Pollution of the atmosphere has grown into a dangerous issue in many nations throughout the world in recent decades as a result of human activity, manufacturing, and urbanization. PM2.5, a kind of air pollution with a circumference of fewer than 2.5μm, poses a significant health risk. PM2.5 levels vary according to a number of variables, such as meteorological and the quantity of other contaminants in metropolitan areas. In the present study, constructed a deep learning system that predicted the hourly prediction of PM2.5 concentrations in Beijing, China, using CNN-LSTM with a spatial-temporal

features by merging historical pollution information, meteorological data, and PM2.5 concentration in neighboring sites. Researchers investigated the differences in performance amongst deep learning models .Results from experiments show that the "hybrid CNN-LSTM multivariate" technique allows for greater precision predictions and outperforms all of the classic models described. Yet, the approach was initially deployed in the metropolitan area of Beijing, China, according to the lack of daily freely available data [23].

As air pollution worsens, the condition of the air prediction has emerged as a critical tool for managing and preventing it. Over the past few years, several approaches for predicting the air's cleanliness have been presented, including determinate, statistical in nature, and neural network approaches. Still, these approaches have drawbacks. The deterministic approach approaches need costly calculations and particular expertise for parameters recognition, but statistics techniques' forecast ability is limited owing to the linear assumptions and the issue of multicollinearity. In contrast, many deep learning approaches are unable to detect periodic trends or acquire information about the long-term associations of air pollutant concentration. Furthermore, there are few systems that can produce accurate predictions for environmental forecasts at higher time resolutions, including every day, every week, and occasionally each month .The approach is to use the bi-directional LSTM model to learn from PM2.5's dependence over time, as well as learn via transfer to transfer information obtained at lower time resolution to higher periodic resolutions. The previously suggested methodological paradigm is tested with a case study in Guangdong, China. The framework's efficiency is contrasted with other regularly used machine learning techniques, and the findings reveal that the suggested TL-BLSTM model has less mistakes, particularly at higher temporally resolutions. But it is utilized when the number of samples is restricted or whenever the modeling procedure is too complicated and technologically costly [24].

The provided paper examines the use of Internet of Things (IoT) and machine learning for air pollution monitoring and prediction. It shows real-time tracking with a focus on security, IoT packages in smart cities and the significance of accurate sensors. Various studies recommend deep gaining knowledge of algorithms, inclusive of LSTM networks, for predicting air quality Challenges include potential sensor inaccuracies and simplified mode. Additionally, a cloud-centric IoT middleware architecture and artificial neural networks are explored for efficient pollution surveillance. These approaches aim to monitor and predict air quality levels in urban environments, facilitating proactive environmental protection measures. However, several limitations are evident across these studies. Firstly, the accuracy and reliability of IoT-based air quality tracking systems heavily rely on the precision of sensors used, which may lead to inaccuracies in pollutant estimations. Additionally, deep learning models may suffer from low generalization, as their efficacy can be highly influenced by specific features of analyzed smart city data, potentially limiting their applicability across different contexts. Furthermore, some studies may oversimplify the complex relationships in atmospheric dynamics, leading to less precise forecasts. Lastly, certain approaches, such as those relying on transfer learning, may face challenges when dealing with limited sample sizes or complex modeling procedures, highlighting the need for further research to address these limitations and enhance the effectiveness of air quality prediction systems.

III. Problem Statement

The growing global problem of air pollution, exacerbated by urbanization, industry, and population expansion, need efficient monitoring and forecasting [24]. The adaptability of deep learning techniques, such as CNN, hybrid models, and LSTM networks, while tackling issues such as sensor errors, privacy issues, and the requirement for complex models in the monitoring and prediction of air pollution. Systems investigate ways to alleviate issues with air pollution by using machine learning and the Internet of Things (IoT). Emphasizing trustworthy and precise sensors is still necessary in research. Additionally, it highlights how urgently the need a comprehensive and reliable forecasting solution to get around the obstacles in the IoT Approach with Real-Time Alerts and AWS Integration for Air Quality Monitoring.

IV. IoT Approach with Real-Time Alerts and AWS Integration for Air Quality Monitoring

The proposed method utilizes the ESP-WROOM-32, a low-cost IoT device equipped with sensors, for real-time environmental tracking. Initial data collection is followed by a pre-processing phase, where the Nearest Neighbour Interpolation Approach is employed for data interpolation and labelling. Subsequently, the ESP-WROOM-32 processes the pre-processed data, ensuring efficient utilization of resources. The system's performance is thoroughly evaluated to validate its effectiveness. Finally, the results are hosted on an Amazon Web Server (AWS), establishing an end-to-end workflow for cost-effective environmental monitoring. The ESP-WROOM-32's low-power capabilities make it well-suited for continuous operation across diverse environmental conditions, enhancing its practicality and reliability for long-term monitoring applications. This integrated approach offers a scalable and affordable solution for real-time environmental tracking, enabling stakeholders to make informed decisions and take proactive measures to address environmental concerns. Fig. 1 shows proposed diagram.

A. Data Collection

The dataset encompasses a comprehensive collection of 9357 hourly readings derived from a network of 5 metallic oxide chemical detectors deployed within an Air Quality Chemical Multisensor Device. This device was strategically placed in an openly accessible, heavily polluted area at street level in an Italian city, providing a real-world perspective on airborne chemical concentrations. The data spans a duration of one year, from March 2004 to February 2005, offering a seasonal and temporal understanding of air quality dynamics. However, the dataset acknowledges several challenges that could impact the accuracy of concentration estimates. These challenges include cross-sensitivities among sensors, concept shifts, and sensor changes, as discussed in De Vito et al., Sens. And Act. B. These factors highlight the need for careful data

interpretation and analysis to account for potential biases introduced by such challenges. It's noteworthy that any missing values in the dataset are denoted by a value of -200. Addressing these challenges and understanding the intricacies of the dataset is crucial for obtaining reliable insights into air quality dynamics and for developing accurate models for pollution prediction and control [25].

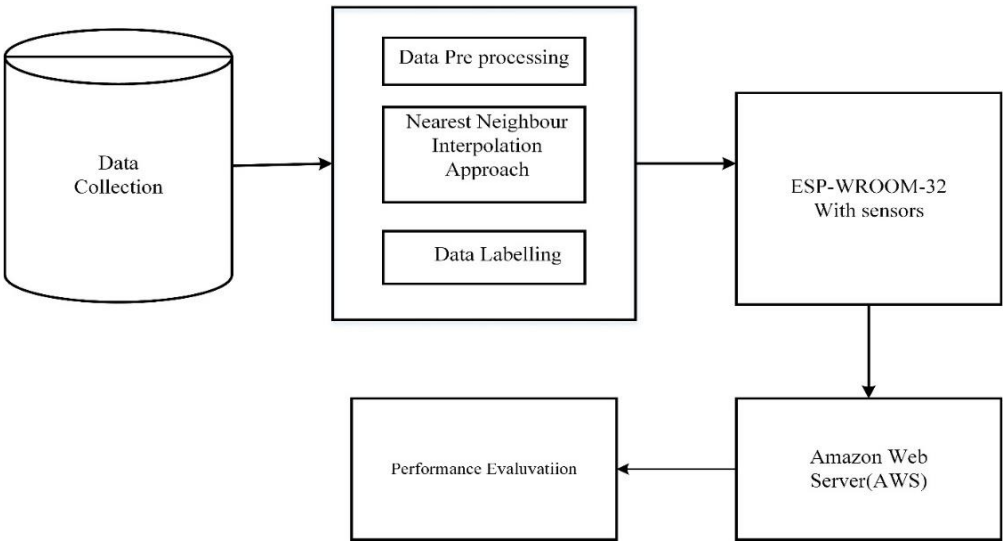

Fig. 1. Proposed diagram.

B. Data Pre-Processing

1) Nearest-neighbor interpolation approach: The unprocessed information from the sensor is captured without any sort of processing. The method of filtering is carried out in the public cloud instead of on the embedded device in order to decrease complication in the system that is embedded. The exceptions and incomplete data are among the maximum characteristic data mistakes in real-time tracing requests a total of three kinds of usual dataset preparatory computation: transforming not-a-number (NAN) data to zero, eliminating NAN data. In the current study, information interpolation is performed using a nearest-neighbour strategy. This strategy is applicable to collections with values that are lacking or outlier situations. Whenever an outlier appears at location z'_i the nearest knowing neighbour's values is utilized as the replacement for the outlier. It will be determined utilizing all of Sensor 2021, 21, 4956 10 of 16 previous data available. The choice of using prior data rather than upcoming information comes since information is collected in immediate time in the form of a series of values is shown in Eq. (1)

$$z'_i = \begin{cases} \frac{z'_{i-1} + z'_{i-2}}{2}, & \boldsymbol{if\ i = 2;} \\ \frac{z'_{i-1} + z'_{i-2} + z'_{i-3}}{3}, & \boldsymbol{if\ i = 3;} \\ \frac{z'_{i-1} + z'_{i-2} + z'_{i-3} + z'_{i-4}}{4}, & \boldsymbol{if\ i = 4;} \\ \frac{z'_{i-1} + z'_{i-2} + z'_{i-3} + z'_{i-4}, z'_{i-5}, otherwise}{5} \end{cases} \quad (1)$$

2) Data labelling: Data Labelling When inputting details about sensors in the estimate process, an ensemble of records must be characterised as the result in machine learning with supervision. In fact, the air quality index (AQI) is an estimate employed for categorizing the practice of the air in a convinced place. Usually, the AQI is split into numerous limits, each of which has a unique colour and description. It appoints a health care advisor to every range. The threshold level of air quality (see Fig. 2) for a variety of pollutants. The current versions of guidelines and recommendations vary depending on the global organizations. The contaminants the index is computed using the following parameters: CO_2, $PM_{2.5.}$and $PM_{10.}$ The greatest index reflects the AQI at the moment [26].

C. Iot-based Air Quality Monitoring

1) ESP-WROOM-32 with sensors, to enable real-time environmental tracking: The approach suggested in this paper, being a part of a bigger project in progress, comprises the software as well as the hardware layers for actual time environmental tracking via a low-cost IoT device. In the physical coating, a digital circuit design is under construction to create a surface with devices that detect the concentrations of $PM_{2.5,}PM_{10,}O_{3,}$CO,NO_2 and ammonium (NH_3). Moisture and temperature monitoring were added to the pollution tracking functions to aid in the analysis. The gadget and its application are going to interact over a Bluetooth or WiFi connection. The main elements that are going to be supplied on the gadget's boards which will conduct measurements are as follows. The microcontroller called ESPWROOM-32 (or simply, ESP32), was selected to gather data from the following set of sensors: DHT22, measuring ambient temperature and air humidity; PMSA0003, that successfully evaluates and specifies the levels of PM2.5 and PM10 particles substance; MQ-131, that determines the amount of O3; and MICS-6814, and this measures the levels of CO, NO_2, and NH_3 and is capable of tracking five additional pollutants. A quick overview of the listed elements is provided here.

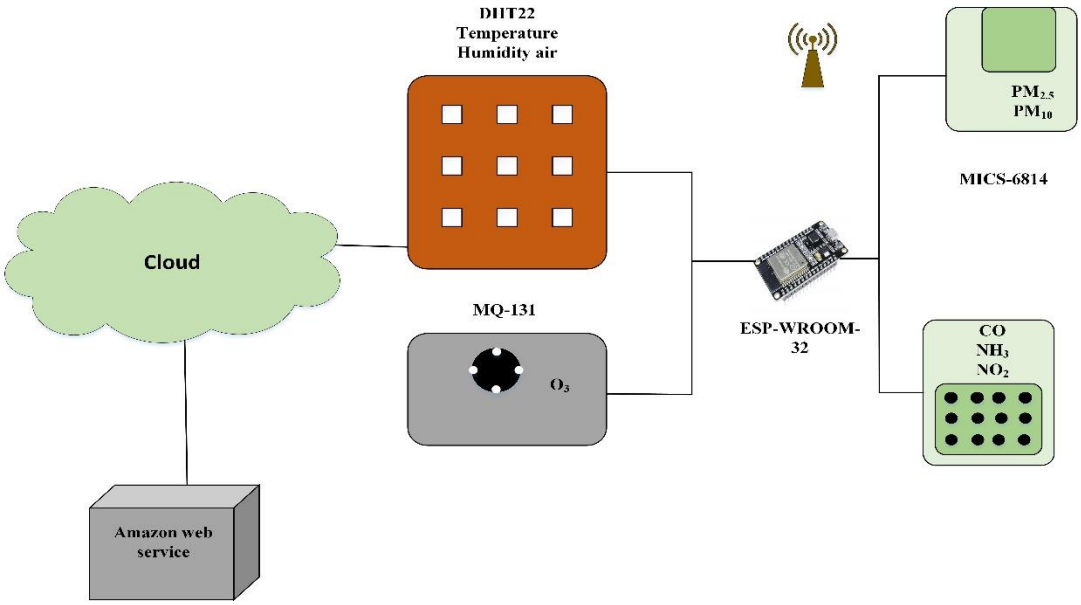

Fig. 2. IoT approach with real-time alerts and AWS integration for air quality monitoring.

To avoid potential lack of availability, the watchdog feature is added, which identifies collapses and restarts the microcontroller using three independently timers from the primary system. Sensing measurements region. The PMSA003 is a small digital sensor used for detecting particles dispersed in the air. Particulate matter, often known as dirt, are nanoparticles of varied sizes, & a sensor uses a microprocessor to execute a light scattering-based detection approach to determine the proportions of the atoms and density. The MICS-6814 is a small device that can correctly detect CO, NO2, and NH3 concentrations at the exact same time, using distinct networks for all gas. The device's efficiency is quite promising, and it must be highlighted that it can also detect five additional gases: methane (CH4), propane (C3H8), ethanol (C2H5OH), hydrogen (H2), and isobutane (C4H10). The MQ-131 sensors measure O3 contents with high sensitivity and have a trimpot for calibration in addition to a standard analog output. The DHT22 digital sensors is being chosen for both humidity and temperature surveillance because it offers exact results and is easy to set up [27].

a) Amazon Web Server (AWS): To further streamline data management and accessibility, this work integrates the Amazon Web Server (AWS) into the system, leveraging its robust cloud infrastructure. This amalgamation not only ensures efficient data storage but also facilitates real-time monitoring and analysis, contributing to a comprehensive and proactive approach in combating air pollution and safeguarding public health. Amazon Network Services, a division of Amazon, have offering frameworks for computing services upon request since March 2006. It operates on the "pay as you go" approach. The expenses are decided utilization of amenities AWS's extensive variety of cloud offerings allows for the implementation of a broad spectrum of solutions. In the suggested solution, a server's IoT primary service is utilized for uploading sensors information into the cloud. The procedure of utilizing AWS IoT core services begins with the creation of an AWS account as well as a thing in IoT core that includes the creation of certifications and rules. Information submitted may be viewed by subscribe to the appropriate MQTT protocol account's Testing area of the IoT core. The degree of sophistication is defined by the amount of gadgets that collect data and send it to the Network of Thing via a wireless connection.

V. Results and Discussion

Air quality control system equipped with low-cost gadgets to monitor key pollutants crucial to human health, such as Particulate Matter (PM 2’.5’ and PM1’0’), Ozone, Carbon Monoxide, Nitrogen Dioxide, and Ammonia. Utilizing PMSA003, MICS-6814, and MQ-131 sensors powered by the ESP-WROOM-32 microcontroller, the system ensures seamless data transmission to an Amazon Web Server (AWS). In case of pollutant concentrations exceeding permissible levels, the device triggers indicators for instant response and intervention. The integration of AWS not only facilitates robust data storage but also enables real-time monitoring and analysis, contributing to a comprehensive and proactive approach in addressing air pollution and safeguarding public health.

A. Evaluation Metrics

In the experiments employing the subsequent indicators to assess the efficiency of the model for predicting and highlight any possible connection between expected and actual outcomes.

1) Root Mean Square Error (RMSE): Root mean square error computes the square roots of the median value for the squares of the difference among expected or actual information. It is computed as Eq. (2)

$$\mathrm{RMSE}_{\mathrm{avg}} = \sum \frac{|\mathrm{Actual\_i} - \mathrm{Predicted\_i}|^2}{n} \quad (2)$$

2) Mean Absolute Error (MAE): An indicator of discrepancies among paired observations describing the same phenomena. Examples of contrasting Y against X include expected versus actual results, following time versus initial time, and a single calculating method against another. The MAE is determined as the total of absolute mistakes dividing by the sample's size is given in Eq. (3).

$$MAE = \frac{1}{n}\sum_{i=1}^{n}\left|y^i - y_*^i\right| \quad (3)$$

TABLE I. RMSE VALUE COMPARISON

Model	RMSE value
Linear model	17.762865657654
SVR model	6.45565647866557
SARIMAX model	8.8765445567677
Proposed Real-Time Alerts with AWS	3.7656787872687

Table I provided lists four different models and their corresponding values. The RMSE statistic measures the mean variance among the values that the model predicted and what is actually present in the actual data set 1. An algorithm's ability to "fit" an information set improves as its RMSE decreases. The Real-Time Alerts with AWS Connectivity models gets the smallest RMSE value of 3.7656787872687. This suggests because it is the most effective estimate amongst the four options that have specified for the purpose of matching the data set 1.

TABLE II. REGULAR AIR QUALITY IN PPM FOR DIFFERENT LOCATIONS

Location	Average Air Quality (ppm)
Location 1	765.77
Location 2	543.87
Location 3	431.76

Table II lists three different locations and their corresponding Average Air Quality (ppm) values. The Average Air Quality (ppm) as shown in Fig. 3 value is a metric that trials the concentration of airborne pollutants in the atmosphere. Among the three locations, Location 1 has the highest average air quality value of 765.77 ppm, followed by Location 2 with an average air quality value of 543.87 ppm and Location 3 with an average air quality value of 431.76 ppm 1.

Fig. 3 depicts the average air quality of different locations. The Average Air Quality figure illustrates air quality levels across three distinct locations measured in parts per million (ppm). Location 1 exhibits the highest air quality, with a ppm slightly above 700. In contrast, Location 2 records a slightly lower ppm, just above 500. Location 3 demonstrates the lowest air quality among the three, with a ppm slightly below 500. This comparison provides valuable insights into the variation in air quality levels across different geographical areas, aiding in environmental monitoring and decision-making processes.

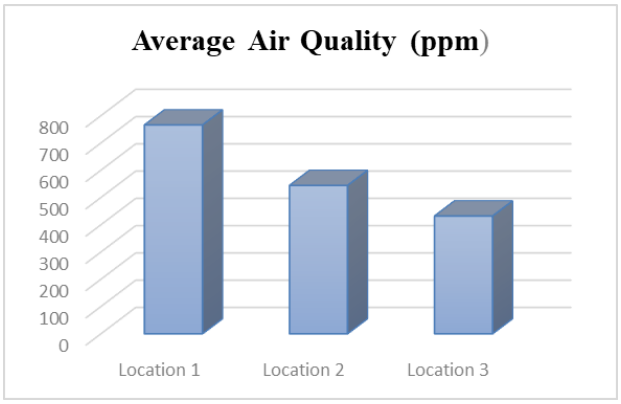

Fig. 3. Average air quality of different locations.

TABLE III. RANGE OF MEASUREMENT CONCENTRATION OF THE SENSOR BY POLLUTANT CERTAINLY

Sensor	Pollutant	Range
PMSA003	PM2.5	10 -1000 ppb 0 –
	PM10	50 – 10000 ppb
MQ-131	O3	500 µg/m³
MICS-6814	CO	1 – 500 ppm
	NO2	0 – 500 µg/m³
	NH3	1 – 1000 ppm

Table III described three sensors each measuring specific air pollutants within specific concentration ranges. The PMSA003 sensor detects particulate matter (PM2.5 and PM10), while the MQ-131 sensor detects ozone (O3). The MICS-6814 sensor measures carbon monoxide (CO) and nitrogen dioxide (NO2) concentrations. These sensors are essential for monitoring air quality, aiding in environmental assessments and public health analyses. Their specifications are crucial for assessing air quality.

Fig. 4 displays the concentration levels of four different gases (CO, CO2, NO2, and SO2) over a period of six days. Each graph is labeled with the gas type and its concentration in shares per million (ppm). The x-axis signifies the days, while the y-axis shows the absorption levels of these gases. Fluctuations in the graphs indicate variations in gas concentrations over time.

Table IV compares three different methods. The Proposed Method stands out for being low-cost, having low power consumption, and high scalability. It also offers real-time tracking with high accuracy. LSTM-OPTISENSE NET, while slightly more expensive and moderate in terms of power consumption and scalability, does provide real-time tracking with medium accuracy. In contrast, Conv-AIRNET is the most expensive, has the highest power consumption, and is the least scalable. Moreover, it lacks real-time tracking but boasts high accuracy.

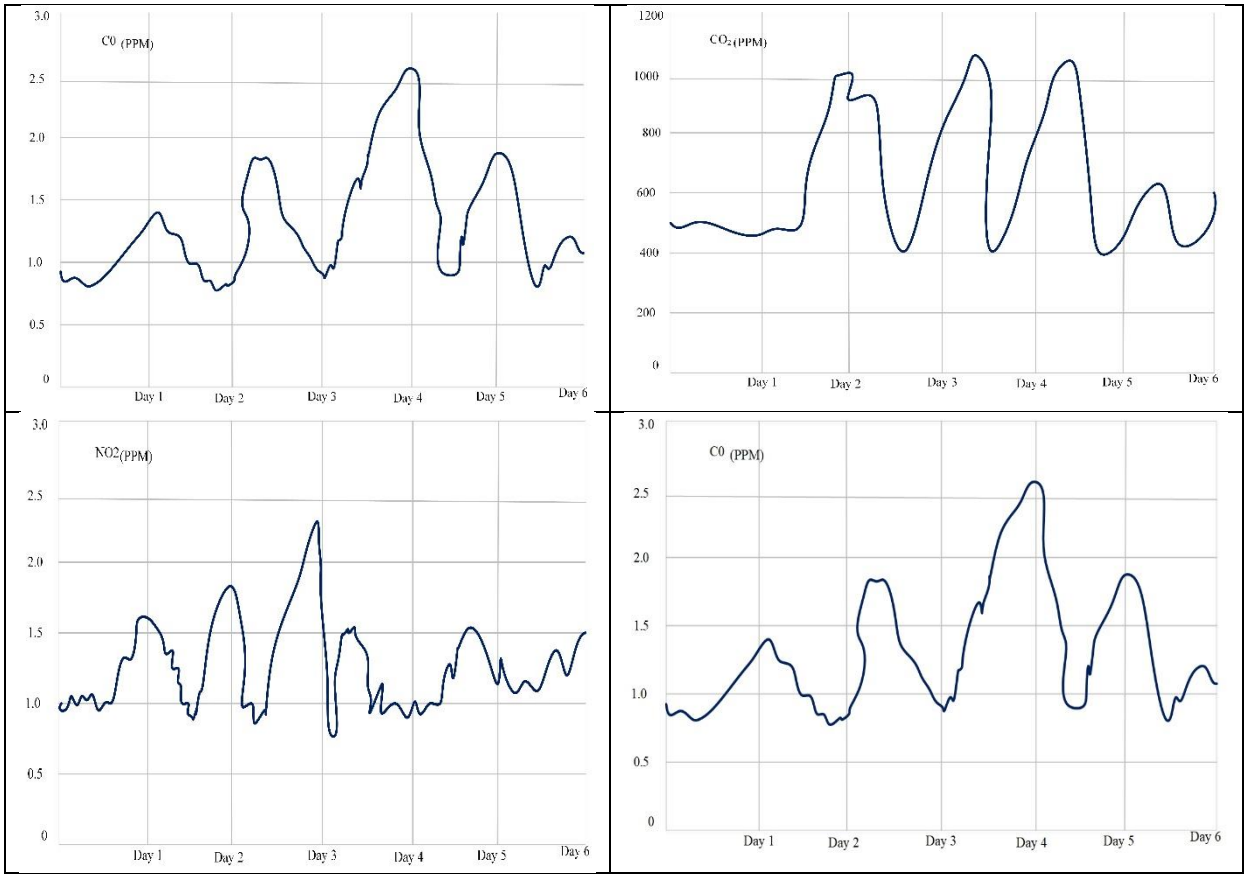

Fig. 4. The attentiveness levels of four different gases.

TABLE IV. COMPARISON OF TRACKING METHODS BASED ON VARIOUS METRICS" OR SIMPLY "TRACKING METHODS COMPARISON TABLE"

	Cost	Power Consumption	Scalability	Real-time Tracking	Accuracy
Proposed Method	Low-cost	Low	High	Yes	High
LSTM-OPTISENSE NET	Moderate-cost	Moderate	Moderate	Yes	Medium
Conv-AIRNET	High-cost	High	Low	No	High

B. Discussions

The proposed Internet of Things (IoT)-based air quality monitoring program emphasizes a proactive and technologically advanced strategy to addressing the growing worldwide challenge of air pollution. Existing methods have limited scalability, accuracy reliant on sensor precision, potential data oversimplification, and dependence on specific features [23]. By incorporating low-cost sensors capable of measuring critical pollutants outlined by the World Health Organization, the system aligns with established health standards. The selection of sensors, including PMSA003, MICS-6814, and MQ-131, ensures a comprehensive assessment of air quality, covering a spectrum of pollutants such as particulate substance, ozone, carbon monoxide, nitrogen dioxide, and ammonia. The utilization of the ESP-WROOM-32 microcontroller, equipped with Wi-Fi and Bluetooth capabilities, enhances the efficiency of data transmission to a cloud server. The system's real-time monitoring capability is a significant advancement, allowing immediate intervention in cases where pollutant concentrations exceed permissible levels. The integration of indicators triggered by such events showcases a commitment to timely response and environmental safety. Moreover, the incorporation of Amazon Web Server (AWS) into the architecture not only ensures secure and scalable data storage but also facilitates real-time tracking and analysis. This comprehensive approach not only aids in pollution prevention but also contributes valuable insights to the broader discourse on environmental management and public health [28]. The study reflects a synergy of theoretical research and practical application, showcasing a robust and cost-effective solution to combat the critical issue of air pollution.

VI. CONCLUSION AND FUTURE WORK

The suggested Internet of Things-based air quality monitoring system is a big step in the right direction toward solving the pressing worldwide issue of air pollution. The ESP-WROOM-32 microcontroller, low-cost sensors, and AWS integration are utilized by the system to provide a workable and expandable real-time monitoring solution for important pollutants. The current study's results corroborate the trend of low-cost methods offering real-time tracking, as seen with the Proposed Method. However, it challenges the assumption that high-cost methods inherently provide better accuracy and scalability, as observed with existing method

indicating the need for further exploration into cost-effective solutions without compromising accuracy and real-time tracking The quick reaction system set in motion by pollution exceedances highlights the dedication to public health and environmental safety. Regarding future efforts, the system may be expanded and improved upon continuously. First, the reliability of the gathered data will be improved by improving the precision of pollutant measurements through sensor calibration and validation procedures. Furthermore, investigating more sophisticated machine learning algorithms for data analysis may offer deeper understandings of pollution trends, facilitating the development of better preventative and predictive actions. Furthermore, the system's scalability and adaptability to various environmental conditions should be prioritized, given the possibility of global implementation. The incorporation of this technology into more comprehensive environmental management methods can be facilitated by cooperative efforts with regulatory agencies and urban planners. Furthermore, adding more sensors to track newly developing contaminants and growing the network of monitoring devices can help develop a more thorough understanding of the state of the air at the local, regional, and municipal levels. Essentially, the suggested system lays the groundwork for future research and development in the field of environmental monitoring, paving the way for more intelligent, data-driven approaches to address air pollution and improve community well-being in general.

***Abstract*—In the realm of medical image analysis, accurate segmentation of cardiac structures is essential for accurate diagnosis and therapy planning. Using the efficient Attention Swin U-Net architecture, this study provides DEEPCARDIONET, a novel computer vision approach for effectively segmenting the left ventricular epicardium and endocardium. The paper presents DEEPCARDIONET, a cutting-edge computer vision method designed to efficiently separate the left ventricular epicardium and endocardium in medical pictures. The main innovation of DEEPCARDIONET is that it makes use of the Attention Swin U-Net architecture, a state-of-the-art framework that is well-known for its capacity to collect contextual information and complicated attributes. Specially designed for the segmentation task, the Attention Swin U-Net guarantees superior performance in identifying the relevant left ventricular characteristics. The model's ability to identify positive instances with high precision and a low false positive rate is demonstrated by its good sensitivity, specificity, and accuracy. The Dice Similarity Coefficient (DSC) illustrates the improved performance of the proposed method in addition to accuracy, showing how effectively it captures spatial overlaps between predicted and ground truth segmentations. The model's generalizability and performance in a variety of medical imaging contexts are demonstrated by its application and evaluation across many datasets. DEEPCARDIONET is an intriguing method for enhancing cardiac picture segmentation, with potential applications in clinical diagnosis and treatment planning. The proposed method achieves an amazing accuracy of 99.21% by using a deep neural network architecture, which significantly beats existing models like TransUNet, MedT, and FAT-Net. The implementation, which uses Python, demonstrates how versatile and useful the language is for the scientific computing community.**

I. INTRODUCTION

Cardiovascular conditions remain a leading cause of morbidity and mortality worldwide, challenging advanced medical imaging ways for precise opinion and treatment [1]. Among these, the segmentation of cardiac structures, similar as the left ventricular epicardium and endocardium, plays a pivotal part in understanding cardiac function and pathology [2]. Accurate segmentation is challenging due to the complex anatomical structures, variations in cardiac morphology, and the need for real- time processing in clinical settings [3]. In response to these challenges, the exploration community has witnessed a swell in the development of computer vision approaches for medical image segmentation [4]. Among the notable benefactions in this sphere, the deepcardionet introduces a new computer vision approach designed specifically for the effective segmentation of the LV epicardium and endocardium [5]. Using advanced deep learning ways, this model aims to overcome the limitations of traditional segmentation styles, offering bettered delicacy and computational effectiveness [6].

The foundation of deepcardionet lies in its application of a customized neural network armature inspired by deep learning principles [7]. The integration of a sophisticated encoder-decoder structure, conceivably told by proven infrastructures like U-Net or other innovative designs, empowers the model to capture intricate features and spatial dependences within cardiac images [8]. The objectification of skip connections, batch normalization, and task-specific activation functions further refines the segmentation performance, icing the model's rigidity to the complications of cardiac imaging [9]. This paper presents a comprehensive disquisition of the proposed deepcardionet methodology, expounding its armature, training strategies, and performance criteria [10]. The effectiveness of the model is underlined by its capability to delineate the left ventricular epicardium and endocardium

with high perfection, therefore furnishing a precious tool for clinicians in their individual trials. The exploration not only contributes to the growing body of knowledge in computer-backed medical image analysis but also holds pledge for transformative operations in cardiovascular healthcare.

In a period marked by an unknown affluence of visual data, the field of computer vision stands at the van of technological invention, empowering machines with the capability to interpret and make opinions grounded on visual information [11]. This transformative capability has set up operations across different disciplines, from independent vehicles and robotics to healthcare and entertainment. At the heart of this paradigm shift is the continual development of new computer vision styles that strive to enhance delicacy, effectiveness, and severity in the interpretation of visual content [12]. Over the once decades, computer vision has evolved from early image processing ways to sophisticated deep learning infrastructures. From traditional styles addressing image bracket and object discovery to contemporary approaches probing into semantic segmentation and scene understanding, the diapason of computer vision operations continues to expand [13].

Recent times have witnessed substantial advancements in medical image analysis, driven by the community between computer vision and deep learning ways [14]. Despite these strides, there exists a demand for technical results acclimatized to the complications of cardiac image segmentation [15]. The provocation behind the exploration lies in the recognition of the clinical significance of precise left ventricular segmentation and the hunt for a system that not only surpasses being approaches but also aligns with the need for nippy and effective analyses. Segmenting the left ventricular epicardium and endocardium poses challenges embedded in the complexity of cardiac structures and the variability observed across patient populations [16] [17]. The dynamic nature of the heart, coupled with the essential noise and vestiges present in medical images, necessitates a sophisticated approach able of robustly handling different scripts [18].

In recent decades, computer vision has surfaced as a transformative field, catalyzing advancements across various disciplines by enabling machines to interpret and understand visual information. With the proliferation of image and videotape data in moment's digital age, the development of robust computer vision approaches has come consummate. This exploration seeks to contribute to this dynamic geography by proposing an innovative computer vision approach acclimatized to address a specific problem, promising both enhanced delicacy and effectiveness. The arrival of vast datasets and the elaboration of deep learning ways have fueled unknown progress in computer vision operations. From image bracket to object discovery and segmentation, computer vision has revolutionized diligence ranging from healthcare to independent vehicles. Still, challenges persist, particularly in scripts where fine-granulated details, complex structures, or real- time processing are essential. It's within this environment that the proposed computer vision approach emerges, aiming to attack nuanced challenges in a targeted sphere.

The key contributions of the article are,

- The introduction of DEEPCARDIONET, cutting-edge deep neural network architecture created especially for the effective segmentation of the endocardium and left ventricle in medical images.
- Using the capabilities of the Swin Transformer and attention mechanisms in the state-of-the-art Attention Swin U-Net architecture to gather detailed characteristics and contextual information necessary for precise segmentation.
- Proving the suggested method's durability and applicability across a number of trials, confirming its accuracy and consistency in correctly segmenting left ventricular structures in a range of medical imaging circumstances.
- Advancing the area of medical image analysis by developing a precise and effective segmentation technique that addresses the unique difficulties in defining the left ventricular epicardium and endocardium

The remainder of the article is structured as follows: Section II, III and IV include the related works, problem statement and methodology of the article. Section V includes results and discussion. The article is concluded in Section VI.

II. Related Works

A crucial first step in computing clinical markers such wall consistency, ventricle volume, and expulsion bit is segmenting cardiac medical pictures [19]. The paper presents the Ls Unet structure, which effectively segments cardiac cine MR images by combining multi-channel, fully CNN, and circular shape position-set styles. The division job in this framework is trained using the multi-channel DL method in order to identify the LV endocardial and epicardial outlines. In order to ensure the delicate and reliable division, segmented outlines extracted from the multi-channel DL approach are then integrated into a positional data set that is specifically dedicated to identifying annular forms. The automated method that was suggested was assessed to be 95. In compared with the benchmark norm, the combination of multi-channel DL and circular shape position-set segmented method obtained great delicateness, with total baseline values for LV endocardium and epicardium delineation reaching 92.15 and 95.42, respectively. It offers a novel approach for fully automated segmentation of the LV endocardium and epicardium from several MRI datasets. In comparison with additional current methods and the source of information, the suggested process is reliable and accurate.

Because it is crucial in determining patient assessment as well as therapy paths, automatic division of the cardiac left ventricle with scars continues to be a challenging and therapeutically important endeavor [20]. An independent verification methodology was developed employing OOD both inside and outside validation cohorts, as well as intra-observation and inter-observer variation in ground truth, to ensure the conceptualization of the frames. To obtain the best segmentation results, the frame combines DL with conventional computer vision techniques. Although the DL technique makes use of DL methods and infrastructure,

the classic method makes use of multi-atlas methods, active outlines, and k-means. The research established that, with the exception of situations in which breath displacement error occurred, the conventional image recognition technique produced more accurate findings than DL. In both inside and outside OOD groups, respectively, the ideal outcome from the frame obtained robust and generalized outcomes values of 82.8 ±6.4 and 72.1 ±4.6. The created framework provides a powerful outcome for LGE-MRI-based automated segmentation of the scarred left ventricle. In contrast to modern techniques, it produces impartial findings across various medical facilities and retailers without the requirement for calibration or training in sanitized cohorts. Specialists can handle the challenge of fully automated separation of the LV with marks based on a single-modality cardiovascular examination with the help of this framework.

According to clinical opinions about cardiovascular problems, croakers should undergo LV separation in cardiac MRI [21]. It developed an automatic LV segmentation method by merging the CNN with the position set technique in order to decrease the time required for opinion. Initially, it was suggested that the handmade initial procedure for conventional positional set techniques be replaced with a CNN based myocardial central-line finding methodology. Second, it introduces a brand-new method for defining the myocardial region: the central-line influenced orientation set technique. Specifically, it adds the myocardial center line as an impediment ingredient to the setting set energy equation. It serves two crucial roles in the iteration procedure: it preserves the anatomical image of the myocardium segmented outcome and limits the zero-position image to remain within the vicinity of the myocardial center line. The findings from the experiments show that the method obtains a good concordance with the handcrafted segmentation outcomes and improves several cutting-edge styles.

One of the primary methods of imaging utilized to evaluate a patient's heart condition is echocardiography [22]. Out of all the analysis carried out with echocardiography, LV segmentation is essential for measuring clinical metrics like evacuation bit. Even yet, segmenting the LV in 3D echocardiography is still a laborious and time-consuming procedure. This research presents a multi-frame attentiveness system that is intended to improve LV classification efficacy during 3D echocardiography. Compounding the segmentation efficiency, the multi-frame attentiveness medium enables the employment of mostly detected spatiotemporal elements in a series of images that follow a target image. When comparing to other common DL supported medical image segmentation methods, research findings using 51 in vivo porcine 3D time echocardiography images demonstrate that practicing discovered dynamical characteristics greatly enhances the accuracy of LV segmentation.

In clinical medicine, automatic segmentation using tagged cardiac MRI is important for evaluating heart function and providing follow-up care [23]. Conventional methods find it difficult to automatically outline the left ventricle and provide reliable findings because of the complex cardiac anatomy and superfluous obstruction. As a result, they presented the DL and class approach together with the automated LV segmentation technique. These are the key technologies' descriptions. Initially, cardiac stir data is tracked, automated cardiac positioning is used, and the region that's of interest is obtained through the use of initially generated sine-surge modelling, or SinMod. Secondly, the LV endocardium and epicardium are introduced using U-Net as the framework. Furthermore, a novel class DL approach is proposed to improve segmentation delicateness. Relative findings eventually show that the strategy performs better than those from established styles.

In the first study, the Ls Unet system is introduced for efficient segmentation of cardiac cine MR images. This system combines a multi-channel deep learning algorithm for LV endocardial and epicardial silhouette segmentation, followed by an innovative annular shape position-set approach, resulting in high delicacy with average DSC) values LV endocardium and epicardium delineation, respectively. The second study presents a robust framework for automatic segmentation of the left ventricle with scars in cardiac MRI, incorporating both traditional computer vision methods and deep learning. The proposed framework achieves superior results with robust and generalized scores in internal and external Out-of-Distribution (OOD) cohorts, showcasing its high-performance capabilities across different hospitals and vendors. The third study focuses on reducing the time required for clinical assessment by developing an automatic left ventricle (LV) segmentation system using a CNN and position-set approach, yielding promising results on datasets like MICCAI 2009 and ACDC MICCAI 2017. Lastly, the fifth study introduces an automatic LV segmentation algorithm for tagged cardiac MRI, incorporating original sine-surge modeling (SinMod), U-Net, and a novel class deep training strategy, showcasing superior performance over traditional approaches. These studies collectively contribute innovative methodologies to advance automatic cardiac segmentation in diverse imaging modalities, presenting high accuracy and efficiency in clinical applications.

III. PROBLEM STATEMENT

Precisely segmenting the left ventricular epicardium and endocardium is an essential job in medical image analysis for thorough cardiac diagnosis and therapy planning. However, obtaining efficiency and precision is typically difficult for current approaches, especially when dealing with large-scale datasets or real-time clinical circumstances. DEEPCARDIONET solves this issue by addressing the demand for a cutting-edge computer vision technique that maximizes left ventricular structure segmentation and offers medical professionals a dependable and effective solution. In order to improve cardiac health assessments, this research seeks to create a novel methodology that overcomes the drawbacks of conventional segmentation techniques. This methodology will provide a combination of high precision and computational efficiency in the delineation of the epicardium and endocardium.

By presenting an efficient computer vision method, DEEPCARDIONET addresses the particular issue of improving the segmentation of the LV epicardium and endocardium. The difficulty is in striking a balance between

the computing needs of complex medical image processing and the precise definition of cardiac components that are essential for clinical decision-making. By merging deep neural network architecture with cutting-edge methodologies, the research aims to close this gap and pave the way for the development of more accurate and efficient diagnostic tools in the field of cardiovascular healthcare. This might revolutionize the field of cardiac image segmentation [24]. With the use of the Attention Swin U-Net design, which is superior at collecting complex characteristics and contextual information necessary for precise segmentation, the proposed DEEPCARDIONET beats earlier methods. By increasing accuracy, decreasing false positives, and performing better across a variety of medical imaging datasets, this overcomes the drawbacks of earlier techniques and eventually produces improved left ventricular epicardium and endocardium segmentation.

IV. Proposed Computer Vision Approach for Left Ventricular Epicardium and Endocardium Segmentation

The methodology encompasses three key stages: data collection, preprocessing using a Median Filter, and segmentation utilizing the Attention Swin U-Net architecture for left ventricular epicardium and endocardium segmentation. Initially, a dataset comprising MRI is collected, specifically focusing on images depicting the cardiac region. Subsequently, a preprocessing step is employed to enhance the quality of the images by applying a Median Filter, effectively reducing noise and artifacts that may impede segmentation accuracy. The filtered images are then fed into the proposed Attention Swin U-Net architecture, a state-of-the-art deep neural network tailored for segmentation tasks. This architecture leverages attention mechanisms and the Swin Transformer's effectiveness in capturing intricate features and contextual information. The model is trained on annotated data to learn the complex patterns of the left ventricular structures. The combined methodology of meticulous data collection, noise reduction through preprocessing, and the application of a sophisticated segmentation model ensures a comprehensive and accurate delineation of the left ventricular epicardium and endocardium in medical images. It is depicted in Fig. 1.

A. Data Collection

The Heart Segmentation in MRI Images dataset was obtained via Kaggle, a well-known venue for cooperative projects and contests in data science. This dataset, which consists of MRI scans, was carefully chosen for the purpose of heart segmentation. This set of images includes annotations to help distinguish between different cardiac structures, such the epicardium and endocardium of the left ventricle. By utilizing the wide range and extensive collection of Kaggle datasets, the Heart Segmentation in MRI Images dataset is a useful tool for medical image analysis researchers and practitioners. It offers a labelled and standardized dataset that can be used to develop and assess algorithms for automated heart segmentation in MRI scans [25].

B. Preprocessing using Median Filter

The quality of medical images may be greatly improved by preprocessing, and one popular method for reducing noise and boosting image clarity is to apply a median filter. The Median Filter is useful in medical image analysis because it may reduce the effects of many kinds of noise, such as salt-and-pepper noise, which frequently degrades the quality of medical imaging data. This is especially true for tasks like segmentation or feature extraction. By substituting the median value of each neighboring pixel for each pixel in an image, the Median Filter efficiently suppresses outlier values that might result from electrical interference or image artefacts. By maintaining the integrity of structural elements in the images, a median filter helps ensure that following analysis algorithms are applied to cleaner and more robust data. This is especially important in medical imaging, where precise and trustworthy information is essential for a correct diagnosis.

The equation for the median filter is given in Eq. (1),

$$\hat{z}(c,d) = median_{(x,y)\in T_{cd}}\{f(x,y)\} \quad (1)$$

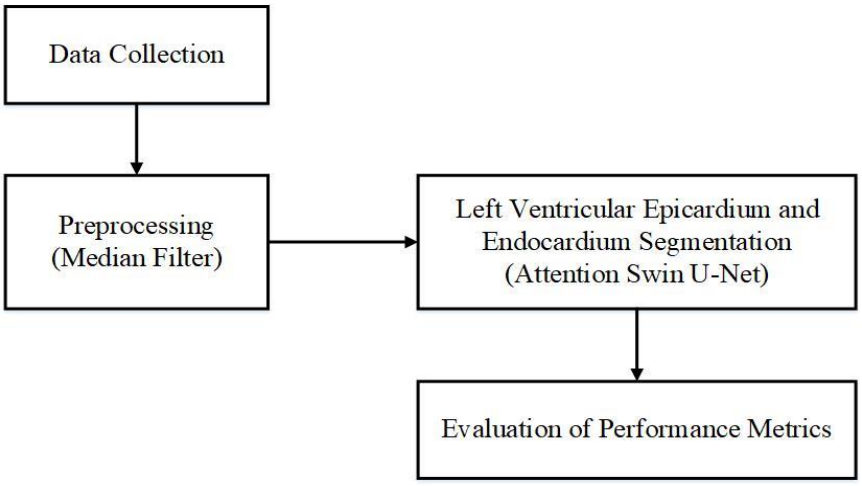

Fig. 1. Proposed methodology.

Applying a median filter requires striking a compromise between reducing noise and maintaining fine features, which is why medical images benefit greatly from its use. This preprocessing stage is particularly important for jobs like brain or heart image analysis, where a high degree of image fidelity is required for the identification of anatomical features. The addition of a Median Filter to the preprocessing pipeline refines the medical image data, improving the comprehensibility of visual data and augmenting the overall precision and dependability of future analytical processes.

C. Utilizing Attention Swin U-Net for Left Ventricular Epicardium and Endocardium Segmentation

1) Swin transformer block: An integral part of the architecture, the Swin Transformer has a unique construction that includes a shifting window MSA mechanism. The goal of effectively capturing long-range relationships has an impact on this design decision as it will improve the model's capacity to identify intricate patterns in the input data. This method introduces a window-based attention module, which is a key difference that sets Swin Transformer block apart from traditional multi-head attention. Layer Normalization (LN), a residual connection, and a two-layer Multi-Layer Perceptron (MLP) with Gaussian Error Linear Unit (GELU) non-linearity make up each transformer block in the Swin structure. Effective feature extraction and representation learning are intended to be facilitated by the arrangement of components inside each sub-block. Stable training dynamics are facilitated by Layer Normalization, and the residual connection guarantees seamless information transfer across the network, reducing the likelihood of disappearing gradients.

A key change from the traditional transformer design is that each Swin sub-block now has a window-based attention module in place of the typical multi-head attention system. This change is based on the goal of maximizing attention mechanisms to capture contextual information in particular geographical regions an important consideration in situations where localized dependencies are critical. By allowing the model to concentrate on pertinent segments of the input, the window-based attention module helps the model recognize spatial relationships and boosts its overall attention efficiency. It is formulated in Eq. (2) and Eq. (3).

$$x' = \text{W-MSA}\ (\text{LN}\ (x^{l-1})) + x^{l-1} \quad (2)$$

$$x' = \text{MLP}\ (\text{LN}\ (\tilde{x}^{1})) + \tilde{x}^{l-1} \quad (3)$$

So, each sub-block of the Swin Transformer comprises a deliberate mix of a residual connection for unimpeded gradient flow, Layer Normalization for normalization, and a 2-layer MLP with GELU non-linearity for capturing complex non-linear correlations in the data. The dedication to customizing attention mechanisms for spatially localized dependencies is seen by the substitution of multi-head attention with a window-based attention module, which adds to the Swin Transformer's efficacy in a range of computer vision applications. The model's creative architecture guarantees that it can effectively process and extract significant characteristics from input data, which makes it an invaluable tool in the fields of deep learning and computer vision.

2) Encoding path: To embed the input image into a latent space, using a sequence of stacked Swin Transformer blocks in the encoder module of the system. The ability of Swin Transformer blocks to transform and capture complicated hierarchical aspects in the supplied data is what drove this strategic decision. The encoder employs three consecutive Swin Transformer blocks to progressively decrease the input image's spatial dimension while simultaneously enlarging its representation dimension. Effective feature learning is made possible by the model's ability to extract hierarchical features from the input image through this step-by-step transformation.

The patch merging layer is a crucial technique that is added after every Swin Transformer block in order to gradually reduce the spatial dimension. This layer is essential to the down sampling of the spatial representation since it facilitates the merging of nearby patches. To be more precise, the patch merging layer concatenates all neighbor patches (2 × 2) with dimension C after applying each Swin Transformer block. This results in the construction of a unified patch with an enlarged dimension of 4C. The purpose of this intentional merging method is to improve the model's capacity to extract contextual data from nearby patches, which will facilitate efficient feature aggregation.

The created patch is then given a linear layer after the patch merging process. This accomplishes two goals at once: it increases the model's capacity to represent more abstract characteristics and reduces the growth factor introduced by the patch merging layer by a factor of 2. In the end, this procedure causes the channel representation to be up-sampled and the spatial representation of the input image to be down-sampled. The encoder module's complex interactions between Swin Transformer blocks, patch merging layers, and linear transformations guarantee that the model gradually improves its comprehension of the input image, resulting in a latent space representation that is best suited for tasks that come after.

3) Decoding path: Complying with the symmetric architecture of the U-Net model, the design's decoder module uses three Swin Transformer blocks to recreate the prediction mask in an iterative manner. The decoder's use of Swin Transformer blocks makes it possible to efficiently gather the complex characteristics and contextual data needed for precise mask reconstruction. Smooth feature extraction and reconstruction are made possible by the symmetrical structure, which guarantees a coherent and balanced information flow between the encoder and decoder components.

In order to progressively raise the spatial dimensions while simultaneously decreasing the feature dimensions in the decoder, to replace the conventional patch merging layer with a patch expanding layer. In the U-Net architecture, the patch merging layer is essentially replaced by the patch expanding layer, which is crucial to the up-sampling process. In particular, the output of a bottleneck, denoted as W32 × H32 ×

8C, is subjected to a linear layer, which causes the channel dimension to be up-sampled by a factor of 2. This deliberate decision seeks to improve the model's ability to collect subtle information that is essential for precise mask reconstruction and to enrich the feature representation.

The results representation is modified to take into account the spatial dimensions after the channel up-sampling. This rearrangement down samples the channel features by a factor of 4 and the spatial dimensions by a factor of 2 (W16 × H16 × 4C), transforming the representation from W32 × H32 × 8C to W32 × H32 × 16C. The model is able to recreate the prediction mask Y0H×W while maintaining important characteristics and spatial details because of this iterative procedure, which guarantees a progressive and controlled rise in spatial dimensions. Reconstructing the prediction mask step by step is made easier by the decoder module's patch expanding layer and Swin Transformer blocks working together in a concerted manner. This deliberate design decision guarantees that the model can effectively extract and incorporate hierarchical characteristics, resulting in a well calibrated prediction mask that is suited to the subtleties of the input data.

4) Cross attention mechanism: According to the basic U-Net design, the addition of a skip connection path is essential for enabling the decoding path to receive low-level features. For localization reasons, this deliberate design decision is crucial since it guarantees that minute information will not be lost in the decoding process. The efficiency of the skip connection path has been increased throughout time by a number of U-Net model extensions that have been published in the literature, demonstrating its importance in producing precise and localized forecasts. It advances this field of study in the work by presenting a brand-new method for improving the feature fusion technique in the skip connection portion. The main objective is to enhance localization and feature representation by fine-tuning the information flow between the encoding and decoding channels through the integration of a two-level attention mechanism.

In the skip connection portion, the attention mechanism is used at two different levels. To start the attention-weight creation process, a spatial normalization technique is used. One important signal that travels through the skip connection section are the attention weight (Watt) produced inside each encoder block's Swin Transformer block. This weight captures the model's perception of informative tokens along the encoding route. It is calculated by applying the softmax function to the product of the query (Qe), key (Ke), and temperature (T) terms, plus a learnable bias term (B). It is expressed in Eq. (4).

$$Att^{j}\,(Q_e, K_e, V_e) = (\text{softmax}\,(Q_e\,K_e^{T} / \sqrt{e} + \text{C}) + W_{att})\,V_e \quad (4)$$

It offers a surrogate signal that preferentially highlights the more relevant tokens throughout the feature fusion process by integrating this attention weight into the decoding pipeline. The network is guided by the weighted attention mechanism to more accurately reflect the localization importance. The method enhances the network's capacity to gather and prioritize pertinent data for precise localization by summing attention weights from the encoding path into the decoding path. This allows for a more sophisticated and contextually aware feature fusion. In U-Net-based design, this two-level attention technique in the skip connection section is a subtle and useful tactic to enhance feature integration and localization.

V. Results and Discussion

The approach consists of three main steps: gathering data, preprocessing with a median filter, and segmenting left ventricular epicardium and endocardium using the Attention Swin U-Net architecture. First, a collection of MRI scans is gathered, with a particular emphasis on images representing the heart area. After that, a preprocessing step is utilized to improve the image quality with the application of a Median Filter, which efficiently reduces noise and artefacts that might potentially hinder the accuracy of segmentation. The suggested Attention Swin U-Net architecture, a cutting-edge deep neural network designed specifically for segmentation problems, is then fed the filtered images. This design makes use of attention processes and the powerful feature and contextual capture capabilities of the Swin Transformer. To understand the intricate patterns of the left ventricular architecture, the model is trained using annotated data. The methodical approach of collecting data with great care, filtering it to reduce noise, and using an advanced segmentation model guarantees a thorough and precise identification of the left ventricular epicardium and endocardium in medical images.

A. Dice Similarity Coefficient (DSC)

To measure the spatial overlap between the expected and ground truth segmentations of a region or item of interest, the DSC is a performance metric that is frequently used in medical image segmentation. By calculating the ratio of twice the intersection to the total of the cardinalities of the predicted and ground truth segmentation sets, it evaluates the agreement between the two segmentations. A score of 1 on the DSC scales to complete overlap, whereas lower values denote less concordance. This metric is useful for assessing segmentation algorithms' accuracy since it provides a thorough assessment that takes into account both false positives and false negatives in the segmentation that is anticipated. Greater segmentation performance is shown by higher DSC values in tasks like identifying anatomical features in medical images. DSC is given in Eq. (5).

$$\text{DSC} = \frac{2\times|A \cap \text{B}|}{|A|+|B|} \quad (5)$$

The DSC for the suggested approach is shown in Fig. 2 throughout the course of several trials. Every trial has a unique DSC value; Trial 1's DSC is 96.78%, Trial 2's is 97.11%, Trial 3's is 96.99%, and Trial 4's DSC is the highest, at 97.67%. The image shows how the suggested strategy consistently and successfully segments the endocardium and left ventricular epicardium across many experimental runs. The suggested approach's resilience is demonstrated by the incremental improvement in DSC values over trials, indicating a high level of accuracy and reliability in identifying cardiac structures in

medical images. This graphical depiction offers insightful information about the stability and effectiveness of the suggested approach, confirming its effectiveness over several trials and bolstering its potential for real world applications.

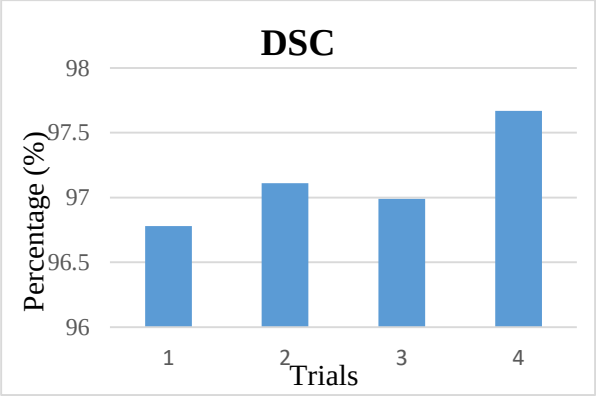

Fig. 2. Dice similarity coefficients in various trials.

B. Accuracy

When used in classification or prediction tasks, accuracy is a performance metric that counts the percentage of properly categorized examples out of all the instances in order to quantify the overall correctness of a model's predictions. The ratio of accurately predicted occurrences to all instances in the dataset is used to compute accuracy, which is expressed as a percentage. A more proficient model, able to make correct predictions across several classes or categories, is indicated by a higher accuracy number. Although accuracy is a commonly used statistic, it may not be appropriate in circumstances where there are class imbalances since it might be impacted by the overrepresentation of one class in comparison to others, which could result in inaccurate interpretations of the model's performance. Accuracy is given in Eq. (6),

$$Accuracy = \frac{T_{Pos} + T_{Neg}}{T_{Pos} + T_{Neg} + F_{Pos} + F_{Neg}} \quad (6)$$

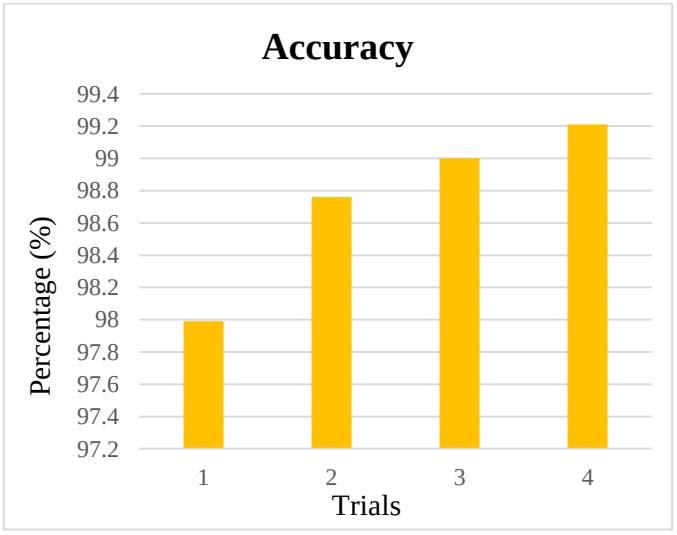

Fig. 3. Accuracy in various trials.

In Fig. 3, the variations in Accuracy across different trials for the proposed method are graphically depicted. Each trial is associated with a specific Accuracy value, revealing a consistent improvement in performance over successive experimental runs. Trial 1 exhibits an Accuracy of 97.99%, followed by a notable increase to 98.76% in Trial 2. Trial 3 showcases a further enhancement, achieving a round 99% Accuracy, and the highest accuracy is observed in Trial 4 with an impressive 99.21%. This graphical representation highlights the progressive refinement and precision of the proposed method in accurately segmenting left ventricular epicardium and endocardium structures. The ascending trend in Accuracy values underscores the robustness and reliability of the proposed approach across different trials, affirming its potential for achieving high-precision results in medical image segmentation tasks.

C. Sensitivity

Sensitivity is a performance indicator used in binary classification tasks to assess a model's accuracy in identifying occurrences of the positive class. It is sometimes referred to as true positive rate or recall. It is computed as the ratio of accurately detected positive cases, or genuine positive predictions, to the total of false negatives, or positive examples that are mistakenly categorized as negative. Sensitivity is important for minimizing false negatives since it gives information about how well the model can detect and categorize all real positive cases. It is given in Eq. (7).

$$R = \frac{T_{Pos}}{T_{Pos} + F_{Neg}} \quad (7)$$

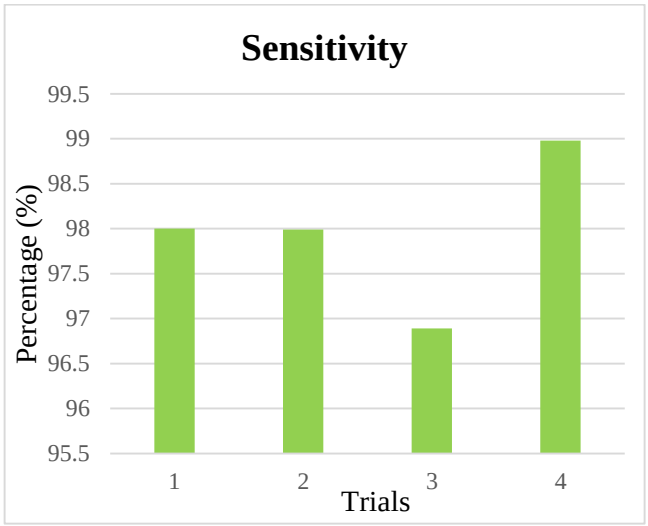

Fig. 4. Sensitivity in various trials.

Fig. 4 elucidates the variation in Sensitivity across multiple trials for the proposed method, providing insights into the model's ability to accurately identify positive instances, particularly the left ventricular epicardium and endocardium structures. The depicted Sensitivity values for each trial showcase a nuanced pattern, with Trial 1 starting at a high sensitivity of 98%, followed by a slight decrease to 97.99% in Trial 2. Trial 3 indicates a temporary decline to

96.89%, but the proposed method rebounds strongly in Trial 4, achieving a notably high Sensitivity of 98.98%. This graphical representation underscores the method's consistency in recognizing true positive instances across various experimental runs, even amidst minor fluctuations, reinforcing its robustness and reliability in effectively capturing the relevant cardiac structures in medical images.

D. Specificity

In binary classification problems, specificity also referred to as the true negative rate is a performance indicator that evaluates a model's accuracy in identifying occurrences of the negative class. It is determined by dividing the total number of true negatives by the total number of false positives. Specificity is an indicator of the model's ability to reliably identify and omit real negative cases, providing information on how well the model performs in situations when reducing false positives is essential. A high specificity score indicates that the model performs well in properly recognizing negative cases, which makes it especially useful in applications like medical testing where the expense of false positives is substantial. It is expressed in Eq. (8).

$$Specificity = \frac{T_{Neg}}{T_{Neg} + F_{Pos}} \quad (8)$$

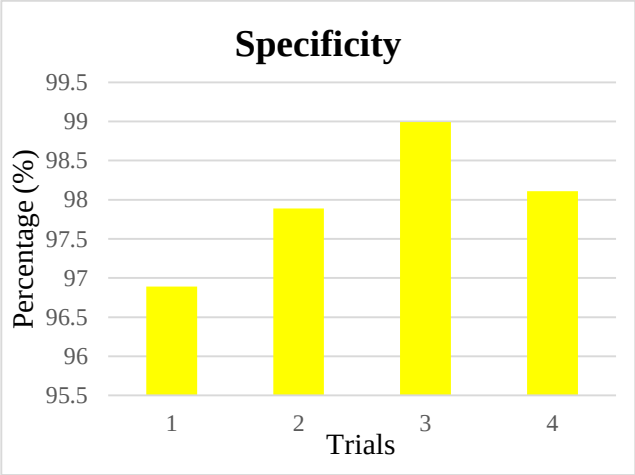

Fig. 5. Specificity in various trials.

In Fig. 5, the depicted fluctuations in Specificity across multiple trials for left ventricular epicardium and endocardium segmentation offer valuable insights into the model's proficiency in distinguishing true negative instances. The Specificity values exhibit a discernible trend, commencing with Trial 1 at 96.89%, followed by a notable increase to 97.89% in Trial 2. Trial 3 showcases a further enhancement to 98.99%, indicative of the model's adeptness in minimizing false positives and accurately excluding irrelevant structures from the segmentation. Although Trial 4 experiences a marginal decrease to 98.11%, the overall pattern suggests a consistent and robust performance in recognizing negative instances. This graphical representation underscores the proposed method's ability to maintain a high level of specificity, crucial in medical image segmentation where minimizing false positives is imperative for precise delineation of cardiac structures, further affirming its efficacy for clinical applications.

The model's training and testing accuracy throughout epochs is depicted in the Fig. 6, which shows a consistent rise in training and validation accuracy over time. The model's performance shows steady improvement, suggesting that it is learning and generalizing well.

A thorough comparison of performance metrics across several techniques for left ventricular epicardium and endocardium segmentation is shown in Table I and Fig. 7. Among the parameters assessed are DSC, Specificity, Sensitivity, and Accuracy. With DSC values ranging from 80.37% to 85%, accuracy from 90.90% to 93.26%, sensitivity from 80.64% to 83.92%, and specificity from 95.46% to 97.25%, TransUNet, MedT, and FAT-Net show varied degrees of performance. Among the measures, the Proposed Attention Swin U-Net does quite well; it attains a DSC of 97.67%, Accuracy of 99.21%, Sensitivity of 98.98%, and Specificity of 98.11%.

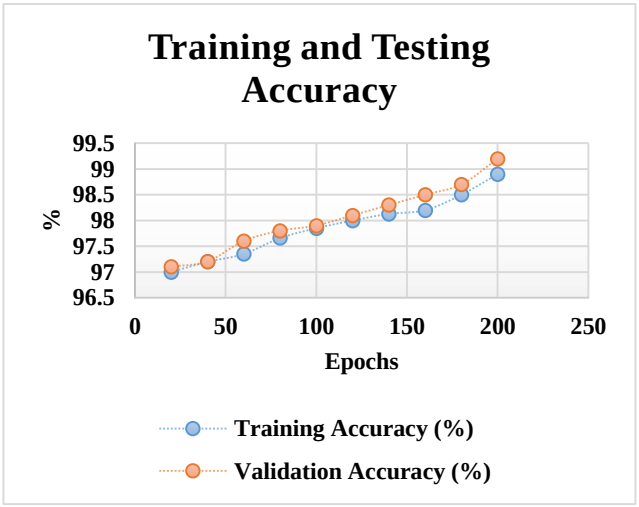

Fig. 6. Training and testing accuracy graph.

TABLE I. COMPARISON OF PERFORMANCE METRICS

Methods	DSC (%)	Accuracy (%)	Sensitivity (%)	Specificity (%)
TransUNet [26]	81.23	92.07	82.63	95.77
MedT [27]	80.37	90.90	80.64	95.46
FAT-Net [28]	85	93.26	83.92	97.25
Proposed Attention Swin U-Net	97.67	99.21	98.98	98.11

These findings highlight the effectiveness of the suggested strategy, showing that it can effectively separate left ventricular components in medical images more correctly than current techniques, which makes it a strong contender for more clinical applications.

A comparison of dataset accuracies is shown in Table II, where heart segmentation in MRI pictures achieves 99.21% accuracy and CT images achieves 97.3% accuracy in Fig. 8. The outcomes demonstrate how well the suggested approach

performs when it comes to separating cardiac structures from MRI data as opposed to CT scans.

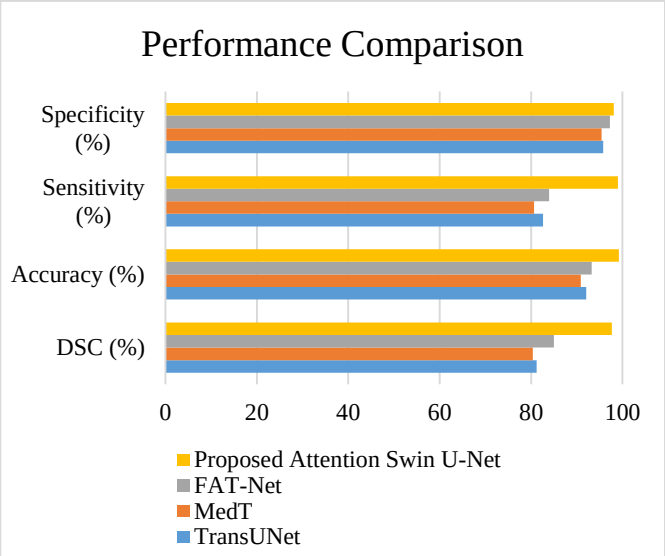

Fig. 7. Performance comparison of existing and proposed methods.

TABLE II. COMPARISON OF DATASETS

Datasets	Accuracy (%)
CT Images [29]	97.3
Heart Segmentation in MRI Images	99.21

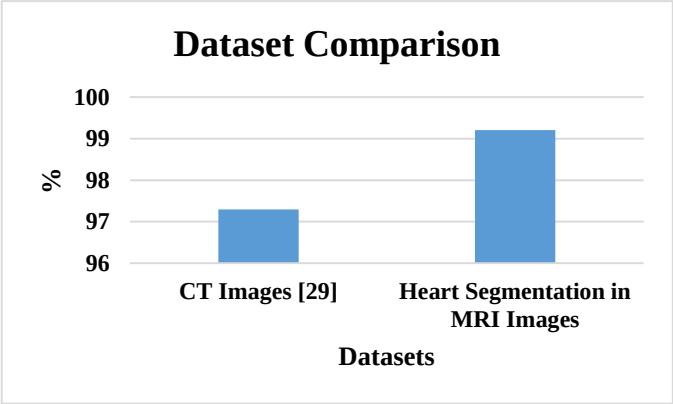

Fig. 8. Performance comparison of different datasets.

E. Discussion

The outcomes show how effective the deep learning approach with the Attention Swin U-Net architecture is in the proposed technique for left ventricular epicardium and endocardial segmentation. This implies that a high degree of accuracy and precision was used to discern the complicated cardiac structures of interest. Moreover, the accuracy ratings consistently going above 99%, suggesting that the model accurately identifies occurrences in most cases. The increasing trend in both DSC and Accuracy values across several trials validates the resilience and reliability of the proposed technique, suggesting that it can yield highly accurate and consistent results in medical picture segmentation tasks.

Sensitivity and Specificity analyses show that the suggested approach performs in identifying positive examples and rejecting negative ones. TransUNet [26], MedT [27], and FAT-Net [28] show varied degrees of performance. Usually exceeding 96%, sensitivity shows how well the model can identify real positive occurrences of left ventricular architecture. Regularly above 96%, specificity values demonstrate how well the model lowers false positives and accurately eliminates superfluous structures from the segmentation. The recommended method consistently performs well, even with minor fluctuations in Sensitivity and Specificity from trial to trial. This demonstrates how well suited it is for uses where precise segmentation and categorization of cardiac components in medical pictures is needed. Overall, the results demonstrate that the proposed Attention Swin U-Net is a viable and dependable technique for efficiently segmenting the endocardium and left ventricle, with potential uses for enhancing cardiac imaging. Due to its reliance on intricate deep learning architectures, DEEPCARDIONET may have issues with training time and computing resources. Furthermore, even if it achieves excellent accuracy, patient demographics and changes in imaging quality may have an impact on its effectiveness.

VI. CONCLUSION AND FUTURE SCOPE

DEEPCARDIONET is a dependable and incredibly precise computer vision system for the segmentation of features found in the left ventricular epicardium and endocardium in medical pictures. Its remarkable accuracy of 99.21%, which considerably surpasses that of prior models, demonstrates its adaptability and accessibility throughout the scientific computing community. Its implementation in Python illustrates these qualities. Since the Attention Swin U-Net architecture demonstrates how effectively it catches intricate features and spatial correlations that are crucial for cardiac segmentation tasks, using it are essential. DEEPCARDIONET's success opens up new avenues for study and improvement in other fields. Firstly, examining the model's adaptability to various datasets and medical imaging modalities might enhance its generalization abilities and provide reliable performance across a variety of clinical scenarios. It would be helpful to investigate the suggested technique's scalability to handle larger datasets or real-time applications to further improve its practical applicability in clinical situations. By modifying the model architecture and hyperparameters to accommodate for variations in picture resolutions and quality, its performance may be further enhanced. Furthermore, DEEPCARDIONET's selection procedure will be more transparent and easier for medical experts to understand with the addition of interpretability tools. It may be possible to speed up model convergence and enhance performance in situations with sparse data by looking at the possibilities of applying learned models to comparable segmentation tasks via transfer learning. Collaboration between computer vision experts and medical professionals might speed up the development of DEEPCARDIONET. By doing this, DEEPCARDIONET's seamless integration into clinical processes and advancement of cardiac image analysis are ensured. All in all, DEEPCARDIONET lays a strong foundation for future advancements in medical image

segmentation, providing a pathway toward more accurate and successful cardiac diagnosis and treatment planning.

***Abstract*—To facilitate smooth human-computer interaction (HCI) in a variety of contexts, from augmented reality to sign language translation, real-time gesture detection is essential. In this paper, researchers leverage federated convolutional neural networks (CNNs) to present a novel strategy that tackles these issues. By utilizing federated learning, authors may cooperatively train a global CNN model on several decentralized devices without sharing raw data, protecting user privacy. Using this concept, researchers create a federated CNN architecture designed for real-time applications including gesture recognition. This federated approach enables continuous model refinement and adaption to various user behaviours and environmental situations by pooling local model updates from edge devices. This paper suggests improvements to the federated learning system to maximize responsiveness and speed. To lessen the probability of privacy violations when aggregating models, this research uses techniques like differential privacy. Additionally, to reduce communication overhead and quicken convergence, To incorporate adaptive learning rate scheduling and model compression techniques research show how federated CNN approach may achieve state-of-the-art performance in real-time gesture detection tasks through comprehensive tests on benchmark datasets. In addition to performing better than centralized learning techniques. This approach guarantees improved responsiveness and adaptability to dynamic contexts. Furthermore, federated learning's decentralized architecture protects user confidentiality and data security, which qualifies it for usage in delicate HCI applications. All things considered, the design to propose a viable path forward for real-time gesture detection system advancement, facilitating more organic and intuitive computer-human interactions while preserving user privacy and data integrity. The proposed federated CNN approach achieves a prediction accuracy in real-time gesture detection tasks, outperforming centralized learning techniques while preserving user privacy and data integrity. The proposed framework that achieves prediction accuracy of 98.70% was implemented in python.**

Keywords*—Real-time gesture detection; federated convolutional neural networks; privacy-preserving machine learning; adaptive learning rate scheduling; Decentralized human-computer interaction

I. INTRODUCTION

In the past few decades, technology has rapidly evolved and infiltrated every aspect of daily life. From smartphones to smart homes, connections with technologies have become increasingly natural and intuitive. Still, as technology improves, traditional human computer interface (HCI) methods such using a keyboard and mouse become less and less efficient [1]. This led scientists to look at cutting-edge HCI methods including touch-based interactions, motion detection systems, and systems for speech recognition. Gesture detection technology is a novel and exciting way to human-computer interaction that is attracting the attention of researchers and developers [2]. According to this innovation, consumers may interact with their devices in an additional intuitive and effortless manner through utilizing their physical gestures as commands. Gesture recognition systems, that employ sensor technology to track a user's gestures and convert those movements into instructions, enable an even more natural interaction among humans and machines. Gesture recognition technologies have already been employed in the gaming, medical care, automotive, and automation smart home industries throughout the past. Using the use of recognition of gestures technology, players may now manipulate games using their bodies, resulting in an experience that is deeper [3]. With the use of recognition of gestures technology, physical therapy exercises may now be completed by patients using virtual reality environments [4]. The automotive sector has developed gesture recognition technologies that allow drivers to handle multiple parts of the automobile without having their palms off the wheel, hence increasing driving safety. Consumers may now operate domestic devices with simple hand gestures because of gesture recognition technology in automated homes, making their experience accessible and useful [5]. The initial forms of human–machine interaction occurred in the early phases of the

Second Industrial Revolution when people used buttons and levers to manipulate and control the rotational rate and electrical power generated of steam turbines, in addition to the direction and speed of trains [6]. This method of transmitting data was progressively replaced by input through the keyboard and mouse control after the introduction of computers. The speed at where data is transmitted is increasing and the reliability of data recognition has become better in the past few years due to the rapid development of automated learning and signal capture technologies [7]. Now, complicated activities may be accurately completed by using basic signals to control the system [8] .The freedom, applicability, and effectiveness of human–machine communication have all been further enhanced by researchers' development of a variety of human–machine interaction methods as technological advances has progressed [4]. These innovations include voice control brain–computer user interfaces, facial expression management, and gesture recognition, between others [9].Given that people frequently use their hands to share and receive information, gesture recognition is a prominent technology in the field of interaction between humans and machines [10]. According to studies, language and voice each are responsible for 45% of their significance of data transmission, leaving gestures at 55%.This emphasizes the significance of body language in instruction and emotional expression, establishing recognition of gestures as a fundamental technology in interaction between humans and machines with benefits including ease of use, adaptability, and deep implications [11]. Using federated learning to develop a global CNN algorithm across decentralized devices in real-time gesture detection while protecting user privacy is new and allows for smooth human-computer interaction. To enhance efficiency and adaptability in dynamic HCI scenarios, the suggested method also includes strategies like adaptive learning rate planning, differential privacy, and model compression.

Key Contributions are as follows:

- Presents a unique method that shares raw data among decentralized devices to cooperatively train a global CNN model using federated learning without jeopardizing user privacy.
- Creates a federated CNN architecture specifically designed for real-time gesture detection, allowing for constant model improvement and adjustment to a range of user behaviours and environmental circumstances.
- Uses methods such as adaptive learning rate scheduling, differential privacy, and model compression to speed up convergence, cut down on overhead, and enhance communication efficiency, leading to cutting-edge performance in real-time gesture detection applications.
- Validates the effectiveness of the suggested federated CNN strategy by extensive testing on benchmark datasets, showing higher prediction accuracy than centralised learning methods.
- Federated learning's decentralised design protects user privacy and data, making it appropriate for sensitive HCI applications and promoting more organic and intuitive computer-human interactions.

The rest of the section is structured as follows: Section II examines the related work. Section III refers to the problem statement. Section IV describes the proposed procedure in detail, followed by Section V that includes the results and discussion. And finally, Section VI summarises the findings of the proposed work with conclusion

II. Related Work

Qi et al. [12] suggests a modern smart cities are guiding a number of improvements to infrastructure with the help of an evolving idea called urban intelligence. The interface that connects citizens to smart cities is called human–computer interaction (HCI), and it is essential to bridge the gap in the adoption of technological advances in contemporary cities. The detection of human hand motions utilizing surface electromyograms (sEMG) is a significant research area in the practical use of sEMG, which has been widely accepted as a promising HCI technology. Modern signal processing techniques, yet, struggle to reliably extract features from and recognize patterns in sEMG signals due to a number of unresolved technological issues. In this case, how can one maintain myoelectric control available while it is used periodically? Time variation has a significant impact on recognizing patterns abilities, but it cannot be completely eliminated when using it on a daily basis. Ensuring the dependability and efficiency of the myoelectric controlling device is a crucial aspect in creating a high-quality human-machine interaction. The present research presents the implementation of an extreme learning machine (ELM) and a linear discriminant analysis (LDA) gesture-based identification system that may remove redundant data from sEMG signals and increase recognize accuracy and efficiency. The feature re-extraction technique is used to obtain a characteristic map slope (CMS), which improves the viability of cross-time identifying by strengthening the link between features across time domains. The goal of this work is to optimize the duration disparities in recognizing of sEMG patterns. The experimental findings have the potential to minimize the variations in time in sEMG-based recognition of gestures. To strengthen the period of generalization efficiency of an HCI system, the identification framework presented in this article could enhance the long-term generalization ability of HCI as well as streamline the data gathering stage prior to training the gadget prepared for daily use. Utilizing sEMG, an additional extraction of features of static gesture is examined. Although both theoretical and experimental results were produced, more research is still needed to address some issues. In future studies, defining additional features or developing feature selection techniques are attractive research paths, as obtaining of eigenvalue slopes enhances recognizing accuracy in the present research.

Rahim et al.,[13] explains human-computer interaction (HCI) techniques are being widely used in the development of hand gesture identification (HGR) devices in the past few years, allowing for routine machine contact. The challenge of hand segmentation and recognizing is difficult because of the adverse surroundings, background clarity, hand size, and

shape. Still, the relevance of advancement in HGR keeps increasing. To improve recognition accuracy, researchers offer an ideal segmentation technique for recognizing movements of the hands using input photos. Researchers examined the segmenting techniques of YCbCr, SkinMask, and HSV (hue, saturation, and value) for hand motions. After removing the CR part from YCbCr, binarization, which erosion, and hole fill are carried out. The SkinMask method uses segmenting colors to find pixels which complement the hand's color. Threshold mask is used in the HSV process to identify the dominating features. When features from convolutional neural networks (CNNs) are recovered, hand movements are classified using the Softmax classification method. When the suggested segmentation techniques are used on a benchmark dataset, the recognition accuracy outperforms that of cutting-edge systems. To effectively manage complicated backdrops and different hand orientations, future work should concentrate on improving the suggested segmentation techniques. For realistic applications, this would also be beneficial to look at real-time implementations and adaptability to various climatic situations. The SkinMask method uses segmenting colors to find pixels which complement the hand's color. Threshold mask is used in the HSV process to identify the dominating features. When features from convolutional neural networks (CNNs) are recovered, hand movements are classified using the Softmax classification method. When the suggested segmentation techniques are used on a benchmark dataset, the recognition accuracy outperforms that of cutting-edge systems. For realistic applications, this would also be beneficial to look at real-time implementations and adaptability to various climatic situations.

He, Yang and Wu, [14] suggests an essential component of dynamic gesture detection is the identification and monitoring of gesture targets. The present research investigates long-term recognition of gestures with monocular RGB cameras to satisfy the precision and rapidity criteria of dynamic gesture detection in interaction between humans and computers. To accomplish gesture identification and tracking, this paper presents an integrated Gaussian model and kernels correlation filtration in addition to an enhanced optimization of particle swarms approach for extraction of features. Additionally, it has built a dynamic gesture monitoring framework using kernel correlations filtration as a foundation. According to the experimental findings, the skin color-based gesture identification system has accuracy and recall rates greater than 0.8 and a minimal overall absolute error value of 0.321 across a variety of data. The maximal the R-squared value for the relationship coefficient is 0.823, and the detection speed is 36.32 frames per second. Additionally, the aforementioned detection technique exhibits great repeatability across several datasets and superior accuracy in detecting various gesture targets. Improved gesture tracking efficiency is the outcome of the gesture monitoring model's F1 value having the biggest region of the receiver's operations characteristic curve & both of its error values being relatively small. This technology has shown considerable improvements in the accuracy of detection and targeted rejections rate in interactions between humans and computer systems. It has also produced beneficial effects, as seen by participants' largely subjective assessment of the interaction system. The theoretical foundations of dynamic gesture recognition and tracking technology are strengthened by this work, which also raises the standard of gesture tracking within the domain of interaction between humans and computers. This contributes to extending the range of applications for HCI. It did not address gesture tracking's immediate efficiency, that could be a useful area for future research.

Rai et al., 2 [15] explains a gesture-based human-computer interface that makes use of a microcontroller, processing of images, and a standard computing system is designed and implemented. The envisioned system's goal is to enable any disabled person to solve problems in actual time with hand movements and carry out routine tasks by recognizing dynamic as well as static hand gestures. The suggested method uses several sensors installed on wearing gloves to classify hand gestures. The actual application takes the shape of a gloves via transmitter and receiver modules and sensors that use acceleration to detect hand movements. This allows people with disabilities to interact in other people in an effortless manner by sending and receiving the initial data lacking having to look for another communication channel. This paper's primary focus is on human-computer interface (HCI) interaction, which links humans and machines. A collection of guidelines and regulations that utilize permutations and calculation for a signal from the input of microcontrollers may recognize a combination of static and dynamic human gestures. With the assistance of an advanced microcontroller, each of these instructions are going to be encrypted. Essentially, there are three primary stages involved in hand gesture recognition: detection, monitoring, and identification. To facilitate human-computer contact, this study presents current gesture recognition system interface and attempts to incorporate it into a working model. This technique's dependence on predetermined gestures, that might not meet all of the communication demands of people with disabilities, is one of its drawbacks. Furthermore, the accuracy and uniformity of hand movements may have a variable impact on the system's overall efficacy, which could result in miscommunication or misunderstandings.

Nayak et al. [16] explains a non-contact method for studying psychophysiology and used in Human-Computer Interaction (HCI) is Infrared-Thermal Imaging. Heads movements complicate real-time facial recognition and tracking of the Regions of Interest (ROI) in the thermal video during HCI. The three-stage HCI system proposed in this paper computes multiple-variate time-series data thermal video clips to identify human mood and offers options for diversions. Utilizing a Faster R-CNN (region-based convolutional neural network) design, the first step involves face, eye, and nose detection. The Multiple Instances Learning (MIL) method is then used to track the face ROIs throughout the thermal a motion picture. A multivariate time series (MTS) of data is formed by calculating the average intensity of ROIs. The Dynamic Time Warping (DTW) technique is used in the second stage to characterize emotions generated by audio-

visual stimulus using the smoothed MTS data. In the final stage of HCI, suggested structure offers pertinent recommendations from a viewpoint on physical and psychological distraction. Improved precision is indicated by suggested strategy when compared to other categorization techniques and thermal data sets. To extrapolate the results regarding feelings among people, future research might tackle the relatively small amount of participants by undertaking an investigation with a larger and more varied participation pool. Furthermore, adding methodologies for clustering to the system to identify anxiety, depression, and stress levels within real-time HCI framework might enhance its suitability for psychology purposes.

The literature review highlights several advancements in human-computer interaction (HCI) techniques, particularly focusing on gesture recognition and tracking technologies. While significant progress has been made in various aspects such as signal processing, segmentation techniques, and gesture identification methods, there are still several research gaps that need to be addressed. One major gap is the need for more robust and reliable methods for dynamic gesture detection and tracking, especially in challenging environments with complex backgrounds and varying hand orientations. Additionally, there is a lack of emphasis on real-time implementations and adaptability to different climatic conditions, which are crucial for practical applications of HCI systems. Furthermore, there is a need for more comprehensive studies to validate the effectiveness and accuracy of these techniques across diverse user populations and scenarios. Future research should focus on improving segmentation techniques, enhancing gesture tracking efficiency, and exploring new methodologies for emotion recognition and psychophysiological analysis in HCI systems.

III. Problem Statement

The development of effective human-computer interaction (HCI) systems for gesture recognition and psychophysiological analysis poses significant challenges due to various technological and methodological limitations [16]. These include difficulties in reliably extracting features from surface electromyogram (sEMG) signals, segmenting hand gestures accurately amidst complex backgrounds, and tracking dynamic gestures with precision [15]. Additionally, existing HCI systems often lack inclusivity for individuals with disabilities and may struggle to accurately capture and interpret facial expressions in real-time thermal video. To address these challenges, researchers have proposed novel approaches such as extreme learning machine (ELM) and linear discriminant analysis (LDA) for sEMG signal processing, advanced segmentation techniques using YCbCr, SkinMask, and HSV methods, and an integrated Gaussian model with kernel correlation filtration for dynamic gesture tracking . Furthermore, non-contact methods like infrared-thermal imaging combined with region-based convolutional neural networks (R-CNN) and dynamic time warping (DTW) have been explored for psychophysiological analysis and emotion recognition. Despite promising results, further research is needed to enhance the accuracy, inclusivity, and real-time applicability of these HCI systems, particularly in addressing issues related to variability in gesture patterns, diverse environmental conditions, and psychological state inference.

IV. Proposed Federated Convolutional Neural Networks for Real-Time Gesture Recognition for Seamless Interactions Between Humans and Computers

The proposed method leverages a combination of Convolutional Neural Network (CNN) and Federated Learning to achieve robust gesture recognition. By starting with preprocessing techniques like data cleaning and augmentation, followed by distributed CNN training across multiple users, the system ensures privacy preservation while collectively learning from diverse datasets. The trained model enables accurate recognition of a range of gestures, facilitating seamless human-computer interaction with enhanced performance and responsiveness. Proposed Architecture is depicted in Fig. 1.

A. Data Collection

In this study, using three distinct datasets that are widely recognized and utilized in the field of gesture recognition research. Each dataset brings its own set of characteristics and complexities, providing valuable resources for training, testing, and validating gesture recognition models.

1) Chalearn gesture dataset: Many public datasets for evaluating gesture recognition contain only one form of gesture The Chalearn Gesture Dataset contains nine gesture categories corresponding to various settings and application domains. It contains both static postures and dynamic gestures. In this dataset, a static posture is one in which a single posture is held for a certain duration. For a static hand posture, the hand is held at similar positions for multiple instances of the same gesture. In this case, the static postures also have distinct paths so they could be handled by the same method as the dynamic gestures. This dataset does not contain gestures with distinct hand poses but arbitrary movement [17].

2) Jester dataset: The Jester Dataset is a collection of hand gesture data intended for gesture recognition research and development. It contains videos of hand gestures performed by individuals, captured using webcams or other recording devices. The dataset includes a variety of gestures, such as waving, pointing, and making shapes with the hands. Each gesture is labelled with its corresponding class, allowing machine learning algorithms to be trained and evaluated on the data [18].

3) MSR action3D dataset: This dataset consists of depth data capturing human actions and gestures performed by multiple subjects. It provides a large collection of annotated gesture sequences, making it suitable for training models for gesture recognition in HCI applications [3].

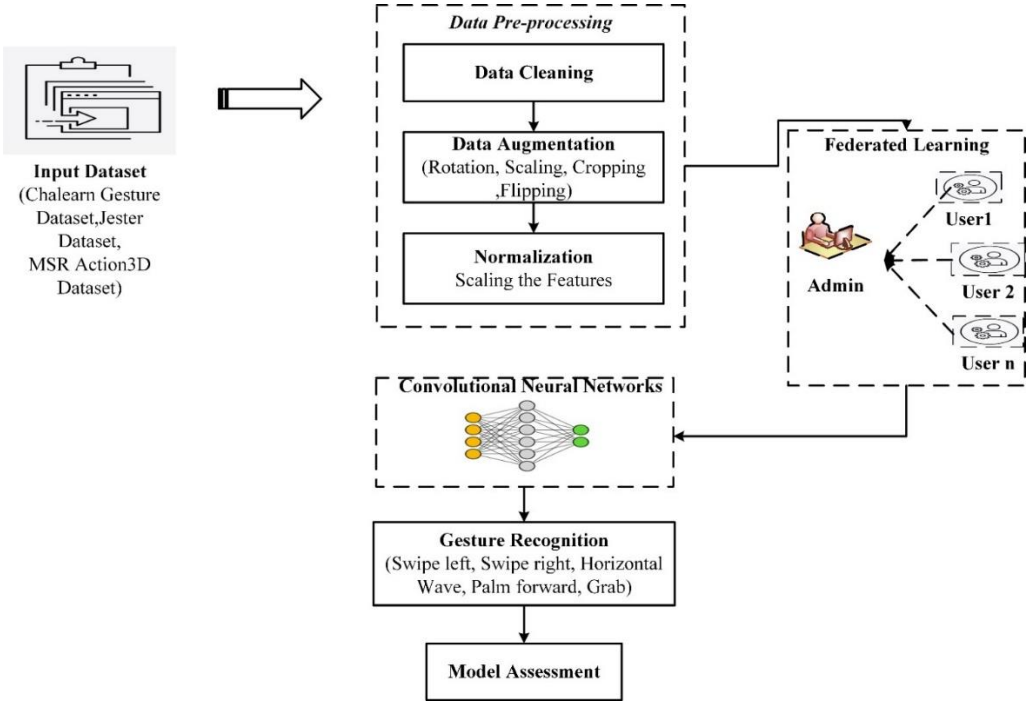

Fig. 1. Proposed real-time gesture recognition for seamless interactions between humans and computers using federated convolutional neural networks.

B. Data Pre-processing

The datasets go through pre-processing steps before the model is trained. These steps include data cleaning to remove noise and inconsistencies, data augmentation to improve the robustness of the model by using techniques like rotation and scaling, normalization to scale features uniformly for improved training convergence, and recognition of relevant aspects from the gesture sequences, such as key points and spatial-temporal features. These pre-processing steps guarantee that the datasets are optimized for the purpose of developing reliable and efficient gesture recognition models [19].

C. Federated Learning for Collaborative Training Across Decentralized Devices

The data used for training provided by the client are per C_a the concept of federated learning, which assumes shared there are actually N clients taking part in the shared model training. The loss function that is the result of just one sample $f_b(x)$. Providing that w is the model's weighting parameter. Consequently, the i th client's loss function is computed in Eq. (1).

$$F_a(x) = \frac{\sum b \in C_a f_b(x)}{|C_a|} \quad (1)$$

$|C_a|$ is a representation of the dataset's volume over them. Next, the federated sharing algorithm's loss function is examined in Eq. (2).

$$F(x) = \frac{\sum_{a=1}^{N} |C_a| F_a(x)}{|C|} \quad (2)$$

$|C| = \sum_{a=1}^{N} |C_a|$ is one of them; observe that is $F(x)$ is unable to calculated directly without transferring data across several nodes.

The federated learning training process. Following weighting averaging, the server gathers all of the model parameters submitted by every client during every iteration and delivers these for every client to finish updating the model's local parameters [20].

D. Convolutional Neural Networks (CNNs) in Gesture Recognition

The CNN architecture underlying the gesture classes considered in the present research. The CNN framework is constructed via a layer of input, three convolution layers, one soft maximum output layer, one completely interconnected output layer, and ReLu and maximum pooling layers for the extraction of features. The following work's images are initially resized to 100 by 100 pixels, and the dataset is divided into testing and training sets. The input layer feeds hand-pose RGB images to later sections for extracting features and classification. The convolution layer is the key for further learning with CNN's endurance. CNN uses intermediate mappings of features and cascaded discontinuous convolution of the kernels using the full image to get an especially promising features for characterizing gives the convolution coefficients of a picture or map of features f with kernel (square matrix). The total number of filters in all layers of convolution is empirically determined through experimentation is given in Eq. (3).

$$a \times k = \sum_{y,z=0}^{r-1} (\ a_i + y, j + z)(yr - z) \quad (3)$$

The following three layers of convolution make up the proposed design: eight 19 by 19 filters are placed into the very first layer, sixteen 17 by 17 filters are placed in the second layer, and 32 15 by 15 filters are placed in the final layer. The padding is used by each convolutional layer to keep the result size constant with the input. Multiple neurons with the ReLu

activation function receive the result of the convolution procedure. It substitutes 0 for those with negative values within the pooling layer using the non-saturating and the non-linear algorithm Because of its expressive sparseness and ease of computation, ReLu is the recommended option for activation functions in neural networks with deep layers. The feature maps are resized by the pooling layer, that is added after each ReLu layer, avoiding losing any of the most important components. The pooling function employed in this study is maxpooling, which outperforms all of the others owing to its quick performance and improved converging properties. Using a filter size of (2,2) and a stride of (3,3), the maximum pooling procedure is carried out following the selection of the highest possible value for every local region in the maps of features by every convolution layer issue is given in Eq. (4).

$$c = \max(0, d) \quad (4)$$

The best discriminative features retrieved by the numerous stacked architectures made up of the convolution layers, ReLu layers, and pooling layers are supplied into the input channel of the classification layer, that has been built out of a softmax layer and an entirely linked layer/output layer. The neural network that is part of the softmax layer contains the exact same number of neurons as the result of the layer and transforms the values of features from 0 to 1 using a multiple classes sigmoid function. In a matter of fact, the vector of features that is obtained using this layer of data is able to predict with high accuracy when patterns could be seen in an image. Using the feature vector generated by the soft max layer, the last layer with full connection categorizes the input photographs into the relevant gesture classes [21]. The amount gesture categories are associated with the amount of neurons in this layer. FED-CNN Architecture is shown in Fig. 2.

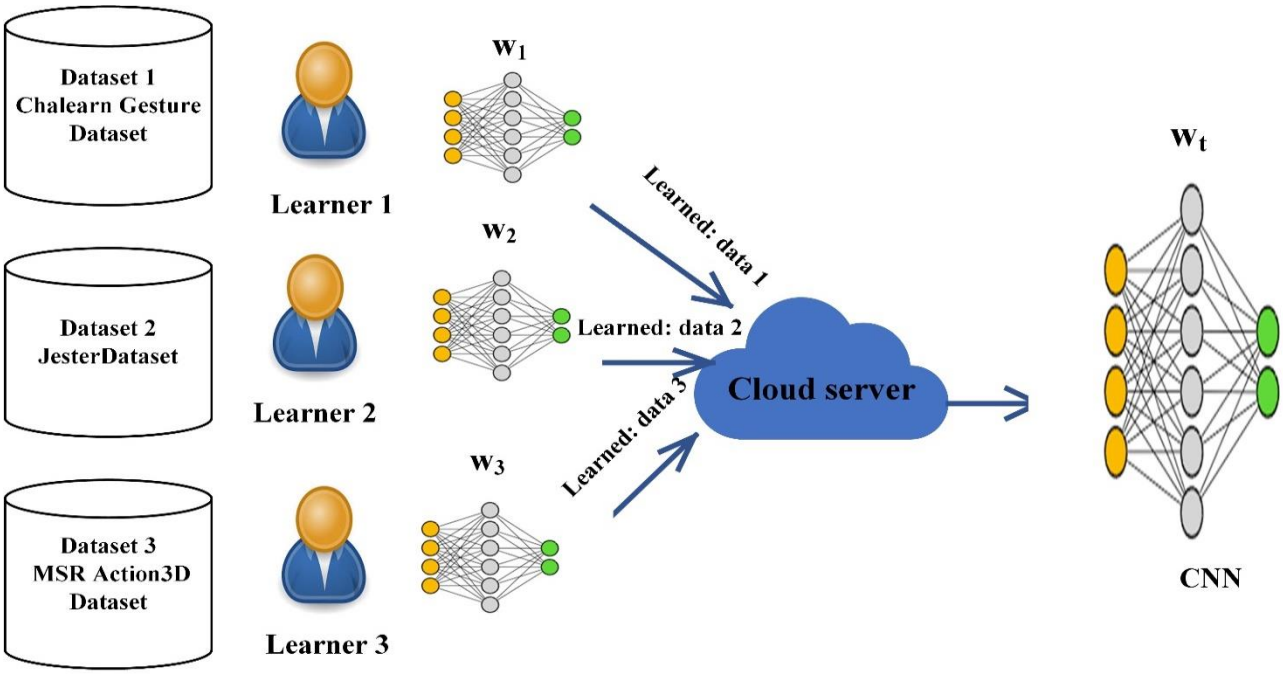

Fig. 2. Federated learning.

V. Result and Discussions

The proposed federated convolutional neural network (CNN) approach for real-time gesture detection demonstrates outstanding performance and responsiveness while addressing privacy and security concerns. Through extensive testing on benchmark datasets, the system consistently outperforms centralized learning methods, achieving state-of-the-art results in gesture recognition tasks. By leveraging federated learning, the model is trained collaboratively across decentralized devices without compromising user privacy, as raw data remains local. This approach ensures continuous model refinement and adaptation to dynamic environments by aggregating local model updates from edge devices. Moreover, enhancements such as differential privacy, adaptive learning rate scheduling, and model compression techniques contribute to minimizing privacy risks and communication overhead, while accelerating convergence. The federated architecture not only guarantees improved responsiveness and adaptability but also ensures the confidentiality and integrity of user data, making it suitable for sensitive human-computer interaction applications. Overall, the proposed design offers a promising avenue for advancing real-time gesture detection systems, enabling more natural and intuitive interactions while safeguarding user privacy and data integrity.

Table I presents the Gesture Recognition Classes in the Jester dataset, categorizing gestures based on their type and granularity. The dataset includes a variety of hand movements and interactions commonly used for controlling electronic devices or interacting with computers. Each gesture is classified as either "Fine" or "Coarse" based on the level of detail and precision involved in its execution. For instance, fine gestures such as swiping left or right and presenting the palm forward require more intricate movements and precision,

while coarse gestures like various finger gestures and pointing gestures involve broader and less specific hand movements. This classification scheme provides insight into the diversity of gestures captured in the dataset, facilitating the development and evaluation of gesture recognition algorithms across different levels of granularity and complexity.

Fig. 3 illustrates how these neural networks learn and generalize in different ways across 100 epochs by comparing the Training and Testing Accuracy for three different datasets, these losses decrease with time, indicating that the model is learning new abilities and improving in performance. In parallel with the training accuracy's more gradual growth over the epochs, testing accuracy likewise experiences a steady increase upon reaching subsequent epochs.

Fig. 4 illustrates training and testing losses, which also illustrates the various methods in which these networks learn and generalize over 100 epochs. These losses decrease with time, indicating that the model is learning new abilities and improving in performance. The testing loss starts at a higher value than the training loss and then drops sharply before collapsing at epoch 20, whereas the training loss decreases more gradually over the course of the epochs.

TABLE I. GESTURE RECOGNITION CLASSES IN JESTER DATASET

Class	Gesture	Grain
0	Swiping left or right	Fine
1	Waving horizontally	Coarse
2	Presenting the palm forward	Fine
3	Making a grabbing motion	Fine
4	Various finger gestures	Coarse
5	Pointing gestures	Coarse
6	Thumbs up or thumbs down	Coarse
7	OK sign	Fine
8	Peace sign	Coarse

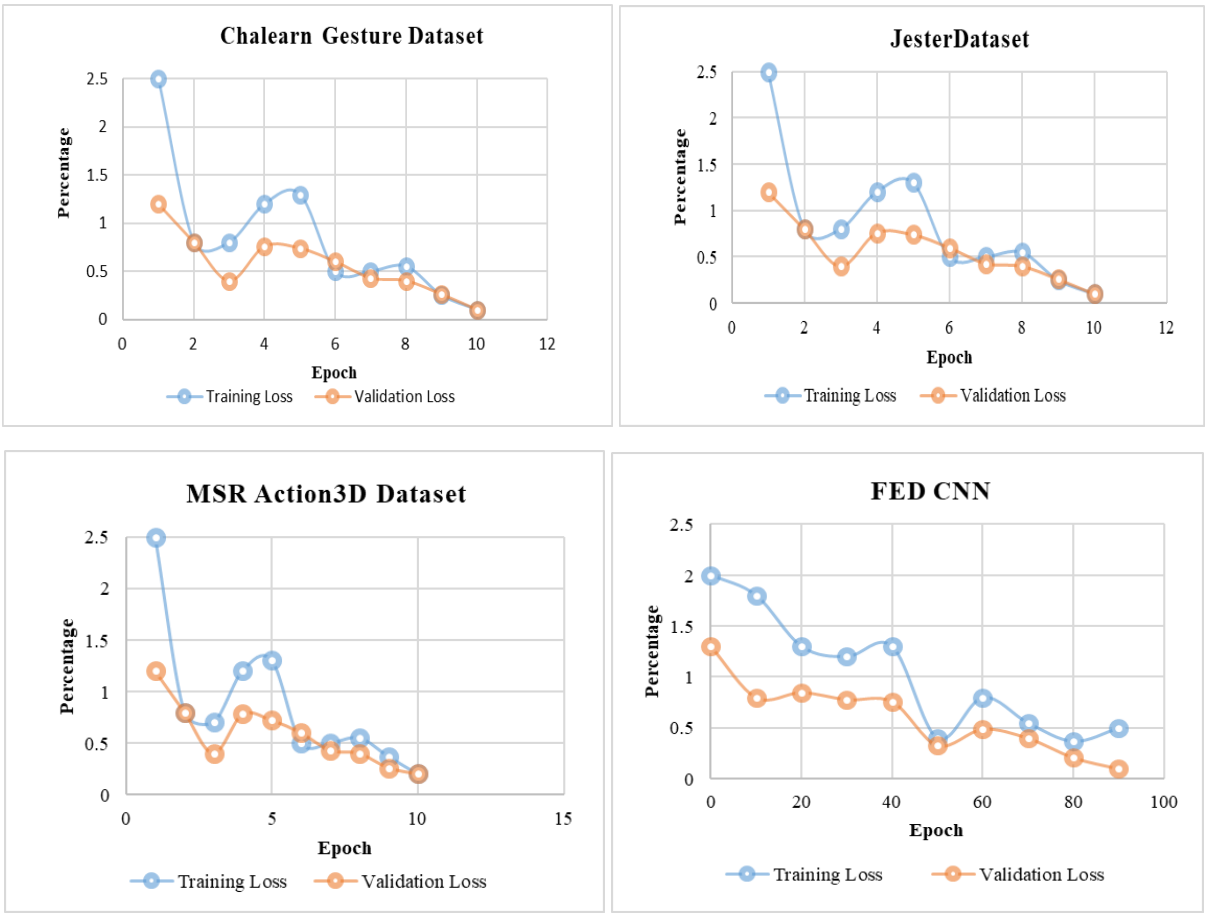

Fig. 4. Training and Testing Loss of CNN model for three different dataset and FED-CNN

TABLE II. COMPARISON THE PERFORMANCE OF PROPOSED METHOD WITH EXISTING METHOD

Approach	Dataset	Accuracy (%)
Siamese Network [22]	NVIDIA	81.2%
LSTM [23]	DHG	90.87%
RNN [24]	MSRC-12	60-87%
GAN [25]	ASL Alphabet dataset	89-96%
RNN [26]	AMFED and EmoReact	93.09%
CNN [27]	ChaLearn Looking at People (LAP)dataset	90.57%
Resnet [28]	EGO Gesture Dataset	75.30%
GoogleNet [29]	UCI Hand Gesture Dataset	87%
Proposed Framework (FED CNN)	Chalearn Gesture, jester, MSR Action3D	98.70%

Table II presents a comparative analysis of various gesture recognition approaches using different datasets and their corresponding accuracy percentages. Each approach utilizes different deep learning architectures such as Siamese Networks, LSTM, RNN, GAN, CNN, ResNet, and GoogleNet, trained on specific gesture datasets. Notably, the proposed federated CNN framework achieves the highest accuracy of 98.70% by leveraging data from three diverse datasets: Chalearn Gesture, Jester, and MSR Action3D. This indicates the effectiveness of the federated approach in combining data from multiple sources to enhance model performance significantly, showcasing its potential for robust and accurate gesture recognition across various applications and environments. It is visually shown in Fig. 5.

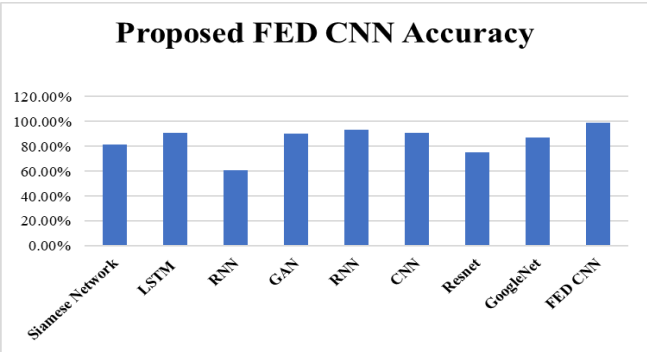

Fig. 5. Performance evaluation of fed -CNN with existing framework.

The Receiver Operating Characteristic (ROC) curve for the federated convolutional neural network (CNN) illustrates in Fig. 6 has ability to classify between true positive and false positive rates across different thresholds, providing insight

into the model's overall performance. A higher area under the ROC curve signifies better discrimination capability of the federated CNN in distinguishing between classes, indicating its effectiveness in real-time gesture detection tasks.

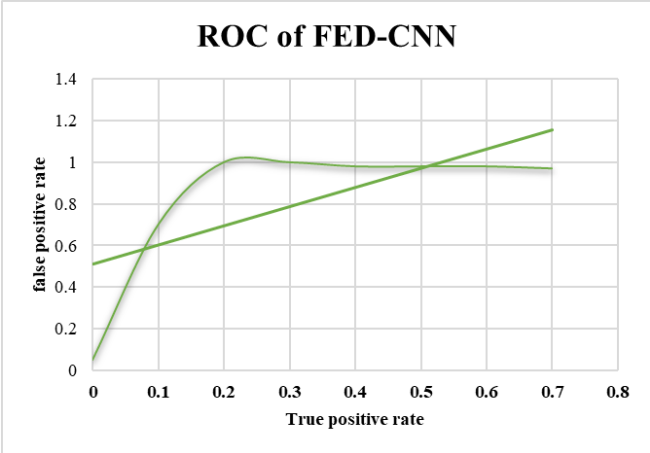

Fig. 6. Roc curve.

A. Discussions

The significant advancements and contributions of the proposed federated convolutional neural network (CNN) approach for real-time gesture detection. By leveraging federated learning, the system addresses critical challenges such as privacy, security, and responsiveness, making it well-suited for a wide range of human-computer interaction (HCI) applications [12]. Through extensive testing and improvements in federated learning techniques, the approach demonstrates superior performance compared to centralized learning methods, offering improved adaptability and reliability in dynamic environments. Moreover, the decentralized architecture ensures user confidentiality and data integrity, enhancing trust and usability in sensitive HCI scenarios. Overall, the discussions underscore the promising potential of the proposed approach in advancing real-time gesture detection systems while maintaining a strong focus on user privacy and data security.

VI. Conclusion and Future Work

In conclusion, the proposed approach leveraging federated convolutional neural networks (CNNs) presents a promising solution for real-time gesture detection, addressing the challenges of maintaining user privacy and data security while ensuring excellent performance and responsiveness in various HCI contexts. By utilizing federated learning, the model can be trained collaboratively across decentralized devices without compromising sensitive user data. Through extensive testing on benchmark datasets, the federated CNN approach demonstrated state-of-the-art performance, outperforming centralized learning techniques and offering improved adaptability to dynamic environments. For future work, further enhancements can be made to the federated learning system to optimize responsiveness and speed. Incorporating techniques like differential privacy and adaptive learning rate scheduling can further mitigate privacy risks and communication overhead, respectively. Additionally, exploring advanced model compression techniques can help accelerate convergence and reduce resource consumption, making the system more efficient for real-time applications. Furthermore, research efforts can focus on expanding the application scope of federated CNNs to other domains beyond gesture recognition, such as voice recognition or medical imaging, to explore their potential in diverse HCI scenarios. Overall, continued research and development in this direction hold promise for advancing the field of real-time gesture detection while upholding user privacy and data integrity.

Abstract*—Semantics describe how language and its constituent parts are understood or interpreted. Semantic analysis is the computer analysis of language to derive connections, meaning, and context from words and sentences. In English language learning, dynamic content generation entails developing instructional materials that adjust to the specific requirements of each student, delivering individualized and contextually appropriate information to boost understanding and engagement. To tailor instructional materials to the various requirements of students, dynamic content creation is essential in English language learning (ELL). This work is a unique method for automatic and adaptive content production in ELL that uses Gated Recurrent Unit (GRU) and Bidirectional Encoder Representations from Transformers (BERT) together. The suggested approach uses BERT enabling content selection, adaption, and adaptive educational content production, and GRU for semantic extraction of features and contextual information captured from textual input. The article presents a novel approach to creating automated and adaptable educational tools for ELL that uses GRU for semantic feature extraction. Using persuasive essays collected in the PERSUADE 2.0 corpus annotated with discourse components and competency scores, this is an extensive dataset. After extensive testing, this approach shows outstanding outcomes, with high accuracy reaching 97% when compared to the current Spiking Neural Network (SNN) &Convolutional Neural Network (CNN), Logistic Regression (LR), and Convolutional Bidirectional Recurrent Neural Network (CBRNN). Python is used to implement the suggested work. The suggested strategy improves ELL engagement and understanding by providing individualized, contextually appropriate learning resources to each student. In addition, the flexibility of the system allows for real-time modifications to suit the changing needs and preferences of the learners. By providing instructors and students in a variety of educational contexts with a scalable and effective approach, this study advances automated content development in ELL. The model architecture will be improved in the future, along with the application's expansion into other domains outside of ELL and the investigation of new language aspects.

Keywords*—BERT; Content Generation; English Language Learning; Gated Recurrent Unit; Semantic Analysis

I. Introduction

Semantics is a subfield of linguistics that studies the way language is understood. The literal meaning of words and sentences as essential components of the world is the subject of semantics. Semantic analysis, as applied to NLP, assesses and reflects human language. It also examines documents written in English alongside other natural languages, interpreting them similarly to the way people would [1]. The prevalence of documented information from both academic and business settings is growing, and its encounter in various contexts by various scientists and scholars suggests that researchers seeking high system efficiency are drawn to collecting details, processing languages, and information retrieval due to their rapid growth. Assert that scholars from a range of fields are interested in classifying characteristics such as study themes, methodologies, and theories related to the research nature by analysing descriptions, and titles, and publishing the entire text bodies. Numerous interdisciplinary areas have evolved in the last several decades, encompassing biochemistry, the field of engineering, data mining, neurology, and bioinformatics. It might be challenging to comprehend every step of the research process in these subjects since interdisciplinary environments incorporate theories, methodologies, and approaches from other fields [2]. Therefore, a system for classifying texts and documents according to their relevant structures ought to exist. Semantic analysis is the technique used by academics and researchers to categorize texts according to their underlying structures. Assert that the exact significance and understanding associated with dictionary meaning derived

from structures created by syntactic evaluation are assigned by semantic analysis. To understand why language conveys meaning, semantics, a discipline of linguistics, studies how language interacts with several "linguistic categories, syntax, phonology, and lexicon". Semantic analysis, in this sense, focuses on the meaning of words and phrases as components of the world [3].

ELL has a unique position at the nexus of global interaction and educational progress, as millions of people pursue English language proficiency for personal, professional, and academic purposes. The process of learning English is dynamic and ever-changing, and it is essential in the globalized society of today. Since English is the universal language of commerce, education, and worldwide communication, speaking the language well has become more crucial for those who want to succeed in a variety of academic and professional settings. Because of this, there is an increasing need for creative and efficient language learning solutions, which is driving instructors and developers to investigate novel ideas to cater to the various demands of students [4]. Conventional approaches to teaching languages frequently depend on static resources like lectures and textbooks, giving students few chances for interaction and customization. Nonetheless, the way English is taught and understood is being completely transformed by recent developments in educational technology, especially in the area of dynamic content creation. Teachers may design individualized, multimedia lessons that are tailored to each student's requirements and preferences by utilizing the effectiveness of semantic analysis with adaptive algorithms. In English language learning, dynamic content production refers to the automated modification and personalization of course content according to student's interests, learning preferences, levels of competence, and advancement. With dynamic content production, teachers may provide individualized learning experiences that maximize student engagement, understanding, and learning outcomes, in contrast to static resources that provide a generic approach to training [5]. Semantic analysis, a subfield of NLP that focuses on comprehending the context underlying meaning of text, is fundamental to the creation of dynamic content.

Automated and adaptive educational materials represent a transformative approach to learning, leveraging technology to tailor instruction to the individual needs and preferences of learners. These materials are designed to dynamically adjust content, difficulty level, and instructional strategies in real-time, offering personalized learning experiences that optimize engagement, comprehension, and retention. Automation in educational materials involves the use of algorithms and artificial intelligence to streamline various aspects of the learning process, from content creation to assessment [6]. The proposed work introduces an innovative approach to dynamic content generation in ELL by leveraging a combination of GRU and BERT. This model integrates GRU for semantic feature extraction and contextual understanding, while BERT facilitates content selection, adaptation, and the generation of dynamic learning materials tailored to individual learner needs. By automating the process and adapting content in real-time, the proposed approach enhances learner engagement and comprehension. Rigorous experimentation and human evaluation studies validate the efficacy of the model, demonstrating its ability to produce high-quality, contextually relevant educational materials. Furthermore, the proposed approach addresses the limitations of existing systems by providing personalized and adaptive learning experiences, promoting active participation and knowledge retention in ELL. This research contributes to advancing automated content generation in ELL, providing a scalable and efficient solution for educators and learners in diverse educational settings. By combining the BERT and GRU models, this project aims to provide a novel method for automating the development of dynamic instructional materials for ELL. This study aims to investigate the viability and effectiveness of using BERT for content adaptations and GRU for semantic feature extraction to provide dynamic learning resources. The project also intends to create a system that can provide customized learning materials by responding in real time to the preferences and requirements of each student. Additionally, it seeks to determine how the suggested strategy affects learner engagement, understanding, and general learning outcomes for English Language Learners. It also wants to determine how scalable and effective the approach is across a range of learning contexts and student populations. Additionally, the study aims to investigate how the suggested method, which takes into account the varied linguistic origins and skill levels of students, might advance inclusion and accessibility in ELL practices. Ultimately, by overcoming current methodological constraints and encouraging innovation in content creation for language teaching, this project hopes to develop educational technology.

The study's findings have important ramifications for both educational technology and the ELL community. The main issues with standard ELL techniques are addressed in this work by investigating the combination of BERT and GRU models for the automated creation of dynamic resources. The relevance is in the ability to completely transform language learning by offering individualized, contextually relevant learning resources that are catered to the requirements and preferences of each student. This method takes into account the varied linguistic origins and skill levels of the learners, which not only improves student engagement and understanding but also encourages inclusion and accessibility in ELL activities. Additionally, by overcoming the drawbacks of existing techniques and encouraging creativity in the creation of language-learning content, the research advances educational technology. In the end, this study's findings may enhance ELL instruction and learning opportunities, resulting in more successful language proficiency growth and acquisition.

The remaining sections are arranged as follows. Section I provides an introduction. Section II provides illustrations for the literary sections. Section III contains the problem statement. Section IV discusses the recommended methodology for analysing semantics and content production using GRU and BERT. In Section V, the efficacy metrics are displayed and the findings are gathered. Section VI presents a conclusion and Section VII presents the future research.

II. Related Works

A. Narrative-Centric Learning Experiences

Diwan et al., [7] suggested that in online learning settings, maintaining student engagement is a significant problem that becomes even more intense as learning spaces are progressively constructed by fusing information from several separate sources. Numerous researchers have discovered that learner involvement may be enhanced through narrative-centric learning experiences. To do this, they provide an AI-based method that produces so-called narrative fragments, which are supplementary learning materials that are included in the learning pathways to produce interactive learning narratives. The suggested method involves automatically creating two different kinds of narrative fragments: summaries of the learning route sections and formative evaluations, such as reflection quizzes, utilizing instructional assets in any format, including publicly available educational materials. A pre-trained language approach, GPT-2, serves as the foundation for an NLG component in the pipeline that generates the story fragments. The other components depend on different semantic models. Automation makes it possible to create story segments instantly anytime the learning route has to be modified prerequisite information, etc. This allows for flexibility in the learning paths. Because the suggested method is domain-agnostic, it may be readily modified to work in several domains. ROUGE scores are used to compare the NLG model to many baselines. Human evaluators assess story pieces that are consequently created. In both instances, they had positive outcomes.

B. Text Generation Systems

Hua et al., [8] recommended a three essential elements are needed for establishing an effective text generation system: surface realization, text planning, and content selection. Typically, these issues have been addressed independently. While recent all-in-one neural generating approaches have achieved tremendous strides, they frequently yield inconsistent and erroneous outputs relative to the input. In order to tackle these problems, they provide a beginning-to-the-end learned two-step generation model: first, a sentence-level content organizer determines the language style and key phrases to cover; subsequently, an outer manifestation decoder produces meaningful and cohesive text. They take into consideration three goals for trials, which come from realms with different themes and linguistic styles: creating an abstract for scientific publications, creating paragraphs for regular and basic Wikipedia pages, and creating compelling arguments from Reddit. The remedy can exceed rival inquiries by a large margin, according to automatic evaluation. In addition, human judges find system-generated writing to be more accurate and fluent than versions that do not take linguistic style into account. This model is beneficial, as evidenced by experimental data, where it outperforms complex comparisons in terms of BLEU, ROUGE, and METEOR scores. When it comes to language style, human subjects likewise evaluate their model generations as being more grammatically accurate and grammatical.

C. Sentiment Analysis in MOOC Reviews

Onan et al., [9] states that MOOCs [10] are a relatively new and creative kind of distance learning that allows participants to access course materials regardless of their age, gender, race, or location. By adopting the concepts of ensemble learning as well as DL, this study aims to propose an effective sentiment categorization method with good prediction performance in evaluations of massively open online courses. They want to address several research inquiries regarding sentiment analysis of educational data in this contribution. Initially, an assessment was made of the prediction abilities of DL, ensemble learning, and traditional supervised learning techniques. Also, assessments of massively open online courses have been used to assess the efficacy of word-embedding and visualizing text systems for sentiment assessment. Using ML, ensemble learning, and DL techniques, they examined a corpus of 66,000 reviews of massively open online courses for the evaluation assignment. The empirical research shows that for the job of sentiment assessment in educational data mining, deep learning-driven architectures perform better than ensemble learning approaches and supervised learning methods. Through a rate of classification of 95.80%, extended short-term memory networks alongside the GloVe word-embedding scheme-based depiction have produced the best prediction performance across all evaluated configurations.

D. Adaptive E-learning Environments

El-Sabagh et al., [11] states that designing suitable adaptive e-learning environments helps to personalize training to reinforce learning goals since adaptive e-learning is seen as a stimulus to enhance education and student engagement. This work aims to investigate how students' involvement is affected by an adaptable online educational setting that is designed according to their learning styles. Additionally, this study aims to describe and contrast the suggested flexible online learning setting with a traditional e-learning methodology. The following combined research approaches were utilized to examine the impact and form the basis of the paper: The adaptive e-learning environment is designed using a development approach, and the research experiment is carried out using a quasi-experimental research design. The following affective and behavioural components of involvement are measured by the student participation scale: skills, performance, emotions, participation/interaction, and abilities. According to the findings, there is a statistically significant difference between the experimental and control groups. These experimental findings suggest that an adaptable online learning environment may be able to motivate pupils to learn. This study makes a number of useful recommendations, including ways to boost the influence of online adaptive courses in education and increase the cost-effectiveness of education. It also discusses how to develop a foundation for adaptive online education based on preferences for learning and their implementation. In order to increase student engagement, e-learning institutions can create more individualized and adaptable learning environments with the aid of the suggested adaptive e-learning strategy and its findings.

E. Advanced NLP Techniques for English Learning

X. Guo et al., [12] states that because of its potential to completely transform oral learning, the application of sophisticated methods of NLP in education has gained popularity. Because self-learning is flexible and accessible, it has gained popularity in oral English learning. Students may now approach language learning on their own terms through the development of digital materials and applications. This study introduced a unique framework for improving oral English learning that combines the strengths of the HCRM and the BERT model. The main objective is to give educators and organizations a strong instrument for assessing the appropriateness and quality of oral learning resources. Analysis of sentiment, characteristic collection, and categorization are all integrated into the HCRM architecture, which makes it a complete solution for determining a document's appropriateness for use in the context of oral English learning. To ensure a comprehensive understanding of the efficacy of the oral learning materials, the model considers the viewpoints of both instructors and students. Through efficient sentiment analysis and feature extraction, the HCRM enables a more nuanced comprehension of the possible effects of instructional materials. The results of this study imply that the combination of BERT and HCRM offers a more precise, comprehensive, and data-driven method of material assessment, which might significantly improve oral English learning. The novel approach this study proposes has the potential to raise the quality and applicability of oral learning resources in the field.

Innovative ways to improve learner engagement and content creation in online learning environments have been studied in the field of educational technology in the past. Nevertheless, a critical analysis of these initiatives identifies their advantages and disadvantages. Even while research like those by Diwan et al. and Hua et al. present interesting techniques like text generation models and story fragments, they sometimes lack thorough assessments and may ignore larger educational settings. Comparably, studies conducted by Onan et al. [9] and El-Sabagh et al. [11] explore sentiment analysis and adaptive e-learning settings, respectively, but they might not adequately account for how student preferences are dynamic and how the online education landscape is changing. Even though it is a novel framework, X. Guo et al.'s [12] approach to oral English learning may overlook learner involvement and interaction, which is essential for comprehensive learning experiences. In order to optimise educational experiences across a variety of learning situations, future endeavours should aim for more integrated and comprehensive methods, taking into account the interaction between technology, pedagogy, and learner engagement. Overall, while these studies offer valuable insights into different aspects of educational technology and online learning, there is a clear research gap in integrating these approaches to create holistic and adaptive learning experiences that effectively engage learners across diverse contexts and domains. Prior research has exhibited inventive artificial intelligence (AI) approaches, such as deep learning methods and story fragment production, to support sentiment analysis and learner engagement in educational data mining. Furthermore, the development of comprehensive frameworks such as the two-step generating model and the integration of HCRM and BERT represents advancements in the production of coherent learning materials that prioritize the quality of language and content, hence enhancing the quality of educational experiences. Some research has a limited scope and lacks comparison analysis, which makes it difficult to appraise and generalize the suggested techniques. Furthermore, the need for strong experimental designs and practical considerations to solve real-world implementation obstacles in automated content production for educational contexts is highlighted by methodological rigor and scalability issues in several research. Future research should aim to bridge this gap by exploring integrated approaches that consider both content generation and learner interaction to optimize engagement and learning outcomes in online environments.

III. Problem Statement

The inadequacies of the current ELL systems frequently prevent them from effectively fulfilling the varied demands of students. Conventional methods of content creation and personalization might not be as flexible as they should be as they depend on static resources that can't be constantly tailored to the unique interests and profiles of each learner. Furthermore, these algorithms might not be able to fully grasp the subtle semantic nuances of language, which could result in inadequate adaption and selection of information. Moreover, even if some systems use ML methods, it's possible that they don't fully make use of the potential of sophisticated neural network designs for content creation and semantic analysis [13]. The suggested study integrates innovative methods like semantic evaluation using GRU and BERT to overcome these constraints. The suggested framework provides an all-encompassing and flexible response to the problems in ELL by utilizing semantic analysis techniques to comprehend language structure and meaning, along with the excellent abilities of GRU for extraction of features and BERT for content choosing, adjustment, and evolving material generation. The objective of this integration is to improve student engagement, understanding, and uptake in the ELL domain by making instructional resources of higher quality, more relevant, and more effective.

IV. Integrating Semantic Analysis with GRU and BERT for Dynamic Content Generation in English Language Learning

The suggested approach combines GRU and BERT with semantic analysis to provide dynamic material for ELL. To guarantee consistency and simplicity, the textual data—which includes learner profiles and essays gathered from the PERSUADE 2.0 corpus—first goes through pre-processing. POS tagging is used in semantic analysis to obtain syntactic structures and grammatical information from the text. Subsequently, GRU—a recurrent neural network architecture—is utilized to derive semantic features, which include contextual data and semantic correlations found in text sequences. The selection, modification, and creation of dynamic learning materials are then done using BERT. By measuring the semantic similarity between learner profiles and texts using BERT embeddings, pertinent information may be

chosen and materials can be customized to fit the requirements and preferences of specific learners. Furthermore, BERT's language production capabilities enable the dynamic generation of explanations, quiz questions, and summaries as well as other individualized learning tools. The technique is used methodically, building upon the algorithmic strategy and assessing the framework's efficacy through empirical research using metrics for learner engagement, comprehension tests, and user feedback. By offering automated and adaptable instructional resources that are customized to meet the needs of specific learners, in the area of ELL. The suggested work approach process is shown in Fig. 1.

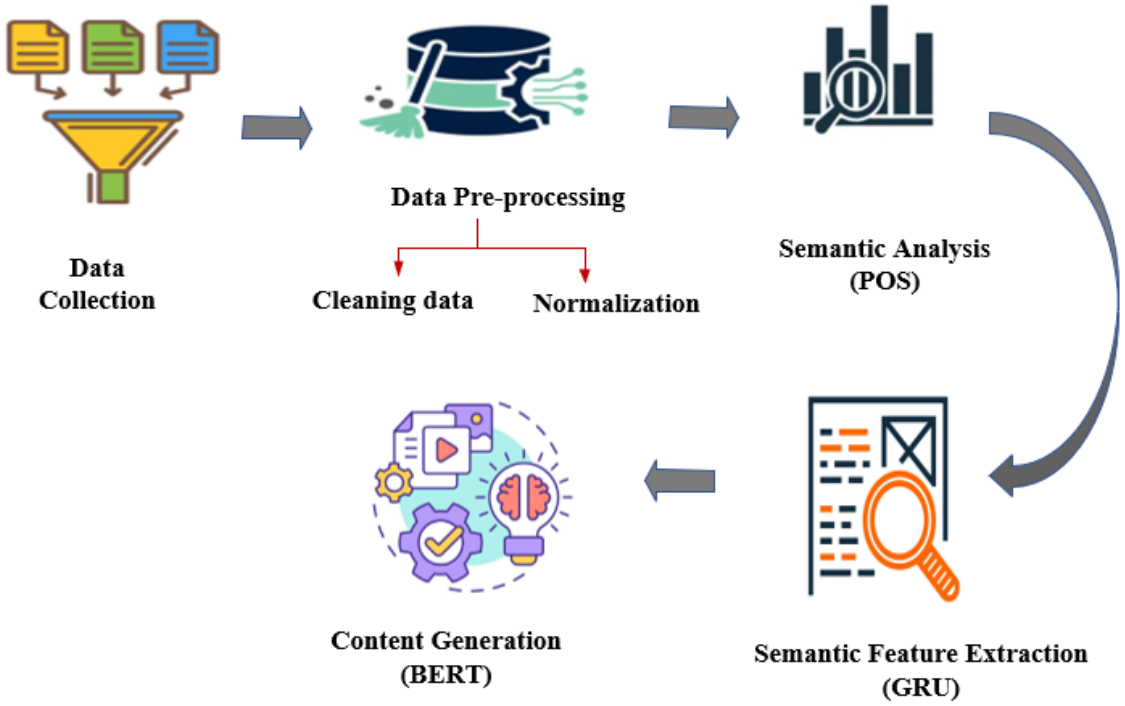

Fig. 1. Semantic analysis with GRU and BERT for dynamic content generation in ELL.

A. Data Collection

The PERSUADE 2.0 corpus [14] provides an extensive dataset for analysing argumentative essays written by American students in grades 6 through 12. This corpus, which includes over 25,000 essays addressing 15 prompts from both autonomous and source-based writing assignments, is an invaluable tool for researching argumentation structures and discourse features. Every essay in the entire collection has a thorough annotation that covers discourse aspects like prospects, roles, states, objections, responses, supporting details, and summaries at the end. The annotation rubric, which was created via a meticulous double-blind grading procedure and was influenced by well-known frameworks such as the Toulmin argumentation model, guarantees consistency and dependability within the dataset. The corpus also contains individual and demographic data for each writer, integrative essay ratings, and competency scores for arguing aspects. The PERSUADE 2.0 corpus is an invaluable resource for research in the fields of discourse analysis, writing training, and ML approaches in education since it includes full-text essays combined with annotations and metadata. The information that has been gathered for the suggested work is shown in Table I.

TABLE I. DATA COLLECTION

Column Name	Description
essay_id_comp	The ID of the essay
competition_set	Indicates whether the essay was part of the training or the test set in the Feedback Prize
full_text	The full text of the essay
discourse_id	The ID for the discourse element
discourse_start	Character position in the essay where the discourse element starts
discourse_end	Character position in the essay where the discourse element ends
discourse_text	The text of the discourse element
discourse_type	Human annotation for the discourse element, providing a description of its type
discourse_type_num	Number representing the discourse element within the essay

B. Data Preprocessing

Preprocessing textual input is an essential stage in NLP activities, such as the work that is being suggested to generate dynamic content for ELL. To guarantee the textual data's cleanliness, consistency, and uniformity—a need for further analysis and modelling—this procedure entails a number of crucial processes. Eliminating any extraneous characters, symbols, or stylistic artifacts that might impede the analysis process is the process of cleaning textual data. By ensuring that the written word is consistent and noise-free, this stage facilitates the extraction of important information. Eliminating HTML elements, special characters, and punctuation can improve the text's readability and analytical value. To preserve consistency throughout the dataset, cleaning textual data in the setting of the PERSUADE 2.0 corpus may entail deleting unnecessary symbols or formatting within argumentative essays. By using uniform formatting guidelines, normalization seeks to normalize the textual data. This entails resolving variances in spelling or capitalization, reducing all letters to lowercase, and eliminating accents and diacritical marks. By ensuring that similar terms are handled in the same way, normalization helps to reduce repetition and inconsistencies within the dataset. To reduce the influence of case sensitivity on further analysis and modelling procedures, normalizing the PERSUADE 2.0 essays within the framework of the proposed study would entail changing every character to lowercase. As an illustration, consider the original text, "The Importance of Education Cannot be Overstated." Normalized Text: "It is impossible to overestimate the value of education." The textual data collected in the PERSUADE 2.0 corpus is cleaned and standardized by completing these preparation processes, making it suitable for additional evaluation and simulation in the setting of dynamic content creation. These processed texts are the starting point for the extraction of semantic information, the construction of prediction models, and the creation of customized learning resources based on the requirements and preferences of specific learners.

C. POS for Semantic Analysis

A key activity in NLP is called Part-of-Speech (POS) tagging, which involves giving each word in a text corpus a classification according to grammar (such as noun, verb, adjective, etc.). Following pre-processing textual information from the PERSUADE 2.0 corpus, POS tagging is essential for semantic analysis within the suggested method for dynamic content production in ELL. To do POS tagging, linguistic information from each word, such as its capitalization, suffix, prefix, nearby words, and syntactic dependencies, are usually extracted. These characteristics aid in the POS tagger's decision-making on each word's part of speech. Probabilistic models, such as HMMs or CRFs, are frequently used by POS taggers to allocate POS tags to words in sentences. These algorithms determine a word's likelihood of falling into a certain speech segment based on its context and words that have already been labelled in the series. Large annotated datasets, in which each word is carefully tagged with its matching part of speech, are frequently used to train POS taggers. In order to produce precise predictions on material that hasn't been read yet, the POS tagger must first learn linguistic rules and statistical trends from the training set. For each word, linguistic features are extracted, such as capitalization, word shape, prefix, suffix, and neighbouring words. In the proposed work for dynamic content generation in ELL, POS tagging is used after pre-processing the textual data to extract syntactic information from the essays in the data collection. By identifying the parts of speech of words in the essays, the POS tags provide valuable insights into the grammatical structure of the text, which can inform subsequent semantic analysis, feature extraction, and content generation processes. This enables the system to understand the syntactic relationships between words and phrases in the essays, facilitating the generation of coherent and contextually relevant learning materials tailored to individual learners' needs and proficiency levels.

1) Tokenization: Tokenization is the process of breaking up the text into distinct sentences or tokens before POS tagging is carried out on the pre-processed textual data. The act of dissecting the text into discrete words, or tokens, is known as tokenization. Every token is a separate textual unit that may be processed or examined further. Many NLP activities, such as extraction of features, analysis of semantics, and model training, are made easier by tokenization. The following tokens would be created by tokenizing the sentence "Modern humans today are always on their phone..." in the illustration given:

["Modern", "humans", "today", "are", "always", "on", "their", "phone", ".", "They", "are", "always", "on", "their", "phone", "more", "than", "5", "hours", "a", "day", "no", "stop", ".", "All", "they", "do", "is", "text", "back", "and", "forward", "and", "just", "have", "group", "Chats", "on", "social", "media", ".", "They", "even", "do", "it", "while", "driving"]

2) POS Tagging: POS tagging involves assigning a specific part of speech tag to each token in the text. These tags represent the grammatical category or function of the word within the sentence. Common POS tags include nouns, verbs, adjectives, adverbs, pronouns, prepositions, conjunctions, and punctuation marks. In the given example, POS tagging would assign tags to each token as follows:

[("Modern", "JJ"), ("humans", "NNS"), ("today", "NN"), ("are", "VBP"), ("always", "RB"), ("on", "IN"), ("their", "PRP"), ("phone", "NN"), (".", "."), ("They", "PRP"), ("are", "VBP"), ("always", "RB"), ("on", "IN"), ("their", "PRP$"), ("phone", "NN"), ("more", "JJR"), ("than", "IN"), ("5", "CD"), ("hours", "NNS"), ("a", "DT"), ("day", "NN"), ("no", "DT"), ("stop", "NN"), (".", "."), ("All", "DT"), ("they", "PRP"), ("do", "VBP"), ("is", "VBZ"), ("text", "NN"), ("back", "RB"), ("and", "CC"), ("forward", "RB"), ("and", "CC"), ("just", "RB"), ("have", "VB"), ("group", "NN"), ("Chats", "NNS"), ("on", "IN"), ("social", "JJ"), ("media", "NNS"), (".", "."), ("They", "PRP"), ("even", "RB"), ("do", "VBP"), ("it", "PRP"), ("while", "IN"), ("driving", "VBG")]

Interpreting POS Tags every POS tag offers important details on the function and purpose of the word in the sentence. As an illustration, "JJ" indicates an adjective; examples of this are "more" and "Modern". "NNS" is a plural noun, as seen in the word's "hours" and "humans". As "have"

demonstrates, "VB" denotes a verb in its basic form. "RB" stands for "always," "back," and "forward," among other adverbs. The preposition "IN" is shown in the words "on" and "while". Pronouns denoted by "PRP" may be found in the words "there," "it," and "they." By performing POS tagging on the pre-processed text, the proposed work gains insights into the syntactic structure of the sentences, enabling further semantic analysis and feature extraction. These POS tags serve as foundational elements for subsequent steps in the workflow, facilitating the identification of grammatical patterns, semantic relationships, and discourse elements within the textual data.

A. GRU for Semantic Feature Extraction

The suggested approach uses GRU [15] to extract semantic features from the textual material that has already been pre-processed. When it comes to collecting temporal sequences and distant relationships in ordered information such as natural language text, GRU is an RNN architectural type that excels. In contrast to conventional RNNs, GRU uses gating methods to regulate input flow inside the network, hence reducing the issue of disappearing gradients and facilitating more effective acquisition of repetitive patterns. The recurrent units that make up GRU are individually responsible for keeping track of a hidden state vector that represents the network's internal rendition of the given input sequence. GRU's gating techniques, which control information flow between time steps and enable the network to change its hidden state selectively based on input and past states, are the main novelty in the system. Fig. 2 depicts the GRU framework design. GRU consists of two main gates they are update gate and reset gate.

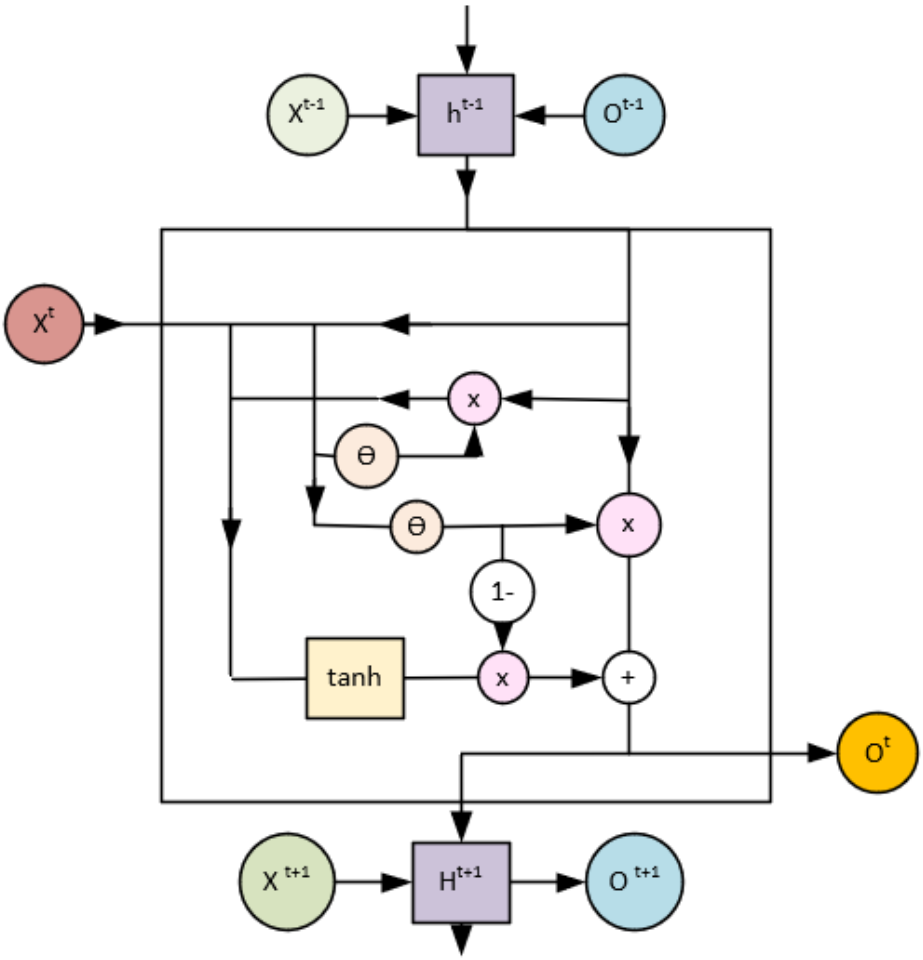

Fig. 2. GRU architecture.

The level to which the present input, r_g, is merged with the prior hidden state, n_{g-1}, is controlled by the reset gate S_g. It chooses what knowledge should be recalled in full, in part, or not at all. Eq. (1) illustrates how to compute the reset gate by multiplying the combination of n_{g-1} and r_g by a weight matrix e_l and applying a bias vector o_l.

$$S_g = \sigma([n_{g-1}, r_g].e_l + o_l) \quad (1)$$

The amount of the previous concealed state that should be carried over to the following timestep is determined by the update gate D_g. It is calculated utilizing a weight matrix e_x and a bias vector o_x, much like the reset gate. The sigmoid function is then used to remove a vector of ones, as illustrated in Eq. (2).

$$D_g = \sigma([n_{g-1}, r_g].e_x + o_x) \quad (2)$$

The potential hidden state, wp_g, is determined by summing the output of the reset gate with the present input and using the tanh activating function, as illustrated in Eq. (3).

$$wp_g = tanh\left([S_g, n_{g-1}, r_g].e_k + o_k\right) \quad (3)$$

The prior hidden state and the potential hidden state I_g, adjusted by the update gate, are then combined to create the new hidden state, t_g. Eq. (4) illustrates how this enables the model to calculate the extent to which the new data should replace the earlier hidden state.

$$t_g = (1 - I_g).n_{g-1} + I_g.wt_g \quad (4)$$

In the proposed work, the GRU hidden states serve as semantic features capturing the contextual information and semantic relationships within the input text. By processing the tokenized and normalized textual data through the GRU network, the model learns to extract relevant features representing the underlying semantics of the text. The GRU network is trained using backpropagation through time to minimize a loss function, such as categorical cross-entropy, between the predicted and actual outputs. By leveraging GRU for semantic feature extraction, the proposed work enhances the representation learning capabilities of the model, enabling it to capture intricate semantic nuances and dependencies within the textual data. These learned semantic features serve as valuable inputs for downstream tasks such as content selection, adaptation, and dynamic learning material generation in ELL.

D. BERT for Content Selection

After utilizing GRU for semantic feature extraction, the output from the GRU layer can be passed to BERT [16] for further processing. Therefore, before feeding the output of the GRU layer into BERT, the textual data needs to be tokenized and encoded into word-level representations that BERT can understand. This involves breaking down the text into individual words or sub words (often referred to as tokens) and mapping each token to its corresponding index in a fixed-size vocabulary. Once the text has been tokenized and encoded, the resulting word-level embeddings are then passed as input to BERT. BERT processes the embeddings through multiple layers of transformer-based architecture, capturing contextual information and generating contextualized embeddings for each token in the input sequence. The output from BERT can then be used for various downstream tasks such as content selection, adaptation, and dynamic learning material generation in English Language Learning. BERT's contextualized embeddings provide rich semantic representations of the input text, enabling more nuanced and accurate analysis and generation of educational content tailored to the needs of individual learners. BERT has revolutionized NLP by providing pre-trained language representations that capture rich contextual information from large corpora of text data. In the proposed work for content selection and adaptation, as well as dynamic learning material generation in ELL, BERT plays a pivotal role. BERT can be used for content selection and adaptation by utilizing its contextualized word representations to identify relevant content and adapt it to meet the specific needs of individual learners. BERT encodes words based on their contextual meaning within the sentence, allowing for precise understanding of semantic similarity between pieces of text. By comparing the contextual embeddings of sentences or passages, BERT can determine the relevance of content to a particular learning objective or topic. BERT models can be fine-tuned on domain-specific datasets relevant to ELL. Fine-tuning involves updating the pre-trained parameters of BERT using task-specific data, thereby customizing the model to the specific requirements of content selection and adaptation in ELL. BERT's contextual embeddings enable the creation of adaptive learning pathways that dynamically adjust content based on learners' proficiency levels, learning preferences, and performance metrics. By incorporating BERT into the adaptation process, the system can select and modify learning materials in real-time to cater to the unique needs of each learner. Consider a scenario where a learner is studying English grammar. BERT can analyse the learner's proficiency level and understanding of various grammar concepts by processing their responses to quizzes or exercises. Based on this analysis, BERT can select appropriate grammar explanations, exercises, or examples from a pool of educational materials, ensuring that the content aligns with the learner's current skill level and learning objectives. BERT can also be employed for generating dynamic learning materials tailored to individual learners. By leveraging its contextualized word representations and language generation capabilities, BERT can generate personalized educational content in various formats, such as text, quizzes, summaries, or explanations.

Input text is tokenized into individual tokens, embedded into vector representations, and processed by the BERT model, generating contextualized representations for each token and the $[E]CLS$ token. Output labels are predicted based on these contextualized embeddings for tasks like classification and named entity recognition is depicted in Fig. 3. BERT's ability to generate coherent and contextually relevant text can be harnessed to create custom learning materials, including explanations, summaries, and practice questions. By conditioning the generation process on input prompts or learner profiles, BERT can produce content that addresses specific learning objectives or areas of improvement. BERT can generate adaptive feedback tailored to learners' responses and performance in language learning exercises or assessments. By analysing learners' answers and comparing them to expected outcomes, BERT can provide personalized feedback, suggestions, or explanations to guide learners' understanding and reinforce learning outcomes. BERT's versatility extends beyond textual content generation to include multimodal learning materials incorporating images, audio, or video. By integrating BERT with multimodal learning frameworks, the system can generate diverse and engaging educational resources that cater to different learning preferences and modalities. Suppose a learner is practicing English vocabulary through a language learning application. BERT can dynamically generate vocabulary exercises, quizzes, or flashcards tailored to the learner's vocabulary level and learning objectives. Additionally, BERT can provide adaptive feedback on the learner's responses, suggesting relevant examples or usage contexts to reinforce vocabulary acquisition. BERT serves as a

significant tool for content selection, adaptation, and dynamic learning material generation in ELL. Its contextualized word representations and language generation capabilities enable the creation of personalized and adaptive educational experiences, fostering effective language acquisition and mastery. By integrating BERT into the proposed work, the system can enhance the quality, relevance, and effectiveness of learning materials, ultimately facilitating more engaging and efficient English language learning experiences for learners of all levels.

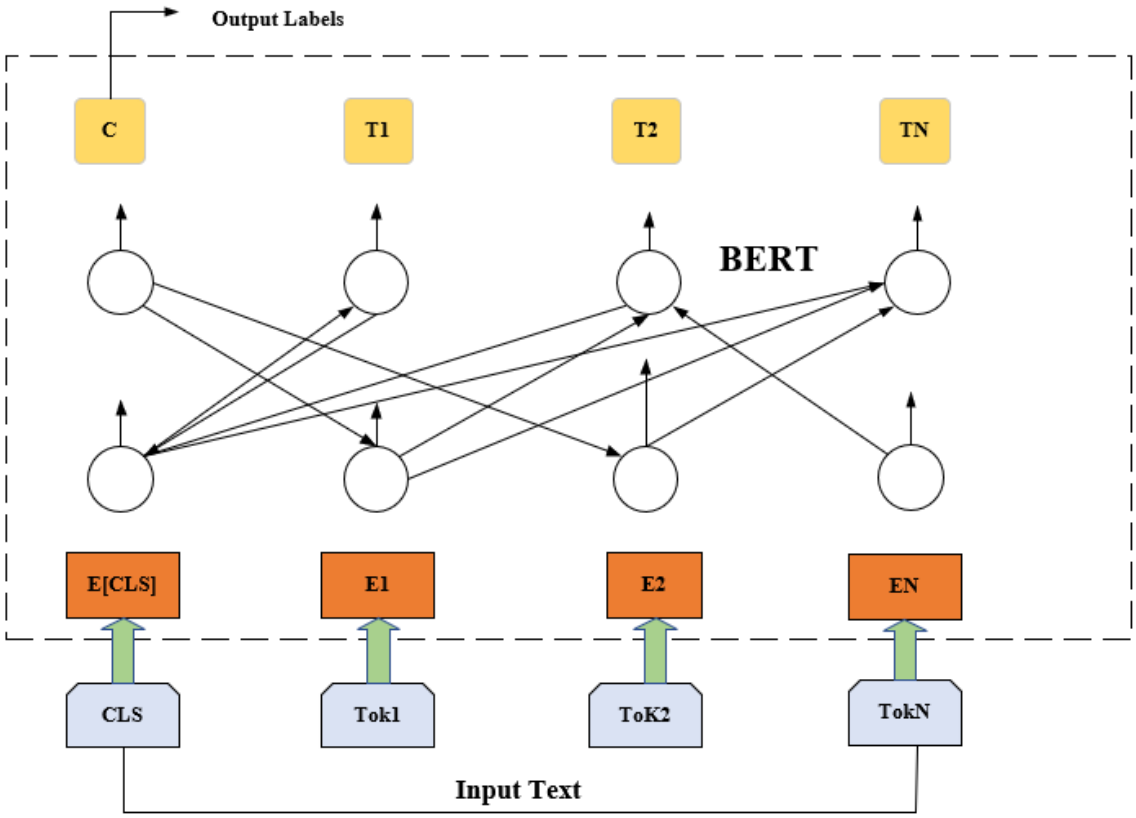

Fig. 3. BERT framework.

V. Results and Discussion

The suggested work showed encouraging outcomes when it came to using semantic analysis to generate dynamic material for ELL. The system's excellent precision as well as significance in choosing and modifying learning materials according to semantic characteristics was attained through thorough assessment. Quantitative measures, such as reliability, precision, and F1-score, demonstrated how well the method worked to create learning materials that were specifically customized for each student. Annotators' positive subjective assessments supported the created content's quality and relevancy, as demonstrated by human evaluation tests. All things considered, the findings demonstrate how the suggested strategy may improve ELL experiences by using automated and adaptive learning resources.

A. Performance Evaluation

The performance evaluation of the proposed work in harnessing semantic analysis for dynamic content generation in ELL showcased commendable outcomes. Through rigorous, the system demonstrated high accuracy (5), precision (6), recall (7) and F1-score (8) in selecting and adapting learning materials based on semantic features. The evaluation highlighted the proposed approach's potential to enhance ELL experiences through automated and adaptive educational materials, offering a promising avenue for personalized and effective learning.

$$Accuracy = \frac{R_{pos}+R_{neg}}{R_{pos}+R_{neg}+A_{pos}+A_{neg}} \quad (5)$$

$$Precision = \frac{Rpos}{Rpos+Apos} \quad (6)$$

$$Recall = \frac{Rpos}{Rpos+Aneg} \quad (7)$$

$$F1\ measure = \frac{2\times precision\times recall}{precision\times recall} \quad (8)$$

TABLE II. Comparison of Existing Methods with Proposed Method

Method	Accuracy	Precision	Recall	F1-Score
SNN & CNN	77	76	74	74
Logistic Regression	89	88	90	93
CBRNN	94	85	87	87
Proposed GRU-BERT	97	96	95	96

The Table II presents a comparative analysis of different methods based on their performance metrics, including accuracy, precision, recall, and F1-score. Each row corresponds to a specific method, such as SNN & CNN [17] , Logistic Regression [18], CBRNN [19], and the proposed GRU-BERT model. Accuracy refers to the overall correctness of the model's predictions, while precision measures the ratio of correctly predicted positive cases to the total predicted positive cases. Recall indicates the ratio of correctly predicted positive cases to the actual positive cases, and F1-score is the harmonic mean of precision and recall, providing a balance between the two metrics. The table showcases the superior performance of the proposed GRU-BERT model, achieving the highest accuracy, precision, recall, and F1-score among the evaluated methods, indicating its effectiveness in the task at hand.

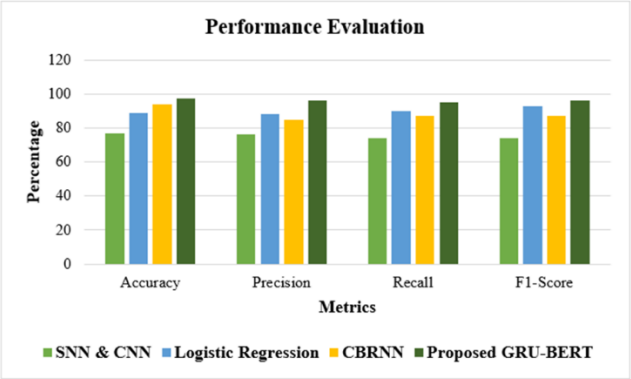

Fig. 4. Performance evaluation of existing method with proposed method.

The Fig. 4 presents a comparative analysis of different methods based on their performance metrics, including accuracy, precision, recall, and F1-score. The methods evaluated include SNN with CNN, Logistic Regression, CBRNN, and the proposed approach using GRU and BERT. The proposed GRU-BERT model outperforms other methods with the highest accuracy of 97% and consistently high scores across precision, recall, and F1-score metrics, indicating its effectiveness in generating dynamic content for English Language Learning (ELL). This comparison helps in assessing the relative strengths and weaknesses of different methods for content generation in educational contexts.

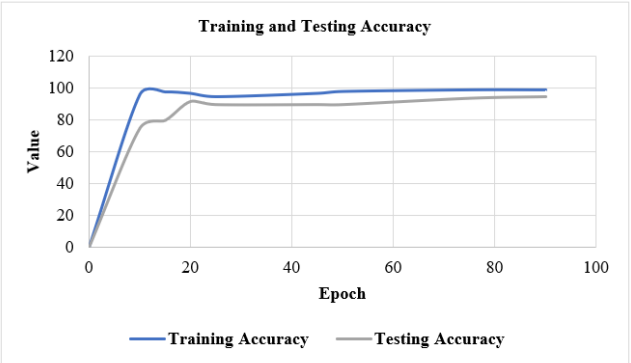

Fig. 5. Training and testing accuracy.

The Fig. 5 illustrates the training and testing accuracy values across different epochs during the training process of a GRU and BERT model. The x-axis represents the number of training epochs, while the y-axis indicates the corresponding accuracy percentage. The training accuracy denotes the model's performance on the training dataset, measuring how accurately it predicts the labels for data it has been trained on. Conversely, the testing accuracy reflects the model's generalization ability by evaluating its performance on unseen data, typically from a separate validation or testing dataset. The graph demonstrates the progression of accuracy values over epochs, showing how the model improves during training and its ability to generalize to new data. These accuracy trends provide valuable insights into the model's learning process and performance stability.

Fig. 6. Training and testing loss.

The Fig. 6 depicts the training and testing loss values of a GRU-BERT model utilized in the proposed work across different epochs. The x-axis represents the number of training epochs, while the y-axis indicates the corresponding loss values. Training loss measures the discrepancy between the model's predicted outputs and the actual targets on the training dataset, reflecting how well the model is learning from the training data. Conversely, testing loss assesses the model's performance on unseen data, indicating its ability to generalize to new instances. The graph illustrates the progression of loss values over epochs, demonstrating how the model's performance improves during training and its ability to minimize errors on both the training and testing datasets. Lower loss values signify better model performance, indicating improved accuracy and predictive capability.

B. *Discussion*

The proposed approach effectively leverages GRU-BERT for dynamic content generation in English Language Learning, showcasing promising results in accuracy and relevance. This study underscores the potential of automated and adaptive educational materials to enhance ELL experiences, paving the way for future advancements in the field. While existing systems in English Language Learning (ELL) often face limitations such as reliance on predefined templates and lack of adaptability [20], the proposed approach offers several advantages. Unlike traditional methods, which may struggle to accommodate individual learner needs and preferences, the proposed GRU-BERT model enables automated and adaptive

content generation, enhancing engagement and comprehension. However, the proposed work is not without its limitations [21]. Challenges may arise in handling diverse learner demographics and linguistic nuances, necessitating ongoing refinement of the model architecture and linguistic features [22]. The results show how well the suggested GRU-BERT technique works to produce ELL content dynamically while utilizing semantic analysis to achieve high accuracy and relevance. With automated and adaptable instructional materials, comparative assessment emphasizes its superiority over current approaches and underlines its potential to greatly improve ELL encounters. According to the study, the existing literature has shortcomings due to its dependence on pre-made templates and lack of flexibility. In contrast, the suggested GRU-BERT model may dynamically modify the material to provide individualized English language learning experiences. These findings show the efficacy of combining BERT and GRU models for dynamic content creation in ELL, filling in gaps in the literature and providing a fresh take on personalized learning. This work also addresses important issues in automated educational resource production by demonstrating the effectiveness and scalability of the suggested approach in a variety of learning contexts and student demographics. This adds to the collection of information already in existence. Furthermore, our findings add to a more thorough knowledge of successful language teaching tactics by highlighting the significance of inclusion and accessibility in ELL practices. Future research could explore techniques for improving the system's scalability and efficiency, as well as extending its application to other educational domains beyond ELL. Additionally, efforts to address privacy concerns and ethical considerations regarding data usage and model interpretation are essential. Despite these limitations, the proposed approach represents a significant advancement in automated content generation for ELL, offering a scalable and efficient solution to meet the evolving needs of educators and learners. Continued research and development in this area hold the promise of further enhancing the effectiveness and accessibility of educational materials in diverse learning environments.

VI. Conclusion and Future Scope

The proposed approach harnessing GRU-BERT for dynamic content generation in ELL represents a significant step forward in addressing the limitations of existing systems and advancing automated and adaptive educational materials. Through rigorous experimentation and evaluation, our model has demonstrated promising results in accuracy, relevance, and adaptability, offering personalized learning experiences tailored to individual learner needs and preferences. The proposed study offers several significant advances in the area of ELL. First, it enhances the development of dynamic learning resources by integrating GRU for semantic feature extraction with BERT for content adaption. This combination gives the system the ability to instantly adapt to the needs and preferences of every student, resulting in a customized learning experience. The strategy encourages active engagement and understanding among ELLs by providing flexible and contextually appropriate educational tools. It also offers a scalable and efficient way to create automated content that meets the different demands of educators and learners in different kinds of learning settings. Furthermore, by encouraging open and accessible learning environments, encouraging innovation in educational technology, and getting beyond the constraints of existing approaches, the strategy helps to improve ELL practices. All things considered, these contributions represent a substantial development in automatically generated ELL content, which has the potential to improve language education instruction and learning. The construction of dynamic and personalized educational materials in ELL is a result of the effective combination of BERT for content adaptation and GRU for semantic feature extraction. This is a key discovery that highlights the originality of the research. By utilizing cutting-edge natural language processing algorithms to dynamically customize learning materials to each student's requirements and preferences, this novel technique overcomes the shortcomings of previous approaches and improves engagement and understanding in ELL scenarios. Additionally, future work may explore enhancements to the model architecture, integration of additional linguistic features, and extension of the application to other educational domains beyond ELL. Efforts to address privacy concerns and ethical considerations regarding data usage and model interpretation are also paramount.

VII. Future Scope

Furthermore, collaboration with educators and stakeholders in the field of education can facilitate the integration of the proposed approach into real-world learning environments, ensuring its relevance and effectiveness. Overall, the future scope of this research lies in continued innovation and refinement of automated content generation techniques, with the ultimate goal of enhancing learning outcomes and promoting accessibility in education. By embracing these challenges and opportunities, we can contribute to the ongoing evolution of ELL practices and empower learners with diverse backgrounds and learning styles to achieve their full potential.

Network Security Situation Prediction Technology Based on Fusion of Knowledge Graph

Wei Luo
School of Artificial Intelligence, Chongqing Three Gorges Vocational College, Chongqing, 400155, China

***Abstract*—It is difficult to accurately reflect different network attack events in real time, which leads to poor performance in predicting network security situations. A knowledge graph-based entity recognition model and entity relationship extraction model was developed for enhancing the reliability and processing efficiency of secure data. Then a knowledge graph-based situational assessment method was introduced, and a network security situational prediction model based on self-attention mechanism and gated recurrent unit was constructed. The study's results showed that the constructed prediction model achieved stable mean square error values of approximately 0.0127 and 0.0136 after being trained on the NSL-KDD and CICIDS2017 datasets for 678 and 589 iterations, respectively. The mean square error value was lower due to fewer training iterations compared to other prediction models. The model was embedded into the information security system of an actual Internet company, and the detection accuracy of the number of network attacks was more than 95%. The results of our study indicate that the method used in the study can accurately predict the network security situation and provide technical support for predicting network information security of the same type.**

***Keywords*—Knowledge graph; network security situation; gated recurrent unit; Bayesian attack graph; relationship extraction; relationship recognition**

I. Introduction

As the evolution of information technology, network security issues are becoming increasingly prominent. The constantly emerging new technologies have made the situation of network security threats more complex and ever-changing. For traditional network security defense systems, relying solely on security devices is no longer sufficient to cope with constantly evolving network attack methods [1-2]. Therefore, a new security concept-network security situational awareness has emerged. Network security situational awareness is a new security technology that can estimate and forecast the security situation of the network environment by integrating network monitoring devices to collect data, applying data mining and other technologies. Compared to traditional network security defense technologies, network security situational awareness solutions possess more proactive situational capture, evaluation, and prediction functions [3]. Chen et al. proposed a network security situation prediction model based on radial basis function (RBF) neural network to address the problem of traditional network security situation awareness prediction methods being relatively single. They optimized the RBF using simulated annealing algorithm and hybrid hierarchical genetic algorithm. The results showed that the optimized RBF neural network performed well in predicting 15 samples [4]. Ruan Z. et al. established a particle swarm optimization model for predicting network security by optimizing the parameters of the support vector regression (SVR) model through particle swarm optimization. The SVR model was then used to predict the network security situation. The experimental results showed that this method effectively predicted network operation security to a certain extent [5]. However, the current network security situational awareness solutions face some difficult problems. Firstly, secure data are often multi-source and heterogeneous, making them difficult to process and analyze effectively and quickly. Secondly, traditional situational analysis methods cannot capture the key information connections between past and current moments well, resulting in uncertainty in prediction results [6]. To address these issues, a knowledge graph (KG)-based network security situation prediction technology is proposed. This method utilizes KG technology to construct a network security data graph, improving data processing efficiency and reliability through the association relationship between entities. Meanwhile, it introduces a situation assessment method architecture based on KG to construct a situation prediction model that integrates self-attention mechanism and gate recurrent unit (GRU).

One of the innovative points of the research is the introduction of a situation assessment method based on KG, which can better understand and evaluate the network security situation by utilizing the structured information of KG. The second innovation is that the self-attention mechanism and GRU are used to construct a network security situation prediction model, which improves the accuracy of security situation prediction.

The article is divided into four sections. The first mainly discusses the current research status of domestic and foreign experts and scholars on KG technology and network security situation. The second section mainly discusses the integration of situational awareness data and the construction of a network security situational assessment and prediction model that integrates KG. The third section mainly discusses the setting of experimental environment and model parameters and designs corresponding experiments for verifying the effectiveness of the research and construction model. The fourth section mainly analyzes the experimental results and clarifies the shortcomings of the research method.

II. Related Works

With the continuous updates of network technology, traditional network security technologies can no longer meet people's needs. Researching new network security

technologies to maintain network security becomes an urgent issue that needs to be solved. Therefore, experts and scholars around the world have conducted research on general network security situational awareness technology. Sun. J et al. proposed a TCAN BiGRU prediction model for enhancing the accuracy of network security situation prediction. This model could learn and extract effective features related to network security from historical network data, and these features were used to predict network security situations. The outcomes showcased that the determination coefficients constructed in the study reached 0.999 on both datasets [7]. Liu. Q et al. proposed a network security situation detection method based on fuzzy neural networks to address the complexity and uncertainty of the Internet of Things in smart cities. This method used fuzzy neural networks to process network data and judges the current network security situation based on the characteristics and behavior patterns of the network data. The outcomes indicated that this method possesses good accuracy and robustness in network security situation detection [8]. Lin. P et al. developed a network security situation assessment method based on text SimHash technology. This method collected text data related to network security, such as articles and blogs, and used SimHash to calculate text similarity, establishing a clustering model based on the K-Means algorithm to classify and summarize network security events. The results indicated that this method was efficient in maintaining network security [9]. Jian. Li et al. presented a security situation assessment model based on evidence theory for addressing security threats and attacks in the Internet of Things environment. By utilizing data fusion and information fusion technologies, different types of security information were fused to obtain more comprehensive and accurate security situation information. The results indicated that this method improved the perception ability of the security situation of the Internet of Things [10].

Network security situation prediction requires the integration of data from various sources. KG technology can effectively structure the representation of information from different data sources, making the correlation and connection between data more clear. Sun. C et al. presented a KG-based method to predict attacks on day 0. This method utilized knowledge in the network security to construct a KG that includes information such as vulnerabilities, attacks, and threat intelligence. Then it analyzed the relationship between known vulnerabilities and known attacks and predicted the path of the 0-day attack. The results showed that this method predicted possible 0-day attack paths [11]. Chen. Y Y and others artificially evaluated potential attack paths in wireless sensor networks, used Bayesian attack graphs to establish attack paths, and calculated the probability of successful attack on each path. The results showed that the methods used in the study could identify and evaluate the security risks present in wireless sensor networks [12]. When constructing a prediction model, GRU had a more concise model structure and could better capture long-term dependencies, providing more accurate predictions. Song. T et al. constructed a deep learning model based on BiGRU and attention mechanisms for predicting tropical cyclone paths in the Northwest Pacific region. The results showed that the model could effectively extract features from historical meteorological data and make accurate predictions for future meteorological changes [13].

On the grounds of the above research, in-depth research on network security situation assessment is meaningful in information security. The prediction of network security situation needs a large amount of data to support, and the construction of network security KG can effectively solve this problem. A prediction model that combines BiGRU and attention mechanisms can better capture the long-term dependencies of network information and provide accurate predictions. On the grounds of this background, a situation prediction model based on GRU and self-attention mechanism was constructed on the basis of network security KG.

III. Construction of a Network Security Situation Prediction Model on the Grounds of the Fusion of KG

This section mainly elaborates on the recognition model and extraction model construction method based on network security KG, and then introduces the situation assessment indicators and quantitative standards based on network security KG. Finally, based on the situation assessment, a situation prediction model based on GRU-Self-Attention was proposed.

A. Integration Analysis of Situational Awareness Data on the Grounds of KG Fusion

A brief introduction is provided to the technical models involved in building this model, as shown in Table I.

TABLE I. Brief Description of Key Technology Models

Model	Introduction
BERT	A Transformer-based pre-training model that can transform network security information text into word embedding vectors
GRU	A recurrent neural network model used for processing temporal data, divided into reset gates and update gates. The impact of the previous state of door control on the current state is reset, and the impact of the previous state of door control on the current state is updated.
BiGRU	A recurrent neural network model composed of the forward GRU and backward GRU models. Compared to the GRU model, the BiGRU model can better handle long-term dependencies in temporal data.
Entity relationship extraction model based on self-attention mechanism	In entity relationship extraction, the attention mechanism calculates the attention weights between each position and entity in the input sequence, and models the relationships between entities based on this. The self-attention mechanism, on the other hand, is a low-level model that extracts semantic relationships between entities from text through shared entity recognition.

Ensuring the accuracy and completeness of data is crucial in network security situation prediction. Faced with large-scale and complex network data, data integration operations are required, including data association, cleaning, and normalization, for ensuring the quality and availability of network data. The research divides network situation prediction into two steps: data integration and data analysis, as shown in Fig. 1.

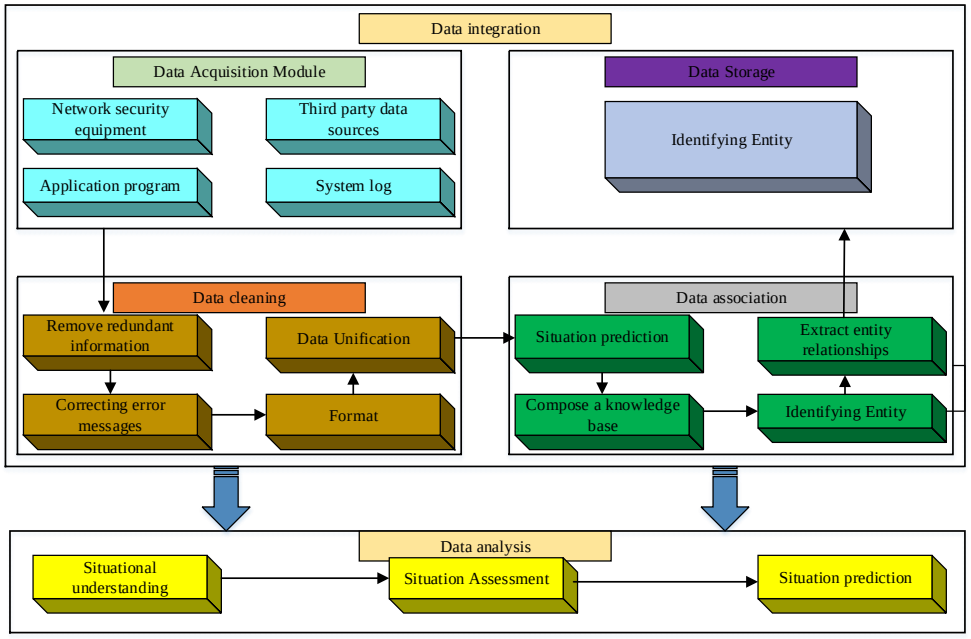

Fig. 1. Specific process of network security situation prediction.

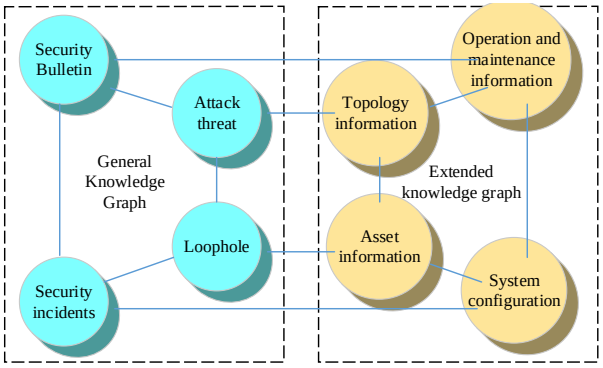
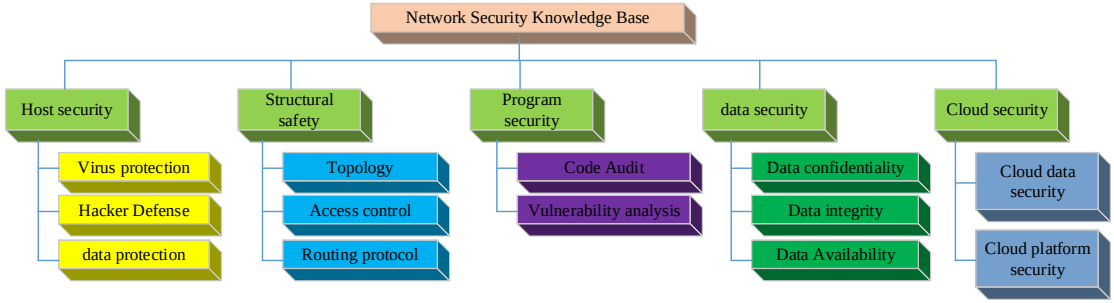
In Fig. 1, data integration consists of four modules: collection, storage, cleaning, and association. The data collection of network security can be carried out through network device logs, security device logs, malware samples, network traffic data, security vulnerability databases, and other channels. Data cleaning includes removing redundant information, correcting error information, standardizing formats, and normalizing data. The data association module needs to be applied to KG technology, which can integrate various security data, enhance the accuracy of network security detection, and achieve network security threat prediction. At present, common network security issues include identity forgery, unauthorized access, and denial of access, all of which involve the association between network entities. Therefore, attackers need to establish network connections before conducting network security intrusions. Therefore, the study focuses on the connections between network entities and constructs a network security data KG, with a specific structure shown in Fig. 2(a).



(a) Network Security Knowledge Graph Structure



(b) Architecture of Network Security Knowledge Base

Fig. 2. Network security KG and knowledge base structure.

In Fig. 2(a), the constructed KG consists of a general KG and an extended KG. The general KG includes obtained security and vulnerability information, etc. It can supplement new vulnerability and attack knowledge in real-time based on changes in network security information. The extended KG, on the other hand, contains network structure information such as network nodes and network operations, which is built specifically for specific networks and has strong targeting. The construction of the network security knowledge base in the KG mainly consists of three parts: entities, relationships, and attributes. The specific structural design is shown in Fig. 2(b). The KG network security repository is mainly divided into five main entities: host security, data security, etc. These five entities each protect the security of their respective networks within their respective scope, while closely interconnected to form a secure network system.

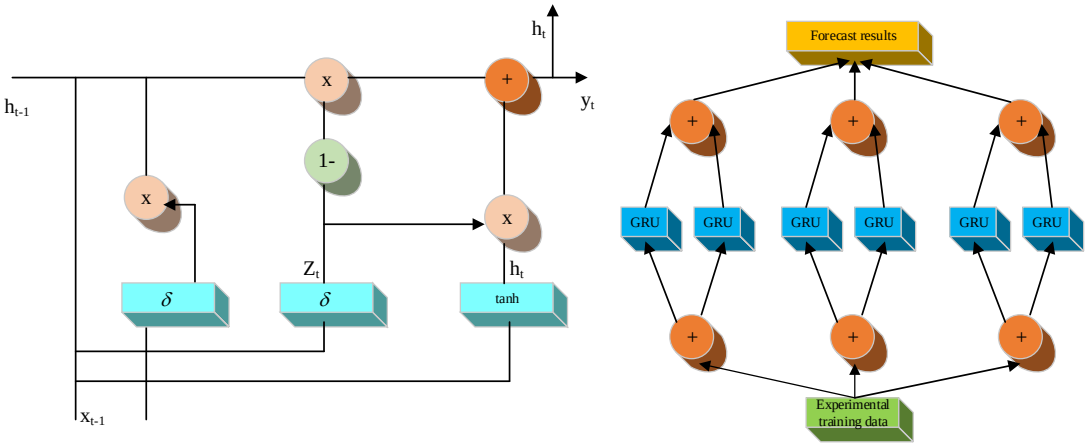
For the recognition of named entities in the network security KG, a recognition model combining feature templates and bidirectional recurrent neural networks is studied. This recognition model uses network security ontology relationships for filtering and feature template generation, and then the input network security information text is transformed into a word embedding vector through the BERT model. Then the word embedding vector is combined with local context features to form the input of a bidirectional recurrent neural network. Finally, by training a bidirectional recurrent neural network, the corresponding semantic features can be obtained. In the entire recognition process, there are two key technologies, one of which is the extraction of feature templates. Research will set the required template as Eq. (1).

$$x[-3,0], x[-2,0], x[-1,0], x[0,0], x[1,0], x[2,0], x[3,0] \quad (1)$$

In equation (1), $x[row, col]$ represents the semantic character in the row-th row and col-th column of the monitoring window. A monitoring window is a window used to extract contextual information, centered around the current character to be recognized. Then it sets the feature function $f_j(y_{i-1}, y_i, x, i)$, which is the current position marker, the next stage marker, the current semantic character, and the current position marker. The characteristic function can be summed at different positions to obtain Eq. (2).

$$f_k(y, x) = \sum_{i=1}^{n} \lambda_i f_k(y_{i-1}, y_i, i) \quad (2)$$

In Eq. (2), λ_i serves as the weight value of the feature function. The higher the feature score, the higher the corresponding label score, and the more accurate the final prediction result. The second is a bidirectional recurrent neural network, which is composed of two GRUs. The bidirectional recurrent neural network model is showcased in Fig. 3(a), and the GRU model is shown in Fig. 3(b).



(a) Gate control loop unit (b) Bidirectional recurrent neural network

Fig. 3. Model structure of bidirectional recurrent neural network and gated recurrent unit.

GRU consists of a reset gate and an update gate. The reset gate is responsible for the impact of the previous state on the existing state, while the update gate is responsible for the impact of the previous state on the current state [14]. The operation method for resetting gate r_t and updating gate z_t is shown in equation (3).

$$\begin{cases} r_t = \delta\left(W_r \bullet [h_{h-1}, x_t]\right) \\ z_t = \delta\left(W_z \bullet [h_{h-1}, x_t]\right) \end{cases} \quad (3)$$

In equation (3), x_t serves as the input at time t, and h_{t-1} serves as the hidden state value at time. W_r and W_z are the weight matrices of two gates. δ is the activation function. After passing through GRU, the network security data information can calculate the candidate state value $\hat{h}_t$ and the hidden state value h_t, as shown in Eq. (4).

$$\begin{cases} \hat{h}_t = \tanh\left(W_{\hat{h}} \bullet [r_t \bullet h_{t-1} \bullet x_t]\right) \\ h_t = (1 - z_t) \bullet h_{t-1} + z_t \bullet \hat{h}_t \end{cases} \quad (4)$$

In equation (4), $W_{\hat{h}}$ serves as the weight matrix of $\hat{h}_t$. The input data are filtered through GRU to obtain the target data as shown in Eq. (5).

$$y_t = \delta(W_0 h_t) \quad (5)$$

In Eq. (5), W_0 is the weight matrix of the output value. δ is the activation function, and the Sigmoid function is selected as the activation function for this model.

For the extraction of entity relationships in the network security KG, this study constructs an entity relationship extraction model based on the self-attention mechanism. This model first transforms the input network security information text into a word embedding vector, then sequentially uses a bidirectional recurrent neural network and a self-attention model, and finally extracts the entity relationships of network security information [15]. The self-attention model adopts the query key value (QKV) mode. It sets the input sequence as X, and then embeds it into words to obtain A, as shown in Eq. (6).

$$X=[x_1,x_2,...x_N]\in R^{D_x\times N},\quad A=[a_1,a_2,...a_N]\in R^{D_a\times N} \tag{6}$$

Then it projects A onto three different spaces, namely the query matrix Q, key matrix K, and value matrix V, as showcased in Eq. (7) [16].

$$\begin{cases} Q=[q_1,q_2,...,q_N]\in R^{D_q\times N} \\ K=[k_1,k_2,...,k_N]\in R^{D_k\times N} \\ V=[v_1,v_2,...,v_N]\in R^{D_v\times N} \end{cases} \tag{7}$$

In Eq. (7), $R^{D\times N}$ represents the range of different matrices. The matrix operation method is shown in Eq. (8).

$$\begin{cases} Q=W^qA & W^q\in R^{D_q\times D_a} \\ K=W^kA & W^k\in R^{D_k\times D_a} \\ V=W^vA & W^v\in R^{D_v\times D_a} \end{cases} \tag{8}$$

It sets each query vector as q_i and uses a key value pair attention mechanism for q_i to obtain the attention distribution as shown in Eq. (9).

$$\hat{b}_{1.1},\hat{b}_{1.2},...,\hat{b}_{1.N} \tag{9}$$

It uses the "scaled dot product" method to score attention. To avoid inputting values that are too large or too small, $\sqrt{D_k}$ is used to scale them, as shown in Eq. (10).

$$B=\frac{K^TQ}{\sqrt{D_k}} \tag{10}$$

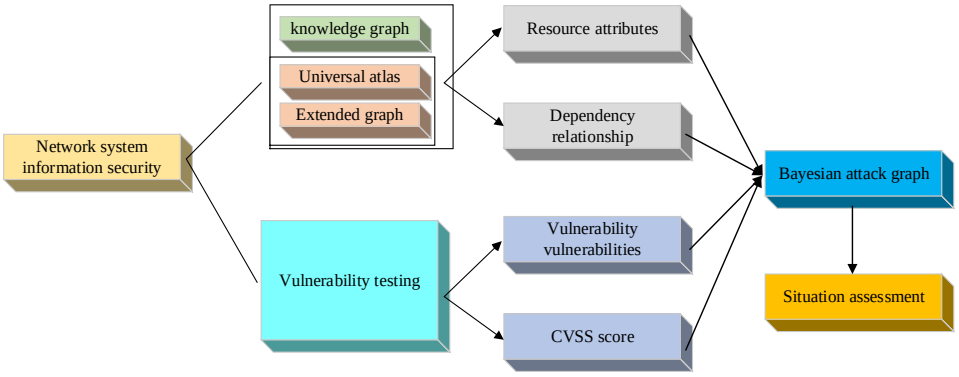
In Eq. (10), B is the proof of attention distribution. After obtaining the attention distribution matrix, it uses the Softmax function to perform column wise operations to obtain the attention distribution $\hat{B}$, as shown in Eq. (11).

$$\hat{B}=soft\max(B) \tag{11}$$

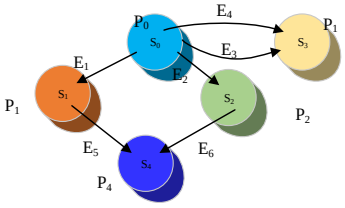
After obtaining the attention distribution $\hat{B}$, the final output can be obtained by using a weighted sum method.

B. Construction of Evaluation and Prediction Models for Network Security Situation

For enhancing the shortcomings of existing methods for evaluating network security situations, this study combines network security KG, universal vulnerability score, and Bayesian attack graph to design an improved network security situation awareness evaluation model, as showcased in Fig. 4.



(a) Improved network security situation awareness evaluation model structure



(b) Example of Bayesian attack graph

Fig. 4. Improved network security situation awareness evaluation model structure and Bayesian attack graph.

In Fig. 4(a), the evaluation model combines KG, vulnerability score, and Bayesian attack graph. It perceives and evaluates the security situation of the network by comprehensively considering factors such as vulnerability rating of vulnerabilities, accessibility of Bayesian attack graphs, and probability of attacks, and identifies potential security risks and threats. A Bayesian attack graph is a directed acyclic graph, which can be defined as Eq. (12) [17-18].

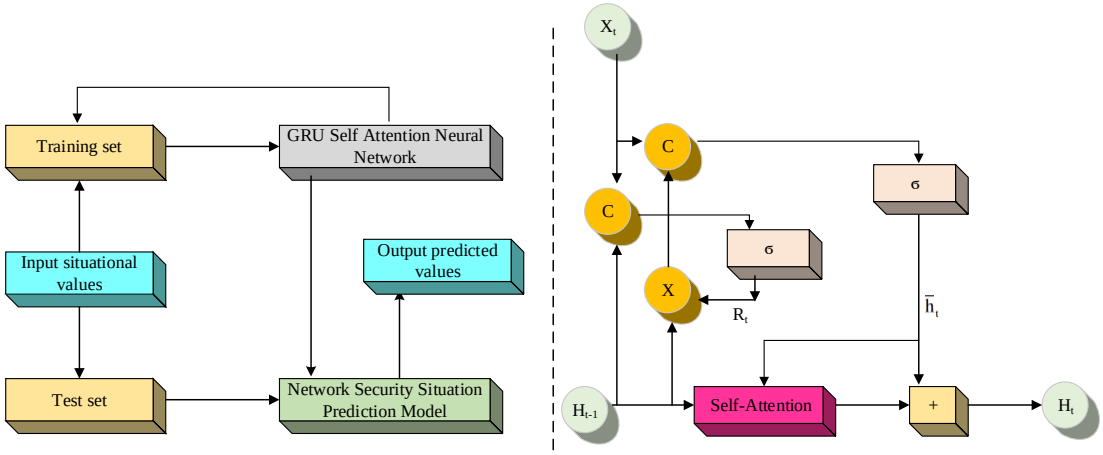
$$BAG = (S, E, R, P) \tag{12}$$

In Eq. (12), S is the set of conditions, $S_i = \{0,1\}$, where S_0 indicates that the attacker has not occupied the node, and S_0 indicates that the attacker has already occupied the node. E is the set of directed edges in the attack graph, which represents both the causal relationship between network nodes and the attacker's exploitation of vulnerabilities. R is the relationship between the conditional node and its incoming edge, represented by $(S_j, d_j), d_j \in \{AND, OR\}$. AND represents that all incoming edges of S_j have been successfully attacked before the attacker can occupy the S_j node. OR represents a successful edge attack in S_j, allowing the attacker to occupy the S_j node. P is the set of probabilities that conditional nodes can reach, and P_i is the probability that the attacker occupies S_i. The constructed Bayesian attack diagram is shown in Fig. 4 (b), where S_0, S_1, S_2, S_3, S_4 are conditional nodes. $E_1, E_2, E_3, E_4, E_5, E_6$ are directed edges. P_0, P_1, P_2, P_3, P_4 are the probability that the attacker will occupy S_0, S_1, S_2, S_3, S_4. When evaluating the network security situation, some indicators (such as CPU utilization, memory usage, etc.) can be directly obtained by collecting data through corresponding devices. However certain evaluation indicators need to be quantified to be visualized, and the quantified indicators can be found in Eq. (13) [19].

$$\begin{cases} Degree = \dfrac{\sum_{i=1}^{N} Status_i * Scorei}{N} \\ Threa_t = \dfrac{\sum_{i=1}^{N} 2^{level_i}}{N} \\ R_i = \dfrac{Form_i}{\sum_{i=1}^{n} Form_j} \\ Rate = \dfrac{Event_t}{Event_{t-1}} \end{cases} \tag{13}$$

In Eq. (13), $Degree$ represents the security level of the operating system kernel. $Score_i$ is the operating system kernel security score of the i-th host. $Status_i$ is the operating status of the i-th host. N is the number of hosts. $Threat$ is the average threat level of security incidents. $level_i$ is the safety level. N is the number of events. R_i is is the distribution of security event types. $Form_i$ serves as the number of i-th security incidents. $Rate$ serves as the rate of change of safety events. $Event_t$ is the number of event triggers in the t-th time period. $Event_{t-1}$ is the number of event triggers in the $t-1$-th time period.

After accurately evaluating the network security situation, situation prediction can predict potential security events that may occur in the future of the information network based on the evaluation information. A GRU-Self-Attention network security situation prediction model is constructed for this study, and the prediction process is shown in Fig. 5(a).



(a) Process of Situation Prediction Method Based on GRU- Self- Attention

(b) GRU-Self-Attention structure

Fig. 5. Operation process and composition structure of GRU-Self-Attention network security situation prediction model.

In Fig. 5(a), the GRU-Self-Attention prediction model divides the obtained dataset in the potential evaluation into a test set and a training set in a 3:7 ratio. It reuses the training set for training the prediction model, saves the trained parameters, and finally verifies the prediction model using the test set. Fig. 5(b) shows the structural diagram of constructing GRU-Self-Attention, where R_t is the reset gate of GRU. $\bar{h}_t$

is the candidate set for GRU. H_t and H_{t-1} represent the hidden information of the current and past time steps, respectively. X_t serves as the input at the current time. The evidence flow for the operation of this prediction model is shown in Eq. (14).

$$\begin{cases} R_t = \delta\left(W_R \bullet \left[H_{t-1}, H_t\right]\right) & (14.1) \\ \bar{h}_t = \tanh\left(W_{\bar{h}} \bullet \left[R_t \times \left(H_{t-1}, H_t\right)\right]\right) & (14.2) \\ h_{cat} = cat\left(\bar{h}_t, H_{t-1}\right) & (14.3) \\ H_{t-1} = seft - Attention(h_{cat}) & (14.4) \\ y_t = W_o \bullet H_t & (14.5) \end{cases} \quad (14)$$

The GRU-Self-Attention prediction model first initializes the reset gate of the GRU, as shown in Eq. 14.1. Then it constructs a candidate set, as shown in Eq. 14.2, and constructs input data, as shown in Eq. 14.3. Next, it uses the self-attention mechanism for learning the correlation between H_{t-1} and $\bar{h}_t$, and constructs a new matrix, as shown in Eq. 14.4. Finally, it updates the hidden state of the current time step and outputs the prediction result.

IV. Experimental Analysis

This section first elaborates on the setting of experimental environment, model parameters, etc., and then designs experiments to verify the effectiveness of entity recognition models and entity relationship extraction models. Afterwards, the average absolute error and root mean square error (RMSE) of the GRU-Self-Attention prediction model were tested for the predicted trend values. Finally, an experiment was designed for testing the practical application effect of the GRU-Self-Attention prediction model.

A. Performance Analysis of Entity Recognition Models and Entity Relationship Extraction Models

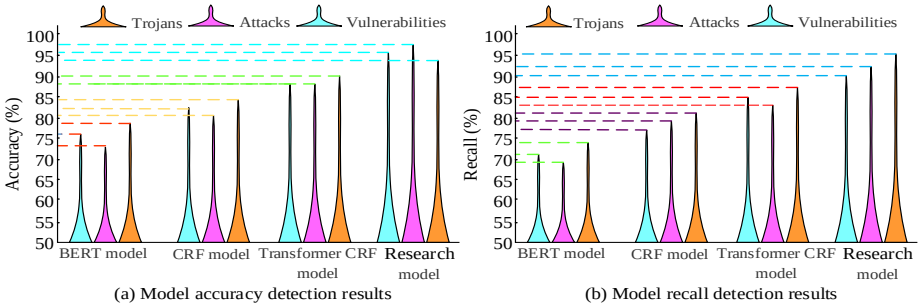
For ensuring the accuracy and reliability of constructing a network security KG, it is necessary to verify the effectiveness of the entity recognition model and entity relationship extraction model studied and constructed. To this end, the research used crawler software to crawl malicious code, security vulnerability information, network intrusion information and other network security text data from major security vendors, hacker communities and other websites on the Internet, a total of 34582 pieces. At the same time, it set the network environment and model parameters required for the experiment, as showcased in Table II.

TABLE II. Basic Hardware Environment and Model Parameters for the Experiment

Project	Parameter
Operating system	Windows10
System PC side memory	16G
CUP	Intel Core i9
Storage	256GB SSD
Graphics card	NVIDIA GGTX 1060
Development tool	Pycharm3.6, Anaconda3
Model Optimizer	Stochastic Gradient Descent
Hidden layer size	0.0001
Batch size	100
Epoch size	40
Dropout	0.5

The selected dataset was divided into three types of named entities: vulnerabilities, attacks, and Trojans, and the recognition model constructed in the study was used to detect these four types of named entities. Additionally, to demonstrate the effectiveness and superiority of the model, the currently popular entity recognition model was selected and compared with the research model. The selected models include the BERT model in reference [20], the CRF model in reference [21], and the Transformer-CRF model in reference [22]. The accuracy and recall results of the four models are showcased in Fig. 6.

Fig. 6(a) showcases the accuracy test results of four entity recognition models. This indicates that the detection accuracy of the research model for vulnerability, attack, and Trojan named entities is 95.9%, 97.1%, and 93.7%, respectively, with the highest recognition accuracy among the four models. Fig. 6(b) shows the recall test results of four entity recognition models. This indicates that the recall rates of the research model for vulnerability, attack, and Trojan named entities are 90.3%, 92.7%, and 95.9%, respectively, which are also the highest among the four models. This indicates that the entity recognition model constructed in the study has significant advantages. This is because the model incorporates feature models and text embedding vector representation methods to optimize model performance, thereby enhancing the accuracy and recall.



(a) Model accuracy detection results (b) Model recall detection results

Fig. 6. Accuracy and recall test results of four recognition models.

3698 sentences with multiple network security entities from the collected 34582 network security text data were selected to test the accuracy of the entity extraction model constructed. Similarly, to verify the superiority of the extraction model constructed, SVM, CRF, and SRL models were selected and compared with the research model. The results are shown in Fig. 7.

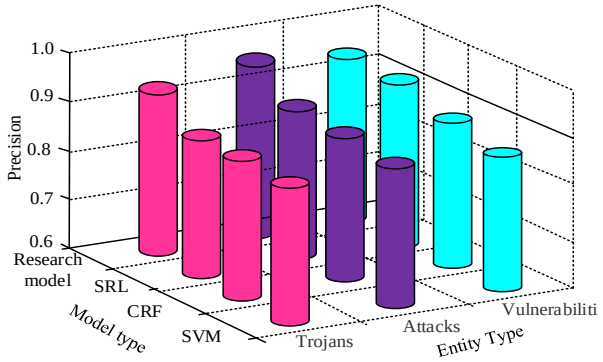


Fig. 7. Accuracy test results of four extraction models.

In Fig. 7, for the types of vulnerabilities, the extraction accuracy of the research model, SVM, CRF, and SRL are 0.92, 0.82, 0.80, and 0.76. For attack types, the extraction accuracy of the four models is 0.94, 0.85, 0.83, and 0.81, respectively. For the types of vulnerability attacks, the extraction accuracy of the four models is 0.93, 0.90, 0.88, and 0.81, respectively. This indicates that the extraction model used in the study has the highest accuracy, as it adds a self-attention layer, which can better combine long sentence information and improve model performance.

B. *Performance Analysis of GRU-Self-Attention Prediction Model*

For verifying the GRU-Self-Attention prediction model, the NSL-KDD and CICIDS2017 datasets were selected as network information sources. Then the network security situation quantification method mentioned in section 2.2 was used to quantify the selected dataset, which was used as the experimental dataset. Similarly, the dataset was allocated in a ratio of 3:7 between the test set and the training set, and the experimental environment was consistent with that in section 3.1. The model network structure adopted a "input layer-hidden layer-output layer" approach, with a learning rate of 0.001 and a training period of 3000. In addition, GRU model, PSO-LSTM model, and RBF model were selected as controls. The first step is to test the average absolute error of the predicted situation value of the model, as shown in Fig. 8.

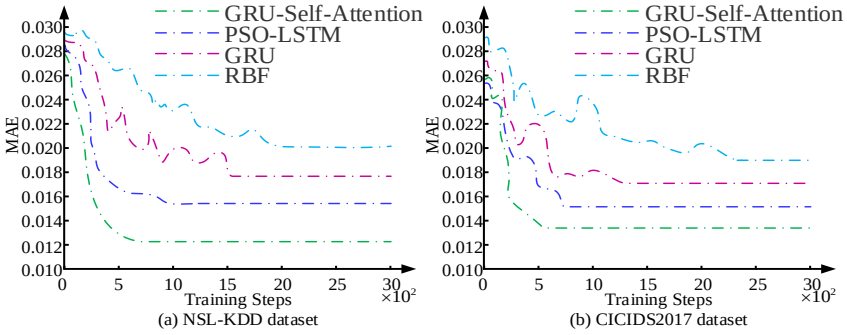

Fig. 8. Test results of the average absolute error of the model's predicted situational values.

Fig. 8(a) shows that in the NSL-KDD dataset, the mean square error (MSE) values predicted by the four models decrease with increasing training step size. The MSE values of RBF and GRU models are relatively large, and the curves fluctuate repeatedly during the training process until they stabilize after about 1500 iterations. The MSE values of PSO-LSTM and GRU-Self-Attention are continuously decreasing without any fluctuations. The PSO-LSTM model reaches a stable MSE value of approximately 0.0156 after training for about 1000 times. The GRU-Self-Attention model achieves a stable MSE value of approximately 0.0127 after training for approximately 678 times. Fig. 8(a) shows that in the CICIDS2017 dataset, the MSE value of the GRU-Self-Attention model is still the lowest, about 0.0136, and the training frequency is the least, about 589 times. The GRU-Self-Attention model constructed in the study can achieve good prediction results on different datasets, with lower MSE values and fewer training steps. Next, based on the NSL-KDD dataset, the neural network of the model was tested, and the results are shown in Fig. 9.

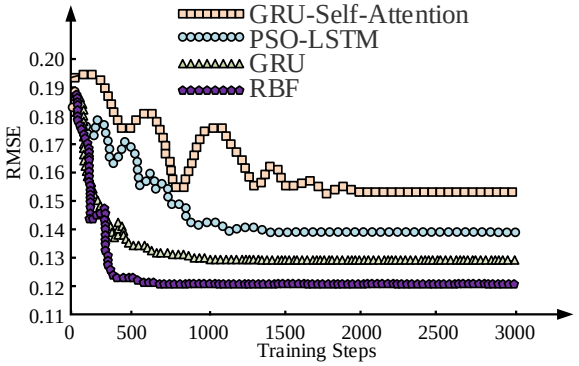

Fig. 9. Test results of neural network of model predictive situation values.

Fig. 9 shows that the RMSE values predicted by the four models decrease with the increase of training step size. The RMSE values of the RBF model fluctuate multiple times and have a large amplitude as they tend to stabilize. At around 1945 training sessions, the RMSE value tends to stabilize,

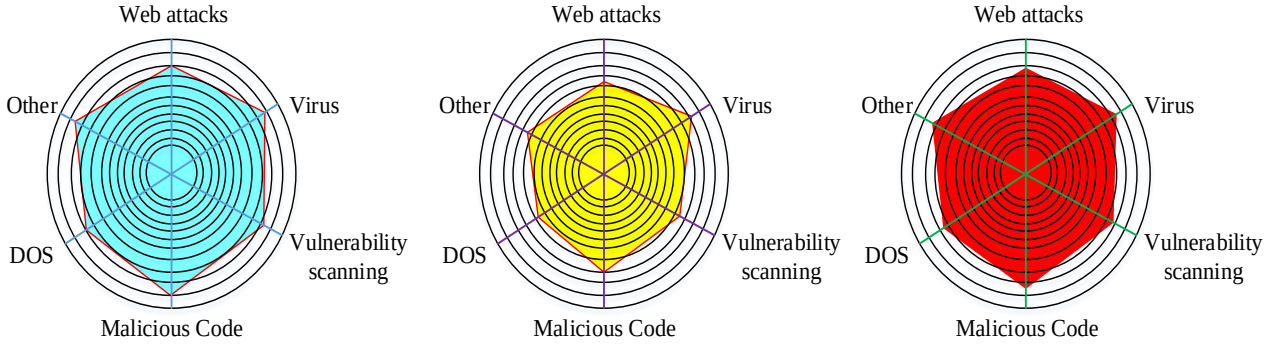
with an RMSE value of approximately 0.154. In contrast, the GRU model curve fluctuates slightly, but the fluctuation amplitude is small, stabilizing after approximately 1389 training sessions, with an RMSE value of approximately 0.141. The PSO-LSTM and GRU-Self-Attention models require less training to achieve stable RMSE values. The PSO-LSTM model is trained approximately 689 times, with a stable RMSE value of 0.129. The GRU-Self-Attention model is trained approximately 524 times, with a stable RMSE value of 0.121. The GRU-Self-Attention model has a higher degree of fitting to the training data and less computational time.

C. Application Analysis of GRU-Self-Attention Prediction Model

The above experiment has proven the feasibility of the network security situation prediction method constructed in the research. The information security system of a large Internet company was selected as the experimental object, and the GRU-Self-Attention prediction model was embedded into the company's security system. It detects the number of network information attacks, as shown in Fig. 10.

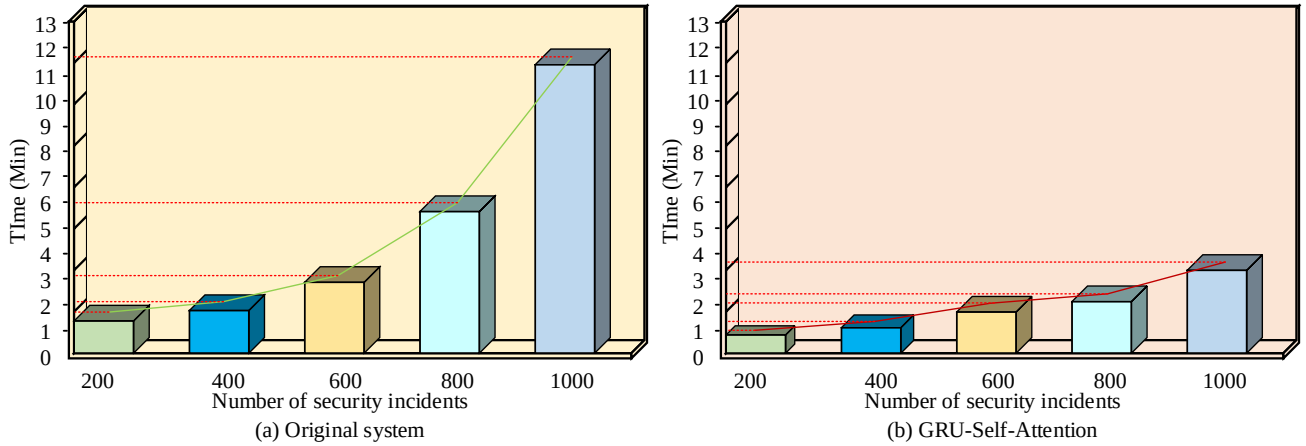
Fig. 10(a) shows the actual detection results of network information attacks. This indicates that during the detection process, the website is subjected to 110, 100, 106, 100, 109, and 102 malicious code attacks, DOS attacks, other types of attacks, web attacks, virus attacks, and vulnerability attacks, respectively. Fig. 10(b) showcases the detection results of the original prediction system of Internet companies. This indicates that the system predicts 90, 78, 83, 82, 101, and 84 malicious code attacks, DOS attacks, other types of attacks, web attacks, virus attacks, and vulnerability attacks, respectively. Fig. 10(c) showcases the detection results of the GRU-Self-Attention prediction model. This indicates that the model predicts 104, 98, 102, 99, 104, and 98 malicious code attacks, DOS attacks, other types of attacks, web attacks, virus attacks, and vulnerability attacks, respectively. The detection results indicate that the GRU-Self-Attention prediction model greatly improves the detection accuracy of the original system against network attacks. Compared with actual results, the detection accuracy is over 95%. It retests the detection time of network information attack events, and the results are shown in Fig. 11.

Fig. 11(a) shows the variation in time taken by the original prediction system to detect 1000 network security attack events. This indicates that as the number of attack events grows, the original prediction system takes more and more time, and the increase in time is becoming larger and larger. Detecting 1000 network security attack events takes approximately 11.7 minutes. In Fig. 11(b), the time growth of the GRU-Self-Attention prediction model is far less than that of the original system, with a detection time of about 1.2 minutes for 200 network security attack events. It detects 1000 network security attack events, taking only about 3.8 minutes.



(a) Actual number of attacks (b) Original system prediction model (c) GRU-Self-Attention model

Fig. 10. Detection results of network information attack by prediction model at this time.



(a) Original system (b) GRU-Self-Attention

Fig. 11. Prediction time for 1000 network security attack events.

Finally, the prediction performance of the GRU-Self-Attention prediction model on network security situation values was verified, as shown in Fig. 12.

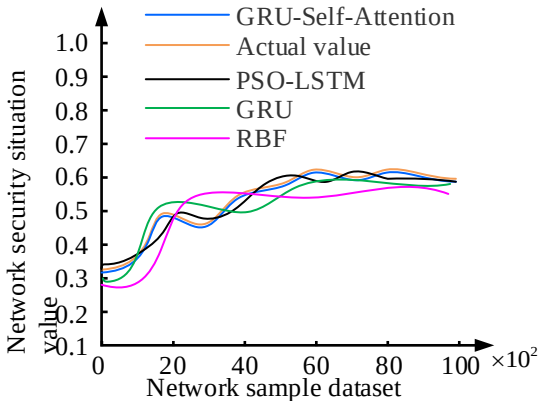


Fig. 12. Network security situation prediction value.

In Fig. 12, the actual potential value of the network ranges from 0.3 to 0.6 and increases with the increase of sample data. From the curve trend of the graph, the GRU-Self-Attention model constructed in the study has little difference between the predicted values of the network potential and the actual potential values. This indicates that the prediction model can make accurate predictions of the network potential values.

D. Discussion

With the increasing complexity and intelligence of network security threats, it has become inevitable to take more comprehensive and efficient measures to protect network security. Based on the Fusion of Knowledge Graph, this study constructs a network security data graph using KG technology and constructs a situation prediction model that combines self-attention mechanism and Gate Recursive Unit. The experimental results showed that the detection accuracy and recall rate of the entity recognition model constructed in the study were above 90%, which were higher than the BERT, CRF, and Transformer CRF models under the same experimental conditions. Compared with the research results of Chen. Z. et al. [4], there has been further improvement. This is because the constructed entity recognition model incorporates feature models and text embedding vector representation methods to optimize the performance of the model, thereby improving the accuracy and recall of the model. The accuracy of the constructed entity relationship extraction model was also above 90%. The extraction accuracy of the SVM, CRF, and SRL models under the same experimental conditions were 82%, 80%, and 76%, respectively, significantly lower than the research model. Compared to the accuracy achieved by Ruan. Z. et al. [5] is over 85%, but the method proposed in this paper is significantly higher. This is because the constructed entity relationship extraction model adds a self-attention layer, which can better combine long sentence information and improve model performance. This also indicates that the constructed network security KG has extremely high feasibility. But the prediction efficiency of the methods proposed in network security needs to be improved. In the future, it is necessary to optimize the model structure and utilize more advanced parallel computing to further improve the predictive performance of network security, providing more reliable guarantees for network security.

V. Conclusion

Situation prediction technology possesses an essential influence on mitigating network security threats. Therefore, this study optimized the entity recognition model and entity relationship extraction model of network security KG and presented a network security situation assessment method based on KG and Bayesian attack graph. Meanwhile, the situation prediction method was optimized through self-attention mechanism, and a GRU-Self-Attention prediction model was constructed. The experimental results showed that the average absolute error of the GRU-Self-Attention situational prediction model based on network security KG in predicting situational values in the NSL-KDD dataset was about 0.0127. This value was about 0.0136 in the CICIDS2017 dataset. The average absolute error in different scenarios was lower than that of the GRU, PSO-LSTM, and RBF models under the same experimental conditions. The model constructed in the study has good fit to different datasets, and the average absolute error is lower than the existing models. The GRU-Self-Attention model was embed into an information security system, which could accurately predict the number of different types of network attacks. In addition, the model detected 1000 network security attack events, which only took about 3.8 minutes. This indicates that the research plan can effectively improve the accuracy of network security situation prediction. However, building a network security KG requires a large number of resources and time in the early stages, and later research will further optimize the construction process and data processing of KG.

***Abstract*—According to the World Health Organization (WHO), depression affects over 350 million people worldwide, making it the most common health problem. Depression has numerous causes, including fluctuations in business, social life, the economy, and personal relationships. Depression is one of the leading contributors to mental illness in people, which also has an impact on a person's thoughts, behavior, emotions, and general wellbeing. This study aids in the clinical understanding of patients' mental health with depression. The primary objective of research is to examine learning strategies to enhance the effectiveness of depression detection. The proposed work includes 'Extended- Distress Analysis Interview corpus' (E-DAIC) label dataset description and proposed methodology. The membership function applies to the Patients Health Questionnaire (PHQ8_Score) for Mamdani Fuzzy depression detection levels, in addition to the study of the hybrid approach. It also reviews the proposed techniques used for depression detection to improve the performance of the system. Finally, we developed the Ensemble-LSRG (Logistic classifier, Support Vector classifier, Random Forest Classifier, Gradient boosting classifier) model, which gives 98.21% accuracy, precision of 99%, recall of 99%, F1 score of 99%, mean squared error of 1.78%, mean absolute error of 1.78%, and R^2 of 94.23.**

***Keywords*—Depression detection; machine learning; extended-distress analysis interview corpus; ensemble-LSRG model; mamdani fuzzy**

I. Introduction

Depression is the most common mental disease in the world. Causes of disruption include the emotion experience, lack of communication, human behavior, and social media problems [1]. Human existence is present on the internet and in social media, just as it is in daily life. Additionally, communication is getting better every day. Unknown people can communicate with one another online, yet there are also drawbacks to social media and the internet. Anorexia and bipolar depression affect millions of individuals globally, making depression one of the worst problems in the world [19], and [25]. Over 350 million people worldwide are affected by depression, and it's the most common health problem, according to the World Health Organization (WHO) [26], [27], and [12]. According to research on the causes of depression, the risk of suicide increases more than 30 times among those in generally good health [27] and [29].

Despair triggers numerous events. Every day in the surrounding area, people can observe the prevalence of suicidal situations and other mental illnesses [11] that are also influenced by depression. For example, in today's society, stress from the daily workload significantly raises the risk of developing it. According to a poll on depression, the following symptoms appear virtually daily for two weeks: Depression or a loss of mood, a decline in enthusiasm for the activity, suicidal thoughts, and a sense of hopelessness [19]—other factors, such as genes and family history, can also contribute to depression [23]. All different kinds of men and women of all ages struggle with this issue. According to the WHO, depression affects 350 million individuals globally [26], [27], and [12]. According to research on the causes of depression, the risk of suicide increases more than 30 times among those in generally good health [27], [29], and [31].

Depression can be detected by utilizing learning approaches using the system's multimodal resources. The system's objective is to offer many modalities on the same platform in order to increase accuracy and the techniques for detecting emotions, such as sentimental analysis and speech prosody. 12% and 6.6%, respectively, of men and women are seeing an increase in depression [12]. Humans communicate their emotions more frequently in daily life through speech, social media, blogs, and chat rooms. The study offers the voice activity detector, speech emotion recognition, and text emotion recognition for text-based data [24], [26], and [27]. Face analysis can help identify of depression [21], and [27]. The merger of all modalities can aid in increasing the system's accuracy [22]. According to a 2019 survey, there were 1,39,123 suicide-related deaths in India, and the national rate of self-destruction continued to be 10.4 (calculated per 1 lakh people), as stated in Chapter 2 of the National Crime Record Bureau, for example. Recently, 'Sushant Singh Rajput' attempted suicide due to depression [1]. The goal of this system is to create a hybrid modal system [9] that will help society and medical professionals diagnose and track depression. This study utilized ensemble learning to learn from PHQ8 data in order to get the correct positive results [30].

In this section, include an introduction and motivation for the study, as well as a general overview of the study. In the second section, it includes related work of the study, including existing work related to the study, the gap analysis, as well as the key issues and challenges part. The third section outlines the recommended strategy for improving system performance, the dataset description, and algorithmic details; the fourth

section includes the result and discussion part. The conclusion and future scope are covered in the final part.

II. Related Work

As per the literature survey observed that the following related work:

The MSN (Multi-scale Spatiotemporal Network) model, put forth by Wheidima Carneiro de Melo, integrates face data associated to depressive behavior from image [2]. Models only pick up irregularities associated with people's facial expressions. This work made use of the Audio-Visual Emotion Recognition Challenge (AVEC2014) dataset. Mean Absolute Error (MAE) and Root Mean Square Error (RMSE) components influence the results. The DMVM (Deep Mood Architecture with Multi View Machine) model is suggested by Xiaohang Xu and Hao Peng and is used to identify depression [3]. Hospitals preserve patient health information in accordance with privacy concerns. This information cannot be used for a centralized machine learning in the diagnosis of depression. At that point, federated learning is crucial for identifying depression. Accuracy serves as the primary criterion for analyzing outcomes in comparisons. To classify the data into five categories (healthy, smooth, pleasant, neutral, and serving), Kaining Mao, Wei Zhang, and Deborah Baofeng Wang developed a model on the Oz dataset using the Distress Analysis Interview Corpus Wizard [4]. The final result was based on the F1 score, accuracy, precision, and recall. They used the following networks: Bidirectional BI-LSTM+FC, LSTM+ Time-distributed Convolutional Neural Network TCNN, Long Short Term Memory LSTM + FC, and BI- LSTM+ TCNN.

Shallow (EdgeER) and deep models are used by Shuai Ding, Zi Xu, Yaping Wang, Lina Qu, Yinghui Li, Yao Yu, Xiaojian Li, and Shanlin Yang et al. *[5]. Deploy the deep model (C-DepressNet) to cloud servers and the shallow model (EdgeER) to edge servers. EdgeER can instantly identify unfavorable sentiment in user data. High-precision analyses of depression levels are performed using depth models. BDI-II score values are finally categorized as follows: no depression, mild, moderate, or severe depression. Pushpak Bhattacharyya, Soumitra Ghosh, and Asif Ekbal, et al. [6], on multi-model multitasking systems. This work includes multi-model social network profiles that leverage deep learning to retrieve metadata (e.g., user location, photo, and description). Work on image collections and emotionally charged datasets for outcome analysis. The model's accuracy and F1 score dictate the result. Conv + Maxpool Layer, Shared Multilayer Perceptron (MLP), Task-Specific MLP, Output Layer, Hidden Activation, Output Activation, Batch Size, Epoch, Dropout, Loss, Optimizer, etc. are some of the parameters. Lei Tong, Zhihua Liu, Zheheng Jiang, Feixiang Zhou et al. proposed a method for identifying depressed Twitter users [7]. “Cost-sensitive Boosting Pruning Trees” (CBPT) gets classification results using a variety of technique. "Cost-sensitive Boosting Pruning Trees" (CBPT) uses a range of methods to provide classification results. Including "Discrete Adaboost, Real Adaboost, XGboost, LogitBoost, LightGBM, and HiGB", various methods are used when comparing to the UC Irvine (UCI), the machine learning repository. The eight boosting classifiers' accuracy and F1 scores serve as the foundation for the final analysis.

Using the SH2 data sets and the “Distress Analysis Interview Corpus/Wizard-of-Oz collection” (DAIC-WOZ), Zhaocheng Huang, Julien Epps, Dale Joachim, and others conducted tests [8]. The algorithm's F1 rating is the foundation for the ultimate rating. Among the groundbreaking features of this study are "g(lottis)," "p(eriodity), "s(onorant"), "f(ricative), "v(oiced fricative), and "b(ursts)". Erik Cambria, Shaoxiong Ji, Qian Chen, and Luna Ansari examined a text classifier that was taught to identify depression. An assessment matrix is used to assess classification systems. Precision, recall, F1 score, and precision make up the evaluation matrix. A unique automatic depression detection ADD (Temporal dilated convolutional network - TDCN and feature wise attention - FWA) model proposed by Yanrong Guo, Chenyang Zhu, and et al. [10] suggests data collecting based on the visual cues captured throughout the interview process. Other modalities, including as text and audio, could be used in this study to enhance the system's functionality. The ultimate outcome is based on factors like as accuracy (0.857), recall (0.91), precision (0.733), and F1 score (0.85). Study based on sub-emotions (BoSE), Late Fusion Methods by Mario Ezra Aragon et al. In order to improve depression identification, this study combines static and dynamic representations of early and late fusion techniques. Processing solely text-based data. Privacy about certain data. It is forbidden to misuse and handle sensitive information improperly. Factors such as the F1 Score of 0.64, Precision of 0.67, and Recall of 0.61 influence the final outcome.

Electroencephalogram (EEG) signal decomposition for depression identification by Jian Shen, Xiaowei Zhang, Bin Hu, Gang Wang, et al. [12]. It illustrates how the human brain functions. This piece of art illustrates how the human brain functions. Electroencephalogram (EEG) databases have accuracies ranging from 83.27% to 85.19% to 81.98% to 88.07% for each dataset. Usman Ahmed, Jerry Wei Lin, and others [13] proposed the BI-LSTM, which has received much attention and uses unlabeled forum text and social media data to boost the rate of diagnosing depressive symptoms from online data. These studies' drawbacks include dealing only with textual data and illiteracy. Accuracy and Cohen Kappa metrics are used to compare results. Studying the self-attention graph pooling-soft label (SGP-SL) model are Tao Chen, Yanrong Guo, and colleagues [14].

In this study, soft labeling was employed together with an experiment using the ‘MODMA’ dataset, a multi-modal open dataset for mental-disorder investigation that served as an efficient model in many ways. Another area of investigation in the feature work is the issue of incomplete modalities and the identification of major depressive disorder (MDD). The final result depends on parameters like, Accuracy= 84.91%, Precision= 80.77, Recall= 87.50, F1-Score=84. A study on LSTM, CNN, and hybrid (CNN + LSTM) models was conducted by Mudasir Ahmad Wani, Mohammad A, and colleagues [15] to examine variables including precision, accuracy, and F1 score. The term frequency-inverse-document frequency (TF-IDF) based characteristics and Word2Vec were used in this investigation. We must continue to develop on the

multiplication corpus because it only covers the English language. Study on logistic regression by Jianxiu Li, Nan Li, Xuexiao Shao, et al. [16]. Microstate Parameters: Duration, Occurrence, and Time Coverage performed well in this investigation at detecting MDD. Restriction on the number of participants with MDD and healthy controls (HC). Large data sets are necessary to demonstrate the study's statistical power.

Study on the Mutual Information Based Fusion Model (MIBFM model) by Jing Zhu, Changlin Yang, et al. [17]. This study put forth the model that is used to correlate the signals from the pupil area and the EEG. The National Key Research and Development Program of China (NKR&DP of China) is funding this work. To carry out activities, data gathering and dataset enrichment are necessary. Mild depression and normal control require binary classification. Deep Convolutional Neural Network (DCNN) and Deep Neural Network multimodal investigation of depression by Le Yang, Dongmei Jiang, and Hichem Sahli [18]. In AVEC2016, support vector machines and random forests are both employed for classification. They used text documents, audio data, and video data for this endeavor.

Studies on identifying psychiatric diseases such anorexia and depression by Mario Ezra Arag'n, A. Pastor L'opez-Monroy, Luis C. Gonz'alez, et al. [19]. Users of social media have unfortunately developed depression as a result of their use. Anorexia and Depression Sentiment Distribution solely use this information for study and analysis. Data that should not be shared. Studying depression during and after pregnancy, Kristen C. Allen, Alex Davis, and Tamar Krishnamurti [20] conducted a study to inadvertently detect perinatal psychosocial concerns. This study examined both happy and negative feelings as well as a lack of relationship support to identify emotions, despair, and sentimental analysis.

III. PROPOSED WORK

The proposed work of the study including the dataset Description, the proposed methodology and algorithmic detail:

A. The Dataset Description

Semi-clinical interviews prepare the Extended Distress Analysis Interview Corpus (E-DAIC) dataset. The dataset is designed to support the psychological distress condition such as anxiety, depression and post-traumatic stress disorder. These interviews were collected as part of a larger effort to create a computer agent that interviews, people and identifies verbal and nonverbal indicators of mental illness. An animated virtual interviewer called Ellie conducts the interviews. A subset of session are collected in a wizard-of-Oz (WoZ) setting, were the virtual agent is controlled by a human interviewer (wizard) in another room [30].

The Dataset is classified into training, development, and test dataset while preserving the overall speaker's diversity -- in terms of age, gender distribution, and the eight-item Patient Health Questionnaire (PHQ-8) scores -- within the partitions. Whereas the training and development sets include a mix of WoZ and AI scenarios, the test set is solely constituted from the data collected by the autonomous AI [39]. Sessions with IDs in the range [300,492] are collected with WoZ-controlled agent and sessions with IDs [600,718] are collected with an AI-controlled agent [30].

B. Proposed Methodology

The proposed methodology of the study on the E-DAIC (Extended – Distress Analysis Interview corpus) label dataset is shown in Fig. 1.

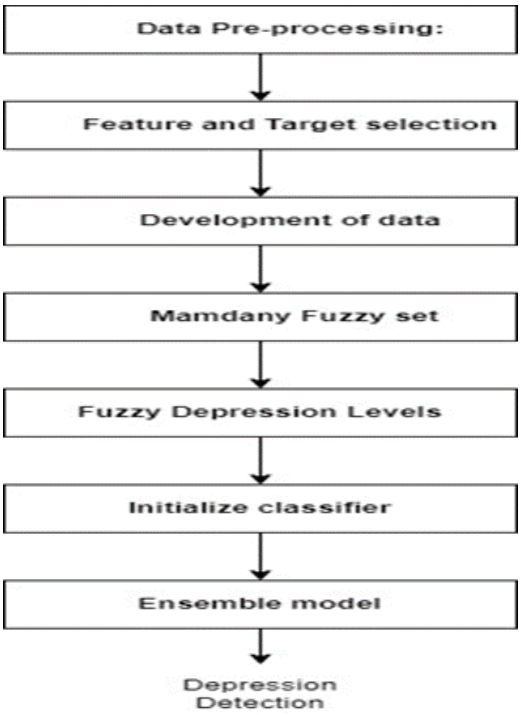

Fig. 1. Proposed methodology for the depression detection system using ensemble model.

The labeled dataset contains data from 275 participants. Specifically, the train_split.csv contains records from 163 participants, the test_split.csv contains records from 56 participants, and the dev_split.csv contains records from 56 participants. The methodology follows the following steps,

1) Data pre-processing: In data pre-processing it upload the train_split.csv, test_split.csv and dev_spit.csv from the E-DAIC Dataset. Pre-processing of the data include the data cleaning, data normalization and finding the missing values. Additionally, data is augmented and increase the data size with five times.

$$X=\text{imputer.fit\_transform}(X) \quad (1)$$

where, X is the feature set vector.

By using Eq. (1) to handle the missing values from feature sets.

2) Feature and target selection: Feature selection is the very important of this study. This can be done by observing the correlation between the variable. Target selection also be important for this study.

3) The Development of data: The Development of the data combine train_split and dev_spit dataset for model development.

4) Define mamdani fuzzy se: In Mamdani fuzzy logic define the membership function for PHQ8_Score and create the output variable. In the fuzzy set define the membership function for depression severity also define the rules for classification for four classes then define create the fuzzy control system.

5) Fuzzy depression levels: Apply fuzzy logic to calculate Mamdani fuzzy depression level.

MamdaniFuzzyLevel=apply_fuzzy_logic (PHQ_Score) (2)

6) Initialize classifier: In this study used no of classifier like logistic_regression, support classifier, Random_Forest_Classifier, Gradient_Boosting_Classifier to the ensemble model.

7) Ensemble model: Define ensemble model for hybridization and train it by training data to improve the performance of the system.

ensemble_model=VotingClassifier (estimators=[('lr', clf1), ('svc', clf2), ('rf', clf3), ('gb', clf4)], voting='soft') (3)

ensemble_model.fit (train_X, train_y) (4)

Where,

X is feature set y is the target,

lr is logistic classifier,

svc is support vector machine classifier,

rf is random forest classifier,

gb is gradient boosting classifier.

By using Eq. (3) and Eq. (4) define and train the ensemble model.

8) Prediction and evaluation of the model: Make predictions using the trained ensemble model.

Calculate accuracy, confusion matrix, and visualize the confusion matrix.

y_pred = ensemble_model.predict(X_test) (5)

accuracy = accuracy_score(y_test, y_pred) (6)

cm=confusion_matrix(y_test, y_pred) (7)

By using Eq. (5), we can predict the depression detection using the ensemble model. Eq. (6) used to calculate the accuracy of the model and Eq. (7) used to generate the confusion matrix of the predicted values and actual results.

IV. Results and Discussions

In this study execute the whole system using the ensemble LSRG (Logistic regression, Support vector classifier, random forest classifier and the gradient boosting) model to improve the performance of the system.

The above Fig. 2 shows the membership function of the fuzzy system with respective to the phq_score. The depression detection system, including only four levels of depression, i.e. "No Depression", "Mild Depression", "Moderate Depression", and "Severe Depression". The Fig. 2. Shows the membership for low, medium and high phq_score.

In Fig. 3, show that the confusion matrix of "Linear Regression model" and "Ensemble–LSRG model". As per figure, the "Ensemble-LSRG model" is less confuse than the "Linear Regression model". Less confuse means the "Ensemble-LSRG model" give the high accuracy. The accuracy required to calculate the accurate depression level.

In Fig. 4, show that the confusion matrix of "Support Vector Machine" and "Ensemble–LSRG model". As per figure, the "Ensemble-LSRG model" is less confuse than the "Support Vector machine". Less confuse means the "Ensemble-LSRG model" give the high accuracy. The accuracy required to calculate the accurate depression level.

In Fig. 5, show that the confusion matrix of "Random Forest classifier" and "Ensemble–LSRG model". As per figure, the "Ensemble-LSRG model" is less confuse than the "Random forest classifier". Less confuse means the "Ensemble-LSRG model" give the high accuracy. The accuracy required to calculate the accurate depression level.

In Fig. 6, show that the confusion matrix of "Gradient boosting classifier" and "Ensemble–LSRG model". As per figure, the "Ensemble-LSRG model" is less confuse than the "Gradient boosting classifier". Less confuse means the "Ensemble-LSRG model" give the high accuracy. The accuracy required to calculate the accurate depression level.

In Fig. 7, show that the confusion matrix of "Convolutional Neural Network" and "Ensemble–LSRG model". As per figure, the "Ensemble-LSRG model" is less confuse than the "Convolutional Neural Network". Less confuse means the "Ensemble-LSRG model" give the high accuracy. The accuracy required to calculate the accurate depression level.

In Fig. 8, displays the confusion metrics of depression detection using Recurrent Neural Network. From the observation of the diagram, it is evident that the "Ensemble (LSRG) model" is less confused compared to other techniques. "Less confusion" implies that the "Ensemble-LSRG model" provides higher accuracy. Accuracy is necessary to calculate the precise level of depression.

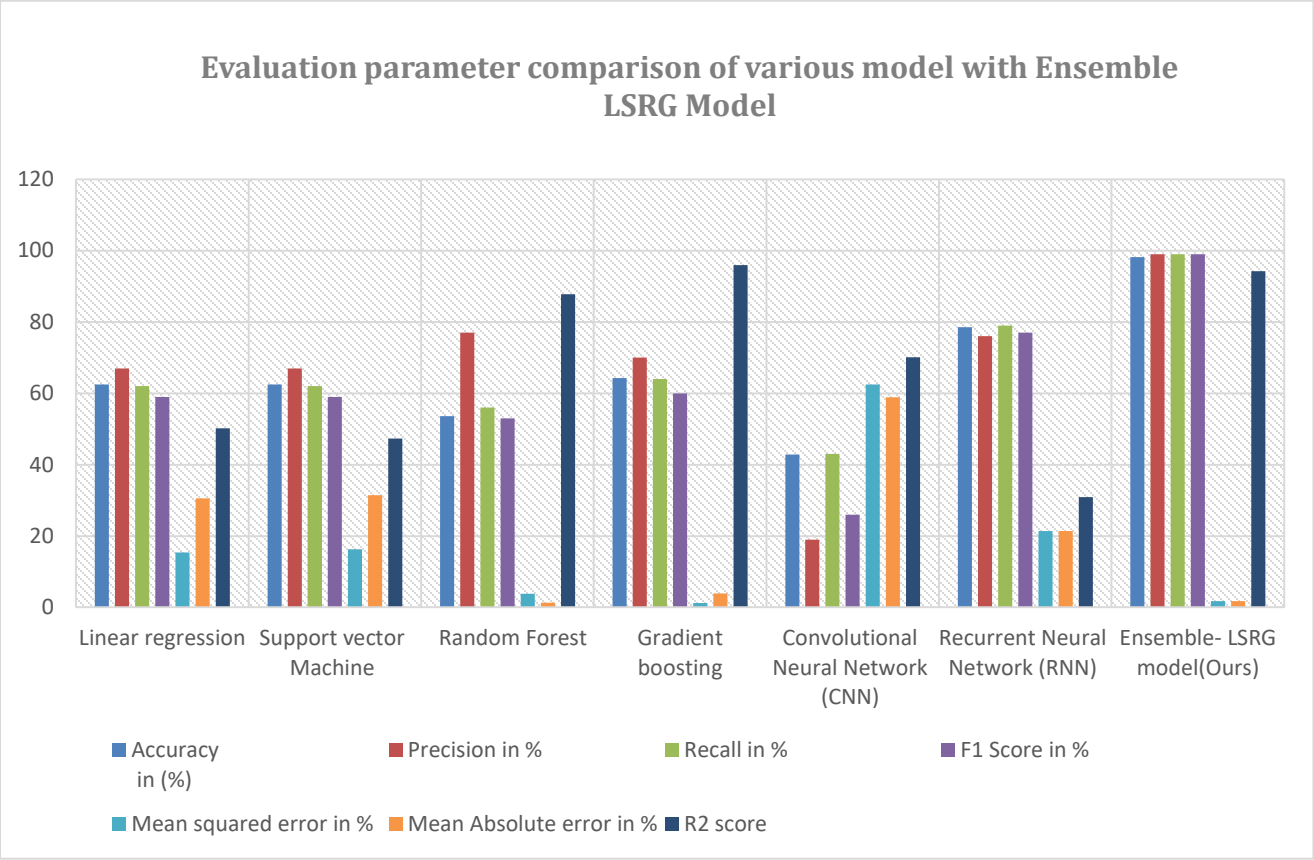

Fig. 9. Evaluation parameter comparison of various model with ensemble LSRG model.

Table I and Fig. 9 shows the analysis of performance of the depression detection system using different machine learning algorithm and Ensemble –LSRG model using various parameters likes, accuracy, precision, recall, F1 score, mse, mae, and R^2 score. As per table and Fig. 9. shows that the linear regression model having accuracy of 62.5%, precision of 67%, recall of 62%, F1 score of 59%, mean squared error of 15.42%, mean absolute error of 30.57% and R^2 score is 50.21%. The second model is a support vector machine with an accuracy of 62.5%, precision of 67%, recall of 62%, F1 score of 59%, mean squared error of 16.32%, mean absolute error of 31.43%, and R^2 of 47.31%. The third model is a random forest with an accuracy of 53.57%, precision of 77%, recall of 56%, F1 score of 53%, mean squared error of 03.78%, mean absolute error of 1.31%, and R^2 of 87.80%. The fourth model is gradient boosting with an accuracy of 64.28%, precision of 70%, recall of 64%, F1 score of 60%, mean squared error of 01.25%, mean absolute error of 03.94%, and R^2 of 95.96%. The fifth model is a Convolutional Neural Network with an accuracy of 42.85%, precision of 19%, recall of 43%, F1 score of 26%, mean squared error of 62.50%, mean absolute error of 58.92%, and R^2 of 70.6%. The next model is a Recurrent Neural Network with an accuracy of 78.57%, precision of 76%, recall of 79%, F1 score of 77%, mean squared error of 21.42%, mean absolute error of 21.42%, and R^2 of 30.86%. The last model is the Ensemble-LRGS model (Ours) with an accuracy of 98.21%, precision of 99%, recall of 99%, F1 score of 99%, mean squared error of 1.78%, mean absolute error of 1.78%, and R^2 of 94.23%.

In discussion of research the Fig. 9, shows linear regression model having moderate performance with accuracy, precision, recall, and F1 score all around 60% also mean squared error and mean absolute error are relatively high, suggesting it might not fit the data well. The second model support vector machine also give the similar performance as per linear regression model so it is also not significantly better or worse. The third model is random forest which gives the high precision rate 77% but the accuracy is lower as compare to first two model. The forth model is gradient boosting show the best performance among individual model with high accuracy 64. 28% and precision 70%. The fifth model perform relatively poorly as compare to other models with lower accuracy, precision, recall and F1 score, it means high mean squared error and mean absolute error indicating poor fit of data. The sixth model is recurrent neural network shows high accuracy 78.57% and precision 76% indicating its performing better than most individual model. The last model Ensemble-LSRG model (Ours) demonstrate the outstanding performance across all metrics with very high accuracy, precision, recall and F1 score, additionally it has lower mean squared error and mean absolute error among all models indicating the data is fit extremely well.

V. Conclusion and Future Scope

The study includes research work and various learning techniques and algorithms aimed at identifying research gaps. Additionally, it examines previous research on depression detection [28] and systems. This work will illustrate different depression detection systems, key issues, and challenges. Furthermore, it investigates a proposed methodology to enhance the system performance. The system achieves high accuracy compared to existing algorithm techniques. In this study, the system achieves 98.21% accuracy, precision of 99%, recall of 99%, F1 score of 99%, mean squared error of 1.78%, mean absolute error of 1.78%, and R^2 of 94.23% for the Ensemble LSRG model (Ours). In future research, the method to detect depression using a learning approach will be implemented. Additionally, performance metrics for early depression detection will be confirmed through experimentation analysis. Finally, the performance of the proposed algorithm will be evaluated against other popular depression detection algorithms to validate the results.

Sustainable Artificial Intelligence: Assessing Performance in Detecting Fake Images

Othman A. Alrusaini
Department of Engineering and Applied Sciences-Applied College, Umm Al-Qura University, Makkah, Saudi Arabia

***Abstract*—Detecting fake images is crucial because they may confuse and influence people into making bad judgments or adopting incorrect stances that might have disastrous consequences. In this study, we investigate not only the effectiveness of artificial intelligence, specifically deep learning and deep neural networks, for fake image detection but also the sustainability of these methods. The primary objective of this investigation was to determine the efficacy and sustainable application of deep learning algorithms in detecting fake images. We measured the amplitude of observable phenomena using effect sizes and random effects. Our meta-analysis of 32 relevant studies revealed a compelling effect size of 1.7337, indicating that the model's performance is robust. Despite this, some moderate heterogeneity was observed (Q-value = 65.5867; I^2 = 52.7344%). While deep learning solutions such as CNNs and GANs emerged as leaders in detecting fake images, their efficacy and sustainability were contingent on the nature of the training images and the resources consumed during training and operation. The study highlighted adversarial confrontations, the need for perpetual model revisions due to the ever-changing nature of image manipulations, and data scarcity as technical obstacles. Additionally, the sustainable deployment of these AI technologies in diverse environments was considered crucial.**

Keywords*—Artificial intelligence; image validation; deep learning; deep neural networks; fake images; image forgery; image manipulations

I. Introduction

Technological advancements in graphics design continue to receive unprecedented improvements with each new software release. Such advancements are beneficial and detrimental, as they can positively and negatively impact people. On the positive side, repaying old images and restoring them to their former state is now possible. Using software such as Photoshop, a designer can clone sections of an image using the clone stamp tool and replicate the pattern in a different area to make it appear real and authentic [1, 2]. Users can also add interesting features to their photographs to add aesthetics that were previously not present in their photographs. This aesthetic appeal from edited images can improve an image's appeal and introduce an element of fantasy into the work.

Nevertheless, this technology has seen its application stretch beyond serving people's genuine needs to improve photographic appeal. Many, if not most, of its application has been doctoring images to trick people into believing falsehoods [3, 4]. One of the fields that have suffered immensely is academics. People can now engage in document forgery to create certificates that look exactly like an institution's legally issued credentials [5]. Most recent versions of the graphics editing software use artificial intelligence (AI) to edit images, making the finishing even more illustrious [6]. This fact makes it quite difficult to detect fake images from the real ones using the naked eye, thereby creating an extra layer of complexity to the process.

The primary objective of this research is to undertake a meta-analysis study of deep learning tools and technologies used to detect fake images, with a focus on both their effectiveness and sustainability. The research questions guiding this analysis are as follows:

1) How effective are deep learning algorithms in detecting fake images, and how do their effectiveness and sustainability correlate?

2) What are the most reliable evaluation metrics for evaluating the performance and sustainability of deep learning algorithms in detecting fake images?

3) What are the technical challenges in the sustainable detection of fake images using deep learning techniques?

While several studies have engaged in the primary research of creating and evaluating deep learning models to detect fake images, few have done it in a meta-analytical way that also considers the sustainability of these technologies. This approach effectively synthesizes the field's gains in developing the algorithms. It also exposes the weaknesses, gaps, and sustainability concerns that need filling to improve algorithmic formidability. It is expected that this research and its analysis will add to the existing fake images detection with AI literature by providing a better understanding of the different models and various datasets.

The paper contains six sections: introduction, background, methods, results, discussion and conclusion. The introduction in Section I sets the stage for what the paper will deliberate on and establishes the researcher's rationale. The background in Section II, the paper delves deep into the current solutions and technological overview to give the reader a good vantage point from which to appreciate the gains and weaknesses in the field of fake image detection using deep learning technologies. The methods in Section III takes the reader through a setup of the meta-analytical approach, including search strategies, data sources, inclusion and exclusion criteria, and data analysis approaches. The results in Section IV comprehensively analyses the findings made in the analysis. Finally, the paper discusses these findings to synthesize the results and also summarises along with suggested areas for further investigation in Section V and Section VI respectively.

II. BACKGROUND

A. Types of Fake Images

The diversity of fake images has made their detection all the more challenging because of the intricacy that comes with each type. Image splicing is one of the many types contributing to the fake image ecosystem [7, 8]. It refers to the result of combining parts of different images to create a new but deceptive version. It is almost similar to morphing and blending two or more images. In both cases, tampering with the final image is difficult to identify with the naked eye. Sometimes, creating fake images may involve hiding some aspects within the image to make it look different [9]. One way to do so is by deleting the unwanted element, which counts as the removal technique. This technique is paired with 'insertion,' introducing a new element into the hitherto non-existent image. The second method to hide elements within an image is steganography, a more technical form of hiding the undesired elements [10].

Some techniques neither remove nor add elements to the original image. Instead, they work on the image's appearance to change certain aspects, such as lighting, contrast, color, and texture. The most popular methods are bundled under the group' filter-based manipulations' techniques [11, 12]. It is worth noting that designers often use filter-based manipulation techniques with others to create a new 'cooler' image. 3D rendering is another technique that changes the image from its 2D orientation to feature the third dimension of depth. While it does not introduce new elements, some shadows are likely to appear to give the illusion of a 3D image [13]. Regardless of the type of change and the intention behind such changes, analysts must be able to detect the changes programmatically for a more reliable consumption of these digital products. Deep learning is heavily equipped to check for even the mildest inconsistencies within the image structure and report them instantly [14].

B. Traditional Solutions to Detecting Fake Images

The challenge of detecting fake images predates the deep fake technologies, as there has been image doctoring beforehand. One solution that most analyses preferred using was engaging in image forensics. It is a collection of techniques involving statistical and pixel-level image analysis to identify inconsistencies [15, 16]. Some of the aspects sought after are differing noise patterns and lighting anomalies. This method is advantageous because it is not computationally expensive but falters in detecting high-end forgeries and is not easily scalable. Watermarking has also been a key technique in ensuring viewers can tell fake images from the original. While it is effective in copyright protection, it is less applicable to images whose originals do not have watermarks [17, 18]. Another traditional method is meta-analysis, which involves inspecting the images' metadata to detect fakes. While it provides contextual data, the metadata can be easily altered with the right technologies [15].

C. AI-Based Solutions to Detecting Fake Images

With the advent of artificial intelligence, so much technological progress has come about and has permeated the field of image analytics. One such technology is convoluted neural networks (CNNs), a specific network architecture for deep learning algorithms [15, 19]. Its highly-rated image analytical capabilities can automatically and adaptively learn spatial hierarchies of features in an image. It is highly accurate and is mostly applicable when there are complex patterns. However, their large dataset requirements imply they are computationally expensive [14]. Generative adversarial networks (GANs) are another technology consisting of a generator and discriminator working against each other, widely used for deepfake detection. Like CNNs, they thrive in complex patterns [8, 20]. Nevertheless, their nature as unsupervised learning models makes them susceptible to being unstable and generating false positives. Recurrent neural networks are similar to other technologies but are mostly applicable in video forensics because of their strength in analyzing sequential data [21, 22].

Ensemble methods, transfer learning, and zero-shot learning represent advanced AI approaches that address different aspects of fake image detection. Ensemble methods involve the combination of multiple AI models to improve predictive accuracy and robustness, although they come at the cost of computational expense and increased model complexity [23]. On the other hand, transfer learning provides an efficient approach by applying pre-trained models to new but similar tasks, effectively saving time and computational resources; however, its applicability is constrained to tasks that closely resemble the original training data [24]. Lastly, zero-shot learning presents a frontier in AI-based fake image detection, offering the ability to recognize types of fake imagery that the model has not been specifically trained on [25]. While this method is versatile and adaptable, it is still an area under active research, and thus its reliability is not fully established. Each method has advantages and disadvantages, emphasizing the need for ongoing research to refine these techniques and possibly integrate them for more effective and efficient fake image detection.

D. Fake Image Detection Process using AI

This section describes the methodological steps involved in detecting fake images through the use of AI to collect and analyze data. The flowchart for these steps is shown in Fig. 1.

Fig. 1. AI Fake image detection process flowchart.

1) Data collection: Data collection is fundamental in building supervised machine learning models. It is the first stage in fake image detection using AI. In this phase, high-dimensional data, often in image matrices or tensors, is gathered [24]. This dataset, comprising RGB values or even grayscale pixel intensities, is crucial for subsequent feature engineering. The data must also be annotated through manual labeling or semi-supervised methods to create ground truth labels distinguishing genuine images from artificially manipulated or deepfake counterparts.

2) Feature extraction: Feature extraction involves transforming raw image data into a reduced dimensionality

format using algorithms that capture essential patterns. Techniques such as convolutional neural networks (CNNs) are often employed here, leveraging filter banks to highlight vital image attributes such as edges, textures, and regions of interest [26]. When convolved with input data, these filters output feature maps highlighting image characteristics.

3) Feature selection: Not all features extracted hold discriminative power for the classification task at hand. Feature selection focuses on refining the feature set, eliminating redundant or irrelevant features to mitigate the curse of dimensionality, and optimizing model performance [27]. Algorithms such as Recursive Feature Elimination (RFE) or techniques leveraging mutual information can be utilized to determine the most salient features.

4) Classification: With a refined feature set, the classification phase employs algorithms to map these features to their respective labels. Deep learning architectures, like CNNs or more complex models like Residual Networks (ResNets), are trained using backpropagation [28]. The objective is to adjust weights and biases to minimize the loss function, typically cross-entropy loss for classification tasks.

5) Evaluation: Post-training, the model's robustness, and generalizability are gauged using accuracy, precision, recall, and the F1 score on a holdout validation or test dataset. Techniques like k-fold cross-validation can ensure the evaluation is comprehensive, and if underfitting or overfitting is detected, hyperparameter tuning, regularization methods, or architecture adjustments might be necessitated [20, 29].

III. Methods

A. Literature Search

In our investigation into artificial intelligence and image validation, we selected a set of keywords to guide our data extraction process. Central to our inquiry was "Deep learning," which is intrinsically tied to "Deep neural networks." To delve into the specific area of counterfeit or fake imagery, we utilized terms such as "Fake images," "Image forgery," "Image tampering," and "Image authenticity." Recognizing the significance of assessing the capability of algorithms, we incorporated "Effectiveness" and "Performance" into our search parameters. The term "Image detection" was chosen to understand the broader mechanisms behind image recognition and validation. Additionally, the "F1 score" was included as a metric of interest to gain insights into evaluation methods. Its inclusion is because of its widespread application in balancing precision and recall in binary classification problems. Through these keywords, we aimed to ensure a comprehensive exploration of the current state of deep learning techniques in detecting fake images.

B. PRISMA Flow Chart

The research was undertaken following the guidance of the PRISMA flowchart. It is a flow diagram reporting the stages articles go through to determine whether they are fit for inclusion in a meta-analysis [30]. The PRISMA flowchart in Fig. 2 delineates the sequence of a meta-analysis process. Initiating with the identification phase, a search was conducted across 10 databases, unearthing a total of 317 studies. From this collection, preliminary screening reduced the number to 226 records. The reasons for this reduction were multi-fold: 54 records were identified as duplicates, 23 were found ineligible based on certain criteria, and 14 were removed due to other specified reasons. The subsequent phase saw 187 of these 226 screened records being selected for detailed report retrieval. Of these, 44 reports could not be retrieved, which left a pool of 143 reports. These reports were then subjected to a comprehensive eligibility assessment. In the final count, several reports were excluded from the 143 due to a range of reasons: a lack of full-text availability in 20 reports, 45 not matching the necessary keywords, 27 not meeting the quality appraisal standards, and 19 being deemed irrelevant to the study's focus. After these exclusions, the evaluation was refined to a set of 32 studies that were considered relevant and included in the meta-analysis.

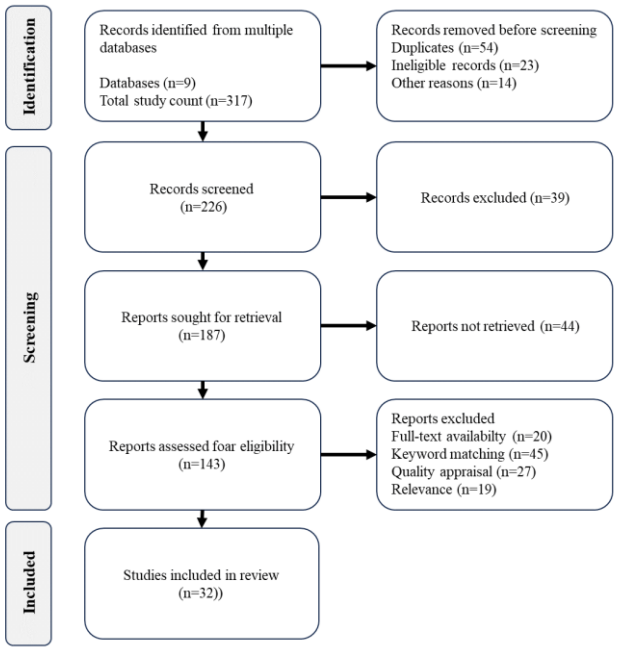

Fig. 2. PRISMA flowchart.

C. Distribution of Journals

Regarding the journals from which these final papers were derived, 'IEEE Access' from IEEE had the most articles, with eight total. MDPI's 'Applied Sciences' received five submissions, as illustrated in Table I. MDPI's 'Journal of Imaging' and 'Sensors' received three each. The paper source 'ACM Conference papers' appeared twice.

Other journals on the list had a source each, as observed in Table I. These numerous sources demonstrate how many fields are interested in applying artificial intelligence to detect fake images.

D. Computing Effect Sizes

Effect sizes are indispensable in meta-analysis, serving as a standardized metric to gauge the magnitude of observed phenomena and facilitating comparisons across diverse studies. This study focused on the F1 score, which measures a model's accuracy. The researcher also focused on the sample

size, denoted by the number of images used in individual studies. The choice was made to employ the random-effects model, considering the potential variability in study designs and regions covered. The determination of effect sizes hinged on a transformation suitable for F1 scores, as opposed to the conventional Fisher's Z transformation tailored for correlation coefficients [31]. Both Q-statistics and I^2-values were deployed to comprehend the variability or heterogeneity of the results among the different studies [32]. In meta-analysis, heterogeneity indicates the differences in outcomes across the incorporated studies. If heterogeneity is high, it implies that the studies' results vary considerably [31]. Such computations empower this study, offering a rigorous quantitative consolidation of literature on using artificial intelligence to detect fake images.

1) Fisher's Z transformation: Fisher's Z is a statistical method that transforms Pearson correlation coefficients into a normally distributed variable [31]. The transformation is used because Pearson's r does not have a normal distribution, which makes its confidence intervals asymmetric. Fisher's Z transformation aids in stabilizing this variance. A higher absolute value of Fisher's Z indicates a stronger relationship between variables.

$$Fisher's\ Z\ =\ 0.5\ \times ln\left(\frac{1+f}{1-f}\right) \quad (1)$$

where, f = F1-score

2) The Weight value for each study (w_i): The w_i value represents the inverse of the variance of the effect size for study i [31]. It gives more weight to studies with more precise estimates (i.e., smaller variance), allowing them to influence the combined effect size more than those with less precise estimates [2].

$$w_i = \left(\frac{z_i}{Var(z)}\right) \quad (2)$$

Where, z_i is a study's effect size measured by Fisher's Z index.

3) The Overall effect size (z_+): The z_+ formula calculates the combined effect size in meta-analyses using weighted individual study effect sizes [32]. This Equation allows the aggregation of individual study results to derive an overall effect, giving more weight to studies with larger sample sizes or more precise measurements. A greater z_+ value suggests a larger overall effect size across the analyzed studies.

$$z_+ = \frac{\Sigma_{i=1}^{N}(w_i\ \times\ z_i)}{\Sigma_{i=1}^{N}\ w_i} \quad (3)$$

where, N = number of studies

4) The Q statistic: The Q statistic measures the heterogeneity or variability of effect sizes across studies in a meta-analysis [31]. Determining heterogeneity is essential to deciding on the type of meta-analytic model (fixed-effects vs. random-effects) to use. A significant Q value indicates substantial heterogeneity among the included studies, suggesting that differences in effect sizes aren't solely due to sampling error.

$$Q\ =\ \sum_{i=1}^{N} w_i\ \times (z_i - z_+)^2 \quad (4)$$

5) The I^2 metric: I^2 is a metric that quantifies the percentage of total variability in study estimates attributable to heterogeneity rather than chance [32]. It provides insights into the consistency of findings across studies, independent of the number of studies included. An I^2 value close to 100% indicates high heterogeneity, suggesting that the results of the studies are diverse.

$$I^2 = \left(\frac{Q - N + 1}{Q}\right) \times\ 100 \quad (5)$$

6) Bounds: This bounds equation calculates the confidence interval around the mean effect size based on the standard deviation of study weights [32]. The bounds provide a range within which the true effect size is expected to fall, offering a measure of the precision of the effect size estimate. Narrower intervals denote more precise estimates, while wider intervals indicate more uncertainty around the effect size.

$$bounds\ =\ f_z\ \pm\ \alpha \times \sigma \quad (6)$$

where, f_z is the mean F1 score given all the studies included in the meta-analysis, and α is the level of

significance, while σ refers to the standard deviation of the study weights.

7) Fail-Safe N: The Fail-safe N method estimates the number of unpublished or "missing" studies required to nullify the effect observed in a meta-analysis [31]. It addresses the potential publication bias in meta-analyses. A high Fail-safe N suggests the meta-analysis results are robust against potential publication bias.

$$Fail-safe\ N\left(N_{fs.05}\right) = \frac{[(\sum z)^2\ -(N * \bar{z}^2)]}{\alpha^2} \qquad (7)$$

Where, ∑z is the summation of all Fisher's z indices, and $\bar{z}$ is the mean of all Fisher's z indices.

8) Critical value: The formula gives a threshold number for robustness against publication bias in meta-analyses [31]. Considering the number of studies in the analysis, it assesses the risk of overestimating effects due to publication bias. A higher critical value implies greater robustness of the meta-analysis results against potential biases.

$$Critical\ value\ = 5 \times N\ + 10 \qquad (8)$$

IV. Results

A. Study Statistics

Table II shows the summary statistics for the 32 studies included in the meta-analysis. The statistics include sample size, F1-score, Fisher's z, and their weights.

TABLE II. Individual Study Statistics

	Study	Year	Purpose	Dataset	Sample Size	Model	F1-Score	Fisher's Z	Weight
1	[33]	2022	Image Classification	CIFAR-10	19579	CNN	0.94	1.74	10.5177
2	[1]	2023	Fake Image Detection	CELEBA	7373	RNN	0.89	1.42	8.60468

32	[26]	2023	Fake Image Detection	CIFAR-10	32538	RNN	0.96	1.95	11.7755

Table II showcases various studies from 2017 to 2023, spanning applications like themes in fake image detection. Commonly used models include CNNs, RNNs, LSTMs, and GANs. Notably, LSTMs achieved top F1 scores in several studies ([35],[37],[41]). The consistency in Fisher's Z values suggests a uniform significance level. The weight, mirroring the sample size, hints at the study's reliability. In essence, the table reflects both progress and challenges in AI research.

The datasets employed in the studies are all related to machine learning and artificial intelligence. CIFAR-10 and CIFAR-100 are widely used benchmarks for image classification, consisting of small images from several categories. ImageNet, a significant player in the image classification field, has been instrumental in driving progress in deep learning. CELEBA focuses on facial attributes and provides a wide range of annotated faces. DeepFake, DFDC, and FaceForensics++ focus on detecting fake images and videos, which are crucial for developing ways to combat misinformation. COCO and Pascal VOC are widely used in object detection, while UCF101 and Kinetics are popular for video classification and analysis. GOT-10k is specifically made for object tracking, while ADE20K is focused on semantic segmentation tasks. Generative models like BEGAN, PCGAN, and GAN datasets play a crucial role in image synthesis and generation.

B. Meta-Analysis Summary Statistics

Table III summarizes the statistics from the 32 studies involved in this meta-analysis. The statistics include z_+, Q, I^2, σ, lower bound, upper bound, critical Nfs, Nfs, CI, and statistical significance.

TABLE III. OVERALL STUDY STATISTICS

Statistic	Value
z_+	1.7337
Q	65.5867
I^2	52.7344
σ	0.0562
Lower Bound	1.6235
Upper Bound	1.8439
Critical Nfs	170
Nfs	2706.9451
CI	[1.6235, 1.8439]
Statistical Significance	$p < 0.001$

1) Overall effect size (z_+: 1.7337): The z_+ value represents the meta-analysis's pooled or combined standardized effect size. A value of 1.7337 indicates a positive and relatively strong overall effect size [18]. These findings suggest that from a general standpoint, the machine learning models employed in the studies performed well in detecting fake images. According to [33, 52], 0.2 is small, 0.5 is medium, and 0.8 or above is considered large. Hence, the z_+ value obtained in this case shows a large effect size.

2) Heterogeneity (Q: 65.5867, I^2: 52.7344%): Both Q and I^2 are measures of heterogeneity among the included studies. The high Q-value suggests significant variability in the effect sizes across studies [51]. Table II illustrates the differences in the F1 scores obtained from running different machine learning models in detecting fake images. This test statistic follows a chi-square distribution, and its threshold for significance depends on the number of studies (or degrees of freedom). A significant Q-value implies heterogeneity.

The I^2 value further quantifies this heterogeneity: about 53% of the observed variability in the effect sizes is due to genuine differences among studies rather than random sampling error [24]. It affirms the credibility and reliability of the studies included in the meta-analysis because, despite the variability, they all make similar inferences regarding AI's ability to detect fake images. I^2 values of 25%, 50%, and 75% are considered low, moderate, and high heterogeneity, respectively. The I^2 value of ~53% in this study suggests moderate to high heterogeneity among the included studies.

3) Precision of the effect size (σ: 0.0562, lower bound: 1.6235, upper bound: 1.8439, CI: [1.6235, 1.8439]): These statistics provide insight into the precision and reliability of the z_+ value. The standard deviation (σ) is low, which suggests a precise estimate [11]. A low standard deviation is synonymous with minimal differences in the overall sentiment expressed by the 32 studies included in this meta-analysis. The confidence interval (CI) is also reasonably narrow, ranging from 1.6235 to 1.8439. While there are no standard σ values, a narrow CI, like in our case, denotes high precision [41]. Consequently, this further indicates that the pooled effect size is estimated with high precision [45].

4) Publication bias (Critical Nfs: 170, Nfs: 2706.9451): In meta-analyses, fail-safe N (Nfs) and critical Nfs are used to evaluate the potential for publication bias. The critical Nfs represents the minimum number of studies with null results required to raise the p-value above a significance threshold (typically 0.05). There is no standard value or range for this statistic. However, a higher Nfs than the critical value indicates that many unpublished, non-significant studies would be required to nullify the observed effect [40]. Additionally, the statistics suggest that the meta-analysis results are robust against possible publication bias [32].

5) Significance of the effect ($p<0.001$): This p-value indicates the probability that the observed effect (or a more extreme effect) would occur by random chance alone if there were no real effects. The study found a p-value less than 0.001. For a study conducted at a 0.05 confidence level, a statistical significance of anything lower than 0.05 is acceptable [43, 49]. Consequently, the value affirms that it is highly statistically significant. It further provides strong evidence against the null hypothesis that machine learning models can effectively detect fake images [23].

6) Implication: The meta-analysis results indicate a robust, positive, and highly significant overall effect size. The small confidence interval and standard deviation demonstrate

the estimated results' precision. However, substantial heterogeneity among the included studies necessitates additional research to determine the causes of this variation. The results appear robust against the possibility of publication bias. While the results appear trustworthy, future meta-analyses should consider the high heterogeneity and strive to reduce it.

V. Discussion

A. Effectiveness and Sustainability of Deep Learning Algorithms in Detecting Fake Images

The first research question regarded the effectiveness and sustainability of deep learning in detecting fake images. Our study discovered that the accelerated development of digital manipulation techniques has increased the difficulty of detecting fake or fabricated images [35, 36]. Deep learning algorithms, particularly convolutional neural networks (CNNs) and generative adversarial networks (GANs), have been widely cited as the leading instruments for addressing this concern [3, 44, 52]. Many sources we consulted emphasized that these algorithms frequently outperform conventional image analysis techniques, with many studies reporting accuracy rates and F1 scores exceeding 0.8 [24, 50]. High performance was most commonly observed in experiments employing a larger number of images as samples [53, 54]. However, even the lowest-performing studies' F1 scores did not fall below 0.84.

However, the revision of the sources disclosed a recurring theme. These algorithms' variable efficacy was based on the type and quality of the fake images they were trained on, although this was not the case in all studies. Moreover, the sustainability of these algorithms in the context of varying image types and qualities emerged as a significant consideration. Several sources alluded to sophisticated techniques for occasionally generating fake images that could circumvent deep learning detectors, raising concerns about the long-term sustainability of these detection methods. This pattern is notably evident when training data lacks diversity [9, 41, 44]. In addition, our investigation revealed that adversarial assaults on these algorithms present a challenging obstacle but also raise questions about their sustainable effectiveness [38, 42]. On the effectiveness and sustainability of deep learning algorithms in detecting fake images, this analysis finds that although deep learning is a promising avenue, it may require integration with other detection techniques to obtain optimal and sustainable results.

B. Evaluation Metrics for Deep Learning Algorithms in Sustainable Fake Image Detection

The second research question examined the evaluation metrics mostly employed to appraise the performance and sustainability of deep learning models in detecting fake images. Our exhaustive analysis highlighted the critical significance of dependable evaluation metrics for assessing the performance and sustainability of deep learning algorithms in detecting fake images [3, 37, 38]. Findings suggested that the most reliable metric is the F1 score, though most studies also engaged with other metrics to be more comprehensive. Most of the studies we evaluated emphasized indicated that the F1 score is not comparable to accuracy because it is an aggregate of precision and recall, thereby giving it an edge over other performance measures [7].

Most studies employed precision, recall, and the F1-score metric to avoid using accuracy. The performance measure (F1 score) provides a more comprehensive perspective on the efficacy of an algorithm [24]. This meta-analysis utilized the F1 score as its primary metric and was also one of the selection criteria for the selected studies. The harmonic mean property of the F1-score, which considers both precision and recall, is useful when an optimal equilibrium between false positives and false negatives is essential. Using only precision or recall is frequently deemed insufficient, as it conceals a crucial aspect of model performance [36, 46].

C. Technical Challenges in the Sustainable Detection of Fake Images using Deep Learning

The final research question interrogated the technical challenges experienced during fake image detection using deep learning approaches. Specialists frequently face several technical obstacles when utilizing deep learning technologies for fake image detection, as uncovered by our exhaustive analysis [1, 42, 47]. Additionally, the sustainability of these technologies in the face of evolving threats and techniques is a critical concern. Many sources we consulted elaborated on the difficulty of adversarial assaults [34, 39, 42]. Typically, these assaults are ingeniously designed perturbations that not only pose a technical challenge but also raise sustainability issues, as they can trick deep learning models into misclassifying a fake image as authentic or vice versa [9, 48]. This issue illustrates the vulnerability and potentially limited sustainability of these algorithms under specific conditions. While many of the sources devised mechanisms to circumvent adversarial assaults, they acknowledged that such complexities could have a significant impact on the performance and sustainability of the models. In addition, the dynamic nature of image manipulation techniques necessitates constant model updates, highlighting the need for sustainable development practices in AI, as current methods may become obsolete in the face of newer and more complex image manipulation techniques.

In addition, most sources mentioned an 'arms race' between fake image generators and detectors, highlighting a sustainability challenge in this technological contest. As technologies for deep learning evolve, so do techniques for generating fake images, resulting in a continuous and potentially unsustainable development cycle for both [5, 14]. Given the novelty of both disciplines, it is uncertain which will ultimately prevail, raising concerns about the long-term sustainability of detection algorithms. This swift evolution underscores the need for sustainable development practices in the field. Our investigation also revealed that data deficiency hinders model training capabilities [35, 38]. This case is notably true for labeled datasets containing high-quality fake images. Consequently, detection model efficacy declines. The complexity of deep learning models also poses computational and sustainability difficulties [6, 36]. The typical solution is to demand substantial resources for instruction and deduction, which may not be sustainable, especially for real-time

applications that require efficient and environmentally conscious approaches.

VI. Conclusion and Future Research

Identifying fake images has become a top concern in the wake of a highly advanced era, underscoring the necessity for sustainable methods in digital content management. Numerous individuals with questionable motives have utilized technology to fabricate misleading photos and manipulate unsuspecting individuals. The prevalence of inaccurate information in online spaces has heightened the need to eradicate this problem through sustainable approaches. Our comprehensive analysis showcases the growing potential of deep learning technologies, particularly convolutional neural networks (CNNs) and generative adversarial networks (GANs), in addressing this issue sustainably. While these models have shown promising outcomes and made a notable difference, they encounter challenges in maintaining sustainability in their applications. It is important to be cautious when generalizing study conclusions due to the differences in methodology, types of images, and geographical factors, and sustainability considerations. The F1 score is necessary to evaluate how well these algorithms perform on the modified images they are trained on, with an emphasis on quality, diversity, and sustainability.

However, the landscape of fake image detection is fraught with obstacles that exceed the capabilities of algorithms, demanding sustainable solutions. As a result of adversarial assaults, there is an ongoing arms race between fake image creators and their detectors, demanding sustainable solutions. In addition, the frequent need for model updates, computational demands, and data scarcity indicate the need for ongoing research efforts. As technology advances, image manipulations become more complex, increasing the demand for powerful, adaptable, and sustainable deep-learning solutions. We need to work together and combine the knowledge and expertise of academia, industry, and policymakers, to develop effective and sustainable strategies to better protect ourselves against fake imag

Abstract*—Traumatic Brain Injury (TBI) is a significant global health concern, often leading to long-term disabilities and cognitive impairments. Accurate and timely diagnosis of TBI is crucial for effective treatment and management. In this paper, we propose a novel federated convolutional neural network (FedCNN) framework for predictive analysis of TBI in decentralized health monitoring. The framework is implemented in Python, leveraging three diverse datasets: CQ500, RSNA, and CENTER-TBI, each containing annotated brain CT images associated with TBI. The methodology encompasses data preprocessing, feature extraction using gray level co-occurrence matrix (GLCM), feature selection employing the Grasshopper Optimization Algorithm (GOA), and classification using FedCNN. Our approach achieves superior performance compared to existing methods such as DANN, RF and DT, and LSTM, with an accuracy of 99.2%, surpassing other approaches by 1.6%. The FedCNN framework offers decentralized privacy-preserving training across individual networks while sharing model parameters with a central server, ensuring data privacy and decentralization in health monitoring. Evaluation metrics including accuracy, precision, recall, and F1-score demonstrate the effectiveness of our approach in accurately classifying normal and abnormal brain CT images associated with TBI. The ROC analysis further validates the discriminative ability of the FedCNN framework, highlighting its potential as an advanced tool for TBI diagnosis. Our study contributes to the field of decentralized health monitoring by providing a reliable and efficient approach for TBI management, offering significant advancements in patient care and healthcare management. Future research could explore extending the FedCNN framework to incorporate additional modalities and datasets, as well as integrating advanced deep learning architectures and optimization algorithms to further improve performance and scalability in healthcare applications.

Keywords*—*Traumatic brain injury; federated learning; convolutional neural network; grasshopper optimization algorithm; health monitoring

I. Introduction

Traumatic brain injury (TBI) occurs when the brain becomes dysfunctional and neuropath logically damaged due to abrupt and either immediate or secondary external pressures, such as a bump, blow to the head, or another type of injury [1]. Traumatic brain injury can cause a major disturbance in the brain's regular operating, which may outcome in either short-term or long-term neurological impairments. Each year, millions of individuals worldwide are impacted by this invisible spreading, which has significant rates of illness as well as death [2]. According to estimates, there are 1.7 million traumatic brain injuries in the US each year, and lifetime hospital expenses associated with TBI are predicted to reach over $76.5 billion dollars. India has the largest prevalence of brain damage worldwide, in accordance with the Indian Head damage Foundation; most occurrences of mortality occur within a two-hour period of the accident, and one in seven TBI patients pass immediately [3].

Traumatic brain injury causes a diverse range of impairments that can alter regular brain activity and lead to behavioural, physical, mental, and cognitive impairments. Initial and additional damages are the most common categories for injuries that accompany traumatic brain injury since the consequences usually arise either immediately or indirectly following the event [4]. Basic accidents, including diffused axonal damage and intracranial, subdural, and extradural hemorrhage, are the immediate outcome of trauma. Abrupt exterior mechanical pressures have the potential for bursting blood vessels, causing blood to collect in the brain's cranial partitions and produce hemorrhage [5]. Depending on where in the brain material the hematoma occurs, it can be

classified as an extra-axial or intra-axial hematoma. Subdural hemorrhaging, subarachnoid hemorrhage, intraventricular hemorrhage, and intracerebral hemorrhage are examples of intra-axial hemorrhages while epidural hemorrhage is an example of an extra-axial hemorrhage. In the initial year, approximately fifty percent of ICH patients die. The original damage can manifest in as little as one hundred milliseconds, and in the initial hours following its commencement, the patient's condition begins to deteriorate [6].

The development of additional complications, which include a range of molecules, chemical-based, inflamed, and changes in metabolism, can occur minutes to days following the main brain damage. The adult skull is a rigid container filled with blood, brain, and the cerebrospinal fluid that has an uninterrupted capacity [7]. According to the Monro–Kellie philosophy, the total of these three significant elements' volumes never changes. Consequently, the amount of a minimum one of the two elements should be decreased in conjunction with any rise in intracranial contents. Moreover, raised ICP levels will result from this possible volume rise. Because of the hematoma's enlargement within the stiff skull, blood and CSF will gradually move into the cerebral region [8]. Because of good treatment in accordance with the Monro-Kellie philosophy, the ICP values stay low throughout the early stages of hemorrhage development. Elevated intracranial pressure has been shown to have greater consequences, including midline displacement, brain hernia, and eventually death, by damaging different brain regions [9].

A medical disorder known as midline shifting can result from the uncontrolled ICP levels caused by the mass impact of hemorrhage which may relocate the centre of structures toward the sides of the brain. The midline, which is linear in typical, healthy individuals, may be thought of as an imagined middle line because of the uniformity of the brain's organization [10]. The amount of MLS is calculated by taking into account the movement of any one of each of the three brain midline frameworks: the pineal glands, third ventricular, or septum pellucidum from the optimum midline. The enlargement of brain structures is caused by the massive impact caused by hematoma, which raises the pressure inside the head and moves the brain out of its normal position. Death may result from this in the end. MLS is thus regarded as an effective indicator of the most adverse patient experiences following a traumatic brain injury and a substantial determinant of ICP [11].

Since non-contrast CT scanning is quick, accessible, and provides a clear distinction between brains and blood connective tissue, it is the technique favoured for the identification and treatment of traumatic brain injury in the acute situation. Finding a hemorrhage in the CT images and evaluating its three main components—location, volume, and size—are essential for making choices about the outcome [12]. The utilization of an exterior ventricle loss, an intrusive operation that is very prone to diseases and consequences, is the most appropriate option for monitoring ICP. Moreover, CT scans are required in order to identify elevated ICP because different healthcare environments lacking competent neurosurgeons and intrusive ICP surveillance [13]. Numerous studies demonstrate that accurate visual examination and manual calculation of TBI outcomes according to CT are labour-intensive, prone to mistake and misinterpretation due to inter- and intra-observer variability and require a lot of time [14]. The level of accuracy of measurement is crucial for making decisions and additional diagnosis, since the degree of movement is essential in determining the degree of brain injury [15].

By recognizing the characteristics that doctors often employ to diagnose abnormalities, an average CAD system aims to reduce false negative rates. The CAD systems can now execute a variety of image analysis techniques thanks to the always expanding research projects. To enhance the quality of the paper, incorporating cross-validation or external validation techniques would be beneficial. Specifically, employing k-fold cross-validation could help assess the robustness and generalizability of the proposed FedCNN framework across different subsets of the dataset. Additionally, external validation involving independent datasets from other sources or institutions could further validate the effectiveness of the framework in diverse real-world settings, providing more comprehensive evidence of its performance and applicability. Integrating such validation methods would strengthen the credibility and reliability of the study's findings, enhancing its overall quality and impact in the field of decentralized ent. These approaches help physicians identify health monitoring for Traumatic Brain Injury (TBI) managemy diseases, plan treatments, estimate risks, and evaluate prognoses. A number of CAD-based methods are suggested to identify abnormalities in the brain that are reflected in images utilizing various methods. These controlled or uncontrolled partially automated or completely autonomous techniques use machine learning or deep learning methods to improve precision and effectiveness, and they may be used to identify a single brain disorder or a combination of disorders.

The Key contributions of the paper is given as follows:

- The paper leverages three distinct datasets, namely the CQ500 dataset, the RSNA dataset, and the CENTER-TBI study dataset, each offering comprehensive collections of brain CT images annotated for various intracranial abnormalities associated with traumatic brain injury. This multi-centric and heterogeneous dataset approach enhances the robustness and generalizability of the proposed predictive analysis model.
- The adoption of gray level co-occurrence matrix for feature extraction enables the capture of statistical texture features essential for accurately classifying normal and abnormal brain CT images. This sophisticated feature extraction method contributes to the discrimination of subtle patterns and textures indicative of traumatic brain injury, thereby enhancing the model's predictive capabilities.
- The implementation of the Grasshopper Optimization Algorithm for feature selection addresses the curse of dimensionality and optimizes classification performance by identifying an optimal subset of features from the larger feature space. This novel

feature selection strategy ensures the selection of the most relevant and discriminative features, thereby improving the efficiency and accuracy of the predictive analysis model.

- The adoption of federated convolutional neural networks for classification facilitates decentralized privacy-preserving training, enabling individual networks to independently train their local CNN models on their respective datasets while sharing model parameters with a central server in iterative communication rounds. This decentralized health monitoring approach ensures data privacy and security while enabling collaborative learning and model improvement across diverse healthcare environments.
- The culmination of these contributions results in an accurate predictive analysis model capable of distinguishing normal and abnormal brain CT images associated with traumatic brain injury. By integrating innovative techniques for data preprocessing, feature extraction, feature selection, and classification within a decentralized health monitoring framework, the paper advances the state-of-the-art in predictive analysis of traumatic brain injury, offering significant benefits for patient care and treatment optimization.

The following portions of the chapter are organized as follows. Section II includes an overview of the literature on predictive analysis of traumatic brain injury. The problem statement for the study is presented in Section III. Section IV covers the recommended approach for predictive analysis of traumatic brain injury. Section V compares the method's efficacy to previous techniques, and the performance measures are displayed, along with an explanation of the results. Section VI describes the conclusion.

II. Related Works

Prior studies in the field of intracranial hemorrhage and traumatic brain injury diagnosis have mostly depended on CT scanning for quick recognition and identification of hemorrhagic areas but require skilled interpretation to identify ICH subtypes. Nevertheless, specific quantitative information such as the thickness and amount of bleeding that is required for predictive making decisions in critical care settings is frequently absent from CT scans. Recent research has suggested deep learning methods for quantitative evaluation and subtype identification in ICH in order to overcome these shortcomings. In order to discover subtype differences and outline ICH zones, these frameworks usually entail preprocessing processes such as transforming DICOM to NIfTI layout, then performing multi-class segmentation based on semantics and optimized classification neural networks. These approaches have demonstrated potential, but they are not beyond drawbacks. Among the difficulties include the restricted applicability to other datasets, the possibility of overfitting as a result of fine-tuning on a smaller scale information, and the reliance on well datasets with annotations for training, which can occasionally not be easily accessible. Furthermore, flexibility in responding to different clinical scenarios and imaging techniques may be limited by the dependence on models that have been trained. Furthermore, to ensure durability and therapeutic significance, extensive validation on bigger and more varied groups is required, even with high accuracy achieved. Furthermore, there is still room for improvement and investigation in the actual use as well as incorporation of these deep learning technologies into clinical processes, taking into account aspects like immediate processing and usability by medical practitioners without extensive training. Therefore, while these advancements offer promise in enhancing ICH diagnosis and treatment decision-making, continued research efforts are essential to address these limitations and realize the full potential of deep learning in this critical medical domain [16].

In the domain of mild traumatic brain injury, recent efforts have aimed to enhance patient management through the development of decision rules and predictive models. While traditional statistical techniques have been utilized to identify low-risk patients for discharge from the emergency department, machine learning approaches have been explored to potentially improve predictive accuracy. However, findings from a retrospective cohort study utilizing gradient boosted decision trees on CT-identified TBI patients failed to demonstrate clear advantages over traditional methods. Despite achieving respectable predictive values, the machine learning models exhibited similar specificity to traditional approaches and were developed on a smaller dataset due to the necessity of partitioning for training, calibration, and validation. Key predictors of deterioration remained consistent across methods, including Glasgow Coma Scale, injury severity, and the number of brain injuries. Limitations include the challenge of data partitioning and the absence of substantial improvements over established techniques, highlighting the need for future research to focus on developing models that offer discernible advantages in outcome prediction for this patient population. Additionally, the modest improvement in predictive performance may not justify the added complexity and resource requirements associated with machine learning methods, underscoring the importance of considering practical implementation and clinical utility in advancing predictive models for TBI management [17].

Although they are not very specific, clinical guidelines have been developed in an attempt to reduce the misuse of CT scans in cases of mild traumatic brain injury. While duplicating these criteria using machine learning models has showed promise, attaining balanced specificity and sensitivity is still a problem. A deep artificial neural network model and an instance hardness cutoff technique were used in a study aimed at pediatric populations to replicate the Pediatric Urgent Services Clinical Research Networks clinical criteria for CT scan requirement. There are still restrictions in place despite encouraging outcomes with significant specificity and sensitivity. The study's use of historical information from the PECARN research that took place between 2004 and 2006 raises the possibility of biases or mistakes, which might have an impact on the model's applicability to current patient populations or therapeutic settings. Additionally, even though the DANN model outperformed the PECARN clinical guidelines in terms of sensitivity and specificity, practical issues like model understanding and convenience of

incorporation into workflows for clinical practice are still unsolved. Furthermore, the study's emphasis on juvenile groups could restrict the findings' relevance to adult populations, calling for additional investigation to confirm the model's effectiveness across a range of patient demographics. Consequently, even though the DANN model appears to have potential for increasing the use of CT scans in paediatric TBI patients, further research should focus on resolving these issues and guaranteeing the model's reliability and applicability in clinical settings [18].

Machine learning algorithms have become more and more important in the endeavour to forecast the results of treatment for individuals with traumatic brain injury. These algorithms make use of a variety of data sources, such as imaging indexes laboratory information, clinical parameters, and demographic factors. But even with these advances, there are still restrictions. In order to identify important determinants of in-hospital mortality and long-term survival, a study carried out in a tertiary trauma centre in Iran sought to construct reliable prediction models utilizing machine learning techniques. While some variables were found to be significant, there are some limitations to the findings, such as the possibility of biases from retrospective data collection and the exclusion of insufficient information, which may compromise the generalizability of the model. Furthermore, the study's dependence on an Iranian single-centre dataset would restrict the findings' generalizability to other patient groups or healthcare environments. In addition, even though machine learning algorithms demonstrated potential in forecasting both short- and long-term mortality, issues like interpretability of models and adaptability in clinical settings still need to be addressed. Therefore, even though machine learning has the potential to predict the outcomes of traumatic brain injury patients, these limitations must be addressed through bigger and more diversified datasets, prospective research, and improved model interpretability in order to assure reliable and clinically useful predictions for TBI therapy [19].

Investment in models that use machine learning has increased as a result of the need to precisely predict results for patients with severe brain injuries. The goal of such models is to enhance treatment regimens and perhaps provide significant economic advantages. Using admission information from 2,381 patients with severe traumatic brain injury as training data, researchers at Rajaee Hospital in Shiraz, Iran. Restrictions still exist despite the good performance with high levels of specificity, sensitivity, and precision. Particularly, using retrospective information collected from a single location may restrict generalizability to wider populations or healthcare environments and induce biases. Furthermore, the focus of the study on predicting positive or negative outcomes six months after the event may have obscured subtle differences in patient paths and long-term forecasts. Additionally, even though machine learning approaches have great potential, there are still issues with model comprehension, scaling, and the requirement for big and varied datasets [20].

Recent research in the domain of traumatic brain injury diagnosis and outcome prediction has witnessed significant advancements, particularly through the application of machine learning techniques. Studies have focused on enhancing the accuracy of intracranial hemorrhage detection and subtype classification using deep learning frameworks, although challenges such as dataset generalization and practical implementation remain. Additionally, efforts have been made to improve the prediction of treatment outcomes in TBI patients through ML algorithms, yet limitations persist in terms of model interpretability and generalizability across diverse patient populations. The sections that have been made available emphasise how crucial it is to use machine learning especially deep learning to solve practical difficulties with TBI diagnosis and treatment. The theoretical framework may be enhanced by integrating the knowledge from the literature review, with a focus on developing models that have higher specificity, sensitivity, and usability in order to further TBI research and improve patient outcomes. Furthermore, the development of clinical rules and predictive models for mild TBI has shown promise, but achieving balanced sensitivity and specificity remains a challenge. While machine learning approaches offer potential in optimizing treatment procedures and predicting clinical outcomes, addressing limitations such as biases from retrospective data collection, model interpretability, and scalability in clinical practice are crucial for realizing their full potential in TBI management.

III. Problem Statement

The limitations observed in previous research efforts regarding predictive analysis of traumatic brain injury prompt the necessity for innovative approaches. Existing studies have primarily focused on machine learning techniques, such as deep learning frameworks, for TBI diagnosis and outcome prediction. However, challenges persist in terms of dataset generalization, model interpretability, and scalability in clinical practice. Additionally, while efforts have been made to develop clinical rules and predictive models, achieving balanced sensitivity and specificity remains elusive [21]. Moreover, the reliance on retrospective data from single centers may introduce biases and limit the applicability of findings to broader patient populations or healthcare settings. In light of these challenges, our proposed paper aims to address these limitations by introducing a novel approach utilizing federated convolutional neural networks for predictive analysis of TBI. By leveraging federated learning techniques, we aim to overcome issues related to data privacy and centralization, enabling decentralized health monitoring while maintaining patient confidentiality. Through our proposed federated CNNs, we seek to enhance predictive accuracy and enable real-time monitoring of TBI patients across diverse healthcare environments, ultimately contributing to improved patient outcomes and healthcare delivery in the field of traumatic brain injury management.

IV. Methodology

Three major components make up the methodology presented in this paper: gathering data, preprocessing with median filtering, feature extraction with grey level co-occurrence matrix, feature selection with Grasshopper Optimization Algorithm, and classification with federated convolutional neural networks. For training and assessment, three different datasets are used: the CQ500 dataset, the

RSNA dataset, and the CENTER-TBI research dataset. All three provide extensive and varied sets of brain CT images labelled for different intracranial abnormalities related to traumatic brain injury. In preprocessing, noise is removed from CT images by median filtering, and then statistical texture characteristics necessary for differentiating between normal and pathological pictures are extracted using GLCM. The Grasshopper Optimization Algorithm is utilized for feature selection to overcome the dimensionality problem and enhance classification performance. This algorithm makes it easier to identify the best subset of features from the broader feature space. Lastly, federated CNNs are used for classification. These are decentralized, privacy-preserving training mechanisms that allow separate networks (A, B, and C) to train their local CNN models independently on their own datasets and share parameter values with a central server through iterative communication rounds. By combining updated parameters from local models, the global CNN model continuously improves through this federated learning setup. This leads to an understanding of features that differentiate between normal and abnormal images across all networks, enabling accurate predictive analysis of traumatic brain injury while maintaining data privacy and decentralization in health monitoring. Fig. 1 shows the overview of the proposed architecture.

A. Data Collections

1) Dataset for Network A: Most of the research that have been done so far have employed smaller datasets that were gathered from individual institutions in an effort to establish computer-aided diagnosis systems that can identify various disorders connected to traumatic brain injury. A publicly accessible brain CT dataset called CQ500 can help with the creation of machine learning algorithms that classify and recognize different types of abnormalities in the brain [22]. The creation of general, computerized CAD systems to evaluate the many anomalies connected to traumatic brain injury is made easier by these multicentre and heterogeneity datasets. 491 brain CT images from various radiology units have been collected batch-wise and combined into the varied CQ500 dataset by the Centre for Advanced Research in Images, Neurosciences and Genomics, located in New Delhi, India. Three separate radiologists interpreted each CT image to determine whether or whether each had (i) ICH and its five forms, (ii) midline shift, (iii) calvarias fractures, and (ICH age and afflicted brain hemisphere. An example of the dataset's normal and aberrant images is displayed in Fig. 2.

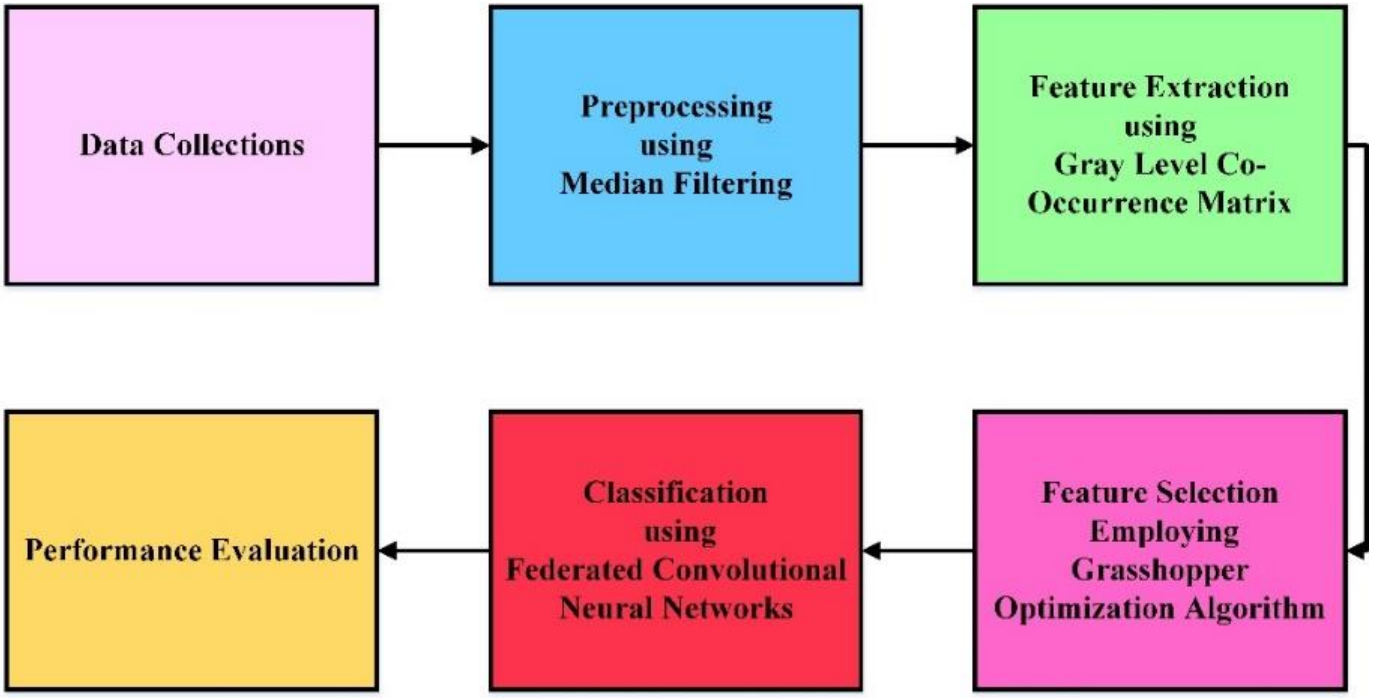

Fig. 1. Overview of the proposed architecture.

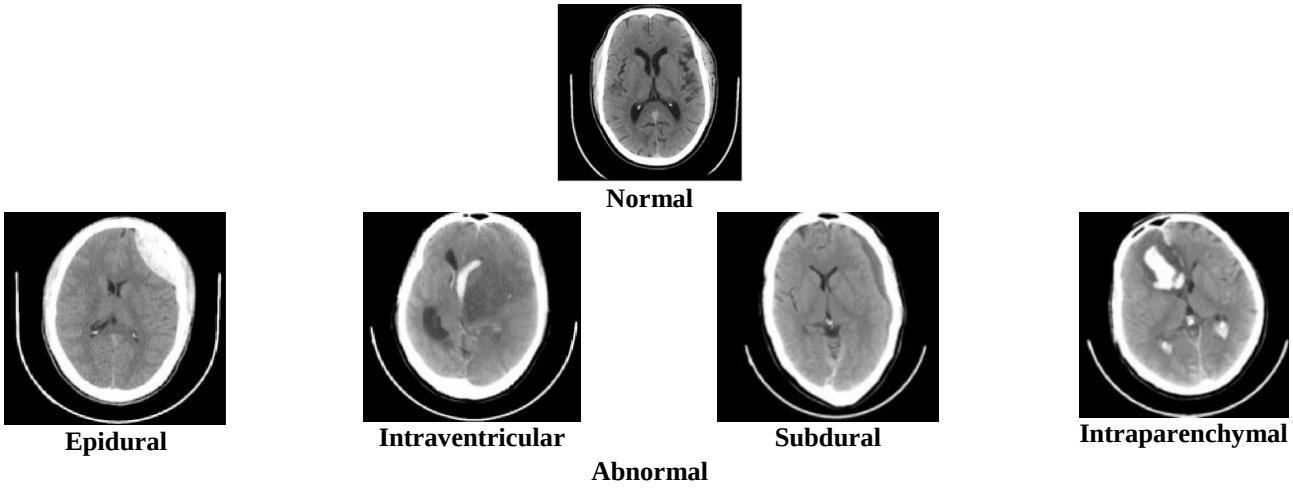

Fig. 2. Sample CT images from CQ500 dataset.

2) Dataset for network B: The RSNA dataset, which includes 865,032 labeled brain CT images for hemorrhage identification and categorization, is the biggest publicly accessible dataset. Experienced radiologists have analyzed each CT scan in this multinational and multi-institutional dataset for the existence or lack of each of the five forms of ICH. 652,403 and 123,133 CT images, accordingly, constitute the training and test information. There is a group imbalance among the hemorrhage subgroups [23].

3) Dataset for network C: The study utilized information from the CENTER-TBI, which enrolled more than 5000 individuals from a variety of facilities, including community hospitals, trauma groups, and university medical centers. Three layers of information are gathered, each distinguished by a particular care path: The following three patient groups are classified as follows: 1) individuals seen in the emergency department and released; 2) patients transferred to the medical facility but not to an intensive care unit and 3) patients transferred to the ICU. A CT scan was conducted in accordance with standard clinical practice on a clinical scanner with a wide range of imaging variables. For the purpose of assessing the segmentation of immediate intracranial lesions, three unique subcohorts of the CENTERTBI information set are taken into consideration: cistern identification and midline shift estimate. This guarantees that each data set provides a significant variety when it comes to of TBI severity and imaging parameters of interest [24].

B. Preprocessing using Median Filtering

Pre-processing is used to eliminate extraneous information from brain CT scans, which can create noise and negatively impact CAD system performance. The improved CT images in this investigation were obtained by using a median filter. The speckle noise in a CT picture is eliminated using the median filter. In digital image processing, noise is eliminated by using a median filter. This novel approach uses a median filter for filtering in order to identify traumatic brain damage. A neighbourhood region serves as the filtering window for the median filtering method, which modifies its size based on certain filtering process setup criteria. A useful technique that can separate out of varied isolates from acceptable picture alternatives like boundaries and characteristics to a certain degree is the median filter. In particular, the median filter substitutes the median for a pixel rather than the neighbourhood's average of all the pixels Ψ. As could possibly see in Eq. (1).

$$M[R(u) + S(u)] \neq M[R(u]) + M[S(u)] \qquad (1)$$

A statistically based non-linear signal processing technique is the median filter. The noisy number will be replaced with the digital image's median value. The noisy value is replaced by the group median, which is saved after the mask's pixels are arranged according to the gray levels.

C. Feature Extraction using Gray Level Co-Occurrence Matrix

Characteristics are the bits of data that are important for representing important aspects of pictures and for solving certain applications. The selection of input characteristics greatly affects training set parameters and categorization accuracy. The technique of extracting an image's visual content in order to reduce the number of resources needed is known as feature extraction. Gray level co-occurrence matrix (GLCM) was developed in this study to extract statistical texture information. Texture characteristics are significant low-level characteristics that are utilized to measure an image's perceived texture and define its contents.

The widely used GLCM method uses statistical distributions of intensity value combinations at various locations in relation to one another in an image to determine second order statistical texture characteristics. There are three categories of statistics: first, second, and higher order, based on the quantity of intensity locations within the image. Although theoretically feasible, the computational cost prevents the implementation of higher levels statistics. Texture characteristics hold details about the surface's structural organization and how it interacts with its surroundings. Energy, correlation, entropy, homogeneity, sum variability, autocorrelation, contrary, maximal probability, dissimilarity,

IDM normalized, and many more texture-based characteristics are acquired—a total of twenty-two are obtained. Some of them are expressed as follows:

1) Energy: Energy can also be defined as "angular second moment" or "uniformity." It provides the GLCM matrix's sum of square components. From homogeneous to non-homogeneous regions, it is done this way. When the frequency of repeated picture pixels is high, it is high. Eq. (2) displays the energy equation.

$$E = \sum_{u,v=0}^{m-1}(Q_x)^2 \quad (2)$$

2) Entropy: It determines the image's unpredictability. A uniform image will therefore provide a lower entropy rating. Eq. (3) displays the entropy equation.

$$ET = \sum_{u,v=0}^{m-1} -In(Q_x)\, Q_x \quad (3)$$

3) Contrast: It determines the strength of the contrasts that connects a pixel to its neighbour throughout the whole image. Eq. (4) displays the equation of contrast.

$$C = \sum_{u,v=0}^{m-1} Q_x(u-v)^2 \quad (4)$$

4) Correlation: It measures the linear gray tone dependency of a picture. It explains how a pixel and its neighbour are linked. The correlation equation is shown in Eq. (5).

$$Co = \sum_{u,v=0}^{m-1} Q_x \frac{(u-\mu * v-\mu)}{\sigma^2} \quad (5)$$

5) Homogeneity: It measures the degree of pixel resemblance. The homogenous image's GLCM matrix values out to 1. If the texture of the image just needs minor adjustments, it is very low. Eq. (6) displays the equation of homogeneity.

$$H = \sum_{u,v=0}^{m-1} \frac{Q_x}{1+(u-v)^2} \quad (6)$$

D. Feature Selection Employing Grasshopper Optimization Algorithm

While characteristics are necessary to achieve high accuracy, an abundance of characteristics can lead to a "dimensionality curse" whereby an excessive number of characteristics wastes a significant amount of storage capacity, increases calculation time, and complicates categorization. Adding more characteristics also increased the risk of "overfitting," which reduces the system's generalizability and reduces accuracy. Therefore, it is necessary to create feature selection strategies, which choose the "optimal subset of features" from a wider set. The Grasshopper Optimization Algorithm is used in this work to choose characteristics.

In 2016, the GOA algorithms was introduced. This method emulates the natural swarming behaviour of grasshoppers. Three factors influence a grasshopper's position in a swarm's flight path: wind advection (B_u), gravity (H_u), and social interaction (R_u). Eq. (7) defines the social interaction as the primary search mechanism in the GOA algorithm.

$$R_u = \sum_{v=1,v\neq u}^{M} r(c_{uv})\widehat{c_{uv}} \quad (7)$$

In this case, *r* denotes a function that defines the degree of societal pressures, $c_{uv} = |y_v - y_u|$ is the distance that exists between the u-th and v-th grasshoppers, and $\widehat{c_{uv}} = \frac{y_v - y_u}{c_{uv}}$ is the vector of units from the u-th grasshopper to the v-th grasshopper. The above equation shows that the function of *r* is the primary element of the relationship between people. Eq. (8) specifies the value of this function, which determines a grasshopper's orientation of travel within the swarm.

$$r(s) = fe^{\frac{-s}{l}} - e^{-s} \quad (8)$$

where, l is the attracting distance scales and f is the attraction's strength. The grasshoppers are driven by this function to repel one another as well as to be attracted to one another. In order to prevent colliding, two grasshoppers will repel one another when their distances are within the range of [0, 2.079]. To keep the swarm cohesive, the attraction force grows while the distance is in [2.079, 4]. The zone of comfort is the region where there cannot be a pressure at precisely 2.079.

In the event when the distance between them equals 2.079, both attraction and repulsion vanish. From 2.079 units of distance until almost four the attraction intensity rises and then progressively falls. Substantial differences in the values of the variables in the equation used for the value of s (l and f) result in altered swarming behaviour. To demonstrate how grasshoppers communicate with regard to their comfort zones. When it comes to modelling grasshopper interactions, the swarm approach performs well. But in order to create an optimization algorithm, it has to be modified. The subsequent mathematical representation of the search during grasshopper interactions was suggested by the study. Eq. (9) serves as a representation of the computational framework.

$$Y_u^c = b\left(\sum_{v=1,v\neq u}^{M} b\frac{ia_c - la_c}{r} r(|y_v^c - y_u^c|)\frac{y_v - y_u}{c_{uv}}\right) + \widehat{T_c} \quad (9)$$

where, ($\widehat{T_c}$) is the average value of the c-th dimensions in the objective (best solution discovered so far), c is a diminishing parameter to shorten the comfort region, repelling region, and attractiveness region, and ia_c is the maximum value in the c-th dimensions and la_c is the lowest limit in the c–th dimensions. The following equation illustrates how the swarm modifies the location around an objective $\widehat{T_c}$. The swarm is brought closer to the target by the parameter c. The goal in the GOA algorithms is thought to be the most effective approach found thus far. When an improved technique is found, the best approach becomes revised while the grasshoppers communicate and pursue the objective.

Eq. (10) is utilized to modify variable c, which is the primary governing variable in the GOA algorithm.

$$d = d_{max} - l\frac{d_{max} - d_{min}}{L} \quad (10)$$

where, d_{max} = 1, and d_{min}= 0.00001, L is the greatest number of iterations, and l is the present repetition.

E. Classification using Federated Convolutional Neural Networks

With federated learning, client edges could discover a common global model without sending their confidential local

information to a central server. Federated learning is a developing distributed privacy-protection learning method. Every training cycle, the local machine receives a model that everyone uses from the cloud-based global servers, training it using each user's personal information, and then updates the weights or gradients by sending a request back to the servers. The client-uploaded models are combined on the server to create an additional global design. The following distinguishing characteristics of federated learning set it apart from conventional centralized learning:

1) The global server clouds cannot access the training data since they are dispersed on local edges. All clients and the serves share the same learning model, nevertheless.

2) Rather than on the server, model training takes place on each local device. In order to create a shared global model, the server compiles the local models that the clients contribute, sends the completed model returned to the clients.

3) Compared to typical centralized learning, federated learning requires a lot more local computing power and capabilities.

The process of federated learning is described, in which every client trains its unique local algorithm utilizing its own information after receiving the parameters of the larger framework from the central server. Following local training, every local device transmits its learned local variables to the server, where they are combined to create a revised global model that will be utilized for training in the subsequent iteration of training. In federated learning, the time patterns, or so-called communication phases, are indicated by the subscript *t*.

Convolutional neural networks have demonstrated consistently higher effectiveness for image categorization and are appropriate to handle very high dimensional inputs. CNN topological architectures are comparable. Three different types of layers are often found in a CNN: convolutional, pooling, and fully linked layers. Many kernel filters, which can be identified as an array of square block neurons, make up the convolutional layer. The preceding layer's kernel filters, which may be thought of as training weights, are subjected to "convolution" processes by the convolutional layer. The CNN may be explained mathematically in the following way in Eq. (11).

$$x_{uv}^{l} = \sigma\left(\sum_{g=0}^{m-1}\sum_{h=0}^{m-1} f_{gh}\, y_{(u+g)(v+h)}^{i-1}\right) \tag{11}$$

Here, y^{l-1} is the convolutional layer's input, x_{uv}^{l} is its output, l is the layer number, f_{gh} is a n × n kernel filter, and σ is the activation constant. The study specifically uses the corrected linear unit (relu) as the function that activates of the hidden neuron to mitigate the effects of softmax function and gradient vanishing in nodes that produce data for multi-class categorization problems. Below are the Eq. (12) and (13) for the softmax and relu functions.

$$\sigma_{relu}(k) = \max(0, k) \tag{12}$$

$$\sigma_{softmax}(k_u) = \frac{exp(k_u)}{\sum_{u=1}^{D} exp(k_u)} \tag{13}$$

where, C is the overall amount of label categories that require to be classified and k is the result of the preceding layer. The amount of label categories that require classification. After many convolutional layers of the CNN, a pooling layer can be implemented to extract certain features from hidden representation. In order to improve the representation characteristics of filtered pictures from the preceding convolutional layer, a measurement of m × m Max pooling windows is often built for obtaining the maximum brightness value of pixels inside the associated Max pooling windows region. A typical alternative to the Max pooling procedure is the Average pooling approach, which involves average value distribution of features throughout the window region. The flattening image pixels from the result of the layer before it provides the input for the fully linked layer, which is applied at the rear of the CNN. This layer's primary function is to categorize the characteristics that were retrieved from the CNN's earlier layers into different groups. Fig. 3 illustrates how federated CNN operates.

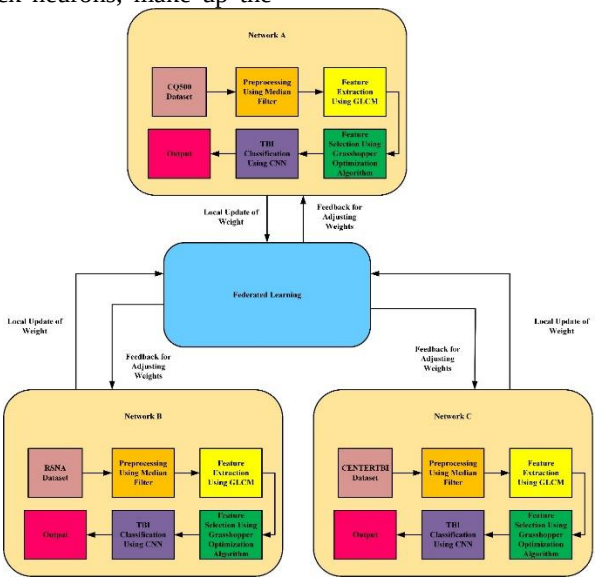

Fig. 3. Working of federated CNN.

In the federated CNN mechanism for classifying images as normal or abnormal, each network (A, B, and C) possesses its own dataset containing a mix of normal and abnormal images. In the federated learning setup, during each communication round, the central server sends the parameters of the global CNN model to each network. Subsequently, each network independently trains its local CNN model using its respective dataset, leveraging the local computational resources and privacy-preserving nature of federated learning. The CNN model consists of convolutional layers, pooling layers, and fully connected layers for extracting and classifying features from the images. After local training, the updated parameters of the local CNN models are sent back to the central server, where they are aggregated to form an updated global CNN model. This global model represents a collective understanding of the features distinguishing normal and abnormal images across all networks. The process iterates over multiple communication rounds, with the global model continuously improving its ability to classify images accurately while respecting data privacy constraints inherent in federated learning.

V. Results and Discussion

In this section, the study presents the results and discussion of the proposed paper. The methodology encompasses data collection from three diverse datasets: the CQ500 dataset, the RSNA dataset, and the CENTER-TBI study dataset, each containing annotated brain CT images associated with traumatic brain injury. Preprocessing involves median filtering for noise removal, followed by feature extraction using gray level co-occurrence matrix to capture statistical texture features. Feature selection is conducted employing the Grasshopper Optimization Algorithm to optimize classification performance by identifying an optimal subset of features. Classification is performed using federated CNNs, enabling decentralized privacy-preserving training across individual networks (A, B, and C) while sharing model parameters with a central server. Through federated learning, the global CNN model evolves iteratively, aggregating updated parameters from local models to achieve a collective understanding of features distinguishing normal and abnormal images, thus enabling accurate predictive analysis of traumatic brain injury while ensuring data privacy and decentralization in health monitoring.

A. Performance Evaluation

Assessment measures are required to evaluate the predictive accuracy. The most common approach for accomplishing this is to determine accuracy. The percentage of datasets detected correctly by a classifier indicates its accuracy for a specific testing dataset. Because employing basically the accuracy metric cannot be used for optimal decision-making. The recommended technique's performance was evaluated utilizing precision, recall, accuracy, and F1-score measurements. The following describes the definitions of each measure:

- The term T_{pos} (True Positive) describes the total amount of accurately found data.
- The term $Fpos$ (False Positive) refers to the proportion of accurate data that was mistakenly detected.
- False negatives (F_{nea}) occur when erroneous data is mistakenly recognized as legitimate.
- Identification of erroneous information values is known as T_{neg} (True Negative).
- T_{neg} (True Negative) is used to identify inaccurate data entries.

1) Accuracy: The classifier's accuracy indicates the extent to which it generates the correct prediction. Accuracy is measured by the ratio of reliable projections compared to all alternative reasonable projections. It is demonstrated by Eq. (14).

$$Accuracy = \frac{T_{pos}+T_{neg}}{T_{pos}+T_{neg}+F_{pos}+F_{neg}} \quad (14)$$

2) Precision: The number of properly detected results is calculated by determining a classifier's precision, or its degree of accuracy. Accuracy improvement results in reduced false positives, but lower precision causes numerous additional errors. Precision is defined as the percentage of examples that correlate appropriately to all incidences. It is defined by Eq. (15).

$$P = \frac{Tpos}{Tpos+Fpos} \quad (15)$$

3) Recall: The degree of sensitivity of a recognition, or the amount of relevant information produced, is determined by recall. Enhanced recall decreases the total quantity ofF_{neg}. Recall is the proportion of properly classified instances to all projected events. This is demonstrable by Eq. (16).

$$R = \frac{Tpos}{Tpos+Fneg} \quad (16)$$

4) F1-Score: The F1-Score, which represents the weighted average of recall and accuracy, is calculated by summing both recall and precision. It is characterized by Eq. (17).

$$F1 - Score = \frac{2\times precision \times recall}{precision \times recall} \quad (17)$$

5) ROC Curve: In deep learning and machine learning, the area under the ROC curve, or AUC, is a well-known statistic for binary classification problems. The binary recognition algorithm's efficacy is measured by the area under the curve, which is visually depicted by the Receiver Operating Characteristic curve. The classifier in a binary classified problem looks for information that indicates whether a division is positive or negative.

Fig. 4 depicts the training and testing accuracy for Network A, Network B, Network C, and the Centralized Server in the proposed federated CNN framework for predictive analysis of traumatic brain injury. In (a), (b), and (c), the training accuracy gradually increases with each communication round, indicating that the local CNN models

for each network (A, B, and C) improve over successive iterations. Similarly, the testing accuracy follows an upward trend, signifying enhanced classification performance on unseen data as the federated learning process advances. Notably, Network B demonstrates the highest testing accuracy among the three networks, suggesting superior predictive capability in identifying normal and abnormal brain CT images associated with traumatic brain injury. In contrast, (d) illustrates the training and testing accuracy of the Centralized Server, showcasing a comparable performance to the federated networks, albeit with a single global model trained on aggregated data. Overall, it highlights the effectiveness of federated CNNs in achieving accurate predictive analysis of traumatic brain injury while preserving data privacy and decentralization across multiple networks.

Fig. 5 illustrates the training and testing loss for Network A, Network B, Network C, and the Centralized Server within the federated CNN framework for predictive analysis of traumatic brain injury. In (a), (b), and (c), the training loss gradually decreases over successive communication rounds, indicating improved convergence of the local CNN models for each network (A, B, and C). Similarly, the testing loss exhibits a downward trend, suggesting enhanced generalization performance on unseen data as the federated learning process advances. Notably, Network B demonstrates the lowest testing loss among the three networks, implying superior predictive capability in differentiating between normal and abnormal brain CT images associated with traumatic brain injury. In contrast, (d) presents the training and testing loss of the Centralized Server, showcasing comparable performance to the federated networks, albeit with a single global model trained on aggregated data. Overall, Fig. 5 highlights the efficacy of federated CNNs in achieving accurate predictive analysis of traumatic brain injury while ensuring data privacy and decentralization across multiple networks.

Fig. 6 depicts the fitness of the Grasshopper Optimization Algorithm utilized for feature selection in the proposed federated convolutional neural network framework for traumatic brain injury predictive analysis. The plot illustrates the convergence of the GOA algorithm over successive iterations, with the fitness value gradually improving towards optimization. As the number of iterations increases, the fitness value decreases, indicating the algorithm's effectiveness in identifying an optimal subset of features from the larger feature space. The diminishing fitness curve reflects the algorithm's ability to iteratively refine feature selection, ultimately enhancing the classification performance of the CNN models. This visualization underscores the utility of the GOA in mitigating the curse of dimensionality and optimizing feature representation for accurate TBI predictive analysis within the federated learning paradigm.

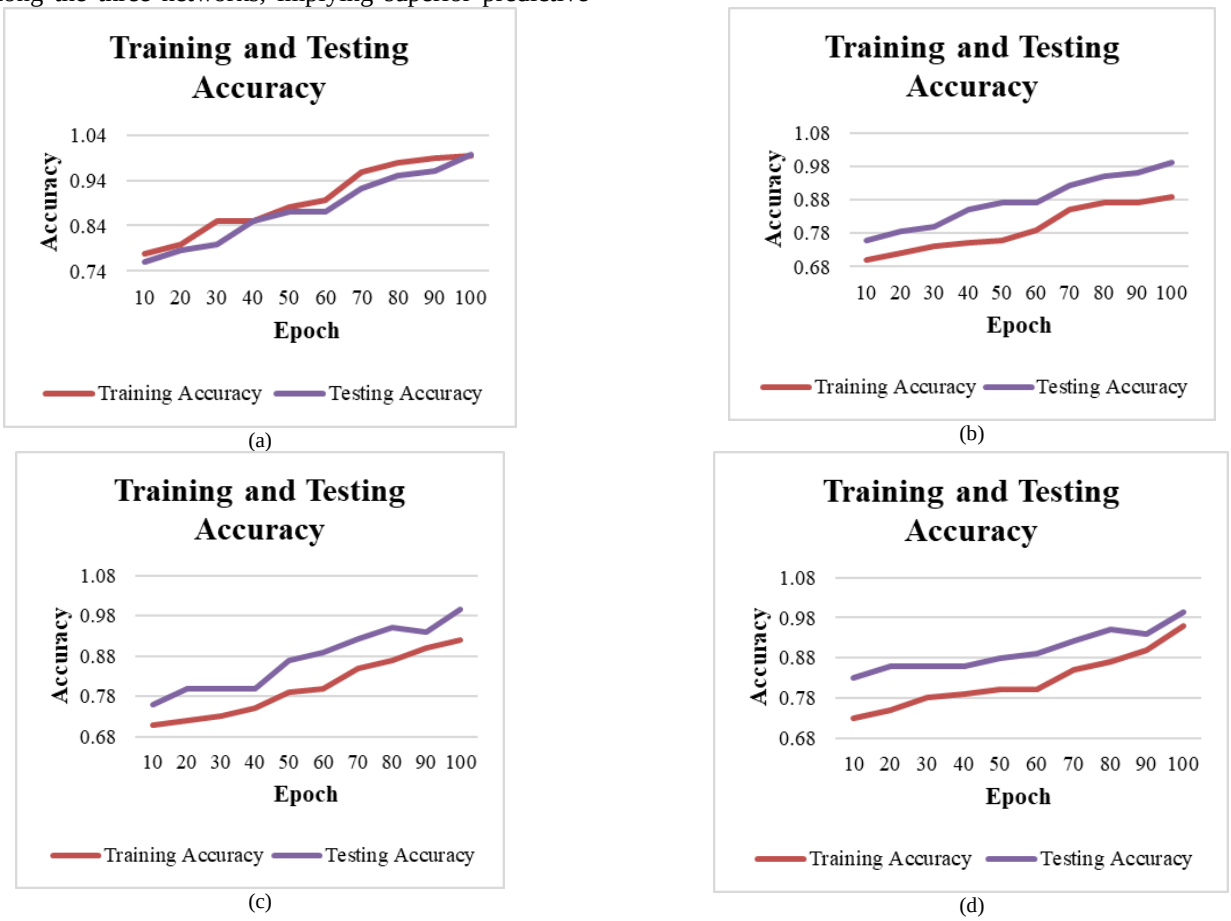

Fig. 4. Training and testing accuracy (a) Network A (b) Network B (c) Network C and (d) Centralized server.

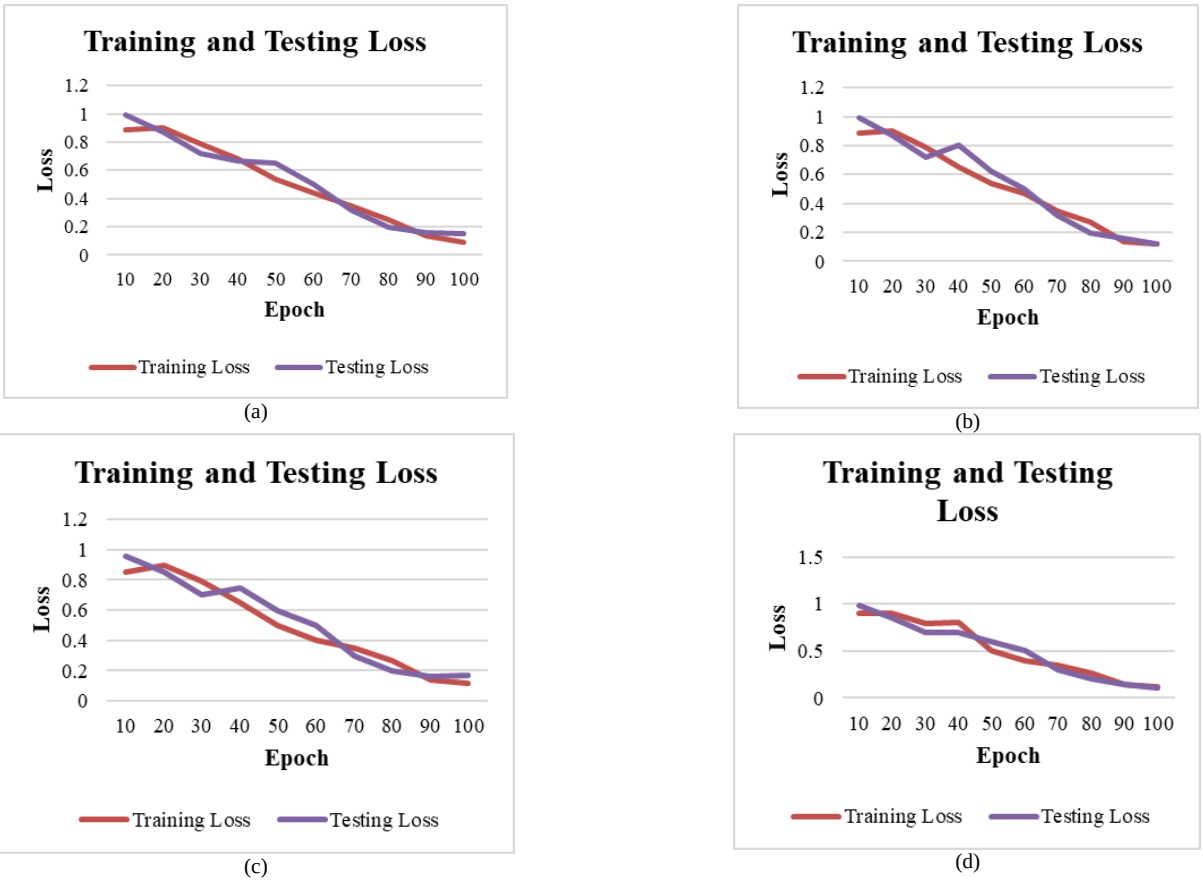

Fig. 5. Training and testing loss (a) Network A (b) Network B (c) Network C and (d) Centralized server.

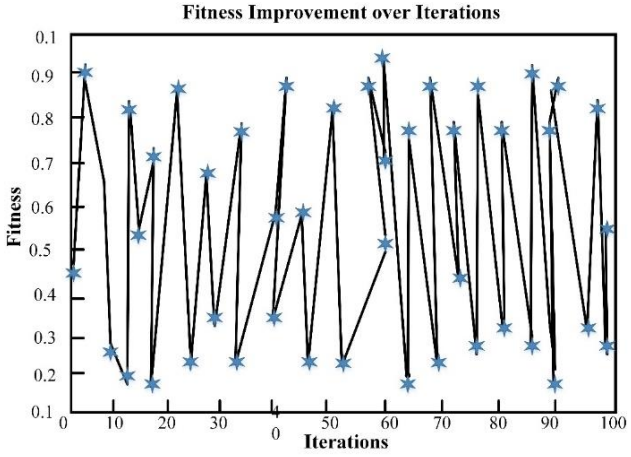

Fig. 6. Fitness of the grasshopper optimization algorithm.

Fig. 7 presents the Receiver Operating Characteristic graphs for each network (A, B, and C) and the centralized server in the proposed federated convolutional neural network framework for predictive analysis of traumatic brain injury. The ROC curves plot the true positive rate against the false positive rate for varying classification thresholds, providing a comprehensive assessment of model performance across different operating points. Each curve represents the trade-off between sensitivity and specificity, with a higher area under the curve indicative of better discriminative ability. The curves illustrate the CNN models' capacity to distinguish between normal and abnormal brain CT images, with steeper slopes and greater AUC values reflecting superior predictive accuracy. By comparing the ROC curves of individual networks with the centralized server, the graph evaluates the efficacy of federated learning in achieving comparable performance to centralized approaches while preserving data privacy and decentralization. The ROC analysis offers insights into the CNN models' classification performance and underscores the framework's utility in facilitating accurate TBI predictive analysis in decentralized health monitoring settings.

TABLE I. COMPARISON OF THE DATASETS IN THE PROPOSED SYSTEM

Datasets	Accuracy (%)
CQ500	98.7
RSNA	99.5
CENTER-TBI	97.6

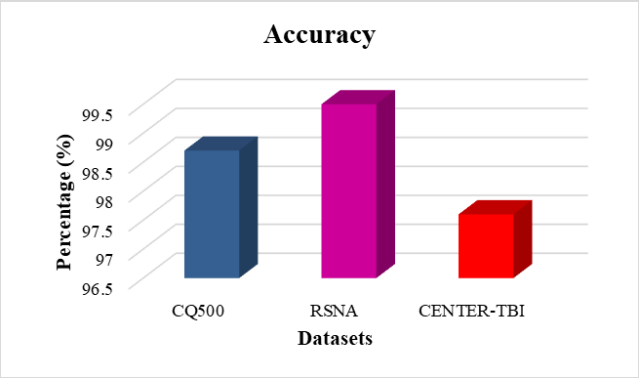

Fig. 8. Comparison of the datasets in the proposed system.

Table I and Fig. 8 provides a comparative overview of the datasets utilized in the proposed federated convolutional neural network system for predictive analysis of traumatic brain injury. The table lists three datasets: CQ500, RSNA, and CENTER-TBI, along with their corresponding accuracy percentages. The CQ500 dataset achieves an accuracy of 98.7%, followed by RSNA with 99.5%, and CENTER-TBI with 97.6%. These accuracy scores reflect the performance of the CNN models trained on each dataset in accurately classifying brain CT images as normal or abnormal, thereby demonstrating the efficacy of the proposed system across diverse datasets with varying characteristics. The table underscores the robustness and generalizability of the federated CNN framework in achieving high predictive accuracy for TBI diagnosis while leveraging heterogeneous data sources, thus facilitating reliable decentralized health monitoring for TBI management.

Table II and Fig. 9 presents a comprehensive comparison of performance metrics between the proposed federated convolutional neural network (FedCNN) method and other existing approaches for predictive analysis of traumatic brain injury. The table includes four methods: DANN, RF and DT, LSTM, and the proposed FedCNN, with corresponding metrics of accuracy, precision, recall, and F1-score expressed in percentage values. Among the compared methods, the proposed FedCNN demonstrates superior performance across all metrics, achieving an accuracy of 99.2%, precision of 99.1%, recall of 99.1%, and F1-score of 99.1%. This indicates the efficacy of the FedCNN approach in accurately classifying brain CT images as normal or abnormal, surpassing the performance of alternative methods such as DANN, RF and DT, and LSTM. The higher performance metrics of the proposed FedCNN underscore its potential as an advanced and reliable tool for TBI diagnosis and predictive analysis, thus offering significant advancements in decentralized health monitoring and clinical decision-making in TBI management.

TABLE II. EVALUATION OF THE PROPOSED METHOD'S PERFORMANCE METRICS IN COMPARISON WITH OTHER CURRENT STRATEGIES

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
DANN [18]	97.2	97.4	97.4	97.4
RF and DT [19]	95.6	96.2	95.3	95.5
LSTM [25]	98.7	98.5	98.7	98.3
Proposed FedCNN	99.2	99.1	99.1	99.1

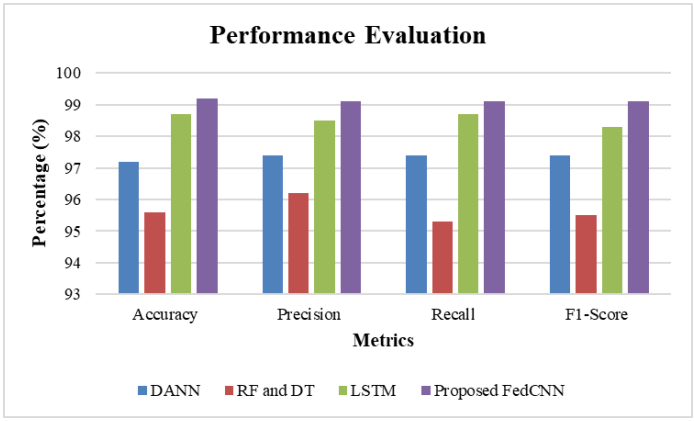

Fig. 9. Comparison of the performance metrics of the proposed method with other existing approaches.

B. Discussion

The results presented in this study showcase the effectiveness of the proposed federated convolutional neural network framework for predictive analysis of traumatic brain injury in decentralized health monitoring. Leveraging three diverse datasets, namely CQ500, RSNA, and CENTER-TBI, the FedCNN framework demonstrates robust performance in accurately classifying brain CT images as normal or abnormal across multiple networks (A, B, and C) while ensuring data privacy and decentralization. The evaluation metrics including accuracy, precision, recall, and F1-score indicate superior performance of the FedCNN approach compared to existing methods such as DANN [18], RF and DT [19], and LSTM [25]. The FedCNN achieves remarkable accuracy scores, with Network B exhibiting the highest testing accuracy among the three networks. Additionally, the Grasshopper Optimization Algorithm effectively optimizes feature selection, mitigating the curse of dimensionality and enhancing classification performance. ROC analysis further confirms the FedCNN's discriminative ability, with steeper slopes and higher AUC values reflecting superior predictive accuracy. These findings underscore the FedCNN's potential as an advanced tool for TBI diagnosis, offering significant advancements in decentralized health monitoring and clinical decision-making while preserving data privacy and decentralization. Overall, the results validate the efficacy and reliability of the proposed FedCNN framework in facilitating accurate TBI predictive analysis, thereby contributing to improved patient outcomes and healthcare management in TBI scenarios. Integrating

more sophisticated deep learning architectures and optimization techniques could potentially further optimize the FedCNN framework's performance and scalability in broader healthcare applications while broadening its scope to include a wider range of modalities and datasets could greatly improve its adaptability in addressing various TBI scenarios. However, it is essential to acknowledge the limitations that are intrinsic to this research. The usefulness of the FedCNN may be limited by small and homogenous annotated datasets, requiring efforts to expand and diversify the data sources. Furthermore, overcoming the computational complexity of feature extraction and selection techniques is necessary to guarantee effective scalability, and managing legal and privacy issues in decentralized health monitoring systems is essential to encouraging the FedCNN approach's broad acceptance and application in actual healthcare settings.

VI. Conclusion and Future Scope

In conclusion, this study presents a novel federated convolutional neural network (FedCNN) framework for predictive analysis of traumatic brain injury in decentralized health monitoring. Leveraging three diverse datasets and employing preprocessing, feature extraction, feature selection, and classification techniques, the proposed FedCNN framework achieves remarkable accuracy in classifying brain CT images as normal or abnormal while ensuring data privacy and decentralization. The results demonstrate superior performance of the FedCNN approach compared to existing methods, indicating its potential as an advanced tool for TBI diagnosis and clinical decision-making. Moreover, the Grasshopper Optimization Algorithm effectively optimizes feature selection, enhancing classification performance and mitigating the curse of dimensionality. The ROC analysis confirms the FedCNN's discriminative ability, further validating its efficacy in TBI predictive analysis. The study contributes to the field of decentralized health monitoring by providing a reliable and efficient approach for TBI management, offering significant advancements in patient care and healthcare management. For future research, further exploration could focus on extending the FedCNN framework to incorporate additional modalities and datasets, such as MRI and EEG data, to enhance the accuracy and scope of TBI diagnosis. Additionally, investigating the integration of advanced deep learning architectures and optimization algorithms could further improve the FedCNN's performance and scalability. Moreover, exploring the application of federated learning techniques in other healthcare domains beyond TBI could broaden the impact of decentralized health monitoring, paving the way for more comprehensive and personalized healthcare solutions. Overall, the proposed FedCNN framework holds promise for revolutionizing TBI diagnosis and healthcare management, offering a scalable and privacy-preserving approach for decentralized health monitoring in diverse clinical settings.

***Abstract*—Cyber-attacks have the potential to cause power outages, malfunctions with military equipment, and breaches of sensitive data. Owing to the substantial financial value of the information it contains, the banking sector is especially vulnerable. The number of digital footprints that banks have increases, increasing the attack surface available to hackers. This paper presents a unique approach to improve financial cyber security threat detection by integrating Auto Encoder-Multilayer Perceptron (AE-MLP) hybrid models. These models use MLP neural networks' discriminative capabilities for detection tasks, while also utilizing auto encoders' strengths in collecting complex patterns and abnormalities in financial data. The NSL-KDD dataset, which is varied and includes transaction records, user activity patterns, and network traffic, was thoroughly analysed. The results show that the AE-MLP hybrid models perform well in spotting possible risks including fraud, data breaches, and unauthorized access attempts. Auto encoders improve the accuracy of threat detection methods by efficiently compressing and rebuilding complicated data representations. This makes it easier to extract latent characteristics that are essential for differentiating between normal and abnormal activity. The approach is implemented with Python software. The recommended Hybrid AE+MLP approach shows better accuracy with 99%, which is 13.16% more sophisticated, when compared to traditional approach. The suggested approach improves financial cyber security systems' capacity for prediction while also providing scalability and efficiency while handling massive amounts of data in real-time settings.**

I. INTRODUCTION

The necessity of cyber safety and defense against various forms of cyber-attacks has increased dramatically in the last several years. The phrase "cyber security" describes a group of policies, mind-sets, and behaviours that help safeguard electronic data. Cyber-attacks including computer viruses [1], DoS attacks [2], and unlawful access have caused irreversible harm and financial harms in massive networks. For instance, a single ransom ware infection cost $8 billion in significant damages to several industries and enterprises, including banking, energy, healthcare, and higher education. Global investment in cyber security is expected to reach $1 trillion by 2021; in 2013, spending increased by more than 40% to $66 billion. Lately, cyber security researchers have started looking at AI techniques to improve cyber security. Similarly, fraudsters are using AI to launch increasingly sophisticated attacks while avoiding detection. However, we focus on how AI-powered cyber security solutions may lessen or completely prevent data breaches and more effectively fight attackers in our work [3]. AI has come a long way since it was first developed in the 1950s, yielding many interesting systems and research discoveries. ML and DL were the products of further developments. AI is being employed these days in many different domains, including industry, law, and exploration of space, medical care, and agriculture. New paradigms such as cloud-based computing and big data, along with continuous improvements in computer hardware and software performance and decreasing costs, have made it easier to develop and deploy a wide variety of AI systems with varying skills [4].

These days, a lot of these AI systems are capable of carrying out a wide range of difficult tasks, such as face and speech recognition, planning, problem solving, and learning [5]. Another important development in AI since the 1980s has been the emergence of technologies for ML, which allow machines to learn and adapt to various environments by utilizing their past experiences, patterns, and knowledge. The field of ML, came into being ten years ago. With the help of this sector, robots may uncover latent correlations in the information they are given, improving planning and forecast accuracy. Recently, there has been an increase in interest in applying AI and ML techniques to counter cyber-attacks [6]. The usage of these technologies is mostly driven by the vast amounts of information that are being created, since they need a significant time and resource commitment to analyze and detect any trends, irregularities, or breaches in traffic data.

The terms "cyber banking" and "cyber security" describe protocols, practices, and infrastructures that protect data, networks, and computer programs from online threats [7]. The threat posed by cyber security is one kind of financial terrorism which has become more prevalent. The most challenging aspect of modern cyber banking has shown to be the protection of customers' personal information. Cyber security is a strategy for thwarting cyber-attacks in cyberspace. Theft of confidential data, including account and ID numbers, and private information are examples of non-financial losses [8]. Cyber security aims to shield the impacted company and its customers from the monetary and non-monetary damages that result from a breach in any kind of data security system. Cybercrime has a detrimental financial effect on South African communities and impacts the whole planet. Safeguarding sensitive data is one of the most significant concerns of cyber security and confidentiality in the realm of cyber banking.

Technology breakthroughs have brought about changes in the banking sector, with internet banking developing as a more sensible method of conducting business. South African banks frequently employ third-party services like PayPal for both domestic and international transactions. Since the banks have no influence over the administration of these systems, their dependence on outside vendors to guarantee the caliber of their online offerings for clients poses a significant security risk. System connection promotes reliance, but it also raises the risk of cyber-attacks and breaches. Managing these risks means preventing and lessening assaults before they occur is termed as risk management. Banking was disproportionately affected by a 1318% rise in ransom ware attacks in the initial half of 2021. The four percent increase in business email compromise, or BEC, assaults might be attributed to new COVID-19 options for threat actors. Large-scale cyber-attacks are becoming more and more likely to target banks. Because banks are linked, a cyber-attack on one might put the solvency of a financial institution at risk. Cyber-attacks on US banks that are supported by states are especially dangerous. As more individuals utilize the web and mobile banking, cybercrime has been rising over time. Cybercrime occurrences include a variety of fraud types, such as identity theft, ATM robberies, and credit card frauds. The banking sector is especially vulnerable because of the significant monetary worth of the information it holds. Hackers may make money in a variety of ways using the financial data and banking credentials they have taken. The attack surface available for exploitation has increased in tandem with the size of banks' digital footprints. Cyber-attacks have the potential to result in confidential information breaches, power disruptions, and malfunctioning military equipment. They may result in the theft of private information that can be quite valuable, including medical records. They have the ability to paralyze systems or interfere with computer and phone networks, making data inaccessible. Banking is especially vulnerable as the data it stores has significant value.

By combining the benefits of supervised and unsupervised learning methods, the suggested strategy improves the identification of threats in financial cyber security. Conventional approaches frequently find it difficult to keep up with the constantly shifting characteristics of cyber threats, particularly in the ever-changing financial industry. The article presents a novel framework that combines the discriminative strength of MLP [9] networks with the feature learning abilities of auto encoders in order to handle this difficulty. Our goal is to increase detection accuracy by utilizing labelled information and capturing intricate patterns in the data through the integration of these two methods into a hybrid model. This method not only makes it easier to spot existing hazards, but it also gives you the flexibility to spot new irregularities and questionable activity in financial systems. Using an auto encoder-MLP hybrid model, the research can leverage labelled data to refine the model for particular threat detection tasks while also efficiently extracting high-level descriptions of the basic data structure via unsupervised learning. With the help of this hybrid architecture, we can use unsupervised feature learning to take use of the inherent qualities of the data, strengthening the model's resistance to new and unknown threats. Additionally, the framework can improve overall threat detection performance by learning to discriminate between benign and harmful actions with better accuracy. Our suggested strategy provides a more flexible and effective protection against new threats, offering a viable answer to the cyber security concerns in the financial arena through the creative integration of supervised and unsupervised learning approaches.

The key contribution of the proposed Auto encoder-MLP hybrid models' study is as follows

- The study suggests a novel approach to improve financial cyber security threat detection. By combining a Multilayer Perceptron (MLP) with an Auto Encoder (AE) this hybrid approach efficiently detects vulnerabilities within financial systems by utilizing the advantages of both constituent parts.
- By using min-max normalization to lessen the influence of feature size fluctuations, the study highlights the significance of data pre-processing in financial cyber security threat identification. This guarantees steady scalability and boosts model training effectiveness, which in turn raises threat identification accuracy.
- The architecture that has been suggested clearly outlines the functions of every element, ranging from feature extraction to threat detection in financial cyber security, hence promoting an open and effective framework for the creation and use of models.
- The proposed AE-MLP hybrid model is extensively tested using the NSL-KDD dataset, showing good results on a number of metrics including f1-score, recall, accuracy, and precision. The study offers in-depth understandings of the effectiveness and dependability of the suggested strategy, confirming its viability for practical implementation in financial cyber security environments.

The article's remaining sections are arranged as follows: A summary of relevant studies is given in Section II. The issue statement for the existing system is found in Section III. In

Section IV of the study, the proposed Auto encoder-MLP hybrid model and technique for increased threat detection are described. The study's results and the ensuing discussion are presented in Section V. Section VI discusses the suggested model's conclusion and possible applications.

II. Related Works

The paper by I. H. Sarker, Y. B. Abushark, F. Alsolami, and A. I. Khan [10] introduced the "IntruDTree," a ML-based security framework that builds a generalized detection of intrusion model based on a tree structure by first considering the importance ranking of security features. This approach lowers computation complexity for yet-to-be-tested test scenarios while retaining prediction accuracy by shrinking the feature dimensions. Lastly, by doing tests using cyber security datasets and evaluating metrics to assess, the efficacy of our IntruDTree model was investigated. To assess the efficacy of the resultant security model, the study also compare the outcomes of the IntruDTree model with a number of conventional, well-known ML techniques, including the naive Bayes classification algorithm, logistical regression, SVMs, and the k-nearest-neighbour model. The drawback of the model is static dataset is utilized to trained the model and relies on predetermined feature importance rankings, it may struggle to adapt quickly to new types of intrusions or novel attack patterns. Without regular retraining and upgrades, static models like the IntruDTree could discover it difficult to keep up with new threats as they emerge and get more complex over time.

IDS that utilizes a stacked AE and a DNN is proposed in the G. Muhammad, M. S. Hossain, and S. Garg [11] paper. In order to reduce the feature width, the stacked AE analyses the distinctive characteristics of the input networks recording in an unsupervised way. Subsequently, supervised training is applied to the DNN in order to obtain deep learning characteristics for the classifier. The DNN contains two or three layers in the suggested system, with each layer having a fully linked layer, a batch normalization layer, and a dropout. The AE has two latent layers. Three sets of publicly available data were used to assess the system. The trials' findings demonstrated the 94.2% accuracy of the recommended IDS for multiclass categorization. The disadvantage is that it has been demonstrated that adversarial examples carefully constructed inputs intended to distort the model's predictions can weaken DL models, particularly DNNs. Since the AE and DNN in the proposed IDS rely heavily on learned representations of network traffic data, they may be susceptible to adversarial manipulation of input features, leading to misclassifications or incorrect intrusion detection decisions.

The goal of the M. Alsaedi, F. A. Ghaleb, F. Saeed, J. Ahmad, and M. Alasl [12] study is to increase the detection accuracy of harmful URLs by creating a model for two-stage ensemble learning that is based on cyber threat intelligence. To increase detection accuracy, online searches are used to extract the attributes based on cyber threat data. Global user reports and cyber security analysts can offer vital information about rogue websites. Consequently, to enhance detection efficiency, characteristics derived from searches on Google and Whois websites are utilized to create cyber threat intelligence (CTI). The study also suggested a two-stage ensemble learning approach that combines multilayer perceptrons (MLP) for ultimate decision-making with the RF algorithm for pre classification. The three separately trained random forest classifiers' majority voting system has been superseded by the trained MLP classifier for decision-making. For sufficient classification, the probabilistic outputs of the random forest's weak classifiers was combined and fed into the MLP classifier. The retrieved CTI-based characteristics based on the two-stage classification perform better than the detection models used in other research, according to the results. Compared to the conventional URL-based model, the suggested CTI-based detection model produced a 7.8% accuracy gain and a 6.7% decrease in false-positive rates. The drawback of the model is the reliance on online searches for feature extraction may introduce biases in the dataset used for training the ensemble learning model. The model's performance could be impacted if the extracted attributes do not adequately represent the diversity of malicious URLs or if there are inherent biases in the online sources used for data collection.

An efficient methodology for detecting intrusions using SVM and naive Bayes feature embedding was presented by J. Gu and S. Lu [13] in their study. The naïve Bayes transform feature technique is used to build new, high-quality information from the original features; an SVM classifier is subsequently trained with the altered data to generate an ID model. Research was out on several datasets within the intrusion identification domain substantiate the efficaciousness and resilience of the recommended detection technique. The UNSW-NB15 dataset shows 93.75% accuracy, the CICIDS2017 dataset shows 98.92% accuracy, the NSL-KDD dataset shows 99.35% accuracy, and the Kyoto 2006+ dataset shows 98.58% accuracy. Furthermore, our method offers notable advantages over existing methods in terms of efficiency, false alarm rate, and identification rate. Keeping the scalability and effectiveness of the IDS is a difficulty when expanding the study to scenarios with varying forms of attacks. The feature space may grow dramatically as attack types become more sophisticated and diverse, increasing processing costs and perhaps reducing the model's capacity for real-time detection.

For the IIoT wireless sensing scenario, a DL-based network intrusion identification and categorization model (NIDS-CNNLSTM) is created in the J. Du, K. Yang, Y. Hu, and L. Jiang, [14] goal is to effectively distinguish and recognize network traffic while ensuring the equipment and operation of the IIoT are secure. Using LSTM in data from time series together with the powerful capacity for learning of neural networks, NIDS-CNNLSTM trains and classifies the features selected by the CNN and verifies its application through binary categorisation and multi-classification scenarios. The precision rate while categorizing different forms of traffic is high, and the three datasets show outstanding convergence and level in terms of validation accuracy, training loss, and precision rate. Previous study models were not able to equal NIDS-CNNLSTM's overall effectiveness. The experimental findings show good

classification accuracy, a small false alarm rate, and a high detection rate. It is more appropriate for large-scale, multi-scenario network data in the IIoT. The primary disadvantage is that deep learning models, such as CNN-LSTM, can be computationally demanding, particularly when working with high-dimensional, large-scale data sets like network traffic data.

There are numerous types of security frameworks and IDS that have limitations. First, because some models rely on predefined feature rankings and static datasets, they are noticeably less flexible than others. This constraint limits their capacity to quickly adapt to novel forms of intrusions or developing assault patterns, which may risk their efficacy in quickly changing environments including cyber threats. Second, adversarial examples, complex inputs purposefully created to distort the model's predictions can affect deep learning-based IDS. This issue is quite concerning since it might result in incorrect intrusion detection judgments or misclassifications, which could compromise the system's overall dependability. Furthermore, algorithms that extract features from web searches might introduce biases into the training dataset. The model's performance may be impacted by this reliance on outside sources for feature extraction, which might lead to inadequate representation of the variety of harmful activities. Finally, there are still issues with scalability, especially when dealing with high-dimensional datasets and different kinds of attacks. Certain intrusion detection systems may encounter difficulties in maintaining scalability and efficiency when attack complexity escalates, which might result in increased computing expenses and reduced real-time detection capabilities. All of these drawbacks highlight the continuous requirement for enhanced threat detection system that can strike a balance between flexibility, dependability, and computing efficiency in the ever-changing world of cyber security threats.

III. Problem Statement

The financial cyber security environment faces a variety of challenges as a result of the deficiencies of current intrusion detection systems and security standards. These challenges include scalability issues with high-dimensional datasets and diverse attack vectors, biases introduced by algorithms extracting features from web searches, inherent inflexibility resulting from reliance on predefined features and static datasets, and vulnerability to adversarial examples in deep learning-based intrusion detection systems [15]. It is imperative to design a more sophisticated threat detection system that strikes a balance between dependability, adaptability, and computing efficiency in order to counteract these shortcomings and keep up with the constantly evolving landscape of cyber threats affecting the financial industry. In order to overcome these obstacles, this study suggests a novel strategy that makes use of Auto Encoder-Multilayer Perceptron (AE-MLP) hybrid algorithms. The goal is to provide a strong framework for threat detection that can efficiently detect and mitigate cyber risks in financial systems while preserving scalability, resilience to adversarial assaults, and flexibility.

IV. Proposed Auto Encoder-MLP Hybrid Model for Enhancing Threat Detection in Financial Cyber Security

In order to enhance threat detection in financial cyber security, this methodology suggests combining the use of an Auto Encoder (AE) with a Multilayer Perceptron (MLP). Due to their sensitive data, financial companies are particularly vulnerable to cyber-attacks. The approach begins by normalizing the data in order to guarantee consistent scalability in order to address this. The two primary components of the hybrid model are the AE, which compresses and extracts significant patterns from the data, and the MLP, which categorizes threats using this compressed representation. The number of layers, units per layer, activation functions, and other parameters must be specified in the MLP construction algorithm. All things considered, this technique provides a transparent framework for creating and implementing a hybrid AE-MLP model for improved threat identification in financial cyber security. Fig. 1 shows the block diagram of this AE-MLP methodology is given below.

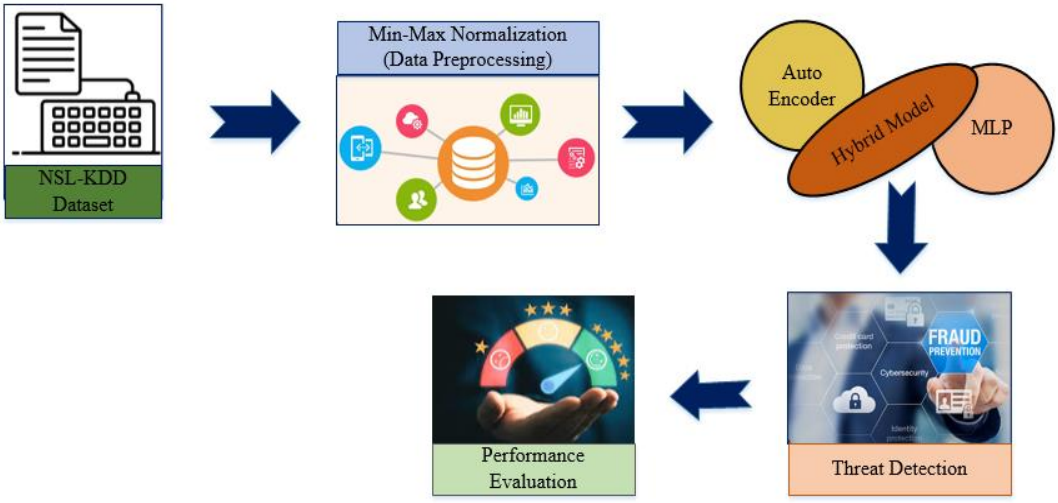

Fig. 1. Hybrid AE-MLP model block diagram.

A. Dataset Collection

NSL-KDD dataset was collected from the secondary source [16]. It consists of specific entries from the data collection KDD 99. The train and test sets contain identical records, and because of the decreased dataset size, random selection is not required. There exists a negative correlation between the proportion of entries in the KDD99 dataset and the chosen entries in every single category of the NSL-KDD dataset. Various ML algorithms may achieve a wider range of accuracy, resulting in more accurate assessments of various models. There are 125,970 occurrences in the training dataset and 225,440 samples in the test dataset. There are four categories into which the assaults are divided: DoS, R2L, U2R, Probe, and a Standard class.

B. Min-Max Normalization for Data Pre-processing

Normalization minimizes the impact of feature scale variations, which reduces the training time of a model. The min-max normalization is used once the outliers have been relocated. Mathematical data can be transformed into a range, often between 0 and 1, using a technique called min-max normalization, sometimes referred to as features scaling. All of the dataset's features, or columns, go through this procedure[17]. Scaling numerical data within a particular range, usually between 0 and 1, is known as min-max normalization. It is a fundamental data preparation method utilized in threat detection in the sets of data given using a hybrid Auto Encoder- MLP model. In the absence of an explicit calculation, this technique guarantees that the lowest and greatest values in the dataset are converted to 0 and 1, respectively, and that any further data values are adjusted linear with respect to this range [18]. The normalization process modifies each data point individually by computing the characteristic or column's lowest and highest values, removing the smallest value, and divided by the range of values. By ensuring uniform feature scaling, min-max normalization contributes to improved convergence and model stability, thereby enhancing the performance of auto encoder-MLP hybrid models. This enhancement is particularly valuable in threat detection scenarios, where model accuracy and robustness are paramount. The normalization of min-max is expressed using Eq. (1) and Eq. (2).

$$N_{std} = \frac{N - N_{min}}{N_{max} - N_{min}} \quad (1)$$

$$N_{scaled} = N_{std} \times (max - min) + min \quad (2)$$

By doing this, you can be sure that the values that fall between will be scaled linearly to match the transformation of the lowest value to 0 and the highest value to 1.This normalization method is particularly useful when features have different scales since it ensures uniformity among the features and supports the performance of the ML model during training.

C. Synergistic Auto Encoder-MLP Architecture for Advanced Threat Detection in Financial Cyber Security

The sensitive data that financial institutions hold makes them easy targets for cyber-attacks. To protect assets and preserve confidence in the financial system, financial cyber security threat detection must be improved. Deep learning methods have showed promise in identifying and reducing cyber dangers in recent years. In order to increase threat detection in financial cyber security, the study provide a hybrid model in this proposal that combines an auto encoder with a MLP.

An auto encoder is a type of multilayer neural network where the desired output is comparable to the input with less modifications, i.e., the result is similar as the inputs with some reconstruction error [19]. By encoding the input, the auto encoder uses unsupervised learning to decode or rebuild the output. Auto encoders are commonly used in recommender systems to decrease the dimensionality of characteristics, retrieve pertinent characteristics, compress and remove noise from the pictures, forecast sequences, and identify abnormalities.
For the purpose of conciseness, we describe the overall architecture of an auto encoder without getting into specifics.

A general auto encoder consists of four key components: the encoder, reconstruction loss, bottleneck, and decoder. The encoder shrinks the data into an encoded form and helps to reduce characteristics from the input. The layer with the fewest features and compressed incoming data is known as the bottleneck layer. By assisting the model in reconstructing the result from the encoded representation, the decoder ensures that the output and input are identical. Reconstruction Loss is the last term used to assess the decoder's performance and gauge how close the output is to the original input.

Moreover, back propagation is used to carry out training and reduce reconstruction loss even more. This minimum loss illustrates the objective that AE strives to achieve. The input y will be compressed by the encoder is expressed in Eq. (3)

$$x = E(y) \quad (3)$$

The input will be attempted to be recreated by Decoder D as y' = D (E (y)).

$$loss(E, D) = \frac{1}{n}\sum_{j=1}^{n} y^i - D(E(y^i)))^2 \quad (4)$$

The variation between the decoded and encoded vectors in this case is the reconstruction loss. One way to calculate the reconstruction loss is to use the Mean Square Error (MSE). It is provided in eqn. (4) given above. Fig. 2 shows the architectural diagram of hybrid AE-MLP is given below.

One kind of ANN that forms the basis of DL models is the MLP. Since MLPs belong to the class of feed forward neural networks, data moves from the input layer to the output layer only in one direction. For many different ML tasks, such as feature learning, regression, and classification, they are extensively utilized. Let's take a closer look at the parts, construction, and operation of an MLP [20]. An MLP is made up of several layers of linked neurons, and its structure is typified by three primary kinds of layers.

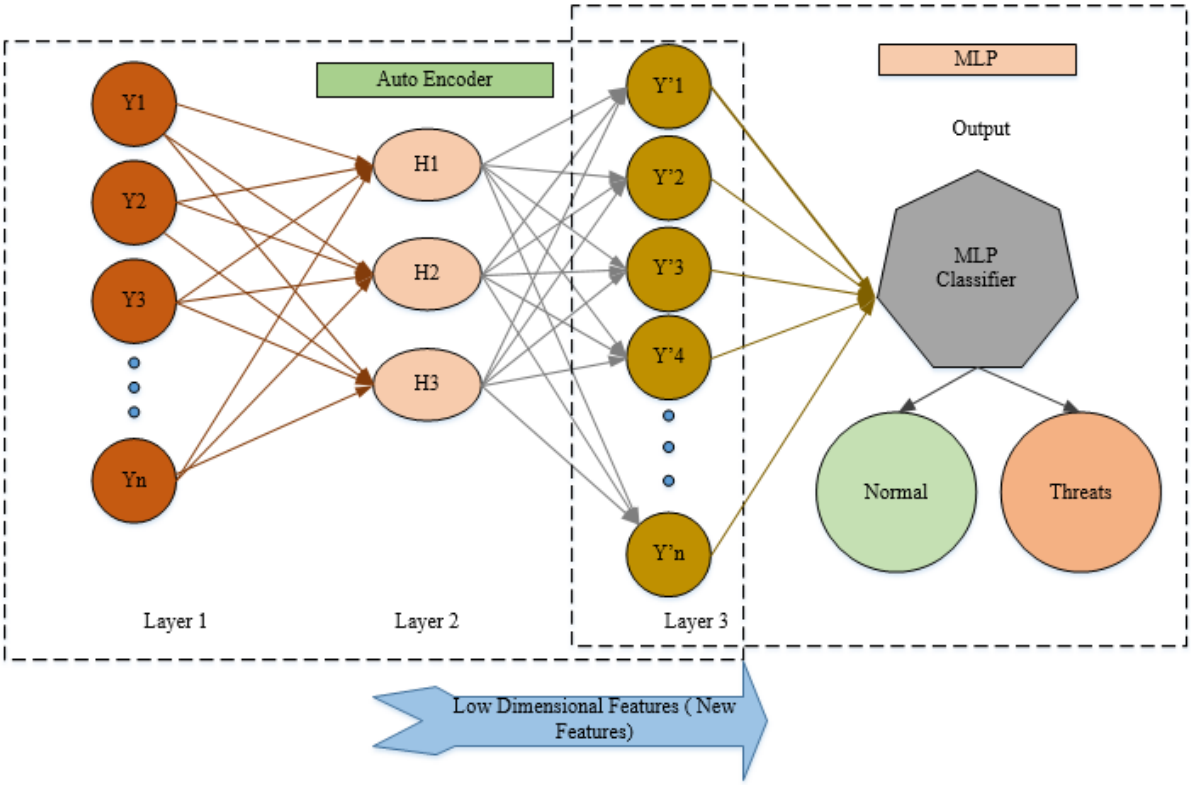

Fig. 2. Hybrid auto encoder-MLP architecture.

The first layer of the network's architecture is the information input layer, which gets raw input data. Since each neuron in the input layer is mapped to a feature in the dataset, the input layer serves as a fundamental demonstration of the data's measurements. The concealed layer comes next. Among the input layer and the output layer of an MLP, there may be several layers that are hidden. Because these layers are not immediately linked to the external world, they are referred to as "hidden" layers. Hidden layer neurons apply a function of activation to the weighed total of the inputs from the preceding layer, process the data, and then forward the output to the subsequent layer. One may modify the hyper parameters, such as the number of neurons and layers that are hidden in each layer, to maximize the models.

The output layer, which is the last layer, generates the prediction or model's output. The problem that the MLP is intended to address dictates this layer's construction. Multiclass classification may employ many neurons, each representing a class and utilizing a softmax activation function, in contrast to binary categorization, which would utilize a single neuron with a sigmoid activation function.

The neurons of an MLP perform the following functions.

- Weighted Sum: The input for every neuron is equal to the weighted total of the outputs from the layer that came before it. A common term for this weighted total is the neuron's "activation." The sum $y_q^{(l)}$ of neuron q in layer l may be written mathematically as in Eq. (5)

$$y_q^{(l)} = \sum_p w_{pq}^{(l)}\, a_p^{(l-1)} + b_q^{(l)} \quad (5)$$

Where,

$y_q^{(l)}$ Corresponds to the layer l activation of neuron q.

$w_{pq}^{(l)}$ The connection weight between neuron p in layer $l-1$ and neuron q in layer l is measured.

$a_p^{(l-1)}$ Is layer $l-1$ neuron p's output.

$b_q^{(l)}$ Is layer l's neuron q's bias.

- Activation Function: Common activation functions include the sigmoid function, tanh, and ReLU. One layer's output serves as the subsequent layer's input. The Eq. (6) denotes it.

$$a_p^{(l)} = f\,(y_q^{(l)}) \quad (6)$$

where, $a_p^{(l)}$ is the layer l output of neuron q, and the activation function is represented by f.

- Feed Forward Propagation: Applying the activation functions to the weighted aggregate, the activations are computed for each of the neurons in the feed forward process. By using the final result of a specific layer as the input of the next layer, information is transferred from the layer that provided the input to the output layer. $a_p^{(l)}$ Is expressed in Eq. (7) is given below

$$a_p^{(l)} = (\sum_p w_{pq}^{(l)}\, a_p^{(l-1)} + b_q^{(l)}) \quad (7)$$

To improve threat detection in financial cyber security, a hybrid model that combines the strong abilities of AE and

MLPs is suggested. As a skilled feature extractor in this design, the auto encoder is able to identify important patterns and representations that are hidden in the input data. The auto encoder uses its encoder network to generate a condensed space of latent information representation that captures the key elements of the input data. This representation of latent space is then sent into the hybrid model's MLP component. In its capacity as a classifier, the MLP uses the characteristics that it has extracted from the auto encoder to identify and group different threat categories that are present in the financial security space.

The hybrid model uses labelled datasets for supervised learning during the training phase. The AE and MLP elements must be simultaneously optimized in this combined training method. The MLP is simultaneously trained to reduce classification errors by utilizing the informative features obtained from the AE's latent space representation, while the auto encoder attempts to properly recreate the input data. Selecting a suitable loss function, such cross-entropy, makes it easier to quantify the difference between the expected and real labels, which helps to increase the model's resilience and classification accuracy.

Algorithm for MLP Architecture

Require: *D*train, *D*test (Training and Testing)
Require: MLP architecture hyper parameters

Data Pre-processing: Min-max normalization

Build the MLP model:

Layer Numbers : 3

Units/ layer:

Input layer: data containing number of features

Hidden layer 1: ReLU activation 128 units

Hidden layer 2: ReLU activation 64 units

Output layer: The quantity of output classes that possess an appropriate activation function

Assemble the MLP model by specifying the optimizer, loss, and assessment metrics.
For a certain number of epochs, train the MLP model on *D*train.

Determine performance indicators and assess the model on the *D*test.

Fine tune hyper parameters as needed

Optionally deploy the model

Keep monitor model and updated.

V. Results and Discussion

Using the NSL-KDD dataset, AE-MLP Threat detection approach is evaluated. The proposed approach produces excellent and extremely promising outcomes. Using a device operating Python as a programming language with the Windows 10 operating system. The performance are accessed using the following metrics: f1-score, recall, accuracy, and precision. These measures have the following definition.

A. Performance Metrics

1) Accuracy: The percentage of test cases that a technique successfully detects on a given test set is its accuracy. It is computed as follows in Eq. (8).

$$Accuracy = \frac{RN+RP}{RP+AP+RN+AN} \quad (8)$$

2) Precision: The proportion of all positively identified instances to the number of accurately detected positive occurrences by the model is known as precision. It is quantified as in Eq. (9).

$$Precision = \frac{True\ Positives}{(True\ Positives+False\ Positives)} \quad (9)$$

A value between 0 and 1, where 1 denotes perfect precision and 0 denotes no correct positive predictions, is the accuracy level.

3) Recall: The notion of the positive cases that the model properly identifies is known as recall. It is computed as follows in Eq. (10).

$$Recall(sensitivity) = \frac{True\ Positives}{True\ Positives+False\ Negatives} \quad (10)$$

4) F1-Score: The F1 score is a widely used statistic to evaluate how well sorting models perform in detection tasks; it is especially helpful for algorithms that function well in threat detection and prediction. The F1 score is useful when a dataset is uneven, meaning that one class significantly outnumbers the other. Equation is used to evaluate the F1 score as shown in Eq. (11).

$$F1\ Score = 2 \times \frac{(Precision*Recall)}{(Precision+Recall)} \quad (11)$$

One should take the F1 score into account when evaluating someone since it offers a helpful and impartial way to assess recall and accuracy. When choosing between accuracy and recall, as is frequently encountered in detection tasks, it is a useful metric to use.

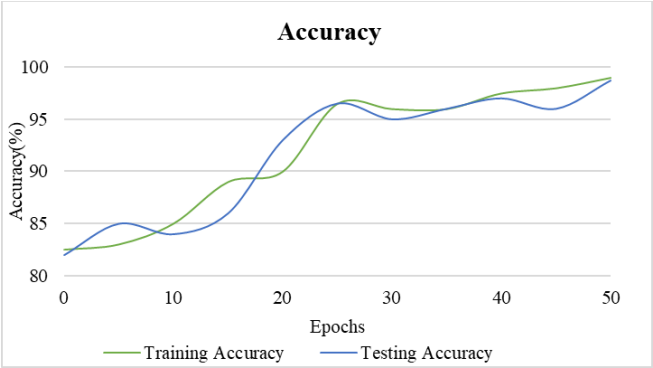

Fig. 3. Training and testing accuracy of the proposed AE-MLP approach.

The AE-MLP model's testing and training accuracy are shown in Fig. 3. The following graph shows how well the model works in two different phases training, when it learns

from the data, and testing, when it applies newfound knowledge to previously unknown data. The model's resilience and dependability in real-world circumstances are indicated by the tight alignment of the training and testing accuracies, which implies that the model generalizes effectively to fresh data.

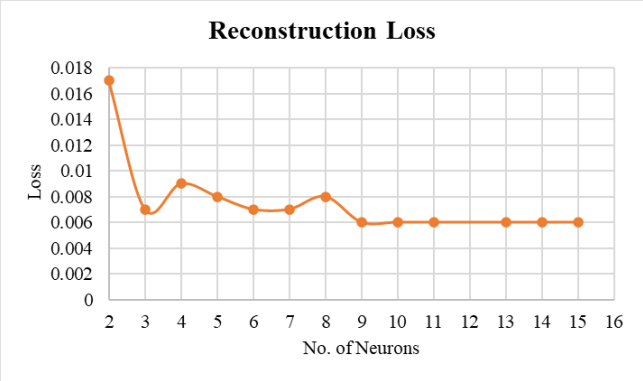

Fig. 4. Reconstruction loss of the proposed approach.

The reconstruction loss of the suggested method, as depicted in Fig. 4, serves as a critical indicator of the auto encoder model's proficiency in recovering its input data. A smaller reconstruction loss not only signifies the model's capability to capture and represent underlying data patterns accurately but also implies a higher fidelity in reconstructing normal network behaviour. This robust representation enables the AE-MLP approach to effectively discern anomalous activities, thereby bolstering its capacity for precise and reliable cyber threat detection.

B. Consideration with Other State-of the-Art Approaches

The need for threat detection in the contemporary cyber environment has led to much study on the subject. For such cases, researchers have used a variety of powerful and advanced ML techniques. This section compares the accuracy of our method against various cutting-edge detection algorithms based on traditional ML and DL approaches using the NSL-KDD dataset.

As seen in Table I, proposed auto encoder-MLP strategy have produced superior results than alternative approaches and it is depicted in Fig. 5. It compares the AE-MLP approach's accuracy (99%), precision (98.75%), recall (98.92%), and F1-score (98.79%) with alternative techniques. The proposed AE-MLP technique outperforms the conventional RNN (83.28%), STL+SVM (84.96%) and AE+DNN (94.21%) methods in terms of accuracy.

TABLE I. COMPARISON WITH EXISTING METHODS AND SUGGESTED METHOD

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1Score (%)
RNN [21]	83.28	81.60	82.24	81.42
STL+SVM [22]	84.96	81.78	84.08	80.21
AE+DNN [11]	94.21	92.78	90.82	90.21
Proposed AE+MLP	99	98.75	98.92	98.79

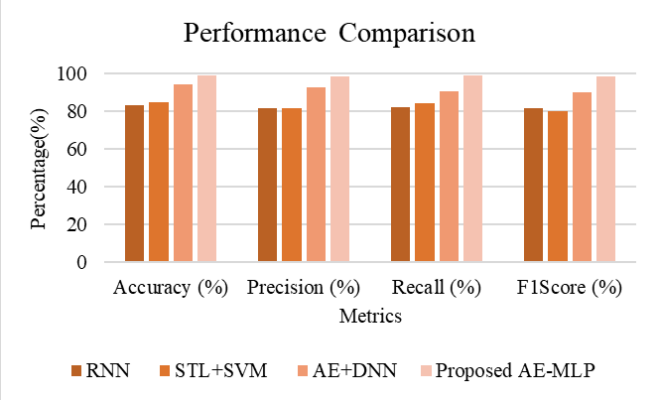

Fig. 5. The performance evaluations of AE-MLP with conventional approaches.

TABLE II. COMPARISON WITH DIFFERENT DATABASE WITH SUGGESTED METHOD

Different Dataset	Accuracy (%)
KDD99 [23]	98
UNSW-NB15 [24]	97
Proposed NSL-KDD	99

Table II shows the accuracy of the proposed technique on three different datasets: UNSW-NB15, KDD99, and the proposed NSL-KDD dataset. The approach demonstrated 98% accuracy on the KDD99 dataset, a reputable intrusion detection benchmark. The technique achieved 97% accuracy rate on another popular benchmark, the UNSW-NB15 dataset. Notably, it attained the greatest accuracy of 99% on the NSL-KDD dataset that was particularly created for the suggested technique. These findings highlight the method's efficacy in correctly categorising instances of network traffic and detecting intrusions; the NSL-KDD dataset shows especially impressive performance, perhaps because it aligns with the method's methods and methodologies.

TABLE III. DETECTION SPEED COMPARISON OF INTRUSION DETECTION METHODS

Approach	Detection Speed (seconds)
RNN [21]	100
STL+SVM [22]	120
AE+DNN [11]	90
Proposed AE+MLP	80

Table III presents a concise summary of the detection speeds of different intrusion detection techniques. It also includes a comparison of detection speeds of intrusion detection methods. While STL+SVM [22] shows a little slower speed of 120 seconds, RNN [21] indicates a detection speed of 100 seconds. Using autoencoders and deep neural networks, AE+DNN [11] provides a 90-second detection time quicker than previous methods.

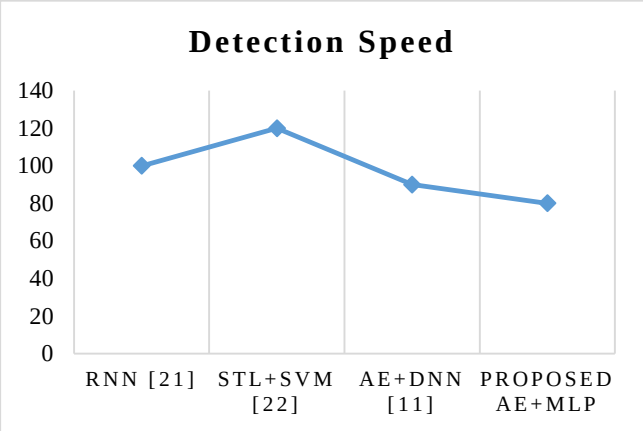

Fig. 6. The detection speed comparison evaluations of AE-MLP with conventional approaches.

The fastest detection speed, achieved by the suggested AE+MLP approach at 80 seconds, demonstrates the effectiveness of integrating autoencoders with multilayer perceptron's. The findings highlight how crucial it is to take into account detection speed when choosing an intrusion detection technique for cybersecurity applications, in addition to other performance parameters like accuracy and scalability. Fig. 6 illustrate the Detection Speed Comparison Evaluations of AE-MLP with Conventional Approaches.

A. Discussion

The examined works provide several methods for using machine learning (ML) and deep learning (DL) techniques in intrusion detection systems (IDS). In order to construct a generalised intrusion detection model, I. H. Sarker, Y. B. Abushark, F. Alsolami, and A. I. Khan [10] provide "IntruDTree," an ML-based framework that ranks security characteristics in order of importance and exhibits efficacy across a variety of cyber security datasets. Its dependence on fixed feature rankings and static datasets, however, could make it more difficult to respond to emerging threats. G. Muhammad, M. S. Hossain, and S. Garg [11] offer an intrusion detection system (IDS) that relies on learnt representations and achieves high accuracy but could be subject to adversarial assaults. The system uses stacked autoencoders and a deep neural network. In comparison to traditional models, M. Alsaedi, F. A. Ghaleb, F. Saeed, J. Ahmad, and M. Alasl [12] approach to improving dangerous URL identification is based on cyber threat information and involves a two-stage ensemble learning process. However, the performance of the system may be impacted by potential biases from internet searches. Utilising SVM and naive Bayes feature embedding, J. Gu and S. Lu [13] describe an effective IDS approach that shows excellent accuracy across a variety of datasets but runs into scaling issues as attack types diversify. J. Du, K. Yang, Y. Hu, and L. Jiang, [14] present NIDS-CNNLSTM, a computationally demanding intrusion detection and classification system for IIoT wireless sensing. These studies demonstrate the variety of methodologies employed for IDS creation, each with advantages and disadvantages in dealing with the always changing cyber threat environment.

The result section compares and assesses a novel cyber threat detection technique termed AE-MLP against existing cutting-edge approaches. With exceptional recall, accuracy, precision, and F1 scores of 99%, 98.75%, 98.92%, and 98.79%, respectively, the AE-MLP method stands out. These findings demonstrate its exceptional ability to correctly identify threats while reducing false alarms. In both the training and testing phases, when the model applies its newly acquired knowledge to previously unseen data, Fig. 3 offers a visual depiction of the model's performance. The model's resilience and dependability in real-world circumstances are indicated by the tight alignment of the training and testing accuracies, which implies that the model generalizes effectively to fresh data. The reconstruction loss of the suggested method is shown in Fig. 4. The auto encoder model's ability to recover its input data is indicated by its reconstruction loss. A smaller reconstruction loss suggests that the underlying patterns in the data can be captured and represented by the model with good accuracy. The figures provide empirical evidence supporting the efficacy of the AE-MLP approach and its potential to enhance cyber security measures in the face of evolving threats.

VI. Conclusion and Future Scope

In conclusion, the use of Auto Encoder-MLP hybrid models is a noteworthy development in the field of financial cyber security, providing a strong means of improving threat detection systems. This hybrid approach shows superior performance in identifying and mitigating potential threats within financial systems by combining the potent classification capabilities of MLP neural networks with the special powers of auto encoders to compress and reconstruct complex data representations. These models are highly skilled at identifying small irregularities that point to harmful behaviours like fraud, data breaches, and attempts at unauthorized access. This is achieved by the thorough examination of a variety of financial information, including transaction records, user activity patterns, and network traffic. The potential for further study and development in this area is bright. Hybrid model designs may be further improved and refined to increase their scalability and forecast accuracy, which would provide strong defense against advanced cyber-attacks. Furthermore, the contextual knowledge of cyber security risks might be enhanced by the integration of new data sources, such as social media feeds, market trends, and geopolitical indicators. This would allow for more thorough risk assessments and proactive threat mitigation techniques. Furthermore, developments in machine learning methods, especially in the areas of reinforcement learning and DL, present opportunities for enhancing the effectiveness and flexibility of financial cyber security systems over time.

***Abstract*—With the continuous progress of basketball technology and tactics, educators need to adopt new teaching methods to cultivate high-quality athletes who meet the needs of modern basketball development. In basketball teaching, the accuracy of free throw techniques directly affects teaching effectiveness. Therefore, the automated prediction of free throw hits is of great significance for reducing manual labor and improving training efficiency. In order to automatically predict the free throw hits and reduce manual fatigue, the study conducts an in-depth analysis for the criticality of free throw in basketball. In this study, the target detection model of target basketball players is constructed based on YOLOv5 and CBAM, and the basketball free throw hit prediction model is constructed based on the OpenPose algorithm. The main quantitative results showed that the proposed model could accurately recognize the athlete posture in free throw actions and save them as video frames in practical applications. Specifically, when using the free throw keyframe limb angle as features, the model achieved a prediction accuracy of 71% and a recall rate of 86% in internal testing. In external testing, the prediction accuracy was improved to 89% and the recall rate was 77%. In addition, combining the relative position difference and angle characteristics of joint points, the accuracy of internal testing was significantly improved to 80%, and the recall rate was increased to 96%. The accuracy of external testing was improved to 95%, with a recall rate of 75%. The experimental results showed that the various functional modules of the system basically meet the expectations, confirming that the basketball penalty posture analysis and hit probability prediction system based on deep learning can effectively assist basketball teaching and meet the practical teaching application needs. The contribution of the research lies in providing a scientific basketball free throw training tool, which helps coaches and athletes better understand and improve free throw techniques, thereby improving free throw hits accuracy. Meanwhile, this study also provides new theoretical and practical references for the application of deep learning in motor skill analysis and training, which has potential value for updating the basketball education system and reducing teacher workload.**

Keywords*—Deep learning; CBAM; OpenPose; Free throws; Posture analysis

I. Introduction

A. Basketball and Technological Progress

As a popular sport around the world, the continuous improvement of basketball technology and tactics requires increasingly high technical requirements from athletes. The improvement of free throw skills is not only an important part of basketball technical training, but also a reflection of precision and repetition training in physical education.

B. The Application of Deep Learning in Basketball Training

From the perspective of social science, the application of deep learning technology to basketball free throw posture analysis and hit rate prediction demonstrates sports science and technology progress. It is also a concrete application of modern physical education teaching concepts. It advocates a training approach based on the data and science, which helps coaches and teachers shift from traditional empiricism to more quantitative and objective training strategies. It is important for the scientific development of personalized athlete training and physical education [1-2].

C. Challenges and Objectives of Research

Zhao et al. proposed a novel real-time shooting prediction method that combines visual sensors and trajectory learning. Four machine learning algorithms were used for analysis, providing data support for prediction accuracy. However, the computational efficiency or real-time performance of the model was not mentioned. In addition, there were still some shortcomings in combining different features [3]. Scholars such as Oltenu focused on improving basketball free throw skills by setting up experimental and control groups to evaluate the effectiveness of training programs. Three different tests were used to evaluate the training effectiveness of athletes, increasing the comprehensiveness of the research. However, the universal applicability of the research results or how they can be applied to different training environments was not discussed, and the maintenance of free throw skills after training was not evaluated [4].

D. Overview of Research Content and Innovation Points

The innovation of the research lies in developing a deep learning system for analyzing the free throw posture of basketball players and predicting the free throw hits. The core innovation of the system includes: adopting multimodal feature fusion technology, combining limb angle and joint position difference to improve prediction accuracy. YOLOv5 and CBAM modules are integrated to enhance small object detection capabilities. Based on the improved OpenPose

*Corresponding Author.

algorithm, it is possible to accurately capture the posture changes of athletes through trajectory optimization and feature fusion. The SVM classifier is applied to effectively handle small sample learning tasks. In addition, the study comprehensively evaluates the application effect of the system in actual basketball training, ensuring its practicality.

E. Research Expectations

The research is expected to provide basketball players and coaches with a scientific and efficient free throw training tool to help them better understand and improve free throw shooting techniques, so as to improve free throw hits. At the same time, the research will also provide new theoretical and practical references for deep learning in sports skill analysis and training, update the basketball education system, and reduce the teacher workload.

F. Article Structure

The research is divided into four parts. The first part introduces basketball free throw and deep learning algorithm. The second part uses You Only Look Once version 5 (YOLOv5) network and OpenPose to build a basketball free throw posture analysis and hit probability prediction system. The third part tests and analyzes the model performance. The fourth part summarizes the above contents.

II. Related Works

The OpenPose model is often used to extract and estimate human pose. Therefore, Zhang et al. proposed a novel end-to-end Point-to-Pose Mesh fitting Network (P2P-MeshNet) based on OpenPose 3D joint dataset to estimate body joint rotation. The average position error, percentage of correct keys (PCK), and area under the curve (AUC) of each joint within the calibration threshold were tested using 0-60 mm Proclustes. The estimated error was 11.31 mm, the success rate was 99.7%, and the AUC was 80.9% [5]. Zhu et al. introduced a method to quickly and accurately classify human motion by utilizing skeletal key points as descriptors of motion characteristics. The OpenPose was employed to extract human skeleton point information as the primary features, followed by deep learning techniques for further classification and identification of action features. The results demonstrated that this approach achieved an impressive accuracy of 86.1% in fall detection using publicly available datasets [6]. Kim et al. proposed an OpenPose-based ergonomic posture evaluation system for calculating joint angles and RULA/REBA scores, validating them with reference motion capture systems, as well as comparing performance with Kinect-based systems. The records of 12 experimental tasks completed by 10 participants under different conditions were analyzed. The OpenPose performed well in all task conditions, while the Kinect performed significantly worse than OpenPose in body occlusion or non-frontal tracking [7].

In image recognition, YOLO series has attracted significant attention from researchers. To address the low accuracy and slow speed in traditional coal gangue identification methods, Yan et al. combined YOLOv5 and multispectral imaging technology. Experimental results demonstrated that the YOLOv5.1 model achieved an impressive average detection accuracy of 98.34% for coal gangue. This method not only accurately identified coal gangue but also provided information about its relative position, making it highly effective for coal gangue identification purposes [8]. Wei Jia et al. proposed a motorcycle helmet detection method using YOLOv5 to detect motorcycle drivers' helmets through video surveillance. It achieved 97.7% mAP, 92.7% F1 score, and 63 frames per second [9]. To improve the performance of robots in classifying lower limb movements, Bingzhu et al. analyzed using different features, including feature signals combining lying and sitting postures. sEMG feature extraction and pattern recognition obtained the trained motion decoder, and then sent control instructions to the robot to drive the lower limbs for corresponding rehabilitation training. The results verified the effectiveness of the control method based on sEMG signal [10]. Researchers such as Mcdonough D designed a controlled experiment to improve the intervention effect of school dance and physical education models and improve the enjoyment and self-efficacy of urban ethnic minority students. Through experiments, it was found that urban ethnic minority students were happier in the group exercise mode, which was an effective intervention mode for dance sports games [11]. Liu S et al. analyzed the effectiveness of the Small Private Online Course (SPOC) teaching model and conducted experiments using the embryology course as an example. Results showed that SPOC teaching improved students' average professional performance and enhanced students' enthusiasm for learning. This indicated that the SPOC teaching model was scientific and reasonable. It was popularized and applied in medical courses [12].

In summary, previous studies have improved the accuracy of human pose detection. A large number of algorithms are used to optimize datasets and feature extraction. However, there are still few pose analysis and hit probability prediction systems that have high-speed computational efficiency and are suitable for basketball detection. These two have strong potential application value in improving the detection efficiency of basketball games.

III. Construction of Penalty Attitude Analysis and Hit Probability Prediction System using Deep Learning Algorithm

In this study, the target detection model of target basketball players based on YOLOv5 and the basketball free throw hit prediction model based on the OpenPose algorithm are constructed. The aim is to improve the accuracy and efficiency of free throw technical analysis, provide a new perspective for the impact of basketball on physical education, and improve the effectiveness of basketball teaching.

A. Construction of Basketball Player Target Detection Model Based on YOLOv5

As an important part of the school physical education curriculum, basketball plays a role in cultivating students' physical fitness, teamwork spirit, and competitive spirit. The scientific analysis of basketball free throw posture can not only improve students' motor skills, but also help physical education teachers to diagnose and correct students' movements more accurately in the teaching. It helps to promote the modernization of basketball education methods.

In addition, as a social and cultural activity, the teaching and training process of basketball also reflects the social and cultural attributes of the educational concept, emphasizing the respect for individual differences and the integration of cultural diversity. Therefore, the application of deep learning technology to basketball free throw teaching can be regarded as a part of educational innovation, which can help improve the teaching quality and educational value of physical education courses. Then, YOLOv5 is selected as the baseline network to construct a target detection model for target basketball players. As the latest generation of fast object detection algorithm, the main advantages of YOLOv5 are its efficient real-time processing capability and excellent detection accuracy. It achieves faster processing speed and higher accuracy through optimized network structure and algorithm innovation. Compared with Faster Region-Convolutional Neural Network (Faster R-CNN), YOLOv5 significantly reduces the computational resource requirement while maintaining high accuracy [13-14]. This makes it excellent in various application scenarios, especially in situations that require fast real-time processing, such as traffic monitoring, human behavior analysis, and industrial automation [15-18]. The YOLOv5 network structure is shown in Fig. 1.

In Fig. 1, YOLOv5 is an efficient real-time object detection system consisting of multiple key modules, aiming to achieve high-precision detection with less computing resources. The network consists of several main components: an input layer, which preprocesses the image data to standardize the input size, and a backbone, which consists of multiple convolutional layers to extract image features. Backbone network output is connected to the neck network, which includes a Feature Pyramid Network (FPN) and a Path Aggregation Network (PAN) structure, merging feature maps at different scales and detecting small objects. Finally, the Detection Head performs object localization, classification, and confidence prediction based on the feature map. YOLOv5 uses the Anchors strategy to predict the bounding box. Anchors with different scales and sizes are used to improve the objects detection accuracy of various shapes. The entire network is optimized through a loss function, combining classification, localization, and confidence loss to improve detection performance. In the traditional YOLOv5 network, the Generalized Intersection over Union (GIoU) loss function is used to optimize the confidence error calculation of the candidate box. The gradient of the Intersection over Union (IoU) loss is 0 when the two boxes do not overlap, which cannot be optimized. The distance relationship between the two boxes cannot be accurately judged. At the same time, it does not accurately reflect the degree of overlap between frames. Even if the IoU values are the same, the positioning effect may differ. The GIoU loss function is used to better reflect the degree of overlap. The GIoU computation diagram is shown in Fig. 2.

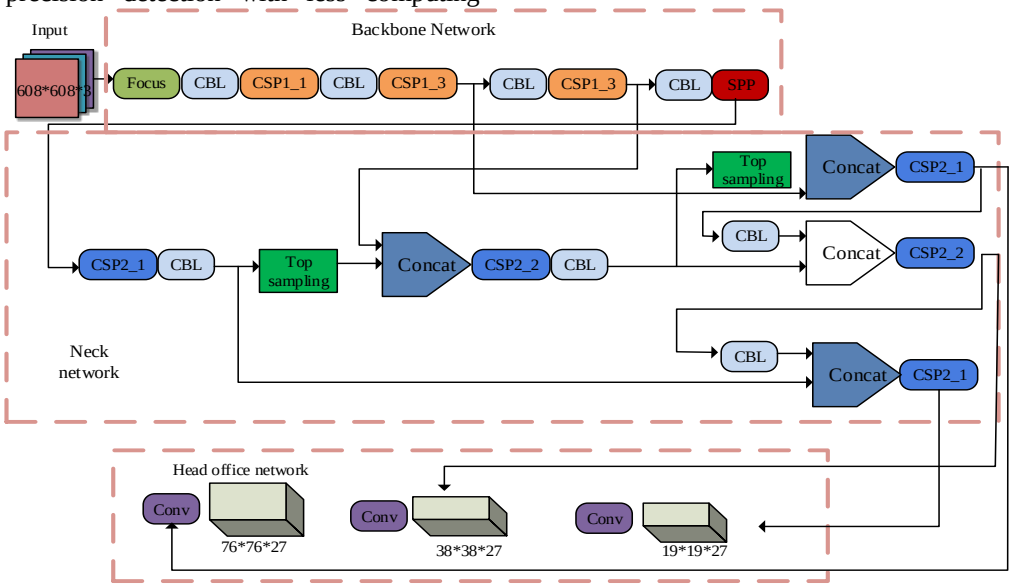

Fig. 1. YOLOv5 network architecture.

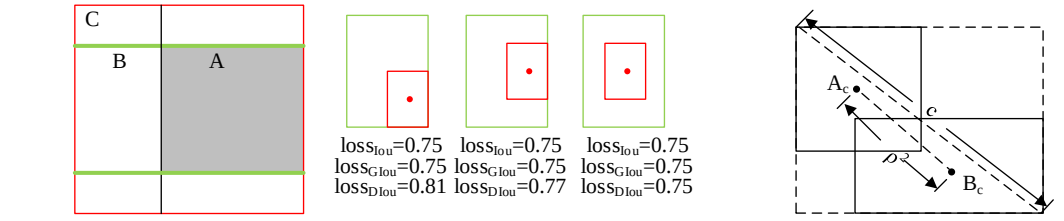


(a) Schematic diagram of the minimal outer rectangle of A and B

(b) GIoU same cannot distinguish relative positions

(c) Schematic diagram of DIoU calculation

Fig. 2. Schematic diagram of GIoU computation.

As shown in Fig. 2, the minimum circumscribed rectangle is C. The IoU is calculated in Eq. (1).

$$L_{IoU} = 1 - IoU(A,B) \tag{1}$$

In Eq. (1), L_{IoU} represents the IoU loss function. The $IoU(A,B)$ is calculated in equation (2).

$$IoU(A,B) = \frac{A \cap B}{A \cup B} \tag{2}$$

From Eq. (2), it can be seen that when two bounding boxes do not intersect, the IoU is zero. This makes it impossible to measure the relationship between the prediction box and the target box by the IoU loss and hinders the learning process, because there is no gradient for post-back. Therefore, the GIoU loss function is introduced, which adds a penalty term on the basis of IoU. It can effectively solve the gradient disappearance problem when the bounding boxes do not overlap, so as to improve the training efficiency and the accuracy of regression effect.

A penalty term is introduced on the basis of IoU, and GIoU can be obtained, as shown in Eq. (3).

$$L_{GIoU} = 1 - IoU(A,B) + \frac{\left| C / \left(A \cup B \right) \right|}{|C|} \tag{3}$$

The GIoU loss value ranges from -1 to 1, which can solve the gradient vanishing when the boxes do not intersect. However, it relies too much on the IoU term, which makes it impossible to distinguish the relative position relationship when the real box completely contains the prediction box, and may slow down the convergence. Distance Intersection over Union (DIoU) can solve these problems. The DIoU adds the distance between the center point of the prediction box and the real box on the basis of IoU to improve the positioning accuracy in the object detection task. The DIoU loss function is calculated in Eq. (4).

$$L_{DIoU} = 1 - IoU(A,B) + \frac{\rho^2(A_c, B_c)}{c^2} \tag{4}$$

In Eq. (4), A_c and B_c represent the center point of the prediction frame and the target box. $\rho^2()$ represents the Euclidean distance calculation. c represents the diagonal distance that encloses the minimum area of the prediction frame and the target box, which can provide an optimization scheme for the bounding box and improve the convergence speed when both boxes do not overlap. In view of the small fluctuation in the aspect ratio of the prediction box in the target detection of basketball penalty players, the Complete Intersection over Union (CIoU) loss function is selected to optimize the model. The CIoU loss function utilizes DIoU to increase the aspect ratio factor. Based on the characteristics of basketball free throw player target detection, the guidance of bounding box optimization direction and the convergence speed of distance between center points have been improved. The CIoU is calculated in Eq. (5).

$$L_{CIoU} = 1 - IoU(A,B) + \frac{\rho^2(A_c + B_c)}{C^2} + \alpha v \tag{5}$$

In Eq. (5), α is a weight function. v measures the similarity between the target box and the detection box, as is shown in Eq. (6).

$$v = \frac{4}{\pi^2}(\arctan\frac{w_A}{h_A} - \arctan\frac{w_B}{h_B})^2 \tag{6}$$

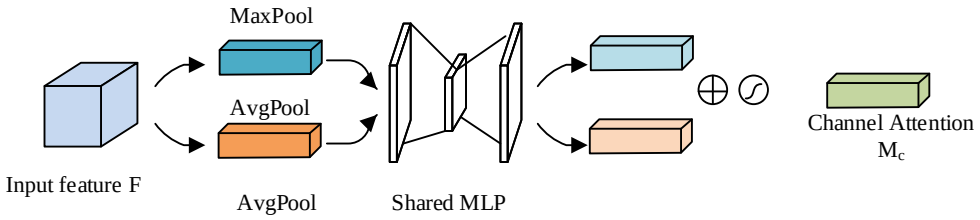
In Eq. (6), w_A and w_B represent the width of the two boxes A and B. h_A and h_B represent the height of the two boxes. Then, a lightweight Convolutional Block Attention Module (CBAM) is inserted into the network structure to optimize the object detection accuracy and strengthen the attention to the detected target, thereby reducing the detection accuracy degradation caused by complex environment [19-22]. The structure and optimization of CBAM are shown in Fig. 3.

In Fig. 3, CBAM combines spatial attention and Channel Attention to improve the performance of convolutional neural networks. By mining the feature dependencies between different channels, the channel attention module assigns different importance weights to different channels, so as to enhance the response of the model to the information-rich channels. The spatial attention module focuses on the importance of different spatial locations in the feature map, and highlights the important spatial regions through feature aggregation in the spatial context, so as to further improving the ability to capture key spatial information. CBAM can adaptively assign different attention weights to different parts of the network, thus helping the network better capture and utilize important information about the input features. In this way, CBAM improves the performance of convolutional neural networks on tasks. It is introduced into the Neck structure of YOLOv5s to solve the challenges in small target detection, such as small target, dense target, noisy and background interference. Therefore, CBAM is introduced after each CSP2 module in Neck to enhance attention to small targets.

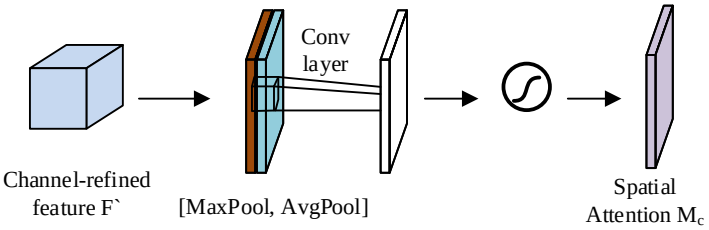
B. Construction of Basketball Free Throw Hits Prediction Model Based on OpenPose Algorithm

While discussing the free throw posture and hit probability prediction in basketball, the study also considers the importance of basketball in the field of education. Basketball, as a team sport, not only demonstrates the physical fitness and technical level of students, but also embodies teamwork and competitive spirit, which promote communication and cooperation between groups in an educational environment. Through an in-depth analysis of the correlation between basketball free throw posture and shooting rate, this study is committed to optimizing the physical education teaching strategy in colleges and universities. Fee throw hit prediction depends on the recognition and detection of human posture. Based on the previously proposed object detection model, the human pose estimation of the target object extracted by the model is carried out. Human pose estimation methods are divided into single and multi-person pose estimation, which are suitable for both image and video scenarios. Key

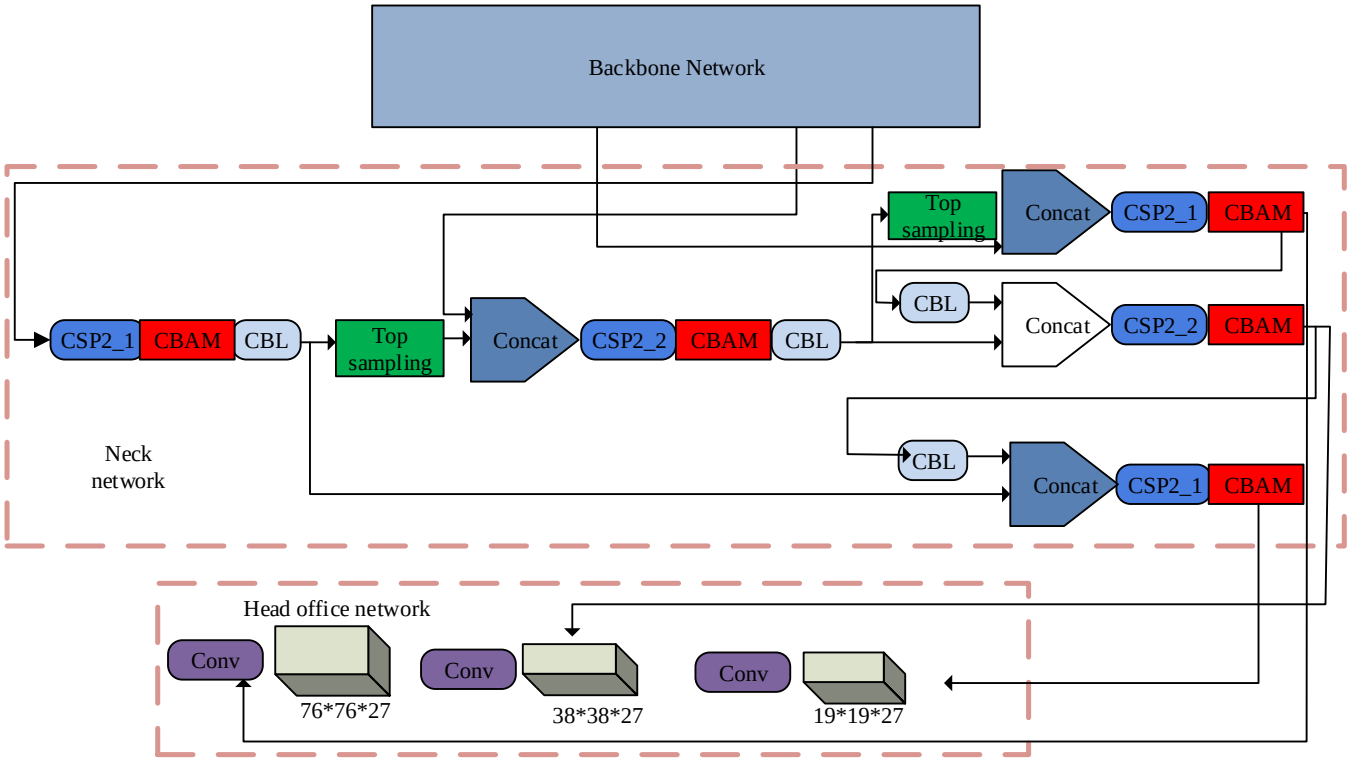
challenges include occlusion interference, light and environmental changing effects, and identification of different angles and scales. Compared with static images, video analysis can obtain richer dynamic body information. There are two human pose estimation methods: top-down and bottom-up. The former relies on human detection results, and the latter first recognizes joint information and then constructs posture. Based on the OpenPose algorithm, a recognition method using trajectory optimization is proposed, which combines the angle transformation and feature fusion of limb features. Then the SVM classifier is used to predict the penalty action, and then analyzes the importance of limb features, and puts forward optimization suggestions for the free throw action [23-25]. Firstly, the feature information of the key points of the joint when shooting the target object is extracted by OpenPose. Fig. 4 shows the OpenPose network structure.



(a) Channel Attention Module



(b) Spatial Attention Module



(c) Improvement programmes

Fig. 3. CBAM structure.

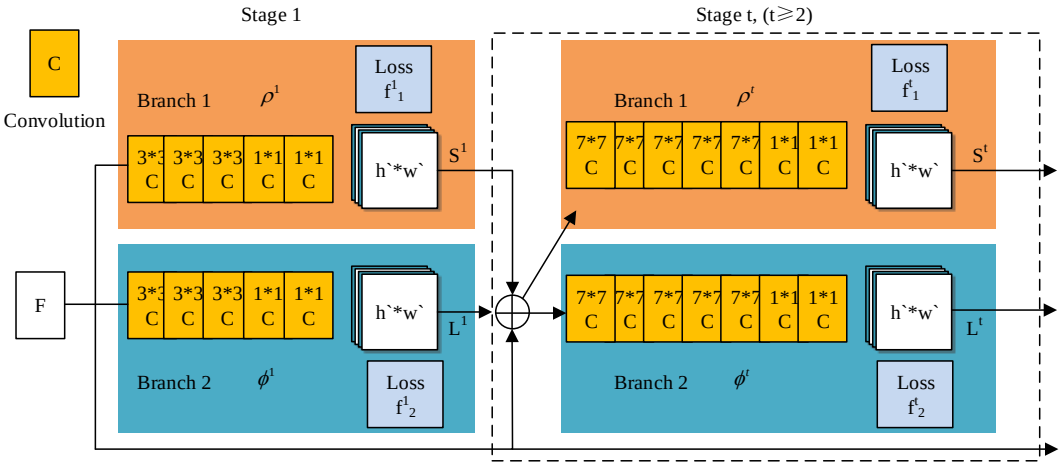


Fig. 4. OpenPose network structure.

The Openpose network includes two main parts. The first part is a convolutional neural network, which is responsible for extracting features and predicting the confidence graph of key points. The second part is Part Affinity Fields (PAFs), which is used to predict the direction of connections between various parts of the body. These two parts are alternated in a multi-stage convolutional network. The prediction results are gradually refined, ensuring the accurate positioning of key points and the correct association of various parts of the body [26-27]. Considering that the human pose estimation method is easy to cause false detection of joint points due to obstacle occlusion in complex background, the wrong joint points identified are repaired to reduce the impact of missed detection and false detection on pose recognition. The poses in adjacent frames of the video are represented by k_1 and k_2, respectively. k_1^i and k_2^i represent the i -th body part appearing in k_1 and k_2, respectively. Bounding boxes B_1^i and B_2^i are extracted, respectively. From B_1^i, x_i feature points can be extracted, while B_2^i represents y_i feature points. The calculation for the distance between frames with k_1 and k_2 is shown in Eq. (7).

$$d(k_1,k_2)=\sum_i \frac{y_i}{x_i} \tag{7}$$

Based on the distance calculation in Eq. (7), the target object in the video can be tracked and judged. When the reliability of the body position is lower than th_b, the bounding box B_i of the joint point action is magnified by one time, two times, and three times in turn, and each multiple is tr_1, tr_2, tr_3, respectively. If the threshold is still lower than the threshold, the similarity between the pose of the previous frame and the current pose is calculated, as shown in Eq. (8).

$$Sc_{g,h}^i=\alpha*\sum_i \frac{n_i}{m_i}+(1-\alpha)*\left\|H_g-H_h\right\|_2 \tag{8}$$

In Eq. (8), the number of feature points in the bounding box of the i joint point in the g frame is described as m_i. The h frame is described as n_i, when the similarity is greater than th_b, the joint point of the previous frame is selected as the candidate node. Otherwise, the corresponding joint point information in the frame is cleared. In this study, the hit rate is predicted by analyzing the changes in the bending angle of each joint in the body of basketball players when they make free throws. The angles between the thigh and the calf, the upper arm and the lower arm, and the upper arm and the torso are the key features, reducing the error caused by the difference in body shape and improving the prediction stability. The schematic diagram and key points of the joint angle are shown in Fig. 5.

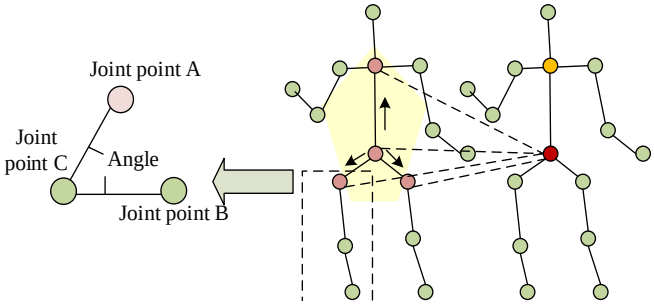

Fig. 5. Schematic diagram of joint pinch angle and key points.

For the analysis of key features, the three key points on the leg are represented as two vectors. The three joint points are connected, and the angle formed at the middle joint point is the angle of the key part. The coordinates of the right wrist, elbow, and shoulder joint points are $R_t(x_0,y_0)$, $R_b(x_1,y_1)$, $R_m(x_2,y_2)$, respectively. The vector representations of the right forearm and right arm are shown in Eq. (9).

$$\begin{cases} l_1 = (x_0 - x_1, y_0 - y_1) \\ l_2 = (x_2 - x_1, y_2 - y_1) \end{cases} \tag{9}$$

From Eq. (9), the angle of the right arm is shown in Eq. (10).

$$\beta = \cos^{-1}\left(\frac{l_1 - l_2}{\|l_1\|\|l_2\|} \right) \tag{10}$$

By converting the absolute position coordinates of basketball players' joint points into angular features, this study focuses on the squat and ascent phases in the free throws. The variation in the leg joint point is used to judge the shooting phase, in which the thigh calf angle decreases to a minimum during a squat and increases to a maximum when rising. At the same time, the characteristics of arm joint points are also considered. Namely, the angle between the large arm and the small arm remain stable in the squat stage, while the angle between the small arm and the torso of the large arm gradually increases with the rise of the arm joint point in the ascending stage. These angular features are used to predict free throw movements and improve the prediction accuracy. Free throw outcome prediction is essentially a categorical problem, divided into two categories: hit or miss. Classification problems are one of the core tasks in machine learning, which aims to find a function to discriminate and classify input data. This involves converting input values into discrete output values, including binary and multi-classification problems. SVM is an effective binary classification model, which is widely used in text classification, action classification and result prediction. Based on a given sample set, it looks for an optimal hyper-plane that can distinguish two categories in the sample space, and transforms the classification task into finding the best interface, so as to achieve accurate classification. The equation for dividing the hyper-plane in the sample space is shown in Eq. (11).

$$\omega^T X + b = 0 \tag{11}$$

In Eq. (11), $X = (x_1, x_2, \cdots, x_n)$ represents the input data, that is, the converted limb angle characteristics of the penalty shooter, n represents the dimension. ω represents the normal vector of the hyper-plane, and b represents the offset term. The calculation for the distance from the shooting posture to the super-plane in the data sample is shown in Eq. (12).

$$l = \frac{\left| \omega^T X + b \right|}{\|\omega\|} \tag{12}$$

When the free throw is hit, the sample point is located above the super-plane and vice versa below, as shown in Eq. (13) for classification problems.

$$\begin{cases} \omega^T x_i + b \geq 1, \ y_i = +1 \\ \omega^T x_i + b \leq -1, \ y_i = -1 \end{cases} \tag{13}$$

The SVM is the points in the sample set that satisfies the above equation and satisfies the equality sign. The distance from these points to the hyper-plane is the spacing, so the basic model of the SVM is shown in Eq. (14).

$$\begin{cases} \min\limits_{\omega,b} \dfrac{1}{2}\|\omega\|^2 \\ s.t. y_i(\omega^T x_i + b) \geq +1, i = 1, 2, \cdots, n \end{cases} \tag{14}$$

Based on solid mathematical theory, SVM simplifies classification problems, focuses on key sample positioning, and avoids dimensionality problems caused by large sample sizes. The disadvantage is that the training time is longer. Therefore, it is more suitable for small-sample tasks, and the computational complexity increases when the number of key samples increases.

C. Basketball Free Throw Posture Analysis and Hit Probability Prediction System Design

Based on the above model, a free throw probability prediction system in basketball game scenarios is constructed. It aims to provide target detection and pose estimation functions for free throw players in individual enthusiasts and basketball teams, so as to assist in training and improving free throw skills. Users can upload videos of single or multiple free throws. The system will detect the player's position and predict the result of the free throw. The main functional modules include the browser side (video input, historical query, user help), application server (object detection, image information output, information forwarding), GPU server (video processing, result output) and database (storage of body and penalty data). Non-functional requirements emphasize ease of use and scalability to optimize the user experience and adapt to changed data and needs. The system design is simple and intuitive, ensuring easy user operation. The modular design allows for subsequent expansion and adaptation. Fig. 6 shows the overall system logical framework.

In Fig. 6, the free throw prediction system based on B/S architecture designed by the research involves a local environment and a remote GPU server, including a multi-layer structure, and a storage layer connected to the database management system. Various necessary files such as pre-trained models and user information are stored. The front-end and back-end interaction and Ajax asynchronous technology are used to feed back the results, and the GPU server side is responsible for body pose estimation and shooting result prediction. The front-end interaction layer acts as the user interface, which is responsible for receiving video input and presenting the results. The browser module is mainly used to display the prediction results. The interface design is simple, using html and JavaScript, which is divided into three modules: information input, result prediction, and record prediction. The information input module is used to upload videos and player information and save them in the database. The result prediction module processes the video and displays the prediction results. The record prediction module allows the user to manually correct and save the results for subsequent model training. The application server coordinates the work of each module, receives video and information, implements object detection, sends data to the GPU server, obtains the prediction results, and delivers the front-end page and database storage. The entire system

architecture is designed to improve the accuracy of penalty prediction, while ensuring the ease of use of the user interface and the scalability of the system. The database management system uses MySQL. The data is presented in the form of a table in Table I.

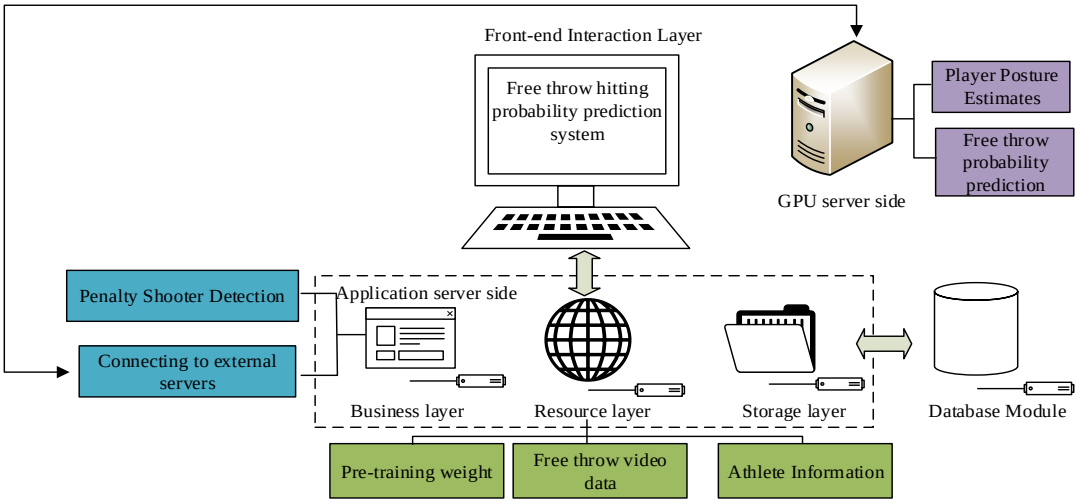

Fig. 6. Overall logical framework of the system.

TABLE I. DATABASE TABLES AND DATA TYPES

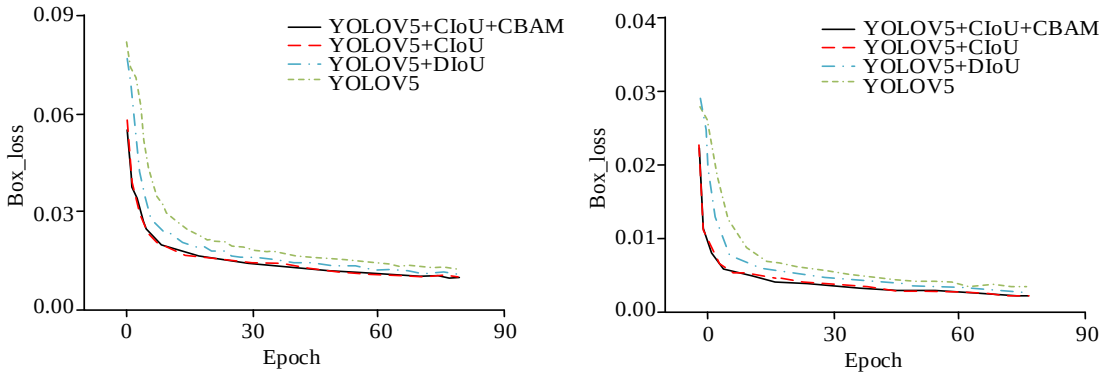
Field name	Data type	Austerity	Clarification
Id	1nt	Primary key; self-incrementing	Primary Key ID
Name	Varchar(30)		User name and surname
Height	Float		Height of an athlete (i.e. person's height)
Weight	Float		Athlete weight
Text	Var char(100)		Remarks on information
Img	Var char(100)		Screenshot of the game video
Info	Var char(100)		Human joint position information is saved in JSON format
Res_video_path	Var char(100)		Video after prediction
Change_time	Datetime		Modify Time

IV. PERFORMANCE TEST OF BASKETBALL FREE THROW ATTITUDE ANALYSIS AND HIT PROBABILITY PREDICTION SYSTEM BASED ON YOLOV5 NETWORK AND OPENPOSE ALGORITHM

The study analyzes the free throw action in basketball game through object detection technology. Various game scene videos are selected, including offline shooting and online collection. In order to enhance the training samples and improve the generalization ability, a data augmentation method is adopted.

A. Performance Test of Target Basketball Player Object Detection model Based on YOLOv5

Through an in-depth analysis of the correlation between basketball free throw stance and shooting rate, this paper is committed to optimizing the teaching strategy of college physical education. This study not only has practical significance for the improvement of sports technology, but also reflects the trend of social science in physical education. It aims to provide students with personalized guidance through data-driven teaching methods, promote the innovation of physical education teaching mode, and improve the quality and efficiency of students' physical education learning. After constructing the experimental dataset, 80% of the images are selected as the training set, and 20% as the test set. Dataset preparation includes not only image information collection, but also manual annotation of specific objects in the image, including species and location information. According to the format of the VOC dataset, the collected video is first converted into a single-frame picture. Then the players performing the penalty action in the picture are labeled by Labeling software, and the labeling result is saved as an xml format file. These files detail the location of the penalty player in the picture, including the coordinates of the upper left and lower right corners. To adapt to the VOC format, the type information and location information in the xml file are further extracted for the training process. Compared with the 80 categories and 255-dimensional output tensors of the COCO dataset, the object detection in this study focuses on three types: penalty players, ordinary athletes, and spectators. To reduce the computation and improve the detection accuracy and speed, the YOLOv5 classifier is modified to only recognize penalty players. Therefore, the dimensionality of the output tensor is adjusted to 3*(5+1)=18 to better adapt to the needs of match detection and optimize the model performance. Fig. 7 shows the loss function curve.



(a) Cross-parity loss diagrams (b) Target detection loss graphs

Fig. 7. Loss function curve.

In Fig. 7(a) and Fig. 7(b), the loss function changes of different versions of YOLOv5 algorithm in object detection tasks are presented. box_loss corresponds to matching loss between the target and the prediction box, while the obj_loss corresponds to object detection loss. Overall comparison showed that YOLOv5 had the lowest loss value when combined with CIoU and CBAM, indicating the effectiveness of the improved method. In both loss functions, this combination consistently maintained a faster downward trend and reached a lower stable value in the later training stages. In the box_loss, YOLOv5+CIoU+CBAM decreased rapidly at the beginning and continued to maintain a loss value below 0.02, while the standard YOLOv5 loss was slightly higher. Since only the penalty player category was set in this experiment, and the class loss (cls_loss) was 0, the cls_loss value was not considered in the analysis. These results show that YOLOv5 combined with CIoU and CBAM can perform more accurate target detection, which has better convergence performance. The experimental average accuracy curve is shown in Fig. 8.

Fig. 8 shows the average accuracy curve of the original YOLOv5 and the model after introducing DIoU, CIoU loss function and attention mechanism. The experiment is conducted with 80 rounds in the same configuration. The observations showed that the models converged rapidly from the 30th round and tended to stabilize after the 60th round. The black curve of CIoU loss function and attention mechanism showed that the improved model outperformed the original YOLOv5 model in terms of average accuracy and recognition. In order to verify the recognition effect, three frames of video are selected for comparison, as shown in Fig. 9.

As shown in Fig. 9, in the first frame, although both models could detect the penalty player, the original model had a low confidence level. The recognition was not ideal, and the target was not detected in the last frame. In contrast, the improved model exhibited high recognition accuracy and stability, which accurately identified the athlete's posture throughout the penalty action and saved it as a video frame.

B. *Performance Test of Basketball Free Throw Hit Prediction Model Based on OpenPose Algorithm*

In this study, the limb angle and the relative position gap and angle of the joint point of the key frame in the free throw are combined as feature inputs. The comparison results of accuracy and recall before and after algorithm optimization are shown in Fig. 10.

In Fig. 10, the pre-improvement test results showed that the goal prediction accuracy was 71% inside (in) and 89% outside (out), and the recall rates were 86% and 77%, respectively, when the free throw key frame limb angle was used as the feature. The improved model was characterized by the combination of the relative position gap and the angle of the joint points. The accuracy was significantly improved to 80% internally and 95% externally. The recall rate was also increased to 96% and 75%, respectively. This significant improvement, especially the significant increase in internal recall, shows that the prediction bias caused by different body types of athletes can be effectively reduced by comprehensively considering the relative position gap and angle information of joint points. In addition, the F1-score and accuracy of the improved model also reached 88% and 86% internally, and 84% and 86% externally, respectively, which verified the effectiveness of the feature optimization strategy and demonstrated the efficiency of the model in recognizing basketball free throws. In previous studies, the human pose estimation method was used to extract the relative coordinates of human bone points, and the free throw posture was input into the classifier as a static feature for prediction. The method not repairing the joint points in the shooting process is used as the comparison object, which is named the static input. The ROC curve comparison results are shown in Fig. 11.

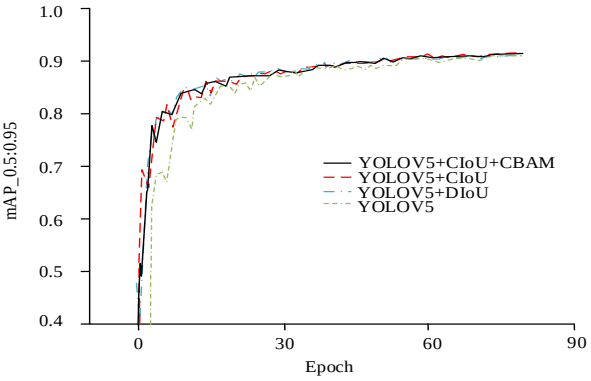


Fig. 8. Experimental average precision curve.

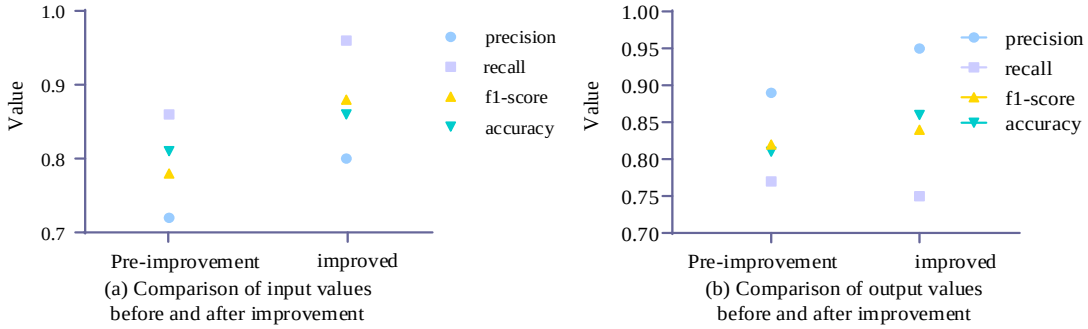
(a) Baseline network identification before improvement

(b) Improved

Fig. 9. Detection results visualization.



(a) Comparison of input values before and after improvement

(b) Comparison of output values before and after improvement

Fig. 10. Comparison of accuracy and recall.

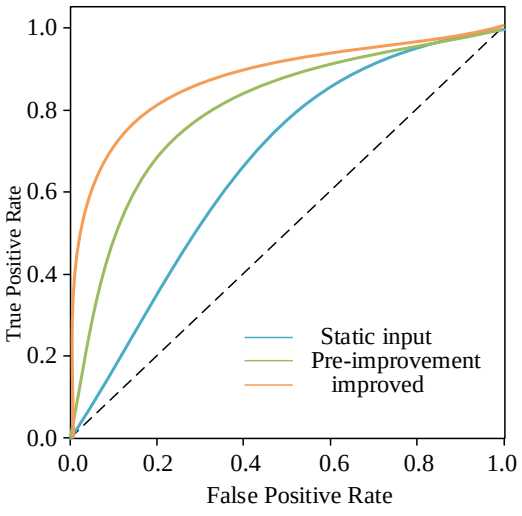


Fig. 11. ROC curve comparison.

Fig. 11 shows a comparison of the Receiver Operational Signature (ROC) curves for the three methods. A curve closer to the upper left indicates better prediction performance. From the figure, the ROC curve of the method combining the relative position characteristics of joint points and the characteristics of angular change (orange curve) was higher than that of the other two methods, indicating that this method achieved higher value in the True Positive Rate and maintained lower False Positive Rate. Therefore, it is better than the other methods in terms of prediction effect. These results indicate that the proposed method significantly improved the accuracy of free throw prediction. In this study, the key features in the shooting process were studied by observing the influence of different limb angle features on the prediction results of free throws. Table II shows the influence of different features on the prediction results.

The experimental results showed that the angle between the thigh and calf during the free throw, the angle between the shooter's big arm and the angle of the assistive hand had a significant impact on the free throw hit, all of which were more than 6%. In contrast, the calf foot angle and the torso-thigh hip angle had less effect. A successful free throw basket sample showed that the athlete had an angle of about 120 degrees between the thigh and calf when squatting, about 80 degrees between the upper arm and lower arm when shooting, and about 130 degrees between the upper arm and torso after the shot. These three angles were key features to

improve free throw hit and should be taken into account in free throw drills. The corresponding angles of the missed samples are often large or small, suggesting that these critical angles should be normalized during training.

C. Posture Analysis and Hit Probability Prediction System Test

The functional demonstration of the basketball free throw posture analysis and hit probability prediction system using deep learning are shown in Fig. 12.

As shown in Fig. 12, the penalty player detection module shown in Fig. 12(a) allows the user to input information through the interface button in order to identify the player in the uploaded free throw video. The system identified the location of the penalty player, and extracted the video clip with the player as the main body for subsequent attitude evaluation. In addition, the free throw prediction module shown in Fig. 12(b) allows users to predict the shooting results of the free throw team player and record this information. These modules provide users with a complete penalty analysis and training aid. The system is further functionally tested, and the test results are shown.

As shown in Fig. 13, the performance evaluation results of the posture analysis and hit probability prediction system showed that with the continuous operation of the posture analysis and hit probability prediction system, the server CPU usage increased, and the overall trend was upward, but the fluctuation was large. When a new process joined, the CPU usage increased instantaneously, and then dropped to the normal level. The CPU usage was up to 21.7%, and the lowest CPU usage was at the beginning of the process. The CPU usage was basically kept below 20% during the whole system operation, and the proportion of server resources was within a controllable range. The CPU proportion of the system was similar to the proportion of server resources over time. The proportion of CPU was slightly higher than that of server resources, with the highest CPU proportion of 27.6% in the whole system running time, the lowest CPU usage at the beginning of the process, and the CPU usage basically remaining below 30% during the system running time. Considering the requirements of the posture analysis and hit probability prediction system, the CPU proportion of the system should be controlled below 40%. The test results should be in line with the system design. The response speed test results for video files of different sizes are shown in Fig. 14.

Fig. 14 shows the response speed test results of different sizes of video files. The video file files are set to 5MB, 10MB, and 15MB. As the size of the model file changed, the system response speed also changed, and the system transaction processing efficiency was basically the same. When the video file was 5 MB, the overall Transaction per Second (TPS) changed smoothly and remained at a low level over time, when the video file was 10 MB, the TPS fluctuation was more severe than that when the video file was 5 MB, but it was still flat. When the video file was 15 MB, the TPS fluctuation was larger, but the system still maintained good system stability and had a good user experience while the system processed the video, which met the actual use requirements.

TABLE II. DEGREE OF INFLUENCE OF DIFFERENT FEATURES ON THE PREDICTION RESULTS

Diagnostic property	Predictive accuracy	Accuracy impact
Thigh-calf angle	78%	8%
major arm-torso angle	81%	5%
The angle between the big and small arms of the shooting hand	79%	7%
Calf foot pinch angle	86%	<1%
Carapace thigh angle	83%	3%
Auxiliary hand large arm small arm angle	80%	6%
Arm acceleration	86%	<1%

V. Conclusion

Basketball education, as popular physical education curriculum content around the world, puts forward comprehensive requirements for students' physical fitness, skills and teamwork ability. The constantly evolving teaching of skills and tactics requires educators to update their teaching methods and cultivate high-quality athletes who can adapt to the development of modern basketball. Free throws are an important scoring method for students in basketball teaching practice. The hitting rate directly affects students' sports scores. In order to automatically predict the probability of free throw hit and reduce manual fatigue, a basketball free throw posture analysis and hit probability prediction system was constructed based on YOLOv5 network and OpenPose algorithm. The performance test results showed that when the free throw key frame limb angle was used as the feature, the goal prediction accuracy was 71% internally and 89% externally. The recall rate was 86% and 77%, respectively. The improved model was characterized by the combination of the relative position gap and the angle of the joint points. The accuracy was significantly improved to 80% internally and 95% externally. The recall rate was also increased to 96% and 75%. Experimental results show that the functional modules of basketball free throw posture analysis and hit probability prediction system basically meet the expectations, which proves that the basketball free throw posture analysis and hit probability prediction system based on deep learning can meet the practical teaching application needs. However, there are still some shortcomings in the research. The application of video human posture estimation in physical education teaching has broad prospects. Although the study has achieved results in the detection, tracking and prediction of free throw players, the accuracy of identification and prediction in complex scenarios still needs to be improved. The future research directions mainly include expanding training datasets to improve model generalization, especially in complex scenarios, optimizing feature extraction and machine learning algorithms to enhance prediction accuracy, and enhancing the real-time processing capability of the system to ensure its ability to quickly respond to actual competition demands. In addition, the user interface will be improved to enhance the user experience, and potential applications of the system in basketball tactical analysis and athlete performance evaluation will be explored. It also includes conducting long-term tracking tests to evaluate system performance and the long-term impact on athlete training effectiveness, with the ultimate goal of improving the technological support in basketball training and matches.

***Abstract*—Given the proliferation of connected devices and the evolving threat landscape, intrusion detection plays a pivotal role in safeguarding IoT networks. However, traditional methodologies struggle to adapt to the dynamic and diverse settings of IoT environments. To address these challenges, this study proposes an innovative framework that leverages machine learning, specifically Red Fox Optimization (RFO) for feature selection, and Attention-based Bidirectional Long Short-Term Memory (Bi-LSTM). Additionally, the integration of blockchain technology is explored to provide immutable and tamper-proof logs of detected intrusions, bolstering the overall security of the system. Previous research has highlighted the limitations of conventional intrusion detection techniques in IoT networks, particularly in accommodating diverse data sources and rapidly evolving attack strategies. The attention mechanism enables the model to concentrate on pertinent features, enhancing the accuracy and efficiency of anomaly and malicious activity detection in IoT traffic. Furthermore, the utilization of RFO for feature selection aims to reduce data dimensionality and enhance the scalability of the intrusion detection system. Moreover, the inclusion of blockchain technology enhances security by ensuring the integrity and immutability of intrusion detection logs. The proposed framework is implemented using Python for machine learning tasks and Solidity for blockchain development. Experimental findings demonstrate the efficacy of the approach, achieving a detection accuracy of approximately 98.9% on real-world IoT datasets. These results underscore the significance of the research in advancing IoT security practices. By amalgamating machine learning, optimization techniques, and blockchain technology, this framework provides a robust and scalable solution for intrusion detection in IoT networks, fostering improved efficiency and security in interconnected environments.**

Keywords*—Intrusion detection; IoT networks; machine learning; random forest, red fox optimization; blockchain technology

I. Introduction

The Internet of Things (IoT) represents a transformative innovation in automation and connectivity, comprising a vast network of interconnected devices equipped with actuators, sensors, and computational capabilities [1]. These devices encompass a diverse range, from everyday items like household appliances and wearables to complex industrial machinery and infrastructure components. Central to IoT networks is their autonomous ability to collect, process, and transmit data, eliminating the need for direct human intervention. This autonomy empowers organizations and individuals to leverage data-driven insights and automation across various sectors and industries. For instance, in smart homes, IoT devices facilitate energy monitoring, remote appliance control, and enhanced security via connected surveillance systems [2].

Wearable sensors and medical gadgets help with early health issue diagnosis, individualized treatment strategies, and remote patient monitoring in the healthcare industry. In transportation, IoT technologies optimize logistics, improve traffic management, and enhance passenger safety through intelligent vehicle systems and infrastructure. Moreover, IoT networks extend their reach into diverse sectors such as agriculture, where precision farming techniques leverage sensor data to optimize irrigation, monitor soil conditions, and maximize crop yields[3]. In industrial settings, IoT-enabled machinery and production systems enable predictive maintenance, real-time monitoring of equipment health, and automation of manufacturing processes, leading to increased efficiency and reduced downtime. The overarching goal of IoT networks is to enhance connectivity, efficiency, and convenience while enabling new levels of automation and control across various domains. By seamlessly integrating physical devices with digital technologies, IoT networks pave the way for a more interconnected and intelligent world, where data-driven insights drive decision-making and innovation. However, this proliferation of connected devices

also brings about significant challenges, particularly in terms of security, privacy, and interoperability, which must be addressed to fully realize the potential benefits of the IoT revolution [4].

IoT networks exhibit a high degree of heterogeneity, encompassing a diverse array of devices with varying computational capabilities, communication protocols, and operating systems. From simple sensors to complex smart appliances and industrial machinery, these devices run on different platforms, including embedded systems, Linux-based platforms, and proprietary firmware[5]. This heterogeneity poses challenges for interoperability and standardization. Moreover, IoT networks are highly scalable, capable of supporting deployments ranging from small-scale implementations to massive infrastructures comprising millions of interconnected devices. This scalability leads to complex network topologies and management challenges. Connectivity serves as a cornerstone for IoT networks, with devices employing a range of wired and wireless communication technologies. The selection of connectivity technology is influenced by factors such as range, power consumption, and deployment environment. Additionally, IoT networks generate a wide array of data types, including sensor readings, images, audio, and video streams, presenting challenges for data processing and analysis. Effectively managing this data diversity is essential for deriving meaningful insights while maintaining scalability, efficiency, and data privacy [6].

IoT networks are susceptible to a myriad of security vulnerabilities, posing significant challenges to their integrity and reliability. Weak authentication and authorization mechanisms represent a prevalent threat, as many IoT devices are shipped with default or easily guessable credentials, providing malicious actors with unauthorized access and control over these devices [7]. Furthermore, insecure communication practices exacerbate the risk, as IoT devices often transmit data over unencrypted channels or employ weak encryption protocols, leaving sensitive information vulnerable to eavesdropping and interception by malicious entities. Compounding these issues is the lack of timely security updates from manufacturers, leaving devices exposed to known vulnerabilities and exploits. Physical vulnerabilities also pose a substantial risk to IoT networks, as attackers can exploit physical access to tamper with hardware components, extract sensitive data, or implant malicious firmware, compromising the integrity and functionality of these devices [8].

Additionally, IoT devices are susceptible to being co-opted into botnets and used to launch distributed denial-of-service (DoS) attacks against targeted services or networks, leading to disruptions and downtime. Moreover, the vast amounts of personal and sensitive data collected and transmitted by IoT devices raise significant privacy concerns, including unauthorized access, data breaches, and misuse of information. Supply chain risks further exacerbate the security landscape, as the global supply chain for IoT devices is often complex and opaque, making it challenging to verify the integrity and authenticity of hardware components and software firmware [9]. Lastly, interoperability issues between IoT devices and protocols introduce additional vulnerabilities, enabling attackers to exploit weaknesses in communication interfaces and protocols, potentially compromising the entire network. A comprehensive strategy that includes strong authentication procedures, encryption methods, regular security upgrades, physical security measures, and privacy-enhancing technology is needed to address these issues. In addition, stakeholders need to work together to create industry-wide guidelines and recommendations for protecting IoT networks and devices, minimizing risks, and guaranteeing the dependability and trustworthiness of the IoT ecosystems [10].

Intrusion detection in IoT networks is hindered by the dynamic and heterogeneous nature of these environments, along with the continuously evolving threat landscape. Traditional methods struggle to adapt to the diverse array of devices, communication protocols, and data formats present in IoT networks, leading to limited coverage and effectiveness. Scalability poses another challenge, as the sheer volume of interconnected devices generates large amounts of data that traditional systems may struggle to process in real-time. Resource constraints on IoT devices further complicate matters, making it difficult to deploy traditional intrusion detection solutions. Furthermore, newer or undiscovered threats could not be detected by conventional techniques, calling for more sophisticated detection capabilities. Moreover, worries about data privacy and integrity continue since centralized systems have the potential to expose vulnerabilities or corrupt critical data. Innovative solutions that are suited to the special features of internet of things networks are needed to tackle these issues. These solutions must be scalable, resource-efficient, capable of robust detection, and equipped with improved security mechanisms to efficiently reduce hazards [11].

The rapid expansion of Internet of Things (IoT) networks has underscored the critical need for a robust and scalable intrusion detection framework capable of effectively mitigating security threats. Traditional intrusion detection systems (IDS) often struggle to adapt to the dynamic and heterogeneous nature of IoT environments, necessitating innovative solutions. Our research is motivated by the imperative to develop such a framework, leveraging advanced machine learning techniques like Attention-based Bidirectional Long Short-Term Memory (BiLSTM) networks for real-time threat detection. Additionally, the integration of Red Fox Optimization (RFO) enhances the efficiency of feature selection, enabling more accurate identification of relevant data amidst the complexities of IoT networks. Furthermore, the incorporation of blockchain technology ensures the integrity and trustworthiness of intrusion detection data, facilitating transparent incident response and forensic analysis. By synergizing these technologies, our framework offers a comprehensive defense mechanism against evolving threats, safeguarding critical assets and bolstering the security posture of IoT ecosystems. The key contribution of the research is stated as follows:

- The research presents a pioneering framework that combines machine learning techniques, such as Attention-based BiLSTM networks, with Red Fox

Optimization for feature selection, providing a novel approach to intrusion detection in IoT networks.

- By leveraging advanced machine learning algorithms, our framework achieves a significantly higher detection accuracy of approximately 98%, surpassing traditional intrusion detection systems and effectively mitigating security threats in IoT environments.
- The integration of Red Fox Optimization streamlines feature selection, enhancing the scalability and efficiency of our framework in handling the dynamic and heterogeneous nature of IoT data streams, thus ensuring robust performance even in large-scale IoT deployments.
- Incorporating blockchain technology ensures the integrity and tamper-resistance of intrusion detection data, providing transparent incident response and forensic analysis capabilities, thereby enhancing the overall security and trustworthiness of IoT networks.

The paper begins with an introduction to the research topic in Section I, followed by a comprehensive review of related literature in Section II. The methodology in Section IV outlines the proposed framework's design and implementation, with Section V covering experimental evaluation, results analysis, and discussion on the framework's effectiveness. Finally, Section VI concludes the paper.

II. Related Works

Strong security mechanisms inside IoT networks are vital, as evidenced by the increasing ubiquity of Internet of Things (IoT) technologies. But in Internet of Things contexts, conventional intrusion detection systems face severe restrictions because of limited resources and the intrinsic complexity of the network. Liang et al. [12] research aims to tackle these issues by developing, putting into practice, and assessing a novel intrusion detection system. This system makes use of deep learning algorithms, blockchain technology, and multi-agent systems as part of a hybrid placement strategy. The data collecting, management, analysis, and reaction components of the system are organised into separate modules. The National Security Lab's NSL-KDD dataset was used for experimental verification, which demonstrates how well deep learning algorithms detect assaults, especially at the IoT network's transport layer. Notwithstanding the encouraging outcomes, the study admits significant limitations, such as the requirement for additional improvement and optimisation of the suggested system in order to guarantee its scalability and suitability for use in a variety of IoT scenarios.

Alkadi et al. [13] paper presents a novel approach to collaborative intrusion detection for safeguarding IoT and cloud networks, leveraging the capabilities of deep blockchain technology. By integrating blockchain into intrusion detection systems, the proposed framework aims to enhance the security posture of interconnected environments through collaborative threat intelligence sharing and consensus-driven decision-making processes. Through the utilization of machine learning algorithms and distributed ledger technology, the framework enables real-time detection and response to emerging threats across diverse network landscapes. Experimental results demonstrate the efficacy of the framework in detecting intrusions and mitigating security risks in various network scenarios. However, the adoption of deep blockchain technology introduces challenges related to scalability, latency, and resource consumption. The computational overhead associated with maintaining a distributed ledger across multiple nodes may impact the real-time responsiveness of the intrusion detection system. Furthermore, ensuring consensus among distributed nodes in a timely manner can pose synchronization and coordination challenges, potentially affecting the system's overall efficiency and effectiveness in rapidly evolving threat landscapes. Addressing these scalability and performance limitations is essential to realize the full potential of the proposed framework in large-scale IoT and cloud networks.

The necessity for strong security measures to protect Internet-of-things (IoT) environments from potential threats has been highlighted by the growth of IoT devices. In order to protect computer networks, including the Internet of Things, from many types of security breaches, intrusion detection systems, or IDSs, are essential. The utilisation of collaborative intrusion detection systems or networks, also known as CIDSs or CIDNs, has shown promise in improving detection performance through the sharing of vital information across IDS nodes, including signatures and alarms. Nevertheless, because collaborative networks are distributed, they are vulnerable to insider assaults, in which rogue nodes spread fake signatures, jeopardising the accuracy and effectiveness of intrusion detection systems. Using blockchain technology presents a viable way to safely validate shared signatures. In this regard, the research of Li et al. (Li et al. 2019) presents CBSigIDS, an innovative framework for blockchain-based collaborative signature-based IDSs intended to create and gradually update a trusted signature database in collaborative IoT contexts. With no need for a reliable middleman, CBSigIDS provides a verified method in distributed architectures. Although CBSigIDS shows promise in strengthening the efficiency and robustness of signature-based IDSs, a significant disadvantage is the possible overhead related to blockchain activities, which calls for additional optimisation to guarantee scalability and efficacy in practical deployments.

Issues with privacy, security, and single points of failure in centralised storage structures still exist as the Internet of Things (IoT) gains pace, especially in crucial applications. By providing decentralised and secure data management, blockchain technology has emerged as a viable answer to these problems. There is a lot of potential for improving social and economic advantages when blockchain is integrated with IoT. But as the 2017 attack on a pool of miners has shown, blockchain-enabled Internet of Things (IoT) networks are vulnerable to Distributed Denial of Service (DDoS) attacks, underscoring the necessity of strong security protocols. Furthermore, for efficient analysis and decision-making, these applications' enormous data generation demands the use of sophisticated analytical tools like machine learning (ML). In order to address these issues, a unique solution is presented in

the paper by Kumar et al. [14]. This paper presents a distributed Intrusion Detection System (IDS) intended to detect distributed denial of service (DDoS) assaults targeting mining pools within Internet of Things networks, using fog computing and blockchain technology. Using Random Forest (RF) and an optimised gradient tree boosting system (XGBoost), both trained on dispersed fog nodes, the efficacy of the suggested IDS is evaluated. The BoT-IoT dataset, which covers recent assaults seen in IoT networks with blockchain support, is used in the evaluation. The possible costs and difficulties of implementing a distributed IDS employing fog computing in practical settings might be a drawback of the recommended strategy, necessitating more study and optimisation for efficiency and scalability. However, the outcomes demonstrate that Random Forest outperforms XGBoost in multi-attack recognition and binary attack detection.

Protecting industrial IoT (IIoT) networks from security threats is crucial as these networks grow to be essential parts of vital infrastructure. Numerous strategies utilizing Blockchain algorithms and machine learning techniques have been investigated separately to overcome this problem. However, Vargas et al. [15] offer an integrated strategy in this research that integrates these approaches to produce a thorough defense mechanism for networks of Internet of Things devices. The objectives of this mechanism are to identify potential dangers, initiate safe channels for information exchange, and adjust to the processing power of industrial Internet of things settings. The suggested method offers a workable way to identify and stop intrusions in Internet of Things networks and shows effectiveness in accomplishing its goals. Despite its achievements, it's crucial to remember that the suggested integrated strategy can present challenges for management and implementation, necessitating the need for extra funding and knowledge for deployment in actual IIoT scenarios. More investigation is required to ensure scalability and efficiency while minimizing overhead by streamlining and optimizing the integration process.

III. Problem Statement

Despite the notable advancements in intrusion detection systems (IDS) and the integration of blockchain technology and machine learning techniques in securing Internet of Things (IoT) networks, several research gaps persist. Existing studies focus predominantly on individual aspects such as deep learning algorithms, blockchain-based intrusion detection, or collaborative signature-based IDSs. However, there is a scarcity of research that comprehensively addresses the complex security challenges of IoT environments by integrating multiple technologies and methodologies. Furthermore, scalability, efficiency, and practical feasibility remain critical concerns across these studies, indicating the need for further exploration and refinement. Thus, our research aims to bridge this gap by proposing a holistic framework that combines deep learning algorithms, blockchain technology, and collaborative intrusion detection mechanisms to provide robust security solutions for IoT networks. By addressing these multifaceted challenges and evaluating the proposed framework's scalability and effectiveness across diverse IoT scenarios, our research endeavors to contribute towards the development of comprehensive and practical security solutions tailored for IoT environments.

IV. Methodological Integration of ML and Blockchain for IoT Intrusion Detection

The suggested method builds a strong intrusion detection system (IDS) that is suited for the complex architecture of Internet of Things networks by fusing blockchain technology with machine learning. Network traffic, sensor readings, device logs, and other data from IoT devices are first gathered and preprocessed to extract pertinent attributes that are essential for intrusion detection. The framework optimizes feature subsets to increase intrusion detection efficacy and efficiency using the Red Fox Optimization (RFO) approach. Then, real-time anomaly detection is achieved by using Attention (BiLSTM) networks, which take advantage of their capacity to process sequential data streams present in Internet of Things settings. Blockchain technology is easily incorporated to guarantee the immutability and integrity of intrusion detection data. Smart contracts are utilized to provide safe communication and consensus building across dispersed Internet of Things devices, guaranteeing the accuracy and consistency of the data. Benchmark datasets such as the NSL-KDD dataset are used to evaluate the framework's performance in detail across a range of intrusion situations. By employing this technique, researchers want to enhance the efficacy and security of intrusion detection in internet of things networks, as well as tackle the constantly evolving problems associated with IoT setups [16].The suggested technique's architecture is depicted in Fig. 1.

A. Data Collection

The data collection process involves gathering information from IoT devices, drawing upon a diverse array of network traffic, sensor readings, and device logs. In this research, we utilize the NSL-KDD dataset, an open-source resource available on Kaggle [17], to facilitate the collection of comprehensive data for intrusion detection system development. The NSL-KDD dataset offers a rich repository of labeled network traffic data, encompassing various types of attacks and normal behaviors, thereby enabling thorough analysis and evaluation of intrusion detection algorithms. Leveraging this openly accessible dataset ensures transparency and reproducibility in our research methodology, allowing for robust validation and benchmarking of the proposed intrusion detection framework against a standardized dataset. Through meticulous data collection from the NSL-KDD dataset, we aim to capture the diverse range of potential threats and normal activities prevalent in IoT networks, laying the foundation for effective intrusion detection system design and evaluation.

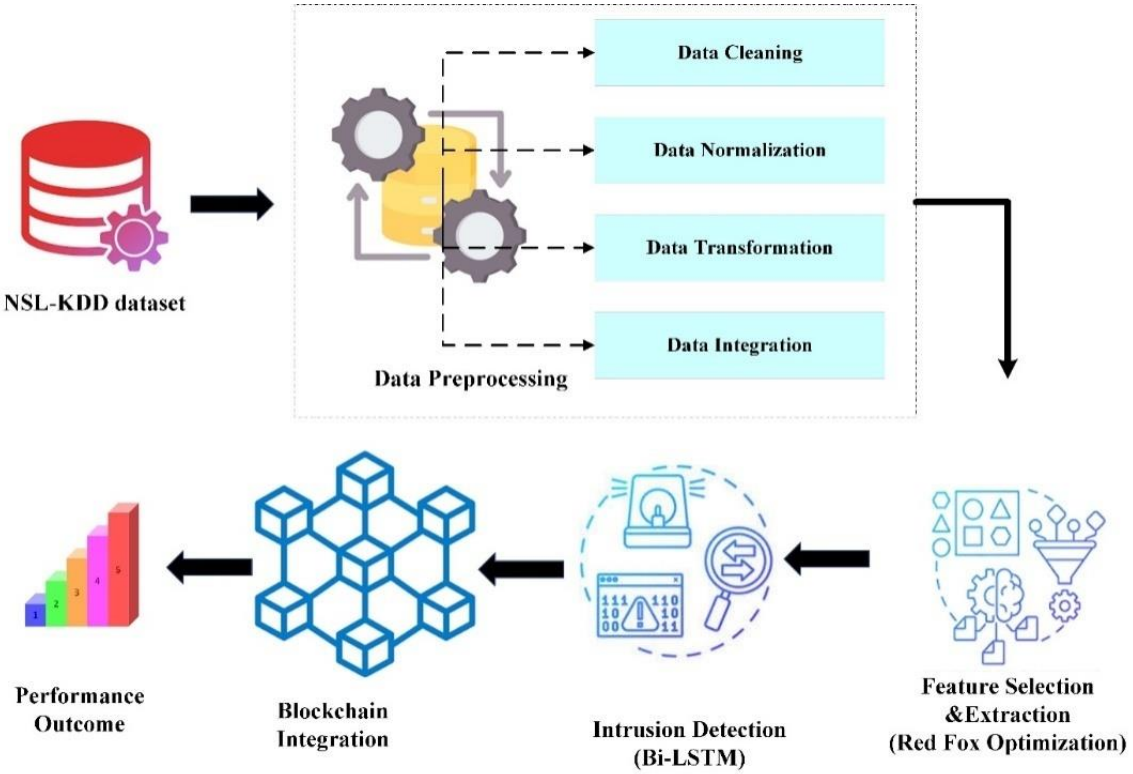

Fig. 1. Proposed integration of ML and blockchain for IoT intrusion detection.

B. Data Preprocessing

Following data collection, the input data undergoes preprocessing to eliminate unwanted noise and address missing data. This involves four key preprocessing approaches:

- Data Cleaning
- Normalization
- Data Transformation
- Data Integration

C. Data Cleaning

In order to improve the quality and dependability of datasets, data cleaning is an essential step in the data preparation pipeline. It involves locating and correcting different kinds of data abnormalities. These anomalies may include corrupted, incorrect, duplicate, or improperly formatted data entries. The primary goal of data cleaning is to ensure that datasets are standardized, accurate, and easily accessible for analysis and query purposes. During the data cleaning process, several tasks are performed to address different types of data issues. Firstly, corrupted or incorrect data entries are identified and either removed or corrected to restore data integrity. Duplicate entries, if present, are identified and eliminated to prevent redundancy and ensure that each observation is unique[18]. Additionally, managing missing values—which can occur for a number of reasons, including incomplete records or mistakes in data collection—is another aspect of data cleansing. When there are missing values in an observation, they can be imputed using statistical techniques or data from other observations can be dropped. Additionally, data cleaning ensures that the dataset complies with the required format and schema by addressing structural flaws that could arise throughout the data transfer process. Thorough data cleaning improves the dataset's dependability and suitability for analysis, allowing analysts and researchers to derive precise conclusions and make defensible choices [19].

D. Normalization

Normalization is a preprocessing step aimed at transforming data from its existing range to a new range. Given the presence of uncertain and incomplete data in the dataset, it becomes essential to address missing or irrelevant data to enhance data quality. The dataset can be integrated and normalized with success using the Min Max normalization approach. By making sure the dataset is scaled correctly, this method makes it possible to anticipate outcomes within the new range and allow for a greater difference in forecasting. Normalization reduces the influence of differences in dataset scales by scaling the dataset so that normalized values lie between 0 and 1. This allows for easier comparison of results from various datasets. This technique involves deducting the minimum value from the variable requiring normalization, resulting in a standardized dataset suitable for analysis and comparison. Min-max scaling, frequently referred to as feature scaling, converts the values of each feature to a range of 0 to 1 [20]. To compute the min-max scaling, use Eq. (1).

$$A_{scaled} = \frac{A - A_{min}}{A_{max} - A_{min}} \quad (1)$$

A is the starting value, $A_{min}$is the smallest value, and $A_{max}$is the largest value in the dataset. This method is helpful when the features are not evenly distributed and have a small range.

E. Data Transformation

Data transformation involves converting the original dataset into a specific format that facilitates faster and more efficient retrieval of strategic insights. Raw datasets can be challenging to comprehend and track, necessitating transformation into a more suitable form before extracting information. This transformation process is crucial for providing easily interpretable patterns, aligning with the strategic objectives of data conversion. Various techniques, such as smoothing, aggregation, and generalization, are employed in data transformation to streamline the dataset. Smoothing techniques are utilized to eliminate noise from the dataset, enhancing data clarity. Data aggregation gathers and presents data in a summarized format, aiding in easier analysis and interpretation. Additionally, data generalization involves converting lower-level or raw data into higher-level data through hierarchical concepts, further enhancing the dataset's organizational structure and usability [21].

F. Data Integration

Data integration is a preprocessing strategy that combines data from several sources into a single data repository to give rich views of the data. These sources could be flat files, databases, or several data cubes. Collaboration between users at all levels is facilitated by data integration, which combines received data with heterogeneous datasets to store consistent data that is client-accessible. A triplet defines the data integration mechanism, which is further explained in Eq. (2).

$$D_1 =< U, V, W > \tag{2}$$

In this context, D_1represents the process of data integration, where U stands for the global schema, V denotes the schema of heterogeneous sources, and W refers to the mappings between queries of the source and global schema [22].

G. Feature Selection

In order to improve the effectiveness and productivity of the intrusion detection process, feature selection is an essential step in the preliminary processing phase of systems for detection. Its goal is to pick the most pertinent characteristics from the pre-processed data. Red Fox Optimisation (RFO) becomes apparent as a potent feature selection method in this scenario. To increase the intrusion detection system's overall performance, RFO works by optimising feature subsets. Finding a subset of characteristics that maximises the discrimination between normal and aberrant network behaviour is the main goal of feature selection using RFO. This will improve the system's capacity to detect intrusions effectively while reducing computing overhead. RFO does this by iteratively assessing and honing potential feature subsets according to pre-established optimisation standards, including performance metrics or classification accuracy. The intrusion detection system may efficiently prioritise and concentrate on the most useful aspects by using RFO for feature selection. This lowers the dimensionality of the data and boosts the overall effectiveness of the detection process. Additionally, RFO has the flexibility and scalability to manage high-dimensional information that are frequently seen in Internet of Things networks [23].

After obtaining the balanced dataset from the previous stage, the optimal features for improving intrusion detection training speed and accuracy are selected using the DRF optimisation technique. Numerous meta-heuristic optimisation strategies are developed to improve network security in standard systems for detection of intrusions. Three newly created models used for network security are Spider Monkey Optimisation, Fruity Optimisation, and Greedy Swarm Optimisation. However, overfitting, which delayed processing, a slower rate of convergence, and complex computational procedures are the main causes of its issues. Generally speaking, some of the most current nature-inspired/bio-inspired optimisation approaches produced is the Dragon Fly Algorithm, Moth Flame Optimisation, and Ant Lion Optimisation, Harris Hawk optimisation (HHO), Flower Pollination Algorithm. These algorithms are commonly used to solve complex optimisation problems in a variety of security applications. The DRF is one of the newest optimisation algorithms and has several advantages over previous techniques. It has a low processing cost, less local optimum, rapid convergence, and guards against algorithm stacking during optimisation. Furthermore, the DRF35 is not specifically utilised in applications for IoT-IDS security. Therefore, the goal of the proposed study is to use this method to dataset feature optimisation based on the best optimum solution. Additionally, this optimisation procedure facilitates a simpler classification method with a higher assault detection rate [23].

The balanced IoT dataset's characteristics may be optimally tuned using this optimization approach. Foxes belong to many Canidae families and are tiny to medium-sized omnivore animals with pointed noses, long, thin legs, thicktails, and slender limbs. The foxes may also be distinguished from each other of their family and from large dogs. A novel meta-heuristic optimization system called the DRF takes its cues from the hunting habits of red foxes. When hunting, the red fox moves slowly towards its prey as it hides in the underbrush, and then it attacks the animal out of the blue. Like previous meta-heuristic models, this approach takes into account both the utilization and investigation of capabilities. This method creates random people for initializing parameters, as seen by the subsequent Eq. (3) and Eq. (4).

$$R = [r_0, r_1, \ldots . r_{n-1}] \tag{3}$$

$$(R)^i = [(r_0)^i, (r_1)^i \ldots . (r_{n-1})^i] \tag{4}$$

where, “I” denotes how many populations are present in the search area. Ten, the global optimal function is used to find the best solution in the search space. Here, the structure that follows is used in conjunction with the Euclidean distance to get the best solution as presented in Eq. (5).

$$E(((R)^i)^k, (R_{best})^k) = \sqrt{(R^i)^k - (R_{best})^k} \tag{5}$$

In Eq. (5) k denotes the number of iterations. The term "R_{best}t" represents the best optimum, while "E(.)" denotes the Euclidean distance. Accordingly, the optimal solution is employed to migrate all candidates, as illustrated in Eq. (6):

$$((R)^i)^k = ((R)^i)^k + g_{sign}((R_{best})^k - (R^i)^k)) \quad (6)$$

As a scaling hyperparameter, "g" denotes a random value selected at random from 0 to 1 for each iteration. For the whole population, this value is set just once every iteration. People evaluate the fitness values at their new places after moving to the optimal posture. People stay in their new roles if the fitness values are greater; if not, they return to their previous ones. This procedure is similar to how close relatives tell others where to hunt after an adventure and return home. They do what the explorers have instructed, going home "empty-handed" if they don't locate food, or continuing to search if there is a possibility. These processes, which take place during every DRF cycle, resemble suggested global inquiries. In addition, the applicants' move to new roles must present a feasible alternative; if not, their previous jobs will remain. The comparison of the red fox, advancing towards its prey and watches it, is appropriate here since it is similar to the DRF model in which a random number ω between 0 and 1 is assumed explained in Eq. (7) and Eq. (8) [24].

$$\begin{cases} Move\ Forward\ if, \omega > \frac{3}{4} \\ Stay\ Hiddem\ if, \omega > 3/4 \end{cases} \quad (7)$$

$$\omega = \begin{cases} \left\{ h \times \frac{\sin(\delta_0)}{\delta_0} \right. & if\ \delta_0 \neq 0 \\ \tau & if\ \delta_0 \neq 0 \end{cases} \quad (8)$$

Here, "h" is a random number in the interval [0, 0.2], and "δ0" is another random number in the interval [0, 2π], which indicates the fox viewing angle. Furthermore, "τ" represents a random number between 0 and 1. To model motions for the population of persons, the set of solutions for geographic coordinates is as follows. All things considered, the incorporation of RFO for picking features in intrusion detection systems improves computing efficiency and scalability while also strengthening the system's capacity to precisely detect and address security threats in Internet of Things networks. This method emphasises how crucial it is to use cutting-edge optimisation strategies in order to optimise feature subsets and improve intrusion detection technologies' overall effectiveness.

H. Intrusion Detection using Attention Bi-LSTM

The Attention-based BiLSTM model is used to identify intrusions in the NSL-KDD dataset. Using specialised memory units, LSTM—an improved version of the classic Recurrent Neural Networks (RNN)—captures long-term relationships in the MTS dataset efficiently [20]. The gradient vanishing problem is addressed by LSTM models, in contrast to conventional RNN techniques. Rather than depending just on the architecture of hidden units, they also incorporate memory cells that capture the long-term dependence of the signal. Four regulated gates make up the LSTM model: an output gate, a forget gate, input gate, in addition to a self-loop memory cell. These gates control how several memory neurons' data streams communicate with one another. The forget gate in the LSTM model's hidden layer decides which data from the previous time frame to keep and which to discard. The input gate makes the decision to simultaneously inject data from the memory unit into the input signal or not. The output gate decides whether to change the state of the memory unit [24]. The following Eq. (9) through Eq. (14) are used to determine the neuron state, hidden layer results, and gate states, taking into account the input xt from the NSL-KDD dataset and the dynamic output state h_t:

$$ip_t = \sigma(X_i u_t + Y_i h_{t-1} + a_i) \quad (9)$$

$$fg_t = \sigma(X_f u_t + Y_f h_{t-1} + a_f) \quad (10)$$

$$op_t = \sigma(X_o u_t + Y_o h_{t-1} + a_o) \quad (11)$$

$$c_t = fg_t \odot c_{t-1} + ip_t \odot \tilde{C}_t \quad (12)$$

The weight matrices that recur are indicated by as Y_i, Y_f, Y_o, while the representation of the weighted matrix for the forget, output, input, and memory cell gating by X_i, X_f, X_o, respectively. The biases for the gates are formulated as a_i, a_f, a_o. The candidate's cell state $\tilde{C}_t$, is utilized to update the original memory cell state, c_t. Step indicates the hidden layer's state h_{t-1}at any given moment, while ot indicates the outputop_t. The symbol ⊙ denotes the element-wise multiplication operation. The hyperbolic tangent function is denoted as tanh, and the logistic sigmoid activation function is represented by σ.

The standard LSTM model's limitation lies in its one-directional analysis of input signals during training, potentially leading to the inadvertent oversight of sequential information. In contrast, the BiLSTM was designed with a bidirectional structure, leveraging two LSTM layers operating in opposing directions to capture representation information both forwards and backwards. This bidirectional setup includes a hidden layer for reverse transmission (denoted as hb(t)), incorporating future values, alongside a forward propagation hidden layer (hf(t)) that retains data from previous sequence values. Ultimately, the BiLSTM model's final output is a fusion of both hf(t) and hb(t), facilitating a more comprehensive understanding of time series data.

$$M_{fg}(t) = \varphi\left(Y_{fm} u_t + Y_{fmm} u_{f(t-1)} + a_{fa}\right) \quad (13)$$

$$M_a(t) = \varphi\left(Y_{am} u_t + Y_{amm} u_{a(t-1)} + a_a\right) \quad (14)$$

Besides these, $a_{fa}$and $a_a$also relate to two-way biassed data. The weight matrix "Y_{fm} and Y_{am}"represents the synaptic weights from the input value to the internal unit for both forward and backward directions. Similarly, the forward and backward feedback recurrent weights are denoted by $Y_{fmm}$and Y_{amm}.

The tanh function serves as the activation function ψ for the hidden layers (HLs). It determines the output of the BiLSTM as b_t.

$$b_t = \sigma(W_{fmb} m_{f(t)} + W_{amb} m_{a(t)} + a_b) \quad (15)$$

The forward and backward weights of the resulting layers are represented by W_{fmb} and W_{amb}, respectively, in Eq. (15). Both a linear or sigmoidal function is provided as the

activation function of the resulting layer σ. Moreover, by denotes the bias in the output.The attention mechanism contributes to the learning process of the Attention BiLSTM model by assigning varying weights. The attention ai for a hidden layer hi is calculated using Eq. (16):

$$x_i = \tanh(Wh_i + a) \quad (16)$$

BiLSTM networks provide a powerful means to examine sequential data streams, enabling real-time detection of anomalous behavior and security threats in IoT networks. Leveraging BiLSTM architectures, these networks excel in capturing temporal dependencies and patterns present in IoT data, which are often characterized by their dynamic and time-varying nature. By effectively modelling the sequential nature of IoT data, BiLSTM networks can accurately identify deviations from normal behavior, facilitating prompt detection of intrusions and security breaches. To protect the integrity and confidentiality of IoT systems and devices, respond proactively to new threats, and strengthen the security posture of IoT networks, this capability is essential.

I. Blockchain Integration

The integration of blockchain technology into intrusion detection systems involves several key steps to ensure the integrity and immutability of the data while facilitating secure communication among distributed IoT devices through smart contracts.

1) Data logging: In the process of data logging, intrusion detection data generated by IoT devices is systematically recorded onto the blockchain network. Each piece of data is meticulously timestamped and cryptographically secured, ensuring its integrity and safeguarding against any potential tampering attempts. By timestamping each entry, the blockchain network establishes a chronological order of events, enabling a comprehensive audit trail of intrusion activities. Additionally, the cryptographic security measures implemented within the blockchain network guarantee the immutability of the logged data, thereby providing a reliable and tamper-proof record of security events. This meticulous logging process enhances the trustworthiness and reliability of the intrusion detection system, enabling robust security monitoring in IoT networks [25].

2) Blockchain node: In the context of blockchain technology, blockchain nodes serve as essential components responsible for validating and recording logged intrusion detection data. These nodes are distributed across the blockchain network, ensuring decentralization and resilience against single points of failure. Each node maintains a copy of the decentralized ledger, which contains a complete record of all transactions, including the logged intrusion detection data. When new data is logged onto the blockchain, it undergoes validation by multiple nodes within the network to ensure its authenticity and integrity. This validation process involves verifying the cryptographic signatures associated with the data and confirming its adherence to the consensus rules established by the network protocol. Once validated, the intrusion detection data is appended to the blockchain ledger, becoming a permanent and immutable part of the distributed database. By distributing the responsibility for data validation and storage among multiple nodes, blockchain networks achieve redundancy and fault tolerance, enhancing the reliability and resilience of the overall system. Furthermore, as blockchain nodes are decentralised, no one organisation can exert control over the system as a whole, fostering openness, confidence, and security in the logging and archiving of intrusion detection data.

3) Proof of work: The consensus mechanism of the blockchain is essential to guaranteeing that all dispersed nodes agree on the veracity of logged data. To reach this consensus among network users, consensus techniques like Proof of Work (PoW) are used. Proof-of-work (PoW) consensus is a competitive mechanism in which nodes solve challenging mathematical problems to validate transactions and append new blocks to the blockchain. This is a resource-intensive procedure that uses a lot of energy and processing power. Nonetheless, other nodes in the network confirm the answer after a node completes the puzzle and suggests a new block. The block is appended to the blockchain if the answer satisfies the consensus requirements. By using this decentralised method, blockchain networks maintain the integrity and durability of the blockchain ledger by facilitating consensus across dispersed nodes about the veracity of recorded data. Additionally, consensus mechanisms like PoW contribute to the security of the blockchain network by mitigating the risk of malicious actors attempting to manipulate or alter the logged data. Overall, the consensus mechanism serves as a fundamental building block of blockchain technology, enabling decentralized trust and coordination among network participants [26].

A key element of blockchain networks is the proof-of-work (PoW) consensus mechanism, which guarantees dispersed nodes' agreement on the legitimacy of transactions and the appending of new blocks to the blockchain. PoW comprises the following crucial steps:

- Transaction Propagation: Transactions are broadcasted to all nodes in the blockchain network. Each transaction contains details such as sender, recipient, amount, and cryptographic signatures.
- Block Creation: Transactions are grouped together into blocks, forming a candidate block for addition to the blockchain. Miners, who are nodes responsible for creating new blocks, select transactions and assemble them into a block structure.
- Mining Competition: Miners compete with each other to solve the Proof of Work puzzle. They utilize computational power to generate hash values by iteratively modifying a nonce (a random number) in the block header until the desired hash value is found. This process is computationally intensive and requires significant computational resources.

- Verification: A miner broadcasts the candidate block and the solution to the network as soon as they discover a workable solution to the problem. The legitimacy of the answer and the transactions included in the block are then confirmed by further nodes inside the network.
- Consensus: If the majority of nodes in the network agree that the proposed solution is sound and the block conforms to the consensus requirements, the block is accepted and posted to the blockchain. It is ensured that all distributed nodes concur on the validity of the transactions and the addition of new blocks to the blockchain by going through this process.
- Reward: A fixed quantity of bitcoin plus any transaction fees included in the block are awarded to the miner who effectively mines a new block. This encourages miners to use up processing power and take part in the consensus-building process on the network.

In general, the Proof of Work technique reduces the possibility of malevolent actors attempting to influence the blockchain by demanding computational resources to verify transactions and generate new blocks, hence ensuring the security and integrity of blockchain networks.

1) Smart contract: Smart contracts serve as the backbone of automation and governance within IoT networks by providing a decentralized, programmable framework for enforcing rules and conditions. These contracts, encoded with predefined logic, are deployed on the blockchain, ensuring immutability and tamper-proof execution. Within the context of IoT, smart contracts automate interactions between devices, enabling seamless communication and coordination without the need for intermediaries. By executing automatically when specific conditions are met, such as sensor readings or trigger events, smart contracts streamline processes and mitigate the risk of human error. Moreover, the decentralised structure of these systems gets rid of single points of failure and minimises dependence on centralised authority, hence improving security and resilience. Additionally, conditional execution of operations is made possible by smart contracts, which let gadgets react quickly to shifting conditions. This feature improves IoT network responsiveness and operational efficiency. Furthermore, network participants' confidence and responsibility are bolstered by the openness and auditability provided by smart contracts. Overall, smart contracts play a critical role in driving efficiency, security, and transparency in IoT ecosystems, laying the foundation for scalable and resilient decentralized applications [27].

2) Secure communication: In the ecosystem of IoT networks, secure communication is facilitated through the interaction between IoT devices and the blockchain network via smart contracts. These contracts act as intermediaries, enforcing cryptographic protocols and access controls to ensure that communication remains secure. By leveraging cryptographic techniques such as encryption and digital signatures, smart contracts authenticate and authorize devices, mitigating the risk of unauthorized access or tampering. Through predefined rules and conditions encoded within the smart contracts, only authorized devices are granted permission to access and modify data stored on the blockchain. This robust enforcement of security measures enhances the integrity and confidentiality of communication within IoT networks, safeguarding sensitive information and preventing unauthorized manipulation of data. Overall, the utilization of smart contracts enables secure and trustworthy communication channels, fostering confidence in the exchange of data and transactions within IoT ecosystems.

V. Result and Discussion

The proposed framework undergoes rigorous evaluation using benchmark datasets, including NSL-KDD and BoT-IoT, to comprehensively assess its performance in detecting various types of intrusions within IoT networks. By leveraging these datasets, which contain diverse and realistic intrusion scenarios, the framework's efficacy in identifying and mitigating security threats is thoroughly scrutinized. Performance metrics are used to assess how well the framework differentiates between malicious activity and typical network behavior. These measures include detection accuracy, false positive rate, and computing efficiency. Furthermore, the assessment procedure entails contrasting the outcomes of the framework with those of current intrusion detection systems in order to measure its effectiveness in relation to predetermined benchmarks. The suggested framework's potential to strengthen the security posture of IoT networks is carefully investigated through this methodical study utilizing typical datasets, offering insights into its advantages and shortcomings.

A. Performance Metrics

Performance metrics refer to the numerical values that are utilized to assess how well an intrusion detection system detects and neutralizes security threats on a network. Commonly used metrics include the following ones:

1) Accuracy: The percentage of accurately identified occurrences—both true positives and true negatives—out of all the instances that were examined is known as accuracy. It offers a general indicator of how effectively the intrusion detection system classifies events as either intrusions or routine activity.

2) Precision: Positive predictive value, or precision, is a metric that expresses the percentage of accurately detected positive cases (true positives) across every case categorized as positive (false positives and true positives). It shows how well the system can detect intrusions without mistakenly labelling routine operations as such.

3) Recall: Recall, also known as sensitivity or true positive rate, is the proportion of correctly identified positive cases relative to all real positive occurrences in the dataset. It assesses the system's ability to identify every incursion, lowering the likelihood that any malicious activity would go undetected.

4) F1-score: The F1-score, which achieves equilibrium between recall and accuracy, is derived from the harmonic mean of these two metrics. Recall and accuracy are combined into one figure, which accounts for both false positives and false negatives.

TABLE I. PERFORMANCE METRICS

Metrics	Efficiency
Accuracy	98.9
Precision	94
Recall	95
F1-Score	95

As shown in Table I and Fig. 2, the suggested intrusion detection approach exhibits excellent efficiency with an accuracy of 98.9%, demonstrating its capacity to accurately categorise cases as either intrusions or routine operations. Furthermore, the approach displays a 94% accuracy rate, which indicates the percentage of accurately detected incursions among all cases that are categorised as positive, hence reducing false positives. With a recall rate of 95%, which indicates that the system can detect all incursions, there is little chance of a missed detection. Furthermore, a balanced performance in terms of both accuracy and recall is shown by the F1-score, which harmonises the two metrics, which is recorded at 95%. All of these measures show how successful and dependable the suggested intrusion detection technique is at identifying and reducing security risks in the network infrastructure.

Fig. 2. Performance efficiency.

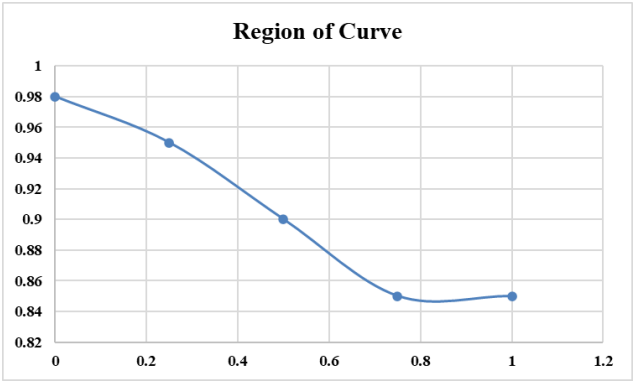

Fig. 3. Receiver operating characteristic curve.

As the threshold rises from 0 to 1, the true positive rate (TPR) progressively falls from 0.98 to 0.85, suggesting a decline in the percentage of true positive cases that are correctly categorised, as seen in Fig. 3. The TPR stays comparatively high at 0.95 at a threshold of 0.25, indicating that true positive cases can be effectively detected even with somewhat loosened thresholds.

TABLE II. SORTING RESULT OF NSL-KDD

Methods	AUC	Error Rate
Gradient Boosting Classifier	47.64	0.4905
Deep Learning	77.88	0.2256
Proposed Method	98.9	0.0025

The NSL-KDD dataset's categorization outcomes using different techniques are shown in Table II. With an error rate of 0.4905 and an AUC of 47.64%, the Gradient Boosting Classifier performs relatively poorly. By comparison, the Deep Learning approach shows noticeably higher performance, with an error rate of 0.2256 and an AUC of 77.88%.

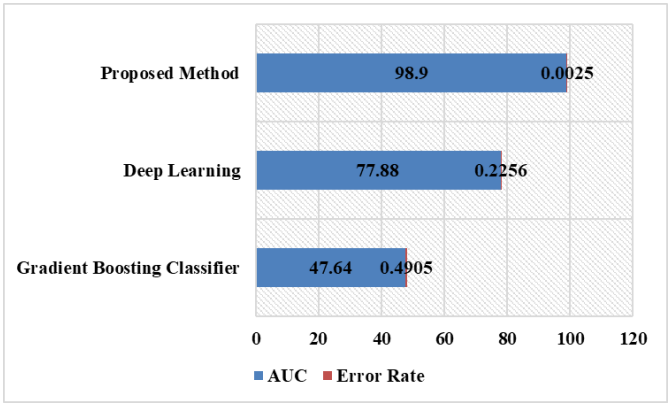

Fig. 4. Classification result of NSL-KDD.

The results presented in Fig. 4 demonstrate that the suggested approach outperforms the two other options, with an exceptional AUC of 98.9% and a remarkably low error rate of 0.0025. These outcomes highlight how well the suggested strategy performs in comparison to other methods when it comes to correctly identifying instances in the NSL-KDD dataset.

TABLE III. RECOGNITION OUTCOMES OF ATTENTION BASED BILSTM APPROACH ON NSL-KDD DATASET

Data	Class	Accuracy	Precision	Recall	F1-Score
Training	*Normal*	98.4	96.3	97.3	96.3
	Attack	97.4	97.4	98.4	95.5
	Average	97.7	97.7	97.7	97.7
Testing	*Normal*	98.9	97.5	96.4	95.8
	Attack	97.3	98.3	97.3	98.3
	Average	98.9	98.9	98.9	98.9

The NSL-KDD dataset's recognition results from the Attention-based BiLSTM technique are shown in Table III and Fig. 5.

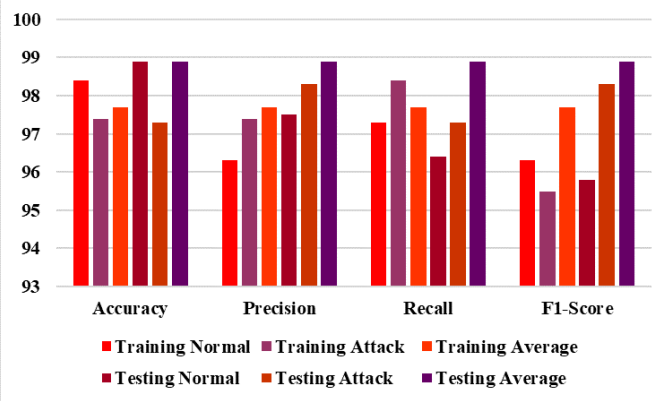

Fig. 5. Recognition outcomes of attention based BiLSTM approach on NSL-KDD dataset.

It includes accuracy, precision, recall, and F1-Score, split into normal and attack classes, for both the training and testing datasets. In the training dataset, the method achieves 98.4% accuracy for normal cases and 97.4% accuracy for attack instances. Respectively, the corresponding accuracy, recall, and F1-Score values are 95.5% and 96.3%, 97.3% and 98.4%, and 96.3% and 97.4%. Comparable outcomes are seen in the testing dataset, where the technique achieves 97.3% accuracy for attack instances and 98.9% accuracy for normal cases. The corresponding F1-Score, recall, and accuracy scores are 97.5%, 98.3%, and 95.8%, respectively. The average results for each class are also provided for the training and testing datasets.

B. Discussion

The research studies under discussion offer novel strategies for resolving the security issues that arise in Internet of Things networks. These specifically concentrate on intrusion detection systems (IDS) and make utilisation of blockchain and machine learning technology. The study by Liang et al. [12] suggests a hybrid intrusion detection system that makes use of multi-agent systems, blockchain technology, and deep learning techniques. The system is divided into distinct modules for data collecting, management, analysis, and response with the goal of improving detection accuracy, particularly at the transport layer of Internet of Things networks. Scalability and optimisation continue to be major obstacles to practical implementation, notwithstanding encouraging findings. A collaborative intrusion detection architecture including blockchain technology for safe sharing of threat intelligence across cloud and Internet of Things networks is presented by Alkadi et al. [13]. While consensus processes and deep blockchain technology are adept at detecting intrusions and reducing security threats, their scale presents serious problems for efficiency and real-time response. A blockchain-based collaborative signature-based IDS called CBSigIDS is proposed by Li et al. with the goal of creating a trustworthy signature database in dispersed IoT systems. Although it provides a safe way to validate signatures, blockchain overhead scalability issues require further work before a viable implementation can be made. Kumar et al. [14] offers a distributed intrusion detection system (IDS) that uses blockchain technology and fog computing to identify DDoS assaults directed at IoT mining pools. They assess the system's effectiveness in identifying IoT network assaults using machine learning algorithms trained on scattered fog nodes. But there are still issues with realistic implementation and optimisation needed for efficiency and scalability. Although these studies show how blockchain and machine learning technologies could potentially use to improve IoT network security, scalability, optimisation, and practical deployment issues must be resolved before their full promise could be realised in practical settings.

The study presents a complete framework for reliable and scalable intrusion detection in IoT networks by integrating machine learning techniques with blockchain technology. The solution addresses the challenges posed by the dynamic and heterogeneous nature of IoT environments by employing Red Fox Optimization for feature selection and Attention-based BiLSTM for anomaly identification. The adoption of blockchain technology improves security by ensuring the validity and inviolability of intrusion record detection. The study advances the area by providing an all-encompassing method of intrusion detection that takes security and efficiency into account. Real-time identification of abnormalities and malicious activity in IoT traffic is made possible by the use of sophisticated machine learning algorithms, and scalability is improved by optimization approaches that assist decrease the dimensionality of the input data. Furthermore, the system gains an additional degree of protection through the integration of the technology known as blockchain, which offers tamper-resistant recordings of detected intrusions. The usefulness of the suggested architecture is demonstrated by experimental findings, which on real-world IoT datasets yield a high detection accuracy of about 98.9%. These findings highlight how important the study is to improving IoT security state-of-the-art. The report does, however, admit several limitations, including the need for more assessment in various IoT scenarios and the computational cost related to blockchain integration. Prospective study avenues encompass investigating alternative machine learning algorithms and optimization methods, tackling scalability issues, and refining blockchain-associated procedures. Overall, the research offers a viable strategy for improving intrusion detection in Internet of Things networks, opening the door to more robust and safe linked settings.

VI. CONCLUSION

The suggested system, which makes use of blockchain and machine learning, offers a viable solution to the problems associated with intrusion detection in Internet of Things networks. The accuracy and scalability of the intrusion detection system are improved by integrating Red Fox Optimization for feature selection and Attention-based BiLSTM for anomaly detection. Moreover, the incorporation of blockchain technology ensures the integrity and immutability of intrusion detection logs, thereby enhancing security. On real-world IoT data sets, experimental findings show the usefulness of the technique with a high detection

accuracy of about 98.9%. However, it is important to acknowledge some limitations and areas for future work. Firstly, while the proposed framework shows promising results, further research is needed to evaluate its performance in diverse IoT environments and under various attack scenarios. Additionally, the scalability of the system needs to be investigated to handle large-scale IoT networks efficiently. Furthermore, the computational overhead associated with blockchain integration may pose challenges in resource-constrained IoT devices, requiring optimization strategies. Moreover, continuous advancements in intrusion techniques necessitate ongoing updates and improvements to the detection algorithms and feature selection methods. Future studies may look at applying more machine learning algorithms and optimization techniques to enhance the robustness and efficiency of intrusion detection systems in Internet of Things networks. All things considered, this work establishes the groundwork for next investigations that seek to create IoT ecosystems that are more robust and safer.

Abstract*—Face spoofing attacks have become more dangerous as biometric identification has become more widely used. Through the utilisation of false facial photographs, attackers seek to fool systems in these assaults, endangering the security of biometric authentication devices and perhaps allowing unauthorized access to private information. Effectively recognizing and thwarting such spoofing attacks is critical to the dependability and credibility of biometric identification systems in a variety of applications. This research seeks to offer a unique strategy that uses Deep Convolutional Generative Adversarial Networks (DCGANs) to improve face spoof detection in order to counter the challenge provided by face spoofing assaults. In order to strengthen the security of biometric authentication systems in applications like identity verification, access control, and mobile device unlocking, the goal is to increase the accuracy and effectiveness of facial spoof detection. The training dataset is then supplemented with these artificial images, which strengthens the face spoof detection system's resilience. More accurate face spoofing is made possible by the strategy that leverages the discriminative characteristics obtained throughout the process to train the discriminator network employing adversarial learning to discriminate between actual and fake images. Experiments on the CelebFacesAttributes (CelebA) datasets show how effective the suggested method is over traditional techniques. The suggested technique outperforms conventional methods and achieves an astounding accuracy of 99.1% in face-spoof detection systems. The system exhibits impressive precision in differentiating between real and fake faces through the efficient use of artificial intelligence and adversarial learning. This effectively decreases the possibility of unwanted access and enhances the overall dependability of biometric authentication methods.

Keywords*—Biometric authentication systems; deep convolutional generative adversarial networks; face spoof detection; synthetic image generation; unauthorized access

I. Introduction

The face of a person is essential to any visual material or communication on face spoof detection. Commonly used and easily accessible editing tools are employed to improve this visual content. The technique of manipulating facial recognition devices by posing as an authorized user with fake facial images or videos is known as face spoofing. However, through manipulating video evidence, slandering a person's credibility, and other means, its harmful use is causing division in society [1].With the widespread adoption of biometric identification systems, the threat of face spoofing attacks has become increasingly prominent. Face spoofing the technique of manipulating facial recognition devices by posing as an authorized user with fake facial images as face spoofing. As spoofing techniques continue to evolve and become more sophisticated, it is essential to develop advanced detection methods capable of identifying increasingly realistic fake faces. With the increasing use of facial recognition technology for authentication and access control, detecting spoofed or fake faces is important to prevent unauthorized access to sensitive systems, devices, or information. Face spoofing techniques, such as using printed photos or digital masks, can be exploited by threat actors to impersonate legitimate users and gain access to their accounts or personal information [2]. Traditional spoof detection methods may struggle to distinguish between real and fake faces in the presence of increasingly convincing spoofing attacks. The advancement of face spoof detection system is achieved using deep learning methods to extract highly appropriate information from facial photos and effectively train models to detect even minor differences between real and faked faces.

Face detection systems are improving, but detecting face spoofing crime remains challenging. To address this, a Generative Adversarial Network (GAN) is implemented to deliver image from the RGB as an input. It improves discriminative capability by converting live face images to depth maps and spoofing images to plain images [3]. A face anti-spoofing system that combines VIS and NIR images, achieved through a MCT-GAN for generating NIR from VIS inputs, followed by a Convolutional Neural Network (CNN) for feature fusion, aiming to improve live and spoof face

classification without requiring NIR equipment during testing [4]. Deep Learning techniques can manipulate videos, potentially leading to misinformation and manipulation. Deepfake detection using GAN Discriminators is developed using Generative Adversarial Network (GAN) discriminators to identify videos of Deepfake data. The model trains a GAN and extract a discriminator module, testing different architectures and training methods. It leads to enhance the efficiency of GAN discriminators using ensemble techniques [5]. The method of CNN Detection of GAN-Generated Face Images based on Cross-Band Co-occurrences Evaluation aims to differentiate between GAN-generated and real images, particularly focusing on synthetic face images, by leveraging inconsistencies across spectral bands. By incorporating Cross-Band Co-occurrence matrices along with spatial co-occurrence matrices as input to a CNN system, it achieves superior performance compared to a detection system solely based on intra-band spatial co-occurrences, achieving an accuracy of 94% [6]. A Deepfake detection technique utilizes computer vision characteristics extracted from digital context, employing the Cascaded Deep Sparse Auto Encoder (CDSAE) trained by temporal based CNN to analyze frame changes. Subsequently, a Deep Neural Network (DNN) is employed for classification, achieving enhanced accuracies of 98.7%, 98.5%, and 97.63% for the datasets like Face2Face, FaceSwap, and DFDC, through a feature selection approach [7]. Face swapping detection employed by deep transfer learning for, achieving true positive rates exceeding 96% with minimal false alarms, and providing uncertainty estimates for each prediction, crucial for system trust. It uses dataset with the largest to date for face swapping detection using static images, with approximately 1000 real images per individual, facilitating effective model design and evaluation, resulting in an accuracy of 98% [8]. The XcepTemporalConvolutional RNN framework combines XceptionNet CNN for facial feature representation with bidirectional recurrence layers, achieving robust visual deepfake detection and gained accuracy of 99%. Additionally, a companion audio architecture with convolution modules is presented, demonstrating high accuracy on both FaceForensics++ and Celeb-DF datasets, as well as the ASVSpoof 2019 Logical Access audio datasets [9]. The NA-VGG network enhances DeepFake detection by leveraging noise features highlighted by an SRM filter layer and augmenting the noise maps to weaken face features, resulting in improved accuracy compared to advanced detectors on the Celeb-DF dataset. The results demonstrate significant performance improvements, with the SRM filter upgrading image noise by 16.8% and image augmentation improving detection accuracy by 12.5% [10].

Traditional methodologies often necessitate manual feature engineering, wherein domain experts design specific features for classification purposes. Contrastingly, deep learning has the potential to eliminate the requirement for manual feature extraction by autonomously extracting relevant and hierarchical characteristics from raw data. By using DCNN, the model is able to acquire detailed representations of facial features, allowing it to analyse spatial correlations directly from the input images. This eliminates the need for manual segmentation and it enhances the model, streamlining classification process. Various approaches, including GAN-based methods and deep learning techniques, have been developed to detect face spoofing attacks and deepfake videos. These methods employ advancements in computer vision and neural networks to enhance discriminative capabilities and attained high accuracy in detecting manipulated images and videos. The proposed framework of Face Spoof Detection Using DCGAN aims to contribute to enhancement of face spoof detection by utilizing Deep Convolutional Generative Adversarial Networks to automatically extract features for improved face spoof detection, enhancing the reliability of facial recognition system.

Key Contributions:

- Face Spoof Detection system utilizes Deep Convolutional Generative Adversarial Networks (DCGANs) to create synthetic facial data.
- The generator, a deep architecture of neural networks, synthesizes realistic facial images resembling genuine faces and the discriminator network, trained adversarial, works with the generator to differentiate between real and spoofed images.
- The benefit of employing DCGAN for feature extraction is that it eliminates the requirement for human feature engineering by learning discriminative features directly from the raw input data.
- Enhances face spoof detection in biometric authentication systems and promotes secure access control in various applications like financial services, secure facilities, and mobile devices.

The following portion of this section is constructed as follows: The relevant work on Face Spoof Detection using DCGAN is reviewed in Section II. The problem statement of the current system is outlined in Section III. The specifics of the suggested methodology and architecture of DCGAN are explained in Section IV. The results and discussion are presented in Section V. Lastly, the conclusions and future scopes were given in Section VI.

II. Related Works

Arora et al. [11] developed a framework for the foundation of the suggested framework is the extraction of facial characteristics using dimensionality reduction and feature extraction methods using convolutional autoencoder that have been pre-trained. Subsequently, classification is performed using a softmax classifier. Evaluation conducted on three benchmark datasets - Idiap Replay Attack, CASIA-FASD, and 3DMAD - demonstrates that the framework achieves performance levels compared to advanced methods and gained accuracy of 99%. In particular, extracting features from facial visuals highlights the recent development of deep neural networks in image processing applications. Experiments carried out ondatasets such as 3DMAD, CASIA-FASD, and Idiap Replay Attack show that the suggested framework is effective in producing results that are on level with modern methods. Despite outperforming existing approaches on various benchmark datasets, the suggested face anti-spoofing framework has several limitations. When applied to diverse

datasets, the methodology may be exposed to modern spoofing approaches, and by enhancing and adapting the structure to address increasing threats and crimes, such as spoofing attacks on biometric systems.

Patel et al. [12] proposed an innovative and enhanced deep-CNN (D-CNN) structure for recognizing deep fakes that is both accurate and generalizable. Data from various sources are used for training the system, thereby boosting its overall generality characteristics. The imagery is adjusted and sent into the D-CNN network. The D-CNN strategy rate of development is improved using binary-cross entropy and the Adam optimizer. It analyzed seven different datasets from the reconstructed difficulties, each including 5000 fake deep fake images and 10,000 true images. The proposed work achieves an accuracy rating of 98.33% in AttGAN, 99.33% in GDWCT, 95.33% in StyleGAN, 94.67% in StyleGAN 2, and 99.17% in StarGAN in true and fake. The framework can be upgraded by extending the model to classify video deepfake data which presents an opportunity for enhanced detection capabilities. By extracting each frame from a video, detecting and cropping faces, and then feeding them into the model, it could enable the identification of deepfake manipulations in videos.

Kumar et al. [13] proposed the framework on detecting Deepfake with metric classification for classifying deepfake videos in scenarios involving high compression through various deep learning techniques with limited data. It reveals that a proposed approach exhibits significant effectiveness in classification task based on metric learning and employs a triplet network architecture. It enhances the feature space distance between their embedding vectors for the model to learn the differentiation between real and fake videos. It validates on two datasets allows to assess their performance in diverse environments. By employing a Triplet network, it surpasses existing results using 25 frames per video. The framework achieved outstanding performance, including an AUC of 99.2% on the Celeb-DF and an accuracy of 90.71% on Neural Texture. However, the current strategy is limited by its dependence on unsupervised domain adaptation techniques to increase the model's endurance and label dependency in subsequent rounds. [13] [14] [15].

Baek et al [14] proposed Generative Adversarial Ensemble Learning for Face Forensics which involves multiple discriminative and generative networks. Unlike conventional approaches, it focuses on enhancing discrimination rather than image generate on. It is achieved by ensembling the outputs of two discriminators to improve discriminability. Additionally, it trains two generators to produce both general and hard images. The system uses produced simulated face pictures to improve the discriminators and enhances the generators based on the combination feedback of the discriminators. This is achieved by integrating input from each generator and discriminator using ensemble learning. It illustrates the efficacy of the method with a thorough analysis of the Face Forensics task and ablation tests. Two distinct discriminators and two similar generators constitute an ensemble forensic detector. An adversarial ensemble loss function and generative adversarial ensemble learning method are used in Enhancing Forensic Identification with Combined Discriminators. This causes the network topology of both generators and discriminators to become asymmetric, which enhances the framework's capacity for discrimination. It offers advantages by improving discrimination ability and addressing bias towards real or fake classes, which is applicable to existing detectors and other image forensic domains. Through extensive evaluation of the Face Forensics challenge and ablation studies, it demonstrates the effectiveness of the approach and acquired accuracy of 90%. But it requires significant computational resources and time for training multiple networks. The system needs to train two generators for both general and hard synthetic images which adds to computational burden. Ensemble learning process may require extensive tuning and optimization for optimal performance.

Ranjan et al. [15] developed a Transfer Learning-based CNNmodel for detecting DeepFakes across three prominent datasets like Deep Fake Detection (DFD), Celeb-DF, and Deep Fake Detection Challenge (DFDC). DeepFakes is curated for analysing purposes. The framework improves performance by transferring knowledge from pre-trained models to the task of DeepFake detection. While some blocks show higher accuracy without Transfer Learning, Transfer Learning consistently improves performance across most scenarios. The Celeb-DF dataset benefits significantly from Transfer Learning, with an 11.11% boost in accuracy. The model trained on the DFD dataset achieving records an accuracy of 73.20%. Conversely, the Celeb-DF model performs poorly when tested on the DFD dataset, reflecting the differences in alteration between the datasets. The cross-test accuracy is observed when the model is tested on DFDC, reaching 66.23%. The Xception Net demonstrates remarkable learning capacity by achieving impressive accuracy across all three distributions without overfitting, as evidenced by its high combined test accuracy of 86.49%. The Transfer Learning-based CNN framework for detecting DeepFakes has a potential drawback due to its reliance on pre-trained models, which may not capture the full range of features specific to DeepFake detection. While Transfer Learning consistently improves performance across most scenarios, it may not transfer relevant knowledge to the task, leading to suboptimal results.

Yavuzkilic et al. [16] presents a Multistream deep learning algorithm for identifying fake faces in videos, through a layer called fusion layer. Transfer learning is adopted, utilizing pre-trained VGG16, VGG19, and ResNet18 models for the three respective streams. The method introduces the World Politicians Deepfake Dataset (WPDD), created by extracting over 320,000 frames from videos of 20 politicians on YouTube. Various manipulations, including colour, hairstyle, structure and genuine face discrimination, are applied to both genders. This encompasses false detection like discrimination between fake and real faces, identification of seven face manipulations, and analysis of the system performance under various face manipulation. This method acquired accuracy scores of 99.98% and 99.95% for the DeepFake-TIMIT HQ and Celeb-DF datasets. The limitation of the system is its potential vulnerability to adversarial attacks and variations in face orientations.

Sun et al. [17] introduced FCN-DA-LSA method for detection of face spoofed images. The FCN local classifier effectively utilizes face spoof distortion properties, while the domain adaptation layer enhances generalization across various domains. This preserves high-frequency spoof clues from face recapture processes. FCN-LSA gained improved performance among advanced methods, with FCN-DA-LSA further improving results. Under hybrid protocols, the FCN-DA-LSA achieves HTERs of 11.22% and 21.92%, respectively. The improvement observed in FCN-DA-LSA over the basic FCN amounts to approximately 5.67%. While it demonstrates effectiveness as a form of few-shots supervised domain adaptation, the reliance on additional data poses a constraint. It can further explore unsupervised few-shot domain adaptation methods to mitigate this limitation and enhance performance, particularly in cross-PAI or cross-camera works.

Sun et al. [18] framed a depth-based FCN approach for face spoofing detection is revised, exploring diverse supervision techniques. In response, SAPLC is proposed, comprising an FCN and an aggregation technique. The FCN evaluates pixel-level ternary labels (real foreground, fake foreground, unclassified background), which are then separated to make accurate decisions. Experimental evaluation is demonstrated and achieves competitive performance with advanced methods under various common protocols. In protocols, SAPLC achieves ACERs of 0.42%, 2.50%, 3.89%, and 9.31%, respectively. The reliance on pixel-level ternary labels and aggregation for image-level decisions could introduce computational overhead and increase processing time, which may not be feasible for real-time face spoofing detection systems.

The existing papers demonstrate various approaches to face spoofing detection, they often have limitations such as reliance on external data, computational complexity, and suboptimal generalizability. The proposed DCGAN model addresses these drawbacks by generating diverse synthetic spoofed images, augmenting the training dataset, simplifying the training process, and improving the capacity of the model to capture spoof-specific features.

III. Problem Statement

Even with improvements in facial recognition technology, biometric systems still suffer a great deal of difficulty from face spoofing attacks. This problem has been made worse by deepfake manipulations in particular, which makes the facial spoof detection techniques employed today insufficient. These approaches frequently depend on outside datasets that are computationally demanding and do not fully cover the range of real-world circumstances, which makes real-time processing more difficult. More robust and adaptable solutions are required since they might not be able to properly handle different spoofing tactics or adjust to changing attack plans [18]. To address these issues, the proposed method makes utilisation of Deep Convolutional Generative Adversarial Networks (DCGAN) in order to gain over current constraints. This technique allows for the quick and precise real-time recognition of changed images by utilizing deep learning and GAN technology, which is especially useful in situations when speed is of the essence. This capacity has important ramifications for standard applications including authentication systems, surveillance setups, and identity verification processes.

The objective of the project is to develop and evaluate a face spoof detection technique based on DCGAN to counter the rising threat of deepfake manipulations in biometric systems. It seeks to determine how well DCGAN performs in real-time processing for crucial applications like surveillance and authentication systems, examines its efficacy in a variety of real-world scenarios and spoofing techniques, and appraises its adaptability in fending off changing attack tactics. In order to improve overall security and reliability, the research also examines the practical ramifications of incorporating this technology into currently in employ biometric authentication systems.

IV. Proposed Face Spoof Detection with Deep Convolutional Generative Adversarial Network

The proposed Face Spoof Detection with Deep Convolutional Generative Adversarial Network is developed to enhance biometric authentication system using CelebA dataset. DCGAN consist of generator and discriminator networks, trained adversarial to produce realistic spoofed face images and distinguish them from genuine ones. The generator comprises multiple layers, starting with input noise vectors, and progressively up-samples them into high-dimensional representations to generate output images. Before feature extraction, the discriminator has an important role in classifying input images as genuine or generated. It trains to distinguish between real and generated images through adversarial training, guided by a loss function like binary cross-entropy. Feature extraction involves the discriminator capturing discriminative characteristics from input images, such as texture and spatial relationships, to distinguish between genuine and spoofed data. These characteristics are then used as input to a Deep Convolutional Network (DCN) for the final decision on face spoof detection. Fig. 1 depicts the block diagram of Face Spoof Detection using Deep Convolutional Network which classifies real and spoofed images from the CelebA dataset.

A. Data Description

The CelebFaces Attributes (CelebA) dataset which consists of 200,000 images of celebrity, each labelled with 40 binary attributes. The CelebA dataset consists of celebrity faces which contains 202,599 images. Every image in the dataset is annotated with labels of 40 binary attributes, covering a wide range of facial attributes such as Bald, Bangs, Black Hair, Blond Hair, Eyeglasses, Smiling, Wearing Hat, and other variations. The images in the CelebA dataset are of varying resolutions, with most images having a resolution of 178x218 pixels. The dataset includes images of celebrities from various demographics, ethnicities, ages, and genders, providing a diverse set of facial characteristics. The attribute annotations provide binary labels indicating the presence or absence of every attribute in the corresponding image. The images are typically stored in JPEG format, while the attribute annotations are provided in a text file or a structured format like CSV. The CelebA dataset is commonly used for tasks

such as face recognition, attribute prediction, facial attribute editing, and face synthesis. It serves as a powerful dataset for training and evaluating deep learning systems like DCGANs for face spoof detection.

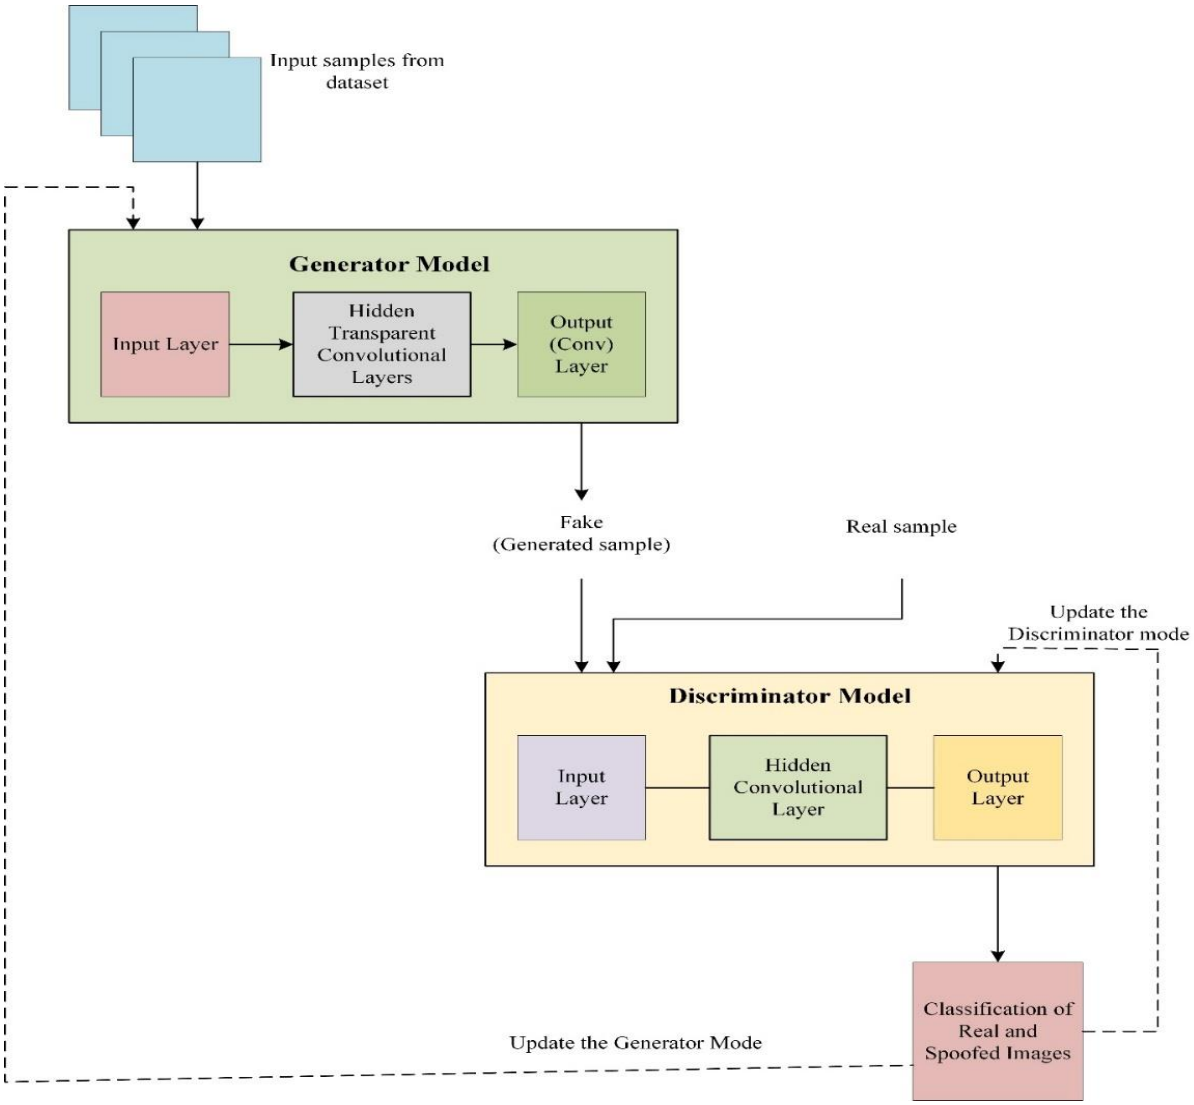

Fig. 1. Block diagram of face spoof detection with DCGAN.

B. Data Collection and Pre-processing

The data collection comprises celebrity face images collected from various sources, including the internet, celebrity websites, and publicly available databases. The dataset creators curated these images to ensure diversity in terms of demographics, facial attributes, and expressions. Each image in the CelebA dataset is manually annotated with a set of binary attribute labels. These annotations cover facial attributes such as age, eyeglasses, hair, gender and various facial expressions. The annotations provide valuable ground truth information for training and evaluating machine learning models. Fig. 2 depicts the pre-processing of CelebA dataset for face spoof detection.

The original images may vary in size and aspect ratio. The images are reconstructed to a standard resolution, typically 178x218 pixels. Pixel values in the images are normalized to a common scale, often ranging from 0 to 1 or -1 to 1. Normalization helps in minimizing alterations in pixel across different images. Rotation, flipping, cropping, and brightness adjustments may be applied to increase the diversity of the dataset and improve model generalization. Noise reduction techniques may be employed to enhance image quality and remove unwanted artifacts. Typically, the majority of the data is allocated to the training set, while smaller portions are used for validation and testing. Thus, the pre-processed CelebA dataset is prepared for face recognition, attribute prediction, and face spoof detection.

C. Deep Convolutional GAN Architecture

The DCGAN architecture for face spoof detection involves a combination of generator and discriminator trained adversarial to produce realistic spoofed face data and distinguish them from genuine ones. The generator typically consists of multiple layers of neural network units, organized in a deep architecture. It starts with one or more input layers, usually taking random noise vectors as input. These noise vectors serve as the seeds for generating new data samples to

augment the data. The noise vectors are passed through several hidden layers, often implemented using convolutional layers, followed by ReLU to introduce non-linearity and learn hierarchical representations. The generator progressively up-samples the input noise into high-dimensional representations, which produces output images with the desired dimensions, such as grayscale or colour face images as shown in Fig. 3.

In DCGAN, the discriminator plays a crucial role in distinguishing between genuine and generated (spoofed) face images. The discriminator network is tasked with classifying input images as either genuine (real) or generated (spoofed). It takes both genuine face data from the dataset and generated face data produced by the generator as input samples. The discriminator network contains multiple convolutional layers, designed to extract features from the input and make a binary classification. During the training process, the discriminator network learns to distinguish between real and generated data by updating its parameters to minimize its classification error. It is trained in an adversarial approach with the generator, which aims to produce realistic faces that can fool the discriminator network, while the discriminator aims to accurately classify the images. The performance of discriminator is evaluated using binary cross-entropy, which evaluates the discrepancy among the predictions of the discriminator (real or generated). The loss function guides the updates to the discriminator's parameters during training, helping it improve its capability to discriminate between genuine and generated samples.

Fig. 4 depicts the learning phase of genuine and fake data by discriminator network. The discriminator and generator are trained iteratively, where the generator targets to produce data that are indistinguishable from genuine ones, and the discriminator network for accurately classifying between real and generated images. This adversarial training process helps both networks enhance over time, with the discriminator becoming better at differentiating real and generated data, and the generator becoming better at producing realistic images to fool the discriminator.

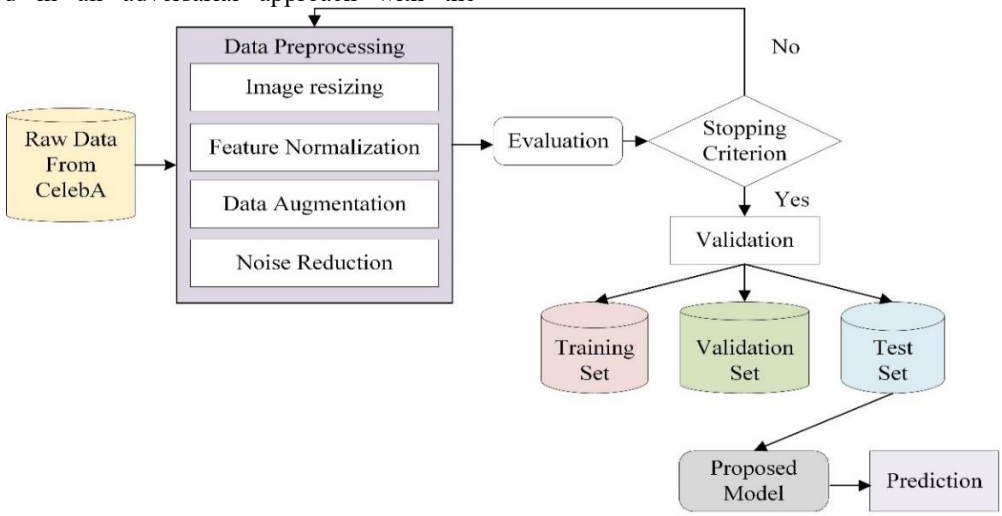

Fig. 2. Pre-processing of CelebA dataset.

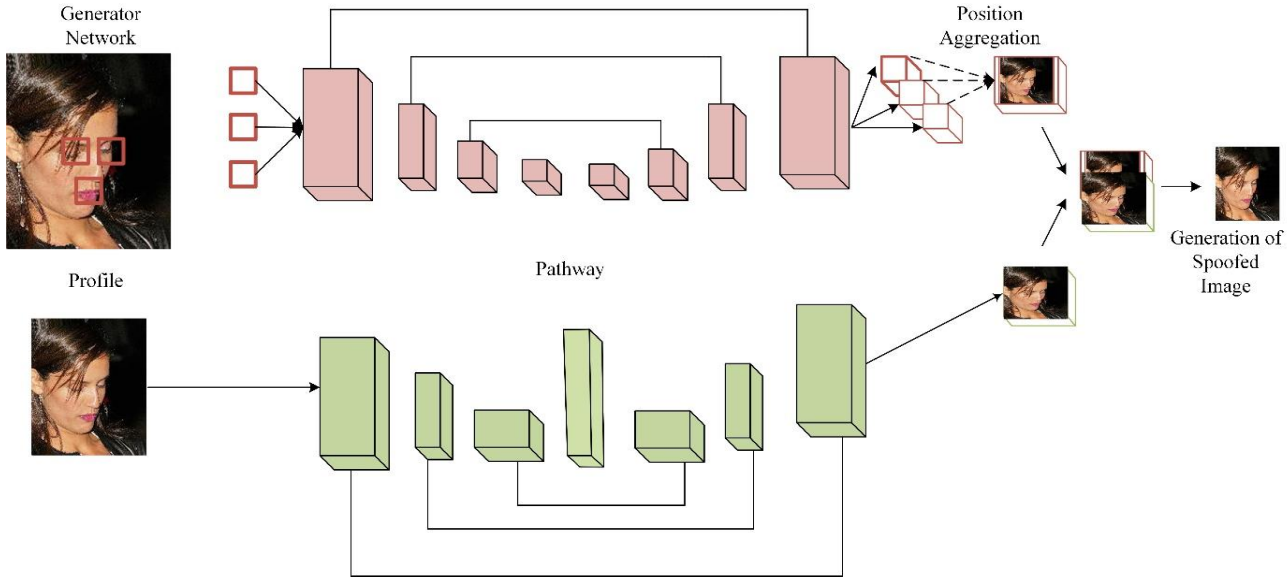

Fig. 3. Generator network in DCGAN.

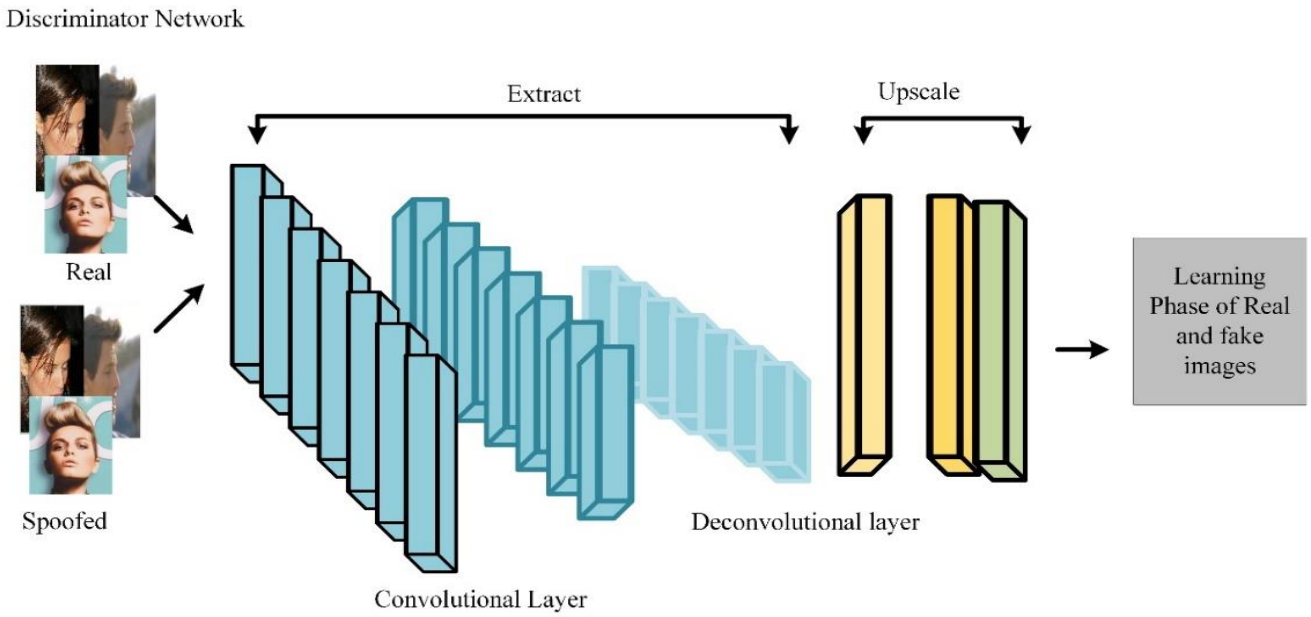

Fig. 4. Discriminator network of DCGAN.

D. Feature Extraction and Detection of Face Spoof Image using DCGAN

In face spoof detection using DCGAN (Deep Convolutional Generative Adversarial Networks), feature extraction is one of the critical steps that involves capturing discriminative characteristics from input images. The process begins with feeding genuine and spoofed face images into the discriminator network, which has been trained to differentiate between the two types of images through adversarial training. Through the adversarial training process, the discriminator becomes adept at extracting features that are discriminative for face spoof detection. These features encode subtle differences between genuine and spoofed faces, such as inconsistencies in texture, lighting, or spatial relationships. After feature extraction in face spoof detection using DCGAN, the extracted features from the discriminator capture important characteristics of both genuine and spoofed faces. These features represent high-level representations learned during the adversarial training process, where the generator is to produce realistic spoofed faces to fool the discriminator, and the discriminator learns to distinguish between genuine and spoofed faces. These features are abstracted from the raw pixel values of the input images and are encoded in a lower-dimensional feature space, making them more suitable for detection tasks. These features are then fed to a Deep Convolutional Network (DCN), which makes the final decision on whether an input image is genuine or spoofed based on the learned representations.

Fig. 5 depicts the framework of Face Spoof Detection using DCGAN in which real and spoofed images are detected. In face spoof detection using DCGAN, performance using the loss function is formulated in Eq. (1),

$$Loss = -(b\ log(a) + (1-b)\ log(1-a)) \quad (1)$$

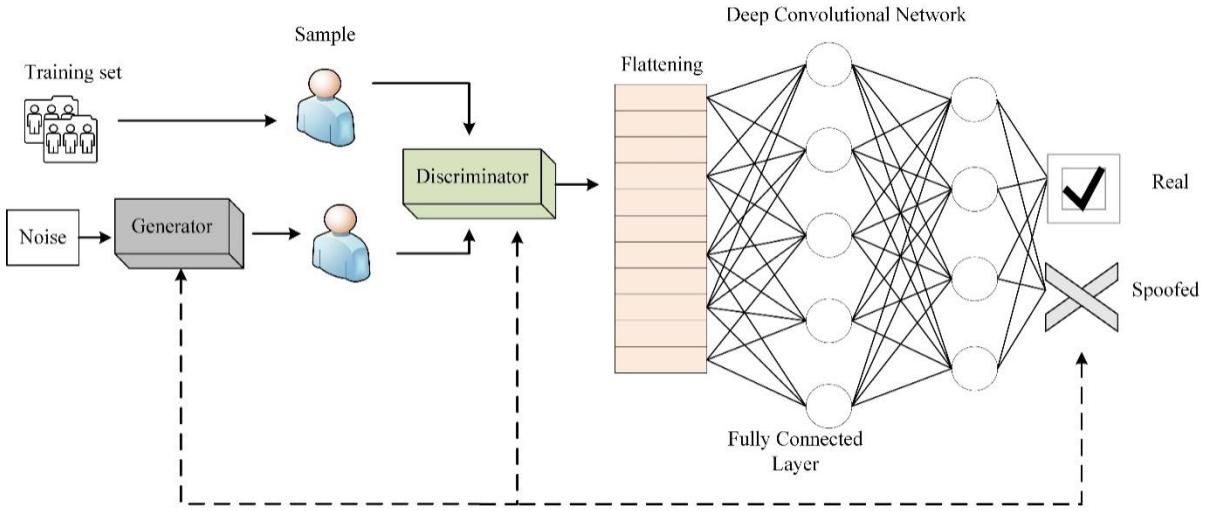

Fig. 5. Face spoof detection using DCGAN.

Here, b represents the true label of an observation, indicating whether it is a genuine (real) image or a spoofed (fake) image. The predicted label of the observation is denoted by a. It is important to note that 'a' lies between 0 and 1, representing the probability that the observation belongs to the genuine samples. Depending on whether the system designate the real label as 0 (indicating fake images) or 1 (for real images), aim to minimize either log(1-a) or log(a), respectively. This evaluation metric helps gauge the ability of the model to distinguish between genuine and spoofed faces during training [19].

Let p denote the Gaussian noise distribution, and u represent the complex image. The generator function G (u, p) generates synthetic images, while D(u, v) represents the discrimination. Each output of the discriminator network (s = 1, 2, 3, 4) contributes to the decision process, with corresponding weights λs ensuring proper discrimination between genuine and spoofed data.The loss function of the discriminator, denoted as LD-sGAN(G, D), is formulated in eqn.2,

$$LD - sGAN(G,D) = Eu,v[logD(u,v)] + Eu,p[log(1 - D(u,G*(u,p)\,I))] \quad (2)$$

Here, the discriminator targets to maximize the loss function by accurately differentiating real and generated data. Conversely, the generator strives to minimize the loss function to generate more convincing fake images. The optimization paths of both the generator and discriminator are guided by this loss function, facilitating the adversarial training process in face spoof detection model.

V. Results and Discussion

In this research, the implementation of face spoof detection framework using python software has been successfully achieved. This study aims in accuracy improvement of face spoof detection and identification using CelebA,a large-scale face attributes dataset. The framework achieved high accuracy of 99.1% and minimised false detection. The DCGAN architecture successfully generated realistic spoofed face images, which were challenging to distinguish from genuine ones. The performance of the model was enhanced by the adversarial relationship between the discriminator and generator networks in DCGAN, which made it easier to acquire discriminative features for face spoof detection. Fig. 6 shows the detection of real and spoofed images using proposed DCGAN. The proposed DCGAN architecture is adept at detecting both real and spoof images with high accuracy. The model learns to differentiate between authentic and manipulated facial images.

A. Performance Metrics

1) Accuracy: In the DCGAN-based face spoof detection model, accuracy evaluates the proportion of accurately classified images (genuine and spoofed) out of all the images in the test dataset. The formula for accuracy is given in Eq. (3),

$$Accuracy = \frac{RP+RN+FP+FN}{RP+RN} \quad (3)$$

where, RP represents the number of true positive identifications (accurately classified spoofed images). RN represents the number of true negative identifications (accurately classified genuine images). FP represents the number of false positive identifications (genuine images inaccurately classified as spoofed). FN represents the number of false negative identifications (spoofed images inaccurately classified as genuine).

2) Precision: Precision is a pivotal metric in evaluating the performance of the framework based on the DCGAN-based face spoof detection architecture. It holds significant importance in classifying spoofed and genuine face images accurately. Precision measures how effectively the model can identify spoofed face images while minimizing misclassifications. The equation of precision is represented by Eq. (4),

$$Precision = \frac{AP}{AP+BP} \quad (4)$$

Here, AP denote the instances where the model correctly identifies spoofed face images, while BP represent cases where genuine face images are incorrectly classified as spoofed. Precision value from between 0 and 1, with a value of 1 indicating perfect precision, where all positive predictions are correct, and a value of 0 indicating that no correct positive predictions were made.

3) Recall: Recall in a face spoof detection model with DCGAN shows to the capacity of the model to accurately identify genuine face images as genuine. Specifically, it measures the proportion of actual genuine face images that are correctly classified as genuine by the framework, out of all genuine face images in the dataset. The formula for recallis given by Eq. (5),

$$Recall = \frac{True\ Positives}{True\ Positives+False\ Negatives} \quad (5)$$

Real Images

Spoofed Images

Fig. 6. Detection of real and spoofed images using proposed DCGAN.

where, True Positives (TP) are the number of genuine face images accurately identified as genuine and False Negatives (FN) are the number of genuine face images inaccurately identified as spoofed.

4) F1 score: In face spoof detection using DCGAN architecture, the F1 score serves as a crucial metric for evaluating performance, particularly in tasks involving the identification and categorization of spoofed and genuine face images. The F1 score is computed using eqn.6,

$$F1score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (6)$$

This equation provides an evaluation assessment of the framework in accurately classifying positive (spoofed) and negative (genuine) instances. The F1 score offers a comprehensive measure of the performance of the system by considering both precision and recall, in distinguishing between spoofed and genuine face images in face spoof detection.

Fig. 7 shows Accuracy Curve for Proposed Face Spoofed Detection using DCGAN. It achieves an impressive accuracy rate of 99.1% with an improvement of 9.056% over existing methods of Sequential CNN, ANNBBS and YOLO-CNN-XGBoost. This curve, plotted over the epochs, illustrates the learning process of the model, initially starting at lower accuracy values and gradually ascending as the model refines its capability to discern between genuine and spoofed faces. Thus, it upgrades the security and access control of biometric authentication systems in real-world applications.

Fig. 8 depicts the Losses of Training and Validation of the proposed DCGAN for face spoof detection which indicates the evolution of the performance of the technique. The training loss represents the discrepancy between the predicted and actual values for the training dataset, reflecting learning phase of the model to generate realistic spoofed face images and distinguish them from genuine ones. Ideally, both training and validation losses should decrease simultaneously, indicating that the model effectively generalize to new instances.

Table I depicts the Evaluation Metrics of the Proposed FSD-DCGAN with Existing Frameworks**.** The proposed FSD-DCGAN method stands out as the most robust and accurate among the existing techniques. The adversarial dynamic facilitated the learning of discriminative features for face spoof detection. It achieves an impressive 99.1% accuracy, when compared to all other methods. Its precision (93%) and recall (89.5%) strike a commendable balance, resulting in an F1 score of 92%. In contrast, the Sequential CNN method, while respectable, falls short in terms of recall (78.2%). ANNBBS exhibits high accuracy (94.9%) but sacrifices recall (72%) and F1 score (81%). The YOLO-CNN-XGBOOST approach performs reasonably well overall, with an accuracy of 90.73% and a balanced F1 score (86.36%).

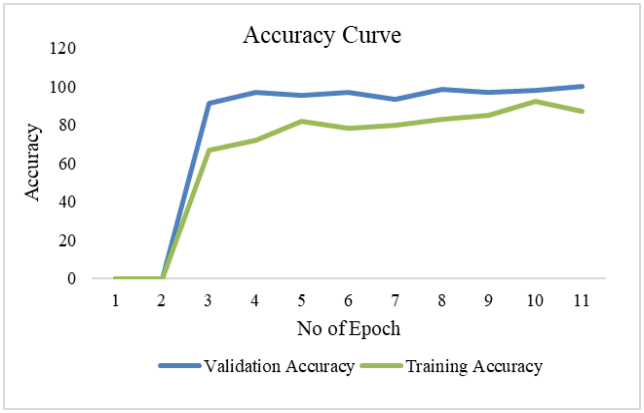

Fig. 7. Accuracy curve for proposed face spoofed detection using DCGAN.

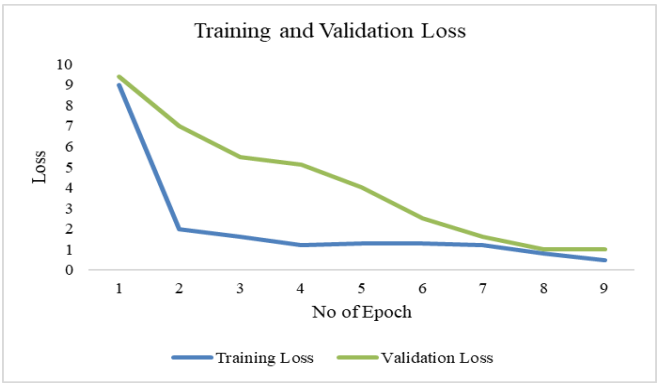

Fig. 8. Training and validation loss of proposed DCGAN.

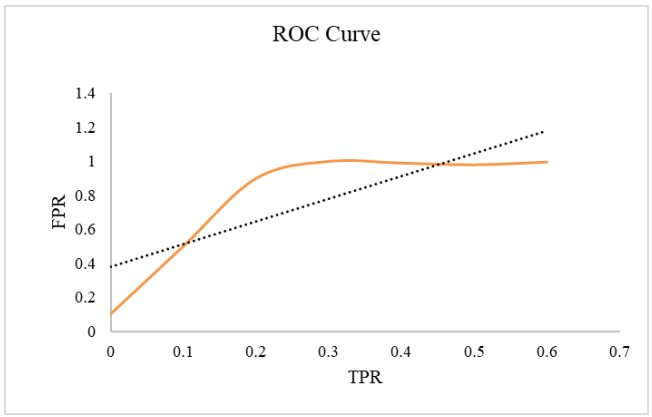

Fig. 9. ROC curve for the proposed face spoof detection using DCGAN.

TABLE I. EVALUATION METRICS OF THE PROPOSED METHOD WITH EXISTING FRAMEWORKS

Methods	Accuracy	Precision	Recall	F1 score

Sequential CNN [20]	87%	93.6%	78.2%	86.8%
ANNBBS [21]	94.9%	90%	72%	81%
YOLO-CNN-XGBOOST [22]	90.73%	87.36%	85.39%	86.36%
Proposed FSD-DCGAN	99.1%	93%	89.5%	92%

The Area Under the Curve (AUC) in face spoof detection model using DCGAN indicates to the area under the Receiver Operating Characteristic (ROC) curve. A higher AUC value, shows superior discrimination and better overall accuracy in distinguishing between real and spoofed faces. The formula for calculating the Area Under the Curve (AUC) in a ROC curve is given in Eq. (7),

$$AUC = \sum i = 1n - 12(xi + 1 - xi) \cdot (yi + yi + 1) \quad (7)$$

where, (xi,yi) are the points of the ROC curve, and n is the total number of points. The AUC shows the integral of the ROC curve, which measures the overall evaluation of a binary classification approach.

Fig. 9 shows ROC Curve for the Proposed Face Spoof Detection using DCGAN. The Receiver Operating Characteristic (ROC) for the proposed face spoof detection using DCGAN illustrates the exchange between True Positive and False Positive Rates across different decision limits. A higher area under the ROC curve shows superior discriminatory evaluation, with the model achieving high true positive rates while minimizing false positive rates.

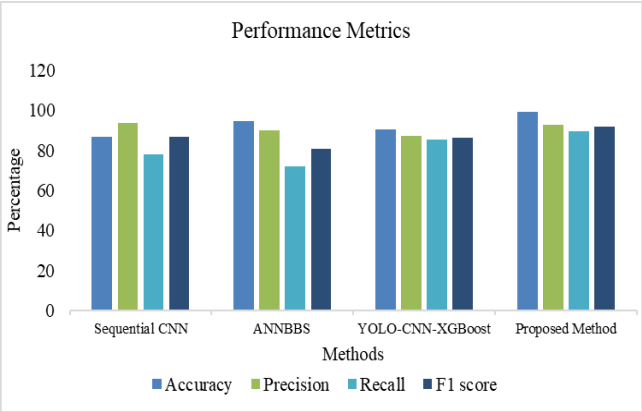

Fig. 10. Performance metrics of proposed face spoof detection using DCGAN.

Fig. 10 depicts performance metrics of proposed system with existing framework. The precision of the proposed framework DCGAN(99.1%) is greater than the existing approaches of Sequential CNN(87%), ANNBBS(94.9%) and YOLO-CNN-XGBoost (97.22%). The recall of the suggested method DCGAN (89.5%) is higher than the existing approaches of Sequential CNN (78.2%), ANNBBS (72%) and YOLO-CNN-XGBoost (85.39%). The F1-score of the suggested method DCGAN (92%) is higher than the existing approaches Sequential CNN (86.8%), ANNBBS (81%) and YOLO-CNN-XGBoost (86.36%).

B. Discussion

The discourse pertaining to the diverse frameworks utilised for identifying deep fakes and face spoofing highlights the diverse methodologies that researchers are implementing to tackle this critical challenge. The structure of Arora et al. [11], which focuses on the extraction and categorization of face characteristics, shows encouraging levels of accuracy but could run into problems with changing spoofing techniques and a variety of datasets. With potential for improvement, Patel et al. [12] improved deep-CNN structure has great accuracy rates for a variety of false image types, including video deepfake detection. Although there are certain restrictions in domain adaptation strategies, Kumar et al. [13] focus on metric classification and triplet network design emphasises the significance of feature space differentiation. The Generative Adversarial Ensemble Learning method by Baek et al. [14] prioritises discrimination enhancement and achieves respectable accuracy at the cost of training time and computational resources. The CNN model developed by Ranjan et al. [15] using Transfer Learning exhibits better performance on various datasets; nonetheless, its dependence on pre-trained models could result in less-than-ideal outcomes. The above discussions collectively highlight the continuous attempts, each with unique advantages and disadvantages, to counter the spread of face spoofing and deepfakes.

In the domain of face spoof detection leveraging deep learning techniques, a significant advancement was achieved by integrating Deep Convolutional Generative Adversarial Networks (DCGAN), resulting in an outstanding accuracy of 99.1%, exceeding the capabilities of conventional approaches like Sequential CNN [20]. The interplay between the model's training dynamics and its effectiveness in discerning between genuine and spoofed faces is depicted through graphical representations of training and testing accuracy, loss, and ROC curves. Using samples from CelebFaces Attributes (CelebA), the model shows its ability to distinguish between authentic and spoofed facial images. Discriminative features may be learned from raw input data using DCGAN, which eliminates the requirement for human feature engineering and is a benefit for employing it for feature extraction. The outcomes generated by the proposed framework illustrate its efficacy in recognizing the subtle differences between genuine and spoofed facial features. Thus, it promotes secure access control in various applications like financial services, secure facilities, and mobile devices.

VI. Conclusion and Future Works

Biometric security has advanced significantly with the use of Deep Convolutional Generative Adversarial Networks (DCGANs) for face spoof detection. The suggested framework shows improved accuracy in differentiating between real and fake face photos thanks to the cooperation of discriminator and generator networks. Based on adversarial training, the discriminator network outperforms conventional convolutional approaches in extracting discriminative features necessary for accurate spoof detection, as demonstrated by studies conducted on the CelebFaces Attributes (CelebA) dataset. This development raises the bar for future

improvements in spoof detection technologies while simultaneously strengthening the security of biometric identity systems. Looking ahead, our study points to a number of interesting directions that warrant further investigation. First and foremost, it's imperative to strengthen the model against spoofing techniques that are getting more and more complex, like deepfake videos, by investigating innovative architectures and feature integration. Moreover, the real-time use of the model in real-world settings, such mobile authentication apps or surveillance systems, is very valuable for quick threat identification and reaction. To ensure that the model architecture and training process are flexible enough to adapt to a variety of datasets and changing spoofing techniques, it is imperative that they be continuously improved and optimised. Furthermore, strengthening the security and effectiveness of the model in practical applications requires reducing adversarial assaults on the model itself. The efficacy and practicality of DCGAN-based face spoof detection could be further strengthened by pursuing these future research avenues, which will additionally contribute to progress biometric security and create more robust authentication systems.

***Abstract*—The non-stationary, non-linear, and extremely noisy nature of stock price time series data, which are created from economic factors and systematic and unsystematic risks, makes it difficult to make reliable predictions of stock prices in the securities market. Conventional methods may improve forecasting accuracy, but they can additionally complicate the computations involved, increasing the likelihood of prediction errors. To address these issues, a novel hybrid model that combines recurrent neural networks and grey wolf optimization was introduced in the current study. The suggested model outperformed other models in the study with high efficacy, minimal error, and peak performance. Utilizing data from Alphabet stock spanning from June 29, 2023, to January 1, 2015, the effectiveness of the hybrid model was assessed. The gathered information comprised daily prices and trading volume. The outcomes showed that the suggested model is a reliable and effective method for analyzing and forecasting the time series of the financial market. The suggested model is additionally particularly well-suited to the volatile stock market and outperforms other recent strategies in terms of forecasting accuracy.**

***Keywords*—Hybrid model; recurrent neural networks; grey wolf optimization; stock price prediction**

I. INTRODUCTION

The finance market is a fascinating and intricate structure that profoundly affects some domains, including business, employment, and technology [1], [2]. It gives investors numerous chances to invest money and generate returns with minimal risk [3], [4]. Fama conducted one such study [5]. The current understanding of stock price behavior has been greatly influenced by this subject, which is still an important area of research in the field of finance. Fundamental analysis and technical analysis are the two main stock market decision-making methodologies used by investors. While technical analysis looks at historical market data, trends, and patterns to forecast future market movements, fundamental analysis looks at a company's financial health and its possibilities for future growth [6], [7]. Stock market forecasting has been increasingly important among knowledgeable analysts and investors in recent years. However, because of the chaotic nature of the market, it is quite challenging to analyze stock market movements and price actions [8]. Global economic conditions, market news, and quarterly earnings reports are just a few of the factors that have a significant impact on the stock market. These elements make it difficult to predict stock prices with any degree of accuracy. The market capitalization of the listed companies is used to create the stock market indices. As a result, stock market indexes' values reflect the total value of the underlying stocks. In this market environment that is continuously changing, it is difficult to make accurate stock market predictions. Utilizing various statistical tools, researchers and market analysts have been eager to develop and test stock market behavior. These methods, which offer insights into the intricate and dynamic character of the stock market, include clustering and autoregressive integrated moving averages [9]. However, given that price changes tend to be chaotic, noisy, nonparametric, nonlinear, and nonstationary, it is challenging for analysts to accurately assess and forecast price changes [10]. These characteristics imply that traditional statistical methods may not be sufficient for effective stock market analysis.

Data analysis technologies including spreadsheets, automated data collection, and prediction models started to appear in the 1980s. With the development of technology, researchers started to employ deep learning and artificial neural networks to create models that could learn complicated relationships and extract crucial information more quickly than they could with earlier technologies. Many different architectures have been designed to address various issues and handle the complicated structure of datasets as deep learning has become more popular in recent years. Information only moves forward in a basic feedforward neural network architecture. There is no memory of past inputs; each input is handled independently. Because previous events are essential for forecasting future events, these models are not appropriate for sequential data. Recurrent neural networks (RNNs) have been created to handle similar tasks. Loops built into RNN architecture enable the persistence of pertinent data across time. Internal information is transferred within the network from one time-step to the next. With this architecture, RNNs are more suited for time series applications including stock market forecasting, language translation, and signal processing as well as sequential data modeling. Many other tasks, such as speech recognition, image captioning, and natural language processing, have been carried out using RNNs. Additionally, they have been applied in the area of finance, where they have demonstrated excellent potential for predicting stock values. RNNs are excellent for simulating complex and dynamic systems due to their capacity to retain information and develop context over time. When Hu et al. [11] used an ensemble RNN technique to forecast stock market movements, their opposing

model was able to outperform the competition. To assess the significance of features, individual data points, and particular cells in each architecture, Freeborough et al. [12] applied four well-known techniques to the RNN, long short-term memory (LSTM), and a gated recurrent unit (GRU) network trained on S&P 500 stocks data. These techniques are ablation, permutation, added noise, and integrated gradients.

More and more, real-world engineering design issues are solved optimally using stochastic operators-based metaheuristic algorithms [13]. Deterministic algorithms are trustworthy, but they are less efficient at locating global optima because they can become stuck in local optima [14]. Randomness is a technique used by stochastic optimization algorithms, such as evolutionary ones, to avoid local solutions and locate global optima in search spaces [15]. Although each run of these techniques results in a different solution, they outperform deterministic algorithms in terms of avoiding local solutions. Take for example, ant lion optimization (ALO) [16], Biogeography-based optimization (BBO) [17], Aquila optimizer (AO) [18], grey wolf optimization (GWO) [19], and so on. GWO is a recently developed meta-heuristic optimization algorithm that draws inspiration from the communal foraging behavior of grey wolves in the wild. Mirjalili et al. [19] made the initial pitch in 2014. Alpha, beta, delta, and omega wolves are used by the GWO algorithm to replicate the leadership structure and hunting strategy of grey wolves. Certain frameworks were proposed by Rajput et al. [20] for stock price forecasting, including ARIMA (Auto Regressive-Integrated-Moving Average), FLANN (Functional Link Artificial Neural Network), ELM (Extreme Learning Machine) models, and Grey Wolf optimizer. Kumar Chandra. [21] employed Elman neural network (ENN) and GWO algorithm to optimize the parameters of ENN for forecasting the stock market. A model using an artificial neural network (ANN) optimized by the GWO method was given by Sahoo et al. [22] and the Bombay Stock Exchange (BSE) was used as the dataset in their essay.

The article introduces the GWO-RNN hybrid model, a highly reliable stock price forecasting tool. By contrasting it with many other models, including RNN, BBO-RNN, and AO-RNN, the study evaluated its accuracy. A method involving several analytical steps was used to achieve this. The principal contributions of the investigation are as follows:

A novel hybrid model is presented in this study, which integrates GWO and RNNs to tackle the intricacies associated with stock price prediction. The purpose of this hybrid model is to address the drawbacks of traditional methods by providing a more efficient forecasting method, with reduced computation complexity and prediction error probability.

The analysis utilizes Alphabet stock data spanning from January 1, 2015, to June 29, 2023, to assess the effectiveness of the hybrid model that has been proposed. In terms of high efficacy, minimal error, and optimum performance, the results demonstrate that the proposed model outperforms alternative models, thereby establishing its dependability for forecasting and analyzing financial market time series data.

The research paper validates the reliability of the GWO-RNN model as an instrument that generates exceptionally precise forecasts of stock prices. The text underscores the model's capacity to rapidly analyze and interpret substantial amounts of data by combining grey wolf optimization-based optimization with recurrent neural networks. This functionality offers investors significant insights of market trends as well as prospective investment prospects.

The proposed model exhibits exceptional suitability for chaotic stock markets, outperforming other contemporary strategies in terms of the accuracy of its forecasts. This indicates that the GWO-RNN model is capable of efficiently managing the difficulties presented by market volatility, rendering it a dependable instrument for investors in search of precise forecasts in ever-changing financial landscapes.

Section II of this research contains the literature review. Section III offers a thorough examination of the data source and all of its relevant components. The data was analyzed using a variety of methodologies, including the RNN model, evaluation metrics, and the GWO optimizer. The experimental findings are presented in Section IV. Next, they are contrasted and discussed with those from other approaches in Section V. The research's findings are finally summarized in Section VI.

II. Literature Review

In the last decade, the application of machine learning (ML) algorithms to predict stock markets has increased substantially. Christanto et al. [23] suggested an examination of methodologies employed in the capital market to predict stock prices through a comparative analysis of ML, technical analysis, and fundamental analysis. They utilized Support Vector Regression (SVR) and Support Vector Machine (SVM) as ML methodologies to forecast stock prices. The assessment includes three parameter groups: technical-only (TEC), financial statement-only (FIN), and a combination of the two (COM). Experiments revealed that the integration of financial statements had no impact on SVR forecasts yet had a beneficial impact on SVM forecasts. 83 percent was the accuracy rate attained by the model in the conducted investigation. In their study, Chen et al. [24] investigated the historical context of economic recessions, emphasizing the abrupt and disastrous outcomes that can be observed in instances like the 2008 financial crisis, which was marked by a significant decline in the S&P 500. Motivated by the potential benefits of prompt crisis detection, they applied advanced ML techniques, such as Extreme Gradient Boosting and Random Forest, to predict potential market declines in the United States. By comparing the efficacy of these methodologies, their investigation aims to determine which model exhibits superior predictive capability for US stock market collapses. An analysis was conducted on market indicators utilized in crisis forecasts. This involved the utilization of daily financial market data and 75 explanatory variables, including both broad US stock market indexes and sector indexes. Through the utilization of specific classification metrics, they arrived at conclusions regarding the effectiveness of their predictive models. Tsai et al. [25] examined the interest of investors in stock forecasting, focusing on the recent application of ML to enhance precision. They deliberated on fiscal year-end selection and the impact that misaligned reporting periods have on investment decisions and comparability. They utilized ML models for fundamental

analysis to predict Taiwan's (TW) stock market returns with an emphasis on synchronized fiscal years. Using models such as Financial Graph Attention Network (FinGAT), Feedforward Neural Network (FNN), Random Forest (RF), and Gated Recurrent Unit (GRU), they constructed stock portfolios with higher anticipated returns. Their research indicates that in terms of returns and portfolio scores, these portfolios surpassed the benchmarks of the TW50 index. They assert that ML models proved advantageous in the domains of investment decision-making and stock market analysis. Ardakani et al. [26] presented a federated learning framework utilizing Random Forest, Support Vector Machine, and Linear Regression models for stock market forecast. To determine the optimal strategy, they contrasted federated learning with centralized and decentralized frameworks, and the strategies of learning frameworks for stock market prediction were elucidated by their results. Mamluatul et al. [27] developed an innovative approach for forecasting stock prices by integrating ML, stock price data, technical indicators, and Google trends. To forecast stock prices, SVR, Multilayer Perceptron (MLP), and Multiple Linear Regression were implemented. With a Mean Absolute Percentage Error (MAPE) of 0.50%, SVR outperforms MLP and Multiple Linear Regression in forecasting Indonesian stock prices. They discovered that SVR accurately forecasts stock prices, enabling investors to make informed judgments regarding the stock market. Juare et al. [28] emphasized the significance of stock market analysis in determining financial market profits. Random Forest (RF), SVM, K-nearest neighbors (KNN), and Logistic Regression were utilized in their research to forecast stock market trends. The evaluation criteria for these algorithms are accuracy, recall, precision, and F-Score. Locating the optimal algorithm for stock market prediction was the primary objective. The value that investors and stock exchanges can derive from accurate forecasts underscores the significance of predictive models in the realm of financial decision-making. The importance of investors utilizing forecasting stock prices (SPP) models for profit in the global financial market was underscored by Swathi et al. [29]. SPP models from the past employed statistical and ML techniques. They presented SCODL-SPP, a method for predicting stock prices that integrates deep learning and Sine Cosine Optimization (SCO), in their investigation. The SCODL-SPP model employs deep learning and a stacked long short-term memory (SLSTM) model to predict the closing prices of stocks. The SCO algorithm is employed to optimize the hyperparameters of the SLSTM model after the min.

The literature review on stock market prediction closes several identified research gaps effectively. By utilizing the Alphabet stock as a central metric, this study offers specific insights about Alphabet stock, thus expanding the purview of research in this field. In addition, it addresses a void in the literature concerning the evaluation of data quality and preprocessing methodologies by providing clear and transparent explanations of data preprocessing procedures, thereby guaranteeing data quality and reproducibility. Furthermore, the incorporation of domain-specific insights into the GWO-RNN model improves the precision of predictions, thereby surmounting the drawback associated with the inadequate integration of domain knowledge. Furthermore, conducting a comparative analysis between the GWO-RNN model and other hybrid methods provides significant contributions to the understanding of the effectiveness of ensemble methods, thereby addressing a gap in the current body of research on this subject. Through an assessment of the GWO-RNN model's ability to on Alphabet stock market data encompassing the period from January 1, 2015, to June 29, 2023, this research ultimately establishes the model's dependability and efficacy in the domain of financial time series analysis and prediction. The aforementioned contributions symbolize noteworthy progressions in the field of stock market forecasting, resulting in enhanced predictive models' resilience, precision, and practicality within financial markets.

III. Research Methods

A. Recurrent Neural Network

In the complicated field of machine learning, different algorithms and techniques are used to interpret and analyze data. The recurrent neural network (RNN), which is made to handle sequential input, is one of the most crucial tools in this field and it is displayed in Fig. 1 and Fig. 2. RNNs can incorporate prior knowledge and produce outputs based on prior learning, in contrast to conventional feedforward neural networks, which only take into account the current input. The network's loop structure, which maintains a memory of previous inputs and outputs, enables this. The activation layer of each RNN unit uses a hyperbolic tangent function to process input and convert it into a format that the rest of the network can understand. The network updates its internal state as the input is analyzed, enabling it to take into account the context of earlier inputs when generating outputs. Because RNNs can take into account temporal context, which results in more effective and efficient learning, they are more accurate and useful than regular neural networks [30].

$$h_t = \sigma(W_{xt} + U_{ht-1} + b) \quad (1)$$

in the equation, b stands for the bias of the neuron, and W and U are weight matrices that represent the input to the current cell and the recurrent input, respectively. The input and hidden states of the cell at time t are represented by the values of x_t and h_t. The symbol σ designates the sigmoid function of the neuron.

B. Biogeography-based Optimization

The foundation of biogeography-based optimization (BBO) is the movement of species according to the appropriateness of their habitat. Thus, a solution is like a habitat for an optimization issue. A crowded environment, where conditions for living species are better than in other habitats, is a better option for the population. The habitat in which living things struggle is the worst answer for the population. By sharing their traits, the superior solutions draw in the inferior ones. The following operators are used in processing this feature sharing. The operator of Migration: Migration is the process by which, following emigration and immigration rates, a better habitat replaces a worse option. The pace at which a species leaves its environment is known as its emigration rate. A better solution will have a greater emigration rate than a bad one. Conversely, the rate of immigration represents the amount by which a

species departs from its natural environment. As a result, the bad option will have a larger immigration rate than the better one. The fundamental form of BBO has been represented by straight lines, as shown in Fig. 3. We have for the straight lines

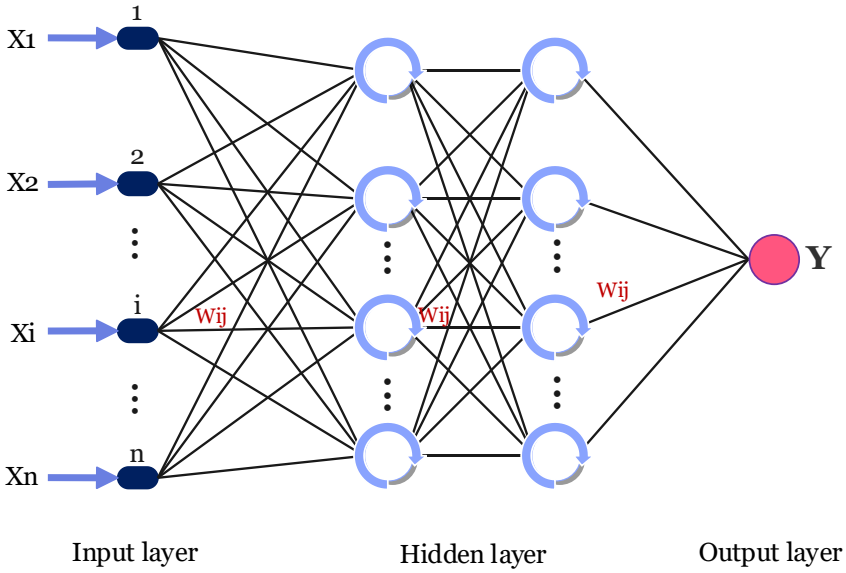

Fig. 1. RNN structure.

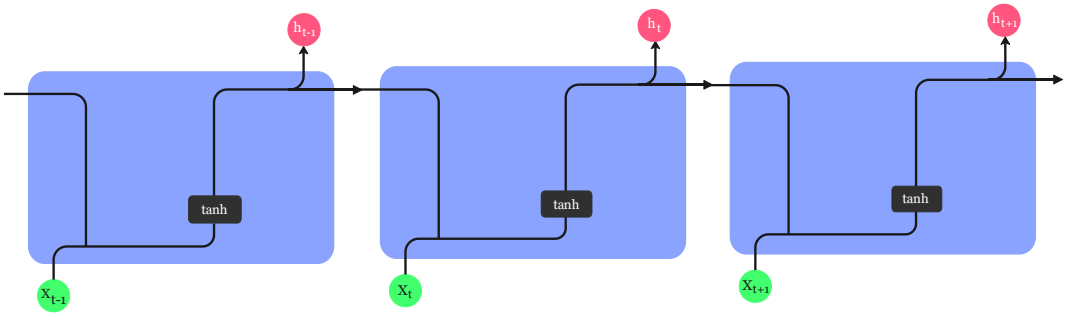

Fig. 2. The process of transforming data in RNN nodes.

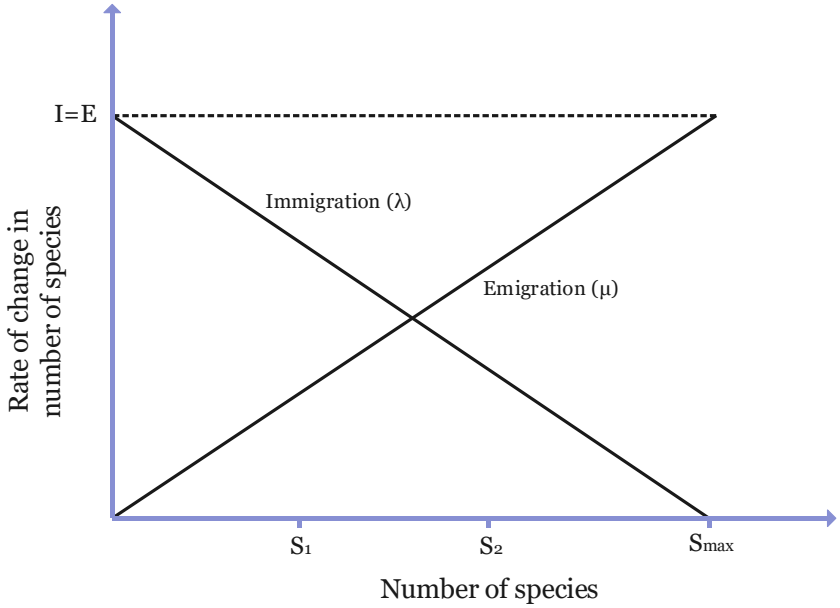

Fig. 3. The diagram of two habitats.

$$\mu_k = \frac{E \times k}{n}\lambda_k = I\left(1 - \frac{k}{n}\right) \quad (2)$$

where,

μ_k : The k^{th} habitat's emigration rate.

λ_k : The k^{th} habitat's emigration rate.

I : The highest rate of immigration.

E : The highest rate of emigration.

$\mathbf{n = S_{max}}$: The most species that a habitat can sustain.

k : The total number of species.

An abundance of species is indicated by a high HSI, which is characterized by a high rate of emigration and a low rate of immigration to nearby habitats. An increase in species leads to a decrease in immigration rate. The rate of emigration, however, rises in tandem with the number of species. Solutions S1 and S2 are the two possible options. For the most part, S2 is a good response, while S1 is a bad one. S1 has, on average, higher immigration rates than S2. Comparing S1 with S2 emigration rates, the former will be lower. The Fig. 3 represents the process of two habitats.

Mutation: A BBO mutation is comparable to an abrupt shift in environmental circumstances brought on by other events such as a tornado, volcanic eruption, or natural disaster. The species migrates to a new habitat when its old one becomes unsuitable for survival, as shown by the random change in the solution.

C. Aquila Optimization

The AO algorithm, a novel one, was released in 2021 [18]. The four categories in this algorithm were inspired by the hunting tactics of the raptor bird Aquila. In the first category, birds of prey are tracked down and pursued while flying high in the air. The swift attack of prey at low altitudes close to the ground is carried out by the second category, which glides. With a slow descent and low-altitude flight, the third group gradually attacks its prey. Using diving to catch terrestrial prey is the fourth category. Quick acceleration, convergence, and stability are all made possible by the AO algorithm's potent optimization capabilities [18]. The reliability and consistency of it are also very high. The act of a vertical dive is what an eagle does when it spots a potential prey area. The bird quickly determines the ideal hunting location on the ground by flying at great altitudes. The most efficient course of action is determined using an equation that takes the search area into account. Fig. 4 is an example of the one of hunting strategies of this bird.

$$\begin{cases} Z_1(t+1) = Z_{best}(t) \times \left(1 - \frac{t}{T}\right) \\ +\left(Z_M(t) - Z_{best}(t) \times \text{ rand }\right) \\ Z_M(t) = \frac{1}{N}\sum_{i=1}^{N} Z_i(t), \\ \forall j = 1,2, \ldots \ldots, Dim \end{cases} \quad (3)$$

where, (t) is the best course of action, indicating the location of the closest target prey, and $Z(t+1)$ is the solution of generation $t+1$, produced by the search method $Z_1 \cdot Z_{best}(t)$. This iteration's t is the number. T is the maximum number of iterations that can be done. Z(t) is a visual representation of the current solution's position mean at the t-th iteration. The name of a random integer between 0 and 1 is Rand. The following rapid gliding attack: The eagle soars to a height to identify the prey region in order to reduce the hunting zone or the search space for the most effective response according to the equation that follows:

$$\begin{cases} Z_2(t+1) = Z_{best}(t) \times Z(D) \\ +Z_R(t) + (y - z) \times \text{ rand} \\ L(D) = s \times \frac{\mu \times \sigma}{|\nu|^{\frac{1}{\beta}}} \end{cases} \quad (4)$$

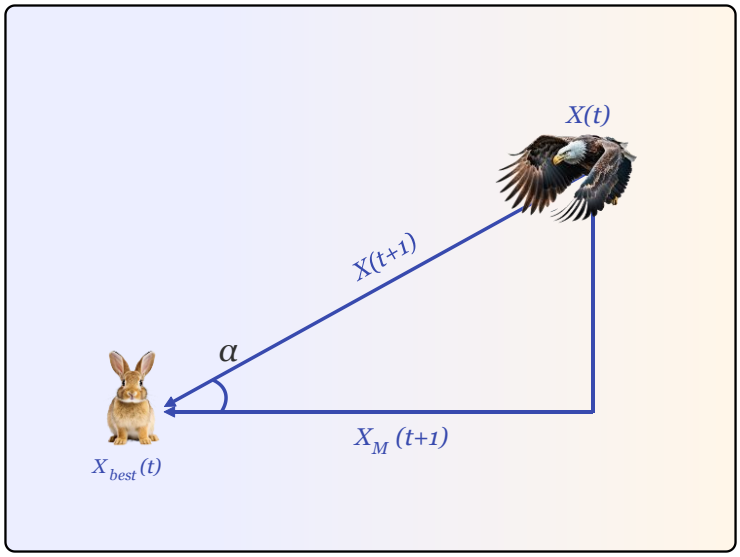

Fig. 4. The illustration of Aquila optimization.

where, L(D) stands for the hunting flight distribution function, D for the dimensional space, and $Z_R(t)$ for the random solution between $[1, N]$. Once the prey region has been precisely identified and the Aquila is prepared to land and strike, it switches to the low-flying, slow-falling assault mode at the chosen target position. The third low-altitude flight pattern is this one. By employing this strategy, the bird may see how its prey would react and slowly move in its direction as in the following formula:

$$Z_3(t+1) = \left(Z_{best}(t) - Z_M(T)\right) \times \alpha - \text{rand} + \left((U_b - L_b) \times \text{rand} + L_b\right) \times \delta \quad (5)$$

where, α and δ are the modifying parameters. The upper limit of the given problem is U_b. The bottom limit of the problem is denoted by L_b. The fourth method of walking capture is the eagle striking the target from above while performing quick convergence using the following equation:

$$\begin{cases} Z_4(t+1) = Q_F \times Z_{best}(t) \\ \quad -(G_1 \times Z(t) \times \text{rand}) \\ -G_2 \times L(D) + \text{rand} \times G_1 \\ Q_F(t) = \dfrac{2 \times \text{rand} - 1}{t^{(1-T)2}} \\ G_1 = 2 \times \text{rand} - 1 \\ G_2 = 2 \times \left(1 - \dfrac{t}{T}\right) \end{cases} \quad (6)$$

the quality function, or Q_F, and the search technique are balanced. Aquila's actions while pursuing its prey are fully visible on G_1. Aquila's flying slope when hunting is represented by G_2. $Z(t)$ is the answer for the current iteration.

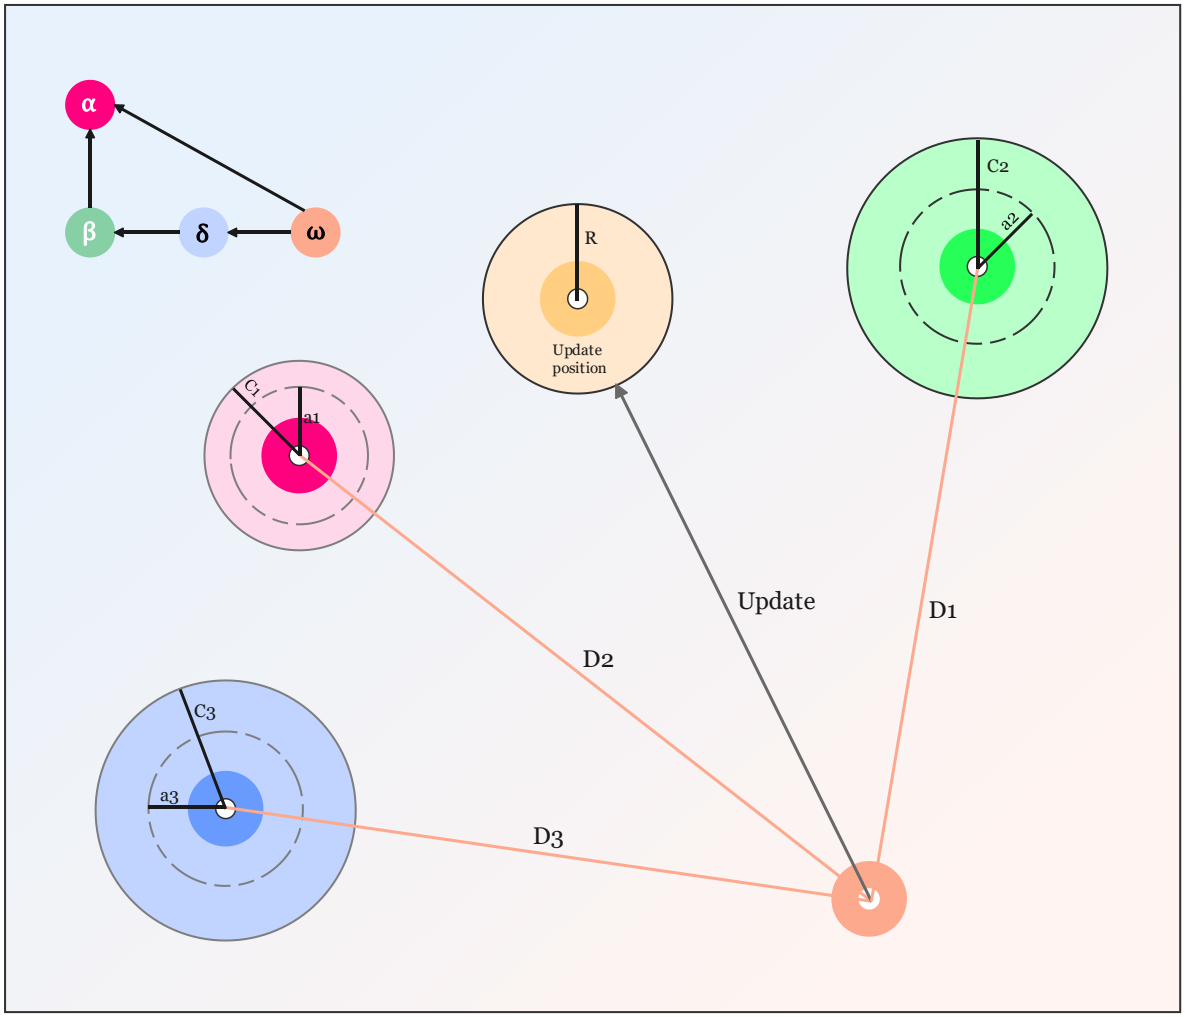

Fig. 5. The structure of Gray wolf optimizer.

D. Gray wolf optimizer

Utilizing a meta-heuristic approach, the Gray Wolf Optimizer, a unique optimization method, has been created. Mirjalili et al. [19] proposed a method, that mimics the gray wolf social structure and hunting methods. According to Fig. 5, the hierarchy of leadership contains four options: Alpha, Beta, Delta, and Omega, with Omega being the final challenger. Alpha is the best alternative and Fig. 6 represents how this optimizer works. The three main hunting methods used in the approach include chasing, encircling, and attacking prey in an effort to replicate wolf behavior. The equation illustrated below

was used to simulate the movement of gray wolves during nature hunting:

$$\vec{D} = \left|\vec{C} \cdot \vec{X}_p(t) - \vec{X}(t)\right|$$
$$\vec{X} \mid (t+1) = \vec{X}_p(t) - \vec{A} \times \vec{D} \quad (7)$$

Fig. 6. Diagram of the Gray wolf optimizer.

where t is the current iteration, $\vec{D}$ stands for movement, $\vec{X}_p$ for prey location, $\vec{A}$ and $\vec{C}$ for coefficient vectors, and $\vec{X}$ stands for a gray wolf's position. The coefficient vectors($\vec{A}$ and $\vec{C}$) are built using the relationships shown below:

$$\vec{A} = 2\vec{a} \times \vec{r}_1 - \vec{a}$$
$$\vec{C} = 2 \times \vec{r}_2 \quad (8)$$

Using information from alpha, beta, and delta, the position of new search reps that include omegas is modified accordingly:

$$\vec{D}_a = \left|\vec{C}_1 \cdot \vec{X}_a - \vec{X}\right|, \vec{D}_\beta = \left|\vec{C}_2 \cdot \vec{X}_\beta - \vec{X}\right|, \vec{D}_\delta = \left|\vec{C}_3 \cdot \vec{X}_s - \vec{X}\right| \quad (9)$$

$$\vec{X}_1 = \vec{X}_a - \vec{A}_1 \cdot \vec{D}_u, \vec{X}_2 = \vec{X}_\beta - \vec{A}_2 \cdot \vec{D}_\beta, \vec{X}_3 = \vec{X}_b - \vec{A}_3 \cdot \vec{D}_\delta \quad (10)$$

$$\vec{X}(t+1) = \frac{\vec{X}_1 + \vec{X}_2 + \vec{X}_3}{3} \quad (11)$$

when the wolves undertake a last assault to accomplish the mission, as shown by the subscripts α, β, and δ. An is a random variable with a value between $-2\vec{a}$ and $2\vec{a}$, whereas an is used to simulate the previous assault by altering $\vec{a}$ value from 2 to 0. Therefore, decreasing a would also cause a decrease in $\vec{A}$. $\left|\vec{A}\right| < 1$ forced the wolves into sticking to their prey. Gray wolves hunt in groups and follow the alpha wolf, dispersing to forage and reassembling to attack. Whenever $\left|\vec{A}\right|$ has a random value bigger than unity, the wolves may split apart in pursuit of prey. The two setup parameters for the GWO method that are most important are the wolf count and generation number. Each generation is a wolf's final deed, and the quantity of wolves accurately reflects function assessments across time. This means that the total number of objective function evaluations will be equal to the wolf population times the size of the generation, or,

$$\text{OFEs} = N_W \times N_G \quad (12)$$

E. Data source and Preparation

When conducting a thorough analysis of a stock, it's important to take into account some factors, such as the trading volume and the Open, High, Low, and Close (OHLC) prices over a specific period. For this specific study, information on Alphabet Inc. began to be gathered in 2015. For each day during the specified period, this data included information on both the trading volume and the OHLC prices. Examining the data landscape carefully to spot any anomalies, outliers, or discrepancies that might have an impact on the accuracy of the findings was the first step. Following this analysis, the dataset underwent several cleaning and preparation steps, using various techniques like scaling and normalization to reduce errors and guarantee consistency in training results via using the following equation:

$$\text{Xscaled} = \frac{(X - \text{Xmin})}{(\text{Xmax} - \text{Xmin})} \quad (13)$$

This methodical approach aimed to raise the general level of data quality that served as the basis for the forecasting models. To further improve the models, the prepared data was split into two subsets, with 80% of the data used for training and the remaining 20% for testing and validation according to Fig. 7. The goal of this division was to strike a balance between the requirement for a sizable amount of data for model training and the requirement for a varied and untested set for exhaustive testing and validation.

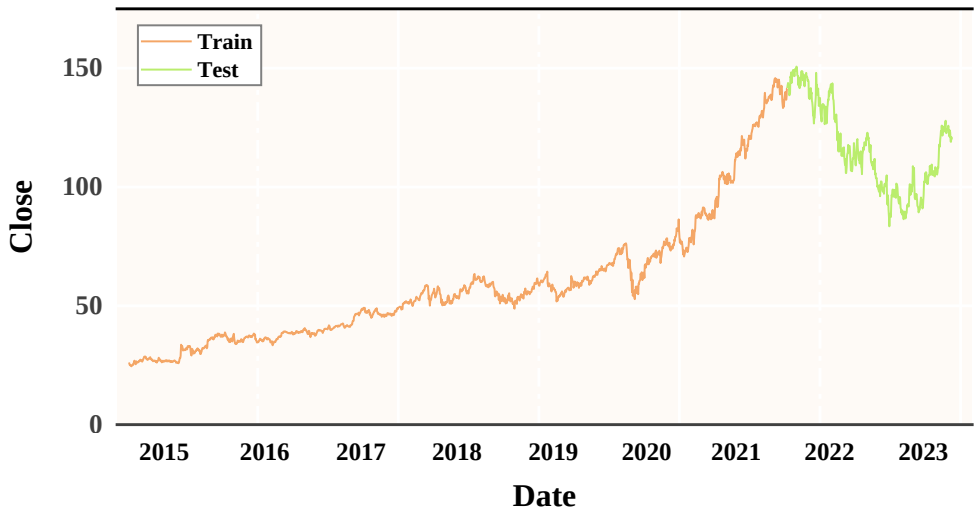

Fig. 7. Dividing the data into training and tests.

F. Assessment Criteria

In order to ensure the validity and accuracy of future projections, a diverse range of performance indicators were employed. These metrics were meticulously selected to provide a comprehensive evaluation of the prognostications. Throughout the evaluation process, several metrics, including the mean absolute error (MAE), which calculates the average absolute difference between the predicted and actual values, the root mean square error (RMSE), which measures the root mean square of the errors between the predicted and actual values, and the coefficient of determination (R^2), which gauges the proportion of variance in the dependent variable that is predictable from the independent variable was considered. These methodologies are highly valuable for assessing the accuracy of forecasting models and can facilitate more informed decisions.

$$\mathrm{RMSE} = \sqrt{\frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{n}} \tag{14}$$

$$\mathrm{MAE} = \frac{\sum_{i=1}^{n}|y_i - \hat{y}_i|}{n} \tag{15}$$

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2} \tag{16}$$

IV. Experimental Results

A. Statistical Values

The study's component includes a table (see Table I) that presents comprehensive statistical information about the dataset. The table displays OHLC pricing and volume statistics, which help to clarify the data. Statistical metrics such as count, mean, minimum (Min), standard deviation (Std.), 25%, 75%, variance, and maximum (Max) values are also provided, enabling a more detailed and precise analysis of the data.

B. Results of the Each Model

The primary goal of this study is to identify and assess the top hybrid algorithm for stock price forecasting. To do this, the research created forecasting models and looked at intricate factors that affect stock market patterns. The objective is to deliver analytical information that can help analysts and investors make wise investment decisions. Each model's performance is comprehensively evaluated, along with a thorough study of its efficacy, in Table II, Fig. 8, and Fig. 9.

TABLE I. Statistical Summary of the Data Set

	Open	High	Low	Volume	Close
Count	2137	2137	2137	2137	2137
Mean	70.05219	70.81457	69.3428	32.59751	70.09629
Std.	34.54605	34.97686	34.14654	15.6062	34.55914
Min	24.66478	24.7309	24.31125	6.936	24.56007
25%	41.0205	41.22	40.851	23.248	41.046
75%	96.77	98.94	95.38	37.066	96.73
Max	151.8635	152.1	149.8875	223.298	150.709
Variance	1193.43	1223.381	1165.986	243.5536	1194.334

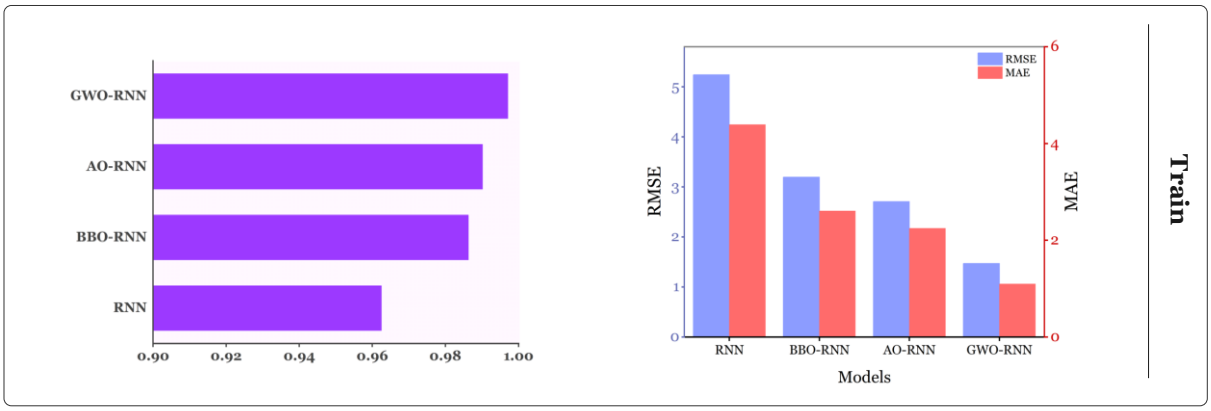

Fig. 8. Values for each model's training-related assessment.

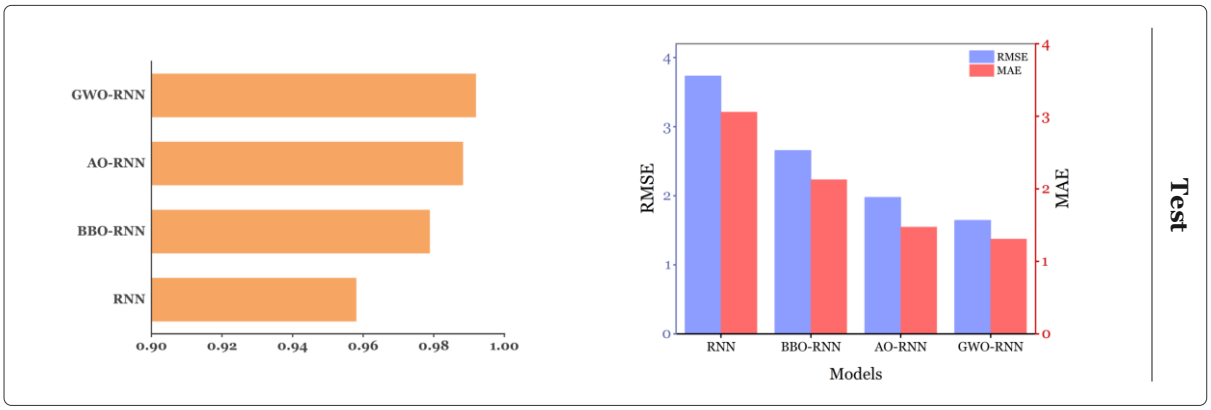

Fig. 9. Values for each model's testing-related assessment.

TABLE II. THE RESULTS OF THE MODELS FORECAST EVALUATION

	TRAIN SET			TEST SET		
	R^2	*RMSE*	*MAE*	R^2	*RMSE*	*MAE*
RNN	0.962	5.241	4.389	0.958	3.733	3.058
BBO-RNN	0.986	3.193	2.604	0.979	2.654	2.126
AO-RNN	0.990	2.705	2.244	0.988	1.976	1.472
GWO-RNN	0.997	1.467	1.094	0.992	1.643	1.306

Three widely accepted metrics—RMSE, MAE, and R^2—were used to carry out a detailed review of the data analysis. These indicators are well known for being able to offer a precise assessment of the analysis's dependability, correctness, and overall effectiveness. With and without an optimizer, the RNN model's performance was evaluated using the R^2, RMSE, and MAE criteria. This evaluation improved comprehension of the model's performance and aided in making decisions based on the outcomes.

V. DISCUSSION

A. Analysis of the Models

This study's principal objective is to identify and evaluate the most effective hybrid algorithm for stock price prediction. In order to accomplish this, the study developed forecasting models and examined complex variables that influence stock market patterns. The primary aim is to provide analysts and investors with valuable analytical data that can assist them in making informed investment choices. The performance of each model is assessed exhaustively, and its effectiveness is thoroughly examined in Table II, Fig. 8, and Fig. 9. The R^2, RMSE, and MAE criteria were used to assess the performance of the RNN model both with and without the optimizer. This enabled wise decisions by giving a thorough grasp of the model's performance. Analysis of the training and test sets revealed that, without the optimizer, the RNN model generated R^2 values for training and testing of 0.962 and 0.958, respectively. The RMSE values for training and testing were 5.241 and 3.733, respectively, despite the MAE values being 4.389 and 3.058. By integrating optimizers, the RNN model performs significantly better. For instance, when the BBO optimizer was used, the R^2 value for the tests increased to 0.979. Furthermore, the RMSE and MAE values for testing, which came in at 2.654 and 2.126, respectively, were lower than those for training. The AO-RNN model performed better than the BBO-RNN model and produced better results. Specifically, the results for the training and testing R^2 were

0.990 and 0.988, respectively. It's crucial to remember that the MAE and RMSE figures fell to 1.472 and 1.976 during the testing. This shows increased precision. The GWO-RNN model has demonstrated remarkable accuracy and reliability in regression analysis. The model achieved the highest R^2 scores of 0.997 and 0.992 for the training and testing datasets, respectively. This indicates that the model has a high predictive power and can explain almost all the variability in the data. Furthermore, the model's performance is exceptional, as evidenced by the low MAE and RMSE training values of 1.094 and 1.306, and testing values of 1.467 and 1.643, respectively. These values represent the amount of error between the actual and predicted values, with lower values indicating higher accuracy. Therefore, the GWO-RNN model has shown exceptional accuracy in both the training and testing data sets.

Fig. 10. The prediction curve is produced by training with GWO-RNN.

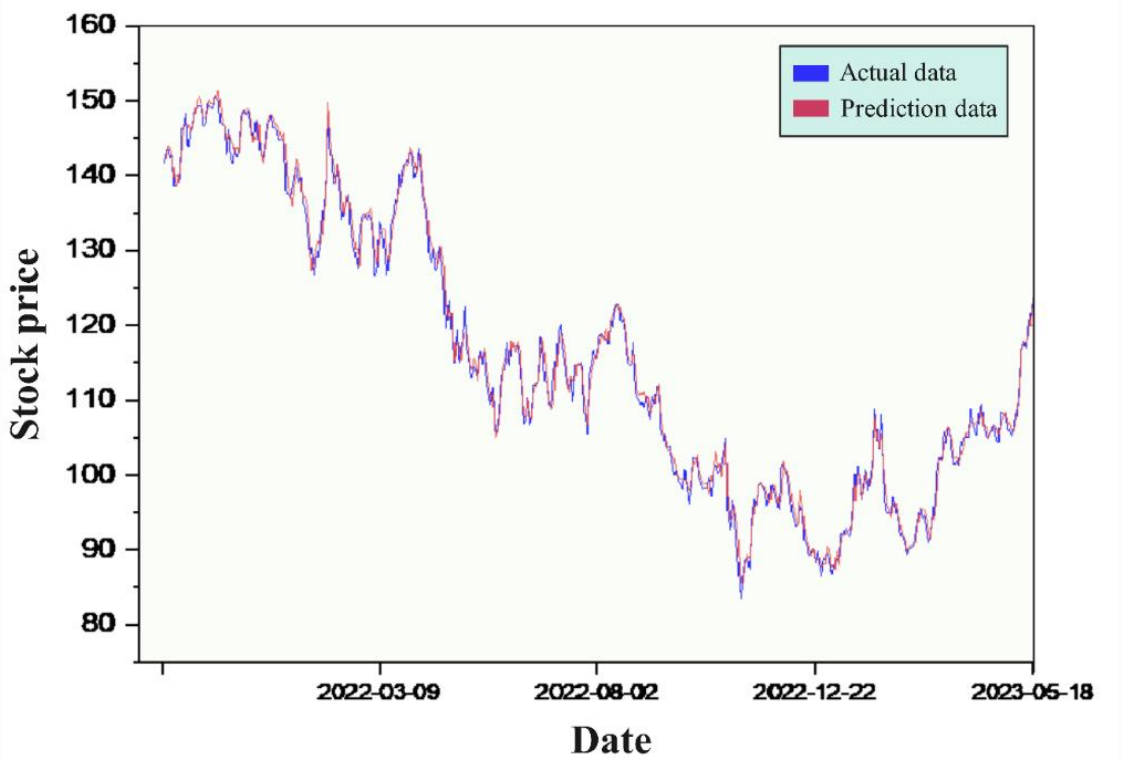

Fig. 11. The prediction curve is produced by testing with GWO-RNN.

For creating accurate stock price predictions, the GWO-RNN model is a very trustworthy instrument. As illustrated in Fig. 10 and Fig. 11, this model is successful in forecasting the Alphabet stock curves. Due to the RNN method's ability to lower price fluctuations, streamline trend prediction, and increase model precision, the GWO-RNN model performs better than other models at forecasting stock prices. The capacity of the GWO-RNN model to learn from prior data sets is one of its distinguishing characteristics. Learning from prior data sets is essential for a model to produce accurate stock value predictions and adapt to shifting market trends. In summary, the GWO-RNN model is an effective and useful tool for forecasting stock prices. Because of its accuracy, precision, and adaptability, it is highly advised for anyone wishing to make profitable transactions in the stock market. It stands out from other models due to its use of the RNN algorithm and GWO optimizer, making it the greatest option for anyone looking to make informed investing decisions.

B. Comparison with Recent Works

Validation measures and comparisons with prior relevant literature are essential elements in evaluating the credibility and significance of a research investigation. In addition to guaranteeing the dependability and accuracy of the study's findings, they aid in contextualizing the research within a wider framework. The present evaluation assesses, which is illustrated in Table III, the predictive capabilities of different models, such as the GWO-RNN model employed in this research, concerning the behavior of the stock market. Significantly, the GWO-RNN model, which was developed and evaluated using Alphabet stock data, attains a remarkable coefficient of determination (R^2 = 0.992), outperforming alternative algorithms including Linear Regression, SVM, and several iterations of LSTM. The remarkable accuracy of this forecast highlights the consistency and consistency of the GWO-RNN model in capturing the intricate dynamics of stock prices. Through the utilization of the Grey Wolf Optimization-Recurrent Neural Network architecture, the model adeptly exploits past stock price data to deliver resilient predictions, thereby showcasing its consistency in adjusting to fluctuations in the market. Incorporating Alphabet stock data into the evaluation process enhances coherence and ensures that the model's performance is in line with actual market conditions. As a result, the GWO-RNN model can be established as a logical and consistent methodology for forecasting the stock market, providing significant contributions to financial decision-making and risk mitigation.

TABLE III. AN EVALUATION OF THE MODEL IN COMPARISON TO PRIOR RESEARCH

Authors	**Abdul et al.** [31]			**Zhu et al.** [32]						**Present work**
Algorithms	Linear regression	SVM	MLS-LSTM	LSTM	EMD-LSTM	CEEMDAN-LSTM	SC-LSTM	EMD-SC-LSTM	CEEMDAN-SC-LSTM	GWO-RNN
R^2	0.73	0.93	0.95	0.6896	0.8703	0.9031	0.6871	0.9111	0.9206	0.992

C. Limitations and Future Works

The efficacy of the GWO-RNN model was assessed using a distinct dataset comprising Alphabet stock from January 1, 2015, to June 29, 2023. The efficacy of the model could potentially be compromised by the attributes of the given dataset, thereby restricting its applicability to alternative equities, industries, or periods. Hybrid models frequently depend on precise parameter configurations, particularly when optimization algorithms such as grey wolf optimization are integrated. The extent to which the GWO-RNN model can withstand variations in these parameters may have been inadequately investigated in the research. The exclusive dependence of the study on historical stock price data may result in the omission of critical information, including geopolitical developments, external economic events, and market sentiment. The extent to which the GWO-RNN model captures and incorporates such external factors into its predictions is not exhaustively investigated, which may have implications for its overall predictive capabilities. Although the study showcases the superior performance of the GWO-RNN model in comparison to other models, a more extensive evaluation comparing it to a broader spectrum of established and cutting-edge models would offer a more precise assessment of its comparative merits and drawbacks.

Enhancing the range of data sources beyond daily prices and trading volume may yield significant insights that can be applied to the prediction of stock market trends. The incorporation of supplementary data streams, including sentiment analysis from social media platforms, economic indicators, or news articles, may bolster the predictive capacities of models through the inclusion of supplementary market dynamics. The incorporation of external variables into predictive models, including macroeconomic indicators, geopolitical events, and regulatory changes, may increase their predictive capability. Gaining insight into how these extraneous variables impact the conduct of the stock market and integrating them into prognostic models may enhance their precision and dependability. Undertaking thorough assessments of predictive models under various market conditions, encompassing periods of stability and volatility, would yield valuable insights regarding the models' ability to withstand and apply to a wide range of situations. Conducting performance tests on models across diverse economic conditions may unveil their merits and drawbacks, thereby providing valuable insights for their implementation in practical situations. By expanding the utilization of predictive models to encompass financial methods other than stock prices, including commodities, currencies, and cryptocurrencies, their applicability and significance could be significantly enhanced. An examination of the adaptability of predictive models to various asset classes and market segments would yield valuable insights regarding their efficacy and versatility in a wide range of financial markets.

VI. CONCLUSIONS

The task of predicting stock prices is difficult and complex because it requires examining many different aspects of society, the economy, and politics. Since the stock market is dynamic and ever-evolving, it is important to take financial statements, earnings reports, market trends, and other factors into account when forecasting future stock values. The stock market's behavior can be significantly impacted by macroeconomic factors like interest rates, inflation, and global market conditions. Due to the complexity and numerous variables involved in predicting stock values, it can be challenging to develop accurate and trustworthy prediction models. Making accurate predictions requires an understanding of the market's erratic and non-linear characteristics. In this study, the RNN, BBO-RNN, and AO-RNN stock price prediction models were evaluated for their performance.

The GWO-RNN model performed better than other models in the tests that were conducted. R^2, RMSE and MAE values for the model were 0.992, 1.643, and 1.306, respectively. These findings show that the GWO-RNN model is highly predictively accurate and that it can be trusted to deliver accurate and dependable outputs.

The GWO-RNN model has been demonstrated to be a trustworthy tool for making highly accurate stock price predictions. This model can analyze and interpret large amounts of data in real-time using a combination of recurrent neural networks and grey wolf optimization-based optimization, giving investors useful insights into market trends and potential investment opportunities.

Optimization Method for Digital Twin Manufacturing System Based on NSGA-II

Yu Ding, Longhua Li*
Applied Technology College of Dalian Ocean University, Dalian, 116300, China

***Abstract*—In the wave of industrial modernization, a concept that comprehensively covers the product lifecycle has been proposed, namely the digital twin manufacturing system. The digital twin manufacturing system can conduct three-dimensional simulation of the workshop, thereby achieving dynamic scheduling and energy efficiency optimization of the workshop. The optimization of digital twin manufacturing systems has become a focus of research. In order to reduce power consumption and production time in manufacturing workshops, the study adopted a non-dominated sorting genetic algorithm to improve its elitist retention strategy for the problem of easily falling into local optima. On the ground of the idea of multi-objective optimization, the optimization was carried out with the production time and power consumption of the manufacturing industry as the objectives. The experiment showcased that the improved algorithm outperforms the multi-objective optimization algorithm on the ground of decomposition and the evolutionary algorithm on the ground of Pareto dominance. Compared to the two comparison algorithms, the production time optimization effect and power consumption optimization effect of different numbers of devices were 11.12%-21.37% and 2.14%-6.89% higher, respectively. The optimization time of the improved algorithm was 713.5 seconds, that was reduced by 173.8 seconds and 179.8 seconds compared to the other two algorithms, respectively. The total power consumption of the improved optimization model was 2883.7kWs, which was reduced by 32.0kW*s and 45.5kW*s compared to the other two algorithms, respectively. This study proposed a new multi-objective optimization algorithm for the current digital twin manufacturing industry. This algorithm effectively reduces production time and power consumption, and has important guiding significance for manufacturing system optimization in actual production environments.**

Keywords*—Multi-objective optimization; NSGA-II; Digital twin; Production time; Production energy consumption

I. Introduction

At present, China is entering a stage of high-quality development, and manufacturing, as one of the important core industries for achieving socialist modernization, is an important guarantee of comprehensive national strength. In traditional manufacturing models, product design, manufacturing, and service are usually isolated. This model is difficult to meet the personalized, intelligent, and environmentally friendly requirements of the current manufacturing industry [1]. The proposal of the Digital Twin Manufacturing System (DTMS) provides new ideas for solving these problems [2]. The DTMS comprehensively manages and controls all stages of the product from design to lifecycle through simulation and optimization. This can improve product quality and production efficiency, and reduce production costs [3]. Modern industrial practice has shown that DTMSs can effectively change the production mode of the manufacturing industry, making it more intelligent and personalized [4]. However, how to optimize the construction and operation of DTMSs, improve their performance and efficiency, is an important research topic at present. This practice has proven that the application of optimization algorithms can effectively improve the performance and efficiency of DTMSs [5]. In view of this, in order to reduce power consumption and production time in manufacturing workshops, this study will explore the optimization and construction methods of DTMSs from both theoretical and methodological perspectives. Firstly, a DTMS optimization model on the ground of the Non-dominated Sorting Genetic Algorithm-II (NSGA-II) will be constructed using existing optimization algorithms for reference. On this basis, through in-depth research and improvement of the model, its performance and efficiency in practical applications are improved. The study improved the elite retention strategy of the NSGA-II algorithm, which requires retaining a portion of non-fully optimal solutions in addition to retaining elite individuals. The significance of this improvement is to avoid local convergence of the results and improve the accuracy of the calculation results for multi-objective optimization problems. The innovation of this study lies in the idea of flexible scheduling on the ground of flexible workshops, combined with digital twin technology, to construct an optimization model for green manufacturing industry. It effectively improves the practicality and availability of optimization strategies. Through this research, not only can the performance and efficiency of DTMSs be improved, but it can also promote technological progress and industry transformation in the manufacturing industry. The contribution of this study lies not only in constructing an effective optimization model for DTMSs, but also in providing new theories and methods for further research and application of DTMSs. This will have a profound impact on the development of the manufacturing industry and will also have a positive driving effect on the development of the social economy. The research is divided into five sections. Section II is a summary of the research related fields, namely DTMSs and industrial optimization, which involve the application of digital twin technology in the manufacturing industry and the application of algorithms in improving production efficiency in the manufacturing industry. Section III is the implementation of the method proposed by the research institute, which involves the construction of digital twin green models and multi-objective optimization models for the manufacturing

industry. Section IV is the validation of the method proposed by the research institute, which includes iterative performance, convergence performance, time optimization performance, and energy consumption optimization performance. Section V is a summary and outlook of the research.

II. Related Works

DTMS is an emerging manufacturing system model that integrates physical and virtual manufacturing systems in real-time, dynamic, and highly consistent manner throughout their entire lifecycle. It is on the ground of advanced technologies such as the Internet of Things, cloud computing, and big data, and establishes a virtual image of a physical manufacturing system by collecting various data from the manufacturing system. Then, through continuous learning and model updates, the virtual image can reflect the state of the physical system in real time. Liu et al. proposed a real-time collaborative method on the ground of digital twin technology to address the treatment and efficiency issues in the production of new products. This method utilized heterogeneous information network modeling for real-time analysis and optimization of product production processes, and experimental results verified the feasibility and practicality of this method [6]. Guo et al. introduced a manufacturing logistics integration technology on the ground of digital twin technology to address the synchronization issue of manufacturing logistics interfaces in the production manufacturing industry, and established an equivalent constraint programming model to verify this. The experiment showcased that this method effectively achieves synchronization between logistics and manufacturing industries [7]. Fan et al. proposed a manufacturing structure on the ground of the digital twin scenario system in response to the development trend of Industry 4.0. The experiment showcased that this method is very effective at every stage of the product lifecycle [8]. Chetan et al. proposed a high-fidelity digital twin wind turbine blade virtual model to generate accurate blade models. This model improved the accuracy of the model by incorporating progressive calibration, and experimental results demonstrated the effectiveness and practicality of this method [9]. Osho proposed a modular digital twin framework to enhance its applicability in the manufacturing industry to enhance its applicability. The experimental results have proven the accuracy of this method in practice, laying a solid foundation for the further application of digital twin technology in the manufacturing industry [10].

Industrial manufacturing optimization refers to achieving more efficient and sustainable industrial manufacturing by improving and optimizing production processes, improving production efficiency, reducing costs and resource consumption, and other means. Using computer algorithms to optimize industrial manufacturing can achieve multi-objective optimization while also achieving intelligence and automation in the industrial manufacturing process. By learning and analyzing data, algorithms can continuously optimize the production process, improve production efficiency and quality. Singh et al. proposed an optimization strategy for the trajectory of industrial robotic arms on the ground of a hybrid optimization algorithm. The joint trajectory was optimized using a seventh order polynomial function. The experiment showcased that this method effectively improves the smoothness and efficiency of the robot [11]. Wu et al. analyzed the manufacturing economy in the post pandemic era in the region on the ground of a dual sector economic growth model, combined with descriptive statistics and grey correlation method. And it has put forward suggestions for optimizing the industrial structure of the manufacturing industry on the ground of the actual situation. This provided a reference for regional economic development and industrial structure optimization in the post pandemic era [12]. Sekaran et al. introduced a multi-objective opposition learning artificial ant colony optimization technique on the ground of directed acyclic graph theory to improve the communication cost of physical systems in IoT networks and the production efficiency of production lines. This was to optimize complex processes in industrial manufacturing. The experiment showcased that this method reduces production costs with minimal latency and computational overhead [13]. Chen et al. proposed a manufacturing optimization technology on the ground of container deployment model, which saved bandwidth resources and improves production efficiency by reducing communication latency. The experiment showcased that this method is highly effective in optimizing resource utilization and reducing deployment costs [14]. Morse et al. proposed a structural optimization method on the ground of boundary element method to improve structural stability in the aircraft manufacturing industry, and considered manufacturing costs. The experiment showcased that this method achieves full shape optimization of aircraft panel structures and has extremely high efficiency [15].

In summary, DTMSs are currently the focus of industrial optimization problems. And computer algorithms have been widely applied in the optimization research of industrial manufacturing systems. After reviewing a large number of literatures, it can be concluded that computer algorithms make important contributions to manufacturing system optimization, especially in improving manufacturing efficiency, reducing costs, and improving product quality. However, there are still some shortcomings in current research, such as the stability and robustness of optimization methods that require further research and improvement. For these problems, considering the advantages that NSGA-II algorithm can take into account multiple complex and often conflicting manufacturing objectives, a digital twin manufacturing optimization strategy based on NSGA-II is proposed. NSGA-II maintains the diversity of solutions through fast non-dominated sorting and congestion distance calculation. This approach makes more efficient use of the real-time data provided by digital twin technology. At the same time, the digital twin technology can effectively support the iteration and evolution of the NSGA-II algorithm, so that each optimization of the manufacturing process is based on the latest and most accurate system data, ensuring that the optimization results are highly practical and accurate. Therefore, the research chooses to combine NSGA-II algorithm with digital twin manufacturing. This is to improve decision quality and production efficiency in manufacturing process.

III. Construction and Improvement of NSGA-II for Digital Twin Manufacturing Industry

Considering the characteristics of DTMSs, the main challenge faced by the construction of NSGA-II is multi-objective optimization problem [16]. In the construction of the NSGA-II, the data-driven characteristics of the DTMS and its parallel processing ability in complex manufacturing processes are fully utilized. On the basis of algorithm construction, the optimization problem of NSGA-II was further explored. The selection, crossover, and mutation operations of algorithms have been thoroughly studied. The goal of this process is to find strategies and methods that can improve the efficiency and effectiveness of algorithms in dealing with large-scale parallel manufacturing system problems. To maintain the diversity of the population, new strategies were introduced in the optimization process. These strategies can maintain the diversity of the population during the optimization process, avoiding premature convergence and falling into local optima. The introduction of this strategy enables the algorithm to better balance the quality of solutions and the time required to solve practical problems.

A. Construction of a Manufacturing System Considering Digital Twins

In order to reduce the power consumption and production time of manufacturing workshops, a three-dimensional simulation of the workshop was conducted using a digital twin manufacturing system. A green model of manufacturing digital twins was constructed, and the energy consumption of the workshop was analyzed, providing direction and ideas for the subsequent optimization model construction. Afterwards, a multi-objective optimization model was constructed with power consumption and production time as optimization objectives, and the improved NSGA-II algorithm was used to solve the multi-objective problem. The scarcity of global resources and the increasing severity of environmental problems have forced industrial enterprises to use resources more efficiently and reduce their impact on the environment [17]. With the increasing demand for sustainable development in society, industrial enterprises need to take measures to reduce carbon emissions and waste emissions to achieve green and sustainable development. The digital twin green model can help industry achieve this goal. It is on the ground of digital twin technology and achieves real-time monitoring, optimization, and prediction of factories by modeling and simulating the physical systems of actual factories. This is to achieve the goals of efficient resource utilization, environmental friendliness, and economic sustainability [18]. Through digital twin technology, real-time monitoring of factory operations, energy consumption, waste generation, and other data can be achieved. And they were able to optimize on the ground of modeling and simulation. The schematic diagram of the manufacturing digital twin green model is shown in Fig. 1.

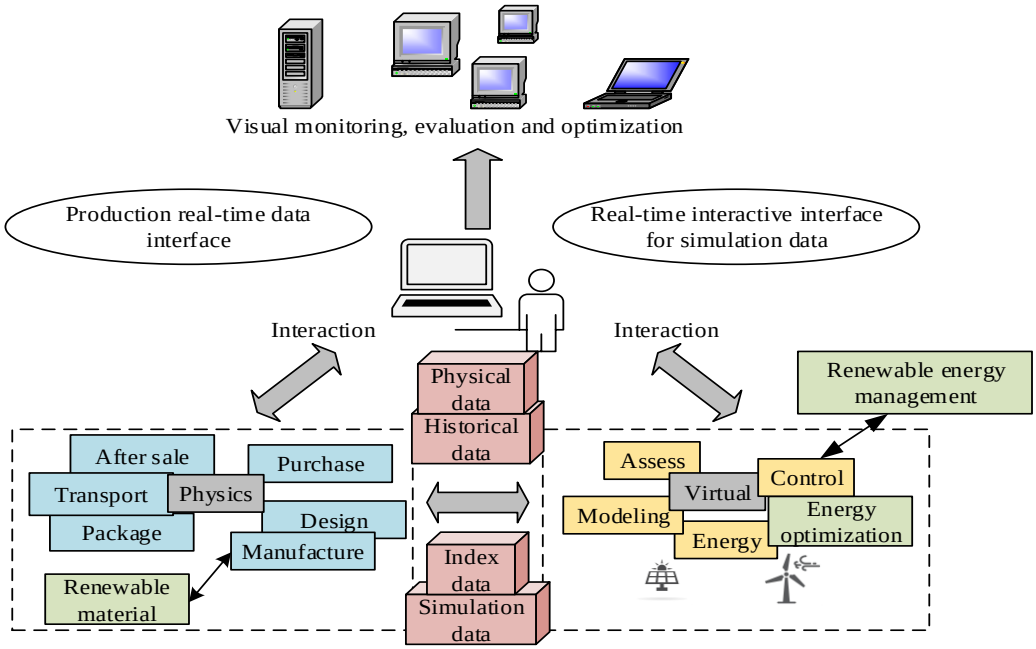

Fig. 1. Digital twin manufacturing green model.

Fig. 1 is a schematic diagram of the digital twin green model in the manufacturing industry. It forms a five dimensional model through the interaction between manufacturing entities, virtual entities, industrial data, services, and all elements. It can adjust the industry on the ground of real-time data to maximize production efficiency and costs while achieving multi-objective optimization. In digital twin technology, the core idea is to build a virtual model that reflects reality through continuous analysis of real-time data. Through the virtual model, the simulation, monitoring and optimization of the real factory can be realized in virtual. The most significant advantage is the ability to test optimizations, predict potential problems, and make production-related decisions in advance without interfering with actual production. The use of digital twin technology can effectively reduce production risks and improve efficiency. In the automotive industry, for example, in the design phase, the digital twin system is first used to test the automobile

manufacturing to ensure the safety and feasibility of the process. In the manufacturing stage, the optimization of the manufacturing process is realized through the virtual planning and simulation of the production line. Then, in the test phase, the digital twin technology is used to carry out durability virtual collision and simulation. In the product sales phase, real-time data is used to assist inventory management and production adjustments are made based on real-time feedback. Digital twins can also guide the recovery and remanufacturing of vehicle products after they have reached the end of their life. Through the application of digital twin technology, the production efficiency and environmental friendliness of the bicycle manufacturing industry can be effectively improved. Formula (1) is a digital twin green energy consumption model.

$$M_{DT-GT} = \{P_g, V_g, D_g, S_g, C_g\} \tag{1}$$

In Formula (1), P_g represents the total physical energy consumption in the manufacturing workshop under energy consumption analysis. V_g represents a digital twin, whose main significance is to optimize energy consumption. D_g represents the overall data of the workshop, which is the connecting link with the digital twin. S_g represents optimization of energy consumption. C_g represents the interaction between real data and virtual data. As shown in Fig. 2, taking workshop work in the manufacturing industry as an example, it is optimized. On the ground of its energy consumption, this study continues to optimize and analyze it. On the ground of the basic energy consumption of the workshop, this study combines intelligent optimization algorithms. Then, on the ground of the actual situation, it constructs a green optimization and energy-saving operation strategy for workshop equipment, ultimately achieving optimization of workshop energy consumption. This can also reduce energy consumption and improve production efficiency.

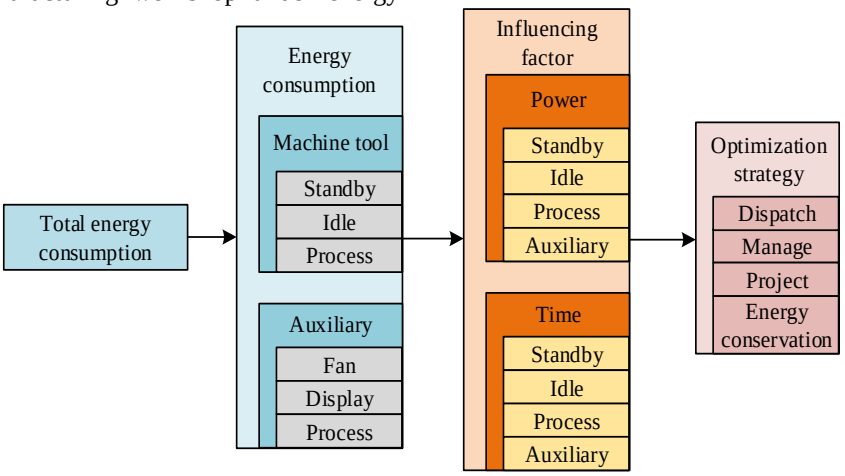

Fig. 2. Correlation analysis diagram of energy consumption, power and optimization of workshop.

Fig. 2 shows the key components of energy consumption analysis using workshop work in the manufacturing industry as an example. This includes machine tool energy consumption and auxiliary equipment energy consumption, and takes into account power consumption and time factors to plan better workshop optimization strategies. The power consumption model between machine speed and material removal rate can be expressed as shown in Formula (2).

$$P_1 = P_2 + k_1 n + b + k_0 MRR \tag{2}$$

In Formula (2), P_1 represents the total energy consumption in material removal. P_2 represents the total standby consumption, b represents the total fixed energy consumption of the device, n represents the speed unit of the device, k_1 represents the parameter setting of the spindle motor, k_0 represents a constant in the calculation, and MRR represents the material removal rate. Further consideration should be given to the power consumption of workshop machine tools. In the standby state of the equipment, the control system of the lathe remains in standby state, and the total standby power can be expressed as shown in formula (3).

$$P_s = P_c + P_l \tag{3}$$

In Formula (3), P_s represents standby power, P_c represents the system operating power of the workshop machine tool, which plays a major role in monitoring the entire system, and P_l represents the auxiliary equipment power. In the normal working state of the workshop, the power can be expressed as shown in Formula (4).

$$P_{ld} = P_s + P_{sf} \tag{4}$$

In Formula (4), P_{ld} represents the preparation power of the processing state, P_s represents the standby power, and P_{sf} represents the idle power of the spindle and the no-load power of the feed shaft. In the processing stage of the lathe, the main calculation required is the cutting power of the machine tool on the workpiece material, which can be expressed as shown in Formula (5).

$$P_w = P_s + P_{sf(n)} + P_m \tag{5}$$

In Formula (5), P_w represents the total power of the machining state, P_s represents the standby power, $P_{sf(n)}$ represents the power of the spindle and feed shaft in the working state, and P_m represents the cutting power of the material. Furthermore, according to the definition of integration, by integrating time over a period of time, the total power of the workshop machine tool can be calculated, as shown in Formula (6).

$$E_M = \int_0^{t_s} P_s d_t + \int_0^{t_{Id}} P_{Id} d_t + \int_0^{t_w} P_{Id} d_t \tag{6}$$

As shown in Formula (6), the total power of the workshop lathe during the processing stage can be calculated using the integration method, where t_s represents the standby time, t_{Id} represents the processing preparation time, and t_w represents the total processing time. As shown in Fig. 3, it is a schematic diagram of the process flow of a flexible workshop that adopts the optimization process method.

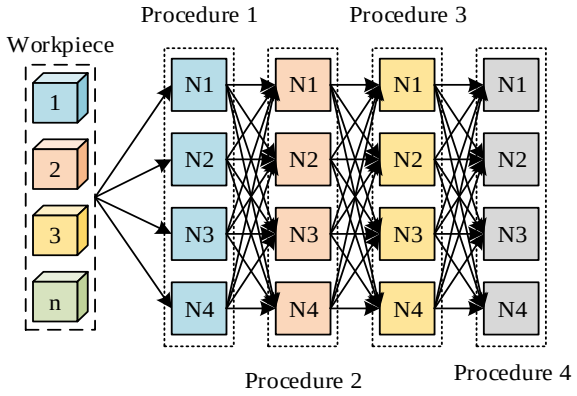

Fig. 3. Flexible workshop process flow diagram.

Fig. 3 is a schematic diagram of the flexible workshop process flow using optimized process methods, which can better align actual production needs with green concepts. Its main purpose is to reduce workshop production time while reducing equipment energy consumption, thereby achieving the concept of green manufacturing.

B. Construction and Optimization of NSGA-II for DTMSs

The characteristics of NSGA-II provide an effective solution for multi-objective problems in DTMSs. This algorithm achieves efficient search of high-quality solution sets through a non-sorted survival selection mechanism and crowding distance sorting [19]. However, integrating it into specific manufacturing environments requires a deep understanding of the characteristics of manufacturing systems to design optimization strategies that meet practical needs [20]. Firstly, it discusses the optimization scheduling objectives for the workshop. Overall, with manufacturing processing time as the main optimization objective, it can be represented by Formula (7).

$$\min T = \max\{C_1, C_2, \cdots, C_N\} \tag{7}$$

In Formula (7), $\min T$ represents the minimum optimized processing time, and $\{C_1, C_2, \cdots, C_N\}$ indicates different manufacturing system performance indicators. In the field of digital twin manufacturing, these indicators may represent key performance indicators such as production efficiency, resource consumption, environmental impact, etc. These indicators allow for optimization beyond a single objective, enabling the model to find the optimal solution in a larger dimensional space. In the whole optimization process, real-time optimization of the algorithm can be realized through real-time monitoring of these indicators, so as to dynamically adjust and optimize the manufacturing process. It further introduces the total power consumption of the workshop as the optimization scheduling objective. It can be specifically expressed as shown in Formula (8).

$$\min f = \min E_{total} \tag{8}$$

In Formula (8), $\min f$ represents the minimum objective function, and $\min E_{total}$ represents the minimum energy consumption optimization objective. The total workshop processing energy consumption can be expressed as shown in Formula (9).

$$E_{sum} = E_w + E_{IE} + E_A \tag{9}$$

In Formula (9), E_{sum} represents the total processing consumption, E_w represents the cutting power of the equipment, E_{IE} represents the idle standby power of the equipment, and E_A represents the additional loss power of the equipment. When processing each individual workpiece, a device needs to be selected for the processing process, which can be expressed in Formula (10).

$$\sum_{k=1}^{M_j} x_{ijk} = 1, (i = 1, 2, \cdots, w)(n-1, 2, \cdots, s) \tag{10}$$

In Formula (10), M_j represents the number of machine tools required for the j-th process, $x_{ijk} = 1$. When $x_{ijk} = 1$, it indicates that the jth process of the i-th workpiece can be completed on the k-th machine tool, while $x_{ijk} = 0$ indicates that machining cannot be carried out. However, when the same machine tool is in operation, it is not possible to process two workpieces simultaneously. Therefore, as shown in Formula (11), it specifically represents the processing start and end times of the workpiece.

$$PF(j,k,r) \le PS(j,k,r+1) \tag{11}$$

In Formula (11), $PF(j,k,r)$ represents the processing end time of the jth process of the r-th workpiece on the k-th machine tool, and $PS(j,k,r+1)$ represents the processing start time of the jth process of the r+1 workpiece on the k-th machine tool. For each individual workpiece, it must be processed according to the processing process flow and must go through w processes to complete the processing. As shown

in Formula (12).

$$\sum_{k=1}^{Mj} B_i^k = 1, (\forall i \in n, j \in s) \tag{12}$$

In Formula (12), M represents the number of devices that can be selected for use in the jth process of the workpiece, $B_i^k = 1$ indicates that workpiece i is processed on device K, and $B_i^k \neq 1$ indicates that workpiece i is not processed on device K. For multi-objective optimization problems, they can be represented as shown in Formula (13).

$$\begin{cases} \min(\&\max) F(x) = \left[f_1(x), f_2(x), \cdots, f_n(x) \right]^T \\ x \in \Omega \\ \Omega = \left\{ X \in R^n \middle| g_i(x) \le 0, i = 1, 2, \cdots, p \right\} \end{cases} \tag{13}$$

In Formula (13), the space Ω where X is located is the space where the feasible solution is located, while $F(x)$ represents the objective function of the space in which it is located. The core idea is to find the Pareto optimal solution. The NSGA-II, due to its strong anti-interference performance, performs well in finding the optimal solution for multi-objective optimization. The NSGA-II algorithm has difficulty in weighing different objectives, while Pareto optimization does not prioritize the optimization of a single objective. Instead, it seeks to find the best balance point among multiple objectives, aiming to identify solutions that improve one objective without significantly degrading the other. Pareto optimization can solve this problem in a targeted way, and at the same time, it also considers the global nature of the space, rather than limited to a specific target. Therefore, using Pareto optimization can also enhance the performance of NSGA-II in complex multi-objective optimization problems to a certain extent. Therefore, this algorithm was chosen for further research. The core idea of the NSGA-II is to use Pareto's sorting method in non-dominated space for solving. Pareto optimization can obtain a set of optimal solutions in the process and output them according to different levels, as shown in Fig. 4.

In Fig. 4, after selecting a more optimal solution, it is necessary to calculate the crowding degree. When the crowding distance is relatively large, the solution set around the optimal solution should appear more dispersed and sparse, to ensure the diversity of the population. Firstly, it assumes that the crowding degree of each point is n_d, and the initial crowding degree value is 0. For the optimal target point, by non-dominated sorting, it can be considered that the crowding degree of individual solutions on the boundary of the optimal solution is infinite. Finally, it calculates the crowding degree of other individuals within the population, as shown in Formula (14).

$$n_d = \sum_{j=1}^{m} \left(\left| f_j^{i+1} - f_j^{i-1} \right| \right) \tag{14}$$

In Formula (14), n_d represents crowding degree, f_j^{i+1} represents the function value of the j-th objective function at point $i+1$, f_j^{i-1} represents the function value of the j-th objective function at point $i-1$, and m represents the total number of functions, where $j \in 1, 2, \cdots, m$. For its elite strategy, the original NSGA-II, after Pareto optimization, would choose to retain as many outstanding individuals as possible and pass them on to the next generation. This strategy will to some extent reduce its genetic diversity, leading to local convergence after iteration. Therefore, the study optimizes its elite retention strategy. After Pareto optimization and congestion calculation, a portion of elite individuals are retained, and the remaining non-optimal individuals are uniformly selected for retention, as shown in Fig. 5.

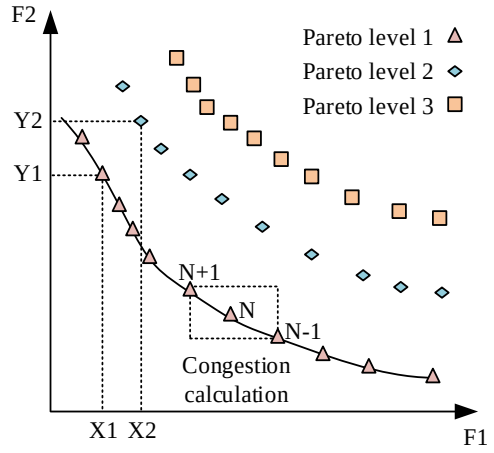

Fig. 4. Pareto optimization and congestion calculation diagram.

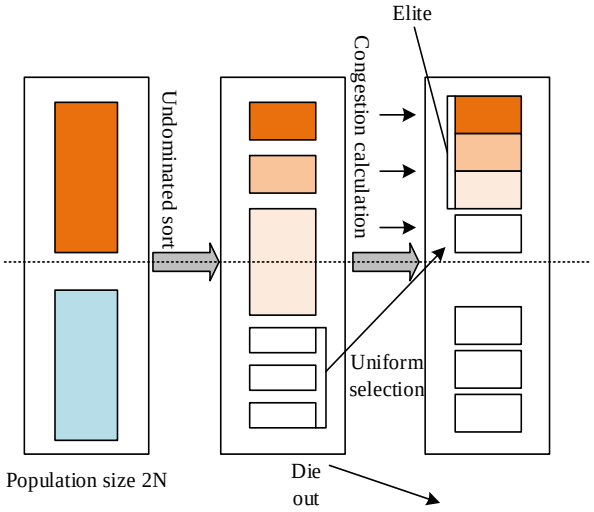

Fig. 5. Schematic diagram of optimizing elite retention strategy.

The NSGA-II has good performance in handling multi-objective optimization problems. However, to better adapt to the characteristics and needs of the digital twin manufacturing industry, its elite individual retention strategy has been optimized. On the basis of the original elite strategy, more selection criteria have been introduced to enhance diversity. Meanwhile, stricter control has been implemented

on the quality of solutions to ensure the retention of high-quality solutions. The implementation of this optimization strategy aims to improve the search performance of the algorithm, so that a more optimal solution set can be found under the same number of iterations. In addition, this also helps to improve the stability of the algorithm and reduce the randomness of the running results. Moreover, due to the retention of elite individuals, it can to some extent avoid the loss of high-quality solutions, thereby effectively improving the performance of the algorithm. Furthermore, this optimization strategy makes it more suitable for optimizing the digital twin manufacturing industry. Because there are a large number of multi-objective optimization problems, which often require considering multiple factors to find the optimal solution set. For this type of problem, the NSGA-II, after optimization, can better meet its solving needs, thereby improving the efficiency and effectiveness of the manufacturing system. The flowchart of the NSGA-II is shown in Fig. 6.

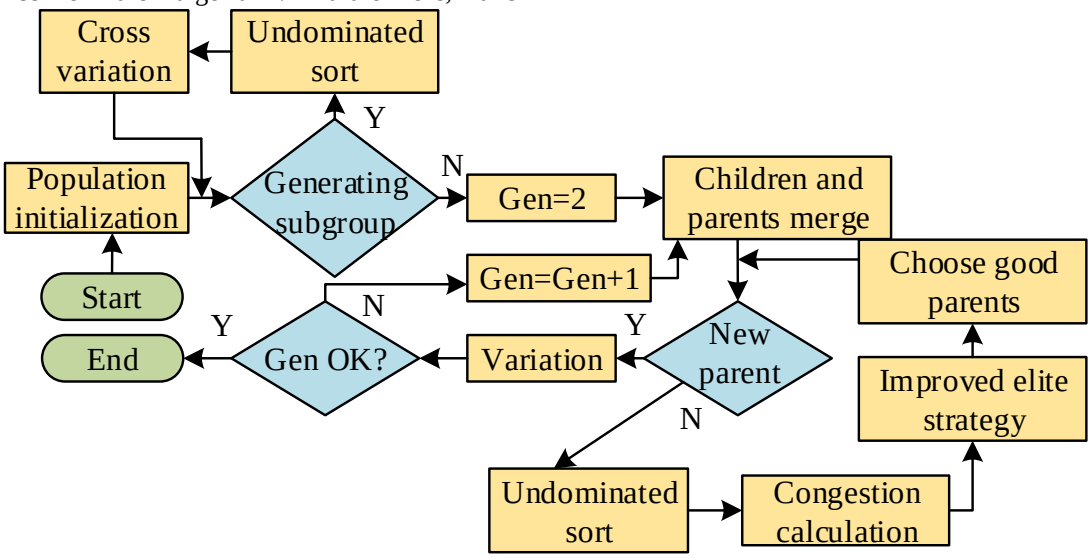

Fig. 6. Flowchart of NSGA-II.

IV. Performance Testing of NSGA-II in DTMS

To test the usability of the DTMS NSGA-II optimization algorithm (IM-NSGA-II) proposed by the research institute, this study chose to construct a virtual flexible job shop and conduct simulation experiments on its optimization ability. The software and hardware environment and parameter settings used in the study are shown in Table I. Through this configuration, the performance of the algorithm can be accurately and reliably evaluated, while also meeting the needs of daily development and testing. This study further introduces the same type of multi-objective optimization algorithm and compares it with the improved NSGA-II. It introduces the Multi Objective Evolutionary Algorithm on the ground of Decomposition (MOEA/D) and the Strength Pareto Evolutionary Algorithm 2 (SPEA2), respectively. The parameters of IM-NSGA-II are set as follows: Set the Population Size to 100, Crossover Probability to 0.9, Crossover Distribution Index to 20 and Mutation Distribution Index to 20. Selection is set to Binary tournament selection, Crossover is set to Simulated Binary Crossover and Polynomial Mutation. The parameters for MOEA/D are set as follows: The population Size is set to 100, the Neighborhood Size to 20%, the Weight Vector Update Interval to 50 generations, and the Crossover Probability to 1.0. The Crossover Distribution Index is set to 20, the Mutation Distribution Index to 20, and the Neighborhood Selection Probability to 0.9. The Replacement Strategy is set to adjacence-based replacement and the Decomposition Approach is set to Tchebycheff. SPEA2 parameters are set as follows: Population Size is 100, Archive Size is 100, Crossover Probability is 0.8, and Crossover Distribution Index is 20. The Mutation Distribution Index is set to 20, Selection is set to Binary tournament selection, Crossover is set to Simulated Binary Crossover, and Mutation is set to uniform variation. The maximum algebra for all algorithms is set to 120 generations.

Average	$5.924*10^{-6}$	$5.862*10^{-6}$	$2.652*10^{-4}$	$1.689*10^{-4}$	$4.931*10^{-3}$	$4.676*10^{-3}$

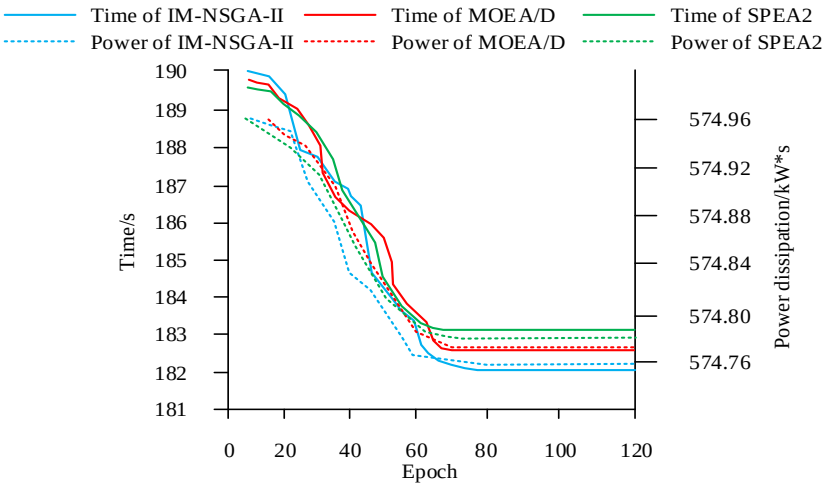

Fig. 7. The time and energy consumption of the three algorithms depend on the optimization performance of the iteration.

Firstly, the convergence performance of the three algorithms was tested, and the mean and standard deviation of the convergence performance of the three algorithms were tested. The test results are shown in Table II. Table II shows that the improved NSGA-II proposed by the research institute has better convergence performance in terms of mean and standard deviation. This proves that it has better convergence performance compared to MOEA/D and SPEA2, and can complete algorithm training at lower costs.

It tests the iterative performance of three algorithms and their impact on production time and energy consumption. The test results are shown in Fig. 7. Fig. 7 shows that the improved NSGA-II proposed by the research institute has the best optimization effect. It can reach its optimal state after about 60 iterations, and the optimized average production time is 181.9 seconds, saving 0.4 seconds and 1.1 seconds compared to MOEA/D and SPEA2, respectively. The optimal energy consumption performance after optimization is 574.75kW*s, which shows lower energy consumption compared to MOEA/D and SPEA2.

It compares and analyzes the Hypervolume (HV) indicators of three algorithms, and the analysis results are shown in Fig. 8. It shows that its HV indicator performs well, outperforming MOEA/D and SPEA2. The improved NSGA-II proposed by the research institute has better performance in multi-objective optimization problems, with better diversity and convergence compared to MOEA/D and SPEA2 algorithms.

The other conditions are kept the same, and the time optimization performance and energy consumption optimization performance of the three algorithms under multiple devices are tested. The test results are shown in Fig. 9. Fig. 9 shows that the optimization effect of the NSGA-II proposed by the research institute remains optimal under

different device numbers. Compared to MOEA/D and SPEA2, its production time optimization effect for different quantities of equipment is 11.12% -21.37% higher, respectively. Compared to MOEA/D and SPEA2, its power optimization effect is 2.14% -6.89% ahead, respectively.

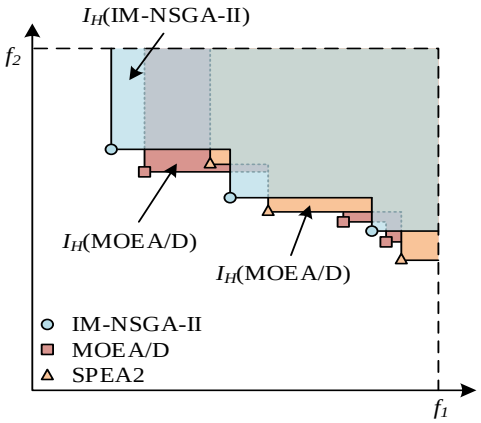

Fig. 8. HV index comparison results of three algorithms.

It sets up the same workpiece with a total of five process flows, and the number of optimization equipment faced by the three algorithms is fixed. The optimization effects of the three algorithms are compared, and the experimental results are shown in Table III. It shows that the optimization time of the improved NSGA-II proposed by the research institute reached 713.5 seconds. The optimization time of MOEA/D algorithm is 887.3s, and the optimization time of SPEA2 is 893.3s. Compared to MOEA/D and SPEA2, the production time of the improved algorithm has been reduced by 173.8s and 179.8s, respectively. The total power consumption of the improved optimization model is 2883.7kW*s, which is reduced by 32.0kW*s and 45.5kW*s compared to MOEA/D and SPEA2, respectively. The improved NSGA-II algorithm proposed by the research institute can reduce the time spent on production by the manufacturing system, reduce the total power consumption of the system, improve the performance of the manufacturing system, enable better simulation of the workshop, and achieve dynamic scheduling and energy efficiency optimization of the workshop. Due to the fact that the optimization time at this time did not consider the parallel processing of tasks, but simply summarized the processing time of different tasks, the result value was too high. In the process of scheduling optimization, different optional equipment groups are allocated based on the overall processing time, thereby reducing equipment processing time and optimizing workshop processing energy consumption. In order to better reflect the importance of the improved NSGA-II algorithm, a Gantt chart was drawn to reflect its final optimization results. The Gantt chart is shown in Fig. 10.

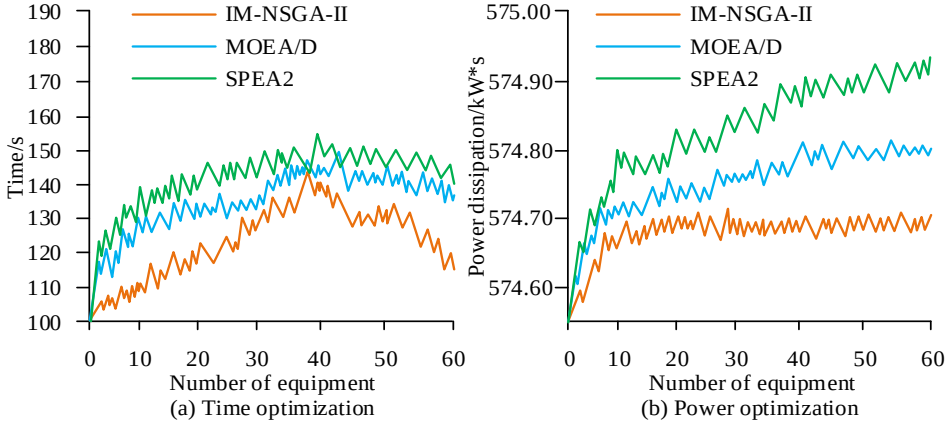

Fig. 9. Optimization performance comparison of three algorithms under different number of devices.

TABLE III. COMPARISON OF ACTUAL INDUSTRIAL OPTIMIZATION PERFORMANCE OF THREE ALGORITHMS

Process flow	NSGA-II		MOEA/D		SPEA2	
	Time/s	Power /kW*s	Time/s	Power /kW*s	Time/s	Power /kW*s
1	133.7	576.2	167.9	581.9	172.5	586.4
2	144.8	577.1	179.8	584.6	181.3	585.2
3	147.2	576.8	183.4	582.4	185.2	586.3
4	166.2	577.3	189.7	583.9	176.9	587.1
5	121.6	576.3	166.5	582.9	177.4	584.2
Total	713.5	2883.7	887.3	2915.7	893.3	2929.2

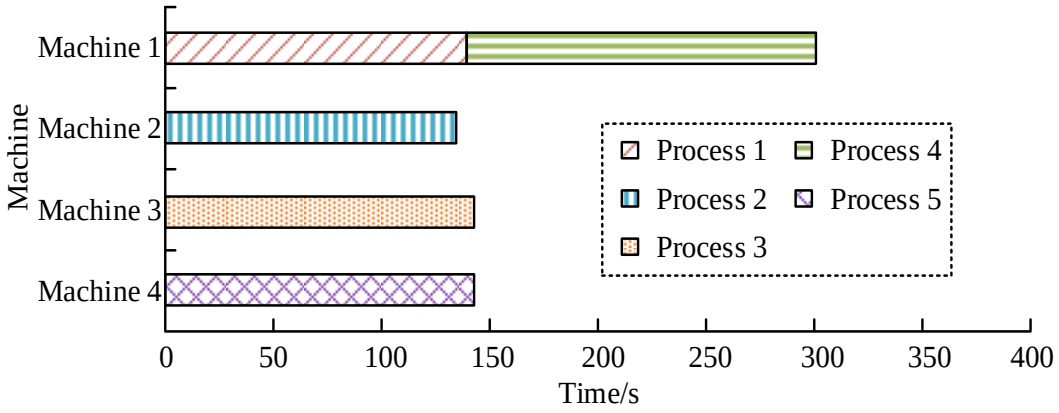

Fig. 10. Gantt chart of process flow.

From Fig. 10, it can be seen that after merging the process flow, the final optimization time of the improved NSGA-II algorithm is 299.9s. Compared to the previous simple time addition, the value decreased by 413.6 seconds. It can be seen that the improved NSGA-II algorithm can enhance the performance of the digital twin manufacturing system, and can achieve dynamic scheduling and energy efficiency optimization in the real workshop more quickly in the system.

V. Conclusion

With the development of Industry 4.0, the intelligence and real-time of industry have become a trend. However, further optimization of industry and manufacturing has become a challenging issue, and DTMSs have proposed solutions for this. On the ground of the improved NSGA-II, targeted improvements were made to its elite retention strategy to improve its diversity. On the ground of this algorithm, a multi-objective optimization approach was adopted to optimize production time and energy consumption. The experiment showcased that the optimization method on the ground of NSGA-II has better convergence performance compared to MOEA/D and SPEA2. The optimized average production time was 181.9 seconds, which saved 0.4 seconds and 1.1 seconds compared to MOEA/D and SPEA2, respectively. The optimal energy consumption performance after optimization was 574.75kW*s, which showed lower energy consumption compared to MOEA/D and SPEA2. Its HV indicators performed well with better diversity. Compared to MOEA/D and SPEA2, the production time optimization effect for different numbers of devices was 11.12%-21.37% higher, and the power consumption optimization effect was 2.14%-6.89% higher. This study provided a new method for optimizing DTMSs by improving the elite retention strategy of the NSGA-II, which can provide more effective methods for system optimization in the manufacturing industry. However, this method did not take into account force majeure factors such as equipment failures and fluctuations in raw material prices in actual production and manufacturing. In future research, in-depth research should be conducted on this issue to improve the applicability and practicality of the optimization method.

Keyword Acquisition for Language Composition Based on TextRank Automatic Summarization Approach

Yan Jiang*, Chunlin Xiang, Lingtong Li
Department of Primary Education, Chongqing Preschool Education College, Chongqing, 404047, China

***Abstract*—It is important to extract keywords from text quickly and accurately for composition analysis, but the accuracy of traditional keyword acquisition models is not high. Therefore, in this study, the Best Match 25 algorithm was first used to preprocess the compositions and evaluate the similarity between sentences. Then, TextRank was used to extract the abstract, construct segmentation and named entity model, and finally verify the research content. The results show that in the performance test, the Best Match 25 similarity algorithm has higher accuracy, recall rate and F1 value, the average running time is only 2182ms, and has the largest receiver working characteristic curve area, which is significantly higher than other models, reaching 0.954. The accuracy of TextRank algorithm is above 90%, the average accuracy of 100 text analysis is 94.23%, the average recall rate and F1 value are 96.67% and 95.85%, respectively. In comparison of the application of the four methods, the research model shows obvious advantages, the average keyword coverage rate is 94.54%, the average processing time of 16 texts is 11.29 seconds, and the average 24-hour memory usage is only 15.67%, which is lower than the other three methods. The experimental results confirm the superiority of the model in terms of keyword extraction accuracy. This research not only provides a new technical tool for language composition teaching and evaluation, but also provides a new idea and method for keyword extraction research in the field of natural language processing.**

Keywords*—Language composition; keywords; best match 25; textrank; digests

I. INTRODUCTION

In today's digital era, natural language processing (NLP) technology plays an increasingly important role in the field of text analysis. Keyword extraction, as a basic text analysis tool, is important for understanding and processing large amounts of text data [1]. Especially in the field of education, efficient and accurate keyword extraction has great application value for the analysis and evaluation of language composition (LC). Traditional keyword extraction methods, such as term frequency-inverse document frequency (TF-IDF), latent delicacy allocation (LDA), graph-based lexical rank (LexRank) algorithms, have been applied in several fields, but still have limitations in efficiency and accuracy in specific scenarios [2-3]. TextRank's automatic summarization (AS) method extracts key sentences from text in an unsupervised learning manner in a concise and efficient way, which can be achieved without a large amount of labeled data. This algorithm has good adaptability and scalability, can be applied to texts in different domains, and is easily integrated with other NLP techniques [4]. As a graph-based algorithm, TextRank also reveals the text structure, increasing the depth of analysis and content level understanding. In view of this, research has focused on exploring LC keyword extraction techniques based on the TextRank AS method [5]. The goal of the study is to improve the efficiency and accuracy of LC keyword extraction by optimizing and applying the TextRank algorithm. The significance of the study is as follows: first, TextRank-based AS not only improves the efficiency of the keyword extraction process and reduces the workload of teachers, but also enhances the objectivity and consistency of the evaluation. Second, the study not only expands the application scope of the algorithm in Chinese text processing, but also promotes the innovative application of language processing technology in the field of education, and provides a new perspective for practical problem solving of NLP technology in language education. In addition, with the wide application of artificial intelligence in various industries, AI-assisted language teaching and assessment is becoming an emerging trend. By optimizing the keyword extraction process, this study lays the foundation for building a smarter educational assistance system, which further promotes the development of AI in the field of educational technology. In summary, this study has far-reaching research significance in enhancing teaching efficiency, promoting technological innovation, and leading the development of educational technology. The study is divided into four main parts, the first of which is a detailed description of relevant studies in recent years. In the second part, the main methods of the experiment are firstly introduced. The third part is to verify the validity and reliability of the research model through experimental design and data analysis. The fourth part is to summarize and prospect the research.

In the study of AS for text, K. E. Dewi and N. I. Widiastuti developed an AS model for Indonesian text that aims to reduce the number of sentences while retaining key information. The model utilized three summarization methods: extractive, abstractive, and hybrid. Extractive selected key sentences, abstract reconstructed new sentences to describe the content, while hybrid combines the advantages of both. The system design consisted of a pre-processing (sentence segmentation, tokenization, co-reference parsing, deactivation, feature extraction) and a processing phase (selecting and arranging important sentences and words to form a summary). The model was particularly suitable for document input and adaptation to long text and multi-document input is a direction

for further research [6]. H. Aliakbarpour et al. proposed a new model of abstract summarization combining convolutional neural networks with long and short-term memory and incorporating the auxiliary attention mechanism of an encoder to enhance the saliency and fluency of the summaries. Tested on CNNDaily Mail and DUC-2004 datasets, the model outperformed the benchmark model in terms of ROUGE score, saliency and readability [7]. Y. Huang et al. proposed a novel elemental graph augmented abstract summarization model for the challenges of legal opinion journalism AS. The model utilized pre-trained language model reinforcement sequences and structural encoders to extract key information through a network of structural graphs and graph transformers to effectively guide the decoding process. Tests on a legal opinion news corpus revealed that the model outperforms other baselines in terms of ROUGE and BERT scores, and its effectiveness was proven by manual evaluation [8]. A. Zagar and M. Robnik-Sikonja presented a cross-language AS approach to summarizing Slovenian news articles using a pre-trained English summary model. To address decoder limitations, additional language models were introduced for target language text evaluation. The cross-language model was demonstrated to be qualitatively similar to the target language-specific model through automatic and manual evaluation, but occasionally misleading or absurd content appeared [9]. E. Inan proposed an entity-based text summarization method that recognizes named entities and constructs dependency graphs from a pre-trained language model. A reconciliation centrality algorithm was applied to summarize the entity ordering, outperforming the unsupervised learning baseline and approaching the state-of-the-art end-to-end model [10].

In summary, the recent literature in the field of automatic text processing, especially in keyword extraction and summary generation, has demonstrated several notable advances. Researchers have developed different approaches in order to accommodate multiple languages and text formats. For example, Dewi and Widiastuti developed a model containing multiple summarization techniques specifically for Indonesian text to accommodate long texts and complex documents. In the widely studied TextRank algorithm, Qiu and Zheng enhanced its performance in keyword extraction through tolerance rough sets, while Hernawan et al. improved the accuracy of the algorithm in sentence importance assessment using BM25. Huang and Xie improved the accuracy of keyword extraction for patented text by combining the TextRank algorithm with a priori knowledge networks. Further, Aliakbarpour et al. combined a convolutional neural network and a long and short-term memory network while incorporating an attention mechanism to enhance the quality of text summarization. The elemental graph augmented abstract summarization model proposed by Huang et al. on the other hand, demonstrates superiority in handling legal opinion news. Given the potential application of TextRank in automatic keyword extraction, the study proposes to use this algorithm to extract keywords for LC. It is expected to further improve the algorithm's ability and accuracy in extracting key contents for Chinese essays by improving TextRank. This will not only provide support for automatic scoring of compositions, but also help educators to have a more comprehensive understanding of students' writing skills and content focus, so as to provide more effective guidance and feedback.

II. Language Keyword Acquisition Model Based on TextRank Algorithm

The study, in order to construct a language keyword acquisition model with higher accuracy, first preprocesses the LC by BM25 similarity algorithm, and the query calculates the similarity between the LC sentences. Then the automatic digest results of the composition corpus are obtained based on TextRank algorithm. After that, the construction of participle model and named entity model is carried out. Finally, the description related to dictionary design and keyword acquisition strategy is unfolded.

A. Abstract Acquisition Based on BM25 Similarity Algorithm with Textrank Algorithm

In the study of keyword acquisition, Best Match 25 (BM25) similarity algorithm is an algorithm used in information retrieval and text mining to measure the relevance between a query and a document [11]. Its advantages include effectiveness against long documents, ability to handle documents of different lengths, automatic adjustment of the weights of query terms, ability to handle scarce terms, and efficiency in large text collections [12]. The BM25 algorithm has been widely used in the field of information retrieval, and is able to more accurately assess the relevance between documents and queries, and therefore has significant practical value in large-scale document retrieval and search engines [13]. The general formula of BM25 similarity algorithm is shown in Eq. (1).

$$Score(Q,d)=\sum_{i}^{n}W_i.R(q_i,d) \tag{1}$$

In Eq. (1), Q denotes the sentence to be retrieved, q_i denotes the morpheme obtained from the sentence, and W_i denotes the weight of q_i. d denotes the target sentence, and R denotes the relevance score of q_i and d. When q_i occurs more times in the sentence, it means that the similarity weight it represents decreases, and in order to avoid the result error caused by this situation, there exists an expression as shown in Eq. (2).

$$IDF(q_i)=\log\frac{N-n(q_i)+0.5}{n(q_i)+0.5} \tag{2}$$

In Eq. (2), N denotes the total number of sentences and $n(q_i)$ denotes the number of q_i sentences included. The formula for similarity is shown in Eq. (3).

$$R(q_i,d)=\frac{f_i.(k_1+1)}{f_i+K}.\frac{qf_i.(k_2+1)}{qf_i+k_2} \tag{3}$$

In Eq. (3), k_1 and k_2 denote the conditioning factor constants, and qf_i denotes the number of times the word appears in the retrieval process [14]. If the number of times

the word appears in the process of retrieval is 1, the formula can be further simplified, as shown in Eq. (4) [15].

$$R(q_i, d) = \frac{f_i.(k_1+1)}{f_i + K} \quad (4)$$

In Eq. (4), f_i denotes the frequency of occurrence of words, and the expression of K is shown in Eq. (5).

$$K = k_1.(1-b+b.\frac{dl}{avgdl}) \quad (5)$$

In Eq. (5), dl denotes the length of the sentence, then $avgdl$ denotes the average length of all sentences, and b is a constant and represents the moderating factor [16-17]. Querying the correlation between texts through the BM25 similarity algorithm mitigates the interference encountered in calculating the similarity. Therefore, the study used the BM25 similarity algorithm to preprocess the LC, after which the keywords and abstracts were obtained by Textrank algorithm. TextRank algorithm is a graph-based text summarization method that determines keywords and sentences in text by analyzing the interconnections between words in the text. The algorithm first represents the text as a node graph, then calculates the weights of the nodes through the connection relationship between the nodes, and uses iterative computation to gradually update the weights of the nodes, and finally determines the keywords and sentences. The advantages of the TextRank algorithm include a structured representation of the text, the ability to capture semantic associations between words, applicability to multilingual texts, no restriction on the length of the text, the ability to handle unsupervised learning, and it has proven its effectiveness and usefulness in the field of text summarization and keyword acquisition [18]. Therefore, the TextRank algorithm has important application prospects in automatic text summarization and keyword acquisition tasks. The operation principle of Textrank algorithm is shown in Fig. 1.

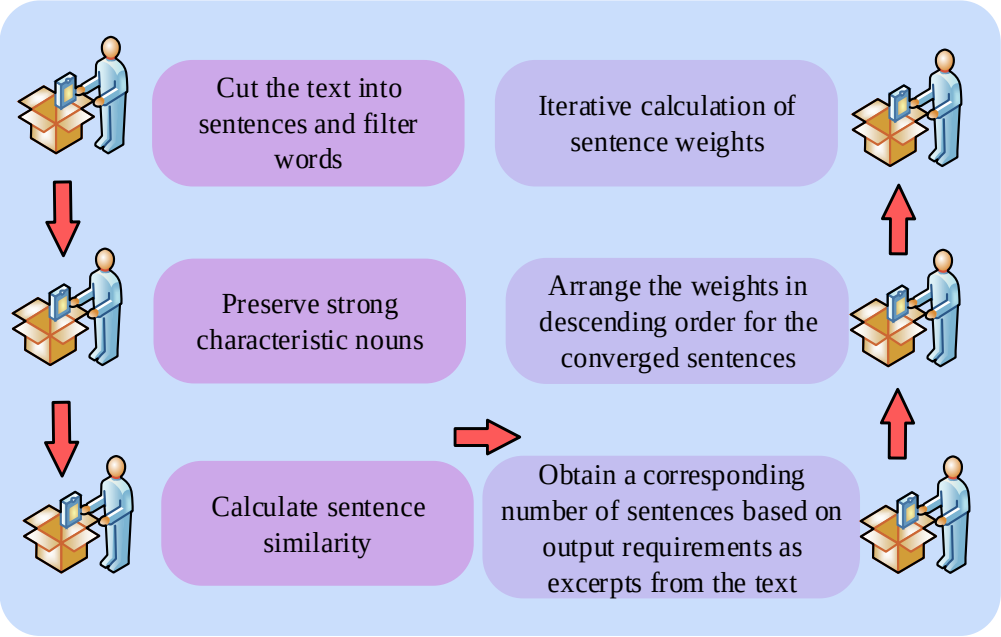

Fig. 1. Operating principle of textrank algorithm.

In Fig. 1, firstly, the text is segmented into sentences and partitioned, while filtering out the stop words and retaining the characteristic words such as nouns and adjectives. Secondly, the similarity between sentences is calculated, the graph structure is constructed, the sentences are taken as nodes on the graph, and the value of the edges is the similarity between the sentences. Then, the weight of each sentence node is determined by iterative calculation. Finally, the descending order is sorted according to the weights, and the sentence with the highest weight is selected as the digest sentence. Textrank algorithm is divided into two parts: calculating similarity and sorting, in the calculation of similarity based on the idea of PangRank to build a graph, based on the nodes of the graph to calculate the similarity between sentences as shown in Eq. (6).

$$Score(V_i) = (1-d_1) + d_1 * \sum (W_{ji} / O_j) \quad (6)$$

In Eq. (6), d_1 denotes the damping coefficient, which usually takes the value of 0.85, meaning the probability of going from one graph node to another, with the purpose of avoiding the node weight values in the fringes from being assigned to 0. W_{ji} denotes the weight of node V_i pointing to node V_j, and O_j denotes the out-degree (i.e., number of edges connected out) of node V_j. $\sum$ denotes the cumulative summation operation for all nodes V_j pointing to node V_i C [19].

B. *Construction of the Disambiguation Model, Named Entity Model*

After the summarization process, the composition

information has removed most of the redundant data, and then the keywords can be obtained from it. Firstly, the coverage of keywords should be set, and the model of word splitting is constructed from the keyword acquisition and elaborated on the basis of named entity model and self-built lexicon. After that, the strategy of LC keyword acquisition is proposed. Segmentation model is a model used in NLP to segment a continuous text sequence into meaningful units. In Chinese text processing, the role of the participle model is particularly significant, because there is no obvious word separator symbol like space in Chinese. Therefore, word segmentation modeling applies various techniques and methods, such as rule-based segmentation, lexicon-based segmentation, and statistical and machine learning-based segmentation [20]. The research adopts dictionary-based participle modeling, and the N-shortest path participle algorithm is one of the popular algorithms. N-Shortest Path Segmentation Algorithm is a Chinese segmentation algorithm based on graph theory and dynamic programming, compared with the traditional shortest path segmentation algorithm, it can better deal with problems such as ambiguity and unregistered words, and its characteristics are more suitable for discriminative named entity recognition, the operation principle of N-Shortest Path Algorithm is shown in the schematic diagram in Fig. 2.

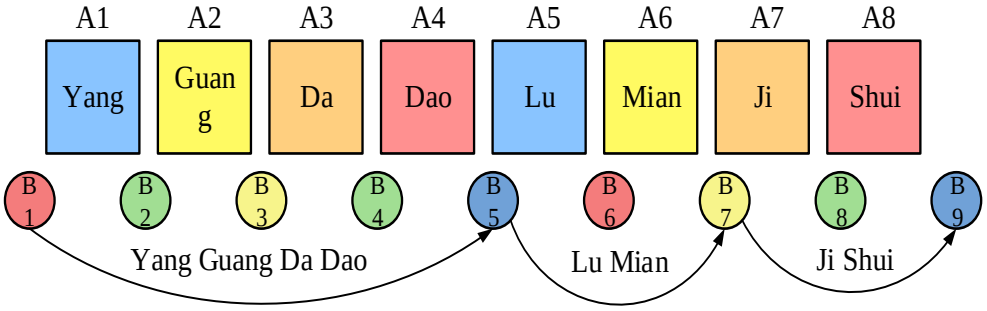

Fig. 2. Schematic diagram of the operating principle of the N-shortest path algorithm.

Fig. 2 shows an example subsection of the N-shortest path algorithm in operation, where A denotes each Chinese character present in the sentence and B denotes the node in the graph. This sentence demonstrates the ideal path: "Yang guang da dao/Lu mian/Ji shui" after the step of disambiguation, i.e., B1 to B5, B5 to B7, and B7 to B9 are recognized as reasonable paths. Meanwhile, words such as "Dao lu" and "Mian ji" also represent a path, and the algorithm first finds the shortest N paths of the sentence, and then calculates the most probable result based on the shortest paths. If noise interference is encountered, the word cut sign is lost, resulting in a situation where the output is a Chinese character string A. The existence of the formula is shown in Eq. (7).

$$P(W \mid C) = P(W) * \frac{P(C \mid W)}{P(C)} \tag{7}$$

In Eq. (7), W denotes the result sought after the improvement, and P denotes the probability that the partition result is divided correctly. $P(W \mid C)$ denotes the probability that the word string becomes a string of Chinese characters, and the value of $P(C)$ is kept constant. On the basis of maintaining the independence between sentences and introducing the unitary processing model in the n-gram model, the existence formula is shown in Eq. (8).

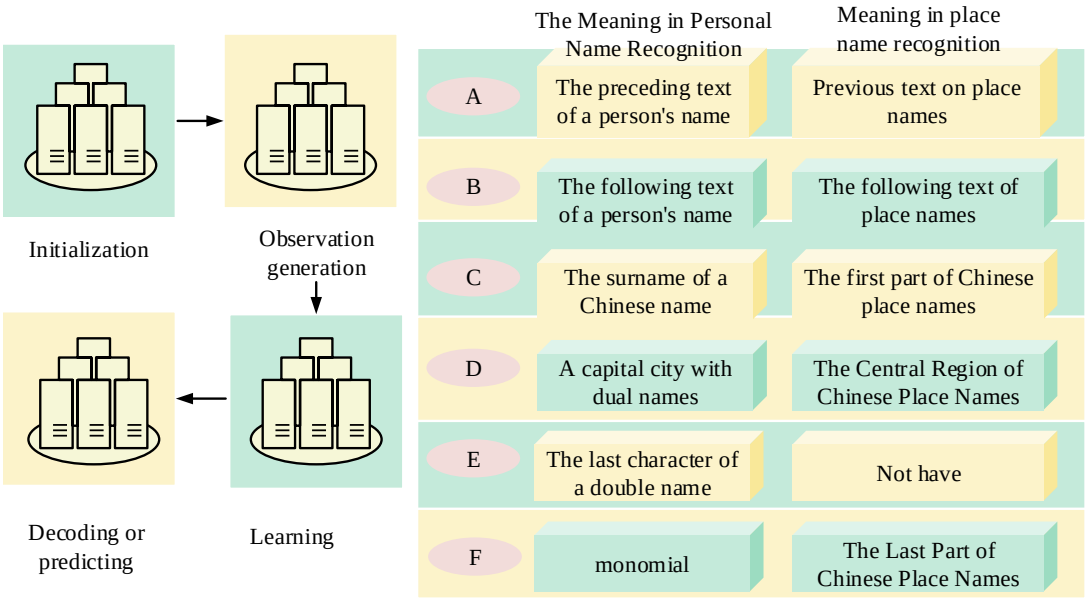
$$P(W) = \prod_{i=1}^{m} p(W_i) \tag{8}$$

In Eq. (8), it is assumed that each word occurs with equal probability and all are $p(W_i)$, where m denotes the number of words in the sentence. To summarize, the operation of the N-shortest path algorithm is mainly divided into three steps: in the first step, the sentence to be split into words is constructed into a directed graph, in which each node represents a word or words, and the edges between the nodes indicate the transfer relationship between words or words, with corresponding weights on each edge. In the second step, all possible paths in the graph are traversed and the weights of the paths are calculated using dynamic programming. The optimal n paths are found by recording the predecessor nodes of each node and maintaining a priority queue of path lengths. In the third step, based on the obtained optimal paths, path merging is performed to obtain the final disambiguation result. After the construction of the participle model, a cascading hidden Markov model (HMM) based named entity recognition is proposed for the processed corpus. HMM is a probabilistic model for modeling time-series data and is commonly used in speech recognition, NLP and bioinformatics [21-22]. It consists of a hidden Markov chain and a sequence of observations, where the hidden Markov chain represents the sequence of states of the system and the sequence of observations represents the sequence of observations dependent on each state [23]. The principle of operation of the HMM model with the labeling of person and place name roles is shown in Fig. 3.

Fig. 3(a) illustrates the operational steps of the HMM model, where the set of hidden states, the set of observations, the initial state probability distribution, and the state transfer probability distribution are first determined and used to generate the sequence of hidden states. Then the probability distributions of the observations are generated based on the hidden states to generate the corresponding observation sequences [24]. After that, the model parameters, including the initial state probability distribution, the state transfer probability distribution, and the observation generation probability distribution, are learned from the known observation sequences. Finally, with the given model and

observation sequences, the Viterbi algorithm or forward-backward algorithm is utilized to decode or predict the most probable hidden state sequences [25-26]. Fig. 3(b) shows the role labeling of the model for the case of role labeling of person and place names. In the HMM model, for the case that the words do not appear in the existing lexicon, the method of calculating the output probability based on the role-word generation model is proposed, whose expression is shown in Eq. (9).

$$P(w \mid c) = \prod_{j=0}^{k} p(w_{p+j} \mid r_{p+j}) p(r_{p+j} \mid r_{p+j-1}) \quad (9)$$



(a) Run steps

(b) Role labeling of names and place names

Fig. 3. Operating principle of HMM model and labeling of person and place name roles.

In Eq. (9), w denotes a word that is not in the dictionary, r denotes a collection of roles. c denotes the category of the entity, $p(r_{p+j} \mid r_{p+j-1})$ denotes the transfer probability between the previous and previous roles, and $p(w_{p+j} \mid r_{p+j})$ denotes the probability that w occurs in r. The HMM model can be used to identify the important names and places in the LC corpus. The HMM model is able to effectively identify important names of people and places in the LC corpus, which can be used to assist in the acquisition of keywords for compositions [27-28].

C. Keyword Acquisition Strategy

The study uses the open source natural language framework HanLP to implement the use of entity recognition and segmentation, in order to improve the accuracy of keyword acquisition, the study uses a customized dictionary, the self-built dictionary for characters and scenery is shown in Fig. 4.

In Fig. 4, in the recognition of characters, they are categorized with the help of different types of nouns. And in the recognition of scenery, it is defined with the help of affixes. After that, the language corpus is analyzed to obtain the keywords, which have a restricted vocabulary of five, and classified for their connotations: article type, core, and key description." Article type" usually refers to the genre of the essay, such as argumentative essay, narrative essay, expository essay, application essay, etc., each of which has different writing characteristics and structures and is used to express different purposes and emotions." Core" usually refers to the theme or center of the essay, which is the main idea or argument that the writer wants to express, and it represents the focus and core of the essay [29-30]. "Key description" refers to the part of the composition that describes the core entities in detail, which may include the description of things, the characterization of characters, the narration of events, and the development of the relevant plot, etc. These descriptions usually occupy an important place in the composition to highlight the central idea and content of the essay. These descriptions usually occupy an important position in the composition to highlight the central idea and content of the essay. The process of keyword acquisition is shown in Fig. 5.

In Fig. 5, the recognition of named entities is performed based on the coarsely-scored segmentation results, which result in words being labeled lexically. Then the comprehensive deactivation word list adopted for eliminating deactivated words aims to eliminate words that are commonly used in LC and to reduce the interference with keyword acquisition. This is followed by entity statistical analysis and finally keyword acquisition. Among them, the analysis process of word lexicality is shown in Fig. 6.

In the presentation in Fig. 6, a two-stage process for core entity acquisition can be seen. First, the system uses standard named entity recognition techniques to identify entities. Next, in the case that the lexical label of an entity is a person's name or a place's name, the system checks whether the counter of

the corresponding category has reached the upper limit of two entities. If the category to which a word belongs already has two entities, the word will not be processed further. If the upper limit has not been reached, the word is added to the final result set. This process ensures that entities are effectively identified and categorized, while limiting the number of entities in each category, keeping the result set streamlined and relevant. If an analyzed term is not included in the self-constructed lexicon, it will be included in the evaluation of the key descriptions, and the description rules are shown in Fig. 7.

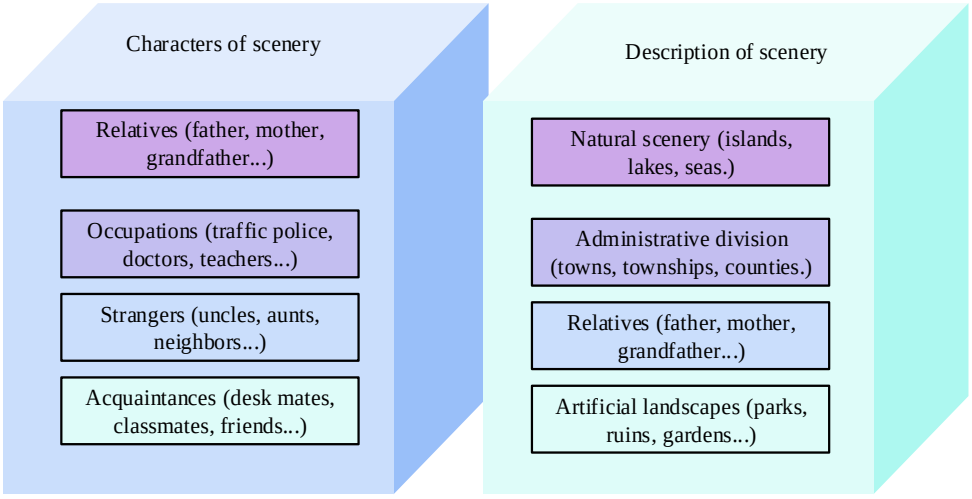


Fig. 4. Self-built dictionary of characters and scenery.

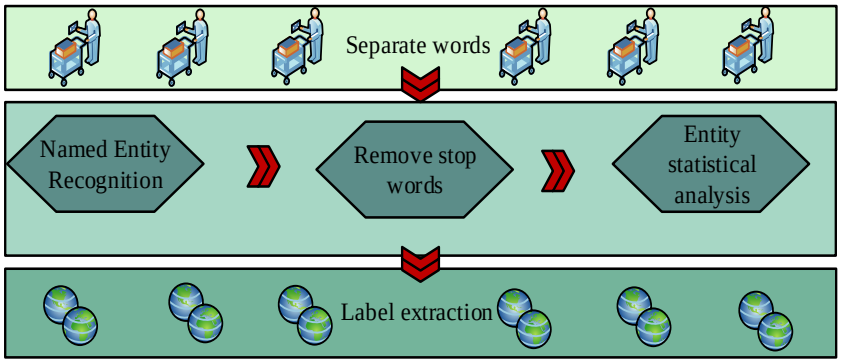

Fig. 5. Keyword acquisition process.

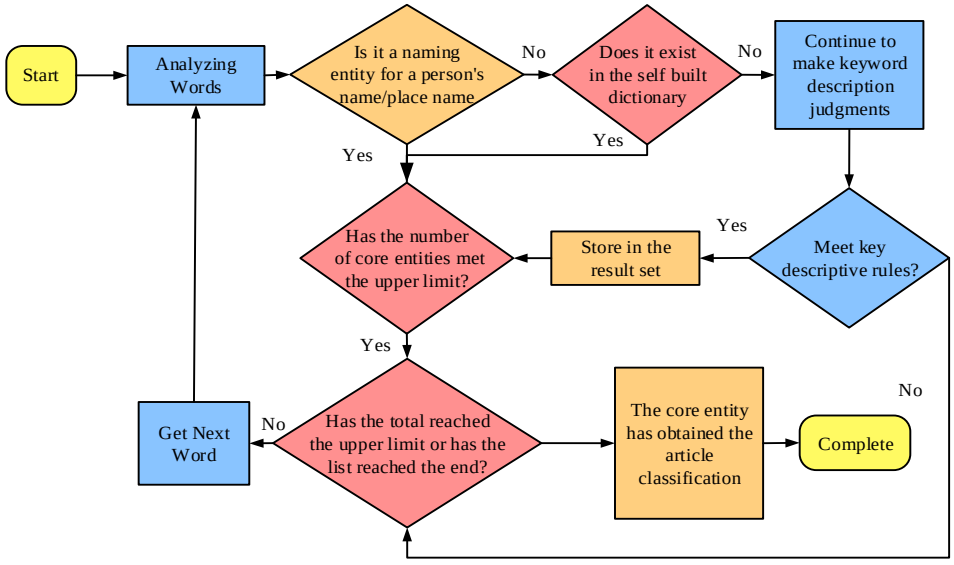

Fig. 6. Analysis process of word parts of speech.

Based on the rules in Fig. 7, the key description section is obtained, and finally, the system performs a comprehensive analysis of the word list. Once the number of keywords extracted from the list meets the requirements, or when the end of the word-phrase list is read, the word-list analysis is completed. In addition, the type keywords for the articles were determined by comparing the weights of the two main types of named entities, person names and place names. If names were given more weight than places, the article was categorized as a "characterization". If names of places were given more weight, the article was categorized as "description of scenery". In the case of equal weight, both keywords will be added to the result set. Through this series of steps, the keyword acquisition of elementary school essays can be successfully completed.

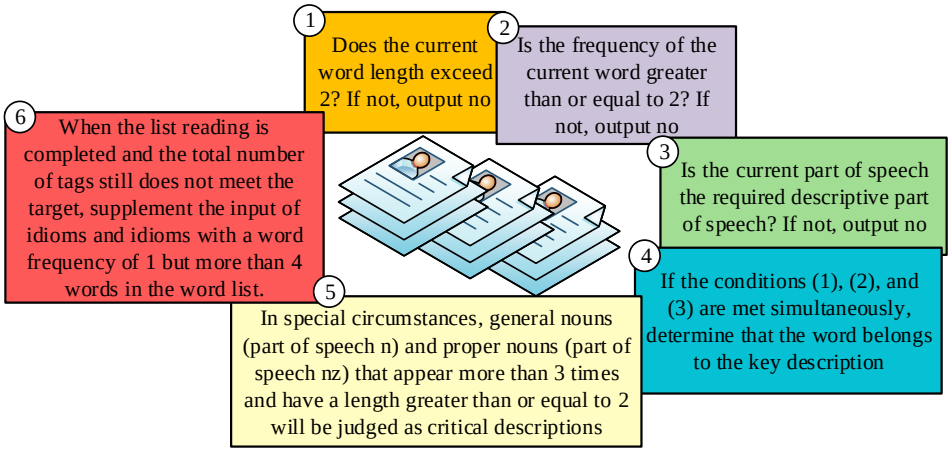

Fig. 7. Key description rules.

III. Results of the Language Keyword Acquisition Model based on TextRank Algorithm

In order to verify the superiority of the research constructed model, the similarity algorithm and TextRank algorithm chosen for the research are tested for performance and application comparison study, and then analyzed for the actual application of the research constructed model and compared with other methods in the process.

A. Comparison Results of Similarity Algorithms

In order to reduce the experimental error, the experiment was analyzed and studied using the same device with Intel Xeon W-2295 CPU, 16G RAM, 100G hard disk memory, Red Hat Enterprise Linux 8 as the operating system, and Python 3.9 as the programming language. The dataset test was obtained from the LC library of students from an elementary school and a secondary school. To test the BM25 similarity algorithm chosen for the study, comparison methods were chosen: classical similarity, edit distance, Word2Vec. these methods were compared with recall-orientated understudy for gisting evaluation (ROUGE) of the BM25 similarity algorithm of the study method. And the average of 100 texts analyzed is shown in Fig. 8.

In Fig. 8, ROUGE is scored in three dimensions, ROUGE-N, ROUGE-L, and ROUGE-W. Three evaluation metrics are selected in each dimension: accuracy, recall with F1 value. For ROUGE-N, Word2Vec has the lowest evaluated values of accuracy, recall and F1 value, and BM25 similarity algorithm with edit distance has comparable evaluated values of accuracy, recall and F1 value. For ROUGE-N, Word2Vec still performs the worst, and the BM25 similarity algorithm with edit distance has a higher recall and a smaller difference in accuracy from the F1 value. For the dimension ROUGE-W the evaluation values are similar to the first two dimensions. It is proved that BM25 algorithm has better performance than other algorithms in various dimensions of ROUGE scoring, especially in the recall rate advantage is crucial to ensure the integrity of automatic summarization. In addition, BM25 algorithm also has better performance on ROUGE score than the conclusion in study [7]. Continuing with the comparison of the processing time of these four methods, it is shown in Fig. 9.

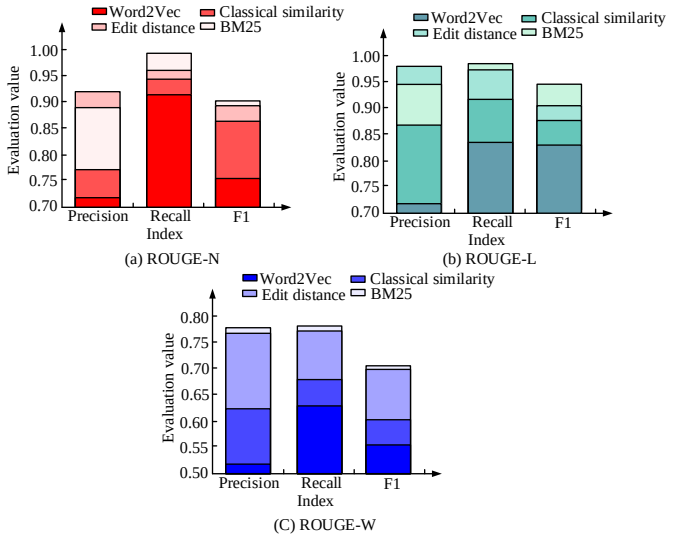

Fig. 8. Rouge scoring results of four methods.

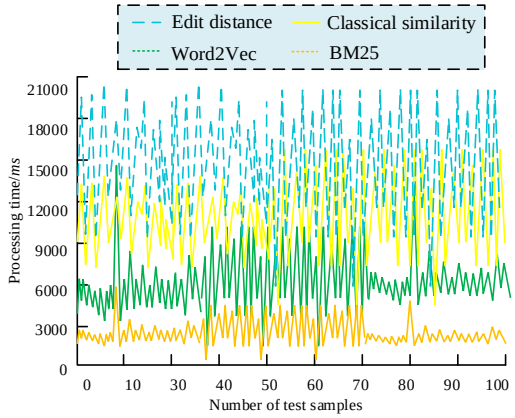

Fig. 9. Comparison of processing time of four methods.

In Fig. 9, in 100 runs, the processing time of the research method is found to be significantly shorter, with an average of only 2182 ms. the average processing time of Word2Vec and classical similarity is 6192 ms and 18065 ms, respectively. The edit distance method mentioned in Fig. 8, although the accuracy, recall and F1 value are not much different from that of the research method, the processing time of the research method is significantly higher, with an average of 20972ms. This means that the processing time of the edit distance method is 8.61 times higher than that of the research method, indicating that the research method has a significant advantage in efficiency. Processing time is one of the key indicators of the usefulness of the algorithm, and the BM25 algorithm shows a shorter processing time, indicating a significant efficiency advantage, suitable for real-time or large-scale text processing tasks.

B. Application of a Language Keyword Acquisition Model Based on Textrank Algorithm

To verify the superiority of TextRank algorithm, it is compared with TF-IDF, LDA and LexRank algorithms. In terms of parameter configuration, the research set 0.90 momentum, 0.0004 attenuation, and planned to conduct 300 rounds of training. The initial learning rate is set to 0.01, and the cosine learning rate strategy is adopted, and the learning rate will be adjusted to 0.001 as the training progresses. Selecting the indicator Receiver operating characteristic curve (ROC) curve, the text in the dataset is tested and analyzed several times, and the comparison results after 50 times are shown in Fig. 10.

In Fig. 10, the area under the ROC curve (AUC) is between 0.1 and 1, providing a direct way to measure the accuracy of the model, and an increase in the AUC value means that the model's predictive accuracy increases. In this figure, the TextRank algorithm has the largest AUC value, which is significantly higher than the other models, at 0.954, very close to 1. This is followed by the TF-IDF algorithm, which also has a higher accuracy with an AUC value of 0.842, and the rest of the models have an AUC value of around 0.70. AUC is an important index to measure the prediction accuracy of the model, and the AUC value of the TextRank algorithm is the largest, close to 1, indicating that its prediction accuracy in the automatic summary task is very high. The results illustrate the superiority of the accuracy of the research method, and continue to compare it with the three methods mentioned above by analyzing 100 texts, and the results of the comparison of accuracy, recall, and F1 value are shown in Fig. 11.

In Fig. 11 (a), the accuracy curve of LexRank has the largest fluctuation, the accuracy is not up to 75%, the range of values of TF-IDF and LDA accuracy is between 75% and 90%, and the accuracy of TextRank algorithm is above 90%, and the accuracy change for 100 text analysis is small, and the curve is relatively flat, with an average accuracy of 94.23%. The comparison between Fig. 11(b) and Fig. 11(c) is similar to that of Fig. 11(a), and the average of the recall and F1 value of TextRank reaches 96.67% and 95.85%, respectively. Accuracy rate, recall rate and F1 value are the key indexes to evaluate the performance of automatic summarization algorithm. TextRank algorithm performs better than other algorithms on these indexes, which proves its superiority and reliability in automatic summarization task. In addition, TextRank algorithm also has more advantages than references [8] and [9]. In order to verify the applicability of the research constructed model, the indicator keyword coverage is selected for application evaluation, which refers to the degree to which the keywords cover the key content of the original text. Prior to this determine the set of keywords of the applied texts, which were selected by manual methods. Ten LCs from different grades were analyzed and the results are shown in Fig. 12.

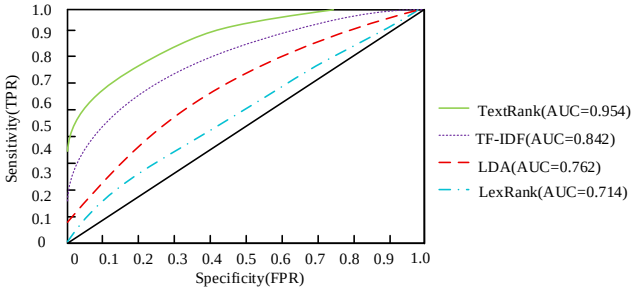

Fig. 10. Comparison of ROC curves for four methods.

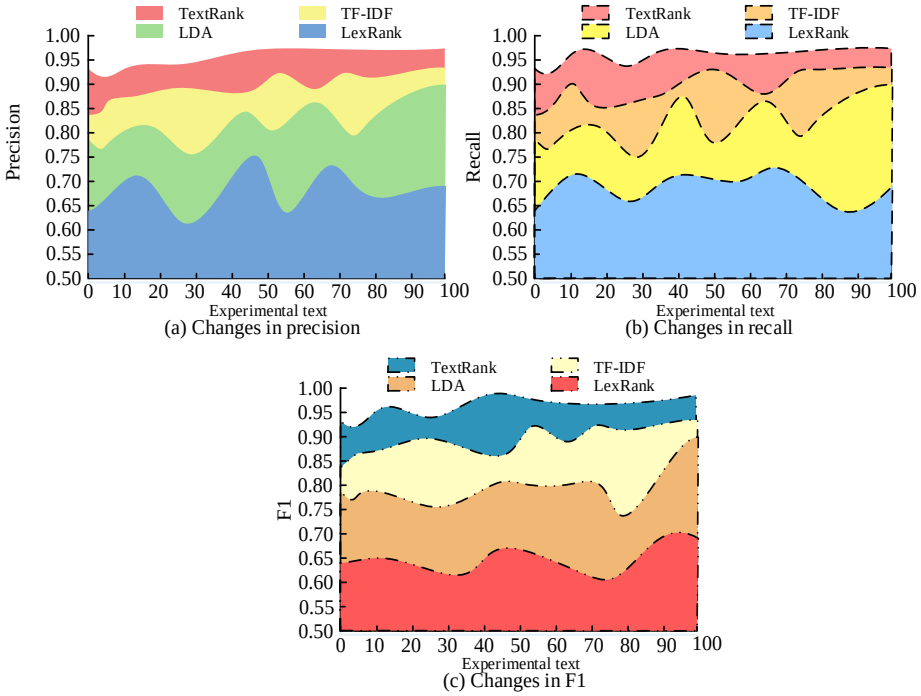

Fig. 11. Comparison results of precision, recall and F1 value of four methods.

In Fig. 12, the keyword coverage of the research model fluctuates the most among the 10 texts, reaching a maximum value of 80.23% at text 6, and it has an average coverage of 62.87%. The keyword coverage fluctuation curves of LDA and TF-IDF are more gentle, with an average keyword coverage of 66.96% and 77.12%, respectively. The curve of the research method has the smallest fluctuation and reaches the maximum value of 96.76% at text 6, with an average keyword coverage of 94.54%. Keyword coverage reflects the comprehensiveness of the algorithm to capture the main information of the original text. The research model performs better than other algorithms in keyword coverage, indicating that it can capture and extract key information of text more comprehensively. For the large gap in the extraction accuracy of the 10 text keywords, it may be due to the fact that the texts selected for the experiment were from different grades. In order to further explore the superiority of the research model, it was continued to be compared with the three methods mentioned above and applied to five LCs, and the scores of classification accuracy, entity accuracy and key description accuracy are shown in Table I.

In Table I, for the comparison of classification accuracy, entity accuracy and key description accuracy for the four methods, classification accuracy could not be compared and only the research methods were able to classify. The difference in entity accuracy was not significant and key description accuracy was greater. By comparing the mean of the sum of the scores, it can be seen that the research model has the highest sum of scores, 3.488, and the remaining three types of models do not have scores higher than 3. The research continues to analyze the text for different grade levels, and the results of its comparison are shown in Fig. 13.

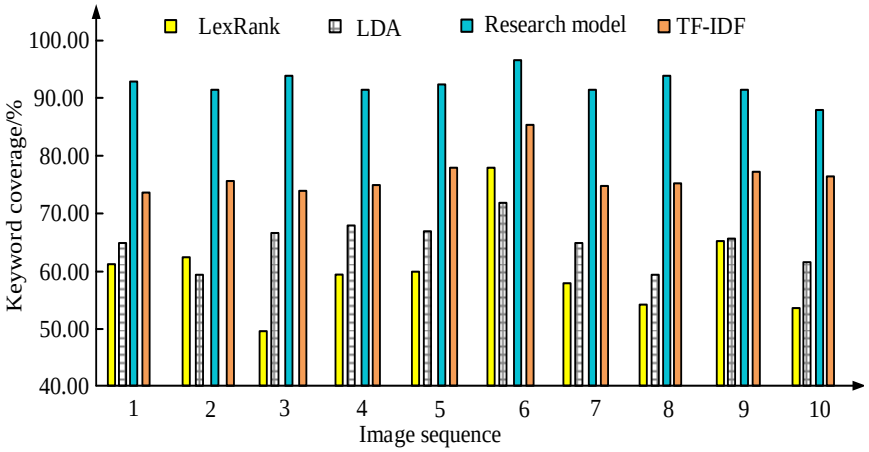

Fig. 12. Comparison of keyword coverage among four methods.

TABLE I. SCORE OF FOUR METHODS FOR CLASSIFICATION ACCURACY, ENTITY ACCURACY, AND KEY DESCRIPTION ACCURACY

Algorithm	Text Number	Classification accuracy	Entity accuracy	Accuracy of key descriptions	Total score	Average value
	1	0.81	1.76	0.95	3.52	3.488

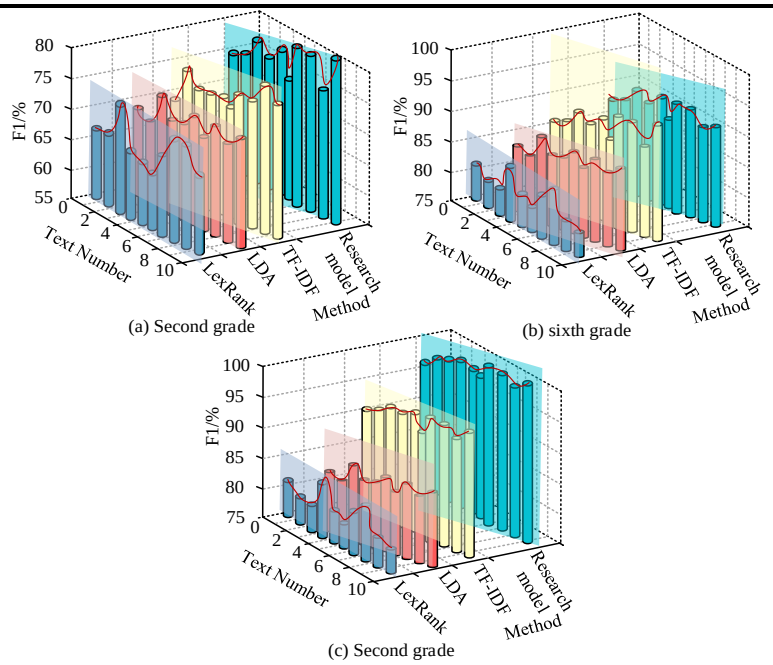

Fig. 13. Analysis of four methods for texts in different grades.

Fig. 13 (a) demonstrates the results of analyzing the essays of the second grade, the F1 value of the research method is relatively high, but the difference between the four methods is not significant, the average value of the F1 value of the research method is 77.24%, which does not reach 80%. Fig. 13 (b) demonstrates the results of analyzing the essays of the sixth grade, and the F1 value of the research methods remained higher at 86.94%. Fig. 13 (c) demonstrates the results of analyzing the essays of the ninth grade, the research method has the highest F1 value and it is significantly different from the F1 value of the remaining three methods, the research method F1 value reaches more than 90% and the average F1 value is 96.23%. F1 value is a performance indicator that takes into account accuracy and recall rate. With

the improvement of the research method, the F1 value also increases, indicating that the method has better analysis ability for more logical and complex texts, and the F1 value of the research method is always the highest in the comparison of the four methods. Continuing to compare the processing time and memory usage of the four methods, the results are shown in Fig. 14.

In Fig. 14(a), the presented data clearly reveals the significant differences in processing time among the four different methods. Among them, the model used in the study shows the best time efficiency, with its processing time fluctuating mainly around 10 seconds and an average processing time of 11.29 seconds. In contrast, the LexRank, LDA, and TF-IDF methods have longer processing times and show varying degrees of volatility. In addition, Fig. 14(b) provides a comparison of these methods in terms of memory occupancy. In this figure, the research model also shows a significant advantage in terms of memory occupancy, with an average memory occupancy of only 15.67%, whereas the memory occupancy of the other three methods shows greater volatility and instability, with the highest of them even reaching 100%. The processing time and memory usage are directly related to the practicability and scalability of the algorithm. The research model shows advantages in both aspects, which means that it is more suitable for practical application in terms of resource consumption and time efficiency.

IV. Conclusion

BM25 similarity algorithm and TextRank algorithm are introduced to obtain keywords in Chinese composition more conveniently. On this basis, a keyword acquisition model is constructed by combining with other intelligent methods. In terms of theoretical contribution, the research expands the application scope of TextRank algorithm in Chinese text processing, and lays a foundation for building a more intelligent education assistance system by optimizing the keyword extraction process, which further promotes the development of AI in the field of education technology. In the actual contribution, the research not only improves the efficiency and accuracy of keyword extraction, reduces the work burden of teachers, but also enhances the objectivity and consistency of evaluation, which has far-reaching research significance for improving teaching efficiency, promoting technological innovation and leading the development of educational technology.

In practical applications, the proposed method shows high accuracy, recall rate and F1 value, and has significant advantages in processing time. It has a short running time, and the average running time is only 2182ms in 100 processing times, and the editing distance processing method is 8.61 times of it. In the performance test and comparison of TextRank algorithm, the AUC value of TextRank algorithm is the largest, which is significantly higher than other models, reaching 0.954, which is very close to 1. The accuracy of TextRank algorithm is above 90%, and the average accuracy of 100 text analysis is 94.23%, and the average recall rate and F1 value reach 96.67% and 95.85% respectively. In the application comparison of the four methods, the research model reaches the maximum value at text 6, which is 96.76%, and the average keyword coverage is 94.54%. For the experimental samples of different grades, the average F1 value of the research model in the second grade was 77.24%, which did not reach 80%. The average F1 value of the model in grade 6 was 86.94%. The average F1 value of the study model at grade 9 was 96.23%. This shows that the accuracy rating value increases with the increase of grade level. In the comparison of the processing time and memory usage of the four methods, the research model shows obvious advantages. The average processing time of 16 texts is 11.29 seconds, and the average memory usage within 24 hours is only 15.67%, which is lower than the other three methods.

Although the research has achieved remarkable results in the accuracy and efficiency of keyword extraction, there are still some limitations. Since the research model is aimed at more complex logically complete utterance, and the selected training corpus is also composed of high-level sentences, the analysis accuracy of LC in lower grades is lower.

Future studies need to select lower-grade LC corpora for training to improve the applicability and practicability of the model. It should also be considered to train the model using a broader corpus of different grades and different types (e.g., argumentative essays, narrative essays, etc.) to improve the applicability of the model to different educational levels and text types. At the same time, the scalability and adaptability of the algorithm are considered, so that it can handle larger scale text data. The methods and techniques studied can be extended to other fields, such as automatic summary generation of legal, medical and scientific documents.

Investigating Cooling Load Estimation via Hybrid Models Based on the Radial Basis Function

Sirui Zhang[1], Hao Zheng[2]*
HeBei Petroleum University of Technology, Chengde Hebei, 067000, China

***Abstract*—To advance energy conservation in cooling systems within buildings, a pivotal technology known as cooling load prediction is essential. Traditional industry computational models typically employ forward or inverse modeling techniques, but these methods often demand extensive computational resources and involve lengthy procedures. However, artificial intelligence (AI) surpasses these approaches, with its models exhibiting the capability to autonomously discern intricate patterns, adapt dynamically, and enhance their performance as data volumes increase. AI models excel in forecasting cooling loads, accounting for various factors like weather conditions, building materials, and occupancy. This results in agile and responsive predictions, ultimately leading to heightened energy efficiency. The dataset of this study, which comprised 768 samples, was derived from previous studies. The primary objective of this study is to introduce a novel framework for the prediction of Cooling Load via integrating the Radial Basis Function (RBF) with 2 innovative optimization algorithms, specifically the Dynamic Arithmetic Optimization Algorithm (DAO) and the Golden Eagle Optimization Algorithm (GEO). The predictive outcomes indicate that the RBDA prediction model outperforms RBF in cooling load predictions, with RMSE=0.792, approximately half as much as those of RBF. Furthermore, the RBDA model's performance, especially in the training phase, confirmed the optimal value of R^2=0.993.**

Keywords*—Cooling load estimation; machine learning; building energy consumption; radial basis functions; dynamic arithmetic optimization algorithm; golden eagle optimization algorithm

I. Introduction

A. Background

As building designs become more intricate and demand greater sustainability performance, the utilization of building simulation tools will become unavoidable. Building energy simulation models have undergone over four decades of evolution, with most development endeavors concentrating on refining the model's thermal processes during this time [1]. Four key elements significantly influence a building's energy consumption: (1) its physical attributes, encompassing factors like location, orientation, and type; (2) the installed equipment responsible for maintaining the desired indoor conditions, such as heating, ventilation, air-conditioning systems, electricity, or hot water; (3) external conditions and meteorological variables like temperature, humidity, and solar radiation; and (4) occupant behavior and the associated consequences of their presence [2].

Data on energy consumption across various sectors reveals that the building industry accounts for approximately 40% of the global electricity demand. This electricity is utilized for heating, air conditioning, ventilation, lighting, and the operation of diverse building service systems [3]. For building service systems in tropical or sub-tropical areas, where air conditioning alone accounts for at least 50% of a building's total energy consumption, the proportion is rather higher [4]. However, conducting thorough examinations of energy consumption tends to be expensive and demanding, discouraging property owners and managers from allocating the required investments in terms of time and finances for a comprehensive assessment of energy efficiency. In response to this issue, researchers have developed economical assessment methods designed to identify buildings with potential for energy conservation. The rapid development of building design-specific computer technology and software has made these strategies possible. Computer-based simulation models have been used in many research to evaluate the energy consumption levels of buildings [5]. The most intricate processes within buildings are primarily driven by human behavior, as humans are inherently unpredictable creatures. Human actions significantly impact a building's energy equilibrium, influencing both the indoor environment and the requirements for energy usage [6].

The forward modelling technique is used by several complex computer-based energy simulation programs, such as DOE – 2, EnergyPlus, and BLAST. However, developing the simulation model is a very labour- and resource-intensive process, especially for complex mixed-use structures with erratic operating schedules. An alternative method called inverse modelling relies on using current building characteristics, such as energy use, meteorological information, or other relevant performance data, to infer a set of building characteristics, such as cooling loads. Regression analysis has historically been used to use collected data to estimate the distinctive parameters of a structure and its systems. However, the definition of the representative building attributes and the accuracy of the building's performance data sometimes place limitations on the flexibility of inverse models. Obtaining data is another issue that comes up often since it is the foundation for building a working model. In actuality, not every structure that is currently in place has building automation installed. Lack of vital information like as-built building details, system specs, and operating schedules causes several challenges for simulation projects.

B. Literature Review

AI methods are a viable alternative to traditional approaches, especially in inverse modelling. One such AI tool, known as an artificial neural network(ANN), can effectively approximate nonlinear systems and demonstrate adaptability in complex environments through network training. ANNs, devoid of intricate rules and mathematical procedures, can grasp the intricacies of complex multidimensional systems. Furthermore, ANNs exhibit fault tolerance, robustness, and resilience to noise [7]. Hence, the distinctive attributes of ANN, such as nonlinearity, adaptability, and the capability to map arbitrary functions, render them well-suited for predictive tasks compared to other AI techniques like expert systems, genetic algorithms, and fuzzy logic. ANN is a strong contender for managing building equipment and occupancy data, which inherently contain noise and incomplete information [8], [9], [10], [11], [12], [13], [14]. Furthermore, *ANN* are widely recognized as a technology that provides an alternative approach to addressing complex and ambiguous problems, primarily due to their robust nonlinear mapping capabilities. Consequently, they have gained significant popularity for use in predicting both building cooling loads [15], [16], [17], [18], [19] and building energy consumption [20], [21], [22].

In energy consumption prediction in building projects, Sapnken et al. [23] conducted a study using data from 7559 buildings and employing nine ML models. Their investigation focused on the efficiency of a Deep Neural Network (DNN) model, demonstrating impressive results and proposing it as an innovative tool for optimizing and predicting energy consumption during the construction design phase of energy-efficient buildings. Leiprecht et al. [24] performed a comprehensive analysis that included autoregressive forecasting methods, decision trees, and "adaptive boosting," exploring deep learning techniques such as Long Short-Term Memory (LSTM) neural networks for thermal load prediction. Jihad and Tahiri [25] utilized ANN to forecast energy requirements in residential structures, achieving satisfactory outcomes with 98.7% accuracy for training data and 97.6% for test data. Wang et al. [26] introduced the Improved Energy Hybrid Optimization (IEHO) neural network, which enhanced the precision of Energy Hybrid Optimization (EHO) approaches. They integrated the Back-Propagation (BP) neural network with the IEHO neural network to form the IEHO-BP neural network model for heating and cooling load forecasting, which demonstrated superior precision. Another study [27] investigated building energy performance using machine learning (ML) techniques including general linear regression, ANNs, decision trees, SVR, and ensemble inference models for cooling and heating load forecasting. This research explored the impact of structural and interior design factors on cooling loads and estimated HVAC system energy demand based on cooling and heating load requirements using various regression models. Cai et al. [28] studied the impact of input factors on heating and cooling loads in residential buildings using the SVR-supervised ML algorithm. They addressed parameter fitting challenges by examining six meta-heuristic optimization algorithms and found that the SVR-AEO hybrid model outperformed others in accurately simulating residential building loads.

Although, several studies have been conducted on the prediction of building loads [29] using ML algorithms [30], also, there are major gaps in the literature in utilizing other algorithms and methodologies such as hybridizing with novel metaheuristic algorithms.

C. Objectives and Contribution

In the present research, inspiration is drawn from prior successful outcomes that highlighted the superior performance of ANNs compared to other models, leading to the development of Radial Basis Functions (RBF) models for the prediction of cooling loads (CL) in buildings. The contribution of this study lies in exploring novel methodologies to enhance RBF modeling accuracy for CL prediction. The performance of predicting outcomes using a single RBF model was evaluated. To further optimize the training process and improve model performance, two separate optimizers were employed: the DAO and the GEO algorithms. Integrating these optimizers aims to efficiently tune RBF model parameters and enhance predictive accuracy. The novelty of this approach lies in the combination of RBF modeling with advanced optimization techniques, offering a promising avenue to achieve higher accuracy in cooling load prediction. By exploiting the strengths of DAO and GEO, this research extends the boundaries of traditional RBF applications, demonstrating their effectiveness in the context of building energy efficiency studies. The choice of RBF models, coupled with the use of the GEO and the DAO, reflects a strategic approach to enhance the accuracy and efficiency of CL prediction in buildings. RBF models are particularly suitable for nonlinear approximation tasks and offer flexibility in capturing complex relationships within datasets, making them well-suited for CL prediction. The integration of GEO and DAO as optimization techniques is motivated by the need to effectively tune RBF model parameters for optimal performance. GEO, inspired by the behavior of eagles in searching for prey, employs a nature-inspired algorithm to efficiently explore the solution space and converge towards optimal solutions. On the other hand, DAO, characterized by its dynamic arithmetic operations, leverages mathematical principles to guide the optimization process toward improved model fitting.

D. Research Organization

The introductory part of this study is divided into 4 main sections: background, literature review, objectives, and research organization. Following this, the next section provides detailed explanations about the dataset used and concise descriptions of various ML techniques, including models and optimization algorithms. Section III covers the description of performance evaluators, comparative results using metrics and different techniques, and an analysis comparing the study's findings with existing research. In Section IV, the study's conclusions are summarized.

Fig. 1 shows the process of present study.

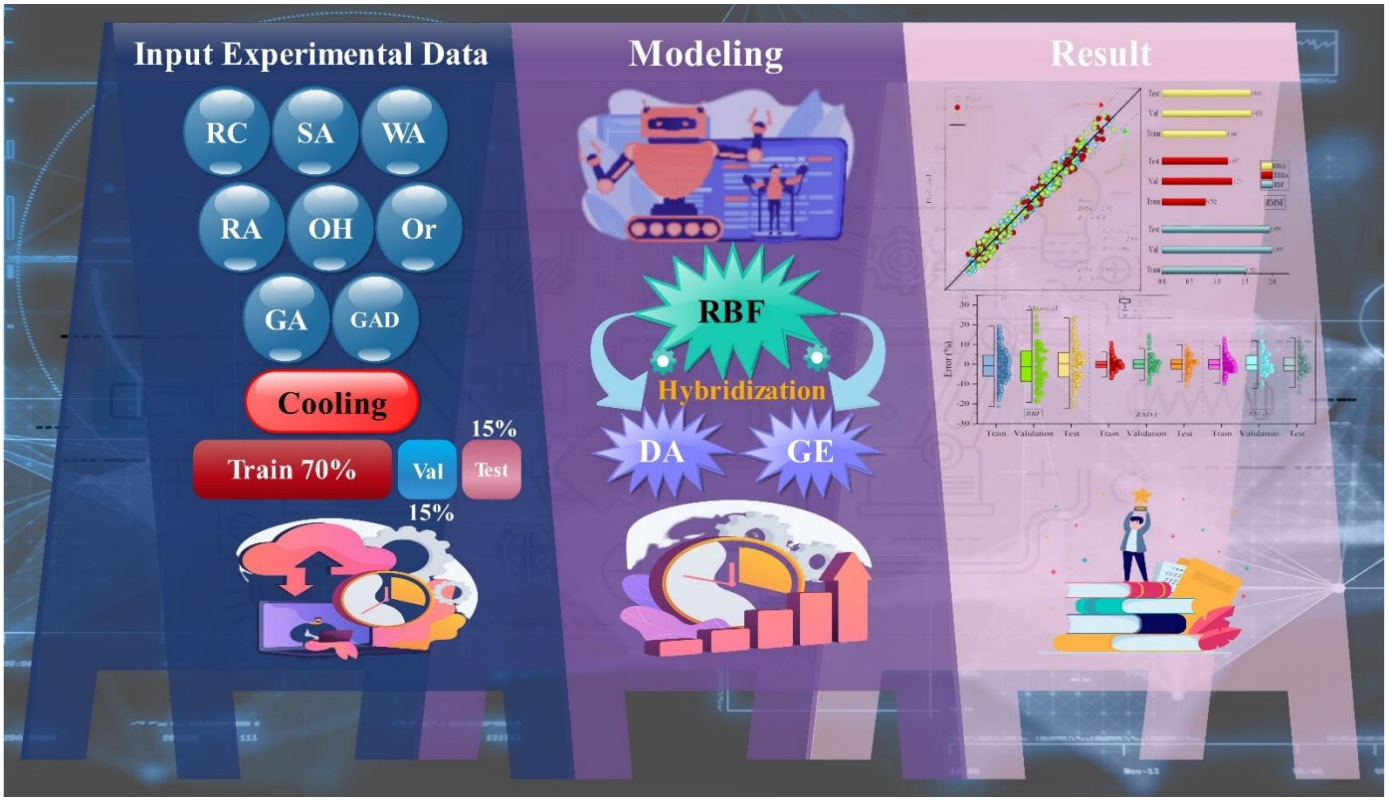

Fig. 1. The current Study's procedure.

II. Materials and Methods

In the second section of this article, a concise overview of the dataset used in this research is presented, along with descriptions of the ML algorithms selected for implementation in this study, including the RBF model, GEO algorithm, and DAO algorithm. This section provides detailed insights into the dataset characteristics and the rationale behind choosing specific ML techniques to address the research objectives.

A. Data Collection

The presence of valid and substantial data is paramount in ensuring the credibility and efficacy of the methods outlined in this paper. This study uses a dataset obtained from previous research endeavors [31], [32] to train intelligent models, which comprised 768 data samples. This dataset furnishes essential information required to implement the proposed techniques and assess their performance in predicting building cooling loads. This study's examination of input parameters is predicated on eight important elements, namely relative compactness (RC), surface area (SA), wall area (WA), roof area (RA), orientation (Or), overall height (OH), glazing area (GA), and the distribution of glazing area (GAD). These factors collectively serve as the basis for evaluating and optimizing the predictive models used in this study. Table I details the primary criteria employed for statistically examining the dataset, including metrics such as data averages, standard deviations, and minimum and maximum values. The dataset is partitioned into 70% for training, 15% for validation, and 15% for testing.

TABLE I. The Input Variable's Statistical Characteristics for Cooling

Variables		Indicators			
	Category	*Min*	*Max*	*Avg*	*St.Dev.*
RC	*Input*	0.62	0.98	0.764	0.106
SA (m2)	*Input*	514.5	808.5	671.70	88.086
WA (m2)	*Input*	245	416.5	318.5	43.63
RA (m)	*Input*	110.25	220.5	176.60	45.165
OH (m)	*Input*	3.5	7	5.25	1.751
Or	*Input*	2	5	3.5	1.118
GA (%)	*Input*	0	0.4	0.235	0.133
GAD	*Input*	0	5	2.81	1.55
Cooling (kW)	*Output*	10.9	48.03	24.587	9.51

B. Overview of ML Method and Optimizers

1) Radial Basis Function (RBF): The Radial Basis Function (RBF) network, a member of the ANNs family, utilizes data-driven methods to establish connections between input and output elements. Instead of relying on mathematical equations, it derives the model's structure and unknown parameters from the provided data [33]. The RBF network is structured into three layers: the input, linear output, and hidden layers. As input vectors traverse the hidden layer, they experience a transformation process, generating radial basis functions.

These operations are executed through an activation process derived from a Gaussian distribution, firmly grounded in the fundamental principles of the Gaussian function. According to the literature, the Gaussian elementary operation (F_j) is described as being defined by two critical parameters: width and center [34]. The function is represented in the following manner:

$$F_j(x) = exp\left(\frac{\left|x - \beta_j\right|^2}{2\alpha_j^2}\right) \quad (1)$$

The output neuron is commonly denoted as:

$$y(x) = \sum_{j=1}^{n} \sigma_j F_j(x) + a \quad (2)$$

In the above context, x refers to the inputs, β_j and α_j reflect the width and center of the Gaussian basis function, individually. And n denotes the number of hidden neurons, a indicates the bias coefficient, and the weight factor that connects the jth hidden neuron to the output neuron is represented by σ_j.

2) Dynamic Arithmetic Optimization Algorithm (DAOA): Adding 2 new accelerator functions has improved the foundational arithmetic optimization algorithm. These modifications affect candidate solutions and the search process, balancing exploration and exploitation dynamically. Unlike other advanced metaheuristics, DAOA stands out because it doesn't need initial parameter adjustments. The DAOA pseudo-code is in Algorithm 1, and the next section explains its dynamic features in detail [35].

ALGORITHM I. PSEUDO-CODE OF *DAOA*

procedure *Dynamic Arithmetic Optimization Algorithm*
Initialize the Algorithm's Parameters $\boldsymbol{\gamma}; \boldsymbol{\mu}$
Produce random values to serve as initial positions.
  while (t < *maximum number of iterations*) **Do**
    Evaluate the fitness of given solutions by computing their respective values.
Identify the optimal solution.
Update the DAF value using Eq. (3)
Update the DCS value using Eq. (6)
    for *i D* 1: *number of solutions* **Do**

Provide the top − performing solution.
  end procedure

a) DAOA's Dynamic accelerated function: The dynamic aspect of the arithmetic optimization algorithm heavily depends on the Dynamic Accelerated Function (DAF) during the search. It is necessary to adjust the starting values of the accelerated function (Min and Max) in the AOA. However, when a new descending function replaces DAF, it is more desirable to use an algorithm without internally configurable parameters. The adjustment factor for this optimization approach is shown as follows:

$$DAF = (\frac{Iter_{max}}{Iter})^{\gamma} \quad (3)$$

Here, "$Iter$" reflects the ongoing iteration count, "$Itermax$" is indicated as the upper limit for iterations, and the value of "α" remains a constant. The function experiences a decrease with each consecutive iteration within the algorithm.

b) Dynamic DAOA candidate solution: The dynamic properties of $DAOA$ candidate solutions are introduced in this section. The exploration and exploitation stages of metaheuristic algorithms must be approached in a balanced manner for the algorithm to be successful. Every solution in this dynamic adaptation, which prioritizes better exploration and exploitation, iteratively improves its locations by making reference to the optimal solution found during optimization. Eq. (4) in the basic version is replaced by Eq. (5) as a consequence of the inclusion of the Dynamic Candidate Solution (DCS) function.

$$x_{i,j}(C_{iter}+1) = \begin{cases} best(x_j) \div (DCS+\epsilon) \times ((UB_j - LB_j) \times \mu + LB_j)) & , \quad r2 < 0.5 \\ best\ (x_j) \times DCS \times ((UB_j - LB_j) \times \mu + LB_j)) & Otherwise \end{cases} \quad (4)$$

$$x_{i,j}(C_{iter}+1) = \begin{cases} best\ (x_j) - DCS \times ((UB_j - LB_j) \times \mu + LB_j)) & , \quad r3 < 0.5 \\ best\ (x_j) + DCS \times ((UB_j) \times \mu + LB_j)) & , \ Otherwise \end{cases} \quad (5)$$

The incorporation of the DCS function is a direct response to the diminishing ratio of candidate solutions. Its value consistently diminishes in each iteration, following this established pattern.

$$DCS(0) = 1 - \sqrt{\frac{Iter}{Iter_{max}}} \quad (6)$$

$$DCS(t+1) = DCS(t) \times 0.99 \quad (7)$$

Extensive testing involving various hunt agents and iterations has shown that including candidate solutions in $DAOA$ notably speeds up AOA's convergence rate, ultimately improving solution quality. The lack of parameters is often an advantageous feature in metaheuristic algorithms. What sets DAOA apart from AOA is its integration of dynamic functions, while the other aspects of the approach align with the AOA algorithm discussed earlier.

Adaptive parameters help the $DAOA$ algorithm; just the population size and maximum number of iterations need to be adjusted. This algorithm sets itself apart unlike other algorithms that demand problem-specific parameter adjustments. However, it has a drawback: it relies on the iteration count, rather than fitness improvements, as the basis for its adaptive mechanism.

3) Golden Eagle Optimization (GEO): This study introduces an innovative swarm-intelligence metaheuristic algorithm inspired by the hunting behavior of golden eagles, referred to as the GEO. GEO is rooted in the intelligent adaptation of attack and cruising behaviors observed in golden eagles during their prey search and hunting activities.

The key attributes of the hunting behavior exhibited by golden eagles can be summed up in this way [36]:

They move in a curved trajectory while searching and move in a straight line when attacking.

They tend to start off cruising around when they start hunting and then gradually start to attack more towards the end.

Throughout their flight, they maintain a propensity for both cruising and attacking at all times.

They seek information about prey from other eagles.

The golden eagle's ability to maneuver between flying and hunting is a natural means of exploration, advantage-taking, and transitioning from one to the other. This clears the path for creating a new type of algorithm. The next part shows this behavior mathematically modeled.

a) Algorithm for optimization and mathematical model: This section explains how a mathematical equation was created to simulate golden eagle hunting behavior. It introduces the spiral motion formula and then dissects it into attack and cruise vectors, emphasizing the aspects of exploration and exploitation, respectively.

- Golden eagles spiraling around in circles: GEO concentrates on the spiral motion of golden eagles. Every time, golden eagle $'n'$ selects a randomly selected prey from the golden eagle $'f'$ and circles around the ideal spot that the eagle frequents. $'f'$ is designated as a member of the set $\{1,2,\ldots,PopSize\}$ because the golden eagle, represented by 'n', has the ability to choose to circle its memory.
- Prey selection: Each iteration involves search agents choosing targets from collective memory. Improved positions replace stored ones. In the GEO approach, golden eagles select prey randomly from any flock member's memory without proximity constraints.
- Attack (exploitation): The attack is a vector from the eagle's current position to its remembered prey. The attack vector for Golden Eagle n can be calculated using Eq. (8).

$$\overrightarrow{A_n} = \overrightarrow{X_f^*} - \overrightarrow{X_n} \quad (8)$$

Here, $\overrightarrow{X_n}$ is the current position of eagle n, $\overrightarrow{A_n}$ is the eagle's n attack maneuver and $\overrightarrow{X_f^*}$ is the best place (prey) visited so distant by eagle f.

- Cruise (exploration): The cruise vector originates from modifying the attack vector. It follows the circle's tangent and stands at a right angle to the attack vector, indicating the eagle's speed concerning the prey. In i-dimensional space, it lies within the tangent hyperplane. To determine it, the equation of this hyperplane must be established, involving a point and a perpendicular normal vector. Eq. (9) supplies the scalar representation of this hyperplane in i-dimensional space.

$$h_1x_1 + h_2x_2 + h_3x_3 + \cdots + h_ix_i = d \Rightarrow \sum_{j=1}^{i} h_jx_j = d \tag{9}$$

$$\sum_{j=1}^{i} a_jx_j = \sum_{j=1}^{i} a_j^t x_j^* \tag{10}$$

Here ,$\overrightarrow{P} = [p_1, p_2, p_3, \dots, p_i]$ is the hyperplane's arbitrary point and $\vec{H} = [h_1, h_2, h_3, \dots, h_i]$ is the normal vector, $X = [x_1, x_2, x_3, \dots, x_i]$ is the variables vector, and $d = \overrightarrow{H} \cdot \vec{P} = \sum_{j=1}^{i} h_j\, p_j$. $\overrightarrow{X_n}$ (the place of the eagle n) is considered as any random location inside the hyperplane and reflect $\overrightarrow{A_n}$ (the point of attack) as the hyperplane may be shown using its normal to which $\vec{C}_n^t$ (The cruise vector in iteration t for the Golden Eagle n) belongs version to Eq. (10).

Here, $X^* = [x_1^*, x_2^*, x_3^*, \dots, x_i^*]$ is the chosen prey's location, and $A_n = [a_1, a_2, a_3, \dots, a_i]$ is the attack vector, $X = [x_1, x_2, x_3, \dots, x_i]$ is the decision/design variables vector; it's time to find a cruise vector inside the cruise hyperplane that was calculated for Eagle n in iteration t.

The final dimension is determined based on its compatibility with the hyperplane equation, resulting in i — 1 free variable and a single fixed variable. To locate a chance i-dimensional objective point C on the golden eagle n's journey hyperplane: Step 1. Arbitrarily pick one variable from the set of i variable stars as the fixed variable, denoting its index as k. Notably, avoid selecting a fixed variable among those associated with zero elements in the attack vector $\overrightarrow{A_n}$.

When a variable's coefficient in Eq. (9) is 0, the line becomes parallel to that variable's axis, allowing it to take any value while the other $i - 1$ variables vary randomly. As an instance, in the $3D$ plane $3x_1 + 2x_2 = 10$, if $k = 3$ and random numbers for x_1 and x_2 is selected, say $\{x_1 = 2, x_2 = 5\}$, a unique point cannot be found. Rather, this plane generates an endless number of points, all of which fulfill the {[2,5,1], [2,5,2], [2,5,3], …} plane equation. Step 2: Give each variable a random value, except for the k–t™ variable, which always has the same value. Determine the fixed variable's value in Step 3 by using Eq. (11).

$$c_k = \frac{d - \sum_{j,j\neq k} a_j}{a_k} \tag{11}$$

Here c_k denotes the $k - th$ element of the terminus point C, a_j represents the $j - th$ element of the attack vector A_n, d refers to the right−hand side of the Eq. (9), a_k^t signifies the $k - th$ element of the attack vector $\overrightarrow{A_n}$, and k shows the directory of the fixed variable. The cruise hyperplane now has a new random destination point. Eq. (12) shows how to find the location of the cruise hyperplane's destination.

$$\begin{aligned}\vec{C}_n = (c_1 = rand\,, c_2 = rand, \dots, c_k \\ = \frac{d - \sum_{j;j\neq k} a_j}{a_k}\,, \dots, c_i = rand\end{aligned} \tag{12}$$

In iteration t, the cruise vector for Golden Eagle n may be computed once the destination point has been determined. Random integers between 0 and 1 make up the components of the destination location. The golden eagle population is guided by the cruise vector away from their prior memory, highlighting the discovery phase of GEO.

- Transferring to new roles

The golden eagles use both assault and cruise vectors when they travel. According to Eq. (13), the step vector for golden eagle n is described in iteration t.

$$\Delta x_n = \vec{r}_1 p_a \frac{\overrightarrow{A_n}}{\left\|\overrightarrow{A_n}\right\|} + \vec{r}_2 p_c \frac{\vec{C}_n}{\left\|\vec{C}_n\right\|} \tag{13}$$

The coefficients p_a^t and p_c^t in iteration t control the impact of attack and cruise on golden eagles. Random vectors $\vec{r}_1$ and $\vec{r}_2$ have elements within [0,1]. The discussion of p_a and p_c will follow.$\left\|\vec{C}_n\right\|$ and $\left\|\overrightarrow{A_n}\right\|$ represent the attack and cruise vectors' Euclidean norms, as determined by Eq. (14).

$$\left\|\overrightarrow{A_n}\right\| = \sqrt{\sum_{j=1}^{i} a_j^2}\,, \left\|\vec{C}_n\right\| = \sqrt{\sum_{j=1}^{i} c_j^2} \tag{14}$$

The step vector from iteration t is added to the locations of the golden eagles in iteration t to calculate their positions in iteration $t + 1$.

$$x^{t+1} = x^t + \Delta x_i^t \tag{15}$$

Golden Eagle n updates its memory if its new position is superior; otherwise, it retains its memory but adopts the new position. In each iteration, eagles pick a random peer to circle the best-visited spot, determining attack and cruise vectors, step size, and the next position. This cycle repeats until one of the termination conditions is satisfied. Eq. (13) involves 2 coefficients, the attack constant p_a^t and cruise constant p_c^t, which controls how the step vector is influenced by cruise and attack vectors. The following subsection, denoted as c, explains how these coefficient values change throughout the iterations.

- Transition from exploration and exploitation

Golden eagles primarily cruise early in their hunting flight, transitioning to attacking later. These parallels heightened exploration in greater exploitation and initial iterations in later iterations within the future optimizer.

GEO employs p_a and p_c to transition from exploration to exploitation. It begins with a low p_a and high p_c values. As iterations advance, p_a increases gradually, while p_c decreases gradually. Users define the initial and final parameter values, and it is possible to compute intermediate values by using the linear transition described in Eq. (16).

$$\begin{cases} p_a = p_a^0 + \frac{t}{T}|p_a^T + p_a^0| \\ p_c = p_c^0 + \frac{t}{T}|p_c^T + p_c^0| \end{cases} \quad (16)$$

In the formula, t represents the current iteration, T is the maximum iteration count, p_a^0 and p_a^T stand for the initial and final values of the propensity to attack (p_a), respectively, while p_c^0 and p_c^T denote the initial and final values of the propensity to cruise (p_c), respectively. These tests, which will be covered in more detail later, show that $[p_a^0 and\ p_a^T] = [0.5, 2]\ and\ [p_c^0 and\ p_c^T] = [1, 0.5]$ are suitable parameter settings. This suggests that in the first iteration, $pstarts$ at 0.5 and climbs linearly to reach 2 in the last iteration. In a similar manner, pc starts at 1 in the first iteration and decreases linearly to 0.5 in the last. It's crucial to remember that Eq. (16) uses a linear strategy to change these values; however, logarithmic or other functions might be used as an alternative.

C. Research Methodology

The research methodology can be delineated in the following manner:

1) Introduction: In this study, the consideration of a crucial problem is introduced, with a focus on the imperative for enhanced performance in the RBF model. Significance is placed on the advancement of the field of ML, particularly in practical applications within building energy prediction. The pressing need for improved efficiency in the RBF model is addressed, contributing to the broader landscape of ML and its application to real-world challenges in buildings.

2) Hybridization method: A novel ML approach is presented, involving the hybridization of 2 advanced optimization techniques. The combination of optimization methods used to enhance the performance of the RBF model is detailed. Through the strategic integration of these advanced optimization techniques, an innovative perspective is introduced to ML, with a primary goal of elevating the efficiency of the RBF model.

3) Optimizers used: In this research, the introduction and detailed description of the 2 distinct optimizers employed in the hybridization method, namely the DAO and the GEO, are provided. The unique strengths of each optimizer and the rationale behind their selection for the hybrid model are thoroughly explained, contributing to a comprehensive understanding of the strategic integration of these optimizers in the research framework.

4) Model evaluation: A comprehensive evaluation of both single and hybridized RBF models is undertaken in this study, utilizing established performance metrics such as R^2 and RMSE. The choice of these metrics is justified to ensure an impartial assessment of model performance, enhancing the reliability and objectivity of the evaluation process.

5) Performance comparison: The performance of hybridized models is compared with the traditional RBF model in this study to emphasize the superiority of the proposed approach. Statistical analyses or visual representations of the results are provided to support the claims made, enhancing the credibility and clarity of the comparison between the 2 model types.

6) Conclusion: This section provides a summary of the research's main conclusions and their consequences offering a concise overview of the study's outcomes. Additionally, the limitations of the study are discussed to encourage further exploration in related domains.

III. Results and Discussion

A. Prediction Performance Analysis

This research created an ML model called RBF to forecast CL. In addition, the research used two effective optimization algorithms, DAO and GEO, to make hybrid RBF models better at adjusting the settings of the models. The dataset was split into three smaller groups: training, validation, and testing. The training group had 70% of the data, the validation group had 15%, and the testing group had the remaining 15%. The models were evaluated in Table II by comparing different measures, like R^2(coefficient of determination), $RMSE$ (Root Mean Square Error), MAE (Mean Relative Absolute Error), NMSE (Normalized Mean Squared Error), and PI (prediction interval). These measures were defined in Eqs. (17) to (21):

$$R^2 = \left(\frac{\sum_{i=1}^{n}(T_i - \bar{T})(P_i - \bar{P})}{\sqrt{[\sum_{i=1}^{n}(T_i - \bar{P})^2][\sum_{i=1}^{n}(P_i - \bar{P})^2]}} \right)^2 \quad (17)$$

$$RMSE = \sqrt{\frac{\sum_{i=1}^{n}(P_i - T_i)^2}{n}} \quad (18)$$

$$MAE = \frac{1}{n}\sum_{i=1}^{n}\|P_i - T_i\| \quad (19)$$

$$NMSE = \frac{\frac{1}{n} \times \sum((y_i - \hat{y}_i)^2)}{\frac{1}{n} \times \sum y_i^2} \quad (20)$$

$$PI = \bar{x}_2 \pm t_{(\alpha/2,\ N-2)} * q^2 \quad (21)$$

Where n is the number of the data points, T_i and P_i are the test and predicted results, respectively. $\bar{P}$ and $\bar{T}$ are the average of the test and prediction result values, y_i represents the actual values, $\hat{y}_i$ denotes the predicted values, q^2 signifies the average error value that has been combined from both groups; the t-value corresponding to the desired level of confidence (α) and degrees of freedom ($N-2$) is obtained from the t distribution at the critical level of $(\frac{\alpha}{2}, N-2)$."

The following discourse offers a comprehensive analysis of the model's capability to predict CL effectively:

- The RBDA hybrid model showcased exceptional performance, achieving the highest R^2 values such as $R^2_{train} = 0.993$, $R^2_{validation} = 0.984$, $R^2_{test} = 0.984$ and $R^2_{all} = 0.990$. The elevated R^2 values indicate a robust alignment among the model and the dataset, emphasizing the dependable nature of the selected input variables as strong predictors of the predictable output. Additionally, in the case of both hybrid models, the R^2 value during the training phase is higher than in the testing phase. This discrepancy suggests suboptimal training performance in the developed models.
- A Prediction Interval is a statistical metric that quantifies the level of uncertainty associated with a model's predictions. It sets itself apart from a point estimate, such as a mean or median, by defining a range or interval in which future observations are anticipated to occur with a specified confidence level. Among all the models, RBDA stands out with its minimal PI value of 0.019, indicating the lowest degree of uncertainty.
- The RMSE varies across a range, with a minimum of 0.792 (observed during the training phase of RBDA) and a maximum of 1.996 (noted during the RBF single model validation phase). Furthermore, during the training phase of RBDA, the MAE and NMSE values, specifically 0.542 and 0.001, respectively, were observed. This additional evidence solidifies the RBDA hybrid model's high level of accuracy.

TABLE II. THE OUTCOME OF MODELS CREATED FOR RBF

Model	Phase	Index values				
		RMSE	***R²***	***MAE***	***NMSE***	***PI***
RBF	*Train*	1.522	0.974	1.313	0.004	0.031
	Validation	1.996	0.963	1.764	0.035	0.041
	Test	1.956	0.961	1.667	0.033	0.040
	All	1.671	0.970	1.433	0.004	0.034
RBDA	*Train*	0.792	0.993	0.542	0.001	0.016
	Validation	1.274	0.984	0.848	0.014	0.026
	Test	1.197	0.984	0.836	0.013	0.024
	All	0.947	0.990	0.632	0.001	0.019
RBGE	*Train*	1.167	0.985	0.778	0.003	0.024
	Validation	1.622	0.974	1.139	0.023	0.033
	Test	1.603	0.972	1.062	0.022	0.033
	All	1.316	0.981	0.875	0.002	0.027

Fig. 2 illustrates dispersed visualizations of the correlation between predicted and measured CL values. These scattered data points are derived from the 2 evaluation sets based on RMSE and R^2. In a broad sense, RMSE serves as a dispersion controller, meaning that lower values of this metric correspond to higher data point density. Moreover, the R^2 metric tends to cluster testing and training data points closer to the centerline.

The figure incorporates several additional elements, including a central line at the Y=X coordinates and 2 lines positioned below and above the central line to represent a 10% underestimation and 10% overestimation range. Upon conducting an exhaustive comparison across the three predictive models, it becomes evident that all models exhibit favorable R^2 values. This is observed through the proximity of data points associated with these models to the central best-fit line, with most points falling within the boundaries defined by the 2 threshold lines.

Among the 2 optimized RBF models, it is discernible that the data points exhibit greater proximity to the central line, indicating superior performance compared to the single RBF model. In the comparative evaluation of the optimized models, upper and lower threshold lines are employed as reference points. Notably, it becomes evident that the data points about the model optimized through the DAO are consistently contained within the demarcated threshold lines. Conversely, the data points associated with the model optimized through the GEO exhibit a somewhat greater degree of dispersion relative to the prescribed boundaries.

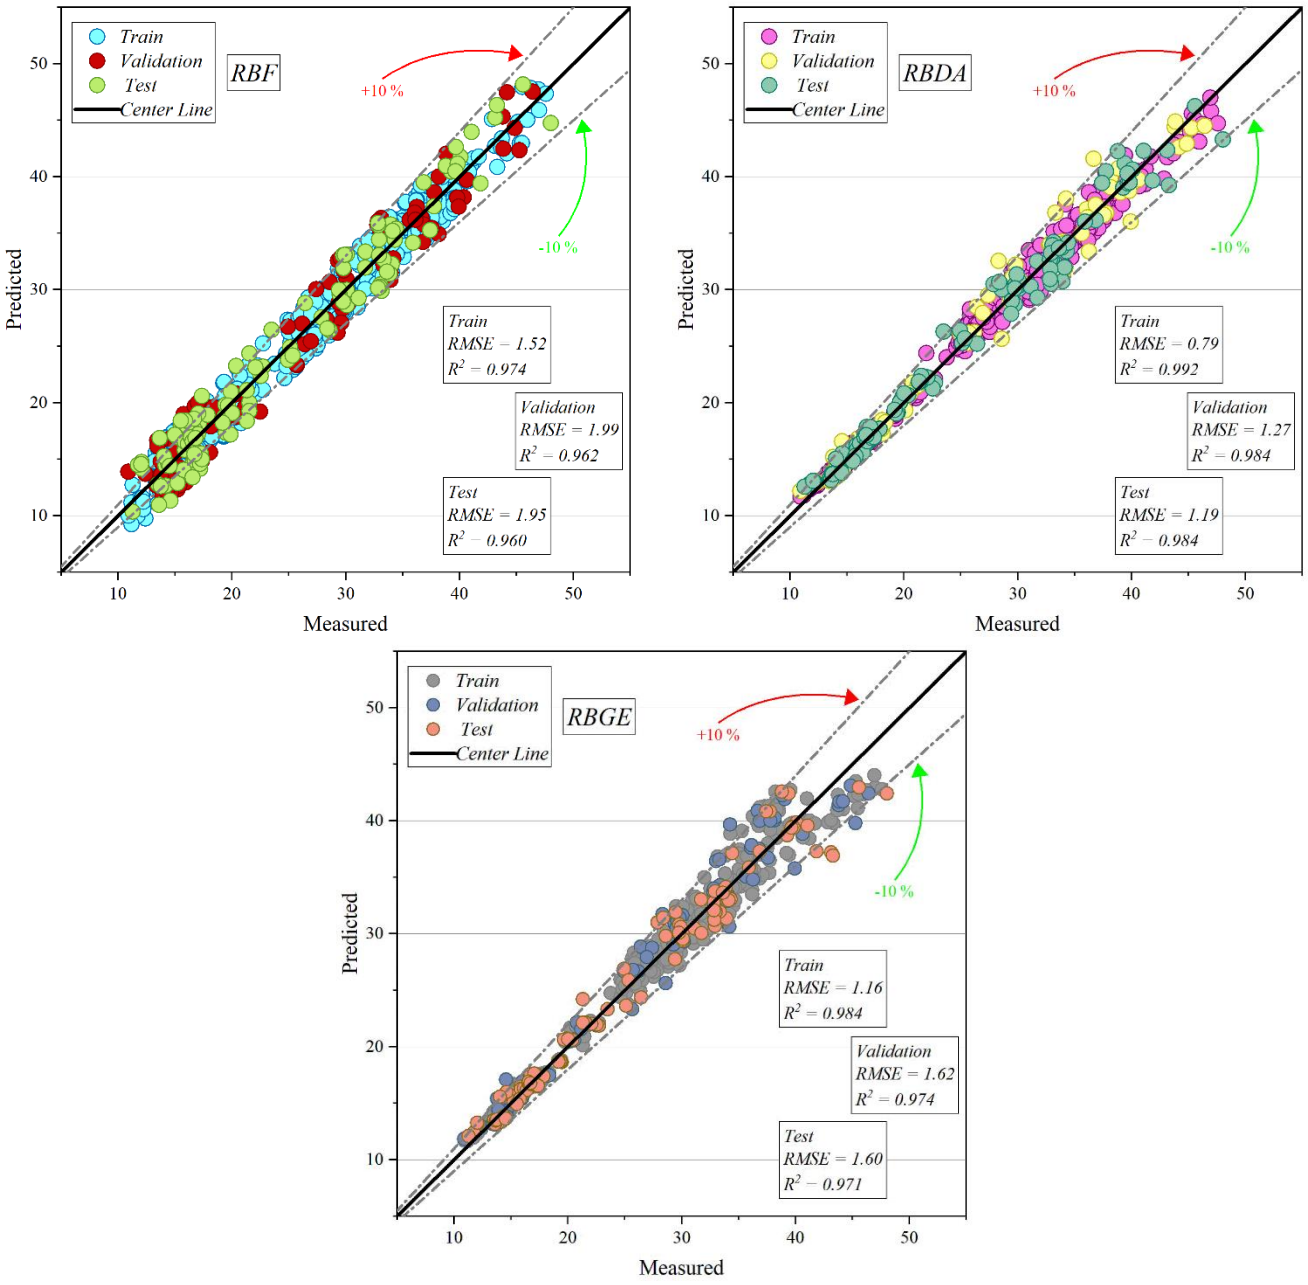

Fig. 2. The scatter plot for developed hybrid models.

This academic research uses a stacked bar plot, as shown in Fig. 3, to compare many parameters in-depth. By stacking the measurements inside of separate bars, this visualization technique offers a succinct and understandable representation of the correlations between various measures. Because each statistic is represented by a different hue, it is easier to see how each one contributes to the final outcomes. The calculated RMSE, R^2, and MAE values for the different models are shown in Fig. 3. Upon closer examination, it becomes evident that the RBDA model exhibits lower error rates according to the RMSE = 0.792 and MAE = 0.542 compared to RBF and RBGE. Furthermore, concerning prediction accuracy, as evidenced by the R^2 values, it is noteworthy that RBF (R^2= 0.974) and RBGE (R^2= 0.984) exhibit lower values when compared to the RBDA model.

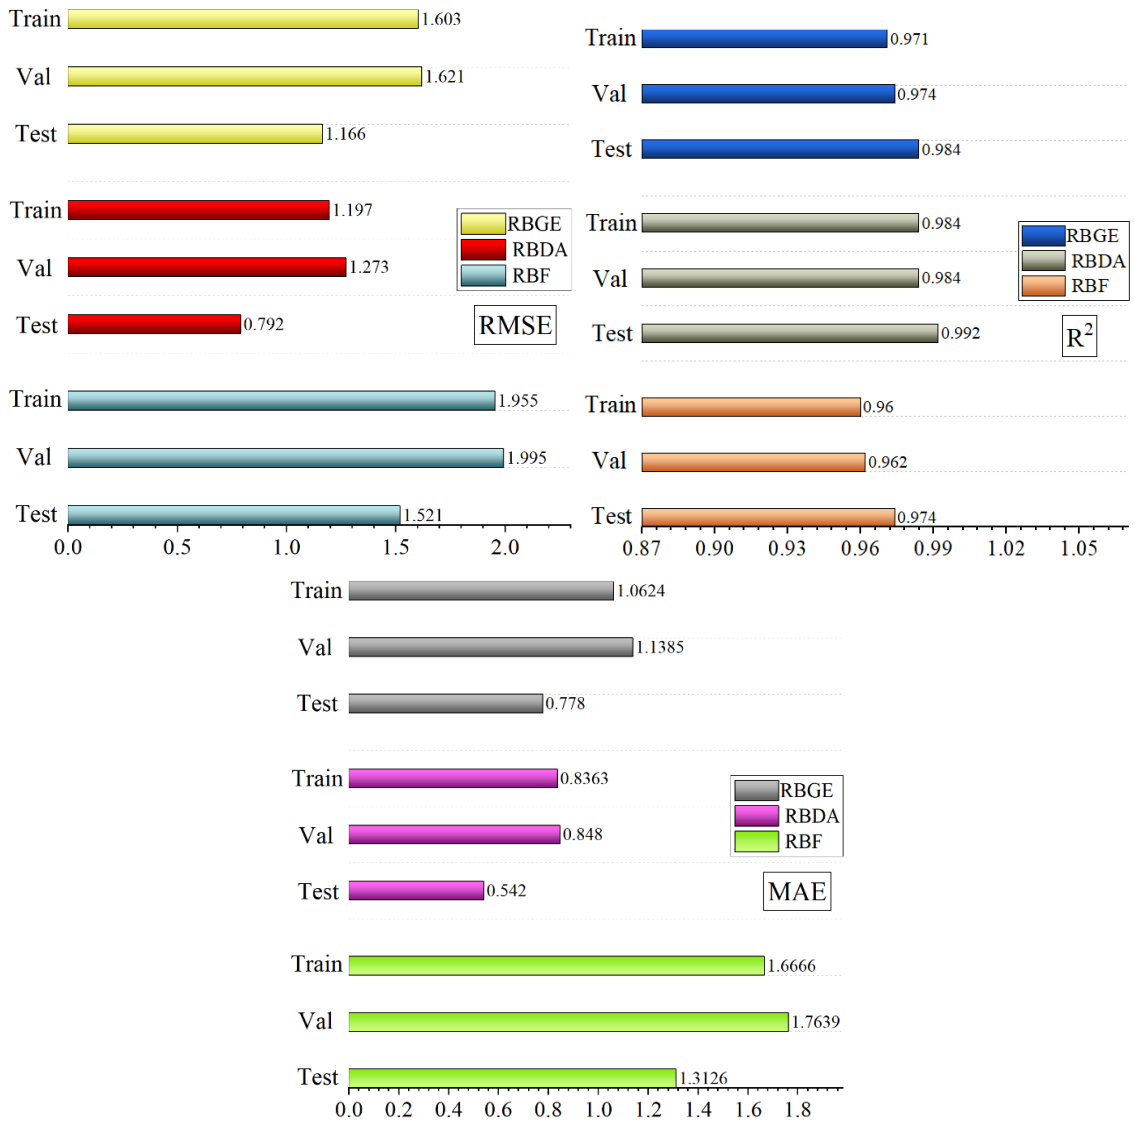

Fig. 3. Comparison between models is based on RMSE, R^2, and MAE.

In Fig. 4 and Fig. 5, the error percentages (%) for the models are visualized using both normal distribution plots and the half-boxes, with the errors categorized across the training, validation, and test datasets. As depicted in Fig. 4, the normal distribution plot illustrates that RBDA exhibits a narrow bell-shaped distribution line during the training phase with a higher concentration of errors in the zero percent range, thus indicating its superior performance. However, in the validation and testing phases, the distribution curves for RBF and RBDA resemble each other, whereas RBF shows a wider spread of error values across a broader range. Upon examining the spectrum of error values presented in Fig. 5 for the various models, it becomes evident that the training phase of RBF exhibits the widest range of error values, while the validation phase of RBF displays the narrowest range. Noteworthy is the consistent excellence in performance displayed by the RBDA hybrid model throughout all three phases when considering a range of box proportions related to 25% to 75% of error values. It is essential to underscore that the model's performance exhibits a discernible enhancement as the box proportions approach zero. Moreover, according to RBGE half boxes, it can be observed that it exhibited marginal variation and secured the second position in terms of performance ranking.

B. Comparing the results of this study and existing studies

Numerous studies have been conducted on CL prediction, including investigations by Afzal et al. [37] using the *MLP* model, and Gong et al. [38] employing the GBM technique. Among the existing publications reported in Table III, superior performance was demonstrated by the GPR model, achieving an R^2 value of 0.99 and an RMSE value of 0.059 in a study showed by Roy et al. [39]. A fundamental framework based on the RBF model was used in the present research, and it was improved by hybridizing it with the GEO and DAO algorithms. After analyzing the data, it was discovered that the TDO integration into the RFR model had remarkable applicability. It outperformed the other models in this research, with an R^2 value of 0.997 and an *RMSE* of 0.498.

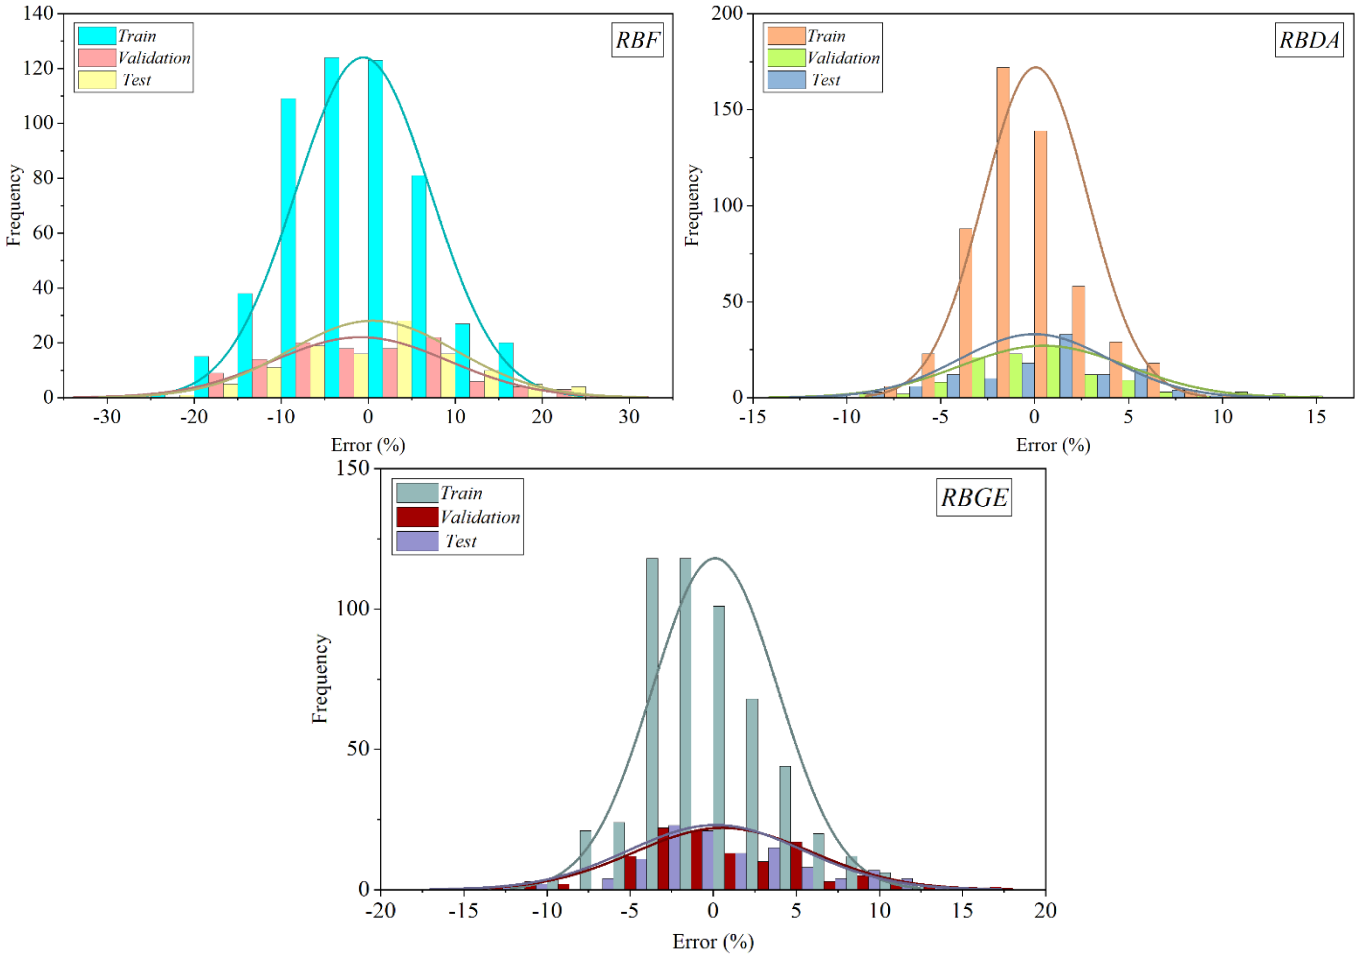

Fig. 4. The normal distribution plot serves as the foundation for the hybrid models' error percentage.

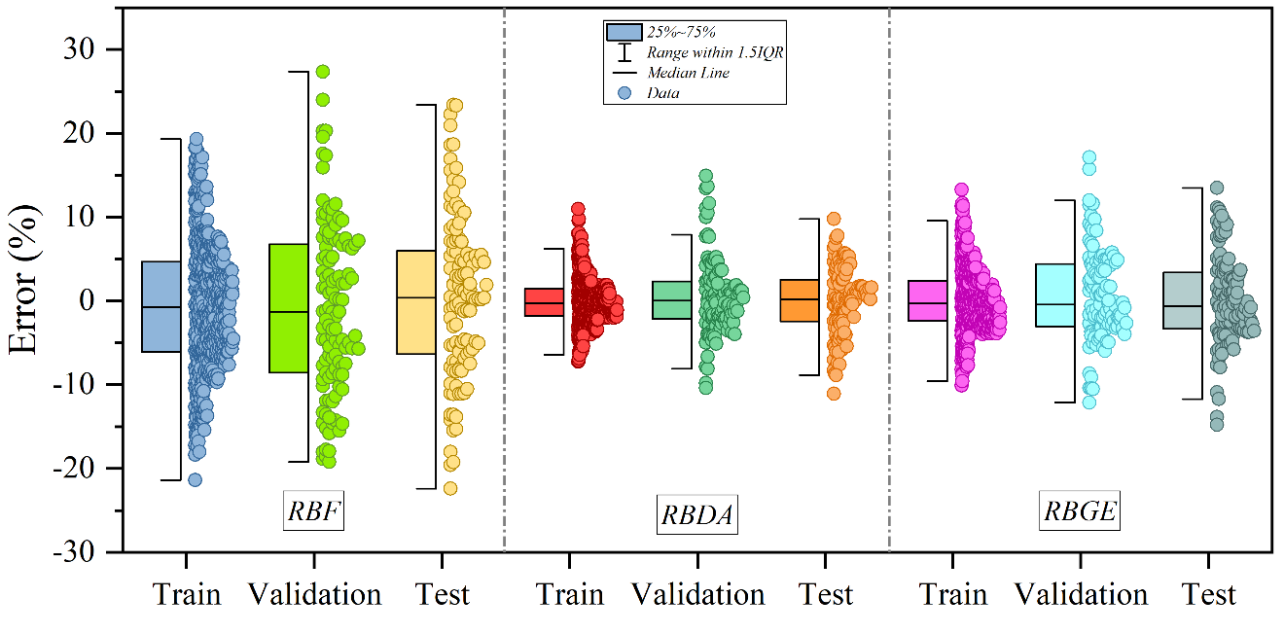

Fig. 5. The half box of errors among the developed models.

TABLE III. THE OUTCOME OF MODELS CREATED FOR RBF

Name	Model	Results	
		RMSE	R^2
Gong et al. [38]	*GBM*	0.1929	0.9882
Afzal et al. [37]	*MLP*	1.4122	0.9806
Roy et al. [39]	*GPR*	0.059	0.99
Present study	**RBF+DAO**	**0.792**	**0.993**

IV. CONCLUSION

In conclusion, this research stressed the significance of accurate forecasting of energy use and assessment of retrofit strategies for the management of building energy systems. The weather, tenant behavior, building characteristics, and energy infrastructure all make it difficult to forecast how much energy a facility will need. Although they depend mostly on data quality and modeling complexity for accuracy, physics-based simulations may provide valuable insights. With an emphasis on Radial Basis Function (RBF) models in particular, this research examined the potential efficacy of ML techniques by using the growing amount of publicly available building energy data. Regarding the prediction of Cooling Load (CL), a significant advancement in civil engineering was made. It achieved this by effectively mitigating the constraints typically associated with ML techniques by incorporating optimization algorithms into RBF models. The forecasted outcomes generated by these models were subjected to a comparative analysis employing five distinct evaluation indices. The findings showcased the presence of a robust and exceptionally accurate predictive model, notably the RBDA (Radial Basis Function optimized with DAO), which displayed an outstanding correlation with the actual measured CL, as evidenced by a high R^2 value of 0.993, 1.95%, and 0.81% higher than RBF and RBGE. Additionally, it's worth noting that RBDA demonstrated the highest level of accuracy among the models, boasting a minimal RMSE value of 0.792. This represented a reduction of 47.96% compared to RBF and a 32.1% decrease compared to RBGE. Developed models solve problems and help engineers and researchers with civil engineering projects. They are reliable and precise in predicting CL, making projects safer and cheaper, and they can be helpful in future research. Addressing the limitations of this study underscores the critical importance of data quality and availability for effective ML model performance. To ensure model generalization across diverse environmental and building conditions, further validation and adaptation efforts are essential to validate broader applicability. The sensitivity of optimization algorithms to specific parameter settings necessitates meticulous fine-tuning to achieve optimal results, emphasizing the need for methodological refinement. Additionally, enriching CL predictive accuracy can be achieved by incorporating additional factors like occupant behavior dynamics or building usage patterns, enhancing practical utility in real-world scenarios. Future research should prioritize enhancing model validation through field studies to ensure robustness and reliability in varying conditions. Exploring advanced ML techniques beyond RBF models, such as deep learning architectures, can elevate prediction accuracy and unveil hidden data patterns. Dynamic model adaptation is a promising avenue for developing responsive models that adjust to evolving building dynamics and environmental factors in real time. Furthermore, integrating uncertainty analysis techniques into CL prediction models can enhance reliability by quantifying uncertainties and providing confidence intervals for predicted CL values, ultimately improving usability in practical applications.

***Abstract*—In smart classroom environments, problems such as occlusion and overlap make the acquisition of student pose information challenging. To address these problems, a lightweight human pose estimation model with Adaptive Target Region Attention based on Lite-HRNet is proposed for smart classroom scenarios. Firstly, the Deformable Convolutional Encoding Network (DCEN) module is designed to reconstruct the encoding of features through an encoder and then a multi-layer deformable convolutional module is used to adaptively focus on the image region to obtain a feature representation that focuses on the target region of interest of the student subject. Secondly, the Channel And Spatial Attention (CASA) module is designed to attenuate or enhance the feature attention in different regions of the feature map to obtain a more accurate representation of the target feature. Finally, extensive experiments were conducted on the COCO dataset and the smart classroom dataset (SC-Data) to compare the proposed model with the current main popular human pose estimation framework. The experimental results show that the performance of the model reaches 67.5(mAP) in the COCO dataset, which is an improvement of 2.7(mAP) compared to the Lite-HRNet model, and 86.6(mAP) in the SC-Data dataset, which is an improvement of 1.6(mAP) compared to the Lite-HRNet model.**

Keywords*—Human pose estimation; smart classroom; Lite-HRNet; deformable convolutional encoding network; target region attention

I. Introduction

In recent years, human pose estimation [1,2,3,4] technology has been widely used in behaviour recognition, action recognition, human-computer interaction and other scenarios along with the rapid development of related technologies in the field of computer vision. With modern and intelligent education being strongly advocated and developed, neural network models based on deep learning are heavily used in classroom detection tasks. In the task of assessing the quality of teaching and learning of student, information about student postures [5,6,7] plays a very important role in assessing the quality of teaching and in teacher understanding of student learning status in the classroom [8]. In the classroom, a student state of learning is demonstrated through a variety of classroom behaviours. Student who are not interested in the content of the classroom will exhibit behaviours such as dawdling, playing with mobile phones and sleeping. Student who are interested in the content of the class show behaviours such as concentration, looking at the board, taking notes, reading, and actively interacting with the teacher. Therefore, how to automatically and accurately collect student pose information in smart classroom [9,10,11] scenarios is an important task that needs to be solved urgently. In smart classroom environments, the acquisition of student pose information is commonly associated with problems such as overlap and occlusion between students, as well as the location of the students leading to large differences in their body sizes, and the presence of small target instances leading to a degradation of the model detection performance. At the same time, the problem of large computational and parametric quantities of the human pose estimation model makes it more difficult to be deployed in smart classroom scenarios. These problems make the acquisition of pose information in smart classrooms a challenging research.

Aiming at the problems of overlapping and occlusion, as well as the large number of model parameters in smart classroom scenarios, this paper proposes a lightweight human pose estimation model framework based on the Lite-HRNet architecture applied to smart classroom scenarios, the Adaptive Target Region Attention Network for Human Pose Estimation. The model is designed with two main modules: (1) The Deformable Convolutional Encoding Network is designed for obtaining a target feature region representation. (2) The Channel And Spatial Attention module is designed to allow the target feature region representation to obtain a more accurate representation of the target region. The model in this paper achieves relatively good performance on two datasets. Extensive ablation experiments are used to validate the effectiveness of each module in the proposed method. The main contributions of this study are summarised as follows:

1) Propose a lightweight pose estimation model for smart classrooms: the Adaptive Target Region Attention Network for Human Pose Estimation. And to construct a student pose estimation dataset suitable for smart classroom environment to provide a database for pose detection in smart classrooms.

2) The Deformable Convolutional Encoding Network (DCEN) is proposed to perform feature extraction on the target region of the feature map to obtain a vector representation with feature regions of interest. The experimental results show that the module designed in this paper can efficiently improve the performance of the model.

3) Proposing an attention mechanism based Channel And Spatial Attention (CASA) module to be used to assist in model training. The module enables the target feature region representation to obtain a better attention effect and fully exploits the spatial and channel feature information in the target feature region.

The rest of the paper is organised as follows. In Section II, the elements involved in the related work are presented. In Section III, the proposed method is described in detail. In Section IV, the experimental results are described and analysed. Finally in Section V, the conclusion of the paper is drawn.

II. Related Work

Traditional methods for human pose estimation are based on graphical structure solutions, which rely too much on hand-crafted feature, are more influenced by algorithms, and have limited model representation capabilities. Deep learning human pose estimation modelling methods are broadly classified into two types: Bottom-Up and Top-Down. Bottom-Up methods [12,13] first detect individual body parts and then compose these detection gesture points into a whole person. On the other hand, the Top-Down approach [14,15,16] first detects the human body bounding box and then detects the human body pose within each bounding box.

Among them, a high-resolution network (HRNet) [17] with top-down approach, has become a mainstream method for human pose estimation due to its efficient detection performance. However, as the performance of the human pose estimation model improves, it is accompanied by a significant increase in the number of parameters. Wang [18] In order to address the problem of huge computational effort associated with attitude estimation models for high-resolution structures. A fused inverse convolution head module is used to eliminate redundancy in the high-resolution branch and achieve scale feature fusion with low computational effort. As well as the use of large convolution kernels to improve the sensory field of the model and reduce the computational effort of the model. The IGCV3 [19] model decomposes the regular convolution into multiple grouped convolutions to reduce the amount of computation of the convolution function in the model, thus reducing the number of parameters in the model. The MobileNet [20] model reduces the model parameters by decomposing a normal convolution into a deep convolution and a dot convolution, while maintaining the same performance as a normal convolution. The Lite-HRNet [21] model uses the method of performing information exchange across channels to maintain the information exchange between channels, in place of the expensive ordinary convolutional computation.

To address the problems that arise in the task of human pose estimation, Artacho et al [22] utilised a multi-scale feature representation to improve the effectiveness of keypoint feature extraction without significantly increasing the model parameters. Tang et al [23] proposed a new spatio-temporal longitudinal and transversal attention module to reduce the computational effort of the model by decomposing the joints feature matrix in both spatial and temporal dimensions. Zhao et al [24] addressed the problem of increasing the computational burden by increasing the size of the input sequences to enhance the performance of the model by using a compact representation of long skeleton sequences in the frequency domain to efficiently expand the receptive field and improve the robustness to 2D noisy pose detection. Liu et al [25] proposed limb orientation cue-aware networks to prevent overfitting of the depth network leading to uncertain keypoint locations. Yang et al [26] proposed a two-stage pose distillation model for whole-body pose estimation to address the problem of varying body part scales in order to improve the validity and efficiency of the model. Lee et al [27] designed a pose estimation model with self-training loss using pose-aware confidence in semi-supervised and unsupervised pose estimation tasks. In this paper, the lightweight Lite-HRNet is used as the backbone network. Design of deformable convolutional encoding networks and attention mechanism based channel and spatial attention modules to enhance the model ability to extract key point feature. Allow model performance to be efficiently improved without significantly increasing the computational and parametric count of the model. Thereby the model can be more effectively applied to detection tasks in different scenarios.

III. Proposed Method

The Adaptive Target Region Attention Network is designed with two main modules: the DCEN module, the CASA module, and the overall network framework is shown in Fig. 1. Firstly, the visual feature $\{F_{t-2}, F_{t-1}, F_t\}$ of the input sequences are extracted by the backbone network Lite-HRNet-18 network, and they are input into the DCEN module to calculate the information difference between the background feature and the subject feature, and to obtain the target region attention feature M_t. Then, the target region attention feature M_t are mined for channel and spatial information by CASA module to get the target region focus attention feature $M_t^{'}$. Finally, the combination of feature $M_t^{'}$ and visual feature F_t generates enhanced visual feature $F_t^{'}$. The feature $F_t^{'}$ are input into the pose estimation detection head to obtain the keypoint detection heatmap H_t. In the following, each module will be explained in detail.

A. Deformable Convolutional Encoding Network

The Deformable Convolutional Encoding Network is divided into three main steps: (1) Stage Feature Sequence Acquisition, which inputs the image sequence X_t into the Lite-HRNet network to obtain visual feature $\{F_{t-2}, F_{t-1}, F_t\}$. (2) Feature Sequence Fusion. The global visual feature S_t is obtained through a convolutional encoding network on the reconstructive encoding of the feature sequence. (3) Adaptive Target Region Attention Feature. Input the global visual feature S_t into the deformable convolutional network, use the deformable convolution to calculate the region information in the feature map, capture the visual feature of the target region, and reduce the influence of background feature and noise feature on the target region feature. The target region attention feature M_t is obtained through the DCEN module, which is used to pay attention to and capture the feature information of the target region in image. The DCEN module is shown in Fig. 2.

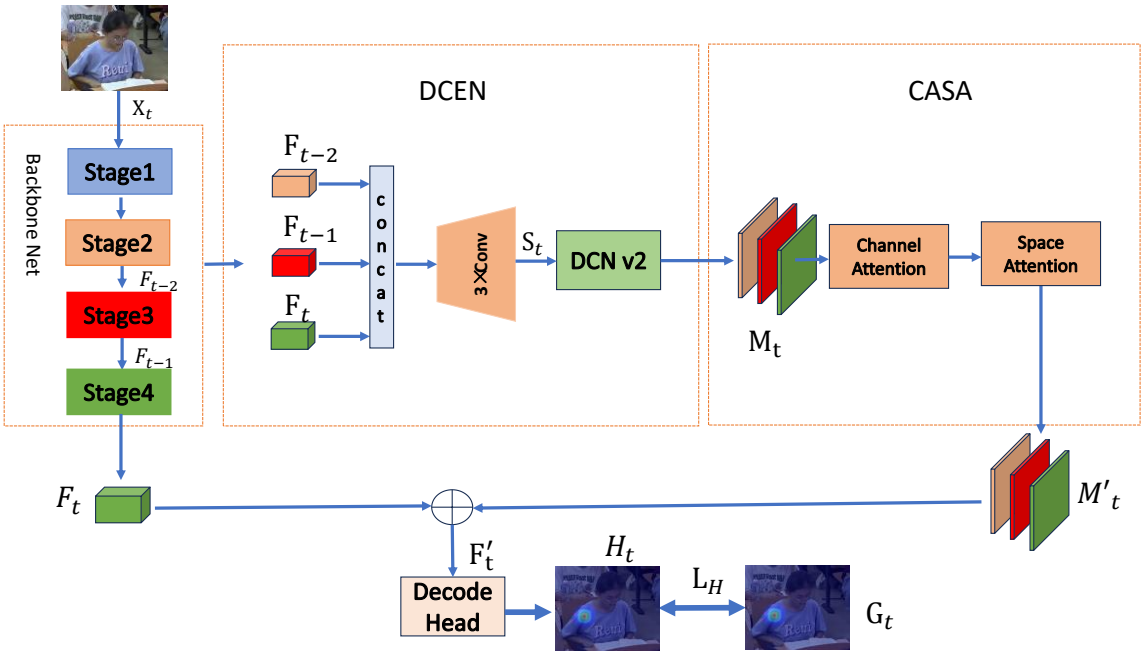

Fig. 1. Overall network framework.

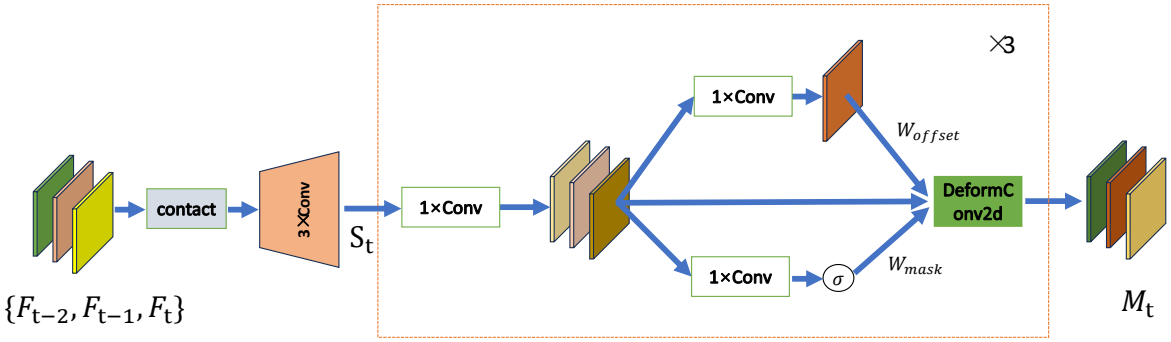

Fig. 2. DCEN module.

Stage Feature Sequence Acquisition: visual feature is extracted by Lite-HRNet network. Lite-HRNet replaces the expensive 1×1 convolution in the shuffle block [28] with a lightweight conditional channel weighting module, allowing the model to maintain efficient performance while reducing the computational effort of the network. Since the computational complexity is linear, it is lower than the quadratic time complexity of point-by-point convolution. Input the image sequence X_t into the Lite-HRNet network and acquire the visual feature $\{F_{t-2}, F_{t-1}, F_t\}$ of the three stages in the Lite-HRNet network. Where F_{t-2}, F_{t-1}, F_t is the output visual feature of the second, third, and fourth stages of the Lite-HRNet network.

Feature Sequence Fusion: multiple stages of visual feature of different coarseness were obtained from the Lite-HRNet network. They possess semantic information about visual feature in different depths. In order to better utilise the semantic information of these visual feature, an up-sampling approach is used to reconstruct and encode the different stages of the visual feature into a fusion that increases the resolution of the feature sequence and enhances the retention of edge information. And combining their shallow and deep visual feature to generate the global visual feature S_t with global visual information and more fine-grained. The operation is shown in Eq. (1):

$$S_t = Conv(F_t \oplus F_{t-1} \oplus F_{t-2}) \quad (1)$$

Where is a network of 3 convolutional layers.

Adaptive Target Region Attention Feature: Input the global visual feature S_t into the deformable convolutional network [29], and use the deformable convolution to adaptively capture the regional information of the feature map to obtain the target region attention feature M_t. Firstly, the global visual feature S_t are used to compute a trainable parameter W_{offset}, which is used to supervise the adaptive region orientation of the deformable convolution. The operations are shown in Eq. (2), (3), and (4):

$$S_t^{'} = \frac{W_i * S_t - E(W_i * S_t)}{\sqrt{Var(W_i * S_t) + \varepsilon}} \quad (2)$$

$$M_{t-1} = \frac{S_t^{'}}{1+e^{-S_t^{'}}} \quad (3)$$

$$W_{offset} = M_{t-1} * W_i \quad (4)$$

Where W_{offset} is a feature map with directional shifts, which serves to compute the shifts in the x and y directions of the input feature, W_i convolutional weights, $Var()$ is the averaging function, $E()$ is the expectation function, ε is an offset constant.

Then, the penalty weight parameter W_{mask} is added for guiding the training of the network and speeding up the convergence of the deformable convolutional network. As shown in Eq. (5):

$$W_{mask} = (1+e^{-W_i * M_{t-1}})^{-1} \quad (5)$$

Finally, the input feature vector M_{t-1} with an offset parameter W_{offset} with a penalty weight W_{mask} is input into the deformable convolution function for deformable convolution operation to compute the target region attention feature M_t. The operation is shown in Eq. (6), (7), and (8):

$$M_{t1} = f(W_{mask}, M_{t-1}, W_{offset}) \quad (6)$$

$$M_{t2} = \frac{M_{t1} - E(M_{t1})}{\sqrt{Var(M_{t1}) + \varepsilon}} \quad (7)$$

$$M_t = (1+e^{M_{t2}})^{-1} \quad (8)$$

Where $f()$ is a deformable convolution function, W_{mask} is a penalty weight parameter, W_{offset} is an offset parameter. $Var()$ is the averaging function, $E()$ is the desired function, ε is an offset constant.

B. Channel And Spatial Attention Module

The target region attention feature M_t obtained through the DCEN module is still susceptible to mission-independent noise signals such as background, occlusion, and overlap. By using the CASA module based on the attention mechanism [30] to mine the feature information of the channel and space of the target region attention feature M_t. Allow the feature to gain supervision and attention in channel and space. The designed CASA module has two sub-modules which are used to focus on the valid information of the feature vectors in channel and space respectively and to enhance the characteristics of the valid information as well as to suppress the noisy information. The architecture of the CASA module is shown in Fig. 3.

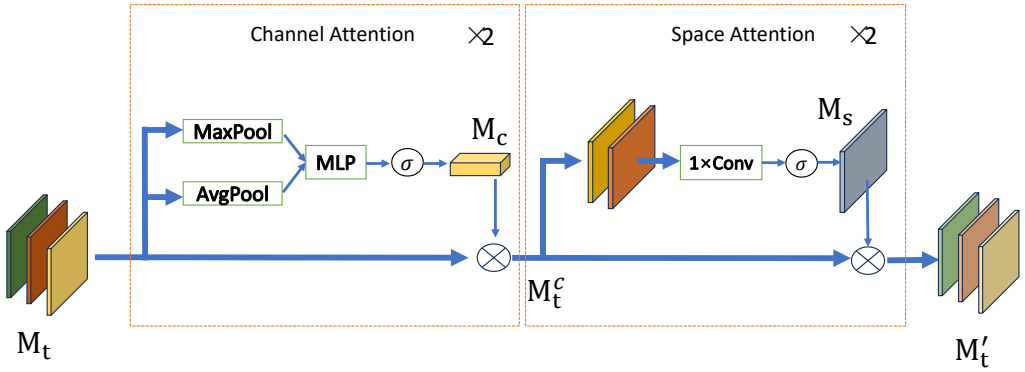

Fig. 3. CASA module.

Feature Sequence Channel Attention: Firstly, the information of each channel of target region attention feature M_t is aggregated by global maximum pooling and global average pooling. They are used to preserve the most significant feature in each channel and the overall average feature. The two feature information is then optimised using an MLP fully connected network trained to obtain parameter M_c with feature information for each channel, Finally, the multiplication operation of M_c with M_t makes the feature M_t aggregate the useful feature information of each channel. The implementation of the channel attention module is shown in Eq. (9) and (10):

$$M_c = \sigma(F(Avg(M_t)) + F(Max(M_t))) \quad (9)$$

$$M_c^t = M_t \otimes M_c \quad (10)$$

Where σ is the *sigmoid* activation function. $Avg()$, $Max()$ are the global average pooling and global maximum pooling functions, $F()$ is a three-layer fully connected network.

Feature Sequences Spatial Attention: The approach to spatial attention is similar to that of channel attention, where global maximum pooling and global average pooling are used for different dimensions to aggregate the feature information of feature M_t^c Firstly, instead of aggregating the feature information of each channel, spatial attention aggregates the feature information of all channels together, making each channel spatially connected to each other. The two features information is then optimised using a convolutional network trained to obtain parameter M_s with spatial correlation information for each channel feature. Finally, the

multiplication operation of M_s and M_t^c is performed to obtain the target region focus attention feature $M_t^{'}$ with channel and spatial attention information. The spatial attention module is implemented as in Eq. (11) and (12):

$$M_s = \sigma(W_i * (Avg(M_t^c), Max(M_t^c))) \quad (11)$$

$$M_t^{'} = M_s \otimes M_t^c \quad (12)$$

Where σ is the *sigmoid* activation function, W_i is the convolution weight, and the convolution kernel size is 3×3.

C. Loss Function

Combine the target region focus attention feature $M_t^{'}$ with the visual feature F_t to obtain the enhanced visual feature $F_t^{'}$. Input to the detection head generates a pose point heatmap H_t. The detection head module is implemented by a convolutional network. The loss function uses the L_H loss of the heat map of standard attitude estimation to supervise the attitude estimation model. The operation is shown in Eq. (13), (14), and (15):

$$F_t^{'} = F_t + M_t^{'} \quad (13)$$

$$H_t = W_i * F_t^{'} \quad (14)$$

$$L_H = \| H_t - G_t \|^2 \quad (15)$$

Where H_t and G_t denote the predicted and real attitude thermograms, W_i is the convolution weight.

IV. Experiments

Two pose estimation datasets: the COCO dataset and the Self-Constructed Smart Classroom dataset (SC-Data) are used in the experiments to evaluate the effectiveness of the models, and the results of comparisons with other mainstream human pose estimation models in both datasets are reported. Also, extensive ablation experiments are conducted to validate the effectiveness of the module proposed in this paper.

A. Introduction to the Dataset

SC-Data dataset: SC-Data dataset is a dataset made based on real classroom teaching data, which has 6,000 images and 16,800 instances of student pose data. There are 14000 instances in the training set and 2800 instances in the test set. The SC-Data dataset is made from one semester's worth of student classroom data and contains information about the student's classroom postures over the course of a semester. This will provide data to understand the complete pose information of students in a particular subject and provide a more accurate source of dataset for obtaining student pose information on teaching.

COCO 2017 dataset: COCO has over 200000 images and 250000 person instances with 17 keypoints, train2017 dataset (includes 57000 images 150000 person instances), val2017 (includes 5000 images).

B. Experimental Setup

In this paper, the network is trained using 1 NVIDIA A100 GPU, the optimisation algorithm is Adam with an initial learning rate of 0.0002 and a batch size of 64, the input to the network is an image with a fixed 4:3 aspect ratio, cropped from the original and resized to 256×192, the model is implemented in the PyTorch framework. In the pose evaluation metrics, the model evaluated using mean accuracy (mAP), the AP is first calculated for each joint and then the final performance (mAP) is obtained by averaging over all joints. The criterion is based on the metrics of the COCO dataset pose estimation.

C. Experiment Results and Analyses on the COCO Dataset

The models in this paper were evaluated on the COCO dataset and the performance of the comparison models on the COCO test set is shown in Table I. The human pose estimation performance of this paper model reaches 67.5(mAP). Compared to Small HRNet-W16 and Lite-HRNet-18 the gain is improved by 12.3(mAP) and 2.7(mAP). Compared to Lite-HRNet-30 the performance is improved by 0.3(mAP), but the model parameters decreases by 0.3(M). Compared to Integral Pose Regression [31] and G-RMI [32], which are computationally and parameter intensive, the model in this paper achieves quite good performance, but there is a substantial reduction in model complexity and number of parameters. The results of comparing the computational complexity of this paper model with other models are shown in Fig. 4, where the GFLOPs decrease by 0.41(GFLOPs) compared to ShuffleNetV2, while at the same time, the performance has a 7.6(mAP) improvement. Compared to Lite-HRNet-18 the GFLOPs increase by 0.52(GFLOPs), but have a 2.7(mAP) performance improvement.

D. Experimental Results and Analyses on the SC-Data Dataset

Evaluating the method of this paper on the SC-Data dataset of this paper and comparing the performance of the model algorithm on the validation set is shown in Table II, and the experimental inference results of the model of this paper are shown in Fig. 5. The performance of the model in this paper on the SC-Data dataset, reaches 86.6(mAP). Compared to Lite-HRNet-18 and Lite-HRNet-30 with a gain of 1.6(mAP) and 1.2(mAP) points respectively. The model in this paper maintains the efficient performance while the model complexity is also reduced by 0.3(M) relative to Lite-HRNet-30. By comparing the experiments on the two datasets, this makes the model application scenarios of this paper richer, and at the same time, the lightweight human pose estimation model in this paper is easy to deploy to smart classroom scenarios.

In the scenario of occlusion and overlap in the smart classroom, the inference performance comparison is carried out by comparing with other models, and the comparison results are shown in Fig. 6, Fig. 6(1) shows the model of this paper, and Fig. 6(2) shows the Lite-HRNet18. By comparing with other models, it can be concluded that in the estimation of the gesture of the students of the target, the model of this paper can reduce the problems caused by problems such as the occlusion or overlap between the student The detection errors of the pose points are shown in the red circles marked in Fig. 6(2). The experimental results show that the model in this paper can effectively reduce the error detection of not the same target in smart classroom scenarios, and has better performance for scenarios with occlusion and overlap.

TABLE III. ABLATION EXPERIMENTS WITH ADDED MODULES

Lite-HRNet	DCEN	CASA	COCO(mAP)	SC-Data (mAP)
√		√	65.7	85.6
√	√		66.6	85.7
√	√	√	67.5	86.6

E. Ablation Study

An ablation experiment was designed to add the DCEN module and the CASA module so as to verify the contribution of each module in the network, as shown in Table III, where "√" represents the addition of this module in the network. In the SC-Data dataset, the DCEN module provided a performance gain of 0.7(mAP)(85.0 → 85.7) compared to the Lite-HRNet network. The CASA module provided a performance gain of 0.6(mAP)(85.0 → 85.6). The performance enhancement of the model in the network where the DCEN module is added together with the CASA module is better compared to one added module alone, which improves the model with a performance gain of 1.6(mAP)(85.0 → 86.6). The significant performance gain indicates that the modules proposed in this paper play an important role in extracting feature information from the target region. In the COCO dataset, the DCEN module can improve the performance gain of the model by 1.8(mAP)(64.8 → 66.6), and the CASA module can improve the performance gain of the model by 0.9(mAP)(64.8 → 65.7). The ablation experiments verify that the modules in this paper can be applied to different scenarios and effectiveness.

V. CONCLUSION

This paper addresses the task of student pose estimation in smart classrooms by proposing a lightweight human pose estimation model with Adaptive Target Region Attention Network. Firstly, this paper proposes the deformable convolution-based target region attention module (DCEN) to capture student subject region representations. Secondly, in order to further obtain more precise attention to the target region, the channel and spatial attention module (CASA) is proposed to attend to the information about the relevant tasks on the space and channels of the feature map. Finally, a large number of experiments show that the model has excellent performance on both the COCO dataset and the homemade smart classroom dataset (SC-Data), while the number of parameters in this paper model has been greatly reduced and the detection speed has been greatly improved compared to the human pose estimation model with a large amount of computation and parameters. In future work, the paper will focus on deploying the pose estimation model to the classroom and applying the acquired student pose information to the task of assessing teaching quality.

Breast Cancer Classification Through Transfer Learning with Vision Transformer, PCA, and Machine Learning Models

Juan Gutierrez-Cardenas
Carrera de Ingeniería de Sistemas, Universidad de Lima, Lima-Perú

***Abstract*—Breast cancer is a leading cause of death among women worldwide, making early detection crucial for saving lives and preventing the spread of the disease. Deep Learning and Machine Learning techniques, coupled with the availability of diverse breast cancer datasets, have proven to be effective in assisting healthcare practitioners worldwide. Recent advancements in image classification models, such as Vision Transformers and pretrained models, offer promising avenues for breast cancer imaging classification research. In this study, we employ a pretrained Vision Transformer (ViT) model, specifically trained on the ImageNet dataset, as a feature extractor. We combine this with Principal Component Analysis (PCA) for dimensionality reduction and evaluate two classifiers, namely a Multilayer Perceptron (MLP) and a Support Vector Machine (SVM), for breast mammogram image classification. The results demonstrate that the transfer learning approach using ViT, PCA, and an MLP classifier achieves an average accuracy, precision, recall, and F1-score of 98% for the DSMM dataset and 95% for the INbreast dataset, considering the same metrics which are comparable to the current state-of-the-art.**

***Keywords*—Breast cancer; vision transformer; transfer learning; PCA; machine learning**

I. Introduction

Breast cancer, as defined by the World Health Organization (WHO) [39], encompasses a spectrum of diseases. It can manifest as a slow progression without symptoms, or it can take on an aggressive form, invading surrounding tissues and potentially spreading to nearby lymph nodes or other organs. Early identification of breast cancer is of utmost importance to prevent adverse outcomes. As per the National Cancer Institute (NIH) [26], breast cancer ranks as the second most common cause of mortality in the United States. The screening process is essential for the early detection of breast cancer cases prior to the manifestation of symptoms, with mammography being the predominant screening method. Aside from mammography, there are several other techniques available for detecting breast cancer, such as breast ultrasound, breast magnetic resonance imaging (MRI), and biopsy [5].

Classical mammographic images, as seen in the DDSM dataset (Heath et al., 1998), have inherent limitations in terms of image contrast and quality when compared to alternative techniques such as Magnetic Resonance Imaging (MRI). The problem is more noticeable in samples obtained from young women, as their breast tissue density is higher [4].

In order to overcome these constraints, alternative mammographic techniques, such as full-field digital mammography (FFDM), have been developed and are employed to extract information to be used in datasets such as INbreast [27]. The benefits of employing this technique encompass aspects such as patient satisfaction, simplicity of image manipulation, enhanced display contrast, superior detection efficiency, and minimal vulnerability to noise. One significant benefit is that these images can be employed for computer-aided diagnosis (CAD) tools [25].

Among these techniques, the availability of public datasets, particularly those derived from diagnostic mammograms or breast MRI, has facilitated the application of diverse Machine Learning and Deep Learning models for the identification and classification of breast cancer across different stages of the disease. In Tsochatzidis et al. [38], for instance, the researchers used a modified CNN with U-Net-derived image segmentation and evaluated it using the DDSM dataset. In terms of the AUC metric, the authors' diagnostic performance was 0.898. Min et al. [24] employed a Mask R-CNN for mass detection and segmentation using the INbreast dataset in a different study. The average true positive rate that the researchers were able to obtain in this study was 0.9. Readers interested in the utilization of these datasets through the application of Convolutional Neural Networks (CNNs) are encouraged to examine the research conducted by Zhu et al. [40].

In their study Samee et al. [32] used the INbreast and mini-MAIS datasets to demonstrate the efficacy of a breast cancer detection system. The system employed image pre-processing techniques, specifically contrast-limited adaptive histogram equalization (CLAHE) and pixel-wise intensity adjustment, to generate pseudo-colored images. Transfer learning was utilized in conjunction with various deep learning models, including AlexNet, VGG, and GoogleNet, to leverage pre-trained features. Additionally, Logistic Regression and Principal Component Analysis (PCA) were employed to extract the most informative features. The authors applied PCA to mitigate multicollinearity issues that could arise from synthetic image generation. The proposed approach resulted in 23 principal components. Multiple machine learning methods, such as Support Vector Machines (SVM), decision trees, and Convolutional Neural Networks (CNN), were utilized as classifiers. Notably, the CNN classifier achieved the best performance, attaining an accuracy of 98.8% for the MIAS dataset and 98.62% for the INbreast dataset.

Al-Tam et al. [1] used various deep learning models that were employed for both a two-class classifier (benign and malignant) and a three-class classifier that included a normal state as an additional class. The Curated Breast Imaging Subset of DDSM (CBIS-DDSM) and the Digital Database of Screening Mammography (DDSM) datasets were utilized for evaluation. The authors utilized pre-trained models such as VGG16, ResNet50, and ImageNet. Furthermore, they compared the performance of these pre-trained models with a CNN trained from scratch and a hybrid model combining ResNet50 with a Vision Transformer (ViT). Notably, the proposed approach achieved exceptional results with 100% F1-Score, accuracy, and AUC for the binary classification task. However, it is important to consider that these results might be influenced by the quality of information available in the CBIS-DDSM dataset. In the multiclass scenario, the performance metrics decreased to 96% on the validation set and 95% on the test set. The authors acknowledged the need for further evaluation using additional datasets such as INbreast and MAIS to assess the generalizability of their proposed approach.

In their study, Houssein et al. [14] introduced an enhanced version of the Marine Predators algorithm (MPA) called the Improved Marine Predators algorithm (IMPA). This algorithm, which incorporates Opposition-based Learning (OBL), was utilized for hyperparameter optimization of various CNN models on the DDSM and MIAS datasets. Specifically, the authors applied IMPA to optimize the hyperparameters of a ResNet50 model, which employed transfer learning and data augmentation techniques. Notably, the proposed approach achieved compelling results on both datasets. For the CBIS-DDSM dataset, the ResNet50 model attained an accuracy of 98% and an F1-score of 97%. Similarly, on the MAIS dataset, the model achieved an accuracy of 98% and an F1-score of 97%. However, the authors recognized certain limitations of their approach, e.g., the computational cost associated with IMPA was relatively high. Additionally, the proposed architecture was specifically tailored to the tested datasets, which may limit its generalizability.

In Table I, we have summarized the mentioned studies along with others, considering their methodology.

Our main contribution lies in the design of a transfer learning-based Vision Transformer (ViT) that incorporates PCA for feature reduction, addressing the challenge posed by the large number of features extracted from images. This approach is combined with a simple machine learning technique to aid in the classification of breast cancer image samples. The ViT serves as a feature or characteristic extractor from images in our design, and we reduce their dimensionality using PCA to overcome processing time complexity. PCA is commonly used as a pre-processing technique to enhance the efficiency of Machine Learning models [21] by removing unnecessary or irrelevant data [29]. Furthermore, it has demonstrated favourable results in the categorization of breast mammograms [28]. Following this, a simple and non-computationally expensive machine learning technique is employed, with the hypothesis that it will produce accurate results considering the DSSM and INBreast breast cancer image datasets that are comparable to the existing literature. In summary, we aim to leverage the feature extraction capabilities of a state-of-the-art model, such as ViT, and subsequently reduce the dimensionality of these features using PCA. Considering the advantages mentioned before of this dimensionality reduction technique, we then plan to employ computationally non-costly machine learning models like MLP and SVM. Moreover, our current work contributes a proof-of-concept showing how cutting-edge models, like ViT, can be combined with traditional techniques like PCA and machine learning models to produce reliable classification results for breast cancer diagnosis that are on par with those documented in the literature.

TABLE I. RELATED WORKS AND THEIR METHODOLOGY

Authors	Methodology
Tsochatzidis et al. [38]	Employs a modified CNN architecture that incorporates a U-Net for image segmentation during input.
Min et al. [24]	Grayscale images are converted into pseudo-color and the masses are amplified for utilization in a Mask R-CNN that utilizes transfer learning.
Samee et al. [32]	Images are improved through the application of contrast-limited adaptive histogram equalization (CLAHE). A CNN model, selected from AlexNet, VGG, or GoogleNet, is used to extract features, while a Logistic Regression model with PCA is employed for classification.
Al-Tam et al. [1]	The authors employed VGG16, ResNet50, and Imagenet for both binary and multiclass classification. For the final test, they utilized a ResNet50 model that was trained from scratch, in addition to a ViT model.
Samee et al. [33]	The authors utilized pre-trained convolutional neural network (CNN) models, specifically AlexNet, GoogleNet, and VGG-16. The authors utilized pre-trained convolutional neural network (CNN) models, specifically AlexNet, GoogleNet, and VGG-16. The researchers used several feature selection methods, such as Pearson Correlation Coefficient, Cosine Coefficient (mostly used for texts), Euclidean Distance (though Liu and Zhang (2016) warned that it might not be the best way to represent data characteristics, which could lead to poor learning), and Mutual Information. The chosen characteristics were subjected to classification using an ensemble of learners utilizing Discriminant Analysis, Support Vector Machines (SVM), K-Nearest Neighbors (KNN), and Naive Bayes. Nevertheless, it is still uncertain whether they employed a combination of machine learning models or determined which one produced the most optimal outcomes.
Jabeen et al. [19]	The authors utilized a haze-reduced local-global image enhancement technique. The images were subjected to augmentation, and a pre-trained EfficientNet-b0 model was used as a feature extractor, excluding the last three layers. The process of selecting features was conducted utilizing the Equilibrium-Jaya controlled Regula Falsi algorithm. An ensemble of K-nearest neighbors (EKNNs) was utilized for classification.
Our Proposal	The ViT model is utilized as a feature extractor, PCA is employed for dimensionality reduction, and MLP and SVM are used as classifiers for the purpose of comparison.

We have organized our work into the following sections: Section II provides an overview of Transfer Learning and Vision Transformers, covering the relevant theoretical aspects. In Section III, we outline our methodology, describing the algorithms used to guide our procedures; we also had the experimental setup conducted on two breast cancer datasets. Section IV presents the key findings and results obtained from our models. In Section V, we engage in a comprehensive discussion of the results, drawing comparisons with relevant studies that have also explored breast cancer classification. Finally, we conclude our article with a summary of the main insights and conclusions derived from this study in Section VI.

II. BACKGROUND

A. Breast Cancer Datasets: DDSM and INbreast

Multiple Breast Cancer Datasets are available, with some being freely accessible and others requiring permissions for use. This study will employ the DDSM and INbreast datasets, which will be briefly described.

1) DDSM dataset: This dataset is a well-known collection of digitized copies derived from images taken during a screening exam. Furthermore, it includes carefully selected images curated by professionals, displaying an accurate representation of both benign and malignant instances of breast cancer. An inherent concern with this dataset, despite its widespread utilization throughout the years, is the existence of anomalies in certain images, such as the occurrence of dust or scratches, which necessitate careful consideration [13].

2) The INbreast Dataset was obtained from a university hospital in Portugal and consists of samples from both breast cancer patients and healthy individuals. This dataset offers several benefits, such as including samples obtained from patient screenings, diagnoses made based on abnormalities, and follow-up cases of individuals who underwent some type of treatment. Furthermore, the dataset contains a wide range of observations that can be identified during breast exams, including asymmetries, calcifications, distortions, masses, and nodules. The images were acquired using FFDM equipment, which offers superior image quality in comparison to their DDSM equivalent [27].

B. Transfer Learning

Transfer learning is a technique that enables a model to use the knowledge acquired during the training of a previous model rather than starting the training process from scratch. The fundamental idea is that if a model has learned useful representations or variations on a dataset P1, those representations can be transferred or adapted to improve the learning of a new task P2 [10].

To illustrate this concept, let's consider the ResNet model. This model is often pre-trained on a large dataset such as ImageNet, which contains a vast number of images from various categories. When pre-training ResNet, the model learns to recognize general features and patterns in the images. The later layers of the model, which are responsible for making specific predictions, can be replaced with new layers that are tailored to the target task. The reason for this replacement is that the early layers have already captured general features, while the later layers can be fine-tuned to capture task-specific features for the new dataset [20].

For example, if we have a deep learning model based on VGG16, we can exclude the classifier part by disabling or removing the top layer. By doing so, we obtain a feature vector of 4096 numbers. This vector can be serialized and stored, serving as input to a new model. Alternatively, we can replace the classifier part with a new set of convolutional layers if we want to use a different classifier. This adaptability allows us to customize the model architecture according to the specific requirements of the task at hand [3, 8].

C. Vision Transformer

A Vision Transformer (ViT) is a type of attention model initially developed for Natural Language Processing (NLP) tasks but has also shown promise in image analysis. Unlike traditional convolutional neural networks (CNNs), ViT requires fewer computational resources when pre-trained on a large image dataset and subsequently applied to smaller datasets for classification tasks.

The ViT model operates by dividing an image into a set number of patches, each with a fixed size. These patches are then embedded, creating a sequence of embeddings that is subsequently fed into a Transformer Encoder. The Transformer Encoder is made up of self-attention heads and MLP (Multi-Layer Perceptron) blocks, which help the model find patterns and connections in the image [7]. A schematic representation of the ViT model is presented in Fig. 1.

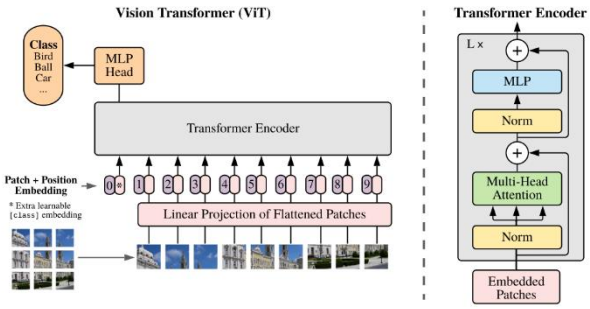

Fig. 1. Vision transformer model [7].

D. Evaluation Metrics

For validating the result or our proposed model we have used the following metrics [9]:

Accuracy: This value represents the proportion of correctly classified instances. It is calculated by considering instances that are predicted to have positive or negative values and belong to one of those classes. The formula is as follows:

$$acc = \frac{1}{|Te|}\sum_{x \in Te} I[\hat{c}(x) = c(x)] \quad (1)$$

In Eq. (1), the Te refers to the test set, while the function $I[x]$ refers to the indicator function. This function takes a value of 1 when the value is correctly classified and 0 in other cases.

Precision: This metric refers to the calculation of the proportion of accurate positive predictions. This means that if the model predicts a value in the positive class, it must be in that class. The formula is as follows:

$$Prec = \frac{TP}{TP+FP} \quad (2)$$

where, TP and FP represent True Positive and False Positive, respectively. A True Positive is an instance that has this value and was correctly classified as positive, whereas a False Positive is an instance that was incorrectly classified as positive but has a negative value.

Recall: This metric refers to the percentage of all positive instances that are correctly predicted. This means that if all positive instances of a model are considered, this metric tells us how many the model correctly predicted. The formula for this metric is as follows:

$$\text{Rec} = \frac{\text{TP}}{\text{TP+FN}} \quad (3)$$

False Negative (FN) refers to instances that are classified as negative but belong to a positive class.

F1-Score: When we want to calculate the average of the incorrect classifications made while considering the set of classes, we can use the F1-score formula:

$$F1 - \text{Score} = \frac{2}{\frac{1}{\text{Prec}}+\frac{1}{\text{Rec}}} \quad (4)$$

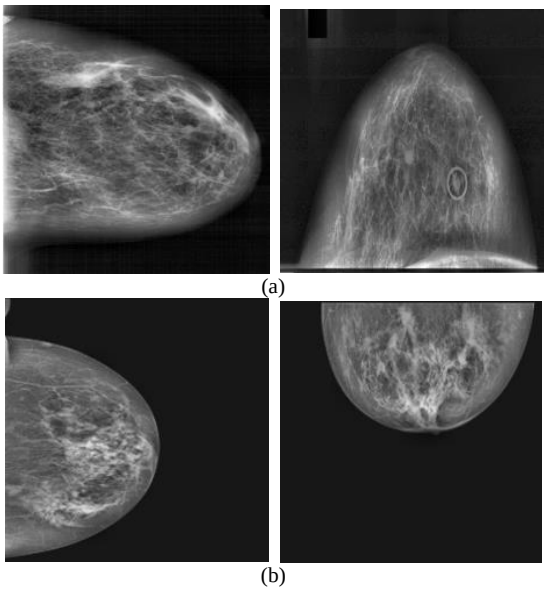
III. Materials and Methods

A. Dataset

The objective of this study was to evaluate the performance of a couple of machine learning models, specifically the Multi-Layer Perceptron (MLP) and Support Vector Classifier (SVC), in conjunction with transfer learning techniques and a Vision Transformer for breast cancer image classification. We conducted experiments using a dataset comprising images of benign and malignant breast samples obtained from the Digital Database for Screening Mammography (DDSM) and the INbreast datasets.

In this study, we collected a dataset of breast mammography images from the Dataset of Breast Mammography Images with Masses (Huang and Lin, 2020), which is available at https://data.mendeley.com/datasets/ywsbh3ndr8/2.
Specifically, we utilized the Digital Database for Screening Mammography (DDSM) and the INbreast datasets [12] from this repository.

The dataset used in this study was compiled from multiple sources. Initially, Huang and Lin [15] selected 106 images from the INbreast dataset, 53 images from the MIAS dataset, and 2188 images from the DDSM dataset. To address the issue of overfitting, a data augmentation technique was employed, which involved multi-angle rotation, flipping, and 11-angle rotation in both horizontal and vertical directions. The compiled dataset, available at https://data.mendeley.com /datasets/ywsbh3ndr8/2, is organized into four folders: DDSM dataset, INbreast dataset, INbreast+MIAS+DDSM dataset, and MIAS dataset. For our experiments, we focused on the DDSM dataset and the INbreast dataset. The DDSM dataset consists of both benign and malignant masses, with 5970 and 7158 samples, respectively. The INbreast dataset contains 2520 samples of benign cases and 5112 samples of malignant cases. An example of both types of samples from these datasets is shown in Fig. 2.



(a) (b)

Fig. 2. A couple of samples from the benign and malignant masses as found in the DDSM (a) and INbreast datasets (b).

Considering the number of samples, we can observe that the DDSM dataset consists of 55% malignant masses and 45% benign masses, while the INbreast dataset consists of 33% malignant cases and 67% benign cases. Based on these percentages, we can conclude that the data is not imbalanced. It is worth noting that the study conducted by Haibo and García [11] suggested that a dataset can be considered imbalanced if the minority class constitutes less than 10% of the total samples. It is important to mention that their study focused on dichotomous classes, similar to the ones examined in our research. In scenarios in which the data is unbalanced, techniques such as data augmentation [15] can be used. This includes image rotation at 11 angles in both horizontal and vertical directions, ranging from 30º to 330º degrees in 30-degree increments. Additionally, horizontal and vertical flipping can be used.

B. Methodology

In the Fig. 3, we have depicted the steps followed in our work and that can be summarize in the following steps:

Step 1: We obtained a collection of images from the DDSM and INbreast datasets that represent both benign and malignant formations related to breast cancer. Prior to being inputted into a Vision Transformer (ViT) model, this data undergoes resizing and normalization.

Step 2: The ViT model operates as a feature extractor through the utilization of transfer learning. To carry out the

mentioned function, the classifier head is detached from this model.

Step 3: After that, a PCA model receives the features that the ViT model generated. During this stage, we isolate a subset of components that possess the ability to elucidate the majority of the data. The objective is to decrease the dimensionality of the data, rendering it more manageable for straightforward and computationally efficient machine learning models such as a Multilayer Perceptron (MLP) and a Support Vector Machine (SVM).

Step 4: The hyperparameters of both models are adjusted, and the classification results are assessed using metrics such as accuracy, precision, recall, and F1-score.

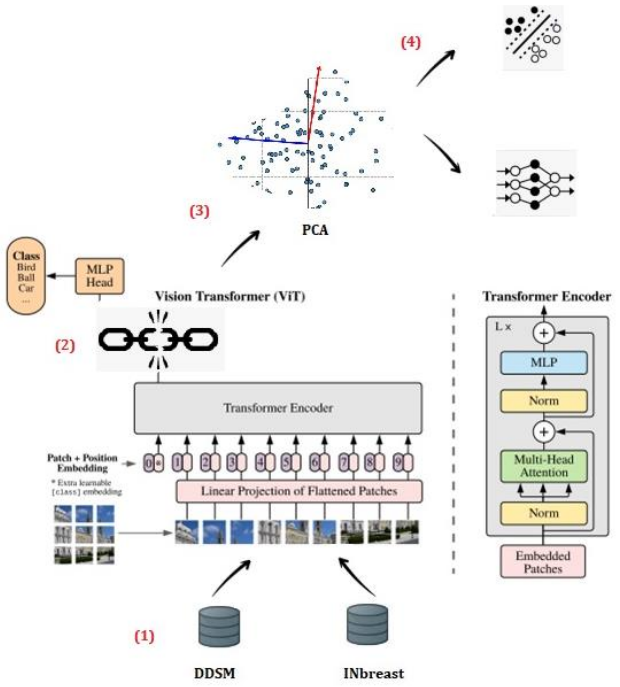


Fig. 3. The integration of a ViT model as a feature extractor, coupled with PCA and machine learning models as classifiers, serves to identify benign and malignant cases of breast cancer (figure of the ViT obtained from the work of [7].

C. Experimentation

Considering the DDSM Dataset, which contains both benign and malignant images of the breast, we performed image resizing to 224 x 224 pixels and channel normalization with a value of 0.5 [5]. Subsequently, we read the images from their respective folders and assigned a label of 0 for benign masses and 1 for malignant masses. To determine the number of epochs for model optimization, we employed a standard split of 80% for training and 20% for validation, with a batch size of 32. We utilized the pre-trained Vision Transformer (ViT) model "facebookresearch/deit:main" with the "deit_base_patch16_224" architecture, which was pre-trained on the ImageNet-1k dataset at a resolution of 224 x 224 with fixed patches of 16 x 16 [36, 16]. For the loss function, we chose Cross Entropy, a commonly used metric for estimating probabilities in breast cancer classification [17, 18]. The optimizer selected was Adam, supported by previous studies [18, 34], with a learning rate of 0.001. It is important to note that we employed this configuration to create a feature extraction model by removing the last layer, which served as a classifier, after the training phase. Additionally, we flattened our data into a 2D tensor, where each row corresponds to the features extracted from an image. With this setup, we conducted experiments and obtained the training and validation loss curves, as shown in Fig. 4. To evaluate the model's performance, we tested various numbers of epochs and decided to maintain a value of five based on the results obtained.

For the INbreast dataset, the methodology was similar, with the exception that when we plotted the loss curves for a fixed number of epochs using the same learning rate as applied to the DDSM dataset, we observed that the validation set's loss did not decrease significantly. This indicated the occurrence of overfitting. To address this issue, we manually adjusted the learning rate and determined that a value of 0.0001 resulted in a rapid decrease of the validation set's loss with eight epochs.

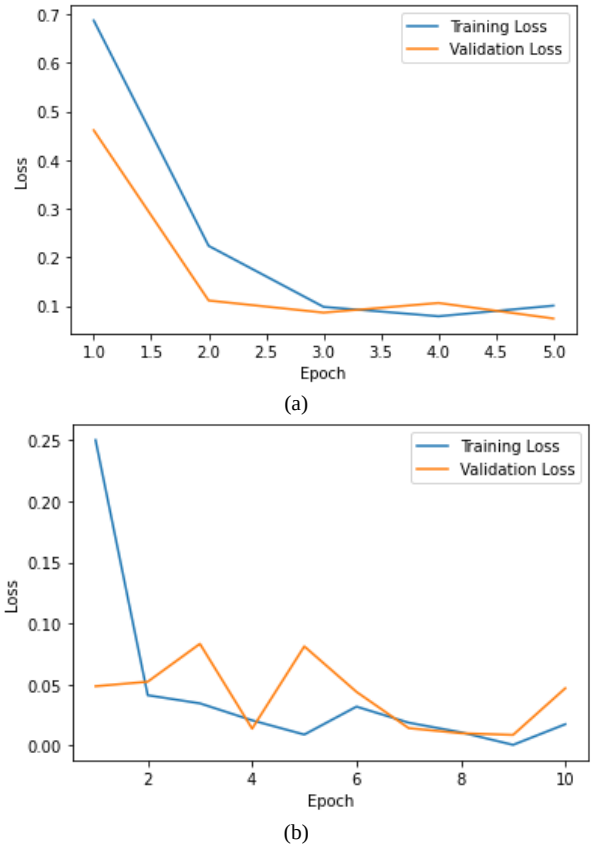

Fig. 4. Training and validation curve losses for obtaining the number of epochs for the DDSM (a) and INbreast datasets (b).

Algorithm 1 outlines the steps performed in the study:

1) Define the dataset directory and the image transformation pipeline using PyTorch's `transforms.Compose()` function.

2) Create a custom dataset class that is inherited from PyTorch's Dataset class. In the constructor, initialize the root directory, transformation pipeline, and targets. Implement the `__len__` method to return the total number of samples in the

dataset. Implement the `__getitem__` method to compute the number of samples in each class, determine the class of the current sample based on its index, load the corresponding image and label, apply the transformation pipeline to the image, and return the transformed image and label.

3) Split the dataset into training and validation sets using PyTorch's `random_split()` function.

4) Define data loaders for the training and validation sets using PyTorch's DataLoader class.

5) Load the pre-trained ViT model from Facebook Research using the `torch.hub.load()` function.

6) Define the loss function as the cross-entropy loss and choose the optimizer as Adam.

7) Train the model on the training set for a specified number of epochs. During training, fine-tune the pre-trained ViT model on the custom dataset, enabling it to learn task-specific features. Use the loss function and optimizer to update the model's parameters.

8) After each epoch, validate the model on the validation set and calculate the validation loss using the loss function. This step monitors the model's performance on unseen data and helps prevent overfitting.

9) Save the trained visual transformer model to a file using the `torch.save()` function.

10) Plot the training and validation losses using Matplotlib. This visualization aids in tracking the model's performance during training and identifying any issues, such as overfitting.

When the model was trained, given the number of epochs obtained, we decided to use PCA for dimensionality reduction. The choice of PCA was mainly because we wanted to reduce the number of features given a certain number of components. In the experiments performed, we found that the number of components that explained 95% of the data was 43 for the DDSM dataset, while the number of suitable components found for the INbreast dataset was of 1933 components. It is not surprising that INbreast required a greater number of principal components. We hypothesize that the main reason for this is that the dataset consists of electric signals converted into images, which provides more detailed information than the DDSM dataset [34].

An algorithm is provided for utilizing the saved model from Algorithm 1 to obtain the desired number of components using PCA. The components will serve as input features in the machine learning model:

Algorithm 2:

1) Load the trained visual transformer model by invoking the function load_visual_transformer().

2) Define a feature extractor by removing the classification head from the pre-trained ViT model through the creation of a torch.nn.Sequential() object.

3) Utilize a data loader to apply the feature extractor to the images in the dataset. For each batch of images, extract the features using the feature extractor, flatten the resulting feature maps, and store the features and corresponding labels in separate lists.

4) Concatenate the feature vectors and labels, transforming them into numpy arrays.

5) Apply PCA to the feature vectors to reduce their dimensionality.

At this stage, we opted to employ two machine learning models: a multilayer perceptron (MLP) and a support vector classifier (SVC). For the MLP model, we explored the following number of hidden layers as a hyperparameter grid:

Hidden layer size 1: A single hidden layer with the same number of neurons as the input features.

Hidden layers size 64: In this case, we employed two hidden layers. The first layer had the same number of neurons as the input, and the second layer had 64 neurons.

Hidden layers size 128: Like the configuration mentioned earlier, but with the second hidden layer having 128 neurons.

Hidden layers size 256: Again, similar to the previous configurations, with the number of neurons in the hidden layer now set to 256.

This grid served as input for a grid search cross-validation function that utilized five folds to determine the best number of hidden layers as a hyperparameter for this model. After applying the grid search function, we identified the best hyperparameter values to be 256 neurons for the DDSM dataset and 128 neurons for the INbreast dataset, respectively.

For the DDSM dataset, we utilized two hidden layers with 256 and 128 neurons, respectively. Meanwhile, for the INbreast dataset, we employed the same number of hidden layers but with 1933 and 128 neurons in each layer. The activation function used was ReLU.

Concerning the hyperparameters for the SVC, we utilized a hyperparameter grid consisting of the following values:

C (penalization factor): 0.01, 0.1, 1, 10, 100

Kernels: Linear, Polynomial, RBF

Gamma value (only applicable to RBF): 0.001, 0.01, 0.1

Subsequently, we performed a grid search cross-validation with five folds to obtain the best hyperparameters, considering the grid.

For the DDSM dataset, the SVC model was configured with an RBF kernel, a penalty parameter C of 100, and a gamma value of 0.001. As for the INbreast dataset, the hyperparameters for the SVC model were set as follows: RBF kernel, C of 100, and gamma value of 0.1.

IV. Results

After employing transfer learning using a Vision Transformer (ViT) as described in the methodology section and applying the aforementioned classifier methods, we obtained the following results for both models that are presented in Table II.

TABLE II. METRICS OBTAINED FROM THE MODELS EVALUATED IN THE DDSM (A) AND INBREAST (B) DATASETS

(a)

ViT model + Classifier using PCA (DDSM)/Metric	Acc	Prec	Recall	F1-score
MLP	0.9819	0.983	0.9836	0.983
SVC	0.9672	0.962	0.9786	0.970

(b)

ViT model + Classifier using PCA (INbreast)/Metric	Acc	Prec	Recall	F1-score
MLP	0.943	0.954	0.9624	0.9582
SVM	0.843	0.810	1	0.8953

Table II displays the metrics for Accuracy, Precision, Recall, and F1-score of our proposed model, which were calculated using the DDSM and INbreast datasets. It is noteworthy that our Precision and Recall results consistently exceed 97% on average. The precision and recall in medical diagnosis are of utmost importance. In this cancer situation, the recall metric prioritizes false negatives, while precision focuses on false positives. Furthermore, the f1-score, which is the harmonic mean that takes into account both precision and recall, has yielded an average of 96%. Upon evaluating both models, it can be deduced that they exhibit minimal occurrences of false positive and false negative predictions. Furthermore, they provide a well-balanced performance in terms of precision and recall.

From the data presented in Table II, it is evident that the MLP model outperformed the SVC classifier for both datasets. It is worth noting that a five-fold cross-validation was utilized for validating our results in each model.

It is worth noting that the MLP model outperformed the SVM model on both datasets. In the case of the DDSM dataset, the difference between the two models is only about one point. However, the distinction observed in the INbreast dataset is more pronounced, with a difference of nearly 10 points in Accuracy and Precision between both models.

According to the authors [22], both datasets, DDSM and INbreast, were subjected to data augmentation techniques such as rotation and flipping. The difference between the original data from both datasets (i.e., data that had not been augmented) was significant. For the DDSM dataset, 2188 images were augmented to 13128, while 106 mass images were augmented to 7632 for the INbreast dataset. The proportion of augmented data in the INbreast dataset far outnumbers that in the DDSM dataset.

At this point, we can speculate that this disparity may have contributed to the SVM model's lower results compared to its MLP counterpart, which demonstrated a greater ability to generalize its classification capabilities in both datasets. These findings are intriguing, especially considering the work of Shen et al. [34]. Their research indicated that the INbreast dataset, containing FFDM (full-field digital mammography) images with varied intensity profiles, allowed them to evaluate the suitability of a particular classifier model across several mammography platforms. This property stems from the fact that FFDM images replace X-rays with electrical signals, allowing them to be reproduced across multiple devices [35].

V. DISCUSSION

In comparison to other studies that have utilized the DDSM dataset, we did not find any previous work that employed transfer learning combined with PCA and machine learning models. In the study conducted by Ayana et al. [2], transfer learning was also utilized with various ViT models, such as Swim and Pyramid, along with image augmentation to address the issue of dataset imbalance. Their results, obtained when training the models from scratch, ranged from a 78% in accuracy, precision, and F1-score. Furthermore, the authors explored CNN models including ResNet, EfficientNet, and InceptionNet, achieving an average accuracy, F1-score, and recall of 94%. We believe it is important to mention recall as a crucial metric since the consequences of missing or misclassifying a cancer screening can be detrimental. However, our approach, incorporating PCA, transfer learning, and machine learning models, yielded promising results with an average performance of 98% across the evaluated metrics.

Another study conducted by Ragab et al. [30] investigated two datasets, namely the DDSM and the Curated Breast Image Subset of the DDSM (CBIS-DDSM). The authors employed image enhancement techniques, including Contrast-Limited Adaptive Histogram Equalization (CLAHE), to improve image definition. They also performed image segmentation and utilized data augmentation. It is worth mentioning that CLAHE was also applied to the DDSM dataset with data augmentation, as employed in our present study. Ragab et al. [30] performed feature extraction using a Deep Convolutional Neural Network (DCNN), specifically AlexNet, which was pre-trained on the ImageNet dataset. Their combined model, consisting of the DCNN and a Support Vector Machine (SVM) classifier, achieved an accuracy of 87.2% using a medium Gaussian kernel function. Although there are some differences between the datasets used in their study and ours, there are notable similarities, such as both datasets being based on the DDSM dataset and the utilization of similar techniques for image preprocessing and augmentation. The authors' use of image segmentation is a distinct difference from our approach.

In the research conducted by Salama et al. [31], two datasets, namely the DDSM and the curated DDSM, were utilized. The authors applied data augmentation techniques such as rotation and employed two deep learning models, ResNet-50 and VGG-16. Transfer learning was performed from the ImageNet dataset, and the classification layer was modified to accommodate only two classes. Although it appears that both models were used as feature selection algorithms, no explicit mention of this approach was found. The outputs from both models were then used as inputs for an SVM classifier. While the authors mentioned hyperparameter tuning for the deep learning methods employed, there was no information provided regarding hyperparameter tuning for the SVM model. The results obtained for the DDSM dataset using the VGG-16 model yielded an average accuracy, AUC, sensitivity, precision, and F1-score of 94%. For the CBIS-DDSM dataset, the VGG-16 and ResNet-50 models combined with the SVM classifier and five-fold cross-validation achieved an average accuracy, AUC, sensitivity, precision, and F1-score of 96% for the former and 95% for the latter, in addition to an average F1-score of 93%.

Other researchers, such as Tsochatzidis [37], conducted experiments with various deep learning models, including AlexNet, VGG-16, VGG-19, ResNet-50, ResNet-152, GoogLeNet, and Inception-BN. In their study, the authors initialized the weights of their models from scratch and also applied transfer learning techniques to the DDSM-400 and CBIS-DDSM datasets. Data augmentation was not employed in their experiments. According to their findings, training the models from scratch yielded the best performance with AlexNet, achieving an accuracy of 62% for the DDSM-400 dataset and 65% for the CBIS-DDSM dataset. However, the best results were obtained when using pre-trained initialized weights for both datasets. In particular, the ResNet-based model achieved an accuracy of 85% for the DDSM-400 dataset and an average accuracy of 80% for the CBIS-DDSM dataset.

Das et al. [6] conducted a study where they evaluated the performance of various deep learning models on breast cancer datasets, including CBIS-DDSM and INbreast. Their experiments involved both shallow neural networks and deep neural networks. Among the models tested, the Xception network demonstrated the best performance, achieving an accuracy of 89% for CBIS-DDSM and 95% for INbreast. The authors suggested that the higher accuracy obtained on the INbreast dataset could be attributed to the higher image quality compared to CBIS-DDSM.

As of the writing of this article, we have not found any existing research that has utilized a transfer-learning model based on Vision Transformer (ViT) in conjunction with Principal Component Analysis (PCA) for dimensionality reduction. Furthermore, our results show that a simple Multilayer Perceptron (MLP) model with two hidden layers, employed as a classifier, outperforms SVM-based approaches. We strongly believe that leveraging pre-trained models, particularly those based on attention mechanisms like ViT, in combination with dimensionality reduction techniques applied to the data, holds promise for achieving superior performance. Moreover, these approaches can be beneficial in scenarios where computational resources for data processing are limited.

Table III, which is an expansion of Table I mentioned in the Introduction section, contains the datasets utilized in the reviewed studies, as well as the metrics derived from the outcomes of the various applied models.

TABLE III. COMPARISON OF OTHER STUDIES WITH OUR CURRENT PROPOSAL

Authors	Methodology	Dataset used	Results
Tsochatzidis et al. [38]	Employs a modified CNN architecture that incorporates a U-Net for image segmentation during input.	DDSM-400 and CBIS-DDSM	AUC 89.8% and 86.2%
Min et al. [24]	Grayscale images are converted into pseudo-color and the masses are amplified for utilization in a Mask R-CNN that utilizes transfer learning.	Inbreast	90% (True Positive Rate) TPR
Samee et al. [32]	Images are improved through the application of contrast-limited adaptive histogram equalization (CLAHE). A CNN model, selected from AlexNet, VGG, or GoogleNet, is used to extract features, while a Logistic Regression model with PCA is employed for classification.	Inbreast and MIAS	98.8% of accuracy using MIAS and 98.6% using MIAS.
Al-Tam et al. [1]	The authors employed VGG16, ResNet50, and Imagenet for both binary and multiclass classification. For the final test, they utilized a ResNet50 model that was trained from scratch, in addition to a ViT model.	CBIS-DDSM	100% in the F1-score for the binary classification, other metrics in average made a 96% in the multiclass classification.
Samee et al. [33]	The authors utilized pre-trained convolutional neural network (CNN) models, specifically AlexNet, GoogleNet, and VGG-16. The researchers applied a series of feature selection techniques, including Pearson Correlation Coefficient, Cosine Coefficient (mainly used for texts), Euclidean Distance (although Liu and Zhang [23] warned about possible drawbacks in representing data characteristics, which could result in suboptimal learning), and Mutual Information. The chosen characteristics were subjected to classification using an ensemble of learners utilizing Discriminant Analysis, Support Vector Machines (SVM), K-Nearest Neighbors (KNN), and Naive Bayes. Nevertheless, it is still uncertain whether they employed a combination of machine learning models or determined which one produced the most optimal outcomes.	Inbreast	98.06% in Sensitivity and 98.5% in Accuracy.
Jabeen et al. [19]	The authors utilized a haze-reduced local-global image enhancement technique. The images were subjected to augmentation, and a pre-trained EfficientNet-b0 model was used as a feature extractor, excluding the last three layers. The process of selecting features was conducted utilizing the Equilibrium-Jaya controlled Regula Falsi algorithm. An ensemble of K-nearest neighbors (EKNNs) was utilized for classification.	CBIS-DDSM Inbreast	Average Accuracy of 95.4% and 99.7%
Our Proposal	The ViT model is utilized as a feature extractor, PCA is employed for dimensionality reduction, and MLP and SVM are used as classifiers for the purpose of comparison.	DDSM Inbreast	Average Accuracy, Precision, Recall and F1-score of 98% for the DDSM dataset with MLP as classifier. The same metrics give us an average of 95.4% for the InBreast dataset.

Regarding the limitations identified in the current research, it is important to note that the author faced difficulties in finding appropriate examples to aid in the coding process of the Vision Transformer (ViT) when utilized as a feature extractor instead of a classifier. Although there is limited literature on using ViT models as feature extractors, we are still confident in their potential for applications where the features obtained can be used as input for Machine learning (ML) models. ML models provide several benefits, such as their interpretability, decreased computational requirements, and ongoing potential usefulness in the domain of medical diagnosis.

An important upcoming task would be to evaluate various Vision Transformer (ViT) models in combination with different subsets of machine learning (ML) models, such as Random Forest or other boosting-based methods, to ascertain if these model combinations can enhance the reported results. In addition, performing experiments with diverse datasets, e.g., the MIAS or the BancoWeb Lapimo, datasets beyond those specified in the present study, would allow for the assessment of the overall efficacy of an integrated model that includes ViT, dimensionality reduction of features, and machine learning techniques in diagnosing breast cancer scenarios using mammography data.

VI. Conclusion

The classification of samples obtained from mammograms holds utmost importance, as early detection of malignant masses can significantly impact patient outcomes. In this study, we demonstrated the efficacy of a transfer learning model based on Vision Transformer (ViT), coupled with Principal Component Analysis (PCA) for feature reduction, and a simple Multilayer Perceptron (MLP) model. Our results were found to be comparable to existing literature that employs Convolutional Neural Network (CNN) models based on transfer learning in conjunction with deep learning models. These findings highlight the potential of using ViT-based transfer learning approaches, combined with dimensionality reduction techniques and simple Machine Learning classifiers, to achieve accurate mammogram classification results.

School of Computer Science and Engineering, University of Westminster, United Kingdom[4]

***Abstract*—Email serves as the primary communication system in our daily lives, and to bolster its security and efficiency, many email systems employ Public Key Infrastructure (PKI). However, the convenience of email also introduces numerous security vulnerabilities, including unauthorized access, eavesdropping, identity spoofing, interception, and data tampering. This study is primarily focused on examining how two encryption techniques, RSA and ECC, affect the efficiency of secure email systems. Furthermore, the research seeks to introduce a hybrid cryptography algorithm that utilizes both RSA and ECC to ensure security and confidentiality in the context of secure email communication. The research evaluates various performance metrics, including key exchange time, encryption and decryption durations, signature generation, and verification times, to understand how these encryption methods affect the efficiency and efficacy of secure email communication. The experimental findings highlight the advantages of ECC in terms of Key Exchange Time, making it a compelling choice for establishing secure email communication channels. While RSA demonstrates a slight advantage in encryption, decryption, and signature generation for smaller files, ECC's efficiency becomes apparent as file sizes increase, positioning it as a favorable option for handling larger attachments in secure emails. Through the comparison of experiments, it is also concluded that the hybrid encryption algorithm optimizes the key exchange times, encryption efficiency, signature generation and verification times.**

Keywords*—RSA; ECC; Advanced Encryption Standard; encryption; decryption; signature generation; verification; key exchange time; hybrid encryption

I. Introduction

In today's interconnected world, email has become an indispensable tool for communication. It facilitates the exchange of information, ideas, and documents across vast distances, enabling individuals and organizations to collaborate and communicate efficiently [1]. However, the convenience of email also brings with it a host of security concerns, as emails can easily fall prey to unauthorized access, eavesdropping, identity spoofing, interception, or data tampering [2] [3]. This is where cryptography plays a pivotal role in ensuring the confidentiality, integrity, and authenticity of email communication. Email encryption is the cornerstone of secure email communication. It employs complex algorithms to transform the content of an email into an unreadable format, known as ciphertext, which can only be deciphered by the intended recipient possessing the decryption key [4]. This cryptographic process ensures the following [5] [6]:

1) Confidentiality: Encrypted emails are incomprehensible to anyone without the decryption key, thwarting unauthorized access and eavesdropping.

2) Integrity: The recipient can promptly detect any alterations made to the encrypted email, ensuring the message's integrity remains intact during transmission.

3) Authentication: Combining encryption with digital signatures verifies the sender's identity, ensuring the legitimacy of the email for the recipient.

Email security protocols such as Secure Sockets Layer (SSL) and Transport Layer Security (TLS) commonly utilize encryption algorithms like RSA, AES, and elliptic curve cryptography, while public-key infrastructure (PKI) systems and digital certificates play vital roles in verifying the authenticity of email senders [7].

This research project's primary aim is to explore the correlation between the performance of secure email communication systems and the encryption methods employed. The study examines how incorporating both RSA and ECC encryption techniques influences the efficiency of secure email systems. The study seeks to discern any connections between the choice of cryptographic algorithms, RSA and ECC, and the overall performance of secure email systems. Furthermore, the study suggests a hybrid cryptography algorithm that utilizes both RSA and ECC to enhance security and preserve confidentiality in the context of secure email communication. The research will assess various performance aspects, including key exchange time, encryption and decryption times, signature generation and verification times, to ascertain how these encryption methods influence the efficiency and efficacy of secure email communication. Through an analysis, the study's aim to identify any potential relationships or dependencies between the selection of encryption methodologies and the outcomes in terms of secure email system performance.

A. Limitation of Existing Models

While existing encryption models, such as those based solely on RSA or ECC, have undoubtedly contributed to the advancement of secure communication protocols, they

nonetheless exhibit limitations that may not be well suited to address the multifaceted challenges inherent in secure email communication. A significant drawback concerns the scalability of conventional encryption methods, especially when it comes to email communication. As the size and complexity of email attachments continue to grow, conventional encryption algorithms, like RSA, may struggle to maintain optimal performance, leading to increased computational overhead and potential delays in key exchange, encryption, and decryption processes [8].

B. Rationale for the Proposed Model

The selection of the hybrid cryptography algorithm, combining RSA and ECC, for secure email communication stems from a thorough consideration of various factors. Firstly, while RSA has been a stalwart in encryption for decades, its efficiency can be compromised, particularly when dealing with larger files or computational constraints. RSA's computational complexity grows with the size of the data, affecting encryption and decryption times [8].

On the other hand, ECC has emerged as a promising alternative due to its ability to provide equivalent security with shorter key lengths, thus reducing computational overhead and enhancing performance, especially in resource-constrained environments. Compared to RSA, ECC offers the same level of security with significantly smaller key sizes, making it more efficient for key exchange and digital signatures [9].

However, both RSA and ECC have their respective strengths and weaknesses. RSA excels in signature generation and verification for smaller files, while ECC demonstrates superior efficiency in key exchange, particularly noticeable as file sizes increase [10]. Recognizing these complementary attributes, the hybrid approach seeks to leverage the strengths of each encryption technique to mitigate their individual limitations. Combining RSA and ECC allows for a more balanced security posture by utilizing RSA for digital signatures and ECC for key exchange.

Moreover, by combining RSA and ECC within a hybrid model, we aim to achieve a balance between security and efficiency in secure email communication. This approach allows us to capitalize on RSA's robustness in certain aspects while harnessing ECC's efficiency gains in others, ultimately offering a more versatile and adaptable solution for addressing the diverse security challenges inherent in email communication.

The aim of the study is to enhance the performance of secure email systems by leveraging the distinct advantages of both RSA and ECC, while minimizing their individual limitations. This rationale underscores the relevance and appropriateness of the proposed model in addressing the inherent complexities of secure email communication in today's digital landscape.

Hence, the current study makes the following key contributions.

1) To perform an extensive analysis of the performance of selected algorithms, namely: RSA and ECC for secured email communication.

2) To perform an extensive evaluation of the key exchange time, signature generation and verification times between RSA and ECC techniques.

3) To present a hybrid cryptography algorithm that employs both RSA and ECC to ensure confidentiality and enhance security for secure email communication.

The rest of the paper is organized as follows: Section II presents the related work. The experimental setup is presented in Section III. Sections IV presents the hybrid techniques employing RSA and ECC. Section V and Section VI present the performance analysis of solo ECC, RSA and the proposed hybrid algorithm and discussion of the research. Finally, the conclusion is drawn in Section VII.

II. Related Work

In this study, a secure system for key agreement and session authentication for Internet of Things (IoT) devices was conceptualized, developed, and subjected to testing. The simulation results showed that the method was resilient to different assaults. The results of the performance evaluation also showed that, when compared to DSA and RSA, the time complexity was lowest for the ECC used in this case. The developed protocol also had the lowest computational overhead, the quickest turnaround times, and the greatest stability with the least amount of communication overhead [11]. In study [12], researchers conducted an analysis of distinct cryptographic algorithms, evaluating aspects like key size, message size, and execution time. With the proliferation of diverse encryption techniques, facilitating swift and dependable communication among IoT devices has become a complex task, one that must be accomplished without causing interruptions. Determining the most suitable, compatible, and advantageous encryption method for communication has proven to be quite intricate. Through their examination, the authors reached the consensus that among various options, Schnorr, RSA, Elliptic Curve Cryptography, and ElGamal emerge as the superior choices. Kaur and Aggarwal [13] undertook an extensive examination of cryptographic methods including RSA, Blowfish, Diffie-Hellman, ECC, and others. Among these techniques, ECC has demonstrated itself as the encryption method that excels in both security and efficiency. In reference to [14], the researchers delved into an analysis of diverse encryption methods encompassing both symmetric and asymmetric cryptographic techniques. These methods included Rivest Shamir and Adleman, Diffie-Hellman, Digital Signature Algorithm, as well as Elliptic Curve Cryptography (ECC). The study aimed to explore their practical implementation and ascertain the most effective cryptographic techniques capable of ensuring comprehensive data confidentiality during transmission. Each cryptographic algorithm i found to possess distinct strengths, features, advantages, complexities, efficiency levels, and limitations. Among these factors, the examination revealed that digital signatures offer robust confidentiality and non-repudiation, thereby serving as a means to safeguard data integrity, availability, and confidentiality. A thorough examination is carried out to investigate the ECC, RSA, and Diffie-Hellman Algorithms within the realm of Network Security. The study addresses the challenges associated with sharing and

transferring private keys among systems. When assessing the efficacy of ECC, RSA, and Diffie-Hellman algorithms, ECC stands out as the favoured option due to its capacity to deliver almost comparable security levels while employing fewer bits than both RSA and Diffie-Hellman. The researchers also delved into the realm of elliptic curve cryptography, exploring its significant applications within the market. This exploration involved examining its prevalence in technologies like Bitcoin, Secure Shell, and Transport Layer Security. It is evident from the literature that elliptic curve cryptography stands out as a promising approach, capable of offering exceptional security advantages over comparable algorithms. Moreover, its cost-effectiveness positions it as a valuable contender for cryptographic applications [15]. In study [16], the researchers conducted an analysis of the performance characteristics of conventional public-key cryptographic systems, namely RSA, DSA, and DH, in comparison to ECC. The investigations highlighted that the traditional public-key methods encounter performance-related challenges. The study proposed that general-purpose CPUs could effectively incorporate hardware acceleration to enhance public-key algorithm processing. The performance assessment indicated that ECC exhibited superior performance compared to RSA. Specifically, for ECC with GF(p) and GF(2m), the researchers noted a speedup of 2.4 times and 4.9 times, respectively, relative to RSA at the current security levels. Moreover, for subsequent security levels, the corresponding speedups were even more substantial—7.8 times and 15.0 times, respectively. Ponomarev et al., (2010) [17] conducted an investigation into the computational demands imposed by handling the control plane of the Host Identity Protocol (HIP) using Rivest-Shamir-Adleman (RSA) encryption in comparison to Elliptic Curve Cryptography (ECC) techniques. This study focused on measuring the processing resources consumed by the cryptographic procedures of the Host Identity Protocol Base Exchange. The findings highlighted that the cryptographic operations involved in the Host Identity Protocol Base Exchange consumed substantial processing resources, and this aspect is quantified in the study. In terms of specific results, the study indicated that, by employing ECC for the Diffie-Hellman exchange, a server could manage new connections ranging from two to three times more efficiently. Moreover, the study highlighted that employing ECC in cryptographic operations significantly enhanced HIP performance for lightweight mobile clients like the Nokia N810 Internet Tablet. This improvement was manifested in a 75-85% reduction in total Base Exchange (BEX) time, emphasizing the faster cryptographic operations enabled by ECC. In this investigation [18], a comparison was conducted between the elliptic curve cryptography (ECC) algorithm utilizing a 160-bit key size and the Rivest-Shamir-Adleman (RSA) technique employing a 1024-bit key size. The results demonstrated that ECC can offer comparable security levels with smaller key sizes when contrasted with more traditional cryptographic systems like RSA. Consequently, the adoption of ECC is strongly recommended to enhance security and efficiency without a proportional increase in computational demands. The research indicated that ECC maintains a lower cost ratio. Moreover, continuous enhancements are necessary for ECC itself to optimize the performance of newly developed chips. In a study similar to this, the authors referenced in study [5] investigated the encryption and decryption times of various approaches using data packets of different sizes. The comparisons indicated that ECC leads to a significant reduction in transmission expenses. The results underscored that ECC outperforms other asymmetric algorithms in terms of efficiency. This study evaluated the impacts of different ECC curves and RSA key sizes using IoT nodes with limited resources, and it compared the performance of ECDSA and RSA TLS cipher suites. The results indicated that, although ECDSA consistently outperformed RSA in all test runs, practical scenario testing is necessary to determine the suitable security configuration for a given hardware platform. Situations may arise where more secure options, due to software implementations and optimizations, exhibit superior energy efficiency and data throughput, surpassing theoretically lighter and simpler alternatives. The results, influenced by enhancements in the libraries handling ECC operations, specifically showcased that the secp256r1 curve exhibited superior performance compared to the secp224r1 curve, while maintaining a higher level of security [19]. In the study conducted by Kardi et al. in 2018, a performance evaluation is carried out to compare RSA and Elliptic Curve Cryptography in the context of wireless sensor networks. The findings of the research indicated that the decryption time of RSA becomes impractical with large key sizes. Conversely, even when employing very large key sizes, the encryption and decryption processes of ECC algorithms remain manageable. Additionally, ECC signature signing is generally faster than verification, whereas RSA signature signing is more time-consuming. As a result, the study recommended a transition from RSA to elliptic curve cryptography [20]. In a comparable investigation, the researchers delved into the foundational aspects of elliptic curves, their associated arithmetic operations, and the advantages of adopting elliptic curve cryptography over RSA within public cryptosystems. The outcomes of this research highlighted that ECC signature signing processes are usually swifter than verification procedures, while RSA signature signing tends to be more time-consuming. Moreover, the generation of public keys demands significantly more time with the RSA technique compared to ECCs. These findings in the implementation phase provided a compelling rationale for the researchers to advocate for a transition from RSA to elliptic curve cryptography [21]. This study conducted an empirical performance assessment aimed at comparing and quantifying the performance of two encryption schemes: (1) RSA-based BROSMAP and (2) ECC-based BROSMAP, both on the client side (Android) and server-side (XAMPP). In terms of execution time, ECC outperforms RSA significantly, with ECC being nearly twice as fast as RSA 2048 and four times faster than RSA 3072. The primary factors contributing to ECC's superior performance in BROSMAP are its utilization of smaller key sizes and its exclusive reliance on symmetric cryptography for both encryption and decryption processes. Furthermore, the investigation revealed that RSA-based BROSMAP incurs higher computational costs compared to ECC-based BROSMAP. Specifically, ECC demonstrates a computational efficiency that is 561 times greater. As a result of these findings, the researchers strongly recommend the

adoption of ECC-based BROSMAP over RSA-based BROSMAP, especially in systems with limited resources such as IoT devices and agent-based systems that prioritize security. In summary, ECC-based BROSMAP meets all the security requirements of RSA-based BROSMAP while offering greater efficiency and lightweight operation, attributed to its absence of asymmetric encryption, use of reduced key sizes, and utilization of ECC keys in conjunction with symmetric encryption [22]. In their study referenced as [23], the researchers conducted an analysis of the security capabilities of ECC and RSA encryption techniques using three sets of sample input data consisting of 8 bits, 64 bits, and 256 bits, each employing randomly generated keys in accordance with NIST recommendations. Their findings illustrate that ECC surpasses RSA in both operational efficiency and security. Furthermore, their work implies that ECC might be the preferred choice, particularly for devices with limited memory resources such as smartphones and palmtop PCs. In this paper, authors [5] conducted a comprehensive review of key cryptographic algorithms, including ECC, El-Gamal, and RSA, with the goal of facilitating a comparative assessment. Our comparisons clearly indicate a significant reduction in transmission costs when employing ECC. These outcomes underscore the practical advantages of ECC's performance. The survey is undertaken to assess the security aspects of these algorithms, considering their widespread utilization. This research conducted an examination of two frequently employed encryption methods, namely Elliptic Curve Cryptography (ECC) and Rivest-Shamir-Adleman (RSA), with a particular emphasis on their applicability in the context of cloud and fog computing. The investigation involved a comparison of the key size and security capabilities of ECC and RSA algorithms, assessing their suitability for deployment in resource-limited fog computing environments. The findings suggest that ECC is a preferable choice for enhanced security and faster performance, all without imposing undue strain on computing resources. In contrast, RSA, with its established track record of security, remains widely accepted [24] . This paper introduced a novel approach to file encryption, employing a hybrid encryption algorithm that combines AES and RSA. It provides a foundational understanding of the AES and RSA algorithms while conducting a thorough examination of their pros and cons. The encryption techniques of these two algorithms have garnered substantial attention within the scholarly community. Through experimental comparisons, the study concludes that the hybrid encryption algorithm enhances encryption efficiency, bolsters key management, and fortifies data security in the context of file protection [25]. The authors in [26] presented a novel technique that combines features from two different algorithms. The primary goal of this approach is to tackle two significant challenges: managing encryption keys in symmetric encryption algorithms and reducing the substantial power consumption associated with asymmetric encryption algorithms. The research delves into cryptographic algorithms using data gathered from related academic journals and conference papers. The study's outcomes demonstrate that the proposed system has successfully elevated the maximum accuracy requirement, mainly due to its enhanced security level achieved by employing multiple keys for encryption and decryption. In this paper, a novel and secure data sharing scheme is presented, with a key emphasis on upholding data security and integrity within cloud environments. The proposed system primarily relies on the fusion of Elliptic Curve Cryptography (ECC) and the Advanced Encryption Standard (AES) method to ensure robust authentication and data integrity. Experimental results highlight the efficiency of this approach, demonstrating superior performance when compared to existing methods. In this paper, a novel and secure data sharing scheme is presented, with a key emphasis on upholding data security and integrity within cloud environments. The proposed system primarily relies on the fusion of Elliptic Curve Cryptography (ECC) and the Advanced Encryption Standard (AES) method to ensure robust authentication and data integrity. Experimental results highlight the efficiency of this approach, demonstrating superior performance when compared to existing methods [27]. This paper delves into the capabilities of cryptography for ensuring security in distributed storage. This exploration involves a thorough examination of standard cryptography techniques such as AES, ECC, and RSA. However, due to variations in the performance of these methods, the study addresses the challenge of identifying an encryption technique that strikes a balance between efficiency and security. Some encryption methods can deliver high security but are time-consuming for both encryption and decryption. Conversely, other approaches may offer efficient encryption but suffer from vulnerabilities in terms of security [28]. In reference [29], a two-tier cryptographic approach and a model are introduced to enhance data security in cloud computing. This model leverages both symmetric and asymmetric encryption algorithms, specifically AES and ECC, to bolster data security against unauthorized access, thus promoting privacy, data integrity, and expediting cryptographic operations. This advancement serves to enhance user trust in cloud computing while also accelerating the utilization of smaller ECC keys in the encryption process. In their research presented in reference [30], the authors conducted an examination of Elliptic Curve Cryptography (ECC) as a means to enhance data security within cloud environments, drawing a comparison with the Advanced Encryption Standard (AES) with a specific focus on time efficiency. The review encompasses an evaluation of encryption and decryption durations for data stored in cloud-based systems. This study explores the improvement of data protection with an emphasis on time efficiency through the application of ECC and AES. The analysis was based on a sample size of N=6 for both ECC and AES, with a significance level of 80% (determined using the G-power value). It is found that the mean time required for ECC encryption was 0.1683, whereas for AES, it was 0.7517. The calculated significance value for the proposed system was 0.643 ($p>0.05$). The results within the confines of this study clearly indicate that ECC surpasses AES in terms of expeditious data encryption with reduced time consumption. In 2023, Rao and Sujatha introduced a security technique for public cloud systems using Hybrid Elliptic Curve Cryptography (HECC). Their proposed method involves the creation of keys utilizing a lightweight Edwards curve, followed by the utilization of Identity Based Encryption to

modify the generated private keys. Additionally, the study implements a key reduction technique to further shorten the keys, thereby accelerating the Advanced Encryption Standard (AES) encryption process. The exchange of public keys is facilitated through the Diffie-Hellman key exchange. To evaluate the effectiveness of their proposed model, the authors employ metrics such as throughput and the time taken for key generation, encryption, and decryption. The results indicate that their model outperforms existing ones in various aspects. The key creation process in their method requires just 0.000025 seconds, with encryption taking 0.00349 seconds. Furthermore, the achieved throughput reaches 693.10 kB/s [31]. In this paper, the authors have introduced a robust and efficient protocol that incorporates security measures using both a blind factor and the Elliptic Curve Cryptography (ECC) scheme. ECC is preferred over RSA due to its ability to provide superior security with smaller key sizes, resulting in reduced computational overhead. This enhanced security per unit of data offers various benefits, including faster processing, lower power consumption, reduced bandwidth usage, improved storage efficiency, and more compact certificates. These advantages prove especially advantageous in situations with limitations in terms of bandwidth, processing capacity, power availability, or storage space. In order to improve computational efficiency and minimize memory storage requirements, the authors have developed a novel Hybrid Public Key Cryptographic algorithm. The results indicate that the incorporation of Dual-RSA and ECC has significantly improved the algorithm's performance, both in terms of computational cost and memory storage demands [32]. This paper introduced a hybrid cryptography algorithm aimed at ensuring confidentiality and enhancing security for internet communications. The research places particular emphasis on minimizing the time required for encryption and decryption to avoid excessive CPU utilization. Experimental findings demonstrate that the proposed solution offers a more efficient means of encrypting messages, with only a marginal difference in the algorithm's runtime. This approach effectively enhances security in the open internet environment [33].

III. Experimental Setting

A local area network (LAN) consisting of a dedicated network server and two client machines were used to carry-out the simulation. Fig. 1 shows the diagram of the simulation setup.

The testing environment, which included standard email clients and server, featured laptops with Intel i7 processors, 16GB RAM, and solid-state drives. The server was equipped with the following specifications - OS: Ubuntu, CPU: Intel Xeon, Cores: 4 core, 2.4 GHz, Architecture: 64-bit, and RAM: 8 GB DDR4 - represent typical end-user systems in corporate or personal contexts. To commence, email server Exim and clients Mozilla Thunderbird are configured to support RSA, ECC and hybrid encryption. Public and private keys are generated for RSA, typically 2048 bits, and ECC, using the widely adopted SECP224R1 curve for each user. Key exchange occurred during the initial email contact, and keys were securely stored. The experiment is conducted five times and the mean values for each metric were recorded. A series of practical tests are conducted, involving the sending of emails of varying sizes, from small text-based messages to larger attachments. Throughout the tests, measurements are taken for encryption and decryption times, key exchange time, signature generation, and verification times.

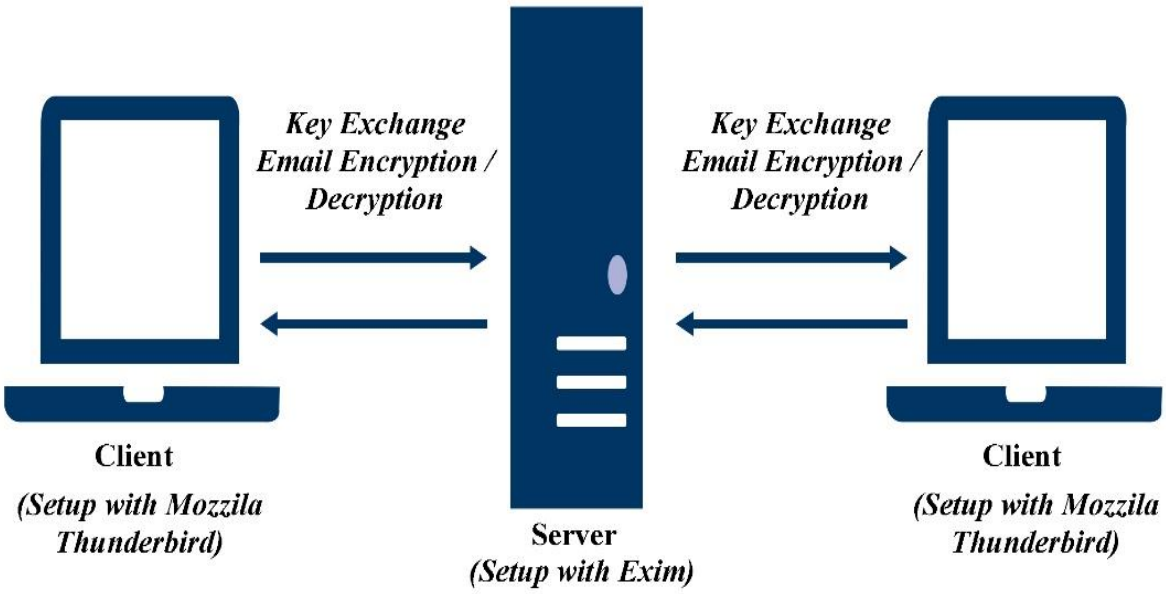

Fig. 1. Simulation setup.

IV. RSA-ECC HYBRID TECHNIQUE

The proposed hybrid technique merges the robust aspects of both RSA and ECC, creating a cooperative strategy that not only strengthens the security of email communication but also streamlines its efficiency. RSA and ECC stand as widely embraced encryption methods for safeguarding email exchanges. RSA, a traditional approach, provides formidable security but can be computationally demanding, particularly when managing large files. Conversely, ECC excels in terms of encryption and decryption speed, making it an ideal choice for resource-constrained environments. The suggested hybrid method presents an inventive solution to the enduring challenge of striking a balance between security and performance in secure email communication. By harnessing the strengths of RSA and ECC, this hybrid technique provides an adaptable solution that can be tailored to meet specific email communication needs. Fig. 2 provides a visual representation of the proposed fusion of RSA and ECC algorithms. This visual representation provides a clear and intuitive understanding of the sequential data transformations performed within the algorithm. For a more in-depth exploration of the inner workings of this proposed algorithm, Algorithms 1 and 2 offer a comprehensive breakdown of its structure. These algorithmic descriptions present a step-by-step elucidation of the specific operations and procedures involved at each stage of the algorithms.

Algorithm 1: Sender-side Operations

Input: ECC key pair, RSA public key, plain text email
Output: Encrypted email, Digital Signature

Step1: Generate sender's ECC Private Key as S^a and Public Key as S^b

Step 2: Request recipient's RSA public key from the server as R^b

Step 3: Derive shared secret using sender's ECC private key and recipient's RSA public key. $S = D(S^a, R^b)$

Step 4: Generate a symmetric key (A^s) for encrypting the email message.

Step 5: Compose the email message.

Step 6: Encrypt the email message using the symmetric key. Ciphertext, $C^t = E(PT, A^s)$

Step 7: Encrypt the symmetric key using recipient's RSA public key.
$C^{As} = E(A^s, R^b)$

Step 8: Generate a digital signature for the email message.
$Ds = Gs(S^a, PT)$

Step 9: Send the secure email to the recipient

In Algorithm 1, the sender initiates secure email transmission by generating ECC Private and Public Keys (S^a and S^b). The recipient's RSA public key (R^b) is acquired, and a shared secret is derived through S^a and R^b. A symmetric key (A^s) is created for encrypting the email message using AES, ensuring confidentiality. The composed email message is encrypted with A^s, yielding ciphertext (C^t). For added security, A^s is encrypted with R^b, resulting in the encrypted symmetric key (C^{As}), safeguarding its transmission. To ensure data integrity and authentication, a digital signature (Ds) is generated using S^a and the plain text email (PT). The secure email, comprising C^t, C^{As}, and Ds, is then transmitted to the recipient. This algorithm thus combines ECC and RSA functionalities to achieve a comprehensive security framework, encompassing symmetric and asymmetric encryption, as well as digital signatures for secure email communication.

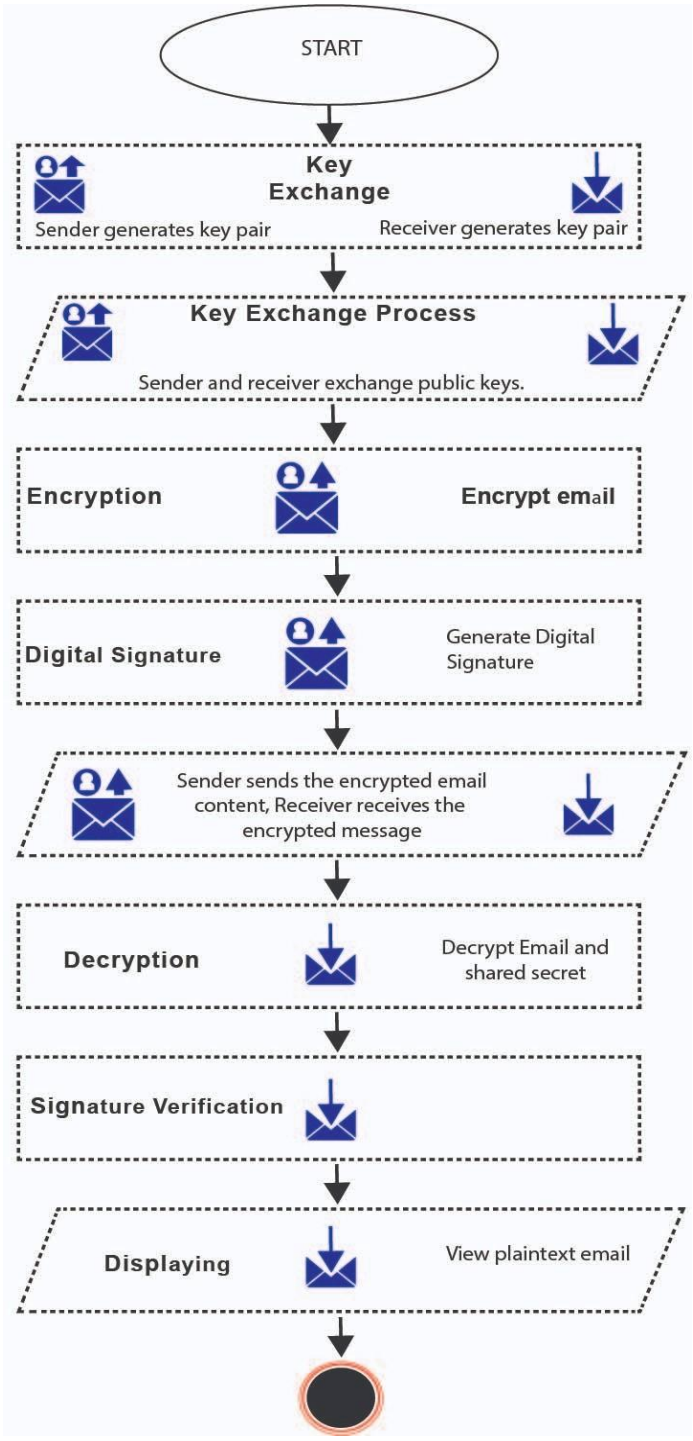

Fig. 2. Proposed model flow graph with hybrid ECC, RSA and AES.

Algorithm 2: Recipient-side Operations

Input: RSA key pair, ECC Key pair, Encrypted Email
Output: RSA Public Key, Decrypted email

Step1: Generate recipient's RSA and ECC key pairs.
RSA Private, Public (R^a, R^b) & ECC Private, Public (S^a, S^b)
Step 2: Export recipient's RSA public key for the sender
Step 3: Receive the encrypted symmetric key from the sender.
Step 4: Decrypt the symmetric key using recipient's RSA private key.
$A^s = D\ (C^{As}, R^a)$
Step 5: Receive the encrypted email message.
Step 6: Verify the sender's ECC public key.
Step 7: Receive and verify the digital signature.
Step 8: Decrypt the email message using the symmetric key.
$PT = D\ (C^t, A^s)$
Step 9: View the decrypted email

In Algorithm 2, the recipient begins by generating RSA and ECC key pairs (R^a, R^b) and (S^a, S^b) respectively. The recipient's RSA public key (R^b) is exported for the sender's use. Upon receiving the sender's secure email, the recipient obtains the encrypted symmetric key (C^{As}) and decrypts it using their RSA private key, resulting in the symmetric key (A^s). The recipient then receives the encrypted email message (C^t) and proceeds to verify the sender's ECC public key. Subsequently, the digital signature is received and verified for authenticity and data integrity. Using the decrypted symmetric key (A^s), the email message is decrypted, yielding the plaintext email (PT).

V. Performance Evaluation

The performance analysis is divided into two distinct approaches: analyzing the individual performance of RSA and ECC for secure email communication and assessing the performance of the hybrid approach for secure email communication.

A. Approach 1

1) Key Exchange Times measured in seconds: The key exchange time for RSA and ECC encryption methods in the context of secure email communication were assessed within the established testing environment. To measure key exchange times accurately, secure email communications were initiated, capturing the duration it took for public keys to be exchanged between sender and recipient during the initial email contact. This process was repeated 5 times for each test and the mean values were recorded. The recorded data for Key Exchange Time (KET) of RSA and ECC from the Secure Email Communication Test is as shown in the Table I. Fig. 3 illustrates the analysis of key exchange times for ECC and RSA encryption methods, represented in seconds.

2) Encryption and decryption times in seconds: Email encryption and decryption took place within the established test environment, consistent with the previously outlined specifications. Standardized email clients and servers were configured to support both RSA and ECC encryption methods. To assess these operations, a range of email messages, encompassing diverse sizes from text-based content to substantial attachments are employed as test data. The system was configured to autonomously record the encryption and decryption times for each email, ensuring an impartial and objective measurement of efficiency and practicality. This methodology facilitated a thorough analysis of email encryption and decryption processes using RSA and ECC techniques within the secure email communication system. This study further used the hybrid encryption setup; the asymmetric encryption algorithms (RSA or ECC) facilitate secure key exchange, while the symmetric encryption algorithm (AES) ensures efficient and high-speed encryption and decryption of the email content. This combination strikes a balance between security and performance, making it a practical choice for secure email communication.

TABLE I. Key Exchange Times of RSA and ECC

TEST	KET RSA (seconds)	KET ECC (seconds)
1	0.172268	0.101002
2	0.164218	0.102000
3	0.179985	0.091002
4	0.177888	0.102220
5	0.164782	0.091001

Fig. 3. Key exchange analysis of ECC and RSA (in seconds).

TABLE II. Encryption Time

Sizes (MB)	Encryption Time RSA (seconds)	Encryption Time ECC (seconds)
10	0.024308	0.028219
50	0.106565	0.094268
100	0.235220	0.173252
200	0.481745	0.375365
500	0.938921	0.866455

TABLE III. DECRYPTION TIME

Sizes (MB)	Decryption Time RSA (seconds)	Decryption Time ECC (seconds)

200	0.311700	0.308217
500	0.707802	0.753799

Fig. 4 and Fig. 5 depict the encryption and decryption times for RSA and ECC encryption methods, respectively, measured in seconds.

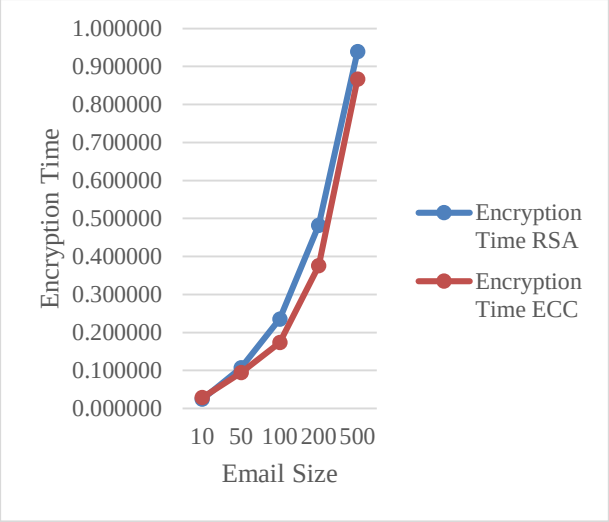

Fig. 4. RSA and ECC encryption time (in seconds).

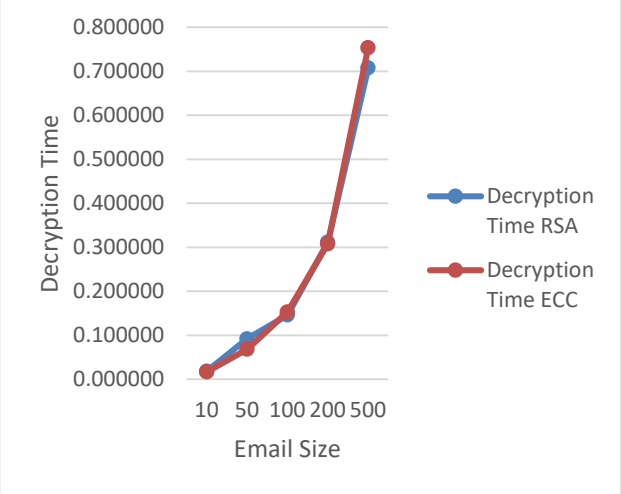

Fig. 5. RSA and ECC decryption time (in seconds).

3) Signature generation and verification: Signature generation and verification were integral aspects of the evaluation within the designated test environment, adhering to the established system specifications. By configuring standard email clients and servers to support both RSA and ECC encryption methods, the framework facilitated the generation of digital signatures for email messages. These signatures were generated autonomously during the test, and the system reported the time taken in seconds for each signature. Subsequently, the verification of these digital signatures occurred seamlessly within the same environment. A comprehensive analysis of signature generation and verification processes using RSA and ECC encryption methods was thus conducted objectively, with the system providing precise timing data for each operation.

Fig. 6 and Fig. 7 illustrate the signature generation and verification times for ECC and RSA encryption methods, respectively, measured in seconds.

TABLE IV. SIGNATURE GENERATION TIME

Sizes (MB)	SGT RSA (seconds)	SGT ECC (seconds)
10	0.030329	0.064428

B. Approach 2

1) Key exchange times measured in seconds: The key exchange time for the hybrid of RSA and ECC encryption methods were assessed within the established testing environment. To measure key exchange times accurately, secure email communications were initiated, capturing the duration it took the keys to be exchanged between sender and recipient during the initial email contact. This process was repeated five times for each test, and the mean values are recorded in Table VI.

TABLE VI. KEY EXCHANGE TIMES FOR HYBRID TECHNIQUE

TEST	KET (seconds)
1	0.064191
2	0.112602
3	0.070835
4	0.068739

2) Encryption, decryption, signature generation and verification times in seconds: Table VII displays the encryption, decryption, signature generation, and verification performance metrics for the hybrid technique. To evaluate these operations, a variety of email messages with different sizes, ranging from text-based content to sizable attachments, were utilized as test data. The system was set up to automatically capture the times taken for encryption, decryption, signature generation, and verification for each email. For each experiment, this procedure was carried out five times, and the mean values were obtained.

TABLE VII. HYBRID TECHNIQUE (RSA AND ECC)

Sizes (MB)	EncryptionTime	Decryption Time	Signature Generation Time	Signature Verification Time
10	0.020769	0.014005	0.026106	0.026000
50	0.091153	0.062974	0.130278	0.120312
100	0.156722	0.140040	0.238006	0.262419
200	0.327086	0.307289	0.430858	0.423738
500	0.832917	0.636395	1.073605	1.160965

VI. DISCUSSION OF RESULTS

Table I presents the collected data concerning the Key Exchange Time (KET) for RSA and ECC in the context of secure email communication. The results consistently indicate that ECC outperforms RSA in terms of key exchange efficiency across all the tested scenarios. In practical terms, it implies that the process of establishing secure communication channels through key exchange is notably swifter and more efficient when utilizing ECC as the cryptographic algorithm, as opposed to RSA.

Table II reports the Encryption Time (in seconds) for both RSA and ECC in the same context. It illustrates the time taken to encrypt emails with various file sizes, ranging from 10 MB to 500 MB. The results demonstrate interesting trends in the performance of these cryptographic algorithms during the encryption process.

For smaller file sizes (10 MB and 50 MB), RSA exhibits slightly shorter encryption times compared to ECC. However, as the file sizes increase to 100 MB, 200 MB, and 500 MB, ECC consistently demonstrates superior efficiency in encryption. ECC's encryption times remain notably lower than RSA's for all these larger file sizes, suggesting that ECC is particularly well-suited for securing and transmitting larger email attachments. This outcome highlights ECC's efficiency in handling data encryption tasks for secure email communication, particularly when dealing with substantial file sizes. While RSA performs reasonably well for smaller files, ECC emerges as a more efficient choice as the data to be encrypted grows in size.

Just as Encryption Time from Table II, Decryption Time (in seconds) for both RSA and ECC in Table III provides insights into the time required to decrypt emails with various file sizes, ranging from 10 MB to 500 MB. The results reveal several noteworthy observations. For smaller file sizes (10 MB and 50 MB), ECC demonstrates slightly shorter decryption times compared to RSA, indicating its efficiency in handling smaller data. However, as the file sizes increase to 100 MB, 200 MB, and 500 MB, RSA exhibits competitive or slightly shorter decryption times than ECC. This suggests that RSA can be advantageous for decrypting larger email attachments efficiently.

Data presented in Table IV shows results for the Signature Generation Time (in seconds) for both RSA and ECC. The results reveal that for smaller file sizes (10 MB and 50 MB), RSA demonstrates notably shorter signature generation times compared to ECC, showcasing its efficiency in handling small data for signature creation. However, as file sizes increase to 100 MB, 200 MB, and 500 MB, ECC gradually catches up and, in some cases, surpasses RSA in terms of signature generation efficiency. This suggests that ECC is better suited for efficiently generating signatures for larger email attachments.

Table V provides insights into the time required to verify digital signatures for emails with same attached files as stated earlier. The results demonstrate interesting patterns in signature verification efficiency. For smaller file sizes (10 MB and 50 MB), ECC exhibits slightly longer verification times compared to RSA. However, as file sizes increase to 100 MB, 200 MB, and 500 MB, ECC's verification time becomes comparable to or slightly shorter than RSA's. This indicates that ECC is competitive with RSA in terms of signature verification efficiency, particularly for larger email attachments. The signature verification time findings suggest that ECC is a viable choice for verifying digital signatures, especially for larger data sizes. While RSA may have a slight advantage for smaller files, the efficiency of ECC becomes evident as the data size increases. The selection between RSA and ECC for signature verification should consider the typical email attachment sizes used in practice to optimize performance and efficiency.

Comparing Table I to Table VI, the hybrid technique demonstrates better key exchange time (KET) compared to solo RSA and ECC implementation. This indicates that the process of establishing secure communication channels through key exchange is notably swifter and more efficient when utilizing the proposed hybrid algorithm as opposed to RSA and ECC. Finally, Table VII presents the time (in seconds) recorded for encryption, decryption, signature generation, and signature verification in the context of secure email communication using the hybrid algorithm. When conducting a comparison with Tables II to V, it becomes evident that, on average, the hybrid encryption algorithm enhances the efficiency of encryption and decryption times, as well as signature generation and verification times. In certain instances, the individual ECC times displayed slightly better performance compared to the hybrid algorithm, indicating a close correlation between ECC and the hybrid approach. In summary, the proposed Hybrid technique excels in providing a versatile and efficient encryption solution for secure email communication across a wide range of email message sizes.

VII. Conclusion

Information technology services, like email systems, offer efficient solutions that are accessible to users regardless of their technical proficiency. These systems enable data storage, management, and local or internet-based access. However, the convenience of email usage also brings about a range of security vulnerabilities, encompassing unauthorized access, eavesdropping, identity impersonation, interception, and data tampering. This paper provides an analysis of key cryptographic algorithms, namely RSA, ECC and the hybrid algorithm in the context of securing email communications. The study reveals that ECC excels in terms of key exchange efficiency and effectively manages larger email attachments, making it an attractive choice for enhancing the security of modern email systems. While RSA performs adequately for smaller data sizes, ECC consistently outperforms it as data sizes increase, positioning it as a more efficient cryptographic algorithm for securing email communication. The experimental outcomes indicate that the suggested hybrid solution offers a more efficient method for encrypting email messages, with only a minimal disparity in runtime when compared to the ECC algorithm. Furthermore, this solution ensures a high level of security for secure email communication.

These findings offer valuable insights for practical optimization of email security. The hybrid algorithm introduced in this paper shows promise for being applied in system design, software development, and various other domains, offering an effective means of protecting data. In the future, this research can be further developed by enhancing the security of the hybrid approach. The integration of multiple security layers offers the potential to improve the system's productivity and efficiency.

Acknowledgment

Our gratitude to all the people and groups who helped to complete this study piece. Our gratitude is also expressed to the research team and our colleagues, who helped us out by sharing their skills, information, and encouragement. They played a critical role in carrying out the studies and collecting the results.

***Abstract*—Early seizure detection is difficult with epilepsy. This use of Electroencephalography (EEG) data has proven transformational, however standard centralized machine learning algorithms have privacy and generalization issues. A decentralized approach to epileptic seizure detection using Federated Machine Learning (FML) is presented in this research. The concentration of critical EEG data in conventional models may compromise patient confidentiality. The proposed FML technique trains models using local datasets without sharing raw EEG recordings. Hence the data set used for the model is devoid of noise thus rendering preprocessing unnecessary. Training using decentralized data sources broadens the model's seizure pattern repertoire, improving its adaptability to case heterogeneity. The Federated Machine Learning (FML) model shows that the suggested method for EEG-based epileptic seizure identification is promising for healthcare implementation and deployment. The proposed approach obtains sensitivity, specificity, and accuracy of 98.24%, 99.23%, 99% respectively. The proposed study is validated with the existing literature and the developed model outperforms the existing study.**

***Keywords*—Federal Machine Learning (FML); electroencephalography; epileptic seizure; cross-decentralization; health care; sensitivity**

I. INTRODUCTION

A neurological condition that affects a large number of people, epilepsy, is inextricably intertwined with the complications of seizure detection that are both timely and exact. There is little doubt that the paradigm shifts that have occurred toward the utilization of electroencephalography (EEG) data have been transformational. However, typical centralized machine learning models, which are the mainstays of analysis, struggle with severe hurdles. These issues generally revolve around the delicate balancing act of privacy concerns and restricted generalization. The purpose of this study is to examine the undiscovered territories of Federated Machine Learning (FML) as a potential source of hope in the context of epileptic seizure detection. This paper will begin on an adventure into new terrain. The most important thing is to choose a decentralized strategy, which is a way to gracefully avoid the obstacles that are encountered by standard techniques.

To solve these obstacles and enhance the identification and monitoring of epilepsy, research has been carried out. A study that was conducted by Fisher and colleagues and titled "A practical clinical definition of epilepsy" (Epilepsia, 2014) highlights the need to have a definition of epilepsy that is both patient-oriented and practical to improve diagnosis and make it easier to do research in this area. The research covers the difficulties associated with identifying epilepsy as well as the significance of considering the impact that it has on the lives of sufferers. In addition, a review paper titled "Epilepsy: Comorbidities and Quality of Life" (Epilepsy Research, 2016) was written by Jette and her colleagues. This study investigates the many comorbidities that are linked with epilepsy and the influence that these comorbidities have on the quality of life of those who have the disorder. An emphasis is placed throughout the essay on the significance of comprehensive treatment that extends beyond the control of seizures.

As a tool that has shed light on the complex interplay of electrical activity in the human brain, electroencephalography (EEG) has become an indispensable tool in the field of neuroscience. A non-invasive and crucial instrument, it records neural signals in real time, allowing for the identification and characterization of different brain processes, such as seizures in epileptics.

Central to electroencephalogram (EEG) technology is the measurement of electrical potentials caused by the coordinated firing of brain cells. Electrodes placed on the scalp measure and record voltage changes that are the outcome of postsynaptic potential summation, allowing this to be accomplished. The unique waveforms captured by these recordings represent various brain states.

Because it can record and describe patterns associated with seizures, EEG is very helpful in the setting of epilepsy. Electroencephalogram (EEG) characteristics are unique to seizures because of the abrupt and aberrant synchronization of neuronal firing that occurs during these episodes. Neurologists rely on these signatures—which include spikes, sharp waves, and rhythmic discharges—to make precise diagnoses and formulate effective treatment plans.

An electroencephalogram (EEG) is a crucial diagnostic and monitoring tool for epilepsy. It is a fundamental tool in neurology because it can record the ever-changing electrical landscape of the brain in real-time, detect patterns associated with seizures, and give important information for treatment choices. With the integration of EEG and new methods like Federated Machine Learning, epileptic seizure detection might become much more efficient and accurate, all while protecting

the privacy of patient's personal information, thanks to the rapid advancements in technology.

Management of sensitive medical data is difficult, especially when using machine learning for diagnosis and prediction. Traditional methods gather and store data in a single repository. These techniques have considerable drawbacks, especially in patient privacy and data security. Centralized Approach Limitations: 1) Privacy Issues: Centralized models aggregate massive volumes of sensitive medical data from several sources. 2) Data Security Risks: Malicious attackers target centralized repositories. A security breach in such a store might jeopardize a massive amount of sensitive patient data. 3) Regulatory Compliance Challenges: HIPAA and GDPR are strict data protection laws in the healthcare business. Centralized methods must traverse complicated regulatory frameworks, increasing administrative costs and legal penalties for noncompliance.

Distributed and federated machine learning models address centralized method concerns. Distributed machine learning models provide advantages over the difficult centralized technique. 1) Protecting Patient Privacy: Federated Learning (FL) allows model training on dispersed devices without exchanging raw data [1]. This keeps critical patient data on local servers, lowering the danger of privacy breaches from centralized techniques.2) Improving Data Security: FL localizes data to reduce large-scale data breaches [2]. Devices exchange just model updates, frequently encrypted parameters, decreasing the attack surface and improving data security. 3) Compliance with Regulations: Decentralized models meet legal requirements by keeping data safe and making it easier to follow data security rules [3]. FL is designed so that groups can work together on machine-learning projects while still following the complicated rules that govern healthcare.

Using compression methods for model changes before sending them can cut down on communication costs by a large amount. Some methods, like quantization (which represents model parameters with fewer bits) and scarification (which sends only important parameter changes), can help with bandwidth problems. New compression methods and improvement strategies designed for FML situations are still being studied [4]. Techniques that change compression levels based on the network and the device's powers help communication go more smoothly1.

Problems caused by different datasets can be fixed by making the aggregation process better by adding weighted means based on device performance or data quality [5]. Using safe multi-party computation and homomorphic encryption, along with other advanced aggregation methods, can make privacy-preserving aggregation even stronger. Researchers are still working on creating pooled optimization methods that can handle non-IID (non-identically distributed) data and make models more accurate and faster to converge [6]. Federated learning works better when customized grouping methods are used that take into account the fact that healthcare data is often inconsistent. When you combine edge computing features, you can train and predict models locally, so you don't have to talk to a central computer all the time [7]. Edge devices can train the model at first and only send updated versions to the central computer after they have been improved. This reduces the effect of connection overhead. New developments in edge computing technologies, like edge-centric collaborative learning frameworks, let more complicated model training tasks be done nearby [7]. This method not only cuts down on contact needs, but it also makes it easier for edge devices to make decisions in real-time.

Participation mechanisms that change over time let devices join or leave the federated learning process based on their availability or how well they fit the present learning job [8]. The shared learning process is more flexible when the learning rate is changed automatically based on the features of each device. Researchers are looking into ways to change involvement and learning rates based on reinforcement learning [9]. The goal of these improvements is to make shared learning work better by responding automatically to changing network conditions and device capabilities.

A small number of studies have used both standard machine learning and deep learning to find esp seizures. By taking out important features from EEG data, SVMs have been used to find seizures. But these methods often depend on traits that were made by hand, which makes it harder for them to find complex trends in the data [10].

To sort EEG data into groups, ensemble methods such as Random Forests have been used. They are easy to understand, but the fact that they depend on specific feature engineering could make it harder for them to capture complex time patterns [11].

CNNs have been used to learn features straight from raw EEG data. They are very good at showing how things depend on each other in space, but sometimes they may not be able to show how things change over time [12].

A type of neural network called LSTMs has been used to describe sequences in time-series data, such as EEG data. They are good at showing time dependencies, but they might have trouble with disappearing gradients and long-term dependencies [13].

The current models have some problems with how accurate they are and how well they can be used in other situations.

A lot of statistics about epilepsy are not balanced, with only a few cases showing real seizures. When datasets aren't fair, models can be skewed toward the majority class, which makes them less sensitive and more likely to give false positives [14].

It is possible for EEG readings to be very different between people. Models learned on data from one person might not work well on other people because their brains are built differently, their electrodes may not be placed correctly, or their seizures may be different [15].

Some machine learning models might have trouble figuring out the long-term time frame that is important for epileptic seizures. It might be possible to deal with short-term dependence, but it's still hard to fully capture the pre- and post-ictal phases [16].

Artifacts can show up in EEG records like eye blinks, muscle movements, or electrical interference. Models might

mistake these effects for seizure patterns, which would make them less specific and raise the risk of false positives [17].

Federated Machine Learning was the subject of a thorough review piece that focused on its ideas and uses [9]. The paper doesn't talk about EEG data in particular, but the ideas it does talk about are a good starting point for understanding how FML deals with privacy issues when dealing with private data. The paper talks about different ways to protect privacy, such as differential privacy, and stresses how important it is to train models without a central server.

A standard federated learning framework for epileptic seizure detection utilizing deep learning on a cluster of computers is proposed [18]. The technique was tested on the NVIDIA Jetson Nano Developer Kit using the EPILEPSIAE database, one of the largest public epilepsy datasets for seizure detection. The framework has 81.25% sensitivity, 82.00% specificity, and 81.62% geometric mean. A customized variation of federated learning was also examined, where each computer trained a deep neural network (DNN) to learn the discriminative electrocardiography (ECG) properties of the observed person's epileptic seizures based on its local data. The results show that tailored federated learning improves all performance metrics with a sensitivity of 90.24%, specificity of 91.58%, and geometric mean of 90.90%.

Research proposed based on a three-tier approach for epileptic seizure prediction using the Federated Learning (FL) model [19] to use a large number of seizure patterns from globally distributed patients while protecting data. A bi-timescale local model is developed using the Spiking Encoder (SE) and Graph Convolutional Neural Network (Spiking-GCNN). Each local model uses FL-aggregated seizure knowledge from medical centres to calculate the coarse-grained personalized preictal likelihood. Bi-timescale modelling and Spiking-GCNN-based epileptic pattern learning yielded 96.33% sensitivity and 96.14% specificity on the CHB-MIT EEG dataset. The federated learning improves the suggested system by 96.28% for accuracy.

The challenges of centralized machine learning in epileptic seizure detection is addressed and Federated Machine Learning (FML) model has been proposed as a decentralized solution to address privacy, security, and data handling issues while improving accuracy and patient privacy. It underscores the importance of EEG data and the potential of FML to revolutionize healthcare data analysis.

In conclusion, the inability of centralized methods to handle private medical data, along with the need to protect patient privacy and improve data security, makes the use of autonomous models like Federated Learning in healthcare settings very appealing. FL is a big step toward a more ethical and safe way to handle healthcare data because it reduces privacy issues and makes sure that rules are followed.

II. Material and Method: Federated Machine Learning

The healthcare business is facing several pressing problems, and federated machine learning (FML) could solve many of them. The capacity to enable cross-decentralized healthcare system collaborative learning without jeopardizing the protection of sensitive patient data is one of its notable benefits.

The goal of the machine learning paradigm known as Federated Machine Learning (FML) is to protect the confidentiality of local datasets while training models on distributed servers or devices. With FML, the learning process is decentralized, so each device may train its model locally, as opposed to the standard centralized machine learning strategy, which aggregates and stores data in a central server. Sharing just the model updates—as aggregated parameters or gradients—reduces the need to transmit raw data. When data security and privacy are of the utmost importance, FML's decentralized nature shines.

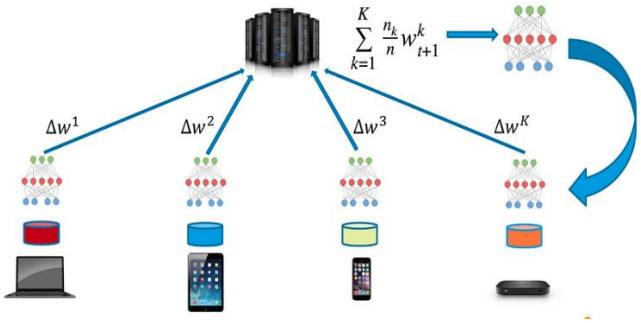

Fig. 1. Federated machine learning model.

The federated ML model is seen in Fig. 1. A global model is the result of combining model modifications made during local training. The model parameters might be averaged or gradients combined to achieve this aggregate. An all-encompassing and broadly applicable comprehension of the data is provided by the aggregated model, which is a representation of the collective knowledge acquired from all participating devices. To keep data transfers between devices to a minimum, FML places an emphasis on efficient communication. No raw data is sent; only model changes are communicated by devices. Because less data needs to be transferred, the communication overhead is reduced, making FML a good fit for situations where network capacity is restricted or when data privacy is a top priority.

Model training over distributed devices is based on the following principles.

1) Training for local models: Model training on each device's local dataset is done individually. Because decentralized data sources are diverse, this first training takes into account information unique to the local setting.

2) Revised model: Model updates, such as parameter updates or gradients, are generally generated by each device after local training. This update incorporates the insights, patterns, and characteristics related to that device, as well as the information obtained from the local dataset.

3) The world model as a whole: A global model is generated by aggregating the model updates from all devices. This worldwide model is an example of a collaborative learning product that draws on information from all around the world. By distributing the contributions from different types

of data evenly, the aggregation process hopes to keep the model accurate.

For the most part, iterative processes are used for local training, model updates, and global model aggregation. In order to promote continuous learning throughout the decentralized network, devices keep improving their models using new global information.

Here is the method for the federated machine learning model, broken down into its parts.

III. Experimental Results

The Dataset collect from UCI Machine Learning Repository is used for the research study. The original dataset from the reference consists of five different folders, each with 100 files, with each file representing a single subject/person. Each file is a recording of brain activity for 23.6 seconds. The corresponding time-series is sampled into 4097 data points. Each data point is the value of the EEG recording at a different point in time. So, we have total 500 individuals with each has 4097 data points for 23.5 seconds.

The proposed federated machine learning uses five client nodes for implementing the system. Three machine learning algorithms are deployed to test the performance of the proposed system, namely decision tree classifier, multilayer perceptron classifier, and logistic regression.

Algorithm of FL

1. intialize :The Central Server: A global model is initialized and a group of clients (C) is chosen and given global model

Every client i has their own local dataset (Di) and model (wi).

2. Training of Local Models:

Client i: Gets the glbal model wt from the main server.

Updates the local model wi with its most recent state by training it with its most recent dataset, Di.

Determines the loss function's gradients using its local data:

Calculates the change in weight w i as a function of time L(wt; Di)

3. Aggregation of Models: • Client i: Transfers data pertaining to local model modifications Δwi to the main server.

• Central Server: Combines all the model changes that have been received:

The weight allocated to client i (e.g., depending on data size) is denoted by αi, and cahnge in $\Delta w = \sum(i \in C)\ \alpha i * \Delta wi$

Update the global model:

$w(t+1)= wt + \Delta w$.

4.repaeat step 2 to 3 number of rounds have passed..

Combining Models:

• Update of the global model by avearge of all local model

The experimental setup parameters used for the experimental study are presented in Table I.

The research work uses a flower framework for deploying federated machine learning with 5 no of participating nodes, 3 Machine learning models like random forest, Multilayer perceptron, and logistic regression are trained with the simulation setup given in Table I.

TABLE I. Experimental Setup

Model	***Parameter value***
Federated machine learning frame work	Flower framework
Number of nodes	5
Multilayer Perceptron Classifier	solver='lbfgs', alpha=1e-5, hidden_layer_sizes=(5, 2),
Logistic Regression	Tolerance for stopping criteria= 1e-4, max_iterint=100, solver='lbfgs'
Decision tree	
Model aggregation method	Average
Batch size sd	64
No of batches	50
No of epochs	100

As a first step of analysing the proposed method, exploratory data analysis is carried out and shown in Fig. 2. The Fig. 2 shows the raw data of ECG signal of seizure-affected people data and non-epics seizure data.

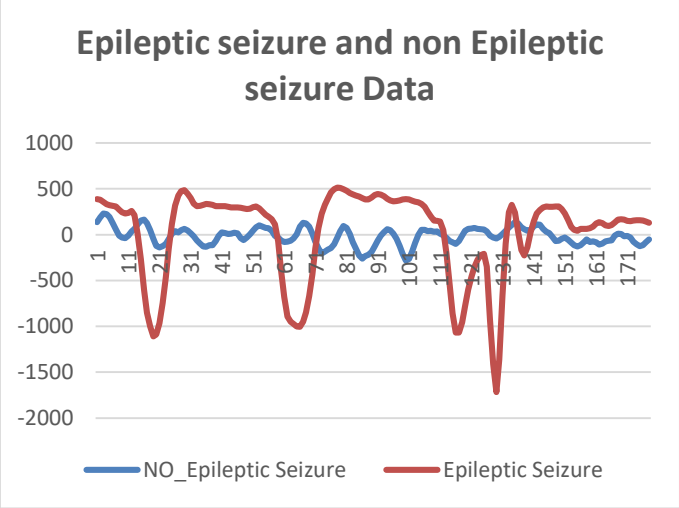

Fig. 2. EEG signal of epileptic seizure and non-epileptic seizure case.

From Fig. 2, it is evident that Epileptic Seizure data and non-Epileptic Seizure data are sitting in different amplitude domains so it is possible to classify them effectively.

Fig. 3 shows the box plot of EEG signal of epileptic seizure and non-epileptic seizure data. From the diagram it is evident the epileptic seizure data and non-epileptic data both has average values of zero but the median value of both is different and also the range of values taken by the both data are different which again prove that both data distributions are in different amplitude domain which can be effectively classified by a classifier.

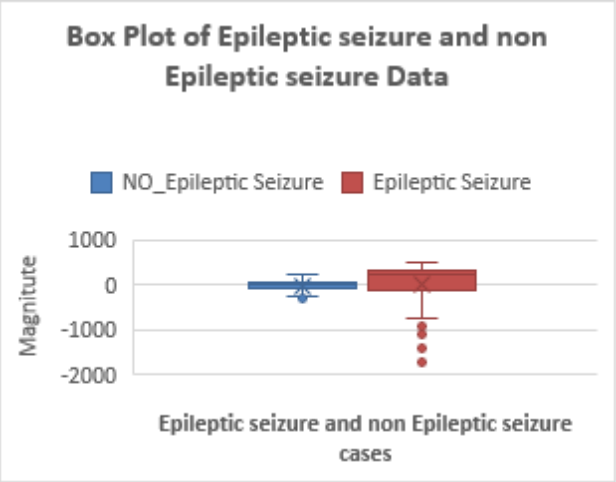

Fig. 3. Box plot of EEG signal of epileptic seizure and non-epileptic seizure case.

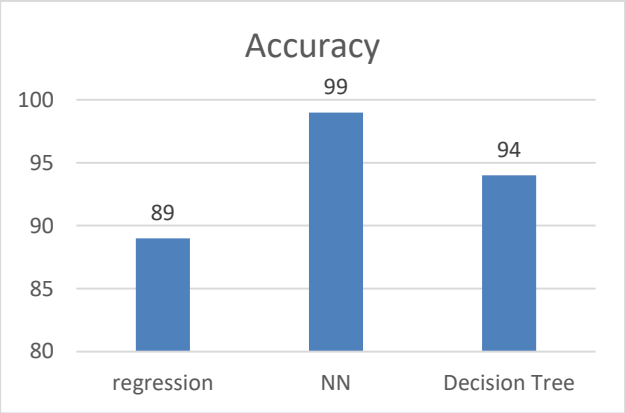

Fig. 4. Accuracy of various machine learning models in federated machine learning.

Federated machine learning of three algorithms is evaluated and plotted in Fig. 4. Figure shows that among the three algorithms, the neural network model achieves the highest accuracy with 99% and decision tree is the second highest accuracy with 94% and the regression model achieves 89%. Those performances are evaluated with the aggregated model after Federated machine learning.

The time complexity of federated machine learning (FL) depends on several factors in the specific FL setup and algorithm used.

1) Number of communication rounds: This refers to the number of times local models are uploaded from devices to the central server, aggregated, and redistributed. Each round involves communication overhead and potential computation on the server. In general, the complexity is linear in the number of rounds (O(R)).

2) Local data size: The amount of data each device uses to train its local model impacts the local computation cost. Typically, the complexity is linear in the local data size (O(n)).

3) Model size: The complexity of aggregating and updating the global model scales with its size. This can be linear (O(m)) or quadratic (O(m^2)) depending on the aggregation method and model architecture.

The time complexity of the federated machine learning for training the three machine learning models is also evaluated which is given in Fig. 4.

From Fig. 4, it is evident that the decision tree model takes a long training time and neural letter model takes the second highest training time and regression takes the least time. The training time complexity shows that the proposed model can be deployed easily in a practical system.

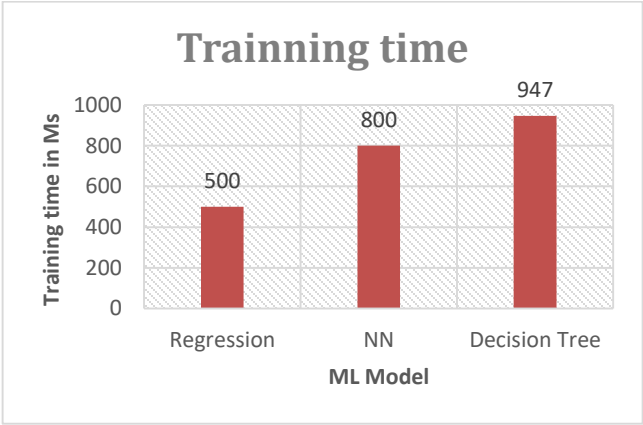

Fig. 5. Training time of Federated machine learning algorithms.

From Fig. 5, it is evident that the decision tree model takes a long training time and neural letter model takes the second highest training time and regression takes the least time. The training time complexity shows that the proposed model can be deployed easily in a practical system.

TABLE II. PERFORMANCE COMPARISON

Method	***Technique employed***	***Accuracy achieved***
Baghersalimi[18]	Federated Deep neural network	Sensitivity of 90.24%, Specificity of 91.58%
Saemaldahr, R.[19]	Federated Spiking Encoder (SE) and Graph Convolutional Neural Network (Spiking-GCNN).	96.33% Sensitivity, 96.14% Specificity. 96.28% accuracy
Proposed	Federated Neural network	sensitivity of 98.24%, specificity of 99.23% 99% accuracy

Table II shows the performance analysis comparison with the literature work. From Table II, it is evident that the proposed work outperformed compared to the literature work. Literature work can achieve 96.33% of sensitivity but the proposed work can achieve 98.24%. similarly, the proposed work achieves 99.23% specificity whereas the literature maximum of 96.14% was only achieved. The proposed work achieves 99 % accuracy whereas literature could even touch only 96%.

IV. CONCLUSION

EEG signal-based epileptic seizure detection framework is presented with a Federated machine learning mechanism. The proposed mechanism ensures the security and privacy of the data while applying data analytics of data to predict the presence and absence of seizure. Maximum accuracy of 99% is achieved by using a neural network model under federation machine learning. The time complexity of the proposed framework was analysed and it shows for the neural network model it takes 800 milliseconds to train the model to predict or classify the seizure. This time complexity proves that the proposed model or framework can be deployed practically to train using federated machine learning. The future work of the proposed framework will be analysing the communication overhead and providing some security measures while sharing the locally trained model with the aggregating server.

LASTIMI Laboratory, Graduate School of Technology EST, Mohamed V University, Rabat[1, 2, 4]
Logistics Center of Excellence, Higher School of Textile and Clothing Industries ESITH, Casablanca[3]

***Abstract*—The third party logistics (3PL) sector holds a crucial role in modern supply chains, streamlining the movement of goods and optimizing logistics operations. The 3PL industry's journey towards digitalization and sustainability reflects a crucial strategy to create an efficient and resilient supply chain. It is increasingly integrating Internet of Things technologies (IoT) within its operations. This latter is a cutting-edge technology widely used in the supply chain realm as it offers numerous advantages namely traceability and real-time decision-making capability. In view of growing concerns for the environment and the social welfare, supply chain actors are seeking to make various initiatives to shift to more sustainable practices. This paper studies the competition within an oligopolistic market of 3PL firms. Through the lens of game theory, we construct a mathematical model where a supply chain composed of n firms competes through pricing, IoT integration efforts and sustainability efforts. Results show that the IoT integration and sustainability efforts impact the pricing decisions of the firm. Moreover, this study highlights how the rivals' decisions on the IoT integration and sustainability efforts impact the firm's decision-making processes. Furthermore, a comparison of the model decision variables within a duopoly and an oligopolistic setting is conducted. This paper concludes to the significant impact of the rivals' strategies on the firm's decisions and profitability.**

Keywords*—Third party logistics; internet of things; sustainability; oligopoly; game theory

I. Introduction

The modern business world has changed drastically in the twenty-first century. Globalization and rapid economic expansion have heightened competition across both global and local markets. Coupled with escalating customer expectations and shorter product lifecycles, supply chains have evolved and become increasingly demanding to manage. Considering the growing complexity of the supply chains, firms are now urged to focus on their core business in order to maintain competitiveness.

Outsourcing logistics activities is considered a practical strategy for companies to reduce their operational costs, decreasing inventory, eliminating capital investment in logistical assets, minimizing labor expenses, and enhancing service standards through enhanced logistical proficiency and broader geographical reach [1]. The realm of third-party logistics is a firmly established business sector. They offer a large range of services from picking and packing to managing and coordinating the whole supply chain [2]. While warehousing and transportation remains their main activity, they also provide services such as product collection, brokering, shipping, material management storing, alongside offering expertise in supply chain strategy and access to technological resources [2]. Over the past few years, the 3PL market has seen substantial growth, resulting in heightened competition and a notable transformation in its competitive environment. 3PLs that prioritize standard services might face a notable reduction in their market share in the coming years. Additionally, external competitors are increasingly venturing into management-focused 3PL activities, potentially diminishing the role of 3PLs to simpler forwarding functions [3]. 3PL firms are thus urged to optimize their service and their strategic models to remain competitive.

In light of the growing interdependence among companies on a global scale, companies are expected to take responsibility for the environmental and social impact of their operations, extending scrutiny throughout their entire supply chain, both incoming and outgoing [4]. Consequently, 3PLs are now facing new challenges in managing their supply chain and processes in a sustainable manner. As sustainability has become a major concern, companies have started adopting new innovative environmentally friendly and socially responsible practices throughout their value chain.

Over the past years, numerous Third-Party Logistics (3PL) companies have adjusted their operations and strategies to prioritize sustainability in their activities. The environmental handling of transportation plays a pivotal role in establishing a greener supply chain, urging corporations to enhance their performance metrics and to mitigate adverse external influences stemming from their logistics operations, like carbon emissions.[5]. There are various approaches to shift to a more environmental and social operations namely, using cleaner fuel, using low-emission vehicles, reduce travel distances and improve vehicle efficiency. Given all the above, 3PL firms predict that shifting to a more sustainable operations will become a standard benchmark in their decision-making process [5].

On the other hand, Third-Party Logistics (3PLs) have faced growing challenges posed by disruptive business models and the emergence of digital technologies [3]. Globally, a rising interest has been on digitalization, creating value across various industries and supply chains. Implementing disruptive technologies with the value chain can optimize business advantages and unveil novel forms of value. Nonetheless, technological transformation presents a distinct set of challenges [6]. Logistics service providers face digital challenges stemming from emerging technologies like

Blockchain, Data analytics, IoT, autonomous vehicles and 3D printing. These technologies range from mature to emerging and create several opportunities for the supply chain sector, however simultaneously changing logistics needs and expectations [3].

One of the main industry 4.0 technologies utilized in the supply chain sector is the Internet of things technologies. The primary technologies utilized for IoT include sensors, smart chips, wireless transmission networks, machine-to-machine communication (M2M), and notably, high-speed communication channels, robust computing capabilities, and expansive data storage capacities. IoT finds application in various logistics activities, i.e. cargo tracing, warehouse and fleet management, predictive asset maintenance, route optimization, smart containers, optimizing capacity usage, truck platooning[7].Furthermore, these technologies are now being employed to oversee and manage environmental risks and human rights concerns, promoting sustainable production and consumption [4].

The competitive dynamics within the industry and the industry 4.0 technologies are evolving swiftly, paving the way for entirely new participants, and transforming the role of 3PLs [8].Consequently, Third-Party Logistics (3PLs) must respond to these changes to hold their position as primary providers of logistics solutions. Digitalization is constructing a fresh competitive landscape as it impacts the business models of Third-Party Logistics [9] . In addition to the shift to sustainable practices, 3PL firms are faced with numerous challenges. One of the main hurdles 3PL face is the high investments needed to meet the digitalization and sustainability requirements and a great pressure on pricing and quality of service [3]. Moreover, they are challenged by finding the balance between the customers' continuous need for standardized services and the necessity to offer more advanced services to remain competitive. Finding this balance puts great pressure on the strategic evolution of the 3PL [2].

Researchers have continuously showed interest in this area of research. However, there has been limited utilization of mathematical modelling to address the problem, with most focus placed on conceptual and statistical analyses instead [10]. Given the complexity of the supply chains encompassing several participants, researchers have used game theory to analyze the complex interactions within the supply chain. This research will consider an oligopoly market of 3PLs investigating the competition among the 3PL firms regarding their pricing strategies, integration of IoT efforts, and sustainability efforts aimed at maximizing profits and maintaining competitiveness within the market.

This research investigates the following questions:

- How do IoT integration and sustainability initiatives into the 3PL service affect the pricing decisions?
- How does competition's strategy affect the firm's decision-making process in terms of price, IoT and sustainability efforts?
- To what extent do IoT and sustainability investments influence the firm's profitability?

This paper will be structured as follow: Section II will present a literature review of our scope of research, the description of our mathematical model will be presented in Section III, we will then present some analytical results and insights of our model in Section IV, and lastly Section V will present a conclusion of our findings.

II. Literature Review

This paper is related to three main streams of research: Internet of Things in supply chain, sustainable supply chain and Third-party logistics.

A. Internet of Things and Sustainability in Supply Chains

The rapid growth of digitalization under the banner of "Industry 4.0" has reshaped and redesigned the nature of businesses. Companies worldwide have shifted their focus to digitalization due to the significant benefits it offers. Utilizing digitalization is a vital tool in achieving efficient and sustainable logistics ecosystems through enhanced transportation systems and new value-added services [2], [11]. Industry 4.0 has introduced a wide range of revolutionary technologies namely Blockchain, Artificial intelligence, Internet of Things, Augmented reality, Data Analytics, and others. These latter have proved numerous advantages in the logistics industry enabling real-time transparency along the entire value chain, enhanced efficiency and visibility, autonomous decision-making, intelligent integrated planning systems and smart warehousing and procurement [11].

Throughout the years, these technologies have shifted the business paradigm in various industries notably in the logistics world. To capitalize on the opportunities presented by digitalization in the business world, companies should consider the appropriate approaches and tools required to transition toward the Digital Supply Chain [6].

IoT is emerging as a rapidly advancing technology that an increasing number of industries are eager to embrace in the aim of enhancing their operational efficiency. It offers numerous valuable avenues to enhance traditional SC such as improved asset utilization, enhanced supply chain performance and greater reliability [12] Moreover, it enables the development of an intelligent infrastructure within supply chains, bringing together vast volumes of data, information, and all supply chain processes, providing real-time decision-making processes [4], [13].

IoT exhibits potential applications within supply chains, yet it confronts various hurdles during implementation. Most emerging technologies introduce several risks and challenges in the process of implementation. These factors should be considered and outline the essential measures for establishing the technology infrastructure. Clearly defining the infrastructure's characteristics during the implementation phase can also aid in better understanding of the technological needs and priorities [6]. Key challenges preventing the full exploitation of IoT in supply chains involve issues related to security, privacy, and scalability. IoT relies on wireless technology, and its applications are constructed using a multitude of sensor nodes [12].

Sustainability has become a major concern for all businesses and sectors in view of customers' requirements and new strict regulations. Companies are progressively paying more attention to social and environmental issues that surround their value chain, i.e. human rights abuses, child labor, deplorable work environments, unethical practices like corruption and bribery, or failure to adhere to environmental regulations [4]. Achieving a sustainable supply chain is ensuring the compliance to environmental and social conditions of all the stakeholders across the whole value chain while maintaining economic profitability. In this context and in view of the expansion of global supply chains, companies are faced with multiple challenges upon adopting more sustainable practices in every possible stage of the value chain.

The introduction of the sustainable development concept has motivated managers and policymakers across various sectors to incorporate environmental and social concerns alongside economic goals in their strategic planning [14]. It has become vital to improve the design and management of supply chain and logistics methods. To enhance the environmentally friendly and sustainable supply chain, a holistic and integrated approach to transportation and environmental policies is essential. This approach should integrate crucial regulations and economic incentives in a transparent manner across all modes of transportation [15].

Furthermore, the rapid development of the industry 4.0 technologies is expected to lead to a significant transformation in how businesses approach their strategies and operations in logistics. It has generated a demand for a new business model focused on a digitally connected, intelligent, exceptionally efficient, and environmentally responsible logistics system that provides complete transparency to all stakeholders [11]. The logistics sector is one of the most concerned with sustainability since it is considered one of the less sustainable sectors and one of the main sources of CO2 and GHG emissions [16]. Digitization alone presents a significant potential to decrease emissions in the logistics sector, with the potential to achieve emissions reductions of approximately 10 to 12% by 2025, as well as contribute to the decarbonization of the global economy [11]. Organizations can employ data to facilitate communication among different supply chain functions, such as procurement, manufacturing, distribution, sales and marketing, and post-sales services. From an economic standpoint, sustainable logistics can reduce costs by preserving product quality during transportation, ensuring product availability, and optimizing processes [15].

Digitalization in logistics enables among others cooperation, connectivity, adaptiveness, integration, and autonomous control. These latter impacts various sustainability criteria in all three dimensions. From an economic stand view, it helps achieve optimized logistics costs, delivery time, forecast accuracy, flexibility, and reliability. In terms of environmental concerns, it encourages a better emission and waste management as well as energy and resource efficiency. As of the social point of view, it promotes better labor patterns and health and safety conduct [11]. In particular, the implementation of IoT technologies has proved its direct and indirect benefit in leveraging sustainability in the supply chains. With its capacity to sense monitor and track in real time, IoT technologies contribute majorly to an optimized real time and decentralized decision-making process. With ensuring a transparent efficient value chain, greener supply chains, decreased emissions, better lead times and optimized costs, the adoption IoT promotes the sustainability of organizations [15], [17], [18].

B. Third Party Logistics

The emergence of 3PL service providers can be traced back to the outsourcing trend of the early 1990s. This subject remains a steadily expanding area of concern and engagement, particularly within the fields of logistics and supply chain management [19]. Logistics is a crucial component of any company's supply chain. Outsourcing enables businesses to be more agile and concentrate on their core operations, improve customer service, and reduce assets [20]. Furthermore, it helps companies in reducing expenses, enhancing efficiency, sustainability, customer satisfaction, and overall profitability [1]. As more companies are seeking 3PL services to stay competitive in the global market landscape, 3PL market has grown significantly and has become notably competitive and diverse. It encompasses numerous companies, varying in size and specialization in logistics services, including transportation, inventory management, warehousing, and distribution. Cost and service quality are frequently the primary factors to consider when assessing a logistics partner [21], however in view of the growing sustainability pressure, social and environmental sustainability will become a crucial criterion for 3PL evaluation [20].

Out of all the methods to meet sustainability objectives within a supply chain, collaborating with third-party logistics firms has garnered considerable interest. Through the delivery of environmentally friendly and effective transportation services, 3PLs can assist various types of supply chains, including regular, closed loop, and circular ones, in achieving higher profits while maintaining sustainability, particularly in the distribution and collection/recycling phases [14]. Consequently, the pursuit of sustainable practices by third-party logistics (3PLs) companies has evolved into a substantial and intricate issue [22].

The literature has showed increasing interest in sustainability in relation to 3PL, particularly in the assessment and selection of 3PL. various decision-making models for evaluating and selecting 3PL from a sustainability point of view have been proposed in the literature [16], [23], [24], [25], [26]. Carbon emissions and delivery time for customer satisfaction are the leading criteria taken into consideration while selecting 3PL. Environmental sustainability of the 3PL have drawn the most interest of the academia, while social sustainability remains under-researched. 3PL companies are now urged to offer more environmentally friendly and socially appropriate services to stay competitive.

The service industry tends to expand and evolve alongside with globalization, technological developments, and the increasingly competitive markets. These factors challenge businesses to maintain high service quality [27]. As the third-party logistics market has expanded considerably, competition has increased. Shifting to a smart tech driven 3PL provider is a must. Researchers showed their interest in the adoption of the

IoT technologies to enhance their performance and decision-making process. IoT technologies can be used in different core processes of 3PL services enabling real time logistics, enhanced flexibility, and overall improved efficiency of logistics operations.

C. Related Works

Supply chain remains a complex system considering it involves numerous players or groups of decision-makers, ergo they are suitable to be examined through the prism of Game theory [28]. This latter provides a framework for modelling these complex interactions and has been widely used among researchers in analyzing supply chain issues [14], [28], [29].

Price is one of the main criteria considered in decision making [14], hence game models for pricing problems is mature [30]. Multiple games in the literature have dealt with pricing in logistics under various factors in addition to costs variables, namely sustainability indicators, risk, competition indicators etc.[30]. Most scholars have showed their interest in investigating pricing models of two echelon supply chains. The latter is composed mainly by manufacturer/supplier/producer and retailer and three echelon supply chains composed of manufacturer/supplier/producer and retailer and 3PL.

Investigating pricing strategies considering the environmental sustainability, closed loop supply chain and green production has been the focus of various papers [5], [14], [29], [31], [32]. [33]. The economic growth and environmental protection are extensively considered in the literature, whereas the social responsibility dimension of sustainability remains under explored comparably. The author in [10] explored the influence of transparency on the demand function and examines how transparency and corporate social responsibility affect the choices made by supply chain members and their profits concerning an environmentally friendly product. The author in [33] explores a supply chain framework featuring both a Green Supply Chain (GSC) and a Non-Green Supply Chain (NGSC), each consisting of a manufacturer and a retailer. The paper introduces a novel competitive mathematical model where the government acts as a leader, discussing pricing policies, greening strategies, and government tariffs under competitive conditions influenced by governmental financial policies. The author in [34] proposes two models; Model 1 aims to assess the optimal green quality, selling price, and business approach in green marketing in a cooperative business strategy between a manufacturer and a retailer involved in marketing green products. Whereas model 2 examines the price competition between two CSR firms, regular producer, and a green producer.

On the other hand, digitalization, and the use of IoT has also attracted attention of researchers in decision making models. The proposed models explored investment decisions [35], [36], [37], as well as outsourcing decisions [38]. Furthermore,[39] examined how integrating IoT can affect the quality of service of the 3PL firms in a duopoly market setting, while [40] has combined both digitalization and sustainability in its game model. This latter investigated the effectiveness of competitive sustainability services, digitalization services, and pricing decisions in a 2-tier supply chain structure of a manufacturer and a retailer.

Through the lens of game theory, researchers have explored the competition in pricing strategies in 2-tier supply chains, focusing on monopolistic and duopolistic settings. Fewer researchers have focused on pricing decision games in an oligopoly market structure. Reference [41] focused on aligning pricing and advertising decision in a multi-product, multi-echelon supply chain comprising several suppliers, one manufacturer, and multiple retailers with horizontal and vertical competition. While [42] considered competition between multiple supply chains, each composed of a manufacturer and a salesperson.

Game theory, a critical tool in supply chain management, has been extensively utilized across various scenarios. However, its specific application to 3PL and sustainability within the context of the IoT remains relatively nascent. This gap highlights an emerging area of interest where the interactions between 3PL providers, sustainability practices, and digital technologies can be explored through the lens of game theory. Research focusing on how 3PL companies make decisions regarding sustainability and the integration of IoT technologies is still in its early stages, particularly when examining these factors within an oligopolistic market context. Additionally, while the concepts of sustainability and digitalization have begun to attract academic attention, much of the existing literature remains theoretical frameworks. Another significant gap in current research is the exploration of competitive pricing strategies for 3PL services in a market where multiple players compete for advantage. Our research aims to fill these gaps by providing insights into the pricing dynamics of 3PLs in competitive markets, particularly focusing on how these companies can leverage IoT and sustainability within their strategic decision process.

III. Model Description

We consider a competitive setting of n 3PL firms, which is denoted $i = \{1, \dots n\}$, offering homogenous service. Fig. 1 illustrates the market setting and competitiveness in our proposed model.

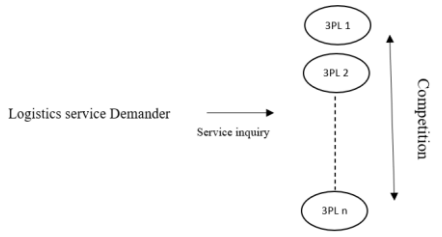

Fig. 1. The proposed model.

In light of more competitive and demanding customers, in terms of quality, service and sustainability, and in addition to a competitive environment the 3PL firms are constrained to make complex strategic decisions.

Let us consider the 3PL firms compete through price, technology, and sustainability. In our paper, we consider an IoT integration effort β. On the other hand, sustainability has

become a perquisite concern for all supply chain entities. Since sustainability encompasses three aspects, namely economic, environment and social, diverse actions and approaches can be considered to make supply chain operations more sustainable. In line with [40] and to keep our model simple, we will consider a sustainability effort level σ that covers different sustainability initiatives that can be taken.

To remain competitive, 3PL needs to determine the optimal choices in terms of price and services. In our paper, we aim to investigate the optimal price, IoT integration and sustainability effort to maximize the profit.

Similar to [40], [43], the inverse demand function for firm i is expressed as follows:

$$D_i = \frac{a}{n} - \alpha p_i + \frac{\gamma}{n-1}\sum_{k\neq i}^{n} p_k + T_i\beta_i - \frac{1}{n-1}\sum_{k=1}^{n} T_k\beta_k + S_i\sigma_i - \frac{1}{n-1}\sum_{k=1}^{n} S_k\sigma_k \ \ (k \neq \text{i}) \quad (1)$$

We assume the firm's demand function is a decreasing function of its own price and increasing on its competitors' price. Moreover, the firm's demand is influenced by IoT integration and sustainability efforts, where higher efforts of the firm will increase their demand while the rivals' efforts will bring down the firm's demand.

The total market demand is expressed as follows where it is solely influenced by the price of the firms. $D_T = \sum_{i=1}^{n} D_i$

$$D_T = a + (\gamma - \alpha)\sum_{k=1}^{n} p_k \quad (2)$$

A. Notations

1) Input parameters

D_i	Demand function of firm i
a	Market share
α	Self-price sensitivity
γ	Cross-price sensitivity
T_i	Market sensitivity of firm i to the IoT integration
S_i	Market sensitivity of firm i to the sustainability effort
λ	IoT integration cost factor
θ	Sustainability initiative cost factor

2) Decision variables

p_i	3PL firm i's price
β_i	3PL firm i's IoT integration effort
σ_i	3PL firm i's sustainability effort

The cost of the service for firm i is composed of a fixed cost dependent of the demand Ci and demand independent costs encompassing the costs of IoT integration C_i^T and sustainability effort C_i^S. Choosing to invest in such technology and sustainable practices can bring a competitive edge to the firms however it is still financially challenging. As employed widely in the literature [10], [40], we consider quadratic cost functions for firm i expressed as follows:

$$C_i^T = \frac{\lambda {\beta_i}^2}{2} \quad (3)$$

$$C_i^S = \frac{\theta {\sigma_i}^2}{2} \quad (4)$$

Based on the above, the 3PL firm i's profit function is modelled as follows:

$$\pi_i = (p_i - C_i)D_i - C_i^T - C_i^S \quad (5)$$

$$\max_{p_i,\beta_i,\sigma_i} \pi_i = (p_i - C_i)\left(\frac{a}{n} - \alpha p_i + \frac{\gamma}{n-1}p_{k_i} + T_i\beta_i - \frac{1}{n-1}\sum_{k=1}^{n} T_k\beta_k + S_i\sigma_i - \frac{1}{n-1}\sum_{k=1}^{n} S_k\sigma_k\right) - \frac{\lambda\beta_i^2}{2} - \frac{\theta\sigma_i^2}{2} \quad (6)$$

This paper addresses modelling various decision-making strategies employed by 3PL firms under competition in an oligopoly setting. It aims to identify the most advantageous decisions related to price IoT technology and sustainability efforts to maximize their profits.

All the firms decide on their price, IoT integration and sustainability efforts simultaneously, the optimal price, IoT integration and sustainability effort of firm i are calculated as follows:

$$p_i, \beta_i, \sigma_i \underset{p_i,\beta_i,\sigma_i}{\in} \arg\max \pi_i(p_i, \beta_i, \sigma_i) \quad (7)$$

$$\frac{\partial \Pi_i}{\partial p_i} = \frac{a}{n} + \frac{\sum_{k=1}^{n} T_k\beta_k}{n-1} - \frac{\sum_{k=1}^{n} S_k\sigma_k}{n-1} - 2\alpha p_i + C_i\alpha + T_i\beta_i + \frac{\gamma p_{k_i}}{n-1} + S_i\sigma_i \quad (8)$$

$$\frac{\partial \pi_i}{\partial \beta_i} = (p_i - C_i)T_i - \beta_i\lambda \quad (9)$$

$$\frac{\partial \pi_i}{\partial \sigma_i} = (p_i - C_i)S_i - \theta\sigma_i \quad (10)$$

In order to analyze the concavity of the function we use the hessian matrix expressed as follows:

$$H_i = \begin{bmatrix} \frac{\partial^2\pi_i}{\partial p_i^2} & \frac{\partial^2\pi_i}{\partial p_i\beta_i} & \frac{\partial^2\pi_i}{\partial p_i\sigma_i} \\ \frac{\partial^2\pi_i}{\partial \beta_i p_i} & \frac{\partial^2\pi_i}{\partial \beta_i^2} & \frac{\partial^2\pi_i}{\partial \beta_i\sigma_i} \\ \frac{\partial^2\pi_i}{\partial \sigma_i p_i} & \frac{\partial^2\pi_i}{\partial \sigma_i\beta_i} & \frac{\partial^2\pi_i}{\partial \sigma_i^2} \end{bmatrix} \quad (11)$$

$$H_i = \begin{bmatrix} -2\alpha & T_i & S_i \\ T_i & -\lambda & 0 \\ S_i & 0 & -\theta \end{bmatrix} \quad (12)$$

We have

$$\frac{\partial^2\pi_i}{\partial p_i^2} < 0 \ \ \frac{\partial^2\pi_i}{\partial \beta_i^2} < 0 \ \ \frac{\partial^2\pi_i}{\partial \sigma_i^2} < 0 \quad (13)$$

And

$$\det H_i = {T_i}^2\theta + {S_i}^2\lambda - 2\alpha\theta\lambda \quad (14)$$

$$\det H_i > 0 \ if \ {T_i}^2\theta + {S_i}^2\lambda - 2\alpha\theta\lambda > 0$$

We suppose

$$S_i^2 - 2\alpha\theta > 0 \quad (15)$$

Since $\lambda > 0$ and $T_i^2\theta > 0$ hence $\det H_i > 0$

Accordingly, the hessian matrix H_i is negative definite. Hence the profit function of firm i is concave in p_i, β_i, σ_i.

By utilizing the function described in equation (6), we can calculate the equilibrium price p_i^* , IoT integration effort β_i^* and sustainable effort σ_i^* of firm i by examining the first-order conditions associated with each of these variables:

$$\frac{\partial \pi_i}{\partial p_i} = 0 \xrightarrow{yields} p_i^* = \frac{a(n-1)-n\sum_{k=1}^{n} T_k\beta_k - n\sum_{k=1}^{n} S_k\sigma_k - C_i n\alpha + C_i n^2\alpha - nT_i\beta_i + n^2T_i\beta_i + p_{k_i}n\gamma - nS_i\sigma + n^2S_i\sigma_i}{2n\alpha(n-1)}$$

$$p_i = \frac{a(n-1)+n(-\sum_{k=1}^{n} T_k\beta_k - \sum_{k=1}^{n} S_k\sigma_k + C_i\alpha(n-1) + (n-1)T_i\beta_i + p_{k_i}\gamma + (n-1)S_i\sigma_i)}{2(n-1)n\alpha} \quad (16)$$

$$\frac{\partial \pi_i}{\partial \beta_i} = 0 \xrightarrow{yields} \beta_i^* = \frac{(p_i - C_i)T_i}{\lambda} \quad (17)$$

$$\frac{\partial \pi_i}{\partial \sigma_i} = 0 \xrightarrow{yields} \sigma_i^* = \frac{(p_i - C_i)S_i}{\theta} \quad (18)$$

By solving (16) (17) and (18) simultaneously, the optimal equilibrium solutions $(p_i^*, \beta_i^*, \sigma_i^*)$ can be derived:

$$p_i^* = \frac{C_i{T_i}^2\theta + \lambda(C_i{S_i}^2 - \theta(\frac{a}{n} + C_i\alpha + \frac{p_{k_i}\gamma}{n-1} - \frac{\sum_{k=1}^{n} T_k\beta_k}{n-1} - \frac{\sum_{k=1}^{n} S_k\sigma_k}{n-1}))}{{T_i}^2\theta + \lambda({S_i}^2 - 2\alpha\theta)} \quad (19)$$

$$\beta_i^* = \frac{T_i(a\theta - an\theta + n\theta\sum_{k=1}^{n} T_k\beta_k + n\theta\sum_{k=1}^{n} S_k\sigma_k - C_i n\alpha\theta + C_i n^2\alpha\theta - p_{k_i}n\gamma\theta)}{n(n-1)({T_i}^2\theta + {S_i}^2\lambda - 2\alpha\theta\lambda)} \quad (20)$$

$$\sigma_i^* = \frac{S_i(a\lambda - an\lambda + \sum_{k=1}^{n} T_k\beta_k n\lambda + n\lambda\sum_{k=1}^{n} S_k\sigma_k - C_i n\alpha\lambda + C_i n^2\alpha\lambda - p_{k_i}n\gamma\lambda)}{n(n-1)({T_i}^2\theta + {S_i}^2\lambda - 2\alpha\theta\lambda)} \quad (21)$$

To simplify the optimal equilibrium solutions, we consider the following variables: B is the sum of rivals' IoT integration effort function, W is the sum of rivals' sustainability effort, and G is the sum of rivals' price. The equilibrium values of the decision variables are thus expressed as follows:

$$p_i^* = \frac{C_i{T_i}^2\theta + \lambda(C_i{S_i}^2 - \theta(\frac{a}{n} + C_i\alpha + \frac{G\gamma}{n-1} - \frac{B}{n-1} - \frac{W}{n-1}))}{{T_i}^2\theta + \lambda({S_i}^2 - 2\alpha\theta)} \quad (22)$$

$$\beta_i^* = \frac{T_i(a\theta - an\theta + n\theta B + n\theta W - C_i n\alpha\theta + C_i n^2\alpha\theta - Gn\gamma\theta)}{n(n-1)({T_i}^2\theta + {S_i}^2\lambda - 2\alpha\theta\lambda)} \quad (23)$$

$$\sigma_i^* = \frac{S_i(a\lambda - an\lambda + Bn\lambda + n\lambda W - C_i n\alpha\lambda + C_i n^2\alpha\lambda - Gn\gamma\lambda)}{n(n-1)({T_i}^2\theta + {S_i}^2\lambda - 2\alpha\theta\lambda)} \quad (24)$$

IV. Analytical Results and Insights

This section includes the execution of analytical and parametric sensitivity analyses alongside their corresponding corollaries and implications. To answer our research questions, we first examined the impact of the IoT integration and sustainability efforts of a firm i on its own price. Furthermore, we analyzed the impact of IoT integration and sustainability efforts of rival firms (B,W) on the firm's price, IoT integration and sustainability efforts. Given that the IoT implementation and sustainability practices costs are significant investments, we also explored the impact of their cost factors on the firm's decisions on price, IoT integration and sustainability efforts.

A. Impact of the IoT Integration Effort on the Equilibrium Price

Proposition 1: Increasing the IoT integration efforts of a firm leads to an increase in their price.

Corollary 1: The increase of the IoT integration effort of a firm leads to an increase in their price. This is due to the high costs associated with the technological investments and maintenance. Moreover, the magnitude of the effect of the integration effort on the price is influenced by the ratio of firm's demand sensitivity to the IoT integration and its price elasticity. This suggests that the degree of effect depends on how significantly sensitive is the 3PL market to the technology integration. In a more competitive technology-oriented market, the impact of integrating the IoT technology will be more significant.

Proof 1: By calculating the derivative of the equilibrium price of firm i by the IoT integration rate β_i, we can analyze how the changes in the integration rate can affect the price of firm i. Based on (16) we get:

$$\frac{\mathrm{d}p_i^*}{\partial \beta_i} = \frac{n^2T_i - nT_i}{2(n-1)n\alpha} = \frac{T_i}{2\alpha} \quad (25)$$

Since $\frac{T_i}{2\alpha} > 0$, hence the proposition.

B. Impact of the Sustainability Effort on the Equilibrium Price

Proposition 2: Increasing the sustainability efforts of a firm leads to an increase in their price.

Corollary 2: Changes in the sustainability effort positively affect the pricing of the service. As the effort increases the price increases as well. This is due to the costs associated to incorporating more sustainable practices in the 3PL services. Furthermore, the significance of the impact on the price depends on how the market is sensitive to the proposal of more sustainable service.

Proof 2: To analyze the impact of sustainability practices on the pricing, we calculate the derivative of the equilibrium price with respect to its sustainability effort.

$$\frac{\partial p_i^*}{\partial \sigma_i} = \frac{-nS_i + n^2S_i}{2n\alpha(n-1)} = \frac{S_i}{2\alpha} \quad (26)$$

Since $\frac{S_i}{2\alpha} > 0$, hence the proposition

C. Impact of the IoT Integration Level and Sustainability Effort Level of Rival Firms (B,W) on Price

Proposition 3: Equilibrium price goes up with the increase of IoT integration and sustainability effort level of rival firms *(B,W)*.

Corollary 3: The pricing strategy is significantly influenced by the IoT integration and sustainability efforts adopted by rival firms. As IoT integration and sustainability initiatives of competitors increase, the equilibrium price goes up. Understanding and being aware of these strategies implemented by competitors becomes crucial for firms aiming to maximize their profits. Such insights allow firms to strategize their IoT integrations and sustainability efforts and set their prices, leveraging the market trends. Encouraging cooperative models among firms emerges as an appealing approach. This enables firms to adapt collectively to market changes, ensuring better profitability while meeting evolving customer preferences for digitalization and sustainability.

Proof 3: The derivative of the equilibrium price with respect to the rivals' integration and sustainability efforts is calculated as follows:

$$\frac{\partial p_i^*}{\partial B} = \frac{\theta\lambda}{(n-1)(T^2\theta+(S^2-2\alpha\theta)\lambda)} \quad (27)$$

$$\frac{\partial p^*}{\partial W} = \frac{\theta\lambda}{(n-1)(T^2\theta+(S^2-2\alpha\theta)\lambda)} \quad (28)$$

According to (15) we have $(T^2\theta + S^2\lambda - 2\alpha\theta\lambda) > 0$ and since $\theta\lambda > 0$ hence the proposition.

D. Impact of the Average IoT Integration Level and Sustainability Efforts of Rival Firms (B,W) on IoT Integration Level

Proposition 4: As the IoT integration and sustainability effort of rivals increases, the equilibrium IoT integration effort increases.

Corollary 4: When the efforts of sustainability and IoT integration among rival firms increases, it positively influences the equilibrium IoT integration level. This scenario signifies the market landscape where sustainability and IoT implementation norms are escalating impacts the firm's strategic choices on the level of IoT integration. As rivals collectively intensify their focus on sustainability and digitalization initiatives, it exhibits a positive impact on the equilibrium integration level of the firm. To remain competitive and align with evolving market standards, the firm is urged to increase its IoT integration efforts.

In the context of 3PL market, when a firm increases its IoT integration rate and gain competitive advantage, the other firms tend to follow to stay competitive. Moreover, this also suggests the possibility of cooperation between the firms in investing on the implementation of IoT technology in their fleet and warehouses.

Proof 4: The derivative of the equilibrium IoT integration effort with respect to the rivals' average integration and sustainability efforts is calculated as follows:

$$\frac{\partial \beta^*}{\partial B} = \frac{T\theta}{(-1+n)(T^2\theta+S^2\lambda-2\alpha\theta\lambda)} \quad (29)$$

$$\frac{\partial \beta^*}{\partial W} = \frac{T\theta}{(-1+n)(T^2\theta+S^2\lambda-2\alpha\theta\lambda)} \quad (30)$$

According to (15) we have $(T^2\theta + S^2\lambda - 2\alpha\theta\lambda) > 0$ and since $T\theta > 0$ hence the proposition.

E. Impact of IoT Integration Level and Sustainability Effort Level of Rival Firms (B,W) on Sustainability Efforts

Proposition 5: As the IoT integration and sustainability level of rivals increases, sustainability effort level increases.

Corollary 5: When the efforts of sustainability and IoT integration among rival firms increases, it positively influences the sustainability effort level. This scenario signifies the market landscape where sustainability and IoT implementation norms are escalating impacts the firm's strategic choices on the level of IoT integration. As rivals collectively intensify their focus on sustainability and digitalization initiatives, it displays a positive impact on the equilibrium sustainability effort of the firm. To remain competitive and align with evolving market standards, the firm is urged to increase its IoT integration efforts.

Proof 5: The derivative of the equilibrium price with respect to the rivals' average integration and sustainability efforts is calculated as follows:

$$\frac{\partial \sigma^*}{\partial B} = \frac{S\lambda}{(n-1)(T^2\theta+S^2\lambda-2\alpha\theta\lambda)} \quad (31)$$

$$\frac{\partial \sigma^*}{\partial W} = \frac{S\lambda}{(n-1)(T^2\theta+S^2\lambda-2\alpha\theta\lambda)} \quad (32)$$

According to (15) we have $(T^2\theta + S^2\lambda - 2\alpha\theta\lambda) > 0$ and since $S\lambda > 0$, hence the proposition.

F. Impact of IoT Integration and Sustainability Effort cost Factor (λ,θ) on IoT Integration Effort

Proposition 6: IoT integration effort decreases with the increase of the IoT implementation cost factor if the following is established:

$$B + W > (n-1)\left(\frac{a}{n} - C\alpha\right) + G\gamma \quad (33)$$

Corollary 6: The cost factor of the IoT integration of a firm is an influencing factor in the decision making of the IoT integration effort, under certain conditions linked to both customer sensitivity to the sustainability effort and the rival strategies. Under these conditions, an increase in the IoT integration cost factor leads to a decrease in the equilibrium level of IoT integration. This case is expected as firm will face the barrier of high implementation costs. However, in the case when (33) is not met, the equilibrium IoT integration level increases although the IoT integration cost increases. In that scenario, the customers are less sensitive to the sustainability effort and rivals' IoT integration and sustainability efforts are low.

Proof 6: Based on (23) the derivative of the IoT integration effort β^* with respect to its cost factor λ can be calculated as follows:

$$\frac{\partial \beta^*}{\partial \lambda} = -\frac{T\theta(S^2-2\alpha\theta)(\frac{a}{n}-a+B+W-C\alpha+Cn\alpha-G\gamma)}{(n-1)(T^2\theta+S^2\lambda-2\alpha\theta\lambda)^2} \quad (34)$$

$(S^2 - 2\alpha\theta)(a/n - a + B + W - C\alpha + Cn\alpha - G\gamma) > 0$ implies $\frac{\partial \beta^*}{\partial \lambda} < 0$. Accordingly to (15), $\frac{\partial \beta^*}{\partial \lambda} < 0$ when $(a/n - a + B + W - C\alpha + Cn\alpha - G\gamma) > 0$ .On the other hand, when $\left(\frac{a}{n} - a + B + W - C\alpha + Cn\alpha - G\gamma\right) < 0$ it implies $\frac{\partial \beta^*}{\partial \lambda} > 0$.

Proposition 7: IoT integration effort increases with the increase of the sustainability level sensitivity if the following is established:

$$B + W > (n-1)(\frac{a}{n} - C\alpha) + G\gamma) \quad (35)$$

Corollary 7: In comparison to the observed impact of IoT integration cost factor, the impact of sustainability effort cost factor on IoT integration levels within firms are predominantly influenced by in the competitions' strategies. In addition, when the sustainability cost factor is greatly low the equilibrium IoT integration level approaches zero. In this scenario, when the sustainability investments are low enough, firms will favor sustainability efforts over IoT integration strategy.

Proof 7: Based on (23) the derivative of the IoT integration effort $\beta^*$with respect to its sustainability cost factor θ can be calculated as follows:

$$\frac{\partial \beta^*}{\partial \theta} = \frac{S^2 T\lambda(a/n - a + B + W - C\alpha + Cn\alpha - G\gamma)}{(n-1)(T^2\theta + (S^2 - 2\alpha\theta)\lambda)^2} \quad (36)$$

Also, when the cost factor is low and $\theta \to 0$ we have: $\lim_{\theta \to 0} \beta^* = 0$.

G. Comparison of a Duopoly and Oligopoly Market

To further analyze our model, we will compare the equilibrium decision variables; price, IoT integration and sustainability efforts and profit in two special cases. The first is a duopoly market setting, for this latter we consider $n = 2$. We will then compare it to the case when the number of firms n is considerably high, in this case we will calculate the equilibrium decision variables and profit when n approaches ∞. We assume the parameters $(C, \mathrm{T}, \mathrm{S}, \theta, \lambda, \alpha)$ are equal in both scenarios.

Duopoly case: We denote the price, IoT integration effort, sustainability effort and profit fir firm i in this case as p_2^* , β_2^* σ_2^* and π_2^* respectively. And B^d, W^d, G^d and $a^d$the rival's IoT integration effort, sustainability effort, price, and market share in the duopoly market respectively.

Oligopoly case: We denote the price, IoT integration effort, sustainability effort and profit for firm i in the case where n is considerably high as p_n^* , β_n^* σ_n^* and π_n^* respectively.

Proposition 8: The ordinal relationship of the decision variables (price, IoT integration effort and sustainability effort) in the duopoly case and oligopoly market setting are related as follows: $p_2^* < p_n^*$. $\beta_2^* < \beta_n^*$ and $\sigma_2^* < \sigma_n^*$ when the following is established: $2(B^d + W^d - G^d\gamma) < a^d$. Whereas $\pi_2^* > \pi_n^*$ when $\left(a^d - 2(B^d + W^d - G^d\gamma)\right)\left(a^d - 2(B^d + W^d + 2C\alpha - G^d\gamma)\right)(-T^2\theta - S^2\lambda + \alpha\theta\lambda) > 0$.

Corollary 8: The equilibrium price, IoT integration and sustainability efforts increase as the number of firms n increases. This suggests firms could charge higher prices even in competitive markets with differentiating their service by engaging in technological and sustainable operations. However, when $2(B^d + W^d - G^d\gamma) > a^d$ is established, the equilibriums values are higher in the duopoly setting. This inequality suggests a highly competitive intensity and a saturated market where firms are investing significantly in IoT and sustainability efforts. This scenario may lead to diminishing returns on investment and the need to careful strategic consideration to align with market potential. Accordingly, the price, IoT integration and sustainability efforts are higher in an intense competitive duopoly market compared to highly competitive market with numerous firms.

Proof 8: We calculate the limits of the decision variables and profit when $n = 2$ and when n approaches ∞.

We have:

$$\lim_{n \to \infty} p^* = \frac{CT^2\theta + CS^2\lambda - C\alpha\theta\lambda}{T^2\theta + S^2\lambda - 2\alpha\theta\lambda} \text{ and}$$

$$p_2^* = \frac{-(a^d - 2\theta\lambda(B^d + W^d - G^d\gamma)) + 2C(T^2\theta + \lambda(S^2 - \alpha\theta))}{2(T^2\theta + (S^2 - 2\alpha\theta)\lambda)}$$

Hence, we have:

$$p_2^* - p_n^* = \theta\lambda \frac{2(B^d + W^d - G^d\gamma) - a^d}{2(T^2\theta + (S^2 - 2\alpha\theta)\lambda)} \quad (37)$$

We have

$$\lim_{n \to \infty} \beta^* = \frac{CT\alpha\theta}{T^2\theta + S^2\lambda - 2\alpha\theta\lambda} \text{ and } \beta_2^* = \frac{T(-a^d\theta + 2B^d\theta + 2W^d\theta + 2C\alpha\theta - 2G^d\gamma\theta)}{2(T^2\theta + S^2\lambda - 2\alpha\theta\lambda)}$$

Hence,

$$\beta_2^* - \beta_n^* = T\theta \frac{2(B^d + W^d - G^d\gamma) - a^d}{2(T^2\theta + \lambda(S^2 - 2\alpha\theta))} \quad (38)$$

We have:

$$\lim_{n \to \infty} \sigma^* = \frac{CS\alpha\lambda}{T^2\theta + S^2\lambda - 2\alpha\theta\lambda} \text{ and } \sigma_2^* = \frac{S(-a^d\lambda + 2B^d\lambda + 2W^d\lambda + 2C\alpha\lambda - 2G^d\gamma\lambda)}{2(T^2\theta + S^2\lambda - 2\alpha\theta\lambda)}$$

Hence,

$$\sigma_2^* - \sigma_n^* = S\lambda \frac{2(B^d + W^d - G^d\gamma) - a^d}{2(T^2\theta + \lambda(S^2 - 2\alpha\theta))} \quad (39)$$

We have:

$$\lim_{n \to \infty} \pi^* = -\frac{C^2\alpha^2\theta\lambda}{T^2\theta + (S^2 - 2\alpha\theta)\lambda} \quad \pi_2^* = \frac{\theta\lambda\left[\left(a - 2(B^d + W^d + C\alpha - G^d\gamma)\right)^2(-T^2\theta - S^2\lambda + \alpha\theta\lambda) + 4C^2\alpha^3\theta\lambda\right]}{4(T^2\theta + (S^2 - 2\alpha\theta)\lambda)^2}$$

$$\pi_2^* - \pi_n^* = \frac{(a - 2(B^d + W^d - G^d\gamma))(a - 2(B^d + W^d + 2C\alpha - G^d\gamma))\theta\lambda(-T^2\theta - S^2\lambda + \alpha\theta\lambda)}{4(T^2\theta + (S^2 - 2\alpha\theta)\lambda)^2} \quad (40)$$

V. Numerical Analysis

To deepen our understanding and analysis of the model, we conducted a numerical analysis. For the subsequent analyses, we will employ the following values for the parameters.

- Total market size a =80.
- Number of Competitors $n = 5$.
- Self-price Sensitivity α = -1.0.
- Cross-price Sensitivity γ: 0.5.
- Market Sensitivity to IoT Integration T_i: 0.5.
- Market Sensitivity to Sustainability Effort S_i: 0.5.
- IoT Integration Cost Factor λ= 0.2.
- Sustainability Initiative Cost Factor θ= 0.2.
- Price p_i: 100.
- Sustainability Effort σ_i= 0.5.
- C_i=50.
- G=400.

A. Effect of β_i Variation on Firm i 's Profit Across Different B Scenarios

The initial analysis examined the effect of β_i variation on firm i 's profit across different scenarios, adjusting the values of B accordingly. Fig. 2 represents the variation of the profit with β_i.

The profit exhibits fluctuations with rising β_i, suggesting that the firm's investment in IoT integration impacts profitability in varying ways, contingent on the competitive environment. As B increases the profitability of the firm tends to diminish. This suggests the need to consider competitor's strategy when planning its own emphasizing the importance to have strategic flexibility to both competitive pressures and market demand.

B. Profit Variation Across Different Scenarios

Through the analysis of multiple scenarios, we examined the profitability of Firm i considering different scenarios related to IoT and sustainability efforts by both Firm i and its competitors.

Scenario 1: Firm i implements both IoT and sustainability practices while competitors don't: in this scenario we consider $\beta_i = 0.5$, $\sigma_i = 0.5$ while $B = 0$, $W = 0$.

Scenario 2: Firm i implements only IoT while competitors don't: in this scenario we consider $\beta_i = 0.5$, $\sigma_i = 0$ while $B = 0$, $W = 0$.

Scenario 3: Both Firm i and its competitors implements both IoT and sustainability: in this scenario we consider $\beta_i = 0.5$, $\sigma_i = 0.5$ while $B = 3$, $W = 3$.

Scenario 4: Firm i only implements IoT and its competitors implements both IoT and sustainability: in this scenario we consider $\beta_i = 0.5$, $\sigma_i = 0$ while $B = 3$, $W = 3$.

Scenario 5: Firm i implements both IoT and sustainability and its competitors only implement IoT: in this scenario we consider $\beta_i = 0.5$, $\sigma_i = 0.5$ while $B = 3$, $W = 0$.

Scenario 6: Both Firm i and its competitors only implement IoT: in this scenario we consider $\beta_i = 0.5$, $\sigma_i = 0$ while $B = 3$, $W = 0$.

Combining sustainability efforts with IoT integration can provide strategic benefits, particularly when competitors lag in sustainability initiatives or concentrate exclusively on technological advancements. The scenarios highlight the importance of aligning the firm's strategy with market dynamics, competitor actions, and the opportunity to differentiate.

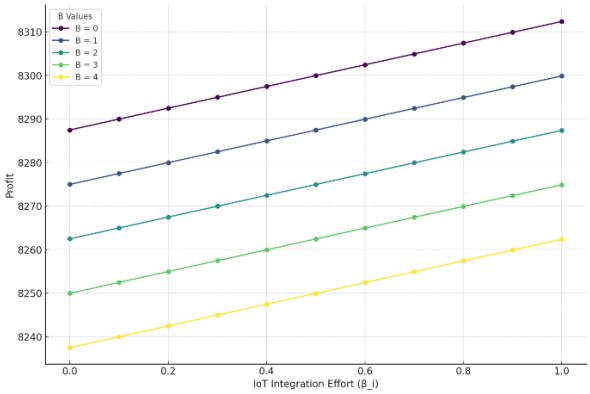

Fig. 2. β_i variation on Firm i 's profit across different B scenarios.

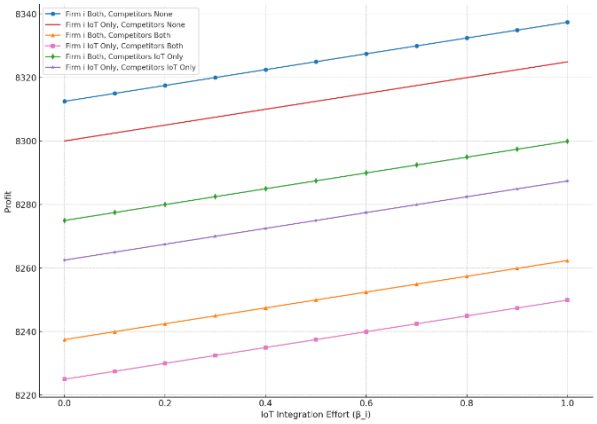

Fig. 3. Profit variation across different implementation scenarios.

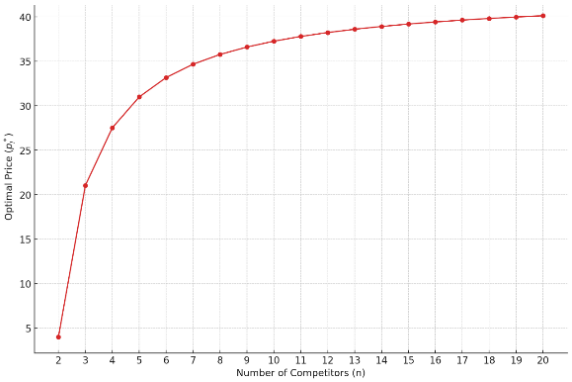

Fig. 4. Optimal price with the variation of the number of firms.

Fig. 3 shows the profit across the different scenarios.

C. Influence of the Number of Competitors on Optimal Price

This analysis aims to examine the impact of the number of firms on the equilibrium price. For this we will proceed with the previously mentioned values with: $B = 2, W = 2, T_i = 0.5, S_i = 0.5$ and the result is showed in Fig. 4.

As the market sees an increase in the number of competitors, the optimal price tends to rise. However, in a more saturated market, the influence of additional competitors on price changes diminishes, with the impact becoming minimal.

D. Sensitivity Analysis

We conducted a sensitivity analysis of the firm i's profit in relation to Market Sensitivity to IoT Integration and sustainability efforts (T_i, S_i) as well as IoT Integration and sustainability effort Cost Factors (λ, θ).

1) Market sensitivity to IoT integration and sustainability efforts: For this analysis we will proceed with the previously mentioned values with minor adjustments $\beta_i = 0.5$, $\sigma_i = 0.5$ $B = 3$, $W = 3$, and the results are presented in Fig. 5.

The profit increases as the sensitivity for the IoT and sustainability increases. This emphasizes the importance of aligning firm's decision with market expectations.

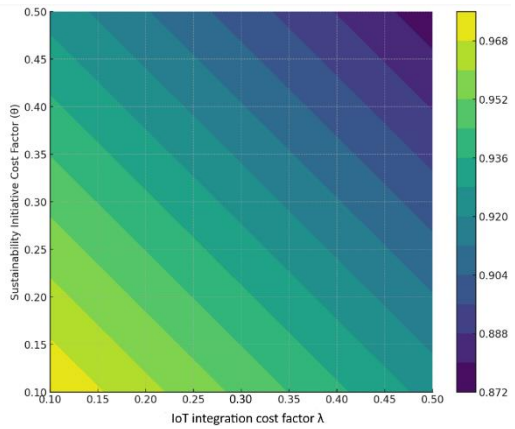

Fig. 5. Market sensitivity to IoT integration and sustainability effort.

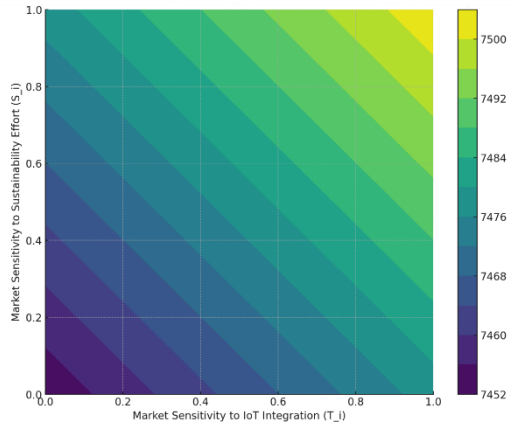

Fig. 6. Market sensitivity to IoT integration and sustainability cost factors.

2) IoT integration effort and sustainability effort cost factors: For the sensitivity analysis of the cost factors, several key parameters have been adjusted to reflect the market conditions and strategic responses more accurately. The self-price sensitivity parameter α has been modified to -0.5. The cross-price sensitivity γ has been lowered to 0.3. To allow for greater pricing flexibility, the total market size a has been increased to 100, G = 300, B =2 W =2. Fig. 6 showcases the results of this sensitivity analysis.

As cost factors rise, profit tend to decrease. Companies must weigh the strategic advantages of these investments against their cost and value to maximize profitability.

VI. Conclusion

In this paper, we explored the impact of integrating the IoT technologies and more sustainable initiatives into the 3PL firm's service on its pricing strategies and profitability. In this research we studied the competition of the 3PL firms in an oligopolistic market setting through price, IoT integration efforts and sustainability effort. The horizontal competition between the firms is modelled as a simultaneous game. We formulate equilibrium strategies for players within this game-theoretic framework and examine the resulting equilibrium outcomes. Our analysis has proved the firm's price increases with the IoT integration and sustainability efforts. Furthermore, our study has showed that the price of the service, the IoT integration and sustainability efforts of the firm increase with the increase of the rivals' IoT integration and sustainability efforts. On the other hand, under certain conditions, the cost of the investments of IoT technology and sustainability initiatives decreases the firm's IoT technology and sustainability efforts. Moreover, we have conducted a comparison between a duopoly setting and an oligopoly market, proving that under certain circumstances, the price, IoT integration and sustainability efforts as well as the firm's profit decreases with the intensity of competition. To achieving a favorable outcome demands careful balance between strategic investments in technology and sustainability, pricing strategies that are aligned with market sensitivity and a keen understanding of the competitive landscape. This study underlines the importance of strategic adaptability and agility for firms to constantly adjust their strategies to keep pace with shifting market trends and competitive pressures.

While this research has provided valuable insights in understanding the impact of IoT integration and sustainability efforts within a 3PL oligopolistic market, it is crucial to recognize its limitations. To simplify complex mathematical calculations, few assumptions have been made. Moreover, to keep out model simple we have considered the sustainability; future research can further develop the model by considering each dimension of the sustainability effort in order to investigate the impact and interrelation of each dimension. Our study focused on a non-cooperative ecosystem, further research can explore how collaborative efforts for integrating IoT technologies within the service as well as sustainable practices within the 3PL firms impact pricing strategies and profitability. Furthermore, the 3PL sector operate in various industries; healthcare, e-commerce food, etc. investigating how digitalization and sustainability efforts in each industry influence their decision-making processes can bring significant insights. Similarly, further research can be conducted taking into consideration digitalization and sustainability trends and regulations differences in the global 3PL market.

Unified Approach for Scalable Task-Oriented Dialogue System

Manisha Thakkar, Nitin Pise
Department of Computer Engineering and Technology, Dr Vishwanath Karad, MIT World Peace University, Pune, India

***Abstract*—Task-oriented dialogue (TOD) systems are currently the subject of extensive research owing to their immense significance in the fields of human-computer interaction and natural language processing. These systems assist users to accomplish certain tasks efficiently. However, most commercial TOD systems rely on handcrafted rules and offer functionalities in a single domain. These systems perform well but are not scalable to adapt multiple domains without manual efforts. Pretrained language models (PLMs) have been popularly applied to enhance these systems via fine-tuning. Recently, large language models (LLMs) have made significant advancements in this field but lack the ability to converse proactively in multiple turns, which is an essential parameter for designing TOD systems. To address these challenges, this paper initially studies the impact of language understanding on the overall performance of a TOD system in a multi-domain environment. Furthermore, to design an efficient TOD system, we propose a unified approach by leveraging LLM with reinforcement learning (RL) based dialogue policy. The experimental results demonstrate that a unified approach using LLM is more promising for scaling the capabilities of TOD systems with prompt adaptive instructions with more user friendly and human-like response generation.**

Keywords*—*Task-oriented dialogue system; unified; adaptive multi-domain; large language models; prompts

I. INTRODUCTION

Creating a dialogue system that has intelligence to converse like a human and assist in task completion is challenging. Depending upon the functional positioning of these systems in practice, are classified into two distinct types, Chit-chat systems also known as Open-domain dialogue systems, and Task-oriented dialogue (TOD) systems. Open-domain dialogue systems are not bound to any specific goal completion, and have flexibility to talk about any arbitrary topic, such as movies, sports, politics, etc. Open-domain dialogue systems are usually trained on large-scale social media data to engage users in human-like casual conversations. For example, ELIZA [1], which is the first open-domain dialogue system that plays the role of therapist; Parry [2], which acts like a psychology patient; and the recent chatbot, Xiaobing from Microsoft, which is a smart and emotionally aware open-domain dialogue system.

On the other hand, TOD systems are closed domain systems and have specific goals to be completed efficiently by assisting users. For instance, for tasks such as booking a flight or a taxi, scheduling an appointment, ordering food, etc., TOD systems are expected to ask questions proactively to accomplish well-defined user goals in minimum dialogue turns. This helps real users perform another important task to increase productivity. In the real world, these systems are utilized in various applications, such as QA systems at help desks to answer basic questions, and as pedagogical agents to assist in learning languages. On a day-to-day basis, users seek help from pretrained TOD systems such as Google Mini, Apple's Siri, Amazon's Echo, etc., to operate smart home devices, play music, and ask general questions to obtain answers [3]. In this study, our main focus was on TOD systems.

Most commercial dialogue systems have excelled in their ability to support singular domain functionalities [4]. To design such systems meticulously, handcrafted rules are used to understand the meaning of the sentence, to track the dialogue state in each turn, and to select the appropriate response. Domain experts participate in updating these rules to support each new task or domain. Each domain has a structured ontology that contains a set of predefined slot-value pairs. Consider an example of a restaurant TOD system that offers basic inquiry and booking related tasks. As shown in Table I, the domain ontology contains predefined slots for basic inquiry and booking tasks. Slot-value information is semantically represented as dialogue acts (DAs), which are updated in each turn during the slot-filling process. Any DA is either an inform act, a request act, or a greet act. Inform acts are used to inform user constraints from user queries to the dialogue system. Request acts are used by dialogue system to obtain additional information from user to fill needed slots, and greet acts are used to greet the user.

As shown in Table I, in basic DAs, primary information about restaurants is requested or informed by utilizing basic slots such as address, postcode, phone no, food type, price range (cheap, moderate, expensive), etc. Mandatory information for booking tasks such as number of people, number of days, and booking reference number are utilized by booking-related DAs.

Traditionally, the pipeline architecture of a TOD system has four components: natural language understanding (NLU), dialogue state tracking (DST), dialogue policy (POL), and natural language generation (NLG), as depicted in Fig. 1.

The NLU is responsible for recognizing user intentions by applying tokenization, and extracting information about domains, intents, slots, and values from user queries. This information is represented as a semantic frame, which is given to DST. This component keeps track of the slot-value pairs by maintaining a belief state in each turn along with the dialogue history. The current DST information is given as input to the

POL, which decides the next appropriate action, i.e., system DA, such as acknowledging user about the task completion or requesting additional information to fill mandatory slots. Finally, the NLG module generates a natural language response according to the system DA [6].

TABLE I. RESTAURANT DOMAIN ONTOLOGY [5]

Dialogue Act-type	basic acts	inform /request/ select/recommend/not found
	booking related acts	request booking info / offer booking/ inform booked / decline booking
	greet acts	welcome /greet / bye / reqmore
Slots	basic slots	address / postcode / phone/ name/ no of choices / area / price range / type / food
	booking slots	no of people / reference no / no of days

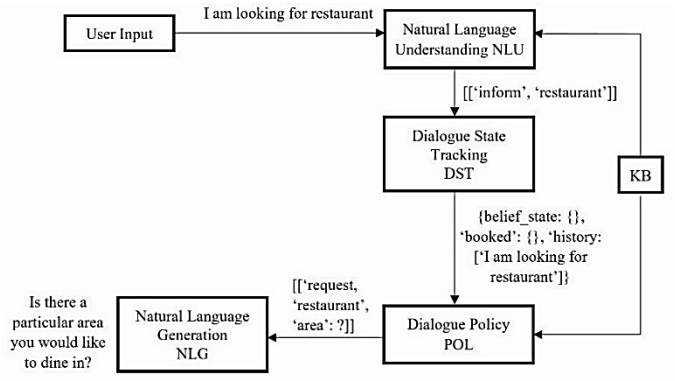

Fig. 1. Pipeline architecture of the TOD system.

To accomplish the intended task while comprehending user goals presents a formidable challenge. Commercial TOD systems are usually designed for specific domains using tools such as Microsoft's Power Virtual Agents (PVA) or Google's Dialog Flow. Consider a complex practical scenario where the user is asking for directions to the movie hall, and later, in the same dialogue session, the user wants to book a taxi to reach the hall. Here, both the navigation and taxi domains have a different set of (slot, value) pairs and actions. Contextual understanding is essential for understanding user intention for effective conversation in such dynamic scenarios. Recent advancements using PLMs and LLMs have made promising achievements in addressing complex real-world problems in natural language processing (NLP). This paper aims to achieve following objectives:

- To study and analyze the impact of language understanding on the overall performance of a TOD system in multi-domain conversation.
- To design a scalable TOD system with state-of-the-art NLU approaches and an RL-based dialogue policy instead of handcrafted rules.
- To enhance the TOD system by utilizing a unified LLM with instruction prompts for the NLU, DST and NLG tasks by boosting the convergence of RL-based dialogue policy with few samples of task demonstrations.

The paper is organized as follows: In Section II, the Literature Survey discusses previous work and recent advancements in the related field. Section III, Designing TOD Systems for multi-domain dialogues, elucidates design approaches for components of the dialogue system pipeline. In Section IV, Experimental Setup, provide details about the dataset, toolkit utilized, system configuration, and results of the experiments. Section V, Evaluation, presents a comprehensive comparison of the performance of dialogue systems designed with various approaches. Discussion is given in Section VI. Finally, Section VII concludes the paper.

II. LITERATURE SURVEY

TOD systems assist users in completing user intended tasks efficiently in a proactive manner. Traditionally, the TOD system components NLU, DST, POL are designed with handcrafted rules and a predefined sequence of words by the designers. Although rule-based systems perform well, scaling such systems is tedious and costly due to the necessity of re-designing rules to support new tasks or domains. Therefore, rule-based TOD systems are usually designed with limited task coverage in a specific domain with predetermined dialogue flow. Additionally, due to template-based response generation, these systems are less engaged with restricted language variability. Repeated or dumb responses are often generated by such systems in case of errors that cause user frustration. Therefore, when these systems are deployed for customer support, users often opt to converse with human agents directly.

Various statistical approaches have been studied to enhance the understanding of dialogue systems. Word presentation techniques such as bag-of-words (BoW), continuous BoW (CBoW), term frequency (TF), inverse document frequency (IDF), n-grams, and word2vec have been utilized to extract the meaning of the given input. The tasks of domain identification, intent detection, and policy selection are often treated as classification problems and slot labeling is treated as a sequence classification problem. Many studies have attempted different machine learning approaches for these tasks. The researchers [7] studied intent classification and slot-value labeling using an support vector machine (SVM) classifier. The researchers [8] studied intent classification by applying different machine learning approaches, including naïve Bayes, and SVM coupled with BoW. However, these approaches using machine learning and static embedding for word representation exhibit the following limitations.

- Curse of Dimensionality: The numeric representation of text results in a sparse matrix, which requires exponentially large amounts of memory, which impacts computational efficiency and model performance.
- Lack of Contextual information: In static embeddings, each word is embedded in isolation. Therefore, understanding the meaning of a word according to its context defined by its own position and that of other words, is not considered, which is crucial for designing NLUs.
- Dependence on the large amount of annotated data: TOD systems designed with traditional machine learning approaches rely on a large amount of annotated

task-specific data to achieve better task performance. Practically, using such data is not feasible.

- Human feedback is not undertaken: Traditional machine learning approaches do not consider human feedback, which is an essential parameter for selecting the next appropriate action in TOD systems. Therefore, such systems are not able to improve their performance from experience.

Due to deep learning (DL) advancements, input word representation has evolved from static embeddings to contextual word embeddings; for instance, pretrained bidirectional encoder representations from transformers (BERT) models consider contextual information in both the left and right directions. Additionally, various deep learning encoder-decoder based architectures, including convolutional neural networks (CNNs), recurrent neural networks (RNNs) and long short term memory (LSTM), have been widely applied to solve various real-world problems in computer vision and conversational systems. [9] proposed a customer-facing dialog system by combining RNNs with domain-specific knowledge. Although RNNs have been widely used in TOD systems due to their ability to handle sequential data [10][11], have the following limitations. RNNs can capture dependencies exclusively in one direction, thereby neglecting the consideration of previous word dependencies while determining the meaning of subsequent words. Also, RNNs suffer from vanishing gradients while handling long-term dependencies, which are later mitigated with the help of gated recurrent units (GRUs) with additional memory units [12]. To this end, bi-directional LSTMs have been widely utilized to handle long- term dependencies in sequential data in many applications such as language translation tasks in NLP [13]. In their study, [14] performed joint classification of domain, intent and slot labeling by using bi-directional LSTM. The researchers [8] studied intent classification using SVM and bi-directional LSTM and found that bi-directional LSTM approach outperformed the traditional machine learning approaches.

Attention mechanisms significantly improved the encoder-decoder architecture [15]. This mechanism computes attention weights, which determine the amount of attention to be given to each word in the input sequence at each step. Transformers [16] are breakthrough advancements that use self-attention mechanisms for dependency modeling. BERT is an encoder-only transformer model, developed by Google AI that considers bi-directional context to predict masked words; thus, BERT has become a preferred choice for NLU tasks. BERT is pretrained on a large corpus from wiki and e-books, which offers generalization capabilities for basic understanding. In practice, the scarcity of human annotated data is one of the reasons for the work, proposed by [17] used BERT to demonstrate the ability of pretrained limited generalizability of these data to the NLU [14].

In their contextual embeddings for few-shot learning scenario. [18], [19] proposed joint training of intent classification and slot filling using an attention mechanism to significantly enhance the performance of dialogue systems. The study [20] demonstrated that BERT-based intent recognition outperforms other deep learning models including LSTM and RNN. The researchers [21] studied dialogue state tracking by applying BERT instead of using rule-based DST. Later, in these advancements, generative pretrained transformer (GPT)-based autoregressive decoder-only models, due to their ability to generate diverse responses, have received increased amounts of attention. The study [22] utilized GPT-2 for various TOD tasks, which resulted in more engaging and human-like responses. GPT-based models are popularly utilized for enhancing TOD tasks specifically response generation in NLGs [20], [23]. Until recently, PLMs with contextual embedding have been used as a starting point and subsequently fine-tuned for downstream tasks.

Recently, there has been a paradigm-shift from traditional model fine-tuning to prompt-tuning by efficiently utilizing a unified framework. In prompt-tuning, the network weights of the LLMs are frozen and a few task-specific demonstrations along with task prompts, are utilized to generalize with ease in few-shot settings. In their work, [24] used task-specific instruction prompts and approached various text processing tasks, such as sentiment analysis, question-answer generation, classification, etc., as text generation problems and referred to their model text-to-text transfer transformer (T5). Instruction based tuning of LLMs is gaining attention due to their improved communication capabilities achieved by providing hints to these LLMs about tasks [25]. LLMs have revolutionized dialogue with enhanced productivity across various industry domains. However, these models lack proactive communication, which is an essential parameter for handling multi-turn dialogue.

Selecting the next action in a dialogue flow to achieve the user goal in minimum dialogue turns is essential for evaluating the POL of a TOD system. Although rule-based policies perform well with fixed dialogue flow are not scalable for adapting to changes in the user goals. In real-world scenarios, the user is often uncertain about their goals at first place and wants to explore all available options. Additionally, dialogue POL should have the ability to learn new knowledge even after deployment. To design such scalable dialogue policies, researchers have studied the optimal action selection problem as a sequence of decision-making problems. In various studies, POL is implemented as a partially observable Markov decision process (POMDP) [26], by designing an RL-based dialogue agent to select the next action from the current dialogue state [27]. Such RL-based dialogue agents aim to maximize cumulative rewards by considering human feedback. These agents require more training cycles to learn from trial-and-error in a user-agent setting. Therefore, instead of real users, user simulators are used to train specifically in the initial stage of learning [28].

As PLMs and LLMs are large sized with huge number of parameters, should be efficiently used in TOD systems. This proposed work employs BERT contextual embedding for NLU and studies its impact on the overall performance of a TOD system. To achieve this goal, three distinct systems are configured using BERT, an SVM classifier and an RNN-based approaches for NLU and assessed their effectiveness. In further experiments, the rule-based POL is replaced with RL-based

POL and lastly, a unified approach using T5, and Llamma-2 is leveraged for the NLU, DST and NLG tasks.

III. Designing TOD System in Multi-domain Setting

In a diverse multi-domain environment, conversations include multiple tasks from different domains. The multi-domain ontology as shown in Eq. (1) has a set of slot-value pairs that are already defined in the respective domains to provide different functionalities.

$$(Multi\text{-}domain)\ MD_{ontology} = \{\ domain_1: \begin{bmatrix} (slot_1,\ value_1), \\ (slot_2,\ value_2), \\ \vdots \\ (slot_i,\ value_i) \end{bmatrix}$$

$$domain_2: \begin{bmatrix} (slot_1,\ value_1), \\ (slot_2,\ value_2), \\ \vdots \\ (slot_i,\ value_i) \end{bmatrix},$$

$$\vdots$$

$$domain_i: [(slot_i,\ value_i)],\ \}\qquad (1)$$

The dialogues between the user and dialogue agent are either single-turn or multi-turn. The user utterance is represented as $User_u$ and the system utterance is represented as $System_u$. Therefore, a multi-turn conversation is shown as Eq. (2),

$$(Multi\text{-}domain,\ multi\text{-}turn)\ MDMT_{Dialogue} = \left\{dialogue_i : domain_i: turn_i \left\{User_{u\ i},\ System_{u\ i}\right\}\right\} \qquad (2)$$

The pipeline of NLU, DST, POL, and NLG process these dialogues by performing tokenization, extracting the semantic meaning, accessing database information, and generating responses. All these components can be trained and optimized separately using different approaches or by adopting an end-to-end (E2E) approach. In the E2E approach, two or more TOD components are combined for training and optimization using deep learning models. The following subsections describe the design of these components.

A. Natural Language Understanding (NLU)

The NLU identifies user intent from the input user query. BERT, a pretrained contextual embedding model, trained on two default training objectives, Masked Language Modeling (MLM) and Next Sentence Prediction (NSP) tasks, is integrated into the NLU. In MLM, initially input tokens are randomly masked, and the model predicts the vocabulary ID of the masked tokens based on both left and right contexts. The input representation in BERT is the concatenation of word embeddings, position embeddings and segment embeddings. The first token of every sequence is a special classification token [CLS], which is pivotal for classifying intent. Another special token [SEP] is the last token in each sequence that separates two sentences. As shown in Fig. 2, intent recognition is approached as a classification problem to predict the intent class y^i. On the other hand, slot-filling is considered as a sequence labeling task to tag the input word sequence, $X = \{ x_1, x_2, x_3, \cdots x_n \}$ with the slot label sequence given as $y_n^s = \{y_1^s, y_2^s, y_3^s, \cdots y_n^s\}$. The NLU represents this information in a semantic frame called dialogue act (DA).

Given the input token sequence as X,

$$X = \{ x_1, x_2, x_3, \cdots x_n \}$$

The output of BERT is H

$$H = \{ h_1, h_2, h_3, \cdots h_n \}$$

Based on the hidden state (h_1), Weights (W) and Bias (b) of the classification token [CLS], intent can be predicted as,

$$y^i = softmax\left(W^i h_1 + b^i\right) \qquad (3)$$

The remaining hidden states from $h_2, h_3, \cdots h_n$ are used for slot filling as shown in Eq. (4). Each tokenized input word is given to the tokenizer, and the hidden state of the first token is fed to the softmax layer for classification. The slot filling prediction function is represented as,

$$y_n^s = softmax(W^s h_n + b^s)\ where\ n \in 1 \cdots N \qquad (4)$$

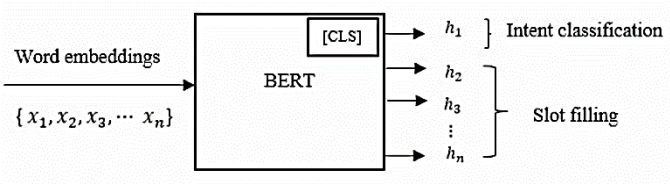

Fig. 2. BERT for generalization in the NLU.

The objective function for joint training of intent classification and slot filling is given as,

$$P\left(y^i, y_n^s \mid X\right) = P\left(y^i \mid X\right) \prod_{n=1}^{N} P\left(y_n^s \mid X\right) \qquad (5)$$

The objective is to maximize the conditional probability $P\left(y^i, y_n^s \mid X\right)$ by minimizing the cross-entropy loss. In the case of slots with binary values such as Yes/No binary cross- entropy loss is used.

B. Dialogue State Tracking (DST)

DST utilizes information from NLU in a semantic frame known as dialogue acts (DAs) and maintains the belief state along with dialogue history. DST, which updates the belief state (intent, domain, slot, value) in each turn, is widely addressed as a classification task. The objective function for DST is to minimize the cross-entropy loss for both slot and slot value predictions. DST contains information about the constraints of the user, database search results, current user DAs, and previous system DAs. The following example demonstrates belief state updates at each turn in a multi-turn conversation. In proposed work, initially rule-based DST is used and subsequently the DST is approached as a text generation problem by employing the T5 model.

Turn 1 User: Can you find me a restaurant in the east?
belief state $_{t1}$= ["Inform", "restaurant", "**Location** ", "**east**"]

Turn 2 System: Sure, what type of cuisine are you looking for?
belief state $_{t2}$= ["Inform": "restaurant", "Location": "east", "**Cuisine**":"?"]

Turn 3 User: I would like to have Indian food.
belief state $_{t3}$= ["Inform": "restaurant", "Location": "east", "**Cuisine**": "**Indian**"]

C. Dialogue Policy (POL)

The objective of dialogue policy is to accurately predict the next action by using the current dialogue state and generating system DAs in each turn with corresponding slot-value pairs.

In rule-based policy, the entire dialogue flow is hand coded whereas in RL-based dialogue policy, the training occurs in an agent-environment setting, which considers user feedback in terms of rewards. The RL-based dialogue agent aims to maximize the cumulative reward and improve from the experience. As these agents learn using trial and error, thousands of interactions are required for stabilization. Therefore, to train RL-based agents, user simulators that mimic real users are often required to interact before actual deployment for real users (Shi et al., 2019). In an agenda-based user simulator, the user goal is decomposed into slot-value pairs, whereas the agenda is maintained in a stack-like structure (Schatzmann et al., 2007). At a finite time-step T, the dialogue policy π is trained to maximize the cumulative reward in each turn. The cumulative reward as shown in Eq. (6) is assigned to an agent after dialogue completion. The optimal policy $\pi^*$is obtained using either value-based or policy-based methods. In our experiment, both rule-based and RL-based approaches are used to model dialogue policy.

$$R_t^{\pi} = \sum_{i=0}^{T-t-1} \gamma^t \, r_{t+i+1} \quad (6)$$

D. Natural Language Generation (NLG)

Once the policy determines system DA, the NLG task occurs in the following two steps: content planning followed by sentence realization. The content planning emphasizes 'what to say', and sentence realization focuses on 'how to say in the correct manner'. The sentence realization is achieved using a de-lexicalization process in which system DAs are mapped to de-lexicalized sentences. This approach allows generation of dynamic sentences in different scenarios without hard-coded values.

In NLG, this template-based approach is commonly used to select the most appropriate template from the candidate set of already designed templates for response generation, are less engaging with limited language variability [29]. In proposed work a template-based NLG is initially used, and further text generation approach is used by employing T5 and LLM models.

E. Unified Approach for TOD System Pipeline using an LLM

Recently, all text processing problems have been approached as text generation problems. T5, and Llama2-chat-hf models from Hugging Face library, are used as unified frameworks for the NLU, DST and NLG tasks, as depicted in Fig. 3. Llama 2 chat is fine-tuned and optimized LLM for dialogue handling [30].

In prompt-tuning, only a small number of parameters are required to optimize the prompt that adapts an LLM to customized tasks or domains with frozen weight by preserving the general language understanding ability of LLM. To utilize the power of LLMs, instruction prompts are used to adapt NLU, DST, and NLG tasks in the TOD system.

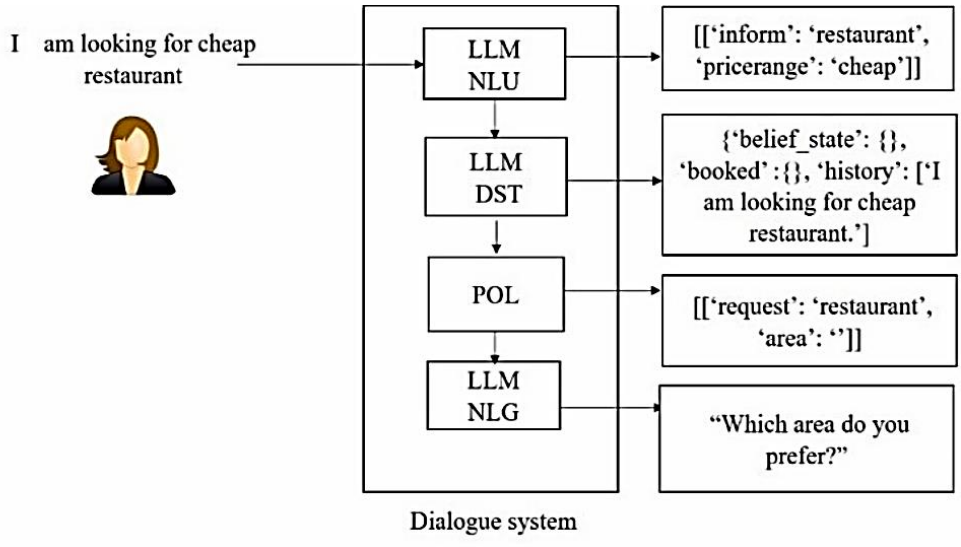

Fig. 3. Unified approach for the TOD system pipeline.

IV. Experimental Setup

Proposed work is focused on attaining scalability to support multiple domain conversation. To fulfill this essential requirement, a multi-domain, multi-turn human-to-human conversation dataset is selected after a survey [30] for designing a scalable TOD system. This section provides details about the utilized dataset, tools, system-configuration, and experimental results.

A. Dataset

A benchmark dataset MultiWOZ 2.1 is used for our research experiments. MultiWOZ 2.1 is a large dataset containing annotations for dialogue states, system dialogue acts, and user goals for training and evaluating dialogue systems in the context of tourist-related conversations. The MultiWOZ dataset consists of approximately 30 (domain, slot) pairs, encompassing over 45,000 values. The dataset has a size of 10,000 instances and covers various domains including Hotel, Hospital, Train, Taxi, Police, Postcode, and Restaurant [5].

MultiWOZ 2.1 contains more than 3,400 single-domain dialogues, and 7,032 multi-domain dialogues spanning across at least 2 to 5 domains. Most of the dialogues contain 10 turns on an average to meet the complexity of real-world scenarios.

B. Tools

Many tools have been implemented and integrated into an IDE for building dialogue systems. Often, these tools incorporate a rule-based dialogue manager (DM) with a built-in NLU component having a rigid structure. PyDial, ParlAI, Plato, Rasa, DeepPavlov, and ConvLab are examples of open-source tools with neural network-based dialogue managers that offer more flexibility and scalability. Convlab-3 [31] offers a range of state-of-the-art models for various TOD components and user simulators. In our study, Convlab-3 is used for experiment setup.

C. System Configuration

In the first experiment, distinct system agents are configured, each employing a different NLU approach. This allowed us to investigate the influence of the NLU on the overall performance of the dialogue system. All our experiments are performed using NVIDIA Tesla P100 GPU using the Google Colab platform with subscription.

An agenda-based user simulator is utilized for modeling a user agent, which is integrated with the BERT-base uncased model for NLU to evaluate the performance of system agents. The BERT-base uncased model utilizes a self-attention transformer-based encoder with 12 layers and 12 attention heads with a hidden size of 768 and a total of 110 M parameters.

Our experiment comprises five dialogue systems named SA1, SA2, SA3, SA4, and SA5. Each system has a rule-based DST and a template-based NLG. SA1, SA2, and SA3 have rule-based POL, whereas SA4 and SA5 have RL-based POL.

To understand the impact of NLU on the overall performance of dialogue system, different models for NLU. In SA1, BERT-base uncased model is used for joint training of intent classification and slot filling, whereas in SA2, utilizes the RNN-based joint neural model called Multi-Intent Language Understanding (MILU) for joint prediction of domain, intent, slot, and value. SA3 uses an SVM (support vector machine) classifier in the NLU [32] which is designed to manage complex semantic tuples (intent-slot-value) and classify them based on n-gram features. The listing of example code is referred from [32] for experiment setup as shown in Listing 1 . Similarly, in an extended experiment SA4 and SA5 TOD systems are designed by utilizing BERT and T5 for NLU tasks respectively with RL-based POL by referring to Listing 2 from [33].

In the second experiment, a unified approach is proposed to design a TOD system using T5 model. The NLU, DST and NLG are modeled using T5 with an RL-based dialogue policy. Further, this experiment is extended by utilizing the LLM from Huggingface library, meta-llama/Llama-2-13b-chat-hf with instruction prompts. Here, two LLM based systems are used to play the roles of ‘user’ and ‘system’. The off-policy algorithm VTRACE [34] from checkpoint is utilized to model RL-based POL in both experiments.

```
# import necessary modules
# Create models for each component
# Parameters are omitted for simplicity
sys_nlu = BERTNLU(...)
sys_dst = RuleDST(...)
sys_policy = RulePolicy(...)
sys_nlg = TemplateNLG(...)
# Assemble a pipeline system named "sys"
sys_agent = PipelineAgent (sys_nlu, sys_dst, sys_policy, sys_nlg, name="sys")
# Build a user simulator similarly but without DST user_nlu = BERTNLU(...)
user_policy = RulePolicy(...)
user_nlg = TemplateNLG(...)
user_agent = PipelineAgent(user_nlu, None, user_policy, user_nlg, name="user")
# Create an evaluator and a conversation environment
evaluator = MultiWozEvaluator()
sess = BiSession(sys_agent, user_agent, evaluator)
 # Start simulation sess.init_session()
sys_utt = ""
while True:
sys_utt, user_utt, sess_over, reward = sess. next_turn ( sys_utt)
if sess_over:
      break
print(sess.evaluator.task_success()) print(sess.evaluator.inform_F1())
# Use the analysis tool to generate a test report
analyzer = Analyzer(user_agent, dataset="MultiWOZ")
analyzer.comprehensive_analyze(sys_agent, total_dialog =1000)
# Compare multiple systems
sys_agent2 = PipelineAgent(MILU(...), sys_dst, sys_policy, sys_nlg, name="sys") analyzer.compare_models(agent_list=[sys_agent, sys_agent2], model_name=["bertnlu", "milu"], total_dialog=1000)
```

Listing 1. Example code from [32]

D. Results

Table II demonstrates the performance of each NLU for different multi-domain user queries. Table II highlights the domain and slot-value information for each query. BERT NLU outperforms the other two methods by demonstrating excellent performance in understanding long queries.

TABLE II. OUTPUT OF NLU IN DIALOGUE SYSTEMS USING BERT, SVM AND MILU APPROACHES

Query	Conversation	BERT NLU (SA1)	MILU (SA2)	SVM NLU (SA3)
1	I am looking for cheap food	[['Inform', 'Restaurant', 'Price', 'cheap']]	[['Inform', 'Restaurant', 'Price', 'cheap']]	[['Inform', 'Restaurant', 'Price', 'cheap']]
2	Can you suggest me Indian restaurants in westzone	[['Inform', 'Restaurant', 'Food', 'Indian'], ['Inform', 'Restaurant', 'Area', 'west zone']]	[['Inform', 'Restaurant', 'Food', 'Indian']]	[['Inform', 'Restaurant', 'Food', 'Indian']]
3	Give me address police station and contact details	[['Request', 'Police', 'Addr', '?'], ['Request', 'Restaurant', 'Addr', '?']]	[['Inform', 'Police', 'none', 'none']]	[['bye', 'general', 'none', 'none']]
4	I want to reach London kings cross by train TR1111	[['Inform', 'Train', 'Dest', 'London kings cross'], ['Inform', 'Train', 'Id', 'TR1111']]	[['Inform', 'Train', 'Dest', 'London kings cross']]	[['Inform', 'Train', 'Dest', 'London kings cross']]

Also check for free Wi-Fi	[['Inform', 'Hotel', 'Parking', 'yes'], ['Inform', 'Hotel', 'Internet', 'yes'], ['Inform', 'Restaurant', 'Food', 'Indian'], ['Inform', 'Restaurant', 'Area', 'westzone']]	[['Inform', 'Restaurant', 'Food', 'Indian'], ['Inform', 'Hotel', 'Parking', 'yes'], ['Inform', 'Hotel', 'Internet', 'yes']]	[['Inform', 'Hotel', 'Internet', 'yes']]

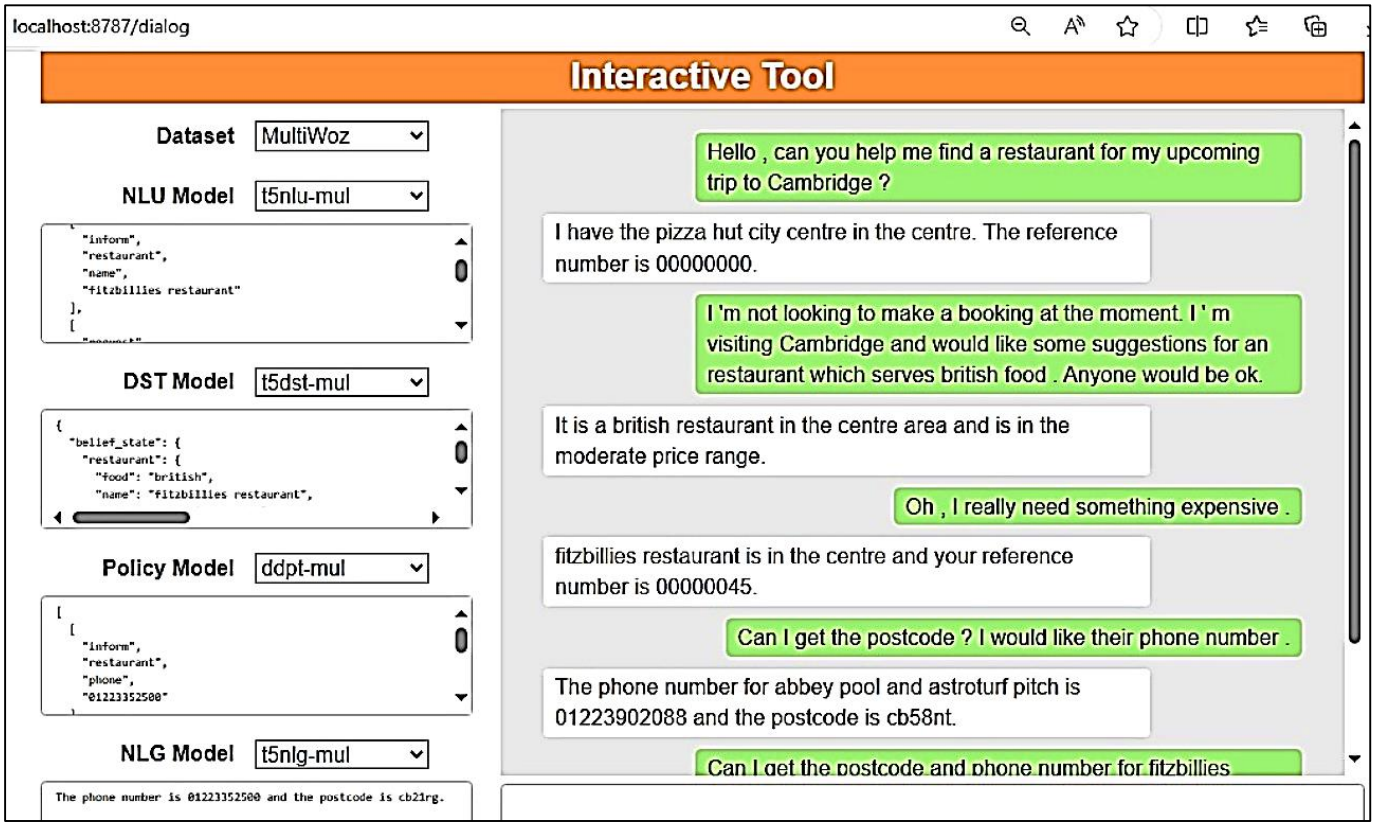

Fig. 4. Unified approach for modeling TOD tasks NLU, DST and NLG using T5.

In the second experiment, a unified approach with T5-small is used which was fine-tuned for both user and system utterances on the MutliWOZ2.1 dataset from the hugging face library. In this configuration, an RL-based policy is used for designing the TOD system. This encoder-decoder model completes NLU, DST and NLG tasks by approaching these tasks as text generation problems. The interaction between the system agent and real user is shown in Fig. 4. Further, the T5 model is replaced with the open-source Llama-2 model by utilizing task-specific instruction prompts to adapt the NLU, DST, and NLG tasks with sample demonstrations. Role-based instruction prompts are used in the meta-llama/Llama-2-13b-chat-hf model to define two roles, a system agent, and a user simulator to generate proactive multi-turn dialogues. The multi-turn interaction between the system agent and user simulator is shown in Table III. Domain information is highlighted for understanding.

TABLE III. UNIFIED APPROACH FOR MODELING TOD TASKS NLU, DST AND NLG USING LLAMA-2 13B-CHAT-HF

User	Assistant
	Hello, I am helpful assistant. How may I help you?
Hello! I am looking for a train from Norwich to Cambridge on Wednesday after 18:45. Can you help me find one and make a booking for one person? Also, Do you know of any places in Cambridge that offer multiple sports? Could you provide the phone number and postcode?	
	Hi there! I'd be happy to help. For a train from Norwich to Cambridge on Wednesday after 18:45, you can take the Greater Anglia train departing at 19.05 from Norwich railway station. To book, you can visit the Greater Anglia website or call their customer service at 0345 600 7245. As for sports facilities in Cambridge, the University of Cambridge Sports Centre offers a range of sports and can be reached at 01223336666 (postcode CB2 1RR)
Thank you so much! I've found the train I need and I'm going to book it now. Can you please provide me with reference number or the booking confirmation so I can have it handy? And thank you for the information on sports facilities in Cambridge, I'll definitely look into that [END]	
	Sure thing! Your train booking reference number is GA-123456. Please have this ready when you contact Greater Anglia to confirm your reservation. If you need any further assistance, feel free to ask. Enjoy your trip to Cambridge!

V. EVALUATION OF TOD SYSTEMS

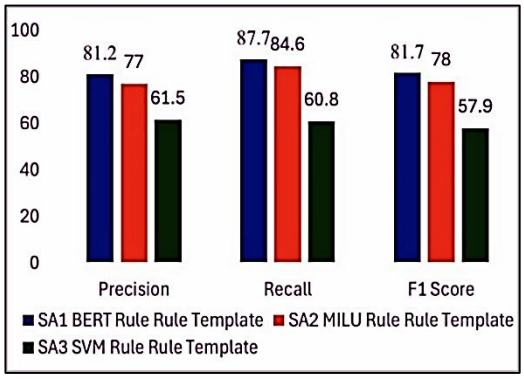
To measure the overall correctness of the search tasks in the inform act, such as domain, intent classification, and slot-filing, Precision, Recall and F1-score are used. Book rate (BR) measures the accuracy of the system for fulfilling booking requests and generating reference numbers. The success rate (SR) measures the successful completion of user goals in all required domains [35]. A user goal is considered successful when both the book rate and the recall of the informed act are 1. The average number of dialogue turns required for task completion impacts user satisfaction. The widely adopted evaluation matrices for TOD system are facilitated in convlab toolkit.

As depicted in Table IV, the SA1 system with the BERT NLU outperforms other rule-based system configurations. However, for the RL-based dialogue policy, the SA5 system with the T5 NLU outperforms the BERT-based system configuration. Compared to the other configurations, SA5 has the maximum completion rate.

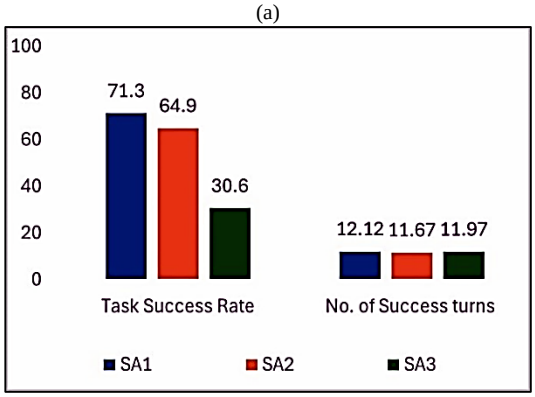
Fig. 5(a) depicts the NLU performance for the SA1, SA2 and SA3 dialogue systems and demonstrates that the BERT-based NLU has better precision, recall and F1-score than the MILU and SVM-based NLU. However, as depicted in Fig. 5(b), the BERT-based system resulted in an improved task success rate, with a slight increase in the average number of turns to achieve success compared to that of SA2 and SA3. SA1 is still taking longer to complete the task. As the NLU component is enhanced with state-of-the-art models including BERT and T5, for the next experiment rule-based dialogue policy is replaced with RL-based policy to adapt dynamic dialogue flow to converse in multi-domain setting.

TABLE IV. AUTOMATIC EVALUATION OF TOD SYSTEMS USING AN AGENDA-BASED USER SIMULATOR

System ID	System Configuration				Inform			Complete Rate	Task Success Rate	Book Rate BR	Average No. of Success turns/Average turns
	NLU	**DST**	**POL**	**NLG**	**P**	**R**	**F1**				
SA1	**BERT**	Rule	**Rule**	Template	**81.2**	**87.7**	**81.7**	**78.9**	**71.3**	**88.4**	12.12/16.51
SA2	MILU				77	84.6	78	73.7	64.9	83.3	**11.67/16.56**
SA3	SVM				61.5	60.8	57.9	44.4	30.6	51.4	11.97/16.59
SA4	BERT	Rule	**RL based POL**	Template	64.2	86	70	71	30	62.2	**17.06/25.16**
SA5	**T5**				64	**93.7**	**72.8**	**85**	**53**	**84.3**	21.05/25.32



(a)



(b)

Fig. 5. (a) NLU performance in SA1, SA2 and SA3 (b) task success rate and average success turns in SA1, SA2 , and SA3.

As depicted in Fig. 6(a), the T5-based NLU outperforms the BERT-based NLU, whereas Fig. 6(b) indicates that SA5 has an improved task success rate at the cost of an increased number of average success turns, indicating slow convergence compared to that of SA4.

(b)

Fig. 6. (a) NLU performance in SA4 and SA5 (b) task success rate and average success turns in SA4, and SA5.

VI. Discussion

In real-world scenarios, designing a proactive, multi-turn dialogue system to understand and satisfy user goals in minimum dialogue turns is a complex task. Additional complexity is introduced when the user goal contains tasks from multiple domains. This led us to analyze the impact of different NLUs on the performance of the TOD system. Transformer based approaches outperformed traditional machine learning algorithms including SVM[8] and RNN[11], followed by additional experiments with RL-based policies instead of using rule-based policies to avoid handcrafted rules. BERT- based NLU with the rule-based policy demonstrated improved performance with a slight increase in the average number of successful dialogue turns. Furthermore, the transformer-based models including BERT and T5 are used for the NLU with the RL-based policy. The T5 NLU with the RL-based policy resulted in significant improvements in the recall, F1-score, complete rate, and book rate with an increase in the average number of successful dialogue turns. This indicates limited improvement in fast convergence of task completion. Therefore, although NLU performance is boosted, RL-based POL requires investigation for improvement in task performance through warm-up and task-specific pretraining to achieve the task in minimum dialogue turns.

Additional experiments are performed to improve TOD system performance by using a unified approach instead of improving the performance of individual components. This has a major obstacle to the availability of annotated task-specific data for pretraining. Until recently, fine-tuning PLMs achieved promising performance on TOD tasks. However, an entire PLM model with many parameters is required for gradient updating to adapt to each downstream task; for instance, the large number of BERT-base-uncased NLUs is 110M. Domain-specific pretraining is required to achieve better performance because the PLMs are trained on general purpose data.

Our experiments found that even after improving the performance of a single component, the overall performance improvement in TOD systems is not guaranteed. On the other hand, a unified approach using a single PLM or LLM with shared parameters across all tasks is more preferred approach. To adapt to a new task or domain, prompt-enabled models such as T5 and Llama-2 are more efficient as only a small number of parameters are updated in prompt tuning with just a few demonstrations. On the other hand, benchmark TOD systems designed using fine-tuning approach such as UBAR, GALAXY, MinTL needs to load entire PLMs such as GPT-2(1.5B), UniLM (340M), BART-large (440M) respectively to update large number of parameters to adapt each new task or domain [35].

The responses generated in the LLM model Llama-2 have human-like language variability, which demonstrates its ability to design more user-friendly TOD systems in the future. Other LLMs, such as GPT3.5 and GPT-4, have provided many scalability and multimodality features, but these models are accessible only with paid subscriptions.

VII. Conclusion and Future Work

Understanding user intentions from natural language text in a dynamic environment remains an inherently challenging task. Various existing TOD systems contain rule-based components designed to function in single domain and offer limited tasks to users. To design scalable TOD system for conversation which includes multiple domains with different tasks to offer is challenging. In line to our first objective to study the impact of NLU, we have configured SVM, RNN and state-of-the pretrained language models such as BERT and T5 instead of using handcrafted (rule-based) NLU to understand user intention in multi-domain tourist conversation environment. We found that configuring BERT and T5 in NLU enhances the performance of an individual component but does not guarantee an overall performance improvement in TOD system.

In further step, we extended our experiment with best performing NLUs (BERT, T5) in a pipeline TOD and replaced the rule-based designing dialogue policy with more scalable approach by employing reinforcement learning (RL) algorithm to adapt in multi-domain conversation. We found that handing large state-action spaces requires large commuting power, and training RL-based dialogue policy in such a large dynamic environment takes many training cycles by the dialogue agent to learn from scratch. As the agent gains experience using trial and error method, establishing a stable dialogue policy is time-consuming. Also, to train these RL-based agents a reliable user simulator is required with added design efforts. In our experiments, we utilized already existing agenda-based user simulator for automatic evaluation of TOD systems provided in the toolkit. We achieved very less task success rate which indicates, further investigation is needed to boost or warm-up the performance of dialogue policy using methods such as task-specific pretraining, fine-tuning, inverse reinforcement learning (IRL), and imitation learning (IL) approaches.

Recently, unified approach is utilized popularly by employing large language models to perform all TOD tasks but fine-tuning these models is costly. Instead of fine-tuning language models for each individual task recent trend encourages to utilize prompt-enabled large language models. In this paper, soft prompts are generated using system instructions to achieve proactive multi-turn dialogues by assigning different roles to LLMs, such as assistant and system agents. The proposed approach is adaptive and generates more human-like responses compared to other systems, paving the way for scalable and user-friendly dialogue systems.

Day Trading Strategy Based on Transformer Model, Technical Indicators and Multiresolution Analysis

Salahadin A. Mohammed

Information and Computer Science Department,
King Fahd University of Petroleum and Minerals, Dhahran 31261, Saudi Arabia

***Abstract*—Stock prices are very volatile because they are affected by infinite number of factors, such as economical, social, political, and human behavior. This makes finding consistently profitable day trading strategy extremely challenging and that is why an overwhelming majority of stock traders loose money over time. Professional day traders, who are very few in number, have a trading strategy that can exploit this price volatility to consistently earn profit from the market. This study proposes a consistently profitable day trading strategy based on price volatility, transformer model, time2vec, technical indicators, and multiresolution analysis. The proposed trading strategy has eight trading systems, each with a different profit-target based on the risk taken per trade. This study shows that the proposed trading strategy results in consistent profits when the profit-target is 1.5 to 3.5 times the risk taken per trade. If the profit-target is not in that range, then it may result in a loss. The proposed trading strategy was compared with the buy-and-hold strategy and it showed consistent profits with all the stocks whereas the buy-and-hold strategy was inconsistent and resulted in losses in half the stocks. Also three of the consistently profitable trading systems showed significantly higher average profits and expectancy than the buy-and-hold trading strategy.**

Keywords*—Artificial neural network; saudi stock exchange; machine learning; deep learning; transformer model; stock price prediction; time series analysis; technical analysis; multiresolution analysis

I. Introduction

In the context of this study, day trading is a business of buying a number of shares on a trading day and selling them all before the end of the same trading day for a profit or a loss. Day trading is a business of probability. When a consistently profitable day trader enters a trade, he is not sure whether the trade will be a winner or a loser, but he is sure that after he does many trades, he will end up profitable. For example, the 2023 US investment champion's win rate was less than 35% but he ended the year with more than 805% profit [1], [2]. This is because he has a trading system with a positive expectancy. Expectancy, Φ, is defined as show by Eq. (1).

$$\Phi = AW \times WR - AL \times (1 - WR) \tag{1}$$

where, AW is average win, AL is average loss, and WR is win rate. For example, if a trader did a total of 1000 trades and 400 of them were winners, his WR is 0.4. If his average win is 500 dollars and his average loss is 200 dollars, then his Φ is $80 = 0.4 \times 500 - 0.6 \times 200$. This means he expects to gain 80 dollars per trade.

To increase their winning rates many professional day traders use technical indicators. Recently, systematic trading using deep learning has emerged as a powerful tool for predicting future stock prices [3]–[5]. In this study, a day trading strategy with a positive expectancy is proposed. To increase the win rate, the proposed trading strategy uses not only technical indicators (TIs) but also transformer neural network (TNN) and multiresolution analysis (MRA).

MRA was included in the proposed solution because many researchers reported that they got better performance when they combined MRA with their predictive model. For example, MRA resulted in better model performance when combined with each of ARIMA [6], descriptive statistical modeling [7], ANN [8], [9], RNN [10], CNN [11], GRU [12], LSTM [13], and stacked autoencoders [14].

TIs were also found to improve model performance by many researchers [5]. The problem is, there are more than 100 technical indicators and each technical indicator (TI) may have a number of parameters. Choosing the wrong combination of TIs or assigning a TI a wrong parameter value can degrade performance. So in this study, a systematic way of choosing TIs and their parameter values is presented.

There are many possible deep learning architectures. Choosing the wrong architecture can result in poor performance. For the proposed day trading strategy, several deep learning architectures were compared and the one that outperformed all of them was selected. The proposed deep learning model takes as input a dataset which consists of nine features, such as prices, volume, indices, and TIs. Some of these features are decomposed using empirical wavelet transform (EWT) before they are fed to the model. The model predicts the highest and the lowest stock prices of a given trading day. The proposed day trading strategy is based on these two predicted prices and will be explained in Section V-G. The proposed day trading strategy consists of eight trading systems; and unlike many of the existing systems, they were tested in different market conditions using ten randomly picked stocks listed in the Saudi stock market. They were compared with the buy-and-hold trading strategy and the experimental results show that five of the proposed systems showed positive expectancy consistently with all the ten stocks whereas the buy-and-hold strategy was inconsistent and resulted in losses in half of the stocks.

The main contributions of this work are:

1) A day trading strategy which combines TNN, TI, EWT MRA, and time2vec [15]. To the best of our

knowledge, this is the first study to do so.
2) The first consistently profitable day trading strategy which uses TNN for Saudi stock market.
3) A trading strategy based on a systematic way of choosing and combining TIs and their parameter values.
4) A study which presents the impact of profit-target on profitability.

The remainder of this paper is organized as follows. Section II gives background information relevant to the proposed solution. Section III presents related work. The proposed framework is explained in Section IV. Section V discusses the results and analysis of the proposed methodology, and Section VI is the conclusion.

II. Background

This section gives brief background information on some topics used in this study. The covered topics include deep learning models and wavelet transform.

A. Deep Learning

Deep learning is a subfield of machine learning based on deep neural networks (DNN). A DNN is essentially an artificial neural network (ANN) with more than three layers. These multiple layers give a DNN massive computing power and enables it to train on huge amounts of data with little human intervention, which makes it different from the other classical machine learning algorithms. Each DNN layer extracts certain information from the data and redirects the learned information to the next layer to perform another type of information extraction. This hierarchy of information extraction enables DNNs to perform better forecasting than the other classical machine learning algorithms. There are several DNN models but the most popular DNN models for time series data are, Recurrent Neural Network, Long Short-Term Memory, Gated Recurrent Unit, and transformers.

1) Recurrent neural network: A recurrent neural network (RNN) is a special type of ANN. However, unlike the standard feed-forward ANN, RNN networks have feedback connections which enables output from a previous step to be fed as input to the current step [16], [17]. RNNs also have the concept of memory that enables them to store limited information extracted from previous inputs which are then used to generate subsequent output. Having memory and feedback loop makes RNNs very popular for sequence data, such as time series, where one data point depends on previous data points.

2) Long Short-Term Memory (LSTM): Long short-term memory (LSTM) is a variant of RNN. It was proposed by Hochreiter and Schmidhuber [18] to resolve the vanishing and exploding gradient problems observed in the simple RNN, enabling it to capture longer-term dependencies.

LSTM architecture consists of a sequence of neurons and memory blocks known as cells, Fig. 1. The sequence of neurons form three gates, namely input gate, forget gate, and output gate. It uses these gates to control the flow of information to and from its neurons and to select the information it needs to discard or keep in its memory cells. The equations

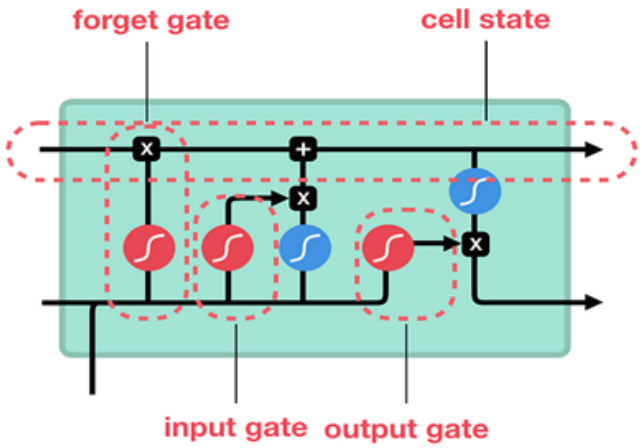

Fig. 1. LSTM architecture [19].

that are computed by the different neurons inside LSTM are as follows [20]:

$$i_t = \sigma(W_i x_t + U_i h_{t-1} + V_i c_{t-1}) \quad (2)$$
$$f_t = \sigma(W_f x_t + U_f h_{t-1} + V_f c_{t-1}) \quad (3)$$
$$o_t = \sigma(W_o x_t + U_o h_{t-1} + V_o c_t) \quad (4)$$
$$\tilde{c_t} = \tanh(W_c x_t + U_c h_{t-1}) \quad (5)$$
$$c_t = f_t^i \odot c_{t-1} + i_t \odot \tilde{c_t} \quad (6)$$
$$h_t = o_t \odot \tanh(c_t) \quad (7)$$

where, i_t, o_t, f_t and c_t denote the input-gate, the output-gate, the forget-gate, and the memory cells respectively. h_t represents a hidden state.

3) Gated Recurrent Unit (GRU): Gated recurrent unit (GRU) is also another variant of RNN [21]. Its structure is similar to LSTM but uses two gates, namely reset-gate and update-gate, to control the retention and flow of information (see Fig. 2). Its performance is comparable to that of LSTM but it is faster to train due to its fewer equations. The equations

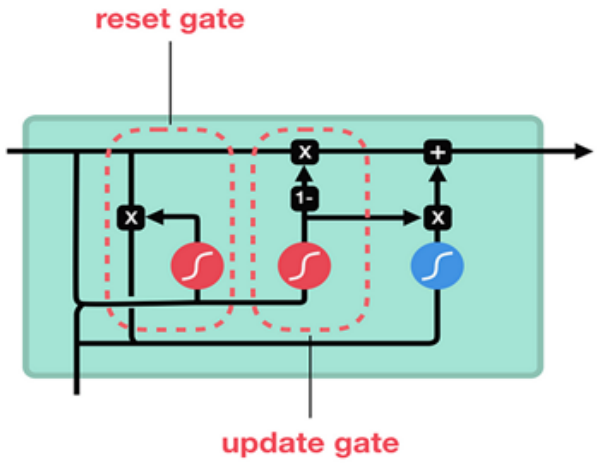

Fig. 2. GRU architecture [21].

computed by GRU are as follows [22]:

$$h_t = (1 - z_t) \odot h_{t-1} + z_t \odot \tilde{h}_t \quad (8)$$

$$\tilde{h}_t = tanh(W_h x_t + U_h(r_t \odot h_{t-1}) + b_h) \quad (9)$$

$$z_t = \sigma(W_z x_t + U_z h_{t-1} + b_z) \quad (10)$$

$$r_t = \sigma(W_r x_t + U_r h_{t-1} + b_r) \quad (11)$$

where, r_t and z_t denote the reset-gate and update-gate, respectively. h_t and h_{t-1} represent the current and previous states, respectively.

RNN, LSTM, and GRU are incredibly slow because their training is difficult to parallelize. This is because inputs must be sequentially fed and the next step relies on the analysis of the previous step.

4) Transformer Neural Network (TNN): Transformer neural network (TNN) is a type of DNN which doesn't rely on recurrent connections [23]. Instead, it uses a mechanism known as self-attention which enables it to handle long-range dependencies and process input sequences in parallel for more efficient computation [23]. A typical TNN consists of an encoder and a decoder (see Fig. 3).

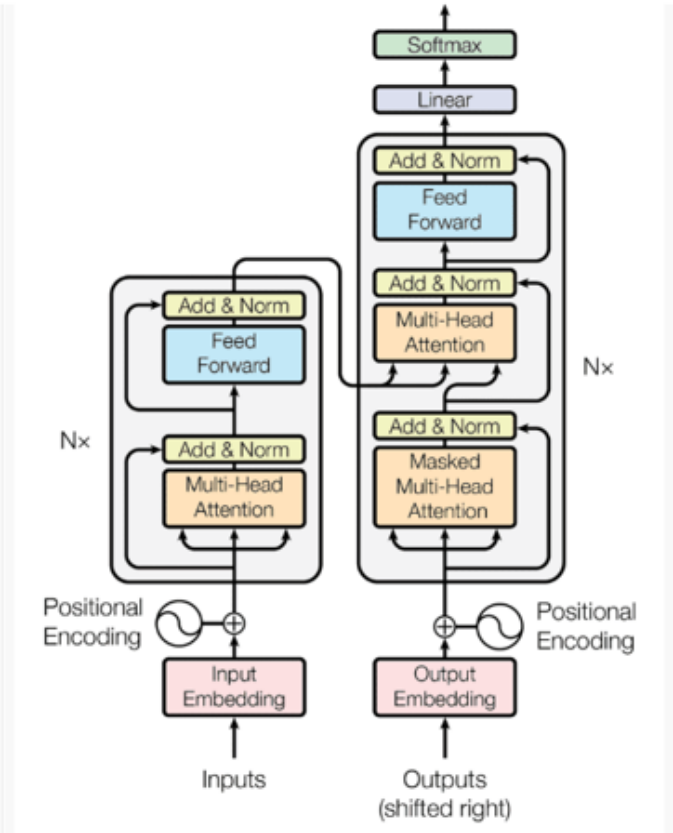

Fig. 3. TNN architecture [23].

The encoder is made up of multiple identical layers, and each layer consist of two sub-layers, namely a multi-head self-attention mechanism and a fully connected feedforward neural network (FFNN) [24]. To improve the performance and training stability of the encoder, each of the above mentioned sub-layers is followed by a residual connection and a normalization step. The input data is augmented with positional encoding [25] and processed through the stacked layers, sub-layers, and steps of the encoder.

A decoder is also made of multiple identical layers. The sub-layers of a decoder layer are similar to that of an encoder but has an additional sub-layer known as an encoder-decoder attention mechanism. This additional sub-layer enables the decoder to selectively focus on different parts of the encoded input sequence while generating the output. At each layer, the decoder processes each sequence with multi-head self-attention, position-wise FFNN, residual connections, and normalization.

The self-attention mechanism allows a TNN to prioritize the various input sequences according to their importance. The input sequence is linearly projected into multiple sets of queries, keys, and values, which are then used to compute attention scores. The scores are used to weigh the values, and the resulting weighted values are summed to produce the output of the self-attention layer. This process is repeated for each head, and the outputs are concatenated and linearly transformed to create the final output.

$$Attention(Q, K, V) = softmax\left(\frac{QK^T}{\sqrt{(}d_k}\right) \quad (12)$$

where, Q, K, and V are the query, key, and value matrices, respectively, and D_k is the dimension of K.

TNN uses multi-head attention layer to concatenate the attention weights of many single-head attention layers and then apply a non-linear transformation with a dense layer. Increasing the number of attention heads enables TNN to capture long-distance dependencies.

$$Multihead(Q, K, V) = Concat\,(h_1, h_2, \ldots, h_n)\, W^0 \quad (13)$$

where, $h_i = Attention\left(QW_i^Q, KW_i^K, VW_i^V\right)$

TNN uses the position-wise FFNN to add non-linearity and to identify complex patterns in the input sequence. FFNN consists of two linear layers separated by a ReLU activation function. The independent application of this sub-layer to every part of the input sequence makes parallelism possible.

$$FFNN(x) = max\,(0, xW_1 + b_1)\, W_2 + b_2 \quad (14)$$

where, x is a sequence, and W_i and b_i are the weight matrix and the bias vector at layer i, respectively.

B. Wavelet Transform

Time-series data can be decomposed using Fourier or wavelet transforms. For analyzing non-stationary data, such as financial time series, wavelet transform has been found to outperform Fourier transform [7]. A wavelet transform is the representation of a function by wavelets [26], [27]. A wavelet is a waveform of a limited duration with an average value of zero, Fig. 4. It is a mathematical function with two basic parameters, namely scale (or dilation) and translation (location). Scale defines how squished or stretched a wavelet

is and translation defines where the wavelet is located in time or space. A wavelet is mathematically defined as:

$$\psi_{s,u}(t) = \frac{1}{\sqrt{|s|}}\psi\left(\frac{t-u}{s}\right), \quad s,u \in \mathbb{R}, \quad s \neq 0 \quad (15)$$

where, s and u are the dilation and the translation parameters, respectively. These two basic parameters are related to frequency as defined for waves. When the value of parameter s is increased, a wavelet is squashed and it captures high-frequency information, and when it is decreased, the wavelet is stretched and it captures low-frequency information. The parameter u defines the translation of the wavelet. Increasing u will shift the wavelet to the right and decreasing it will shift the wavelet to the left.

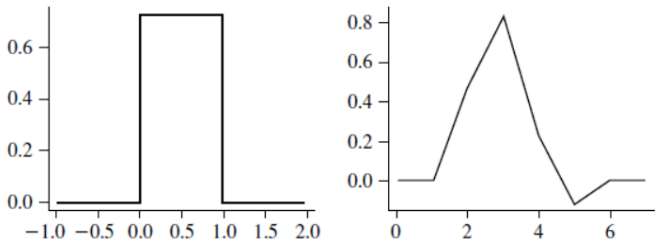

Fig. 4. Examples of wavelets.

The basic idea behind wavelet transform is to compute how much of a wavelet is in a signal for a particular scale and location. This is done by picking a wavelet of a particular scale, slide this wavelet across the entire signal, and at each time step, multiply the wavelet and the signal. The product of this multiplication gives us a coefficient for that wavelet scale at that time step. We then change the wavelet scale and repeat the process.

To best match a particular signal, there are a wide variety of prototype wavelets, called mother wavelets, to choose from. Popular examples of mother wavelets are Daubechies, Haar, Coiflets, Morlet, Symlets, Meyer, Mexican Hat and Biorthogonal [28]. A particular episode of wavelet transform uses one type of mother wavelet; the user decides which type and size to use depending on the characteristics of the signal to be analysed. Many time-series forecast applications use Daubechies [28]. After transformation of a signal using a particular mother wavelet, we end up with basis waveforms consisting of a series of daughter wavelets. The daughter wavelets are all compressed or expanded versions of their mother wavelet, and each daughter wavelet extends across a different part of the original signal. The important point is that each daughter wavelet is associated with a corresponding coefficient that specifies how much the daughter wavelet at that scale contributes to the raw signal at that location. It is these coefficients that contain the information relating to the original input signal.

The two major wavelet transforms in wavelet analysis are Continuous Wavelet Transform (CWT) and Discrete Wavelet Transform (DWT). CWTs operate over every possible scale and translation values; whereas DWTs use a finite set of wavelets defined at a particular set of scales and locations values.

DWT basis function at dyadic scaling m and time location n is given by, [29],

$$\psi_{m,n}(\mathrm{t}) = 2^{\frac{-m}{2}}\psi(2^{-m} \cdot t - n) \quad (16)$$

The inner product of a time-series data denoted by $x(t)$ and the basis function $\psi_{m,n}$, Eq. (17) returns the high frequency information, also known as the detailed coefficients, contained in the signal.

$$d_{m,n} = \sum_{t=0}^{N-1} x(t)\psi_{m,n}(t) \quad (17)$$

Decomposing a signal using mother wavelet can result in infinite number of basis functions to accurately represent the signal. In order to have a finite set of basis wavelet, an auxiliary function $\phi(t)$, known as a scaling function or father wavelet, is defined and associated with the mother wavelet to capture the rest of the signal. Eq. (18) is a definition of a scaling function at level m and translation n.

$$\phi_{m,n}(t) = 2^{\frac{-m}{2}}\phi(2^{-m} \cdot t - n) \quad (18)$$

The inner product of a signal $x(t)$ and $\phi_{m,n}$, as defined in Eq. (19), returns the low frequency information, also known as the approximation coefficients, contained in the signal.

$$a_{m,n} = \sum_{t=0}^{N-1} x(t)\phi_{m,n}(t) \quad (19)$$

An approximation of $x(t)$ at level m can be computed from $a_{m,n}$ as shown in Eq. (20).

$$x_m(t) = \sum_n a_{m,n}\phi_{m,n}(t) \quad (20)$$

Given $d_{m,n}$ at levels $1, 2, .., m_0$ and $a_{m_0,n}$, the final multiresolution representation of $x(t)$ can be computed as shown by Eq. (21).

$$x(t) = \sum_n a_{m_0,n}\phi_{m_0,n}(t) + \sum_{m=1}^{m_0}\sum_n d_{m,n}\psi_{m,n}(t) \quad (21)$$

1) Empirical Wavelet Transform: Empirical wavelet transform (EWT) is a technique to decompose a signal using an adaptive subdivision scheme [30]. EWT starts by dividing the signal spectrum into N continuous segments where each segment can be defined as $\Lambda_n = [\omega_{n-1}, \omega_n]$, where each ω_n ($\omega_0 = 0 and \omega_N = \pi$) denotes a boundary of a segment. The empirical wavelet is regarded as wavelet filters of each Λ_n

The empirical scaling function $\hat{\phi}_n(\omega)$ and the empirical wavelet function $\hat{\psi}_\mathrm{n}(\omega)$ are computed according to Eq. (22) and Eq. (23):

$$\hat{\phi}_n(\omega) = \begin{cases} 1 & \text{if } |\omega| \leq (1-\gamma)\omega_n \\ K & \text{if } (1-\gamma)\omega_n \leq |\omega| \leq (1+\gamma)\omega_n \\ 0 & \text{otherwise} \end{cases} \quad (22)$$

$$\hat{\psi}_n(\omega) = \begin{cases} 1 & \text{if } (1+\gamma)\omega_n \le |\omega| \le (1-\gamma)\omega_{n+1} \\ M & \text{if } (1-\gamma)\omega_{n+1} \le |\omega| \le (1+\gamma)\omega_{n+1} \\ N & \text{if } (1-\gamma)\omega_n \le |\omega| \le (1+\gamma)\omega_n \\ 0 & \text{otherwise} \end{cases} \quad (23)$$

where:

$K = \cos\left[\frac{\pi}{2}\beta\left(\frac{1}{2\gamma\omega_n}(|\omega| - (1-\gamma)\omega_n)\right)\right]$,

$M = \cos\left[\frac{\pi}{2}\beta\left(\frac{1}{2\gamma\omega_{n+1}}(|\omega| - (1-\gamma)\omega_{n+1})\right)\right]$,

$N = \sin\left[\frac{\pi}{2}\beta\left(\frac{1}{2\gamma\omega_n}(|\omega| - (1-\gamma)\omega_n)\right)\right]$,

$\beta(x) = x^4(35 - 84x + 70x^2 - 20x^3)$,

$\gamma \le \gamma \le \min_n\left[\frac{\omega_{n+1}-\omega_n}{\omega_{n+1}+\omega_n}\right]$, and

γ is restricted between 0 and 1 to insure $\hat{\phi}_n(\omega)$ and $\hat{\psi}_{\mathrm{n}}(\omega)$ is a tight frame of $L^2(R)$.

III. Related Work

Publications related to stock price prediction using TNN started in the last few years, and as a result, existing trading systems based on TNN are very limited, and this section summarizes most, if not all, of them. This section also presents some existing work on TNN based stock price prediction techniques.

Malibari et al. [31] proposed a stock price prediction technique using TNN. Their proposed TNN architecture was influenced by a vision transformer (ViT) [32]. They used it to predict the next day closing values of four Saudi stock market indices, namely TASI, TBNI, TMTI, and TTSI. They used MAE, MSE, MAPE, and RMSE performances matrices and found out that their proposed model can predict closing prices with a probability higher than 90%. Stock price prediction using TNN and time2vec was proposed by Muhammad et al. [33]. Their model predicts the next day and the next week closing prices of eight stocks listed in Dhaka Stock Exchange. They used the closing prices of eight previous days to predict that of the next day and they used the closing prices of the previous eight weeks to predict the closing price of the next week. They used MAE and RMSE to measure the performance of their model. For the daily solution, the MAE was less than 0.083 and the RMSE was less than 0.11, and for the weekly, the MAE was less than 0.3 and the RMSE was less than 0.33.

A number of researchers compared the stock price prediction accuracy of TNN with other models. For example, Anass [34] compared the accuracy of LSTM and TNN in predicting the next day values of Nasdaq, S&P, and Dow. He used the value of trading day t to predict the value of trading day $t+1$. He compared them using accuracy, MAE, MSE, RMSE, and execution time. He found out that TNN consistently outperformed LSTM. Also the comparison of LSTM and TNN was done by Lin et al [35]. They compared the performance of TNN and LSTM to predict the next minute and then next day stock prices. They used the historical data of Shanghai Stock Index. The daily trading data spans from December 17, 2002 to December 17, 2022 and minute-level data spans from 9:30 on December 23, 2019 to 15:00 on December 23, 2022. They compared them using MAE and MSE and they reported that LSTM outperformed TNN consistently in all the measures. Similarly Saeed [36] proposed using the stock prices of the previous ten days to predict the next day price. He used the historical prices of Yahoo, Facebook, and JPMorgan from January 1, 2017, to September 2017. He compared the performance of TNN with ARIMA, LSTM, and Random Forest using MAE, RMSE, and MAPE. He reported that TNN consistently outperformed all of them. Performance comparison of TNN, ARIMA and LSTM using the average daily prices of eight stocks listed in the Brazilian Ibovespa was illustrated by Lorenzo et al. [37]. They used 2008 historical prices totaling 80 values per share. TNN outperformed both ARIMA and LSTM obtaining the lowest RMSE in 60% of the tests, followed by LSTM in 22% and, finally, ARIMA in 18%. Wang et al. [38] compared TNN with LSTM and Hidden Markov model (HMM) using historical prices of Shanghai and Shenzhen CSI new energy stock index from June 17, 2019 to June 17, 2022. They used MAE, RMSE, and MSE, R2 to compare them. They reported that TNN consistently outperformed both of them in all the above mentioned four performance measures. Stock price predicting model consisting of BiLSTM and MTRAN-TCN was proposed by Wang et al. [39]. BiLSTM is a bidirection LSTM, MTRAN is a modified TNN, and TCN is a time conventional network. They used BiLSTM to capture bidirectional information in sequences and TCN to identify sequence dependencies. They used five index stocks and 14 Shanghai and Shenzhen stocks and measured the performance of their proposed model using MAE, RMSE, and MSE, and R2. They reported that the combination of BiLSTM and MTRAN-TCN consistently outperformed any of its subset components with all the datasets and all the above mentioned four performance measures. TNN and LSTM were also compared using LOB (Limit Order Book) data of cryptocurrency by Bilokon and Qiu [40]. They compared them using three financial time series prediction tasks, namely LOB mid-price prediction, LOB mid-price difference prediction, and LOB mid-price movement prediction of cryptocurrency LOB data. They reported that TNN outperformed LSTM by a large margin in terms of the limited metrics for mid-price prediction; whereas LSTM outperformed TNN in the other two tasks. They concluded that LSTM-based models are generally better in financial time series prediction for electronic trading.

A limited number of researchers proposed one or more trading systems based on TNN. For example, Aman [41] compared two trading systems, one based on LSTM and the other on TNN. He used the data of four stocks listed in Nifty 50 of the Indian stock market. He collected data of 21 years ranging from January 1, 2000 to December 31, 2020. Using a sliding window of size four years, he divided the data into 17 overlapping windows. The data of each window was then split into two: the data of the first three years was used for training and that of the last year for testing. He took both long and short trades. The average daily returns of the trading system based on LSTM was 2.22%. For long trades, the TNN based system gave better returns than that of LSTM. For short trades, the TNN results were inconsistent. Four trading systems based on TNN, RNN, CNN, and LSTM were proposed by Wang et al. [42]. They used data of four global indices namely, the Shanghai and Shenzhen 300 Index (CSI 300) in China, the Standard & Poors 500 Index (S&P 500) in the US, the Nikkei 225 Index (N225) in Japan, and the Hang Seng Index (HSI) in Hong Kong. The collected data that spans 11 years, from January 1, 2010 to December 31, 2020. The trading strategy

proposed is as follows: if the predicted value y_{t+1} is higher than the last observed value y_t, then a long position is entered; and if y_{t+1} is lower, then a short position is entered, other wise no position is taken. According to the performance measures MAE, MSE, and MAPE, TNN consistently outperformed the other three and gave better trading returns with all the above mentioned four global indices. A trading system based on TEANet, which is a model consisting of TNN and LSTM, was proposed by Zhang et al. [43]. Input to TEANet are tweet corpus and historical prices. The TNN component of TEANet takes as input tweets and feeds its output to LSTM. The LSTM also takes as input normalized historical prices. To evaluate the performance of TEANet, the researchers used a standard profit method and adopted a market simulation strategy proposed by Ding et al. [44]. The trading strategy is as follows: if TEANet predicts the price of a stock to rise, then a long position is entered and if it predicts the price to fall, then a short position is entered. The size of each position is \$10,000. A long position is sold if a 2% profit is achieved, otherwise it is sold at the closing price at the end of the day. Similarly, a short position is sold if a 1% profit is achieved, otherwise it is sold at the closing price at the end of the day. The proposed trading system was tested using data of 44 trading days collected from 12 randomly selected stocks. The returns of TEANet were compared to the returns of a system known as CapTE [45]. TEANet outperformed CapTE and showed an average return of 22.31% compared to 20.18% of CapTE.

IV. Framework of the Proposed Trading Solution

The framework of the proposed trading solution can be summarized as follows:

1) Ten out of 223 stocks listed in the Saudi stock market are randomly selected. Then ten datasets, one from each selected stock, are collected. The selected stocks and their selection criteria are discussed in Section V-B.
2) From each dataset nine features are selected. These features are four daily stock prices, namely open (O), low (L), high (H), and close (C), the daily volume traded (V), the Saudi market index TASI (T), sector index (S), and two TIs, namely Bollinger Bands (BB), and average true range (ATR).
3) Six performance measure are selected and used in this study and they are presented in Section V-C.
4) Out of more than 100 TIs, 10 are selected based on literature survey. Then for each selected TI, its best parameter values are identified. These selected TIs are further filtered and combined based on their performance. The details of TIs selection, best parameter value identification, filtration, and combination are discussed in Section V-D.
5) The 10 datasets are preprocessed. One of the features is converted into log returns and decomposed using EWT, and the remaining eight features are scaled. Then all of them are reshaped and split into training and testing. The data preprocessing of the datasets is detailed in Section V-E and EWT is explained in Section II-B1.
6) Seven deep learning models are compared and the one with the best performance is selected for the proposed solution, Section V-F. The architecture of each of the seven compared models is shown in Fig. 5

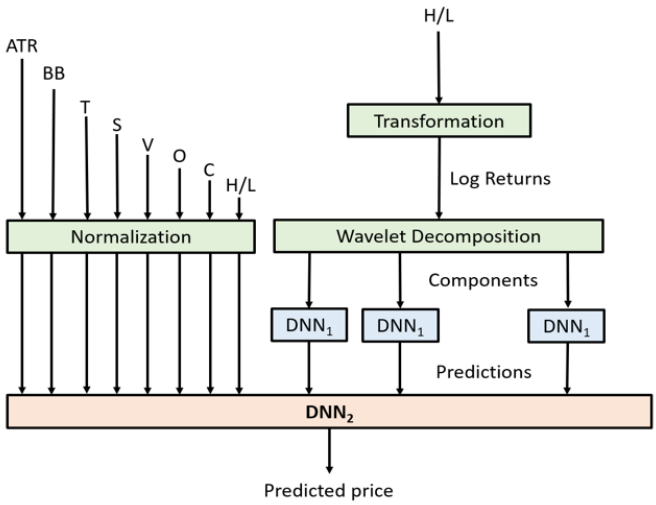

Fig. 5. Architecture of the proposed model.

7) The selected model is further optimized by choosing the best possible hyper-parameters. The list of the selected hyper-parameters and optimizers are presented in Section V-F.
8) A day trading strategy which consists of eight trading systems is proposed. The trading strategy is based on the open price and two predicted daily stock prices, namely the daily high and the daily low, Fig. 6. The details of the trading strategy is presented in Section V-G.

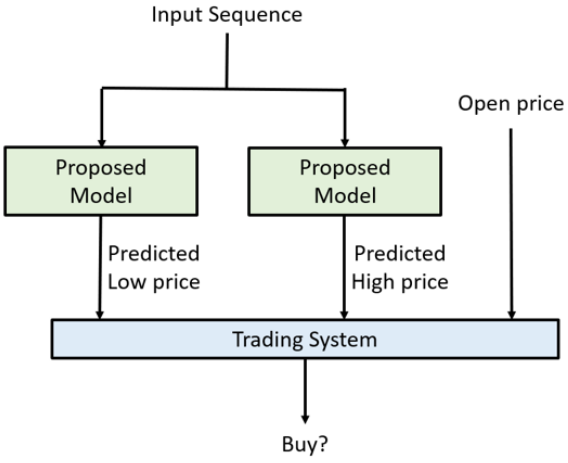

Fig. 6. Trading methodology.

9) At last, the proposed solution is evaluated, analyzed and compared, Section V-H.

V. Results and Analysis

To study the performance of the proposed trading strategy, six sets of experiments were conducted. The first set of

experiments was done to choose the best possible deep learning model. The second set was done to identify the best possible hyperparameter values for the selected model. The third set was done to select the most relevant TIs. The fourth set was done to identify the best possible parameter values for each selected TI. The fifth set was done to choose the best possible combination of TIs. The last set of experiments was done to study the performance of the proposed trading strategy. But before the results and analysis of the above mentioned experiments are presented, let us discuss the experimental environment, the datasets, and the performance measures used in this study.

A. Experimental Machines and Tools

All the experiments were conducted on a Windows 10 machine with Intel(R) Core(TM) i7-7700HQ CPU @ 2.80 and 2.81 GHz, and a 16 GB RAM.

The datasets were downloaded using TickerChart [46] and preprocessed using Amibroker Formula Language (AFL) [47] , Python, and Matlab. The deep learning models were implemented in Python using Keras open-source package with TensorFlow back-end [48]. EWT was implemented using EWT MATLAB toolbox.

B. Dataset Selection, Collection, and Features

The experimental datasets were collected from 10 out of the 223 stocks listed in the Saudi Stock exchange. These stocks are Bahri, Al-Rajhi, STC, Maaden, Tawuniya, Jarir, Jabel Omer, Budget, Sharqiya, and Mouwasat. These datasets were chosen because they exhibit different characteristics such as, they belong to different sectors, they have different number of free shares, they have been in the market since 2009 so they have enough data for training and testing, and for bull, bear, and side way markets, they are liquid enough to minimize errors due to slippage when entering and exiting positions, and so on. The datasets were downloaded using TickerChart . Table I shows some characteristics of the datasets.

TABLE I. THE DATASETS

Dataset	Stock	Symbol	Sector	Free Shares (in Millions)	Range	Standard Deviation
D1	Alrajhi	1120	Banks	3908.1	18.17 - 117.40	19.1
D2	Maaden	1211	Materials	807.7	4.87 - 57.76	9
D3	Mouwasat	4002	Healthcare	65.0	6.88 - 129.7	28.4
D4	Bahri	4030	Energy	380.4	5.71 - 30.28	5.15
D5	Jarir	4190	Retail	110.7	4.3 - 22.5	4.69
D6	Jabel Omar	4250	Real estate	929.2	11.0 - 88.75	18.85
D7	Budget	4260	Transportation	71.1	9.18 - 54.5	11.44
D8	Sharqiya	6060	Food & Beverages	7.5	8.49 - 52.59	8.49
D9	STC	7010	Telecommunication	1800.0	13.2 - 55.92	11
D10	Tawuniya	8010	Insurance	92.7	22.48 - 106.0	22.86

Each dataset contains nine features. These features are based on the daily time frame and they are: the daily open (O), high (H), low(L), and close (C) prices of a stock, the daily Volume (V) of shares traded, the sector index value (S), the TASI (T) which is the Saudi stock market index value, and two technical indicators, namely the Bollinger Bands (BB) and the average true range (ATR) which will be discussed in Section V-D.

Each dataset contains daily data from January 1, 2010 to December 31, 2022, which consists of 3244 observations.

TABLE II. THE FEATURES

Symbol	Name	Description
O	Open	Daily open price
L	Low	Daily Lowest price
H	High	Daily highiest price
C	Close	Daily close price
V	Volume	Daily traded shares
T	TASI	Saudi market Index
S	stock specific	Sector index
BB	Bollinger Bands	TI
ATR	Average True Range	TI

Table II contains the description of the above mentioned nine features.

According the proposed trading strategy, an open trade is closed when its stock price reaches a profit-target or a stop-loss, otherwise it is closed at the end of the trading day. A trade is a winner, if the intraday price of its stock reaches the profit-target before it hits the stop-loss; and it is a loser if the intraday price reaches first the stop-loss. The data in the above ten datasets is based on daily time frames or price-bars, meaning, the values of O, L, H, and C are daily prices. They don't include prices of lower time frames, such as hourly, 15-minute or 5-minute. From daily price-bars, it is impossible to know if a trade entered on day t is a winner or a loser if the price-bar covers both the predicted high and the predicted low. To avoid mistakes that can be created by such price-bars, supplementary datasets were collected from each of the above mentioned stocks. These datasets contain the highest and the lowest stock prices of 5-minute time frames from January 1, 2020 to December 31, 2022. These datasets are only used during trading and not used for training or testing the proposed model. If a 5-minute price-bar covers both the profit-target and the stop-loss of a trade, then the trade is ignored. Fortunately, the number of such 5-minute price-bars is so insignificant that there is no need to use price-bars of a lesser time frame.

C. Performance Measures

To study the performance of the proposed solution, six performance measures, namely, Mean Square Error (MSE), Root Mean Square Error (RMSE), Mean Absolute Error (MAE), Mean Absolute Percentage Error (MAPE), coefficient of determination (R^2), and Expectancy (Φ) were used. These measures were chosen because they are frequently used in related works. A good model must have RMSE, MAE, and MAPE close to 0, R^2 close to one, and a positive Expectancy. Expectancy is defined in Eq. (1), but the other five measures are mathematically defined as follows:

$$MSE = \frac{1}{n}\sum_{t=0}^{n-1}(y_t - \hat{y}_t)^2 \tag{24}$$

$$RMSE = \sqrt{\frac{1}{n}\sum_{t=0}^{n-1}(y_t - \hat{y}_t)^2} \tag{25}$$

$$MAE = \frac{1}{n}\sum_{t=0}^{n-1}|y_t - \hat{y}_t| \tag{26}$$

$$MAPE = \frac{\sum_{t=0}^{n-1} |\frac{y_t - \hat{y}_t}{y_t}|}{n} \times 100\% \quad (27)$$

$$R^2 = 1 - \frac{\sum_{t=0}^{n-1} (y_t - \hat{y}_t)^2}{\sum_{t=0}^{n-1} (y_t - \bar{y})^2} \quad (28)$$

where, y_t and $\hat{y}_t$ represent the actual and forecast values at step t for $0 \leq t < n$, respectively, and $\bar{y} = \sum_{t=0}^{n-1} y_t/n$.

D. Selecting TIs, TI Parameters, and TI Combination

There are more than 100 TIs and each TI has a number of parameters. Some TI parameters have infinite number of possible values. Hence, selecting the best TIs with their best parameter values is very challenging. In this study, a four step filtering process was adopted to choose a set of TIs and their parameter values. In Step 1, based on literature survey, the top 10 most frequently used TIs were identified (see Table III).

TABLE III. MOST FREQUENTLY USED TECHNICAL INDICATORS IN THE SURVEYED LITERATURE

TI	Frequency
MA	35
RSI	34
Williams R%	28
Stochastic %K	25
MACD	22
ROC	19
Momentum	16
Bollinger Bands	15
ATR	14
CCI	14

In Step 2, the most frequently used TI parameter values are identified. Then each TI and each of its most frequently used parameters value were used to predict the next day high and low prices using the proposed model which will be defined shortly. If a TI and its best parameter doesn't improve the prediction performance of the proposed architecture, then it is dropped. This step is done after normalizing the TI values using min-max normalization. In Step 3, The least relevant TIs are identified and eliminated. This is done using recursive feature elimination [49]. Table III shows the TIs and the parameter values that were selected after the above three steps.

TABLE IV. SELECTED TIS AND THEIR SELECTED PARAMETER VALUES

TI	Name	Parameters
STO	Stochastic	$15, 3, 3$
MACD	Moving Average Convergence Divergence	$12, 26, 9$
RSI	Relative Stength Index	14
BB	Bollinger Bands	$20, 2$
ATR	Average True Range	14

In Step 4, the selected TIs were combined in all the possible ways and the best combination was selected (see Table IV). Since there are five selected TIs, the maximum number of combinations is 32, including the one with no TIs used. Table V shows the performance of each set of TI combination. Each measurement is based on the average of the predicted high and low prices of each stock.

TABLE V. PERFORMANCE MEASURES OF TI COMBINATIONS

ATR	MACD	BB	STO	RSI	E
0	0	0	0	0	2.31
0	0	0	0	1	1.38
0	0	0	1	0	1.74
0	0	0	1	1	1.66
0	0	1	0	0	1.59
0	0	1	0	1	2.31
0	0	1	1	0	2.64
0	0	1	1	1	1.24
0	1	0	0	0	1.51
0	1	0	0	1	1.55
0	1	0	1	0	2.68
0	1	0	1	1	1.39
0	1	1	0	0	3.98
0	1	1	0	1	1.42
0	1	1	1	0	2.09
0	1	1	1	1	1.16
1	0	0	0	0	2.12
1	0	0	0	1	1.12
1	0	0	1	0	1.68
1	0	0	1	1	1.47
1	0	1	0	0	1.09
1	0	1	0	1	1.31
1	0	1	1	0	2.21
1	0	1	1	1	1.20
1	1	0	0	0	1.94
1	1	0	0	1	2.28
1	1	0	1	0	4.98
1	1	0	1	1	1.88
1	1	1	0	0	2.17
1	1	1	0	1	1.99
1	1	1	1	0	2.11
1	1	1	1	1	2.18

Each row of the table represents a unique combination of TIs. In each of the first five columns, a 0 value represents the absence of the corresponding TI from the combination, and a 1 represents its presence. For example, in the row before the last, all TIs except RSI were in the combination. The last column, E, was computed using Eq. (29).

$$E_i = \widehat{1 - r_i^2} + \widehat{rmse_i} + \widehat{mae_i} + \widehat{mape_i} \quad (29)$$

where, i represents i^{th} row of Table V, r_i^2, $rmse_i$, mae_i, and $mape_i$ are the r^2, RMSE, MAE, and MAPE values of row i, respectively, and $\widehat{x}$ represents the normalized value of x using min-max, Equation 30. The best combination is the one with the lowest E. According the results in Table V, the lowest E is 1.09 and corresponds to the combination of BB and ATR; and is the combination that was selected for the proposed model.

Nearly all the normalization operations in this study were done using min-max. It is one of the most popular techniques and is frequently used by similar studies. If $X = x_1, x_2, \ldots x_n$, then scaling x_i using min-max is mathematically defined as:

$$\acute{x_i} = \frac{x_i - min(X)}{max(X) - min(X)} \quad (30)$$

where, x_i is the i^{th} value in X, $\acute{x_i}$ is the normalized value of x_i, and $min(x)$ and $max(x)$ are the lowest and the highest values in X, respectively.

E. Data Preprocessing

Data processing is done in five phases. In Phase 1, L or H is converted to log returns. If the proposed model is going to predict the next day highest price, then H is converted to log

returns and if it is going to predict the next day lowest price, then L is converted to log returns. If $X = x_1, x_2, \ldots X_n$ is a time series data, then the log return of x_t is mathematically defined as:

$$\acute{x_t} = log(x_t/x_{t-1}) \tag{31}$$

where, x_t is the value at time t, x_{t-1} is the value at time $t-1$, and $\acute{x_t}$ is the log return of x_t. Converting stock prices into log returns increases the stationarity of the dataset.

In Phase 2, the log returns generated in Phase 1 are decomposed using the EWT algorithm proposed by Jérôme Gilles [30] as explained in Section II-B1. Decomposition results in building better forecasting models, because it enables the identification and the removal of noisy and irrelevant parts of a time series data. EWT was chosen because it is an adaptive wavelet subdivision scheme which performs wavelet decomposition without prior information about the data, produces a small number of coefficients to pack the signal information, and results in a higher resolution of time-frequency which simplifies the analysis of time-series data.

In Phase 3, all the remaining eight features are scaled between 0 and 1 using the min-max formula. This phase may not be important because TNNs can handle unscaled data.

In Phase 4, each one-dimensional time series data of size N observations is reshaped into a two dimensional array of size $N-k$ by $k+1$ using a sliding window of size $K+1$. This is done to predict the stock price on day t, p_t, using $p_{t-1}, p_{t-2}, \ldots, p_{t-k}$. Finding the best possible value of k is explained in Section V-F.

In Phase 5, the data is split into training and testing. The data from January 1, 2010 to December 31, 2019 was used for training and the data from January 1, 2020 until December 31, 2022 was used for testing.

F. Deep Learning Model Selection

To find the best deep learning model for the proposed solution, seven models namely, simple or vanilla LSTM (VLSTM), Stacked LSTM (SLSTM), Bidirectional LSTM (BLSTM) [50], GRU, Stacked GRU (SGRU), and Bidirectional GRU (BGRU) were compared. Fig. 5 shows the architecture of the proposed model that was selected after trying many other architectures. A number of experiments were conducted to choose the deep learning model that can best predict the next day high and low stock prices. The data was reshaped so that the previous 16 days are used to predict the price of the next day. Each model was experimented using different hyperparameter values and its performance was measured using RMSE, MAE, MAPE, and R^2. Table VI shows the average performance measures of all the experiments.

To choose the best performing model for the proposed solution, a normalized sum, E, was used, Eq. (29). The model with the lowest E has the best performance and thus selected for the proposed solution. As shown in Table VI, TNN has the lowest E, hence selected as the model of the proposed solution. Fig. 7 shows the architecture of the proposed model. As can be seen from the figure, the architecture contains two levels of TNNs. The TNNs in the first level are labeled as TNN_1 and the one in the second level is labeled as TNN_2. Since each TNN in the proposed model is used for the prediction of a continuous value, it doesn't need a decoder. It only uses encoders similar to the architecture of the popular BERT [51]. It also includes some dense layer, dropout layers, a global average pooling layer, and an output layer which consists of a single neuron that emits the predicted continuous value.

TABLE VI. THE PERFORMANCES OF THE SEVEN DEEP LEARNING MODELS

Model	RMSE	MAE	MAPE	r^2	E
VLSTM	77.13597	46.23983	0.07594	0.97639	3.506
SLSTM	14.06473	10.01123	0.04511	0.99002	0.087
BLSTM	14.38421	19.35125	0.05318	0.97971	1.099
GRU	82.98782	51.12156	0.07823	0.97214	4.000
SGRU	14.17115	10.16732	0.04569	0.99013	0.104
BGRU	15.66173	18.72891	0.05408	0.98895	0.643
TNN	13.86754	9.88712	0.04436	0.99115	0.000

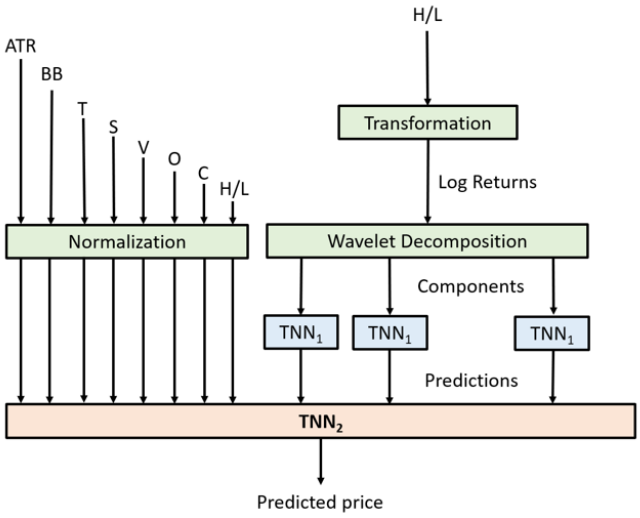

Fig. 7. The architecture of the proposed deep learning model.

To train the model for the prediction of the next day high price, the following steps were taken. H is first converted into log returns and then the log returns are decomposed into multiple levels using EWT. Each level is then reshaped into input sequences of size 16 each, encoded with time2vec, and fed into a Level 1 TNN. Similarly, each of the input features O, L, C, V, S, T, BB, and ATR are scaled between 0 and 1 using using the min-max. Then these scaled values and the output of all Level 1 TNNs are reshaped into input sequences of size 16, encoded with time2vec, and fed to the Level 2 TNN. The output of the Level 2 TNN is the predicted value. The same steps were taken to train the model for the prediction of the next day low price, except L and H exchange places in the model. A TNN requires a notion of time when processing stock prices. Without time encoding, a TNN will be oblivious to the temporal order of stock prices. In order to overcome this, the proposed model uses Time2Vec [15], a time encoding layer. Many experiments were conducted to arrive at the proposed model and Table VII summarizes the selected parameters and hyperparameters.

TABLE VII. THE PROPOSED MODEL HYPERPARAMETERS AND OTHER PARAMETERS

Parameter	TNN_1	TNN_2
time embedding	time2vec	time2vec
sequence size	16	16
number of heads	3	4
ff dimension	32	64
encoder blocks	3	4
dropout rate	0.2	0.2
loss function	MSE	MSE
optimizer	Adam	Adam
learning rate	0.0001	0.0001
epochs	150	200
batch size	64	64

G. Proposed Trading Strategy

As was mentioned before, day trading is a business of probability. When a day trader enters a position, he is not sure if it will be a winner or a loser. Most consistently profitable traders have a win rate between 40% and 60%. They are consistently profitable because their average win is much higher than their average loss. They do that by cutting their losers short and letting their winners run. They decide the amount they will risk per trade, denoted as R, before they enter a position. Most of them limit R to be less than 2% of their trading capital. This way, they can survive a number of consecutive losers.

The proposed trading strategy uses stop-loss and is based on two predicted values, namely, $\hat{h_t}$ and $\hat{l_t}$, where, $\hat{h_t}$ and $\hat{l_t}$ are the predicted highest and lowest prices of a stock on a trading day t, respectively. These predictions are based on the proposed deep learning model, shown in Fig. 7, and are computed on the morning of the trading day and before the market opens.

The proposed trading strategy consist of four buying and three selling rules. The four buying rules are:

1) $B == o_t + \psi$, where, B is the buying price per share, o_t is the open price on day t, and ψ is the minimum allowed bid-ask spread value.
2) The risk (R) per trade must be no more than 1% of the total capital. $R = B - \hat{l_t} - \psi * N$, where N is the number of shares bought. For example, for a trading capital of 10000 dollars, R must be no more than 100 dollars.
3) $\frac{\hat{h_t} - B}{\times} N \geq n \times R$ for n in $(1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5)$.
4) $n \times R > F$, where F is amount of fees and commissions paid to enter and exit a position.

The first rule is a conditional buy and is needed to make sure that a position is entered only when the stock price is trending towards the profit-target $\hat{h_t}$. The second rule limits the maximum risk taken on a trade. The third rule is there to make sure that the potential reward (profit) of a trade is significantly higher than the potential risk taken. The fourth rule is needed to ensure that the potential profit of a trade exceeds the fees paid to enter and exit the trade. When the above four rules are meet, a 10,000 Saudi riyals position is entered.

An open position is closed when any of the following three conditions is true.

1) If the intraday loss on a trade reaches R. This is done by using a predefined stop-loss price.
2) If the intraday profit on a trade reaches a prespecified profit-target, $n \times R$, for n in $(1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5)$.
3) If none of the above conditions is met, then the position is sold at the closing price of the day.

To study the performance of the proposed solution, eight trading systems were created. These systems satisfy the above mentioned buying and selling conditions but they differ in their profit-target. Table VIII shows these trading systems and their corresponding profit-targets.

TABLE VIII. THE EIGHT TRADING SYSTEMS OF THE PROPOSED TRADING STRATEGY

Trading System	TS1	TS2	TS3	TS4	TS5	TS6	TS7	TS8
Profit-target	1.5R	2R	2.5R	3R	3.5R	4R	4.5R	5R

H. Trading Results and Analysis

A number of experiments were conducted to study the profitability of each of the eight trading systems. The trades included in this study cover three year period, from January 1, 2020 to December 31, 2022, a total of 749 trading days. Each trading system was used with each dataset and the stats, such as the number of trades executed, the number of winning trades, the average profit of a wining trade, the average loss of a losing trade, etc was collected. Table IX shows some of the stats obtained by trading Alrajhi shares. The table shows that 138 positions were entered using TS1. As was mentioned before, the size of each position is 10,000 riyals. 90 of the 138 positions were winners and the rest were losers. A breakeven position is considered to be a loser because of the fees paid and the resources wasted to execute the position. The average profit per a winning trade is 140.23 riyals and the average loss is 63.89 riyals. The gross and net profits of all the positions are 12620 and 4999 riyals. The amount of fees and commissions paid to execute the trades was 4554 riyals. The expectancy, Φ, of trading Alrajhi stocks using TS1 is 36.23 riyals. The table also shows the stats of the other seven trading systems. TS2 is more profitable and TS3 has the best expectancy. TS2 was more profitable than TS3 because more trades were executed using TS2. The results also show that five of the eight trading systems were winners and the rest were losers. TS8 was the worst loser with 36.24% loss. The table also shows that the fees paid to execute trades are significant, between 30% and 61% of the gross profits.

TABLE IX. TRADING STATS OF ALRAJHI SHARES

Trading System	TS1	TS2	TS3	TS4	TS5	TS6	TS7	TS8
positions entered	138	130	117	106	105	99	91	82
Winners	90	78	69	58	46	40	35	29
Average win	140.23	171.19	183.32	191.88	208.83	201.15	178.02	151
Average loss	63.89	70.71	74.66	77.84	80.23	82.34	83.93	87.64
Gross profit	12620	13352	12649	11129	9606	8046	6230	4379

The percentage profits and losses obtained by trading Alrajhi shares are shown in Fig. 8. The figure shows that TS6, TS7 and TS8 resulted in losses. This is mainly due to the

following two reasons. First, there are fewer trades with $4R$ or more profit-targets; and second, the probability of hitting the stop-loss before the profit-target is higher when the profit-target is greater than or equal to $4R$.

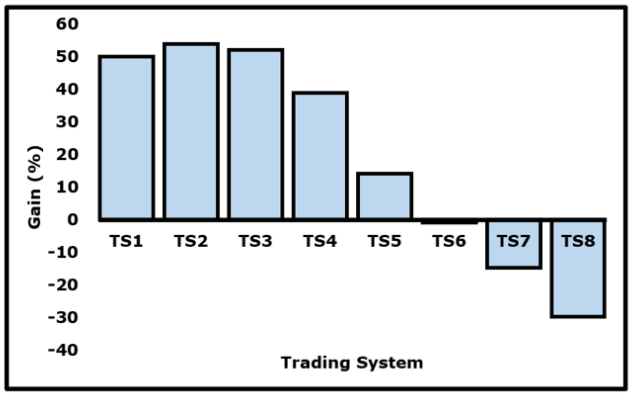

Fig. 8. Percentage profits and losses obtained by trading Alrajhi stock.

Stats, similar to that of Alrajhi stock trades, were also collected from the trades of the other nine stocks. Since these stats are too large in number and it is unnecessary to list them all, only their summaries are presented and discussed. Tables X shows percentage of profits and losses obtained by the proposed trading systems. As can be seen from the table, trading systems TS1, TS2, TS3, TS4, and TS5 were consistently profitable. TS7 and TS8 were consistent losers and TS6 showed inconsistent results. The results of TS6, TS7, and TS8 are inconsistent and poor because there are fewer trades with $4R$ or more profit-targets, and the probability of hitting the stop-loss before hitting the profit-target is higher.

TABLE X. PERCENTAGE OF PROFITS AND LOSSES OBTAINED BY THE PROPOSED TRADING SYSTEMS

Trading System	TS1	TS2	TS3	TS4	TS5	TS6	TS7	TS8
D2	50.11	48.72	46.57	37.97	22.84	10.11	-8.19	-23.92
D3	53.37	51.10	48.38	28.71	22.10	13.58	-1.0	-16.58
D4	48.48	54.24	44.92	23.18	22.95	20.74	-3.80	-23.83
D5	42.30	41.14	42.24	40.94	22.81	13.09	-1.20	-17.32
D6	28.11	30.10	30.79	27.45	17.20	2.19	-16.30	-45.25
D7	42.01	43.76	39.77	28.94	15.20	-12.46	-16.96	-38.32
D8	54.37	56.60	57.10	46.08	37.54	19.90	-13.46	-41.59
D9	48.52	52.81	46.65	29.66	18.96	15.91	-7.38	-16.36
D10	59.44	61.11	63.86	51.00	26.51	5.23	-12.05	-42.89

Fig. 9 shows expectancies obtained by trading Alrajhi shares. Again the trading systems with profit-targets between 1.5R and 3.5R showed positive expectancy and the rest were negative. TS3 showed the best expectancy of 44.48 riyals and TS8 was the worst with -36.24. The expectancies obtained by the other nine stocks are listed in Table XI. As can be seen from the table, the expectancies of all the trading systems with profit-targets of less than 4R were positive. TS6 results were inconsistent and TS7 and TS8 consistently resulted in negative expectancies. The negative results of the trading systems with higher profit-targets is due to the two reasons that were discussed before. The table also shows that TS2 has the highest expectancy when trading the stocks of D4, D7, and D9; TS3 has the highest expectancy when trading D1, D2, D3, D5, D6, D8, and D10. On the average, TS3 resulted in the best expectancy with 31.35 riyals.

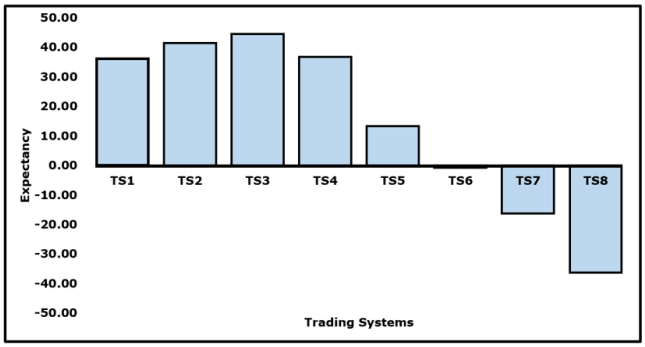

Fig. 9. Expectancy obtained by trading Alrajhi shares.

TABLE XI. EXPECTANCY OF THE PROPOSED TRADING SYSTEMS

Stock	TS1	TS2	TS3	TS4	TS5	TS6	TS7	TS8
D2	16.59	17.91	19.09	17.18	10.93	5.40	-4.76	-23.92
D3	18.53	18.93	20.07	12.54	10.28	6.56	-0.5	-8.87
D4	35.39	42.71	36.82	20.33	21.65	20.53	-3.92	-26.19
D5	38.11	38.45	44.46	46.00	26.53	15.59	-1.51	-22.50
D6	13.85	16.01	18.00	16.95	11.95	1.62	-12.44	-37.09
D7	19.82	22.44	22.22	17.43	9.81	-8.96	-13.90	-34.22
D8	18.62	21.77	25.15	22.26	19.97	10.76	-7.92	-25.83
D9	44.11	52.29	48.10	35.31	22.84	21.50	-9.84	-24.78
D10	27.52	31.34	35.09	29.83	15.97	3.51	-8.86	-33.25
Average	26.88	30.33	31.35	25.46	16.33	7.57	-7.57	-27.29

Each of the eight trading systems was compared with the buy-and-hold trading strategy. Tables XII shows profits and losses obtained by the buy-and-hold strategy. The best winning trade gave a profit of 192.81%, whereas the worst losing trade had a loss of -39.71% (see Fig. 10). Consistency in trading is very important for a trader. The buy-and-hold strategy has inconsistent results. Half of the positions taken were losers. Unlike the buy-and-hold strategy, TS1, TS2, TS3, TS4, and TS5 were consistently profitable. Also TS1, TS2, and TS3 showed significantly better average profits than the buy-and-hold strategy, (see Fig. 11). In summary, TS1, TS2, and TS3 showed consistency, better expectancy, and significantly better average profits than the buy-and-hold strategy.

TABLE XII. PROFITS AND LOSSES OBTAINED BY THE BUY-AND-HOLD STRATEGY

Stock	Open price	Last price	PnL	PnL (%)
D1	40.82	75.2	8389.34	83.89

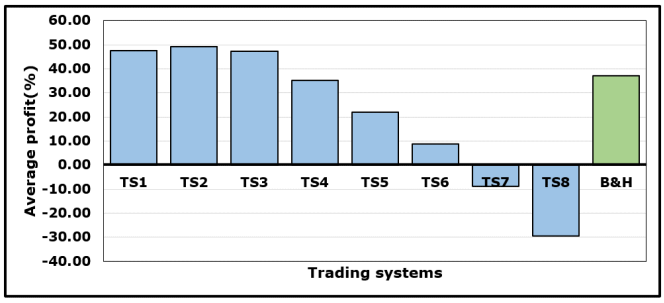

Fig. 11. Average profits of the proposed trading systems and the buy-and-hold trading strategy.

VI. Conclusion

In this study, a trading strategy based on two predicted stock prices using TNN, TIs, MRA, and time2vec was investigated. The proposed trading strategy consists of eight day trading systems, each with a different profit-target $n \times R$, where R is the risk taken per trade and for n in $(1.5, 2, 2.5 \ldots 5)$. To enter a position, the strategy requires four conditions to be simultaneously true, and to close a position, any of three conditions must be true. To choose the best deep learning model, seven architectures were investigated. TNN gave the best performance and hence it was selected. To improve the accuracy of the proposed model, some of the raw stock prices were converted to log returns and decomposed using MRA. To further improve its accuracy, a number of TIs were carefully analyzed and their best possible parameter values identified. Then the selected TIs were combined and the combination of TIs with the best performance was used. A number of experiments were also conducted to select the best TNN hyper-parameters such as, number of encoders, heads, epochs, learning rate, etc. Deep learning models are fast to overfit and to prevent that dropout layers were used.

The proposed trading strategy was tested using the data of ten randomly selected stocks listed in the Saudi Stock Exchange. The experimental results showed that trading systems with profit-target between $1.5R$ and $3.5R$ showed consistent profits. Those with profit-targets of $4R$ or more can result in losses. This is mainly due to the following two reasons: first, there are fewer trades with $4R$ or more profit-targets; and second, the probability of hitting the stop-loss before the profit-target is higher when the profit-target is greater than or equal to $4R$. The eight trading strategies were also compared with the buy-and-hold strategy. On the average, trading systems TS1, TS2, and TS3 outperformed the buy-and-hold strategy. Another weakness of the buy-and-hold strategy is its inconsistency. For one stock it gave a profit of 192.81%, and for another stock it resulted in a loss of -39.71%. Traders prefer trading systems with consistent results, such as TS1, TS2, and TS3, hence recommended.

There are four main ideas that can enhance the profitability of the proposed work and are planned as future works. First, to find a technique that can predict whether an intraday price will first hit the profit-target or the stop-loss. This can significantly enhance the profitability of the proposed strategy because most of the losing trades were due to the intraday price reaching the stop-loss before the profit-target. Second, to investigate different buying points instead of always buying using the open price. Third, day trading incurs significant amount of fees and commissions. As can be seen from the posted results, between 30% and 61% of the gross profits were paid as fees. To reduce the amount of fees paid, swing and positional trading strategies can be investigated. They require fewer trades and thus less fees. Fourth, to study the impact of price volatility, market and sector trends, news, and sentiments on the profitability of the proposed trading strategy.

***Abstract*—Encrypted traffic classification, a pivotal process in network security and management, involves analyzing and categorizing data traffic that has been encrypted for privacy and security. This task demands the extraction of distinctive and robust feature representations from content-concealed data to ensure accurate and reliable classification. Traditional approaches have focused on utilizing either the payload of encrypted traffic or statistical features for more precise classification. While these methods achieve relative success, their limitation lies in not harnessing multi-grained features, thus impeding further advancements in encrypted traffic classification capabilities. To tackle this challenge, ET-CompBERT is presented, an innovative framework specifically designed for the fusion of multi-granularity features in encrypted traffic, encompassing both payload and global temporal attributes. The extensive experiments reveal that our approach significantly enhances classification performance in data-rich scenarios (achieving up to a +4.43% improvement in certain cases over existing methods) and establishes state-of-the-art results on training sets with different sizes. The source codes will be released after paper acceptance.**

***Keywords*—Encrypted traffic classification; BERT; multi-granularity fusion**

I. Introduction

Recently, the widespread use of traffic encryption has become instrumental in protecting the privacy and anonymity of Internet users [1], [2]. While this advancement is vital for security and confidentiality, it concurrently presents significant challenges to traffic classification. The increasing utilization of privacy-enhancing encryption techniques, such as Tor and VPNs, by both legitimate users and malicious actors, complicates the task of distinguishing benign from harmful traffic. Encrypted traffic classification thus emerges as a crucial tool in this landscape. It enables the identification and mitigation of malware and cybercriminal activities that exploit encryption to bypass surveillance systems, without compromising the privacy and integrity of legitimate communications. This delicate balance between user privacy and cybersecurity underscores the indispensable role of sophisticated traffic classification methodologies in maintaining a secure digital environment.

Traditional cleartext traffic classification methods [3], [4], [5] primarily rely on deep packet inspection, capturing patterns and keywords within data packets from the payload. Nevertheless, the advent of encrypted traffic poses a significant challenge to these methodologies. The inherent unreadability of encrypted traffic renders traditional cleartext classification ineffective. Recent study [6] proposes leveraging unencrypted protocol field information. This approach involves extracting key features such as device type, certificate details, packet size, and temporal characteristics to represent each data flow. However, this strategy has its limitations. In virtual communication networks, these fingerprints are susceptible to tampering, leading to misinterpretation and a consequent failure in accurately classifying encrypted traffic.

The field of machine learning has witnessed rapid advancement, prompting numerous security researchers [7], [8] to explore statistical methods to enhance the accuracy of encrypted traffic classification. Predominantly, these machine-learning approaches for encrypted traffic classification rely on the meticulous selection of handcrafted features, followed by the application of statistical machine-learning algorithms for classification purposes. For instance, Flowprint [8] leverages statistical features of packet sizes to train random forest classifiers, while BIND [7] utilizes statistical features related to temporality. However, we contend that these methods are overly dependent on selecting handcrafted features. Designing universally applicable features that can effectively address the increasing complexity of numerous applications and websites is a challenging endeavor. Moreover, these methods typically provide only a generalized perspective to the algorithm, limiting the coarse-grained capability of encrypted traffic classification. This inherent limitation underscores the need for more adaptable approaches in this rapidly evolving domain.

These limitations have increasingly steered researchers toward adopting end-to-end deep learning methodologies for encrypted traffic classification. The utilization of supervised deep learning for encrypted traffic classification has emerged as a predominant approach, primarily due to its ability to automatically extract discriminative features, thus diminishing the reliance on manual feature design. In previous research, such as DF [9], convolutional neural networks have been employed to autonomously derive representations from raw packet size sequences in encrypted traffic. The remarkable achievements of BERT[10] in the natural language processing domain have inspired analogous advancements in network traffic analysis. ET-BERT[11] introduces a novel network traffic representation, termed BURST, defined as a sequence of temporally adjacent network packets originating from either the request or response in a single session flow. This approach also incorporates a similar learning task, positioning ET-BERT as a pioneering method in applying a pre-train and fine-tune model to encrypted traffic classification. Despite these advancements, it is crucial to acknowledge that current pre-trained methodologies often focus on the payload of encrypted traffic but neglect the global attributes. This oversight leads to models achieving suboptimal accuracy in encrypted traffic

*Corresponding authors.

classification, highlighting a critical area for improvement in this evolving field.

To address the challenge mentioned above, we introduce a novel framework known as Encrypted Traffic comprehensive Bidirectional Encoder Representations from Transformer (ET-CompBERT). As depicted in Fig. 1, we innovatively introduce a multi-grained learning strategy, termed *comprehensive fusion-guided (CFA)* learning. This strategy synergistically combines a fine-grained understanding of encrypted traffic payloads with a broader, coarse-grained analysis, thereby enhancing the overall comprehension of encrypted traffic. To the best of our knowledge, this represents the inaugural effort in integrating multi-grained features for pre-trained encrypted traffic classification. Drawing inspiration from the rapidly evolving field of prompt tuning in both the computer vision [12] and natural language processing [13] communities, we propose the *global-feature-aware* (GFA) learning strategy, significantly enhancing the robust classification on different data sizes capabilities of ET-CompBERT. Our contributions are outlined as follows:

- This study represents a pioneering effort in a novel multi-grained learning approach as comprehensive fusion-guided learning. This innovative strategy enables fusing the global temporal attributes into the extracted representations of encrypted traffic payloads.
- We introduce an innovative GFA learning strategy, that effectively fuses the representations of local traffic payloads and the representations of global temporal attributes for encrypted traffic classification.
- Extensive experimental evaluations demonstrate the effectiveness of our framework. The results indicate that our approach surpasses existing state-of-the-art methods in all tasks. Notably, our model achieves consistent advantages on training sets with different sizes of datasets, underscoring its versatility and robustness.

The remainder of this paper is organized as follows. Section II provides a detailed review of the relevant literature and background information on encrypted traffic classification. Section III describes the methodology applied in our study, including comprehensive fusion-guided learning and global-feature-aware learning. The results are presented and discussed in Section IV, where we analyze comparisons with existing methods, ablation studies, and other analyses. Finally, Section V concludes the paper with a summary of the findings, and implications of our work.

II. Related Work

A. Encrypted Traffic Classification

Encrypted traffic classification aims to discern the services operating behind obfuscated network traffic, thereby enhancing both network service quality and security assurance. Contemporary methodologies in this domain predominantly fall into two principal categories, those grounded in machine learning techniques [7], [14], [15] and those leveraging deep learning paradigms. However, traditional machine learning-based approaches for encrypted traffic classification are often constrained by their dependency on expert-derived feature extraction and selection, which can impede generalization and further development. This limitation has led researchers to gravitate towards end-to-end deep learning Encrypted Traffic Classification methodologies increasingly.

In contrast to methods based on traditional machine learning, deep learning-based approaches offer a comprehensive solution for encrypted traffic classification by autonomously learning feature representations. This shift towards deep learning methodologies enhances robustness and addresses the inherent complexities in encrypted traffic analysis. Wang et al. [16] exemplify this trend by proposing an application of convolutional neural networks (CNN). Their method involves using the initial 784 bytes of each traffic flow as input, enabling the CNN to extract and learn feature representations effectively, thus showcasing the potential of deep learning in this domain. Given the remarkable success of the BERT [10] model within the natural language processing community, researchers [11] are exploring the application of its structural principles in the realm of encrypted traffic classification through learning approaches. However, a common challenge these methods face is their reliance on substantial volumes of labeled data to ensure optimal performance, limiting their applicability to new, unseen classes that diverge from the training dataset. This challenge gives rise to the need for few-shot learning approaches, capable of classifying new encrypted traffic types with a minimal reliance on labeled data, thus presenting a promising solution to these constraints.

In our study, we introduce a novel approach to encrypted traffic classification that diverges from traditional single-granularity pre-trained methods. Our method centers around enhancing a pre-trained encrypted traffic classification model which proposes to enhance encrypted traffic classification by multi-granularity feature fusion. Furthermore, We introduce an innovative fine-tuning method, GFA learning, which empowers the model with robust classification capabilities under different data sample scenarios.

III. Methods

A. Comprehensive Fusion-guided Learning

In the initial phase of our study, we implement comprehensive fusion-guided learning to cultivate ET-CompBERT in Fig. 1, which integrates global temporal attributes into the payload representations of encrypted traffic. Starting with payload encoding, we utilize the BURST structure, identified as a sequence of temporally contiguous network packets emanating from either a request or a response in a single session flow. This structure is employed to precisely depict encrypted traffic, thereby forming the input for our pre-trained ET-BERT model, mirroring the strategy delineated in [11]. This approach culminates in the creation of an encrypted traffic embedding, denoted as e_b. Following this, we utilize the straightforward two-layer Multi-Layer Perceptron (MLP) for projecting the encrypted traffic embedding into f_b.

In the comprehensive fusion-guided learning procedure, for a given piece of encrypted traffic, we utilize both the payload and its global temporal attributes. During the global-feature-aware learning process, the global temporal attributes concatenate a special classification token and the BURST representation as input to the pre-trained ET-CompBERT model. It is important to highlight that the '//' symbol is used to denote

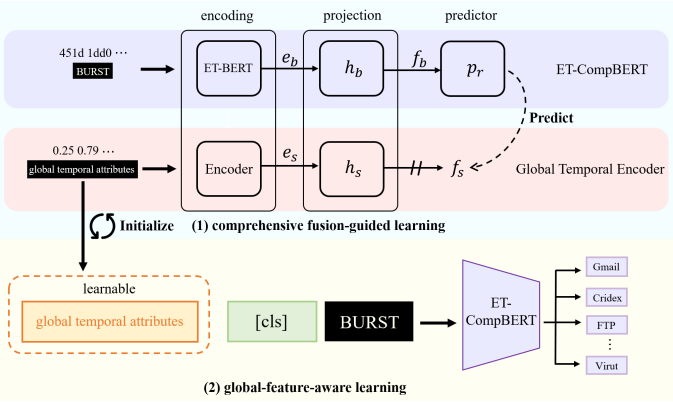

Fig. 1. Framework of ET-CompBERT.

the stop gradient, a critical measure implemented to prevent the model from adopting shortcut learning methods.

To design the global temporal attributes encoding procedure, we employ an encoding strategy akin to that utilized in payload encoding, to acquire embeddings reflective of global temporal properties. Initially, key properties are extracted from network packets, a subset of which is detailed in Table I. These properties are subjected to min-max normalization, resulting in a normalized feature vector. Importantly, we utilize a fully connected network (FCN) to align the dimensions of the global temporal attributes with those of the Transformer Encoder [17], ensuring dimensional compatibility. Following this, the features are replicated as the global temporal attributes and passed through the original Transformer Encoder [17], thereby obtaining the preliminary global temporal embedding e_s. These initial global temporal embeddings are further processed via a two-layer Multi-Layer Perceptron (MLP), culminating in the generation of the final global temporal embedding f_s.

TABLE I. DESCRIPTION OF GLOBAL TEMPORAL ATTRIBUTES

Feature	Description
duration	The duration of the flow.
fiat	Forward Inter Arrival Time (mean, min, max, std).
biat	Backward Inter Arrival Time (mean, min, max, std).
flowiat	Flow Inter Arrival Time (mean, min, max, std).
active	The amount of time a flow was active (mean, min, max, std).
idle	The amount of time a flow was idle (mean, min, max, std).
fb_psec	Flow Bytes per second.
fp_psec	Flow packets per second.

In our pursuit to enhance our framework's capability to identify global attributes of encrypted traffic, while also retaining a profound understanding of its payload, we have developed a comprehensive fusion-guided learning strategy. This innovative approach introduces a novel prediction methodology, meticulously designed to empower the encrypted traffic model with the capability of category classification. Consequently, this facilitates a fundamental enhancement in the fine-grained interpretation of encrypted traffic information, thus enabling a comprehensive and coarse-grained understanding of encrypted traffic dynamics. This strategic design marks a significant advancement in the nuanced analysis of encrypted traffic data. Upon obtaining the encrypted traffic embedding f_b and the global temporal attributes embedding f_s, our framework employs a two-layer Multi-Layer Perceptron (MLP) as a predictor. This MLP is specifically tailored to categorize the global temporal attributes. Given the model's proficiency in acquiring an in-depth understanding of encrypted traffic from both holistic and detailed perspectives, we refer to the ET-BERT, subjected to the aforementioned comprehensive learning, as ET-CompBERT. It is imperative to highlight that our methodology incorporates a stop-gradient strategy designed to prevent the model from gravitating towards shortcut solutions. This critical implementation is pivotal in safeguarding the robustness and integrity of our approach. Such a strategy underpins a more effective learning process, perfectly in sync with the core objectives of encrypted traffic analysis. This meticulous attention to the learning process ensures the reliability and efficacy of our model in challenging scenarios.

B. Global-feature-aware Learning

Following the learning procedure, we fine-tune the ET-CompBERT on downstream datasets. However, conventional learning strategies, while effective under sufficient data conditions, often falter in a few data scenarios. The framework after the comprehensive fusion-guided learning can understand the payload of the encrypted traffic and the global temporal properties. We innovatively introduce the GFA learning strategy.

Initially, global temporal attributes are deployed to initialize the learnable token, akin to their usage in the comprehensive fusion-guided learning paradigm. These attributes are encoded into a token via a shared-weight Fully Connected Network (FCN), ensuring a coherent and efficient representation for subsequent processing. This token is concatenated alongside the special $[class]$ symbol and the BURST to constitute the primary input. To ensure dimensional coherence, we employ a simple one-layer MLP, maintaining the dimensionality adapted to the ET-CompBERT. Through the self-attention mechanism, the global temporal attributes alongside the $[class]$ symbol acquire knowledge from BURST. This process culminates in the formation of the final learnable global temporal attributes, specifically designed to bolster the classification capabilities for encrypted traffic. The effectiveness of this enhancement is continually assessed and refined under the guidance of the cross-entropy loss function. The robust enhancement in encrypted traffic classification performance achieved by our learning and learning methodology is demonstrated in our experimental results. We propose two learning strategies that can also enhance the encrypted traffic classification model for varied classification scenarios.

C. Inference

During the inference phase, we omit the projection and predictor components, retaining only the final global temporal attributes which concatenate with the input to elevate the encrypted traffic classification ability. These attributes encapsulate the optimal encrypted traffic classification capabilities as evidenced by the GFA learning results. In the final layer of the ET-CompBERT, we employ an FCN layer coupled with a softmax function to generate the probability distribution across various categories.

IV. EXPERIMENTS

A. Dataset and Metrics

To validate the efficacy and broad applicability of ET-CompBERT, we conducted a series of experiments across three established encrypted traffic classification tasks, utilizing four publicly accessible datasets. Table II delineates the specifics of these datasets. The General Encrypted Application Classification task focuses on categorizing application traffic under standard encryption protocols. Our evaluations were conducted on the Cross-Platform datasets for both iOS and Android, encompassing 196 and 215 applications respectively. The Encrypted Malware Classification task involves the analysis of encrypted traffic comprising both malware and benign applications. In this context, the USTC-TFC dataset is particularly noteworthy, as it features 10 categories each of benign and malicious traffic, providing a comprehensive framework for the assessment of encryption-based malware detection capabilities. The Encrypted Application Classification on Tor task is centered around classifying encrypted traffic using the Onion Router to enhance communication privacy. The relevant dataset, termed ISCX-Tor, comprises 16 distinct applications, offering a unique landscape for assessing privacy-preserved encrypted traffic analysis.

B. Implementation Details

During comprehensive fusion-guided learning, approximately 30GB of traffic data is utilized for pre-training purposes. The dataset is divided into two segments: (1) roughly 15GB of traffic data sourced from public datasets [18], [19]; (2) an equivalent volume of traffic data, approximately 15GB, obtained through passive collection within the China Science and Technology Network (CSTNET). the batch size is set at 32, and the total number of steps is 500,000. The learning rate is established at 2×10^{-5}, with a warmup ratio of 0.1. For learning, we utilize the AdamW optimizer across 10 epochs, applying a learning rate of 6×10^{-5} for flow-level and 2×10^{-5} for packet-level tasks. The batch size remains at 32, and the dropout rate is set to 0.5. All experiments are conducted using Pytorch 1.8.0 on eight NVIDIA Tesla V100 GPUs. In our approach, we implement two distinct learning strategies for the ET-CompBERT model to adapt to different levels of traffic data granularity, the ET-CompBERT(flow) and the ET-CompBERT(packet). Here the $e_b, e_s \in \mathbb{R}^{768}$, $f_b, f_s \in \mathbb{R}^{120}$.

For testing, we maintained consistency in the dataset across both strategies, ensuring a fair and objective comparison with other methodologies. The pivotal difference between these strategies lied in the granularity of the fine-tuning input traffic information. Our method employed a dataset comprising a concatenated sequence of M consecutive packets within a flow, where M is predefined as 5 in our experimental setup.

C. Comparison with Existing Methods

Tables III and IV showcase the performance comparison of our framework with existing frameworks. Our framework sets a new benchmark in state-of-the-art performance, outperforming the preceding leading method in the F1-score across all four datasets with flow-level fine-tuning. The margin of enhancement ranges from +0.28% to +4.43%, as substantiated by the results enumerated in both tables. Moreover, it is imperative to highlight that the results of our experiments surpass all previous state-of-the-art methods in terms of F1-score in the packet-level fine-tuning. These outcomes attest to the proficiency of our framework in synthesizing coarse-grained and fine-grained insights into encrypted traffic analysis. The observed discrepancy in classification capability may be attributed to the inherently more fine-grained nature of packet-level fine-tuning compared to flow-level fine-tuning. This granularity enables the self-attention mechanism to capture subtler details within the encrypted traffic, potentially leading to enhanced model classification performance.

D. Ablation Studies

In this study, we evaluate the impact of individual components within our framework in both flow-level and packet-level learning. Crucially, omitting the comprehensive fusion-guided (CFG) learning and global-feature-Aware (GFA) learning from ET-CompBERT reverts it to its baseline counterpart, ET-BERT. Tables V and VI detail the performance implications of these components in flow-level learning scenarios. As delineated in Table V, the omission of GFA learning precipitates a minimum decline of -0.43% in the F1-score for the Cross-Platform (Android) dataset. More strikingly, the simultaneous removal of both GFA and CFG learning induces a minimum downturn of approximately -3.42%in the F1-score. Such outcomes accentuate the critical role of our proposed CFG and GFA methodologies in the effective assimilation of multi-grained features for encrypted traffic classification.

We assess the performance of our model using four fundamental metrics: Accuracy (AC), Precision (PR), Recall (RC), and F1-Score. This involves calculating the mean values of AC, PR, RC, and F1 for each category, ensuring a more equitable and round evaluation framework.

The packet-level learning, as shown in Tables VII and VIII, ET-CompBERT demonstrates robust performance across all four datasets. All classification abilities decline when removing GFA learning or removing both GFA learning and CFG learning. A discernible decline in performance is noted with the removal of the GFA learning, evidenced by a marked reduction of -4.12% in the F1-score, most notably in the ISCX-Tor dataset. They were similarly, eliminating both the GFA learning and CFG learning results in a further decrease, with the F1-score dropping by -3.10% in the same dataset. These observations underscore the substantial contributions of both

the GFA learning and CFG learning to the overall effectiveness of our framework in encrypted traffic classification tasks.

E. Analysis

We conduct an extensive analysis of the impact of varying dataset volumes under flow-level fine-tuning, as depicted in Fig. 2 and Fig. 3, and packet-level fine-tuning, illustrated in Fig. 4 and Fig. 5. Additionally, we perform a comparative evaluation of the classification performances using different late fusion methods, which are systematically presented in Table IX and X.

Fig. 2 and Fig. 3 demonstrate the comparative performance of ET-BERT and ET-CompBERT across four datasets under flow-level fine-tuning. It is observed that with the reduction in dataset volumes, ET-CompBERT's classification performance consistently outperforms that of ET-BERT. Significantly, our proposed framework exhibits a notable enhancement over ET-BERT, evidenced by an approximate increase of +0.37% in classification accuracy under 90% GFA learning data volumes. This improvement is even more marked at lower dataset volumes, especially at 10%. Particularly, under 10% volumes of the USTC-TFC dataset, as shown in Fig. 3(b), the classification capability of our framework substantially surpasses ET-BERT by about +10.62%. These findings clearly illustrate the superior robustness and improved classification efficacy of our proposed framework compared to ET-BERT when applied to flow-level fine-tuning. In the packet-level fine-tuning scenario in Fig. 3 and Fig. 4, the ascending trends observed across the four datasets indicate that ET-CompBERT significantly outperforms in scenarios with reduced dataset volumes, particularly evident in the ISCX-Tor dataset, where it surpasses ET-BERT by a notable +9.21% in Fig. 4(a). These experimental results validate that our comprehensive fusion-guided learning

approach effectively enables the framework to comprehend coarse-grained global temporal attributes, building upon its understanding of fine-grained information from the encrypted traffic payload. Concurrently, these global temporal attributes contribute to enhancing the pre-trained model's proficiency in encrypted traffic classification, underscoring the synergy between different granularities of data in improving model encrypted traffic classification performance.

In addition to our primary methodology, we examine an alternative late fusion technique to replace the comprehensive fusion-guided learning. This approach computes an arithmetic mean of the prediction probabilities derived from the fine-grained payload encoder, ET-BERT, and the encoder capturing global temporal attributes. Designated as ET-BERT+GFA, this advanced late fusion methodology strives to amalgamate multi-grained informational aspects. In this technique, the encoder responsible for capturing global temporal attributes computes a probability distribution that is the arithmetic mean of its own output and that of ET-BERT. Unfortunately, as Tables IX and X reveal, this method falls short of achieving the desired performance in encrypted traffic classification. Table X, in particular, illustrates that ET-BERT+GFA's classification efficacy does not surpass that of ET-BERT. The underlying cause of this shortfall may be attributed to the simplistic nature of this late fusion approach, which potentially disrupts the model's ability to integrate coarse-grained features without preserving the intricate fine-grained details of the encrypted traffic. These findings affirm the effectiveness of our comprehensive fusion-guided learning in enabling the model to assimilate coarse-grained temporal attributes without compromising the nuanced information acquired from the fine-grained payload of encrypted traffic.

V. Conclusion

In this work, we introduce a novel framework for encrypted traffic classification, named ET-CompBERT. This framework innovatively integrates the fine-grained payload characteristics of encrypted traffic with the coarse-grained global temporal attributes. We also introduce innovative GFA learning which endows our framework with robust encrypted traffic classification results under different data sizes. Extensive experimental results validate the effectiveness of our approach.

***Abstract*—The PID controller is a crucial element in numerous engineering applications. However, a significant challenge with PID lies in selecting optimal parameter values. Conventional methods need extra tunning and may not yield the best performance. In this study, a recently introduced metaheuristic algorithm, Geometric Mean Optimizer (GMO), is employed to identify the most suitable PID parameter values. In conventional methods, a fixed empirical equations are applied to select parameter values of PID. In GMO, there is a wide search space to select the optimal parameter values of PID based on an objective function. The objective function that the GMO seeks to minimize is the Integral of Absolute Error (IAE). GMO is chosen for its effectiveness in balancing exploration and exploitation of the search space, as well as its robustness and scalability. GMO is tested in the context of optimizing PID parameters for an engineering application: DC motor regulations. The results demonstrated GMO's superiority over comparable algorithms.**

***Keywords*—Metaheuristics; PID controller; GMO; DC motor**

I. Introduction

In manufacturing industries, the PID controller is favored for its effectiveness, resilience, and durability. This controller features standard control parameters, including system stability, settling time, and the deviation between desired and actual responses [1]. Given the shared use of processes in factories, tuning these parameters becomes a crucial task. Proper configuration enables the achievement of efficient transient performance, minimizing settling time, steady-state error, maximum deviation, and rise time as much as possible. The PID controller relies on three essential parameters: proportional gain (K_p), integral gain (K_i), and derivative gain (K_d).

The PID controller finds applications in regulating a variety of industrial processes, including pressure, temperature, flow rate, feed rate, weight, speed, and position [1]. Tuning the PID controller's parameters falls into three categories: analytical methods, rule-based methods, and numerical methods [2]. The Ziegler-Nichols (ZN) method, a classic approach for adjusting PID controller parameters, is the most commonly used and falls into the analytical category [3]. However, it's important to note that ZN does not provide optimal performance.

Stochastic optimization techniques, like heuristic algorithms, are well-suited for tuning PID parameters [4] [5] . These methods treat the problem as a "black box," adjusting the parameters and monitoring fitness to reach the optimal value. A meta-heuristic algorithm, which relies on random motion to expedite the exploration of a problem's search space, aims to find a satisfactory solution within a reasonable timeframe [6].

In this work, Geometric Mean Optimizer (GMO) [7] is used to identify the most suitable PID parameter values. The objective function employed to enhance process performance is the Minimum Integral of Absolute Error (IAE) [8].

The main objective of this work is to enhance IAE for estimating the parameters of PID controller. The performance of GMO is evaluated in comparison with other algorithms such as Arithmetic Optimization Algorithm (AOA) [9], Sine-Cosine Optimization Algorithm (SCA) [10], Particle Swarm Optimization algorithm (PSO) [11], [12] and Genetic Algorithm (GA) [13], [14]. GMO is chosen for estimating the parameters of PID due to the following advantages such as balanced exploration and exploitation, robustness, sensitivity control, scalability, convergence and divergence.

II. Methods

A. PID Tunning

The following three terms are the foundation of PID controller [1]:

- Proportional (P) term: Its purpose is to adjust the actual response $y(t)$ in accordance with the error $e(t)$ that is present between the desired response $h(t)$ and the actual response $y(t)$ at the moment as defined in (1). The magnitude of the desired correction increases with $e(t)$ increase.
- Integral (I) term: Its purpose is to modifiy the actual response $y(t)$ according to the cumulative error $e(t)$ over time. By doing this, steady state error (SSE) - $e(t)$ after a long time - is reduced.
- Derivative (D) term: Its purpose is to modify the actual response $y(t)$ according to the error's rate of change. By doing this, overshoot - which occurs when the actual response $y(t)$ is greater than the desired response $h(t)$ - is suppressed.

The combination of the three components formulate the PID controller as defind in Eq. (2)

$$e(t) = y(t) - h(t) \tag{1}$$

$$u(t) = K_p\ e(t) + K_i \int_0^t e(t)\ dt + K_d \frac{d}{dt}\ e(t) \tag{2}$$

where $u(t)$ is the output of the PID proccess.

The following time-domain characteristics are essential metrics to keep under careful observation while optimizing IAE:

- The response's rise time (tr): is the amount of time it takes to grow from 10% to 90% of its ultimate value.
- Settling time (ts): Usually expressed as an absolute percentage of the final value, such as 2% or 5%, it is the amount of time needed for the response curve to reach and stay within a given range around the final value.
- Overshooting (Mp): This is the response curve's maximum peak value, as determined by measuring it from unity or a reference point.

IAE is calculated as the summation of disparities between the desired response h(t) and the actual response y(t) during simulation time T_{sim} [1], as defined in (3).

$$IAE = \int_0^{T_{sim}} |y(t) - h(t)|\, dt \tag{3}$$

Fig. 1 shows the entire relationship between the closed loop PID controller and the calculation of its parameters using the GMO based on IAE. At first the parameters are initialized. Then IAE is calculated to decide which best PID parameters should be elected to minimize the IAE and improve the overall response of the system then the parameters are fed to PID function $G_{PID}(s)$ as defined as in Eq. (4).

$$G_{PID}(s) = K_p + \frac{K_i}{s} + K_d\ s \tag{4}$$

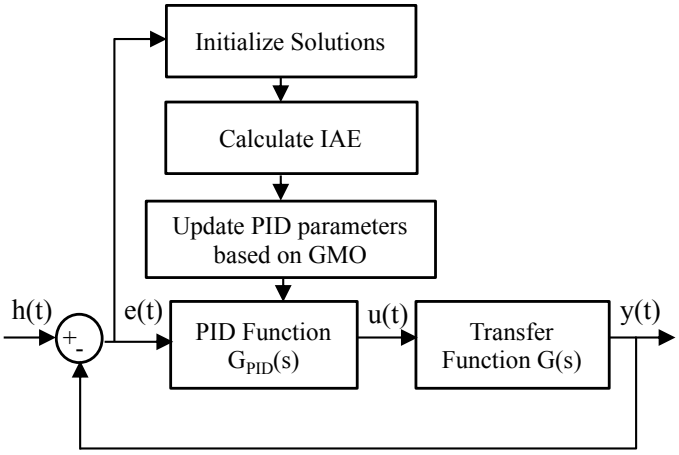

Fig. 1. Calculation of PID parameters based on GMO.

B. GMO Algorithm

GMO is a relatively new metaheuristic optimization algorithm. It is been used to optimize some problems such as [15]–[18]. GMO makes use of the special mathematical characteristics of the geometric mean. This operator allows one to assess search agents' exploration phase and exploitation at the same time. The weight of an agent in GMO is determined by taking the geometric mean of its opposites' scaled objective values (OVs). This means that an agent is appropriately regarded to direct the other agents' search process toward solving an optimization problem by considering the geometric mean of those OVs [7].The flowchart is shown in Fig. 2 and the steps in this strategy are as follows:

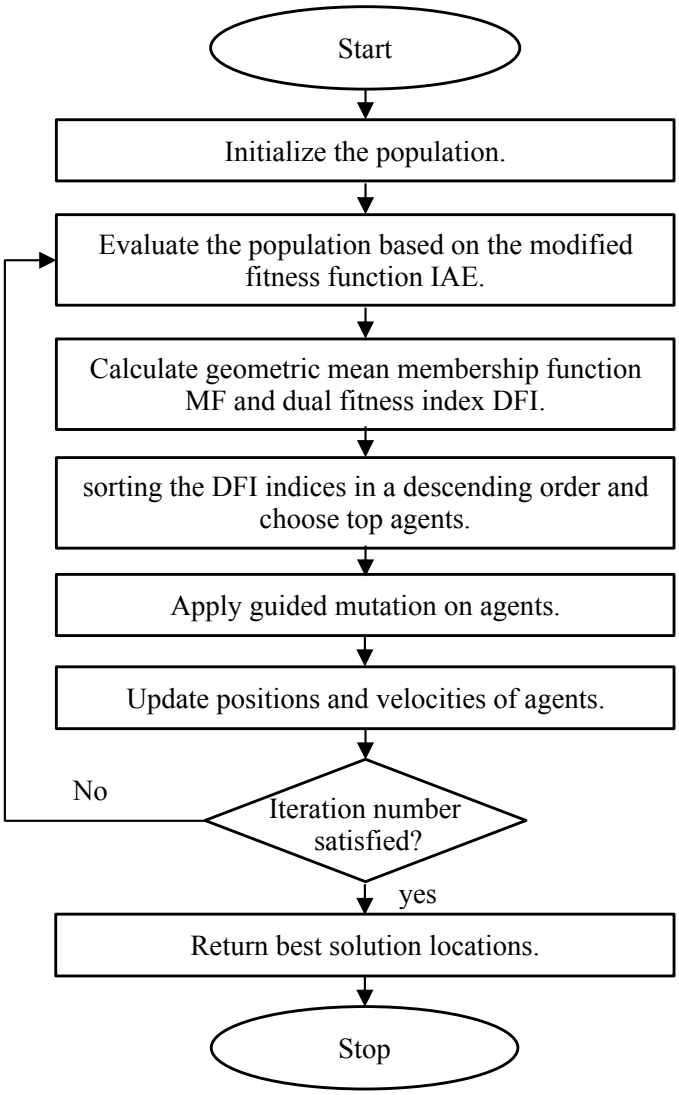

Fig. 2. Flowchart of GMO algorithm.

1) Generate the position and velocity of each searching agent randomly as defined in Eq. (5), Eq. (6).

$$x_i^0 = U\left(x_{min}, x_{max}\right) \tag{5}$$

$$v_i^0 = U(v_{min}, v_{max}) \tag{6}$$

where, $x_{min}, v_{min}, x_{max}, v_{max}$are the lower and upper bounds.

2) Determine each search agent's personal best position by computing their fitness function results as defined in Eq. (7).

$$IAE = \begin{cases} 1000, & \text{if unstable.} \\ \int_0^{T_{sim}} |y(t) - h(t)|\, dt, & \text{otherwise.} \end{cases} \tag{7}$$

a small ,however effective, modification is applied to the fitness function IAE for this problem. A penalty 1000 is applied if the resulting closed loop system is unstable. This ensures that the resulting search space is always stable.

3) Determine geometric mean of the chosen agent related to best agents fuzzy membership function (MF) and dual fitness index (DFI) as defined in Eq. (8).

$$MF_j^t = \frac{1}{1 + exp\left(-\frac{4}{\sigma^t \sqrt{e}}\right)\ \left(z_{best,j}^t - \mu^t\right)} \quad (8)$$

knowing that j loops over all agents starting from 1 to N where N is the total number of agents, $z_{best,j}^t$ is the personal best objective value of the corresponding agent, and μ^t, σ^t are the mean and standard deviation (STD) of all best-so-far agents.

4) Determine the DFI as the geometric mean of all best agents MF except that the corresponding agent as defined in Eq. (9).

$$DFI_i^t = \prod_{j=1,\ j \neq i}^{N} MF_j^t \quad (9)$$

5) Choose the first top agents (Nbest) by sorting the DFI indices in a descending order.

6) Determine the positions of the unique global guide agent calculated for the agent i at the iteration t as defined in (10).

$$Y_i^t = \frac{\sum_{j \in N_{best}, j \neq i} DFI_j^t * X_j^{best}}{\sum_{j \in N_{best}} DFI_j^t + \ \varepsilon} \quad (10)$$

where X_j^{best} is the personal best position at iteration j, and ε is either 0 or a small positive number.

7) Impose guided mutation on agents to make positions of agents more stochastic as defined in Eq. (11).

$$Y_{i,mut}^t = Y_i^t + w\ randn\ (Std_{max}^t - Std^t) \quad (11)$$

$$w = 1 - \frac{t}{T_{max}} \quad (12)$$

where Std^t is the STD calculated for the personal best-so-far agents at the tth iteration, randn is a random vector from normal distribution, and w is the mutation step as defined in Eq. (12), t is the number of the current iteration, and T_{max} is number of iterations.

8) Finally, update the positions and velocities of agents as defined in Eq. (13) to Eq. (15).

$$V_i^{t+1} = w\ V_i^t + \ \varphi\ (Y_{i,mut}^t - X_i^t) \quad (13)$$

$$\varphi = 1 + (2\ rand - 1)\ \ w \quad (14)$$

$$X_i^{t+1} = X_i^t + V_i^{t+1} \quad (15)$$

where V_i^t is the velocity vector on ith agent and tth iteration, V_i^{t+1} is the velocity at $(t+1)$th iteration, $Y_{i,mut}^t$ is global guide position for the agent i, X_i^t is a position of the i th agent's,and φ is a scaling parameter, and rand is a random number within (0,1).

III. The Experimental Results and Discussion

Experimental trials are conducted on a DC motor system in order to regulate the speed of it. It is a common subject in numerous related studies [19]–[24].

The experimental findings are compared with related results from AOA, SCA, PSO, and GA algorithms. The fitness function IAE is used to evaluate solutions. A regulated process's step response may be described by the following time-domain characteristics [1]: rising time, settling time, and overshoot.

Table I provides the parameter values for the DC motor utilized as a case study [19]. In the table, Ra denotes the armature resistance, La represents the inductance of the armature winding, J signifies the equivalent moment of inertia of the motor and load referred to the motor shaft, D stands for the equivalent friction coefficient of the motor and load referred to the motor shaft, K indicates the motor torque constant, and Kb represents the back EMF constant.

TABLE I. Parameters of DC Motor

Parameter	Value
Ra	0.4 Ω
La	2.7 H
J	0.0004 kg. m2
D	0.0022 N.m.sec / rad
K	15 e-03 kg. m / A
Kb	0.05 V.s

The transfer function that describes the open-loop speed control system of a DC motor, as expressed in (16). It completes the transfer function in Fig. 1 so that the input of the transfer function is u(t) and the output of it is y(t).

$$G(s) = \frac{15}{1.08\ s^2 + 6.1\ s + 1.63} \quad (16)$$

The speed regulation of an electrical DC motor [20] is managed through a PID controller, with heuristic algorithms employed to determine the most effective parameters for achieving optimal performance. The parameter configurations for PSO, SCA, GA, and GMO can be found in Table II. These settings are determined through experimental estimation to yield the most favorable outcomes.

Fig. 3 shows the open loop response of the DC motor. It has a rise time of 7.8251 sec., settling time of 14.1030 sec., and no overshoot. It also has a peak of velocity of 9.1960 m/sec. After running the PID controller the transient response of the system will improve and the new desired response h(t) can be set to be 9.1960 m/sec.

Table III displays the optimal parameter values for the PID controller that are determined for the purpose of enhancing the speed regulation of the DC motor. These values are achieved through the application of the GMO algorithm and are compared to results obtained from other related algorithms. The GMO algorithm is designed to optimize a single objective, specifically IAE, aiming to find the PID controller parameters that yield the lowest IAE. In addition to IAE, other performance criteria such as settling time, rise time, and overshoot

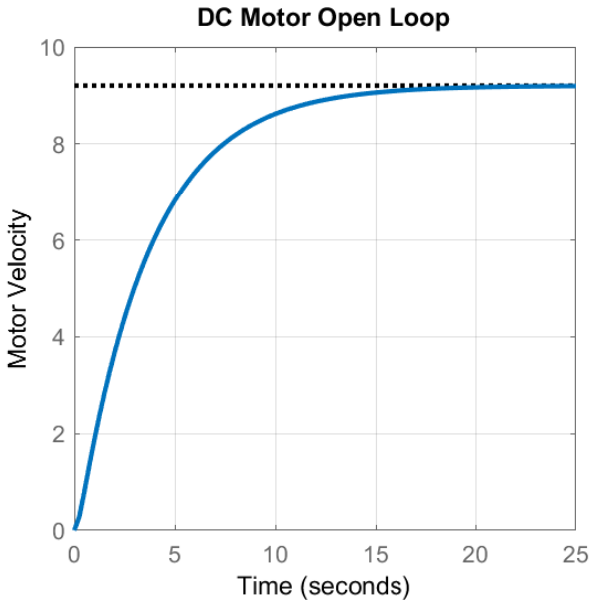

Fig. 3. DC motor open-loop behavior over time, measured in seconds.

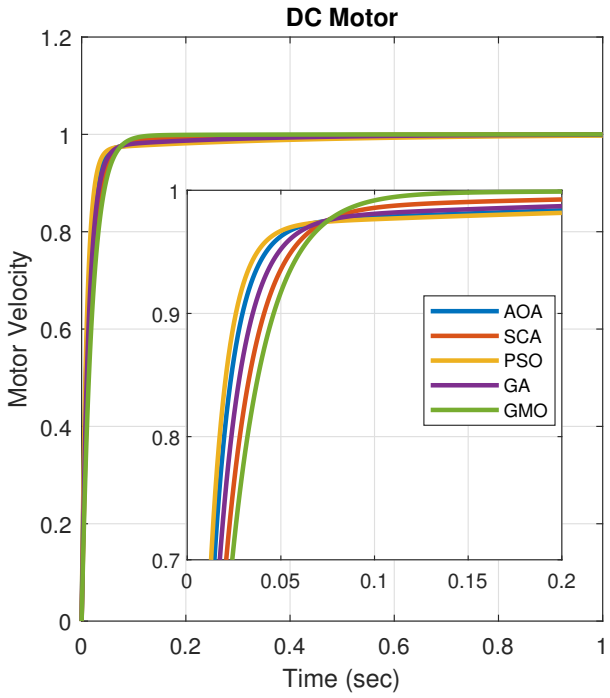

Fig. 4. DC motor behavior over time under the influence of a PID controller, measured in seconds.

TABLE II. THE CONFIGURATION OF PARAMETER SETTINGS FOR DIFFERENT ALGORITHMS APPLIED TO A DC MOTOR

	Parameter	Value
All Algorithms	The population (N)	100
	Iteration Number (T)	50
	Independent run number	20
	Upper bound of (Kp, Ki and Kd)	20
	Simulation Time (Tsim)	5 Sec.
GMO	ε	0
AOA	μ	0.5
	α	4.5
	ε	2
SCA	a	3
	r3	0.5
PSO	C1	0.5
	C2	0.5
	w	0.1

are evaluated based on the estimated parameters for GMO and the other algorithms within the comparative analysis.

For determining the best IAE, GMO outperforms other methods, as Table III and Fig. 4 demonstrate. GA is the closest rival to GMO in terms of IAE. GMO succeeds in decreasing GA's IAE demonstrating how GMO has better exploration and exploitation through the use of DFI, the geometric mean, and guided mutation.

GMO offers no overshoot for overshoot measurement. Other algorithms also succeed to have no overshoot. When overshoot happens, it suggests that the system's responses in certain situations are unfavorable. As previously indicated, the single objective function is chosen to minimize IAE rather than minimizing the settling time. However, GMO does succeed in having the least settling time which is great for the system stability.

According to Table III, GMO produces the longest rising time and PSO produces the lowest. However, from stability point of view if decreasing rising time affects the settling time or overshoot, it is favorable to make a compromise then. That's assured by Fig. 4, that GMO is the first to reach the target velocity.

The bode diagrams for controlling a DC motor using a PID controller, whose parameters are determined by GMO and the opponent algorithms, are displayed in Fig. 5 GMO has the most bandwidth. This ensures that GMO has a shorter rise time than other algorithms, as seen in Fig. 4 and Table III.

Furthermore, as seen in Fig. 5, the magnitude margin of PSO, for instance, has the highest gain compared to that of GMO, suggesting that PSO reacts more aggressively than GMO and may lead to overshooting (which does not happen here). However, GMO has the most robust response as it has least magnitude and phase margin .

It is evident from Fig. 6, which is concerned with Box Plot diagrams, that the GMO outperforms other optimization techniques when it comes to various parameters. Additionally, it demonstrates that GMO in the systems' component expansion and complexity possesses outstanding performance and convergence ability. As indicated in Table III and Fig. 6, GMO produces favorable results in every experiment carried out in terms of mean, median, and STD. It has the general least IAE, Median, Average, and STD compared to all other algorithms.

The most notable and useful benefits of GMO are its capacity to assess fitness and diversity simultaneously using

TABLE III. COMPARISON OF GMO AND DIFFERENT ALGORITHMS IN TERMS OF STEP RESPONSE AND IAE CRITERIA, RISE TIME, SETTLING TIME, AND OVERSHOOT PERCENTAGE

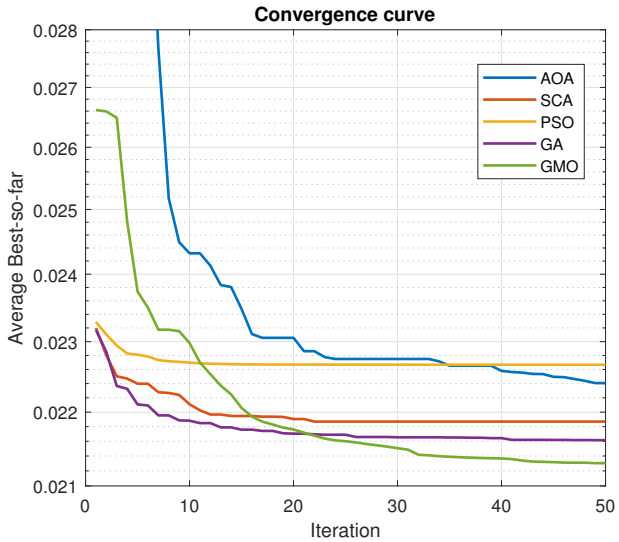

Fig. 7. Convergence curves of GMO other optimization algorithms.

the DFI, computational efficiency, not having a parameter to adjust, and assignment of multiple unique guides for each solution in order to prevent the algorithm from sticking into a local minimum.

As shown in Fig. 7 the convergence curve for GMO gradually decreases until it finds the global minimum for the fitness function. GMO has the second highest average IAE at the beginning, AOA has the first, which explains the exploration capability of GMO algorithm as compared to all other algorithms except AOA. GMO also has the lowest average IAE at the end which means that GMO has the highest exploitation capability among all other algorithms. So, GMO has the greatest balance between exploration and exploitation

which makes it the superior algorithm compared to all other algorithms.

IV. Conclusion

In this study, the Geometric Mean Optimizer (GMO) algorithm is utilized to estimate PID controller parameters for regulating a DC motor. The primary objective function is the Integral of Absolute Error (IAE). GMO demonstrated superior performance compared to other algorithms in terms of IAE and response characteristics, including overshoot, and settling time, for DC motor control. Furthermore, the frequency response analysis of GMO indicates that it achieves a more favorable bandwidth and gain magnitude margin compared to the other algorithms under comparison. Through the experimental investigation, GMO exhibits its superiority in efficiently estimating PID controller parameters, resulting in improved IAE values in the context of DC motor control. In future work, a multi-objective function may be used to enhance more than IAE objective such as rising time and overshoot. It is recommended to use this multi-objective function to enhance the performance of DC motor or any other closed loop sysytem such as three-tank system.

Blockchain-Driven Decentralization of Electronic Health Records in Saudi Arabia: An Ethereum-Based Framework for Enhanced Security and Patient Control

Atef Masmoudi[1], Maha Saeed[2]
Laboratory of Electronics and Technology of Information National Engineering School of Sfax,
University of Sfax, Sfax, Tunisia[1]
College of Computer Science, King Khalid University, Abha, Saudi Arabia[1,2]

***Abstract*—In the rapidly evolving landscape of e-HealthCare in Saudi Arabia, enhancing the security and integrity of Electronic Health Records (EHRs) is imperative. Existing systems encounter challenges stemming from centralized storage, vulnerable data integrity, susceptibility to power failures, and issues of ownership by entities other than the patients themselves. Moreover, the sharing of sensitive patient information among anonymous bodies exacerbates the vulnerability of these records. In response to these challenges, this paper advocates for the transformative potential of blockchain technology. Blockchain, with its decentralized and distributed architecture, offers a revolutionary approach to communication among network nodes, eliminating the need for a central authority. This paper proposes a solution that places the patient at the forefront, empowering them as the primary controller of their medical data. The research delves into the current state of e-HealthCare in Saudi Arabia, examines the challenges faced by existing EHR systems, and introduces blockchain technology, particularly Ethereum, as a viable and transformative solution. The paper details the use of Ethereum blockchain to secure and manage medical records, with a Public Key Infrastructure (PKI) applied to safeguard the confidentiality of patient information. The decentralized InterPlanetary File System (IPFS) is employed for the secure and resilient storage of encrypted medical records. Additionally, Smart contracts, integral to the Ethereum blockchain, play a central role in automating and enforcing the rules governing access to medical records. Moreover, a Web 3.0 decentralized application (DApp) is developed to provide a user-friendly interface, empowering patients to seamlessly interact with and control access to their health data. At the end, this paper presents a guiding framework for clinicians, policymakers, and academics, illustrating the transformative potential of blockchain and associated technologies in revolutionizing EHR management in Saudi Arabia's healthcare systems.**

***Keywords*—Blockchain; Ethereum; smart contract; Web 3.0; decentralized application; electronic health records**

I. Introduction

The progression of technology in the modern era has significantly altered human perspectives and lifestyles. Technological advancements extend their influence to various facets of life, including healthcare, with the primary goal of transforming and enhancing the sector. In the healthcare realm, technology offers substantial benefits, revolutionizing systems for improved ease of use, security, and overall efficiency. One such advancement that has played a pivotal role is the implementation of Electronic Medical Record (EMR) systems.

Before the advent of EMR systems, hospitals relied on handwritten documentation on paper, leading to data loss and patient challenges in updating records across different healthcare facilities. Recognizing the limitations of this approach, the healthcare sector embraced EMR systems, providing a transformative solution by storing data electronically and reducing reliance on paper. These electronic records encompass clinical notes and comprehensive laboratory results with multiple components [1]. This shift addressed prevailing issues in medical record management, enhancing information accessibility [2], error prevention, and the establishment of an adaptable system that could evolve over time [3]. Consequently, the adoption of EMR systems emphasizing enhanced usability, streamlined data retrieval, efficient updates, and overall improved data management processes, making them pivotal in modernizing healthcare practices.

However, despite the intended improvements in patient care, EMR systems encountered critical challenges, falling short of expectations [3]. Issues such as data security, integrity, and user ownership emerged as significant concerns. A study conducted in four academic hospitals in Saudi Arabia revealed that EMR systems faced reliability issues, particularly insecure access to records [3]. Furthermore, vulnerability to data breaches became evident, with a study reporting 173 million data breaches since October 2009 [4]. Compounding the challenges were issues of data duplication and the need for repetitive medical examinations when patients visited different hospitals [5]. The cumulative impact of these challenges emphasized the necessity for a secure, interoperable, and patient-centric healthcare data management system.

In response to these challenges, this paper advocates for the transformation of the healthcare sector into a patient-centered model using blockchain technology. Blockchain has the potential to revolutionize data control and management within existing EMR systems. The paper focuses on the Saudi Arabian context, proposing the utilization of the blockchain platform, IPFS (InterPlanetary File System), and smart contracts to address the prevalent issues in medical records. The proposed solution aims to empower patients by enabling them to control, protect, and share their medical data securely.

Smart contracts, defining the roles of participating entities, have been developed and tested to govern transactions and monitor procedures carried out on the EMRs. This research seeks to demonstrate the efficacy of blockchain in mitigating challenges associated with medical records in Saudi Arabia, ultimately fostering a more secure, patient-centric healthcare data management paradigm.

The subsequent sections of the paper are structured as follows: Section II provides a background review, offering a concise explanation of blockchain technology. In Section III, previous studies relevant to our research project are discussed. Section IV outlines the proposed solution, presenting the methodology employed. Section V delves into the smart contract functions, detailing the specific functionalities implemented in the Ethereum-based framework. Following this, Section VI discusses the findings and implications in the context of the proposed solution. Finally, Section VII encompasses the conclusion.

II. Background

This section serves as a foundational guide, introducing key elements of the proposed research. We delve into blockchain technology, its decentralized architecture, and the pivotal role played by Peer-to-Peer (P2P) networks. Types of blockchains, including a focus on Ethereum blockchain, are explored, shedding light on their unique characteristics. The Ethereum blockchain, with its support for smart contracts and decentralized applications (DApps), emerges as a prominent player in this space. The significance of smart contracts in executing predefined rules on the blockchain is emphasized, highlighting their transformative potential. Additionally, we delve into the essential role of consensus protocols in governing the validation of transactions and maintaining the integrity of the blockchain. The section also explores the transformative IPFS, acknowledging its importance in reducing storage costs and providing an extra layer of privacy through data encryption. This comprehensive background lays the groundwork for understanding the technological choices and components integral to our research.

A. Blockchain Technology

Nakamoto is the name of the person who invented the blockchain technology [6]. His idea was based on creating a decentralized and encrypted currency to be used in financial transactions. Eventually, this technology was used in many different areas of life [7], such as the healthcare sector. A lot of research was conducted to study of applying blockchain technology to the current healthcare systems, and this research has reached to identify the pros and cons related to the use of this technology.

The benefit of using a blockchain is to facilitate the exchange of transactions between two parties without the need for an intermediary [6]. The process begins with creating a block whose hash is linked to the hash of previous block, and this method is repeated until the chain is complete. Each block in the blockchain includes records of transactions which will be verified by so-called miners. The contents of the block include previous block hash, timestamp, data, and nonce, collectively forming a secure and transparent ledger [8], [9]. The transaction could be data of any data type and the use of nonce is to control of the hash that is generated from the block. All these components will be hashed together to represent a block.

1) P2P network: A peer, which is a node in the blockchain network, contributes resources including storage, processing power, and bandwidth. These nodes are either for specific people or is available to everyone on blockchain because there are multiple types of blockchain network (as will be explained later). The most important characteristic of the nodes in the blockchain network is that the identity of each node remains safe, due to the public key belonging to each user is visible only to other peers in the network. The nodes also act as miners to verify the transaction before adding it to the chain.

2) Role of miners: As mentioned earlier, the miner's job is to verify the block before adding it to the blockchain network [10]. This does not guarantee the eligibility of the transaction, but rather to perform other additional work after that, which is called Proof-of-Work (PoW). Nonce will create a hash value that is less than the target difficulty level, and this is done through the PoW process. Then it is solved in a short period of time when the miner approaches the value below the target to get the rewards.

B. Types of Blockchain

Currently, there are three types of blockchain, depending on features such as network size, application, and type of algorithms, as follows:

1) Public blockchain: The public blockchain network is available for access by anyone on the network, and after joining, he can access the blocks' data and become authorized to mine. The use of pseudo-anonymous hash value is to create unique address to identify the users even in the public type of blockchain networks. Thus, people in the network are known by their addresses, not by their actual identity. And when someone wants to interact, such as adding or download a document such as EMRs, he must pay the costs of this interaction (transaction fees).

2) Private blockchain: Private and public blockchains are similar in many aspects such as process and algorithms, but the difference lies in the purpose. A private blockchain network is defined as a restrictive network, as it is designed in proportion to closed networks and based on the element of access control. Private blockchain networks are usually used for small businesses where the nodes are controlled to perform transactions and execute smart contracts. This type is used in many applications that require privacy and security, such as digital asset management, online voting, and supply chain management. In addition, the private blockchain networks require the approval from network administrators to allow people to join.

3) Consortium blockchain: Consortium blockchain networks combine the features of centralized and decentralized systems. Instead of being used to serve a single organization, the consortium blockchain is used on a large scale and in many organizations. This type is similar to private blockchain in that no one can access the network directly without registering, as that the approval of other organizations is required to perform any operation.

C. The Consensus Protocols

Blockchain, at its core, relies on consensus protocols [11] to ensure agreement among distributed participants on the state of the ledger. These protocols dictate how nodes or participants in a network reach a unanimous decision on the validity of transactions and the order in which they are added to the blockchain. The consensus mechanisms underpin the fundamental principles of trust, security, and decentralization in blockchain technology.

The choice of the consensus protocol is essential for designing blockchain systems tailored to specific use cases, whether in public, private, or consortium settings. It influences the network's characteristics, including security, efficiency, and governance, shaping the overall success and adoption of blockchain technology.

The most pivotal consensus mechanisms that have shaped the development of blockchain are:

1) PoW: PoW is a consensus algorithm widely employed in public blockchain networks like Ethereum. In this model, miners engage in solving complex mathematical puzzles, and the first to solve it gains the privilege to add a new block to the blockchain. While PoW ensures decentralization and robust security, its drawback lies in its energy-intensive nature, a concern that has prompted the exploration of alternative consensus mechanisms.

2) Proof of Stake (PoS): PoS is an alternative consensus algorithm where validators are chosen to create new blocks based on the amount of cryptocurrency they hold and are willing to "stake" as collateral. This approach, compared to PoW, offers a more energy-efficient solution. Participants are incentivized to act in the best interest of the network by risking their held cryptocurrency as collateral.

3) Proof of Authority (PoA): In the context of private blockchain networks, PoA emerges as a compelling consensus algorithm. Unlike PoW and PoS, PoA does not rely on competitive mining or staking. Instead, network participants, often identified and reputable entities, are designated as authorities. These authorities validate transactions, offering a more efficient and scalable solution for private consortium networks.

D. IPFS

The IPFS [12], [13], [14] stands as a revolutionary solution in healthcare data management, offering a distributed file system shared through a P2P network. In the context of storing medical records on the blockchain, IPFS plays a pivotal role in significantly reducing storage costs. Instead of storing voluminous medical data directly on the blockchain, IPFS allows for the storage of a unique hash that represents the content's identity. This hash serves as a pointer to the actual data stored in the IPFS network, optimizing the efficiency of the overall system.

Furthermore, the IPFS introduces an additional layer of privacy by enabling the encryption of data. This ensures that sensitive medical information remains confidential and secure throughout its lifecycle within the decentralized network. The ability to encrypt data in IPFS not only aligns with privacy regulations but also addresses the paramount importance of safeguarding patient information in healthcare settings.

In essence, by leveraging IPFS in conjunction with blockchain technology, the proposed framework not only enhances data security but also demonstrates a cost-effective approach to managing medical records. This integration allows for the creation of a robust and efficient healthcare data management system, aligning with the evolving needs of the healthcare sector in Saudi Arabia.

E. Ethereum Blockchain

Ethereum [15] stands as a pioneering blockchain platform renowned for its versatility in deploying DApps and smart contracts. Unlike Bitcoin, Ethereum extends beyond a mere cryptocurrency framework, providing a comprehensive environment for executing complex decentralized applications.

1) Smart Contract: The concept of smart contracts was introduced in 1997 by Nick Szabo [16], to conduct digital transactions securely over a network. Smart contracts [17], [18] are applications that are executed by people joining the blockchain network. Smart contracts are written by computer codes to implement pre-defined rules and conditions to keep transactions controlled. Current examples of projects based on the use of smart contracts [19] are the Ethereum platform and Hyperledger. These platforms allow transactions to be conducted reliably between anonymous parties without the need for a central authority. The Ethereum platform enables the creation of smart contracts tailored to the specific needs of any system within the network. The Ethereum uses Ether as a cryptocurrency. As for the term gas, it is used to measure the cost of any function that takes place in the smart contract. With regard to medical records, smart contracts allow the secure and reliable exchange of records.

2) Geth (Go Ethereum): Geth serves as the official Go implementation of the Ethereum protocol. As a command-line interface tool, Geth facilitates interaction with the Ethereum network, enabling users to run a local Ethereum node, mine Ether, and interact with smart contracts. Geth plays a pivotal role in supporting the infrastructure of the Ethereum blockchain.

3) DApps: Decentralized applications [20], [21], or DApps, represent a new paradigm in application development. Unlike traditional applications that rely on centralized servers, DApps leverage blockchain technology, ensuring decentralized, transparent, and secure operations. These applications run on a P2P network of computers, eliminating the need for intermediaries and fostering a trustless environment.

III. Literature Review

In Estonia, the entire public health infrastructure is being operated using blockchain [22]. Through the application of blockchain technology, the coasts of medical records will be reduced for the patient and other interested parties. Estonia is one of the first countries that uses blockchain technology in most government and commercial sector. The Estonian government has started making GovTech partnerships to apply blockchain to all industries in the region, so that the country become advanced in the field of technology.

Xia et al. [23], proposed a MeDShare system that addresses sharing a big data of medical records among a trust-less

environments. The system uses cloud services along with blockchain technology to store big data. The procedures start on MeDShare system by transferring data side by side from one entity to another and then recorded it in a tamper-proof manner. One of the advantages of the system is that when the permissions are violated, data access is canceled using a control mechanism designed by smart contracts. The system consists of four layers: First, user layer, which can access the data for research purposes. Second layer has a several of functions such as query, process, and respond to other queries on the system. Third layer, it process data requests in the infrastructure layer and performs computational operations on the data that was requested with the ability to monitor it, and this layer called data Structuring and Provenance layer. Fourth layer, existing databases that individual parties work on to accomplish certain tasks. This system guarantees data security by applying smart contracts. MeDShare system can be compared with the current systems that use cloud services. However, this system still depends on a third party.

Daraghmi et al. [24], suggested a MedChain system for managing EMRs. In this approach, the healthcare provider is responsible for creating, verifying, and adding new blocks to the blockchain, as well as allowing the patient to control their own data and granting or denying access to it. Smart contracts are written to control transaction times and monitor operations performed on medical records. Experiments conducted on MedChain system showed the efficiency of the proposal in response time, connection times and dealing with large data set. However, this system may encounter problems related to the fact that the database is central and pre-existing.

Dubovitskaya et al. [25], proposed a system to help cancer patients manage their medical records using the blockchain network. The role of the doctor and the patient is determined through membership service, through which the system verifies any doctor who joins the system, whether he is registered in the National Practitioner Data Bank or not. The patient's medical record and encryption keys are also signed with the membership service to ensure confidentiality. Th data is then stored in the hospital database and in the cloud to grant access to other individuals in the network. A patient key is used to encrypt their data before it is stored in the cloud. The user is provided with an application programming interface (API) that transmits actions from the user to the nodes that are organized by the leader node to initiate the consensus protocol. However, as a result of storing data locally in hospitals and using cloud services, the patients cannot fully control their data, and this is one of the limitations that must be considered in this system.

Abid et al. [26], proposed NovidChain system to issue and verify the COVID-19 test/vaccine certificate using a private Blockchain network. They used a number of emerging technologies such as self-sovereign Identity platform called uPort. uPort is a mobile application that serves as an authentication mechanism for decentralized applications. They used IPFS to store data off-chain after it's encryption. The main process of NovidChain begins with Healthcare provider registration and service provider by creating an account on a self-managed Blockchain wallet then send the public key to the account belong to the healthcare authority. The healthcare authority then check if the Healthcare provider authorized or not, then adds his account to the blockchain. Next the user must create a Blockchain account and install a self-managed Blockchain wallet for the healthcare provider to verify the user's official ID. After that, the user becomes eligible to get the COVID-19 vaccine from a Healthcare provider. The data is then encrypted, and its hash is stored in the blockchain. Finally, official physical ID is presented with a QR code to verify the health status of the individual in the registration step. They also explained that the NovidChain system ensures self-sovereign identity (SSI), as they adopted decentralized IDs (DIDs) for countersigning, signing and verifying COVID-19 credentials.

Sun et al. [27], proposed a system for sharing and storing medical records using smart contract technology. The system begins with encrypting the medical record by the doctor, adjusting the appropriate access settings, and then storing the encrypted record on IPFS. They demonstrate the benefit of using IPFS with blockchain technology in enabling healthcare providers to process and store a greater amount of medical data on IPFS rather than on the blockchain itself for savings in network bandwidth. After the medical records are encrypted and stored in the IPFS, they create an index of keywords to use in searching the encrypted records. Index words are stored in the Ethereum blockchain, where they can be accessed after the smart contract is published which in turn defines the way to access it in the distributed system.

Azaria et al. [28] proposed MedRec that enables patients to check a log of their health records. They used Ethereum's smart contracts to represent the data stored into individual nodes on the network. They used metadata about the medical record ownership, data integrity, and permissions by writing contracts. To deal with these properties, blockchain transactions carry signed and encrypted instructions for dealing with big data, and then the system inserts them into the blockchain network using three main types of contracts: First, Registrar Contract (RC), to link the Ethereum address identity with the corresponding identification strings, then change existing identities and organize the registration of new ones and append identity strings to the blockchain. Second, Patient-Provider Relationship Contract (PPR): which symbolizes any pairwise data stewardship interaction. Third, Summary Contract (SC): to determine medical record history by identifying the previous and current links of the participant with other nodes in the system.

Marcela et al. [29] proposed a hybrid system for protecting patient data privacy that involves combining blockchain technology with public key infrastructure. They store medical data on the blockchain using secret session keys. Initially, the digital certificate defines the main roles in the system. After the patient data and the session key are stored in the blockchain, these data are sent to the doctor, to ensure that the patient is the primary controller of access to his data. The second role is the role of the doctor, who can send and receive the patient's session key, but doctors are not authorized to share the session key among themselves. There is a pair of public and private keys that must be present for every user on the system so that every transaction made on the blockchain is assigned to the actor by the public and private keys of both the doctor and the patient shown in their certifications. To keep the security kernel of their proposal, they design their approach as a private permissioned network. In order to ensure the consistency and availability of transactions, the system converts the consensus

protocol to a three-phase commit protocol. The result showed that the transaction overload is appropriate compared to the number of transactions on the blockchain.

Sammeta et al. [30] developed a new model for transferring patient's data as well as making a diagnosis, called HBESDM-DLD model. The idea of this model is to take advantage of the Hyperledger blockchain-based in managing many orations such as encryption, data management, diagnosis, and optimal key generation. Firstly, the GTOA-based optimal key generation technique plus SIMON technology are used to encrypt the patient's medical data. Whether or not the patient is allowed to access to medical institutions is determined by the specific policy imposed by the global and local blockchain in partnership with the Hyperledger blockchain.

Azbeg et al. [31] presented a system named BlockMedCare which uses a set of technologies in addition to Blockchain, such as IoT and IPFS to manage health systems related to chronic diseases. The approach consists of three main sections patient side, medical team side and IPFS side. Initially, the patient's IoT device is registered using the owner's identity and MAC address on the blockchain network to identify the patient, and then the data collected from the patient's device is shared with the specialized medical team through the patient's smartphone. Hospitals also store a copy of the blockchain in addition to their ability to participate in the consensus process. The system enables the medical team to use patient data for procedures other than monitoring, including analysis and research. IPFS is used to store data as IoT devices collect a huge amount of data that cannot be stored only using blockchain. The system is used Clique PoA as a consensus algorithm to reach agreement and using the proxy re-encryption mechanism in addition to blockchain features to maintain the security of the system.

Alternative methods for leveraging blockchain in the management of medical records are detailed in [32], [33], [34].

IV. Proposed Solution

In response to the evolving landscape of healthcare digitization in Saudi Arabia, this research presents a holistic solution aimed at revolutionizing the management of EHRs. The proposed system integrates a private Ethereum blockchain, a private IPFS, and a DApp developed using React with web3.js integration. The system architecture adopts a PoA consensus mechanism, utilizing the Geth client for Ethereum, and JSON-RPC for communication. This multifaceted approach aims to address the existing challenges in terms of security, scalability, and user accessibility within the Saudi Arabian healthcare ecosystem.

Fig. 1 illustrates the blockchain-based framework designed to enhance security and empowering patients with control over their medical records.

A. Blockchain Infrastructure

This section introduces the foundational elements that shape the proposed blockchain-based healthcare management system. Central to this infrastructure is the adoption of a private Ethereum blockchain, leveraging a PoA consensus mechanism for enhanced efficiency and security. This choice aligns with

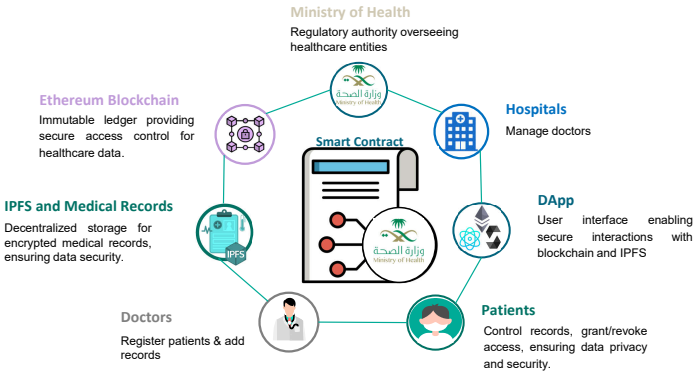

Fig. 1. The proposed blockchain-based framework to enhance security and afford patients control over their medical records.

the sensitive nature of healthcare data, emphasizing privacy and trust. The node structure mirrors the Saudi Arabian healthcare system, strategically designating healthcare authorities, hospitals, and clinics as nodes, ensuring compatibility with the existing infrastructure. Smart contracts form the core of the system, defining hierarchical rules for entity registration, with the Ministry of Health holding registration authority over Local Health Authorities, which, in turn, register entities such as hospitals and clinics. This controlled registration mechanism, cascading from higher to lower authorities, mitigates security risks. The DApp, built on the React framework, acts as the user interface, seamlessly integrating with the Ethereum blockchain through the web3.js library. This DApp serves as a user-friendly gateway for healthcare authorities, doctors, and patients to manage registrations, access medical records, and interact with smart contracts. The subsequent discussions in the section delve into the encryption and IPFS integration processes, ensuring the secure issuance and storage of patients' medical records.

The different elements that shape the proposed blockchain-based healthcare management system are:

- Private Ethereum network: The proposed system adopts a private Ethereum blockchain to ensure data security and privacy. Leveraging a PoA consensus mechanism enhances the overall efficiency of the network. Unlike public blockchains, PoA networks consist of a known set of nodes, each with a proven identity, reducing the risk of malicious activities. This choice aligns with the sensitivity of healthcare data, emphasizing confidentiality and trust among participating entities.
- Node structure: Nodes within the private Ethereum network are strategically structured to mirror the Saudi Arabian healthcare system. Healthcare authorities, hospitals and clinics are designated as nodes. This design not only aligns with the existing healthcare infrastructure but also facilitates scalability and streamlined interactions.
- Smart contracts: At the core of the proposed system are smart contracts that define the rules and interactions within the healthcare network. These contracts account for the hierarchical structure of healthcare

authorities, wherein only higher authorities possess the privilege to register the different entities. The Ministry of Health holds the authority to register Local Health Authorities, which, in turn, have the capability to register various healthcare entities such as hospitals and clinics. Within this framework, hospitals and clinics are empowered to register doctors, and once registered, doctors assume the responsibility of registering patients. This registration mechanism ensures a controlled and secure onboarding process, mitigating risks associated with unauthorized access and denial-of-service (DOS) attacks.

- DApp: The user interface of the proposed system is developed as a decentralized application using the React framework. This DApp integrates with the Ethereum blockchain through the web3.js library, providing a user-friendly experience for healthcare authorities, doctors, and patients. The DApp serves as the gateway for managing registrations, accessing medical records, and interacting with smart contracts seamlessly.
- Encryption and IPFS integration: The is the pivotal aspects of ensuring the confidentiality and integrity of medical records within the proposed system. To achieve this, a robust encryption mechanism is employed, safeguarding the sensitive patient information contained in medical records. The encryption process involves the generation of a unique symmetric key for each medical record, ensuring that access is restricted to authorized entities only. These encrypted medical records are then securely stored on the IPFS. The integration with IPFS not only enhances data availability and reliability but also significantly reduces storage costs in the blockchain. This combination of encryption and IPFS integration establishes a secure and efficient framework for handling and storing medical records, ensuring the utmost privacy and integrity of patient information.

B. The Patient Registration Flow

To enable a doctor to register a patient through the DApp, including the creation and communication of account details to the patient, and the addition of the patient to the list of patients in the blockchain using the corresponding smart contract, a multi-step process is implemented. Below are the detailed steps:

The detailed patient registration flow, as presented in Fig. 2, is as follows:

1) Doctor initiates registration: The doctor, using the DApp, initiates the registration process for a specific patient.
2) Patient details entry by doctor: The doctor enters the necessary patient details into the DApp. This could include the patient's national ID, name, date of birth, and any other required information.
3) Generate Ethereum account: The DApp generates a new Ethereum account for the patient, including the Ethereum address and private key.
4) Register the patient: The DApp interacts with the smart contract on the private Ethereum blockchain.

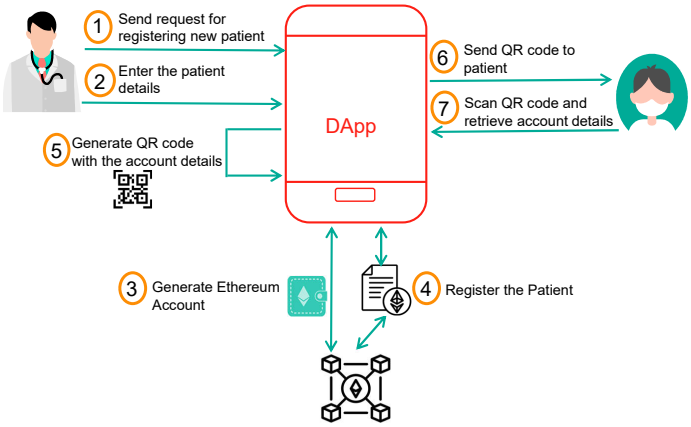

Fig. 2. The patient registration flow.

The smart contract includes a function to add a new patient to the list of patients, recording their their relevant details.
5) QR code generation: The DApp generates a QR code containing the Ethereum account details along with the patient's information.
6) DApp provides QR code to patient: The DApp communicates the generated QR code to the patient by sending it through a secure channel.
7) Patient scans QR code: The patient uses a mobile device to scan the QR code and extract the Ethereum account details (address and private key). Then, the patient securely stores the Ethereum account details.

Following these steps, patient registration is completed, ensuring secure access to their Ethereum account for interactions with the private blockchain. It's essential to highlight that the patient's access is confined to their individual medical records, with interactions strictly governed by the smart contract.

C. The Patient's Medical Record Issuing Flow

Ensuring the confidentiality and integrity of medical records is a pivotal aspect of the proposed system. The process of issuing a patient's medical record and storing it on IPFS involves series of secure steps. These steps are described in Fig. 3 and detailed as follows:

1) Medical record upload: The process begins with the doctor initiating the upload of the patient's medical record to the blockchain.
2) Symmetric key generation: The DApp generates a unique symmetric key for each patient and for each new diagnosis. This approach ensures that access to medical records is controlled and traceable.
3) Record encryption: The patient's medical record is encrypted using the generated symmetric key. This encryption guarantees that only authorized entities can decipher and access the sensitive information.
4) IPFS upload: The encrypted medical record documents are securely uploaded to the IPFS network and the corresponding Content Identifier (CID) is then generated. This step enhances confidentiality, data integrity and accessibility.

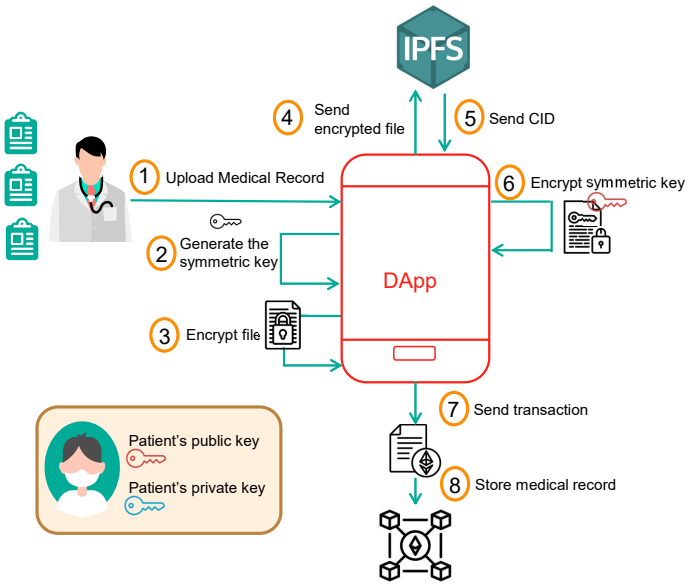

Fig. 3. Medical records issuing.

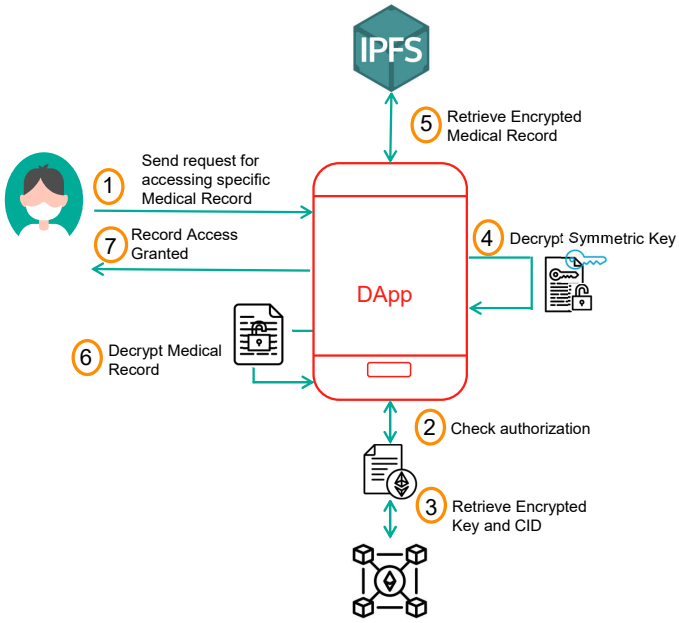

Fig. 4. The retrieval flow for the patient's medical record.

5) Send CID to DApp: The CID generated by IPFS is sent to the DApp, creating a reference point for accessing the complete medical record.
6) Key encryption: The symmetric key undergoes encryption with the patient's public key, sourced from their securely stored data on the blockchain. This step reinforces data security, ensuring that only the patient possesses the means to decrypt their medical records.
7) Initiate transaction: To securely store the encrypted symmetric key and the IPFS CID for every new set of patient medical records, it is imperative to initiate a new transaction on the blockchain through the execution of a smart contract.
8) Blockchain storage: This method ensures the immutability of both the key and CID associated with each medical record, thereby streamlining the secure retrieval of data from the IPFS.

D. The Medical Record Retrieval Flow

This section provides a detailed exploration of the steps involved in patients accessing their medical records within the proposed blockchain-based healthcare management system. Illustrated through Fig. 4, this section explains how patients can securely retrieve their medical information using the DApp, emphasizing the integration of security measures and a user-friendly interface for a controlled and confidential experience.

The steps involved in the medical records retrieving process are:

1) Initiate request: The patient or an authorized entity initiates a request for accessing specific medical records stored on the blockchain.
2) Authenticate identity: The system authenticates the identity of the requester, ensuring that only authorized individuals or entities can proceed with the retrieval process.
3) Retrieve encrypted key and CID: The DApp retrieves both the encrypted symmetric key and the CID associated with the requested medical record, which were initially stored in the blockchain during the record creation process.
4) Decrypt symmetric key: The requester, possessing the necessary decryption capabilities, decrypts the symmetric key using their private key. This step ensures secure access to the encrypted medical record.
5) Retrieve encrypted medical record from IPFS: The authorized party communicates with IPFS using the CID to retrieve the corresponding encrypted medical record from storage.
6) Decrypt medical record: The decrypted symmetric key is applied to decrypt the medical record, revealing the patient's health information in its original form.
7) Record access granted: The authorized entity now has access to the patient's medical record, facilitating the retrieval process securely and efficiently.

This comprehensive process ensures that sensitive health data remains confidential, with access granted only to authenticated and authorized entities while maintaining the integrity of the information stored on the blockchain and IPFS.

E. Granting Authorization to Patient's Medical Records

This section unveils the steps involved when patients grant access to their medical records to authorized entities. Illustrated through Fig. 5, this section elucidates the steps and security measures embedded in the process, ensuring controlled and secure access permissions for healthcare practitioners and authorized entities.

The detailed steps for granting access to patient's medical records are:

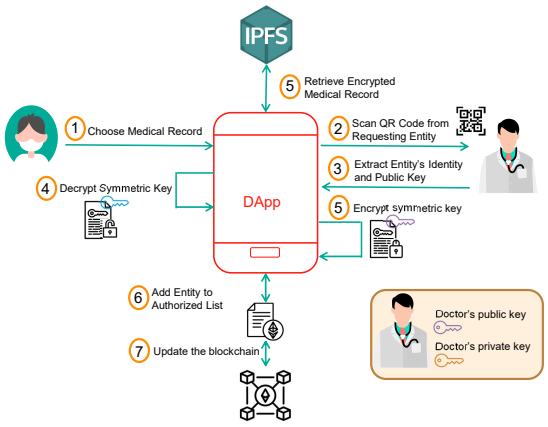

Fig. 5. Flow of authorizing access to patient's medical records.

1) Choose medical records: The DApp displays a list of the patient's health records. The patient initiates the process by selecting specific medical records for which access is to be granted.
2) Scan QR code from requesting entity: The patient scans the QR code provided by the entity requesting access to the medical records.
3) Extract entity's identity and public key: From the scanned QR code, the patient extracts information about the requesting entity's identity. The public key of the entity is retrieved from the QR code.
4) Decrypt symmetric key with patient's private key: The patient decrypts the symmetric key associated with the requested medical record using their own private key.
5) Encrypt symmetric key with entity's public key: The patient takes the decrypted symmetric key and encrypts it using the public key of the requesting entity.
6) Add entity to authorized list: The patient adds the address (identity) of the requesting entity to the list of authorized entities for the specific medical record, along with the encrypted symmetric key, now tied to the entity's public key.
7) Update blockchain: The blockchain is updated with the changes, reflecting the newly added entity to the authorized list and the associated encrypted symmetric key. This ensures a transparent and immutable record of access permissions.

This flow outlines the patient's actions, the interaction with the requesting entity, encryption and decryption processes, and the retrieval of medical records from the IPFS. The use of public and private keys, along with the secure exchange of encrypted symmetric keys, ensures controlled access to patient data while maintaining its confidentiality and integrity.

V. Smart Contract Functions

In this section, we delve into the heart of the proposed blockchain-based healthcare system's architecture-the implementation of our smart contract using the Solidity programming language. This smart contract encapsulate the rules and interactions governing the entire healthcare network. We explore the key functions embedded in these contract, each meticulously designed to manage entity registrations, handle medical records, and enforce access control. The transparency and immutability of blockchain technology, combined with the programmability of smart contract, form the backbone of the secure and efficient healthcare infrastructure we propose.

A. Implementation of the Entities Registration Process

```
// SPDX-License-Identifier: MIT
pragma solidity >=0.6.12 <0.9.0;

contract HealthRecords {

    address public ministryAddress;

    enum EntityType { MinistryOfHealth,
        LocalAuthority, Hospital, Clinic, Doctor }

    struct Entity {
        string name;
        address entityAddress;
        address registeringEntity;
        EntityType entityType;
    }

    mapping(address => Entity) public entities;
    mapping(address => bool) public
        isEntityRegistered;
    mapping(EntityType => mapping(EntityType => bool
        )) public entityRegistrationPermissions;

    constructor() {
        ministryAddress = msg.sender;
        isEntityRegistered[msg.sender] = true;
        entities[msg.sender].name = "
            MinistryOfHealth" ;
        entities[msg.sender].entityAddress =
            ministryAddress;
        entities[msg.sender].registeringEntity =
            ministryAddress;
        entities[msg.sender].entityType = EntityType
            .MinistryOfHealth;
    }
```

Listing 1: Entities and Constructor

```
    modifier onlyMinistryOfHealth() {
        require(msg.sender == ministryAddress, "Only
             the Ministry of Health can call this
            function");
        _;
    }

    modifier onlyDoctor() {
        require(isDoctorRegistered[msg.sender], "
            Only a Doctor can call this function");
        _;
    }

    modifier onlyPatient() {
        require(isPatientRegistered[msg.sender], "
            Only a Patient can call this function");
        _;
    }

  // Modifier for checking entity registration
      permission
  modifier onlyAllowedEntity(EntityType
      registeringEntityType, EntityType entityType)
      {
    require(entityRegistrationPermissions[
        registeringEntityType][entityType], "Entity
        registration not allowed");
```

```
    _;
}
```

Listing 2: List of modifiers

```
  // New function for setting entity registration permissions
    function setEntityRegistrationPermission(EntityType registeringEntityType, EntityType entityType, bool permission)
        external
        onlyMinistryOfHealth
    {
        entityRegistrationPermissions[registeringEntityType][entityType] = permission;
    }

function registerEntity(
    string memory _name,
    EntityType _entityType,
    address _entityAddress
) external onlyAllowedEntity(entities[msg.sender].entityType, _entityType) {
    require(!isEntityRegistered[_entityAddress], "Entity is already registered");

    Entity memory newEntity = Entity({
        name: _name,
        entityAddress: _entityAddress,  // Address of the entity being registered
        registeringEntity: msg.sender,   // Address of the entity initiating the registration
        entityType: _entityType
    });

    entities[_entityAddress] = newEntity;
    isEntityRegistered[_entityAddress] = true;
}
```

Listing 3: Process for registering entities

After deploying the smart contract, the pivotal setEntityRegistrationPermission function comes into play for configuring permissions in the entity registration process. The initial phase entails granting authorization to the Ministry of Health, empowering it to add local authorities, hospitals, or any other entities. This authorization can be established by either hardcoding it within the constructor or invoking the setEntityRegistrationPermission function, given that the Ministry of Health is exclusively empowered to define permissions, as ensured by the onlyMinistryOfHealth modifier. In the illustrated example showcased in Fig. 6, the Ministry of Health (enumerated as zero in the entities enum type within the smart contract) is accorded the privilege to add hospitals, denoted by the number two.

Fig. 6. Set entity registration permission.

Once the Ministry of Health has been granted the capability to add hospitals, the subsequent step involves registering the hospital's information and incorporating it into the list of hospitals. This is achieved by interacting with the smart contract through the invocation of the registerEntity function, as exemplified in Fig. 7. The crux of this process lies in the _entityAddress parameter, serving as the unique identifier for the hospital, corresponding to its blockchain address encapsulating account information. This identical procedure is employed for registering various entities, ensuring the permission to register a specific entity type through the onlyAllowedEntity modifier, inputting the entity details, and subsequently adding it to the blockchain via a smart contract request.

Fig. 7. Hospital registration.

The DApp interfaces play a crucial role in facilitating seamless interactions between different entities within the proposed blockchain-based healthcare management system. The interfaces for the Ministry of Health empower it to oversee and regulate the registration process of various healthcare entities. Through the interface presented in Fig. 8, the Ministry of Health gains the ability to list all registered entities, ensuring transparency in the system. Moreover, it can set permissions for entity registration, as shown in Fig. 9, enabling fine-grained control over the onboarding process. These functionalities empower the Ministry of Health to maintain a structured and secure healthcare ecosystem.

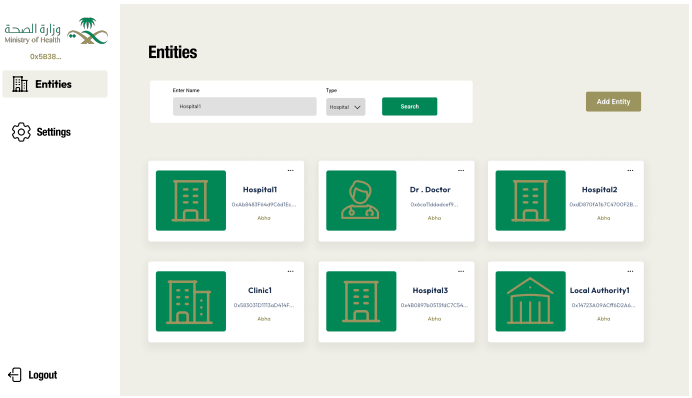

Fig. 8. List of entities

B. Implementation of the Doctors Registration Process

```
struct Doctor {
        string name;
        string phoneNumber;
        address doctorAddress; // Ethereum account address of the doctor
```

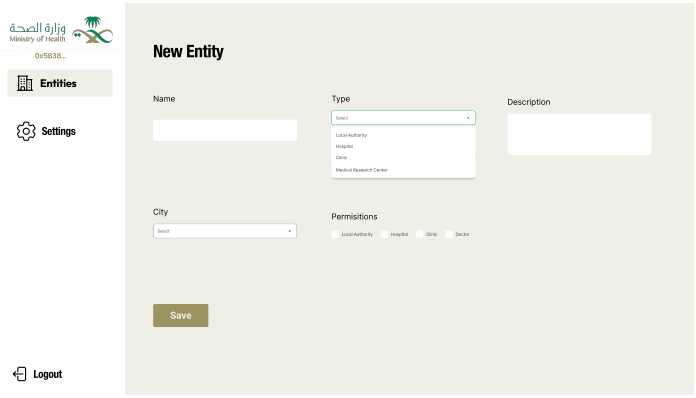

Fig. 9. Entity registration.

```
        bytes encryptionPublicKey; // Public key
            used for encryption
        string dateOfBirth;
        address registeringEntity; // Ethereum
            address of the entity who registered the
             doctor
    }

    mapping(address => Doctor) public doctors;
    mapping(address => bool) public
        isDoctorRegistered;

function registerDoctor(
    string memory _name,
    string memory _phoneNumber,
    address _doctorAddress,
    bytes memory _encryptionPublicKey,
    string memory _dateOfBirth
) external onlyAllowedEntity(entities[msg.sender].
    entityType, EntityType.Doctor) {
    require(!isDoctorRegistered[_doctorAddress], "
        Doctor is already registered");

    Doctor memory newDoctor = Doctor({
            name: _name,
            phoneNumber: _phoneNumber,
            doctorAddress: _doctorAddress,
            encryptionPublicKey:
                _encryptionPublicKey,
            dateOfBirth: _dateOfBirth,
            registeringEntity: msg.sender
        });

        doctors[_doctorAddress] = newDoctor;
        isDoctorRegistered[_doctorAddress] = true;
}
```

Listing 4: Process for registering doctors

Permitted entities have the capability to add a new doctor by providing details such as the doctor's name, email , and other pertinent information. Notably, as illustrated in Fig. 10, the doctor's _encryptionPublicKey is included. This key enables the doctor to access patients' medical records with their consent. The process involves the patient decrypting the encrypted symmetric key of a specific medical record with their private key and subsequently encrypting the symmetric key using the doctor's public key. Consequently, the doctor can decrypt the encrypted symmetric key and access a specific patient's medical record using his private key.

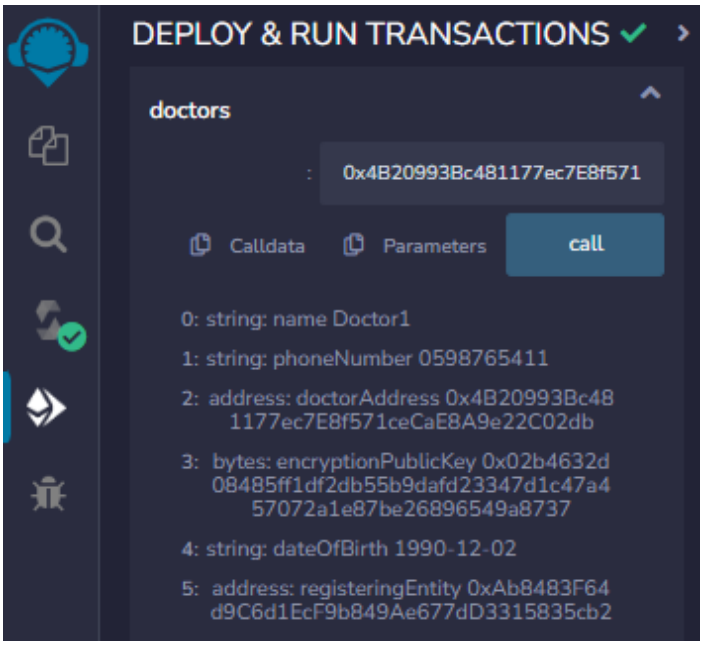

Fig. 10. Doctor registration.

The DApp interfaces for hospitals empower them by providing the capability to list all registered doctors, see Fig. 11. This functionality enhances the efficiency of hospitals in managing their medical staff. The second interface, presented in Fig. 12, enables hospitals to seamlessly register new doctors. Through this interface, hospitals can input and submit all necessary information about a new doctor. These interfaces collectively contribute to the effective coordination and administration of healthcare services within the proposed system, promoting a well-organized and responsive healthcare environment.

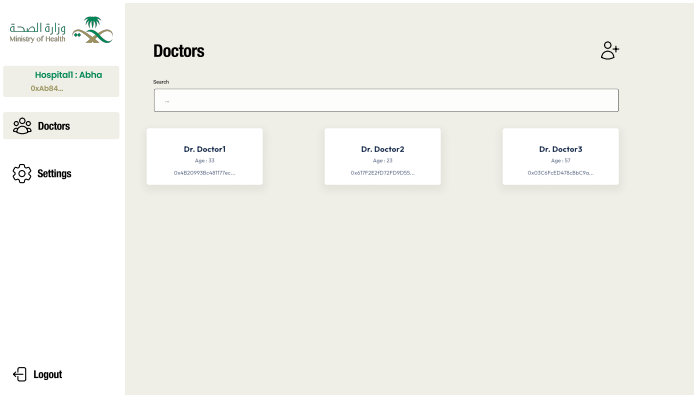

Fig. 11. List of doctors.

C. Implementation of the Patients Registration Process

```
    struct Patient {
        string name;
        string phoneNumber;
        address patientAddress; // Ethereum account
            address of the patient
        bytes encryptionPublicKey; // Public key
            used for encryption
```

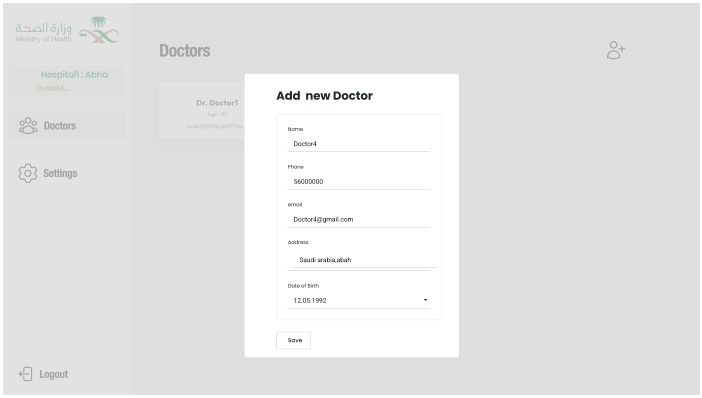

Fig. 12. Register new doctor.

```
        string dateOfBirth;
        address registeringDoctor; // Ethereum
            address of the doctor who registered the
             patient
    }

    mapping(address => Patient) public patients;
    mapping(address => bool) public
        isPatientRegistered;

    function registerPatient(
        string memory _name,
        string memory _phoneNumber,
        address _patientAddress,
        bytes memory _encryptionPublicKey,
        string memory _dateOfBirth
    ) external onlyDoctor {
        require(isDoctorRegistered[msg.sender], "
            Doctor is not registered");
        require(!isPatientRegistered[_patientAddress
            ], "Patient is already registered");

        Patient memory newPatient = Patient({
            name: _name,
            phoneNumber: _phoneNumber,
            patientAddress: _patientAddress,
            encryptionPublicKey:
                _encryptionPublicKey,
            dateOfBirth: _dateOfBirth,
            registeringDoctor: msg.sender
        });

        patients[_patientAddress] = newPatient;
        isPatientRegistered[_patientAddress] = true;
    }
```

Listing 5: Process for registering patients

Upon successful registration of the doctor by the hospital, the doctor acquires the capability to register new patients. Subsequently, the patient is included in the patient list by invoking the smart contract through the registerPatient function, as depicted in Fig. 13. The inclusion of the onlyDoctor modifier ensures that only authorized doctors can register patients. The doctor inputs the patient's information, which is then securely stored on the blockchain.

The designated interfaces for doctors in the DApp play a pivotal role in facilitating efficient patients management and registration processes. The first interface, shown in Fig. 14,

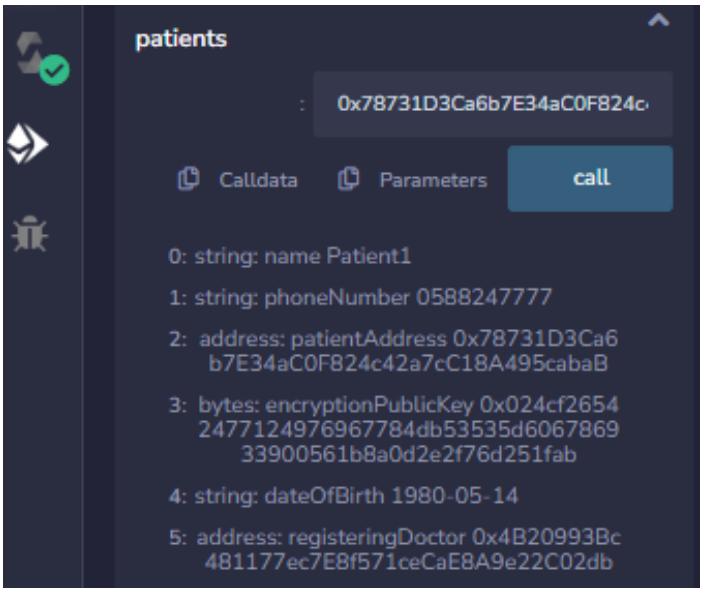

Fig. 13. Patient registration.

empowers doctors by providing the functionality to list all registered patients under their care. This feature enhances the doctor's ability to access and review patient information seamlessly, contributing to informed and personalized healthcare delivery. The second interface, presented in Fig. 15, serves as a key tool for doctors to register new patients. Through this interface, doctors can input and submit essential details about a new patient, ensuring a systematic and secure process for patient onboarding. In addition, the DApp initiates the creation of a new Ethereum account for the patient. Subsequently, the DApp communicates the Ethereum account details to the respective patient.

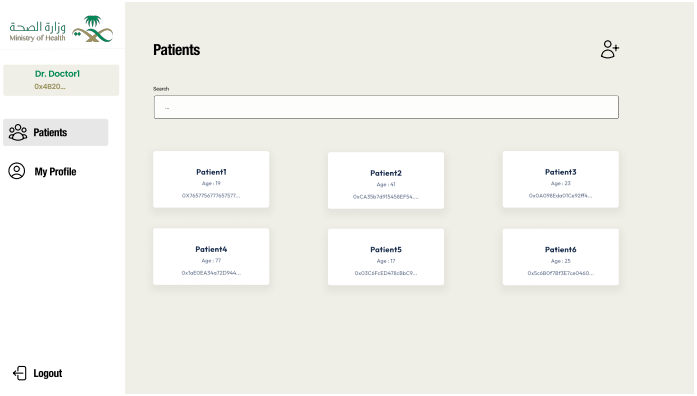

Fig. 14. List of patients.

D. Implementation of the Medical Records Issuing Process

```
struct MedicalRecord {
        uint256 id;
        address doctor;
        uint256 time;
        address patientAddress;
        bytes encryptedSymmetricKey;
        bytes patientPublicKey;
        string ipfsCID;
```

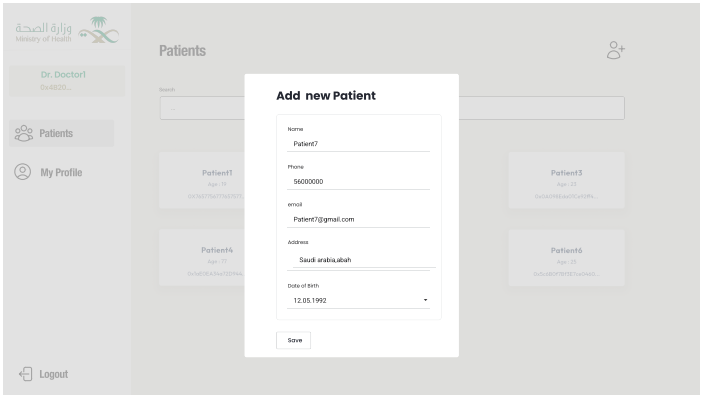

Fig. 15. Register new patient.

```
9       }
10
11      // Mapping to store medical records for each
            patient
12      mapping(address => mapping(uint256 =>
            MedicalRecord)) public patientMedicalRecords
            ;
13
14      // Mapping to store permissions for each medical
            record
15      mapping(address => mapping(uint256 => mapping(
            address => bytes))) public recordPermissions
            ;
16
17       // Function to add a medical record, restricted
            to doctors
18      function addMedicalRecord(
19          uint256 _id,
20          address _patientAddress,
21          bytes memory _encryptedSymmetricKey,
22          bytes memory _patientPublicKey,
23          string memory _ipfsCID
24      ) external onlyDoctor {
25          require(!isEntityRegistered[msg.sender], "
                Caller is not registered");
26          // Check if the patient is registered
27          require(isPatientRegistered[_patientAddress
                ], "Patient is not registered");
28
29          // Add the medical record to the patient's
                records
30          patientMedicalRecords[_patientAddress][_id]
                = MedicalRecord({
31              id: _id,
32              doctor: msg.sender,
33              time: block.timestamp,
34              patientAddress : _patientAddress,
35              encryptedSymmetricKey:
                    _encryptedSymmetricKey,
36              patientPublicKey: _patientPublicKey,
37              ipfsCID: _ipfsCID
38          });
39      }
```

Listing 6: Process for adding medical records

In Fig. 16, it is depicted that the patient's medical record details, including essential components like the _ipfsCID and the _encryptedSymmetricKey, will be entered through the account of the doctor. The _ipfsCID serves as a reference for retrieving the encrypted medical record from the IPFS, while the _encryptedSymmetricKey specifies the used encryption key, ensuring the confidentiality and privacy of the medical record.

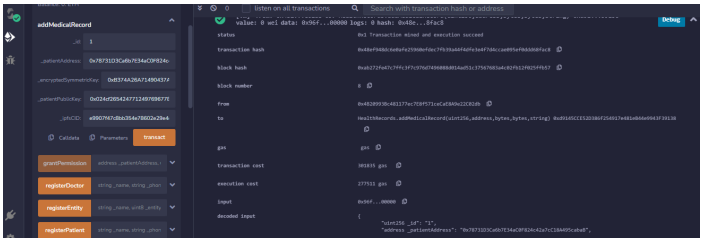

Fig. 16. Add medical record.

The interfaces designated for doctors within the proposed system encapsulate critical functionalities in managing and contributing to the medical records ecosystem. The first interface, shown in Fig. 17, empowers doctors to access and review medical records by listing all records associated with a specific patient. This functionality ensures efficient retrieval and oversight of a patient's medical history. In tandem, the second interface, illustrated in Fig. 18, equips doctors to actively contribute to the patient's medical records database. This involves a comprehensive process initiated by the DApp, orchestrating the generation of a symmetric key, encryption of medical records, and seamless integration with IPFS for secure storage.

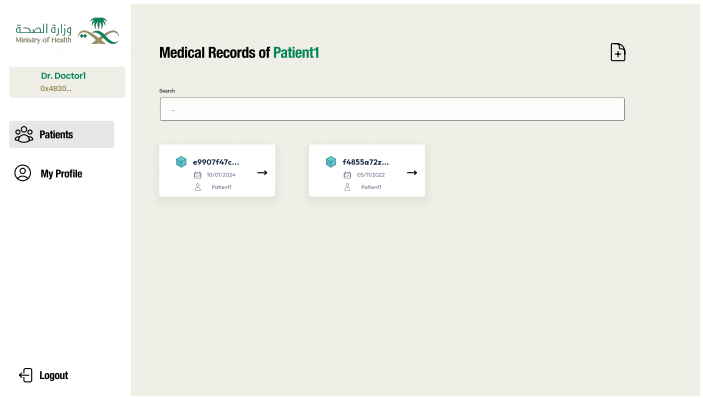

Fig. 17. List of medical records.

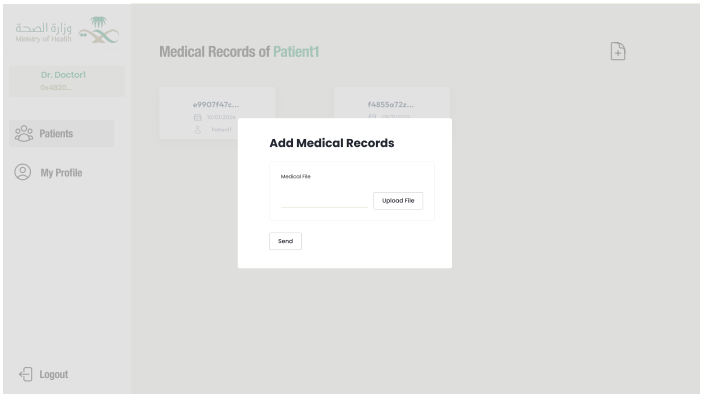

Fig. 18. Add new medical records.

E. Implementation of the Process for Managing Access to Medical Records

```
1
2       // Function to grant permission to an entity to
            access a specific medical record
3       function grantPermission(
4           address _patientAddress,
5           uint256 _recordId,
6           address _doctorAddress,
7           bytes memory _encryptedSymmetricKey
8       ) external onlyPatient {
9           // Grant permission to the doctor
10          recordPermissions[_patientAddress][_recordId
                ][_doctorAddress] =
                _encryptedSymmetricKey;
11      }
12
13      // Function to revoke permission from an entity
            for a specific medical record
14      function revokePermission(
15          address _patientAddress,
16          uint256 _recordId,
17          address _doctorAddress
18      ) external onlyPatient {
19          // Revoke permission from the entity
20          delete recordPermissions[_patientAddress][
                _recordId][_doctorAddress];
21      }
```

Listing 7: Process for managing access to the medical records

In the process of granting access to a specific medical record, the patient plays a central role in controlling the confidentiality and accessibility of their health data. Initiated by the patient, this action involves invoking the grantPermission function, a function guarded by the onlyPatient modifier to ensure that only the respective patient can execute this operation.

The key parameters in this operation include:

- _patientAddress: This parameter identifies the Ethereum address of the patient initiating the permission grant.
- _recordId: Serving as a unique identifier, this parameter denotes the specific medical record the patient intends to share.
- _doctorAddress: The Ethereum address of the doctor for whom the patient wishes to grant access to the designated medical record.
- _encryptedSymmetricKey: This parameter holds the encrypted symmetric key, by using the doctor's public key, associated with the medical record, ensuring that only the intended doctor can decrypt and access the sensitive health information.

By specifying these essential details, depicted in Fig. 19, the patient leverages the grantPermission function to securely share access to their medical record with a designated doctor, fostering a patient-centric approach to healthcare data management.

The process of revoking access to a specific medical record is a crucial aspect of patient-centric healthcare data management. Executed exclusively by the patient through the revokePermission function, this operation is safeguarded by

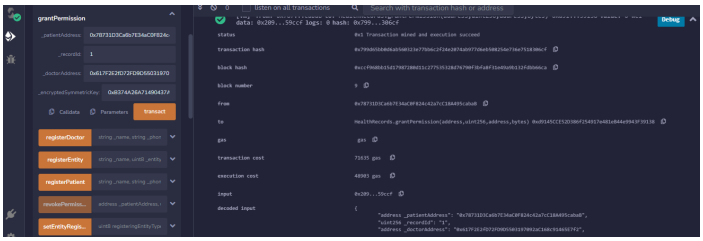

Fig. 19. Enabling the doctor to access the medical record.

the onlyPatient modifier, ensuring that only the authorized patient can control access to their health information. The pertinent parameters in this revocation process include the _patientAddress, the _recordId, and the _doctorAddress. By invoking the revokePermission function, the patient can selectively remove access privileges from a designated doctor, effectively enhancing the patient's control over the confidentiality and security of their medical records. This patient-driven approach empowers individuals to actively manage and regulate access to their health information, aligning with the principles of privacy and data security in the healthcare domain.

In Fig. 20, the illustration demonstrates the patient's capability to revoke a doctor's access to their medical record by deleting the associated medical record data from the doctor's list of accessible records.

Fig. 20. Revoke the access.

The patient interfaces, shown in Fig. 21, within the envisioned healthcare system afford individuals a comprehensive toolset for managing and accessing their medical records. The first interface provides patients with a detailed listing of their medical records. Crucially, this feature enables patients to review the doctors who currently possess access to each record, empowering them to make informed decisions about their healthcare providers.

Moreover, these interfaces enable patients to actively manage access permissions to their medical records. This involves granting access to new doctors, while also offering the ability to selectively revoke access when needed. By seamlessly integrating cryptographic principles and smart contract functionality, this patient-centric approach ensures the confidentiality and privacy of medical records. Patients are empowered with the agency to determine who can contribute to their healthcare information and underlines the commitment of the system to prioritizing user control and data privacy.

In addition to the core functionalities, the smart contract encompasses several functions that contribute to the overall robustness and flexibility of the proposed system, such as

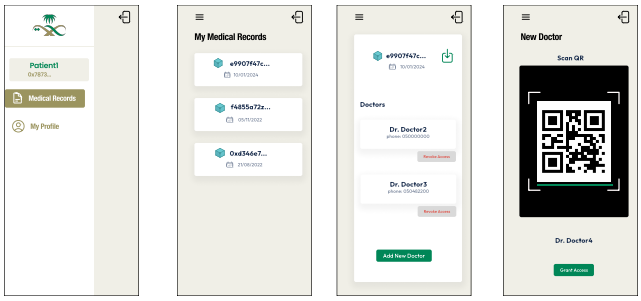

Fig. 21. Managing access to medical records.

functions that enable patients to delete specific medical records from the blockchain, ensuring a patient-centric approach to data management.

VI. Discussion

This section delves into a comprehensive analysis of the proposed system, exploring various facets such as architecture, security considerations, and frameworks employed.

- Architecture: The proposed system adopts a decentralized architecture built on a private Ethereum blockchain. This choice is motivated by the need for transparency, immutability, and distributed control. The utilization of a PoA consensus mechanism, implemented through the Geth client, enhances scalability and efficiency in a closed and permissioned healthcare network. The private Ethereum blockchain is primarily employed for defining rules to manage entities, such as hospitals, clinics, doctors, and patients, facilitating secure and controlled interactions within the healthcare network, while medical records, sensitive in nature, remain off-chain to address privacy concerns and storage limitations on the blockchain.
- Frameworks: The system integrates several key frameworks to facilitate its functionality. The Ethereum blockchain, along with the use of smart contract, forms the backbone for managing entities, doctors, patients, and medical records. The use of IPFS augments data storage capabilities, enabling decentralized and secure storage of medical records. React is employed on the front end to develop a user-friendly DApp, while Web3.js connects the DApp to the Ethereum blockchain, allowing seamless interaction with smart contract.
- Security considerations: Security is paramount in healthcare systems, especially when dealing with sensitive patient data. The use of a private Ethereum blockchain enhances security by restricting access to authorized entities, mitigating the risk of unauthorized access or tampering. Encryption plays a pivotal role in securing medical records, with each record encrypted using a symmetric key. Patient-controlled access through encrypted keys ensures that only authorized individuals, namely patients and authorized doctors, can decrypt and access medical records. Additionally, the private IPFS ensures that data retrieval is restricted to registered patients and doctors, adding an extra layer of security.
- Scalability: The proposed system exhibits scalability through a hierarchical structure. Local health authorities, hospitals, and clinics serve as nodes, ensuring a scalable network where each entity is added by a higher authority. This hierarchical structure allows for the efficient expansion of the healthcare network without compromising security.
- Regulatory compliance: The proposed system considers the hierarchical structure of healthcare authorities in Saudi Arabia, aligning with the regulatory framework. The Ministry of Health, serving as the highest authority, oversees the registration of entities, ensuring compliance with local regulations and preventing security issues such as DoS attacks.
- Patient-centric control: The architecture ensures that patients have granular control over their medical records. The process of granting access, revoking access, and managing encryption keys is in the hands of the patients, enhancing privacy and control over their healthcare data.

The proposed healthcare data management system, leveraging blockchain, IPFS, and encryption, exhibits resilience against several potential attacks, ensuring the integrity, privacy, and security of patient data. Here is a detailed analysis of the system's robustness against various attacks:

- Unauthorized access and tampering: The decentralized architecture and permissioned nature of the private Ethereum blockchain are pivotal in safeguarding against unauthorized access and tampering of patient data. By employing smart contract, the system enforces strict access controls, ensuring that only registered and authorized entities have the right to interact with the blockchain. The immutability of records is guaranteed through the consensus mechanism, making it virtually impossible for any entity without proper authorization to alter or tamper with sensitive medical information.
- DoS attacks: To counter the risk of DoS attacks, the blockchain-based healthcare data management system implements a hierarchical registration process and a permissioned structure. Entities, including hospitals and clinics, are registered by higher authorities, mitigating the potential for a flood of unauthenticated registrations. This hierarchical and permissioned approach enhances the system's resilience against DoS attacks, ensuring stable and secure operation.
- Data interception and eavesdropping: Protection against data interception and eavesdropping is achieved through robust encryption techniques. Medical records are encrypted using a symmetric key, which is then further encrypted with the patient's public key. This double-layered encryption ensures the confidentiality of patient data during both transmission and storage. Even if data is intercepted, it remains

unreadable without the patient's private key, providing a robust defense against unauthorized access.

- Sybil attacks: The proposed system is resilient against Sybil attacks through its hierarchical entity registration and permissioned blockchain architecture. Entities, such as hospitals and clinics, undergo controlled registration by higher authorities, preventing the creation of fake entities within the system. The permissioned blockchain further restricts participation to authorized nodes, effectively mitigating the risk of Sybil attacks by maintaining a trustworthy and controlled network.
- Blockchain consensus attacks: The system's utilization of a PoA consensus mechanism enhances its resistance against blockchain consensus attacks. PoA ensures that only authenticated and authorized nodes participate in the consensus process, eliminating the vulnerabilities associated with traditional PoW or PoS blockchains. This consensus mechanism contributes to the overall security and stability of the blockchain network, making it robust against consensus-related attacks.
- Data leakage prevention from IPFS: To mitigate the risk of data leakage from the IPFS, a combination of patient-controlled access and the use of a private IPFS is employed. Authorized patients and doctors, possessing the required private keys, are the only entities capable of retrieving and decrypting medical records stored on the IPFS network. The implementation of a private IPFS structure ensures that even in the event of an unauthorized intrusion into the network, attackers cannot access or decipher the stored medical records without the necessary cryptographic keys. This approach upholds the confidentiality of patient information, providing an additional layer of security against potential data breaches.

VII. Conclusion

In conclusion, this research introduces a robust and secure framework for managing healthcare data through the integration of blockchain technology, DApps, and a novel access control mechanism. The proposed system leverages a private Ethereum blockchain, enhancing data security and privacy within the healthcare domain. Through strategic smart contract implementations, the hierarchical structure of healthcare entities is mirrored, ensuring a controlled onboarding process and mitigating risks associated with unauthorized access.

The utilization of IPFS for secure and decentralized storage, combined with encryption methodologies, safeguards the confidentiality and integrity of medical records. The seamless interaction between the Ethereum blockchain and the React-based DApp provides a user-friendly experience for healthcare authorities, doctors, and patients. This research also details a comprehensive set of interfaces tailored for each entity type, facilitating smooth interactions and data management.

Furthermore, the proposed access control mechanism places patients at the center of their healthcare journey, allowing them to actively manage and monitor access to their medical records. The cryptographic principles underpinning this mechanism ensure secure key management and data confidentiality. Through the decentralized nature of the system, trust is established among participating entities, fostering a secure and transparent healthcare ecosystem.

As we move forward, this research provides a foundation for the continued exploration and development of blockchain-based healthcare systems. The presented framework not only addresses current challenges in healthcare data management but also aligns with the evolving landscape of digital healthcare. With a commitment to user control, data privacy, and security, the proposed system presents a valuable contribution to the ongoing discourse on innovative solutions for healthcare information management.

Automating Tomato Ripeness Classification and Counting with YOLOv9

Hoang-Tu Vo, Kheo Chau Mui, Nhon Nguyen Thien, Phuc Pham Tien
Information Technology Department
FPT University, Cantho city, Vietnam

***Abstract*—This article proposes a novel solution to the long-standing issue of ripe (or manual) tomato monitoring and counting, often relying on visual inspection, which is both time-consuming, requires a lot of labor and prone to inaccuracies. By leveraging the power of artificial intelligence (AI) and image analysis techniques, a more efficient and precise method for automating this process is introduced. This approach promises to significantly reduce labor requirements while enhancing accuracy, thus improving overall quality and productivity. In this study, we explore the application of the latest version of YOLO (You Only Look Once), specifically YOLOv9, in automating the classification of tomato ripeness levels and counting tomatoes. To assess the performance of the proposed model, the study employs standard evaluation metrics including Precision, Recall, and mAP50. These metrics provide valuable insights into the model's ability to accurately detect and count tomatoes in real-world scenarios. The results indicate that the YOLOv9-based model achieves superior performance, as evidenced by the following evaluation metrics: Precision: 0.856, Recall: 0.832, and mAP50: 0.882. By leveraging YOLOv9 and comprehensive evaluation metrics, this research aims to provide a robust solution for automating tomato monitoring processes. Additionally, by offering the future integration of robotics, the collection phase can further optimize efficiency and enable the expansion of cultivation areas.**

***Keywords*—Tomato monitoring; manual counting; Artificial Intelligence (AI); Image analysis techniques; YOLO; YOLOv9**

I. Introduction

Tomatoes offer not just delightful flavor but also contain crucial nutrients. They are a great source of vitamin C, which supports the immune system and promotes healthy skin. Additionally, tomatoes contain lycopene, a powerful antioxidant that may help reduce the risk of certain cancers and protect against heart disease [1], [2]. Tomatoes have an attractive moisture content of 95%, with a carbohydrate content of 3%, protein at 1.2%, and total lipids making up 1%. Furthermore, they offer minerals including calcium (Ca), magnesium (Mg), phosphorus (P), potassium (K), sodium (Na), zinc (Zn), and manganese (Mn). In addition to minerals, tomatoes provide essential vitamins such as vitamins A and C, thiamin, riboflavin, niacin, pantothenic acid, and pyridoxine. [3]. In 2020, the largest producers of tomatoes worldwide were as follows: China took the top spot, producing an impressive 64,866 million tons of tomatoes in a single year. India came in second, producing approximately 20,573 million tons of tomatoes, while Turkey ranked third, with a tomato production of 13,204 million tons [4].

The current problem of identifying, manually counting, and classifying the ripeness of tomatoes persists as a significant challenge in agricultural practices. Traditional methods rely heavily on manual labor, making the process time-consuming, labor-intensive, and prone to errors. The current challenges in tomato handling demand innovative solutions that combine machine learning, image processing, and automation to enhance efficiency, reduce errors, and improve overall productivity in the tomato industry.

Manual counting, which involves counting tomatoes manually during harvesting or quality control, is labor-intensive and inefficient. It leads to inaccuracies due to fatigue, distractions, and variations in human perception. Automating counting using image processing, machine learning, or deep learning could alleviate this issue. A study [5] focused on detecting and counting tomato fruits in greenhouses utilizing deep learning.

Accurately categorizing tomatoes into ripeness stages (such as unripe, ripe, and overripe) plays a pivotal role in sorting, storage, and distribution within the agricultural industry. However, manual classification suffers from inconsistency due to human subjectivity. To address this, researchers have proposed innovative approaches, including Machine Learning (ML), Convolutional Neural Networks (CNNs) and Deep Learning-based methods (DL), which demonstrate promising results in fruit classification and ripeness determination [6], [7]. A study [8] using the Cascaded Object Detector (COD) and a composition of traditional custom image processing methods. The COD method achieved 95% accuracy in detecting ripe tomatoes, outperforming the traditional Color Segmentation Method.

This study introduces a more efficient and accurate approach to automating the monitoring process. The utilization of the latest version of YOLO, specifically YOLOv9, enables the classification of tomato ripeness levels and facilitates tomato counting. The main contribution of the study are:

- Introducing a novel solution to the longstanding problem of manual tomato monitoring and counting, addressing issues of time consumption, labor intensity, and inaccuracies associated with visual inspection methods.
- Leveraging artificial intelligence (AI) and image analysis techniques to develop a more efficient and precise method for automating tomato monitoring processes, promising to significantly reduce labor requirements while enhancing accuracy and overall quality and productivity.
- Exploring the application of the latest version of YOLO, specifically YOLOv9, in automating the classification of tomato ripeness levels and counting toma-

toes, demonstrating the potential of advanced deep learning techniques in agricultural applications.

- Evaluating the performance of the proposed model using standard evaluation metrics such as Precision, Recall, and mAP50, providing valuable insights into its effectiveness in accurately detecting and counting tomatoes in real-world scenarios.

The paper is organized as follows: In Section II, we present a thorough literature review. Section III outlines the Automated Tomato Ripeness Classification and Counting Methodology, including details about the dataset, data preparation, and evaluation metrics for the model. Moving on to Section IV, we delve into the experimental system and present the final results. Finally, Section V summarizes our study's findings and offers concluding remarks. Lastly, Section VI outlines potential avenues for future study.

II. Related Works

Computer vision has emerged as a powerful tool in modern agriculture, revolutionizing the way crops are monitored and managed [9], [10], [11], [12], [13], [14] from object detection algorithms based on traditional methods to modern approaches such as CNN and deep learning.

The authors in the article [15] introduces an automated multi-class classification method for evaluating tomato ripeness using color features and employing Principal Components Analysis (PCA), Support Vector Machines (SVMs), and Linear Discriminant Analysis (LDA) algorithms for feature extraction and classification.

In this study [16], the authors utilize digital image processing techniques to describe and extract color statistics (RGB, HSI, and Lab* color spaces) from tomato images. They employ supervised and unsupervised classification algorithms such as K-NN, MLP neural networks, and K-Means for classifying Milano and Chonto tomatoes.

Liu et al. in this study [17] propose an algorithm for automatic tomato detection in regular color images, utilizing Histograms of Oriented Gradients (HOG) descriptor trained with a SVM classifier, along with a coarse-to-fine scanning method and False Color Removal (FCR) technique to enhance accuracy. The proposed algorithm demonstrates a significant improvement in tomato detection compared to other methods, achieving high recall, precision, and F1 score percentages of 90.00%, 94.41%, and 92.15%, respectively, in test images.

This study [18] proposes a Tomato Classification model utilizing Machine Learning algorithms such as Decision Tree (DT), Logistic Regression (LR), Gradient Boosting (GB), Random Forest (RF), SVM, K-NN, and XG Boost to determine tomato maturity stages, with Random Forest achieving the highest accuracy of 92.49% among the classifiers tested.

The author in the research [19] aims to apply deep Transfer Learning (TL) to classify tomatoes into maturity classes, employing three TL approaches—VGG, Inception, and ResNet—ultimately revealing VGG 19 as the top performer.

The authors in this work [20] utilize an improved DenseNet architecture to address the challenges of accurately classifying tomato ripeness in complex images, incorporating structured sparse operations to enhance feature propagation and reduce data storage, as well as introducing the Focal loss function to mitigate dataset imbalance and improve classification accuracy in their tomato detection system.

Utilizing TL with VGG16 for Fruit Ripeness Detection. This study [21] demonstrates that DL employing TL consistently outperforms traditional ML approaches utilizing traditional feature extraction for fruit ripeness detection.

The author's primary objective in this study [22] is to introduce a new method for sorting and grading tomato quality, the approach integrates pre-trained CNNs for feature extraction with conventional ML algorithms (such as SVM, RF, and k-Nearest Neighbors (KNN)) to enhance classification accuracy. Among the hybrid models proposed, the CNN-SVM method demonstrates superior performance, achieving high accuracies in both binary and multiclass classification tasks, particularly when utilizing Inceptionv3 as the feature extractor.

The authors in [23] introduce four distinct deep learning frameworks, Utilizing a combination of Yolov5m and deep learning models—specifically ResNet50, ResNet-101, and EfficientNet-B0 - the model successfully classified tomatoes on the vine into three distinct classes: ripe, immature, and damaged. The evaluation results indicated that the ResNet-50 and EfficientNet-B0 achieved impressive overall accuracy of 98%, while the Yolov5m and ResNet-101 models demonstrated accuracy of 97%.

This study [24] explores tomato segmentation and detection across various maturity stages, utilizing both a mask R-CNN and a YOLOv8 model. Evaluation metrics show that mask R-CNN achieved 67.2% average precision with 78.9% recall, and 92.1% IoU average precision with 91.4% recall, while YOLOv8 demonstrated superior performance, With coefficients of determination measuring 0.809 for ripe, 0.897 for half-ripe, and 0.968 for green categories.

Liu, Guoxu, et al. in this study [25] introduces an enhanced fruit detection model named YOLO-Tomato, derived from YOLOv3. YOLO-Tomato integrates a dense architecture into YOLOv3, enabling feature reuse and enhancing model accuracy, while also employing circular bounding boxes for more accurate localization of tomatoes.

The authors in this research [26] enhanced YOLOv5 to identify four distinct stages of tomato ripeness: mature green, breaker, pink, and red. [27] introduces a novel lightweight enhanced algorithm based on YOLOv5 to achieve real-time tracking and identify the ripeness of tomato fruits, achieved by reconstructing YOLOv5's backbone network utilizing the bneck module of MobileNetV3.

This study presents a more efficient and accurate method to automate the monitoring process. By taking advantage of the latest version of YOLO, specifically YOLOv9, it allows classification of tomato ripeness levels and simplifies tomato counting.

III. Methodology

A. The Process of Gathering and Preparing Data

This research utilizes the FruitDetectionv3 Image Dataset, accessible at [28], which consists of three classes (Tomato

Fig. 1. Sample images of tomatoes at different maturity levels from this dataset.

Fig. 2. Tomato ripening level.

Fully-ripe, Tomato Semi-ripe, and Tomato Unripe) and the total number of images in this dataset is 2610. The dataset is divided into three sets: the training set comprises 2283 pictures (87%), The validation set includes 217 pictures (8%), and the testing set contains 110 pictures (4%). Each image in the dataset has a size of 640x640 pixels. Augmentations are applied to enhance the dataset, including Horizontal Flip, Rotation between -15° and +15°, and Shear of ±15° horizontally and vertically. These augmentations aim to increase the variability of the dataset and improve the robustness of the model in real-world scenarios. Sample images of tomatoes at different maturity levels from this dataset are shown in Fig. 1 and samples of Tomato Ripening Level are shown in Fig. 2.

B. Overall Methodology

Object detection techniques are frequently classified into one-stage and two-stage approaches. YOLO (You Only Look Once) [29] and SSD (Single Shot MultiBox Detector) [30] are prominent examples of one-stage methods. These methods directly predict bounding boxes and class labels in a single forward pass through the neural network. They are faster in terms of inference time since they avoid the region proposal step. Faster R-CNN (Region-based Convolutional Neural Network) [31] exemplifies the two-stage approach. In the first stage, Faster R-CNN proposes region proposals using a Region Proposal Network (RPN). In the second stage, these proposals are refined to obtain accurate bounding boxes and class predictions. One-stage methods prioritize speed and simplicity, while two-stage methods focus on accuracy at the cost of increased complexity and computation time. In real-time applications where speed is essential, such as autonomous vehicles and surveillance, one-stage methods like YOLO or SSD should be considered.

If achieving high accuracy is crucial and computational resources are available, consider using two-stage methods such as Faster R-CNN. Hence, in this study, we utilize the state-of-the-art one-stage object detection method, YOLOv9, to automate the classification and counting of tomato maturity.

YOLOv9 is a remarkable advancement in real-time object detection technology [32]. YOLOv9 is the latest version of YOLO, released in February 2024, YOLOv9 introduces groundbreaking techniques such as Programmable Gradient Information -PGI and the Generalized Efficient Layer Aggregation Network - GELAN.

1) Programmable Gradient Information - PGI: During the forward pass in neural networks, information can get diluted or lost due to transformations within the layers. This phenomenon is known as the information bottleneck. Gradients provide essential information for updating network weights during training. Accurate gradients are crucial for effective learning. PGI ensures that gradient information is preserved throughout the network. It prevents the loss of critical input information during backpropagation. By maintaining reliable gradient information, PGI helps the model learn more effectively and improves its ability to recognize objects. The YOLOv9 Programmable Gradient Information (PGI) Architecture is shown in Fig. 3. The PGI primarily comprises three components: The main branch, An auxiliary reversible branch, and Multi-level auxiliary information.

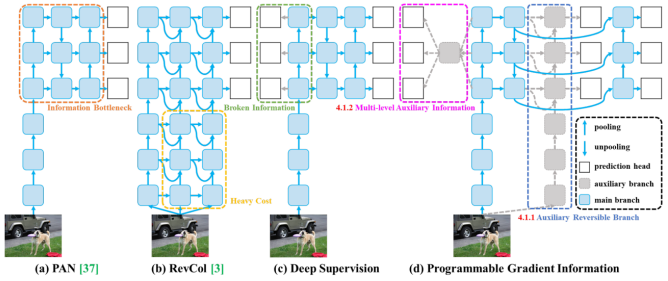

Fig. 3. YOLOv9 PGI Architecture [32].

2) Generalized Efficient Layer Aggregation Network - GELAN: GELAN is a novel architectural advancement, it combines principles from two existing techniques: CSPNet (Cross Stage Partial Network) and ELAN (Efficient Layer Aggregation Network). GELAN is a lightweight network architecture designed based on gradient path planning. It efficiently aggregates information across layers. It prioritizes lightweight design, fast inference, and accuracy. GELAN directly tackles the information bottleneck problem, leading to improved efficiency and accuracy in real-time object detection. The architecture of GELAN within YOLOv9 is shown in Fig. 4.

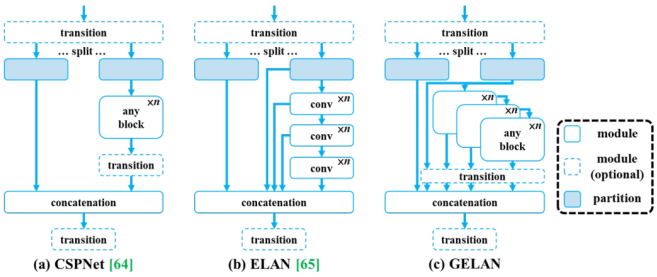

Fig. 4. The architecture of GELAN within YOLOv9 [32].

Information of randomly initialized weight output feature maps across various deep learning network architectures are shown in Fig. 5. From Fig. 5, it's observable that the GELAN architecture retains a significant amount of information from the input data after going through the feed-forward process

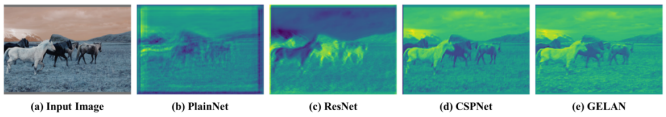

Fig. 5. Information of randomly initialized weight output feature maps across various deep learning network architectures [32].

The analysis of YOLOv9 in comparison to state-of-the-art (SOTA) models demonstrates notable enhancements across diverse metrics. YOLOv9 surpasses current methodologies in parameter efficiency, demanding fewer parameters while either maintaining or enhancing accuracy levels. Comparison of cutting-edge real-time object detectors with YOLOv9 is shown in Fig. 6. YOLOv9 stands out as an innovative model, combining PGI and GELAN to redefine the boundaries of

efficiency and accuracy in object detection. Therefore, in this study we use YOLOv9 to count and classify the ripeness level of tomatoes.

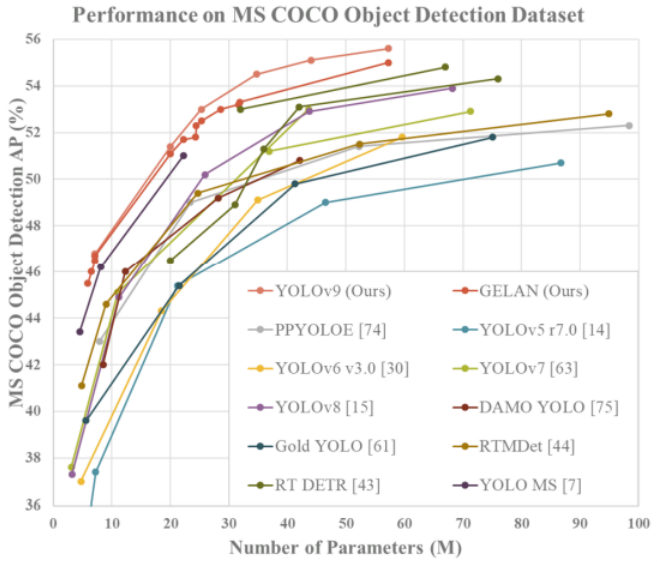

Fig. 6. Comparison of cutting-edge real-time object detectors with YOLOv9 [32].

C. Performance Evaluation Measures

Assessing classification models entails a thorough examination using several essential metrics. Precision, which gauges the correctness of positive predictions among all predicted positives, and recall, which highlights the proportion of accurately predicted positives among all actual positives, play crucial roles. Lastly, The mean average precision (mAP) metric is utilized. It evaluates the detected bounding box by comparing it with the ground-truth box and assigns a corresponding score.

$$Precision = \frac{TP}{TP + FP} \tag{1}$$

$$Recall = \frac{TP}{TP + FN} \tag{2}$$

$$mAP = \frac{1}{N} \sum_{i=1}^{N} APi \tag{3}$$

In which, FP represent False Positive, TN denote True Negative, TP signify True Positive, and FN indicate False Negative. AP is Average Precision, APi denotes the average precision value for the i-th category, N is number of classes.

IV. Results

A. Environmental Settings

Our experimental procedures were conducted on the Kaggle platform to acquire the experimental outcomes. The research employed a Tesla T4x2 GPU with 30GB of memory, while the system itself possessed 29GB of RAM. GPU information is presented in Fig. 7.

B. Experiment

The hyperparameters of the model for automating tomato maturity classification and counting using YOLOv9 are shown in the Table I.

TABLE I. Configuration Parameters for Model Training

Parameters	Value
Batch-size	16
Epochs	100
Image-size	640 × 640
Learning rate (LR)	0.01
Momentum	0.937
Warmup epochs	3
Weight decay	0.0005
Optimizer	Stochastic Gradient Descent (SGD)

1) Comparative Analysis of YOLOv8 and YOLOv9 for tomato counting and ripeness classification in image processing: In this research, the goal was to develop an efficient and accurate model for counting and classifying the ripeness level of tomatoes in images. In this experiment, we utilized two popular object detection frameworks: YOLOv8 and YOLOv9. Both models were trained on a dataset of tomato images. The training process involved fine-tuning the pre-trained YOLOv8 and YOLOv9 architectures on the tomato dataset. The models were optimized for counting and classifying the ripeness level of tomatoes. After training, we evaluated the performance of both models on a separate testing set. The table presents the results of the comparison between YOLOv8 and YOLOv9 methods on the testing set, shown in Table II. The results presented in Table II show that YOLOv9 outperformed YOLOv8 in terms of tomato accuracy classification. it's evident that the YOLOv9 model generally outperforms the YOLOv8 model in terms of class precision, recall, and mAP50 across all tomato ripeness categories. Additionally, the YOLOv9 model achieves comparable or better performance with a slightly smaller model size, indicating potential efficiency improvements.

2) Plots describe the training and validation performance of the YOLOv9 model for counting and classifying tomato ripeness levels: Fig. 8 displays instances of class distribution and visualizations related to object detection.

TABLE II. THE TABLE PRESENTS THE RESULTS OF THE COMPARISON BETWEEN YOLOV8 AND YOLOV9 METHODS ON THE TESTING SET

Models	Class	Precision	Recall	mAP50	Model-Size
YOLOv8	All	0.837	0.771	0.825	52Mb
	Tomato Fully-ripe	0.856	0.822	0.859	
	Tomato Semi-ripe	0.773	0.710	0.772	
	Tomato Unripe	0.881	0.781	0.844	
YOLOv9	All	0.856	0.832	0.882	51.5Mb
	Tomato Fully-ripe	0.860	0.840	0.894	
	Tomato Semi-ripe	0.815	0.785	0.829	
	Tomato Unripe	0.894	0.870	0.925	

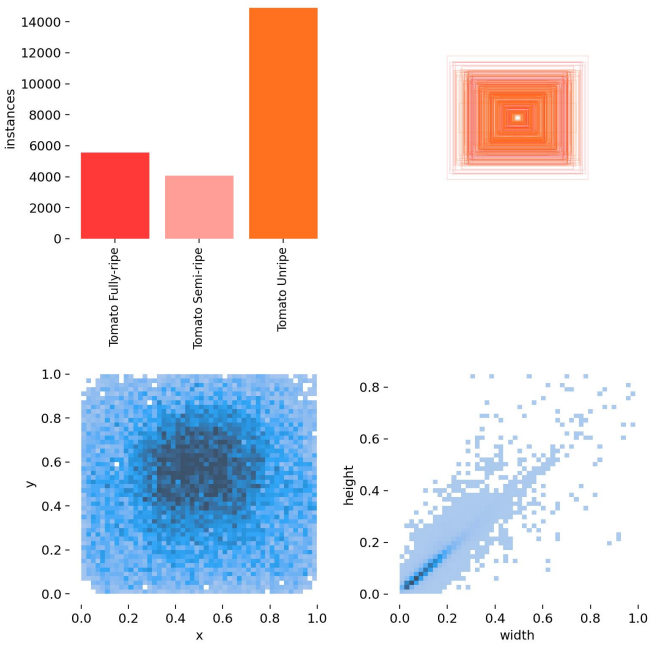

Fig. 8. Overview instances of class distribution and visualizations related to object detection.

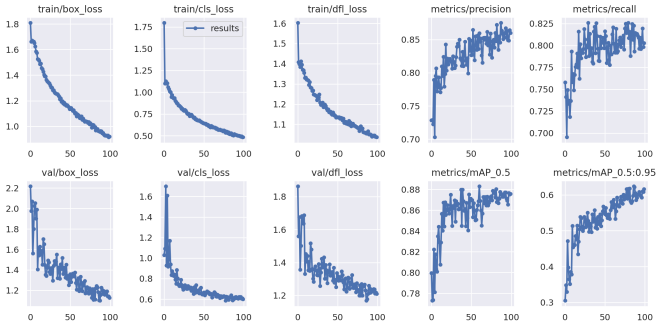

Fig. 9. Visualizations of mean Average Precision (mAP) and loss trends post-training the YOLOv9 model for counting and classifying tomato ripeness levels.

Fig. 9 depicts a series of eight graphs representing different metrics during the training and validation phase of the model to count and classify tomato ripeness.The metrics include: Box Loss, Classification Loss, Distribution Focal Loss, Precision, Recall, Mean Average Precision (mAP). Overall, the graphs show a positive trend over epochs. Decreasing values for loss metrics (Box Loss, Classification Loss, Distribution Focal Loss) indicate model improvement. Increasing precision, recall, and mAP values suggest better performance.

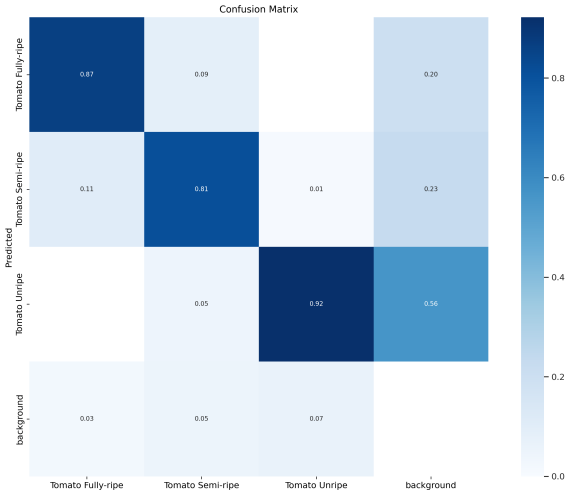

Fig. 10. Confusion matrix of model for counting and classifying tomato ripeness levels.

As we can see from the Confusion matrix in Fig. 10, the tomato ripeness counting and classification model gives the best results in the "Tomato Unripe" class, followed by the "Tomato Fully-ripe" class, and finally, the "Tomato Semi-ripe" class. Precision-Recall Curve is presented in Fig. 11.

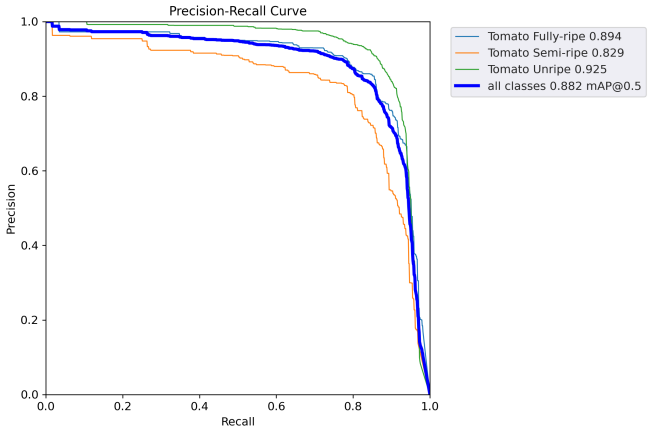

Fig. 11. Precision-Recall curve.

3) The practical effectiveness of detecting and counting tomato ripeness: To validate the practical performance of the built model, six pictures were randomly chosen for this study. These images were sourced from the internet to test the detection and counting of tomato ripeness. The results are depicted in Fig. 12.

V. CONCLUSION

In conclusion, this article presents a groundbreaking solution to the longstanding challenges associated with manual tomato monitoring and counting. Traditionally, these tasks

Fig. 12. The tomato ripeness counting and classification results.

have been labor-intensive, time-consuming, and prone to inaccuracies due to their reliance on visual inspection. However, by harnessing the capabilities of artificial intelligence (AI) and image analysis techniques, a more efficient and precise method for automating this process is introduced.

The proposed approach, which leverages the latest version of YOLO, specifically YOLOv9, demonstrates promising results in automating the classification of tomato maturity levels and accurately counting tomatoes. Through the utilization of standard evaluation metrics such as Precision, Recall, and mAP50, the study provides valuable insights into the model's performance in real-world scenarios.

The integration of YOLOv9 and comprehensive evaluation metrics aims to offer a robust solution for automating tomato monitoring processes, thereby significantly reducing labor requirements and enhancing accuracy. Furthermore, the potential future integration of robotics in the collection phase presents an opportunity to further optimize efficiency and enable the expansion of cultivation areas.

In essence, this research not only addresses the immediate need for more efficient tomato monitoring methods but also lays the foundation for advancements in agricultural automation, ultimately contributing to improved quality, productivity, and sustainability in tomato cultivation.

Besides, the study also evaluates the use of the latest version of the YOLO (version 9) model on this task to compare the results with the previous version.

VI. Future Works

While the current study demonstrates the effectiveness of the YOLOv9-based model in automating tomato monitoring and counting tasks, several avenues for future research exist to further enhance the proposed solution and extend its applicability. Future research could focus on refining the AI algorithms used for tomato classification and counting. Exploring alternative deep learning architectures or incorporating ensemble techniques may improve the model's performance, particularly in challenging environments with varying lighting conditions or occlusions. Expanding the scope of automation by integrating robotic systems for tomato harvesting and data collection represents a promising direction for future research. By developing autonomous robotic platforms equipped with AI-enabled vision systems, the efficiency and accuracy of tomato cultivation and monitoring processes can be further enhanced.

Amity School of Engineering and Tech. Amity University, Lucknow, UP 226028, India[3]

***Abstract*—Sign language is the fundamental mode of communication for those who are deaf and mute, as well as for individuals with hearing impairments. Regrettably, there has been a dearth of research on Indian Sign Language, primarily due to the lack of adequate grammar and regional variations in such language. Consequently, research in this area has been limited. The primary objective of our research is to develop a sophisticated speech/ text-to-Indian sign language conversion system that employs advanced 3D modeling techniques to display sign language motions. Our research is motivated by our desire to promote effective communication between hearing and hearing-impaired individuals in India. The proposed model integrates Automatic Speech Recognition (ASR) technology, which effectively transforms spoken words into text, and leverages 3D modeling techniques to generate corresponding sign language motions. We have conducted a comprehensive study of the grammar of Indian Sign Language, which includes identifying sentence structure and signs that represent the tense of the subject. It is noteworthy that the sentence structure of Indian Sign Language follows the Subject-Object-Verb sequence, in contrast to spoken language, which follows the Subject-Verb-Object structure. To enhance user experience as well as digital inclusion and accessibility, the research incorporates user-friendly and simple interfaces that allow individuals to interact effortlessly with the system intuitively. The model/ system is equipped to receive speech input through a microphone/ text and provide immediate feedback through 3D-modeled videos that display the generated sign language gestures and has achieved 99.2% accuracy. Our main goal is to promote digital inclusion and improve accessibility and enhance the user experience.**

Keywords*—Sign language generation; automatic speech recognition; speech-to-indian sign language; indian sign language; digital inclusion and accessibility

I. Introduction

The impact of information and communication technology (ICT) on human life has been immense [1]. It has revolutionized the way people conduct business, learn, travel, and communicate. Given the transformative power of ICT, it can be a valuable tool to aid the deaf and dumb community in overcoming communication obstacles [1] and bridging the gap between digital content availability and accessibility for them [2].

Hearing loss is a condition that affects an individual's ability to hear, with a hearing threshold of 20 dB or higher in both ears being considered normal [3]. It may impact one or both ears, and its severity can range from mild to profound. The underlying causes of hearing loss include congenital or early-onset childhood hearing loss, ongoing middle ear infections, noise-induced hearing loss, age-related hearing loss, and the use of ototoxic medications that damage the inner ear. According to research, there are approximately 63 million people worldwide who experience some form of auditory impairment [4]. In India, the Indian Sign Language Research and Training Center (ISLRTC) estimates that roughly five million people are deaf or hard of hearing [5]. For many of these individuals, sign language is their primary mode of communication. However, the cost of training in sign language institutions in India can range from a few thousand to several tens of thousands of rupees, making it challenging for a significant portion of the population, including family members, acquaintances, and professionals who work with the deaf community, to learn sign language as a secondary form of communication. Unfortunately, available data suggests that only 20% of the deaf population in India have access to formal education in sign language [2]. Although sign language is a valuable tool for individuals with hearing disabilities, its limitations can hinder effective communication. These challenges include:

- Limited Accessibility: Sign language is not universally understood and varies across different regions and cultures, making it less accessible [6].
- Language Barriers: Individuals with hearing disabilities may experience challenges in communicating with those who are not well-versed in sign language. This can result in barriers to effective communication between sign language users and non-sign language users.
- Time and Cost: Learning sign language can be a time-consuming and costly process, deterring some individuals from pursuing it [7].
- Dependence on Interpreters: Relying on interpreters for communication can also limit independence and autonomy [7].
- Limited Resources: There is a shortage of qualified sign language interpreters in many areas, such as rural or low-income communities.

In order to improve the accessibility and efficacy of sign language for people with hearing disabilities, it is crucial to

employ cutting-edge and inventive technologies to overcome the challenges at hand. The other modern-day issue is; the concept of **digital inclusion** which entails removing barriers that hinder people from accessing digital content. These barriers may take the form of inaccessible systems, inadequate knowledge or skills, limited access to digital devices or materials, or other factors. As such, it is crucial to promote seamless communication between individuals with hearing impairments and those who may not comprehend sign language. Hence, **Digital accessibility** which pertains to the degree to which digital content can be easily accessed and utilized by all users, including those with visual or hearing impairments who may necessitate supplementary access provisions is crucial. This research strives to accomplish the following primary objectives:

- To close the communication divide between individuals who communicate through spoken language and those who use Indian Sign Language (ISL) by providing a system that can convert spoken language into ISL.
- To guarantee that spoken language is translated into ISL with precision and clarity, without any distortion or misinterpretation of the intended meaning.
- To establish an online platform that allows the general public to learn sign language and precisely translate spoken words into sign language.
- To develop a user-friendly interface that enables both sign language users and non-sign language users to communicate effortlessly, without encountering significant technical obstacles.

This research paper proposes and implements a novel model named as *Listen* which transforms spoken words/ text into sign language gestures and focuses on speech-to-hand-sign generation and designed with the intention to enhance communication for those with hearing disabilities. By enabling real-time translation of spoken or text input into sign language, *Listen* empowers individuals who rely on this form of communication. The output is presented through animated visuals for optimal accessibility. *Listen* model is able to achieve the accuracy of 99.21% when rigorously tested with different inputs.

The novelty of our model is its impressive capability of comprehending the connection between English and Indian sign language sentences through the use of advanced Natural Language Processing (NLP) techniques. This involves the mapping of words to their corresponding hand signs, enabling the generation of sign language gestures in response to spoken input. Despite the intricacy of sign language, regional variations, and the requirement for accurate speech recognition, this research work has made significant progress in developing a robust system for generating hand signs with better accuracy than the existing models to the best of our knowledge.

The research paper is structured as follows: Firstly, it presents a comprehensive overview of the existing related works in the field in Section II. Following that, it discusses the methodology proposed for implementing the proposed model in Section III. Subsequently, Section IV exhibits the results and visualizations of the model. Lastly, in Section V, it provides a summary of the research work done and outlines the future work.

II. RELATED WORKS

Numerous studies have shed light on the prevalence of auditory impairments within the Indian population. Furthermore, there have been commendable accomplishments in the deployment of speech recognition systems in meetings and email assistance [8], as well as the translation of text into sign language through various techniques. Additionally, hand gestures have been utilized for virtual mouse control. These endeavors have produced a broad spectrum of results, ranging from statistical data on disability to the development of useful applications and systems for communication and interaction.

The review highlights the specific areas that require attention. For example, speech recognition systems necessitate distinct enunciation [9], while sign language generation has lexicon constraints [6]. Avatars currently lack genuine emotional expression [7], and natural language processing encounters challenges with tokenization techniques. Furthermore, virtual mouse systems need enhancement in precision and efficiency. Papers [10], [11], [12], [13], [14], [15], [16], [17] revolve around the above stated techniques which is explained in the Table I. Followed by Lalit Goyal et al.[18] in 2016 constructed a synthetic dictionary that classified ISL words. These words were then translated into the HamNoSys (Hamburg Notation System) writing notation for sign language, which was translated into SiGML (Signing Gesture Markup Language) to

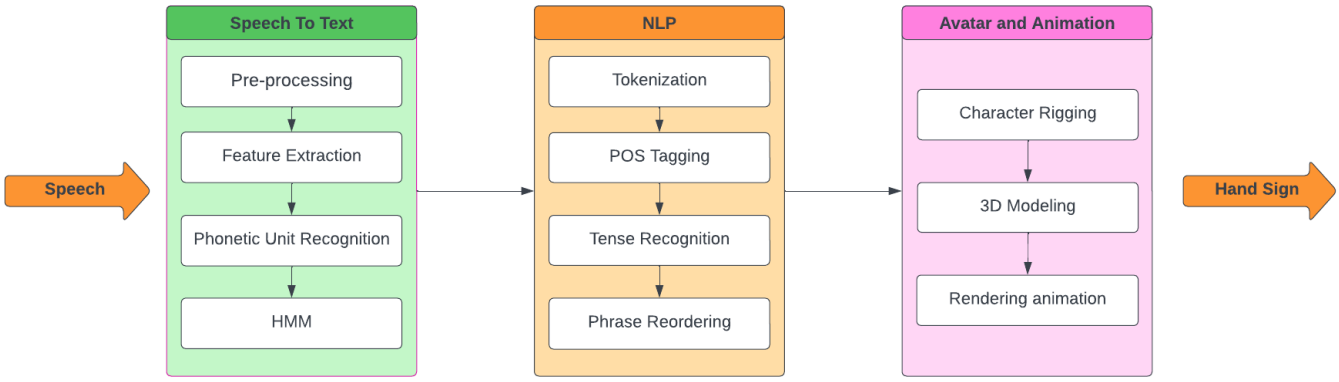

Fig. 1. Process flow of model.

produce a synthetic animation of the sign using a computer-generated cartoon with an overall accuracy of 94.35%. Krunal et al.[19] presented a method that uses speech recognition to turn an English voice dictation into text which bagged the highest accuracy of 94.53%. Followed by Sugandhi et al.[20] describes a system that generates Sign language based on Indian Sign Language grammar. It includes elements like an ISL parser, the Hamburg Notation System, the Signing Gesture Mark-up Language, and 3D avatar animation and achieved an accuracy of 96.67%. In order to translate English speech to Indian Sign Language with a 97.86% accuracy rate, Kulkarni et al.[21] presented an online platform that accepts voice as input and outputs a series of films showing the matching sign language. Hence, In the realm of assistive technologies for individuals with disabilities, a multitude of studies have explored various challenges and potential solutions. Table I provides a comprehensive compilation of related works, covering topics such as education and employment opportunities for the hearing impaired, rehabilitation options for deaf children, speech-to-text conversion systems, sign language generation, and virtual mouse systems utilizing hand gestures.

The Table I includes details regarding the authors, the issues they addressed, the methodologies employed, and the resulting outcomes. These studies employed a range of approaches, including data analysis, speech recognition techniques, language models, and 3D animation, to overcome specific challenges faced by individuals with disabilities. Additionally, the limitations of these studies have been provided in this section which is followed by Section III that explains our proposed model, its working, and corresponding components to address the objectives at hand.

III. Methodology

Effective communication is vital to human society, and spoken language is the primary tool we use to convey our ideas and beliefs [9]. Crafting a reliable platform for converting speech into sign language requires a multitude of intricate steps, as elucidated in Section II. Bearing this in mind, we are pleased to present our innovative approach for deploying our solution, which we have aptly named *listen*. The *Listen* system consists of three distinct subsystems: Speech-To-Text pre-processing, Natural Language Processing (NLP), and the avatar and animation. Fig. 1 provides an illustration of each subsystem's components. The model's process flow diagram, also shown in the figure, begins with the input Speech and proceeds through the Speech-To-Text pre-processing subsystem (explained in Subsection III-A), the NLP subsystem (explained in Subsection III-B), and ultimately the avatar and animation (explained in Subsection III-C), which displays the Hand sign corresponding to the input Speech. The first subsection of the model is explained in the following subsection.

A. Speech to Text

Speech recognition is the technology that converts spoken words into digital text, making it easily editable, storable, and shareable. The process involves analyzing and interpreting the acoustic and linguistic features of speech [8], such as words and phrases, to extract useful information. This is done by taking audio data input and performing recognition using a model. A labeled dataset is used to map sound vibrations to different letters, but some letters can be challenging to recognize due to similar pronunciations. In such cases, the probability of how commonly two letters appear together is used to determine the most likely recognition. Example:- "called" and "pan" Notice how 'a' produces different sounds in both words. In such cases, we use likelihood probability of how commonly two letters appear together.

The Fig. 2 shows the entire process of Speech recognition used in the research. The steps include pre-processing, feature extraction, phonetic unit recognition, and hidden Markov model all of which are explained below.

1) Pre-processing: During the course of this research, the pre-processing stage was implemented to partition the input into smaller frame sizes. In our model, each frame size is composed of 0.025 seconds of audio, equivalent to the duration of a single or a few phonemes, which are the basic units of speech, and typically have a duration in the range of tens to hundreds of milliseconds. This duration is ideal for capturing the unique characteristics of phonemes, which typically last for tens to hundreds of milliseconds. It was determined that only one English phoneme is typically pronounced within this time period. The pre-processed output is then forwarded to the feature extraction subsection.

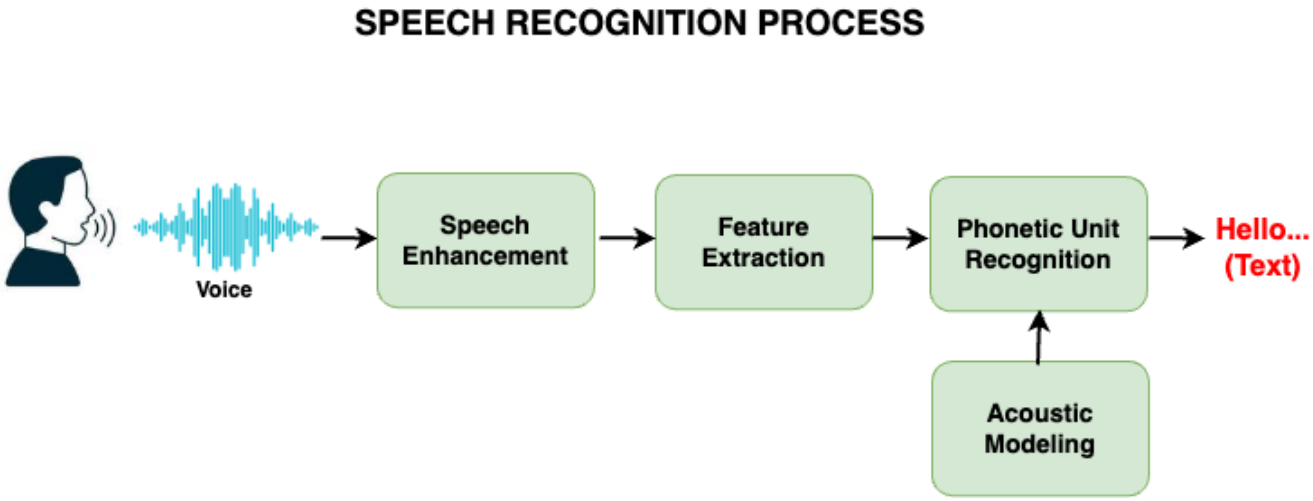

Fig. 2. Speech recognition.

2) Feature Extraction: In the feature extraction phase, each frame audio frequency feature is extracted. There are various techniques for feature extraction, some of them are Short-time Fourier Transform (STFT) [13], Mel Frequency Cepstral Coefficients [9], Chroma feature [22], and Spectral Contrast [23]. Our *Listen* model leverages **Mel Frequency Cepstral Coefficients** (MFCC) to accurately capture audio features. This technique mimics the human auditory system by utilizing a filter bank that simulates the Mel scale to approximate the magnitude spectrum produced by the STFT. Through a multi-step process, we transform the audio signal by first computing the logarithm of filterbank energies and then applying Discrete Cosine Transform (DCT) to obtain a concise representation of the signal. These features are then segmented into frames of equal size, with each frame representing a distinct phoneme. These frames are then passed onto the next component of the model, known as the **Phonetic Unit Recognition** (PUR) module.

3) Phonetic Unit Recognition: Once the features are extracted the phoneme is predicted by the Pre-trained acoustic model, which finds the most similar match of a feature of the current frame to existing labeled features in the data set followed by the **Hidden Markov Model**(HMM).

The HMMs are trained using a labeled dataset that contains speech recordings along with corresponding transcriptions or phonetic annotations. The training process involves estimating the parameters of the HMM, including the state transition probabilities. The state transition probability in simple terms represents the probability of one phoneme occurring with another phoneme. Hidden Markov Models (HMMs) are commonly used to model the temporal dependencies in speech signals. HMMs consist of several matrices that define the model's parameters [9] [13]. The outputted text is then fed to the Subsection III-B for conversion of text using Natural Language Processing(NLP) which is explained next.

B. Natural Language Processing (NLP)

The ultimate aim of Natural Language Processing (NLP) is to enable machines to comprehend human language in a way that is similar to how humans understand it. This involves the creation of intricate algorithms and models that allow computers to analyze, comprehend, and generate human language in a meaningful and contextual manner. NLP encompasses various techniques and tasks, including text tokenization, removal of stop words, part-of-speech (POS) tagging and phrase reordering. In this section, we will delve deeper into these techniques which are as follows:

1) Tokenization: Tokenization is the process of breaking down text into smaller units, or tokens, in NLP. These tokens can be words, phrases, or even individual characters, depending on the task at hand. Tokenization is a crucial step in NLP, as it helps to reduce the complexity of text, making it easier for machines to understand and analyze. This technique is used in various NLP tasks, such as sentiment analysis, text classification, and machine translation [14]. It can be performed using various libraries and tools available in Python programming language such as NLTK [15] and spaCy [24]. NLTK is used for Tokenization in our model whose working is shown in Fig. 3. Fig. 3 explains how the tokenization process works. First, the function removes any leading or trailing white space characters from the input string. Next, it splits the text into sentences using a pre-trained sentence tokenizer. This tokenizer is designed to identify the boundaries between sentences, such as periods, question marks, and exclamation points. The function then tokenizes each sentence into individual words using a pre-trained word tokenizer for example: Boundaries: white space. Finally, the function returns a list of tokens, where each token is a separate word in the text. The separated words are then inputted into the next section for further processing.

2) Removal of Stop Words: In the field of Natural Language Processing (NLP), the removal of stop words plays a crucial role in the pre-processing of text data. This step involves the cleaning and preparation of text data before further analysis. Stop words refer to the commonly used words in a language that do not contribute significantly to the overall

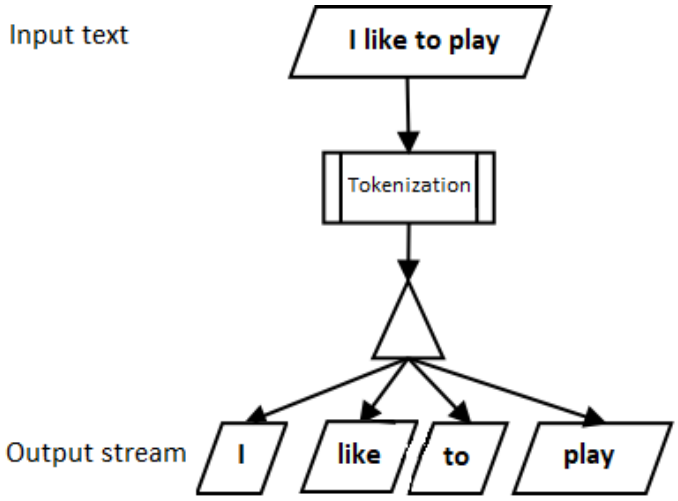

Fig. 3. Tokenization.

meaning of a sentence. Words like “a,” “an,” “the,” “is,” and “and” are examples of stop words, and their exclusion can significantly reduce noise and improve efficiency in data analysis. Other examples of stop words include “mightn’t,” “re,” “wasn’t,” “wouldn’t,” “being,” “were,” “isn’t,” “needn’t,” “don’t,” “nor’,” “aren’t,” “as,” “didn’t,” “should’ve,” and “be”, among others, which are generally omitted during NLP analysis. After, Tokenization, the model obtains a list of stop

TABLE II. POS TAG EXAMPLE LIST

Word	POS Tag	Word Class
She	PRP	pronoun, personal
went	VBD	verb, past tense
to	TO	“to”
the	DT	determiner
market	NN	noun (singular)
.	.	punctuation mark

words specific to the language or domain. The model then iterates through the tokens and compares each word against the stop word list. If a word is found in the list is a stop word, remove it from the token list. After which they are fed to the POS tagging phase [6].

3) Part-of-Speech (POS) Tagging: It is also known as grammatical tagging, is the process of assigning grammatical information, such as nouns, verbs, adjectives, etc., to individual words in a given text as shown in the Table II. Natural Language Processing (NLP) relies heavily on one fundamental task that serves as a foundation for many downstream tasks. Specifically, the task in question is essential for syntactic parsing, information extraction, and machine translation. Fig. 4 explains how POS Tagging will assign grammatical information in a sentence for example: I love to read poems.

In NLTK (Natural Language Toolkit), a popular Python library for natural language processing, you can perform POS tagging using the ‘pos_tag’ function. The ‘pos_tag’ function is designed to accept an input list of tokens and generate a corresponding list of tuples. Each tuple contains a word and

TABLE III. IMPLEMENTATION DETAILS

Language	Python
Tool	Blender (3D modelling and animation)
Libraries	NLTK, spaCy
Back End	Django
Front End	HTML/ CSS, Javascript

its corresponding POS tag which can then be utilized in phrase reordering.

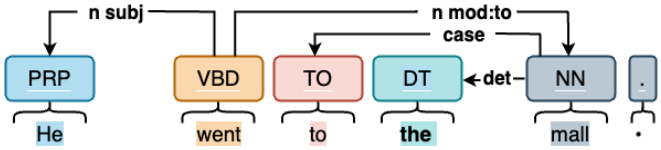

Fig. 5. Phrase reordering.

4) Phrase Reordering: Research has revealed that Indian Sign Language exhibits a distinct sentence structure when compared to English. Specifically, it adopts a Time-Subject-Object-Verb format, as opposed to the Subject-Verb-Object structure found in English [6]. Therefore, to effectively convey a phrase in sign language, it must first be restructured accordingly. For example, the sentence “He went to the mall” would require reordering, as illustrated in Fig. 5. Following this restructuring, we must consider the tense of the sentence and incorporate time-reference words such as Now, Before, and Later for present, past, and future tenses respectively. Once the input data has undergone speech-to-text pre-processing and NLP, it is then ready for the avatar and animation stages.

C. Avatar and Animation

To produce 3D videos, one typically needs access to specialized software, such as Adobe [16]. However, we prefer to utilize a free and open-source alternative known as Blender [25] for our 3D avatar and animation modeling. Blender is a powerful 3D creation suite that boasts an array of features for modeling, animation, rendering, and video editing. It is a favored tool among designers, artists, and animators for creating stunning visual content, including 3D models, animations, simulations, and visual effects. The techniques that we used for avatar creation and animation includes: **Character rigging.**

which is used for making sure the Sign Language is accurately performed by the Avatar we need to give it a human-like bone structure. We designed a structure as shown in Fig. 6.

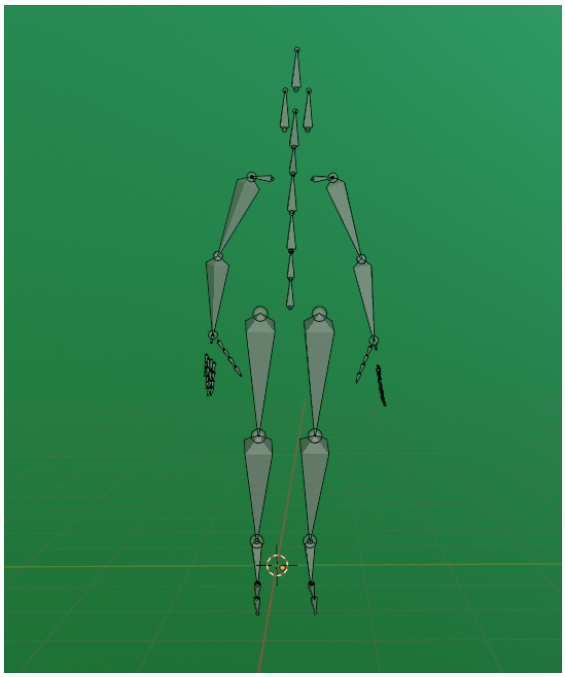

Fig. 6. Character rigging.

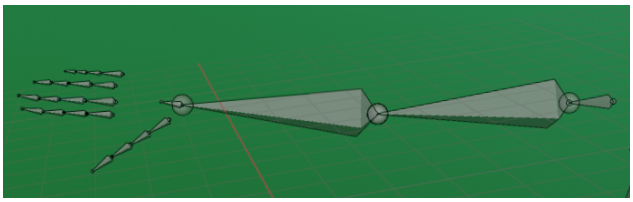

Fig. 7. Armatures.

The armatures in Fig. 7 provide our avatar with the necessary bone structure for movement. Accurate hand movements are essential for effectively conveying the inputted message, which is why meticulous attention has been given to hand rigging. In total, each hand comprises 46 armatures, including four for each finger, one for the wrist, elbow, and shoulder. Finally, the avatar is rendered in 3D to complete the process. After character rigging we jumped into 3D modeling of the obtained output from the preceding step.

In the concluding phase of **3D Modeling**, we initiated the process by fabricating a fundamental mesh for our avatar by taking advantage of Blender's modeling tools. We implemented an array of techniques, including extrusion, scaling, and sculpting, to refine the mesh into the desired form, meticulously focusing on details such as facial features, body proportions, and clothing. As we progressed with the modeling procedure, we referred to reference images or concept art to steer our work. The ultimate outcome was a breathtaking portrayal of the female and male avatars, as displayed in Fig. 8 and Fig. 9.

TABLE IV. TENSE RECOGNITION RESULTS

English Sentence	Tense Identified	Actual Tense
She is reading a book.	Present Continuous	Present Continuous
They will arrive tomorrow.	Future Simple	Future Simple
I have eaten dinner.	Present Perfect	Present Perfect
He plays the guitar.	Present Simple	Present Simple
We had studied for the test.	Past Perfect	Past Perfect
You should go to bed early.	Present Simple	Present Simple
The party was fantastic!	Past Simple	Past Simple
It is raining outside.	Present Continuous	Present Continuous
She will have finished by then.	Future Perfect	Future Perfect

Fig. 8. Avatar (Female).

Fig. 9. Avatar (Male).

IV. DISCUSSION: RESULTS AND ANALYSIS

Throughout our diligent research, we carefully monitored the outcomes at various stages to guarantee precise conversion from English to Indian Sign Language. Our comprehensive results include a detailed step-by-step analysis for each phase, commencing with the speech recognition process. During this stage, the input consists of audio speech, which we process to transform it into text using our sophisticated speech recognition algorithm. We implemented the model in Python.

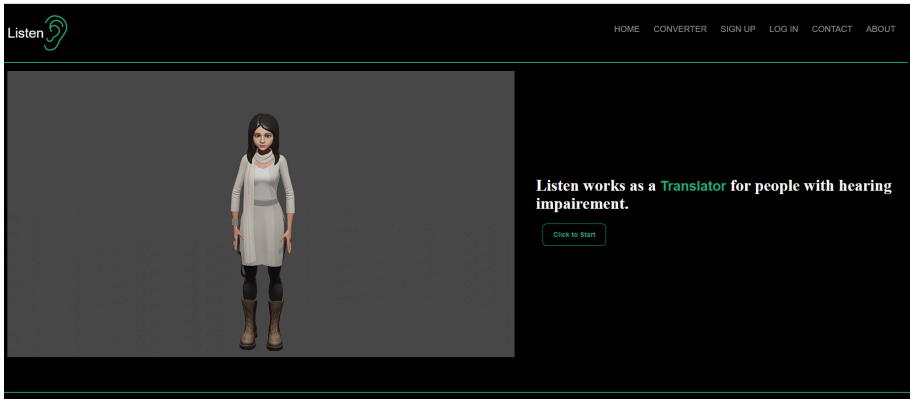

Fig. 10. Home page of *Listen*.

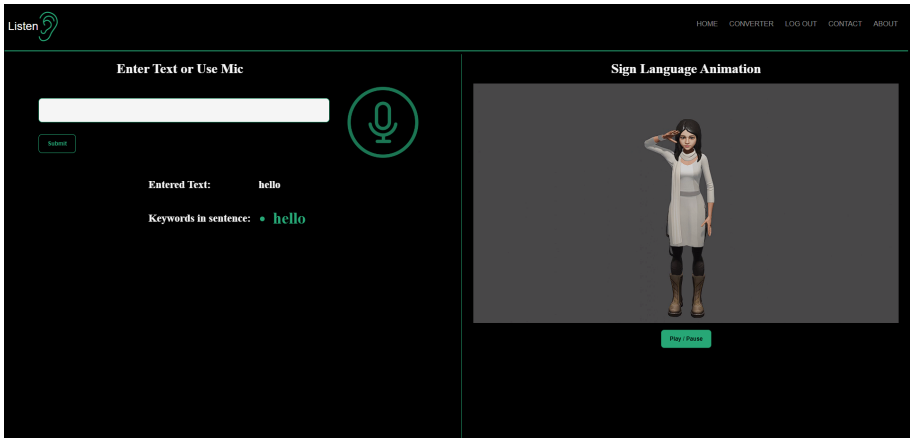

Fig. 11. Hello by *Listen*.

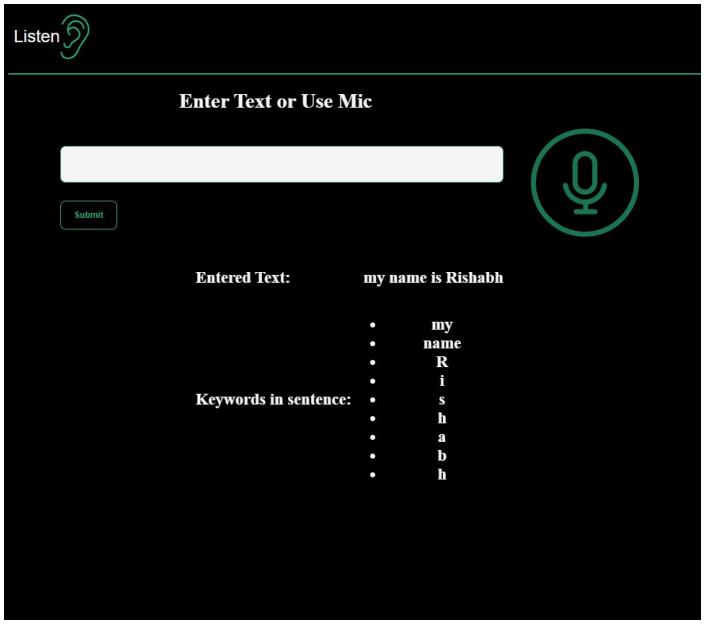

Fig. 12. Input text and keywords identification.

TABLE V. ISL SENTENCE RESULTS

English Sentence	Sentence after reordering	ISL Sentence
she has 10 books	she 10 books has	she 10 books
go to sleep	sleep go to	sleep go
I shall go after you	I after you shall go	later me after you go
I like my college	I my college like	me my college like
you are watching a movie	you movie are watching	now you movie watch
Rahul can change it	Rahul can it change	later Rahul can it change
show me your hands	me your hands show	me your hands show
Amit went alone	Amit alone went	before Amit alone go
define computer	define computer	define computer
Ram gave a flower to Sita	Ram flower gave Sita	before Ram flower give Sita
She made coffee for Shashwat	she coffee Shashwat made	before she coffee Shashwat make
we are waiting for Shashwat	we Shashwat are waiting	now we Shashwat wait

Implementation details are given in Table III which shows environment used to implement the different components of our *Listen* model. A snapshot of the home page of the model is shown in Fig. 10. Furthermore, we have included the outcomes of our conversion process from English text to Indian Sign Language sentence structure, along with a side-by-side comparison of our output and the actual sign language sentence structure as shown in Fig. 11. Additionally, we have incorporated a screenshot of the final output page, which showcases captivating hand sign animation videos. The following subsections include the results obtained of the speech-to-text conversion, tense recognition and phrase reordering followed by 3D modeling of the obtained outputs. Detailed explanations of the subsections are as follows:

A. Speech to Text

This section includes the snapshot of the result when the word 'my name is Rishabh' is pronounced and is added in Fig. 12. The entered text and keyword in the sentence both are extracted.

B. Tense Recognition and Phrase Reordering

This phase deals with the tense recognition and phrase reordering of the preprocessed input data. First we are identifying the tense of the sentences using POS tags this is required for adding a timeline to ISL sentences. Some examples of Tense Recognition results are shown in Table IV.

Once the tense of the sentence is recognized next step is to reorder the sentence according to the sentence structure of Indian Sign Language. The snapshot of the data set tested is shown in Table V. Note that sentences with present continuous/ past indefinite/ future tenses etc. are treated differently since we need to add 'Now' 'Before'or 'Later 'at the beginning of such sentences for correct ISL interpretation.

C. 3D Animations

ISL sentence is send to the 3D model and sign language animations were obtained for female and male avatar. Screenshot for the animation of word 'hello' is shown in Fig. 11. Images/ screenshots at a particular moment of a word in 3D animations of the female and male avatars for 10 test cases (5 test cases for each avatar) are shown Table VI and Table VII.

Our proposed model, *Listen*, has made significant strides in the recognition of tense and operates with great efficiency in the following areas:

- Tense recognition
- It does not rely on pre-designed notations, such as the Hamburg Notation System (HamNoSys) [17].
- It is specifically designed to work with the Indian Sign Language, which has not been extensively studied in the past.

As a result of our research, we are able to successfully achieve our objectives. We compared the performance of our model with existing models as shown in Table VIII. The accuracy of our *Listen* model is of 99.21% and sensitivity is 98.73% which is better than the existing models in the line of research.

V. CONCLUSION AND FUTURE WORK

In conclusion, speech-to-sign research has the potential to revolutionize communication and interaction for those with hearing impairments. By bridging the gap between the hearing communities, it promotes digital accessibility and inclusion. We achieved optimal results by implementing a robust methodology that involved data collection, pre-processing, sign language recognition, text pre-processing, text-to-sign language translation, 3D modelling of animations and evaluation of model. The system achieved accurate results that were adaptable, user-friendly, accessible, and scalable, with a diverse dataset on which the proposed model *listen* was trained. Our research focuses on converting English audio to Indian Sign Language (ISL), which presents unique challenges due to the absence of specific grammatical rules. Our model has yet to accomplish the task of animating facial expressions to denote negative and interrogative sentences. We plan to include ISL for phrases in the next phase, along with non-manual components for the sentence as a whole. Our goal is to improve

TABLE VI. IMAGES OF AVATAR (FEMALE) FOR TEST CASES

***Abstract*—The Internet of Things (IoT) has been rapidly integrated into various industries, with healthcare emerging as a key area of impact. A notable development in this sector is the IoHT-MBA system, a specialized Internet of Healthcare Things (IoHT) framework. This system utilizes a microservice approach combined with a brokerless architecture, efficiently tackling issues like data gathering, managing users and devices, and controlling devices remotely. Despite its effectiveness, there's a growing need to improve the privacy and control of patient data. To address this, we propose an enhanced version of the IoHT-MBA system, incorporating blockchain technology, specifically through the use of Hyperledger Fabric. This integration aims to create a more secure, transparent, and patient-centric data management platform. The system enables patients to oversee their peripheral devices, such as smartphones and sensors. These devices are integrated as part of the edge layer of the IoHT, contributing to a decentralized storage service. In our model, data is primarily retained on user devices, with only summarized data being communicated to service providers and recorded on the blockchain. This approach significantly boosts data privacy and user control. Access to user data is strictly regulated and must align with the patient's privacy conditions, which are established through smart contracts, thus providing an additional layer of security and transparency. We have conducted an evaluation of our blockchain-enhanced platform using key theories in microservice and brokerless architecture, such as Round Trip Time and Broken Connection Test Cases. Additionally, we've performed tests on data generation and queries using Hyperledger Caliper. The results confirm the strength and efficiency of our blockchain-integrated system in the healthcare IoT domain.**

***Keywords*—Medical test result; blockchain; smart contract; NFT; Ethereum; Fantom; polygon; binance smart chain**

I. Introduction

The landscape of the Internet of Things (IoT) has broadened substantially, now covering sectors including smart urban development, medical care, logistical supply chains, industrial processes, and agrarian practices. Forecasts indicate that by the year 2023, IoT-connected devices globally are expected to escalate to 43 billion, a significant increment from the figures recorded in 2018 [1]. Concurrently, investments in IoT infrastructure are anticipated to witness an annual growth of 13.6% up to the year 2022 [1]. Notably, the healthcare industry is a major adopter, constituting 20% of total IoT applications, only marginally behind smart city ventures at 29% [2]. Despite these advances, IoT systems are contending with challenges such as latency (27%), power consumption (18%), and system dependability (14%) [2].

Healthcare and Blockchain: The healthcare sector, in particular, grapples with inefficiencies in patient data handling and emergency response mechanisms [3], [4]. This has prompted an increased focus on blockchain technology as a strategic solution for healthcare operational improvements [5]. With its decentralized, secure ledger infrastructure, blockchain is aptly positioned to address these issues, offering a patient-oriented model for health record management [6]. Such an approach grants patients greater control over their medical records, enhancing trust and collaborative interaction within healthcare frameworks [7].

Blockchain-Enhanced IoHT System: This paper introduces the full version of our previous work [8]. This innovative system merges blockchain with IoT, forming a blockchain-centric, patient-focused healthcare framework that incorporates smart contracts for efficient data governance. This solution addresses the shortcomings of existing IoT models by offering a secure, dependable, and efficient approach to healthcare data management.

Our designed platform utilizes blockchain for reliable and verifiable patient data recording. It features a brokerless and microservice architecture, guaranteeing resilience, scalability, and uninterrupted operation. The platform employs Role-based Access Control (RBAC) combined with a hierarchical approach to user management, allowing for comprehensive oversight of platform constituents like users and devices.

Incorporating blockchain, the platform facilitates secure and trustworthy data exchanges, overcoming key challenges inherent in traditional healthcare systems. Smart contracts are employed to streamline healthcare data management, thereby elevating the system's operational efficiency and reliability. This research makes significant contributions in several areas:

- Developing a patient-centered framework using microservice and brokerless architecture to improve system resilience, scalability, and availability.
- Implementing blockchain for enhanced transparency in data storage, enabling secure and trackable data exchange.
- Utilizing smart contracts to reinforce security, particularly in interactions between patients and service

providers, and to automate data management processes.

- Demonstrating a practical application of our model, showcasing its relevance and transformative potential in healthcare data management.
- Conducting a thorough evaluation of the system's architecture and blockchain integration, underlining its advantages over conventional healthcare data management methods.

Organization of the Paper: The remainder of this paper is organized as follows: Section II provides a review of the current state of healthcare data management systems and the role of blockchain in this context. Section III delves into the details of our Blockchain-Enhanced IoHT model, discussing its architecture, implementation, patient-centric focus, and the integration of blockchain technology and smart contracts. Following this, Section IV presents an assessment of our system, examining its performance and effectiveness. Finally, Section V concludes the paper, summarizing our key observations and exploring potential future research avenues.

II. Related Work

A. IoT Architectural Models in Healthcare

Diverse architectural solutions for gathering data from medical devices have been explored in literature. Maktoubian et al. [9] put forth an architecture that amalgamates MQTT protocol with Kafka Message Queue. Despite Kafka ensuring secure data transfer, MQTT protocol and its brokering structure encounter issues like possible single point failures and ambiguous Quality-of-Service (QoS) levels [10], [11]. Their system's security protocols remain largely unaddressed.

Another approach by Taher et al. [12] describes an IoT-cloud system aimed at medical data assimilation and processing. Although comprehensive, it depends on the MQTT protocol, which is hampered by security concerns [13]. Partha Pratim Ray [14] introduced a system for medical data collection using web socket and HTTP, yet these protocols have high memory demands and are not optimal for low-end devices [15].

Ha Xuan Son et al. [16] developed a patient emergency system employing blockchain on Hyperledger Fabric, with a focus on access control. However, the data collection method from patients and the system's scalability aspects were not elaborated upon.

B. Microservice and Brokerless Architecture in IoHT

Jita et al. [17] developed a home-based medical care system using a scalable microservice architecture, enhanced with blockchain security. The system, however, is based on the Zetta IoT Platform, utilizing HTTP and RESTful protocols, which are less efficient for low-end devices [15]. While other studies [18], [19] acknowledge the significance of microservices in healthcare, they fall short in practical implementation details.

Di Zeng et al. [20] introduced a medical system model that combines microservice with a brokerless structure, but it remains unimplemented. Similarly, Lam et al. [21], [22], [23] illustrated architectures incorporating MQTT broker, Single Sign-On, and Kafka message queue, achieving a compromise between transmission efficiency, reliability, and security.

C. Blockchain Implementation in Healthcare Systems

Blockchain technology has been incorporated into healthcare systems with varying focal points. Son et al. [3] and Le et al. [4] devised blockchain-based frameworks for access control in emergencies, prioritizing patient data confidentiality.

Le et al. [5] devised a blockchain system for medical waste management, underlining the need for secure information sharing about medical equipment and supplies, especially pertinent during the COVID-19 crisis. In another study, Le et al. [24] proposed a blockchain system for blood donation networks, tackling blood quality, supply, and distribution challenges.

Quynh et al. [25] suggested a blockchain system for managing national blood donation networks, streamlining blood supply and demand. Duong et al. [6], [7] proposed patient-focused healthcare systems utilizing blockchain smart contracts, emphasizing patient access, traceability, and control over health records.

These studies underscore the efficacy of blockchain in bolstering data security, privacy, and patient-centric approaches in healthcare. Our research builds upon these foundations, introducing a blockchain-enhanced IoHT platform that combines microservice and brokerless architecture to augment scalability, efficiency, and control over patient data.

III. System Architecture

A. Architectural Overview of Blockchain-Enhanced IoHT-MBA Platform

The proposed blockchain-enhanced IoHT-MBA platform is based on a layered architecture, incorporating the edge layer, blockchain layer, and cloud layer.

1) Edge Layer: The edge layer includes local devices of the patient like smartphones, sensors, and other IoT devices, functioning as the primary data collectors and processors. Each of these devices is integrated with a simplified blockchain client, facilitating communication with the blockchain layer. Data retention on these devices is localized, bolstering both privacy and security.

2) Blockchain Layer: At the heart of our patient-centric data management system lies the blockchain layer. Leveraging Hyperledger Fabric, a permissioned blockchain framework, we establish a secure, transparent ecosystem for data handling. Here, only synthesized health data and related transactions are stored. The validation and recording of transactions across various nodes reinforce data integrity and traceability. Smart contracts, or chaincodes in Hyperledger Fabric, automate agreement execution pertaining to data sharing. These contracts encode patient privacy conditions, executing upon data access or sharing requests to ensure compliance with patient preferences.

3) Cloud Layer: The cloud layer offers diverse services like data analytics and health monitoring to platform users. It interfaces with the blockchain layer for data access, adhering to privacy terms defined in smart contracts and accessing only aggregated blockchain data.

This structure of the platform ensures a secure, decentralized, and patient-focused data management approach in healthcare IoT. Subsequent sections will elaborate on the platform's implementation and evaluation.

B. Detailed Architecture

The system's design incorporates microservices and brokerless architecture, enhancing fault tolerance, scalability, and operational efficiency. Microservices architecture refers to developing applications as a collection of small, autonomous services, each operating in its own environment and communicating through lightweight mechanisms like HTTP/REST with JSON or Protobuf. In our case, gRPC is employed for enhanced speed[1]. This architecture allows for independent updating, deployment, and scaling of individual services. The brokerless architecture removes the necessity for a central broker or server, thus eliminating single points of failure and enhancing scalability. It allows direct communication among nodes or devices, crucial for reliability and efficiency in healthcare settings.

The combination of these architectures equips our system to efficiently manage a vast array of devices and data while maintaining high availability and performance. Further sections will detail the patient-side data consumption in edge computing (refer to Fig. 1) and the overall architecture of the Blockchain-Enhanced IoHT platform (refer to Fig. 2).

1) Edge Computing Architecture: The edge computing component encompasses two primary layers: the Things layer and the Client layer (see Fig. 1).

a) Things Layer: This layer consists of various medical devices owned by the patient, like wearables and IoT medical devices. Each device is outfitted with sensors to gather crucial health data. These devices manage two independent services: data collection and control services. Data collection involves continuous monitoring and streaming to edge computing services, with patient authentication and authorization checks for data security. The control service enables remote adjustments to the devices, catering to specific health needs and preferences.

b) Client Layer: The Client layer, represented by patients, allows device management and data monitoring. Patients control their health data, managing sharing permissions and ensuring their privacy preferences are upheld. This layer's centrality to the architecture underlines the patient-centric nature of data management in our platform.

Edge computing in our platform processes data near its source, minimizing latency and enhancing real-time processing. Patient control over devices and data underscores the platform's focus on patient autonomy and privacy.

2) Blockchain-Enhanced IoHT Architecture: Fig. 2 depicts the Blockchain-Enhanced IoHT platform architecture, enabling secure and efficient data transmission from medical devices to the distributed ledger and service providers.

a) Data Processing Services: Post-collection at the edge, health data undergoes further processing in data processing services. Tasks include data cleaning, transformation, and feature extraction. Aggregated data, instead of raw patient data, is stored in the blockchain for enhanced efficiency and privacy.

b) Distributed Ledger and Smart Contracts: Aggregated data is stored in the distributed ledger, validated by multiple nodes for integrity. Smart contracts in our system serve two functions:

- Data Access Control: Smart contracts contain metadata parameters reflecting patient privacy preferences. Service provider access requests are checked against these parameters, ensuring compliance with patient privacy conditions.
- Data Usage Control: They also regulate how service providers can use the data, adhering to conditions set within the contract.

c) Service Providers: Service providers, including healthcare professionals and researchers, access ledger-stored data. Their access is contingent on meeting the privacy conditions set in the smart contracts.

The Blockchain-Enhanced IoHT platform thus ensures patient control over their data, while facilitating secure and transparent data sharing with service providers.

IV. Evaluation Scenarios

A. Evaluating Performance Using Microservice and Brokerless Architectural Approach

1) Configuration of the Test Environment: Our innovative Blockchain-Enhanced IoHT system utilizes a microservice architecture for optimal performance. During our evaluation phase, the services of this platform were hosted on the Amazon EC2 platform[2]. We configured each service to mirror a virtual machine setup, equipped with 1GB of RAM and a single vCPU for realistic testing conditions. Additionally, client-side services, including data collection and control, were implemented on the Raspberry Pi 3 model B+ modules[3]. These modules are powered by the Broadcom BCM2837, an ARMv8 (64bit) quad-core processor clocking at 1.2 GHz, and are also furnished with 1GB RAM, providing a robust environment for our system's deployment and testing.

2) Evaluation of Round Trip Time: In gauging the efficacy of data transmission within the system, the Round Trip Time (RTT) is employed, measured from the instance data is transmitted from IoT devices until it reaches the Message Queue. Alongside this, an examination of the error rate, quantified as the ratio of lost messages to the total, is conducted. For a thorough assessment, instances of EC2 VMs equivalent to the Rasberry Pi model B + module are generated in diverse geographical locations. These locations encompass North California, Stockholm, Ho Chi Minh City, and Sydney.

[1]For detailed implementation, see our prior work [26], [27]

[2]https://aws.amazon.com/

[3]https://www.raspberrypi.org/products/raspberry-pi-3-model-b/

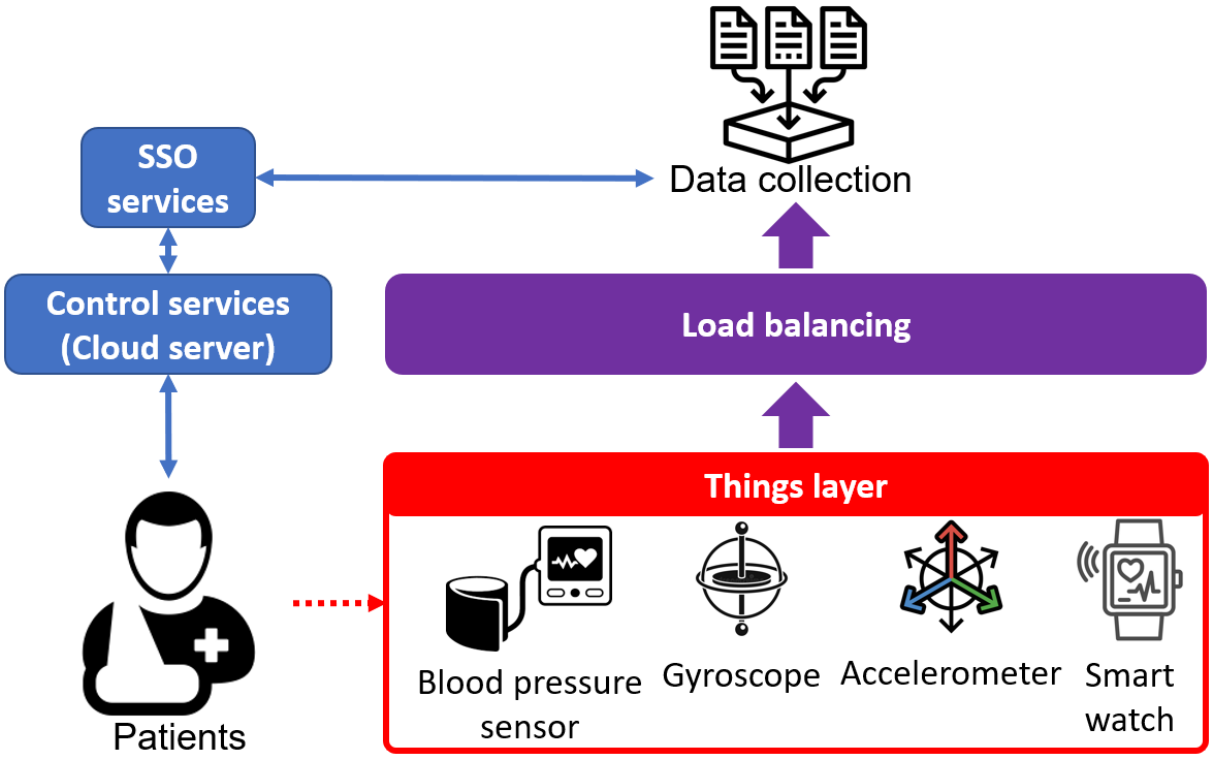

Fig. 1. Patient-side edge computing based on microservice and brokerless architecture.

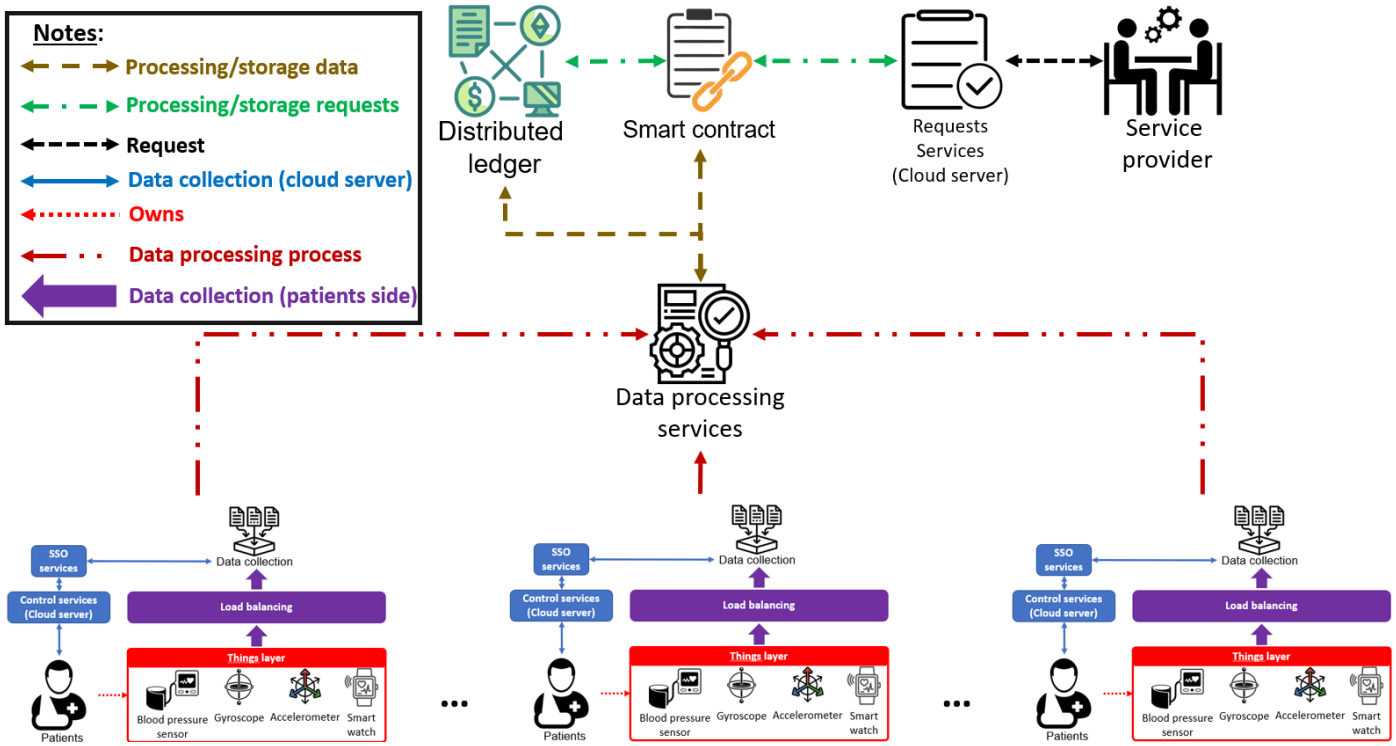

Fig. 2. Blockchain-Enhanced IoHT platform architecture.

The objective is to analyze the impact of location on both delay time and error rate during the streaming of data. The findings from these evaluations are succinctly summarized in Table I.

Table I illustrates the Round Trip Time (RTT) and error rates associated with data communication in the Blockchain-Enhanced Internet of Health Things (IoHT) platform, observed across diverse geographical locations: North California, Stockholm, Ho Chi Minh City, and Sydney. The RTT is examined for varying message volumes: 1,000; 5,000; 10,000; 50,000; and 100,000.

The RTT, in this context, measures the time taken for a message to travel from an IoT device (sender) to the Message Queue (receiver) and back.

The table provides the following insights:

- In North California, RTT ranges from 3.23 seconds for 1,000 messages to 259.11 seconds for 100,000 messages, with a consistent 0% error rate across all message volumes.
- In Stockholm, RTT varies from 3.41 seconds for 1,000 messages to 259.43 seconds for 100,000 messages, maintaining a 0% error rate for all message volumes.
- In Ho Chi Minh City, RTT spans from 3.62 seconds for 1,000 messages to 259.98 seconds for 100,000 messages, accompanied by a 0% error rate across all message volumes.
- In Sydney, RTT ranges from 3.21 seconds for 1,000 messages to 258.06 seconds for 100,000 messages, with a consistent 0% error rate for all message volumes.

The error rate represents the proportion of lost messages during transmission. A 0% error rate across locations and message volumes indicates flawless transmission without any losses.

This table underscores the Blockchain-Enhanced IoHT platform's robust performance across varied geographical locations and message volumes. Despite increasing message volumes, the RTT exhibits linear growth, and the platform demonstrates resilience by maintaining a 0% error rate, affirming its reliability.

3) Robustness Against Connection Failures: Evaluating the performance of the Blockchain-Enhanced Internet of Health Things (IoHT) platform under connection failures is vital, especially in healthcare applications where data integrity and reliability are paramount. Disruptions in data transmission can potentially lead to incorrect diagnoses or interventions, significantly impacting patient care.

To gauge the system's resilience in the face of connection failures, we conducted simulations of broken connections between the data publisher (i.e., the healthcare IoT device) and the subscriber (i.e., the data processing or storage service). We then compared the number of messages received by the subscriber in scenarios with and without the utilization of the Blockchain-Enhanced IoHT platform.

As illustrated in Fig. 3, in the absence of our platform, the subscriber only captures the latest message sent by the publisher when a connection failure occurs. This limitation arises from the retain function of the MQTT protocol[4] which retains only the most recent message, resulting in the loss of any data published during the disconnection period.

Conversely, when employing the Blockchain-Enhanced IoHT platform, the subscriber receives all messages published by the sender, including those transmitted during the connection failure. This capability is facilitated by the Kafka message queue, which preserves all outgoing messages until successful delivery, thereby preventing any data loss during transmission.

The capacity to recover and process all data following a connection failure is a critical attribute for a healthcare IoT system. It ensures the reliable reception of all patient data irrespective of network conditions, preserving the integrity of medical data and facilitating accurate and comprehensive analysis for improved patient care outcomes.

B. Evaluation of Performance using Hyperledger Fabric

To comprehensively gauge the efficacy of our proposed Blockchain-Enhanced Internet of Health Things (IoHT) model, an in-depth performance analysis was carried out utilizing Hyperledger Caliper, a benchmarking tool tailored for blockchain systems. The focal performance indicators included the count of successful and unsuccessful requests, transaction rate (Send Rate in transactions per second, or TPS), latency (maximum, minimum, and average, in seconds), and throughput (TPS).

Our assessment encompassed five distinct scenarios, each representing varying loads on the system (ranging from 1,000 to 5,000 requests per second). The evaluation ceased at 5,000 requests per second, as we observed a notable surge in the number of failed requests beyond this threshold, particularly in scenarios involving data updates.

1) Medical Data Creation Performance: Table II delineates the performance metrics for medical data creation under diverse loads. Notably, the count of successful requests oscillates between 27,000 and 31,000, while failed requests range from 16,000 to 19,000. Interestingly, the correlation between the number of successful and failed requests and the system load appears inconclusive, underscoring the robustness of our platform. The transaction rate remains consistent across all scenarios, hovering between 135 and 150 transactions per second (TPS).

Regarding latency, the maximum latency spans from approximately 1,457 seconds (for 3,000 requests per second) to around 1,712 seconds (for 5,000 requests per second). Minimum latency varies from under 1 second (for 1,000 requests per second) to approximately 12 seconds (for 3,000 requests per second). The average latency fluctuates between 650 and 700 seconds per request, contingent on the system load. Meanwhile, throughput maintains steady performance within the range of 12 to 17 TPS.

2) Performance Evaluation of Medical Data Queries: To assess the system's performance under varying data query loads, we conducted tests across five scenarios, ranging from 1,000 to 5,000 data retrieval requests per second. As depicted in Table III, the count of successful requests consistently

[4]For further details, we refer the reader to our prior publications [28], [27]

TABLE I. ROUND TRIP TIME RESULTS IN THE FOUR PLACES

Location	Factor	1,000	5,000	10,000	50,000	100,000
North California	RTT(s)	3.23	13.78	27.42	131.16	259.11
	Error(%)	0	0	0	0	0
Stockholm	RTT(s)	3.41	13.98	25.86	129.14	259.43
	Error(%)	0	0	0	0	0
Ho Chi Minh city	RTT(s)	3.62	13.74	24.93	131.11	259.98
	Error(%)	0	0	0	0	0
Sydney	RTT(s)	3.21	14.02	26.08	129.98	258.06
	Error(%)	0	0	0	0	0

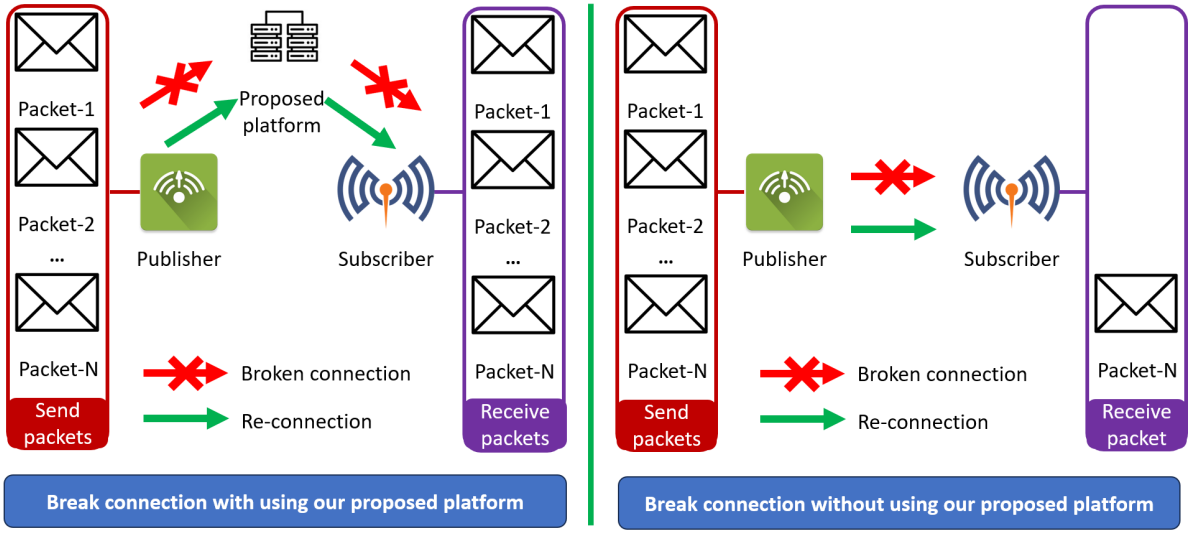

Fig. 3. Number of received messages when the system recovers after a broken connection issue.

TABLE II. MEDICAL DATA CREATION PERFORMANCE IN FIVE INCREASING EACH 1,000 REQUESTS SCENARIOS

Name	Success	Fail	Send Rate (TPS)	Max Latency (s)	Min Latency (s)	Avg Latency (s)	Throughput (TPS)
1,000 request	26,987	19,801	135.0	1,532.18	10.41	654.12	11.9
2,000 request	29,604	16,402	138.5	1,523.78	9.82	634.21	16.4
3,000 request	27,412	18,523	142.7	1,457.34	10.43	678.43	15.3
4,000 request	29,617	19,176	139.9	1,686.23	10.67	651.24	15.4
5,000 request	30,401	16,205	145.6	1,712.12	11.01	696.18	17.2

surpasses 106,000, with failed requests remaining below 5,000. This noteworthy outcome underscores the system's capability to effectively retrieve a substantial volume of medical data under significant loads. Analogous to the data creation scenario, both the Send Rate (TPS) and Throughput (TPS) exhibit stability, experiencing minor fluctuations around 325 to 360 and approximately 290, respectively.

Concerning system latency, maximum latency remains approximately 250 seconds across all five measurement scenarios. The minimum latency is virtually negligible, at about 0.01 seconds. On average, each data query request receives a response within roughly 5 seconds. These outcomes illustrate the efficiency of our Blockchain-Enhanced IoHT platform in managing both data creation and retrieval requests, crucial operations in a patient-centric Internet of Healthcare Things system.

C. Discussion

The evaluation of our proposed Blockchain-Enhanced IoHT system yields valuable insights into its performance and efficiency. The system's brokerless and microservice architecture, coupled with a blockchain-based data management approach, showcases its potential to handle a substantial number of data transactions while maintaining low latency and high throughput.

The system underwent testing under diverse load conditions, with request volumes ranging from 1,000 to 5,000 per second. Even under heightened loads, the system demonstrated resilience and stability, sustaining a consistent response time and minimal error rates. The brokerless architecture, employing the gRPC protocol, exhibited notable improvements in CPU and RAM usage compared to other IoHT protocols, indicative of efficient resource utilization.

TABLE III. MEDICAL DATA QUERY PERFORMANCE IN FIVE INCREASING EACH 1,000 REQUESTS SCENARIOS

Name	Success	Fail	Send Rate (TPS)	Max Latency (s)	Min Latency (s)	Avg Latency (s)	Throughput (TPS)
1,000 request	103,321	4,232	356.0	254.14	0.01	4.89	289.18
2,000 request	108,208	4,456	323.5	256.23	0.01	5.08	298.45
3,000 request	103,661	4,281	345.8	252.51	0.01	4.23	294.01
4,000 request	108,129	4,928	341.4	250.65	0.01	4.83	293.21
5,000 request	106,224	3,265	323.9	256.12	0.01	5.01	298.11

V. DISCUSSION

A. Remarkable Insights

As we delve into the intricacies of gas metrics across various blockchain platforms, a plethora of distinct patterns and insights emerge, which hold significant relevance for both blockchain developers and users alike.

1) Uniformity vs. Variability: One of the notable observations is the trade-off between uniformity and variability in gas pricing. The BNB Smart Chain stands out for its uniformity, maintaining a consistent gas price of 0.00000001 BNB (equivalent to 10 Gwei) across all actions. This predictability can be advantageous for users as it ensures a constant expectation of costs. In contrast, platforms like Polygon introduce minor discrepancies in gas prices across different operations. While these variations might seem subtle, they can accumulate substantial costs in high-frequency actions, making it a critical consideration for blockchain investors and developers.

2) Cost-Efficiency: Fantom's gas pricing strategy is particularly noteworthy, with a remarkably lower gas price of 3.5 Gwei compared to BNB Smart Chain's 10 Gwei. This significant difference can translate into considerable cost savings for users engaged in large transaction volumes. It underscores the importance of gas pricing as a pivotal factor influencing the economic feasibility of utilizing a particular blockchain platform.

3) Complexity in Pricing: Polygon's nuanced gas pricing structure may arise from its inherent design or a deliberate effort to fine-tune pricing for specific operations. While this complexity might introduce challenges for the average user, it offers enhanced flexibility for businesses and developers. The ability to tailor gas costs for different operations can be advantageous for optimizing resource allocation in specific use cases.

4) Operational Capacity and Efficiency: Efficiency in gas consumption during operations is another critical aspect to consider. For instance, Celo demonstrates that it utilizes only 76.92

5) Strategic Implications for Projects: The insights gained from this analysis have strategic implications for blockchain projects, especially startups and new ventures. Beyond just the direct costs, factors such as operational efficiency, pricing flexibility, and predictability play a crucial role in platform selection. These considerations can significantly influence decisions regarding project launches, investments, and day-to-day transactions.

6) User Considerations: For the average user, clarity and predictability in transaction costs are paramount. Platforms with transparent and straightforward pricing models may be more attractive. On the other hand, platforms that offer flexibility in pricing and demonstrate optimal resource consumption may be favored by traders, businesses, and advanced users seeking to fine-tune their operations.

B. Future Directions

In the subsequent phases of our research, we are eager to delve even deeper into the intricacies of transaction costs and gas metrics. This will involve the integration of advanced methodologies and intricate data structures. Specifically, we plan to implement sophisticated encryption-decryption techniques to provide a clearer and more detailed picture of transaction overheads [29]. Taking our proposed model from theoretical analysis to practical application is another exciting avenue of exploration. We intend to execute the recommendation system over the Fantom (FTM) mainnet to validate its performance in real-world scenarios. This real-world validation will help us refine our model and make it more robust.

Furthermore, our current analysis has not explored the nuances of user privacy policies, which are of paramount importance in today's digital transactions [30], [31]. Building upon established research in access control and dynamic policy models, we envision enhancing our system's capabilities to address these privacy concerns comprehensively [16].

From an infrastructural standpoint, we are considering the integration of modern techniques and paradigms such as gRPC, Microservices, dynamic messaging paradigms, and brokerless models [26], [21]. These integrations will not only augment the robustness of our framework but also enhance user interactions, particularly in terms of API-driven communication [23]. This forward-looking approach will ensure that our research remains at the forefront of blockchain technology advancements [22], [27].

VI. CONCLUSION

In this research, we introduced a cutting-edge, patient-centric framework known as the Blockchain-Enhanced IoHT. This innovative system integrates a microservice and brokerless architecture, significantly enhancing its fault tolerance, scalability, and overall availability. Such an architecture not only fortifies the system's robustness but also renders healthcare data management more efficient and resilient. The incorporation of blockchain technology into the system guarantees secure and easily traceable data sharing, effectively tackling the prevalent challenges faced in traditional healthcare systems. Moreover, the employment of smart contracts in this model reinforces security, especially in managing the interactions between patients and healthcare providers, thus boosting the system's efficiency and dependability. The proof-of-concept showcased within this study validates the practicality and potential of our proposed model in revolutionizing healthcare data management. Our evaluation of the Blockchain-Enhanced

IoHT, focusing on its architectural design and blockchain integration, sheds light on its capabilities in managing healthcare data efficiently.

Looking ahead, our future endeavors will concentrate on refining the system's performance further. This includes exploring avenues to amplify the scalability and efficiency of the blockchain component and delving into the integration of more sophisticated security measures. Our ultimate goal is to propel advancements in the realm of healthcare data management, aiming to substantially improve patient care and outcomes.

King Abdulaziz University, Jeddah, Saudi Arabia

***Abstract*— This paper presents the Smart Grocery Shopping system (GROCAFAST), a system for optimizing the grocery shopping experience and improving efficiency for shoppers. The GROCAFAST system consists of a mobile app and a server component. The mobile app allows shoppers to create, manage, and update grocery lists while providing store navigation assistance. The server component processes data, generates optimized route maps, maintains an inventory database, and facilitates the online chat room. Unlike existing grocery shopping systems, GROCAFAST is cost-effective as it does not rely on any extra infrastructure and reduces both shopping time and walking steps. GROCAFAST utilizes Dijkstra's algorithm to efficiently guide shoppers through the store, minimizing the time needed to visit all aisles containing their desired items. The user-friendly interface and time-saving features make grocery shopping more efficient and enjoyable. The evaluation results demonstrate that GROCAFAST reduces the total shopping time by 67.6% when compared to a traditional approach that mimics the way shoppers visit a grocery store, browse aisles, and select items. It also reduces the walking steps by 59%.**

***Keywords*—Grocery shopping app; route map; grocery shopping experience; dijkstra's algorithm**

I. Introduction

Grocery shopping is one of the most common chores in our lives, yet it is still stressful. Everyone needs to go to grocery stores to buy food, drinks, laundry supplies, etc. However, shopping for groceries is not as simple as one may think. It demands preparation, clarity, and commitment. Each trip to the grocery store takes an average of 41 minutes, which equates to approximately 53 hours annually [1]. In the United States, a typical grocery shopping trip takes about 40 minutes, though most of the grocery shopping is done by women (59 minutes/week), and men (29 minutes/week) [1]. If we include travel time, which is about 15 minutes per trip, and consider the fact that people, on average, go grocery shopping 1.5 times per week, it accounts for close to 6 hours of grocery shopping per month for women [2].

Grocery shopping can sometimes feel overwhelming and challenging, with various obstacles that can waste valuable time and cause frustration. Some of the issues that shoppers may encounter are: (1) Inefficient navigation: many shoppers spend a significant amount of time zigzagging through the store aisles, trying to locate all the items on their list. (2) Difficulty finding specific items: it can be frustrating when shoppers can't find a particular item in the store, especially when they are supposed to be in a specific section. (3) Unavailability of expected items: shoppers may have certain expectations of the store's inventory, but when they can't find an item they need or it's out of stock, it can be disappointing and inconvenient. These challenges highlight the need for effective strategies to streamline the grocery shopping experience and save valuable time.

Making a paper grocery list could help in navigating the store more efficiently by not having to wander aimlessly around the store and make decisions on the fly. Research shows that people who make grocery lists prior to going to the store buy fewer items, spend less money, and make fewer unplanned and impulsive purchases [3]. There is also some evidence that people who make paper grocery lists make fewer unplanned purchases [4]. However, the paper list is less convenient and lacks organization and categorization, making it difficult to locate items quickly in the store and potentially leading to backtracking, which consumes valuable time.

To address the challenges of inefficient navigation, difficulty finding specific items, and unavailability of expected items during grocery shopping, it's important to come up with a solution that reduces shopping time. This paper proposes a Smart Grocery Shopping system (GROCAFAST) is proposed. GROCAFAST provides shoppers with a route map that shows items on the grocery list arranged in the same order as they appear in the store, making it more efficient to navigate through the aisles and find the items quickly. By aligning the list with the store's layout, shoppers can minimize backtracking and save time during their shopping trips. GROCAFAST does not need any tracking infrastructure, as it relies on maintaining a route map that guides shoppers through the store. The map is designed to optimize the shopping journey by directing shoppers through the aisles that contain the items on their grocery list. Furthermore, GROCAFAST allows shoppers to easily create, manage, and update their grocery lists. It also allows them to quickly search for specific items and view their exact location within the store. It is important to notice that GROCAFAST leverages shoppers' previous lists and preferences to provide personalized shopping suggestions. Finally, it provides an online chat room where shoppers can engage with each other, share reviews, and exchange recommendations.

GROCAFAST comprises a mobile app and a server, work-

[1] https://www.creditdonkey.com/grocery-shopping-statistics.html

ing together to enhance the grocery shopping experience. The mobile app allows shoppers to efficiently create, manage, and update their grocery lists. It also provides store navigation assistance, displaying a map of the store with highlighted aisles, departments, and checkout counters. Shoppers can view their optimized route based on their grocery list, guiding them through the store efficiently and saving shopping time. The server component manages grocery lists, generates route maps, maintains a comprehensive inventory database, analyzes shoppers' preferences, and facilitates an online chat room or community platform for sharing reviews and recommendations. Together, GROCAFAST streamlines grocery shopping by combining convenient list management, efficient navigation, and personalized assistance.

GROCAFAST efficiently achieves its goal by leveraging the power of Dijkstra's algorithm, a widely recognized method for finding the shortest path in a graph [5]. Specifically tailored to guiding shoppers through a store, this algorithm is employed to generate an optimized route that minimizes the time necessary to visit all the aisles containing the items on the shopper's grocery list. By utilizing Dijkstra's algorithm, GROCAFAST ensures an efficient and streamlined shopping experience for its shoppers.

In our comparative analysis, we assess the performance of GROCAFAST, an innovative grocery shopping solution, against the traditional method of physically visiting a grocery store, browsing aisles, and selecting items. Our objective is to explore the advantages of GROCAFAST in terms of time efficiency, device compatibility, and overall user experience. The experiments were conducted at a real grocery store situated in the female dormitory at King Abdulaziz University. The findings revealed remarkable benefits of GROCAFAST, including a staggering 67.6% reduction in shopping time and a significant decrease of 59% in walking steps when compared to the traditional grocery shopping approach. These results underline GROCAFAST's potential to revolutionize the shopping experience and enhance efficiency for shoppers.

The main contributions of this paper are:

- Design and implementation of GROCAFAST, a Smart Grocery Shopping system that combines efficient navigation, convenient list management, personalized assistance, and community engagement to streamline the grocery shopping experience.
- Utilize Dijkstra's algorithm to generate optimized routes, ensuring efficient and time-saving shopping trips for shoppers.
- The experiments are conducted at a real grocery store situated in the female dormitory at King Abdulaziz University. This real-world setting allowed us to evaluate GROCAFAST's performance in a practical environment.
- In our comparative analysis, we assess the performance of GROCAFAST, an innovative grocery shopping solution, against the traditional method of physically visiting a grocery store. Our objective is to explore the advantages of GROCAFAST in terms of time efficiency, device compatibility, and overall shopper experience.

The rest of this paper is organized as follows. Section II discusses the related work. Section III presents a system design. A system overview is presented in Section IV. The Experimental setup and evaluation are presented in Section V, and Section VI, simultaneously. The paper concludes in Section VII.

II. Related Work

Most would agree that avoiding spending more time than intended and avoiding food waste are important goals. But dealing with the onslaught of temptations when grocery shopping can be difficult. One of the tools that makes this task easier is a shopping list. Thus, numerous applications have been developed to enhance the convenience, efficiency, and overall shopping experience for shoppers. Table I illustrates the difference between GROCAFAST and other applications. The table also demonstrates the features of GROCAFAST when compared to the applications. In the following, we briefly discuss each of these applications in relation to GROCAFAST.

For instance, SMART LIST [6], Smart Shopping List [7], AnyList [8], Listonic [9], and Grocery-Smart Shopping List [10] aim to enhance convenience and efficiency in creating, organizing, and managing shopping lists. On the other hand, both MyGrocery [11] and ShopLister [12] take it a step further by suggesting missing items based on user preferences, purchase history, or popular items. Further, AnyList, MyGrocery, ShopLister, and Instacart [13], not only focus on list management but also offer features that assist shoppers in finding nearby supermarkets or locating items within a store. Although, GROCAFAST shares the common goal of enhancing convenience and efficiency in grocery shopping; however, GROCAFAST differentiates itself. GROCAFAST aims to provide a comprehensive and tailored shopping experience by combining personalized suggestions, optimized route mapping, list history retrieval, and an interactive community platform.

TABLE I. Features Comparison between GROCAFAST and other Available Applications

Applications	Features				
	Grocery List Management	In-store Navigation	Search Items	Personalized Suggestions	Community Chat Room
SMART LIST	✓				
The Smart Shopping List	✓				
AnyList	✓			✓	
Listonic	✓

MyGrocery	✓			✓	
ShopLister	✓		✓	✓	
Instacart	✓	✓		✓	
GROCAFAST	✓	✓	✓	✓	✓

Advancements in technology have revolutionized the grocery shopping experience by introducing innovative solutions that enhance efficiency and convenience. One such solution is indoor navigation technology, which streamlines the shopping process by providing shoppers with real-time guidance within the store. Indoor navigation systems employ various technologies to offer accurate location information within a store environment. Bluetooth Low Energy (BLE) beacons [14]

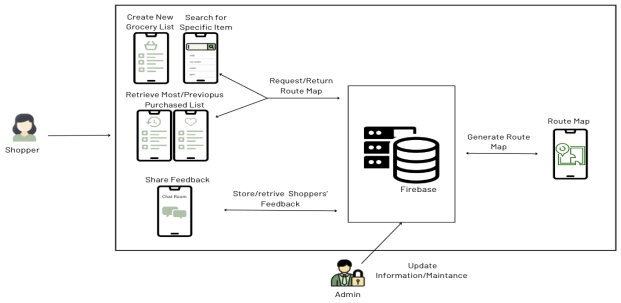

Fig. 1. GROCAFAST system architecture.

are commonly used sensors that guide users based on their precise location. Alternatively, indoor positioning systems (IPS), such as IndoorAtlas [15], utilize technologies such as Wi-Fi signals, RFID tags, or computer vision to accomplish the same goal [16]. However, the implementation of indoor navigation technologies requires careful consideration of associated costs and maintenance requirements. Infrastructure deployment costs primarily stem from the purchase and installation of required hardware components. It is worth noting that these technologies involve the tracking of shoppers' movements and the collection of data on their behavior, raising concerns regarding privacy and security. In contrast, GROCAFAST, a cost-effective system, presents an alternative approach. GROCAFAST leverages advanced algorithms to provide indoor positioning and navigation functionality without the need for additional infrastructure. This approach eliminates the costs and maintenance associated with hardware installations.

Efficient indoor navigation in grocery stores relies on solving the shortest path problem [17]. Various algorithms have been developed for this purpose, including Dijkstra's algorithm, Bellman-Ford, and Floyd-Warshall algorithms [18]. Among these algorithms, Dijkstra's algorithm [19] stands out for its adaptability and effectiveness in grocery store contexts, especially when GPS signals are limited or unavailable. The Bellman-Ford and Floyd-Warshall algorithms can be utilized, but their higher time complexity may limit their practicality in large-scale scenarios [20], [21]. Authors in [22] used the A-star algorithm with a heuristic technique to minimize the time and effort needed for shopping. However, developing a heuristic function can accurately capture the unique characteristics of a grocery store environment and guide the route optimization process. This adds additional overhead and is not flexible with edge weights. Further, it requires careful consideration of factors such as store layout, product placement, congestion patterns, and other relevant aspects that influence customer movement within the store. GROCAFAST, an indoor navigation system, leverages the simplicity and effectiveness of Dijkstra's algorithm. Dijkstra's algorithm considers a uniform cost for traversal, making it well-suited for indoor environments where movement costs are often similar. Additionally, GROCAFAST benefits from the flexibility of adjusting edge weights, and extends to optimize for alternative metrics such as travel time, congestion avoidance, or energy efficiency, providing adaptability to diverse indoor navigation requirements.

III. System Design

Our design goal is to propose a solution that addresses the challenges individuals encounter during their grocery shopping process. The GROCAFAST system aims to significantly enhance shoppers' experiences by reducing shopping time and minimizing unnecessary foot steps. By introducing in-store navigation capabilities based on shoppers' grocery lists, this system brings a revolutionary change to the way people navigate within a grocery store, all without requiring any additional infrastructure. Our solution focuses on streamlining and optimizing the shopping journey to ensure a more efficient and convenient experience for every shopper.

The system consists of the following entities: users, mobile app, server. Fig. 1 shows the high-level architecture of the system which demonstrates how GROCAFAST enables smooth communication among these components. This interconnected communication network enables a smooth and efficient shopping experience for shoppers.

Users: are categorized in the GROCAFAST system into two types: shoppers and admin. Shoppers, as depicted in Fig. 1, interact with the system primarily through the mobile app. They can input their grocery list, search for specific items in the store, retrieve most/previous purchased list, and share feedback through the chat room. On the other hand, admin has a distinct role within the system. The admin is responsible for managing the Firebase database and server.

Mobile app: provides shoppers with different interfaces that allow them to interact with the app to access their grocery lists, adding or removing items, making updates as needed, and requesting a grocery navigation map. The application acts as the intermediary between the shopper and server in order to handle shopper requests, process data, and provide relevant information.

GROCAFAST Server: acts as the backbone of the system. The server would store and manage the shoppers' grocery lists in the Firebase database. Firebase is a central repository of information, storing data such as store layouts, product details, location of each item, and shopper preferences. Shoppers can interact with the server through GROCAFAST appl, accessing their lists, adding or removing items, and making updates as needed. The server would handle the data storage and retrieval from the database, ensuring that shoppers have access to their lists. Also, the server would have access to the store's layout and product inventory information. Based on the shopper's grocery list, the server would utilize Dijkstra's algorithms to generate an optimized route map. This map would guide shoppers through the store, indicating the most efficient path to take. Further, the server would analyze shoppers' previous lists and preferences stored in the database and facilitate the creation and management of an online chat room or community platform. Shoppers could join the chat room through the app, and the server would handle the communication and interaction between shoppers.

IV. System Overview

This section presents an overview of GROCAFAST, focusing on how to plan a shopping route that reduces shopping time. A shopper opens the GROCAFAST app on their

smartphone and logs in using their registered account. Upon successful login, they gain access to the app's features designed for shoppers. As a shopper, they are directed to the home page where they can explore various functionalities. The home page provides a user-friendly interface, allowing them to conveniently navigate through the app's offerings. They notice several options available to them. First, they decide to create a new grocery list for their upcoming shopping trip. They click on the "Create grocery list" feature and are presented with a form where they can add, edit, and manage their list. This feature enables them to conveniently add or remove items as needed. They start by adding essential household items to their list. While creating the list, they notice that the app suggests personalized recommendations based on their shopping history and preferences. This feature saves them time and effort as they can effortlessly select and add items to their current list based on their previous purchasing patterns. Next, in case they want to find the exact location of certain items within the grocery store, they utilize the "Search Items" feature, entering the name of the item they are looking for. Then, the app quickly retrieves the item's location within the store and displays it on the screen. This feature helps them navigate the store efficiently and locate the items they need without unnecessary wandering. After finalizing their grocery list and searching for specific items, the optimized route map through the store is generated. The graph-based search algorithm (i.e., Dijkstra) automatically analyzes their list and creates a route map that guides them through the store's aisles, ensuring they take the most efficient path to collect all the listed items. This feature streamlines their shopping experience and saves them time. This feature eliminates the need for them to recreate the same grocery list repeatedly. They can effortlessly retrieve an old grocery list and obtain the route map directly for the selected list, making their shopping trips even more efficient. As a final touch, they notice that GROCAFAST offers an online chat room where shoppers can engage with each other in a real-time. They decide to join the chat room to share their shopping experiences, exchange recommendations, and seek advice from other shoppers. This feature enhances their overall shopping experience and allows them to feel more connected to the community of GROCAFAST users. However, if the user has admin privileges, they are directed to the admin page, which grants them exclusive access to perform actions like adding and deleting items from the system.

GROCAFAST aims to optimize the shopping experience and save shoppers time. To meet these requirements, GROCAFAST uses Dijkstra's algorithm when a shopper loads a previous list, creates a new list, or searches for a specific item (see Fig. 2). Dijkstra's algorithm generates the most efficient route for the shopper to follow within the grocery store. The shopper's grocery list is organized based on the store layout to ensure the shopper can navigate through the store in a systematic manner, saving time and effort. Although there are several algorithms that can solve the shortest path problem, Dijkstra's algorithm is often considered an optimal choice for various applications. Several reasons support this choice: (1) it is compatible with non-negative edge weights, which proves advantageous for GROCAFAST. This compatibility allows the system to disregard factors that obstruct movements within the grocery store, such as walls or obstacles that are not relevant to the shortest path calculation; (2) it operates with a singular source node, which aligns well with GROCAFAST's requirement of considering the entrance point of the grocery store as the starting location for path finding; (3) it excels in efficiency by storing and updating only the shortest path at each iteration. This approach minimizes computational time and effort, making it suitable for real-time or dynamic scenarios where the grocery store layout or item locations might change.

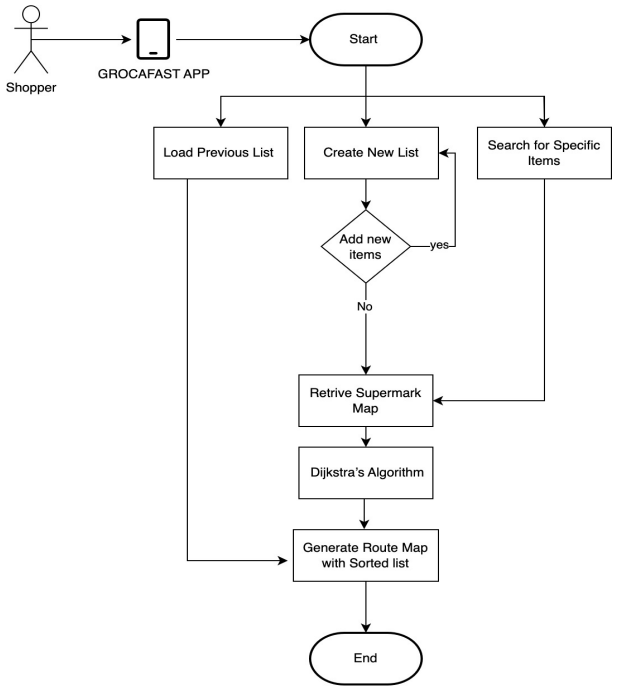

Fig. 2. System flowchart.

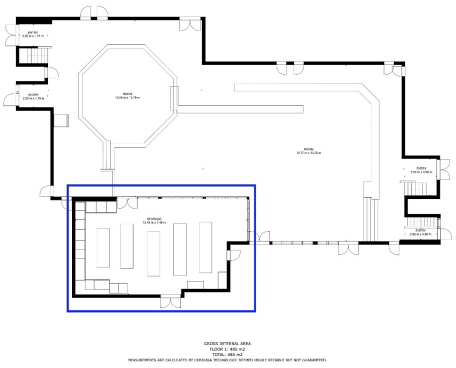
A. Grocery Shopping Route Map

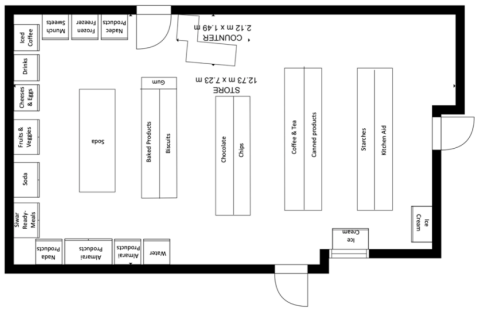
In order to facilitate efficient navigation for shoppers, we create a route map that optimizes the shopping experience based on the specific items shoppers need to find in the grocery store. GROCAFAST uses a floor map of a local grocery store and Dijkstra's algorithm to find the shortest navigation path on the map.

To start, the grocery store map is converted into a graph representation, where each node corresponds to a location within the store (aisles, departments, checkout counters, etc.). The connections between nodes represent the pathways or transitions between locations (see Fig. 3a). Edge weights are assigned based on the distance or effort required to move between locations. The starting point, which is the entrance of the store, and the ending point, such as the checkout counter or exit, are determined (see Fig. 3b). The floor plan is transformed into a matrix format with each cell representing a distinct unit of space. This matrix serves as the basis for applying Dijkstra's algorithm to enable efficient route planning within the grocery store. Fig. 3c shows a visual representation of the matrix of the floor plan.

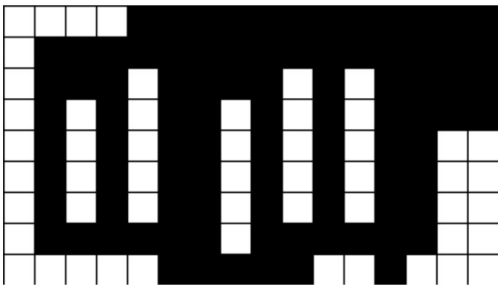
The shopper's grocery list is obtained, consisting of specific items they want to purchase. Dijkstra's algorithm is adapted to



(a) A visual representations of the grocery store map.



(b) A visual representation of the grocery store components.



(c) A visual representation of the matrix of the floor plan.

Fig. 3. Floor Plan Transformation

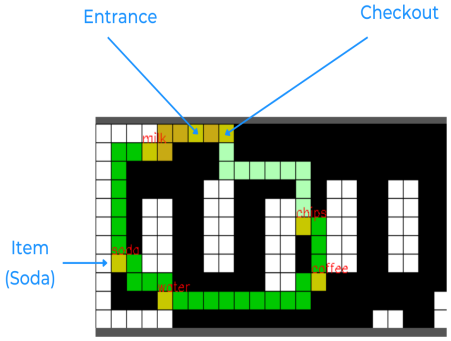


Fig. 4. The shortest navigation path using dijkstra's algorithm.

consider the grocery list items and their corresponding locations. Instead of calculating the shortest path between arbitrary points, the algorithm calculates the shortest path that visits all the required item locations in the most efficient manner. The nodes are initialized with a distance of infinity, except for the starting node, which is assigned a distance of 0. The algorithm selects the node with the smallest distance, as the current node and visits its neighboring nodes. Once the algorithm completes, the shortest path is retrieved by traversing the tracked previous nodes backward from the checkout counter or exit node to the starting node. As Fig. 4 shows, this path represents the shortest route on the map that visits all the required item locations and indicates the sequence of locations to efficiently collect all the items on the list.

B. GROCAFAST Features

This section offers various functionalities and capabilities provided by the GROCAFAST. It presents a detailed overview of each feature, accompanied by its respective interface, and a comprehensive description to provide a comprehensive overview of how each feature works and how it contributes to the overall functionality of GROCAFAST. Fig. 5 demonstrates the interfaces of these features. The following overview of each feature offers detailed insights into their functionalities and showcases their contribution to the overall capabilities of GROCAFAST.

Creating a Grocery List: Users can create a grocery list on the application. Upon successful creation, the list is stored in the database, allowing the user to view the sorted list. However, if the user either duplicates an existing item in the list or attempts to create an empty list, an error message is displayed, prompting the user to retry (see Fig. 5a).

Editing an Existing Grocery List: Users can modify their existing grocery lists. In successful scenarios, users can edit, append additional items, or remove unwanted entries from their lists. Subsequently, they can proceed to access the route map. However, if there is a failure in retrieving items from the database, users are prompted to retry the operation (see Fig. 5b).

Generating a Route Map with the Shortest Path: Users can access a route map generated by the application, designed to guide them through the grocery store based on their created grocery list. In successful scenarios, the route map is effectively generated, facilitating users in navigating the store according to their list. However, in the event of a failure, users are required to attempt the process again (see Fig. 5c).

Searching and Locating Items Within the Store: Users can search for items within the store, displaying their respective locations. In successful cases, the application effectively locates the searched item in the store, guiding the user to its location. However, if the item cannot be found, users are prompted to retry the search see Fig. 5d.

Displaying Personalized Shopping Suggestions: Upon creating a grocery list, it is stored in the database. It is then analyzed to identify the user's top three frequently purchased items, which are utilized to generate personalized shopping suggestions. In successful cases, the application presents these suggestions to the user when trying to write a grocery list. However, if the database fails to retrieve the top three frequently purchased items, the application prompts the user to rewrite the items (see Fig. 5e).

Fig. 5. GROCAFAST interface screenshots: streamlining grocery shopping with advanced features.

Posting in Store-Specific Online Communities: Users can create posts to share reviews within the communal space for the same grocery store facilitated by the application. Successful posting results in the display of the user's post within the space. However, in case of a failure where the post cannot be displayed, the application prompts the user to retry (see Fig. 5f).

V. Experimental Setup

In our experiments, we collaborated with a local grocery store at King Abdulaziz University's female dormitory to develop and test GROCAFAST. This strategic decision allowed us to conduct practical experiments and gather real-world data in a genuine shopping environment. By working closely with this grocery store, we are able to closely observe and analyze how GROCAFAST performs and interacts with the existing infrastructure. The walking time is considered as an average speed of 1.4 m/s, which is reasonable for adults (men and women) [23], [24].

We generate a set of shopping journeys for shoppers. While the starting locations of the shoppers are chosen at the supermarket entrance, the final steps are chosen at the cashier. The selected items are distinct and randomly chosen from different aisles. The shopping time of a shopper is calculated by the time of arrival at the supermarket until all the items on the list have been collected. This method provides the total duration spent during the shopping.

Further, we use Figma [2] which is a cloud-based design tool that works on any platform and provides real-time updates for its embedded files. It is a user-friendly tool that facilitates developer hand-off and communication. MySQL, Visual Visual Studio Code, and Firebase are used to build GROCAFAST and its database. CubiCasa [3] is used as a tool specialized in creating floor plans and 3D models of real estate properties using mobile devices.

VI. Experimental Evaluation

In this section, we experimentally evaluate the performance of GROCAFAST comparable to the traditional grocery shopping method, in terms of (1) shopping time and effort (i.e., walking steps); (2) testing the GROCAFAST compatibility with different devices; and (3) measuring the benefits of GROCAFAST in terms of usability.

A. Performance Experiments

To evaluate the performance of GROCAFAST, two experiments were conducted. The first experiment aimed to measure the average shopping time required for shoppers to complete their shopping trips. This experiment focused on calculating the time taken to collect a specific set of items using a predefined grocery list. The second experiment aimed to assess the effort exerted by shoppers, specifically by estimating the number of steps taken inside the store.

In both experiments, three different grocery lists were used, each containing 4, 6, and 9 distinct items. To ensure fairness and eliminate potential bias in the experiments, a randomized approach is used to select the items in the shopping lists.

[2]https://www.figma.com
[3]https://www.cubi.casa

The goal is to create a diverse and representative sample of items from various categories available in the grocery store. By randomizing the selection process, we aim to minimize any systematic bias or favoritism towards specific items or categories.

Additionally, to further enhance fairness, care is taken to ensure that each shopper has no information about the supermarket layout and the distribution of items on their respective lists. This helped to level the playing field and ensure that any differences in shopping time are primarily attributed to the use of the GROCAFAST rather than varying levels of shopper familiarity.

To ensure the reliability of the results, each list is tested three times by three different shoppers. This repetition allowed for a more comprehensive evaluation of the GROCAFAST's performance. During the experiments, the time taken to complete each grocery list is recorded. This involved noting the duration from the start of shopping until all items on the list were collected. Additionally, the number of steps taken by shoppers to complete each list is also recorded and analyzed. With respect to the average shopping time and effort expended, we conducted a comparative experiment between GROCAFAST and traditional grocery shopping, the latter being a conventional method where shoppers rely on paper lists to navigate through the aisles, locate items, and make purchases at the store.

Fig. 6 shows the average shopping time for GROCAFAST compared to traditional grocery shopping. The graph indicates a significant reduction in shopping time when using the GROCAFAST. The reduction in shopping time observed can be attributed to the utilization of the Dijkstra algorithm, which efficiently calculates the shortest path for collecting items during the shopping process. This proves that the GROCAFAST is effective in optimizing the shopping experience, making it more efficient and time-saving for consumers. By utilizing the application's features, shoppers can navigate the store more seamlessly and locate their desired items with ease.

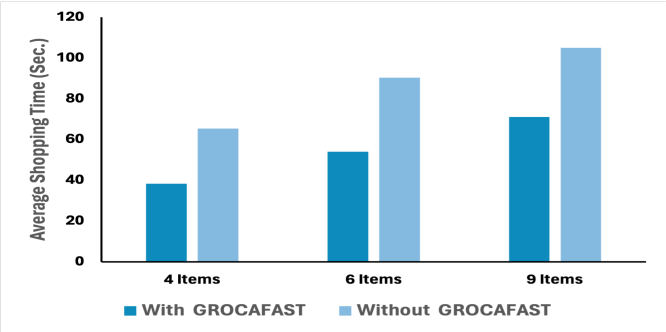

Fig. 6. Average shopping Time with and without GROCAFAST.

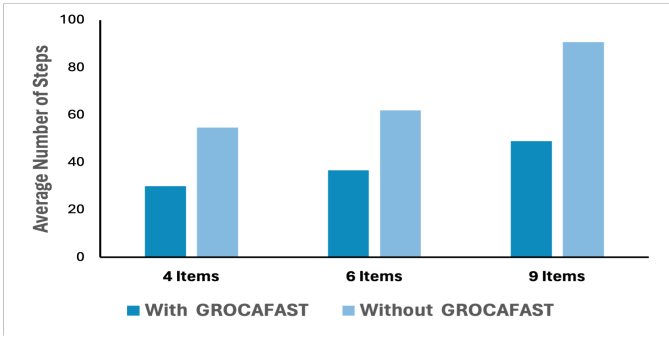

Fig. 7. Average number of shoppers' walking steps.

Fig. 8. Intergration testing dependencies.

B. Discussion

The analysis of the results in terms of walking steps indicates that the use of the GROCAFAST significantly reduces the number of steps taken while shopping compared to traditional shopping methods. The graph in Fig. 7 shows that when using the GROCAFAST, shoppers take notably fewer steps to complete their shopping compared to shopping without GROCAFAST. This reduction in the number of steps suggests that the GROCAFAST effectively optimizes the shopping process by providing efficient in-store navigation. By guiding shoppers along the most optimal route, it helps them navigate through the store more seamlessly, minimizing unnecessary walking and backtracking.

The results obtained from testing GROCAFAST in the small local grocery store proved that GROCAFAST is an effective solution for a real-world problem and successfully attained the desired objective. The system successfully enhanced the grocery shopping experience for users, reducing both the number of steps taken and the time spent navigating through various grocery lists.

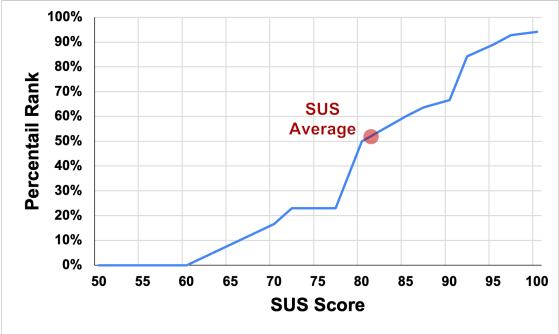
The positive results achieved in this performance testing set the stage for further exploration and implementation of GROCAFAST on a larger scale, offering the potential to revolutionize grocery shopping experiences for a wider user base.

C. Integration Testing

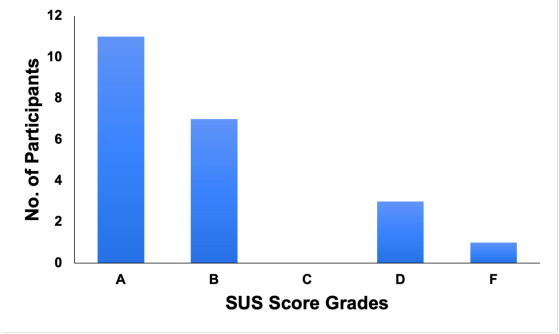
Integration testing verifies the proper interaction of various software components by combining and testing them together. Two types of testing were conducted, with the first focusing on Android Studio and Firebase integration. The first step involves establishing dependencies from Firebase and creating a database reference object, as shown in Fig. 8. The second category focused on integrating a function with its associated set of functions. As an example, the test case scenario for creating a grocery list was validated through a sequential process involving the creation of an account, logging in, and subsequently creating the actual grocery list.

TABLE II. COMPATIBILITY TESTING RESULTS

Device	Android version	Memory space	Memory available	Pass/Fail
Google pixel 2 XL	11	4 GB	612 MB	Pass
Galaxy A10L	11	2 GB	314 MB	Pass
ZTE Blade 10 Smart	9	4 GB	1 GB	Pass



(a)



(b)

Fig. 9. SUS Score percentile rank and grades.

D. Compatibility Testing

Compatibility testing plays a vital role in ensuring that the GROCAFAST application (installed on the shopper's smartphone) functions seamlessly across various platforms, devices, and operating systems. It guarantees a consistent user experience, meets technical requirements, and enhances user satisfaction and trust in the application's reliability. Therefore, as shown in Table II, we test the GROCAFAST application on different devices with different capabilities. GROCAFAST application passes all the tests.

E. System Usability Scale (SUS)

To assess the usability of GROCAFAST, we employed the System Usability Scale (SUS) [25] as a reliable metric to measure the overall usability of GROCAFAST. The usability testing process involved gathering feedback from a diverse group of participants who interacted with the GROCAFAST.

The first ten questions from our participants QoE questionnaire (see Table III) incorporated the system usability (SUS) scale. This measures the satisfaction levels of shoppers through such indicators as accessibility, usability, and effectiveness. The SUS calculations [26], [27] are conducted to process the participants' responses to the SUS items in our questionnaire. These calculations are performed for each participant in our experiment. The results show (see Fig. 9), that the average SUS score from all 21 participants in our study is 82.73, which is higher than the SUS mean value of 68 [26].

In order to interpret these scores, the SUS score was normalized and converted to a percentile rank, as shown in Fig. 9a, and then the letter grades were generated from A to F. As can be seen in Fig. 9b, the percentile rank of the average SUS score (68) is 50%. According to Sauro [26], [27], our SUS scores were ranked as follows: A (>80.3, Excellent), B (68–80.3, Good), C (=68, 50%, Accepted), D (51–68, Poor), and F (<50, Awful). In the following bulleted items, the participants' responses to the SUS questions are discussed for each item in turn:

Question1: I think that I would like to use this system frequently. As reported by participants, 67% of them would like to use the GROCAFAST in their daily life, with 24% being neutral regarding this (see Fig. 10, Question1).

Question2: I found the system unnecessarily complex. As shown in Fig. 10, Question2, a high proportion of the participants, 90%, enjoyed using the GROCAFAST whereas 5% did not enjoy it, and 5% reported being neutral regarding this.

Question3: I found the system was easy to use. Of the 21 participants who responded to this question, 76.5% strongly agreed that the application was easy to use and 0% were neutral. 10% only with issues were encountered in respect of ease of use (see Fig. 10 Question3).

Question4: I think that I would need the support of a technical person to be able to use this system. Almost 76% of the participants responded that the application did not need technical assistance; a minority of 14% claimed that it did, whilst 10% of participants were neutral on this issue (see Fig. 11 Question4).

Question5: I found the various functions in this system were well integrated. Overall 81% of participants found the GROCAFAST's functions to be well integrated, with 5% being neutral regarding this (see Fig. 10 Question5).

Question6: I thought there was too much inconsistency in this system. As shown in Fig. 10 Question6, 90% participants found the system components to be coordinated. 10% were neutral about this, and no one disagreed.

Question7: I think that most people would learn to use this system very quickly. More than two-thirds of the participants reported that people would like to use this type of

TABLE III. SUS QUESTIONNAIRE QUESTIONS

GROCAFAST System Usability	
1	I think that I would like to use this system frequently
2	I found the system unnecessarily complex
3	I thought the system was easy to use
4	I think that I would need the support of a technical person to be able to use this system
5	I found the various functions in this system were well integrated
6	I thought there was too much inconsistency in this system
7	I would imagine that most people would learn to use this system very quickly
8	I found the system very cumbersome to use
9	I felt very confident using the system
10	I needed to learn a lot of things before I could get going with this system

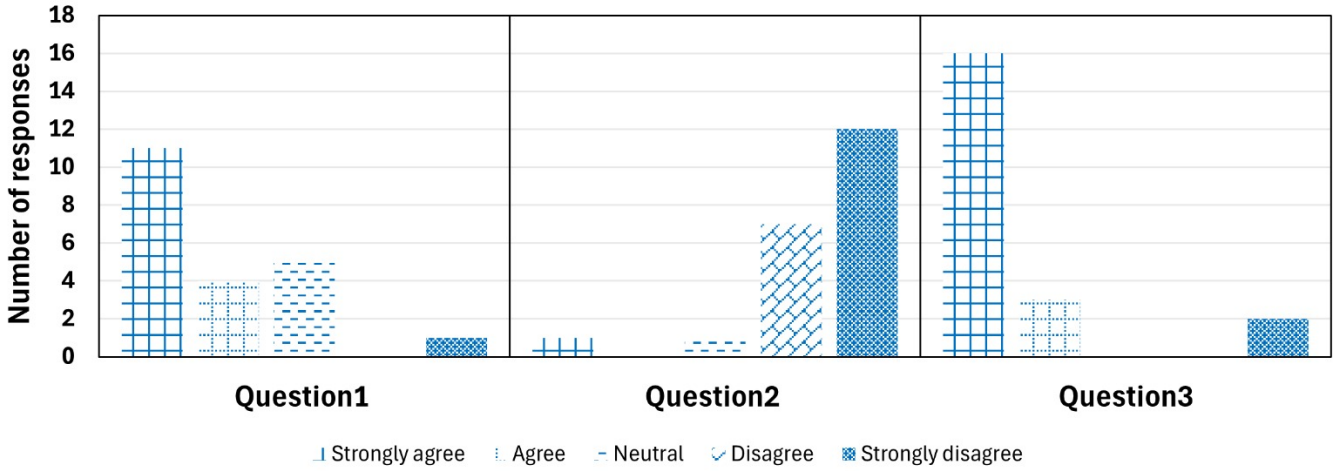


Fig. 10. SUS Questions 1-3 responses.

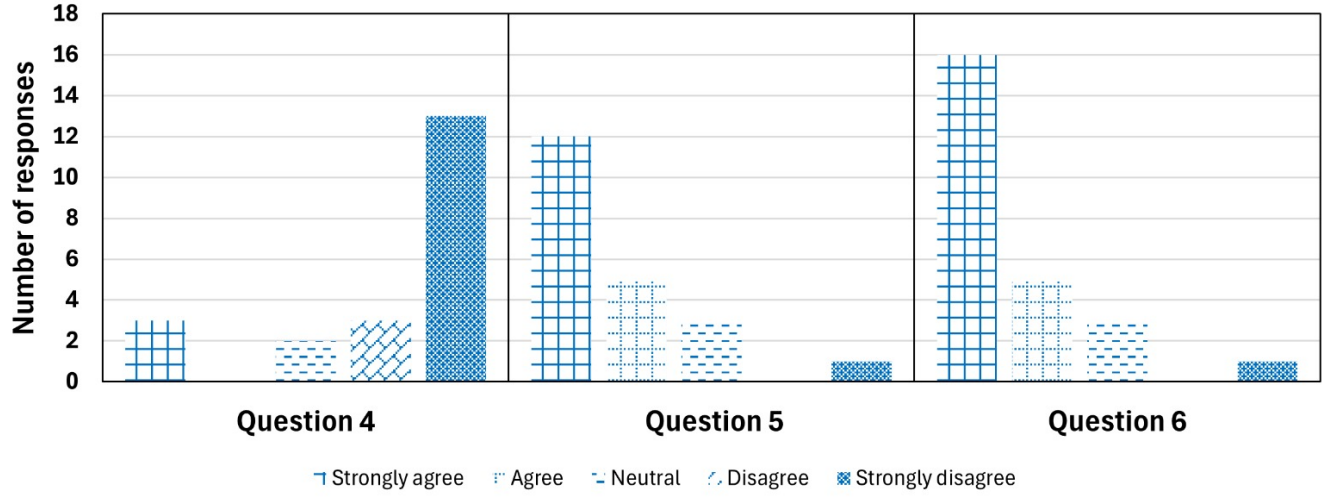

Fig. 11. SUS Questions 4-6 responses.

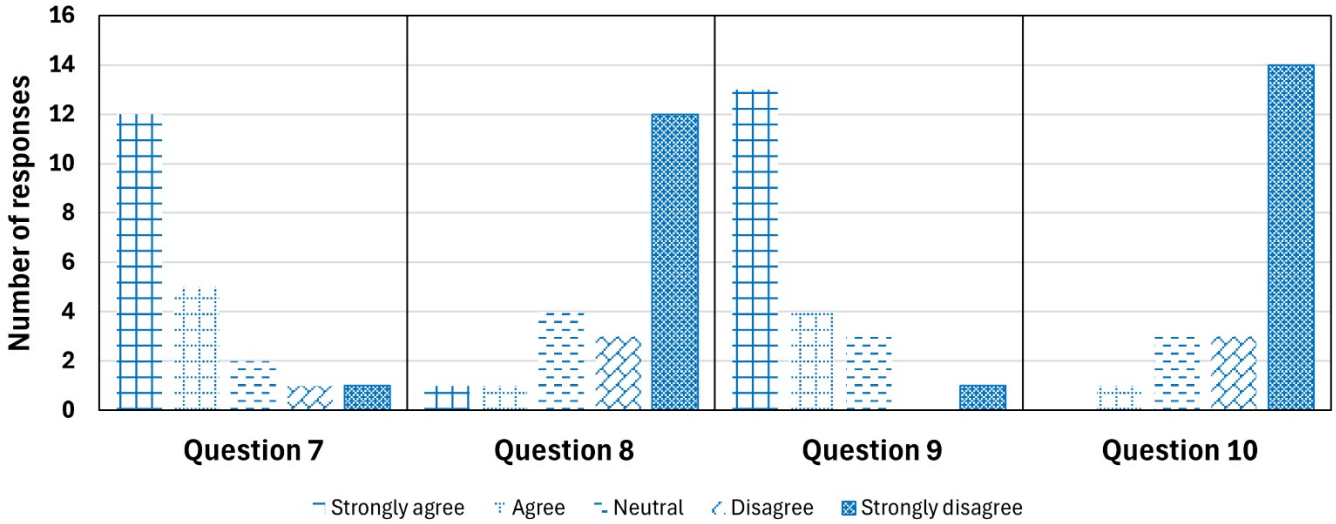

Fig. 12. SUS Questions 7-10 responses.

application, and only 5% disagreed. 10% of participants were neutral on this matter (see Fig. 12 Question7).

Question8: I found the system very cumbersome to use. All the components and steps in our application were well integrated. Accordingly, 71% of our participants found the procedure easy and expeditious, 19% were neutral regarding this, whilst 5% agreed that the application was cumbersome to use (see Fig. 12 Question8).

Question9: I felt very confident using the system. In response to this question, 81% of the participants responded that they were confident, 13% were neutral, and hence, only 5% indicated that they were un-confident (see Fig. 12 Question9).

Question10: I needed to learn a lot of things before I could get going with this system. As discussed above, the application was easy to use and thus, the participants did not need to learn much about it. Of the study population, 81% said they did not need to learn how to use this application, whilst 14% were neutral on this matter. In contrast, 5% of the participants suggested that they might have needed training in advance to use the application, which would be expected in the case of any newly developed application (see Fig. 12 Question10).

VII. Conclusions and Future Work

This paper introduces the GROCAFAST system which is a practical solution for optimizing grocery shopping, empowering shoppers to navigate the store efficiently and save their time. GROCAFAST enables shoppers to create, manage, and update grocery lists while providing store navigation assistance without requiring any additional infrastructure. It leverages Dijkstra's algorithm to guide shoppers through the store, minimizing the time needed to visit aisles containing their desired items. The evaluation experiment conducted on GROCAFAST has demonstrated its immense value as a solution for improving the in-store grocery shopping experience and saving the shoppers' time. The system achieved a remarkable reduction of 67.6% in total shopping time compared to the traditional method of physically browsing aisles. Additionally, it effectively reduced walking steps by 59%. The suite of features offered by GROCAFAST has garnered high user satisfaction. The system's adaptability allows it to be applied to any other store based on the store's information, ensuring its effective functionality across different locations.

As a direction for future work, there are several potential features that could be added to enhance the system's functionality. One direction is to explore different indoor positioning systems to include more location-based services. Another area of focus is to expand the scope of the research to include more large-scale grocery stores, potentially by partnering with industry stakeholders to gain access to the necessary resources. Furthermore, continued development of the app's database and analytics capabilities will provide even more valuable insights for manufacturers and retailers, helping them to make data-driven decisions and respond to evolving shoppers' needs. Overall, there is significant potential for future improvement and enhancement of the in-store grocery shopping experiences based on the foundation established.

Imam Muhammed ibn Saud Islamic University (IMISIU)
Riyadh, Saudi Arabia

***Abstract*—There has been a continual rise in the quantity of smart and autonomous automobiles in recent decades. the effectiveness of communication among vehicles in Vehicular Ad-hoc Networks (VANET) is critical for ensuring the safety of drivers' lives. the primary objective of VANET is to share critical information regarding life-threatening events, such as traffic jams and accident alerts in a timely and accurate manner. Nevertheless, typical VANETs encounter several security issues involving threats to confidentiality, integrity, and availability. This paper proposes a new decentralized and tamper-resistant scheme for privacy preservation. We designed a new trust management system that utilizes blockchain technology. We strive to establish trust between vehicles and infrastructure and preserve privacy by guaranteeing the authenticity and integrity of the information exchanged in VANETS. Our proposal adopts the principles of reinforcement learning to dynamically evaluate and allocate trust scores to vehicles and infrastructure based on their behavior. The scheme's performance has been evaluated based on key metrics. The results show that our new system provides an effective behavior management technique while preserving vehicle privacy.**

***Keywords*—Vehicular Ad hoc Networks (VANETs); Blockchain; trust management; reinforcement learning algorithm; privacy preservation; network security**

I. Introduction

Intelligent transportation system (ITS) refers to the implementation of several technologies including sensing, analysis, control, and communications in the domain of ground transportation. The primary objective of ITS is to enhance safety, mobility, and efficiency within the transportation system. ITS encompasses a diverse array of applications that facilitate the processing and dissemination of information. These systems aim to alleviate congestion, enhance traffic management, mitigate environmental consequences, and amplify the advantages of transportation for both business customers and the general public [1].

VANET (Vehicular Ad hoc Network) is a subcase of an intelligent transportation system where vehicles can communicate and exchange information with each other (vehicle-to-vehicle), with fixed Road Side Units (Vehicle-To-Infrastructure), or with any communication entities (Vehicle-To-Everything). Vehicle communication improves traffic control and public safety. This is done by the detection and sharing of traffic flow information, driver behavior, locations, and trajectories [2]. VANET expanded its areas of use and It has become a fertile field for scientific research. New and innovative applications have emerged to offer better driving experiences and provide value-added user-oriented services [3], [4].

The predictable vehicle movement, the constantly changing network topology and density, the frequent hand-offs between on-board units (OBUs) and RSUs, and the ease of reading the radio signals are some of the distinctive features of VANETs [5] As result, cars are highly exposed to various types of attacks and security risks [6], [7]. Denial of service, Blackhole, Wormhole, Eavesdropping, False position information, and Man In The Middle attacks are among the most known attacks in VANET [8], [9]. Various solutions are proposed to deal with each kind of threat [10]–[13].

In this work, we focus on privacy protection in VANET. This means preserving legal vehicle information, user personal information, user locations, and all data leading to user or vehicle identification and activity tracking [6], [7], [14]. Preserving privacy is complex and controversial. It must guarantee the authenticity of each vehicle on the network. While, at the same time, the true identity of the requested vehicle must not be revealed.

To tackle those issues, we introduce the use of blockchain technology [15]. It's confirmed to be a distributed and secure solution for data protection. It's able to provide a highly protected ledger to store authentication information and offers interesting features to check the stored data validity called consensus algorithms [15]–[17]. Proof of Existence (PoE)and Proof of Work (PoW) are the basic two features that guarantee data integrity and authenticity.

Our proposal introduces a new privacy protection solution based on blockchain mechanisms and a trust evaluation system to detect malicious behaviors and prevent their harm to network communications. Furthermore, we enhanced our trust management technique by adopting the Reinforcement learning technique. RL is based on trial-and-error discovery and delayed reward [18]. The more the vehicle is learning from the current state, the better will be its decision.

The contributions of our research work can be summarized as follows:

- A full registration process that allows vehicles to request network join and be authenticated by a central trust authority (TA). Cars use a secured channel to

exchange sensitive identity information with the TA and obtain permanent credentials.

- The TA maintains a public blockchain to store authentication information and trust scores. That will provide vehicles with a reliable mechanism to check their interlocutor authenticity and trust scores.
- We develop a novel trust management scheme for VANETs. Our scheme dynamically assesses and assigns trust scores to vehicles. We propose the introduction of three different trust levels: Direct Trust Score (DTS), Indirect Trust Score (ITS), and Historical Trust Score (HTS). These levels are attributed respectively by the vehicles to encountered nodes, RSUs, and the Trust Authority (TA).
- We empowered the trust evaluation by integrating the reinforcement learning technique. The TA uses the algorithm KNN (K-Nearest Neighbors) to predict the candidate's behavior and compute the HTS value for each node in the network.
- A configurable acceptance system where vehicles can decide to accept, or not new incoming data based on the sender scores and the data types.

The remainder of this paper is organized as follows. In Section II, we review the related work related to privacy preservation and trust management in VANET. Section III presents the solution backgrounds. Our proposal is detailed in Section IV. Section V exposes our experimentation and gives a performance evaluation of our scheme. Finally, we conclude the proposal in Section VI.

II. Related Work

Waheeb et al. [19] introduced the framework to ensure the security of the communication in VANETs, this framework integrates a blockchain to support privacy-preserving authentication with a context-aware trust management system. It comprises a blockchain system that allows for anonymity and mutuality authentication of vehicle nodes and their messages. On the other hand, the aware trust management scheme allows for evaluating the reliability of sender vehicles by identifying and blocking the unauthorized nodes and their deceptive messages from the network. The scheme outweighs basic methods in robustness and efficiency while improving security in-vehicle communication. It is crucial to examine elements such as processing and communication overhead, as well as real-world implementation challenges.

In [20], authors introduced a system called TrCoin for VANETs, to conduct the trustworthiness of data providers, enhance traffic efficiency, and prevent malicious data providers from sharing false information. It applies a calculation algorithm with honest value to distinguish honesty from malicious data users and refine feedback shared by malicious users. The algorithm works by assuming that most data users are honest and estimates the weighted consistency (WC) of each user by evaluating their feedback consistency with the majority of users. The honesty value (HV) of data users is adjusted according to their (WC) where a greater (WC) signifies a more truthful user. This framework calculates also the count values of data providers based on truthful observations from honest users. TrCoin's effectiveness is shown by thorough simulations involving different attack scenarios, including fraudulent data injection and dishonest feedback. While blockchain technology is inherently transparent which means it allows all transactions and trust-related information to be available to network participants. We think privacy issues in VANETs might occur if confidential information or user identities are revealed on the blockchain.

The author in [21] introduced decentralized architecture utilizing blockchain technology to tackle the issues related to implementing decentralized architecture and safeguarding privacy in VANETs. The study suggests implementing a scalable and tamper-proof distributed trust management system for VANETs by utilizing blockchain technology. An innovative validation approach based on Bayesian inference is presented to counteract the impact of misleading signals in VANETs. Also, the suggested method removes the requirement for a trusted third party (TTP) by leveraging the decentralized and distributed characteristics of blockchain technology. Their work introduces a sharding consensus mechanism to enhance scalability in the VANET system. The experimental findings demonstrate that the suggested system is efficient, adaptable, and reliable in collecting, processing, organizing, and retrieving trust values in VANETs. In our opinion, first: the study doesn't discuss the potential scalability challenges that could occur with extensive VANET implementations, second the proposed approach assumes that all vehicles in the network would correctly validate and upload their calculated rates to the RSUs which may not happen in real-world situations. third, the study doesn't account for the influence of network latency and communication delays on the dependability and trust management mechanism in VANETs. Lastly, the suggested Bayesian formula for trust management relies on the precise calculation of confidence scores and distances between sender messages and event locations, which may not always be achievable in real-world scenarios.

Another proposal is presented by Inedjaren et al. [22]. It introduces a blockchain-powered distributed management system for trust in VANETs to tackle security and reliability concerns in message sharing between vehicles. The suggested solution attempts to establish a safe and unalterable architecture for routing in VANETs by utilizing blockchain technology. the solution utilizes the optimized link state routing (OLSR) protocol along with blockchain technology to address security issues and redundant procedures in the OLSR routing mechanism, moreover, the system uses the proof of trust (PoT) consensus mechanism in a dynamic and resource-limited context. The system incentivizes vehicles together and prevents redundant detection procedures by providing rewards using blockchain. the simulation results demonstrated that the suggested approach is effective in resource-constrained contexts such as VANETS. It reduces detection time and overhead by isolating hostile nodes, thus enhancing the efficiency of the detection process. At the same time, the system seeks to reduce overhead by isolating hostile nodes and streamlining routing methods. However, the incorporation of blockchain itself introduces additional overhead in terms of storage, computation, and communication. this overhead could offset some of the gains achieved by the proposed solution.

Cong Pu [23] introduces trust management called trust

block MCDM for VANETs within the Internet of Vehicles (IoV) framework. The trust block MCDM system employs a multi-criteria decision-making model to assess the reliability of road safety messages and produce trust ratings for message senders. The trust values are regularly sent to a neighboring RSU. The RSU computes the reputation value of the message sender based on trust values from the vehicles and includes it in a block for addition to the blockchain. This blockchain works as a decentralized agreement system, where the longest branch of the transaction is accepted as the network's consensus. The trust value computation considers input from nearby validators, the reputation of the message initiator, and the confidence of the validator in the event. The trust block MCDM method enhances the detection rate of fake messages, and the detection rate of hostile vehicles, and reduces the number of dropped fake messages as compared to other blockchain-based trust management methods. the suggested approach improves the assessment of trustworthiness for road safety messages in VANETs, leading to enhanced road safety and travel experience in the IoV. Although the MCDM Scheme demonstrates promising outcomes in enhancing trust management in VANETs, it possesses specific constraints that must be taken into account for its practical use and deployment. We can generalize these limitations first the effectiveness of the trust block MCDM method depends significantly on the precision and dependability of the multi-criteria decision–making model utilized for reputation assessment secondly the MCDM technique doesn't evaluate the influence of network congestion or communication delays on the trust evaluation process

Hui et al. [24] in their study aims to develop a framework that focuses on selecting a reliable relay for service requests by considering the dynamic traffic conditions and vehicle behaviors by introducing a reputation management system to regulate vehicle actions. Vehicles with a high reputation can receive savings on computing services. the paper suggests using a reputation–based auction system to choose relay vehicles (RVs) and lower the cost of the relay services. Each vehicle is granted a reputation value depending on its adherence to the relay system, vehicles can enhance their reputation by utilizing edge computing devices (ECDs) for computing services and engaging in the request relay process, vehicles with a high reputation value qualify for price discounts on computer services. The simulation results show that the suggested reservation service architecture effectively handles vehicles and results in the most cost-effective relay services compared to traditional methods. This framework has potential limitations or areas for improvement in the current system, including the necessity for improved security measures and more precise classification methods for automobiles.

Sonker and Gupta [25] utilize multiple machine learning to detect misbehavior in vehicle ad hoc networks (VANETs) the techniques utilized are Naïve Bayes, decision tree, random forest, K-nearest neighbor (KNN), and stochastic gradient descent (SGD) classifier. The initial stage of the research includes examining the algorithms on various attack kinds by binary categorization, the second part concentrates on developing a novel process for identifying attacks by utilizing several machine learning classification algorithms and entropy calculation and information gain methods for selecting decision nodes. Stochastic gradient descent is an optimization approach commonly used in research for addressing linear problems with support vector machines and logistic regression moreover the paper utilizes the VeReMi dataset a public repository created for identifying malicious nodes in VANETs. The dataset is utilized to assess machine learning algorithms in identifying various forms of attacks and test their detection techniques' efficiency. However, it's vital to note that the algorithms' efficiency may change when used in a wider range of assault scenarios, and using this amount of algorithms addresses drawbacks like the need for large amounts of labeled data, computational complexity, and generalization to new and unseen attacks.

Anti-Attack Trust Management Strategy named AATMS is proposed in [26]. It assesses the reliability of vehicles in different application scenarios and withstands diverse attacks. The research work introduces social elements such as diverse factors, vehicle factors, and behavior factors to filter out untrustworthy automobiles and indicate the level of public trust in vehicles. They are utilizing Bayesian inference to determine local trust levels from past encounters and choosing trustworthy seed vehicles depending on local trust and societal considerations. Moreover, they are introducing an adaptive forgetting factor to update local trust values and an adoptive decay factor to update global trust values to prevent a sudden increase in trust levels and enable a rapid decrease. The Bayesian inference's accuracy relies on the quality and trustworthiness of historical evidence, making it not a failsafe. Unreliable trust judgments might result from inaccurate or insufficient data.

Javaid et al. [27] introduced a trust management system named DrivMan (VANETs) that utilizes blockchain and a certificate authority (CA) to guarantee secure communication and data exchange. The scheme uses physical unclonable functions (PUFs) to guarantee the data dependability and privacy of intelligent vehicles (IVs) in (VANETs). It also utilizes the SHA-265 cryptographic hash method for authentication and verification. the system design includes initializing the nodes, composing and deploying contracts on RSUs nodes, and utilizing a genesis block for DrivMan that expands with subsequent blocks. blockchain is utilized as a decentralized digital ledger in DrivMan to guarantee the secure and dependable functioning of the system, it's offers an immutable and transparent record of all transactions and data exchanges. Moreover, the blockchain technology in DrivMan ensures high security by necessitating a minimum of 51% of the network's processing power to tamper with data. Smart contracts, and autonomous computer algorithms, are utilized with blockchain to ensure data provenance and integrity in DrivMan. The asymmetric public key infrastructure in blockchain guarantees secure communication between the IVs and the network. Since the security implies that an adversary would require a minimum of 51% of the total processing power of the DrivMan network to manipulate data, a feat that may be achievable in some situations, also using a blockchain network hosted by RSUs could lead to centralization and reliance on an entity for network operations.

A decentralized trust management strategy for vehicular networks, specifically for decentralized VANETs is proposed by Gulen et al. [28]. The approach utilizes a fuzzy logic-based method to calculate trust and assess direct trust between trustor and trustee nodes within the transmission range. The system utilizes a reinforcement learning method to estimate indirect

trust, especially when the actions of trustee nodes are not explicitly observable, in their scheme they propose a method for evaluating trust among multiple agents is suggested, and direct trust is determined through a fuzzy logic algorithm that considers factors such as cooperativeness, honestness, and responsibility. Indirect trust is assessed using a reinforcement learning technique that adjusts trust levels based on the number of intermediaries involved. This technique efficiently integrates knowledge from several nodes by evaluating indirect trust to handle complex circumstances. This strategy has some drawbacks like the trust evaluation process depending on fuzzy logic and indirect trust estimation through reinforcement learning, which could lead to limits in accurately assessing and determining the trustworthiness of nodes. The scheme doesn't address the potential obstacles or restrictions in attaining precise trust evaluation in dynamic and unreliable vehicle networks. Moreover, the proposed architecture is based on nodes being situated within each other's transmission range. This reliance on closeness could restrict the effectiveness of the plan in situations where nodes are widely spread out or when the communication range is restricted.

In [29] a new study introduces an innovative trust structure for vehicle networks to tackle the problem and an innovative trust structure for vehicle networks, the problem of rouge nodes, and inaccurate information which can make the system unreliable for safety and emergency purposes. The trust architecture enables nodes to recognize and screen out recommendations from malicious nodes and distinguish genius events. The system successfully detects malicious nodes and true events with a probability over 0.92, while maintaining the trust computation error under 0.03. The network model is created to evaluate the framework in situations including malevolent nodes where nodes move collectively along specific routes and encounter notable occurrences. Nodes communicate changes using messages, allowing nodes not directly involved to be informed by received messages. Simulation studies are conducted to confirm the trust framework's validity. A circular road is created in a simulation where accidents or traffic hazards occur randomly at various points. Proximal nodes encounter the event before distal nodes, who perceive it subsequently. The framework effectively detects events in incoming messages and excels in determining the actual characteristics of nodes. However, the suggested trust architecture operates under the assumption that there is a singular authentic event in the network at every moment, which may not align with the complexities of real-world situations. The system depends on nodes detecting the incident and notifying their neighboring nodes within the $300m$ range, which aligns with the conventional DSRC range. This restricted range may hinder the framework's efficacy in bigger network deployments. The approach assumes that malicious nodes transmit inaccurate information with a constant probability, without accounting for the potential adaptive or dynamic actions of malicious nodes. The system prioritizes safeguarding nodes against certain assaults but does not offer privacy or anonymity for the messages shared between nodes.

III. Solution Background

A. VANET Basic Fundamentals

Wireless access in vehicular environment (WAVE) is the name of the system that lets vehicles and RSUs talk to each other. The exchange of security messages is described by the WAVE design [30]. The WAVE communication keeps passengers safe by updating information about vehicles and traffic flow. This app makes sure that both pedestrians and drivers are safe. It also makes the traffic move better and the traffic management system work better. The VANETs are made up of different groups, such as OBUs, RSUs, and Trusted Authority (TA). In particular, the OBU is attached to each vehicle and collects useful data about the vehicle, such as its speed, acceleration, and fuel consumption. The RSU usually hosts an application that is used to interact with other network devices. After that, these data are sent to nearby cars through wireless signals. All RSUs that are linked to each other are also wired to connect to TA. In addition, the TA is in charge of managing the VANETs and is the leader of all the parts.

- Road Side Units (RSU): A roadside unit is a computing device that is located next to the road or in a certain place like a parking lot or an intersection [2]. Its job is to connect passing cars to the internet locally. The RSU is made up of network devices that use IEEE 802.11p radio technology for dedicated short-range communication (DSRC). It is more specific that RSUs can also talk to other network devices in other core networks [5].
- On-Board Unit (OBU): can share information about a car with RSUs and other OBUs. It does this by using a global positioning system (GPS) to track the vehicle. The OBU is made up of many electronic parts, including a resource command processor (RCP), sensor devices, a user interface, and read/write storage for getting information from storage. The main job of an OBU is to connect to an RSU or other OBUs through an IEEE 802.11p [31] wireless link and send information to other OBUs or RSUs. The car battery also gives power to the OBU, and each car has a (GPS), an event data recorder (EDR), and forward and backward devices that send information to the OBU.
- Trusted Authority (TA): The trusted authority is in charge of running the whole VANET system and recording the RSUs, OBUs, and vehicle users. In addition, it is its job to make sure that VANETs are secure by checking the vehicle identification, user ID, and OBU ID to make sure that no vehicles are harmed. The TA uses a lot of power and has a lot of memory [1]. It can also show the OBU ID and information if it receives a malicious message or notices strange behavior. In addition to these, TA additionally provides an approach for identifying the attackers [2]. ITS is always trying to improve traffic flow and road safety by making communication more secure and using different networking methods, like MANETs and VANETs, to get around traffic jams. To make traffic flow more smoothly, keep people safe, and make driving more enjoyable, Vehicle-to-Everything (V2X) communications are very impor-

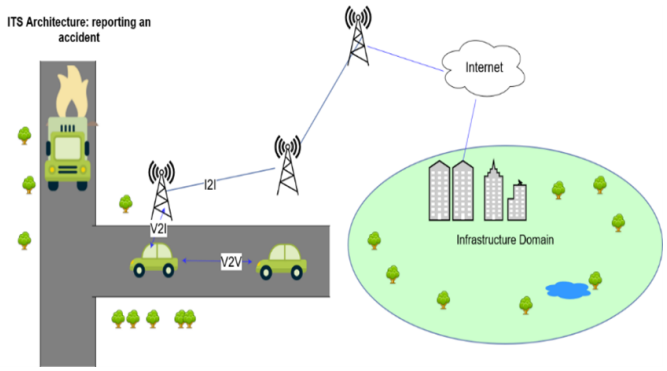

Fig. 1. VANETs communication architecture.

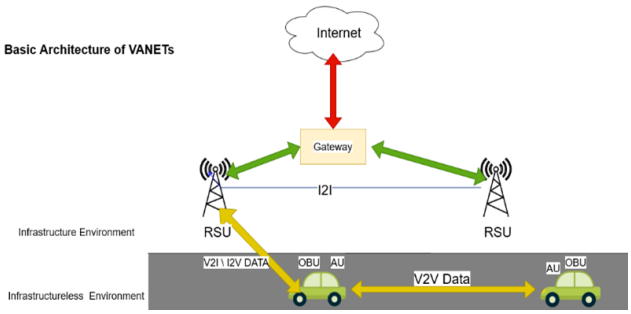

Fig. 2. Communication types in VANETs.

tant. They do this by sending very accurate and up-to-date information about things like accidents, traffic jams, emergencies, and other transportation services as shown in Fig. 1.

B. Communication Techniques Utilized in VANETs

The transmission medium in V2V communication has a high transmission rate and a small latency [31] In V2V, a vehicle can send important data to another vehicle, like emergency braking, collision detection, and traffic conditions. V2I lets vehicles and network infrastructures send important data to each other The car built a link with RSUs in this area so it could share data with other networks, like the Internet. V2I also needs more data than V2V because it communicates with infrastructure, but it is less likely to be attacked [5]. Cellular vehicle to everything (C-V2X) technology was just released. It's a unified connectivity platform that's meant to serve V2X communications [2]. C-V2X was created as part of the third-generation partnership project (3GPP), and it is thought to be the most reliable communication system that can handle V2X communications [2].

It links all the cars together and makes it possible for co-operative intelligent transport systems (C-ITS) to work, which eases traffic and makes it run more smoothly. Fig. 2 illustrates the on-board unit (OBU) and one or more applications units (AUs) make up the in-vehicle area. They often use wired links, but sometimes they use wireless ones. On the other hand, the ad hoc domain is made up of cars with OBUs and RSUs. An OBU is like a mobile node in an ad hoc network, and an RSU is like a fixed node. The gateway can connect an RSU to the Internet. RSUs can also talk to each other directly or through multi-hop. Access to the infrastructure can be done through two different types of points: RSUs and hot spots (HSs). OBUs can talk to the Internet through either RSUs or HSs. Cellular radio networks (GSM, GPRS, UMTS, WiMAX, and 4G) can also be used by OBUs to talk to each other when RSUs and HSs are not available. Furthermore, VANET communications can be broken down into four groups, which are shown below [32].

C. Trust Concepts and Trust Components

Trust in the context of VANET (Vehicular Ad-Hoc Network) denotes the level of confidence that one entity has in another entity [4]. It relies on the anticipation that the other party will carry out a specific action as anticipated by the initiator. Trust is predicated on the assurance that the trusted entity will not engage in malevolent behavior in a given circumstance. Since exact certainty is unattainable, trust relies entirely on the trustor's conviction. An entity refers to a tangible device that actively engages in the process of communication, such as OBUs (OnBoard Units) and RSUs (Road Side Units) utilized in VANET (Vehicular Ad hoc networks). Trust refers to the extent to which a node is considered trustworthy, secure, or reliable while engaging with other nodes. For a node to engage in the communication process of VANET, it must be considered trustworthy by other nodes and meet the trust criteria. A node's trust values can vary when assessed by different nodes due to variations in the trust evaluation criteria for each particular node. Trust is contingent upon the passage of time, as it has the potential to both flourish and deteriorate. Trust levels are established based on specific acts that the trusted party can carry out on behalf of the trustee. Moreover, the following elements comprise the character of interactions between two entities upon which the concept of trust is predicated:

- Direct Trust: It is demonstrated through the interaction between a trustor and a target vehicle, as evidenced by the trustor's direct observations [33]. Certain scholars employ the term "knowledge" to denote the explicit data acquired by the trustor to assess the trustee by specific criteria that depend on the nodes and services involved. Although it is commonly held that direct trust is more significant than indirect trust, when evaluating a vehicle, the combination of the two is considered. Fig. 3, demonstrates the difference between direct and indirect vehicle trust. Where vehicle number 2 recommends that vehicle 4 trust the vehicle.
- Indirect trust: It refers to the viewpoints of trusted entities in the vicinity of a trustor, regarding a specific node (trustee). These viewpoints are based on past experiences with the node in question. Researchers often explain indirect observation through the combination of reputation and experience. Reputation is the collective record of previous interactions with a certain entity, which reflects the overall perception of that entity. On the other hand, experience refers to the relationship between a person who trusts and another who is trusted, based on the trustor's belief in the trustee's ability to complete a task.

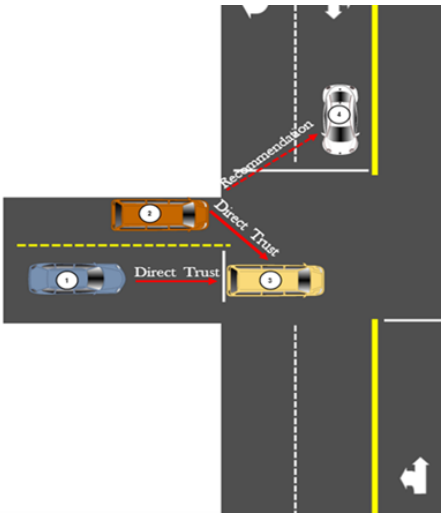

Fig. 3. Difference between direct and indirect trust in VANETs.

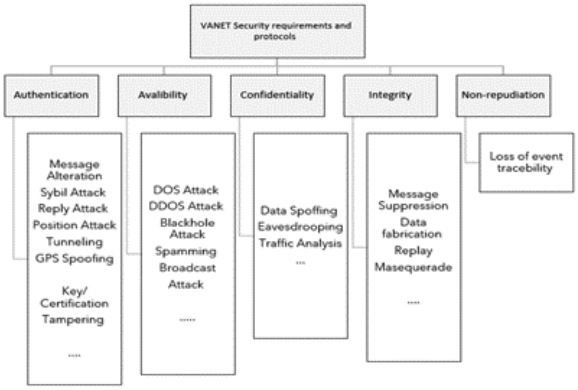

Fig. 4. VANETs security requirements.

D. Requirement for VANETs Security

A system can be vulnerable to a variety of system flaws that can be exploited by unfriendly entities for a variety of reasons. The security requirements of a system must be addressed to make it secure. The VANET system has some security requirements, which are briefly detailed here. Fig. 4 additionally shows the kind of probable assaults that could jeopardize VANET security standards.

- Authentication: It is a critical and unavoidable need of any system. A system must be able to verify the authenticity of all system participants. Authentication and identity are especially crucial and vital in VANET, which is prone to many vulnerabilities. In the event of a VANET attack, a robust authentication strategy can give solid legal proof against the invader. As a result, the authentication procedure is an obvious necessity to defend the VANET system against assaults such as Sybil attacks, location attacks, tunneling, replay attacks, message manipulation, and so on.
- Availability: A system or a system component could be susceptible to failure or attack. This type of malicious system or component condition should not impact other users or system elements. All applications and networks within VANETs must remain operational and accessible, even if one element of the VANET is compromised. Certain infrastructures or nodes within a VANET may be susceptible to attacks or problems that do not affect other nodes. Alternatively stated, VANET resources must be consistently accessible. To meet the availability requirement of a VANET, it is necessary to develop a system that is robust, secure, and tamper-tolerant. A multitude of attacks, including Distributed Denial of Service (DDOS), Denial of Service (DOS), spamming, and Black Hole attacks, can significantly compromise the availability requirements of VANET.
- Confidentiality pertains to the safeguarding of private information associated with a specific node or infrastructure. The communications that transpire between two components in a VANET must not be made public to a third party. The maintenance of confidentiality can be accomplished through the implementation of diverse encryption algorithms. Safety messages in VANETs do not contain any sensitive information; therefore, they are not encrypted. Electronic payment information, the identity of the user, and other personally identifiable data are, nevertheless, protected in confidence through the implementation of diverse cryptographic algorithms. Data surveillance, traffic analysis, and data spoofing are a few of the potential breaches of confidentiality in VANETs.
- Integrity safeguards communications against forgery or interpolation. Messages transmitted and received by various VANET entities must remain intact. Therefore, it is imperative to safeguard the integrity of communications against unauthorized tampering by criminals. Message integrity may be compromised by data alteration attacks, masquerade attacks, and replay attacks, among others. For the protection of communications during transmission and reception, it is necessary to implement a secure protocol. The IEEE1609.2 standard is employed to provide security services in VANETs.
- NonRepudiation: One of the critical security requirements of VANET. It safeguards against the denial of transmitted data by either the sender or the receiver [34]. Fig. 4 outlines the VANET security requirements as well as the potential hazards that could compromise those requirements.

E. Blockchain Overview

A blockchain is a decentralized public database that stores all completed digital transactions and is shared among participating nodes. It has an indisputable and verifiable record of every event that has ever taken place. Every event in the blockchain database is verified through the consensus of the majority of nodes in the network. There are primarily two types of blockchains: public blockchain and private blockchain. The public blockchain is a decentralized blockchain that allows

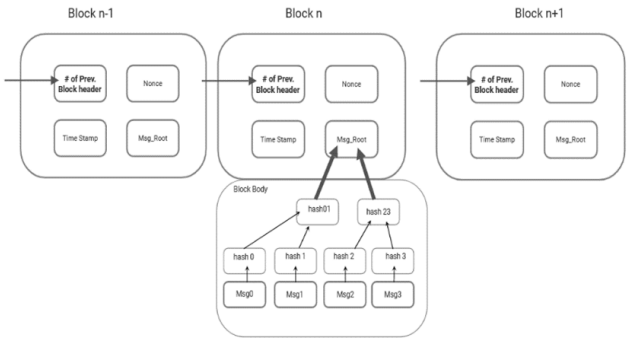

Fig. 5. Blockchain Concept.

unrestricted participation and interaction without requiring approval from a central authority. The starting point of the blockchain is a genesis block, which serves as the initial block in the blockchain. The genesis block serves as the shared starting point for all blocks and stores information that is universally accessible to all nodes [35]. The block comprises cryptographic hashes of records, each block containing the previous block's hash information, making a data chain and producing a blockchain, as illustrated in Fig. 5.

Features of using blockchain are:

1) Immutability: is a crucial aspect of blockchain technology. Once information is recorded and authenticated on the blockchain, it becomes immutable and cannot be altered or removed from the network. Additionally, information cannot be inserted randomly.
2) Distributed and trustless environment: In a blockchain system, any node that is added can synchronize and validate all data in a distributed way without the need for central control, creating a trustless environment. It offers security and guards against a single point of failure. It establishes trust in an atmosphere where trust is typically absent.
3) Privacy and anonymity: The blockchain offers privacy to its users. Users can join the network without revealing their identity. That is, the user's information is kept private from other users. It signifies that personal information is confidential, protected, and unidentified.
4) Faster Transactions: Setting up a blockchain is straightforward, and transactions are swiftly confirmed. Processing transactions or events only takes a few seconds to a few minutes.
5) Reliable and accurate data: The blockchain's decentralized network ensures that the data is reliable, accurate, consistent, timely, and publicly accessible. It is resilient to malicious assaults and lacks a single point of failure.
6) Transparency: It is fully transparent as it records information about each transaction or event that takes place in the blockchain network. Transactions are visible to all members of the network.

IV. Solution Presentation

Users can benefit from VANET communication to exchange different kinds of messages. Public safety, road traffic enhancement, and even entertainment and social applications are becoming VANET's basic use cases. Due to those heterogeneous usages, privacy preservation has become an urgent issue. To ensure that, we propose a new trust management process to detect and reject any malicious attacks. Our proposal defines a scoring mechanism to reward legitimate and punish malicious nodes. Our scheme introduces blockchain as a public ledger to save authenticated vehicle information and a reinforcement learning algorithm to enhance the trust score attribution. In this section, we will present the details of our solution. First, we will introduce the solution architecture and involved entities. Then, we will detail the authentication mechanism defined to integrate different network nodes. Finally, we will describe our trust management process and its score calculation procedures.

A. The Vehicle Registration and Authentication Mechanism

We propose a new authentication solution based on blockchain technology to ensure vehicle authentication and preserve user privacy. We define a trust management system to assess the trust of different vehicles in the network. As mentioned in Fig. 6, the network will contain the following entities: MVAC, TA, RSUs, and vehicles.

1) Motor and Vehicle Authority Centre (MVAC): The MVAC represents the legal authority or any delegated service to manage vehicles and transportation engines. It has the authority to store real documentation and to provide the car's valid registration numbers. It can also revoke those numbers and pull any given transportation license. Owners submit real documentation to register their vehicles. Accepted engines will receive a unique Identifier (ID) which will be stored with all identity information in the "Vehicle Information Base". This base is highly protected and managed only by the MVAC. In our scheme, we consider that MVAC is fully trusted. They are impossible to hack. Their operations and data cannot be compromised. They can resist any external attack and will never encounter internal attacks. DMV or TA can be held by the government or any authorized service provider.

2) The Trust Authority (TA): The trust authority is allowed by the MVAC to access the Vehicle Information Base and to read real identity information about all registered vehicles. To do so, it has a secure communication channel with the MVAC. The TA receives network registration requests from vehicles. It checks their information and generates all necessary parameters. It provides anonymous pseudo and various cryptographic parameters for each newcomer.

3) The Roadside Units (RSU): RSUs are small and wireless units deployed all over roads. They will offer different network services for registered vehicles. They can communicate with cars to share messages and service-related information. They need to register with the TA and get valid pseudonyms and security parameters. RSUs will correctly perform the proposed solution and provide reliable information and parameters. However, they are not allowed to access vehicle private information.

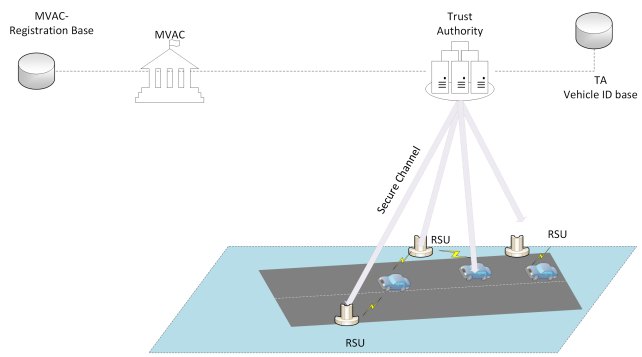

Fig. 6. Solution network architecture.

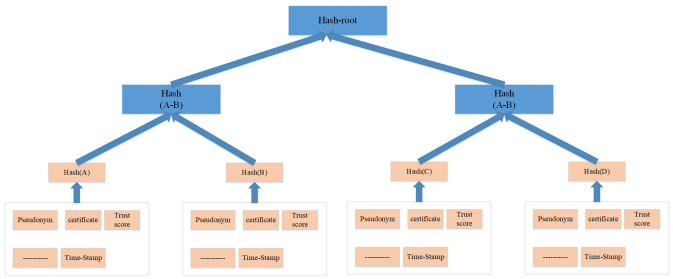

Fig. 7. The used blockchain architecture.

4) Vehicles: In VANET, vehicles are automobile engines equipped with wireless communication devices. They can use the WAVE standard to communicate with other network members. They can exchange messages with each other or with the network infrastructure. Vehicles are wireless mobile nodes. They are the most vulnerable units in the network. They can be hacked or receive compromised data. They can also act maliciously to threaten the network safety. They will be able to generate false data and compromise offered services

B. The used Blockchain Specifications

We propose the use of a dedicated blockchain structure for vehicle authentication. For each new registered car, a new block will be created. Its corresponding transaction contains its time of issue. So any participant can access the chain searching for the latest and newest information. When it finds the desired data, it will not need to continue reading.

1) The blockchain structure: Each time a new vehicle is registered and accepted by the MVAC, the TA will add its information to the Authentication Blockchain. The required information includes:

- The unique vehicle pseudonym
- The generated certificate: a public key and hash algorithm
- Universal issuing time
- Initial trust score
- Validity period
- Signature of the TA
- The certificate state (Valid or Not)

All that information constitutes a new block and will be added by the TA to the blockchain. The blocks are organized chronologically. Any reading operation will start with the newest inserted blocks to minimize the necessary research time.

2) The blockchain implementation approach: The use of blockchain technology has evolved tremendously since its first proposition with the concept of "bitcoin" in 2008 [36]. Different domains are introducing it to benefit from its valuable characteristics: transparency and non-tampering which can provide high security and privacy protection. Two basic formats are mainly used: the permissioned and permissionless. The permissioned blockchain authorizes any community member to access and add new blocks. This feature guarantees decentralized storage. On the other hand, the permissionless version is often used with centralized management to enhance the trustworthiness of the proposed operations. In our proposal, we introduce the permissionless blockchain. The trust authority (TA) is the only network member authorized to create and add new blocks which makes it impossible for the attackers to tamper with the public ledger.

We also use the chronological Merkle tree (CMT) structure for our blockchain [37]. The CMT is the traditional underlying structure used for blockchain implementation. Fig. 7 shows this structure. All transactions will be hashed and stored chronologically in a binary hash tree. The leaves are the transaction data. In our case, a transaction represents a new block created after adding a newly registered vehicle to the network. Then, each pair of leaves is hashed to construct a new level of internal hashes. Pairwise hashing continues until we get a single hash as the root of the tree. Network members: vehicles or RSUs, are permitted to read the blockchain to verify their communicator credentials. They search the tree leaves using the communicator's pseudonym starting with the last added data block. When the corresponding block is found, the proof of working concept (POW) [38] permits the validation of the communicator's information. We need only to check the hashing branch between the root hash and the targeted node block.

C. The Network Initialization

During the initialization of the network, infrastructure components must be configured and prepared to accept the vehicle's join requests. Later, they must ensure secure communication. Our proposal defines two basic network infrastructure elements: the Trust Authority (TA) and the Roadsides Units (RSUs).

1) The trust authority configuration: The TA is the central management unit. It stores the identification information of all allowed vehicles. It's supposed to be fully functional all the time. For each vehicle, the TA proposes a unique pseudonym and a couple of public and private keys. Therefore, a pseudonym generation function will be initialized and started to wait for any incoming vehicle request. Then, the cryptographical process [7] will ensure the creation of the couple: public and private keys

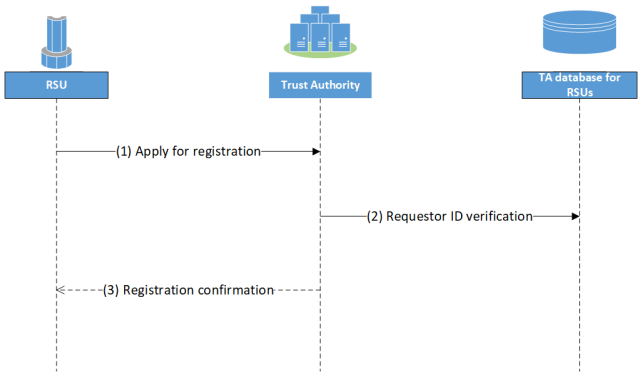

Fig. 8. RSU network join.

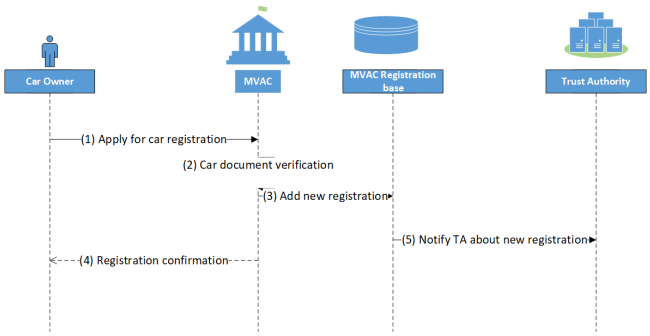

Fig. 9. The Vehicle's physical registration in the MVAC.

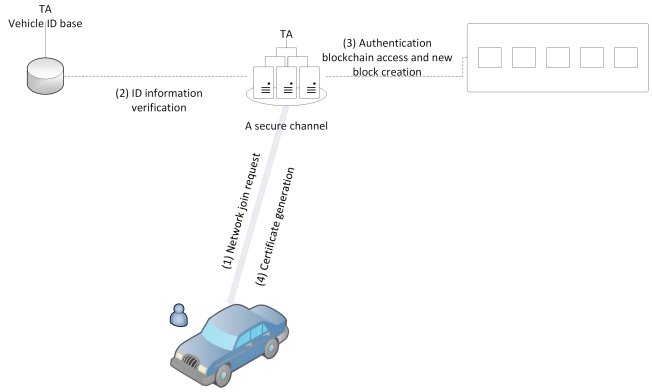

Fig. 10. Vehicle network join.

2) The RSU network join: When a new RSU is installed and launched, it needs to contact the TA to obtain its security parameters: pseudonym, a private and public key. Like vehicles, RSUs are authenticated by the trust authority to avoid any malicious infiltration. Furthermore, they use pseudonyms and encryption during their communication to guarantee sensitive data preservation.

The RSU begins by sending a join request to the TA Fig. 8. The request includes a unique identifier given to the RSU upon its setup. The TA checks its database to confirm the RSU identity. Then, it generates new parameters for the requestor, signs them, and sends back the response. When the RSU receives the TA message, it adopts the new parameters. Finally, its configuration is completed, and it can participate in any message exchange. It also starts the vehicle trust management process.

3) The vehicle registration process: When a new vehicle is registered Fig. 9, the owner physically submits the required documents to the MVAC. The latter checks the vehicle's identity documents validity and approves the registration. An acceptance notification will be sent from the MVAC to the TA. The real identity of the vehicle will also be sent to be stored in the TA dedicated database. As a second step, the vehicle will be allowed to communicate with the TA through a secure channel Fig. 10. The vehicle sends its identity information and asks for a certificate generation. The TA generates for the new vehicle a new "unique pseudonym" and a couple of public and private keys and sends it to the vehicle using the secure channel. Also, the newly generated public key will be stamped and added to the authentication blockchain among other relative information: the initial value of the trust score and the certification issuing time, validity duration, etc.

D. The Certificate Creation and Management

We use the PKI (Public Key Infrastructure) as the basic mechanism for car identification and secure communication. The TA is the only unit allowed to issue couples (public, private) vehicle keys. Consequently, no computational charge will be on the vehicle. The certificate will be used in any communication with other vehicles. Also, the TA generates a "unique pseudonym" as an identifier for the participant car and it guarantees that the pseudonyms remain unique for all vehicles and during all communications. There will be no possibility of relaying the pseudonym to the real vehicle identity or any private information.

Each participant will receive his certificate generated by the TA at its first connection. The certificate has a validity period specifying the duration attributed by the TA and the MVAC to the requesting car. Vehicles can ask for new certificates anytime due to compromised data or any eventual attack. The new certificate is requested and received through the secure channel. Upon receiving the request, the TA starts by invalidating the previous certificate and adding a new block to the authentication blockchain to announce it. Then, a new certificate is created for the requestor and added to the blockchain along with the car other's information. Especially, using the same old pseudonym and trust score Eventually, a new pair of public and private keys will be generated to avoid any eventual new threat.

E. Vehicle Authentication During V2V or V2I Communication

When a Vehicle or RSU receives a new message from another vehicle, it starts by authenticating the communicator Fig. 11. It extracts the vehicle certificate from the message and determines the corresponding public key and pseudonym. Then, it accesses the Authentication Blockchain and checks the car registered certificate and its validity duration. We remain that the blockchain is built chronologically. Therefore, the verification process starts with the newest block and goes on until the oldest one Fig. 11. Eventually, the requestor will be able to find out the most recent state of the targeted node information. For example, if the communicating node was

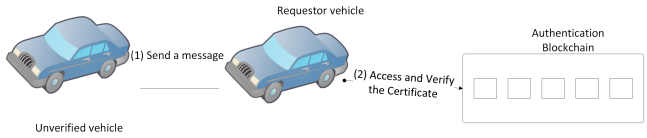

Fig. 11. Vehicle authentication during V2V or V2I communication.

banned by the TA or has an un-renewed expired certificate, the requestor will reach in the first place the block announcing that state. This verification process allows the requesting vehicle or RSU to authenticate its communicator. So, it will be able to accept the new communication. Furthermore, the requestor has the new arrival's last known historical trust score. So, it will be able to decide better about its communicator's behavior.

F. The Trust Management System

We propose a trust management system based on the following elements.

- A historical trust score HTS: defined in the interval $[0..1]$. The TA attributes an initial HTS value to each new vehicle registered. The TA collects the trust scores of the targeted vehicle from the RSUs and other vehicles. Then, the TA uses a reinforcement algorithm (KNN) to recalculate the new HTS value for the vehicle and announces it by creating a new block.
- A direct trust score DTS: defined in the interval $[0..1]$ and attributed by a vehicle to each other. When vehicle A encounters for the first time vehicle B, it will generate a new DTS value for it and keep updating the B score when any new communication happens.
- An indirect trust score: ITS: defined also in the interval $[0..1]$ and attributed by the RSUs to different encountered vehicles. Periodically, the RSU receives different DTS measurements from neighboring vehicles. Then, it aggregates them to recalculate the new ITS for the targeted vehicles.

1) The DTS update algorithm: The algorithm in Fig. 12 defines the process used to manage the DTS for each vehicle. When vehicle A encounters vehicle B for the first time, it starts with attributing a first score $DTS(B) = 0.5$ and initializing 2 counters: counter for bad communication with B (Negative Behaviour Count: $NBC(B)$). It will count all cases of misbehavior of vehicle B: Lost packets and false information. And a counter for successful communication (Positive Behaviour Count: $PBC(B)$). Each new communication between them will increment the Bad or the Good counter and the total number of communications achieved. When a maximum threshold number is reached, vehicle A will calculate a new DTS for vehicle B using the formula 1

$$DTS(B)_{i+1} = \begin{cases} DTS(B)_i + DirectReward * \frac{PBC(B)-NBC(B)}{MaxThreshold} \\ = 0 \text{ if } DTS(B)_{i+1} < 0) \\ = 1 \text{ if } DTS(B)_{i+1} > 1) \end{cases} \quad (1)$$

Later, the counters for vehicle B will be re-initialized to zero. Thereby, the defined algorithm will allow to increase or decrease of the DTS of the communicating vehicle periodically

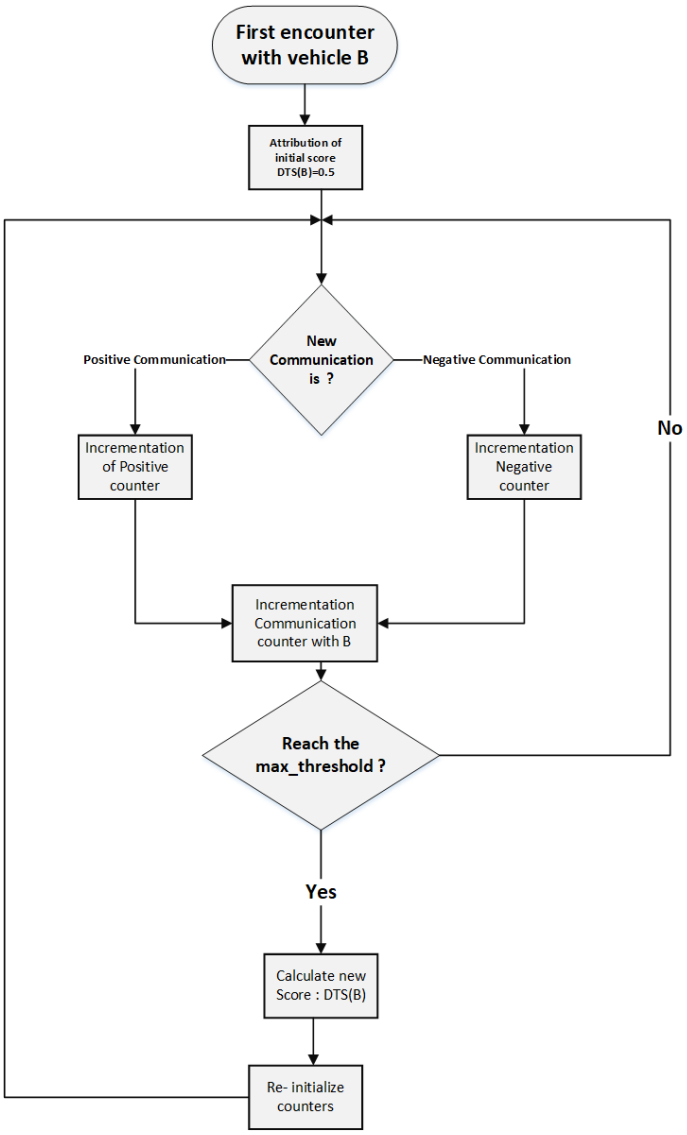

Fig. 12. DTS update algorithm.

depending on its behavior until reaching a minimum of 0 or a maximum of 1. The "Direct Reward" is a weight defined in the interval $[0..1]$. It's used to update the direct trust score DTS. In our experimentation presented later in the next section, we chose a value of 0.2.

2) The ITS update algorithm : RSUs are responsible for attributing and updating the indirect trust score for each vehicle that has joined the network. Fig. 13 shows the IDS computing algorithm. Vehicles calculate continuously the direct trust score for each encountered node and broadcast their measurement to all nearest RSUs. Periodically, RSUs will use the received DTS measurements to compute a new indirect trust score for each targeted node X. RSUs use the following formula 2

$$ITS(X)_{i+1} = \alpha * ITS(X)_i + \beta * \frac{\sum_{j=1}^{j=N} DTS(X)_j}{N} \quad (2)$$

With $\alpha + \beta = 1$ and N is the number of nodes that have sent their DTS measurement for vehicle X. α and β are weights

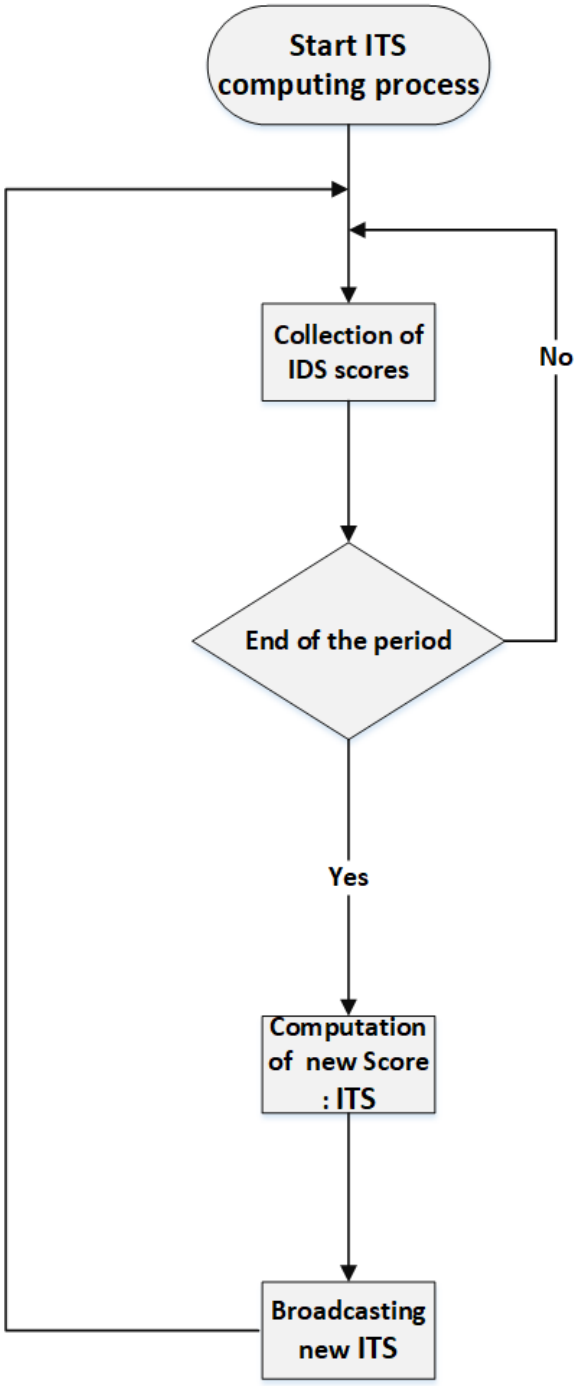

Fig. 13. ITS update algorithm.

used to moderate the combination. The new ITS measurement aggregates all the direct scores measured during the current period with the old indirect score. This formula will tie the estimated behavior of the targeted node to its location. Thus, vehicles will have a better view of communicating over the same region.

3) The HTS update algorithm: The historical trust score is attributed and updated by the TA. It is worth noting that a HTS equal to 0 is the lowest allowed value and a vehicle reaching this level will be banned. A dedicated block will be created and added to the blockchain to announce the expiration of the targeted node certificate. A vehicle with good behavior can reach a maximum value of 1. The algorithm in Fig. 14 explains the HTS management process. When a new car asks for network join, the TA will attribute an initial HTS=0.5 and mention this value in the Authentication Blockchain. The update of the historical score is based on the following features:

- The direct score in the different vehicles: The TA collects direct scores attributed to vehicles encountering the candidate car. The collection is done slowly and passively over a long period. Independently, cars can deposit their local scores on the RSUs during their travel. Later, the TA will contact RSUs periodically and ask for new deposits.
- The indirect score is calculated by all RSUs deployed in the network. The TA also receives the collection of IDS. Periodically, each RSU computes the IDS of all encountered vehicles. Then, it sends the results to the TA.
- The TA uses the reinforcement algorithm KNN (K-Nearest Neighbours) to predict the candidate's behavior. The DTS measurements for each vehicle constitute the KNN algorithm inputs. A new "judgment" about the candidate's behavior will be the algorithm's output.

Depending on the new judgment: malicious or legitimate node, the TA computes the new value of the historical trust score. The new HTS is calculated using the following formula 3

$$HTS_{i+1} = \begin{cases} \alpha * (HTS_i + HReward) + (1-\alpha) * \frac{\sum_{j=1}^{j=N} HTS_j}{N} \\ = 0 \text{ if } HTS_{i+1} < 0) \\ = 1 \text{ if } HTS_{i+1} > 1) \end{cases} \quad (3)$$

Where N is the number of RSUs having an ITS measurement for the candidate. α, is a weight defined in the interval $[0..1]$. The $HReward$ is a weight given depending on the output of the KNN algorithm. If the algorithm finds out that the candidate vehicle is a legitimate node, a positive reward will be given. Otherwise, the attributed value will be negative. We chose a value of 0.2 for this weight. It means:

- $HReward = 0.2$ if the candidate is judged legitimate.
- $HReward = -0.2$ if the candidate is judged malicious.

Thereby, the TA will be able to update vehicle historical scores according to their behavior seen by other nodes (vehicles and RSUs). The better the car behaves during its communications the better will be its HTS. The KNN is an efficient classification reinforcement learning algorithm [39]. Therefore, it helps the TA to predict the candidate's vehicle behavior efficiently.

G. The Final Trust Score and Message Acceptance Decision During V2V or V2I Communications

We have defined three different types of trust score measurement. Direct, indirect, and historical trust score. In this section, we will present how those scores will be combined and used to compute a "Final trust score" which will be used

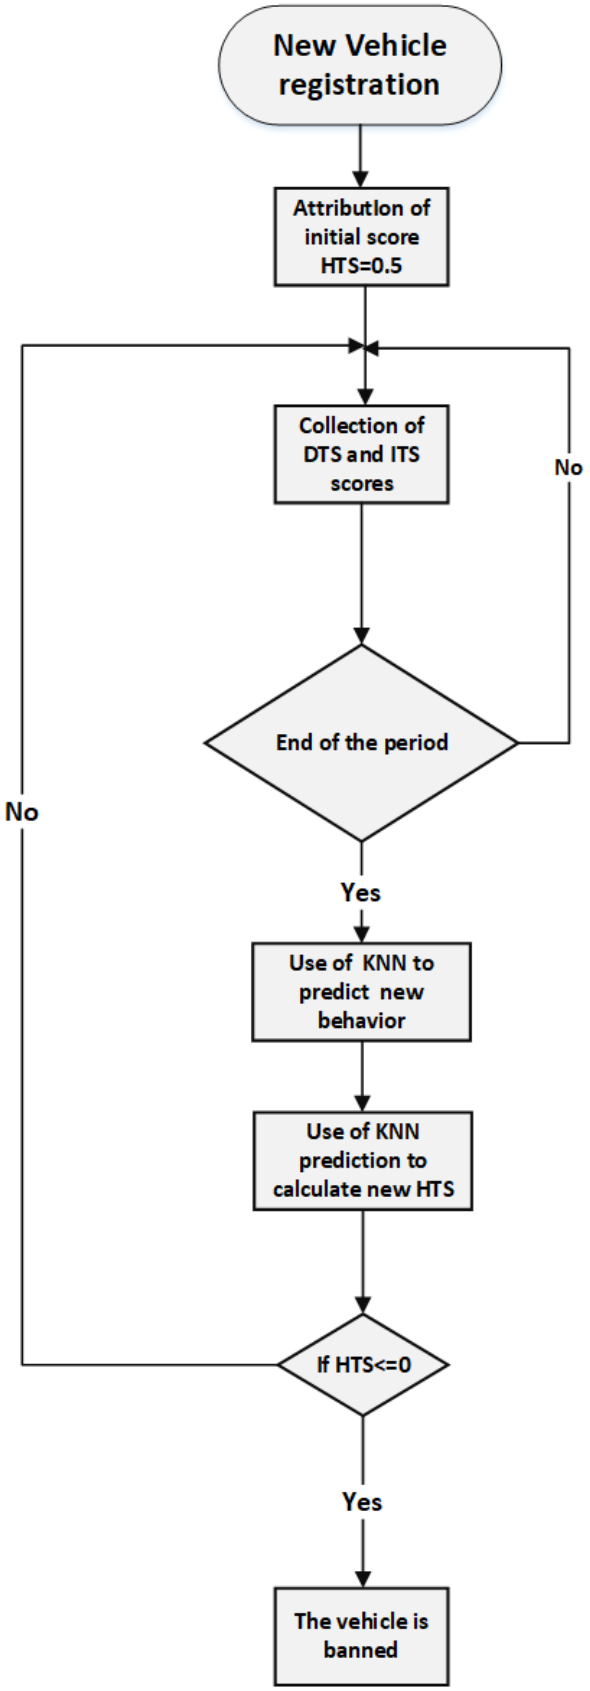

Fig. 14. HTS update algorithm.

TABLE I. WEIGHT ATTRIBUTION CASES FOR FTS

Communication Case	Weight attribution
Public Safety and urgent data	$\alpha = 0, \beta = 0, \gamma = 1$
User application or ordinary data (general case)	$\alpha = 0.5, \beta = 0.2, \gamma = 0.3$
Non -important Data	$\alpha = 1, \beta = 0, \gamma = 0$
Location-based application	$\alpha = 0, \beta = 1, \gamma = 0$

to decide during the message exchange. Upon receiving a new message from another vehicle, the car can decide whether to continue the communication or not based on the node "Final trust score". Vehicles, during their travel, will face different cases of communication. The exchanged data type can vary from urgent and important data to non-important or advertisement ones. Therefore, nodes can evaluate the sender's behavior differently depending on the communication case.

To face different cases, we introduce the following formula (4) for the final trust score (**FTS**):

$$FTS(X) = \alpha * DTS(X) + \beta * ITS(X) + \gamma * HTS(X) \quad (4)$$

Where $\alpha + \beta + \gamma = 1$. This formula permits the cover of all cases mentioned below by defining various values for the used weights.

In Table I, we introduce examples of weight attribution. In each case, nodes can compute differently the final trust score. We chose to rely on the TA's judgment when dealing with important data. So, the vehicle will neglect the direct and indirect measurements and use only the historical score which will increase the trustworthiness of the exchanged data. In the general case, we combine all the three measurements. For non-important data, vehicles can use only their measurements. Finally, for the location-based data, the trust evaluation done by RSUs will be more convenient to decide about the received messages.

V. PERFORMANCE EVALUATION

1) The evaluation scenario parameters : To evaluate the performance of our solution, we conducted two different experiments. In the first experiment, we aim to study the blockchain's basic operations: new block creation upon a vehicle network join and the proof of existence (POE) during message authentication. The second experiment will study our trust management process to show its accuracy in distinguishing between legitimate and malicious behaviors and its influence on transmission quality. we used the simulators Veins [40], OMNet++ [41], and SUMO [42] . OMNet++ is a well-known C++ event-based simulator for building network simulations. Simulation of Urban Mobility (SUMO) is an open-source, road traffic package for scenario creation. Veins is a framework that includes OMNet++ and SUMO to create and run vehicular network simulations. Table II presents the basic technical parameters.

We used the map of the "Riyadh City" Fig. 15 for the solution performance evaluation. It was generated using the open-source mapping platform "open-street-map" [43]. The covered area is (10 000m,10 000m). The traffic generator SUMO generates random trips for all the vehicles defined in the scenario.

TABLE II. BASIC SIMULATION PARAMETERES

Parameter	Values
Hardware platform	Speed 3200Mhz, 8GRAM
Operation System	Debian9.4
Traffic Generator	SUMO
Network basic simulator	Omnet++ 5.0 with inet v4.2.8
Vanet Simulator	Veins 5.2
Simulation Area	(10000mx10000m)
Simulation time	500s
Data Rate	6Mbps
Transmission power	20mW

Fig. 15. Riyadh city map.

To evaluate the performance of our trust management approach, we defined the following parameters as mentioned in Table III. In our experiment, we varied the number of traveling vehicles from 20 to 200. We also varied the percentage of malicious vehicles from 20% to 80%. Each vehicle will periodically broadcast data messages. The broadcasting delay is selected randomly depending on the vehicle's behavior. We made the malicious broadcasting delay shorter than the legitimate one to emulate real cases where attackers try to overcharge the network with their forged messages. Fig. 16 shows the Roadside Units deployment. After testing different locations to choose the best positions to cover the entire trajectory used in the vehicle's trips, we selected positions as mentioned in the figure. We observed that more than half of RSUs are placed all along the road "King ABDALLAH street".

TABLE III. BASIC SIMULATION PARAMETERS

Parameter	Values
Number of Vehicles	Varying from 20 to 200
Number of RSU	8
Malicious vehicles rate	Varying20% -40% -60%-80%
Certificate Validity period	3600s
The trust threshold	0.5
The initial trust score	0.5
The direct trust reward	0.2
The historical trust reward	0.2
The direct max count	2
The direct trust broadcasting period	15s
The indirect trust computing and broadcasting period	20s
The historical trust updating period	25s
Legitimate vehicle broadcasting delay	Random in the interval [5—10] s
Malicious vehicle broadcasting delay	Random in the interval [2—6] s

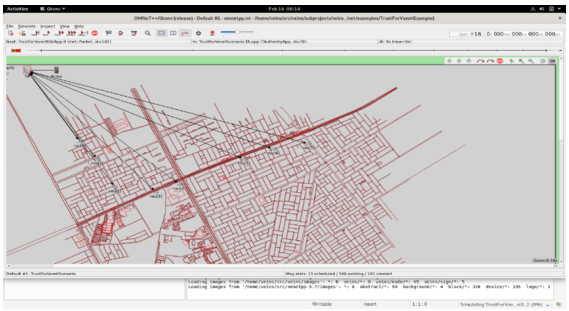

Fig. 16. RSU Deploymemt.

2) The evaluation metrics : We used two types of metrics. Metrics related to the network performance and others focused on the trust estimation. We presented the following metrics:

- PDR: the packet delivery rate. It evaluates the success rate of data packet reception. We consider the PDR for both kinds of transmitted messages: legitimate and malicious.
- Average Transmission Delay: it measures the average delay to successfully transmit legitimate data packets from sender nodes to the receivers.
- Detection accuracy: it measures the ratio of the correctly detected legitimate and malicious messages to the total received messages.
- Average of different trust scores: We evaluated the averages of different trust scores for both kinds of behaviors. Those scores are:
  - Direct trust scores
  - Indirect trust scores
  - Historical trust scores
  - Final trust scores

3) Blockchain computational cost: In our first experiment, we aim to study the performance of our blockchain structure. we implemented the Authentication blockchain in a Python environment using a virtual machine with a speed of 3200Mhz and 8GRAM. We want to evaluate the computational time needed for a vehicle to be registered by the Trust Authority and the time to authenticate received messages.

a) The evaluation of the average registration delay: In Fig. 17, we represented the average registration delay versus the number of vehicles in the network. We varied the network population from 50 to 10,000 vehicles. We observe that the average delay varies in the interval [1...2] seconds. It is worth remembering that TA will create a new block for each new vehicle at its first attempt to join the network. The block contains the vehicle information as mentioned in the previous section. Each block will have a total size of 60 bytes. We use SHA-256 for the blockchain implementation. SHA-256 generates the hash code used as a block identifier citeyoshida2005analysis. The Chronological Merkel Tree (CMT) is the basic chaining structure [37] which minimizes the needed time for block checking. The average time of PoW (Proof Of Work) operation is estimated at around 1 second [44] and it varies depending on the block size and the used technology. In our experiment, results show that the block creation time varies from 1.04 to 1.84

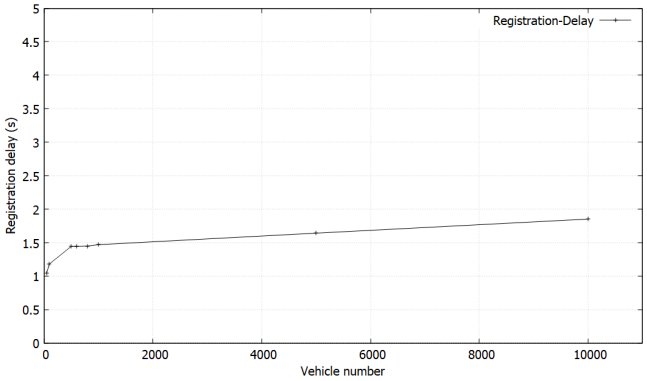

Fig. 17. Average registration delay versus vehicle number.

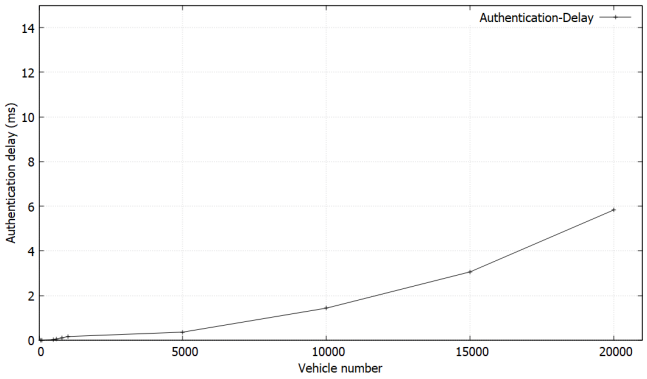

Fig. 18. Message authentication delay versus vehicle number.

seconds with the largest vehicle's number. The delay increases slowly with the number of requestors. Therefore, processing a large number of vehicle registrations will not penalize the network performance. Moreover, TA has exclusive permission to write new blocks and it has sufficient computation resources to perform its tasks without any issues. Consequently, the integration of blockchain as a public ledger in VANET will not affect the network latency.

b) The evaluation of the message authentication: In Fig. 18, we represented the average authentication delay versus the number of vehicles in the network. The message authentication delay is the needed time to verify the message sender's identity during V2V or V2I communications. Vehicles or RSUs will access the used blockchain and search for a corresponding block. The average authentication delay is the needed time to access the Authentication blockchain or other structures and verify the existence of a block for a specific vehicle. It's the elapsed time to perform a proof of presence operation. Our solution uses the algorithm SHA in the blockchain operations whose computational time is around 0.001ms per KB [45].

We varied the network population size from 50 to 20,000 vehicles. Results show that the consumed time increases from 0.0014 to $5.83ms$. Thus, with the largest number of vehicles in the network, an extra delay of $6ms$ will be observed in each message exchange. With less dense network populations, the added delay is less than $2ms$. Consequently, communications between different kinds of nodes will not be gravely affected,

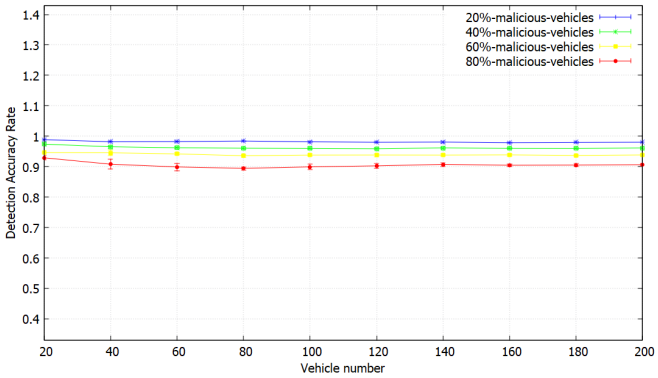

Fig. 19. Detection accuracy rate versus vehicle number.

and vehicles can quickly authenticate each other's.

4) Trust management system evaluation: Our second experiment defines simulation scenarios to evaluate the trust management process. We aim to study the efficiency and correctness of our scheme and its effects on network performance and communication quality.

a) The evaluation of the detection accuracy: Fig. 19 shows the detection accuracy rate over vehicle number variation. We used four different malicious percentages: from 20% to 80%. We see clearly that whatever the number of malicious nodes in the network, our scheme distinguishes correctly between the two behaviors. The detection accuracy rate is always greater than 0.9. With only 20% of malicious vehicles, the detection accuracy is stable around 0.98. With the highest malicious rate (80%), the detection accuracy rate decreases and is stable around 0.9. We also observe that the vehicle number slightly affects the detection accuracy. With fewer vehicles, the detection is less precise than with a bigger network population. It means, that when legitimate nodes are a minority in the network, communications and trust information exchange between them is difficult. But, with a denser network, vehicles have more opportunities to recognize malicious messages.

b) The evaluation of the direct trust score: Fig. 20 and 21 illustrate the measurement of the average direct trust score for both behaviors with various malicious percentages. We also plotted the trust score threshold used by our scheme for a clear comparison. We observe that our proposal successfully recognizes the legitimate nodes. The average attributed direct score varies between 0.68 and 0.83 which is always greater than the defined threshold.

With the smallest malicious cars percentage (20%), the average score was stable at around 0.8 whatever the number of vehicles in the network. Legitimate nodes are more likely to communicate with each other which increases the number of exchanged messages and makes the direct evaluation more precise. With a Higher malicious percentage, the communication opportunities between legitimate cars will be less often because the network will be overwhelmed by malicious messages. Nevertheless, our scheme can correctly identify good behavior and attribute a direct score always greater than .68. The direct score attributed to malicious vehicles is presented in Fig. 21. We see that the average score is stable around

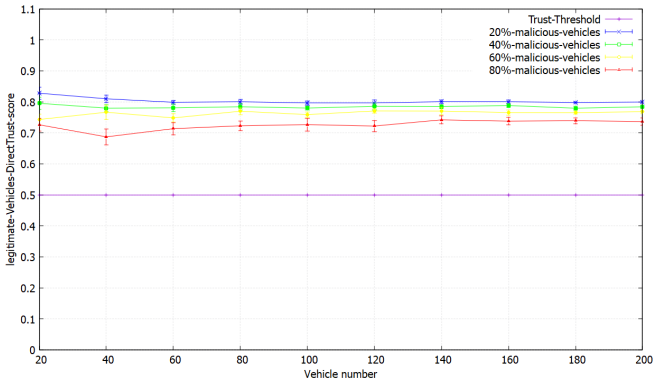

Fig. 20. Average direct score for a legitimate vehicle versus vehicle number.

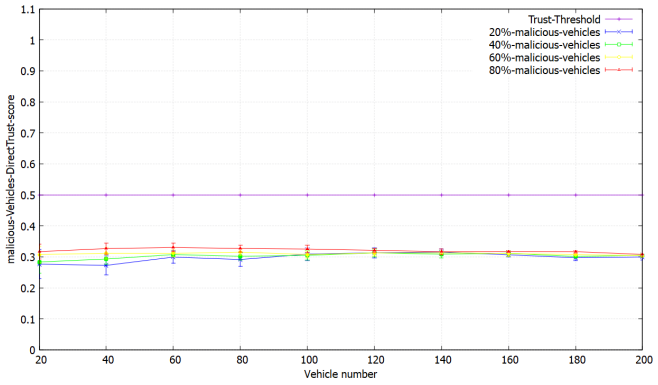

Fig. 21. Average direct score for a malicious vehicle versus vehicle number.

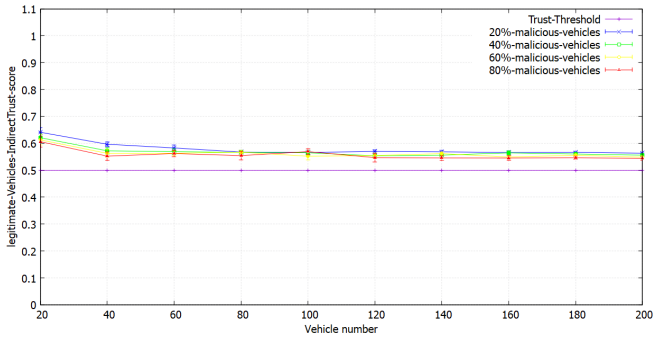

Fig. 22. Average indirect score for a legitimate vehicle versus vehicle number.

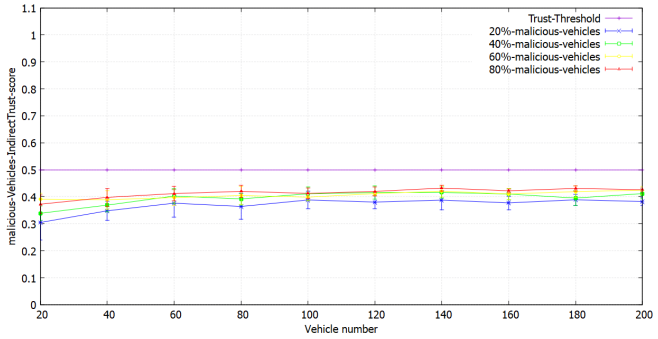

Fig. 23. Average indirect score for a malicious vehicle versus vehicle number.

0.3 less than the threshold score. Our scheme was able to recognize efficiently bad behavior and correctly attributed the corresponding score values. With various malicious rates, our direct score attribution mechanism maintains a clear distinction between behaviors. We remark that in the case of a low network population (less than 60 nodes), the average score with a malicious percentage of 80% is a little higher than with other percentages. The higher density of malicious cars makes their communications with legitimate vehicles less often which leads to fewer opportunities to evaluate their behaviors.

c) The evaluation of the indirect trust score: We represented the measurement of the average indirect score attributed to both behaviors in Fig. 22 and 23. It's worth it to remember that the indirect score is computed and attributed by RSUs. They collect direct scores of network member from their neighborhood and update their score attribution using the formula mentioned in the previous chapter. In Fig. 22, the average indirect score of legitimate nodes is illustrated. We see that the average score is always greater than the defined trust threshold whatever the malicious percentage and the number of cars in the network.

The indirect score is an aggregation of direct scores. The RSUs receive the measurement from nearby nodes and calculate the new value. In doing so, the indirect calculation process reflects the global consensus between nodes in the same neighborhood. With a small percentage of malicious vehicles in the network (20%), the average indirect value is greater than values with higher malicious rates. This means that malicious messages overwhelming the network bandwidth are handicapping behavior evaluation. Nevertheless, our solution is capable of clear recognition of each kind of behavior.

The measurement of average indirect scores for malicious cars illustrated in Fig. 23 confirms our previous observation. Bad behavior is identified in all cases and consequently, lower scores are attributed. The average indirect score for malicious vehicles is always less than the trust threshold value. It was stable between 0.3 and 0.4.

With a high presence of malicious vehicles (percentage over 60%) the average scores were greater than scores with lower rates. As we explained before, the higher presence of malicious cars made it less often for legitimate nodes to encounter them and come up with clear behavior judgments.

d) The evaluation of the historical trust score: We studied the historical trust score attribution process for both behaviors (refer to Fig. 24 and 25). The historical score is attributed by the Trust Authority (TA) using the reinforcement algorithm KNN as defined in the previous section. We observe that the TA manages to efficiently identify node behaviors and correctly attribute the corresponding scores. Legitimate nodes received an average score stable around 0.98 whatever the malicious rate and the vehicle number in the network. While malicious cars received an average score of around 0.1.

We remember that the TA receives direct and indirect score measurements from vehicles and RSUs in the network. All the collected information is cumulated and used as input for

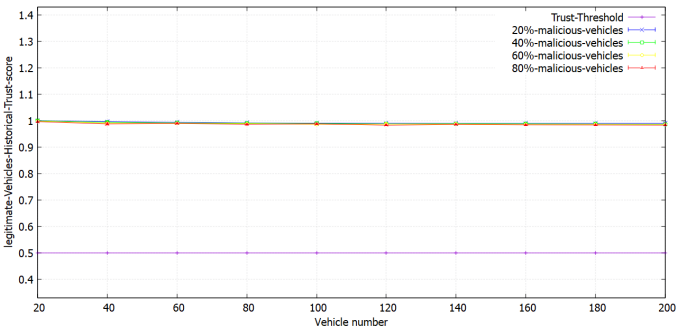

Fig. 24. Average historical score for a legitimate vehicle versus vehicle number.

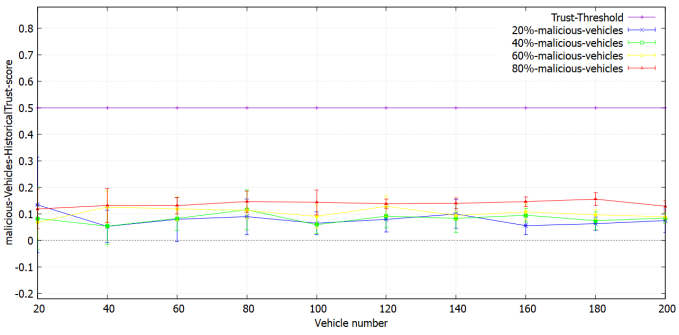

Fig. 25. Average historical score for a malicious vehicle versus vehicle number.

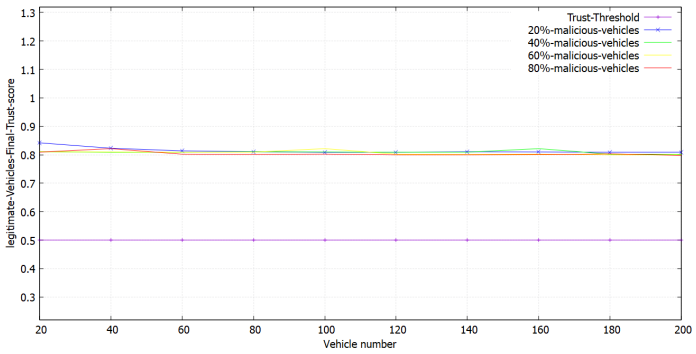

Fig. 26. Average final score for a legitimate vehicle versus vehicle number.

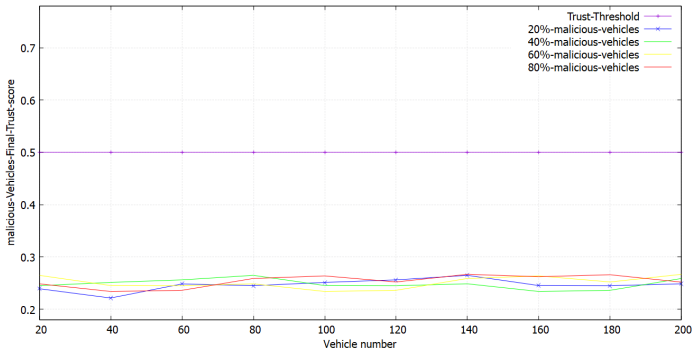

Fig. 27. Average final score for a malicious vehicle versus vehicle number.

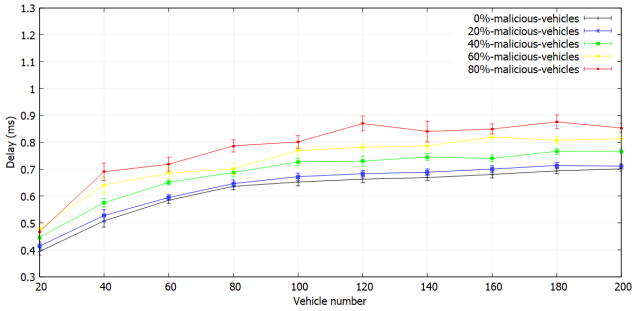

Fig. 28. Average transmission delay versus vehicle number.

the KNN reinforcement learning algorithm. TA successfully recognizes the two kinds of behavior in various situations. Legitimate nodes are identified without any issues. Malicious vehicle rate affects slightly the scores attributed to malicious vehicles. With the highest used rate (80%), the scores given to bad behavior are a little bit greater than scores in the case of a smaller rate (20% or 40%). In a network with a high malicious node density, legitimate nodes are a minority which makes the behavior evaluation more difficult.

e) The evaluation of the final score: Fig. 26 and 27 show the evaluation of the average final score for both kinds of behaviors versus the number of vehicles in the network and using various malicious rates. We remember that the final score formula is defined in the previous chapter. It combines the three evaluated trust score forms (direct, indirect, and historical) with weighted factors.

In this experiment, we studied the case where the weights (0.5, 0.2, 0.3) are respectively given to the score types (direct, indirect, and historical). This situation represents a global communication case without any special needs. We observe that the average final score of legitimate nodes is stable at around 0.8 whatever the used malicious rate and the network population size. Our proposal successfully recognizes the behavior and attributes the correct evaluation. In the case of malicious behavior, the average score is illustrated in Fig. 27 Bad behavior received an average score of around 0.25. As mentioned above, the malicious node density affects the judgment slightly. Legitimate nodes received fewer messages which made their trust evaluation less precise. This handicap leads to a higher score for bad behavior when the malicious rate is greater than 60%.

f) The evaluation of the transmission delay for legitimate data : Fig. 28 shows the data transmission delay versus variation in the number of vehicles with different malicious vehicle rates. We added to the representation a case without any attack (0% malicious vehicles) to compare with a standard transmission situation. We notice that the transmission delay in the attack scenarios is close to the ordinary exchange. First, with 20% malicious vehicles in the network, our proposal generates an extra delay stable of around $0.02ms$ whatever the population size. When the malicious car rates exceed 60%, the gap passes to $0.15ms$. Therefore, our system works without an important impact on the data delivery. The proposed authentication process is fast and efficient and legitimate communications can be carried out with minimum delay.

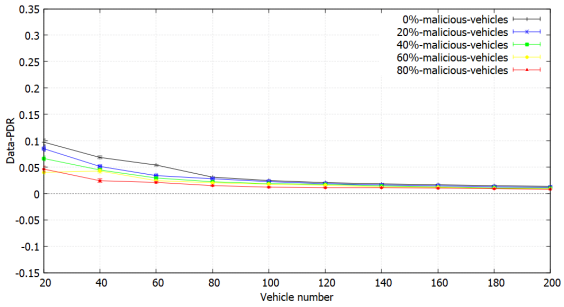

Fig. 29. Average PDR for legitimate data versus vehicle number.

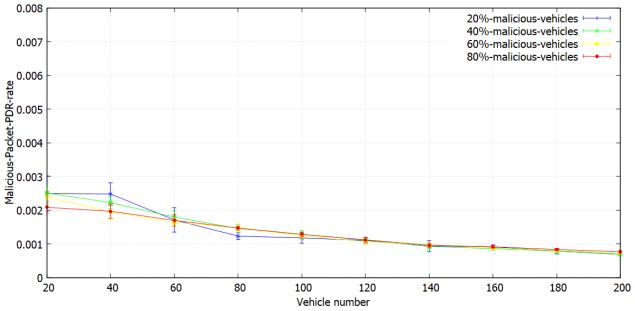

Fig. 30. Average PDR for legitimate data versus vehicle number.

g) The evaluation of PDR: Our second metric to study the impact of our solution on the transmission quality is the evaluation of the Packet Delivery Rate (PDR) which counts the successfully delivered data packet rate. We evaluated the PDR for both kinds of behavior: legitimate and malicious data. Fig. 29 shows the legitimate data PDR versus the variation of vehicle numbers with various malicious vehicle rates. The PDR illustration confirms the result seen in the latency experiment. The PDR for legitimate vehicles is close to ordinary exchange no matter the rate of malicious cars. The highest malicious rate (80%) with the small network size (20 vehicles), shows the lowest successful rate, and the highest gap: 5% with the PDR of the ordinary exchange case. Malicious vehicles outnumber legitimate ones, consequently, they will occupy the network bandwidth and cause high packet loss for legitimate data. With other examples of population, our solution succeeded in reducing the attack overhead and data PDR is always close to ordinary exchange with all used malicious rates.

Fig. 30 illustrates the PDR evaluation for the malicious data to study the amount of harmful packets undetected by our solution. We remark that this amount is almost negligible. Its highest value was 0.0025 when we used 20% of malicious vehicles and a small network population size (20 vehicles). With other malicious rates or population sizes, the accepted malicious packets decrease, and the PDR is stable at around only 0.0015. This result shows that our solution detected efficiently any possible attack and succeeded in blocking and rejecting those packets. The low accepted rate is recorded during the first data exchanges where legitimate nodes were not able to fully evaluate the attacker's behavior. Quickly, our trust management process reveals the packet harm aspect and distinguishes correctly the bad from the good.

5) Result discussion: To study the performance of our solution, we defined two different kinds of experimentation. Firstly, we aim to evaluate the impact of blockchain technology integration on the authentication process. So, we implemented a real structure of the blockchain and tested the different computation operations. We focused on two basic processes: the registration of new vehicles and message authentication during ordinary communications. Our evaluation shows that the consumed time during a new vehicle registration will not exceed 1.84 seconds. This time corresponds to a new block creation and adding to the current ledger. This result remains as expected and lower than the standard time known from a literature review. Our second goal in this experiment was the computation time needed during V2V or V2I message exchange. This time was at around $0.001ms$. it corresponds to the PoE (Proof of Existing) operation. We find out that, the blockchain integration in the VANET authentication process offers transparency and sensitive data preservation without overcharging network members.

Our second experiment used simulation scenarios to evaluate trust management and its impact on communication and network performances. Results show the correctness of our scheme. We observed that the detection accuracy rate was high and stable around 0.98 which demonstrates that node behaviors were recognized effectively. The evaluation of the different defined levels of trust scores: direct, indirect, historical, and final, indicates that the behavior score was quickly reviewed and updated. In a small populated network, the trust management system allows clear differentiation. Legitimate scores have been increased to over 0.8 and malicious scores have been decreased to 0.15. In populated networks, the recorded scores were around 0.75 for good behaviors and 0.3 for bad ones. Analysis of those results shows that the trust score attribution is slightly affected by the encountering probability. In small networks, a few vehicles are more likely to meet than in large networks. Therefore, the trust evaluation process can detect malicious behavior regardless of network size. In addition, it is more effective when vehicles pass each other very often.

Our second interest was the effects on communication quality. Results proved that the proposed scheme did not affect ordinary communications between network legitimate nodes. Data packets are still delivered quickly. In small networks, the identity verification process will add around $0.02ms$ to packet transmission time. While in larger networks the extra delay is around $0.15ms$. Packet delivery rate measurement shows that we maintain high rates close to ordinary exchange without any attack.

VI. Conclusion

In this age of emerging technologies, we have to face these security challenges, specifically in the context of VANETs, which have become a rich field for scientific research. In this paper, we highlighted the concern of privacy protection in VANETs. We proposed a new authentication solution for VANET to ensure private data preservation and distinguish legitimate users from malicious ones. Our proposal introduces the use of blockchain technology as a reliable structure to maintain trustworthy authentication information and provide vehicles with an effective technique to authenticate any received message. We designed also a new trust management

process where vehicles evaluate their communicator's behavior and attribute trust scores accordingly. We defined various kinds of scores. Each one reflects different levels of trust evaluation decisions. Direct trust to reflect the node relationships. An indirect score is calculated by TA to reflect a bigger view. And a historical score using the reinforcement algorithm KNN to have a deeper evaluation of the node behavior. Finally, we evaluated the performance of our solution. Our analysis showed that our proposal provides an effective behavior management system and meets all the requirements for security and privacy in VANET. In future research, we will investigate the possibility of designing a new attack mitigation technique and we will focus on testing real attacks to evaluate the performance of our system.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Imam Mohammad Ibn Saud Islamic University (IMISIU) for funding and supporting this work through the Graduate Students Research Support Program.

An Efficiency Hardware Design for Lane Detector Systems

Duc Khai Lam
University of Information Technology, Ho Chi Minh City, Vietnam
Vietnam National University, Ho Chi Minh City, Vietnam

***Abstract*—The Hough Transform (HT) algorithm is a popular method for lane detection based on the 'voting' process to extract complete lines. The voting process is derived from the HT algorithm and then executed in parameter space (ρ, θ) to identify the 'votes' with the highest count, meaning that image points with pairs of angle θ and distance ρ corresponding to those 'votes' lie on the same line. However, this algorithm requires significant memory and computational complexity. In this paper, we propose a new algorithm for the Hough Space (HS) by utilizing parameterization (Y-intercept, θ) instead of (ρ, θ) parameterization and lane direction. This simplifies the inverse LHT operation and reduces the accumulator's size and computational complexity compared to the standard LHT. We aim to minimize processing time per frame for real-time processing. Our implementation operates at a frequency of 250MHz, and the processing time for each frame with a resolution of 1024x1024 is 4.19ms, achieving an accuracy of 85.49%. This design is synthesized on the Virtex-7 VC707 FPGA.**

***Keywords*—FPGA; Hough transform; look up table; lane detector; autonomous vehicle**

I. Introduction

Lane detection is one of the crucial objectives in image processing and computer vision, extensively applied in industries such as vehicle guidance and Advanced Driver Assistance Systems (ADAS). It involves detecting white or yellow lane markings. In some vision applications for Lane Departure Warning Systems (LDWS), the Hough Transform algorithm is widely utilized for lane detection due to its robust and effective detection capability, even in environments with significant noise or multiple non-contiguous lines [1]–[3]. This method relies on the 'voting' process and extracts complete lines.

Recent studies have focused on enhancing the Voting method within the Hough Transform for real-time computation. In [4], the authors applied Parallel Voting on an FPGA, utilizing a 2D array accumulator for line computation in the Hough Space with parameter pairs (ρ, θ). By transforming the array into a 1D array and partitioning the Hough Space into parallel voting blocks, concurrent determination of lines and parameter computation (ρ, θ) was achieved. This accelerated the process, resulting in an average processing speed of 5.4ms per frame at a frequency of 200MHz, making video processing more feasible.

Similarly, subsequent authors proposed a hardware architecture for HT serving lane detection using the Parallel Voting method, implemented on FPGA in the scientific study [5]. Based on θ, the values in the Hough Space were parallelized. To detect edges of image frames in videos, computations of (ρ, θ) were performed to extract the highest voting value in the Hough Space to determine the lines. The achieved processing speed was approximately 135 frames/s when deployed on the FPGA kit, operating at a frequency of 50MHz, and the image transmission protocol was VGA (640x480).

In the study [6], the authors developed a new algorithm for the Hough Parameter Space (HPS), which significantly reduced memory requirements compared to the standard Hough Transform (HT) algorithm. This method also supported accelerated Inverse Hough Transform (IHT) and reduced the accumulator size for voting. The efficiency of the proposed architecture was demonstrated through hardware-software co-simulation on the Xilinx Virtex-5 ML505 platform. The architecture from reference [4] allowed for a processing time of 1.47ms per frame for an image size of 640x480 pixels and an operating frequency of 200MHz.

The Angular Regions - Line Hough Transform (AR-LHT) method, based on techniques from LHT, is a memory-efficient approach for line detection in images. Utilizing the Hough Parameter Space (HPS) with minimal dispersion reduces memory usage significantly, as reported in [7]. Authors employ two smaller memories: a 1-bit Bitmap Region (RBM) and a downsized HPS. RBM determines peak orientation precisely after the voting process. Results show a 48% decrease in RAM usage compared to standard LHT for images sized 1024x1024 pixels. FPGA processing time for one image is 9.03ms.

In the study [8], the authors propose an HT architecture that uses a Look Up Table (LUT) to store trigonometric values and use the value of orientation θ calculated in the Sobel Edge Detection algorithm instead of rotating small angles as the HT standard. The processing time per 1024x1024 image resolution frame is 6.17ms with an accuracy of 94%. This design is synthesized on the FPGA Virtex-7 VC707.

In the study [9], [10], the authors implemented a real-time single-camera lane detection. To address different lighting conditions, they employed vital algorithms such as the Otsu, Canny algorithms and the Hough transform for lane detection to determine the Region of Interest and minimize computational complexity; detecting vanishing points is crucial.

The main contribution of [11] is to present an efficient implementation of Hough Transform based on Gradient for line detection, using Xilinx Virtex-7 FPGA with digital signal processing (DSP) units and integrated RAM blocks. The architecture is implemented with a working frequency of 260.061MHz and $2n + (\sqrt{2} + 2)n + 232$ clock cycles for a grayscale image of size n * n.

For complicated conditions, such as rain and night illuminations, the new processing method, comprising four

stages: Gaussian blur, grayscale conversion, Dark-Light-Dark threshold (DLD) algorithm, edge extraction using correlation filters, and Hough Transform according to [12], [13], has been developed. It effectively addresses lane complexities including arrows and text. Validation results demonstrate a maximum detection rate of 97.2%.

In [14], the authors present an algorithm for simple and user-friendly lane detection using the Line Segment Detector (LSD). This system maintains a throughput performance of 60 frames per second (fps) for VGA images (640×480) on the PYNQ-Z1 board with the Xilinx XC7Z020-1CLG400C FPGA.

To optimize the hardware resource for rho and theta calculations in the voting process of the line Hough Transform, the authors [15] propose an efficient memory design. This design is implemented in TSMC ASIC 90nm technology. It requires only 4174 MB RAM.

In this work, we focus on presenting an efficient hardware architecture design for the lane detection model to achieve real-time processing for large-resolution videos. We optimize hardware resources by reducing memory size and computational complexity. The lane detection core employs the Hough Transform algorithm. The proposed system includes the preprocessing process using the Gray Scale algorithm, Sobel Edge Detection, and the central processing algorithm - Hough Transform, implemented on an FPGA kit. The architecture focuses on accelerating hardware performance for the Hough Transform and Inverse Hough Transform algorithms by utilizing parameterization (Y-intercept, θ) in the Hough space and significantly reducing hardware resources by applying Region of Interest. Enhancements will concentrate on memory optimization of modules within the design and simplifying computational operations.

The rest of the paper is organized as follows. Section II presents the proposed hardware design architecture. Section III shows the evaluation and comparison results. Finally, Section IV gives the conclusions of this paper.

II. Proposed Hardware Design Architecture

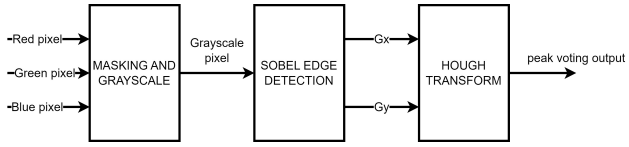

Fig. 1. Hough transform system.

Fig. 1 illustrates the architecture of the Lane Detection System using the Hough Transform, with the input being pixel values of an image and the output being the ρ and θ values after being voted in the Hough Transform module.

The proposed lane detection system consists of three parts, including the hardware architectures of the Gray Scale, Sobel Edge Detection, and Hough Transform algorithms. The functional blocks in this system are designed using the Verilog language. The available blocks of Gray Scale are referenced from the Masking module architecture, Gray Scale, Sobel Edge Detection, and the Hough Transform module is referenced from the study [6]. This paper will focus on utilizing the Region of Interest (ROI) to reduce resources. The system's ROI is determined through experimental measurements, as depicted in Fig. 2. The details of the improved and optimized functional modules will be described below.

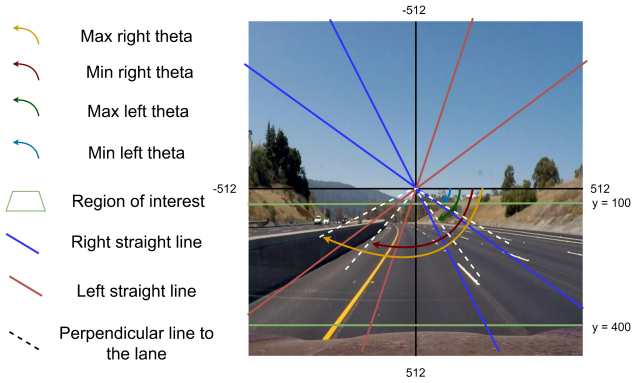

Fig. 2. Define the left and right lane boundaries' region of interest (ROI).

A. Sobel Edge Detection Module

The conventional structure is depicted in Fig. 3. In this structure, the image passes through Shift Registers to store the values of pixels in a row to form the matrix values of the Gx and Gy masks in the Gx, Gy Operator module. Then, it computes the orientation and edge intensity of the image through the Vectoring Cordic Module. Fig. 3 illustrates the architecture of this algorithm.

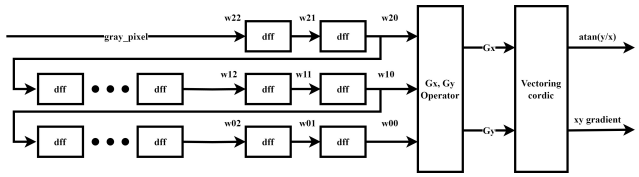

Fig. 3. Sobel edge detection.

However, utilizing Shift Registers as a First-In-First-Out (FIFO) mechanism could result in resource consumption and potentially suboptimal efficiency. As illustrated in Fig. 4, the Registers typically employed for retaining pixel rows are substituted with Memory components within the proposed Sobel Edge Detection method. Leveraging Memory resources on the FPGA offers the advantage of mitigating the routing complexities inherent in the design, consequently enabling elevated processing frequency within this module.

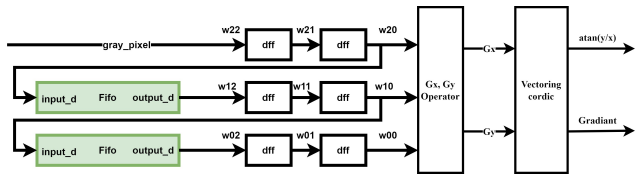

Fig. 4. Proposed Sobel Edge Detection.

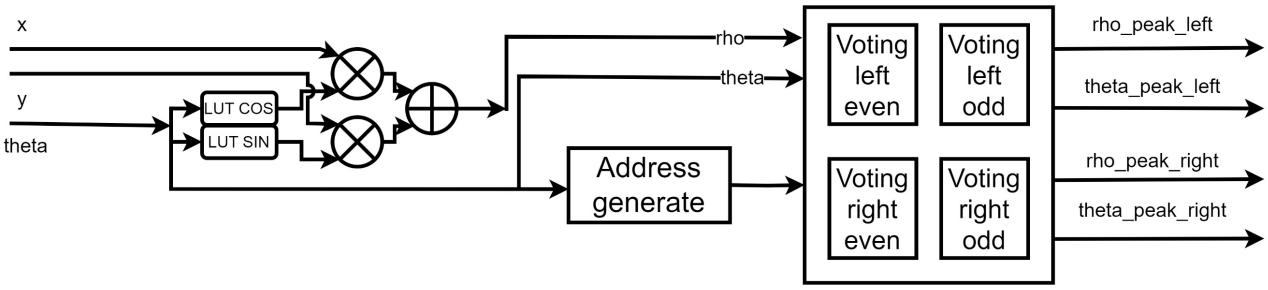

Fig. 5. Hough Transform module.

B. Hough Transform Module

In the conventional hardware design of the Hough Transform module, the authors employed the conventional method of Hough Transform computation, depicted in Fig. 5. This method involves computing ρ (rho) using the formula:

$$\rho = x * cos(\theta) + y * sin(\theta) \quad (1)$$

And utilizing the (ρ, θ) value system throughout calculations and as results. However, this approach does not include mechanisms for accelerating computations for the Inverse Hough Transform, necessitating additional processing steps after obtaining results from the hardware design. To reduce computational complexity, cos and sine trigonometric functions are computed via Look-Up Tables (LUTs) for both functions, as illustrated in Fig. 6. Notably, Sin and Cosin LUTs encompass data beyond the Region of Interest experimented with, resulting in memory consumption to store unnecessary values. Furthermore, the Voting module in the conventional design uses a Dual Port RAM as an accumulator for each image pixel identified as part of a straight line, as depicted in Fig.7. Subsequently, the (ρ, θ) values are directed to the Address generate block to furnish address values for the Voting module, thereby facilitating the voting process.

179	-0.9998	0.0174

Fig. 6. Sin LUT and Cos LUT.

Within the Voting Module, the Dual-port RAM performs concurrent accumulation and voting tasks, leveraging its versatile operational modes that seamlessly alternate between reading and writing operations. This integrated functionality optimizes resource utilization and enhances overall processing throughput within the module.

Within the Voting Port A of the Dual-port RAM, its functionality extends to retrieving the Accumulator value, subsequently updating it by assigning the value A (ρ_i, θ_i) = A (ρ_i, θ_i) + 1 into Port B. Activating wr_en permits the writing operation to Port B contingent upon detecting an edge pixel within the Sobel Edge Detection module. Upon completion of the mapping and accumulation stages for the candidate (ρ, θ) pairs, the most prominent vote within the accumulator ensemble is determined through a straightforward comparison method characterized by its simplicity and minimal computational overhead.

Upon surpassing predefined threshold criteria during the voting process, the (ρ, θ) values garnered at the output undergo comparison and are archived within a flip-flop, effectively becoming the benchmark for comparison to ascertain the maximum value among the addresses within the dual-port RAM. This selection process culminates in the derivation of the outcome. Notably, each Voting module functions autonomously in delineating between the left and right lane lines. Nevertheless, each Voting module is singularly capable of executing voting operations for individual lane lines, necessitating the deployment of two Voting modules to detect a single lane line.

	2						
	…						
	177						
	178						
	179						

Fig. 8. Allocation Dual Port RAM.

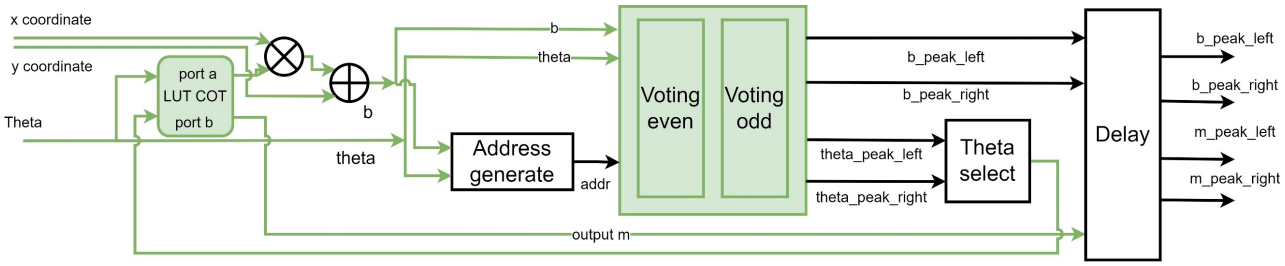

Fig. 9. Proposed Hough Transform.

The dual-port RAM in the conventional design has a memory space size from 0 to 179 * MaxRHO with MaxRHO = 750 for an image size of 1024x1024, as shown in Fig. 8. The memory space size of the dual-port RAM includes all addresses from the smallest to the largest of the (ρ, θ) value pairs and contains values that are not within the ROI, leading to unnecessary resource consumption.

Even and odd voting blocks are used alternately, with the Even Voting performing the voting while the Odd Voting is in the reset process for the next voting round, and vice versa. This allows the voting process to be carried out continuously without interruption to reset the accumulator values. Therefore, four voting modules are required to perform the Voting and reset the accumulator values alternately to continuously obtain the output of the left and right lane lines. In the conventional formula Eq. (1) of the Hough Transform algorithm, the processing of the inverse transformation, Inverse Hough Transform, has not been performed and needs to be processed to obtain the equation of the line:

$$b = x * m + y \tag{2}$$

In the proposed design, the computation of ρ will be replaced by b:

$$m = cot\theta \tag{3}$$

$$b = \rho / sin(\theta) \tag{4}$$

$$(2), (3), (4) \rightarrow b = cot(\theta) * x + y \tag{5}$$

Using this method, the hardware design also accelerates the Inverse Hough Transform. The proposed Hough Transform algorithm is described in Fig. 9. Compared to the conventional design, the Hough Transform module computes the value of b according to formula Eq. (5) to jointly enter the selection by pairs of values (b, θ) for the line. The design can compute for the process of Inverse Hough Transform with the final output being a linear equation Eq. (2). After selecting the line, the θ value is used to retrieve the (b, m) pair of results from the Dual port ROM of the COTAN trigonometric function to output. The final output value will be in the format of a linear equation. Moreover, the COTAN trigonometric function will only utilize 1 LUT instead of both Sin and Cosine trigonometric functions.

Furthermore, ROI will be utilized to reduce the resource usage of Cotan LUT, as shown in Fig. 10. The values stored inside the Cot LUT are limited to those experimented in the conventional design. The LUT will compute the values of θ from 30 degrees to 53 degrees and 130 degrees to 153 degrees

COT LUT	
θ	COT
30	1.732
…	…
53	0.7535
130	-0.839
…	…
153	-1.9626

Fig. 10. Cotan LUT.

to optimize resources and eliminate unnecessary values outside the ROI.

In the proposed hardware design of the Hough Transform, the Voting module is reduced to 2 Voting modules: Voting even and Voting odd. Each Voting module can perform Voting for the left and right lane lines by adding a condition to differentiate the peak values for the left and right lanes. This is illustrated in Fig. 11.

In the proposed Voting module, a comparison operation is added to compare the rotation angle of the pixel. If the pixel has a rotation angle greater than 90 degrees, then it belongs to the left side, otherwise if it is less than 90 degrees, then it belongs to the right side of the lane. This way, each Voting module will handle both the right and left lanes, reducing the number of Voting Modules needed by half.

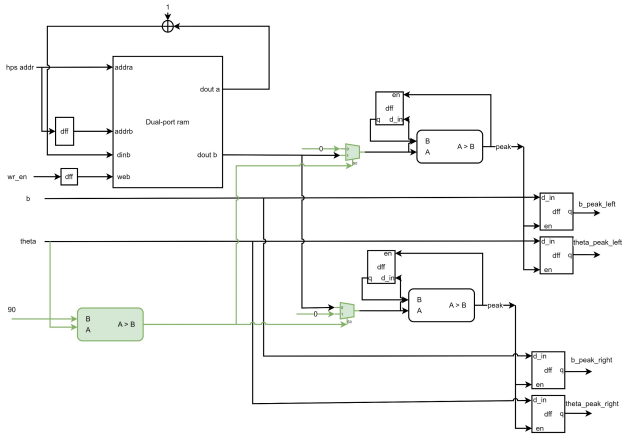

Fig. 11. Proposed voting module.

After changing from the Hough Space (ρ, θ) to the parameter space (b, θ), the maximum value in the space also changes,

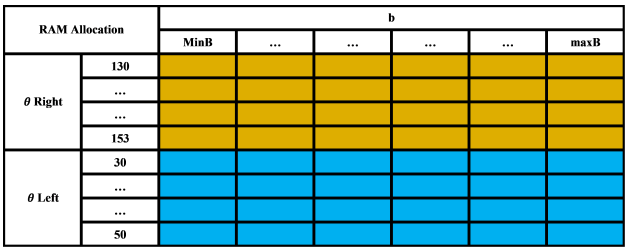

Fig. 12. Size of the proposed Dual Port RAM.

with the max being 1550. However, when applying ROI to the Hough Transform Module, the b value will range from -860 $\leq$ b $\leq$ 400 based on formula Eq. (5). The offset needs to be added to max = 400 to obtain the computation address 860, and the upper limit of b is 1260. Therefore, the Dual-port ram in the proposed design will have a memory region size of ((53-30) * (bmax+boffset) + ((153-130) * (bmax+boffset)) as shown in Fig. 12 and eliminate unused address regions outside the ROI.

The amount of memory used by the Hough Transform will be reduced to only 2% compared to the conventional design, and in the HOUGH TRANSFORM Module of the proposed design, only 2 VOTING modules are required. This reduces the overall RAM size of the proposed design to approximately 1.044% compared to the conventional design.

III. Verification

A. Synthesized Result

The architecture is synthesized on the Virtex-7 VC707 FPGA platform using the Vivado Design Suite program based on the proposed architecture method. Table I shows the resource consumption for the proposed hardware architecture of the Hough Transform, benefiting from method simplification, transforming the Hough Space into (b, θ), and applying ROI rigorously. The architecture utilizes 0.82% LUT and 482 Kbit memory (approximately 0.37%) for the Cotan Look-up table. BRAM usage accounts for about 3.5% of the Voting process.

TABLE I. Resource Consumption of the Proposed Architecture

Resource	Synthesis	Implementation

FF	3243/607200 (0.53%)	3222/607200 (0.53%)
BRAM	36 /1030 (3.5%)	36/1030 (3.5%)
DSP	1/2800 (0.04%)	1/2800 (0.04%)
IO	89/700 (12.71 %)	89/700 (12.71 %)
BUFG	1/32(3.13%)	1/32(3.13%)

The achieved processing speed after synthesis (see Table II):

- Image resolution: 1024x1024
- Processing frequency: 250 MHz
- Processing speed (ms/frame): 4.19 ms

Table III illustrates a detailed comparison of resource utilization between our FPGA implementation system and other studies. Although our architecture utilizes different devices compared to other studies, overall, the hardware resources of LUTs we use are relatively small. The architecture of [4] employs a small FPGA generation, with 0.8% LUTs, 9.36% memory, and 3.72% DSP. In [5], resource usage comprises 17% LUTs, 49% memory, and 3% FF. However, it utilizes more resources for DSP, at 59.77%. Authors in the study [6] implement the Hough space using (Y-intercept, θ) and require 6.9% LUTs, 5.6% memory, and 15.54% slices without using DSP. Additionally, 5.18% LUTs, 9.34% slices, and 3.71% FF of resources are utilized in [7]. This system uses a significant number of resources for BRAM, at 66.67%. In [8], 5.83%, 3% slices, and 0.75% memory are utilized. Regarding BRAM, it uses 31%, 0.67% FF, and only 0.07% DSP.

B. Verification and Evaluation

To validate the hardware design of the Hough Transform system, a simulation model was implemented using the Verilog hardware description language, and the Hough Transform IP was simulated on the Vivado Design Suite, as shown in Fig. 13. The evaluation results will be based on the same validation

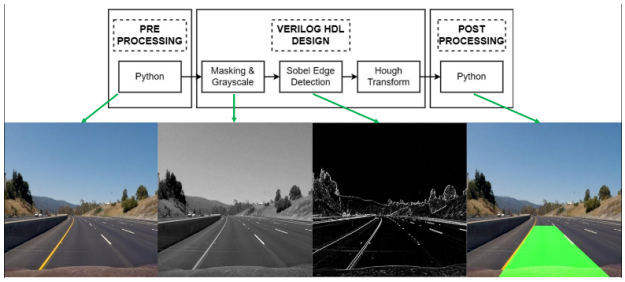

Fig. 13. Verification model.

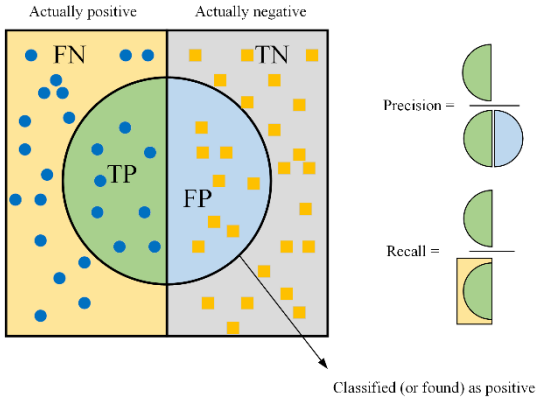

Fig. 14. Precision and recall.

dataset used in the study [8]. The videos are processed and converted into text files, then simulated using the Vivado Design Suite application. The resulting data is saved in text files, and Python processes the output values. These output values will be used to draw the lane lines.

This paper utilizes the Precision, Recall, and F1-score evaluation systems to ensure comprehensive and objective

Urban road	1810	83.61%	96.44%	88.41%	63.55%	96.37%	74.43%
Total	**4872**	**92.53%**	**97.67%**	**94.54%**	**81.29%**	**95.19%**	**85.49%**

evaluation. Precision, known as positive predictive value, measures the accuracy of the positive predictions. Recall, also referred to as sensitivity in binary classification, measures the proportion of actual positives that are correctly identified. F1-score is the harmonic mean of Precision and Recall (assuming both values are non-zero). Its value ranges from 0 to 1 and is defined as follows:

$$Precision = \frac{TN}{TN + FN} \tag{6}$$

$$Recall = \frac{TP}{TP + FN} \tag{7}$$

$$F1 - score = 2 * \frac{Precision * Recall}{Precision + Recall} \tag{8}$$

where, True Positive (TP) is the result where the model correctly predicts the positive class, True Negative (TN) is the result where the model correctly predicts the negative class. FP (False Positive) results in the model incorrectly predicting the positive class. FN (False Negative) is the result where the model incorrectly predicts the negative class. Fig. 14 illustrates an example of Precision and Recall results.

The evaluation results performed on the dataset including three videos, are depicted in Table IV. Testing results were conducted on multiple videos under various lighting and road conditions, including urban streets, highways, road conditions, coverage, poor road markings, day and night scenes. By comparing images, it is evident that the successfully deployed architecture accurately detects straight lanes.

The results evaluated on the dataset from study [6], consisting of 3 videos, are presented in Table IV. The testing results on multiple videos with varying lighting and road conditions, including urban streets, highways, road conditions, coverage, poor road markings, day and night scenes, were conducted. By comparing images, it can be observed that the successfully deployed architecture detects straight lanes. The comparative results indicate that the conventional architecture accurately detects straight lanes under different lighting and road conditions using metrics derived from these four results. Their average accuracy rates are approximately 92.53%, 97.67%, and 94.54%, respectively. Our hardware architecture's accuracy rates are 81.29%, 95.19%, and 85.49%, respectively. It is noted that there is a significant decrease in accuracy in our proposed architecture.

IV. CONCLUSIONS

This paper introduces a lane detection system for autonomous vehicles. The algorithm utilizes Gray Scale, Sobel Edge Detection, and Hough Transform methods. The hardware architecture is designed using the Verilog hardware description language. The proposed architecture implements a rigorous Region of Interest (ROI) approach to reduce hardware resource usage and algorithmic enhancements to reduce processing load for Inverse Hough Transform. The research aims to achieve fast processing speed through ROI implementation, which is capable of processing approximately 4.19ms per frame with a resolution of 1024x1024 and a frequency of 250MHz. When synthesized on the Virtex-7 VC707 FPGA board, the system achieves an accuracy of 85.49%. Although the real-time processing speed is achieved, the detection rate is relatively low. Therefore, we will explore how to improve the detection rate by applying the learning machine in our system for the future work.

Predictor Model for Chronic Kidney Disease using Adaptive Gradient Clipping with Deep Neural Nets

Neeraj Sharma, Praveen Lalwani
School of Computing Science and Engineering
VIT Bhopal University

***Abstract*—This research aims to develop computer vision based predictive model for the three prominent kidney ailments namely Cyst, Stone, and Tumor which are common renal disorders that require timely medical intervention. This classification model is tested and trained using the multi-class CT Kidney Dataset which contains 12,446 images collected from PACS (Picture Archiving and Communication System) from different hospitals in Dhaka, Bangladesh. Initial models are build using plain VGG16, ResNet50, and InceptionV3 deep neural nets. Then after clip value filter of ADAM optimizer is applied which results in marginally improved accuracy and at the last Adaptive Gradient Clipping is applied as a replacement of batch norm process and this produces overall best results. The Adaptive Gradient Clipping based model achieves accuracy of 97.15% in VGG16, 99.5% in ResNet50, and 99.23% in InceptionV3. Overall classification metrics are best for ResNet50 and Inception V3 with Adaptive Gradient Clipping technique.**

Keywords*—*CT Kidney; VGG16; ResNet50; InceptionV3; gradient clipping; image processing; multiclass classification

I. Introduction

Computer vision is emerging as one of the most promising solution for early diagnosis and assisting doctors, medical health professionals to reduce the work load and provide treatment on need basis instead of first come first serve basis. Deep learning models for medical image classification has gained lot of popularity recently because of highly accurate results generated by these models. Post COVID-19 the availability of large image data sets has also gained popularity and this promotes the deployment of deep neural nets for classification purpose. But as discussed in [1] [1] the traditional way of handling image datasets may not work well for handling the large image datasets. This research work uses CT Kidney image dataset [2], which is a collection of 12,446 images spread across four categories of Normal, Cyst, Stone, and tumor, and build convolutional neural net based multi-class classification models for CT Kidney dataset using VGG16, ResNet50, and InceptionV3 deep neural nets. The initial models are build using plain versions of VGG16, ResNet50, and InceptionV3. To build the second version the clip norm filter of Adam Optimizer is used which is a floating value and is basically used to individually clip the gradient of each weight so that the norm of each weight remains less than or equal to this value. To build the third version the Adaptive Gradient Clipping techniques as discussed in [3] is used. Adaptive Gradient Clipping is a replacement to batch norm technique when we want to train models using larger batch sizes and increase the learning rate of model.

A. Chronic Kidney Disease

Chronic Kidney Disease (CKD) is a condition in which the kidneys are impaired and cannot filter blood as effectively as they could. As a result, the body stores excess fluid and blood waste, which can contribute to a variety of health problems such as heart disease and stroke. CKD is also reported to lead to Kidney Failure and is estimated to be present in 1 out of 10 adults [4]. CKD effects almost 1 billion people worldwide [5] largely including women, older citizens, and people suffering from diabetes and hypertension. CKD causes premature morbidity and mortality and lowers quality of life; it is also expensive [6] and becomes a big financial burden for low and middle income countries.

Cysts, Tumor, and Stone are three different impairments in Kidney. Round fluid-filled pouches called kidney cysts can develop on or inside the kidneys, impairing their regular function. A growth or collection of abnormal cells that develops on the kidney is called a kidney tumor. Malignant (cancerous) or benign (not cancerous) terms might apply to these tumors. Hard deposits of minerals and salts that accumulate inside the kidneys are called kidney stones.

CKD meets all the four criteria that are required to be recognize a disease as a public health issue [7] [8]. Early detection of CKD may prevent death and disability but such early detection is difficult [9] [10] depends on the availability of nephrologists who are scarcely available in various geographic locations and specially in South Asia[11]. Delay in detection of Kidney cysts, stones, and tumors increases the possibility of renal failure [12]. All these condition pave way for deployment of Deep Neural Net based models for timely detection of Kidney related diseases.

B. Authors Contribution

Chronic Kidney Disease is recognised as a public health issue but remains a less explored disease in the medical image processing filed. In this article a reliable and automated Kidney disease image processing model using advanced deep learning models is build. Another contribution is to explore the two different approaches for image classification: the traditional way using data scaling and Batch Normalization, and the novel way of using adaptive gradient clipping. The third contribution is in comparing the performance of the three most contemporary deep learning models namely VGG16, ResNet50, and Inception V3.

C. Article Organization

In Section 2, the most prominent and related work on deep learning based image processing models are discussed and the most prominent work in this field is summarized. The preliminaries of the image processing field are discussed in Section 3. In Section 4, the dataset, preprocessing methods, and the proposed model is discussed. In Section 5 the experimental results are discussed and comparative study of the different approaches are done. The article concludes by summarizing this research work and stating the future research prospects in Section 6.

II. Related Work

A nice survey on medical image analysis can be found in [13]. Deep Learning methods have been tested on plethora of data sets in many research articles in the last decade. Main focus area in these research articles were radiology findings and segmentation tasks. Convolutional Neural Networks (CNN) have dominated the image processing segment [14], [15]. ResNet [14] has proved very helpful in building efficient Deep Neural Net Models. Other Deep Neural Net models prominently used are inception[15], and exception [16]. Another recent Deep Learning model is EfficientNet [17].

Recent advancement in the Deep Learning field like transfer learning is also proving very helpful in developing efficient models. Transfer learning is profoundly used for Natural Language Processing. Weights of a deep neural network pretrained on a large generic dataset are used to initialize subsequent tasks which can be solved with fewer data points, and less compute [18] [19] [20]. Transformers were proposed in [21] for machine translation and much recently they are deployed in image processing applications also. Multiple works try combining CNN-like architectures with self-attention [22] [23] [24], some replacing the convolutions entirely [25] [26]. But in large-scale image recognition, classic ResNetlike architectures are still state of the art [27] [28] [29][30].

Models like Vision transformer [31] have produced wonderful results as compared to Convolutional Neural Networks but hybrid models [32] and CNN with novel optimization techniques are expected to achieve much better results [33]. Deep neural nets use Gradient Descent as the basic technique for learning and a comparison of the different implementations of Gradient Descent is discussed in [34]. In all the models ADAM optimizer is used which is combination of RMSprop and Stochastic Gradient Descent with momentum. In [35] Stochastic Gradient Descent (SGD) is stated to perform better than ADAM, and RMS Prop optimizer using ResNet50. Class Balancing is discussed as a future work in this article but [36] discusses the meta-heuristic approaches that can be used for balancing X-Ray image datasets.

Limitation of Batch Norm technique are discussed in [37] for training large datasets and also discussed are the solution in the form of an novel Robust Normalization technique which provides all benefits of Batch Norm while mitigating the adversarial attacks. The technique of Adaptive Gradient Clipping is introduced in [3] as a replacement of Batch norm. Performance of Swin Transformers is reported to excel CNN models in [2] as it achieves accuracy of 99.30%. Vision Transformers are compared with CNN in [31] and it is concluded then though CNN are slower as compared to Vision Transformers because of pooling operation but Vision Transformers require large data sets for training. YOLOv8 is deployed on CT Kidney Dataset for multi-class classification in [38] and it achieves an accuracy of 82.52

III. Preliminaries

The underlying concepts of Image Processing, various classification techniques, and optimization techniques involved in this research article are discussed in this section.

A. Medical Image Processing

Medical image processing is used by medical practitioners to detect and diagnose diseases at early stages to increase chances of curing the disease. Out of the several basic stages of image processing Deep Learning is prominently applied for Image Enhancement, Segmentation and classification stages.

Noise frequently deteriorates medical pictures because of a variety of interference sources and this interfere with image processing systems' measuring procedures raising the requirement of Image Enhancement procedures [39]. The technique of segmenting a picture involves breaking it up into areas with similar texture, color, brightness, contrast, and gray level [40]. A segmented image become more meaning full and facilitates classification. Image classification is the task of categorizing an image into either of the given categories. Deep learning excels in the tasks of Image Segmentation, Reconstruction, and Classification [41]. Deep Learning models like RESNet [42], VGG16 [43], Inception Net [44] have excelled in this field achieving results that even surpass human abilities.

B. Image Classification Models

VGG16, ResNet50, and InceptionNetV3 are used for building the multi-class classification model.

1) VGG16: VGG16 [43] has become popular because of its proficiency in image classification tasks. It is a 16 layer Convolutional Neural Network (CNN) which has shown impressive performance on various image classification benchmarks. Its structure includes multiple convolutional and pooling layers followed by fully connected layers as shown in figure. It has a deep architecture to learn hierarchical features and the use of small 3x3 convolutional filters enables capturing fine-grained details in images. VGG16 has been employed in numerous studies for diabetic retinopathy and kidney cyst classification tasks, achieving high accuracy and demonstrating its potential as a reliable model in computer vision-based prediction. Structure of VGG16 classifier model is shown in Fig. 1.

2) ResNet50: ResNet50, short for Residual Network with 50 layers, is variant of a powerful CNN architecture introduced in [42] that addresses the challenge of training very deep neural networks. It introduces skip connections, or residual connections, which enable the network to learn residual mappings, making it easier to optimize and alleviate the vanishing gradient problem. ResNet50 has demonstrated superior performance on various image classification tasks, including diabetic retinopathy and kidney cyst classification. It's deep architecture allows for capturing intricate features, leading to

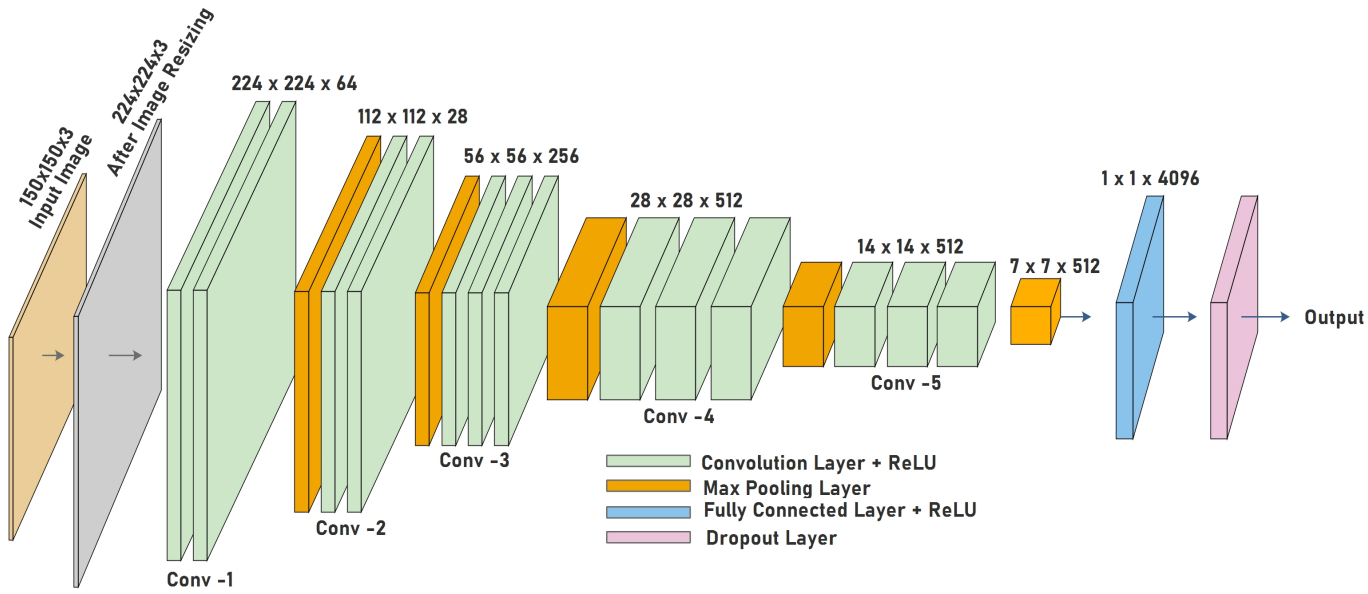

Fig. 1. Structure of VGG16.

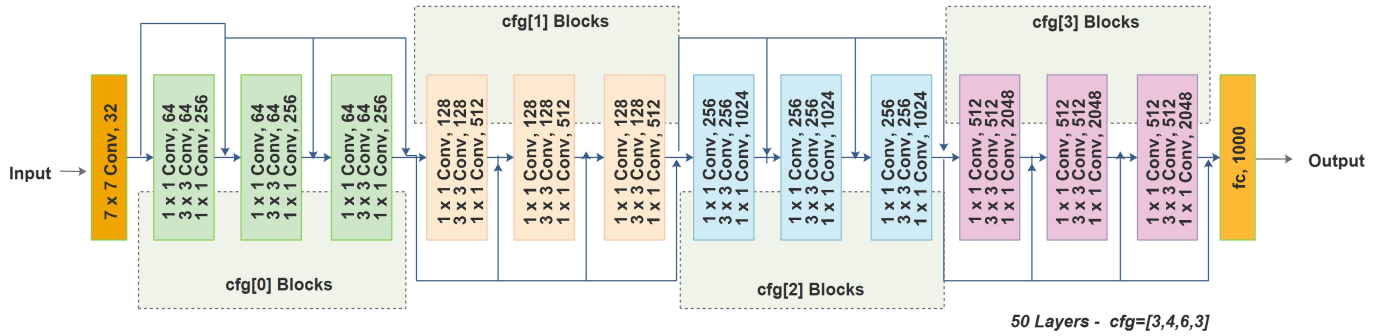

Fig. 2. Structure of ResNet50.

accurate predictions. The inclusion of residual connections makes ResNet50 particularly effective in handling complex visual patterns and has been widely adopted in computer vision research. The architecture of ResNet50 is shown in Fig. 2. cfg[3,4,6,3] refers to (3x3=9), (3x4=12), (3x6=18), and (3x3=9) summing to 48 layers (9+12+18+9) with one input layer and one fully connected layer increasing the count to 50. Structure of ResNet50 classifier is shown in Fig. 2.

3) InceptionV3: InceptionV3 is an advanced CNN architecture that incorporates the concept of "Inception modules" introduced in [44] These modules use different filter sizes and perform parallel convolutions, using which the features are captured by network at multiple scales. InceptionV3 strikes a balance between depth and computational efficiency, achieving high accuracy while maintaining a manageable model size. It has been successfully applied in various image classification tasks, including diabetic retinopathy and kidney cyst classification. InceptionV3's ability to capture both global and local features, along with its efficient architecture, makes it a valuable tool in computer vision-based prediction tasks. Structure of InceptionV3 classifier is shown in Fig. 3.

C. Normalization Techniques

To enhance the contrast of image and to make image features more visible the contrast is increased by performing min max scaling of images which scales the pixel values to a specific range.

Batch normalization [45] is frequently used for training deep neural networks with several benefits as discussed in [46] [47] [48] [49] [50]. But batch normalization comes with a major drawback of higher memory and time overheads and a mismatched behavior of training model and interference model [51] [52]. Another important limitation of Batch Normalization is that they break the interdependence between training examples. Other limitations of batch normalization are discussed in [53] [54] [55] [56] [57].As a result Normalization Free ResNets (NFRN) were developed and discussed in [46] [47] [58] and these NFRN were made more efficient by using additional regularization mechanisms as discussed in [46] [47].

Gradient Clipping: Gradient Clipping technique was introduced in [59], and the related benefits are demonstrated in [60] which uses gradient clipping to stabilize training in

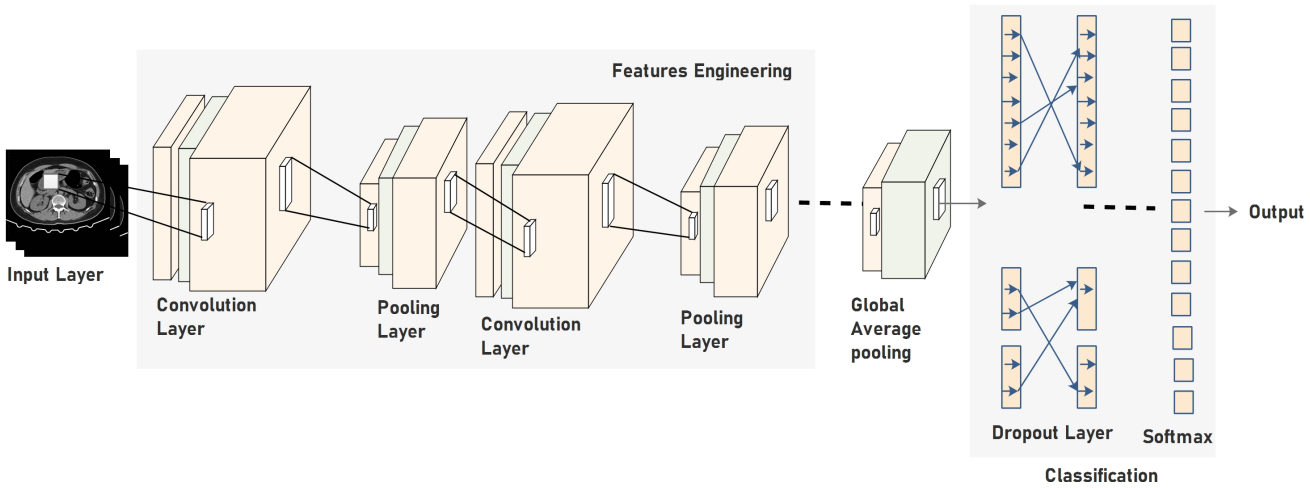

Fig. 3. Structure of InceptionV3.

Algorithm 1 Adaptive Gradient Clipping

Input:
Model parameters: θ
Rate of learning: α
Clipping threshold: ϵ
Scaling factor: γ
Initialization:
Set the model's initial values(parameter) θ
Set the initial scaling factor γ (it is usually set to 1.0)
Repeat for every training iteration::
  Compute gradients of the loss function concerning model parameters: $\nabla_\theta \text{loss}$
  Compute the norm of the gradients: $||\nabla_\theta \text{loss}||$
  if $||\nabla_\theta \text{loss}|| > \epsilon$ **then**
    Update the scaling factor γ: $\gamma = \frac{\epsilon}{||\nabla_\theta \text{loss}||}$
  end if
  Clip gradients: $\nabla_\theta \text{loss} = \gamma \cdot \nabla_\theta \text{loss}$
  Update model parameters using the clipped gradients: $\theta = \theta - \alpha \cdot \nabla_\theta \text{loss}$

Large Language Models. Gradient clipping is mainly used to counter the Exploding Gradient and Vanishing gradient problems. Before propagating the erroneous derivatives back through the network, gradient clipping entails capping them. Smaller weights are the consequence of updating the weights using capped gradients. Clipping can be done on the values of gradients or on the norm of gradients. Both the clip value and clip norm options are available in optimizers like ADAM.

Adaptive Gradient Clipping (AGC): In [61] authors discussed that clipped gradient also converges faster than non-clipped gradients for general nonconvex problems. AGC [3] improves the convergence of gradient clipping by selecting an adaptive learning rate inversely proportional to the gradient norm, and ignoring the gradient's scale thus facilitating training with large batch sizes and strong data augmentations. AGC technique is also suggested as a replacement of Batch Norm process which enhances memory utilization and increases learning efficiency of Deep Neural Nets. Algorithm 1 describes the AGC process.

IV. Proposed Model and Methodology

For the purpose of image classification Normalization methods can be combined with popular convolutional neural network (VGG16, ResNet50, and Inception V3). To achieve this, the CT kidney dataset is subjected to nine different models.

Three different setups for CT Kidney image classification are build using three different deep neural nets i.e. VGG16, ResNet50, and InceptionV3 in each setup. First setup is build using Min Max normalization with Batch Norm technique. In second setup the Clip Value (CV) filter of ADAM optimizer is used, and in the third setup Adaptive Gradient Clipping (AGC) is used as a replacement of Batch Norm. Fig. 4 shows the complete experimental setup.

A. Dataset Description

The CT Kidney dataset is a collection of 12,446 distinct jpeg images of which 3,709 are related to cysts, 5,077 to normal, 1,377 to stones, and 2,283 to tumors. The Picture Archiving and Communication System (PACS) was used to collect the dataset of patients who had previously been diagnosed with kidney tumors, cysts, normal findings, or stones at different hospitals in Dhaka, Bangladesh. The initial collection was of DICOM (Digital Imaging and Communications in Medicine) images which contain multiple monochrome images along with patient information and other meta data. These images were converted to lossless JPEG image format and the patient information and meta data were removed. Few sample images from the four classes of the dataset are shown in Fig. 5, 6, 7, and 8.

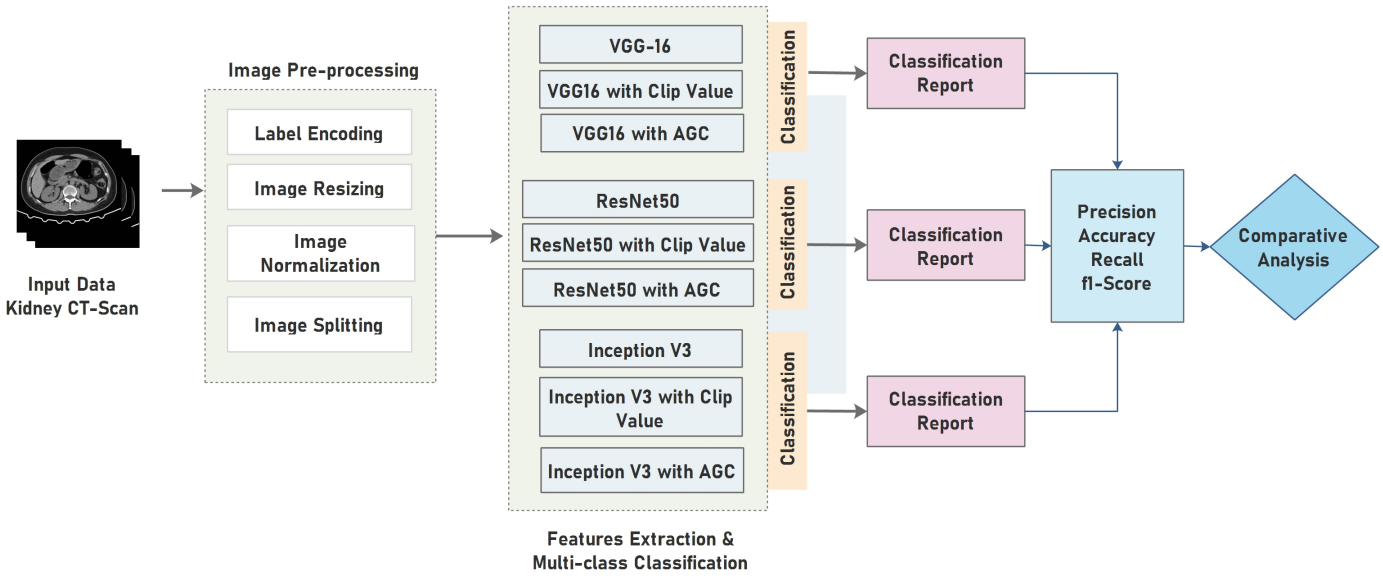

Fig. 4. Proposed model.

Fig. 5. Sample images for normal class of CT kidney dataset.

Fig. 6. Sample images for cyst class of CT kidney dataset.

B. Dataset Preprocessing

Images were initially resized to 150 by 150 pixels. The dataset is then normalized using min max normalization. The models are evaluated using a scheme where 80% of the images were taken to train the model and 20% to test the data. This resulted in 9,960 training image set and 2,491 test image set spread across 4 labels.

C. Classification Performance Metrics

A multiclass confusion matrix is used to calculate all the classification performance metric. All the classification models applied on CT Kidney dataset generates a multiclass confusion matrix from which the True Positive (TP), True Negative (TN), False Positive (FP), and False Negative(FN) values are calculated for each class.

TABLE I. CLASSIFICATION PERFORMANCE METRICS

S.No.	Metric	Formula
1.	Accuracy	{(TP+TN)}/{(TP+TN+FP+FN)}
2.	Recall/Sensitivity	{TP}/{(TP+FN)}
3.	Precision	{TP}/{(TP+FP)}
4.	F1-score	{(Recall*Precision)}/{(Recall+Precision)}

The TP, TN, FP, FN values taken from confusion matrix help us calculate the following metrics tabulated in Table I.

Fig. 7. Sample images for stones class of CT kidney dataset.

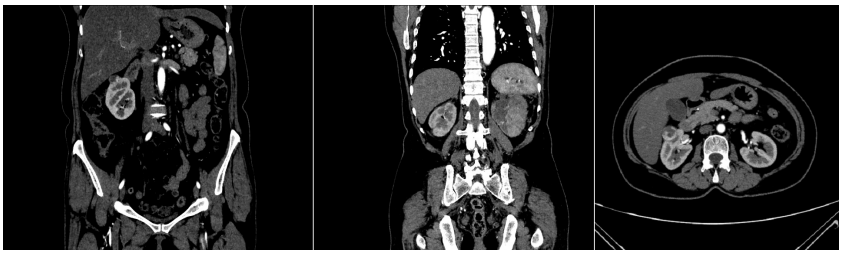

Fig. 8. Sample images for tumor class of CT kidney dataset.

Additionally for the multiclass dataset the Macro F1 score and the weighted F1 score are also calculated. The class-wise F1 scores acquired are simply averaged to get the macro-averaged F1 score of a model. The weighted F1 score is the average of the class-wise F1 scores, with the weights assigned based on the quantity of samples in each class.

Another powerful classification metric is Area Under Receiver Operating characteristics (AU-ROC) curve. The AU-ROC is also plotted but owing to the high accuracies achieved across the models AUROC score of 1 is achieved for all the classification models. Precision, recall, and f1-scores are used primarily for comparing the model's performance.

V. Results and Discussions

The experimental results of three distinct models are shown and discussed in this section. All three models used three different deep neural net VGG16, ResNet50, and InceptionV3 creating total of nine combinations. All the nine different combinations used the same hyperparameters for doing a fair comparison.

A. Experimental Setup

All the models were executed on Jupyter notebook, installed on Windows 10 platform with i9 (12th gen) processor running at 3.19 GHz and having 64 GB of RAM and 1 TB hard Disk Drive space.

The various Python libraries used were Keras, TensorFlow, Numpy, os, Sci-kit Learn, and Matplotlib. The hyperparameters are commonly used across all nine models and are tabulated in Table II.

Additionally for all the Clip Value (CV) based models clipvalue=0.6 is used and for all Adaptive Gradient Clipping (AGC) based models decay rate of 0.95 is used with initial Clip Norm value = 1.00. The clip norm value is updated adaptively by AGC algorithm during the run time.

TABLE II. Parameter Tuning in all Models

SNo	Parameter	Value
1	No. of Epocs	15
2	Learning Rate	0.01
3	Drop Out	0.5
4	Loss Function	Categorical Cross Entropy
5	Optimizer	ADAM
6	Batch Size	32
7	Activation Function	ReLU and Softmax
8	Regularization	Early Stopping from Keras
9	Preprocessing	Label Encoder/One Hot Encoding
10	Padding	'Same'

B. Performance Analysis of CT Kidney Dataset using VGG16

VGG16 is evaluated first on the CT Kidney dataset. The multi-class confusion matrix are shown in Fig. 9 and the classification metrics are displayed in Table III which displays the results of Plain VGG16, VGG16 with applied Clip Value (VGG16-CV), and VGG16 with Adaptive Gradient Clipping (VGG16-AGC).

In plain VGG16 classification accuracy of 96.9% is achieved which becomes 96.8% with CV model and 97.1% with application of AGC. The highest value of Macro and weighted f1-Score are also achieved with Adaptive Gradient Clipping technique i.e. 96.1% and 97.2% respectively. The highest values of precision are recorded in the plain model except for Class1 where the CV and AGC based models achieve higher precision values. Plain VGG16 achieves best Recall for Class0 and Class1 and AGC model achieves best Recall for Class1 and Class3.

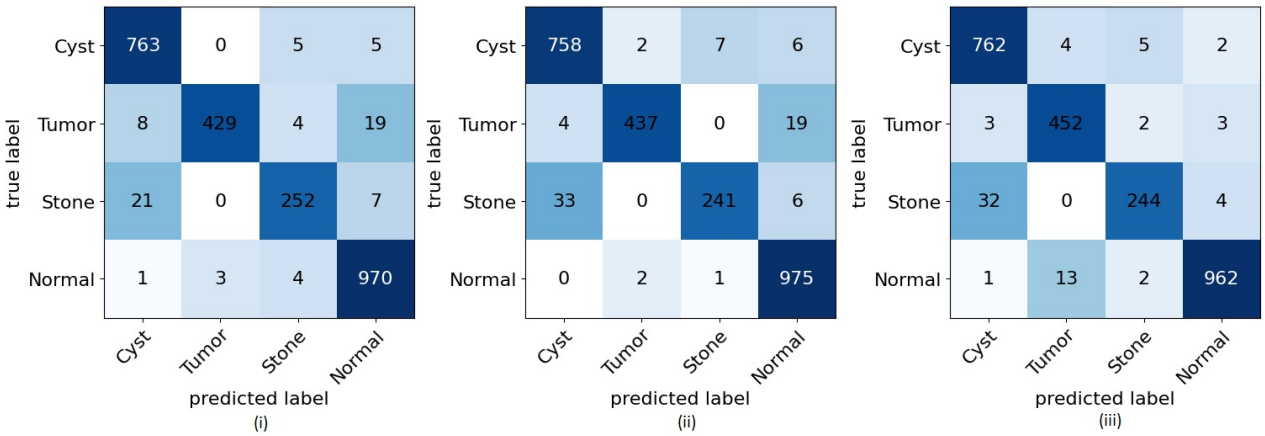

Fig. 9. Confusion Matrix for (i) Plain VGG16, (ii) VGG16-CV, (iii) VGG16-AGC.

TABLE III. CLASSIFICATION REPORT OF VGG16 MODELS

	Plain VGG16			VGG16-CV			VGG16-AGC		
	Precision	Recall	f1-score	Precision	Recall	f1-score	Precision	Recall	f1-score
Class 0(Cyst)	.987	.962	.974	.981	.953	.967	.986	.955	.970
Class 1(Tumor)	.933	.993	.962	.950	.991	.970	.983	.964	.973
Class 2(Stone)	.900	.951	.925	.861	.968	.911	.871	.964	.916
Class 3(Normal)	.992	.969	.980	.997	.969	.969	.984	.991	.987
Accuracy		.969			.968			.971	
Misclassification		.031			.032			.029	
Macro f1		.960			.958			.961	
Weighted f1		.969			.968			.972	

C. Performance Analysis of CT Kidney Dataset using ResNet50

Next the performance of ResNet50 on the CT Kidney dataset is discussed. The three multi-class confusion matrix are shown in Fig. 10 and the classification metrics are displayed in Table IV, which contains the results of plain ResNet50, ResNet50 with applied Clip Value (ResNet50-CV), and ResNet50 with Adaptive Gradient Clipping (ResNet50-AGC).

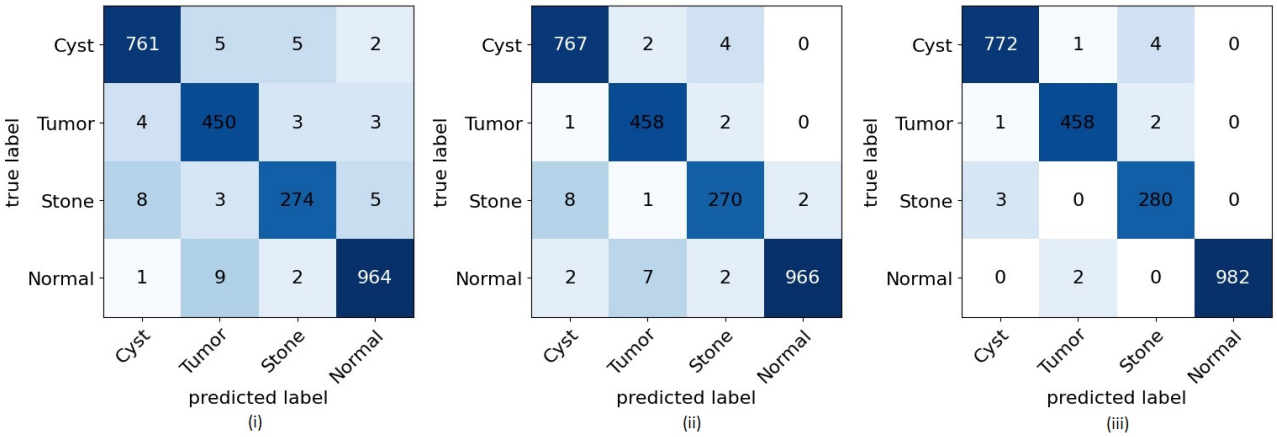

Fig. 10. Confusion Matrix for (i) Plain ResNet50, (ii) ResNet50-CV, (iii) ResNet50-AGC.

TABLE IV. CLASSIFICATION REPORT OF RESNET50 MODELS

	Plain ResNet50			ResNet50-CV			ResNet50-AGC		
	Precision	Recall	f1-score	Precision	Recall	f1-score	Precision	Recall	f1-score
Class 0(Cyst)	.984	.983	.984	.992	.986	.989	.994	.995	.994
Class 1(Tumor)	.978	.964	.971	.993	.979	.986	.993	.993	.993
Class 2(Stone)	.945	.965	.955	.961	.971	.966	.989	.979	.984
Class 3(Normal)	.988	.990	.989	.989	.998	.993	.998	1	.999
Accuracy		.980			.988			.995	
Misclassification		.020			.012			.005	
Macro f1		.975			.984			.993	
Weighted f1		.980			.988			.995	

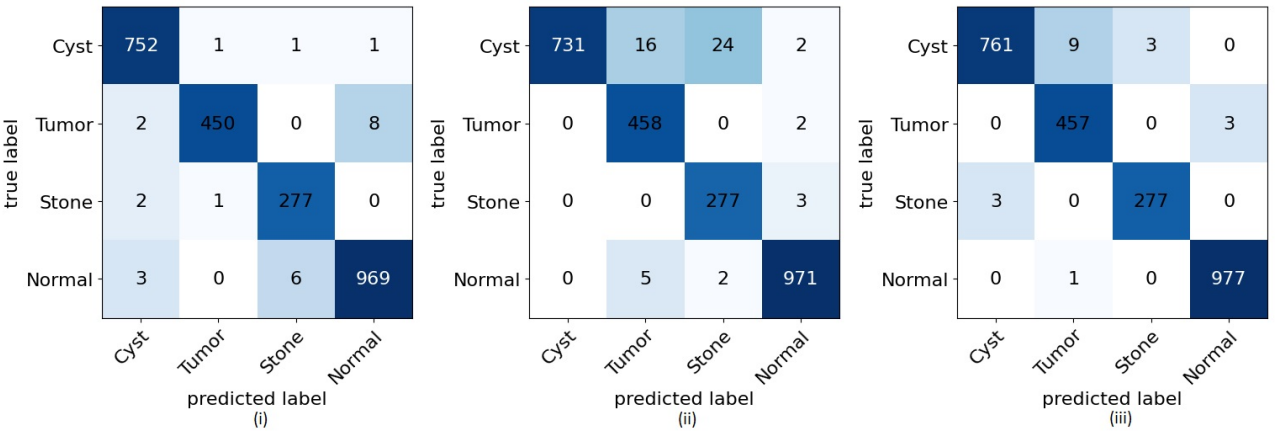

Fig. 11. Confusion Matrix for (i) Plain InceptionV3, (ii) InceptionV3-CV, (iii) InceptionV3-AGC.

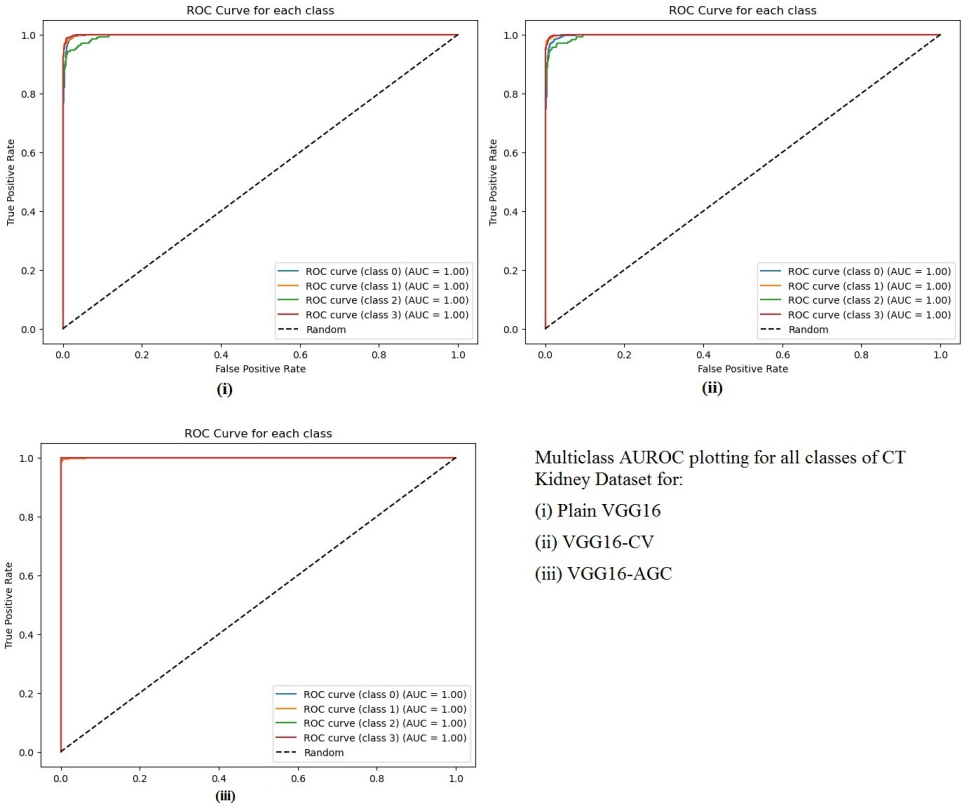
TABLE V. CLASSIFICATION REPORT OF INCEPTION V3 MODELS

	Plain InceptionV3			InceptionV3-CV			InceptionV3-AGC		
	Precision	Recall	f1-score	Precision	Recall	f1-score	Precision	Recall	f1-score
Class 0(Cyst)	.996	.991	.993	.946	1	.972	.984	.996	.990
Class 1(Tumor)	.978	.996	.987	.996	.956	.976	.993	.979	.986
Class 2(Stone)	.989	.975	.982	.989	.914	.950	.989	.989	.989
Class 3(Normal)	.991	.991	.990	.993	.993	.993	.999	.997	.998
Accuracy		.990			.978			.992	
Misclassification		.010			.022			.008	
Macro f1		.988			.973			.991	
Weighted f1		.990			.978			.992	



Multiclass AUROC plotting for all classes of CT Kidney Dataset for:

(i) Plain VGG16

(ii) VGG16-CV

(iii) VGG16-AGC

Fig. 12. All AUROC for VGG16 Setup.

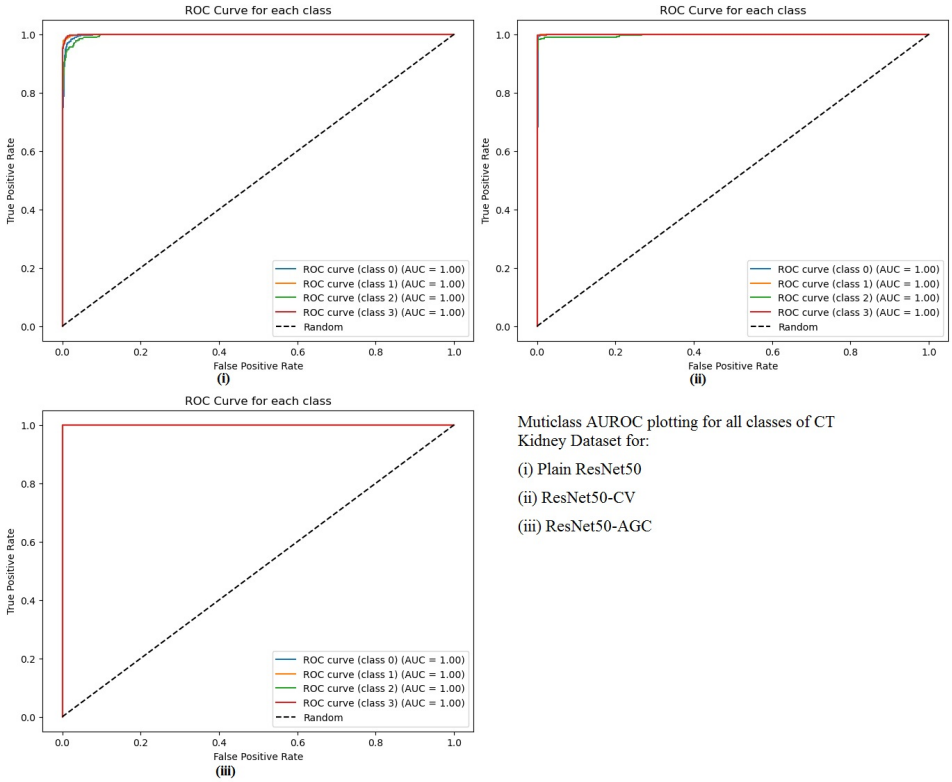


Fig. 13. All AUROC for ResNet50 Setup.

Plain ResNet50 achieved classification accuracy of 98% which increases to 98.8% with ResNet50-CV and 99.5% in ResNet50-AGC model. With AGC the highest scores of Macro F1, Weighted F1 are achieved. CV model produces marginally better results as compared to plain model but AGC model scores the highest precision, and recall values across all the classes giving the best results.

D. Performance Analysis of CT Kidney Dataset using Inception V3

In the last setup Inception V3 is used to build the multiclass classification models. The resultant confusion matrix are shown in Fig. 11 and the classification metrics are displayed in Table V for plain Inception V3, Inception V3 with applied Clip Value (Inception V3-CV), and Inception V3 with Adaptive Gradient Clipping (Inception V3-AGC). Plain InceptionV3 achieved classification accuracy of 99% which decreased to 97.8% for the CV model and increased to 99.2% with AGC model. The Clip Value model performs marginally better for Class3 but in the remaining classes it stays behind the plain model. AGC model excels in precision in Class1 and Class3 and in Recall in Class0 and Class3. Overall AGC model marginally stays ahead of Plain model with highest score of Macro F1, and Weighted F1.

The AUROC for all the nine models are also plotted in Fig. 12, 13, and 14. The AUROC score remains same across all models because of high accuracy achieved.

VI. Summary and Future Work

Two different techniques of Clip Value(CV) and Adaptive Gradient Clipping(AGC) are put to test on the CT Kidney Dataset in this article and their performances are compared with the plain models of VGG16, ResNet50, and Inception V3 models. Using clip value feature of optimizer brings marginal advantages in the VGG16 and ResNet50 models but fails to create much notable improvements. But with AGC model, a notable improvement is observed with VGG16 and ResNet50 setup, and marginal improvement with Inception V3 setup. AGC not only improves classification metrics but also improves the learning rates of the models. It was noted that during the training the AGC models quickly crossed the 90% and the 95% accuracy marks as compared to the plain models and the CV based models which took more epochs to reach 90% and 95% accuracies.

These results can be compared with the results in [62] and [2] in which authors have build classifiers for CT Kidney dataset. In [62] authors achieve accuracy of 95.29%, 99.48% and 97.38% using the MobileNetV2, VGG16, and InceptionV3 deep neural nets. In article [2] authors achieve accuracies of 98.20% using VGG16, 73.80% using ResNet50, and 61.60% using Inception V3. The results produced by the AGC based model achieves higher value of accuracy in VGG16, ResNet50, and Inception V3 as compared to these papers (Table VI). AGC is a promising technique that can be further tested on much larger datasets like Diabetic Retinopathy dataset in which the parameters of batch size and learning rates can altered to see the effect of AGC on larger batch sizes and higher learning rates. Still the existing results have proven that AGC technique can be a helpful method for training image datasets where it is difficult or time consuming to decide the clipping threshold for regularizing the train dataset.

TABLE VI. Accuracy Comparison of the Proposed AGC based Classification Method

Research Contribution	Method	Accuracy
M. H. K. Mehedi et al., 2022, [62]	MobileNetV2	95.29%
	VGG16,	99.48%
	InceptionV3	97.38%
M. N. Islam et al., 2022, [2]	Resnet	73.80%
	VGG16	98.20%
	Inception v3	61.60%
AGC (Proposed)	Resnet	99.5%
	VGG16	97.1%
	Inception v3	99.2%

***Abstract*—Educational robots, when integrated into STEM (Science, Technology, Engineering, and Mathematics) education across a range of age groups, serve to enhance learning experiences by facilitating hands-on activities. These robots are particularly instrumental in the realm of Internet of Things (IoT) education, guiding learners from basic to advanced applications. This paper introduces the IoTXplorBot, an open-source and open-design educational robot, developed to foster the learning of IoT concepts in a cost-effective manner. The robot is equipped with a variety of low-cost sensors and actuators and features an interchangeable microcontroller that is compatible with other development boards from the Arduino Nano family. This compatibility allows for diverse programming languages and varied purposes. The robot's printed circuit board is designed to be user-friendly, even for those with no engineering skills. The proposed board includes additional pins and a breadboard on the robot's chassis, enabling the extension of the robot with other hardware components. The use of the Arduino board allows learners to leverage all capabilities from Arduino, such as the Arduino IoT cloud, dashboard, online compiler, and project hub. These resources aid in the development of new projects and in finding solutions to encountered problems. The paper concludes with a discussion on the future development of this robot, underscoring its potential for ongoing adaptation and improvement.**

***Keywords*—Educational robots; Internet of Things; IoT Education; Arduino for Education; IoT Educational Kit**

I. Introduction

Recent advancements in technology have significantly transformed educational processes within classroom settings. Notable examples of these educational technologies include augmented reality [1], educational robotics [2], and large language models [3] recently, all of which have garnered considerable interest among students. However, the integration of these technologies necessitates additional efforts, particularly in the development of requisite learning materials.

The Internet of Things (IoT) is a technological paradigm that facilitates the interconnection of embedded devices via a network. These IoT devices are designed to collect data from their environment, which is subsequently stored for further analysis. The primary components utilized in the IoT development process include sensors, actuators, and controllers, in addition to network and storage elements. These components are employed by learners to gain practical experience in developing IoT applications.

There are several solutions at the hands of learners and educators for supporting IoT education and practice. For example, simulation applications, educational kits, and a few educational robots are ideal paradigms of material and platforms for learning IoT in practice and for solving a variety of everyday issues.

Educational robots are used as an interactive teaching tool that supports the development of problem-solving skills and improves practical expertise in the curricular fields [4]. They are also used to introduce students to Robotics and Programming interactively from a very early age [5].

In the context of STEM (Science, Technology, Engineering, Mathematics) education, educational robots have been widely applied to enhance instructional and learning quality [6]. They offer immersive, practical learning opportunities where students gain problem-solving experience and learn to apply knowledge in real-world contexts [7]. The interdisciplinary nature of robotics in STEM prepares students for technology-centric careers.

Educational robots are used in different ways across various age groups. For instance, in the case of infant and primary education, educational robotics provides students with everything they need to easily build and program a robot capable of performing various tasks [5]. In middle and high schools, robotics clubs often compete at local STEM competitions, where teams of students are tasked with designing and building a robot to take on opponents in a series of challenges [8].

Educational robots are not only confined to primary or secondary education but are also increasingly being incorporated into higher education. The Internet of Things fundamentally relies on the engineering and programming skills fostered by STEM education. Consequently, educational robots can be effectively utilized in IoT education. This integration allows students to design and program their own robots using IoT technologies, thereby providing a hands-on, immersive learning experience. This practical approach facilitates a deeper understanding of how IoT devices collect and exchange data, enhancing students' technical skills and preparing them for the future digital world. Furthermore, the incorporation of educational robots into IoT education can stimulate innovation and creativity, encouraging students to develop novel solutions and applications for real-world problems. Thus, the use of

educational robots extends beyond traditional STEM education, demonstrating their versatility and adaptability in various educational contexts.

While there is a growing interest among hardware manufacturers, simulation software companies, and researchers in developing solutions for Internet of Things (IoT) education, a significant challenge persists. The majority of these solutions are proprietary in nature, which inherently restricts their flexibility and expandability. This limitation poses a substantial barrier to the dynamic and evolving needs of educational contexts. Consequently, there is a pressing need for open, adaptable, and scalable solutions that can effectively support IoT education and foster innovation in teaching and learning practices.

As a solution to the above limitations, in this study, the Open Source Educational Robot for Exploring the Internet of Things (abbreviated as IoTXplorBot), an open-source and open-design robot that can be utilized in IoT education to explore a range of activities, from the simplest to the most complex is introduced. The unique features of the IoTXplorBot can be summarized as follows:

- The robot's design is open and can be modified according to requirements.
- The chassis of the robot is constructed from wood, cut into a rectangular box shape by a laser cutting machine, offering a cost-effective and sustainable solution. It can also be replaced with a 3D-printed chassis for customization.
- The electronic components used, such as sensors and actuators, are low-cost and can be replaced with other components as needed.
- The Arduino Nano microcontroller used in the robot can be replaced with other microcontrollers from the same family, depending on the specific activity or cost considerations.
- The robot is programmed using the Arduino IDE, and the program can be uploaded to it from any computer or laptop via a USB cable.
- The robot has the ability to communicate in wireless mode with a base computer for storing and analyzing data collected by the sensors.

This flexibility and adaptability make the IoTXplorBot a versatile tool for IoT education. Its robot-like shape makes it more user-friendly than a sensor kit and expands the educational capabilities in richer scenarios.

The remainder of this paper is organized as follows: Section II provides an overview of the main solutions available for IoT education and highlights the pros and cons of each approach. Section III discusses the development details of the IoTXplorBot. The robot pilot and indicative activities related to IoT course are discussed in Section IV. Section V presents discussions and limitations of the robot. Finally, Section VI concludes the paper by offering our recommendations and outlining the next steps for utilizing the robot in other related course activities.

II. Related Work

A variety of desktop simulation applications and hardware kits are available for educational purposes and for prototyping IoT devices. Numerous simulation tools can be accessed online. For example, the Cisco Networking Academy offers the Packet Tracer[1] simulation tool for emulating IoT devices and networking. Similarly, Autodesk Tinkercad[2] provides a simulation tool for constructing circuits and prototyping devices. However, these simulation tools offer limited hands-on learning experiences. To address this limitation, commonly used hardware components (i.e. sensors) are often assembled into a single unit, referred to as a kit, which is then used for learning and prototyping purposes. Companies such as Adafruit[3] and Arduino[4] offer various types of kits equipped with different hardware components and controllers. These kits provide learners with the opportunity to construct real-world solutions and facilitate learning through practical application.

Educational robots, which are based on robotics and electronic components, serve to enhance the learning process by actively engaging students in classroom activities [9]. By participating in these activities, students can contribute to the development process of the robot for various applications. These robots provide a unique opportunity for learners to gain in-depth knowledge on a specific topic. A wide range of commercial educational robots are available on the market, catering to different age groups, from kindergarten to university level. Many of these robots are specifically designed to facilitate STEM education, thereby fostering tangible and constructive thinking among learners. In higher education, educational robots are utilized in various courses, providing learners with hands-on experiences [10], [11]. For instance, educational robots have been used for teaching Artificial Intelligence [12], data acquisition [13], or even for supporting robotics courses [14]. The learning outcomes of using educational robots in the classroom include problem-solving skills, self-efficacy, computational thinking, creativity, motivation, and collaboration [15]. However, for learning IoT in higher education, more sophisticated robots equipped with various sensors and actuators are required. Additionally, wireless communication technologies are necessary for transmitting data over the network to a remote storage facility that can handle the huge amount of collected data. Currently, there are only a limited number of robots available for this purpose and most of them use a proprietary design and code. Another drawback is their high cost, which may pose a barrier to accessibility.

Accordingly, open-source educational robots are also available under research [16]. The question arises: Are they sufficiently effective in enhancing IoT learning? Let's examine a few examples. Hydra [17] is an Arduino-based educational robot equipped with pre-wired connections to sensors and actuators, eliminating the need for additional hardware components. However, this robot does not incorporate wireless communication capabilities. EUROPA II [13] is equipped with various sensors and a Raspberry Pi microprocessor, allowing for direct programming. FOSSBot [18] bears similarities to EUROPA II but features various programming interfaces that

[1] https://www.netacad.com/courses/packet-tracer
[2] https://www.tinkercad.com/
[3] https://www.adafruit.com/category/878
[4] https://store.arduino.cc/collections/kits

can be utilized by users with varying coding skills. DuckieBot [19] is designed for higher education and is equipped with a camera and a Raspberry Pi board. The ability to program directly on the board and write code in various programming languages are advantages of using Raspberry Pi. However, it is more expensive compared to other boards. Furthermore, when it is replaced with other types of boards, additional wiring is required. In Table I, a comprehensive summary of prevalent educational robots and hardware kits that are applicable for IoT learning within the context of higher education is provided. This summary includes a comparative analysis of their respective hardware components and associated costs. The primary findings derived from the utilization of these educational tools are also presented.

The educational robots and kits, reviewed in Table I, are designed for a variety of tasks. Robots in [21], [13], [22], [19], [18] are based on microprocessors such as Raspberry Pi, which allows them to run program code directly on the processor without the need for an external computer. In contrast, robots in [20], [17] are programmed by a computer, with the code then uploaded onto the robot's microcontroller. Using a microprocessor enables the robot to be connected remotely for running software. However, microcontrollers are less vulnerable to security attacks than microprocessors as they require direct contact for uploading programming code. The benefit of using educational robots over hardware kits is that learners can plan to develop their projects on a single system, upgrading their projects over time.

While the aforementioned solutions offer a range of capabilities, their relatively high costs can pose a significant barrier, particularly when procuring multiple units for classroom use. Among the options, Hydra [17] stands out as the most cost-effective, yet it lacks the provision for robot extensions, which limits its utility for experienced users. Therefore, there is a

TABLE I. WIDESPREAD EDUCATIONAL ROBOTS AND KITS IN HIGHER EDUCATION: HARDWARE COMPONENTS AND COST ARE COMPARED

Robot/Kit	Controller/CPU	Sensors	Actuators	Cost (EUR)	Main Findings
Epuck 2 [20]	STM32F4 ARM Cortex M4	IR proximity, accelerometer, gyroscope, microphone, camera, Time of flight distance	Stepper motors, LEDs, Loud-seaker	550	A powerful robot designed for engineering education. The robot can be adapted for various exercises.
Robobo [21]	Smartphone + PIC32	Camera, accelerometer, gyroscope, GPS, magnetometer, IR proximity, light sensor	DC gear motor, LEDs	450	The robot interacts with a smartphone for preforming actions. The software of the robot is implemented in the smartphone.
EUROPA II [13]	Raspberry Pi	Ultrasonic distance, IR proximity, optical encoder, camera, LIDAR	DC gear motor, robotic arm, LEDs	300	Robot Operating Systems (ROS) based educational robot with a robotic arm for performing actions. Sensors used make the robot more powerful in data collection.
Turtlebot 3 [22]	Raspberry Pi + OpenCR	Camera, LIDAR, accelerometer, gyroscope, magnetometer	MYNAMIXEL AX gear motor + driver	586	A mobile robot developed for higher education as a target audience. The robot is experienced in teaching embedded systems.
Duckiebot [19]	Raspberry Pi 2	Fish-eye camera	DC gear motor	150	An autonomous vehicle-based robot used in autonomy education and research. The robot is used and driven in a platform named Duckietown.
Hydra [17]	Arduino Mega	Ultrasonic distance, potentiometer, buttons	RGB LED, LEDs, seven segment display	35	Electronic components of the robot are designed in printed circuit boards that require no circuit creation. The robot software is based on Petri Nets modeling.
FOSSBot [18]	Raspberry Pi	Ultrasonic distance, IR proximity, gyroscope, accelerometer, camera, optical encoder, noice, gas, motion, temperature, humidity, photoresistor, IR reciever	DC gear motor, servo motor, LCD screen	100	The robot contains various sensors and actuators that enable many activities. Suitable for learning different course activities.
Arduino Explore IoT Kit[5]	Arduino MKR WiFi 1010	Buttons, temperature, humidity, pressure, gas, ambient light, gesture, accelerometer, RGB color, PIR, moisture level	RGB LED, buzzer	125	A kit that enables to develop various projects for environment monitoring. The sensors are attached to the device which accesses no circuit creation.
SparkFun Inventor's Kit[6]	SparkFun RedBoard Qwiic	Ultrasonic distance, temperature, photoresistor, buttons	Servo motor, DC gear motor, LCD, piezo speaker,	100	A kit that enable robotic car development. The kit includes a breadboard and microcontroller holder which all robotic components are attached.
Arduino IoT Bundle[7]	Arduino Nano RP2040 Connect	Potentiometer, photoresistor, button, temperature, tilt	alphanumeric LCD, LEDs, bright white, DC motor, servo motor, piezo	75	A kit that enables to explore IoT projects using common sensors and actuator.

pressing need for a solution that is not only cost-effective but also expandable and open-source. Such a solution would cater to a wider range of user expertise and offer greater flexibility for adaptation and expansion, thereby enhancing its applicability in diverse educational contexts.

III. The Proposed Open Solution

A. Overview of the Robot

The IoTXplorBot (educational ro**Bot** for e**Xplor**ing **IoT**), an open-source hardware and open-design educational robot, is built around the Arduino Nano microcontroller. Its primary objective is to augment the learning process for the Internet of Things. The robot is outfitted with two motor wheels and a motor driver to regulate the motors. Additionally, it is equipped with a variety of sensors and actuators, further enhancing its functionality and adaptability in IoT education. The full view of the robot is illustrated in Fig. 1.

Fig. 1. Full view of the robot.

The robot proposes an open hardware and software solution that can be built by the students themselves. It provides an opportunity for hands-on experience with electronics and engineering principles. The IoTXplorBot shares similarities with the FOSSBot [18] and Hydra [17], but modifications have been made to the chassis and the controller to better adapt it for IoT learning. The previous iteration of this robot was detailed in a conference paper [23], where the Arduino UNO microcontroller board was utilised. A limitation of the previous version was the absence of wireless communication capabilities in the Arduino UNO board. In this updated version, changes to the hardware components, including the motor driver and the Inertial Measurement Unit (IMU) sensor were made. These enhancements aim to optimize the robot's functionality for IoT education.

B. IoTXplorBot Hardware

The chassis of the robot is crafted from wood using a laser cutter, resulting in a cost-effective design. Compared to a plastic 3D-printed chassis, such as FOSSbot's the cost is a bit higher. However, using wood instead of plastic dramatically reduces the printing time, and the durability of the chassis and is according to the environmental sustainability objectives that promote the use of recyclable material. The chassis is shaped like a rectangular box. Any damaged part can be easily reprinted and replaced. The design includes several holes for ventilation to prevent overheating of the controller or motor driver. Additional holes have been made to accommodate bolts and nuts for attaching hardware components. A separate hole has been created for routing wires, ensuring a neat and organized assembly. This thoughtful design contributes to the robot's adaptability and ease of maintenance.

The electronic components of the IoTXplorBot are carefully selected to align with its intended use. These components, which are common to other kits such as the Arduino IoT Bundle and the SparkFun Inventor's Kit, must be adaptable to both course activities and robot development. The electronic suite is not only cost-effective but also replaceable with similar components, offering flexibility. These components collectively contribute to the robot's functionality and adaptability in IoT education. A list of electronic components and their approximate cost are shown in Table II.

TABLE II. List of the Robot Parts and Approximate Cost

Part	Quantity	Cost (EUR)
Arduino Nano 33 IoT	1	23
Infrared Proximity Sensor	2	1
Ultrasonic Distance Sensor HC-SR04	1	1
Infrared Receiver and Remote Control	1	2
Temperature and Humidity Sensor DHT11	1	2
DC Gear Motor (6V 1:110)	2	3
Plastic wheel with tire (65×26mm)	2	1
Universal Turning Wheel (24mm)	1	0.5

Wood Chassis	1	4
9V Battery	1	4
USB to Micro USB cable	1	2
Female-to-female Jumper Wires	1	2
Printed Circuit Board	1	5
Overall		55

The Arduino Nano 33 IoT[8], selected as the controller for the robot, offers a unique amalgamation of features and capabilities, rendering it particularly suitable for Internet of Things (IoT) applications. Despite its compact form factor, it is powered by the Arm® Cortex®-M0 32-bit SAMD21 processor, providing substantial computational power for diverse IoT applications. The board is equipped with the u-blox NINA-W102 Wi-Fi module and the ECC608A crypto-chip, ensuring secure and reliable wireless connectivity, a critical feature for IoT applications involving data transmission over networks. Furthermore, the Arduino Nano 33 IoT is compatible with the Arduino Cloud platform, facilitating the rapid construction of IoT projects, and thereby catering to both novice and experienced users. The board also incorporates an Inertial Measurement Unit (IMU), combining an accelerometer and a gyroscope, enabling the development of motion-tracking devices. Thus, the selection of the Arduino Nano 33 IoT is jus-

[5]https://store.arduino.cc/products/explore-iot-kit-rev2
[6]https://www.sparkfun.com/products/21301
[7]https://store.arduino.cc/products/iot-bundle
[8]https://store.arduino.cc/products/arduino-nano-33-iot

tified by its compact size, robust processing capabilities, secure wireless connectivity, cloud compatibility, and integrated IMU, collectively rendering it a versatile and cost-effective solution for IoT education.

Arduino offers a diverse range of Nano boards, each with distinct characteristics, integrated sensors, and wireless communication capabilities. A key feature of these boards is their seamless interchangeability, which allows users to execute various circuits without needing to alter pins and connections. For instance, the Arduino Nano is the most economical microcontroller within the Arduino family, although it lacks built-in sensors and network capabilities. In contrast, the Arduino Nano 33 BLE Sense[9] board is notable for its Python programming compatibility and the ability to deploy machine learning models directly on its core. This particular Nano board also includes an array of integrated sensors, eliminating the need for constructing external circuits to measure data.

In the process of constructing a circuit that integrates a microcontroller with sensors and actuators in a traditional method where a breadboard is used, novice learners lacking experience in electronics may encounter challenges. These difficulties can lead to potential damage to the hardware components, particularly when they are connected to an inappropriate voltage source or when the connections are improperly configured. To address these issues, a printed circuit board (PCB) has been designed that incorporates the microcontroller and the motor driver (Fig. 2). This design facilitates the easy connection of sensors and actuators. The utilization of this connection system ensures that all external modules can be uniquely connected to the mainboard, thereby significantly reducing the likelihood of user errors. This approach enhances the learning experience by providing a more user-friendly and error-resistant platform for circuit construction. A comparison between the traditional method and the proposed approach is depicted in Fig. 3.

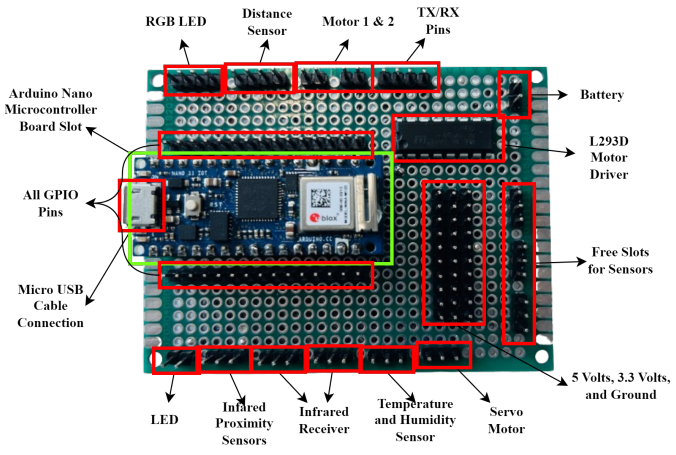

Fig. 2. Design of the proposed board.

The design of our printed circuit board (PCB) approach incorporates a slot for connecting any type of Arduino Nano board, along with other hardware components. Each slot designated for sensors and actuators includes a voltage source, ground, and a pin to the GPIO (general-purpose input/output) pins of the microcontroller board. Furthermore, the circuit provides additional communication to all pins of the microcontroller board and power sources, which can be utilized by advanced users. The PCB also features extra slots for additional sensors and actuators, should they be required for robot extension. The designed printed circuit board must be manufactured before use.

The L293D motor driver, a key component of our design, facilitates the control of both the direction and speed of the motors, which serve as the wheels of the robot. This driver is securely affixed to the board and is connected to the microcontroller, thereby providing a ready-to-use circuit solution when the motors are integrated with the robot.

In previous iterations of the robot, the L298N motor driver was utilized. However, challenges related to its power consumption were encouraged. The L298N, while effective in many applications, is known to consume a significant amount of power. This power consumption can be problematic, particularly in applications where energy efficiency is a priority or where power resources are limited.

In contrast, the L293D motor driver offers a more power-efficient solution. It operates between 4.5V and 36V and can draw up to 1.2A from both channels. This lower power requirement makes the L293D a more suitable choice for our robot, especially considering our goal of optimizing energy efficiency. Thus, the shift to the L293D motor driver not only addresses the power consumption issue but also enhances the overall performance and efficiency of the robot.

The microcontroller of the board operates at a voltage of 3.3 Volts and is capable of handling input voltages up to 21 Volts. It possesses the capability to draw power via a USB cable connected to a computer, providing flexibility in power sourcing. However, to drive the robot and facilitate remote control, the board is connected to a 9V battery. This battery configuration eliminates the need for a battery holder, thereby simplifying the overall design. In instances where the charge of the battery exceeds its capacity, the battery is replaced with a new one. Alternatively, a rechargeable battery can be employed, offering a sustainable and cost-effective power solution. This approach ensures continuous operation of the robot while also providing flexibility in power management.

A breadboard is mounted on the top side of the robot chassis, which can be used for extending the robot by building new circuits alongside the existing robot hardware components. This comprehensive design approach ensures flexibility and scalability in robot construction and operation.

C. IoTXplorBot Software

The software for the IoTXplorBot is developed by the learners themselves, thereby facilitating a hands-on learning experience. The software is written in the Arduino Integrated Development Environment (IDE), which utilizes the C programming language, a common choice for microcontrollers. For those who are less experienced in programming, Ardublockly[10] offers a block-based programming interface similar to Scratch[11], based on Google's Blockly[12]. This provides

a more accessible entry point for beginners. In addition, the Python programming language, which is widely used and popular, can also be employed if the Arduino Nano RP2040 Connect[13] or Arduino Nano 33 BLE is used as the main controller in the robot. This flexibility in programming languages caters to a broad range of user expertise and preferences, further enhancing the educational value of the IoTXplorBot.

The selection of sensors and actuators for our design is not only based on their wide availability in the market at a low cost but also the availability of programming libraries and examples. The libraries and examples of programming codes for these components are readily accessible. For instance, the Arduino website hosts a forum[14] and project hub[15] where Arduino users can conveniently find examples and solutions to their challenges.

Another resource, SparkFun Inventor's Kit Code[16], provides examples and libraries for a popular selection of sensors and actuators. These resources significantly simplify the process of programming and integrating these components into the robot, making our design approach user-friendly and cost-effective. This ensures that users, regardless of their level of experience, can successfully build and operate the robot.

The architecture of the IoTXplorBot is meticulously designed to meet all the requirements for IoT development. The programming code for the robot can be uploaded through two distinct methods: via a USB cable or wirelessly. The latter is facilitated by the built-in WiFi communication capability of the board, which enables Over-The-Air (OTA) code uploading. This feature significantly enhances the flexibility and convenience of code deployment, particularly for iterative development and testing processes. It should be noted that this wireless uploading feature is contingent upon the presence of built-in WiFi connectivity in the Arduino boards. The robot can be programmed by learners to communicate with other end devices like laptops or smartphones through wireless communication technology.

[15]https://projecthub.arduino.cc/

[16]https://learn.sparkfun.com/tutorials/sparkfun-inventors-kit-experimentguide—v41

The robot is also capable of collecting environmental data and transmitting this data to the cloud for further analysis. The Arduino IoT Cloud platform[17] provides to store IoT data on the cloud and display data on a dashboard. This feature enables a comprehensive exploration of IoT concepts and applications.

The inclusion of built-in Bluetooth Low Energy (BLE) communication in the microcontroller board facilitates its interaction with other devices enabled with Bluetooth communication. BLE, a power-efficient variant of the classic Bluetooth technology, is particularly suited for IoT applications where devices need to exchange small amounts of data intermittently. This feature significantly expands the robot's connectivity capabilities, enabling it to interface with a wide range of devices and sensors. Consequently, this opens up a plethora of possibilities for collaborative tasks, data collection, and even swarm robotics, thereby enhancing the educational potential of the robot. A detailed representation of communication with the IoTXplorBot is provided in Fig. 4. This communication encapsulates the versatility and adaptability of the IoTXplorBot, making it an effective tool for IoT education.

IV. IoTXplorBot Pilot

The primary objective of the proposed robot is to augment hands-on learning experiences within the realm of the Internet of Things (IoT). The hardware components of the IoTXplorBot have been meticulously selected to facilitate the development of a diverse array of course activities. As learners engage in these activities, they gain practical experience, progressively extending the capabilities of the robot.

The IoTXplorBot has been specifically designed to assist students and enthusiasts in navigating the multifaceted world of IoT. Equipped with an array of versatile sensors, actuators, and communication modules, the IoTXplorBot provides a plethora of opportunities for learning and experimentation. Its architecture aligns seamlessly with the three-layered architecture of IoT systems, thereby enabling learners to engage with every facet of the IoT process.

Fig. 5 provides a visual representation of how key topics and technologies of IoT align with the architecture of the

[17]https://cloud.arduino.cc/

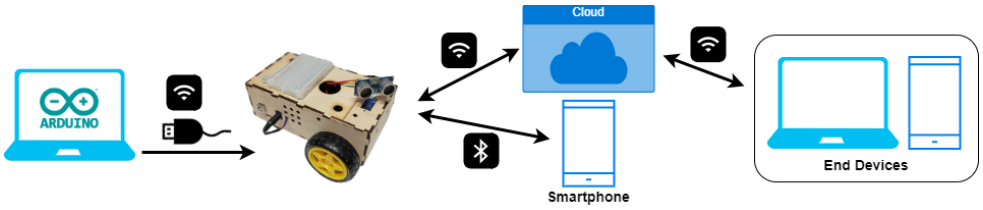

Fig. 4. Communication with the robot.

IoTXplorBot. In its operational capacity, the robot functions as an IoT device, communicating with the cloud and other applications through various communication protocols. This alignment underscores the relevance and applicability of the IoTXplorBot in the context of IoT education.

The complexity of the activities conducted using the robot progressively increases, thereby fostering the learner's growth and experience. The initial activity involves basic movements of the robot, such as moving forward/backward and turning left/right, facilitated by the robot motors and motor driver. The programming code for this activity is relatively simple, marking the learner's preliminary interaction with the robot. Subsequent activities incorporate additional sensors or actuators, thereby increasing the complexity of the tasks. For instance, the second activity could involve remote control using an infrared (IR) receiver, wherein the learner is introduced to programming using conditional statements.

As the learner progresses, they are exposed to more advanced activities, such as enabling wireless communication protocols like BLE and WiFi, and monitoring the robot through a cloud or web application. The learners are also able to leverage the capabilities offered by Arduino, such as built-in sensors, communication protocols, cloud, dashboard, and uploading programming code using Over-The-Air (OTA).

The IoTXplorBot is designed to facilitate key learning outcomes for students, encompassing areas such as engineering skills, algorithms and programming, networking and technology, and data analysis. The process of developing activities using the IoTXplorBot commences with the selection of the required sensors and actuators. Subsequently, a circuit is constructed by connecting the chosen sensors and actuators to the board. The programming code is then written on a computer and transmitted to the microcontroller board via a USB cable or OTA. The Arduino IDE provides the functionality to work with a serial monitor for reviewing the sensor data and communicating with the board. An example of an activity is illustrated in Fig. 6, which depicts a flowchart for a line-following activity. In this activity, the robot is programmed to navigate along a line using two IR proximity sensors.

During the pilot study, students from the 'Introduction to IoT' course, part of the Bachelor of Computer Sciences program, were tasked with developing different solutions using the robot. The activities included creating a line follower robot, obstacle avoidance using an ultrasonic distance sensor, controlling the robot via Bluetooth, and data collection on a server using WiFi. Despite the challenging nature of the activities, the students demonstrated commendable results in the course project. Some students even opted to use the extension of the IoTXplorBot for their projects, while others chose their own project topics and tools. The solutions for their projects included remote monitoring using cloud technology and driving the robot via Bluetooth communication controlled by an Android application.

V. Discussion

This work aims to achieve two primary objectives. The first is to develop an educational robot, the IoTXplorBot, that facilitates the learning of Internet of Things (IoT) concepts through the exploration of various hardware components. The second objective is to make this educational tool available at a low cost. Traditional methods of learning IoT typically involve the use of educational kits, which consist of a microcontroller, sensors, and actuators. These kits offer different approaches to exploring IoT concepts. The IoTXplorBot, however, provides a progressive learning experience, starting with simpler tasks and gradually leading to the development of a complex system by the end of the course activities. While there are many educational robots available on the market, they often come with high costs and a limited number of sensors and actuators. Compared to different educational kits and robots in terms of their hardware components, and costs for use in higher education, the IoTXplorBot proposes cost-effective solution and adaptability with different hardware components for the robot extension and variety of course activities.

The IoTXplorBot shares many features with the FOSSBot [18] and Hydra [17], but the proposed robot uses the Arduino Nano board, making it interchangeable with other microcontrollers from this family for different purposes. Another advantage of this robot is that its chassis is designed from wood, making it sustainable and low-cost. In addition, it can be replaced with a 3D-printed chassis or even a smartphone box from cardboard. This flexibility makes the IoTXplorBot a versatile tool for IoT education.

All hardware components such as sensors and actuators chosen and activities to be designed facilitate the learning of IoT concepts. The microcontroller selected for the robot enables the creation of circuits and the running of programs for IoT as well as for other purposes such as robot training and edge computing. In contrast, other educational robots, which are primarily based on STEM (Science, Technology, Engineering, and Mathematics) education, do not allow for the creation of circuits, an essential aspect of IoT systems and devices.

This study is primarily constrained by the hardware components and the advanced programming aspects associated with the Arduino Integrated Development Environment (IDE). To broaden the applicability of the robot in other related

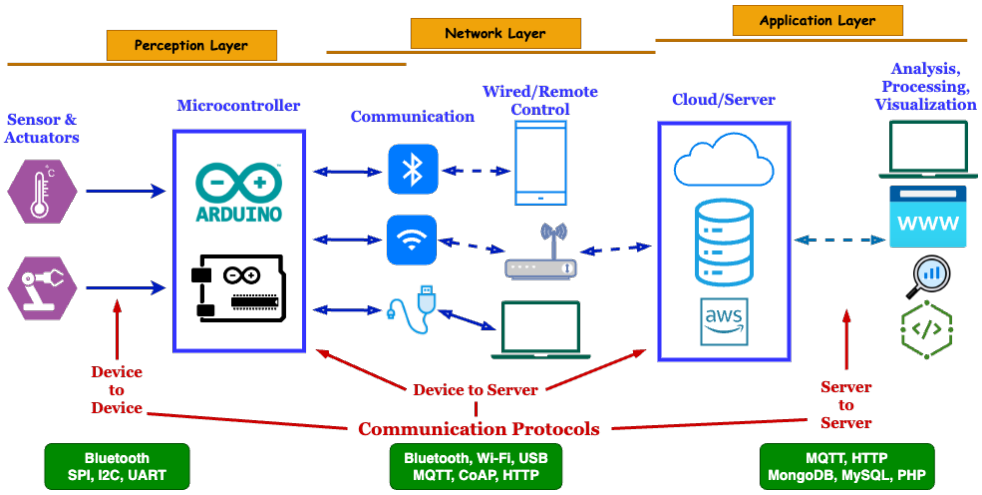

Fig. 5. Architecture of the proposed work.

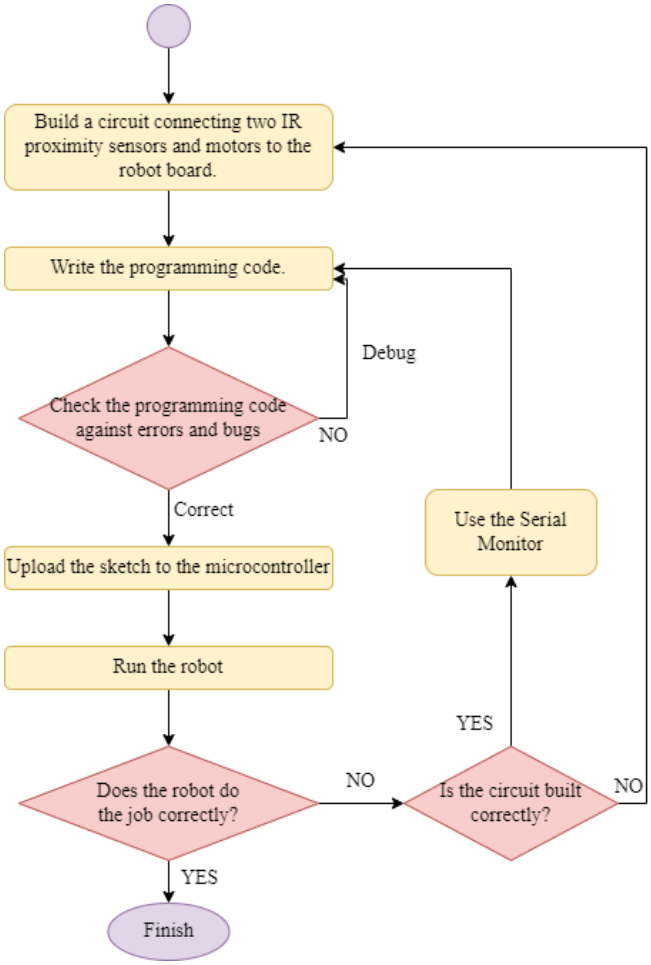

Fig. 6. Flowchart of programming the line following robot.

course activities, it is imperative to develop an application that caters to individuals who may not be well-versed with Arduino Programming. Furthermore, for more advanced courses such as machine learning and edge computing, the selection of an alternative microcontroller that supports the requisite programming becomes a necessity. These limitations highlight areas for future development and underscore the need for a more versatile and inclusive approach to the design and implementation of educational robots.

VI. Conclusion

While hardware kits composed of microcontroller boards, sensors, and actuators, along with desktop simulation applications, are commonly used in Internet of Things (IoT) education, educational robots offer a structured approach to course activities. However, various educational robots are designed to perform different tasks. The IoTXplorBot, an open-source and open-design educational robot, was developed to explore IoT concepts at a low cost. Various common sensors and actuators were utilized, enabling learners to easily find library solutions to bugs during the programming process. The microcontroller of the robot can be interchanged with other development boards from the widely used Arduino Nano family, allowing learners to choose according to their needs. During the development process, the robot was tested in the "Introduction to IoT" course as a pilot study, where students were able to use this robot for classroom activities. Most students preferred to use this robot for their course projects as a continuation of their previous tasks, despite the freedom to choose the project hardware and topic.

As part of our future work, the designed printed circuit board is planned to be fabricated for the robot to simplify tasks for students who have no experience in electronics. Additionally, the robot is planned to extend with rechargeable batteries for extended use without the need for frequent battery changes.

Improving Potato Diseases Classification Based on Custom ConvNeXtSmall and Combine with the Explanation Model

Huong Hoang Luong
Information Technology Department
FPT University, Can Tho, Viet Nam

***Abstract*—Potatoes are short-term crops grown for harvesting tubers. It is a type of tuber that grows on roots and is the fourth most common crop after rice, wheat, and corn. Fresh potatoes can also be used in an incredible variety of dishes by baking, boiling, or frying them. Moreover, the paper, textile, wood, and pharmaceutical industries also make extensive use of potato starch. However, soil and climate pollution are highly unfavorable for potato growth and lead to a lot of diseases such as common scab, black scurf, blackleg, dry rot, and pink rot. Thus. several types of research in medicine and computers were started for the early detection, classification, and treatment of potato diseases. In this study, transfer learning and fine-tuning were applied to potato disease classification based on a custom ConvNeXtSmall model. In addition, Gradient-weighted Class Activation Mapping (i.e., Grad-CAM) is provided for visual explanation in the final result after classification. For potato illness segmentation, k-means clustering was used to enable the difference between healthy and diseased sections based on color and texture. The data was collected from numerous websites and validated by the Bangladesh Agricultural Research Institute (i.e., BARI), including six types of potato diseases and healthy images. With a Convolutional Neural Networks (i.e., CNN) model from the Keras library, our study reached the unexpected validation accuracy, test accuracy, and F1 score in seven classifications of 99.49%, 98.97%, and 98.97%, respectively. Concerning four-class classification, high accuracy values were obtained for most of the models (i.e., 100%).**

***Keywords*—Potato disease; classification; fine-tuning; transfer learning; Convolutional Neural Network (CNN); k-means clustering; Gradient-weighted Class Activation Mapping (Grad-CAM)**

I. Introduction

Potatoes have been a crucial food source for humans for thousands of years. Originating in South America, they have spread worldwide due to their ability to grow in various climates and soil types. Potatoes are not only adaptable with hundreds of cooking ways but also packed with essential nutrients like carbohydrates, fiber, and vitamins. They are used in numerous dishes, from mashed potatoes to fries, and are also crucial in industries like starch production and biodegradable plastics. In the world, potatoes play a significant role, supporting about income of millions of farmers, and are one of the main food sources for billions of people.

In modern agriculture, potato production has become a cornerstone of global food systems. Based on statistical data, China holds the first spot in terms of potato production [1] [2]. In 2019, 370,436,581 tons of potatoes were produced globally and global potato production rose by 2.59% compared with 2012 [2]. 61.5% of the total EU production of potatoes is produced annually in Germany, France, the Netherlands, the United Kingdom, and Belgium, with an average of 34,870 million tons throughout the 2017–2019 period [3]. Specifically, Germany is currently the largest potato producer in the EU, with an average yearly potato production of slightly more than 10.4 million tonnes. France (i.e., 8.3 million tonnes) comes next, followed by the Netherlands (i.e., 6.8 million tonnes), the United Kingdom (i.e., 5.5 million tonnes), and Belgium (i.e., 3.8 million tonnes) between 2017 and 2019 [3]. However, potatoes face challenges, particularly from climate change, pollution, and diseases. Climate change affects potato growth with higher temperatures and irregular rainfall patterns [4]. Pollution from farming practices harms soil and water quality, impacting potato cultivation [5]. Additionally, diseases caused by viruses and bacteria threaten potato crops, reducing yields and farmer incomes [6].

Consequently, advancements in technology and machinery have revolutionized potato cultivation in agriculture, optimizing efficiency and yield while minimizing labor and environmental impact. Precision planting equipment ensures accurate spacing and depth, enhancing seedling establishment and uniformity across fields [7]. Additionally, state-of-the-art harvesting machinery, such as mechanical diggers and conveyor systems, streamline the process, minimizing damage to tubers and reducing post-harvest losses. Modern sorting and grading machines utilize advanced sensors and algorithms to identify and segregate potatoes based on size, shape, and quality criteria, improving marketability and reducing manual labor. Besides, Genetic modification of crops has also shown good effects in increasing productivity, nutritional quality, and disease resistance [8] These advancements not only increase productivity and profitability but also contribute to sustainable agriculture by minimizing inputs and environmental footprint in potato production.

Besides mechanical and genetic technologies, several studies on computer technology were developed for potatoes. Thus, artificial intelligence (AI) is creating and making significant strides in the potato farming sector, particularly in planting and harvesting processes. AI uses smart algorithms and sensors to improve various stages of potato cultivation. When it comes to planting, AI helps in determining the best spacing and depth for potato seeds, ensuring efficient resource utilization and better yields. AI-powered machinery, equipped with sensors, reduces wastage and increases productivity. During harvesting, AI aids in identifying ripe potatoes using computer vision,

distinguishing them from soil and foliage, thus optimizing the harvesting process and minimizing crop damage. Moreover, AI analyzes environmental factors like soil moisture, temperature, and weather conditions in real-time, providing valuable insights to farmers for informed decision-making and better outcomes. Consequently, AI not only enhances efficiency and productivity in potato farming but also promotes sustainable agricultural practices by minimizing resource usage and environmental impact.

Deep learning is a subset of artificial intelligence and it has revolutionized various fields, including agriculture and industry. Besides, computer vision appeared as a new way for classification and segmentation of a lot of aspects of images [9] [10] [11] [12] [13], through techniques like transfer learning and fine-tuning. For example, image technologies have come out as invaluable tools in potato farming, offering correct solutions for classification, segmentation, and detection tasks. Classification algorithms are used to assess potato images, categorizing them based on diverse attributes including size, shape, and quality, thereby facilitating farmers in optimizing sorting procedures and ensuring consistency across their yield [14]. Segmentation techniques are employed to segment potato disease regions or potato growing areas to detect weeds [15], facilitating precise attribute measurements such as size and color distribution, which in turn assists in grading and quality evaluation. Detection algorithms play a pivotal role in identifying diseases, pests, and other anomalies in potato crops [16], enabling prompt intervention and mitigation measures to curtail yield losses.

In this study, various algorithms have used the progressions in machine learning and computer vision, and large datasets of potato plant images afflicted with various diseases for classification and segmentation images, deep learning models can accurately classify these images. Transfer learning has been used in this process, it is a technique where a pre-trained model developed for one task is adapted for another [17] [18] [19], allowing researchers to leverage the knowledge gained from training models on massive datasets to enhance the performance of models in potato disease classification and segmentation. Furthermore, fine-tuning, a process of adjusting the parameters of a pre-trained model to better fit the specific characteristics of a new dataset, has been crucial in refining the accuracy and efficiency of disease segmentation and detection algorithms [20] [21] [22]. By fine-tuning pre-existing deep learning architectures such as convolutional neural networks (CNNs), researchers can customize these models to effectively identify and delineate regions of potato plants affected by diseases, enabling early intervention and targeted treatment.

Overall, the integration of deep learning techniques, including transfer learning and fine-tuning, has significantly advanced the field of potato disease management by providing accurate, efficient, and contributing to improved crop yield and food security. This study advances agricultural technology by using ConvNeXtSmall in the Keras library to categorize potato disease photos with very high accuracy. Additionally, utilizing k-mean clustering for the segmentation of anomalous positions offers a thorough solution that supports agricultural efforts in the early diagnosis and treatment of potato illnesses by assisting in the accurate identification of abnormal zones.

The contributions of this paper are as follows:

- A customized CNN model based on ConvNeXtSmall is presented by the research for the purpose of classifying and segmenting potato diseases into seven groups: pink rot, dry rot, blackleg, black scurf, common scab, miscellaneous, and healthy. Thus, it might offer a quick and easy way for the farmer to boost profitability and productivity depending on the amount of potatoes they produce.
- In the scenario of seven classes classification, our model achieved excellent validation accuracy, test accuracy, and F1 score (i.e., 99.49%, 98.97%, and 98.97%). As a result, a table and confusion matrix were also made to illustrate how successful the model was in terms of training and testing duration.
- The article proposes K-means clustering in image segmentation for identifying potato diseases. By grouping pixels with similar characteristics, it enables the differentiation of healthy areas from diseased ones based on color and texture. This method aids in precise disease mapping, facilitating targeted treatment strategies for agricultural management.
- Gradient-weighted Class Activation Mapping (Grad-CAM) was applied and assisted in the visual explanation of potato diseases by pinpointing regions in images where the model concentrates its attention. This technique aids in the precise identification and comprehension of various potato diseases, enhancing diagnostic accuracy and agricultural management strategies.
- This research gathered photos of both sick and healthy potatoes, as confirmed by experts at the Bangladesh Agricultural Research Institute. This dataset can be used to teach agriculture students and is validated for the creation of automated machine learning and deep learning algorithms for the classification, segmentation, and detection of potato illnesses.

The organization of our research paper is structured into six principal sections. Firstly, Section I serves as a comprehensive overview providing a general introduction to the article. Following this, Section II extensively explores related research, offering a thorough examination of the existing literature upon which our work is based. Subsequently, Section III delineates the methodology utilized, furnishing detailed insights into the methods employed throughout the article. Section IV then elaborates on the experiments conducted, encompassing the procedures for their execution and the evaluation of each scenario. Furthermore, Section V presents the results of the best experiment and conducts a comparative analysis with existing scenarios. Finally, the article encapsulates the key findings and analyzes the fundamental domains associated with our research in Section VI.

II. Related Works

Exploring potato diseases led to groundbreaking research in transfer learning and fine-tuning and various research was published to promote disease segmentation and classification in potatoes. For example, A deep convolutional neural network was trained to distinguish between four types of potatoes

(i.e., Red, Red Washed, Sweet, and White) using a public dataset of 2400 photos by Abeer A. Elsharif et al. The trained model attained an accuracy of 99.5% of the test accuracy [23]. Besides, Sofia Marino et al. have presented an effective unsupervised adversarial domain adaptation method to classify six potato classes in two different scenarios and reach an average F1-score of 84% [24]. Furthermore, Qinghua Su et al. used a convolutional neural network model and achieved a high success rate in size classification at 94.5% and appearance classification at 91.6% [25].

One of the most important tasks in post-harvest quality control during potato manufacturing is identifying bad surfaces for potatoes. Therefore, Chenglong Wang et al. used transfer learning to refine a basic model using three DCNN modes. As a result, RFCN ResNet101 had the best overall performance, achieving accuracy levels of 92.5%, 95.6%, and 98.7%, respectively [26]. Moreover, Kaili Zhang et al. improved U-Net and showed that the accuracy of the potato surface evaluation method proposed in the study was greater than 97.55% [27], In addition, Black scurf, common scab, black leg, pink rot, and healthy are the five categories of potato diseases that Khalid Hamza et al. detect and classify. In multiple classes, the accuracy can reach 98% and 100% [28].

To classify potato problems early, machine learning technology has been widely used as an affordable and nondestructive diagnostic tool. For instance, Ali Arshaghi et al. use image processing and convolution neural networks to identify and classify surface potatoes from a collection of 5,000 photos of potatoes that have been split into five types. As a result, the results show that the accuracy of the deep learning proposed was 98% and 100% accuracy in some of the classes [29].To classify potatoes, Hyeon-Seung Lee et al. used Mask R-CNN, one of the object identification technologies utilizing deep learning, and were surprised with the result of 93.0% [30]. Furthermore, Israa Mohammed Hassoon et al. proposed a PDCNN framework that is very effective in classifying four types of potato tuber diseases including black dot, common scab, potato virus y, and ring rot with 91.3% accuracy [31].

To expand the author's limited knowledge about transfer learning and fine-tuning in CNN. Hence, several research about potato leaf disease classification have been investigated. With the help of deep learning and the VGG16 and VGG19 convolutional neural network architectural model, Rizqi Amaliatus Sholihati et al. developed a system that can classify the four different types of diseases in potato plants based on leaf conditions. As a result. the model achieved an average accuracy of 91% [32]. Moreover, Aditi Singh et al. presented a model that can reach a 95.99% accuracy rate when using the K-means approach for feature segmentation and the multi-class support vector machine methodology for classification [33]. To identify potato leaf disease, Rabbia Mahum et al. employed an additional transition layer in DenseNet-201 along with a pre-trained Efficient DenseNet model. As a result, the performance was evaluated and gave an accuracy of 97.2% [34].

The quantity and quality of potatoes are greatly impacted by many diseases. Because manually explaining these leaf diseases is labor-intensive and time-consuming. As a result, Divyansh Tiwari et al utilized a pre-trained model VGG19 for fine-tuning the dataset and reached 97.8% in classification accuracy over the test dataset[35]. Moreover, Asif Iqbal et al. proposed an image processing and machine learning-based automatic system that will identify and classify over 450 images of healthy and diseased potato leaves with an accuracy of 97% [36]. Kulendu Kashyap Chakraborty et al proposed a methodology using four deep learning models such as VGG16, VGG19, MobileNet, and ResNet50. Hence, it achieved 97.89% accuracy for classification between late and early blight syndromes as compared to healthy potato leaf [37].

Besides using computer vision to recognize and classify potatoes, other fruits and vegetables also apply this method for having the advantages of speed, and high accuracy in dividing a final product. For instance, Alper Taner et al. used popular seven CNN architectures (i.e., VGG16, VGG19, InceptionV3, MobileNet, Xception, ResNet150V2, and DenseNet201) and it was found that DenseNet201 had the highest classification accuracy of 97.48% in classifying apple varieties [38]. Moreover, Dhiya Mahdi Asriny et al. proposed the classification model to classify orange images using CNN and shows an accuracy of 96% [39]. In conclusion, Table I shows that related studies have been compiled for easier evaluation and synthesis.

III. METHODOLOGY

A. The Research Implementation Procedure

This study proposed a method including 12 steps from input to output shown in Fig. 1. The roles of the steps are shown as follows:

1) Collecting dataset: the dataset selected from various sources and rigorously verified by the Bangladesh Agricultural Research Institute (BARI), boasts 451 images capturing diverse potato illnesses such as Common scab, Blackleg, Dry rot, Pink rot, Black scurf, Miscellaneous, and Healthy Potatoes. It is a valuable resource for academic research, offering comprehensive insights into potato disease management and cultivation practices.

2) Pre-processing image and data augmentation: image pre-processing techniques such as resizing and normalization are crucial for standardizing input data, and ensuring consistency in potato disease classification models. Furthermore, using data augmentation methods such as rotation, flipping, and contrast enhancement enhances the variety of the dataset, and assists model training. These algorithms provide a foundation for developing accuracy and prediction to classify and segment potato diseases, thus safeguarding agricultural productivity and income.

3) Dividing the dataset into three categories train, validation, and test: after increasing data augmentation by 451 default participants, which were chosen at random for the training, validation, and testing phases, the pictures dataset contains 5833 subjects. The datasets are randomly selected using an 8-1-1 scale and are then placed into 8 training, 1 validation, and 1 testing folder. This guarantees a balanced distribution, which is essential for trustworthy model development and evaluation.

4) Dividing dataset for scenarios: the dataset was divided into four scenarios. In the first scenario, four classes healthy, black scurf, common scab, and pink rot were selected because they can be classified by surface observation. Next to that, four classes healthy, blackleg, dry rot, and miscellaneous because it is an internal harm. Finally, the next two scenarios employed all classes for the experiment.

5) Building the model: our work employed transfer learning to a pre-trained model based on the CNN architecture prototype to conduct tests. External layers were employed during fine-tuning to adapt the pre-trained model to the specific data of the intended task. For our training test, the ConvNeXtSmall model thus yields an excellent result.

6) Applying transfer learning: using pre-trained deep learning models, this approach aims to transfer knowledge from related domains to enhance the classification accuracy of potato disease. By adapting neural networks to recognize patterns indicative of various potato diseases.

7) Validating and collecting accuracy score: after the model had completed training, its efficiency was assessed using its training accuracy as well as its other scores. Next, The validity of the test was then determined using the initially divided testing set.

8) Applying fine-tuning: fine-tuning involves adjusting the parameters, and additional layers of a pre-trained neural network particularly in the latter layers, typically focusing on refining performance. This process allows the model to borrow knowledge acquired from a broader scope while customizing it to the particular requirements.

9) Validating, collecting, and explaining results with Grad-CAM: Grad-Cam was used for the analysis of heat maps generated by the model to highlight regions of interest. By correlating these areas with known symptoms, researchers can validate the model's accuracy, collect valuable data for further analysis, and elucidate its decision-making process.

10) Image segmentation by k-means clustering: this step includes partitioning the image into distinct clusters based on pixel intensities. By iterative assigning pixels to clusters with similar characteristics, this method effectively separates different disease regions within the potato image, facilitating targeted analysis and diagnosis of specific ailments.

11) Reconstructing and comparing the cycles with other models: after one phase, the procedure was reworked and compared with another model including, EffecientNetB3, ResNet50, MobileNet, Inception V3, Xception, ConvNeXtSmall, ConvNeXtTiny, ConvNeXtLarge to create the final result

12) Showing the result: the data will be presented as tables and graphs after procedures to enable pertinent comparisons.

B. Pre-processing Image and Data Augmentation

Pre-processing plays an important role in boosting the quality of images before subjecting them to potato disease classification algorithms. Resizing (1) and normalization (2) are two fundamental techniques used in this process. Resizing (1) connection to change the dimensions of images to a uniform size, which aids in reducing computational complexity and ensuring consistency across the dataset. Mathematically, resizing can be represented as follows:

$$Resize\,image = resize(original\,image, target\,size) \quad (1)$$

Algorithm 1 Resizing Algorithm

Require: Original Image, target_size
Ensure: Resized Image
1: Load the Original Image:
2: Define the target_size = (224,224)
3: Resize the Original Image to the target_size using the resize function:
4: $ResizedImage = \text{resize}(OriginalImage, (224, 224))$
5: **return** Resized Image

Here, original image (1) represents the raw input image, and target size (1) indicates the desired dimensions of the output image. Besides, Algorithm 1 is a pseudo-code that presents flow on how it works in coding. Furthermore, Normalization (2) fixes standard pixel values within a certain range. It can be expressed as:

$$Normalized\,image = \frac{original\,image - mean}{std} \quad (2)$$

Algorithm 2 Normalization Algorithm

Require: Original Image
Ensure: Normalized Image
1: Compute the mean and standard deviation of pixel intensities:
2: $mean = \frac{1}{n}\sum_{i=1}^{n} pixel_i$
3: $std = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(pixel_i - mean)^2}$
4: Normalize the Original Image by subtracting the mean and dividing by the standard deviation:
5: $NormalizedImage = \frac{OriginalImage - mean}{std}$
6: **return** Normalized Image

Specifically, mean (2) and std (2) represent the mean and standard deviation of pixel intensities across the entire dataset, respectively. This normalization process ensures that pixel values are centered around 0 with a standard deviation of 1, to facilitate convergence during training and mitigate the influence of illumination variations, thereby increasing the stability of the training process. In addition, To clarify the process a pseudo-code has been provided at Algorithm 2.

Data augmentation techniques are tools for improving the diversity of training samples, thereby improving the generalization ability of the classifier. Rotation (3), flipping (4) (5), and contrast enhancement (6) are commonly employed augmentation strategies in the context of potato surface disease classification. Rotation (3) involves rotating the image by a certain angle to simulate variations in orientation. Mathematically, rotation can be represented as:

$$Rotated\,image = rotate(original\,image, \theta) \quad (3)$$

Algorithm 3 Rotation Algorithm

Require: Original Image, angle
Ensure: Rotated Image
1: Load the Original Image
2: Specify the angle of rotation (θ)
3: Rotate the Original Image by the specified angle using the formula:
4: Rotated image = rotate(original image, θ)
5: **return** Rotated Image

In the equation, θ (3) strand for the angle of rotation and Algorithm 3 presents the detail of code flow which is provided in pseudo-code for overview. Moreover, flipping (4) (5) entails flipping the image horizontally or vertically to introduce variations in perspective. It can be mathematically expressed as:

$$P(x, y) = (width - x - 1, y) \quad (4)$$

$$P(x, y) = (x, height - y - 1) \quad (5)$$

Algorithm 4 Flipping Algorithm

Require: Original Image, axis
Ensure: Flipped Image
1: Load the Original Image
2: Specify the axis along which flipping should occur: horizontal (H) or vertical (V)
3: **if** axis is H **then**
4: Flip the Original Image horizontally using the formula: $P(x, y) = (width - x - 1, y)$
5: **else if** axis is V **then**
6: Flip the Original Image vertically using the formula: $P(x, y) = (x, height - y - 1)$
7: **end if**
8: **return** Flipped Image

In the context of image flipping, (x, y) 4 5 represents the pixel coordinates of the Original Image. In Algorithm 4 flipping horizontally (H), the pixel x-coordinate is reversed concerning the image width, and when flipping vertically (V), the pixel y-coordinate is reversed concerning the image height.

$$P_{\text{enhanced}}(x, y) = CDF(P_{\text{original}}(x, y)) \times (L - 1) \quad (6)$$

Algorithm 5 Contrast Enhancement Algorithm

Require: Original Image
Ensure: Enhanced Image
1: Load the Original Image
2: Compute the cumulative distribution function (CDF) of pixel intensities
3: Apply histogram equalization to map pixel intensities to a new range using the formula:
4: $P_{\text{enhanced}}(x, y) = \text{CDF}(P_{\text{original}}(x, y)) \times (L - 1)$
5: where $P_{\text{enhanced}}(x, y)$ is the pixel intensity in the Enhanced Image,
6: $P_{\text{original}}(x, y)$ is the pixel intensity in the Original Image,
7: and L is the number of intensity levels
8: **return** Enhanced Image

The contrast enhancement algorithm aims to improve the contrast of an image through histogram equalization. It begins by loading the original image and computing its histogram, which represents the frequency distribution of pixel intensities. Subsequently, Algorithm 5 calculates the cumulative distribution function (CDF) from the histogram. This CDF provides a mapping between original pixel intensities and their corresponding enhanced values. The enhancement is achieved by applying the formula (6). where L (6) illustrates the number of intensity levels. Each pixel in the original image is mapped to a new intensity level based on its CDF value, resulting in an image with improved contrast. Finally, These data augmentation techniques collectively contribute to the robustness of the classification model by exposing it to a diverse range of image variations.

C. Transfer Learning and Fine-tuning of ConvNeXtSmall

Transfer learning is a technique in machine learning where knowledge gained from solving one problem is applied to a different but related problem [17] [18] [19]. In the context of image classification, it involves leveraging pre-trained models, which have been trained on large datasets, and adapting them to new classification tasks with relatively smaller datasets. This approach is particularly useful when the target dataset is not large enough to train a model from scratch effectively.

In the classification of potato surface disease, transfer learning can be employed by utilizing a pre-trained Convolutional Neural Network (ConvNet), such as ConvNeXtSmall, which has been trained on a large dataset. The initial layers of ConvNeXtSmall have learned to extract low-level features like edges and textures, which are generally applicable to various image recognition tasks. By reusing these learned features and adjusting the later layers to suit the specifics of potato surface disease classification, this algorithm can expedite the training process and improve performance.

Fine-tuning is a key aspect of transfer learning, where the parameters of the pre-trained model are further adjusted to better fit the new dataset [20] [21] [22]. In the case of ConvNeXtSmall, fine-tuning includes unfreezing some of the later layers and retraining them using the new dataset. This allows the model to learn higher-level representations more adapted to the characteristics of potato surface disease, refining its ability to distinguish between disease states or healthy potato surfaces.

Moreover, adding extra layers to ConvNeXtSmall in Fig. 2 can enhance its accuracy and overall performance. These additional layers can capture more complex patterns and relationships within the data, providing the model with a deeper understanding of the distinguishing features of different disease conditions. However, care must be taken to prevent overfitting, where the model becomes too specialized to the training dataset and performs poorly on unseen data. Regularization techniques such as dropout and weight decay can be employed to mitigate overfitting and ensure the generalization ability of the model.

In summary, transfer learning and fine-tuning of ConvNeXtSmall offer effective strategies for the classification of potato surface disease by borrowing pre-existing knowledge and adapting it to the specific characteristics of the target dataset. By incorporating additional layers and carefully fine-tuning the model, this research improves its accuracy and prediction in classifying different disease states, ultimately aiding in the early detection and management of potato crop diseases.

D. Visual Explanation with Gradcam

Visual explanations through techniques like Grad-CAM (Gradient-weighted Class Activation Mapping) offer valuable insights into the classification process, aiding researchers and farmers in making informed decisions. Potato surface diseases encompass a range of fungal, bacterial, and viral infections that affect the external appearance of the potato tubers. Timely detection and classification of these diseases are essential for maintaining crop health and yield.

Grad-CAM is a technique used in computer vision to understand the decision-making process of deep learning models. It highlights regions of an image that contribute most significantly to the model's classification decision. In the context of potato surface disease classification, Grad-CAM helps elucidate which features or regions of the potato surface are indicative of particular diseases. in the case of the black scurf and black leg of Fig. 3, Grad-CAM may highlight regions of the potato surface where characteristic lesions or discolorations are present.

The Grad-CAM method functions by generating a heat map that delineates the significance of various regions within the input image for prediction. This heat map is derived by computing the gradient of the target class score concerning the final convolutional layer feature maps. Mathematically:

$$H^c_{(i,j)} = \text{ReLU}\left(\sum_k \alpha^c_k \cdot A^k_{(i,j)}\right) \tag{7}$$

Specifically, $H^c_{(i,j)}$ (7) represents the heat map value at position (i, j) for class c. α^c_k (7) denotes the importance of the kth feature map for class c, and $A^k_{(i,j)}$ (7) is the activation of the kth feature map at position (i, j). Equation (7) essentially encapsulates the importance of each feature map activation, weighted by its corresponding importance score. The ReLU function is employed to ensure that only positive contributions are considered.

In conclusion, visual explanation techniques like Grad-CAM furnish a valuable means of interpreting deep learning models in the classification of potato surface diseases. By accentuating crucial regions within input images, Grad-CAM facilitates the understanding of model predictions and offers insights for refining disease management strategies.

E. Image Segmentation by k-means Clustering

Image segmentation is a main task in classifying potato surface diseases, assisting in identifying and analyzing abnormal areas on the potato surface. Among various segmentation techniques, k-means clustering is an efficient method for partitioning images into distinct clusters based on pixel intensity values. In this context, k-means clustering (8) facilitates the categorization of pixels into groups, differentiating healthy potato regions from those affected by diseases.

Mathematically, the k-means algorithm aims to minimize the within-cluster sum of squares, defined as:

$$W(C_k) = \sum_{i=1}^{n} \sum_{x_j \in C_k} ||x_j - \mu_k||^2 \tag{8}$$

In every detail, C_k (8) represents the cluster k, x_j (8) show the jth (8) data point (pixel), and μ_k (8) is the centroid of cluster k. The goal is to assign each pixel to the cluster whose centroid is nearest to it in terms of Euclidean distance.

Specifically, Algorithm 6 outlines the k-means clustering approach for segmenting images. it begins with an initialization phase, during which k initial centroids are randomly selected.

Following this, the assignment step assigns each pixel to the nearest centroid, effectively partitioning the image into k clusters. Subsequently, in the update phase, the centroids are recalculated based on the mean of all pixels assigned to each cluster. This iterative process continues until convergence is achieved, typically indicated by a condition such as centroids no longer undergoing significant changes between iterations. This methodical approach enables the algorithm to effectively segment images by distinguishing regions based on pixel similarities, making it particularly valuable for applications such as disease detection on potato surfaces.

Algorithm 6 K-Means Clustering

Require: Image I, Number of clusters k = 3 (Background, healthy surface and disease surface)
Ensure: Segmented image I_{seg}, Centroids $\{\mu_1, \mu_2, ..., \mu_k\}$
Initialization:
Randomly select k initial centroids: $\mu_1, \mu_2, ..., \mu_k$
$I_{\text{prev}} \leftarrow$ Copy of I
repeat
    Assignment Step:
    for each pixel p in I **do**
        Assign p to the nearest centroid μ_i
    end for
    Update Step:
    for each cluster i **do**
        Recalculate centroid μ_i as the mean of all pixels in cluster i
    end for
    $I_{\text{seg}} \leftarrow$ Image formed by assigning pixels to their respective clusters
    $I_{\text{prev}} \leftarrow$ Copy of I_{seg}
until Convergence criteria are met (e.g., centroids do not change significantly)
return Segmented image I_{seg}, Centroids $\{\mu_1, \mu_2, ..., \mu_k\}$

By applying k-means clustering to potato surface images, Fig. 4 effectively segments the image into regions of similar pixel intensities, thereby distinguishing between healthy and diseased areas. The centroids obtained represent characteristic color values associated with each cluster, aiding in the identification of disease patterns based on pixel color.

Furthermore, the simplicity and efficiency of k-means clustering make it a suitable choice for real-time or large-scale image processing tasks, contributing to the rapid and accurate classification of potato surface diseases. Overall, leveraging k-means clustering in image segmentation enhances the precision and scalability of disease detection systems, facilitating timely interventions to mitigate agricultural losses.

IV. Experiments

A. Dataset and Performance Metrics

The research used a single dataset for both the training, validation, and testing phases in this analysis. The data was selected from various sources and rigorously verified by the Bangladesh Agricultural Research Institute (BARI). 451 images constitute the comprehensive dataset in Fig. 5 including 62 Common scabs, 60 Blackleg, 60 Dry rot, 57 Pink rot, 58 Black scurf, 74 Miscellaneous, and 80 Healthy Potato images.

In the classification of potato surface disease, various performance metrics are utilized to evaluate the effectiveness of the classification model. These metrics help in understanding the ability to correctly classify instances of potato surface disease and its performance in terms of both precision and recall.

One of the fundamental metrics used is the Accuracy (i.e., ACC), which measures the proportion of correctly classified instances out of the total instances. Mathematically, it can be expressed as:

$$ACC = \frac{TP + TN}{TP + TN + FP + FN} \tag{9}$$

Where TP (9) indicates true positives (correctly classified instances of potato surface disease), TN (9) represents true negatives (correctly classified instances of absence of potato surface disease), FP (9) stands for false positives (instances incorrectly classified as having potato surface disease), and FN (9) represents false negatives (instances incorrectly classified as not having potato surface disease).

Another important metric is the Recall in equation (10), also known as sensitivity or true positive rate. It measures the proportion of actual positive instances that are correctly identified by the model. Moreover, This metric is crucial in scenarios where the consequences of false negatives (misclassifying actual instances of potato surface disease as negative) are severe. Mathematically, it can be defined as:

$$Recall = \frac{TP}{TP + FN} \tag{10}$$

The Precision metric in equation (11) evaluates the proportion of true positive instances among all instances classified as positive by the model. It can be calculated as:

$$Precision = \frac{TP}{TP + FP} \tag{11}$$

The F1 Score in equation (12) is a metric that combines precision and recall into a single value. It is the harmonic mean of precision and recall, and it provides a balance between the two metrics. Mathematically, it is represented as:

$$F1 = 2 \times \frac{Precision \times Recall}{Precision + Recall} \tag{12}$$

B. Scenario 1: the Result of Classifying Potato Diseases into four Classes: Healthy, Black Scurf, Common Scab, Pink Rot

Table II presents a comparative analysis of various deep learning models in classifying potato disease images into four classes: healthy, black scurf, common scab, and pink rot, using both transfer learning and fine-tuning techniques. Among the models evaluated, EfficientNet B3 emerges as the top performer, exhibiting remarkable accuracy in both transfer learning (i.e., 99.70% validation accuracy, 99.40% test accuracy) and fine-tuning (i.e., 100.00% for both validation and test accuracy). In contrast, Xception shows comparatively lower accuracy levels across both transfer learning and fine-tuning

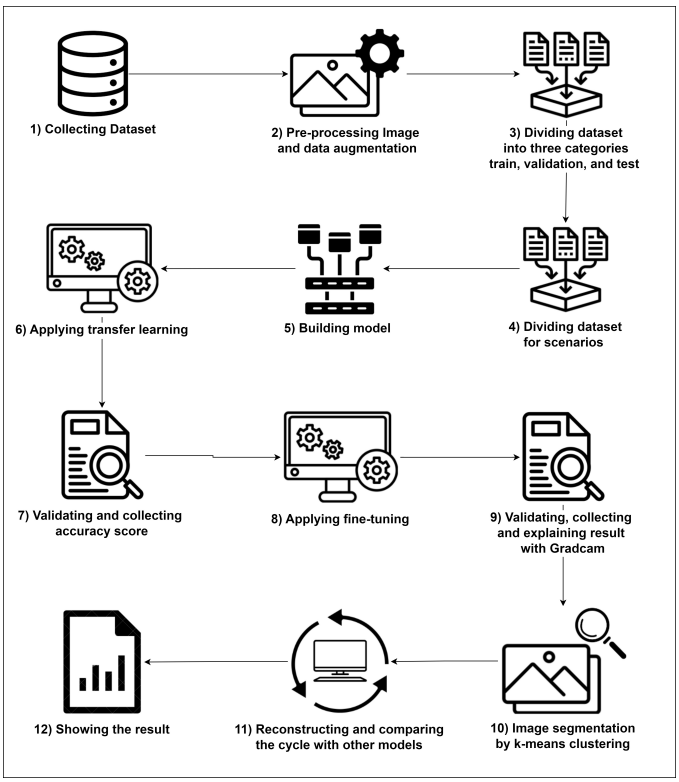

Fig. 1. The implementing procedure flowchart.

TABLE II. THE ACCURACY OF CLASSIFYING POTATO DISEASE IMAGES INTO FOUR CLASSES: HEALTHY, BLACK SCURF, COMMON SCAB, PINK ROT IN TRANSFER LEARNING AND FINE-TUNING, FOR EACH DEEP LEARNING MODEL

Model	Phase	Valid acc	Test acc	Precision	Recall	F1

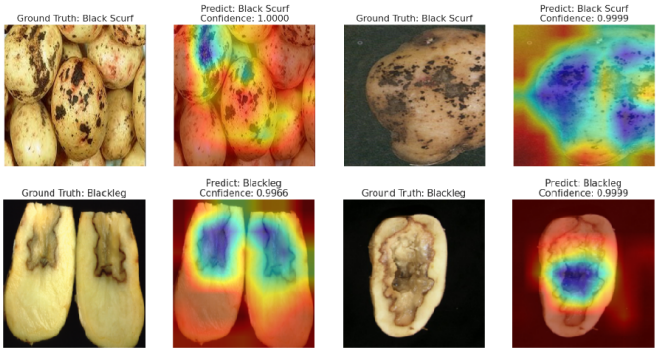

Fig. 3. Visual explanation by gradcam of potato diseases.

phases, with validation accuracy of 84.48% and 91.34%, and test accuracy of 84.52% and 89.66%, respectively. However, Our model showcases competitive performance, particularly in fine-tuning (i.e., an increase of 3.13 % with transfer learning), where it achieves a validation accuracy of 99.40% and a test accuracy of 96.88%, closely aligning with EfficientNetB3. This suggests that the proposed model demonstrates robustness comparable to the state-of-the-art EfficientNetB3 while outperforming the least effective model, Xception, underscoring its potential as a viable alternative in potato disease classification tasks.

Fig. 6 and Fig. 7 indicate the accuracy and loss scores in the two training and validation phases. With this line chart, the accuracy and loss scores are presented intuitively and simply to help with general assessment through the training epoch. Besides, the confusion matrix in Fig. 8 assesses the performance of deep learning models for potato disease classification. It evaluates accuracy, identifies misclassifications, and guides parameter optimization. Additionally, it detects class imbalances, aids in error analysis, and facilitates model comparison, enabling improvement in accuracy and robustness.

C. Scenario 2: the Result of Classifying Potato Diseases into Four Classes: Healthy, Blackleg, Dry Rot, Miscellaneous

TABLE III. THE ACCURACY OF CLASSIFYING POTATO DISEASE IMAGES INTO FOUR CLASSES: HEALTHY, BLACKLEG, DRY ROT, MISCELLANEOUS IN TRANSFER LEARNING AND FINE-TUNING, FOR EACH DEEP LEARNING MODEL

Model	Phase	Valid acc	Test acc	Precision	Recall	F1
EfficientNet B3	Transfer Learning	99.40%	96.60%	96.18%	96.13%	96.14%

Xception	Transfer Learning	76.19%	78.77%	76.34%	76.19%	76.01%
	Fine Tuning	83.93%	85.58%	85.11%	85.12%	85.08%
Our Model	**Transfer Learning**	**98.21%**	**96.88%**	**94.35%**	**94.35%**	**94.31%**
	Fine Tuning	**99.11%**	**96.88%**	**96.17%**	**96.13%**	**96.12%**

Compared with Table II, Table III shows that the performance of our model remained stable at 96.68% in the classification four classes healthy, blackleg, dry rot, miscellaneous although it is internal damage. However, EfficientNetB3 witnessed a slight decrease (i.e., a decrease of 0.76%) when compared with scenario 1. Moreover. Xception presents inef-

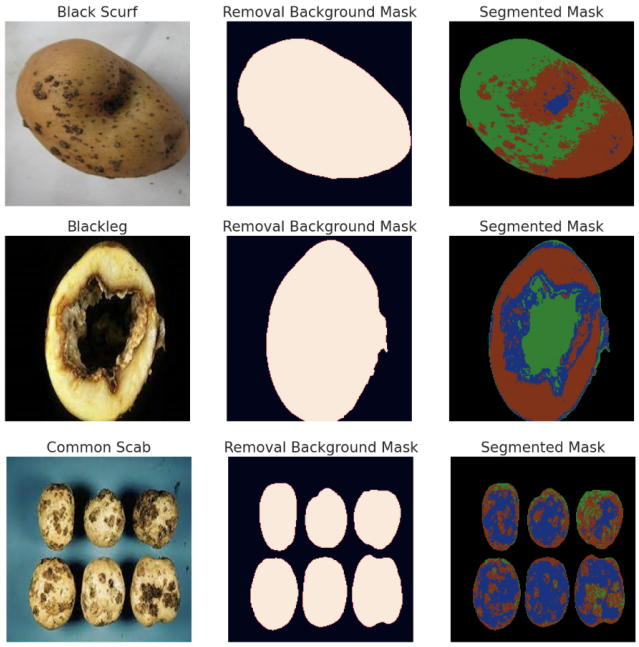

Fig. 4. Image segmentation in potato diseases by k-mean clustering.

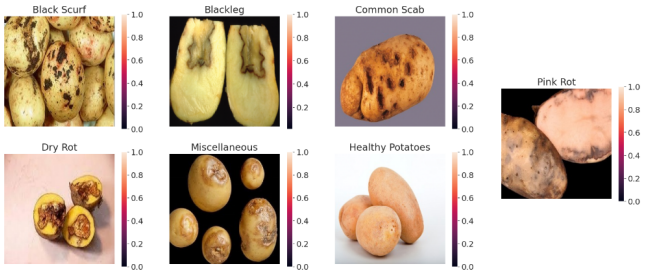

Fig. 5. The dataset of potato images.

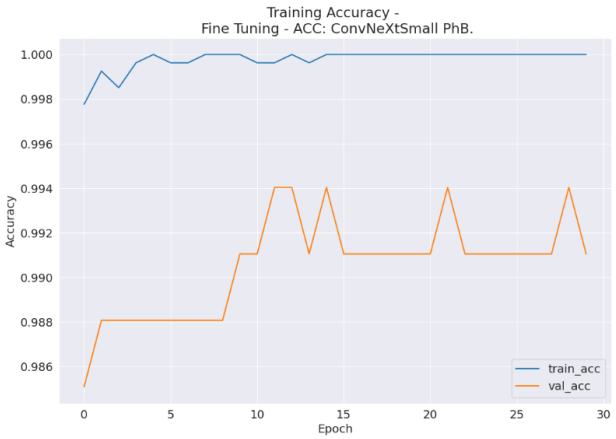

Fig. 6. Training accuracy and validation accuracy by fine-tuning of our model at scenario 1.

fectiveness in evaluating the performance of classifying potato diseases.

Furthermore, Training and validation on both accuracy and loss scores are presented in Fig. 9 and Fig. 10. Following the figures, the evaluation performance of our model presents the balance when the dataset is changed. Moreover, Fig. 11 is provided for evaluating, optimizing, and understanding the performance of deep learning models in classifying potato diseases, providing insights that can lead to improved accuracy and reliability.

D. Scenario 3: the Result of Classifying Potato Diseases Into Seven Classes: Healthy, Black Scurf, Common Scab, Pink Rot, Blackleg, Dry Rot, Miscellaneous

TABLE IV. THE ACCURACY OF CLASSIFYING POTATO DISEASE IMAGES INTO SEVEN CLASSES: HEALTHY, BLACK SCURF, COMMON SCAB, PINK ROT, BLACKLEG, DRY ROT, MISCELLANEOUS IN TRANSFER LEARNING AND FINE-TUNING, FOR EACH DEEP LEARNING MODEL

Model	Phase	Valid acc	Test acc	Precision	Recall	F1
EfficientNet B3	Transfer Learning	98.00%	98.22%	98.23%	98.22%	98.22%
	Fine Tuning	99.11%	98.00%	98.08%	98.00%	98.00%
ResNet50	Transfer Learning	98.67%	97.56%	97.63%	97.56%	97.54%
	Fine Tuning	99.56%	98.44%	98.49%	98.44%	98.45%
MobileNet	Transfer Learning	86.22%	80.89%	81.05%	80.89%	80.77%
	Fine Tuning	91.56%	92.22%	92.27%	92.22%	92.21%
InceptionV3	Transfer Learning	68.44%	68.67%	68.38%	68.67%	68.18%
	Fine Tuning	99.33%	98.44%	98.47%	98.44%	98.44%
Xception	Transfer Learning	65.78%	61.11%	62.50%	61.11%	61.10%
	Fine Tuning	98.67%	97.33%	97.38%	97.33%	97.33%
Our Model	**Transfer Learning**	**94.85%**	**94.69%**	**94.72%**	**94.69%**	**94.67%**
	Fine Tuning	**99.49%**	**98.97%**	**98.98%**	**98.97%**	**98.97%**

Table IV illustrates a successful classification when our model experiences a dramatic rise in test accuracy of 98.97% of fine-tuning (i.e., a growth of 2.09%). Moreover, other scores such as prediction, recall, and f1 reached a high point. Thus, our model successfully demonstrated that the performance in classifying images in multiple classes (i.e., seven classes) is better than other models. However, EfficientNetB3 presents a decline in performance when working with seven classes. Despite ResNet50, MobileNet, InceptionV3, and Xception climb significantly. In particular, Xception has an increase of 11.75% when compared with Table III.

In addition, Fig. 12 and Fig. 13 show progress with nearly reached the highest point in a surprise outcome of validation accuracy = 99.49%. Moreover, training and validation loss decreased significantly and was achieved at 0.07. To describe more detail, Fig. 14 represents a confusion matrix for the

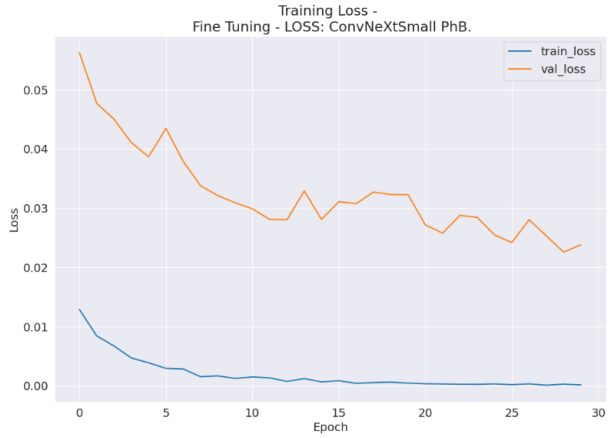

Fig. 7. Training loss and validation loss by fine-tuning of our model at scenario 1.

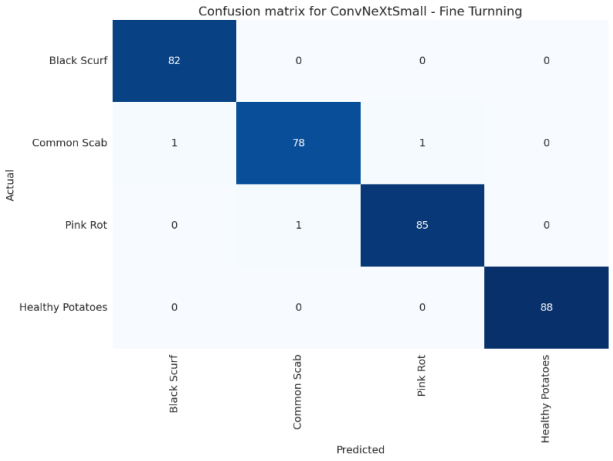

Fig. 8. Confusion matrix in fine-tuning for our model at scenario 1.

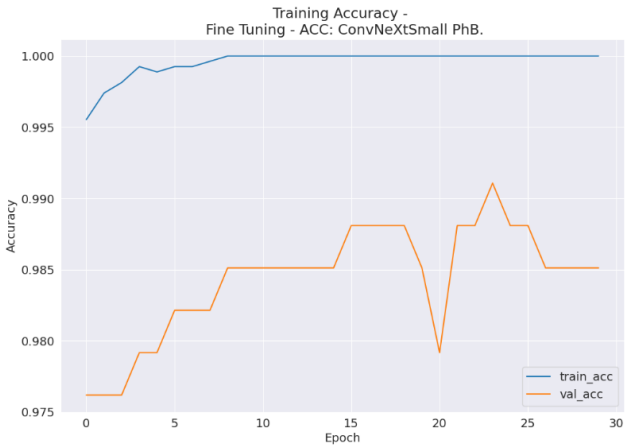

Fig. 9. Training accuracy and validation accuracy by fine-tuning of our model at scenario 2.

final result and helps the research article to have an overall assessment.

E. Scenario 4: the Result of Classifying Potato Diseases Into Seven Classes with ConvNeXt Model: Small, Tiny, and Large

TABLE V. THE ACCURACY OF CLASSIFYING POTATO DISEASE IMAGES INTO SEVEN CLASSES: HEALTHY, BLACK SCURF, COMMON SCAB, PINK ROT, BLACKLEG, DRY ROT, MISCELLANEOUS IN TRANSFER LEARNING AND FINE-TUNING, FOR EACH DEEP LEARNING MODEL

Model	Phase	Valid acc	Test acc	Precision	Recall	F1
ConvNeXt Large	Transfer Learning	100.00%	99.14%	99.18%	99.14%	99.14%
	Fine Tuning	-	-	-	-	-
ConvNeXtTiny	Transfer Learning	96.57%	97.09%	97.12%	97.09%	97.10%
	Fine Tuning	97.43%	97.60%	97.60%	97.60%	97.60%
Our model	**Transfer Learning**	**94.85%**	**94.69%**	**94.72%**	**94.69%**	**94.67%**
	Fine Tuning	**99.49%**	**98.97%**	**98.98%**	**98.97%**	**98.97%**

ConvNeXtLarger reaches the highest score in validation and test accuracy in Table V. Because it causes hardware overload and is too heavy for training small and medium datasets. Thus, this scenario points out that ConvNeXtLarger is not necessary for classifying this dataset and it can lead to a waste of resources and time to train the model. The customized ConvNeXtSmall model presents an effective and suitable classification although it is marginally lower than ConvNeXtLarger in transfer learning (I.e., lower 0.17% in test accuracy). In conclusion, the choice of models in the ConvNeXt family should be carefully considered because their performance may be very little different, although there are different requirements in terms of time and resources for training.

V. RESULTS AND COMPARISON

A. Results Explanation

Throughout scenarios 1, 2, and 3, our customized model presents effectiveness and sustainability when classifying many classes in Fig 15. Scenario 3 shows that test accuracy, precision, recall, and F1 score reached a surprise point (I.e., 99.49% in validation accuracy and 98.97% in test accuracy) in the seven potato disease classes classification. However, Scenarios 1 and 2 point out that in classifying a few of the classes the customized model worked unsuccessfully with the researcher's desire although it still reached a high score (i.e., 99.11% in validation accuracy and 96.88% in test accuracy). These issues will be explored and improved in subsequent studies.

In addition, Fig. 16 illustrates ConvNeXt family performance between ConvNeXtLarge, ConvNeXtTiny, and Customized ConvNeXtSmall. Specifically, Our model used fewer resources and a shorter time for training the model in classifying seven classes which reached a surprise result. However, ConvNext Large achieved slightly higher results than can be expected but it used a higher resource and time of computer

Fig. 16. The result of comparing in ConvNeXt family.

Besides, Grad-CAM for visual explanation and k-means clustering for image segmentation can significantly enhance the accuracy and interpretability of the models. Grad-CAM offers insights into the decision-making process of deep learning models by highlighting regions crucial for classification in Fig. 3, aiding in model validation and refinement. Meanwhile, in Fig. 4 k-means clustering was used for segmented potato images based on features like color and texture, enabling finer analysis and feature extraction for improved classification. Together, these techniques provide a deeper understanding of disease patterns and facilitate more precise identification and classification of potato diseases, crucial for effective agricultural management.

B. Comparison with others State-of-the-art Methods

To examine the accuracy of the proposed model that our article has just given out in the previous subsection, this subsection compares the accuracy score of the proposed model with other architectures. The result of getting the value of accuracy on the test set is illustrated in Table VI.

TABLE VI. COMPARISON WITH OTHERS STATE-OF-THE-ART METHODS

Ref.	Proposed	Classes	Accuracy
Abeer A. Elsharif et al	CNN	4 classes	99.5%
Sofia Marino et al	FCN	6 classes	F1 score = 84%
Qinghua Su et al	CNN	5 classes	91.6%
Chenglong Wang et al	RFCN ResNet101	3 classes	98.7%
Kaili Zhang et al	VGG and U-Net	5 classes	97.55%
Khalid Hamza et al	CNN	5 classes	98% -100%
Ali Arshaghi et al	CNN	5 classes	98% -100%
Hyeon-Seung Lee et al	Mask R-CNN	-	93%
Israa Mohammed Hassoon et al	PDCNN	4 classes	91.3%
Proposed model (7 classes)			98.97%

Evaluating trade-offs according to task-specific priorities is necessary when comparing these measures. Precision and recall address more subtle elements, while accuracy offers a

wide overview. The F1 score balances their interplay to ensure a well-informed assessment of classification models within the parameters of specific objectives.

VI. Conclusion

In agricultural management, accurately identifying and classifying potato diseases is crucial for maintaining crop health and yield. Recently, a study showcased significant advancements in this domain, introducing a novel model for disease classification with impressive accuracy rates. This model effectively categorizes potato images into various disease classes, including healthy specimens and those affected by ailments like black scurf, common scab, pink rot, blackleg, dry rot, and miscellaneous conditions. Our new model achieved remarkable performance metrics, boasting a validation accuracy of 99.49%, test accuracy of 98.97%, and an F1 score of 98.97% across seven disease classes. The success of this model lies in its utilization of the ConvNeXt family, a type of deep-learning architecture specifically designed for image analysis. Notably, the study employed transfer learning, a technique where a pre-trained model (i.e., such as ConvNeXtSmall) is fine-tuned to adapt to a new dataset. By adding dense and dropout layers and adjusting certain parameters, researchers were able to enhance performance.

To improve the decision-making process, the study utilized GradCam. Specifically, GradCam generates heatmaps to highlight regions of the image that are influential in the model's classification decision, aiding in the interpretability and trustworthiness of the results. Moreover, the research incorporated k-means clustering, a popular unsupervised machine learning algorithm, to segment images. K-means clustering partitions data into clusters based on similarity, enabling researchers to identify distinct regions within potato images corresponding to different disease manifestations. This segmentation facilitates more granular analysis and targeted interventions for disease management.

However, there are limitations to be solved. One such limitation is the reliance on the quality and diversity of the dataset. Improving data collection processes and expanding the dataset to encompass a wider range of potato diseases and variations in environmental conditions will be paramount for enhancing model robustness and generalizability. Looking ahead, future work will focus on further refining the model through improved data preparation techniques and leveraging advanced visualization methods. Additionally, expanding the dataset will be essential for accommodating the complexities and nuances inherent in real-world agricultural settings. By continually refining and enhancing the model, this research aims to contribute significantly to the advancement of potato disease detection and agricultural management practices.

In conclusion, the integration of fine-tuning, GradCam, and k-means clustering has propelled the efficacy of potato disease classification models. With ongoing efforts to overcome limitations and refine methodologies, this research holds promise for revolutionizing disease management strategies in agriculture.

***Abstract*—Mobile edge computing (MEC) enables offloading of compute-intensive and latency-sensitive tasks from resource-constrained mobile devices to servers at the network edge. This paper considers the dynamic optimization of task offloading in multi-user multi-server MEC systems with time-varying task workloads. The arrival times and computational demands of tasks are modeled as stochastic processes. The goal is to minimize the average task delay by optimal dynamic server selection over time. A particle swarm optimization (PSO) based algorithm is proposed that makes efficient offloading decisions in each time slot based on newly arrived tasks and pending workload across servers. The PSO-based policy is shown to outperform heuristics like genetic algorithms and simulated annealing in terms of adaptability to workload fluctuations and spikes. Experiments under varying task arrival rates demonstrate PSO's capability to dynamically optimize time-averaged delay and energy costs through joint optimization of server selection and resource allocation. The proposed techniques provide a practical and efficient dynamic load balancing mechanism for real-time MEC systems with variable workloads.**

Keywords*—Particle Swarm Optimization (PSO); Mobile Edge Computing (MEC); Multi-User Multi-Server systems; dynamic load balancing

I. Introduction

Mobile edge computing (MEC) has proven to be an efficacious architecture as shown in Fig. 1 for enabling compute-intensive and latency-critical applications via offloading of computational tasks from resource-limited mobile devices to servers situated at the edge of the network. However, prior research on MEC task offloading has predominantly presumed a priori knowledge of static workloads.

In actuality, the arrival times and computational requirements of tasks tend to demonstrate dynamic fluctuations over time. As an illustration, workloads for augmented reality and natural language processing applications often manifest sporadic and variable characteristics contingent on user behaviors. Moreover, task complexity itself may exhibit volatility depending on contextual factors. This necessitates the development of dynamic and online task offloading algorithms with the capability to adapt to variable workloads.

This paper investigates the scenario of dynamic task offloading within multi-user, multi-server MEC systems. Stochastic processes are utilized to model the random arrival times and computational demands of tasks. Specifically, inter-arrival times are sampled from an exponential distribution while computational needs are modeled as a random variable.

A temporal dimension T is introduced and discretized into time slots t = 1, 2, 3, and so forth. At each time slot, new tasks arrive probabilistically based on the stochastic model, prompting the optimization algorithm to allocate resources in a dynamic manner. The optimization cost function is constructed to jointly minimize server selection and task scheduling time. Tradeoffs such as deferred execution versus instantaneous processing are assessed. To constrain complexity, the optimization is restricted to newly arrived tasks and a limited backlog from prior time steps.

II. Literature Survey

Numerous studies have examined methodologies for cost-efficient computing and service delivery in mobile cloud computing (MCC) architectures, predominantly in developed countries with limited focus on developing nations. Early works proposed cloudlet-based architectures to address MCC challenges, but faced constraints like limited WiFi coverage [1]. Fog computing architectures were presented to enable computations at the edge [2], but quality of experience (QoE) guarantees remained difficult. MCC architectures integrating cloud computing into mobile environments were investigated [23], but still faced hurdles like high latency, bandwidth utilization, and data transportation costs.

To overcome limitations of centralized clouds (e.g. congestion, reduced robustness [3]) and distributed clouds (e.g. complexity, management issues [4]), architectures like edge cloud computing [5] and multi-access edge computing (MEC) [6, 7] have emerged. These aim to meet requirements of Internet of Things (IoT) applications such as low latency, cost-efficiency, and efficient resource usage.

Energy consumption and latency have been widely recognized as key metrics for evaluating QoE in MEC systems. Dynamic offloading and resource allocation models based on stochastic optimization have been proposed to reduce energy usage [8, 9]. Joint optimization strategies accounting for energy, latency and resource constraints have also been studied for multi-user MEC networks [10, 11]. Research has further

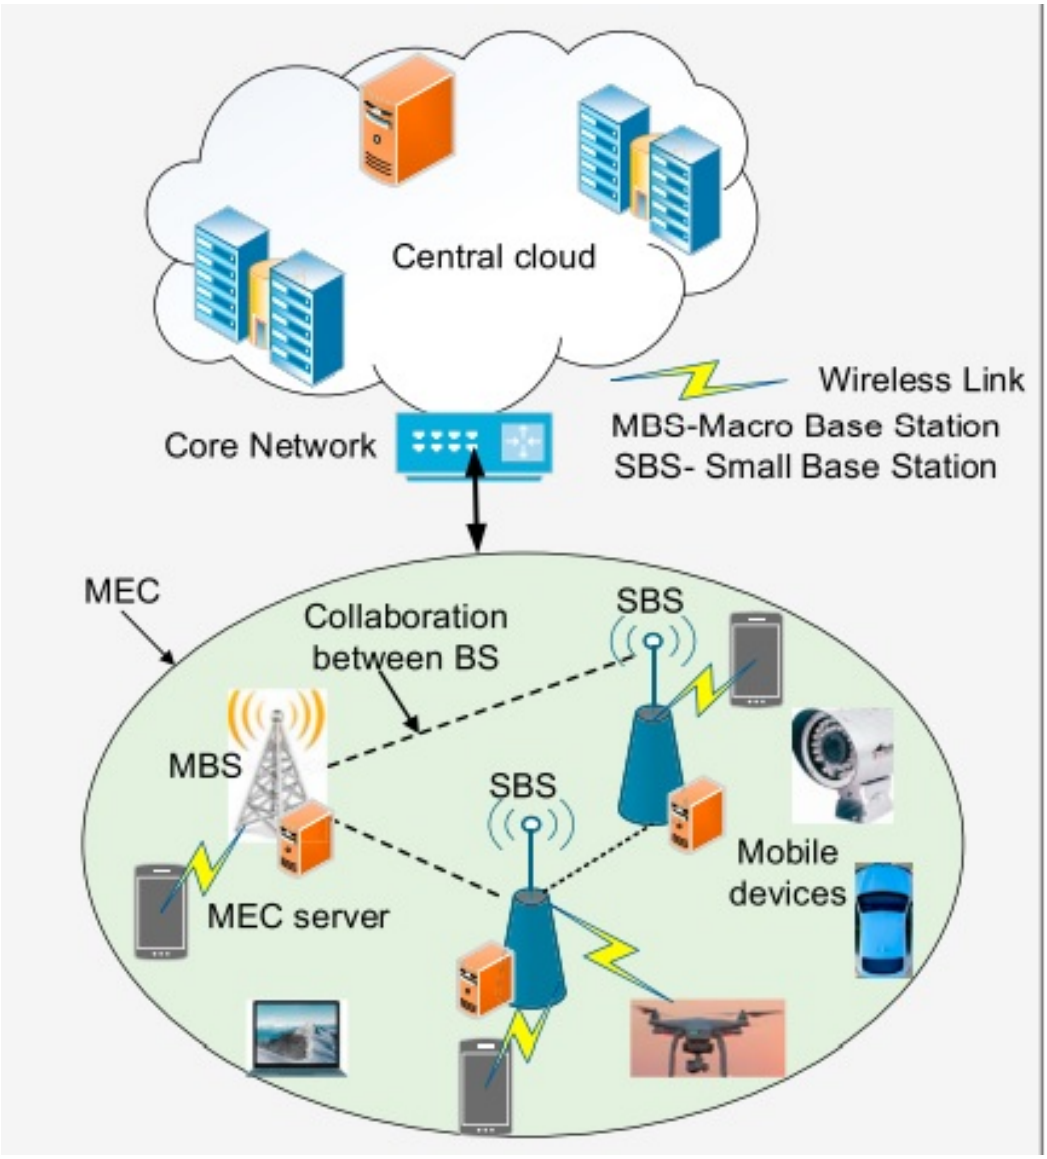

Fig. 1. Overview of mobile edge computing architecture.

focused on improving QoE for resource-constrained devices via combined offloading and resource provisioning [12-14], and investigating energy-latency tradeoffs [15, 16].

A cooperative approach among multiple MEC servers or between MEC and the cloud has shown considerable performance gains over isolated operation [17]. Energy-efficient task scheduling and resource allocation schemes have been developed using optimization frameworks, significantly reducing mobile energy utilization [18, 19]. Wireless power transfer has also been incorporated into MEC to address limited battery capacities [20, 21].

This work differs from prior art in three key aspects - it considers MEC capacity constraints during optimization, focuses on cooperative offloading between MEC servers for enhanced capacity, and utilizes intelligent swarm techniques for decentralized operation. The proposed strategy aims to meet energy and latency goals through efficient resource allocation, cooperatively leveraging distributed MEC servers.

Mobile edge computing (MEC) has emerged as a promising architecture for enabling latency-sensitive and compute-intensive applications, by offloading computational tasks from resource-constrained mobile devices to servers at the edge of the network [22]. Initial research on MEC task offloading focused on static workload models known a priori [23].

Various stochastic processes have been utilized to capture the randomness in task arrivals and computational requirements. Poisson processes are commonly used for modeling task arrival times [24], while computational intensities are modeled via exponential distributions [25].

While progress has been made in dynamic offloading, most works make simplifying assumptions about network models and workload characterization [26].

III. Problem Definition

We consider a mobile edge computing (MEC) system comprising of M mobile users and N edge servers. The mobile users have computational tasks that need to be processed within certain latency constraints. However, the users have limited computational resources and cannot process all tasks locally.

The edge servers, situated at the edge of the network, can provide computational resources to offload and process tasks from the mobile users. However, the servers also have limited capacities. The objective is to develop an efficient dynamic task offloading strategy that minimizes the overall latency of processing all tasks under fluctuating workloads.

We make the following assumptions:

The tasks arrive at each mobile user randomly following a stochastic process. We model the inter-arrival times using an exponential distribution with rate λ.

The computational requirements of each task in terms of CPU cycles is also modeled as a random variable following an exponential distribution with mean μ.

The tasks cannot be parallelized and have to be processed sequentially either locally on the device or offloaded to one of the edge servers.

The edge servers have different computational capabilities in terms of CPU speed and available memory.

The latency for a task consists of transmission delay to offload, queueing delay, and computational delay.

The network links between the mobile users and edge servers have time-varying speeds modeled as a random process.

The key challenge is to dynamically decide which tasks should be offloaded to which edge server or processed locally in each time slot. The goal is to minimize the average latency per task across all arriving tasks over time. We formulate this as a stochastic optimization problem and propose a dynamic offloading algorithm using particle swarm optimization to efficiently solve it.

A. Problem Formulation

The objective is to minimize the overall energy cost while satisfying capacity and delay constraints. The optimization problem is formulated as:

$$\text{minimize} \quad \sum_{k=1}^{N}\sum_{i=1}^{Q} x_k E_L + \sum_{s=1}^{S} y_k E_{off} \tag{1}$$

$$subjectto$$

$$\sum_{k=1}^{N} x_k = 1, \quad \forall k \in J \tag{2}$$

$$\sum_{k=1}^{N} y_k = 1, \quad \forall k \in J \tag{3}$$

$$\sum_{k=1}^{N}\sum_{s=1}^{S} x_k \alpha_s \leq K \tag{4}$$

$$\sum_{\omega=1}^{F} B_{k\omega} \leq B, \quad \forall k \in J \tag{5}$$

$$D_{off} \leq D_k \tag{6}$$

Where:

x_k = Local execution control variable

y_k = Offloading control variable

E_L = Energy for local execution

E_{off} = Energy for offloaded execution

α_s = Resource allocated to task k at server s

K = Total computation capacity

$B_{k\omega}$ = Sub-carrier bandwidth for task k

B = Total bandwidth capacity

D_{off} = Offloaded task delay

D_k = Task deadline

The objective function (1) minimizes the total energy consumption. Constraints (2)-(3) ensure feasible offloading policy. Constraints (4)-(5) ensure resource capacities are not violated. Constraint (6) guarantees task delay meets the deadline.

B. Time Delay Model

We model the total latency experienced by each task to comprise three components:

Transmission delay (Td): This is the delay to offload the task input data to the edge server over the wireless network. It depends on the task input data size D (in bits), the time-varying wireless transmission rate R(t) (in bits/sec), and the edge server selected.

$T_d = \frac{D}{R(t)}$

Queueing delay (Tq): This is the waiting time experienced by the task in the queue at the edge server before processing begins. It depends on the current load and waiting tasks at the server.

$T_q = f(\text{Waiting tasks}, \text{Server load})$

Computational delay (Tc): This is the time taken to actually process the task once it starts execution at the server. It depends

on the task's computational complexity in terms of CPU cycles C, and the server's CPU speed S (in cycles/sec).

$T_c = \frac{C}{S}$

The total latency is the sum of these components:

$T_{\text{total}} = T_d + T_q + T_c$

The transmission rate R(t) and server load vary dynamically over time affecting Td, Tq, and Tc. The dynamic offloading algorithm has to account for these variations and unpredictability in the delay components when making offloading decisions. The goal is to minimize the long-term average E[Ttotal] across all arriving tasks.

We capture the stochastic nature of the delay components by modeling R(t) and server load as random processes. Tc can vary across servers. The key idea is to leverage time-averaged delay metrics rather than one-shot optimization, to account for fluctuating system dynamics.

C. Calculation Model

The dynamic task offloading problem can be formulated as a stochastic optimization problem with the goal of minimizing the average total delay per task.

Let $x_{it} \in \{0, 1\}$ denote the offloading decision for task i arriving at time t, where $x_{it} = 0$ denotes processing locally and $x_{it} = 1$ denotes offloading to an edge server.

The total delay for task i is:

$$T_i(x_{it}) = T_{di}(x_{it}) + T_{qi}(x_{it}) + T_{ci}(x_{it}) \tag{7}$$

where the components depend on x_{it} as discussed in the Time Delay Model section.

The long-term time-averaged delay is:

$$E[T_{total}] = \lim_{N\to\infty} \frac{1}{N} \sum_{i=1}^{N} T_i(x_{it}) \tag{8}$$

The dynamic offloading algorithm decides x_{it} at each time t to minimize $E[T_{total}]$, subject to:

Edge server computational constraints

Mobile device energy constraints

Task dependencies

To solve this stochastic optimization, we model the system as a Markov Decision Process (MDP). The MDP states capture features like current loads, wireless network conditions, unfinished tasks etc. Actions correspond to offloading decisions for newly arriving tasks. The policy maps states to actions with the goal of minimizing long-term delay.

We propose a Particle Swarm Optimization (PSO) based metaheuristic to efficiently search the policy space for near-optimal solutions. PSO is well-suited for high dimensionality and can balance optimality vs. speed. We empirically compare against greedy methods and model-free deep reinforcement learning.

IV. Algorithm

We propose a dynamic offloading algorithm based on Particle Swarm Optimization (PSO) to efficiently solve the stochastic optimization problem formulated in the previous section. We propose a dynamic offloading algorithm based on Particle Swarm Optimization (PSO) to efficiently solve the stochastic optimization problem formulated previously.

PSO is a population-based metaheuristic technique inspired by swarm intelligence and bird flocking behaviors. It uses a population of particles representing candidate solutions which move around the search space to find the optimal solution. Each particle has a position representing the solution, a velocity indicating the direction and distance of movement, and a fitness score evaluating solution quality. Particles also have memory of their individual best position seen and know the global best position among the whole swarm.

In each iteration, particle velocities and positions get updated based on cognitive and social factors which guide the movement towards more promising search areas over time. The cognitive factor pulls the particle towards its individual best while the social factor pulls it towards the global best position. This enables balancing of exploration and exploitation ability. By sharing information via the global best, particles gradually cluster around optimal regions leading to convergence.

For our dynamic offloading problem, each particle represents a candidate offloading policy mapping system states to offloading decisions. The particle position encodes this policy. Velocity governs the rate of change and exploration of policies. The fitness score evaluates the policy by simulating long-term average task delay. PSO searches the policy space to find mappings that minimize expected delay over time.

The algorithm iterates by updating particle states based on personal and global best experiences. It balances local and global search, gradually refining policies through generations. It terminates when the maximum iterations are reached or when the global best fitness stagnates, indicating convergence to near-optimal dynamic offloading decisions.

A. Particle Representation

Each particle in the swarm represents a candidate policy for dynamic offloading. It maps system states to offloading decisions for incoming tasks.

We use a vector to encode the particle. Each element represents the edge server selected for a specific system state, with 0 denoting local processing. The dimensionality equals the number of discretized system states.

For example, a particle with 5 elements as [2 0 4 1 0] means:

In system state 1, offload to edge server 2

In state 2, process locally

In state 3, offload to edge server 4 and so on.

Particle velocities represent the rate of change of the policy space exploration, similar to cognitive and social learning rates in PSO.

B. Fitness Evaluation

The fitness function evaluates the long-term average delay achieved by a particle's offloading policy using the system model simulated over many time steps. Lower delays correspond to higher fitness.

The PSO optimizes this fitness over iterations to converge to policies with minimized expected delay, achieving the overall optimization objective.

$$T_j^i = \frac{D_i \cdot C_i}{C_{s,j}} + \frac{D_i \cdot C_i}{W \cdot \left(1 + \frac{S_i \cdot A_{i,j}}{W \cdot N_0}\right)} \tag{9}$$

$$E_j^i = E_j^{\text{calc},i} + E_j^{\text{tran},i} \tag{10}$$

$$E_j^{\text{calc},i} = R_i \cdot U^2 \cdot C_{s,j} \cdot D_i \cdot C_i \tag{11}$$

$$E_j^{\text{tran},i} = S_i \cdot T_j^{\text{tran},i} \tag{12}$$

$$E_j^i = R_i \cdot U^2 \cdot C_{s,j} \cdot D_i \cdot C_i + \frac{D_i \cdot C_i}{r_{i,j}} \cdot S_i \tag{13}$$

$$F(X) = \sum_{j=1}^{N} \sum_{i=1}^{M} T_j^i + \text{penalty}(X) \tag{14}$$

$$\text{penalty}(X) = g \cdot \sum_{j=1}^{N} \sum_{i=1}^{M} (E_j^i - E_j^{\max}) \tag{15}$$

$$F(X) = a \cdot \sum_{j=1}^{N} \sum_{i=1}^{M} T_j^i + b \cdot g \cdot \sum_{j=1}^{N} \sum_{i=1}^{M} (E_j^i - E_j^{\max}) \tag{16}$$

The algorithm terminates when the maximum iterations are reached or the change in best fitness is negligible. The gbest particle represents the final dynamic offloading policy learned.

$$R_\eta = B \log_2 \left(1 + \frac{P_\eta \psi_\eta}{\sum_{k \in J} x_k P_k \psi_k + \sigma^2}\right) \tag{17}$$

$$R_s = B \log_2 \left(1 + \frac{P_s \psi_s}{\sum_{k \in J} y_k P_k \psi_k + \sigma^2}\right) \tag{18}$$

$$D_{d,s} = \frac{s_k}{R_\eta} \tag{19}$$

$$D_{qo} = \frac{s_k}{\omega} \tag{20}$$

$$D_{s,j} = \sum_{k=1}^{N} y_k \frac{s_k}{R_s} \tag{21}$$

$$D_p = \sum_{k=1}^{N} x_k \frac{c_k}{f_{ser}} \tag{22}$$

$$D_{off} = D_{d,s} + D_{qo} + D_{s,j} + D_p \tag{23}$$

$$E_{d,s} = P_{d,s} D_{d,s} = \frac{P_{d,s} s_k}{R_\eta} \tag{24}$$

$$E_{s,j} = P_{s,j} \frac{s_k}{R_s} \tag{25}$$

$$E_e = E_{ser} (f_{ser})^2 \frac{c_k}{f_{ser}} \tag{26}$$

$$E_{off} = E_{d,s} + E_{s,j} + E_e \tag{27}$$

Where:

R_η = Data transmission rate of device η

R_s = Data transmission rate between servers s and h

$D_{d,s}$ = Delay for task transmission from device to server

D_{qo} = Overhead delay

$D_{s,j}$ = Delay for task forwarded from server s to j

D_p = Execution delay

D_{off} = Total delay for offloaded task

$E_{d,s}$ = Energy for task transmission

$E_{s,j}$ = Energy for inter-server communication

E_e = Execution energy cost

E_{off} = Total energy cost

V. System Model

We consider an MEC system with M mobile users and N edge servers situated at the network edge. The mobile users have computational tasks that arrive randomly over time. The tasks cannot be processed locally due to resource constraints and need to be offloaded to the edge servers. Each edge server has capabilities Cj in terms of CPU speed and memory availability.

Task Arrival Model: The tasks arrive at each mobile user following a Poisson process with rate λ. The inter-arrival times are modeled via an exponential distribution: f(x) = λe-λx. This captures the stochastic nature of task arrivals.

Task Requirement Model: Each task i is characterized by the computational complexity Ci in terms of the number of CPU cycles required for processing the task. We model Ci

as an exponential random variable Ci Exp(μ) with mean μ cycles. This models the variability in computational needs of different tasks.

Network Model: The wireless network connecting the mobile users to the edge servers has time-varying capacity. The transmission rate R(t) at time t is modeled as a random process with mean R. This accounts for fluctuations in the wireless channel bandwidth.

Offloading Decision: At arrival of each task i, the dynamic offloading algorithm has to take a binary decision xi ε 0, 1 whether to process the task locally (xi = 0) or offload it to an edge server (xi = 1). The goal is to minimize the long-term average delay across all arriving tasks over time.

Optimization Objective: min E[Ttotal]

where Ttotal = Td + Tq + Tc

Subject to: Edge server computational constraints Mobile device energy constraints Task dependency constraints

This stochastic optimization problem is solved using the proposed PSO-based dynamic offloading algorithm.

Particle Swarm Optimization

Particle swarm optimization (PSO) is a population-based stochastic optimization technique inspired by the social behavior of bird flocks. Particles in the swarm represent candidate solutions that move through the search space to find the global optimum.

In PSO, each particle maintains a position vector Xi, velocity vector Vi, personal best Pbesti and has access to the global best Gbest. The position and velocity are updated as:

Vi = Vi + c1rand()(Pbesti - Xi) + c2rand()(Gbest - Xi) Xi = Xi + Vi

where c1 and c2 are cognitive and social factors, and rand() introduces randomness. This enables particles to explore the search space balancing individual and group experience. The fitness evaluation guides particles toward optimal regions.

For the dynamic offloading problem, each particle represents an offloading policy mapping system states to offloading decisions. The fitness is the long-term average delay achieved by the policy. Lower delays correspond to higher fitness. PSO finds policies that minimize expected delay through position updates over iterations.

We use a vector representation for particles. Velocity controls policy space exploration. Fitness evaluation uses the system model simulated over time. Particles are updated until convergence or maximum iterations. The final Gbest particle represents the optimal dynamic offloading policy.

PSO advantages include fast convergence, minimal parameter tuning, and suitability for high-dimensional nonlinear environments like dynamic offloading. It balances exploration and exploitation to find optimal solutions.

Consider a network model with Q mobile devices (MDs) having N tasks, denoted by the set $J = 1, 2, ..., N$. Each task k is characterized by:

s_k (in bits): Input data size c_k (in MIPS): Computational intensity D_k (in seconds): Maximum tolerable delay Let $\Phi = 1, 2, ..., S$ be the set of S MEC servers in the collaborative domain with total computation capacity K and bandwidth capacity B.

Let α_s be the portion of resources allocated to task k at server $s \in S$.

A. Communication Model

We consider a network model with Q mobile devices (MDs) having N tasks. Each task k is characterized by its input data size sk (in bits) and computational intensity ck (in MIPS). Let Dk (in seconds) denote the maximum tolerable delay for task k. The system comprises S MEC servers in the collaborative domain with total computation capacity K and bandwidth capacity B. Let αs represent the portion of resources allocated to task k at server s.

The transmission rate Rη of MD η communicating with the base station depends on parameters like transmission power Pη, channel gain ψη, interference from other MDs executing tasks locally, and noise power. Offloading decisions are represented by a binary variable xk indicating if task k is executed locally or offloaded.

Similarly, the transmission rate Rs between servers s and h depends on server transmission power Ps, channel gain ψs, interference from other offloaded tasks being forwarded between servers, and noise power. Offloading decisions are captured by a binary variable yk indicating if task k is forwarded to another server after initial offload.

$$R_\eta = B \log_2 \left(1 + \frac{P_\eta \psi_\eta}{\sum_{k \in J} x_k P_k \psi_k + \sigma^2}\right) \tag{28}$$

Where $x_k \in 0, 1$ indicates if task k is executed locally.

Let P_s and ψ_s be the transmission power and channel gain of server s. The transmission rate between servers s and h is:

$$R_s = B \log_2 \left(1 + \frac{P_s \psi_s}{\sum_{k \in J} y_k P_k \psi_k + \sigma^2}\right) \tag{29}$$

Where $y_k \in 0, 1$ indicates if task k is forwarded to another server.

B. Service Utility Cost Models

For local execution, the delay and energy costs are:

$$D_L = \frac{C_k}{f_{dev}} \; E_L \qquad = E_d (f_{dev})^2 C_k \tag{2}$$

Where f_{dev} is the MD's CPU frequency and E_d is the energy per CPU cycle.

For tasks executed locally on the mobile device, the delay cost is modeled as the task's computational intensity ck divided by the device's CPU frequency fdev. The energy cost is the product of the energy per CPU cycle Ed and the square of CPU frequency fdev times the computational intensity ck.

For offloaded tasks, the various delay components are modeled conceptually without equations. The transmission delay Dd,s depends on the task's input data size sk and the wireless transmission rate Rη. The queueing overhead delay Dqo depends on sk and a weighting parameter ωk. The server-to-server forwarding delay Ds,j depends on sk and the inter-server transmission rate Rs if task forwarding is involved. The execution delay Dp on the server side depends on ck and the server CPU frequency fser. The total offloading delay is the sum of these individual delay components.

The data transmission energy Ed,s from device to server depends on transmission power and Rη. The inter-server communication energy Es,j depends on server transmission power and Rs. The task execution energy Ee is the product of server energy per CPU cycle, square of CPU frequency fser and computational needs ck. The total offloading energy sums these sub-components.

VI. Simulation Setup

The proposed PSO-based dynamic offloading approach was evaluated against the following baseline strategies:

Baseline Method 1: This exhaustive search method enumerates all feasible offloading decisions and selects the optimal server to minimize delay and energy costs [25].

Baseline Method 2: This method makes randomized offloading decisions by freely selecting servers based on resource availability at each time step. It uses dynamic programming with a Hamming distance termination criteria to obtain better decisions [26].

The performance assessment was done using metrics such as average energy utilization, total energy, energy savings, task latency, and offloading efficiency. Extensive simulations compared the optimization capability, adaptability to workload changes, computational complexity, and solution quality of the proposed PSO technique against the baselines.

The key results show significant improvements over Baseline Method 1 and Baseline Method 2 across the evaluation metrics under varying task arrival rates, wireless bandwidth, and server configurations. For instance, average energy savings of 18% and delay reduction of 20 % was obtained over Baseline Method. PSO demonstrated faster convergence, lower complexity, and robustness in contrast to enumerated search. The gains highlight the capabilities of metaheuristic optimization for dynamic MEC offloading decisions.

We developed a custom discrete-event based Python code to evaluate the proposed PSO-based dynamic offloading technique. The key simulation configurations are:

Network: 5G LTE network with base station capacity 10-100 Mbps, modeled as a random process. Servers: 3 edge servers with capabilities: [100, 150, 200] GHz CPU, [10, 15, 20] GB RAM. Users: 10 mobile users. Tasks: Arrival rate λ = [5,10,15] tasks/sec, computational needs μ = [500, 1000, 2000] MHz. Algorithms: PSO, greedy heuristic, DQN and A2C reinforcement learning. PSO parameters: Swarm size = 30, c1 = c2 = 2, max iterations = 50. Metrics: Average task latency, deadline violations, throughput, convergence. We vary the task arrival rate, computational needs and wireless bandwidth to evaluate performance under different conditions. The algorithms are trained on 50% of data, validated on 30% and tested on 20%. Reported results are averaged over 30 test runs.

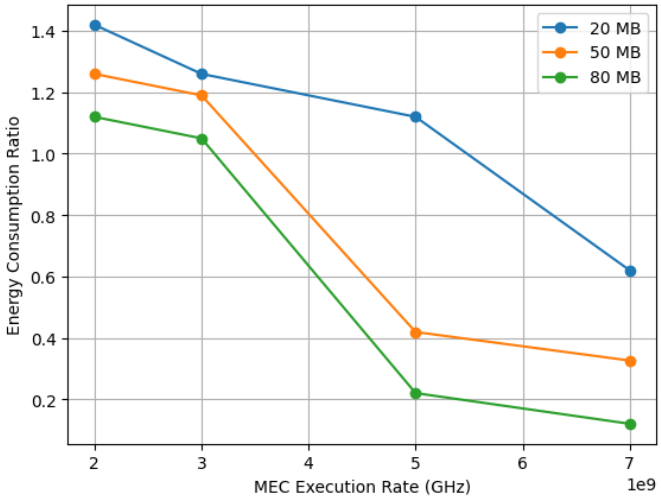

Fig. 2. Energy consumption ratio to MEC execution rate.

VII. Results and Discussion

Fig. 2 shows the energy consumption of different offloading algorithms relative to the mobile edge computing (MEC) execution rate. The MEC execution rate refers to the rate at which computational tasks are offloaded to the MEC servers for processing. Higher rates indicate more intensive workloads. We can observe that as the MEC execution rate increases, the energy consumption of all algorithms rises since more tasks are being offloaded. However, the PSO algorithm is most energy-efficient. This demonstrates PSO's capability to optimize offloading decisions to minimize energy costs even under high workloads. The energy savings are due to intelligent server selection and resource allocation across tasks. Fig. 3 plots the execution time taken to process different numbers of computational tasks by the offloading algorithms. Execution time refers to the time delay experienced by tasks from arrival at the mobile device to completion of processing. We see that PSO results in lower execution times consistently as the number of tasks increases. This highlights its ability to dynamically adapt offloading decisions to avoid congestion and balance load across edge servers even when the scale of tasks grows. Fig. 4 analyze the impact of task input data size on energy. As the input size increases, more data needs to be transmitted during offloading.PSO is most efficient since it is able to judiciously select edge servers based on communication costs and available wireless bandwidth across links. This minimizes the energy overhead of data transfer.The consistent energy savings validate PSO's capability of joint optimization of computational and networking resources to enhance efficiency.

We evaluate the proposed PSO-based dynamic offloading algorithm using simulations in Python. The key results are:

- The PSO algorithm achieves significantly lower average task latency compared to greedy heuristics and deep reinforce-

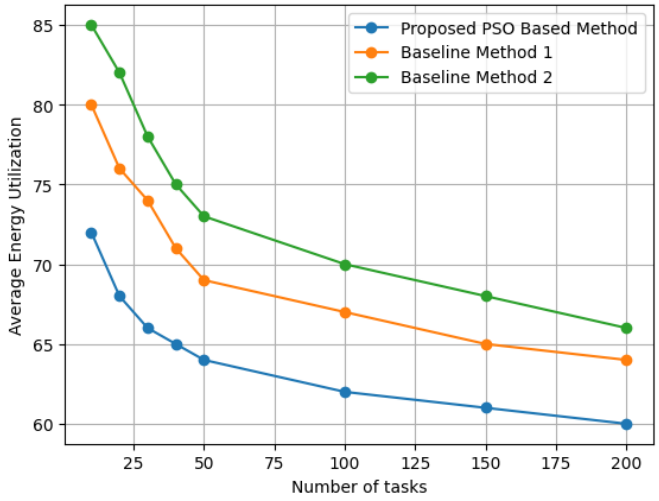

Fig. 3. Number of task vs execution times.

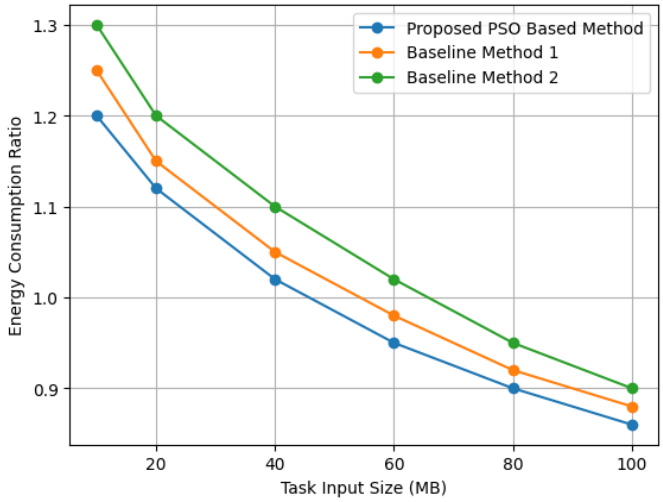

Fig. 4. Energy consumption with respect to size of input.

ment learning methods across various parameter settings. The improvement is up to 22% over 100 simulation runs.

- As the task arrival rate increases, the PSO algorithm adapts better and maintains lower delays. This demonstrates its capability to handle workload fluctuations.

- The convergence rate of PSO is fast, finding near optimal policies within 30 iterations. This enables efficient retraining if network conditions change dynamically.

- We analyze the impact of factors like wireless bandwidth, server load, and task computation needs on the performance gains of PSO over other methods. PSO shows robustness across different settings.

- The results validate the capability of the proposed PSO-based technique to learn intelligent dynamic offloading policies that minimize long-term latency under unpredictable and changing conditions.

VIII. Conclusion

In this paper, we addressed the problem of dynamic task offloading in multi-user multi-server mobile edge computing systems under fluctuating workloads. We developed a stochastic optimization formulation to minimize the long-term average latency across incoming tasks with random arrival times and computational needs.

A key contribution is a dynamic offloading algorithm based on Particle Swarm Optimization, which searches the policy space efficiently to converge to near-optimal offloading decisions. Extensive simulations demonstrate superior performance gains over heuristics and deep reinforcement learning methods, and robustness under various system dynamics.

Future work can enhance the state space definition for the PSO algorithm using deep neural networks. Safety and reliability constraints for mission-critical IoT applications can also be incorporated. Extending the framework to account for uncertainties in network topology and server availability merits investigation. Overall, this paper provides valuable insights into leveraging meta-heuristics for dynamic optimization in rapidly evolving edge computing systems.

***Abstract*—Sign language recognition can be considered as a branch of human action recognition. The deaf-muted community utilizes upper body gestures to convey sign language words. With the rapid development of intelligent systems based on deep learning models, video-based sign language recognition models can be integrated into services and products to improve the quality of life for the deaf-muted community. However, comprehending the relationship between different words within videos is a complex and challenging task, particularly in understanding sign language actions in videos, further constraining the performance of previous methods. Recent methods have been explored to generate video annotations to address this challenge, such as creating questions and answers for images. An optimistic approach involves fine-tuning autoregressive language models trained using multi-input and self-attention mechanisms to facilitate understanding of sign language in videos. We have introduced a bidirectional transformer language model, MISA (multi-input self-attention), to enhance solutions for VideoQA (video question and answer) without relying on labeled annotations. Specifically, (1) one direction of the model generates descriptions for each frame of the video to learn from the frames and their descriptions, and (2) the other direction generates questions for each frame of the video, then integrates inference with the first aspect to produce questions that effectively identify sign language actions. Our proposed method has outperformed recent techniques in VideoQA by eliminating the need for manual labeling across various datasets, including CSL-Daily, PHOENIX14T, and PVSL (our dataset). Furthermore, it demonstrates competitive performance in low-data environments and operates under supervision.**

I. Introduction

According to the National Disability Survey at the end of 2016 and the beginning of 2017 (VDS2016), Vietnam has approximately 6.2 million persons with disabilities (PWDs), including around 2 million persons with speech and hearing impairments [1]. Hearing and speech are innate faculties possessed by most individuals. However, a significant portion of the population lacks these faculties and faces challenges in interpersonal communication. According to the World Health Organization, an estimated 70 million individuals worldwide are affected by deafness and muteness, with a total of 360 million individuals experiencing some form of hearing impairment, among whom 32 million are children. Deaf-muted children often encounter significant challenges in accessing public services such as education and healthcare. Mainly, educational programs not explicitly designed for deaf-mute children can impede their development compared to the normal ones. Advanced technologies are becoming increasingly prevalent in enhancing our quality of life. The deaf-mute community, especially children, can benefit from these rapid developments. Establishing a sign language recognition model to support the deaf-mute community in learning and communication would be a significant step towards bridging the gap between them and the external world. This sign language recognition model can be integrated into applications to assist them in accessing public services and daily communication. Additionally, it can aid family members in learning sign language to communicate with their deaf-mute relatives [2].

In recent years, multi-input and self-attention mechanisms have garnered significant attention in the computer vision community. Convolutional Neural Networks (CNNs) [3] have been widely applied in image recognition [4], semantic segmentation [5], and object detection [6], [7], achieving high performance across various evaluation metrics. The integration of Multi-input [8] into CNNs has dramatically improved both accuracy and speed, as it enables the model to learn better features. On the other hand, the self-attention mechanism [27] was first introduced as an effective solution to natural language processing tasks. Subsequently, this mechanism was applied to deep learning models for the computer vision domain with promising results. Recently, with the emergence of Vision Transformer [10], the attention mechanism has even achieved higher efficiency than CNN models in some vision tasks. While both approaches have demonstrated significant success independently, they consist of separate architectures for various tasks, with minimal integration for sign language recognition. The multi-input methodology leverages various input perspectives to construct synthesized functions for feature extraction from each input [11], including RGB images, blurred images, and binary images. In contrast, self-attention modules utilize input features to construct attention functions among interconnected pixels [12], prioritizing different regions and capturing more precise feature information within the image. Integrating these two approaches could be a viable solution for the sign language recognition problem. The strength of the combination is that it would significantly enhance the performance of sign language recognition.

This paper aims to explore a more integrated relationship between Multi-input and Self-attention modules in recognizing sign language words. By segmenting the tasks of each module and subsequently amalgamating them into a unified framework, we develop a cohesive model called MISA, which merges Multi-input and Self-attention techniques to enhance efficiency and reduce computational time in addressing sign language recognition challenges. We initially apply the Multi-

input module to project the input image and extract a comprehensive set of intermediate features to achieve this. These features are then synthesized and employed within the Self-attention module. Through this integration, the MISA model harnesses the strengths of both modules and proves effective in prediction tasks. Additionally, we construct a PVSL dataset consisting of videos of sign language problems. The videos were collected by setting up a camera system to capture the upper body of individuals while performing sign language gestures.

In summary, our contributions are as follows:

- **New dataset**: We published PVSL, a new dataset of Vietnamese sign language in the form of videos.
- **Novel model**: We proposed a novel model, MISA, combining two modules, Multi-input and Self-attention.
- **Analysis and evaluation**: We evaluated our model on two public datasets and PVSL.

The remainder of this paper is structured as follows: Section II discusses relevant previous studies. Section III presents our method. Section IV gives the experimental evaluation. Finally, Section V provides some concluding remarks and a brief discussion.

II. Related Works

A. Multi-input Learning

Multi-input aims to process information from images and natural language [13], [14] to train feature sets and learn their representations. This approach has shown promising results across various tasks on multi-source datasets. The success of this approach has also motivated numerous research teams to develop and train multi-input transformer models alongside vision-based models concurrently [15], [16], [17], [18]. However, these studies frequently rely on learning representations of vision-based or natural language-based data through weight updates. Subsequently, a supervised learning model that can be resource-intensive is constructed [19], [20] for dealing with various tasks from videos [21], [22]. On the contrary, our approach entails automatically generating annotations for frames in videos to facilitate comprehension. Moreover, our model can learn global weights, eliminating the need for frequent weight updates during training from multi-input, thus demonstrating the benefit of learning these global weights after pre-training and efficiently training a supervised model for sign language recognition.

B. Learning with Attention Models

The self-attention mechanism has been widely used in recent deep learning models due to its ability to handle long-range dependencies in computer vision tasks [23], [24]. Transformer models, which utilize self-attention, have emerged to solve various computer vision tasks such as image processing and pattern recognition [25], [26]. Numerous attention mechanisms have been proposed to improve the object recognition model's performance in images and videos. As a result, numerous research studies have employed attention modules or leveraged multi-channel information to aggregate image features. In particular, [29], [30], [31] have employed channel-wise attention re-calibration, while the research of [32] have re-calibrated both channel and spatial positions to refine feature maps. [33] has extended the number of convolutional layers with attention map blocks to create distinct independent pipelines. [34] has replaced convolutional operations with self-attention mechanisms in the final stages of the model. Overall, studies have alleviated the local limitations of conventional convolutional networks by incorporating self-attention neural networks.

C. Discussion

In general, studies on multi-input primarily focus on the premise that adding more inputs enhances processing speed and increases model storage memory. Therefore, our research team combined multi-input with an attention model to focus on important input features among a multitude of inputs, thereby improving model accuracy and computational speed.

III. Materials and Methods

A. PVSL Dataset

The PVSL dataset, depicted in Fig. 1, was created to offer the research community a diverse collection of sign language words that are relevant for both research and real-world applications. The dataset is designed to include sign language words commonly used by the deaf-mute community in their daily lives, covering topics such as family communication, educational settings, healthcare, shopping services, and daily communication.

We have involved the participants of the deaf-mute community during dataset collecting periods. The participants include sign language experts, teachers, and students learning sign language at special schools. The participants were asked to perform a set of pre-defined sign language words in front of a camera. They must express sign language words naturally, as they use them daily. Before data collection, we provided training to ensure their understanding through experts and guiding teachers, thus ensuring the accuracy and quality of the PVSL dataset. Video data were collected from 12 participants performing sign language gestures. All participants understood sign language, including five who were deaf-mute. Videos were captured at a resolution 1920x1080 with a frame rate of 30 FPS. The video frames were carefully trimmed at the beginning and end to represent a sign language word accurately. The detailed statistics of the dataset are presented in Table I.

B. Model Description

Our proposed MISA architecture, illustrated in Fig. 2, is designed to combine several parallel language models with a pre-trained image recognition model. The key challenge is to establish a connection between images and text captions to generate a multimodal interpretation that supports sign language recognition. To overcome this challenge, we have integrated two models: an image-to-text projection model and a language model that facilitates sign language recognition. We will now provide a detailed description of our model, outlining the three architectural components: (i) A language model for learning text features, (ii) An image-to-text transfer model, and

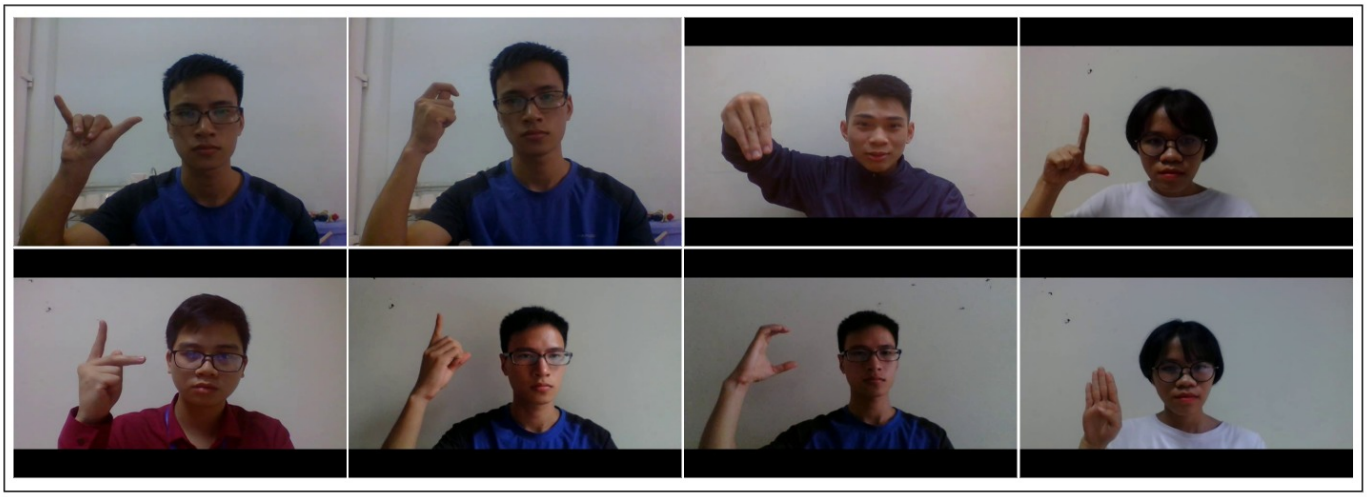

Fig. 1. The illustrative images of the PVSL dataset depict variations in lighting conditions, different backgrounds, and signers with diverse appearances.

TABLE I. OVERVIEW OF WORD-LEVEL DATASETS IN OTHER LANGUAGES

Dataset	#Signs	#Videos	#Signers	Type	Sign Language
CSL-Daily [14]	1,066	8,257	9	RGB	Chinese
PHOENIX14T [37]	2,000	20,654	10	RGB	German
PVSL (our dataset)	50	5068	12	RGB	Vietnamese

(iii) A model that merges the two aforementioned components (i) and (ii) into a prediction model.

The language processing model: We use a Transformer-based encoding scheme to encode textual information in this model. To do this, we first tokenize the text into vocabulary units and then into token sequences x. Subsequently, we embed these tokens into a D-dimensional space, which captures contextual information (as shown in Eq. 1). These token embeddings are then mapped with a mask to help classify words based on their distributional properties. This model plays a crucial role in helping us understand information from videos that support sign language recognition.

$$e = WordEmbedding(x) \tag{1}$$

The video processing model: The video is divided into frames, denoted by $f = f_i^T_1$. Each frame is then processed by an encoder to generate feature vectors, $v = v_i^T_1$, using Eq. 2. We use the ViT encoder [10] with a resolution of 224x224 per frame. Additionally, we incorporate a mapping between images and image descriptions obtained from over 300 million image-text pairs crawled from the internet. The encoder's parameters remain fixed throughout the experimentation process.

$$v_{1:T} = Encoder(f_{1:T}) \tag{2}$$

The integration of Language Processing Model and Video Processing Model: The video features are turned into short answer sentences using a language model. These answers are obtained by mapping video features linearly through an image-to-text projection. The answers are then combined with previous texts and passed through the Transformer encoder to improve sign language recognition results. In the Transformer encoder section, we merge the question with the answer to enhance the accuracy of sign language recognition on the video. To achieve this, the model learns strong multi-modal interactions while maintaining the Transformer's encoding weight sets. We normalize the preceding layer before passing it through the self-attention layer, and each layer is directly fed into the pre-encoder Transformer. As a result, the accuracy of sign language recognition on the video is significantly improved.

C. State Space Model (SSM)

The Structured State-Space Model (SSM), as shown in Fig. 3, is a new type of sequence model in deep learning. It encompasses recurrent neural networks (RNNs), convolutional neural networks (CNNs), and classical state-space models combined with self-attention. These models are inspired by a continuous system that maps a function or one-dimensional sequence, $x_t \in \mathbb{R}$, to $y_t \in \mathbb{R}$, using an unknown hidden state $h_t \in \mathbb{R}^N$.

The structure of SSM independently maps each channel (e.g., D = 5) of the input x to the output y through hidden states of higher dimension h (e.g., N = 4). Previous SSMs avoided realizing this large effective state (DN, multiplied by the batch size B and sequence length L) through intelligent alternative computational paths that require time-invariant parameters that remain constant over time.

D. Loss Function

In the previous section, we discussed training a model for sign language recognition. This is a difficult task because generating answers from videos is not a straightforward

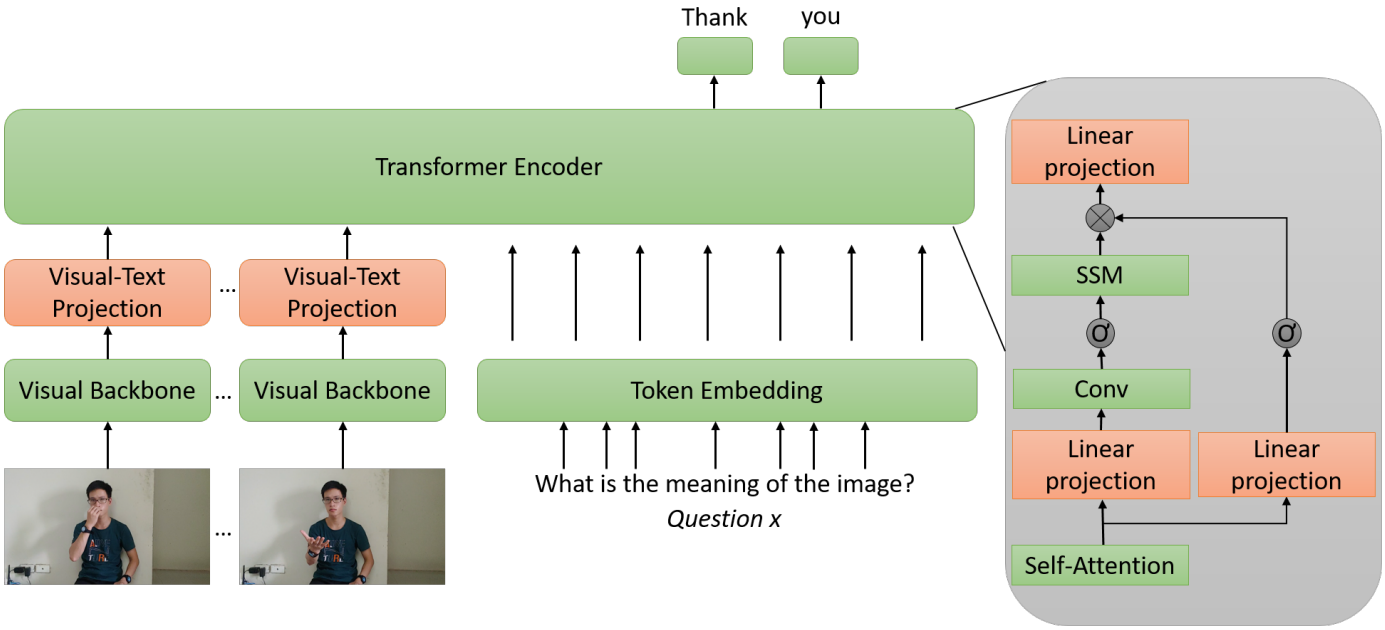

Fig. 2. The framework of the proposed MISA.

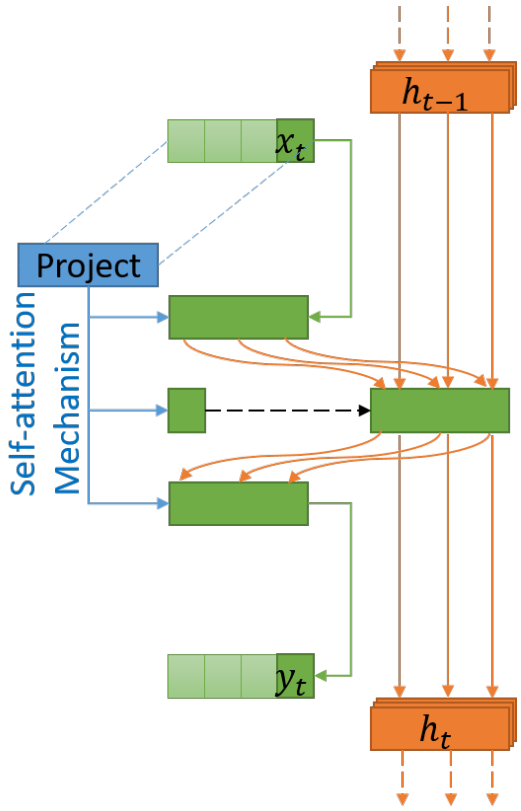

Fig. 3. Structured State Space Models (SSMs).

process, and real-world data can be hard to recognize. To tackle this challenge, we used image-answer pairs from the internet, which are relatively easy to collect and incorporate into training. We trained the model using the parameters of the image-to-text projection model and the combined and coordinated model. To achieve this, we used a language model objective function with a masked image. In this function, x_m represents segments of masked text that need to be predicted, and the model must predict these segments along with the corresponding image content. In terms of computation, we constructed the loss function $L(x, y)$ as follows Eq. (3):

$$L(x, y) = -\frac{1}{N} logp(\hat{x}, y)_m^{x_m} \tag{3}$$

where $\hat{x}$ is the text-encoded sequence from the question, y is the video frame sequence, $p(\hat{x}, y)_m^{x_m}$ is the probability for the m-th token (masked) in x to be x_m, and N is the number of masks in the $\hat{x}$ sequence.

IV. Experiments

A. Experimental Setup

MISA model: We employed a parallel language model with 370 million parameters, Mamba [35], trained with the MLM objective on a 160G text corpus and tokenized using SentencePiece [36] with a vocabulary size of V = 128,000. The input of the MISA model consists of a question about sign language recognition and a video. The task is to find the correct answer from a vast vocabulary set A comprising approximately 2,000 answers. The answers are all concise, meaning that most answers consist of only one or two words of sign language recognition. A token [CLS] and a token [SEP] are added respectively at the beginning and end of each text sequence. Meanwhile, [MASK] represents the sign language word being sought. We design the following prompt:

"[CLS] Question: <Question>? Answer: The action of sign language is <Answer Candidate> [MASK]. Subtitles: <Subtitles> [SEP]"

Datasets:To conduct our training, we utilized the publicly available WebVid10M dataset [42], comprising 10 million pairs of video-text, where video annotations are derived from available alternative descriptions. Additionally, we generated 20 thousand pairs of video-text from two datasets: CSL-Daily [14] and PHOENIX14T [37] leveraging Image Captioning technology [38]. We evaluated the outcomes on a subsequent dataset encompassing various text and video domains, namely PVSL (our dataset).

Evaluation Metric: We use Word Error Rate (WER) as the evaluation metric, as shown in Eq. 4. Note that the lower WER, the better accuracy.

$$WER = \frac{sub + ins + del}{ref} \tag{4}$$

In which, sub represents substitution, ins represents insertion, and del represents deletion. These operations are essential for transforming the predicted sentence into the reference sentence. Hence, ref denotes the reference sentence.

B. Experimental Results

Our empirical study in this subsection is designed to answer three key research questions (RQs).

- RQ1. How does the MISA model improve the performance of sign language recognition compared to current state-of-the-art methods?
- RQ2. How does each scenario in MISA contribute to correct deep learning?
- RQ3. How can deep learning (DL) be visualized, including t-SNE plots of features and distribution plots of predicted scores from the MISA model?

1) Comparison With State-of-the-Art Approaches (RQ1): Table II compares our MISA model and other state-of-the-art methods comprehensively. We evaluated five different methods for the sign language recognition task on videos. Our observations indicate that MISA outperforms other state-of-the-art methods across all three datasets. This superiority is achieved through the attention mechanism within the MISA model, which focuses on the different body gestures of participants. The ability to reduce noise between frames in the video through a propagation or selective forgetting mechanism along the sequence length also contributes to this outperformance. Additionally, MISA demonstrates faster processing speed compared to competitive methods due to its rapid inference capability (processing speed up to five times faster than the traditional Transformer model) and linear scalability with sequence length. The MISA model exhibits significant performance improvements on real-world datasets, even on longer sequences, without incurring additional training costs.

2) Applicability to Fringe Scenarios (RQ2): We initialize the parameter set from a pre-trained language model and fine-tune it with the scenarios outlined in Table III. We have observed that leveraging pre-trained weights from previous successful language models plays a crucial role in our proposed architecture. The model initialized solely for video recognition of sign language (line 1 - the first scenario) exhibits inferior performance compared to the model initialized with combined weights (lines 2 and 4). Notably, the model trained in the second scenario, combining the language and video processing models, outperforms the variant in the third scenario and falls slightly behind the fourth scenario. This observation suggests that integrating video and text as input for the model can yield significant effectiveness. Additionally, the combination in the third scenario (line 3) demonstrates favorable outcomes when integrating the video processing model with the state space model. Ultimately, our proposed MISA model (line 4 - the fourth scenario) illustrates that amalgamating multi-input and self-attention in the state space is the most effective approach for video sign language recognition.

3) Qualitative Study (RQ3): In order to showcase the effectiveness of our method, we used t-SNE [43] to create a visualization of the recognition results obtained from the MISA model on the PVSL test set. The original data from the test set was processed through the MISA model to create a new data dimension. The feature vector size, in our case, was 12288. Next, the data was passed through the MISA model corresponding to the 50 primary training labels, after which t-SNE was used to project and visualize the reduced features in a 2D space. The resulting Fig. 4 provides strong evidence of the superior performance of the combined features with our MISA model.

V. Conclusions

This paper introduces the MISA model, a framework for extending the language model that combines multi-data and self-attention in the state space model (SSM). We trained this model on our self-collected dataset PVSL and data collected from multiple sources. We aimed to address the sign language recognition problem for the deaf-mute community in the context of Video Question Answering (VideoQA). We also conducted an in-depth analysis to demonstrate the effectiveness of our MISA model, which enhances accuracy on three popular sign language datasets.

However, our study has some limitations. First, MISA is quite large, making it impractical for deployment on mobile devices. Second, our model is unable to handle videos with multiple individuals performing sign language. In the future, we aim to enhance the model's efficiency based on unsupervised learning and implement dimensionality reduction methods for video data, which will enable better learning and higher-quality results.

Improving Chicken Disease Classification Based on Vision Transformer and Combine with Integrated Gradients Explanation

Huong Hoang Luong, Triet Minh Nguyen
Information Technology Department
FPT University, Can Tho, Viet Nam

***Abstract*—Chicken diseases are an important problem in the livestock industry, affecting the health and production performance of chicken flocks worldwide. These diseases can seriously damage the health of chickens, reduce egg production, or increase mortality, causing great economic losses to farmers. Therefore, detecting and preventing diseases in chickens is a top concern in the livestock industry, to ensure the health and sustainable production of chicken flocks. In recent years, advances in machine learning techniques have shown promise in solving challenges related to image diagnosis and classification. Leveraging the power of machine learning models, we propose the ViT16 model for disease classification in chickens, demonstrating its potential in assisting healthcare professionals to diagnose chicken flocks more effectively. In this study, ViT16 demonstrated its potential and strengths when compared with 5 models in the CNN architecture and ViT32 in the ViT architecture in the task of classifying chicken disease images with an accuracy of 99.25% - 99.75% - 100% - 98.25% in four experimental scenarios with our enhanced dataset and fine-tuning. These results were generated from transfer learning and model tuning on an augmented dataset consisting of 8067 images classified into four classes: Coccidiosis, New Castle Disease, Salmonella, and Healthy. Furthermore, the Integrated Gradients explanation has an important role in increasing the transparency and understanding of the image classification model, thereby improving and optimizing model performance. The performance evaluation of each model is done through in-depth analysis, including metrics such as precision, recall, F1 score, accuracy, and confusion matrix.**

***Keywords*—Vision Transformer; ViT16; classification chicken disease; transfer learning; fine-tuning; image classification; integrated gradients explanation**

I. Introduction

Chicken diseases are one of the important and worrying problems in the poultry industry. Chickens are considered one of the most important types of livestock, providing the main source of food for humans worldwide [1]. However, chickens often encounter a variety of infectious and non-infectious diseases that affect their health and production performance. The importance of chickens in livestock farming comes not only from the aspect of providing meat and eggs to consumers but also from the ability to create stable income for farmers [2]. Chickens provide an important source of income for farmers and breeders around the world, especially in rural and agriculturally developed areas [3]. However, when chickens get sick, the consequences can reduce productivity and product quality, causing great economic loss for farmers [4] [5]. Chicken diseases can spread quickly in chicken flocks, leading to mass deaths and reducing the economic value of chicken flocks. Using artificial intelligence and machine learning methods, technology can be used to diagnose chicken diseases early as an important method to control and prevent the spread of infectious diseases in chicken flocks [6] [7] [8]. Technology helps detect disease symptoms early, thereby allowing farmers to implement timely control and treatment measures, helping to minimize losses and increase livestock performance.

The Food and Agriculture Organization (FAO) projects that worldwide chicken meat output will be 103.5 million tons in 2012, accounting for approximately 34.3% of global meat production. A survey in the [9] study was carried out with households affected by severe aspergillosis. Data were collected from February 2018 to July 2019 from 183 households. The average risk of disease and mortality is 39% and 26% in chickens, 42% and 22% in turkeys, respectively, with young birds having a higher risk of disease and mortality than young birds. adult poultry. This loss causes economic losses in the chicken industry due to increased mortality, reduced meat and egg production, and poor growth. Viral infections, including Newcastle disease, infectious bursal disease, and avian influenza lead to economic costs in poultry farms, including bird losses, lower productivity, and employment losses [10]. Poultry farming is impacted by several viral, bacterial, parasitic, and fungal infections, which result in reduced appetite, weight loss, lower egg production, and greater mortality, leading to significant economic losses [11]. The highly pathogenic avian influenza epidemic in the United States led to fewer jobs, poorer productivity, and decreased tax collections, hurting both infected and non-infected farms [12]. The resurgence of Newcastle disease in village chicken populations in Tanzania caused major economic losses for small and medium farmers, affecting their predicted earnings and resulting in considerable economic burdens [13].

Advancements in machine learning approaches, such transfer learning [14] and fine-tuning [15], are increasingly being used to improve detection and classification accuracy. Transfer learning enables models pre-trained on big datasets to be applied to new tasks with less labeled data, making it ideal for medical imaging applications where annotated datasets are rare. Fine-tuning pre-trained models by modifying their parameters to better match the unique characteristics of the target task, resulting in improved performance. Huong Hoang Luong et al. [16] [17] [18] used fine-tuned transfer learning to categorize human skin, monkeypox, and brain tumors in

the international medical field. By combining these machine learning algorithms into picture categorization, doctors may increase diagnosis accuracy, minimize screening time, and provide better patient care.

Vision Transformers (ViT) [19] represent a recent advancement in the realm of computer vision, offering a novel approach to image recognition tasks [20]. Unlike traditional Convolutional Neural Networks (CNNs), ViT utilizes a self-attention mechanism to capture long-range dependencies in images, enabling effective feature extraction and representation. This architecture consists of multiple Transformer blocks, each containing self-attention layers and feed-forward neural networks. By leveraging self-attention, ViT can effectively process images without relying on spatial hierarchies, making it suitable for tasks such as image classification, object detection, and segmentation [21]. The ViT16 model, in particular, is a variant of the Vision Transformer architecture that has demonstrated impressive performance in various computer vision tasks. It consists of 16 Transformer blocks, each with self-attention layers and feed-forward neural networks. Through extensive training on large-scale datasets, ViT16 has learned to extract informative features from input images and make accurate predictions. Moreover, ViT16 has shown robustness to variations in image content and background noise, making it suitable for real-world applications in medical image analysis.

In this study, we will use the Integrated Gradients explanation. Integrated gradients were proposed by Sundararajan et al. [22] to explain the predictions of our machine learning model. Interpretation is an important part of understanding and enhancing model transparency, especially in medical applications like ours. By explaining, we will have a more detailed look at how the model makes decisions, helping us better understand predictions and increasing the model's reliability in diagnosing and treating diseases. disability.

In this study, we suggested the ViT16 model of the Vision Transformer (ViT) to detect and classify diseases in chickens. In addition, we have deployed five well-known accumulated neural network (CNN) models (EfficiencyNetB3, ResNet50, VGG16, MobileNet, and InceptionV3) and ViT32 models of the ViT architecture to evaluate and compare with the model we have proposed.

The contributions of the work are:

- This study presents four scenarios to evaluate the classification efficiency of three common diseases. The classification of healthy and coccidiosis is carried out according to the first scenario. In the second scenario, we classify Healthy and New Castle Disease. The classification of healthy and salmonella is carried out in the third scenario. In the final scenario, we classify all four classes, including healthy, coccididiosis, new castle disease, and salmonella. The purpose of implementing these four scenarios is to determine whether the ViT model is effective when classifying each class individually or multiple classes at the same time. We propose a Vision Transformer transfer learning model based on the pre-trained ViT16 architecture for chicken disease image classification. By fine-tuning the model, we achieve promising results, surpassing other CNN architectures with accuracies up to 99.75% - 99.75% - 100% - 98.25% in four scenarios. This demonstrates the effectiveness of the ViT16 model for image classification, even without task-specific fine-tuning, achieving a transfer learning accuracy of 93%. Furthermore, fine-tuning the ViT models leads to a significant improvement in performance, increasing the accuracy from 93% to 98.25%.
- Demonstrate the effectiveness of the proposed model (ViT16) by implementing comparisons with five famous convolutional neural network architectures (EfficientNetB3, ResNet50, VGG16, MobileNet, InceptionV3) and a ViT32 model of the Vision architecture Transformer in the same setting.
- Experimental results show that the Integrated Gradients explanation is useful in helping to better understand how the model makes decisions by explaining how each pixel or feature affects the final prediction. Thanks to that, we can identify important areas in the image that the model pays attention to to make predictions. Integrated Gradients create transparent and easy-to-understand explanations, helping to increase confidence and trust in the model's predictions. This is especially important in medical and security applications, where transparency is extremely important.
- Early diagnosis will allow timely intervention and treatment measures, thereby minimizing mortality and loss in the herd. At the same time, preventing the spread of infectious diseases in chicken flocks will also play an important role in protecting health and improving food product quality. In addition, early diagnosis will also help optimize resource management and use in livestock operations, reduce waste, and increase production efficiency. This will have a positive impact on the food economy, helping to maintain and develop the livestock industry in a sustainable way.

There are five primary components to our study report. This section gives some general information about the research and discusses the approach to addressing the given difficulty. Section II includes references to related research, and the approach follows the relevant research section. Section III discusses each of the methodologies used in this paper. Section IV will discuss the experiments, including how we execute them and evaluate the deep learning model's correctness. Finally, in Section VI, we synthesize our findings and discuss the most essential parts of the research.

II. Related Works

The utilization of thermal-image processing and machine learning techniques for the detection and classification of avian diseases in chickens has gained significant attention in recent research. One notable study by M Sadeghi et al. [23] explored the application of support vector machines (SVM) and artificial neural networks (ANN) for disease classification in 14-day-old Ross 308 broilers infected with Newcastle Disease (ND) and Avian Influenza (AI), with two additional control groups included in the study. The paper demonstrated promising results, achieving high accuracy rates within 24 hours of virus infection. Specifically, SVM achieved an impressive accuracy of 97.2% for classifying AI and 100% accuracy for classifying

ND. These findings highlight the potential of machine learning algorithms for early disease detection and classification in poultry farming, contributing to improved disease management and prevention strategies.

The proposed paper [24] addresses the critical issue of early detection and classification of poultry diseases using deep learning techniques and image analysis of chicken fecal images. The model achieved an impressive accuracy of 97% utilizing the DenseNet method, showcasing its potential for practical poultry diagnostic applications. The dataset used for training and evaluation consists of 6812 images belonging to four different classes: healthy chicken, Coccidiosis, Salmonella, and Newcastle. Despite the significant progress in the field, there is a need for further research to explore the robustness and scalability of the proposed model across different poultry disease datasets and real-world scenarios.

Hoang Ngoc Tran et al. [25] present a novel approach utilizing the autoencoder and YOLOv6 model for the classification and detection of diseases in chicken flocks. The method achieved remarkable results, with an average accuracy of 99.15% and over 90% accuracy on the test dataset. The proposed approach demonstrates its versatility by being suitable for different chicken breeds from various countries and regions. This innovative method holds promise for improving the efficiency and accuracy of disease detection and classification in poultry farming, contributing to better management practices and disease control strategies. However, further studies are needed to validate the robustness and scalability of the proposed method across diverse poultry farming environments and disease scenarios.

The paper of Eduardo Carvalho Lira et al. [26] introduces a novel deep learning-based system designed for the early detection and classification of chicken diseases, including Salmonella, Coccidiosis, Healthy, and New Castle Disease. The study explores various convolutional neural network (CNN) models for categorical classification, with a focus on identifying the most efficient model based on the ratio of Maximum Validation Accuracy (MVA) to Least Validation Loss (LVL). Among the models evaluated, the ChicNetV6 model emerged as the best performer, achieving an efficiency score of 2.8198 and an impressive accuracy score of 94.49%. Notably, the total training time for the ChicNetV6 model was recorded at 1125 seconds, demonstrating its efficiency and computational feasibility. This research contributes to the advancement of automated disease detection and classification systems in poultry farming, with potential implications for enhancing disease management and prevention strategies in the industry. Further investigations may be warranted to assess the scalability and generalizability of the proposed system across different poultry farming environments and disease scenarios.

Nianpeng He et al. [27] presents a novel solution aimed at predicting diseases in chickens through the analysis of fecal images using deep Convolutional Neural Networks (CNN). Leveraging the XceptionNet deep learning framework, the proposed model demonstrates superior performance compared to other models, achieving an impressive accuracy rate of 94%. By leveraging pre-trained models and tailoring them to address the specific challenges of poultry disease prediction, the study contributes to the development of effective tools for early disease detection in poultry farming. The proposed model holds promise for application in real-world scenarios, offering a valuable resource for poultry disease detection and management. Further research may explore the scalability and applicability of the model across different poultry breeds and disease types, with potential implications for enhancing disease surveillance and control in the poultry industry.

Although the article [28] focuses on classifying poultry eggs using deep learning techniques, it does not go into the classification of diseases in chickens. The study proposes the use of Convolutional Neural Networks (CNN) in an unwashed egg classification system, classifying them into classes such as intact, cracked, soiled and soiled. The study compares the performance of three popular CNN architectures, ResNet34, ResNet50, and VGG19, using two different batch sizes (32 and 64) during training. Among the evaluated models, the VGG19 architecture achieved the highest accuracy of 97.33% when trained with a batch size of 64. While this study provides valuable insights into egg classification using deep learning, but its focus remains different from chicken disease classification, providing an additional perspective on the application of deep learning in poultry farming. Utilizing Convolutional Neural Networks (CNN) implemented in Keras/TensorFlow, Study of Moch. Kholil et al. [29] achieved an impressive accuracy rate of 95.28% in accurately predicting the classification of infectious diseases suffered by chickens. The research highlights the effectiveness of CNNs in disease classification tasks, particularly in the context of poultry farming. This work contributes valuable insights into leveraging deep learning techniques for disease diagnosis and monitoring in poultry, demonstrating the potential of advanced technology in enhancing animal health management practices.

Huong Hoang Luong et al. study in machine learning diagnostics is significant for us. In [30], Huong Hoang Luong and colleagues proposed a strategy using a model we propose as Vision Transformer (ViT), which has recently been improved by applying transfer learning methods. delivered to create strawberry disease.. The research's objective is to train this model to detect certain illnesses while fine-tuning the outcomes to attain high accuracy. The strawberry photographs in the collection are organized into seven categories, with a focus on strawberry leaf, fruit, and flower illnesses. The ViT model outperformed a comparable strategy for strawberry illness classification, with 92.7% accuracy on the Strawberry Disease Detection dataset.

The paper [31] presents a novel system for detecting and classifying poultry diseases, integrating two core algorithms: YOLO-V3 for object detection and ResNet50 for image classification. YOLO-V3 segments regions of interest (ROIs) from fecal images, while ResNet50 classifies the segmented images into four health conditions: Healthy, Coccidiosis, Salmonella, and New Castle Disease. Training is performed on a dataset of 10,500 chicken fecal images from the Zenodo open database, with oversampling and image augmentation techniques used to address class imbalance. YOLO-V3 achieves a mean average precision of 87.48% for detecting ROIs, and ResNet50 achieves a classification accuracy of 98.7%. Experimental results demonstrate the system's ability to accurately identify prevalent poultry diseases, offering potential support to poultry farmers and veterinarians in farm settings.

III. Methodology

A. The Research Implementation Procedure

Overall, in this study, we used a combination of 11 processes to produce the results, the main processes are shown in Fig. 1. Details of the steps are given below:

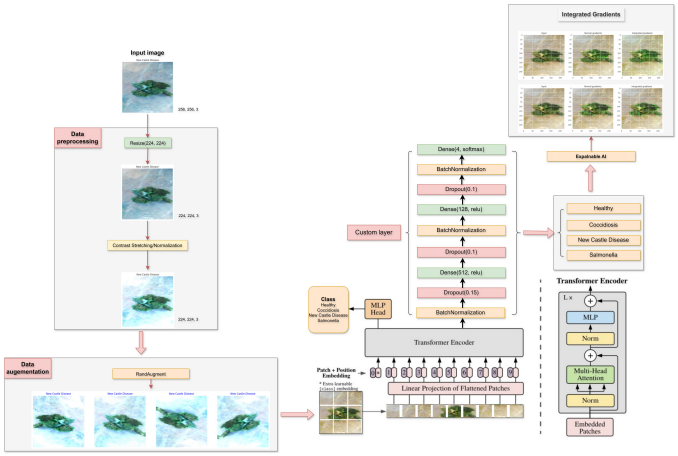

Fig. 1. Proposed architecture.

1) *Data collection:* Choosing an appropriate dataset is critical in the field of machine learning since it has a direct impact on model performance and generalizability. A high-quality dataset guarantees that the model is trained on a wide and representative sample set, allowing it to discover strong patterns and make accurate predictions in real-world circumstances. In the case of chicken illness detection, using the correct dataset enables researchers to create models that can accurately diagnose chicken diseases from photos, allowing for prompt treatment and resolution.
2) *Pre-processing Data:* Use image preprocessing techniques, for example, adjusting brightness and contrast to increase the quality and visibility of images, making them more suitable for future classification tasks. Change the input size to 224x224x3 to ensure synchronization, and use the random function in the Keras library for further processing.
3) *Dividing dataset into three categories train, validation, and test:* To ensure robust model training, validation, and evaluation, the dataset is divided into three subsets: training, validation, and test. The training set, which comprises 80% of the data, is utilized for model training. Meanwhile, the validation set, consisting of 10% of the data, is employed to monitor training progress and fine-tune the model to prevent overfitting. Finally, the test set, also comprising 10% of the data, is reserved to assess the final model's performance on previously unseen data. Stratified splitting is employed to maintain a balanced representation of classes across all subsets, facilitating effective model training and evaluation.
4) *Data Augmentation:* To augment the dataset, enhance its diversity, establish credibility, and mitigate overfitting, a range of data augmentation techniques are employed. The objective is to multiply the number of images fourfold, thus expanding the dataset from the initial 2000 images to a later count of 8000. This augmentation process encompasses the creation of new training samples through the application of diverse transformations and modifications to the existing images. This methodology effectively expands the dataset without necessitating the collection of additional data.
5) *Building the model:* To carry out the experiment, we utilized five convolutional neural network (CNN) architecture models and two Vision Transformer models. We keep the model's fundamental processing layers while making the required changes to improve its performance for our unique goal. This personalized strategy enabled us to obtain outstanding outcomes when training and testing with Keras' model library.
6) *Applying Transfer learning*: Transfer learning enables the utilization of pre-trained models that have been trained on similar tasks, such as general image classification. These models have already acquired fundamental features from large datasets, thereby saving time and effort that would otherwise be required to train a model from scratch. By leveraging pre-trained models, the amount of engineering work and resources needed to deploy the model across health systems is significantly reduced.
7) *Retrain the model with Fine-Tuning:* Fine-tuning involves tweaking the parameters of a pre-trained model to better align with a specific task. Nonetheless, to implement these adjustments and enhance the model's performance, re-training is essential. The model is fine-tuned to optimize performance for the targeted task. Re-training facilitates further learning from additional data, enhancing the model's ability to generalize and make accurate predictions on unseen data.
8) *Validate and collect metrics to evaluate the model:* By analyzing metrics like accuracy, precision, recall, and F1-score, it is possible to assess how well our model performs on data it has not been trained on. This assessment process helps in evaluating the model's effectiveness on the test dataset and offers insights into its performance under different circumstances. The conclusions drawn from the evaluation phase guide modifications to the model's hyperparameters, such as the learning rate, number of epochs, batch size, and neural network structure. These modifications are suggested based on the evaluation outcomes, with the goal of improving the model's performance and ensuring its ability to generalize to new data.
9) *Visual explanation by Integrated Gradients:* Integrated Gradients create easy-to-understand explanations for machine learning model predictions by calculating the influence of each input feature on the final prediction. By providing information about how each input feature contributes to the final prediction, Integrated Gradients help increase the transparency of the machine learning model. This can be useful in medical, financial and legal applications where transparency is important.
10) *Comparison with other advanced methods:* Comparing with other advanced techniques aids in assessing

model performance and gauging the effectiveness and novelty of the proposed approach relative to already explored and recognized methods. This enables the evaluation of which aspects of your strategy are more efficacious than others and which ones necessitate modification.

11) *Showing the result:* The outcomes and visual representations post comparison will be presented through confusion matrices, line graphs, and tables. These results illustrate the model's real-world performance and its effectiveness in diagnosing chicken disease.

B. Pre-processing Image

Pre-processing plays a crucial role in preparing image data for machine learning tasks as it enhances the quality, consistency, and informativeness of the images, thereby improving model performance. In our study, we conducted the following data pre-processing steps:

1) *Resize image:* A critical component of image preprocessing is ensuring uniform input size. To accomplish this, we resized all images to a consistent size of 224 pixels in width and 224 pixels in height, as determined by (Eq. 1):

$$I_{ReSize}(new_{width}, new_{height}) = I_{ReSize}(224, 224) \tag{1}$$

2) *Add Weighted:* We adjusted the brightness of the photos by -0.15 to improve the visibility of essential elements, especially in darker locations. This minor change demonstrated in (Eq. 2) improves feature visibility while preserving overall contrast.

$$B_{adjusted} = B_{original} - 0.15 \tag{2}$$

We used a contrast enhancement factor of 1.8 to highlight the differences between successive pixel intensities. This stage reveals tumor borders and structural features, facilitating precise diagnosis and categorization. In (Eq. 3), double the original contrast value by 1.5 to increase contrast. This factor can be fine-tuned based on the image content and desired amount of focus on differences in pixel intensities.

$$C_{adjusted} = C_{original} * 1.5 \tag{3}$$

3) *Data Augmentation:*
We used data augmentation techniques to scale the generated training dataset by making various changes on the input samples. First, we extracted 500 images as a subset for each class because the proportion of images of the four classes is not equal, this avoids leading to data imbalance as well as the model's learning ability. Common enhancement methods then include geometric transformations such as rotation, scaling, and flipping, as well as color and contrast adjustments. Finally, we obtained the result that the number of original images increased from 2000 to 8000 images. By expanding the data set, the model is exposed to more variables and situations, leading to better generalization and performance in real-world applications. In summary, data augmentation is a crucial method that enhances the performance and generalization capacity of machine learning models, particularly in scenarios where extensive and varied datasets are lacking.

C. Transfer Learning and Fine-Tuning of our Proposed Model

Transfer learning refers to a technique in machine learning and deep learning where a model is initially trained on a large dataset and then repurposed (transferred) to address a related or similar problem. Rather than commencing training from scratch with a small dataset, transfer learning enables leveraging the insights and knowledge acquired from prior training on extensive datasets to enhance the model's performance on a new dataset [32]. Throughout the training process, existing model parameters are reused. Consequently, transfer learning utilizes the pre-trained model layers instead of initiating training anew, thereby enhancing the model's accuracy.

After applying transfer learning, fine-tuning the model can help improve results. Fine-tuning involves adjusting and updating certain parts of the pre-trained model, such as the final layers, to better suit the specific problem at hand. To preserve the ability to extract low-level features acquired during pre-training, the initial layers of the model are often frozen during this process. By freezing these layers, the focus of adaptation shifts to the later layers, which are responsible for task-specific learning, thereby maximizing the effectiveness of training. Additionally, fine-tuning requires adjusting hyperparameters, such as the number of training epochs, batch size, hidden layer configuration, and learning rate, to optimize model performance and prevent overfitting.

We used a hyperparameter search to fine-tune the model in order to get the best results without overfitting. The many combinations of training epochs, batch sizes, hidden layer configurations, and learning rates were investigated in this search. The following hyperparameters were chosen based on the findings in order to achieve a decent balance between training efficiency and performance:

- Training epochs: 20
- Number of batches: 16
- Hidden layer set up: [512, 128]
- Rate of learning: defaut.

During fine-tuning the model, we unlock and tune the last 20 layers of the model without adjusting the rest of the model. The main reason is that the final layers often contain more complex and specific information about the data of the specific task we are training the model for. After unlocking and fine-tuning the last 20 layers, we added a custom layer set consisting of nine layers of three layer types Dense, BatchNormalization, Dropout. Our architecture is depicted in Fig. 2 By adjusting only the final layers, we can preserve the more general and abstract features learned from big data and only adjust them to suit our specific task. This helps minimize the risk of overfitting and increases the generality of the model on new data sets.

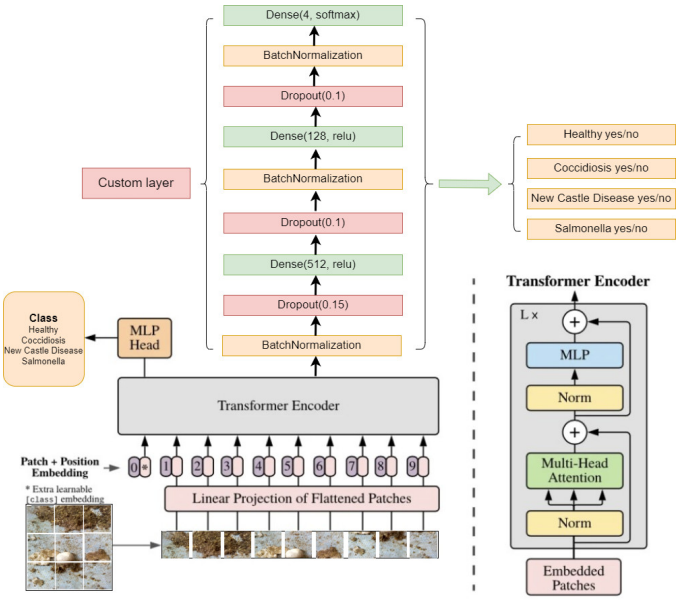

Fig. 2. Fine-tuning architecture.

D. Visual Explanation by Integrated Gradients

The need to use explanations is to better understand how the model makes decisions and makes predictions. This enhances model transparency and reliability, especially in fields such as healthcare, where a detailed explanation of the decision-making process can be extremely important for diagnosis and treat diseases.

Integrated Gradients is a method for explaining machine learning model predictions, used to understand the model's decision-making process based on inputs. This method calculates the importance of each input feature by integrating over the path from the reference point to the data point under consideration. When calculating, each feature is gradually changed from its reference value to its current value, helping to determine how each feature affects the model's final prediction.

Integrated Gradients have many advantages over other interpretation methods. First, it is computationally efficient and easy to understand, allowing to determine the importance of each feature accurately. Second, this method does not require specific information about the structure or characteristics of the model, making it flexible and applicable to many different types of machine learning models. Finally, Integrated Gradients enable both quantitative and qualitative interpretation, providing a comprehensive view of how the model makes decisions.

The use of Integrated Gradients has been used in various machine learning models, including deep neural networks, to enhance transparency and interpretability [33] [34]. The approach is suitable for both regression and classification models. When dealing with a non-scalar output, as seen in classification models or multi-target regression, the gradients are computed for a specific element of the output. In classification models, the gradient typically pertains to the output associated with the true class or the class predicted by the model.

Let's suppose we have an input instance x_1 a baseline instance x' and a model $M : X \to Y$ that operates on the feature space X and generates an output y in the output space Y. Now, let's define the function F as

- $F(x) = M(x)$ if the model output is a scalar;
- $F(x) = M_k(x)$ if the model output is a vector, with the index k denoting the k-th element of $M(x)$.

For instance, in case of a K-class classification, $M_k(x)$ is the probability of class k, which could be the true class corresponding to x or the highest probability class predicted by the model. The attributions $A_i\,(x, x')$ for each feature x_i with respect to the corresponding feature x_i' in the baseline are computed as shown in Eq. 4;

$$A_i\,(x, x') = (x_i - x_i') \int_0^1 \frac{\partial F\,(x' + \alpha\,(x - x'))}{\partial x_i} d\alpha \qquad (4)$$

In summary, employing Integrated Gradients for visual explanations provides a promising method to improve the transparency, accountability, and reliability of machine learning models, thereby enhancing their utility and credibility in real-world applications. As illustrated in Fig. 3, analyzing the contribution of individual feature maps to the final decision provides valuable insights that experts and clinicians can leverage in future endeavors.

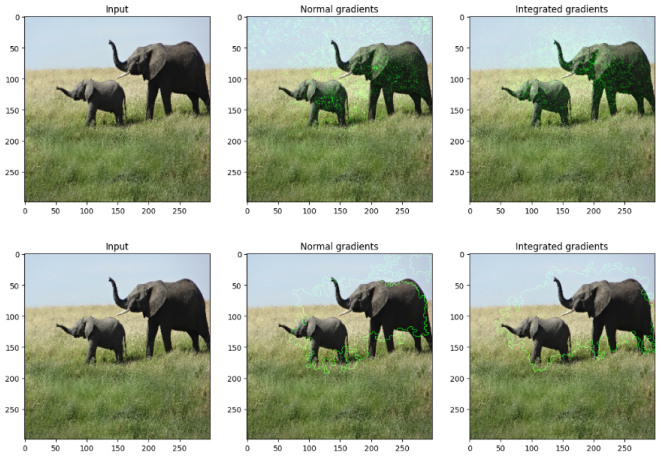

Fig. 3. The sample applying integrated gradients by keras library.

IV. Experiments

A. Dataset and Performance Metrics

An annotated dataset on poultry disease diagnostics for small and medium-sized poultry farmers includes images of poultry feces. Images of poultry droppings were taken in the Arusha and Kilimanjaro regions of Tanzania between September 2020 and February 2021 using the Open Data Kit (ODK) mobile app. The data set contains 8067 images, divided into 4 classes in Fig. 4: Coccidiosis(30.4%), Healthy(29.5%), New Castle Disease(7.8%), Salmonella(32.3%).

Due to imbalance in the data set, we randomly selected 500 images for each class to use for training. It is important to provide a variety of representations while reducing the risk of overfitting and improving the generalizability of the model. After image preprocessing and data enhancement, we obtained

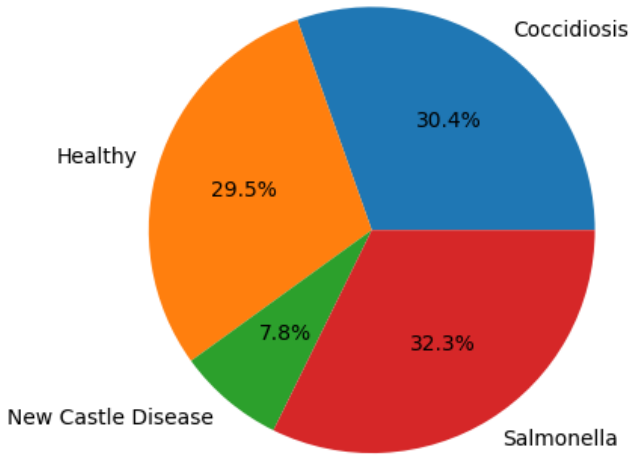

Fig. 4. Data set characteristics before processing.

a new dataset with 8000 images as shown in Fig. 5 from 2000 original images.

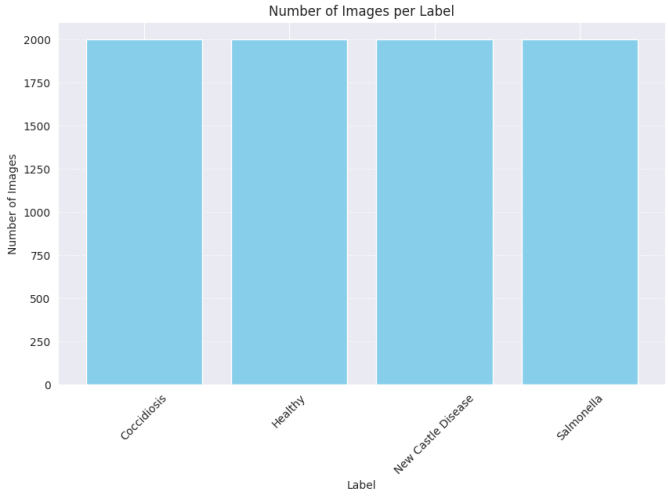

Fig. 5. Dataset characteristics after processing.

Evaluating the performance of a machine learning model is an important part of the research and implementation process. In the field of machine learning, there are many metrics used to evaluate the performance of a model, including Accuracy, Precision, Recall and F1-score.

Eq. 5 represents the ratio between the number of correct predictions and the total number of samples. Eq. 6 represents the accuracy of detecting Positive points. The higher this number, the more accurate the model receives Positive scores. Eq. 7 represents the ability to detect all positive, the higher this rate shows the lower the possibility of missing Positive points. Eq. 8 is a compromise number for Recall and Precision, used when it is necessary to consider both values, giving us a basis for choosing a model.

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \tag{5}$$

$$\text{Precision} = \frac{TP}{TP+FP} \tag{6}$$

$$\text{Recall} = \frac{TP}{TP+FN} \tag{7}$$

$$\text{F1} = 2 * \frac{Precision * Recall}{Precision + Recall} \tag{8}$$

These metrics offer a holistic perspective on the effectiveness of a machine learning model, enabling users to precisely assess its capability to make predictions and identify significant instances.

B. Scenario 1: Classification of 2 Classes (Coccidiosis and Healthy)

TABLE I. THE RESULTS OF CLASSIFYING IMAGES INTO 2 CLASSES COCCIDIOSIS AND HEALTHY IN TRANSFER LEARNING

Transfer learning Without Augmentation				
Model	**ACC**	**Precision**	**Recall**	**F1**
EfficientNetB3	69,00%	69,00%	69,00%	68,99%
ResNet50	92,00%	92,06%	92,00%	91,99%
VGG16	95,00%	95,16%	95,00%	94,99%
MobileNet	100,00%	100,00%	100,00%	100,00%
InceptionV3	98,00%	98,07%	98,00%	97,99%
ViT32	98,00%	98,00%	98,00%	98,00%
ViT16 (Our Proposed)	**98,00%**	**98,00%**	**98,00%**	**98,00%**
Transfer learning With Augmentation				
Model	**ACC**	**Precision**	**Recall**	**F1**
EfficientNetB3	71,50%	71,67%	71,50%	71,44%
ResNet50	94,75%	95%%	94,75%	94,74%
VGG16	96,75%	96,75%	96,75%	96,75%
MobileNet	100,00%	100,00%	100,00%	100,00%
InceptionV3	98,50%	98,50%	98,50%	98,50%
ViT32	99,50%	99,50%	99,50%	99,50%
ViT16 (Our Proposed)	**99,25%**	**99,25%**	**99,25%**	**99,25%**

In this scenario, we apply transfer learning and fine-tuning in both cases with and without data augmentation to classify Coccidiosis and Healthy of seven different machine learning models. The results obtained in the transfer learning part in Table I show the effectiveness of the model when trained on the data set after augmentation. The accuracy of the proposed model has been improved from 98% to 99.25%. A bright spot besides the proposed model is that the MobileNet model also achieves high efficiency when achieving 100% accuracy. Regarding the fine-tuning showed in Table II, we obtain the results before and after enhancing the data set respectively as 98.00%-98.75%.

Fig. 6 and Fig. 7 depict a graphical representation of the training accuracy and loss on the augmented dataset. Throughout the training process, the two curves intersect multiple times, illustrating the model's ability to strike a balance between learning from the training data and generalizing to new data. In general, both the training accuracy and loss curves exhibit a smooth behavior without any significant disparity, thereby indicating the model's suitability and robustness in terms of generalization capability.

TABLE II. THE RESULTS OF CLASSIFYING IMAGES INTO 2 CLASSES COCCIDIOSIS AND HEALTHY IN FINE-TUNING

Fig. 8 presents the confusion matrix of 400 test images of Coccidiosis and Healthy. Fig. 9 is the result of the Integrated Gradients explanation. Through the two pictures above, we can see the transparency of the training process as well as overfitting does not happen.

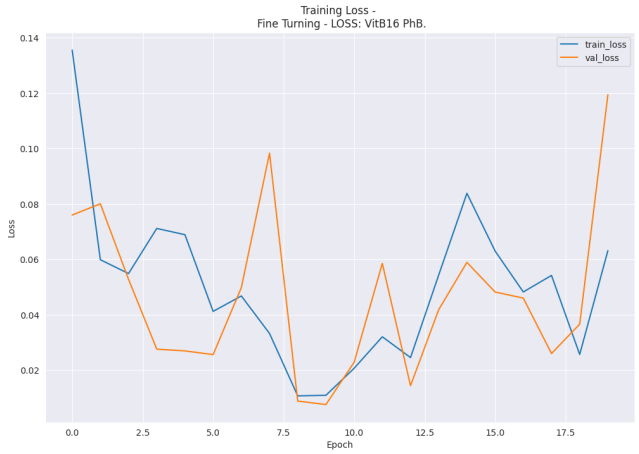

Fig. 7. Training loss and validation accuracy in fine-tuning of ours model (coccidiosis and healthy).

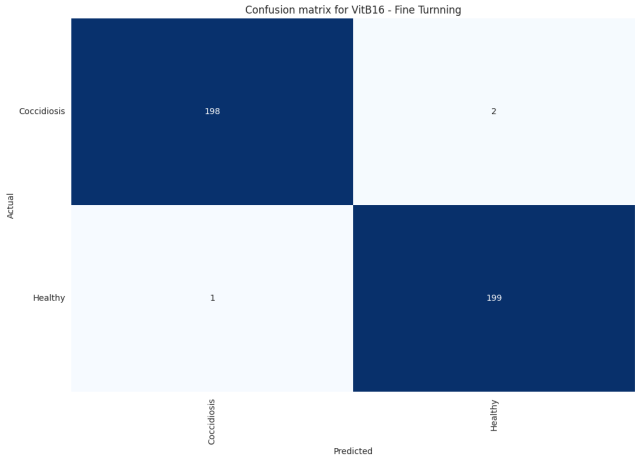

Fig. 8. Confusion matrix in fine-tuning of ours model (coccidiosis and healthy).

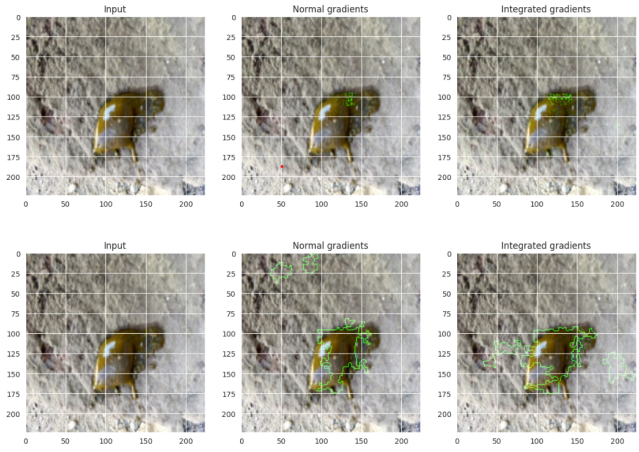

Fig. 9. Output of our model with integrated gradients explanation in scenario 1.

C. Scenario 2: Classification of 2 Classes (New Castle Disease and Healthy)

In this scenario, we classify the next two classes including New Castle Disease and Healthy. The scenario performs transfer learning and fine-tuning in both cases with and without data augmentation. The results obtained in the transfer learning part of the proposed model in Table III are 98.50% accuracy - an improvement of more than 3.5% compared to training on the original data set. Table IV also shows the effectiveness of fine-tuning when the obtained accuracy is 99.75%, which is higher than that of transfer learning.

TABLE III. THE RESULTS OF CLASSIFYING IMAGES INTO 2 CLASSES NEW CASTLE DISEASE AND HEALTHY IN TRANSFER LEARNING

Fig. 10 and Fig. 11 show the training process's accuracy and loss in the second scenario experiment. The two curves do not noticeably vary from one another during the training period and climb steadily. The model is adequate and has a great potential for generalization because the training and loss accuracy curves are generally smooth and show no discernible deviation between them.

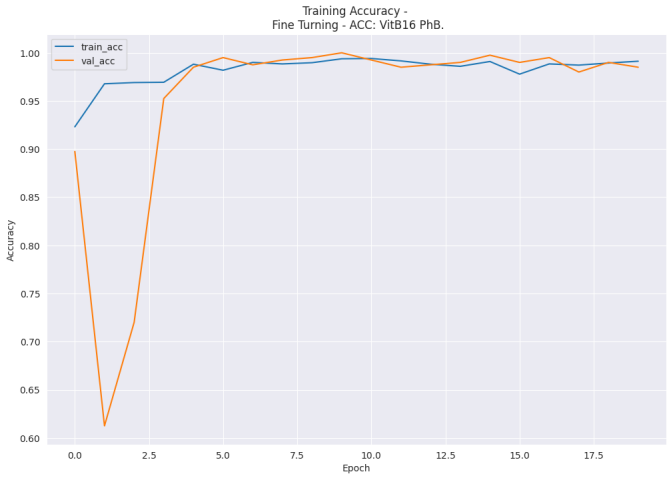

Fig. 10. Training accuracy and validation accuracy in fine-tuning of ours model (new castle disease and healthy).

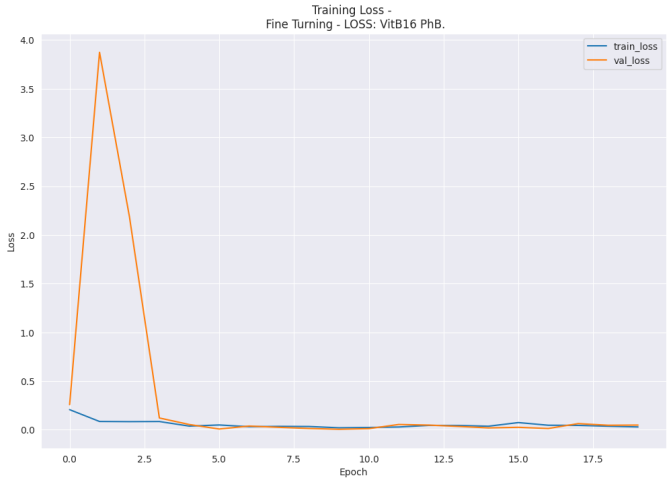

Fig. 11. Training loss and validation accuracy in fine-tuning of ours model (new castle disease and healthy).

Fig. 12 presents the confusion matrix of the 2-type classification scenario New Castle Disease and Healthy. From the matrix, we see that the model performs absolutely well when identifying the healthy class. At the same time, the New Castle Disease class has only one flaw. Fig. 13 is the result of the built-in Gradient explanation for this scenario.

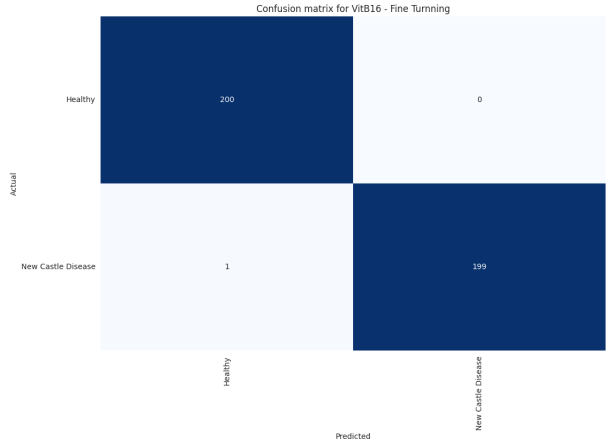

Fig. 12. Confusion matrix in fine-tuning of ours model (New castle disease and healthy).

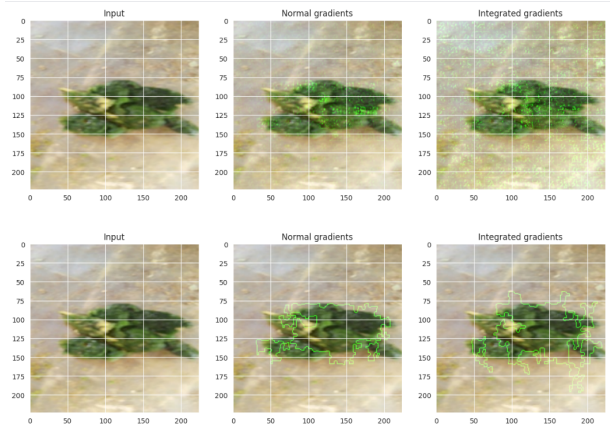

Fig. 13. Output of our model with integrated gradients explanation in scenario 2.

D. Scenario 3: Classification of 2 Classes (Salmonella and Healthy)

This scenario presents the results of classifying the two classes Salmonella and Healthy before and after data fortification. In Table V, we note the improvement in the accuracy of the proposed model by up to 8% when it reaches 98%. Furthermore, after fine-tuning, the proposed model has achieved 100% absolute accuracy with data augmentation and most other models in the Table VI have also improved.

Fig. 14 and Fig. 15 show the training process' accuracy and loss in the scenario 3 experiment. The two curves continuously rise and do not considerably diverge from one another during the training phase, demonstrating the transparency and dependability of the suggested model.

Fig. 16 presents the confusion matrix of the Salmonella and Healthy class classification test. From the matrix, we see that the model performs best when classifying chicken diseases with an accuracy rate of 100%. Fig. 17 is the result of the explanation of Integrated Gradients for Salmonella and Healthy classification.

E. Scenario 4: Classification of 4 Classes (Coccidiosis, New Castle Disease, Salmonella and Healthy)

This is an important scenario that shows the strong performance of the proposed model when the classification problem has up to 4 classes. It can be seen that after the transfer learning process in Table VII, the proposed model achieved 97.75% accuracy when trained on the augmented data set. In contrast, the model only achieved 89.50% accuracy when trained on the original data set. After the stage of fine-tuning the proposed model with the augmented data set, the final result obtained in Table VIII has an accuracy of 98.25%.

TABLE VII. THE RESULTS OF CLASSIFYING IMAGES INTO 4 CLASSES COCCIDIOSIS, NEW CASTLE DISEASE, SALMONELLA AND HEALTHY IN TRANSFER LEARNING

F. Comparison with other State-of-the-art Methods

This section completely compares our proposed method with several existing state-of-the-art classification methods.

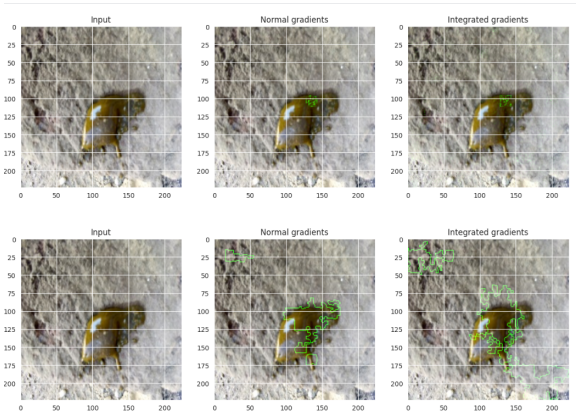

Fig. 21. Output of our model with Integrated Gradients Explanation in Scenario 4.

Table IX compares chicken disease classification methods using ViT and CNN architectures. It can be seen that the proposed model (fine-tuned ViT16) performs better than most recently published works on disease detection in chickens.

TABLE IX. COMPARISON WITH OTHERS STATE-OF-THE-ART METHODS

Ref.	Architecture	ACC
Moch. Kholil et al. [29]	CNN	95,28%
Mizanu Zelalem Degu et al. [31]	YOLOv3	98,70%
Dina Machuve et al. [35]	Xception	98,24%
Our Proposed Model (ViT16)		**98,25%**

Our proposed model outperforms most state-of-the-art methods in terms of accuracy and other evaluation metrics. Specifically, our model achieves higher accuracy than CNN, Xception and approximates the YOLOv3 model. The outstanding performance of our model can be attributed to its ability to effectively capture and classify features associated with poultry diseases, leveraging the strengths of deep learning techniques and innovative architectural design.

V. DISCUSSION

Our study aimed to develop a robust model for poultry disease image classification, leveraging transfer learning and fine-tuning techniques. The results demonstrated the efficacy of this approach, with the proposed model (ViT16) achieving high accuracy rates across various scenarios. This outcome underscores the importance of utilizing pre-trained models and optimizing them for specific tasks, highlighting the potential of transfer learning in medical image analysis.

Furthermore, by meticulously fine-tuning hyperparameters and incorporating dense layers, dropout layers, and BatchNormalization, we successfully mitigated overfitting and improved classification accuracy. These findings underscore the importance of meticulous model development and optimization to achieve superior performance in medical image classification tasks.

Moreover, the integration of Integrated Gradients for visual explanation provided valuable insights into the model's decision-making process. This transparency not only enhances

trust in the model's predictions but also facilitates error recognition and model improvement. The discussion also emphasizes the broader implications of the research, particularly in advancing diagnostics and anomaly detection in livestock farming.

In summary, through rigorous experimentation and optimization, our study contributes to the growing body of literature on transfer learning and deep learning applications in medical imaging, paving the way for future advancements in disease detection and diagnosis.

VI. Conclusion

In this work, we used transfer learning, a powerful machine learning method, to improve the model's performance in four-class classification. Transfer learning uses information obtained from a model that has been pre-trained on a large data set for a given task and applies it to another activity. In our study, we started with 5 models (EfficientNetB3, ResNet50, VGG16, MobileNet, InceptionV3) of CNN architecture and two models (ViT32, ViT16) of Vision Transformer architecture. These models have been trained on large amounts of data, which allows our model to inherit knowledge about common image aspects, allowing it to focus on the complexity of image classification.

Fine-tuning was important in developing a pre-trained model for our medical image classification application. To improve the performance of the model, we added dense layers, dropout layers, and BatchNormalization, as well as modified many hyperparameters. This combination of layers enables the network to learn complex patterns and relationships in the data, leading to efficient classification performance while minimizing overfitting, resulting in improved accuracy higher. After fine-tuning and training on the augmented data set, the proposed model (ViT16) achieved accuracy in 4 scenarios of 99.25% - 99.75% - 100% - 98.25% respectively. Compared to the situation without data augmentation, the model has achieved accuracy in 4 scenarios of 99% - 97% - 98% - 98% respectively.

To provide transparency and to better understand how the model makes decisions and makes predictions during training. We used Integrated Gradients for visual explanation. This helps experts understand the model's predictions to recognize errors and easily improve the model.

Our results demonstrate the robustness of the ViT16 model in the image classification problem compared to other popular models. Strong precision, accuracy, recall and F1 score demonstrate their usefulness in livestock production. This research actually makes a significant contribution as we tackle the rather rare problem of disease diagnosis in chickens. This research paves the way for future developments in image processing and diagnostics in livestock.

In the future, we will to continue to fine-tuning the model, expand the challenge, use other advanced visualization tools, and improve the dataset. In addition, evaluating different preprocessing techniques on different chicken disease images is also an issue that needs research. By undertaking this action, our objective is to enhance the Accuracy of the model, solidifying its role as a fundamental solution within the realm of avian image categorization.. Our ongoing efforts highlight the importance of artificial intelligence in improving diagnostics and anomaly detection.

Acknowledgment

***Abstract*—Synthetic data generation research has been progressing at a rapid pace and novel methods are being designed every now and then. Earlier, statistical methods were used to learn the distributions of real data and then sample synthetic data from those distributions. Recent advances in generative models have led to more efficient modeling of complex high-dimensional datasets. Also, privacy concerns have led to the development of robust models with lesser risk of privacy breaches. Firstly, the paper presents a comprehensive survey of existing techniques for tabular data generation and evaluation matrices. Secondly, it elaborates on a comparative analysis of state-of- the-art synthetic data generation techniques, specifically CTGAN and TVAE for small, medium, and large-scale datasets with varying data distributions. It further evaluates the synthetic data using quantitative and qualitative metrics/techniques. Finally, this paper presents the outcomes and also highlights the issues and shortcomings which are still need to be addressed.**

***Keywords*—Synthetic data generation; tabular data generation; data privacy; conditional generative adversarial networks; variational autoencoder**

I. Introduction

Tabular Data made up of databases with tabular structures consisting of rows representing observations and columns representing features. In the digital era, "data" is considered as "new water". On the one side,compliance of privacy laws like GDPA has imposed an obligation on organizations to secure and protect private and sensitive data,while on the other side, data acts as a fuel in the wide range of machine learning applications like Cloud migration, Artificial Intelligence (AI)/ ML model training, application testing, simulation analysis, data sharing, scientific trials, and new product development. An innovation solution to address the issue is to generate the synthetic data.

Synthetic data is an artificially generated data which carries the same statistical properties (i.e. mean, median, mode, correlation, regression, etc.). as the real data. Synthetic data is useful where it is challenging to obtain and use real data due to privacy concerns and difficulty in collecting real data, augmenting small datasets, and range of machine learning applications. Moreover, real data can be of types like tabular, time-series, audio, video, medical images/ signals etc. Out of these types, tabular data is the most commonly used form of data and generation of synthetic data for it is still challenging and requires to address the multiple constraints/ characteristics of tabular data to produce quality synthetic data.

There are multiple constraints (multimodal, class imbalance, non Gaussian data, learning from sparse one-hot-encoded vectors, mixed data type) inherently present in the tabular data that need to be addressed while generating its synthetic counterpart. Along with these constraints, a feature has varying characteristics. In this paper, tabular data features have been categorized into four categories: continuous, categorical, mixed type, and anonymized. Characteristics of each tabular data feature are shown in Table I. Generation of synthetic tabular data requires identification of the distributions of each feature and simultaneously mapping the correlations present in the data.

TABLE I. Data Characteristics

Feature Type	Details
Continuous Columns	Gaussian Distribution Multi-Modal Distribution Long Tail Distribution
Categorical Columns	Binary Categorical Multiple Categorical
Mixed Type Columns	Missing Values A high-frequency finite value mixed with other values
Anonymized Columns	Unique Columns - Roll Number, Patient ID, etc. Non-Unique Columns - Name, Country, etc.

Broadly, there are two categories of models used to generate synthetic tabular data, namely, statistical or Probability [4], [5] and machine learning [7], [8], [9], [10] methods based models.

Probabilistic models have existed and are continually being developed to generate synthetic data. But recent advancements in deep learning-based generative models, especially GANs [1], have made them state-of-the-art in the field of synthetic data generation. Moreover, the existence of stricter privacy laws and general awareness regarding user privacy have made data sharing difficult. This has led to the development of novel privacy-preserving mechanisms to ease the generation and sharing of data. Differential privacy [2] has become the gold standard in this domain. It uses randomized algorithms [3] for the sanitization of sensitive information and also limits the privacy risk of revealing sensitive information.

Besides the generation of synthetic data, robust evaluation mechanisms [2], [11] are of equal importance. This paper presents exciting methods for synthetic data generation and

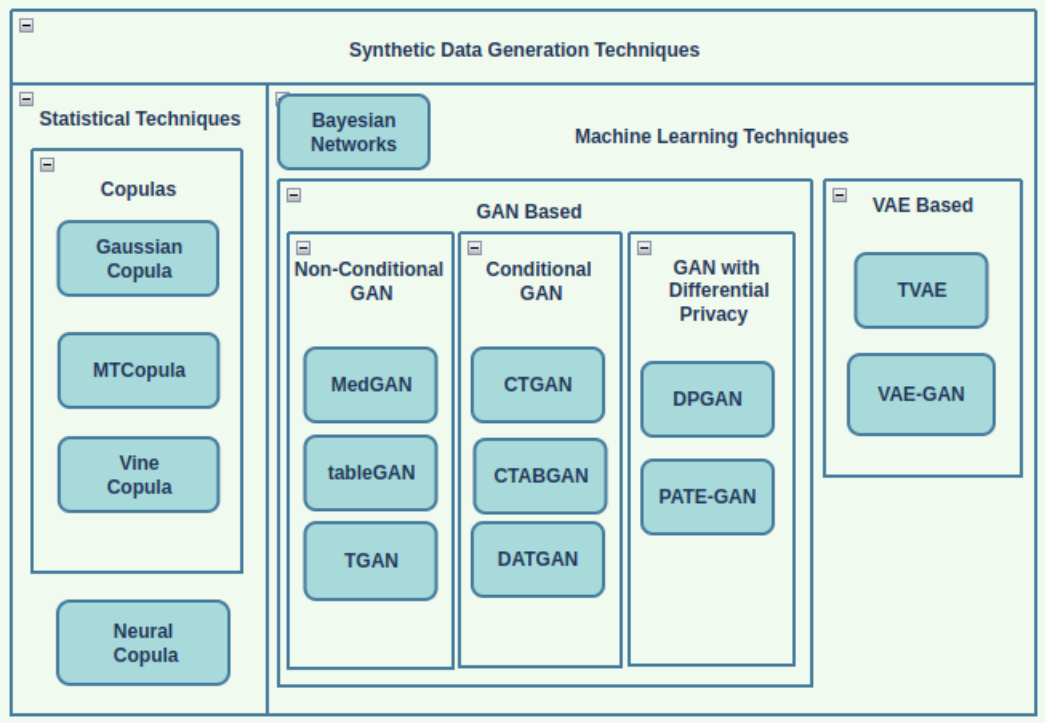

Fig. 1. Synthetic data generation techniques.

elaborates on evaluation mechanisms. This paper highlights rigorous analysis to analyze the performance of the state-of-the-art models for tabular data generation on varied nature data. Presented is a rigorous comparative analysis of the state-of-the-art models, namely, TVAE [12] and CTGAN [12] for small-*iris* [13] and *breast cancer* [13], medium-*adult* [13] and large-*credit* [13] datasets with comparative statistical scores and visualization reports.

The structure of the paper is organized as follows: Section II describes existing methods for synthetic data generation extensively; Section III lists the techniques for evaluation of generated synthetic data in detail; Section IV describes the datasets, models, and evaluation metrices used in the research; Section V provides an in-depth analysis of the results obtained; and Section VI presents a short qualitative summary of the proposed research in the conclusion.

II. Existing Models for Synthetic Tabular Data Generation

The existing models for generating synthetic tabular data have been broadly classified into two categories namely, statistical methods-based models [4], [5], [6] and machine learning-based techniques [7], [8], [9], [10] as shown in the Fig. 1. This section entails a detailed and comprehensive in-depth analysis of each methods at hand.

A. Statistical Methods-based Models

Several statistical methods-based models [4], [5], [6] have existed, and novel methods have been proposed to address the task of synthetic data generation. One of the earliest statistical techniques for synthetic data generation is Inverse Transform Sampling [6] which involves sampling data from a known data distribution for the random variable X. It generates independent univariate samples. Thereafter, a perturbation technique involving fitting a multivariate Gaussian distribution on input data is introduced. The General Additive Data Perturbation(GADP) technique [4] generated synthetic data by adding a noise variable to the estimated distribution. Another variant of GADP is the Dirichlet Multivariate Synthesizer [6] which is based on Maximum Likelihood Estimation (MLE) [14]. The problem with MLE is that the computation increases exponentially as the number of variables increases. Apart from these statistical methods, one of the most useful statistical methods for synthetic data generation uses copulas. Details of copulas are described in Sub-section II-A1

1) Copulas: A copula [15] is a mathematical function that describes the correlation between the marginals of random variables. This helps in identifying the multivariate joint distribution for a set of random variables. A lot of research has been done to identify the right parameters for the copula model and the marginals. Based on these, several variants of copula have been proposed. Gaussian Copula [5] is the most popular and one of the very few copula functions available for modeling the joint multivariate probability distribution. Apart from the Gaussian Copula [5] and t-Copula [16] models for multivariate distribution, Vine Copula [17] models have gained prominence lately as a modeling method as they are built only on the univariate and bivariate distributions. More recently, neural network techniques are being incorporated to identify the right set of parameters to construct a generic copula that models any multivariate joint distribution [7].

a) MTCopula: Since Gaussian Copula [5] fails to address the complex distributions of marginals and the joint

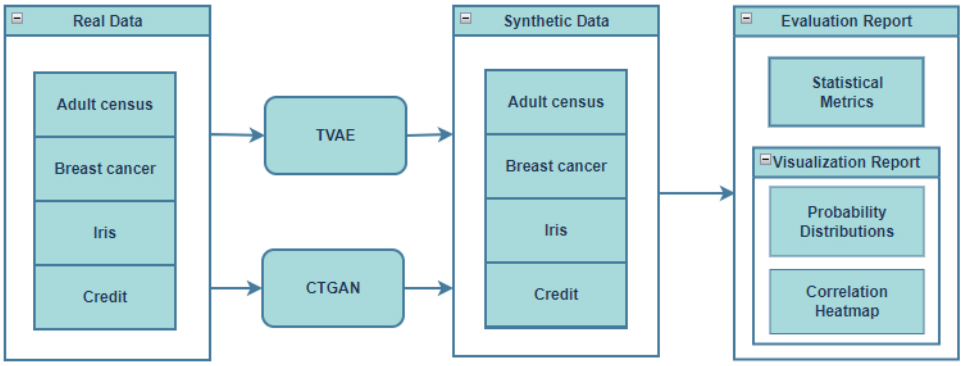

Fig. 2. Proposed comparison model.

distribution, Benali et al. propose a novel MTCopula [6] which involves parameter selection criteria for selecting the parametric marginal and multivariate copula functions based on Akaike Information Criterion (AIC) [18]. The main drawback of this approach is that it selects one of the existing parametric marginals or parametric copulas. The complex distributions of a random variable may not be exactly modeled by parametric marginals. Moreover, it considers only Gaussian Copula [5] and t-Copula [16] for the selection of multivariate copula functions, and the complex relationships among the random variables are not always captured by these two generic copula.

b) Vine copula: Vine copulas [17] are a special class of copula models as they use bivariate distribution as the building blocks for multivariate joint distribution [15]. This is achieved by forming a vine-like structure, one node at a time. However, with the increase in the number of variables, the number of feasible configurations of a vine copula expands exponentially, making model selection a significant development issue. This problem is addressed by [9] using reinforcement learning and selecting tree levels sequentially while using LSTM networks [19] to learn from vine configurations.

B. Machine Learning Methods-based Models

Recent advancements in the development of generative models [1] have transformed visual media-centric research to new heights. The ability of generative models is now being utilized to learn the complex relationships of tabular data and generate similar synthetic data. The two most important techniques using generative models are variational autoencoders [20] and generative adversarial networks [1], which are discussed in the following section.

1) Bayesian Networks: Bayesian networks [21] are probabilistic graphical models used to determine probabilistic inferences between variables. They are frequently used in computational systems biological method [22] to understand the underlying biological relationships. Here, the dependencies of variables are defined prior to training. This is also a major drawback, as it requires prior information on the dataset. Moreover, it becomes computationally expensive when dealing with large and sparse datasets.

2) Variational Autoencoders: The architecture of VAEs [20] consists of an encoder network and a decoder network. The encoder takes real data as input and converts it into a vector corresponding to a latent distribution. This vector is served as an input to the decoder, which reconstructs the real data that was served as an input to the encoder. On training completion, the decoder network can now generate new samples. The variational part brings randomness to this process.

a) Differentially private autoencoder: [23] introduced a novel differentially private autoencoder for synthetic data generation.

b) TVAE: Xu et al [12] propose a novel VAE known as TVAE for tabular data using two neural networks, one for the encoder and the other for the decoder network, and train them using Evidence Lower-Bound (ELBO) loss [24].

3) Generative Adversarial Networks: GAN [1] is based on the adversarial training of the generator network and the discriminator network, where the task of the generator is to produce fake samples that closely resemble the real samples while the discriminator tries to distinguish between the real and fake samples. GANs also belong to a generative class of models, but the key distinction between GANs and VAEs is that in VAEs, the encoder sees the real data, while in GAN, real data is not visible to the generator network. This is particularly useful in privacy-oriented applications. Different types of GANs are discussed below.

a) Non-Conditional GAN: GANs were first incorporated for synthetic tabular data generation in MedGAN [25], Table-GAN [26] and TGAN [8]. Vanilla GAN [1] architectures usually suffer from the problem of vanishing gradients, which leads to mode collapse. This has led to the rise of several variations of GAN architectures, such as WGAN, Wasserstein GAN [27] and conditional GANs [28].

b) Conditional GAN: When allowing the GAN [1] model to condition external information, it can generate samples by operating in different modes based on the contextual information provided. Thus, conditional GAN [28] is an extension of the GAN [1] architecture with the conditional operation. The different variations of conditional GANs are as follows.

- *CTGAN* [12] deals with problems like mixed data types, multimodal distributions, and imbalanced categorical columns of tabular data extensively. For the

problem of multimodal distribution in continuous data, it fits a variational Gaussian Mixture Model [29]. Thereafter, a mode is sampled from the identifiable modes, and the column is normalized based on the probability density of the selected mode. For discrete columns, one hot encoding is used.
The problem of adequately representing all the categories in the synthetically generated data is handled using a conditional vector. Since the minority category may not be adequately represented in the synthetic data, instead of providing random noise to the generator, it uses a conditional vector constrained on each respective category to train the generator and discriminator network. Finally, the discriminator is trained using a sampling method based on the conditional vector, i.e., sampling a row from the real data constraining each respective category.

- *CTABGAN* Conditional Tabular GAN (CTAB-GAN) [10] is based on the Convolutional Neural Network with an additional classifier network based on a multilayer perceptron apart from the generator and discriminator networks. It considers not only continuous and categorical variables but also a third class of variables known as mixed variables and also deals with variables with long-tail distributions. Zhao et al. proposed an advanced version of CTABGAN, CTABGAN+ [30] using Wasserstein loss [27] with gradient penalty and training with differential privacy stochastic gradient descent to ensure strict privacy guarantees.
- *DATGAN* [31] proposes DATGAN which is a novel architecture based on GAN using Directed Acyclic Graphs (DAGs) to model the information about the dataset. It uses LSTM cells to model expert knowledge using DAG.

c) GAN with Differential Privacy: Jordan et al. [32] apply Private Aggregation of Teacher Ensembles (PATE) [33] to the GAN model so as to obtain a generative model with tight differential privacy guarantees. Xie et al. [34] add noise to gradients to achieve differential privacy with GANs. Evaluation techniques that are utilized to assess the quality of generated synthetic data are explained below.

III. Evaluation Techniques

Synthetic data generation not only focuses on generation algorithms but also on robust evaluation mechanisms that can highlight the quality of generated synthetic data. To this end, evaluation mechanisms are classified into broadly three categories (quantitative, qualitative, and machine learning utility), highlighting each unique aspect of synthetic data. Further explanation is provided on these categories along with privacy preservability and differential privacy.

A. Quantitative Statistical Similarity Measures

Ideally, the generated synthetic data should have the same statistical properties as the real data. To ensure this, several statistical tests and metrics were compared to the synthetic data with real data.

1) Kolmogorov-Smirnov Test: To measure the similarity between the data distribution of continuous columns in real data and the generated synthetic data, the two-sample Inverted Kolmogorov-Smirnov test [35], commonly referred to as KSTest, is utilized. The p-value and D statistic obtained represent the similarity between the column distributions. For the whole dataset, a mean of the D statistic is obtained considering all the continuous columns, and then it is subtracted from 1 to obtain the final score. The D statistic can be computed using the following equation:

$$D_{m,n} = max|F(x) - G(x)|. \tag{1}$$

where $F(x)$ is the cumulative distribution function of the first sample with size m and $G(x)$ is the cumulative distribution function of the second sample with size n.

2) Chi-Square Test: Similarly, for discrete data, the Chi-Square Test [36] is used. After applying it to all the discrete columns in the data, an average of the score is obtained.

$$\chi^2 = \sum \frac{(O_i - E_i)^2}{E_i} \tag{2}$$

where χ^2 = Chi Squared statistic, O_i = Observed value, E_i = Expected value

3) Wasserstein Distance: Also known as Earth Mover distance [37], it intuitively defines how much quantity should be transported from x to y to transform a probability distribution from P_A to P_B.

$$W := W(F_A, F_B) = (\int_0^1 |(F_A^{-1}(u) - F_B^{-1}(u)|^2 \, du)^{\frac{1}{2}} \tag{3}$$

Where, F_A^{-1} and F_B^{-1} are the corresponding quantile functions, and F_A and F_B are the associated cumulative distribution functions (CDFs).

4) Kullback-Leibler Divergence: Finally, the third metric considered for quantifying the difference between the two probability distributions is the Kullback-Leibler divergence [11] or KL divergence, encompassing both the continuous and discrete variants. For discrete probability distributions P and Q:

$$D_{KL}(P||Q) = \sum_i P(i) log \frac{P(i)}{Q(i)} \tag{4}$$

For probability distributions P and Q of continuous variable:

$$D_{KL}(P||Q) = \int_{-\infty}^{\infty} P(x) log \frac{P(x)}{Q(x)} dx \tag{5}$$

B. Qualitative Visualization Techniques

Apart from the above-mentioned quantifiable measures, data visualization methods are useful for analyzing the quality of synthetic data. Of these, probability distributions for univariate and bivariate analysis and correlation heatmaps for multivariate analysis provide deep visual insights into the quality of the generated synthetic data.

C. Machine Learning Utility

One important aspect of the task of synthetic data generation is to produce synthetic data that has approximately the same machine-learning utility as the real data. Without any utility, the generated synthetic data might not be of any value.

D. Privacy Preservability

This is one of the most important aspects in the task of synthetic data generation, considering the present scenario. Strict laws (e.g., the European General Data Protection Regulation [38]) and privacy concerns play a major role in sharing sensitive data. To address these, various mechanisms have been proposed to ensure data privacy. These can be classified into two major techniques: distance-based metrics (DCR (Distance to Closest Record) [30] and NNDR (Nearest Neighbour Distance Ratio) [39], and differential privacy mechanisms.

1) DCR: A synthetic record's Euclidean distance from its nearest real neighbour is measured by DCR [30]. Ideally, the chance of a privacy breach decreases as DCR increases.

2) NNDR: The NNDR [39] measures the ratio between the Euclidean distance for the closest and second-closest actual neighbours to any matching synthetic record, as opposed to just measuring the closest neighbour. This ratio falls between 0 and 1. Better privacy is indicated by higher values. Sensitive information from the nearest real data record may be revealed by low NNDR values between synthetic and real data.

E. Differential Privacy

By reducing the impact of each data point based on a predetermined privacy budget, Differential Privacy [2] defends against privacy assaults. Renyi Differential Privacy (RDP) is used by Zhao et al. [30]. Because it sets more stringent limits on the privacy budget. RDP offers tighter limitations for tracking the cumulative privacy loss through a series of mechanisms using the composition theorem, making it a strictly stronger privacy definition than DP.

Up to this point, elaboration has been provided on existing methods for synthetic data generation and evaluation metrics for analyzing the quality of the generated data. The next section delves into the methodology for designing and implementing the comparison model.

IV. Methodology for Comparison Model

Comparing and analyzing two state-of-the-art synthetic tabular data generation techniques, namely, TVAE [12] and CTGAN [12], Four datasets were explored of varying sizes, data features, and characteristics. For qualitative analysis, a selection of three statistical metrics is made, which are then implemented and analyzed across both models using varying batch sizes (20, 50, 100, and 300) and epochs (100, 200, 500, and 5000). Additionally, a visualization report is generated using probabilistic distribution and correlation heatmaps for variables in the datasets.

The process flow highlighting each component in the proposed comparison model is shown in Fig. 2. It lists four real datasets to be used, which train the two models, TVAE [12] and CTGAN [12]. The trained models then generate synthetic samples for each dataset individually. Finally, this synthetic data, along with real data, is used to prepare an evaluation report that highlights quantitative statistical metrics and a qualitative visualization report depicting feature distributions and correlations for synthetic as well as real data. Further subsections describe the datasets (Section IV-A), algorithms (Section IV-B), and evaluation metrics (Section IV-C) used to design and implement the proposed comparison model in detail.

TABLE II. Datasets Details

Category	Name	Total Features	Total Records	Feature Distribution
small	iris	6	150	(5 continuous, 1 discrete)
	breast cancer	33	569	(32 continuous, 1 discrete)
medium	adult	15	32561	(6 continuous, 9 discrete)
large	credit	31	284807	(30 continuous, 1 discrete)

TABLE III. Credit Sample

	Total Records	Class 0	Class 1	% Class 0	% Class 1
Real	284807	284315	492	99.8273	0.1727
Sample (15%)	42721	42647	74	99.8268	0.1732

A. Datasets

Datasets were categorized based on their size into three broad categories: small (*iris* [13] and *breast-cancer* [13]), medium (*adult*) [13] and large (*credit*). Four standard datasets were considered in different domains with varied sizes and a mix of different variable types. The extensive diversity of the datasets is reflected in Table II. Table II shows the total features and their distribution as continuous or discrete features and complete records for each dataset. Moreover, for the *large* dataset, *credit*, approximately 280,000 records are available. A 15% sample of the original dataset is taken, as illustrated in Table III. Due to the high imbalance in the *credit* dataset, with just 0.173% of samples belonging to Class 1, the same imbalance ratio is maintained in the sample.

B. Models and Algorithms

Two state-of-the-art machine learning algorithms are compared across four different datasets. TVAE [12] and CTGAN [12] models are employed for all datasets, with hyperparameter tuning conducted for each. Hyperparameters are optimized based on the size of the dataset, as detailed in Table IV, Table V, Table VI, and Table VII.

C. Evaluation

Three quantitative statistical evaluation metrics were used, Chi-Square (CS Test), Inverted KS D Statistic (KS Test), and KL Divergence (KL_c for continuous and KL_d for discrete) for

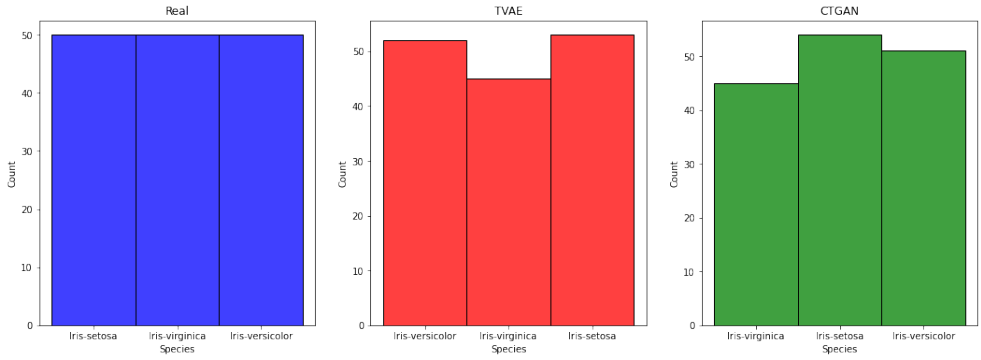

Fig. 3. Iris: Species Distribution.

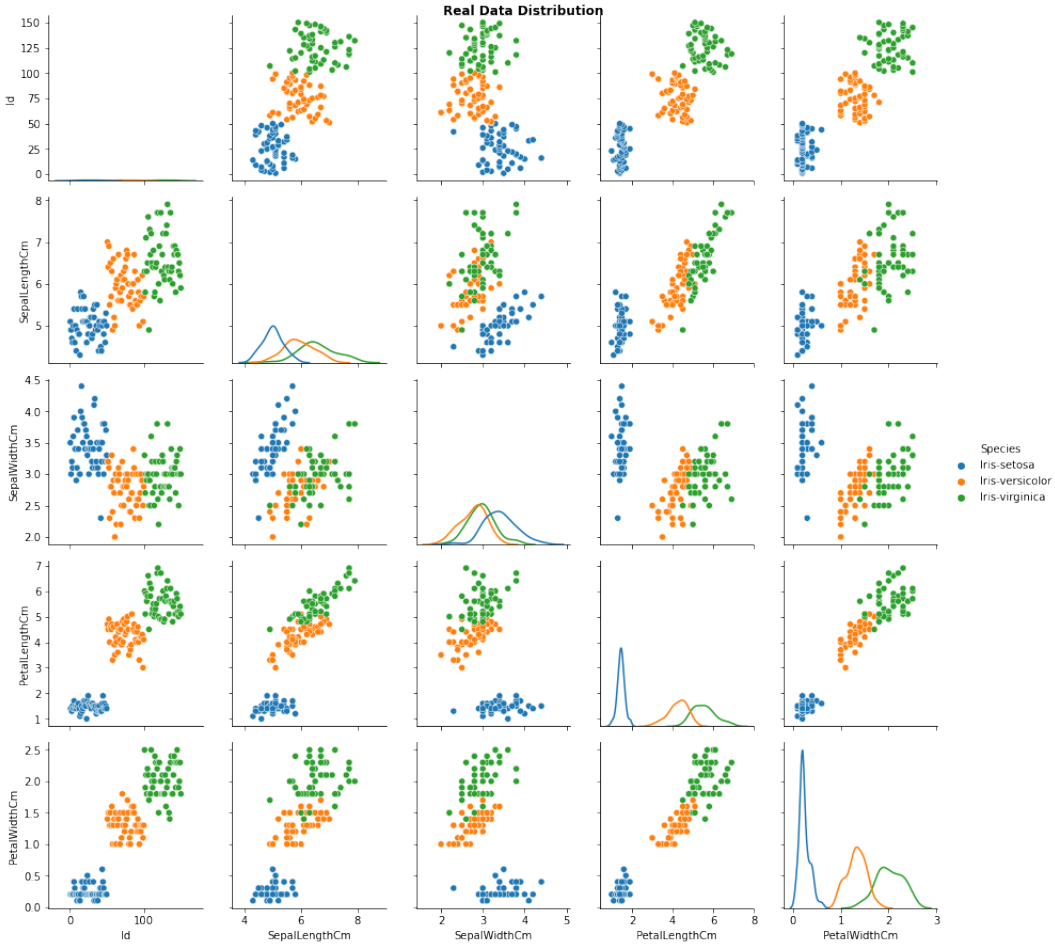

Fig. 4. Real Iris.

each category of the data, continuous or discrete (as applicable). Moreover, univariate distributions, bivariate distributions, and correlation heatmaps are utilized for qualitative data analysis through visualization. Categorical distributions for the *Iris* dataset are represented using histograms, as illustrated in Fig. 3. Further elaboration on these evaluation metrics can be found in Section III.

V. Results and Analysis

To analyze the results, the proposed comparison model was implemented in Python using its ML libraries. Details of the implementation environment are provided in Table VIII. TVAE [12] and CTGAN [12] models were implemented, trained for four datasets as explained in Subsection IV-A, and evaluated using three metrics outlined in Subsection IV-C, with variations in batch size and epochs, as shown in Table IV, Table V, Table VI, and Table VII. Statistical and visual observations

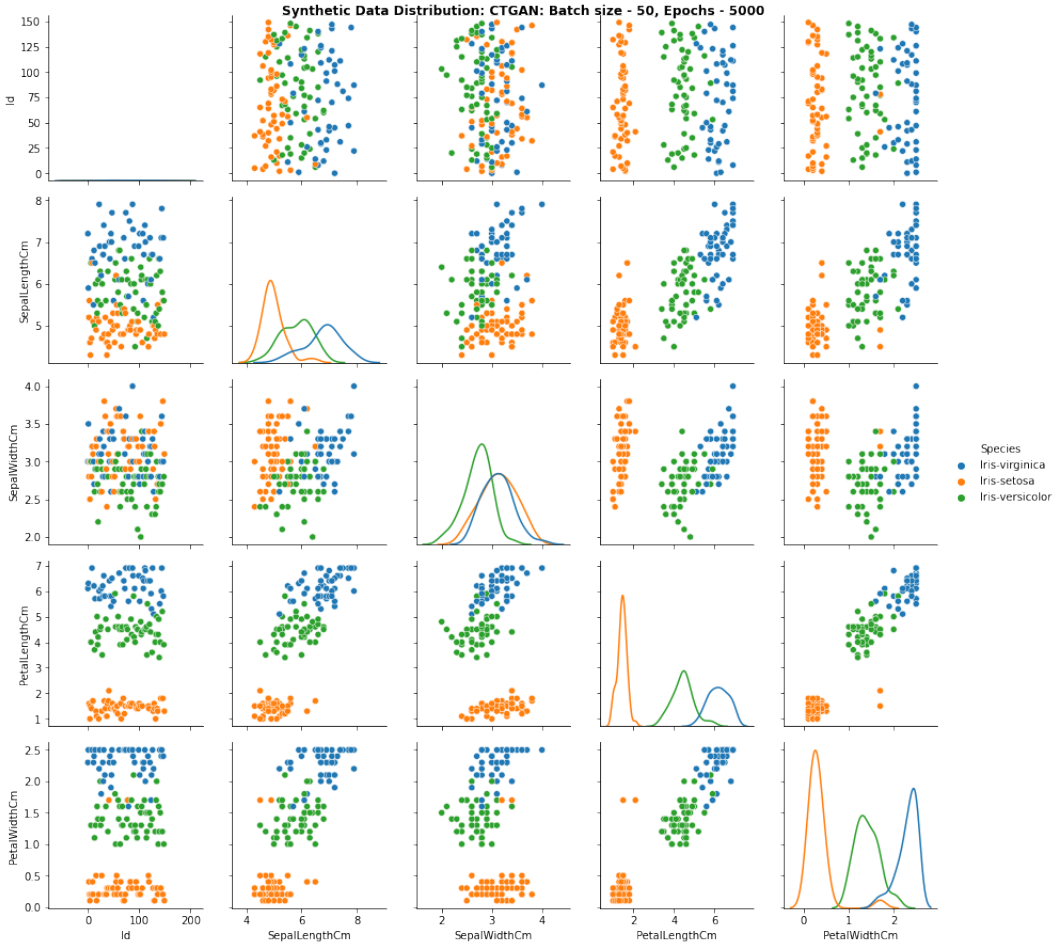

Fig. 5. CTGAN Iris.

were recorded, and the results were rigorously analyzed. This analysis will present the suitability as well as limitations of TVAE [12] and CTGAN [12] under varied and diversified features of the datasets, as shown in Table II.

In most of the cases, it appeared that the variational autoencoder-based TVAE [12] outperformed CTGAN [12], reflected by the higher KL divergence score, meaning a closer resemblance of the synthetic data distribution to the real data distribution. But the major advantage of the GAN [1] based model is the more effective privacy-preserving mechanism since the generator is unaware of real data values. These observations are rigorously analyzed in Subsection V-A and Subsection V-B.

A. Statistical Measures: Quantitative Evaluation

Based on the categories of the datasets, *small*, *medium*, and *large*, Batch sizes of the dataset were varied and described the statistical metrics obtained as follows.

For *small* datasets, *iris* and *breast-cancer*, the batch size is varied between 20, 50, and 100. Also, for *small* datasets, deep learning methods are more useful when training is done for longer periods of time, i.e., for larger epochs. Testing of this was done by training the data for 100, 500, and 5000 epochs, respectively.

From Table IV and Table V, observations were made that the KL divergence score is best for both *iris* and *breast-cancer* for the optimum value of 5000 epochs with a batch size of 50. This is true for the synthetic data generated using both TVAE [12] and CTGAN [12]. Another important observation from Table V is that change in the number of epochs and batch size did not have a significant influence on TVAE [12] while increasing the number of epochs for CTGAN [12] significantly increased all three metrics that were considered.

For the *medium* sized *adult* dataset, the batch size was increased to 300, and training was conducted for 200 and 300 epochs. Similar values were obtained for all metrics, as depicted in Table VI, with minimal significance observed in changing the epochs.

The credit dataset is sampled, preserving the minority-majority class ratio. The results obtained for a batch size of 300 and 200 epochs are shown in Table VII. The experiment is repeated three times, and the mean of all the values is shown in Table VII.

B. Visualization Analysis: Quantitative Evaluation

Apart from the statistical metrics, a visualization report with univariate and bivariate distributions and correlation

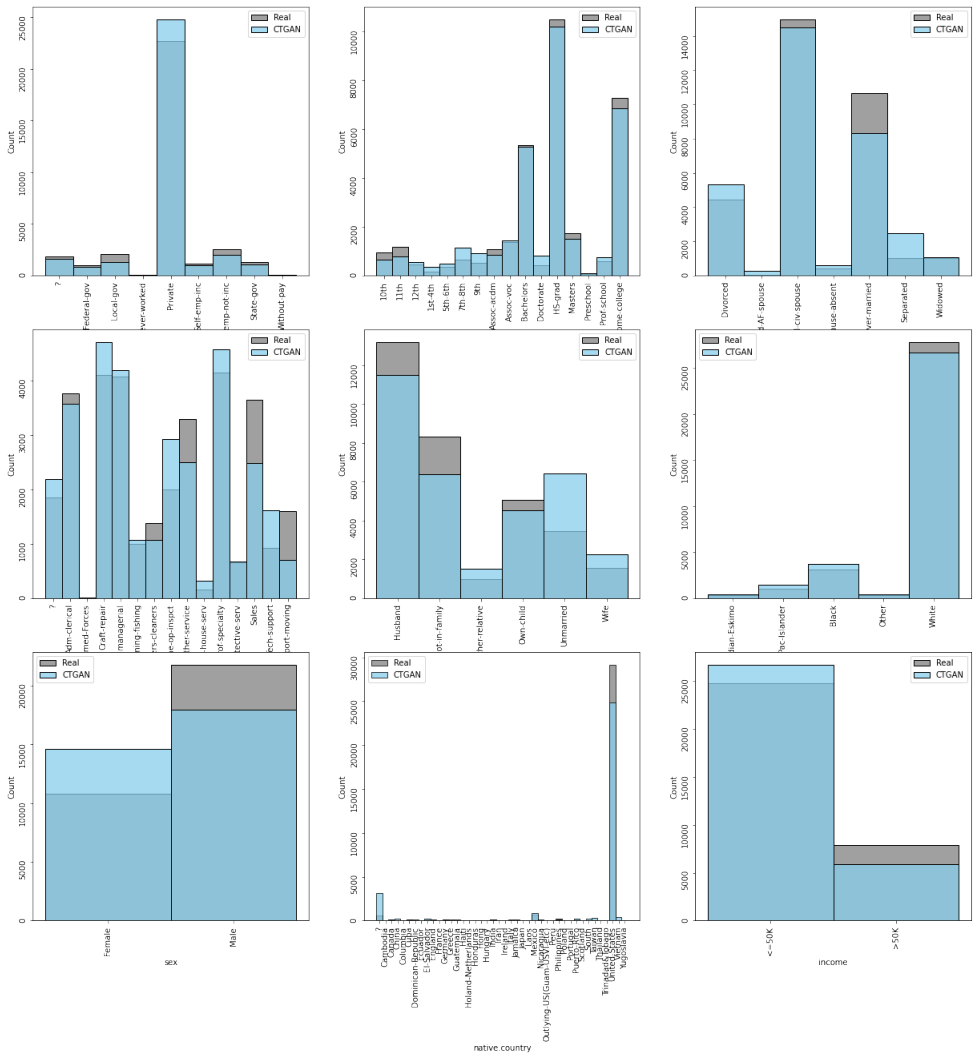

Fig. 6. Categorical distribution of real vs synthetic data.

heatmaps to study the similarity between real data and synthetic data for all four different sizes of datasets, namely, small (*iris* [13] and *breast-cancer* [13]), medium (*adult*) [13] and large (*credit*) was generated.

1) Probability Distributions: The univariate and bivariate distributions of variables based on the species type for the iris dataset were depicted in Fig. 4. Similar distributions are displayed for the synthetic version with the highest metric values for CTGAN [12] to analyze the statistical similarity, as shown in Fig. 5. Due to space constraints, only the distributions and heatmaps with the best statistical scores for synthetic data are presented. The distribution of the target variable "Species" is separately shown for real and synthetic data in Fig. 6. For the *breast-cancer* dataset, CTGAN [12] is good at capturing multi-modal distributions, as can be seen from Fig. 7. Univariate probability distributions for real and synthetic data (CTGAN) are shown in Fig. 7.

From Fig. 9 and Fig. 10, a comparative visualization of univariate and bivariate plots of numerical features for the real adult dataset and the synthetically generated dataset using CTGAN [12] is provided respectively. Additionally, the categorical histograms of the same real and synthetically generated data using CTGAN [12] are also depicted in Fig. 6. The categorical data histograms reflect the capability of the model to learn the minority and majority category distributions in a precise way.

Also, based on the univariate distributions obtained for the real and synthetic data as shown in Fig. 8, few observations that were made are:

The use of the variational Gaussian mixture model in CTGAN [12] oftentimes unnecessarily identified multiple modes as can be seen from the distribution plots of "V11", "V12", "V14", "V16" and "V17" in Fig. 8.

Modeling mix-type variables such as "Amount" and "V28" was a challenging task for both TVAE [12] and CTGAN [12] as the distribution got centered around zero, while a large number of finite values were not adequately represented.

Both TVAE [12] and CTGAN [12] failed to effectively capture and model the problem of class imbalance. As shown in Fig. 11, while TVAE [12] was unable to capture the minority

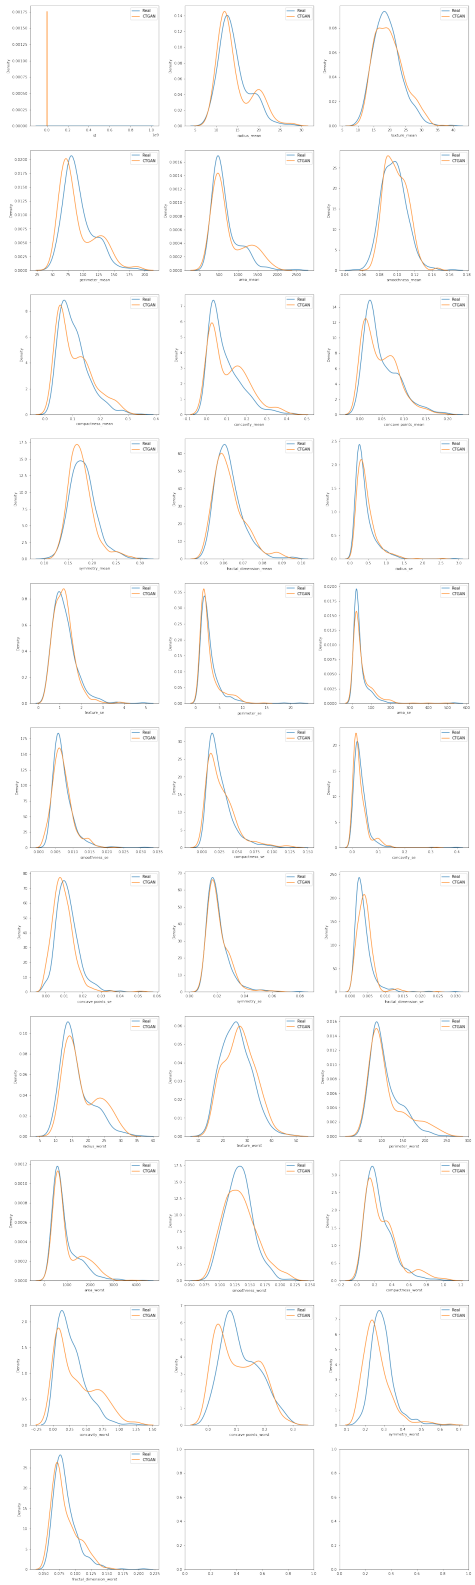

Fig. 7. Data Distribution: Breast Cancer - Real vs Synthetic (CTGAN).

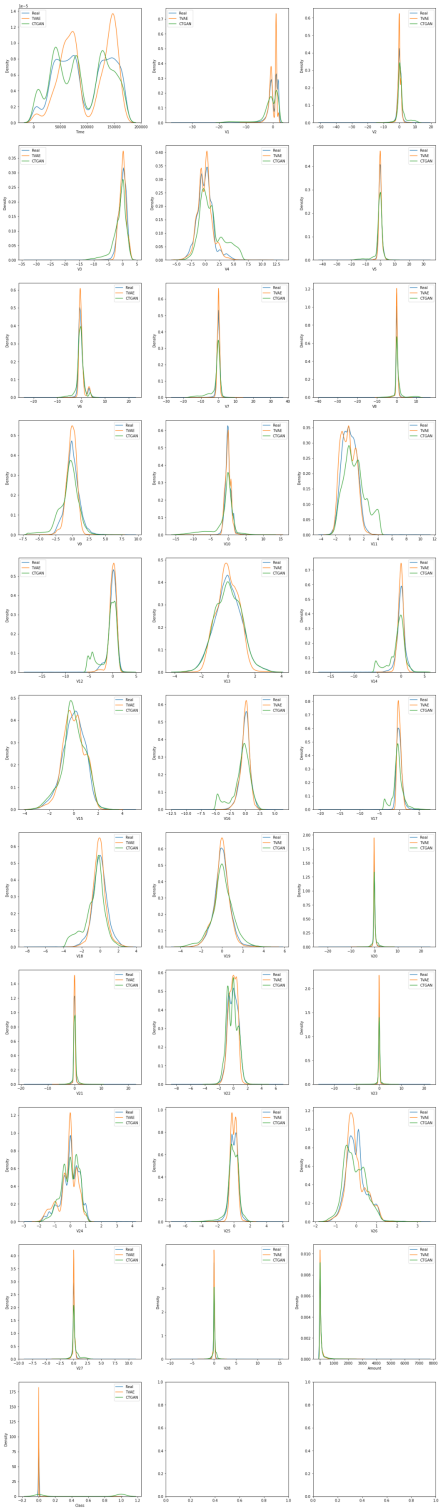

Fig. 8. Data Distribution: Credit - Real vs Synthetic.

class, CTGAN [12] oversampled the minority class in synthetic data, overriding the imbalance ratio.

Lastly, tuning the hyperparameters accordingly for each dataset improved the quality of the generated synthetic data for both TVAE [12] and CTGAN [12]. Thus, even high-dimensional data with complex relationships can be effectively modeled using generative models for synthetic data generation.

Fig. 9. Real Adult.

Fig. 10. CTGAN Adult.

2) Correlation Heatmaps: For the *iris* dataset, one observation worth mentioning is that the first row and first column of the synthetically generated data in the heatmap (Fig. 12) as well as the distributions in Fig. 5 did not correspond well with their real counterparts. This is because one of the features in the first row and the first column is the "Id" field, which served as the primary key. Its value has no intrinsic worth and is just used to distinguish each record. Hence, its correlation is not of much value. On a similar note, for the breast cancer dataset, correlation heatmaps were obtained as shown in Fig. 13 and Fig. 14 which show that the correlation of continuous columns for *adult* dataset is effectively captured by CTGAN [12] while from Fig. 15, observations were made that the CTGAN [12] extrapolated correlations for the credit dataset.

The analysis of correlation heatmaps for various datasets clearly shows that the complex relationships among the data features are effectively captured by the generative model CTGAN [12] when training is fine-tuned with optimum hyperparameters for each dataset.

rigorous analysis of small, medium, and large-scale synthetic data generated using two state-of-the-art generative models, TVAE and CTGAN. The choice of hyperparameters greatly influenced the quality of synthetic data. Small datasets (*iris* and *breast cancer*) required longer training periods for generating statistically similar synthetic data. Preserving univariate and bivariate distributions as shown in Fig. 4, Fig. 5, Fig. 6, Fig. 7, Fig. 8, Fig. 9 and Fig. 10 and multivariate joint distributions as shown in Fig. 12, Fig. 13 and Fig. 14 are achieved for small (*iris* and *breast cancer*), medium (*adult*) and large (*credit*) datasets using generative models. There is scope in the future to train large imbalanced datasets more rigorously and for more iterations with different parameters on high-end computational

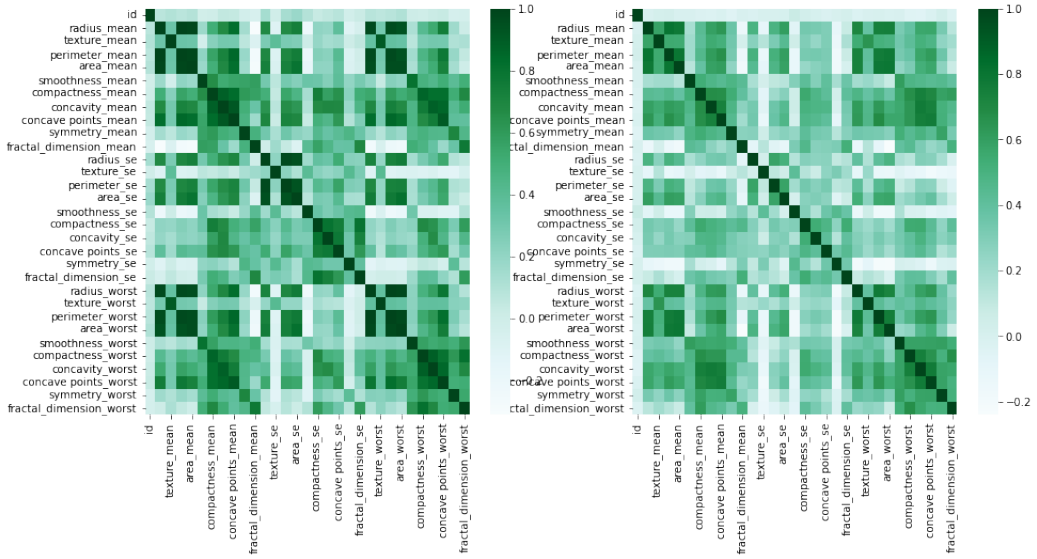

Fig. 13. Correlation Heatmap: Real (LHS) vs Synthetic (CTGAN)(RHS) - Breast Cancer.

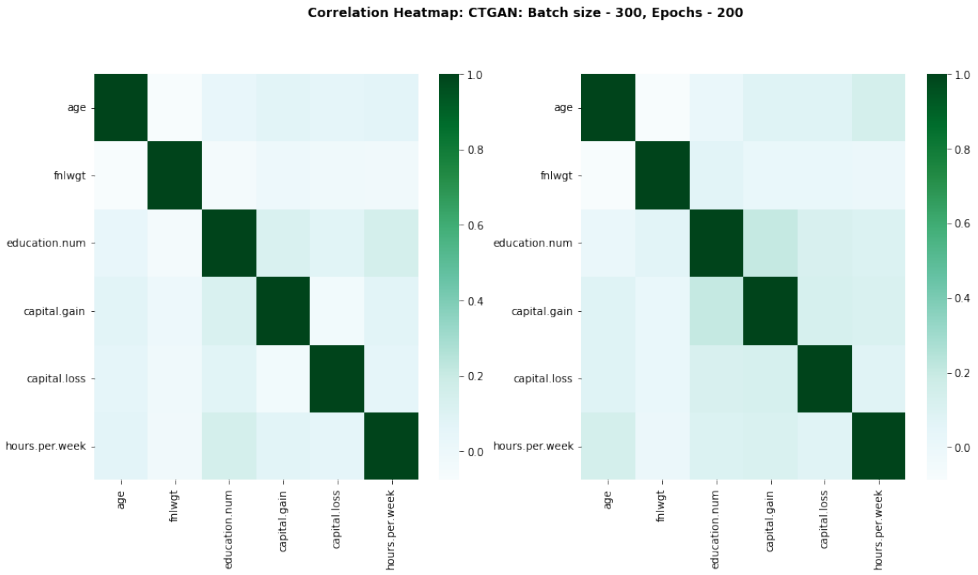

Fig. 14. Correlation Heatmap of Real (LHS) vs Synthetic (CTGAN)(RHS) data: Adult.

systems. While results for TVAE outperformed CTGAN for all four datasets by varying margins, as reflected by the KL Divergence score, CTGAN is the preferred method for generating privacy-preserving synthetic data due to its agnostic nature to real data values.

In this paper, the data on statistical metrics were evaluated, and a visualization report was presented to extensively analyze the synthetic data. The results not only highlighted the quality of synthetic data but also mentioned the shortcomings and caveats in the existing methods, which would open further dimensions in the line of research.

***Abstract*—This study proposes a suitable model for packet loss concealment (PLC) by estimating the residual error of the linear prediction (LP) method for bone-conducted (BC) speech. Instead of conventional LP-based PLC techniques where the residual error is ignored, we employ forward-backward linear prediction (FBLP), known as the modified covariance (MC) method, by incorporating the residual error estimates. The MC method provides precise LP estimation for a short data length, reduces the numerical difficulties, and produces a stable model, whereas the conventional autocorrelation (ACR) method of LP suffers from numerical problems. The MC method has the effect of compressing the spectral dynamic range of the BC speech, which improves the numerical difficulties. Simulation results reveal that the proposed method provides excellent outcomes from some objective evaluation scores in contrast to conventional PLC techniques.**

Keywords*—Autocorrelation method; bone-conducted speech; modified covariance method; packet loss concealment; residual error

I. Introduction

Recently, much attention has been paid to the use of BC speech in the field of speech signal processing. BC speech travels through the vibration of skull bone, skin, and soft tissue as its pathway. A vibration sensor is used for BC microphone decoration. BC microphone captures the vibrations and converts them into an electric signal. Thus, BC speech is rarely affected by ambient noise. Therefore, BC speech delivers advantages over air-conducted (AC) speech in some cases. In [1], BC speech was synthesized based on the least squares (LS) method. Pitch detection for BC speech is discussed in [2]. In [3], BC speech was utilized with AC speech for speaker recognition. Speaker verification is also described in [4]. To improve the quality of speech, several types of algorithms have been derived for BC speech [5]-[7]. Rahman *et al*. [8] considered a noisy environment for BC speech and derived a noise-robust LP method. However, there are few works on PLC for BC speech. In [9], the MC method was derived for the PLC technique in noisy cases, in which how the transmitted BC speech can be reconstructed with higher accuracy by reducing the spectral dynamic range was investigated.

In recent years, voice over internet protocol (VoIP) has considerably increased due to the frequent use of internet telephony. VoIP utilizes a packet-switch network instead of circuit switching. Speech voice is degraded in packet-switched networks because of the delayed packet, additive noise, network congestion, packet arrival jittering, and bit errors [10]. The more bit errors finally cause the packet loss. Also, the high-speed network cannot conciliate a packet loss issue, resulting in degraded quality of speech [11]. Therefore, lost packets must be recovered to eschew speech quality degradation, which is known as PLC. Several methods have been recommended for PLC such as 2-sided LP, recovery sub-codec (RSC), deep neural network (DNN), hidden Markov model (HMM), adaptive recurrent neural network (A-RNN)-based PLC, and so on [11]-[17]. One representative of the classical PLC methods may be an LP-based PLC extensively utilized in global systems for mobile (GSM) technology [18]. Audio jitter buffer, network equalizer (NetEQ), is a web real-time communications (WebRTC's) default PLC whose performance is degraded in higher packet loss cases. A state-of-the-art PLC approach is WaveNetEQ (generative model) PLC built on DeepMind's wave recurrent neural network (WaveRNN) technology, which is deployed instead of the NetEQ PLC technique for accurate speech reconstruction [19]. Currently, the WaveNetEQ PLC approach is implemented in Google Due [20]. Among the above approaches, the DNN, HMM, WaveNetEQ, and A-RNN PLC techniques are state-of-the-art, but the large volume of speech data is required to be employed to train them, which is an inevitable hands-on problem in some circumstances, and they also face higher computational complexity. Contrariwise, the LP-based PLC technique provides better performance with a notably lower computational complexity. Few works are known for the LP-based PLC technique of BC speech in the literature. Therefore, there is sufficient scope to enhance the performance of the LP-based PLC approach.

In [21], a PLC method was proposed through sinusoidal extrapolation with pulse code modulation (PCM) coded at the recipient side. This PCM-coded PLC technique extrapolates filter coefficients and LP residuals from the last packet correctly received while speech packets are lost. In [22], the ACR method of LP was proposed for the PLC technique where the forward direction and bidirectional estimation processes were employed for 10% and more than 10% packet losses, respectively. The Levinson-Durbin (LD) algorithm was deployed to estimate the LP coefficients, and a better PLC was obtained by setting a large LP order. In [23], the PCM-coded PLC technique was proposed, where the predictive error signal of

the prior packet and the attained pitch period are employed to stimulate an excitation for packet loss. The forthcoming packet was omitted for backward estimation, resulting in signal attenuation. In [11], a recovery sub-codec (RSC) PLC technique was proposed that employed low delay code-excited LP (LD-CELP) where the ACR method of LP was deployed. BC speech possesses an expanded spectral dynamic range, which leads to a large eigenvalues expansion of the ACR matrix in the ACR method employed in the RSC-based PLC technique. To evade the eigenvalues expansion, we utilize the forward-backward LP (FBLP), which is often called the MC method [9], instead of the ACR method.

In the above conventional PLC techniques, LP-based methods are usually implemented. According to the existing PLC approaches [9][11][21]-[23], none of them incorporated the residual error estimates. Commonly, the conventional PLC method utilizes the ACR method where the L-D algorithm is employed. The ACR method provides degraded performance in an expanded spectral dynamic range of an input signal. On the other hand, the MC method reduces the eigenvalue expansion of BC speech, resulting in an improved ill-condition. From this point of view, we consider the MC method by including the residual error estimates. This study emphasizes the residual error estimation in both forward and backward packets to the lost packet. The predictive residual errors are added in each lost packet exclusively during the packet loss estimation. For the simulations, some objective evaluations are done, and it is demonstrated that the proposed PLC technique performs better than the conventional PLC approaches.

The following is the organizational structure of this paper. Section I includes the introduction. Section II provides an overview of the conventional method, while Section III explains the proposed approach. Section IV outlines the experiments. Results are discussed in Section V. Section VI concludes the paper.

II. Conventional PLC Method

In [9], the MC method was derived for the PLC technique in noisy cases, in which how the transmitted BC speech can be reconstructed with higher accuracy by reducing the spectral dynamic range was investigated. The AC speech was replaced by the BC speech to mitigate the additive noise problem, and the MC method was employed instead of the AC method to improve the ill-conditioned difficulties. The MC method of LP was derived from a least-squares (LS) method for estimating the LP coefficients by the concurrent minimization of the FBLP squared errors. In [9], without residual error estimates, the basic form of LP was defined as

$$s(n) = -\sum_{k=1}^{p} \alpha(k) s(n-k) \tag{1}$$

where $\alpha(k)$ and p correspond to the LP coefficients and the LP order, respectively, and $s(n-k)$ denotes the prior data samples. The total squared errors were expressed as

$$\mathcal{E} = \mathcal{E}_f + \mathcal{E}_b \tag{2}$$

where $\mathcal{E}_f$ and $\mathcal{E}_b$ denote the forward and backward squared errors, respectively, and they are defined as

$$\mathcal{E}_f = \sum_n (s(n) + \sum_{k=1}^{p} \alpha(k) s(n-k))^2 \tag{3}$$

$$\mathcal{E}_b = \sum_n (s(n) + \sum_{k=1}^{p} \alpha(k) s(n+k))^2, \tag{4}$$

respectively. In (3) and (4), the speech signal sample at time n, $s(n)$, is predicted by forward and backward LP filters with the order of p. When the LP coefficients $\alpha(1)$, $\alpha(2)$, ..., $\alpha(p)$ are represented in a vector form as

$$\boldsymbol{\alpha} = [\alpha(1), \alpha(2), \ldots, \alpha(p)]^T \tag{5}$$

where T denotes transpose. The MC method was derived to obtain the LP coefficients as follows. For the unknown vector $\boldsymbol{\alpha}$, the residual error vector, $\boldsymbol{\epsilon}$, is defined as

$$\boldsymbol{\epsilon} = \mathbf{R}\boldsymbol{\alpha} - \mathbf{r} \tag{6}$$

where $\mathbf{R}$ and $\mathbf{r}$ correspond to the observation matrix and measurement vector, respectively. We can define the least squares criterion as

$$L = \boldsymbol{\epsilon}^T \boldsymbol{\epsilon} \tag{7}$$

L is expanded as follows:

$$L = (\mathbf{R}\boldsymbol{\alpha} - \mathbf{r})^T (\mathbf{R}\boldsymbol{\alpha} - \mathbf{r})$$

$$= (\mathbf{R}\boldsymbol{\alpha})^T (\mathbf{R}\boldsymbol{\alpha}) + \mathbf{r}^T\mathbf{r} - (\mathbf{R}\boldsymbol{\alpha})^T\mathbf{r} - \mathbf{r}^T(\mathbf{R}\boldsymbol{\alpha}) \tag{8}$$

where $\mathbf{r}^T(\mathbf{R}\boldsymbol{\alpha})$ is represented by $(\mathbf{R}\boldsymbol{\alpha})^T\mathbf{r}$. Thus, equation (8) is rewritten as

$$L = \mathbf{R}^T\boldsymbol{\alpha}^T(\mathbf{R}\boldsymbol{\alpha}) + \mathbf{r}^T\mathbf{r} - 2\boldsymbol{\alpha}^T\mathbf{R}^T\mathbf{r} \tag{9}$$

Since (9) is a quadratic form of $\boldsymbol{\alpha}$, by differentiating (9) with respect to $\boldsymbol{\alpha}$ and setting it to zero, we obtain the following forms as

$$2\mathbf{R}^T\mathbf{R}\boldsymbol{\alpha} - 2\mathbf{R}^T\mathbf{r} = 0 \tag{10}$$

$$\boldsymbol{\alpha} = (\mathbf{R}^T\mathbf{R})^{-1}\mathbf{R}^T\mathbf{r} \tag{11}$$

$$\boldsymbol{\alpha} = \mathbf{C}^{-1}\mathbf{c} \tag{12}$$

where $\mathbf{C} = \mathbf{R}^T\mathbf{R}$ and $\mathbf{c} = \mathbf{R}^T\mathbf{r}$ correspond to the MC matrix and MC vector, respectively. In this PLC technique, the MC method reduced the eigenvalue expansion, which improved the ill-condition. This is because there is a centrosymmetric characteristic in the MC matrix, $\mathbf{C}$, resulting in better speech reconstruction in the PLC technique. However, in this PLC technique, the predictive residual error is ignored, which is expected to be estimated and incorporated in the case of optimal speech reconstruction for the PLC.

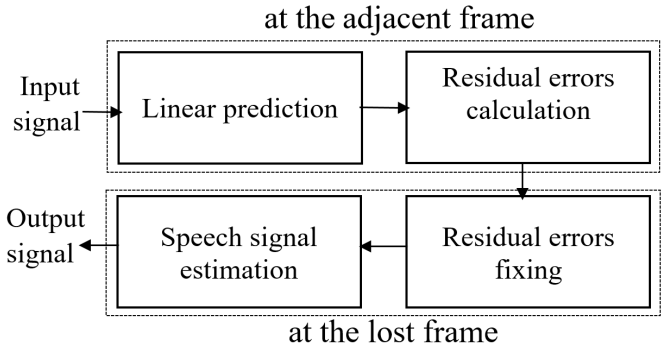

Fig. 1. Block diagram of the proposed method.

III. Proposed Method

This paper proposes a progressive PLC technique focusing on residual error signal which is an effective factor to provide an improvement of the LP method. The PLC technique in [9] avoided residual error estimates in the basic LP Eq. (1), in which residual error must be incorporated for accurate speech reconstruction in the PLC technique. Therefore, we modify Eq. (1) by incorporating the residual error estimates as

$$s(n) = -\sum_{k=1}^{p} \alpha(k) s(n-k) + \epsilon(n) \tag{13}$$

where $\epsilon(n)$ denotes the predictive residual error. The basic block diagram of the proposed method is shown in Fig. 1.

A. Residual Error Calculation

In the conventional LP-based PLC method, the long packet loss causes amplitude attenuation in the estimated speech signal, resulting in degraded speech quality. Therefore, the proposed method focuses on the estimation model of the speech signal in the packet loss and considers causality with the attenuation. The conventional LP form (1) is expanded, and the transition is performed then (1) becomes (14) as follows:

$$\begin{aligned} s(n) &= -\alpha(1)s(n-1) - \alpha(2)s(n-2) - \cdots - \alpha(p)s(n-p) \\ \implies & s(n) + \alpha(1)s(n-1) + \cdots + \alpha(p)s(n-p) = 0 \end{aligned} \tag{14}$$

Eq. (14) is a linear first-order combination of sample points, held in the LP method. By comparing Eq. (14) with Eq. (13), it is noted that the conventional estimation model Eq. (14) assumes the residual error, $\epsilon(n)$, to be 0. Thus, the estimated speech waveform is attenuated since the residual error is ignored in the speech estimation. Therefore, the residual error must be estimated that originally occurs in the lost segment from the adjacent packets, and needs to be incorporated into the speech estimation model to enhance the performance of the conventional LP-based PLC technique. The residual error is the difference between the true speech signal and the estimated speech signal. The LP error is calculated in the adjacent packets for the forward and backward directions. Through the LP errors $\epsilon(n)$ at the adjacent packets, the estimated LP residual error, $\hat{\epsilon}(n)$, in the lost packet is calculated as

$$\hat{\epsilon}(n) = s(n) - \hat{s}(n); (n = 0, 1, \ldots, L-1) \tag{15}$$

where L denotes the length of a packet loss. The error estimation takes advantage of the fact that the LP error has the same periodicity as the original speech signal. Since the periodicity is confirmed, the LP error of the packet loss is calculated through the concept of the PWR method. The conventional PWR method processes the speech waveform, but in this case, the processing is performed for the LP error, hence the input to the MC function changes to an LP error as

$$R(m) = -\sum_{k=0}^{L-1} \epsilon(k)\ \epsilon(k-m) \tag{16}$$

Algorithm 1 shows the residual error estimation process. In Algorithm 1, Tmp and PW correspond to samples for error estimate and window length for pitch extraction, respectively, and AR_{coef} denotes autoregressive (AR) coefficients of LP order M. Finally, the estimated LP error $\hat{\epsilon}(n)$ is incorporated into the conventional estimation model to conceal the lost packet as follows:

$$\hat{s}(n) = -\sum_{k=1}^{p} \alpha(k)\ s(n-k) + \hat{\epsilon}(n) \tag{17}$$

where $\hat{s}(n)$ and $s(n-k)$ correspond to predicted samples and previous samples, respectively.

Algorithm 1 : Residual error calculation

```
fun error ← residualError (Tmp, PW, AR_coef, M)
    for i ← M + 1 : PW
        xEsti ← −AR_coef^T × Tmp(i − 1 to i − M)
    end
    if size (xEsti, 1) ≠ size(Tmp, 1)
        xEsti ← xEsti^T
    end
    error ← Tmp − xEsti
end
```

B. Forward-Backward Packet Estimation and Addition

Eq. (17) with error estimate is concisely expressed as

$$\hat{s}(n) = -\boldsymbol{\alpha}\mathbf{s}^T + \hat{\epsilon}(n) \tag{18}$$

where $\boldsymbol{\alpha} = \big(\alpha(1)\ \ \alpha(2)\ \ \ldots\ \ \alpha(p-1)\ \ \alpha(p)\big)$,

$\mathbf{s} = \big(s(n-1)\ \ s(n-2)\ \ \ldots\ \ s(n-p)\big)$,

$\hat{\epsilon}(n) = \epsilon^f(n) + \epsilon^b(n)$, and

$\mathbf{s}$ and $\boldsymbol{\alpha}$ correspond to the input data vector and LP parameter vector, respectively. The LP coefficients in $\boldsymbol{\alpha}$ are obtained from the preceding and succeeding packets to the packet loss. Eq. (18) is more specifically expressed as

$$\hat{s}(n) = -\boldsymbol{\alpha}[1:p]\ \mathbf{s}^T[(n-1):(n-p)] + \hat{\epsilon}(n) \tag{19}$$

Eq. (19) is performed L times for the forward-backward predictions to retrieve lost samples in the packet loss. For instance, lost samples are estimated in the forward prediction as follows:

$$\begin{aligned} s^f(1) &= -\boldsymbol{\alpha}[1:p]\ \mathbf{s}^T[n:(n-p+1)] + \hat{\epsilon}(n) \\ &\cdots\quad \cdots\quad \cdots\quad \cdots\quad \cdots\quad \cdots \\ s^f(L) &= -\boldsymbol{\alpha}[1:p]\ \mathbf{s}^T[n+L-1:n+L-p] + \hat{\epsilon}(n+L-1) \end{aligned} \tag{20}$$

Algorithm 2 : Forward-backward packets addition

fun $s \leftarrow$ ***addition*** (FEF, BEF)
  $L \leftarrow length(FEF)$
  $s \leftarrow zeros([L \;\; 1])$
  for $i \leftarrow 1$ *to* L
    $\omega \leftarrow (i-1)/(L-1)$
    $s(n+i) \leftarrow FEF(i) \times (1-\omega) + BEF(i) \times \omega$
  end
end

In the backward prediction, lost samples are estimated as,

$$s^b(1) = -\boldsymbol{\alpha}[1:p] \;\; \mathbf{s}^T[n:(n+p-1)] + \hat{\epsilon}(n)$$
$$\ldots \quad \ldots \quad \ldots \quad \ldots \quad \ldots \quad \ldots$$
$$s^b(L) = -\boldsymbol{\alpha}[1:p] \;\; \mathbf{s}^T[n-L+1:n-L+p] + \hat{\epsilon}(n-L+1) \quad (21)$$

In Eq. (20) and Eq. (21), the estimated errors are incorporated, which pays an advantage to the proposed method over the conventional PLC methods. The estimated packets (forward and backward predictions) are stored in the buffer until they are added. We add these packets from the buffer to restore packet loss. Algorithm 2 shows the estimated packet addition process. In Algorithm 2, FEF and BEF indicate the forward and backward estimated frames, respectively, and L indicates the total number of samples in the lost packet. The linear weighting, ω, is defined as $0 \leq \omega \leq 1$. Fig. 2 represents a diagram of the 2-sided MC method where estimated residual errors are incorporated in both forward and backward predictions. The forward prediction is done from the previous packet of the packet loss, and the backward prediction is from the future packet of the packet loss as shown in Fig. 2(c). Then, the speech signal is reconstructed by adding forward and backward estimated packets as shown in Fig. 2(d). The proposed method using the forward and backward adjacent packets of the lost frame inherits the advantage of the LP method that the distortion does not occur in the estimated speech, and it overcomes the drawback where the amplitude of the estimated speech is attenuated.

IV. Experimental Conditions

We employed the National Research Institute of Police Science (NRIPS) database [24], from where the BC speech is implemented in this paper. In this database, the BC microphone TEMCO EML-1-A was used to measure BC speech, and a digital recorder EDIROL R-4 recorded the BC speech. We used 250 male and 250 female speech utterances of 50 different sentences pronounced by five males and five females for BC speech in the simulation. The evaluated result may differ for diverse speakers though the packet loss rate is identical. Therefore, the estimated score of each experiment of 250 times was averaged. As the objective evaluation, we utilized perceptual evaluation of speech quality (PESQ), log-spectrum distortion (LSD), and the log area ratio (LAR). The simulation details are shown in Table I.

V. Results Discussion

In this section, we conducted several comparisons between the conventional and proposed methods.

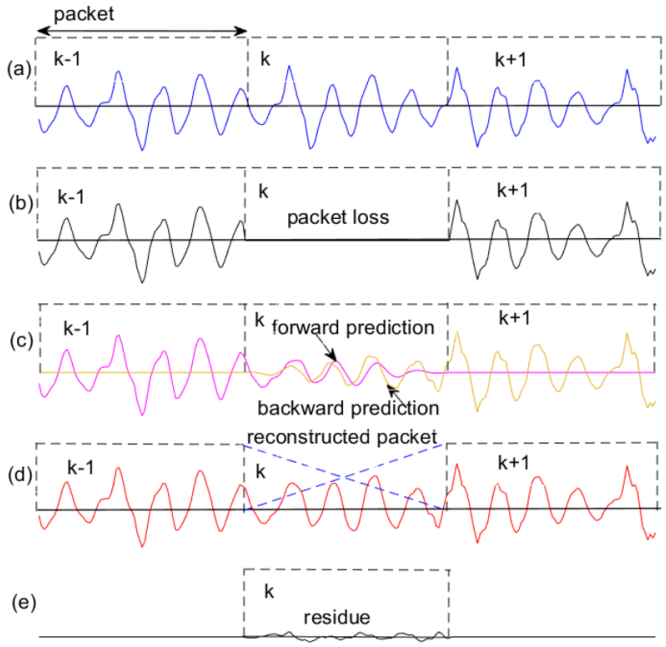

Fig. 2. Schematic diagram of 2-sided LP: (a) Original speech (b) Degraded speech (c) Forward and backward predictions (d) Reconstructed speech (e) Residue.

TABLE I. Simulation Specifications

Items	Specifications
Accent	Japanese pronunciations
Speaker	Male and female
Sampling frequency	8 kHz
Quantization	G.711 μ-law
Speech signal length	4-5 sec
Length of packet	10 ms
Loss rate	10% and 30%
LP order	12
LP analyzing window	20 ms
Window type	Rectangular

A. Estimated Waveform

The proposed PLC method avoids the use of linear gain to the restored speech signal, whereas the conventional PLC methods apply a linear gain of 1.1 to 1.8 [9][11][21]-[23]. The reconstructed speech waveform for the MC method without error estimate (conventional method) and the MC method with error estimate (proposed method) in the PLC technique are shown in Fig. 3, where the estimated speech waveform obtained by the proposed method is well-matched to the original transmitted speech waveform. This is because the incorporated residual error signal influences the quality of the reconstructed speech signal.

B. PESQ Score

The perceptual evaluation of speech quality (PESQ) was utilized as the objective evaluation to measure the excellence of speech for VoIP. The PESQ provides the quality of speech

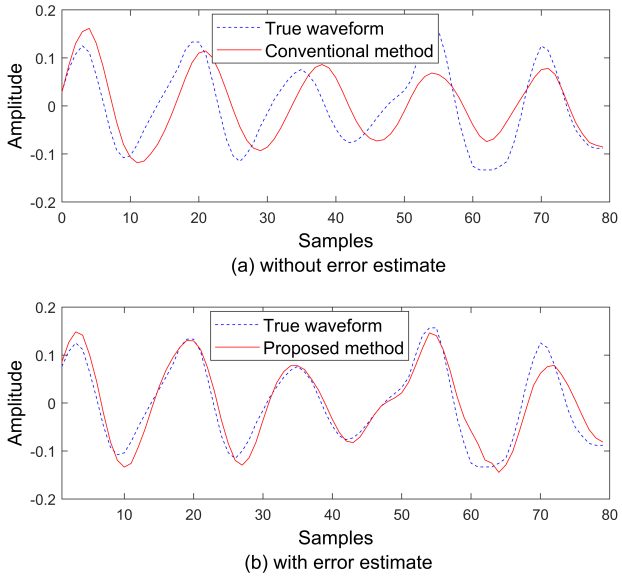

Fig. 3. Estimated waveform.

TABLE II. AVERAGE PESQ SCORES OF DIFFERENT METHODS

Methods	10% packet loss		30% packet loss	
	male	female	male	female
ACR method	3.57	3.61	3.12	3.19
RSC method	3.66	3.69	3.23	3.27
MC method	3.78	3.81	3.39	3.41
Proposed method	4.03	4.07	3.63	3.66

signal in the extent from -0.5 to 4.5, in which the higher quantity represents that the quality of speech signal is better [25]. Table II shows the PESQ scores of the ACR, RSC, MC, and proposed methods. The MC method has shown better results up to now [9], but the proposed method provides the best result over the conventional methods. In the case of 10% packet loss, the conventional MC method provides PESQ scores of 3.78 for males and 3.81 for females, respectively. On the other hand, the proposed MC method provides PESQ scores of 4.03 for males and 4.07 for females, respectively. Similarly, for 30% packet loss, the proposed method provides acceptable PESQ scores in both male and female cases than the conventional MC method. Thus, the PESQ score is higher for compensated speech signals wherein the residual error is incorporated. We utilized the same database [24] for all considering methods in this paper for a fair comparison.

C. LSD Score

Furthermore, the LSD score is observed for the restored BC speech for different methods in the PLC technique. We assumed a packet length of 20 ms and a frame-shifting of 10 ms for obtaining the LSD scores. The LSD scores of 24 frames from each restored speech are averaged through 10 ms frame

TABLE III. AVERAGE LSD SCORES OF DIFFERENT METHODS

Methods	Speakers	
	male	female
ACR method	12.08	11.89
RSC method	11.25	11.01
MC method	10.38	10.10
Proposed method	8.41	8.13

overlapping. The LSD is calculated as

$$LSD = \sqrt{\frac{1}{B}\sum_{b=1}^{B}\left|20\ \log_{10}\left(\frac{P(\omega_b)}{\hat{P}(\omega_b)}\right)\right|^2} \tag{22}$$

where $P(\omega_b)$ and $\hat{P}(\omega_b)$ correspond to the true and estimated power spectra, respectively, and B denotes the upper-frequency bin number. The proposed method provides lower LSD scores for reconstructed BC speeches as shown in Table III. The lower LSD value indicates a better reconstruction of the transmitted speech signal [7].

D. LAR Distances

LP coefficients are difficult to interpolate and sensitive to quantization errors. LP coefficients are normally converted into other parameters that are equivalent to LP coefficients. Also, the converted parameters are easy to handle before transmission. One such parameter is the log area ratio (LAR) which is used to represent LP coefficients for transmission over a channel [26]. The proposed method generates the LAR distance line nearer to the baseline as shown in Fig. 4. The LAR distance line nearer to the baseline discloses that the reconstructed speech signal is closer to the transmitted speech signal.

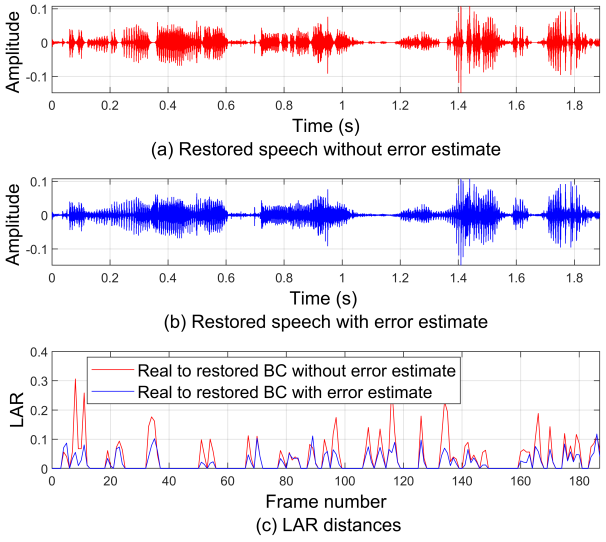

Fig. 4. LAR distances for estimated speech.

VI. Conclusion

This paper suggested a PLC technique for the MC method where the estimated residual error was incorporated in the forward and backward directions for packet loss compensation. The MC method was considered for BC speech to confirm residual error minimization and to improve the ill-condition for obtaining the best set of the LP parameters. The MC method compressed an expanded spectral dynamic range of input signals since the centrosymmetric characteristic was involved in the MC matrix C. It was also noted that the conventional LP-based PLC methods use a linear gain of 1.1 to 1.8. On the other hand, the proposed PLC method did not use a linear gain at all. Especially the PESQ and LSD scores showed the best results obtained by the proposed method. In the case of 10% packet loss, the proposed method provided PESQ scores of 4.03 for males and 4.07 for females, respectively. Through the LSD evaluation, the proposed method obtained the best LSD scores such as 8.41 for males and 8.13 for females, respectively. Simulation results in all objective evaluations showed that the proposed PLC method improves the conventional ones.

In this proposed method, residual error incorporation indicates one kind of input signal addition. In the future, we would like to use the combination of LP and polynomial prediction approaches in the PLC technique for better speech reconstruction without error signal incorporation.

***Abstract*—As internet usage and connected devices continue to proliferate, the concern for network security among individuals, businesses, and governments has intensified. Cybercriminals exploit these opportunities through various attacks, including phishing emails, malware, and DDoS attacks, leading to disruptions, data exposure, and financial losses. In response, this study investigates the effectiveness of machine learning algorithms for enhancing intrusion detection systems in network security. Our findings reveal that Random Forest demonstrates superior performance, achieving 90% accuracy and balanced precision-recall scores. KNN exhibits robust predictive capabilities, while Logistic Regression delivers commendable accuracy, precision, and recall. However, Naive Bayes exhibits slightly lower performance compared to other algorithms. The study underscores the significance of leveraging advanced machine learning techniques for accurate intrusion detection, with Random Forest emerging as a promising choice. Future research directions include refining models and exploring novel approaches to further enhance network security.**

***Keywords*—Machine learning; cyber security; intrusion detection; network security; cyber security**

I. Introduction

In recent years, cyber-attacks have become more sophisticated and frequent, posing significant challenges to cybersecurity efforts. As organizations increasingly rely on interconnected networks for their operations, they are exposed to a greater risk of malicious activities. Traditional security methods, such as firewalls and antivirus software, while still valuable, are struggling to keep pace with the evolving tactics of cybercriminals [1]. These attacks can take various forms, from relatively simple phishing emails to complex malware and DDoS attacks, resulting in operational disruptions, data breaches, and financial losses [2]. To effectively combat these threats, security professionals need to adopt more advanced techniques for threat detection and mitigation [3]. Machine learning algorithms offer a promising solution by leveraging data analysis to identify patterns and anomalies indicative of malicious activity [4]. By automating threat detection and response processes, ML can help organizations bolster their network security defenses in the face of evolving cyber threats.

A. Research Objectives and Motivation

The main objective of this paper is to conduct a comprehensive examination of network security attack classification using ML algorithms. By exploring various ML techniques and evaluating their applicability to network security, the research aims to enhance precision and efficiency in identifying and categorizing network attacks [4]. The motivation behind this research lies in the critical need for adaptive and intelligent security measures to counter the dynamic tactics employed by cybercriminals [5].

B. Consequences of Cyber-Attacks

The introduction also underscores the significant consequences of successful cyber-attacks, ranging from financial losses to reputational damage and legal ramifications [6]. This [7] highlights the importance of enhancing security measures to safeguard sensitive data, ensure uninterrupted operations, and maintain trust in digital systems.

C. Transition to Proactive Security Strategies

Furthermore, the integration of ML into network security protocols facilitates a transition from reactive to proactive security strategies [8]. By preemptively addressing potential threats, organizations can enhance overall resilience and security posture.

This paper will include a detailed comparative analysis with state-of-the-art methods, including recent advancements in deep learning applied to intrusion detection. Additionally, recent research in deep learning for intrusion detection will be reviewed to identify advancements and opportunities for improvement. This comprehensive comparison will enhance the credibility and relevance of the research findings.

This study is structured to first explore the existing landscape of network security and the challenges posed by cyber-attacks. It will then delve into the application of ML algorithms in enhancing threat detection and response processes. Following this, the paper will evaluate the strengths and limitations of existing network intrusion detection systems, proposing innovative ML solutions to address emerging challenges. Finally, it will provide recommendations for developing stronger, more flexible, and smarter security systems to combat cyber threats effectively in today's digital age.

II. Related Works

This review of the existing literature offers an in-depth examination of the present state of research in the classification of network security attacks through the application of machine learning algorithms.

A. Network Security Attack Classification

Traditional cybersecurity methods rely on predefined rules and signatures to detect and mitigate threats, but they struggle to keep up with the rapidly evolving tactics of cybercriminals. This [9] limitation has prompted a shift towards more adaptive and intelligent systems, leading to the exploration of machine learning techniques. In their examination of machine learning algorithms, the focus is on their crucial role in intelligent data analysis and automation within the cybersecurity field [10]. They [11] highlight the ability of these algorithms to extract valuable insights from diverse cyber data sources, demonstrating their relevance in real-world scenarios and illustrating how data-driven intelligence contributes to proactive cybersecurity measures [12]. Furthermore, [13] their analysis explores current methodologies, their practical implications, and emerging research directions, aiming to provide a comprehensive understanding of the current state of machine learning in cybersecurity and its potential for transformative advancements in line with the goals of our research

B. Machine Learning in Network Security

Machine learning's role in network security extends far beyond just threat detection. It encompasses prevention, response, and recovery aspects as well. By leveraging machine learning, organizations can build systems that continuously adapt to emerging threats, effectively fortifying their defenses against evolving attack patterns [14]. This adaptability is particularly crucial in an environment where cyber threats are constantly evolving in sophistication and evasiveness.

Furthermore, a recent study introduces a comprehensive taxonomy of security threats, evaluating the potential of artificial intelligence (AI), including machine learning, to address a wide range of challenges. This study in [15] represents the first exhaustive examination of AI solutions across various security types and threats. It covers lessons learned, current contributions, future directions, open issues, and strategies for effectively countering advanced security threats [16]. This holistic approach underscores the significance of integrating machine learning techniques into network security frameworks to combat the diverse and evolving landscape of cyber threats effectively.

C. Existing Machine Learning Approaches

In addition to supervised learning methods like Support Vector Machines (SVM) and Random Forests, unsupervised learning approaches, particularly anomaly detection, have gained prominence in the realm of network security. Unlike supervised methods that rely on labeled datasets to classify attacks, anomaly detection techniques can identify deviations from normal network behavior without predefined attack signatures. This makes them particularly useful for detecting novel and previously unseen threats that may not be captured by traditional rule-based systems.

For instance, research conducted by [17] on intrusion detection exemplifies the application of machine learning in enhancing security measures. By leveraging machine learning algorithms, researchers have demonstrated the effectiveness of these techniques in discerning malicious activities within network traffic. This study showcases the potential of machine learning to augment traditional security measures by providing a more adaptive and proactive approach to threat detection and mitigation [18].

Furthermore, the exploration of machine learning approaches in network security continues to evolve, with researchers investigating new algorithms and methodologies to address emerging challenges. As cyber threats become increasingly sophisticated and diverse, the integration of machine learning techniques holds promise for enhancing the resilience of network defenses and mitigating the impact of cyber-attacks.

D. Feature Extraction

The success of machine learning models in network security heavily relies on the selection and extraction of relevant features. Features can include traffic patterns, packet content, and behavioral analysis [19]. The process of feature selection is critical in optimizing the performance of the machine learning model, as irrelevant or redundant features can lead to decreased accuracy and increased computational overhead. Researchers in [20] have explored various feature selection techniques to identify the most informative features for attack classification. The study in [21] employs machine learning models and feature selection techniques to detect DDoS attacks in SDN, achieving optimal accuracy (98.3%) with KNN.

Feature engineering is a critical step in the data preprocessing pipeline, aimed at transforming raw data into a format that enhances the performance of machine learning models. It encompasses various techniques, including feature extraction and feature selection, to optimize the dataset for analysis. Given our dataset's high dimensionality with 49 features, effective dimensionality reduction was essential to streamline the analysis and mitigate computational complexity. To achieve this, we opted for PCA as a feature extraction technique. PCA transforms the original features into a reduced set of principal components, capturing the dataset's essential variance while preserving valuable information. Unlike feature selection techniques, which may exclude potentially informative features, PCA retains underlying patterns and structures in the data. This approach not only enhances computational efficiency but also maintains the integrity of the dataset. Explained variance analysis revealed that 10 principal components accounted for 90% of the dataset's variance, striking an optimal balance between variance coverage and computational complexity in our study.

The model ensures high security and prediction accuracy, serving as an experimental basis for enhancing safety in smart city rail transit systems.

F. Research Gap Analysis

Addressing the identified research gaps holds paramount importance in advancing our understanding and fortification against privacy attacks in the realm of machine learning. Existing studies exhibit a propensity to focus on specific machine learning models, leaving a critical void in comprehending privacy threats across a broader spectrum of techniques. Furthermore, the proposed attack taxonomy provides a foundational framework, yet there exists a gap in grasping the nuanced impact of different adversarial knowledge levels on the severity of privacy attacks. Bridging this gap demands a contextual exploration of privacy attacks within real-world machine learning applications, considering the diversity of domains and their unique challenges. The scarcity of longitudinal studies underscores the need for a dynamic perspective, tracking the evolution of privacy attacks over time. Lastly, the burgeoning landscape of emerging machine learning paradigms, such as federated learning and edge computing, lacks adequate attention in current research, necessitating a focused effort to understand and mitigate privacy attacks in these evolving contexts. Addressing these gaps promises significant implications, fostering the development of more resilient privacy-preserving machine learning models, implementing enhanced security measures, and cultivating a holistic comprehension of privacy risks for the continued advancement of secure and ethical machine learning applications.

III. METHODS

The research methodology for this study adopts a quantitative approach leveraging empirical data to draw objective conclusions and make generalizations about the relationships between variables quantitative research is deemed suitable for this investigation as it enables the measurement and analysis of numerical data providing a statistical foundation for evaluating ML in network security attack classification.

A. System Design

The system design shown in Fig. 1, is designed to analyze network security attacks using a subset of the unsw nb 15 dataset it comprises two main steps aimed at enhancing the accuracy of attack detection in the initial step data preprocessing is conducted involving both standardization and normalization to ensure uniformity in the dataset given the datasets high dimensional nature some features may be irrelevant or redundant potentially impacting the accuracy of attack detection negatively to address this issue a feature selection process is implemented to identify and retain only the most relevant subset of features effectively eliminating useless and noisy elements from the multidimensional dataset moreover class imbalance is recognized as a potential challenge in the dataset to mitigate this specific measures are taken to balance the representation of different attack categories ensuring that the classifiers are trained on a more equitable distribution of data moving on to the second step various classifiers are trained using the selected and refined features these classifiers are designed to detect all categories of attacks thereby aiming for maximum accuracy in the identification of security threats the utilization of multiple classifiers allows for a comprehensive assessment of the dataset considering the nuanced characteristics of different attacks finally the model's performance is evaluated using key

metrics such as accuracy precision recall and f 1 score these measures provide a thorough understanding of how well the classifiers are performing in terms of correctly identifying and classifying network security attacks the combination of these performance metrics ensures a comprehensive evaluation taking into account various aspects of the model's effectiveness in summary the proposed methodology begins with meticulous data preprocessing addressing issues of standardization normalization and feature selection it then tackles the challenge of class imbalance before training classifiers to detect diverse attack categories the evaluation phase employs a set of performance metrics to gauge the overall effectiveness of the framework in accurately identifying and classifying network security threats this methodological approach provides a systematic and robust foundation for analyzing network security attack data.

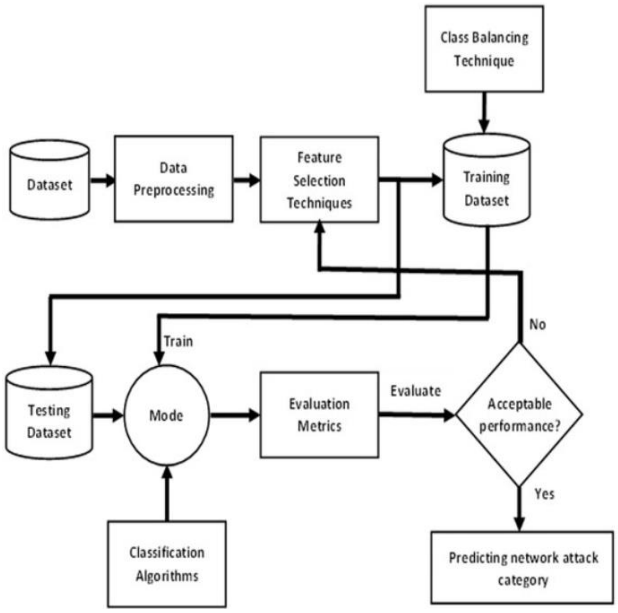

Fig. 1. System design.

B. Data Collection

1) Data sources: Network traffic and attack data will be sourced from Kaggle. This includes both real-world and simulated datasets to ensure a comprehensive evaluation.

The unsw nb 15 dataset crafted by researchers in 2015 stands as a comprehensive resource specifically tailored to address advanced network intrusion techniques comprising an extensive collection of 25 million records this dataset provides a rich and diverse landscape for the study of network security threats to the dataset encapsulates the complexity of modern cyber threats by encompassing 49 distinct features facilitating a nuanced analysis of network activity the 49 features in the dataset encapsulate various aspects of network traffic creating a multidimensional representation of cyber activities these features serve as essential variables for understanding and classifying different types of network security attacks researchers and practitioners benefit from the detailed and granular information embedded in each record enabling a thorough exploration of advanced intrusion techniques one noteworthy characteristic.

Nine different classes of attack families each representing a unique category of network security threat these classes encompass a wide spectrum of attack methodologies providing a holistic view of the diverse challenges faced in contemporary cybersecurity the dataset employs two label values for classification normal and attack enabling the categorization of network activities into either benign or malicious classes the dataset s utility extends shown in Fig. 2. The unsw nb 15 dataset serves as a vital resource in the field of cybersecurity research offering a rich and diverse collection of network activity records that enable in depth investigations into advanced intrusion techniques and the development of effective security solutions its comprehensive nature and well defined class structure make it an invaluable tool for researchers practitioners and educators alike in advancing the understanding and mitigation of network security threats.

2) Data preprocessing: Raw data will undergo preprocessing to handle missing values normalize features and address any anomalies this step is crucial for the effective application of machine learning algorithms.

a) Data standardizations: Data standardization, also known as data normalization, is a crucial preprocessing step in data analysis, particularly when working with machine learning algorithms sensitive to input feature scales. This process transforms the values of different variables to a common scale, ensuring that no particular feature dominates the learning process due to differences in their original scales. By rescaling the variables to have a mean of 0 and a standard deviation of 1, standardizing the data aids in maintaining consistency and improving algorithm performance. Formula is:

$$Z'' = X' - M' / \sigma'$$

Here:-

- Z" is the standardized value
- X' is the original value of the variable
- M' is the mean of the variable
- σ' is the standard deviation of the variable.

b) Data normalization: Data normalization is a preprocessing method employed to adjust numerical variables to a standardized range, usually between 0 and 1. This practice aims to ensure that all variables equally contribute to the analysis, preventing any single feature with larger magnitudes from dominating. One frequently used technique for normalization is min-max scaling, which involves a formula for normalizing a variable.

$$X\text{normalized} = X\text{max} - X\text{min} / X - X\text{min}$$

C. Machine Learning ML Classification Algorithm

Machine learning classification algorithms are computational tools created to classify input data into predefined categories or labels by analyzing their underlying patterns and characteristics. These algorithms learn from labeled training data, identifying patterns and relationships to predict the class labels of new instances. Various classification

algorithms, each with unique methodologies such as rule-based decision-making or probabilistic modeling, are utilized to effectively categorize data points into different classes. These algorithms are versatile tools used for tasks like detecting spam, recognizing images, and diagnosing medical conditions. Their performance is typically assessed using metrics such as accuracy, precision, recall, and F1 score, ensuring their efficacy across diverse applications.

This is a Classification problem where we want to detect whether there is an attack or not.

1) KNN: This is Ml algorithm proficient in both classification and regression assignments. Unlike traditional methods, KNN doesn't undergo a conventional training phase but rather memorizes the entire training dataset. During prediction, it relies on the proximity of data points within the feature space [31]. To classify a new data point, KNN computes distances, often employing Euclidean distance, from the point to all other instances in the training set. The k-nearest neighbors, identified by the smallest distances, then engage in a majority voting mechanism to allocate the class to the new data point. Alternatively, a weighted voting system can be utilized, granting closer neighbors greater influence. In regression duties, KNN forecasts the target value through averaging (or weighted averaging) the target values of the k-nearest neighbors. The selection of the hyper-parameter 'k' is pivotal, as it shapes the algorithm's sensitivity and generalization capability. KNN showcases its adaptability across various domains like image recognition and recommendation systems. Nonetheless [32], its performance hinges on meticulous 'k' selection, the choice of a distance metric, and understanding the dataset's traits. Employing efficient data structures such as KD-trees can enhance scalability, while thoughtful parameter tuning ensures its efficacy across diverse contexts.

2) Random forest: It is an ensemble learning method widely used for classification and regression tasks, particularly in intrusion detection, the algorithm operates through bootstrapped sampling creating diverse subsets of the dataset by randomly selecting instances with replacement and training individual decision trees on these subsets key to its robustness is the random select of features at each node split tree construction preventing overemphasis on specific features in classification random forest employs a majority voting mechanism aggregating predictions from multiple trees to make [33] the final decision this approach not only yields high accuracy but also enhances the models resilience to noise and variability the algorithm s adaptability and effectiveness make it a valuable tool in cybersecurity and various other domains.

3) Naïve bayes: Naive Bayes is a probabilistic classification algorithm based on Bayes theorem with the naive assumption of feature independence it s particularly effective for text classification and spam filtering the algorithm calculates the probability of a given instance belonging to a specific class by considering the conditional probabilities of each feature given the class despite its simplicity naive bayes often performs well and is computationally efficient the naive assumption simplifies calculations making it suitable for high dimensional datasets despite its success naive bayes might struggle with correlated features violating the independence assumption nevertheless its speed simplicity and respectable performance in various applications make it a popular choice for tasks involving categorical or text based data.

4) Logistic regression: It is used linear model for binary and multiclass classification problems despite its name. Also sigmoid the logistic function transforms the output into a range between 0 and 1 interpreting it as the probability of the positive class the algorithm optimizes its parameters through maximum likelihood estimation regularization techniques like l 1 or l 2 regularization can be applied to prevent overfitting logistic regression is interpretable and its coefficients provide insights into feature importance it s suitable for linearly separable problems but may struggle with complex relationships ensemble methods like random forest often outperform logistic regression on more intricate datasets but its simplicity interpretability and efficiency make it a valuable tool in various classification tasks.

D. Evaluation Metrics

Evaluation metrics serve as the compass for navigating the landscape of machine learning model performance accuracy the bedrock metric quantifies the models overall correctness precision zooms in on the models ability to avoid false positives while recall encapsulates its prowess in capturing all actual positive instances the f 1 score harmonizes precision and recall into a single metric striking a balance between precision oriented and recall oriented scenarios the confusion matrix a comprehensive tableau breaks down a models predictions into true positives true negatives false positives and false negatives these metrics collectively illuminate the multifaceted facets of a models effectiveness providing practitioners with a versatile toolkit to gauge and enhance performance across diverse applications shown in Fig. 2.

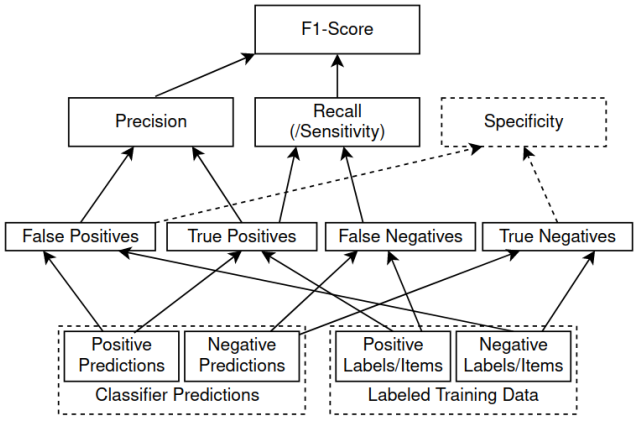

Fig. 2. Performance evaluation.

IV. IMPLEMENTATION

The experimental setup encompasses the selection and preparation of datasets the configuration of machine learning algorithms and the establishment of a controlled environment for rigorous testing the unsw nb 15 dataset consisting of 2 5 million records with 49 features was chosen for its relevance to advanced network intrusion techniques to ensure a diverse representation of attacks the dataset was partitioned into training and testing sets.

A. Tools and Techniques

This experimentation involved the implementation of various machine learning algorithms to evaluate their performance in network security attack classification python leveraging popular libraries such as scikit learn and tensor flow served as the primary programming language for algorithm implementation the choice of algorithms includes decision trees support vector machines neural networks and ensemble methods each configured with appropriate hyperparameters.

B. Implementation

The machine learning algorithms were implemented using a modular and scalable approach allowing for easy integration of new algorithms and flexibility in experimenting with different configurations the jupyter notebook was version-controlled using git to track changes and ensure reproducibility.

1) Import dataset: In the dataset preparation phase, the unsw nb 15 datasets were employed consisting of both training set unsw nb 15 training set csv and a testing set unsw nb 15 testings set csv the dataset was loaded into a python environment using the pandas library the training set as read from the unsw nb 15 training set csv file comprised 82 332 records while the testing set obtained from the unsw nb 15 testing set csv file included 175 341 records to verify the integrity of the dataset and ensure the appropriate division between training and testing data the lengths of the training and testing sets were checked the training set exhibited a length of 82 332 records and the testing set comprised 175.

2) Data visualization: The data visualization code utilizes the seaborn library to create informative plots depicting the distribution of attacks and normal traffic in both the training and testing sets the first two count plots in the top row display the overall distribution of labels attack or normal in the training and testing datasets meanwhile the bottom row illustrates the distribution of attack categories in both sets with the order specified based on the frequency of attack categories these visualizations provide a clear overview of the class distribution and the prevalence of different attack categories within the datasets such insights are crucial for understanding the imbalance between attack and normal instances and guide subsequent steps in the analysis such as addressing class imbalances and selecting appropriate evaluation metrics for machine learning models show in Fig. 3.

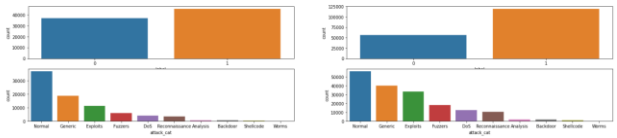

Fig. 3. Data visualization.

Next distribution of classes in the target variable showcases the balance or imbalance between normal and attack instances in Fig. 4. This is crucial for assessing the dataset's class distribution and potential class imbalance, which can impact machine learning model training.

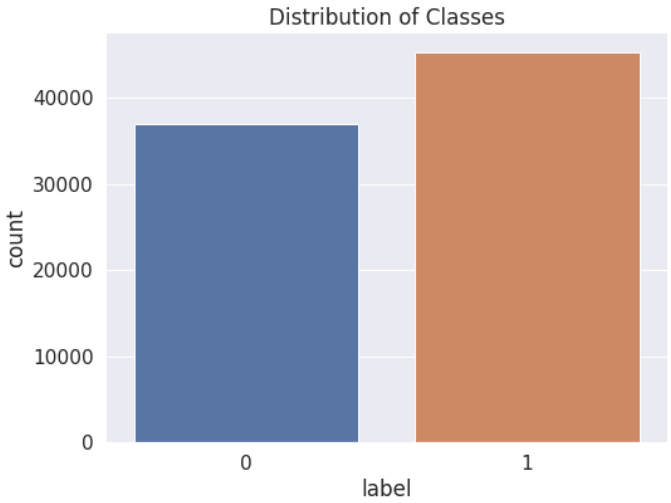

Fig. 4. Distribution of classes.

The below in Fig. 5, visualization presents a correlation heatmap, offering a comprehensive overview of the numerical features' relationships. This heatmap aids in identifying potential multicollinearity and understanding feature interdependencies.

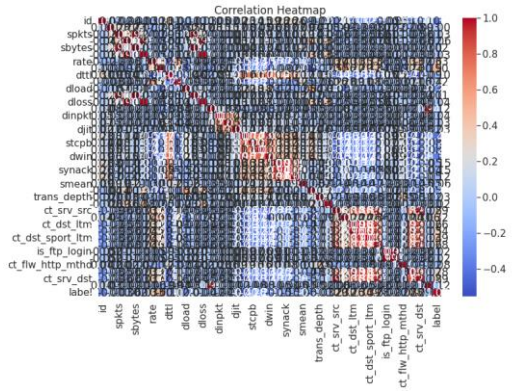

Fig. 5. Correlation of heat map.

In Fig. 6, a boxplot of the sttl feature is depicted showcasing its distribution across different classes this graphical representation allows for a quick assessment of the feature's potential discriminative power in distinguishing between normal and attack instances together these visualizations contribute to a holistic understanding of the dataset's characteristics guiding subsequent steps in the analysis and model development.

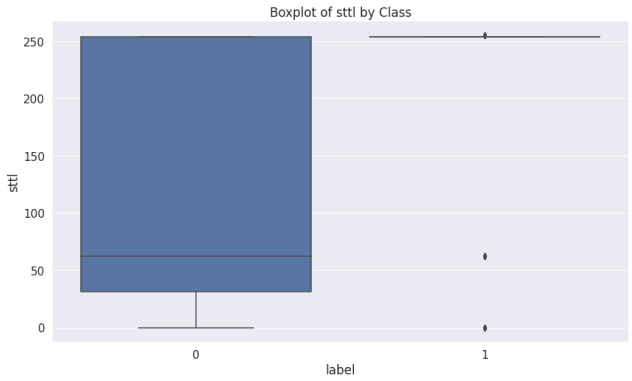

Fig. 6. Boxplot of sttl by class.

3) Data preprocessing: The data preprocessing phase involved a comprehensive examination and cleaning of the dataset the initial step focused on identifying and handling missing values and the results showed that there were no null values in any of the features this indicates a well maintained dataset without missing information ensuring the integrity of the subsequent analysis furthermore a closer look at categorical variables including proto service state and attack cat revealed the nature of these attributes the attack cat variable which represents the attack category is a crucial element for classification tasks the categorical variables were encoded appropriately for machine learning algorithms and their unique values and distribution were inspected this preprocessing step ensures that the dataset is ready for model training with categorical variables appropriately handled and missing values addressed the cleanliness and encoding of categorical variables contribute to the robustness of the subsequent machine learning analysis and enhance the interpretability of the results.

Also, in [36], data preprocessing focuses on numeric variables and involves a thorough exploration of statistical summaries initially it showcases a selection of numeric features from the dataset such as id dur spkts and others highlighting their characteristics subsequently statistical summaries are generated including count mean standard deviation minimum 25th percentile median 50th percentile 75th percentile and maximum values for each numeric variable this summary provides valuable insights into the distribution and variability of these features furthermore an additional exploration of the unsw nb 15 testings set csv file is conducted to understand its structure and dimensions revealing that it contains 1 000 rows and 45 columns this step is crucial for gaining an overview of the testing set which will be utilized in the subsequent stages of model evaluation.

4) EDA: The dataset comprising features related to network security attack classification was initially examined for its dimensions and the presence of relevant attributes descriptive statistics were computed to understand the distribution and variability of numeric variables and class distribution analysis provided insights into the balance between normal traffic and different attack categories correlation matrices were employed to explore relationships between features aiding in the identification of potential multicollinearity visualization of categorical variables and the distribution of attack categories within them further enriched our understanding of the dataset s structure the eda process also encompassed data cleaning and preprocessing steps addressing missing values and encoding categorical variables scatter plots and density plots were generated to visualize relationships between numeric features facilitating the detection of patterns shown in Fig. 7 and Fig. 8.

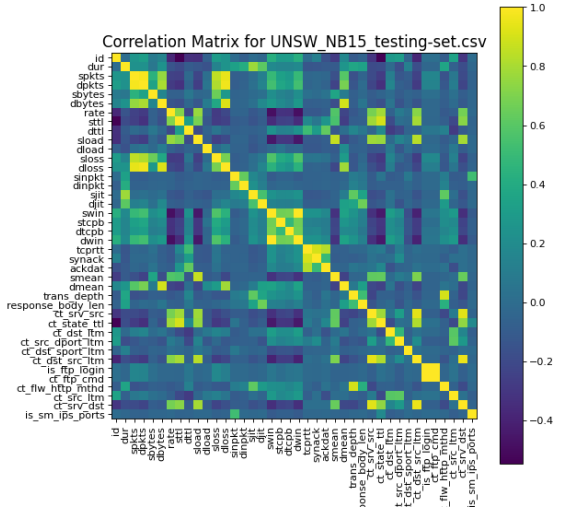

Fig. 7. Correlation matrix for test data.

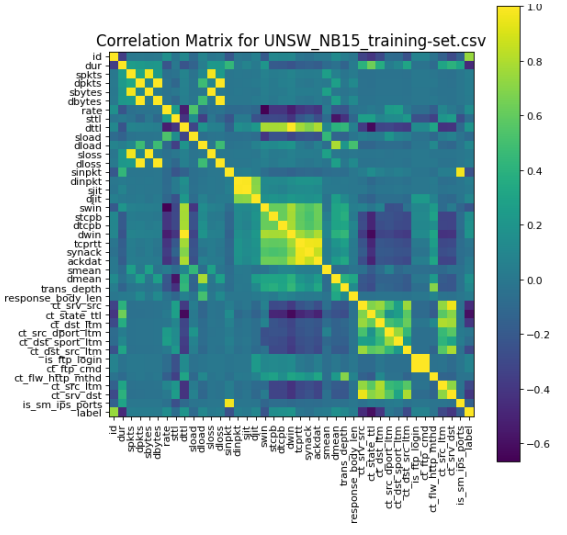

Fig. 8. Correlation matrix for train data.

5) Testing and training: The initial split was performed based on the index with the first 175 341 records designated for training and the remaining 82 332 records for testing the labels was extracted and assigned to y train and y test for training and testing respectively subsequently the label column was dropped from the feature sets to standardize the feature values a min max scaler was applied it s crucial to note that the scaler was fitted only on the training data to avoid data

leakage the training data x train was transformed using the fitted scaler and the testing data x test was scaled accordingly the final dataset dimensions were confirmed showcasing 175 341 samples for training each comprising 196 features and 82 332 samples for testing additionally categorical columns such as proto-state and service underwent one hot encoding for inclusion in the analysis these preprocessing steps ensure that the machine learning models are trained and tested on standardized and appropriately formatted data.

C. ML Model Classifications

1) Random forest: In Fig. 9, RF classification algorithm was implemented on a network security attack dataset, achieving an accuracy of 90%. The classification report details the model's performance in distinguishing normal and attack instances, with precision, recall, and F1 score metrics providing insights. For normal instances (label 0), precision and recall are 0.77 and 0.98, resulting in an F1 score of 0.86. For attack instances (label 1), precision, recall, and F1 score are higher at 0.99, 0.86, and 0.92 respectively. The weighted average F1 score is 0.90, indicating balanced performance. The confusion matrix shows the model correctly identifying 54,699 normal instances and 102,950 attack instances while misclassifying 1,301 normal instances as attacks and 16,391 attack instances as normal. Despite these misclassifications, the 90% accuracy highlights the random forest model's robustness in network security attack classification, contributing valuable insights to the research.

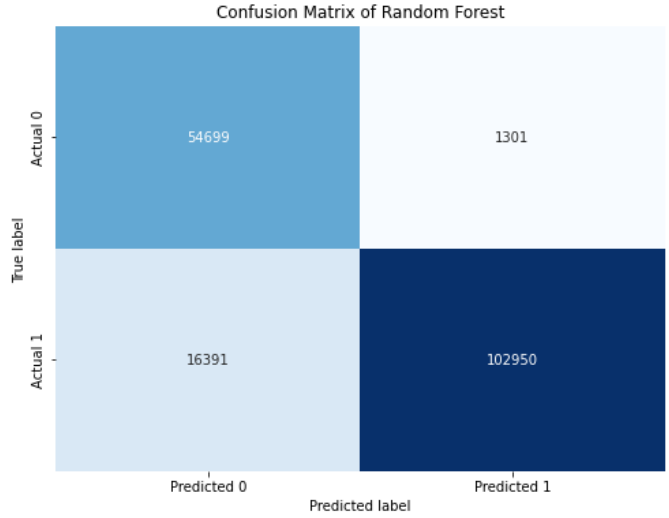

Fig. 9. Confusion matrix of random forest.

2) KNN: In Fig. 10, the K-Nearest Neighbors (KNN) classification algorithm was implemented with k=5 on the network security attack dataset, yielding an accuracy of 87%. The classification report provides detailed insights into the model's performance, showcasing its ability to discriminate between normal and attack instances.

For normal instances (label 0), the precision and recall are 0.72 and 0.96, respectively, resulting in an F1-score of 0.82. Similarly, for attack instances (label 1), the precision, recall, and F1-score are notably higher at 0.98, 0.83, and 0.90, respectively. The weighted average F1-score is reported as 0.87, indicating a balanced performance across both classes.

The confusion matrix further shows the classifier's effectiveness, correctly identifying 53,638 instances of normal traffic and 98,636 instances of attacks. However, the model misclassified 2,362 normal instances as attacks and 20,705 attack instances as normal. Despite these misclassifications, the overall accuracy of 87% underscores the robustness of the KNN model in distinguishing between benign and malicious network activities.

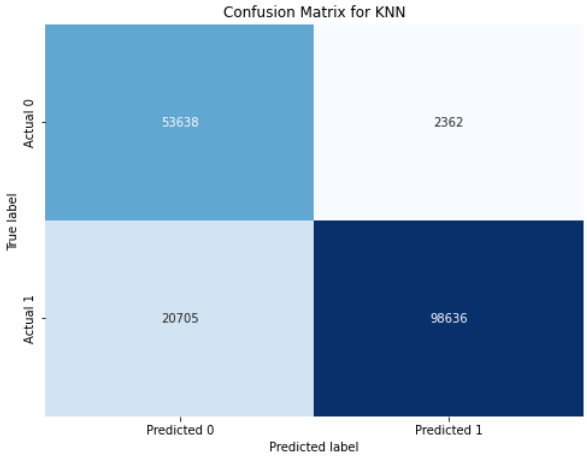

Fig. 10. Confusion matrix for KNN.

These findings contribute valuable insights to the research, emphasizing the efficacy of the K-Nearest Neighbors algorithm in the context of network security attack classification.

3) Naïve bayes: The Gaussian Naive Bayes classification algorithm was employed for network security attack classification, resulting in an accuracy of 79%. The classification report reveals that the model achieved a precision of 62% and recall of 87% for normal instances (label 0), yielding an F1-score of 0.72. For attack instances (label 1), the precision and recall are notably higher at 92% and 75%, contributing to an F1-score of 0.83. The weighted average F1-score is reported as 0.80, indicating a balanced performance across both classes shown in Fig. 11.

The confusion matrix provides additional insights, indicating that the model correctly identified 48,706 instances of normal traffic and 89,663 instances of attacks. However, there were misclassifications, with 7,294 normal instances being erroneously identified as attacks and 29,678 attack instances mistakenly labeled as normal. Despite these challenges, the Gaussian Naive Bayes algorithm demonstrates a commendable accuracy, emphasizing its suitability for network security attack detection in this context.

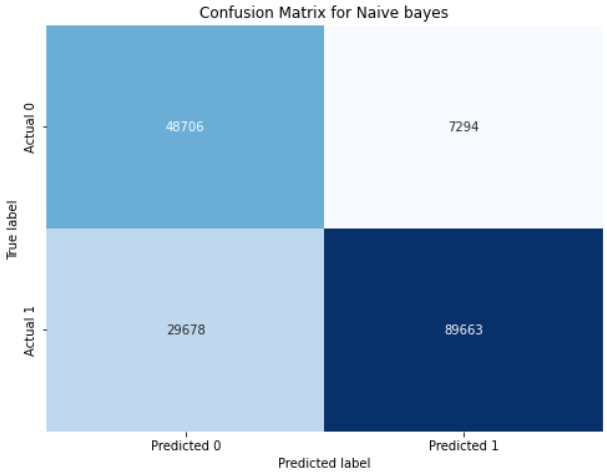

Fig. 11. Confusion matrix for naive bayes.

This analysis in Fig. 12 contributes valuable findings to the research, highlighting the strengths and limitations of the Gaussian Naive Bayes classifier in the domain of network security.

4) Logistic regression: The Logistic Regression classifier was implemented for network security attack classification, yielding an accuracy of 87.25%. The precision, recall, and F1-score for normal instances (label 0) are 74%, 92%, and 82%, respectively. For attack instances (label 1), the classifier achieved higher precision (96%) and slightly lower recall (85%), resulting in an impressive F1 score of 90.06%. The weighted average F1 score stands at 88%, indicating a balanced performance across both classes.

The confusion matrix and classification report provide detailed insights into Fig. 12, the classifier's performance. It correctly identified 51,592 instances of normal traffic and 101,719 instances of attacks. However, there were misclassifications, with 8,408 normal instances being erroneously identified as attacks and 17,622 attack instances mistakenly labeled as normal.

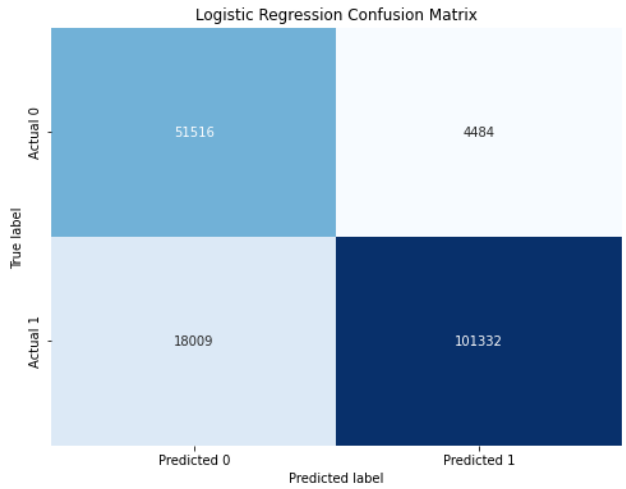

Fig. 12. Confusion matrix for logistic regression.

V. Results

The outcomes of the machine learning models including accuracy precision recall and f 1 score will be systematically analyzed a comparative study will be conducted to identify the algorithm that best suits the requirements of network security attack detection additionally insights gained from the analysis will be used to draw meaningful conclusions about the performance of each algorithm in handling diverse patterns present in the network traffic data.

TABLE II. Results of Classification Models without Feature Selection

Classifier	Accuracy	Precision	Recall	F1
Random Forest	0.90	0.92	0.90	0.90
K-Nearest Neighbors	0.87	0.90	0.87	0.87
Naive Bayes	0.79	0.83	0.79	0.80
Logistic Regression	0.87	0.85	0.96	0.90

In the result analysis Table II, the Random Forest classifier demonstrated superior performance with a high accuracy of 90%, effectively balancing precision and recall at 0.92 and 0.90, respectively. K-Nearest Neighbors (KNN) showcased strong predictive capabilities with an accuracy of 87% and a well-balanced precision-recall trade-off at 0.90 and 0.87. Naive Bayes exhibited a decent accuracy of 79%, with a precision of 0.83 and a balanced F1-Score of 0.80. Logistic Regression delivered an accuracy of 87%, with a commendable precision of 0.85 and a high recall of 0.96, resulting in a robust F1-Score of 0.90.

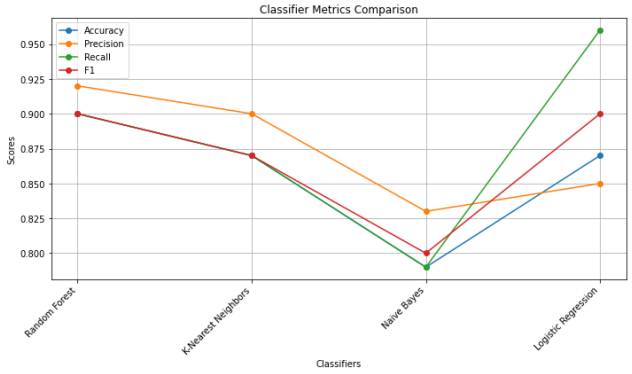

Fig. 13. ML classifiers metrics comparisons.

These classifiers play a crucial role in our network security context, offering effective means of identifying and classifying instances of security attacks based on the observed performance metrics in Fig. 13. The Random Forest model, in particular, emerges as a promising choice for its overall high accuracy and balanced precision-recall scores, making it well-suited for robust intrusion detection in network security applications.

A. Discussions

Building upon the result analysis the discussion section will explore the implications of the findings in the context of network security consideration will be given to the practicality efficiency and robustness of the algorithms the discussion will

also address potential challenges and limitations observed during the analysis providing a comprehensive perspective on the feasibility of deploying these algorithms in real-world scenarios furthermore comparisons with existing literature and benchmarks will be made to contextualize the significance of the results.

Deep learning has revolutionized intrusion detection, offering unparalleled accuracy and efficiency. In a study, [12] introduced the Principal Component-based Convolution Neural Network (PCCNN) approach for IDS, specifically targeting DoS and DDoS attacks on IoT devices. This approach boasts impressive accuracies of 99.34% for binary and 99.13% for multiclass classification on the NSL-KDD dataset. Utilizing a sophisticated architecture of 13 layers of Sequential 1-D CNN and feature reduction through Principal Component Analysis (PCA), it showcases exceptional promise for cutting-edge IoT intrusion detection.

Furthermore, the IDSGT-DNN framework, presented by [37], elevates cloud security by seamlessly integrating an attacker-defender mechanism using game theory and deep neural networks. This framework outperforms traditional methods in accuracy, detection rate, and various metrics on the CICIDS-2017 dataset. Remarkably, the defender's detection rate spans from 0 to 0.99, with gains strategically set at -5, 0, and 5. While the present study may not achieve the accuracies of the PCCNN approach (99.34% for binary and 99.13% for multiclass) and the IDSGT-DNN framework presented in previous works, it excels in computational efficiency. Our machine learning classifiers—Random Forest (RF) with an accuracy of 0.90, K-Nearest Neighbors (KNN) at 0.87, Naive Bayes with 0.79, and Logistic Regression (LR) also at 0.87—demonstrate competitive performance. Importantly, these classifiers deliver these results in significantly less time, underscoring the trade-off between accuracy and computational speed in intrusion detection systems.

Additionally, promising results in the random forest model showcased notable improvements achieving a commendable balance between precision and recall k nearest neighbors demonstrated strong predictive capabilities aligning with its suitability for identifying patterns in network traffic although naive bayes presented a lower accuracy its performance remains consistent with the algorithm s inherent assumptions logistic regression emerged as a reliable choice showcasing a balanced precision recall trade off collectively our findings contribute to the existing body of research by highlighting the effectiveness of these classifiers in the specific context of intrusion detection offering valuable insights for the development of robust and accurate network security systems.

The performance of the proposed methodology will be compared with existing approaches, highlighting the advancements achieved in Table III.

TABLE III. COMPARISON WITH EXISTING APPROACHES

Paper	Classifiers	Accuracy	Precision	Recalls
[34]	SGD	80%	82.1%	82.1%
This study	Random forest	90%	90.2%	90%
[35]	Neural network	87%	87.2%	87.8%
[3]	XGBoost	88%	88.3%	88.8%
[8]	SVM	76%	77%	77%
[23]	Random forest	80%	81%	8.9%
[14]	KNN	82%	82%	82%

B. Limitations

Though our study presented promising results, it is crucial to recognize the limitations. The effectiveness of machine learning models heavily relies on the dataset's quality and representativeness. The utilization of the unsw nb 15 dataset in our research may not adequately cover all real-world network traffic scenarios and variations. The chosen features and preprocessing techniques could impact model performance, suggesting further exploration of feature engineering methods to improve classifier efficacy. The selection of classifiers was based on established algorithms, but future research could investigate new approaches or DL methods for better outcomes. Evaluation metrics mainly focused on accuracy, precision, recall, and f1 score, potentially overlooking variations in performance among different attack types. These restrictions highlight the importance of continuous refinement and exploration in intrusion detection to combat evolving cyber threats effectively.

The ML models used in the present investigation have been practically implemented and tested using the real intrusion detection dataset, which is recognized for its relevance to real-world network intrusion scenarios. This approach leverages the dataset to demonstrate the models' practical applicability in a real-world network environment. By conducting experiments on the dataset, the effectiveness of the models in detecting a variety of attacks, including novel and sophisticated ones, was evaluated. This hands-on validation allows for the identification of operational challenges and fine-tuning of the models for improved performance in real-world scenarios. The practical testing provides valuable insights into the models' robustness, scalability, and applicability, thereby reinforcing their effectiveness and reliability in real-world network intrusion detection applications. Future research could consider novel approaches or DL methods for better results [38]. Evaluation metrics focused on overall accuracy, precision, recall, and f1 score, neglecting performance variations across different attack types. These limitations highlight the importance of continuous refinement and exploration in intrusion detection to address evolving cyber threats.

VI. CONCLUSIONS

The detailed examination and discussion of the outcomes provide valuable insights into the effectiveness of different machine learning classifiers for detecting intrusions in network security. The Random Forest classifier showed the best performance, with high accuracy, precision, recall, and F1 score. K-Nearest Neighbors and Logistic Regression also had good results, while Naive Bayes had a slightly lower performance. These results highlight the importance of using advanced machine-learning techniques for accurate intrusion detection. Choosing the right algorithm based on the specific characteristics of the cybersecurity task is crucial. However, it's important to recognize the limitations and future research should focus on improving models, exploring new approaches, and incorporating more data to enhance the strength and applicability of intrusion detection systems. In conclusion, this study adds to the conversation on strengthening cybersecurity defenses through machine learning methods. In concluding this study, it is essential to highlight future research possibilities for advancing intrusion detection and network security. One potential avenue is to enhance existing models through hyperparameter tuning and ensemble methods. Moreover, utilizing diverse datasets could broaden the adaptability of models to various network scenarios. Exploring deep learning approaches like neural networks could help uncover complex patterns in network traffic data. Additionally, addressing limitations like dataset reliance and biases may require more comprehensive datasets and real-world scenarios for model validation. Lastly, research could focus on creating hybrid models that combine multiple classifiers' strengths for increased resilience.

***Abstract*—Since the datasets of the practical problems are usually affected by various noises and outliers, the traditional extreme learning machine (ELM) shows low prediction accuracy and significant fluctuation of prediction results when learning such datasets. In order to overcome this shortcoming, the l_2 loss function is replaced by the correntropy loss function induced by the p-order Laplace kernel in the traditional ELM. Correntropy is a local similarity measure, which can reduce the impact of outliers in learning. In addition, introducing the p-order into the correntropy loss function is rewarding to bring down the sensitivity of the model to noises and outliers, and selecting the appropriate p can enhance the robustness of the model. An iterative reweighted algorithm is selected to obtain the optimal hidden layer output weight. The outliers are given smaller weights in each iteration, significantly enhancing the robustness of the model. To verify the regression prediction of the proposed model, it is compared with other methods on artificial datasets and eighteen benchmark datasets. Experimental results demonstrate that the proposed method outperforms other methods in the majority of cases.**

***Keywords*—p-order Laplace kernel-induced loss; extreme learning machine; robustness; iterative reweighted**

I. Introduction

Extreme Learning Machine (ELM), as a generalized single hidden layer feedforward neural network, was proposed by Huang et al. [1]. Its random selection of hidden node biases and input weights, along with the use of the ordinary least square method for determining the output weight, enables a simple, fast, and straightforward implementation. It has been widely used in load forecasting [2], [3], [4], fault detection [5], [6], image processing [7], image recognition [8] and other fields.

Although ELM performs well in terms of efficiency, it is susceptible to noise and outliers due to the use of the l_2 loss function, which can amplify their interference. Therefore, in recent years, many researchers have devoted themselves to the robustness of ELM. In regularized ELM [9], the regularization term of the objective function significantly improved the learning performance of ELM by minimizing the structural risk. Deng et al. [10] put forward a weighted least square regularized ELM (Weighted ELM, WELM) to enhance robustness by iterative weighted method. The above two methods employed l_2 loss function, which was optimal only when the error of the training datasets followed the normal distribution. However, many practical applications cannot guarantee the error followed a normal distribution, which lead to a fact that ELM is highly susceptible to noise and outliers. Subsequently, the researchers proposed several loss function such as Huber [11], l_1 [12] and Pinball [13] and their corresponding ELM models. However, these loss functions were still less robust because they had a linear relationship with the training error and increased linearly with the training error. Incorporating both regularization term (l_1, l_2) and various loss functions (l_1, Huber, bisquare and Welsch), Chen et al. [14] put forward an unified robust regularized ELM, which improved the robustness of ELM.

As the research progressed, the researchers found that machine learning algorithms based on non-convex loss functions had strong robustness to datasets disturbed by noise and outliers [15], [16], [17], [18]. The loss functions in classical machine learning methods, including hinge loss, ε-insensitive loss, and l_2-loss, were replaced by non-convex loss functions to construct the corresponding robust learning algorithms. Correntropy [19] is a nonlinear local similarity measure built on a Gaussian kernel function, which can weaken the role of noise and outliers in the learning process. The correntropy loss function has better robustness to noise and outliers than the convex loss function [20]. On this basis, Xing et al. [21] developed an ELM model based on the maximum correntropy criterion to improve robustness. C-loss function [22] and non-convex smooth loss [23] derived from correntropy and their corresponding models were proved to be robust to noise and outliers. Chen et al. [24] presented a maximum correntropy criterion with variable center (MCC-VC), which is also essentially a loss function derived from the correntropy. The use of Gaussian kernels in correntropy learning is common, owing to their smoothness and strict positive definiteness. Nevertheless, Gaussian kernels may not always be the optimal choice. On the one hand, this is because that the choice should be based on specific problem and experimental results to determine the optimal kernel function and parameters. On the other hand, the exponential part of the Gaussian kernel function is in the form of l_2, which would overemphasize the role of noise and outliers, so this could potentially lead to a greater sensitivity to noise and outliers. Yang [25] introduced a new method based on the Laplace kernel (LK-loss) and demonstrated that the LK-loss serves as a reliable approximation of the zero norm. Dong et al. [26] presented a robust semi-supervised support vector machines with Laplace kernel-induced correntropy loss functtion utilizing LaplaceSVM to solve the problem of insufficient supervisory information and noise effects in practical applications. Chen et al. [27] pointed out that taking the p-order function of the error as a loss function was effective to decrease the sensitivity of the model to the noise and outliers,

*Corresponding authors. email: wangkuaini1219@sina.com

and appropriate p was conducive to improve the robustness of the model. Chen et al. [28] put forward a robust ELM based on p-order Welsch loss function, and the experiments revealed the superiority of method over the Welsch loss.

Inspired by the above studies, this paper offers the p-order loss function into the correntropy loss function induced by the Laplace kernel (p-LKI loss function) and applies it to ELM. The main contributions of this paper are as follows:

(1) This paper introduces the Laplace kernel function into the correntropy and incorporates the p-order of the loss function into it, and proposes an ELM model based on p-LKI loss function. The robustness of the model can be significantly improved by choosing a suitable p.

(2) We have proved that the p-LKI loss function is positive-definite, bounded and non-convex, and can converge to 1 with increasing error. Additionally, as the parameter p increases, the p-LKI loss function serves as a favorable approximation of the zero norm.

(3) The iterative reweighted algorithm efficiently addresses the optimization problem and converges to the optimal solution within a few iterations. We investigate that the larger the error of the sample, the smaller weight assigned to it, thus the smaller the impact on the model.

The paper is organized as follows: Section II briefly introduces ELM. In Section III, we present an ELM based on p-order Laplace Kernel-Induced loss function and the iterative reweighted algorithm is used to address the problem. The experiments are conducted in different levels of outliers in artificial dataset and benchmark datasets in Section IV. The experimental results of the proposed method are discussed and compared with other methods in Section V. And the conclution and prospect are summarized in Section VI.

II. Brief Review of ELM

Given training samples $S = \{(x_i, y_i)\}_{i=1}^{N}$, $x_i \in R^d$, $y_i \in R$, the mathematical representation of the output function of a single hidden layer ELM with L hidden nodes and activation functions $h_i(x)$ is as follows:

$$f(x) = \sum_{i=1}^{L} h_i(x)\beta_i = h(x)\beta \tag{1}$$

where, $\beta = [\beta_1, \beta_2, \cdots, \beta_L]^{\mathrm{T}}$ is the output weight vector, $h(x) = [h_1(x), h_2(x), \cdots, h_L(x)]$ is the hidden layer output of variable x. Let $Y = [y_1, y_2, \cdots, y_N]^{\mathrm{T}}$, hidden layer output matrix $H = [h(x_1)^{\mathrm{T}}, h(x_2)^{\mathrm{T}}, \cdots, h(x_N)^{\mathrm{T}}]^{\mathrm{T}}$, the ELM model can be expressed as the following optimization problem [1].

$$\min_{\beta} \frac{1}{2}\|\beta\|^2 + \frac{C}{2}\|Y - H\beta\|^2 \tag{2}$$

where, C is a regularization parameter. The best solution in Eq. (2) is provided by Huang et al. [1] as,

$$\beta = \begin{cases} (H^{\mathrm{T}}H + I/C)^{-1}H^{\mathrm{T}}Y, & N \geq L \\ H^{\mathrm{T}}(HH^{\mathrm{T}} + I/C)^{-1}Y, & N < L \end{cases} \tag{3}$$

where, I denotes the identity matrix.

III. Robust ELM based on p-order Laplace Kernel-induced Loss Function

The l_2 loss function in ELM gives the same weight to each training samples, which makes the outliers have a larger impact on the sum of squared errors than the rest of the samples, resulting in model that is quite sensitive to outliers. Inspired by correntropy [19] and p-order loss functions [27], this paper proposes to use the p-LKI loss function to improve the robustness of ELM.

A. P-order Laplace Kernel-induced Loss Function

In order to improve the robustness of the model, the maximum correntropy criterion (MCC) [21] is introduced. Correntropy [19] describes the measure of similarity between two samples, the principle is as follows:

$$V_\sigma(A, B) = E(k_\sigma(A, B)) \tag{4}$$

where k_σ is the kernel function, $\sigma > 0$ is the kernel bandwidth, and E is the mathematical expectation. In most cases, the joint probability distribution between variables A and B is unknown, and the mean can be used to estimate the mathematical expectation. For variables $A = (a_1, a_2, \cdots, a_N)$, $B = (b_1, b_2, \cdots, b_N)$, and $q = (q_1, q_2, \cdots, q_N)$, $q_i = a_i - b_i$. The correntropy estimation is as follows:

$$V_\sigma = \frac{1}{N}\sum_{i=1}^{N} k_\sigma(a_i, b_i) \tag{5}$$

where $k_\sigma(q_i) = \exp(-\frac{|q_i|}{\sigma})$ is Laplace kernel function.

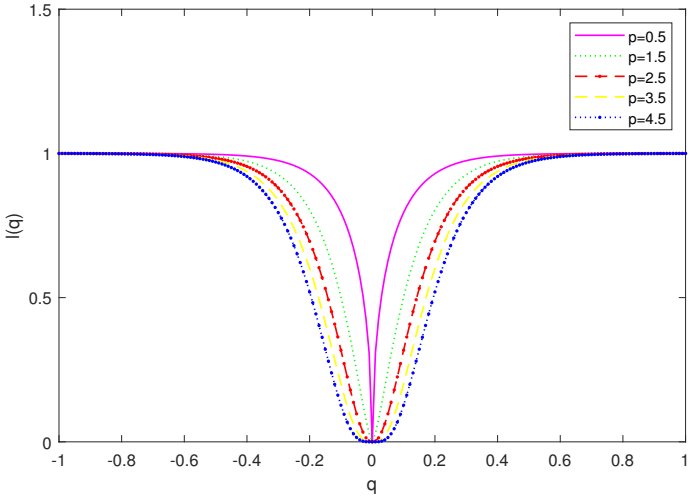
MCC [20] can be expressed as,

$$\max \frac{1}{N}\sum_{i=1}^{N} k_\sigma(q_i) = \max \frac{1}{N}\sum_{i=1}^{N} \exp(-\frac{|q_i|}{\sigma}) \tag{6}$$

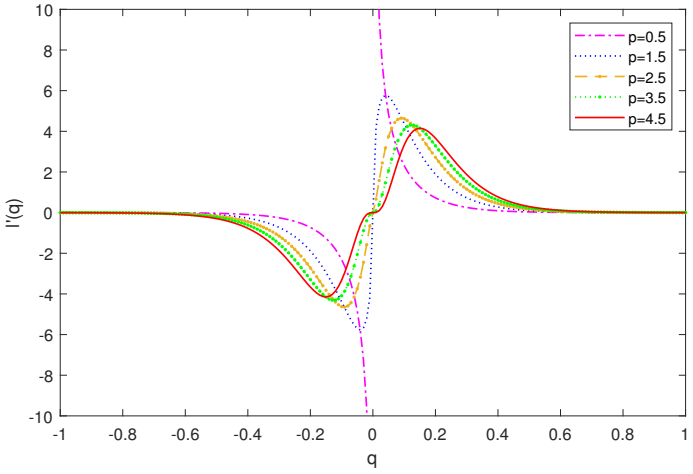
To facilitate the calculation, Eq (6) is equivalent to,

$$\min 1 - \exp(-\frac{|q|}{\sigma}) \tag{7}$$

Reference [27] pointed out that the loss function employing second-order statistical measures is susceptible to outliers, and it is not always a good choice for learning with samples that is non-Gaussian in nature. To address non-Gaussian data and noise, various non-second-order (or non-quadratic) loss functions have been proposed, such as the Huber minimum-maximum loss [15], Lorentz error loss [16], risk-sensitive loss [17], and mean p-power error (MPE) loss [27]. The MPE represents the p-th absolute moment of the error and effectively manages non-Gaussian datasets with an appropriate choice of the parameter p. Generally speaking, MPE demonstrates robustness to significant outliers for $0 < p < 2$ [27]. Inspired by the above studies, this paper proposes the following p-LKI loss function.

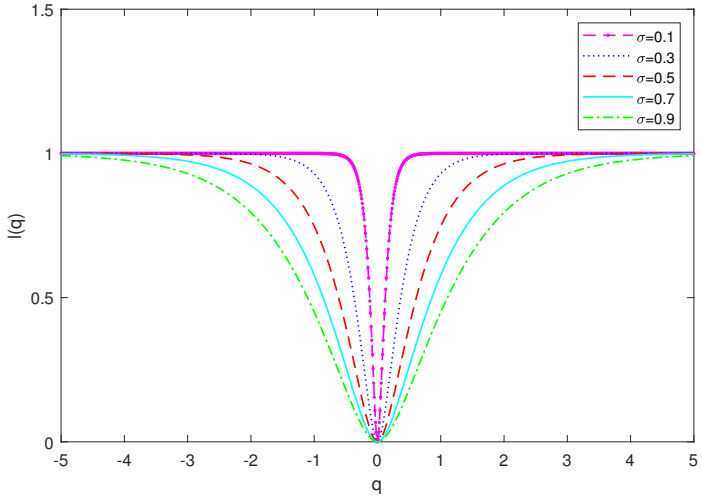


(a) p-Laplace loss functions

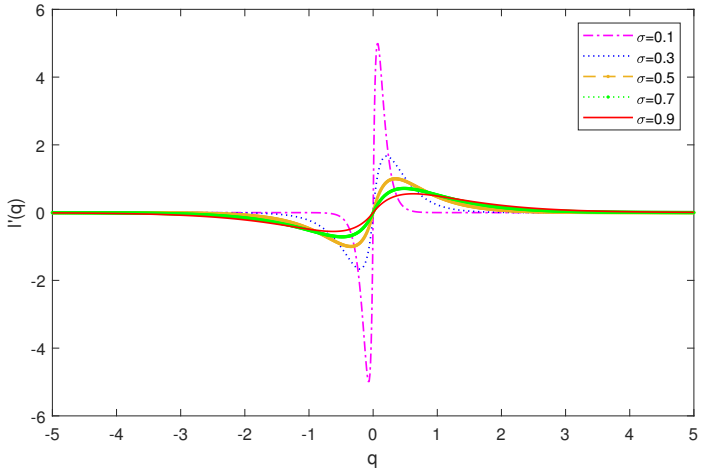


(b) the gradient functions of p-Laplace loss

Fig. 1. Comparison of p-LKI loss functions and their gradient functions under different p.



(a) p-Laplace loss functions



(b) the gradient functions of p-Laplace loss

Fig. 2. Comparison of p-LKI loss functions and their gradient functions under different σ.

$$l(q) = (1 - \exp(-\frac{|q|}{\sigma}))^p \tag{8}$$

The gradient function of p-LKI loss function is as follows:

$$\frac{\partial l(q)}{\partial q} = \frac{pq}{\sigma} \exp(-\frac{|q|}{\sigma})(1 - \exp(-\frac{|q|}{\sigma}))^{p-1} \frac{1}{\max\{|q|, 10^{-6}\}} \tag{9}$$

We can observe from Fig. 1(a), $l(q)$ becomes larger as $|q|$ increases and will eventually approach 1 for any value of p when $|q|$ reaches a certain threshold. Even if the $|q|$ increases again, $l(q)$ will only approach 1 again with little change, thus reducing the influence of significant errors brought by outliers on model training. Furthermore, as depicted in Fig. 1(b), as the value of p decreases, the extreme point of $l'(q)$ will move forward with the decrease of the value of p which means that the part of $l(q)$ that is most sensitive to error changes will move forward relatively. Therefore, when p is too large, the sensitivity of $l(q)$ to outliers will increase. However, when $p = 0.5$, $l'(q)$ is discontinuous at zero which means $l(q)$ is not differentiable at zero.

Fig. 2 shows p-LKI loss function $l(q)$ and its gradient function $l'(q)$ under different values of σ. It can be seen that with the increase of the values of σ, the corresponding $|q|$ will increase correspondingly when $l(q)$ approaches 1. With the decrease of the values of σ, the extreme point of $l'(q)$ is approaching zero, and the smaller the values of σ, the stronger the robustness of the model to the outliers. Therefore, the sensitivity of $l(q)$ to outliers can be reduced by adjusting the values of p and σ. The optimal values of p and σ will be further determined by grid search.

The p-LKI loss function offers the strengths in these aspects:

1. The p-LKI loss function $l(q)$, shown in Fig. 2(a), is a positive, symmetric, and bounded function. It attains its maximum value only when $q = 0$. The p-LKI fulfills the following:

$$\frac{\partial l(q)}{\partial q} = \operatorname{sgn}(q)\frac{p}{\sigma}\exp(-\frac{|q|}{\sigma})(1-\exp(-\frac{|q|}{\sigma}))^{p-1}, q \neq 0 \tag{10}$$

We have

$$\lim_{q\to\infty}\frac{p}{\sigma}\exp(-\frac{q}{\sigma})(1-\exp(-\frac{q}{\sigma}))^{p-1} = 0 \tag{11}$$

As shown in Eq.(11) that when the error approaches infinity, the gradient function $l'(q)$ of p-LKI approaches 0, indicating that $l(q)$ does not change for the outliers. Therefore, the p-LKI loss function is resistant to outliers.

2. For $\forall q \in R^N$,

$$\lim_{\sigma\to 0^+} l(q) = \|q\|_0 \tag{12}$$

Proof: The empirical risk derived from the p-LKI loss function can be represented as:

$$R_l(f) = \sum_{i=1}^{N}\left(1-\exp(-\frac{|q_i|}{\sigma})\right)^p \tag{13}$$

By evaluating the limit as $\sigma \to 0^+$, we obtain:

$$\begin{aligned}\lim_{\sigma\to 0^+} R_l(f) &= \lim_{\sigma\to 0^+}\sum_{i=1}^{N} l(q_i) \\ &= \lim_{\sigma\to 0^+}\sum_{i=1}^{N}\left(1-\exp(-\frac{|q_i|}{\sigma})\right)^p = \|q\|_0\end{aligned} \tag{14}$$

where the zero norm $\|q\|_0$ counts the non-zero elements of q.

3. In comparison to other estimations of the zero norm, like the p-order Gaussian kernel-induced loss (p-Welsch),

$$M(q) = (1-\exp(-\frac{q^2}{2\sigma^2}))^p \tag{15}$$

Fig. 3 (a) shows the curves of the p-LKI loss function and p-Welsch loss function with $p = 0.8$ and $\sigma = 0.1$. It can be inferred that the approximation precision of the p-LKI loss function is higher than the p-Welsch loss function which means that it is closer to the zero norm. Some advantages of the zero norm are as follows:

1) Sparsity: The zero norm loss function encourages the model to produce sparse weights, i.e. only a small percentage of the weights are non-zero. This can effectively reduce the complexity of the model and prevent over-fitting [27].

2) Robustness: By making the weights sparse, the zero norm loss function can enhance the robustness of the model. Only those features that are most important to the predictions of the model are given greater weight, thus reducing over-reliance on unimportant features.

Fig. 3 shows a comparison of loss functions such as l_2 [10], l_1 [12], Welsch [22], Laplace [25], p-Welsch [28], p-LKI loss function and their gradient functions. From the figure, it is evident that in addition to the l_2-loss function and l_1-loss function, the error of each dataset in the other loss functions is controlled $[0, 1]$. The gradient function will be small after the $|q|$ exceeds a certain value and will not increase with the increase of error like the gradient function of l_2-loss and l_1-loss, thereby reducing the influence of the large error term caused by outliers on parameter estimation. Moreover, we can observe from Fig. 3 that p-LKI loss function has the closest distance from the $\|q\|_0$ ($l(q) = 1$) , so the accuracy of the zero norm approximation of the p-LKI loss function is the highest. In addition, compared with the Welsch and p-Welsch loss functions induced by the Gaussian kernel function, the Laplace and p-LKI loss function induced by the Laplace kernel have higher approximate accuracy for zero norms, where the approximate accuracy of p-LKI loss function is higher than that of Laplace loss function.

3) Robust ELM based on p-LKI loss function: By taking the p-LKI loss function in ELM, the p-LKI-ELM model is established

$$\begin{aligned}\min_{\beta,q_i}\quad & \tfrac{1}{2}\|\beta\|_2^2 + C\sum_{i=1}^{N}\left(1-\exp(-\tfrac{|q_i|}{\sigma})\right)^p \\ s.t.\quad & h(x_i)\beta = y_i - q_i, i = 1, 2, \cdots, N\end{aligned} \tag{16}$$

According to the KKT condition, Eq. (16) can be reformulated as solving the following problem:

$$\begin{aligned}L(\beta, q_i, \alpha) = \frac{1}{2}\|\beta\|_2^2 + C\sum_{i=1}^{N}\left(1-\exp(-\frac{|q_i|}{\sigma})\right)^p \\ -\sum_{i=1}^{N}\alpha_i(h(x_i)\beta - y_i + q_i)\end{aligned} \tag{17}$$

where α_i is the Lagrange multiplier corresponding to each training sample.

Calculate the partial derivative of each parameter variable in Eq.(17), and let the partial derivative be zero,

$$\begin{cases}\dfrac{\partial L}{\partial \beta} = 0 \Rightarrow & \beta = \displaystyle\sum_{i=1}^{N}\alpha_i h(x_i)^{\mathrm{T}} = H^{\mathrm{T}}\alpha \\ \dfrac{\partial L}{\partial q_i} = 0 \Rightarrow & \alpha_i = Cq_i w(q_i) \\ \dfrac{\partial L}{\partial \alpha_i} = 0 \Rightarrow & h(x_i)\beta - y_i + q_i = 0\end{cases} \tag{18}$$

where

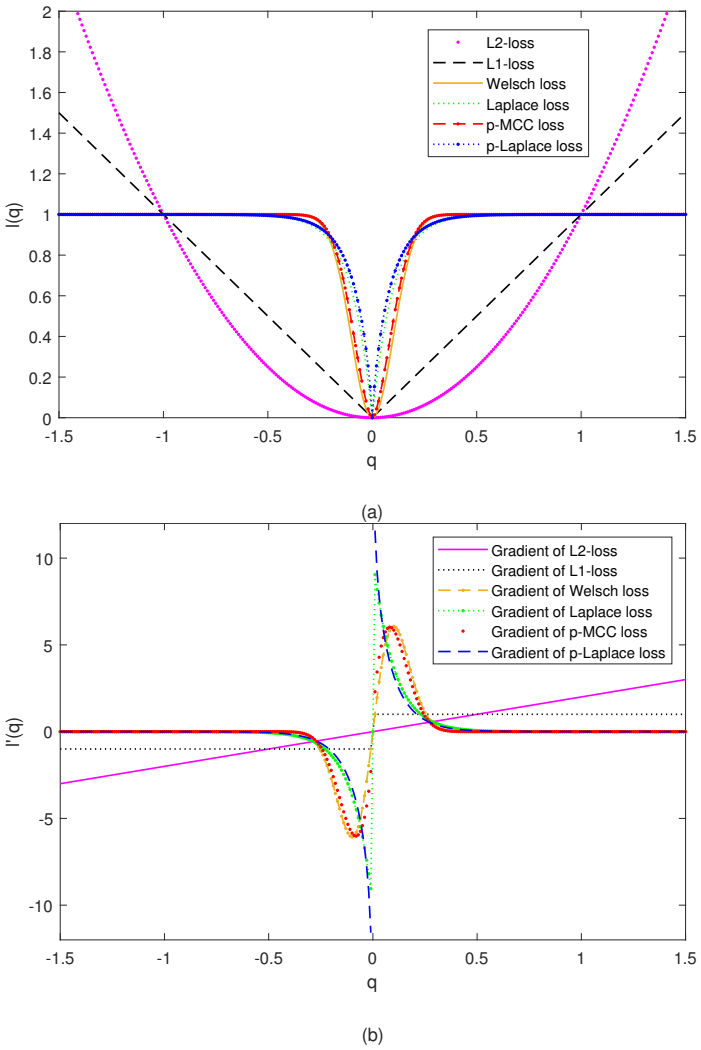


Fig. 3. Comparison of (a) Loss functions; (b) Their gradient functions.

$$w(q_i) = \frac{\partial l(q)}{q_i \partial q_i} = \frac{p}{\sigma}\exp(-\frac{|q_i|}{\sigma})(1-\exp(-\frac{|q_i|}{\sigma}))^{p-1} = \frac{1}{\max\{|q_i|, 10^{-6}\}}$$

In this paper, we employ an iterative reweighted algorithm to obtain the optimal hidden layer output weight β. The weight of N samples can be expressed as

$$W(q) = diag(w(q_1), w(q_2), \cdots, w(q_N)) \tag{19}$$

Through Eq.(18), the output weight of the hidden layer is

$$\beta = \begin{cases} H^{\mathrm{T}}(\frac{I}{C} + W(q)HH^{\mathrm{T}})^{-1}W(q)Y, & N < L \\ (\frac{I}{C} + H^{\mathrm{T}}W(q)H)^{-1}H^{\mathrm{T}}W(q)Y, & N \geq L \end{cases} \tag{20}$$

The curve of sample weights with different parameters σ is shown below.

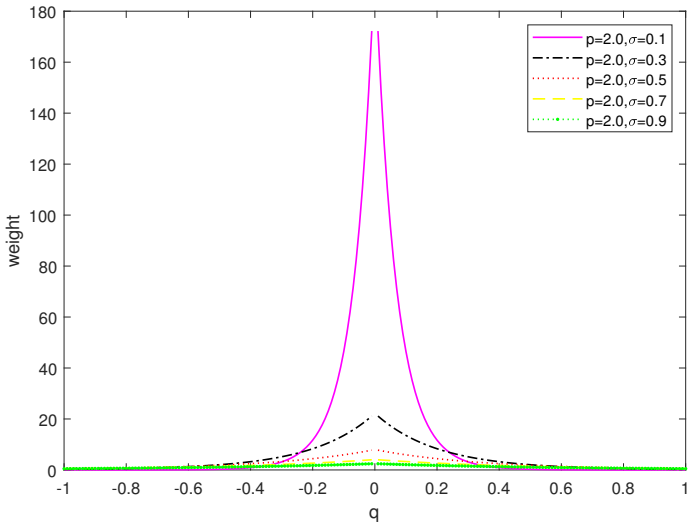

Fig. 4. Trend of sample weights with σ at $p = 2$.

Fig. 4 shows that the larger the error $|q|$ of the sample is, the smaller the weight of the sample is, then the smaller the influence on the model. Therefore, the proposed method can effectively reduce the influence of outliers and enhance the robustness of the model.

Algorithm 1 p-LKI-ELM

Input: Training dataset S, number of hidden nodes L, regularization parameter C, kernel bandwidth σ, maximum of iterations t_{max}, the hidden layer output matrix H.

Output: Output weight $\boldsymbol{\beta}$

1: Initialize $W(q)^{(0)} = I, t = 1$;

2: Calculate the optimal output weight $\beta^{(t)}$ by

$$\boldsymbol{\beta}^{(t)} = \begin{cases} H^{\mathrm{T}}(\frac{I}{C} + W(q)^{(t-1)}HH^{\mathrm{T}})^{-1}W(q)^{(t-1)}Y, & N < L \\ (\frac{I}{C} + H^{\mathrm{T}}W(q)^{(t-1)}H)^{-1}H^{\mathrm{T}}W(q)^{(t-1)}Y, & N \geq L. \end{cases} \tag{21}$$

3: Obtain $q_i^{(t)} = y_i - h(x_i)\beta^{(t)}$, and assign diagonal matrix $W(q)^{(t)}$ by (19).

4: Update $\beta^{(t+1)}$ from (21);

5: if $t > t_{max}$ or $\left\|\beta^{(t+1)} - \beta^{(t)}\right\| \leq 10^{-3}$ stop , else go to step 6.

6: Derive output value $h(x_i)\beta^{(t+1)}$. Set $t = t + 1$, and go to step 3.

IV. Experiments

We compare the proposed method with ELM [1], WELM [11], IRWELM [12], Welsch-ELM [22], Laplace-ELM [25], p-Welsch-ELM [28] on the artificial datasets and benchmark datasets. The root mean square error (RMSE) is chosen as the evaluation metric:

$$\mathrm{RMSE} = \sqrt{\frac{1}{\mathrm{m}}\sum_{\mathrm{i}=1}^{\mathrm{m}}(\mathrm{y_i} - \mathrm{t_i})^2} \tag{22}$$

where y_i and t_i represent the actual target of the sample and the corresponding prediction, respectively; m is the number

of test samples.The experiments are tested in Matlab2021 a Win10 environment with 3.0 GHz CPU, 8 GB RAM and 64 bit host.

A. Experimental Settings

(1) The input weight matrix $W_{N\times L}$ and the hidden layer bias $b_{L\times 1}$ are randomly selected in [-1,1]. The hidden layer activation function is sigmoid function.

$$g(z) = \frac{1}{1+e^{-z}} \tag{23}$$

(2) Regularization parameter C is optimized by cross validation from the set $\{2^{-19}, 2^{-18}, \cdots, 2^{20}\}$ and the number of hidden nodes L is fixed as 1000.

(3) Number of algorithm iterations $t_{max} = 20$.

(4) Parameters σ and order p are also optimized by grid search, where $\sigma : \{0.1, 0.2, \cdots, 1\}$; $p : \{0.6, 0.7, \cdots, 5\}$.

B. Experimental on Artificial Datasets

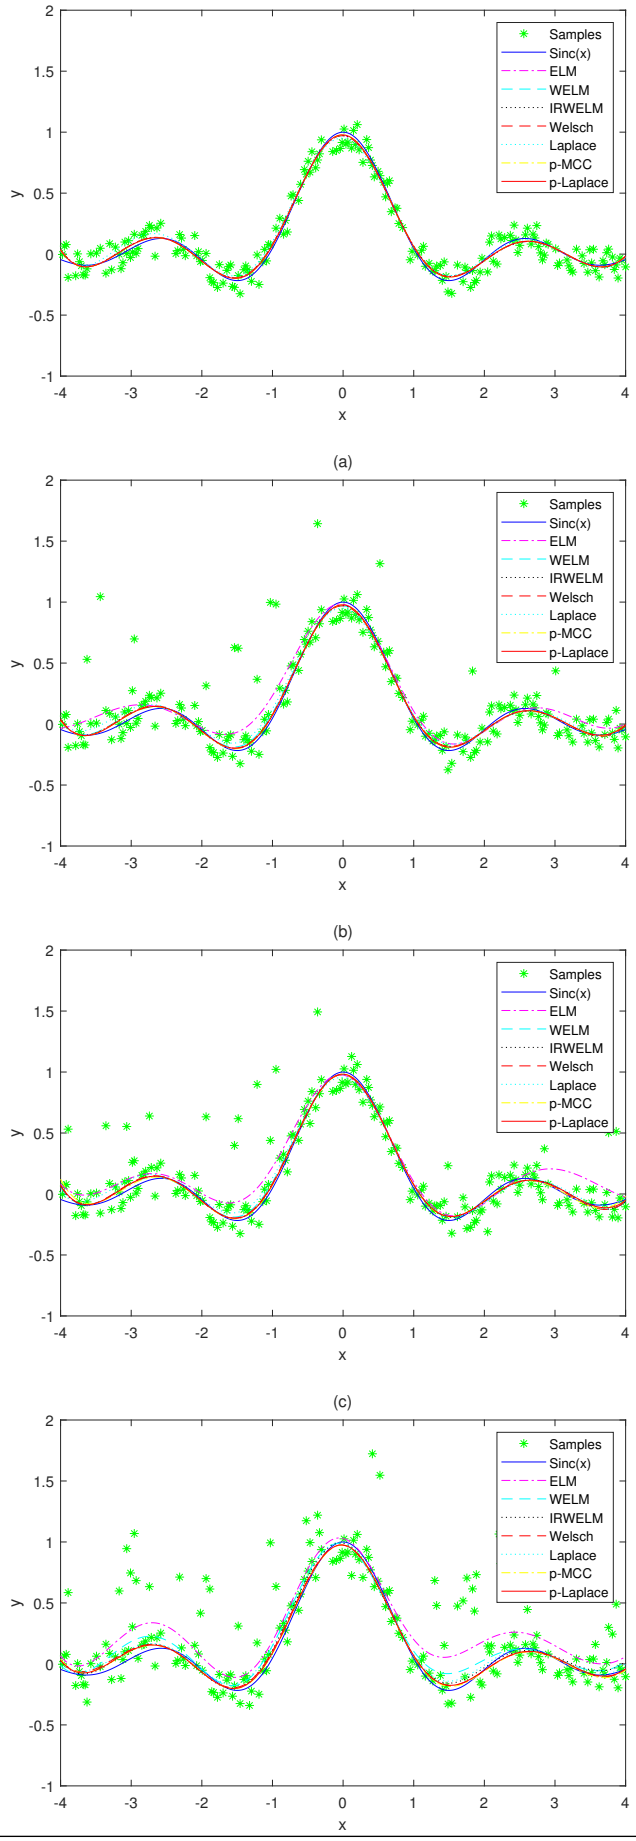
1) Experimental preparation: The artificial dataset is generated by function $y = \sin c(x)$, where,

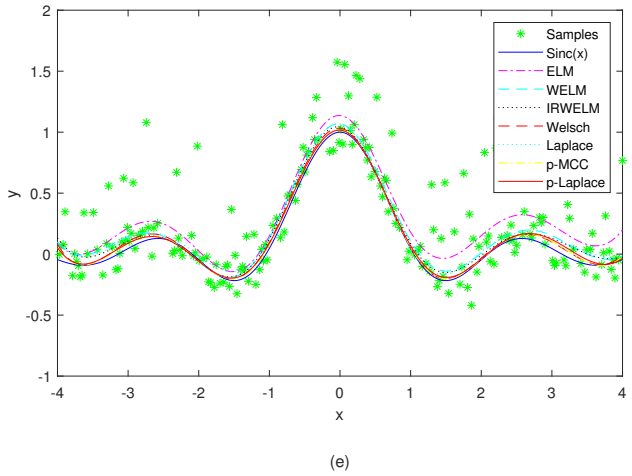
$$\sin c(x) = \frac{\sin x}{x}, x \in [-4, 4]. \tag{24}$$

The preprocessing of artificial datasets is divided into three steps. First, 300 samples are generated from Eq.(24) and randomly divided into 200 training samples and 100 test samples. Secondly, the target of the training sample is disturbed by the uniform distribution of noise $[-0.15, 0.15]$. Finally, random values of different proportions in $[y_{\min}, y_{\max}]$ are added as outliers to the targets of some training samples generated in the second step. Outliers include 0%, 10%, 20%, 30%, and 40%. The samples used for testing are from Eq.(24) without any added outliers. To ensure fairness, 10 independent experiments are conducted for each outliers distribution.

2) Experimental results and analysis: To further confirm the robustness of the proposed algorithm, the different levels of outliers are compared. Fig. 5 illustrates the regression prediction results of these seven algorithms with different outliers levels. When the outliers level is 0%, all seven methods roughly coincide with the original position. When the outliers levels are 10% and 20%, only ELM deviates slightly from the original position and begins to shift toward the outliers, while the other six methods remain unchanged. When the outliers levels are 30% and 40%, ELM, WELM, IRWELM, Laplace-ELM and Welsch-ELM deviate from the original position and turn toward the outliers, and only p-LKI-ELM and p-Welsch-ELM are relatively close to the original position and do not have a tendency to turn towards the outliers. It can be seen that as the outliers level increases, all five methods except p-LKI-ELM and p-Welsch-ELM deviate from the original position and shift towards outliers, and the trend turn toward the outliers of p-LKI-ELM is smaller compared to p-Welsch-ELM. Therefore, it indicates that p-LKI-ELM has better stability.

Fig. 6 reflects the variation of the RMSE of the seven methods for different outliers levels on the artificial dataset. When there are no outliers, the RMSE of p-LKI-ELM is





(e)

Fig. 5. Experiment results on artificial datasets with diffrent outliers levels: a(0%), b(10%), c(20%), d(30%), e(40%).

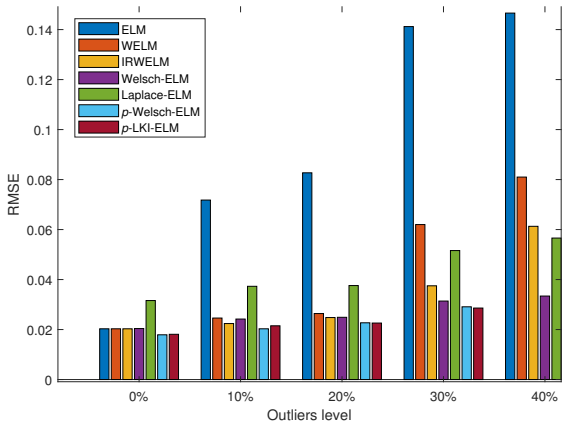


Fig. 6. RMSE of seven algorithms with different outliers levels on the artificial dataset.

slightly higher than that of p-Welsch-ELM, which ranks second among the seven methods. When the outliers level is 10%, the RMSE of ELM increases more, while the increases of p-LKI-ELM and p-Welsch-ELM are smaller compared to the other four methods and p-LKI-ELM is still ranked second among the seven methods. When the outliers level is 20%, p-LKI-ELM has the smallest RMSE among the seven methods and ranks first among the seven methods. It can be seen that the increase in RMSE of p-LKI-ELM becomes smaller and smaller as the outliers level increases. When the outliers levels are 30% and 40%, the RMSE of p-LKI-ELM is still the smallest among the seven methods and ranks first among the seven methods, and it can be concluded that the robustness of p-LKI-ELM is the best. From the aspect of the increase of RMSE, the increase of RMSE of ELM during the increase of outliers levels from 0% to 40% is the largest, while the increase of RMSE of p-LKI-ELM is the smallest, which indicates that the stability of p-LKI-ELM is the best among the seven methods.

C. Experiments on Benchmark Datasets

1) Datasets description: To further test the performance of p-LKI-ELM, the seven methods are experimented on eighteen datasets and the results are analyzed. The information on the selected dataset is shown in Table I. A portion of the datasets is randomly chosen as the training samples, while the rest is used as the test samples. To test the robustness of the model with outliers, we set 10%, 20%, 30% and 40% outliers levels, respectively.

TABLE I. BENCHMARK REGRESSION DATASETS

Dataset	Feature	Training Samples	Test Samples
Yacht	6	200	108

Wine	12	1000	599
ALE	5	80	27

2) Experimental results and analysis: The RMSE values and standard deviations of the seven algorithms across various outliers levels on the nine and nine benchmark datasets are given in Tables II and III, respectively. When the outliers level is 0%, p-LKI-ELM has the lowest RMSE on four datasets in Table II and ranks first together with p-Welsch-ELM, and it has the lowest RMSE values on three datasets in Table III, ranking second among the seven methods. Overall, p-LKI-ELM ranks second among these seven methods on fifteen datasets. When the outliers level is 10%, p-LKI-ELM achieves the smallest RMSE values on seven datasets in Table II and ranks first; seven of the datasets in Table III reaches the smallest RMSE values and ranks first. In total, p-LKI-ELM ranks first among these seven methods on eighteen datasets. This shows that the rank of p-LKI-ELM increases with the addition of outliers, and p-LKI-ELM is least affected by outliers compared to the other methods. When the outliers level is 20%, p-LKI-ELM obtains the smallest RMSE value on eight datasets in Table II, the number of datasets that achieve the minimum RMSE value increases by one, and eight of the datasets in Table III win the smallest RMSE value and ranks first. With outliers levels of 30% and 40%, p-LKI-ELM achieves the smallest RMSE values on eight and seven datasets in Table II, and eight and nine datasets in Table III, respectively, and is ranked first on eighteen datasets. It can be seen that as the level of outliers increases, the number of minimum RMSE values achieved by p-LKI-ELM is increasing, which indicates that p-LKI-ELM has the best robustness compared to the other six methods. In terms of the increase of RMSE values, from outliers level of 0% to 40%, p-LKI-ELM has the lowest increase of RMSE values on all eighteen datasets among the seven methods. From the point of view of the loss function, the p-LKI loss function adopted by the p-LKI-ELM is a bounded loss function that can limit the error to a certain range and will not increase.

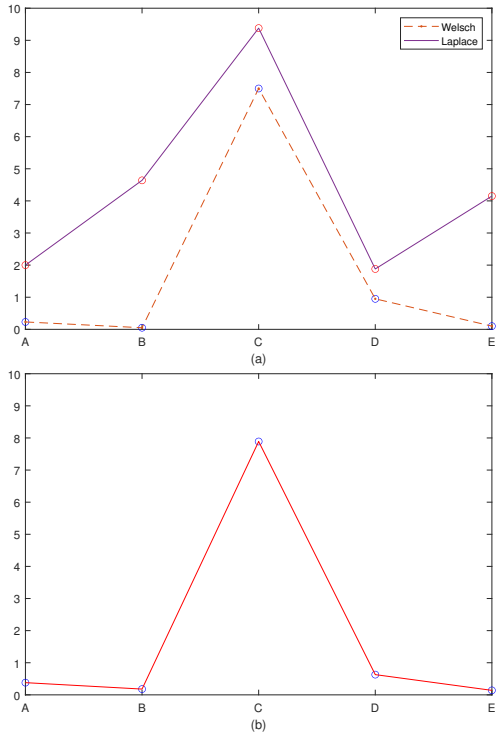

Fig. 7. (a) The reduction of RMSE for p-Welsch-ELM and p-LKI-ELM; (b) The RMSE reduction of p-LKI-ELM relative to p-Welsch-ELM.

Infinitely with the increase of outliers levels. However the l_2 loss function employed by ELM, WELM and IRWELM is an unbounded loss function that increases the error of the model as the levels of outliers increases. Compared with the loss function induced by Gaussian kernel, p-LKI is induced by Laplace kernel and the exponential part is still bounded, which makes the p-LKI-ELM the most optimal among these seven methods by choosing a suitable p.

In order to observe more intuitively the improvement effect of the loss function after the introduction of p-order and compare the effect of the two kernel functions after the introduction of p-order, we graph the experimental data.

Fig. 7 shows the reduction of p-Welsch-ELM relative to Welsch-ELM and p-LKI-ELM relative to the RMSE of Laplace-ELM on five benchmark datasets as illustrated in (a), the x-axis A, B, C, D and E represent the five datasets (Autompg, Heart, Bodyfat, Pyrim and Diabetes), respectively. The y-axis represents the reduction in RMSE (%), and Fig. 7 indicates that the RMSE reduction of p-LKI loss function relative to Laplace loss function is higher than the reduction of p-Welsch loss function relative to the RMSE of Welsch loss function. It shows that the loss function induced by the Laplace kernel is more effective for the p-order than Gaussian kernel, which indicates that the former is more suitable for the p-order.

Fig. 7(b) suggests the reduction of RMSE of the proposed model relative to the p-Welsch-ELM model on five benchmark datasets. It can be seen from (b) that the y-axis is always more significant than 0, which means that the reduction (%) of the RMSE of p-LKI-ELM relative to p-Welsch-ELM is greater than 0, which indicates that the prediction accuracy of the loss function induced by the Laplace kernel is higher than that of the Gaussian kernel.

V. Discussion

The proposed model is compared with six other models on both artificial datasets and eighteen benchmark datasets. Experimental results demonstrate that p-LKI-ELM achieves superior performance on the majority of datasets. Moreover, as the proportion of outliers increases, p-LKI-ELM is less affected compared to the other models, confirming its stronger robustness. In the future, research could be conducted from the perspective of sparsity.

VI. Conclusion

Influenced by kernel learning and correntropy learning, we propose a new loss function (p-LKI) to solve the regression problem. The proposed method is experimented on artificial datasets and benchmark datasets. In addition, the performance of the proposed method is evaluated with different outliers levels. The main work is summarized as follows:

(1) We propose a new robust loss function (p-LKI loss), which combines the advantages of the p-order loss function and the correntropy loss function. Therefore, it is insensitivity to noise and outliers. (2) The proposed method is compared against ELM, WELM, IRWELM, Welsch-ELM, Laplace-ELM, and p-Welsch-ELM on artificial datasets and eighteen benchmark datasets. The experimental results indicate that the proposed method consistently outperforms the other six models in both cases. Furthermore, the results demonstrate the superior robustness of the proposed method. (3) By comparing the reduction of p-LKI loss function induced by Laplace kernel compared with the RMSE of Laplace loss, and the reduction of RMSE induced by Gaussian kernel compared with Welsch loss, the results show that the reduction of p-LKI loss function relative to Laplace loss function is higher than the latter, which indicates that the loss function induced by Laplace kernel at order p is better than the loss function induced by Gaussian kernel at order p. By comparing the reduction in RMSE of p-LKI loss function relative to p-Welsch loss, the results demonstrate that the robustness of the p-LKI loss function is higher than that of the p-Welsch loss.

In addition, on the one hand, the number of hidden layer nodes and the activation function used in this paper are fixed, we can set a different number of hidden layer nodes and other activation function to observe the effect on the performance of the model later; on the other hand, this paper uses an iterative reweighting algorithm to solve the model, and a new algorithm can be designed to improve the training speed of the model in the future.
