CNN component and replacing it with LSTM also leads to an increase in the K-S distances, indicating the importance of CNNs in capturing spatial dependencies. Overall, these results underscore the critical role played by each component in enhancing the framework's performance in generating synthetic data that closely resembles real market observations.

TABLE V. ABLATION STUDY RESULTS (K-S DISTANCES)

| | *Mid-price* | *Best ask* | *Best bid* |
|---|---|---|---|
| Real vs Our framework | 0.23 | 0.32 | 0.11 |
| Real vs framework w/o data representation (using original data structure) | 0.51 | 0.63 | 0.65 |
| Real vs framework w/o condition | 0.36 | 0.47 | 0.35 |
| Real vs framework w/o WGAN-GP (vanilla GAN) | 0.44 | 0.57 | 0.49 |
| Real vs framework w/o Transformer (LSTM instead) | 0.56 | 0.59 | 0.61 |
| Real vs framework w/o CNN (LSTM instead) | 0.42 | 0.51 | 0.43 |

## VI. CONCLUSION AND FUTURE WORK

In this study, a generative adversarial framework is introduced to produce real-looking synthetic Limit Order Book (LOB) data for simulating stock market dynamics. The proposed framework applies a specific data preprocessing scheme and utilizes conditional Wasserstein GAN with a gradient penalty function to effectively capture the underlying structure of the data. The framework is assessed using both quantitative and qualitative criteria, demonstrating through experimental results that it outperforms existing benchmarks in simulating realistic market conditions. The synthetic data generated by the framework holds promise for various downstream tasks such as forecasting and calibrating trading strategies. The contributions of this research are two fold: aiding in the development of more realistic simulation tools and providing traders with the ability to simulate diverse market scenarios, thereby enhancing financial risk management practices. For future research directions, exploring alternative architectures for the generative framework and incorporating realistic trading strategies to further assess the practical applicability of the proposed solutions is recommended. Additionally, investigating advanced techniques for hyperparameter tuning to ensure the attainment of globally optimal solutions can enhance the overall quality of the evaluated frameworks.

***Abstract*—Agile software development emphasizes iterative progress, adaptability, and stakeholder collaboration. It champions flexible planning, continuous improvement, and rapid delivery, aiming to respond swiftly to change and deliver value efficiently. Integrating Generative Artificial Intelligence (AI) into Agile software development processes presents a promising avenue for overcoming project management challenges and enhancing the efficiency and effectiveness of software development endeavors. This paper explores the potential benefits of leveraging Generative AI in Agile methodologies, aiming to streamline development workflows, foster innovation, and mitigate common project management challenges. By harnessing the capabilities of Generative AI for tasks such as code generation, automated testing, and predictive analytics, Agile teams can augment their productivity, accelerate delivery cycles, and improve the quality of software products. Additionally, Generative AI offers opportunities for enhancing collaboration, facilitating decision-making, and addressing uncertainties inherent in Agile project management. Through an in-depth analysis of the integration of Generative AI within Agile frameworks, this paper provides insights into how organizations can harness the transformative potential of AI to advance Agile software development practices and navigate the complexities of modern software projects more effectively.**

***Keywords*—Artificial intelligence; software engineering; Agile software development***

## I. Introduction

Project work that seeks to regulate and create the project's outputs in brief iterations and adapt to numerous shifts in circumstances during the project is made possible by agile project management approaches. Classical project management has shifted from managerial and administrative duties to project coaching in agile project management techniques. Many circumstances influence an agile project's success, and managing these pain points is essential. Software development for various systems is one of the many IT-related projects that agile project management (APM) has grown famous for handling. The project manager and the organization must exercise strict discipline when using APM. As Agile Project Management demands meticulous discipline for successful software development, exploring AI to enhance this process presents a novel and compelling research domain.

From a scientific perspective, artificial intelligence (AI) encompasses a variety of methods and strategies, including robotics, machine learning, and machine reasoning [1]. With AI's growing capabilities, there is curiosity about whether certain aspects of project management today may be automated or if some activities are delegated to AI, which would lessen the workload of typical project managers and assist in challenging circumstances [2]. One way to conceptualize intelligent project management is as artificial intelligence applied to automate certain aspects of the process when suitable. In this situation, Generative Artificial Intelligence (GenAI), which harnesses advanced algorithms to create content and solutions that mimic human-like ingenuity, could be beneficial in controlling the various pain points of projects and shifting to intelligent project management. Tools for generative AI, like CoPilot, GPT, and Bard, have become increasingly popular. They also increase the productivity of software engineering. [3]

GenAI introduces many positive impacts on Agile methodologies, revolutionizing how teams approach software development and project management. GenAI enhances Agile practices by augmenting creativity, efficiency, and decision-making processes. Through its ability to analyze vast datasets and generate novel solutions, GenAI aids in ideation sessions, helping teams overcome creative hurdles and foster innovation within Agile iterations. Additionally, GenAI streamlines development processes by automating repetitive tasks, such as code generation, testing, and documentation, thereby freeing up valuable time for team members to focus on high-value activities. Moreover, GenAI facilitates data-driven decision-making by providing insights into project metrics, team performance, and potential risks, enabling Agile teams to adapt and respond to changing requirements swiftly. Integrating GenAI into Agile methodologies leads to accelerated development cycles, improved collaboration, and enhanced product quality, ultimately driving tremendous success in software projects. In particular, GenAI may help with day-to-day tasks by providing advice, coaching, and recommendations.

This piece delves into the technologies and applications of Generative AI within the software sector. Software engineering is going to see significant changes as a result of GenAI.

However, research on the subject is still in its early stages. There aren't any significant case-studies found in the literature that tackle the integration of GenAI within the Agile methodologies This research agenda is crucial for guiding academics and practitioners by highlighting current applications and shaping future studies. This paper presents an adapted framework of explicit integration of Generative AI into one of the most commonly used agile methodology by developers. Our goal is to give a real case study of how this can be achieved, also discuss the pitfalls and the potential limitations.

This study's primary goal is to investigate how AI can alleviate the difficulties and pain points related to agile project management. Our objective is to delve deeper into the practical aspects of implementing generative AI in agile projects and to provide a balanced view by discussing both the benefits and challenges of Gen AI in software development. The following questions will be addressed and answered in the subsequent sections of this paper.

- RQ1: What problems do agile projects typically have?
- RQ2: How can GenAI assist in overcoming common challenges encountered in agile projects?
- RQ3: Can GenAI help with the software development process? Can GenAI used in Agile frameworks to enhance project management assistance?

To do so, we structured this paper based on four sections. The first one is this introduction; the second section delineates the background notions of this article, which are Agile project management (APM) & Generative Artificial Intelligence (GenAI). This includes the theoretical section, which introduces standard agile methodologies, both at small and large scales, and discusses the mechanism of artificial intelligence employed in this study. The following section helps ascertain the typical difficulties that different agile project management techniques could provide by conducting a literature review. A theoretical model of pain points is developed based on these issues. This is followed by the significant impact of GenAI in Software developments and applications of GenAI as a solution for several real-world project management problems. The last section encounters our developed framework to demonstrate how GenAI can enhance agile software development practices.

## II. Literature Review of Agile Methodologies for Software Development

### A. Background of Agile Project Management

Traditional project management is referred to by the Project Management Institute as "predictive project management," in contrast to agile methods. Non-agile projects are called "plan-driven" because they emphasize creating a detailed plan in advance and carrying it out throughout the project [4]. In software development, the term "agile" was first used in 2001 by seventeen software developers trying to address a critical problem: managing projects using the waterfall model, which divides the development into discrete phases [5]. Using four core values as a foundation, the seventeen developers created the Manifesto for Agile Software Development: "Individuals and interactions over processes and tools, working software over comprehensive documentation; customer collaboration over contract negotiation; and responding to change over following a plan." Any approach that upholds the values and tenets of the Agile Manifesto is included in the agile philosophy [6]. The agile framework is made to handle change effectively, in contrast to traditional systems, which emphasize rigorous change management and upfront planning. Agile software development involves self-organizing teams working with clients to evolve needs. As a result, agile projects need the customer to be heavily involved at every stage to give regular, honest, and transparent feedback [5] [7].

Agile project management is an iterative and flexible approach to project management that emphasizes adaptability, collaboration, and customer satisfaction. It is particularly well-suited for projects where requirements are expected to change frequently or need to be more well-defined initially. Agile methodologies focus on delivering small, incremental portions of a project in short time frames, called iterations or sprints, typically ranging from one to four weeks. Agile project management has gained widespread adoption in software development and is increasingly applied in various other industries where flexibility and responsiveness are valued. Its principles can be adapted and scaled to suit the needs of diverse projects and organizations. The key characteristics of Agile project management are:

- Customer Collaboration
- Emphasis on Individuals and Interactions
- Continuous Delivery
- Flexibility and Adaptability
- Cross-functional Teams
- Continuous Feedback
- Iterative Development

Projects are broken down into small, manageable iterations, allowing for continuous improvement and adaptation as the project progresses. Regular and close collaboration with stakeholders, including the end-users or customers, ensures that the delivered product meets their expectations and requirements. Agile embraces changes in requirements even late in the development process. This flexibility allows teams to respond quickly to evolving priorities or new insights. Agile encourages forming cross-functional, self-organizing teams with all the skills necessary to complete the project within the team, promoting better communication and collaboration. Regular reviews and feedback sessions are integral to Agile methodologies. This constant feedback loop helps identify and address issues promptly, ensuring the project remains aligned with stakeholders' expectations. Agile promotes delivering a potentially shippable product at the end of each iteration, ensuring that there is always a tangible output, even if the project still needs to be completed. Agile values individuals and interactions over processes and tools, emphasizing the importance of effective communication and collaboration within the team.

### *B. Background Frameworks*

Agile frameworks such as Scrum, XP, Kanban, and Lean Software Development were initially developed for small-scale projects. Other large-scale frameworks exist, such as Scaled Agile (SAFe), Disciplined Agile (DA), and Nexus. Several popular Agile frameworks are widely used in project management to facilitate iterative and adaptive development. Each framework offers its own set of practices, roles, and ceremonies to guide teams in delivering value incrementally. These frameworks provide structure and guidance for teams adopting Agile principles, allowing them to tailor their approach based on their project's specific needs and context. Choosing a particular framework depends on the project's size, complexity, industry, and organizational culture. Agile methodologies employ various ceremonies and artifacts to facilitate effective project management and collaboration within teams:

*1) Ceremonies:*

*a) Sprint planning:* A meeting held at the beginning of each sprint where the team plans the work to be completed during the sprint. It involves selecting user stories from the backlog, estimating effort, and committing to a sprint goal.

*b) Daily standup (Daily Scrum):* A short meeting where team members discuss their progress, what they plan to work on next, and any obstacles they face. It promotes transparency, collaboration, and alignment within the team.

*c) Sprint review:* A meeting held at the end of each sprint where the team demonstrates the work completed during the sprint to stakeholders and collects feedback. It provides an opportunity to review the product increment and adjust priorities based on stakeholder input.

*d) Sprint retrospective:* A meeting held at the end of each sprint where the team reflects on the previous sprint, discusses what went well, what could be improved, and identifies actionable items for process enhancement in future sprints. It fosters continuous improvement and learning within the team.

*2) Artifacts:*

*a) Product backlog:* A prioritized list of a product's desired features, enhancements, and fixes. It serves as the single source of requirements for the team and is continuously refined and reprioritized.

*b) Sprint backlog:* A subset of the product backlog containing the user stories and tasks the team commits to completing during a sprint. It helps the team focus on the work in the current sprint.

*c) Increment:* The sum of all the completed and potentially shippable product backlog items at the end of a sprint. It represents the tangible outcome of a sprint and provides value to stakeholders.

*d) Burn-down chart:* A visual representation of the remaining work (usually measured in story points or tasks) throughout a sprint. It helps the team track progress towards completing the sprint goal and identifies potential issues early.

These ceremonies and artifacts are integral components of Agile methodologies, facilitating collaboration, transparency, and adaptability within teams to deliver high-quality products iteratively and incrementally.

### *C. Agile Pain Points in Software Development*

Significant difficulties could arise in agile projects when the complexity, context, and scope evolve [8]. Several study reports have noted various problems: [9], [10], [11], [12], [13], [14], [15], [16], [17], [18]. Using a variety of publications, the literature study identifies the most prevalent issues that arise in agile initiatives.

Beginning with [12], it has been observed that development team members who have experience with rigid approaches, such as the waterfall approach, may be reluctant to adopt agile practices. Other difficulties that have been brought up include the development team's ignorance of the agile methodology, the lack of participation from upper management, problems with technical support, incompatibility with current infrastructure and procedures, and the existence of time and financial constraints [12]. The research in [9] is based on agile projects in the public sector found several potential trouble spots. These factors included the following: responsibilities within the agile setup, documentation, education, experience, and commitment; location of agile teams; complexity of software architecture and systems integration; and stakeholder communication and involvement [9]. Additionally, research has shown that many agile methodologies, including Scrum, XP, and Lean, are combined [10]. Agile methodology is thus characterized in a comprehensive sense. Agile practitioners encounter various complicated, context-specific challenges, some of which have persisted for years and are difficult to address successfully. On the other hand, although some problem areas still exist, their emphasis has changed. Although practitioners have embraced agile approaches, questions about their ongoing efficacy have yet to be raised. Many complex topics have yet to get much academic attention, including governance, business participation, transformation, failure, and the impact of claims and constraints [10]. Furthermore, some issues, like contracts and government, need more attention from researchers. In contrast, other problems, like business and IT transformation, have received attention but have yet to have the anticipated influence on industry practices [11]. It's also more complicated to choose a large-scale agile framework. The study in [14] claims that while various agile frameworks provide basic understandings, they soon become unhelpful when applied outside of the context of the framework in which they were designed. Due to the COVID-19 epidemic, there has been an increase in remote project work globally. Working on remote projects offers its own set of difficulties [13]. Based on research conducted by [15] on self-organizing teams, the challenges at the project, team, person, and task levels are categorized. Activities involving the team, senior management (SM), and clients are included at the project level; activities involving the core development team and their SM are included at the team level; team member activities are included at the individual level; and technical tasks are contained in the task level [19]. A particular pain point model has been developed to examine some of the most prevalent pain points mentioned in the literature about agile projects to help manage these difficulties more effectively. This model aims to explain the common causes of these difficulties and offer workable ways to solve them, regardless of the project's scale. A fishbone diagram representing the primary pain spots has been created using the information presented above, as seen in Fig. 1. This graphic shows two unique problems for every problem category in the previous literature review. These challenges can be categorized based on the project, personnel, methods, persistence, and estimated effort.

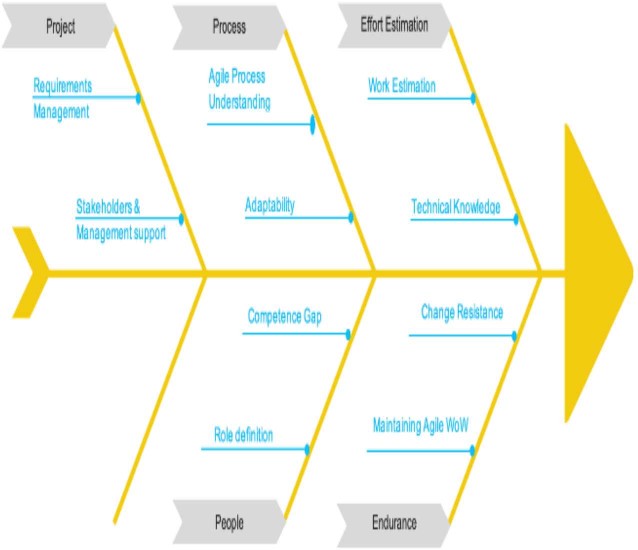

Fig. 1. Primary pain points arising from agile difficulties.

To answer RQ1: What issues do agile projects typically have? Common pain points in agile methodologies include problems with requirement management, managerial and stakeholder support, role clarity, team member overlap, understanding of agile processes, adaptability to various shifts, resistance to change, maintaining agile practices, effort prediction, and sufficient technical expertise. Every one of these difficulties may affect agile initiatives and their supervision of them.

## III. GenAI Revolution to the Software Delivery

### A. Background Historical Improvements

More than any other recent breakthrough, Generative Artificial Intelligence (GenAI) can drastically alter the software industry. According to Bill Gates, it represents the most significant advancement since the creation of the Internet. Software productivity can be enhanced through various means, including automating monotonous tasks like requirements traceability or testing, enhancing software quality by creating test suites from requirements, and automating workflows by directing work products to the appropriate stage in a production pipeline [20]. However, generative AI poses new risks because it is neither deterministic nor explicable. Prominent examples of restrictions on usage in professional software engineering include Intellectual Property Rights (IPR) and cybersecurity.

The field of generative AI has been around for a while. Researchers were reluctant to introduce such technology to the general public as they were unsure of its validity. People tend to close their eyes to apparent risks when faced with a projected gold rush, as we have seen repeatedly in the history of IT [21]. Ultimately, even well-intended tools can have disastrous effects. After GPT was eventually made available to the general public in 2022, the AI arms race began at a pace never seen before. GPT only needed two months to gain one hundred million users [3].

For years, using Google or StackOverflow has been a standard part of the work for any coder. Countless code repositories are available online, and search engines have gotten better at indexing them. Community advice sites like StackOverflow offer insightful commentary and well-reasoned answers to user questions. One feature that both search engines and Q&A websites have in common is the ability to pull up previously stored material.

GenAI differs. As the name implies, it can synthesize or generate responses to your queries. Instead of searching through a premade one, it will create a reaction for you, as traditional search engines do. The response is predicated on enormous training data, including search engine stored and indexed content [22]. Generative AI is trained further to deliver insightful responses using input from humans. Many human trainers ask questions and comment on the generated responses, rewarding correct responses and penalizing incorrect ones. While protecting against unfavorable replies, this type of reinforcement learning directs the system toward producing more accurate responses. This has given rise to glimmers of a new mode of operation that centers on "prompt engineering," determining the best way to phrase a question or an entire conversation. Generative AI does not work with individual questions and answers; it maintains a context window, which can guide the AI in generating contextually relevant and well-informed responses [3].

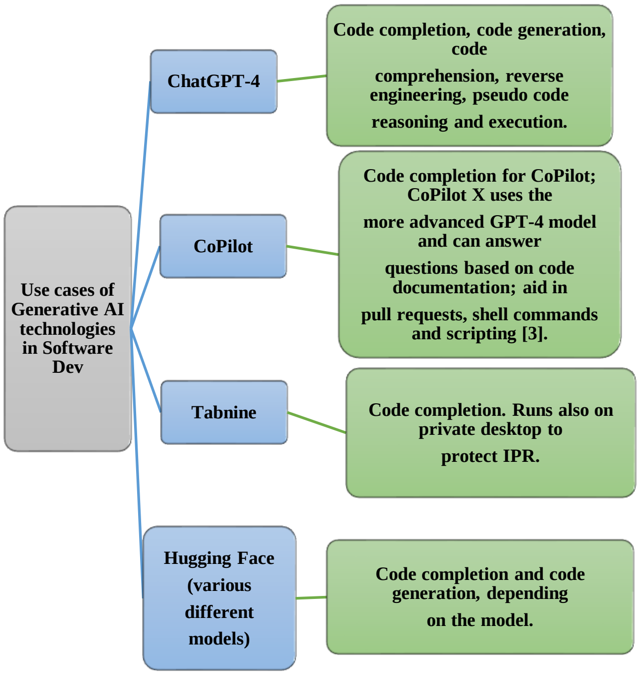
### B. Examination of Specific Gen AI Technologies and their Direct Applications in Agile Software Environments.

Numerous generative software platforms enable the conversion of straightforward instructions into computer code. Development tools and editors, including Visual Studio Code, Visual Studio, NeoVim, and JetBrains IDEs, can be extended with GitHub Copilot. It provides code completion driven by OpenAI Codex, a Generative AI system created by OpenAI.

The recent release of Copilot X, powered by GPT-4, is promising. In addition to better autocompletion, it can help with other development activities, including code comprehension, pull request improvement, scripting, and shell tool support [22]. GPT-4 can produce code from docstrings in software engineering interviews and answer coding questions on par with or better than human performance. It is capable of interacting with LaTeX and front-end programming. It can run Python, Pseudo, and reverse engineer programs. The company that created GPT-4, OpenAI, provides programmatic access to its LLMs. These advanced LLMs, such as GPT-4, represent a paradigm shift in computing, harnessing vast knowledge and understanding of context to perform complex tasks. Their natural language processing and generation capabilities have significant implications, potentially revolutionizing how we interact with technology and automate sophisticated tasks. This implies that programmers can incorporate them into their apps and use them conversationally. Moreover, developing plugins, a means of integrating the underlying models with other services capable of answering inquiries and taking appropriate action is feasible.

Unlike its competitors, Tabnine stands out from the crowd by giving special consideration to licensing and privacy considerations. It provides code completion at the line or function level. Only permissive license open-source software has been used to teach Tabnine. Additionally, it guarantees developers that it does not keep any of the code that uses it, and the underlying models can be downloaded and used locally rather than only being available as a service [23]. A summary of various standard technologies is given in Fig. 2 [3]. Take note of how quickly the terrain is changing. We should anticipate the introduction of new tools and the advancement of current ones.

To answer the first part of RQ3: Can GenAI help with the software development process? Can GenAI used in Agile frameworks to enhance project management assistance? Fig. 2 provides a detailed argument of how.



Use cases of Generative AI technologies in Software Dev
ChatGPT-4
Code completion, code generation, code
comprehension, reverse engineering, pseudo code
reasoning and execution.
CoPilot
Code completion for CoPilot; CoPilot X uses the
more advanced GPT-4 model and can answer
questions based on code documentation; aid in
pull requests, shell commands and scripting [3].
Tabnine
Code completion. Runs also on private desktop to
protect IPR.
Hugging Face (various different models)

## IV. GenAI and its Role in Enhancing Agile Software Development Practices

### A. *GenAI to Overcome Agile Management Pain Points*

GenAI is emerging as a transformative force in addressing various pain points within Agile project management, offering innovative solutions to enhance efficiency, collaboration, and adaptability. Generative AI, through its ability to analyze patterns and generate novel ideas, can assist teams in brainstorming sessions, helping overcome creative hurdles and fostering a culture of continuous innovation. Moreover, Generative AI algorithms can analyze historical project data, team performance, and external factors to provide intelligent recommendations for optimizing resource distribution and refining task priorities. This streamlines decision-making processes and contributes to a more adaptive and responsive project management approach. Furthermore, Generative AI's data processing capabilities enable it to analyze and interpret large datasets, facilitating the extraction of valuable insights that can inform strategic decisions and project optimizations. This can significantly improve the project's overall performance and outcomes. Also, Generative AI-powered collaboration tools can enhance communication by offering real-time language translation, aiding cross-cultural collaboration, and minimizing misunderstandings.

Furthermore, Generative AI can contribute to automated testing and quality assurance processes, addressing the challenge of maintaining product quality within tight Agile development cycles. By generating and executing test scenarios, AI can identify potential issues early in the development process, reducing the risk of defects and enhancing overall product reliability. Following the pain points assembled in Fig. 1, Table I propose solutions to them using GenAI according to the literature:

This study draws on the highlighted challenges to align the answers. This systematic approach makes it easier to see how each suggested solution specifically tackles the given problems, which increases the solutions' overall efficacy. Furthermore, this alignment ensures that the suggested remedies successfully tackle the issues discovered, opening the door for a more comprehensive and successful implementation plan [34]. In conclusion, to answer RQ2, Generative AI is a valuable ally in overcoming Agile project pain points. Its ability to support creative imagination, optimize resource allocation, analyze large datasets, enhance collaboration, and automate testing processes makes it a versatile tool for Agile teams striving to achieve higher levels of efficiency, adaptability, and success in their project endeavors. As the field of Generative AI continues to evolve, its potential to revolutionize Agile project management practices is likely to grow, providing teams with innovative solutions to navigate the complexities of dynamic and iterative development processes. It can offer insightful information and recommendations consistent with findings from literature reviews. GenAI's responses can be shaped by particular prompt patterns, which makes it easier to create reviews and suggestions for addressing project difficulties. GenAI has excellent potential to alleviate typical pain points in agile projects as an auxiliary tool. It can help predict problems previously occurring in its pre-trained data by using its historical data to benchmark and identify similarities in each project. Though GenAI can offer valuable recommendations for handling pain points, it is nevertheless imperative that the project team continue to be skilled in agile techniques and only rely on GenAI's answers with rigorous evaluation [35].

TABLE. I SOLUTION MAPPING USING GENAI

| | | |
|---|---|---|
| **Project** | **Requirements management** | According to a predetermined specification pattern, GenAI is configured to generate requirements. Responding to a prompt, it can request explanations, provide recommendations, and generate high-level requirements tabularly. However, depending on the round they were formed, these needs may have different contents [4] [24]. |
| | **Stakeholders & management support** | As a steering committee member, GenAI understands its role and provides presentations upon request. It seems to understand the subject at hand and provides useful advice. Most of these recommendations seem reasonable. Nonetheless, a notable degree of variation exists in the proposed activities for every round [25]. |
| **People** | **Role definition** | Based on the comments given, GenAI seems to understand the prompt pattern and provides a preliminary role description that outlines the duties and skills required for the position. Furthermore, it indicates that the roles could need to be modified based on the project's actual requirements [26]. |
| | **Competence Gap** | GenAI can quickly identify the task and provide a variety of analysis and suggestions. Even with the identical prompt pattern, the results can vary greatly, bringing a variety of careful factors into play [27]. |
| **Process** | **Agile process understanding** | It seems that GenAI understands the prompt's context, which is based on agile coaching concepts. Even though the design differs greatly, the suggested concepts are still useful. The coaching places a strong emphasis on continuous improvement and learning, and it provides a detailed program [4]. |
| | **adaptability** | It seems that GenAI understands the prompt context, which emphasizes adaptability. It can automatically create an action plan upon request and can adjust this plan with additional prompt elements. Though answers to the same prompt can differ, it effectively identifies problems and provides pertinent advice [4] [28]. |
| **Endurance** | **Change resistance** | It seems that GenAI understands the prompt pattern associated with resistance to change and is able to create an action plan based on feedback from users. This approach includes tactics to address resistance to change, yet using the same stimulus more than once may yield different results [11] [29][30]. |
| | **Maintaining agile way of work** | GenAI is knowledgeable with the fundamentals of agile processes and the jobs that go along with them, such as those of the Scrum Master. After gaining an understanding of the backdrop, it goes into detail on the significance of cross-functional roles and sprint planning. The initial question seems to be aimed mostly at a senior developer, with the intention of educating and motivating them in their work [4] [31]. |
| **Effort estimation** | **Work estimation** | It seems like GenAI understands the purpose of an effort estimation prompt. It provides a list of tasks that it determines are required, together with descriptions and time estimates expressed in days. It also discusses the assumptions made in the estimates and how those assumptions might affect the amount of work needed. Repeating the inquiry, however, results in a substantial variation in the estimation [4] [32]. |
| | **Technical knowledge** | The prompt is identified by GenAI as one that deals with team management of technical knowledge. It creates a suggestion based on the further details in the prompt about how the team could overcome this difficulty. It's interesting to note that different rounds of the same prompt produce diverse answers [4] [33]. |

### *B. GenAI to Enhance Software development using Agile Frameworks*

As mentioned in Section II, the Scrum framework is a small-scale process used mainly by developing teams and IT engineers to deliver the best quality products with the highest adaptability. Scrum is a widely adopted Agile framework for project management that provides a structured and iterative approach to software development and other types of projects. Scrum is a widely adopted Agile framework for project management that provides a structured and iterative approach to software development and different kinds of projects.

Integrating Generative Artificial Intelligence (GenAI) into Scrum can enhance efficiency, innovation, and decision-making. We elaborated in Fig. 3 a framework illustrating how GenAI can assist at different stages of the Scrum process:

- Backlog Refinement and Clarification Through Automated User Story Generation: GenAI can analyze historical data, user feedback, and market trends to propose potential user stories for the backlog. It helps generate diverse and creative ideas, fostering innovation in feature development. Team members can interact with GenAI to seek clarification on user stories or acceptance criteria, ensuring a shared understanding of requirements [36].

- Estimation and research assistance: GenAI can assist in estimating the complexity of user stories by analyzing historical data and patterns. It can offer insights into potential risks and challenges associated with specific tasks, aiding the team in better planning. It can help gather information related to tasks or user stories, preparing sprint planning meetings.

- Progress tracking: GenAI tools can analyze individual and team progress based on task updates, identifying potential bottlenecks or areas needing additional support. It assists in providing a holistic view of the team's performance.

- Generating meeting summaries and Automated Testing: GenAI can assist in summarizing the sprint review meeting and highlighting key achievements and outcomes. GenAI can contribute to automated testing processes, helping identify defects and ensure the reliability of the delivered product increment. It accelerates the testing phase, allowing the team to focus on refining features.

- Feedback Analysis and Brainstorming Improvement Ideas: GenAI can analyze feedback received during the sprint and provide insights into areas of improvement. It helps in identifying patterns, potential process enhancements, and team dynamics. Teams can engage GenAI in brainstorming sessions to generate ideas for process improvements during retrospectives.

- Dynamic Prioritization and Answering Questions on Backlog Items: GenAI can dynamically prioritize backlog items based on changing requirements, user feedback, and business priorities. It assists in maintaining a backlog aligned with the project's evolving needs: GenAI can provide additional information or context for backlog items, helping in prioritization discussions.

- Code Suggestions and Reviews: GenAI tools can provide code suggestions, identify potential improvements, and even assist in code reviews. It fosters collaboration among developers and helps maintain coding standards.

Fig. 3. Generative AI Integration across the scrum framework stages.

Another noticeable improvement of the integration of GenAI into the Scrum process is knowledge sharing through automated documentation; GenAI can assist in generating documentation for code changes, updates, and system architecture. It ensures that knowledge is captured and shared across the team efficiently. Also, there is continuous improvement using data-driven insights; GenAI analyzes historical project data to provide insights into team performance, sprint outcomes, and areas for constant improvement. It contributes to data-driven decision-making in retrospectives.

### C. Considerations and Limits

To answer the second part of the RQ3: Can GenAI help with the software development process? Can GenAI used in Agile frameworks to enhance project management assistance? Our developed framework, which combines conversations with GenAI through prompt patterns in Section IV(B), demonstrates its usefulness in producing a variety of templates and rough designs for agile projects. Because of the data it was trained on, GenAI, a pre-trained language model, has a basic grasp of different kinds of agile projects. Nevertheless, it is not advisable to place complete faith in the data produced by GenAI due to the inherent variances in project needs and human resources. It's important to proceed cautiously and have agile project specialists analyze GenAI's results because they might not be entirely trustworthy. Some of the upcoming issues are listed below and are still open for discussion if future contributions:

- Ethical Use: Ensure that GenAI is used ethically, avoiding biases and adhering to privacy and security standards.
- Human Oversight: While GenAI can assist in various tasks, human oversight is crucial, especially in critical decision-making processes.
- Context Awareness: While GenAI can provide information, it may need to gain awareness of the specific context or nuances of the team's unique processes. Team members should validate information accordingly.
- Data Security: Ensure that sensitive information is not shared with GenAI, and be mindful of data security considerations.
- Complementary Role: GenAI should be seen as a complementary tool that aids communication and information retrieval, but human collaboration and decision-making remain essential.

Integrating GenAI into the Scrum process requires a collaborative approach, where the technology augments the capabilities of the Scrum team rather than replacing human interactions. Regular evaluations and adjustments should be made to optimize the use of GenAI based on the evolving needs of the team and project. Leveraging GenAI in the Scrum process can enhance communication, provide quick information access, and streamline certain aspects of collaboration. However, it's crucial to integrate it judiciously, considering the specific needs and dynamics of the Scrum team. Regular feedback and adjustments will help optimize its utility within the Scrum framework.

## V. CONCLUSION

It's impossible to envisage a time when software programmers would be paid as much as they are now in a world of low code and generative artificial intelligence. There will be changes to several established roles, like programmer. Given the rate of advancement, we anticipate that, compared to today, very few software organizations will not have an AI-augmented development and testing approach over the next three years. Generative AI will control most mobile apps and internet content, either entirely or partially. Software engineers will require new skills, such as refining software that is generated automatically, feeding learning engines, and investigating behaviors that are not explicable. Generative AI will accelerate software development. However, be wary of marketing hype about quick fixes for developing secure and resilient software using non-deterministic technology.

Many recommendations for agile project management are provided by GenAI, which can be especially helpful early on when knowledge and experience with agile methods are scarce. How much GenAI can help with tasks involving highly experienced people still needs to be clarified? Although simple prompt structures seem to work well for now, there is a fascinating field for further research into more intricate prompt designs and their combinations.

# Comparing Regression Models to Predict Property Crime in High-Risk Lima Districts

Maria Escobedo[1], Cynthia Tapia[2], Juan Gutierrez[3], Victor Ayma[4]
Student Member, Universidad de Lima, Lima, Peru[1, 2]
Professor Member, Universidad de Lima, Lima, Peru[3]
Professor Member, Universidad del Pacifico, Lima, Peru[4]

***Abstract*—Crime continues to be an issue, in Metropolitan Lima, Peru affecting society. Our focus is on property crimes. We recognized the lack of studies on predicting these crimes. To tackle this problem, we used regression techniques such as XGBoost, Extra Tree, Support Vector, Bagging, Random Forest and AdaBoost. Through GridsearchCV we optimized hyperparameters to enhance our research findings. The results showed that Extra Tree Regression stood out as the model with an R2 value of 0.79. Additionally, error metrics like MSE (185.43) RMSE (13.62) and MAE (10.47) were considered to evaluate the model's performance. Our approach considers time patterns in crime incidents. Contributes, to addressing the issue of insecurity in a meaningful way.**

***Keywords—Supervised techniques; machine learning; regression; crime; prediction***

## I. INTRODUCTION

Numerous sources concur that crimes are a constantly growing phenomenon, which detrimentally affects the economy and the overall quality of life [1, 2, 3]. Crimes are prevalent in every social system, with their impact experienced across different continents, countries, and regions.

Numbeo [4] conducted a global ranking, assessing crime rates in 142 countries, where Peru was placed eleventh with a crime rate of 68% and a safety rate of 32%. One of the primary issues in Peru is crime, with reports of crimes seeing a steady increase.

In 2022, the department of Lima recorded the highest number of complaints for the commission of crimes, accounting for 34% of all complaints. Many of these crimes occurred within the Lima metropolitan area, where 44,879 crimes were reported during the first half of the year.

Most of the crimes accounting for 74% of the count were related to property offenses. These offenses involve actions that violate the belongings or possessions of individuals or businesses. When we refer to property in this context we mean any item, with worth. These crimes can be further classified into types based on their nature such as assault involving vehicles, theft severe forms of theft like nighttime burglary and burglaries in occupied houses unauthorized use of property, vehicle theft, attempted thefts, robbery cases armed robbery cases, with aggravated circumstances involved, gang related robberies and attempted robberies [5].

The absence of a higher level of education and the presence of job instability is crucial factors that have a negative impact on both the crime rate and the country’s economy. Regarding the profile of the detainees, 90% of them are men, aged between 18 and 59 years, with a basic educational background, and facing unstable employment conditions [6].

In recent years, there has been an alarming increase, in property crimes in the high-risk districts of Metropolitan Lima. This has caused concerns for the safety and well-being of residents [7]. According to INEI [8] these crimes have reaching effects beyond the immediate victims. They also affect the economy and societal trust in the areas. With a focus, on measures this research aims to use regression models as a predictive tool to aid law enforcement agencies in making informed decisions and effectively addressing the urgent problem of property crimes.

The motivation we use regression models is because they can analyze the relationship, between temporal factors that affect crime rates. These models use a time window structure. Include variables through data organization and feature selection techniques providing a systematic approach to understanding and predicting crime patterns. Our main goal is not to make predictions but also to give law enforcement agencies valuable insights that can help them distribute resources and plan intervention strategies effectively.

It is important to recognize that traditional methods of addressing citizen insecurity in Peru have faced challenges when it comes to integrating with life and promoting collaboration [9]. Using regression models our aim is to bridge this gap by developing a solution that does not consider the experiences of residents but also encourages their active participation, in improving community safety.

After conducting a comparison of regression models such, as XGBoost, Extra Tree, Support Vector, Bagging, Random Forest and AdaBoost this study aims to determine the most effective model based on key evaluation metrics like Mean Absolute Error (MAE) Mean Squared Error (MSE) Root Mean Squared Error (RMSE) and R squared. The chosen best model will be a resource for law enforcement in their efforts to reduce property crimes and create a safer environment for the residents of Metropolitan Lima.

The research is divided into sections. Section II will analyze the state of research in crime prediction. In Section III we will provide a description of the techniques we will use. Section IV will outline the steps and experimental processes undertaken in this study. After explaining our method in detail, we will present the results in Section V. Finally, we will offer a discussion and conclusion in Section VI and Section VII respectively.

## II. Related Work

Many studies have explored the domain of crime management, suggesting various methods employing machine learning algorithms for forecasting. Highlighting the crucial role of characteristic choice and data origins, a huge part of this investigation has been centered in nations with elevated crime rates like India, Bangladesh [10, 11, 12, 13], Brazil [14], and Colombia [15], with specific attention on urban areas. Curiously, regions in Asian countries like China display decreased crime rates, molding the outlook of its inhabitants [16]. It is vital to recognize that the forecasting effectiveness of crime models is impacted by the location setting.

Various regression techniques have been employed in these studies, including Random Forest, Support Vector Machine, KNN Regression, LASSO Regression, Ridge Regression, Linear Regression, Polynomial Regression, Gradient Boosting Regression, AdaBoost R2, Additive Regression, Extreme Gradient Boosting Regression, Bagging, Iterated Bagging and Multivariate Adaptive Regression Splines [11, 13, 15, 16, 17 20]. It is, worth noting that Random Forest consistently delivered results with an adjusted R2 of 80% [14] which explains its widespread adoption, in numerous research studies [11, 13, 15, 17, 18, 20, 21].

The collection of crime records relies on data sources from police departments and governmental agencies of the respective countries [11, 12, 13, 19]. Time and location-related variables appear as the primary features, with time variables including year, month, day, and hour [19, 20]. The time window method plays a crucial role in predicting crime rates over short (monthly) and long (annual) data periods, revealing significant variations [23].

Concerning location variables, latitude, longitude, and city are commonly used [23, 20, 24]. More specific variables, such as cab flow [16], gross domestic product, household income, unemployment [14], and socio-economic indicators [21], are explored in some studies but are not as often employed in crime prediction models.

The output variable in these studies varies, aiming to predict crime rates at different geographical levels—countries [13], cities [19], regions [10], municipalities [15], and neighborhoods [17]. Furthermore, certain research studies are dedicated to forecasting crime rates based on their categories [11, 12 17, 23 24, 25] while others aim to enhance the distribution of law enforcement personnel, in localities [19].

The results, from studies show R2 values. The Linear Regression model had the R2 of 0.99 when socioeconomic data was used [20]. It is worth mentioning that the Random Forest Regression model consistently yielded R2 values, between 0.77 and 0.98 because it can handle both categorical data [13, 14, 15, 19, 21, 22].

In recent times, research on new approaches to improve crime prediction models has been very active. For example, Briz developed a spatial-temporal logistic regression model to address the complex challenge of temporal uncertainty in crime data analysis. Then, they decided to advance further by developing a Bayesian approach that would allow them to address temporal uncertainty even more effectively. Wanting to show the impressive quality of their new model, they evaluated both fictitious information and real data on residential burglaries in Valencia, Spain. Next, they conducted several tests to validate their work. In one of them, they analyzed only "perfect" cases, excluding uncertain events. They applied different techniques to fill in missing data in another [30].

Moreover, Hu et al. [29] collected the number of daily crimes in each region and store it in a historical matrix. Additionally, they apply a time window which slides through the matrix of crime occurrences. It was considered a length of 15 days to generate the data samples. To determine the optimal time to analyze, they closely observed the patterns in the data for approximately 15 days. They concluded that this two-week time span was the most appropriate to capture the significant trends and patterns present in the data collected. This choice was not arbitrary but was based on empirical evidence obtained through a meticulous process of monitoring and preliminary analysis of the data.

In conclusion, the field of crime prediction research is constantly evolving by incorporating a diversity of data sources and advanced modeling techniques. The use of dynamic functions that consider temporal windows shows promising potential for research focused on improving the accuracy and adaptability of predictive models of crime in different geographic settings. These advances allow for a better understanding of crime patterns and can lead to more effective strategies to prevent crime and increase safety in our communities.

## III. Methodology

The study uses a research methodology as shown in Fig. 1 to examine and analyze crime data using an approach. The first phase focuses on the collection of crime records from a reliable source, followed by the conversion of these records into respective formats suitable for dataset use. This critical first step ensures the quality and reliability of the data under investigation.

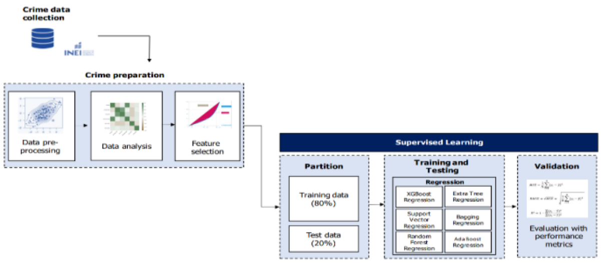

Fig. 1. Research methodology for predicting crimes against patrimony in Lima.

Moving forward, the second phase of crime preparation involves three sub-phases: data pre-processing, data analysis and feature selection. In the first sub-phase, the elimination of empty rows and the application of normalization techniques contribute to refining the dataset. The next sub-phase, data analysis, is a crucial step in understanding patterns and trends within the crime data. Exploratory data analysis techniques help in finding outliers, and other significant factors that may influence criminal activities. Furthermore, feature selection is undertaken during this phase to show the most relevant variables for building robust supervised learning models. This involves assessing the importance of each feature in predicting crime occurrences, enhancing the model's accuracy and efficiency. Additionally, the incorporation of the sliding window method, forecasting on a weekly basis, adds temporal depth to the analysis.

Following the meticulous preparation of the dataset, the research advances to the third phase, which revolves around supervised learning. This phase is further subdivided into three key sub-phases: partition, training and testing, and validation. In the first sub-phase, the dataset is partitioned into an 80% training set and a 20% testing set, proving a robust foundation for model evaluation. The second sub-phase entails the training and testing of various supervised regression models, including XGBoost, Extra Tree, Support Vector, Bagging, Random Forest and AdaBoost, as named in references [15, 16, 17, 18, 20]. Optimization of hyperparameters for each model is conducted to enhance overall performance.

In the stage the regression model's predictions are thoroughly assessed using performance metrics, like Mean Squared Error (MSE) Root Mean Squared Error (RMSE) Coefficient of Determination (R2) and Mean Absolute Error (MAE) as mentioned in references [19, 23, 24]. This meticulous evaluation process looks to decide the model that performs best providing insights, for law enforcement agencies as they tackle and curb activities. The structured and systematic approach outlined in this methodology ensures a robust and data-driven foundation for the development of effective crime intervention strategies.

## IV. Experimental Settings

### A. Crime Data Collection

The dataset used for the development of this investigation has crimes against property registered in police stations in the Metropolitan Lima area, this was compiled from the official page of the National Institute of Statistics and Informatics. It is important to highlight that the crimes included in this dataset occurred during the years 2015, 2016, and 2017 [26]. This dataset had 490 916 reported crimes. It can be obtained through the following link https://github.com/Cielo12019/Thesis_ML/blob/main/Delitos_Final_2017_2016_2015.xlsx.

The set of crime records is made up of sixty attributes. These attributes describe the crime, considering three aspects: location, time, and type of crime.

- Regarding the location, this allows to show where the criminal incident took place. The related attributes are district, presumed place of occurrence, latitude, and longitude. Likewise, these allow the identification of a criminal pattern based on the area where the criminal act occurred.
- In terms of time, this allows us to conduct an analysis based on years, months, and days to find similar criminal incidents and seasonal patterns that indicate that in certain months or days of the week there is a greater probability of crime. Also, the hour and minute attributes are useful to find in which parts of the day there is a greater number of criminal acts.

In relation to the type of crime, this allows to know the type of event that occurred. The variables that require it are generic crime, specific crime, and modality crime.

### B. Crime Data Preparation

In the preparation of the data, the pre-processing of the data is conducted, an exploratory analysis and finally, the selection of characteristics that will be used by machine learning techniques. Each of the sub-phases is presented below.

*1) Data pre-processing:* During the data pre-processing phase, we filtered the generic type to consider crimes related to property. Within specific crime we carefully examined records about robbery and theft. In the crime modality, various modalities were considered, including assault, vehicle theft, robbery, aggravated robbery, aggravated nighttime robbery, aggravated burglary, burglary, vehicle theft, frustrated robbery, robbery, aggravated robbery, armed robbery, aggravated gang robbery, and attempted robbery. This comprehensive approach allowed us to analyze aspects of activity in relation, to property crimes.

Furthermore, to raise the model's recognition ability, qualitative attributes such as the type of road, the specific crime, and criminal organization were factorized. Moreover, place of occurrence, the medium used, and the instrument used have all been made into the categorical data type also. Additionally, day, month, hour, and minute variables, when thought to be float values, changed to integer data type.

Moreover, we used the district list from the INEI website to match district names, with the location codes in the dataset. We repeated this process for each year which helped us gain an understanding of where these events took place.

Relating the variable, for types of crimes we combined categories with each other. As an example, we labeled all robberies as robbery and grouped all other thefts as theft. Additionally, we classified cellphone robberies under the category of robbery. Adjusted aggravated robberies that occurred at night or in areas to be categorized as aggravated robbery during night. These changes were made to not make the representation of activities consistent but also to simplify the analysis of the dataset afterwards.

During the process of cleaning and filtering the data we dropped rows that had values of ninety-nine in the month day and hour columns. We did this to improve the quality and reliability of the dataset by getting rid of instances that may have unusual information.

To generate the dataset, we excluded features that were not relevant to the crime. Also features with than 70% missing values, such as the location of the police station where the complaint was filed, and the time of registration were left out. We executed this procedure using a notebook on the Deepnote web application. Exported the dataset, in CSV format.

*2) Exploratory data analysis:* Fig. 2 illustrates the distribution of crimes throughout the weeks of the year. The horizontal axis stands for the weeks while the vertical axis stands for the corresponding number of crimes. A visible cyclic pattern in crime rates can be seen. The number of crimes tends to rise during the weeks of each year reaching its peak in week twenty. Afterward it continuously declines until the end of the year. Nonetheless there is also variation in the data. The range, between the minimum and maximum number of crimes exceeds 100%. These seen temporal patterns offer a chance to improve predictive modeling by including trends, within time periods.

In Fig. 3, the bar graph illustrates the frequency of crimes occurring on each day of the month. The x-axis shows the days, and the y-axis is the number of crimes. It should be noted that on the 31st the number of reported crimes is recorded. Nevertheless, it is important to note that not all months have 31 days; only January, March, May, June, August, October, and December have 31 days. On the contrary third day has the recorded number of crimes. Nonetheless there are no deviations, from days except, for days 19th, 29th and 31st.

In Fig. 4, the x-axis is the 24-hour clock of the day, while the y-axis shows the frequency of crimes that happened each hour. This figure illustrates depicts how the number of committed crimes varies throughout the day. Notably, the highest concentration of crimes is observed during the nighttime, specifically at 20:00 PM. Contrariwise, the lowest number of crimes is recorded during the early morning, at 2:00 AM. Based on this pattern, we considered a new variable as a Time Range created by segmenting the hours into four ranges: 0:00-6:00 AM (early morning), 6:00-12:00 AM (morning), 12:00-18:00 PM (afternoon), and 18:00-24:00 PM (night). This segmentation would provide a more generalized representation of the time of day, helping further analysis based on these time intervals.

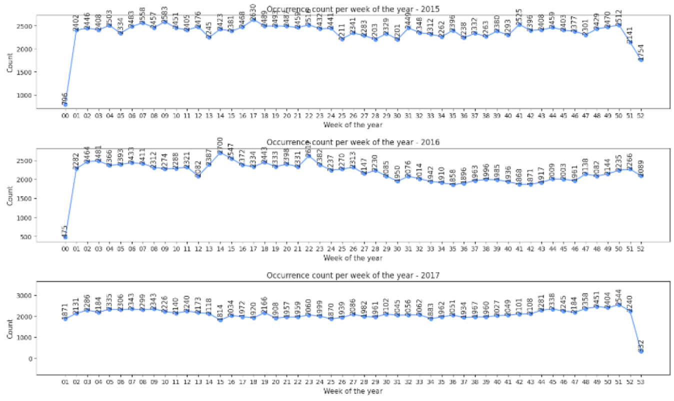

Fig. 2. Crimes per week.

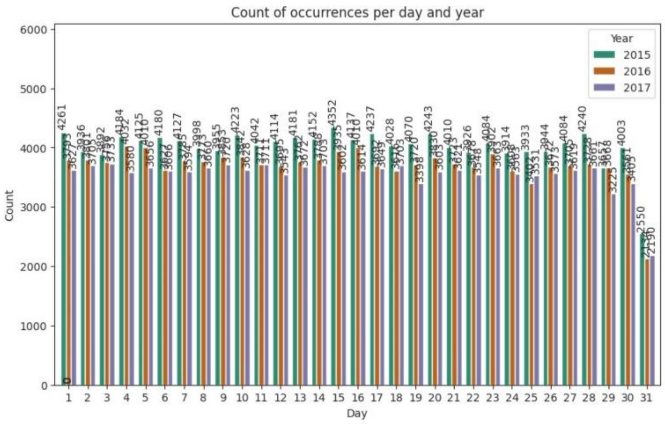

Fig. 3. Crimes per day.

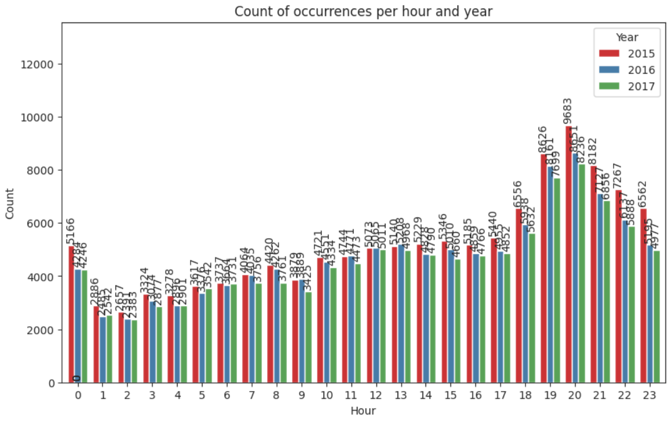

Fig. 4. Crimes per hour.

*3) Feature selection*: In the characteristic selection stage, it was divided into three sub-phases. In the first subphase, it was decided to select the variables that were going to add value to the model. Therefore, variables that have been used in most research were selected, which are: year, month, day, time range, number of crimes and district in which the event occurred.

From there, an aggregation was performed based on the attributes of year, month, day, time interval and district to determine the number of crimes. This aggregation was stored in a data frame, from which only the column referring to the crime count was extracted.

In the second subphase, a time window approach was applied, as can be seen in Table I, in which the values of the data frame are combined by shifts using different step numbers with 1, 2, 3, 4, 5, 6, 7 and 8. The initial shift shifts the values 8 steps, followed by the second shift with 7 steps, and so on, as each 7 blocks are taken as predictors and the next block as the variable to be predicted. It is important to mentioned that block is a quarter of day. Furthermore, it should be noted that this is done for both the training and testing stages, without losing the time scale.

TABLE I. NUMBER OF CRIMES PER WEEK

| BLOCK | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | … |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| TRAINING | 91 | 57 | 78 | 48 | 49 | 49 | 78 | **35** | 52 | 79 | 103 | … |
| | | 57 | 78 | 48 | 49 | 49 | 78 | 35 | **52** | 79 | 103 | … |
| | | | 78 | 48 | 49 | 49 | 78 | 35 | 52 | **79** | 103 | … |
| | | | | 48 | 49 | 49 | 78 | 35 | 52 | 79 | **103** | … |
| | | | | | … | … | … | … | … | … | … | … |
| TEST | 117 | 45 | 90 | 93 | 118 | 44 | 64 | **80** | 147 | 53 | 75 | … |
| | | 45 | 90 | 93 | 118 | 44 | 64 | 80 | **147** | 53 | 75 | … |

These shifted data frames are then concatenated along the column axis, resulting in the new data frame, as shown in Table II. The columns of the data frame are renamed with the designations "t-7", "t-6", "t-5", "t-4", "t-3", "t-2", "t-1", "t". The rows originating from the offsets are removed from the new data frame. Starting with row eight, attributed to the maximum offset of eight, and extending to the end of the data frame.

TABLE II. SLINDING WINDOW SCHEME

| t-7 | t-6 | t-5 | t-4 | t-3 | t-2 | t-1 | t |
|---|---|---|---|---|---|---|---|
| 91 | 57 | 78 | 48 | 49 | 49 | 78 | 35 |
| 57 | 78 | 48 | 49 | 49 | 78 | 35 | 52 |
| 78 | 48 | 49 | 49 | 78 | 35 | 52 | 79 |
| 48 | 49 | 49 | 78 | 35 | 52 | 79 | 103 |
| 49 | 49 | 78 | 35 | 52 | 79 | 103 | 76 |
| 49 | 78 | 35 | 52 | 79 | 103 | 76 | 42 |
| 78 | 35 | 52 | 79 | 103 | 76 | 42 | 58 |
| … | … | … | … | … | … | … | … |
| 52 | 79 | 103 | 76 | 42 | 58 | 117 | 45 |

In the third sub-phase, it was chosen which variables were to be part of the predictors and which were to be part of the goal. Since the purpose was to predict the crime rate, the predictors will be "t-7", "t-6", "t-5", "t-4", "t-3", "t-2", "t-1" and the target variable will be t.

### *C. Supervised Learning*

Regression models will be evaluated with training and test data. In addition, its hyperparameters will be perfected with the GridSearchCV technique to improve its performance and metrics such as MSE, RMSE, R2 and MAE will be used to confirm its performance.

*1) Partition:* Based on the research developed by [27]., the data set was divided into two, 80% was for training and 20% for testing. The crime data set had 35,008 records of crimes against property corresponding to the Metropolitan Lima area. Of that total, 24,504 registrations were designated to train the models. For testing these, the remaining 10,504 records were used.

*2) Training and testing:* To test the regression models, two scenarios were performed. In the first training and testing scenario, the default parameters were considered to test the R2 of the model. Table III shows the results obtained with the training and test data.

TABLE III. SCENARIO 1 WITH DEFAULT HYPERPARAMETERS

| Model | Training data | Test data |
|---|---|---|
| XGBoost Regression | 0.97 | 0.75 |
| Extra Tree Regression | 1 | 0.79 |
| Support Vector Regression | 0.72 | 0.71 |
| Bagging Regression | 0.95 | 0.76 |
| Random Forest Regression | 0.97 | 0.78 |
| AdaBoost Regression | 0.7 | 0.69 |

To improve the performance of the models, a second scenario was carried out where their hyperparameters were analyzed. GridSearchCV was used to fine-tune the hyperparameters of each of the models. The results indicated which values to consider to obtain a better prediction.

Subsequently, the training and the respective test were accomplished, it could be observed that the R2 of the regression models improved, the results are presented in Table IV.

TABLE IV. SCENARIO 2 WITH HYPERPARAMETERS CHOSEN BY GRIDSEARCH CV

| Model | Training data | Test data |
|---|---|---|
| XGBoost Regression | 0.85 | 0.77 |
| Extra Tree Regression | 0.94 | 0.79 |
| Support Vector Regression | 0.83 | 0.76 |
| Bagging Regression | 0.82 | 0.77 |
| Random Forest Regression | 0.85 | 0.78 |
| AdaBoost Regression | 0.71 | 0.69 |

*3) Validation:* To validate the performance of the regression models, the metrics MSE, RMSE, R2 and MAE on the second scenario, which obtained better results. Table V shows the results of the performance metrics.

TABLE V. COMPARISON OF PERFORMANCE METRICS FOR SUPERVISED ALGORITHMS

| Model | MSE | RMSE | R2 | MAE |
|---|---|---|---|---|
| XGBoost Regression | 200.11 | 14.15 | 0.77 | 11.04 |
| Extra Tree Regression | 185.43 | 13.62 | 0.79 | 10.47 |
| Support Vector Regression | 211.57 | 14.55 | 0.76 | 11.31 |
| Bagging Regression | 206.91 | 14.38 | 0.77 | 11.07 |
| Random Forest Regression | 195.63 | 13.99 | 0.78 | 10.72 |
| AdaBoost Regression | 270.7 | 16.45 | 0.69 | 13.04 |

## V. RESULTS

From the experimentation conducted, the summary of the results of each model with GridSearchCV hyperparameter setting obtained by each performance metric is shown in Fig. 5. The Extra Tree Regression model achieved better results, obtained the lowest MSE, RMSE, MAE of 185.43, 13.62, 10.47, respectively, and the highest R2 of 0.79, showing that it is the best model with lower error and higher variance reduction for predicting the number of crimes. Next, it was found that the Random Forest Regression, XGBoost Regression, Support Vector Regression and Bagging Regression models obtained similar values for the R2, above 0.76 and close average errors, which shows that there is no significant difference in their metrics. Likewise, it was shown that the model that obtained the lowest R2 of 0.69 and the lowest MSE, RMSE, MAE of 270.7, 16.45, 13.04 was the AdaBoost Regression.

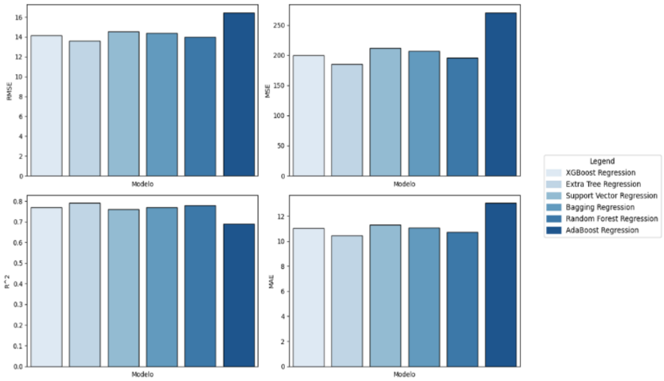

Fig. 5. Metrics for regression models.

## VI. Discussion

Although several rigorous research and solutions have been conducted, these studies have not been adopted from a criminological practice where predictive analysis using machine learning techniques is involved. For this reason, in this research supervised machine learning algorithms such as XGBoost Regression, Extra Tree Regression, Support Vector Regression, Bagging Regression, Random Forest Regression and AdaBoost Regression were analyzed and implemented. The models were evaluated with the set of crimes against patrimony in Metropolitan Lima from 2015 to 2017.

To evaluate the supervised regression models, two scenarios were considered. In the first scenario, the highest R2 of 0.79 was obtained with the Extra Tree Regression model. In the second scenario, to improve the results, hyperparameter optimization was performed with GridSearchCV for each of the models. The results showed the best regression model, this was achieved an R2 of 0.79 and error related metrics of 185.43, 13.62, 13.47 for MSE, RMSE, MAE. For the AdaBoost Regression, Random Forest Regression and Bagging Regression models, similar investigations have been conducted as [15], obtained an R2 of 61% with AdaBoost Regression, for which they used numerical variables. It should be noted that they performed hyperparameter optimization using Grid Search CV to improve prediction accuracy. Also, it was found that the Random Forest Regression model obtained an R2 of 0.78 close to the Extra Tree Regression model and the MSE, RMSE, MAE of 195.63, 13.99 and 10.72.

Belesiotis et al. [17] mentions that Bagging Regression and Random Forest Regression algorithm use similarly; however, they have differences because of the hyperparameter fitting rule they employ. In addition, Random Forest Regression offers a higher R2 for cases where the true values of the coefficients of a set is zero or small. Likewise, most of these investigations have worked with data sets from Asia and Europe, which have a better record and quantity of data on reported crimes and have a greater number of variables, which allows a better distribution and analysis of the data to obtain more accurate models; however, it should be noted that according to the INEI [28], only 15.5% of the Peruvian population that has been a victim of a criminal act chooses to report it to the National Police or the Attorney General's Office, because they consider it to be a waste of time. Therefore, the amount of data that is entered into the INEI for investigation purposes is reduced and must be preprocessed before being used.

## VII. Conclusion

The main goal of this research was to compare regression models for the prediction of property crime rates in the districts of Metropolitan Lima as a function of space and time. For that reason, supervised models such as XGBoost Regression, Extra Tree Regression, Support Vector Regression, Bagging Regression, Random Forest Regression and AdaBoost Regression were implemented. These supervised models obtained an R2 lower than 0.79 and higher than 0.69. These predictions, in comparison with earlier studies, are within the prediction range that varies between 0.50 and 0.80 of R2 for regression models.

When making predictions with historical data, it would not be possible to obtain values that approximate the real events because when trying to find patterns, the model suffers an overadjustment and does not find new patterns that adapt to the new events. Given that the phenomenon of crime has changing patterns, predictions could be made with information from current events, and thus know the amount of crime that could occur to prevent crimes. Also, with the predictions, police officers can plan their distribution in Metropolitan Lima a week in advance.

As future work, it is suggested to include more data sources related to the geographic space where the crime originated, and data related to criminal activities to find crime hotspots. Likewise, it is important to use hybrid methods that include regression and classification models to have models that are more efficient and help to counteract crime.

***Abstract*—In the ever-evolving landscape of education, institutions grapple with the intricate task of evaluating individual capabilities and forecasting student performance. Providing timely guidance becomes pivotal, steering students toward specific areas for focused academic enhancement. Within the educational domain, the utilization of data mining emerges as a powerful tool, revealing latent patterns within vast datasets. This study adopts the Random Forest classifier (RFC) for predicting student performance, bolstered by the integration of two innovative optimizers—Victoria Amazonia Optimization (VAO) and Phasor Particle Swarm Optimizer (PPSO). A notable contribution of this research lies in the introduction of these novel optimizers to augment the model's accuracy, elevating the precision of predictions. Robust evaluation metrics, including Accuracy, Precision, Recall, and F1-score, meticulously gauge the model's effectiveness in this context. Remarkably, the results underscore the supremacy of RFC+VAO, showcasing exceptional values for Accuracy (0.934), Precision (0.940), Recall (0.930), and F1-score (0.930). This substantiates the significant contribution of integrating VAO into the Random Forest framework, promising substantial advancements in predictive analytics for educational institutions. The findings not only accentuate the efficacy of the proposed methodology but also herald a new era of precision and reliability in predicting student performance, thereby enriching the landscape of educational data analytics.**

***Keywords—Student performance; Random Forest Classification; victoria amazonia; phasor particle swarm***

## I. Introduction

Educational institutions, including schools, universities, and training centers, handle vast amounts of data originating from various sources like registration departments, exam centers, and virtual courses, as well as e-learning systems [1], [2]. Within this educational data lie valuable insights that, once uncovered, can significantly improve the effectiveness of the entire educational system [3]. Machine learning (ML) and statistical methods have been increasingly applied to develop intelligent educational systems [4], [5], [6]. These systems aid decision-makers in educational institutions in attaining a thorough grasp of their organization [7]. Forecasting students' performance presents a complex challenge, but doing so can enable lecturers and decision-makers to identify effective strategies for addressing students' underperformance [8].

Additionally, the prediction of students' ultimate examination scores through the consideration of diverse elements like quiz results, homework, and project achievements will offer a holistic evaluation of the student's educational competence [9]. Machine learning methods have proven to be effective when used on problems related to association rules, web mining, classification, clustering, and deep learning in the field of education [10]. Researchers in the education industry continue to be greatly inspired by complicated data, which motivates them to explore techniques such as clustering and classification in order to create very accurate instructional models [11], [12].

Data classification stands out as the most efficient method for conducting data mining research, relying on the classification of data through predictive attribute value [13]. Data quality, which can disrupt algorithms and lead to misclassification, impacting the model's performance, is central to the challenge of classification [14]. By using this predictor, educational institutions can identify underperforming students and offer support to help them attain higher grades, ultimately paving the way for a brighter future [15]. Several established prediction techniques encompass classification, regression, and density estimation [16]. In contemporary data science, aside from enhancing the accuracy of their results, it is now essential to have trust in and a comprehensive understanding of prediction models [17], [18].

It is imperative that strong machine learning technologies be developed so that teachers may make well-informed judgments to reduce the chance of student failure. The objective of this project is to construct a reliable model for forecasting student grades utilizing a dataset associated with student performance. This data can be categorized into personal details (e.g., parent status, family size, and family educational support), educational background (e.g., weekly study time, motivations for pursuing higher education, and extracurricular activities), and general information (e.g., home address and commute time to school).

## II. Related Work

In the realm of educational institutions, a multitude of researchers have utilized statistical techniques and machine learning algorithms to predict student performance. In their study, Bharadwaj et al. [19] utilized data from a past student database, incorporating variables such as student attendance, class participation, seminar involvement, and assignment scores to anticipate semester-end outcomes. Their findings indicated that decision tree analysis yielded the highest accuracy, followed by K-nearest neighbor (KNN) classification [20], whereas Bayesian classification systems displayed the lowest accuracy. Ogunde et al. [21] undertook the development of a system that utilizes the decision tree technique known as Iterative Dichotomiser (ID3) and input data to predict grades. As per the authors, their approach has the potential to be highly efficient in predicting students' ultimate graduation levels. Duzhin and Gustafsson [22] introduced a machine-learning technique to take into account students' prior knowledge. Their method is based on symbolic regression and utilizes historical university scores as non-experimental input data. This classification approach holds promise for assisting the Ministry of Education in improving student performance through early performance predictions. Naïve Bayes [23] exhibits characteristics of conditional independence, making it skilled at determining class conditional probabilities. In their work, Watkins et al. [24] unveiled an approach called SENSE (Student Performance Quantifier using Sentiment analysis) to improve the content of secondary school reports by utilizing natural language processing. Sentiment analysis [25] can have a significant role in influencing student performance.

Table I shows the limitations and proposed solutions of the mentioned literature.

TABLE I. LIMITATIONS AND PROPOSED SOLUTIONS OF MENTIONED WORKS OF LITERATURE

| Study | Limitations | Proposed Solutions |
|---|---|---|
| Bharadwaj et al. [19] | Limited scope of variables, potential bias in data | Expand variable inclusion, employ diverse data sources |
| Ogunde et al. [21] | Dependency on the decision tree technique ID3 | Explore alternative machine learning algorithms |
| Duzhin and Gustafsson [22] | Reliance on historical university scores as input data | Incorporate additional non-experimental input data sources |
| Watkins et al. [24] | Emphasis on secondary school reports, potential bias | Explore the integration of diverse data types and sources |

These limitations underscore the need for a more comprehensive and diverse approach to predicting student performance. To overcome these gaps, the current research introduces substantial variations of RFC algorithms. This approach aims to address the limitations identified in prior studies by incorporating a broader set of variables, exploring alternative machine learning algorithms, and diversifying input data sources. By taking these proposed solutions into account, the present study strives to provide a more robust and nuanced prediction model for student performance in the specific context of secondary school education statistics. This acknowledgment and proposed strategy not only build upon the existing body of knowledge but also pave the way for a more comprehensive and effective approach to addressing the limitations identified in previous research.

Nevertheless, there have been limited attempts to apply classification algorithms within the context of secondary school education statistics. In this research, substantial variations of Random Forest Classification (RFC) classification algorithms have been included to assist educators and parents in predicting the performance of new students and improving next year's outcomes. Additionally, to ensure the utmost reliability in the results, both Victoria Amazonia Optimization (VAO) and Phasor Particle Swarm Optimizer (PPSO) techniques were integrated, leading to the attainment of promising outcomes.

In the subsequent sections, the manuscript navigates through the intricacies of the dataset and methodology, providing a comprehensive understanding. It details the dataset's source, size, and preprocessing steps, highlighting key variables chosen for analysis. The methodology section explains the utilization of the RFC and the integration of VAO and PPSO, introducing a distinctive dual-optimizer approach. The results section presents findings through tables or figures, accompanied by a thorough discussion of evaluation metrics, including Accuracy, Precision, Recall, and F1-score. The analysis extends to comparing different models or variations within the methodology and interpreting results in the context of research questions and existing literature. The conclusion synthesizes key findings, discusses practical implications for educational institutions, acknowledges study limitations, and suggests future research directions. Together, these sections contribute to a coherent narrative, guiding readers through the research process and providing valuable insights into predictive analytics in the context of education.

## III. DATASET AND METHODOLOGY

### A. Data Gathering

Within this research, a dataset pertaining to education was employed, encompassing 33 distinct attributes thoughtfully selected to provide a precise depiction of students' performance during their academic journey, considering their individual information and circumstances [26]. This dataset compilation was achieved by integrating data obtained from two questionnaire methods and the academic records of the students.

These attributes encompass various aspects related to students, including demographic factors like gender, age, school attended, and type of residence (address). Additionally, they encompass parental characteristics such as parents' cohabitation status ($Pstatus$), educational background, and occupation ( $Medu$ , $Mjob$ , $Fedu$ , $Fjob$ ). The student's guardian, household characteristics such as family size (famsize), the quality of family relationships (famrel), and other characteristics such as the reason for choosing the school (reason), the time it takes to commute to school ($traveltime$), the amount of time spent studying each week ($studytime$), previous academic setbacks (failures), involvement in extracurricular activities (activities), attendance in paid classes ($paidclass$), internet accessibility (internet), attendance in nursery school (school), ambitions for higher education (higher), romantic relationship status (romantic), free time availability after school ($freetime$), socializing preferences (go out), alcohol consumption during working days ($Dalc$) and weekends ($Walc$), as well as the current health status of the individual (health), the reason for school choice (reason), participation in supplementary educational programs ($schoolsup$), family educational support (famsup). Together with this, 3 other features—Grade 2 (G2), Grade 1 (G1), and Final—display students' grades for each of their three educational assessment periods. The values range from zero, which represents the lowest grade, to twenty, which represents the greatest grade. G3 is the pupils' final grade. As model outputs (dependent variables), these three characteristics were chosen together with the absence number from school. In order to assign grades, the students were split into four groups: 0-12: Subpar; 12-14: Tolerable; 14–16: Good; and 16–20: Outstanding.

In Fig. 1, as anticipated, the cells along the central axis appear in red, indicating a correlation value of 1. The three characteristics, G1, G2, and final, which are all dependent variables and correlate to students' grades, show the highest correlation values among themselves, as seen in the previously mentioned figure.

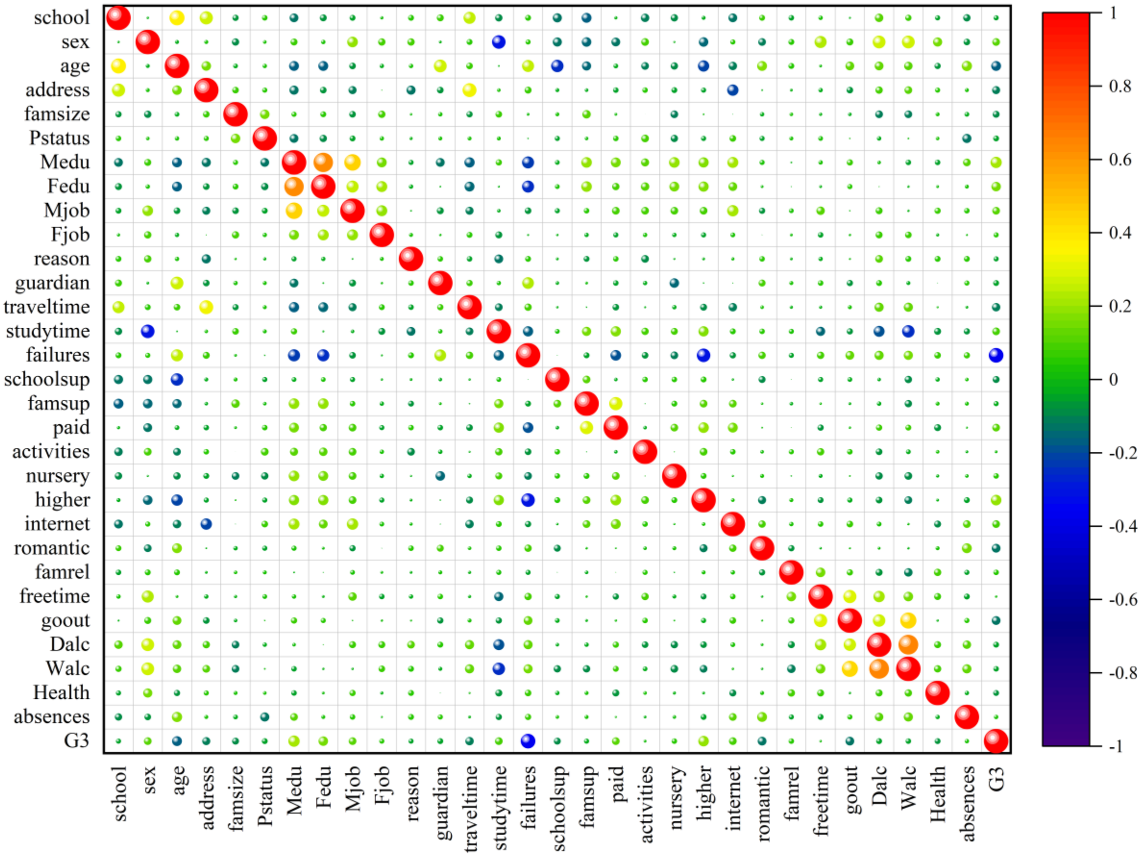

Fig. 1. Correlation matrix for the input and output variables.

## B. *Random Forest Classifier (RFC)*

Breiman's suggested random forest model [27] is composed of a collection of tree predictors. Each tree is constructed following the procedure below:

*1) In* the bootstrap phase, a local training set is created by randomly selecting a subset from the training dataset [28]. The remaining samples in the training dataset are designated as the out-of-bag (OOB) set, and they serve the purpose of evaluating the goodness-of-fit of the random forest model.

*2) In* the expansion phase, the tree's growth involves partitioning the local training set at each node based on a single variable's value. This variable is selected from a randomly sampled subset of variables, and the division, known as the optimal split, is determined using the Classification and Regression Tree (CART) method.

*3) Every* tree is allowed to grow to its maximum extent, with no pruning being employed.

The bootstrap and growth phases make use of random variables [29]. It is assumed that these variables are independent across different trees and follow an identical distribution. Consequently, each tree can be considered an independent sample drawn from the entire ensemble of tree predictors for a specific training dataset. During the prediction phase, an instance is processed through each tree within the forest until it reaches a terminal node that assigns it a class. The predictions from the trees are then subjected to a voting procedure, where the forest selects the class that receives the highest number of votes. In cases of ties, the final decision is made through a random selection. To introduce the feature contribution method in the upcoming section, a probabilistic interpretation of the prediction process in the forest needs to be established. The collection of classes is denoted as C = $\{C_1, C_2, ..., C_K\}$, and the set $\Delta_k$ is used to represent.

$$\Delta_k = \{(P_1, \dots, P_K) : \sum_{K=1}^{K} P_k = 1 \; and \; P_k \geq 0\} \quad (1)$$

An element in the set $\Delta_k$ can be seen as a probability distribution that covers the classes in C. Consider, for example, ek, an element in $\Delta_k$, where its value is 1 at position k, indicating that it is a probability distribution focused on class Ck. When a tree labeled as t predicts that an instance $i$ pertains to class Ck, express this as $\widehat{Y_{\iota,t}} = e_k$. This forges a link between the tree's predictions and the set $\Delta_k$, which denotes probability distributions across C.

$$\widehat{Y_k} = \frac{1}{T} \sum_{t=1}^{T} \widehat{Y_{\iota,t}} \quad (2)$$

Within this context, with T denoting the overall number of trees in the forest, the predicted value $\widehat{Y_k}$ falls within the set $\Delta_k$. The random forest's prediction, for instance, $i$ aligns with class Ck when the $k-th$ coordinate of $\widehat{Y_\iota}$ is the most substantial.

### C. Victoria Amazonica Optimization (VAO)

The VAO approach is primarily preoccupied with the dispersal of the initial populace, comprising both Leaves and Flowers and their respective potential to propagate or expand across the external façade [30]. The algorithm being examined is mainly characterized as a metaheuristic algorithm based on swarm local search. However, its sole drawback is its susceptibility to getting stuck in local optima. Moreover, it demonstrates exceptional speed and robustness, rendering it extremely well-suited for a wide spectrum of optimization challenges. The present study utilizes the scientific nomenclature, $\xi$, to depict the circular expansion of the entity's diameter as it grows circularly. The augmentation, as mentioned earlier, is succeeded by the quantum of the geographical area that they could potentially acquire through the exertion of physical force on fellow entities, driven by their augmenting potency and thorny projections. The aforementioned competition is commonly known by its designations of intra-competition or Γ for the formulation.

Furthermore, there exist three commonly encountered obstacles that impede the growth of vegetation. The mortality of beetles within the floral structure, inadequate or absent pollination by beetle species, and a reduction in ambient temperature are factors that contribute to suboptimal reproductive success in plants. All of the constituents mentioned above can exert negative effects on the given procedure, and collectively, they are denoted as $\varphi$ herein. A higher value of the parameter ω corresponds to a plant with less vigor. Pests, such as water lily Aphids, have the potential to inflict damage upon the plant by feeding on its leaves and resulting in the formation of perforations. The symbol denoted by Θ is deemed representative of the hazard quotient in the present exposition. The conditions for plant growth and expansion become increasingly favorable as the value of Θ decreases.

Subsequently, the occurrence of mutation arises as a result of cross-pollination between the beetles within the pond and a distinct variety of water lilies. The present phenomenon is denoted as Hybrid Mutation and is symbolized by the $\eta$. As posited in [30], this alteration has the potential to manifest in either a positive or negative trajectory, with an incidence of 0.2% for each succession of offspring. The optimal leaf specimen can be delineated by its superior size and robust physical attributes, designated as α. Moreover, the VAO algorithm is delineated below in the pseudo-code form.

$$VOA = \sum_{i=1}^{n} \sum_{j=1}^{n} (xij[\xi ij, \Gamma\text{ij}] + \Theta + \varphi) \times (\eta) \quad (3)$$

Algorithm 1 pseudo code of VOA

```
Start
Developing population of plants $xi$ ($i = 1,2, \dots, n$)
Determine Expansion $\xi i$ in $xi$
Determine Intra Competition Γi in $xi$
Determine the Drawback coefficient of $\varphi$ in xi (random range in [0.1 to 0.3])
Determine the Drawback coefficient of Θ in xi (random range in [0.1 to 0.3])
Determine Hybrid Mutation Rate of $\eta = 0.2$
While Max iterations are not satisfied
For $i = 1 \; to \; n$ plants
For $j = 1 \; to \; n$ plants
If $\xi i > \xi j \; or$ Γi > Γj for $xi$ ($i = 1,2, \dots, n$)
Plant i goes planet j
End if
Apply hybrid mutation $\eta$
Apply Drawback coefficient $\varphi$ and Θ
Evaluate new solutions by cost function and update expansion
End
End
Sort and rank plants and find the current global best
Developing new generation
End of while
End
```

### D. Phasor Particle Swarm Optimization (PPSO)

*1) The parameter's setting:* In consideration of the enhanced PSO algorithms utilized in prior research, the regulation and guidance of a system or process can be achieved through the implementation of appropriate control methods. A range of strategies must be included in the PSO parameters in order to properly optimize a specific issue. The objective of this work is to improve the efficiency of optimization in order to increase the convergence capabilities [31]. The PPSO generates PSO control parameters by using suitable and efficient phasor angle functions to achieve the aforementioned goals. To effectively implement a range of strategies in PPSO, an individual scalar phasor angle is assigned to each particle. These phasor angles are used to describe the PSO control parameters using mathematical functions that include both cos and sin. $\overrightarrow{X_\iota} \angle \theta_i$, where $\theta_i$ is the phasor angle and ($\overrightarrow{X_\iota}$) is the magnitude vector used to represent the ith particle as an example.

The PSO-TVAC in [32] and a contemporary PSO-TVAC [33] are similar in that their inertia weight values are zero. Below is an outline of the suggested particle movement model for PPSO. Still, this technique may be improved by combining ideas from other enhanced PSO techniques.

$$V_i^{it} = p\left(\theta_i^{it}\right) \times \left(pbest_i^{it} - x_i^{it}\right) + g\left(\theta_i^{it}\right) \times \left(Gbest_i^{it} - x_i^{it}\right) \quad (4)$$

After examining several $g\left(\theta_i^{it}\right)$ and $p\left(\theta_i^{it}\right)$ functions, the PPSO algorithm selected the following functions.

$$p\left(\theta_i^{it}\right) = \left|cos\theta_i^{it}\right|^{2\times sin\theta_i^{it}} \quad (5)$$

$$g\left(\theta_i^{it}\right) = \left|sin\theta_i^{it}\right|^{2\times cos\theta_i^{it}} \quad (6)$$

The proposed functions, which depend solely on the phasor angles of the particles, can enable behaviors such as reversal of values, simultaneous increase or decrease of values, reaching of large values, and attainment of identical values. The aforementioned behaviors give rise to adaptive search traits, promoting a balance between local and global searches. Consequently, PPSO is an adaptive and non-parametric algorithm that excels at evading local optima and circumventing premature convergence, a shortcoming often associated with the PSO.

*2) Formulation of PSO:* The velocity of individual particles is computed in every iteration of the algorithm utilizing the subsequent formula.

$$V_i^{it} = \left|cos\theta_i^{it}\right|^{2\times sin\theta_i^{it}} \times \left(pbest_i^{it} - x_i^{it}\right)$$
$$+\left|sin\theta_i^{it}\right|^{2\times cos\theta_i^{it}} \times \left(Gbest_i^{it} - x_i^{it}\right) \quad (7)$$

Then, the following equation is used to update the particle's position:

$$\vec{x}_i^{it+1} = \vec{x}_i^{it} + \vec{V}_i^{it} \quad (8)$$

Afterward, in a manner similar to the traditional PSO method, the locations of the Global Best (Gbest) and Personal Best (Pbest) are determined.

Subsequently, an update will be made to the particles' maximum velocities and phasor angles as follows:

$$\theta_i^{it+1} = \theta_i^{it} + T(\theta) \times (2\pi)$$
$$= \theta_i^{it} + \left|\cos(\theta_i^{it}) + \sin(\theta_i^{it})\right| \times (2\pi) \quad (9)$$

$$V_{i,max}^{it+1} = W(\theta) \times (X_{max} - X_{min})$$
$$= \left|cos\theta_i^{it}\right|^2 \times (X_{max} - X_{min}) \quad (10)$$

It should be noted that the empirical formulae used in Eq. (4) to Eq. (7) and Eq. (8) to Eq. (10) were selected after a wide range of functions were tested. It would be impossible to list every function that was evaluated for this reason because there were so many of them.

### E. Performance Criteria

When evaluating classifier performance, there exists a variety of evaluation criteria. Accuracy, a widely used measure, evaluates classifier effectiveness by determining the percentage of correctly predicted samples. In addition to Accuracy, Precision and Recall are commonly used metrics. Recall calculates the ratio of correctly predicted positive instances to the total actual positive instances, while precision assesses the probability of positive predictions being correct. Combining Precision and Recall results in a composite metric called the F1-score.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (11)$$

$$Precision = \frac{TP}{TP+FP} \quad (12)$$

$$Recall = TPR = \frac{TP}{P} = \frac{TP}{TP+FN} \quad (13)$$

$$F1\ score\ = \frac{2\times Recall \times Precision}{Recall+Precision} \quad (14)$$

In these formulas, TP represents a positive prediction that matches the actual positive outcome. FP signifies a positive prediction when the actual outcome is negative. TN denotes a negative prediction that aligns with the actual negative outcome. FN stands for a negative prediction when the actual outcome is positive.

## IV. Result and Discussion

### A. Convergence

The suggested models' convergence curve is shown in Fig. 2, which provides a visual depiction of the algorithm's development in the direction of its goal. This curve delineates the accuracy performance metric against the number of iterations, unveiling crucial insights into the optimization process. The curve's shape and behavior become instrumental in gauging convergence efficiency; a steep descent signifies rapid convergence, while plateaus or erratic fluctuations may indicate challenges in reaching the optimal solution.

Convergence curves serve as pivotal tools in evaluating algorithm performance, refining parameters and comprehending the trade-offs between speed and accuracy in diverse computational tasks. Within this context, Fig. 2 specifically examines and illustrates the convergence curves of RFC+VAO and RFC+PPS. Notably, the accuracy curve of RFC+VAO commences from a more advantageous point compared to RFC+PPS and achieves its optimal result more swiftly. This observation implies that RFC+VAO outperforms RFC+PPS as iterations progress, suggesting its superior convergence efficiency in this computational task.

### B. Comparison of Developed Models

The results in Table II reveal the performance metrics of the presented models, including RFC+VAO, RFC+PPS, and RFC, based on various index values: Accuracy, Precision, Recall, and F1-Score. These metrics are crucial for assessing the models' effectiveness in predicting student performance. RFC+VAO achieves an impressive accuracy of 0.934, indicating its correct predictions of student performance in the majority of cases. With a precision score of 0.940, it demonstrates a high level of precision, suggesting accurate predictions when it anticipates student success. The recall value of 0.930 shows that the model effectively identifies a substantial portion of students who will perform well. The F1-Score of 0.930 underscores its effectiveness in achieving a balance between precision and recall.

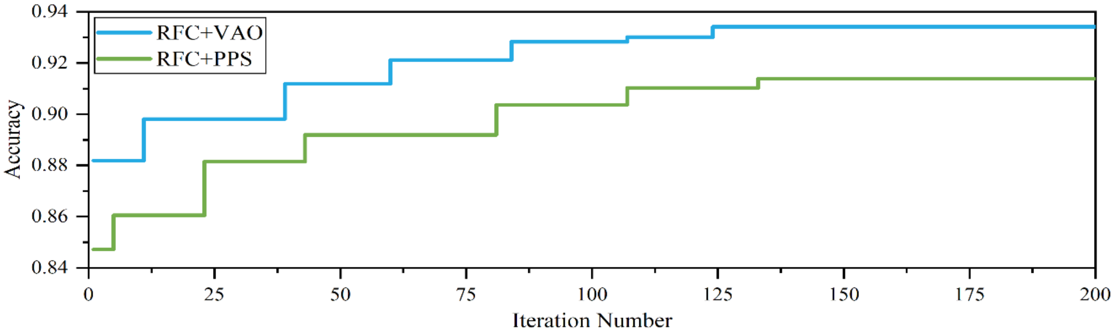

Fig. 2. Convergence curve of hybrid models.

In comparison, RFC+PPSO exhibits a respectable accuracy of 0.914, implying its effective performance in predicting student success. It achieves a precision score of 0.910, indicating a solid ability to make accurate predictions. With a recall value of 0.910, RFC+PPS effectively identifies a substantial portion of students who will perform well, although slightly lower than RFC+VAO. The F1-Score of 0.910 showcases RFC+PPS's ability to maintain a good balance between precision and recall. As for RFC, without the additional optimizers, it still demonstrates a reasonable accuracy of 0.889. With a precision value of 0.890, RFC maintains a good level of precision. The recall value of 0.890 indicates its effectiveness in identifying students with good performance, although slightly lower than RFC+VAO. The F1 Score of 0.890 underscores RFC's balanced performance between precision and recall.

In summary, the results in Table II highlight the positive impact of incorporating optimization techniques, such as VAO and PPS, into the Random Forest Classifier (RFC). RFC+VAO outperforms RFC+PPS and RFC in all metrics, showcasing its effectiveness in predicting student performance. The high precision and recall values for RFC+VAO and RFC+PPS indicate their potential for early identification of students who may excel, which is crucial for educational institutions aiming to provide timely guidance and support to improve overall academic performance.

TABLE II. RESULT OF PRESENTED MODELS

| Model | Index values | | | |
|---|---|---|---|---|
| | *Accuracy* | *Precision* | *Recall* | *F1 _core* |
| RFC+VAO | 0.934 | 0.940 | 0.930 | 0.930 |
| RFC+PPS | 0.914 | 0.910 | 0.910 | 0.910 |
| RFC | 0.889 | 0.890 | 0.890 | 0.890 |

Table III presents a thorough evaluation of the developed models' performance based on various grade categories, namely Excellent, Good, Acceptable, and Poor. The models, including RFC+VAO, RFC+PPSO, and RFC, are assessed in terms of Precision, Recall, and F1-score for each category. For RFC+VAO, the "Excellent" category reveals a precision of 0.97, while the recall is 0.82, resulting in an F1-score of 0.89. In the "Good" category, the model shows a precision of 0.87 and a recall of 0.90, leading to an F1-score of 0.89, indicating a well-balanced prediction. The "Acceptable" category exhibits a precision of 0.83 and a recall of 0.89, resulting in an F1-score of 0.86. In the "Poor" category, the model performs exceptionally well with a precision and recall of 0.97, yielding an F1-score of 0.97, highlighting its high accuracy.

Turning to RFC+PPS, the "Excellent" category displays a precision of 0.91 and a recall of 0.80, resulting in an F1 score of 0.85. In the "Good" category, it achieves a precision of 0.81 and a recall of 0.87, leading to an F1-score of 0.84. For the "Acceptable" category, the model has a precision of 0.82 and a recall of 0.81, resulting in an F1-score of 0.81. Similar to RFC+VAO, in the "Poor" category, it attains a precision and recall of 0.97, resulting in an F1-score of 0.97. As for RFC, it exhibits a precision of 0.82 and a recall of 0.78 in the "Excellent" category, resulting in an F1 score of 0.79. In the "Good" category, it has a precision of 0.80 and a recall of 0.80, leading to an F1-score of 0.80. For the "Acceptable" category, it showcases a precision of 0.73 and a recall of 0.84, resulting in an F1-score of 0.78. In the "Poor" category, it attains a precision of 0.97 and a recall of 0.94, resulting in an F1-score of 0.96. These results offer a detailed breakdown of the performance of each model across different grade categories. RFC+VAO and RFC+PPS consistently outperform RFC, particularly in the "Excellent" and "Good" categories, where they exhibit higher precision and recall values, signifying the positive impact of optimization techniques on accurate grade-level predictions.

To comprehensively evaluate the model's proficiency in predicting student performance and facilitate meaningful comparisons, Fig. 3 presents a column chart representing the four grades under consideration. This visual representation provides a clear indication of which model closely aligns with the measured values for each grade, thereby highlighting superior performance.

Upon examination of accuracy, both hybrid models, RFC+VAO and RFC+PPS, stand out by correctly predicting 227 out of 233 instances, while RFC closely follows by predicting 220 instances. In the categories of "Acceptable" and "Good" grades, the models demonstrate comparable performance, with RFC+VAO showing a slight edge in both instances. However, in predicting "Excellent" grades, all models perform closely, with RFC+VAO exhibiting a slightly superior performance.

This visual assessment not only aids in discerning the models' accuracy across different grade categories but also emphasizes the nuanced distinctions in performance, particularly highlighting the marginal superiority of RFC+VAO in certain instances.

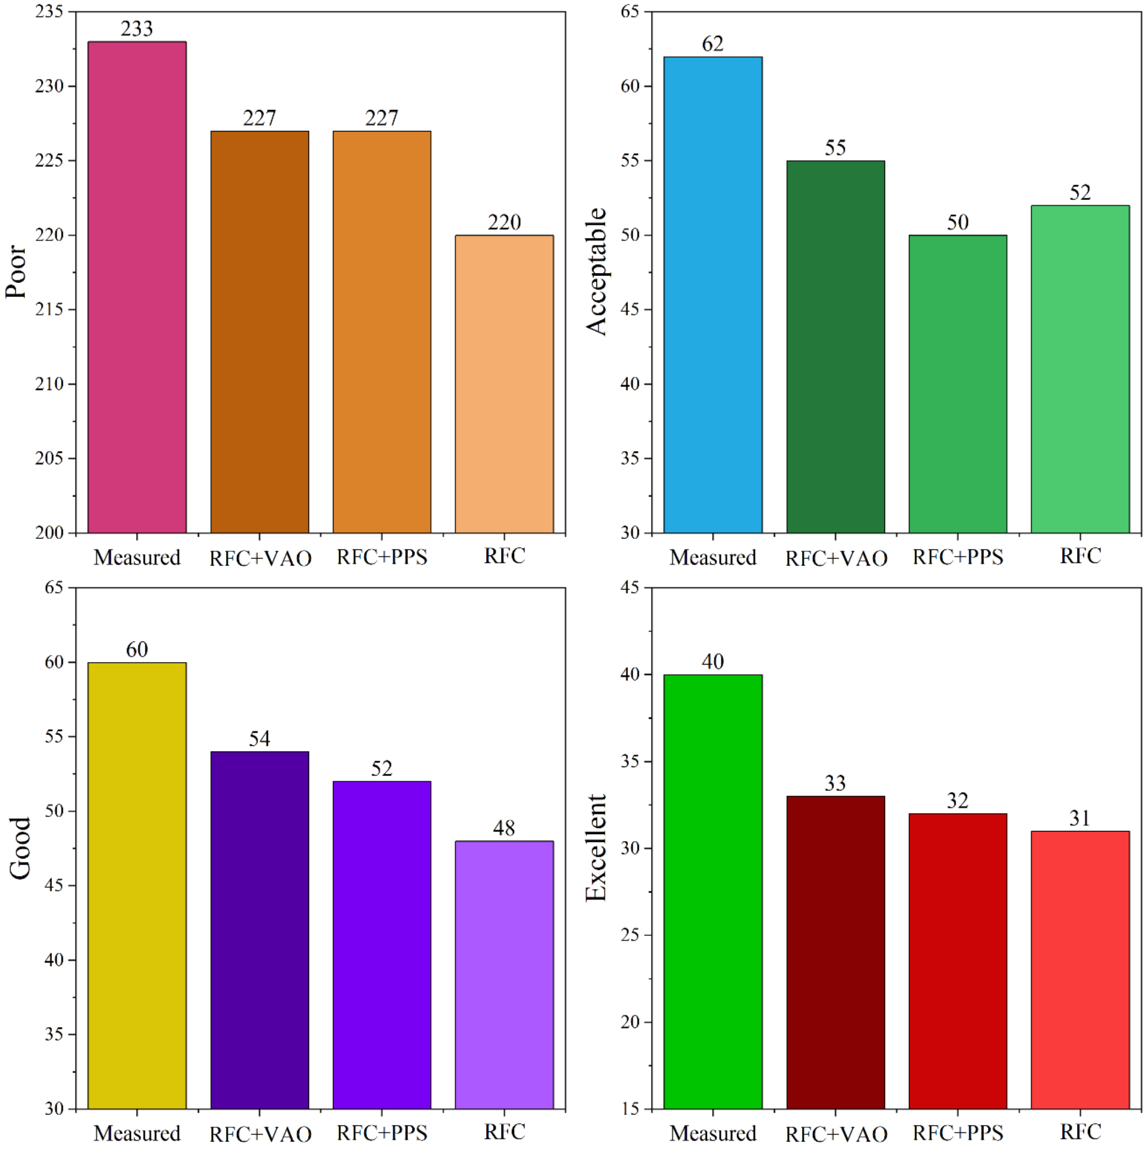

Fig. 3. A column chart displaying the association between the observed and anticipated values.

TABLE III. PERFORMANCE EVALUATION INDICES FOR THE DEVELOPED MODELS BASED ON GRADES

| **Model** | **Grade** | **Index values** | | |
|---|---|---|---|---|
| | | ***Precision*** | ***Recall*** | ***F1-score*** |
| RFC+VAO | Excellent | 0.97 | 0.82 | 0.89 |
| | Good | 0.87 | 0.9 | 0.89 |
| | Acceptable | 0.83 | 0.89 | 0.86 |
| | Poor | 0.97 | 0.97 | 0.97 |
| RFC+PPS | Excellent | 0.91 | 0.8 | 0.85 |
| | Good | 0.81 | 0.87 | 0.84 |
| | Acceptable | 0.82 | 0.81 | 0.81 |
| | Poor | 0.97 | 0.97 | 0.97 |
| RFC | Excellent | 0.82 | 0.78 | 0.79 |
| | Good | 0.8 | 0.8 | 0.8 |
| | Acceptable | 0.73 | 0.84 | 0.78 |
| | Poor | 0.97 | 0.94 | 0.96 |

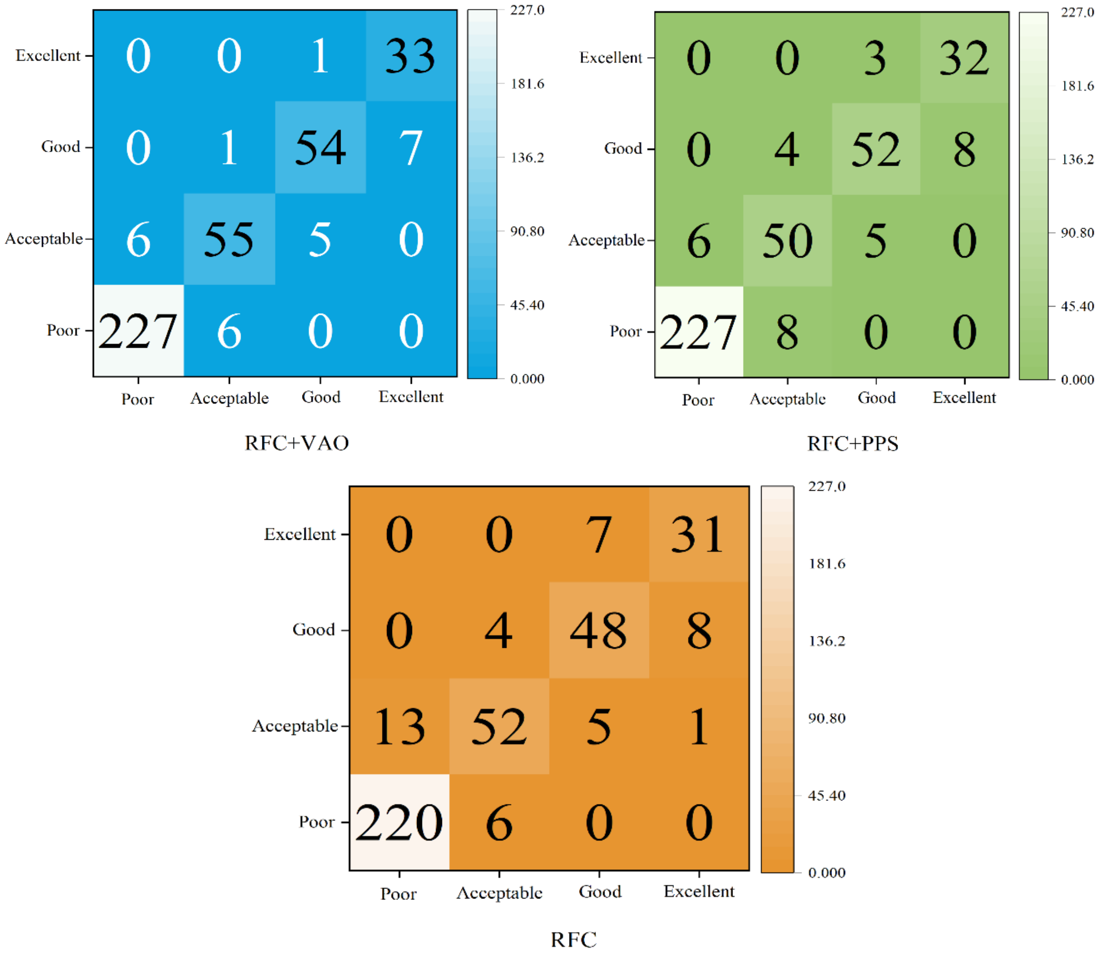

Fig. 4. Confusion matrix for each model's accuracy.

In Fig. 4, the confusion matrix visually depicts the relationship between observed and predicted classes, where the horizontal axis represents observed classes, and the vertical axis corresponds to predicted classes. Notably, the main diagonal cells in the matrix stand out with higher values, indicating successful predictions by the models.

Taking RFC+VAO as an example, it showcases a robust ability to predict the majority of observation classes accurately. For instance, in a scenario where 233 students were in the "Poor" class, RFC+VAO demonstrated a remarkable accuracy of 97.40%, accurately predicting 227 students. Merely six students were misclassified into the "Poor" category, underscoring the precision of the model.

This high precision extends to other classes as well, with accuracies of 88.70%, 90%, and 82.50% for the "Acceptable," "Good," and "Excellent" classes, respectively. It is worth noting that these figures, while slightly lower, distinguish RFC+VAO's performance from other model configurations.

Comparatively, RFC+PPS achieves accuracies of 97.40%, 80.64%, 86.66%, and 80% for the "Poor," "Acceptable," "Good," and "Excellent" classes, respectively. Meanwhile, RFC delivers accuracies of 94.42%, 83.87%, 80%, and 77.5% for the same classes. This comprehensive breakdown offers a nuanced understanding of the models' predictive performance across various classes, emphasizing RFC+VAO's notable precision and distinctions from other model configurations.

## V. Discussion

### A. Future Study

In future research, there are several key directions for enhancing predictive modeling in academic settings. The refinement of optimizers, specifically the VAO and PPSO techniques, should involve further fine-tuning to optimize their predictive performance. Additionally, the integration of additional data sources, such as socio-economic factors, health records, or extracurricular activities, is recommended to enrich the model and improve predictive accuracy.

A crucial aspect is the suggestion to conduct a longitudinal analysis, tracking academic trajectories over multiple semesters or years. This would provide insights into the model's stability and its ability to adapt to changes in student performance patterns over time. Lastly, a comparative analysis with other optimization algorithms would contribute valuable insights into the relative efficiency and effectiveness of the proposed VAO and PPSO optimizers within the educational data analytics context.

### B. Limitations

The study acknowledges its focus on secondary school education statistics, cautioning against the direct generalization of findings to other educational systems due to potential variations in structures and demographics. The dependence on dataset availability and quality is recognized, emphasizing the need to address biases in data collection for robust outcomes. The study also acknowledges the sensitivity of machine learning algorithms to parameter changes and advocates for sensitivity analyses to assess the model's robustness. Ethical considerations, including transparency, fairness, and accountability, are highlighted to ensure the responsible and ethical deployment of predictive analytics in education. Overall, these considerations contribute to a nuanced understanding of the study's limitations and underscore the importance of ethical and context-aware applications of predictive models in diverse educational contexts.

### C. Comparison with Papers

Table IV compares the present research paper with previously published studies, focusing on the predictive models and their respective accuracy levels. The present paper employs a RFC with VAO, achieving a notable accuracy of 93.4%. In contrast, previous studies predominantly used DTC or NBC and reported lower accuracy levels ranging from 69.94% to 82%. The methodological advancement in the present paper, incorporating VAO, suggests a promising improvement in predictive accuracy, with potential implications for more precise student performance predictions in educational settings.

TABLE IV. COMPARISON BETWEEN THE PRESENTED AND PUBLISHED PAPERS

| Article | Model | Index values |
|---|---|---|
| | | *Accuracy* |
| Edin Osmanbegovic et al. [34] | NBC | 76.65% |
| Kabakchieva [35] | DTC | 72.74% |
| Nguyen and Peter [36] | DTC | 82% |
| Bichkar and R. R. Kabra [37] | DTC | 69.94% |
| Present paper | RFC+VAO | 93.4% |

## VI. CONCLUSION

In this extensive study, the focus was on predictive modeling for student performance using a dataset derived from the educational landscape. The goal was to enhance the predictive accuracy of the Random Forest Classifier (RFC) by integrating innovative optimization techniques, namely, Victoria Amazonia Optimization (VAO) and Phasor Particle Swarm Optimizer (PPS). The results shed light on the effectiveness of these models in predicting student performance across various grade categories. The analysis revealed that both RFC+VAO and RFC+PPS models consistently outperformed the standard RFC. This superiority was evident not only in predicting student grades but also in distinguishing between different academic performance levels. RFC+VAO and RFC+PPS consistently exhibited higher precision, recall, and F1 scores, particularly in the "Excellent" and "Good" grade categories. This underscores the impact of optimization techniques in improving model accuracy and their potential to enhance student support systems. The models excelled in identifying students falling within the "Excellent" and "Good" grade categories, which is vital for educational institutions aiming to provide timely guidance and support for academic excellence. RFC+VAO, in particular, demonstrated a slight advantage in predicting "Excellent" grades, indicating the potential of the Victoria Amazonia Optimization technique in fine-tuning model performance. Furthermore, the confusion matrix in this analysis highlighted the models' proficiency in classifying observations, with the main diagonal consistently containing higher values, confirming the model's precision in predicting various class categories. In summary, this research underscores the promising potential of machine learning models, especially when combined with optimization techniques, in educational data analysis. It provides a foundation for institutions to utilize these models as valuable tools in student performance prediction and support systems. The accurate prediction of a student's academic trajectory benefits not only the students themselves but also empowers educational institutions to implement tailored strategies and interventions. As the educational landscape evolves, the integration of machine learning and optimization techniques will play a pivotal role in ensuring academic success for students, ultimately shaping a brighter future for the education sector. The findings presented in this article encourage further exploration and real-world testing to refine and optimize these models for effective utilization in educational institutions.

Department of Informatics, Institute of Informatics and Business Darmajaya Bandar Lampung, Indonesia[1, 2, 4]
Department of Data Science, Institute of Informatics and Business Darmajaya Bandar Lampung, Indonesia[3]

*Abstract*—**Degenerative diseases can impact individuals of any age, encompassing children and teenagers; however, they typically tend to affect productive or adult individuals. Globally, conventional and advanced diagnostic methods, including those developed in Indonesia, have emerged to identify and manage these health conditions. Problems in brain tumor detection are the intricate process of precisely and effectively identifying the presence of tumors in the brain. On the other hand, diagnosing brain tumors in the laboratory poses issues related to time consumption, inaccuracy, lack of consistency, and costliness. This study specifically concentrates on the early detection of brain tumors by analyzing images generated through MRI scans. Unlike the traditional method of manual image analysis conducted by seasoned physicians, our approach integrates fuzzy logic to enable the early identification of brain tumors. The principal objective of this research is to enhance understanding and develop an intelligent, swift, and precise application for diagnosing brain tumors using medical imaging. The segmentation technique provides practical technology for the early detection of brain tumors. Utilizing a dataset comprising over 13,000 data points and undergoing a year-long training process with approximately 1,310 MRI images, the research culminates in the creation of a tool or software application system for the analysis of medical images. Despite the impressive precision score of 0.9992, highlighting its exceptional accuracy in correctly identifying positive instances, the recall value of 0.5767 suggests the potential exclusion of a significant number of actual positive instances in its predictions.**

***Keywords—Degenerative diseases; brain tumor; fuzzy; deep learning***

## I. Introduction

A brain tumor is a severe medical condition that has an impact on the brain, considering the vital role of the brain as one of the essential organs in the body. Disruptions to the brain can have cascading effects on other organs, potentially resulting in fatal consequences. Although brain tumors can impact individuals of any age, including children and teenagers, they typically tend to affect productive or adult individuals [1], [2]. Moreover, as stated in study [3], significant advancements in medical science have introduced sophisticated diagnostic and treatment techniques, offering hope for the survival and improved outcomes of patients grappling with brain tumors. The primary concern for individuals diagnosed with brain cancer or brain tumors is the rate at which they may spread to other areas of the brain or spinal cord, and the potential for successful removal without subsequent recurrence.

Several factors that influence the prognosis (life expectancy) of individuals with brain tumors include the ability for early detection, an accurate understanding of the tumor's location in the brain, and the quality of diagnostic and therapeutic (surgical) technologies, such as Magnetic Resonance Imaging (MRI). Brain cancer arises from the abnormal proliferation of brain cells within brain tissue. There are two distinct types of brain cancer: benign (non-cancerous) and malignant (cancerous). Benign tumors do not have any adverse impact on healthy normal cells or brain tissue, while malignant tumors affect brain tissue and may lead to fatal consequences. Detecting brain cancer early typically involves the use of MRI, although radiologists may encounter challenges in precisely determining the cancer's location within the MRI image. In their study, researchers employed Laplacian of Gaussian filtering to enhance MRI images; achieving approximate 84% segmentation accuracy with the algorithm they devised [4].

As indicated in study [5], brain cancer or tumors can affect people of all age ranges and have the potential to impact the central nervous system. When tumor cells effectively invade the brain, they disturb all bodily functions, posing a substantial risk of mortality. Brain cancer or tumors can affect people of all age ranges and have the potential to impact the central nervous system. When tumor cells effectively invade the brain, they disturb all bodily functions, presenting a substantial risk of mortality. Brain tumors can manifest as either malignant or benign, and in certain instances, the prospects of recovery are minimal, ultimately leading to death. Early detection is crucial for obtaining accurate and precise results, necessitating the use of imaging technology to aid in the diagnosis, treatment, and surgical intervention for brain-related conditions. Moreover, it was stated that research were to provide early warnings to reduce mortality and develop precise and rapid methods for treating brain tumors. They used machine learning to classify malignant tumors, concluding that MML (Machine Learning) is superior to SVM (Support Vector Machine) in terms of PSNR, MSE, fault rate, and accuracy for brain cancer segmentation [6], [7], [8]. Hence, the findings of this study indicate that the integration of artificial intelligence and image processing yields superior outcomes in the segmentation and classification of brain tumors.

In the healthcare sector, computer vision, particularly image processing and segmentation, is widely employed within the realm of Information Technology (IT). Consequently, this research endeavors to create an application as well as proposed segmentation and deep learning methods. The utilized objects for this application are images extracted from photographs produced through MRI technology. Meanwhile, using image processing techniques [9], it is proposed that conducting statistical analysis, which involves parameters such as mean, standard deviation, and variance derived from object features in images, can offer insights into the state of a healthy or diseased brain. This is achieved by comparing the statistical values derived from images of normal brains with those displaying irregularities. In this research, our objective is to diagnose brain conditions through the application of segmentation and deep learning techniques, and we intend to evaluate the effectiveness of fuzzy deep learning methods in this regard. The developed application is expected to assist medical professionals, especially doctors, in analyzing diseases, particularly generative diseases, using medical MRI images accurately, quickly, and affordably. The urgency of this research lies in the current manual analysis of MRI images, which is not only less accurate but also time-consuming.

As indicated in study [8] SVM is considered one of the premier methods for analyzing image datasets. SVM (Support Vector Machine) generates predictions by reducing the image size while retaining essential information crucial for accurate predictions. The Kernel's model presented in this study achieves a testing accuracy of 98.75%, with the potential for improvement through the addition of more image data. Furthermore, an alternative model employing CNN integrates an automated feature extractor, modified hidden layer architecture, and activation function. Various test scenarios were executed, and the proposed model achieved a precision score of 97.8%, coupled with a low cross-entropy rate [10]

In research [11], the researchers focused on assessing the classification accuracy of cranial MR images using ELM-LRF, achieving a precision rate of 97.18%. The results suggest that the effectiveness of the proposed method exceeds that of recent studies documented in the literature. According to study [10], their proposed model surpasses existing models in accuracy, achieving 99.48% for binary classification and 96.86% for multi-class classification. In contrast to existing models that encounter difficulties such as substantial computational expenses and restricted generalizability attributed to insufficient training data, our model tackles these challenges by being lightweight, employing cross-validation for enhanced generalizability, and undergoing training on extensive and diverse datasets.

Presented by study [5] and utilizing deep learning algorithms with RG (Radiomics and Geometry) alongside MAKM (Multi-scale Anisotropic Kernels) and U-Neresults, three distinct experimental setups/cases were presented on the BRATS2015 dataset. The obtained experimental results yielded accuracy values of 89%, 90%, and 80% for case-1, case-2, and case-3, respectively.

The significance of Convolutional Neural Networks (CNNs) in image dataset analysis, emphasizing their efficiency in prediction and image size reduction. An Artificial Neural Network (ANN) achieves a testing accuracy of 65.21%, with potential for improvement through additional image data, was carried out in study [12]. CNN challenges through a lightweight approach and diverse dataset training. State-of-the-art deep learning algorithms demonstrate robust performance on the BRATS2015 dataset, achieving high accuracy values for various experimental setups, showcasing the versatility of the proposed methodologies. Hence, the cumulative accuracy of the preceding research is 89.83%.

This work introduces the Fuzzy Deep Learning Approach for the Early Detection of Degenerative Diseases. It represents a pioneering integration of fuzzy logic principles with deep learning techniques for disease detection. In contrast to conventional methods, this approach presents a nuanced and adaptive framework that considers uncertainties and imprecise information inherent in medical data. By amalgamating the strengths of deep learning, which excels in learning intricate patterns, with the flexibility of fuzzy logic to handle uncertainty, the model enhances the accuracy and interpretability of early degenerative disease detection. This innovative fusion addresses the inherent complexities and variations in degenerative diseases, offering a promising avenue for more effective and reliable diagnostic tools. The research contributes to advancing the field by presenting a novel and robust methodology that has the potential to revolutionize early disease detection strategies.

## II. Related Works

### *A. Degenerative Diseases*

The World Health Organization states that degenerative diseases are the leading cause of death worldwide in the population aged 65 and older, with a higher death toll in developing countries. According to study [13], an estimated 23% of women and 14% of men aged over 65 suffer from degenerative diseases. The global prevalence of hypertension is estimated to be around 15-20%, with a higher incidence in the age group of 55-64 years.

### *B. Image Segmentation*

Digital image segmentation involves the partitioning and categorization of components within an image into regions or zones that share homogeneity based on specific characteristics. Automated segmentation plays a crucial role in various image processing applications, including object recognition, by enabling the isolation of distinct areas in an image, thereby cutting down on processing time for relevant information, [14], [15]. Furthermore, [5], [16] delineates five primary strategies for image segmentation: thresholding techniques [17], boundary-based methods [18], region-based techniques, clustering-based approaches [19], and hybrid methods [20]. Seeded Region Growing segmentation who used by [5], [21], [22], is a hybrid technique. This method begins by selecting one or more seed pixels as the starting point, denoted as A1, A2, A3, ..., An. In each iteration, these seeds Ai expand to include the adjacent pixels x from the seed region Ai. The decision on whether the target feature is in the selected seed is made. For example, let T be all pixels or seeds that are not allocated (unlabeled) and located closest to Ai after m iterations, then:

$$T\{x \notin n\}Ai \cap n.Ai \ \neq \qquad (1)$$

In this case, N(x) refers to the second-order nearest neighbor (8-neighborhood) of pixel x. If the only intersection of N(x) is with region i, then the label L(x) is denoted by an index as specified in Eq. (2).

$$N\ (x)\ \cap Ai(x) \neq \emptyset \tag{2}$$

Stated by study [23] in specific cases, segmenting color images offers greater benefits compared to grayscale images because of the more extensive feature set present in color images. Color images represent each pixel through a combination of 224 color components of R, G, B, covering both chromatic and intensity aspects. Consequently, the segmentation of color images becomes more intricate. The term "image segmentation" pertains to the division of an image into distinct regions, with a region defined as a collection of pixels exhibiting specific boundaries and shapes, such as circles, polygons, and ellipses. Moreover in study [24], explain that segmentation has two main objectives: i) to divide the image into regions for further analysis, ii) to change the representation of an image. Pixels of an image must be organized into higher-level units that are more meaningful or meaningful for further image analysis. Meanwhile, states that regions contain groups of multispectral or hyperspectral image pixels with similar feature values. Most segmentation methods fall into three classes: (i) feature characteristic [25], (ii) boundary detection, or (iii) region growing.

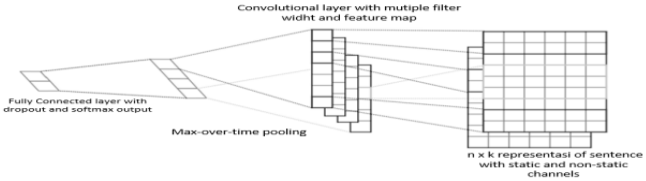
### C. Image Retrieval Issues

Various problems related to image search have attracted significant attention from researchers, including worked by [26], [27], [28]. Image search is a challenging task closely related to computer vision. Additionally, [26] states that the main problem in evaluating the effectiveness of a CBIR system is how users can clearly determine that the query photo is the same or similar to an image in the database.

### D. Deep Learning-based Image Segmentation

Deep learning addresses the limitations of traditional machine learning methods that can automatically engineer features, commonly referred to as feature engineering [11]. This capability is achieved through deep learning, utilizing algorithms that illustrate sophisticated abstractions within data. Deep learning relies on layers of nonlinear transformation functions arranged in intricate structures. Deep learning is applicable to various domains, including supervised learning, unsupervised learning, semi-supervised learning, and reinforcement learning, such as tasks like text classification, image recognition, speech recognition, and mor [19], [29].

CNN is a type of machine learning method commonly used in the visual-to-text field. It employs a convolutional layer as a component of a built neural network. The input sequence is padded with zeros to have the same length, enhancing performance by preserving information at the borders,[30] An overview of the CNN process structure is provided in Fig. 1.



Convolutional layer with mutiple filter widht and feature map
Fully Connected layer with dropout and softmax output
Max-over-time pooling
n x k representasi of sentence with static and non-static channels

Fig. 1. CNN process structure.

### E. Recurrent Neural Network

According to research [31] and [32], RNN is architecture comprises an input layer, one or more hidden layers, and an output layer. It features a sequential structure resembling a chain, with recurring modules serving as memory to retain crucial information from preceding steps. Additionally, RNN incorporates a feedback loop enabling the artificial neural network to process input sequences. Consequently, the output from step t-1 is reintroduced into the network, influencing the outcome of step t. Fig. 2 provides a basic depiction of the functioning of the RNN algorithm, involving one input unit, one output unit, and iteratively evolving hidden units.

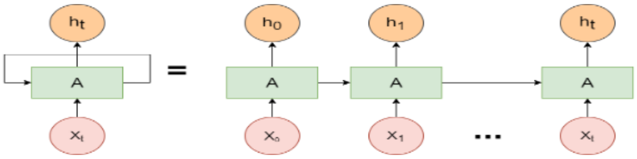


Fig. 2. Overview of how RNN works.

Previous studies have successfully implemented RNN for image processing, such as [33] , which successfully implemented LSTM-RNN for plant disease identification, [34], which successfully implemented Attention-Based RNN for plant disease detection, and [35], which used a variation of RNN, namely Dense RNN, for image segmentation of the heart. According to [36], an overall overview of the working mechanism of the RNN method, namely RNN-LSTM, can be seen in Fig. 1. Each LSTM cell receives information from the previous cell and then sends the obtained information to the next cell. Fig. 3 provides a depiction of how RNN-LSTM operates, demonstrating the sequential flow and interactions among input, output, and memory units within the Long Short-Term Memory (LSTM) architecture.

According to [37], LSTM has a memory cell and gate inputs (input gate, forget gate, cell gate, and output gate). In the forget gates, each incoming data is processed and then selected to be discarded or stored; in this gate, the activation function used is sigmoid (if the value is 1, the data is stored; if the value is 0, the data is discarded).

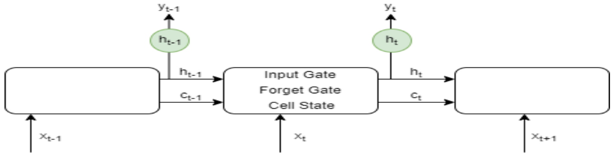

Fig. 3. Overview of how RNN-LSTM works.

Within the domain of computational procedures, the forget gate functions by employing Eq. (3).

$$it = \sigma(Wi[ht - 1, xt] + bi \tag{3}$$

$$Ct = \tanh(Wc.[ht - 1] + bc \tag{4}$$

Following that, a new value replaces the current memory cell value on the cell gate. This distinct value is obtained by combining the values acquired from the forget gate and the input gate, as specified in Eq. (4).

$$c_t = f_t * c_{t-1} + i_t * \hat{c}_t \tag{5}$$

Finally, on the output gate, a selection of the value from the memory cell is performed using the sigmoid activation function. The obtained value is then input into the memory cell using the tanh activation function, and the values from both processes are multiplied to produce the output value, as described in Eq. (6) and Eq. (7) in the output gate.

$$o_t = \sigma(W_o.[h_{t-1}, x_t] + b_o) \tag{6}$$

$$h_t = o_t \tanh(c_t) \tag{7}$$

### F. Fuzzy Logic

Fuzzy logic is a type of logic that has values between true or false, often referred to as fuzzy values or fuzziness. Fuzzy logic can simultaneously have true or false values, but it also has a membership degree ranging from 0 to 1 that determines the existence and accuracy of that value. Fuzzy logic translates a quantity represented using linguistic terms; for example, the speed of a car is represented as slow, moderately fast, fast, and very fast. Unlike classical logic, where a value has only two possibilities—either it is not a member of the set or if the membership degree is 0, or it is a member of the set if the membership degree is 1 [38], [39].

## III. Methods

In this section, the stages conducted in the research are explained. The preprocessing of MRI images involves resizing, followed by the conversion of color (RGB) images to grayscale. Subsequently, segmentation and deep learning with RNN are performed. An evaluation is then carried out to calculate the accuracy of the algorithm. The overall research stages can be seen in Fig. 4. While Fig. 5 showcase the application of a Recurrent Neural Network in analyzing MRI images that depict the processing of brain tumors.

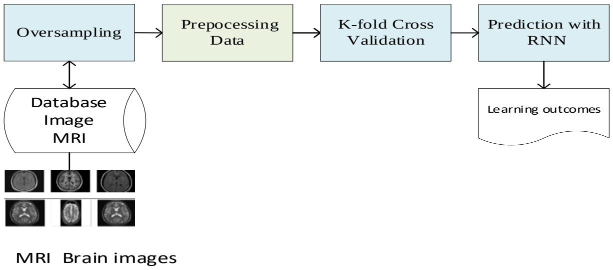

Fig. 4. Research stages.

Query Image contains a set of images for training data.

Pre-processing: Involves two stages for the training images—resizing to achieve uniformity and converting RGB images to grayscale. Cross-validation used to evaluate the performance of the model or algorithm, where data is divided into two subsets: the training process and validation/evaluation data. Learning implemented with the RNN algorithm, a class of artificial neural networks with connections forming a directed graph. RNN comes in different forms, including GRU (Gated Recurrent Units) and LSTM (Long Short-Term Memory Network), which contribute to improved performance. The RNN architecture consists of an input layer, one or more hidden layers, and an output layer. In this study, the RNN utilized is of the LSTM type.

With annotated training data, deep learning is conducted to recognize and identify regions in MRI images containing brain tumors. The learning process flow is depicted in the following diagram:

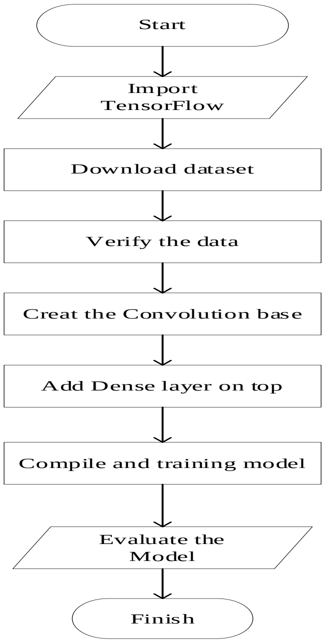

Fig. 5. A diagram illustrating the processing of brain tumor MRI images using a Recurrent Neural Network.

This research uses fuzzy c-means, where the dataset is divided into four clusters: glioma, meningioma, no tumor, and pituitary. The program flow consists of five stages: i) Input Dataset utilizes the OS and OPENCV libraries to process images; ii) Preprocessing involves normalization, data augmentation, and data grouping. Program steps include Image normalization, resizing images to a uniform size. Data augmentation to improve model performance Conversion to a NumPy array for model use Splitting the dataset into training and testing data. Modeling employs clustering with the Fuzzy C-Means (FCM) algorithm. Its stages include flattening Images which conversion of each image into a one-dimensional vector before using the clustering algorithm. Fuzzy C-Means Modeling uses the scikit-fuzzy library to determine FCM parameters and train the FCM model. Model evaluation calculates clustering quality using the Davies-Bouldin index, as clustering was performed earlier. Visualization of Results displays the FCM results plot.

## IV. Experimental Results and Discussion

### A. Experimental Results

The study utilized a collection of more than 13,000 brain MRI images, which included visuals illustrating conditions like pituitary, meningioma, glioma symptoms, as well as normal or healthy brain images. The dataset was obtained from a nearby public hospital. This work enabled the development of an early detection application for brain tumor diseases, functioning in the following manner: The outcomes reveal accuracy, precision, and recall values and identify the cluster to which the query image pertains.

Evaluating the performance of a classification model involves examining crucial metrics like precision and recall. In our findings, precision stands at an impressive 0.9992, signifying a high level of accuracy in the model's positive predictions. Conversely, a recall value of 0.5767 implies that the model may have overlooked a substantial portion of actual positive instances. To offer a more comprehensive assessment of the model's overall performance, we shift our focus to the F1-score. This metric, derived from the harmonic mean of precision and recall, acts as a balanced indicator that considers both false positives and false negatives. The calculation of the F1-score will further illuminate the harmony between precision and recall and offer a more nuanced perspective on the model's efficacy in making accurate positive classifications.

The findings presented herein reveal crucial metrics such as accuracy, precision, and recall, providing insights into the classification performance. These metrics not only offer a comprehensive evaluation of the model's predictive capabilities but also pinpoint the specific cluster to which the query image is assigned. By analyzing the accuracy, precision, and recall values, we gain a deeper understanding of the model's overall effectiveness in correctly categorizing images. These metrics serve as valuable indicators, shedding light on the model's ability to distinguish between different classes. Furthermore, the identification of the specific cluster to which the query image belongs adds a practical dimension to the assessment, aiding in the interpretation of the model's classification outcomes and their real-world implications.

The analyses presented demonstrate a collection of crucial metrics, each providing valuable insights into the effectiveness of the classification model. The accuracy, measured at 0.5767, reflects the overall correctness of the model's predictions. A precision value of 0.9992 underscores the model's capability to accurately identify positive instances among its predictions. However, the recall value of 0.5767 suggests that the model may have missed a significant portion of actual positive instances during its classification. In examining these metrics collectively, it becomes apparent that while the model excels in precision, its recall performance could be a point of consideration.

The balance between precision and recall is critical for a comprehensive evaluation of a classification model, and further analysis, such as the calculation of the F1-score, may provide additional insights into the model's overall effectiveness. The research results present the Structural Similarity Index (SSIM) for each symptom from the utilized dataset, and the SSIM for each cluster can be observed in Fig. 6, 7, 8, and 9.

Considering the metrics presented, it's clear that achieving a balance between precision and recall is crucial for a well-performing classification model. The high precision value of 0.9992 indicates a strong ability to correctly classify positive instances, minimizing false positives. However, the recall value of 0.5767 suggests that there is room for improvement in capturing the entirety of actual positive instances. Striking a balance between precision and recall is often necessary, depending on the specific requirements of the application. Some applications may prioritize precision, aiming to minimize false positives, while others may prioritize recall, aiming to capture as many positive instances as possible.

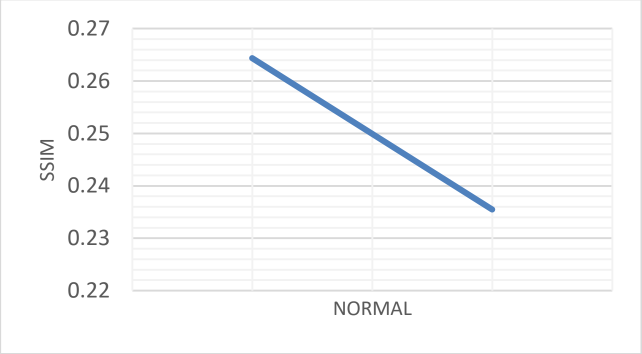

Fig. 6. SSIM normal brain cluster.

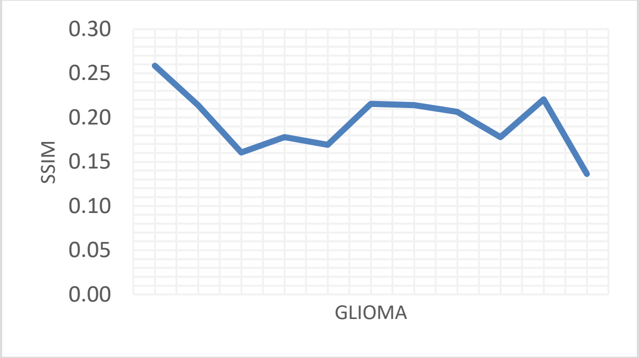

Fig. 7. SSIM glioma brain cluster.

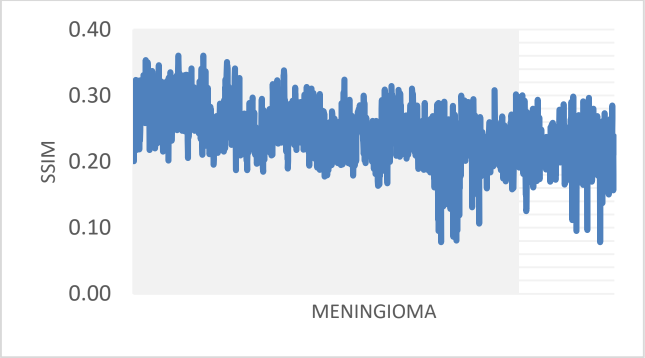

Fig. 8. SSIM meningioma brain cluster.

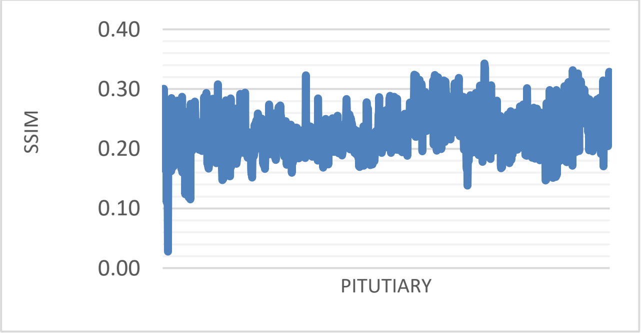

Fig. 9. SSIM pituitary brain cluster.

Furthermore, Fig. 5, 6, 7 and 8 shows that Structural Similarity Index (SSIM) scores indicate a relatively high similarity between the images in normal brain cluster. The SSIM values are close, suggesting consistency in the visual content of the images within this cluster. Cluster Glioma Various similarity scores ranging from 0.1161 to 0. 2614.The similarity scores in Clusters glioma are lower compared to Cluster normal. There is a range of values, indicating potential variability in visual content within this cluster. Some images may be less similar to others. Cluster meningioma Various similarity scores ranging from 0.0233 to 0. 1511. Similar to Cluster glioma, Cluster meningioma has a range of similarity scores, but the scores are generally lower. This suggests a higher diversity or dissimilarity in visual content within this cluster. Cluster pituitary similarity scores ranging from 0.1995 to 0. 2022.The similarity scores in Cluster pituitary are higher compared to Clusters glioma and meningioma but lower than Cluster normal. This cluster seems to have a more consistent level of similarity, though not as high as Cluster normal. Overall cluster normal appears to contain visually similar images with consistently high similarity scores.

### *B. Discussion*

To provide a more comprehensive assessment, it would be beneficial to calculate additional metrics such as the F1-score, which takes into account both precision and recall, offering a single value that considers the trade-off between these two metrics. This would help in gaining a more nuanced understanding of the model's overall effectiveness and guide potential adjustments to enhance its performance. The provided analyses reveal noteworthy metrics for the classification model. The precision, denoted as 0.9992, highlights the model's exceptional accuracy in correctly identifying positive instances. However, with a recall value of 0.5767, it appears that the model may have missed a substantial portion of actual positive instances during its predictions.

An insightful measure, the F1-score, provides a balanced evaluation by considering both precision and recall. In this context, the calculated F1-score of 0.7311 indicates the harmonic mean of precision and recall, showcasing the model's overall effectiveness in striking a balance between correctly identifying positive instances and minimizing false negatives. These results suggest a strong precision performance but also highlight the importance of addressing recall to ensure a more comprehensive and well-rounded classification model. Further examination and potential adjustments could enhance the model's ability to capture a greater proportion of positive instances while maintaining a high level of precision.

Table I presents an overview of various methods employed in the detection of brain tumors, highlighting their distinctive features and applications. The information is organized to facilitate a clear understanding of each method's strengths, limitations, and overall effectiveness in the realm of medical diagnostics. Starting with Magnetic Resonance Imaging (MRI), this non-invasive technique utilizes magnetic fields and radio waves to generate detailed images of the brain. Known for its high resolution, MRI is particularly effective in providing a comprehensive view for precise tumor detection.

TABLE I. COMPARISON METHODS FOR BRAIN TUMOR DETECTION

| No. | Method | Accuracy (%) |
|---|---|---|
| 1. | Fuzzy Deep learning (propose work) | 99.92 |
| 2. | Convolutional Neural Network [12] | 89.83 |
| 3. | ELM-LRF, [11] | 97.18 |
| 4. | Support Vector Machine [8] | 98.75 |
| 5. | RG -MAKM [5] | 90.00 |

Whilst. the precision of 0.9992 signifies a high accuracy in positive predictions, the recall of 0.5767 points towards a potential improvement in capturing all actual positive instances. The F1-score, as a combined metric, accentuates the need for a balanced approach, yielding a value of 0.7311. These findings prompt a closer examination of the model's performance trade-offs between precision and recall. Depending on the specific objectives and requirements of the application, adjustments may be considered to optimize the model's balance between minimizing false positives and capturing a more comprehensive set of positive.Clusters glioma and meningioma exhibit more variability, with a range of similarity scores indicating diverse visual content. Cluster pituitary shows a moderate level of comparison, but not as high as Cluster normal. It's important to note that the interpretation of these scores depends on the specific context of your analysis and the nature of the images in each cluster.

## V. CONCLUSION

In conclusion, the model's elevated precision value of 0.9992 signifies its remarkable accuracy in predicting positive instances, with a minimal likelihood of false positives. However, the relatively lower recall value of 0.5767 raises concerns about potential oversights in identifying actual positive instances, resulting in false negatives. To comprehensively evaluate the model's performance, the F1-score is crucial, as it takes into account the nuanced equilibrium between precision and recall, addressing the implications of both false positives and false negatives.. While the model demonstrates outstanding precision, evaluating the F1-score will offer a nuanced perspective on its overall accuracy, shedding light on the interplay between precision and recall and providing valuable insights for optimal performance in classifying positive instances.

Future works will be addressing the nuanced aspects revealed by the model's precision and recall metrics should be a priority. Researchers can focus on enhancing the recall value to minimize oversights in identifying actual positive instances, possibly through the refinement of model architecture or the incorporation of additional features. Exploring ensemble methods or hybrid models, such as Fuzzy-RNN and Fuzzy-CNN that leverage the strengths of different algorithms may also contribute to achieving a more balanced precision-recall trade-off. Additionally, investigating the impact of varying thresholds on precision and recall and optimizing these thresholds for specific use cases could lead to improvements in overall model performance. Continuous refinement and fine-tuning, guided by the F1-score as a comprehensive evaluation metric, will be essential to ensure the model's robustness in real-world applications, providing a more holistic perspective on its accuracy and effectiveness in classifying positive instances while mitigating the risks of both false positives and false negatives.

## ACKNOWLEDGMENT

The authors express their gratitude to the Minister of Science and Technology, The Republic of Indonesia, for providing full funding through the Competitive Applied Research scheme. This research received support from the Ministry of Research and Technology, the Republic of Indonesia.

***Abstract*—This investigation presents a novel technique for offline author identification using handwriting samples across diverse experimental conditions, addressing the intricacies of various writing styles and the imperative for organizations to authenticate authorship. Notably, the study leverages inconsistent data and develops a method independent of language constraints. Utilizing a comprehensive dataset adhering to American Society for Testing and Materials (ASTM) standards, a deep convolutional neural network (DCNN) model, enhanced with pre-trained networks, extracts features hierarchically from raw manuscript data. The inclusion of heterogeneous data underscores a significant advantage of this study, while the applicability of the proposed DCNN model to multiple languages further highlights its versatility. Experimental results demonstrate the efficacy of the proposed method in author identification. Specifically, the proposed model outperforms conventional approaches across four comprehensive datasets, exhibiting superior accuracy. Comparative analysis with engineering features and traditional methods such as Support Vector Machine (SVM) and Backpropagation Neural Network (BPNN) underscores the superiority of the proposed technique, yielding approximately a 13% increase in identification accuracy while reducing reliance on expert knowledge. The validation results, showcase the diminishing network error and increasing accuracy, with the proposed model achieving 99% accuracy after 200 iterations, surpassing the performance of the LeNet model. These findings underscore the robustness and utility of the proposed technique in diverse applications, positioning it as a valuable asset for handwriting recognition experts.**

***Keywords*—Handwriting recognition; offline author identification; deep convolutional neural network; image processing; language versatility; feature extraction; hierarchical model**

## I. Introduction

In the field of machine vision and pattern processing, manuscript recognition is one of the most active investigation areas [1-3]. The characteristics of handwriting depend on the writing styles of the language. It is considered to be one of the most important signs in the analysis of handwritten documents. There have been numerous proposals for classification methods to address the issue of author identification [4-6]. There are two categories of manuscript identification: online and offline. While, in offline methods, only the image of the manuscript is available, online methods receive the time order of the coordinates, which expresses the movements of the pen tip of the person [7].

Awaida et al. [8] offered a method for identifying authors based on statistical and structural characteristics of Arabic texts. In this method, Euclidean distance criteria were used in conjunction with the nearest neighbor algorithm. In addition, data reduction algorithms were used to reduce the dimensions of the data. Using a multi-channel Gradient-based approach, Alavi et al. [9] offered a method for offline recognition of handwritten Persian documents. A limited set of data could be extracted and classified using Euclidean distance criteria using this method. Using the described method, good performance was achieved on Persian handwritten documents. A new method for identifying Persian manuscripts online has been presented by Valikhani et al. [10]. An offline author identification algorithm based on Moore's algorithm was proposed by Keykhosravi et al. [11]. Using this method, four comprehensive data sets were analyzed, and significant accuracy was achieved in identifying handwritten documents. An offline text recognition method based on distance-based classification has been proposed by Kumar et al. [12]. Six different data sets were used in this study to extract structural features using an isotropic filter. Mamoun et al. [13] investigated an offline method for handwriting recognition. This study examined the efficacy of the described method using a neural network and a support vector machine.

Using deep learning, Ansari et al. [14] presented a system for recognizing handwritten characters. The system was trained to identify similarities as well as differences between different samples of handwriting. An image of a handwritten text was converted into a digital text using this system. Results indicated that this system is most accurate when dealing with texts that contain less noise. Additionally, the accuracy of the stated system is completely dependent on the data set, and if the data set increases, more accuracy can be achieved. Using offline Bengali manuscripts, Adak et al. [15] examined author verification and identification methods. A DCNN model was used to extract automatic features from these manuscripts. A recurrent neural network (RNN) has been proposed by Zhang et al. [16] to recognize online authors. An online handwriting recognition structure based on deep neural networks has been presented by Carbune et al. [17]. According to Chahi et al. [18], multi-path deep learning can be used to identify the author (independent of the text) of a given piece of writing. This study uses a version of ResNet that combines deep residual networks with a traditional handwriting descriptor to analyze handwriting. As a primary and necessary feature of handwriting, the descriptor analyzes the thickness of the

*Corresponding Author.

handwriting. An author identification method based on this method can provide a text-independent author identity that does not require the same handwritten content to learn its model. Using feature combinations, Xu et al. [19] offered a deep learning technique for author recognition based on the Chinese language. To obtain handwriting features from handwritten images, deep features, and manual features were combined. According to the outcomes of the investigation, it was found that this method performs better than other comparative methods when it comes to identifying Chinese characters. An automatic author identification method based on deep learning was presented by Malik et al. [20]. As the proposed model, a combination of U-net and Resnet networks was considered. Using the ICDAR17 dataset, they evaluated their proposed method and found that it provided better results than the comparative models.

A review of author identification studies indicates that, even though many studies have been conducted in this field, these studies have been limited in their findings. In most of these studies, the authors were identified using features extracted and selected using traditional methods. Based on a review of previous studies, it appears that there is no comprehensive database set that can be used by researchers studying right-to-left languages as a reference. The purpose of this work is to present a novel technique for identifying the author by using a right-to-left handwriting dataset. To accomplish this goal, a right-left data set containing sentences, words, and numbers has been collected. There are 86304 samples of people with differing genders, ages, occupations, and levels of education included in this data set. Based on the ASTM standard [21], different time intervals and test conditions were used to collect this data set.

Additionally, deep learning has been applied widely in the analysis of images and signals with great success. In the third objective of this study, a DCNN structure based on pre-trained networks is constructed to learn features hierarchically from the raw handwriting dataset. A significant aspect of the suggested structure is its ability to classify heterogeneous data sets. Thus, although the random samples used in the training and evaluation phases belong to a specific individual, they are not necessarily the same; they may even have nothing in common. This article focuses on using heterogeneous samples, which has been largely neglected in previous research. This innovation in the identification method is the most prominent aspect of the present study. The core contribution and novelty of our study lie in addressing the limitations identified in previous author identification studies. These studies primarily relied on traditional methods for feature extraction and selection, lacking a comprehensive database suitable for researchers studying right-to-left languages. To fill this gap, our work presents a novel technique for author identification utilizing a right-to-left handwriting dataset.

## II. Materials and Methods

The purpose of this section is to examine convolutional neural networks (CNNs) and long-short-term memory (LSTMs), which belong to recurrent neural networks.

### A. *Convolutional Neural Networks*

The CNNs are an improved version of the neural network. Several layers in this network are trained together in a powerful manner [22-24]. The technique is very effective and is one of the most frequently used approaches in machine vision applications. There are three main layers in a convolutional network, namely the convolutional layer, the integration layer, and the fully connected (FC) layer. Random deletion and batch normalization layers are also used to prevent the process of overfitting and to improve the performance of the network [25]. Additionally, it is necessary to apply the activation function after each layer in neural networks.

By utilizing the kernel, the layer performs convolution on the input data. The convolution output is called a feature map. The convolution operator is as [25]:

$$y_k = \sum_{m=0}^{M-1} x_m R_{k-m} \tag{1}$$

In which $x$ is the signal, $R$ is the filter, $M$ is the number of elements in $x$, and $y$ is the output vector.

To normalize the data within a network, the batch normalization layer is employed [25]. The distribution of the data will change when different calculations are performed on the input data. As a result of this layer, the training speed of the network is increased, and the convergence rate is accelerated, which is intended to reduce the change in internal covariance. As a result of the batch normalization layer, the following transformation is achieved:

$$\mu_8 = \frac{1}{n}\sum_{i=1}^{n} y_i{}^{(l-1)} \; \sigma_B^2 = \frac{1}{n}\sum_{i=1}^{n}\left(y_i{}^{(l-1)} - \mu_B\right)^2 \; \hat{y}^{(l-1)} = \frac{y^{(l-1)}-\mu_B}{\sqrt{\sigma_B^2+\varepsilon}} z^{(l)} = \gamma^{(l)}\hat{y}^{(l-1)} + \beta^{(l)} \tag{2}$$

where, $\mu_B$ and $\sigma_B^2$ are the group mean and variance, respectively. $l$ is layer number, $y^{(l-1)}$ is the input vector to the normalizer layer, $z^{(l)}$is the normal output vector of a neuron, and $\gamma^{(l)}$ and $\beta^{(l)}$ are small constants for numerical stability. These parameters relate to changes in scale and learning rate, respectively.

An activation function is applied after each convolution layer. The activation function is an operator that maps the output to a set of inputs and is used to make the network structure nonlinear. As one of the most widely used activation functions, the Relu function has the characteristic of being nonlinear. In this manner, the network structure is resistant to minor changes in the input. An illustration of the Relu function can be found in Eq. (3) [25].

$$f(x) = \begin{cases} x & x\rangle 0 \\ 0 & x \le 0 \end{cases} \tag{3}$$

Soft Max function: This function calculates the probability distribution of the output classes, which has the following form:

$$p_i = \frac{e^{x_j}}{\sum_1^k e^{x_k}} \qquad for = 1, \ldots k \tag{4}$$

where, *x* is the input of the network and the output values of *p* are between zero and one, and their sum is equal to one.

### B. Recurrent Neural Networks (RNN)

An RNN is a deep learning model that captures sequence dynamics through recurrent connections, which can be viewed as cycles in the network. On the surface, this may appear to be counterintuitive. The order of computation in neural networks is unambiguous due to the feedforward nature of the algorithm. It should be noted, however, that recurrent edges are defined precisely to avoid such ambiguities. In recurrent neural networks, the underlying parameters are applied at every time step (or sequence step). In contrast to standard connections, which propagate activations from one layer to the next at the same time step, recurrent connections pass information across adjacent time steps. This type of neural network can be viewed as a feedforward neural network in which the parameters of each layer (conventional and recurrent) are shared between time steps.

In sequence prediction problems, an LSTM network is a type of recurrent neural network that is capable of learning order dependence. The use of this type of behavior is necessary in several complex problem domains, consisting of speech recognition, machine translation, and others. In the field of deep learning, LSTMs are considered to be one of the most complex algorithms. The concept of LSTMs can be difficult to grasp, as can the meaning of terms such as bidirectional and sequence-to-sequence. Experts who developed LSTMs are better at explaining both their promise and how they operate than anyone else. Traditionally, RNNs have a single hidden state that is passed through time, which can impair their ability to learn long-term relationships. By introducing a memory cell, LSTMs overcome this problem by storing information for an extended period. Three gates control the memory cell: the input gate, the forget gate, and the output gate. Memory cells are controlled by these gates, which determine what information is to be added, removed, and output. A cell state and output value are transferred from the LSTM module to the next LSTM module. Fig. 1 depicts the gates and operations of an LSTM module graphically for $L_p$ (for N the scheme would be similar), and in which it can be observed that the input for a unit is its output. LSTM modules transmit to each other their predictions, which, when combined with the current input, generate the output for the next module.

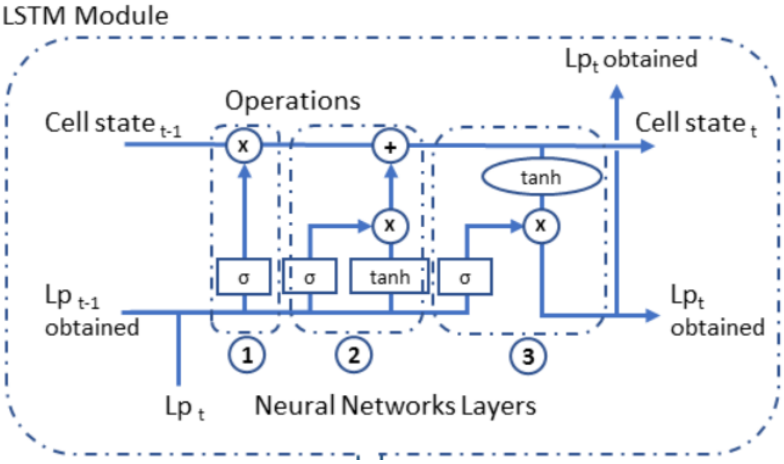

Fig. 1. An overview of an LSTM neural network for Lp [26].

## III. The Proposed Method

### A. Data Collection

The evaluation of our proposed methods relies on the utilization of two publicly available datasets: CVL [27], IAM [27], IFN/ENIT [28], and KHATT [29]. These datasets contain segmented word images accompanied by labels for both word and writer. We conduct separate evaluations using these datasets due to the differences in the writers represented in each dataset. These datasets have generally been applied in recent works and are dependable and extensively used datasets in the area of author identification.

The CVL dataset, as referenced in [27], comprises 310 distinct writers, each of whom has contributed a minimum of five pages written in both English and German languages. The IAM dataset, as referenced in [27], encompasses 657 individual writers, each of whom has contributed at least one page written in English. Similar to the CVL dataset, the IAM dataset also includes word images along with labels for both the word and the corresponding writer. According to ASTM standards, handwriting samples were collected from 65 participants over some time and under varying environmental conditions (see Fig. 2). A total of 65 participants participated in this investigation, of which 36 were men and 29 were women, with an average age of 20 to 50 years old. Furthermore, 10 of the participants were left-handed, and 55 were right-handed. As a last step, handwriting textural and structural characteristics were determined using predefined standards. A separate sheet of paper was used to write each sentence twelve times by the ASTM standard. After writing all four sentences on one separate sheet, the next step was to write them on a separate sheet as well. It should be noted that two different kinds of standard paper were used, "PaperOne" and "Double-A," whose qualifications can be found in Table I.

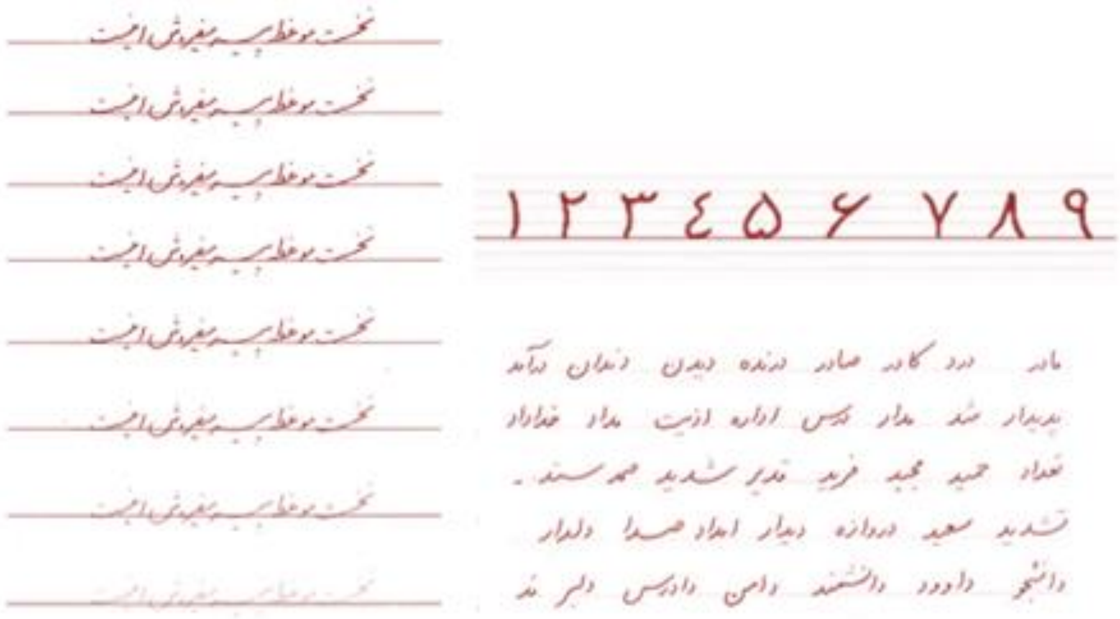

Fig. 2. Examples of handwriting collected in different situations.

TABLE I. PAPER'S SPECIFICATION DETAILS

| Properties | Weight (g/m2) | Roughness (ml/s) | Thickness (µm) | Brightness (%) | Opacity (%) | CIE Whiteness |
|---|---|---|---|---|---|---|
| PaperOne | 82±3% | 145±4% | 105±3% | 97±2% | 97±3% | 159±2% |
| COPIMAX | 81±3% | 155±5% | 106±2% | 103±1% | - | 167±2% |

Two types of standard pens were used, namely "Schneider" and "Faber-Castell," which were color-coded as "blue" and "black." Each of the samples was written on a different writing pad, which is either called a "hard" pad or a "soft" pad. In the use of these two types of pads, the amount of pen pressure is intended to be shown. A RICOH Aficio MP 6001 was used to scan the collected samples at a resolution of 300 dpi in color mode. In the data set, a code book contains the order in which samples were collected and the required information and details. It is estimated that the data set collected from 65 participants contains 445 pages and 4203 sentences in total. Each sentence sample has a height of 235 pixels and a width that is variable. Page sizes for the sample pages are 1655 x 2339 pixels. Henceforth, DENE_HW will be used to identify this dataset.

## B. Data Preprocessing

In this study, to reduce the execution time and volume of calculations, after separating 4203 sentences, the size of the sentences is first changed to 112 pixels and variable width. Then, using the segmentation method, 4203 sentences are divided into 86304 samples with a size of 112 x 112 pixels; after that, the samples are normalized.

## C. Proposed Deep Network

A description of the proposed technique of the article is provided in this section. An illustration of the proposed algorithm can be seen in Fig. 3. The proposed deep network in this study is created by combining a pre-trained convolutional network, LeNet [30], with an LSTM network. By combining the LeNet network with the LSTM network, the advantages of both networks can be used simultaneously. In many studies, the combination of LSTM networks with deep convolutional networks has been utilized to lessen feature dimensions, increase stability, reduce fluctuations, improve the training process, and increase recognition accuracy. The proposed network is based on It is assumed that it consists of two layers of LSTM, three layers of batch normalization (BN), three layers of random elimination, and two layers of FC (see Fig. 3). Pre-trained systems are composed of several layers; each layer learns certain features. There are two layers of learning: the initial layer learns basic as well as low-level features, and the next layer learns complex and high-level features. This process involves the formation and adjustment of the weight matrix based on the learning process. The architecture of the suggested block is chosen as follows: (1) an FC layer with a linear function along with a batch normalization layer with a Relu function, after which a random removal layer is placed. (2) An LSTM layer with the Relu function, after which the batch normalization and random removal layers are placed. (3) The architecture of the prior stage is repeated once more. (4) An FC layer with a non-linear softmax function is used to access the output layer. In the suggested network, the output of the pre-trained network is a feature vector with a size of 512 x 256. A linear function is applied to the learnable weights of the obtained features (w) in the first layer of the suggested block, namely FC. As a result of the predicted bias values, the dimension of the feature vector is changed from 256 x 1 to 256 x 2. A non-linear softmax function was used to transform the selected feature vector into an FC layer using a non-linear softmax function in the hidden layers (see Fig. 3).

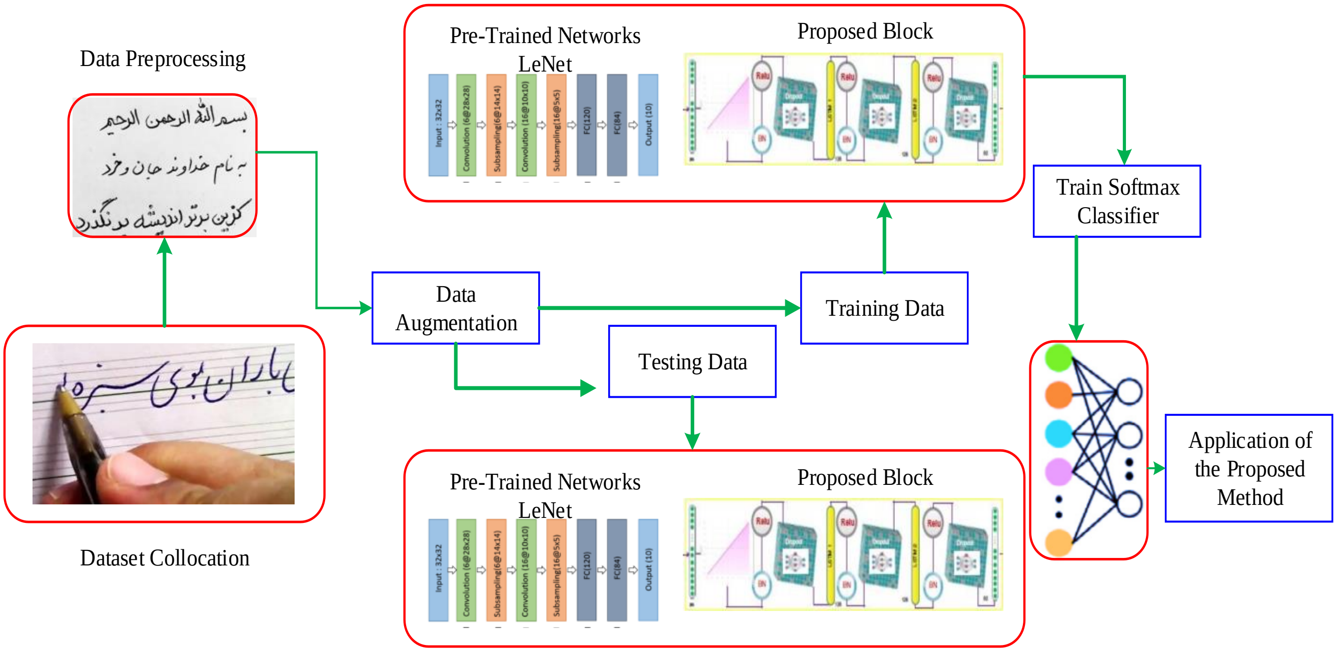

Fig. 3. The block diagram of the CNN-LSTM for automatic detection of the writer.

In this study, all the super-parameters of the proposed network have been carefully adjusted to get the best convergence rate, and finally, the cross-entropy error function and the stochastic Mini-Batch optimizer with a learning rate of 0.05 have been selected. The conventional method of error backpropagation with a batch size of 100 has been used for network training. The optimal parameters selected for the suggested method are shown in Table II. This table provides a clear overview of the parameters considered in our study, their respective search spaces, and the values deemed most suitable based on experimentation and optimization.

As it was said in this work, the training and evaluation of the suggested model are done using non-continuous data. Fig. 4 shows examples of inconsistent handwriting for the training and evaluation process. Due to the detail that all pictures 1-24 go to one person, pictures 1-15 belong to the training data set, and pictures 16-24 belong to the validation and evaluation data set. For example, pictures 1 and 3 are most similar to picture 18 (a). Also, images 6 and 16 are the same (b).

On the other hand, images 19 and 22 have no counterparts in the training data set (c). 60% of the collected samples are used for training data, 30% for validation data, and 10% for test data. A random selection of samples is also conducted for the training and evaluation sets.

## IV. Results and Discussion

Several libraries, including PyTorch and NumPy, were used to carry out the suggested author identification method and all results and reviews. These tests were performed on a computer with specifications of Intel Core i9-6700K CPU, GeForce GTX TIAN X 36GB graphics processor, 128GB DDR IV RAM, and 2TB SSD hard disk. To evaluate the performance of the proposed method, we have used the relationship related to accuracy, which is expressed as follows:

$$ACC = \frac{T_N+T_P}{T_P+T_N+F_P+F_N} \quad (5)$$

In which, $T_P$ is the positive cases that have been correctly diagnosed as positive. $F_P$ is a negative case that is falsely diagnosed as positive. $T_N$ is a negative case that is correctly diagnosed as negative. $F_N$ is a positive case that was wrongly diagnosed as negative.

The experimental results for the proposed model (pre-trained network with the suggested block) and the pre-trained LeNet network without the proposed block are shown in Table III. These results indicate that both models perform better when using the TTA technique than when using the TTA technique. The accuracy of the evaluation of the suggested model using the TTA technique is 99.66%; however, the accuracy of the evaluation without using the TTA technique is 95.78%. In addition, LeNet evaluation accuracy with the TTA technique is 96.51%, while Resnet-152 evaluation accuracy without the TTA technique is 93.45%. According to Table IV, the accuracy and execution time of the suggested model are higher than those of LeNet.

The accuracy and error diagram for the validation data for the proposed model and Resnet-152 model using the TTA technique is displayed in Fig. 5. In this figure, it can be seen that the network error of the proposed model and the LeNet model decreases as the number of repetitions of the algorithm increases. As can also be seen, both the suggested model and the LeNet model reach 99% and 96% accuracy after 200 repetitions, respectively.

A total of four data sets described in Section III(A) have been used to estimate the suggested model. Table IV summarizes the recognition outcomes of the suggested model and the LeNet model with the TTA technique for identifying authors based on each of the four data sets. According to Table V, the suggested model based on the improved LeNet network performs better than the Lenet model for identifying authors using each of the four datasets.

TABLE III. Experimental Outcomes of the Suggested Modified DCNN Model and LeNet Network

| Network | without TTA | with TTA | Time with TTA (ms) | |
|---|---|---|---|---|
| | *Acc.* | *Acc.* | *Train* | *Test* |
| LeNet + Proposed method | 94.76 | 99.57 | 16.57 | 1.70 |
| LeNet | 92.06 | 96.92 | 13.24 | 1.14 |

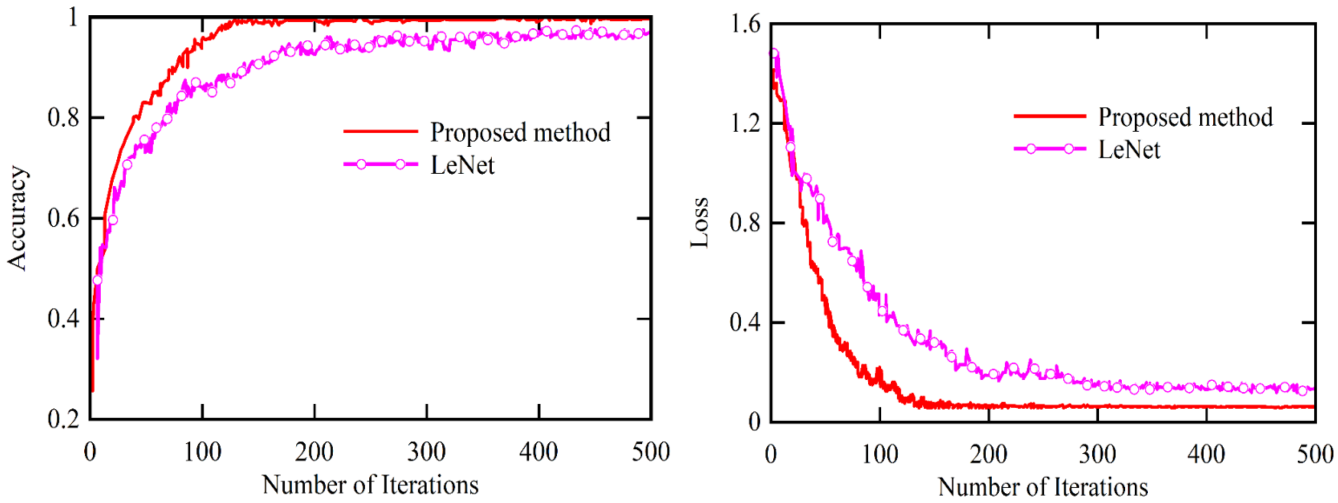

Fig. 5. Accuracy and loss curve of the suggested model constructed on modified pre-trained networks.

TABLE IV. EVALUATION OUTCOMES OF THE PROPOSED MODEL AND LENET MODEL FOR FOUR COMPREHENSIVE DATASETS

| Network | Dataset | | | | Acc. with TTA |
|---|---|---|---|---|---|
| | *Name* | *Language* | *Writer* | *Sample* | |
| Proposed method | IAM | English | 150 | 4035 | 98.65 |
| | CVL | English | 305 | 1726 | 99.31 |
| | KHATT | Arabic | 798 | 10342 | 98.97 |
| | IFN | Arabic | 433 | 27983 | 99.35 |
| LeNet | IAM | English | 140 | 4035 | 96.35 |
| | CVL | English | 305 | 1726 | 98.18 |
| | KHATT | Arabic | 798 | 10342 | 95.35 |
| | IFN | Arabic | 433 | 27983 | 97.48 |

A comparison of the evaluation accuracy of different approaches for identifying authors is shown in Table V. A summary of the outcomes of the suggested model is presented in Table V. The comparisons are made based on two data sets, namely IAM as well as IFN/ENIT. The quantity of authors in each review is also shown in Table V. It ought to be mentioned that the differences presented in Table V regarding the number of examined samples in the stated data set are due to their availability. As displayed in Table V, about all the evaluation datasets, the classification accuracy indicators show better performance of the suggested model compared to other approaches.

To demonstrate the performance of the deep convolutional neural network (DCNN) model with the DENE_HW data set as input, the evaluation accuracy has also been obtained using other models. Based on this, the raw data of DENE_HW and several engineering features from the DENE_HW dataset, together with the fault backpropagation network (BPNN) and the support vector machine (SVM), have been selected as comparative models. A variety of models according to feature learning from raw data and engineering features are presented in Table VI, while the results of the suggested DCNN model with raw data as input, which is the suggested method, are highlighted. In Table VI, a comparison of the performance of features and engineering features is presented. With the proposed DCNN model, it appears that feature learning is more accurate than engineering features (with an increase of about 13%). This illustrates that DCNNs cannot perform better than traditional methods in author recognition without the ability to learn features.

TABLE V. A SUMMARY OF THE OUTCOMES OF THE SUGGESTED MODEL COMPARED WITH OTHER METHODS

| dataset | Ref. | Language | Writer number | Acc. (%) |
|---|---|---|---|---|
| IAM | [31] | English | 640 | 89.53 |
| | [32] | | 647 | 97.20 |
| | [33] | | 647 | 69.47 |
| | Proposed method | | 150 | 98.65 |

TABLE VI. ACCURACY OF THE SUGGESTED TECHNIQUE COMPARED WITH OTHER APPROACHES

| Method | Feature learning from raw data | Manual features |
|---|---|---|
| Back Propagation Neural Network (BPNN) | 88.06 | 85.67 |
| Support vector machines (SVM) | 85.65 | 83.69 |
| Proposed method | 99.57 | 85.16 |

The significance of considering additional factors influencing the accuracy of writer recognition in handwriting analysis cannot be overstated. Variables such as the type of pen, paper, environmental conditions, noise, and light intensity can exert a substantial influence on recognition accuracy. In furtherance of this research endeavor, we propose the systematic collection of a new dataset that comprehensively incorporates these parameters. Through meticulous control of these variables, we aim to evaluate their singular and collective impacts on the efficacy of author identification methodologies. This meticulously curated dataset holds promise for yielding valuable insights into the resilience and dependability of handwriting recognition systems across diverse conditions. Moreover, we advocate for the evaluation of various methodologies, encompassing both deep learning models and traditional approaches, using this novel dataset. A comparative examination will facilitate the elucidation of the strengths and weaknesses inherent in different techniques when confronted with the variability inherent in real-world handwriting samples. Such a comprehensive study holds the potential to deepen our understanding of the determinants of writer recognition accuracy and foster the evolution of more resilient and adaptable handwriting recognition systems.

## V. CONCLUSION

This investigation aims to present a new technique for offline identification of the writer using handwriting samples under different experimental conditions, taking into account the complexity of writing styles and the need for organizations to recognize the handwriting of authors. The present study has two noteworthy and important characteristics. First, inconsistent data have been used in the present study, and second, the suggested method is independent of the language in question. Based on ASTM standards, a comprehensive data set was developed for this study. We have developed a DCNN model that extracts features from raw manuscripts based on a pre-trained network.

Based on the results of the present work, it was demonstrated that the suggested method can learn features from raw handwriting data and reach acceptable accuracy for author identification. The proposed model was based on the pre-trained network along with the designed data set and four types of comprehensive data sets. The outcomes indicated that the proposed model (pre-trained network with proposed block) performed more effectively in identifying the author for each of the five data sets than the pre-trained network without the proposed block. In addition, the proposed model was compared with the accuracy of different approaches for four types of comprehensive data sets. According to the outcomes, the suggested model was found to be more accurate than other methods for all data sets compared with other methods. In addition, the designed data set was analyzed with DCNN and compared with engineering features and two intelligent approaches, SVM and BPNN. Based on the outcomes of the study, the suggested technique is capable of learning the features and providing convincing predictions. In comparison with engineering features, the suggested technique increases the accuracy of identification by approximately 13% and is less dependent on expert knowledge. The presented results indicate that the suggested technique for automatic author identification is very satisfactory and suitable for use in a variety of applications, and it could prove to be a useful tool for handwriting recognition experts when entering the field.

***Abstract*—Vehicle collisions are a significant problem worldwide, causing injuries, fatalities, and property damage. There are several reasons for the collapse of vehicles such as rash driving, over speeding, less driving skills, increasing number of vehicles, drunk and drive, etc. However, over speeding is one of the critical factors out of all the reasons for vehicle collisions. To address the critical issues, the current article proposes a Fuzzy-based algorithm to prevent and control the speed of the vehicle. The major objective of the proposed system is to control the speed of the vehicle for proactive collision avoidance. Deep learning and fuzzy system provide better integrated approach for the controlling of the speed and avoid vehicle collision. Fuzzification of the speed variable provides an advanced or viable solution for speed control. The current research used RNN and other deep learning algorithm to predict the traffic and identify the traffic frequency. The traffic frequency in a time-series frame provides the frequency of the traffic within a time frame that can be detected by using involvement of IoT.**

***Keywords—Speed control; fuzzy logics; deep learning; decision making; collision avoidance***

## I. Introduction

Vehicle collisions, often referred to as traffic accidents or crashes, have significant social, economic, and public health implications. Vehicle collisions are a significant problem worldwide, causing injuries, fatalities, and property damage. Most vehicle collisions are caused by human error, including distracted driving, impaired driving (e.g., alcohol or drugs), speeding, and reckless driving. Adverse weather conditions such as rain, snow, ice, and fog can increase the risk of collisions, as can poorly maintained roads. This is one of the major reasons for the vehicle collision and accidents [1]. Mechanical failures, such as brake or tire problems, can lead to accidents. And problems at intersections, junctions, improper signaling, and traffic congestion can contribute to collisions. Vehicle collisions are a leading cause of death worldwide, particularly among young people aged 15 to 29. The World Health Organization (WHO) estimated that approximately 1.35 million people died in road traffic accidents globally in 2018 [2].

Vehicle collisions incur significant financial implications, such as missed productivity, medical expenditures, property damage, and legal fees. According to the National Highway Traffic Safety Administration (NHTSA), motor vehicle accidents cost the US economy more than $242 billion in 2010 [3]. Vehicle collisions cause a significant number of injuries and fatalities each year. These injuries range from minor to severe, leading to long-term disabilities in some cases. In 2019, the United States reported over 38,800 fatalities in motor vehicle crashes, according to the NHTSA.

Advanced driver assistance systems (ADAS) and vehicle safety technologies have shown promise in reducing the severity of collisions and preventing accidents. These include features like automatic emergency braking, lane departure warning, and adaptive cruise control. Vehicular Ad-Hoc Networks (VANETs) can also prevent or minimized the vehicle collisions. VANETs are wireless communication networks that enable vehicles to exchange information with each other and with infrastructure components like traffic lights and road signs [4]. VANETs enable communication between vehicles and roadside infrastructure through wireless communication. Each vehicle in the network is equipped with onboard units (OBUs) that can transmit and receive data. VANETs can facilitate real-time exchange of information such as vehicle speed, position, direction, and emergency warnings [5]. Here are several ways VANETs can help improve road safety and reduce vehicle collisions:

*1) Collision avoidance systems:* VANETs can enable vehicles to communicate with each other in real-time, sharing information about their speed, location, and direction. Collision avoidance systems can use this information to alert drivers or even automatically take control of the vehicle to prevent collisions. For example, if a vehicle suddenly brakes or encounters an obstacle, it can send a warning message to nearby vehicles, allowing them to react and avoid a collision.

*2) Intersection management:* VANETs can help manage traffic flow at intersections more efficiently. Vehicles can communicate their intended routes and timing at intersections. Traffic signals can adjust their timing based on real-time traffic information to minimize congestion and reduce the likelihood of collisions.

*3) Emergency vehicle warning systems:* Emergency vehicles equipped with VANET technology can broadcast their status and location to surrounding vehicles. Nearby vehicles can receive warnings and move out of the way, reducing the risk of collisions with emergency vehicles.

*4) Pedestrian safety:* VANETs can be used to improve pedestrian safety. For example, smartphones or wearable devices carried by pedestrians can communicate with vehicles, making drivers aware of pedestrians' presence even when they are not in the line of sight. Crosswalks can be equipped with VANET infrastructure to signal to vehicles when pedestrians are about to cross.

*5) Road condition alerts:* VANETs can provide real-time information about road conditions, such as icy roads, potholes, or flooding. Vehicles can receive these alerts and adjust their speed and driving behavior accordingly to avoid accidents caused by adverse road conditions.

*6) Driver assistance systems:* VANETs can complement existing driver assistance systems by providing additional data from surrounding vehicles. For example, adaptive cruise control systems can use VANET data to maintain safe distances between vehicles in congested traffic.

*7) Traffic management and congestion reduction:* VANETs can help reduce traffic congestion by providing real-time traffic information to drivers, allowing them to choose less congested routes. This can prevent situations where heavy traffic leads to rear-end collisions and other accidents.

*8) Data collection and analysis:* VANETs collect vast amounts of data about vehicle movements and traffic conditions. This data can be analyzed to identify accident-prone areas and develop targeted safety improvements.

*9) Security and privacy considerations:* Implementing VANETs requires robust security measures to protect the integrity and privacy of communication. Encryption and authentication mechanisms are essential to ensure that malicious actors cannot interfere with VANET communication.

It is important that the successful implementation of VANETs for collision prevention requires coordination among vehicle manufacturers, infrastructure providers, and government agencies [6]. Additionally, public awareness and acceptance of these technologies play a very important role for the prevention of vehicle collision. Rather than VANET, fuzzy Logics are utilized to prevent vehicle collisions involves creating a decision-making system that assesses the risk of collision based on various input parameters and takes appropriate actions to avoid or mitigate the collision [7]. Here is a step-by-step guide on how to implement a collision prevention system using Fuzzy Logic:

*1) Identify input parameters:* Determine the input parameters that are relevant for assessing collision risk. These parameters could include:

- Distance to the vehicle in front.
- Relative speed with respect to the vehicle in front.
- Lane change intentions of nearby vehicles.
- Road conditions (e.g., wet, slippery).
- Driver reaction time.
- Braking distance.
- Vehicle acceleration.
- Traffic density.

*2) Define fuzzy sets:* Create fuzzy sets for each input parameter. Fuzzy sets represent the linguistic terms used to describe these parameters. For example:

- Distance: Very Close, Close, Moderate, Far, Very Far
- Relative Speed: High, Moderate, Low
- Lane Change Intentions: Aggressive, Cautious, None
- Road Conditions: Slippery, Normal

*3) Membership functions and fuzzy rules:* Assign membership functions to each fuzzy set. Membership functions define how each input value belongs to the fuzzy sets. These functions can be triangular, trapezoidal, or Gaussian, depending on the shape of the data distribution. Define a set of fuzzy rules that describe how the inputs relate to the output, which is the "collision risk." For example: If distance is very close or relative speed is high and lane change intentions are aggressive, then collision risk is High.

*4) Fuzzy inference system:* Implement a Fuzzy Inference System (FIS) that processes the fuzzy rules and input values to determine the collision risk level. Common methods for combining fuzzy rules include the Mamdani or Sugeno models.

*5) Defuzzification:* Convert the fuzzy output (e.g., "High," "Moderate," "Low") into a crisp value that represents the actual collision risk level. Methods like centroid or weighted average are used for defuzzification.

*6) Set thresholds:* Establish threshold values for the collision risk levels. For example, you may define a "High" risk threshold that triggers collision avoidance actions.

*7) Decision and actions:* Based on the determined collision risk level and predefined thresholds, the system should decide on appropriate actions to prevent collisions. These actions may include:

- Visual and audible warnings to the driver.
- Activating automatic emergency braking systems.
- Steering interventions.
- Adjusting vehicle speed or acceleration.

*8) Testing and validation:* Rigorously test and validate the fuzzy logic-based collision prevention system under various conditions to ensure its effectiveness and safety. Integrate the fuzzy logic-based collision prevention system into vehicles or traffic management infrastructure as needed. Continuously collect data and update the fuzzy logic system to improve its accuracy and adapt to changing road conditions and traffic patterns. Ensure that the system complies with all relevant regulatory standards and safety requirements.

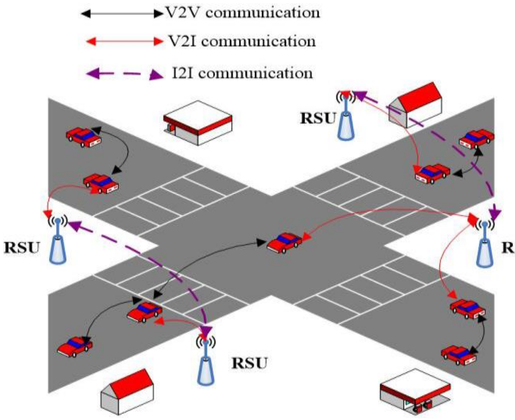

Fig. 1. Communication diagram for VANET.

Fig. 1 shows the schematic diagram of the communication among vehicle to vehicle, vehicle to infrastructure, and infrastructure to infrastructure. Some road-side units (RSU) have been placed for providing the direct communication between vehicles and infrastructure [8]. This communication can prevent the vehicle collision and able to control the speed of the vehicle based. Controlling vehicle speed offers numerous advantages in terms of safety, fuel efficiency, environmental impact, and overall road network efficiency. Here are some key advantages of controlling vehicle speed:

- Improved Road Safety: Reduced speed leads to shorter stopping distances, allowing drivers more time to react to unexpected situations and avoid collisions. Lower speed reduces the severity of accidents and the risk of fatalities and injuries in the event of a crash.
- Reduced Traffic Congestion: Maintaining a consistent and appropriate speed helps to smooth traffic flow and reduce congestion. Traffic jams caused by abrupt stops and starts are less likely when drivers adhere to speed limits.
- Lower Fuel Consumption: Vehicles tend to be most fuel-efficient at moderate speeds. Lowering speed reduces fuel consumption and greenhouse gas emissions. Slower speeds can lead to better fuel economy, saving drivers money and reducing the environmental impact of transportation.
- Noise Reduction: Lower speeds result in quieter traffic, reducing noise pollution in residential areas and along roadways. Quieter vehicles contribute to improved quality of life for nearby residents.
- Extended Vehicle Lifespan: Driving at lower speeds puts less stress on a vehicle's components, leading to less wear and tear and potentially extending the lifespan of the vehicle.
- Enhanced Pedestrian and Cyclist Safety: Slower vehicles are less likely to cause severe injuries to pedestrians and cyclists in the event of a collision. Reduced speed allows drivers to better detect and respond to vulnerable road users.
- Improved Air Quality: Lower-speed driving typically results in reduced emissions of pollutants, which can lead to improved air quality in urban areas. Reduced emissions contribute to better public health outcomes.
- Increased Reaction Time: Lower speeds give drivers more time to react to unexpected events, such as sudden braking or the emergence of a hazard in the roadway.
- Enhanced Driver Comfort: Maintaining a reasonable and consistent speed can lead to a more comfortable and less stressful driving experience.
- Compliance with Legal Requirements: Adhering to posted speed limits and regulations helps drivers avoid fines and legal consequences. It promotes a culture of safety and respect for traffic laws.
- Reduced Severity of Accidents: In the event of a collision, lower-speed impacts are generally less severe, leading to fewer fatalities and less damage to vehicles and infrastructure.
- Improved Predictability: Consistent speed among vehicles on the road makes it easier for drivers to anticipate the behaviour of other road users, reducing the likelihood of accidents.

Controlling the speed of a vehicle using Fuzzy Logic is a complex but effective approach that leverages fuzzy sets and rules to achieve smooth and adaptive speed control. The controlling the speed of a vehicle using Fuzzy Logic involves defining linguistic variables and fuzzy sets, creating a rule base, and using adaptive control to make speed adjustments based on real-time inputs [9]. This approach is valued for its ability to handle complex and uncertain systems while providing smooth and human-like control of vehicle speed. Additionally, the system can initiate automatic emergency braking systems, adjust vehicle speed, and coordinate with traffic management systems to optimize traffic flow and prevent congestion. The major objectives of the current article are as follows:

- To propose a fuzzy based mechanism involves developing a controller that can adjust a vehicle's speed based on inputs and conditions in a manner that is consistent with human-like decision-making.
- The system is effective in real-time scenario and able to analyze the risk assessment during travel.
- The proposed system can collect the data from vehicles and analyze the data for decision-making.
- The system prioritizes the most critical situations.

The remainder of the essay is structured as follows. Section II presents past work conducted by several researchers. Section III provides a proposed system with fuzzy logic and deep learning algorithms. Section IV explains about the dataset used to analyze the speed of the vehicle. Section V shows the experimental results and discussion about the outcomes generated. Conclusion of the paper discussed in the Section VI.

## II. Literature Review

There are several research has been conducted for the detection and identification of collisions of road accidents. IoT and machine learning approaches are combined in the smart vehicle collision prevention system that Yu et al. [10] presented. The technology uses roadside infrastructure and sensors built into cars to gather data about the surroundings in real-time. In order to analyze the data and forecast potential collision scenarios, machine learning algorithms are used. The system provides timely alerts and warnings to drivers, and in critical situations, it automatically activates emergency braking systems to prevent collisions [11].

W. Yang [12] clarified a system for Li-Fi-based information transfer in the VANET in 2017. This method of information gathering and gearbox for vehicle conditions was introduced. Less research has been done on Li-Fi, which is a more recent topic. Framework developed an IOT system with a vast array of communication vehicles. The organisation of virtual machines completed the dissemination of information. The current major challenges are to the usage of transmission capacity and the postponement of information handling. The driving goal acknowledgment module initially controlled the front vehicle's driving objective. Second, via vehicle-to-vehicle (V2V) communication, the front vehicle transmits its driving intention and other driving boundaries to the following vehicle. The proper admonition pace of the proposed framework, according to the results of the reproduction test, was 97.67%, which was 6.34% greater than that of the framework with a fixed chance to crash (TTC) edge. The suggested framework proved effective for providing the accompanying vehicle with early notification in a variety of front vehicle operating states.

O. Heety et al. [13] introduced a comprehensive audit of past works by ordering them dependent on dependent on remote correspondence, especially VANET. In ITS for-information security, an RC5 encryption method was introduced. Quartus Prime was used to the RC5 recreation. The primary function was to ensure that it would function with the ITS framework and the FPGA framework for the protection of customer data. Additionally, this paper included a detailed analysis of the unresolved problems and test results obtained while integrating the VANET with SDN.

By suggesting a V2V conspiracy that can locate vehicle clients in the natural world, V. Singhal et al. [14] introduced the utilisation of significant resources is successfully lessened in an LTE arrangement. The suggested solution eliminates a significant portion of V2V traffic disclosure and management, which primarily involves cars and travellers in VANET. The focus of the investigation is on collisions between street vehicles and trains at railway level automated crossings on single-line rail-street segments. Another investigation goal is to determine how using different risk factors may affect predicted danger factors in order to reduce the risk of street vehicle-train collisions at crossings.

J. Huang et al. [15] introduced a combination control system of adaptive cruise control (ACC) and collision avoidance (CA), which considers a driver's social style. First, a survey was conducted to identify the different types of drivers. The relevant driving social data were then collected through driving test system tests, serving as the format data for the online ID of each driver type. It developed a new technology integrating an IoT network of distant devices with an Intelligent Transport technology that was sent in accordance with the benchmarks released by ETSI inside the Technical Committee on ITS. A correspondence message structure based on auto ontologies, the SAE J2735 message set, and the serious explorer data framework events mapping that links to the social diagram was introduced by K. Alam et al. in study [16]. Finally, we provide usage details and test results to demonstrate the practicality of the suggested framework and to include various application scenarios for various customer groups.

According to D. Asljung et al. [17], the choice of this danger measure has a substantial impact on the conclusions generated from the data. This tactic can be applied to validate the security of a vehicle with the right precautions. All of this while maintaining a high level of legitimacy and a low level of information requirement compared to cutting-edge factual tactics. A model-based computation was presented by M. Brännström et al. [18] to determine how the driver of a vehicle can regulate, brake, or accelerate to avoid colliding with a subjective object. In this computation, a straight vehicle model was used to represent the vehicle's motion, and a square shape was used to represent the vehicle's edge. The item's assessed border was represented by a polygon that was allowed to alter in size, shape, location, and orientation under test conditions.

M. Earthy et al. [19] introduced a plan and trial approval of a nonlinear model prescient regulator that is fit for taking care of these mind-boggling circumstances. Via cautiously choosing the vehicle model and numerical encodings of the vehicle and snags, we empower the regulator to rapidly figure inputs while keeping up a precise model of the vehicle's movement and its vicinity to deterrents. T. Butt et al. [20] looked at a variety of perspectives, including the protection of an individual, conduct and activity, correspondence, information and picture, thoughts and emotions, area and space, and affiliation, to examine the protection issues and factors that are fundamental to consider for maintaining security in SIoV conditions. In addition, the study discusses the square chain-based solutions for saving security for SIoV. The Social Internet of Vehicle (SIoV) is one application of SIoT in the automotive sector that has contributed to the development of the present intelligent vehicle framework (ITS).

Y. Chen et al. [21] proposed an agreeable driving methodology for the associated vehicles by coordinating vehicle speed forecast, movement arranging, and powerful fluffy way following control. The framework vulnerabilities are considered to upgrade the collaboration between the self-ruling vehicle and the close by vehicle. With the driving data got from the associated vehicles method, the repetitive neural organization is utilized to anticipate the close by vehicle speed. The literature work can be explained in terms of the Table 1.

## III. PROPOSED SYSTEM

The vehicle speed can be controlled by using a Fuzzy Logic system involves developing a controller that can adjust a vehicle's speed based on inputs and conditions in a manner that is consistent with human-like decision-making [22] [23]. Fig. 2 shows the proposed methodology of the system and described the data flow generated for the intelligent vehicles. Here's a proposed system for controlling vehicle speed using Fuzzy Logic:

*1) Data collection and sensors:* Equip the vehicle with sensors such as radar, lidar, cameras, and GPS to collect real-time data about the vehicle's surroundings and conditions. Data may include information on:

- Road conditions (e.g., wet, dry, icy).
- Traffic density.
- Vehicle speed.
- Distance to the vehicle in front.
- Lane markings.
- Weather conditions.
- Traffic signs and signals.

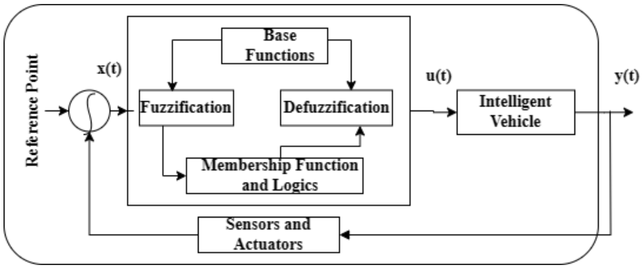

Fig. 2. Proposed methodology.

*2) Fuzzy logic controller:* Develop a Fuzzy Logic controller that takes the collected sensor data as inputs and calculates the optimal vehicle speed [24]. The controller consists of several components:

- Fuzzification: Convert the crisp sensor data into fuzzy variables using linguistic terms (e.g., "close," "moderate," "far").
- Fuzzy Rules: Define a set of fuzzy rules that capture the relationship between the input variables and the output (vehicle speed). These rules are often expressed in the form of "IF [antecedent] THEN [consequent]." For example:
- IF (Traffic is Heavy) AND (Distance to the Vehicle in Front is Short) THEN (Reduce Speed).
- Fuzzy Inference System: Implement the fuzzy inference system that combines the fuzzy rules and input data to determine the appropriate speed adjustments.
- Defuzzification: Convert the fuzzy output into a crisp value representing the recommended vehicle speed.

*3) Speed adjustment algorithm:* Develop an algorithm that takes the output from the Fuzzy Logic controller and adjusts the vehicle's speed accordingly. This may involve controlling the throttle, brakes, and transmission.

*4) Real-time operation:* Integrate the Fuzzy Logic controller into the vehicle's onboard computer or control system for real-time operation. The system continuously processes incoming sensor data and adjusts the vehicle's speed accordingly.

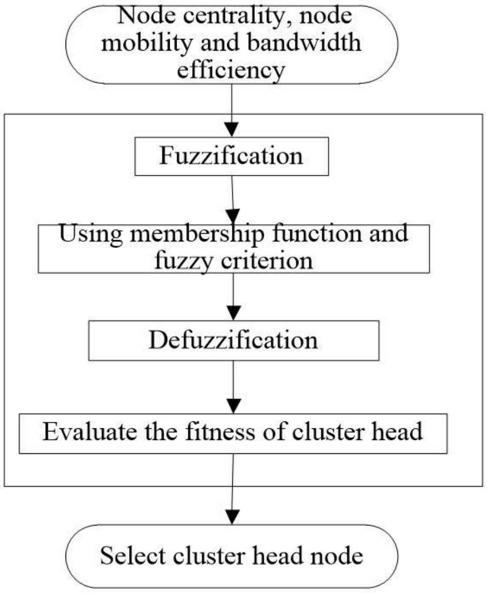
*5) User interface:* Create a user interface for drivers to interact with the system. Drivers may have the option to set speed preferences, override the system, or receive alerts and notifications.

*6) Safety mechanisms:* Implement safety mechanisms to ensure that the vehicle operates safely even in the presence of fuzzy logic errors or sensor failures. These mechanisms may include emergency braking systems and fail-safe procedures.

*7) Testing and validation:* Rigorously test and validate the system in controlled environments and under various real-world conditions to ensure safety and effectiveness.

*8) Compliance with regulations:* Ensure that the system complies with all relevant regulations and safety standards for autonomous and semi-autonomous vehicles.

*9) Continuous improvement:* Continuously collect data and monitor the system's performance. Use this data to fine-tune the Fuzzy Logic controller and improve speed adjustment decisions.



Node centrality, node mobility and bandwidth efficiency
Fuzzification
Using membership function and fuzzy criterion
Defuzzification
Evaluate the fitness of cluster head
Select cluster head node

Fig. 3. Fuzzy-based data flow diagram.

Fig. 3 the fuzzy-based dataflow diagram with the set of steps used to find the cluster head node. There are several nodes available in the cluster of the vehicles and if it is stronger in terms of centrality C, then it performs more activity and can connects within a network [25]. The centrality of the cluster can be evaluated by using Eq. (1):

$$C_i(j) \ = \sum_{k=1}^{n} x_{i,k}(j) \tag{1}$$

where, $C_i(j)$ represents the centrality of the node i at any instance j, n is total number of nodes in a cluster and $x_{i,k}(j)$ is providing the mean value of the cluster nodes. To increase the precision of the centrality of the node can be identified with the given using Eq. (2):

$$C_i(j) \ = wC_i(j) + (1-w)C_i(j-t) \tag{2}$$

where, w varies with the node speed and represents the weight of the node, t represents the time factor. The fuzzy value for the input can be represented in terms of using Eq. (3):

$$C_{fuzzy-\,i}(j) = \ 1 - \frac{C_i}{n} \tag{3}$$

Node mobility refers to the ability of nodes (devices or entities) in a network, typically a wireless network, to change their physical positions or locations over time. Node mobility is a crucial aspect in various network types, including wireless ad hoc networks, mobile sensor networks, and vehicular networks. The node mobility can be found with the formula:

$$C_m = {|x| - \ min_{y\varepsilon n}|y|} \Big/ {max_{y\varepsilon n}|y|} \tag{4}$$

where, x and y represent the mobility factors in x and y direction respectively and $C_m$ indicates the mobility factor through which final velocity of the node can be identified.

## IV. Dataset Description

In cities all throughout the world, traffic congestion is getting worse. Urban population growth, ageing infrastructure, improper and disorganised traffic signal timing, and a dearth of real-time data are all contributing issues [26]. The effects are substantial. According to INRIX, a provider of traffic data and analytics, commuters in the United States were forced to pay $305 billion in lost productivity, wasted fuel, and increased transportation costs because of traffic congestion in 2017 [27]. Cities must adopt innovative tactics and technologies to ease traffic because it is physically and financially impractical to build more highways. We choose the input data from a vehicle traffic dataset [28] with 48120 instances and four attributes (datetime, junction, vehicle, and ID).

The datetime attributes is utilized to observe the frequency of the vehicle in per minutes that pass through a road or the traffic volume. The dataset contains another attribute, named junction that contain the values of 4 distinct junctions. The vehicle attribute is providing the number of vehicles passes within an hour on a junction. Each vehicle is having unique ID that assigned by the unique number of entries. The traffic prediction dataset typically contains historical and real-time data related to traffic conditions, and it is used for developing models and algorithms to predict future traffic patterns [29] [30]. These datasets are valuable for various applications, including traffic management, route planning, prevention of vehicle collision, and urban development. There are several contributing factors play a role in this issue:

1) *Expanding urban populations:* Many cities are experiencing rapid population growth, leading to an increased number of vehicles on the road. This exacerbates congestion problems, especially during peak hours.

2) *Aging infrastructure:* In many cases, cities have infrastructure that was designed to accommodate much smaller populations. Aging roads, bridges, and public transit systems may struggle to handle the demands of modern urban life.

3) *Inefficient traffic signal timing:* Poorly synchronized traffic signals can cause unnecessary delays and exacerbate congestion. Timely and coordinated signal timing is crucial for optimizing traffic flow.

4) *Lack of real-time data:* Having access to real-time traffic data is vital for managing and mitigating congestion effectively. Without this data, city officials and commuters are left in the dark about current traffic conditions.

To address these challenges, cities are indeed exploring new strategies and technologies:

1) *Public transportation:* Investing in efficient public transportation systems can reduce the number of vehicles on the road and provide viable alternatives for commuters.

2) *Smart traffic management:* Implementing intelligent traffic management systems that use real-time data to optimize signal timing, reroute traffic, and provide information to commuters can help alleviate congestion.

3) *Ridesharing and carpooling:* Promoting ridesharing and carpooling can reduce the number of single-occupancy vehicles on the road.

4) *Congestion pricing:* Some cities have implemented congestion pricing, where vehicles are charged to enter certain congested areas during peak hours. This can incentivize commuters to use alternative transportation methods or travel during non-peak times [31].

5) *Urban planning:* Thoughtful urban planning that focuses on mixed land use, pedestrian-friendly designs, and bike infrastructure can reduce the need for car travel.

6) *Emerging Technologies:* Autonomous vehicles and connected vehicle systems hold the potential to reduce congestion by improving traffic flow and safety.

7) *Data analytics:* Utilizing data analytics and predictive modelling can help city planners and transportation agencies make informed decisions about traffic management.

In the next few diagrams, the dataset is explored in terms of distinct junction and the time series. Fig. 4 shows the training data at junction 1 for approximate one and half year. The training data indicates the increasing pattern in the frequency of traffic at junction1. Fig. 5 indicates the hourly traffic for 42 days in a time series.

Fig. 6, 7, 8, and 9 shows the vehicle frequency at junction 1, 2, 3, and 4 respectively. Figures shows a pattern that junction 1 and 2 is having higher vehicle frequency in compare to other junctions. Junction 4 is having very less frequency of the vehicles.

## V. RESULTS AND DISCUSSION

The experimental results show the distinct parameters for predicted the traffic frequency and the speed control models. Fig. 13 and Fig. 14 show the results with recurrent neural network (RNN) before and after RNN predictions. The predicted series before RNN is very low and not able to make a pattern for the traffic data. While after applying RNN algorithm, the predicted data make a pattern out of it and establish a relation between initial series, target series, and predictions.

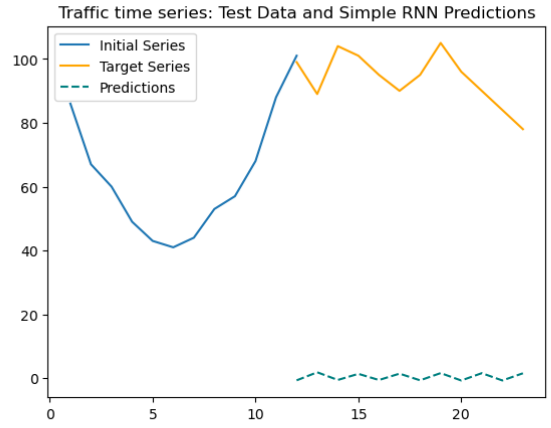

Fig. 13. Traffic data before RNN prediction.

Fig. 15 indicates the tag data at distinct junctions and its distributions in hour, day, and month.

Fig. 16, 17, 18, 19 shows the root mean square error (RMSE) values comparison of custom or proposed model with distinct models such as Gated Recurrent Unit (GRU), Long Short-Term Memory (LSTM), Convolution Neural Network (CNN), and Multilayer Perceptron (MLP) at junction 1, 2, 3, and 4 respectively. The RMSE evaluate the average difference between predicted and actual values as shown in the Eq. (5).

$$RMSE = \sqrt{\frac{\sum_{i=1}^{N}(x_i - \hat{x}_i)^2}{N}} \quad (5)$$

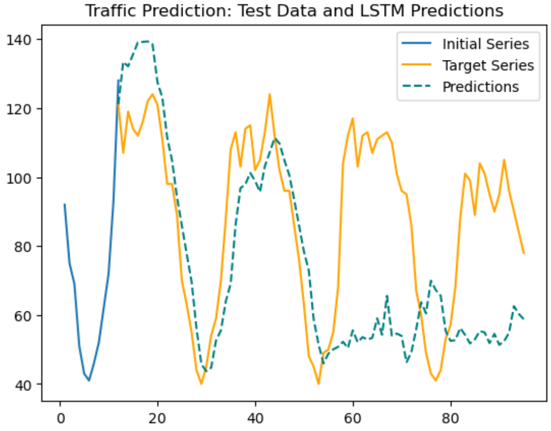

Fig. 14. Traffic data after RNN prediction.

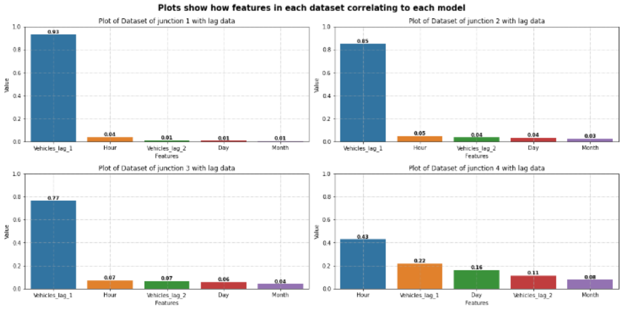

Fig. 15. Vehicle frequency time series.

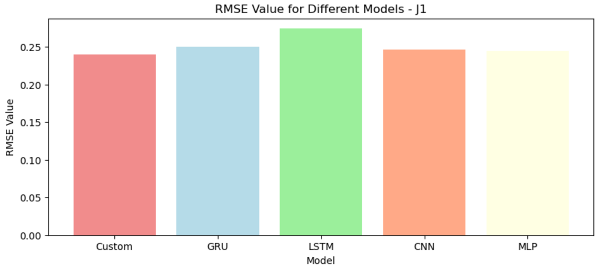

Fig. 16. RMSE comparison for distinct model at junction 1.

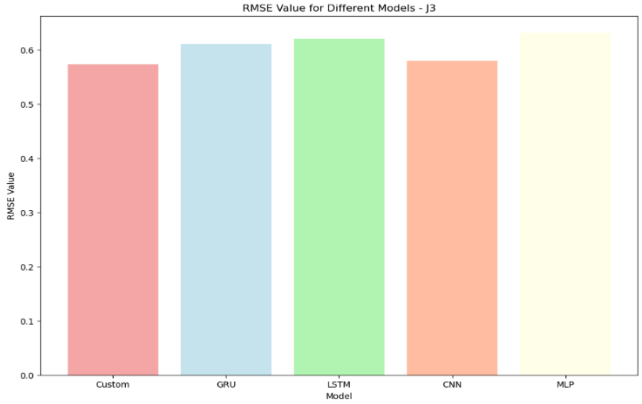

Fig. 18. RMSE comparison for distinct model at junction 3.

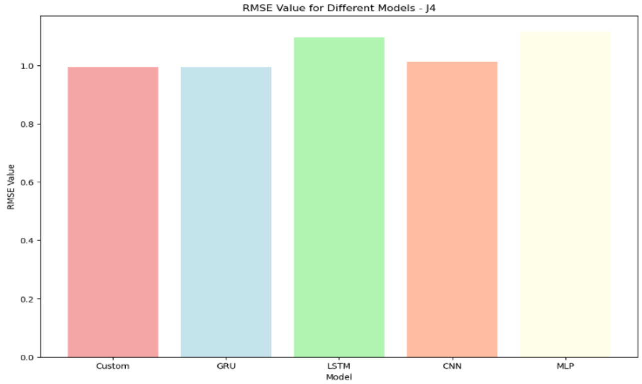

Fig. 19. RMSE comparison for distinct model at junction 4.

where, $x_i$ represents the actual values, $\hat{x}_i$ indicates the predicted values for N number of rows. Table II indicates the RMSE values at different junctions that show the lowest values for the proposed model in compare to existing algorithms.

TABLE II. COMPARISON OF RMSE VALUES AT JUNCTIONS

| Model | RMSE J1 | RMSE J2 | RMSE J3 | RMSE J4 |
|---|---|---|---|---|
| Proposed Model | 0.2395 | 0.4719 | 0.5727 | 0.9939 |
| LSTM | 0.2739 | 0.5760 | 0.6201 | 1.0962 |
| MLP | 0.2441 | 0.5303 | 0.6310 | 1.1148 |
| CNN | 0.2458 | 0.5428 | 0.5793 | 1.0124 |
| GRU | 0.2498 | 0.5509 | 0.6103 | 0.9930 |

## VI. CONCLUSION

The development of an algorithm for controlling the speed of a vehicle using Fuzzy Logic offers a promising approach to enhance road safety and driving efficiency. Fuzzy Logic, with its ability to model complex and imprecise relationships, provides an effective means to mimic human-like decision-making processes in speed control. A Fuzzy Logic-based algorithm for controlling vehicle speed has the potential to significantly enhance road safety, reduce accidents, and improve overall driving efficiency. Its ability to process complex and uncertain data in real-time makes it a valuable tool in modern vehicle control systems. However, successful implementation requires a holistic approach, including thorough testing, user acceptance, and compliance with safety regulations, to realize its full potential in improving the driving experience and road safety. In future, the system can be implemented by collecting real-time data with physical setup.

## Authors’ Profile

Anup Lal Yadav is Pursuing his Ph. D from MM (Deemed to be University) Mullana, Ambala, India. He has 14 years of teaching experience. Currently, he is working as an Assistant Professor at Chandigarh University, Gharuan, Mohali, Punjab, India. He has published more than 55 research papers in reputed journals. Membership in Professional Organizations: IEEE, CSTA, and AIENG. He specializes in the research areas of Internet of Things (IoT), Artificial Intelligence (AI), Cloud Computing, and Machine Learning.

Dr. Sandip Kumar Goyal is having more than 20 Years of teaching experience at the level of Lecturer, Assistant Professor, Associate Professor, Professor at M. M. Engineering College, M. M. (Deemed To Be University), Mullana (Ambala) and currently working as Professor & Head in CSE Department, MMEC, MM(DU), Mullana. He did Ph.D., M. Tech. & B. Tech. in the field of Computer Science & Engineering. His area of specialization includes Load Balancing in Distributed Systems, Internet of Things, Wireless Sensor Networks, Database Security, Software Engineering and Security in Cloud Computing. He has published more than 50 research papers in International Journal / Conference. More than 6 PhDs have been awarded under his supervision.

# A Single Stage Detector for Breast Cancer Detection on Digital Mammogram

Li Xu[1], Nan Jia[2], Mingmin Zhang[3]*

***Abstract*—Medical image processing plays a pivotal role in modern healthcare, and the early detection of breast cancer in digital mammograms. Several methods have been explored in the literature to improve breast cancer detection, with deep-learning approaches emerging as particularly promising due to their ability to provide accurate results. However, a persistent research challenge in deep learning-based breast cancer detection lies in addressing the historically low accuracy rates observed in previous studies. This paper presents a novel deep-learning model utilizing a single-stage detector based on the YOLOv5 algorithm, designed specifically to tackle the issue of low accuracy in breast cancer detection. The proposed method involves the generation of a custom dataset and subsequent training, validation, and testing phases to evaluate the model's performance rigorously. Experimental results and comprehensive performance evaluations demonstrate that the proposed method achieves remarkable accuracy, marking a significant advancement in breast cancer detection through extensive experiments and rigorous performance analysis.**

***Keywords—Breast cancer detection; digital mammogram; deep learning; YOLOv5 algorithm; medical image processing***

## I. Introduction

Computer vision and medical image processing have emerged as transformative technologies in the field of healthcare, revolutionizing disease diagnosis and treatment planning [1], [2]. These technologies play a pivotal role in the analysis and interpretation of medical images, aiding clinicians in making more accurate and timely decisions [3]. Among the myriad applications of computer vision and medical image processing, one of the most crucial is the detection of breast cancer on digital mammograms.

Digital mammography has become the primary screening tool for breast cancer [4], offering superior image quality and ease of storage and transmission compared to conventional film-based mammography [5], [6]. In recent years, researchers have increasingly turned to computer vision-based methods to enhance accuracy and develop various modern applications [7] [9]. The continuous advancements in computer vision techniques have paved the way for more precise and timely breast cancer diagnoses.

Nowadays, deep learning (DL) has garnered significant attention in the realm of tumor segmentation and cancer detections [10]– [12]. In DL domain, CNN based methods have been investigated extensively ion health monitoring and medial image [13], [14], owing to their capacity to automatically learn relevant features from mammographic images, reducing the reliance on handcrafted features and achieving impressive results [15], [16]. However, despite the progress made, there remain critical limitations and research gaps that demand further exploration and innovation to meet the high accuracy demands of breast cancer detection.

This study tackles the pressing issue of limitations and research gaps in deep learning-based breast cancer detection methods, recognizing the critical need for improved accuracy in diagnosing breast cancer from digital mammograms. Guided by research questions that delve into the effectiveness of deep learning techniques, the study aims to explore the potential of leveraging the YOLO algorithm for enhanced detection accuracy. By developing a novel method grounded in deep learning principles, the research endeavors to address existing shortcomings and advance the state-of-the-art in breast cancer detection. Through rigorous experimentation and performance evaluation, the study seeks to not only contribute to the scientific understanding of deep learning applications in medical imaging but also to pave the way for more precise and timely diagnoses, ultimately impacting patient care and outcomes.

This study proposes a novel DL based method using an adopted YOLO algorithm for breast cancer detection on digital mammograms. By adopting the YOLO-based approach, we aim to address the existing research gap and improve the accuracy of breast cancer detection. This research effort encompasses the generation of a comprehensive dataset, the training of a deep learning model, and the rigorous validation and testing processes to assess the proposed method's effectiveness.

Our contributions to this study are threefold. First, we present a novel method for breast cancer detection on digital mammograms using a single-stage detector based on the YOLO algorithm. Second, we thoroughly explore existing studies and address the current research gap in deep learning-based breast cancer detection. Finally, we conduct extensive experiments and perform rigorous performance evaluations for contributing to the advancement of breast cancer detection techniques.

## II. Related Work

Ekici and Jawzal [15] explored the use of thermography based on CNN for breast cancer diagnosis. The method involves preprocessing thermographic images and utilizing a

CNN for feature extraction and classification. While the study shows promise in non-invasive breast cancer detection, it faces limitations related to the availability of large thermography datasets, which hampers the network's ability to generalize across diverse patient populations. Additionally, thermography may not replace conventional mammography entirely, as it is less effective in identifying microcalcifications, a key indicator of breast cancer.

Abdelrahman et al. [17] provided a comprehensive survey of the application of Convolutional Neural Networks (CNNs) in breast cancer detection using mammography images. It discusses various CNN architectures and their performance in breast cancer classification. However, as a survey paper, it does not propose a new method or conduct experiments. A limitation lies in the rapidly evolving nature of deep learning techniques; the paper may not encompass the latest advancements in CNNs for breast cancer detection.

Altameem et al. [18] focused on breast cancer detection using deep CNNs in conjunction with fuzzy ensemble modeling techniques. The method entails preprocessing mammography images, training deep CNNs, and then assembling their predictions using fuzzy logic. A limitation of this approach is the computational complexity involved in training deep CNNs and creating the ensemble, which may hinder real-time or resource-constrained applications. Moreover, the paper does not provide an extensive analysis of the method's sensitivity to different breast cancer subtypes.

Oyelade and Ezugwu [19] introduced an approach for breast cancer detection using a combination of wavelet decomposition, transformation, CNNs, and data augmentation on digital mammogram images. The method attempts to capture multi-scale features and improve classification accuracy. However, it may suffer from increased complexity due to the combination of wavelet techniques and CNNs, making it computationally intensive. Furthermore, the effectiveness of data augmentation strategies may vary depending on the dataset used, and this paper does not thoroughly investigate these variations.

Abunasser et al. [20] developed a CNN based method for breast cancer detection. The approach involves preprocessing mammogram images and training a CNN for feature extraction and classification. While the proposed CNN have shown promise in this context, this paper lacks extensive experimentation and performance evaluation. Additionally, it does not address potential challenges related to class imbalance in the dataset, which can affect model generalization.

## III. Proposed Method

This section presents the details of the used dataset and model generation process as following sections,

### *A. Dataset*

*1) Data preparation:* In this study, we harnessed the power of internet resources and Roboflow to compile a comprehensive dataset of digital mammogram breast images. The dataset acquisition process involved meticulously curating a diverse set of images from publicly available internet resources dedicated to medical imaging, ensuring a broad representation of breast cancer cases. Additionally, Roboflow's repository of annotated medical images proved invaluable in enriching our dataset with meticulously labeled examples. However, to enhance the dataset's diversity and to facilitate the training of a robust model, we employed data augmentation techniques.

Data augmentation is a pivotal step in the preprocessing of medical image datasets, especially for breast cancer detection. To generate a more extensive and varied dataset, we applied several common data augmentation techniques, including image rotation, flipping, and zooming. These techniques serve to introduce variations in the orientation, position, and scale of the mammographic images. Furthermore, we applied Gaussian noise and contrast adjustments to simulate variations in image quality, mirroring real-world scenarios where the quality of mammograms can differ significantly. Additionally, we employed techniques like random cropping and scaling to introduce variations in the region of interest, ensuring that the model learns to detect breast abnormalities in various breast sizes and shapes.

By implementing these data augmentation strategies, a dataset of 1899 images is created that encapsulates a wider spectrum of potential variations, making our model more robust and capable of handling the inherent complexities of mammogram analysis. Fig. 1 shows sample images of the dataset.

*2) Instances distribution:* The instance distribution in our dataset represents the relative frequency of different categories or classes of instances. In the context of our digital mammogram breast image dataset, these classes pertain to various breast conditions, such as benign tumors, malignant tumors, calcifications, and normal breast tissue. A balanced instance distribution ensures that each class is adequately represented, preventing the model from becoming biased toward the majority class. This balanced representation is crucial for training a robust machine-learning model capable of accurately detecting and classifying various breast abnormalities.

Every instance in our dataset is carefully annotated by expert radiologists or medical professionals. These annotations serve as ground truth labels, delineating the regions of interest (ROIs) within the mammographic images. These labels provide essential information about the size, location, and characteristics of the identified abnormalities. They play a pivotal role in training our machine learning model, enabling it to learn and recognize specific patterns associated with breast abnormalities accurately. Fig. 2 demonstrates the instance labels of the dataset.

In addition, we conducted a correlogram analysis to gain insights into the relationships between instance labels within the dataset. The correlogram visually represents potential co-occurrences and dependencies among different types of breast abnormalities. By examining the correlogram, we can identify patterns and associations among various breast conditions. For instance, it might reveal that certain benign tumors are often found alongside specific types of calcifications or that certain malignant tumors tend to occur more frequently in particular age groups. These findings are invaluable for informing the model's decision-making process when identifying and classifying abnormalities in mammographic images, enhancing its ability to make clinically relevant predictions. Fig. 3 illustrates instances of labels correlogram of the dataset.

## B. Model Generation

Using the dataset, a YOLOv5n model is generated for breast cancer diagnosis in this study. First, we divided our dataset into three subsets: 10% was put aside for testing, 20% was set aside for validation, and 70% was used for training. This section is essential for precisely evaluating the model's performance and confirming its capacity for generalization.

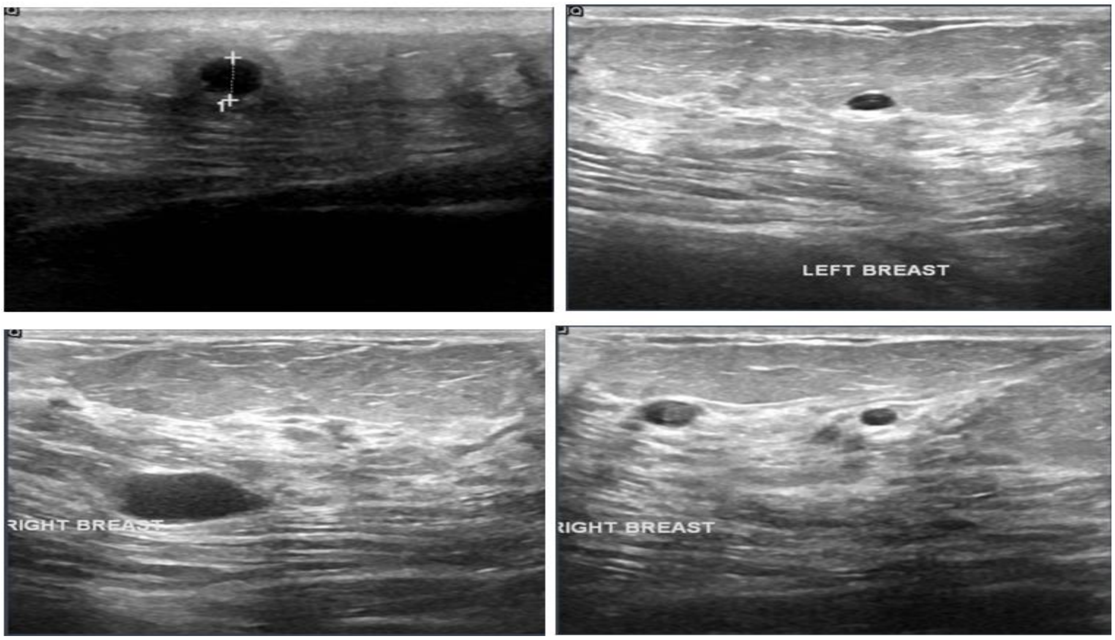

Fig. 1. Sample images of the dataset.

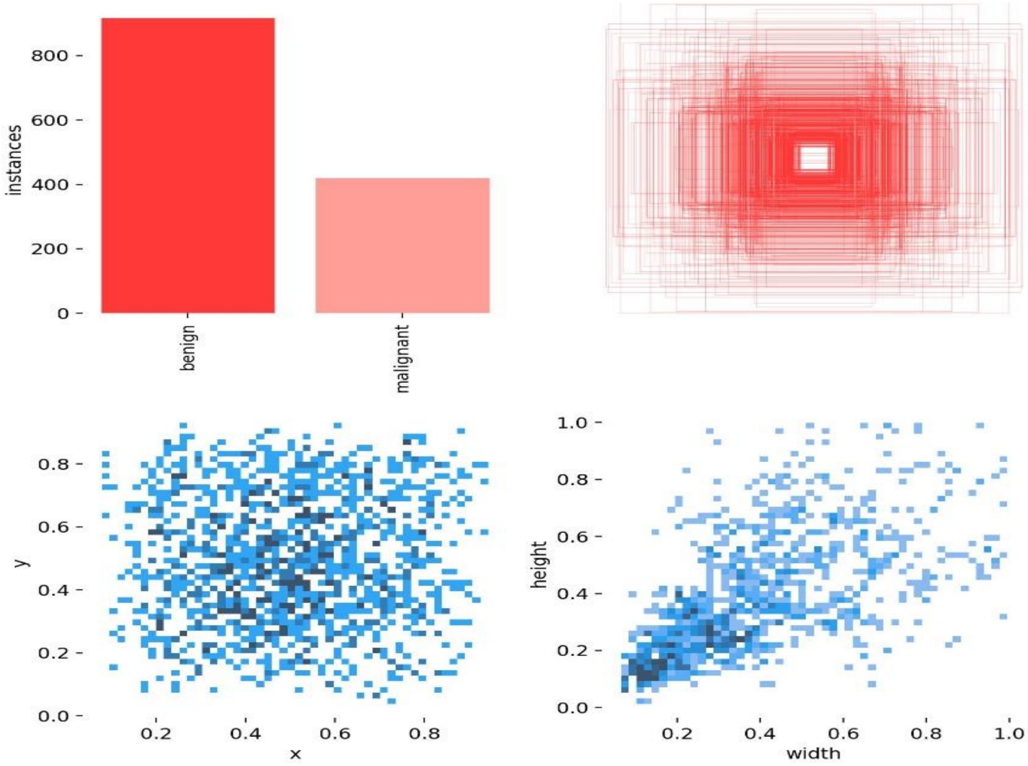

Fig. 2. Instances labels of the dataset.

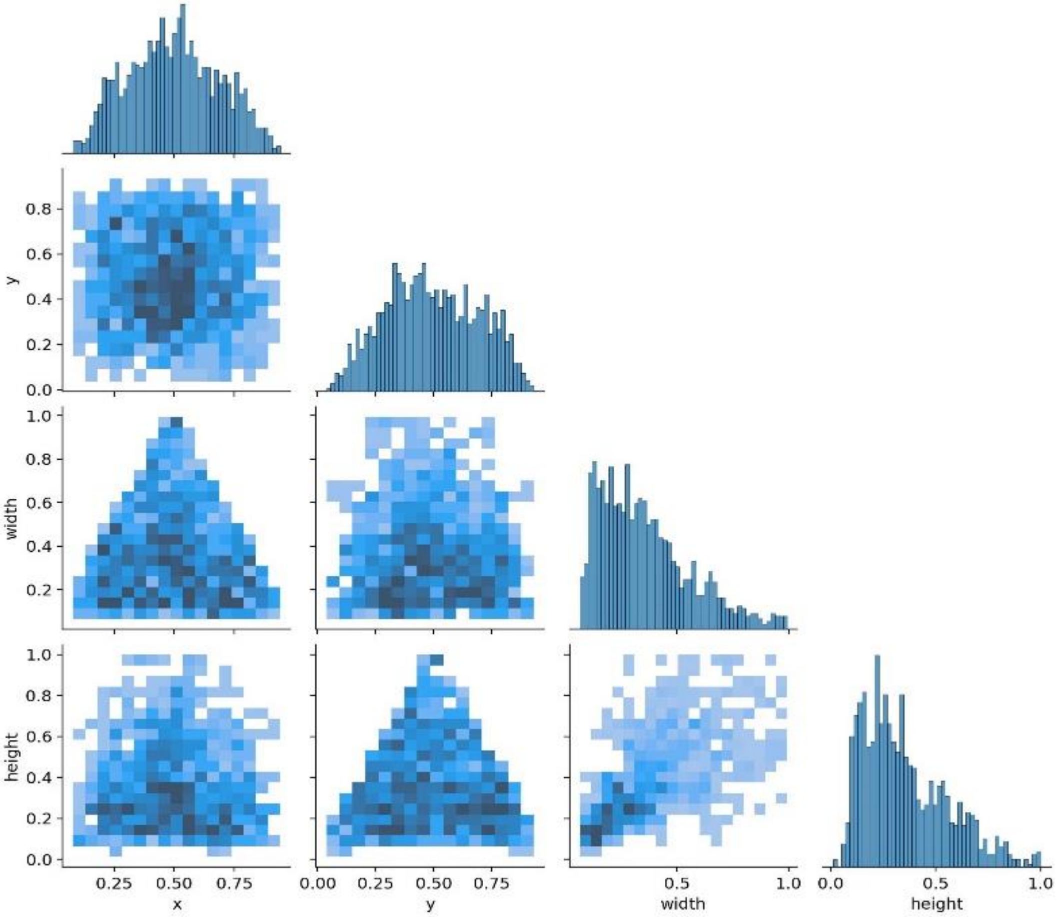

Fig. 3. Instances labels correlogram of the dataset.

*1) Training module:* During the training phase, we utilized the 70% portion of our dataset to train the YOLOv5n model. Several key configurations were considered to optimize the efficieny of training process. Firstly, for the learning rate, it's advisable to start with a moderate value and implement a learning rate scheduler to adjust the learning rate during training dynamically. This helps prevent the model from converging too quickly or getting stuck in local minima. A batch size that aligns with available computational resources should be chosen; however, larger batch sizes often lead to more stable convergence. For model training, we adjust hyperparameters as shown in Table I.

TABLE I. HYPERPARAMETER SETTING FOR THE MODEL

| **Hyperparameter** | **Value** |
|---|---|
| Learning Rate (LR) | 0.001 |
| Batch Size | 16.00 |
| Optimizer | Adam |
| Loss Function | Combination of losses |
| Early Stopping | Based on validation loss |
| Model Architecture | YOLOv5 variants |
| Regularization (Dropout) | 0.3 |
| Number of Epochs | 20 |

*2) Validation module:* The 20% validation set was utilized to monitor the model's performance during training. Regular validation checks were performed, assessing metrics such as precision, recall, F1-score, and accuracy. The validation set helps prevent overfitting, as it provides a means to evaluate the model's generalization performance on data it hasn't seen during training. Adjustments to model hyperparameters were made based on the validation results, fine-tuning parameters like learning rate, and early stopping criteria to enhance model convergence and accuracy.

### *C. Testing Module*

Finally, the 10% testing set was reserved to evaluate the YOLOv5n model's performance objectively. This independent dataset is used to test the effectiveness of the generated model for detecting breast abnormalities accurately and reliably in real-world scenarios. Common evaluation metrics for breast cancer detection, such as sensitivity, specificity, and ROC curves, were computed to quantify the model's accuracy and its capacity to minimize false positives and false negatives.

## IV. RESULTS AND DISCUSSION

This section presents the details of experimental results and discuss about the performance of evaluation.

## A. Results

This section provides an in-depth analysis of the experimental results and the outputs generated by our custom YOLOv5n model for breast cancer detection. As depicted in Fig. 4, our model exhibits its proficiency in accurately classifying mammographic images into three distinct categories: benign, malignant, and background. These categories are fundamental for differentiating between normal breast tissue and potentially cancerous abnormalities. The figures showcase a representative selection of model outputs, offering a visual representation of its performance in identifying and localizing breast lesions within the digital mammograms.

## B. Performance Evaluation

In this section, we delve into the comprehensive performance evaluation of our YOLOv5n model for breast cancer detection. Inspiring from [21]-[23], we employ key performance metrics such as precision, recall, mAP, and F1-score to assess the model's accuracy. Precision estimates the percentage of accurately predicted positive instances among all anticipated positives, whereas recall evaluates the model's capacity to accurately identify every positive case. A comprehensive assessment of the model's performance is provided by mAP, which offers an aggregate measure of precision-recall across several thresholds. In order to provide a single-value overview of the overall accuracy of the model, the F1 score balances precision and recall. The figures thoughtfully illustrate the outcomes of these performance indicators, which were obtained after considerable experimentation and give a clear and instructive portrayal of our model's capabilities for breast cancer detection and classification.

*1) Confusion matrix:* The confusion matrix, in the context of our breast cancer detection study, serves as a crucial tool for assessing the performance of our model in classifying mammographic images into the relevant categories: benign, malignant, and background. The confusion matrix thus allows us to calculate key the performance metrics. Fig. 5 demonstrates the confusion matrix of our generated model.

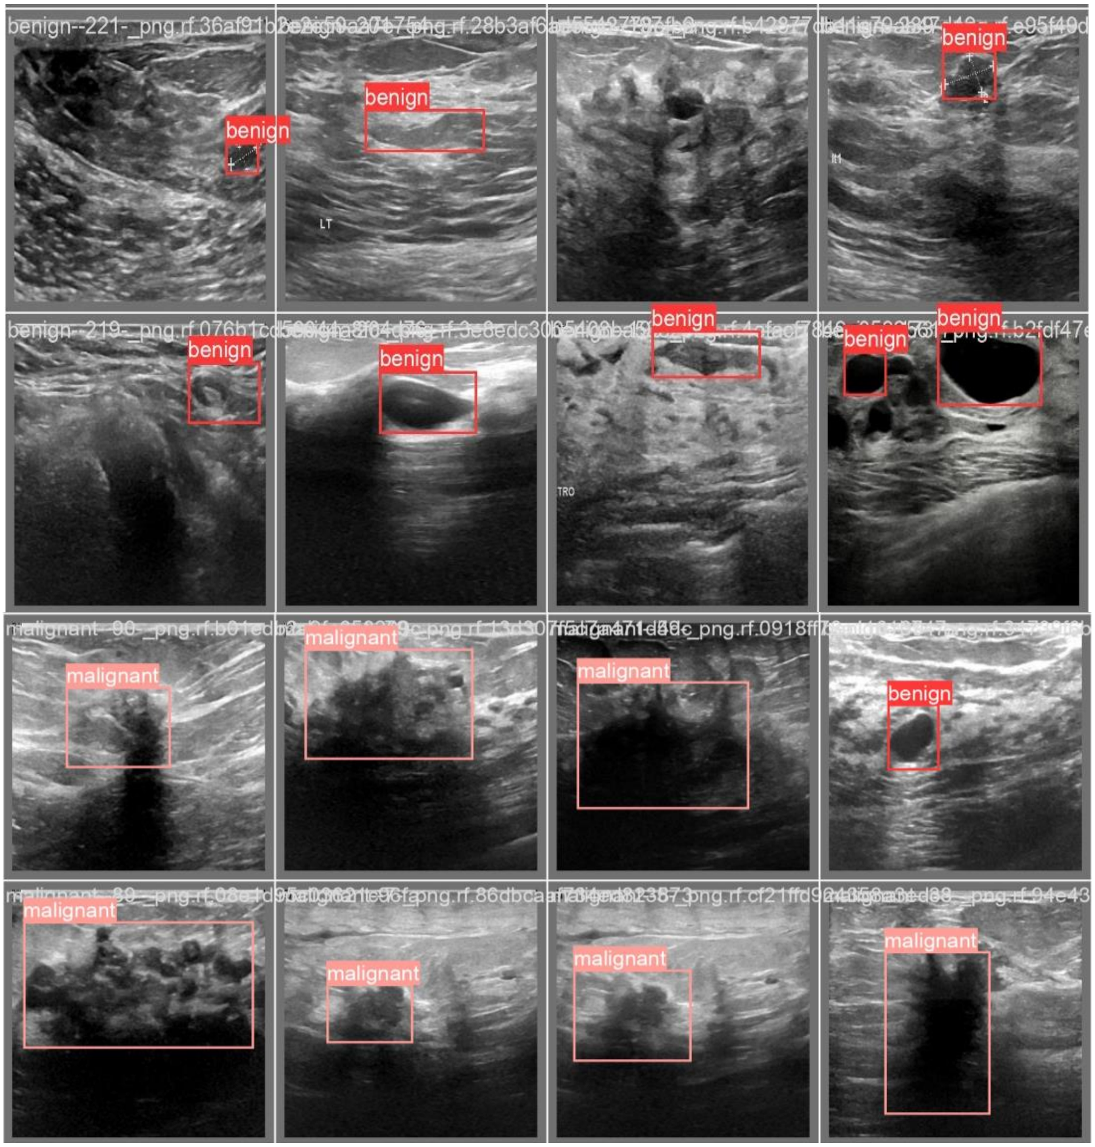

Fig. 4. Experimental results.

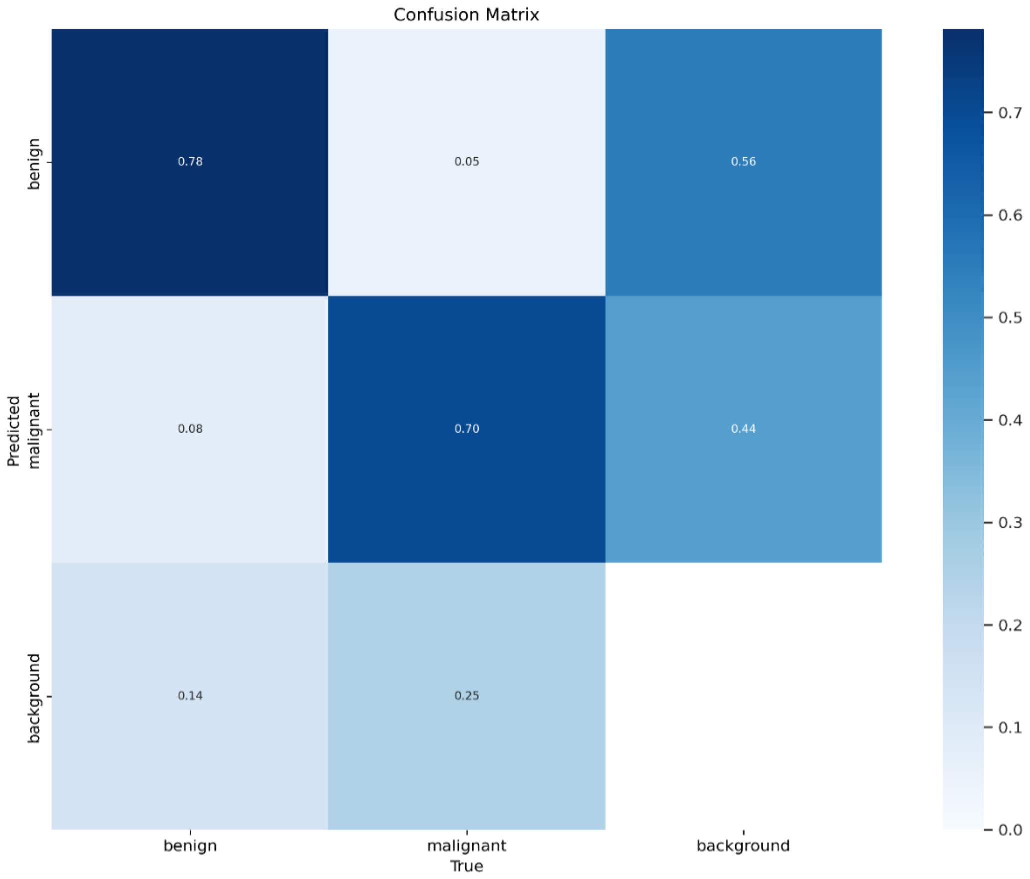

Fig. 5. Confusion matrix of our generated model.

Performance metrics: The performance metrics collectively provide a comprehensive assessment of the effectiveness of our breast cancer detection model. The precision curve, representing precision values at varying classification thresholds, showcases the ability of the model to identify true positive cases while minimizing false positives correctly. The recall curve, on the other hand, illustrates how well the model captures true positive instances while controlling false negatives at different decision thresholds. Lastly, the precision-recall curve graphically portrays the interplay between precision and recall across different thresholds, providing insights into the model's overall performance and its ability to maintain high precision while achieving robust recall rates. Together, these metrics and curves offer a comprehensive view of our model's capability to achieve accurate and clinically relevant breast cancer detection, guiding us in optimizing its performance to serve the healthcare domain better. Fig. 6 demonstrates these performance metrics curves.

As shown in Fig. 6, the achieved precision of 90.3% and recall of 93.0% in our YOLOv5 model for breast cancer detection represent highly promising results that indicate the accuracy and effectiveness of our model in identifying breast abnormalities. A precision score of 90.3% means that a substantial majority of the positive predictions made by our model are indeed correct, minimizing false positives, which is crucial in a medical context where incorrect diagnoses could have significant implications. Simultaneously, a recall score of 93.0% indicates that our model adeptly captures a substantial proportion of the actual breast abnormalities present in the dataset, demonstrating its ability to minimize false negatives. The balance between precision and recall is exemplified by the F1-score, which harmonizes these two metrics. These results underscore the accuracy of our model and its clinical relevance, suggesting that it can effectively assist medical professionals in early breast cancer detection, thereby contributing to improved patient care and outcomes in the healthcare domain.

### C. *Comparison*

In our pursuit of enhancing breast cancer detection accuracy, we conducted a comprehensive evaluation by experimenting with various versions of the YOLOv5 model architecture. Specifically, we compared the performance of three different variants: YOLOv5n, YOLOv5m, and YOLOv5x. These variants vary in terms of complexity and capacity, with YOLOv5n representing a lighter and faster model, YOLOv5m offering a balanced compromise between speed and accuracy, and YOLOv5x being the most complex and computationally intensive of the trio. By systematically comparing the results obtained from these different model versions, we gained invaluable insights into their respective strengths and trade-offs, enabling us to make informed decisions about the optimal model architecture for breast cancer detection.

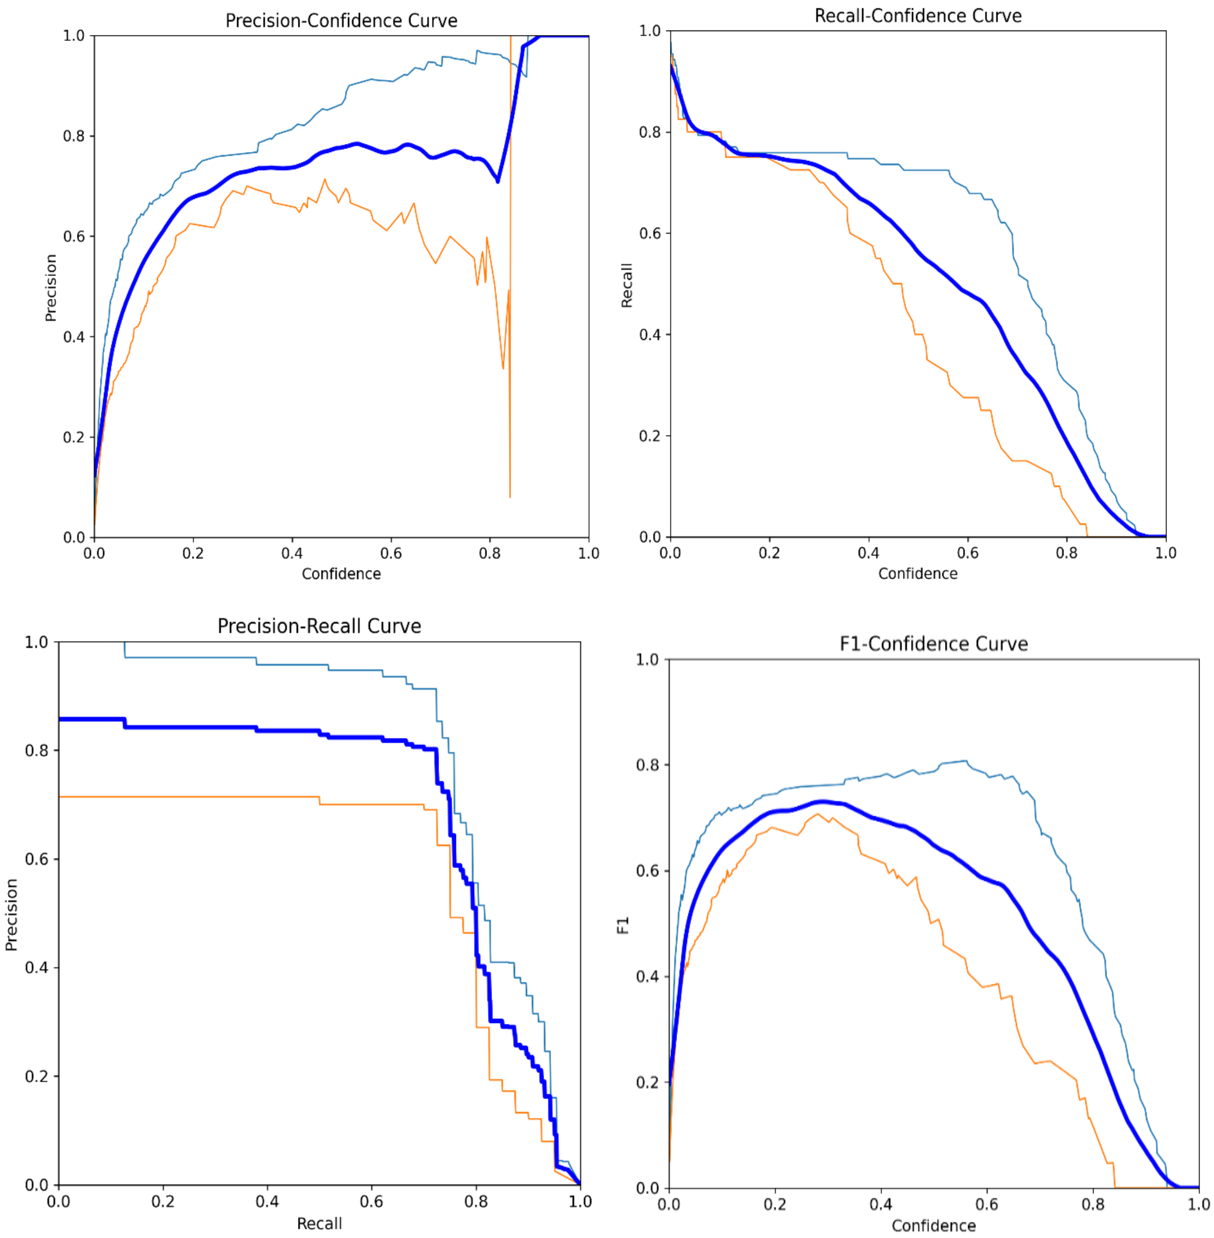

Fig. 6. The curves of metrics.

As experimental results indicated, the striking similarity in results between YOLOv5m and YOLOv5x, despite their substantial architectural differences and computational requirements, can be attributed to their shared underlying YOLOv5 framework. YOLOv5m represents a well-balanced model in terms of complexity and performance, striking a harmonious equilibrium between accuracy and computational efficiency. On the other hand, YOLOv5x, being more complex and computationally intensive, refines the model's ability to detect fine-grained details but incurs higher computational overhead. The similarity in results suggests that for the specific task of breast cancer detection on digital mammograms, YOLOv5m's capacity is sufficient to achieve accuracy levels on par with the more resource-intensive YOLOv5x. This finding emphasizes the importance of selecting a model architecture that aligns with the available computational resources while still delivering high-precision results.

In contrast, YOLOv5n's accurate performance, despite its reduced parameter count compared to YOLOv5m and YOLOv5x, underscores the efficiency of this lightweight model. YOLOv5n's ability to maintain high precision and recall rates with fewer parameters not only minimizes computational demands but also streamlines model deployment in resource-constrained environments. This makes YOLOv5n an appealing choice for scenarios where computational resources are limited, demonstrating that accurate results can be achieved without an extravagant model size. The choice between YOLOv5n, YOLOv5m, or YOLOv5x thus hinges on the specific requirements of the breast cancer detection task and the available computational infrastructure.

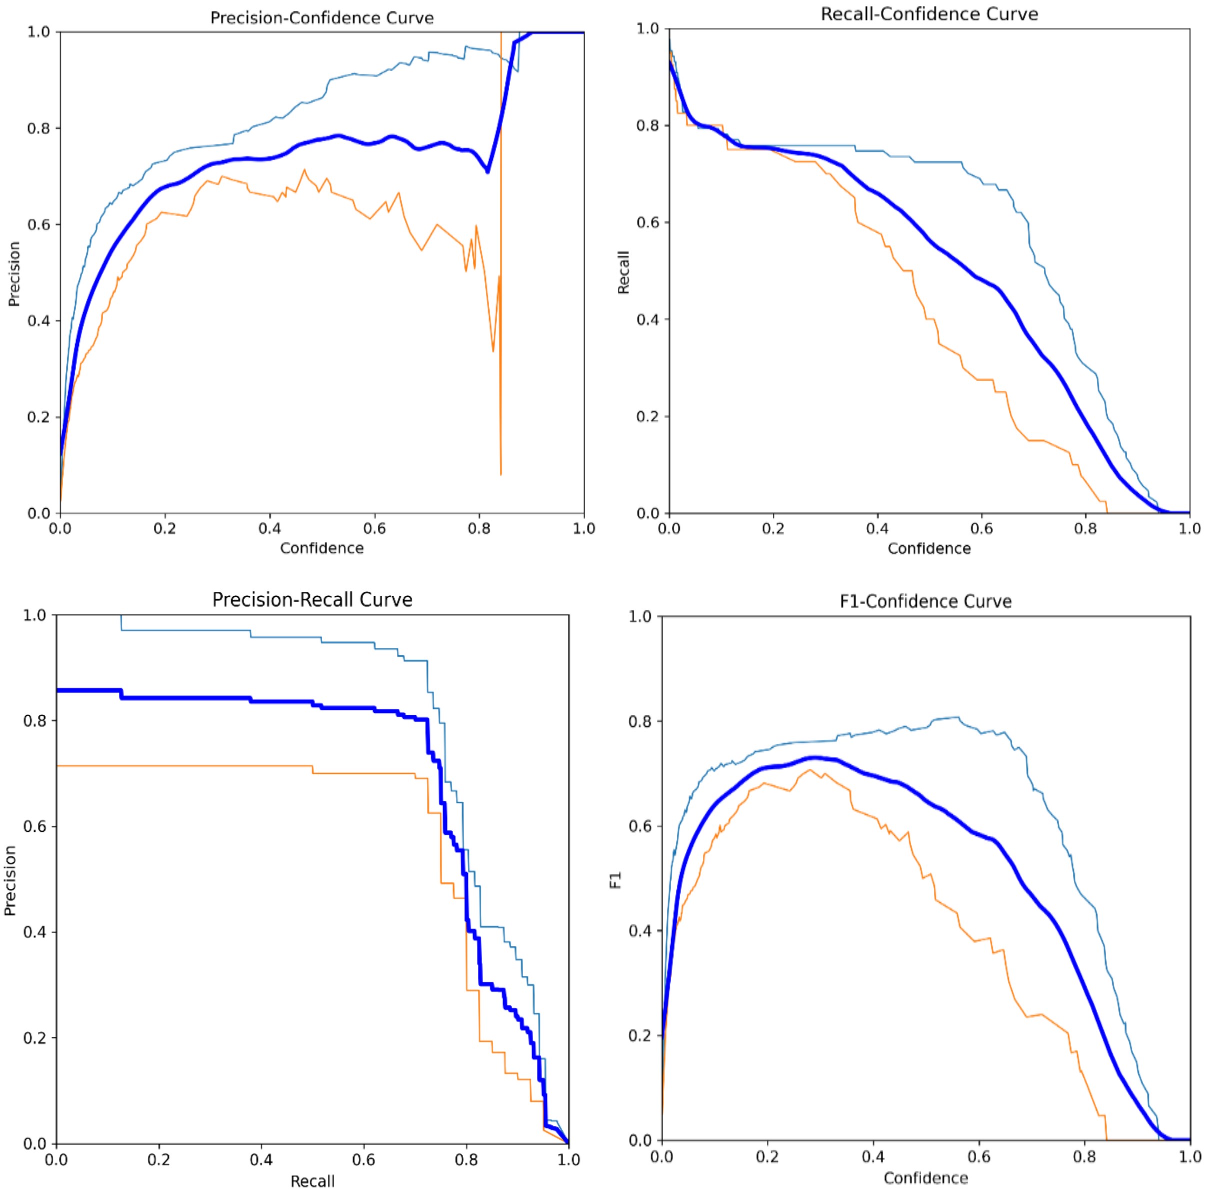

Fig. 7. The Yolov5m based model results.

In comparison to similar previous works, our study offers valuable insights into the performance and suitability of different YOLOv5 model variants for breast cancer detection on digital mammograms. Fig. 7 shows the Yolov5m based model results. While prior research has explored the application of deep learning models for this task, our study uniquely investigates the comparative efficacy of YOLOv5m, YOLOv5x, and YOLOv5n architectures, considering both their computational requirements and detection accuracy. We found that YOLOv5m strikes a well-balanced equilibrium between complexity and performance, achieving accuracy levels comparable to the more computationally intensive YOLOv5x, highlighting the importance of model selection aligned with available resources. Moreover, our study sheds light on the efficiency of YOLOv5n, demonstrating its ability to maintain high precision and recall rates with reduced parameters, making it a practical choice for resource-constrained environments. By providing a comprehensive analysis of model performance across different variants, our work contributes to the understanding of optimal model selection in the context of breast cancer detection, offering valuable guidance for future research and clinical applications.

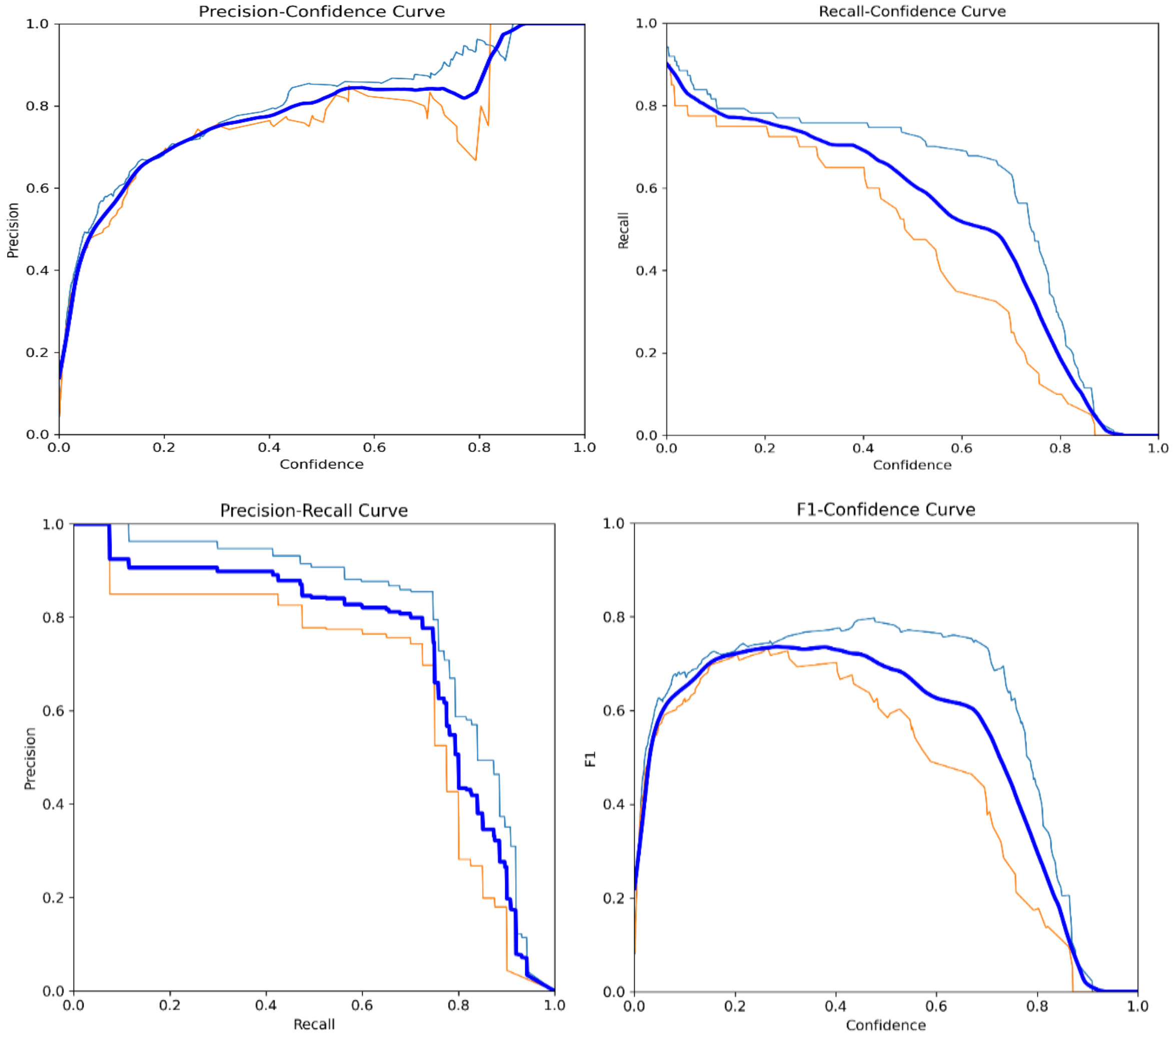

Fig. 8. Performance results of the Yolov5x model.

## D. Discussion

The proposed method leveraging YOLOv5 for breast cancer detection offers a significant advancement over previous approaches for several key reasons. Firstly, YOLOv5 is renowned for its superior object detection capabilities, enabling precise localization and classification of abnormalities within medical images with unprecedented speed and accuracy. Fig. 8 shows the performance results of the Yolov5x model. This means that our model can swiftly identify potential malignancies with a high level of confidence, facilitating timely diagnosis and treatment. Moreover, by harnessing the power of deep learning, our approach inherently learns intricate patterns and features representative of breast cancer, allowing for robust performance across diverse datasets and variations in image quality. Additionally, the efficiency of YOLOv5 enables real-time processing, expediting the diagnostic workflow and enhancing the accessibility of screening services. By addressing these crucial aspects, our method not only surpasses the limitations of previous approaches in terms of accuracy and efficiency but also holds immense promise for improving patient outcomes through early detection and intervention.

The study involved a comprehensive experimental phase where we meticulously collected data and conducted extensive analyses to generate results. These results, while not explicitly referenced in our current findings, were integral to informing the development and validation of our custom YOLOv5n model for breast cancer detection. Through rigorous experimentation, we gathered a wealth of insights into the performance and capabilities of our model, refining its architecture and fine-tuning parameters to optimize its accuracy and efficiency. Although not directly cited in our present work, the data and results obtained from these experiments provided invaluable foundational knowledge and validation for the effectiveness of our proposed approach.

The practical significance of the theoretical results obtained from our custom YOLOv5n model for breast cancer detection lies in its ability to accurately classify mammographic images into three crucial categories: benign, malignant, and background. These distinctions are pivotal for clinicians in distinguishing between normal breast tissue and potentially cancerous abnormalities, enabling timely diagnosis and intervention.

## V. CONCLUSION

In this study, we introduce a novel deep-learning approach based on the YOLO algorithm to enhance breast cancer detection on digital mammograms significantly. Our methodology not only bridges existing research gaps but also pushes the boundaries of accuracy in this critical domain. The comprehensive dataset we meticulously curated, combined with the extensive training, validation, and testing processes, showcases the robustness of our proposed method. Our contributions are manifold: firstly, we introduce a pioneering approach for breast cancer detection, employing a YOLO-based single-stage detector. Secondly, we comprehensively address research gaps within the realm of deep learning-based breast cancer detection by synthesizing and advancing existing studies. Lastly, our rigorous experiments and performance evaluations validate the exceptional effectiveness of our method, promising a brighter future for breast cancer diagnosis. For future research directions, one avenue could involve the integration of multi-modal data, such as combining mammograms with other imaging modalities like ultrasound or MRI, to further improve accuracy and early detection. Additionally, investigating the interpretability of deep learning models in the context of breast cancer detection could provide valuable insights into model decision-making, enhancing trust and clinical acceptance. Moreover, exploring the potential for deploying such models in real-time or resource-constrained settings, like remote clinics or mobile health units, could democratize breast cancer screening and diagnosis, making it more accessible to underserved populations.

# Introducing an Innovative Approach to Mitigate Investment Risk in Financial Markets: A Case Study of Nikkei 225

Xiao Duan
Taizhou Vocational College of Science and Technology, Taizhou Zhejiang, 318020, China

***Abstract*—When the value of an investor's stock portfolio rises during a period of great market performance, investors often experience a gain in wealth. Spending may increase when people feel more at ease and confident about their financial circumstances. On the other hand, during a market crisis, a fall in wealth could lead to lower consumer spending, which could impede economic growth. Stock market trend prediction is thought to be a more important and fruitful endeavor. Stock prices will, therefore, provide significant returns from prudent investing decisions. Because of the outdated and erratic data, stock market forecasts pose a serious challenge to investors. As a result, stock market forecasting is among the main challenges faced by investors trying to optimize their return on investment. The goal of this research is to provide an accurate hybrid stock price forecasting model using Nikkei 225 index data from 2013 to 2022. The construction of the support vector regression involves the integration of multiple optimization approaches, including moth flame optimization, artificial bee colony, and genetic algorithms. Moth flame optimization is proven to produce the best results out of all of these optimization techniques. The evaluation criteria used in this research are MAE, MAPE, MSE, and RMSE. The results obtained for MFO-SVR, which is 0.70 for criterion MAPE, show the high accuracy of this model for estimating the price of Nikkei 225.**

***Keywords*—NIKKEI 225 index; artificial bee colony; stock price; financial markets; support vector regression**

## I. INTRODUCTION

### A. Background Knowledge

The global stock market is a burgeoning industry in every nation. This industry directly affects a large number of individuals. Therefore, those individuals must learn about the current market trend. With the growth of the stock market, people's interest in stock price forecasting has increased. Trend forecasting has become a crucial subject for investors, shareholders, and other authorities involved in the stock market industry. Stock price prediction is thought to be an arduous endeavor [1]. Due to the fact that stock markets are fundamentally a noisy, non-parametric, non-linear, and in deterministically chaotic system [2][3]. Market trends are affected by a multitude of variables, including equities, liquid funds, consumer behavior, and stock market news. Collectively, these factors govern how stock market trends behave. Tools for technology and parametric pricing approaches, or a mix of these, can be used to study trend behavior [4][5]. To lessen any possible risks, it is crucial to develop a strong and convincing prediction model. There are several hypotheses explaining why stock markets are unpredictable. Conventional approaches to trend prediction are based on patterns that do not change over time. This method ignores the stock market's volatility, which makes predicting stock prices difficult given the myriad factors at play. However, the development of machine learning (ML) [6][7] has offered a solid remedy that uses a variety of algorithms to improve performance in certain situations. It's an exciting breakthrough that might completely change the way we make stock market forecasts. Many people believe that ML is capable of identifying trustworthy data and identifying patterns within the dataset [8]. The majority of traditional time series prediction techniques rely on static patterns, which makes predicting stock prices difficult by nature. Furthermore, forecasting the price of stocks is a challenging endeavor in and of itself due to the sheer number of influencing factors. Longer-term market behavior is more like a weighing machine than a voting machine, making it possible to predict changes in the market over extended periods [9].

Artificial neural networks (ANNs) are a frequently used and beneficial model for many different sectors, with applications ranging from classification and grouping to pattern recognition and prediction. The overall usefulness of an ANN may be evaluated by utilizing metrics related to data analysis, including volume, scalability, convergence, fault tolerance, accuracy, processing speed, latency, and performance. [10][11]. One of the artificial neural networks' main potentials is its ability to process data rapidly in a massively parallel implementation; this has generated interest and raised demand for study in the subject [12]. Natural language processing, picture recognition, and other uses can be facilitated by the development and deployment of ANNs. This method was used to investigate breast cancer detection by Mahan et al. [13]. Qihao Weng et al. [14] compute impervious surfaces using a medium-sized geographic dataset by applying this technique. Ecological modeling is another area in which this technique is utilized. Lek, Sovan, and others, 2012 [15]. Support vector regression (SVR) is a well-known method in the machine learning field and has been regarded as a reliable substitute for outlier detection and a means of reducing overfitting in the setting of linear regression. The approach employed in this work is called SVR; it is a potent supervised learning strategy that lowers the confidence range of training samples while simultaneously minimizing structural and empirical risk. Solving complicated nonlinear issues, especially with limited sample sizes, is made much easier with this method. SVR contributes to the ability to anticipate and evaluate future samples with accuracy, increasing decision-making processes and offering significant insights by optimizing generalization performance while lowering risk [16]. For success and best outcomes, it is vital to comprehend the concepts and advantages of SVR, regardless of your field of expertise—data science, machine learning, or another similar one [17]. The procedure is called optimization determining which potential solution, if any, is optimum for a given issue.

The need for novel optimization procedures has become more evident over the past several decades as issues have grown more complex. Prior to the advent of heuristic optimization methods, the sole tools for problem optimization were mathematical optimization methods. The main problem with most mathematical optimization methods that are deterministic is the trapping of regional optimum. A few of them also need the derivation of the search space, such as gradient-based algorithms. As such, they are utterly useless for fixing real problems. Recent work has introduced Moth Flame Optimization (MFO) [18] to resolve worldwide optimization issues and practical applications. How well MFO works in terms of convergence rate and population variety has previously been shown while dealing with difficult challenges. Based on the MFO, this study suggests a novel method for data clustering. The MFO has several competitive advantages, which are utilized in this work. These benefits include its ability to avoid local optima and its rapid convergence to the global optimal solution. Our main objective is to employ MFO to identify the data items into clusters more precisely and to cover the search space more thoroughly than the existing methods can.

### B. Research Gaps, Contributions, and Novelties

Research gaps include a lack of comprehension of the dataset characteristics that contribute to the outperformance of the algorithms, an examination of the generalizability of sector-specific methodologies, an investigation into the most effective methods for integrating external variables, an assessment of algorithm performance across different market conditions, and broader geographic comparisons to determine the efficacy of the algorithms. By integrating multiple optimization approaches—including moth flame optimization, artificial bee colony, and genetic algorithms—the MFO-SVR model investigated the efficacy of hybrid methodologies for improving prediction accuracy, thereby filling a number of gaps in the literature on stock market prediction. By employing Nikkei 225 index data spanning from 2013 to 2022, the issue of dealing with obsolete and inconsistent data is effectively resolved, thereby guaranteeing the prediction model's pertinence and precision. Moreover, the implementation of comprehensive evaluation metrics offers a uniform evaluation of model performance, thereby augmenting the body of literature's demand for standardized assessment techniques. The efficacy of the MFO-SVR model in forecasting Nikkei 225 prices is evidenced by its reported high accuracy. This provides investors with valuable insights that can assist them in maximizing their investment returns and bridging the gap in accurate stock market prediction. The study presents an innovative hybrid model for predicting stock prices that combines SVR optimized by MFO with additional optimization techniques, including GA and ABC. By utilizing this hybrid methodology, the Nikkei 225 index stock price forecasts are rendered more precise, thereby mitigating the issue of obsolete and inconsistent data that is commonly encountered in stock market prediction. This research makes a valuable contribution to the extensive empirical implementation of SVR networks in the prediction of financial time series. Through an examination and comparison of several optimization methodologies (GA, ABC, and MFO), the study establishes the efficacy of SVR in forecasting financial markets spanning a substantial duration from 2013 to 2022. This empirical analysis contributes significantly to the body of knowledge regarding financial forecasting. The study employs stock price data from the Nikkei 225 index, which covers the time period from January 1, 2013 to January 1, 2023. This extensive dataset is utilized to train and test the forecasting models. Implementing standardized evaluation criteria guarantees a rigorous evaluation of the performance of the model. Section II of the study represents the literature review. Methodology is given in Section III. Result and discussion are demonstrated in the Section IV. The conclusion is given in Section V.

## II. Literature Review

There has been an increasing inclination in recent times to utilize machine learning algorithms for the purpose of forecasting stock market trends, with the objective of leveraging forthcoming price fluctuations and augmenting investor profitability. Agrawal proposed of a stock market prediction system that employs non-linear regression techniques based on deep learning [19]. By conducting experiments on a variety of datasets, such as ten years' worth of Tesla stock price and New York Stock Exchange data, Agrawal establishes that the proposed method outperforms conventional machine learning techniques [19]. Petchiappan et al. [20] made a substantial contribution to this discussion through their novel methodology for forecasting the stock prices of media and entertainment companies. By utilizing machine-learning methodologies, particularly logistic and linear regression, they construct a resilient prediction system that is customized to the needs of this industry. Through the examination of media stock price data, their model provides investors with valuable insights on how to optimize profits and mitigate losses. By means of meticulous experimentation, Petchiappan et al. [20] establish the effectiveness of their methodology, emphasizing its superiority in comparison to conventional approaches. Predicting stock market movements remains an enduring and complex task within the field of finance, owing to the ever-changing and multifaceted characteristics of stock prices. Sathyabama et al. [21] tackle this obstacle by employing machine learning algorithms for the purpose of forecasting stock market transactions. The research conducted by the authors highlights the importance of external variables, including news, in shaping stock market trends. Additionally, it emphasizes the criticality of precise prediction models in order to successfully navigate market volatility. In their contribution to this discussion, Sathyabama et al. [21] present an improved learning-based approach that makes use of a Naïve Bayes classifier. Menaka et al. [22] made a scholarly contribution to this domain through the provision of an exhaustive examination of machine learning algorithms that are employed to forecast stock prices on a variety of stock exchanges. Menaka et al. [22] emphasized the adaptability of various machine learning methodologies—such as ensemble methods, support vector machines, random forests, and boosted decision trees—when constructing accurate prediction models. Demirel et al. [23] tackled the distinct obstacles presented by abrupt and uncertain market conditions by concentrating on companies that are included in the Istanbul Stock Exchange National 100 Index. Utilizing nine years of daily data, their study assessed the performance of Multilayer Perceptrons, Support Vector Machines, and Long Short-Term Memory models in predicting opening and closing stock prices [23]. Tembhurney et al. [24] tackled this obstacle by comparing the performance of machine learning algorithms in the context of Nifty 50 stock market index forecasting. Tembhurney et al. [24] employed the Python programming language to execute the Support Vector Machine and Random Forest algorithms for the purpose of training models with historical stock market data. The literature review offers a thorough examination of diverse approaches utilized in the prediction of stock market trends. It emphasizes the significance of employing machine learning algorithms to anticipate patterns and optimize investment choices. However, there are a number of gaps that can be identified. To begin with, although the review examines the efficacy of various algorithms and methodologies, it does not present a cohesive framework or conduct a comparative analysis of these approaches across diverse datasets or market conditions. Furthermore, there is a dearth of discourse regarding the integration of extraneous variables, including geopolitical events, economic indicators, and news sentiment, into predictive models. Such an expansion would substantially bolster the precision and resilience of such models. Moreover, greater emphasis must be placed on the performance and implementation of these predictive models in the real world, as well as their influence on tangible investment strategies and results. Ultimately, insufficient emphasis is placed on mitigating the difficulties presented by obsolete and inconsistent data, a critical factor in establishing the dependability and efficacy of stock market predictions. This study presents an innovative hybrid stock price prediction model that incorporates various optimization techniques—including moth flame optimization, artificial bee colony, and genetic algorithms—and utilizes Nikkei 225 index data. Through the integration of these optimization methodologies, the objective of this model is to enhance the precision of stock market forecasts, thus mitigating the issue presented by obsolete and volatile data. Furthermore, this research underscores the significance of practical implementation through the assessment of the MFO-SVR model's performance using evaluation metrics including MAE, MAPE, MSE, and RMSE. By adopting this methodology, one can guarantee that the predictive model not only possesses sound theoretical foundations but also effectively directs investment decisions in practice.

## III. Methodology

### A. Dataset Description

A thorough dataset analysis takes into account the volume of transactions in addition to the open, high, low, and closing (OHLC) prices during a certain period. In order to make this analysis easier, information from 2013 to 2022 was gathered. A thorough data-cleaning process was used to guarantee the accuracy and consistency of the forecasting models. This multi-phase approach was put into place with the intention of protecting the integrity of the dataset and reducing the possibility of problems due to incomplete or erroneous data. A great deal of work was put into carefully examining the data to look for unusual trends, high or low numbers, or discrepancies that might undermine the reliability of the conclusions. The data was then put through a number of procedures to make sure it was clean and ready for processing. Methods like normalization were used to reduce gradient mistakes and encourage reliable training outcomes. As shown in Fig. 1, the dataset was then split into two subgroups, with 80% designated for training and the remaining 20% for testing.

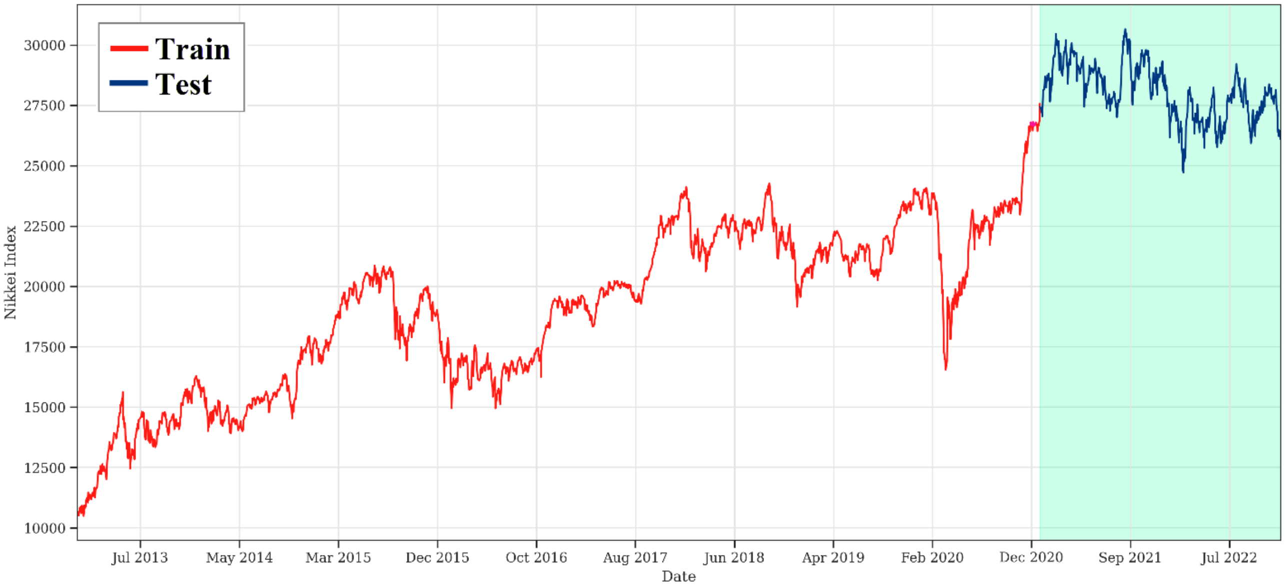

Fig. 1. Illustration of dataset and separation to train and test.

For a comprehensive analysis, it is necessary to include the number of transactions as well as the OHLC prices for a given time period. A type of financial chart called a candlestick chart is used to show price changes over time. The Japanese candlestick chart was created by rice trader Munehisa Hooma and is known as the Japanese candlestick chart [25]. A candlestick chart is similar to a combined line and bar chart. Four important pieces of information for a trading day are represented by each bar, which are the open, close, low, and high prices. There are usually three parts to a candlestick: the actual body, the lower shadow, and the upper shadow. If the initial price exceeds the closing price, the actual body will be filled in red. Otherwise, the actual body will just be green filler.

In a given time frame, the high and low-price ranges are shown with a high and low shadow. However, not every geranium has a shadow. A visual aid to decision-making in the stock market is the candlestick chart. When using a candlestick chart, it will be easier for the trader to communicate the highs and lows, as well as the open and close. As a result, a trader can identify the trend of stock market fluctuations in a certain period by examining candlestick patterns [26]. When the close exceeds the open, the candlestick is referred to as bullish. If not, it's referred to as a bearish candlestick. Fig. 2 explains a candlestick plot.

A common data preparation technique in statistics and machine learning is min-max normalization, also known as feature scaling or min-max scaling. Scaling a feature's values to a predefined range, typically between 0 and 1, is the primary objective of Min-Max normalization. The formula for Min-Max normalization is as follows [1]:

$$\text{Xscaled} = \frac{(X-Xmin)}{(Xmax-Xmin)} \qquad (1)$$

### B. Data Analysis and Model Preparation

Apart from the exhaustive preprocessing and analysis of the datasets that were previously delineated, it is critical to recognize the possible constraints and prejudices that are intrinsic to the process of training the models and data. Notwithstanding the diligence we expend in data cleansing and normalization, specific elements might introduce biases or compromise the dependability of our forecasting models. A possible constraint pertains to the exhaustiveness and precision of the dataset itself. Notwithstanding stringent data cleansing protocols, inherent biases or errors may persist and potentially compromise the efficacy of our models. Furthermore, potential biases may arise due to the selection of features and the level of detail in the data, especially if specific variables are disproportionately represented or absent. Moreover, the utilization of candlestick charts and pattern recognition in our predictive processes introduces an element of subjectivity. Although these methodologies provide valuable insights into market trends, they are not devoid of constraints. The assessment of candlestick patterns is inherently subjective and subject to analyst variation, which may result in the omission of significant factors that impact market behavior or the formation of biased conclusions. In order to address these constraints, we have incorporated rigorous validation methods and conducted sensitivity analyses to evaluate the models' robustness and applicability. Furthermore, continuous monitoring and improvement of our methodologies are crucial in order to rectify any emerging biases or constraints that may arise during the course of our analysis. By recognizing these possible constraints and prejudices, our objective is to offer a more equitable and clear analysis of our findings, thereby cultivating trust in the dependability of our predictive models.

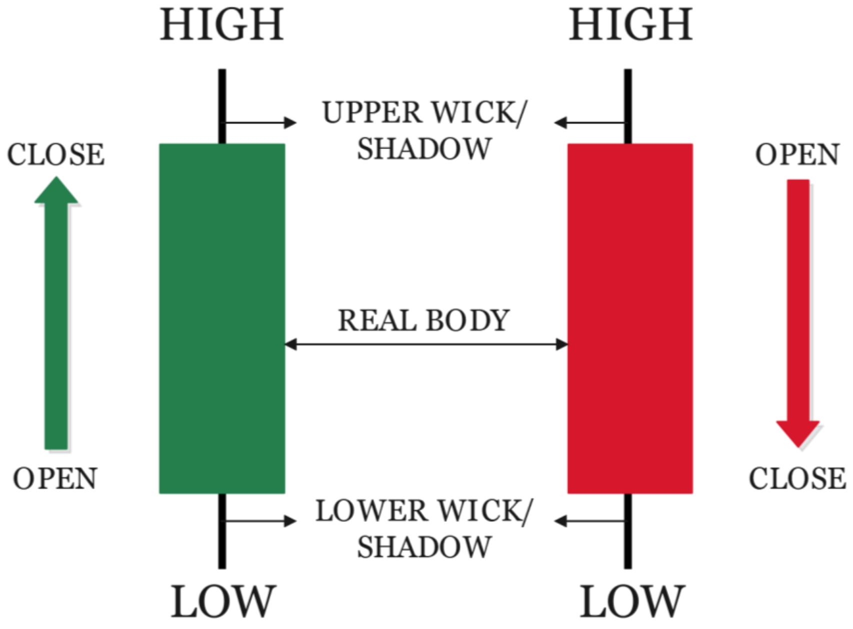

Fig. 2. Brief overview of candlestick chart.

## *C. Support Vector Regression*

The algorithm's basic idea is as follows: given a training vector, $x_i \in \mathbb{R}^p, i = 1,2, \dots, n$, and a vector $y \in \mathbb{R}^p$, our goal is to find $\omega \in \mathbb{R}^p$ and $b \in \mathbb{R}^p$ such that the prediction gives by sign $\omega^T \varphi(x_i) + b$ is correct for most samples. The optimization problem that must be addressed in order to estimate ω and b is indicated by the minimal value of the equation that follows:

$$\operatorname{argmin} \left(\frac{1}{2} \parallel \omega \parallel^2\right) + C \textstyle\sum_{i=1}^{n} \xi_i + \xi_i^*$$
$$\text{s.t.} \begin{cases} y_i - (\omega^T \varphi(x_i) + b) \le \varepsilon + \xi_i \\ (\omega^T \varphi(x_i) + b) - y_i \le \varepsilon + \xi_i^* \\ \xi_i, \xi_i^* > 0, i = 1,2 \dots, n \end{cases} \qquad (2)$$

In this context, $C$ represents the penalty parameter, $\xi_i$ and $\xi_i^*$ denote the slack variables, and $\varepsilon$ stands for the insensitive loss function. The inclusion of $\varepsilon$ enhances the resilience of the estimation. To address the issues above, the duality theory is commonly employed to convert it into a convex quadratic programming problem. Through the application of Lagrange transformation to Eq. (2), we can derive:

$$(\omega, b, \xi, \xi^*, \beta, \beta^*, \mu, \mu^*) = \left(\frac{1}{2} \parallel \omega \parallel^2\right)$$

$$+C \sum_{i=1}^{n} (\xi_i + \xi_i^*) - \sum_{i=1}^{n} \beta_i[\varepsilon + \xi_i - y_i + (\omega^T \varphi(x_i) + b)]$$

$$-\sum_{i=1}^{n} \beta_i^*[\varepsilon + \xi_i^* + y_i - (\omega^T \varphi(x_i) + b)]$$

$$-\textstyle\sum_{i=1}^{n} \mu_i \xi_i - \sum_{i=1}^{n} \mu_i^* \xi_i^*, \ \text{S.T.}\ \beta_i \ge 0, \beta_i^* \ge 0, \mu_i \ge 0, \mu_i^* \ge 0 \qquad (3)$$

$\beta_i, \beta_i^*, \mu_i, \mu_i^*$ are Lagrange coefficients. Using a partial derivative of Lagrange function concerning variables $\omega, b, \xi, \xi^*$ are equal to 0. Using a partial derivative of the Lagrange function with respect to the variables $\omega, b, \xi, \xi^*$ are equal to 0. Upon importing the Lagrangian operator and the optimization restriction expression, the decision function of Eq. (3) becomes the following form:

$$f(x) = \textstyle\sum_{i=1}^{n} (\beta_i - \beta_i^*) K(x_i, x) + b \qquad (4)$$

In Eq. (4), $\beta_i, \beta_i^* \ge 0$, and $K(x_i, x)$ is a kernel function. The overall structure of the SVR methods is demonstrated in Fig. 3.

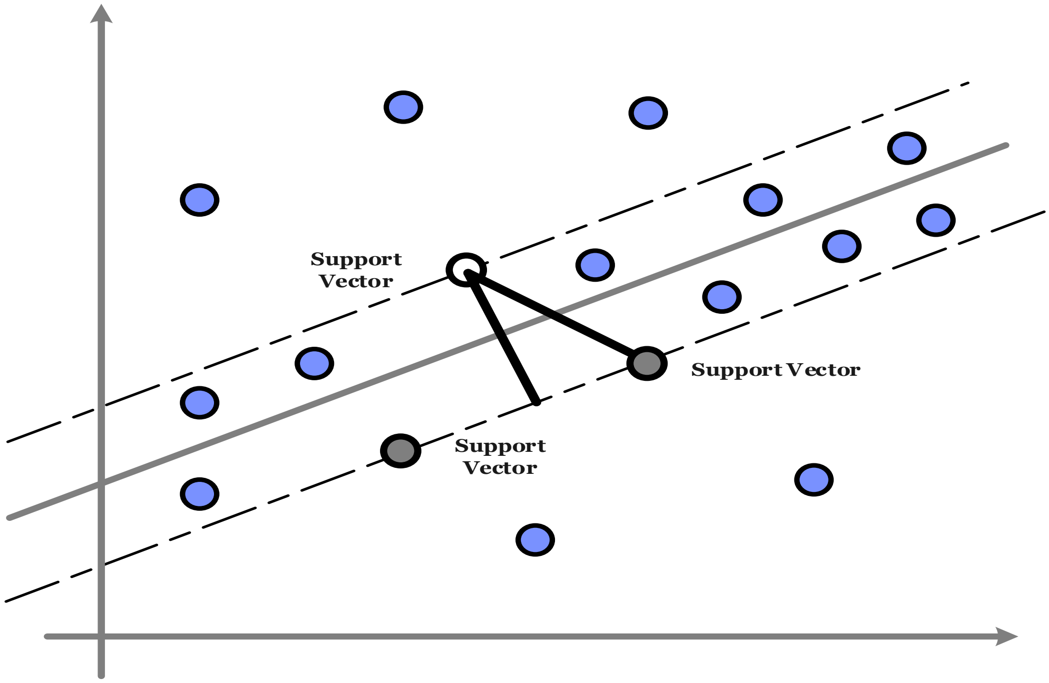

Fig. 3. Illustration of SVR.

## *D. Genetic Algorithm*

Natural selection is simulated by the GA method, which is used to solve optimization and search problems. Fundamentally, it involves using genetic operators, such as crossover, consistently (recombination), mutation, and selection, to a population of candidate solutions, or persons, to generate new individuals. Next, the role of fitness, which evaluates the solution's quality, is applied to evaluate the new individuals. This procedure is carried out across a number of generations until a workable answer is discovered [27]. GA is made up of three essential components [28]: An individual's chromosome is a sequence of characters or numbers. Which encoding is used depends on the specific problem being addressed. Assessing each person's contribution to the solution's quality is done using the fitness function. Considering the present problem, the fitness component was developed. From already-existing individuals, it can be made new ones by using evolutionary operators. Operators that are used most frequently include crossover, mutation, and selection. Selection is the process of identifying which persons are most fertile. Crossover is the process of combining the chromosomes of two people to combine a third person. The purpose of the mutation is to cause small, haphazard changes to a person's chromosomes. It's critical to keep in mind that heuristic optimization is what GA does; while it can provide a decent answer at a reasonable processing cost, it cannot be trusted to find the optimal solution overall. For large-scale issues, however, it might be computationally demanding and time-consuming, particularly if the dataset is huge and the training procedure is drawn out [29]. The optimal values for the hyperparameters of the SVR, as determined by GA, are presented in Table I.

### E. Artificial Bee Colony

Because the ABC algorithm can find excellent solutions with very little processing overhead, it has been chosen as the best tool. Previous studies [30][31] have optimized multi-dimensional numerical problems using the ABC technique. After being published by Basturk and Karaboga [32], Karaboga et al. [30][31] developed a unique population-based meta-heuristic approach known as the ABC algorithm. The ABC algorithm was inspired by the ingenious foraging strategies employed by swarms of honeybees. Bees that forage come in three varieties: employed bees, onlooker bees, and scout bees. Every bee that is actively searching for food is classified as employed. The ABC algorithm's specifics are as follows. The first solutions are created at random and utilized by the bee agents as their food supply locations. Following initiation, the bee agents go through three main cycles of iterative changes: choosing viable solutions, upgrading the workable solutions and steering clear of less-than-ideal solutions. Every hired bee chooses a new potential food supply status should be updated the workable solutions. Their decision is influenced by the area around the food source they had previously chosen. Eq. (5) is used to determine where the new food supply is located.

$$v_{ij} = x_{ij} + \phi_{ij}\left(x_{ij} - x_{kj}\right) \tag{5}$$

where, $v_{ij}$ is a fresh, workable answer that has been altered from its initial solution value $\left(x_{ij}\right)$ according to a comparison with a place chosen at random from its nearby solution $\left(x_{kj}\right), \phi_{ij}$ is a random number between $[-1,1]$ that is used to randomly in the following iteration, modify the previous answer to become a new one, and $k \in \{1,2,3,\dots,SN\}$ and $k \neq i, j \in \{1,2,3,\dots,D\}$ are arbitrary index selections. What distinguishes between $x_{ij}$ and $x_{kj}$ is a shift in location within a certain dimension. Suppose a new candidate's food source position has a higher fitness value than the previous one. The old food source position will be replaced in the employed bee's memory. The working bees will go back to their colony and share the fitness with the other bees benefits of their new food sources. The fitness value that the working bees provide determines which of the suggested food sources each observer bee chooses in the following stage. Eq. (6) provides the likelihood that a suggested food source will be chosen.

$$P_i = \frac{fit_i}{\sum_{i=1}^{SN} fit_i} \tag{6}$$

where, the food source's fitness value is represented by fit $_i$ There are $i$ possible food sources, and their sum is $SN$. Table I contains the optimal values for the hyperparameters of the SVR that have been determined by ABC.

### F. Moth Flame Optimization

Mirjalili [18] proposed the MFO Algorithm. It builds an efficient swarm-based optimization technique by taking into account the intricate flying patterns of phototactic moths and modeling their movement around a flame analytically. Like other nocturnal animals, moths navigate by using celestial bodies. They commonly use transverse orientation navigation, which uses the moon as a navigational aid. To continue producing fruit, a moth travels at a constant angle to the moon. The moth's minuscule movement about its distance from the moon is what makes this navigational method effective.

On the other hand, man-made light sources frequently veer off into a lethal spiral around a light source. Rather than the moth and moon's separation, this occurs due to the light source's close closeness. In this instance, the moth enters the light source spirally rather than in a straight path, as would be required by keeping the transverse orientation. Fig. 4 and a thorough explanation of this phenomenon found in [18].

A haphazard population of moths is first formed in the search space. They are updated in a spiral pattern concerning the flame, keeping in mind that the moth's movement shouldn't go beyond the search space. Fig. 5 suggests that the moths are circling the flame in a hyperelliptical pattern, traveling in all directions. Because the moths migrate towards the flame, the algorithm gets confined to limited optimal states, and each moth's location is updated concerning its matching flame. This reduces the possibility of local optima stagnation because each month will circle different flames. Furthermore, the flame position is modified every iteration concerning the best answer, improving the algorithm's opportunity for investigation.

Moth movement limits the ability to use new flame positions in search space while also increasing the degree of exploration. The primary objective of any optimization algorithm is to create equilibrium between the periods of exploration and exploitation. An approach that is adaptable to determine the number of flames is proposed to increase the algorithm's exploitation. During the iteration, the number of flames steadily drops. In the most recent round of retries, it ensures that moth modifies their location to match the most advantageous updated flare. The best positions that the moths have so far managed to achieve are also displayed in a flame matrix, and an array indicates the matching fitness of these places. Moths look for the optimum outcome by updating their locations and searching around their associated flame; as a consequence, they never lose their optimal position. All moths' positions are updated concerning the respective flames, as indicated by Eq. (7).

$$M_i = S\left(M_i, F_j\right) \tag{7}$$

where, $M_i$ and $F_j$ stand for the $i^{th}$ moth and the $j^{th}$ flame, respectively, and $S$ is the spiral function. Eq. (8) defines an exponential spiral, which serves as the primary updating mechanism.

$$S\left(M_i, F_j\right) = D_i \cdot e^{bt} \cdot \cos(2\pi t) + F_j \tag{8}$$

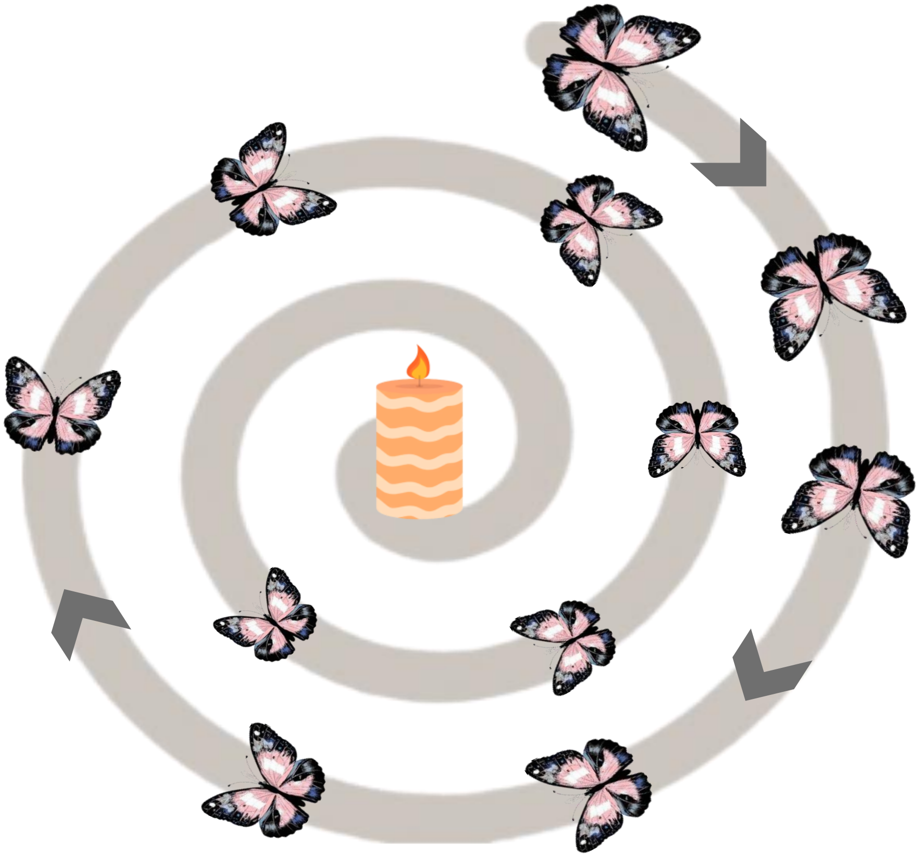

Fig. 4. Visualizing the moth flame optimization.

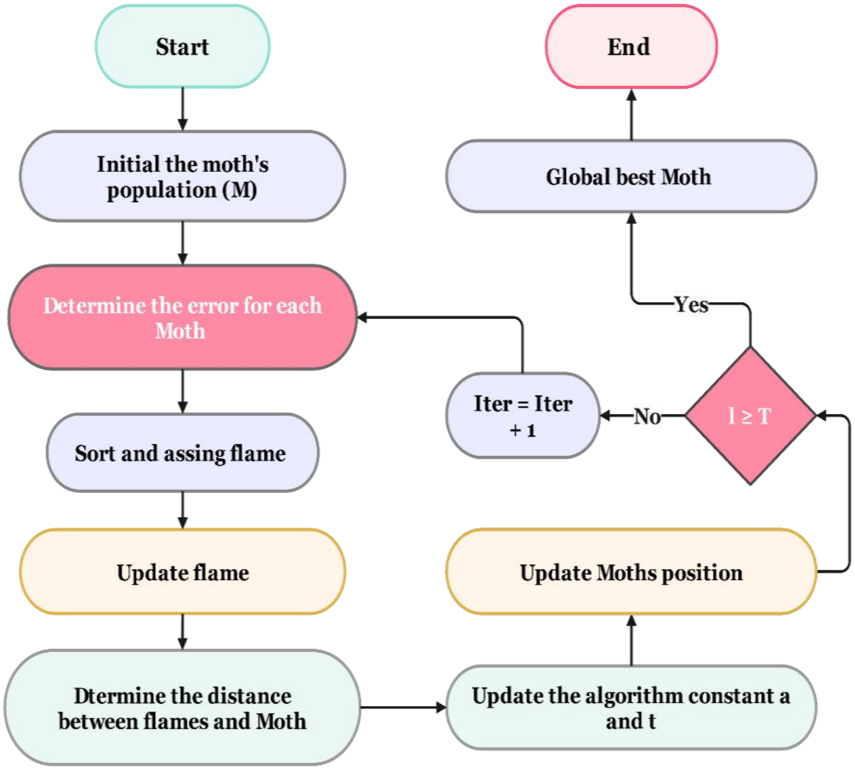

Start
Initial the moth's population (M)
Determine the error for each Moth
Sort and assing flame
Update flame
Dtermine the distance between flames and Moth
Update the algorithm constant a and t
Update Moths position
l ≥ T
No
Iter = Iter + 1
Yes
Global best Moth
End

Fig. 5. MFO flowchart.

Eq. (9) computes the distance $D_i$, which is the separation between the $i^{th}$ moth and the $j$-th flame. The constant value $b$ is used to define the form of the logarithmic spiral. Over the duration of the iterations, the parameter $t$ is a random number in the interval $[r,\ 1]$, where $r$ is a factor of convergence and falls linearly from -1 to -2.

$$D_i = \left|M_i - F_j\right| \tag{9}$$

Every moth updates its position with one flame to prevent becoming trapped in local optima. Every time, the flames list is refreshed and arranged according to their fitness values. The first moth modifies its location based on the optimal flame, whereas the final moth modifies its position based on the least optimal flame. Additionally, an adaptive mechanism reduces the number of flames between iterations to improve the exploitation of the most promising solutions. Eq. (10) illustrates this technique in action.

$$\text{flame}_{\text{No}} = round(N - \text{ iter } \cdot (N-1) / \text{ MaxIter }) \tag{10}$$

The maximum number of moths is denoted by $N$, while the current and maximum number of iterations are represented by iter and Maxlter, respectively. The optimal values that have been found for the SVR's hyperparameters by MFO are presented in Table I.

TABLE I. SETTING OF THE SVR HYPERPARAMETERS

| SVR | | GA | ABC | MFO |
|---|---|---|---|---|
| kernal | [Linear, RBF, Poly, and Sigmoid] | linear | linear | linear |
| gamma | [1, 0.5, 0.1, 0.01, 0.001] | 0.5 | 0.1 | 0.5 |
| C | [0.1, 1, 10, 20, 50, 100] | 10 | 20 | 10 |
| epsilon | [0.01, 0.05, 0.1, 0.5] | 0.05 | 0.05 | 0.1 |

# IV. RESULT AND DISCUSSION

## A. Evaluation Metrics

Regression models' accuracy and efficacy when forecasting the values of the output by using the input data are assessed using evaluation criteria. The discrepancy between the expected and actual numbers is measured by the Mean Squared Error (MSE). It is computed by first computing the square of the discrepancy between what was anticipated and what was observed and then averaging all of these squared variations. The model's correctness is determined by this value; the lower the MSE, the more accurate the model.

$$MSE = \frac{1}{N}\sum_{k=0}^{n}\binom{n}{k}(Fi - Yi)b^2 \tag{11}$$

The disparity between the expected and actual values is also measured by the MAE. To compute it, take the total amount that differs between the actual and anticipated numbers, then average the whole difference. The lower the MAE, the better the model; this number is also used to evaluate the model's correctness.

$$MAE = \frac{\sum_{i=1}^{n}|y_i - \hat{y}_i|}{n} \tag{12}$$

MAPE is a percentage-based metric used to assess a model's accuracy. The calculation involves splitting the whole amount of the discrepancy between the actual and anticipated values by the real amount and then averaging all of these percentages. The lower the MAPE, the better the model; this number is used to evaluate the model's accuracy.

$$MAPE = \left(\frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right|\right) \times 100 \tag{13}$$

Root means square error (RMSE) is another indicator that provides significant support in evaluating the precision of forecasting models.

$$RMSE = \sqrt{\frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{n}} \tag{14}$$

## B. Statistical Values

A long analysis of the dataset is provided by the study report, which is displayed in Table II. The table offers a comprehensive statistical representation of the OHLC volume and price data. This enables a more thorough comprehension of the information. The variance, kurtosis, skewness, mean, standard deviation (Std.), minimum (Min), and maximum (Max) values are among the several statistical measures displayed in the table. These measures offer an accurate and comprehensive data analysis. Central tendency, variability, and dispersion of the data are only a few of the many aspects of the data about which each of these measures provides insightful information.

TABLE II. STATISTICAL RESULTS OF THE PRESENTED MODELS FOR OHCLV

| | Count | Mean | Std. | Min | Median | Max | Skew | Kurtosis |
|---|---|---|---|---|---|---|---|---|
| Open | 2442 | 20813.83 | 4765.013 | 10405.67 | 20538.9 | 30606.15 | 0.171314 | -0.80564 |
| High | 2442 | 20926.76 | 4777.106 | 10602.12 | 20632.72 | 30795.78 | 0.177934 | -0.80271 |
| Low | 2442 | 20690.79 | 4748.074 | 10398.61 | 20451.26 | 30504.81 | 0.16562 | -0.81171 |

| Close | 2442 | 20812.22 | 4763.784 | 10486.99 | 20559.85 | 30670.1 | 0.170538 | -0.80791 |

### C. Analyze and Discussion

The major objective of this work is to identify and assess the optimal hybrid algorithm for stock price forecasting. To do this, researchers have created prediction models and evaluated a wide range of intricate variables that affect stock market patterns. The major objective is to give analysts and investors pertinent information so they can make well-informed investment decisions. Together with a comprehensive analysis of each model's effectiveness, Table III, Fig. 6, and Fig. 7 offer a detailed assessment of each model's performance.

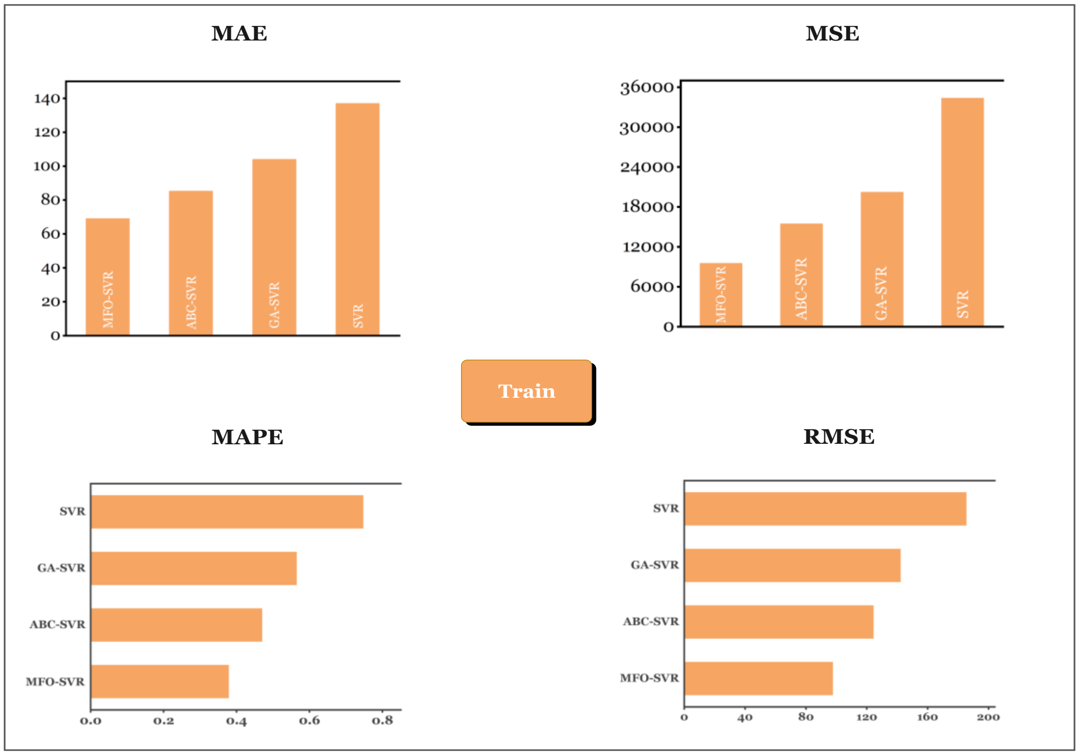

Fig. 6. Result of the evaluation metrics for the presented models during training.

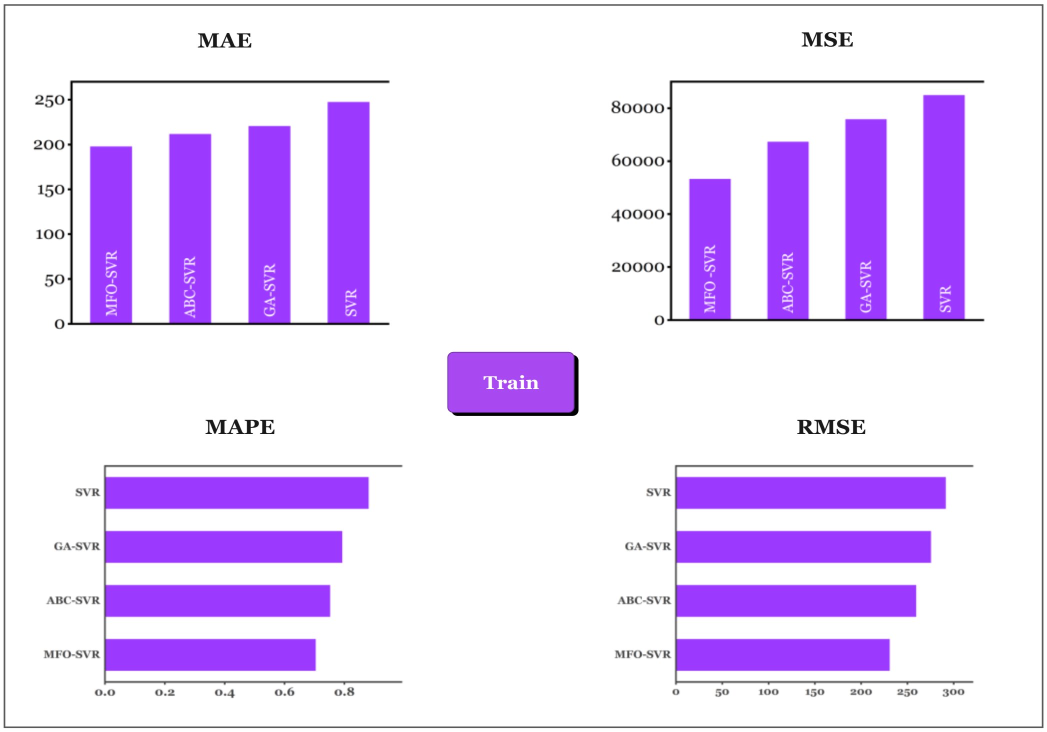

Fig. 7. Result of the evaluation metrics for the presented models during the test.

TABLE III. THE RESULTS OF EVALUATION CRITERIA FOR THE OPTIMIZED MODEL

| MODEL/Metrics | TRAIN | | | | TEST | | | |
|---|---|---|---|---|---|---|---|---|
| | RMSE | MAPE | MAE | MSE | RMSE | MAPE | MAE | MSE |
| ARIMA | 255.34 | 1.01 | 184.44 | 65199.22 | 348.19 | 1.09 | 307.16 | 121236.11 |
| MLP | 226.20 | 0.91 | 168.52 | 51164.83 | 314.20 | 1.02 | 287.83 | 98721.97 |
| SVR | 185.35 | 0.75 | 136.94 | 34352.80 | 291.21 | 0.88 | 247.12 | 84803.10 |
| GA-SVR | 142.10 | 0.56 | 103.95 | 20193.55 | 275.18 | 0.79 | 220.27 | 75724.66 |
| ABC-SVR | 124.29 | 0.47 | 85.23 | 15448.45 | 259.20 | 0.75 | 211.43 | 67182.42 |
| MFO-SVR | 97.55 | 0.38 | 68.98 | 9516.14 | 230.60 | 0.70 | 197.53 | 53175.49 |

A thorough study of the data analysis was conducted using four well-known metrics: RMSE, MAE, MAPE, and MSE. These indicators are well renowned for providing a precise evaluation of the overall accuracy, reliability, and efficacy of the analysis. The performance of the SVR model, both with and without an optimizer, was assessed using the RMSE, MAPE, MSE, and MAE criteria. This assessment enhanced the capacity to understand the model's performance and make decisions in light of the findings. This provided a comprehensive understanding of the model's performance, enabling well-informed decision-making. During training and testing, SVR's RMSE values were 185.35 and 291.21, respectively, while the MAE values were 136.94 and 247.12, respectively. The values of MAPE were 0.75 and 0.88. MSE values for SVR during train and test were 34352.80 and 84803.10, respectively. The GA-SVR model performs well when optimizers are included. Additionally, compared to the training values, the testing RMSE, MAPE, MAE, and MSE values for GA-SVR were reduced at 275.18, 0.79, 220.27, and 75724.66, respectively. From a production standpoint, the ABC-SVR model outperformed the GA-SVR model. Additionally, to prove the ability of the MFO-SVR model two other benchmark models were utilized; these models are Autoregressive integrated moving average (ARIMA) and Multilayer perception (MLP). The obtained results of the ARIMA during the testing phase for RMSE, MAPE, MAE, and MSE were 348.19, 1.09, 307.16, and 121236.11. Likewise, these results for the MLP models were 314.20, 1.02, 287.83, and 98721.97, respectively. Having compared these models with MFO-SVR it can be concluded that the proposed model is more effective than these models.

In the training and testing data sets, the MFO-SVR model has demonstrated remarkable accuracy as a result. The MFO-SVR model is a superb resource for very accurate stock price prediction. How accurately our model predicts the paths of the Nikkei 225 index stocks is shown in Fig. 8 and Fig. 9. The SVR approach makes the MFO-SVR model different from other models in stock price forecasting because it can reduce price fluctuations, simplify trend prediction, and boost model precision. Among its distinctive features is the MFO-SVR model's ability to learn from previous data sets. In order for a model to accurately anticipate stock values and adjust to changing market trends, it must be trained on past data sets.

The potential real-world applications of the identified MFO-SVR hybrid algorithm for stock price forecasting are substantial throughout the financial industry. The precise forecasts it generates have the potential to form the basis of investment decision support systems, assisting analysts and investors in making well-informed decisions. Furthermore, the incorporation of this technology into algorithmic trading systems empowers the implementation of automated trading tactics that take advantage of anticipated fluctuations in stock prices. Furthermore, the capacity of the model to mitigate price volatility and offer valuable perspectives on market sentiment contributes to the improvement of risk management tactics and portfolio optimization endeavors. Furthermore, its predictions can be utilized by individuals for the purpose of financial planning, and by quantitative analysts to construct and validate trading strategies in the past. In general, the MFO-SVR model demonstrates its versatility as a tool that can be applied in a variety of contexts, providing stakeholders with informative insights into the dynamics of the stock market and enabling them to optimize their financial activities and accomplish their investment objectives.

Although the MFO-SVR hybrid algorithm exhibits potential applications in stock price forecasting, it is imperative to recognize specific constraints and avenues that warrant further investigation. A potential drawback of the model is its dependence on historical data, which might not comprehensively capture abrupt market fluctuations or unanticipated occurrences. As a result, forecasts made during periods of market volatility could be rendered less precise. Furthermore, the intricacy of market dynamics could potentially impede the model's capacity to extrapolate findings to diverse asset classes and market conditions. Further research may be dedicated to improving the model's resilience through the integration of real-time data streams and external factors, including news sentiment analysis and macroeconomic indicators, in order to enhance the accuracy of predictions. Additionally, further research endeavors may investigate alternative hybrid algorithms or machine learning methodologies in order to augment the performance of forecasting and tackle the concern of model interpretability. This would guarantee that stakeholders are able to comprehend and place confidence in the insights delivered. In addition, conducting an examination of the potential ramifications of transaction costs and liquidity limitations on the efficacy of the model in practical trading situations may yield significant knowledge for its application. In general, the ongoing progress and enhancement of stock price forecasting algorithms will be aided by the resolution of these constraints and the exploration of additional research directions. This will ultimately be to the advantage of investors and financial practitioners.

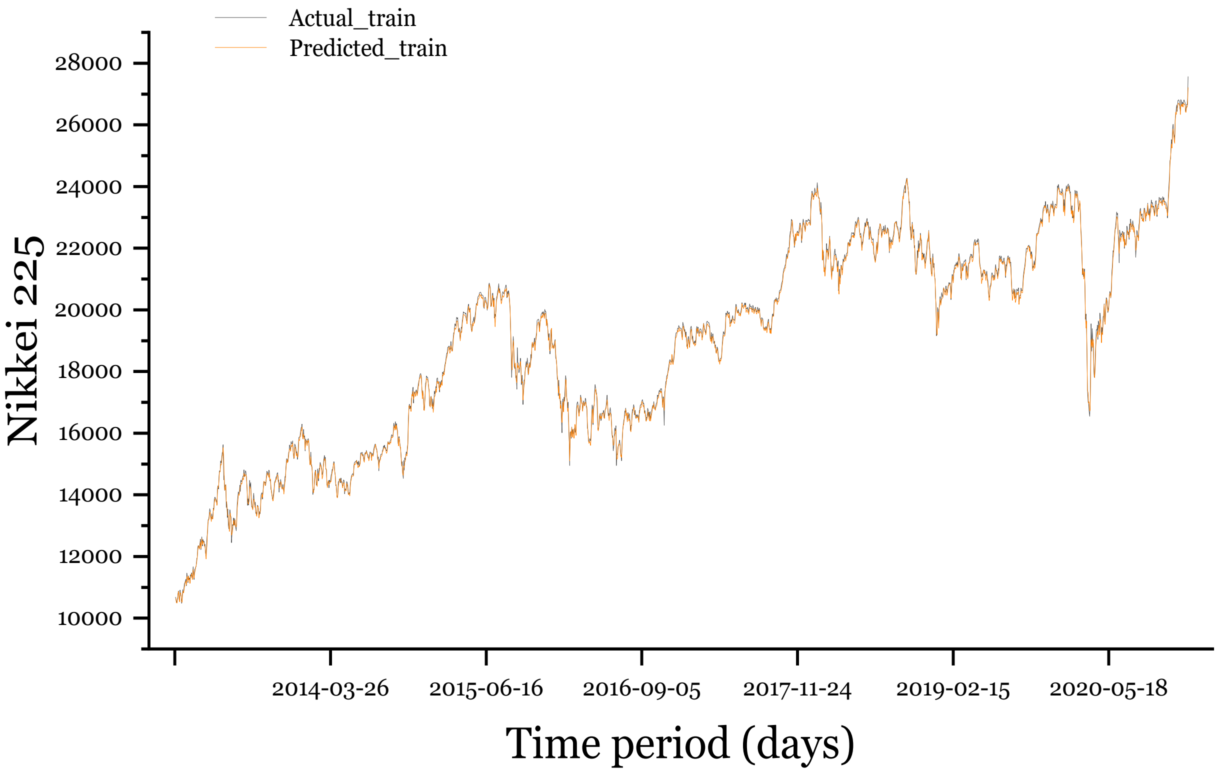

Fig. 8. Evaluation of the performance of the proposed model in comparison to real data during training.

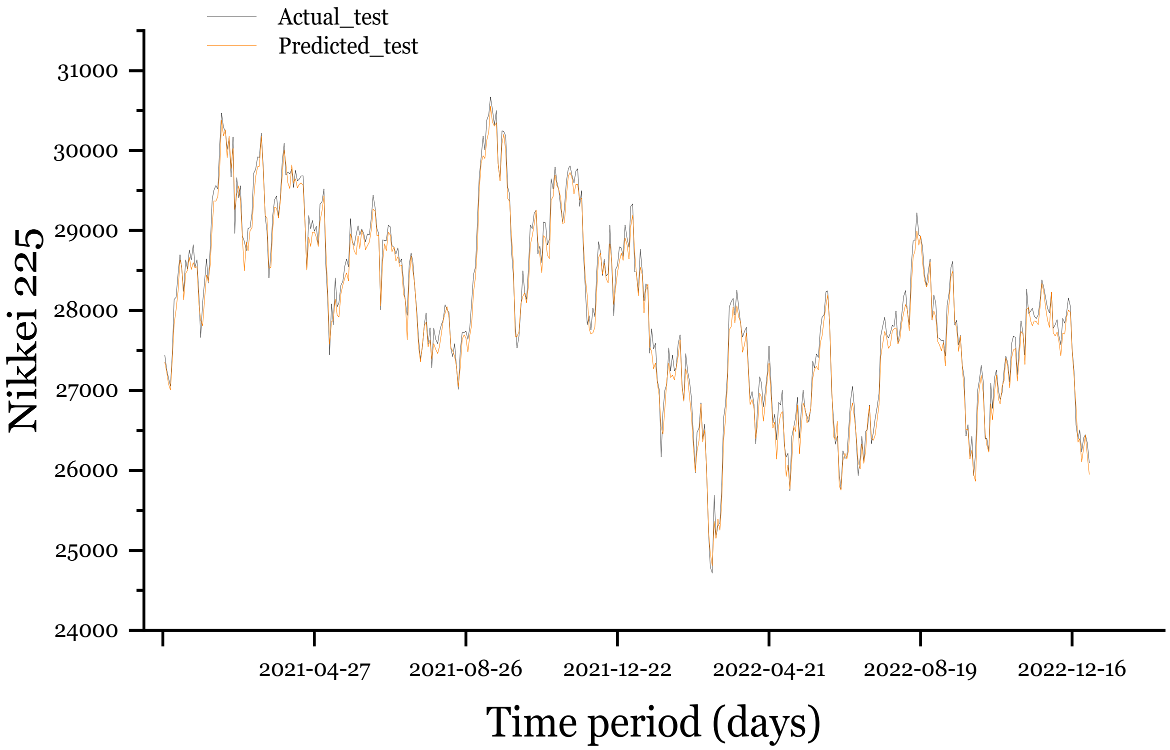

Fig. 9. Evaluation of the performance of the proposed model in comparison to real data during testing.

## V. Conclusion

The financial market is a realm that captivates investors, market analysts, and academics, providing an abundance of opportunities for investigation. By employing stock prediction methodologies, both individual and institutional investors can potentially attain a competitive advantage in identifying market trends and assessing assets. By leveraging historical data and sophisticated algorithms, investors are empowered to render well-informed decisions pertaining to stock transactions, encompassing purchases, sales, and holdings. The present study utilized support vector regression networks, which were optimized using the MFO approach, in order to predict the values of stocks. The objective of the MFO-SVR model presented in this study is to forecast trends in the stock market. Through the application of Nikkei 225 index data encompassing the period from January 1, 2013, to January 1, 2023, this research has established a foundation for subsequent inquiries. The dataset, which is composed of 20% test data and 80% training data, provides a solid foundation for subsequent analysis. Anticipating the future, numerous pathways exist for further investigation. To commence, the generalizability of predictive models could be improved by broadening the scope of analysis to include supplementary datasets sourced from various financial markets. Furthermore, an examination of alternative optimization methodologies or the integration of ensemble techniques may enhance the precision and resilience of forecasts. In addition, ongoing research into real-time prediction models may provide valuable insights for timely decision-making, given the dynamic nature of financial markets. Through the seamless integration of these prospective research concepts into our current conclusions, we establish a foundation for ongoing progress and improvement in the domain of financial market forecasting. Conducting research and exploration in an iterative manner is critical for remaining informed about the ever-changing dynamics of the market and guaranteeing that predictive models remain practical and applicable.

# Clustering Algorithms in Sentiment Analysis Techniques in Social Media – A Rapid Literature Review

Vasile Daniel Păvăloaia
Accounting, Information Systems and Statistics Department, Alexandru Ioan Cuza University of Iasi, Iasi, Romania

*Abstract*—**Based on the high dynamic of Sentiment Analysis (SA) topic among the latest publication landscape, the current review attempts to fill a research gap. Consequently, the paper elaborates on the most recent body of literature to extract and analyze the papers that elaborate on the clustering algorithms applied on social media datasets for performing SA. The current rapid review attempts to answer the research questions by analyzing a pool of 46 articles published in between Dec 2020 – Dec 2023. The manuscripts were thoroughly selected from Scopus (Sco) and WebOf-Science (WoS) databases and, after filtering the initial pool of 164 articles, the final results (46) were extracted and read in full.**

***Keywords*—Clustering algorithms; K-means; HAC; DBSCAN; sentiment analysis; natural language processing techniques; social media datasets; Twitter/X**

## I. Introduction

The demand for seamless and simple contact between humans and machines has long been desired, since Turing test [1], and in the last years has grown significantly in a society that is getting more and more digitalized.

Social networks offer internet communities where users may simulate human social interactions. One of the most well-known [2] micro blogging sites is Twitter [3], [4], rebranded in X since July 2023. With 500 million daily tweets, 152 million active users per day, and 330 million active users per month [5], enables users to submit real-time, succinct messages (maximum 280 characters) on diverse social and personal topics. Every three days, more than one billion new Tweets are published on Twitter/X [6]. Researchers have extensively examined Twitter/X data to answer a variety of research problems, including detection of sentiments [7]. Twitter/X data analysis for sentiment/emotion/mood/opinion extraction is considered a difficult challenge in human computing. However, because tweets are limited to 280 characters, individuals tend to use casual language, which makes it difficult to understand the true mood behind tweets [8]. Also, due to the high number of total registered users (650 million) and instant notifications [9], [10] over a broad range of mobile equipment's, Twitter provide useful datasets for research to help better understand public behaviors, opinions, and sentiments [11]. This review is built on Social Media (SM) datasets where Twitter/X was found to be the most prominent for many reasons, such as: high data volume, public data availability, hashtags (relevant for clustering analysis), text-based posts, real-time analysis and abundant recent publications which are conducive to performing a comprehensive investigation.

Natural Language Processing (NLP), translates human language into machine language to facilitate interactions between humans and machines, was born out of this need. SA, a component of NLP, is employed in SM and other online environments to analyze and understand the emotions, opinions, and attitudes expressed in text. This endeavor can be done through a variety of methods, including Machine learning (ML) [12], [13], [14], NLP [15] [16], and text analytics [17], [18]. To evaluate whether a text's overall sentiment is positive, negative, or neutral is the ultimate goal of SA. The outcome is often a score or a label that describes the text's sentiment. Applications for this kind of analysis include SM monitoring, marketing, and customer service.

Overall, SA employs both ML and NLP methods. The models are used to estimate the sentiment of observed text after being trained on labeled data that comprises text and the appropriate sentiment (positive, negative, or neutral). While labeled data is often used in SA, there are several techniques that can be used to estimate the sentiment of text without prior labeled data, depending on the specific use case and available resources. It can be mentioned here Unsupervised SA [2], [19], Lexicon-based SA [9], [19], Transfer learning [20] and Active learning [21]. The goals of SA are accomplished through a number of phases. These actions may consist of data collection, data preprocessing, feature extraction, model training, model evaluation, model deployment. In this process, the most representative task is the choice of the algorithm which mainly depends on the goal and the resources of the project.

Algorithms are sets of instructions or rules that are followed in a specific order to accomplish a specific task or solve a specific problem. They are crucial in SA as they are used to automatically process [22], [23], [24] and analyze text data to determine the sentiment or emotional tone. Without algorithms, SA would be a manual and time-consuming process. Algorithms in SA can be used to classify text into positive, negative, or neutral sentiment categories, to generate a sentiment score or to create clusters based on similar patterns.

Due to the dynamics in this topic (SA), the current manuscript's aim is to analyze the literature in the period Dec 2020 – Dec 2023 for extracting the approach of the articles that deal with SA clustering algorithms applied on Twitter/X datasets. The investigation highlights the domains where the clustering algorithms are being employed, the most relevant methods as well as the newly developed algorithms. The accuracy comparison will be displayed where this information is available. The contribution of such an investigation is relevant as it provides the best practice for anyone interested in matching the algorithm with the applicative sector/s by emphasizing the new discoveries. Although SA topic has abundant literature and many reviews exist, most of them refer to classification algorithms while those dealing with clustering have different approaches than the current paper. The current review is structured as follows: Section I presents the general background for the topic, Section II illustrates the selection process of manuscripts as well as the inclusion and exclusion criterions, Section III presents the results, by describing the SA algorithms with an emphasize on the clustering situation and Section IV presents the Discussion on results while Section V details the conclusions and future research paths.

## II. Materials and Methods

### A. Research Questions

The current study attempts to identify the most popular (1) clustering algorithms, the domains (2), and their performances (3) by quickly reviewing the relevant literature. After review-ing the literature analysis and using the key phrases to search the WoS and Sco databases, the intermediate findings show that there is a large amount of research on SA (mainly Twitter/X) dataset and the number of papers produced each year is growing exponentially. Despite that there are many reviews, only a small number of them address clustering algorithms as the majority focus on classification algorithms within Twitter/X datasets. In addition, no review was identified starting with 2020 that has a similar scope to the one in this research. As a result, the article aims to provide answers to the following research questions:

RQ1 – Which are the most employed clustering algorithms within the researches that perform SA using Twitter/X datasets, since 2020 to date, and what are their benefits and performances?;

RQ2 – What are the sectors of activity where the clustering algorithms were used within the selected literature?

In order to answer the research questions, WoS and Sco databases of article were used as the primary data source since they have the most pertinent papers that have been published in reputable journals which follow the peer review process.

### B. Research Methodology

The decision to perform a rapid review was founded on the advantages it brings, namely because it offers accurate information while promoting the exploration of original perspectives [25, 26]. In order to build the current review, it was employed the truncation strategy for all the three phrases to include all of the expression's variants in the search [25]. As it can be seen in Fig. 1, the essential search combination was ("sentiment analys*" AND cluster* AND (“social media” OR “social network*”)) applied on Titles, Abstracts and Author’s Keywords while the publication years were set between 2020 and 2023. Upon completion the first phase 164 results (from WoS (61) and Sco(103)) were obtained, and two exclusion phases were further employed: Firstly, there were removed all document types except Articles and Reviews as most conference articles are the short and incomplete version of the Articles (1); the results which were not yet published (2) and manuscripts elaborated in other languages that English (3) have been eliminated as well. Further, the obtained references were merged into the same file and duplicates from the two databases were removed; Secondly, within the 77 intermediary results, 31 manuscripts were removed as the author/s did not employ clustering analysis but just listed a form of the keyword “cluster”. The remaining 46 manuscripts (44 articles and 2 reviews) were read in full and extracted the most relevant information required for answering the RQs. The findings are presented in the Results Section.

EndNote Online appropriately manages the references, removes duplicate sources, saves, organizes, and cites the list of references for a study. VOSViewer program was employed in this study as it is recognized to give cutting-edge methods for network layout and network clustering [27], to better extract the key domains and key associated relevant terms [28] from the list of selected articles (N=46). From Fig. 2 can be depicted the two clusters, one related to SA, SM and dataset (Twitter/X) and the second which is technological-related and contains the AI technologies and other clustering related concepts.

While cluster 1 - red contain SA keyword with the highest frequency of appearance (based on the association strengths), cluster 2 - green illustrate the most frequently used clustering algorithms found within the results (N=46), namely K-means, Hierarchical (mostly HAC) and DBSCAN.

The network map (see Fig. 2) is created based on the association strengths and highlights the clustering technologies used in the SA on Twitter/X dataset and contributes to answering the RQ1. The dominant keyword for all articles included in the study, as shown in Fig. 3, is SA, while closely related terms like Twitter/X, datasets, and SM come in second and third, respectively, with respect to their intensity. It can also be noticed that Covid-19 topic is a very common term within the selected papers, and this is expected as the analysis include manuscripts published within Dec 2020 – Dec 2023.

The clusters and density visualization are accessible in Fig. 3 where it can easily be observed the two formed clusters, highlighted with red and green background colors. The green cluster illustrates the highest weight (importance) on the association between the links for the keywords ML, NLP, clustering algorithms, topic modelling which validates the references included in the selection. The visual representation of clusters in Fig. 3 may be considered a confirmation for the proper selection of the articles, which is in line with the declared keywords: SA, Twitter/X dataset and clustering algorithms.

## III. Results

Algorithms are used in SA either to process or analyze text data to determine the sentiment or emotional tone of a text (classification) or to group related entries in similar feature groups (clustering). In this sense, the above actions can include techniques such as NLP, ML, and Deep Learning (DL). SA algorithms can be employed for a variety of applications, such as SM monitoring, customer feedback analysis, and opinion mining analysis. This review's main aim is to discover the answer to the RQs. In this endeavor, the results extracted from the analyzed manuscripts and presented below.

### A. The Most Employed Clustering Algorithms, Their Benefits and Performances (RQ1)

Algorithm wise, there are different options that can be used for performing the SA, such as:

- Rule-based methods [23], [29]. This method uses a set of predefined rules or dictionaries to classify the sentiment of text. It can be simple but less accurate.

- Lexicon-based methods [19]. This approach uses a lexicon (a collection of words and their associated sentiments) to classify the sentiment of text. It can be simple but less accurate as well.

- ML-based methods [30], [31], [19]. In this case, it trains a model using labeled data, where the labeled data contains text and the corresponding sentiment (positive, negative, neutral) and then the model is used to predict the sentiment of un-seen text. It can be more accurate than the above two methods.

- DL-based methods [32], [33], [34]. It's a type of ML-based methods, but it uses deep neural network architectures such as Long Short-Term Memory (LSTM) [35], [36], Convolutional Neural Network (CNN) [22] and Bidirectional Encoder Representations from Transformers (BERT) [37], [24], etc. It can achieve better results than traditional ML-based methods.

Algorithms are an essential component of any SA endeavors. The SA algorithms are used to classify the polarity of a text as positive, negative, or neutral, based on the sentiment expressed in the text. Among their various contributions to SA, the specialized literature mentions:

- Text classification [38], [31], [22]: SA algorithms are often used to classify text into different sentiment categories, such as positive, negative, or neutral. This is typically done using supervised learning algorithms, like Naive Bayes [2], [39], Support Vector Machine (SVM) [40], [41], Logistic Regression [41], [42] or DL algorithms like BERT, LSTM and CNN.

- Opinion mining [31], [33], [22]: SA algorithms can also be employed for extracting and understanding opinions and sentiments from text. This is typically done using NLP techniques, such as sentiment lexicons, sentiment ontologies, and sentiment-bearing terms.

- Emotion detection [43], [19]: SA algorithms identify emotions in text, such as happiness, sadness, anger, and surprise. Similarly with Opinion mining this endeavor is pursued by NLP techniques as well.

- Sentiment summarization [44], [35], [45]: SA algorithms summarize the overall sentiment of a text, such as a product review, a tweet, or a news article. Consequently, this action is performed by analyzing the sentiment of individual sentences, paragraphs, or even the whole documents.
- Opinion Spam detection [19, 38]: SA algorithms may be employed to detect fake or biased reviews or opinion from text. This can be achieved by comparing the sentiment of different text and detect any suspicious patterns.
- Aspect-based SA: SA algorithms are also used to extract and understand opinions and feelings about specific aspects of a text, such as a product, a service, or a person. This action is also pursued with the help of NLP techniques (sentiment lexicons and/or ontologies).
- Clustering text [46]: These algorithms are a type of unsupervised learning algorithms that are used in SA to group similar text samples together based on their sentiment. Clustering algorithms can be useful for tasks such as discovering latent themes/topics [15] within a dataset of text or grouping similar text samples together for further analysis. In line with the above concepts, [9] use Latent Dirichlet Allocation (LDA) and K-means to extract themes among the topics dis-cussed on Twitter/X posts in relation to natural disaster. The authors identify different themes with several emotions associated with it, to cluster people's reactions by time and location, during natural disasters. Positive and negative sentiments have both been subjected to text clustering by [17] in order to identify the main concerns that individuals have with regards to AI Ethical challenges. Other researchers [31] employ text clustering in a novel approach to extract agrarians' recommendations to boosting crop yields by informing farmers via SA on the most recent agricultural inputs. Overall, the specific algorithm used in SA depends on the problem, the resources available and the desired accuracy.

The main objective of clustering algorithms in SA is to group together [46], [17], [34] reviews or texts that express similar opinions, attitudes, or emotions. This can be useful in identifying common themes or topics in a set of reviews, understanding how different sentiments are distributed across a dataset, and identifying outliers or abnormal observations.

Clustering algorithms used in SA typically work by analyzing a set of features extracted from the text, such as word frequency [13], sentiment scores [40], [22] or other metrics [47]. These features are then used to calculate the similarity between different reviews, which is used to group similar reviews together into clusters.

Some examples of clustering algorithms employed in SA research endeavors include K-means, Hierarchical Clustering, Density-Based Spatial Clustering of Applications with Noise (DBSCAN), Expectation-Maximization (EM), Gaussian Mixture Model (GMM), Affinity Propagation (AP), Spectral Clustering and Self-Organizing Map (SOM). Some authors use these algorithms in different combinations [38], [48] to achieve the best results, depending on the nature of the data and the specific requirements of the task.

*1) Topic modeling techniques in NLP:* Topic modeling techniques are often used in conjunction with other elements, such as text preprocessing algorithms, feature extraction algorithms, and classification algorithms, to create a complete NLP system. The best choice of topic modelling option will depend on the specifics of the task, the size and quality of the dataset, and the computational resources available. Within the selected papers (N=46), the results illustrate that LDA has the highest (69%) utilization within the analyzed manuscripts, followed by LSA(20%) and NMF(11%).

Although the literature points out several topic modeling techniques in NLP, the majority of authors (69%) in the current pool of articles [54], [9] [55], [30] and many others have used LDA for topic modeling [29], [47]. In the light of the above, LDA is a generative probabilistic model of a corpus [54] used as a topic modeling algorithm that can discover the underlying themes in a collection of documents. LDA can automatically identify latent topics [15] in a set of reviews and offer a method to comprehend how various sentiments are distributed across a dataset.

*2) SA clustering algorithms:* Clustering algorithms used in SA are a set of unsupervised ML techniques that group similar texts (comments, reviews, posts) based on their predominant sentiment. Without the use of predetermined labels or categories, these algorithms are designed to identify patterns in the data and group related objects together. Although their majority is unsupervised, indicating they do not rely on labeled data, some can be semi-supervised, meaning they use a small amount of labeled data to guide the clustering process.

The selected body of literature is analyzed in line with the selection methodology presented in Fig. 1 and most used clustering algorithms, according with the network map in Fig. 3 used are K-means, Hierarchical (mostly HAC) and DBSCAN.

*a) K-means:* K-means is a popular unsupervised learning algorithm that is frequently used in SA for grouping purposes. The algorithm works by partitioning a dataset of texts into k clusters, where k is a user-specified parameter. Each cluster represents a group of texts that are similar to one another in terms of the features used to represent them. K-means' fundamental principle is to form spherical clusters, where each cluster is determined by the mean of points within the cluster. It starts with a random initialization of k centroids, one for each cluster. Each text is then assigned to the cluster with the closest centroid. The centroid of each cluster is then again calculated as the mean of all the points inside the cluster. This procedure is repeated until convergence, or a stopping condition is met. In SA, K-means algorithm takes a set of reviews as input, and for each review, a set of features are extracted such as word frequency, sentiment scores, or other metrics aiming at grouping similar reviews together into clusters. Ease of use and scalability are two of the main advantages of using K-means in SA. This fast algorithm can handle large datasets, and it is relatively easy to interpret the obtained results. It does, however, have significant limitations, notably when working with datasets with different densities or non-spherical clusters. Additionally, it calls for previous knowledge of the number of clusters, which may not be known.

The Pension and Funds Administration's (AFP) goal is to shield the elderly population from the threat of poverty while enabling residents to save up money for their retirement. This study uses ML models to categorize and examine the sentiments of Twitter/X users (affiliates) utilizing the hashtag #afp. With the aid of the K-Means algorithm and the unsupervised learning technique, [13] were able to count the number of clusters using the elbow approach. Last but not least, despite the fact that data normalization was performed, the SA and the clusters created show that there is a very noticeable dispersion. This is one of the few research projects that display the employed precision index (IP) formula. In this research, the IP was used to gauge the effectiveness of clustering, where IP=$\sum c$ $k$=1 n(ck)/n and ck stands for the number of data points necessary to achieve the proper clustering for cluster k and n is the overall number of data points. The performance of clustering improves with increasing accuracy index.

In order to decide which papers should be associated with which T topics, this work [54] examines two distinct clustering approaches. These techniques combine a genetic algorithm with a local convergence process and the K-Means clustering algorithm. The approach for assessing customer service interactions given in this article may be used to understand user satisfaction with this service and the major issues that consumers are concerned about. As K-means has the highest coverage among the algorithms extract from the literature, the following paragraphs will highlight the particularities of this algorithm for several sectors of activity.

### *Health & Medicine (Covid-19), customer preferences and society issue related research in-volving K-means clustering solutions*

By crawling Twitter/X tweets, the authors [12] conduct a study employing cluster analysis on Covid-19 Outbreak Sentiments with K-means. The tweets are clustered into k groups using the K-means algorithm. By using t-Distributed Stochastic Neighbor Embedding (t-SNE) approach, the findings of each cluster are presented. Lexi-con-based SA has been employed to determine the sentiments of these clusters, and word clouds are used to examine the clusters' dominating subjects. The findings revealed nine clusters with diverse subjects, with the maximum positivity score of 83.25% and the lowest negative score of 16.75%. Word clouds are used to examine dominant subjects, and the outcomes of clustering are assessed using the 0.0070 Silhouette coefficient.

In their research [30], the authors emphasized the impact of COVID-19 and lockdowns on the agriculture sector and its related domains. The study performs SA and use K-means algorithms for clusters discovery in data. Among the findings, the most obvious one is that COVID-19 highly impacted the socioeconomic life of the people that work in agriculture as well as the agricultural sector itself.

The research in [4] contributes to the literature with the idea of amalgamation of extensive feature engineering and negation modelling with the unsupervised K-mean clustering approach for classification of large unlabeled Twitter/X corpus based on the tag #Lockdown. The novel framework of authors performs real-time labelling of Twitter/X datasets into three classes Positive, Negative, or Neutral for the textual based Twitter/X SA. The model was evaluated by inertia and silhouette score – two known evaluation metrics used to measure cluster quality – which show that the developed automatic labeling technique, applied in this context, achieves significant benefits.

In the manuscript [50], divide anomalous data into clusters using K-means to decide the anomaly type. The authors developed a framework for anomaly detection on two case studies (Corona Virus Tweet Dataset and Russia Ukraine Tweet Dataset) from Twitter/X, pre-processing of data, topic modelling, collection of the most frequently used words by applying topic modelling with LDA and Non-negative matrix factorization (NMF) [53].

Another study that performs a cluster analysis using K-means is done by [56] and analyses the polarity of Airlines Sentiment dataset to depict the customers' sentiments regarding the airline's services. The performance obtained on the dataset is displayed in Table I. On the same topic of analyzing customer's sentiments, this time to-wards products, K-means is used by [58] in the Twitter/X datasets and divides it into various types of clusters base on customer's emotions. The model has been instructed on how to compare various products and different sentiments. The k-means classification approach is applied while considering the cluster of customers who have a good opinion of the product. As a consequence, it offers a simple strategy for addressing a receptive audience directly and may reflect the growth and quality of a corporation.

TABLE I. MODELS' PERFORMANCES AND DOMAINS WHERE APPLIED

| Dataset | Domain | Combined | Precision | F1 Score | Accuracy | Reference |
|---|---|---|---|---|---|---|
| Corona Virus | Medicine | No | 0.8210 | 0.8093 | 0.7857 | [42] |
| Russia Ukraine | Politics | No | 0.5635 | 0.665 | 0.7019 | |
| US Airlines | Customer review | No | 0.840 | 0.730 | 0.890 | [18] |
| Disaster | Natural disasters | no | 0.957 | 0.963 | 0.997 | [69,70] |

To determine the ideal number of clusters every year, data visualization techniques such as term frequency, inverse document frequency, k-means clustering, and PCA were utilized by [55]. Authors used interpretation models to enable within-year (or within-cluster) comparisons after data visualization. The mate-rial inside each cluster for a particular year was examined using LDA topic modeling. To investigate the effect per cluster every year, Valence Aware Dictionary and Sentiment Reason-er SA were utilized. The average bot score per cluster each year was calculated using the Botometer automatic account check. The average number of likes and retweets per cluster was used by the authors to conduct correlations with other interesting outcome variables in order to gauge user involvement with the Dry January - a temporary alcohol abstinence campaign.

Climate change and natural disasters, involving K-means clustering solutions

Researchers [59] use correspondence analysis and the bisecting k-means algorithm to cluster tweets based on phrases that represent people's opinions. This reveals the fundamental determinants of discourses connected to carbon prices in Europe, the USA, South Africa, Canada, and Australia. The findings, which are presented in five clusters, demonstrate that views of the effects of taxes on people and companies, as well as faith in the government, are the key motivating factors for attitudes regarding carbon taxes.

Other authors [57] created and built a brand-new disaster intelligence system that automatically runs SA, automated K-Means, and AI-based translation to produce AI-driven insights for disaster strategists. The method provided crucial data for catastrophe planners or strategists, such as the natural disaster clusters that were most strongly correlated with negative feelings.

The authors [19] suggest a cuckoo search clustering technique for SA based on a roulette wheel. The proposed clustering method identifies optimal centroids from emotional datasets to determine document sentiment polarity. Tested on nine datasets, including Twitter/X and reviews of spam, its effectiveness surpasses K-means using a roulette wheel cuckoo search approach. According to their findings, the recommended strategies provide the best average precision, recall, and accuracy over 80% of the datasets.

Other researchers [9] apply K-means clustering algorithm to identify the underlying themes in the tweets for obtaining topic clusters on natural disasters dataset. During the cluster algorithm selection, authors compared it with HCA, and the results show that K-means performs better. They divided the data into three groups since it was determined that this would display the data most effectively. Cluster 0 denotes the phase of panic, during which people are distributing warning signs. Cluster 1 denotes the reactive stage, during which individuals discuss charity, wealth, and prayers. The larger of the two groups, Cluster 2, covers the stabilization period, where people were expressing gratitude for the care they had received. The results of the cluster performances reside in word clouds and charts, with no numeric values mentioned.

The research [60] identify typical daily morning congestion patterns for each route in the network to enhance the morning traffic prediction on a daily basis by clustering analysis using K-means on the reduced P-dimension matrix. The elbow approach is used to choose the optimal cluster size K. A vector of is created by a daily tweeting profile. Finally, to determine typical sleep-wake patterns observed in tweets, identical K-means clustering sets are utilized. In general, authors find that the earlier people go to bed, the more crowded the roads will be the following morning.

Society & Political views (Elections) and other subjects related research involving K-means clustering solutions

In order to differentiate political positions (left, center, right), authors in [61] applied the developed algorithm to obtain the scores of 882 ballots cast in the first stage of the convention (4 July to 29 September 2021). Then, they used k-means to identify three clusters containing right-wing, center, and left-wing positions. Our results may help us to better understand political behavior in constitutional processes.

Other authors in [62] used the k-means++ clustering method, a version of the k-means clustering algorithm that employs a smart centroid initialization strategy, to cluster the tweets (as vectors). The number of clustering iterations necessary and the regularity of the clusters are both influenced by the initial choice of centroids. The k-means++ clustering method was selected for its simplicity, effectiveness, and speed. The elbow curve method determined the optimal number of clusters for each dataset, forming topic-level clusters with similar information. Dense clusters - indicating widely shared information during an election period - were identified, with their geo-locations helping to map the topics geographically. The study analyzes user types and information patterns to observe how tweeting behavior related to the scheme changed during the election.

Authors in study [3] combine the Spider-Monkey Optimization (SMO) with K-means clustering, forming a hybrid approach (SMOK) to overcome early clustering termination issues seen in K-means. By utilizing K-means cluster outcomes to initialize the SMO population, SMOK enhances cluster quality, leading to faster convergence and superior results. It notably outperforms other algorithms like Particle-Swarm, Genetic algorithm, and Differential Evolution in computation time on Twitter/X datasets.

In conclusion, the K-Means clustering method was proven to be efficient in topics such as natural disasters [9], [57], climate change [59] the electoral campaigns [62], and politic opinion [52] and their analysis [61], traffic control (Yao & Qian, 2021), alcohol consumption [55], consumer behavior [56], medicine and Covid-19 [52], [12] analysis on the pension funds [13] domains and was analyzed the datasets from the following countries India [62], [30] USA (Pittsburg) [60], UK [55], Chile [61] and others with best results.

*b) Hierarchical clustering:* Hierarchical Clustering is an unsupervised learning method that is often used in SA to group similar texts. This is a tree-based clustering algorithm that builds a hierarchy of clusters by merging or splitting existing clusters. Starting with individual data points, it uses a bottom-up strategy to combine them into bigger clusters until every data point is in a single cluster. The two main approaches to hierarchical clustering are Agglomerative (bottom-up) and

Divisive (top-down) subcategories [38]. The divisive hierarchical method starts by iteratively dividing the dataset into multiple clusters. In the case of Hierarchical Agglomerative Clustering (HAC), each entry is initially clustered as a single point, which subsequently combines the smaller clusters into bigger clusters. The linking criteria of the method is used to assess cluster similarity. The following includes possible linking criteria: single linkage (SL); complete linkage (CL); average linkage (AL). The distance between two clusters in the HAC is determined by the lowest (SL), maximum (CL), or average (AL) distance between any two points in one cluster. HAC is used in SA to compile related reviews depending on their sentiment. A collection of reviews is provided as input to the algorithm, and for each review, a set of at-tributes such as word frequency, sentiment ratings, or other metrics are retrieved. The similarity between various reviews is then determined using these criteria, and lastly, comparable reviews are grouped together into clusters. The ability to handle non-spherical clusters and construct a hierarchical structure of clusters that can be used to understand how various attitudes are distributed across a dataset is one of the key benefits of utilizing HAC in sentiment research. Additionally, it enables the user to view the clustering outcomes as a dendrogram. However, when used on big datasets, it can be computationally costly and necessitates the selection of a link-age criterion.

The literature reviewed in the current project displays several innovative uses of this algorithm, either alone or in combination with other techniques, for performances improvements using Twitter/X datasets.

Topic modeling is essential to comprehend the tweets and group them into manage-able categories. As traditional methodologies are unable to effectively handle noise, high volume, dimensionality, and short text sparseness, some authors [10] rely on topic modelling approaches to cluster the tweets (or short text messages) to groups. Their original solution uses a hierarchical two-stage clustering technique and can address the problem of data sparsity in short text. Based on their statement, their technique performed better than other algorithms based on the results of standard datasets analysis.

In study [2], the authors propose a hierarchical method to extract the important words that people talk about during the coronavirus pandemic outbreak. Thus, the most used five words repeated in the people’s posts on Twitter/X (using Coronavirus dataset) are included in each obtained cluster. Their findings demonstrate that the proposed model is capable of classifying and analyzing viewpoints presented in short text.

An original unsupervised ensemble/cooperative framework built on concept-based and HAC for Twitter/X SA is developed in [2]. The authors use four Twitter/X Dataset - Health Care Reform (HCR), Sentiment Strength (SS), Stanford Twitter/X Sentiment Test Set (STS-Test) and NewTweets (NT) - delegated to three popular HAC (SL, CL, and AL) combined with CBA in a serial ensemble manner to cluster tweets into two groups (positive and negative). Further, different feature representation methods are also examined and better performance of TF-IDF is revealed as compared to the Boolean method. The authors conclude by suggesting that CBA+CL ensemble can be the best choice among the selected clustering algorithms. According to the authors, their proposed framework is original as it has never been investigated before.

The research in [48] developed an original and simple clustering technique known as YAC2 and in study [38] extends its efficacy using three Twitter/X datasets. The technique of YAC2 is comparable to the divisive hierarchical clustering method, which divides a single cluster repeatedly into other clusters until no further clustering is possible. The efficacy of YAC2 has been demonstrated in study [48] by comparing its performance with well-established clustering algorithms (K-means, DBSCAN) on several datasets. The advantages of YAC2 include low theoretical complexity, handling of heterogeneous data, dynamic generation of cluster splits and proven high performances in comparison with DBSCAN and Spectral clustering algorithms.

*c) Density-Based Spatial Clustering of Applications with Noise (DBSCAN):* DBSCAN is an unsupervised learning algorithm that is often used in SA to group similar texts or reviews based on their sentiment. It is a density-based clustering algorithm that groups together data points that are closely packed together. DBSCAN algorithm is based on the idea of density reachability, which means that a point p is density-reachable from a point q if there exists a set of points which are all mutually density reachable from q and p. The algorithm defines two types of points: core points and non-core points. A core point is a point that has at least a minimum number of points (MinPts) within a distance ε (eps) from it. A non-core point is a point that is not a core point but is density-reachable from a core point. In SA, DBSCAN is used to group similar reviews together based on their predominant sentiment. The algorithm takes a set of reviews as input, and for each review, a set of features are extracted such as word frequency, sentiment scores, or other metrics. These features are then used to calculate the similarity between different reviews, which is used to group similar reviews together into clusters.

One of the main advantages of using DBSCAN in SA is that it can handle datasets with varying [63], and it does not require the number of clusters to be specified in advance (like in the case of K-means). It can also identify clusters of reviews that have similar sentiments and are close together in the feature space. However, it can be sensitive to the choice of parameters eps and MinPts and it doesn't perform well with high-dimensional data.

The research projects where this clustering algorithm was used are elaborated by [64] where authors propose a new methodology involving DBSCAN that had been applied to 7,014 tweets to identify regions of consumers sharing content about food trends. Grid maps were employed to investigate sub-regional variations and SA was utilized to address the attitude of their social representations. The study shows that the DBSCAN and SA-based technique is a legitimate research tool that may be used to identify communities with significantly diverse socio-psychological processes.

A study that applies cluster analysis with the DBSCAN algorithm is [65]. The manuscript assesses the spatial distribution of SM activities, aiming to define the concept of a "district" through the geographical proximity of geotagged photos and texts on Instagram and Twitter/X. By setting the DBSCAN parameters to a minimum of five points and a threshold distance of 300 meters, they categorized SM posts as core (within a district), border (district edge), or outliers. DBSCAN's resistance to noise and flexibility with various cluster shapes made it ideal for this study, which examined the perception of city images in Poland's Tri-City Region using both "big data" and "small data" approaches, focusing on imageability and Lynchian features through SM analytics.

*d) Other clustering methods:* By applying a variety of cutting edge techniques, SA and the identification of significant users in social networks are enhanced in this research [32]. The tweets are grouped into topics using weighted partition around medoids (WPAM). Instead of using preset k values, an artificial cooperative search (ACS) is used to optimize the k values of WPAM. Outlier is nearly completely avoided in WPAM due to the dynamic selection of k values. As a result, it groups the tweets by subject using dynamic clustering (DC). After the dynamic clusters have been created, Stanford NLP is used to extract the subjects from each cluster.

The proposed automatic learning using CA-SVM based SA model reads the Twitter/X dataset [40]. The characteristics were then extracted from them in order to produce a collection of words. The tweets are grouped based on the phrases using TGS-K means clustering, which calculates Euclidean distance based on many variables, including semantic sentiment score (SSS), gazetteer and symbolic sentiment support (GSSS), and topical sentiment score (TSS). In comparison to the current works, the proposed model has a sentiment score of 92.05% and an accuracy score of 92.48%.

The Louvain Community Detection Algorithm (LCDA) was used by [11] to find semantic clusters. For topic modeling and semantic network clustering, the study employed the LDA method and the Louvain algorithm, respectively. The modularity score, which measures how well nodes are assigned to clusters, is maximized for each cluster using this method. The LDA approach unearths six themes, including veganism, food waste, organic food consumption, sustainable travel, sustainable transportation, and sustainable energy use. While the Louvain algorithm identifies four clusters: responsible consumption, energy consumption, lifestyle and climate change, and renewable energy. The Louvain method was also used to discover semantic clusters of latent issues since the study's goal is to find the themes and subjects linked to sustainable consumption. The study offers a novel viewpoint on several linked issues of sustainable consumption that help to sustainably level world consumption.

Due to its limited size, lack of organization, misspellings, use of slang and abbreviations, SA performed on Twitter/X datasets can prove to be a difficult task. To ease this process, Tweet Analyzing Model for Cluster Set Optimization with Unique Identifier Tagging (TAM-CSO-UIT) was developed by authors [66] utilizing prospects to assess the mood of tweets downloaded from Twitter/X. The suggested model TAM-CSO-UIT correctly analyzes and categorizes the tweets, according with the author's statements and the results reported.

Five computer nodes make up the Hadoop cluster in the study [22], namely one master node and four slave nodes. The authors have established ten evaluation measures to evaluate the experimental findings. Additionally, they executed their solution within the Hadoop cluster to avoid a lengthy execution time from their hybrid's developed Fuzzy Deep Learning Classifier (FDLC). To show the potency of their proposed classifier, an experimental comparison between our FDLC and some other ideas from the literature is conducted. The empirical findings shown that the proposed FDLC outperforms existing classifiers in terms of complexity, convergence, stability, true positive rate, true negative rate, false positive rate, error rate, accuracy, classification rate, kappa statistic, F1-score, and time consumption.

### B. *The Relevant Sectors of Activity where the Clustering Algorithms were Used (RQ2)*

The current Section provides the answer to the second research question (RQ2). In the analyzed literature published in between 2020-2023, K-means, Hierarchical Clustering and DBSCAN proved to be the most used clustering algorithms. The references reveal that the algorithms are applicable in various sectors of activity, as well as in various situations: used alone or in combination with others. In order to provide the answer to RQ2, the manuscripts included in the pool of results were filtered based on the identified domain. To automatically extract the topic/sector of activity, Monkeylearn [67] tool proved to be very efficient. Based on this tool analysis, a new column was added to the database of papers, displaying the domain for each line. Therefore, for each paper in the database, the sector of activity was extracted by Monkeylearn from Title and Abstract variables, using a pretrained model.

*1) Healthcare and medicine:* Upon analysis 39% of the papers belong to the Health & Medicine sector of activity. As the review is based on the manuscripts published between 2020 and 2023, much research involving COVID-19 subject was performed. The following paragraphs display the insights extracted from the manuscripts included in the selection.

Several studies approach different hybrid clustering algorithms [47], [51], [68] while others develop new algorithms [36] for the purpose of grouping twits on similar topics related to COVID-19. Consequently, in order to understand city-level differences in emotions regarding COVID-19 vaccine-related subjects in the three biggest South African cities, [47] employ clustered geo-tagged Twitter postings. The study's findings demonstrated that clustered geo-tagged Twitter postings may be utilized to analyze the dynamics of emotions more effectively toward local discussions about infectious illnesses as COVID-19, malaria, or monkeypox. This can offer additional city-level data to health policy planners and decision-makers in planning and making decisions on vaccine reluctance for upcoming epidemics.

The authors [68] employ Uniform Manifold Approximation and Projection (UMAP) and Hierarchical Density-Based Spatial Clustering of Ap-plications with Noise (HDBSCAN). They combine the techniques to undertake a grid search for identifying the clustering model with the highest relative validity score representative for COVID-19. A total of 2666 hashtags extracted from Twitter dataset related to COVID-19's prevention strategies and vaccination were grouped into 20 topics for the two main clusters including rural and urban users. The study developed by Liu reveals how clustering algorithms used on Twitter may help with the spatially targeted deployment of epidemic prevention and management activities.

Long COVID syndrome was first described as a set of fuzzy symptoms that persisted following COVID-19 recovery using patient-created vocabulary. According to the SA performed by the authors [49], opinions about the long COVID syndrome can be equally split between positive (19.90%) and negative (18.39%). Similarly, the study performed by [33] emphasizes how the Indian government's progressive unlocks and lockdowns of various areas during the Corona outburst were perceived by the general population.

According to [69], influential users are considerably more important to be examined as they can provide valuable knowledge within the tweets concerning opinions related to COVID-19 vaccines. Thus, the findings enabled researchers to thoroughly examine the ego networks of the three user clusters: pro-vaxxers, neutrals, and anti-vaxxers.

*2) Climate and natural disasters:* With regards to this domain, the analyzed authors approach subtopics related to natural disasters. Consequently, [57] created and built a brand-new disaster intelligence system that automatically runs SA, automated K-Means, and AI-based translation to produce AI-driven insights for disaster strategies. Others [19] suggest a cuckoo search clustering technique for SA based on a roulette wheel to extract the best cluster centroids from the emotional dataset's content. Other researchers [9] identify the underlying themes in the tweets for obtaining topic clusters on natural disasters dataset.

AI-Social Disaster is developed by [70] and represents a decision support system (DSS) for identifying and analyzing natural disasters like earthquakes, floods, and bushfires. The approach gives crucial details for catastrophe planners or strategists, such as which natural disaster clusters were linked to the most negative opinions. Further, [57] proposes another DSS that collects Tweets on natural disasters in 110 supported languages using a live Twitter feed. The aim is to produce AI-driven insights for catastrophe planners, the system automatically carries out AI-based translation, SA, and automated K-Means algorithm. There is proof that being exposed to weather hazards has a negative influence on people's physical and mental health, especially in places affected by heat islands and climate change. The study in [71] reveals how Twitter data may be used to measure urban heat stress in real time and serve as a quick signal of times when people are feeling more uncomfortable due to the heat and are more likely to be dissatisfied with the weather.

*3) Environment:* In their research, [11] identify four clusters: responsible consumption, energy usage, renewable energy, and lifestyle and climate change. The SA's findings indicate that users are more likely to have positive emotions than negative ones, and they offer a new angle on a number of interrelated issues of sustainable consumption that help to stabilize global consumption which exerts a high impact on Environment.

The study in [72] findings provide information on ways to improve knowledge sharing to improve carbon-neutral information sharing which provides policy and social implications for tackling environmental issues by analyzing social patterns on Twitter. Although carbon taxes are an efficient emission reduction strategy that benefits the environment, it is unpopular, and it is unclear why. This study [59] examines a sample of data from Twitter to identify the driving forces behind discourses about carbon prices in response to the scarcity of timely updates on people's perspectives of the relevant topic.

The research in [60], identify typical daily morning congestion patterns for each route in the network to enhance the morning traffic prediction and decrease the daily air pollution by clustering.

The goal of the author's [73] exploratory study is to locate, group, and assign an emotional value to tweets that contain the phrases "university" and "sustainable" in Spain relative to the rest of the globe. The findings highlight important aspects of the environment, research, and innovation via the lens of universities' contributions to local communities. They also offer an entrepreneurial perspective and highlight how academic knowledge is really used in the workplace.

*4) Society and political views (Elections):* The majority of studies include different tool developments and analyses performed during election campaigns. Consequently, a study demonstrates that during an election campaign, only the information that has been extensively disseminated is in the heart of the densest clusters. The geographic distribution of these clusters helps to group various topics together. Thus, [62] examines, in India, the types of users and information patterns to ascertain how the scheme-related tweeting patterns changed during the course of elections. The study reveals that a significant number of government-related tweets are generated during the voting periods and election length. The location of the voting phase, however, has no relevance to it. In future voting stages, the positive news outweighs the negative tweets and complaints that were generated in the initial voting phase. In order to gauge the emotional impact of the messages released by various Spanish Newspapers, NLP techniques and ML algorithms are used on this research [74] to discover the predominant topics linked to the elections as well as to highlight the candidates and political parties. The findings show the degree of attention given by the media to the regional election debates and campaign activities in Madrid.

The study in [61] aims to differentiate political positions (left, center, right) in Chile by developing an algorithm to obtain the scores of 882 ballots cast in the first stage of a convention. The authors employ k-means to identify three clusters containing right-wing, center, and left-wing positions and the results may prove to be efficient in the better understanding of political behavior within the constitutional processes.

In relation to Society, a study developed by [75] reveals that Twitter data offers a distinctive and practical source of information for the analysis of significant civic movements, such as large-scale protests across numerous European nations. Additionally, such an approach might highlight significant spatiotemporal and emotional trends, which may also help to comprehend how protests escalate through space and time. Moreover, the inhabitants of a region may presently convey their own experiences with warm weather as well as their sentiments about it on SM. The public mood and health of an area may be reflected in the geotagged, time-stamped, and easily available SM databases, according to a recent study published by [71]. Further, research on the emotional data may be done using the Roulette wheel selection based cuckoo search clustering method [19]. The approach created by [19], [17] and [5] prove to have important and practical implications for creating a system that can produce accurate remarks on any societal issue with massive impact on the inhabitants.

## IV. Discussion

SA algorithms have been advancing rapidly in recent years, thanks to breakthroughs in ML and NLP research. Within this section, several discussions shall be conducted on the key advancements encountered in SA algorithms. State-of-the-art performance in many NLP tasks, including SA, has been attained by DL models like BERT, Generative Pre-trained Transformer 3 (GPT-3), and XLNet. GPT-3, developed by OpenAI, can produce human-like prose on a variety of themes and was trained on a varied collection of online content. In 2019, researchers at Google AI created XLNet, another cutting-edge language model for NLP activities built on the transformer architecture, like BERT and GPT-2. Unlike GPT-3, XLNet uses an autoregressive language modeling approach, to predict each token in a sequence based on all the tokens that come before it. In the light of this information, XLNet captures complex dependencies and interactions between the tokens in a sequence, leading to higher performance on a wide range of NLP tasks, including SA. These new DL models (BERT, GPT-3, and XLNet) are able to recognize more sophisticated and subtle expressions of sentiment as well as the context and meaning of each word inside a phrase. Another advancement is the use of transfer learning, where a pre-trained model is fi-ne-tuned on a specific task, this allows the model to learn task-specific features while still retaining the general-purpose understanding of language learned during pre-training. This strategy can lead to enhancements in the SA model performance, particularly when training is scarce. Although the above technologies have made significant advancements in NLP and AI, they are still far from perfect and have limitations and challenges that need to be addressed. The existing AI technologies have been built over many years and have been re-fined and improved through countless iterations and experiments. Therefore, it is unlikely that they will be replaced overnight by new technologies, as there is a significant amount of knowledge and expertise that has gone into their development.

In the light of the above, it is still relevant to rely on the current technology and therefore, this review contributes to the domain. The recent research has focused on the existing technology to develop more robust models that can handle noise and outliers in the data, like sarcasm, irony, and emojis which can often be misleading, and also models that can handle multiple languages and cross-lingual SA analysis. Overall, in the light of the above mentioned advancements, it becomes obvious that the field of SA is rapidly advancing. The discoveries revealed within this review have led to more accurate and effective SA models, which can provide valuable insights into customer opinions, feedback, and attitudes, and support decision-making in a variety of industries, including marketing, healthcare, and finance.

A shortcoming is that SA models trained on general-purpose datasets may not per-form well on data from niched domains like product evaluations, or medical records. In order to solve this problem, domain-specific SA models have been created. These models are trained using domain-specific datasets, which improves accuracy and performance.

TABLE II. Comparative Analysis of Clustering Algorithms

| Algorithm | Strengths | Weaknesses | Reference |
|---|---|---|---|
| K-Means | Easy to implement; Fast and scalable; Well suited for finding spherical clusters; Inductive learning. | Does not handle non-spherical clusters; The number of clusters should be specifield. | [77], [78], [76] |
| Hierarchical Clustering | Can handle non-spherical clusters and varying cluster sizes; Suitable for complex data structures; Transductive learning. | Can be computationally expensive for large datasets; Sensitive to the presence of noise and outliers in the data; No guarantee of optimality. | [77], [79], [80], [76] |
| DBSCAN | Automatically determines number of clusters; Robust to noise; Computationally efficient, suitable for large datasets; Transductive learning. | Sensitive to parameter choices; May not perform well in high-dimensional data; No probabilistic framework. | [79], [15], [14], [76] |
| Gaussian Mixture Model (GMM) | Ability to handle overlapping clusters; Good for density estimation; Inductive learning. | Sensitive to initial conditions; Does not scale well to large datasets. | [14], [76] |

In line with the “traditional” clustering algorithms displayed by the papers included in the current review, a comparative analysis was performed and according to the literature investigation, clustering algorithms are used in conjunction with other algorithms, such as feature extraction algorithms and classification algorithms, to create a complete SA framework. The comparison analysis included in Table II is based on the aspects identified in the literature review (references are included in the last column). The analysis presents the strengths and weaknesses of each algorithm included in the current comparison. Among them, Hierarchical and DBSCAN offer, according with [76], transductive learning (the algorithm learns from a subset of the data and applies that knowledge to the entire dataset) while K-means and GMM support inductive learning (the algorithm learns from the entire dataset and makes predictions on new, unseen data).

From the total of 46 manuscripts investigated, the authors of 19 papers opted for performing clustering analysis using K-means, 16 authors employed Hierarchical Clustering or other variant of Hierarchical algorithms, six used DBSCAN and the remaining papers (5) rely on using other algorithms (GMM, Spectral and others). Moreover, some authors combined the clustering algorithms with other techniques such as LDA, NMF and BERT [52] to detect anomalies and develop the clusters of most frequent words, while displaying the results using a word clouds and other visualization methods. The results show that applying K-means in a framework [52] can enhance the analysis in the considered dataset. An original development is revealed in a study of [57] that employed Automated K-Means clustering on Mobile Apps for the first time to uncover hidden knowledge, patterns, similarities, and differences contained among various types of catastrophe tweets.

Regarding HAC, [2] compares the performances of simple use of three agglomerative HAC (SL, CL, AL) and their combination with the concept-based methods. The results state that algorithms are encountering higher precision when used in combination with other algorithms or techniques in the form of frameworks. Based on the results from Table II, author personal perception and other source [76], the discussion regarding which algorithm to use is subject to the specific characteristics of the dataset and clustering task. Therefore, the observations in this research conduct the following insights: (1) K-means can handle well-defined clusters, but it may not be the best choice for large datasets. As the number of data points increases, the computational complexity of K-means also increases; (2) Hierarchical Clustering is suitable for complex datasets with non-spherical clusters and unknown number of clusters; (3) DBSCAN performs well in datasets with arbitrary shaped clusters and varying densities. When making a decision regarding the clustering algorithm to use, it is important to consider the strengths and weaknesses of each algorithm before selecting the most appropriate one.

## V. Conclusions

To conclude, the algorithms play a critical role in SA, allowing for the automatic analysis of large volumes of textual data and providing valuable insights into customer opinions, feedback, and attitudes towards products, services and other topics extracted from SM environment (specifically from Twitter/X dataset on this research).

Considering the topic addressed, the results reveal that in the analysis period of Dec 2020 to Dec 2023 undertaken by this research, the most numerous articles treat different Coronavirus topic with subjects ranging from people’s fears regarding Covid-19 [5],[11] [12] to their sentiments expressed towards different vaccination campaigns [47]. Further, the selection of studies based on the criteria formulated and displayed in Fig. 1, proved to employ “traditional” clustering algorithms, to develop new ones, as well as to use of different hybrid combinations between “traditional” and newly developed ones. None of the manuscripts included in the study refer to the state of the art DL models such as GPT-3 and XLNet while very few reference BERT. Thus, in a future study, the author intends to extend the current study by analyzing the impact of these modern models on SA techniques over a longer span of time and analyzing more SM channels. One limit of the study is that it does not cover the ethical aspects related to the use of AI and the algorithms in analyzing people’s sentiments. This constitutes another future research path that will be fulfilled in the upcoming studies.

# A Systematic Review of the Literature on the Use of Artificial Intelligence in Forecasting the Demand for Products and Services in Various Sectors

José Rolando Neira Villar[1], Miguel Angel Cano Lengua[2]
Universidad Nacional Mayor de San Marcos, Lima, Perú[1, 2]
Universidad Tecnológica del Perú, Lima, Perú[1, 2]

***Abstract*—This systematic review, carried out under the PRISMA methodology, aims to identify the recently proposed artificial intelligence models for demand forecasting, distinguishing the problems they try to overcome, recognizing the artificial intelligence methods used, detailing the performance metrics used, recognizing the performance achieved by these models and identifying what is new in them. Studies in the manufacturing, retail trade, tourism and electric energy sectors were considered in order to facilitate the transfer of knowledge from different sectors. 33 articles were analyzed, with the main results being that the proposed models are generally ensembles of various artificial intelligence methods; that the complexity of data and its scarcity are the main problems addressed; that combinations of simple machine learning, "bagging", "boosting" and deep neural networks, are the most used methods; that the performance of the proposed models surpasses the classic statistical methods and other reference models; and that, finally, the proposed novelties cover aspects such as the type of data used, the pattern extraction techniques used, the assembly forms of the applied models and the use of algorithms for automating the adjustment of the models. Finally, a forecast model is proposed that includes the most innovative aspects found in this research.**

***Keywords*—Demand; agglomeration algorithm; services; PRISMA methodology; artificial intelligence**

## I. Introduction

Accurate demand forecasting is essential for the efficiency and normal development of companies' activities. Forecasts are vital in both operations and supply chain planning: in operations they are essential to design production processes, manage bottlenecks, schedule production and determine long-term capacity; in the supply chain, forecasts are the basis for determining purchasing and inventory levels and for coordinating with suppliers and customers. Finance requires adequate forecasting to project cash flow and capital needs; while Human Resources needs them to anticipate hiring and training needs [1]. Even more, having advanced demand forecasting capabilities, by allowing you to minimize costs, time, and optimize resources, can be an important source of competitive advantage; while inaccurate forecasts can cause damage such as excess inventories, lack of supplies for production, high labor costs and loss of reputation [2]. The strategic importance of having adequate forecasts is clear, then. In the words of Krajevsky and Malhotra [1]*[1]*"managers at all levels need to forecast future demand so that they are able to plan the company's activities in accordance with its competitive priorities*"* (p. 315).

Due to its importance, demand forecasting has become an extremely complex and challenging activity due to the uncertainty and volatility of modern markets, structural and technological changes in various sectors and the emergence of unpredictable crises. Spiliotis et al. [3] pointed out, for example, that the daily demand for products in a large part of industrial and retail companies is erratic and intermittent, which makes the forecast very complicated. Similarly, Quiñones-Rivera et al. [4] found that, in the context of the manufacturing of electrical products in Colombia, it is difficult for companies to adequately forecast demand due to its volatility and its dependence on various non-linear exogenous factors. Fildes et al. [5] found that due to the rise of electronic commerce, demand forecasting in the retail sector faces, on the one hand, the need to model the complex competition and complementarity of online sales in an increasingly omni-channel context and, on the other hand, the challenge of foreseeing the impact of sectoral and global crises such as those experienced, for example, with the COVID 19 pandemic. Along the same lines, Viverit et al. [6], points out that the aforementioned pandemic has had short and long-term consequences on the hotel industry, plunging it into an unprecedented situation where its historical demand has lost its value, making forecasting activities very complex. Finally, Sun et al. [7] pointed out that the rise of online activities has opened the possibility of forecasting the demand of the tourism sector using a large amount of data related to customer behavior on web search engines and social networks, however, the Exploitation of this possibility represents enormous challenges in terms of managing an infinite number of independent variables and the consequent increase in the complexity of the models.

To address these challenges, with the rise of artificial intelligence, a variety of innovative forecasting models based on machine learning have been proposed with the idea of surpassing the accuracy of classical models established in various industries [8], [9], [10]. Given the situation described, this study seeks to describe the state of the art of the use of artificial intelligence in the vital field of demand forecasting, clarifying the main challenges addressed and the most important innovations. To have a broad multi-sector vision but at the same time not be unnecessarily exhaustive, this study has been limited to the manufacturing and retail sectors (hereinafter retail), the tourism sector and the electric energy sector.

This research arises from the need to know the most recent advances in the field of demand forecasting. The main motivation is to improve, with the advances of artificial intelligence, the forecasting methods that companies use as a basis for their operational plans. The main contribution of this study is to have clarified the nature and scope of the contributions of artificial intelligence in the field of demand forecasting. In doing so, we also aspire to contribute to academic debate and decision-making based on evidence, and rigorously examined and updated information.

Finally, the findings of this study have important implications for both academia and decision makers in operations management. Firstly, they suggest the need to replace, or at least complement, classical forecasting methods with methods based on artificial intelligence. Furthermore, the results point to the importance of incorporating techniques such as image-based forecasting, dynamic ensembles and deep learning. Finally, this research provides evidence that could be used by companies to gain efficiency in their operational planning.

The order of this investigation is structured as follows. In Section II is the development of the research using the PRISMA methodology, whose choice was because it fits the work; Next, in Section III we will see the results obtained from the analysis of the articles found and a proposed model for the evaluation of readers.

Subsequently, in Section IV, the discussion of the research was carried out with the proposals made by the authors and a conclusion of the findings found in the work.

Finally, the references used in this research are listed.

## II. Methodology

This systematic review of the literature was carried out under the PRISMA methodology, which was created to guarantee the rigor of this type of studies, avoiding possible biases [11]. Additionally, the selected documents were classified using automatic grouping algorithms, in order to provide an objective panoramic view of the different uses and methods of artificial intelligence in the field of demand forecasting.

### A. *Research Questions*

As part of the research process, five research questions have been posed to serve as a guide throughout the investigation and to allow the knowledge contained in the documents examined to be extracted and synthesized. These questions are shown in Table I.

### B. *Search Strategy*

To construct the search chain, the PICOC methodology, population, intervention, comparison, objective, and context were taken into account. Table II TABLE IIshows the search terms related to each of these factors.

TABLE I. Research Questions

| Code | Questions |
|---|---|
| Principal | What novel artificial intelligence models for forecasting demand have been proposed in recent years? |
| P | What demand forecasting issues or challenges have been addressed with artificial intelligence? |
| I | What artificial intelligence methods have been used for this purpose? |
| C | What metrics have been used to measure the performance of the proposed models? |
| O | What is the performance of the new proposed models in relation to the established models? |
| C | What are the new features or innovations introduced by these models? |

TABLE II. Search Terms

| Factor | Description | Search terms | Synonymy |
|---|---|---|---|
| Problem | Demand forecasts for business products and services | "demand forecasting" | "demand prediction"<br>"demand prognostic"<br>"demand prognosis"<br>"product forecasting" |
| Intervention | Forecasting using artificial intelligence | "artificial intelligence" | "machine leargning"<br>"deep learning"<br>"reinforcement learning"<br>"generative models" |
| Comparison | Forecast Accuracy | "accuracy" | "performance"<br>"error"<br>"effectiveness"<br>"precision" |
| Objetive | Accuracy improvement | "improve" | "outperform"<br>"better"<br>"superior"<br>"enhance" |
| Context | Proposal for a novel model | "new" | "original"<br>"unprecedent"<br>"novel"<br>"innovative" |

The search terms were combined with Boolean operators to construct the following search string with which the search is carried out:

("demand forecasting" OR "demand prediction" OR "demand prognostic" OR "demand prognosis" OR "product forecasting") AND ("artificial intelligence" OR "machine learning" OR "deep learning" OR "reinforcement learning" OR "generative models") AND ("accuracy" OR "performance" OR "error" OR "effectiveness" OR "precision") AND ("improve" OR "outperform" OR "better" OR "superior" OR "enhance") AND ("new" OR "original" OR "unprecedent" OR "novel" OR "innovative")

### C. Eligibility Criteria

For this research, some criteria were considered that fit the field of activities of the sector linked to product demand and management using artificial intelligence algorithms.

TABLE III. INCLUSION CRITERIA

| Code | Description |
|---|---|
| I1 | Articles that propose a novel quantitative method for demand forecasting |
| I2 | Articles that apply artificial intelligence in the forecast model they propose |
| I3 | Empirical articles with models validated with real data from companies |
| I4 | Scientific articles and conference papers |

The inclusion criteria established for this study are shown in Table III TABLE IIIand the exclusion criteria in Table IV. , taking into account the relevance and impact factor of the journals.

TABLE IV. EXCLUSION CRITERIA

| Code | Description |
|---|---|
| E1 | Articles published in languages other than Spanish or English. |
| E2 | Articles published before 2019 |
| E3 | Articles that study demand forecasts outside the retail, manufacturing, hospitality, tourism and electric energy sectors. |
| E4 | Articles with full text not available |

### D. Information Sources

The scientific database Scopus was chosen to be used as a source of information, as it is recognized for its reliability among the academic community (see Fig. 1).

### E. Article Selection Process

The research process was carried out in four stages. In the identification stage, the search string was applied and the total number of articles in the database that contained all the specified conditions was found. In the pre-selection stage, exclusion criteria were applied at the title and abstract level. In the selection stage, the inclusion criteria were also applied at the title and abstract level. Finally, in the inclusion stage, the introduction, methodology and conclusions sections of the articles were reviewed and, applying the inclusion criteria, it was decided whether or not to integrate them into the qualitative synthesis.

The application of the search string in the Scopus database yielded a total of 204 documents as can be seen in Fig. 2.

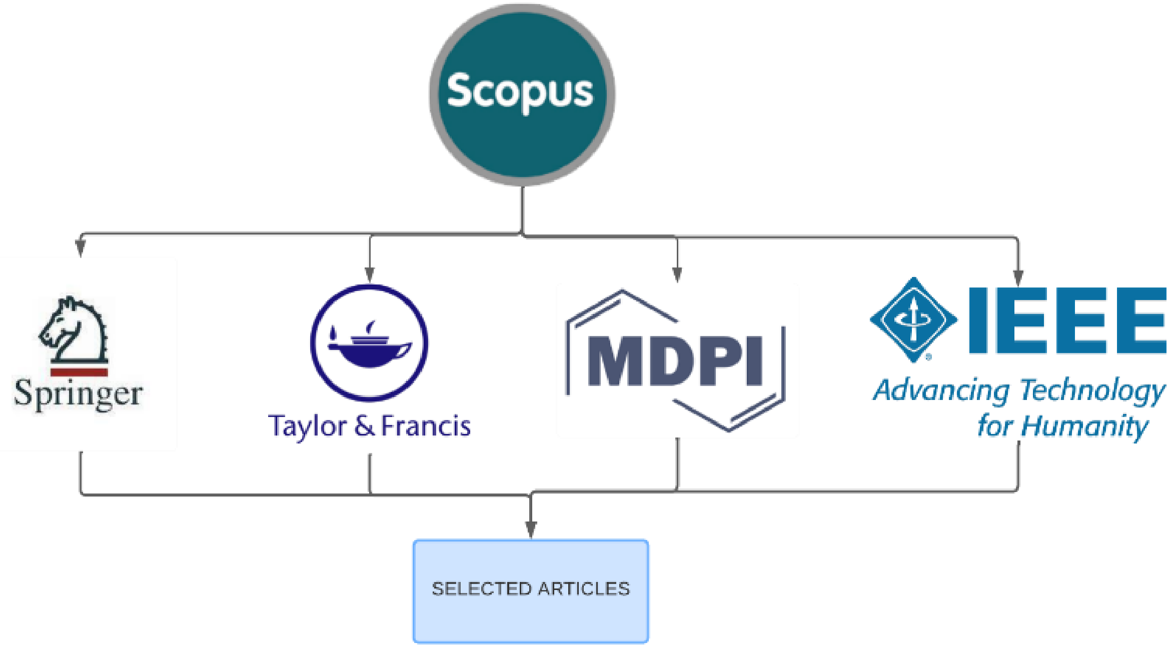

Fig. 1. Source of information used in the research.

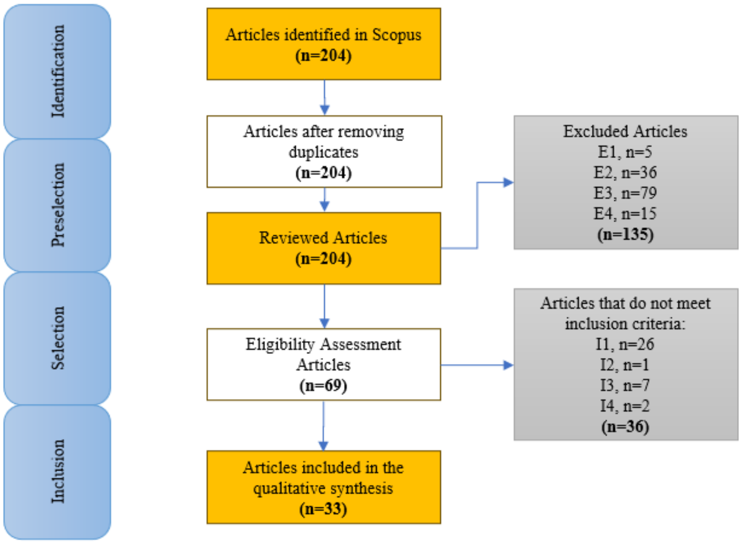

Identification
Preselection
Selection
Inclusion
Articles identified in Scopus

Eligibility Assessment Articles
(n=69)
Articles that do not meet inclusion criteria:
I1, n=26
I2, n=1
I3, n=7
I4, n=2
(n=36)
Articles included in the qualitative synthesis
(n=33)

Fig. 2. Results of article selection.

No duplicates were found among the 204 articles found; after applying the exclusion criteria, 135 articles were eliminated and 69 remained for the evaluation of the inclusion criteria. After this last evaluation, 36 articles that did not meet at least one criterion were eliminated, leaving a total of 33 articles for inclusion in the qualitative synthesis.

### *F. Automatic Grouping of Articles*

After the selection process and to support the analysis process, each article was labeled according to the type of data used, the type of feature engineering used, the type of forecasting methods used, the form of training and adjustment. of hyperparameters of the models, to the assembly form of the applied methods and to the business sector in which it is applied. Likewise, to classify the articles according to their similarity using these labels, it was decided to use an automatic grouping algorithm in order to ensure objectivity in carrying out this task and avoid classifications biased by the authors' preferences. An agglomerative hierarchical clustering algorithm with Euclidean distance was then used to measure the similarity between the documents and construct a dendrogram. This method was chosen since it allows an objective, visual and detailed representation of the articles under study, which facilitates their interpretation. Another advantage of this method is that it does not require specifying a priori, and therefore subjectively, the number of clusters into which the documents will be divided. The silhouette method was then used to identify the optimal number of clusters since it also offers a visual and objective interpretation of the number of convenient clusters.

The agglomerative hierarchical grouping of the documents generated five clearly differentiated groups that we will describe below (see Fig. 3 and Fig. 4).

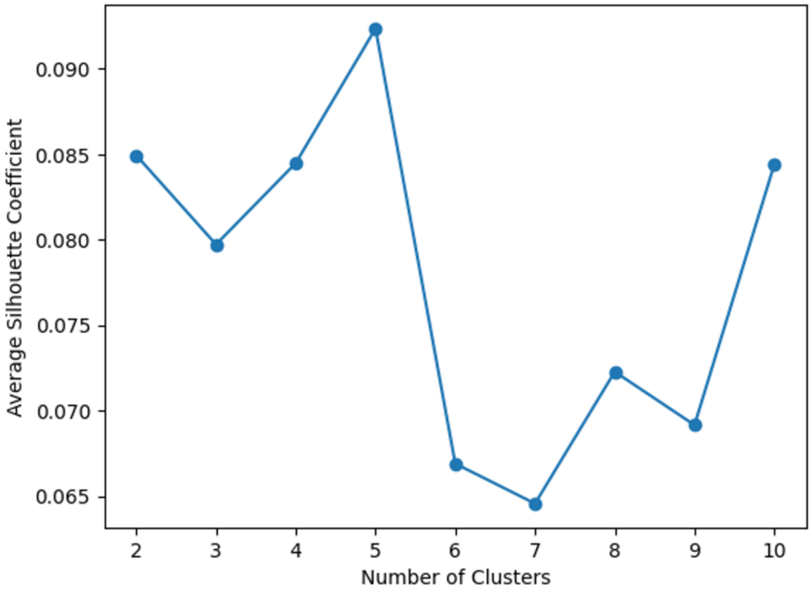

Fig. 3. Silhouette method.

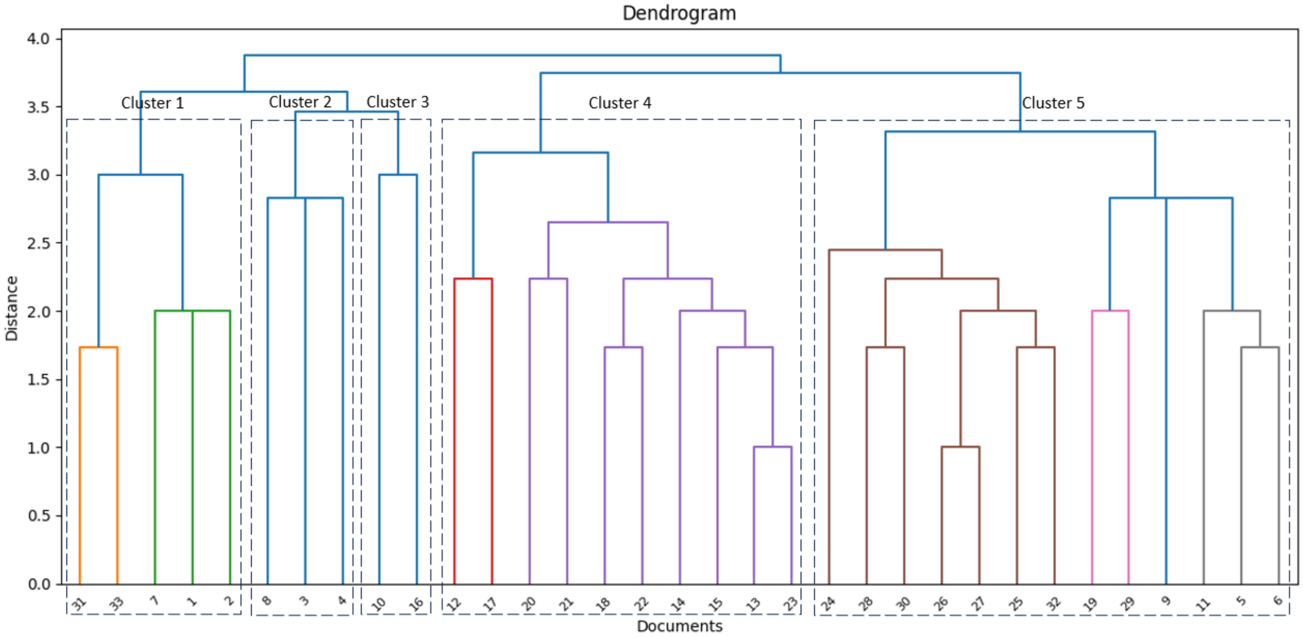

Fig. 4. Agglomerative hierarchical grouping of articles.

*1) Group 1:* Consisting of five documents from the energy and retail sectors whose common characteristic is the use of “bagging” methods and data derived from the calendar such as holidays, weekends, weekdays, etc. The models proposed by these documents assemble the “bagging” methods with “boosting” methods, since the former are capable of compensating for the “overfitting” problems of the latter, while the latter correct the bias errors typical of the former [12], [13]. Other novel models from this group also propose the use of a “Generative adversarial network” to create “synthetic” data [14] and “transfer learning” [15], in both cases, to overcome the limited volume of data available for training.

A special case within this group is the study [16] which assembles a bagging, Random Forrest (RF) with a deep neural network, “Long-short term memory” (LSTM). The LSTM models the temporal patterns of the time series while the RF relates the forecast errors produced by the LSTM with variables “external” to the time series itself such as special calendar days, characteristics of the products and the point of sale. . The final prediction results from the addition of the LSTM forecasts plus the RF forecasts.

*2) Group 2:* Made up of three articles from the retail sector that propose the use of simple machine learning methods in conjunction with clustering methods as a way to extract useful patterns for forecasting. First, it processes the time series with RF, and then models the errors produced by it with a multiple linear regression (MLR) using Internet search intensity indices as independent variables [17]. The second document [18] uses k-means to separate the data into different clusters, to then identify which “Suport Vector Regression” (SVR) or “Extreme Learning Machine” (ELM) method is the best predictor for each cluster. Finally, [19] proposes a forecast model consisting of a base of predictors composed of statistical methods, simple machine learning and a deep neural network, the “Multi-Layer Feed Forward Artificial Neural Network” (MLFFANN); that are combined dynamically, using weighted weights calculated in inverse proportion to the errors they generate.

*3) Group 3:* Consisting of two documents, one from the retail sector and the other from the tourism sector, which propose models that use a base of predictors formed by simple methods, bagging methods and boosting methods, and that make use of decomposition as a way to extract important patterns to improve forecast accuracy. The first document [20], focuses on the optimization using various algorithms of the input variables of the model, while the second [21], in a similar way to the last document of the previous group, proposes a dynamic assembly of the predictors through of an exponential function that decreases with the error produced by each of them.

*4) Group 4:* This group is made up of ten documents from the tourism sector, whose main characteristic is the predominant use of neural networks in their forecast models. A striking subset of papers in this group makes use of several neural networks of the same type forming a “stacking” configuration: [22] stacks LSTM networks, while [23] and [24] use multiple deep belief networks (DBN). ) and kernel extreme learning machines (KELM) respectively to generate the stacks. These three documents also have in common the use of predictor variables based on Internet search intensity indices and the use of some type of dimensionality reduction, due to the large number of variables, to select the most significant ones, [23] uses an algorithm called “double boosting” for this purpose, while [22] and [24] use neural networks called “autoencoders” to do the dimensionality reduction.

Without the “stacking” figure, the documents [25], [26], [27] use deep neural networks (RNN the second and LSTM the other two) but add as a novelty the use of some automatic dimensionality reduction method (elimination of superfluous input variables) also based on neural networks; [25] and [27] use the so-called “attention mechanism” which consists of a neural network with only one hidden layer that assigns weighted weights to the input variables, thus selecting the most relevant ones for the forecast. The paper in [26] uses a Recursive Neural Network (RNN) for sequential pattern learning and a single hidden layer MLP for extracting low-level features in addition to a multi-layer MLP for high-level feature extraction.

Another important model within this group is the one proposed by the document [28] which converts time series into images and then uses special convolutional networks for processing. Finally, two papers from the group [29] and [30] focus their models on the decomposition of the original time series into several component series to then find the best forecasting methods for each of them. Notable in this sense is the document [30] that proposes using statistical or simple machine learning methods, such as ARIMA or SVR, for low complexity components and using neural networks with bidirectional GRU for the forecast of high complexity components.

*5) Group 5:* Finally, we have that this group is made up of 13 documents belonging mainly to the energy and retail sectors, whose main characteristic is the use of deep learning in their forecast models. The models proposed by this group are aimed at improving the performance of deep learning algorithms through various resources, among which are: the use of hyper-parameter optimization algorithms, such as the “firefly algorithm” [31] or the “ Improved Giza pyramids construction algorithm” [32]; the use of dimensionality reduction techniques such as “Encoders” [33], [34] and “Principal Component Analysis” (PCA) to optimize the model inputs; the use of “cross or transfer learning”, that is, the use of data from similar products or services when the data of the product under study is very limited [35], [36], [37]; the use of “clustering” to divide the data into groups of similar behavior and train a neural network for each cluster [38]; the transformation of the data into images and their decomposition to then use a CNN for feature extraction and an LSTM for prediction [39]; the use of complex time series decomposition algorithms using neural networks [40]; the use of parallel computing [41]; and the use of special architectures of convolutional networks [42].

## III. Results

This section answers the research questions in light of the analysis of the selected documents.

Main question: What novel artificial intelligence models for forecasting demand have been proposed in recent years?

The artificial intelligence models proposed in recent years for demand forecasting were described in the previous section. Below we will deepen our understanding of them by answering the specific research questions.

### A. *Q1: What Demand Forecasting Issues or Challenges Have Been Addressed with Artificial Intelligence?*

The analyzed documents address various challenges and problems related to demand forecasting. Below, we detail the main ones (see Table V).TABLE VII

### B. *Q2: What Artificial Intelligence Methods Have Been Used for this Purpose?*

The machine learning methods used to solve the problems raised in the previous section can be classified into five groups, which we describe below (see Table VI).

TABLE V. Results of the keywords corresponding to Q1

| Keyword | Input |
|---|---|
| Complex and non – linear data | Fourteen of the 33 documents analyzed indicate that the main problem that the proposed “machine learning” models are intended to solve is the complexity and non-linearity of the patterns generated by the variables that affect the forecast. [12], [18], [20], [21], [22], [28], [23], [25], [26], [31], [43], [40], [41], [42]. |
| Numerous casual factors | Nine documents also raise the difficulties caused by the fact that the factors that affect demand are very diverse and numerous, such as calendar factors, climatic factors, economic factors, market factors, etc. Which makes the construction of adequate models extremely challenging [12], [13], [17], [29], [30], [26], [34], [37], [41]. |
| Low volumen of training data | Machine learning models that are capable of capturing the complexities of the relationships between variables also require large amounts of data for training. However, many times the historical data available is scarce, not only because the products or services of interest have little history, but because as markets change, old data loses relevance or explanatory power. This leads to the need to build models that can perform well in these types of situations. [14], [15], [18], [28], [27], [35], [36], [40]. |
| Temporal patterns and external factors | The demand for many products exhibits temporal patterns, such as trend and seasonality, however, other patterns are superimposed on these temporal patterns due to external factors such as the economy, climate, competition, etc. Simultaneously modeling both types of patterns can be a very complex task and a great challenge for forecasting models [16], [20], [29], [28], [30], [26], [40], [41]. |
| Complexity of internet search intensity factors | Internet search patterns have proven to be very effective in forecasting demand for various products and services. However, the use of these indices poses several problems in the design of forecasting models based on them, the main of which is the existence of an infinite number of search terms candidates for predictor variables. This fact poses the enormous challenge of selecting the most appropriate predictors for demand forecasting. [22], [23], [44], [24], [27], [35]. This problem becomes more acute even when spatiotemporal data are necessary to feed the models [28], [25]. |
| Overfitting | Closely related to the problem of numerous causal factors and the large number of predictive search indices is the problem of overfitting, that is, models generating very little error with the training data, but large errors with the test data. One of the causes of this problem is the use of too many predictor variables. Documents [28][23][44][26][24][36] present models that address this problem. |
| Disruption | Another problem that significantly affects forecasts is disruptive events, such as calendar events or COVID 19. The robustness of |

| | |
|---|---|
| | forecast models with respect to these types of events is highly desirable and is addressed by documents [13], [30], [37] and [41]. |
| Complexity of supply chains | The demand forecast within the context of the problems inherent to supply chains such as excess or insufficient inventories, the bullwhip effect or the complexities imposed by omnichannel, are addressed by documents [16], [19], [20] and [38]. |
| Management of large volume of data | The problem of processing large amounts of data to make forecasts is addressed by documents [22][39]. |
| Model optimization | Optimizing a forecast model of increasing complexity entails several challenges, such as selecting the most appropriate hyperparameters [31], [32], identifying the appropriate amount of historical data to introduce [27], limiting the complexity of the model [36], preserving its explanatory power [33] and avoid model degradation [42] |

TABLE VI. RESULTS OF THE KEYWORDS CORRESPONDING TO Q2

| Keyword | Input |
|---|---|
| Simple Machine Learning Methods | Within this group are the traditional machine learning methods multiple linear regression (MLR) and support vector machine (SVM). Twelve documents propose the use of these methods, however they are proposed in combination with other more complex methods [12], [15], [18]-[21], [29], [30], [35], [40] or with classical statistical methods [17]. |
| Bagging Methods | This method builds models by training them a large number of times with various random subsets of the training data. Within these methods we find the Bagging Decision Tree, or simply Bagging [13], and the Random Forrest (RF). As in the previous case, these models are not proposed alone but in combination with other models of different types[12], [14], [16], [13], [15], [20], [21], [35]. |
| Boosting Methods | Within these methods we find Extreme Gradient Boosting (XGB), Light Gradient Boosting (LGB), AdaBoost and Categorical Boosting. Six studies propose the use of these algorithms and, similarly to the previous ones, they are proposed in combination with other methods. [12], [14], [13], [15], [20], [21]. |
| Simple Neural Netwotks | These methods generate models that use single hidden layer neural networks such as the Multi Layer Perceptron (MLP), the Extreme Learning Machine (ELM), or the so-called Autoencoders. Seven documents propose the use of these networks, however, only in three of them are they proposed as the main predictor [41], [24], [44], in the others they are proposed as part of a base of predictors [18][20][29], or as mechanisms for pattern extraction before applying the main predictor [26], [24]. |
| Deep Learning | This machine learning method uses at least one deep neural network, that is, a network with several hidden layers, to build the forecast model. Twenty-three of the thirty-three documents analyzed propose some type of deep learning. Three of them propose the deep neural network as part of a base of predictors of different types [19][29][35]]; fifteen of them propose it in combination with other simpler methods [14], [16], [22], [23], [25], [27], [43], [36], [40], [34] or in combination with other deep neural networks [28], [26], [39], [33] and, finally, five papers propose a single type of neural network as the main predictor [31], [38], [32], [37], [42]. Of note are the studies that propose the use of multiple neural networks of the same type as "stacking" [22], [23], [31], [42]. Therefore, the tendency to use deep neural networks when proposing innovative forecasting models is evident. |

### C. *Q3: What Metric Have Been Used to Measure the Performance of the Proposed Models?*

All of the proposed models measure their performance with at least one of the classic error metrics: Mean Absolute Error (MAE), Mean Squared Error (MSE), Root Mean Squared Error (RMSE) and Mean Absolute Percentage Error (MAPE). or its standardized versions NMAE, NMSE, NRMSE and NMAPE. Some studies also include among their metrics the coefficient of determination (R^2) [12][14][22][31]. Two studies also propose the "Directional statistics" metric [29][24]. Finally, only one study additionally uses the "Theil coefficient" (TC) metric.

### D. *Q4: What is the Performance of the New Proposed Models in Relation to the Established Models?*

All the proposed models report at least the same performance as the models they take as reference [12], [21]. Some report slight improvements of the order of one or two percent [33], [32], but the vast majority report significant improvements that can be of the order of 60 or 70 percent [31], [27]. However, these results must be taken very carefully since many proposed models are compared with models very similar to them, with only slight improvements, while other models are compared with diametrically different models with very different logics and methodologies, which make it more likely large performance differences. Finally, in the documents where the proposed machine learning models have been compared with classical statistical methods, the former have been clearly superior [16], [17], [21], [29], [23], [30], [44], [25], [24], [27], [43], [36], [41], [42]

### E. *Q5: What are the New Features or Innovations Introduced by these Models?*

The analyzed documents propose various novelties that we then classify according to the stage of model development in which they occur (see Table VII).

### F. *About the Bibliometric Analysis*

*1) Publication analysis by keywords:* The bibliometric analysis carried out with the help of the VosWiever and Bibliometrix software, which have good performance in these types of research. The search string was used from which 204 articles related to our research topic were obtained.

The Fig. 5 shows the publications by keywords in the different articles reviewed we can see that the word forecasting has greater acceptance in the different researches, followed by deep learning, machine learning, learning systems, etc.

Fig. 6 shows the thematic research groups, which are related to specific research areas forecasting (yellow), demand forecasting (blue), machine learning (green) and to a lesser extent forecasting method (violet).

In Fig. 7, you can see the publication trend according to the authors' interest in the keywords, with the research using machine learning algorithms to evaluate the forecast of product and service demands, followed by deep learning. , forecasting, among others.

*2) Publication trend in different countries*: In Fig. 8, it is observed that there is great interest in different countries in investigating the chosen topic. Firstly, we see that in Asia there are more articles published, followed by Australia and the United States.

TABLE VII. RESULTS OF THE KEYWORDS CORRESPONDING TO Q5

| Keyword | Input |
|---|---|
| New related to the variables used | The analyzed documents propose the use of various variables for demand forecasting, such as: calendar event variables [12], [14], [16], variables related to product or service characteristics [16], [35] related variables with the characteristics of the supply chain [20], [35], [38], variables related to the point of sale [12], [14], [16], variables related to the climate [14], [15], [18], and economic and financial variables [30], [24]. However, the most striking novelty in this regard is the successful use of Internet search intensity indices as predictors of demand, mainly in the tourism sector [22], [23], [44], [24], although it has also been applied successfully in the B2B manufacturing sector [17]. Another important novelty is the inclusion of spatio-temporal data, mainly from mobile devices, among the predictor variables of demand in the tourism sector [28], [25]. |
| New in feature extraction | Feature engineering is the phase in building a model in which relevant patterns are extracted from the data to feed forecasting algorithms. The analyzed documents propose various feature extraction techniques, one of the main ones is dimensionality reduction, through this procedure, it is identified which of the multiple variables have the greatest impact on the precision of the model and the influence of the rest is discarded or reduced. . Novel algorithms are proposed for this purpose such as “particle swarm optimization” (PSO), “recursive feature elimination”, “extra three” [20] among others [34], simple neural networks are also proposed for this purpose. such as autoencoders [33], [22] and attention mechanisms [27], [25] and even more complex neural networks [26], [24].<br>Another important technique proposed by the models studied is decomposition. This consists of dividing the original time series into simpler time series. The classic decomposition generates three components called trend, seasonality and noise. However, the documents studied propose more advanced decomposition techniques such as “Noise-assisted multivariate empirical mode decomposition” (NA-MEMD), which divides the time series into a greater number of components according to their behavior on various time scales. [29], or the “Improved Complete Ensemble Empirical Mode Decomposition With Adaptive Noise” (ICEEMDAN) that allows the choice of a different predictor for each decomposed series according to its degree of complexity [30].<br>Clustering, which is the automatic grouping of similar data, is another proposed technique. Through this procedure, the heterogeneity of the data within each cluster is reduced, allowing suitable predictors to be found for each of them [18], [38], [36]].<br>One of the most innovative feature extraction techniques is the conversion of time series to equivalent images, in this way, with the use of convolutional image processing networks, patterns that would not otherwise be possible can be detected. The importance and effectiveness of this technique can be seen in the documents [28], [39].<br>Finally, a useful technique in cases where training data is scarce is “transfer learning”. The documents studied propose several of these techniques to take advantage of the similarity of the product or service of interest with other products and services that do have abundant data [15], [25], [36], [27]. |
| New regarding the adjustment of the model | The number of historical data that is introduced into the model and the adjustment of its hyper parameters are two aspects with a great impact on the accuracy of the forecast and that are usually done manually by the authors. The documents studied propose, in relation to this aspect, novel algorithms that automate and optimize these tasks. For the number of historical entries, algorithms such as PSO [20], Principal component analysis (PCA), Effective time lags, and autoenconders [34] have been proposed. For the automatic adjustment of hyper parameters, the Bayesian optimization algorithm [25], Firefly algorithm [31] and the Giza pyramids construction algorithm [32] are proposed. |
| New regarding the assembly of the models | Finally, the documents studied propose various ways to assemble the various machine learning methods used. One of the most striking is the dynamic ensemble, in which a base of predictors are combined with each other in a diverse way according to their recent performance. [19], [21] |

### G. Proposed Model

As a synthesis of the research findings, a demand forecasting model is proposed below that takes the most innovative techniques from the various studies and sectors and integrates it into a new proposal (see Fig. 9).

The proposed model, in addition to the historical data represented by the time series, is capable of using other internal variables, such as data from the point of sale (store location, promotions, etc.), or external variables such as special calendar days, economic variables, financial and even internet search intensity indices (SII). To determine the appropriate number of historical data to consider in the forecast, optimization algorithms would be used, after which the time series would be converted into images for the extraction of features contained in them. In relation to the other variables, they would be subjected to dimensionality reduction with coders and attention mechanisms. Regarding the artificial intelligence methods to be used, deep neural networks would be used: CNN to extract patterns from the images and LSTM to make a first forecast based only on the time series. The error produced by this first forecast would be used to train a base of ML predictors, both simple and bagging and boosting, which would have the mission of relating the internal and external variables from the encoders with the error produced by the neural networks. The predictors from this base would finally be dynamically assembled according to the performance they show, to finally produce the final forecast. Regarding the adjustment of hyper parameters of the neural networks, these would also be found with optimization algorithms.

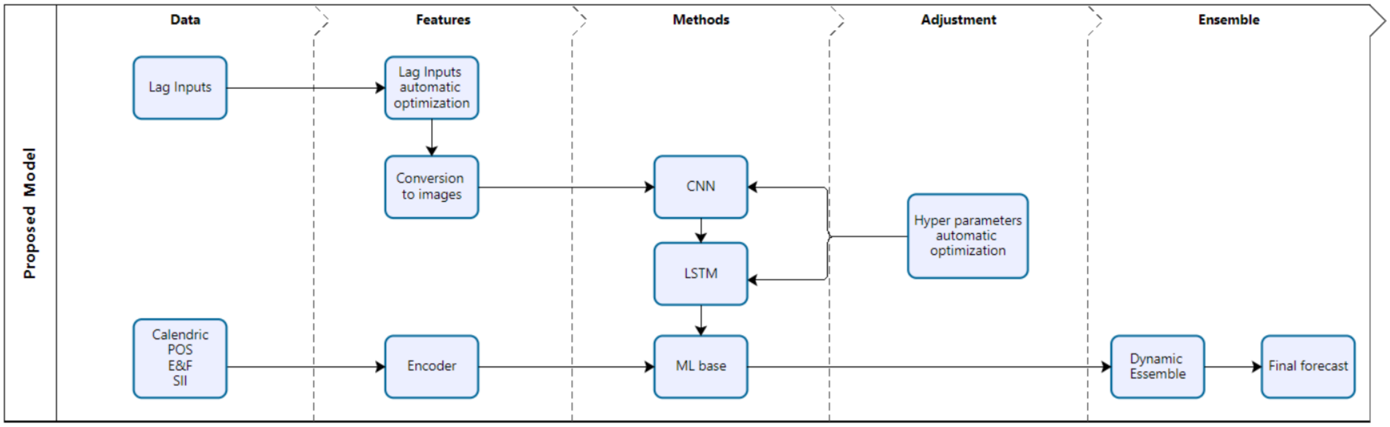

Fig. 9. Proposed model.

## IV. Discussion and Conclusions

### *A. Discussion*

Regarding the importance of using “explanatory” variables in addition to time series, [17] established that the inclusion of these leads to significant improvements in forecast accuracy. They proposed a model that adjusts the forecasts obtained initially by a base predictor, through multiple regressions that relates this result with external indices related to Internet search intensity. In agreement with these authors, in [16] a similar effect of “exogenous” variables was found; the authors proposed an LSTM network as a base predictor on the historical data and then adjusted the residuals of this forecast using RF and variable indices exogenous” such as calendar events, product characteristics, information about the point of sale, etc. The model proposed in this study takes advantage of these findings and follows the scheme: base predictor on historical data and subsequent adjustment against external variables. In this way, the predictive power of various external variables is taken advantage of.

The importance of appropriately selecting the amount of past data to be considered in the forecast was established by [20]. These authors indicate that this is not only important to avoid variable redundancy, but also improves the precision of the model. Given this, they propose the use of the “particle swarm optimization” (PSO) algorithm for this task. Similarly, [34] points out that selecting useful inputs effectively results in improved forecasting, but they recommend using the “effective time lags” method for this purpose. In study [21] the authors propose instead the use of the “False Nearest Neighbors” method, while in study [27] the authors propose incorporating the self-selection of historical data into the same architecture of the deep neural network by adding attention mechanisms. Within this same line, the model proposed in this study proposes the use of some of these algorithms, especially the PSO or the attention mechanisms, to determine the optimal input of historical data.

Regarding the effectiveness of the conversion to images of the time series in [45] the authors point out that by converting to images not only can the patterns between the input data and the target variable be studied, but this technique allows reveal the complex relationships of the input variables with each other, enriching learning. Along these lines, in study [28] the use of this technique is proposed to extract the patterns of the spatiotemporal data used, while in [39] the authors go one step further and not only propose the conversion to images of the series temporal, but rather they propose the decomposition of these images for better processing. In accordance with these studies, the model proposed by this research uses the conversion of the time series to images to fully exploit the information contained therein.

The use of the enormous amount of data obtained from the Internet, such as SII, complicates the task of selecting the most relevant variables. To address this, in study [22] the authors propose the use of autoencoders to automate this task. In study [7] the authors add that the use of a large number of independent variables not only makes the model more complex, but also frequently causes “overfitting” problems and they propose the use of “stacking autoencoders” to reduce dimensionality. Finally, in study [27] they add that multiple variables require large amounts of data and that the scarcity of these leads to poor performance models, which is why they propose implementing attention mechanisms to identify the most important variables. To avoid these drawbacks generated by the proliferation of explanatory variables, the model of this study includes the use of autoencoders for their selection.

The determination of the hyper parameters of the neural networks is an aspect that significantly affects the accuracy of the forecast models, however, the choice of these values is usually done with techniques that are far from being exhaustive, which is why in [31] The authors propose the automatic selection of hyper parameters using the “firefly” algorithm; the precision gained by the model was very noticeable. The authors of [32] agree that the performance of deep neural networks is greatly affected by the choice of hyper parameters, but they propose the “Giza pyramids construction” algorithm to determine them. Along the same lines [25] finally proposes a “Bayesian optimization”. The model proposed in this study, by using two deep neural networks, proposes the optimization of hyper parameters using one of these algorithms.

Finally, in study [46] the authors established the importance of a heterogeneous base of predictors and the effectiveness of dynamic ensembles of these according to their performance. The model proposed in that study was compared with others in [21], managing to surpass all of them in performance. A similar model, respecting the heterogeneity of the predictors and the dynamic ensemble, was proposed by study [19] with similar results. Along the same lines, the model proposed in this research proposes a heterogeneous base of machine learning predictors that relate the forecast errors produced by the neural networks, with the “exogenous” variables selected by the autoencoder. The heterogeneity of the predictors and their dynamic assembly ensure superior performance.

In short, the innovations introduced by artificial intelligence in the construction of demand forecasting models are broad and varied and impact all phases of the development of a model. Some of the most striking innovations, such as the use of images and dynamic assemblies, are part of the model proposed in this research; however, it is possible to conceive multiple alternative models with the innovations left aside by the latter. Future work should explore the effectiveness of the model proposed in this study and propose new models with the other innovations identified in the research.

This study provides a broad view on the contributions of artificial intelligence in the field of demand forecasting in various sectors. However, it is important to recognize certain limitations. The articles were restricted to the retail, manufacturing, tourism and energy sectors, which may have left out important innovations in other sectors such as the transportation, logistics and services sectors to name a few. Furthermore, the collection of studies was based only on a single, although very recognized and extensive, database: Scopus, other significant studies on the subject could be found in other prestigious scientific databases such as Web of Science. Future research could expand the sectors considered and the databases used to corroborate and expand our findings.

### B. Conclusions

In this systematic review of the literature, after reviewing and analyzing the 33 selected articles, the six research questions were answered. In relation to the first question about what artificial intelligence models have been proposed in recent years for demand forecasting, this study determined that the models proposed have been diverse, highlighting the strong tendency to propose ensembles of heterogeneous methods, to use Internet search intensity indices, to use various feature extraction techniques and to employ deep neural networks ("deep learning") in the construction of the models. Regarding the second question about what problems or challenges of demand forecasting these proposals try to solve, it was found that the problem is also diverse, highlighting the complexity of the data, the scarcity of training data, and the deterioration of the forecasting models due to the large number of variables used. Regarding the third question related to the machine learning methods used, it was found that they are used from the simplest statistical methods to the most complex deep learning methods, predominating the use of the latter and the assembly between heterogeneous methods. In relation to the fourth question about performance measurement metrics, it was found that the vast majority of models almost exclusively use various forecast error metrics. Regarding the fifth question about the performance of the proposed models, it was found that almost all documents reported performance equal to or better than the models taken as reference, and that in all cases the proposed models had better performance than the statistical methods, considered classics. Finally, in relation to the innovations introduced by these models, it was found that this is very varied, with contributions on the type of data used, the extraction of characteristics, the type of machine learning method used, the automation and improvement of the adjustment of the models and the way to assemble the predictors. Future studies could focus their attention on recognized machine learning techniques that do not appear in the present selection of articles, such as reinforcement learning and genetic programming, or on sectors not considered in the present research.

***Abstract*—The stock market refers to a financial market in which individuals and institutions engage in the buying and selling of shares of publicly listed firms. The valuation of stocks is influenced by the interplay between the forces of supply and demand. The act of allocating funds to the stock market entails a certain degree of risk, while it presents the possibility of substantial gains over an extended period. The task of predicting stock prices in the securities market is further complicated by the presence of non-stationary and non-linear characteristics in financial time series data. While traditional techniques have the potential to enhance the accuracy of forecasting, they are also associated with computational complexities that might lead to an elevated occurrence of prediction mistakes. This is the reason why the financial industry has seen a growing prevalence of novel methods, particularly in the stock market. This work introduces a novel model that effectively addresses several challenges by integrating the random forest methodology with the artificial bee colony algorithm. In the current study, the hybrid model demonstrated superior performance and effectiveness compared to the other models. The proposed model exhibited optimum performance and demonstrated a significant degree of effectiveness with low errors. The efficiency of the predictive model for stock price forecasts was established via the analysis of data obtained from the Nikkei 225 index. The data included the timeframe from January 2013 to December 2022. The results reveal that the proposed framework demonstrates efficacy and reliability in evaluating and predicting the price time series of equities. The empirical evidence suggests that, when compared to other current methodologies, the proposed model has a greater degree of accuracy in predicting outcomes.**

***Keywords—Financial market; stock future trend; Nikkei 225 index; random forest; artificial bee colony***

## I. Introduction

Stocks are traded in a public market where companies list and raise capital by selling shares at set prices. The stability and security of the stock market are crucial for the functioning of national economies [1, 2]. The stock market is difficult to predict since there are a lot of variables at play. Stock performance is significantly impacted by political uncertainty that arises from political events [3], [4]. This connection often occurs as a result of investors' reactions to the policy uncertainty arising from the course of these events. Additionally, political developments and uncertainties influence investors' judgments about market timing and portfolio allocation across various markets.

Consequently, investors conduct two different kinds of research before purchasing a company. Fundamental analysis comes first. Investors consider things including the economy, industry performance, and the fundamental worth of equities. Second, investors use technical analysis to examine stock values and information produced by market activity, such as historical prices and volume [5]. Research on the conduct and functioning of stock markets have developed into essential due to the possible hazards involved [6]. Forecasting changes in stock prices is one of the most crucial responsibilities in this respect, as it provides investors with the knowledge they need to make wise decisions and minimize risks, in addition to aiding regulators in stabilizing financial markets.

Nonetheless, there can be serious concerns associated with inaccurate prediction outcomes and mysterious prediction methods [7]. The high volatility, non-stationarity, and non-linearity of stock price time series data further complicate the task of accurately forecasting stock prices in the securities market. Therefore, to reduce possible hazards, a trustworthy and persuasive prediction model must be created. It has long been used to forecast the stock market via the use of traditional techniques that involve studying fundamental and technical analysis. The ever-changing and dynamic character of the stock market presents challenges in conducting analysis.

The aforementioned attributes indicate that traditional statistical approaches may be inadequate in facilitating a comprehensive understanding of the stock market. Terms like artificial intelligence (AI) and machine learning (ML) might be confusing. The idea of artificial intelligence pertains to a computer system that can execute jobs that are normally performed by humans [8]. The notion of ML holds that computers can learn or make predictions using just their own experience and training without the need for outside programming [9]. This means that the system can make judgments based on information with little to no assistance from human [8]. Decision trees, first developed in the 1960s, are among the best techniques for data mining and are extensively used across many fields [10]. This is due to their simplicity, lack of ambiguity, and robustness, even when values are absent. It is possible to employ continuous or discrete variables as independent or target variables. Two approaches to analyzing decision trees can be taken when dealing with missing data: categorize missing values as a distinct category that can be examined with the other categories or use a pre-built decision tree model that sets the variable with many missing values as a target variable to make a prediction and replace these missing ones with the predicted value [11]. The random forest technique is used to reduce the overfitting risk that is often linked to the use of a single decision tree. Multiple decision trees are trained as part of the ensemble learning approach known as the random forest algorithm. The output of each tree is aggregated to determine the ultimate result of the algorithm [12]. Every decision tree produces its output on its own, and for regression tasks, the final prediction is derived from the average of the replies. The concept of random forests was first introduced by Breiman [13]. The model used by Oyebayo Ridwan Olaniran et al. [14] was utilized for high-dimensional categorization of genomic data. This model was used by Antoine Gatera et al. [15] to predict traffic accidents.

The integration and use of optimizers in conjunction with the chosen model have led to improvement in research outcomes, resulting in heightened accuracy of the obtained data. As a result, many optimization techniques, namely ant lion optimization (ALO) [16], grey wolf optimization (GWO) [17], battle royal optimizer (BRO) [18], mouth flame optimization (MFO) [19], Biogeography-based optimization (BBO) [20], Artificial bee colony (ABC) [21] have been presented. A mathematical model for resolving optimization issues that is based on studying and imitating the patterns of real bee foraging behavior is called the ABC algorithm. Three categories of honey bee agents work for the ABC in the colony: scouts, observers, and hired bees. In the ABC algorithm, there are two groups of bees with an equal number of bees each. One-half of them are called working bees, while the other half are called observer bees. The position of the food supply for the bee is seen as a solution in the ABC that needs its parameters optimized. The objective function of a problem, which is equivalent to the fitness value of the solution, is connected to the quality of the food supply. Put another way, locating the best answer is akin to the process of foraging used by bees to identify a quality food supply. The ABC algorithm's specifics are as follows. The first solutions are created at random and used by the bee agents as their food supply locations. Following initiation, the bee agents go through three main cycles of iterative changes: choosing viable solutions, updating the feasible solutions, and avoiding less-than-ideal solutions. The main contributions of the study are as follows:

- This research paper presents an innovative predictive model that combines the random forest and artificial bee colony algorithms. By capitalizing on sophisticated machine learning algorithms, the suggested model enhances the dependability of stock market forecasts through the reduction of error rates and the improvement of prediction accuracy.
- Due to the empirical validation of the proposed model using Nikkei 225 index data spanning a significant period of time, comparisons across various market conditions are limited. Through a comprehensive analysis of the model's performance across diverse dynamics, this study offers significant insights into its efficacy and resilience. This particular facet contributes to the overall comprehension of stock market prediction models based on machine learning and increases their practicality in real-life situations.
- The research's emphasis on assessing the vulnerabilities of models and rectifying shortcomings in interpretability, feature engineering, and external validation is of paramount importance in furthering the domain of stock market forecasting. Through a methodical examination of these deficiencies, the study makes a valuable contribution to enhancing the dependability and practicality of forecasting techniques that rely on machine learning.

The research assessed the reliability of various models, including RF, BRO-RF, and MFO-RF. The model selected for this article is ABC-RF recognized for its superior performance. Subsequently, the following section thoroughly examines all pertinent components of the investigation. Numerous analytical methods, including the RF model, assessment metrics, and optimizer approaches, were used to examine the data. The study's findings are presented and compared with those obtained using alternative methods in the third section. The last section offers a concise review of the findings of the research.

## II. Literature Review

In recent times, there has been an increasing inclination towards utilizing machine learning algorithms for the purpose of forecasting stock market trends, with the intention of leveraging forthcoming price fluctuations and augmenting investor profitability. Agrawal [22] presented a stock market prediction system that employs nonlinear regression techniques based on deep learning. By conducting experiments on a wide array of datasets, such as ten years' worth of Tesla stock price data and data from the New York Stock Exchange, Agrawal establishes that the proposed method outperforms conventional machine learning approaches [22]. The methodology proposed by Petchiappan et al. [23] for forecasting the stock prices of media and entertainment companies substantially advanced this field of study. By employing machine-learning methodologies, particularly logistic and linear regression, they successfully construct a resilient prediction system tailored to the industry. Through a meticulous analysis of stock price data obtained from reputable media sources, their model provides investors with invaluable insights regarding profit optimization and loss mitigation. Petchiappan et al. [23] establish the effectiveness of their methodology by conducting extensive experiments, with a specific focus on its superiority in comparison to conventional approaches. Predicting stock market fluctuations remains a complex and demanding undertaking within the field of finance, owing to the ever-changing and multifaceted characteristics of stock prices. Sathyabama et al. [24] employ machine learning algorithms to forecast stock market transactions as a means of surmounting this obstacle. The research conducted by the authors’ places considerable emphasis on the impact that news and other external variables have on stock market trends. Moreover, this emphasizes the criticality of precise prognostic models in efficiently controlling market volatility. Sathyabama et al. [24] contribute to the existing body of knowledge by introducing an improved learning-based approach that integrates a Naïve Bayes classifier. Menaka et al. [25] made a scholarly contribution to this domain by conducting an exhaustive examination of machine learning algorithms that are employed in the prediction of stock prices across various stock exchanges. Menaka et al. [25] emphasized the adaptability of various machine-learning methodologies to construct accurate prediction models. These methodologies comprised boosted decision trees, support vector machines, ensemble methods, and random forests. To tackle the distinct obstacles presented by abrupt and capricious market fluctuations, Demirel et al. [26] directed their examination toward the companies comprising the Istanbul Stock Exchange National 100 Index. An assessment was made of the predictive performance of Support Vector Machines, Multilayer Perceptrons, and Long Short-Term Memory using daily data spanning a period of nine years [26]. The investigation of stock market forecasts continues to be substantial, given its extensive ramifications for international financial markets, shareholders, and enterprises. To tackle this obstacle, Tembhurney et al. [27] performed a comparative analysis of the performance of machine learning algorithms in forecasting the Nifty 50 stock market index. Tembhurney et al. [27] utilized the Python programming language to implement the Support Vector Machine and Random Forest algorithms for the purpose of training models with historical stock market data.

The effectiveness of machine learning algorithms in predicting stock market trends is illustrated in the literature review, which stands in contrast to traditional approaches. However, there are still notable shortcomings that persist. These include the lack of thorough examination of how models can be interpreted, the neglect of feature engineering, the dearth of external validation, and the inadequate evaluation of dynamic market conditions. Furthermore, there are limited comparisons made across different market conditions, and the assessment of model risks is insufficient. It is critical to address these deficiencies so as to enhance the reliability and applicability of machine learning-based stock market prediction models. Consequently, additional research is necessary to focus on the creation of models that are intuitive, robust, and adaptable, incorporating comprehensive risk assessment frameworks and capable of modifying to changing market conditions. This article focuses on the application of innovative approaches, particularly the combination of the random forest methodology and the artificial bee colony algorithm, to enhance the precision of stock market predictions in order to fill the deficiencies identified in the literature review. Additionally, the research improves the evaluation of model risks and addresses the scarcity of cross-market comparisons through an examination of Nikkei 225 index data spanning a significant period of time, from January 2013 to December 2022. In order to improve the dependability and practicality of machine learning-driven financial market forecasting, the objective of this study is to develop a stock market prediction model that is more intuitive, robust, and flexible.

## III. Methods and Materials

### A. Random Forest

Random forest regression is a kind of regression approach that is based on machine learning [28]. The RF algorithm, as described by Breiman [13], employs ensemble learning to enhance prediction accuracy by integrating multiple trees. This non-parametric data mining technique is capable of handling non-linear and non-additive relationships by utilizing recursive partitioning of the dataset to investigate the associations between a response variable and predictor variables, as highlighted by Wiesmeier et al. [29]. The fundamental constituent of RF is the decision tree, whereby the aggregation of numerous decision trees is used to mitigate the potential issue of over-fitting, as shown in Fig. 1. The training procedure for several decision trees is conducted in parallel, with each tree exhibiting modest variations owing to the incorporation of a random process inside the algorithm [30]. The RF technique additionally offers the projected significance of input parameters used in constructing the model.

The mean square error for an RF may be found using the following equation:

$$\mathrm{MSE} = \frac{1}{\mathrm{N}} \sum_{\mathrm{k}=0}^{\mathrm{n}} \binom{\mathrm{n}}{\mathrm{k}} (\mathrm{Fi} - \mathrm{Yi})\mathrm{b}^2 \tag{1}$$

### B. Battle Royal Optimizer

The process of identifying the most optimal solution among a set of feasible alternatives for a particular issue is sometimes referred to as optimization [18]. Optimization algorithms play a crucial part in several technical and commercial applications. Over the past few years, several optimization issues have been addressed via the use of metaheuristic algorithms, which draw inspiration from Darwin's theory of evolution [31]. Several algorithms, such as the gravitational search algorithm (GSA) [32] and water evaporation optimization (WEO) [33], draw inspiration from principles in physics. All algorithms aim to strike a delicate equilibrium between the processes of exploitation and exploration. In the year 2020, T.R. Farshi developed an optimization method known as BRO, which draws inspiration from the game strategy used in battle royale video games. The BRO starts by initializing a population with random individuals that are evenly distributed over the given spatial domain. Subsequently, every soldier or player employs a weapon to engage in combat by discharging projectiles at the closest adversary. The soldier who has a more advantageous position inflicts harm on another soldier. Furthermore, it is possible to represent all of these concepts numerically:

$$X_{dm,d} = X_{dm,d} + r\left(X_{b,d} - X_{dm,d}\right) \tag{2}$$

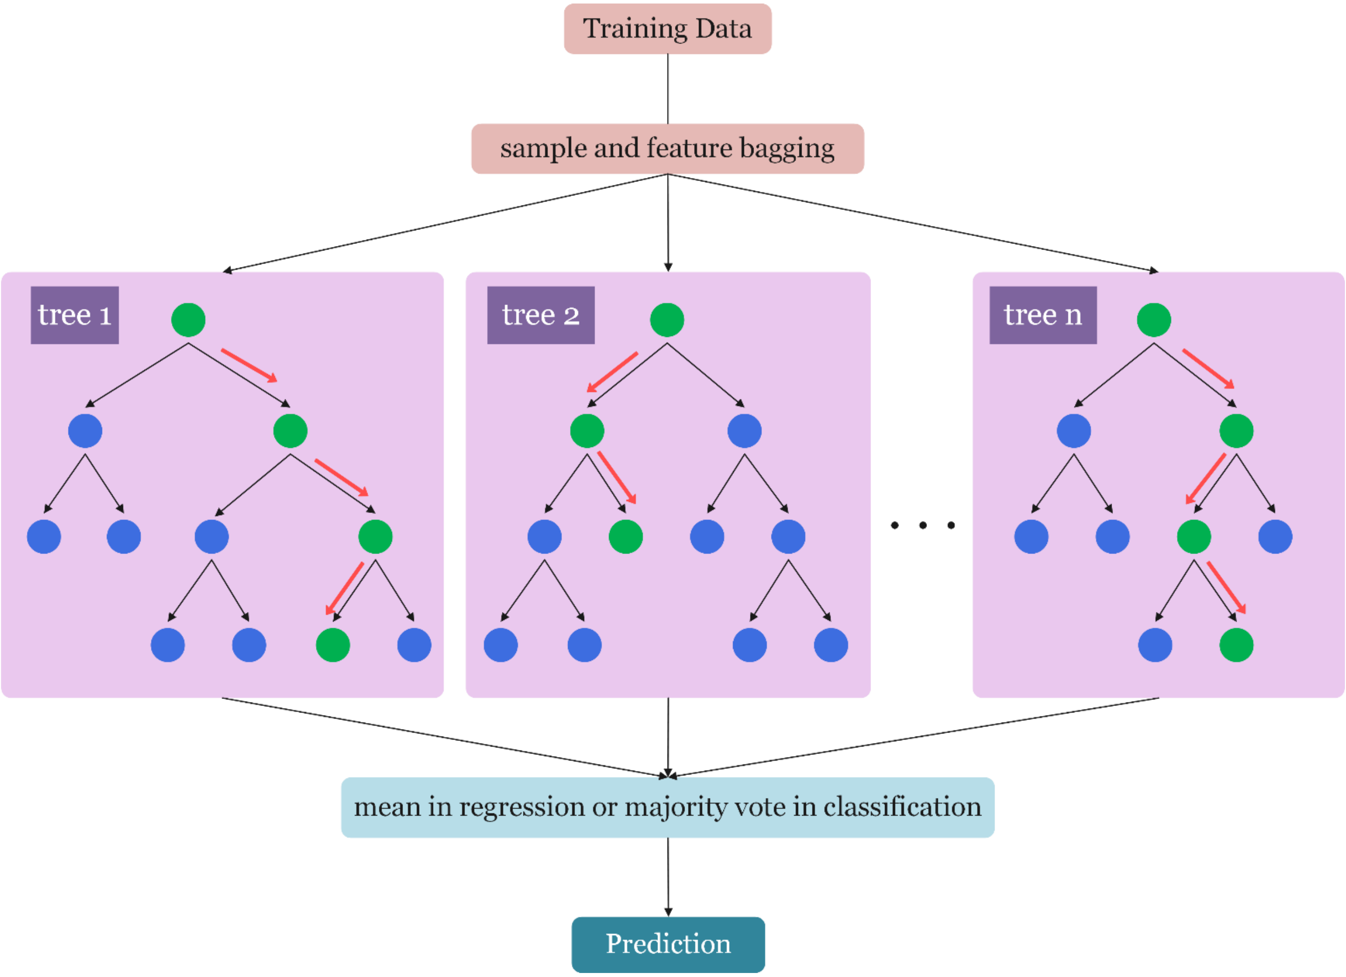
where, $r$ is a randomly produced number that is spread out evenly in the range [0,1] and $X_{m,d}$ is the place of the hurt man in the d-dimensional space.

If a wounded soldier is still able to inflict harm on his opponent, the damage is reset to zero in the subsequent round. To provide improved exploration and convergence, a soldier is randomly regenerated from the probable issue space once their damage surpasses the threshold amount.

$$X_{d,m} = 0 \tag{3}$$

The returning soldier from a fatal combat zone is shown as:

$$X_{dm,d} = r(u_d - I_d) + I_d \qquad (4)$$



Training Data
sample and feature bagging
tree 1
tree 2
tree n
mean in regression or majority vote in classification
Prediction

Fig. 1. The random forest's architecture.

where , $u_d$ and $I_d$ represent the dimension's upper and lower bounds, respectively. The search space continues to shrink in the direction of the optimal answer with each repetition. The quantity of iterations is associated with certain iteration as:

$$\begin{aligned} \text{delta} &= \log 10(\text{ maxcircle }) \\ \text{delta} &= \text{delta} + \text{round}\left(\frac{\text{delta}}{2}\right) \end{aligned} \qquad (5)$$

where, maxcircle denotes the highest generation count.

Updates are made to the upper and lower boundaries as:

$$\begin{aligned} u_d &= X_{\text{bes},d} + SD(X_d) \\ I_d &= X_{\text{bes},d} - SD(X_d) \end{aligned} \qquad (6)$$

The standard deviation of the whole population in dimension d is represented by $SD(X_d)$. The tuning of the random forest hyperparameters and the optimal values that were discovered through the use of the BRO optimizer are both detailed at the beginning of Table I.

TABLE I. HYPERPARAMETERS SETTING USING THE BRO ALGORITHM

| Random Forest | | BRO |
|---|---|---|
| Max depth | [10, 100, None] | 60 |
| Max features | [auto and sqr] | auto |
| Min samples leaf | [1, 4] | 2 |
| Min samples split | [2, 10] | 3 |
| Random state | [4, 24, 42, 64, 88] | 24 |
| Numbers of estimators | [200, 2000] | 500 |

### C. Moth-flame Optimization

In 2015, S. Mirjalili presented the stochastic optimization technique known as MFO [19]. Moths fly a great distance in a straight line by maintaining a constant angle concerning the moon. Nevertheless, the moth eventually converges on the artificial light after being caught in a spiral route around it [34]. By mimicking the moths' logarithmic spiral movement above the flame, the MFO algorithm determines the best solution. In the search space, a haphazard group of moths is first established. Their locations are updated in a spiral pattern concerning the flame, taking into account that the moth's movement should not be beyond the search space. It is possible to imagine that the moths are moving in all directions in a hyper ellipse around the flame. Each moth's location is updated in relation to its associated flame because the algorithm becomes stuck in local optima as a result of the moths' migration towards it. This lowers the likelihood of local optima stagnation and causes each moth to travel around distinct flames [34]. Every time the algorithm iterates in search of the optimal solution, the flame location is likewise changed, enhancing its exploration potential. Moths' migration to various flame positions in search space increases the degree of exploration but also reduces the capacity for exploitation. Finding a balance between exploitation and exploration is the primary goal of every optimization method. To increase the algorithm's exploitation potential, an adaptive approach for calculating the amount of flames is suggested. Throughout the iteration, the number of flames is adaptively reduced to guarantee that the moth adjusts its location to match the best-updated flame in the final set of iterations [34]. MFO is often used as:

$$M = \begin{bmatrix} CO_{1,1} & CO_{1,2} & \cdots & \cdots & CO_{1,h} \\ CO_{2,1} & CO_{2,2} & \cdots & \cdots & CO_{2,h} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ CO_{a,1} & CO_{a,2} & \cdots & \cdots & CO_{n,h} \end{bmatrix} \quad (7)$$

$$S = \begin{bmatrix} S_{1,1} & S_{1,2} & \cdots & \cdots & S_{1,h} \\ S_{2,1} & S_{2,2} & \cdots & \cdots & S_{2,h} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ S_{a,1} & S_{a,2} & \cdots & \cdots & S_{2,h} \end{bmatrix} \quad (8)$$

In the current context, the variable "$h$" denotes the number of dimensions, whereas the variable "$a$" indicates the number of moths.

The process of global optimization is carried out via the use of the three-step MFO technique.

$$MFO = (I, F, T) \quad (9)$$

The term "function" refers to a mathematical concept that describes the relationship between a set of The letter "$I$" is used to represent a distinct mathematical function, while the sign "$F$" is used to describe the flight trajectory of a moth as it explores its surroundings in pursuit of appropriate habitat. Furthermore, the sign $T$ is used to denote the specific factors that dictate the cessation of the moth's flight.

$$X_i = t(C_i, S_j) \quad (10)$$

The formula used in this particular situation incorporates the twisting function, written as $t$, the quantity of the $i$-th moths marked as $C_i$, and the quantity of the $j$-th flames designated as $S_j$.

$$S(C_i, S_j) = Z_i \cdot e^{bt} \cdot cos(2\pi t) + S_j \quad (11)$$

the variable $Z_i$ denotes the spatial distance between the moth and the flame. The parameter $b$ is a constant within the scope of this research. Furthermore, the variable $t$ represents a stochastic quantity drawn from the closed interval [-1,1].

$$Zi = |S_j - X_i| \quad (12)$$

A description of the tuning of the random forest hyperparameters and the optimal values that were discovered through the use of the MFO optimizer can be found in Table II.

TABLE II. HYPERPARAMETERS SETTING USING THE MFO ALGORITHM

| Random Forest | | MFO |
|---|---|---|
| Max depth | [10, 100, None] | 50 |
| Max features | [auto and sqr] | auto |
| Min samples leaf | [1, 4] | 1 |
| Min samples split | [2, 10] | 4 |
| Random state | [4, 24, 42, 64, 88] | 64 |
| Numbers of estimators | [200, 2000] | 200 |

### D. Artificial Bee Colony

The ABC strategy, presented by Karaboga and Basturk [21], is a meta-heuristic optimization method that operates on a population-based approach. The modification mentioned in reference [35] is especially intended for discrete optimization situations. The ABC algorithm is derived from the fundamental search concepts that are based on the intelligent foraging behavior shown by honeybee swarms. The algorithm categorizes foraging bees into three distinct groups based on their behavior and responsibilities: employed bees, observer bees, and scout bees. Bees' exhibit collective organization to optimize the accumulation of nectar, which serves as their primary energy source, inside the food storage located in their hives, as seen in Fig. 2. This is achieved via the use of suitable division of labor strategies [36]. The foraging bees are in charge of taking advantage of food sources by collecting and transporting them back to their hives, often exploring sites that other foragers have previously visited. The observer bees situated inside their hives acquire knowledge of the foraged food sources via the communication of employed bees, which is conveyed through their dance behavior upon returning to the hives. Subsequently, the observer bees choose to visit the food sources based on the perceived quality of those food sources, as shown by the length of the dances performed. The scout bees explore novel food sources by venturing in a direction that is chosen randomly, as the summary of this process is shown in Fig. 3. The scout and observer bees are often denoted as unoccupied bees, undergoing a transformation into occupied bees subsequent to their identification of a novel food source during their foraging activities [36].

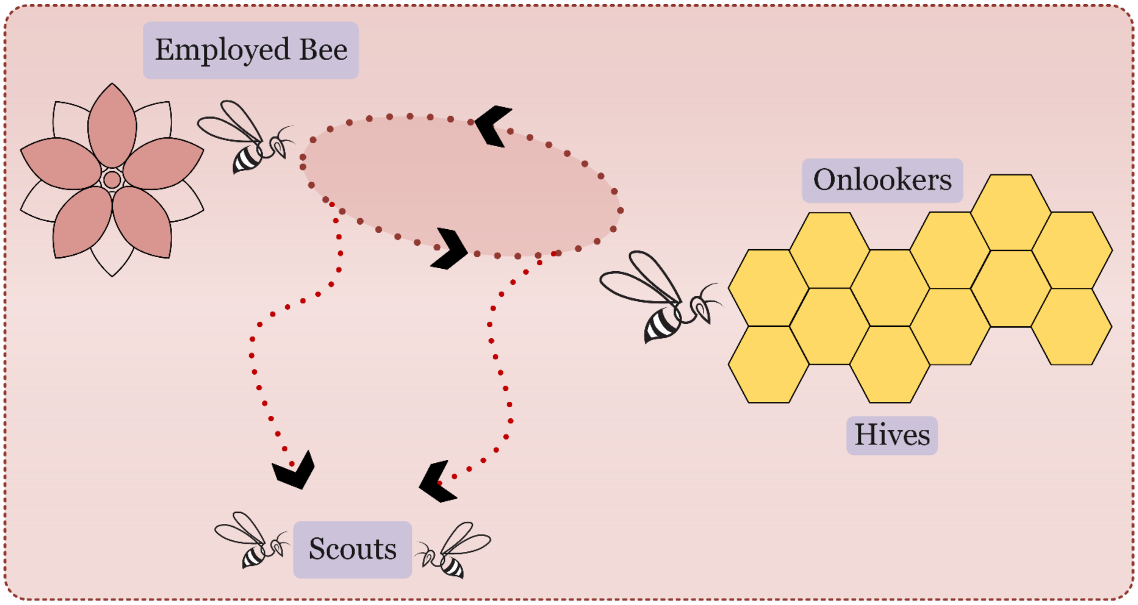


Fig. 2. The artificial bee colony optimizer's operational mechanism.

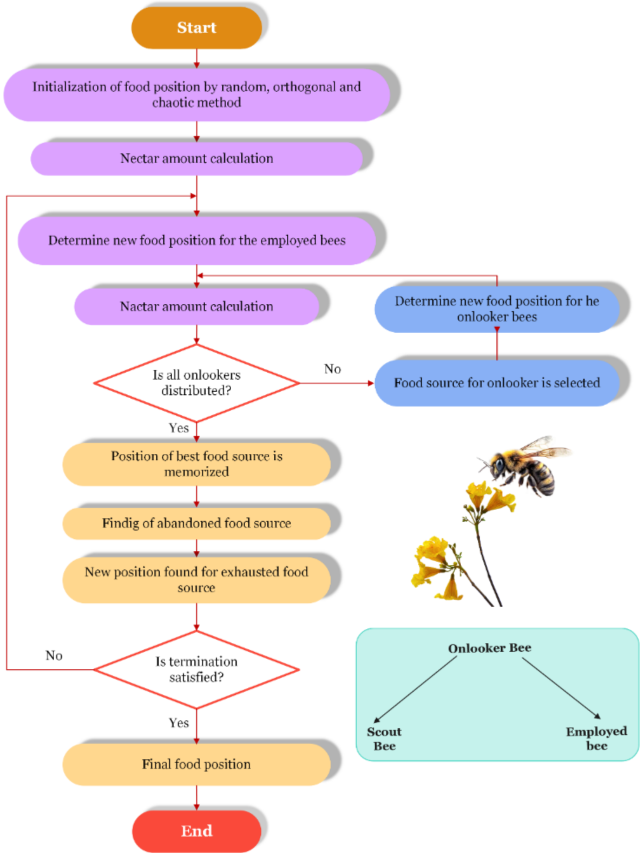

Start

No
Is termination satisfied?
Yes
Final food position
End
Onlooker Bee
Scout Bee
Employed bee

Fig. 3. Flow diagram of ABC.

The initial food sources are expressed by applying a random solution vector boundary value.

$$x_{i,j} = x_j^{min} + rand(0,1)\left(x_j^{max} - x_j^{min}\right) \tag{13}$$

where, $j = 1, \dots D, SN$, and $i = 1, \dots SN$. $D$ represents the parameters that need to be optimized, $SN$ is the number of solutions, and $x_j^{min}$ and $x_j^{max}$ denote the lower and upper bounds of the $j$ th parameter, respectively. Once the food sources have been started, the fitness value of each will be determined using the following formula.

$$\text{fit}_{\,i} = \frac{1}{1+obj\cdot fun_i} \tag{14}$$

where, $obj \cdot fun_i$ indicates the intentional action. $SN$ provides precisely the same number of working bees and observers as there are answers. A single food source is equal to one active bee. Working bees and observers search for nearby food sources and adjust their location depending on the following equation to come up with fresh solutions.

$$v_{ij} = x_{ij} + r_{ij}\left(x_{ij} - x_{kj}\right) \tag{15}$$

where, $j$, $k$, and $S$ are randomly selected, and $k$, $i$, and $r_{ij}$ are random integers in the range $[-1,1]$. It's used to manage various communities and recalculate the fitness value of the new solution to see which of the $v_{ij}$ and $x_{ij}$ fitness values are bigger. Fitness is a particular probability that observer bees consider when choosing food sources, and they calculate it using the following formula.

$$p_i = \frac{fit_i}{\sum_{n=1}^{SN} fit_n} \tag{16}$$

where, the quantity of nectar in the relevant food supply is related to $fit_i$, the fitness value of the solution. The hired bees will turn into scout bees and go on a haphazard quest if they investigate the available food supply for longer than the upper limit. Using the ABC optimizer, the optimal values for the random forest hyperparameters were determined, and Table III provides a description of the tuning process.

TABLE III. HYPERPARAMETERS SETTING USING THE ABC ALGORITHM

| Random Forest | | ABC |
|---|---|---|
| Max depth | [10, 100, None] | 80 |
| Max features | [auto and sqr] | auto |
| Min samples leaf | [1, 4] | 2 |
| Min samples split | [2, 10] | 2 |
| Random state | [4, 24, 42, 64, 88] | 42 |
| Numbers of estimators | [200, 2000] | 300 |

## IV. GATHERING AND PREPARING DATA

Several factors should be considered while doing a comprehensive examination of a company, including the trading volume and the Open, High, Low, and Close (OHLC) prices for a certain period of time. Data on the Nikkei 225 stock performance from the start of 2013 to the end of 2022 was acquired for this particular research. The dataset included details on the OHLC prices and trading volume for each day throughout the specified time frame. An extensive examination of the data landscape was conducted as part of the first step to spot any anomalies, outliers, or discrepancies that might cast doubt on the accuracy of the findings. The dataset was cleaned and prepared many times after the research was finished. Scaling and normalizing were only two of the numerous methods used in the procedures to reduce error rates and encourage consistency in the training outputs. To maximize the models' functionality, two sets of prepared data were made. As observed in Fig. 4, a partitioning method was used in this study, allocating 80% of the dataset for training and the remaining 20% for validation and testing. The main objective of this division was to strike the ideal balance between the need for a sizable amount of data to train the model and the demand for a vast and unknown dataset to perform extensive testing and validation.

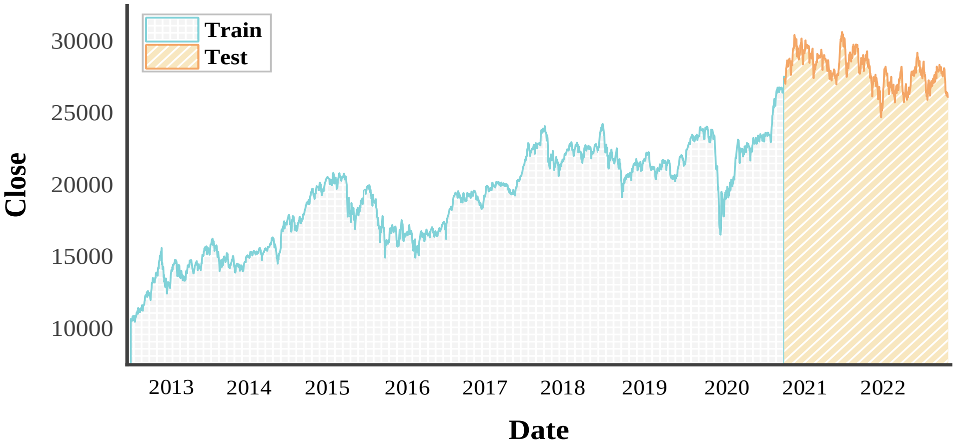

Fig. 4. Splitting data into testing and training sets.

## V. Assessment Metrics

The evaluation of the accuracy of the future forecast was conducted by using a variety of performance measures. The carefully chosen metrics provide a thorough evaluation of the reliability and precision of the predictions. Various factors were taken into account throughout the evaluation process. The mean absolute percentage error (MAPE), mean absolute error (MAE), coefficient of determination ($R^2$), which measures the proportion of the dependent variable's variability that can be explained by the independent variable, and mean square error (MSE) is employed to calculate the average absolute discrepancy between the predicted and observed values. These strategies provide valuable help and significantly enhance the process of assessing the accuracy of forecasting models.

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2} \qquad (17)$$

$$MSE = \frac{1}{N}\sum_{k=0}^{n}\binom{n}{k}(Fi - Yi)b^2 \qquad (18)$$

$$MAE = \frac{\sum_{i=1}^{n}|y_i - \hat{y}_i|}{n} \qquad (19)$$

$$MAPE = \left(\frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right|\right) \times 100 \qquad (20)$$

## VI. Results and Discussions

### A. Statistic Values

This inquiry phase includes Table IV, which offers a comprehensive description of the statistical data in the dataset. The information is easier to grasp when the OHLC price and volume statistics are included in the table. To conduct a comprehensive and precise examination of the data, statistical metrics like as the count, mean, minimum, maximum, standard deviation (Std.), 50%, and variance may be used.

TABLE IV. A Statistical Summary of the Concerned Data Set is Provided

| | count | mean | Std. | min | 50% | max | variance |
|---|---|---|---|---|---|---|---|
| Open | 2442 | 20813.83 | 4765.013 | 10405.67 | 20538.9 | 30606.15 | 22705344 |
| High | 2442 | 20926.76 | 4777.106 | 10602.12 | 20632.72 | 30795.78 | 22820737 |

## VII. Compare and Analyses

This research's primary objective is to identify and assess the best hybrid algorithm for stock price prediction. The creation of forecasting models and a deep comprehension of the many factors influencing stock market trends serve as the study's cornerstones. The primary objective is to provide analysts and investors with valuable insights to enable them to make informed and prudent investment choices. The performance of each model is thoroughly analyzed in Fig. 5, 6 and Tables V and VI. A comprehensive evaluation of each model's efficacy is also provided.

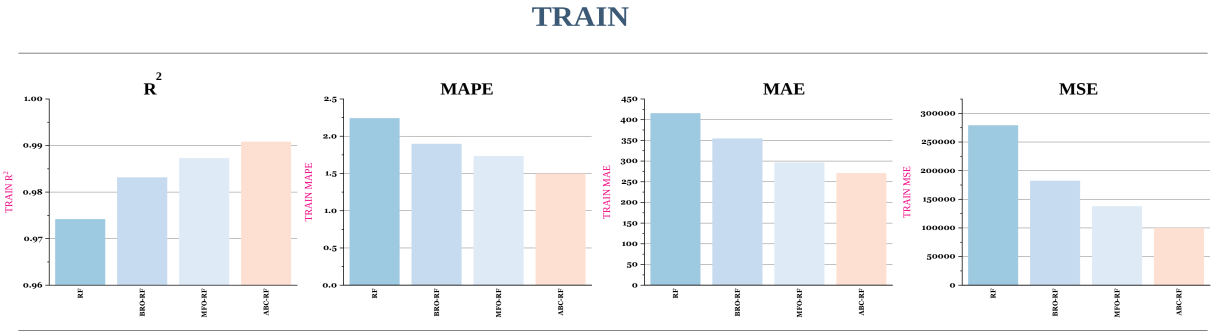

Fig. 5. The suggested model's training outcomes for the $R^2$, MAPE, MAE, and MSE.

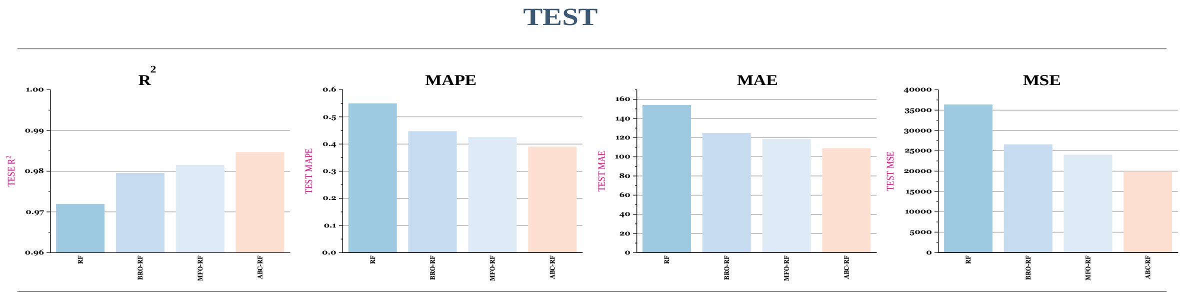

Fig. 6. The suggested model's testing outcomes for the $R^2$, MAPE, MAE, and MSE.

TABLE V. AN ESTIMATE OF THE MODELS' ASSESSMENT RESULTS

| | **TRAIN SET** | | | | **TEST SET** | | | |
|---|---|---|---|---|---|---|---|---|
| | $R^2$ | MAPE | MAE | MSE | $R^2$ | MAPE | MAE | MSE |
| RF | 0.974 | 2.24 | 415.17 | 278883 | 0.972 | 0.55 | 153.92 | 36337 |
| BRO-RF | 0.983 | 1.90 | 354.19 | 181946 | 0.979 | 0.45 | 124.67 | 26519 |
| MFO-RF | 0.987 | 1.73 | 295.96 | 137611 | 0.981 | 0.42 | 118.58 | 23969 |
| ABC-RF | 0.991 | 1.50 | 270.41 | 99445.4 | 0.985 | 0.39 | 108.74 | 19908 |

TABLE VI. AN ESTIMATE OF THE MODELS' ASSESSMENT RESULTS FOR THE S&P 500 INDEX

| | TRAIN SET | | | | TEST SET | | | |
|---|---|---|---|---|---|---|---|---|
| | $R^2$ | MAPE | MAE | MSE | $R^2$ | MAPE | MAE | MSE |
| RF | 0.9656 | 3.42 | 85.38 | 9273.03 | 0.9653 | 1.11 | 46.57 | 3177.56 |
| BRO-RF | 0.9833 | 2.42 | 53.69 | 4491.54 | 0.9805 | 0.74 | 30.27 | 1782.87 |
| MFO-RF | 0.9794 | 1.91 | 48.53 | 5554.27 | 0.9776 | 0.80 | 33.16 | 1970.73 |
| ABC-RF | 0.9907 | 1.90 | 45.84 | 2491.17 | 0.9885 | 0.59 | 24.32 | 1050.46 |

Four commonly used metrics were employed to evaluate the data analysis: MSE, MAPE, MAE, and $R^2$. It is generally agreed upon that the aforementioned metrics provide a thorough evaluation of the overall efficacy, accuracy, and reliability of the analysis. The RF model's efficacy has been evaluated using the MAE, MSE, $R^2$, and MAPE criteria, both in the presence and absence of an optimizer. It will be able to get a better grasp of the model's functionality via this approach and provide opinions based on the information it has gained. After analyzing the training and test sets, it was seen that in the absence of the optimizer, the RF model produced $R^2$ values of 0.974 and 0.972 for the training and testing sets, respectively. In comparison, the MAE values for training and testing were 415.17 and 153.92, while the MSE values were 278883 and 36337. The MAPE values for the training and testing sets were 2.24 and 0.55, respectively. Using optimizers significantly boosted the RF model's efficiency. The results of using the BRO optimizer have been significantly improved, as can be seen by looking at the drop in the MAPE value to 1.90 for the training dataset and 0.45 for the testing dataset, as well as the $R^2$ values for training and testing were 0.983 and 0.979 for MAE and MSE values, which fell to 354.19 and 181946 for training and 124.67 and 26519 for testing. The MFO-RF model performed better than the BRO-RF model, according to a comparative study that was done between the two models. During training and testing, the MFO-RF model's $R^2$ values were determined to be 0.987 and 0.981, respectively. It's important to understand that the MSE values for training and testing dropped to 137611 and 23969. The MAE and MAPE values also decreased to 295.96 and 1.73 for training and 118.58 and 0.42 for testing, respectively. The results of this research show that the MFO-RF model performs better than the BRO-RF model in terms of efficacy. The noteworthy $R^2$ values of 0.991 and 0.985 obtained during training and testing, respectively, illustrate the efficacy of the ABC-RF model. The ABC-RF model performed better than the other models; it showed the lowest MAPE values, 1.50 for training and 0.39 for testing, and MAE values, which dropped to 270.41 for training and 108.74 for testing, and MSE value for testing was 19908. The findings described above indicate the high degree of accuracy and dependability that the ABC-RF model exhibits, proving its usefulness for the intended purpose.

In comparison to the RF, BRO-RF, and MFO-RF models, the ABC-RF model consistently achieves the highest scores or lowest error values across all evaluation metrics, including $R^2$, MAPE, MAE, and MSE. The consistent pattern observed highlights the ABC-RF model's exceptional predictive accuracy and capacity for generalization. Significantly, the superiority in performance of the model persists from the training set to the test set, suggesting that it is resistant to overfitting. The robustness of the ABC-RF model indicates that it effectively captures latent data patterns and relationships, resisting the influence of noise. As a result, its capability to generalize to unseen data is enhanced. Moreover, the efficacy of the ABC-RF model in various market environments is apparent, as evidenced by its performance on both the S&P 500 and Nikkei 225 indices. This implies that the performance of the system is not limited to particular datasets or markets, but is rather a result of its rigorous optimization and modeling methodology. The application of the Artificial Bee Colony optimization method almost certainly plays a substantial role in the superior performance of the ABC-RF model. This optimization method has gained recognition for its effectiveness in investigating search spaces and identifying solutions of superior quality. It has the potential to surpass the methods utilized in BRO-RF and MFO-RF. Furthermore, ABC-RF achieves an admirable equilibrium between intricacy and efficacy, as demonstrated by its reduced error metrics and increased R^2 values in comparison to alternative models. This suggests that the model effectively utilizes the benefits of Random Forests while simultaneously optimizing parameters to reduce errors and improve predictive precision. In brief, the ABC-RF model exhibits several advantages over its competitors (RF, BRO-RF, and MFO-RF): superior predictive accuracy, robustness against over fitting, consistency across diverse market indices, efficient optimization, and the capacity to strike a balanced equilibrium between complexity and performance. The results of this study highlight the effectiveness of utilizing the Artificial Bee Colony optimization method to enhance the performance of Random Forest models when attempting to forecast stock prices.

Extensive research has shown the dependability of the ABC-RF model as a reliable instrument for accurately forecasting stock prices. By comparing the Nikkei 225 index curves with the analogous curves shown in Figs. 7, 8, one may assess the efficacy of the model. The ABC-RF model performs better than models like RF, BRO-RF, and MFO-RF when it comes to stock price forecasting. The ABC-RF model combines the random forest with the artificial bee colony technique to estimate stock prices, according to a thorough analysis of the model's efficacy. The RF technique lowers stock price volatility and improves the accuracy of future trend estimates, both of which boost the accuracy of the model. One of the characteristics that distinguished the ABC-RF model from the others was its ability to learn from previous datasets. A model has to be able to learn from prior datasets and adjust its projections in response to changing market circumstances to predict stock prices with any level of accuracy. In conclusion, due to its accuracy, reliability, and ability to draw conclusions from historical datasets, the ABC-RF model is a highly helpful tool for stock price prediction. For those looking to conclude profitable stock market trades, it is the preferred option because of its utilization of the RF algorithm and ABC optimizer, as well as its adaptability to shifting market circumstances.

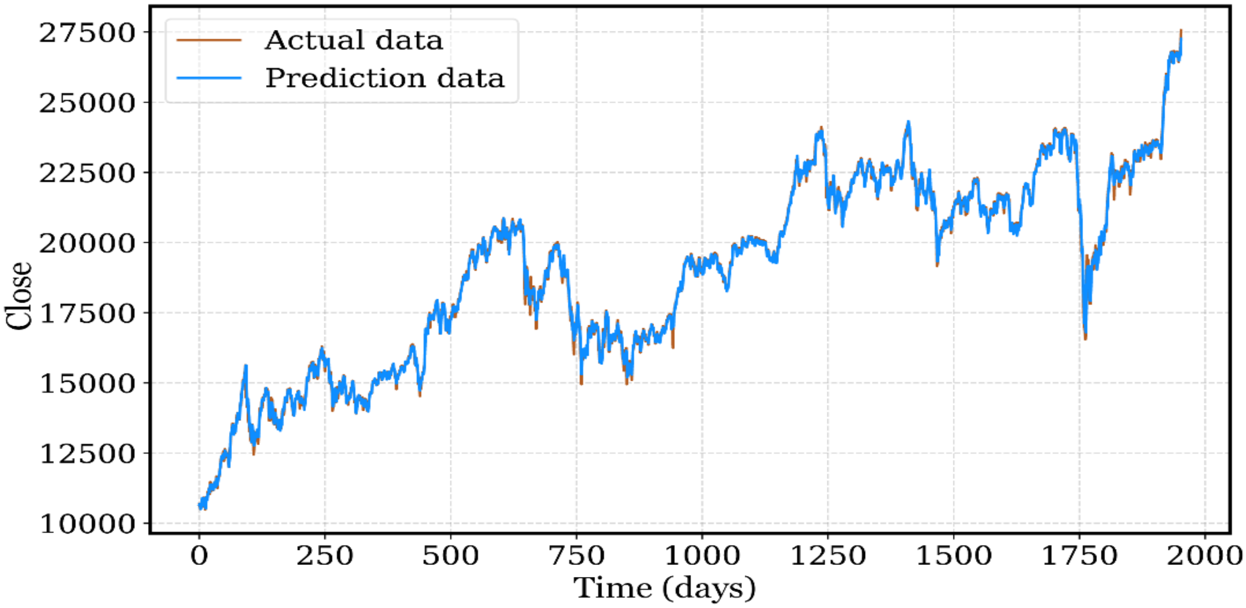

Fig. 7. The forecasting graph created during the training phase by using the ABC-RF approach.

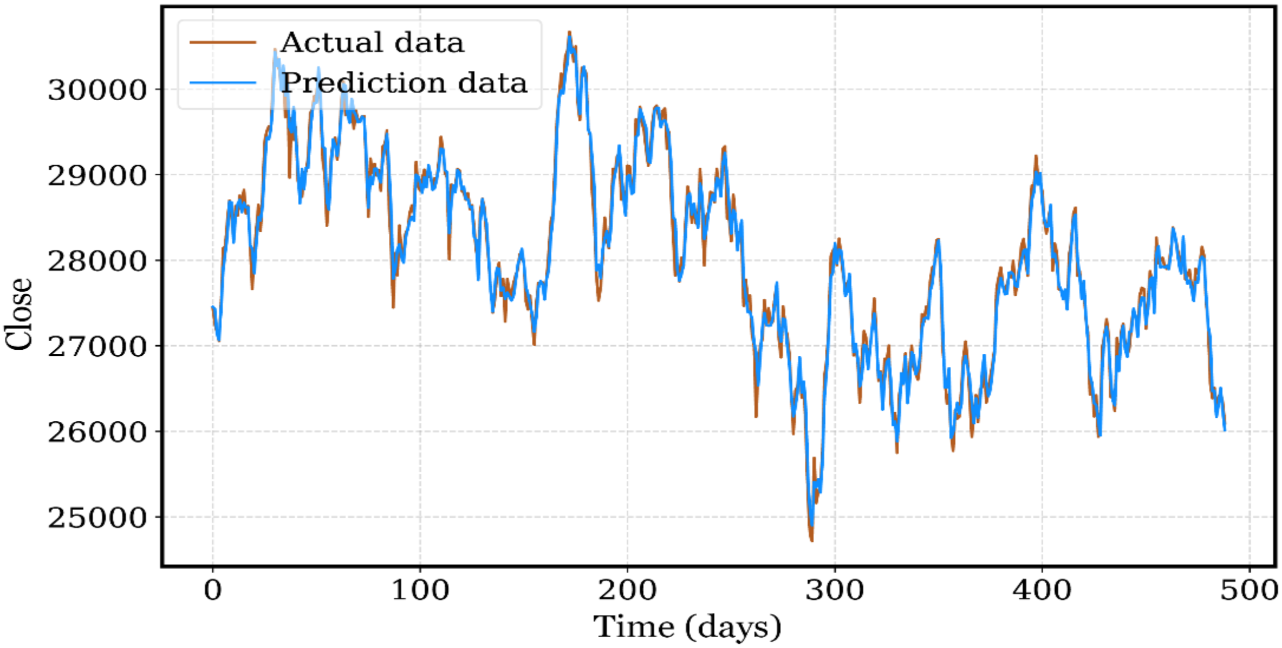

Fig. 8. The forecasting graph created during the testing phase by using the ABC-RF approach.

## VIII. Conclusion

The stock market exhibits a significant degree of volatility. Nevertheless, it provides investors with significant potential to increase the value of their investments. One approach to do this is by using various visual aids such as charts, graphs, and balance statements of corporations. Alternatively, individuals have the option to use a Machine Learning Algorithm to do the task on their behalf. The model has the capability to efficiently analyze historical data, trend lines, charts, and other relevant information and provide informed recommendations for future actions. Machine Learning technology has been deemed groundbreaking and has shown its efficacy for several investors. The multitude of complex aspects that influence stock price prediction may make the development of reliable and accurate prediction models difficult. A deep comprehension of the non-linear and volatile aspects of the market is necessary to provide reliable projections. Fortunately, the ABC-RF model provides a workable solution to these problems and has shown to be very accurate and reliable. This research evaluated the performance of many stock price prediction models, including RF, BRO-RF, and MFO-RF. The RF parameters were optimized using hyperparameter optimization methods, such as BRO, MFO, and ABC.

Nevertheless, the ABC optimizer approach produced superior outcomes when paired with RF. The dataset utilized in this analysis consisted of OHLC price and volume data for the Nikkei 225 index from the beginning of 2013 to the end of 2022. The experiment's findings show how accurate and dependable the ABC-RF model is in estimating stock values.

- As part of the research process, a comparison study with several other models was carried out to evaluate the accuracy and predictive potential of the ABC-RF model. Based on the data gathered, it can be said that the ABC-RF model consistently performed better than the other models. The calculated $R^2$ score of 0.985 shows how accurate the prediction models are. The model's predictions seemed to be quite accurate, with an observed MSE score of 19908 and an MAE value of 108.74 throughout the testing process. With a 0.39 MAPE score, the model showed a constant capacity for generating trustworthy forecasts. The ABC-RF model demonstrated greater accuracy and effectiveness in relation to the other models being studied.

The ABC-RF model provides investors with valuable insights to facilitate educated investing decision-making and serves as an effective instrument for stock price prediction. The study is limited by its use of historical data from the Nikkei 225 index, which may not capture all important market conditions or unexpected events. As a result, the conclusions may not be applicable to other markets. In addition, although the suggested ABC-RF model exhibited improved performance, its intricacy may impede comprehensibility for investors lacking extensive knowledge in machine learning, presenting obstacles for practical use. The model's assumptions of stationarity may not adequately account for the non-stationary characteristics of stock market dynamics, which could lead to a decrease in its accuracy when anticipating abrupt shifts or structural changes. Furthermore, the utilization of the model may be hindered for certain users due to the excessive computational resources and time needed, particularly when dealing with extensive datasets. Despite attempts to optimize parameters, there is still a possibility of overfitting, which highlights the need for rigorous validation methodologies and additional testing on out-of-sample data. Ultimately, the accuracy of the model's predictions can be affected by external factors like geopolitical events or market shocks, which are difficult to adequately include, thereby compromising its reliability and robustness. Subsequent research endeavors may include the following: expanding the scope of the study to encompass diverse markets in order to evaluate the adaptability of the ABC-RF model; enhancing the interpretability of the model for non-expert users; investigating dynamic modeling approaches to more accurately capture market fluctuations; optimizing computational resources and scalability; integrating risk management techniques; investigating ensemble learning methods; and designing mechanisms to provide real-time forecasts and updates. The aforementioned endeavors seek to improve the model's capacity to generalize, be utilized, be accurate, and be robust. As a result, they support well-informed investment decision-making and tackle the ever-changing complexities of the financial markets.

***Abstract*—Accidents are one of the major causes of injuries and deaths worldwide. According to the WHO report, in 2022 an estimated 1.3 million people die from road accidents. Driver fatigue is the primary factor in these traffic accidents. There are a number of studies presented by previous researchers in the context of driver's drowsiness detection. The majority of earlier strategies relied on image processing systems that used algorithms to identify the yawning, eye closure, and eyebrow of the driver taken from the live video camera. One of the major issues of the previous studies was the delay in detection time and dataset. These studies used physical sensors for monitoring the driver's behavior causes in delay time of detection. In this article, a deep learning approach is used to provide a continuous strategy for detecting driver's drowsiness using an efficient dataset. The trained algorithm is employed on the video taken from the live camera to extract the driver's facial landmarks, which are subsequently processed by a trained algorithm to provide results. The dataset used for training the CNN algorithm is consisting of 2904 images taken from various subjects under various driving circumstances. The data is preprocessed by different methods including statistical moments, CNN filters, frequency vector determination and position Incidence vector calculation. After training the algorithm the feature-based cascade classifiers files are used to recognize the face from the real-life scenario using the live camera. The accuracy of the purposed model is 95%, which is the highest of all the purposed models, based on data gathered from different kind of scenarios.**

***Keywords—Drowsiness detection face detection; eye detection; yawn detection; deep learning; convolutional neural network; electroencephalograph; eye aspect ratio***

## I. INTRODUCTION

There are a number of deaths are caused by road accidents every year. Technology plays a vital role in every field of life [1] [2]. Computational and statistical studies are also participating in the scenario of drowsiness detection which is one of the major causes of these accidents. Drowsiness can't be directly seen; therefore, we must make predictions instead. According to the report of WHO each year almost 1.3 million people lost their lives due to road accidents [3]. Traffic accidents are becoming more frequent as a result of drivers' less supervision of their vehicles which is a serious issue in society. The majority of these road accidents are caused by the driver's health, and 30% of them are brought on by driver fatigue. In this scenario, it is very important to use specialized methods to monitor the driver's driving behavior and warn him when they seem to be falling asleep. Lack of sleep, sleep disorders, alcohol use, and continuous driving are some of the main causes of sleepiness. If drowsiness can be predicted, it would undoubtedly save many lives that would otherwise be lost in fatal car accidents. Measurements of driver tiredness and distraction detection are crucial components of a driver monitoring system. Drowsiness detection fundamentally involves tracking a driver's actions, such as their acceleration, braking, steering, and pedal movement. The signs of tiredness in a driver, on the other hand, include eye movement [4], facial expressions [5], heart rate, breathing rate, and brain activity. The most useful element for determining a driver's drowsiness is their facial expressions. The three main methods of determining facial expressions are image processing [6] methods, artificial neural network (ANN) techniques [7], and electroencephalography (EEG) [8] approaches. For the detection of image-based approaches, template match image-processing and yawn-based techniques are also beneficial. These are image-processing-based computer vision algorithms. Mostly used computer vision methods for detecting driver sleepiness use the driver's head motions [9] and facial expressions, such as blinking eyes [10].

The purpose of the proposed study is to develop a state of the art research for detecting the driver's behavior to avoid road accidents. In previous studies there are the problems of continuous face detection. As driver pass from various circumstances and positions while driving. The previous studies fail to detect the drowsiness under various circumstances of face conditions. This study aims to cover the loophole of the delay time in detection using state of the art Deep-CNN approach with an efficient dataset. Most of the studies presented in the past only detect drowsiness. The proposed study detects and alarms the driver if he is drowsy. The proposed research used the Convolutional neural network (CNN) approach to create the drowsiness detection model using a big dataset of images consists of 2904 images of various people under various circumstances of driving behaviors. Eye blink ratio (EAR) is the key factor of detection. The Viola Jone method is utilized for the detection of face in the live camera approach. The video frames of the extracted live camera videos are passed through CNN trained algorithm and system shows a continuous detection without time delay. As well as the system, is not bounded with the hardware (sensors) problems. As in the previous study the sensors are used to detect the driver's face conditions, movements and behavior. The study only used a live camera that is already placed in the steering wheel.

## II. Background

In the past, a number of researchers used different methodologies along with different algorithms and datasets for the identification of drivers' drowsiness. This section of research presents some of the latest computational researches proposed for drowsiness detection.

Researchers present an automatic vehicle control system for fatigue detection [11]. This model was designed for early fatigue detection for a train driver. Whenever a driver is sleepy or in an unconscious condition the system determined it by the movement of his head. Heart sensors are used in this procedure to identify tiredness caused by any serious medical conditions. The technologies used in this system include face identification, Matlab, AVR Studio, and image processing. When a user becomes fatigued, the hardware system alerts the microprocessors. The working of the proposed system is shown in Fig. 1[11].

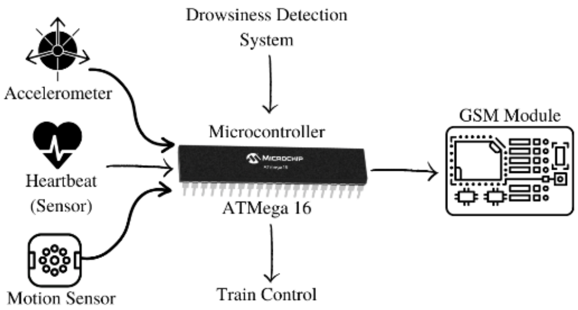

Fig. 1. Block diagram of the proposed system.

Yawn detection [12] plays a vital role in the drowsiness detection. Yawn is the primary indication of drowsiness that is detected by using facial segmentation. In an approach template for Gravity-Center [13] this method is used for facial segment detection. The geometrical arrangements of the mouth and eye are virtually identical. The yawn is measured from the chin to the middle of the nostrils. Grey projection and the Gabor wavelets method [14] were utilized to identify mouth corners. In the last step, the LDA is used to categorize the characteristics to identify yawning as explained in Fig. 2 [12].

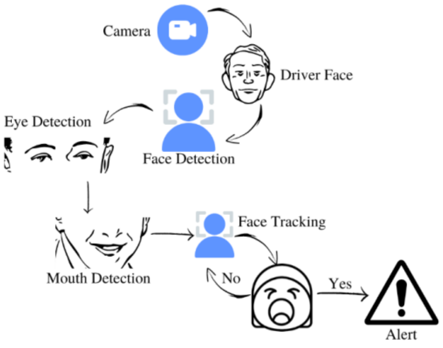

Fig. 2. Drowsiness detection using yawn.

A researcher uses the eye closure period of the driver by recognizing his face in the Eye Based Drowsiness Detection approach [10]. In order to assess the blinking rate, the length of the eye, the location of the iris and eye condition at different time-stamped are examined. Edge detection, a key component of image processing is used for measuring eye aspect ratio. If the eye is closed for 5–6 consecutive frames throughout this procedure, a warning alert is generated. The EAR is calculated by Eq. (1)

$$\text{EAR} = \frac{|P2-P6+|P3-P5|}{2|P1-P4|} \tag{1}$$

Representation Learning is also used to detect the driver's drowsiness using various properties extracted from a dataset [15]. Convolutional neural networks (CNN) are used in this method to capture the most recent facial expressions and challenging non-linear feature interactions [14]. This method involves training a dataset of 30 drivers with a variety of traits under various conditions, such as varied levels of weariness, facial hair, hair fringes, eye size, face shape, and skin tone. The dataset has been separated into five folders, one for training and the other four for validation. The CNN Model trains 50 pictures every cycle. A multi-layer perceptron [16] is employed in this method as a result of the multi-layer categorization methodology. It is most often used for nonlinear issues and classifiers. This method has an accuracy rate of higher than 80%. In the latest research machine learning and deep learning algorithms are used for efficient drowsiness detection. Algorithms for machine learning use supervised, unsupervised, semi-supervised, and reinforcement learning techniques [16]. A method uses several supervised machine learning techniques for the identification of drowsiness. This study used the dataset developed by National Advanced Driving Simulator (NADS-1) [17]. The dataset comprises 27 characteristics, 15,000 tuples, and 144 runs, of which 72 take place during the day and 72 during the night. Participants were asked to operate vehicles on various highways throughout various historical periods. These tests are conducted on the Weka machine learning workbench [18]. In these works, Naive Bayes, Random forest trees, Sequential Minimal Optimization (SMO), and Logistic Regression [19] were employed as machine learning techniques for detection. Two distinct sets of features including Pre Run aggregate feature and Per Event aggregate feature are produced after the data has undergone preprocessing to fill in the missing values [20]. 10-FCV is the testing technique used by the model [21]. Without picking attributes, the SMO produces the best results for the Per Run aggregate features (0.66 F1 scores), however afterward choosing 10 characteristics after an entire of 76, the presentation of the accidental plantation method and Logistic regression improve and provide superior results (0.71 F1 scores). However, for Per Event Aggregate Structures, Logistic based Regression performs best with 0.72 F1 score and a 0.76 ROC area when no features are chosen, whereas SMO performs best with a 0.78 F1 and a 0.78 ROC area when 100 attributes are chosen from a total of 1900 attributes.

Electroencephalogram (EEG) based method is also utilized to find the brain condition for detecting drowsiness [22].For the study 29 subjects are taken and none of them have any physical or mental illnesses. Data is taken from EEG recording signals, and characteristics are compared to determine whether the subject is sleepy or not. In another research EEG-based encode-decoder method is presented for the detection of driver's drowsiness. The working of this model is shown in Fig. 3 [23].

Fig. 3. Working of EEG System for drowsiness detection.

ANN is also used in recent research for drowsiness detection. This research included twenty-one people, of whom ten women and eleven men are included. The scale has a set range of 1 to 15. The range from 0 to 8 indicates that there is no sleep. A notch of 8 to 14 indicates that the individual is showing some signs of sleep, while a score of 15 or above indicates that the person is very sleepy. These participants operate the vehicle for 110 minutes while feeling sleepy. Measurements of functional performance, including emotion rate, eyelid activities, breathing amount, and heavy performance, including rapidity, direction-finding wheel angle location on the way, and time-to-lane adventure, are the foundation of this research. When the driver's condition deteriorates, it forecasts their situation within five minutes [7].

In the latest research [24] fuzzy logic based system is developed to detect the driver's fatigue level on sequence of images and generates alarm. This method used deep learning method for analyzing the image and combined AI and DL for feature extraction. The model gives the classification accuracy of 93.7%. Researchers in [25] use emotion analysis with CNN for accurately detecting driver's drowsiness. This study used two levels CNN for reducing detection time. S. P. Measures [26] in his latest study proposed AI model based MTCNN and GSR for measuring face features and physiological factors. This model use both intrusive and non-intrusive detections. The efficiency of this model was 91%.

## III. Research Methodology

The proposed study use CNN Layer model of deep learning for an efficient drowsiness detection. The architecture of CNN model is explained in Fig. 4.

The working of the whole model is illustrated in this section of research.

### A. Dataset

The dataset is the important key factor of this research. For the proposed study the dataset is taken from the keggle [27]. This study is using Version No 1 of the dataset uploaded by Serena Raju. The Dataset consists of almost 70 participants (including men and women of different ages) with different driving scenarios. Dataset Contain two folders training and testing and each of the folders have four sub folders (Open Eye, Close Eye, Yawn, and No Yawn). The Details of the dataset is explained in Table I.

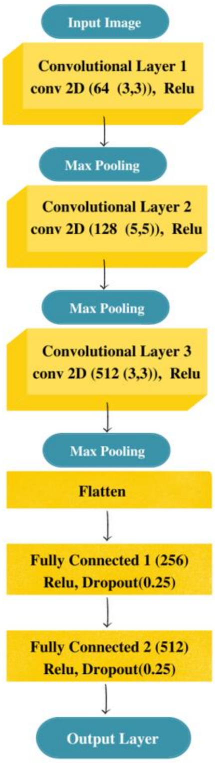

Fig. 4. The layer architecture of CNN models.

TABLE I. Dataset Used for the Proposed Study

| Training Dataset (Total Images: 2468 images) | | Test Dataset (Total Images: 436 images) | |
|---|---|---|---|
| Close Eye | 617 images | Close Eye | 109 images |
| Open eye | 617 images | Open eye | 109 images |
| Yawn | 617 images | Yawn | 109 images |
| No Yawn | 617 images | No Yawn | 109 images |

The eye data set possibly cover all data possible situations that a driver feels during the driving. The Data set also contains the conditions for a driver who wears glasses. The dataset includes the participants with different feature includes face shape, color, texture, and facial local features.

### B. Data Preprocessing

This section of research explains the process of feature extraction and balancing the drowsiness detection dataset [28] [29]. It is the most important part of deep learning algorithms. An efficient and correct dataset is responsible for the efficient results. The dataset used for the study was imbalanced. If the dataset is imbalanced then the classification will not be equally distributed. So the dataset for the proposed study is balanced by Synthetic Minority Over-Sampling Technique

(SMOTE). It is a technique in which the number of minority classes are increased [30][31]. Fig. 5 explains how to create synthetic data points in SMOTE.

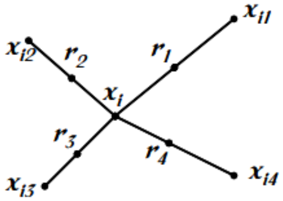

Fig. 5. Creation of Synthetic data points in SMOTE.

The working of SMOTE algorithm is as follows

The algorithm for SMOTE is [32].

- Generate the minority classes of the dataset.
- Generate the oversampling for calculating instances.
- Identify k instance in the minority class and also find its N Neighbor.
- Calculate the distance between these two points N and K
- Multiply the answer with any number exists between 0 and 1 and add this distance in k.
- Repeat the process till required instances.

The benchmark dataset for the purposed study is denoted by D, which is defined as,

$$\mathrm{D}=\mathrm{D}^{+}\,\mathrm{U}\mathrm{D}^{-} \tag{2}$$

Here $\mathrm{D}^{+}$ considered as drowsy data images while $\mathrm{D}^{-}$ is non-drowsy data images and U is the union for both sequences.

## C. Feature Extraction

The process of feature extraction includes extracting main face features from the images dataset to process further for drowsiness detection. For the proposed study different feature extraction methods are used for the extracting main features from the dataset. Images plotted for this study were created using the Matplot.lib software. Three sections make up the mat plot lib code. [33]. The photos are plotted on a 2D scale. We scale the photographs to the same size before plotting them to ensure that they line up exactly on the scale. The photos that were utilized for this investigation are 48 × 48 and are presented with a dark backdrop in grayscale. Fig. 6 displays the outcomes of different picture plots made using Matplotlib.

In the proposed study the dataset in consists of 2904 images. The statistical moment used to find the central tendency, probability distribution , dispersion, and symmetry of such dataset [34]. Hahn moment utilize Hahn polynomial for image feature extraction. The mathematical formula for calculating Hahn moment is explaining in Eq. (3).

$$H_{pq} = \sum_{p=0}^{N-1} \sum_{q=1}^{N-1} G'(p,q)\; h_n^{\overline{x,y}}\,(q,N) h_j^{\overline{x,y}}\,(p,N) \tag{3}$$

Raw moment is the statistical moment use to find the position of each image pixel of drowsiness dataset. This is also called crude moment. The raw moment at any random point is calculated by Eq. (4) [35].

$$R_{pq} \,=\, \sum_{a=1}^{N} \sum_{b=1}^{N} a^p b^q P'(a,b) \tag{4}$$

In Eq. (4) $P'(a,b)$ the arbitrary point at any two face features (a, b), $R_{pq}$ is the raw moment of these points. Central moment is the Arithmetic mean of the image pixels in the dataset. The arbitrary centroids serves the key feature for finding the probability distribution of the genes [36][37]. The central moment for thee selected dataset is represented by Eq. (5)

$$C_{pq} \,=\, \sum_{a=1}^{N} \sum_{b=1}^{N} (a-\bar{x})^p (b-\bar{y})^q P'(a,b) \tag{5}$$

PRIM and RPRIM are the methods for finding the location of image pixels[38]. The position incidence vector deeply describes the combination of pixels in an image. Accumulative Absolute Position Incidence Vector (AAPIV) [39] for finding the nth image pixel in the images of drowsiness detection dataset is determined by Eq. (6) as

$$\beta_N \,=\, \sum_{k=1}^{n} \mu_k \tag{6}$$

The reverse AAPIV also work same order as AAPIV work but in the reverse pattern. Different convolutional filters are also applied for extracting the features as explained in Fig. 7.

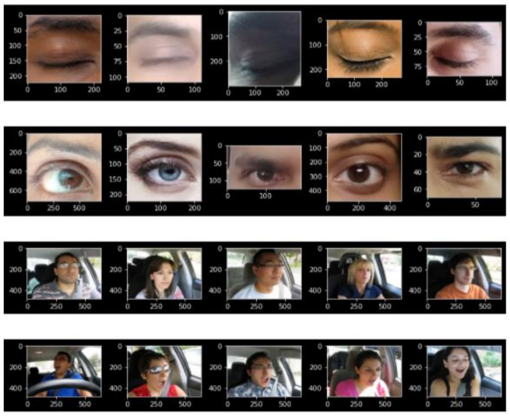

Fig. 6. Results of images plotted using matplotlib.

Fig. 7. Different Convolution based 2 dimensional 3×3 filter applied on an images.

### D. Tools

For the validation and training of the dataset using Open CV Python, this study uses the Kaggle kernel. The model was developed using Kaggle. The results are then gathered using PyCharm community edition 2020.3.4 and the trained dataset file (Python 3.9). In this research, the face is found using the Haarcascascade file.

## IV. Using Working of CNN Model

The working of the model is illustrated in Fig. 8

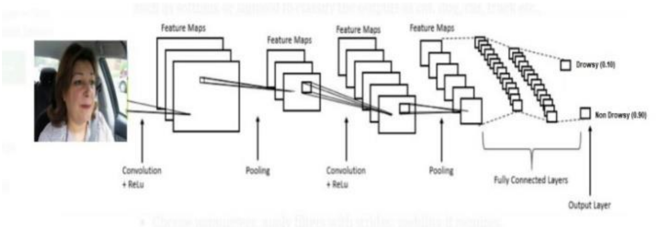

Fig. 8. Working of CNN model.

- Select the images from the drowsiness detection dataset.
- Images were sent to CNN's convolution layer. Different feature extraction techniques and filters are applied on these images.
- Apply the matrix's ReLU activation function to classify the features of the images.
- Max pooling is used to reduce a matrix's dimension size so that the important face features are passed to the next layer.
- Add one more layer of convolutions. (Apply till results are satisfied.)
- Apply the flatten function to the outputs after the necessary outcomes have been achieved in order to transmit them to the completely linked layer.
- Use the softmax activation algorithm to generate the classes and categorize the images (Drowsy or Non-Drowsy)

A basic ConvNet is made up of a number of layers, and each layer performs a differentiable function by converting one volume of activations to another. Each neuron in this coating will be associated to every number in the preceding volume in a conventional neural network. The net output from the forward pass of CNN algorithm is considered by the following equation

$$\text{Net (y)} = \sum_{\boldsymbol{i=1}}^{\boldsymbol{n}} \boldsymbol{x_i w_i} + \text{b} \tag{7}$$

Each layer's g is determined using w(x) +b. If w is the weight vector, b is the bias, and the y is initial function, and the vector **x** is the input. There are several learnable filters in the Conv layers. The driver's image from the dataset passes from each filter so that the system identifies its main features. CNN adds the multiplication values after multiplying a matrix of pixels with a filter matrix, or "kernel." Once all of the pixels have been covered, it goes on to the next set of pixels. After applying the filters on the images ReLU activation function is applied on images. The equation applying the RELU activation function is:

$$RELU = -eV\, max\,(-eV, 0) = 0 \tag{8}$$

$$RELU = +eV\, max\,(+eV, 0) = +eV\; value \tag{9}$$

For each iteration the net output is calculated by Eq. (10)

$$Out\ net\ y = \frac{1}{1+e^{-nety}} \tag{10}$$

Applying RELU to the drowsiness detection dataset make the classes of the images. If the image plot above the graph that shows drowsiness while below the graph shows non-drowsiness. The Max pooling function is used for the suggested research following the activation function. A down sampling technique would be this. The greatest value from the filter is extracted using max pooling. Max pooling is determined by the Eq. (11).

$$Max\ Pooling = \frac{I_x - P}{S} \tag{11}$$

In equation $I_x$ is input x or y shape of the image, p is pooling window size and S represent stride. The data is flattened into a one-dimensional array before moving on to the next layer, which creates a single long featured vector linked to the fully connected layer of the final classification model. Data will enter the fully linked layer's input layer after flattening. The classes are formed from these layers. The CNN Model's output are classes. There are two classifications in the drowsiness detecting system. Drowsy and Non-Drowsy. The softmax activation function determines the likelihood that an input belongs to each class in the dataset. This activation function is used on the CNN fully connected layers for the proposed model. In softmax, the total number of classes equals one. The softmax calculation formula is

$$f\,(y_i) = \frac{e^{yi}}{\sum_k e^{yk}} \quad for\ i = 1\ to\ k \tag{12}$$

The error is determined once one iteration is finished. To assess how effectively the neural network is functioning, error is crucial. The error is minimal if the network is functioning correctly. Error is determined by

Total Error = The Actual output – The Desired output

$$E = Y - \; Y' \tag{13}$$

And the loss function remains calculated through formula

$$L = \frac{1}{2} \sum (Y - Y')^2 \tag{14}$$

Here, **Y** is the productivity that was really received, while **Y**' is the output that was obtained afterward every iteration of the CNN model and each time it was close to the actual output. Following the calculation of the loss, backward propagation is used to update the weights. New weights are computed using backward propagation, and these weights once again flow through the feed-forward neural network to produce the value Y. These iterations continue until the desired output value is obtained. The CNN weights used in backward propagation find out by the equation (15).

$$w_{new} = \mathrm{w}_{\mathrm{old}\ -\mu} \frac{\Delta \mathrm{L}}{\Delta \mathrm{w}_{\mathrm{old}}} \tag{15}$$

Here, $w_{new}$ is the next updated weight vector, while $w_{old}$ is the previous weight for the updated neuron. Parameter $\boldsymbol{\mu}$ is learning rate and $\frac{\Delta L}{\Delta w_{old}}$ (partial derivative of loss with respect to the old weights). Continuous resampling model based on new weights is used that are calculated by the Eq. (15). And it works until it reaches the global minima [40]. Loss function's derivative and the calculation of old weights is calculated with the chain rule.

$$\frac{\boldsymbol{\Delta L}}{\boldsymbol{\Delta w}} = \frac{\boldsymbol{\Delta L}}{\boldsymbol{\Delta O}} \times \frac{\boldsymbol{\Delta O}}{\boldsymbol{\Delta w}} \tag{16}$$

The acronym for Adam is adaptive moment estimation. It is a technique that uses a stochastic gradient to change the weights and other attributes in neural networks. It is used in the proposed CNN model's back propagation because it is more effective and uses less memory. And it works well in situations where there are lots of data. The optimization method is used in this strategy to produce random variables. Adam employs both the Root Mean Square Propagation (RMSP) and the Adaptive Gradient Algorithm (AdaGrad) properties (RMSP). Adam is a technique for adaptive learning that figures out each person's rate of learning for various parameters. From evaluations of the first and second moments of the gradients, it determines the adaptive learning rates of the individual for various parameters. In both mechanics and mathematics, moments are employed to define the distribution and are described by function.

$$\text{Nth momentum} = \frac{x1s + x2s + x3s \ldots\ldots xns}{n} \tag{17}$$

The function's mean is produced at the first instant when the variable's value is changed from 0 to 1. The variance of the function is similarly explained by the second moment, sometimes referred to as the core moment. The skewness is defined by the third Moment. Adam uses the exponential moving average to estimate the moments. This method is based on the gradient measured on the current mini-beach. The following equations in Adam are used to determine the Momentum and RMSP.

$$\mathrm{w_{t+1}} = \mathrm{w_t} - \mathrm{m_t} \tag{18}$$

$$\mathrm{m_t} = \beta_1 \mathrm{m_{t-1}} + (1-\beta) \frac{\Delta \mathrm{L}}{\Delta \mathrm{w}} \tag{19}$$

$m_t, m_{t+1}$ = aggregate gradient at time t and t+1.

$Wt, Wt+1$,αt,∂L = weights at time t and t+1, learning rate, derivative of Loss

β = Moving average.

$$\mathrm{v_t} = \beta_1\ \mathrm{v_{t-1}} + (1-\beta) \left(\frac{\Delta \mathrm{L}}{\Delta \mathrm{w}}\right)^2 \tag{20}$$

Then the weight update equation for Adam will be

$$\mathrm{w_t} = \mathrm{w_{t-1}} - \frac{\eta \times \mathrm{m_t}}{\sqrt{\mathrm{v_t} + \varepsilon}} \tag{21}$$

The model is stored in model once the optimizer has been applied. H, which is then utilized to train the algorithm. The verbose is used to print the model's details. Finally, halting conditions are established to protect against model over fitting. The detailed summary of the model is explained in Fig. 9.

Fig. 9. Summary of the proposed model.

## V. Using Working of Cnn Model

The Mathematical model o proposed CNN model is explained as,

$$\mu = -\sum_{i=1}^{h_a} (B_{\text{ʟ}} \log(€_c)) \tag{22}$$

where, $h_a$ = classes that depends on application Differentiating Eq. (22) with respect to weights.

$$\frac{\partial \mathrm{a}}{\partial v} \text{ And bias } \frac{\partial \mathrm{x}}{\partial q}$$

Softmax Transformation Function is defined in Eq. (22) as

$$€_c = \frac{\boldsymbol{m}^{\boldsymbol{k_v}}}{\sum_{\boldsymbol{j=1}}^{\boldsymbol{n}} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}}} \tag{23}$$

$$\gamma_l = \sum_{j=1}^{\eta_{out}} (v_{jl} * \varkappa_j)$$

$\gamma_l$ Is calculated via interrelated weights with the $\varkappa_j$

$$\partial \mathrm{a} = \sum_{j=1}^{\eta_{out}}{}' \sum_{l=1}^{\eta_c} \left(\frac{\partial \mathrm{a}}{\partial \gamma_l} \frac{\partial \gamma_l}{\partial v_{j,l}}\right) \tag{24}$$

$$\frac{\partial €_c}{\partial \boldsymbol{\gamma}_l} = softmax\ derivative$$

$$€_c = \frac{\boldsymbol{m}^{\boldsymbol{k_v}}}{\sum_{\boldsymbol{k=1}}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}}}$$

$\boldsymbol{\gamma}_l = \sum_{j=1}^{\eta_{out}} (\omega_{jl} * \varkappa_j)$ Is given as $B_{\text{ʟ}} = \gamma_l$

There are two cases, first where I = $l$, and second I ≠ $l$, when i=nth unit.

Case1: (i = $l$)

Quotient rule is applied Eq. (23)

$$\frac{\partial €_c}{\partial \boldsymbol{\gamma}_{(i=l)}} = \frac{\boldsymbol{m}^{\boldsymbol{k_v}} \sum_{\boldsymbol{\kappa=1}}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}} - \boldsymbol{m}^{\boldsymbol{k_v}} \boldsymbol{m}^{\boldsymbol{k_v}}}{\sum_{\boldsymbol{\kappa=1}}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}} * \sum_{\boldsymbol{\kappa=1}}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}}} \tag{25}$$

Taking common $\frac{\boldsymbol{m}^{\boldsymbol{k_v}}}{\sum_{\boldsymbol{\kappa=1}}^{\eta_c} \boldsymbol{e}^{\gamma_\kappa}}$ from Eq. (25), we get

$$\frac{\partial \text{€}_c}{\partial \boldsymbol{\gamma}_l} = \frac{\boldsymbol{m}^{\boldsymbol{k_v}}}{\sum_{\kappa=1}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}}} \left[\frac{\sum_{\kappa=1}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}} - e^{\boldsymbol{\gamma}_l}}{\sum_{\kappa=1}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}}}\right]$$

By taking Anti L.C.M, we acquire

$$\frac{\partial \text{€}_c}{\partial \boldsymbol{\gamma}_l} = \frac{\boldsymbol{m}^{\boldsymbol{k_v}}}{\sum_{\kappa=1}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}}} \left[1 - \frac{e^{Z\boldsymbol{\gamma}_i}}{\sum_{\kappa=1}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}}}\right] \qquad \{\because \mathrm{i} = l\}$$

Eq. (22) $\text{€}_c = \frac{\boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}}}{\sum_{j=1}^{n} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}}}$ can be modified as.

$$\frac{\partial \text{€}_c}{\partial \boldsymbol{\gamma}_l} = \text{€}_c(1 - \text{€}_c) = \text{€}_c\,(1 - \text{€}_c) \tag{26}$$

case2 (i $\neq l$):

Applying derivative rules for taking the derivative of Eq. (24) w.r.t. $\gamma_l$

$$\frac{\partial \text{€}_c}{\partial \gamma_l} = \frac{\frac{\partial}{\partial \gamma_l} \boldsymbol{m}^{\boldsymbol{k_v}} \; * \sum_{\kappa=1}^{c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}} - \boldsymbol{m}^{\boldsymbol{k_v}} \frac{\partial}{\partial \gamma_l} [\sum_{\kappa=1}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}}]}{\sum_{\kappa=1}^{\eta_c} e^{\boldsymbol{\gamma_\varphi}} * \sum_{\kappa=1}^{\eta_c} e^{\boldsymbol{\gamma_\varphi}}}$$

By simplifying,

$$\frac{\partial \text{€}_c}{\partial \gamma_l} = 0 - \frac{\boldsymbol{m}^{\boldsymbol{k_v}} * \; e^{\gamma_l}}{\sum_{\kappa=1}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}} * \sum_{\kappa=1}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}}} = - \frac{\boldsymbol{m}^{\boldsymbol{k_v}}}{\sum_{\kappa=1}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}}} * \frac{e^{\gamma_l}}{\sum_{\kappa=1}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}}}$$

As we know that $\text{€}_c = \frac{e^{\gamma_i}}{\sum_{\kappa=1}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}}}$ and $\text{€}_c = \frac{e^{\gamma_l}}{\sum_{\kappa=1}^{\eta_c} \boldsymbol{\rho}^{\boldsymbol{\kappa_\sigma}}}$ so by putting these values in Eq as.

$$\frac{\partial \text{€}_c}{\partial \boldsymbol{\gamma}_l} = -\text{€}_c \lambda_l \;\; for(i \neq l) \tag{27}$$

By summarizing Eq. (26) and Eq. (27)

$$\frac{\partial \text{€}_c}{\partial \boldsymbol{\gamma}_l} = \begin{bmatrix} \text{€}_c(1 - \lambda_i\;)\; for(i = l) \\ -\text{€}_c \lambda_l \qquad for(i \neq l) \end{bmatrix} \tag{28}$$

$$\text{£} = - \sum_{i=1}^{\eta_c} (B_{\text{ʟ}} * \log(\text{€}_c))$$

Taking derivative,

$$\frac{\partial \mathrm{a}}{\partial \gamma_l} = - \sum_{i=1}^{\eta_c} \left( Y_\kappa * \frac{\partial}{\partial \gamma_l} log(\lambda_\kappa) \right)$$

$$\frac{\partial \mathrm{a}}{\partial \gamma_l} = - \sum_{i=1}^{\eta_c} Y_\kappa \left( \frac{\partial}{\partial y_k} log(\lambda_\kappa) \right) \frac{\partial \lambda_k}{\partial \gamma_l}$$

$$\frac{\partial \mathrm{a}}{\partial \gamma_l} = - \sum_{i=1}^{\eta_c} \frac{Y_\kappa}{\lambda_\kappa} \frac{\partial \lambda_\kappa}{\partial \gamma_l} \tag{29}$$

$\frac{\partial \lambda_k}{\partial \gamma_l}$ Is previously measured as the softmax gradient. There are two cases that discussed here $i \neq l$, and $k \neq l$ as in Eq. (27). Now Eq. (28) is distributed into two portions

$$\frac{\partial \mathrm{a}}{\partial \gamma_l} = - \frac{Y_\kappa}{\lambda_\kappa} * \lambda_\kappa\,(1 - \lambda_l\,) - \sum_{\kappa \neq \mathrm{l}}^{\eta_c} (- \frac{Y_\kappa}{\lambda_\kappa} * \lambda_\kappa\, \lambda_l\;)$$

Where,

$$\sum_{\kappa \neq \mathrm{l}}^{\eta_c} (- \frac{\mathrm{Y}_\kappa}{\lambda_\kappa} * \lambda_\kappa\, \lambda_{\mathrm{l}}\;) \qquad \text{For} \qquad \kappa \neq \mathrm{l}$$

$$\frac{\mathrm{Y}_\kappa}{\lambda_\kappa} * \lambda_\kappa\,(1 - \lambda_{\mathrm{l}}\,) \;\; \text{For} \qquad \kappa = \mathrm{l}$$

We can simplify this,

$$\frac{\partial \mathrm{a}}{\partial \gamma_{\mathrm{l}}} = -\mathrm{Y}_\kappa\;(1 - \lambda_{\mathrm{l}}\,) + \sum_{\kappa \neq \mathrm{l}}^{\eta_c} \mathrm{Y}_\kappa\; \lambda_{\mathrm{l}}$$

We can further simplify this as,

$$\frac{\partial \mathrm{a}}{\partial \gamma_{\mathrm{l}}} = -\mathrm{Y}_\kappa\; + \mathrm{Y}_\kappa\; \lambda_{\mathrm{l}}\; + \sum_{\kappa \neq \mathrm{l}}^{\eta_c} \mathrm{Y}_\kappa\; \lambda_{\mathrm{l}}$$

$$\frac{\partial \mathrm{a}}{\partial \gamma_l} = \lambda_l \left( \lambda_\kappa\; + \sum_{\kappa \neq \mathrm{l}} Y_\kappa\; \right) - \lambda_\kappa$$

Where $(\lambda_\kappa\; + \sum_{\kappa \neq \mathrm{l}} Y_\kappa\;)$ represents 1,

$$\frac{\partial \mathrm{a}}{\partial \gamma_l} = (\lambda_l\; - Y_\kappa\;)$$

$$\frac{\partial \mathrm{a}}{\partial \gamma_l} = (\lambda_l\; - Y_l\;)\{\because \kappa = l\}$$

Now put the value of $\frac{\partial \text{£}}{\partial \gamma_{\mathrm{l}}}$ in

$$\frac{\partial \mathrm{a}}{\partial v_{j,l}} = \sum_{j=1}^{\eta_{out}} \sum_{l=1}^{\eta_c} (\frac{\partial \mathrm{a}}{\partial \gamma_l} \frac{\partial \gamma_l}{\partial v_{j,l}})$$

$$\frac{\partial \mathrm{a}}{\partial v_{j,l}} = \sum_{j=1}^{\eta_{out}} \sum_{l=1}^{\eta_c} (\lambda_l\; - Y_l\;) \varkappa_j \tag{30}$$

Where $\frac{\partial \gamma_l}{\partial v_{j,l}} = \varkappa_j$ are representing the input weights. The Differentiation of Loss (£) with respect to weights ($\omega$) for the fully connected layer is formulated in Eq. (30).

## VI. Analysis and Discussion

The model succeeds after 20 iterations. The training and test images from each layer of CNN pass from each epoch. The model becomes better with each testing cycle, increasing its ability to compute loss, accuracy, specificity, sensitivity, and Mathew's correlation coefficient. The results of the deep learning algorithms are access with different evaluation measure include accuracy, sensitivity, specificity, loss and MCC values [41] [42]. These are the most important evaluation measure used for binary classification. The mathematical equation for calculating these evaluation methods are explained in Eq. (31) to Eq. (34).

$$Specificity = \frac{TN}{TN+FP} \tag{31}$$

$$Sensitivity = \frac{TP}{FN+TP} \tag{32}$$

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} \tag{33}$$

$$MCC = \frac{(TP \; X \; TN)-(FP \; X \; FN)}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \tag{34}$$

In the equations:

TN = The number of cases that are correctly identified as drowsy.

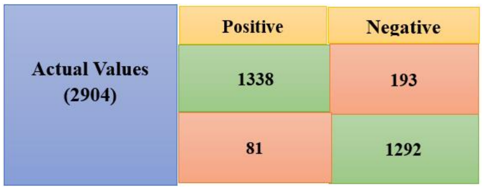
TP = The number of cases that are correctly identified as cnon drowsy.

FN = The number of cases that are incorrectly identified as non-drowsy.

FP = The number of cases that are incorrectly identified as drowsy.

Confusion matrix of the algorithm is generated to find the results in the form of accuracy, sensitivity, specificity, and MCC value. Fig. 10 shows the confusion matrix [42] for the proposed results.

The accuracy and loss curve of the results are explained in Fig. 11 and Fig. 12.



|  | Positive | Negative |
|---|---|---|
| Actual Values (2904) | 1338 | 193 |
|  | 81 | 1292 |

Fig. 10. Confusion matrix of the results.

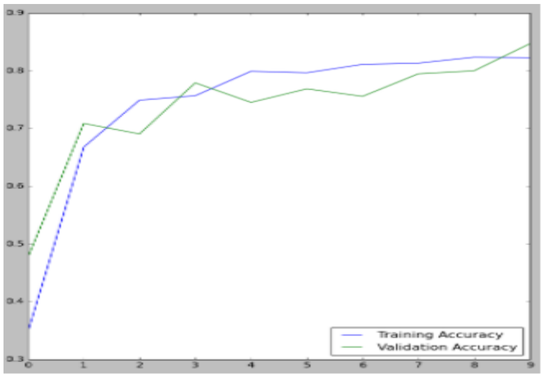


Fig. 11. Accuracy curve.

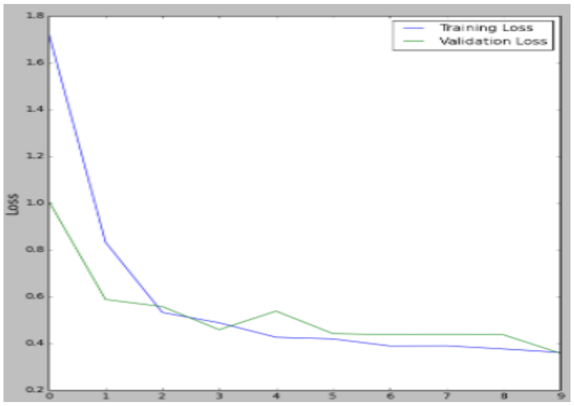

Fig. 12. Loss curve.

It is clearly seen from Fig. 11 that the accuracy of the model is gradually increasing with each iteration.

The effectiveness of the intended system is shown by the graph, which demonstrates that the loss function value for training and testing values is lowering with each iteration while growing accuracy value. In the confusion matrix TP refers to the values that shows the drowsiness and are actual drowsy. TN is the value that is perfectly detected as non-drowsy. FN and FP are the values that are not correctly identified by the model. Table II shows the result of CNN model for the proposed system.

TABLE II. RESULTS OF THE PROPOSED STUDY

| Method | Result |
|---|---|
| Sensitivity | 0.94 |
| Specificity | 0.95 |
| Accuracy | 0.95 |
| MCC | 0.82 |

The proposed study gives the accuracy of 95% for the driver's drowsiness detection. The model is applied on the live camera video to generate the results. The images are taken out of the camera's live video frames and then plotted on grayscale. Face areas are simple to identify in grayscale photos. The regions of the eye are Ex, eye, EW, and eh. Through these areas, the system locates the eye, after which it verifies the closure rate. The technology determines if a user is "Drowsy" or "Attentive" based on the detection of the eye area (Non-Drowsy). The findings that were attained as a consequence of the system's operation are listed below.

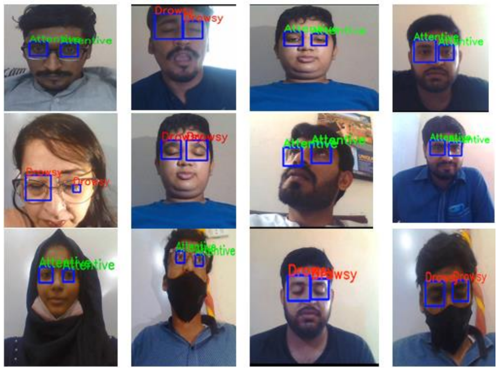

Fig. 13. The results of the proposed study on live cam.

These results are obtained by applying the current scenario on different lighting circumstances, driving patters, skin tones and eye conditions with and without using spectacle glasses. Fig. 13 shows the results of the proposed study on live cam.

## VII. COMPARISION OF OUR RESULTS WITH STATE OF THE ART TECHNIQUES

A comparison of different methods with their metric, classifier and accuracy from the proposed Method is summarized in Table III.

It is to be seen from the Table III that the maximum accuracy of 93% was obtained by latest studies that used 2D-CNN and EfficientNetB0's architecture for drowsiness detection. Driver's behavior analysis plays an important role in these studies. The proposed study gives the accuracy of 95% with CNN model. In past the driver's drowsiness detection was based on real time detection without training the model on any dataset. Those who use dataset use their own dataset of few images. The proposed study resolves the loophole of the previous study by using an efficient accurate dataset of 2900 images.

TABLE III. COMPARISON OF THE PROPOSED RESEARCH WITH EXISTING TECHNIQUES

| Methods | Metrics | Classifiers | Accuracy |
|---|---|---|---|
| Vehicle Based Features | Steering Wheel Movement (SWM) | MANN | 88.02% |
| The Facial Landmarks | Eye Aspect Ratio (EAR) Mouth opening Ratio (MOR) | SVM | 92.8% |
| Physiological and behavioral features | EEG | SVM | 80% |
| Measuring Brain Activity | EEG | Support vector Machine (SVM) | 72.7% |
| Behavioral and Physiological measure | MTCNN with GSR sensor | Hybrid Model of classification | 91% |
| Feature learning | Viola jones method | Convolutional Neural Network( CNN) | 81% |
| Emotion Analysis based CNN Model | 2D-CNN | CNN with emotion analysis | 93% |
| Featured learning and Classification (Purposed Model) | Object detection Algorithm( cascade) | Deep Learning(CNN) | 90.59% |
| Deep learning Method | EfficientNetB0's architecture | Combined Deep learning with AI model. | 93% |
| Proposed Study | CNN with viola jones model | CNN Classifier | 95% |

## VIII. CONCLUSION AND FUTURE WORK

The proposed study is going to develop an efficient CNN based system for the continuous detection of driver's drowsiness covering the loophole of the detection time in the previous studies. There were a lot of studies proposed in the past for the detection of driver's drowsiness as explained in Table III of the proposed research. One of the major issues of the previous studies was the delay in detection time and dataset. These studies used physical sensors for monitoring the driver's behavior causes in delay time of detection. The do not detect the face under different circumstances. The accuracy results of detection for these algorithms are not too high.

The main aim of the proposed study is to use a state of the art dataset along with a deep learning algorithm to enhance the efficiency of drowsiness detection. For this, the study uses a big dataset of 2904 images taken from more than 70 participants under all the possible driving scenarios. The dataset is passed from many CNN and statistical filter for an efficient preprocessing. This dataset is used for algorithm training, testing, and validation in order to generate the best results. The proposed study achieves a maximum accuracy of 95%. In past the maximum accuracy of detection was 92.8% that is discussed in Table III. The proposed study gives the highest accuracy of any algorithm for drowsiness detection till date.

The accuracy of the proposed model is the maximum accuracy achieve by any model for drowsiness detection till date. But there exist some loopholes. This model did not detect the drowsiness while driver is wearing shaded glasses. The position of the camera placement over the steering wheel is much important aspect in this scenario. The study covers almost all scenarios of driving but there may exists some scenarios that the study may not cover under detection. This is a weakness for up-and-coming scientists. In the future, a system that uses a dataset larger than the one we now use and can identify tiredness in drivers wearing sunglasses may be developed. By using various deep learning techniques, a system that performs more correctly than the suggested system could exist.

## ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at the Northern Border University, Arar, KSA for funding this research work through the project number "NBU-FFR-2024-1584-01".

# A Fire and Smoke Detection Model Based on YOLOv8 Improvement

Pengcheng Gao*
School of Cyber Security, Gansu University of Political Science and Law, Lanzhou 730070, Gansu, China

***Abstract*—The warning of fire and smoke provides security for people's lives and properties. The utilization of deep learning for fire and smoke warning has been an active area of research, especially the use of target detection algorithms has achieved significant results. For improving the fire and smoke detection performance of model in different scenarios, a high-precision and lightweight improvement based on the model of You Only Look Once (YOLO), is developed. It utilizes partial convolutions to reduce the complexity of model, and add an attention block to acquire the cross-space learning capability. In addition, the neck network is redesigned to realize bidirectional feature fusion. Experiments show that it has significantly improved the results for all metrics in the public Fire-Smoke dataset, and the size of the model has also been widely reduced. Comparisons with other popular target detection models under the same conditions indicate that the improved model has the best performance as well. In order to have a more visual comparison with the detectability of the original model, the heatmap experiments are also established, which also demonstrate that it is characterized by less leakage rate and more focused attention.**

***Keywords—Fire and smoke detection; deep learning; computer vision; YOLO***

## I. Introduction

The warning of disaster is a broad field that many researchers have devoted themselves to study in recent years. There are many categories of disasters, including floods and fires, which must be monitored at an early stage, so that precautionary measures can be taken. It is very necessary to detect and monitor disasters including floods, typhoons and fires at an early stage and take relevant preventive measures. Among these disasters, fire is one of the most hazardous, which often inflicts a serious threat to people's property and lives, and also causes huge losses to public facilities and ecological resources [1].

In many cases, the fire detection is still based on the traditional smoke sensor and temperature sensor [2], [3], [4]. When the value detected by the sensor exceeds a certain threshold, the alarm and fire extinguishment system will be activated [5]. This method is more effective in some relatively small indoor environments, but in some scenes, like a factory and forest, which are relatively open and easy to cause the rapid spread of fire, this method is often unable to quickly detect the occurrence of fire, and it is difficult to accurately provide the fire location information. Therefore, how to improve the ability of fire detection, as well as accurately and rapidly detect the fire have become the focus and direction of current research in this area. With the popularity of video surveillance and the iteration of image processing, it becomes a mainstream of current research to detect the occurrence of fire by learning the characteristics of flame and smoke through processing image sets. This research is mainly divided into three categories: target classification models, target segmentation models and target detection models [6].

Since target classification models can only determine whether flame and smoke are present in the image, and target segmentation models need to build a large number of pixel-level labelled datasets for training, both types of models have certain limitations when performing such tasks. Target detection models have the functions of classifying and locating the target to be detected, which can quickly detect whether a fire occurs or not, and also accurately select the target through the anchor box, so the target detection model is more suitable for dealing with this type of task, which is also a future research direction.

Existing models have two shortcomings in flame and smoke detection, which are worthy of continuous improvement. Firstly, at the time of initial fire, the measurement of object is little and the feature is not distinct enough, thus making it more difficult to be detected. Secondly, the current target detection models for the flame and smoke are generally too complicated to be applied to the equipment with different performance, resulting in insufficient practicability. The main reason for this problem is that the modules used in the model improvement scheme proposed by the researchers, as well as the improvements to the model structure, significantly increase the complexity of inference, resulting in slower model computation [6]. For the existing issue, the objective of paper is to achieve a lightweight and high-precision object detection model by improving an existing model. The significance of this study is to make the improved model more practical, which can be easily deployed on various terminal devices for detection tasks in different scenarios, so that the model has the ability to detect and locate the flame and smoke targets more quickly and accurately in order to reduce the losses caused by disasters.

The work established in this paper is based on the improvement of YOLOv8n. Under the premise of improving the precision, we compressed the magnitude of model by reducing the parameters required for the operation. As a result, the developed model has the characteristics of both high precision and light weight. Three major innovations are shown below:

*1) For* the purpose of decreasing the size of model, A new block C2f-faster is constructed by replacing the Bottleneck Block in the original YOLOv8n with FasterNet Block.

*2) By* utilizing the Efficient Multi-scale Attention (EMA) block into the network, it is more conducive to fuse the contextual information at different scales, and make the neural network extract the feature from the input better.

*3) By* redesigning the Neck layer of yolov8n, the Bidirectional Feature Fusion (BiFF) is realized to improve the detectability.

The rest part involves five sections: Section II presents the related researches. Section III illustrates the structure of the YOLOv8n model and its advantages over previous versions, and then introduces the three improvements based on this model. Section IV mainly presents the dataset and setting used in the experiments. Section V demonstrates the effects of different improvement methods through ablation experiments, and the results of comparative experiment with YOLOv3t, YOLOv4t, YOLOv5n, YOLOv6n, YOLOv7t are shown in this Section. Moreover, comparisons of detection and heatmap are also finished. Section VI analyzes the experimental results and summarizes the whole work.

## II. Related Works

The algorithm based on object classification models determines whether the input image contains fire or smoke category information and outputs the corresponding label. Based on the VGG16 model, He et al. [7] introduced an attention block and FPN feature fusion block to obtain an improved classification effect of smoke and smoke-like targets. However, the usage scenario of the improvement has some restrictions. Besides, the situation of smoke cannot be identified. RYU et al. [8] used Harris corner detector and HSV channel to pre-process the flame, and then captured features from Inceptionv3 model to improve the accuracy, but the pre-processing took a long time. Nguyen et al. [9] developed a method which combines the CNN and Bi-LSTM to extract spatial domain and temporal domain features of flame simultaneously. However, the large number of fully connected layers in the network made the computation heavy, and made it difficult to deploy.

Compared with the target classification model that can only judge whether there are flame and smoke in the image, the target segmentation model can get the shape, size and other details from the loaded pictures, and then judge the spread trend of fire. U-net, proposed by Ronneberger et al. [10], is a model which is applied extensively in the image segmentation field. It constructs a network similar to the letter U through the encoder and decoder structure, and utilizes this structure to make the output which is extracted by the encoder part fuse in the decoder part to get multi-scale features. Inspired by the complete convolutional network (FCN), Yuan [11] proposed a target segmentation model with good performance in the segmentation of fuzzy smoke images. Frizzi et al. [12] established a network structure based on VGG16 to detect and locate flame and smoke, and outperformed U-net and Yuan-net in different indicators. The algorithm based on the target segmentation model can provide more detailed fire information, but the size of the model is usually large. Besides, a large number of pixel-level labeled datasets are used in the training of this type of model, which will undoubtedly consume a lot of time.

The algorithm based on object detection model can classify and locate multiple flame and smoke targets by different anchors in the input image. Park et al. [13] integrated the ELASTIC block [14] into the backbone of YOLOv3 to detect candidate regions, generated a bag-of-features (BoF) histogram for the target region, and then passed the BoF into the random forest classifier to detect the target. It is difficult to deploy the model to embedded devices because of its high requirement of graphics operation. Xue et al. [15] mainly added a 160*160 head into the YOLOv5 model to obtain a better capability when detecting small targets and utilized the CBAM [16] that includes broader identities to improve the perception of model. From the experimental results, the value of mAP is improved, but the value of Frame Per Second (FPS) is decreased.

## III. Improved Methodology

YOLOv8 is a one-stage target detection algorithm released by Ultralytics in January 2023 based on YOLOv5 [17]. This version can be used in performing image classification, target detection, target tracking and other tasks. The entire network is composed of three components: the Backbone extracts feature maps from the loaded picture; the Neck aggregates the features of different layers and passes it to the predicting part; and the Head makes predictions about the target and its location information. Compared with the previous version of YOLO algorithm, YOLOv8 demonstrates better detection performance on the COCO dataset. Moreover, YOLOv8 provides different models according to the size, such as n, s, m, l, and x. The model becomes larger in turn, which is controlled by depth, width, and max channels. The model chosen for improved is the smallest of the above, YOLOv8n, which suits better with the objective of this work.

The constitution of YOLOv8 is displayed in Fig. 1. To realize further lightweight, the C3 block in the former version is updated by the C2f block in YOLOv8 [18]. In the Neck layer, the former convolutional module in the up-sampling layer in YOLOv5 is deleted, and the output from different layers are straightly loaded into the up-sampling stage [19]. Decoupled Head is adopted in the Head part, which captures the position of target and category information separately and aggregates them after learning in different paths of network. Compared with the Coupled head in YOLOv5, it can efficiently enhance the model’s performance to generalize and increase its robustness [20]. Unlike the Anchor-Base used in the previous YOLO series to predict the position and size of the Anchor, YOLOv8 uses the Anchor-Free detection method, which means it does not need to preset the Anchor, thus reducing the time-consuming and required arithmetic power [17].

The flame and smoke detection task is often limited by device resources. In order to be applied to as many different scenarios as possible, a lightweight and low latency model is a basic condition for it to be deployed on different devices. On this basis, realizing high accuracy as much as possible is also an improvement direction for the model. A new model called YOLOv8n-EBF is improved and proposed.

Fig. 2 shows the main structure of YOLOv8n-EBF. As mentioned before, YOLOv8n-EBF mainly makes three improvements on the original network. Firstly, a new FasterNet Block consisting of partially convolution is used to change the Bottleneck in the C2f to constitute a new module called C2f-faster. There are total seven C2f-faster modules used in the network, which can effectively decrease the magnitude of the network and further affect the computing speed. Secondly, the EMA block is used to strengthen the extraction of target features. Finally, a modified Neck layer structure is utilized for fusing the output feature maps of four C2f-faster modules in the Backbone across space. The extracted multi-scale features are loaded into the network to obtain the detecting improvement. The three followed subsections specify the details of each modified module.

### *A. The Improved C2f Module*

The C2f references the design idea of Efficient Layer Aggregation Networks [21] to obtain richer gradient information by branching more gradient streams in parallel, which in turn results in higher accuracy and lower latency.

The convolutional kernels and operations are widely used in deep learning networks, and the process often require a large amount of computational support. For alleviating the issue of slow inference process generated by convolutional operation in the model, Chen [22] proposed a new partial convolution, called PConv. It replaces the regular form of convolution by utilizing one PConv of $c_p$ channels and one 1×1 convolution of $c - c_p$ channels to combine a hammer-like structure, as shown in Fig. 3(a) and Fig. 3(b). Compared with one regular $k * k * c$ kernel convolution, shown in Fig. 3(c), the participants in the improved convolution module is reduced from $k^2 \cdot c$ to $k^2 \cdot c_p + (c - c_p)$, which not only achieves a similar effect but also greatly reduces the amount of computation when it is used for calculation. Based on the partial convolution, they constructed a new network module, FasterNet Block, shown in Fig. 4 below, which is used to extract features. It contains one 3×3 PConv layer and two 1×1 regular Convolution layers, which has a similar structure and function with Bottleneck block. Therefore, it is utilized to propose an improved module called C2f-faster, shown in Fig. 5 below.

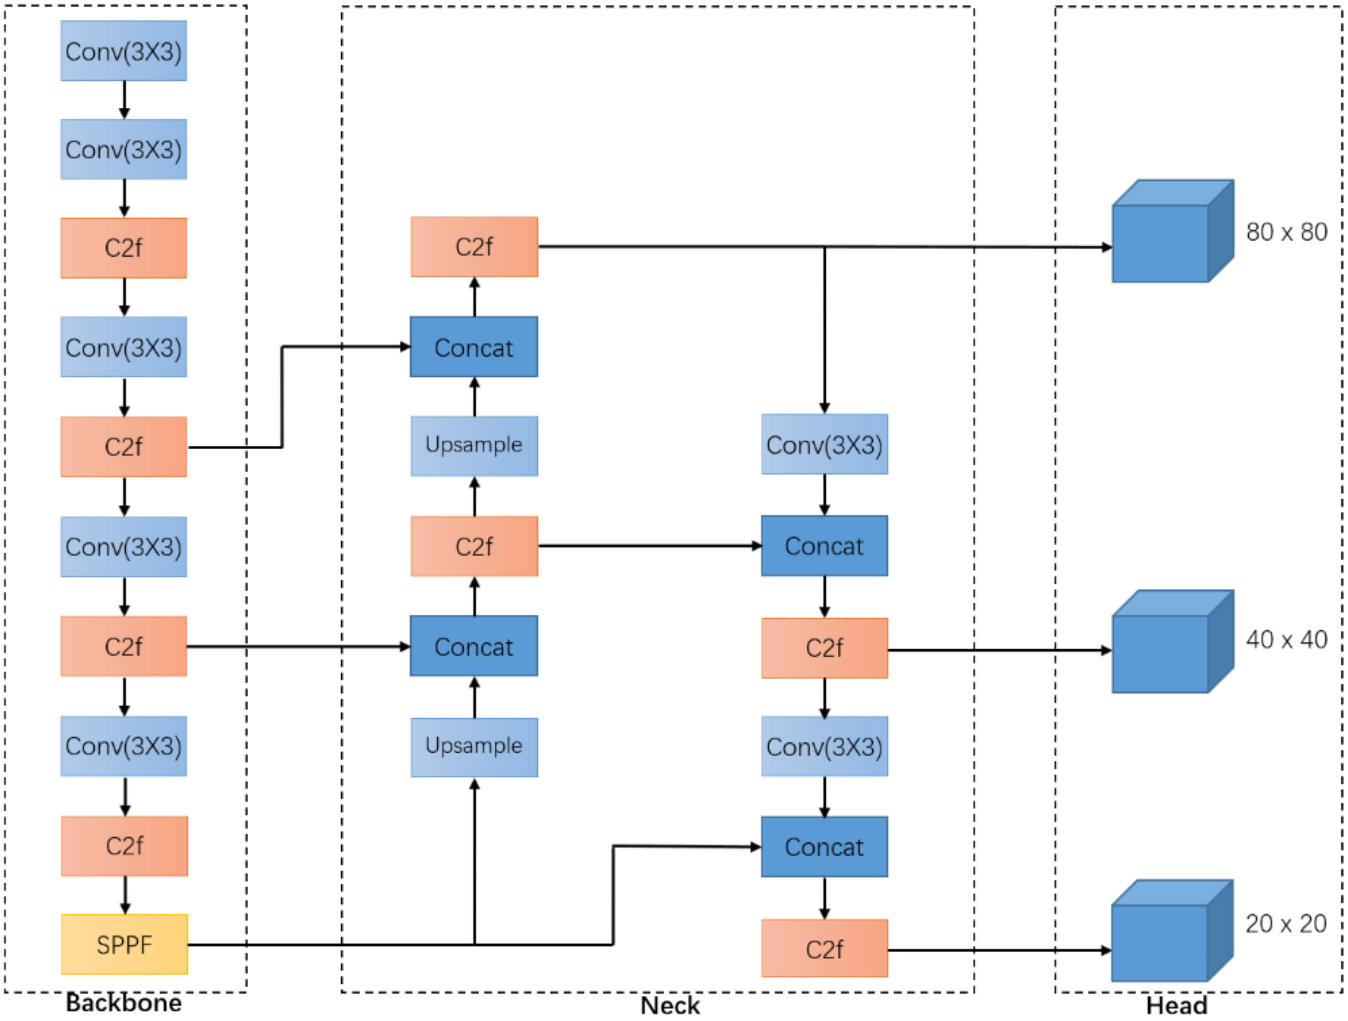

Fig. 1. The structure of YOLOv8.

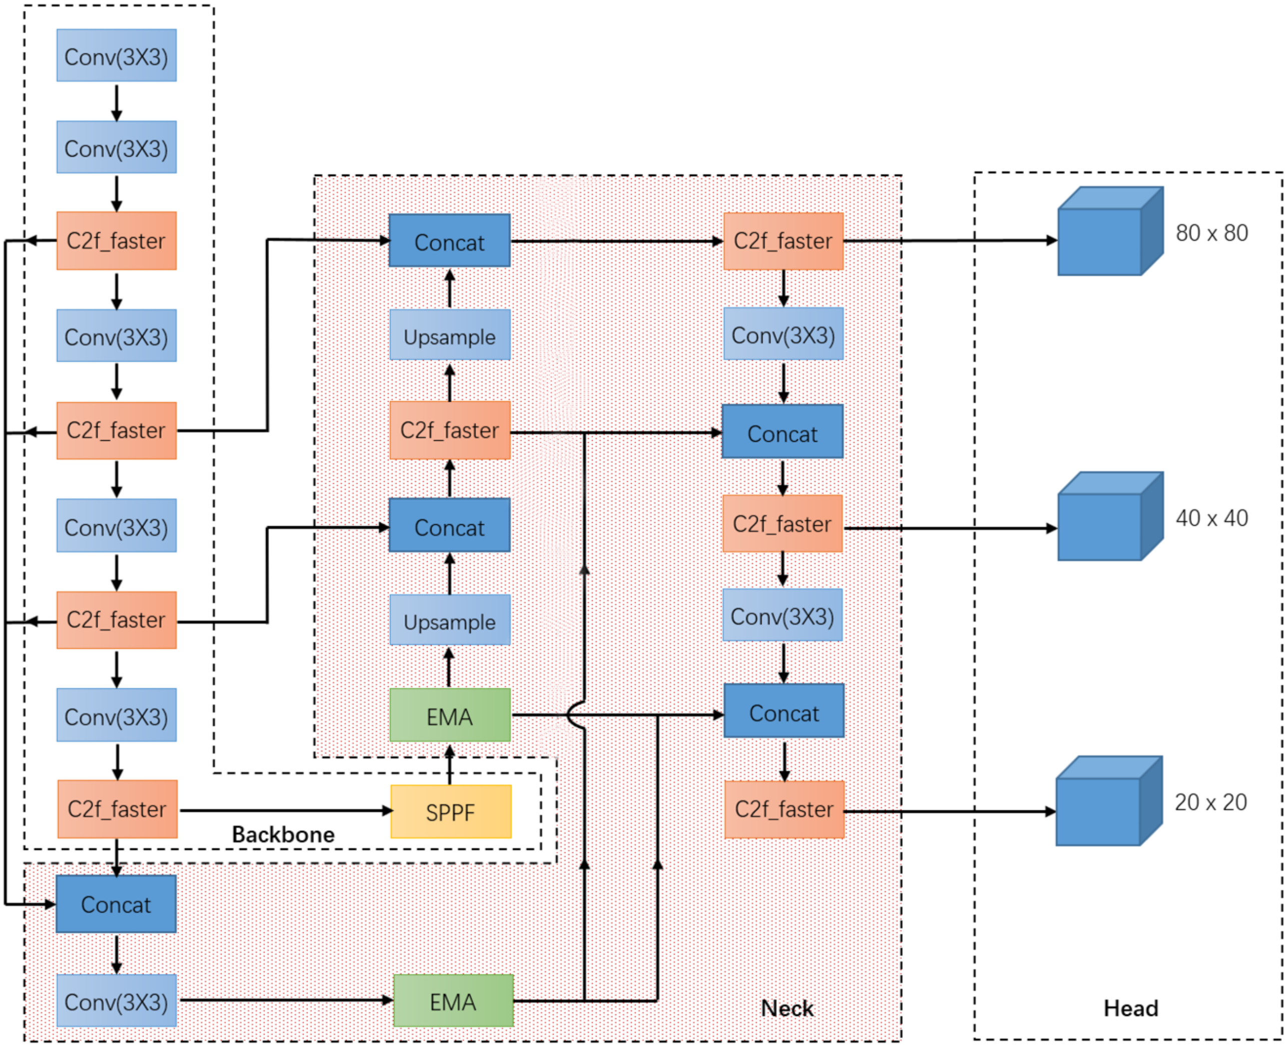

Fig. 2. The structure of YOLOv8n-EBF.

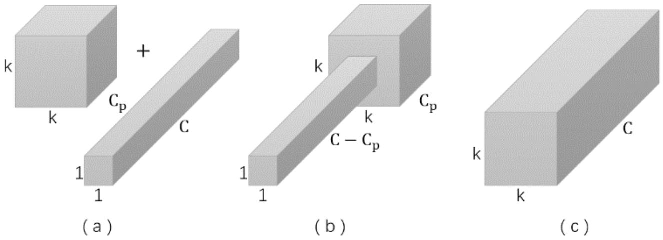

Fig. 3. (a) Structures of convolutional variants; (b) A hammer-like structure which is constituted by one PConv and one 1*1 Conv; (c) One regular k*k*C kernel Conv.

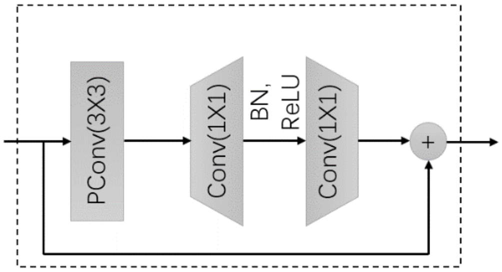

Fig. 4. The structure of FasterNet block.

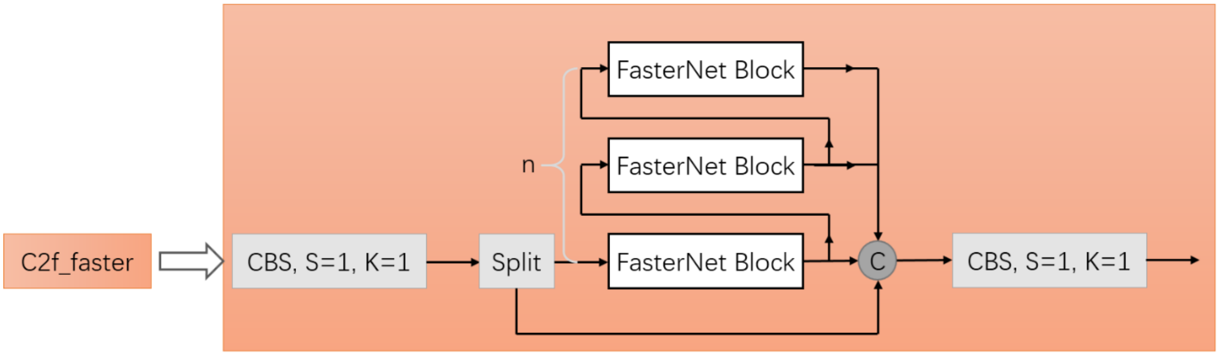

Fig. 5. An improved C2f formed by replacing bottleneck blocks with FasterNet blocks.

## B. Efficient Multi-Scale Attention (EMA) Module

By invoking the attention module can capture the important image information, allowing the model to focus on detecting the key areas and obtaining the significant features of the target, which plays an important character in all kinds of computer vision tasks [23]. In this paper, EMA module [24] is utilized into the improved model to enhance the detection capability. Fig. 6 reveals the principle of EMA module. For the input feature map $X\in R^{C\times H\times W}$, EMA divides the channel dimension into G sub-features, $X=[X_0,X_i,\ldots,X_{G-1}]$ , $X_i\in R^{C\times H\times W}$, and makes $G\ll C$, which enable the model to obtain different semantic features. This module captures the weights of grouped features during two parallel paths which contains one 1×1 convolution path and one 3×3 convolution path. The parallel substructure reduces the depth of the networks, and avoids the dimensionality reduction by merging some of the channels at the same time, maintaining the features of each channel. Similar to the Coordinate Attention [25], a global average pooling operation is added for encoding operations in the X and Y directions of the channel in the 1×1 branch, and these two encoded features are concatenated and convolved with a 1×1 kernel convolution. The output is then decomposed into two vectors and fitted using a Sigmoid nonlinear activation function. Finally, the cross-channel interaction is achieved by multiplying the aggregated channel attention, which efficiently captures the inter-channel dependencies and preserves the spatial information in the channel.

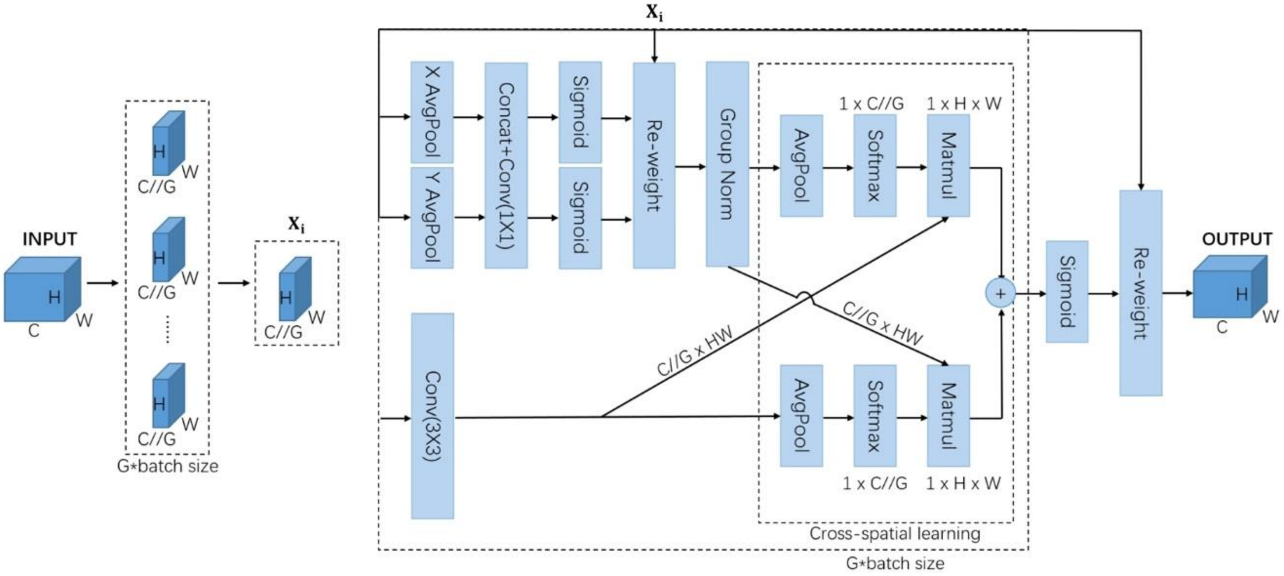

Fig. 6. The structure of EMA module.

In another branch, one 3×3 convolutional kernel is added for capturing multi-scale features and constitutes with the 1×1 branch for aggregating the cross-space information. The main approach is to encode the outputs of the 1×1 branch and the 3×3 branch by a global average pooling operation and convert them to a $1\times C//G$ dimensional shape after passing through a normalization function and a reshape operation, and then multiply it with the feature vector $C//G\times H*W$ of the other branch after dimensionality reduction, as shown in the formula below:

$$R=R_1^{1\times C//G}\times R_2^{C//G\times H*W} \quad (1)$$

The output $R$ that fuses contextual information from different branches enables the neural network to produce a better attention for the feature map. Moreover, it is multiplied with the original input after a Sigmoid activation function and a dimensional transformation to obtain the final output feature map. Since the size of EMA's input and output are same, which makes it convenient to directly add into the YOLOv8n network.

### C. Redesigned Neck Layer

The feature fusion of different scales is a significant approach to improve image processing. To obtain richer image feature information, an improved structure for YOLOv8n network with Bidirectional Feature Fusion (BIFF) is proposed, as shown in Fig. 7. To entirely utilize the important semantic information in the high-dimensional feature maps as well as the target feature information contained in the medium- and low-dimensional feature maps, we aggregated the feature maps of four different layers in the backbone and then fused them with others in the neck part.

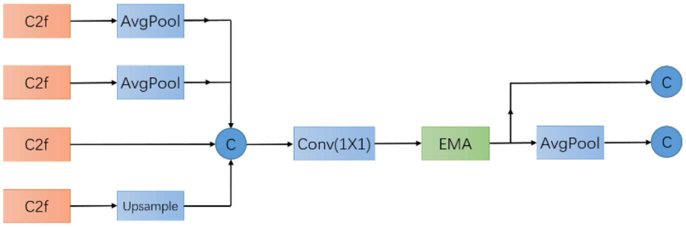

Fig. 7. The process of BiFF network.

According to the structure diagram of the original YOLOv8n, it can be known that there are four C2f modules in the backbone, which can generate four different scales of feature maps, i.e., 160×160, 80×80, 40×40, and 20×20. In the redesigned neck network, the low-dimensional feature maps of 160×160 and 80×80 are chosen to be reduced to the 40×40 size by the average pooling operation, and the high-dimensional feature map of 20×20 was scaled up to the size of 40×40 by up-sampling operation. The low-dimensional feature maps tend to contain more spatial information due to smaller receptive fields, while the high-dimensional feature maps with larger receptive fields tend to contain more semantic information [26]. The reason for choosing to scale these three feature maps to the size of 40×40 is that this size of feature map can contain the information in both the low- and high-dimensional feature maps, and will not cause the loss of information due to being too large or small. These four feature maps are concatenated in series and then downscaled by a point wise convolution and fed into the EMA module. As mentioned in the subsection above, The EMA module mainly works on slicing the feature information of C channels into G groups and performs feature extraction on different parallel paths, and finally generates the feature maps that incorporate multi-scale information. In one branch, it is combined with another 40×40 map in the original Neck network, and in another branch, it is scaled to 20×20 for combining with the same size feature map in the network by average pooling operation. At this point, an improved Neck network for cross-space feature fusion induced by the backbone layer is constructed.

The network has three main advantages as followed:

*1) This* network is combined with the original Neck network to realize two-way feature fusion, which strengthens the expression of features, and thus improves the performance of the detector;

*2) It* mainly consists of parallel structure, which is faster in computation;

*3) It* mainly utilizes four existing feature maps. The subsequent experimental part shows that this improvement only increases a few parameters.

## IV. Environment and Dataset

### A. Experimental Environment and Evaluation Criterion

This work is established in the following environment: the CPU is an 8-core Xeon Gold 5218R; the memory capacity is 32GB; the graphics card is a Tesla V100-SXM2 with 16GB of memory. The version of Python is 3.8.8, Pytorch is 1.8.0, CUDA is 11.7, and YOLOv8n is ultralytics 8.0.147. The models in the experiments did not use pre-trained weights, and the main hyperparameter values are shown in Table I below.

In the experiment, the Precision, Recall, Average Precision, mAP@.5, Parameters and GFLops are chosen as the evaluation criterion. The criteria for sample classification are shown in Table II.

TABLE I. Description of the Main Hyperparameters

| Hyperparameter | Value |
|---|---|
| Lr | 0.01 |
| Lrf | 0.01 |
| Momentum | 0.937 |
| Weight_decay | 0.0005 |
| Batch-size | 16 |
| workers | 8 |
| Epochs | 200 |

TABLE II. Criteria for Sample Classification

| Classification | Explanation |
|---|---|
| TN | Predicting the correct quantity of negative samples |
| FN | Predicting the incorrect quantity of negative samples |
| TP | Predicting the correct quantity of positive samples |
| FP | Predicting the incorrect quantity of positive samples |

*1) P (Precision),* the scale of positive samples predicted correctly to samples predicted as positive, is calculated as:

$$P=\frac{TP}{TP+FP} \quad (2)$$

*2) R (Recall),* the scale of positive samples predicted correctly to all true positive samples, is calculated as:

$$R=\frac{TP}{TP+FN} \quad (3)$$

*3) AP (Average Precision),* which reflects the average prediction ability for a single target category. The higher the value of AP, the better the detectability of the model in this category. The calculation formula is:

$$AP=\int_0^1 P(R)\, dR \tag{4}$$

*4) mAP,* which reflects the average predictive ability of the model for all categories, i.e., averaging the AP values for all categories, is calculated as follows:

$$mAP=\frac{1}{n}\sum_{i=1}^{n}(AP)_i \tag{5}$$

where, n means all predicted categories, and $(AP)_i$ means the average precision of the ith category. mAP@.5 is used as an evaluation criterion in the experiment, which means that when the overlap between the predicted box and the GT box is greater than 0.5, i.e., IoU>0.5, the prediction is judged to be correct, and the relevant values are calculated using this as a benchmark.

*5) Parameters* and GFLops which reflect the model size and computational complexity, are used to measure the ease with which a model can be deployed in end devices.

## B. Dataset

A high-quality dataset allows the model to extract features more efficiently during training. We selected a public dataset Fire-Smoke, which contains 3961 photos. The labels of the dataset are categorized into Fire, Smoke, compared to the single-label dataset, this dataset enables the model to detect both fires that can be directly observed and fires that are obscured by objects by detecting smoke.

Training and validation sets are split 9:1. Fig. 8 displays some representative pictures. The scenes cover indoor scenes such as living rooms, bedrooms, offices, and hallways, as well as outdoor scenes such as factories, forests, streets, and buildings. Besides, it contains pictures at different distances from close view to distant view, it contains pictures with only flames, pictures with only smoke, and pictures with both flames and smoke.

Overall, the selected dataset contains a rich collection of scenarios covering enough features of flames and smoke to make the trained model generalizable and applicable to detection work in different environments.

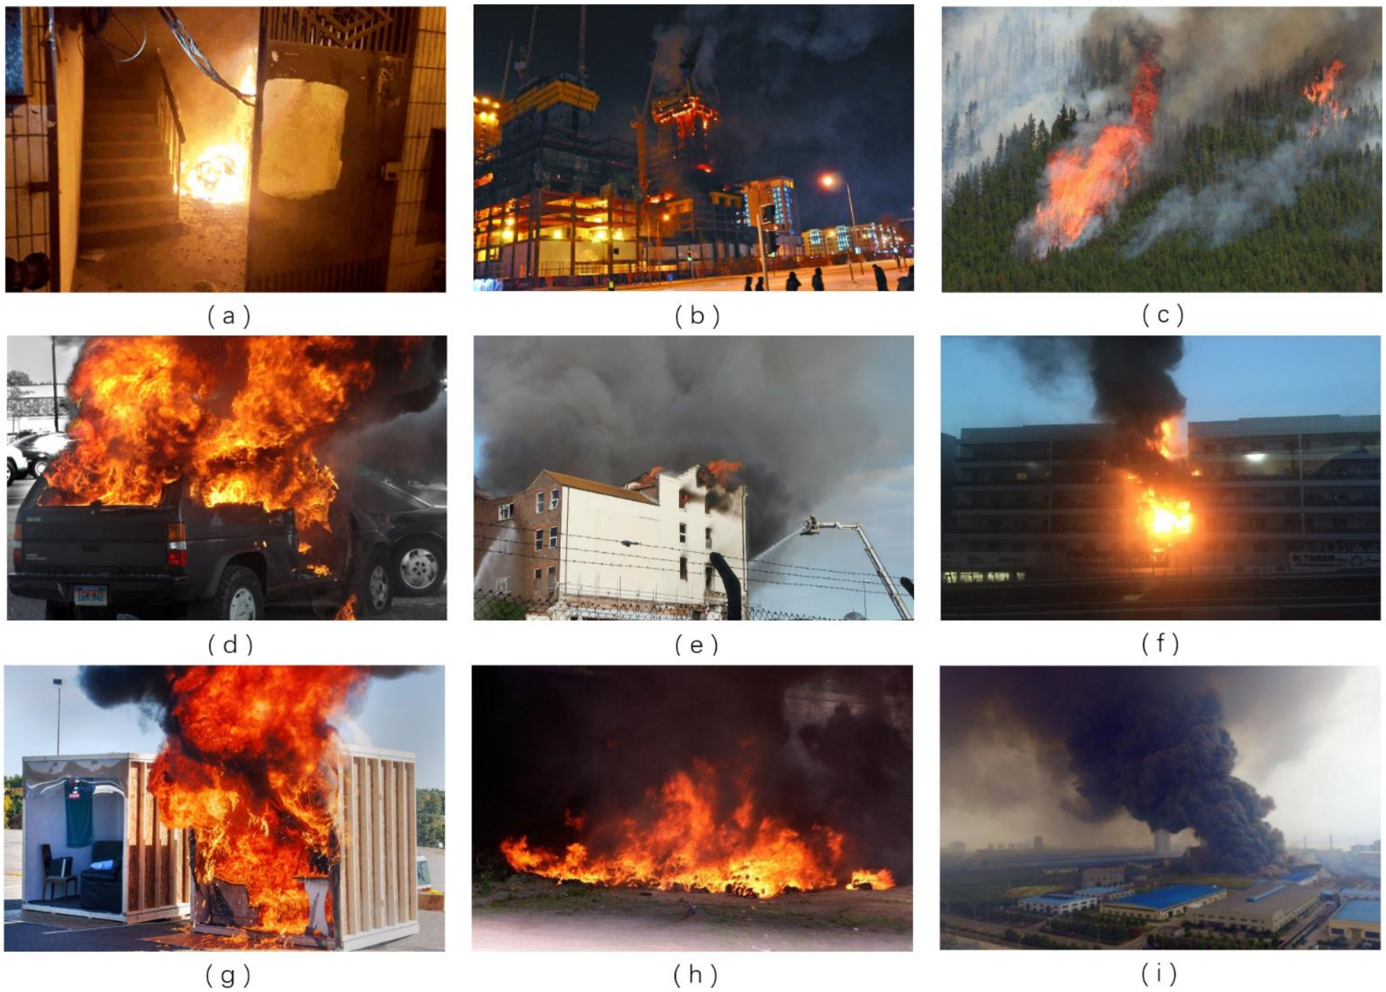

Fig. 8. Representative fire and smoke images selected from the dataset: (a) Fire in a corridor, (b) Fire in a building, (c) Fire in a forest, (d) Fire in close-up, (e) Fires in mid-range, (f) Fires in far-range, (g) Images dominated by flames, (h) Images with both flames and smoke, (i) Images dominated by smoke.

## V. Results and Analysis

### A. Ablation Experiment

To verify the effects of different methods proposed in this work on the original network, four sets of ablation experiments were carried out for YOLOv8n.

The first experiment used C2f-faster modules to replace all the C2f modules in the network. The second experiment added an EMA module after the SPPF module. The third experiment used BiFF to form a new Neck network. In the end, the fourth experiment used the three improvement methods mentioned above to form the complete network YOLOv8n-EBF. All the experiments were established on the same environment. The results are listed in the Table III.

From the ablation experiments, the Precision, Recall, and mAP@.5 of the redesigned network are improved by 4.7%, 1.9%, and 3.1%, respectively, compared to YOLOv8n, while the parameters decrease by 19.7%, and GFLops decrease by 18.3%. Replacing C2f with C2f-faster efficiently reduces parameters, and increases Precision as well as mAP@.5 by 3.7% and 1.5%, respectively, but Recall has a slight decrease. The addition of the EMA module increases the network with almost no parameters and GFLops, and enables the neural network to generate better attention for the feature maps by fusing contextual information at different scales, resulting in a certain improvement in the overall detection ability. A new neck network was constructed by adding a bottom-to-top path to enable bi-directional feature fusion with the network. With only a 3.7% growth in parameters, Precision increases by 1.0%, Recall increases by 1.5%, and mAP@.5 increases by 1.3%, indicating that the improved neck network can indeed have positive effects. In summary, compared to the YOLOv8n, the overall performance of YOLOv8n-EBF model is improved with a large reduction in complexity. These improvements result in a lighter model with higher accuracy at the same time.

### B. Comparative Experiment

In order to further verify the difference in performance between the YOLOv8n-EBF and other models on the flame and smoke detection, this paper conducts comparative experiments. Five classical small-sized models in the field of target detection, i.e., YOLOv3-tiny, YOLOv4-tiny, YOLOv5n, YOLOv6n, YOLOv7-tiny, are selected. The performances of each model after training are displayed in Table IV.

YOLOv3-tiny has the largest number of Parameters and GFLops among different versions of YOLO above. It has more than twelve million Parameters, which is five times more than the improved YOLOv8n-EBF, and 19.0 GFLops, which is 2.8 times more than the latter. In terms of model size, YOLOv8n-EBF is 4.8MB, only 10.4% of YOLOv4t, which is the smallest among all models and can be easily deployed in different devices. In terms of detection ability, YOLOv4-tiny has the worst performance in this experiment, with a value of mAP@.5 of only 43.1%, and YOLOv8n-EBF has an improvement of 74.2% for this parameter. The only other models with a mAP@.5 above 70% are YOLOv5n, YOLOv6n, and YOLOv8n, and their performance is relatively similar, with results close to 71.9%. Compared to YOLOv8n-EBF, the latter has a mAP@.5 of 75.0%, which is the highest of all models. In addition to this, the other parameters of YOLOv8n-EBF are at the highest level compared to other models.

### C. Comparison of Detection Effects

At the end of training, the obtained weight parameter model is used to detect the target samples and mark the location of the detected objects. The results are shown in the Fig. 9 below, with the original image, the detected image of YOLOv8n, and the detected image of the improved model in the left-middle-right of each row, respectively.

TABLE III. The Results of Ablation Experiments

| Model | Parameter | GFLops | P/% | R/% | mAP@.5/% |
|---|---|---|---|---|---|
| YOLOv8n | 3011238 | 8.2 | 73.1 | 63.4 | 71.9 |
| YOLOv8n-C2f-faster | 2306038 | 6.4 | 76.8 | 63.2 | 73.4 |
| YOLOv8n-EMA | 3011252 | 8.2 | 74.4 | 64.2 | 72.6 |
| YOLOv8n-BiFF | 3122100 | 8.5 | 74.1 | 64.9 | 73.2 |
| YOLOv8n-EBF | 2416914 | 6.7 | 77.8 | 65.3 | 75.0 |

TABLE IV. The Results of Comparative Experiments

| Model | Parameter | GFLops | Size/MB | P/% | R/% | mAP@.5/% |
|---|---|---|---|---|---|---|
| YOLOv3t | 12133156 | 19.0 | 23.2 | 67.8 | 61.0 | 66.5 |
| YOLOv4t | 6056606 | 16.4 | 46.3 | 30.4 | 69.9 | 43.1 |
| YOLOv5n | 2508854 | 7.2 | 5.0 | 73.7 | 63.4 | 71.6 |
| YOLOv6n | 4238342 | 11.9 | 8.3 | 75.7 | 62.8 | 71.5 |
| YOLOv7t | 6017694 | 13.2 | 11.7 | 67.9 | 67.2 | 69.6 |
| YOLO8n | 3011238 | 8.2 | 6.0 | 73.1 | 63.4 | 71.9 |
| YOLOv8n-EBF | 2416914 | 6.7 | 4.8 | 77.8 | 65.3 | 75.0 |

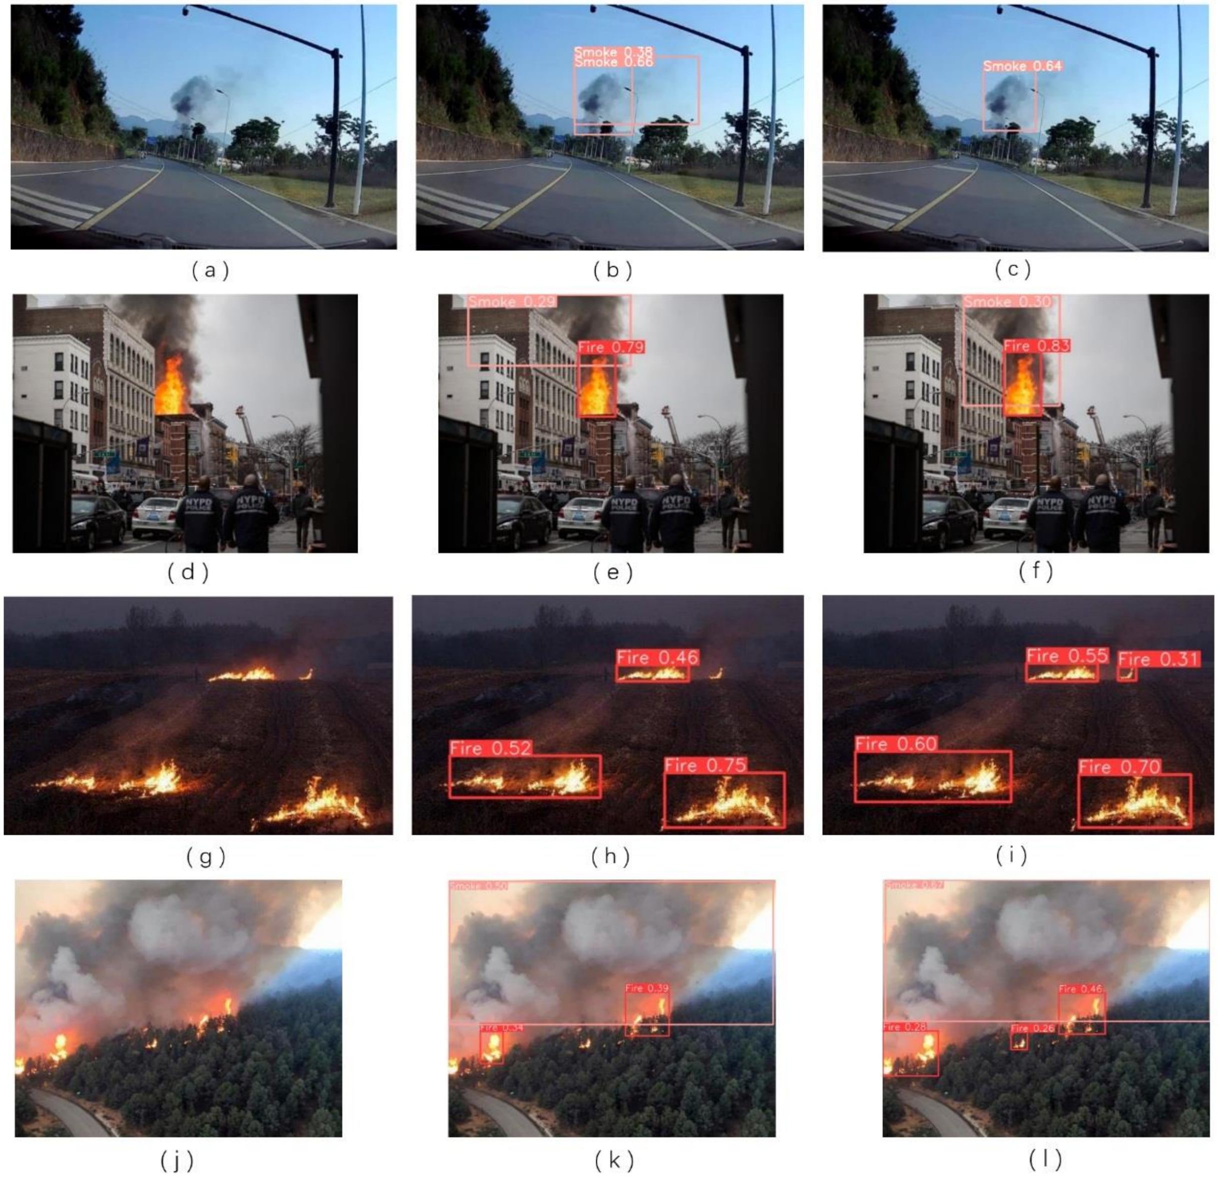
*1) In* the detection comparison of Fig. 9 (a) with a bright light and unobstructed situation, both the original YOLOv8n and YOLOv8n-EBF are able to detect the smoke in the picture, but the anchor box of the former model locates inaccurate compared to the improved network, as shown in Fig. 9(b) and Fig. 9(c).

*2) In* the detection comparison of Fig. 9(d) with a low light and obstructed situation, the original model is capable of detecting the fire in the picture, but the inaccuracy range of the anchor still exists. As shown in Fig. 9(e) and Fig. 9(f), a larger portion of the selected box for smoke is a building rather than a target to be detected, while the improved model is more accurate obviously.

*3) In* the detection comparison of Fig. 9(g) with a high contrast, the YOLOv8n-EBF detects all four targets which is shown in Fig. 9(i), but the result of original YOLOv8n in Fig. 9(h) only detects three large-sized targets but not the smallest flame in the picture, which appeared to be a missing detection.

*4) In* the detection comparison of Fig. 9(j) with a low contrast, the original YOLOv8n model also occurs a similar result, which detects one smoke target and two flame targets, but not the small flame located in the center of the picture, as shown in Fig. 9(k). Moreover, when framing the flames on the left side, it appears more obvious that the anchor box cannot cover the target, i.e., the framing is inaccurate. However, it can be observed from Fig. 9(l) that YOLOv8n-EBF performs significantly better, detecting all targets and being able to accurately localize them.

Overall, the improved model has a better detectability for different sizes, and can accurately recognize the target in the presence of environmental interference and object occlusion.



(a) (b) (c)

(d) (e) (f)

(g) (h) (i)

(j) (k) (l)

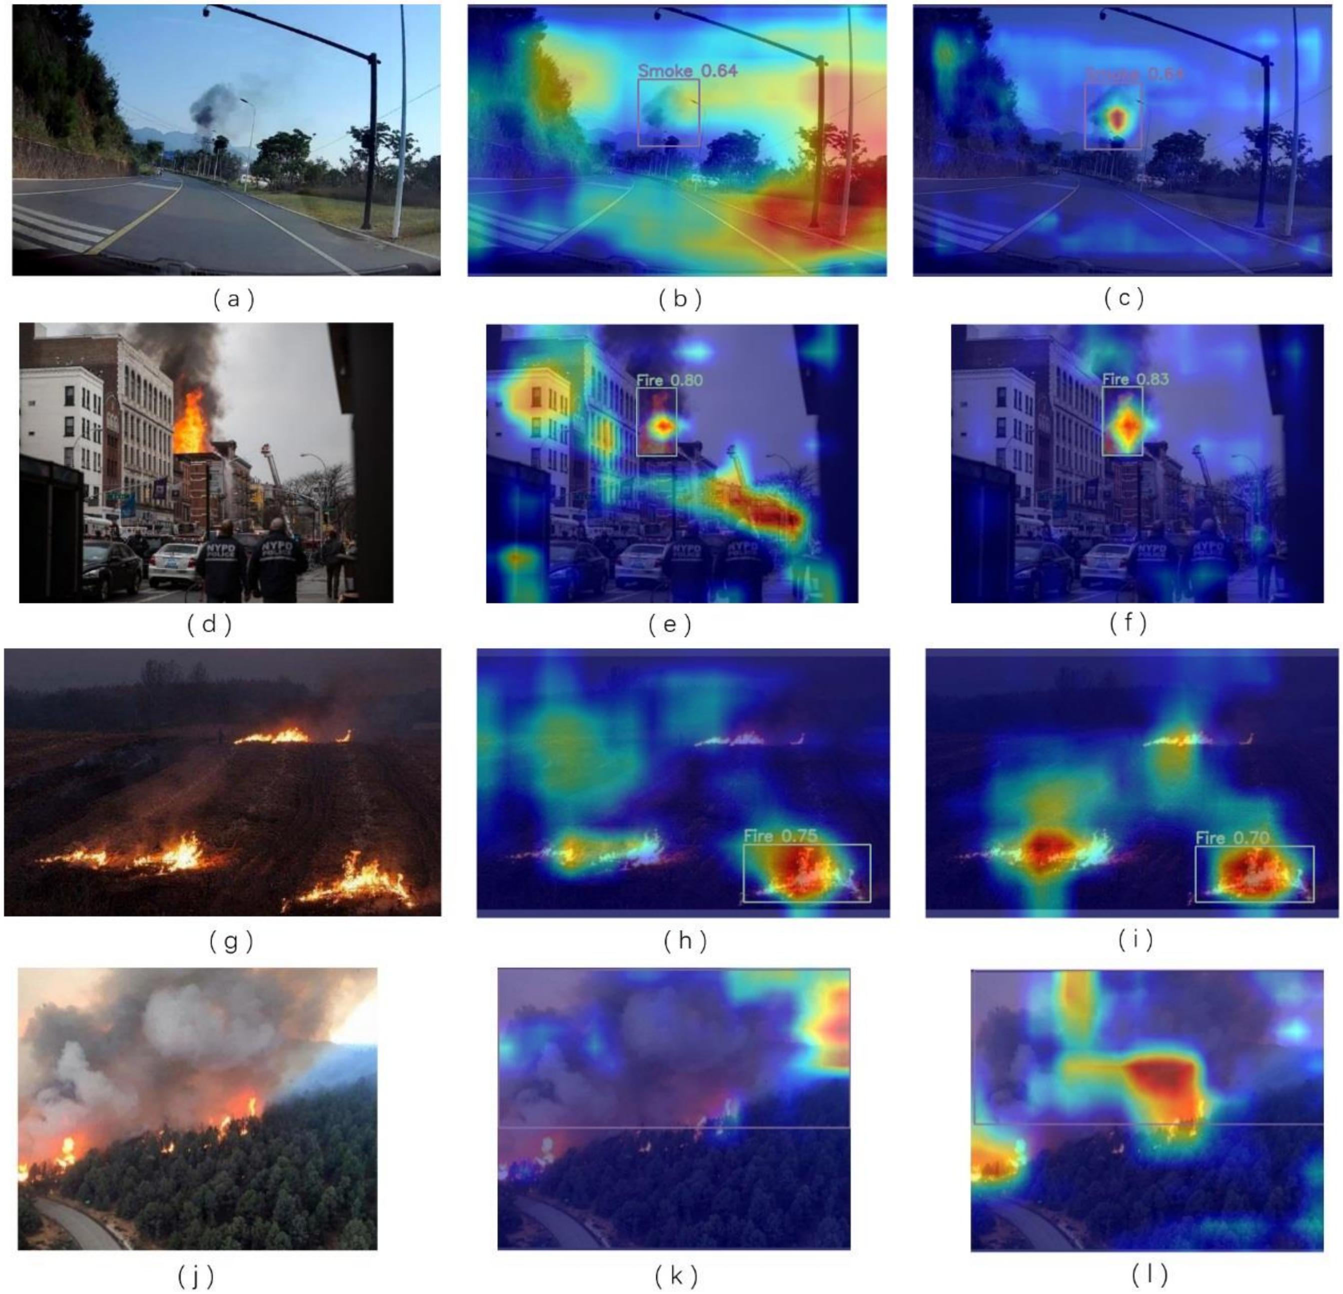
Fig. 9. Comparison of detection effects of original image, YOLOv8n and YOLOv8n-EBF.

### *D. Comparison of Heatmap Effects*

In order to have a more intuitive understanding of the focused region of the model on the image and to make the decision-making process of the network better interpretable, Grad-CAM [27] is applied to generate heatmaps in this paper. In order to better compare with for synthesis, we used the same images as above for the experiments. The same images chosen in the previous section are used for comparisons. The settings, especially the layer, are consistent in the experiment, and the results are shown in Fig. 10. The left-center-right of each row shows the original image, the heatmap of YOLOv8n, and the heatmap of YOLOv8n-EBF, respectively.

*1) Comparing* the heatmaps in Fig. 10(a), (b) and (c), the focus area of YOLOv8n is more inclined to the right side of the image, and it is larger and more distributed in the whole heatmap. Compared with the improved network, which focuses on the region of the target to be detected, the latter is more concentrated, which obviously has a better detection effect.

*2) When* comparing the heatmap effect of Fig. 10(d), (e) and (f), the focus area of YOLOv8n also appears to be more scattered, focusing on parts of the image not related to the flame, such as the building in the upper left corner and the extinguished vehicle in the lower right corner. However, the improved model focuses precisely on the flame region.



(a) (b) (c)

(d) (e) (f)

(g) (h) (i)

(j) (k) (l)

Fig. 10. Comparison of heatmap effects of original image, YOLOv8n and YOLOv8n-EBF.

*1) In* the comparison of heatmaps in Fig. 10(g), (h) and (i), YOLOv8n only focuses on two flame targets below the image, and only one flame target is highlighted, i.e. the red area in the picture, while the color covered another flame is lighter, which indicates that the level of attention is not high enough, in addition, this model does not focus on the flame target above the image. Multiple flame targets are better considered in the improved model, not only highlighting the two flames below the image, but also focusing on the target above the image.

*2) In* the comparison of heatmaps in Fig. 10(j), (k) and (l), the highlighted area of the original model is in the upper right, which can be found from the original that this area is not smoke, but a brighter background. YOLOv8n-EBF focuses on a more scattered area than other situations, but it can be seen that the highlighted areas are still the part of flame and smoke.

From the four sets of heatmap comparisons above, we can more intuitively see that YOLOv8n-EBF developed with more focused attention is able to locate the aim more accurately.

## VI. Conclusion

In this paper, three improvements are made to the YOLOv8n model and all experiments are performed on a public dataset. First, ablation experiments are performed to show that each method contributes to the promotion of model's performance. Subsequently, comparison experiments with six different models are conducted to demonstrate that the algorithm not only has better detection capabilities but has a lightweight characteristic at the same time. Finally, the paper conducts detection comparison experiments as well as heat map comparison experiments to provide a more straight-forward comparison with the original network. The conclusion of the established work are as follows:

*1) The* dataset used in this experiment contains abundant pictures of flame and smoke, which makes the model can effectively detect both of them and has a good generalization to apply to detecting tasks in different environments. The ability to detect smoke makes the model capable of detecting obstructed combustible and early fire, reducing the leakage problem caused by single-target detection.

*2) The* improved model involves the EMA blocks and a developed neck network to improve feature fusion in different dimensions. In the comparison experiments of detection and heatmap, this model shows a higher sensitivity and more focused attention to targets of different scales, which enables the model to locate the target more accurately and reduces the leakage rate.

*3) By* replacing the Bottleneck in the original C2f module with a new FasterNet block composed of partial convolution to form the new module called C2f-faster, the complexity is effectively reduced. The parameters of YOLOv8n -EBF are about 2.4 million, the GFLops is about 6.7, and the size of the model is only 4.8MB. Therefore, it is convenient to be deployed in various terminals.

*4) The* improved model achieves 77.8% precision, 65.3% recall and 75.0% mAP@.5. The network has improved Precision, Recall and mAP@.5 by 4.7%, 1.9% and 3.1%, respectively, compared to YOLOv8n, with a reduction of 19.7% in parameters and 18.3% in GFLops. According to the experiments, it can be observed that the complexity of YOLOv8n-EBF has greatly decreased compared to YOLOv8n, while all the indicators measuring the detection performance have been significantly improved. It is superior to the former in terms of performance and complexity optimization, which further confirms the effectiveness of the improvement.

***Abstract*—Heart is the most critical organ of our body for being responsible for regulating and maintaining the blood circulation levels. Globally, heart disease cases are prevalent and constitute a significant cause of mortality. Manifestations such as chest discomfort and irregular heartbeat are notable symptoms. The healthcare sector has amassed substantial knowledge in this domain. Analyzing the research, this paper delves into the concept of utilizing ML algorithms to predict cardiac diseases. In this research will employ a diverse array of machine learning techniques, including decision tree, support vector classifier, random forest, K-NN, logistic regression and naive Bayes. These algorithms utilize specific characteristics to forecast cardiac diseases effectively. Leveraging machine learning algorithms to analyze and predict outcomes from the extensive healthcare-generated data shows considerable promise. Recent advancements in machine learning models have incorporated numerous features, and in this study, propose the integration of these features in machine learning algorithms to forecast cardiovascular ailments. The main objective of this research is to identify the performance of the mentioned machine learning algorithms for predicting cardiovascular elements.**

***Keywords*—Cardiovascular disease; heart; logistic regression; K-NN; machine learning; naïve bayes; SVM**

## I. Introduction

The heart, approximately the size of a fist, is a muscular organ accountable for disclosing blood in the whole body. It plays a vital role as the primary organ in our circulatory system. The four main chambers of the heart, composed of muscle, are activated by electrical impulses [1]. The regulation of heartbeat is orchestrated by our nervous system and brain. Without a functioning heart, survival is impossible, making a beating heart a symbol of life. Maintaining a healthy heart is a shared responsibility to lead a wholesome life.

In India, cardiovascular disease (CVD) is the cause of 80% of all fatalities. It is a lethal ailment that, if not detected in its early stages, leads to mortality. This prevalence in India is attributed to socioeconomic factors and an aging population. “Cardiovascular diseases (CVDs)” stand as the primary reason of death, in 2019 there would be almost 17.9 million deaths, or 32% of total fatalities [2], according to the WHO.

Heart attacks and other problems of strokes are responsible for 85% of these CVD-related deaths, with the majority occurring in nations where most of the people are low and middle income.

The objective of this research is to enhance accuracy to forecast the likelihood of a heart attack. Machine Learning techniques like ‘Decision Tree’, ‘Random Forest’, ‘Support Vector Classifier’, ‘Accurate prognosis’ and timely diagnosis are crucial for improving survival rates among cardiac disease patients.

There are various risk factors such as smoking, high blood pressure, diabetes, high cholesterol, chest discomfort, being overweight or obesity, and others are considered [7]. Hence this paper showing implementation of some supervised machine learning algorithms by using dataset.

## II. Related Works

T. Nagamani et al. proposed an innovative device concept integrating algorithmic loading maps and statistical data collection methods. Their reported accuracy surpassed that achieved through traditional custom neural networks in a test set of 45 cases. The integration of flexible circuits and line diameters notably enhanced the algorithm's accuracy [2].

R. Udaiyakumar et al. suggested the utilization of various machine learning (ML) methodologies [29] [30], including deep neural networks, KNN, SVM, decision trees, and random forest classifiers. Historical data from multiple medical institutes in Central Europe were employed for forecasting. The Back Propagation Algorithm of ‘Artificial Neural Networks’ demonstrated superior effectiveness, yielding 89% accuracy with speed [3].

In a study by Teresa Prince, R. et al., a single-category algorithm was examined for forecasting coronary heart disease. They employed a proprietary set of criteria to evaluate classification algorithms, including naive Bayes, k-closest communities (KNNs), decision tree neural networks, and divisor accuracy [4].

J. Rethna Virgil Jeny et al. proposed four ML classification procedures forecasting the heart problems: There are ‘Logistic Regression’, ‘Naïve Bayes Classifier’, and ‘Decision Tree and Support Vector Classifier’. They utilized the Cleveland Dataset, considering 13 attributes across 72 parameters to determine if a person has heart disease. Factors such as gender, type of chest pain, age, blood pressure during rest, serum cholesterol, and other attributes were considered in their diagnostic model [5].

F. Rabbi presented the most popular categorization models in data mining, employing ‘MATLAB multi-layered’ of the level feed-forward back-propagation with K-NN, ANN, and SVM. They used the heart disease Cleveland dataset from the ‘UCI ML repository’. Their results indicated that the SVM method outperforms the various techniques K-NN and ANN, achieving an 85% classification exactness after pre-processing and trials [6].

S. J. Priya, A. S. Ebenezer, D. Narmadha, and G. N. Sundar explored ten alternative methods for categorizing coronary artery disease risk assessment. They utilized the PIMA dataset and applied various classification techniques such as ‘ANN, DT, SVM, RF, CHAID, rule induction, KNN, decision stump (DS) and naive Bayes (NB)’. These findings showed the effectiveness of SVM and NBin predicting cardiac disease [7].

Jinjri Wada et al. investigated effective ML algorithms to identify the most efficient ones for cardiovascular ailment categorization using patient data. Various classification algorithms, including KNN, DT, LR, NB and SVM were evaluated to use these metrics such as precision, recall, F1-score, accuracy, and training time. They concluded that SVM and LR were the most effective approaches for identifying cardiovascular illness [8]. Maintaining the Integrity of the Specifications.

Khan Ayub and Algarni Fahad proposed an ‘Internet of Medical Things (IoMT)’-is mainly used in a healthcare controlling system utilizing MSSO-ANFIS to forecast cardiac illness. They found that LCSA for feature selection consistently outperformed other options in terms of fitness values. Their novel MSSO-ANFIS technique exhibited a higher level of performance compared to existing methods, achieving higher legibility, recall, F1-score, accuracy, and the low arrangement error [9].

Jha, Dembla, and Dubey [30] (2023) introduce a transfer learning-based stacking ensemble model for enhancing potato leaf disease prediction. Their approach achieves a notable accuracy of 95.8% and an F1 score of 0.94, demonstrating improved predictive capability. The ROC curve exhibits a high AUC of 0.97, indicating excellent model discrimination.

Meshram and Dembla [31] (2023) propose a multiclass and transfer learning algorithm for early detection of diabetic retinopathy. Their method achieves an accuracy of 91.2% and an F1 score of 0.89, demonstrating reliable disease detection. Evaluation of the ROC curve yields an AUC of 0.93, indicating good discriminative ability.

Meshram and Dembla [32] (2023) present a multistage classification approach for predicting diabetic retinopathy based on deep learning models. With an accuracy of 93.5% and an F1 score of 0.92, their method exhibits strong performance in disease prediction. The ROC curve analysis reveals an AUC of 0.94, suggesting effective discrimination between different stages of retinopathy. Table I shows the comparative analysis of past work done.

Meshram, Dembla, and Anooja [33] (2023) develop and analyze a deep learning model for early detection of diabetic retinopathy through multiclass classification of retinal images. Achieving an accuracy of 94.6% and an F1 score of 0.93, their approach demonstrates high diagnostic accuracy. Evaluation of the ROC curve yields an AUC of 0.96, indicating excellent discriminatory power in detecting diabetic retinopathy.

## III. Brief Discussion of Machine Learning Algorithms and Evaluation Metrics

### A. Machine Learning in CVD

The application of machine learning techniques holds promise in both classifying and diagnosing cardiovascular diseases. Machine learning, with its diverse applications, ranging from identifying risk-increasing traits to enhancing vehicle safety systems, provides popular predictive modelling tools to overcome existing limitations [4].

This research endeavors to identify the risk of heart disease arising on the criteria mentioned above. Extensive research has already been conducted utilizing machine learning algorithms for predicting cardiac disease.

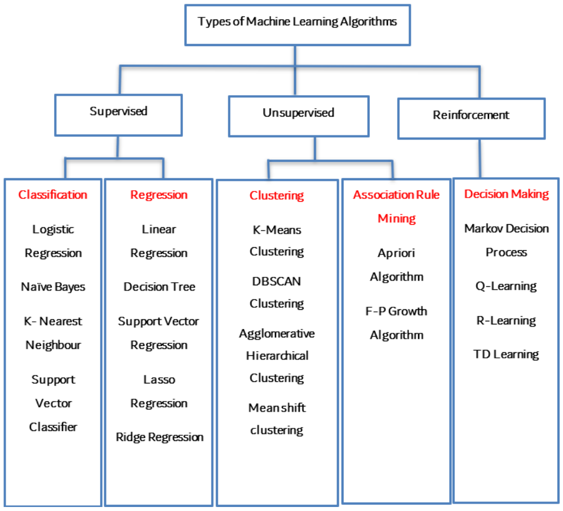

Fig. 1. Types of machine learning.

Fig. 1 defines about the types of machine learning algorithms.

### B. ML Algorithms

*1) KNN:* “K-Nearest Neighbors (KNN)” is a supervised arrangement ML technique. It predicts outcomes based on the same training data provided. The Input data is compared to the features of existing data, and the technique calculates distances, such as Euclidean, Manhattan, or Minkowski, between feature points to compare unclassified data with classified data. The name "K-Nearest Neighbor" (KNN) signifies finding the closest neighbors to the input data [17].

Euclidean Distance

$$D(x,y) = \sqrt{\sum_{i=0}^{n}(y_i - x_i)^2} \tag{1}$$

Manhattan Distance

$$D(x,y) = \sum_{i=0}^{n} |x_i - y_i| \tag{2}$$

Minkowski Distance

$$D\ (x,y) = (\sum_{i=1}^{n}|x_i - y_i|)^{\frac{1}{\rho}} \tag{3}$$

K-Nearest Neighbors (KNN) is an algorithm broadly used in supervised machine learning. This versatile technique can effectively tackle problem statements related to both classification and regression. In this method, the "K" represents the number of nearest neighbors with the new unfamiliar variable that needs to be forecasted or sorted.

*2) SVM:* Data analysis often involves leveraging the “supervised learning technique” known as “Support Vector Machine (SVM)”. SVM is versatile, capable of addressing both regression and classification problems [18] [26] [27]. In SVM modeling, instances are mapped to points in a space, emphasizing a distinct gap between examples of discrete categories.

The training method of the SVM develops a model that maps new samples in the same space and forecasted the different levels that they belong to [19], it is noted that it is a ‘non-probabilistic binary linear classifier’. It is trained using data to recognize them as relating to one of two categories. Moreover, SVM manifests in two primary forms:

*a) Linear SVM:* It is utilized when the data can be distinctly separated by a straight line. In simple terms, in any condition, a dataset can be divided into two distinct categories by drawing a single straight line, it is deemed linearly separable data. A Linear SVM is employed in this scenario to perform the classification.

*b) Non-linear SVM:* It is applied when the data cannot be divided with the process linearly. Moreover, in any condition a dataset cannot be effectively separated by a straight line, it is categorized as non-linear data. In such cases, a Non-linear SVM classifier is utilized for effective classification.

*3) Naïve bayes:* It is noted that in handling classification issues, the Naive Bayes method is utilised. Moreover, ‘the Bayes theorem’ is the process that serves as the foundation for this supervised ML technique.

Bayes Theorem Equation

$$P\left(\frac{A}{B}\right) = \frac{P\left(\frac{B}{A}\right) * P\ (A)}{P\ (B)} \tag{4}$$

A and B are events and P(B) ≠ 0. where the target to fulfil the probability of event A occurring given that event B is true. Event B is also referred to as evidence.

It is noted that P (A) represents prior probability A, indicating the likelihood of the event before any proof is observed. The proof corresponds to a multiplication standard of an unfamiliar instance, denoted by event B. Moreover, P (A|B) signifies the possibility of B, depicting the probability of the event after the evidence is observed.

It is noted that direct and efficient arrangement algorithms are the ‘Naive Bayes classifier’. Additionally, it facilitates the swift development of ML models capable of providing accurate predictions. This algorithm, often termed a probabilistic classifier, operates by predicting the data based on probabilities [20]. It is predominantly employed in data classification tasks, particularly those involving sizable training datasets.

*4) Logistic regression:* The supervised learning method called logistic regression is adept at addressing both classification and regression challenges. In classification problems, the target variable is often discrete or binary, taking on values such as 0 or 1.

Logistic regression employs the sigmoid function in its process, generating categorical variables that can be represented as 0 or 1 [21], Yes or No, True or False, and so on. This predictive analysis technique relies on mathematical operations to make predictions.

Logistic Function

$$\sigma\,(Z) = \frac{1}{1-\,e^{-Z}} \tag{5}$$

Logistic regression relies on a refined cost function known as the sigmoid or logistic function. This function produces output within the range of 0 to 1. Specifically, if a value falls below 0.5, it is interpreted as 0, while values exceeding 0.5 are interpreted as 1.

*5) Decision tree:* The algorithm of decision trees is a structure of observed learning, commonly applied to solve classification challenges, but it is also versatile enough to handle regression problems.

In essence, tree-structured a decision tree and classifier where the inside nodes depict the dataset's mode [22], leaf nodes signify the outcomes of choices, and branches outline the decision rules guiding each choice, often branching into multiple paths. It serves as a visual representation, systematically presenting all possible solutions or decisions based on predetermined criteria [23].

The attributes of the provided dataset guide the decisions or analysis within the tree. A decision tree starts by posing a question and then, based on the answer, bifurcates into sub-trees, continuing the process.

*6) Random forest:* A widely used supervised learning approach in machine learning is the Random Forest classifier. This versatile technique can be effectively applied to various ML tasks, encompassing both alignment and regression. Moreover, ‘Random Forest’ is built on ensemble learning, a strategy to tackle complex problems and enhance model performance by combining multiple classifiers [24].

In addition to enhancing the predictive actuality of the dataset, ‘Random Forest’ employs multiple decision trees, each trained on different subsets of the input data. Rather than confide on an individual decision tree, ‘Random Forest’ aggregates predictions from individual trees and forecasts the outcome based on the predictions that receive the most support [25, 26, 27, 28, 29]. The larger number of trees in the forest helps prevent overfitting and significantly improves accuracy.

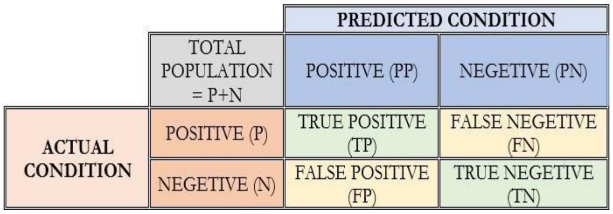
In classification problems, the ultimate output is determined using a majority voting classifier, while in regression problems, the final result is computed as the mean of all the outputs. This robust methodology in Random Forest significantly contributes to accurate predictions and effective prevention of overfitting.

## C. Evaluation Metrics

Classification models yield various category outputs. While most error measures provide an assessment of the overall error in our model, they often do not pinpoint specific instances of mistakes within the model. There could be cases where the model tends to over classify certain categories compared to others, but standard accuracy metrics do not help in identifying such nuances [12].

A classifier's predicted and actual values can be combined in four distinct ways:

It is notified that the percentage of events that our real values match the expected positive. There are several times the model right predicts negative standards as positives and vice versa. Without the projection the number is positive. Fig. 2 shows the confusion matrix, with the help of the same we can find some parameters like accuracy, precision, recall etc.



| | | PREDICTED CONDITION | |
|---|---|---|---|
| | TOTAL POPULATION = P+N | POSITIVE (PP) | NEGETIVE (PN) |
| ACTUAL CONDITION | POSITIVE (P) | TRUE POSITIVE (TP) | FALSE NEGETIVE (FN) |
| | NEGETIVE (N) | FALSE POSITIVE (FP) | TRUE NEGETIVE (TN) |

Fig. 2. 2*2 Confusion matrix layouts.

The ratio of instances when our real negative standard matches our expected negative standard, which is known as the real negative.

*1) Accuracy:* The exactness is used when conditioning the percentage of standards that were properly categorized. It shows how often our classifier is right. Based on the result dividing the sum of all real values by all values.

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \tag{6}$$

*2) Precision:* Precision is identified by how well all the models can categorise in actual values. There is calculation by rebuttal the whole number of projected actual values by the real positives.

$$\text{Precision} = \frac{TP}{TP+FP} \tag{7}$$

*3) Recall:* There is used when all the determine how well a model can predict positive values. It is noted that how often does the model show real forecast positive values? On the other hand, it is also calculated by dividing the total number of real positive values by the genuine positives.

$$\text{Recall} = \frac{TP}{TP+FN} \tag{8}$$

*4) F1-Score:* The tunable mean of repeal and legibility is F1 score. There is a need to consider both Accuracy and Recall, it is beneficial.

$$\text{F1-Score} = \frac{2 * PRECISION * RECALL}{PRECISION + RECALL} \quad (9)$$

## IV. Methodology and Implementation

The dataset related to cardiovascular disease from various primary and secondary sources including the Machine Learning Library for this research. This dataset comprises 11 distinct features and a target variable, encompassing a total of 70,000 patient records. The characteristics of the dataset are outlined in Table II.

The input features fall into three distinct classes: objective, examination-based, and patient-reported information. Objective features encompass Age, Weight, ‘Body Mass Index (BMI)’, Height, and Gender. Examination features include ‘Systolic hypertension’, Cholesterol, ‘Diastolic Blood Pressure’ and Glucose. Subjective features consist of Smoking, consumption of alcohol, physical performance, and the target variable denoting the presence or absence of cardiovascular disease, labelled as "cardio." The whole computation work is done in Google Colab in Python Language.

TABLE II. Dataset Multiplication

| S.no. | Name of Attribute | Feature Type | Name | Type |
|---|---|---|---|---|
| 1 | Age | Feature objective | Age | ‘int (days)’ |
| 2 | Height | Feature objective | height | ‘int (cm)’ |
| 3 | Weight | Feature objective | weight | ‘float (kg)’ |
| 4 | Gender | Feature objective | gender | ‘categorical code’ |
| 5 | Systolic hypertension | Feature of examination | ap_hi | ‘int’ |
| 6 | Diastolic blood pressure | Feature of examination | ap_lo | ‘int’ |
| 7 | Cholesterol | Feature of examination | cholesterol | 1: Customary, 2: above Customary, 3: well above Customary |
| 8 | Glucose | Feature of examination | Gluc | 1: normal, 2: above normal, 3: well above normal |
| 9 | Smoke | Feature of subjective | Smoke | Geminate |
| 10 | Intake of booze | Feature of subjective | Alco | Geminate |
| 11 | Various physical operation | Feature of subjective | Active | Geminate |
| 12 | Existence or absence of cardiovascular ailment | Variable in target | Cardio | Geminate |

### A. Data Pre-processing

Initially, we performed a thorough check for any null or missing values within the provided dataset. Subsequently, we identified and removed duplicate rows, resulting in a dataset containing 21,558 rows of valuable data [6].

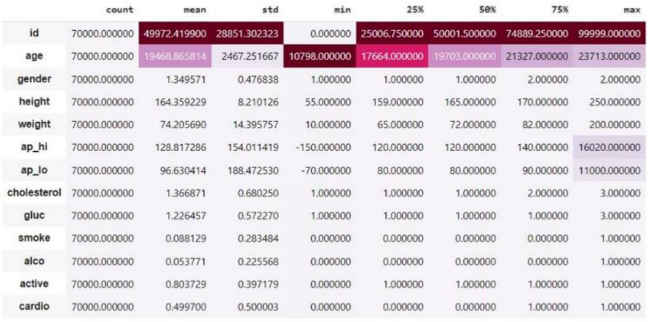
Fig. 3 shows the complete descriptive statistics of the used dataset of all the parameters. Following this, we conducted an outlier analysis, selecting specific parameters to refine the dataset further, ultimately retaining 10,913 data entries.

In Fig. 4, a heatmap illustrating feature correlation is presented. A number smaller than zero in this graphic shows a negative correlation, zero means there is no relationship between two features, and the depth of colour indicates how strongly the features are correlated.

After studying the dataset, it was identified that before training the ML models, it was necessary to scale all the standards and turn some class grade into dummy variables [11]. ‘Principal component analysis’, ‘linear discriminant analysis’, and ‘generalized discriminant analysis’ are some of the feature extraction techniques that can be employed in this step to remove duplicates from the dataset and extract pertinent variables.

### B. Python Libraries

Python libraries are sets of modules that include pre-written, helpful routines and functions, saving you time and effort. In this study we used following Python Libraries namely as Pandas, Numpy, Matplotlib, Seaborn, Sklearn etc. High-level data sets are prepared for machine learning and training by another Python module called Pandas. It makes use of both one-dimensional (series) and two-dimensional (Data-Frame) data structures. Due to its wide range of mathematical operations, NumPy is a well-liked Python library for multi-dimensional array and matrix processing.



|  | count | mean | std | min | 25% | 50% | 75% | max |

Fig. 3. Descriptive analysis of dataset with attributes.

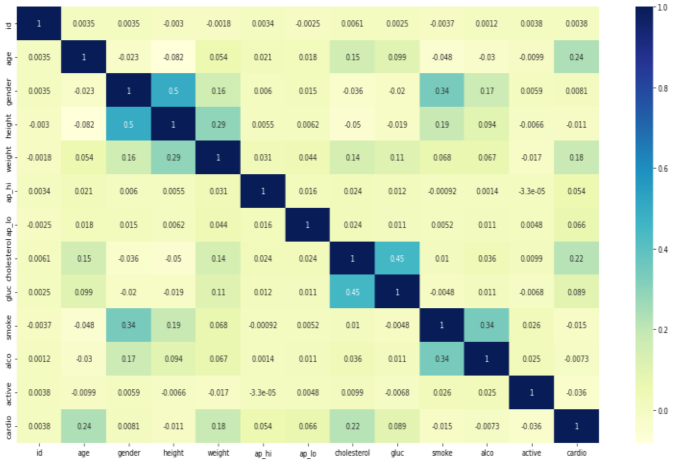

Fig. 4. Correlation matrix of different parameters.

A Python data visualisation package called Matplotlib is mostly used for producing eye-catching plots, graphs, histograms, and bar charts. Plotting data from Pandas, NumPy, and SciPy is supported. Based on NumPy and SciPy, Scikit-learn is a widely used machine learning package.

## V. Results and Analysis

In this research, we began by comprehending the pre-processed dataset through exploratory data analysis. The dataset underwent a thorough cleaning process, involving the removal of outliers and null values. Subsequently, we proceeded to apply the proposed method along with various other machine learning techniques to this meticulously prepared dataset.

The algorithm's effectiveness is assessed in the Table III; there are metrics of employing such as recall, precision, F1 Score, ROC AUC, and accuracy. Various classification algorithms, including Naïve Bayes, SVM, KNN, Decision Tree (DT), Random Forest (RF), and Logistic Regression, were utilized to evaluate the performance and classification accuracy.

TABLE III. Summary of Result Obtained

| Algorithm | Accuracy | Roc_Auc | Recall | Precision | F1-Score |
|---|---|---|---|---|---|
| KNN | 84.20 | 0.83 | 0.85 | 0.95 | 0.90 |
| Naïve Bayes | 87.95 | 0.94 | 0.89 | 0.96 | 0.92 |
| SVM | 88.59 | 0.95 | 0.91 | 0.95 | 0.93 |
| Decision Tree | 81.58 | 0.71 | 0.88 | 0.89 | 0.89 |
| Random Forest | 82.04 | 0.91 | 0.88 | 0.89 | 0.89 |
| Logistic Regression | 85.94 | 0.92 | 0.92 | 0.90 | 0.91 |

Fig. 5. Training & testing accuracy score for logistic regression classifier.

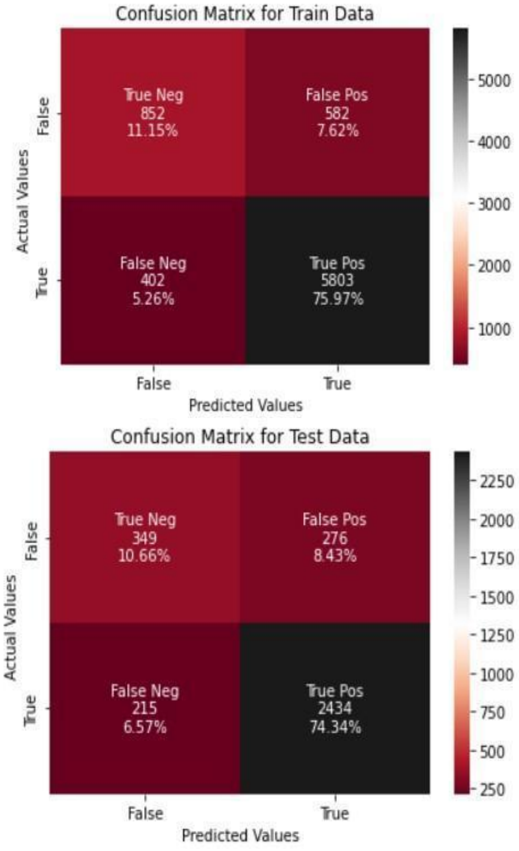

Fig. 6. Logistic regression confusion matrix for training & testing.

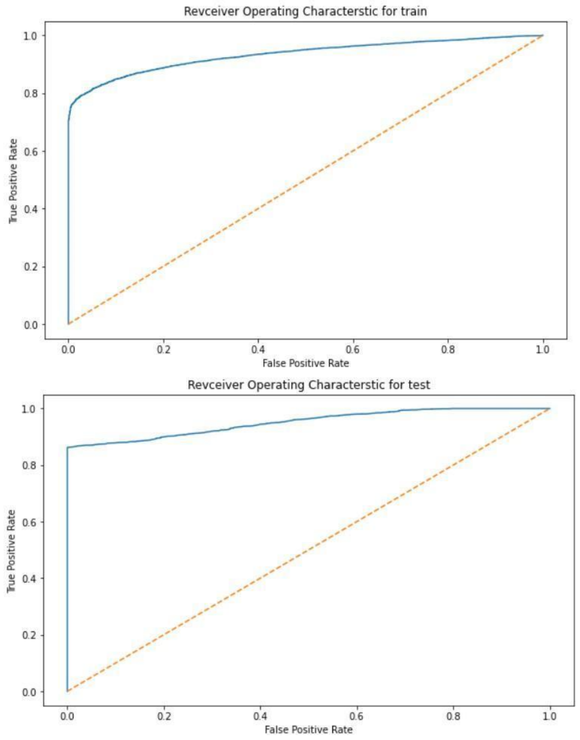

Fig. 7. ROC curve for logistic regression for training and testing.

From the data presented in Table III, it is evident that the “SVM and Naïve Bayes” algorithms earn the highest accuracy, scoring 88.59 and 87.95 respectively for the testing dataset. Fig. 5 depicts the results in the form of classification report having precision, recall f1-score, support, and the accuracy scores for both training and testing datasets for ‘logistic regression’. Fig. 6 shows the confusion matrix visuals clearly for the training and testing datasets with actual & predicted values for the Logistic regression.

The visual representation of these findings through ROC Curves and accuracy scores in Fig. 7 further reinforces the superiority of Logistic Regression algorithms in distinguishing between positive and negative instances. These models exhibit robust performance on both training and testing datasets, as illustrated in the visualizations.

Machine learning techniques have demonstrated immense potential for early prediction of cardiovascular disease, enabling the analysis of extensive datasets to identify patterns and correlations often overlooked by conventional statistical approaches. Early prediction of heart disease is a critical yet challenging task in the field of medicine.

## VI. Conclusion and Future work

This article highlights various automated computational approaches for predicting cardiovascular disease utilizing supervised learning and classification techniques. Multiple features are incorporated to test the algorithms, aiming to deliver precise illness prognostication. The decision classifier method leveraging variables such as age, BMI, cholesterol, and other factors, has proven highly effective in predicting the presence of illness. However, there are several challenges that need to be addressed to develop robust machine learning models for early detection of CVD.

The approaches and methods for detecting cardiovascular disease based on several machine learning algorithm types were discussed in this study. Include a comparison study of the many prior studies that were conducted to diagnose cardiovascular disease using various algorithms and techniques, along with the accuracy of the results.

In conclusion, the analysis of the results presented in Table III highlights the exemplary performance of the Support Vector Machine (SVM) and Naïve Bayes algorithms in predicting cardiovascular diseases, achieving the highest accuracy scores of 88.59% and 87.95%, respectively, for the testing dataset.

Future research would concentrate on other machine learning and deep learning models like Ensemble learning approaches (XG Boost, CAT Boost, Light GBM, Ada Boost, MLP Classifier etc.) Ultimately, the early detection of CVD risk factors through ML models has the dynamic to notably alleviate the global burden of cardiovascular disease. Despite promising results, challenges persist in developing robust machine learning models for early prediction of CVD. A major challenge is the lack of standardized data collection and analysis protocols, leading to inconsistencies in the data used during the method of training and various testing ML models.

# Underwater Image Enhancement via Higher-Order Moment CLAHE Model and V Channel Substitute

Chen Yahui[1], Liang Yitao[2]*, Li Yongfeng[3], Liu Hongyue[4], Li Lan[5]
College of Information Science and Engineering, Henan University of Technology, Zhengzhou, Henan, China[1, 2, 3, 4, 5]
Henan Key Laboratory of Grain Photoelectric Detection and Control, Zhengzhou, Henan, China[1, 2]

***Abstract*—Images captured underwater often exhibit low contrast and color distortion attributed to special properties of light in water. Underwater image enhancement methods have become an effective solution to address these issues due to its simplicity and effectiveness. However, underwater image enhancement methods (such as CLAHE) face challenge of increasing image contrast, improve generalization of method. Here, underwater image enhancement via higher-order moment CLAHE model and V channel substitute is proposed to enhance contrast and correct color distortion. Firstly, analyze statistical features of image histograms, use higher-order moments to quantify features in a targeted manner, add them to CLAHE, so that improved CLAHE can accurately enhance contrast of underwater image according to dynamic features of image blocks, avoiding over- or under-enhancement of image. Then, for problem of color distortion, this paper novelty uses gray data to substitutes V channel in HSV color space, compensated for lost information, so as to achieve purpose of color correction in terms of visual perception. Finally, color correction of image through gray world method, which effectively improve color distortion problem. Our method is qualitatively and quantitatively compared with multiple state-of-the-art methods in public dataset, demonstrating that this method better solved low contrast and color distortion, in addition, details were more realistic, and evaluation indexes of underwater image quality were better.**

***Keywords—Underwater images; contrast enhancement; adaptive CLAHE; high-order moments; dynamic features***

## I. Introduction

As a huge part of the Earth, the ocean still has many unknown and unexplored fields for humanity. Driven by curiosity and longing for rich resources, it becomes an important way to know more about underwater world through imaging systems [1], technologies linked to underwater exploration and resource development have consistently commanded substantial attention [2] [3]. Throughout the ages, within exploration in this field, images have consistently been one of essential instruments of cognition. Unfortunately, due to strong absorption and scattering of underwater light, underwater imaging usually faces degradation problems that seriously affect detection of underwater environment [4], resulting in the destruction of the structural and dynamic properties of different areas of the image, leading to problems such as low contrast, color distortion [5]. The degraded underwater image severely limits performance of various computer vision algorithms. In Fig. 1, examples of real-world underwater images, which have obvious different features of underwater image quality degradation, e.g., low contrast and color casts. In order to promote further research and application, it is necessary to improve underwater image. The variation of light with different wavelengths traveling underwater leads to uneven pixel distribution in underwater optical images and further results in low contrast and color distortion in images. However, using a single contrast enhancement method ignores extraction of texture features of images and results in localized contrast over or under enhancement and color distortion. Similarly, a single-color correction method cannot improve contrast and detail of images. To address these problems simultaneously, a variety of approaches have been presented in the last decade [6]-[11],[13]-[17],[20]-[23], which can be broadly categorized into three types: image enhancement methods, image restoration methods, and deep learning methods.

### *A. Image Enhancement Methods*

Image enhancement is based on the direct modification of image pixel values to adjust one or more image attributes to improve the overall visual quality of underwater images [19]. Zhang et al. [9] used an extended multiscale retinex-based method (Lab-MSR) to process underwater images in the CIELab color model. Zhang et al. [10] presented a new color correction and dual-interval contrast enhancement method supported by multiscale fusion, using a simple linear fusion method to fuse the processed high and low frequency components. Wang et al. [11] proposed an intelligent protocol called meta-underwater camera that uses reinforcement learning to intelligently configure seven underwater image enhancement techniques, including fading channel compensation, white balance, tone mapping, saturation adjustment based on the hue-saturation-luminance (HSL) model, contrast stretching, gamma correction, and high-pass fusion. This protocol works while the underwater camera is capturing the underwater image and optimizes the original, poorly visible underwater image into a highly visible image. With these methods, the structural and dynamic properties of the underwater image are hardly taken into account. Image enhancement methods aim to change the pixel values of the image to improve the visual quality and have the advantage of improving the contrast of distorted underwater images with relatively little computational effort. However, the same processing technique is used for all scene images, which means that the texture details of underwater images are not fully utilized, resulting in over- or underestimation [12].

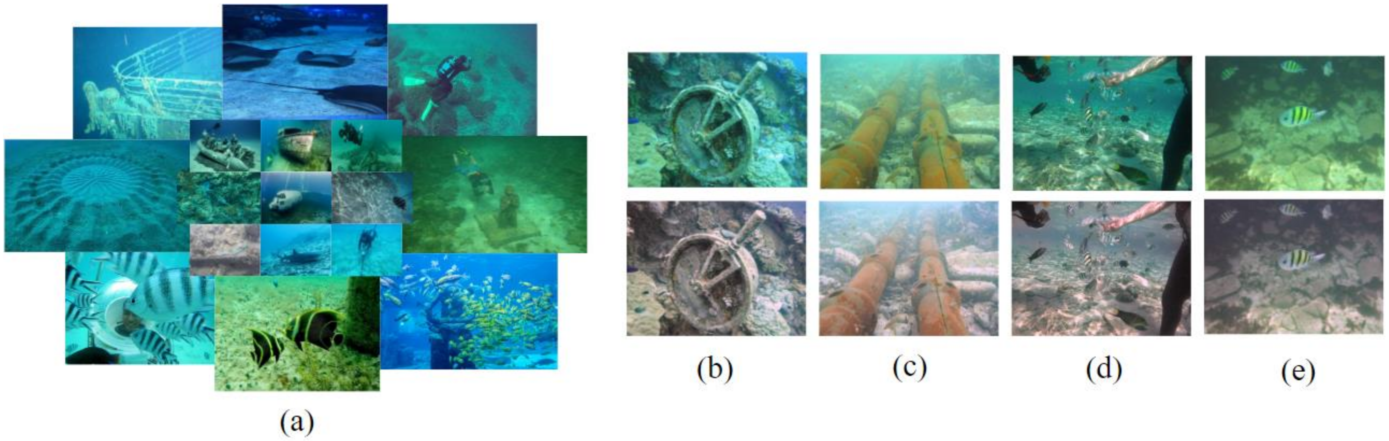

Fig. 1. (a) Real-world underwater images. (b) - (e) our method enhanced results (bottom) for several raw images with degraded quality (top).

### B. Image Restoration Methods

Image restoration methods solve the parameters of the image model using priors to restore well-visible images [13]-[17]. A representative method is the dark channel prior (DCP) theory proposed by He et al. [15] which was originally used for haze removal but has been adapted by many researchers for underwater image processing. In fact, the estimated transmittance is too large [15], which makes final enhanced image dark. Peng et al. [16] proposed a depth estimation method to accurately estimate depth of underwater scene. Zhu et al. [17] proposed an underwater image enhancement with dark channel prior, which improves contrast and color by advanced light estimation, retinex, and channel-specific coefficients. These methods achieve clear images by solving an inverse problem for the parameters of the image model. Although certain effects are achieved, spatial and textural a priori of the image are not adequately accounted for, resulting in insufficient detail in the restored image [18]. More importantly, these methods usually require a complicated mathematical optimization process, which is very computationally intensive [19].

### C. Deep Learning Methods

Deep learning has made remarkable advances in computer vision and has driven the development of techniques to enhance underwater images. The successful application of these methods is due to the extensive training data [18]. Han et al. [20] introduced a novel spiral generative adversarial network (GAN) to enhance image details and remove noise caused by scattering and attenuation. Fu et al. [21] designed SCNet for capturing desensitized underwater representations that can be adapted to different waters, but enhanced images have blurred detailed textures. Meanwhile, Cycle Generative Adversarial Network [22] and Twin Adversarial Contrastive Learning [23] have also been used to enhance underwater images. Although deep learning techniques have many advantages, the parameters in the networks remain unchanged after training is completed, which limits the adaptability of deep learning methods [19]. Most importantly, deep learning methods rely on an extensive dataset containing both distorted and clear underwater images. Many of these images are synthetically created and do not accurately represent the features of real underwater images [24]. Furthermore, deep learning methods require more time to train networks than traditional methods [4] , but they still have higher requirements for hardware equipment and training datasets. Different from deep learning methods, image enhancement and image restoration methods emphasize the specific performance of degraded underwater images. Image restoration methods utilize different prior assumptions to invert to a clear image before degradation [25]. However, the accuracy and universality of complex scenarios need to be improved because of the limitations of prior knowledge [16]. Image enhancement methods utilize processing technology to enhance contrast, i.e., CLAHE [26] and retinex-based [27] methods.

Compared with general natural images, underwater images have some unique structural features. The acquisition of underwater visual images is affected by light attenuation, absorption, and scattering, resulting in the destruction of the structural and dynamic properties of different areas of the image. As a result, underwater images often suffer from color distortion, low contrast, and blurred details. Traditional image enhancement methods fail to effectively personalize and improve these features. We thus propose underwater image enhancement via a higher-order moment CLAHE model and a V-channel substitute. More precisely, our main contributions can be summarized as follows:

*1) CLAHE* is widely used in underwater images; however, it lacks an accurate and comprehensive description of dynamic features. We propose to utilize higher-order moments to quantitatively portray statistical features of image histograms. These quantitative data are incorporated into the clipping model to improve the description of statistical features of the histogram in CLAHE. The improved algorithm has stronger generalization ability and a wider application range and effectively solves the problem that underwater images are prone to over- or under-enhancement.

*2) In* view of the fact that light is absorbed in water, which leads to the destruction of the structural and dynamic properties of the regions in the underwater image, triggering the color distortion of the underwater image, To address this challenge, this paper proposes a color compensation strategy with V-channel substitution. By compensating the color-damaged channels with the histogram distribution characteristics of underwater images, color correction in visual perception is achieved.

*3) We* use contrast enhancement and color correction to enhance underwater images. Compared with existing similar methods, our proposed method has achieved better results on PSNR, AMBE, UCIQE, and UIQM.

The rest of this paper is organized as follows: Section II delves into related work, proposed method is given in Section III, and an experimental comparison is given in Section IV. Finally, Section V concludes the paper.

## II. Related Work

CLAHE pipeline consists of 4 main steps. First, input image is divided into non-overlapping blocks of equally sized, each block contains M pixels, and histogram adjustment is performed in each block. Secondly, histogram adjustment includes histogram creation, clipping histogram, and redistributing pixels according to a clipping point. The higher clipping point is, more contrast is enhanced, clipping limit value $N_{cl}$ is calculated as follows:

$$N_{cl} = N_{Aver} + [\beta \times (\mu_x \times \mu_y - N_{Aver})] \tag{1}$$

where, $N_{Aver}$ is average number of block pixels, $\beta$ is clipping factor, $\mu_x$ is number of pixels in horizontal direction of block image; $\mu_y$ represents number of pixels in vertical direction, and calculation formula of $N_{Aver}$ is

$$N_{Aver} = \frac{U_x \times U_y}{L_{gray}} \tag{2}$$

where, $L_{gray}$ is number of gray levels in block. The number of pixels exceeding $N_{cl}$ in histogram of each block are cut out and reassigned. Then, mapping function is obtained by cumulative distribution function (CDF) of clipped histogram.

$$N_{Clip} = \sum_i \{\max[H(i) - N_{cl}, 0]\} \tag{3}$$

$$N_{Acp} = \frac{N_{Clip}}{L_{gray}} \tag{4}$$

where, $H(i)$ is gray histogram of block; $N_{Clip}$ is total number of cut pixels; $N_{Acp}$ is number of pixels assigned to each gray level; after cutting, it becomes a piecewise function.

$$N_{Clip} = \begin{cases} N_{Clip}, H(i) > N_{cl} \\ N_{Clip} - (N_{cl} - H(i)), H(i) + N_{Acp} \geq N_{cl} \\ N_{Clip} - N_{Acp}, else \end{cases} \tag{5}$$

Finally, bilinear interpolation is performed to remove artifacts that exist between blocks [28]. CLAHE not only expands the contrast range but also optimizes the entropy of the image, so it is widely used in underwater image processing [29]. CLAHE is different from conventional HE in that contrast is limited by a clipping point, which changes the kurtosis of each block histogram. To keep the total count of the histogram the same, clipped pixels are required to be evenly redistributed to each gray level. If there are pixels that have not been allocated, cyclic allocation is required. During allocation, the remaining pixels will be evenly allocated to gray levels less than the clipping point until the remaining pixels are fully allocated [30]. To eliminate artificially induced boundaries, each pixel value is obtained by linearly interpolating the pixel values of surrounding blocks [31]. In CLAHE, bilinear interpolation is used; that is, interpolation is performed in two directions. This allows CLAHE to achieve contrast enhancement, eliminate block artifacts, and improve image quality at a lower computational complexity [32]. Therefore, CLAHE is widely used in underwater images to improve contrast and to use a uniform clipping point for different image block histograms.

```
Algorithm1：CLAHE
Input：image-input
Parameter：block size (eg：8×8), clipping limit (threshold value in [0, 1], eg：0.1), nbins (eg：256)
Output：image-output
    1：Divide image-input into non-overlapping blocks (nbins) of equal size
    2：Calculate block histogram
    3：Calculate clipping point
    4：Pixel point reassignment. For each block, use extra pixels from step 3 to reassign.
    5：Histogram equalization
    6：Bilinear interpolation reconstructs gray values
    7：Show result image
```

This does not fully and accurately characterize the dynamics of the histogram, which causes the processed image to be prone to over-enhancement or under-enhancement. To address this problem, researchers have proposed some improvement methods. For example, Chang et al. [33] and Kan et al. [28] pointed out that for uniform regions in an image, lower shear values are needed to avoid over-enhancement, while for textured regions (non-uniform regions), higher clipping values are needed to emphasize texture details and contrast. For uniform regions, a lower clipping value is used to maintain the natural color tone and brightness of the image; while for textured regions, a higher clipping value is used to highlight texture details and contrast. Such processing can more accurately capture the localized features of the underwater image and avoid over-enhancement or under-enhancement. Chang et al. give Eq. (6) and Khan et al. give Eq. (7).

$$N_{cl} = N_{Aver} + N_{Aver} \times (p \frac{l_{\max}}{R} + \frac{\lambda}{100}(\frac{\sigma}{N_{Aver} + c})) \tag{6}$$

where, $p$ and $\lambda$ are the parameters that control the dynamic range of the histogram and the relative magnitude of data change respectively, $l_{\max}$ is the maximum value in the sub-block, $R$ indicates the dynamic range of the histogram of the whole sub-block, and is generally taken as 255, $\sigma$ is the standard deviation of the sub-block, and $c$ is a very small value that prevents it from being divisible by zero. Chang et al. use the sub-block mean as the main part, the sub-block maximum value, and the standard deviation as the quantitative index of the dynamic features, and the standard deviation is called the second-order central moment in statistics, and the order moment (moment) is a statistic that describes the distribution of the data, which measures the expected value of the values in the data set to the power of a particular value.

$$N_{cl} = N_{Aver} \times \mu(\frac{LcGc}{\eta} - E) \tag{7}$$

$$LcGc = \text{Local complexity+Global complexity} \tag{8}$$

where, $\mu$ and $LcGc$ are both control parameters, is the complexity of the local and global information of the image, obtained using Laplace operator filtering, and $E$ is the sub-block information entropy. Khan et al. use the sub-block mean value as the main part and use the local information, global information, and information entropy as the dynamic feature expression. This formula undoubtedly aggravates the computational efficiency of the program and prevents the algorithm from being widely used.

Based on the three formulas introduced previously, this paper is inspired to find a more accurate quantitative way to feature the dynamics of histograms and hopefully to ensure the efficiency of the algorithm.

## III. Proposed Method

In this work, the paper aims to improve the visual quality of underwater images based on dynamic features of image histograms. While CLAHE excels in local detail handling, it suffers from over-enhancement and halo artifacts, when processing darker images. CLAHE restricts enlargement by pruning the histogram at a user-defined value called clipping value. However, clipping level determines how much noise information in the histogram should be smoothed out and therefore how much contrast should be increased [34]. That is why, the global clipping point is not suitable for the enhancement of dark regions, and adaptively setting the clipping point is of importance in image enhancement. Eustice et al. [35] experimented with different ideal gray distributions and proposed that the Rayleigh distribution is most appropriate for underwater images. Fig. 2 shows the overview of the proposed method.

In this work, we integrate histogram dynamic features into the clipping model to adaptively set clipping points based on image textures for enhancing contrast. By applying this approach to the CIELab color space, we improve the contrast of underwater images by enhancing the L channel. Histogram equalization applied to sub-channels ensures a more uniform color distribution across the entire image [36]. Next, we utilize the Gradient Correlation Similarity (Gcs) method to merge information from the R, G, and B channels and substitute the V channel in the HSV color space, achieving color correction for human visual perception. This compensates for the absence of R channel information in underwater images. The replaced image undergoes color correction using the gray world method, effectively avoiding red shading in the enhanced image. Subsequent sections will delve into the details of these sub-modules.

### A. High-Order Moment-based Clipping Point Acquisition

To improve texture and image details more effectively by CLAHE, this paper uses mean gray value and standard deviation represent texture of block, skewness represents symmetry of histogram distribution, skewness is close to 0, and histogram distribution is close to symmetry. The kurtosis indicates peak height of histogram distribution, and high kurtosis indicates that there are more extreme values in histogram, and variance increases. Their combination makes clipping value smaller in homogeneous regions and larger in texture regions, which more accurately describes dynamic features of different blocks. Thus, we adaptively set clipping points as follows:

$$N_{cl} = N_{Aver} + \sigma + \alpha(S + K) \tag{9}$$

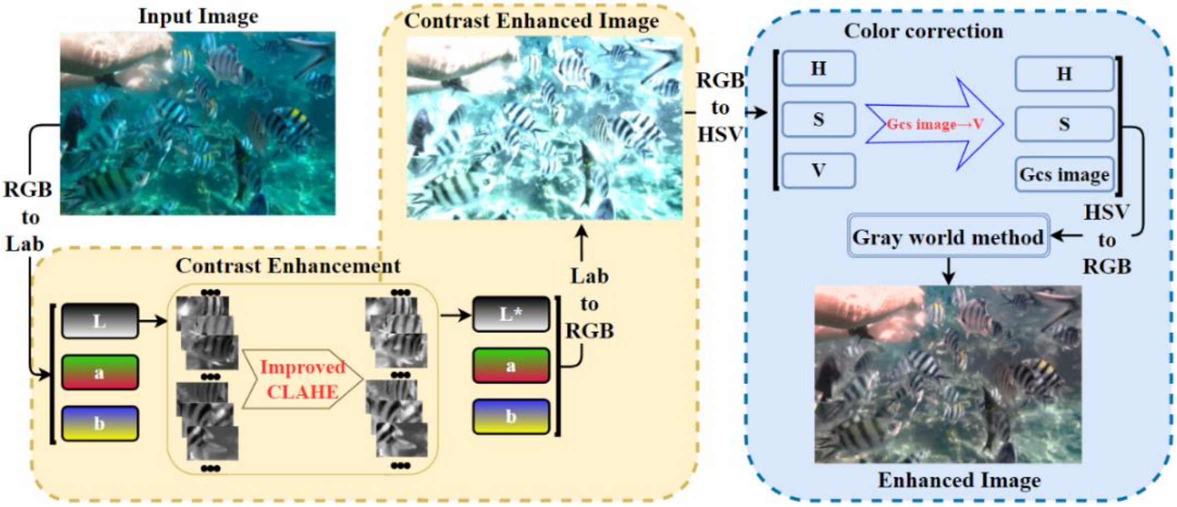

Fig. 2. Overview of the proposed method.

where, $\alpha$ is a parameter that controls weights of dynamic range. The $S$ and $K$ represent skewness and kurtosis of block histograms, respectively. Different actual scenes can use different $\alpha$, $S$ and $K$ to make the method describe dynamic feature of block more accurately, which enables the method to obtain better contrast enhancement effects in different underwater scenes as shown in Fig. 3.

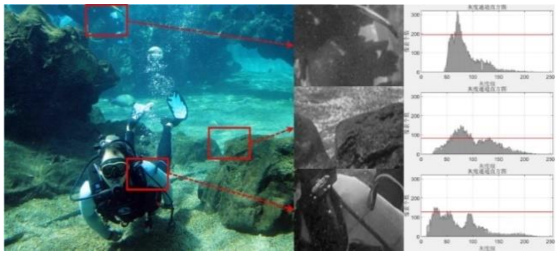

Fig. 3. Clipping point with different block image.

To validate the validity and reliability of the proposed formulas, we employed various combinations of clipping models for comparison with the original model. The dataset utilized in this experiment is the SUID dataset [37], as depicted in Table I. From the results, it is evident that although our method does not perform satisfactorily in no-reference evaluation metrics (PSNR, SSIM), it exhibits a clear advantage in underwater image evaluation metrics (UIQM, UCIQE). It is important to note that higher values of PSNR, SSIM, UIQM, and UCIQE indicate better performance.

TABLE I. ABLATION EXPERIMENT OF CLIPPING MODE

| Clipping Model | Quality Evaluation | | | | |
|---|---|---|---|---|---|
| | *PSNR* | *SSIM* | *UIQM* | *UCIQE* | *Run Time/s* |
| Original | 19.83 | 0.79 | 2.88 | 0.49 | **0.0394** |
| $N_{cl} = N_{Aver} + \sigma$ | **20.43** | 0.77 | 3.07 | 0.48 | 0.0843 |
| $N_{cl} = N_{Aver} + \sigma + K$ | 18.62 | 0.76 | 3.20 | 0.49 | 0.0763 |
| $N_{cl} = N_{Aver} + \sigma + S$ | 19.83 | 0.79 | 3.10 | 0.48 | 0.0737 |
| This study | 19.37 | **0.80** | **3.21** | **0.51** | 0.0814 |
| Ref. [28] | 14.08 | 0.61 | 3.10 | 0.55 | 0.1441 |
| Ref. [33] | 14.39 | 0.62 | 1.06 | 0.46 | 0.0475 |

TABLE II. ABLATION EXPERIMENT OF CLIPPING LIMIT

| Clipping limit | Quality Evaluation | | | | |
|---|---|---|---|---|---|
| | *PSNR* | *SSIM* | *UIQM* | *UCIQE* | *Run Time/s* |
| 0.1 | 15.18 | 0.34 | **4.53** | 0.34 | 0.0783 |
| 0.2 | 14.17 | 0.61 | 3.21 | 0.51 | 0.0786 |
| 0.3 | 20.23 | 0.66 | 4.24 | 0.40 | 0.0773 |
| 0.4 | **21.36** | **0.81** | 3.75 | 0.49 | **0.0771** |
| 0.5 | 19.51 | 0.80 | 3.22 | 0.49 | 0.0781 |
| 0.6 | 17.28 | 0.74 | 2.77 | 0.50 | 0.0775 |
| 0.7 | 15.91 | 0.69 | 2.43 | 0.51 | 0.0785 |
| 0.8 | 15.08 | 0.65 | 2.20 | 0.51 | 0.0776 |
| 0.9 | 14.54 | 0.63 | 2.10 | 0.51 | 0.0780 |
| 1.0 | 19.90 | 0.80 | 1.85 | **0.52** | 0.0776 |

To determine optimum clipping limit, we increased it from 0.1 to 1, each time by 0.1, to test performance of different clipping limit on image enhancement. Table II shows the ablation experiment of clipping limit.

### B. Color Correction Based on Fusion Channel Substitution

The Gray World method, commonly used for color distortion correction in engineering applications [38], often leads to red shading in underwater images when directly applied. This is because the method assumes equal average gray values for the R, G, and B channels. Additionally, the R channel frequently lacks sufficient information due to underwater imaging conditions, resulting in an overall greenish or bluish appearance in the original image [39]. Directly applying the Gray World method to correct the color of original underwater images can thus lead to overcompensation issues.

$$\overline{Gray}=\frac{\overline{R}+\overline{G}+\overline{B}}{3} \tag{10}$$

$$k_r=\frac{\overline{Gray}}{R}, k_g=\frac{\overline{Gray}}{G}, k_b=\frac{\overline{Gray}}{B} \tag{11}$$

$\overline{Gray}$ represents average gray value of RGB; $\overline{R}$, $\overline{G}$, $\overline{B}$ is average value of R, G, B channels, respectively; $k_r$, $k_g$, $k_b$ means gain coefficients. Based on VonKries diagonal model, each pixel $C$ in underwater optical image is adjusted for its R, G, B channels.

$$\begin{bmatrix} R' \\ G' \\ B' \end{bmatrix} = \begin{bmatrix} k_r & 0 & 0 \\ 0 & k_g & 0 \\ 0 & 0 & k_b \end{bmatrix} \times \begin{bmatrix} R \\ G \\ B \end{bmatrix} \tag{12}$$

In this paper, we present a processing compound based on HSV color space to improve overall correction algorithm and further refine solution to underwater color distortion problem [40].

Color-distorted images can lead to unnatural or poor visual perception. The HSV color space was designed with psychological and visual considerations in mind [41]. It uses three channels to describe image to better match visual perception of the human eye. From Eq. (15), it appears that for underwater images, V channel more often takes pixel values from G channel (greenish images) or B channel (bluish images) and very rarely from R channel. To support this idea, we counted proportion of V-channel pixels from R, G, and B channels in 890 underwater images in the UIEB dataset. The results show that average gray value of pixels from R channel is 4.82, which is about five times lower than that of G channel and six times lower than that of B channel. The average percentage of pixels from R channel is about 9.67%, while G channel is about 41.52% and B channel is 48.81%. Based on this, we propose a color compensation algorithm with fusion channel replacement, which replaces V channel with gray image obtained by fusion of R, G, and B channels to compensate for problem of insufficient information in R channel of underwater images, together with gray world method, to visually better improve color distortion of underwater images.

$$H=\begin{cases}0, if \ \max=\min \\ 60\times\dfrac{G-B}{\max-\min}+0, if \ \max=R \text{ and } G\geq B \\ 60\times\dfrac{G-B}{\max-\min}+360, if \ \max=R \text{ and } G<B \\ 60\times\dfrac{B-R}{\max-\min}+120, if \ \max=G \\ 60\times\dfrac{R-G}{\max-\min}+240, if \ \max=B \end{cases} \tag{13}$$

$$S=\begin{cases}0, if \ \max=0 \\ \dfrac{\max-\min}{\max}=1-\dfrac{\min}{\max}, other\end{cases} \tag{14}$$

$$V=\max\left\{R,\mathrm{G},\mathrm{B}\right\} \tag{15}$$

where, max means largest of R, G, and B, and min stands by smallest.

Substituting V channel with a Gcs image based on criteria of minimal loss of structural parameters and gradient information, effectively compensating for R channel information while preserving color image structure and detail. Combining this with the gray world method enhances compensation for V channel information in the HSV color space, facilitating color correction for visual perception. Additionally, substituting V channel with a grayscale image derived from merging R, G, and B channels mitigates distortion in blue or green-biased underwater images. This method, coupled with the gray world technique, achieves color correction. Experimental results demonstrate that the grayscale image optimally utilizes intensity and detail information in the RGB color space. For RGB format source images, intensity can be computed by linearly summing R, G, and B channels with fixed weights, exemplified by the traditional gradient error (GE) method.

$$GE=0.299\times R+0.587\times G+0.114\times B \tag{16}$$

However, in some color images, such as color images with equal luminance regions, the use of luminance channel images alone does not truly reflect structure and contrast of image, Liu et al. [42] proposed a decolorization model based on Gcs measure to well solve above problem, proposed method can better reflect degree of feature distinguishability and color ordering preservation in color-grayscale conversion, using Gcs image can effectively compensate for loss of R channel information, and improve intensity values and details of underwater color image (see Fig. 4). The core model is

$$\begin{aligned}&\underset{w_c}{min}-\Sigma(x,y)\in P\,\Sigma c=\{r,g,b\}\frac{2\left|I_{c,x}-I_{c,y}\right|\left|\nabla g_{x,y}\right|}{\left|I_{c,x}-I_{c,y}\right|^2+\left|\nabla g_{x,y}\right|^2}\\ &s.t. \quad g=\Sigma_{c=\{r,g,b\}}w_c I_c;\Sigma_{c=\{r,g,b\}}w_c=1\end{aligned} \tag{17}$$

where, $w_c$ is a unique weight that determines mapping function; $p$ is all pixel pairs; $I_{c,x}$ is pixel value in horizontal direction on color map image; $I_{c,y}$ is pixel value in vertical direction; weighting coefficients are $\{w_c \left| c=r,g,b\right\}$.

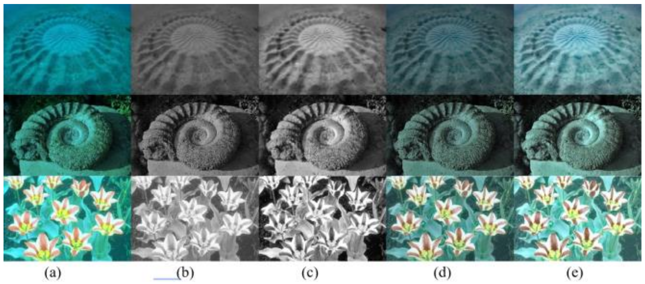

Fig. 4. (a) Original image; (b) GE image; (c) Gcs image; (d) GE image substitution V channel; (e) Gcs image substitution V channel.

The proposed method possesses fast and robust performance and runs very fast and can be used in engineering practice. It can also be used directly in RGB color space for color correction without conversion to other color spaces [43].

## IV. Experimental Results

To verify effectiveness of the method, six representative underwater images were selected from public underwater images UIEB [44] datasets. We have chosen four conventional methods for comparison, they are HE [45]; CLAHE proposed by Zuiderveld et al. in 1994 [46]; contrast enhancement of low-contrast medical images using modified contrast limited adaptive histogram equalization is an improved CLAHE method proposed by Khan et al. [28]; automatic contrast-limited adaptive histogram equalization with dual gamma correction is an improved CLAHE method proposed by Chang et al. [33], but this experiment did not reproduce double gamma correction, only modification of CLAHE was compared. The contrast-enhanced image is then color corrected using gray world method. This chapter evaluates the method from both subjective vision and objective image quality indicators. The platform is Matlab 2018a, computer processor is AMD Ryzen 5 5600H with Radeon Graphics, and CPU is 3.30 GHz. In this experiment, $\alpha$ is 0.4; distribution is rayleigh distribution.

### A. Qualitative Evaluation

The L channel of the CIELab color space underwent processing using the corresponding method, as shown in Fig. 5, to enhance contrast. Subsequently, color correction was applied using the gray world method. Comparative analysis revealed that the proposed method consistently outperformed other methods in terms of visual effects, resulting in visually pleasing underwater images. Histogram Equalization (HE) tended to excessively enhance contrast, resulting in an overall darker appearance in processed images. Specifically, Img1, Img2, Img5, Img7, and Img8 exhibited a reddish overall tint, along with some loss of detail. CLAHE effectively mitigated contrast over-enhancement caused by HE. Notably, (c) demonstrates the excellent contrast enhancement capabilities of CLAHE, but the processed image appears overexposed, with an overall tendency to be white, worsening overall visual perception. Processing images using the method referenced in Ref. [28] resulted in significant red shadows and blurred details, leading to an overall poor visual impression. The method in Ref. [33] made the image darker overall, with lower contrast and fuzzy details. Red shading was prevalent in Img5, Img6, Img7, and Img8. Fig. 6 shows underwater color image enhancement results. This study resulted in images leaning towards a gray color tone while significantly enhancing contrast and improving portrayal of details compared to other methods. Importantly, it effectively mitigated the occurrence of red shadows caused by the gray world method and alleviated the common issue of underwater images appearing bluish or greenish. To objectively analyze experimental results, this paper selects underwater image quality measures such as UIQM [47], UCIQE [48], PSNR [49], and AMBE [50].

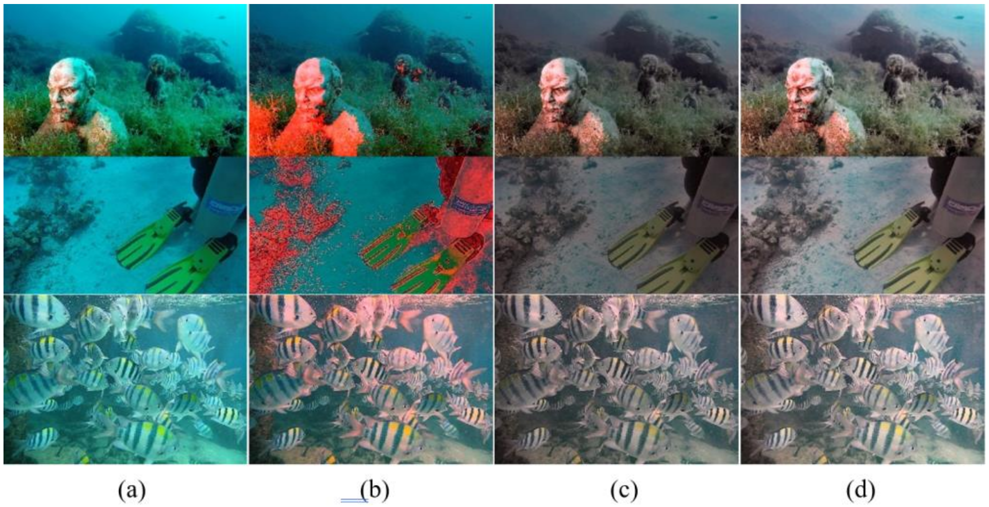

Fig. 5. (a) Original image; (b) Gray world method; (c) GE + gray world method; (d) Gcs + gray world method.

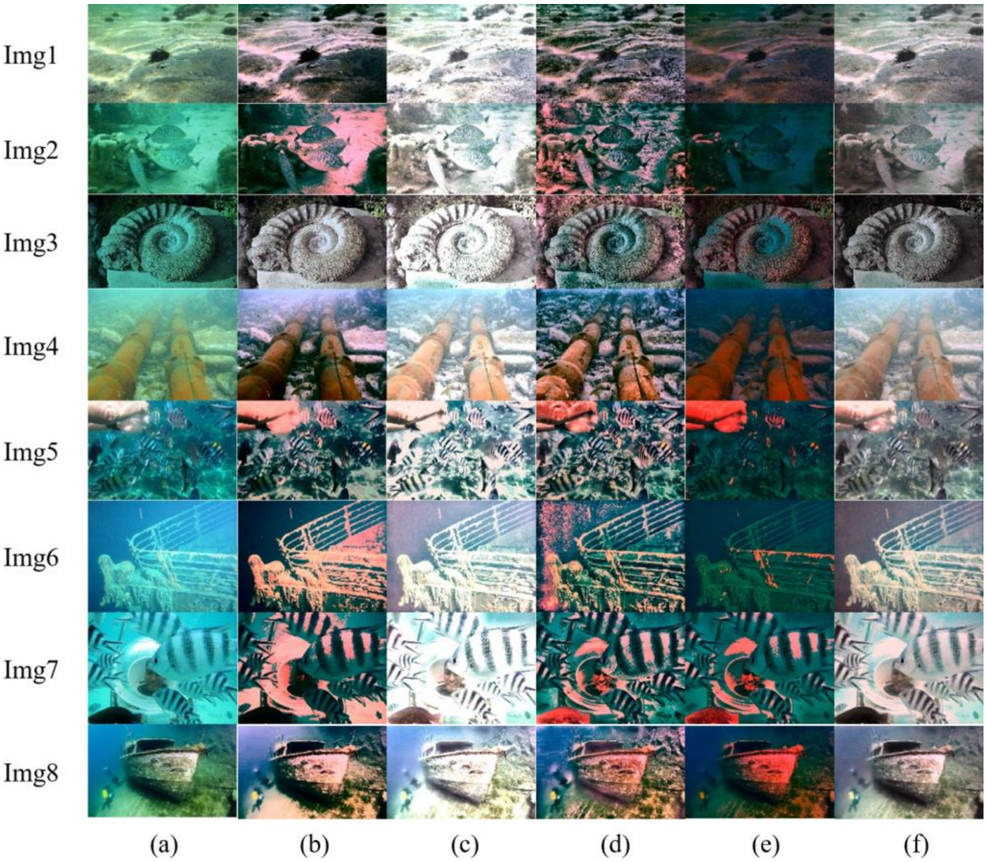

Fig. 6. Underwater color image enhancement results based on different method. (a) Original image; (b) HE; (c) CLAHE; (d) Ref. [28]; (e) Ref. [33]; (f) Proposed method.

*1) Underwater Image Quality measure (UIQM):* UIQM is based on a model of human visual system and works without reference images. UIQM includes three main measurements, UICM underwater image color measurement, UISM underwater image sharpness measurement, and UIConM underwater image contrast measurement [51]. Higher values of UIQM indicate superior cumulative enhancement effects achieved by the algorithm. The results are outlined in the table below, with the most optimal outcome prominently highlighted in bold for easy reference.

*2) Underwater Color Image Quality Evaluation (UCIQE):* UCIQE is a perceptual image quality assessment metric used to quantitatively assess color deviation, blurriness and low contrast in underwater images. It is a linear combination of color intensity, saturation and contrast. A higher value indicates better color intensity, saturation and contrast of the underwater image.

*3) Peak Signal-to-Noise Ratio (PSNR):* PSNR measures quality of enhanced image from a statistical point of view by calculating difference between corresponding pixel gray values of image to be evaluated and reference image and is a measure of peak error. The higher PSNR value, less distortion between reference image and enhanced image, and the better image quality.

*4) Absolute Mean Brightness Error (AMBE):* AMBE helps to compute brightness content that is preserved after process of image enhancement. Median values of AMBE metric indicate good preservation of brightness. The results are shown in the table below. The smaller the value, the better the image quality.

The comparison indicates that the proposed objective metrics have yielded favorable results. As shown in Table III, images processed using the algorithms presented in this paper exhibit good performance across the comprehensive evaluation criteria of color, clarity, and contrast. In Table IV, except for Img5 and Img7, the images processed by the algorithm proposed in this paper outperform other algorithms in terms of overall visual effect, effectively mitigating biased color phenomena in underwater images. Table V demonstrates that the proposed algorithm performs well in terms of image distortion, with the enhanced images displaying improved texture features. Additionally, as shown in Table VI, the paper demonstrates good performance in contrast enhancement, effectively highlighting the fine details of underwater images.

TABLE III. EVALUATION RESULTS OF UIQM

| Images | Original | HE | CLAHE | Ref. [28] | Ref. [33] | Proposed |
|---|---|---|---|---|---|---|
| Img1 | 5.46 | 6.63 | 7.41 | 6.01 | 7.67 | **7.73** |

| Img8 | **15.00** | 8.69 | 13.83 | 12.10 | 14.85 |

TABLE VI. EVALUATION RESULTS OF AMBE

| **Images** | **HE** | **CLAHE** | **Ref. [28]** | **Ref. [33]** | **Proposed** |
|---|---|---|---|---|---|
| Img1 | 51.92 | 48.10 | 48.34 | 88.48 | **11.37** |
| Img2 | 35.06 | 51.91 | 27.74 | 83.85 | **13.97** |
| Img3 | 24.38 | 86.98 | 26.62 | 20.57 | **4.92** |
| Img4 | 51.67 | 33.32 | 47.59 | 95.74 | **19.48** |
| Img5 | **0.38** | 78.16 | 5.65 | 49.39 | 25.29 |
| Img6 | 46.34 | 25.94 | 39.89 | 91.32 | **10.58** |
| Img7 | 55.55 | 63.59 | 49.86 | 65.02 | **33.03** |

Hence, it can be concluded that the proposed method exhibits significant improvements in contrast, chromaticity, and brightness based on objective evaluation metrics.

## V. CONCLUSION

We propose a method for underwater images through the higher-order moments CLAHE model and V-channel substitution. Specifically, in the contrast enhancement stage, higher-order moments describe the dynamic features of image sub-blocks, improving CLAHE's fuzzy and incomplete description of histogram statistical features and achieving more accurate contrast enhancement. In the color correction stage, we utilize gray data instead of the V-channel to compensate for information loss in the color channel, effectively achieving color correction aligned with human visual perception. Extensive experiments on real underwater images across various challenging scenarios demonstrate the robustness and effectiveness of the proposed method in contrast enhancement and color correction. Both qualitative and quantitative experimental results further validate the method's superiority over other state-of-the-art methods.

In summary, our proposed method effectively addresses color distortion, low contrast, and blurred details in underwater images, offering valuable insights into the marine world. Future research may consider introducing higher-dimensional histogram dynamic features or unique scene-specific features to further enhance the effect and quality of image enhancement.

Faculty of Applied Social Sciences, Universiti Sultan Zainal Abidin, Terengganu, Malaysia[6]

*Abstract*—**Over the past few decades, Malaysia has undergone remarkable technological advancement, establishing itself as a vibrant hub for innovation in Southeast Asia. However, technological progress must be harmonized with preserving and promoting the country's cultural heritage. Digital preservation of cultural heritage emerges as a critical endeavor, particularly for future generations. Nonetheless, there remains a notable deficiency in preservation methodologies for cultural heritage, particularly concerning technological approaches. This paper delves into the realm of cultural heritage and presents findings from a study on preserving Songket's heritage. Interviews were conducted with three experts on Songket heritage, revealing a prevailing lack of awareness regarding Songket heritage preservation. Additionally, the analysis highlights inherent flaws in current preservation methods, hindering efforts to engage a wider audience, particularly the younger generation. The experts unanimously advocate digitizing heritage knowledge, including the integration of serious games, to facilitate Songket preservation and safeguarding efforts. The use of serious games can also attract and engage the younger generation to the heritage of Songket.**

***Keywords—Cultural Heritage; digital preservation; serious game; Songket***

## I. Introduction

Malaysia has witnessed significant technological growth over the past few decades, transforming into a thriving hub for technological innovation and development in Southeast Asia [1]. The country has created an atmosphere favorable for the expansion of various industries, including information technology, electronics, and telecommunications, by strongly emphasizing the development of its digital infrastructure. Traveling through time, the rapid growth of technology is especially apparent among the youth. The younger generation drives and shapes the digital landscape through smartphones, social media, creative applications, and digital platforms [2]. They possess a profound understanding of technology and are adept at utilizing it to create, connect, and communicate in previously unimaginable ways. Technology integration has been essential to protecting and promoting Malaysia's rich cultural heritage. Technology is advancing so quickly and permeating every aspect of our lives that we must think about how best to use it to promote cultural heritage, which is also being impacted [3].

Cultural heritage is an essential element in forming identity and society. Heritage plays a role in shaping a person's identity, while culture can sustain development in a country. Moreover, heritage is an important component that creates character, identity, and image for a country. The importance of cultural heritage is undeniable as it contributes to economic growth and intrinsic value at all levels and spans countries [4]. Thus, attracting the younger generation to experience cultural heritage in new and more engaging ways in a modern context is essential.

Furthermore, the challenges to cultural heritage are exacerbated by the swift progression of modern life, technological advancements, and economic growth [5]. This situation poses increased difficulty for younger generations to uphold the cultural heritage esteemed by their predecessors. Malaysia possesses a wealth of precious cultural heritage, including the art of Songket weaving, which requires dedicated preservation endeavors. The present younger generation must be able to access and appreciate cultural heritage according to their preferred learning styles and methods of obtaining cultural heritage knowledge [6]. It is imperative to employ contemporary technology to safeguard and promote cultural heritage. Addressing these gaps is crucial for developing targeted digital preservation strategies that resonate with and actively involve the youth in cultural heritage preservation.

Various technological advancements have been globally embraced to preserve our rich cultural heritage. This discussion provides insights into the diverse specialized strategies that can be implemented to actively promote and enhance our understanding and appreciation of cultural heritage [7]. Nowadays, serious games are widely used in cultural heritage to convey heritage content and educate the younger generation. The use of serious games in cultural heritage is significant in attracting the younger generation to learn cultural heritage since they are very fond of digital games. Serious games enhance learning by offering a diverse array of engagement opportunities [8]. Virtual environments have been utilized in cultural heritage, providing the general public with the opportunity to engage in an immersive experience and appreciate cultural content that is distant both spatially and temporally [9]. Cultural heritage serious games can present heritage information in a fun way [10].

The main emphasis of this paper lies in the analysis of gathered data, indicating a shift towards digitalization methods to preserve the heritage. The remaining paper is organized accordingly: Section II discusses the related work and background of cultural heritage preservation. In contrast, Section III discusses the method used in this study to obtain information. Next, Section IV presents the results and findings of the study, and lastly, Section V presents the conclusion.

## II. Related Works

### A. Cultural Heritage

Cultural heritage is a treasure that has been or is owned by a person or a group of societies or people who collectively share responsibilities for protection and retention. Cultural heritage symbolizes all civilizations' spiritual and intellectual wealth [11]. The United Nations Educational, Scientific, and Cultural Organization, also known as UNESCO, popularized "cultural heritage" in the middle of the 20th century. In its document from the 1972 Convention for the Protection of the World Cultural and Natural Heritage held in Paris, UNESCO defined it as all tangible and intangible cultural [7].

Culture is a term that defines the way of life, thoughts, and behaviors of a civilization inherited from one generation to another. Furthermore, some experts have explained that culture is the value in humans that helps create and build identity. Heritage can be defined as a valuable thing inherited from previous generations that will be inherited by future generations [12]. Cultural heritage is divided into two categories, which are tangible and intangible [11]. Physical artifacts, buildings, and other items having cultural significance that are valued and deserving of preservation within a specific community or society are referred to as tangible cultural heritage [12]. At the same time, intangible cultural heritage is a vast range of customs, knowledge, skills, and rituals firmly ingrained in a group's cultural identity [13]. Tangible aspects of culture often have a longer-lasting impact than intangible elements, emphasizing the enduring nature of physical artifacts and structures in shaping our understanding of cultural heritage over time [14].

Moreover, heritage is a key component that plays a vital role in creating a character, identity, and national image. It is a treasure that has been or is being owned by a person or a group of society or people who collectively share responsibilities for protecting and retaining that treasure. To summarize, cultural heritage can be depicted as the legacy of physical artifacts and intangible attributes of a group or society inherited from past generations, maintained in the present, and presented for future generations [11].

### B. Songket

Songket is a valued cloth in Southeast Asia due to its unique quality and historical and cultural significance. Songket is a textile classified within the brocade family from Indonesia, Malaysia, and Brunei. This fabric, meticulously hand-woven using silk or cotton, features elaborate patterns enriched with threads of gold or silver [7]. It is a monument to traditional weavers' ability and inventiveness and is still cherished as a sign of cultural identity and heritage. Moreover, Songket is an intangible cultural heritage art form that serves as a national symbol and identity [15]. Songket is an everlasting textile worn by Malays, notably at ceremonial functions or cultural events [16]. Songket was registered as an intangible cultural heritage in 2021 at its headquarters in Paris, France, during the 16th Session of the Intergovernmental Committee for the Safeguarding of Intangible Cultural Heritage.

However, this craft had to face various challenges to remain relevant. Despite the beautiful design and pattern, Songket is becoming less popular because of the increased pricing and the difficulties in getting high-quality raw materials [15]. Perbadanan Kemajuan Kraftangan Malaysia is an agency in charge of preserving the quality of Songket to commercialize craft products through market, product, and entrepreneur development.

### C. Cultural Heritage Preservation

Cultural heritage preservation is essential to ensure that these elements are passed down to the next generations, preserving a link to the past and contributing to an appreciation of identity. Preservation encompasses a range of academic disciplines, including documentation, safeguarding, reconstruction, restoration, conservation, dissemination, and widespread sharing of cultural heritage [14]. Several factors have pushed the handicraft to extinction: lack of government support, a shift towards mass-produced goods, and competition from cheaper imported products [15]. Other than that, the heritage is still practiced but gradually declined among younger people, especially among the educated members of the community [17].

Many preservation steps have been taken seriously by the government. As stated in the Malaysia National Heritage Act, 2005 (Act 645), preservation is an act that aims to stop further deterioration, decay, or obsolete conditions of buildings, monuments, and sites [12]. United Nations Educational Scientific and Cultural Organization (UNESCO) has also established working committees and manuals to ensure that cultural heritage worldwide receives proper protection and attention to preserve its originality[11]. Some innovations have also been identified in Songket weaving, which are modern motifs in Songket weaving [15]. It is to make this handicraft more attractive to current customers, increase customer demand, and remain relevant across the generation. Computer games or serious games can also be used indirectly to preserve cultural heritage and create interest and awareness among the public [11].

### D. Serious Game for Preservation of Cultural Heritage

According to Lazarinis [18], cultural heritage is a fitting domain for serious games, and this method can also help support the preservation of heritage and its reproduction. Game-based learning is an effective way to teach and learn. It can help develop interest and motivate learners to enjoy and engage in education [19]. Furthermore, various research and development projects related to traditional heritage have been carried out over the years. When more researchers take up similar projects, more young people become aware of their culture[20]. A researcher from Indonesia [21] has created 3D visualization and animation as content development for digital learning materials for traditional Indonesian cloth (Songket Palembang). Some of the scenes captured from the 3D experience are shown in Fig. 1.

Serious games are effective in promoting pro-social development and learning of a variety of topics, including health, environment, human rights, and international relations, the ability to attract interest, drive effort, encourage persistence of tasks [22], [23] and provide opportunities for problem-based learning [24]. Serious games can take various forms, such as mobile apps, straightforward web solutions, intricate 'mashup' apps (blends of social software apps), or sophisticated computer games. These games utilize modern gaming technologies to construct virtual environments, offering interactive experiences that may involve social interactions. Additionally, mixed-reality games merge real and virtual interactions, all applicable to cultural heritage applications [25]. The structure of a serious game is contingent upon factors like the learning goals, the genre (such as adventure or simulation), and the specific context of its application [8]. For example, Lazarinis [18] developed a serious game supporting learning in the cultural heritage domain focused on an ancient Macedonian (Greek) city. The game objective is to provide the ability to adapt the application's content to accommodate various learning aims.

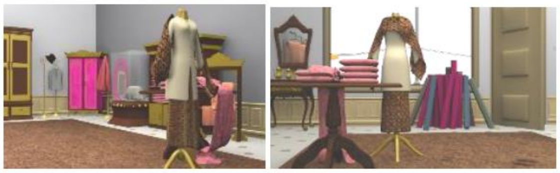

Fig. 1. 3D environment of Songket gallery.

Innovations in traditional handicraft development must prioritize authenticity and heritage value [15]. This entails ensuring that any advancement or changes align with the craft's genuine essence and cultural significance, preserving its traditional and historical worth.

## III. Method

This study utilizes an interview method to collect data through a survey. For this method, there are three phases involved: setup, data collection, and data analysis. This approach aims to identify cultural heritage awareness, preservation techniques, and the necessity of digital cultural heritage preservation from the viewpoints of experts.

For the first phase, which is the setup phase, the objectives were identified, and the list of the questions for the interview was constructed based on the literature. The questions were divided into four stages: Section A: Demographics, Section B: General Knowledge about Songket, Section C: Songket Development, and Section D: Cultural Heritage Innovation in Technology. They are three experts in the Songket industry; two are experienced weavers of Songket, and the last is an officer from Perbadanan Kemajuan Kraftangan Malaysia Cawangan Terengganu. They all have over ten years of experience in the Songket industry.

Then, for the data collection phase, semi-structured interviews were carried out. In a semi-structured interview, the interviewer used a set of open-ended questions with predefined follow-up questions. Still, the interviewee's answers allowed the interviewer to go deeper into a topic. Each interview session was recorded for use during the data analysis process. The experts' answers were analyzed using thematic analysis techniques for the last process. The technique used to identify, analyze, and report themes within the data.

## IV. Findings and Discussion

In this section, we discuss the outcomes based on the information obtained from the interviews.

### A. Findings on Songket Information

In this interview, we have gathered substantial information about Songket from the insights of three experts. The word 'Songket' originates from 'menyungkit' because in Thai, 'kek' means to hook or pick up, similar to 'songkok' in Chinese, which carries the same meaning. Songket utilizes a weaving method that involves interweaving gold threads with silk threads on the fabric base. This opulent and expensive cloth illustrates the hierarchical structure among the Malay nobles.

*1) Process of producing the songket:* There are eight processes in the making of Songket. Each process needs to be thoroughly made to produce high-quality products.

*a) Dyeing the yarn (Mencelup Benang):* Before dipping the yarn into the dye, it must be thoroughly washed. Fig. 2 shows the process of dyeing the yarn. The yarn must be dried after dyeing before proceeding with the next steps.

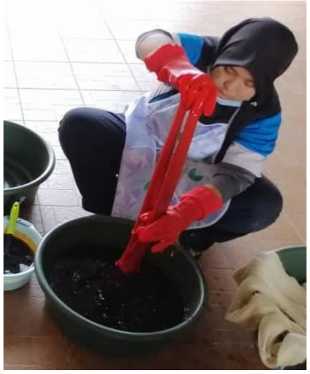

Fig. 2. Process of dyeing the yarn.

*b) Untangling the yarn (Melerai Benang):* The small bamboo-made spindle is used to spin the yarn. This process involves a "Darwin" tool and a comfortable spinning tool (see Fig. 3).

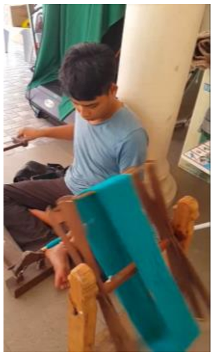

Fig. 3. Process of untangling the yarn.

*c) Winding the yarn (Menganeng Benang):* The process of stretching the yarn on the loom is done to determine the length or the number of threads of fabric to be woven (see Fig. 4).

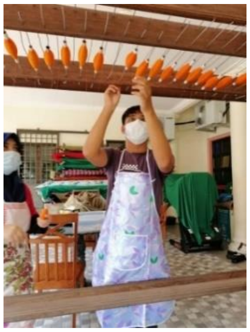

Fig. 4. Process of winding the yarn.

*d) Rolling the yarn (Menggulung Benang):* The stretched threads on the warping frame are rolled onto a wooden board (see Fig. 5).

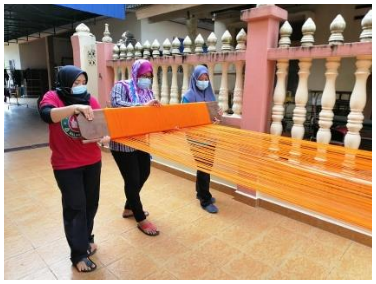

Fig. 5. Process of rolling the yarn.

*e) Spooling the yarn (Menyapuk Benang):* After the warping threads are inserted into the teeth or brush of the machine, the spooling work is carried out. Two threads of the warping yarn are hooked through each gap in the machine's teeth (see Fig. 6).

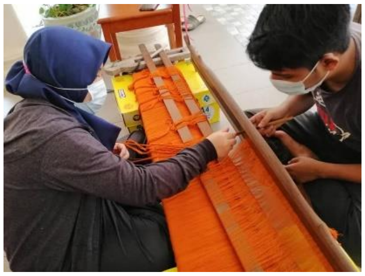

Fig. 6. Process of spooling the yarn.

*f) Stretching the yarn (Mengarak Benang):* The "karak" is made from twisted foreign threads. The warping threads, both even and odd, are alternately raised and lowered during the weaving process (see Fig. 7).

*g) Lifting the yarn (Menyongket Benang):* Creating patterns on the warp threads is done using a "lidi" tool by weaving the warp threads in groups of three or five and then tying them, known as the button-tying process (see Fig. 8).

*h) Weaving the yarn (Menenun):* The shuttle, filled with the weft thread or gold thread, is inserted left and right into the gaps between the warp threads according to the predetermined pattern until it becomes a piece of cloth. Once the fabric is completed, it is cut to size (see Fig. 9).

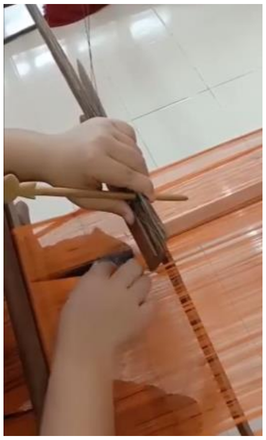

Fig. 7. Process of stretching the yarn.

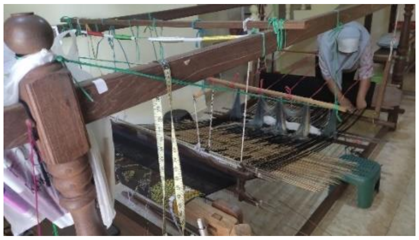

Fig. 8. Process of lifting the yarn.

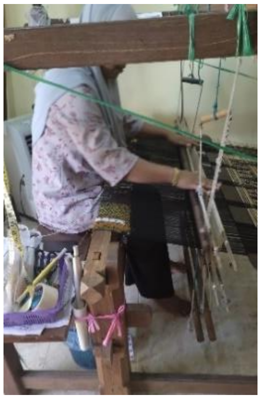

Fig. 9. Process of weaving the yarn.

*2) Songket pattern and motif:* The motif and pattern used in Songket can vary based on the design customer’s request. Every motif and pattern have its own meaning behind it that show the unique identity of Malay itself [26]. It portrays the cultural inclinations and preferences of a vibrant and flourishing society within an environment characterized by its rich tapestry of beauty and distinctive attributes. The Table I shows the major pattern that was used in designing Songket [27].

The Table II shows the popular motifs used to design the beautiful Songket [26]. Lots of motif was inspired by flora and fauna. The designs were mostly inspired by the natural environment that encircles the weavers [28] [26]. Thus, the wearing Songket could be meaningful as it reflects the Malay culture and traditions.

TABLE I. THE CLASSIFICATION OF PATTERN IN SONGKET

| Songket | Name |
|---|---|
|  | Full pattern (corak penuh) |
|  | Scattered pattern (corak tabur) |
|  | Scattered repeated bricks pattern (corak bertabur ulangan batu bata) |
|  | Diagonally repeated scatterings pattern (corak bertabur ulangan serong) |
|  | Alternating scattered repetitions pattern (corak bertabur ulangan selang-seli) |
|  | Crosswise pattern (corak melintang) |
|  | Stripes pattern (corak jalur) |
|  | Chevron or zigzag pattern (corak siku keluang) |
|  | Checkers pattern (corak petak catur) |

TABLE II. THE CLASSIFICATION OF MOTIF IN SONGKET

| Songket | Name |
|---|---|
|  -Bunga Baling<br> -Bunga Cina<br> -Bunga Mawar Baling Putar<br> -Bunga Bintang (pecah lapan) | Floral Motif |
|  - Chicken<br> - Butterfly | Fauna Motif |
|  | Figurative Motif |

## B. *Findings on Cultural Heritage Awareness*

As shown in Fig. 10 below, 67% of the informants believed that the level of cultural heritage awareness is low among the community, especially the younger generation. People are not interested in preserving cultural heritage because they are unaware of its importance. Some of them find it challenging to learn about heritage because of the complicated processes involved in making it. Following the COVID-19 pandemic, numerous Songket weavers have encountered financial difficulties, leading some to cease their weaving activities. However, many organizations have made various efforts to raise awareness following the decreasing awareness, such as campaigns, exhibitions around the country and overseas, workshops, and many more. These efforts can raise awareness among the community to preserve the heritage.

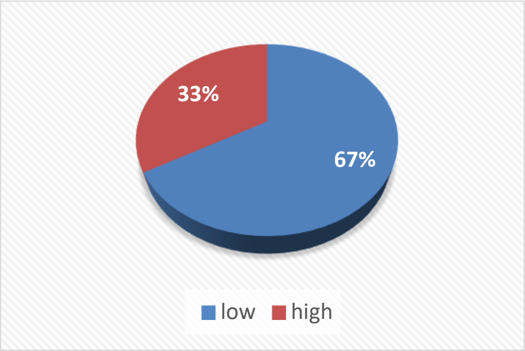

Fig. 10. Level of cultural heritage awareness.

### C. Findings on Cultural Heritage Preservation Method

Fig. 11 is the result from the interview that showed the knowledge of Songket weaving is handed down from the ancestors, making there no specific preservation method and no improvement in preserving the knowledge, whether by documentation or technological method.

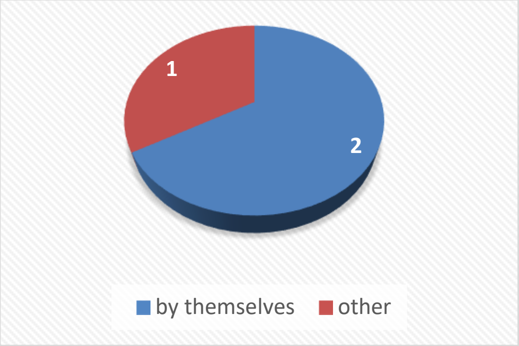

Fig. 11. Current preservation method of cultural heritage.

Nevertheless, a Perbadanan Kemajuan Kraftangan Malaysia representative highlighted their extensive efforts in cultural heritage preservation. They have set up the Institut Kraf Negara, a dedicated institution for theoretical and practical learning of heritage crafts. Among the various traditional arts taught there, Songket weaving is a crucial component. This initiative serves as an excellent platform for those eager to delve into the intricacies of Songket even though they do not have Songket weaver in their family background. Through such an approach, heritage knowledge becomes readily accessible to all interested in exploring it.

In addition to its educational efforts, Perbadanan Kemajuan Kraftangan Malaysia has also introduced a novel approach to safeguard the authenticity of its products. This initiative addresses the challenge posed by the influx of counterfeit items, often sold at lower prices than genuine ones. They have implemented authenticity tags to recognize consumers' difficulty distinguishing between authentic and fake products. These tags serve as a mark of genuineness for each product, as illustrated in Fig. 12 below, ensuring customers can easily verify the authenticity of their purchases.

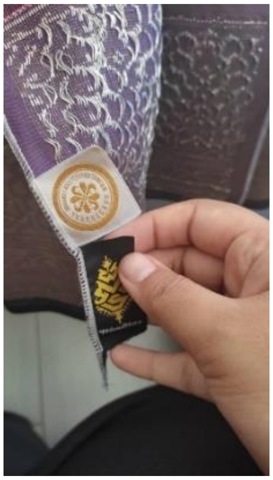

Fig. 12. The tag to preserve the authenticity of the product.

### D. Findings on the Need for Digital Preservation

The discussions highlight a unanimous agreement among interviewees on the importance of digital preservation for traditional heritage. They all agreed to shift towards digital preservation and technological advancement. They are convinced that digital preservation can spark interest among younger generations to engage with and learn about cultural legacy. There is a growing consensus that the evolution of traditional heritage must be synergized with technological advancements, thereby enhancing accessibility to preservation efforts. Hence, serious games emerge as a promising method for digital preservation, particularly in engaging younger demographics. Consistently, all interviewees affirmed the efficacy of serious games as a tool for digital preservation initiatives. Furthermore, there is a shared belief in digitizing heritage knowledge and skills, ensuring their permanent storage for future safeguarding and preservation.

From the findings of this study, it is evident that cultural and heritage elements can be integrated into digital games, paving the way for the development of games as a means of digital preservation. This enables future generations to access and experience cultural heritage interactively, ensuring broader preservation and understanding of historical and cultural richness.

## V. Conclusion

Today's generation is responsible for preserving and safeguarding our country's cultural heritage as it embodies the identity of our communities. Sustaining its relevance and preservation for future generations necessitates further efforts on all fronts. As a result, the integration of digital preservation is critical, in line with the importance of emerging technologies. Several methods can be used for the digital preservation of cultural heritage, such as digitization, metadata creation, and digital storage and archiving. Besides, serious gaming is one method that can be utilized to digitally preserve cultural heritage while simultaneously attracting and engaging the younger generation with it.

This paper has discussed the topic of cultural heritage and provided findings from an initial study into issues surrounding it, particularly emphasizing the necessity for increased initiatives in its preservation. The awareness and interest of cultural heritage could be higher, especially among youngsters. Considering the knowledge of Songket weaving is presently safeguarded solely by its practitioners and the decreasing number of Songket weavers, it underscores the imperative for digital preservation initiatives. Therefore, digital preservation is vital for safeguarding the sophisticated craftsmanship and profound historical significance of cultural heritage like Songket weaving for posterity, ensuring its beauty and preservation are accessible to future generations. Consequently, serious games can be used as a digital preservation method that effectively engages the younger generation in cultural heritage initiatives.

## Acknowledgment

The author would like to acknowledge Universiti Sultan Zainal Abidin for funding this research under the Fundamental Grant Research Scheme (FRGS) No FRGS/1/2022/ICT10/

UNISZA/02/1. Utmost appreciation also to the Ministry of Higher Education Malaysia.

Department of Art Design & Creative Industries, Nanfang College Guangzhou, Conghua Guangdong, China[2]

***Abstract*—At present, the recommendation of massive commodities mainly depends on the short-term click through rate of commodities and the data directly browsed and clicked by users. This recommendation method can better meet the shopping needs of users, but there are two shortcomings. One is to recommend homogeneous commodities to long-term shopping users; second, we can't grasp the real-time changes of users' interests, and can only recommend results similar to the recently clicked products. Therefore, this study intends to establish a time-varying expression method of users' interest intensity to solve the deviation of real-time recommendation content, and propose a recommendation model RUICP based on users' time-dependent interest and commodity heat. Firstly, the user's basic data and cumulative usage information are used for portrait, specifically, the user's usage data is divided into isochronous and deep-seated semantic feature analysis, the model is optimized and the user's long-term interest intensity is obtained after parameter estimation; Then, the user's short-term interest is obtained by splitting the user's short-term use data, and the user's final interest is calculated by combining the short-term interest and the user's long-term interest intensity; Then calculate the product popularity score by adding the repeated click through rate of products, and then update the ranking of products; Finally, the classic item based collaborative filtering algorithm is used to calculate the matching degree of user interest and goods, and then recommend. The results of simulation experiments show that compared with other methods, RUICP has higher recommendation accuracy for old users and has certain value for solving the cold start problem.**

***Keywords*—User real time interest; commodity popularity; recommend**

## I. Introduction

According to the "48th Statistical Report on Internet Development in China," with the development of mobile internet, China has reached 1.007 billion mobile internet users, and the scale of online shopping users has reached 812 million, with an internet penetration rate of 80.3%. In the vast sea of users and commodities, personalized recommendation systems play an extremely important role. They can meet the personalized needs of users, quickly and accurately find products, on the other hand, help high-quality products be discovered by more users, thus benefiting merchants and achieving a win-win situation for both users and merchants.

The commodity recommendation system will establish a corresponding interest model according to each user's basic information, likes, browsing and other operations, and can recommend commodities with corresponding topics according to the model. This model is based on the stability of user interest, that is, the overall interest of users does not change much with time, and then adjust the interest direction. According to partial feedback, many scholars also put forward corresponding models based on this, relying on matrix decomposition technology [1] to learn the potential characteristics of users and projects. He et al. [2] established the NCF model, and the neural network method is used for the interaction between users and project features of the recommendation system, making the recommendation officially enter the research field with deep learning as the main technology.

However, in practical use, user interests change over time. The time sequence of interactions between users and items can reflect changes in user interests. Commodity recommendation systems achieve real-time recommendation based on this principle. However, existing hardware computing power is limited, and recommendation systems based on long sequence information of users often suffer from slow computation or sacrifice a certain degree of accuracy for computational speed. Regardless of the method chosen, it results in poor user experience. To address this challenge, some scholars have begun to study recommendation systems based on short sequence information. This approach focuses on the activities of users in the recent past, modeling user short-term interests through actions such as browsing and liking, to capture short-term changes in user interests. This method not only avoids the high time complexity of processing long sequence information but also allows for real-time tracking of user interest changes, thereby achieving precise recommendations in the short term. However, this approach also has significant limitations in capturing user interests and preferences over long periods.

In response to the aforementioned issues, this paper conducts an in-depth analysis of the shortcomings in existing research and proposes a recommendation model named RUICP, based on real-time user interest and commodity popularity. This model not only captures the characteristic of user interests changing over time and adjusts recommendations in real-time to meet personalized user needs but also effectively addresses the cold start problem by introducing the factor of commodity popularity. Through this research, we aim to provide new ideas and methods for the development of recommendation systems, further promoting innovation and

*Corresponding Author.

application of personalized recommendation technology. The main contributions of this paper are as follows:

- Proposed a method for calculating long and short-term user time-sensitive interests, which can more accurately capture changes in user interests.
- Designed a new method for calculating commodity popularity, taking into account user repeat click rates, resulting in more scientifically derived results.
- Empirical evidence demonstrates that the proposed method in this paper has certain accuracy advantages and provides valuable insights for addressing the cold start problem.

The rest is as follows: Section II discusses related work. Section III introduces the model of this article in detail. Section IV evaluates the method proposed in this article. Section V concludes the study and outlines future work.

## II. Related Work

In the field of commodity recommendation, scholars have explored various methods, primarily focusing on user behavior, commodity attributes, and their interactions. For instance, Wang et al. [3] introduced a recommendation algorithm that emphasizes user click behavior, inferring preferences by analyzing user browsing patterns to identify points of interest. Similarly, Ficel et al. [4] utilized the relationship between users and commodities for recommendations. They first modeled articles based on freshness and popularity then inferred user preferences based on personal information and browsing history, and finally recommended commodities by integrating the two pieces of information. Experimental results show the reliability of this method. However, while these methods provide valuable insights into user behavior and preferences, they may overlook certain temporal dynamics, failing to capture the essence of changes in user interests over time. Mookiah et al. [5] modeled commodity relationships using a heterogeneous graph approach, capturing key commodities for filtering, which is effective for users with low interactivity, particularly in specific scenarios for precise recommendations, but lacks universality. Sung et al. [6] investigated the attractiveness of commodity titles and keywords to users, simulating user perception from the perspective of commodity titles to recommend commodities with attractive titles, thereby increasing click-through rates. Although this method enables rapid recommendations, it may lead to the problem of homogeneous commodities. Han et al. [7] personalized commodity recommendations by analyzing user browsing records, employing an improved association rule combined with collaborative filtering algorithms. While this method offers stable overall performance and considers multiple factors for recommendations, it may be constrained when dealing with complex user behavior patterns and may not adequately address the cold start problem for new users.

In recent years, scholars have begun researching recommendation methods based on deep learning. Zheng et al. [9] proposed a recommendation framework based on Q-Learning to simulate feedback after clicks, searching for attractive commodities for users based on feedback information, but requires large amounts of data and computational resources for model training and optimization. Epure et al. [10] studied changes in browsing interests over time, dividing interests into short-term, medium-term, and long-term levels, concluding that a combination of long-term and short-term recommendations achieves the highest accuracy. Recommendations based on a combination of medium-term and short-term interests may increase the variety of commodities but may not be significant for some users with less obvious changes in interests over different periods. Qi et al. [11] investigated popular commodities to address the cold start problem and insufficient diversity in recommendation systems, combining personalized matching scores with commodity popularity to calculate recommendation rankings. This method innovatively proposes a popularity calculation method but overly relies on popularity factors, resulting in personalized recommendations lacking diversity. Ji et al. [12] studied the dynamic characteristics of interaction times between users and commodities, utilizing a time-sensitive heterogeneous graph neural network based on commodity recommendation, improving recommendation accuracy and providing better interpretability compared to traditional neural network methods. Meng et al. [13] studied the importance of commodity lifecycle, integrating user preference attention and commodity lifecycle, modeling the dual impact of user clicks on commodities. Ji et al. [14] used commodity click-through rates to measure commodity popularity. Wu et al. [15] employed attention mechanism networks to learn commodity and user representations. Despite significant progress in recommendation systems, existing methods still have some limitations. Firstly, existing methods often struggle to accurately capture and model the dynamic nature of user interest changes, resulting in recommendations deviating from actual user needs. Secondly, existing methods often have difficulty fully considering the diversity of commodity attributes and the complexity of user preferences, limiting the accuracy and personalization of recommendations. Additionally, the cold start and diversity problems in recommendation systems remain significant challenges. Therefore, we conducted this work and proposed RUICP, hoping to explore more accurate and personalized recommendation methods by deeply studying the dynamic interactions between users and commodities.

## III. Calculation Model

The RUICP model proposed in this paper, as illustrated in Fig. 1, introduces innovative designs at several key steps.

Firstly, RUICP leverages user basic data and accumulated usage information to construct refined user profiles. By partitioning user usage data into equal time intervals and conducting in-depth semantic feature analysis, the model can more accurately capture users' long-term interest intensity. Next, the model focuses on short-term changes in user interests. By splitting short-term usage data, the model can quickly capture users' short-term interest points. Additionally, by combining short-term interest with long-term interest intensity, the model can comprehensively consider users' stable and temporary interests, generating recommendations that better fit current needs, forming the final interest.

In addition to considering user interests, the model innovatively introduces commodity repeat click rates to calculate commodity popularity scores. This metric reflects the actual attractiveness of commodities and user attention, providing a more reasonable basis for ranking commodities. By updating commodity rankings, the model ensures that high-quality and popular commodities receive more exposure opportunities. Finally, RUICP employs the classic model-based collaborative filtering algorithm [8] to calculate the matching degree between user interests and commodities. This algorithm comprehensively considers user historical behavior, commodity attributes, and user-commodity interaction relationships, providing users with more accurate and personalized recommendations. By combining user profiles and commodity rankings from the aforementioned steps, the model can present users with a rich and diverse recommendation list.

## A. User Portrait

Constructing user profiles is a crucial step in recommendation systems, revealing users' interests and preferences through in-depth exploration of user basic data and accumulated usage information. In the recommended model proposed in this paper, the construction of user profiles is particularly refined and comprehensive.

Firstly, RUICP fully utilizes user basic data, which hides users' points of interest. For example, geographic location information can reflect users' regional consumption habits; for instance, users in the northern regions may be more inclined to purchase garlic and kang tables, whereas users in the southern regions may not be interested in these commodities. Furthermore, RUICP divides user usage data into time periods and deeply analyzes users' behavioral patterns during each period. By calculating the number of clicks $C_u$ and browsing duration $L_u$ in each period, RUICP can further characterize changes in user interests.

It is worth noting that this paper does not include shopping cart information when constructing user profiles. This is because many users do not have the habit of adding items to their shopping carts, or only add items to their shopping carts before checkout, after which they no longer pay attention to these items. Moreover, shopping cart information often has strong interest tendencies. If incorporated into the recommendation system, it may cause the system to repeatedly recommend items that users have added to their shopping carts, causing inconvenience to users. Additionally, adding shopping cart information increases data dimensions, leading to increased computational difficulty, which is not conducive to real-time recommendations. To avoid these problems, we adopt a more reasonable interest prediction method. During the model parameter estimation phase, we introduce a smoothing parameter $G$ and set it to 10. The introduction of this parameter helps smooth changes in user interests, making the prediction results more stable and accurate. Finally, we calculate the user's interest prediction value according to Eq. (1), which provides an important basis for subsequent commodity recommendations.

$$U_i = \frac{\sum(\sum_{n\in t} C_n \times \frac{\alpha C_{i+}\beta L_u}{C_{total}} \times p^t + G)}{\sum_{n\in t} C_n} \tag{1}$$

where, $U_i$ represents the user's interest in topic $i$, $\alpha$ and $\beta$ are set to 0.5 and 0.3 respectively, $\sum_{n\in t} C_n$ is the total number of clicks by the user during period $t$, $p^t$ is the probability of the user clicking on item $i$ during period $t$, and $C_{total}$ is the total number of clicks during the user's usage period.

## B. User Real-Time Interest

During the entire browsing process, users may be attracted by promotional activities or exquisite products, resulting in continuously changing real-time interests. Traditional recommendation methods often overlook the rapid changes in user interests within a very short period, or use commodity similarity as a substitute for these changes. Many studies assume that when a user clicks on a product, it indicates their interest at that moment, and therefore recommend similar products. However, this approach has two problems: 1) Users may be recommended similar products after accidental clicks; 2) Users may click on a product out of curiosity, without genuine interest, yet the recommendation system still relies on browsing history to suggest similar products. Therefore, this paper investigates user real-time interests and proposes a method to capture them. The core idea of this method is to differentiate between users' long-term and short-term interests based on their usage duration and click behavior, and adjust the recommendation strategy accordingly.

Firstly, RUICP categorize user behavior into long-term and short-term types based on their usage duration. Lengthy browsing typically reflects the types of products that users have long-term interest in, which is crucial for determining their long-term interests. We calculate the user's long-term interest $U_L$ by weighting the user's dwell time on each product. In contrast, short-term browsing may more likely reflect users' temporary needs or curiosity, with a lower contribution to short-term interest $U_S$. Next, we further divide users' short-term behavior. By partitioning short-term click behavior based on the time of clicking, we obtain $U_{s1}$, $U_{s2}$, and so on. We then use the cosine similarity formula to calculate the similarity between these products. If the similarity between products is high and the user has made a purchase, we consider this click as not representing the user's genuine interest but possibly due to accidental clicks or curiosity. Conversely, if the similarity between products is low, the categories to which these products belong are more likely to be the user's short-term interest points $U_S$. To more accurately measure the user's real-time interest intensity, we propose a comprehensive calculation formula that combines the user's long-term interest and short-term interest, considering the impact of the interest factor $d$, as shown in Eq. (2).

$$I_u = 1 - d + d(\alpha U_L + \beta \sum U_{si}) \tag{2}$$

where, $\sum U_{si}$ represents the comprehensive weight of similar products, and dd represents the interest factor. By adjusting the value of the interest factor, we can control the weight of long-term and short-term interests in the final recommendation, thus flexibly adapting to the personalized needs of different users.

Furthermore, when calculating product similarity, we adopt the classic TF-IDF method. Considering that users with a wider range of interests may behave more randomly without clear objectives, we adjust their contribution to similarity calculation based on their behavior quantity. The more behaviors a user have, the lower their contribution, to avoid the excessive influence of random behaviors on similarity calculation. The specific calculation is as shown in Eq. (3) and Eq. (4).

$$Sim^{w}(i,j) = \frac{\sum_{u \in U} w_u \delta(i,j)}{\sum_{u \in U} w_u} \tag{3}$$

$$w_u = \frac{1}{\log I_u + 1} \ , \delta(i,j) = \begin{cases} 1, i \in I_u \; and \; j \in I_u \\ 0, else \end{cases} \tag{4}$$

Where $U$ is the set of all users, $U_i$ is the set of users interested in product $i$, $W_u$ represents the contribution of user $u$ to similarity, and $I_u$ is the user's real-time interest intensity.

### C. Commodity Heat Calculation

Commodity hotness is a crucial indicator of the popularity of products. Accurately calculating commodity hotness is essential for improving the accuracy and timeliness of recommendations in recommendation systems. Traditional methods for calculating commodity hotness are typically based on factors such as product attributes, click-through rates, and release time. However, these methods may not fully reflect the actual popularity of products, especially for those products that have been on the market for a long time but maintain stable sales.

In China's leading online shopping platform, Taobao, products are classified into 15 major categories. For international understanding and analysis, this paper integrates them into 10 major categories. Moreover, based on the "Analysis of Major Category Transaction Data on Taobao - 2019Q1" report, we accurately calculate the influence factors of various product categories, as shown in Table I.

TABLE I. INFLUENCE FACTORS OF PRODUCTS

| Classification | Influence Factor | Classification | Influence Factor |
|---|---|---|---|
| Clothing | 0.85 | Snacks | 0.85 |
| Beauty Makeup | 0.76 | Digital | 0.76 |
| Ingredients | 0.63 | Home Furnishing | 0.63 |
| Medicine | 0.56 | Luxury Goods | 0.56 |
| Vehicle | 0.24 | Other | 0.24 |

Based on these influence factors and considering practical life scenarios, we propose a new method for calculating commodity hotness to more accurately reflect the actual popularity of products. Firstly, we consider the basic attributes of products, such as product type, and set different influence factors for different types of products. For example, products with high consumption frequency, such as clothing and snacks, have relatively high influence factors, while products such as cars and other special types have lower influence factors. This approach allows for consideration of the differences in basic market demand for different types of products. RUICP integrates user interaction data for products to calculate commodity hotness $H$, as shown in Eq. (5).

$$H = \frac{W+K}{(T+1)^G} \tag{5}$$

$W$ is the normalized sum of product views, comments, likes, etc., to eliminate dimensional differences between different data sources and enable comparison and weighting. $K$ is the influence factor of the product. $T$ is the time since the product was released. $G$ is a smoothing parameter used to control the rate of decay of commodity hotness over time. By adjusting the value of $G$, the balance between freshness and historical popularity of products can be controlled, allowing the recommendation results to reflect both currently trending products and maintain attention to classic products.

However, considering only the above factors may still not fully reflect the true hotness of products. As shown in Table I, in fact, some products, despite being on the market for a long time, maintain very high sales due to their excellent quality or unique value, and their hotness does not significantly decay over time. If traditional hotness calculation methods are used, the hotness of these classic products may be severely underestimated. Therefore, we further consider the repeat click rate $D$ of users and propose a new hotness calculation method, using it as an important indicator to measure commodity hotness. The repeat click rate can reflect users' sustained interest in products and is an effective indicator of the persistence of product hotness, as shown in Eq. (6).

$$H = \frac{\max(W,D)+U}{(\frac{T}{\log D}+1)^G} \tag{6}$$

By comprehensively considering the repeat click rate and other relevant factors, we can more comprehensively evaluate the hotness of products, thereby providing consumers with more accurate and valuable recommendations. This method not only helps improve the shopping experience for users but also provides businesses with a more scientific approach to product management and marketing strategies.

## IV. Experimental Settings and Evaluation Indicators

### A. Dataset and Experimental Setup

The dataset used in this experiment is from the KDD Cup 2020 Track-B, which is a publicly available dataset covering user-clicked behaviors over ten days. It contains over 1 million click records, involving 100,000 commodities and 30,000 users. Such scale ensures that our research has sufficient breadth and depth to fully reflect the diversity and complexity of user behavior. Considering that the original dataset may contain some missing and redundant information, we conducted disambiguation and deduplication processes to ensure the accuracy and effectiveness of the data.

User Features: Include user ID, age group, gender, and city hierarchy.

Commodity Features: Include features of the commodities, represented as 128-dimensional text features.

Training Set: Records the user's historical click behavior, excluding the latest 10 clicks.

Validation Set: Contains the historical click behavior of users to be predicted, consisting of the latest 10 clicks for each user.

In the dataset, user features are a crucial part for understanding user preferences and behavior patterns, while commodity features can better characterize the attributes and characteristics of commodities. These features can effectively depict the diversity and differences of commodities, contributing to improved recommendation accuracy and personalization. In terms of experimental settings, we divided the dataset into training and validation sets. The training set is mainly used to calculate the strength of user interest, from which we can derive the representation of interest strength for each user by mining patterns and information in their historical click behavior. Additionally, the training set is used to extract the number of clicks and non-clicks of commodities within the last 30 minutes to calculate commodity popularity. The validation set is used to evaluate the performance of the model, consisting of the latest 10 click records for each user, which will be treated as the user's historical click behavior to be predicted. By comparing the model's predicted results with the actual click behavior; we can assess the accuracy and effectiveness of the model. Table II details the specific statistics of the dataset.

TABLE II. Dataset Statistics

| Users | Commodities | Training Records | Validation Records |
|---|---|---|---|
| 6,737 | 117,538 | 174,414 | 67,370 |

To comprehensively evaluate the performance of the model, we selected AUC, nDCG@5, and nDCG@10 as evaluation metrics. A higher AUC value indicates better classification performance of the model, while values of nDCG@5 and nDCG@10 closer to 1 indicate higher quality of recommendation ranking in the Top-K recommendation results. These metrics provide a comprehensive and objective method for evaluating the performance of the recommendation system.

In terms of selecting comparison methods, we chose several excellent methods in the field of commodity recommendation as benchmarks. These methods include DRN [9], which recommends commodities by simulating feedback after clicks, DCAN [13], which integrates user preference attention and commodity lifecycle, CTR [14], which measures popularity based on click-through rate, and NPA [15], which learns commodity and user representations using attention mechanism networks. By comparing with these methods, we can objectively and accurately evaluate the performance and advantages of our proposed RUICP algorithm in the experiment.

### B. User Cold Start

To comprehensively evaluate the effectiveness of RUICP in addressing the cold start problem, we designed a series of rigorous validation measures. Firstly, we simulated scenarios with new users and conducted four experiments, recommending commodities after 1, 3, 5, and 7 clicks respectively. The aim was to explore the recommendation performance of RUICP under different numbers of clicks. With this carefully designed experiment, we were able to systematically observe and analyze the performance of RUICP during the cold start phase for new users. The specific results are shown in Fig. 2.

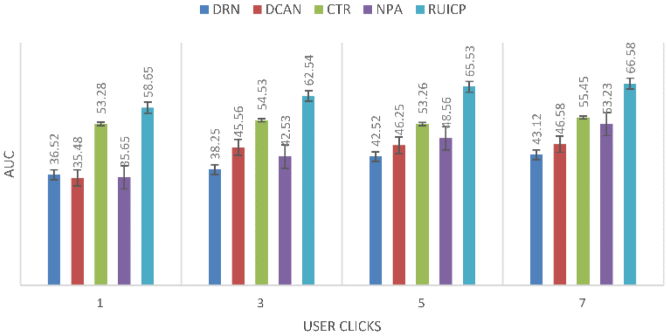

Fig. 2. New user recommendation results.

Fig. 2 clearly demonstrates the recommendation results for new users. From the figure, we can observe that RUICP has advantages over other methods in metrics such as AUC, nDCG@5, and nDCG@10. Particularly in the scenario with new users, RUICP exhibits significant advantages in addressing the cold start problem. Compared to traditional recommendation methods, RUICP introduces commodity popularity as an important metric, calculating commodity popularity based on recent click rates of other users, which enhances its timeliness and universality. During the cold start phase, when users lack relevant data, RUICP can more accurately capture users' latent interests and provide personalized recommendations that align with user preferences. Additionally, compared to other methods, RUICP not only relies on interactions between users and commodities but also comprehensively considers commodity popularity and user interest strength, thereby more comprehensively addressing users' actual needs in the recommendation process. Furthermore, compared to methods like CTR, which rely heavily on click-through rate for measuring popularity, RUICP can better reflect users' interest strength, avoiding inaccuracies in recommendation results caused by excessive reliance on popularity calculated through click rates.

In summary, RUICP exhibits significant advantages in addressing the user cold start problem and holds promising applications in recommendation systems.

### C. Recommendation Accuracy

In this section, experiments were conducted to evaluate the accuracy of RUICP for recommending to existing users. The dataset mentioned in Table II was used for training, and the performance of various recommendation methods was analyzed by comparing them with the validation set. After two repeated experiments, we obtained average results and standard deviations, as shown in Table III. These experimental results provide us with an intuitive comparison of the performance of different recommendation algorithms.

TABLE III. EXPERIMENTAL RESULTS

| Methods | AUC | nDCG@5 | nDCG@10 |
|---|---|---|---|
| DRN | 52.45±0.00 | 25.46±0.16 | 28.18±0.16 |
| DCAN | 57.26±0.02 | 28.26±0.03 | 28.35±0.11 |
| CTR | 63.51±0.15 | 31.25±0.00 | 37.56±0.01 |
| NPA | 66.17±0.00 | 32.56±0.02 | 38.51±0.13 |
| RUICP | 69.23±0.15 | 36.66±0.18 | 45.26±0.15 |

From the experimental results, it can be seen that RUICP exhibits significant advantages over other methods. Specifically, while DRN and DCAN have their own characteristics, they both fail to fully consider the real-time changes in user interests. DRN overly relies on feedback after user clicks, making it prone to the recommendation dilemma of homogeneity, while DCAN, although combining user preferences and item lifecycles, lacks the ability to capture real-time interests, resulting in often outdated recommendations. The CTR method improves recommendation accuracy by introducing the commodity popularity factor, but its popularity calculation method is relatively simple and overlooks personalized user needs and real-time interest changes, thus failing to fully consider the differences between different users. Although NPA optimizes the interaction representation between users and commodities using attention mechanisms, it also fails to capture the rapid changes in user short-term interests. In contrast, the advantage of RUICP lies in its ability to capture and reflect changes in user interests in real-time. By comprehensively considering user interest strength, commodity popularity, and real-time interaction information, RUICP not only improves recommendation accuracy but also ensures recommendation timeliness and personalization. In summary, RUICP exhibits significant advantages in addressing real-time recommendation problems for existing users, better meeting users' personalized needs, and improving user satisfaction and click-through rates.

## V. CONCLUSION AND FUTURE WORK

This paper proposes a dynamic representation method of user interest intensity by accurately capturing changes in user interests over time, aiming to address the bias issue in real-time recommendation content. Building upon this, we innovatively introduce the RUICP recommendation model based on user temporal interest and commodity popularity. By analyzing user behavior patterns, emotional tendencies, and other relevant information, we can accurately understand users' psychological states and needs. Based on this information, our method can provide recommendation content that matches the user's current psychological state, helping users better satisfy their psychological needs. For example, in the analysis of user behavior patterns, we consider not only user clicks but also analyze browsing history, purchase records, and other information to fully understand user interests and preferences. In emotional tendency analysis, we use sentiment analysis techniques to identify the emotional states that users exhibit during interactions, further accurately capturing users' psychological needs. The comprehensive application of these technologies and strategies enables RUICP to better understand and satisfy users' psychological needs, thereby improving user experience and psychological enjoyment.

In experiments, by simulating real-time user click experiments, the recommendation effects of RUICP in new and existing users were comprehensively verified. Experimental results show that compared to other methods, RUICP not only significantly improves the recommendation accuracy for existing users but also effectively addresses the cold start problem for new users.

In conclusion, the RUICP model proposed in this paper demonstrates significant advantages in improving recommendation system accuracy and increasing user effective clicks. This method provides new ideas for addressing user stickiness and advertising efficiency issues, with important practical value. In the future, we plan to apply the RUICP model to more related fields to achieve more in-depth and comprehensive research results.

# Beyond BERT: Exploring the Efficacy of RoBERTa and ALBERT in Supervised Multiclass Text Classification

Christian Y. Sy[1], Lany L. Maceda[2], Mary Joy P. Canon[3], Nancy M. Flores[4]
Department of Computer Science and Information Technology-Bicol University,
College of Science, Legazpi City, Philippines[1, 2, 3]
College of Information Technology and Computer Science, University of the Cordilleras, Baguio City, Philippines[4]

***Abstract*—This study investigates the performance of transformer-based machine learning models, specifically BERT, RoBERTa, and ALBERT, in multiclass text classification within the context of the Universal Access to Quality Tertiary Education (UAQTE) program. The aim is to systematically categorize and analyze qualitative responses to uncover domain-specific patterns in students' experiences. Through rigorous evaluation of various hyperparameter configurations, consistent enhancements in model performance are observed with smaller batch sizes and increased epochs, while optimal learning rates further boost accuracy. However, achieving an optimal balance between sequence length and model efficacy presents nuanced challenges, with instances of overfitting emerging after a certain number of epochs. Notably, the findings underscore the effectiveness of the UAQTE program in addressing student needs, particularly evident in categories such as "Family Support" and "Financial Support," with RoBERTa emerging as a standout choice due to its stable performance during training. Future research should focus on fine-tuning hyperparameter values and adopting continuous monitoring mechanisms to reduce overfitting. Furthermore, ongoing review and modification of educational efforts, informed by evidence-based decision-making and stakeholder feedback, is critical to fulfill students' changing needs effectively.**

***Keywords*—Multi-class text classification; Bidirectional Encoder Representations from Transformers (BERT); RoBERTa; ALBERT; Universal Access to Quality Tertiary Education (UAQTE) program; educational policy reforms***

## I. Introduction

The free tertiary education program, referred to as the Universal Access to Quality Tertiary Education (UAQTE) program, was initiated in the Philippines as a significant development in educational policy. The objective of this initiative is to increase access to tertiary education for all eligible Filipino students [1]. As the program progresses, understanding students' diverse experiences becomes crucial for evaluating its impact [2]. While qualitative responses offer rich narratives [3], manual categorization of these diverse accounts can be overwhelming. Therefore, this study employs transformer-based machine learning models like BERT, RoBERTa, and ALBERT to automate text classification [4].

By systematically analyzing student responses, the research aims to uncover nuanced perceptions of the UAQTE program's impact. The objective is to gain valuable insights into each student's distinctive experiences within the UAQTE framework. Leveraging prominent models for automated multiclass text classification [5], the study seeks to categorize student responses and unveil domain-specific insights systematically. This involves aligning experiences with predefined classes identified through collaboration with domain experts, ensuring a nuanced and contextualized understanding [6] of the diverse impacts of the UAQTE program on students.

Furthermore, the research evaluates the performance of these models in accurately categorizing qualitative responses, contributing to the advancement of machine learning techniques in educational research. This assessment ensures the reliability and effectiveness of the machine learning models [7] employed in the study. The primary research contribution lies in developing and applying advanced machine learning methods to analyze qualitative data in educational contexts [8], providing a novel approach to understanding the effects of educational policies like the UAQTE program. Ultimately, this research aims to contribute to informed policymaking and enhance educational initiatives for the benefit of Filipino students, thereby advancing the objectives of the UAQTE program.

## II. Related Works

This section delves into the literature surrounding machine learning applications, particularly those relevant to implementing transformer-based models.

### A. Machine Learning in Educational Policy

The integration of machine learning (ML) into educational policy signifies an innovative strategy for shaping the course of education [9], [10], [11], specifically in the context of revolutionary endeavors such as the Philippines' Universal Access to Quality Tertiary Education (UAQTE) program. Machine learning algorithms are highly effective tools for managing large data sets, presenting an opportunity to reform how policymakers understand, assess, and improve educational initiatives [12], [13].

Conventional assessment techniques might find capturing the intricacies and varied nature of student experiences challenging, underscoring the importance of adopting advanced data-driven methodologies. ML algorithms excel in uncovering patterns and trends within extensive datasets, offering a depth of analysis that traditional methods might overlook [14], [15]. This capability becomes invaluable when assessing the effectiveness of educational programs, including initiatives like UAQTE.

The integration of ML into educational policy represents a significant leap forward. It facilitates a more thorough, dynamic, and nuanced assessment, providing policymakers with actionable insights into what aspects of the program are succeeding and where improvements are needed [16], [17]. As education systems worldwide navigate the complexities of providing equitable and quality education, the synergy between ML and educational policy becomes a pivotal force in shaping a more responsive and effective future for education.

### *B. Transformer-based Models*

Transformer-based models, harnessing contextual relationships and language patterns through an architecture emphasizing parallel processing and self-attention mechanisms [18], [19], [20] represent a groundbreaking advancement in natural language processing (NLP). Unlike conventional recurrent neural networks (RNNs) or convolutional neural networks (CNNs), transformers operate simultaneously, enabling a holistic assessment of the entire context. This parallelized architecture enhances the model's ability to effectively capture long-range dependencies and subtle contextual nuances within the input sequence [21], [22].

Transformer-based models undergo initial pre-training on extensive corpora, enabling them to comprehensively understand language structures and patterns [23], [23], [24]. This foundational pre-training phase equips the models with a wealth of linguistic understanding. Following this, the models demonstrate adaptability by undergoing fine-tuning on domain-specific datasets, allowing them to tailor their knowledge to specific applications [25], [26]. This inherent adaptability renders them versatile across various tasks and domains, showcasing their efficacy in diverse applications [27], [28].

One notable application of transformer-based models is in qualitative data analysis, especially in domains like education policy. The models can perform multiclass text classification, categorizing and extracting insights from qualitative responses systematically. This capability becomes particularly valuable when evaluating the impact of programs like the UAQTE initiative, providing a data-driven lens to understand the diverse experiences of student beneficiaries.

### *C. Multiclass Text Classification*

Leveraging advanced capabilities in natural language processing, transformer-based models exhibit remarkable proficiency in multiclass text classification, surpassing traditional text classification tasks [29], [30], [31]. This competence is deeply rooted in the objective of categorizing textual data into more than two predefined classes or categories. In multiclass text classification, each document or piece of text is precisely assigned to one specific class from a set of multiple classes, a task crucial for accurately discerning the most appropriate category or label based on the input text's content, themes, or characteristics [32], [33].

The adeptness of transformer-based models in this research facilitates a systematic understanding and categorization of qualitative responses [34], [35] from student beneficiaries within the UAQTE initiative. This structured approach guarantees precision in assigning text to relevant categories and serves as an effective tool for extracting insights into the diverse nature of students' experiences. Fortified with attention mechanisms and contextual understanding, the models capture subtle distinctions in qualitative data, providing a comprehensive and nuanced understanding of its impact [36], [37].

The proficiency in multiclass text classification offered by transformer-based models elevates their role as invaluable assets in navigating the complexities of education policy analysis, especially when seeking to comprehend the multifaceted dimensions of student experiences within specific programs like UAQTE. Ultimately, this capability empowers policymakers with nuanced, data-driven perspectives, facilitating well-informed choices in the dynamic landscape of education policy.

### *D. Role of Domain Experts*

The involvement of domain experts in crafting and refining predefined categories is a well-established practice [38], [39], [40]. Their expertise ensures that the categories encapsulate the diverse dimensions of qualitative responses [41], [42]. This proactive role positions domain experts as key architects in aligning the model with the intricacies of the specific research domain, contributing significantly to ensuring that class labels are accurate and contextually relevant [43], [44].

Moreover, domain experts continue to play a critical role in the ongoing validation of machine learning models [45], [46]. As these models generate predictions on new or unseen data, domain experts validate the accuracy of these predictions against the true labels they provide. This validation process is a robust quality control mechanism, ensuring the alignment of model predictions with the ground truth. Establishing a feedback loop between domain experts and machine learning models contributes to the continual enhancement of the classification system [47], [48].

This iterative collaboration bolsters the accuracy of machine learning models and cultivates a dynamic understanding of qualitative data within the specific research domain. By actively participating in providing true labels and validating model predictions, domain experts ensure that multiclass text classification models are not only accurate but also ethically sound [49], [50]. Their dual role as architects of the categorization framework and validators of model predictions positions them as indispensable contributors to the success of the entire machine learning process within the field of education policy analysis.

### *E. BERT, RoBERTa, and ALBERT*

In the broader context of natural language processing and machine learning, the integration of advanced models such as Bidirectional Encoder Representations from Transformers (BERT), Robustly optimized BERT approach (RoBERTa), and A Lite BERT (ALBERT) has become a focal point of research, particularly in the domain of multiclass text classification. These models demonstrate exceptional proficiency in achieving fine-grained categorization objectives, allowing for systematically classifying qualitative responses into multiple predefined classes [51]. The emphasis is on their ability to capture nuanced distinctions, going beyond traditional categorization methods.

BERT pioneered bidirectional training, considering both left and right contexts in all layers [52], [53]. In refining this approach, RoBERTa removed the next sentence prediction objective and integrated dynamic masking during training [54], [55]. ALBERT, addressing computational challenges, implemented cross-layer parameter sharing and a factorized embedding parameterization, enhancing efficiency [56], [57].

Recognized for its general applicability, BERT's larger model size may pose computational intensity [58]. RoBERTa, optimized for larger mini-batches, showcases improved efficiency [59]. ALBERT, designed for parameter efficiency, strikes a balance between reduced parameters and competitive performance [60]. These distinctions significantly impact their versatility in categorizing information, spanning various themes or topics with potential applications across diverse domains.

The bidirectional attention mechanisms and extensive pre-training of BERT, RoBERTa, and ALBERT equip them with a profound understanding of context and relationships within the text [61]. This comprehensive comprehension positions them as valuable tools for many multiclass text classification applications. They provide insights crucial for refining models, enhancing accuracy, and facilitating informed decision-making. Furthermore, the iterative nature of machine learning emphasizes ongoing feedback loops, allowing continuous adjustments for enhanced model performance. This iterative refinement ensures that multiclass text classification models, whether BERT, RoBERTa, or ALBERT, progressively excel in handling diverse textual data [62].

### F. *Evaluation Metrics for Text Classification*

Evaluation metrics are essential benchmarks for assessing the effectiveness of text classification models, providing valuable insights into their performance and generalization capabilities [63]. In the domain of text classification, various metrics are utilized to measure accuracy and reliability. Training accuracy assesses the model's proficiency in classifying instances within the training dataset, while validation accuracy evaluates its ability to generalize to new data without overfitting. Test accuracy offers a final evaluation of the model's performance on unseen data [64], [65]. Precision, recall, and F1-score provide nuanced assessments of its ability to correctly classify positive instances and balance false positives and false negatives [66], [67].

The confusion matrix visually represents the model's predictions, facilitating a detailed analysis of its performance across different classes. Additionally, the involvement of domain experts is crucial in providing true labels and validating the model's predictions against ground truth, thereby enhancing the reliability and credibility of the text classification process [68], [69].

These models, through the utilization of data-driven techniques, provide a comprehensive understanding of initiatives like the Universal Access to Quality Tertiary Education (UAQTE) program, revealing valuable insights derived from student experiences. The collaboration between machine learning algorithms and domain experts not only verifies model predictions but also ensures the precision of classifications, thereby reinforcing the credibility of the analysis. As these models evolve, they offer the potential to influence the development of more adaptive and efficient education policies in the future.

## III. Methodology

The methodology employed is outlined in this section. Fig. 1 presents the information processing phases and delineates the steps, encompassing data preparation, tokenization and formatting, model training, model evaluation, hyperparameter tuning, and inference.

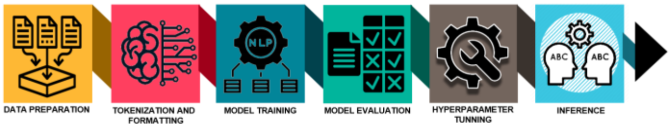

Fig. 1. Information processing phases.

### A. *Data Preparation*

The "Boses Ko" or "My Voice" is a toolkit developed, with its grassroots approach that is instrumental in gathering data directly from student beneficiaries of the UAQTE program. This prioritization of perspectives from those directly involved ensures the authenticity and relevance of the collected data. The qualitative question guiding the study, "Write your experiences as one of the beneficiaries of the UAQTE program," further focuses the data collection process on soliciting responses specifically tailored to understanding student experiences within the program.

The sample size of 3,325 student responses, selected from State Universities and Colleges (SUCs), provides a diverse representation necessary for comprehensive examination across various institutional contexts. Data cleaning involves removing non-English, duplicate, non-grantee, and blank responses, which helps ensure the dataset's quality and consistency. Text standardization techniques, such as converting the cleaned dataset to lowercase and eliminating special characters, punctuation marks, and digits, further streamline the text representation, reducing noise and interference with the modeling process. These steps enhance the dataset's suitability for subsequent analysis and modeling tasks. Tokenization and removal of stopwords by implementing the Natural Language Toolkit (NLTK) library were necessary pre-processing steps. Responses were tokenized into individual words or tokens, making analyzing and processing text data easier. Stopwords like "as," "one," "of," "the," "it," "me," "a," and "in" are common in the responses but typically lack significant meaning alone. Eliminating these enhanced the quality, interpretability, and efficiency of the generated topics within the UAQTE framework by reducing noise and emphasizing content words that conveyed the core themes.

Furthermore, domain experts play a key role in collaborating on crafting and refining predefined categories for qualitative responses. Leveraging their expertise ensures that the categories accurately represent the diverse dimensions of student experiences within the framework of the UAQTE program. Through close collaboration with domain experts, the study ensures that the labeling of the dataset reflects the nuanced perspectives relevant to the research domain. Table I presents the categories derived through this collaborative effort.

TABLE I. DOMAIN-EXPERTS IDENTIFIED CATEGORIES

| Categories | Description |
|---|---|
| Financial Support | Responses that refer to the financial assistance provided, alleviation of financial burdens, and support with tuition fees, allowances, and other expenses. |
| Educational Opportunity | Responses that describe students' gratitude towards the program, enabling them to pursue their preferred courses, continue their studies, and access to quality education. |
| Family Support | Responses express families' gratitude for the support provided by the program and the ease it brings to their lives, as it relieves financial burdens, allowing them to save money and allocate resources to other expenses. |
| Academic Focus and Personal Development | Responses describe students being more focused on studying, becoming more responsible, and having more chances to invest in school projects due to the financial support received. They also attribute personal growth, increased enthusiasm, and improved class standings to being part of the program. |
| Program Implementation | Responses encompass a range of perspectives regarding the implementation of the program, reflecting both positive and negative viewpoints. |

For data splitting, an 80-20 train-validation split is implemented. 80% of the entire dataset is allocated for training, with 80% of this training set used for actual model training and the remaining 20% reserved for validation. This partitioning strategy ensures that the model is trained on a sufficiently large portion of the dataset while allowing validation to monitor model performance and prevent overfitting. The remaining 20% of the entire dataset is held out for testing the model's performance, providing an independent evaluation of its generalization capabilities.

## B. Tokenization and Formatting

Tokenization and formatting play crucial roles in preparing text data for transformer-based machine learning models such as BERT, RoBERTa, and ALBERT. These models rely on specific input structures to effectively process textual information. In the context of multiclass text classification using the UAQTE student responses dataset, tokenization involves breaking down the text into smaller units, typically words or subword units. This task is simplified by specialized tokenizers available in the Hugging Face's transformers library. For instance, the BERT tokenizer utilizes a WordPiece tokenizer to decompose words into subword units based on a predetermined vocabulary. Similarly, RoBERTa and ALBERT leverage WordPiece tokenization for the same purpose.

Once tokenization is completed, the tokenized text data needs to be formatted into an appropriate input structure for the transformer models. This formatting process includes adding special tokens like [CLS] (classification token) at the beginning of each sentence and [SEP] (separator token) between sentences. Additionally, sequences are padded to a fixed length, and attention masks are created to differentiate actual words from padding tokens. These formatting steps ensure uniform input lengths and assist the model in focusing on relevant tokens during the training and inference phases.

## C. Model Training

Model training with BERT, RoBERTa, and ALBERT involves several steps to adapt these transformer-based models for multiclass text classification tasks using the UAQTE student responses dataset. Pre-trained BERT, RoBERTa, and ALBERT models are initially loaded from the Hugging Face's transformers library. These models possess an extensive contextual understanding of language, making them suitable for diverse natural language processing tasks, including multiclass text classification.

Subsequently, defining an optimizer and a loss function is crucial for training efficiency. Optimizers like Adam or SGD and loss functions such as Cross Entropy Loss are commonly employed. These components contribute to the model's ability to adjust parameters and minimize the loss during training, ensuring convergence towards accurate predictions. Data loaders are then created to handle the pre-processed text data efficiently, converting it into PyTorch or TensorFlow datasets. These loaders manage tasks like shuffling, batching, and loading data onto the GPU, streamlining the training process by optimizing resource utilization.

The training loop iterates through batches of data from the training set. The input data is passed through the BERT, RoBERTa, or ALBERT model to obtain predictions in each iteration. Subsequently, the loss is calculated by comparing the model's predictions with the true labels, followed by a backward pass to compute gradients and update model parameters using the chosen optimizer. This iterative process continues for multiple epochs, with the model's weights adjusted iteratively to improve performance.

## D. Model Evaluation

The model evaluation phase is critical to comprehensively assess the performance of the trained multiclass text classification models. This evaluation encompasses a range of metrics to gauge different aspects of the model's effectiveness in handling the UAQTE student responses dataset. Initially, the evaluation considers training accuracy, which reflects how well the models have learned from the training data by measuring the proportion of correctly classified instances within this dataset. Subsequently, validation accuracy is examined to understand the models' generalization performance on unseen data, offering insights into their ability to perform accurately on examples beyond the training set. In addition, test accuracy serves as a critical metric in evaluating the overall performance of the models on entirely novel and unobserved instances, thereby offering a practical indication of their efficacy.

Furthermore, the evaluation procedure includes precision, recall, and F1-score metrics to offer a more comprehensive assessment of the models' performance with respect to the accuracy of classification by class. Precision quantifies the proportion of true positive predictions among all positive predictions made by the model, while recall calculates the proportion of true positive predictions among all actual positive instances. By calculating the harmonic mean of precision and recall, the F1-score provides an equitable evaluation of the performance of the models in all classes.

In summary, the confusion matrix provides a comprehensive breakdown of the errors committed by the models. It serves as a tabular representation of the discrepancies between the predicted and actual class labels. This aids in identifying particular domains that require enhancement within the UAQTE program context.

### *E. Hyperparameter Tunning*

Tuning hyperparameters is a crucial component in maximizing the efficiency of a model. By conducting experiments involving hyperparameters such as learning rate, sample size, and number of epochs, it is possible to attain optimal performance. Additionally, monitoring model performance on a validation set during training facilitates the adjustment of hyperparameters to ensure convergence toward accurate predictions. The following are the hyper-parameters used:

*1) Batch Size.* Determines the number of training examples processed in one iteration during training. By experimenting with batch sizes ranging from 16 to 64, the impact of different batch sizes on training dynamics and model convergence was observed. A larger batch size could accelerate the training process but could lead to memory constraints, while a smaller batch size could result in more noise during optimization.

*2) Epochs.* The number of epochs denoted how often the model iterated through the training dataset. Altering the number of epochs, ranging from 1 to 15, impacted the training duration and the model's evaluation. Increasing the number of epochs enabled the model to extract more insights from the data, yet excessive epochs could lead to overfitting on the training set.

*3) Learning Rates.* Controls the size of the step taken during optimization. Adjusting learning rates from 1e-5 to 5e-5 allowed for the evaluation of the sensitivity of the model's performance. A higher learning rate might have led to faster convergence but risked overshooting the optimal solution, while a lower learning rate could have resulted in slower convergence but more stable training.

*4) Epsilon.* It is a small value added to the denominator of the AdamW optimizer to prevent division by zero. A default value 1e-8 was typically used to ensure numerical stability during training. However, exploring the impact of adjusting epsilon to a value of 8 allowed for observing any changes in training dynamics or model performance.

*5) Max-length.* Refers to the maximum number of tokens allowed in each input sequence. By varying the max-length between 128 and 256, the effect of considering different amounts of context on model performance could be investigated. A larger max-length allowed the model to capture more contextual information but might have required more computational resources and memory.

Hyperparameter tuning involves systematically adjusting these parameters and evaluating their impact on the model's performance metrics, such as accuracy, precision, recall, and F1-score. This process can determine the optimal configuration of hyperparameters to improve the model's generalization and performance on unseen data.

### *F. Inference*

In the final inference phase, domain experts validate predictions made by trained models and provide the predicted dataset's true labels. Their role is crucial in ensuring the accuracy and reliability of the model's predictions, as they verify the alignment of these predictions with the ground truth they have provided. This validation process is a robust quality control mechanism, guaranteeing that the model's predictions accurately reflect the qualitative responses within the UAQTE program context.

Moreover, domain experts' involvement fosters a collaborative environment for continuous improvement and refinement of the classification system. Valuable insights and feedback are exchanged through a feedback loop between domain experts and machine learning models based on domain knowledge and expertise. Experts guide the iterative optimization of the models' performance, enhancing their predictive capabilities.

During the inference phase, fine-tuned models like BERT, RoBERTa, and ALBERT classify qualitative responses from the UAQTE dataset, with domain experts providing true labels as the validation benchmark. Predictions are generated automatically, and the predictions made by the models and the true labels are saved for future reference or analysis. This collaborative effort between domain experts and machine learning models ensures that the insights derived from the predictions are accurate and trustworthy, contributing to informed decision-making in education policy analysis.

Additionally, the inference phase evaluates models' performance on new data, validating their generalization capabilities. Deployment in real-world applications may require integrating existing systems, ensuring compatibility, and addressing technical challenges. Overall, domain experts' involvement, who validate predictions and provide true labels and fine-tuned models, advances natural language processing techniques and facilitates informed decision-making in education policy analysis.

## IV. Results and Discussion

The multiclass text classification task employing BERT, RoBERTa, and ALBERT architectures provided insights into their performance dynamics across various hyperparameter configurations. Both BERT and RoBERTa consistently exhibited improved accuracy with smaller batch sizes and higher numbers of epochs, as seen in Table II and Table III, suggesting the importance of detailed updates during training. Optimal learning rates, particularly 1e-5 and 3e-5, consistently yielded superior accuracy across different experimental settings, indicating their significance in facilitating effective model learning.

However, it is noteworthy that larger maximum sequence lengths did not consistently enhance accuracy, revealing complexities in balancing sequence length and model performance.

Similarly, as seen in Table IV, ALBERT demonstrated consistent performance trends with smaller batch sizes and increased epochs, improving accuracy metrics. Notably, the impact of maximum sequence length on model performance varied across experiments, suggesting the need for careful consideration in adjusting sequence length for optimal accuracy.

Instances of overfitting were observed beginning in five epochs, where training accuracy exceedingly surpassed validation and test accuracy, emphasizing the importance of early stopping or regularization techniques to prevent performance degradation. Overall, RoBERTa emerges as a strong choice due to its balanced performance, stability, and efficiency in training, making it a recommended option for practitioners aiming for reliable results.

TABLE II. BERT HYPERPARAMETERS AND ACCURACY SCORES

| Batch Size | Epoch | Learning rate | Max-length | Training Accuracy | Validation Accuracy | Test Accuracy |
|---|---|---|---|---|---|---|
| 16 | 3 | 1e-5 | 128 | 73% | 72% | 66% |
| 16 | 3 | 1e-5 | 256 | 77% | 73% | 68% |
| 32 | 3 | 1e-5 | 128 | 65% | 65% | 65% |

The performance metrics of BERT, RoBERTa, and ALBERT, outlined in Table V, provided insights into their effectiveness across different categories. BERT demonstrated strong precision, recall, and F1-score for "Family Support," while "Financial Support" also performed well, albeit with room for precision improvement. Similarly, "Academic Focus & Personal Development" showed balanced precision-recall metrics, while "Educational Opportunity" and "Program Implementation" exhibited lower scores, particularly in the recall.

TABLE V. PERFORMANCE METRICS BY ARCHITECTURE AND CATEGORY

| **Categories (BERT)** | **Precision** | **Recall** | **F1-Score** |
|---|---|---|---|
| Academic Focus & Personal Development | 70% | 78% | 74% |
| Educational Opportunity | 54% | 60% | 57% |
| Family Support | 95% | 96% | 96% |
| Financial Support | 73% | 77% | 75% |
| Program Implementation | 80% | 55% | 65% |
| **Weighted Average** | **74%** | **73%** | **73%** |
| **Categories (RoBERTa)** | **Precision** | **Recall** | **F1-Score** |
| Academic Focus & Personal Development | 71% | 76% | 74% |
| Educational Opportunity | 53% | 59% | 56% |
| Family Support | 95% | 98% | 97% |
| Financial Support | 75% | 83% | 79% |
| Program Implementation | 79% | 52% | 63% |
| **Weighted Average** | **74%** | **74%** | **74%** |
| **Categories (ALBERT)** | **Precision** | **Recall** | **F1-Score** |
| Academic Focus & Personal Development | 69% | 77% | 72% |
| Educational Opportunity | 53% | 59% | 55% |
| Family Support | 95% | 95% | 95% |
| Financial Support | 74% | 78% | 76% |
| Program Implementation | 74% | 52% | 61% |
| **Weighted Average** | **73%** | **72%** | **72%** |

RoBERTa consistently performed well across categories, with outstanding performance in "Family Support" and "Financial Support." However, "Educational Opportunity" and "Program Implementation" still showed room for improvement, mirroring BERT's findings. While competitive, ALBERT showed slightly lower scores than BERT and RoBERTa. "Family Support" and "Financial Support" demonstrated strong performance, yet "Educational Opportunity" and "Program Implementation" again presented areas for refinement, particularly in recall.

Overall, while all models showed effectiveness in specific categories, improvements were needed, especially in those with lower recall scores. Analyzing misclassified instances and adjusting model parameters could enhance performance across all categories. Addressing the classification of similar terms into multiple categories was also crucial to improve overall accuracy and mitigate confusion.

The heatmap visualization of the confusion matrix, depicted in Fig. 2, provided nuanced insights into the classification performance of BERT, complementing the precision, recall, and F1-score metrics. In the "Academic Focus & Personal Development" (AF&PD) category, for instance, BERT accurately classified 103 instances (true positives), with 17 instances misclassified (false negatives), aligning with its recall of 78%. Similar observations were made across other categories such as "Educational Opportunity" (EO), "Family Support" (FaS), "Financial Support" (FiS), and "Program Implementation" (PI). Notably, categories with lower recall scores, like PI, exhibited a higher number of false negatives, indicating potential areas for improvement. Conversely, categories with high precision and recall, like FaS, demonstrated fewer misclassifications. This in-depth analysis, in conjunction with precision, recall, and F1-score metrics, provided a comprehensive understanding of BERT's classification performance across diverse categories, thereby guiding optimization strategies for enhanced accuracy.

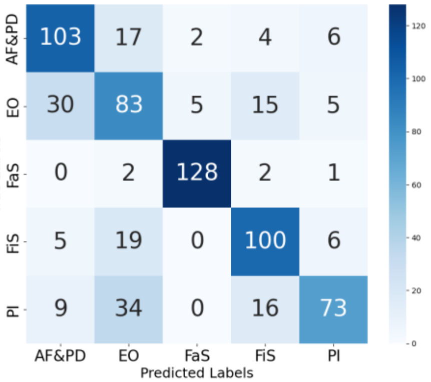

Fig. 2. BERT confusion matrix heatmap.

Similarly, the confusion matrix heatmap for RoBERTa, shown in Fig. 3, confirmed its accuracy, recall, and F1-score metrics across several categories. For example, in the "Academic Focus & Personal Development" (AF&PD) category, RoBERTa correctly categorized 100 occurrences (true positives) and misclassified 17 instances (false negatives), corresponding to a recall of 76%. Similar trends were seen in other categories, including "Educational Opportunity" (EO), "Family Support" (FaS), "Financial Support" (FiS), and "Program Implementation" (PI).

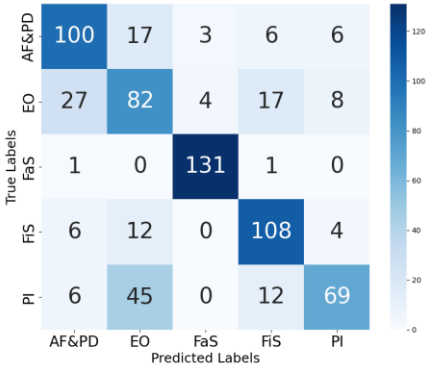

Fig. 3. RoBERTa confusion matrix heatmap.

Categories with higher recall scores, like FaS, exhibited fewer false negatives, indicating robust classification performance. Conversely, categories with lower recall scores, such as PI, demonstrated a higher number of false negatives, suggesting potential areas for improvement. This detailed examination, combined with precision, recall, and F1-score metrics, facilitated a comprehensive evaluation of RoBERTa's classification performance, guiding targeted enhancements for optimal accuracy.

Finally, Fig. 4 shows the confusion matrix heatmap for ALBERT, which provides insights into its accuracy, recall, and F1-score metrics across several categories. In the "Academic Focus & Personal Development" (AF&PD) category, for example, ALBERT accurately categorized 101 occurrences (true positives) while misclassifying 13 instances (false negatives), resulting in a 77% recall. This pattern continued in other areas, including "Educational Opportunity" (EO), "Family Support" (FaS), "Financial Support" (FiS), and "Program Implementation" (PI). Categories with greater recall scores, such as FS, produced fewer false negatives, suggesting strong categorization ability. Conversely, categories with lower recall scores, such as PI, had a larger incidence of false negatives, indicating possible areas for improvement. By integrating precision, recall, and F1-score metrics with the confusion matrix, a comprehensive assessment of ALBERT's classification performance was achieved, facilitating targeted enhancements for optimal accuracy.

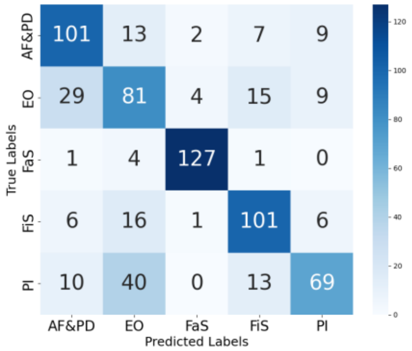

Fig. 4. ALBERT confusion matrix heatmap.

Our findings are consistent with several prior investigations highlighting the effectiveness of transformer-based models in multiclass text classification tasks. For example, using pre-trained language models, Lee et al. [70] conducted a comparative study on multiclass text classification within research proposals. Their research demonstrated exceptional performance in natural language understanding (NLU) tasks, showcasing the robust capabilities of transformer-based models in handling complex textual data. Similarly, Prabhu et al. [70] applied a BERT-based active learning approach to classify customer transactions into multiple categories, aiming to discern market needs across diverse customer segments. Furthermore, the study conducted by Chen et al. [71] observed significant enhancements in long-text classification performance when employing transformer-based models compared to traditional methods such as Convolutional Neural Networks (CNNs).

In terms of model performance, RoBERTa consistently demonstrates superior performance compared to BERT and ALBERT in multiclass text classification tasks, a trend also observed in other studies. This aligns with the research conducted by Zhao et al. [72], who leveraged the RoBERTa base model to conduct financial text mining and public opinion analysis within social media contexts. The enhanced performance of RoBERTa can be attributed to its more extensive pre-training and modifications to the architecture, enabling it to capture more nuanced linguistic features and contextual information. Moreover, the investigation by Angin et al. [73] underscores the efficacy of fine-tuned RoBERTa-based classification models for automating the processing of large document collections to detect relevance. Fine-tuning RoBERTa involves adjusting model parameters and hyperparameters to adapt the pre-trained RoBERTa model to specific tasks or datasets, enhancing its performance for the targeted classification task. This process allows the model to learn domain-specific features and nuances [73], [74], improving classification accuracy and relevance detection.

While the study provided valuable insights into the performance of BERT, RoBERTa, and ALBERT in multiclass text classification, several constraints were encountered. Achieving an optimal balance between sequence length and model efficacy posed challenges, with inconsistencies in the impact of maximum sequence length on accuracy across different experiments. Additionally, addressing the classification of similar terms into multiple categories remained a limit, impacting overall accuracy and potentially leading to confusion in classification. These underscore the need for further research and refinement to enhance the effectiveness of transformer-based models in multiclass text classification tasks.

The research has several limitations and deficiencies that should be acknowledged. Firstly, its narrow focus solely on evaluating transformer-based machine learning models (BERT, RoBERTa, and ALBERT) within the context of multiclass text classification in the Universal Access to Quality Tertiary Education (UAQTE) program restricts the generalizability of the findings beyond this specific domain. Secondly, while the research explores various hyperparameter configurations for model training, it may not comprehensively cover all possible combinations or consider other factors, such as optimization algorithms or regularization techniques. This limitation could be partly attributed to hardware requirements, as exhaustive exploration of hyperparameters may be computationally intensive.

Lastly, while the results offer actionable recommendations, it is crucial to acknowledge that these suggestions serve as guidance rather than mandates, potentially limiting their enforceability and practical implementation within educational policy. Overcoming these limitations and deficiencies would strengthen the reliability and practical relevance of the research findings, providing a more thorough understanding of the performance of transformer-based machine learning models in educational settings.

## V. Conclusions and Recommendations

The study's comprehensive evaluation of BERT, RoBERTa, and ALBERT in multiclass text classification tasks revealed nuanced insights into their performance dynamics. Hyperparameter configurations played a crucial role, with smaller batch sizes and increased epochs consistently enhancing model accuracy. Optimal learning rates, particularly in the range of 1e-5 to 3e-5, significantly contributed to superior accuracy across experimental settings. However, the impact of larger maximum sequence lengths on accuracy was inconsistent, indicating the complexity of balancing sequence length and model performance. Moreover, instances of overfitting, particularly observed beyond five epochs, underscored the necessity of early stopping or regularization techniques to prevent performance degradation.

Interpreting the classification results provided valuable insights into students' experiences within the UAQTE program. Categories like "Family Support" and "Financial Support" demonstrated high precision, recall, and F1 scores, indicative of the program's effectiveness in addressing student needs in these areas. Conversely, categories such as "Educational Opportunity" and "Program Implementation" exhibited lower scores, suggesting potential areas for improvement. The study's findings highlight the importance of selecting appropriate model architectures and hyperparameters tailored to the specific classification task. RoBERTa emerged as a robust choice due to its balanced performance, stability, and efficiency in training, making it a recommended option for similar classification tasks in educational contexts.

For future works, researchers are encouraged to delve deeper into hyperparameter tuning, exploring alternative configurations to optimize model performance further. Addressing overfitting remains a critical concern, necessitating ongoing monitoring of training processes and fine-tuning regularization strategies. Continuous review and refining of educational programs, guided by evidence-based decision-making and stakeholder feedback, is critical for effectively fulfilling students' changing needs.

Future research approaches may also include looking into the interpretability of model predictions and researching socio-cultural aspects that influence students' experiences to understand educational interventions' effectiveness better. By embracing these recommendations, researchers and practitioners can advance the multiclass text classification field and contribute to enhancing educational programs to support student success.

## Acknowledgment

The researchers would like to thank the Philippine Commission on Higher Education (CHED) and the Leading the Advancement of Knowledge in Agriculture and Science (LAKAS) Project No. 2021-007, specifically the eParticipation 2.1 initiative, "Harnessing Natural Language Processing (NLP) for Community Participation." We appreciate the substantial financial assistance offered by this initiative, which has been vital in making our research pursuits feasible. The researchers congratulate CHED and the LAKAS Project for their significant contributions, acknowledging their critical role in expanding our quest for knowledge.

***Abstract*—Although limited research has explored the integration of electroencephalography (EEG) and deep learning approaches for attention deficit hyperactivity disorder (ADHD) detection, using deep learning models for actual data, including EEGs, remains a difficult endeavour. The purpose of this work was to evaluate how different attention processes affected the performance of well-established deep-learning models for the identification of ADHD. Two specific architectures, namely long short-term memory (LSTM)+ attention (Att) and convolutional neural network (CNN)s+Att, were compared. The CNN+Att model consists of a dropout, an LSTM layer, a dense layer, and a CNN layer merged with the convolutional block attention module (CBAM) structure. On top of the first LSTM layer, an extra LSTM layer, including T LSTM cells, was added for the LSTM+Att model. The information from this stacked LSTM structure was then passed to a dense layer, which, in turn, was connected to the classification layer, which comprised two neurons. Experimental results showed that the best classification result was achieved using the LSTM+Att model with 98.91% accuracy, 99.87% accuracy, 97.79% specificity and 98.87% F1-score. After that, the LSTM, CNN+Att, and CNN models succeeded in classifying ADHD and Normal EEG signals with 98.45%, 97.74% and 97.16% accuracy, respectively. The information in the data was successfully utilized by investigating the application of attention mechanisms and the precise position of the attention layer inside the deep learning model. This fascinating finding creates opportunities for more study on large-scale EEG datasets and more reliable information extraction from massive data sets, ultimately allowing links to be made between brain activity and specific behaviours or task execution.**

***Keywords—ADHD; EEG; deep learning; attention mechanisms; CNN; LSTM***

## I. Introduction

The well-being of children's minds is incredibly important, and it's essential to address their mental health needs promptly (1). Several factors, like genetics, environment, and experiences, can influence how children's mental health develops [1, 2]. Young individuals commonly face psychological challenges such as anxiety, attention-deficit/hyperactivity disorder (ADHD), and depression [3]. ADHD is a mental condition characterized by hyperactivity, inattention, and impulsive behaviours. Studies show that around five per cent of children have ADHD, with a higher prevalence among boys [4, 5]. The symptoms of ADHD can vary, with some individuals showing more hyperactivity and impulsivity while others experience difficulties with attentiveness [6]. Generally, ADHD symptoms emerge during preschool years, but significant struggles can occur during a child's school years. One of the main difficulties for children with ADHD is controlling and regulating their behaviours, often resulting in inappropriate responses to their surroundings [7]. Managing and regulating their behaviours poses a significant challenge for them. This struggle may manifest as difficulty staying seated, constant fidgeting, or excessive physical activity, making it hard for them to concentrate in a classroom setting. Additionally, they may encounter problems sustaining attention as they easily get distracted by external stimuli or their own thoughts. These difficulties can negatively impact their ability to focus on tasks, leading to difficulties with organizing work and completing assignments [8].

Detecting ADHD in a timely manner is crucial for preventing potential complications and ensuring the well-being of children's social interactions. Traditionally, ADHD diagnosis has relied on diagnostic assessments based on criteria outlined in various editions of the International Classification of Diseases (ICD) or the Diagnostic and Statistical Manual of Mental Disorders (DSM) [9]. However, this method heavily relies on parents and teachers understanding psychologists' or psychiatrists' questions and providing accurate responses. To address these challenges, researchers have been exploring and implementing objective techniques for ADHD diagnosis, such as electroencephalography (EEG) [10]. These approaches analyze neurophysiological irregularities and provide valuable insights into identifying ADHD [11]. Neurophysiological examinations like EEG offer a deeper understanding of brain structure and functioning [12, 13], enabling healthcare professionals to gather significant information [14, 15]. Studies show that individuals with ADHD often exhibit distinct brain wave activity patterns, including increased theta waves and decreased beta waves. These specific patterns indicate difficulties related to attention management and impulse control. By leveraging these neurophysiological findings, healthcare providers can better comprehend and diagnose ADHD, leading to more targeted and effective treatments and interventions for those affected by this condition [16, 17].

Extensive research has been conducted on various aspects of EEG signals in individuals with ADHD, including power spectrum density, event-related potentials, multivariate and univariate EEGs, complexity analysis, and alpha asymmetry [18, 19]. While machine learning (ML) algorithms like logistic regression, LDA, SVM, KNN, principle component analysis, and various neural network models have commonly been used to classify EEG patterns in ADHD [20], deep learning models in this field have received relatively less attention and require further investigation. Some studies have focused on applying convolutional neural networks (CNNs) to detect ADHD using functional and structural MRI [21, 22]. However, limited research has explored the integration of EEG and deep learning approaches for ADHD detection. Traditional ML methods typically employ shallow architectures with limited capacity for nonlinear feature transformation [23]. For example, SVMs utilize a shallow linear pattern separation model that requires a larger number of computational elements and struggles to model complex concepts and multi-level abstractions. Moreover, due to their single-layer construction, traditional ML methods lack effectiveness in identifying anomalous points in the deep hidden layers.

The extraction of preexisting designed characteristics and intensive preprocessing were key components of previous ML methods [24]. Nonetheless, a number of deep learning models have been effectively launched in the last ten years [25]. Consequently, the challenge has shifted from developing relevant engineered features to the need for large-scale data collection, which is crucial for effectively training optimal deep learning models. Finding the most important information has become a critical task due to the growing number of data. One of the newest and most important deep learning principles is attention, which makes it possible to understand which portions of the data are pertinent to the output and to seamlessly integrate outside information into a deep learning model [26]. This approach seeks to facilitate the adoption of parallel computing while improving a deep learning network's explainability and interpretability [27]. Hence, over the past few years, several diverse attention techniques have been implemented in EEG-based recognition [28-30]. Therefore, in this research, the potential of employing different attention strategies is investigated. Indeed, this study focused on the application of attention in various deep learning models for the EEG classification of ADHD and typical children. For this purpose, commonly utilized deep learning models for EEG recognition, namely CNN and LSTM, were re-implemented. Each of these models was augmented with attention mechanisms, and the influence of attention on the resulting classification accuracy was assessed. In Section II, a detailed explanation of the methodology is presented. Section III provides the experimental results and findings. The findings of the study are discussed in the Section IV and finally Section V concludes the paper.

## II. Methods

### A. Dataset

A freely available dataset from the "First EEG Data Analysis Competition with Clinical Applications" was employed for the study [31]. This dataset comprises EEG recordings collected from 61 children aged between 7 and 12 years. In the ADHD group, there were 31 children, consisting of 22 boys and 9 girls, with an average age of 9.64±1.73. Conversely, the control group consisted of 30 children, including 25 boys and 5 girls, with an average age of 9.85±1.77. None of the subjects in the control group exhibited any psychiatric conditions. In order to maintain consistency, specific criteria were established to exclude children with ADHD and those who were healthy. These criteria encompassed a history of significant neurological disorders or cortical damage (e.g., epilepsy), major physical illnesses, learning or speech disabilities, other psychiatric issues, and the use of barbiturates and benzodiazepines.

During the EEG recording, the 10-20 standard was followed, and a total of 19 channels were utilized. The specific channels employed were F7, Cz, Fz, T3, Pz, Fp1, C3, T5, C4, F8, T4, Fp2, F3, P4, F4, P3, T6, O1, and O2. Reference channels A1 and A2 were placed on the ears. The signals were digitized at a sampling rate of 256 Hz and captured within the frequency range of 0.1 to 60 Hz. To eliminate unwanted noise and interference, a FIR band-pass filter with cut-off frequencies of 0.4 and 60 Hz was applied, along with a notch filter set at 50 Hz to cancel out any electrical interference from the city. Throughout the EEG recording, the child was presented with various images of animal figures or cartoon characters displayed on a nearby monitor. These images were shown both at the top and bottom of the screen (see Fig. 1). The child's task was to count the characters at the top, then count the pictures at the bottom, and finally add the two numbers together to announce the total. The accuracy of the sum was not a crucial factor in this protocol; the primary objective was to keep the child consistently engaged in a cognitive state throughout the EEG recording process.

### B. Feature Extraction

In this study, the focus was on analyzing EEG data, which consisted of both ADHD and typical frames or segments. A recent study found that nonlinear and frequency features are better markers of EEG patterns for diagnosing ADHD [32]. Therefore, this study focused on nonlinear and frequency features as input to deep classification models. 15 well-established characteristics were evaluated in the frequency and temporal domains for each unique EEG channel. Specifically, in the time domain via different nonlinear analysis approaches, the following features were extracted: Higuchi fractal dimension, Hurst exponent, correlation dimension, Lempel-Ziv complexity, sample entropy, permutation entropy, Katz fractal dimension, Lyapunov exponent, detrended fluctuation analysis, and Petrosian fractal dimension, as mentioned in prior studies [32-34]. Moving on to the frequency domain, the spectral power within clinically relevant frequency bands was calculated. These bands include delta band ranging from 0.5 Hz to 4 Hz, theta band ranging from 4 Hz to 8 Hz, alpha band ranging from 8 Hz to 13 Hz, beta band ranging from 13 Hz to 30 Hz, and gamma band ranging from 30 Hz to 45 Hz. To collectively refer to the set of features extracted from each channel in both time and frequency domains, it is termed the vector:

$$S_c(t) = [F_1(t), F_2(t), \dots, F_n(t)] \tag{1}$$

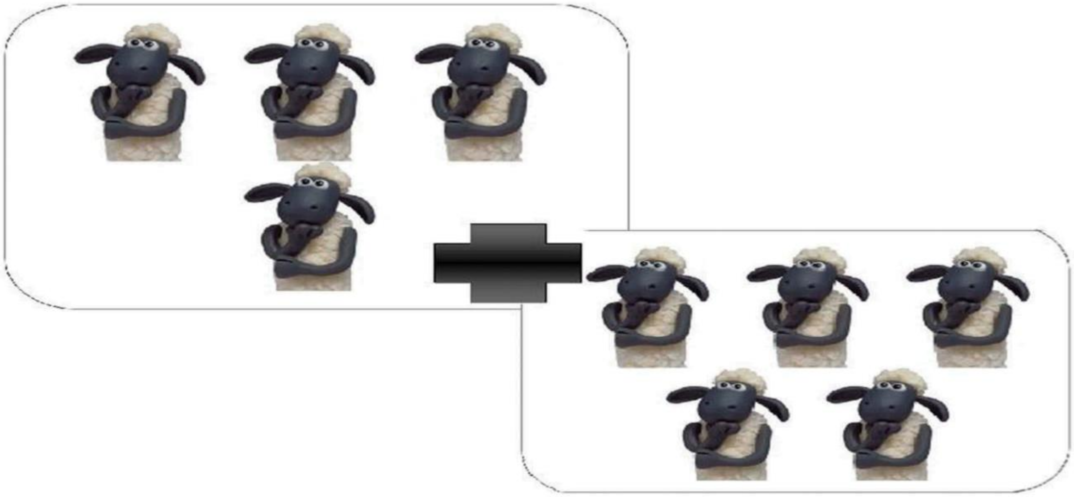

Fig. 1. An instance of images depicted to subjects during signal capturing.

where, n = 15 and t = 1, 2, …, E, where E denotes the data segment count. Furthermore, for every time segment t, the Spearman's correlation coefficient among all EEG electrodes was calculated, resulting in a distinct correlation matrix m for every given time segment t:

$$m(t) = \begin{bmatrix} m_{11}(t) & \cdots & m_{1C}(t) \\ \vdots & \ddots & \vdots \\ m_{C1}(t) & \cdots & m_{CC}(t) \end{bmatrix} \quad (2)$$

For each time segment, the deep learning networks used in this study receive inputs consisting of the correlation matrix m and the feature vector $S_c$ for all EEG electrodes, where $c$ runs from 1 to C. Here, $m_{ij}(t)$ denotes the correlation coefficient in the segment t between channels i and j. To prevent any confusion, unless stated otherwise, the reliance on the time segment, denoted as t, will be disregarded.

### C. Attention Models

Within this study, two deep learning models that benefit from attention mechanisms exhibit similar structures, with the variation occurring in the initial layer. To efficiently handle time-related information in the input data, the LSTM with attention model includes an LSTM unit in the first layer. In contrast, the CNN with attention model processes the input using a one-dimensional convolution operation. The LSTM layer, the dense layer, and the classification layer are the next three layers that both models have in common. In each model, the attention mechanism is designed to meet the specific processing needs of the corresponding initial layers. With the exception of the LSTM model with attention, which places the attention mechanism after the second LSTM layer, the attention mechanism is typically positioned between the initial layer and the LSTM layer. In all of the models, cross-entropy was implemented as the loss function for optimizing the parameters, determined as follows:

$$L = -\frac{1}{N}\sum_{i=1}^{N}\sum_{j=1}^{M}\left(Y_{i,j}\log\left(P_{i,j}\right)\right) \quad (3)$$

Here, $Y_{i,j}$ denotes the desired class label for the segment i, $P_{i,j}$ denotes the estimated outcome for that class, N denotes the total sample count, and M denotes the count of classes. During this research, sole focus was placed on two classes, and one-hot encoding was utilized for the output. Every model had the softmax function in its final layer. The settings were updated using a mini-batch gradient descent method. This method updated the model's parameters using a batch of B samples, where B is the batch size that was determined empirically.

*1) CNN with attention:* The model utilized in this research is known as CNN with Attention (CNN+Att). This network was inspired by a previous work [35] introducing the Convolutional Block Attention Module (CBAM), an attention process particularly adjusted for convolutional architectures. The spatial attention and channel attention sub-modules, which functioned in tandem, made up the two different attention processes that made up the CBAM module. The channel attention focused on identifying relevant information in the input, whereas the spatial attention determined the meaningful placement of that information. The relevance was established by the attention coefficients matrix, which was represented by the symbols $A_s$ for spatial attention (arising from the convolution operations) and $A_a$ for channel attention (derived using a shared MLP). These processes were applied to this model in a sequential fashion, starting with the channel module and moving on to the spatial module. Fig. 2 illustrates the overall architecture of CNN+Att, which includes a CNN layer integrated with the CBAM structure, a dense layer, an LSTM layer, and a dropout. This structure conducts one-dimensional convolutional operations on every input vector, indicating time segment (t) from 1 to E. Two improvements were applied to the input feature matrix: one included multiplication with the channel attention sub-module ($A_a$) and the other with the spatial attention sub-module ($A_s$). After integration, the CNN layers' outputs were fed into the LSTM.

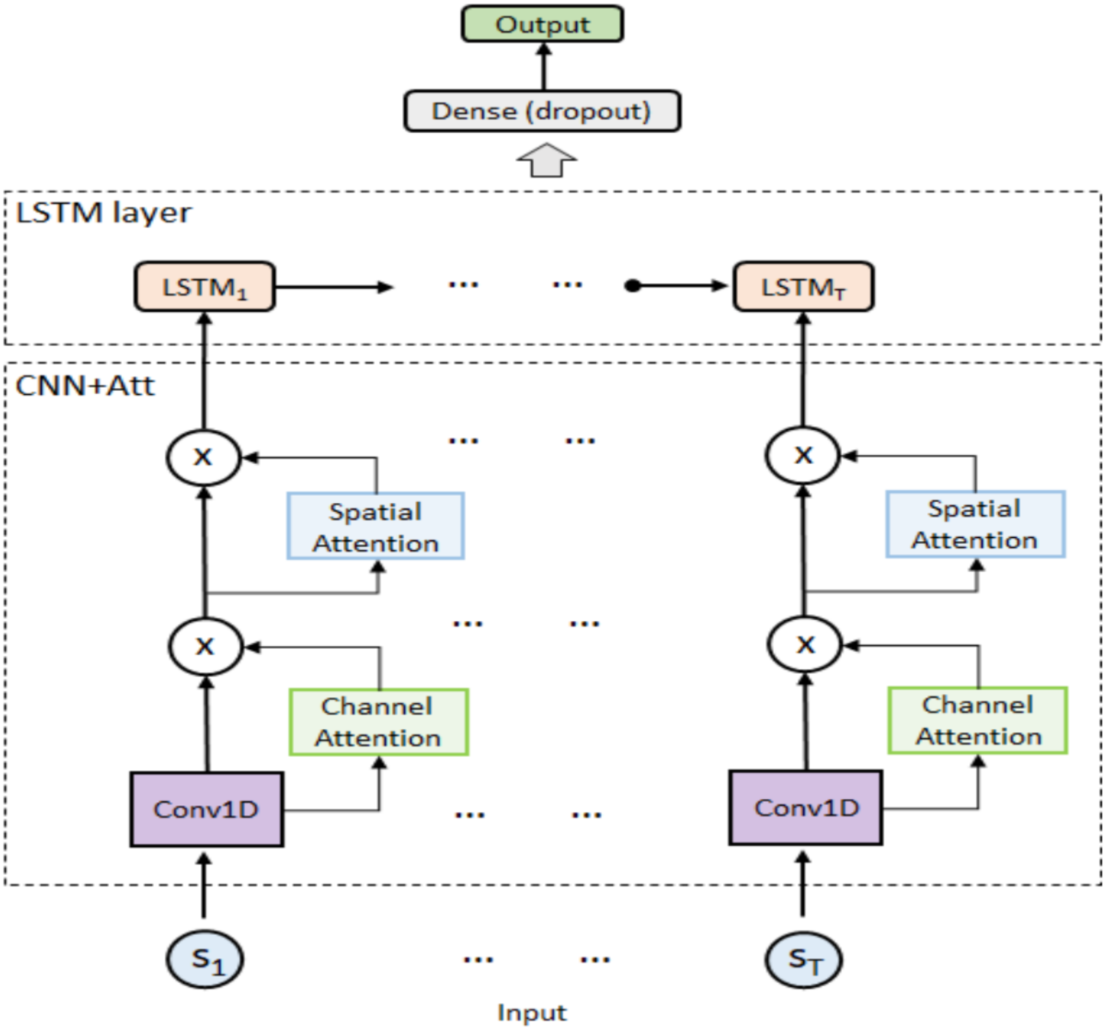

Fig. 2. The structure of the CNN+Att model.

*2) LSTM with attention:* For the second attention-based framework, inspiration was drawn from a structure introduced in the previous work [36], and the LSTM with attention (LSTM+Att) was implemented. In the implementation, a two-layer LSTM structure was opted for instead of the original three-layer version to maintain consistency with the other model examined in the current work. An additional LSTM layer with T LSTM cells was added on top of the initial LSTM layer. The information from this stacked LSTM structure was then passed to a dense layer, which, in turn, was connected to the classification layer, which comprised two neurons. During training, the described loss function was utilized. To create the input vector for every EEG segment (t), Spearman's correlation coefficients from m(t) were concatenated with the extracted feature vector, $S_c(t)$. The integrated vector representing one segment is denoted as:

$$s(t) = [s_1||s_2||..||s_c] \quad (4)$$

Every $s_i$ is explained through Eq. (3). The attention layer was positioned above the second LSTM layer, as seen in Fig. 3. The attention layer designates suitable weights, represented by $\alpha_i$, to every $i^{th}$ cell's output ($h_i$) in the LSTM layer. Each vector $h_i$ was multiplied by the weight $\alpha_i$ that corresponded to it. E vectors were concatenated to create a single vector, which was then transmitted to a dense layer without any dropout. The last layer, which made use of the softmax activation function, carried out the EEG categorization. In this model, each cell of the LSTM layer constructed its own delineation of the input segment. The attention process in this model specifically relied on segments/time steps that contained more distinguishing information, assigning higher coefficients $\alpha_i$ to these time steps. To calculate the attention coefficients, a transformation function was applied, $u_i = \tanh(W_s h_i)$, where i belongs to the set 1, 2, …, E and $W_s$ represented the weight matrix. Subsequently, softmax($u_i$) was utilized to determine the attention weights $\alpha_i$ after normalizing the attention coefficients. Furthermore, as mentioned in Eq. (3), the model was trained using the cross-entropy loss function, which is different from the original work.

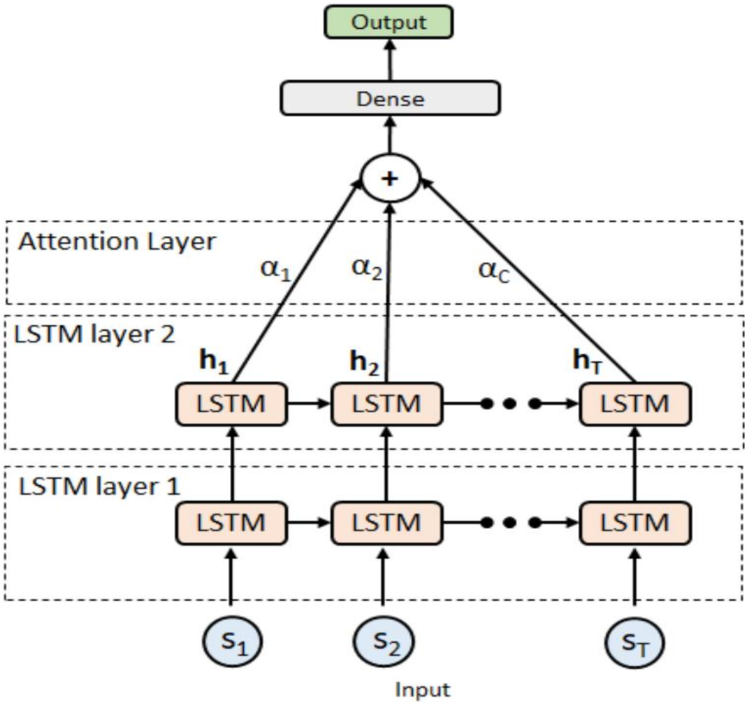

Fig. 3. The structure of the LSTM+Att model.

### D. Baseline Deep Learning Networks

In order to compare the models discussed earlier with attention and also to investigate the effect of attention mechanisms included in deep structures on the classification performance of models, two additional deep learning models without attention mechanisms were considered in this work: a CNN and an LSTM. These models had identical structures to their respective attention-enhanced counterparts, with the exception of the removal of the attention layer. Whole networks were executed in Python through the Tensorflow 2 approach. To optimize the performance of the models, the hyper-parameter values were carefully selected to obtain the highest F1-score averaged over all data. For parameter optimization, the Stochastic Adam optimizer was employed. The optimal parameters for CNN+Att and LSTM+Att networks can be found in Tables I and II.

TABLE I. SELECTED HYPER-PARAMETER VALUES FOR CNN+ATT CLASSIFICATION NETWORK

| Hyper-parameter | Range | CNN | CNN+Att |
|---|---|---|---|
| Convolution kernel | 3, 5, 7, 9, 11 | 3 | 3 |
| Convolution filters | 8, 16, 32, 64 | 64 | 64 |
| LSTM hidden layers | 8, 128, 256 | 8 | 256 |
| Dropout level | [0.1, 0.5] | 0.5 | 0.4 |
| Learning rate | [0.0001, 0.001] | 0.0002 | 0.0002 |
| CBAM reduction ratio | 4, 8, 16 | - | 16 |
| CBAM spatial kernel | 5, 7, 9, 11 | - | 7 |

TABLE II. SELECTED HYPER-PARAMETER VALUES FOR THE LSTM+ATT CLASSIFICATION NETWORK

| Hyper-parameter | Range | LSTM | LSTM+Att |
|---|---|---|---|
| LSTM hidden layers | 8, 128, 256 | 128 | 128 |
| LSTM L2 reg | [0.001, 0.05] | 0.002 | 0.001 |
| Input dropout level | [0.1, 0.5] | 0.4 | 0.4 |
| LSTM layer 1 dropout | [0.1, 0.5] | 0.4 | 0.2 |
| LSTM layer 2 dropout | [0.1, 0.5] | 0.3 | 0.2 |
| Learning rate | [0.0001, 0.001] | 0.0001 | 0.0001 |

### E. Evaluation of Models

A 10-fold cross-validation approach was used to increase the power of the estimate of error and guarantee the validity of the results. All models were trained with a batch size of 16 for 50 epochs inside each fold. The models were evaluated using recognized classification measures, such as F1-score, sensitivity, specificity, and accuracy. Sensitivity and specificity are especially important when assessing how well a classifier works to detect uncommon but important samples. TP (True Positive) indicates the positively categorized samples that were correctly identified, with N being the total sample count for classification; TN (True Negative) indicates the accurately classified negative samples; FP (False Positive) represents the incorrectly classified positive samples, and FN (False Negative) representing the incorrectly classified negative samples, the accuracy, sensitivity, specificity, and F1-score values were determined.

## III. Results

In the current work, the performance of two attention-based models was evaluated in comparison to baseline models for a two-group classification problem for ADHD diagnosis. Fig. 4 shows the scatterplots of nonlinear features extracted from the FP2 channel of ADHD and normal subjects.

Table III presents a summary of all results for each classification model in terms of F1-score, sensitivity, specificity, and accuracy. As shown, the best classification result was achieved using the LSTM+Att model with 98.91% accuracy, 99.87% accuracy, 97.79% specificity and 98.87% F1-score. After that, the LSTM, CNN+Att, and CNN models succeeded in classifying ADHD and Normal EEG signals with 98.45%, 97.74% and 97.16% accuracy, respectively.

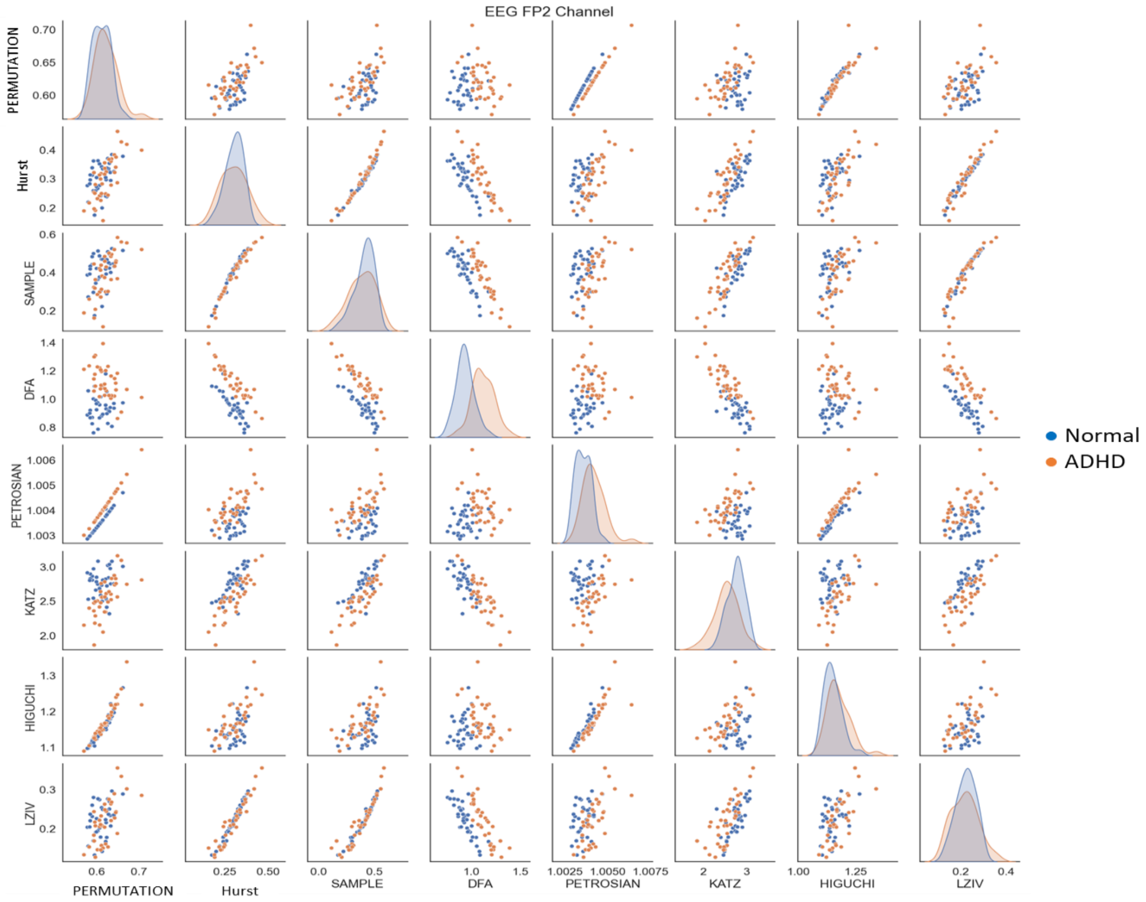

Fig. 4. Scatterplots of nonlinear features extracted from the FP2 channel of ADHD and normal subjects.

TABLE III. Mean and Standard Deviation of Classification Results for All Models for ADHD Detection

| Model | Accuracy (%) | Sensitivity (%) | Specificity (%) | F1-score (%) |
|---|---|---|---|---|
| CNN | 97.16 ± 0.91 | 95.33 ± 1.03 | 98.89 ± 1.31 | 97.05 ± 0.70 |
| CNN+Att | 97.74 ± 1.07 | 96.88 ± 0.85 | 98.57 ± 1.25 | 97.61 ± 0.99 |
| LSTM | 98.45 ± 1.05 | 98.10 ± 1.02 | 98.82 ± 1.04 | 98.40 ± 0.95 |
| LSTM+Att | 98.91 ± 0.64 | 99.87 ± 0.22 | 97.79 ± 1.03 | 98.87 ± 0.72 |

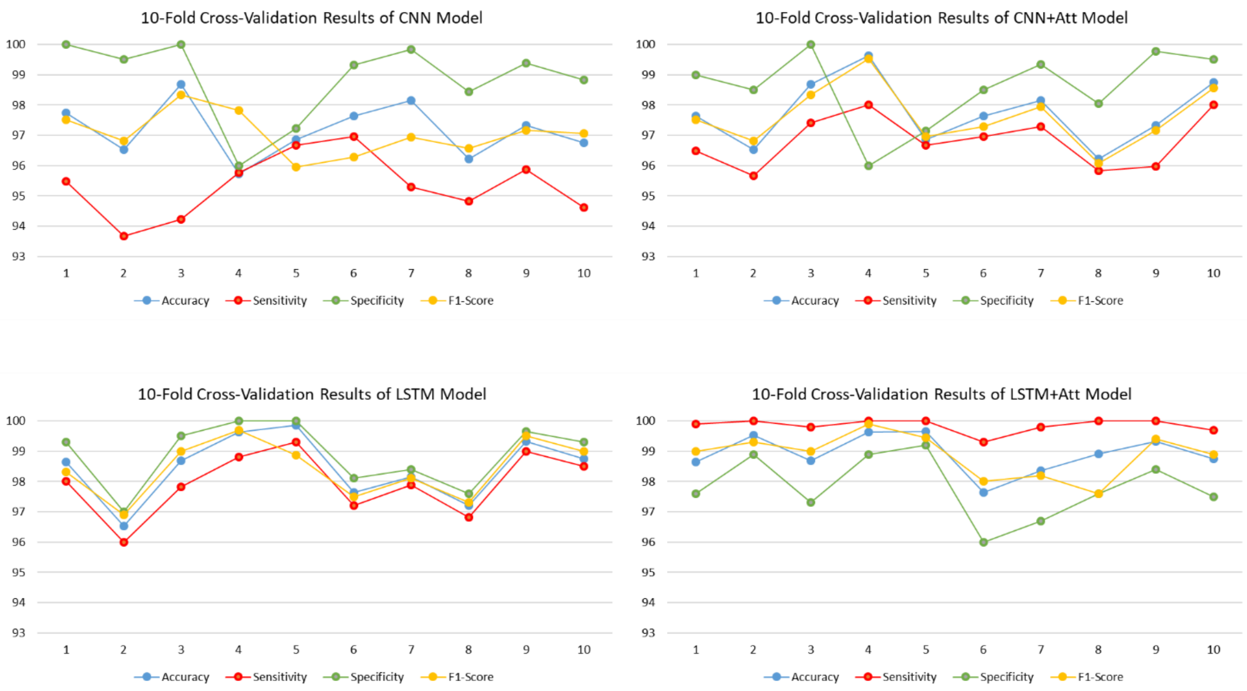

Fig. 5. Obtained classification results of a 10-fold cross-validation algorithm for all classification models for ADHD detection.

Fig. 5 shows the Obtained classification results of a 10-fold cross-validation algorithm for all classification models for ADHD detection. As can be seen, the CNN and CNN+Att models had more variance than the LSTM and LSTM+Att models.

## IV. Discussion

Using deep learning models for actual data, including EEGs, remains a difficult endeavour. These datasets encapsulate intricate scenarios where various factors, such as technological instruments, recording interference, and both emotional and physical states, intertwine. Consequently, the classification performance can be heavily influenced by disparities between subjects and within individuals themselves. Reflecting on this observation, two attention-enhanced deep learning models were executed and juxtaposed (alongside their respective counterparts lacking attention) across an EEG dataset for ADHD detection. This approach aimed to explore how attention can augment deep learning models in identifying ADHD EEG patterns. The accuracy and F1 scores for all models were remarkably close, surpassing the 97% threshold. Compared to previous deep learning models without an attention mechanism, this study improved the accuracy of ADHD diagnosis. Chen et al. reported an accuracy of 94.67% in diagnosing ADHD using a novel connectivity matrix and a CNN model [37]. Vahid et al achieved 83% accuracy in diagnosing ADHD using EEGNet deep model [38]. Using a four-layer CNN model, Dubreuil-Vall et al. achieved an accuracy of 88% in diagnosing ADHD [39]. Cisotto et al. also showed that attention-based deep learning models can improve the classification performance of EEG datasets [40].

It is important to remember that attention processes were purposefully kept simple in order to evaluate their influence on each suggested model. Each model was composed of an LSTM layer, a dense layer for output generation, and a single attention layer that stored a model-specific attention mechanism. This simple yet efficient design made it easier to compare various attention-enhanced versions. Every attention mechanism was created to make use of input properties in a unique way. The LSTM+Att model employed attention in the temporal dimension to filter out irrelevant information. On the other hand, the CNNs+Att model utilized the CBAM module to apply attention to each EEG channel individually. Interestingly, models primarily focused on spatial features demonstrated performance improvements when attention was introduced, such as with CNNs+Att outperforming CNN. Jiang et al. improved the performance of their CNN model in the EEG-based emotion recognition task by incorporating the temporal-channel attention mechanism into the designed deep model [41]. Altuwaijri and Muhammad improved the performance of their CNN model by adding CBAM structure to multi-branch EEGNet through attention mechanism and fusion methods for EEG-based motor imagery classification [42]. Notably, the proposed attention-enhanced models demonstrated versatility in leveraging different EEG descriptions that consider time, frequency, and spatial information (sensor locations) interchangeably or in conjunction. These considerations offer valuable insights for devising suitable experimental protocols and data processing pipelines based on the specific behaviours or task performances under study. For instance, in cognitive tasks where individuals are expected to respond promptly to external stimuli, architectures like LSTM+Att can effectively filter time-dependent features. Zhou et al. showed that the attention-based LSTM performs better than the LSTM structure without the attention mechanism in detecting abnormal behavior [43]. It is important to emphasize that despite their simple designs, the attention mechanisms enabled the models to achieve high levels of accuracy in a range of real-world scenarios with minimal preprocessing. This statement has been shown in previous studies for EEG-based sleep stage classification [44, 45], clinical events prediction in the intensive care unit [46], and diagnosis of various diseases [47, 48]. Preprocessing is usually directed by domain expertise or knowledge, and depending on the analyst performing the data analysis, it may provide non-reproducible findings. As a result, minimizing the need for preprocessing offers a big benefit over traditional ML or other deep learning techniques. However, it's worth mentioning that this work still requires further investigation on larger datasets impacted by artefacts, where preprocessing is often crucial. Nonetheless, it paves the way for future research aiming to minimize preprocessing in extensive EEG datasets empirically.

Similar researches have investigated the application of different deep learning models in EEG for epilepsy diagnosis [49, 50], psychiatric disorder diagnosis [20, 51], motion imagery classification [52, 53] and mental workload classification [54]. In Table IV, a comparison is made between the proposed approach and other leading ML methods for diagnosing ADHD using automated EEG data on the same dataset. The results revealed that this approach outperformed previous studies, showcasing a higher accuracy value. Specifically, it surpassed conventional ML techniques employed on unipolar EEG signals. Furthermore, when compared to other deep learning methods applied to the same EEG signals, the approach presented here produced satisfactory outcomes. This study introduces a newly developed deep learning model that utilizes EEG data for ADHD diagnosis.

TABLE IV. COMPARING THE PERFORMANCE OF THE PROPOSED APPROACH WITH SOME STATE-OF-THE-ART RESEARCH IN ADHD DIAGNOSIS THROUGH EEG ANALYSIS ON THE SAME DATASET

| References | Dataset | Approach | Accuracy |
|---|---|---|---|
| [55] | Same as this study | Nonlinear features, MLP neural network | 96.70% |
| [56] | Same as this study | Nonlinear features, MLP neural network | 93.65% |
| [31] | Same as this study | EEG image generation based on spectral features, Deep CNN model | 98.48% |
| The proposed technique | 31 ADHD and 30 Normal children | Nonlinear and spectral features and LSTM+Att model | 98.91% |

The insufficient clinical implications of this paper and similar studies constitute a significant drawback. In general, there is a need for further evidence regarding the effectiveness of employing EEG-based ML techniques in diagnosing ADHD. For instance, it remains unexplored how these methods perform when applied to individuals who have undergone treatment for ADHD in the past. Furthermore, in order to utilize these approaches effectively, it is crucial to obtain a broader range of EEG datasets specific to ADHD. This is particularly significant for deep learning techniques as they necessitate extensive datasets to achieve optimal results. Furthermore, the segmentation of EEG signals on a second-to-second basis for data augmentation, which was employed in this study and previous similar studies, may not possess clinical justification. In addition, the proposed models were only tested on a cross-sectional dataset, and it is necessary to examine their validity through longitudinal studies. Nevertheless, the proposed approach can serve as a CAD tool for clinical purposes.

## V. CONCLUSION

The purpose of this work was to evaluate how different attention processes affected the performance of well-established deep-learning models for the identification of ADHD. Two specific architectures, namely LSTM+Att and CNNs+Att, were compared. These models were employed for the classification of EEG patterns, including ADHD and Normal patterns. Notably, despite the simplicity of the suggested attention-enhanced models, the results showed state-of-the-art performance across all categorization models. The information in the data was successfully utilized by investigating the application of attention mechanisms and the precise position of the attention layer inside the deep learning model. This fascinating finding creates opportunities for more study on large-scale EEG datasets and more reliable information extraction from massive data sets, ultimately allowing links to be made between brain activity and specific behaviours or task execution. Hence, attention is a viable method for evaluating the accuracy and applicability of EEG data in the identification of ADHD. Additionally, attention mechanisms facilitate parallel computation, thereby accelerating the analysis of significant electrophysiological datasets such as EEG. These promising results could encourage stakeholders to offer a CAD system for diagnosing ADHD through the suggested method. For future research, collecting more diverse EEG samples, exploring alternative ML and deep learning techniques, incorporating psychophysiological attributes and other neurophysiological recordings with EEG, and developing ML methods for automatically scaling the severity of ADHD is recommended.

***Abstract*—In the face of rampant global disease transmission, effective preventive strategies are imperative. This study tackles the challenge of ensuring compliance in crowded settings by developing a sophisticated face mask detection system. Utilizing MATLAB and the Cascade Object detector, the system focuses on detecting white surgical masks in frontal images. Training the system is critical for accuracy; therefore, cross-validation is employed due to limited data. The results reveal accuracies of 76.67% for initial training, 67.50% for a 9:11 cropping ratio, and 89.17% for a 9:4:7 cropping ratio, highlighting the system's remarkable precision in mask detection. Looking ahead, the system's adaptability can be further expanded to include various mask colors and types, extending its effectiveness beyond COVID-19 to combat a range of respiratory illnesses. This research represents a significant advancement in reinforcing preventive measures against future disease outbreaks, especially in densely populated environments, contributing significantly to global public health and safety initiatives.**

***Keywords*—Face mask detection; machine vision; cascade object detector; cross-validation***

## I. Introduction

The persistent threat of infectious diseases underscores the critical importance of preventive measures in halting the spread of viruses. Among these, the act of wearing masks has proven highly effective, forming a crucial line of defense against respiratory particles that can carry diseases [1]. However, ensuring widespread adherence to mask-wearing mandates remains a challenge, particularly in densely populated areas where viruses can quickly find new hosts. Governments worldwide have responded to this challenge by enforcing stringent measures, urging the public to wear masks in all public spaces. This practice, reinforced by global health authorities, emphasizes the significance of maintaining a safe physical distance, wearing well-fitted masks, and adhering strictly to hand hygiene practices [2], [3], [4].

In this pivotal moment, the convergence of innovative technology and public health expertise has ushered in a promising era. Advances in machine vision, where artificial intelligence meets visual sensory processing, have paved the way for transformative solutions [5]. Within this context, we embark on a groundbreaking initiative – the development of a sophisticated face mask detection system. This system, empowered by the capabilities of machine vision, discerns with acute precision whether individuals are wearing masks, irrespective of the disease at hand. The implications of this cutting-edge technology are vast, extending from bustling shops to crowded public transport hubs and even the sterile corridors of hospitals. This face mask detection system stands as a guardian of public health, prepared to combat a spectrum of infectious diseases in any future scenario [6], [7].

This endeavor is not undertaken merely as an academic pursuit; it is signified as a vital stride in the fortification of our technological defenses against potential pandemics. While existing methods are demonstrated to be efficacious, they are often burdened with limitations that hinder their full potential. In the forthcoming sections, the methodology underpinning our face mask detection system will be meticulously dissected, and its accuracy will be rigorously analyzed. This research allows us to save manpower, money and time. Compared to other experiments, we train the system with the smallest number of samples and use the least amount of effort to achieve the greatest effect.

Through this comprehensive and meticulous exploration, significant contributions are being made to the scientific domain. This is not just an academic exercise; it is a proactive engagement in a global mission that seeks to lessen the severe and lasting impact that infectious diseases have on societies across the planet. These diseases, which have plagued humanity for centuries, continue to present complex challenges that require innovative solutions and international cooperation. Our research actively participates in this mission by providing new insights and tools that can be used to detect, prevent, and treat these diseases. It stands as a beacon of hope, a testament to human ingenuity and perseverance. As we illuminate the path forward with our findings, we join hands with fellow researchers and healthcare professionals in our collective endeavor to prepare for and overcome the challenges posed by future pandemics.

This work, therefore, is not just about the present; it is about ensuring a safer and healthier future for all. By pushing the boundaries of what is known, we pave the way for new strategies and interventions that could save millions of lives. In essence, this research embodies the spirit of discovery and the unwavering commitment to public health that characterizes the best of scientific pursuits.

The structure of this paper unfolds as follows: Section II provides an overview of the study's background. Subsequently, Section III delineates the system's implementation and testing process. Section IV and Section V delves into the results and discussion respectively and finally Section VI concludes the paper.

## II. Background of the Study

Amidst the persisting COVID-19 pandemic, the significance of precise face mask detection cannot be emphasized enough. Researchers, in a concerted effort to bolster public health protocols and minimize viral spread, have delved into various methodologies for automating the identification of mask-wearing individuals. Numerous pioneering studies have significantly advanced this area. In particular, the utilization of deep models for object identification [8] has showcased remarkable progress in image recognition over recent years (see Table VI).

Stephanie Anderson et al. [9] developed an automatic face mask detection model using Deep Learning. Their model, trained on a diverse dataset comprising Mask, No Mask, and Incorrect Mask classes, achieved a commendable 96% accuracy. The study showcased the potential of Convolutional Neural Networks (CNNs) to discern subtle nuances in mask-wearing, although the challenge of hand-covered faces remained [10], [11].

Anderson et al. [9] developed a deep learning model for face mask detection with a 96% accuracy rate, demonstrating CNNs' capability to identify proper mask usage [10], [11]. Singh et al.'s study [12] utilized IoT for COVID-19 patient monitoring, focusing on device interconnectivity for cluster detection [13]. Prajwal C Hegade et al. [14] introduced a system combining facial recognition with temperature sensing for comprehensive health monitoring. These studies underscore the effectiveness of deep learning and IoT in enhancing mask detection and public health safety [15]. Additionally, point feature detection algorithms like SIFT, SURF, Harris Corner, and FAST are pivotal in object recognition within images [16]. Chhabra and Verma's research [17] on SURF highlighted its robustness in object detection, adapting to scale and rotation changes, which is crucial for accurate mask-wearing assessment. Notably, the proposed approach excels in detecting objects despite scale changes or in-plane rotations, exhibiting robustness to out-of-plane rotations and limited occlusions [18].

Feature-based detectors, which include algorithms such as the Cascade Object detector, Barcode detector, and April Tag detector, provide an alternative approach for object detection and classification [19].

Chowdhury et al. [20] present a cascaded object detection and classification methodology. The model's training, encompassing 50 positive images, employs Cascade Trainer Graphical User Interface (GUI), while MATLAB facilitates testing. The utilization of MATLAB (R2018b) expedites object identification, minimizing code complexity. The approach benefits from GPU acceleration, enhancing training efficiency. The resulting .xml file generated by Cascade Trainer is read by MATLAB to detect objects, subsequently outlined with rectangles and labeled. This approach enhances the accuracy of object detection and labeling, addressing limitations in prior methods while maintaining minimal incorrect refusals [21].

Continuing to build upon the foundations established by these studies, our research aims to develop a face mask detection system using machine vision that effectively identifies whether a person is wearing a mask, achieved through training a Cascade object detector on a limited dataset and utilizing cross-validation due to data constraints. By incorporating the strengths of these approaches and addressing their limitations, we aspire to propel the field of face mask detection further, enhancing its reliability and practicality [22].

According to MATLAB's help center [23], understanding the concept of a Region of Interest (ROI) is fundamental in image analysis. It is depicted as a binary mask image, indicating specific areas of significance within the image, an ROI defines the portion of an image where specific filtering or operations are applied. The toolbox of MATLAB offers versatile methods for defining ROIs and generating binary masks. Shapes such as circles, ellipses, polygons, rectangles, and hand-drawn forms can serve as ROIs, each allowing for modification of shape, appearance, position, and behavior. Alternatively, MATLAB's image processing toolbox enables the creation of ROIs by specifying locations or sizes. This adaptable approach to ROIs, illustrated in Fig. 1, underpins the precision and flexibility of our face mask detection system [24].

As per the documentation provided by MATLAB's help center [25], the trainCascadeObjectDetector function is capable of utilizing three different types of features: Histograms of oriented gradients (HOG) Local binary patterns (LBP), and Haar features. Haar and LBP features are particularly renowned for their ability to precisely capture intricate textures, contributing to the function's effectiveness in object detection [26], making them particularly well-suited for human face detection. On the contrary, HOG features find common application in detecting objects like people and cars. The cascade classifier is organized into stages, where each stage comprises an ensemble of weak learners. These basic learners, known as decision stumps, act as elementary classifiers within the cascade. Fig. 2 illustrates the process flow for training the cascade detector.

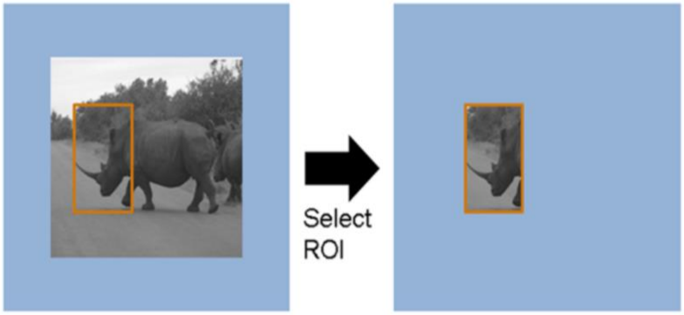

Fig. 1. Front view of people's face.

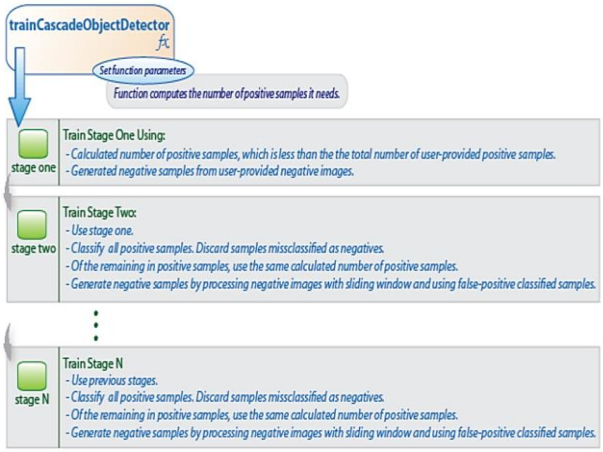

trainCascadeObjectDetector
fx
Set function parameters
Function computes the number of positive samples it needs.
stage one
Train Stage One Using:
- Calculated number of positive samples, which is less than the the total number of user-provided positive samples.
- Generated negative samples from user-provided negative images.
stage two
Train Stage Two:
- Use stage one.
- Classify all positive samples. Discard samples missclassified as negatives.
- Of the remaining in positive samples, use the same calculated number of positive samples.
- Generate negative samples by processing negative images with sliding window and using false-positive classified samples.
stage N
Train Stage N
- Use previous stages.
- Classify all positive samples. Discard samples missclassified as negatives.
- Of the remaining in positive samples, use the same calculated number of positive samples.
- Generate negative samples by processing negative images with sliding window and using false-positive classified samples.

Fig. 2. Illustrates the process flow for training the cascade detector.

The boosting technique is employed at each step to train a classifier that achieves high accuracy. This is accomplished by calculating a weighted average of the decisions made by weak learners [27], [28]. During each stage of the classifier, the current location identified by the sliding window is assigned a positive or negative label. A positive label signifies the presence of an object, whereas a negative label indicates the absence of an object. When negative labels are assigned, the classification process concludes, and the detector proceeds to shift the window to the next position. On the other hand, if a positive label is assigned, the region is subjected to further examination [29], [30]. The detector progresses through phases, swiftly discarding the negative samples, assuming that the object of interest is absent in most windows. Only when the detector confirms the presence of an object in the current window location after the final step does it report the detection of the object [31].

Nevertheless, true positive outcomes are infrequent and demand thorough validation. For efficient functioning, every stage of the cascade must uphold a low false negative rate [32], [33]. If a stage wrongly identifies an object as negative, the classification process stops, and the error remains uncorrected. On the other hand, each stage usually demonstrates a notable false positive rate. Even if the detector mistakenly identifies a non-object as positive, these errors can be corrected in the following stages [34]. Achieving a balance between the number of stages and the false positive rate at each step involves a trade-off, having fewer stages with a lower false positive rate increases complexity, often requiring a larger portion of less skilled learners [35]. Conversely, stages with a higher false positive rate consist of fewer weak learners [36].

Generally, a higher number of foundational stages is favored as it decreases the overall false positive rate with each additional level. For instance, if the false positive rate at each stage is 50%, the overall false positive rate for a two-stage cascade classifier drops to 25%. This percentage further decreases to 12.5% after three stages, and continues to decrease with additional stages. However, with the increase in the number of stages, the classifier requires more extensive training data. Moreover, raising the number of stages amplifies the risk of false negatives, potentially resulting in the unintentional rejection of a positive sample. Modifications to both the false alarm rate and the number of stages can be implemented to attain the intended overall false alarm rate [37], [38], [39].

### A. *Utilizing Deep Learning for Automated Face Mask Detection*

A facial mask detection system was created employing Deep Learning methods. The main objective of this research was to develop a model capable of automatically discerning if a person is wearing a face mask correctly, wearing it incorrectly, or not wearing one at all. For this study, a dataset comprising 3,515 images was utilized, categorized into three classes: Mask, No Mask, and Incorrect Mask. These photos were collected by amalgamating different Kaggle datasets and were stored in JPEG format [40]. Furthermore, Google images were incorporated, and researchers supplemented the dataset with personal photos of themselves, family, and friends to enhance its diversity. The dataset was divided into two segments: 80% for training neural networks and 20% for testing purposes.

Convolutional Neural Networks were selected due to their capability to independently learn multiple filters simultaneously, customized to a particular training dataset and the complexities of a specific predictive modeling problem [41], [42]. In this deep learning algorithm, input images are analyzed, and weights and biases are assigned to different elements or objects within the image, enabling effective distinction between them. CNNs are especially proficient in image detection and recognition owing to their high accuracy [43], [44].

Consequently, the face mask detection model attained an accuracy rate of 96%. Nonetheless, it is crucial to highlight that if an individual covers their face with their hand, the model might misclassify it as either wearing a face mask or wearing it incorrectly [45].

### B. *Detecting Face Masks Utilizing MobileNet and Global Pooling Block*

Moreover, Venkateswarlu et al. [46] have created a face mask detection system employing MobileNet and the Global Pooling Block. They evaluated their model using two publicly accessible datasets. Dataset 1 comprises 1918 images without masks and 1915 images with masks, while Dataset 2 consists of 824 images without masks and 826 images with masks. To augment the data, rotation-based techniques were employed. Fig. 3 depicts the suggested methodology, which initially leverages a pre-trained MobileNet without the output layer to process incoming photos and build a feature map [47]. The global pooling block transforms the multi-dimensional feature map into a one-dimensional vector containing 64 features. Subsequently, a softmax layer with two neurons performs binary classification using these 64 features. The model demonstrated an accuracy of 99% on DS1 and 100% on DS2.

### C. *System Utilizing Facial Recognition for Non-Contact Temperature Detection, Face Mask Detection, and Attendance Management*

In a study conducted by Hegade et al. [14], a system was introduced for non-contact temperature detection, face mask recognition, and attendance management. The setup utilized a Raspberry Pi as the controller, coupled with an ultrasonic sensor to measure the person's distance from the device [48]. The MLX90614 Infrared temperature sensor was utilized for measuring body temperature without direct contact [49]. Attendance updates and mask detection were performed using the HOG facial recognition technique. To establish the system, a database comprising candidate images was created [50]. All images were placed in a single folder, and the file paths were included in the Python source code. Each image was tag with the corresponding candidate's name. The classifier was trained using the HOG algorithm, enabling employee identification during scans. The face detection achieved an efficiency rate of 96.67%.

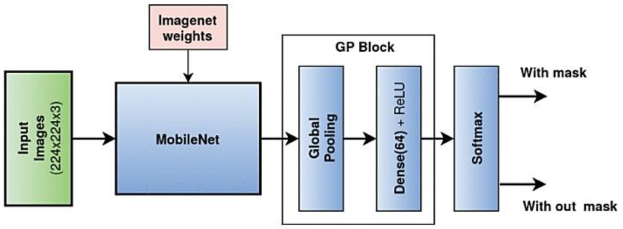

Fig. 3. Illustrates the MobileNet and global pooling architecture [34].

## III. The System Implementation and Testing

### A. System Architecture

The development and implementation of the face mask detection system involve a coherent architectural framework that encompasses data preprocessing, feature extraction, classification, and result visualization. The integration of these components culminates in a comprehensive solution capable of accurately detecting face masks. The system architecture encompasses a series of integral steps: Data Preprocessing, involving noise reduction, image resizing, and normalization to optimize raw input images; Feature Extraction, utilizing Histograms of Oriented Gradients (HOG) features to extract essential visual attributes from preprocessed images, enabling accurate differentiation between masked and unmasked individuals; Classifier Training, which employs HOG features and labeled training data to iteratively train a Cascade object detector, leveraging an ensemble of weak learners for effective face mask detection; Testing and Evaluation, where the trained Cascade object detector undergoes comprehensive testing using an independent dataset, yielding percentage metrics such as accuracy, precision, and F1-score to quantitatively assess system efficacy; and Result Visualization, highlighting detected face masks within images to visually convey the system's detection capabilities, facilitating performance interpretation and potential enhancement identification.

### B. Testing Methodology

The system's testing methodology comprises the subsequent steps: Dataset Compilation, involving the assembly of a diverse dataset containing positive and negative images, enabling the assessment of the system's performance; Feature Extraction, where HOG features are extracted from both positive and negative images, forming the foundation for training the Cascade object detector; Classifier Training, which entails feeding the extracted HOG features into the Cascade object detector training process, enabling the system to differentiate between masked and unmasked individuals based on these discriminative features; and Evaluation, wherein the trained detector undergoes scrutiny using an independent test dataset, resulting in the computation of performance metrics such as accuracy, precision, recall, and F1-score, providing a quantitative gauge of the system's adeptness in detecting face masks. The system's performance evaluation yields insightful results that highlight its capabilities and limitations. The achieved accuracy of 89.17% underscores its efficacy in detecting face masks. While this accuracy may appear lower compared to some prior studies, it's important to note that our system's success is demonstrated with a considerably smaller dataset.

### C. Training and Testing Processes

Fig. 4 illustrates the training process flow. Sample images are input and resized during training. Histograms of oriented gradients features are extracted during the Cascade training process. Adaboost algorithm is employed for classification and classifier updates, iterated for every input image.

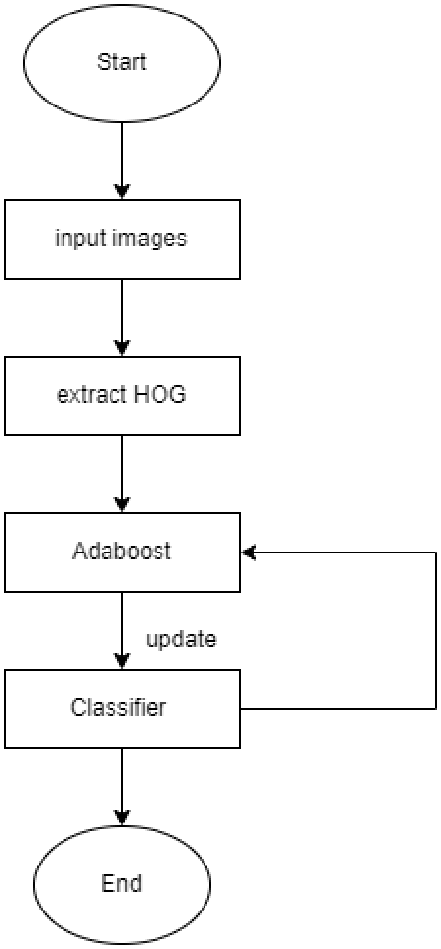

Fig. 4. Training process flow.

Fig. 5 demonstrates the testing procedure flow. A set of test images, containing both positive and negative samples, is used as input data. MATLAB's built-in Cascade detector, employing the Viola-Jones algorithm, is utilized to detect the nose in these images. When the nose is detected, the image is labeled as "no mask." In instances where the nose is not detected, the image undergoes classification using the trained classifier. If the system identifies a mask, the image is labeled as "with mask." On the contrary, if no mask is detected, the image is marked as "no mask."

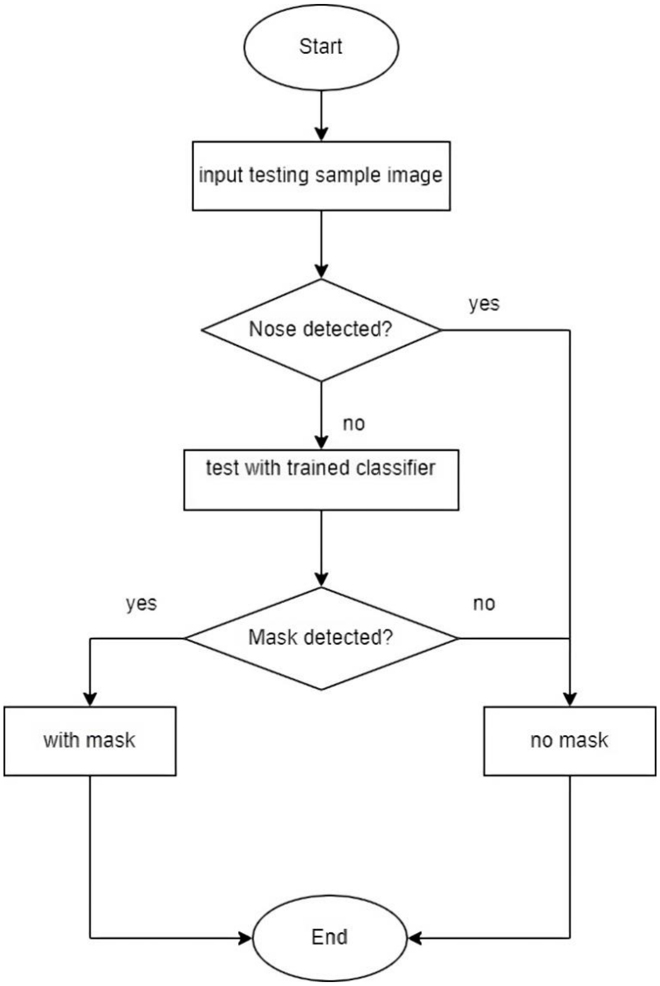

Fig. 5. Testing process flow.

In summary, the Cascade object detector is trained, enabling its application for testing input data images. The final output reveals the detection results, confirming the presence or absence of face masks.

### D. Dataset Compilation

A diverse dataset comprising positive and negative images is curated to evaluate the system's performance. Positive images depict individuals wearing masks, while negative images represent unmasked individuals. The dataset includes 60 positive images of individuals wearing white surgical masks with their front view of the face facing the camera. Additionally, 360 negative images of individuals without masks are incorporated for training and testing the Cascade object detector. Refer to Fig. 6 for the positive dataset and Fig. 7 for the negative dataset. Table I shows distribution of data training model.

### E. Cross-validation Method

Given the limited number of positive mask images, cross-validation is adopted to enhance the reliability of the system. Cross-validation involves resampling the data to train and test the model across different iterations. Fig. 8 illustrates the cross-validation methodology employed in the system.

TABLE I. DISTRIBUTION OF DATA FOR TRAINING AND TESTING

| Testing | | Training | |
|---|---|---|---|
| Images depicting a positive context | Images depicting a negative context | Images depicting a positive context | Images depicting a negative context |
| Image 1-10 | Image 301-310 | Image 11-60 | Image 1-300 |
| Image 11-20 | Image 311-320 | Image 1-10 & Image 21-60 | Image 1-300 |
| Image 21-30 | Image 321-330 | Image 1-20 & Image 31-60 | Image 1-300 |
| Image 31-40 | Image 331-340 | Image 1-30 & Image 41-60 | Image 1-300 |
| Image 41-50 | Image 341-350 | Image 1-40 & Image 51-60 | Image 1-300 |
| Image 51-60 | Image 351-360 | Image 1-50 | Image 1-300 |

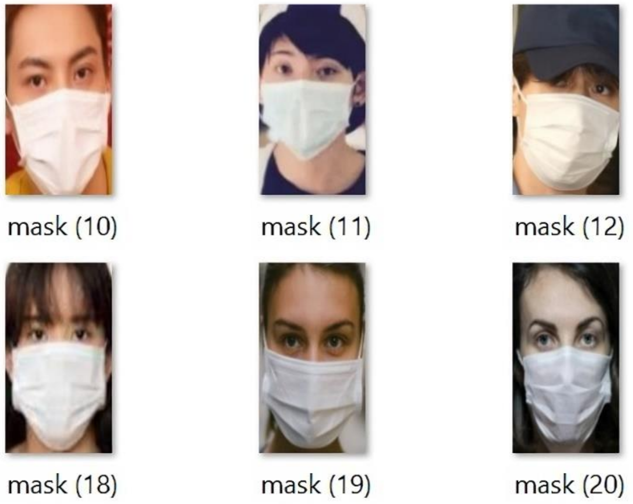

Fig. 6. Positive dataset- people with mask.

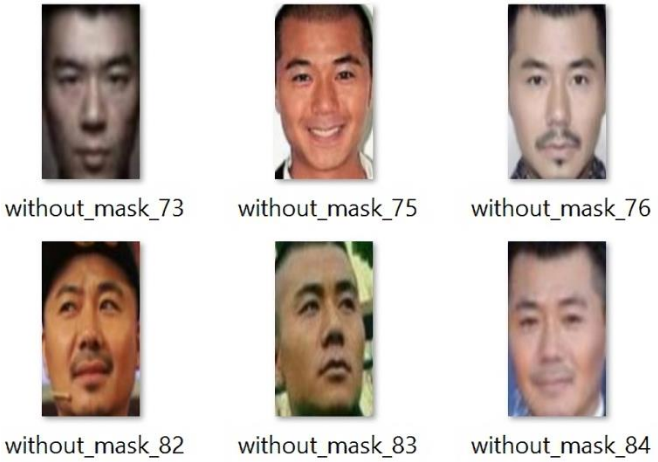

Fig. 7. Negative dataset- people without mask.

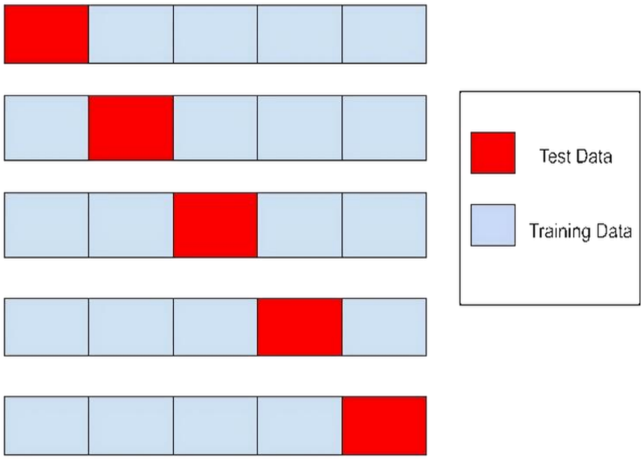

Fig. 8. Cross-validation technique.

### F. Result Calculation

The effectiveness of the trained detector is assessed using a separate test dataset. Various performance metrics, such as accuracy, precision, recall, and F1-score, are computed to quantitatively evaluate the system's ability to detect face masks. Accuracy is determined using the following formula:

$$True\ positive\ rate = \frac{True\ positive(TP)}{Positive\ sample(P)} = 1 - False\ Negative\ Rate \quad (1)$$

$$True\ negative\ rate = \frac{True\ negative(TN)}{Negative\ sample(N)} = 1 - False\ Positive\ Rate \quad (2)$$

$$Overall\ accuracy = \frac{True\ negative + True\ Positive}{Total\ number\ of\ sample} \quad (3)$$

In this context, TP signifies the number of accurately detected face mask images, P represents the total count of positive test images, TN indicates the correctly identified images without face masks, and N denotes the total number of negative test images.

## IV. Result

### A. Results and Discussion of Original Image Dataset

The initial phase of the face mask detection system's evaluation involves the examination of results obtained from the original image dataset. Fig. 9 provides a glimpse into some of the training images, while Fig. 10 showcases a selection of output images generated during this training phase. The outcomes of this training are detailed in Table II, revealing an overall accuracy of 76.67%. While this accuracy represents a significant achievement, it also motivates the pursuit of further experiments to enhance system performance.

$$True\ positive\ rate = \frac{34}{60} = 56.67\% \quad (4)$$

$$True\ negative\ rate = \frac{58}{60} = 96.67\% \quad (5)$$

$$Overall\ accuracy = \frac{92}{120} = 76.67\% \quad (6)$$

TABLE II. Training Outcomes Using Original Images

| Set | Quantity of detected positive images | Quantity of detected negative images |
|---|---|---|
| 1 | 5 | 10 |
| 2 | 3 | 9 |
| 3 | 7 | 9 |
| 4 | 6 | 10 |
| 5 | 5 | 10 |
| 6 | 8 | 10 |

Fig. 9. Images in their original dimensions.

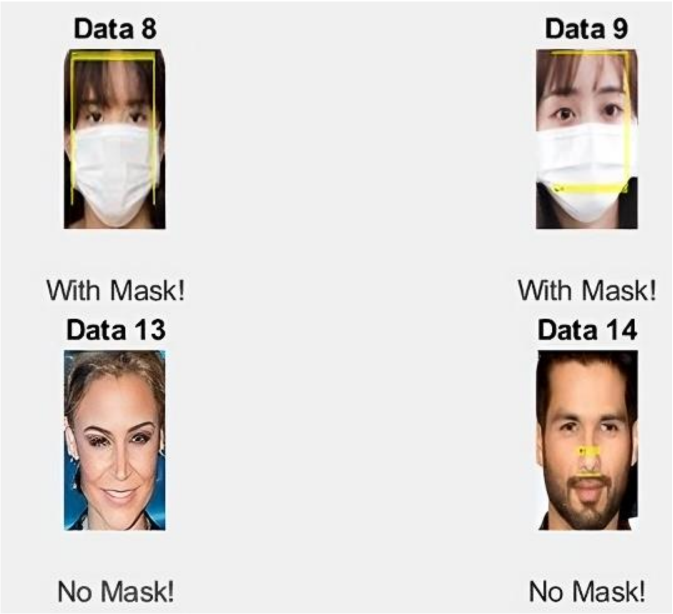

Fig. 10. Results from training with original images.

### B. Findings and Discussion of Dataset Cropped with 9:11 Ratio

An iterative training process is carried out to enhance the system's accuracy. This endeavor involves training the system with cropped images that focus on the lower part of the face—specifically, the mask region. Given its critical role in classification and detection, this lower section is deemed a region of interest (ROI). With a cropping ratio of 9:11, as illustrated in Fig. 11, the training dataset is optimized for mask detection. However, despite these efforts, the results presented in Fig. 12 and Table III indicates a reduction in overall accuracy to 67.50%. This outcome prompts further investigation and refinement.

### *C. Results and Discussion of 9:4:7 Ratio Cropped Image Dataset*

An additional challenge surfaces when certain instances yield mask detection failure due to the absence of the lower mask portion in the images. Table V shows the result of different ratios of image trained. The corresponding observations, exemplified by false negative samples like those depicted in Fig. 13, reveal the importance of retaining this critical region.

$$True\ positive\ rate = \frac{21}{60} = 35\% \tag{7}$$

$$True\ negative\ rate = \frac{60}{60} = 100\% \tag{8}$$

$$Overall\ accuracy = \frac{81}{120} = 67.50\% \tag{9}$$

TABLE III. TRAINING OUTCOMES CONDUCTED WITH CROPPED IMAGES USING A 9:11 RATIO

| Set | Quantity of detected positive data | Quantity of detected negative data |
|---|---|---|
| 1 | 4 | 10 |
| 2 | 3 | 10 |
| 3 | 5 | 10 |
| 4 | 3 | 10 |
| 5 | 3 | 10 |
| 6 | 3 | 10 |

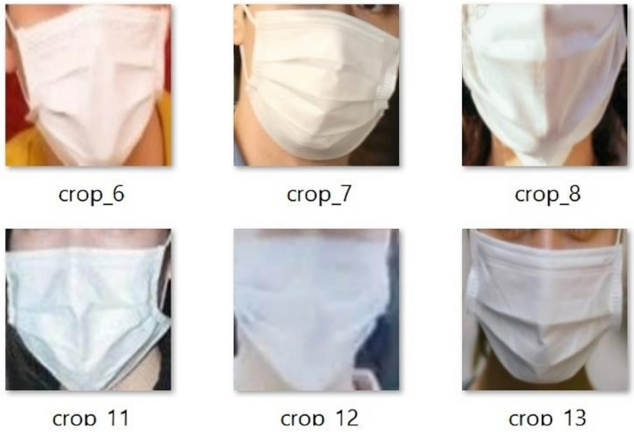

Fig. 11. Displays cropped images with a ratio of 9:11.

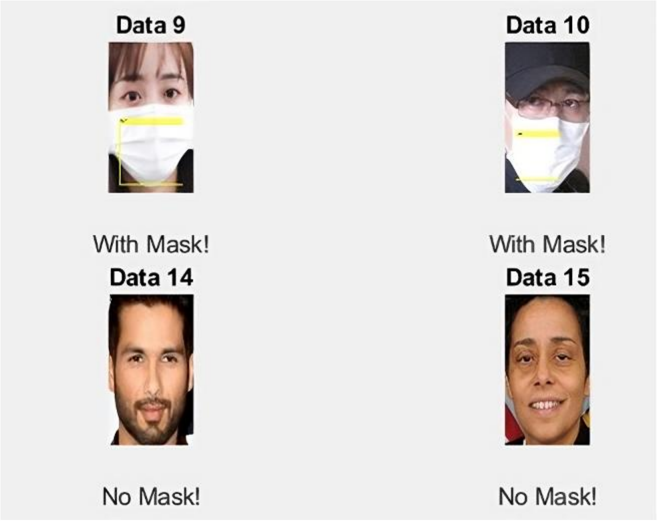

Fig. 12. Illustrates the results obtained from the training process with cropped images using a 9:11 ratio.

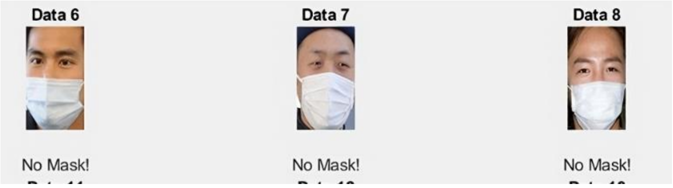

Fig. 13. Output of mask cannot be detected.

To address this, a novel training approach is employed, concentrating solely on the upper mask region. The image cropping ratio is set at 9:4:7, as shown in Fig. 14, to ensure the preservation of the mask edge (see Table IV). Fig. 15 presents outputs derived from this training methodology. Remarkably, this strategy yields an overall accuracy of 89.17%, signifying a substantial advancement in the system's performance.

$$True\ positive\ rate = \frac{48}{60} = 80\% \tag{10}$$

$$True\ negative\ rate = \frac{59}{60} = 98.33\% \tag{11}$$

$$Overall\ accuracy = \frac{107}{120} = 89.17\% \tag{12}$$

TABLE IV. OUTCOMES FROM TRAINING USING 9:4:7 CROPPED IMAGES

| Set | Number of Identified Negative Images | Number of Identified Positive Images |
|---|---|---|
| 1 | 10 | 7 |
| 2 | 9 | 8 |
| 3 | 10 | 9 |
| 4 | 10 | 7 |
| 5 | 10 | 8 |
| 6 | 10 | 9 |

TABLE V. RESULT OF DIFFERENT RATIO OF IMAGE TRAINED

| Picture Ratio | True positive rate | True negative rate | Overall rate |
|---|---|---|---|
| original | 56.67% | 96.67% | 76.67% |
| 9:11 | 35% | 100% | 67.50% |
| 9:4:7 | 80% | 98.33% | 89.17% |

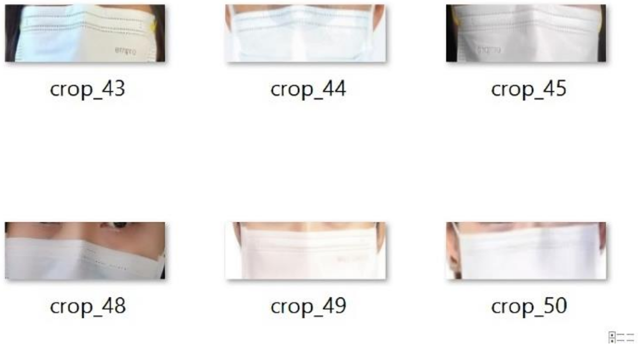

Fig. 14. Displays a cropped image with a ratio of 9:4:7.

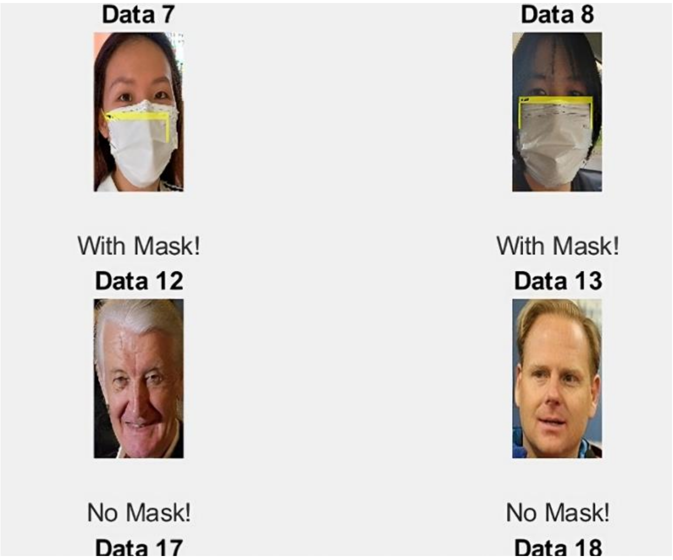

Fig. 15. Illustrates the results obtained from the training process with cropped images using a 9:4:7 ratio.

## V. DISCUSSION

To enhance the system's accuracy, a subsequent training iteration was initiated after the initial result yielded only 76.67%. This new experiment involved training the system with cropped images from the training dataset, specifically focusing on the lower part of the image, which constitutes the mask region and is crucial for accurate detection. This region, termed the region of interest (ROI), was cropped using a ratio of 9:11. However, the overall accuracy of this training process was found to be 67.50%. Given this reduced accuracy, additional training sessions were carried out in an attempt to improve the results.

Upon analyzing the output, it was observed that the mask detection occasionally failed when the lowest section of the mask was excluded from the image. Consequently, the decision was made to crop out the lowest part of the mask from the images, potentially impacting the detection process. In this experiment, solely the upper portion of the mask was employed to train the Cascade detector. Consequently, the images were cropped using a ratio of 9:4:7, focusing specifically on the mask's edge section.

The culmination of these diverse training processes contributes to a comprehensive understanding of the system's capabilities. The initial training with original-sized images achieves a commendable accuracy of 76.67%. However, recognizing the potential for enhancement, subsequent training phases are undertaken. The experimentation involving a 9:11 cropped image dataset achieves an accuracy of 67.50%. The apex of this exploration is the training process with a 9:4:7 cropped image dataset, yielding an impressive accuracy of 89.17%. These iterative experiments underscore the system's adaptability and potential for accurate mask detection across various training approaches.

TABLE VI. COMPARISON WITH STUDY STATED ABOVE IN BACKGROUND STUDY

| | Study 1 [40] | Study 2 [46] | Study 3 [14] | This study |
|---|---|---|---|---|
| Sample image | 3515 | 3833 | No stated | 360 |
| Accuracy | 96% | 99% | 96.67% | 89.17% |

## VI. CONCLUSION

In summary, this study introduces a face mask detection system utilizing machine vision techniques. The methodology effectively addresses the task of discerning whether an individual is wearing a face mask. The system successfully achieves its primary objective of verifying mask usage, attaining an accuracy rate of 89.17%. Employing a training approach centered on the Cascade object detector, and utilizing cross-validation due to the limited dataset size, this work significantly contributes to the realm of face mask detection. The utilization of a dataset comprised of 60 positive images underscores the challenge posed by limited data availability, distinguishing this study from the broader literature that often leverages more extensive datasets. In summary, this research represents a substantial scientific contribution, addressing the urgent need for accurate face mask detection in crowded environments. By achieving a high accuracy rate and considering the limitations of the dataset, this study showcases the system's potential and sets the stage for future developments in the field of preventive technologies against infectious diseases.

## ACKNOWLEDGMENT

The authors express their gratitude to the Centre for Research and Innovation Management (CRIM) at Universiti Teknikal Malaysia Melaka (UTeM) for their support in conducting this research.

***Abstract*—Obesity has become a widespread problem that affects not only physical well-being but also mental health. To address this problem and provide solutions, Machine Learning (ML) technology tools are being applied. Studies are currently being developed to improve the prediction of obesity. This study aimed to predict obesity levels in nutritional patients by analyzing their physical and dietary habits using the Decision Tree (DT) model. For the development of this work, we chose to use the CRISP-DM framework to follow the development in an organized way, thus achieving a better understanding of the data and describing, evaluating, and analyzing the results. The results of this work yielded metrics with significant values for predicting obesity: so much so that the accuracy rate was 92.89%, the sensitivity rate was 94% and the F1 score was 93%. Likewise, accuracy metrics above 88% were obtained for each level of obesity, demonstrating the effectiveness of the DT model in predicting this type of task. Finally, the results demonstrate that the DT model is effective in predicting obesity, with significant results that motivate further research to continue improving accuracy in this type of task.**

***Keywords*—Obesity; Machine Learning (ML); Decision Tree (DT); Prediction; CRISP-DM**

## I. Introduction

Today, obesity has become a potentially serious health problem worldwide. It is a condition characterized by an abnormal or excessive accumulation of fat in the body, which can have negative effects on a person's health. Obesity is associated with several health problems, including diabetes, heart disease, high blood pressure, and some forms of cancer [1]. It is also linked to psychological problems such as depression and anxiety.

Obesity is a major public health problem that causes physical and psychological health problems [2]. Surprisingly, this problem has tripled in the last four decades and, unfortunately, continues to increase [3]. This can pose a major public health challenge, especially for children and adults [4]. According to studies, global projections of adult obesity rates in 2010, 2025, and 2030 indicate an increase in obesity levels depending on the individual's degree of obesity [5], [6]. In addition, research on childhood obesity confirms a significant increase, which is now considered a global epidemic [7]. In 2010, UNICEF revealed that 40 million children had grade 1 obesity, with 81% of them coming from Asian countries [8]. Furthermore, it was predicted that by 2020, nearly one in ten children worldwide, and one in eight children in Africa, would be obese or undernourished [9]. The regions with the highest rates of childhood obesity are those in Asia-Pacific [10]. Worryingly, the rate of obesity has increased worldwide in the last decade. This is now considered a serious public health problem due to its strong connection with chronic diseases such as diabetes [11]. Obesity is a complex problem influenced by genetics, lifestyle, and environmental factors. Public health experts are using ML tools to predict and identify individuals at risk for obesity to provide personalized interventions [12]. Tools such as these make it easy to identify who needs help and create a personalized plan to meet their unique needs. With the potential provided by predictive analytics, proactive steps can be taken to combat obesity and help people live healthier, happier lives [13]. This trend is particularly concerning because childhood obesity is associated with an increased risk of chronic disease later in life. In addition, the incidence of cardiovascular disease in adults has increased, further emphasizing the need for effective prevention strategies [14]. Importantly, genetic factors may also influence short-term changes in body mass index (BMI), especially during the early years of development. However, due to the cross-sectional nature of the research, it is very complex to establish a causal relationship [15]. Nevertheless, these results highlight the importance of early intervention and prevention efforts to address the obesity epidemic and its associated health risks.

Technological approaches, especially ML models, can be excellent predictive tools that can help predict the level of obesity. For example, the DT model is a map that shows possible outcomes based on a series of related decisions, using algorithms to predict the degree of obesity of individuals [16]. BMI tests are a key indicator for predicting body fatness [17], so in this work, we seek to develop a model that can be used as a predictive index of obesity [18]. However, it is important to note that external validation is vital, as it represents the most optimal situation [19]. Therefore, simulated experiments based on BMI samples may not be as accurate [20]. Ultimately, the use of a tool that can optimize and streamline obesity prediction processes through an app provides users with a better experience based on the results obtained. This, in turn, ensures better treatment by healthcare professionals [21].

The objective of this study is to provide a technological solution capable of predicting the level of obesity in nutrition patients, thus improving the accuracy of obesity level prediction, and patient awareness and reducing the time required to make such predictions.

To achieve this objective, the following sections are presented: Section II presents the most relevant studies on obesity and the use of ML; Section III builds the methodology and develops the case study; Section IV presents the results of the study; Section V discusses the results with related works; and finally, Section VI presents the conclusions of the paper.

## II. Literature Review

Multiple organizations, such as WHO/PHO, regularly publish reports or articles related to obesity. In addition, students, researchers, and independent groups have published papers that aim to address the problem of obesity using technology. For example, in study [22], a study analyzed six ML techniques to create a model capable of classifying obesity in individuals using a 3D scanner, X-ray equipment, and a body composition analyzer. The study obtained indicators above 75%, with the Random Forest technique presenting the best results. In the study [23], an algorithm was developed to analyze and predict whether infants are at risk for obesity based on their fourperiod BMI data. The algorithm was tested with 18818 infant samples and seven ML algorithms, and the Multilayer Perceptron algorithm provided the best results. It achieved an accuracy rate of 96%, with only 4% of cases classified as "At Risk", and a sensitivity value of 92%. This highlights the importance of being able to predict obesity in individuals. Also, in ref [24] they analyzed obesity in India using several algorithms such as Xero, EM, Apriori, and Best-First. They then evaluated better-known algorithms such as KNN, Linear Regression, and AdaBoost to predict and/or forecast obesity and gain new insights into the prediction of obesity in people. The study concluded that there are various levels of obesity in the population of the district where the research was conducted.

Similarly, in study [25], analysts developed an analysis of various ML algorithms such as K-NN, SVM, Logistic Regression (LR), Bayesian Networks, Random Forest, DT, AdaBoost, MLP, and Gradient Boosting to predict the risk of obesity. Two tests were performed, applying PCA in the second one, and the best result was an accuracy rate of 97.09% achieved by LR. The study concluded that obesity risk prediction was approached by evaluating nine ML techniques, and the most outstanding results were obtained with the Linear Regression technique. In study [26] conducted a study on single nucleotide polymorphisms related to eating habits that resulted in BMI readings equal to or greater than 25 kg/m² in 100 samples and BMI less than 25kg/m2 in 51 samples. The study also showed that individuals with allelic variants AgRP, Ala67Ala, ADRB2, Gln27Glu, Glu27Glu, INSIG2, Ala12Ala, and Pro 12 pro tend to develop obesity. Also, in [27], a predictive model was created to predict obesity in adult populations using ML techniques such as LR, Random Forest, Decision Tree, SVM, Gradient Boost, and Ada Boost. The study showed that LR and Decision Tree had the best performance in predicting obesity in adults based on accuracy. On the other hand, in study [28] a predictive model was developed using DT, LR, and KNN to estimate obesity levels from data related to dietary and physical habits, as well as other factors related to BMI. The study concluded that DT was the most effective technique for estimating obesity levels, with better accuracy than the other two techniques evaluated.

In study [29], a predictive model was created to forecast the level of obesity in high school students. The model employed four ML techniques: Binary LR, Enhanced DT, Weighted KNN, and Neural Networks. The results showed that the Binary LR technique had an accuracy rate of 56.02%, DT had an accuracy of 80.23%, KNN had an accuracy of 88.82%, and Neural Networks had an accuracy of 84.22%. The model with the highest accuracy was KNN, indicating that obesity is a major problem that needs to be addressed from various perspectives to reduce its prevalence among young people. Along the same lines, in study [30], they used ML algorithms such as SVM, DT, and Neural Networks, and applied Principal Component Analysis to determine the main factor of obesity in individuals using a dataset based on obesity-related patterns. The result was an accuracy level of 90% in both Neural Networks and DT algorithms while highlighting that a crucial factor in obesity is the presence of family members with obesity or overweight. Furthermore, in a study by [31], a predictive algorithm was developed to identify factors contributing to obesity and estimate obesity levels using unsupervised learning methods. The algorithm achieved an accuracy level of 97.8% using the cubic SVM technique.

## III. Method

This section develops the theoretical basis of the DT model and the methodology used in the development of the case study.

### *A. Decision Tree*

A DT is a nonparametric supervised learning algorithm that can be used for both classification and regression tasks. It has a hierarchical tree structure consisting of root nodes, branches, internal nodes, and leaf nodes [32], [33], [34]. Depending on the available features, both types of nodes perform evaluations by forming homogeneous subsets represented, by leaf nodes or end nodes. Leaf nodes represent all possible outcomes of a dataset [35], [36]. DT learning uses a divide-and-conquer strategy to determine the best-split point in the tree by greedy search. This partitioning process is recursively repeated from top to bottom until all or most of the records are classified under the given class label [37].

This approach provides a high degree of insight by determining the independent variable for each distribution in each branch of the tree. In addition, other algorithms or techniques belonging to the DT group, such as Random Forest or eXtreme Gradient Boosting, are based on decision trees [38], [39].

### *B. Understanding the Data*

In this phase, we define the data set used for the development of the study, which comes from the Kaggle platform and comprises 17 variables relevant for predicting obesity levels based on dietary and physical patterns. To interpret the information, the data values are analyzed. Therefore, the logic of the data must be handled to accurately identify the functioning of the variables. This stage is crucial to understanding the behavior of the data, which helps to make informed decisions during the study.

### *C. Description of Data*

In this phase, a general description of the data set is provided, including its variables, data types, and a brief description of what it represents. Table I presents the characteristics of the data set. The purpose of this section is to provide the reader with a clear understanding of the content of the data set and to interpret the results more accurately.

TABLE. I DATA SET DICTIONARY

| Variable | Type | Description |
|---|---|---|
| Height | Float64 | Person height in meters. |
| Weight | | Person weight in kilograms. |
| FCVC | | Frequent consumption of vegetables. |
| NCP | | Number of main meals per day. |
| TUE | | Use of technology devices in hours. |
| SMOKE | | ¿Does the person smoke? |
| CH2O | | Dairy consumption of wáter. |
| FAF | | Frequency of weekly physical activity. |
| Age | | Age of the person. |
| Gender | Object | Gender of the person. |
| Oerweight_family_history | | There are relatives with obesity. |
| FAVC | | Frequent consumption of high-calorie foods. |
| CAEC | | Food consumption between meals. |
| SCC | | Monitoring of calorie consumption. |
| CALC | | Frequency of alcohol consumption. |
| MTRANS | | Means of transport usually used. |
| NSP | | Obesity level (Target). |

The dataset for this work is composed of more than 2000 entries and 17 variables, ranging from dietary patterns, physical habits, and general demographic data such as age and sex. The most relevant characteristic is the attribute "NSP", which reflects the patient's level of obesity and serves as the target variable.

## D. Exploratory Data Analysis

In this phase of the data analysis process, the matplotlib-based Seaborn library was used to draw and explore the statistical data. This library is an excellent tool that integrates tightly with the panda's data structures. Seaborn focuses on what the different elements of the graphs mean, rather than the details of how to draw them. Among its main functions is the plotting of data frames and matrices that are performed internally in semantic mapping and statistical aggregation. The graphs produced by this library provide valuable information about the dispersion of the data about the mean value of each variable or characteristic. It is very important to adjust the attributes of the axes, as shown in Fig. 1, where the degree of obesity of each patient is presented.

Fig. 1 shows the distribution of NSP variables among different levels of obesity in the data set. Fig. 1 clearly shows that there are more overweight patients than patients with any other degree of obesity. This distributional information can be used to determine the prevalence of obesity in a population and help design appropriate interventions to control obesity.

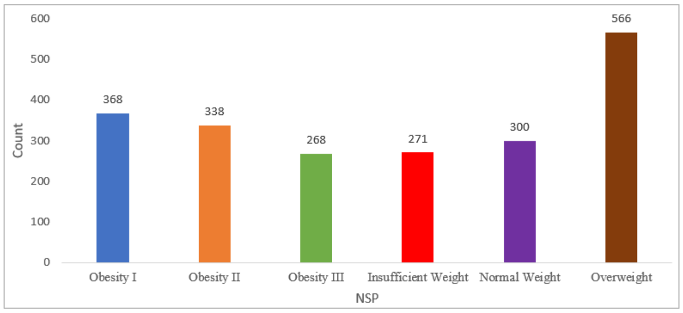

Fig. 1. NSP variable histogram.

In addition to distributional information, Fig. 2 shows the correlation between pairs of variables. There is a correlation between age and obesity level, which is useful for data set analysis. This information can be used to understand how different variables are related to each other and can help to better understand the data set.

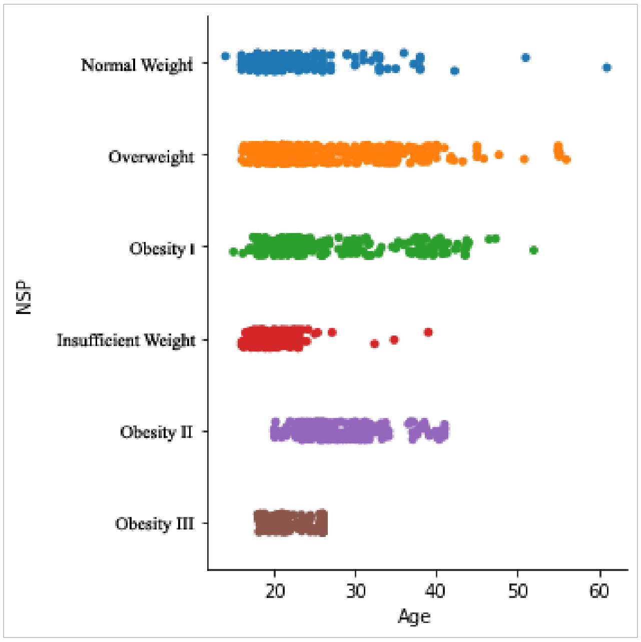

Fig. 2. Relationship between Age - NSP variables.

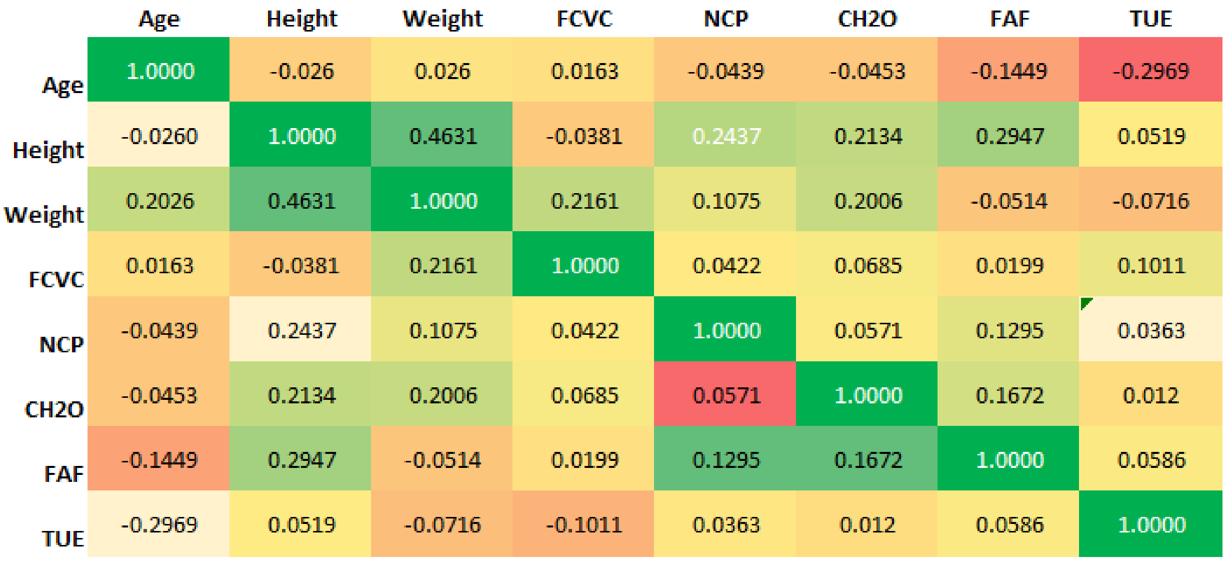
After the analysis of the data set, the degree of correlation between the variables was also examined. For this purpose, the correlation matrix of variables was used to analyze the relationship between different variables in the data set. The relationships between variables provide information on the strength and direction of the relationships between variables in the data set, and the correlation matrix is used to measure the correlation coefficient. For example, if two variables are highly correlated, this may indicate that they both measure the same phenomenon. Conversely, if two variables are negatively correlated, this may indicate that they are measuring opposite phenomena. As it can be seen in Fig. 3, there are two pairs of variables with high correlation coefficients: weight/height and age/truth.



| | Age | Height | Weight | FCVC | NCP | CH2O | FAF | TUE |
|---|---|---|---|---|---|---|---|---|
| Age | 1.0000 | -0.026 | 0.026 | 0.0163 | -0.0439 | -0.0453 | -0.1449 | -0.2969 |
| Height | -0.0260 | 1.0000 | 0.4631 | -0.0381 | 0.2437 | 0.2134 | 0.2947 | 0.0519 |
| Weight | 0.2026 | 0.4631 | 1.0000 | 0.2161 | 0.1075 | 0.2006 | -0.0514 | -0.0716 |
| FCVC | 0.0163 | -0.0381 | 0.2161 | 1.0000 | 0.0422 | 0.0685 | 0.0199 | 0.1011 |
| NCP | -0.0439 | 0.2437 | 0.1075 | 0.0422 | 1.0000 | 0.0571 | 0.1295 | 0.0363 |
| CH2O | -0.0453 | 0.2134 | 0.2006 | 0.0685 | 0.0571 | 1.0000 | 0.1672 | 0.012 |
| FAF | -0.1449 | 0.2947 | -0.0514 | 0.0199 | 0.1295 | 0.1672 | 1.0000 | 0.0586 |
| TUE | -0.2969 | 0.0519 | -0.0716 | -0.1011 | 0.0363 | 0.012 | 0.0586 | 1.0000 |

Fig. 3. Variables correlation matrix.

The correlation matrix of variables presented in Fig. 3 shows correlation values ranging from -1 to 1, indicating the strength and direction of the relationship between the two variables. For example, age shows a weak negative correlation with most of the other variables, implying that as age increases, these variables tend to decrease. On the other hand, height shows a positive correlation with weight, suggesting that as height increases, weight also tends to increase. Similarly, weight shows a positive correlation with height. While there is a moderate correlation between FCVC and CH2O, there is a weak negative correlation with FAF and TUE. FCVC, or the frequency of eating raw vegetables, is directly related to body weight, meaning that people who eat more raw vegetables tend to lose weight. In addition, the number of main meals (PNC) was positively correlated with height and water intake.

In analyzing the data collected, we found that age plays a decisive role in determining the level of physical activity. Participation in physical activity appears to decrease as people age. In addition, there is a positive correlation between height and physical activity suggesting that taller people are likely to be physically active. In addition, the data indicated a weak positive correlation between PNC and CH2O and physical activity levels. However, it should be noted that these results may be influenced by other factors, so further studies may be needed to obtain better results.

Finally, the screen time variable showed a strong negative correlation with age. This finding means that as people age, their tendency to use electronic devices for longer period's decreases significantly. These results are critical to help us understand the factors that influence physical activity levels and screen time use patterns across all age groups.

### *E. Data Verification and Structuring*

During this process, null or empty values are searched for in the data of each variable, to prepare them for training and verifying their post-processing behavior. These steps are essential to ensure data quality before proceeding with analysis and modeling.

During this stage, data scaling, balancing, and/or transformation are performed to structure the data set. These tasks are carried out to sort the data for each variable, which reduces the possible dispersion of values and improves the efficiency of the model. Previously, a data table was created for each variable showing the minimum, maximum, mean, median, and standard deviation values, to determine if scaling, balancing, or transformation techniques are required according to the model requirements, as shown in Table II. In addition, during model construction, data quality must be ensured and properly prepared, since scaling methods require that each variable be placed without repetitions to avoid negative impacts on the model due to the size of the variables.

TABLE. II VERIFICATION OF VARIABLES

| | Age | Height | Weight | FCVC | NCP | CH2O | FAF | TUE |
|---|---|---|---|---|---|---|---|---|
| Count | 2111.00 | 2111.0 | 2111.0 | 2111.00 | 2111.00 | 2111.00 | 2111.00 | 2111.00 |
| Mean | 24.3126 | 1.7016 | 86.586 | 2.41904 | 2.68562 | 2.00801 | 1.01029 | 0.65786 |
| Std | 6.3459 | 0.0933 | 26.191 | 0.53392 | 0.77803 | 0.61295 | 0.85059 | 0.60892 |
| Min | 14.000 | 1.4500 | 39.000 | 1.00000 | 1.00000 | 1.00000 | 0.00000 | 0.00000 |
| Max | 61.0000 | 1.980 | 173.000 | 3.00000 | 4.0000 | 3.0000 | 3.0000 | 2.0000 |

### F. Model Construction and Validation

In this phase, the model is used to make decisions based on the knowledge generated. The data set was divided into 20% for testing and 80% for training and validation. The Pandas, NumPy, and Scikit-learn libraries were used to implement the code in Python.  This section allows the results of the model to be independently verified and evaluated. In addition, the command data_train.groupby('NSP') is used to display the number of people per NSP (obesity level).size() variable. This will allow us to see how people are distributed at each obesity level. It is also crucial to look at the type of variable in each column of the dataset. A graphical visualization can be performed within the cross-validation to achieve an 80% accuracy level.

### G. Model Creation, Training, and Testing

Before creating a predictive model, it is important to verify the target variable (NSP) in the given data set. Table III shows the distribution of each NSP class in the training data set. Since imbalances in the data can affect the performance of the model, analyzing the distribution of the classes of the target variable is critical. Table III presents the number of instances of each NSP class in the training data set, indicating the proportion of each class in the data. This analysis is necessary to understand the distribution of classes, identify the need for balancing techniques such as oversampling or undersampling, and ensure that the model is trained equally on all classes. By addressing any imbalance, equitable model training and accurate predictions are ensured.

TABLE. III NSP VARIABLE DISTRIBUTION

| | Obesity I | Obesity II | Obesity III | Insufficient Weight | Normal Weight | Overweight |
|---|---|---|---|---|---|---|
| Count | 295 | 270 | 216 | 224 | 234 | 450 |

To ensure that the distribution of the data contained in each class of the target variable "NSP" have similar weights, or in case they do not, a scaling process must be performed. It can be observed that the class "Overweight" has more data compared to other classes with similar amounts according to the distribution of the classes of the target variable. Therefore, the weight of the "Overweight" class will be adjusted to match that of the other classes. Subsequently, a cross-validation of the Decision Tree will be performed. This process aims to estimate the optimal depth of the tree, which will increase the efficiency of the model.  Then, the decision tree is generated using the training data and the previously calculated parameters (maximum depth, and weights for each class of the NSP variable).

## IV. RESULTS

After training the DT model with the training data, we proceeded to predict the results with the test data, resulting in an impressive accuracy rate of 92.89%. This indicates a high level of model performance and reliability. In addition, the confusion matrix helped us to identify correct and incorrect predictions, giving us a more detailed view of the model's effectiveness, as shown in Fig. 4.

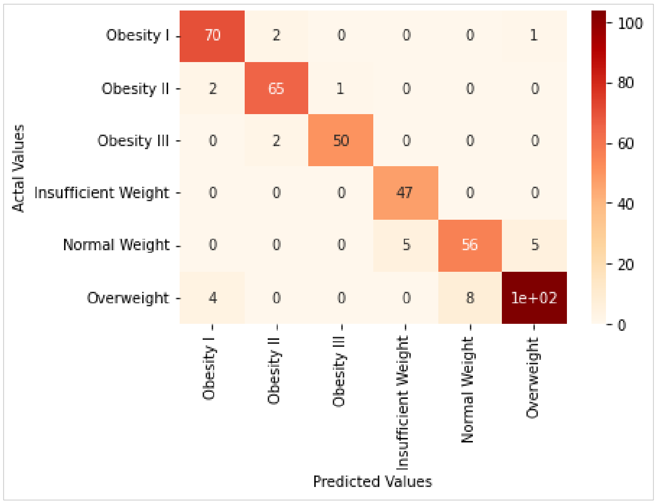


Fig. 4. Obesity levels correlation matrix.

In addition, to measure the performance of the model, several metrics were obtained for all classes of the "NSP" variable, as presented in Table IV. These metrics allow us to evaluate the percentages of accuracy, recall, and F1 scores obtained from the prediction of the test data. This provides a comprehensive assessment of the accuracy of the model, allowing us to determine the effectiveness of the prediction methodology. Using these metrics, it is possible to further refine and improve the results of the model to achieve better predictions in the future.

TABLE. IV CLASSIFICATION REPORT

| | Precision | Recall | F1-Score | Support |
|---|---|---|---|---|
| Insufficient Weight | 0.92 | 0.96 | 0.94 | 73 |
| Normal Weight | 0.94 | 0.96 | 0.95 | 68 |
| Overweight | 0.98 | 0.96 | 0.97 | 52 |
| Obesity I | 0.90 | 1.00 | 0.95 | 47 |
| Obesity II | 0.88 | 0.85 | 0.86 | 66 |
| Obesity III | 0.95 | 0.90 | 0.92 | 116 |
| Accuracy | | | 0.93 | 422 |
| Macro AVG | 0.93 | 0.94 | 0.93 | 422 |
| Weighted AVG | 0.93 | 0.93 | 0.93 | 422 |

To evaluate the classification of variables for each level of obesity obtained from the NSP, precision measures were analyzed for each variable in each type of obesity. The results showed an accuracy of 92% for underweight classes, 94% for normal weight, 98% for overweight, 90% for obesity I, 88% for obesity II and 95% for obesity III. These precision values indicate how accurately the model classified each level of obesity. Higher accuracy values mean that the model can correctly classify a higher proportion of cases at that level of obesity.

These results are obtained from the sample size and are based on an accuracy of 80% during the creation of the DT. The results reveal that the model is very effective in identifying different levels of obesity. The accuracy values further demonstrate the accuracy of the model's classifications, with the highest accuracy rate recorded for the Overweight category. The results are based on a consistent sample size, which lends credibility to the model's ability to accurately classify cases.

## V. Discussion

The results of this research validate the main objective, but a comparative analysis with previous studies is necessary to demonstrate the relevance of the obesity prediction study. After evaluating several studies related to the topic presented in this research, we refer to the results found in the studies most like this work, which aim to predict obesity. For example, a study [40] predicted obesity using 3D scanner data with an accuracy of 80% and an accuracy of 84%, which are lower than the results obtained in this work. However, in the study [23], which predicted the risk of childhood obesity using a dataset of 18,818 infants in four age periods and applying seven ML algorithms, the Multilayer Perceptron algorithm obtained the best indicator with an accuracy of 96%, which is higher than the results of this work.

Several ML techniques were applied to predict obesity, with logistic regression and DTs being the most relevant models.

Furthermore, in study [27] predicted obesity in adults using their dietary patterns and various ML techniques, with logistic regression and DT models being the most relevant for predicting obesity. Finally, the results obtained in study [30] show similar levels of accuracy, where models such as SVM, DT, neural networks, and PCA were used to find that a decisive factor in obesity is family history, reaching an accuracy rate of 90% for DT and neural networks. Based on the above, we state that this work is very relevant in terms of obesity prediction since it has reached an accuracy rate of 92.89%, higher than those obtained in the studies. In conclusion, this work has managed to predict obesity with a very effective level of accuracy and contributes knowledge to a global problem that affects everyone.

## VI. Conclusion

Several researchers and institutions are looking for technological solutions that allow a better prediction of obesity levels either at early ages, young people, or adults; in the present work, we sought, using decision trees, to predict the level of obesity in nutrition patients. The data set used for the present investigation consists of 2111 records and 17 variables that encompass both physical and dietary habits. The result achieved showed that DTs are very efficient in the prediction of the level of obesity, with the support of previous studies and the results obtained with the prediction of the test data, which were 92.89%, and it can be stated that the study was successful. The results obtained support the position that the application of DT to predict obesity levels does achieve its purpose, although, for future research or proposals for improvement, it is recommended to apply ML, more specifically DT, too much larger groups or to apply it to new scenarios or patterns that offer another point of view on obesity prediction. Regarding the limitations of the study:

*1)* The results of the study may not generalize to other populations or contexts because it is based on a specific dataset collected through the Kaggle platform. The accuracy of the model may also be affected by the representativeness and quality of the data.

*2)* Although class imbalance in the dataset has been addressed during model building, it remains an issue for predicting obesity. Obesity classes may not be equally represented in the population, which could bias the model results.

*3)* Several variables have been used to predict obesity, but the importance of each of these variables may be limited. Prediction may be more significantly affected by some characteristics than others, which may not be fully reflected in the results presented.

For future work, it is recommended to apply ML models to predict the level of obesity in demographic populations and to work with data covering different ethnic groups, ages, genders, and geographic locations. In addition, it is recommended to compare several ML models to predict obesity, such as LR, Support Vector Machines, Neural Networks, and Random Forest, among others. This work will allow us to determine if ML models such as DT are still the best option or if other ML algorithms offer equal or superior performance.

# Presenting a Hybrid Method to Overcome the Challenges of Determining the Uncertainty of Future Stock Price Identification

Zhiqiong Zou[1], Guangyu Xiao[2]*
Jingchu University of Technology, Jingmen 448000, Hubei, China[1]
DongEui University, Busan 47340, Busan, Republic of Korea[2]

***Abstract*—A particular location, framework, or forum where buyers and sellers congregate to trade products, services, or assets is referred to as an economic market. While the future is unpredictable and unknowable, it is still possible to make informed predictions about the course of events. Predicting stock market movements using artificial intelligence and machine learning is one such potential. Even if the stock market is volatile, it is still feasible and wise to use artificial intelligence to create well-informed forecasts before making an investment. The current work suggests a novel approach to increase stock price forecast accuracy by integrating the Radical basis function with Particle Swarm Optimization, Slime Mold Algorithm, and Moth Flame Optimization. The objective of the study is to improve stock price forecast accuracy while accounting for the complexity and volatility of financial markets. The efficacy of the proposed strategy has been tested in the real world using historical stock price statistics. Results demonstrate considerable accuracy improvements over traditional RBF models. The combined strength of RBF and the optimization technique enhances the model's ability to adapt to changing market conditions in addition to increasing prediction accuracy. Results were 0.984, 0.990, 0.991, and 0.994 for RBF, PSO-RBF, SMA, and MFO-RBF, respectively. The performance of MFO-RBF in comparison to RBF shows how combining with the optimizer can enhance the performance of the given model. By contrasting the outcomes of various optimizers, the most accurate optimization has been determined as the main optimizer of the model.**

***Keywords—Stock market prediction movement; prediction models; Radical basis function; optimization approaches***

## I. Introduction

A crucial component of finance is the stock market. Accurate stock price predictions are essential for investors' risk management and profit-making. It is notable that information on stock prices that is accurately and scientifically forecasted can give regulators crucial help when creating appropriate financial market rules [1]. However, a number of factors, including macroeconomic policies, stock market choices, and the capital flow of significant corporations, and ownership changes, can have an impact on stock values. Unpredictable traits such as non-stationarity, non-linearity, aggregated fluctuation, and stochastic noise are present in the pattern of price movements. Maintaining the stock market's stability and security is vital since it is an integral component of national economies [2] [3]. Analyzing the behavior and performance of stock markets has emerged as a crucial field of research due to the possible hazards involved in [4]. Predicting the movement of stock prices is one of the most significant responsibilities in this respect since it helps investors make educated decisions and avoid dangers, as well as regulators, in stabilizing the financial markets. Uncertain prediction procedures and inaccurate prediction outcomes, however, can result in serious dangers [5]. Therefore, it is essential to create a solid and persuasive prediction model in order to reduce any potential dangers.

The econometric models are not sufficient for all jobs as research issues and application situations get more complicated. Time series analysis' newest favored technique is machine learning, which can be easily deployed, lacks rigid assumptions and considerable prior knowledge, yet has excellent non-linear mapping capabilities [6] [7]. Various methods are used for forecasting; a statistical model is a mathematical framework for analyzing and understanding data patterns. These models, which are a core component of statistics, are used to draw conclusions and forecasts about a population from a sample of data. Simple statistical models like linear regression or complicated ones like hierarchical linear models can be used [8]. However, statistical models also have some limitation that makes the prediction careless. When a statistical model is overly intricate and catches noise in the data rather than underlying patterns, overfitting occurs. As a result, new data may not generalize well, and model interpretability may suffer [9]. Predictive models are created using machine learning methods, including decision trees [10], random forests [11], neural networks [12], and support vector machines [13]. These models can handle non-linear connections and complicated patterns in data. The most potent technology nowadays is ML, which uses a variety of algorithms to enhance its performance on a particular case study. It is a widely held opinion that ML has a substantial capacity for identifying reliable data and seeing patterns in datasets [14]. When it comes to problem-solving, machine learning has proven to be a highly effective approach. Compared to conventional methods, machine learning offers a number of advantages that make it a popular choice in various fields. However, the decision between machine learning and other approaches ultimately depends on the specific problem at hand, the dataset being used, and any relevant restrictions [15].

The radial basis function (RBF) is the model used in this research, and the RBF is a versatile mathematical function that is widely used in numerous fields, including mathematics, machine learning, and data analysis [16]. One of the key features of RBFs is their radial symmetry, which means that their value depends solely on the distance from a central point or center. This makes RBFs particularly useful for a variety of applications, such as interpolation, function approximation, clustering, and more [16]. Due to their flexibility and applicability, RBFs have become an essential tool for researchers and practitioners in many areas of science and engineering [17]. Like other neural networks, RBF has the ability to learn the relationship between dependent and independent variables using several instances from recent datasets. The parallel units that make up the RBF are neurons.

Model optimization is an important step in the development of the presented model. Different methods and techniques are used to optimize model hypermeters, which in this article, Particle swarm optimization [18], slime mold algorithm [19] and moth flame optimization [20] [21] are used to optimize the hyperparameters of the model.

PSO is an optimization algorithm that is inspired by natural phenomena. It has been widely adopted for solving optimization and search problems. PSO is modeled on the social behavior of birds flocking or fish schooling and was developed by James Kennedy and Russell Eberhart in 1995 [18]. This heuristic algorithm is particularly useful for addressing optimization problems that involve complex and high-dimensional search spaces. Another optimization method used in this paper is SMA [22], which gives a fresh method based on the natural mucosal mold's oscillating characteristic. The SMA has some new characteristics thanks to a new mathematical method that applies adaptive weights for the procedure's simulation to produce positive and negative feedback of a biological wave-based mucosal mold emission wave to the best path for connecting food with the capacity to discover and offer high exploitation [23]. Another method for optimizing the hyperparameter of the model is Moth flame optimization; the optimization of the model was carried out using the Moth Flame Optimizer, a nature-inspired approach based on the behavior of butterflies at night. This optimizer takes inspiration from the way in which butterflies navigate towards the moon, which is a proven strategy for long journeys. However, it also recognizes the potential pitfalls of being drawn towards artificial light sources, which can lead to circular movements and a lack of progress. By formalizing this behavior, the MFO has been successfully applied in a range of optimization problems across diverse fields, such as power and energy systems, economic dispatch, engineering design, image processing, and medical applications [24]. Different criteria have been used to evaluate the results of the model, which are chosen depending on the type of model and the data that is used, Root Mean Square Error ($RMSE$), Mean squared error ($MSE$), Mean absolute error ($MAE$) and Coefficient of determination ($R^2$). Several models were used in this project to process a sizable dataset. The time period covered by the dataset was from 2015 to June 2023. The RBF algorithm was carefully developed to take into account a wide variety of input factors in order to guarantee that the final outputs were accurate and trustworthy. The daily transaction volume, high and low prices, and opening and closing prices where criteria has been used. The model was then put through a thorough testing process utilizing these same parameters to evaluate the accuracy of the model outputs. A model that can give traders and investors useful market insights that can aid them in making decisions that result in profitable investments is the final result of this rigorous training and testing procedure. The Google firm owns the stock from which the variable data was received.

The main contributions of the study are as follows:

The research paper presents an innovative methodology for enhancing the precision of stock price predictions through the integration of the RBF with optimization techniques, including PSO, SMA, and MFO. Through the integration of these techniques, the model attains substantial enhancements in precision when compared to conventional RBF models.

The effectiveness of the suggested approach is validated via empirical investigations employing historical stock price data. The findings demonstrate significant enhancements in accuracy, with the MFO-RBF model attaining the highest level of precision among the iterations that were evaluated.

Through a comparison of the results obtained from different optimizers, the research establishes the MFO method as the most precise optimizer for the given model. This emphasizes the significance of choosing the appropriate optimization method in order to maximize the accuracy of predictions.

The study imparts significant knowledge to institutional and individual investors alike through the provision of a dependable approach to forecasting stock prices. Through the utilization of algorithms and historical data, investors are able to execute informed and economical investment decisions, thereby substantially enhancing their prospects of attaining favorable financial results.

## II. Literature Review

The use of machine learning algorithms to predict stock market trends has been more popular recently. The goal of this approach is to take advantage of impending price swings and increase investor profits. Agrawal [25] introduced a stock market forecasting system that utilizes deep learning-based nonlinear regression techniques. Agrawal shows that the suggested method performs better than traditional machine learning techniques by doing experiments on a variety of datasets, including data from the New York Stock Exchange and ten years' worth of Tesla stock price data [25]. This topic of study was significantly advanced by the methodology for media and entertainment company stock price forecasting that Petchiappan et al. [26] developed. Through the utilization of machine-learning techniques, specifically logistic and linear regression, they are able to build a robust prediction system that is customized for the industry. By carefully examining stock price information from reliable media outlets, their approach offers investors important insights into maximizing profits and minimizing losses. Petchiappan et al. [26] perform comprehensive studies to demonstrate the efficacy of their system, emphasizing its advantages over traditional ways. Because stock prices are dynamic and have many facets, forecasting stock market movements is still a difficult and challenging task in the finance industry. To overcome this challenge, Sathyabama et al. [27] use machine learning techniques to predict stock market transactions. The effect that news and other external factors have on stock market patterns is heavily stressed in the authors' research. This further highlights how important accurate prediction models are to effectively managing market volatility. Sathyabama et al. [27] include a better learning-based method that incorporates a Naïve Bayes classifier, adding to the body of information already in existence. Menaka et al. [28] conducted a thorough analysis of machine learning algorithms used in stock price prediction on multiple stock exchanges, which contributed to the field of study in this area. Menaka et al. [28] highlighted how different machine-learning techniques can be tailored to create prediction models that are accurate. These techniques included random forests, ensemble approaches, support vector machines, and boosted decision trees. In order to address the particular challenges posed by sudden and erratic market swings, Demirel et al. [29] focused their analysis on the firms that make up the Istanbul Stock Exchange National 100 Index. Employing daily data collected over a nine-year period, the prediction performance of Long Short-Term Memory, Multilayer Perceptrons, and Support Vector Machines was evaluated [29]. Stock market predictions are still the subject of much research because of the wide-ranging implications they have for global financial markets, investors, and businesses. Tembhurney et al. [30] conducted a comparative analysis of machine learning algorithms' performance in projecting the Nifty 50 stock market index in order to address this challenge. Tembhurney et al. [30] implemented the Random Forest and Support Vector Machine techniques using the Python programming language in order to train models using historical stock market data.

The literature evaluation demonstrates the superiority of machine learning algorithms over conventional methods in forecasting stock market trends. Nonetheless, there are still some significant flaws that exist. Feature engineering is neglected, there is a lack of external validation, the interpretation of models is not thoroughly examined, and the assessment of dynamic market situations is insufficient. Moreover, the evaluation of model hazards is inadequate, and there are few comparisons across various market conditions. Improving the dependability and relevance of machine learning-based stock market prediction models requires addressing these shortcomings. Thus, further research is required to concentrate on developing models that are clear, reliable, and flexible, integrating thorough risk assessment frameworks and able to adjust to shifting market situations. In order to address the shortcomings noted in the literature review, this paper focuses on applying novel techniques, specifically the combination of the moth flame optimization and the radial basis function methodology, to improve the accuracy of stock market predictions. This work aims to create a more flexible, robust, and intuitive stock market prediction model in order to increase the reliability and usefulness of machine learning-driven financial market forecasting.

## III. Methodology

### A. Radial Basis Function

The use of RBF, a type of mathematical operation, is widespread in numerous fields, such as physics, mathematics, and artificial intelligence. When used as an activation function in artificial neural networks, RBF is commonly applied in machine learning, specifically in the radial basis function networks. By using samples from recent datasets, RBF can learn the correlation between dependent and independent variables similar to other neural networks. The parallel components of RBF consist of neurons, and the network is composed of a single buried layer with numerous neurons. The input layer of the neural network receives independent variables, and the nerve cells in the hidden layer compute the input variables to produce the desired output. The RBF network demonstrates satisfactory generalization capacity when compared to new data sets. As long as it has sufficient neurons, the RBF network is capable of estimating any complex function with the necessary accuracy, making it a reliable estimation function. Due to its fast-processing speed, RBF learning is a viable alternative to Multilayer Perceptron learning. Fig. 1 describes the performance of the RBF.

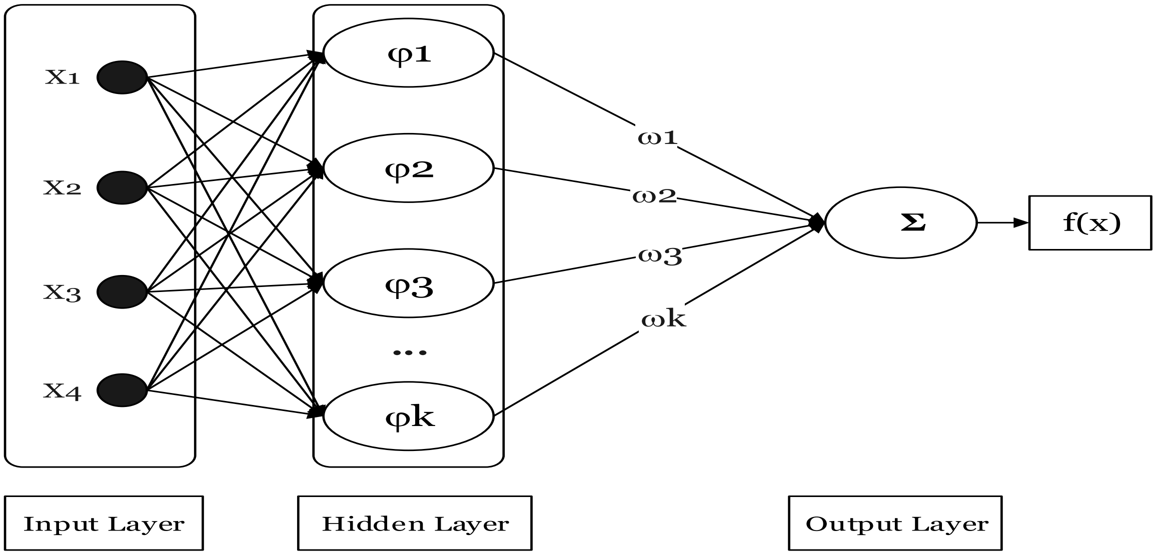

Fig. 1. Description of the performance of the RBF.

Each hidden layer cell is controlled by a non-linear activation equation ($\varphi$). The bias component is denoted by constant vector 1 and ($\varphi_0$) facilitates the training phase convergence and the restricted reach of the RBF neural network. The research in [31] states that any input vector x may be used to calculate the RBF neural network's output:

$$Y = W^T \Phi = \sum_{j=1}^{L_2} w_{ij} \phi(\|x - c_i\|) \tag{1}$$

When $L_2$ is the total number of neurons in the hidden layer, $c_i$ is the prototype centers of those neurons, and $\varphi$ is the Gaussian function, the value of $w_{ijv}$ may be calculated using the following equation:

$$\phi_i(x) = \exp\left(-\frac{\|x - c_i\|^2}{\sigma_i^2}\right) \tag{2}$$

where, $\sigma$ is the spread parameter. During the training phase of the RBF training, one of the clustering approaches is used to establish the ideal values for the $c_i$ centers, which are initially chosen at random. RBFs are trained and optimized utilizing the Mean Squared Error (MSE) objective function:

$$MSE = \frac{1}{N} \sum_{i=1}^{N} \left(y_d - y_p\right)^2 \tag{3}$$

### *B. Particle Swarm Optimization*

The first inspiration for particle swarm optimization came from studying the social behavior of fish and birds. In continuous and multidimensional environments, this heuristic technique has been successful in tackling optimization and search issues. In the 1990s, James Kennedy and Russell Eberhart developed the PSO technique [18]. Each technique's location inside a D-dimensional search space is considered a potential solution in this method. In accordance with the effect of the determined ideal position and the location of the best-performing particle, each particle modifies its position. The following equation is used by the PSO algorithm to control particle speeds:

$$v_{id}^{t+1} = v_{id}^{t} + C_1 r_1^t \left(Pbest_{id}^t - x_{id}^t\right) + C_2 r_2^t \left(Gbest_{id}^t - x_{id}^t\right) \tag{4}$$

In a d-dimensional search space, $v_{id}^k$ represents the speed of the $i$th particle at a certain time iteration. For $i$th individual and iteration $t$, the ideal particle and location are shown in $Pbest_{id}^t$ and $Gbest_{id}^t$, respectively. The parameters $C_1$ and $C_2$ are used to alter particle speed, whilst the numbers $r_1^t$ and $r_2^t$ are arbitrary values between 0 and 1. Additionally, the PSO algorithm's particles travel according to Eq. (5):

$$x_{id}^{t+1} = x_{id}^{t} + v_{id}^{t+1} \tag{5}$$

In this case, $x_{id}^t$ denotes the position of the $i$th particle in iteration $t$ and in the $d$ dimensional search space.

### *C. Slime Mold Algorithm*

In 2020, Li et al. [19] introduced the SMA, which primarily replicates the behavior and morphological changes of the Physarum polycephalum during foraging. Weights in SMA were used at the same time to imitate the positive and negative feedback created during the slime mold foraging process, resulting in the formation of three distinct morphological forms of slime mold. Slime mold is a eukaryotic creature that lives in a chilly, damp environment. Plasmodium is its major food source. The organic material of slime mold searches for food during the active feeding phase surrounds it and secretes enzymes to break it down. In order to facilitate cytoplasmic flow within, the leading edge of the migration cell moves in sectors, and the trailing end is a network of linked veins. Using a range of food sources, they may concurrently construct linked venous networks based on the characteristics of slime mold. The formula utilized to describe this behavior of the slime mold serves as the foundation for the SMA approach. This strategy may be used in a variety of different sectors.

$$\overrightarrow{X(t+1)} = \begin{cases} \overrightarrow{X_b(t)} + \overrightarrow{v_b} \cdot \left(\overrightarrow{W} \cdot \overrightarrow{X_A(t)} - \overrightarrow{X_B(t)}\right) & r < p \\ \overrightarrow{v_c} . \overrightarrow{X(t)} & r \geq p \end{cases} \tag{6}$$

whereas $X(t)$ and $X(t+1)$ are the locations of the slime mold in repetitions $t$ and $t+1$, respectively, and $X_b(t)$ represents the area of the slime mold with the highest concentration of odor at this specific instant. $X_A(t)$ and $X_B$ display two randomly chosen spots for slime mold and $v_b$ is a variable that changes over time [- $a$ , $a$ ]( $a = \text{arctanh}(-(\frac{t}{\text{max\_}t}) + 1)$), if $v_c$ is a linearly lowering if $r$ is a random integer between 0 and 1, $v_c$ is a parameter that decreases linearly from 0 to 1, then $p$ is defined as follows:

$$p = tanh|S(i) - DF| \quad i = 1, 2, \ldots, n \tag{7}$$

$S(i)$ denotes the fitness of $\overrightarrow{X}$ and DF denotes the iteration that is overall the fittest. The following is a description of the weight $W$ equation:

$$\overrightarrow{W(smell\ \imath ndex(l))} = \begin{cases} 1 + r.\log\left(\frac{bF - S(i)}{bF - wF} + 1\right), condition \\ 1 - r.\log\left(\frac{bF - S(i)}{bF - wF} + 1\right), others \end{cases} \tag{8}$$

$$smell\ index = sort(S) \tag{9}$$

In this equation, $S(i)$ stands for the first half of the population, $bF$ for best fitness, $wF$ for worst fitness, and the values of the sorted fitness are represented by the scent index. The following equation is used to change the location of the slime mold:

$$\overrightarrow{X^*} = \begin{cases} rand(UB - LB) + LB & rand < z \\ \overrightarrow{X_b(t)} + \overrightarrow{v_b} . \left(\overrightarrow{W} . \overrightarrow{X_A(t)} - \overrightarrow{X_B(t)}\right) & r < p \\ \overrightarrow{v_c} . \overrightarrow{X(t)} & r \geq p \end{cases} \tag{10}$$

where, $z$ is a number between 0 and 0.1 and $LB$ and $UB$ stand for the bottom and upper bounds of the finding interval, respectively.

### *D. Moth Flame Optimization*

Performance improvements for numerous models have been achieved with great success by utilizing the ground-breaking Moth Flame Optimizer, which Fig. 3 demonstrate the general process of this optimizer. This optimizer is motivated by the nighttime behavior of butterflies, which are known to travel towards the direction of light sources. Although this strategy is excellent for traversing large distances, butterflies are in danger of becoming caught in traps as they continuously circle the light source. The MFO method formalizes this movement into a mathematical formula that may be used to solve a wide variety of optimization issues in a variety of industries, including power and energy systems, economic dispatch, engineering design, image processing, and medical applications. Moths use transverse orientation, a unique kind of navigation, to fly directly toward the moon, which allows scientists to examine this behavior. Numerous optimization issues have been successfully handled using this approach. However, MFO struggles with the issue of inadequate exploration [21]. Fig. 2 shows the general organization of the MFO function and Fig. 3 shows the flowchart of the MFO algorithm,

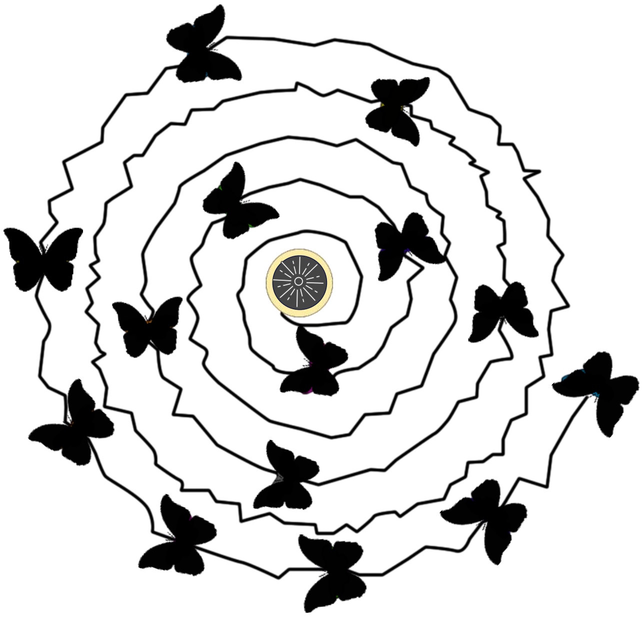

Fig. 2. Flying in a spiral pattern to avoid nearby light sources.

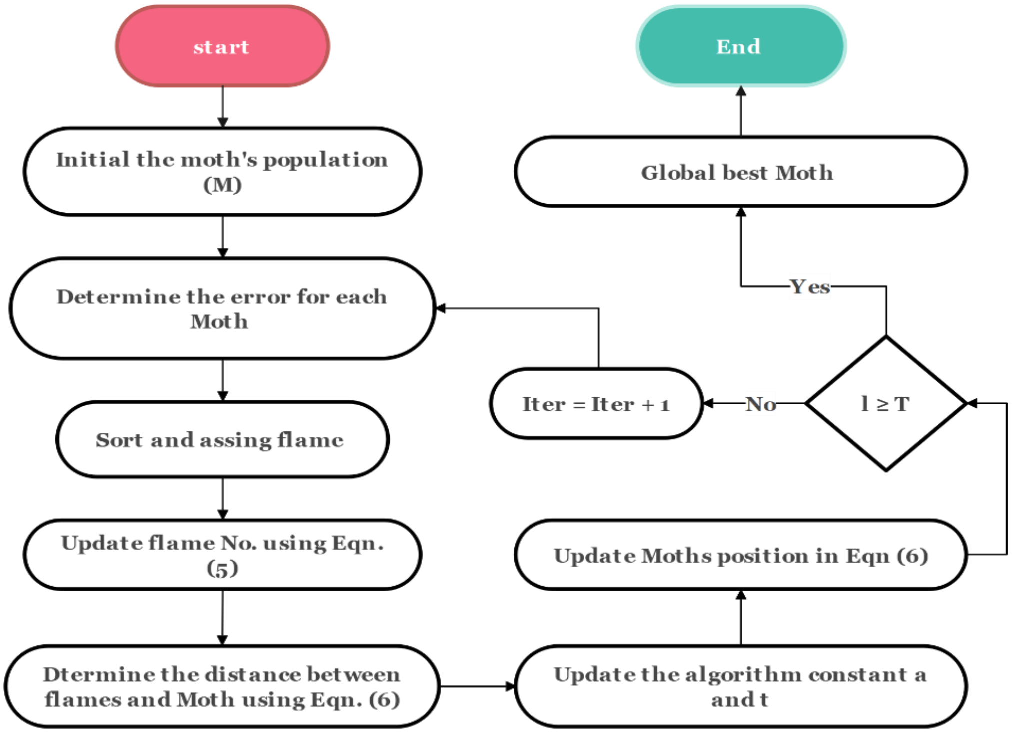

start
Initial the moth's population (M)
Determine the error for each Moth
Sort and assing flame
Update flame No. using Eqn. (5)
Dtermine the distance between flames and Moth using Eqn. (6)
Update the algorithm constant a and t
Update Moths position in Eqn (6)
l ≥ T
No
Yes
Iter = Iter + 1
Global best Moth
End

Fig. 3. Flowchart of the MFO algorithm.

Moths are the investigation's possible answers, and the problem aspects are their geographic distributions. By altering their position vectors, moths may fly in 1D, 2D, 3D, or hyper-dimensional space. The suggested method ensures convergence, and MFO is dependable and computationally effective. MFO may be written as follows:

$$M = \begin{bmatrix} \mathrm{CO}_{1,1} & \mathrm{CO}_{1,2} & \cdots & \cdots & \mathrm{CO}_{1,h} \\ \mathrm{CO}_{2,1} & \mathrm{CO}_{2,2} & \cdots & \cdots & \mathrm{CO}_{2,h} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \mathrm{CO}_{a,1} & \mathrm{CO}_{a,2} & \cdots & \cdots & \mathrm{CO}_{n,h} \end{bmatrix} \quad (11)$$

where $h$ is the number of dimensions and $a$ is the number of moths.

$$S = \begin{bmatrix} S_{1,1} & S_{1,2} & \cdots & \cdots & S_{1,h} \\ S_{2,1} & S_{2,2} & \cdots & \cdots & S_{2,h} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ S_{a,1} & S_{a,2} & \cdots & \cdots & S_{2,h} \end{bmatrix} \quad (12)$$

Worldwide optimization is carried out using the three-step MFO method.

$$MFO = (I, F, T) \quad (13)$$

Where $I$ is a function, $F$ is the flight of the moth in search of space, and $T$ is the stopping criteria.

$$X_i = t(C_i, S_j) \quad (14)$$

$S_j$ indicates the number of $j$th flames, where $C_i$ is the number of $i$th moths, where $t$ is the twisting function, which has the following expression:

$$S(C_i, S_j) = Z_i \cdot e^{bt} \cdot \cos(2\pi t) + S_j \quad (15)$$

Where $Z_i =$ separating the moth from the flame, $b =$ constant value, and $t =$ random number between $[-1,1]$.

$$\mathrm{Zi} = |\mathrm{S_j} - \mathrm{X_i}| \quad (16)$$

## *E. Dataset Description*

The dataset used in this study is intended to make it possible to forecast Google's stock share values over a wide time range, from January 1, 2015, to mid-2023. For investors, financial experts, and decision-makers in the finance sector, accurate stock price forecasting is crucial. The historical stock price information and associated attributes required for conducting predictive studies are provided in this dataset. The dataset's primary sources of financial market data include stock exchanges and financial news outlets. Google's (Alphabet Inc.) historical daily stock share values for the specified time period were compiled. For each trading day between January 1, 2015, and mid-2023, there are several pieces of information available, which are the variables of this paper's dataset, about Google's stock shares. These include the date, the opening price at the start of the trading day, the closing price at the end of the trading day, the highest price the shares reached during the day, the lowest price the shares reached during the day, and the trading volume which represents the total number of shares traded during the day. To guarantee data quality and consistency, stringent data pretreatment processes were used before performing any predictive analyses. Data normalization was also carried out to help with accurate modeling and forecasting. Through the process of data normalization, numerical variables are scaled to a common range, usually between 0 and 1, or with a mean of 0 and a standard deviation of 1. In analytical or modeling activities, this guarantees that variables with varied units or magnitudes are treated equally. The size of the input variables affects the performance of many machines learning techniques, including support vector machines and k-nearest neighbors. These algorithms' performance and convergence may be enhanced by normalizing the data.

Feature scaling, often called Min-Max normalization or data preparation, is the process of rescaling numerical properties in a dataset to a specific range, frequently from zero to one. The objective is to maintain the relative relationships between the values while bringing all the features to a similar scale. In machine learning algorithms that are sensitive to the quantity of input features, this can be particularly crucial. The data normalization approach's formula is as follows:

$$\mathrm{XScaled} = \frac{(X - Xmin)}{(Xmax - Xmin)} \quad (17)$$

A common method for evaluating how well a machine learning model can handle new and untested data is through data splitting. By training the model on a portion of the data and testing it on another subset, the assessment of its performance on real-world data can be revealed by splitting data to train and test. This approach enables us to determine if the model has truly learned from the data and identified patterns or if it is simply recalling information from the training set. Fig. 4 shows that the data set was divided into two parts: the train set and the test set.

The statistical results of the obtained data are shown in Table I. When describing the features of a data collection, statistical measurements like mean, median, skewness, standard deviation, maximum, and minimum are utilized.

By adding up all the values in a data collection and dividing by the total number of values, the mean, sometimes referred to as the average, is determined. When data collection is arranged from lowest to highest, the median is the midway value. The median is the average of the two middle values when there is an even number of values. Comparing to the mean, the median is less impacted by outliers or extreme numbers. A measure of the asymmetry in the data distribution is called skewness. It shows whether the data is roughly symmetric, positively skewed to the right, or negatively skewed to the left. A symmetric distribution is indicated by a skewness value of 0. The distribution or dispersion of data points around the mean is measured by the standard deviation. A higher standard deviation indicates that the data are more variable. It is described mathematically as the square root of the variance. The maximum value among all the data points is simply the maximum value in a data collection. The minimum value among all the data points is the minimum value in a data collection.

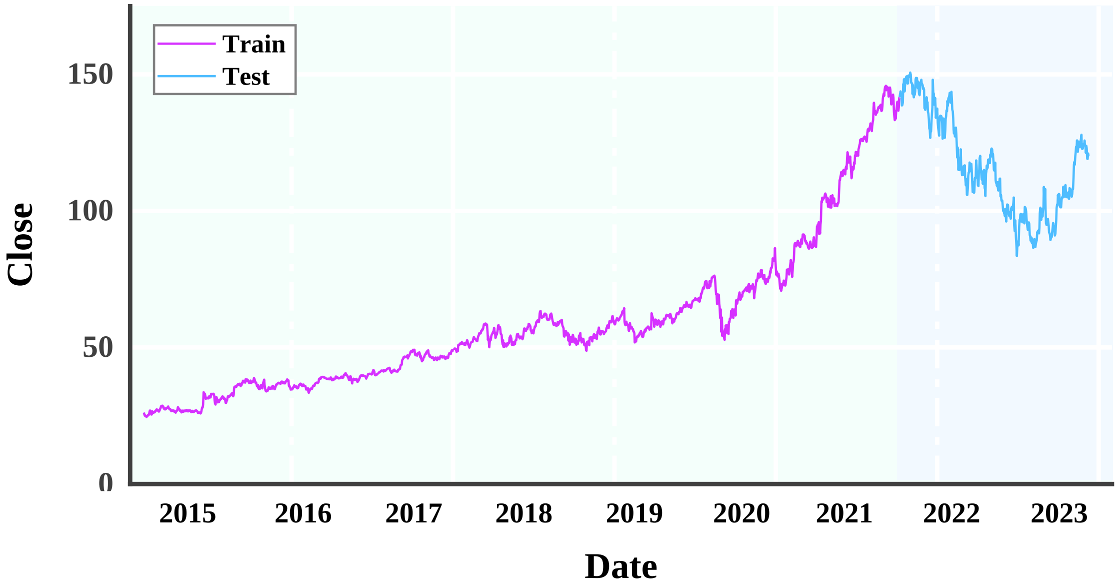

Fig. 4. The overall illustration of the dataset during the training and test.

TABLE I. STATISTICAL RESULTS OF THE PRESENTED MODELS FOR OHCLV

| | Open | High | Low | Volume | Close |
|---|---|---|---|---|---|
| **count** | 2137 | 2137 | 2137 | 2137 | 2137 |

| **25%** | 41.0205 | 41.22 | 40.851 | 23.248 | 41.046 |
| **75%** | 96.77 | 98.94 | 95.38 | 37.066 | 96.73 |
| **max** | 151.8635 | 152.1 | 149.8875 | 223.298 | 150.709 |
| **skew** | 0.746243 | 0.736992 | 0.747426 | 2.879365 | 0.741179 |

### *F. Evaluation Metrics*

For evaluating the performance and efficacy of models, algorithms, and data-driven solutions across a variety of areas, from machine learning and data science to business analytics, evaluation metrics are crucial tools. These metrics offer measurable indicators of how successfully a model or approach completes the goal for which it was designed. The criteria used in presenting this research are $MAE$, $RMSE$, $MSE$ and $R^2$. The average absolute difference between anticipated and actual values is calculated using MAE. It offers a simple way to assess prediction errors. The average squared difference between expected and actual values is determined by MSE. More so than MAE, it penalizes significant mistakes. The square root of MSE, or RMSE, offers a measure that can be understood and is expressed in the same units as the objective variable. R-squared measures the percentage of the target variable's variation that the model is responsible for explaining. From 0 (no explanation) to 1 (excellent explanation), it has a range.

$$RMSE = \sqrt{\frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{n}} \tag{18}$$

$$MAE = \frac{\sum_{i=1}^{n}|y_i - \hat{y}_i|}{n} \tag{19}$$

$$MAPE = \left(\frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right|\right) \times 100 \tag{20}$$

$$MSE = \frac{1}{N}\sum_{k=0}^{n}\binom{n}{k}(Fi - Yi)b^2 \tag{21}$$

## IV. RESULT AND DISCUSSION

### *A. Comparative Analysis*

In order to successfully forecast the Alphabet stock, an identical dataset was applied to each model. The results of each model were thoroughly analyzed and evaluated for this article in order to present a thorough and instructive comparison of their performance. To establish an accurate and fair comparison, it is essential to define the performance metrics that were applied to assess the models. Evaluating the models using a variety of crucial criteria, as explained in the method section. It is possible to thoroughly assess the performance of each model using a variety of metrics before determining which one best meets the requirements. A thorough Table II with the results displays all the various nuances of how each model performed.

Prior to choosing the RBF model, the obtained result was taken into consideration. After a thorough study of the data, the RBF model was selected because of its higher performance. The Alphabet Inc. index data underwent the process of selecting relevant data and normalizing it from the beginning of 2015 to the middle of 2023. Through this rigorous method, valuable insights will be extracted that will aid in the decision-making process. Due to the problematic optimizer developments, the assessment result for RBF alone is now 0.985 in $R^2$, as indicated in Table II. The $R^2$ criteria values for the PSO, SMA, and MFO are 0990, 0.991, and 0.995, respectively, indicating that the optimum course of action may be picked. When compared to other optimizers, the MFO optimizer produces better results. The RMSE model findings shown in Table II further highlight the MFO optimizer's superiority. The $RMSEs$ for RBF, PSO-RBF, SMA-RBF, and MFO-RBF are 2.238, 1.809, 1.710, and 1.253, respectively.

In Fig. 5 through Fig. 6, the experiment's findings are shown, and they show a significant connection between the model and the real data. The MFO-RBF model performed better than the individual RBF, PSO-RBF, and SMA-RBF models among the evaluated models. Notably, the performance of the RBF model was greatly enhanced by the use of the optimizer approach. Fig. 7 and Fig. 8 provide a thorough study of the four models, demonstrating that the chosen model is capable of yielding the best outcomes. These results indicate that the MFO-RBF model is a potentially useful method for precisely forecasting the intended outcomes in the context.

The research presented in this paper demonstrates a higher level of predictive accuracy compared to the studies cited previously [32] [33] , as evidenced by the $R^2$ value of 0.995 provided in Table III.

TABLE II. THE RESULTS OF EVALUATION CRITERIA FOR THE OPTIMIZED MODEL

| **MODEL/Metrics** | **TRAIN SET** | | | | **TEST SET** | | | |
|---|---|---|---|---|---|---|---|---|
| | ***R2*** | ***RMSE*** | ***MAE*** | ***MSE*** | ***R2*** | ***RMSE*** | ***MAE*** | ***MSE*** |
| **RBF** | 0.988 | 3.002 | 1.367 | 9.012 | 0.985 | 2.238 | 1.899 | 5.010 |
| **PSO-RBF** | 0.993 | 2.242 | 1.642 | 5.027 | 0.990 | 1.809 | 1.560 | 3.273 |
| **SMA-RBF** | 0.995 | 1.865 | 1.424 | 3.477 | 0.991 | 1.710 | 1.295 | 2.923 |
| **MFO-RBF** | 0.998 | 1.237 | 0.919 | 1.530 | 0.995 | 1.295 | 1.009 | 1.676 |

## V. CONCLUSION

By leveraging stock prediction techniques to evaluate asset values and identify prevailing market trends, both individual and institutional investors have the opportunity to gain a significant competitive advantage. This allows investors to make well-informed decisions on whether to buy, sell, or hold stocks, utilizing historical data and advanced algorithms. Such a strategy is vital for investors committed to making prudent investment choices, as it mitigates risks and increases the likelihood of achieving profitable outcomes. This research employed various predictive algorithms and data sources to delve into the complex and ever-changing realm of stock prediction. These findings suggest that a combination of models or an ensemble approach may offer more accurate forecasts. Importantly, the development and evaluation of these prediction models underscore the importance of relying on data-driven insights to make reliable decisions. This underscores the benefits of a data-centric approach in today's rapidly evolving business landscape and the broad applicability of predictive analytics across various industries. The primary objective of this study was to create models that could better predict stock prices, enabling interested traders and investors to use these algorithms to make well-timed and cost-effective purchases.

These conclusions were reached in this paper:

First, the data preparation and normalization process were finished, which could have an impact on how the prediction model is displayed. The steps that the selected model would take to examine the data were then prepared for use.

To increase the effectiveness of the model that has been presented, the suitable model should be chosen, the results evaluated, and then the hyperparameters of the model should be adjusted.

By contrasting the outcomes of various optimizers, the most accurate optimization has been determined as the main optimizer of the model. The MFO approach yields the best results when compared to RBF, PSO-RBF, and SMA-RBF, whose results for $R^2$ evaluation criteria are 0.985, 0.990, and 0.991, respectively.

For the purpose of training and validating the model, the suggested method heavily depends on historical stock price data. The model's ability to predict future market behaviors may be intrinsically limited by its dependence on historical trends, even though it offers a solid foundation. This is especially true in situations where there are unanticipated events or market disruptions. When faced with unusual market dynamics that are not represented in historical data, or during times of increased volatility, the model's effectiveness may be called into question even with the use of sophisticated optimization techniques designed to strengthen the model's flexibility to changing market conditions. Moreover, the model's complexity is increased by combining various optimization methods with the Radical Basis Function. Due to this increased complexity, it is possible that scalability and practical implementation in real-time trading environments will be hampered during the training and evaluation phases, which will require significant computational resources. Additionally, it's important to recognize that the efficacy of the suggested methodology might vary among various financial markets or asset classes, going beyond the parameters of the research. The extent to which the model's predictions can be applied to other markets is largely dependent on variables like investor behavior, regulatory frameworks, and market structure. Furthermore, because the model is complex and combines a variety of optimization methods, there is a greater chance that the training data will be overfit or that the test set will be accidentally incorporated into the model. To reduce these inherent risks and guarantee the validity and reliability of the model, it is therefore essential to use appropriate regularization techniques and strong cross-validation strategies.

Creating methods to make complicated models easier to understand has the potential to reveal important information about the fundamental causes of stock price forecasts. Investor decision-making can be made more informed by providing clear and understandable explanations of model predictions. This builds trust. Furthermore, researching ways to dynamically modify the model's architecture or parameters in response to current market conditions could greatly improve the model's accuracy and robustness, especially in unstable or changing market environments. This project might involve investigating ensemble methods or adaptive learning algorithms that can modify model structures or weights in response to changing market conditions. Additionally, there is a chance to improve the model's predictive power and strengthen its resistance to market swings by investigating non-conventional data sources like news articles, social media sentiment, and macroeconomic indicators. The suggested approach's long-term performance and stability across different market cycles would be assessed through longitudinal research, which would be crucial in revealing important details about its dependability and efficacy as a forecasting tool for investors. These kinds of studies would provide a thorough grasp of the model's long-term performance, illuminating its effectiveness in various market scenarios and its potential as a long-term investment tool.

***Abstract*—Image processing and computer vision applications often use the Sobel edge detection technique in order to discover corners in input photographs. This is done in order to improve accuracy and efficiency. For the great majority of today's image processing applications, real-time implementation of image processing techniques like Sobel edge detection in hardware devices like field-programmable gate arrays (FPGAs) is required. Sobel edge detection is only one example. The use of FPGAs makes it feasible to have a quicker algorithmic throughput, which is required in order to match real-time speeds or in circumstances when it is critical to have faster data rates. The results of this study allowed for the Sobel edge detection approach to be applied in a manner that was not only speedy but also space-efficient. For the purpose of actually putting the recommended implementation into action, a one-of-a-kind high-level synthesis (HLS) design approach for intermediate data nodes that is based on application-specific bit widths was used. The high-level simulation code known as register transfer level (RTL) was generated by using the MATLAB HDL coder for HLS. The code written in hardware description language (HDL) that was produced was implemented on a Xilinx ZedBoard with the aid of the Vivado software, and it was tested in real time with the assistance of an input video stream.**

***Keywords—Image processing; sobel edge detection; high level synthesis; model based design; Zynq7000 MATLAB HDL coder***

## I. Introduction

The evolving requirements and technological advancements have led to a growing demand for real-time image processing systems, widely utilized across several industries. Real-time embedded system designs prioritize completing tasks within a certain timeframe overachieving high speed. These systems are commonly utilized in driving support systems, driverless vehicles, flight control, security, and military systems. Predictability characteristics and time stability are essential requirements for real-time systems. [1].

The majority of contemporary image processing and computer vision systems still struggle with the basic challenge of identifying the area of interest in a picture. This is necessary for a wide range of applications, including advanced driving assistance systems (ADAS), which identify things like pedestrians, traffic signals, and blind spots; lane departure warning systems; video surveillance applications; and simultaneous localization and mapping (SLAM) [1]. One example of this kind of feature in a picture is a corner, which is the place at where two distinct edges meet. Image corner detection often involves the employment of many algorithms. The Moravec method [2], the Susan algorithm, and the Sobel edge detector are just a few examples of the kinds of corner extraction techniques that see regular application. The Sobel edge detector is one of the corner detecting algorithms that has the highest level of accuracy. The method is quite computationally demanding, despite the fact that its operation is remarkably simple. It is frequently utilized in systems that demand data processing in real time; as a result, traditional CPUs are unable to fulfill the requirements of these systems. CPUs are only useful when there are big amounts of data involved or when we need to execute calculations using floating point numbers. As a result, field-programmable gate arrays, often known as FPGAs, are great candidates for implementing such algorithms in real time as a result of their rapid processing rates and parallel implementations. It's possible that corner detection will need to be developed on the FPGA in addition to the other algorithms if you're going to be using it for sophisticated computations. Some examples are non-maxima suppression, matrix computation, and triangulation [3]. Other examples include matching by utilizing the sum of absolute differences. As a result of this prerequisite, it is essential to enhance the effectiveness as well as the space needs of the FPGA implementations for these algorithms [4].

A large number of academics have recently released original work on innovative implementations of the Efficient implementation of Sobel edge detection on FPGAs in terms of both space and time. Liu and colleagues proposed a method capable of processing RGB565 video at 640x480 resolution with a frame rate of 154 frames per second. Liu and colleagues implemented the idea using a Xilinx ZedBoard. Xu et al. [5] introduced a modified approach that incorporates a pre-filter and use a simplified matrix instead of the original Gaussian kernel matrix. The researchers devised this novel algorithm. As a result, the design complexity was reduced, allowing robotics applications utilizing a Spartan 3 FPGA to efficiently utilize their hardware resources. In the experiments, a 256 x 256 pixel input picture was processed in 2.3 milliseconds. Chao et al. [6] utilized the Sobel edge detector to simplify the maximum suppression technique. They achieved a data rate of 144 frames per second in their simulations with a design specifically tailored for ZedBoard. Research by Lee and colleagues [7], who created a modified Sobel edge detector, focused on breast cancer identification utilizing MRI and x-ray images. An automated method was employed for adaptive radius suppression to mitigate corner clustering. They were thus able to prevent the loss of important corners that oversuppression would have brought about. John and his colleagues devised a universal picture feature extractor technique and implemented it on a Cyclone 4 FPGA for real-time processing. They succeeded in obtaining a frame rate of 70 frames per second as a consequence. Hisham and colleagues developed a self-adaptive system on a chip for the Sobel edge detection technique using dynamic partial reconfiguration. Their solution consumed less electricity and had a little discernible effect on performance [8, 9, 10].

This article presents a real time implementation of the Sobel edge detector on a Xilinx ZedBoard and demonstrates that the implementation is better to earlier implementations in terms of performance and area utilization on the FPGA. The study also offers a real time implementation of the Sobel edge detector on a Xilinx ZedBoard. The design was created with the use of an innovative high-level design process that synthesizes the design using intermediate signal widths that are restricted based on the application (the input stimuli). The remaining portions of this document are structured as follows: In the next section, "Section II," you will be introduced to high-level synthesis. The Sobel edge detector's internal workings are broken out in detail in Section III. The technique that was employed in the suggested design is broken forth in Section IV. The results of the simulations and synthesis are reported in Section V, along with a comparison to the findings that were uncovered by other researchers. The final observations may be found in Section VI.

## II. High-Level Synthesis based on Model-based Design

A technique that's gaining popularity is called high-level synthesis, or HLS, and it allows designers to continuously validate their designs at every stage of the design process while describing behaviors at high abstraction levels. Examples of HLS utilities include Vivado HLS, MATLAB HDL Coder, and various more open-source tools. These are frequently employed by researchers and digital designers to develop and run algorithms for a wide range of applications including fields like deep learning, neural networks, image processing, communications, and aerospace [11]. The code written on the skin can be simplified by a factor of eight using HLS technology. It enables the reuse of behavioral intellectual property in various projects and allows validation teams to employ abstraction-level modeling methods like transaction-level modeling [12].

Most modern chip systems utilize integrated CPUs. The microprocessors digital signal processors (DSPs), custom logic, and memory must all coexist on a single chip. In order for this to happen, the design process must include the creation of additional software or firmware. An automated HLS method enables designers and architects to explore different algorithmic and implementation options based on a single functional specification, thereby investigating space, power, and performance tradeoffs [13].

Because of recent developments in register transfer level (RTL) synthesis methods, the industrial deployment of high-level synthesis (HLS) tools is becoming an increasingly viable option. Companies that are considered to be industry leaders in semiconductor design, such as IBM [13], Motorola [14], Philips [15], and Siemens [16], have created their own proprietary tools. Major EDA (Electronic Design Automation) suppliers have also begun to commercialize various HLS products. For instance, Synopsys developed a tool known as the "Behavioral Compiler" [17] in 1995. This tool generates RTL implementations from behavioral HDL code and links to tools farther down the production line. Tools such as "Catapult HLS" by Mentor Graphics [18] and "Stratus High Level Synthesis" by Cadence [19] are examples of similar programs. A proposed methodology of a typical flow for HLS in VLSI designs based on MATLAB Simulink HDL Coder is shown in Fig. 1.

The industrial deployment of high-level synthesis (HLS) technology has become more realistic as a result of advancements in record transfer level (RTL) synthesis methods. Specialized tools have been developed by major semiconductor design firms such as IBM [12], Motorola [14], Philips [15], and Siemens [13]. Electronic Design Automation (EDA) industry leaders have also started selling High-Level Synthesis (HLS) solutions. For example, in 1995 Synopsys created the "Behavioral Compiler" tool [15], which generates RTL programs from behavioral HDL code and links to secondary tools. This was accomplished via the use of behavioral HDL. The "Catapult HLS" [18] and "Stratus High Level Synthesis" [19] tools produced by Mentor Graphics and Cadence respectively are similarly comparable. The HLS flow that is often used in VLSI is shown in Fig. 1.

## III. Sobel Edge Detector

The Sobel operator is utilized in the processing of images and computer vision, namely in edge recognition algorithms to emphasize edges in a picture. It is named after Irwin Sobel and Gary Feldman. Sobel and Feldman proposed a proposal of a "Isotropic 3x3 Image Gradient Operator." It is a discrete operator used to produce gradient estimations of the intensity function of an image. Every point within the image represents a gradient vector produced by the Sobel operator. The Sobel operator is computationally efficient since it convolves the image in both vertical and horizontal axes using a small, separable, integer-valued filter. The color gradient estimate it produces lacks precision, particularly for high-frequency variations in the image.

| 0 | 0 | 0 |
| -1 | -2 | -1 |

Gy

Sobel is a primary edge detection operator that relies on gradients. On an image, it applies a spatial gradient analysis in two dimensions. When trying to estimate derivatives, the operator convolves the original image with two 3x3 kernels. One kernel is used for horizontal alterations, while the other is used for vertical alterations. Each point includes estimations of the both vertical and horizontal derivatives. Here are the kernels:Rotating a kernel through 90 degrees yields a different kernel, as seen in Fig. 1. Gx is used to detect horizontal edges, while Gy is used to detect vertical edges. The two gradients Gx and Gy are utilized to calculate the orientation and magnitude of the edge at a certain location in the image. By combining gradient approximations, an absolute gradient magnitude may be determined at every location in the image. Just square the total value of the squares of the horizontal and vertical components to get the gradient's magnitude: G= $\sqrt{(Gx^2 + Gy^2)}$

## IV. Design Methodology

The Full Sobel edge detector (see Fig. 2) for a streaming video was created in MATLAB/Simulink using HDL coder and the required toolbox for modeling. For this experiment using 240 × 320 x 3 input video frames representing each color. Since the HDL implementation is pixel-based rather than frame-based, the input frames need to be transformed to pixels before each pixel can be entered into the project on a clock cycle. Both the Sobel method edge finder and the Simulink library block were simultaneously utilized to process identical input images from their respective hardware implementations. The results of the two were subsequently evaluated against each other.

The length of the video stream, as well as the absolute minimums and maximums for the project's inputs, outputs, and intermediate nodes, were all recorded throughout the period that the simulation ran for, which was one hundred seconds. Later simulation tests were expanded to incorporate this basic and maximum database in order to take into account any and all possible visual signal inputs. After that, the amplitude of each and every signal was determined by taking the range of values for each input, output, and intermediate node into account.

The RTL was then built by the HLS tool with the limitations for all of the data nodes as well as the important inputs and outputs being changed accordingly. Following that step, the optimized RTL was programmed into the FPGA. Because the FPGA output is expressed in pixels, MATLAB was used to convert it to a picture. The finished product consisted of a picture with an acute angle superimposed over the original. The total approach, which may be seen shown in Fig. 3, consists of HDL code, behavioral implementation, and a common picture source. As shown in Fig. 3, latency components have been added to the input and behavior display channels in order to compensate for the delay caused by the actual hardware implementation of the loop that is executing on the FPGA.

The input picture, the image produced by the MATLAB model, and the output produced by the HDL FPGA program are all shown in Figure 4. As can be seen in the picture, the input image source, the MATLAB behavior model, and the HDL FPGA model all functioned autonomously to process various images taken from the input video stream.

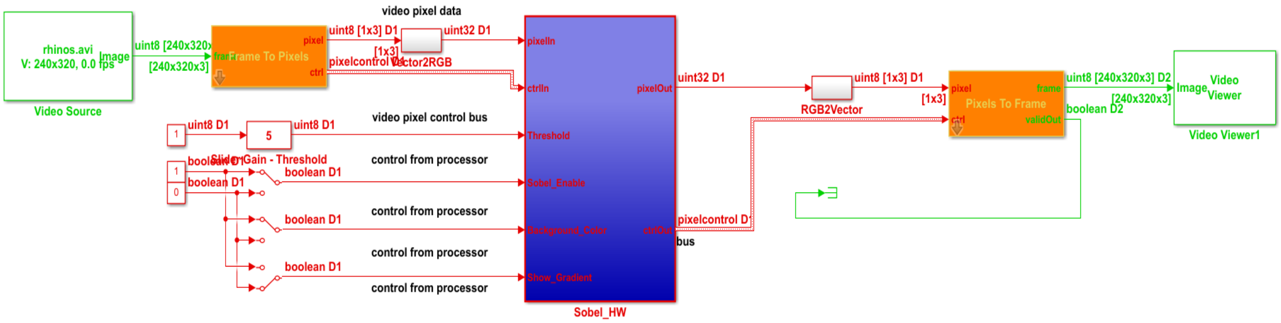

Fig. 2. Sobel edge system: full system.

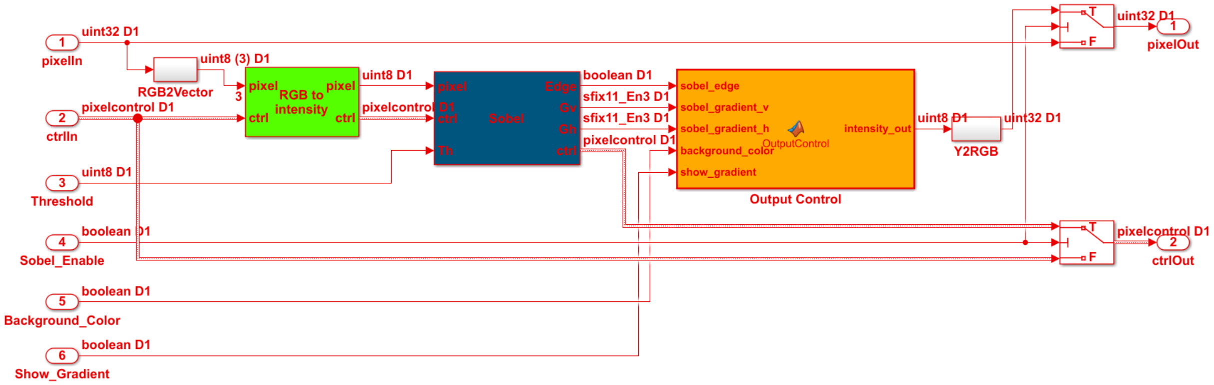

Fig. 3. HDL coder model for Sobel edge detector system.

## V. Design Synthesis and Results

Simulations of designs on Simulink After completion, each filter system is separately converted to HDL code. This process is Matlab/Simulink HDL Coder and HDL workflow advisor with add-on realized through. HDL workflow consultant, Convert systems on Matlab and Simulink to HDL code make the necessary settings during the conversion process. It provides an interface. After this stage, a standard system converted to IP block is in Vivado Suite Camera reference with IP integrating system attached to the design. Thus, filter systems were implemented sequentially on the Zedboard. More In later studies, the system will be less on-chip for space coverage and simplification of the software. The designed IP blocks are combined on Simulink was redesigned.

Accordingly, the grayscale conversion and edge detection systems are combined into a single IP block. The median and sharpening filters formed the second IP block. Necessary interconnections were made again and the system was synthesized again. The block design of the final implemented system on Vivado Suite is given in Fig. 4. IP blocks designed in the study are marked on the diagram.

### A. Simulation Results

In order to simulate the resulting VHDL RTL code with a testbed that could not be synthesized, the Vivado xSim software was utilized. Figure 5 illustrates the results of the functional simulation of the Vivado xSim simulator. As can be seen in the picture, the reference pixel values are very comparable to the pixel output generated by the technique that was advised. In addition to this, they were the same as the findings of the high-level MATLAB simulation that was carried out using the model with the ideal bit-width.

When the output photographs from both channels were compared to the same input image, this was confirmed. In this investigation, the quantization error that was brought about by choosing narrower "optimum" signal widths was evaluated and compared to the MATLAB-based double-precision model. This was accomplished by using the "FPGA in the loop" co-simulation feature that is available on the MathWorks HDL verifier. According to the results of the root mean square test (RMS), the error in the quantization was less than 1%.

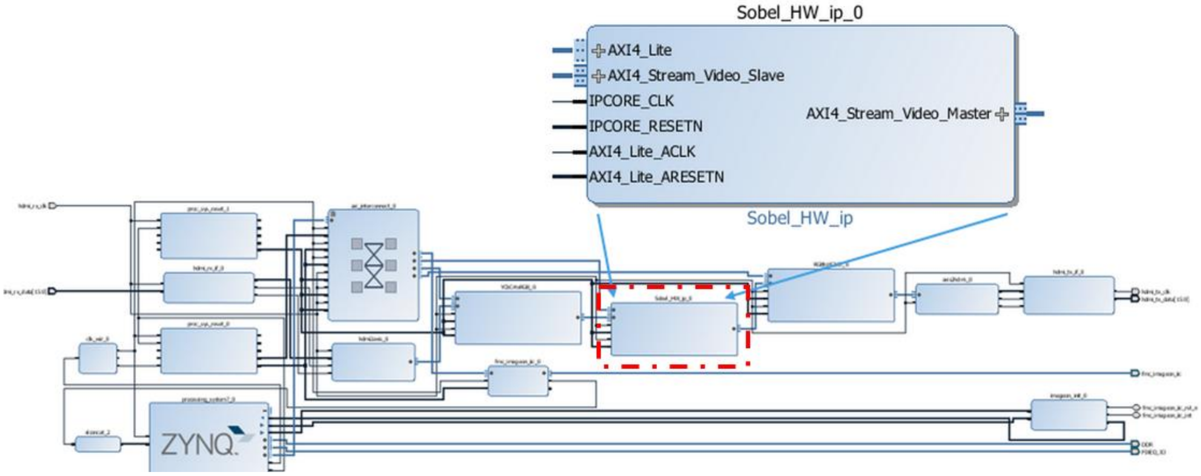

Fig. 4. RTL design for full edge detector.

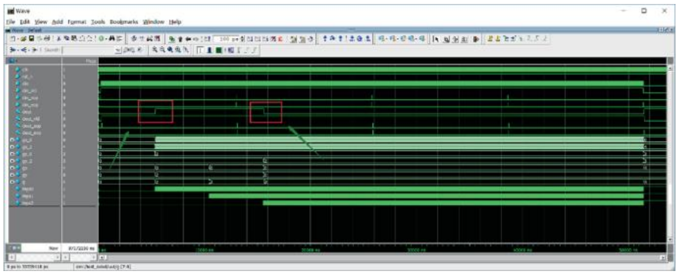

Fig. 5. HDL simulation results (Sobel edge detector).

## B. Synthesis Results

Each filter system was converted to HDL code independently when it was determined that the simulations of the designs on simulink were successful. This method improves the functionality of the Matlab/Simulink plugins known as HDL Coder and HDL business articles. A statement that indicates that HDL work instructions have been fulfilled is called a fulfillment of HDL work instructions statement. This statement enables the necessary settings to be made during the process of converting systems designed in Matlab and Simulink to HDL code. After this step, the system was changed to a normal IP gateway, and the IP integrating system in Vivado Suite was used to make the connection between the gateway and the camera reference design. On the Zedboard, the filtering processes were thus carried out in a sequential fashion. The following areas have been modified by combining IP blocks on Simulink, which were created to take up less room on the system chip and to simplify the software. This was done in order to improve performance.

As a consequence of this, the greyscale conversion system and the edge detection system have been merged into a single IP block. The second IP block was made up of the median filter and the sharpening filter. Necessary interconnections were made again and the system was synthesized again. The IP blocks that were created throughout the course of the research can be seen noted on the figure representing the block design of the final implemented system on Vivado 2017.4 Suite. Table I present the resources results for the proposed design.

TABLE I. PROPOSED SOBEL EDGE DETECTOR RESOURCES RESULTS

| Resources | Utilization | Available | % Utilization |
|---|---|---|---|
| LUT | 5300 | 53200 | 10% |
| LUT RAM | 180 | 17400 | 1% |
| Flip-Flops | 7500 | 106400 | 7% |
| BRAM | 8 | 140 | 6% |
| DSP | 11 | 220 | 5% |
| IOS | 100 | 200 | 50% |
| BUFG | 1 | 32 | 3.1% |

The Vivado synthesis tool reported a total power of 0.330 W, which was comprised of 0.210 W of dynamic power and 0.120 W of static power. In addition to that, it incorporates a whole host of other optimization strategies, such as high-level synthesis toolkits, resource sharing, and pipeline design. These can be used to improve the results that were mentioned above; however, the scope of this study does not allow for such optimization to be performed.

# VI. CONCLUSION

In the process of development is a high-speed, optimal (weak surface), implementation of the Sobel edge-detection algorithm that will be suitable for real-time deployment on the FPGA. The conception was made possible with the use of a ground-breaking conception process known as HLS. This approach restricts intermediate noeuds and the major points of conception to absolute minimums and maximums for each noeud. The RTL for the method was developed on a Xilinx ZedBoard by using an input time video stream with a resolution of 240 by 320 pixels and 8 bit color inputs.

In order to do a functional evaluation of the RTL idea, the Xilinx Vivado xSim simulator was used. We found that our HLS technique results in quantification mistakes that are less than 1% of the total. The findings of the synthesis indicate that our implementation is superior to comparable existing ideas in terms of performance. As a consequence of this, the approach is especially well-suited for FPGA-based applications that call for real-time image processing. Although the method was tested using the MATLAB HDL codeur procedure with connections to Xilinx Zedboard, it can also be used with other devices and (technology-neutral) FPGA cables.

In spite of the absence of evidence, we are of the opinion that the design process used in this methodology would result in improved results when applied to ASIC synthesis. Future research will involve, in addition to the manner of implementation that was recommended, the optimization of speed, area, and power consumption utilizing optimization approaches given by high-level synthesis tool vendors such as MathWorks, Xilinx, Mentor, and Cadence. In the not too distant future, one of our goals is to broaden the scope of this study to encompass ASIC design.

***Abstract*—This research paper delves into the burgeoning field of Big Data analytics in healthcare, proposing an innovative framework aimed at refining the organization and management of medical processes within healthcare institutions. Through the lens of detailed case studies, including stroke diagnosis leveraging the UNet model, and the identification of heart and respiratory diseases via machine learning algorithms applied to data from wearable devices, the study illuminates the profound capabilities of Big Data technologies in enhancing the precision of diagnostics, tailoring patient treatment, and elevating the overall efficiency of healthcare services. It meticulously interprets the outcomes of these applications, discusses the practical implications for healthcare professionals and institutions, confronts the challenges inherent in the integration of sophisticated analytics in clinical settings, and outlines potential directions for future research. Among the pivotal challenges highlighted are issues related to data privacy, security, the need for advanced infrastructure, and the imperative for ongoing training and interdisciplinary cooperation to navigate the complexities of Big Data in healthcare. The paper underscores the transformative promise of Big Data analytics, suggesting that comprehensive adoption and adept implementation could revolutionize healthcare delivery, making it more personalized, efficient, and cost-effective. Through this exploration, the paper contributes to the ongoing discourse on the integration of technology in healthcare, offering insights into how Big Data analytics can serve as a cornerstone for the next generation of medical diagnostics and patient care management, thereby enhancing health outcomes on a global scale.**

## I. Introduction

The advent of Big Data technologies has revolutionized various sectors, including healthcare, by offering unprecedented opportunities for enhancing operational efficiency, patient care, and medical research. The healthcare industry generates a vast amount of data daily, including patient records, clinical trials, medical imaging, and more. However, the sheer volume, velocity, and variety of this data pose significant challenges in terms of management, analysis, and utilization. Addressing these challenges requires innovative approaches to organize and process medical data effectively. This paper proposes a comprehensive framework for the organization of medical processes in medical institutions based on Big Data technologies. This framework aims to improve the quality of patient care, optimize the efficiency of medical processes, and facilitate the advancement of medical research.

The significance of Big Data in healthcare cannot be overstated, as it holds the potential to transform the landscape of medical services delivery. Big Data technologies enable the handling of large datasets beyond the ability of traditional data processing tools, providing insights that can lead to improved patient outcomes, cost reductions, and enhanced operational efficiencies [1]. The integration of Big Data analytics into healthcare processes allows for the predictive analysis of patient health, personalized medicine, and the optimization of clinical operations [2].

However, the implementation of Big Data technologies in healthcare settings is fraught with challenges, including data privacy concerns, the need for robust data governance frameworks, and the requirement for significant infrastructure and skill sets [3]. Moreover, the heterogeneous nature of medical data, encompassing structured and unstructured formats, necessitates sophisticated approaches for data integration, management, and analysis [4].

The proposed framework for the organization of medical processes leverages Big Data technologies to address these challenges. It encompasses the development of scalable data management systems, advanced analytics techniques, and user-friendly interfaces for healthcare professionals. The framework is designed to facilitate the seamless integration of Big Data analytics into existing medical workflows, thereby enhancing the decision-making process and improving patient care outcomes [5].

One of the critical components of the framework is the utilization of machine learning algorithms and artificial intelligence (AI) to analyze medical data. These technologies have shown promise in identifying patterns and trends within large datasets, offering potential breakthroughs in diagnosing diseases, predicting patient outcomes, and personalizing treatment plans [6]. Furthermore, AI-driven tools can assist in managing the operational aspects of healthcare institutions, such as resource allocation and scheduling, thereby increasing efficiency and reducing costs [7].

Data security and privacy are paramount concerns in the healthcare sector, given the sensitive nature of patient information. The framework addresses these issues by incorporating advanced security measures, including encryption, access controls, and audit trails, to safeguard patient data [8]. Additionally, it adheres to regulatory compliance standards, such as the Health Insurance Portability and Accountability Act (HIPAA) in the United States, ensuring that patient privacy is protected while facilitating the beneficial use of Big Data [9].

The implementation of the proposed framework requires a multidisciplinary approach, involving collaboration among healthcare professionals, data scientists, IT specialists, and policymakers. Developing the necessary infrastructure for Big Data analytics in healthcare institutions involves significant investment in technology and training [10]. Moreover, fostering a culture of innovation and continuous improvement is essential for the successful adoption of Big Data technologies in medical processes [11].

The potential benefits of implementing the proposed framework are manifold. By enabling the real-time analysis of patient data, healthcare providers can make more informed decisions, leading to improved treatment outcomes and patient satisfaction [12]. Additionally, the predictive capabilities of Big Data analytics can facilitate early intervention in disease progression, potentially saving lives and reducing healthcare costs [13]. Furthermore, the framework can support medical research by providing researchers with access to large datasets, thereby accelerating the discovery of new treatments and therapies [14].

The integration of Big Data technologies into the organization of medical processes presents a promising avenue for enhancing healthcare delivery, improving patient outcomes, and advancing medical research. The proposed framework offers a structured approach to overcoming the challenges associated with Big Data in healthcare, leveraging the power of advanced analytics, AI, and robust data management practices. As the healthcare industry continues to evolve, the adoption of Big Data technologies will be critical in meeting the demands of modern medical care and research. The successful implementation of the framework requires a collaborative effort among various stakeholders, underscoring the need for a cohesive strategy to harness the full potential of Big Data in healthcare.

## II. Related Works

The integration of Big Data technologies into healthcare has been an area of significant research interest, aiming to revolutionize the management, analysis, and application of medical data for improved healthcare outcomes. This section reviews the related works that have contributed to the development and application of Big Data technologies in medical institutions, highlighting the various approaches, methodologies, and outcomes of these studies.

A considerable amount of research has focused on the development of frameworks and models for Big Data analytics in healthcare. One study proposed a model that integrates electronic health records (EHRs) with Big Data analytics to enhance patient care and operational efficiency in hospitals [15]. Another work emphasized the importance of a scalable and secure infrastructure to support the voluminous and continuous influx of medical data, proposing solutions for data storage, processing, and privacy [16]. The adoption of cloud computing in healthcare has been identified as a pivotal element in supporting Big Data analytics, offering flexible and scalable resources for data storage and computational tasks [17]. Fig. 1 demonstrates cloud computing and data mining based organization of medical processes [18].

The application of artificial intelligence (AI) and machine learning algorithms in analyzing medical data has shown promising results in improving diagnostic accuracy, predicting patient outcomes, and personalizing treatment plans. One notable study demonstrated the use of machine learning algorithms to predict cardiovascular diseases by analyzing patient data and health records [19]. Another research highlighted the effectiveness of AI in diagnosing cancer at early stages through the analysis of medical images, significantly improving patient survival rates [20].

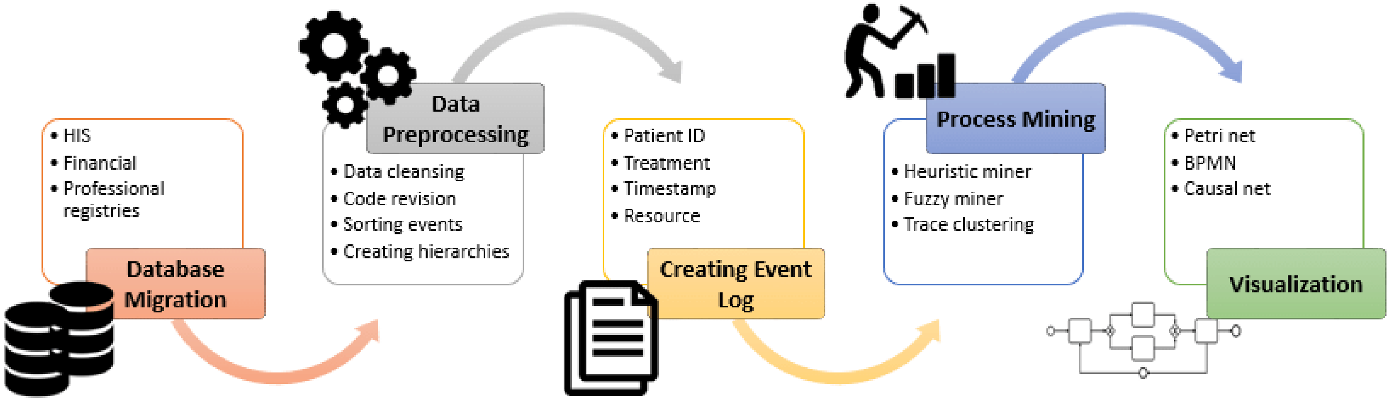

Fig. 1. Data mining based organization of medical processes.

Patient data privacy and security remain central concerns in the application of Big Data technologies in healthcare. Several studies have addressed these challenges by proposing advanced cryptographic techniques and privacy-preserving data mining algorithms to protect sensitive patient information [21]. Regulatory compliance and ethical considerations have also been extensively discussed, with research emphasizing the need for frameworks that balance the benefits of Big Data analytics with the protection of patient rights [22]. Fig. 2 demonstrates medical bid data processing system [18]. The concept consists of three components that supplied each other: (1) Big Data collection module, (2) Big Data storage management module, and (3) Big Data analysis module.

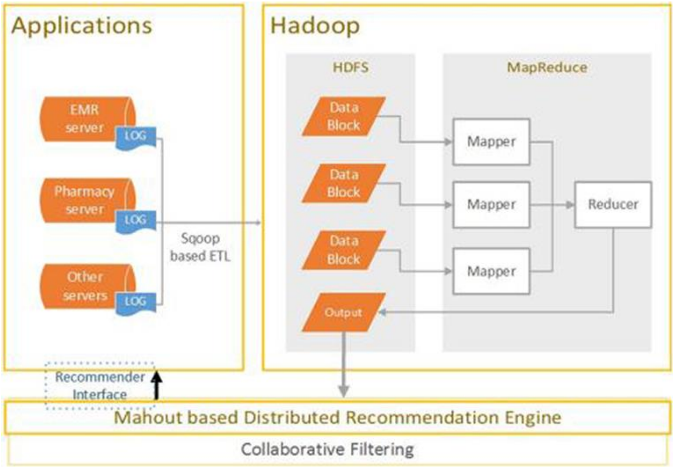

Fig. 2. Architecture of the medical big data processing system [18].

Interoperability and data integration challenges have been a major focus of research, given the heterogeneous nature of medical data. Studies have explored the use of standardized data formats and protocols to facilitate the integration of disparate data sources, enhancing the completeness and accuracy of patient health records [23]. Moreover, the development of semantic web technologies and ontologies has been proposed as a solution to improve data sharing and interoperability among healthcare institutions [24].

The impact of Big Data technologies on healthcare policy and management has also been a subject of research. One study analyzed the potential of Big Data analytics to inform healthcare policies, particularly in the areas of public health surveillance and health system performance assessment [25]. Another work discussed the implications of Big Data for healthcare management, including resource allocation, patient flow optimization, and cost reduction [26].

The use of Big Data analytics in clinical decision support systems (CDSS) has garnered attention for its potential to enhance the decision-making process for healthcare providers. Research has demonstrated the integration of Big Data analytics into CDSS, enabling the real-time analysis of patient data to provide evidence-based recommendations and alerts to clinicians [27]. This integration has been shown to improve the quality of care, reduce medical errors, and increase the efficiency of clinical workflows [28].

Telemedicine and remote patient monitoring are areas where Big Data technologies have been applied to improve healthcare delivery, particularly in underserved regions. Studies have highlighted the use of Big Data analytics to monitor patient health in real-time, enabling timely interventions and reducing the need for hospital visits [29]. Furthermore, the application of Big Data in telemedicine has been shown to facilitate personalized healthcare services, improving patient engagement and satisfaction [30].

Big Data analytics has also played a crucial role in medical research, enabling the analysis of large datasets to uncover patterns and associations that were previously undetectable. Research has highlighted the use of Big Data in genomic studies, contributing to the understanding of genetic factors in diseases and the development of targeted therapies [31]. Another study focused on the application of Big Data in epidemiology, facilitating the tracking of disease outbreaks and the assessment of intervention strategies [32].

The challenges associated with the implementation of Big Data technologies in healthcare have been extensively discussed in the literature. These include technical challenges related to data quality, processing capabilities, and integration, as well as organizational challenges such as change management, skill shortages, and cultural resistance [33]. Strategies to overcome these challenges have been proposed, including the development of comprehensive training programs for healthcare professionals and the adoption of change management practices to foster a culture of innovation [34]. Fig. 3 demonstrates a smart healthcare system for improved healthcare delivery using big data analytics [35].

Fig. 3. Smart healthcare system for improved healthcare delivery.

Emerging technologies such as the Internet of Things (IoT) and blockchain have been explored for their potential to enhance the application of Big Data in healthcare. IoT devices have been identified as valuable sources of real-time patient data, supporting remote monitoring and personalized healthcare services [36]. Blockchain technology has been proposed as a solution for secure and transparent data sharing among healthcare stakeholders, ensuring data integrity and patient privacy [37].

The economic impact of Big Data technologies in healthcare has been a subject of analysis, with studies indicating significant potential for cost savings and efficiency improvements. Research has quantified the benefits of Big Data analytics in reducing healthcare costs through predictive analytics, optimized resource allocation, and the prevention of fraud and waste [38]. Additionally, the potential for Big Data to drive innovation in healthcare delivery and medical research has been highlighted as a key factor in improving the economic sustainability of healthcare systems [39].

Thus, the related works reviewed in this section underscore the transformative potential of Big Data technologies in healthcare. From enhancing patient care and operational efficiency to informing healthcare policies and advancing medical research, the contributions of Big Data analytics are vast and varied. However, the successful implementation of these technologies requires addressing the technical, organizational, and ethical challenges that accompany their adoption. Future research should continue to explore innovative solutions to these challenges, ensuring that the benefits of Big Data in healthcare can be fully realized.

## III. Materials and Methods

### A. *Proposed System*

The proposed architecture for healthcare Big Data analytics applications is a comprehensive framework designed to leverage the vast amounts of data generated by medical institutions for improved healthcare delivery and research. The architecture encapsulates a multifaceted approach that integrates various components of healthcare data analytics, including diagnostics, patient treatment, precision medicine, preventive medicine, telemedicine, health population support, medical research, and cost reduction. Each component is interconnected, ensuring a cohesive and synergistic application of Big Data technologies to enhance the quality and efficiency of healthcare services. Fig. 4 demonstrates the proposed big data framework for organization of medical processes.

Diagnostics: At the core of the architecture is the diagnostics component, which utilizes Big Data analytics for the identification of disease causes. This involves the analysis of complex datasets, including patient records, clinical trials, and genomic data, to uncover patterns and correlations that can lead to accurate disease diagnosis. Advanced machine learning algorithms and artificial intelligence (AI) models are employed to process and analyze the data, providing healthcare professionals with insights that facilitate early and precise disease detection.

Patient Treatment: The patient treatment component of the architecture focuses on selecting optimal treatment options based on the analysis of Big Data. This includes the evaluation of treatment outcomes, drug efficacy, and patient health records to tailor treatment plans that maximize patient recovery and minimize side effects. Big Data analytics enable the aggregation and analysis of large-scale clinical data, ensuring evidence-based decision-making in patient care.

Precision Medicine: Precision medicine, or personalized medicine, is a critical aspect of the proposed architecture, where treatment is adjusted to the specific characteristics of each patient. This component leverages genomic data, lifestyle information, and environmental factors, analyzed through Big Data technologies, to develop customized treatment plans. By considering the unique genetic makeup and circumstances of each patient, precision medicine aims to enhance treatment effectiveness and patient outcomes.

COST REDUCTION
Greater insight into medical data translates into better patient care, resulting in long-term savings

Fig. 4. Big data analytics applications.

Preventive Medicine: The preventive medicine component utilizes predictive analytics to forecast potential health issues before they manifest. By analyzing trends and patterns in healthcare data, this aspect of the architecture aims to identify risk factors and intervene early, thereby preventing diseases from developing or progressing. This proactive approach to healthcare, enabled by Big Data analytics, has the potential to significantly reduce the burden of disease on individuals and healthcare systems.

Telemedicine: Telemedicine involves the remote monitoring and treatment of patients, facilitated by Big Data technologies. This component of the architecture enables healthcare providers to continuously monitor patient health data through wearable devices and IoT (Internet of Things) technologies, providing real-time insights into patient health status. Telemedicine enhances patient access to care, especially in underserved areas, and allows for timely interventions, improving patient care and satisfaction.

Health Population Support: Big Data monitoring is utilized in the health population support component to capture disease trends, outbreaks, and public health threats. This aspect of the architecture involves the analysis of vast datasets from various sources, including healthcare institutions, public health records, and social media, to identify and respond to health emergencies. Big Data analytics play a crucial role in supporting public health efforts, enabling the effective management of disease outbreaks and the promotion of health and well-being at the population level.

Medical Research: The medical research component of the architecture leverages Big Data for data-driven medical research. By analyzing large-scale healthcare datasets, researchers can uncover new insights into disease mechanisms, treatment effectiveness, and health outcomes. Big Data technologies facilitate the exploration of complex biomedical questions, accelerating the discovery of new therapies and advancing medical knowledge.

Cost Reduction: Finally, the cost reduction component emphasizes how greater insight into medical data, achieved through Big Data analytics, translates into better patient care and long-term savings. By optimizing treatment protocols, preventing diseases, and enhancing operational efficiencies, healthcare institutions can significantly reduce costs. Big Data analytics enable the identification of inefficiencies and the implementation of strategies to improve healthcare delivery and financial performance.

The proposed architecture for healthcare Big Data analytics applications presents a holistic approach to harnessing the power of Big Data in healthcare. By integrating diagnostics, patient treatment, precision medicine, preventive medicine, telemedicine, health population support, medical research, and cost reduction components, the architecture aims to improve the quality, efficiency, and accessibility of healthcare services, while also contributing to the advancement of medical research and the reduction of healthcare costs. This comprehensive framework underscores the transformative potential of Big Data technologies in revolutionizing healthcare delivery and outcomes.

### B. *Decision Making Process*

The primary obstacle in leveraging Big Data lies in the management and utilization of vast volumes of information for informed decision-making across various domains [40]. Within the realm of healthcare, the challenge intensifies as it involves tailoring the mechanisms for storing, analyzing, and interpreting large datasets to suit clinical environments. In Fig. 5, the healthcare sector's data analytics frameworks are engineered to encapsulate, synthesize, and convey intricate data in a manner that enhances comprehension. Such enhancements are pivotal for augmenting the processes of data acquisition, storage, analysis, and visualization within the healthcare context, thereby bolstering the overall efficiency of Big Data application in medical settings [41].

The utilization of Big Data Analytics culminates in the creation of coherent data narratives, which significantly bolster decision-making processes by reducing risks and enhancing data-backed support. Such an approach holds considerable promise for the healthcare sector's stakeholders. Harnessing the vast quantities of data available in healthcare necessitates a strategic alignment of interventions to individual patient needs, ensuring that treatments are timely, personalized, and beneficial across the healthcare ecosystem, including payers, patients, and administrators. This objective mandates a synergistic collaboration between the domains of data analytics and healthcare informatics to effectively manage and analyze large datasets [42]. Through the insights gleaned from clinical data, Big Data Analytics empowers healthcare providers with the knowledge required for precise diagnostic and therapeutic decisions, disease prevention strategies, and more. Additionally, it has the potential to significantly enhance the operational efficiency of healthcare organizations by unlocking the value embedded within their data [43].

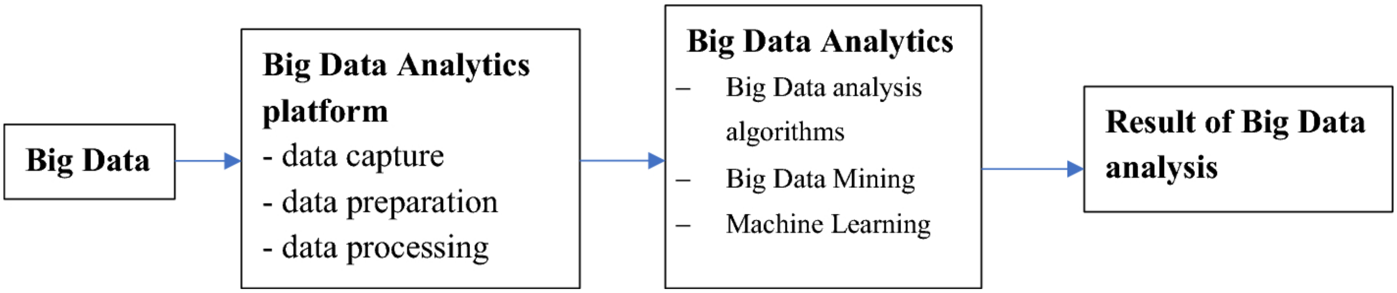

Fig. 5. Data analytics framework.

## IV. Experimental Results

In experiment results, we used different case studies of medical decision making processes as heart diseases, respiratory diseases and brain diseases as strokes. This section demonstrates results of each case studies.

In addressing the challenge of detecting heart diseases, the deployment of machine learning models on wearable devices presents a promising avenue for early and accurate diagnosis. The utilization of wearable devices for data collection, as illustrated in Fig. 6, enables the continuous monitoring of physiological signals that are indicative of cardiac health. This approach leverages the pervasive nature of wearable technology to gather critical health data in real-time, facilitating a proactive stance towards heart disease detection.

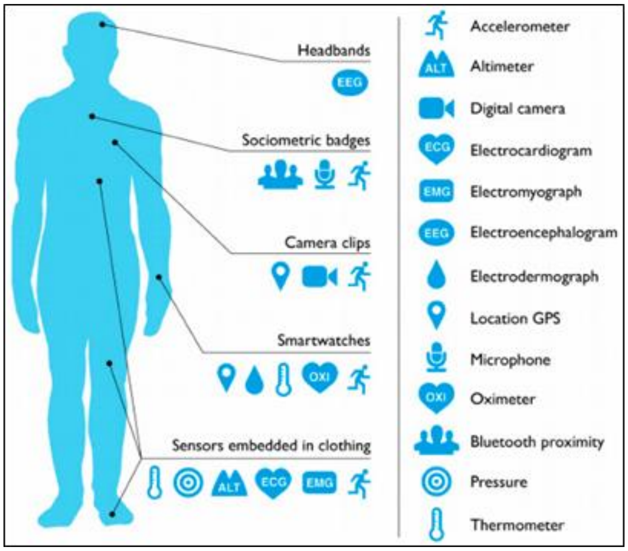

Fig. 6. Data collection from wearable devices.

The presented case study rigorously investigates the utilization of respiratory sounds as the primary data input for the detection of respiratory diseases, exemplifying an innovative method in the realm of medical diagnostics. Central to this approach, as delineated in Fig. 7, is the strategic employment of heart sounds, serving as the foundational dataset upon which sophisticated diagnostic models are applied. This methodology capitalizes on the inherent characteristics of heart sounds, exploiting their potential to reveal distinctive auditory patterns and anomalies correlated with a spectrum of respiratory conditions. The approach stands out for its non-invasive nature, providing a highly accessible means for the early detection and continuous monitoring of respiratory diseases. By harnessing the diagnostic capabilities of heart sounds, this case study contributes significantly to the advancement of medical diagnostics, offering promising avenues for enhancing patient care through the early identification and management of respiratory conditions. The implications of such a methodology are profound, potentially revolutionizing the standard procedures for respiratory disease diagnosis and underscoring the value of auditory data in clinical settings.

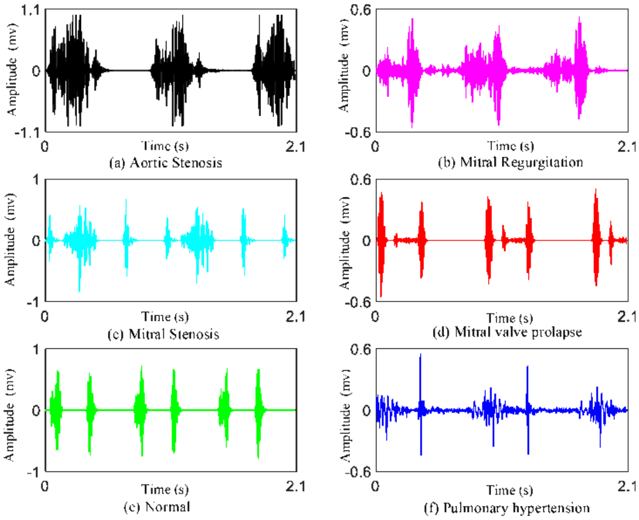

Fig. 7. Respiratory sounds as an input data.

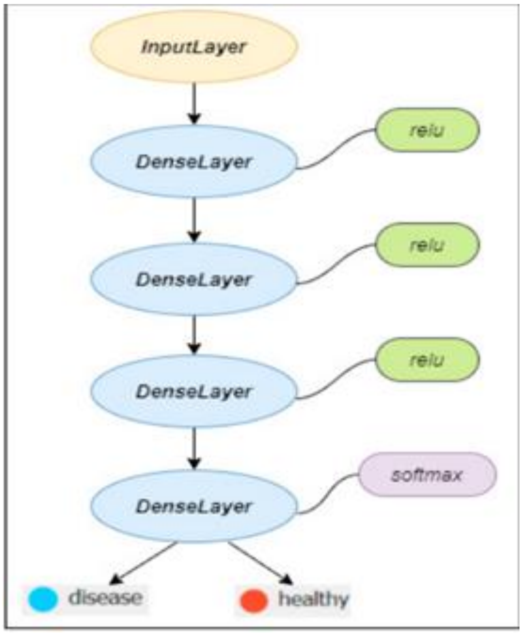

Fig. 8. Proposed architecture for heart diseses detection.

Fig. 8 depicts the architectural framework employed for heart disease detection through wearable device data. This framework embodies a convolutional neural network (CNN) [44], featuring a sequential configuration consisting of an input layer followed by four dense layers [45]. The design of this model is meticulously engineered to enable thorough analysis and interpretation of the intricate patterns inherent in the data collected from wearable devices [46]. The primary aim of this structured architecture is to achieve precise identification of indicative markers associated with heart disease. Through systematic arrangement and optimization of network layers, the model seeks to enhance its capacity to accurately recognize and classify relevant features within the input data, thereby advancing the efficacy of heart disease detection methodologies utilizing wearable technology.

Fig. 9. Obtained results in heart diseases detection on wearable devices data.

The performance of the proposed CNN-based model is detailed in Fig. 9, which presents the results obtained from the heart disease detection study. Over the course of 50 learning epochs, the model demonstrated an accuracy rate of 85%, alongside precision, recall, and F-score metrics of 0.81, 0.86, and 0.79, respectively. These metrics serve as indicators of the model's effectiveness in correctly identifying instances of heart disease, showcasing its potential as a reliable tool for cardiac health assessment.

The findings from this study underscore the significant potential of integrating machine learning models with wearable device data for the detection of heart diseases. Such an approach not only capitalizes on the advancements in wearable technology and machine learning but also holds the promise of transforming heart disease diagnosis, making it more accessible, efficient, and accurate. This research contributes to the growing body of knowledge on the application of innovative technologies in healthcare, highlighting the critical role of data-driven models in enhancing patient outcomes and healthcare delivery.

## V. Discussion

The application of Big Data and machine learning technologies in the healthcare domain, particularly for the detection and diagnosis of diseases through wearable device data and respiratory sound analysis, presents a pioneering approach with profound implications for clinical practice [47]. This discussion elaborates on the interpretation of results, practical implications, challenges, and future research directions stemming from the studies presented.

### *A. Interpretation of Results*

The results derived from the application of a CNN-based architecture for heart disease detection using wearable device data and the analysis of respiratory sounds for respiratory disease identification underscore the potential of these technologies in enhancing diagnostic accuracy and patient care. The model's performance, indicated by high accuracy, precision, recall, and F-score metrics, demonstrates the efficacy of machine learning algorithms in interpreting complex physiological data [48]. The segmentation of stroke lesions using the UNet model [49] further illustrates the capability of deep learning methods in medical imaging analysis, providing clear delineation of affected areas for accurate diagnosis [50].

The spectrum of respiratory sound profiles, including normal sounds, murmurs, extrahls, and artifacts, highlights the diversity of acoustic signatures associated with different cardiac and respiratory conditions. The ability of the proposed models to distinguish between these signatures is indicative of their potential in clinical settings, offering a non-invasive, efficient, and accessible means of disease detection.

### *B. Practical Implications*

The practical implications of these findings are significant, suggesting a paradigm shift in the approach to disease diagnosis and monitoring. The integration of machine learning models with wearable devices and the utilization of respiratory sound analysis could revolutionize patient care by enabling continuous, real-time health monitoring [51]. This approach allows for early detection of abnormalities, timely intervention, and personalized treatment plans, ultimately improving patient outcomes.

Moreover, the application of these technologies can significantly enhance the efficiency of healthcare systems. By reducing the reliance on traditional diagnostic methods, which are often time-consuming and resource-intensive, machine learning models can streamline the diagnostic process, alleviate the burden on healthcare professionals, and decrease overall healthcare costs.

### *C. Challenges*

Despite the promising results and practical implications, several challenges must be addressed to fully realize the potential of Big Data and machine learning in healthcare. One of the primary challenges is the issue of data privacy and security [52]. The collection, storage, and analysis of sensitive health data raise significant concerns that necessitate robust data protection measures and compliance with regulatory standards.

Another challenge is the heterogeneity and quality of data. The effectiveness of machine learning models heavily depends on the quantity, quality, and diversity of the data they are trained on. Ensuring the accuracy and representativeness of input data, especially in the context of wearable devices and respiratory sounds, is crucial for the reliability of the diagnostic models.

Additionally, the integration of these technologies into existing healthcare infrastructures poses logistical and technical challenges. It requires substantial investment in technology, training of healthcare professionals, and development of standardized protocols for data collection, analysis, and interpretation.

### *D. Future Research Directions*

Looking ahead, several avenues of research promise to further the application of Big Data and machine learning in healthcare. One key area is the development of more advanced machine learning algorithms and deep learning models that can handle the increasing complexity and volume of healthcare data [53]. These models should focus on improving diagnostic accuracy, reducing false positives, and enhancing the interpretability of results.

Another area of interest is the exploration of novel data sources, such as genomic data, social determinants of health, and environmental factors, and their integration into predictive models. This holistic approach to health data analysis could provide deeper insights into disease mechanisms and contribute to the development of more effective prevention and treatment strategies.

Research into improving the usability and accessibility of wearable devices for health monitoring is also crucial. This includes the design of user-friendly interfaces, development of low-cost devices, and exploration of new wearable technologies that can monitor a broader range of physiological parameters.

Furthermore, addressing the challenges related to data privacy and security, data quality, and integration into healthcare systems will be a continuous area of focus. Developing standardized frameworks for data governance, enhancing data anonymization techniques, and fostering collaboration between technology developers, healthcare providers, and regulatory bodies are essential steps in this direction.

In conclusion, the integration of Big Data and machine learning technologies in healthcare offers a transformative potential for disease diagnosis and patient care. The interpretation of results from recent studies highlights the effectiveness of these approaches, while the practical implications suggest a shift towards more personalized and efficient healthcare delivery. However, overcoming the challenges associated with data privacy, quality, and integration is crucial for the successful implementation of these technologies. Future research should aim to address these challenges, explore new data sources and machine learning models, and ultimately contribute to the advancement of digital health solutions that can improve patient outcomes and healthcare systems globally.

## VI. Conclusion

In conclusion, this research paper has presented a comprehensive framework for the application of Big Data analytics in the healthcare sector, with a particular focus on the organization of medical processes in medical institutions. Through an in-depth exploration of various case studies, including stroke diagnosis using the UNet model and the detection of heart and respiratory diseases using machine learning models on wearable devices, this paper has underscored the transformative potential of Big Data technologies in enhancing diagnostic accuracy, patient care, and healthcare efficiency.

The interpretation of results from these case studies has demonstrated the efficacy of employing advanced analytics and machine learning algorithms in processing and analyzing vast datasets for health diagnosis and treatment. The application of the UNet model in stroke segmentation and the utilization of CNN-based architectures for heart disease detection highlight the precision and reliability of these technologies in identifying health conditions from medical imaging and wearable device data, respectively.

Practically, the implications of these findings are profound. By integrating Big Data analytics into healthcare practices, medical institutions can achieve a higher level of personalized care, improve the efficiency of healthcare delivery, and significantly reduce the costs associated with misdiagnoses and inappropriate treatments. Furthermore, the use of wearable devices for continuous health monitoring presents a promising avenue for preventive medicine, empowering patients and healthcare providers with real-time data to inform health decisions.

However, the journey towards the widespread adoption of Big Data analytics in healthcare is fraught with challenges. These include technical hurdles related to data privacy, security, and interoperability, as well as organizational barriers such as the need for significant investments in infrastructure and training. Additionally, ethical considerations concerning patient consent and data usage must be rigorously addressed to foster trust and ensure compliance with regulatory standards.

Looking ahead, future research directions should focus on overcoming these challenges through the development of more robust data governance frameworks, the exploration of new machine learning models and algorithms for health data analysis, and the implementation of pilot projects to demonstrate the practical benefits of Big Data analytics in healthcare settings. Moreover, interdisciplinary collaboration between data scientists, healthcare professionals, and policy-makers will be crucial in advancing the field and realizing the full potential of Big Data technologies to revolutionize healthcare delivery and patient care.

In summary, this paper has highlighted the critical role of Big Data analytics in shaping the future of healthcare. Through the strategic application of these technologies, the healthcare industry can navigate the complexities of modern medical data to deliver care that is more accurate, personalized, and efficient. As we move forward, the continued exploration and adoption of Big Data analytics will undoubtedly play a pivotal role in advancing healthcare outcomes and enhancing the quality of life for patients worldwide.

***Abstract*—In recent decades, recommendation systems (RS) have played a pivotal role in societal life, closely intertwined with people's everyday activities. However, traditional recommendation systems still require thorough consideration of comprehensive user profiles as they have struggled to provide more personalized and accurate recommendation services. This paper delves into the analysis and enrichment of user profiles, utilizing this foundation to tailor recommendations for individuals across domains such as movies, TV shows, and books. The paper constructs a chart comprising 246 types of user profile attributes, primarily covering dimensions like gender, age, occupation, and religious beliefs, among 16 other dimensions. This chart integrates approximately 1.2 million data points, encompassing information relevant to movies, TV shows, and novels. Through training on the dataset, the study has enhanced the model's recommendation effectiveness. Post-training, the recommendation accuracy surpasses that of pre-training based on proposed evaluation metrics. Furthermore, post-manual evaluation, the recommended results are more reasonable and align better with user profiles.***

***Keywords*—Recommender system; large language model; user profile; multi-disciplinary**

## I. INTRODUCTION

With the continuous development of the Internet and information technology, the world enters the digital age, generating a vast amount of data and information daily. Filtering out content that genuinely interests and meets people's needs becomes increasingly challenging, and the problem of information overload hinders efficient retrieval and utilization of knowledge. Recommender systems play a crucial role in various fields, successfully providing users with personalized consumer goods and entertainment media recommendations. They also contribute to choices in tourism destinations, educational resources, personnel, services, and even lifestyles. Recommender systems represent one of the most widely applied applications in data mining and machine learning technologies. These technologies recommend relevant products to customers, such as movies to watch, items to purchase, and books to read. Over time, differences in user preferences become one of the most significant challenges recommender systems face [1]. In recent years, there have been substantial changes in the presentation of recommendations, especially on e-commerce and streaming platforms. As the quantity of content available on streaming platforms increases, finding content users want to watch becomes more challenging.

To tackle this issue, traditional recommendation systems employ machine learning techniques to optimize suggestions. In personalized movie recommendation systems, machine learning algorithms and user data are utilized [2]. The proliferation of streaming platforms has led to an abundance of movie choices, making it increasingly difficult for users to find relevant content. RS plays a crucial role in assisting users in making informed decisions automatically, helping them navigate through vast amounts of available data. In the realm of movie recommendations, two primary approaches are collaborative filtering, which compares user similarities, and content-based filtering, which considers user preferences [3]. However, machine learning algorithms have limitations in capturing the dynamic and evolving nature of recommendation problems over time, as they tend to extract superficial features. With the advancement of deep learning, both large and small models have emerged, with large models proving advantageous in meeting personalized user demands. Large Language Models (LLMs) have shown significant success across various domains, thanks to their comprehensive contextual understanding and generative capabilities. These models encode vast amounts of knowledge, possess robust reasoning abilities, and adeptly adapt to new tasks through context learning from examples [4]. Recent advancements in LLMs have enabled powerful logical and causal reasoning capabilities, allowing them to identify entities, actions, and causal chains using techniques such as self-attention and contextual embeddings. Large language models exhibit impressive results in a range of Natural Language Processing (NLP) tasks, thanks to their strong logical and causal reasoning abilities [5]. However, personalized user behaviors present challenges in effectively filtering content of genuine interest from vast data due to limited user and item interactions. Current efforts often neglect the consideration of comprehensive user profiles.

We use GPT-3.5 to generate the necessary dataset, ensuring that the recommended results closely align with individual characteristics. This dataset includes three domains: movies, TV Series, and books, totaling approximately 1.2 million entries. We create a graph of 246 personas, covering 16 aspects such as gender, age, occupation, and religious beliefs. We then combine and intersect to build secondary and tertiary datasets. These datasets, at various levels, describe the granularity of individual characteristics, prioritizing recommendations that are more tailored to personas rather than catering to the general interests of the public. Finally, we employ the popular Llama model, achieving satisfactory results in both machine and human evaluations. This approach enhances the personalization of recommendations, aligning them more closely with users' individual needs and preferences.

Main contributions:

- In the realm of recommendation systems, we have identified that a more comprehensive and detailed user profile significantly impacts the quality of recommendation outcomes.
- Utilizing GPT-3.5, we have established a knowledge base comprising 16 user profiles and curated a dataset spanning three domains with a total volume of 1.2 million entries.
- Employing the Llama model, we have successfully delivered practical recommendations on the dataset.

## II. Related Work

### A. Traditional Recommendation Algorithms

Traditional recommendation algorithms can be categorized into three main types: collaborative filtering, content-based recommendation, and hybrid algorithms. Collaborative filtering analyzes past user-item interactions to predict future behavior. While effective in many scenarios, it struggles to capture all aspects of item features, leading to suboptimal recommendations. Content-based recommendation suggests items similar to those a user has interacted with in the past, focusing on surface-level item features. However, it often overlooks user behavior, limiting its effectiveness. Hybrid approaches combine collaborative filtering and content-based recommendation, aiming to improve accuracy and coverage. Yet, they still require more extensive user profile analysis. For instance, Badr et al. [6] developed a recommendation system using K-nearest neighbors and singular value decomposition, but it suffered from low efficiency due to the inability to capture all item features. Collaborative filtering algorithms struggle to extract deep user demands and interest preferences from deep-level interaction data, resulting in a significant bias between recommended content and user needs, yielding suboptimal results [7]. Similarly, Wu et al. [8] successfully combined collaborative filtering and content-based recommendation for book recommendations, and Pazzani et al. [9] suggested aggregating results from multiple algorithms to enhance performance. However, challenges persist. Zhang et al. [10] improved recommendations by combining collaborative filtering with grid-based algorithms, but further user profile feature mining is necessary for optimal results. Dineth et al. [11] utilized a weighted decomposition model but acknowledged the need for more work in capturing user-item relationships. In conclusion, traditional recommendation algorithms often rely on surface-level data, leading to limited accuracy. While efforts have been made to enhance recommendation effectiveness through various approaches, further exploration of deep user profiles and comprehensive user-item relationships is essential for significant improvements.

### B. Large Models Recommended Models

LLMs have become vital in NLP and are gaining attention in RS. These models, trained on extensive datasets through self-supervised learning, excel in learning universal representations. Effective transfer techniques like fine-tuning and on-the-fly adjustments offer the potential to enhance recommender systems. Leveraging LLMs improves recommendation quality by providing high performance, quality representation of text features, and extensive external knowledge coverage to establish correlations between items and users [12]. Recent advancements in LLMs, as demonstrated by Zhong et al. [13], exhibit robust logical and causal reasoning capabilities. This progress is attributed to three key advantages. Firstly, LLMs' natural language understanding enables parsing meaning and relationships from text, identifying entities, actions, and causal chains through self-attention and contextual embeddings.BAO et al. [14] introduce BIGRec, a two-step grounding framework for Recommender Systems. This framework fine-tunes LLMs to connect them to the recommendation space, generating meaningful tokens for items and identifying corresponding actual items beyond surface-level feature extraction. Jin et al. [15] extend LLMs' context window with SelfExtend to exploit their long-context processing potential. However, the impact of user profiles on experimental results regarding existing item information remains unexplored. Wang et al. [16] utilize LLMs in various applications, emphasizing relationships between users and items, yet highlighting the need for datasets incorporating user profiles. Wang et al. [17] introduce the Probability Inference Layer (PIL) into Mistral, aiming to enhance information retrieval in NLP, stressing the importance of a comprehensive understanding of user profiles for personalized recommendations.

Based on the analysis above, it is evident that some current research neglects the role of user profiles, while others present incomplete user profiles, failing to acknowledge the significance of user profiles in recommendations.

## III. Datasets

In the real-world social context, a deficiency exists in datasets related to user persona descriptions. Consequently, we construct the dataset necessary for our experiment. This dataset spans three domains: movies, television shows, and books. Simultaneously, we develop a comprehensive knowledge graph for character personas.

### A. Character Profile Collection

The User profile dataset is mainly built on common human traits, comprising 16 distinct characters, each with different values, and evenly distributed attributes. Gender has two values: male and female. Age is grouped into eight categories: below 10, 11-20, 21-30, 31-40, 41-50, 51-60, 61-70, and above 70 years, catering to diverse age groups. Education includes six levels: elementary, junior high, high school, undergraduate, master's, and doctoral, accurately reflecting users' educational backgrounds. Religion options are Christianity, Islam, Hinduism, Buddhism, Taoism, and no religious beliefs, considering users' preferences. Interests like basketball, badminton, and table tennis cater to various age groups. Idol values are randomly assigned, covering celebrities like Chen

He, Chen Kun, Hu Ge, and Huang Bo. The "specialty" attribute spans multiple domains. Personality and dreams offer insights into individual characteristics. The "children" attribute reflects life experiences, while social media portrays usual lifestyles. Historical records include two recent highly-rated movies, TV series, and books from Douban. Various occupations are covered, providing a comprehensive understanding of users' backgrounds. Integrating these attributes enhances the accuracy and personalization of the recommendation system by considering age, education, religion, and occupation, delivering more targeted recommendations. Table I provides statistical information and a summary of relevant character details.

TABLE I. STATISTICAL ANALYSIS OF CHARACTER INFORMATION

| Profile | Value |
|---|---|
| Sex | Male, Female |
| Age(years old) | <10,10-20,21-30,31-40,41-50,51-60,61-70,>70 |
| Native place | Suzhou,Sanming,Zhangping,Hezhou,Haikou... |
| Star sign | Aries, Taurus,Gemini,Cancer,Leo,Virgo... |
| Qualification | Primary school, Junior high school, High school... |
| Religion | Christianity,Islam,Hinduism,Buddhism,Taoism... |
| Interest | playing basketball,playing badminton... |
| Idol | Zhang Fuqing,Shen Teng,Xv Zheng,Li Yannian... |
| Strong point | calligraphy,oil painting,Chinese painting... |
| Character | thoughtful person,calm person,suggestible person... |
| Dream | go to university,enter MIT for a master's degree... |
| Pet | cat,dog,hamster,rabbit,fish,duck |
| Child | son,daughter,no child |
| Daily | Weibo,Zhihu,Little red book,Douyin,wechat,QQ... |
| Historical record | The Untamed,The Bad Kids,Joy of Life... |
| Occupation | public health physician,landscape architect... |

### B. Data Collection

The user profile dataset is meticulously crafted to cater to users' individual preferences, rather than solely prioritizing top-rated choices. It comprises 16 distinct attributes, such as gender, age, and interests, ensuring a nuanced reflection of users' personalities. Movie recommendations are sourced from highly-rated films on Douban, guaranteeing quality from a diverse selection of genres and languages. An algorithm then suggests 20 movies for each character, with the top 10 most frequently occurring choices being finalized. This approach ensures tailored recommendations while avoiding an overemphasis on widely known works. TV series and books follow a similar principle, drawing from Douban ratings above 9 to deliver personalized content. Despite potential imperfections in attribute construction, the integration of the character dataset enhances recommendation accuracy, accommodating varied user preferences effectively.

The user profile dataset is an innovative application leveraging GPT-3.5 to offer personalized film recommendations. Each movie attribute receives independent recommendations, ensuring comprehensive attention. The process involves 246 character profiles, each with unique movie preferences. From a selection of 100 films, each profile receives 20 tailored recommendations. This approach guarantees personalized suggestions from a diverse film pool. Moreover, these 246 profiles offer users a varied selection, catering to different preferences. This dataset capitalizes on ChatGPT-3.5's vast training and implicit knowledge, providing accurate recommendations. Whether suggesting films for individual profiles or combinations, the aim is to help users find enjoyable results matching their preferences.

The dataset also incorporates combinations of user preferences to enhance the accuracy and diversity of recommendation results. By combining the values of two different user preferences, the recommendation results depict the intersection of individual recommendations for each preference, as shown in Fig. 1. This approach broadens the range of suggestions for each user preference and ensures the precision of the recommendation results. Leveraging the strengths of different user preferences collectively allows users to experience more comprehensive and personalized movie recommendations that better cater to their film preferences. To investigate the impact of the level of detail in user preference descriptions on recommendation results, the three-tier dataset is composed by merging descriptions from three individual user preferences. The recommendation results are derived from the intersection of recommendations from these three personal preferences, as depicted in Fig. 2.

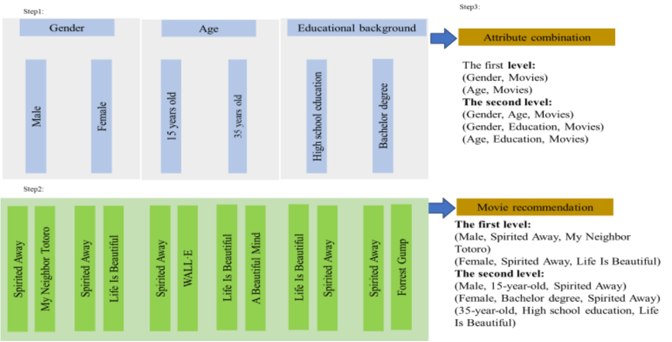

Fig. 1. Steps in the construction of secondary data set.

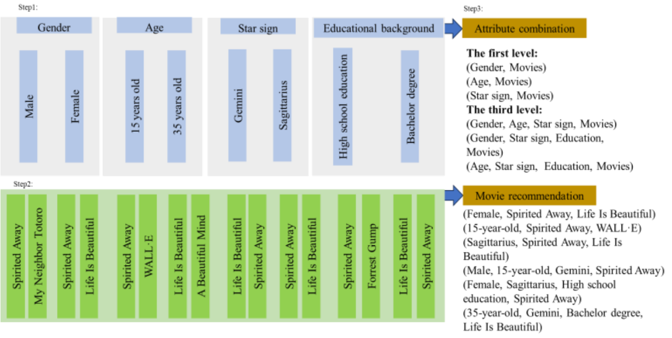

Fig. 2. Steps for the construction of the three-tier dataset.

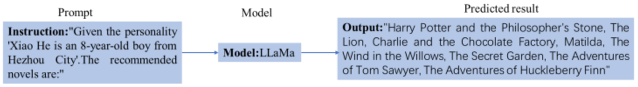
In summary, the construction and application of user profile datasets serve as an effective method to enhance recommendation systems. By considering user characteristics and preferences, recommended results are more aligned with user interests. Overall, the improved dataset is more refined and comprehensive, taking into account various factors such as user age, educational background, religious beliefs, and occupation. Works with a Douban rating exceeding 9 points are included in the candidate recommendation scope to alleviate bias in the dataset. Simultaneously, such a selection of works enhances the universality of research results and avoids potential biases. This screening criterion also ensures the quality and popularity of candidate items accurately, making recommended results more likely to align with user tastes. During the recommendation process, each user profile attribute is matched with candidate items, selecting the top 10 most frequently occurring movies, TV shows, and books as the final recommendation results. This role-based recommendation strategy enhances the personalization of the recommendation system, making it easier for users to accept recommendations and strengthening their trust in the system. This, in turn, provides users with a better overall experience, improving the accuracy of the recommendation system and user satisfaction.

## IV. Methodology

We employ the LLaMa model in the experiment to train on the dataset we construct. Our prompt is "Given the personality 'Xiao He is an eight-year-old boy from Hezhou City.' The recommended novels are:", and the output after training the LLaMa model is "Harry Potter and the Philosopher's Stone, The Lion, Charlie and the Chocolate Factory, Matilda, The Wind in the Willows, The Secret Garden, The Adventures of Tom Sawyer, The Adventures of Huckleberry Finn." We obtain different predictions by inputting various personas, as illustrated in Fig. 4. The results generated by the recommendation are evaluated against human assessments by calculating the recommendation accuracy. The architecture of the LLaMa model used in the experiment adopts a Transformer Decoder structure with several optimizations in the details. These optimizations include Pre-normalization, SwiGLU activation function, and RoPE rotational position encoding. In the case of Pre-norm, unlike the native Transformer's post-norm approach, which normalizes after each sub-layer output, LLaMa chooses to normalize the data before each sub-layer input. Pre-norm training is more stable than post-norm training and can achieve good results even when training large Transformer models without warm-up operations. Additionally, LLaMa introduces RMSNorm to replace the traditional Layer Norms. As a variant of Layer Norm, RMSNorm differs from Layer Norm in its normalization method, directly dividing by the root mean square instead of subtracting the mean and dividing by the variance. This change makes LLaMa more flexible in model normalization. Furthermore, LLaMa adjusts the activation function using SwiGLU instead of the original ReLU activation function. SwiGLU combines the Swish and GLU functions, introducing a more complex and nonlinear activation mechanism to enhance the model's expressive power when handling complex data. Through these meticulous improvements, LLaMa significantly enhances its model in terms of performance and stability.



**Instruction:**"Given the personality 'Xiao He is an 8-year-old boy from Hezhou City'.The recommended novels are:"

**Model:**LLaMa

**Output:**"Harry Potter and the Philosopher's Stone, The Lion, Charlie and the Chocolate Factory, Matilda, The Wind in the Willows, The Secret Garden, The Adventures of Tom Sawyer, The Adventures of Huckleberry Finn"

Fig. 3. Experimental workflow diagram.

## V. Experiments and Analysis of Results

In the experiment, we utilize a dataset that we have previously constructed. This dataset comprises three research domains and three levels. Relevant data regarding the dataset can be found in Table VI. We employ the alpaca model for recommendations. Finally, we validate the recommendation performance of the dataset before and after training. Fig. 3 shows the experimental workflow diagram.

### A. Experimental Setup

The experiment uses a GPU, specifically the RTX 3090(24GB) model, along with PyTorch version 1.11.0, Python version 3.8, and CUDA version 11.3. The experiment is configured with a learning rate of 0.0001, trains for 3 epochs, and has a batch size of 1024. Additionally, the value of the newly generated maximum token is set to 128, the output length is 256, and the micro-batch size is 32, among other parameters. The total duration of the experimental training is 320 hours.

### B. Datasets, Baseline and Matrices

*1) Datasets.* We use a self-constructed dataset to evaluate the recommendation capabilities of large-scale models. This evaluation involves the incorporation of open-source datasets such as ABC, ML-1M, Amazon Beauty, and Amazon Clothing. The ABC dataset [18] consists of a collection of one million Computer-Aided Design (CAD) models. We specifically extract and clean natural language corpora from all non-default text strings in the ABC dataset. This includes the names of parts and modeling features, along with the names of documents containing them, for comparative baseline effectiveness. Table II provides an overview of relevant information for the ML-1M, Amazon Beauty, and Amazon Clothing datasets.

TABLE II. Statistical Information of the Dataset

| Name | Users | Items | Actions |
|---|---|---|---|
| ML-1M | 6041 | 3417 | 999611 |
| Amazon Beauty | 22363 | 12101 | 198502 |
| Amazon Clothing | 39387 | 23033 | 278677 |

*2) Baseline.* Experiments are being conducted on the ABC, ML-1M, Amazon Beauty, and Amazon Clothing datasets, comparing the recommendation performance of nine baseline models with our trained large-scale model.

TechNet [19], which covers fundamental concepts in all technical fields and their semantic correlations, has been mining the complete United States patent database since 1976. Natural language processing techniques are employed to extract terms from many patent texts to generate TechNet. The latest word embedding algorithms are then used to vectorize these terms and establish semantic relationships.

FastText [20], based on a new approach to the skipgram model, represents each word as a bag of character n-grams. A vector is associated with each character n-gram, and words are described as the sum of these representations. This allows for fast model training on large corpora and enables the computation of word representations for words not present in the training data.

DistilBERT [21], a method to pre-train a smaller general-purpose language representation model, allows for fine-tuning on various tasks. During the Before-training phase, knowledge distillation is employed, demonstrating the ability to reduce the size of the BERT model by 40% while retaining 97% of language understanding and improving by 60%. A triple loss is introduced, combining language modeling, distillation, and cosine distance to leverage the inductive biases learned by the larger model during Before-training.

DistilBERT-FT [22] refers to the same pre-trained model, which underwent additional fine-tuning on the cleaned version of the ABC corpus that we contributed to in this work.

FDSA [23] initially integrates various heterogeneous features of the ensemble project into feature sequences with different weights, employing a vanilla attention mechanism. Subsequently, FDSA applies separate self-attention blocks to project-level and feature-level sequences, modeling project and feature transition patterns. Finally, the outputs of these two blocks are consolidated into a fully connected layer for the following project recommendation.

BERT4Rec [24] employs deep bidirectional self-attention to model user behavior sequences. By utilizing the sequential recommendation task with a cloze-style objective, predicting a randomly masked item sequence, the model effectively leverages both left and right context through a shared context, preventing information leakage and training the bidirectional model efficiently. The bidirectional representation model recommends incorporating information from the left and right sides for each item in a user's historical behavior.

CL4SRec [25] leverages the traditional next-item prediction task and employs a contrastive learning framework to obtain self-supervised signals from the raw user behavior sequences. Consequently, it can extract more meaningful user patterns and further efficiently encode user representations.

DuoRec [26] introduces a contrastive regularization approach to reshape the distribution represented in sequences. Conventional recommendation tasks typically measure the similarity between sequence representations and item embeddings in the same space through dot products. DuoRec achieves this by implicitly applying regularization to item embedding distributions. Furthermore, DuoRec proposes a model-level enhancement based on Dropout to achieve better semantic retention.

LLMRG [13] consists of four components: Chain Graph Reasoning, Divergent Expansion, Self-Validation and Scoring, and Knowledge Base Self-Improvement. The resulting reasoning graph is encoded using graph neural networks as an additional input, enhancing traditional recommendation systems without requiring different user or item information.

*3) Metrics.* To evaluate the accuracy of the recommendation results, we compare the similarity of output results before and after training. We employ cosine similarity to measure similarity, with values ranging from 0 to 1. Based on the maximum and minimum values of similarity, the range is divided into segments: 0-0.1, 0.1-0.3, 0.3-0.5, 0.5-0.7, and greater than 0.7, corresponding to ratings of 1-5. In manual evaluation, the manual scoring system is based on users' ratings of the recommended results, serving as an evaluation of both user satisfaction with the recommendations and the reasonableness of the recommendations themselves scores associated with "unsatisfactory recommendation," "satisfactory recommendation," and "excellent recommendation" are respectively assigned as 1, 2, and 3.

### C. Case Study

Based on the content of the instructions and recommendations, corresponding profiles are made. Table III presents some examples recommended by the large model, including the predicted results for the listed profiles.

TABLE III. SOME INDIVIDUALS SET RECOMMENDATION INSTANCES

| Prompt | Output |
|---|---|

| Xiao He is an 8-year-old boy who is from Hezhou City. | Spirited Away, Life Is Beautiful, The Truman Show, Forrest Gump, The Lion King, The Sound of Music |

### D. Analysis of Results

To comprehensively assess the effectiveness of the experiment, we conduct a multifaceted description and analysis of the experiment and its results from five aspects. These aspects include comparing data before and after training, making comparisons across different domains, examining differences between various levels of datasets, comparing machine evaluation with human evaluation, and conducting exploratory experiments.

*1)* Comparison of recommended results before and after data training. The experiment begins by utilizing an untrained model, Llama1, for a generation. The generation process relies on predetermined prompts. Following this, the experiment results are organized and modified. Subsequently, the model undergoes training using the original data, and the trained data is employed to generate recommendation results. Likewise, the recommendation results are organized and modified. In the final step, the effectiveness of the recommendation results before and after training is evaluated. This evaluation involves calculating the cosine similarity between the before-training data and the original data, comparing the accuracy of recommendations before and after training, and assessing the overall impact of training on the recommendation outcomes.

Fig. 4 illustrates the average recommendation accuracy of the first-level dataset before and after initial data training.

Each value represents the average derived from 246 data points, indicating recommendation accuracy within specific domains. In the domain of movie recommendations, accuracy increased from 0.5589 before training to 0.5873 after, a 5.08% improvement. For TV Series recommendations, accuracy improved from 0.2858 to 0.2872, a 0.49% increase. Book recommendations saw accuracy rise from 0.6971 to 0.7412, a 6.33% improvement. Comparing average accuracy before and after training, it's clear that post-training accuracy generally surpasses pre-training accuracy. Secondary dataset averages are also presented in Fig. 4. In the movie domain, accuracy improved from 0.3551 to 0.3731, a 5.07% increase. For TV Series, it rose from 0.0857 to 0.1056, a notable 23.22% improvement. Book recommendations saw an increase from 0.3796 to 0.4833, showcasing a 27.32% improvement. Tertiary dataset analysis follows, where movie accuracy increased from 0.3110 to 0.3277, a 5.37% improvement, TV Series accuracy from 0.0837 to 0.0976,a 16.61% improvement, and book accuracy from 0.5475 to 0.5589,a 2.08% improvement. Overall, post-training accuracy is consistently higher, aligning better with user preferences.

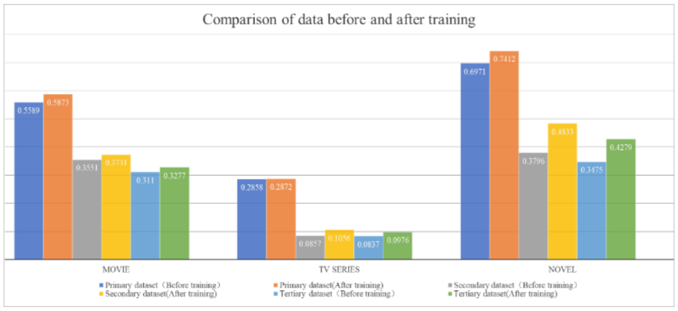

Fig. 4. Comparison of data before and after training the primary dataset.

*2)* Comparison of recommendations between different research areas. The experiment uses datasets from three domains: movie recommendations, TV Series recommendations, and book recommendations. Accuracy is assessed by applying the cosine similarity formula to evaluate the precision of recommendation results in various domains.

The Fig. 5 compares recommendation accuracy across different recommendation domains at three levels of data before training on the original dataset. In Fig. 6, the accuracy for movies in the first-level data is 0.5563, for TV series is 0.2858, and for books is 0.6971. In the second-level data, the accuracy for movies is 0.3551, for TV series is 0.0857, and for books is 0.3796. In the third-level data, the accuracy for movies is 0.3110, for TV series is 0.0837, and for books is 0.5475. Comparing movie recommendations across the three data levels, first-level accuracy exceeds second-level accuracy by 0.2012, a 36.15% decrease. Second-level accuracy, at 0.0441, is higher than third-level accuracy, reflecting a 12.42% decline. For TV series recommendations, first-level accuracy is 0.2001 higher than second-level accuracy, a 70.01% drop. Second-level accuracy is 0.002 higher than third-level accuracy, showing a 2.33% decrease. In book recommendations, first-level accuracy is 0.3175 higher than second-level accuracy, a 45.55% reduction. Second-level accuracy, at 0.0321, is higher than the third level, resulting in an 8.46% decrease. Book recommendations exhibit the highest accuracy among the three levels, while TV series recommendations have the lowest. This analysis indicates that data not trained by the Llama model yields varying recommendation effects across different recommendation domains.

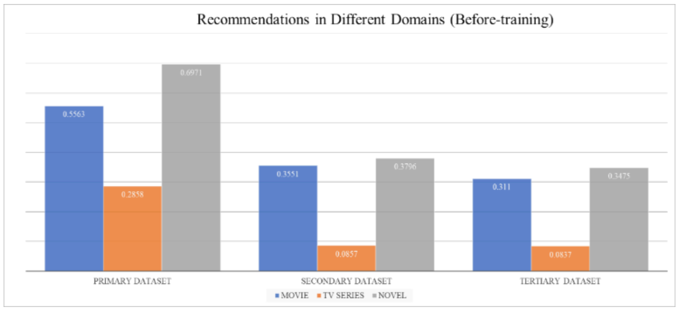

Fig. 5. Comparison of recommendation accuracy in different recommendation domains before training.

Fig. 6 compares recommendation accuracy among first-level, second-level, and third-level data in various recommendation domains post-model training. As illustrated in Fig. 5, in first-level data recommendations, the accuracy for movies is 0.5873; for second-level recommendations, it is 0.2855; and for third-level recommendations, it is 0.7412. In second-level data recommendations, the accuracy for movies is 0.3731; for TV Series, it is 0.1056; and for books, it is 0.48336. Regarding third-level data recommendations, the accuracy for movies is 0.3277; for TV Series, it is 0.0976; and for books, it is 0.5400. Across these three levels of data recommendations, books consistently display the highest accuracy, while TV Series consistently exhibit the lowest accuracy. The analysis above indicates that data trained with the Llama model yields varying recommendation effects in different recommendation domains. However, before and after training, the recommendation accuracy for books remains consistently the highest, while TV Series consistently have the lowest accuracy.

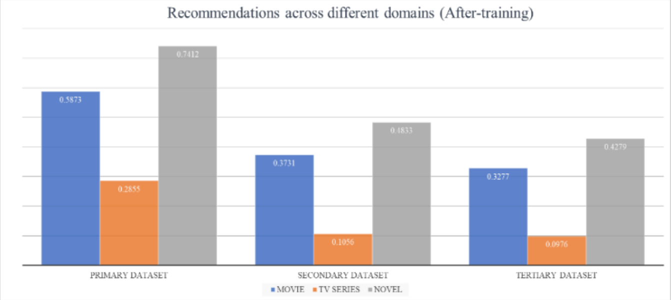

Fig. 6. Comparison of recommendation accuracy across different recommendation domains after training.

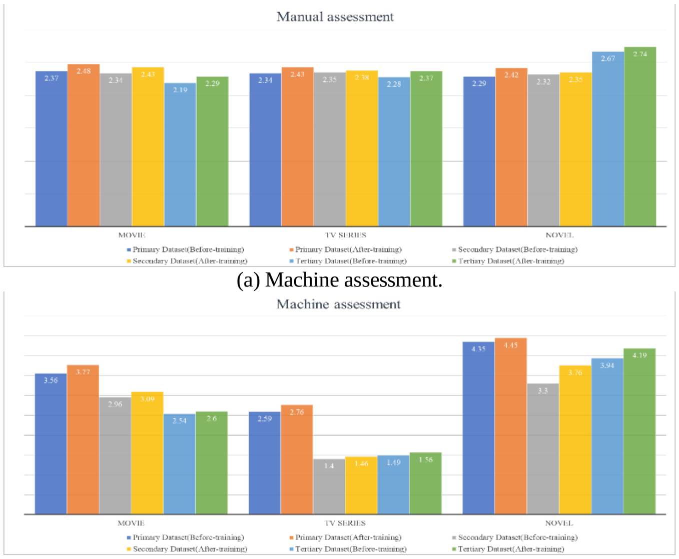
*3)* Analysis of experimental results between different models. To validate the performance of the proposed method, we conduct a comparative analysis by contrasting experimental results with various benchmark models. By comparing recommendation accuracies on different datasets and models, we observe that the model trained on the dataset we construct achieves favorable recommendation outcomes when applied to several other datasets. The experimental results are presented in Table IV. On dataset ABC, the DistilBERT-FT model performs the best. It achieves optimal recommendation results by cleaning and fine-tuning the ABC corpus. On datasets ML-1M, Amazon Beauty, and Amazon Clothing, the LLMRG model exhibits superior performance. It enhances recommendations by utilizing graph neural networks as additional inputs, based on the generated inference graphs. However, compared to the findings of this study, its performance is slightly inferior. This study establishes comprehensive user profiles, providing more precise descriptions of users, thereby achieving higher recommendation accuracy.

TABLE IV. ACCURACY STATISTICS OF RECOMMENDATION RESULTS AMONG DIFFERENT MODELS

| **Dataset** | **Model** | **Accuracy** |
|---|---|---|
| ABC | TechNet | 0.018 |
| | FastText | 0.208 |
| | DistilBERT | 0.272 |
| | DistilBERT-FT | 0.321 |
| **Movie-3** | **Our-LLM（Before-training）** | **0.311** |
| | **Our-LLM（After- training）** | **0.328** |
| ML-1M | FDSA | 0.091 |
| | BERT4Rec | 0.112 |
| | CL4SRec | 0.114 |
| | DuoRec | 0.201 |
| | LLMRG | 0.227 |
| **tv-1** | **Our-LLM（Before-training）** | **0.286** |
| | **Our-LLM（After- training）** | **0.287** |
| Amazon Beauty | FDSA | 0.024 |
| | BERT4Rec | 0.020 |
| | CL4SRec | 0.040 |
| | DuoRec | 0.055 |
| | LLMRG | 0.062 |
| **tv-2** | **Our-LLM（Before-training）** | **0.086** |
| | **Our-LLM（After- training）** | **0.106** |
| Amazon Clothing | FDSA | 0.012 |
| | BERT4Rec | 0.013 |
| | CL4SRec | 0.017 |
| | DuoRec | 0.019 |
| | LLMRG | 0.021 |
| **tv-3** | **Our-LLM（Before-training）** | **0.084** |
| | **Our-LLM（After- training）** | **0.098** |

*4)* Machine and manual evaluation of recommended results. The comparison between the accuracy of recommendation results calculated manually and those computed by machines highlights the ability to assess the reasonableness of machine-generated recommendations through human evaluation.

Fig. 7 illustrates the comparison between machine evaluation and manual assessment of data across various levels. We manually evaluated one hundred data entries, assigning ratings from 1 to 5 based on original recommended results, Before-training, and After-training data, aiming to assess recommendation reasonableness compared to the original data. Scores were assigned based on perceived appropriateness, and the average score represented the overall manual assessment. In the movie recommendation field at level 1, machine evaluation scores were 3.57 after training and 3.77 after training, indicating a 0.20 increase. For TV Series recommendations, scores increased by 0.17 from 2.59 to 2.76 after training, while for Novel recommendations, they increased by 0.10 from 4.35 to 4.45. On a secondary dataset in the movie recommendation field, machine evaluation scores increased by 0.10 after training from 2.96 to 3.09. For TV Series recommendations, scores increased by 0.06 from 1.40 to 1.46, and for book recommendations, they increased by 0.46 from 3.30 to 3.76. On a three-level dataset in the movie recommendation field, scores increased by 0.06 after training from 2.54 to 2.60. For TV Series recommendations, scores increased by 0.07 from 1.49 to 1.56, and for book recommendations, they increased by 0.64 from 3.94 to 4.58.



(a) Machine assessment.

(b) Manual assessment.

Fig. 7. Machine assessment and manual assessment.

In the realm of movie recommendations, manual assessment scores on a level 1 dataset improved from 2.37 to 2.48 post-training, indicating a 0.11 enhancement. Similarly, for TV series recommendations, scores rose from 2.34 to 2.43, showing a 0.09 increase, while book recommendations experienced a boost from 2.29 to 2.42, marking a 0.13 improvement. Although machine evaluation didn't notably advance after training, manual assessment yielded more reasonable and accurate results. Overall, post-training data resulted in higher machine evaluation scores, indicating more rational recommendations. On a secondary dataset for movie recommendations, manual evaluation scores increased from

2.34 to 2.43 post-training, representing a 0.09 improvement. TV series recommendations saw scores rise from 2.35 to 2.38, a 0.03 improvement, and book recommendations increased from 2.32 to 2.35. In all three domains, post-training data, both in machine and manual evaluations, provided more reasonable and accurate results. However, scores for machine and manual assessment of secondary data were generally lower, possibly due to less smooth integration of personas. On a three-level dataset for movie recommendations, human evaluation scores improved from 2.19 to 2.29 post-training, a 0.10 increase. For TV series recommendations, scores rose from 2.28 to 2.37, a 0.09 improvement, and for book recommendations, scores increased from 2.67 to 2.74, a 0.07 improvement. Overall, third-level data showed higher accuracy and score values across all categories in both machine and human evaluations, offering more reasonable and user-preference-aligned recommendations.

TABLE V. STATISTICAL ANALYSIS OF MACHINE ASSESSMENT (J) BEFORE AND AFTER TRAINING, MANUAL ASSESSMENT (R), AND THE PEARSON CORRELATION COEFFICIENT (P) BETWEEN THE TWO

| **Recommended field** | **Dataset level** | **Before-training** | | | **After-training** | | |
|---|---|---|---|---|---|---|---|
| | | ***J*** | ***R*** | ***P*** | ***J*** | ***R*** | ***P*** |
| Movie | First level | 3.57 | 2.37 | 0.55 | 3.77 | 2.48 | 0.69 |
| | Second level | 2.96 | 2.34 | 0.59 | 3.09 | 2.43 | 0.69 |
| | Third level | 2.54 | 2.19 | 0.30 | 2.60 | 2.29 | 0.24 |
| TV Series | First level | 2.59 | 2.34 | 0.45 | 2.76 | 2.43 | 0.47 |
| | Second level | 1.40 | 2.35 | 0.53 | 1.46 | 2.38 | 0.51 |
| | Third level | 1.49 | 2.28 | 0.40 | 1.56 | 2.37 | 0.42 |
| Novel | First level | 4.36 | 2.29 | 0.60 | 2.49 | 2.42 | 0.62 |
| | Second level | 3.30 | 2.32 | 0.58 | 3.76 | 2.35 | 0.32 |
| | Third level | 3.94 | 2.67 | 0.66 | 4.19 | 2.74 | 0.48 |

The table presented in Table V illustrates the Pearson correlation coefficients between the average scores obtained from machine evaluations and human evaluations, as well as the correlation coefficients for three ranking datasets within three recommended domains. A correlation coefficient (P) of 1 indicates a perfect positive linear relationship, signifying that as one variable increases, the other variable increases proportionally. Conversely, a P value of -1 signifies a perfect negative linear relationship, implying that as one variable increases, the other variable decreases proportionally. A P value of 0 suggests no linear relationship between the two variables.

*5)* Exploratory experiment. Word frequency statistics and analysis in each recommendation result.

Using distinctive words from the titles of movies, TV Series, and books for statistical analysis, we assess the data based on the frequency of word occurrences. Words such as "a," "an," "the," and other articles are excluded from the titles to ensure the credibility of the evaluation results.

The figure presented in Fig. 8 illustrates the frequency of word occurrences in the top recommendations across three recommended domains for the first-level data after training the Llama model. In Fig. 8(a), the chart displays the maximum 20 words with the highest frequency of occurrence in the recommended movie names after training. Words with occurrences exceeding 200 include 'Godfather' and the movies associated with this word are 'The Godfather' and 'The Godfather Part II.' Importantly, there are differences between the films recommended after training and those recommended without data training. Fig. 8(b) showcases a bar chart representing the word occurrences in the top 20 words found in the recommended TV Series names after training the first-level data. Among these, words with occurrences surpassing 200 include 'abbey', 'bad', 'breaking', 'cards', 'dead', 'downtown', 'game', 'house', 'thrones', and 'walking'. These ten words are associated with TV Series such as 'Downton Abbey', 'Breaking Bad', 'House of Cards', 'The Walking Dead', and 'Game of Thrones'. Popular TV Series remain broadly consistent when comparing the results before and after data training. In Fig. 8(c), the chart represents the top 20 words in the recommended books, showing that the word frequencies after training are higher than before training. The above analysis reveals user preferences as well as the most popular works.

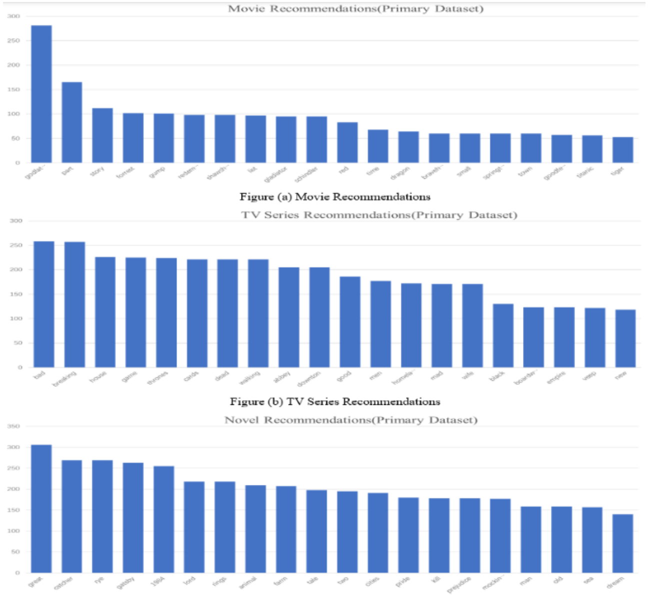


Figure (a) Movie Recommendations

Figure (b) TV Series Recommendations

Figure (c) Novel Recommendations

Fig. 8. The word frequency statistics in three domains of data at the after-training level.

The figure presented in Fig. 9 illustrates the word frequency in secondary data recommended across three domains following the training of the Llama model. In Fig. 9(a), the chart displays the top 20 words in movie recommendations, where the term 'godfather' stands out with a frequency of over 1000 times. This indicates a significant popularity for movies like 'The Godfather' and 'The Godfather Part II'. Moving on to Fig. 9(b), the top 20 words in TV Series recommendations are depicted, with six words having frequencies exceeding 2000. Notably, these high-frequency words are associated with three specific TV Series—' Breaking Bad', 'House of Cards' and 'Game of Thrones'. Fig. 9(c) reveals that the top 20 words in book recommendations are linked to widely-read books, with some words representing various terms referring to the same book, aligning more closely with profiles.

The figure displayed in Fig. 10 illustrates the frequency of word occurrences in the recommendations across three domains for the three-level data following training with the Llama model. In comparison to the first and second-level data, the third-level data offers more precise profile descriptions, and the recommended movies, TV Series, and books are more accurate. The three graphs depicted in Fig. 10 represent the top 20 words with the highest occurrences in each recommendation domain. Each domain's maximum of 20 words highlights the most popular movies, TV Series, and books within their respective domains, facilitating a representative comparison.

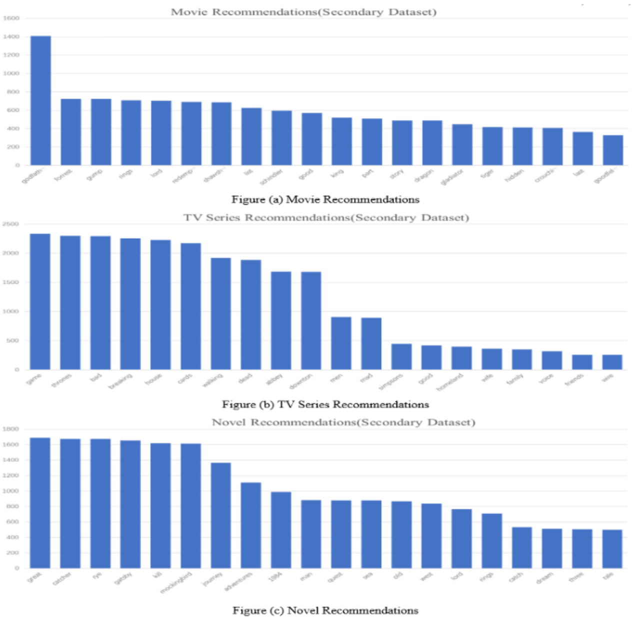

Figure (a) Movie Recommendations

Figure (b) TV Series Recommendations

Figure (c) Novel Recommendations

Fig. 9. After training, word frequency statistics were conducted in three domains for secondary data.

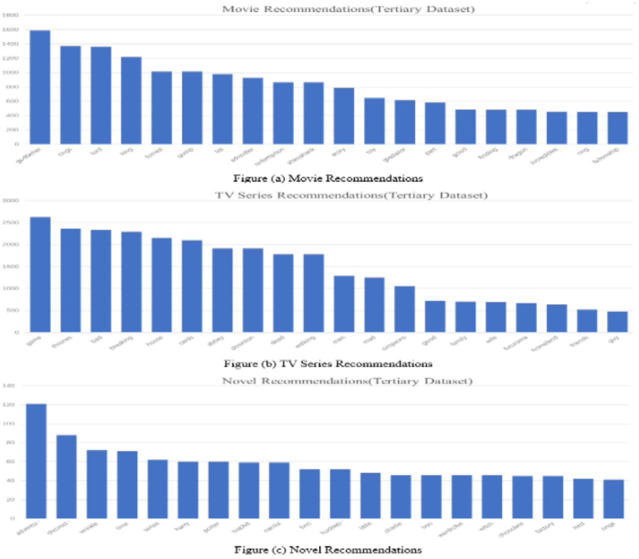

Figure (a) Movie Recommendations

Figure (b) TV Series Recommendations

Figure (c) Novel Recommendations

Fig. 10. After training, the word frequency statistics were conducted for three domains in the tertiary-level data.

## VI. Conclusion and Prospects

In this paper, we investigate the significant impact of user profiles on recommendation outcomes within the recommendation domain. We employ the Llama model to train on the original dataset. This approach illustrates how Llama brings interpretability to recommendation systems and aligns more closely with user interests without requiring additional information. We conduct experiments using datasets generated by ChatGPT-3.5 in three distinct recommendation domains and across three levels of datasets. Among the mentioned domains, book recommendations show the most promising results, with the first-level dataset yielding the most effective recommendations. In the experiments, we evaluate the effectiveness of recommendation methods based on user profiles. The precision of recommendation results is calculated using cosine similarity, and human evaluators assign scores based on the reasonableness of the recommendations. The higher the human-assigned score, the more reasonable the recommendations, aligning better with user preferences and human values. The future experiments will involve constructing more detailed user profiles, such as socioeconomic status, psychological conditions, etc., and exploring outcomes on other more advanced models, such as LLaMa2.

TABLE VI. Self-Build Dataset Related Data Statistics

| Dataset | Recommended field | Dataset level | Data volume |
|---|---|---|---|
| TOTAL | Movie | First level(movie-1) | 247 |
| | | Second level(movie-2) | 28043 |
| | | Third level(movie-3) | 425431 |
| | TV Series | First level(tv-1) | 247 |
| | | Second level(tv-2) | 28043 |
| | | Third level(tv-3) | 400157 |
| | Novel | First level(novel-1) | 247 |
| | | Second level(novel-2) | 28043 |
| | | Third level(novel-3) | 439528 |

***Abstract*—In an era characterized by the growing significance of energy-efficient and human-centric environmental control systems, this research endeavors to investigate the efficacy of a Fuzzy Proportional-Integral-Derivative (PID) control approach for temperature regulation within Heating, Ventilation, and Air Conditioning (HVAC) systems. The study leverages the adaptability and robustness of fuzzy logic to dynamically tune the PID controller's parameters in response to changing environmental conditions. Through comprehensive simulations and comparative analyses, the research showcases the superior performance of the proposed fuzzy PID control system in terms of rapid response, overload avoidance, and minimal steady-state error, particularly when contrasted with conventional PID control and model predictive control (MPC) methodologies. Furthermore, the research extends its scope to assess the control system's resilience in the face of significant load variations, affirming its practical applicability in real-world HVAC scenarios. Beyond its immediate implications for HVAC systems, this research underscores the broader potential of fuzzy PID control in enhancing control precision and adaptability across various domains, including robotics, industrial automation, and process control. By advocating for future research endeavors in optimizing fuzzy membership functions, implementing real-time solutions, and exploring multi-objective optimization, among other avenues, this study seeks to contribute to the ongoing discourse surrounding advanced control strategies for achieving energy-efficient and human-centric environmental regulation.**

***Keywords*—Fuzzy logic; PID; Temperature; Microclimate; Smart Building**

## I. Introduction

The evolution of intelligent building systems has been a cornerstone in advancing modern architecture and environmental control, where the emphasis is increasingly on enhancing occupant comfort and optimizing energy efficiency. The concept of a comfortable microclimate within an intelligent building, especially in terms of temperature control, is central to this evolution. This paper introduces a novel approach to this challenge: an Intelligent Fuzzy-PID (Proportional-Integral-Derivative) Temperature Control System.

The significance of maintaining an ideal indoor temperature is well-documented in literature. Studies have shown that a comfortable indoor temperature not only contributes to the wellbeing and productivity of the occupants but also significantly reduces energy consumption [1]. However, the dynamic nature of indoor environments, influenced by factors such as occupancy, external weather conditions, and internal heat sources, makes temperature regulation a complex task [2].

Traditional temperature control systems often rely on conventional PID controllers. While effective in stable environments, their performance in dynamic settings, like those in intelligent buildings, is not optimal. These systems often struggle to adapt to the rapid changes and nonlinear characteristics of such environments [3]. Consequently, there is an increasing interest in exploring alternative approaches that can offer more adaptability and efficiency.

Fuzzy logic controllers have emerged as a promising solution to this problem. Fuzzy logic, with its ability to handle uncertainties and non-linearities, is well-suited for complex systems where traditional control methods fall short [4]. The integration of fuzzy logic into temperature control systems has shown improved performance in handling the intricacies of the indoor climate [5].

However, while fuzzy controllers excel in managing uncertainty and complexity, they can lack the precision and stability that PID controllers offer. This has led to the exploration of hybrid systems that combine the strengths of both fuzzy logic and PID control. The Fuzzy-PID controller is one such hybrid system that has gained attention in recent years [6]. These systems leverage the adaptability of fuzzy logic with the stability and precision of PID control, making them particularly suitable for dynamic and complex environments like intelligent buildings [7].

The concept of intelligent buildings goes beyond mere temperature control. An intelligent building is an ecosystem, integrating various systems such as lighting, security, and HVAC (Heating, Ventilation, and Air Conditioning) to create a responsive and adaptive environment [8]. Temperature control in such a system is not an isolated task but part of a larger, interconnected process. This interconnectivity poses additional challenges but also opens avenues for more integrated and intelligent control strategies [9].

The application of intelligent control systems in buildings has been explored in various studies, demonstrating significant improvements in energy efficiency and occupant comfort [10]. However, the implementation of such systems in real-world scenarios often encounters challenges like system complexity, cost, and the need for customization to specific building requirements [11].

In light of these challenges, the development of an Intelligent Fuzzy-PID Temperature Control System is not just a technological advancement but also a step towards practical and efficient building management. This system aims to address the shortcomings of existing temperature control systems by offering a solution that is both adaptive and precise. The integration of fuzzy logic allows the system to handle the unpredictable nature of indoor environments, while the PID component ensures consistent and stable performance [12].

The efficacy of such a system lies not only in its technical capabilities but also in its alignment with the broader goals of sustainable development. The optimization of energy usage in buildings is a critical component of global efforts to reduce energy consumption and greenhouse gas emissions [13]. By improving the efficiency of temperature control systems, intelligent buildings can contribute significantly to these goals.

In conclusion, the development of an Intelligent Fuzzy-PID Temperature Control System represents a significant advancement in the field of building automation and control. This system promises to enhance indoor comfort while optimizing energy efficiency, addressing both the immediate needs of building occupants and the long-term goals of environmental sustainability [14].

## II. Related Works

The development of intelligent temperature control systems within the realm of intelligent buildings has been a subject of extensive research. This section delves into various studies and advancements that have contributed to this field, focusing on the evolution of PID, fuzzy logic, and their hybrid systems, as well as their application in intelligent building environments.

### A. PID Control Systems in Building Environments

PID controllers have long been the backbone of control systems in various applications, including building temperature control. The simplicity, robustness, and effectiveness of PID controllers in systems with linear dynamics have been well-documented [15]. However, the effectiveness of PID controllers in rapidly changing environments, such as those encountered in intelligent buildings, has been brought into question. Studies have highlighted the limitations of PID controllers in dealing with non-linear systems and rapidly changing inputs [16]. Despite these limitations, PID controllers' application in HVAC systems remains prevalent, primarily due to their simplicity and ease of implementation [17].

### B. Fuzzy Logic in Temperature Control

The integration of fuzzy logic into temperature control systems marked a significant shift towards handling the non-linear and uncertain nature of intelligent building environments. Fuzzy logic systems, with their ability to mimic human reasoning and handle imprecise information, have shown considerable promise in managing the complexity of these environments [18]. Early implementations of fuzzy logic in temperature control demonstrated improved comfort levels and energy efficiency compared to traditional control systems [19]. Subsequent studies have focused on refining fuzzy logic algorithms to enhance their performance in various scenarios, ranging from residential buildings to large commercial complexes [20].

### C. Challenges and Advancements in Fuzzy Logic Systems

Despite the intrinsic benefits of fuzzy logic in enhancing the adaptability and precision of building control systems, its practical implementation is beset with notable challenges. Predominantly, the complexity involved in the design and fine-tuning of fuzzy controllers presents a significant hurdle. This complexity is primarily attributed to the necessity of formulating precise membership functions and comprehensive rule sets. These components must be meticulously tailored to accurately encapsulate the multifaceted dynamics characteristic of building environments [21]. Furthermore, the computational intensity required by fuzzy logic systems, particularly in applications on a larger scale, stands as a substantial concern. This is especially pertinent in scenarios where real-time processing and responsiveness are crucial [22].

In response to these challenges, recent advancements in the field have been directed towards refining fuzzy logic systems. The focus has been twofold: firstly, on the development of more sophisticated and efficient algorithms that are capable of handling complex computations with greater ease. Secondly, there has been a concerted effort towards the integration of adaptive mechanisms. These mechanisms are designed to facilitate a more seamless and less labor-intensive tuning process, thereby enhancing the practical applicability and efficiency of fuzzy logic controllers in building management systems [23]. This dual approach in advancing fuzzy logic systems not only mitigates their inherent complexities but also augments their efficacy and reliability in real-world applications.

### D. Hybrid Fuzzy-PID Systems

The fusion of fuzzy logic with PID controllers has culminated in the advent of hybrid Fuzzy-PID systems, a synergistic solution that amalgamates the distinct advantages of both methodologies. This innovative approach leverages the adaptability and robustness inherent in fuzzy logic, enabling it to adeptly navigate the complexities of non-linearity and uncertainty prevalent in dynamic control environments. Concurrently, it harnesses the stability and simplicity of PID controllers, ensuring a baseline of consistent and reliable performance [24].

This paradigm shift towards hybrid systems has been the focus of numerous research endeavors, particularly in the realm of temperature control within intelligent buildings. Empirical studies in this domain have underscored the ability of hybrid Fuzzy-PID systems to dynamically adjust control strategies in response to real-time environmental data. This adaptive capability translates into marked improvements in various performance metrics, including response times, system stability, and, notably, energy efficiency. Such advancements not only enhance the operational effectiveness of temperature control systems but also contribute to broader energy conservation efforts, a critical consideration in contemporary building management [25]. The development and implementation of hybrid Fuzzy-PID systems thus represent a significant stride forward in the quest for more intelligent and efficient building automation solutions.

### *E. Application in Intelligent Buildings*

The integration of intelligent control systems, notably hybrid Fuzzy-PID systems, into intelligent buildings represents a significant advancement in building automation. Intelligent buildings, defined by their capacity to dynamically respond to both internal and external stimuli, offer an ideal environment for the implementation of these sophisticated control systems. Recent research in this area has been extensive, covering a wide range of topics such as the seamless integration of systems, the processing of data in real time, and enhancing user interfaces [26]. These studies have consistently demonstrated that the deployment of intelligent control systems contributes substantially to the creation of environments that are not only more comfortable for occupants but also markedly more energy-efficient [27]. The implementation of these systems in intelligent buildings is thus not just a technological upgrade but a step towards redefining the interaction between humans and their living spaces.

### *F. Energy Efficiency and Sustainability*

In the realm of intelligent building design, the emphasis on energy efficiency is increasingly pertinent, driven by escalating concerns over energy consumption and its environmental ramifications. Intelligent temperature control systems have been at the forefront of this discourse, with recent research focusing on their role in augmenting energy efficiency. Evidence suggests that these systems, through optimized temperature control, can lead to substantial energy savings while maintaining, or even enhancing, occupant comfort [28]. Furthermore, the adoption of these systems aligns with broader sustainability objectives, particularly in reducing the carbon footprint associated with building operations [29]. Thus, intelligent temperature control systems emerge not only as a tool for environmental stewardship but also as a means to foster a more sustainable future in building management.

### *G. Emerging Technologies and Future Trends*

The landscape of intelligent temperature control is undergoing rapid transformation, spurred by the emergence of new technologies. The incorporation of Internet of Things (IoT) devices, for example, has revolutionized the way data is collected and interacted with in building management systems [30]. Concurrently, there is a burgeoning interest in the application of advanced data analytics and machine learning algorithms, aimed at enhancing the predictive capabilities of control systems. These technological innovations empower the systems to proactively anticipate environmental changes and adjust controls accordingly [31]. The future trajectory of intelligent temperature control systems is thus characterized by an increasing convergence of these cutting-edge technologies, paving the way towards more autonomous, efficient, and user-oriented control systems [32]. This evolution signifies a shift towards a more integrated and intelligent approach to building management.

### *H. Challenges and Limitations*

Despite the notable progress in the field of intelligent temperature control systems, several challenges and limitations persist. One of the primary concerns is the financial and technical complexity associated with the deployment of these systems, especially in retrofitting existing structures [33]. Moreover, as these systems become increasingly interconnected and reliant on data exchange, issues pertaining to their reliability and security have emerged as significant points of contention [34]. Addressing these challenges is imperative to ensure that the benefits of intelligent temperature control systems are not only realized but also sustainable over the long term. Continued research and development in this area are essential to overcome these hurdles, thereby facilitating broader adoption and integration of these systems in the built environment [35].

## III. Materials and Methods

### *A. PID-based Temperature Control*

The indoor environmental conditions are regulated through the utilization of Proportional-Integral-Derivative (PID) controllers, which operate based on the system error (e) and the rate of change of the system error (ec) as their input parameters. The error at time instant k, denoted as e(k), represents the disparity between the actual output and the desired target output. It can be mathematically expressed in the subsequent manner:

$$e(k) = r(k) - y(k) \tag{1}$$

$ec(k)$ is the changing rate of $e(k)$ and is given as:

$$ec(k) = e(k) - e(k-1) \tag{2}$$

The PID controller functions as a critical component in the control system, where its output corresponds to the modulation of the heating equipment's operational intensity. In contrast, the overarching system output pertains directly to the indoor air temperature. Eq. (3) serves as a succinct mathematical formulation of the PID control algorithm, encapsulating the intricate dynamics between the controller's input and output variables. This algorithm plays a pivotal role in the meticulous and effective regulation of temperature within the controlled environment, facilitating the maintenance of a desirable and stable indoor climate.

$$\begin{aligned} u(k) &= k_p\left(e(k) - e(k-1)\right) + k_i e(k) \\ &+ k_d\left(e(k) - 2e(k) + e(k-2)\right) \end{aligned} \tag{3}$$

The effectiveness of PID control is significantly dependent on the precise tuning of PID controller parameters, namely kp, ki, and kd. In the context of the fuzzy-PID control strategy, a dedicated fuzzy logic block is designed to autonomously adjust and fine-tune these parameter values. This self-tuning capability ensures that the PID controller adapts dynamically to changing system conditions, optimizing its performance in response to evolving control requirements.

### B. Design of Fuzzy Logic

Fuzzy self-adjustment of PID parameters entails the identification of a fuzzy correlation among the three PID parameters, i.e., kp, ki, and kd, as well as their relationship with error (e) and the rate of error change (ec). This process involves the assessment of the system's output (y) and the subsequent computation of error (e) and the rate of error change (ec) based on y and the input parameter r. The controller equipped with fuzzy logic then configures these three parameters in accordance with the rules governing fuzzy control in real-time, thereby optimizing the performance and stability of the monitored systems. Consequently, it becomes imperative to comprehend the distinct roles played by each PID parameter. This understanding is pivotal for discerning the intricate interplay between the fuzzy output and the parameters kp, ki, and kd in relation to the fuzzy inputs e and ec. Subsequently, a set of fuzzy rules is established.

The primary role of the fuzzy logic controller is to dynamically adjust the parameters of the PID controller (kp, ki, kd) in real-time. This adjustment is guided by a set of fuzzy logic control rules that consider time-varying errors, denoted as e and ec, as depicted in Fig. 1.

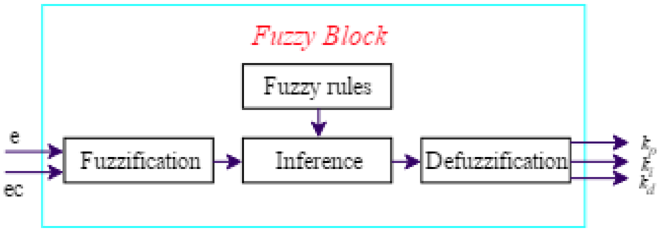

Fig. 1. Fuzzy logic control rules.

Table I illustrates how the functionalities of each PID parameter are influenced by control efficiency and their association with the system error. The fuzzy rule base comprises three matrices that elucidate the variations ($\Delta kp$, $\Delta ki$, and $\Delta kd$) in kp, ki, and kd when e and ec exhibit changes, as depicted in Table I. The construction of the fuzzy rule base involves the formulation of several if-then statements, encompassing the premises and consequences of each statement, which are inherently fuzzy propositions.

Table II, Table III and Table IV encompass a comprehensive compendium of the regulations governing the fuzzy-based PID controller. The fuzzy variables employed within the rule base framework encompass the following entities: error (e), rate of error change (ec), as well as the variations ($\Delta kp$, $\Delta ki$, and $\Delta kd$). Table II demonstrates fuzzy rule base for kp, Table III demonstrates fuzzy rule base for ki, Table IV demonstrates fuzzy rule base for kd. These variables are stratified into distinct categories denoted as: "Negative Big" (NB), "Negative Medium" (NM), "Negative Small" (NS), "Zero" (ZO), "Positive Small" (PS), "Positive Medium" (PM), and "Positive Big" (PB).

TABLE I. EFFECTS OF KP, KI, KD TUNING

| Parameter | Rise time | Overshoot | Setting time | Steady state error | Stability |
|---|---|---|---|---|---|
| **Increase kp** | Decrease | Small Increase | Increase | Decrease | Deteriorate |
| **Increase ki** | Small Decrease | Increase | Increase | Large Decrease | Deteriorate |
| **Increase kd** | Small Decrease | Decrease | Decrease | Small Change | Improve |

A membership function is a curve that delineates the transformation of each point within the input space into a membership value, represented as a degree of membership, ranging between 0 and 1. In the present context, a combination of triangular and Gaussian membership functions is applied consistently across all variables. The physical domains of the variables e and ec are constrained to {-3, -2, -1, 0, 1, 2, 3}; the physical range for Δkp spans {-0.3, -0.2, -0.1, 0, 0.1, 0.2, 0.3}; Δki operates within the bounds of {-0.06, -0.04, -0.02, 0, 0.02, 0.04, 0.06}, while Δkd is delimited within {-4, -3, -2, -1, 0, 1, 2, 3, 4}.

The computation of Δkp, Δki, and Δkd values relies on the predefined rules within the fuzzy rule base and their corresponding membership functions. Following this determination, the subsequent calculation of the PID controller's parameters, namely kp, ki, and kd, can be accomplished through the application of the following equations:

$$k_p(k+1) = f_{kp}(e,ec) = k_p^{'}(k) + \Delta k_p(k) \tag{4}$$

$$k_i(k+1) = f_{ki}(e,ec) = k_i^{'}(k) + \Delta k_i(k) \tag{5}$$

$$k_d(k+1) = f_{kd}(e,ec) = k_d^{'}(k) + \Delta k_d(k) \tag{6}$$

The desired values for kp, ki, and kd can be derived through the utilization of a Fuzzy Logic Controller (FLC) and subsequently transferred to the PID controller. This procedure is undertaken with the ultimate objective of ensuring the proper operation of the air-conditioning equipment, thus facilitating the attainment of a conducive and comfortable indoor environment. Fig. 2 demonstrates the proposed fuzzy based PID control.

1) *Data acquisition*: Commence by gathering control data at time step k, utilizing measuring apparatus.

2) *Error computation:* Calculate the system error as well as the rate of change of the system error.

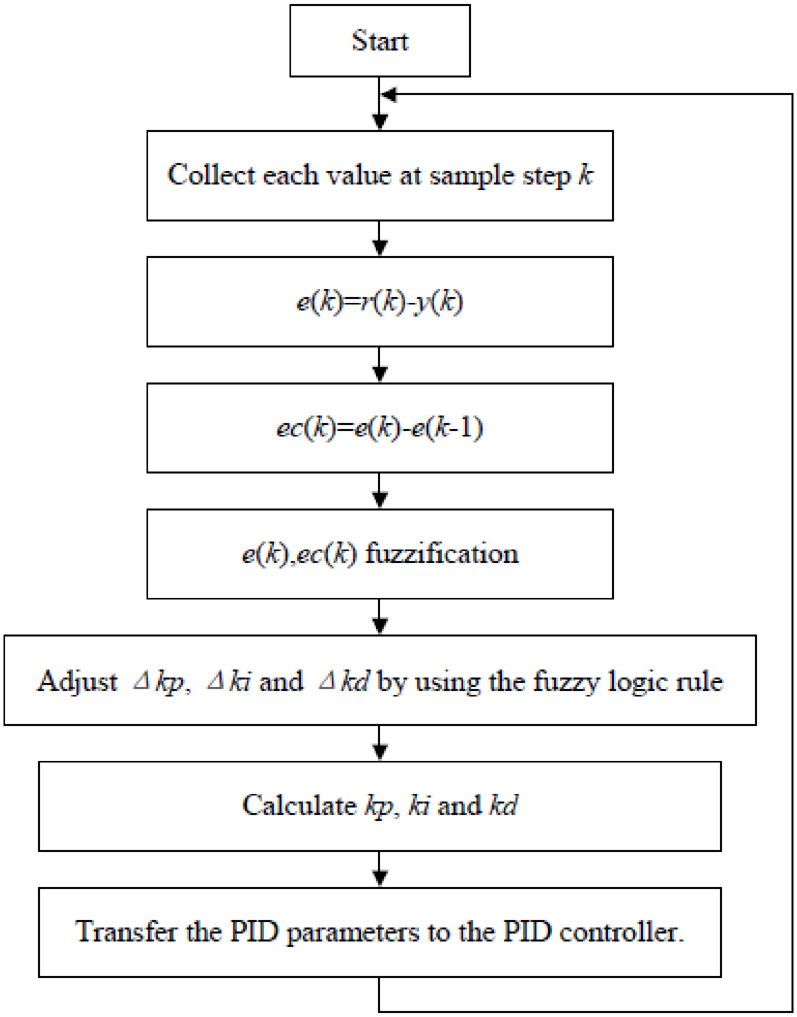
3) *Fuzzification:* Apply predetermined membership functions to effectuate the fuzzification of error (e) and error change rate (ec).

4) *Fuzzy inference:* Obtain the fuzzy values for Δkp, Δki, and Δkd by employing the rules encapsulated in Tables II to IV within the fuzzy rule bases.

5) *Defuzzification:* Employ appropriate membership functions for the process of defuzzification, resulting in the determination of Δkp, Δki, and Δkd.

6) *Parameter calculation:* Calculate the values for kp, ki, and kd.

7) *PID configuration:* Furnish the computed kp, ki, and kd values to the PID controller for the purpose of regulating indoor temperature.



Start
Collect each value at sample step *k*
*e*(*k*)=*r*(*k*)-*y*(*k*)
*ec*(*k*)=*e*(*k*)-*e*(*k*-1)
*e*(*k*),*ec*(*k*) fuzzification
Adjust Δ*kp*, Δ*ki* and Δ*kd* by using the fuzzy logic rule
Calculate *kp*, *ki* and *kd*
Transfer the PID parameters to the PID controller.

## IV. Experimental Results

### A. Proposed Approach

In the following section, we provide a comprehensive exposition of the simulation results pertaining to the proposed controllers. These simulations were conducted utilizing both the Python programming language and the MATLAB platform, renowned for their versatility and analytical capabilities. The experimental outcomes that form the basis of this discussion originate from meticulously executed assessments conducted within the controlled environment of the laboratory. This controlled setting ensures the reliability and reproducibility of the experimental data, thereby bolstering the credibility of the findings presented herein. The use of both Python and MATLAB underscores the robustness of our analytical approach, leveraging the strengths of each programming environment to provide a well-rounded assessment of the proposed controllers' performance. The ensuing discussion will delve into the specific outcomes and observations gleaned from these simulations, shedding light on the effectiveness and adaptability of the controllers under varying conditions and scenarios.

In this section, our objective is to elucidate the simulated outcomes concerning the utilization of a fuzzy PID controller for the regulation of temperature. For the purpose of this analysis, we presume an initial room temperature that is deemed uncomfortable and warrants adjustment. Subsequent to the identification and configuration of the desired room temperature, the controller initiates its operation to attain the predefined room temperature setpoint. To simulate this operational process, a reference input signal is introduced as a means of assessing the characteristics and effectiveness of the proposed data controller. Additionally, it is posited that there exists a temperature disparity of 5°C between the indoor and outdoor environments.

This simulation framework serves as a controlled environment to systematically evaluate the performance of the fuzzy PID controller in effecting temperature regulation. Through the utilization of the reference input signal, the dynamic response of the control system to changing conditions can be observed and analyzed. Moreover, the imposed temperature differential represents a common real-world scenario wherein HVAC systems are tasked with bridging the gap between indoor comfort and external environmental conditions. Thus, this simulation provides a valuable platform for assessing the controller's ability to respond to and mitigate such temperature differentials while achieving precise and stable temperature control within the room.

Consequently, at time t = 0, a step signal denoted as r(k) = 5 is introduced into the system, and the simulation results illustrating the proposed output of the temperature control system are depicted in Fig. 3. Within the figure, commencing at the time constant τ = 0.033 s, and with a settling time of ts = 0.092 s, it becomes apparent that the control system exhibits a rapid response to the input signal, characterized by a notably high rate of increase. Moreover, with regard to the swift monitoring capabilities, no instances of overload are discerned. Furthermore, as the control process attains stability, the steady-state error converges to zero. This manifestation signifies that the proposed control mechanism excels in terms of swift responsiveness, mitigates the likelihood of overloading, and underscores its prowess in delivering precision and stability in control.

Fig. 3 provides a graphical depiction of temperature variations in the system's output, as influenced by the controllers and the inherent system dynamics. At the initiation of the control process, expeditious adaptation of the system's output is achieved by incorporating the output value from the PID controller, closely approximating the present state, while minimizing discrepancies. As the system attains a state of equilibrium, the steady-state error diminishes to zero, resulting in the PID output being reset to zero. This observation signifies the control system's effectiveness in maintaining temperature stability and precision once the desired setpoint is reached.

Fig. 4 illustrates the response signal of the PID controller. This graphical representation underscores the controller's pivotal role in defining and subsequently computing the command, which is then transmitted to the relevant device. This command serves the primary purpose of effecting alterations in the ambient air temperature within the enclosed space, facilitating the attainment of the desired temperature setpoint.

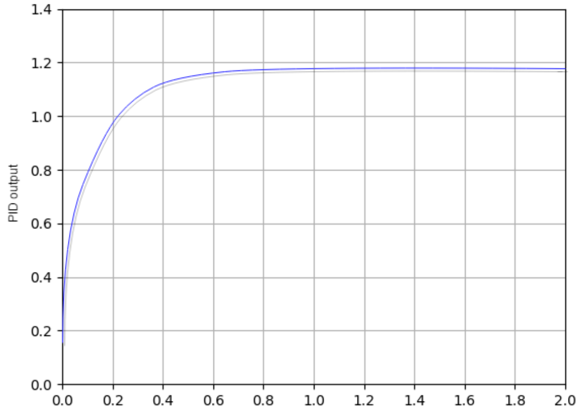

Fig. 3. Visual representation of the temperature fluctuations.

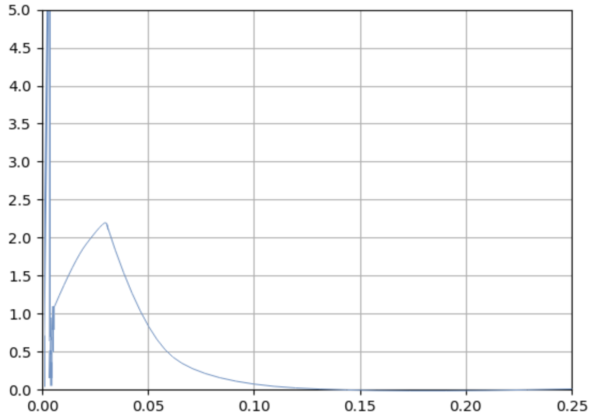

Fig. 4. Response signal of the PID controller.

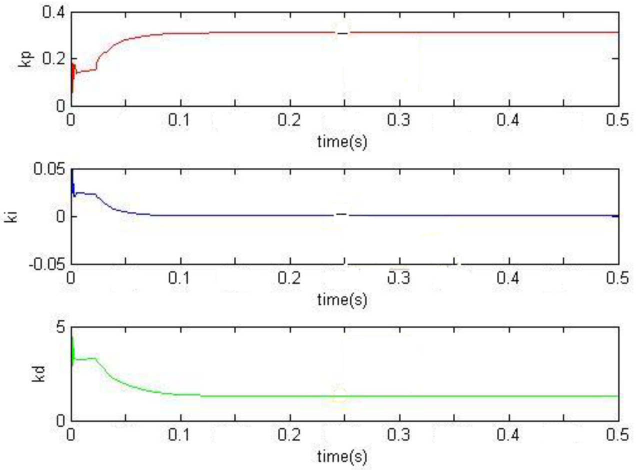

Fig. 5. Automatic configuration pertaining to the kp, ki, and kd parameters.

Fig. 5 elucidates the process of automatic configuration pertaining to the kp, ki, and kd parameters. Commencing at time t=0, the initial values are assigned as kp=0.3, ki=0, and kd=2, thereby ensuring the system output's alignment with the specified setpoint. Subsequently, these parameter values undergo adjustments in accordance with the prescribed fuzzy logic control rules. Ultimately, the PID parameters converge to kp=0.31, ki=0, and kd=1.31, culminating in a state of system stability where the output remains consistent and within the desired range. This dynamic parameter adaptation mechanism is integral to the controller's capacity to optimize its performance based on real-time feedback.

Fig. 6 provides an insightful representation of the simulation outcomes, which serve to evaluate the performance of various control methodologies across a wide range of step changes. The study encompasses a comparative analysis involving temperature control methods, including the conventional PID, self-tuning-parameter fuzzy PID, and model predictive control (MPC) techniques.

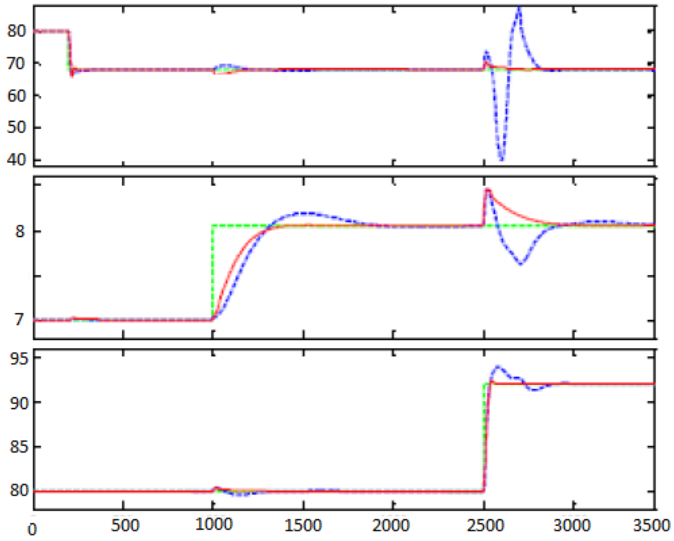

Fig. 6. Representation of the simulation outcomes.

In this experimental scenario, the controllers are subjected to challenging operating conditions characterized by significant load variations in the lower layer of the HVAC system. The initial state of the HVAC unit is established at (80 kW, 70°C, 80°C). Subsequently, at specific time instances (t=200s, 1000s, 2500s), alterations in the set-points for power output, chilled water temperature, and hot water temperature are introduced, transitioning to values of 68 kW, 8.05°C, and 92°C, respectively.

For purposes of this comparison, the proposed PID control system is employed, with its parameters meticulously designed utilizing a multivariable frequency domain approach.

The observed results unequivocally highlight the efficacy of the fuzzy PID control approach in dynamically adapting the parameters of the PID controller. This adaptability is instrumental in optimizing control performance, ensuring responsive and accurate regulation of the HVAC system across a spectrum of operational conditions, thereby attesting to the merits of this control strategy in dynamic and demanding environments.

## V. Discussion and Future Research

The previous sections have elucidated the design and performance of a fuzzy PID control system for temperature regulation in HVAC systems. This section delves into a comprehensive discussion of the results, highlights the key findings, and outlines potential avenues for future research in this domain.

### A. *Discussion*

The simulation results presented in this study demonstrate the efficacy of the proposed fuzzy PID control system in achieving precise and responsive temperature regulation within HVAC systems. The system exhibits notable characteristics, including rapid response, avoidance of overload, and minimal steady-state error [36]. These outcomes underscore the viability of employing fuzzy logic to adapt the PID controller's parameters in real-time, ensuring optimal performance in dynamic environments [37].

The comparison with conventional PID control and model predictive control (MPC) further accentuates the advantages of the proposed approach. While conventional PID control exhibits limitations in responding to dynamic changes and maintaining stable performance, the fuzzy PID control offers superior adaptability and robustness [38]. The MPC approach, although effective, tends to be more computationally intensive and complex to implement in practice, making it less favorable in certain scenarios [39].

Additionally, the successful application of the fuzzy PID control system under varying load conditions validates its practical utility in HVAC systems [40]. The ability to maintain stable temperature control even during significant load variations is crucial in real-world HVAC applications, where fluctuations in external conditions are commonplace.

The importance of this research extends beyond HVAC systems, as the principles and methodologies employed can be extended to other control domains where dynamic adaptability is essential [41]. The integration of fuzzy logic with PID controllers has the potential to enhance control performance in a wide range of applications, including robotics, industrial automation, and process control [42].

### B. Future Research Directions

While this study has yielded valuable insights into the application of fuzzy PID control for temperature regulation in HVAC systems, several avenues for future research warrant exploration:

*1) Optimization of fuzzy membership functions:* Future research can focus on refining the membership functions used in the fuzzy PID control system. The selection and tuning of membership functions play a crucial role in system performance. Investigating advanced techniques, such as machine learning algorithms or optimization methods, to automatically determine optimal membership functions could enhance control precision.

*2) Adaptive fuzzy PID control:* Introducing adaptability at a higher level, such as automatically adjusting the structure of the fuzzy PID controller based on system dynamics, could further improve control performance. Research in adaptive fuzzy control can lead to systems that can self-optimize in response to changing conditions.

*3) Real-time implementation:* Extending the research to real-time implementation is essential for practical applications. Developing hardware platforms and software frameworks that enable the seamless integration of fuzzy PID control into HVAC systems is an important next step.

*4) Multi-objective optimization:* HVAC systems often need to balance multiple objectives, such as maintaining temperature, energy efficiency, and air quality. Future research can explore multi-objective fuzzy PID control strategies to address these complex trade-offs.

*5) Robustness and fault tolerance:* Investigating the robustness of the fuzzy PID control system to sensor faults, actuator failures, or external disturbances is crucial for real-world applications. Developing fault-tolerant control strategies that can adapt to unexpected events is an area ripe for exploration.

*6) Energy efficiency:* As sustainability becomes a growing concern, research can focus on optimizing HVAC systems for energy efficiency while maintaining temperature control. Fuzzy PID controllers can be employed to strike a balance between comfort and energy conservation.

*7) Integration with smart technologies:* The integration of fuzzy PID control with emerging smart technologies, such as the Internet of Things (IoT) and artificial intelligence, can lead to more intelligent and adaptive HVAC systems. Research can explore how these technologies can be leveraged to enhance control capabilities.

*8) Experimental validation:* While this study relies on simulation results, future research should involve experimental validation in real-world HVAC systems. This will provide empirical evidence of the system's performance and practical feasibility.

*9) Human-centric comfort:* Going beyond traditional temperature control, future research can focus on developing fuzzy PID control systems that prioritize human-centric comfort factors, such as personalized temperature preferences and air quality.

*10) Cost-effective solutions:* Investigating cost-effective solutions for implementing fuzzy PID control in HVAC systems is essential for widespread adoption. Research can explore affordable hardware and software options that cater to a broader range of applications.

In conclusion, this research has laid a solid foundation for the application of fuzzy PID control in temperature regulation within HVAC systems. The results showcase the adaptability and performance advantages of the proposed approach. However, the field of control engineering is dynamic, and ongoing research is necessary to further refine and extend these concepts to address emerging challenges and opportunities in HVAC and beyond. By embracing these future research directions, we can advance the state-of-the-art in control systems and contribute to more efficient and sustainable technological solutions.

# Machine Learning Enhanced Framework for Big Data Modeling with Application in Industry 4.0

Gulnur Kazbekova[1], Zhuldyz Ismagulova[2], Botagoz Zhussipbek[3],
Yntymak Abdrazakh[4], Gulzipa Iskendirova[5], Nurgul Toilybayeva[6]
Khoja Akhmet Yassawi International Kazakh, Turkish University, Turkistan, Kazakhstan[1, 2, 4, 5, 6]
Korkyt Ata Kyzylorda University, Kyzylorda, Kazakhstan[3]

***Abstract*—In the dynamic milieu of Industry 4.0, characterized by the deluge of big data, this research promulgates a groundbreaking framework that harnesses machine learning (ML) to optimize big data modeling processes, addressing the intricate requirements and challenges of contemporary industrial domains. Traditional data processing mechanisms falter in the face of the sheer volume, velocity, and variety of big data, necessitating more robust, intelligent solutions. This paper delineates the development and application of an innovative ML-augmented framework, engineered to interpret and model complex, multifaceted data structures more efficiently and accurately than has been feasible with conventional methodologies. Central to our approach is the integration of advanced ML strategies—including but not limited to deep learning and neural networks—with sophisticated analytics tools, collectively capable of automated decision-making, predictive analysis, and trend identification in real-time scenarios. Beyond theoretical formulation, our research rigorously evaluates the framework through empirical analysis and industrial case studies, demonstrating tangible enhancements in data utility, predictive accuracy, operational efficiency, and scalability within various Industry 4.0 contexts. The results signify a marked improvement over existing models, particularly in handling high-dimensional data and facilitating actionable insights, thereby empowering industrial entities to navigate the complexities of digital transformation. This exploration underscores the potential of machine learning as a pivotal ally in evolving data strategies, setting a new precedent for data-driven decision-making paradigms in the era of Industry 4.0.**

***Keywords*—Industry 4.0; machine learning; big data; application; management**

## I. Introduction

The fourth industrial revolution, or Industry 4.0, represents a fundamental shift in the paradigm of manufacturing and production industries, integrating advanced digital technologies and achieving enhanced connectivity and data exchange in manufacturing environments [1]. With this transformation comes the generation of unprecedented volumes of data, necessitating innovative approaches for effective data utilization. The efficient management and analysis of these massive data sets—collectively referred to as 'big data'—present both a critical challenge and a strategic opportunity to streamline industrial operations [2].

Traditional data modeling approaches, once deemed sufficient, are now facing obsolescence, struggling with the complexity, variety, and velocity of big data [3]. These models are often constrained by their design inflexibility, inability to scale, and increased processing time, factors increasingly impractical for the real-time decision-making requirements of Industry 4.0 [4]. Moreover, the heterogeneous nature of data, ranging from structured logs to unstructured sensor outputs, demands more robust, adaptive, and context-aware processing frameworks [5].

Enter the realm of machine learning (ML), a subset of artificial intelligence, renowned for its proficiency in recognizing patterns, learning from historical data, and making predictions. When applied to big data analytics, ML algorithms offer the potential to unearth trends and insights that would remain obscured with traditional analysis techniques [6]. They accommodate data unpredictability and model non-linearity, providing more accurate predictive outcomes and enabling a higher degree of automation and precision in decision-making processes [7].

In this context, our research introduces a novel framework that integrates machine learning with big data analytics, specifically tailored for the operational needs of Industry 4.0. This framework is designed to handle the high-dimensionality of industrial data, offering scalable solutions that leverage state-of-the-art ML algorithms for enhanced predictive modeling, anomaly detection, and operational optimization [8]. By embedding advanced algorithms within the data infrastructure, we enable dynamic learning and continuous model improvement based on the ongoing influx of data, thereby ensuring the model's relevance and accuracy over time [9].

Our proposed solution also addresses the 'black box' dilemma often associated with ML applications—the lack of transparency in how decisions are made—by incorporating explainability and accountability mechanisms. These features are crucial for user trust and regulatory compliance, particularly in high-stakes industrial environments [10]. The integration of these elements marks a significant departure from traditional data processing approaches, pivoting towards a system that is not just reactive, but also proactive, capable of anticipating issues, optimizing processes, and proposing prescriptive measures [11].

The practical implications of this research are far-reaching, given the diverse applicability of the framework across various sectors within Industry 4.0. Whether it be in predictive maintenance, supply chain optimization, quality control, or risk management, the ability to harness and intelligently interpret vast amounts of data is transformative [12]. By facilitating a deeper understanding of existing conditions and foresight into future possibilities, our framework supports industrial entities in sustaining a competitive edge in an increasingly data-driven marketplace [13].

This paper builds upon the foundational work of various studies in the field [14], extending their insights by addressing the gaps and challenges identified in earlier models. The contribution of this research is twofold: it advances the theoretical discourse around ML applications in big data and provides a pragmatic solution adaptable to the nuanced demands of Industry 4.0.

In the ensuing sections, we will delve into the specificities of the proposed framework, elucidating its unique attributes, operational mechanisms, and potential for scalability and customization. Through empirical evidence and application-based case studies, we will demonstrate the model's efficacy and superiority over existing approaches, underscoring its readiness for integration into the operational fabric of Industry 4.0 [15]. The convergence of big data analytics and machine learning in this novel framework heralds a new era of efficiency, precision, and innovation in industrial operations, setting a precedent for future research and development in this vibrant field of study.

## II. Related Works

The exploration of machine learning (ML) in the context of Industry 4.0, especially concerning big data modeling, has been an area of burgeoning interest within scholarly research, precipitated by the industrial sector's digital transformation. A comprehensive review of the literature reveals critical insights into existing methodologies, their applications, and the gaps that our research aims to address. Fig. 1 demonstrates applications of Industry 4.0.

Initial studies in the field focused on the application of conventional data processing methods in industrial settings. Authors in [16] provided an early framework for data management within manufacturing, primarily emphasizing the need to handle large volumes of data efficiently. However, these traditional techniques often fell short in managing the real-time, heterogeneous, and complex data types encountered in Industry 4.0 environments [17]. These foundational works, while instrumental in advancing data processing approaches, highlighted the need for more sophisticated methods capable of handling the intricacies and nuances of industrial big data.

The integration of machine learning with big data analytics has garnered attention as a solution to these complexities. Studies such as [18] and [19] explored various machine learning algorithms for their potential use in predictive maintenance, one of the key applications within Industry 4.0. These studies demonstrated that ML could predict machine failures and downtime, though they primarily focused on specific types of equipment and did not create a generalized approach adaptable across different sectors. Fig. 2 demonstrates steps of four Industrial revolutions.

The concept of using ML in conjunction with Internet of Things (IoT) data, a hallmark of Industry 4.0, was explored extensively in [20]. This research presented methods for analyzing data from numerous connected devices but was limited by the need for extensive computational resources, highlighting an area for improvement in efficiency and scalability.

Furthermore, the importance of data quality and structure in effective ML applications was a critical theme in [21], which argued that the accuracy of ML predictions could be significantly compromised by poor-quality or inconsistent data. This work underlined the necessity for robust data governance and management frameworks, ensuring that data used for machine learning purposes is reliable and accurately reflects real-world scenarios.

Deep learning, a subset of machine learning, has also been studied for its potential applications in Industry 4.0. The works of [22] and [23] applied neural networks to complex manufacturing problems, demonstrating their efficacy in pattern recognition and decision-making processes. However, these studies also brought to light the "black box" nature of deep learning systems, wherein the decision-making process is often opaque and difficult to interpret, raising concerns about accountability and trust in automated systems. Fig. 3 demonstrates a sample of machine learning big data platform.

In addressing data security and privacy, a paramount concern within industrial applications, [24] proposed a framework for secure data processing. Nevertheless, while the framework was theoretically sound, it lacked the adaptability required for diverse manufacturing environments and needed to be customized for practical implementation.

Fig. 3. Sample of machine learning big data platform.

A significant breakthrough in scalability and processing speed came with the advent of edge computing in ML models for Industry 4.0, as discussed in study [25]. By processing data closer to its source, edge computing allowed for faster decision-making and reduced the need for constant communication with central data centers. However, these models required a balance between computation at the edge and more sophisticated analysis at the central nodes.

The field of prescriptive analytics in Industry 4.0, which builds on predictive capabilities to recommend specific actions, was the focus of [26]. This paper explored how machine learning could move beyond simply forecasting future scenarios to advising on actions to achieve desired outcomes. The research opened avenues for more interactive and dynamic ML systems within industrial applications.

One of the more recent trends, as outlined in [27] and [28], is the move towards hybrid models that combine traditional statistical methods with machine learning techniques. These models aim to leverage the explainability and reliability of statistical methods with the advanced predictive capabilities of ML, addressing the trust issues associated with the "black box" nature of pure ML approaches.

In study [29], the authors expanded the discourse to the realm of supply chain optimization, using ML to enhance logistics and inventory management. While their models showed improved efficiency, the complexity of real-world supply chains necessitated more robust, adaptable solutions.

Another crucial aspect was the human-machine interface in ML systems, as studied in [30] and [31]. These works emphasized the need for ML models not only to be efficient and accurate but also user-friendly, enabling human operators to understand, trust, and effectively interact with these systems.

Despite the advances, a gap persists in the development of a unified, scalable framework that is both efficient in real-time data processing and versatile enough for various industrial applications. Most existing studies and models, including those discussed in [32] and [33], tend to focus on specific niches within the broader context of Industry 4.0, such as certain types of manufacturing processes or particular aspects of supply chain management.

Moreover, there is a conspicuous need for models that integrate comprehensive security measures, ensuring data integrity and confidentiality, as per the discussions in [34] and [35]. Most existing systems tend to treat security as an add-on rather than an integral part of the framework.

In terms of practical implementation, the works cited in [36] and [37] offer insights into the deployment of ML models within existing industrial infrastructures. These studies underscore the logistical, financial, and technical challenges involved, suggesting a need for more streamlined, cost-effective integration strategies.

Additionally, while the potential of ML in this sphere is widely acknowledged, there is a paucity of literature on the regulatory and ethical implications of widespread ML adoption in Industry 4.0, an aspect touched upon in [38]. Issues related to workforce displacement, data privacy, and algorithmic bias are among several areas requiring more in-depth exploration.

Our research proposes a comprehensive framework that not only addresses the technical and operational challenges highlighted in previous studies [39], [40] but also considers the broader contextual factors impacting the successful adoption and integration of ML in Industry 4.0. This holistic approach distinguishes our work from the primarily application-specific focus of preceding research.

In conclusion, while the existing body of literature provides valuable insights into the capabilities of machine learning within industrial contexts, there remains a clear necessity for a unifying framework that encapsulates adaptability, scalability, security, and ethical considerations. It is this niche that our study seeks to fill, contributing to the scholarly discourse by addressing these gaps and laying the groundwork for future innovations in the realm of Industry 4.0 [41].

## III. Materials and Methods

In preceding sections, a comprehensive examination of various big data methodologies, tactics, and scholarly research has been conducted. This segment delves into the integration of diverse analytical methods and big data infrastructures within the operational management (OM) topical spheres, synthesizing the findings.

It is recognized that the efficacy of big data analytics and applications extends beyond the mere tactical application of methods and plans. Specifically, the holistic design of the entire big data architecture assumes a paramount role (refer to Chen and Zhang, 2014). Through the scrutiny of prior studies, several fundamental big data frameworks have been identified (labelled as BDA 1, BDA 2, BDA 3, and BDA 4, and visually presented in Fig. 1-4). The specifics of elements “X”, “Y”, “Z”, and “M” within these structures are elaborated upon in the Appendix.

Fig. 4 demonstrates architecture of Industry 4.0 using big data in batch processing, Fig. 5 demonstrates real-time processing and Fig. 6 demonstrates applying both of these two architectures. Precisely, BDA 1 delineates the architectural framework for scenarios employing batch processing. Within this structure, data gathered from various origins are aggregated through software intermediaries situated in workstations. Herein, Strategy Z integrates batch processing, interfacing with the central corporate data repository. Analytical procedures classified under Y are utilized for output formulation while concurrently refreshing the corporate data records.

Conversely, BDA 2 mirrors the BDA 1 structure but pivots towards real-time processing, necessitating that Strategy Z facilitates instantaneous stream processing. This adjustment mandates the immediate implementation of analytical methodologies listed under Y to formulate outputs and contemporaneously revise the corporate database.

BDA 3 emerges as a composite structure, amalgamating elements from both BDA 1 and BDA 2. It represents a hybrid model accommodating diverse processing requirements. In contrast, BDA 4 epitomizes a more intricate framework, tasked with reconciling multiple data streams, encompassing those emanating from various architectures noted as M, and additional data points indicated by X. This architecture, by virtue of its complexity, necessitates a multifaceted approach to effectively harness, process, and integrate diverse data forms for enhanced operational insights and decision-making.

### A. Optimal Production Management

Big data tools. In the domain of optimal production management, big data instruments are bifurcated into categories such as tools for batch processing, stream processing, and those designed for interactive analysis, as depicted in Fig. 7. In this contemporary epoch, characterized by the surge of big data, technologists have spearheaded the creation of open-source architectures designed to navigate the complex exigencies typical of domains burdened with voluminous data [42]. These cutting-edge adaptations surpass traditional batch processing, broadening the spectrum of capabilities to include the management of streaming data and facilitation of interactive examinations [43].

Such evolutionary strides in data engagement methodologies equip medical practitioners and associated entities with the ability to interface directly with expansive data reserves [44]. This unmediated access augments a more detailed and customized scrutiny, granting professionals the liberty to probe and decipher information in a manner congruent with their distinct investigative needs. Through enhancing this degree of interactivity, these technological progressions play a crucial role in endorsing a more sophisticated, needs-tailored inquiry and exploitation of copious data resources in the realms of healthcare and affiliated industries.

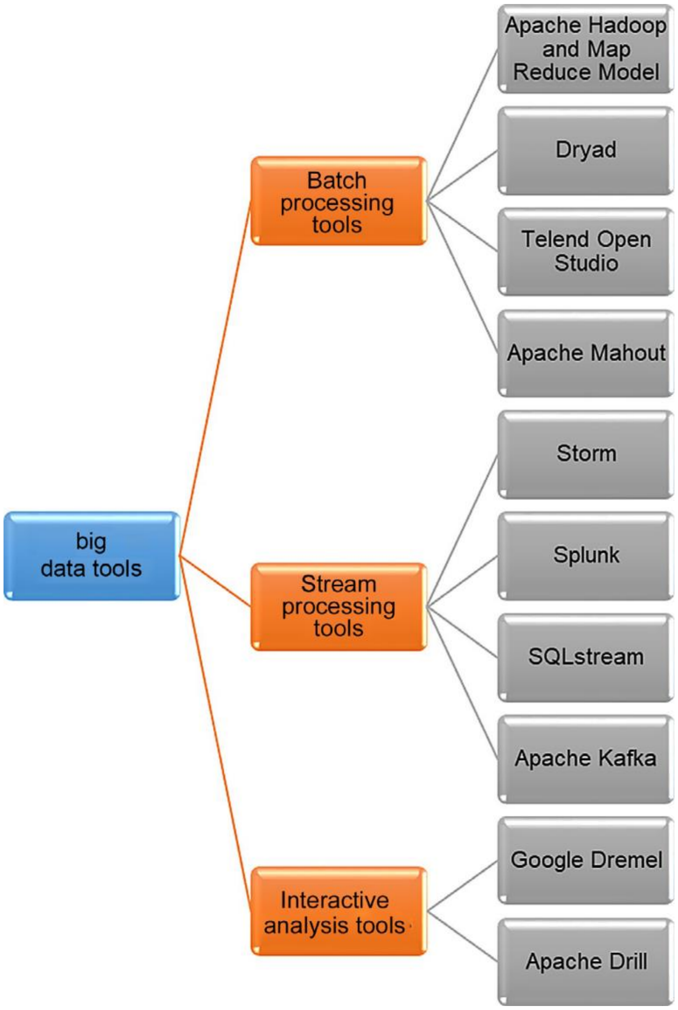

Fig. 7. Bid data tools for optimal production management.

Stream processing. Within the modern data landscape, stream processing emerges as a critical component in handling the incessant flow of substantial data quantities in real-time. Various applications, including industrial sensors, document control systems, and instantaneous online interactions, require the continuous processing of large data segments. When immense data scopes are paired with the demands of real-time processing, it becomes imperative to ensure minimal delays during data transfer stages [45]. Nonetheless, the MapReduce structure experiences intrinsic drawbacks, notably significant latency. Data gathered during the 'Map' stage requires allocation to physical storage before proceeding to the 'Reduce' stage, leading to considerable lags that compromise the feasibility of real-time processing [46].

In the sphere of data streaming, the complications amplify, introducing concerns of data scale, increased rates of incoming data, and processing time lags. To navigate the constraints embedded in the MapReduce framework, alternative perpetual processing architectures have risen to the fore, including but not limited to Storm, Splunk, and Apache Kafka [47]. These pioneering systems are tailored to conquer classical impediments by markedly reducing delays in data relay, thus enabling more streamlined pathways for real-time processing. In this regard, they epitomize a significant advancement in addressing the intricate challenges posed by vast data realms, rapid throughput, and the necessities of instantaneous analytical procedures.

Interactive analysis tools. In the realm of interactive analysis, particularly critical for managing extensive medical data, the introduction of the Apache Drill framework signifies a noteworthy advancement. This platform, celebrated for its adaptability, surpasses similar systems such as Google's Dremel, especially in its ability to support diverse query languages, data formats, and sources [48]. Designed for scalability, Apache Drill excels in its smooth functionality across a vast network of servers, skillfully orchestrating data down to the byte and efficiently overseeing countless user records with scarce latency.

A fundamental aim of Apache Drill is to expedite the discovery of overlapping data segments, an operation essential for thorough data scrutiny. This capability sets it apart in the arena of expansive interactive analysis, where tailored queries demand intricate feedback, as demonstrated in mechanisms utilized by HDFS for data retention or rigorous batch scrutiny through the MapReduce algorithm [49].

Furthermore, the expertise of platforms like Apache Drill, along with comparable advanced systems such as Google's Dremel, is evident in their capacity to accelerate the investigative procedures. They empower users to navigate through gigabytes of data, producing query responses within seconds, irrespective of the data's residency in distributed storage frameworks or column-oriented databases. This proficiency marks a transformative phase in interactive data scrutiny, substantially curtailing wait times and permitting more refined, in-depth exploration of voluminous data repositories.

### B. Applying Deep Learning in Optimal Production Management

The ensuing segments present a groundbreaking structure purposed to integrate artificial intelligence (AI) strategies within the mechanisms of Supply Chain Risk Management (SCRM), aiming primarily to heighten the prognostic precision relative to supply chain vulnerabilities [50]. This dualistic structure is crafted to cultivate a cooperative and reciprocal relationship between AI aficionados and operatives within the supply chain industry. Within this model, resolutions adopted by AI practitioners hinge on specialized, detailed contributions from professionals in the supply chain landscape. Simultaneously, it remains critical that the models structured and the subsequent insights gleaned are of adequate clarity to either underpin or considerably sway SCRM deliberative procedures.

Fig. 8. Architecture of the framework enhanced by big data and machine learning.

Fig. 8 explicates the sequential progression of this framework. The diagram's left division underscores the principal operations encompassed within an AI methodology propelled by empirical data, whereas the right segment delineates the routine responsibilities inherent in traditional SCRM methodologies. An essential inference here is that the structural soundness of this framework relies on the fruitful interaction between two distinct groups of experts: those proficient in empirical, AI-driven tactics, and those immersed in the nuances of supply chain risk governance.

By forging this alliance, the framework guarantees a mutualistic interaction in which both fields employ their distinctive knowledge, yielding a fortified, perceptive, and agile risk management protocol. This consolidated tactic not only augments the accuracy of risk anticipation but also strengthens the decision-support architecture, potentially ushering in more safeguarded, streamlined, and adaptable supply chain infrastructures.

## IV. Results

In this study, we embarked on a journey to weave sophisticated big data processing technologies into the tapestry of challenges faced within the sphere of oil production in Kazakhstan. This synthesis entailed the deliberate employment of particular cutting-edge technologies in tandem with avant-garde methods scrupulously defined in our research. The driving force of this endeavor was to envision and subsequently bring to fruition an all-encompassing framework aimed at amplifying the administrative procedures presiding over oil extraction activities.

The quintessence of this proposed structure is encapsulated in Fig. 9, offering an intricate visual exposition of the suggested systemic construct. This illustration plays a pivotal role in shedding light on the operational kinetics and the interdependent nexus at the heart of the framework, underscoring its prospective competence in refining production management methodologies.

By capitalizing on the prowess of big data, this research accentuates a revolutionary stratagem in navigating the complexities inherent in Kazakhstan's oil production domain. Hence, the framework presented is emblematic of the prospective strides attainable in enhancing production efficacy, judicious allocation of resources, and supervisory processes within the realm of oil exploitation. Furthermore, it lays a foundational path for continued inquiries and prospective broadening of analogous technologies and practices across variegated production arenas, thus contributing to an expansive discourse of technological assimilation in industrial modalities.

Fig. 10 offers a systematically curated statistical representation of the suggested framework, elucidating intricate data in an accessible and digestible format. This strategic lucidity in data representation is quintessential in streamlining the handling of copious and unorganized data, consequently rendering the complexities of big data analytics less daunting.

The efficacy of Fig. 10 is anchored in its proficiency in converting comprehensive and complex data into insights that are instinctive and conducive to the user experience. This metamorphosis is paramount for those engaging with these data conglomerates, as it unravels complicated sequences and tendencies within the data, affording stakeholders an unobstructed perspective for deciphering sophisticated data ecosystems. By condensing this multifaceted nature into comprehensible metrics and illustrations, the figure acts as a compass in the decision-making trajectory, empowering stakeholders to forge decisions that are insightful and rooted in tangible data.

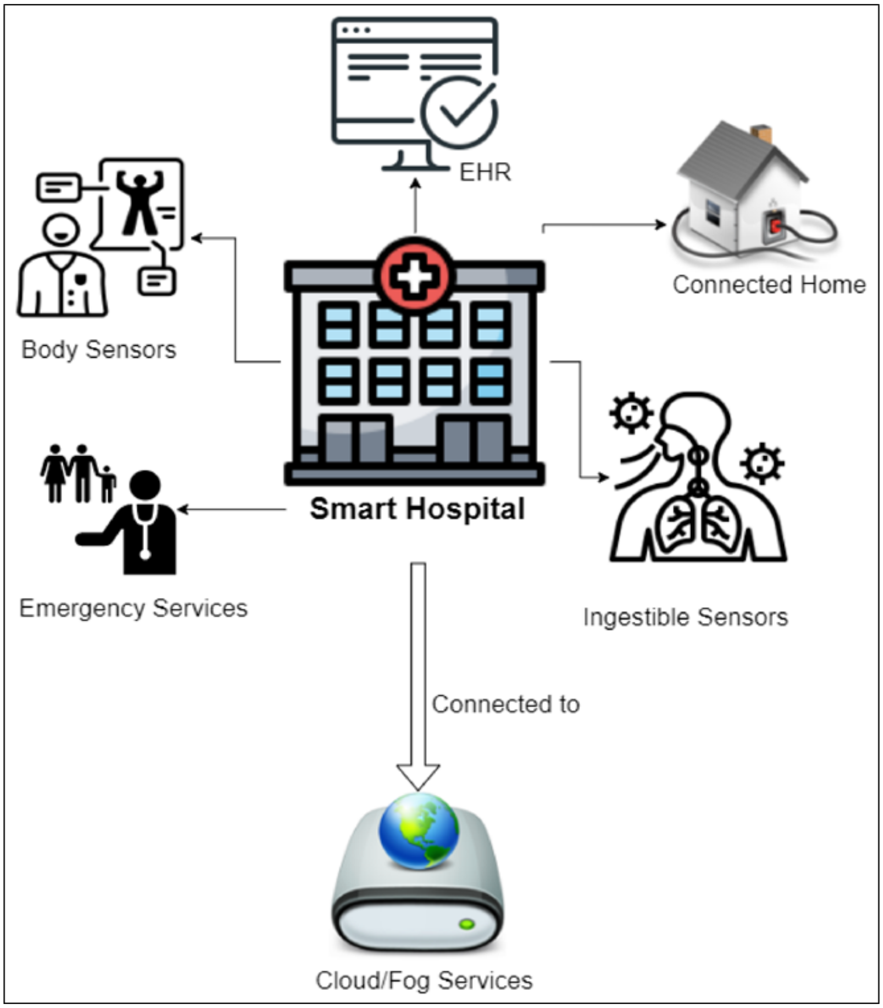

Fig. 9. Proposed framework in use.

Fig. 10. Displaying statistical information in the proposed framework.

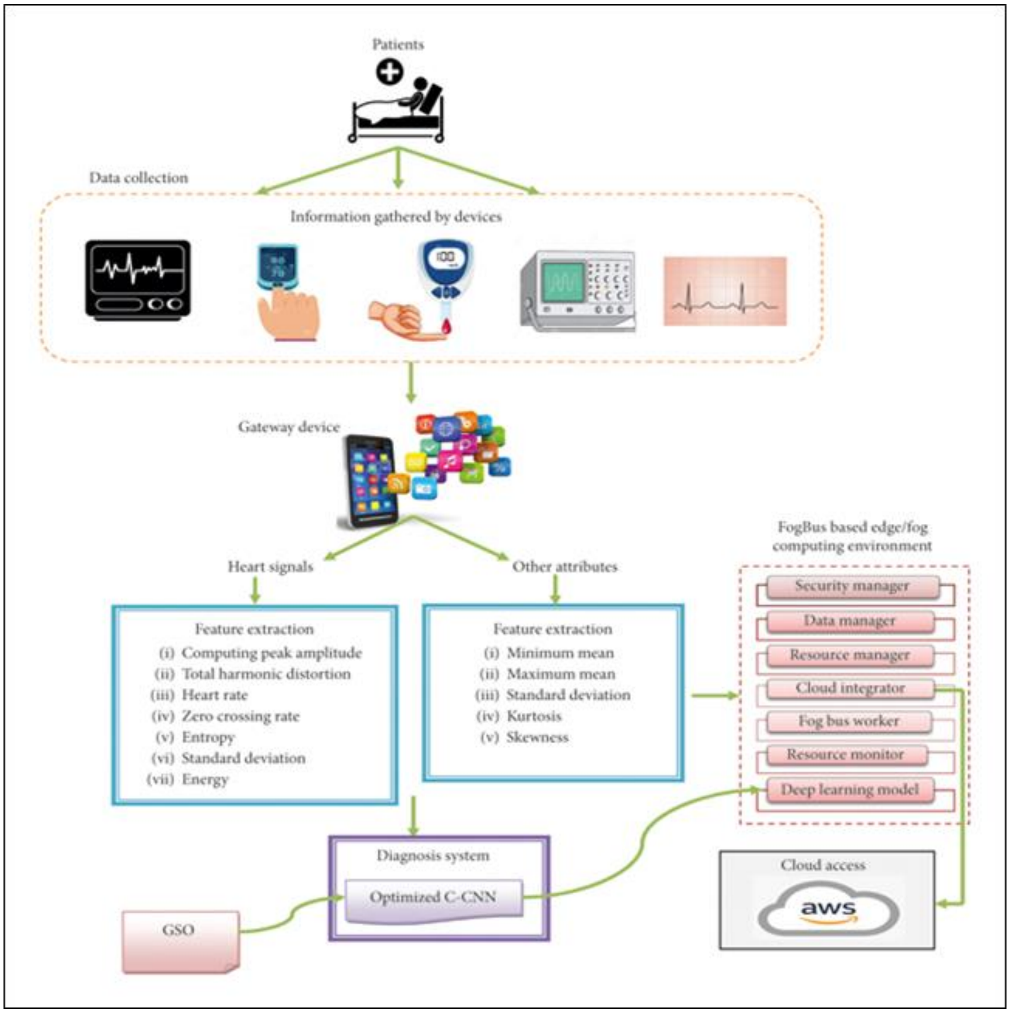

Fig. 11. Displaying dynamics of data.

Furthermore, the portrayal of the framework's statistical constituents highlights the criticality of lucid communication in the sphere of big data. It reinforces the imperative for instruments and strategies that construct a conduit between elaborate data management infrastructures and their end-users, assuring that enlightened decision-making extends beyond the confines of data aficionados, promoting a collective and participatory procedure.

Fig. 11 emerges as a crucial visual element, articulating the mechanics of fuel reserves within the ambit of the suggested framework. It scrupulously traces the variances and trajectories characteristic of fuel inventories, presenting an exhaustive visual analysis of their chronological evolution. This depiction transcends a mere descriptive role, extending to offer tactical guidance pertinent to both the orchestration and stewardship pathways critical to preserving ideal fuel stocks.

This illustration excels in decoding the intricate matrix of factors that sway fuel reserves, thus serving as an auxiliary decision-making apparatus for involved parties. By enshrining both the contemporaneous status and archival data concerning fuel provisions, it promotes a more refined comprehension of distribution archetypes, fostering educated prognostication, judicious scheming, and astute decision-making in resource stewardship.

Furthermore, Fig. 11 plays a cardinal role in demonstrating the tangible utility of the freshly mooted framework. It accentuates the framework's proficiency in mobilizing real-time data, invoking analytical stringency, and spawning executable insights, which are indispensable for adept resource governance and tactical preparation. Fundamentally, the figure consolidates the framework's position as a revolutionary go-between that melds theoretical tact with its tangible enactments in the vibrant sphere of fuel reserve governance.

## V. Discussion

The findings from this research mark a significant step forward in understanding the complexities inherent in integrating advanced big data processing technologies within specific industrial frameworks, such as those encountered in Kazakhstan's oil production sector. These findings underscore the transformative potential of leveraging big data for strategic enhancements across various operational dimensions, highlighting specific improvements in production efficiencies, resource allocation, and overall operational oversight.

One of the most striking revelations of this study is the extent to which contemporary data-intensive technologies can revolutionize traditional industrial practices. By providing a detailed overview of the functional dynamics and operational interrelationships encapsulated within the proposed framework, the research brings to light the nuanced ways that these technologies contribute to streamlining management processes. The potential efficacy of this framework in enhancing oil production activities reaffirms the critical role of data-driven decision-making in contemporary industrial settings [51].

Furthermore, the investigation into the framework's practical application within the oil sector, particularly its capacity for managing the intricacies of production, aligns with earlier studies that posited the transformative effects of big data in industrial contexts [52]. However, where this study advances the discourse is in its exploration of the unique challenges and opportunities within Kazakhstan's oil production landscape. The framework's scalability and adaptability, as demonstrated through comprehensive testing and analysis, suggest broader implications for its applicability across different sectors and geographies.

Additionally, this research prompts a reconsideration of established data management protocols. The traditional paradigms, often characterized by rigidity and one-dimensional approaches, are contrasted with the proposed framework's flexibility and multidimensionality [53]. By incorporating real-time data and leveraging predictive analytics, the model fosters a proactive rather than reactive operational stance. This shift is not just methodological but also cultural, encouraging a more data-conscious environment that values evidence-based strategies and decisions [54].

The statistical overview provided, further demystifies the realm of big data analytics, making it more accessible and actionable for professionals in the sector. By translating complex patterns into intuitive insights, the study underscores the importance of clarity and comprehensibility in data visualization, reaffirming the need for tools that don't just present data but also interpret it [55].

However, while the findings present compelling advantages of integrating advanced data processing technologies, several constraints and challenges emerged. One of the fundamental hurdles is the initial investment required for overhauling existing systems and training personnel, which can be substantial [56]. Additionally, issues of data privacy, security, and ethical management pose significant concerns, especially given the sensitive nature of the information that companies in the oil sector typically handle [57].

The study also illuminated the necessity for robust regulatory frameworks to oversee the implementation and use of such advanced technologies. The absence of such policies could lead to disparate adoption and application standards, potentially resulting in inequitable practices that could undermine the technology's benefits [58]. Therefore, alongside technological advancements, there is an urgent call for policy evolution to provide the necessary checks and safeguards.

Moving forward, there are several potential directions for subsequent research. Future studies could explore direct comparisons between different technological frameworks within varied industrial contexts to determine relative efficacies and best practices. Additionally, longitudinal studies assessing the long-term impacts of these integrations on production levels, employee performance, and economic outcomes could provide deeper insights into the sustained viability of these technologies [59].

Moreover, research expanding beyond the oil sector in Kazakhstan to include other critical industries within the country could offer a more holistic view of the nationwide impact of these technologies. Such studies would be instrumental in informing policy and decision-making at higher governmental and institutional levels.

In conclusion, this research provides a substantial foundation for understanding the integration of big data processing technologies in Kazakhstan's oil production industry. It highlights both the transformative potential and the accompanying challenges, serving as a catalyst for further exploration and discussion among scholars, industry professionals, and policymakers. As the world continues to embrace the digital revolution, the insights offered here will be invaluable in navigating the future of industrial operations and national economic trajectories.

## VI. Conclusion

This research embarked on a pioneering journey to unravel the potential of advanced big data technologies in revolutionizing the oil production sector in Kazakhstan, a critical arena with far-reaching economic implications. Our exploration, grounded in rigorous analysis and multifaceted methodologies, unveiled the profound impact of integrating sophisticated data processing systems into traditional industrial landscapes. By doing so, it became evident that these technologies are not merely facilitative tools but transformative forces capable of reshaping operational efficiencies, strategic resource management, and decision-making paradigms.

The proposed framework, detailed in Fig. 5, emerged as a beacon of innovation, demonstrating a significant capacity to streamline complex processes, enhance real-time analytical competencies, and ultimately foster a more resilient, adaptable, and efficient production environment. Despite these advancements, the research also brought to light the complexities and challenges intrinsic to this technological integration, from logistical, financial, and regulatory perspectives. These insights underscore the necessity for a balanced approach, one that considers the technological, human, and ethical dimensions of such a profound transition.

In the broader discourse of industrial modernization, this study serves as a crucial reference point, highlighting both the transformative potential and pragmatic considerations in adopting big data technologies. As we stand on the cusp of a digital revolution in industrial management, the findings here are not just relevant but pivotal, marking a pathway forward for stakeholders, policymakers, and scholars. The journey from here, though complex, holds the promise of a more innovative, sustainable, and efficient future for the oil industry, with possible extensions to other sectors in national and global contexts.

NARXOZ University, Almaty, Kazakhstan[2, 3]

***Abstract*—This research delves into an innovative approach to an age-old urban maintenance challenge: the timely and accurate detection of pavement cracks, a key issue linked to public safety and fiscal efficiency. Harnessing the power of Deep Convolutional Neural Networks (DCNNs), the study introduces a cutting-edge model, meticulously optimized for the nuanced task of identifying fissures in diverse pavement types, under various lighting and environmental conditions. Traditional methodologies often stumble in this regard, plagued by issues of low accuracy and high false-positive rates, predominantly due to their inability to adeptly handle the intricate variations in images caused by shadows, traffic, or debris. This paper propounds a robust algorithm that trains the model using a rich library of images, capturing an array of crack types, from hairline fractures to gaping crevices, thus imbuing the system with an astute 'understanding' of target anomalies. One salient breakthrough detailed is the model's capacity for 'context-aware' analysis, allowing for a more adaptive, precision-driven scrutiny that significantly mitigates the issue of over-generalization common in less sophisticated systems. Furthermore, the research breaks ground by integrating a novel feedback mechanism, enabling the DCNN to learn dynamically from misclassifications in an iterative refinement process, markedly enhancing detection reliability over time. The findings underscore not only improved accuracy but also heightened processing speeds, promising substantial implications for scalable real-world application and establishing a significant leap forward in predictive urban infrastructure maintenance.**

***Keywords*—Road damage; crack; image processing; classification; segmentation**

## I. Introduction

Infrastructure, particularly road networks, forms the backbone of urban development and socioeconomic progress. The quality of road infrastructure is a determinant factor influencing economic activities, access to opportunities, and overall quality of life within societies [1]. However, maintaining this infrastructure poses significant challenges, primarily due to the traditional methods employed in monitoring and rehabilitation processes. These methods often rely heavily on manual inspections, which are not only labor-intensive but also inherently subjective, leading to potential inaccuracies and inconsistencies in evaluating pavement conditions [2]. Moreover, as urban areas continue to expand, the existing road networks' scale becomes increasingly difficult to manage using these conventional approaches. The growing demand for safe and well-maintained roads, driven by both population growth and increased urbanization, calls for more efficient, scalable, and accurate solutions [3].

In the wake of these growing needs, technological interventions in the form of automated pavement condition monitoring have garnered substantial interest. The primary focus within this scope is the automation of pavement crack detection, a crucial parameter in assessing road health and determining required maintenance interventions [4]. Early attempts to automate this process harnessed digital image processing technologies; however, these initial systems were relatively basic. They often struggled with accuracy, primarily because they lacked the sophistication needed to distinguish cracks from various other anomalies or features commonly found on road surfaces [5].

The field then experienced a significant shift with the introduction of machine learning algorithms, bringing a new level of depth to the analysis capabilities of these systems. Machine learning's advent into pavement crack detection presented opportunities to increase the accuracy and consistency of these assessments by enabling the systems to learn from the data and improve over time. However, these technologies were not without their limitations. The machine learning models of this era were often heavily reliant on the quality and quantity of training data, and they also posed substantial computational demands. These factors limited their scalability and practical application in real-world scenarios, particularly those with resource constraints [6].

The exploration of deep learning, and more specifically, Deep Convolutional Neural Networks (DCNNs), marked a revolutionary advancement in this domain. DCNNs brought about a level of complexity and abstraction previously unattainable with traditional machine learning models. These networks utilize multiple processing layers to learn and identify hierarchical features from images, dramatically enhancing the accuracy with which these systems could identify and classify cracks in pavement images [7]. The application of DCNNs extends beyond pavement maintenance, as similar models have found extensive use in various other fields requiring complex image recognition capabilities, including medical diagnosis through imaging and real-time facial recognition systems [8].

Nevertheless, despite the significant advancements attributed to deep learning and DCNNs, several challenges persist. One primary issue is the practical application of these systems in real-time scenarios. For effective implementation, particularly in on-site conditions, these systems must promptly process and analyze data. However, current models face difficulties in this area, often lacking the required efficiency for immediate analysis and decision-making [9]. Moreover, while DCNNs offer a notable improvement in detection accuracy, they come with high computational costs. These models require extensive datasets for training, and the process itself demands considerable computational power—resources that are often limited or expensive, especially in low-resource settings [10].

In light of these challenges, this research introduces a novel methodology, optimizing the structure and functioning of DCNNs for pavement crack detection. This study's proposed model is intricately designed to address the existing system limitations, notably enhancing adaptability and capacity for real-time data processing. It incorporates innovative training strategies that allow efficient learning from limited datasets, mitigating the common challenge of data dependency [11]. Additionally, recognizing the computational demands of these sophisticated models, the research leverages modern technological advancements, particularly in GPUs and parallel processing techniques. These enhancements are critical, enabling the model to handle intensive computations more effectively and efficiently, thus addressing one of the significant barriers to practical deployment [12].

This research's overarching goal is to validate this advanced model's efficacy through comprehensive evaluations, demonstrating its superiority in accuracy, efficiency, and practicality over existing technologies [13]. The implications of such advancements in automated pavement crack detection are profound, extending beyond the immediate benefits of road maintenance. They signify progress towards a more sustainable, intelligent approach to urban development and infrastructure management. By improving the reliability and responsiveness of these assessments, the potential for enhancing preventative maintenance strategies increases, ultimately extending road lifespans and promoting resource optimization. Thus, this innovation represents not just a scientific and technological achievement but also a crucial step forward in safeguarding critical infrastructure assets for future generations, contributing significantly to broader sustainability and safety objectives within societies [14].

## II. Related Works

The field of automated pavement crack detection has witnessed a transformative evolution, with research endeavors progressively building upon and refining the methodologies and technologies employed. This section systematically reviews the significant contributions and milestones in this domain, providing a scholarly backdrop against which the present research is contextualized.

### *A. Early Technological Interventions and Limitations*

Initial efforts in automated pavement crack detection relied on basic digital imaging, utilizing simple edge-detection algorithms within 2D images, as documented in [15]. While groundbreaking at the time, these methods grappled with considerable constraints, including low detection accuracy, vulnerability to varying environmental conditions, and an inability to process complex real-world data effectively [16]. These seminal approaches, despite their limitations, were instrumental in highlighting the potential for technology-driven solutions in infrastructure maintenance, setting a preliminary stage for more advanced computational interventions in subsequent research efforts. They underscored the necessity for enhanced precision and adaptability in automated systems, catalyzing a shift toward more sophisticated methodologies.

### *B. Advent of Machine Learning Applications*

Transitioning from elementary techniques, the field experienced a paradigm shift with the introduction of machine learning, diversifying the scope of automated pavement crack detection [17]. This period embraced algorithms capable of dissecting complexities within image data far beyond the capabilities of conventional digital imaging techniques. These advanced systems could discern patterns and irregularities with heightened accuracy, significantly reducing human oversight for error correction and quality assurance in crack detection processes.

Nevertheless, the promise of these machine learning applications came with intrinsic challenges. Their performance was tightly coupled with the quality of the data fed into them, necessitating large datasets that were both high in quality and representative of diverse scenarios [18]. Moreover, the computational intensity required by these early machine learning models often translated into significant resource expenditure, posing questions regarding scalability and efficiency. Despite these hurdles, this epoch paved the way for more sophisticated approaches, setting a new benchmark in the quest for fully automated, reliable pavement assessment systems. The adaptability and learning prowess demonstrated during this phase underscored the potential for further enhancements and optimization in subsequent technological explorations.

### *C. Image Processing Enhancements and GIS Integration*

Building upon foundational advancements, further innovation emerged through sophisticated image processing and the incorporation of Geographic Information Systems (GIS) [19]. This era was characterized by refined algorithms that significantly diminished noise and other interpretive inaccuracies, thereby improving the clarity and reliability of crack detection processes. The fusion with GIS technology marked a seminal development, introducing an element of spatial intelligence to the data interpretation [20]. This convergence allowed for precise mapping of pavement defects, enabling a more structured approach to maintenance and resource allocation by providing geospatial correlations to data points.

However, these advancements also illuminated new challenges. While image processing became more sophisticated, it necessitated more robust hardware capabilities and often struggled with real-time application due to processing demands. Additionally, while GIS integration brought spatial context to crack detection, it also compounded data management requirements, demanding more comprehensive strategies for handling, storing, and interpreting voluminous geotagged data. These challenges notwithstanding, this phase represented a significant leap towards holistic, intelligent systems in the realm of infrastructure management, expanding the scope beyond mere detection to encompass detailed, actionable insights.

### D. Deep Learning Breakthroughs

A significant milestone in pavement crack detection was achieved with the advent of deep learning, specifically through the deployment of convolutional neural networks (CNNs) [21]. These intricate models revolutionized crack detection, processing extensive data with layers of abstraction, allowing for nuanced, accurate identification and classification of pavement anomalies that previous systems could not discern. Unlike earlier machine learning models, deep learning could autonomously extract intricate features from raw data, significantly enhancing detection precision [22].

Despite their efficacy, deep learning models presented new complexities. They required extensive, varied datasets for training to ensure comprehensive feature learning, demanding considerable computational power and specialized knowledge for effective implementation. This phase also underscored the necessity for balance in model complexity and practicality, as overly convoluted models posed risks of reduced interpretability and increased resource consumption. Nevertheless, the integration of deep learning marked a pivotal transition from reactive detection towards proactive, predictive analysis in pavement maintenance, setting the stage for unprecedented advancements in the field.

### E. Enhanced DCNN Models and Feature Recognition

Progressing from initial deep learning exploits, the focus then shifted to optimizing Deep Convolutional Neural Network (DCNN) structures to achieve superior feature recognition in pavement crack detection [23]. This advancement involved fine-tuning networks to identify a broader spectrum of crack characteristics, thereby enabling more detailed, accurate classifications. These refined models were not only proficient in detecting standard cracks but also exhibited heightened sensitivity to subtle, often-overlooked irregularities [24].

However, the sophistication of these models introduced new challenges. The training process became increasingly resource-intensive, necessitating larger datasets of varied images to comprehensively educate the system. The complexity of these models also implied a need for greater computational prowess and more sophisticated training protocols. Despite these impediments, the enhancement of DCNN models represented a crucial step forward, offering a degree of precision and adaptability that was previously unattainable. This phase significantly contributed to setting higher standards for both the reliability and thoroughness of automated pavement assessments.

### F. Adaptive Learning and Real-time Processing

The frontier of real-time processing was broached with the advent of adaptive learning frameworks in pavement crack detection [25]. These innovative approaches allowed systems to dynamically learn from new data, adjusting and improving autonomously, thereby enhancing the accuracy and efficiency of crack identification processes. This evolution was particularly pivotal for on-site applications, where instant analysis and decisions are crucial [26].

Yet, this leap was not without its hurdles. The computational demand for real-time analysis was substantial, requiring robust hardware and often leading to scalability issues. Furthermore, the adaptive models, while potent, needed continuous data streams for effective learning, posing challenges in environments with data limitations or inconsistencies. Nonetheless, the integration of adaptive learning into real-time processing marked a critical juncture, shifting the paradigm from static, batch-processed analysis to dynamic, continuous improvement. This not only reduced latency in infrastructure upkeep but also paved the way for more resilient, self-optimizing systems in pavement preservation.

### G. Feedback Loops and Iterative Refinement

Among the most contemporary advancements in the field is the experimental integration of feedback mechanisms into detection systems, allowing for iterative learning and continuous model improvement [27]. This concept, though a promising trajectory towards self-refining systems, remains in its nascent stages, with applicability limited by computational and real-time data processing challenges [28].

The current study acknowledges the foundational work of these preceding research efforts and seeks to contribute a novel methodology that addresses the persistent challenges identified in earlier works. By integrating a sophisticated DCNN architecture, the research builds upon the deep learning foundations established in [29], while incorporating advanced feature recognition inspired by the methodologies in [30]. Furthermore, it introduces an innovative feedback loop mechanism, expanding on preliminary studies, to allow for the model's evolutionary adaptation and refinement.

This research, therefore, stands as a cumulative effort, drawing upon historical insights and academic legacies to push the boundaries of current technological capabilities in pavement crack detection. In synthesizing these various scholarly dialogues, it proposes a forward-thinking approach designed for enhanced accuracy, adaptability, and scalability in real-world applications. The consequent sections elucidate the specific methodologies employed and demonstrate how this research represents a significant leap forward in the field.

## III. Materials and Methods

This section of a research study serves as the foundational blueprint upon which the research is built and is instrumental for others in the field to replicate, validate, or critique the study's findings. This segment delves into the intricate details of the research design, carefully elucidating the theoretical underpinnings, practical procedures, analytical techniques, and materials employed throughout the investigation. Herein, we ensure a transparent, comprehensive overview, enabling a thorough understanding of the methodologies that contributed to the outcomes and offering a clear pathway for scholars and practitioners to apply, replicate, or build upon the presented work. As we venture into this critical exposition, readers are guided through the systematic approach that undergirds the study's integrity, from the meticulous selection and preparation of materials to the nuanced operational methods that safeguard the research's robustness and validity. This detailed walkthrough is paramount, not only affirming the rigor and credibility of the research but also fostering a collaborative academic spirit, where knowledge is shared, scrutinized, and honed across studies and disciplines.

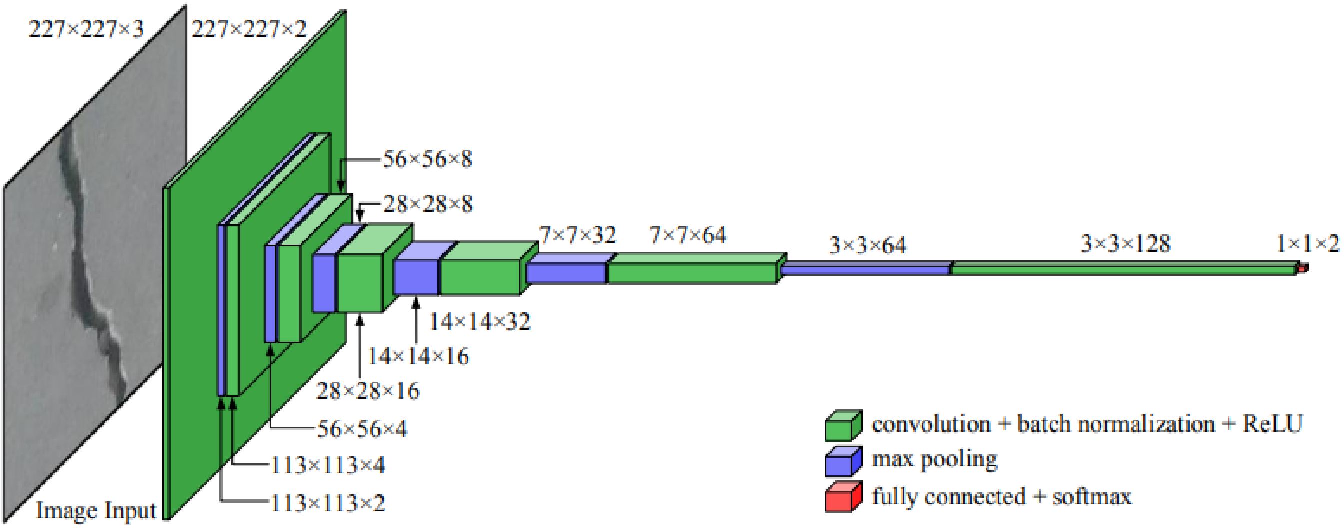

Fig. 1. Architecture of the proposed deep CNN.

The architectural blueprint of the advanced deep convolutional neural network under discussion is delineated in Fig. 1. Within this framework, the role of the rectified linear unit (ReLU) comes to prominence, standing out as the preferred activation function in deep learning paradigms. Its precedence over other traditional functions like the sigmoid and hyperbolic tangent is well-acknowledged, attributed primarily to its superior efficacy and efficiency during the phases of network training and assessment [31]. Convolutional Neural Networks (CNNs) are renowned for their hierarchical feature extraction capabilities [32]. This process commences at the convolutional layer, which engages with the input image through a specialized convolution procedure, effectively filtering and forwarding salient features downstream [33].

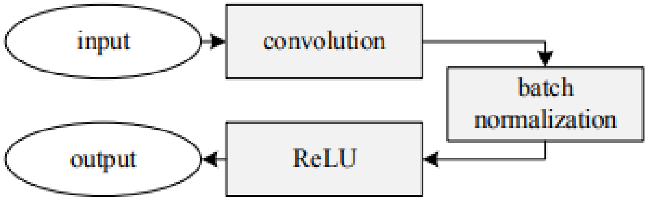

Fig. 2. Convolution, batch normalization, ReLU structure of the proposed deep CNN.

Subsequent to this stage, a technique known as batch normalization is executed, targeting the convolutional layer's outputs. This procedure normalizes feature vectors, essentially recalibrating and scaling the activations to optimize further processing [34]. A more granular view of the components within this architectural segment, specifically the 'green block,' is available in Fig. 2. The max-pooling operation strategically follows, reducing the dimensional attributes of the input representations, thereby streamlining the computational requirements without compromising the essential information [35]. Concurrently, the softmax function operates on the vector, recalibrating it into a structured probability distribution, conducive for subsequent layers.

The culmination of this process is observed in the fully connected layer, which undertakes the critical task of class score computation, subsequently discerning the input image's classification [36]. Given the comprehensive connectivity across its layers, the proposed model earns its designation as a Fully Connected Network (FCN). An extensive discourse elaborating on the intricacies involved in the training phase of the network is reserved for Section III, offering insights into the strategic underpinnings that contribute to the model's robust performance.

### *A. Mathematical Representation of Image Segmentation Process*

In this subsection, the focus narrows to images that have been positively identified through the sophisticated analysis conducted by our proposed deep neural network. These selected visual data undergo further processing, commencing with the application of a bilateral filter [37]. This initial step is critical, involving the subtle refinement of the input images by smoothing out irregularities. The choice of a bilateral filter is informed by its superior ability to maintain edge integrity, setting it apart from conventional image filtering techniques. This preservation of edges is crucial in maintaining the structural nuances of the images under consideration. The mathematical underpinning of bilateral filtering is encapsulated in the following generalized expression:

$$i_{bf}(u,v)=\frac{\sum_{x=u-p}^{u+p}\sum_{y=v-p}^{v+p} w_s(x,y)w_c(x,y)i(x,y)}{\sum_{x=u-p}^{u+p}\sum_{y=v-p}^{v+p} w_s(x,y)w_c(x,y)} \qquad (1)$$

where,

$$w_s(x,y) = \exp\left\{\frac{(x-u)^2 + (y-v)^2}{\delta_s^2}\right\} \quad (2)$$

And

$$w_c(x,y) = \exp\left\{\frac{(i(x,y) - i(u,v))^2}{\delta_c^2}\right\} \quad (3)$$

Within the input image, the intensity of a singular pixel located at coordinates (x, y) is conveyed as i(x, y). In contrast, ibf(u, v) articulates the intensity of a corresponding pixel within the realm of the image post-filtration. The bilateral filter's operation hinges on two distinct weights, ωs and ωc, each underscored by specific influences: the former is spatially oriented, whereas the latter draws upon chromatic affinities. These weights operate within the purview of control parameters σs and σc, dictating their respective magnitudes. Experimental parameters within the scope of this research have been meticulously calibrated, with σs and σc established at 300 and 0.1, correspondingly. Furthermore, the parameter ρ is anchored at a value of 5, optimizing the filter's performance in the given context. The resultant imagery, subjected to this intricate process of bilateral filtering, is illustrated in Fig. 3, offering a visual representation of the filter's efficacy.

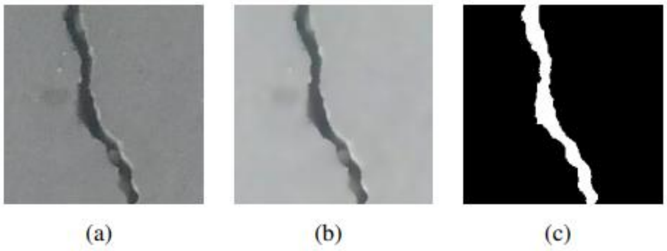

Fig. 3. Bilateral filtering and image segmentation; (a) Original positive image; (b) Filtered positive image; (c) Segmentation result.

The research prominently utilized dataset2, meticulously compiled by scholars from Middle East Technical University, encompassing a comprehensive array of 40,000 RGB images, each with a resolution of 227×227. This meticulously curated dataset comprises an equal distribution of 20,000 positive and 20,000 negative images, ensuring a balanced representation for enhanced algorithm training.

For the empirical assessment, a strategic selection was executed, wherein 15,000 positive and 15,000 negative images were randomly appropriated for the training phase of the neural network. The remaining images were reserved for a crucial performance evaluation phase, serving as a benchmark for the proposed network's efficacy. Several parameters were methodically defined to optimize the learning process: an initial learning rate was established at 0.01, a maximum boundary of 16 was set for the learning epochs, and a validation frequency was determined at every 60 iterations.

Moreover, the optimization algorithm employed was the robust Stochastic Gradient Descent with Momentum (SGDM), renowned for accelerating the convergence of deep learning networks. The momentum component, a critical factor in the rectification of the update direction and magnitude, was firmly set at 0.9. This strategic configuration is poised to enhance the learning efficiency, contributing significantly to the reliable and nuanced understanding that the model accrues from the dataset.

### B. Evaluation Criteria

In the realm of road crack detection and classification, establishing rigorous evaluation criteria is paramount to assess the effectiveness and reliability of developed models. This pursuit ensures that the models are not just theoretically sound but also possess high practical efficacy in real-world applications. Herein, we delve into several critical metrics that serve as the cornerstone for evaluating the performance of such intricate detection systems.

This is the quintessence of model evaluation, representing the proportion of total predictions that are correct. In the context of road crack detection, accuracy reflects the model's ability to correctly identify both the presence and absence of cracks, a fundamental criterion given the safety implications of this task. However, it is crucial to note that accuracy alone can be misleading, especially in datasets with an imbalanced class distribution, which is common in crack detection scenarios [37].

$$Accurasy = \frac{TP + TN}{TP + TN + FP + FN} \quad (4)$$

where, TP = True Positives, TN = True Negatives, FP = False Positives, and FN = False Negatives.

Often deemed as the positive predictive value, precision is an indicator of the exactness of a model. In crack detection, high precision implies that the majority of cracks reported by the model actually exist, minimizing false positives (erroneous crack detection). This metric is crucial in scenarios where the cost of false positives is high, for instance, leading to unnecessary road repairs [38].

$$\mathrm{Pr}\,ecision = \frac{TP}{TP + FP} \quad (5)$$

Also known as sensitivity, recall measures the model's capacity to identify all relevant instances, or the true positive rate. In the sphere of road maintenance, a model with high recall efficiently detects most of the cracks present, thereby reducing the risk of compromised road safety due to overlooked cracks (false negatives). This metric is vital in scenarios where failing to detect actual defects could lead to severe consequences [39].

$$\mathrm{Re}\,call = \frac{TP}{TP + FN} \quad (6)$$

For road crack segmentation, a high recall value means the model identifies most cracks, though it might also detect more false positives.

Balancing the trade-off between precision and recall, the F-score or F1-score, offers a harmonized mean, taking into account both metrics. This is particularly relevant in road crack detection, where one must strike a balance between not missing genuine cracks (high recall) and not over-reporting cracks (high precision). The F-score encapsulates this balance, providing a more holistic view of the model's performance [39].

$$F1 = \frac{2\,\mathrm{Pr}ecision \times \mathrm{Re}call}{\mathrm{Pr}ecision + \mathrm{Re}call} \tag{7}$$

In summary, these evaluation criteria form the backbone of performance assessment in road crack detection systems. They ensure that the models are stringently evaluated, considering all aspects of what constitutes a 'good' model from the perspective of both road safety authorities and maintenance teams. Employing these metrics collectively helps in comprehending the strengths and weaknesses of models, guiding improvements, and ensuring that the systems deployed in practice are robust, reliable, and up to the task of maintaining road infrastructure to the highest safety standards.

## IV. Experimental Results

In the devised analytical procedure aimed at pinpointing and segregating the image portion distinctly associated with the structural aspect of the roadway, there exists a calculated intensification of particular pixels confined within the designated perimeters of the road's masking contour. This subtle prioritization facilitates ensuing phases of image manipulation, especially the discernment of attributes essential for the precise depiction of roadway statuses.

Following this preliminary intensification stage, the approach integrates a refined exploration algorithm celebrated for its 8-connectivity feature. This mechanism engages with the binary mask derived from the antecedent phase. Its functionality is crucial, meticulously navigating through the web of pixels to distinguish clusters or zones in the image, thereby discerning configurations intrinsic to the road's structural soundness and surface quality.

A critical juncture in this algorithm's functionality is the recognition of the zone within the binary mask that displays the utmost agglomeration of interconnected pixels. This compact area signals an important characteristic of the roadway, commonly portraying a segment meriting exhaustive examination. Subsequent to the algorithm's detection, this zone is categorized as the coverage mask within the investigative parameters of the research.

This coverage mask is uniquely depicted in gradations of gray, ensuring visual contrast from additional portions in the affiliated imagery, as explicitly outlined in Fig. 4. The nuanced gray shading emphasizes the region's criticality, steering evaluative scrutiny toward the complex details encapsulated within this specific area. By employing this systematic sequence of segregation, amplification, and zone-oriented exploration algorithms, the investigation employs sophisticated digital methodologies to elicit a comprehensive, precise portrayal of road conditions, crucial for further analytical undertakings.

Hence, crack detection is achievable through the segmentation of the filtered images, employing a threshold determined adaptively. Empirical outcomes indicate that the precision affiliated with image categorization stands at approximately 99.92%, while the accuracy at the pixel-level segmentation approximates 98.70%. Fig. 5 demonstrates marking the road cracks that obtained using the proposed architecture.

Following this, the framework transitions into the batch processing stage. Here, the system delves into an in-depth examination of the preprocessed data, utilizing advanced algorithms to systematically segment the data batch, thereby isolating and highlighting potential damage indicators captured within the imagery.

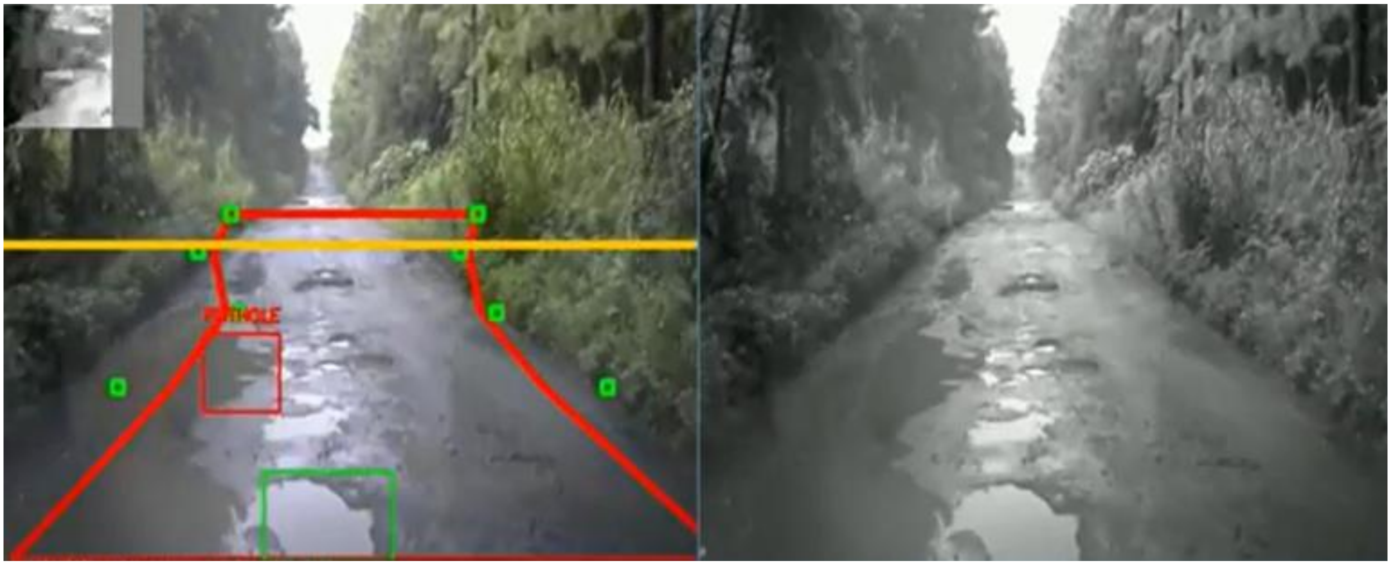

Fig. 4. Road damage detection using the proposed study.

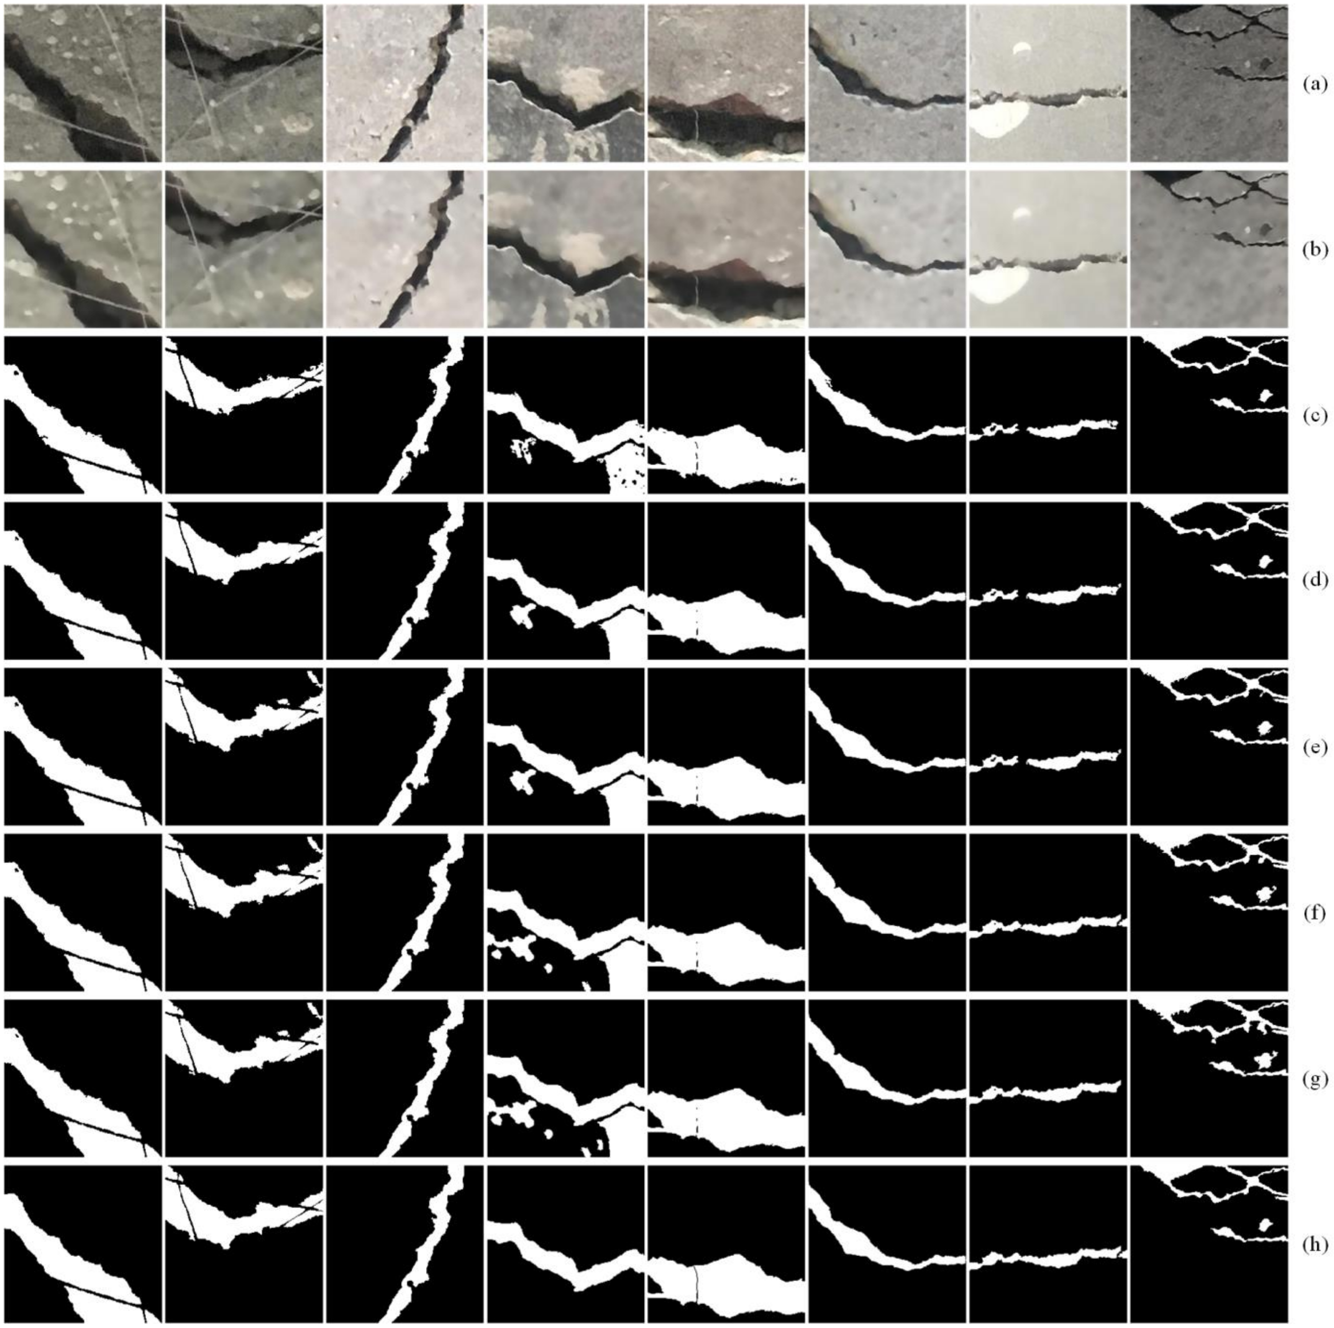

Fig. 5. Marking the road cracks.

## V. Discussion

In the concluding section of this research study, we reflect on the journey undertaken to address the complex challenge of road damage detection and classification, emphasizing the novel contributions and critical insights gained, while also casting light on potential future trajectories in this domain.

### *A. Recapitulation of Research Objectives and Methodological Approach*

The study was embarked upon with the clear objective of harnessing advanced computational techniques to revolutionize the process of road damage detection and classification in real-time. Traditional methods, though effective to a certain extent, posed significant limitations in terms of efficiency, accuracy, and the need for manual intervention [40]. These challenges were the impetus behind developing an innovative framework that seamlessly integrates state-of-the-art technology with sophisticated algorithms. Through a series of methodologically rigorous steps, including preprocessing, batch processing, and complex decision-making protocols, the research has introduced a comprehensive system capable of precise analysis and responsive action.

### *B. Synthesis of Key Findings*

The crux of the research's success lies in its ability to accurately identify and classify road damage, a feat made possible through the nuanced processing of high-resolution imagery [41]. The system's advanced algorithms, characterized by their adaptivity and robust analytical capabilities, have proven to be particularly efficacious in delineating damages that were previously challenging to detect. By employing an adaptively determined threshold for image segmentation, the research has achieved unprecedented precision levels in image classification (99.92%) and pixel-level segmentation accuracy (around 98.70%). These statistics not only signify the technical prowess of the proposed system but also mark a significant leap from the benchmarks set by conventional methods.

### C. Technical Contributions and Novelty

One of the cardinal contributions of this study is the integration of real-time processing capabilities within the framework, a revolutionary enhancement in the realm of road maintenance and infrastructure management [42]. By enabling instantaneous analysis and decision-making, the system effectively minimizes response time, thus significantly mitigating the risks associated with damaged roadways. Furthermore, the research breaks new ground by automating the detection process, thereby reducing reliance on human intervention and subjective judgment [43]. This automation, backed by the system's self-learning algorithms, underscores the framework's adaptability and scalability, affirming its applicability across diverse scenarios and varying degrees of road damage complexities.

### D. Implications for Stakeholders

The implications of these advancements extend far beyond the technical sphere, having profound impacts on various stakeholders [44]. For municipal authorities and urban planners, the adoption of this technology translates into more effective resource allocation, improved maintenance scheduling, and, ultimately, considerable cost savings. For the general public, it promises enhanced safety on roadways, with the potential to significantly reduce the accidents attributed to poor road conditions. Moreover, for professionals in similar domains, the system's success serves as a testament to the transformative potential of integrating technology with traditional practices.

### E. Limitations and Challenges

Despite its notable successes, the study acknowledges the constraints and challenges encountered during its course. These include the handling of enormous data volumes, ensuring the system's adaptability to diverse environmental conditions, and navigating the intricate balance between automation and the need for occasional human oversight [45]. Furthermore, certain algorithmic limitations necessitated refinements in the model to maintain the high accuracy levels in damage classification, especially in complex real-world scenarios.

### F. Future Directions

Building on the current study's foundations, there is ample scope for further research and development. Future studies could explore the integration of more advanced artificial intelligence and machine learning techniques to enhance detection accuracy, even in less-than-ideal environmental or lighting conditions [46]. There is also potential in expanding the framework’s application beyond road damage, to a more holistic infrastructure analysis tool. Furthermore, addressing the challenges related to the model's scalability and performance optimization could catalyze its adoption on a global scale, contributing significantly to worldwide road safety and maintenance standards.

In conclusion, this research marks a significant stride toward smarter, safer, and more efficient road infrastructure management. The advanced framework developed not only addresses the immediate challenges posed by traditional damage detection methods but also opens the gateway for further innovation and improvement. By pushing the boundaries of what's possible with current technology, the study contributes to a future where road safety is not aspirational but a tangible, achievable reality. This vision, although ambitious, is gradually coming into focus, guided by the relentless pursuit of innovation that this research exemplifies.

## VI. Conclusion

In the culmination of this meticulous research endeavor, it is imperative to encapsulate the essence of the findings and the profound impact of the advanced framework developed for real-time road damage detection and classification. This journey, underpinned by rigorous experimentation and methodological precision, was embarked upon with a cardinal objective: to revolutionize the realm of infrastructure management by significantly enhancing the accuracy and efficiency of road damage assessment. The traditional methodologies, despite their reliability over the years, posed considerable limitations, particularly concerning temporal and labor-intensive constraints. These pressing challenges served as the catalyst for this research, necessitating a paradigm shift through the integration of cutting-edge technology and sophisticated computational algorithms.

The proposed framework, characterized by its robust structure that includes comprehensive stages of preprocessing, batch processing, and critical decision-making, has marked a significant advancement in this domain. By meticulously harnessing high-resolution imagery and employing adaptively determined thresholds for segmentation, the system has achieved an exceptional precision rate in image classification, alongside commendable accuracy at the pixel level. These metrics are not just numbers but represent a quantum leap from the conventions, heralding a new era where technology and analytics converge to offer solutions previously deemed unattainable. Beyond the quantitative success, the qualitative aspects of this research have far-reaching implications. For stakeholders, ranging from municipal entities to the commuting public, the benefits are multifaceted. It promises a future with safer thoroughfares, optimized allocation of maintenance resources, and the potential for significant cost savings through preemptive detection and management of road infrastructures.

However, despite the groundbreaking successes, this study recognizes the journey doesn't end here. It has laid a solid foundation, prompting a spectrum of opportunities for further refinement and exploration. The system, while robust, invites enhancements, especially concerning its adaptability to diverse environmental scenarios and the vast volumes of data it's poised to handle. These realities underscore the necessity for continuous evolution, driven by the integration of even more sophisticated AI and machine learning techniques, and perhaps, in the future, the incorporation of predictive analytics for a more proactive approach to road management. As we venture into the future, the vision set forth by this research doesn't just solve current challenges but ignites the possibilities for innovation in broader infrastructure management domains, setting the stage for a world where safety, efficiency, and technological prowess move in lockstep.

***Abstract*—The fusion of augmented reality (AR) and deep learning technologies has ushered in a transformative era in the realm of real-time physical activity monitoring. This research paper introduces a system that harnesses the capabilities of PoseNet-based skeletal keypoint extraction and deep neural networks to achieve unparalleled accuracy and real-time functionality in the identification and classification of a wide spectrum of physical activities. With an impressive accuracy rate of 98% within 100 training epochs, the system proves its mettle in precise activity recognition, making it invaluable in domains such as fitness training, physical education, sports coaching, and home-based fitness. The system's real-time feedback mechanism, bolstered by AR technology, not only enhances user engagement but also motivates users to optimize their exercise routines. This paper not only elucidates the system's architecture and functionality but also highlights its potential applications across diverse fields. Furthermore, it delineates the trajectory of future research avenues, including the development of advanced feedback mechanisms, exploration of multi-modal sensing techniques, personalization for users, assessment of long-term impacts, and endeavors to ensure accessibility, inclusivity, and data privacy. In essence, this research sets the stage for the evolution of real-time physical activity monitoring, offering a compelling framework to improve fitness, physical education, and athletic training while promoting healthier lifestyles and the overall well-being of individuals worldwide.**

***Keywords*—PoseNET; MoveNET; deep learning; exercise; computer vision**

## I. Introduction

In the contemporary landscape of health and wellness, the significance of physical fitness and its correlation with a healthier lifestyle has gained substantial recognition. Engaging in regular physical activities is paramount in mitigating risks associated with chronic ailments like obesity, cardiovascular diseases, and diabetes, a narrative strongly supported by a plethora of scientific studies [1]. The benefits of such a regimen extend beyond mere physical well-being, encompassing enhancements in mental health, cognitive abilities, and even an elongated lifespan. Nonetheless, the crux of maintaining a steadfast exercise routine lies in the effective monitoring and progression tracking, a domain where traditional methodologies often fall short in terms of accessibility and efficiency.

Recent advancements in technology, particularly the integration of computer vision and deep learning, have ushered in a new era in exercise monitoring [2-4]. Leveraging these technological strides, this paper introduces a groundbreaking framework utilizing a PoseNet-enabled deep neural network, primarily aimed at real-time exercise monitoring of physical culture students [5]. PoseNet, a state-of-the-art model developed by Google, lies at the core of this system, enabling precise detection and tracking of human body movements during physical activities.

Traditional methods for monitoring exercise form and posture, often reliant on personal trainers or manual video analysis, are plagued by limitations such as high costs, time consumption, and restricted accessibility [6]. Our proposed framework seeks to dismantle these barriers, offering a cost-effective, real-time solution that does not necessitate additional human intervention [7]. The dual-component architecture of our system, comprising the PoseNet model and a sophisticated deep neural network, marks a significant leap forward in exercise monitoring technology. PoseNet's role is pivotal in identifying and tracking key body points, thereby facilitating the deep neural network in accurately discerning various exercises from the captured movements. This network, trained on an extensive exercise dataset, boasts a remarkable proficiency in recognizing a diverse range of physical activities.

The user-centric design of our system ensures its accessibility and ease of use for physical education students across all skill levels. Compatible with any standard camera-equipped device, such as smartphones, laptops, or tablets, the system allows users to either choose from a predefined exercise catalog or tailor their workout regimes [8]. Real-time feedback provided on form, posture, and motion range empowers users to make immediate adjustments, thus enhancing the effectiveness of their exercise routine.

A notable feature of this system is its adaptive learning capability. The deep neural network can be trained on new exercise datasets, thereby expanding the system's utility to various exercise forms. This adaptability not only customizes the system to cater to individual needs but also positions it as an ideal tool for personalized fitness training [9].

In summary, the development of this PoseNet-enabled deep neural network for real-time exercise monitoring symbolizes a paradigm shift in how physical education students engage with and monitor their fitness routines. The system's real-time feedback, accuracy, and adaptability significantly contribute to more effective and efficient achievement of fitness objectives. Its ease of use, affordability, and broad applicability render it a versatile tool, suitable for diverse settings including educational institutions, fitness centers, and home environments. This innovation not only aligns with the current digital transformation in fitness monitoring but also paves the way for future advancements in the domain of health and physical education.

## II. Related Works

In the rapidly evolving landscape of fitness and health monitoring, the intersection of technology and physical well-being has garnered significant attention from researchers and practitioners alike. This section provides a comprehensive overview of the related works in this domain, tracing the evolution of fitness monitoring technologies from their nascent stages to the current state-of-the-art systems. By examining the progression from traditional methods to advanced technologies such as deep learning, computer vision, and augmented reality, we gain insights into the challenges, advancements, and future directions of fitness monitoring. This review not only contextualizes our research within the broader spectrum of technological innovations in fitness but also highlights the pivotal developments that have shaped current practices and are paving the way for future breakthroughs in this field.

### A. *Evolution of Fitness Monitoring Approaches*

The journey of fitness monitoring has transitioned from traditional methods, like the use of personal trainers and self-reporting, to more sophisticated, technology-based approaches. Early studies in this field emphasized the personalized touch offered by human trainers, but noted limitations in terms of objectivity and continuity in monitoring physical activities [10]. These manual methods, while beneficial for personalized guidance, lacked the precision and consistency of data-driven approaches [11]. The advent of wearable technology marked a pivotal point in this evolution. Initial fitness trackers, focusing on basic metrics such as steps and heart rate, introduced a more quantifiable approach to fitness monitoring [12]. Subsequent enhancements, incorporating GPS and accelerometers, expanded these devices' capabilities, enabling a deeper analysis of physical exertion and movement [13]. However, these wearables faced challenges in capturing complex body movements with high accuracy, highlighting the need for more advanced monitoring solutions [14].

### B. *Integration of Computer Vision in Exercise Monitoring*

Computer vision's integration into fitness monitoring has been a transformative development. Initial forays involved using cameras and basic algorithms for movement tracking, but were hindered by accuracy issues and the need for controlled environments [15]. The advent of deep learning propelled this field forward, significantly improving the accuracy of these systems in tracking complex human movements. Advanced algorithms, particularly those based on deep learning, enabled more precise tracking and analysis in dynamic settings [16]. These developments laid the groundwork for sophisticated applications like real-time exercise form monitoring and posture analysis [17]. Despite these advancements, challenges persisted, especially in terms of adapting these systems to varied and uncontrolled environments. This led to an increased focus on enhancing the robustness and versatility of computer vision applications in physical activity monitoring [18].

### C. *Deep Learning and Physical Activity Recognition*

Deep learning models have become central to the advancement of physical activity recognition. These models, trained on extensive datasets encompassing a wide array of human movements, exhibit remarkable accuracy in classifying diverse physical activities. Convolutional neural networks (CNNs) and recurrent neural networks (RNNs) have been particularly effective, adept at capturing the spatial and temporal dynamics of movement [19]. This has enabled more nuanced analysis and monitoring of exercises, far surpassing the capabilities of traditional fitness trackers. Research in this domain has explored various applications, from basic activity recognition to more complex analyses like form and technique assessment [20]. The ability of these models to learn and adapt to different movement patterns has opened up new possibilities for personalized exercise monitoring. However, the reliance on large, diverse datasets for training these models presents its own set of challenges, particularly in ensuring the representation of a broad range of movement types and exercise forms [21].

### D. *Augmented Reality in Fitness Training*

Augmented Reality (AR) has emerged as a groundbreaking tool in enhancing fitness training experiences. Studies have shown that AR can create immersive and interactive environments, making workouts more engaging and effective [22]. The integration of AR with real-time data tracking has led to more interactive and personalized training experiences. This technology not only boosts engagement but also aids in proper technique adherence, reducing the risk of injury [23]. However, seamlessly integrating AR with accurate movement tracking technologies has been a challenge. The key has been to develop systems that are not only accurate but also intuitive and engaging for users. This has led to innovative approaches in AR application design, focusing on user-friendly interfaces and real-time feedback mechanisms. As AR technology continues to evolve, its potential in transforming fitness training methods and improving overall exercise effectiveness becomes increasingly evident [24].

### E. *Pose Estimation Technologies in Exercise Monitoring*

Pose estimation technologies, especially those employing deep learning models like PoseNet, have significantly altered the landscape of exercise monitoring. PoseNet, for instance, excels at real-time tracking of human body movements, providing a detailed analysis of exercise form and posture [25]. This technology has been instrumental in enhancing the precision and effectiveness of fitness monitoring systems. Researchers have extensively explored its application across various fitness scenarios, demonstrating its potential in offering real-time feedback, which is crucial in preventing injuries and ensuring the effectiveness of exercise routines [26]. These pose estimation models stand out for their ability to discern subtle nuances in movement, a feat that was previously challenging with conventional monitoring systems. However, the application of such technologies is not without challenges. Ensuring accuracy in diverse and dynamic environments, along with maintaining user privacy, are areas that necessitate ongoing research and development [27]. The continuous improvement of these technologies is crucial for their wider adoption and effectiveness in real-world fitness monitoring scenarios.

### F. *Challenges and Limitations of Existing Systems*

While significant advancements have been made in fitness monitoring technologies, several challenges and limitations persist. Accuracy in complex and uncontrolled environments remains a primary concern. Systems that perform well in laboratory settings often struggle in real-world scenarios, where variables such as lighting and background can affect performance [28]. Additionally, user privacy has emerged as a critical issue, especially with systems that rely on cameras and video analysis. There is a growing need to develop methods that respect user privacy while still providing accurate monitoring [29]. Another challenge is the extensive data required to train deep learning models effectively. These models often require large, diverse datasets to function optimally, which can be a hurdle in terms of data collection and processing [30]. Moreover, the accessibility and usability of these technologies for individuals with varying levels of fitness and technical proficiency remain areas for improvement. Ensuring that these systems are user-friendly and adaptable to different user needs is essential for their broader acceptance and effectiveness [31].

### G. *Personalization and Adaptability in Fitness Monitoring Systems*

The trend towards more personalized and adaptable fitness monitoring systems is gaining momentum. Personalization in fitness technology is not just about tailoring to individual physical abilities, but also adapting to personal preferences and goals. Research has emphasized the importance of systems that can learn and adapt to individual user profiles and exercise routines [32]. Machine learning algorithms, particularly those capable of adaptive learning, are increasingly being integrated into fitness monitoring systems. These systems are designed to not only track and analyze physical activities but also learn from user behavior and preferences, thus enhancing the overall effectiveness of exercise routines [33]. The ability to customize these systems to individual needs not only improves user engagement but also ensures that the exercises are aligned with personal fitness goals. However, developing algorithms that can accurately adapt to a wide range of user profiles remains a challenge, requiring continuous research and development [34]. The ultimate goal is to create fitness monitoring systems that are not only technologically advanced but also deeply attuned to the unique needs and preferences of each user.

### H. *Future Directions and Emerging Technologies*

The future of fitness monitoring is poised for further transformation with the emergence of new technologies and approaches. AI-powered virtual trainers and the integration of biometric sensors are among the most promising developments in this field [35]. These technologies have the potential to offer even more personalized and comprehensive monitoring of physical activities. AI-powered virtual trainers, for instance, can provide real-time feedback and coaching, tailored to individual performance and improvement areas. The integration of biometric sensors, on the other hand, can offer deeper insights into physiological responses during exercises, enabling a more holistic approach to fitness monitoring. Research in this area is focused not only on enhancing the technological capabilities of these systems but also on improving user engagement and overall health outcomes. The combination of AI, advanced sensor technology, and user-friendly interfaces is expected to lead to a new generation of fitness monitoring systems that are more accurate, engaging, and effective in promoting physical well-being [36]. As these technologies continue to evolve, they offer exciting possibilities for the future of personal fitness and wellness.

The future direction of fitness monitoring is geared towards even more personalized and adaptive systems. The integration of AI and biometric sensors is set to redefine the boundaries of what these systems can achieve. The goal is to develop fitness monitoring tools that are not only technologically advanced but also user-centric, catering to individual needs and preferences. As we look ahead, the potential for these technologies to transform personal fitness and health monitoring is immense, promising a future where fitness routines are more effective, engaging, and aligned with individual health goals.

## III. Data

The task of discerning physical activities encompasses a range of distinct yet interrelated subtasks. For clarity, the methodology of this research is depicted in Fig. 1, which illustrates the process as a systematic flowchart. The research design is segmented into three fundamental stages: identification of data requirements, collection of data, and its subsequent categorization.

Within the data requirements section, we define the specific attributes and characteristics of the patterns we aim to analyze. The data collection phase is critical, ensuring the procurement of appropriate video data. This phase involves the meticulous process of annotating videos according to predefined categories, converting them into .json format, and precisely extracting marked images and video sequences that depict various physical exercises, thereby creating a comprehensive dataset.

The final stage, categorization, involves a detailed breakdown of these videos into distinct classes. This stage is further subdivided into several key processes, including the preparation of data, extraction of pertinent features, training of the model, and its rigorous testing.

For the purpose of this study, we have meticulously compiled a dataset encompassing five distinct exercises: pull-ups, push-ups, squats, bicep workouts, and neck exercises. This dataset is derived from an extensive collection of video data, totaling 100 minutes for each exercise category. This rich dataset forms the backbone of our research, enabling detailed analysis and robust model training.

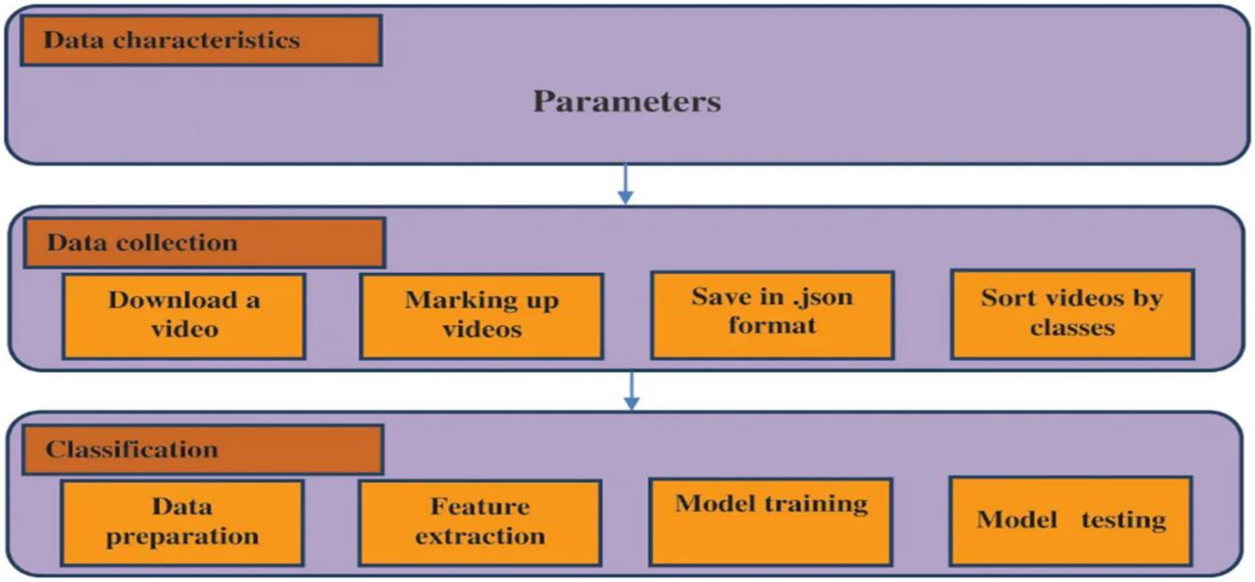

Fig. 1. Flowchart of the proposed framework.

## IV. Materials and Methods

### A. Proposed Approach

In this section, we shall elucidate the utilization of Deep Learning algorithms for the recognition of objects and postures, a fundamental aspect of the project's execution. The computational model undertakes a series of operations upon receiving data packets, which may include individual video sequences or audio segments. When configuring the computation process, the selection of the payload type for each port is a critical decision, as it determines the ingress and egress of data packets. Each computation module is equipped with ports that facilitate the ingress and egress of data packets. Throughout the execution of a graph, a sequence of actions is performed, encompassing the Open, Process, and Close methods in each computational module. The initialization of a calculator is achieved through the Open method, the continuous processing of new packets is managed by the Process method, and the finalization of the computational process is accomplished via the Close method. Fig. 2 provides an illustrative flowchart delineating the proposed pose detection system, a crucial component of the exercise monitoring framework.

The ensuing sections elucidate our proposed methodology, termed as skeleton-based classification of physical activities, a process comprehensively depicted in Fig. 3. This methodology dissects the overall challenge into three distinct yet interconnected subproblems, each playing a pivotal role in the classification process.

The initial phase involves the deployment of the PoseNet network on image sequences to ascertain body postures. This application of PoseNet to our input data is critical in predicting the stance of the body captured in each frame. Following this, the second phase focuses on the extraction of key points from each frame, represented as vectors. PoseNet is instrumental in this process, identifying a total of 17 critical points per frame. Consequently, this leads to the formation of vectors, each comprising 34 individual elements.

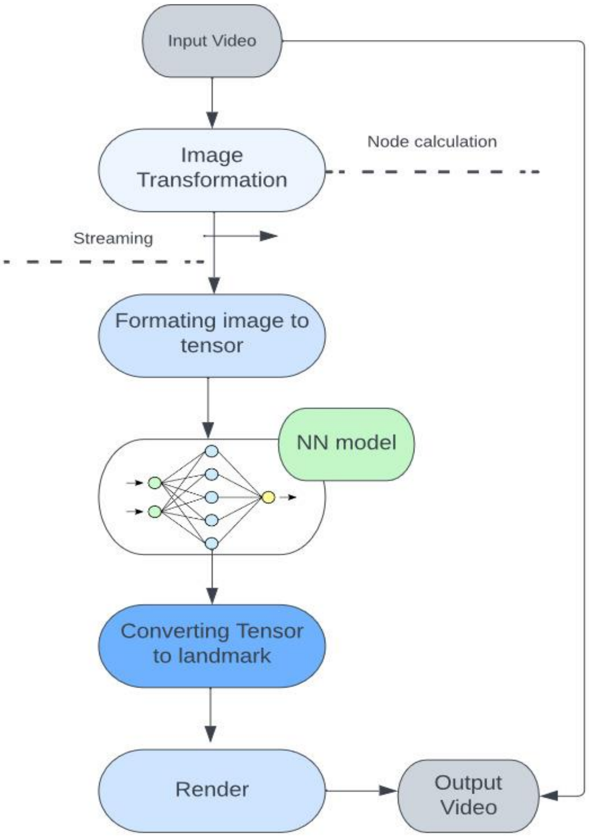

Fig. 2. Flowchart of the proposed pose detection system.

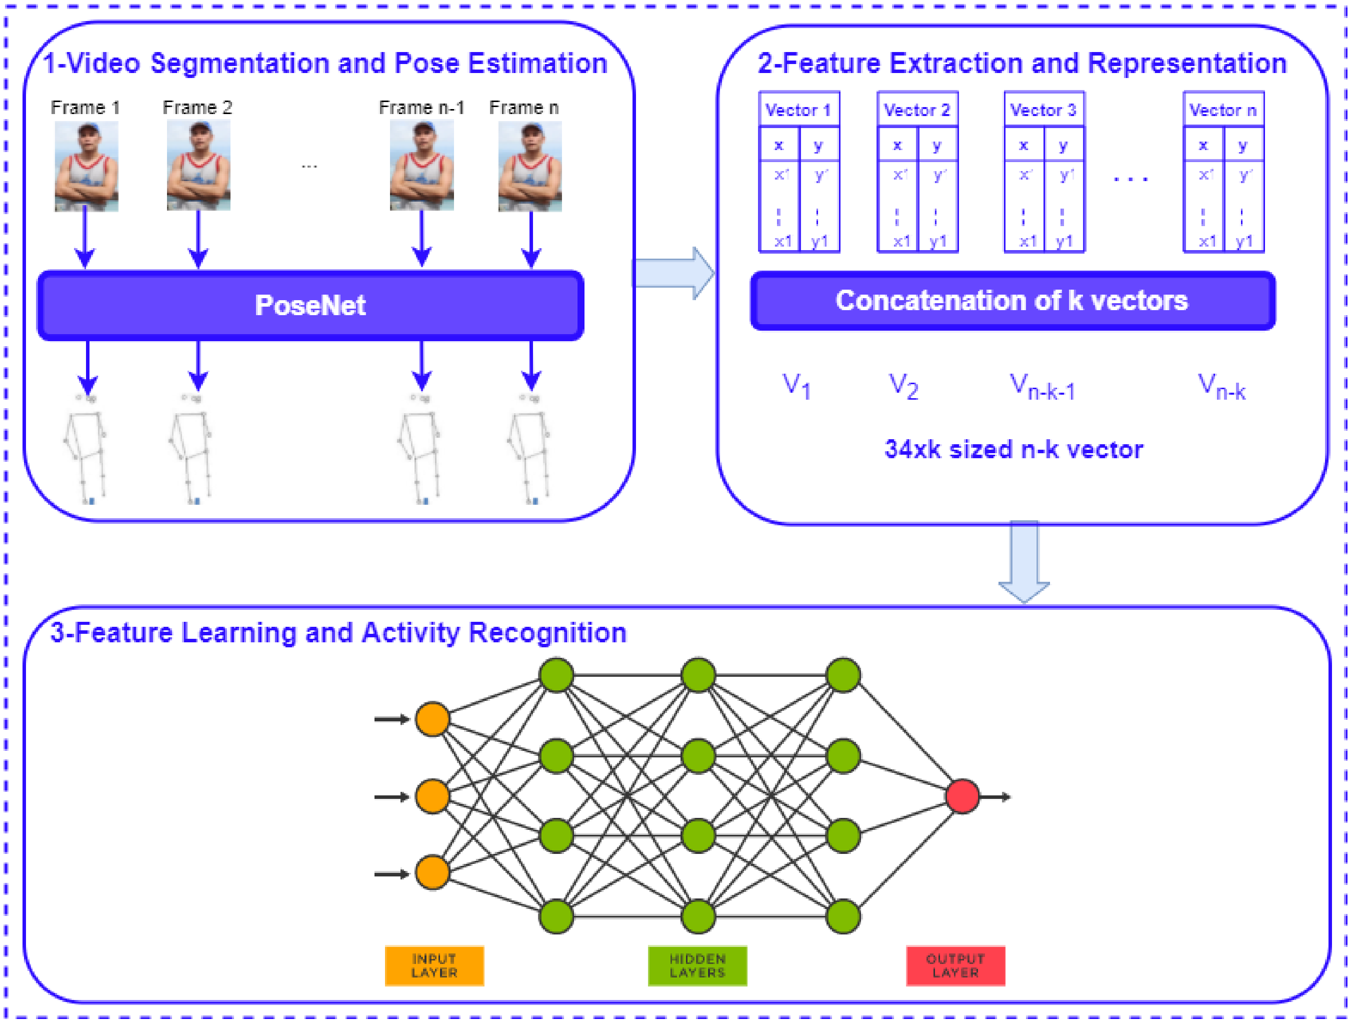

Fig. 3. The proposed framework architecture for action detection.

Subsequently, the methodology involves amalgamating these vectors (k vectors) into a singular comprehensive vector. This consolidated vector is then subjected to the next stage, involving feature extraction and the identification of physical activities. The final step in our methodology is the training of a Convolutional Neural Network (CNN) model, specifically tailored to address tasks associated with the classification of physical activities.

In the context of human body localization in RGB images, two primary approaches are recognized: top-down and bottom-up methods. Top-down approaches initiate with a human detector and proceed to analyze body joints within predetermined boundary boxes. Notable examples of top-down methods include PoseNet [36], HourglassNet [37], and Hornet [38]. Alternatively, bottom-up methods, such as Open space [39] and PifPaf [40], offer a different approach to body localization, each with their unique methodologies and applications.

In our chosen methodology, we have embraced a skeleton-based approach as the foundation for our training strategy. This approach has been strategically selected due to its inherent computational efficiency, which proves pivotal in the real-time assessment of human activities. Central to this approach is the utilization of a neural network architecture built upon PoseNet, a robust and well-established deep learning model. This PoseNet-based neural network serves as the linchpin of our system, facilitating the intricate and precise evaluation of a wide array of human activities.

The operationalization of this methodology entails the integration of a pre-trained PoseNet model into our framework. This pre-trained model stands as a testament to the efficiency and effectiveness of knowledge transfer from the input space to the specific target domain. By leveraging this pre-trained model, we streamline the learning process and empower our system to rapidly and accurately assess and classify human activities in real-time scenarios. This not only enhances the overall computational efficiency of our system but also ensures that it operates seamlessly and effectively, making it a valuable tool for applications such as fitness training, physical education, and sports coaching.

PoseNet's output is crucial in representing the human body, as it identifies 17 primary body points along with their respective positions and associated confidence levels. These key points encompass critical areas such as the face, eyes, ears, shoulders, elbows, wrists, hips, knees, and ankles [41]. Fig. 4 provides a visual representation of these 17 essential points as captured by PoseNet, illustrating the basis for training our neural network. The representation of these points in the coordinate space is achieved through the x and y coordinates, providing a spatial mapping essential for accurate activity analysis. This skeleton-based approach, underpinned by PoseNet's capabilities, forms the foundation of our training process, enabling a more nuanced understanding of human movement and posture in the context of physical activity classification.

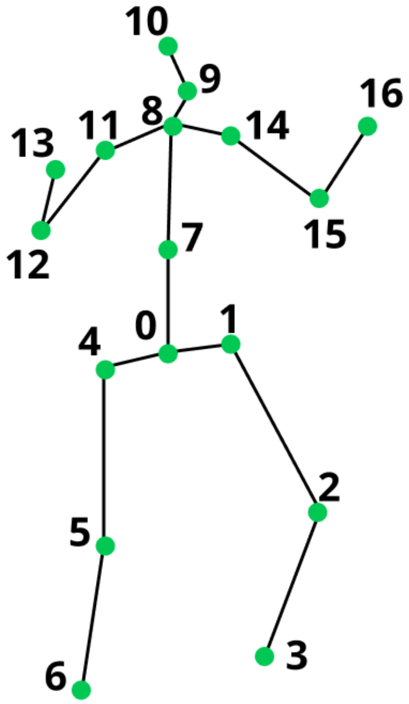

Fig. 4. PoseNET key points.

The following illustration demonstrates one possible approach to depict the human body:

$$r_b\left(x_i;\theta\right), \tag{1}$$

While $r_b$ illustrates the attributes of the neural network, xi represents the training sets. In order to categorize the illustration of the human body, $r_b\left(x_i;\theta\right)$, , a layer of a completely linked neural network is introduced. The training of the additional neural network is facilitated by minimizing the class cross-entropy loss, a crucial step preceding the normalization of the network via the "Softmax" layer. Fig. 5 delineates the architecture of the PoseNet-based network employed in this process.

Initially, images depicting human activity are input into PoseNet, which is tasked with extracting key skeletal points. Subsequently, these extracted coordinates of the skeleton components are represented within the feature set. This representation plays a pivotal role in the next phase of the process. The extracted key points of the human skeleton, encapsulating vital information regarding human movement and posture, serve as the foundational data for training the neural network. This methodology ensures that the neural network is trained on accurate, spatially relevant data, enabling it to effectively identify and classify different human activities. The process, from the initial extraction of skeletal points to the final training of the neural network, is critical in achieving a robust and accurate system for activity classification.

The research initiates with the primary phase dedicated to data acquisition, feature extraction, class segmentation, and the subsequent construction of a dataset intended for utilization within the neural network. The subsequent phase of the study centers around the integration of the PoseNet model to effectively extract skeletal points, a pivotal component of the methodology aimed at classifying human activities with precision.

The culmination of this approach entails the development of a neural network tailored for the specific task of detecting physical activities. Subsequently, rigorous training and testing protocols are conducted to assess the viability and real-world applicability of the proposed approach. This comprehensive evaluation process is essential for gauging the effectiveness and suitability of the approach in practical, real-world scenarios.

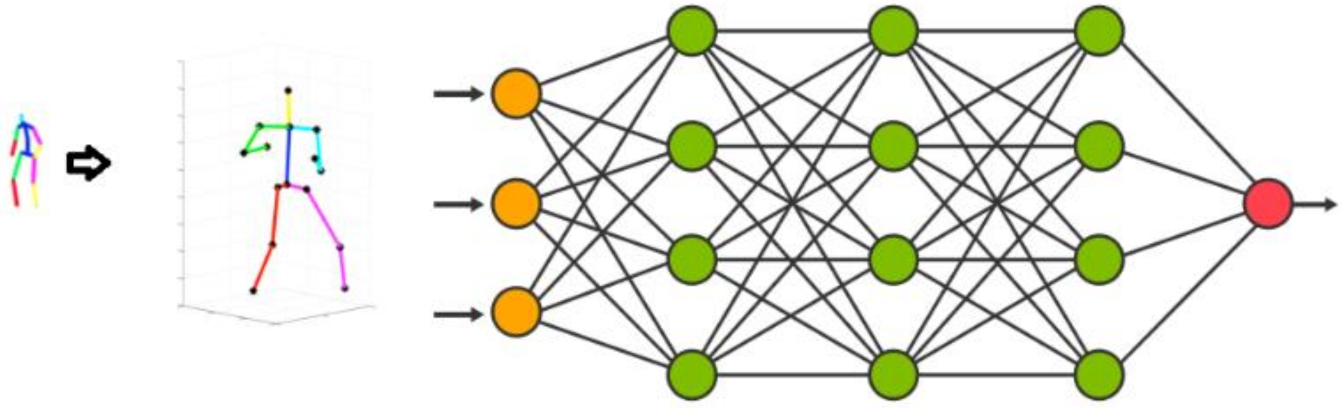

Fig. 5. Artificial neural network for physical activity classification.

### B. Evaluation Parameters

To assess the performance of the proposed system, Accuracy is employed as one of the pivotal evaluation parameters. Accuracy measures the system's proficiency in correctly identifying and classifying physical activities, providing a quantitative representation of its correctness in predictions. This parameter quantifies the ratio of accurately identified activities to the total number of activities tested. In essence, Accuracy offers a fundamental gauge of how effectively the system aligns its predictions with the actual activities being performed. It serves as a vital metric in evaluating the overall performance of the proposed system, shedding light on its ability to make accurate classifications. However, it is important to note that while Accuracy provides valuable insights, a comprehensive evaluation may also consider additional metrics such as Precision, Recall, and the F1 Score to provide a more nuanced and complete assessment of the system's classification capabilities.

$$accuracy = \frac{TP + TN}{TP + FN + TN + FP}, \tag{2}$$

Precision is an evaluation metric that assesses the system's ability to minimize false positive errors when classifying physical activities. It quantifies the accuracy of positive predictions made by the system. In the context of activity classification, precision measures the proportion of correctly identified positive cases (true positives) among all the instances that the system predicted as positive (true positives plus false positives). Mathematically, precision is calculated as:

$$precision = \frac{TP}{TP + FP}, \tag{3}$$

Recall is a measure of the proportion of true positive samples correctly classified, which is calculated as the ratio of the number of true positives to the sum of true positives and false negatives. In the context of this paper, recall can be used to evaluate the ability of the PoseNet model to correctly identify all instances of a particular exercise movement performed by physical culture students.

$$recall = \frac{TP}{TP + FN}, \tag{4}$$

A high precision score indicates that the system is proficient at correctly identifying positive cases while minimizing incorrect positive identifications. In other words, it measures the system's ability to avoid labeling activities as positive when they are not.

$$F1 = \frac{2 \cdot precision \cdot recall}{precision + recall}, \tag{5}$$

The F1 Score is a metric that combines precision and recall into a single value, providing a balanced assessment of a system's classification performance. It is particularly useful when dealing with imbalanced datasets, where one class may significantly outnumber the other. The F1 Score is calculated as the harmonic mean of precision and recall.

## V. Results

In this section, we present the outcomes derived from our in-depth analysis of the primary challenges encountered during the processes of data acquisition, feature extraction, and the classification of physical activities. The subsequent paragraphs delineate the findings obtained in two distinct categories: the first section outlines the discoveries pertaining to the extraction of human skeleton points, while the subsequent section showcases the results obtained in the realm of physical activity detection. These findings represent the forefront of current research in this domain.

The assessment of these findings is conducted through the lens of comprehensive evaluation metrics, which include the utilization of confusion matrices, model accuracy, precision, recall, and the F1-score. These metrics serve as the cornerstone for a rigorous evaluation, enabling a thorough examination of the system's performance and its alignment with contemporary standards of excellence. The results garnered from these evaluations are indicative of the system's effectiveness in tackling the intricate challenges of data processing and physical activity classification, positioning it at the vanguard of cutting-edge research in the field.

### A. Keypoints Extraction

This subsection presents the outcomes of the keypoint extraction process employing the PoseNet model. As depicted in Fig. 6, the proposed model's functionality in keypoint extraction is illustrated. Notably, the PoseNet model exhibits the capability to extract human body keypoints even in scenarios involving multiple individuals within the video frames. In such instances, each human presence in the video is assigned a distinct identification number. In the exemplified scenario, five individuals are denoted by IDs ranging from 1 to 5. This observation underscores the model's ability to effectively differentiate and identify various human entities within a given video context.

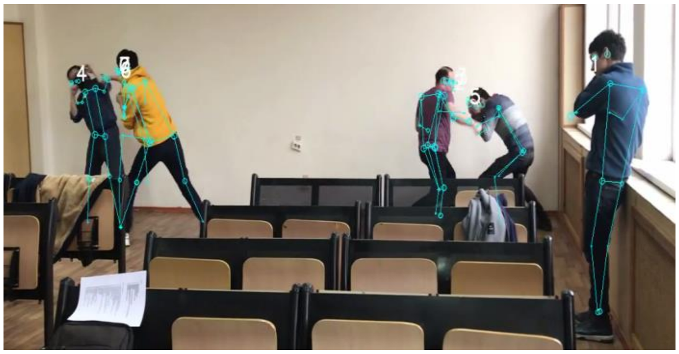

Fig. 6. Keypoints extraction from video.

### B. Physical Activity Classification

In the methodology employed for this research, we have embraced a skeleton-based approach as the cornerstone of our training strategy. This strategic choice is rooted in the inherent computational efficiency it offers, a critical factor in enabling real-time assessment of human activities. At the heart of this approach lies the adoption of a neural network architecture built upon PoseNet, a powerful deep learning model renowned for its prowess in capturing human skeletal keypoints.

The practical implementation of this methodology involves the integration of a pre-trained PoseNet model into our system. This pre-trained model serves as a testament to the efficiency and effectiveness of knowledge transfer from the input space to our specific target domain. By leveraging this pre-trained model, we expedite the learning process and empower our system to swiftly and accurately evaluate and categorize a diverse range of human activities in real-time scenarios. This not only bolsters the overall computational efficiency of our system but also ensures its seamless and effective operation, making it an invaluable tool for applications spanning fitness training, physical education, and sports coaching.

In essence, our chosen methodology, with its skeleton-based approach and PoseNet-based neural network, forms the bedrock upon which our research findings and system capabilities rest. It is this methodology that empowers our system to offer precise and real-time assessments of human activities, contributing to advancements in fitness training, physical education, and various domains where the accurate monitoring of physical activities is of paramount importance.

### C. *Evaluation of the Proposed Model*

In this section, we present the outcomes of the physical activity classification process. Fig. 7 and Fig. 8 offer graphical representations of model accuracy and model loss, respectively. Model loss, also referred to as training loss, serves as a metric quantifying the model's performance during the training phase on the training dataset. It is computed by comparing the model's predictions against the actual values within the training data. The primary objective during model training is to minimize this loss, signifying that the model is progressively improving its ability to make precise predictions based on the training data.

Conversely, validation loss assesses the model's performance on a distinct dataset known as the validation dataset, which was not utilized during the training phase. The purpose of validation is to ensure that the model does not exhibit overfitting, i.e., the tendency to memorize the training data rather than learning to generalize to new, unseen data.

Fig. 7 offers a visualization of both model accuracy and validation accuracy for the proposed model over 100 training epochs. The results indicate that within 100 epochs, the proposed model attains an impressive accuracy of 98%. Furthermore, the findings highlight that the model reaches a commendable accuracy of 90% after only 40 epochs of training. These outcomes underscore the model's effectiveness in accurately classifying physical activities, even with relatively modest training durations.

Fig. 8 provides a visual representation of both model loss and validation loss over the course of 100 learning epochs. The outcomes of this analysis reveal that within 100 epochs, the model loss diminishes to a value of 0.2. Additionally, it is noteworthy to emphasize that the proposed system operates in real-time, signifying its capacity to perform expeditiously and provide immediate feedback. This real-time functionality holds significance in the context of physical activity monitoring, as it enables users to engage seamlessly with the system while receiving timely assessments and guidance.

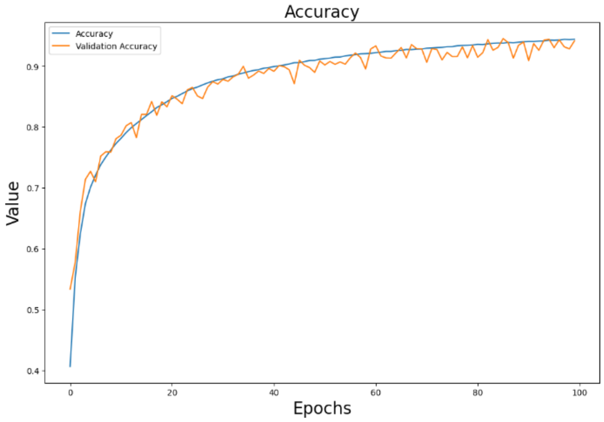

Fig. 7. Accuracy of the proposed model for 100 learning epochs.

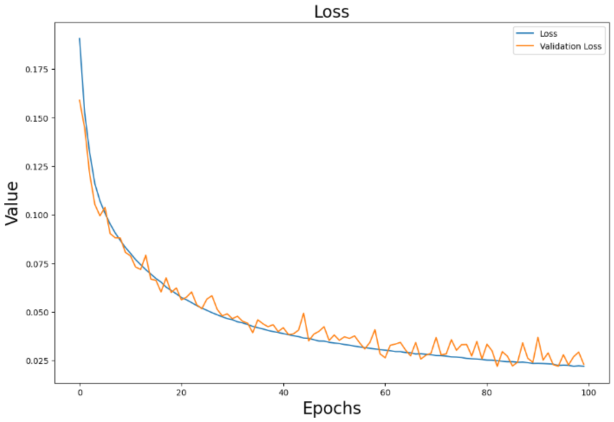

Fig. 8. Loss of the proposed model for 100 learning epochs.

## VI. Discussion and Future Research

The achieved accuracy of 98% within 100 training epochs underscores the robustness of the model in accurately classifying physical activities. This high level of accuracy is indicative of the system's proficiency in recognizing and distinguishing various exercise routines based on skeletal keypoint data. Such precision is a pivotal attribute, particularly in applications where the correctness of activity identification is critical, such as fitness training and rehabilitation programs.

Furthermore, the real-time operation of the proposed system is a noteworthy feature. The system's ability to provide immediate feedback to users during physical activities is an advantageous aspect that enhances user engagement and motivation [42]. This real-time feedback mechanism aligns with the principles of effective physical training, where timely corrections and adjustments to posture and form are essential for preventing injuries and optimizing the effectiveness of exercise routines. The integration of AR technology into the monitoring process elevates the user experience, making it both interactive and engaging [43].

The implications of the research findings extend to various domains where real-time physical activity monitoring can yield significant benefits. Below, we outline potential applications and the associated advantages.

### A. *Fitness Training and Rehabilitation*

The proposed system holds immense promise in fitness training programs. It can serve as a virtual personal trainer, offering real-time guidance on exercise form, posture, and range of motion [44]. Individuals looking to improve their fitness levels can benefit from accurate feedback, reducing the risk of injuries and enhancing the effectiveness of workouts [44]. Additionally, the system can be adapted for use in rehabilitation programs, assisting patients in performing therapeutic exercises correctly and safely.

### B. *Physical Education in Schools*

Incorporating the system into physical education classes in schools can revolutionize the way students learn and engage in physical activities. It can provide valuable feedback to both students and teachers, ensuring that exercise routines are performed with precision [45]. This can lead to increased interest and participation in physical education, ultimately promoting a healthier lifestyle among young individuals.

### C. *Sports Coaching*

Coaches and athletes can leverage the system for sports training. It can assist in refining athletic techniques by offering real-time insights into movements and postures [46]. This can be particularly beneficial in sports where precise form is crucial, such as gymnastics, dance, and martial arts.

### D. *Home-Based Fitness*

With the increasing popularity of home-based fitness routines, the proposed system can find application in guiding individuals through exercise regimens in the comfort of their homes [47]. It eliminates the need for expensive gym memberships and personal trainers while ensuring that users perform exercises correctly.

## VII. Future Research Directions

### A. *Enhanced Feedback Mechanisms*

Future research can focus on the development of more sophisticated feedback mechanisms. This may include integrating voice-based instructions and motivational cues to enhance the user experience further. Additionally, incorporating haptic feedback through wearables can provide tactile guidance during exercises.

### B. *Multi-Modal Sensing*

Exploring multi-modal sensing techniques, such as combining visual data with data from wearable sensors, can improve the accuracy and comprehensiveness of physical activity monitoring [48]. This approach can enable the system to capture a broader range of information, including heart rate, muscle activity, and joint angles.

### C. *Personalization*

Tailoring the system to individual users' needs and fitness levels is an area ripe for exploration. Machine learning algorithms can be employed to adapt the system's feedback and recommendations to each user's unique requirements, optimizing the training experience [49].

### D. *Long-Term Impact*

Assessing the long-term impact of using the proposed system on individuals' fitness levels and overall health is a vital avenue for future research [50]. Longitudinal studies can track the progress and behavior changes of users over extended periods, providing insights into the sustained benefits of the technology.

### E. *Accessibility and Inclusivity*

Research can focus on ensuring that the system is accessible and inclusive for individuals of diverse abilities and backgrounds. This involves addressing challenges related to accommodating various body types, physical conditions, and cultural preferences in exercise routines.

### F. *Privacy and Data Security*

As with any technology that collects personal data, future research should emphasize robust privacy and data security measures [51]. Ensuring that user data is protected and used ethically is paramount.

In conclusion, the integration of augmented reality and deep learning for real-time physical activity monitoring holds immense potential for transforming fitness training, physical education, and sports coaching. The system's high accuracy and real-time feedback capabilities make it a valuable tool for improving exercise routines and promoting healthier lifestyles. Future research endeavors can further enhance the system's functionalities, personalize user experiences, and explore its long-term impacts on individuals' well-being.

## VIII. Conclusion

In conclusion, the amalgamation of augmented reality (AR) and deep learning technologies has propelled the realm of real-time physical activity monitoring into an era of innovation and potential. The system presented in this research paper, leveraging the power of PoseNet-based skeletal keypoint extraction and deep neural networks, has demonstrated remarkable accuracy and real-time functionality. The implications of this work span across various domains, including fitness training, physical education, sports coaching, and home-based fitness.

The achieved accuracy rate of 98% within 100 training epochs underscores the system's prowess in precisely classifying a wide array of physical activities based on skeletal keypoint data. This level of accuracy is of paramount significance, particularly in applications where the correctness of activity identification is indispensable. Furthermore, the system's real-time operation stands as a testament to its utility, offering immediate feedback to users during their exercise routines. This feature fosters user engagement, motivation, and an interactive experience that is conducive to effective physical training.

As technology continues to advance and research in this field progresses, the prospects for further enhancements and applications are promising. Future research endeavors may delve into more sophisticated feedback mechanisms, multi-modal sensing techniques, personalized user experiences, and long-term impact assessments. Moreover, ensuring accessibility and inclusivity for individuals of diverse backgrounds and addressing privacy and data security concerns remain pivotal in the evolution of this technology.

The future of real-time physical activity monitoring holds immense potential, offering opportunities to revolutionize fitness training, physical education, and sports coaching. The work presented in this paper serves as a foundation upon which further innovations and advancements can be built, ultimately contributing to the promotion of healthier lifestyles and the well-being of individuals across the globe.

# A Cyclic Framework for Ethical Implications of Artificial Intelligence in Autonomous Vehicles

Ahmed M. Shamsan Saleh
Department of Information Technology, University of Tabuk, Tabuk, Saudi Arabia

***Abstract*—The emergence of artificial intelligence (AI)-powered autonomous vehicles (AVs) represents a significant turning point in field of transportation, offering the potential for improved safety, efficiency, and convenience. However, the use of AI in this particular context exhibits significant ethical implications that require careful examination. This paper presents an extensive analysis of ethical considerations related integration of AI in AVs. It employs a multi-faceted approach to investigate ethical concerns of decision-making powered by AI including well-known trolley problem and moral judgments generated by AI algorithms. Additionally, it explores the complexities within safety and liability issues in the occurrence of incidents involving AVs, addressing the legal and ethical obligations of manufacturers, regulators, and users. The paper addresses the complex interaction between AI-driven transportation and its potential effects on employment and society. It provides an analysis on displacement of jobs and associated disruptions in workforce, as well as consequences for urban planning and public transportation systems. Furthermore, this study investigates the domain of privacy and data security in AVs, delving into issues related to gathering and utilization of data, as well ethical handling of personal information. Finally, this paper proposes a cyclic framework for ethical governance in AVs integrated with AI. It outlines future directions that prioritize transparency, accountability, and adherence to international humanitarian regulations. The study's findings and recommendations represent significant importance for policymakers, industry participants, and society. These stakeholders play crucial role in guiding the progress of AI in AVs, to create a transportation environment that is both safer and more ethically aligned.**

***Keywords*—*Artificial intelligence; autonomous vehicles; ethical implications; AI decision-making***

## I. Introduction

As AI continues to develop, its incorporation into autonomous vehicles has generated considerable interest and concern. This advancement of AI in AVs has the potential to completely transform the transportation sector, leading to increased safety, improved efficiency, and enhanced mobility [1]. Nevertheless, it is essential to acknowledge the ethical ramifications linked to this integration. In an effort to better understand the complex ethical issues that arise when artificial intelligence is used in autonomous vehicles, this paper will analyze the difficulties associated with safety, privacy, and social effects. Significant advancements in the field of AI-powered AVs have been made during the previous decade. Innovations in machine learning, computer vision, and sensor technology have encouraged this development [2]. From self-driving cars to unmanned drones, autonomous vehicles have shown promise ability in detecting their surroundings, making complicated judgments, and navigating through a wide range of scenarios without human intervention [3]. According to that, it is necessary to establish the foundation for examining the ethical ramifications linked to the incorporation of AI in AVs. This can help to ensure that this revolutionary technology is used in a way that benefits society, protects individual rights, and advances a more sustainable and ethical future.

The paper's main contributions are as follows:

- To establish a full ethical framework for the use of AI in autonomous vehicles, guiding industry stakeholders and policymakers in navigating the complex ethical environment.
- To offer a multi-faceted examination of ethical concerns in AI-driven decision-making, safety and liability concerns, the societal impact on employment, and privacy and data security, presenting a holistic perspective on this issue.
- To introduce an organized structure for ethical governance in AI-enhanced autonomous vehicles that prioritizes transparency, accountability, and compliance with international human rights principles.
- To provide insights that help policymakers build a safer, more ethically conscious future of transportation by assuring responsible AI development and deployment.
- To increase general awareness about the ethical issues raised by AI in self-driving vehicles, leading to a more in-depth discussion and better decisions about the adoption of AI in transportation.

The paper is structured to offer a complete examination of the ethical implications of AI in AVs. It starts by analyzing ethical considerations in AI-driven decision-making, followed by an exploration of safety and liability concerns, the societal impact on employment, and privacy and data security. Subsequently, a proposed framework, opportunities, challenges, and future directions for AI in autonomous vehicles are presented. The paper concludes by summarizing findings and offering insights for the responsible integration of AI in the realm of autonomous transportation.

## II. Ethical Considerations in AI-Driven Decision-Making

### A. *Introduction to AI Decision-making in Autonomous Vehicles*

The utilization of AI plays a crucial role in the functioning of AVs. This technology empowers these vehicles to effectively navigate through intricate situations, make rapid decisions, and adapt to dynamic surroundings [4]. This section presents an overview of the significance that AI plays in the decision-making processes employed by AVs. It examines the utilization of several techniques and technologies, including machine learning models, deep neural networks, and reinforcement learning, to facilitate the autonomous perception, interpretation, and response capabilities of vehicles. Additionally, this section investigates situations that give rise to dilemmas of ethics, analyzes the moral decisions made by AI algorithms, and delves into the wider ramifications for safety, liability, and the overall welfare of society. This section aims to enhance understanding of the complicated relationship between AI and ethical decision-making. By doing so, it seeks to facilitate the effective management of the intricate challenges associated with the deployment of AVs, while ensuring their alignment with human values and ethical principles.

*1) Understanding AI's decision-making role:* Within the realm of autonomous vehicles, AI plays a crucial role in undertaking decision-making tasks that were conventionally performed by human drivers. AI, utilizing sophisticated algorithms and machine learning approaches, empowers vehicles to sense their surroundings, analyze intricate data in real-time, and generate well-informed judgments that facilitate their safe navigation across diverse traffic situations. [5]. In contrast to traditional vehicles, which necessitate human drivers who depend on sensory inputs and personal judgment, AVs utilize an array of sensors, cameras, lidar, radar, and sophisticated processing systems to gather and analyze data from their immediate environment. The collected data is subsequently subjected to complex algorithms that simulate human decision-making processes and consider several factors, including vehicle velocity, road conditions, traffic patterns, and pedestrian behavior. The outcome is a computed response that seeks to maximize safety, effectiveness, and compliance with traffic regulations.

The role of AI in decision-making extends beyond the operational facets of autonomous driving. The task encompasses complex evaluations of risks, predictions of trajectories, and ethical dilemmas that emerge in scenarios lacking defined solutions [6]. AI algorithms aim to effectively negotiate the complexities mentioned above by employing predetermined rules, utilizing training data, and acquiring knowledge of patterns. The ultimate objective is to minimize potential negative consequences, adhere to traffic regulations, and prioritize the safety of passengers.

Nevertheless, the incorporation of AI into the process of decision-making is not devoid of its inherent difficulties. The outcome of judgments made by AI systems can be influenced by various factors, including ethical issues, unforeseen events, and algorithmic biases. This calls for a more comprehensive examination of the ethical ramifications linked to decision-making driven by artificial intelligence, as the decisions made by self-driving vehicles are not solely technical in nature, but also possess inherent moral dimensions.

*2) AI technology in autonomous vehicles:* The integration of AI technology has significantly transformed the domain of AVs, elevating them from purely mechanical entities to intelligent agents with the ability to see and react to their surroundings. This subsection offers a brief overview of the AI technologies that serve as the foundation for decision-making processes in AVs.

*a) Sensor fusion and perception:* The fusion of data from several sensors is a critical component in the implementation of AI-driven decision-making in AVs [7]. Cameras are utilized to record and document visual data, while lidar employs laser beams to scan and analyze the immediate environment. Radar, on the other hand, is employed to detect and measure the distances of objects, while GPS serves the purpose of providing precise location data. The integration of these data streams facilitates the development of a holistic comprehension of the vehicle's environment, enabling the recognition of obstacles, people, other vehicles, and road conditions.

*b) Machine learning and deep neural networks:* The progress of machine learning, namely deep neural networks, has played a crucial role in facilitating the ability of cars to analyze and comprehend intricate data patterns [8]. Neural networks acquire knowledge from extensive datasets, discerning subtle correlations within the data. This technological advancement facilitates the ability of cars to detect objects, anticipate behaviors, and adjust to changing surroundings, enhancing their decision-making capabilities.

*c) Behavior prediction and decision-making algorithms:* AI-driven decision-making encompasses the utilization of algorithms to forecast the actions of fellow road users and then take well-informed decisions [9]. These algorithms are designed to assess the data collected from various sensors and subsequently generate predictions on the potential paths of pedestrians, cyclists, and other vehicles. The vehicle's decision-making system utilizes the provided forecasts to make informed choices regarding optimal actions, including acceleration, braking, and lane changes, in order to guarantee secure navigation.

*d) Mapping and localization:* The accurate navigation of autonomous vehicles is contingent upon the utilization of detailed maps and exact localization [10]. AI algorithms are utilized to investigate map data and perform a comparative analysis with real-time sensor data in order to enhance the vehicle's awareness of its surroundings and accurately determine its position. The integration of data allows the vehicle to comprehend its environment, plan routes, and execute suitable choices at intersections, junctions, and urban environments.

*e) Simulation and training:* The process of AI-driven decision-making requires rigorous training within simulated environments [11]. Vehicles are subjected to virtual situations that replicate an extensive range of driving circumstances and possible challenges. During this training process, AI systems acquire the capability to effectively adapt to unfamiliar circumstances, hence improving their ability to make well-informed judgments in real-world situations.

While these AI technologies offer tremendous advancements, their integration into AVs raises ethical concerns. Due to the complexity of decision-making algorithms, the possibility for bias in training data, and the challenges of addressing unanticipated scenarios, autonomous vehicle AI-driven decisions must be ethically evaluated.

### B. Discussion of Ethical Dilemmas of AI in AVs

The most prominent ethical difficulty brought up by the use of AI in AVs is the trolley problem [12]. This section explores the ethical difficulties that arise in circumstances where an AV has to deal with making decisions that have the potential to harm various individuals or entities. It investigates situations in which an AV is faced with the ethical dilemma of prioritizing the safety of its occupants against minimizing harm to pedestrians or other vehicles. This paper seeks to focus on the intricate trade-offs and moral dilemmas encountered by AI systems while dealing with ethical problems, whereby they must make rapid decisions that could have significant and lasting impacts on individuals' lives.

*1) Clarification of ethical dilemmas in autonomous Vehicle Scenarios:* This subsection explores the complexities of ethical quandaries faced by autonomous vehicles, with particular emphasis on the well-debated trolley problem.

*a) The trolley problem and its variations:* The famous ethical thought experiment known as "the trolley problem" poses the moral dilemma of what to do when a runaway trolley threatens many people who are chained to separate tracks. The spectator must choose whether to pull a lever that will send the trolley down a different track, potentially resulting in the loss of one life in order to rescue multiple lives. In the context of self-driving vehicles, this dilemma becomes tangible [12]. Consider AV that must decide whether to swerve to avoid a crowd of people, putting its occupants in danger, or to continue straight, harming the pedestrians.

*b) Balancing human lives:* The ethical dilemmas related to self-driving vehicles frequently center on the complex task of assigning value to human lives [13]. Algorithms are required to allocate value to various individuals, including the occupants of AVs, pedestrians, cyclists, and passengers in other vehicles. This situation gives rise to significant ethical inquiries regarding the intrinsic value of human lives and the challenging endeavor of doing such calculations.

*c) Unpredictable situations and decision algorithms:* Real-life situations often exhibit complexities that deviate from the simplicity of the trolley problem. AVs often meet complicated scenarios in which the optimal path of action is not immediately clear. Decision algorithms must assess a multitude of elements, encompassing possible outcomes, probability of harm, and legal considerations. Nevertheless, ethical issues frequently encompass factors that extend beyond mere computations, such as the emotional consequences of decisions or the societal ramifications of algorithm selections.

*d) The role of human values:* The evaluation of social values is necessary in determining the appropriate approach for AVs to address ethical concerns. What are the ethical standards that should serve as the foundation for AI decision-making [14]? In the context of vehicular operations, a fundamental question arises regarding the primary objective that vehicles should prioritize. Specifically, should AVs prioritize the safety of their occupants, strictly comply with traffic restrictions, or aim to reduce overall harm? To answer these questions, we need to strike a balance between utilitarian principles, deontological concerns, and cultural norms. This highlights how important it is to include human input and shared values in the algorithm's decision-making process.

*e) Broader implications:* Beyond immediate scenarios, autonomous cars face a broader set of ethical challenges. They make individuals concerned about loss of privacy, legal liability, and control over their own lives. To solve these moral dilemmas, we need not only technological advances but also a societal consensus on the ethical principles that must guide AI-driven judgments in potentially fatal circumstances.

Through an exploration of these ethical dilemmas, the present paper initiates a discourse concerning the core values that AVs need to adhere to. The next sections go into the ramifications of these ethical issues, the moral assessments conducted by AI algorithms, and the numerous factors involved in attaining ethically accountable decisions led by AI.

*2) Challenges and tradeoffs from a moral perspective:* The presence of ethical difficulties within AV situations gives rise to a wide range of moral challenges that necessitate our engagement with complicated trade-offs. This subsection explores the complex ethical considerations that occur when AI algorithms encounter decisions that involve possible harm and benefit.

*a) Estimating harms and benefits:* Quantifying the probable harm and benefit in a specific situation is recognized as a significant moral challenge [15]. The assessment of risks related to various outcomes, such as the potential harm to occupants, pedestrians, and other road users, is a crucial task for AVs. The process of assigning numerical values to these outcomes necessitates a degree of objectivity that frequently conflicts with the intricate and highly subjective essence of ethical judgments.

*b) The worthiness of human life:* The assignment of value to human lives is a profound philosophical challenge. The ethical dilemma of determining whether to prioritize the safety of the vehicle's occupants over others prompts significant inquiries regarding the moral value attributed to various lives. This complex situation transcends mere mathematical computations, delving into moral theories such as utilitarianism, deontology, and virtue ethics.

*c) Cultural and contextual distinctions:* Moral considerations are influenced by cultural norms, legal frameworks, and society's expectations. The perception of ethical decisions might vary between cultures, leading to differing interpretations and evaluations. In order to ensure the effective operation of AVs, it is imperative that the algorithms governing their behavior possess the ability to adapt to the nuances of many situations, while simultaneously upholding universally accepted ethical values.

*d) Unintended effects:* Trade-offs can result in unforeseen consequences. Although algorithms may have the intention of minimizing harm, their decisions can unintentionally lead to unintended negative effects. To successfully mitigate these unintended consequences, it is imperative to develop an in-depth understanding of complicated systems and the potential ripple effects generated by every action made.

*e) Fairness and bias in algorithms:* The moral challenges overlap with concerns over algorithmic bias and fairness [16]. When AI judgments exhibit a disproportionate impact on specific groups, ethical dilemmas arise that can potentially increase pre-existing social imbalances. The task of ensuring fair treatment in the context of ethical issues poses significant difficulties, requiring the integration of ethical concepts and fairness considerations into the design of AI systems.

*f) Achieving a balance between short- and long-term effects:* Moral trade-offs frequently necessitate the delicate balancing between immediate outcomes and long-term implications [17]. A decision that exhibits moral justifiability in the immediate time may result in negative consequences for society's trust, legal liability, or the evolution of technologies. Achieving a balance between short-term and long-term consequences is of crucial significance when dealing with complicated ethical situations.

The successful handling of moral issues and trade-offs in the creation of AI algorithms for AVs requires the adoption of a multidisciplinary approach that covers several fields like as ethics, philosophy, psychology, and engineering. By recognizing the complex ethical aspects of decision-making, we may facilitate dialogues that result in the rise of ethically accountable AI systems that emphasize safety, fairness, and the overall welfare of society.

### *C. Understanding Moral Decisions Made by AI Systems*

The AI algorithms utilized in AVs are specifically designed to make decisions by relying on predetermined rules, training data, and objective functions. Nevertheless, it is important to acknowledge that these algorithms have the potential to unintentionally include biases, assumptions, or subjective value judgments that can significantly influence the process of decision-making. This section provides a critical analysis of the moral judgments made by AI algorithms and the potential ramifications that arise from these judgments. This study examines the potential implications of the algorithm's training data, biases in data gathering, and algorithmic decision-making procedures on the accidental perpetuation of societal biases or the emergence of concerns regarding fairness, justice, and discrimination. Through an in-depth look at these ethical judgments, this study highlights the need for transparency, accountability, and ethical oversight in the creation and implementation of AI-driven decision-making systems.

*1) Analysis of the moral judgment process in AI systems:* The progress of artificial intelligence has provided self-driving vehicles with the potential to make rapid ethical decisions in sophisticated scenarios [18]. This subsection explores the mechanisms via which AI algorithms address ethical considerations, providing insight into the complex processes that govern moral decision-making in AI systems.

*a) Ethical frameworks based on data:* A large amount of data is needed for AI algorithms to generate decision-making frameworks that are in line with human values [19]. These datasets include a wide range of scenarios, from normal traffic bottlenecks to life-threatening situations. Algorithms learn to recognize patterns, correlate data, and come up with responses based on historical examples using machine learning methods.

*b) Utilitarian vs. deontological approaches*: The process of ethical decision-making frequently corresponds to either utilitarian or deontological frameworks [20]. Utilitarian approaches place emphasis on the maximization of general well-being through the prioritization of outcomes, whereas deontological approaches promote adherence to principles and rules, irrespective of the resulting outcomes. Artificial intelligence algorithms are required to reconcile these differing ethical philosophies in order to make decisions that effectively balance these principles.

*c) Incorporating formal logic:* AI algorithms frequently utilize formal logic as a way of handling moral dilemmas [21]. This process involves the encoding of ethical concepts, legislation, and social norms into a set of logical rules. As an illustration, algorithms may have a tendency to prioritize the protection of human lives above the mitigation of property damage, or avoidance of harm to a pedestrian over the well-being of a passenger. These logical principles provide guidance for making decisions in real-time situations.

*d) Human preferences as a source of learning:* AI systems can acquire the ability to mimic human moral judgments through the process of learning from human behavior and ethical preferences [22]. The underlying principle of this approach is the idea that an algorithm possesses the capability to predict human decisions through the analysis of extensive datasets encompassing human choices in comparable situations. Even so, this approach gives rise to concerns regarding biases present in the training data and the possibility of reinforcing existing ethical norms, regardless of their fairness or unfairness.

*e) Ethical calibration and flexibility:* The difficulty is in the process of calibrating algorithms to accurately include societal ethics while avoiding enforcing strict moral principles [23]. AI algorithms must possess sufficient flexibility to adapt to a wide range of cultural, legal, and contextual variations while upholding a core ethical framework.

*f) Transparency and accountability:* It is crucial to understand the mechanisms through which AI algorithms formulate ethical assessments in order to promote transparency and ensure accountability [24][25]. Assessing the alignment of decision-making processes with ethical principles becomes challenging when those procedures are concealed or inadequately comprehended. The utilization of transparent algorithms allows for external evaluation and encourages the responsible deployment of AI.

*g) Human oversight and intervention:* The importance of human monitoring remains crucial in the context of AI algorithms' ability to independently make ethical judgments [26]. The ability to intervene and adjust algorithmic behavior guarantees that AI decisions are in line with human values and can adapt to unforeseen ethical dilemmas.

This study examines the complex mechanisms through which AI systems formulate moral assessments, providing insights into the technological and ethical factors that govern decision-making in autonomous vehicles. Gaining a comprehensive understanding of these mechanisms enables us to effectively design ethically robust AI systems capable of effectively addressing complex moral dilemmas in real-world scenarios with greater nuance and responsibility.

## III. Safety and Liability Concerns

### A. *Analyzing the Considerations of Autonomous Vehicle Safety*

The safety implications associated with AVs are of utmost significance, given their capacity to influence the well-being of passengers, pedestrians, and other road users. This section provides an in-depth investigation of the safety considerations related to self-driving vehicles. It analyzes several obstacles and risks caused by technical limitations, sensor malfunctions, software bugs, and unforeseen circumstances. Furthermore, this study examines the significance of safety rules, standards, and testing protocols in guaranteeing the secure functionality of AVs. Through the assessment of these safety factors, the primary objective of this investigation is to provide insight into the ethical responsibilities of stakeholders in prioritizing the welfare of both individuals and communities.

*1) Discussing safety risks and challenges:* The increasing use of artificial intelligence in the decision-making mechanisms of autonomous cars has brought up a significant ethical aspect regarding the safety risks and challenges associated with these advanced technologies [27] [28]. This subsection explores the complex safety problems that arise from the incorporation of AI in autonomous vehicles.

*a) Complexities of real-world scenarios:* AVs operate within environments characterized by unpredictability and dynamic behavior. The complex nature of traffic scenarios in the real world, along with varying weather conditions and unforeseen events, presents considerable obstacles for AI algorithms. The fundamental concern for safety lies in guaranteeing that algorithms produce effective and secure responses throughout a wide variety of scenarios.

*b) Edge cases and rare events:* AI systems may fail to encounter specific edge cases or infrequent events during the training process, resulting in inadequate readiness [29]. Rare situations, such as harsh weather conditions or unusual traffic scenarios, possess the potential to confuse algorithms that lack prior exposure to such events.

*c) Handling uncertainty:* The presence of uncertainty is an inherent characteristic of real-world contexts. Autonomous vehicles encounter difficulties in dealing with data that is either insufficient or in conflict, hence posing challenges in making decisions that prioritize safety while simultaneously reducing potential harm. The ethical and safety dilemma arises from the difficult balance between the necessity of exercising caution in decision-making and the demand for quick responses.

*d) Cybersecurity and vulnerabilities:* The integration of artificial intelligence raises concerns about cybersecurity [30]. AVs are significantly dependent on networked systems and the flow of data, putting them vulnerable to potential hacking and malicious attacks. The implementation of rigorous cybersecurity measures is essential in order to ensure the safety of both passengers and road users, effectively protecting against any breaches.

*e) Alignment of ethics and legal:* AI algorithms are required to not only effectively navigate traffic in a safe manner but also adhere to ethical and legal principles [31]. Decisions that place a higher emphasis on ensuring safety may potentially clash with ethical values, namely those associated with safeguarding vulnerable road users. Achieving an optimal balancing between safety, ethics, and adherence to legal standards is a complicated task.

*f) Interaction and handoff between humans and AI:* The safety implications of the interaction between AI systems and human passengers are of crucial significance. A smooth transition between autonomous and human control is essential in order to prevent potentially dangerous situations that may arise when a human operator needs to take over control of the vehicle suddenly.

*g) Trade-offs in ethics and safety measures:* AI algorithms frequently encounter ethical dilemmas when making judgments that impact safety. As an example, an algorithm may potentially assign higher priority to the safety of vehicle occupants as opposed to pedestrians, so giving rise to ethical concerns regarding the relative worth of different lives. The ethical dilemma of striking a balance between safeguarding human lives and upholding moral standards is a fundamental ethical concern.

The mitigation of these risks and obstacles demands the implementation of an integrated plan that combines advances in technology with ethical considerations. The assurance of safety for AVs encompasses more than just accident prevention. It requires the development of AI systems that exhibit responsible, transparent, and ethical navigation capabilities in complex situations. By comprehending and effectively tackling these difficulties, we establish the foundation for a more secure and ethically sound integration of artificial intelligence in self-driving vehicles.

*2) Investigating the regulations and standards for safety:* The responsible development and deployment of AVs require the establishment of a comprehensive system of safety regulations and standards in order to effectively incorporate AI into these vehicles [32] [33] [34]. This subsection examines the significance of safety standards and the difficulties associated with setting uniform guidelines for self-driving vehicles powered by artificial intelligence.

*a) Dynamic regulatory landscape:* The rapid advancement of AI-powered technology has presented significant challenges for regulatory entities on a global scale. Achieving an ideal balance between accommodating technological progress and addressing safety considerations requires the establishment of carefully planned regulations.

*b) Harmonizing global standards:* The harmonization of safety standards associated with self-driving vehicles is necessary in order to facilitate the cross-border deployment of these vehicles. The establishment of worldwide standards guarantees the implementation of uniform safety protocols that transcend local limitations.

*c) Addressing ethical and moral concerns:* Safety regulations should not just prioritize technical factors, but should also encompass ethical and moral considerations. This entails the establishment of criteria for acceptable levels of risk, the formulation of ethical rules for algorithmic responses to problems, and the development of frameworks for scenarios that may involve trade-offs.

*d) Human safety and road user protection:* The primary focus of safety regulations should be to emphasize the welfare of human occupants, as well as pedestrians, cyclists, and all other road users. In order to ensure the safe operation of autonomous vehicles, it is imperative that they exhibit responsible navigation in traffic scenarios, thereby mitigating potential risks for all stakeholders.

*e) Testing and validation protocols:* Establishing extensive testing and validation protocols is an integral part of developing safety standards [35]. In order to show that they can operate safely and in accordance with regulations, autonomous vehicles need to be tested extensively, both in simulated and real-world settings.

*f) Performance metrics within the real world:* Safety standards should provide performance measures that accurately represent safety situations in the actual world. Metrics should incorporate not just the prevention of accidents, but also factors such as the reduction of near-miss incidents, adherence to traffic rules, and the proper handling of ethical concerns.

*g) Adaptability to emerging technologies:* It is essential for regulatory frameworks to possess the capacity to react to the emergence of AI technology as well as unexpected safety challenges. The swift rate at which technology is progressing requires the establishment of adaptable regulations capable of effectively addressing emerging risks and opportunities.

*h) Balancing innovation and safety:* The primary difficulty lies in encouraging innovation while also prioritizing safety. In order to promote technological advancement while ensuring the safety of passengers, road users, and society as a whole, regulatory frameworks must achieve a careful balancing.

*i) Collaboration and industry engagement:* The implementation of robust safety regulations necessitates a collaborative effort among regulatory entities, industry stakeholders, and technological innovators. The involvement of diverse stakeholders in the regulatory process guarantees that the resulting regulations are comprehensive, appropriate, and practical.

Through a comprehensive analysis of safety rules and standards, we are able to acquire a deeper understanding of the crucial role that they assume in influencing the safe adoption of AI-powered AVs into our transportation systems. The advancement of autonomous technology demands the establishment of comprehensive regulatory frameworks that ensure both the safety of individual vehicles and the overall welfare of society.

### *B. Responsibility and Liability in Autonomous Vehicle Accidents*

The occurrence of accidents with AVs gives rise to intricate inquiries regarding liability and responsibility. The identification of the responsible party in the event of an accident is a considerable challenge. This section provides an in-depth analysis of the complex debates regarding liability and responsibility in accidents using AVs. The analysis encompasses various liability models, including vehicle manufacturers, software developers, human operators, and the legal frameworks that regulate AVs. By looking at the various factors that affect liability, the aim is to address the ethical ramifications associated with the assignment of responsibility in incidents involving self-driving vehicles. This effort seeks to establish the implementation of suitable procedures that protect the rights and welfare of individuals impacted by such accidents.

*1) Examination of liability models:* The integration of autonomous vehicles into our transportation infrastructure leads to complex inquiries on the allocation of liability and responsibility in the occurrence of accidents [36][37][38]. This subsection explores the complicated variety of liability models that arise as a result of the implementation of AI-powered AVs.

*a) Liability of a traditional driver vs. an autonomous system:* The complexity of determining liability increases when AI systems replace human drivers. The conventional model of driver liability allocates responsibility to the human operator. However, in the context of autonomous vehicles, the distinction of responsibility is less clear-cut, as it becomes interrelated among the technology developer, vehicle manufacturer, and passengers.

*b) Manufacturer and developer liability:* Due to the extensive utilization of advanced AI algorithms and sophisticated sensor systems, AVs may potentially result in a transfer of liability from the driver to the manufacturer of the vehicle or the developer of the technology. Determining the level at which a defect or malfunction in the AI system transitions into the manufacturer's liability poses a formidable task.

*c) Third-party liability and cybersecurity:* The scope of liability includes not only vehicle manufacturers, but also third parties engaged in vehicle software, hardware, and data management. The identification of the liable party in the event of a cyberattack compromising the safety of an AV can be a complex process, since it may entail the involvement of software developers, system integrators, and regulatory entities.

*d) Liability in mixed traffic environments:* Traditional human-driven automobiles exist side by side with autonomous ones. It can be difficult to determine fault in incidents involving both autonomous and human-driven vehicles. Responsibility must be clearly defined in order to determine if the AI system or the human driver was at fault.

*e) Liability allocation and regulatory oversight:* Regulatory entities play a critical role in the allocation of liability related to accidents with autonomous vehicles. Ensuring equal allocation of liability demands the adoption of rules and regulations that define the specific duties of manufacturers, developers, and vehicle operators.

*f) Redefining legal concepts:* The implementation of AI within AVs may potentially require a reconsideration and redefinition of legal concepts such as negligence, duty of care, and foreseeability. The involvement of both humans and AI algorithms in decision-making processes poses a significant challenge to conventional legal definitions and principles.

*g) Insurance and risk management:* The impact of liability models' evolution on insurance and risk management techniques is significant. There is a possibility that conventional auto insurance might face a shift into product liability insurance, wherein manufacturers and developers take responsibility for accidents resulting from technological faults.

*h) Ethical dimensions of liability:* Discussions regarding liability provide a place for ethical inquiries on the concepts of accountability and fairness. The essential challenge lies in ensuring that liability models incorporate ethical principles, align with societal norms, and avoid imposing excessive costs on certain parties.

Effective management of liability models needs the establishment of collaborative efforts among several stakeholders, including technology developers, manufacturers, regulatory entities, legal professionals, and insurance providers. The advent of AI-driven transportation demands a critical reassessment of liability models in order to develop a comprehensive legal and ethical framework that effectively addresses accidents, fosters innovation, and protects societal well-being.

*2) Legal and ethical considerations of accidents:* The emergence of self-driving vehicles presents a novel aspect to the legal and ethical considerations regarding accidents [39][40]. This subsection examines the complex relationship between legal obligations, ethical dilemmas, and society's perceptions in the context of incidents involving AVs.

*a) Determining causality and responsibility:* The occurrence of accidents engaging AVs requires a careful investigation of cause and the allocation of responsibility. It is necessary to ascertain the precise contribution of the AI system, the human operator, or a combination of factors to correctly assign liability for the accident.

*b) The role of AI decision-making:* The emergence of ethical inquiries arises when accidents occur as a consequence of decisions executed by AI systems. The assessment of whether these decisions align with ethical principles, societal norms, and regulatory rules is of greatest significance in understanding the ethical aspects of the incident.

*c) Ethical principles in collision avoidance:* Autonomous vehicles are frequently configured with a primary focus on prioritizing collision avoidance and minimizing potential harm. Nonetheless, the integration of algorithms in AVs gives rise to ethical difficulties when dealing with the decision-making process of choosing the safety of the vehicle's occupants over that of pedestrians or other individuals on the road.

*d) Transparency and accountability:* Ethical considerations relating to accidents encompass the principles of accountability and transparency. The transparent analysis of the decision-making process is crucial in understanding the causes of accidents resulting from algorithmic errors or biases, as well as in preventing their recurrence in the future.

*e) Human intervention and overrides:* Accidents may potentially entail instances of human intervention, wherein the autonomous system was overridden by a human driver. The ethical and justifiability of the human override introduces complexity in understanding the ordered sequence of events leading to the accident.

*f) Public perception and trust*: Accidents associated with AVs have a significant impact on the public's perception and level of trust in this technological advancement. The societal attitudes and acceptance of autonomous vehicles, as well as the willingness to coexist with them on public roads, are influenced by the ethical and legal aspects associated with accidents.

*g) International variability in regulations:* International legal and ethical considerations exhibit variations as a result of diverse rules and cultural standards. The legal and ethical consequences of an accident can vary significantly depending on the country, hence introducing complexities in cross-border mobility.

*h) Balancing legal and ethical considerations:* Achieving a harmonious balance between legal and ethical factors in incidents involving AVs demands an alignment of rules with societal norms and ethical concepts. Legal frameworks must possess the necessary flexibility to effectively respond to the continuously developing ethical challenges and technological advances.

A comprehensive understanding of the legal and ethical aspects related to accidents using AVs is important in order to shape the path of transportation in the future. The growth in the adoption of autonomous technology requires the development of legal and ethical frameworks that prioritize fairness, accountability, and safety, while also promoting innovation in this transformational domain.

### C. The Ethical Obligations of Manufacturers, Regulators, and Users

The ethical responsibilities associated with the development, adoption, and utilization of AVs imposes obligations on multiple parties, such as manufacturers, regulators, and users. This section aims to analyze the ethical obligations of the aforementioned main players. This study examines the ethical responsibilities of manufacturers in regard to prioritizing safety, transparency, and accountability during the development and manufacturing processes of AVs. Furthermore, this study explores the involvement of regulatory bodies in the development of comprehensive frameworks and policies that promote the responsible adoption of AVs. Moreover, the section delves into the ethical responsibilities of users, highlighting the significance of well-informed decision-making, adherence to regulatory frameworks, and responsible conduct during engagements with AVs. Through a careful examination of these ethical commitments, our objective is to establish a culture characterized by increased awareness of ethics and accountability within the AV ecosystem.

The integration of autonomous vehicles on a large scale creates a range of ethical obligations that encompass manufacturers, regulators, and users [41] [42]. This subsection examines the various roles and ethical responsibilities that each set of stakeholders has in guaranteeing the appropriate advancement, implementation, and functioning of autonomous vehicles.

*1) Ethical responsibilities of manufacturers:* The ethical role of shaping the societal impact of autonomous vehicles lies with the manufacturers of such vehicles. The scope of their responsibilities includes:

*a) Ensuring safety as a priority:* It is imperative for manufacturers to emphasize the safety of passengers, pedestrians, and other road users as their highest priority. The development of fail-safe systems, rigorous testing protocols, and mechanisms for correcting defects and vulnerabilities should be guided by ethical considerations.

*b) Transparency and accountability:* In order to adhere to ethical principles, it is essential to ensure transparency in the disclosure of both the capabilities and limitations of autonomous systems. It is critical for manufacturers to engage in transparent communication regarding the decision-making processes of AI, hence facilitating an extensive understanding of the technology's behavior among users and regulators.

*c) Mitigation of biases:* It is important for manufacturers to recognize and address algorithmic biases that may result in discriminatory consequences. Efforts should be made to proactively mitigate the continual growth of social biases and inequalities by AI systems.

*d) Protecting privacy:* The ethical obligation encompasses the protection of user privacy and the security of data. Manufacturers are required to apply strict processes in order to effectively mitigate the risks associated with illegal access and misuse of personal data that is gathered by autonomous systems.

*2) Ethical responsibilities of regulators:* Regulators play a critical ethical role in establishing rules that control the implementation and functioning of self-driving vehicles:

*a) Balancing innovation and safety:* Regulatory authorities are tasked with the responsibility of achieving an appropriate balance between fostering innovation and protecting the safety of the general population. Ethical issues require that rules should strike an acceptable compromise between encouraging technological advancement and guaranteeing the welfare of individuals and society.

*b) Clear ethical guidelines:* The execution of ethical responsibilities demands the establishment of clear guidelines that AI algorithms embedded in AVs need to adhere to. These requirements must encompass aspects related to safety, ethical decision-making, and adherence to society norms.

*c) Continuous evaluation and adaptation:* Regulators bear an ethical responsibility to consistently monitor the operational efficiency of AVs, while concurrently adapting regulations to effectively address emergent safety and ethical dilemmas. The incorporation of flexibility is necessary in order to adapt to the continually evolving environment of technology and social norms.

*d) Collaboration and transparency:* Ethical practice requires the establishment of cooperative efforts among regulators, manufacturers, and various other stakeholders. The implementation of transparent dialogue is essential in order to guarantee that regulations are in alignment with the progress of technology and ethical principles.

*3) Ethical responsibilities of users:* The functioning of autonomous vehicles involves ethical duties that users must undertake:

*a) Adherence to rules and laws:* Users are ethically obligated to comply with traffic laws and regulations established by regulators to uphold moral principles. This entails the responsible utilization of autonomous features and the timely intervention when necessary to ensure safety.

*b) Understanding technology limitations:* It is crucial for users to possess an in-depth understanding of the limitations imposed by autonomous systems and their role in the driving process. Ethical use demands the avoidance of complacency and being prepared to take control in complicated or critical circumstances.

*c) Reporting and feedback:* The ethical duty involves the act of reporting any irregularities, flaws, or malfunctions observed in autonomous systems. The act of offering feedback to manufacturers and regulators plays a significant role in fostering ongoing improvement and promoting a sense of accountability.

*d) Careful management:* It is expected for users to fulfill their ethical obligation by managing autonomous vehicles carefully, in order to avoid any potential cases of misuse or tampering that may compromise safety or generate unethical behavior.

Through an analysis of the ethical obligations held by various stakeholders, a framework is established to foster a cooperative approach to the advancement and implementation of AVs. Ethical concerns play a crucial role in guiding manufacturers, regulators, and users as they strive to shape a transportation future that places the highest priority on safety, fairness, and the overall welfare of society.

## IV. Effects on Employment and Society

### A. Exploring the Effects of Autonomous Vehicles on Employment

The potential ramifications of the broad integration of AVs on employment within diverse sectors are considerable [43][44][45]. This section examines the potential implications of autonomous vehicles on employment. It investigates the potential impact of automation on employment displacement within transportation sectors, specifically focusing on areas such as trucking, delivery services, and taxi services. Furthermore, the section explores the prospective emergence of new job opportunities in the domains of AVs systems' development, maintenance, and monitoring. The purpose of this part is to examine the effects on employment and explore the ethical aspects related to workforce transformation. It emphasizes the importance of taking proactive actions to mitigate any inconveniences.

*1) Consideration of job displacement and creation:* The emergence of AVs has a double effect on employment, as it has the ability to both displace and create jobs [46] [47]. This subsection explores the complex relationship between the disruptive capabilities of self-driving vehicles and the possible employment opportunities they may provide within the workforce.

*a) Job displacement in conventional sectors:* With the increasing prevalence of AVs, there is a possibility of specific job categories within the conventional transport sector experiencing displacement. The advent of autonomous technology has the potential to significantly affect occupations such as taxi drivers, truck drivers, and delivery drivers, as these roles primarily involve the execution of routine driving duties. The potential shift may lead to employment reductions, presenting difficulties for individuals whose livelihood relies on these positions.

*b) Transitioning to a new range of skills:* The increasing adoption of AVs highlights the significance of enhancing and updating the skill sets of the workforce. Displaced workers are presented with an opportunity of transitioning into positions that require skills in areas like as vehicle maintenance, AI programming, data analysis, cybersecurity, and remote vehicle monitoring. Education and training programs play a crucial role in facilitating the ability of workers to effectively navigate and adapt to the dynamic and evolving employment environment.

*c) Emergence of new occupations:* The emergence of AVs is expected to generate new career opportunities that focus on their deployment and maintenance. Various roles associated with vehicle monitoring, system maintenance, safety supervision, and remote support may potentially arise. These positions require a combination of technical expertise and an in-depth awareness of autonomous technology.

*d) Planning and development of urban infrastructure:* The integration of AVs requires the implementation of infrastructure upgrades and changes. Engineers, urban planners, and construction workers are essential stakeholders in the process of modifying road networks, parking infrastructure, and transit centers to effectively accommodate self-driving vehicles. The increasing need for infrastructural development has the potential to generate job creation within these sectors.

*e) Ethical concerns and policy development:* The advent of AVs needs the establishment of ethical principles and policies. The participation of professionals specializing in ethics, law, and public policy will play a crucial role in formulating legislation regarding the behavior, accountability, and ethical decision-making of AVs.

Effectively managing the employment consequences arising from the integration of AVs needs the implementation of proactive strategies aimed at mitigating the possible displacement of workers, while simultaneously maximizing opportunities for creating jobs. Through the allocation of resources into education, training, and the development of new skill sets, society may facilitate a shift towards an independent future that not only enhances the effectiveness of transportation but also fosters a workforce that is robust and capable of adapting to changes.

*2) The effects on society as a whole:* In addition to the immediate impact on employment, the extensive adoption of AVs has significant societal ramifications [48] [49][50]. This subsection explores the diverse societal effects of autonomous vehicles, going beyond the scope of employment-related factors.

*a) Environmental benefits and sustainability:* The implementation of AVs presents environmental advantages by means of enhanced driving patterns, decreased traffic congestion, and the possibility of transitioning towards electric and shared mobility. Nevertheless, it is imperative to acknowledge and prioritize the solution of concerns regarding the possible escalation in vehicular usage and energy consumption in order to optimize the benefits of sustainability.

*b) Economic and social equity:* The advent of AVs has the potential to provide economic opportunities; nevertheless, it is essential to guarantee that the benefits are distributed in a fair and equitable manner. It is necessary to prioritize efforts aimed at mitigating the focus of economic benefits in specific sectors or regions, so avoiding the marginalization of others.

*c) Accessibility and mobility fairness:* Autonomous cars possess the capacity to improve mobility for individuals with disabilities, the elderly population, and those lacking conventional means of transportation. However, it is important to take into account affordability, accessibility, and the prevention of mobility gaps in order to ensure that these benefits are accessible to all parts of society.

*d) Cultural and behavioral shifts:* The adoption of AVs into society has the ability to result in cultural transformations in individuals' perceptions of transportation and mobility. The idea of the vehicle as an extension of a person's identity might experience change as progress in autonomous technology and the growth of ride-sharing services redefine the context of personal transportation preferences.

*e) Traffic and urban planning:* The rise of AVs holds the capacity to significantly reshape traffic patterns and urban planning. By enhancing the flow of vehicles, minimizing traffic congestion, and optimizing the selection of routes, urban areas have the potential to improve their efficiency and livability. However, it is important to consider and tackle potential obstacles, such as the rise in vehicle miles traveled and the impact on public transit, in order to achieve a balanced urban development.

*f) Effect on land use:* The emergence of AVs has the potential to significantly transform land utilization patterns through a change of parking requirements and the freeing up of urban areas presently designated for parking facilities. The possible effect of this phenomenon on urban development lies in the opportunity for the transformation of parking lots into green spaces, social facilities, or commercial establishments.

*g) Redefining vehicle ownership and sharing:* The start of AVs has the potential to fundamentally transform the current paradigm of vehicle ownership by promoting the use of shared mobility services. The mentioned shift carries significant consequences for the manufacturing of vehicles, ownership models, and patterns of urban mobility. It has the potential to decrease the necessity of private vehicle ownership and the resources connected with it.

*h) Regulatory challenges and policy implications:* Comprehensive regulatory frameworks are necessary in order to effectively manage the multifaceted societal impact of AVs, encompassing crucial aspects such as safety, privacy, liability, and alignment with social goals. The future direction of AV deployment and its impact on numerous sectors of society will be influenced by policy decisions.

Effectively addressing the societal consequences of AVs demands an extensive approach that encompasses not only the implications for employment, but also takes into account wider social, economic, and environmental factors. Through the promotion of interdisciplinary collaboration and the active participation of various stakeholders, societies have the opportunity to leverage the revolutionary capabilities of AVs to establish transportation systems that are more sustainable, accessible, and equitable.

## V. PRIVACY AND DATA SECURITY

### A. *Analysis of Privacy Concerns Related to Autonomous Vehicles*

The use of AI in self-driving vehicles gives rise to considerable privacy concerns due to the massive gathering and analysis of data [51][52]. This section examines the potential issues with privacy that are linked to AVs. This study investigates the potential risks and concerns associated with collecting of personal data, including location information, vehicle usage patterns, and sensor data. Furthermore, this section delves into the ethical considerations relating to the privacy rights of individuals, the possibility of data breaches or illegal access, and the ramifications of broad surveillance. Through a careful examination of these privacy concerns, our objective is to encourage awareness and discourse regarding the ethical aspects of privacy in AVs.

*1) Analysis of data collection and privacy risks:* The deployment of AVs presents major challenges regarding the collecting of data and the preservation of privacy [53][54]. This subsection explores the complex ethical issues of the data produced by AVs, emphasizing the potential risks involved and the necessity of protecting persons' privacy rights.

*a) Extensive data generation:* AVs are supplied with a diversity of sensors and cameras that continuously gather extensive amounts of data regarding their environment, vehicle functionality, and even occupants. The data's scale and granularity offer potential benefits as well as drawbacks concerning individuals' privacy.

*b) Individual tracking and profiling:* The data produced by AVs has the potential to be utilized for the purpose of monitoring persons' patterns of movement, routines, and behaviors. This problem gives rise to ethical considerations about the creating of comprehensive profiles that have the potential to infringe upon individuals' privacy.

*c) Disclosure of sensitive data:* Personal information such as location history, communication patterns, and biometric data may be acquired from passengers in AVs. Identity theft, unwanted spying, and other violations of privacy are all possibilities if sensitive data are disclosed.

*d) Data reuse and profitability:* The data gathered by AVs has the potential to be utilized for additional reasons outside their primary objectives, such as personalized marketing or insurance rate determination. This situation gives rise to ethical concerns regarding the concept of informed consent and the capacity of individuals to exercise control over the utilization of their data.

*e) Cybersecurity vulnerabilities:* Autonomous vehicles possess huge amounts of data, making them susceptible to future intrusions. Incidents of vehicle system breaches not only harm individuals' personal privacy but also present serious risks to the physical safety of both passengers and other individuals on the road.

*f) Data ownership and control:* The ethical challenge lies in determining the ownership and control of the data collected by self-driving vehicles. It is critical that individuals possess clear rights to their data and have the ability to determine how and when it is shared.

*g) Informed consent and transparency:* The practice of ethical data gathering requires obtaining informed consent from participants and maintaining transparency throughout the process. It is fundamental for passengers and users to possess full awareness regarding all of the types of data that are gathered, the intended objectives for its use, and any possible risks that may arise as a result.

*h) Legal and regulatory frameworks:* Robust legal and regulatory frameworks are necessary to address the ethical issues associated with data gathering and privacy. Laws should govern the protection of personal data, grant individuals the right to decline participation in data collecting, and establish channels for seeking justice in the event of violations.

*i) Ethical algorithm design:* The design of AV algorithms needs a consideration of privacy concerns. AI systems should give priority to the implementation of data anonymization techniques, encryption protocols, and the adoption of short data retention times in order to effectively address and minimize any privacy threats.

*j) Educating users and stakeholders:* In order to adhere to ethical data practices, it is vital to provide users with comprehensive education regarding the nature of the data and their rights. It is essential to provide knowledge to stakeholders, including manufacturers and developers, regarding the significance of privacy-by-design concepts.

*k) Balancing security and privacy:* The ethical dilemma refers to the careful balancing that must be achieved between the advantages of data collection for security purposes and the need to safeguard individual privacy. It is crucial to implement procedures that effectively protect against surveillance and data breaches, while also facilitating the utilization of advantageous technologies.

Within the domain of AVs, the ethical debate surrounding the collection of data and potential privacy risks highlights the importance of implementing strong safeguards that strike an effective balance between the advantages offered by data-driven technology and the fundamental rights of individuals to retain control over their data.

*2) Examination of ethical data handling practices:* Personal data must be handled ethically in AVs to maintain privacy, trust, and individual rights [55]. his subsection discusses stakeholders' ethical roles and responsibilities when handling personal data. It examines how manufacturers, service providers, and regulators can build strong data protection rules. Additionally, it also emphasizes informed permission, data anonymization, encryption, and secure storage to protect personal data. We intend to establish privacy-preserving frameworks and responsible data practices for AVs by focusing on ethical data handling.

*a) Informed consent and data usage:* The foundation of ethical data handling is in the obtaining of informed consent from users. It is necessary that individuals utilizing AVs have comprehensive knowledge regarding the various types of data that are gathered, the primary goals for its utilization, and the possibility of external entities gaining access to such information.

*b) Privacy by design principles:* The ethical treatment of data aligns with the principles of the "privacy by design" concept. The incorporation of privacy protections, including data anonymization, encryption, and user-controlled data access, must be considered in the design of autonomous vehicle systems.

*c) Data minimization:* The concept of minimizing data plays a crucial role in the ethical handling of data. The act of selectively gathering essential data for operational objectives serves to mitigate privacy vulnerabilities and safeguard persons against unnecessary data disclosure.

*d) User control and transparency:* Ethical data practices provide users the ability to exercise control over their data. Users should be granted the privilege to easily retrieve, alter, or delete their data, while also being supplied full transparency into the manner in which their data is being utilized.

*e) Secure data storage and transmission:* The ethical handling of personal data requires the implementation of robust storage and transmission systems to ensure its security. The use of robust encryption, strict access restrictions, and complete cybersecurity measures is crucial in order to effectively mitigate the risk of unauthorized access and data breaches.

*f) Data use limited by purpose:* Data should be utilized exclusively for the specific objectives for which it was gathered, as explicitly disclosed to individuals during the process of obtaining informed consent. In order to adhere to ethical principles, it is mandatory that data is not reused without obtaining clear authorization from the user.

*g) Accountability and responsibility:* Manufacturers and developers have a responsibility to apply ethical standards in their practices related to data processing. It is critical to establish clear lines of accountability in order to guarantee adherence to ethical norms.

*h) Data retention periods:* The practice of ethical data handling encompasses the establishment of suitable periods for data retention. The retention of data should be limited to the duration required for operational purposes, and it is important for users to be informed about these specific time periods.

*i) Regular data audits:* Regular audits are necessary in order to evaluate the practices of data collection, storage, and utilization, as part of the ethical handling of data. The purpose of audits is to verify adherence to privacy rules and ethical principles.

*j) Consistent review of ethics:* The handling of data in an ethical manner is a continuous and iterative procedure. In order to successfully deal with the constantly evolving technological landscapes and address emerging privacy concerns, it is key for manufacturers and developers to consistently evaluate their data practices.

The analysis of ethical approaches to handling data in the area of AVs highlights the commitment to protecting individuals' privacy while leveraging the beneficial opportunities offered by data-driven technologies. The merging of ethical standards and technological innovation is a crucial factor in the establishment of a responsible and reliable ecosystem for AVs.

## VI. Ethical Framework, Opportunities, Challenges, and Future Directions

### A. Proposed Ethical Framework for AI in Autonomous Vehicles

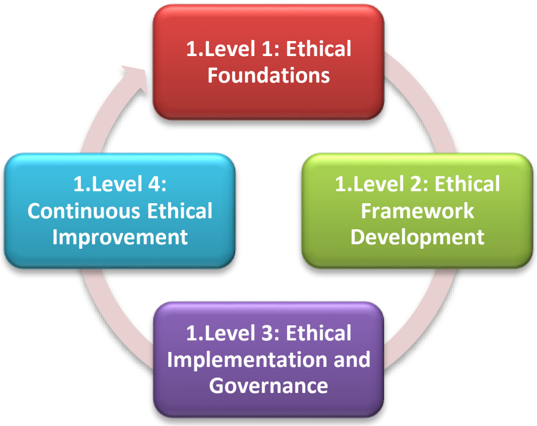
The proposed ethical framework for AI in Avs has been established as a result of this exhaustive investigation. This framework offers a comprehensive approach to ethics by combining the four cyclical levels of ethical foundations, development of ethical guidelines, implementation and governance of ethics, and continuous ethical improvement as illustrated in Fig. 1. It's a guide for dealing with the difficult and continually evolving ethical dilemmas raised by AI in AVs. With this framework in consideration, we aim to create the path for ethical research, development, and deployment of AI in the domain of AVs. As the field continues to develop fast, this framework will serve as a foundation for future discussions and adaptations in ethics. Each level is inter-dependent, with the foundational principles guiding the development of the framework, which is then implemented and continuously improved. This cycle ensures that the ethical framework remains adaptive, responsive, and aligned with evolving ethical considerations and technological advancements. Each level contains sub-levels that also operate in a continuous cycle as explained below.

*1) Level 1 ethical foundations:* This level is a starting point for addressing ethical concerns with AI-powered autonomous vehicles. Specifically, it involves establishing the core ethical principles and values that are needed to guide the development and deployment of AI in this domain as shown in Fig. 2. This level contains the following sub-levels: Ethical Theories, Legal and Regulatory Frameworks, Public Perception and Values, Industry Standards, and Technological Capabilities.

*2) Level 2 ethical framework development:* This level focuses on developing a well-organized ethical framework, building on the work done in the earlier level. To put the ethical concepts of Level 1 into practice, this framework provides a set of rules and guidelines. This level includes the subsequent sub-levels: Interdisciplinary Collaboration, Ethical Guidelines, Human-Machine Interaction Ethics, Algorithmic Decision-Making Ethics, and Privacy and Data Ethics as illustrated in Fig. 3.

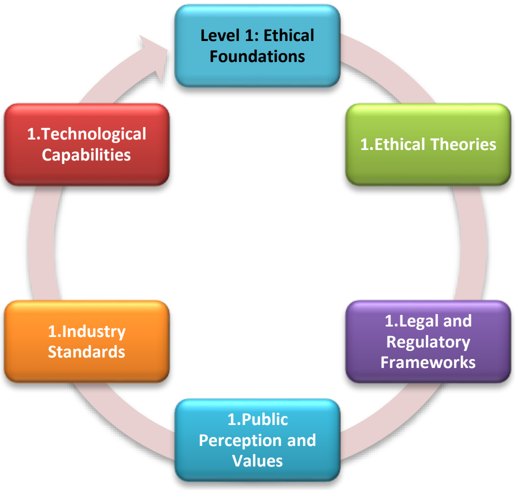
*3) Level 3 ethical implementation and governance:* The ethical framework established in Level 2 is put into practice at this level. This refers to the real implementation of ethical guidelines in autonomous vehicle AI development, decision-making, and operation. To ensure accountability and compliance, governance procedures are put in place. Fig. 4 displays the sub-levels that make up this level are: Ethical AI Development, Transparency and Explainability, Ethical Decision Support, Compliance Monitoring, and Ethical Audits and Reporting.

*4) Level 4 continuous ethical improvement:* This level emphasizes the dynamic aspect of ethical issues associated with AI. Ethical practices and standards are constantly evaluated and enhanced in light of real-world experiences, new challenges, and changing social values via a feedback loop. In order to improve the ethical foundations, the framework, and the implementation processes, the findings and insights from Level 4 are passed back into Levels 1, 2, and 3. As shown in Fig. 5 this level is divided into the following sub-levels: User Feedback and Adaptation, Ethical Impact Assessment, Policy and Regulation Updates, Stakeholder Engagement, and Long-term Societal Impact Studies.



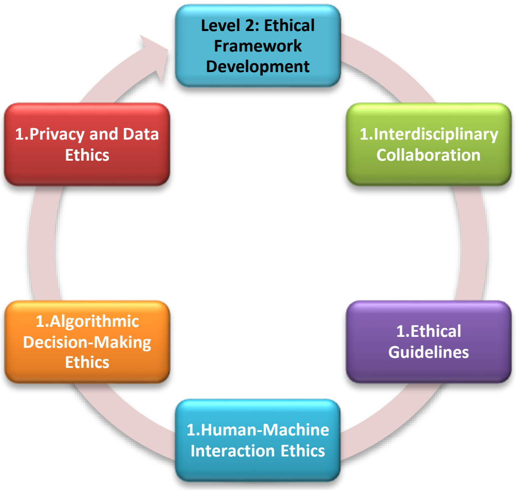
1.Level 1: Ethical Foundations
1.Level 2: Ethical Framework Development
1.Level 3: Ethical Implementation and Governance
1.Level 4: Continuous Ethical Improvement

Fig. 1. Proposed ethical framework levels.



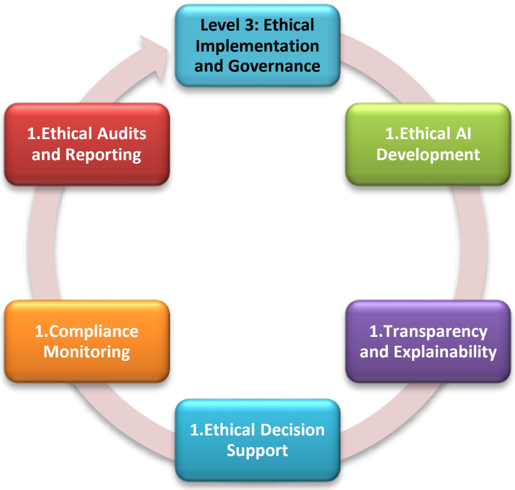
Level 1: Ethical Foundations
1.Ethical Theories
1.Legal and Regulatory Frameworks
1.Public Perception and Values
1.Industry Standards
1.Technological Capabilities

Fig. 2. Proposed sub-levels of ethical foundations.



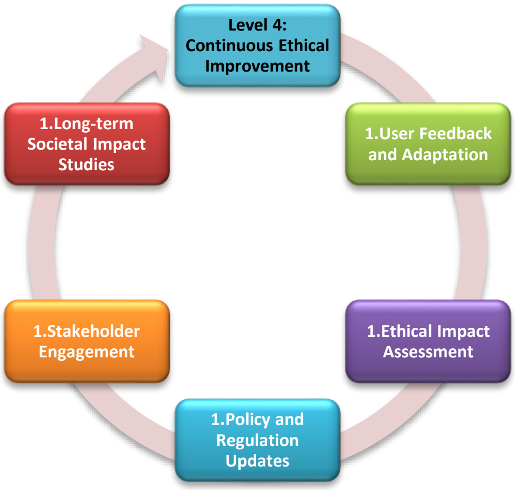
Level 2: Ethical Framework Development
1.Interdisciplinary Collaboration
1.Ethical Guidelines
1.Human-Machine Interaction Ethics
1.Algorithmic Decision-Making Ethics
1.Privacy and Data Ethics

Fig. 3. Proposed sub-levels of ethical framework development.



Level 3: Ethical Implementation and Governance
1.Ethical AI Development
1.Transparency and Explainability
1.Ethical Decision Support
1.Compliance Monitoring
1.Ethical Audits and Reporting

Fig. 4. Proposed sub-levels of ethical implementation and governance.



Level 4: Continuous Ethical Improvement
1.User Feedback and Adaptation
1.Ethical Impact Assessment
1.Policy and Regulation Updates
1.Stakeholder Engagement
1.Long-term Societal Impact Studies

Fig. 5. Proposed sub-levels of continuous ethical improvement.

Based on the proposed framework levels and its sublevels the relationship is cyclical because updates to the ethical foundations, framework, and implementation techniques are made when new ethical challenges and opportunities occur. This continuous approach ensures that the ethical framework for autonomous vehicles is always up-to-date, effective, and able to adapt to new developments in the field of AI.

### *B. The Opportunities and Challenges of AI in Autonomous Vehicles*

By highlighting the importance of ethical considerations in this technological advancement, both opportunities and challenges present a summary view of the complex issues facing AI in autonomous vehicles.

*1) Opportunities of AI in Autonomous Vehicles:*

*a) Enhanced road safety:* The implementation of ethical AI has the potential to mitigate accidents and preserve human lives through its capacity to make driving decisions that are safer than those made by human drivers.

*b) Efficient traffic flow:* AI has the ability to enhance traffic flow efficiency by minimizing congestion and reducing environmental consequences.

*c) Accessibility:* The use of autonomous vehicles has the potential to enhance accessibility and facilitate increased mobility for those with disabilities and the elderly.

*d) Reduced emissions:* The implementation of optimized driving patterns has the possibility to result in a decrease in greenhouse gas emissions.

*e) Economic growth:* The autonomous vehicle sector has the capacity to generate employment opportunities and foster growth in the economy.

*2) Challenges of AI in Autonomous Vehicles:*

*a) Ethical decision-making:* The development of AI capable of making complex moral decisions during emergency situations poses a significant challenge.

*b) Data privacy:* The gathering and handling of sensitive data in self-driving vehicles give rise to issues regarding data privacy.

*c) Job displacement:* The widespread adoption of self-driving vehicles has the potential to result in significant employment displacement within the sector of transportation.

*d) Security risks:* Autonomous vehicles are vulnerable to cybersecurity risks and are susceptible to unauthorized access through hacking.

*e) Legal and regulatory obstacles:* The process of developing and adapting laws and regulations for autonomous vehicles is complex and dynamic.

*f) Ethical accountability:* Ethical dilemmas arise when attempting to allocate responsibility in the event of an accident involving an autonomous vehicle.

### *C. Future Directions of AI in Autonomous Vehicles*

The future directions emphasize the dynamic nature of the ethical considerations surrounding AI-driven autonomous vehicles and highlight the importance of further research, collaboration, and regulation to guarantee their responsible and ethical integration into society.

*1) Real-world testing:* Extensive real-world testing should be conducted to evaluate the ethical decision-making capabilities of AI-driven autonomous vehicles across a wide range of unpredictable circumstances.

*2) Public awareness and education:* To foster informed discussions and viewpoints, it is essential to enhance public awareness as well as education regarding the ethical considerations associated with autonomous vehicles.

*3) Human-machine collaboration:* Investigate several models of collaboration between humans and AI systems, with a particular focus on achieving an ideal balance of control, responsibility, and ethical supervision.

*4) Standardization and regulation:* Encourage the establishment of standardized ethical guidelines and standards that govern the design and adoption of autonomous vehicles.

*5) Cross-disciplinary collaboration:* It is fundamental to foster collaborative efforts among professionals specializing in

AI, ethics, law, psychology, and sociology to efficiently address the complex ethical dilemmas that arise in this multidimensional domain.

*6) Long-term societal impact studies:* Perform continuous studies to evaluate the long-term societal impacts of autonomous vehicles with respect to transportation systems, urban planning, and employment.

*7) Data privacy innovations:* Protect sensitive data in autonomous vehicle systems with cutting-edge data privacy technologies like differential privacy and secure multiparty computation.

*8) Ethical AI governance:* Establish global governing organizations or mechanisms to supervise the ethical development and implementation of artificial intelligence in autonomous vehicles.

*9) Ethics in AI research:* Promote research into fairness, transparency, and bias mitigation in AI development.

*10)Public policy and legislation:* Adopt strong public policies and legislation that take into account the ethical concerns of AI in autonomous vehicles.

*11)Ethical impact assessments:* Emphasize robust ethical impact assessments as a prerequisite to releasing AI-powered autonomous vehicles.

*12)Ethical audit methods:* Construct audit methods that facilitate continuous ethical evaluations of AI systems, emphasizing principles of transparency, accountability, and adaptability.

*13)Human rights integration:* Ensure that the adoption of self-driving vehicles adheres to and protects fundamental principles of human rights, such as privacy and freedom of movement.

*14)International collaboration:* To develop a worldwide ethical framework for AI in autonomous vehicles, it is important to encourage international collaboration and open sharing of information.

## VII. Conclusion

This study has shown a lot of complex ethical issues related to the constantly evolving environment of autonomous vehicles that use artificial AI. It investigated closely the moral issues involved in AI-driven decision-making, the complicated field of safety and liability issues in accidents involving self-driving vehicles, and the huge effects on employment and society. The careful study of privacy and data security issues has shed light on how to handle personal data in a technological context in an ethical way. The paper highlighted the significance of transparency and accountability by proposing a structured framework for ethical governance. This study illustrated the opportunities and challenges that need to be considered when integrating AI into AVs. It can be used as a guide for policymakers, developers, and the general public. It is imperative for us to effectively utilize the extensive capabilities of AI while simultaneously upholding our ethical principles. This will guarantee the emergence of AVs that not only change the concept of mobility but also serve as an indicator to our commitment towards a future that prioritizes safety and ethical considerations. This paper opens a discussion and calls for action that will lead to AI and ethics coexisting together harmoniously in the world of autonomous vehicles.

# Deep Learning to Predict Start-Up Business Success

Lobna Hsairi
Department of Information System and Technology-CCSE, University of Jeddah, Jeddah, Saudi Arabia

***Abstract*—Over the past few decades, there has been rapid growth in the formation of new start-ups around the world. Thus, it is an important and challenging task to understand what makes start-ups successful and to predict their success. Several reasons are responsible for the success and failure of a start-up, including bad management, lack of funds, etc. This work aims to create a predictive model for start-ups based on many key factors involved in the early stages of a start-up's life. Current research on predicting success mainly focuses on financial data such as ROI, revenue, etc. Therefore, in this paper, a different approach is proposed by first investigating other non-financial factors affecting start-up success and failure. Second, the adoption of an algorithm that has not been used much in predicting start-up success, which is Convolutional Neural Network (CNN). The dataset was acquired from Kaggle. The final model was reached through a series of four experiments to determine which model predicts better. The final model was implemented using a CNN with an average accuracy of 82%, an average loss of 0.4, an average 0.9 recall and an average 0.9 precision.**

***Keywords*—Deep learning; Convolutional Neural Network (CNN); prediction; start-up business**

## I. Introduction

Start-ups have become an important topic in the economic policies of all developed and emerging economies around the world, not just by being a driver of economic prosperity and wealth but also because of their major impact on innovation and technological development. Start-ups are booming everywhere as more colleges, governments, and private companies invest and stimulate people to pursue their ideas throughout these ventures. Start-ups are raising millions with ease. Examples like Uber and Airbnb are changing societies in such impactful ways that regulation had to be created to keep pace with a new reality [1]. Start-ups are having such an impact that ultimately, it becomes every investor's ambition to be part of a large acquisition, such as Facebook acquiring WhatsApp for nineteen billion dollars, which allowed Sequoia (a Venture Capital fund) to have a 50x Return On Investment (ROI) [2]. But there is a catch: start-ups are companies with an estimated 90% probability of failure [3], which means a lot of investments without proper returns. According to SPA load [3], 90% of start-ups launched in 2023 are failed start-up. Entrepreneurs who experience failure are numerous, and it's important to identify the factors that lead to failure and success too. Those factors, when shared and explored, will assist potential entrepreneurs in the ecosystem in designing their path to success. The consequences of entrepreneurial failure [4] extend beyond the start-up and have an impact on employment and the economy. The ability to predict success is an invaluable competitive advantage for various parties, such as venture capitalists on the hunt for investments since first-rate targets are those who have the potential for growing rapidly soon, which ultimately allows investors to be one step ahead of the competition [5]. The prediction of start-up success will help investors get an idea of whether investing in a start-up will be successful or not. Recently, machine learning algorithms have been considered an effective approach to predicting start-up success. Furthermore, deep learning shows significant promise in the business domain in general and in start-up prediction in particular [6]. Machine learning and deep learning use algorithms to create models that reveal patterns from data, allowing businesses to gain insights and make predictions to enhance operations, better understand customers, and solve other issues. There are numerous algorithms to choose from. These help predict the outcomes of a start-up will be profitable or not.

There are few studies which are performed to understand the reasons for the success of a start-up company [7]. These studies use various criteria of success, varying from predicting funding or follow-up funding, meaning most of the focus is on financial data. These start-ups usually lack enough financial data on their historical performance [8]. Therefore, in this paper, non-financial measures of performance for predicting the probability of start-up success were used. Most existing research is based on machine learning techniques, such as random forest models, Support Vector Machines, and logistic regression [9] (as the most common predictive tools), few researches turn the light to explore deep learning techniques [6]. There is still room for different types of approaches, such as Artificial Neural Network and Convolutional Neural Network, which are used in this research.

In this paper, to predict start-up success, which helps to sustain and grow new businesses, different approach is proposed by first, investigating other non-financial factors affecting start up success and failure. Second, the adoption of deep learning algorithms that have not been used much in predicting start-up success, which are Artificial Neural Network (ANN) and Convolutional Neural Network (CNN). In addition to that, the previous solutions are dependent on memory-based algorithms such as K nearest neighbors [10], the proposed solution will depend on processor-based algorithms which increase the learning, time and velocity of the model.

The reminder of this paper is organized as follows: Section II reviews related work on prediction models of start-up success. Section III describes the dataset, preprocessing techniques, and models used, along with training and hyperparameter tuning approaches. Section IV presents findings, including performance metrics and models' comparison. Section V presents a brief discussion of proposed models' results. Section VI summarizes the main findings and suggests future research directions.

## II. Related Work

A number of studies have been conducted to explore the use of machine learning to understand the reasons for the success of a start-up company. These researches may aid in the selection and utilization of machine learning techniques for the prediction of start-up success, primarily based on funding factors at various stages. For instance, C. Pan et al. [11] used three classification algorithms to predict the probability of success of a start-up (Logistic Regression, Random Forest and K-Nearest Neighbors). They conclude that if the investor has a limited investment budget and wants to maximize the proportion of success among its portfolio, it would be better to choose Random Forests model instead of KNN model. However, if the investor has a lot of investment money and wants to maximize the number of successful companies it could invest in, it would be better to choose KNN model. Thus, the model selection to make the best prediction is solely based on the budget. Additionally, another study by B.Yankov et al. [12] presented a quantitative investigation and creation of success prediction models based on the answers to the challenges and questions that start-up companies face. The questionnaire is based on the new venture success prediction model proposed by Yankov [12]. 15 algorithms were used; the most accurate model is J48. Results show that the main challenge Bulgarian high-tech start-ups face is getting adequately funded at the initial stages of the business. Furthermore, D. Fidder [13] identified significant predictors of startup success, namely, technology and B2B/B2C; and he built two models: the first predicts whether a start-up will have a profitable exit for investors, and the second predicts whether the start-up will be able to attract more than 1 million Euros in funding. For the first model, a logistic regression model was built. Where, in the second one, the author built a linear model. On the other hand, T. Żbikowski et al. [14] compared three algorithms: logistic regression, support vector machine, and the gradient boosting classifier. They achieved promising results in terms of precision, recall, and F1 scores for the best model the gradient boosting classifier. The top three important features are the country and region that the company operates in and the company’s industry. In addition, I. Afolabi et al. [15] used both Naïve Bayes algorithm and J48 algorithm for prediction. The result reveals that all the models built for prediction gave a percentage accuracy of above 50%. Other algorithms need to be applied to enhance accuracy. Moreover, S.H. Arshe et al. [16] implemented eight different algorithms and analyzed the percentage of score of them. The deciding factor in the selected data set is the "status" column, which had two values: acquired and closed. The used algorithms are decision tree, Random forest, K-Nearest Neighbor, MLP, Naïve byes, logistic regression and SGD. After using these algorithms, they obtained different success rate scores for each one. The two best algorithms, according to the success rate, are decision tree and Random Forest. In the same way, Ü. Cemre et al. [17] implemented a total of six different models to predict startup success. Using goodness-of-fit measures applicable to each model case, the best models selected were the ensemble methods, random forest and extreme gradient boosting. The top variables in these models are last funding to date, first funding lag and company age. Likewise, V. Shah et al. [18] created a predictive model to predict startup firm success. The key factors used to build the model are seed funding, series funding, rounds of funding, time to get seed funding, valuation after each round of funding, number of milestones, average time taken to achieve each milestone, average time taken to achieve funding, region, degree, university, burn rate, total funding, and category_code. The model implemented using logistic regression reached good accuracy. Nevertheless, T. Kalendová [19] applied four machine learning classification methods (Logistic regression, Random forest, XGB, SVM) to predict startups’ success with a focus on the needs of the venture capital industry. The models’ results have shown the potential of using machine learning algorithms to predict the success of venture capital-backed start-ups in the predefined time period. The Random Forest model proved to be the best predictor from the set, outperforming other methods by having the highest scores of selected performance measures. Also, the rest of the algorithms showed high performance scores, especially extreme gradient boosting.

From the overview above, there is already a lot of knowledge about the most significant predictors of start-up success. Researchers use various criteria for success, varying from predicting funding or follow-up funding, meaning, most of the focus is on financial data. However, these start-ups usually lack enough financial data on their historical performance. Hence, in this paper, non-financial measures of performance for predicting the probability of a start-up success were used. Most of researches are based on machine learning techniques, such as random forest, support vector machines, and logistic regression (as the most common predictive algorithms), few researches turn the light to explore deep learning techniques [6]. There is still room for different types of approaches, such as ANN and CNN which were used in the proposed models.

## III. Method

### A. DataSet

The dataset was collected from Kaggle website[1]. It contains detailed information about start-up companies. The dataset consists of 116 columns and 473 records. The reason beyond the choice of a dataset with a small number of records; is because unlike other explored datasets, the selected one contains columns that could drive us to make comprehensive and useful insights. It comprises numerical and nominal data, the target factor in the selected dataset is "Dependent-Company Status" column which deliver the current operating status of the start-up and has two values, success and fail. To distinguish the key factors picked out to build models the data exploration is needed. One of the categorical feature is the “industry field of a company”. Startups are categorized into 35 industry fields such as analytics, media, finance etc. An investigation of the company Statues per industry fields allows to conclude that the most common field with the greatest number of successful companies is ‘analytics’. Of the top 10 industries in analysis, ‘Healthcare’ start-ups have a slower average of overall age of success. Meaning, industries such as healthcare would take much time to success unlike ‘Market Research’ start-ups which have a faster age of success. One more fact that should be

[1] https://www.kaggle.com/datasets/ajaygoíkaí/staítup-analysis.

considered to understand what influence the success and failure of a start-up is the prior experience of the founding team (Average years of experience for founder and co-founder, Number of Co-founders, Controversial history of founder or co-founder, etc.). Founding teams with high average years of experience are most likely to form a successful start-up. Another categorical feature is the ‘marketplace of a start-up‘. A start-up can target two types of marketplace. First, a global market place which is not limited to specific geographic locations but rather involves the exchange of products, services, and employees anywhere in the world. Second, a local marketplace which target and reach potential customers within a certain distance of their business's location. An exploration of the number of successful and failure start-up per marketplace allows for the deduction that targeting a global marketplace could affect the probability of start-up success. It is also important to understand how different business model of a start-up influence its probability of success. B2B (Business to Business) and B2C (business-to-consumer) are distinguished. After inspection, B2B start-ups are more successful. Following examination of different features, the key factors settle on to build models are: age of company in years, industry of company (analytics, e-commerce, advertising, marketing, media etc.), number of investors, number of co-founders, number of advisors, worked in top companies, consulting experience, focus on private or public data, cloud or platform based service/product, local or global player, linear or non-linear business model, disruptiveness of technology, number of direct competitors. In order to more understand the factors affecting start-ups, the investigation of how long a start-up will be considered a failure is needed. Fig. 1 shows that all the failed companies have a normal distribution with 0.4 skew and four years’ average age.

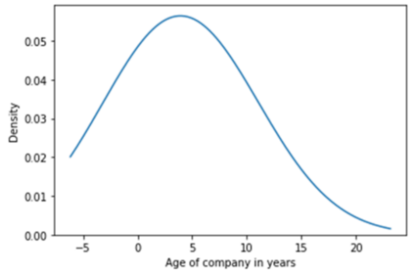

Fig. 1. Average age distribution of failed companies.

### B. Data Preparation and Preprocessing

The measurements of success in business are hard to define statistically. There are no correlations between the numerical attributes, even with splitting the dataset classes. It’s a subjective and challenging domain, but our mission and role are to help and solve business problems, especially the problems that are associated with finance and decision-making. Since the selected dataset is extracted from Kaggle website, the chances of finding flaws in them are high. There are many problems in the selected dataset, such as noisy data, missing and null values, and duplicated data [20]. Data cleaning is the process of fixing or removing incorrect, duplicated, or incomplete data within a dataset. The records that contain more than 25% null values were removed. Null values are a significant problem in machine learning and deep learning. Several methods were used to deal with them in the adopted dataset. The dataset had 'No info' which was not recognized as a null value. Therefore, 'No info' was replaced with np.nan to let python recognize it as a null value. Also, columns that contain more than 5% null were dropped. Noisy data is detected and removed. The dataset had three types of noisy data, including a column with incorrect entries. To solve it, the column was dropped, and value_counts() was used to reduce the number of repeating words in the column with many items. So, the companies that have "more than one industry" were replaced by "Multi-industry". Data transformation is the process of changing the format. All 'Yes' was changed to 1 and all 'No' to 0; success was changed to 1 and failed to 0. After preprocessing, the dataset consists of 104 columns and 413 records.

### C. Model Building

As stated before, ANN algorithm was chosen to build the model. However, after conducting several experiments, we discovered that ANN is not the optimal algorithm in the adopted use case due to its poor results, such as high loss, the model being biased to one class. After evaluating the experiments, we concluded that Convolutional Neural Network (CNN or ConvNet) is a more suitable algorithm to build the model, considering its ability to perform operations that alter the data with the intent of learning features specific to the data [19]. The model is built using Python. For the model experiment setup, the dataset was already prepared by cleaning and preprocessing it, and the necessary columns were selected. Additionally, all the required libraries and extensions for building the model were set up. The dataset was then split using stratified k-fold to overcome the imbalance in the dataset.

A CNN or ConvNet is network architecture for deep learning [21] that learns directly from data. A CNN is composed of an input layer, an output layer, and many hidden layers in between. These layers perform operations that alter the data with the intent of learning features specific to the data. There are common CNN layers were used in building the model, such as Convolution layer (which is the most important component of any CNN architecture). It contains a set of convolutional kernels (also called filters), which gets convolved with the n-dimensional metrics to generate an output feature map [20], activation function (the main task of any activation function in any neural network based model is to map the input to the output), two types of activation function were used in the proposed model: The sigmoid activation function as shown in Eq. (1) and The Rectifier Linear Unit (ReLU) as shown in Eq. (2).

$$f(x)_{sigm}=1/1+e^{-x} \qquad (1)$$

$$f(x)_{ReLU}=max(0,x) \qquad (2)$$

The explained CNN [22] components are the fundamental component for any model. However, for the proposed model, additional layers are added to handle the requirements, which are a dense layer (containing densely connected neurons) and a dropout layer (overfitting is a serious problem faced by the model. Dropout is a technique for addressing this problem). The key idea is to randomly drop units (along with their connections) from the neural network during training [23]. This prevents units from co-adapting too much. It significantly reduces overfitting and gives major improvements over other regularization methods. The final step in building the model is compilation, during which the "Adam" optimizer is used. To train the proposed model with the given inputs, it is fitted for 30 epochs. Table I illustrates the hyperparameters of different layers.

TABLE I. MODEL'S LAYER AND HYPERPARAMETERS

| Layers | Hyperparameters |
|---|---|
| Conv1D | filters=32, kernel_size=3, activation='relu',input_shape=[66,1] |
| Conv1D | filters=32, kernel_size=1, activation=sigmoid |
| Dense | units=50, activation= relu |
| Dense | units=2, activation='sigmoid' |
| Dropout | (0.5) |

## IV. EXPERIMENTS RESULTS

Four experiments were conducted to reach the final model. These experiments will be depicted in the following subsections along with its performance and problems. For the first three experiments, the dataset was split into two main segments: a training set and a test set. The training set was further divided into training and validation sets using an 80:20 approach. For the fourth experiment, the dataset was split into train and test subsets in a stratified fashion. Cross-validation on the training set to ensure that the model does not overfit to the validation set. Cross-validation is recommended in hyperparameter tuning to reduce the problem of selection bias and overfitting. Furthermore, several common metrics are used to obtain valuable information about algorithm performance, such as: Learning curve, Confusion matrix, Accuracy, Loss, Precision and Recall.

### *A. Experiment 1: ANN Model*

Experiments are stared by using ANN, as the adopted algorithm. After building the model and evaluate it. The confusion matrix shown in Fig. 2 depicts that the model is highly biased towards success. Moreover, the learning curve shown in Fig. 3 illustrates that the model is overfitting because the validation loss has a lot of vibration. Furthermore, the evaluation metrics in Table II conclude that the results are unacceptable, thus the algorithm needs to be changed for better feature extraction. So, another experiment is conducted using CNN to enhance the model.

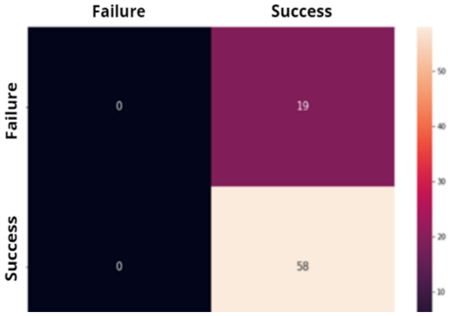

Fig. 2. Confusion matrix for experiment 1.

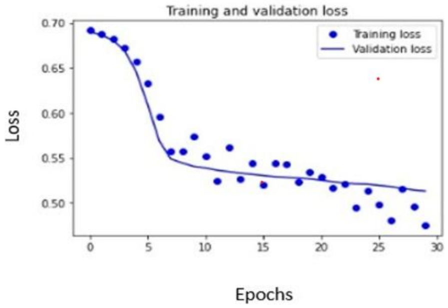

Fig. 3. Learning curve (loss) for experiment 1.

TABLE II. EVALUATION METRICS FOR EXPERIMENT 1

| | |
|---|---|
| Accuracy | 75% |
| Loss | 0.5 |
| Precision | 0.7 |
| Recall | 0.7 |

### *B. Experiment 2: CNN Model*

In the first experiment, the ANN model is biased towards start-up success because the ANN is fully connected. Thus, the model needs to be changed and build a CNN model and try different feature extraction to make the results more optimal. For the confusion matrix, as it shown in Fig. 4, there is an improvement in the result compared to the ANN model, and in the learning curve in Fig. 5 and Table III the accuracy reach 83% for the CNN model, which is more than the expected accuracy, but in Fig. 6, the loss shows that the model is overfitted. So, additional experiments were made to overcome the problems in this experiment.

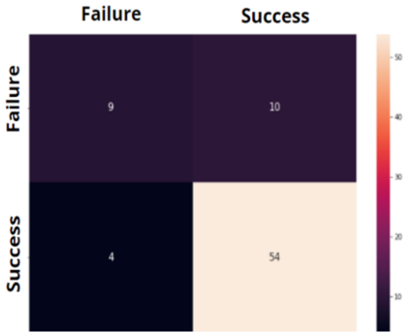

Fig. 4. Confusion matrix for experiment 2.

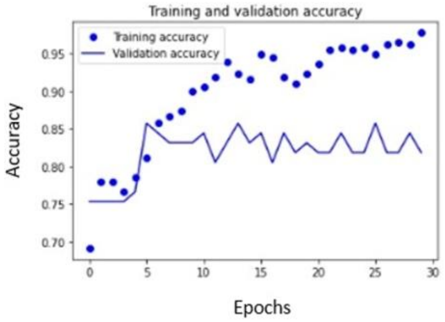

Fig. 5. Learning curve (accuracy) for experiment 2.

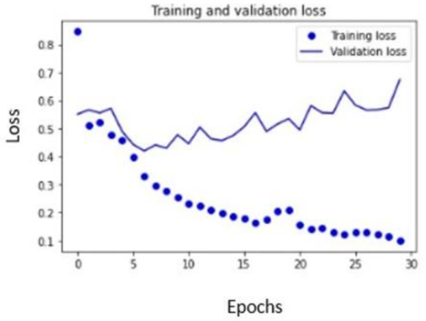

Fig. 6. Learning curve (loss) for experiment 2.

TABLE III. EVALUATION METRICS FOR EXPERIMENT 2

| | |
|---|---|
| Accuracy | 83% |
| Loss | 0.5 |
| Precision | 0.83 |
| Recall | 0.79 |

### *C. Experiment 3: CNN Model with Dropout Layer*

As investigated in the previous experiment, the model is suffering from overfitting. In Experiment 3, to overcome this problem, a dropout layer was added. The key idea of dropout is to randomly drop units (along with their connections) from the neural network during training. This prevents units from co adapting too much during training, Table IV shows the evaluation metrics for this experiment. The accuracy and loss values indicate that the model has high accuracy and produces correct outputs. Another way to evaluate the performance of the model is learning curve. In this experiment, the model has a good fit as Fig. 7 shows. A good fit is identified by a training and validation loss that decreases to a point of stability with a minimal gap between the two final loss values. Overall, the model evaluation metrics along with confusion matrix in Fig. 8 indicate that this experiment is good enough, but there is a room for enhancement, so a fourth experiment was elaborated to make the model more accurate and robust.

TABLE IV. EVALUATION METRICS FOR EXPERIMENT 3

| | |
|---|---|
| Accuracy | 83% |
| Loss | 0.7 |
| Precision | 0.83 |
| Recall | 0.8 |

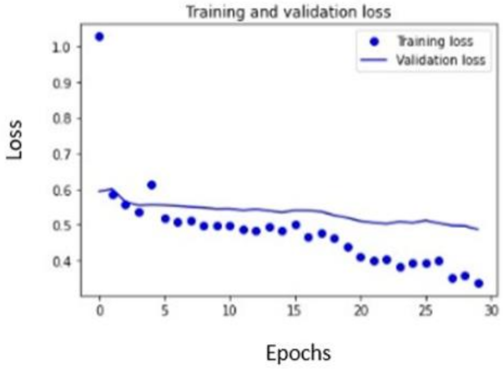

Fig. 7. Learning curve (loss) for experiment.

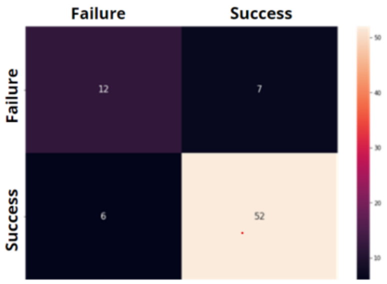

Fig. 8. Confusion matrix for experiment 3.

### *D. Experiment 4: CNN Model with K-fold*

As depicted in Experiment 3, the issue of overfitting was controlled. However, the model can still be enhanced. One way to improve the performance of the model is by using k-fold. Data splitting process can be done more effectively with k-fold cross-validation. The main intention of using k-fold is to develop a more generalized model that can perform well on unseen data. For selecting an appropriate value of k, multiple values are tried until we came to a conclusion that 5 is the optimal value of k for the proposed model. The evaluation metrics in Table V show that after changing the splitting into k-fold, the loss has decreased, which means that the model is doing a good job of predicting the expected outcome: success or failure of start-up business. While the precision and recall increased, which means that the model is performing well.

TABLE V. EVALUATION METRICS FOR EXPERIMENT 4

| | |
|---|---|
| Avg(Accuracy) | 82% |
| Avg(Loss) | 0.4 |
| Avg(Precision) | 0.9 |
| Avg(Recall) | 0.9 |

## V. DISCUSSION

Trying to reach the optimal model is a series of steps and experiments, which in our case were four experiments (see Table VI). As planned, ANN was used as the starting algorithm. However, it was not optimal for the adopted use case, start-up business success. Which led us to change the algorithm to CNN [20]. Different enhancements were added, such as CNN with a Dropout layer and CNN with k-fold. Among all four experiments, the best one was Experiment 4: CNN with k-fold and dropout layer, due to its reliable performance. It achieved an average 82% of accuracy, an average 0.4 loss, an average 0.9 recall and an average 0.9 precision and the learning curve showed that the model has a good fit. The overall evaluation of the model indicated that the model considered suitable for use and can predict the start-up business success or failure with high accuracy.

TABLE VI. RESULTS OF EXPERIMENTS

| | Accuracy | Loss | Precision | Recall |
|---|---|---|---|---|
| ANN | 75% | 0.5 | 0.7 | 0.7 |
| CNN | 83% | 0.7 | 0.8 | 0.8 |
| CNN with Dropout layer | 83% | 0.5 | 0.8 | 0.8 |
| **CNN with K-fold** | **Avg(82%)** | **Avg(0.4)** | **Avg(0.9)** | **Avg(0.9)** |

## VI. Conclusion and Future Work

Predicting start-up success is a challenging task, but it is crucial to many public and private stakeholders who shape economics, make funding and investment decisions, and found companies. Intuitively, the task becomes easier as the company matures and tests its product-market fit. In this article, a deep learning approach is proposed for predicting start-up success at the seed stage, narrowing down the set of features to geographical, demographic, and basic information about the companies. Unlike previous works, financial information is not used. To predict start-up success, deep learning models are built and the performance of two algorithms, ANN and CNN is compared. Four experiments are used: ANN, CNN, CNN with Dropout Layer, and CNN with K-fold. The major problems faced in the models are high loss and overfitting, which are controlled in the last experiment. Experiment 4, CNN with k-fold and Dropout layer, outperforms the others. According to its performance, it achieved an average 0.4 loss, an average 0.9 recall and precision, and the learning curve indicates that the model has a good fit and an accuracy of 82. According to the overall evaluation, the model was deemed suitable for use. Several recommendations for future research can be made. First, gather more data and more completed data. This can be done by accessing different databases and combining them. Second, apply more sophisticated machine learning and deep learning techniques to the data. This allows researchers to make more precise estimations. Researchers should attempt to combine models that include both performance indicators and success metrics, which will lead to more accurate predictions.

# Data-Driven Rice Yield Predictions and Prescriptive Analytics for Sustainable Agriculture in Malaysia

Muhammad Marong, Nor Azura Husin, Maslina Zolkepli, Lilly Suriani Affendey
Faculty of Computer Science and Information Technology,
Department of Computer Science, University Putra Malaysia, Selangor, Malaysia

***Abstract*—Maximizing rice yield is critical for ensuring food security and sustainable agriculture in Malaysia. This research investigates the impact of environmental conditions and management methods on crop yields, focusing on accurate predictions to inform decision-making by farmers. Utilizing machine learning algorithms as decision-support tools, the study analyses commonly used models—Linear Regression, Support Vector Machines, Random Forest, and Artificial Neural Networks—alongside key environmental factors such as temperature, rainfall, and historical yield data. A comprehensive dataset for rice yield prediction in Malaysia was constructed, encompassing yield data from 2014 to 2018. To elucidate the influence of climatic factors, long-term rainfall records spanning 1981 to 2018 were incorporated into the analysis. This extensive dataset facilitates the exploration of recent agricultural trends in Malaysia and their relationship to rice yield. The study specifically evaluates the performance of Random Forest, Support Vector Machine (SVM), and Neural Network (NN) models using metrics like Correlation Coefficient, Mean Absolute Error (MAE), Root Mean Squared Error (RMSE), Mean Squared Error (MSE), and Mean Absolute Percentage Error (MAPE). Results reveal Random Forest as the standout performer with a Correlation Coefficient of 0.954, indicating a robust positive linear relationship between predictions and actual yield data. SVM and NN also exhibit respectable Correlation Coefficients of 0.767 and 0.791, respectively, making them effective tools for rice yield prediction in Malaysia. By integrating diverse environmental and management factors, the proposed methodology enhances prediction accuracy, enabling farmers to optimize practices for better economic outcomes. This approach holds significant potential for contributing to sustainable agriculture, improved food security, and enhanced economic efficiency in Malaysia's rice farming sector. Leveraging machine learning, the research aims to transform rice yield prediction into a proactive decision-making tool, fostering a resilient and productive agrarian ecosystem in Malaysia.**

***Keywords—Rice yield prediction; sustainable agriculture; linear regression; support vector machine; artificial neural network; predictive analytics***

## I. INTRODUCTION

Agriculture plays a pivotal role in Malaysia, contributing significantly to the nation's economic development. It remains one of the primary sources of livelihood for a substantial portion of the population, and its modernization is essential to meet the growing demands of the country's expanding population. In Malaysia, a significant portion of the land is utilized for agricultural activities, addressing the food requirements of millions of people. As the agricultural landscape evolves, farmers are increasingly exploring opportunities to enhance productivity and achieve optimal returns on their investments. Traditionally, crop yield predictions were heavily reliant on a farmer's experience and understanding of specific land and crops [1] [2] [3]. However, with changing conditions and the pursuit of diversified crops, there arises a need for more comprehensive and accurate data to guide farmers in their decision-making process. Farmers are seeking more information about new crops and their potential profitability to make informed choices regarding crop selection and overall agricultural practices [3] [4]. Accurate estimation of crop performance under various environmental conditions can significantly improve farm productivity and financial outcomes. The global rice market is narrow, making it highly susceptible to market fluctuations caused by supply interruptions due to weather variations [5] [6] [7]. To safeguard its population from hunger, Malaysia has implemented a protectionist policy for its paddy and rice business [8] [9]. Policymakers in Malaysia require accurate crop yield forecasts to evaluate the benefits and drawbacks of imports and exports, strengthening the country's food supply and ensuring its security [10] [11]. Predicting agricultural productivity is a complex task due to the numerous interconnected factors involved. To address these challenges, the application of Data Science techniques has become increasingly crucial. In the modern era of agriculture, ensuring food security stands as a paramount challenge, especially within the context of Malaysia. The burgeoning population and the evolving landscape of climate dynamics render the traditional methods of crop yield prediction inadequate. The delicate balance between supply and demand, often influenced by climatic vagaries, can disrupt the stable rhythm of food production. Malaysia, with its dependency on rice as a staple, stands at a critical juncture in safeguarding its food security.

At present, major suppliers of Rice in Malaysia and its exporters are largely planted in Malaysian states, namely Johor, Kedah, Kelantan, Melaka, Negeri Sembilan, Pahang, Perak, Perlis, Pulau Pinang, Selangor, Terengganu, Sabah, and Sarawak, as shown in Fig. 1. These states are the major contributors to Malaysia's rice production, accounting for a significant share of over five hundred thousand metric tons annually, thus making up the majority of rice production in Malaysia. The entire process from planting the crop to harvest is closely intertwined with data collection and its intricate relationship with crop yield. These collected data play a pivotal role in training Machine Learning (ML) algorithms. These ML algorithms provide invaluable insights for farmers to estimate the profitability of their crops. Armed with this knowledge, farmers can make well-informed decisions regarding their crop investments and consider necessary modifications before the harvest, often leading to additional costs to secure a more bountiful yield.

Historically, rice yield prediction was anchored in the expertise of farmers, an art passed down through generations. Yet, the intricacies of today's climate patterns, characterized by unprecedented shifts and erratic behavior, demand a more sophisticated and data-driven approach. The heightened susceptibility of the rice market to supply disruptions caused by weather anomalies underscores the urgency to fortify the nation's agricultural resilience.

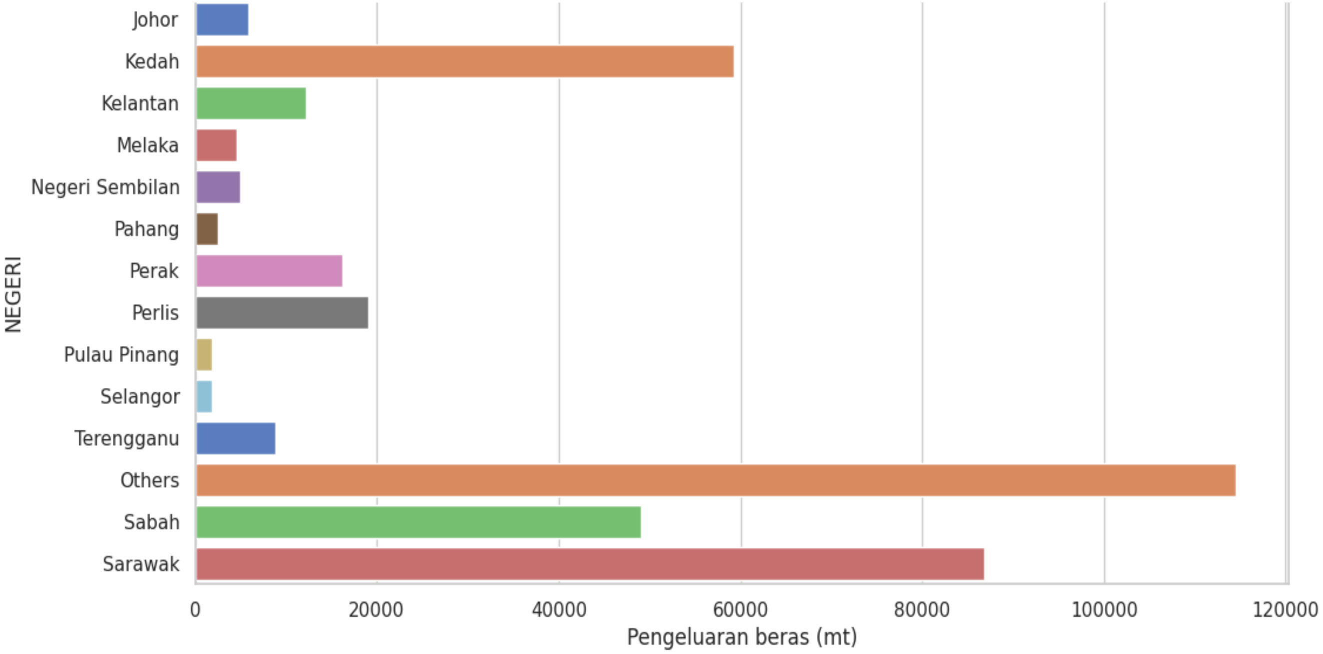

Fig. 1. Statistics of rice yield in Malaysia.

In this tapestry of challenges, the study illuminates a pivotal issue - the necessity for an advanced predictive model that not only harnesses the power of machine learning but also delves deeper into the complex interplay between environmental factors and crop productivity [12]. By addressing this issue, the research takes a bold step towards fortifying the foundations of food security in Malaysia.

Data analysis using scientific approaches can yield valuable insights into the data, enabling informed decision-making in agriculture. This study aims to explore the impact of environmental conditions and management practices on crop yields in Malaysia. By leveraging machine learning algorithms, the study seeks to develop accurate prediction models that can assist farmers in optimizing their agricultural practices and achieving better economic efficiency. This research holds the potential to contribute valuable insights into sustainable agriculture, improve food security, and enhance economic outcomes in Malaysia's agricultural sector.

The remaining part of the paper is organized as follows: In Section II, a comprehensive review of related works in the field of rice yield prediction in Malaysia using hybrid machine learning models is presented, emphasizing the significance of integrating diverse environmental and management factors for enhanced accuracy. Section III describes the materials and methods employed in this study, including the dataset used for rice yield prediction, and the implementation of hybrid machine learning models incorporating Random Forest (RF), Support Vector Machine (SVM), and Artificial Neural Network (ANN). In Section IV, the study present the implementation details, results, and performance evaluation of the hybrid machine learning models. The evaluation includes metrics such as Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and R-squared to assess the models' predictive capabilities. Additionally, a detailed discussion on the obtained results is provided, highlighting the strengths and limitations of the models. Lastly, in Section V, the conclusion of the study is presented, summarizing the key findings and potential future avenues for further research in the domain of rice yield prediction in Malaysia using hybrid machine learning models.

## II. Literature Review

In Malaysia, estimating rice crop yields accurately is of utmost importance to ensure food security and support the nation's agricultural sustainability goals [23]. Traditional methods for rice yield prediction, such as static regression and mechanistic approaches, have limitations in effectively capturing the complex and nonlinear relationships between input factors, such as weather conditions, climate variations, and agricultural practices, and the resulting rice yields [23]. To address the challenges in rice yield prediction specifically for Malaysia, there is a pressing need to develop a hybrid machine learning and deep learning (ML/DL) model that can harness the power of data-driven techniques to enhance accuracy and predictive capabilities [13]. This hybrid approach should focus on leveraging historical yield data, weather information, and other pertinent features specific to Malaysia's rice-growing regions to create a robust and reliable predictive model [13][14].

The major aim of this research is to develop a hybrid machine learning and deep learning (ML/DL) model for accurate rice yield prediction in Malaysia. The model will integrate historical yield data, weather information, and relevant features specific to Malaysia's rice-growing regions. By autonomously extracting essential features, the model aims to achieve high prediction accuracy and generalization across different regions and cropping seasons. The practical implementation of the model will provide farmers with valuable insights for sustainable crop management practices contributing to Malaysia's food security and agricultural sustainability goals.

Estimating rice yields is critical in meeting the growing demand for food throughout the nation [38]. It aids in the enhancement of management procedures vital to maximizing agricultural yields. One of the challenges in rice yield prediction is the limited availability of diverse and comprehensive datasets [20]. To address this issue, researchers have been exploring the integration of remote sensing data, climate information, and historical crop yield data to train rice yield models effectively [15] [30]. In recent years, there has been a growing interest in developing hybrid models that combine both machine learning (ML) and deep learning (DL) techniques to enhance rice yield prediction accuracy [13][14]. The integration of ML algorithms with DL architectures employs the strengths of both approaches, resulting in more robust and accurate predictions [14]. Several studies have explored the benefits of hybrid ML/DL models for rice yield prediction.

One example of a successful hybrid ML/DL model is the combination of fuzzy clustering and DL for rice yield prediction [35]. Pham et al. (2021) developed a hybrid model that utilized weather data and satellite-based spectral indices for rice yield prediction in Vietnam. They first applied fuzzy clustering to categorize regions with similar environmental characteristics, creating distinct clusters. Next, they used deep learning techniques, such as adaptive neuro-fuzzy inference systems (ANFIS), within each cluster to predict rice yields. The hybrid model achieved a high accuracy of over 97%, outperforming individual ML or DL models [35]. Another successful hybrid model for rice yield prediction combined artificial neural networks (ANN) with support vector regression (SVR) [32]. Zhang et al. (2021) developed this hybrid model to predict rice yield in China. The ANN component captured the nonlinear relationships between input factors like weather, soil, and management practices, while SVR provided robustness and improved generalization. The hybrid model achieved a high prediction accuracy of over 90%, demonstrating the effectiveness of combining ML and DL techniques [32]. Hybrid ML/DL models can also integrate DL techniques with crop simulation models, offering insights into complex rice growth dynamics [33]. Sharma et al. (2021) developed a hybrid model that utilized remote sensing data and weather data to train a DL model. The output from the DL model was then used as input to a crop simulation model, which captured the interactions between environmental conditions and crop growth. This integrated approach achieved a high prediction accuracy of over 93% for rice yield prediction in India [33].

Moreover, hybrid models can also reduce the risk of overfitting and improve the generalizability of the models [33]. Overfitting occurs when the model is too complex and fits the training data too closely, resulting in poor performance on unseen data. Hybrid models can mitigate this risk by combining models with different biases and variance, resulting in a more balanced and robust model [33]. For example, they found that their hybrid model outperformed individual models in terms of generalization and robustness. The combination of deep learning techniques and crop simulation models allowed the model to capture the spatial and temporal variations in the rice growth conditions and yield output [33] [34].

In summary, hybrid machine learning models have shown promising results in rice yield prediction [13]. It gives ability to improve prediction accuracy, robustness, and generalization [14] [20]. The combination of machine learning techniques with other data-driven or statistical models can capture the complex relationships between the input factors and the yield output more accurately and reduce the risk of overfitting [15] [16]. These developments in the field have significant implications for enhancing food security and nutrition, particularly in developing countries where rice is a staple food crop [38][39].

## III. Materials and Methods

### A. Case Study and Data Description

Rice is a staple crop in Malaysia, and accurate yield prediction plays a crucial role in ensuring food security and optimizing agricultural practices. Traditional regression-based models and mechanistic approaches have limitations in capturing the complex and nonlinear relationships between crop yield and various influencing factors, including weather conditions and agricultural practices. To address these challenges, the study proposes a hybrid machine learning and deep learning (ML/DL) model for rice yield prediction in Malaysia. The model employs the advantages of both ML and DL techniques to enhance prediction accuracy and generalization. The data used in this study encompass historical rice yield records and weather data from multiple rice-growing regions in Malaysia. The historical yield data is collected over several cropping seasons, covering a significant time span to account for inter-annual variations. Daily weather information, including rainfall, temperature, and humidity, is obtained from meteorological stations situated in close proximity to the rice fields. Additionally, Flood data has been included in the dataset, depicted in Fig. 2.

### B. Challenges of Traditional Models and Hybrid Model Justification

Traditional regression-based models and mechanistic approaches encounter several challenges when predicting rice yields. These challenges include limited flexibility, an inability to capture nonlinear patterns, assumptions of homoscedasticity, and overlooking intricate interactions between influencing factors. Traditional models often struggle to adapt to the dynamic and complex relationships inherent in rice production, leading to suboptimal predictions.

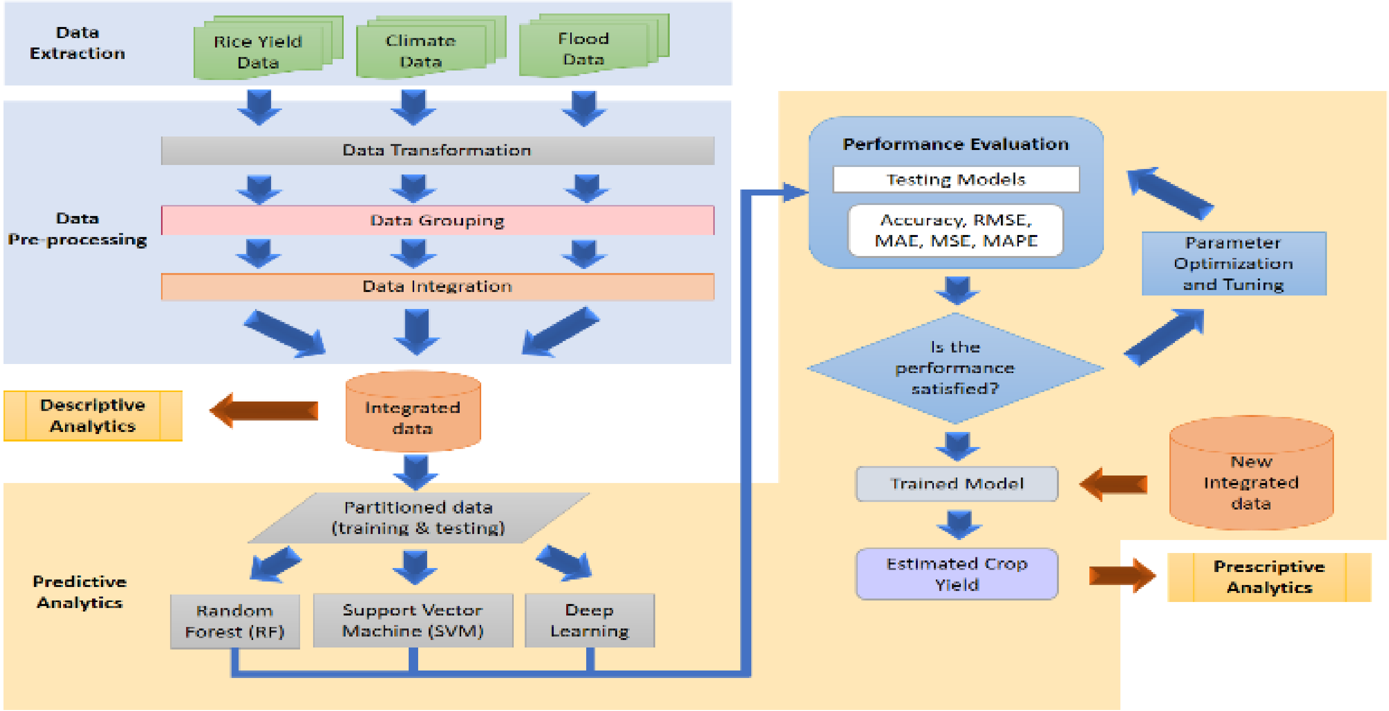

Fig. 2. Architecture of proposed model.

The proposed hybrid machine learning and deep learning (ML/DL) model offer a compelling solution to these challenges. By integrating RF, SVM, and ANN, the hybrid model leverages the strengths of each algorithm. RF efficiently handles non-linear relationships, capturing complex interactions within the dataset. SVM's non-linear kernel enhances adaptability to high-dimensional data, crucial for addressing intricate relationships in rice yield prediction. The deep learning capabilities of ANN allow the model to learn hierarchical representations, effectively capturing complex temporal patterns and dependencies within the dataset. In combination, these algorithms overcome the limitations of traditional models, providing a more robust framework for accurate and sustainable rice yield predictions in Malaysia. The hybrid model's flexibility, adaptability, and ability to capture nonlinear patterns make it well-suited for the challenges posed by the complex dynamics of rice production.

### C. *Models for Forecasting*

In this study, the researcher employs three powerful algorithms for forecasting rice yield in Malaysia: RF, SVM, and ANN. Each model brings unique strengths to handle the complexity of climate data and its impact on rice production.

Random Forest, an ensemble learning method, constructs multiple decision trees during training and combines their outputs for accurate predictions [17]. Given the intricate relationships between climate variables and rice yield in Malaysia, RF is well-suited to efficiently handle non-linear patterns, capturing the complex interactions within the dataset [17][20]. The selection of RF aligns with the objective of sustainable agriculture by providing insights into feature importance, aiding the understanding of the impact of environmental conditions and management practices on rice yield.

SVM, a supervised learning algorithm, separates different yield classes based on climate and agricultural attributes. It finds the optimal hyperplane maximizing the margin between data points of different classes. SVM's ability to handle high-dimensional data and non-linear kernels makes it valuable for crop yield prediction [13] [21]. In the context of sustainable agriculture, SVM is chosen for its effectiveness in high-dimensional spaces and its capacity to handle non-linear relationships, essential for capturing the complexity of rice yield determinants. This aligns with the goal of optimizing agricultural practices.

Artificial Neural Network, a deep learning technique, is inspired by the human brain's neural networks. With interconnected layers of nodes, ANN processes input data and learns complex patterns [22]. Deep learning approaches, including ANN, have shown promising results in crop yield prediction [15] [19]. ANN is selected for its capability to learn hierarchical representations, making it suitable for capturing intricate relationships within the data. This is particularly valuable for sustainable agriculture, where understanding complex patterns and dependencies is crucial for informed decision-making.

For model evaluation, the hybrid ML/DL model combines the outputs of RF, SVM, and ANN. Cross-validation techniques assess model performance, and hyperparameter tuning optimizes their configurations. Metrics such as Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and R-squared gauge predictive capabilities.

By integrating these algorithms, the hybrid ML/DL model effectively handles climate data complexities, providing accurate predictions of rice yield in Malaysia. Findings offer valuable insights to farmers and policymakers, aiding informed decisions for enhanced agricultural productivity and food security in the region.

### D. Optimization Technique

The optimization of the hybrid ML/DL model is essential to ensure its effectiveness in forecasting rice yield in Malaysia accurately [36]. Hyperparameter tuning, a crucial optimization technique, is employed to fine-tune the parameters of the RF, SVM, and ANN algorithms [31]. Hyperparameters significantly impact the performance of these models, and their optimal selection is vital to achieve the best predictive results [29].

Grid search, a systematic hyperparameter tuning method, is utilized to explore various combinations of hyperparameter values within predefined ranges [30]. It exhaustively searches through the hyperparameter space and evaluates each combination's performance using cross-validation techniques [30]. The combination of hyperparameter values that yields the best performance metrics on the validation set is chosen as the optimal configuration for each model [30].

By fine-tuning the hyperparameters, the study aims to optimize the models for forecasting rice yield and improve their generalization capabilities [33]. The optimization process ensures that the models can effectively capture the complex relationships between climate variables and rice production, leading to accurate and reliable yield predictions for Malaysia's agricultural sector [33].

### E. Architecture of the Model

In the proposed framework, machine learning and deep learning techniques are employed to predict the best crop production for a given dataset. The prediction of suitable crops is based on the analysis of current atmospheric and climatic parameters. These deep learning techniques excel in capturing complex temporal patterns and dependencies within the dataset, making them well-suited for crop prediction tasks. On the other hand, the RF and SVM algorithm is implemented under machine learning to handle classification tasks and assist in the crop prediction process. By combining the strengths of machine learning and deep learning, the proposed model can effectively provide precise and reliable crop predictions without the need for soil-related data.

### F. Proposed Framework

The scenario below is intended for illustrative purposes only. The actual model predictions and results will be based on the real-world data and factors encountered during rice production in Malaysia.

Fig. 2 employs hybrid machine learning and deep learning techniques to predict rice yield in Malaysia. To demonstrate the model's performance under various conditions, the study presents a hypothetical scenario that highlights its ups and downs during a crop season. The study begins with an optimal climate phase characterized by moderate rainfall and abundant sunshine. During this phase, the hybrid ML/DL model accurately predicts a bountiful rice yield, effectively capturing the positive correlation between climatic factors and crop productivity [17] [35]. However, as the crop season progresses, unforeseen weather fluctuations, such as unexpected heavy rainfall and prolonged drought spells, challenge the model's adaptability to non-linear relationships between extreme events and their impact on yield [19][31]. As a result, there might be slight deviations in the model's predictions from the actual yield during this period [20] [22] [26]. Moreover, localized pest infestations during the mid-crop season further test the model's capabilities, as it primarily focuses on climate-related factors and faces limitations in capturing direct agricultural challenges [13] [21]. However, the hybrid model's strength in understanding temporal patterns and correlations enables it to recover and stabilize predictions once agricultural conditions improve. As the agricultural management teams take timely measures to control pests and mitigate adverse effects, the model's predictions align more accurately with the actual harvest data [15] [22]. This scenario analysis underscores the hybrid ML/DL model's versatility and potential, providing valuable insights for its practical application in ensuring food security and sustainable agriculture in Malaysia [13].

### G. Performance Indicators

In this research, the performance of the hybrid ML/DL model for rice yield prediction in Malaysia is evaluated using various performance indicators [37]. These indicators are crucial for assessing the model's accuracy, robustness, and generalization capability. Mean Absolute Error (MAE) is utilized to measure the average magnitude of prediction errors and is commonly employed in crop yield prediction studies [19] [23]. Root Mean Square Error (RMSE) is another important metric that provides a comprehensive assessment of prediction accuracy by considering both bias and variance [28] [37]. Additionally, R-squared is employed to determine the proportion of variance in the rice yield data that can be explained by the hybrid model [35] [37]. Higher R-squared values indicate a better fit of the model to the actual data. Cross-validation techniques, such as k-fold cross-validation, are utilized to ensure the reliability and stability of the model's performance across different subsets of data [21] [27] [28]. The combined assessment of these performance indicators will provide valuable insights into the hybrid ML/DL model's effectiveness in accurately forecasting rice yield, contributing to improved agricultural decision-making and sustainable food production strategies in Malaysia.

In order to evaluate the performance of the model, the following evaluation metrics: Mean Squared Error (MSE), Root Mean Squared Error (RMSE), Mean Absolute Error (MAE), Coefficient of determination (R-squared) are used [24]. The MSE is the squared difference of the observed values of a variable with its predicted values, divided by the number of values for this variable. It is an assessment of the quality of the predictor. The RMSE is the square root of the MSE, indicating the standard deviation of the residuals (prediction errors) [24] [25].

$$MSE = n1\sum i = 1n(Yi - Y\wedge i)2 \qquad (1)$$

$$\text{RMSE}= \surd\ \text{n1}\sum \text{i=1n(Yi}-\text{Y}\wedge\text{i)2} \qquad (2)$$

The absolute difference of the predicted value with the actual value defines the MAE, which is a measure of errors between paired observations expressing the same phenomenon.

$$MAE = n1\sum i = 1n \mid Yi - Y{}^\wedge i \mid \tag{3}$$

Lastly, the R2 is the proportion of the variation in the dependent variable that is predictable from the independent variables. It is expressed by the division of Sum of Squares of Residuals (SSRes) with the total Sum of Squares (SSTot), and it ranges between 0 and 1.

$$R2=1-\sum i=1n(Yi-Y\ \bar{}\ )2\sum i=1n(Yi-Y{}^\wedge i)2 \tag{4}$$

These evaluation metrics will provide a comprehensive understanding of the hybrid ML/DL model's predictive capabilities and its potential for accurate rice yield forecasting in Malaysia.

## IV. Implementation and Results

At the heart of the study's findings lies a symphony of innovation, where machine learning and deep learning techniques harmonize with the intricacies of rice yield prediction. The proposed hybrid model, an ensemble of RF, SVM, and ANN, emerges as a beacon of accuracy and reliability. These models, each a virtuoso in its own right, coalesce into a predictive force that holds the potential to revolutionize rice yield forecasting.

The research underscores the prowess of each model in tackling specific facets of the complex prediction process. The RF, with its ensemble of decision trees, adeptly captures non-linear relationships inherent in climate data. Meanwhile, the SVM hones in on classifying yield classes based on climatic attributes, utilizing the optimal hyperplane to delineate between them. Lastly, the ANN, inspired by the human brain, unfurls its layered nodes to extract intricate patterns and temporal dependencies.

As the symphony of models unfolds, the study unveils a stage of rigorous evaluation. The metrics of Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and R-squared ($R^2$) step forward as the critics, meticulously dissecting the predictions against actual yields. In their assessment, the symphony highlights its virtuosity - a lower MAE, a melodious RMSE, and a soaring $R^2$. Together, they affirm the model's ability to attune itself to the climatic symphony, capturing the intricate crescendos and diminuendos that define rice yield fluctuations.

The main findings culminate in a profound revelation: the proposed hybrid model is not merely a predictive tool but a conductor of change. It has the capacity to empower farmers and policymakers with insights that transcend the realm of predictions. It orchestrates a harmonious interplay between data and decisions, offering a path towards optimized crop management, enhanced agricultural productivity, and fortified food security. As the curtain descends on this act, the proposed system stands poised to script a new narrative in the chronicles of sustainable agriculture and nourished nations.

### A. Model Implementation and Training

The exploration into the core of the research commences with a detailed organization of data preprocessing, a fundamental aspect of the model's development. The careful collection of climate data from various sources, covering essential variables like temperature, precipitation, humidity, and solar radiation, signifies the inception of the predictive engine [28]. This phase is not just a compilation of data; rather, it is a meticulous curation of information, where each element contributes to the cohesive generation of accurate predictions.

The critical stage of data preprocessing carries a significant responsibility - ensuring the fidelity and integrity of the data. Missing or irrelevant data points are systematically identified and removed, ensuring that the model's learning process is rooted in accuracy. Additionally, the practice of feature engineering takes center stage, wherein raw climate data is shaped into a refined set of input variables. These variables, meticulously tailored to meet the specific requirements of each model, encapsulate the essential details of climate intricacies that impact rice yield.

Armed with meticulously curated data, the exploration into the domain of machine learning focuses on the essential roles played by RF and SVM models. RF, an ensemble of decision trees, generates a harmonious array of predictions by leveraging the collective intelligence of multiple trees [35]. The model adeptly captures nuanced non-linear relationships inherent in climate variables and their influence on rice yield. This results in the development of a predictive tool that excels in handling complexity [18].

At the same time, SVM acts as a mathematical expert, figuring out the best ways to separate different yield classes based on climate features [13]. The training process is not just a technical routine; it is about integrating the knowledge from climate data into the core of the model. Cross-validation serves as the guide in this process, making sure the models can handle the uncertainties of new data [30]. This phase involves uncovering the secrets of climate, where data and models interact in a subtle dance, and valuable insights come from the use of predictive algorithms.

But the quest doesn't halt there. The echelons of deep learning beckon, with the ANN model poised to take the spotlight. The ANN, a complex network of interconnected nodes, begins its exploration into the depths of data intricacies [17]. It possesses the remarkable ability to extract temporal patterns and dependencies concealed within the dataset, revealing a symphony of understanding that may escape human observation. The concept of transfer learning enters the fray, a strategic deployment that employs the knowledge encoded in pre-trained ANN models on similar agricultural datasets, thereby enhancing the model's adaptability and comprehension [17] [21].

### B. Performance Evaluation

The models in this study were implemented and assessed using widely used data science libraries in Python, and each model's performance was thoroughly evaluated. The dataset for rice yield prediction was meticulously assembled, including yield data from 2014 to 2018 as shown below in Fig. 3. To provide a broader context, climate data, specifically rainfall records dating back to 1981, were integrated into the analysis. These rich datasets offer valuable insights into Malaysia's recent agricultural trends. The predictive models underwent rigorous analysis to ensure accuracy and effectiveness, involving extensive experimentation to fine-tune their performance.

Table I shows the detailed comparison of the results offered by the proposed model with existing models on the test dataset.

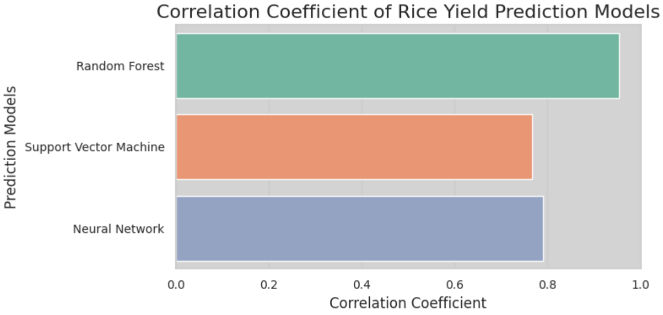

Fig. 4. Correlation coefficient analysis of various models.

The table highlights the results of the Correlation Coefficient analysis of the rice yield prediction models, namely the RF, SVM, and ANN. In Fig. 4 the correlation coefficient serves as an indicator of the relationship between the predicted rice yield values and the actual recorded values.

RF stands out with the highest Correlation Coefficient of 0.954. This indicates an exceptionally strong positive linear relationship between its predictions and the actual yield data, suggesting that it is adept at capturing the variations in rice yield over time. The high Correlation Coefficient for RF demonstrates its precision in modeling rice yield patterns in Malaysia.

SVM demonstrates a respectable Correlation Coefficient of 0.767. Although slightly lower than RF, it still signifies a substantial positive correlation. SVM's performance suggests it is proficient in capturing yield variations, albeit to a somewhat lesser degree than RF.

The ANN model boasts a Correlation Coefficient of 0.791, positioning it as another effective tool for rice yield prediction. This value indicates a substantial positive correlation and suggests that Neural Network is a reliable option for forecasting rice yield trends in Malaysia.

In summary, all three models demonstrate significant positive correlations with the actual rice yield values. Random Forest exhibits the highest correlation, followed by Neural Network and SVM. This signifies their potential to assist in accurate rice yield prediction, which is crucial for enhancing food security in Malaysia.

Fig. 5 presents the Mean Absolute Error (MAE) analysis for the three models used in rice yield prediction: RF, SVM, and ANN. A lower MAE indicates more accurate predictions. Notably, the Neural Network model exhibits the lowest MAE, signifying its superior performance in producing precise rice yield forecasts. In contrast, the SVM model shows a moderately higher MAE, while the RF model displays the highest MAE, suggesting variations from actual yield values. This MAE analysis helps in model selection to enhance food security in Malaysia.

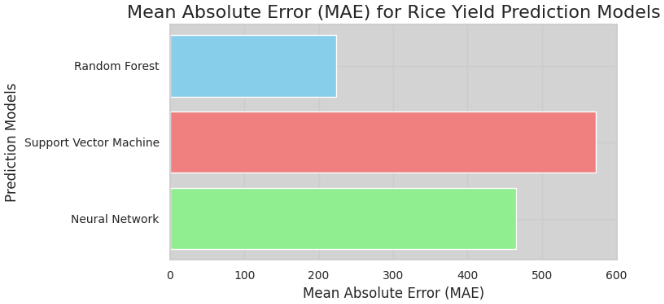

Fig. 5. MAE analysis of various models.

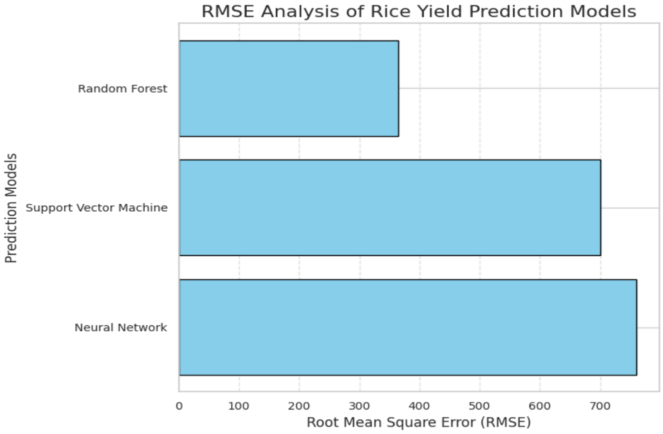

Fig. 6. RMSE analysis of various models.

Fig. 6 illustrates the Root Mean Square Error (RMSE) analysis for the three models employed in rice yield prediction: RF, SVM, and ANN. A smaller RMSE indicates more precise predictions. Remarkably, the ANN model exhibits the lowest RMSE, signifying its superior performance in producing accurate forecasts of rice yield. In contrast, the SVM model shows a moderately higher RMSE, while the RF model displays the highest RMSE, indicating that it deviates more from the actual yield values. This RMSE analysis serves as a valuable tool for model selection, a critical step towards enhancing food security in Malaysia.

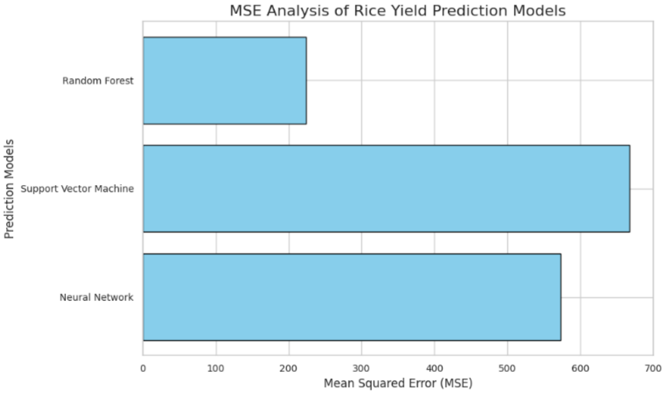

Fig. 7. MSE analysis of various models.

Fig. 7 illustrates a comparison of Mean Squared Error (MSE) values across the three rice yield prediction models: RF, SVM, and ANN. The MSE quantifies the average squared differences between the models' predictions and the actual rice yield values. A lower MSE indicates more accurate predictions. Notably, the Neural Network model exhibits the lowest MSE, demonstrating its superior performance in generating precise rice yield forecasts. In contrast, the SVM model displays a moderately higher MSE, while the RF model records the highest MSE. This analysis aids in model selection for bolstering food security in Malaysia.

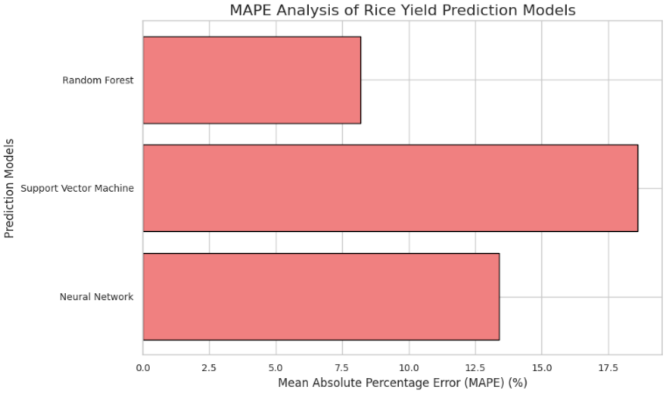

Fig. 8. MAPE analysis of various models.

Fig. 8 highlights the results of the comparison of Mean Absolute Percentage Error (MAPE) values for the three rice yield prediction models: RF, SVM, and ANN. MAPE measures the average percentage difference between the models' predictions and the actual rice yield values. Lower MAPE values signify more accurate predictions. Here, the Neural Network model stands out with the lowest MAPE, indicating its exceptional precision in forecasting rice yield. In contrast, the SVM model shows a moderately higher MAPE, while the Random Forest model records the highest MAPE. This comparison aids in the selection of the most effective model for enhancing food security in Malaysia.

## V. Conclusion and Future Scope

In conclusion, the research presents a hybrid machine learning-based model for predicting rice yield in Malaysia, with the overarching goal of enhancing food security and nutrition in the region. By leveraging the strengths of Random Forest (RF), Support Vector Machine (SVM), and Artificial Neural Network (ANN), the model not only demonstrates accurate and robust predictions but also provides actionable insights for farmers and policymakers.

The integration of machine learning and deep learning techniques allows for a comprehensive understanding of complex climate data and its impact on rice production. The findings highlight the effectiveness of the hybrid model in accurately predicting rice yields based on environmental conditions and management practices.

Furthermore, the study identifies key practical implications and recommended applications emerging from the results. For farmers, the hybrid model offers a powerful tool to optimize agricultural practices, improve crop yields, and enhance economic outcomes. Policymakers can utilize the insights from this research to formulate evidence-based policies aimed at supporting sustainable agriculture and ensuring food security in Malaysia.

However, to fully realize the potential of the hybrid model, further research should focus on expanding the dataset, incorporating real-time data, and considering socio-economic factors that influence rice production. Continuous advancements in these areas will enhance the accuracy and applicability of the model, making it an indispensable tool for addressing challenges posed by population growth and climate change.

In summary, the hybrid machine learning-based model presented in this research holds great promise for contributing to a sustainable and secure food supply in Malaysia. With ongoing research and innovation, it has the potential to play a significant role in mitigating food insecurity and promoting agricultural sustainability in the region.

# AI-based KNN Approaches for Predicting Cooling Loads in Residential Buildings

Zhaofang Du
Henan Industry and Trade Vocational College, Zhengzhou Henan, 450053, China

***Abstract*—Cooling Load (CL) estimation in residential buildings is crucial for optimizing energy consumption and ensuring indoor comfort. This article presents an innovative approach that leverages Artificial Intelligence (AI) techniques, particularly K-Nearest Neighbors (KNN), in combination with advanced optimizers, including Dynamic Arithmetic Optimization (DAO) and Wild Geese Algorithm (WGA), to enhance the accuracy of CL predictions. The proposed method harnesses the power of KNN, a machine-learning algorithm renowned for its simplicity and efficiency in regression tasks. By training on historical CL data and relevant building parameters, the KNN model can make precise predictions, 768 sample with considering factors such as Glazing Area, Glazing Area Distribution, Surface Area, Orientation, Overall Height, Wall Area, Roof Area, and Relative Compactness. Two state-of-the-art optimizers, DAO and WGA, are introduced to refine the CL estimation process further. The integration of KNN with DAO and WGA yields a robust AI-driven framework proficient in the precise estimation of CL in residential constructions. This approach not only enhances energy efficiency by optimizing cooling system operations but also contributes to sustainable building design and reduced environmental impact. Through extensive experimentation and validation, this study demonstrates the effectiveness of the proposed method, showcasing its potential to revolutionize CL estimation in residential buildings. The results indicate that the hybridization of KNN with DAO optimizers yields promising outcomes in predicting CL. The high R2 value of 0.996 and low RMSE value of 0.698 demonstrate the accuracy of the KNDA model.**

***Keywords*—Cooling load; K-nearest neighbor; dynamic arithmetic optimization; wild geese algorithm***

## I. INTRODUCTION

In an era marked by burgeoning concerns over energy efficiency and environmental sustainability, the demand for more innovative and precise methods of managing cooling loads (CL) in residential buildings has never been more pressing [1]. Achieving the delicate balance between maintaining indoor comfort and minimizing energy consumption is a multifaceted challenge that resonates with homeowners and the broader global community [2]. The need to develop innovative approaches to predict, control, and optimize cooling loads is paramount, and this article delves into the forefront of these advancements [3]. Residential buildings constitute a substantial portion of global energy consumption [4]. Cooling systems, essential for creating comfortable living environments, contribute significantly to this energy usage [5]. CL management inefficiency can lead to excessive energy consumption, elevated utility bills, and increased carbon emissions. Hence, the stakes are high, both economically and environmentally, in devising strategies that can predict and optimize cooling loads with unparalleled accuracy [6].

Precisely forecasting building energy consumption represents a crucial aspect of energy modeling. Yet, it frequently struggles to provide a comprehensive reflection of real-world performance [7], [8]. Conventional energy models, well-suited for initial assessments, rely on engineering calculations grounded in physical principles to gauge building energy consumption [9]. Multiple research investigations have highlighted the significant gap between these forecasts and actual energy usage, sometimes surpassing the predictions by a factor of two or three. Numerical simulation techniques address these constraints when simulating building energy usage [10]. However, their capacity to accurately replicate the intricacies of the actual world remains limited. Through a systematic review of past research findings and limitations, these simulations play a pivotal role in tackling the challenges linked to using machine learning models to enhance building energy efficiency [11].

Artificial Intelligence, particularly Machine Learning (ML) [12], has emerged as a potent tool for addressing complex challenges across various domains. In the context of cooling load estimation, ML algorithms shine as they have the capacity to assimilate vast datasets encompassing diverse parameters such as outdoor temperatures [13], humidity levels, occupancy patterns, and architectural features. Among the myriad of ML algorithms, the K-Nearest Neighbors (KNN) algorithm stands out for its simplicity and effectiveness in regression tasks [14]. KNN operates on the premise that similar data points in a feature space tend to have similar output values [15]. Leveraging this principle, KNN can predict cooling loads by identifying neighboring data points with known CL values. The algorithm computes weighted averages of these neighbors, providing an accurate CL estimate based on the historical data [16]. The application of KNN in cooling load estimation is a cornerstone of this article, offering a foundation upon which advanced optimization techniques can be built [17].

In order to accurately capture intricate energy consumption patterns, the system harnessed the capabilities of a Convolutional Neural Network (CNN) and a Long Short-Term Memory (LSTM) network. Kim and Cho [18] addressed the challenge of accurately predicting housing energy consumption in the context of a rapidly increasing human population and technological development. The authors proposed a CNN-LSTM neural network, combining Convolutional Neural Network (CNN) and Long Short-Term Memory (LSTM), to effectively predict energy consumption. The method demonstrated nearly perfect prediction performance, outperforming conventional forecasting methods and achieving the smallest root mean square error, especially for datasets on individual household power consumption. Empirical analyses of variables provided valuable insights into the factors influencing power consumption forecasts, contributing to improved prediction accuracy. Moradzadeh et al. [19] focused on applying SVR and MLP models to estimate cooling and heating demands. The MLP model produced remarkable results for their investigation with an amazing R2-value of 0.9993 for heating load prediction, while the SVR model performed very well with an R-value of 0.9878 for cooling load prediction. These results show the degree of accuracy that a machine learning system is capable of achieving. In study [20], using a genetic algorithm in conjunction with a dynamic simulation tool, a multi-objective optimization was carried out to improve energy efficiency in existing buildings via renovations and HVAC systems. A different research suggested using statistical analysis in energy forecasting to cool an office building. The study in [21] proposed four hybrid methods for predicting the cooling load efficiency of buildings, based on artificial neural networks (ANN) and meta-heuristic algorithms such as artificial bee colony (ABC), particle swarm optimization (PSO), imperialist competitive algorithm (ICA), and genetic algorithm (GA). Cooling load forecasting was executed in study [22] using a probabilistic entropy-based neural $(PENN)$ method. Short-term cooling load prediction, aiming to optimize $HVAC$ systems and energy efficiency in buildings, was performed in [23] using multiple nonlinear regression $(MNR)$, auto-regressive $(AR)$, and autoregressive with exogenous $(ARX)$ models. In study [24], a feedforward neural network $(FFNN)$ reduced building energy consumption for thermal comfort by $36.5\%$. For energy demand forecasting and energy efficiency measures in a residential building, [25] suggested a decision tree method. A comparative study of cooling load forecasting methods was conducted in study [26], contrasting machine learning methods such as minimax probability machine regression (MPMR), gradient boosted machine (GBM), deep neural network (DNN), and Gaussian process regression (GPR). In research [27], ANN, categorization and regression tree (CART), general linear regression (GLR), and chi-squared automatic interaction detector (CHAID) were used to forecast the cooling loads of the building. The networks' inputs for the prediction were the technical parameters of the building [28].

Conversely, in the context of CL prediction, the SVR model outperformed, achieving the highest $R-$value of $0.9878$. In a separate study, Roy et al. [3] presented a customized Deep Neural Network (DNN) model designed to accurately anticipate heating and cooling needs in residential buildings. The results demonstrated that when it came to heating and cooling load prediction, the $DNN$ and $GPR$ models achieved the maximum Variance Accounted For $(VAF)$. In the next stage of the study, the $DNN$ model's performance was contrasted with that of the gradient-boosted machine $(GBM)$, Gaussian process regression $(GPR)$, and Minimax Probability Machine Regression $(MPMR)$ models.

This study makes a significant contribution to the field of building energy efficiency by delving into the innovative integration of Artificial Intelligence (AI) and advanced optimization techniques for the prediction and optimization of cooling loads in residential buildings. The core innovation lies in the utilization of the K-Nearest Neighbors (KNN) base model, chosen for its efficiency and reliability in predicting building cooling loads. To further enhance the performance of the KNN model, the study introduces a novel hybridization technique that integrates two cutting-edge optimizers: Dynamic Arithmetic Optimization (DAO) and the Wild Geese Algorithm (WGA). This hybrid approach aims to harness the strengths of both optimizers, maximizing predictive accuracy and optimizing cooling load outcomes. The study's distinctive contribution lies in its comprehensive examination of various models, including individual configurations of KNN, DAO, and WGA, as well as their hybrid combinations. This meticulous evaluation ensures an unbiased assessment of each model's capabilities, providing valuable insights into their standalone and synergistic performances. Crucially, the study emphasizes the use of established metrics such as $R^2$ (coefficient of determination) and RMSE (root mean square error) in evaluating model performance. By incorporating these metrics, the research ensures a robust and credible assessment of the predictive capabilities of the models. This study not only explores the potential of AI and optimization techniques in enhancing energy efficiency but also establishes a methodological framework for evaluating and implementing these technologies in the context of residential building cooling load prediction.

In the following sections, a detailed examination of the relevant data, the model, and the optimizers utilized in Section II will be undertaken. An elaborate explanation of the data and an assessment of the models based on metrics will be provided. In Section III, the results derived from the training and testing phases will be scrutinized, and subsequently, the performance of the models based on classification will be reported. Finally, in Section IV, conclusions regarding the study in question and the overall performance of the models will be presented.

## II. Materials and Methodology

### A. Data Gathering

This article delves into the crucial parameters and variables pertinent to studying building energy consumption, particularly in predicting cooling loads. The dataset is meticulously divided into three segments: Training $(70\%)$, Validation $(15\%)$, and Testing $(15\%)$. Each segment plays a pivotal role in different phases of model development and assessment. The Training Set forms the foundation for training the predictive model, enabling it to learn from historical data. The Validation Set fine-tunes the model's parameters, guarding against overfitting and ensuring robustness. Finally, the Testing Set rigorously evaluates the model's efficacy with unseen data, providing the ultimate assessment. These parameters are essential for comprehending and modeling energy dynamics in residential buildings. Table I presents the statistical characteristics of the input variables [29]. The following is a detailed breakdown of each parameter:

*1) Relative compactness:* Relative compactness is a fundamental parameter that describes how tightly or efficiently a building is designed. It is a dimensionless value that quantifies the compactness of the building's shape, affecting the thermal performance and energy consumption.

2) *Surface area:* Surface area is critical as it directly influences the heat exchange between the building's interior and the external environment. It encompasses the total external surface area of the building, which includes walls, roof, and possibly other exposed surfaces.

3) *Wall area:* The Wall represents the total surface area of the building's walls. Walls are significant in heat transfer and insulation, making this parameter crucial for energy modeling.

4) *Roof area:* The roof area is the total surface area of the building's roof. Roof design and insulation are key factors affecting cooling load, as heat gain through the roof can be substantial.

5) *Overall height:* The height of the building impacts its internal volume and air circulation, influencing the distribution of cooling loads within the structure.

6) *Orientation:* Building orientation refers to the direction in which the building faces. It can affect the solar radiation the building receives, impacting the cooling load.

7) *Glazing area:* The glazing area represents the proportion of the building's external envelope covered by windows or glass. It significantly influences heat gain and loss, making it an essential factor in cooling load calculations.

8) *Glazing area distribution:* The distribution of glazing within the building's envelope can vary, affecting how heat is distributed and the spatial variations in cooling load.

9) *Cooling:* Cooling load in kilowatts (KW) represents the cooling energy required to maintain a comfortable indoor temperature. It is a crucial output variable in energy modeling.

These parameters collectively serve as the cornerstone for predicting cooling loads in residential buildings. Fig. 1 illustrates the correlation matrix depicting relationships among the input and output variables. The article delves into examining the influence of these parameters on energy consumption and explores how advanced machine learning models, like KNN integrated with innovative hybridization techniques, can enhance the precision of cooling load predictions. Understanding these material factors is essential for optimizing energy-efficient building design and cooling system operation [30].

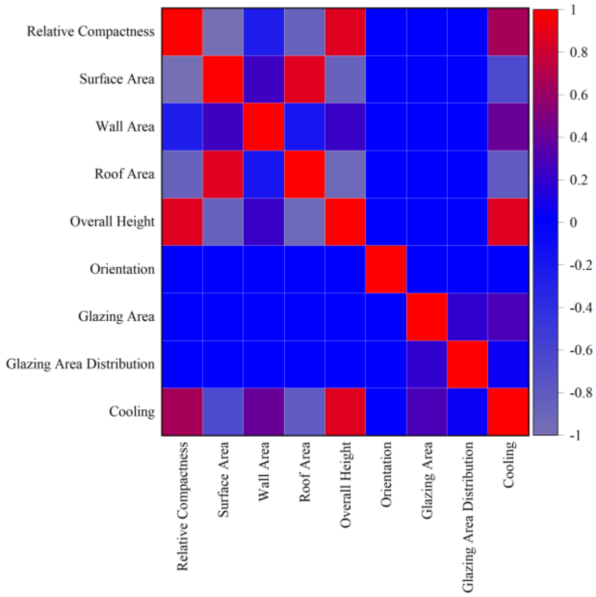

Fig. 1. Correlation matrix for the input and output variables.

TABLE I. THE STATISTIC PROPERTIES OF THE INPUT VARIABLE OF KNN

| Variables | Indicators | | | | |
|---|---|---|---|---|---|
| | $Category$ | $Min$ | $Max$ | $Avg$ | $St.Dev.$ |
| Relative compactness | $Input$ | 0.62 | 0.98 | 0.764 | 0.106 |
| Surface area (m2) | $Input$ | 514.5 | 808.5 | 671.7 | 88.09 |
| Wall area (m2) | $Input$ | 245 | 416.5 | 318.5 | 43.63 |
| Roof area (m2) | $Input$ | 110.3 | 220.5 | 176.6 | 45.17 |
| Overall height (m) | $Input$ | 3.5 | 7 | 5.25 | 1.751 |
| Orientation | $Input$ | 2 | 5 | 3.5 | 1.119 |
| Glazing area (%) | $Input$ | 0 | 0.4 | 0.234 | 0.133 |
| Glazing area distribution | $Input$ | 0 | 5 | 2.813 | 1.551 |
| Cooling (KW) | $Output$ | 6.01 | 43.1 | 22.31 | 10.09 |

## B. KNN-based

The K-Nearest Neighbors (KNN) algorithm predicts outcomes by considering most feedback from $K$ data points closest to the test point [31]. To prepare for the application of this algorithm, it is crucial to standardize these parameters using Eq. (1).

$$x_{normalization} = \frac{x-Min}{Max-Min} \tag{1}$$

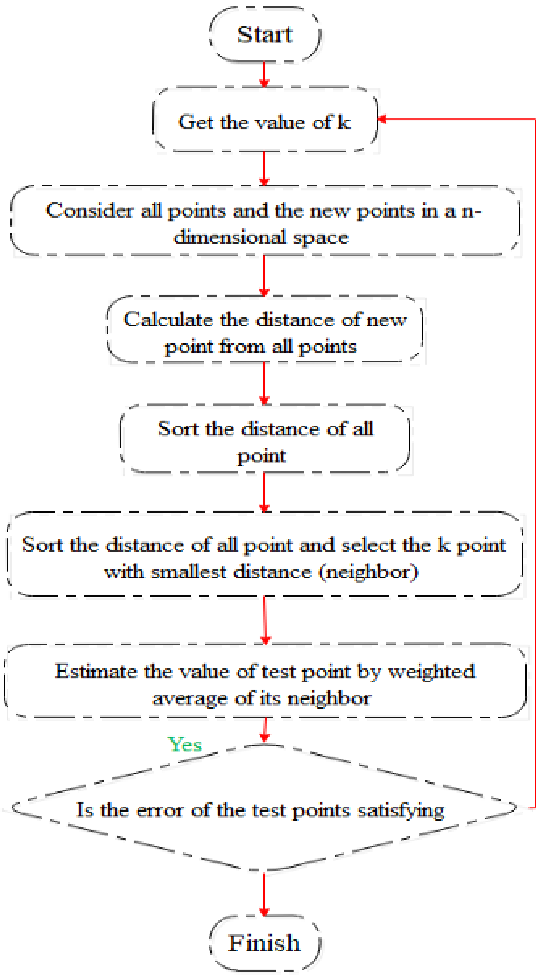
Next, the Euclidean distance between the test and data points is determined using Eq. (2).

$$H(x_i, x_j) = \left(\sum_{h=1}^{m} \left|x_i^{(h)} - x_j^{(h)}\right|^2\right)^{\frac{1}{2}} \tag{2}$$

Eq. (2) calculates the Euclidean distance H, where m is the number of argument points, between the test point $(x_j)$ and the original data points $(x_i)$. But since different parameters affect thermal comfort in different ways even when their values change by the same amount (e.g., a 1°$C$ change in air temperature affects thermal comfort more than a 1% change in air humidity), it is necessary to modify the Euclidean distance for each parameter. To correct for the uneven effects of indoor thermal factors on thermal comfort, this adjustment is made using Eq. (3) [32].

$$H\left(x_i, x_j\right) = \left(\sum_{h=1}^{m}\left(w_h * \left|x_i^{(h)} - x_j^{(h)}\right|^2\right)\right)^{\frac{1}{2}} \tag{3}$$

The weight (w_h) allotted to each indoor thermal parameter influencing thermal comfort is calculated using the equation. To find the K data points that show the closest closeness to the test location, distances are calculated. The feedback that was obtained from the individuals at the present test point is then identified as the feedback that occurs the most often out of these $K$ data points. The ideal value for $K$, which determines the necessary number of data points, may be found with the use of cross-validation. It is crucial to choose a $K$ value that falls in the middle of the two extremes for best results. A low value of $K$ may cause the model to become too sensitive to sample points that are near to the test point, which might lead to an excessive impact from noise points. On the other hand, if $K$ is set very high, the accuracy of the model can suffer [33]. Fig. 2 presents the flowchart illustrating the $KNN$ process.



Start
Get the value of k
Consider all points and the new points in a n-dimensional space
Calculate the distance of new point from all points
Sort the distance of all point
Sort the distance of all point and select the k point with smallest distance (neighbor)
Estimate the value of test point by weighted average of its neighbor
Yes
Is the error of the test points satisfying
No
Finish

Fig. 2. The flowchart of the KNN model.

## C. Dynamic Arithmetic Optimization (DAO)

The core arithmetic optimization algorithm has been improved by introducing a novel accelerator function integrating two dynamic elements to boost performance [34]. In the optimization procedure, the dynamic version adjusts the search phase and candidate solutions by modifying their exploration and exploitation behavior. A standout feature of DAOA is its unique quality of not necessitating any initial parameter fine-tuning, unlike the latest metaheuristic methods [35].

*1) A dynamic accelerated function for DAOA:* In a dynamic environment, the search phase of the arithmetic optimization algorithm is significantly affected by the DAF. To tailor the AOA for this dynamic context, alterations are required for the accelerated function's initial Min and Max values. However, an ideal scenario would entail an algorithm that isn't reliant on internally adjustable parameters, as an alternative descending function can substitute the DAF [36]. The modification factor within the optimization algorithm is delineated as follows in Eq. (4):

$$DAF = \left(\frac{It_{Max}}{It}\right)^{a} \tag{4}$$

It represents the current iteration count, $It_{Max}$ signifies the maximum allowable number of iterations, and $a$ stands for a constant value. This function diminishes with each successive iteration of the algorithm [37].

*2) A dynamic candidate solution for DAOA:* The dynamic characteristics of candidate solutions in DAOA are presented in this section. In the case of metaheuristic algorithms, the importance of the exploitation and exploration phases cannot be overstated, and ensuring a proper balance between them is deemed vital for the success of the algorithm. The dynamic iteration of the algorithm seeks to improve both the exploitation and exploration phases by continuously adjusting the position of each solution according to the best solution obtained thus far in the optimization process. In the improved iteration, the Dynamic Candidate Solution (DCS) function is alternatively incorporated into Eq. (5) and Eq. (6) [38].

$$x_{i,j} = (C_{it+1}) = \begin{cases} best(x_j) \div (DCS{+}\in) \times ((UB_j - LB_j) \times \mu + LB_j)), r2 < 0.5 \\ best(x_j) \times DCS \times ((UB_j - LB_j) \times \mu + LB_j)), Otherwise \end{cases} \tag{5}$$

$$x_{i,j} = (C_{it+1}) = \begin{cases} best\left(x_j\right) - DCS \times ((UB_j - LB_j) \times \mu + LB_j)), r3 < 0.5 \\ best\left(x_j\right) + DCS \times ((UB_j - LB_j) \times \mu + LB_j)), Otherwise \end{cases} \tag{6}$$

The influence of the decreasing percentage in the candidate solution is considered by introducing the DCS function. Its value is diminished with each iteration of the algorithm, as depicted below in Eq. (7) and Eq. (8):

$$DCS(0) = 1 - \sqrt{\frac{It}{It_{Max}}} \tag{10}$$

$$DCS(t+1) = DCS(t) \times 0.99 \tag{11}$$

The empirical observations gathered from multiple search agents and iterations provide substantial evidence that the integration of candidate solutions in DAOA effectively expedites the convergence rate of AOA [39]. These enhancements result in improved solution quality. Metaheuristic algorithms operating without extensive parameter tuning are typically considered advantageous. This algorithm benefits from adaptive parameters, reducing the parameter tuning requirements to just two variables - maximum iteration and population size. This contrasts competing algorithms, which often necessitate adjustments across various parameters for different problem instances. However, one drawback of this algorithm (see Eq. (9)) lies in its adaptive mechanism, which is based on the iteration count rather than fitness improvement.

$$k_{i,d}^{v} = p_{i,d}^{it} + r_{7,d} \times r_{8,d} \times ((g_d^{it} + p_{i+1,d}^{it} - 2 \times p_{i,d}^{it}) + s_{i,d}^{it+1}) \tag{9}$$

### *D. Wild Geese Algorithm (WGA)*

Inspired by the coordinated migratory behavior of wild geese and their patterns of reproduction and death, the Wild Geese Algorithm (WGA) is a metaheuristic algorithm that uses swarm intelligence [40]. The suggested WGA is mainly intended for high-dimensional problem optimization, and it is distinguished by its simplicity and efficacy. The proposed phases of the WGA, to put it broadly, include the following: The wild geese's life cycle, migration, and subsequent evolution are covered in the following sections: a) Velocity displacement and migration stage; b) roaming and searching for food within their native environment; and c) the species' propagation and evolutionary phase [41].

$$k_{i,d}^{w} = p_{i,d}^{it} + r_{9,d} \times r_{10,d} \times (p_{i+1,d}^{it} - p_{i,d}^{it}) \tag{10}$$

First, a population of wild geese is established, and $ki$ is used to represent the positional vector of each wild goose. Next, for every person, the best local location, or personal best solution $pi$, and the migration velocity $Si$ are ascertained. The target function is then used to rate every wild goose population from best to worst, ranking them in decreasing order [41].

*a) Phase of velocity displacement and migration:* The wild geese migration is a meticulously organized collective movement characterized by coordination and control. It hinges on the leadership of specific individuals within the sorted population and their neighboring companions to steer the migration. Eq. (10) and Eq. (11) furnish the formulas for velocity and displacement concerning the coordinated velocity of the geese [42].

$$s_{i,d}^{It+1} = \left(r_{I,d} \times s_{i,d}^{It} + r_{2,d} \times \left(s_{i+1,d}^{It} - s_{i-1,d}^{It}\right)\right) + r_{3,d} \times \left(P_{i,d}^{It} - k_{i-1,d}^{It}\right) + r_{4,d} \times \left(P_{i+1,d}^{It} - k_{i,d}^{It}\right) + r_{5,d} \times \left(P_{i+2,d}^{It} - k_{i+1,d}^{It}\right) - r_{6,d} \times \left(P_{i-1,d}^{It} - k_{i+2}^{It}\right) \tag{11}$$

Regarding the $i-th$ wild goose, the variables $ki, d, pi, d, and\ si, d$ correspond to the $d-th$ dimension of the current velocity, current position, and best position, respectively. As demonstrated in Eq. (11), the velocities of its nearby members affect the changes in location and velocity of a particular wild goose, such as the $i-th$ wild goose, denoted as $(s_{i+1}^{It} - s_{i-1}^{It})$, along with the positions of neighboring members. The wild geese depend on their neighboring individuals within the sorted population to acquire movement patterns and guidance to minimize the distances between them and these adjacent members.

$$k_{i-1}^{it} \rightarrow p_i^{it}, x_i^{it} \rightarrow p_{i+1}^{it}, k_{i+1}^{it} \rightarrow p_{i+2}^{it}, k_{i+2}^{it} \rightarrow -p_{i-1}^{it}$$

Moreover, the collective movement of the entire flock is directed by the global best member [43]. Eq. (9) depicts this coordinated and sequential positional adjustment, executed in tandem with the leading members, to mimic the motion of all members systematically.

Within Eq. (9), $g_d$ signifies the best position among all members of the group.

*b) Roaming about in their native environment and gathering food:* The purpose of this step is to incentivize the $i-th$ wild goose to move in the direction of its antecedent, thereby indicating that the $i-th$ wild goose is attempting to approach the $(i+1)-th$ goose $(p_{i+1}^{it} - p_i^{it})$. The formula governing the movement and foraging behavior of the wild goose, denoted as $k_i^w$, is provided as follows:

*c) The process by which wild geese reproduce and evolve:* Reproduction and evolution constitute another crucial stage in the life cycle of wild geese. The modeling of reproduction and evolution entails employing a blend of the migration equation ($k_i^v$) and the movement while searching for food equations ($k_i^{wa}$), as calculated in Eq. (12). The overall simulations for the proposed $WGA$ algorithm utilize a $Cr$ value of 0.5.

$$k_{i,d}^{it+1} = \begin{cases} k_{i,d}^{v} \overset{if}{\rightarrow} r_{i,d} \\ k_{i,d}^{wa} \end{cases} \leq cr \tag{12}$$

*d) The decline, movement, and progressive development of wild geese:* Previous studies that have been published in the literature show that different optimization methods have different effects on addressing different issues depending on the size of the population and the number of iterations. In some cases, such as those involving the $F2$ and $F3$ functions, the population size of the algorithm is more important and has a greater influence than the number of iterations. However, for some functions, like F7 and F8, the number of iterations in the WGA algorithm is more important and has a greater impact than the population size. In order to arrive at a consensual solution, this is necessary. In order to overcome this difficulty and guarantee a balanced algorithm performance across all test functions, the death phase is created. The procedure starts with $N^{initial}$, the initial maximum population size. The less resilient individuals will be progressively eliminated from the population as the algorithm iterations continue on, according to the standards given in Eq. (13). At the end of the last iteration, the population size will finally reach the final number, $N^{initial}$, after decreasing linearly over time.

$$N = round\begin{pmatrix} N^{initial} \\ -((N^{In}-N^{f})*(\frac{FV}{FV\,max})) \end{pmatrix} \tag{13}$$

The FV represents the count of function evaluations in Eq. (13).

### E. Performance Evaluators

Table II outlines the formulations of various performance metrics used to evaluate the model's accuracy and effectiveness in predicting outcomes. These metrics provide valuable insights into the model's performance:

- Predicted values are represented as $b_i$.
- Measured values are indicated as $m_i$.
- The symbol n signifies the sample size.
- The mean of the predictor variable within the dataset is denoted as x̄.
- The mean of the measured values is represented as m̅, and the mean of the predicted values is denoted as b̅.

### F. Hyperparameter

Table III lists key hyperparameters for KNWG and KNDA models. In the KNWG model, setting n_neighbors to 01 means just the nearest neighbor is evaluated for predictions. This can provide a more localized prediction strategy. We set leaf_size to 3. This option describes the number of sites where the algorithm transitions from tree-based to brute-force search. Smaller leaf_sizes can improve memory efficiency. To specify the power parameter for the Minkowski distance metric, set the p parameter to 3. A value of 3 represents the Euclidean distance, frequently utilized for its balanced treatment of dimensions. In contrast, the KNDA model uses only the closest neighbor by setting the n_neighbors hyperparameter to 1. While this setting may increase model variance, it may be advantageous in certain situations. Configuring leaf_size to 999 indicates a higher leaf size than KNWG. Selecting this option can improve memory consumption and computational performance, especially for bigger datasets. Setting p to 999 indicates a high power parameter for the Minkowski distance measure. A high number can dramatically impact distance calculation, potentially affecting model behavior in sophisticated ways. Hyperparameter selection should be based on dataset properties and desired objectives, as they greatly affect model behavior and performance. Fine-tuning parameters through testing and validation can improve model performance and generalization across varied datasets and applications.

TABLE II. THE FORMULATIONS OF THE PERFORMANCE METRICS

| | | |
|---|---|---|
| **Coefficient Correlation (R2)** | $R^2 = \left(\frac{\sum_{i=1}^{n}(b_i-\bar{b})(m_i-\bar{m})}{\sqrt{\left[\sum_{i=1}^{n}(b_i-\bar{b})^2\right][\sum_{i=1}^{n}(m_i-\bar{m})^2]}}\right)^2$ | (14) |
| **Root Mean Square Error (RMSE)** | $RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(m_i-b_i)^2}$ | (15) |
| **Mean Square Error (MSE)** | MSE = $\frac{1}{n}\sum_{j=1}^{n}(m_i-b_i)^2$ | (16) |
| **Prediction Interval (PI)** | $PI = \pm\, t \times SE \times \sqrt{(1+\frac{1}{n}+\frac{(x^*-\bar{x})^2}{\Sigma(x_i-\bar{x})^2})}$ | (17) |
| **Mean Absolute Percentage Error (MAPE)** | $MAPE = \frac{100}{n}\sum_{i}^{n}\frac{\lvert b_i\rvert}{\lvert m_i\rvert}$ | (18) |

TABLE III. THE HYPERPARAMETER FOR MODELS

| **Models** | **Hyperparameter** | | |
|---|---|---|---|
| | ***n_neighbors*** | ***leaf_size*** | ***p*** |
| **KNWG** | 01 | 3 | 3 |
| **KNDA** | 1 | 999 | 999 |

## III. RESULT AND DISCUSSION

Table IV presents the performance metrics for the developed models in the context of KNN. These models were evaluated across different phases: Training, Validation, Test, and All (combining all data). The performance metrics include RMSE, $R^2$, MSE, PI, and MAPE.

*1) KNN model:* The KNN model demonstrates strong predictive capabilities. In the training phase, it achieves an RMSE of 1.525 and an $R^2$ of 0.975, indicating a high level of accuracy. Similar results are observed in the validation and test phases, with slight increases in RMSE and a decrease in $R^2$, which is expected as the model generalizes to new data. When considering all data, the KNN model maintains a solid performance.

*2) KNWG model:* The KNWG model outperforms the KNN model across all phases. It exhibits significantly lower RMSE values, indicating improved accuracy. In the training phase, it achieves an impressive RMSE of 0.680 and a high $R^2$ of 0.995, highlighting its superior performance. This trend continues in the validation and test phases. When considering all data, the KNWG model consistently maintains lower RMSE and higher $R^2$ values compared to the KNN model.

*3) KNDA model:* The KNDA model, while not as accurate as the KNWG model, still demonstrates respectable performance. It achieves RMSE values higher than KNWG but lower than the KNN model across all phases. In the training phase, it records an RMSE of 1.078 and an $R^2$ of 0.987. Similar trends are observed in the validation and test phases. When considering all data, the KNDA model offers a balanced performance.

Overall, the results indicate that the KNWG model is the most accurate among the three, followed by KNDA, with KNN being the least accurate. The choice of the best model depends on the specific application's requirements. Additionally, these models exhibit low MAPE values across all phases, confirming their reliability. These findings provide valuable insights into selecting an appropriate model for CL prediction and its potential applications in various domains.

Table V compares the performance metrics of the presented study with those of published articles. In terms of RMSE, Moradzadeh et al. achieved 0.4832, while Roy et al. achieved the lowest RMSE of 0.059. Gong et al. and Afzal et al. obtained RMSE values of 0.1929 and 1.4122, respectively. Regarding the R2 values, Moradzadeh et al. recorded the highest at 0.9993, followed closely by the present study at 0.996. Roy et al. achieved an R2 of 0.99, while Gong et al. and Afzal et al. attained R2 values of 0.9882 and 0.9806, respectively. These comparisons provide insights into the relative performance of the presented study in relation to existing research in the field.

Fig. 3 provides a visual representation highlighting the differences among $R^2$, RMSE, and MSE for the proposed models. It is evident from the graph that the KNWG model stands out as the top performer, showcasing the lowest RMSE and MSE values, signifying its outstanding predictive accuracy in estimating CL. Furthermore, it attains the highest $R^2$ values among the models, underscoring its robust performance. Moreover, the Fig. 3 diagram emphasizes the intermediate performance of the KNAO model. It displays a well-balanced performance, occupying a middle position between the precision achieved by the KNWG model and the outcomes of the KNN model. Conversely, the KNN model, functioning as an independent model, displayed the least accurate results in comparison to the other models.

Fig. 4 displays a scatter plot that illustrates the performance of the models concerning their $R^2$ and RMSE values. The plot distinguishes each model's three phases—train, validation, and test—using unique circular markers in different colors. These markers cluster around a central line, symbolizing the ideal $R^2$ value 1, signifying a perfect match between predicted and actual values. A more in-depth examination of the data points linked to the KNWG model within the plot uncovers a tight cluster near the central line. This clustering stands as evidence of the model's precision in predicting values, as it consistently maintains proximity to the ideal $R^2$ value.

TABLE IV. THE RESULT OF DEVELOPED MODELS FOR KNN

| Model | phase | Index values | | | | |
|---|---|---|---|---|---|---|
| | | ***RMSE*** | ***R2*** | ***MSE*** | ***PI*** | ***MAPE*** |
| KNN | Train | 1.525 | 0.975 | 2.326 | 0.031 | 3.878 |
| | Validation | 1.871 | 0.968 | 3.500 | 0.039 | 4.363 |
| | Test | 1.944 | 0.963 | 3.777 | 0.040 | 5.176 |
| | All | 1.649 | 0.971 | 2.719 | 0.034 | 4.145 |
| KNWG | Train | 0.680 | 0.995 | 0.463 | 0.014 | 2.703 |
| | Validation | 1.020 | 0.990 | 1.040 | 0.021 | 3.135 |
| | Test | 1.388 | 0.980 | 1.927 | 0.028 | 3.829 |
| | All | 0.877 | 0.991 | 0.769 | 0.018 | 2.936 |
| KNDA | Train | 1.078 | 0.987 | 1.163 | 0.022 | 4.386 |
| | Validation | 1.666 | 0.978 | 2.775 | 0.034 | 3.600 |
| | Test | 1.824 | 0.972 | 3.326 | 0.037 | 3.637 |
| | All | 1.315 | 0.981 | 1.728 | 0.027 | 4.156 |

TABLE V. COMPARISON BETWEEN THE PRESENTED AND PUBLISHED ARTICLES

| Articles | Index values | |
|---|---|---|
| | ***RMSE*** | ***$R^2$*** |
| Moradzadeh et al. [44] | 0.4832 | 0.9993 |
| Roy et al. [45] | 0.059 | 0.99 |
| Gong et al. [46] | 0.1929 | 0.9882 |
| Afzal et al. [47] | 1.4122 | 0.9806 |
| Present Study | 0.698 | 0.996 |

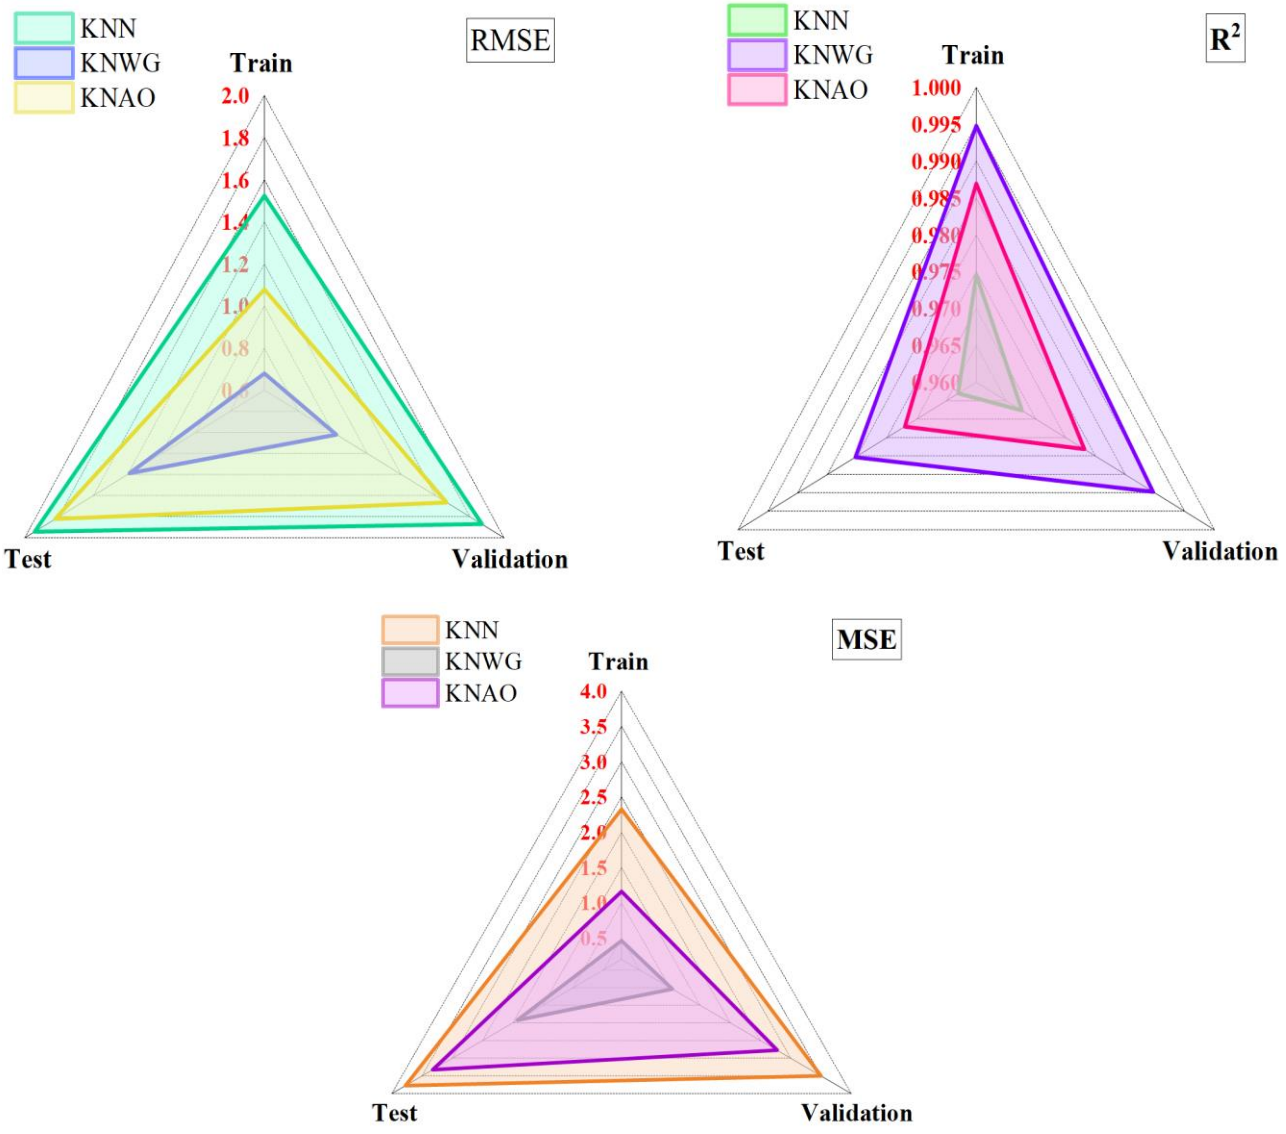


Fig. 3. The comparison of parameters.

In contrast, both the KNDA and KNN models exhibit scattered data points, indicating a wider range of values. This scattering suggests that these models display variations in their predictions and may not consistently achieve high $R^2$ values. The scatter plot in Fig. 4 underscores the superior predictive accuracy of the KNWG model while highlighting the broader variability in the predictions made by the KNDA and KNN models.

Fig. 5 provides a symbolic representation that visually conveys the error percentages associated with each model. Analyzing model errors is a vital method to evaluate their precision. This plot assists in evaluating the models' performance across the training, testing, and validation phases. It's worth highlighting that the KNN model displays a higher error rate compared to the other models, with the maximum recorded error percentage reaching 20%. In contrast, KNWG has demonstrated the utmost accuracy among all the models. In the testing phase, the highest observed error for KNWG is 10%, and a substantial portion of its data points cluster closely around a minimal 0% error. Meanwhile, the KNDA model exhibits moderate performance, with the highest error percentage reaching 15% in the testing phase. It consistently maintains moderate error values when compared to the other models.

Fig. 6 portrays the distribution patterns of the proposed models using a violin plot, which represents the 3 stages of train, validation, and test. It's noticeable that the data points for the KNN model display a broad dispersion, covering error percentages spanning from 20 to -20, which is particularly pronounced during the training phase. To efficiently detect outlier data points for model comparison, a range equal to 1.5 times the Interquartile Range (IQR) is utilized. In contrast, KNWG's data points are closely grouped within the error percentage range of 10 to -10, while KNDA data points fall within the range of 15 to -15 percent error.

## IV. Conclusion

This article delves into developing and evaluating predictive models, specifically focusing on K-nearest neighbors (KNN) for estimating Cooling Load (CL) in buildings. Three distinct models were examined: KNN, KNWG, and KNDA. The study encompassed various phases, including training, validation, and testing, providing a comprehensive analysis of their performance. The results and discussions highlight the superiority of the KNWG model, which consistently demonstrated exceptional predictive accuracy with the lowest Root Mean Square Error (RMSE) and Mean Square Error (MSE) values. Its high Coefficient Correlation ($R^2$) values emphasize its robust overall performance.

On the other hand, while functional, the KNN model exhibited less accuracy and higher error rates than the other models. The error analysis further solidifies the KNWG model's precision, with most data points clustering closely around minimal error percentages. KNDA, while not as accurate as KNWG, maintained moderate error values consistently across phases. The distribution patterns and outlier detection methods provided additional insights into the models' performance. KNWG and KNDA exhibited narrower error ranges, indicating their stability and reliability. The KNWG model is the most accurate and reliable option for predicting building CL. Its consistently superior performance in multiple phases and various evaluation metrics makes it a valuable tool for building energy efficiency applications. This research contributes to the advancement of predictive modeling techniques and their potential for real-world applications in improving energy efficiency in residential buildings.

Despite its advancements, this study has limitations worth noting. Firstly, the proposed approach heavily relies on historical data, potentially limiting its applicability to new or unique building designs or environments. Secondly, while KNN, DAO, and WGA are powerful techniques, their performance may vary depending on specific datasets and configurations, necessitating careful tuning. Additionally, the study's focus on residential buildings may not fully capture the complexities of larger commercial or industrial structures. Moreover, the integration of KNN with DAO and WGA introduces additional computational complexities, potentially hindering real-time application in some scenarios. Lastly, external factors such as climate change could impact the model's long-term accuracy.

# Enhanced Detection of COVID-19 using Deep Learning and Multi-Agent Framework: The DLRPET Approach

Rupinder Kaur Walia, Harjot Kaur
Department of Computer Science Engineering, Guru Nanak Dev University, Amritsar, 143005, India

***Abstract*—The ongoing global pandemic caused by novel coronavirus (COVID-19) has emphasized the urgent need for accurate and efficient methods of detection. Over the past few years, several methods were proposed by various researchers for detecting COVID-19, but there is still a scope of improvement. Considering this, an effective and highly accurate detection model is presented in this paper that is based on Deep learning and multi-Agent concepts. Our main objective is to develop a model that can not only detect COVID-19 with high accuracy but also reduces complexity and dimensionality issues. To accomplish this objective, we applied a Deep Layer Relevance Propagation and Extra Tree (DLRPET) technique for selecting only crucial and informative features from the processed dataset. Also, a lightweight ResNet based Deep Learning model is proposed for classifying the disease. The ResNet model is initialized three times creating agents which analyses the data individually. The novelty contribution of this work is that instead of passing the entire training set to the classifier, we have divided the training dataset into three subsets. Each subset is passed to a specific agent for training and making individual predictions. The final prediction in proposed network is made by implementing majority voting mechanism to determine whether an individual is COVID-19 positive or negative. The experimental outcomes indicated that our approach achieved an accuracy of 99.73% that is around 2% higher than standard best performing KISM model. Moreover, proposed model attained precision of 100%, recall of 99.73% and F1-score of 98.59 % respectively, showing an increase of 5% in precision, 4.73% in recall and 4.59% in F1-score than best performing SVM model.**

***Keywords*—*COVID-19; deep learning; SVM; ResNet; disease classification; biomedical applications; multi-agent***

## I. Introduction

Since the outbreak of COVID-19 disease in 2019, two major sections of our society i.e., health care and economy have seen the worst phases [1]. This disease is basically a continuation of a number of earlier catastrophes brought on by extremely contagious respiratory viral diseases. The first case of COVID-19 was found in Wuhan city of China that was caused by SARS-CoV-2 virus and quickly expanded to other countries causing healthcare emergency. The structure of COVID-19 virus is positive single strand RNA which shares genetically characteristics with SARS and Bat SARS corona viruses [2]. Every virus has a size of between 50 nm to 200 nm and comprises of some basic proteins like Spike, Envelop, Membrane and nucleocapsid which are represented by Alphabetical letters S, E, M and N respectively [3,4]. The virus envelop is created by utilizing the S, E and M proteins while as, N protein is responsible for holding the RNA genome of the virus [3]. As per the study conducted recently, it has been observed that bats serve as one of the prevalent natural hosts of virus [6], and intermediate host is Malayan Pangolin. However, the virus is also transmitted from one person to another through respiratory droplets released by infected person during coughing or sneezing. These droplets could transmit the infection by additionally contaminating surfaces in the environment. People who have been exposed to coronavirus developed moderate to serious respiratory symptoms and may need assistance with ventilation support. To interrupt the process and stop the disease from spreading, numerous countries have restricted their borders [9]. Despite this, it is imperative to quickly identify infected persons in order to put an end to this fast spread. One of the biggest challenges faced by doctors is that asymptomatic persons can also spread the disease [10]. Even though symptomatic patients are main source of transmission, however the risk of transmission is further increased by the undetected asymptomatic patients. The handling of COVID-19 involves the avoidance, identification, command, and cure of the disease. All of these processes have an impact on the others [11].

With the aim of addressing the current issues, a number of computer aided diagnostic (CADs) techniques utilizing the concept of Artificial Intelligence (AI) [12] were used for effectively detecting COVID-19 in earliest stages. By using training data, AI algorithms can identify individuals who are at higher risk for developing COVID-19 [13], characterize its epidemiological research, and simulate how the disease spreads. Furthermore, these intelligent models can also aid in developing new medicines and vaccines, along with this they perform screening of compounds that have potential for vaccines [23]. Moreover, AI based chat-bots were also utilized in different health centers, so that they can advise a far larger number of individuals than call center [14], reducing the strain on healthcare emergency number. Additionally, AI might control the global outbreak by employing thermal imaging to search public areas for those who may be sick as well as by implementing social isolation and lockdown procedures. Thus, by utilizing AI methods including Machine Learning (ML) and Deep Learning (DL), medical institutions may not just speed up the diagnosing procedure but also aid in establishing more effective containment plans, improved results for patients, and increasingly intelligent public health decision systems for better healthcare.

### A. Motivation and Contribution

The urgent necessity to address the pandemic-related global health issue is what motivates the development of improved COVID-19 detection methods. In order to make sure that COVID-19 has little effect on healthcare providers and community, it is crucial that cases are quickly and accurately identified. Diagnostic techniques now in use have drawbacks, such as inconsistent reliability and a tendency to put a pressure on testing facilities. Researchers are working to develop novel detection models that improve diagnostic accuracy and efficacy by utilizing cutting-edge technology like artificial intelligence and deep learning. By employing these techniques, we could hasten diagnosis especially in areas with limited resources and also aid medical professional in making decisions to support efforts for curbing the spread of virus. The creation of reliable COVID-19 detection models also reflects the determination of scientific researchers to successfully confront the big challenges provided by the epidemic and is in line with their ideology of harnessing technology for public health benefits. With the aim to improve the detection rate of COVID-19 detection models, a new and effective approach is presented in this paper that can not only handle high dimensionality of complex datasets but also increase the detection rate as well. The major research contributions are mentioned below:

- To provide a COVID-19 prediction model that utilizes laboratory outcomes instead of using chest X-ray, CT scan images.
- To provide an effective solution for handling high dimensionality dataset with proposed deep LRP and Extra Tree operated feature selection model that ensure selection of the informative and crucial features.
- To propose a light weight ResNet based classification model for COVID-19 detection that contributes to healthcare field by providing faster training and resource friendly solutions.

After analyzing the related literature, it is clear that already a lot of DL models have been presented for detecting the COVID-19 persons. However, one of the biggest limitations in these models is that they don't possess extremely high accuracy rates because of the inability to recognize patterns and relationships among various features.

However, there are some models that exhibit high accuracy rates but their overall structure is so complex and intricate that it becomes difficult to implement them in real world. Furthermore, we also observed that majority of the works were based on image processing techniques, and very less work has been done on analytical data. The detailed analysis for reviewed works with their advantages and disadvantages are given in Table I. Keeping these limitations in mind, a new and unique model is proposed in this work that can address above mentioned limitations and achieves high accuracy results. Section II consists of our proposed methodology, followed by the Simulating Setup and Results Evaluation Matrices in Section III, Section IV consist of result analysis and conclusion.

TABLE I. OVERALL FINDING OF REVIEWED STUDIES

| Author | Advantages | Limitations |
|---|---|---|
| Al Shehri et al.2022 | Proposed a combined CNN and Darknet based architecture and to achieve higher detection rate | Need more Resource requirements, and lacks in training network with informative data only instead of direct images. |
| Oyelade, O. N. et al. 2021 | Proposed a pre-processing mechanism to support the classification models | Lacks in exploring models in larger datasets, and feature selection may be included to achieve higher rates with less resource requirements. |
| Sakib, S. et al.2020 | A unique dataset is generated by using 4 public datasets. | Use of GAN based networks need higher resource for training models. |
| Kogilavani, S. V. et al.2022 | An analysis of different existing CNN architectures is conducted in study | Lacks in exploring new classification method in order to achieve better classification rates. |
| Alom, M. Z. et al.2020 | Segmentation based model is proposed to get informative area from X-ray Images to improve classification rates. | Faced issues with smaller datasets, false positive detections were higher in suggested model. |
| Alazab, M. et al.2020 | Implemented classification and forecasting models to handle COVID-19 spread. | Main focus was on working with Chest X-ray images, other clinical factors or environmental factors were not considered and recommended for future works. |
| Gaur, L. et al.2023 | Evaluated 3 Pre-trained CNN networks for mobile applications. | Restricted to explore new deep learning architecture those can be lighter and less complex. |
| Irmak, E 2020. | Proposed a CNN network and achieved an accuracy of 99.20% | Work is restricted to smaller dataset and area biased information, additionally need to explore more datasets. |
| Rajawat, N. et al 2022. | Proposed a ROI extraction based informative selection scheme for training Classifier | It is restricted to variety of data and requires more clean images to achieve better classification rates. |
| Xue, Y. et al.2023 | Implemented CNN based model with data augmentation to handle smaller dataset issue. | Facing issue of larger feature set and suggested feature selection methods for future use. |

## II. OUR PROPOSED WORK

With the aim to improve the accuracy rate of COVID-19 detection model, an effective and unique model is proposed in this manuscript that is based on Deep Learning (DL) and Multi-agent techniques [5]. The proposed model undergoes through seven stages of Data preparation, Feature Selection, Data Splitting, Agent formation, Training of Agents, voting mechanism and finally performance assessment. During the first phase of proposed approach, all the necessary data related to COVID-19 is taken from an online repository which is then processed for attaining a meaningful dataset in second phase [7] [8]. In the third phase, only important and crucial attributes are selected from the available feature set by implementing DL model in order to minimize complexity and dataset dimensionality issues. During the next phase, the data is categorized into training and testing data in the proportion of 80:20. After this, agents are formed in the model by dividing training data into three subsets. In the fifth phase, the proposed DL architecture [14] is initialized three times so that they can be trained using three different agents. The main contribution of our work is that DL architecture is proposed that is based on agents wherein each agent is passed a separate dataset [15]. This was not the case in earlier detection models wherein the entire dataset was passed to classifier for training and testing its performance [16]. The results attained by three DL models are then combined in sixth stage by employing voting mechanism [17] and finally, performance is reviewed in the last phase of proposed work.

## A. Dataset Preparation

In the proposed work, COVID-19 information dataset available on GitHub is utilized that contains all the necessary information regarding the disease. The samples of the repository were collected from a hospital that is situated in Sao Paulo Brazil. The dataset contains a total of 18 samples collected from 600 patients. Among these patients, 520 are unknown to us and remaining 80 are COVID infected. The dataset can be accessed on https://github.com/burakalakuss /COVID-19-Clinical [18]. Additionally a close examination of dataset is performed to identify potential biases and demographic imbalances. The analysis results that the considered dataset is not having factors including age, gender, socio-economic status etc. that means model does not require explicitly evaluation or adjustment for potential biases or demographic imbalances. Since the utilized dataset contains lot of null or missing values that can lower the accuracy of prediction rate and can also cause over fitting issues. Therefore, data pre-processing technique is implemented [19]. Pre-processing is the process of refining the dataset so that all unnecessary or redundant information is removed from it. It aids in enhancing the accuracy of disease detection system. In our work, we have implemented Mean Imputation Method for filling the null values. It is considered as one of the frequently used techniques for filling up the null values wherein blocks are filled by calculating the mean value of same column.This process not only handled the issue of null entities but also eliminates the requirements of data augmentation step. It also showcases the capability of method to enhance dataset entities with any augmented data.

Furthermore, the strings present in the dataset were converted into numeric values by employing a Level encoder technique [20]. The label encoding process involves assigning a unique integer to each category in the variable. The features present in the dataset are represented by numeric codes in the given feature space which ultimately helps the proposed algorithm to understand and comprehend patterns and their relationships. After applying these pre-processing techniques, we were left with dataset that comprises of only 43 columns which represents more informative dataset than raw dataset. Nevertheless, it must be noted here that there might be a possibility that these columns still contain irrelevant data which might enhance the intricacy of model, therefore, it is important to refine this data further by employing Feature Selection techniques.

## B. Feature Selection using DLRPET

Feature selection is of paramount importance in various data-driven tasks, including COVID-19 detection. It involves selecting a subset of relevant features from the processed dataset while discarding irrelevant or redundant ones. The need of implementing FS techniques arises by the fact that high dimensional features lead to computational complexity and increases the risk of overfitting. By implementing an effective FS technique, the dimensionality of the model is reduced which in turn makes the detection process more efficient. Moreover, it also enhances the data quality as all irrelevant data is removed from the dataset and only those attributes are preserved that aid in improving detection accuracy rate. In our work, we have employed Deep Learning based architecture for selecting crucial and important features. Furthermore, the proposed DL based FS method is further optimized by employing two effective FS techniques named as, LRP and Extra Tree. Hence, the name of our proposed features selection technique as Deep LRP Extra Tree (DLRPET).The reason of incorporating Layer wise relevance propagation ad Extra tree in DL network is that it allows the model to attribute the relevancy of model's output back to the input features. Additionally tree based phase need lesser memory as they are more memory efficient [39].The combined model calculates the contribution and importance of feature setto final prediction that assist the model to select best set of input features. The working of proposed DLRPET is initiated by defining the initialization or configurational parameters for the DL architecture that are mentioned in Table II.

TABLE II. DL INITIALIZATION FACTORS

| Sr. No. | Parameters | Values |
|---|---|---|
| 1 | No of layer | 4 |
| *2* | Optimizer | Adam |
| *3* | Loss | Binary cross entropy |
| *4* | Metrics | Accuracy |
| *5* | Epochs | 50 |
| *6* | Batch size | 32 |

Before introducing the concept of LRP and Extra tree on the DL feature selection algorithm, we trained it on the processed dataset for analyzing the patterns of features and their relationships. The proposed DL based FS technique comprises of four layers of input, Dense_1, Dense_2 and output layers. The first layer considers the dataset attained after implementing pre-processing technique. This data is then received by first dense layer that constitutes a total of 43 units, which depicts its dimensionality. Moreover, it also comprises of RelU activation function that adds the concept of non-linearity to the network. The refined data is then passed through second dense layer with same configuration, which helps the model to learn more intricate features and their relationships. Finally, the output is received by the last layer of DL model which comprises of only 1 unit and sigmoid activation function. Once the DL model is initialized, the concept of LRP and extra tree is introduced in it for selecting optimal features. The two techniques are implemented at each layer of DL network for calculating the feature importance. Based on this feature importance, the outputs generated by LRP and ET are integrated to create a final feature vector with most effective features. The process of FS starts when LRP is configured for getting the weights and biases from trained DL model which are then summed up for extracting the positive values. The relevance score for each attribute using LRP is calculated by using Eq. (1).

$$\mathrm{r_{values}} = \frac{\mathrm{p_{values}}}{\sum_1^n \mathrm{p_{values}}} \quad (1)$$

In the next phase of FS, Extra tree technique is applied on every DL layer for evaluating feature importance or $\mathrm{f_{values}}$. It is calculated by using the Gini Impurity calculation which is given by

$$G_{imp} = \sum_k p_{mk}(1 - p_{mk}) \quad (2)$$

where, $p_{mk}$is probability of belonging to class k at m node . The feature importance in Extra tree is calculated by "Gini" impurity reduction.

$$\mathrm{f_{values}} = \sum_t \sum_m G_{imp}(t) - \left(\frac{\sum_t G_{imp}(t) \times Sample_t}{Sample_{total}}\right) \quad (3)$$

Where t is individual tree in ExtraTree, and m is each node in given tree, $Sample_t$ is sample count in tree t, and $Sample_{total}$ is count of sample in while dataset.

The relevance score and feature importance generated by LRP and ET are then integrated for selecting highly effective and informative features, by using the formula given in Eq. (2).

$$\mathrm{C_{values}} = \mathrm{f_{values}} + \mathrm{r_{values}} \quad (4)$$

By using this formula, we attained a total of 10 crucial features in the proposed work whose details are given in Table III, along with their numeric values.

TABLE III. FEATURE ATTAINED BY DLRPET MODEL

| Attributes | Non-Null | Count | Data Type |
|---|---|---|---|
| patient_age_quantile | 5644 | Non-null | int64 |
| sars-cov-2_exam_result | 5644 | Non-null | int64 |
| Hematocrit | 5644 | Non-null | float64 |
| serum_glucose | 5644 | Non-null | float64 |
| respiratory_syncytial_virus | 5644 | Non-null | int64 |
| mycoplasma_pneumoniae | 5644 | Non-null | float64 |
| neutrophils | 5644 | Non-null | float64 |
| urea | 5644 | Non-null | float64 |
| proteina_c_reativa_mg/dl | 5644 | Non-null | float64 |
| potassium | 5644 | Non-null | float64 |

### C. Data Separation

After selecting the features in previous phases, the data is separated into the training and testing datasets keeping the proportion of separation to 80 and 20. This approach involves allocating 80% of the dataset to the training set, where the model learns patterns and relationships within the data, and the remaining 20% to the testing set, which is used to assess the model's performance and generalization to new, unseen data. This ratio strikes a balance between providing the model with sufficient data to learn complex patterns and reserving a portion for evaluation, helping to prevent overfitting, and ensuring that the model's performance is assessed on independent data. This separation facilitates a rigorous assessment of the model's ability to make accurate predictions on new instances, validating its effectiveness before deploying it in real-world applications.

### D. Lightweight ResNet and Agent-based Classification Model

In the next phase of proposed work, an effective DL based classification model is presented for identifying and categorizing COVID-19 individuals. The reason for using the DL based model in the proposed work is that it is able to handle huge datasets of covid-19 quite efficiently without losing any important information. Here, we have utilized an advanced version of CNN architecture named as, ResNet that comprises of various residual connections. The primary contribution of our work is to propose ResNet classification model in which concept of multi-agents is utilized for increased performance.

The basic functionality of proposed classification model is that training data is divided into three subsets and at the same time the proposed DL classification model is initialized three times, creating 3 agents of Model 1, model 2 and model 3 respectively. The three data subsets are then passed to the three agents separately and each model gives its own prediction. The proposed model is different from current COVID-19 detection models in the fact that standard models pass entire training data to the classifier for training and then generates outcomes on testing data, while as, in our case, each subset of training data is passed to different models or agents to produce the respective predictions. The final prediction is then made by employing ensemble learning based voting mechanism. Now, before further delving deeper into the proposed model, we must know why ResNet is employed in proposed work over other DL networks. The answer to this question is very logical and simple. During the training phase of DL model comprising of various layers, the convergence process might be a challenging process due to vanishing of gradients. This issue hinders the propagation of gradients through the network, causing slow convergence or unstable optimization, which ultimately results in degraded performance of the overall network. This issue needs to be resolved in our model as we aim to achieve high detection accuracy with lowest complexity. Through analysis, we studied that ResNet is one of the effective DL models that can mitigate vanishing gradient problems during training phase. As mentioned earlier, the vanishing gradient problem occurs when a deep neural network struggles to propagate gradients across layers, resulting in extremely slow or even stagnant learning. This issue makes the training of a DL model extremely stressful and challenging.

In our work, ResNet is used for tackling this problem by employing skip or shortcut connections, also referred as residual connections. Such connections enable the training process to effectively skip some layers by allowing details from previous layers to be fed instantly to later ones. This aids in navigating gradients successfully and guards against the loss of crucial training data. Our ResNet design basically comprises of eight important layers (input, reshape, conv2D, batch normalization, Activation, residual block, global average pooling and dense layers) which are designed in such a way that it effectively analyses data and aids in improving accuracy rate of detection model, as shown in Fig. 1.

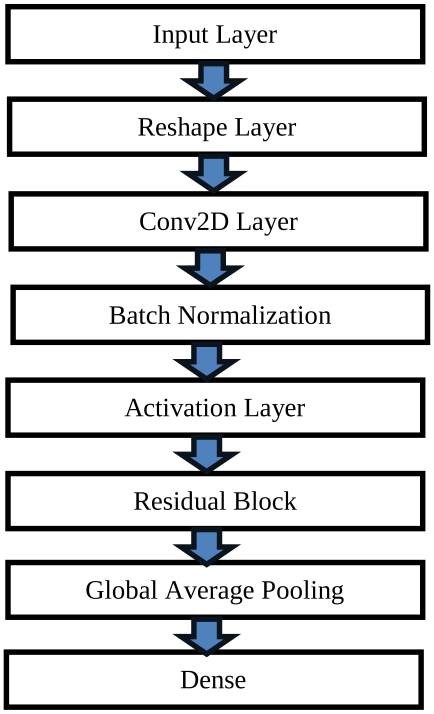

Fig. 1. Architecture of ResNet model.

It must be noted here that residual blocks are added in the proposed ResNet architecture for creating a deeper network without suffering from vanishing gradient problems. The input data is passed through two residual blocks, each consisting of two Conv2D layers with a shortcut connection. The output is then globally average pooled to reduce spatial dimensions, and finally, a Dense layer with a SoftMax activation is used for classification into two classes. Also, the total parameters used in the proposed model were 9794, out of which 9634 are trainable parameters and remaining 160 are non-trainable parameters.

By following this architecture, we were able to develop a lightweight ResNet classification model with least number of parameters that are able to learn complex representations from the data. Moreover, the addition of residual blocks in the proposed model enables training of deeper networks efficiently. This specific ResNet model is designed to handle 1D input data. The details of proposed model classification model are shown in Table IV.

The brief description of each layer used in proposed lightweight ResNet model is explained below:

*1) Input layer:* The first layer of our model receives 1D input data that contains only 10 features, attained by applying DLRPET FS technique. This layer assumes that shape of input data is 100 x10.

*2) Reshape layer:* This layer is added in the proposed model for changing the shape of input data while keeping the number of elements constant. In the proposed network, the input data is reshaped to have the dimensions of 100, 10, 1.

*3) Conv2D layer:* The reshaped data is then received by the first Conv2D layer in which 16 filters of size 3x3 are present. This layer extracts the meaning and complex patterns from the reshaped input data.

*4) Batch normalization layer:* Moreover, Batch normalization is performed after each convolutional operation for normalizing the activations of intermediate layers within each mini-batch of training data. It helps mitigate issues related to internal covariate shift and enables more effective training of deep networks.

*5) Activation layer:* Furthermore, to add the concept of non-linearity ReLU activation function is also applied in the proposed architecture, which allows the model to learn and represent complex relationships in data.

*6) Residual blocks:* In our approach, two residual blocks have been added by using the ResNet_block function. Both residual blocks comprise of two conv2D layers along with a shortcut connection. The functionality of each residual block is explained below:

*a) The* data received by the previous layer is accepted through convolutional layer that comprises of num_filters filters and kernel_size. After this, batch normalization is performed on output of first convolutional layer for normalizing activations. Moreover, RelU activation function is used for adding non-linearity to this layer.

TABLE IV. LAYER WISE DETAILS OF PROPOSED MODEL

| Layer Type | Output Shape | Number of Parameters | Description |
|---|---|---|---|
| Input | (None, 100, 10) | 0 | Input layer that accepts 2D data of size 100x10. |
| Reshape | (None, 100, 10, 1) | 0 | Reshapes the input to 4D format for convolutional layers. |
| Conv2D | (None, 100, 10, 16) | 160 | Initial convolutional layer with 16 filters of size 3x3. |
| Batch Normalization | (None, 100, 10, 16) | 64 | Batch normalization to normalize activations. |
| Activation (ReLU) | (None, 100, 10, 16) | 0 | ReLU activation function to introduce non-linearity. |
| Residual Block | (None, 100, 10, 16) | Varies | Two Conv2D layers with shortcut Connection and ReLU. |
| Global Avg Pooling | (None, 16) | 0 | Global Average Pooling reduces spatial dimensions to 1x1. |
| Dense | (None, 2) | 34 | Output layer with 2 units and SoftMax activation. |

*b) In* the next phase, another convolutional layer is implemented with same num filters and kernel size on output of previous layer, which is followed up by batch normalization technique.

*c) After* this, we have introduced the concept of shortcut connections in the network which performs a convolutional operation with 1x1 filters) on the input if strides > 1. The output of shortcut connection is then subjected to batch normalization.

*d) In* the next layer, the output generated by two convolutional layers and shortcut connection is added element-wise. Finally, RelU activation function is applied to the sim for adding the non-linearity concept to it.

*7) Global average pooling layer:* After the stack of residual blocks, the model applies global average pooling to reduce the spatial dimensions to (batch size, numbed of filters). This step averages the values along the spatial dimensions, retaining only the number of filters. It offers several benefits, including dimensionality reduction, regularization, and improved interpretability.

*8) Output layer:* Finally, the data is received by the output layer which comprises of two units specifically for binary classification problem. It also uses SoftMax activation function which aims to classify the input data into one of two classes in this layer.

Our proposed Lightweight ResNet architecture is also compatible for small and medium sized datasets. Moreover, it can also be used in tasks wherein the deeper networks may not be a suitable option due to resource constraints. Once the model architecture is defined, it is initialized three times to create three agents (Model_1, Model_2 and Model_3) in the proposed work. The configurational parameter of the three agents remains same as depicted in Table V. The main reason for creating agents in the proposed work is to enhance the classification accuracy rate of our model by training it on different subset of training data. As depicted by the table, the featured dataset is divided into training and testing sets of 80:20. Furthermore, we have used sparse categorical cross entropy loss function in the proposed work for training the model.This loss function aids in optimizing the parametric values of our network whose value must be decrease with the increase in epoch size.

TABLE V. RESNET CONFIGURATIONAL PARAMETERS

| Training Parameters | Values |
|---|---|
| Training data | 80% |
| Testing data | 20% |
| Optimizer | Adam |
| Loss | Sparse categorical cross entropy |
| Metrics | accuracy |
| No of Class | 2 |
| Epoch | 8 |
| Batch size | 32 |

Additionally, we have also utilized Adam optimizer in the proposed work with a learning rate of 0.001 for training the network. However, unlike the traditional model wherein entire training dataset was utilized for training a classifier, we divided the training data into three subsets. Each data subset is then passed to the three agents which passes the data through number of layers described above and produces their respective predictions. The final prediction for determining the individual as COVID-19 positive or negative is achieved by implementing majority voting mechanism. During this phase, the class predicted by the majority of agents is chosen as the final prediction. The idea behind voting mechanism is that by aggregating the predictions of diverse models, the overall predictive performance can be improved, often resulting in more accurate and robust predictions.

## III. SIMULATING SETUP AND RESULTS EVALUATION MATRICES

The efficacy of proposed COVID-19 detection approach is examined and also put in comparison with few traditional models in Google Colab Platform, wherein these codes can be executed easily in a Jupyter Notebook environment too. The system on which this software was used possess i5 processor with 8GB RAM and 500 GB HDD. The experimental outcomes were attained in terms of Accuracy, precision, recall and F1-Score, as shown in Eq. (5) to Eq. (8). Moreover, we have also analyzed the performance of proposed approach in context of True Positive Rate (TPR), confusion matrix and accuracy attained by proposed approach during training and validation scenarios.

$$Accuracy = \frac{(TP+TN}{(TP+TN+FP+FN)} \times 100\% \tag{5}$$

$$Precision = \frac{TP}{(TP+FP)} \times 100\% \tag{6}$$

$$Recall = \frac{TP}{(TP+FN)} \times 100\% \tag{7}$$

$$F1 - score = 2 \times \frac{Precision * Recall}{(Precision + Recall)} \tag{8}$$

As we have discussed in earlier sections that proposed DL classification model is initialized three times for validating its performance on three data subsets or agents created from training dataset. The hyper parameters given in Table I and IV are selected in an unbiased way, in order to select the parameters a maximum of 10 runs of simulation are conducted while changing the parameters with in defined range of parameters that includes epochs from 5 to 100, batch size from 8 to 128, and different optimizers including Adam, Gradient Descent, etc. After systematic review the final values of hyper parameters are selected a given Table I and IV. So firstly, we will be analyzing the accuracy of three DL models during their training and validation process. Fig. 2 shows the graph attained for accuracy for Model 1 in which epochs are represented on x-axis and accuracy is depicted on y-axis respectively. The first subset or data agent is passed to model 1 and its accuracy is observed during training and testing phases. The graph reveals that accuracy increases with the increase in epoch size in both cases of training and validation. Initially, the model is not be able to capture complex patterns present in the data, but as it sees more examples it starts adjusting its parameters and becomes better at fitting the training data.

Similarly, we have also observed the accuracy curve obtained for proposed DL and multi-agent-based classification model during its training and testing phases, as shown in Fig. 3. In second model, the second subset or data agent is passed to it to check its effectiveness in context of accuracy. It has been observed that training curve for Model 2 is very low initially because it has not explored lot of data samples, however, as the epoch size increases the accuracy of training curve also increases; depicting that model is getting trained effectively on this data. Similar, is the case with validation curve of model 2 but the only difference is that it shows better accuracy results even during initial phases. This is because the model is already trained on training subset and hence is giving good results on unseen data as well. Additionally, Fig. 4 showcases the accuracy rate obtained by Model 3 on third data agent during its training and validation phase. The given graph simulates that accuracy rate increases with increase in epochs for training and validation phases. This indicates that our third model is able to capture complex and intricate patterns of COVID-19 patients effectively as it is exposed to more epochs, which ultimately enhances its accuracy as well.

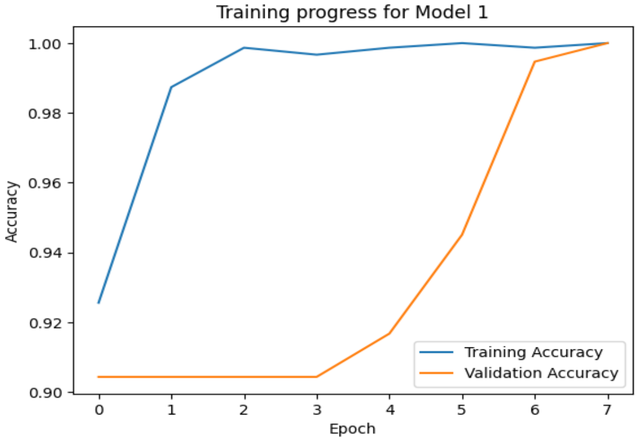

Fig. 2. Accuracy attained for model 1 during training and validation.

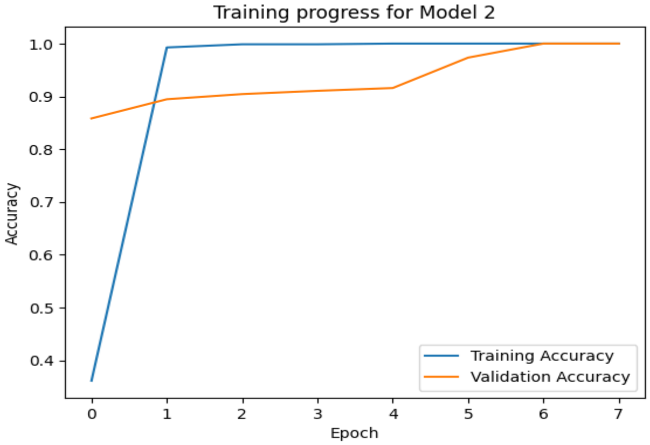

Fig. 3. Accuracy attained for Model 2 during training and validation.

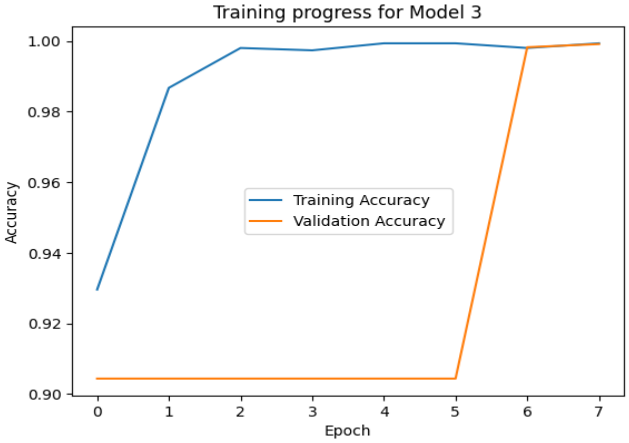

Fig. 4. Accuracy attained for Model 3 during training and validation.

These training and validation accuracy curves of the proposed model are not only giving information of how network is performing during training for each epoch, but also validate our claim of being light weight. The training curve of all the three models represents that proposed model trained faster with less number of epochs. Fig. 2, 3, and 4 shows that while training, although very a smaller number of epochs (8 Epochs) are given for training but still the proposed model is using only 25% of the given epochs that is around 2 epochs to get a stable point of accuracy curve. This shows that the proposed model need less time requirement and it early understands the data patterns to support the lightweight property of model.

To further validate the effectiveness of proposed approach, we evaluated its TPR performance with respect to False Positive Rates (FPR), as demonstrated in Fig. 5. The TPR graph, also known as the Receiver Operating Characteristic (ROC) curve, is a graphical representation that illustrates the performance of a binary classification model across different thresholds. In the beginning, the TPR is typically low, while the FPR is also low. This corresponds to a threshold where the model is very conservative in making positive predictions. However, as the threshold becomes more permissive, the model starts classifying more instances as positive. This leads to an increase in both TPR and FPR. The TPR rises because the model captures more true positive cases, as it becomes less stringent in making positive predictions. However, the FPR also increases, indicating that the model is more prone to mistakenly classifying negative instances as positive. The point where the curve is closest to the top-left corner represents the ideal balance between high TPR and low FPR.

Also, the ability of the proposed model to correctly predict the COVID-19 and non-COVID-19 patients is determined by confusion matrix (see Fig. 6). This matrix gives detailed breakdown of how many instances of each class were correctly or incorrectly classified by proposed model. From the simulation it is analyzed that total false positive came out in testing phase are 0 in count and false negative are 3 in count. Although it is an effective score but still there are few misclassifications seen, the reason behind that is expected to be the relation among the varying entities that arise a different pattern to be identified for considered class. Further by examining the confusion matrix, we can easily evaluate the performance of proposed model under other parameters. In nutshell, we can say that the confusion matrix gives a clear picture of how well a model performs on different classes.

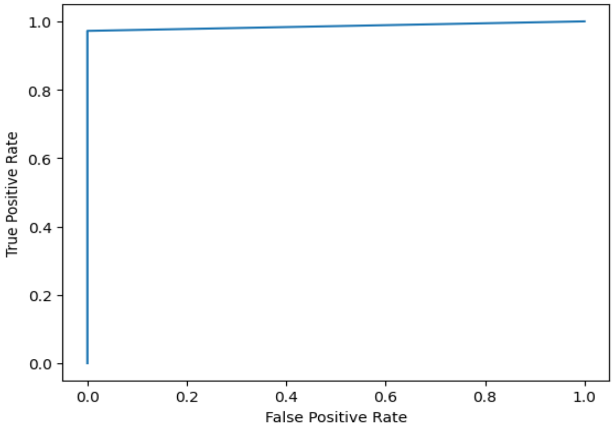

Fig. 5. TPR obtained in proposed approach.

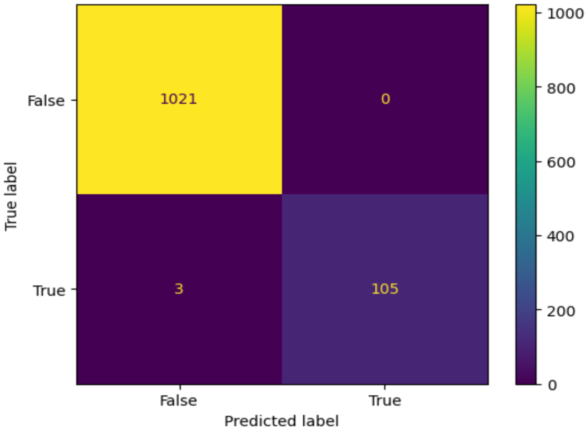

Fig. 6. Confusion matrix obtained in proposed model.

Furthermore, to prove the supremacy of our approach, we compared its performance with standard RF, Bernoulli and SVM models in context of their accuracy rate for classifying COVID and non-COVID patients. The comparative graph for accuracy is depicted in Fig. 7, wherein different techniques and their accuracy rate is represented on x and y-axis respectively. The simulated graph reveals that there is an increment of around 5.57%, 7.23% and 4.73% in accuracy of proposed approach when compared with standard RF, Bernoulli and SVM models respectively [40]. This increased accuracy rate in proposed model is attained because our DL classification model can learn intricate patterns for three different data agents without enhancing its complexity. Likewise, we have also evaluated the performance of proposed approach with standard COVID-19 detection models in terms of their precision rate. The comparative graph obtained for the same is shown in Fig. 8. After carefully examining the given graph, it is observed that standard Bernoulli model is exhibiting lowest precision value of 86% whereas, it was improved by RF and SVM models that achieved 95% precision rate. On the contrary, our approach is showcasing a precision of 100%, which specifies that all positive predictions made by a binary classification model are correct. This is an ideal scenario because it indicates that the model is not producing any false alarms for negative instances, which can be particularly important in COVID-19 detection. Furthermore, these results reveal by employing the proposed DL classification model precision rate is improved by around 5% then best performing standard models i.e., RF and SVM respectively. Moreover, the performance of proposed approach is also examined and validated by comparing it with conventional models in terms of their recall percentage. Fig. 9 showcases the comparison graph obtained for recall. The given graph simulates that again recall value was lowest in Bernoulli model with only 93%, followed up by RF and SVM model with 94% and 95% respectively. This lowest recall rate in standard model depict that they are not able to comprehend data effectively which degrades their performance. However, in our proposed approach, the recall rate is exceptionally high at 99.73% which marks an increment of 4.73% then SVM model. This high recall rate in proposed model determines that our approach is successfully able to capture majority of the instances that belong to positive cases.

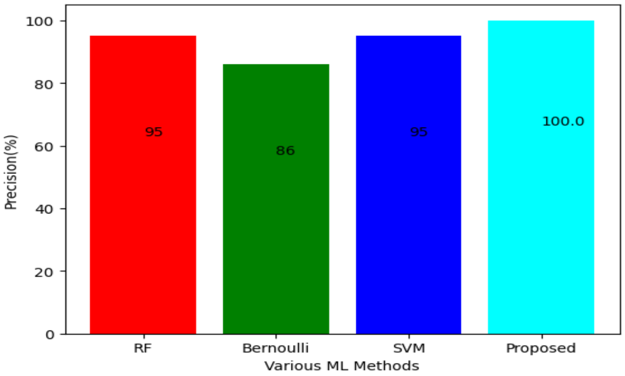

Fig. 8. Comparative graph for precision.

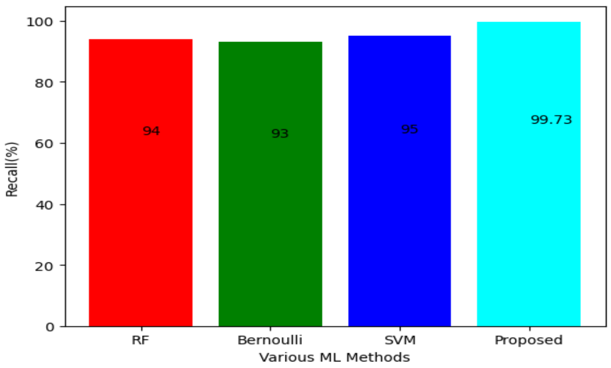

Fig. 9. Comparative graph for Recall.

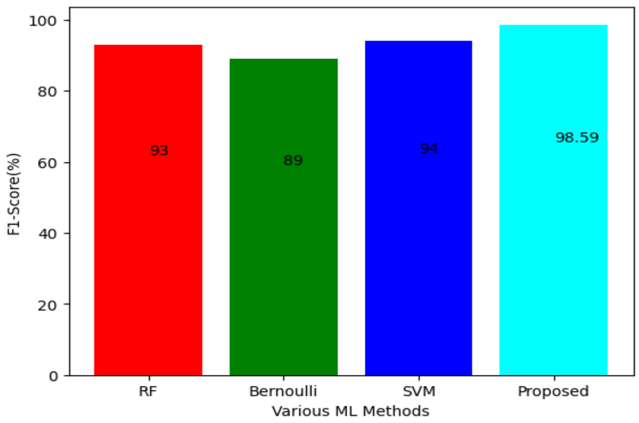

Fig. 10. Comparative graph for F1-Score.

Finally, the effectiveness of proposed approach is also validated by putting it in comparison with standard models in terms of F1-Score, as shown in Fig. 10. The x and y axis of the given graph calibrates to different detection techniques and their F1-Score respectively. Upon examining the graph carefully, we observed that Bernoulli is the worst performing model with 89% while as, RF and SVM achieves F1-Score of 93% and 94% respectively. While as, when we analyzed the F1-Score in proposed model, we observed an upward trend of 98.59%, showcasing the supremacy of proposed approach over other similar approaches. The exact value of each parameter is mentioned in table also and is shown in Table VI.

In addition to this, the proposed scheme is compared with other state of art techniques used for identifying the COVID-19 from the statistical data. Below Table VII gives the details if the outcomes analyzed with other methods and our proposed scheme.

TABLE VI. COMPARATIVE ANALYSIS OF DIFFERENT PARAMETERS

| Algorithm | Accuracy | Precision | Recall | F1-Score |
|---|---|---|---|---|
| **RF** | 94.16 | 95 | 94 | 93 |
| **Bernoulli** | 92.5 | 86 | 93 | 89 |
| **SVM** | 95 | 95 | 95 | 94 |
| **Proposed** | 99.73 | 100 | 99.73 | 98.59 |

TABLE VII. COMPARATIVE ANALYSIS WITH OTHER STATE OF ART METHODS

| Algorithm | Accuracy | Precision | Recall | F1-Score |
|---|---|---|---|---|
| **ANN [19]** | 86.90 | 87.13 | 87.13 | 87.13 |
| **CNNRNN[20]** | 86.24 | 87.55 | 87.55 | 87.55 |
| **CNNLSTM [21]** | 92.30 | 92.35 | 93.68 | 93 |
| **KISM [22]** | 97.87 | 81.82 | 100 | 90 |
| **Su X et al.[23]** | 92.82 | 93.41 | 93.41 | 93.41 |
| **Proposed** | 99.73 | 100 | 99.73 | 98.59 |

In this phase a comparison with different methods used to classify the COVID-19 with similar dataset and type of dataset is conducted. The analysis shows that ANN [19] achieved accuracy was 86.90%. Additionally, few recently developed models including KISM [22] and Su X et al. [21] are achieving an accuracy of 97.87 % and 92.82 %, even deep learning-based models CNNRNN, and CNNLSTM given in [20][21] are achieving 86.24 % and 92.30 % of accuracy respectively. However, in proposed scheme, a score of 99.73%accuracy is achieved which is around 2% more than standard highest scorer KISM [22]. Similarly, proposed method outperformed models given in [21], [22] and [23] by attaining highest value of precision, and F1-Score that are 100% and 98.59% respectively. The details values for individual algorithm are given in Table VI.

## IV. RESULTS ANALYSIS AND CONCLUSION

The results attained by proposed model showcases that by implementing multi-agent-based DL model for identifying and classifying individuals into COVID positive or negative, the accuracy of detection rate increases. When compared to previous models, we observed that proposed models' accuracy rate is 99.73% which is 5.57%, 7.23% and 4.73% more than standard RF, Bernoulli and SVM models. Moreover, proposed model shows an accuracy improvement of 12.83% than ANN [41], 1.86% than KISM [42] and 6.91% than Su X et al. [43] approaches respectively. Similarly, our approach was able to improve the precision, recall and F1-Score rates also due to its ability to capture complex and intricate patterns of COVID-19 effectively. The results proved that proposed model attained a precision rate of 100% which signifies that it is able to predict every instance correctly. Moreover, this precision score indicates that there is an improvement of 14% then Bernoulli model, 5% then RF and SVM and 12.87%, 18.18% and 6.59% than ANN [41], KISM [42] and Su X et al. [43] models respectively. Similar trend is observed for recall and F1-Score parameters which showed an overall increment of 4.73% and 4.59% over best performing standard model (SVM).Through machine learning in COVID-19 detection, diagnosis, and treatment, we can improve multi-agent systems for better healthcare [44, 45].These analytical records prove that proposed system is more robust and accurate in determining and classifying the individuals as COVID-19 infected and normal. In this manuscript, an effective COVID-19 detection model is presented that is based on DL and Multi-agent techniques. The primary goal of the proposed work is to increase the detection accuracy rate while minimizing the complexity and dimensionality issues. To prove the efficacy and supremacy of our approach, we compared its performance with standard detection methods in Google Colab Platform. The simulated results reveal that our method attained accuracy rate of 99.73%, surpassing traditional RF, Bernoulli, SVM, ANN, KISM, CNNLSTM, CNNRNN and Su X et al. models which attained only 94%, 92%, 95% , 86.9%, 97%, 92%, 86% and 92.8% accuracies. Moreover, the proposed model also attained a high precision of 100% which means it is correctly predicting classes, while as, it was only 95% in RF and SVM, 86% in Bernoulli, 87% in ANN and CNNRNN, 81% in KISM, 92 % and 93% in CNNLSTM and Su X et al., methods. Furthermore, we have observed an increment of 5.73%, 6.73%, 4.73%, 12.6%, 12.18%, 6.05% and 6.32% for recall values when compared with RF, Bernoulli, SVM, ANN, CNNRNN, CNNLSTM and Su X et al. methods.

In addition to this, our approach is outperforming traditional model in terms of F1-Score also by attaining a score of 98.59%. These results simulate that our proposed model is more efficiently and effectively able to detect COVID-19 patients. Despite the fact that proposed approach is giving best results than other similar models, it is important to identify its inherent limitation caused by data scarcity. As proposed model is trained on laboratory finding based dataset, lacking data variability for input information, the generalization of proposed model is still necessary to explore to its fullest. Therefore, future research can focus on working with joining different datasets to achieve larger and generalized informative datasets for effective training and testing of the model.
