Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

CONTENTS

A Comparative Analysis of Traditional and Machine Learning Methods in Forecasting the Stock Markets of China and the US

Shangshang Jin
Department of Art and Science, Johns Hopkins University, Washington, D.C., United States

***Abstract*—In the volatile and uncertain financial markets of the post-COVID-19 era, our study conducts a comparative analysis of traditional econometric models—specifically, the AutoRegressive Integrated Moving Average (ARIMA) and Holt's Linear Exponential Smoothing (Holt's LES)—against advanced machine learning techniques, including Support Vector Regression (SVR), Long Short-Term Memory (LSTM) networks, and Gated Recurrent Units (GRU). Focused on the daily stock prices of the S&P 500 and SSE Index, the study utilizes a suite of metrics such as R-squared, RMSE, MAPE, and MAE to evaluate the forecasting accuracy of these methodologies. This approach allows us to explore how each model fares in capturing the complex dynamics of stock market movements in major economies like the U.S. and China amidst ongoing market fluctuations instigated by the pandemic. The findings reveal that while traditional models like ARIMA demonstrate strong predictive accuracy over short-term horizons, LSTM networks excel in capturing complex, non-linear patterns in the data, showcasing superior performance over longer forecast horizons. This nuanced comparison highlights the strengths and limitations of each model, with LSTM emerging as the most effective in navigating the unpredictable dynamics of post-pandemic financial markets. Our results offer crucial insights into optimizing forecasting methodologies for stock price predictions, aiding investors, policymakers, and scholars in making informed decisions amidst ongoing market challenges.**

***Keywords*—Machine learning; Holt's LES; SVR; LSTM; GRU**

I. Introduction

The post-COVID-19 era has ushered in an era of heightened volatility and uncertainty in financial markets worldwide [1]. Particularly, the stock markets of China and the United States, two leading global economies, have garnered significant attention from investors, policymakers, and scholars alike. Precise forecasting of stock prices in these markets is crucial for informed decision-making and effective risk management. However, the challenge of accurate stock price prediction remains formidable due to the complex interplay of factors such as economic indicators, market sentiment, geopolitical events, and policy changes.

Our study adopts a two-pronged methodological approach. Initially, we leverage traditional econometric models, specifically the AutoRegressive Integrated Moving Average (ARIMA) model [2] and Holt's Linear Exponential Smoothing (Holt's LES) [3], known for their robustness in time series forecasting. These models, grounded in historical data patterns and statistical principles, offer a foundational understanding of stock price movements, emphasizing the linear aspects of financial time series. However, the intricate dynamics of post-pandemic markets—characterized by abrupt changes and non-linear patterns—necessitate a more adaptive and sophisticated analysis framework. Enter machine learning techniques: Support Vector Regression (SVR) [4], Long Short-Term Memory (LSTM) networks [5], and Gated Recurrent Units (GRU) [6]. These methods bring to the fore the capability to model complex, non-linear relationships and capture deep temporal dependencies, which are often missed by traditional models. By incorporating both traditional and machine learning methodologies, our study aims to harness the complementary strengths of each approach, ensuring a comprehensive and nuanced exploration of forecasting accuracy in the tumultuous environment of post-COVID-19 stock markets. This hybrid approach not only facilitates a direct comparison of predictive performances but also sheds light on the evolving nature of financial time series analysis in response to unprecedented market conditions.

In this study, we conduct a comparative analysis of the forecasting performance of both traditional and machine learning models on the daily stock prices of the S&P 500 Index in the United States and the SSE Index in China in the post-COVID-19 period. We assess the forecasting accuracy of ARIMA, Holt's LES, SVR, LSTM, and GRU models using evaluation metrics such as R-squared (R^2), Root Mean Square Error (RMSE), Mean absolute percentage error (MAPE), and Mean Absolute Error (MAE). By shedding light on the strengths and weaknesses of different forecasting approaches, this study seeks to contribute to the ongoing pursuit of effective stock market prediction tools in the post-COVID-19 era.

II. Related Work

Traditionally, stock price prediction has relied on econometric models and time-series analysis techniques like AutoRegressive Integrated Moving Average (ARIMA) and Linear Exponential Smoothing Model (LSE) . These models excel at capturing linear relationships and seasonality in the data. Nevertheless, their ability to handle the inherent complexities and non-linearities of stock market dynamics is limited [7].

Machine learning and deep learning techniques have emerged as promising alternatives for stock market prediction, offering the potential to capture intricate patterns and relationships in financial data [8], [9]. Methods such as Support

Vector Regression (SVR), Long Short-Term Memory networks (LSTM), and Gated Recurrent Units (GRU) can process large-scale datasets, recognize non-linear relationships, and learn from sequential information, making them well-suited for forecasting stock prices.

For instance, Gülmez [9] explored machine learning models for stock market prediction, underscoring the effectiveness of the LSTM model with two dropout layers. The study noted the potential for performance improvement by optimizing hyperparameters such as the number of neurons, batch size, and epoch count. Gülmez's research also employed the Support Vector Regression (SVR) model, optimizing hyperparameters via grid search with Scikit-learn's library. Employing 10-fold cross-validation and RMSE as a loss measurement, the study highlighted that hyperparameter tuning significantly impacts the SVR's forecasting performance.

Md et al. [10] introduced a novel Multi-Layer Sequential Long Short-Term Memory (MLS LSTM) model for stock price prediction, utilizing Samsung stock data from 2016 to 2021. Comprising three vanilla LSTM layers and a dense layer, the MLS LSTM model exhibited high accuracy (95.9% and 98.1%) and a low average error percentage (2.18%) on the testing dataset. The study revealed that multi-layered LSTMs outperform single-layered LSTMs, with added layers enhancing accuracy.

In another study, Yu et al. [11] proposed a predictive model for stock price index realized volatility (RV) based on optimized variational mode decomposition (VMD), deep learning models, including LSTM and GRU, and the Q-learning algorithm. The model was applied to the RV sequences of the SSEC, SPX, and FTSE indices. The VMD method decomposed the RV sequences into intrinsic mode functions (IMFs), which were then predicted using the LSTM and GRU models. Q-learning determined the optimal model weights for an integrated approach. Performance evaluation using MAE, MSE, HMAE, HMSE, and MDM demonstrated the model's superior performance over comparison models in both emerging and developed markets.

Recent literature shows that machine learning methods, including SVR, LSTM, and GRU, have gained popularity due to their ability to tackle non-linear problems and learn complex patterns in large-scale datasets [12]. These models can capture complex relationships in financial data and enhance prediction accuracy. However, they come with drawbacks such as high computational requirements, risk of overfitting, and reduced interpretability [13], [14]. Additionally, machine learning models often require meticulous hyperparameter tuning, which can be time-consuming and computationally intensive [15].

III. Methodology

In this study, we examine the predictive performance of both traditional statistical methods and machine learning techniques for forecasting the stock price. We compare the ARIMA model and the ETS model from the traditional methods against the SVR, LSTM networks, and GRU networks from the machine learning approaches. Our analysis focuses on one-step-ahead out-of-sample forecasting.

A. AutoRegressive Integrated Moving Average (ARIM)

The ARIMA model, commonly recognized as the Box-Jenkins model, is a fundamental tool in time-series forecasting. It merges autoregressive (AR) and moving average (MA) components to effectively model stationary time series with minimal parameters. In contrast to pure AR and MA models, the ARIMA model introduces a differencing (I) component to ensure stationarity of the series [2]. By blending these three components—autoregressive, differencing, and moving average—the ARIMA model offers a holistic approach to capturing temporal dependencies in data [16].

It is expressed as follows:

$$(1 - \sum_{i=1}^{p} \phi_i L^i)(1 - L)^d X_t = (1 + \sum_{i=1}^{q} \theta_i L^i)\epsilon_t \quad (1)$$

Here, ϕ_i denotes the AR parameters, θ_i the MA parameters, d is the order of differencing, L is the lag operator, X_t is the time series value at time t, and ϵ_t signifies the white noise error term.

B. Holt's Linear Exponential Smoothing Model (Holt's LES)

Holt's Linear Exponential Smoothing model, also known as the Holt's Linear model, is a time-series forecasting method that captures the linear trend and level components in the data. It is particularly useful for datasets with trends but no seasonal patterns. The model uses two smoothing equations to estimate the level and trend components, respectively [17].

Let y_t be the observed value at time t, l_t be the estimated level at time t, and b_t be the estimated trend at time t. The smoothing equations are given by:

$$\begin{aligned} l_t &= \alpha y_t + (1 - \alpha)(l_{t-1} + b_{t-1}) \\ b_t &= \beta(l_t - l_{t-1}) + (1 - \beta)b_{t-1} \end{aligned} \quad (2)$$

Here, y_t is the observed value, l_t the estimated level, and b_t the estimated trend at time t.α and β are smoothing parameters between 0 and 1. The h-period ahead forecast is:

$$\hat{y}_{t+h} = l_t + h \cdot b_t \quad (3)$$

In this study, the optimal values of α and β a re determined by minimizing the Mean Squared Error (MSE) of the model on the training data.

C. Support Vector Regression (SVR)

SVR is a machine learning algorithm for regression analysis. It extends the concept of Support Vector Machines (SVM) used for classification tasks to the regression context. SVR aims to find a hyperplane that best fits the data points while maximizing the margin from the closest data points (support vectors) (Liu, Wang and Gu, 2021).

Given a training dataset $D = \{(x_1, y_1), \ldots, (x_n, y_n)\}$, SVR aims to find a function $f(x) = w \cdot x + b$ that approximates the relationship between the input features x and the target variable y.

SVR introduces the ε-insensitive loss function, meaning that the error is only considered if it exceeds a certain threshold ε. The SVR objective is to minimize the cost function:

$$L(w,b) = \frac{1}{2} \parallel w \parallel^2 + C \sum_{i=1}^{n} (\xi_i + \xi_i^*) \tag{4}$$

subject to the constraints:

$$\begin{aligned} & y_i - w \cdot x_i - b \leq \epsilon + \xi_i \\ & w \cdot x_i + b - y_i \leq \epsilon + \xi_i^* \\ & \xi_i, \xi_i^* \geq 0 \end{aligned} \tag{5}$$

where, w denotes the weight vector and b is the bias term. C is the regularization parameter that controls the trade-off between maximizing the margin and minimizing the error. The slack variables, ξ_i and ξ_i^*, handle instances that are difficult to separate perfectly.

In this study, we use the Radial Basis Function (RBF) kernel, which is defined as:

$$K(x,z) = \exp(-\gamma \parallel x - z \parallel^2) \tag{6}$$

D. Long Short-Term Memory (LSTM)

LSTM networks, introduced by Hochreiter and Schmidhuber [5], are a specialized variant of recurrent neural networks (RNN) meticulously engineered to address sequence prediction challenges. Their distinctive architecture, which facilitates the retention of patterns over extended durations, renders LSTMs especially proficient for time series modeling. In the context of this study, we harness the capabilities of the LSTM network for our forecasting endeavors.

LSTM networks consist of memory cells that are regulated by three gates: forget, input, and output gates. These gates determine how information flows through the memory cells.

Forget Gate:

$$f_t = \sigma\big(W_f \cdot [h_{t-1}, x_t] + b_f\big) \tag{7}$$

Input Gate:

$$\begin{aligned} i_t &= \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \\ \tilde{C}_t &= \tanh(W_C \cdot [h_{t-1}, x_t] + b_C) \end{aligned} \tag{8}$$

Update of Cell State:

$$C_t = f_t \times C_{t-1} + i_t \times \tilde{C}_t \tag{9}$$

Output Gate:

$$\begin{aligned} o_t &= \sigma(W_o[h_{t-1}, x_t] + b_o) \\ h_t &= o_t \times \tanh(C_t) \end{aligned} \tag{10}$$

where, σ represents the sigmoid function, W and b are the weight matrices and biases for each gate, respectively, x_t is the input at time t, and h_t is the output.

E. Gated Recurrent Unit (GRU)

Introduced by [18], GRUs are a streamlined variant of the RNN designed to adeptly capture long-term sequence dependencies. Functioning as a simplified version of LSTMs, GRUs are characterized by two pivotal gates: the update gate and the reset gate. The update gate is instrumental in determining the proportion of the preceding hidden state that should be relayed to the subsequent state. Concurrently, the reset gate ascertains the extent to which the prior hidden state is disregarded. The computations for the GRU model are as follows:

$$\begin{aligned} r_t &= \sigma(W_r \cdot [h_{t-1}, x_t] + b_r) \\ z_t &= \sigma(W_z \cdot [h_{t-1}, x_t] + b_z) \\ \tilde{h}_t &= \tanh(W \cdot [r_t \odot h_{t-1}, x_t] + b) \\ h_t &= (1 - z_t) \odot h_{t-1} + z_t \odot \tilde{h}_t \end{aligned} \tag{11}$$

where, r_t and z_t are the reset and update gates at time t respectively, σ denotes the sigmoid activation function, W and b are the weight matrices and bias vectors, $\odot$ represents element-wise multiplication, and h_t is the hidden state at time t.

F. Grid Search Hyperparameter Tuning

In this study, optimizing hyperparameters becomes paramount to ensure the robustness of machine learning models. As demonstrated in Fig. 1, our approach harnesses a comprehensive grid search to navigate the vast hyperparameter space. For the SVR model, adjustments are made to the regularization parameter, gamma, and epsilon values. Meanwhile, the LSTM's performance is fine-tuned considering the number of units, dropout rate, and batch size. On the other hand, the GRU model sees alterations in its units, batch size, and number of epochs. This methodical approach, anchored in a three-dimensional exploration, seeks to refine our forecasting tools, aligning them with the sophisticated dynamics of today's financial markets.

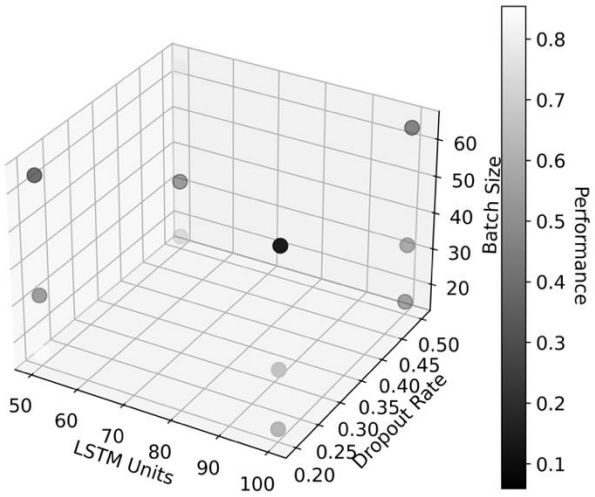

Fig. 1. 3D visualization of grid search.

G. Evaluation Metrics

To evaluate the predictive performance of the models, followed by [19] and [20], we utilize several well-established metrics: R-squared (R^2), Root Mean Square Error (RMSE), Mean Absolute Percentage Error (MAPE) and Mean Absolute Error (MAE). Each metric provides a different perspective on the quality of the predictions.

R^2 : R^2 measures the proportion of the variance in the dependent variable that is predictable from the independent variable. It ranges from 0 to 1, with 1 indicating perfect prediction. It is calculated as follows:

$$R^2 = 1 - \frac{\sum (y_t - \hat{y}_t)^2}{\sum (y_t - \bar{y})^2} \quad (12)$$

RMSE (Root Mean Square Error): RMSE represents the square root of the second sample moment of the differences between predicted and observed values or the quadratic mean of these differences. It is interpreted as the standard deviation of the unexplained variance:

$$RMSE = \sqrt{\frac{1}{n}\sum_{t=1}^{n} (y_t - \hat{y}_t)^2} \quad (13)$$

The Mean Absolute Percentage Error (MAPE): MAPE provides an easy-to-interpret measure of the average prediction error in percentage terms. It is especially useful when comparing the performance of different models on the same dataset.

The MAPE is calculated as follows:

$$\text{MAPE} = \frac{100}{n}\sum_{t=1}^{n} \left|\frac{y_t - \hat{y}_t}{y_t}\right| \quad (14)$$

Mean Absolute Error (MAE): MAE measures the average of the absolute differences between the predicted and observed values. It provides an idea of the magnitude of the error, without considering the direction. Lower MAE values indicate a better fit to the data. It is calculated as:

$$MAE = \frac{1}{n}\sum_{t=1}^{n} |y_t - \hat{y}_t| \quad (15)$$

where, y_t is the actual value at time $t, \hat{y}_t$ is the predicted value at time , and $\bar{y}$ represents the mean of the actual values.

H. Forecasting Algorithm

Our methodology, detailed in Fig. 2, commenced by dividing the data into training and testing subsets. Depending on the chosen model-traditional techniques like ARIMA and Holt's LES or more contemporary machine learning approaches-appropriate parameter optimization processes were undertaken, with the latter employing a grid search. Using a rolling window framework, we executed forecasts for three distinct time horizons: H=1, 10, and 30 days. Utilizing the rolling window approach, each forecast integrated the most recent observation from the testing set into the training dataset. This method allowed our models to consistently update and adapt based on the newest economic data available. Once the end of the testing data was reached, we compared the performance of the various models under different forecasting time horizons using key metrics such as R^2, RMSE, MAE and MAPE.

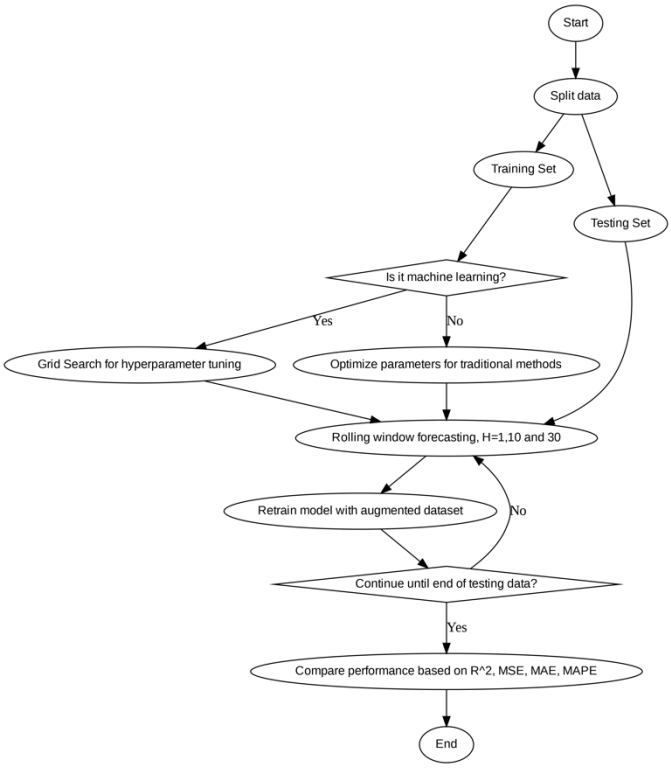

Fig. 2. Flowchart of algorithm.

IV. Numerical Results

A. Data Description

This study evaluates the daily performance of two major stock market indices, the S&P 500 and the Shanghai Stock Exchange (SSE) Composite Index, spanning December 31, 2012, to December 31, 2022. These indices were chosen due to their importance in representing overall stock market performance in the United States and China, respectively, and their influence on global financial markets. Both are market-capitalization-weighted, capturing broad market movements efficiently.

We obtain daily closing prices of the indices from the Yahoo Finance API, a publicly accessible and reliable data source extensively used in financial research. The data, adjusted for splits and dividends, provide an accurate representation of the indices' performance over the period.

The data are partitioned into training and testing sets. The training set, consisting of data before 2020, is used to calibrate forecasting models, while the testing set, from January 1, 2020, to December 31, 2022, evaluates their out-of-sample performance.

Table I summarizes the descriptive statistics of the daily closing prices for both indices over the study period. The S&P 500 index, with a mean of 2742.1700 and standard deviation of 873.0140, traded between 1426.1900 and 4796.5600. The SSE

index had a mean of 3017.0600, standard deviation of 527.9180, and prices between 1950.0100 and 5166.3500. The S&P 500 displays a negative kurtosis of -0.6494 and positive skewness of 0.6749, suggesting a less peaked and right-skewed distribution. The SSE index, with a kurtosis of 0.8312 and near-zero skewness of 0.0525, indicates a more peaked and symmetric distribution. There are 2519 and 2428 observations for the S&P 500 and SSE indices, respectively. Fig. 3 and Fig. 4 depict the time series of daily closing prices for the S&P 500 and SSE indices.

TABLE I. DESCRIPTIVE STATISTICS FOR THE S&P 500 AND SSE INDICES

Index	S&P500	SSE
Mean	2742.1700	3017.0600
Std	873.0140	527.9180
Minimum	1426.1900	1950.0100
Maximum	4796.5600	5166.3500
Kurtosis	-0.6494	0.8312
Skewness	0.6749	0.0525
Count	2519	2428

Fig. 3. S&P 500 index price.

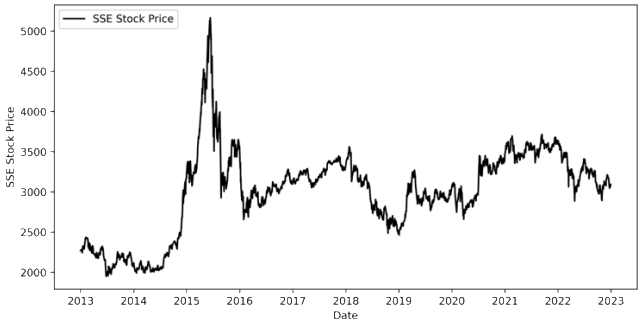

Fig. 4. SSE index price.

B. Determination of Parameters of Traditional Methods

For the ARIMA models, we use an automatic order selection method that seeks to minimize the Akaike Information Criterion (AIC). The ARIMA model parameters include the order of the autoregressive (AR) and moving average (MA) components, as well as the degree of differencing. Given the daily frequency of the data, we focus on non-seasonal models. Through this procedure, we identify ARIMA (2,1,0) as the best model for the SSE index, while ARIMA(1,1,1) with an intercept is chosen for the S&P 500 index.

For the Holt's LES models, an optimization procedure is applied to estimate the smoothing parameters for the level and trend components. The models are fitted to the training data of both indices. For the SSE index, the estimated smoothing level is approximately 0.995, and the smoothing trend is about 0.0237. For the S&P 500 index, the respective values are approximately 0.907 and 0.0212. The initial level and trend for both models are estimated based on the training data.

C. Determination of Optimal Hyperparameters

In this study, we employ a grid search approach to optimize the hyperparameters for the SVR, LSTM, and GRU models across different time horizons (H=1/10/30). For the SVR model, we consider three hyperparameters: the regularization parameter (C), gamma (γ), and epsilon (ε). For the LSTM and GRU models, the hyperparameters assessed include the number of units, dropout rate, and batch size. The selection of these hyperparameters is crucial as they directly affect the models' forecasting performance. We evaluate various hyperparameter combinations using a training dataset to identify the best-performing models, which are subsequently tested on a separate test dataset. We use a radial basis function (RBF) kernel for the SVR model. For the LSTM and GRU models, we compile them using the Adam optimizer and mean squared error (MSE) loss function, which is well-suited for regression tasks like stock price prediction. This hyperparameter optimization process is conducted across different forecasting horizons to evaluate the models' suitability for both short-term and long-term forecasting. The Hyperparameters are given in Table II.

TABLE II. HYPERPARAMETER SETTINGS FOR MACHINE LEARNING MODELS ACROSS VARIOUS TIME HORIZONS (H=1/10/30)

Model	Name of Parameter	S&P 500	SSE
SVR	Regularization parameter	10/10/10	10/10/10
	Gamma	0.1/0.1/0.1	0.1/0.1/0.1
	Epsilon	0.1/0.1/0.1	0.1/0.1/0.1
LSTM	Units	100/100/50	100/100/100
	Drop out	0.2/0.2/0.2	0.2/0.5/0.5
	Batch size	16/16/64	16/32/16
GRU	Units	70/70/30	50/50/50
	Batch size	16/64/32	16/64/16
	epochs	30/70/50	50/50/50

D. Comparison and Analysis

Table III presents the evaluation results for forecasting the S&P 500 index using various models: ARIMA, Holt's LES, SVR, LSTM, and GRU. The performance of each model is assessed across three-time horizons: 1-day, 10-day, and 30-day.

For the 1-day time horizon, the ARIMA model stands out, achieving an R^2 of 99.04%, MAPE of 1.06%, RMSE of 53.93, and MAE of 38.78. The Holt's LES model closely follows, with similar metrics. Both SVR and GRU models exhibit

strong performance, with R^2 values exceeding 98%. Notably, the LSTM model shows the lowest R^2 of 94.70% and the highest MAPE of 2.71%.

TABLE III. EVALUATION OF S&P 500 INDEX FORECASTING ACROSS DIFFERENT TIME HORIZONS

Models	R^2	MAPE	RMSE	MAE
Time Horizon =1				
ARIMA	**99.04%**	**1.06%**	**53.93**	**38.78**
Holt's LES	99.02%	1.06%	54.48	38.62
SVR	98.95%	1.18%	56.31	43.16
LSTM	94.70%	2.71%	126.80	108.05
GRU	98.16%	1.60%	74.72	61.29
Time Horizon =10				
ARIMA	95.52%	2.27%	116.65	83.72
Holt's LES	94.93%	2.34%	124.00	87.07
SVR	94.18%	2.77%	132.87	103.20
LSTM	91.89	3.27%	156.82	131.59
GRU	94.18%	2.73%	132.84	100.79
Time Horizon = 30				
ARIMA	83.94%	4.35%	220.74	157.45
Holt's LES	75.48%	5.02%	272.73	181.37
SVR	81.06%	5.21%	239.69	189.03
LSTM	85.80%	4.42%	207.60	176.05
GRU	80.21%	5.34%	245.04	194.03

In the 10-day horizon, the ARIMA model again leads with an R^2 of 95.52% and the lowest MAPE of 2.27%. Holt's LES, SVR, and GRU models all report R^2 values above 94% and MAPE values under 3%. The LSTM model lags, with the lowest R^2 of 91.89% and the highest MAPE of 3.27%.

For the 30-day horizon, the LSTM model surprisingly achieves the highest R^2 of 85.80%, but with a relatively high MAPE of 4.42%. The ARIMA model follows with an R^2 of 83.94% and the lowest MAPE of 4.35%. The Holt's LES model's performance diminishes, recording the lowest R^2 of 75.48% and a higher MAPE of 5.02%. SVR and GRU models display similar R^2 values around 80% and MAPE values above 5%.

In summary, the ARIMA model consistently performs well across all time horizons, exhibiting the highest R^2 and the lowest MAPE for the 1-day and 10-day horizons. While the LSTM model underperforms in shorter horizons, it surprisingly has the highest R^2 for the 30-day horizon. The Holt's LES model performs well for shorter horizons but declines for the 30-day horizon. SVR and GRU models show moderate performance across all horizons.

Table IV presents the evaluation results of forecasting the SSE index. For the 1-day horizon, all models display strong performance, with R^2 values exceeding 97%. The SVR model leads with an R^2 of 97.81% and the lowest MAPE of 0.80%. ARIMA and Holt's LES models both achieve R^2 values around 97.78% and similar MAPE values of 0.81%. LSTM and GRU models also perform well, with R^2 values above 97.5% and MAPE values under 0.85%.

TABLE IV. EVALUATION OF SSE INDEX FORECASTING ACROSS DIFFERENT TIME HORIZONS

Models	R^2	MAPE	RMSE	MAE
Time Horizon =1				
ARIMA	97.78%	0.81%	36.25	26.34
Holt's LES	97.72%	0.81%	36.31	26.25
SVR	97.81%	0.80%	35.97	25.98
LSTM	97.49%	0.85%	38.54	27.72
GRU	97.65%	0.83%	37.27	27.19
Time Horizon =10				
ARIMA	90.16%	1.65%	76.34	53.31
Holt's LES	88.84%	1.78%	81.26	57.34
SVR	90.48%	1.56%	75.05	50.38
LSTM	94.74%	1.27%	55.82	40.89
GRU	92.98%	2.91%	145.90	113.95
Time Horizon = 30				
ARIMA	77.34%	2.73%	115.69	88.71
Holt's LES	72.21%	2.95%	128.34	95.70
SVR	77.27%	2.54%	116.00	82.29
LSTM	94.78%	1.25%	55.61	40.98
GRU	58.89%	3.80%	156.00	123.29

In the 10-day horizon, the LSTM model stands out with the highest R^2 of 94.74% and the lowest MAPE of 1.27%. SVR closely follows with an R^2 of 90.48% and a low MAPE of 1.56%. ARIMA and Holt's LES models both report R^2 values around 90% and MAPE values under 1.8%. The GRU model exhibits a solid R^2 of 92.98% but the highest MAPE of 2.91%.

For the 30-day horizon, the LSTM model clearly dominates with an R^2 of 94.78% and the lowest MAPE of 1.25%. The ARIMA and SVR models perform similarly, both achieving R^2 values around 77% and MAPE values under 2.75%. The Holt's LES model lags, with an R^2 of 72.21% and a higher MAPE of 2.95%. The GRU model shows the lowest performance with an R^2 of 58.89% and the highest MAPE of 3.80%.

In summary, the LSTM model consistently performs well across all time horizons, especially for the 30-day horizon, where it excels. The ARIMA and SVR models display similar moderate performance across all horizons. The Holt's LES model's performance declines for longer horizons. The GRU model exhibits strong performance in the 10-day horizon but struggles in the 30-day horizon.

V. CONCLUSION

The task of predicting stock market indices is essential for risk management, portfolio allocation, and derivative pricing, all of which contribute to stabilizing the financial market order. In this study, we compared the performance of several predictive models—ARIMA, Holt's LES, SVR, LSTM, and

GRU—across different time horizons (1-day, 10-day, and 30-day) for two prominent stock indices: the S&P 500 and the SSE. The models were evaluated based on four metrics: R-squared (R^2), Mean Absolute Percentage Error (MAPE), Root Mean Squared Error (RMSE), and Mean Absolute Error (MAE).

Our empirical results indicate that:

- LSTM consistently performs well across all time horizons for both indices, especially in the 30-day horizon. It outperforms the other models in terms of both R^2 and MAPE. This result can be attributed to the model's ability to capture long-term dependencies in the data and its inherent adaptability in learning complex nonlinear relationships.
- ARIMA and SVR models display moderate performance across all time horizons for both indices, showcasing their robustness and applicability. The ARIMA model benefits from its ability to account for time trends, seasonality, and autoregressive behaviors. On the other hand, the SVR model leverages its capacity to model nonlinear relationships by using kernel functions.
- Holt's LES model performs well for the 1-day and 10-day horizons but struggles for longer horizons. The model's declining performance is attributed to its primary reliance on short-term trends, which may not capture more complex behaviors over longer time horizons.
- The GRU model performs well for shorter horizons but faces difficulties in the 30-day horizon. This could be due to the challenges posed by long-term dependencies in the data. GRU, similar to LSTM, is designed to address such challenges, but our results suggest that LSTM may be better suited for this particular dataset.
- Through extensive experimentation, we confirmed the robustness and applicability of our findings. For both indices, the results were consistent across different time horizons and evaluation metrics, confirming the validity of our conclusions.

In summary, our study provides valuable insights for investors and market analysts. The results can be used to enhance trading strategies, optimize portfolio allocations, and improve risk management approaches. Regulators may also benefit from these insights by identifying market anomalies and intervening when necessary to ensure financial market stability.

Despite the contributions of this study, we acknowledge that multivariate prediction was not considered. In future research, we will incorporate additional factors closely related to the stock indices' movements, such as macroeconomic indicators and sentiment analysis, to enhance the accuracy of our predictions. Incorporating these factors will not only improve the forecasting accuracy but also contribute to a deeper understanding of the underlying relationships that drive stock market dynamics. Besides, the methodologies and insights gained from this study hold the potential for broader applications beyond the S&P 500 and SSE indices. For instance, these models could be adapted to forecast emerging market indices, where volatility and data irregularities present unique challenges.

***Abstract*—Most Chest X-Rays (CXRs) are used to spot the existence of chest diseases by radiologists worldwide. Examining multiple X-rays at the busiest medical facility may result in time and financial loss. Furthermore, in the detection of the disease, expert abilities and attention are needed. CXRs are usually used for the detection of heart and lung region anomalies. In this research, multi-level Deep Learning for CXRs ailment detection has been used to identify solutions to these issues. Spotting these anomalies with high precision automatically will significantly improve the processes of realistic diagnosis. However, the absence of efficient, public databases and benchmark analyses makes it hard to match the appropriate diagnosis techniques and define them. The publicly accessible VINBigData datasets have been used to address these difficulties and researched the output of established multi-level Deep Learning architectures on various abnormalities. A high accuracy in CXRs abnormality detection on this dataset has been achieved. The focus of this research is to develop a multi-level Deep Learning approach for Localization and Classification of thoracic abnormalities from chest radiograph. The proposed technique automatically localizes and categorizes fourteen types of thoracic abnormalities from chest radiographs. The used dataset consists of 18,000 scans that have been annotated by experienced radiologists. The YoloV5 model has been trained with fifteen thousand independently labeled images and evaluated on a test set of three thousand images. These annotations were collected via VinBigData's web-based platform, VinLab. Image preprocessing techniques are utilized for noise removal, image sequences normalization, and contrast enhancement. Finally, Deep Ensemble approaches are used for feature extraction and classification of thoracic abnormalities from chest radiograph.**

I. Introduction

In accordance with the changing to the atmosphere, lifestyle, climate change, and other elements, disease on health is increasingly growing. That has raised the risk of illness. In 2016, around 3.4 million people have deceased from Chronic Obstructive Pulmonary Disease (COPD), which is most regularly caused by smoking and pollution, and 400,000 people deceased from asthma, according to the World Health Organization (WHO) [1]. Especially in developing countries and countries with low or intermediate incomes, where millions of people live in poverty and are exposed to air pollution, the chances of chest disease are extremely high. As said by the World Health Organization, over four million premature people die each year as a result of diseases caused by household air pollution. Therefore, the steps required to minimize air pollution and carbon emissions need to be taken. Implementing effective diagnostic systems that can help diagnose chest diseases is also important. A new coronavirus disease recognized as COVID-19 has been causing serious chest damage and respiratory issues since late December 2019. Moreover, pneumonia, a type of chest disease, may be caused by the COVID-19 causative virus or other viral or bacterial infections [2].

Currently, the huge amount of Chest radiographs produced is nearly entirely examined via visual inspection, which is performed by an expert. This necessitates a wide range of skills and concentration, but it also provides a chance to employ automatic computational procedures such as Computer-Aided Diagnosis (CADs). In recent times, considerable focus and effort have been devoted to refining CAD systems using Computer Vision (CV) approaches [3-4]. The classification of medical images is one of the most difficult challenges and the most important task. The goal of the categorization procedure is to provide images with diagnoses based on their content.

Image analysis systems that are automated permit radiologists to drastically minimize their burden while simultaneously improving the standard of patient treatment. Earlier techniques frequently included both handcrafted feature representations and classifiers. Unfortunately, establishing algorithms for extracting features demands a great deal of domain knowledge and is a time-consuming procedure. Intrinsically, computer-aided diagnostics of thoracic disorders comprised of two sequential steps: the identification of pathologic irregularities and the classification of those abnormalities [5]. Computer-Aided detection and diagnosis systems will decrease the burden on doctors in urban hospitals and increase the quality of diagnosis in rural areas. Firstly, the radiologist is helped by CAD instruments to produce a statistical and well-educated decision. When the amount of data increases, radiologists will find it extremely

difficult to undergo all the X-Rays that are taken to retain the same degree of quality [6].

Automation and augmentation play a critical role in supporting radiologists in maintaining the diagnostic standard. As a result, early detection of chest illnesses is now more important than ever. Detecting abnormalities on chest radiographs is a tough task because of the complex nature and variety of thoracic disorders, as well as the low quality of chest X-ray. The majority of publicly free available chest X-ray datasets are labelled, but do not provide the locations of abnormalities that were present in each case [7]. The classification of pathologic irregularities in a chest radiograph is also a difficult task, because a chest radiograph may comprise numerous sorts of thoracic disorders, and their locations and sizes are typically widely varied, as presented in Fig. 1.

During the last few years, Deep Learning has attained extraordinary performance on a variety of classification grounded on images [8]. This achievement in identifying objects in natural photographs has revived interest in pursuing Deep Learning to medical images. The ability of Deep Learning models to interpret and identify images has obtained accuracy at the human level. In terms of medical image analysis, Deep Learning, that has a broad field of applications, particularly in medicine, fulfilling high achievements. Consequently, with the aid of Deep Learning, it has become an essential component of the medical sector [9].

The research objective is precise and automated localization and classification of Chest X-ray pictures are needed in medical health care units. Much work has been done to assist radiologists during recent years, but still accuracy, robustness and optimization are issues to address.

The first significant issue is that the exact disease location in Chest X-Ray pictures is currently not specified. The second major issue is that it has not yet been found to classify abnormalities in pictures. The accuracy of the existing model was needed to be improved. The present research is carried out to resolve the challenges.

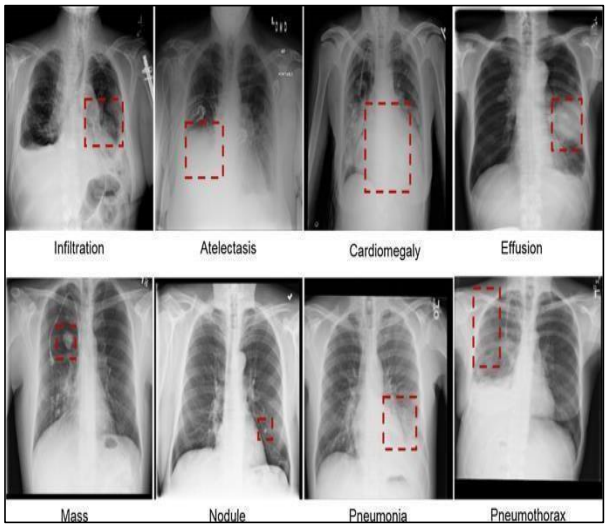

Fig. 1. Example of chest disease.

II. Literature Review

In recent years, several researchers have focused their efforts on the localization and classification of thoracic abnormalities from chest radiography using deep learning architecture. In study [10] the authors introduced a new approach utilizing Convolutional Neural Networks (CNN) to work using unstable lower class X-ray images [11]. The methodology used by the author increased the specificity by a wide margin for classifying multiple TB manifestations. In training the network, they investigated the feasibility and effectiveness of shuffle sampling with cross-validation and found its outstanding impact in the classification of medical images. In big TB image dataset from Peru, they achieved 85.68% classification accuracy, exceeding modern classification precision in this region. In healthcare services in low and middle-income states, their techniques and findings indicate an optimistic route for further precise and quick diagnosis of TB [12].

In study [13] the authors introduced seven days monitored deep learning system filled with squeeze-and excitation blocks multi-map transfer and maximum minimum pooling for identifying thoracic sicknesses and locate doubtful lesion regions. On the Chest X-ray 14 dataset the detailed discussion and lessons have completed. Quality of the presented deep learning system and its enhanced efficiency against the modern pipelines have been demonstrated by both numerical and visual findings, which suggested an integrated weakly monitored deep learning system for mutually conduct thoracic illness classification and localization on chest X-rays utilizing just the multi-class disruptive sickness mark with a mean accuracy of 83.2 %.

Researchers proposed a completely unique approach relying on vicinity conscious Dense Networks (DNetLoc), for category of pathologies, wherein they considered each spatial facts and high-decision photograph statistics for irregularity category, ensuing in an extra correct category of the abnormalities. Two datasets, particularly ChestX-Ray14 statistics set and PLCO statistics set, were used in this research. The ChestX-Ray14 statistics set incorporated thirty thousand, eight hundred and five sufferers and one hundred twenty chest X-ray snap shots. The resultant file consisted of fourteen pathology classes. In the PLCO statistics set, there were 185,421 snap shots from fifty-six thousand and seventy-one sufferers. Twelve most normal pathology labels were selected, among which five pathology labels also consisted of spatial facts. For all trials, the distinct facts were as follows: 70 percent for training, 10 percent for validation, and 20 percent for testing. For the PLCO facts set, a completely closing mean AUC score of 87.4 percent was achieved [14].

In research [15], two methods were explored for detecting pulmonary TB using CNNs which was based on the patient CXR image. Many image preprocessing techniques have been tested to identify the variety which delivers the maximum accuracy. A hybrid method also investigated with the main statistical CAD framework along through neural nets. Simulations were performed on the base of four hundred and six normal and 394 abnormal images. Simulations displayed that excellent results were provided by a trimmed area of

interest combined with contrast enhancement. The proposed method obtained 92.54% accuracy. Still better outcomes were obtained when images have been further improved with the hybrid process. They used Montgomery country and Shenzhen hospital x-ray set. The main advantage of the hybrid method was its significantly better accuracy by reducing over fitting. In the future, they wanted to obtain more clinical data and thus vastly improve the accuracy of the detection [16].

Tuberculosis is a transferable sickness that motives unpleasant health and demise in tens of lots and lots of people each 12 months worldwide. The MODS is a test to diagnose TB infection and drug sensitivity in 7-10 days with minimum rate and immoderate specificity and sensitivity proper far from a sputum sample, based completely on the seen recognition of particular Mycobacterium tuberculosis boom cording patterns in a broth culture. Despite of its benefits, in remote, constrained useful resource environment, MODS stays limited because it needs eternal and professional technical frame of employees for image-based completely diagnostics. Therefore, it is much critical to create possibility solutions that are based mostly on accurate automated interpretation and assessment of MODS cultures. In [17], CNN was validated for automated assessment of Microscopic Observed Drug Susceptibility (MODS) cultures digital snap shots. CNN become professional on a dataset of 12,510 MODS top notch and horrible snap shots obtained from 3 wonderful laboratories, in which it completed 96.63 percent accurateness and a sensitivity and specificity beginning from ninety-one percentage to ninety-nine percentage [18]. The variations discovered out features resemble seen cues used by expert diagnosticians to explain MODS cultures and proposing that our model can also have the capability to simplify and scale. It accomplished strongly whilst validated during held-out laboratory datasets and can be advanced upon with facts from novel laboratories [19]. This CNN can help laboratory personnel, in low useful resource settings and is a step towards easing automatic diagnostics get right of entry to dangerous areas in developing countries [20].

III. Strategy and Methodology for Disease Detection

As the purpose of this project is implementing a localizer and classifier, it will be reached by making a program able to localize and classify thoracic abnormalities using multi-level deep learning. This research is not only technical, developing and implementing a software to distinguish different types of disorders and defects with the present technologies; but it is also a research project, since it examines the already existing knowledge and implementations related to this field of study. So, the strategy followed will be the one denominated as 'Design and Creation' [21]. Following the Design and Creation plan is using an iterative process and keeping in mind that each step must be ended before moving on to the next as shown in Fig. 2.

A. Image Data Acquisition and Preprocessing

A publicly available image dataset present on Kaggle database is used in this study [22]. The corresponding website and unique ID for the dataset is:

https://www.kaggle.com/c/vinbigdata-chest-xray-abnormalities-detection/data. It is available with over 14 different sets of observations for chest radiographs as mentioned below:

- Another lesson.
- Pleural effusion.
- Pleural thickening.
- Pneumothorax.
- Nodule/Mass
- Transfer Learning with Yolo5
- Aortic enlargement
- Atelectasis
- Calcification.
- Cardiomegaly.
- Consolidation.
- ILD.
- Infiltration.
- Lung Opacity.

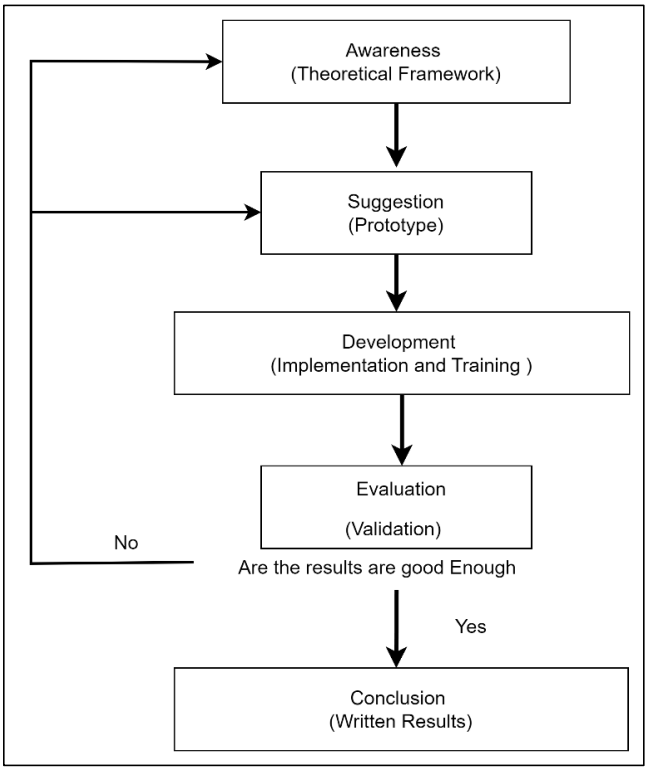

Fig. 2. Strategy diagram representation.

Since Yolo5 comes with Transfer Learning (TL) technique, it is briefly explained here. TL is a machine learning technique in which a model developed for one job is utilized as the basis for another task. The accuracy of the model must be sufficiently high, which requires a huge

amount of training data. TL is used to address the issue of sparsity. Transfer learning occurs when a network or model is trained on a dataset and a certain domain and then applied to train on a different dataset and task [23]. The source domain is referred to as the training domain, whereas the target domain is referred to as the target domain.

Similarly, tasks in distinct domains are referred to as source and target tasks. For instance, a classifier trained on book reviews can be used to categorize movie reviews: two domains, but the same goal. Transfer learning also occurs when the source and target are distinct; for example, a classifier for handwritten letters is used to classify numerical numbers. An image classifier used to conduct object detection is another example of transfer learning; once again, the domains are similar but the goals are distinct. This research concentrated on the case of jobs that span multiple domains yet are performed in a comparable manner (classification). Specifically, an ImageNet-trained CNN was used for another image-related dataset which is a well-known technique in the deep learning literature [24, 25, 26]. Yolo5 is illustrated in Fig. 3 for transfer learning, and the same statistics are applied to the dataset Investigated for this research.

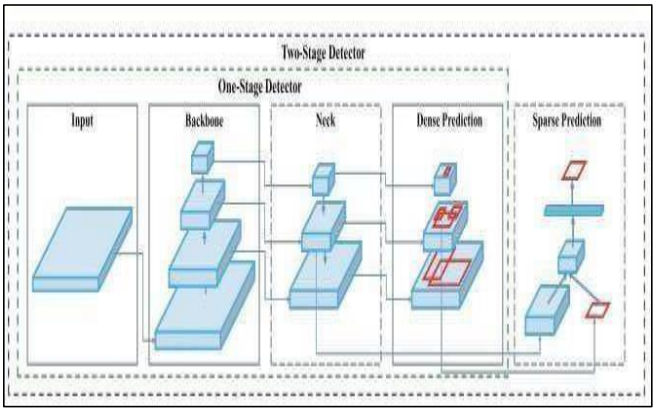

Fig. 3. Transfer learning using Yolo5.

B. Transfer Learning Strategy for Deep Learning

Deep learning systems and models are multi-layered architectures that acquire knowledge of various aspects at various stages (hierarchical representations of layered features). To obtain the last output these layers are connected to the final layer (often a completely connected layer in the case of supervised learning). This tiered architecture enables us to use a pre-trained network (such as ResNets or Inception V3) for other tasks without having to use its final layer as a fixed feature extractor. Deep learning systems and models are composed of multiple layers with distinct layer characteristics. Finally, these layers are joined to the last layer to produce the final output [27]. This layered architecture enables us to use a pre-trained network (for example, ResNets or InceptionV3) as a fixed feature extractor for a variety of tasks without requiring it to have a final layer [28]. Fig. 4 shows transfer learning cutting approach.

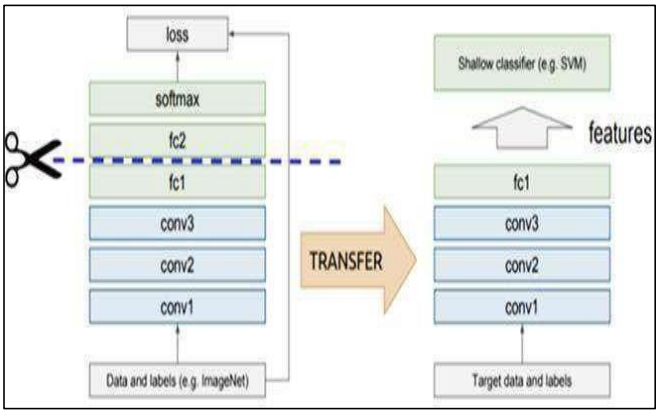

Fig. 4. Transfer learning cutting approach.

IV. Proposed Model

The proposed framework makes use of an image collection to localize and classify several catheters abnormalities plant diseases. The block diagram in Fig. 5 demonstrates that the suggested paradigm persists across major phases.

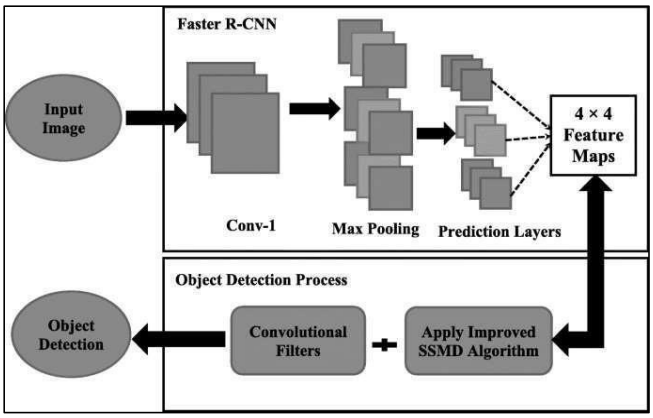

Fig. 5. Methodology diagram of proposed method.

A. Evaluation Measures for Classification

After the training process, algorithms were tested on the testing dataset. The performance of the model was validated by utilizing accuracy, recollection, precision and F1-score. Performance metrics that were employed in this research are explored in detail below.

1) Classification accuracy: The accurateness of classification is measured as the proportion of correct predictions to the total number of accurate predictions.

$$\text{Accuracy} = \frac{\text{Number of Correct Predictions}}{\text{Total Numer of Predictions}} * 100\% \quad (1)$$

2) Precision: Classification accuracy is not always a reliable indicator of a model's overall performance, as demonstrated by several examples. One of these cases is when the distribution of classes is imbalanced. If all the samples are treated as if they are of the highest quality, a high accuracy rate will be received, which does not make sense. Precision, on the other hand, indicates the inconsistency you find when utilizing the same instrument over and over again, for as when

measuring the same part again. Precision is one of such measures, which is characterized in Eq. (2):

$$\text{Precision} = \frac{\text{True Positives}}{\text{True Positives} + \text{False Positives}} \quad (2)$$

3) F1 score: F1-score is a well-known metric that combines recall and precision. It is defined in Equation 3 as follows:

$$F1score = 2 * \frac{\text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}} \quad (3)$$

4) AUC score and ROC curve: Area under curves (AUC) reflects the level of separability, and receiver operating characteristic (ROC) is a probability curve. ROC curve is a graph that displays the relationship between sensitivity (true positive rate) and specificity (rate of false positives).

V. Experimental Results

The proposed framework makes use of an image collection to localize and classify several. We accomplished lung segmentation to focus the learning around the lung area, where the COVID-19 radiomic features are located. For this, the U-net model that had been popular for biomedical image segmentation was adopted [29]. The Segmentation model was trained using three publicly available lung segmentation datasets: Montgomery [11], HIN [25], and JSRT [13]. The three datasets provided manual segmentation masks (i.e., segmentation labels) [30]. The segmentation was not perfect. The resulting output mask often contains only part of the lung area and tend to be scattered over the whole lung area. To minimize the possibility of missing COVID-19 related radiomic features, the smallest square area was cropped out that enclosed the predicted mask. All such square lung areas were subsequently resized into 512 × 512, whether they were larger or smaller [31].

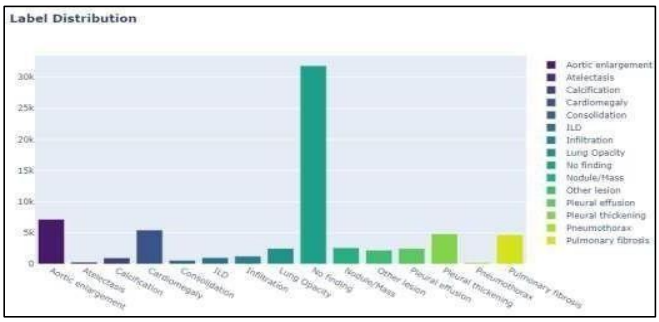

Fig. 6. Label distribution for catheter.

The dataset contains the X-rays of patients, multiple X-rays for individual patients, where the observation of each patient is documented in the dataset. The observation interval is different for patients. The distribution is represented in bar graph shown in Fig. 6.

Fig. 7 represents the bounding box area per percentage of image for each disease. The error and histogram are represented in boxes for ILD calcification, infiltration, lung opacity, Nodule Mass and pulmonary fibrosis for the dataset.

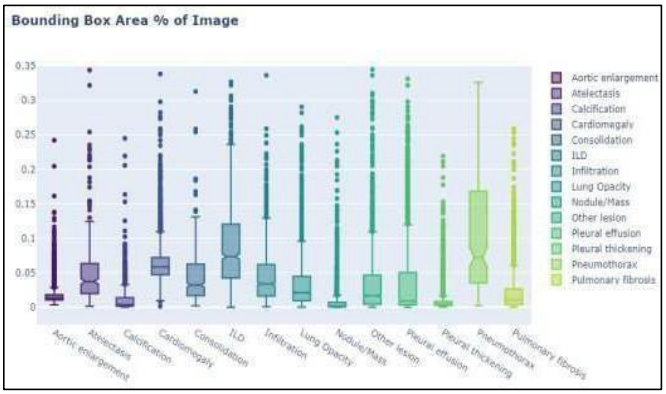

Fig. 7. Bounding area of image for figure.

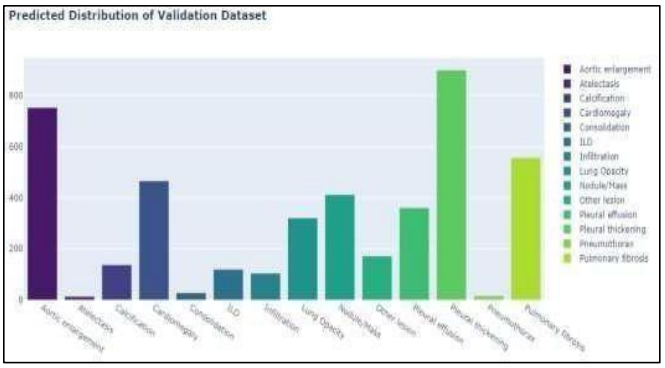

Fig. 8. Predicted distribution of validation dataset.

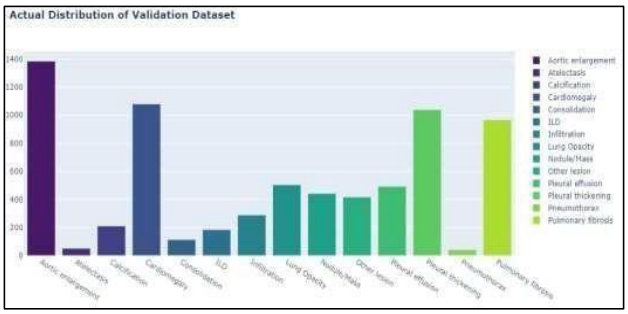

Fig. 9. Actual distribution of dataset.

Fig. 8 represents the predicted distribution of validation dataset while Fig. 9 shows the actual distribution of the dataset, where each defect is represented in bar graph and with different color for individual defect.

VI. Conclusion and Future Work

Most Chest X-rays are used to spot the existence of chest diseases by radiologists worldwide. By studying several X-rays in busiest health center can lead to a loss of money and time. Furthermore, in the detection of the disease, expert abilities and attentions are needed. CXRs are usually used for the detection of heart and lung region anomalies. In this research, multilevel deep learning is used for chest X-rays ailment detection to identify solutions to these issues. Spotting these anomalies with high precision automatically significantly improves the processes of realistic diagnosis. However, the absence of efficient, public databases and

benchmark analyses makes it hard to match the appropriate diagnosis techniques and define them. The publicly accessible VINBigData dataset is used to address these difficulties, and the output of established multi-level deep learning architectures is studied on various abnormalities. A high accuracy in chest X-Ray irregularity detection is achieved on this dataset. The focus of this research is to develop a Multi-level Deep learning approach for Localization and Classification of thoracic abnormalities from chest radiograph. The proposed technique automatically localizes and classifies fourteen types of thoracic abnormalities from chest radiographs. The used dataset consisting of eighteen scans that have been explained by experienced radiologists. The YoloV5 model is trained with fifteen thousand independently labeled images and evaluated on a test set of three thousand images. These annotations are collected via VinBigData's web-based platform, VinLab. Image preprocessing techniques are utilized for noise removal, image sequences normalization, and contrast enhancement. Finally, Deep Ensemble approaches are used for feature extraction and classification of thoracic abnormalities from chest radiograph.

***Abstract*—This research investigates the fusion of the Analytic Hierarchy Process (AHP) with clustering techniques to enhance project outcomes. Two quantitative datasets comprising 20 and 100 software requirements are analyzed. A novel AHP dataset is developed to impartially evaluate clustering strategies. Five clustering algorithms (K-means, Hierarchical, PAM, GMM, BIRCH) are employed, providing diverse analytical tools. Cluster quality and coherence are assessed using evaluation criteria including the Dunn Index, Silhouette Index, and Calinski Harabaz Index. The MoSCoW technique organizes requirements into clusters, prioritizing critical requirements. This strategy combines strategic prioritization with quantitative analysis, facilitating objective evaluation of clustering results and resource allocation based on requirement priority. The study demonstrates how clustering can prioritize software requirements and integrate advanced data analysis into project management, showcasing the transformative potential of converging AHP with clustering in software engineering.**

I. Introduction

Software engineering is built on several pillars and involves more than just programming. It contains every piece of supporting information, design principle, or idea required to make these programmes function as intended. Software requirements prioritisation (SRP) is one of the design principles that enable software that is being considered for development to function as intended [1].

A subfield of requirements engineering called requirements prioritisation assists in selecting requirements based on the interests of stakeholders. Giving each requirement a priority to decide the order in which they should be implemented is a step in the software engineering process. A requirement engineering decision process is used to decide which features or requirements will be developed in the upcoming release while considering technical, resource, risk, and budget constraints [2]. Choosing the order in which requirements should be addressed is a crucial step in the software development process. This process aids in managing the priority and urgency of software requirements while considering stakeholders' interest, cost, resource, and time issues. Numerous academics have provided definitions for the ranking of software demands in order of importance. Software requirement prioritisation is a process that determines the order in which needs will be implemented [3]. The process of selecting the best set of requirements from several conflicting and competing expectations gathered from various stakeholders participating in a software development project, according to Karlsson and Ryan [4].

The success or failure of a project is largely dependent on the software requirements specification in general and the prioritisation of software requirements in particular. Almost 80% of software projects fail to achieve the Standish Group's definitions of success based on time, cost, and scope criteria each year [5]. The failure is often due to shifting requirements, as requirements are often documented and rarely changed. This suggests that software projects fail due to their inability to evolve efficiently to match shifting requirements or accommodate new ones. This highlights the importance of release management and the need for proper decision-making about the functionality of a software product's release. A well-selected release will minimize problems with shifting requirements in future releases.

As a remedy to this issue, many requirements prioritisation techniques have been put forth. These techniques aim to reduce the length and cost of software development projects by supporting developers in identifying the most important and urgent requirements. Each method has limitations and makes both explicit and implicit assumptions about the project context during requirements prioritisation [6]. These presumptions must be considered while experimentally assessing a requirement prioritisation approach for usefulness, utility, application, or effectiveness.

One technique for ranking software requirements is to use clustering techniques. Similar observations, data points, or feature vectors can be clustered together based on shared characteristics using the clustering technique [7]. Clustering algorithms are used in the prioritising process to group and categorise requirements based on similarity or relatedness. This enables effective requirements prioritisation based on the characteristics of each cluster and the discovery of patterns and relationships between them. Clustering algorithms can assist in managing the complexity of prioritising various requirements by organising requirements into meaningful clusters that can then be prioritised more successfully.

This study thoroughly explores an innovative and promising method for requirement prioritisation that combines the Analytic Hierarchy Process (AHP) and clustering techniques. With the use of the data mining approach known as clustering, it may be possible to group together requirements that are similar, making it easier to handle them and improving the decision-making process. AHP, on the other hand, is a structured method for making decisions based on several factors and enables the creation of priorities based on both qualitative and quantitative judgments.

As we seek to assess the accuracy of quantitative records, it is crucial to assign requirements the proper level of importance to determine the core set of requirements. To do this, the MoSCoW technique, a tried-and-true framework for prioritising requirements, is used that divides each into Must-haves, Should-haves, Could-haves, and Won't-haves categories based on how important and consequential they are. A robust evaluation framework is also developed using metrics like the Dunn Index, Silhouette Index, and Calinski Harabaz Index. These metrics provide quantitative insights into the quality and cohesion of clusters, aiding decision-making processes.

Let's suppose a software development team is tasked with prioritizing features for an e-commerce platform using clustering techniques. They assign priorities within each cluster based on business impact and technical complexity. For example, they prioritize product search functionality (Cluster A) and payment processing (Cluster B) based on their significance for user experience and revenue generation. This approach streamlines decision-making, ensuring high-priority features align with business goals and user needs, ultimately optimizing the software development process.

Our overarching objective in this research is to evaluate the results of combining clustering methods with the Analytic Hierarchy Process (AHP). Our view of this integration's potential impact will be greatly influenced by the outcomes of this integration, which are expected to provide a distinctive perspective on requirement prioritisation and project management. In keeping with this goal, we have developed two key research questions that will direct our empirical studies and provide the information required to make well-informed decisions.

RQ1: Is a semi-automated approach to SRP processes possible with the incorporation of clustering techniques?

RQ2: Does the fusion of AHP and clustering generate better results?

The remainder of the paper is structured as follows: It commences with the state of the art for clustering algorithms and prioritisation techniques in Section II. Following this, Section III gives an overview of established techniques for clustering and requirements prioritisation. In Section IV, we elaborate on the methodology proposed for clustering requirements using AHP including how to determine the number of clusters, evaluate clusters, and associate MoSCoW categories with them. Section V presents and analyzes the results of an effectiveness study conducted on two different datasets. Section VI is dedicated to addressing the effectiveness of the proposed method. Lastly, Section VII presents the Results. Section VIII encapsulates the conclusions drawn from the research.

II. LITRUTURE REVIEW

Table I extensively evaluates several works on algorithms for clustering and requirements prioritisation. Notably, a wide range of techniques were investigated within the state of the art, including Binary Search Tree, Analytic Network Process, Spanning Tree, Numerical Analysis, Bubble Sort, MoSCoW, and Analytical Hierarchical Process. Remarkably, the Analytical Hierarchical Process (AHP) was the method of choice among researchers due to its constant production of superior results. The section also discusses several clustering techniques, such as K-Means, Partition Around Medoids, BIRCH, Agglomerative Hierarchical Clustering, and Gaussian Mixture Model (GMM). This review of the literature provides an overview of the field and paves the way for the creation of an original and useful framework, laying the groundwork for succeeding research phases.

TABLE I. LITERATURE REVIEW

Year	*Title*	*Techniques Used*	*Results*	*Ref.*
2015	Applying the analytical hierarchy process to system quality requirements prioritisation	AHP	The AHP technique effectively removes discrepancies between stakeholders' interests and the business goals.	[8]
2015	Comparison of Requirement Prioritisation Techniques to Find the Best Prioritisation Technique	binary search tree, AHP, hierarchy AHP, spanning tree matrix, priority group/Numerical Analysis, bubble sort, MoSoW, simple ranking, and Planning Game		[9]
2016	An Evaluation of Requirement Prioritisation Techniques with ANP	ANP, binary search tree, AHP, hierarchy AHP, spanning tree matrix, priority group and bubble sort	AHP is the best requirements prioritisation technique amongst all the requirements prioritisation techniques	[10]
2016	An approach to the estimation of the degree of customization for ERP projects using prioritised requirements	Framework using AHP	AHP framework gave better results	[11]
2017	Fuzzy_MoSCoW: A fuzzy based MoSCoW method for the prioritisation of software requirements	Fuzzy MoSCoW	ANP is the best technique among the seven techniques,	[12]

Year	Title	Techniques Used	Results	Ref.

2020	A Novel Approach for Software Requirement Prioritisation	MAHP, a combination of AHP and MoSCoW		[13]
2020	Prioritisation of Software Functional Requirements from Developers' Perspective	Spanning Tree and AHP	AHP framework gave better results	[14]
2022	E-AHP: An Enhanced Analytical Hierarchy Process Algorithm for Prioritising Large Software Requirements Numbers	Enhanced AHP	E-AHP gives better results for large projects	[15]
2015	Efficient agglomerative hierarchical clustering	Efficient agglomerative hierarchical clustering	Experimental results show consistent performance across various settings, proving efficient AHP to be reliable.	[16]
2016	A hierarchical clustering method for multivariate geostatistical data	Aglomerative hierarchical clustering	Proposed clustering method yields satisfactory results compared to other geostatistical methods.	[17]
2017	Milling tool wear state recognition based on partitioning around medoids (PAM) clustering	PAM	PAM outperforms k-means and fuzzy c-means in Ti-6Al-4V alloy end milling experiments.	[18]
2017	Malware family identification with BIRCH clustering	BIRCH	BIRCH excels in malware family identification with high accuracy and low clustering time.	[19]
2020	Unsupervised K-Means Clustering Algorithm	Unsupervised K-Means	The U-k-means algorithm is robust to data structure and performs better than existing algorithms.	[20]
2020	Applications of Clustering Techniques in Data Mining: A Comparative Study	K-Means, Hierarchical Clustering, DB Scan, OPTICS, Density-Based Clustering, EM Algorithm	The paper emphasises the value of K-means clustering in consumer data analysis and business decision-making	[21]
2020	A Comparative Study on K-Means Clustering and Agglomerative Hierarchical Clustering	K-Means and Agglomerative Hierarchy	K-means performs faster for large datasets and agglomerative hierarchical is better for smaller ones.	[22]
2021	Gaussian Mixture Model Clustering with Incomplete Data	GMM	Experiments validate the effectiveness of the proposed algorithm.	[23]
2022	Bayesian Inference-Based Gaussian Mixture Models with Optimal Components Estimation Towards Large-Scale Synthetic Data Generation for In Silico Clinical Trials	BGMM-OCE	BGMM-OCE outperforms other synthetic data generators in terms of computational efficiency and unbiasedness	[24]
2022	Design and Implementation of an Improved K-Means Clustering Algorithm	Improved K-Means	Enhanced algorithm works better than conventional K-Means.	[25]
2022	Gaussian mixture model clustering algorithms for the analysis of high-precision mass measurements	GMM	Results from GMMs were closely congruent with values that had previously been published.	[26]

A. Research Gap

The limited investigation of the Analytical Hierarchy Process (AHP) as a technique for clustering requirements in the context of planning a project's next release is the area of research that will be addressed in this research. Although most of the literature now in existence focuses on the use of AHP in requirements prioritisation and decision-making, there is a striking paucity of studies that explore its potential utility in grouping or clustering requirements to speed up the release planning process. In the context of release planning, AHP in integration with clustering can be used to enhance how requirements are organised, classified, and prioritised. This will ultimately result in more effective and efficient project management.

III. Techniques Used in the Study

A. Requirements Prioritisation Techniques

Software engineering professionals utilise a collection of methodologies called software requirements prioritisation techniques to rank the importance or priority of various software project requirements. Because not all requirements

can be addressed at the same time during software development due to restricted resources (such as time and money), prioritising requirements is essential. To ensure the successful delivery of a software product, it is crucial to identify and concentrate on the most important and significant needs. The two techniques that we will be using in this study are AHP and MoSCoW.

1) Analytical hierarchical process: The Analytical Hierarchy Process (AHP) is a systematic decision-making technique [27] proposed by Thomas L. Saaty in the 1970s. It was developed for complex decision-making so that the decision-maker could set priorities and get to the best option possible [28]. AHP starts by modeling the decision issue as a hierarchical structure and breaks it into three parts: a goal or aim, criteria that help achieve the goal, and alternatives or possibilities that need to be examined. In the next step, experts or decision-makers are requested to compare the criteria and options at each level of the hierarchy in pairs. They utilise a scale to indicate the relative importance of things, often ranging from 1 (equal importance) to 9 (much more essential). Then a consistency check is done to make sure the comparisons are reliable. To determine if decision-makers judgments are consistent, the AHP technique uses mathematical calculations. It may be necessary for decision-makers to reevaluate their conclusions if contradictions are found.

AHP uses pairwise comparison data to determine the relative weights or priorities of the criteria and alternatives. These weights reflect the preference for each choice relative to the criteria and the significance of each criterion in reaching the overall aim. The scores of the options for each criterion are then combined using the estimated weights. Depending on the decision context, different aggregation techniques, such as weighted sum or weighted average, might be used. To rank and evaluate the options based on their overall desirability or performance in relation to the goal, AHP aggregates the aggregated scores. Lastly, decision-makers can use the prioritised rankings and scores to make decisions. Based on the established criteria and their relative relevance, AHP offers an organised and clear way to assess and choose the best alternative.

2) MoSCoW: The Dynamic Software Development Method (DSDM) provides the foundation for the MoSCoW method [29]. It is a common strategy for prioritising requirements. As a matter of fact, it is one of the easiest techniques [30]. The acronym stands for must have, should have, could have, and won't have. The importance or priority of a certain feature within a project is represented by each category. The core project scope is made up of must-haves, which are important and non-negotiable components necessary for project success. Should-haves are crucial characteristics that greatly enhance the value of the project and ought to be applied whenever practical. Could-haves offer flexibility for prospective improvements because they are desired but not necessary. To manage scope and avoid feature creep, won't-haves are expressly left out of the current phase or project. MoSCoW supports resource allocation and project planning by assisting project teams and stakeholders in prioritising requirements, ensuring that critical components are addressed first while providing clarity on what may be postponed or excluded.

B. Clustering Algorithms

The need to find knowledge in multidimensional data is growing since massive volumes of data are being continuously collected today. One of the crucial steps in mining or extracting massive information is data miming. Clustering is the most intriguing area of data mining, which seeks to identify underlying patterns in data and identify some useful subgroups for additional investigation. Each group, or cluster, is made up of things that are dissimilar from those in other groups yet like one another [31].

A total of five clustering algorithms have been used in this paper and each algorithm is briefly discussed in this section.

1) K-Means: In machine learning and data mining, the clustering algorithm K-Means is very famous and frequently employed [32]. It requires the number of clusters to be specified prior to the operation [33]. It seeks to divide a given dataset into the specified number of clusters (K) according to how similar the data points are to one another to maximise certain clustering criteria. K-Means is an iterative technique that minimises the sum of squared distances between data points and the centroids of each cluster to give results. The k-means algorithm is a well-liked clustering technique that minimises clustering error [34].

2) Partition Around Medoids (PAM): The PAM method partitions a distance matrix into a predetermined number of clusters [35]. The goal of PAM is to divide a dataset into a predetermined number of clusters by choosing actual data points, known as medoids, as representatives of the clusters. PAM is meant to work with dissimilarity or distance matrices. Like centroids, medoids are chosen from the actual data points, which makes PAM more resistant to noise and outliers.

3) Agglomerative hierarchical clustering: The process of clustering data points into a hierarchical structure of clusters is called agglomerative hierarchical clustering. Due to the exponential rise of real-world data, hierarchical clustering is crucial for data analytics [36]. In this type of clustering, each item at first represents a separate cluster. The appropriate cluster structure is then created by repeatedly merging clusters until all data points are members of a single cluster, or until a stopping requirement is satisfied. A dendrogram, which is a tree-like structure created because of this procedure, shows the clustering hierarchy visually.

4) Gaussian Mixture Models (GMM): Gaussian Mixture Models (GMMs) are probabilistic models used for modelling complicated data distributions in statistical analysis and machine learning. Much research has been done on it due to its usefulness and efficiency [37]. They presume that a variety of Gaussian (normal) distributions, each with its mean and covariance, were combined to produce the data. These

parameters are intended to be learned, and GMMs estimate the likelihood that data points will belong to each Gaussian component. They are frequently used for tasks like clustering, density estimation, and data generation.

5) BIRCH: Balanced Iterative Reducing and Clustering Using Hierarchies is an effective hierarchical clustering algorithm made for grouping huge datasets. Its key characteristic is to employ low memory resources for high-quality clustering of large-scale data datasets and to only scan datasets once to reduce I/O overhead [38]. A comparable B + tree structure known as a Clustering Feature Tree (CF Tree) is used by Birch to perform clustering [39].

IV. Proposed Methodology

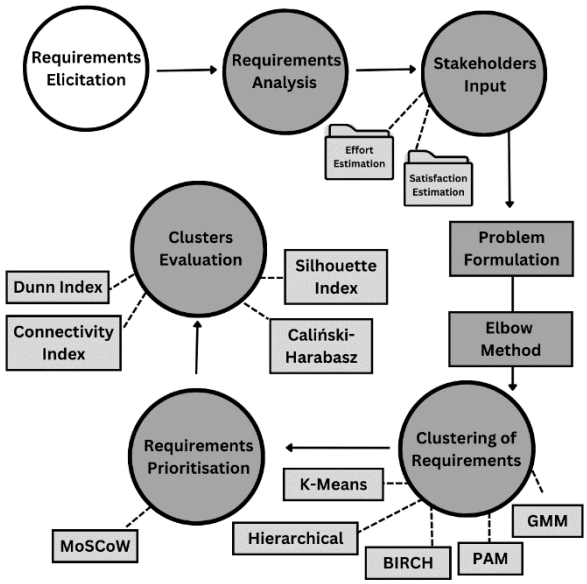

Fig. 1. Proposed methodology.

This study presents a method for prioritizing requirements for the next release using requirements prioritisation methods. It considers the effort required for implementing a requirement and its satisfaction with stakeholders. Clustering algorithms are applied to cluster requirements, and the technique is used to extract a group of requirements for the next release. The validity of clusters is evaluated. In the end MoSCoW is applied to assign importance to the clusters. The Fig. 1 provides a bird's eye view of the process.

A. Requirements Elicitation

Requirement elicitation is a crucial step in requirement engineering, gathering stakeholders' needs and expectations for a software project through discussions, interviews, and surveys, ensuring comprehensive documented requirements.

B. Requirements Analysis

Requirements Analysis involves a thorough examination of requirements to eliminate ambiguity, address inconsistencies, and evaluate feasibility. It aims to create a refined representation of the software's functionalities.

C. Stakeholders' Input

Stakeholders actively contribute to the decision-making process by offering critical input on two important factors: the amount of work necessary to accomplish the project and the expected degree of satisfaction. Their insights cover both effort (resource allocation, time commitments, and potential obstacles) and satisfaction (alignment with organisational goals and client needs). Through the careful balancing of resource optimisation and stakeholder satisfaction throughout project planning, this dual input enables informed decision-making.

D. Problem Formulation

1) Quantitative data: Consider a situation where we have a list of requirements, R = r1, r2 ,..., rn, that reflect the new features that various customers have recommended for a forthcoming software version. Each stakeholder i is given a weight wi to indicate their significance. This implies that some stakeholders' preferences will be taken into consideration more so than others when deciding what issues need to be solved in a software version. The set of customer weights is denoted by the notation W = w1, w2, ..., wn.

Each requirement rj in the set R has a corresponding development effort value ej that calculates the resources or cost necessary for its implementation. The notation for this collection of effort values is E = e1, e2 ,..., en. This is measured by a value vij, which expresses the significance of need rj for customer i. In essence, higher vij values indicate that stakeholder i is given more priority.

Summing up a requirement's importance ratings across all stakeholders yields the total value of including it in the upcoming software release, or its global satisfaction, abbreviated as **sj** (sj = m i=1 wi vij). By considering each stakeholder's own priorities and weights, this indicates the overall satisfaction that the addition of requirement rj would offer to all stakeholders. The set of requirement satisfactions that result is denoted by S = s1, s2,..., sn [40].

2) AHP dataset: For the pairwise comparisons of each criterion in this study, the quantitative data set is used. As a result, the AHP data set for our requirements generated. Following the collection of pairwise comparison judgments, the eigenvector approach is used to determine the respective weights of the two criteria, effort, and satisfaction. Then, a square matrix known as the comparison matrix is formed, with elements $\mathbf{c_{ij}}$ standing in for the weighting of the criteria effort ($\mathbf{c_i}$) and satisfaction ($\mathbf{c_j}$). By dividing each column by its sum, the matrix is normalised, producing a matrix of normalised values. To determine the priority vector for each level, the normalised values in each row are averaged. The consistency ratio (CR), which assesses whether the judgments line coherently, is used in a consistency check to ensure consistent pairwise comparisons. Adjustments are made if the CR exceeds a predetermined limit, which is commonly set at 0.1. The priority vectors show the relative weights of the requirements after the consistency check has been successful.

E. Elbow Method

The elbow method is a heuristic in data science and machine learning for determining the optimal number of

clusters in a dataset. It involves considering a range of potential cluster numbers and computing the sum of squared distances between data points and cluster centers. The study applies the elbow method to the requirements dataset, calculating the within-cluster sum of squares (WCSS) for varying cluster numbers and plotting these values.

F. Clusters Formation

In this phase clusters of requirements are formed. It involves organizing and grouping similar requirements into clusters using techniques like similarity analysis or domain categorization. This process enhances manageability and provides a structured approach for analysis. Five distinct clustering algorithms will be employed: K-Means, Agglomerative Hierarchical Clustering, Partitioning Around Medoids (PAM), Gaussian Mixture Model (GMM), and BIRCH. These algorithms help extract meaningful patterns and structures from requirements, aiding in informed decision-making during the prioritization process.

G. Clusters Evaluation

The evaluation of clusters is crucial for assessing the quality and validity of data analysis or machine learning algorithms. Three mechanisms are used: Dunn Index, Silhouette Index, and Caliński-Harabasz Index, which are calculated after cluster formation and used to rate them.

1) Dunn index: The Dunn Index is a clustering validation statistic that unsupervised machine learning researchers use to rate the accuracy of their clustering findings. It gauges the separation between clusters, or how far away various clusters are, in relation to the compactness of clusters, or how near the data points inside a cluster are to one another. Better clustering with smaller within-cluster distances and larger between-cluster distances is indicated by a higher Dunn Index.

$$\textbf{Dunn Index} = \textbf{min\_intercluster\_distance} / \textbf{max\_intracluster\_distance}$$

Where:

Min_intercluster_distance: The minimal distance between any two centroids that belong to separate clusters.

Max_intracluster_distance: The maximum distance between any two data points within the same cluster.

2) Silhouette index: The Silhouette Index is a tool for clustering evaluation that assesses how cohesive and well-separated clusters are. Higher values denote better clustering quality; the range is -1 to 1. (b(i) - a(i)) / maxa(i), b(i) is the formula for calculating the silhouette score for a single data point, where a(i) is the average distance inside the same cluster and b(i) is the smallest average distance to another cluster. Greater clustering is suggested by average silhouette scores that are higher across all data points.

$$S(i) = (b(i) - a(i)) / \max\{a(i), b(i)\}$$

Where:

S(i): The silhouette score for data point i.

a(i): The average distance between data points i and all other data points in the same cluster.

b(i): The shortest average distance between data point i and all other data points in a distinct cluster.

3) Caliński-Harabasz index: The Calinski-Harabasz Index, commonly referred to as the Variance Ratio Criterion, is a clustering evaluation metric used in unsupervised machine learning to rate the calibre of clusters. It calculates the difference between the variances within and between clusters. Better-defined and more distinct clusters are indicated by higher Calinski-Harabasz Index values.

$$CH = B/W\{(N-K)/(K-1)\}$$

Where:

B: Between-cluster variance, which measures the variance between different clusters.

W: Within-cluster variance, which measures the variance within individual clusters.

N: Total number of data points.

K: Number of clusters.

H. Requirements Prioritisation

The MoSCoW approach is used in this study as a useful tool to prioritise requirements clusters. Requirements clusters are systematically classified and ranked using MoSCoW based on their importance and criticality to the project. This will help in improving efficiency and efficacy of the project planning and resource allocation and will make sure that the development efforts are concentrated on the most important and impactful clusters of needs.

V. Methodology Implementation

A. Formulation of Problem

1) 20 Requirements Problem: There are twenty requirements and five stakeholders in this dataset, and it was drawn from [41]. The level of priority or value assigned by each stakeholder to each requirement is shown in Table II along with the development effort connected to each requirement. The stakeholder weights are offered in the range of 1 to 5 (Table III). These values might be thought of as linguistic terms like "without importance" (1), "less important" (2), "important" (3), "very important" (4), and "extremely important" (5). They also line up with the relative importance of each need. There is an estimated effort score that corresponds to each requirement, ranging from 1 to 10.

TABLE II. 20 Requirements Problem

Customers' Weights	***C1***	***C2***	***C3***	***C4***	***C5***
	1	4	2	3	4

a) 20 Requirements Problem using Quantitative Approach: To convert the data into two dimensions to apply clustering on it, we considered Section 4.4.1. Here:

R = {r1, r2, ……., r20},

E = {1, 4, 2, …….,4},

W = {1, 4, 2, ……., 4}.

This is how 'S' (Satisfaction) was calculated for r1.

$S = \sum (Vij * Wi)$

S= {(4*1) + (4*4) + (5*2) + (4*3) + (5*4)}

S= 62

So, satisfaction for r1 was calculated to be 62 whereas the effort is 1. The rest was also calculated similarly, and this Table IV was generated as a result.

TABLE IV. QUANTITATIVE DATASET FOR 20 REQ. PROBLEM

ID	***Eff.***	***Sat.***	***ID***	***Effort***	***Sat.***

R20	3.19100441	10.0644868

2) 100 Requirements Problem: There are five stakeholders in this data set as well, but there are 100 requirements this time and it was obtained from [42].The difficulty of selecting requirements from a bigger set in the early timeboxes of establishing true agile software projects led to the selection of this dataset. Because of this, we now have 100 requirements rather than simply 20. For the development effort, each requirement has a value that runs from 1 to 20. The maximum development effort in this case is 20 units, or 4 weeks, which roughly corresponds to the timescale set by agile approaches (such as Scrum's proposed iteration length of 2 to 4 weeks). Stakeholders rate the significance of criteria on a scale of 1 to 3. Here, the digits 1-3 stand for (1) not necessary, (2) preferable, or (3) required [43].

The Effort and Satisfaction for each requirement was calculated in the similar way as it was calculated for 20 Requirements problem. The Quantitative and AHP datasets for 100 requirements problem is given in Table VI:

B. Determining No. of Clusters

To determine the ideal number of clusters, the elbow approach was used on data sets from the 20 and 100 Requirements Problem. The ideal number of clusters is depicted in Fig. 2 and 3.

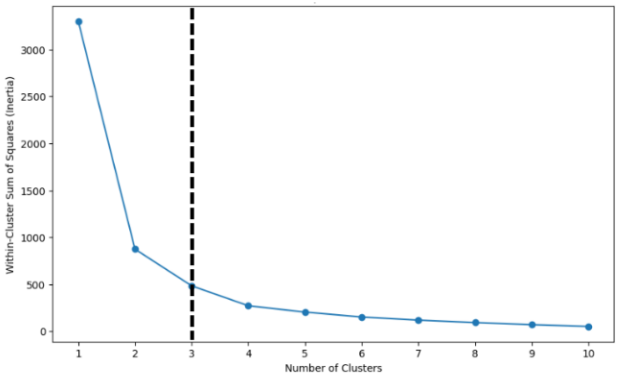

Fig. 2. Optimum no. of clusters using AHP dataset for 20 req. problem.

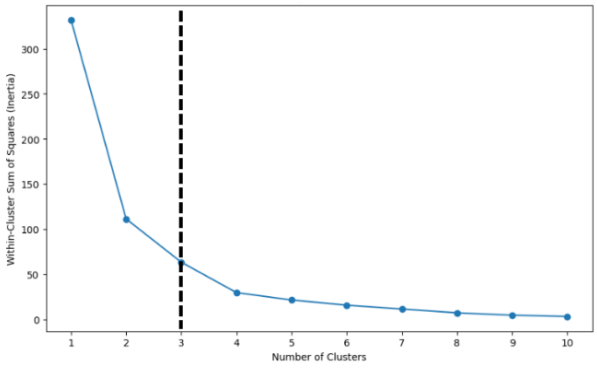

Fig. 3. Optimum no. of clusters using AHP Dataset for 100 req. problem.

C. Clusters Formation and Evaluation

The elbow method's findings show that three clusters are the ideal number for both the 20 and 100 Requirements Problems. We made 3 and 4 clusters because we are employing MoSCoW in addition to AHP for requirement prioritising. This is because MoSCoW has four characteristics.

In the publication [40], quantitative dataset was used to evaluate three clustering algorithms: K-means, Hierarchical Clustering, and Partition Around Medoids (PAM). In this research, we compare the values acquired by the Analytic Hierarchy Process (AHP) approach to the values of quantitative dataset. The benefits and drawbacks of various techniques are better understood through holistic comparison, which also advances knowledge of efficient clustering methodologies and their real-world applications.

The graphical depiction of 100 requirements datasets for Agglomerative Hierarchical Clustering is illustrated in Fig. 4 and 5. This visualization provides a clear representation of the analyzed data, offering insights into the observed trends and patterns.

To gain a deeper knowledge of how the proposed technique interacts with various clustering algorithms, evaluation indices for both types of data sets, namely Quantitative and AHP, are also calculated using Gaussian Mixture Models (GMM) and BIRCH (Fig. 6 and 7).

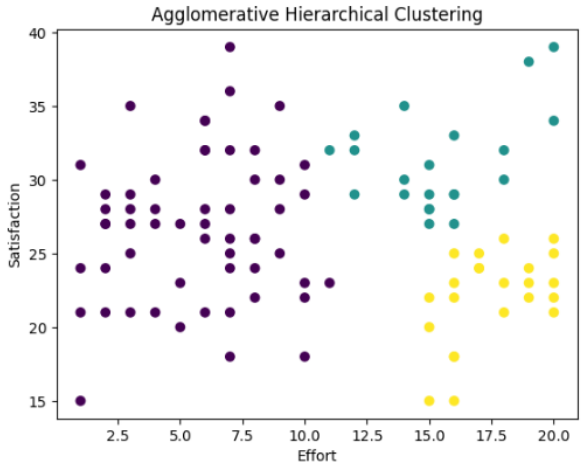

Fig. 4. Hierarchical clustering for 100 req. problem using quantitative dataset.

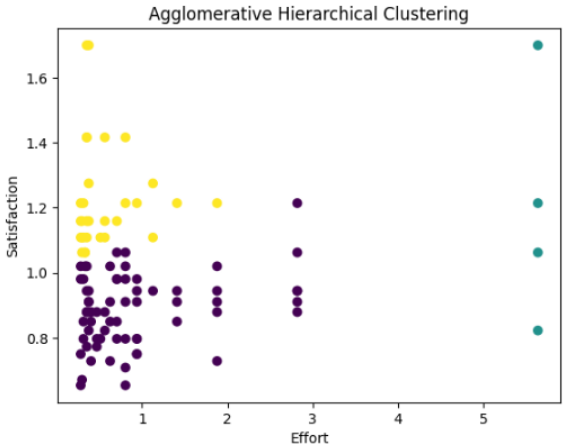

Fig. 5. Hierarchical clustering for 100 req. problem using AHP dataset.

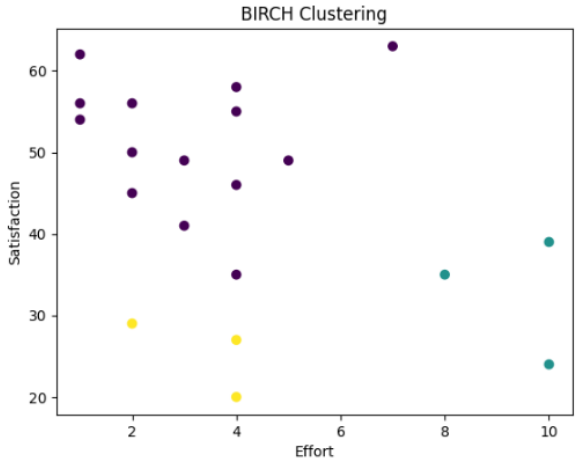

Fig. 6. BIRCH clustering for 20 req. problem using quantitative dataset.

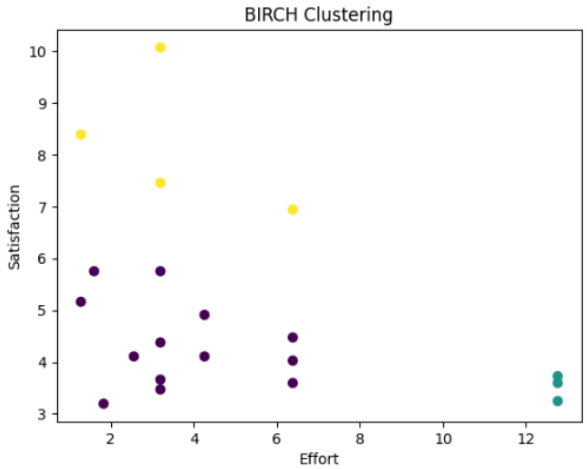

Fig. 7. BIRCH clustering for 20 req. problem using AHP dataset.

All in all, five clustering algorithms: K-Means, Partition Around Medoids, Agglomerative Hierarchical Clustering, Gaussian Mixture Models, and BIRCH and three evaluation metrics: the Dunn Index, the Silhouette Index, and the Calinski-Harabasz Index are used in this research.

The outcomes of each clustering algorithm for cluster evaluation metrics are provided in the Tables VII-XVI.

1) K-Means
2) PAM
3) Hierarchical
4) GMM
5) BIRCH

D. Prioritisation of Requirements

The MoSCoW method is used to prioritize requirements clusters. Clusters with higher satisfaction and minimal effort were given the highest priority and are designated as "MUST" fulfillments. Clusters with higher satisfaction and minimal effort are designated as "SHOULD" requirements. Clusters in the "COULD" category are considered for enhancement due to their higher effort cost. Clusters in the "WON'T" category are intentionally deferred due to higher effort requirements. This dynamic prioritization methodology offers a nuanced perspective for optimizing software requirements in line with project goals.

VI. DISCUSSION

Our study compared the Analytic Hierarchy Process (AHP) with quantitative dataset approaches in requirement prioritization and clustering, highlighting performance differences across multiple evaluations. Each comparison table illustrates instances where either AHP or the quantitative dataset method performed better, with the superior values highlighted for clarity Table (VII-XVI). Out of 54 evaluations, AHP showed superior performance in 39 cases, emphasizing variability between methods.

The effectiveness of AHP in generating compact and meaningful clusters underscores its potential for handling complex datasets in software engineering. By leveraging a structured decision-making approach that incorporates both qualitative and quantitative judgments, AHP successfully groups requirements with closer features or similarities together more cohesively. This results in coherent and relevant requirement groupings, which in turn facilitates improved decision-making and prioritization within software development processes. AHP's ability to create compact clusters highlights its utility in enhancing the efficiency and effectiveness of software engineering practices.

VII. RESULTS

The Analytic Hierarchy Process (AHP) and the quantitative datasets were compared 54 times in total using evaluation metrics. The purpose of these comparisons was to assess the efficiency and performance of the AHP approach in comparison to the quantitative data representation. 39 of these 54 comparisons revealed that the AHP technique performed better than other approaches. This indicates that, in contrast to the quantitative data technique, AHP typically produced more favorable outcomes or results.

This finding's relevance stems from the AHP approach's consistent propensity to outperform the quantitative data representation over a sizable majority of the comparisons. This series of outcomes highlights the possible advantages of applying the AHP approach to cluster or analyse the provided dataset, suggesting that it might be a more efficient and reliable method for producing valuable insights or groups.

VIII. Conclusion and Future Work

The importance of using data mining techniques to efficiently prioritise requirements in software engineering is shown by this study. It also emphasises the extraordinary excellence of the Analytic Hierarchy Process (AHP) in the context of software engineering for prioritising software requirements. Based on a detailed analysis of five clustering algorithms and three cluster assessment indices, our results consistently demonstrate that AHP outperforms traditional quantitative data representations in the majority of the 54 comparisons conducted. Furthermore, the combination of AHP with the MoSCoW needs prioritisation framework not only led to better results but also enhanced resource allocation, flexible planning, and increased stakeholder satisfaction. This study recommends using AHP, data mining techniques, and the MoSCoW framework as the suggested methodology for prospective projects.

Since the data sets were generated manually with the help of stakeholders in this research. In the future, we can use machine learning algorithms. These algorithms can be trained on historical project data to learn the underlying patterns and characteristics of similar projects. By improving the overall efficiency of requirements prioritisation techniques, this integration could pave the way for more sophisticated and context-sensitive approaches to managing software requirements.

Comparative Analysis of Telemedicine in Media Coverage Pre- and Post-COVID-19 using Unsupervised Latent Dirichlet Topic Modeling

Haewon Byeon
Department of Digital Anti-Aging Healthcare (BK21),
Medical Big Data Research Center, Inje University, Gimhae 50834, South Korea

***Abstract*—Telemedicine, driven by technology, has become a game-changer in healthcare, with the COVID-19 pandemic amplifying its significance by necessitating remote healthcare solutions. This study explores the evolution of telemedicine through news big data analysis. Our research encompassed a vast dataset from 51 media outlets (total 28,372 articles), including national and regional dailies, economic newspapers, broadcasters, and professional journals. Using LDA analysis, we delved into pre- and post-pandemic telemedicine trends comprehensively. A crucial revelation was the prominence of "medical law" in telemedicine discussions, underscoring the need for legal reforms. Keywords like "artificial intelligence" and "big data" underscored technology's pivotal role. Post-pandemic, keywords like "COVID-19," "online healthcare," and "telemedicine" surged, reflecting the pandemic's impact on remote healthcare reliance. These keywords' increased frequency highlights the pandemic's transformative influence. This study stresses addressing healthcare's legal constraints and maximizing technology's potential. To seamlessly integrate telemedicine, policy support and institutional backing are imperative. In summary, telemedicine's rise, propelled by COVID-19, signifies a healthcare paradigm shift. This study sheds light on its trajectory, emphasizing legal reforms, tech innovation, and pandemic-induced changes. The post-pandemic era must prioritize informed policy decisions for telemedicine's effective and accessible implementation.**

***Keywords*—Telemedicine; COVID-19; medical law; healthcare transformation; LDA topic modeling**

I. Introduction

One important factor that is rapidly evolving in the modern healthcare environment is the increase in telemedicine services. This is achieved through the combination of advancements in information technology and innovative approaches in the medical field, providing patients with more effective and convenient healthcare services. Particularly, the importance of telemedicine has been further emphasized after the outbreak of COVID-19 in early 2020.

The COVID-19 pandemic has placed a significant burden on the global healthcare system. With the increase in patients and limitations in healthcare personnel, traditional methods of healthcare service delivery have faced constraints. As an alternative, telemedicine has gained prominence, offering patients the opportunity to safely receive medical consultations from their homes. This transformation has become a significant catalyst for revolutionizing the healthcare system, especially as the COVID-19 pandemic has brought about revolutionary changes in the medical field worldwide. Patients can now consult with doctors through computers or smartphones within the comforts of their own homes. In response to these changes, healthcare institutions have strengthened their telemedicine systems and strived to introduce new technologies to provide the best possible healthcare services to patients.

Extensive research has been conducted on telemedicine in the last decade [1-4]. However, these studies predominantly focus on specific geographical regions or timeframes, resulting in a constrained understanding of telemedicine trends pre- and post-COVID-19 pandemic. Moreover, the reliance on survey-based methodologies in these studies introduces potential biases due to subjective responses and recall inaccuracies. To address these shortcomings and enhance the accuracy of findings, leveraging big data from news sources for unsupervised topic modeling emerges as a promising alternative. This method offers an objective and expansive analysis of telemedicine's evolution and its perception in media discourse across different temporal contexts.

Unsupervised topic modeling has been extensively applied in research utilizing text data, such as identifying industrial accident-related issues using website text data [5], discerning attitudes towards vaccines via Twitter [6], exploring topics on climate change through news articles [7], and investigating topics related to the Omicron variant [8]. With the increasing prevalence of such studies, the efficacy of unsupervised topic modeling applied to news articles has been substantiated [9, 10].

An examination of telemedicine trends pre- and post-COVID-19 constitutes a critical area of inquiry within contemporary healthcare research. Such comparative analyses are instrumental in elucidating the evolution and emerging patterns in telemedicine, thereby offering valuable insights for the enhancement of future healthcare systems and the optimization of patient services.

The organization of this study is as follows: Section II delineates the methodology for data collection and the implementation of Latent Dirichlet Allocation (LDA) modeling. Section III details the outcomes of the network analysis conducted, Section IV discusses the implications of these findings. Finally, Section V concludes the paper.

II. Materials and Methods

A. Data Collection

This study utilized news articles from a total of 51 media outlets, including 10 national dailies, 8 economic dailies, 26 regional dailies, 5 broadcasting companies, and 2 professional journals, analyzed through the news big data analysis service, BIGKinds, provided by the Korea Press Foundation (see Table I). BigKinds integrates big data analytics with a database composed of news articles, offering analytical support. Since 1990, approximately 70 million news contents have been transformed into big data within this platform. Furthermore, by converting unstructured text into structured data, it provides information, making it a service capable of analyzing societal phenomena through articles.

TABLE I. Media Subject To Analysis

Category (Number)	Daily newspaper name
Professional journals (2)	Electronic Newspaper, Digital Times
Broadcasting company (5)	KBS, SBS, MBC, YTN, OBS
National daily newspaper (10)	Kyunghyang Shinmun, Chosun Ilbo, Donga Ilbo, Hankook IlboHankyoreh, JoongAng Ilbo, Kookmin Ilbo, Munhwa Ilbo, Naeil Shinmun, Segye Ilbo, Seoul Shinmun
Economic daily Newspaper (8)	Maeil Economy, Money Today, Seoul Economy, Asia Economy, Aju Economy, Financial News, Korea Economy, Herald Economy
Local daily newspaper (26)	Busan Ilbo, Chungbuk Daily, Chungcheong Daily, Chungcheong Today, Daegu Ilbo, Daejeon Ilbo, Gangwon Ilbo, Gwangju Daily, Gwangju Ilbo, Gangwon Provincial Daily, Gyeonggi Ilbo, Gyeongin Ilbo, Gyeongnam Newspaper, Gyeongnam Provincial Daily, Gyeongsang Daily,Halla DailyInternational Newspaper, Jemin Daily, Jeonbuk Ilbo, Jeonbuk Provincial Daily, Jeonnam Ilbo, Joongbu Daily, Joongbu Daily, Maeil Daily, Mudeung Ilbo, Ulsan Daily, Yeongnam Ilbo

TABLE II. Number of Articles Analysis

	Before the COVID-19 pandemic	After the COVID-19 pandemic	Total
Total number of articles	5,232	23,884	29,116
Number of excluded articles	92	652	744
Number of analysis articles	5,140	23,232	28,372

To investigate the trends in remote healthcare before and after the COVID-19 pandemic, keywords such as telemedicine, remote medical treatment, and non-face-to-face medical care were searched and analyzed. The collected articles were divided into two periods: pre-COVID-19 pandemic period, from January 1, 2016 to November 30, 2019, and post-COVID-19 pandemic period, from December 1, 2019 to the endemic declaration date on May 5, 2023. After excluding duplicate and irrelevant news articles, a total of 5,140 and 23,232 articles were analyzed for the two respective periods (see Table II).

B. Analysis Method

Firstly, frequency analysis was conducted to investigate the occurrence of words based on the collected text data of news articles, followed by the analysis of word weights using TF-IDF. TF-IDF is the most commonly used weighting algorithm and is widely used in keyword extraction and topic classification [11]. LDA topic modeling is an algorithm that is useful for extracting latent topics from big data consisting of text [12]. LDA (Latent Dirichlet Allocation) is one of the most common topic modeling methods, contributing to the extraction of coherent topics from data [13]. The fundamental concept of LDA is to represent the latent topics in a document composed of text data as a random mixture, wherein topics are characterized by the distribution of words [14]. A diagram of the procedure for this study is presented in Fig. 1. All analyses conducted in this study were performed using Python.

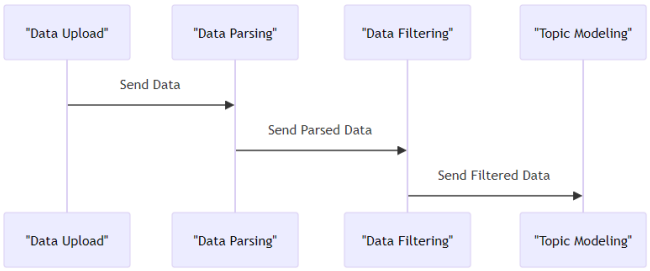

Fig. 1. Flowchart of the research procedure.

C. Network Analysis

Fig. 2 present the results of a keyword network analysis conducted on keywords related to telemedicine. The network analysis depicts the interconnectedness between words using noun phrases extracted through Structured SVM from the top 100 articles with high accuracy.

Fig. 2 represents the pre-pandemic network, with weights ranging from 6 to 58. The keyword analysis revealed that medical law exhibited the strongest association. This suggests that telemedicine is currently considered illegal under existing medical laws, and therefore, it is speculated that the revision of medical laws is crucial for the implementation of telemedicine. Additionally, keywords such as Ministry of Health and Welfare, United States, China, and Japan emerged as related keywords for similar reasons.

Fig. 3 illustrates the network configuration in the post-pandemic context, characterized by varying connection weights that range between 8 and 71. The keyword analysis revealed similarities to the pre-pandemic network, with the addition of keywords related to COVID-19, National Security Council, and Deputy Chief of Policy Committee. This difference can be attributed to the temporary rise in the importance of telemedicine due to the enabling of remote medical services during the COVID-19 pandemic.

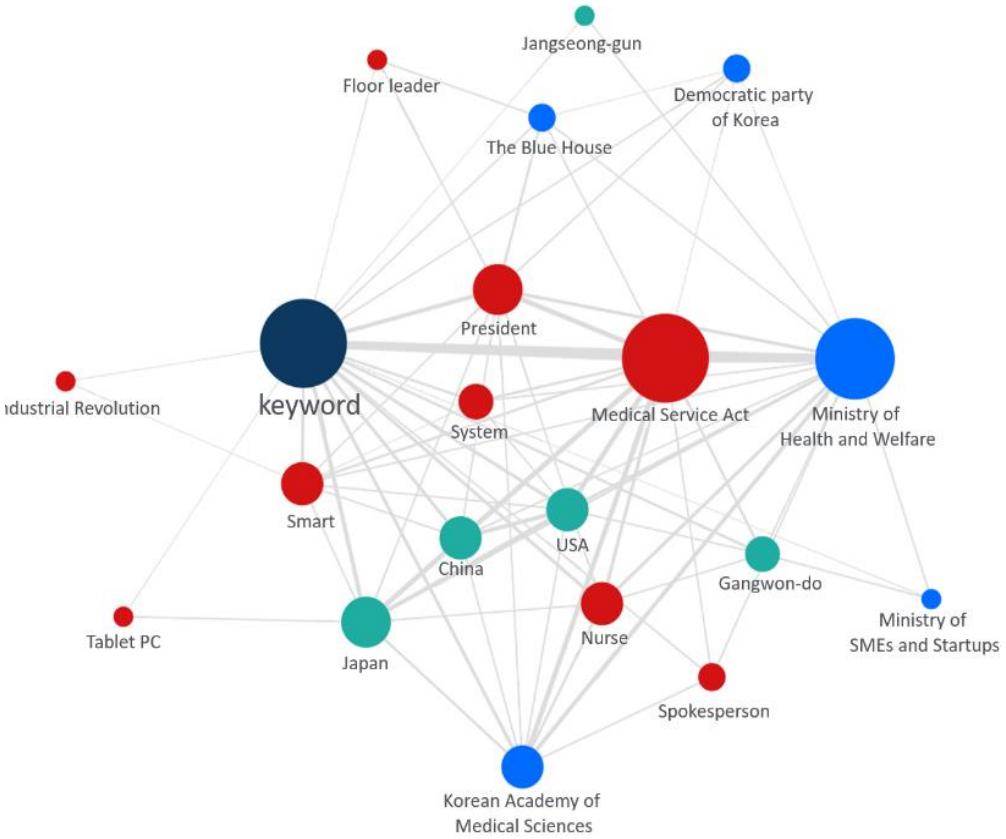

Fig. 2. Analysis of the relationship between keywords related to telemedicine: A comparative study before the COVID-19 pandemic.

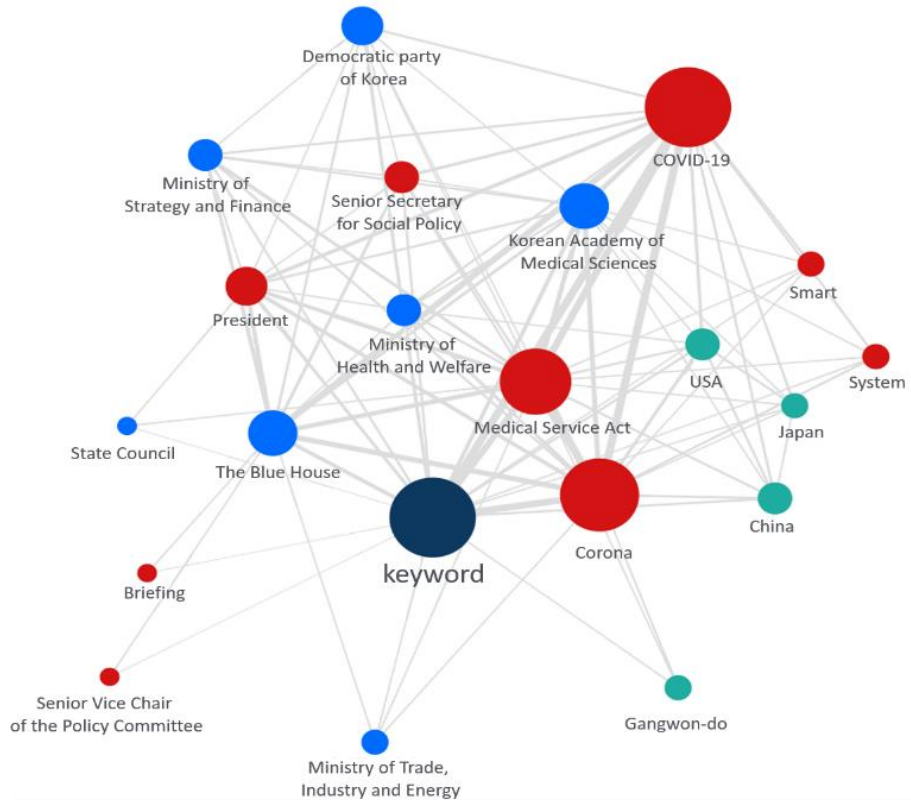

Fig. 3. Analysis of the relationship between keywords related to telemedicine: A comparative study after the COVID-19 pandemic.

III. Results

A. Frequency Analysis Result

Table III presents the frequency analysis of relevant keywords before and after the COVID-19 pandemic. The results show that after the pandemic, additional keywords related to COVID-19, online, and telemedicine were identified.

B. LDA Topic Modeling

Fig. 4 illustrates the results of calculating coherence scores using Gensim, a Python package. Gensim is a tool for topic modeling, analyzing the interrelationships between words to reinterpret the content of documents in a new and profound meaning. Additionally, by simplifying the representation of documents, it is utilized to enhance the efficiency of information processing [15]. The number of topics is determined based on the coherence scores, resulting in three topics before the occurrence of COVID-19 and seven topics after. The optimal number of topics is determined by the highest coherence score.

TABLE III. Top 15 Keywords Before and After the COVID-19 Pandemic

Before the COVID-19 pandemic			After the COVID-19 pandemic		
Word	Frequency	TF-IDF	Word	Frequency	TF-IDF
Telemedicine	1550	1857.13745	COVID-19	11943	7945.69675
Korea	1230	1757.94827	The coronavirus	4257	7222.98417
United States	950	1602.92958	Online	3643	6748.47047
Telemedicine	781	1470.58678	Confirmed case	2981	6119.80347
China	750	1442.55203	Face-to-face	2893	6025.80369
Job	748	1440.69989	United States	2757	5875.23554
Korea	564	1245.3022	Seoul	2391	5435.70132
Japan	482	1139.8296	Korea	2377	5417.82679
Seoul	448	1092.12789	Remote Healthcare	1850	4680.13852
Medical Law	432	1068.79851	Infectious disease	1849	4678.6079
Big Data	429	1064.35893	AI	1659	4377.62493
A pilot project	399	1018.78418	Medical staff	1632	4333.1425
Cheong Wa Dae	383	993.565504	Start-up	1579	4244.51904
Smartphone	365	964.393884	Coronavirus	1526	4154.11628
Competitiveness	347	934.33424	Job	1480	4074.16339

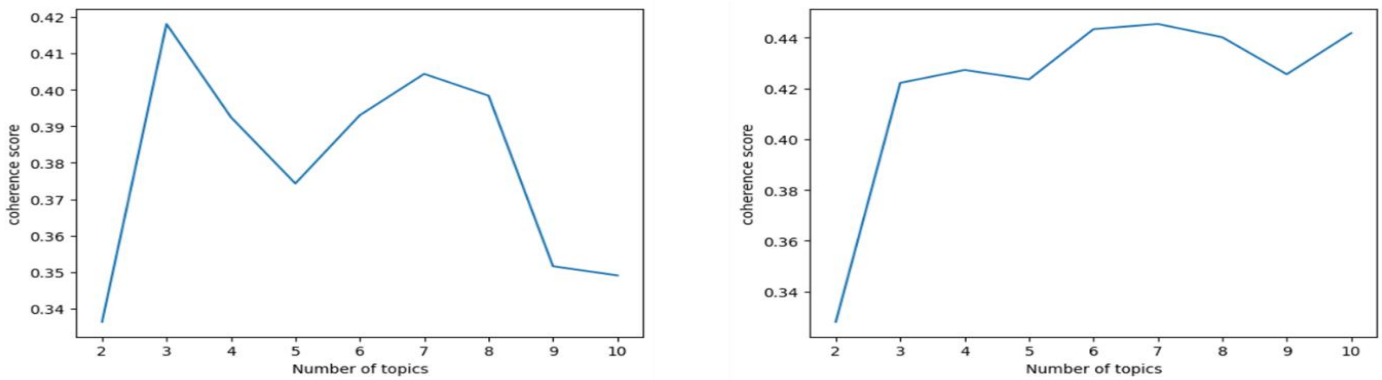

Fig. 4. Coherence scores before and after the COVID-19 pandemic.

The results of topic modeling before and after the COVID-19 pandemic are presented in Table IV and Table V. Since the topic weights were low in the 6th word of each topic, the top 5 words for each topic are provided. Before the COVID-19 pandemic, topics related to remote healthcare and technology (Topic 1), global remote healthcare (Topic 2), and remote healthcare and medical law (Topic 3) were identified, focusing on the definition and technological aspects of remote healthcare, global implementation of remote healthcare, and policy and technological considerations in the adoption of remote healthcare.

The results of topic modeling after the COVID-19 pandemic are presented in Table V. It was observed that topics related to COVID-19 emerged, given the temporary allowance of remote healthcare during the pandemic. Additionally, topics related to the definition of remote healthcare and its social

implications were identified, such as Topic 6 and Topic 7, in order to facilitate the full implementation of remote healthcare.

TABLE IV. TOPIC MODELING BEFORE THE COVID-19 PANDEMIC

Group	Topic name	Top 5 words
1	Remote healthcare and Science and Technology	Seoul, Network, Artificial Intelligence, Big Data, Deputy Prime Minister
2	Global remote healthcare	Korea, United States, China, jobs
3	Remote healthcare and medical law	Remote healthcare, medical law, pilot projects, telemedicine, Ministry of Health and Welfare

TABLE V. TOPICS MODELING AFTER THE COVID-19 PANDEMIC

Group	Topic name	Top 5 words
1	Temporary introduction	Remote healthcare, Telemedicine, Temporary, Medical, Medical law
2	Position on remote healthcare	Medical circles, medical associations, Korean Medical Association, collusion, Cheong Wa Dae
3	COVID-19 and remote healthcare	Confirmed cases, Health centers, Medical institutions, Respiratory tract, Patients with diseases
4	COVID-19 and remote healthcare in major countries	Korea, United States, online, China, COVID-19
5	COVID-19 and home treatment	COVID-19, Seoul, Online, Coronavirus, Confirmed Cases
6	Remote healthcare and Science and Technology	AI, Artificial intelligence, Untact, Big data, Cloud
7	Social Effects of remote healthcare	New Deal, Jobs, Korean Version, COVID-19, Infectious Diseases

IV. DISCUSSION

In this study, we analyzed keywords related to telemedicine and visualized the relationships between them in a network format. Through this, we were able to explore the trends and implications for the adoption of telemedicine before and after the COVID-19 pandemic. Particularly, we found that the keyword "medical law" had the highest centrality in both networks. This indicates that telemedicine is currently constrained by medical laws and suggests the need for policy discussions to improve this situation [15,16]. Additionally, keywords such as "Ministry of Health and Welfare," "United States," "China," and "Japan" appeared frequently in both networks for similar reasons, indicating significant discussions regarding telemedicine in each country [17-20]. In summary, this study confirms the importance of the legality of medical laws for the expansion and development of telemedicine.

In this study, we also observed that various forms of medical technology and artificial intelligence are closely linked with the activation of telemedicine. Keywords such as "Seoul," "network," "artificial intelligence," "big data," and "Deputy Prime Minister" were connected in the network. These connections indicate a strong association between telemedicine and scientific technology and emphasize the importance of technology in the future of the medical field [21, 22].

Frequency analysis revealed that after the COVID-19 pandemic, not only keywords related to COVID-19 but also keywords related to online, non-face-to-face, and remote consultations increased. This indicates an increased need for telemedicine due to the COVID-19 pandemic. Moreover, these keywords carry higher weights compared to before, highlighting the impact of COVID-19 on the medical and health sectors [23, 24].

Furthermore, through LDA topic modeling, we identified three topics before the COVID-19 pandemic and seven topics after. This revealed various subjects such as telemedicine and scientific technology, global telemedicine, and telemedicine and medical laws. This diversity demonstrates the rapid activation of telemedicine and the ongoing discussions and research from various aspects [25, 26].

In synthesizing these findings, it becomes evident that the COVID-19 pandemic has amplified awareness and underscored the necessity of telemedicine. Nevertheless, legal constraints within the medical field persist, necessitating future discourse and policy development to rectify these issues. Moreover, comprehensive research exploring the social impacts and equity of telemedicine from multifaceted perspectives remains a critical need.

V. CONCLUSION

This study has established the role of the COVID-19 pandemic as an accelerating force in the transformation of the telemedicine sector, highlighting the importance of adaptive medical regulations and the application of advanced scientific technology, with our big data analysis emphasizing the growing necessity of telemedicine and the essential nature of structured policies for its effective deployment. Future research should build on this groundwork by integrating an expanded range of big data sources, such as social media, healthcare forums, and patient surveys, while implementing longitudinal studies to thoroughly characterize the long-term sustainability and patterns of telemedicine utilization.

Further investigations are warranted to probe the public's acceptance of telemedicine and its incorporation into health systems, necessitating the application of sophisticated opinion analysis methods—including sentiment analysis—and the execution of comparative international studies. Such exploratory research is necessary to delineate strategies that are sensitive to cross-cultural differences and capable of adjusting to the evolving healthcare demands informed by global technological trends and shifting societal expectations in the aftermath of the pandemic.

***Abstract*—There are problems such as low scalability and low convergence accuracy in the economic dispatch of smart grids. To address these situations, this study considers various constraints such as supply-demand balance constraints, climb constraints, and capacity constraints based on the unified consensus algorithm of multi-agent systems. By using Lagrange duality theory and internal penalty function method, the optimization of smart grid economic dispatch is transformed into an unconstrained optimization problem, and a distributed second-order consistency algorithm is proposed to solve the model problem. IEEE6 bus system testing showed that the generator cost of the distributed second-order consistency algorithm in the first, second, and third time periods was 2.2475 million yuan, 5.8236 million yuan, and 3.7932 million yuan, respectively. Compared to the first-order consistency algorithm, the generator cost during the corresponding time period has increased by 10.23%, 11.36%, and 13.36%. The actual total output has reached supply-demand balance in a short period of time with the changes in renewable energy, while maintaining supply-demand balance during the scheduling process. The actual total output during low, peak, and off peak periods was 99MW, 147MW, and 120MW, respectively. This study uses distributed second-order consistency algorithm to solve the economic dispatch model of smart grid to achieve higher convergence accuracy and speed. The study is limited by the assumption that the cost functions of each power generation unit are quadratic convex cost functions under ideal conditions. This economic dispatch model may not accurately reflect practical applications.**

***Keywords*—Distributed consistency algorithm; convex optimization; economic dispatch; smart grid**

I. Introduction

In the context of rapid climate change and the crisis of non-renewable energy, traditional power grids have faced enormous challenges, such as low stability, strong concentration, and poor coordination of the power system. Therefore, the development of smart grids is urgent, and their advantages are as follows: they can achieve bidirectional flow of electricity and information, are suitable for different types of storage facilities and power generation equipment, and can automatically detect and repair system faults. Under the goal of ensuring stability, economy, and sustainability, smart grids are developing towards a more environmentally friendly, economical, safe, and efficient direction. The economic dispatch of smart grids (EDoSG) is a process that considers multiple constraints to ensure the overall stability, safety, and economic operation of the system. Its essence is a multi-objective optimization problem. Studying EDoSG under the dual carbon target has positive significance [1-3]. With the complexity of smart grid network structure and the increase in grid scale, EDoSG has encountered significant obstacles. For example, in practical situations, factors such as energy storage devices (ESD) and renewable energy are complex and variable, and the accuracy of model solving algorithms is low. Centralized power grid economic dispatch has poor scalability, low flexibility, and low robustness, while distributed economic dispatch (DED) can achieve plug and play of power sources, avoiding the drawbacks of the former [4-5]. At the same time, the consistency theory of multi-agent systems (MAS) has been recognized by economic dispatch researchers due to its own characteristics [6-7]. In response to various constraints such as supply-demand balance (SDB) constraints, climb constraints, and capacity constraints in EDoSG optimization problems, this study will transform the optimization problem into an unconstrained optimization problem through Lagrange duality theory (LDT) and internal penalty function method (IPFM). Additionally, it combines with the consistency algorithm to design a distributed second-order consistency algorithm (D2OCA), aiming to improve the operational accuracy and convergence effect of the solving algorithm, and thereby reduce the cost of smart grids. As one of the fundamental issues in the operation of smart grids, the economic dispatch problem of smart grids is studied. A more practical smart grid economic dispatch model is considered for distributed dispatch analysis. Intelligent economic dispatch with energy storage devices and renewable energy under complex constraint conditions has outstanding advantages in practical applications. The advantages of the research are as follows: Based on the D2OCA, a consistency algorithm that can be used to solve economic scheduling problems considering generators, energy storage units (ESU), and renewable energy is proposed. The convergence performance of the proposed algorithm is verified through simulation comparison with traditional consistency algorithms. The constructed economic dispatch model achieves collaborative optimization by exchanging information with adjacent units and making autonomous decisions to adjust its own output in the communication network. The technology proposed in the study can always meet the SDB constraints

and the capacity constraints of each power generation unit during the scheduling process, and can converge to the optimal solution in a relatively fast time. This scheduling method has advantages such as strong scalability, information confidentiality and security, and robustness. It is of great significance in the fields of smart grid economy, stability, and safe operation. This study elaborates on the content from the following four sections. Section I analyzes the current situation of centralized EDoSG and smart grid DED both domestically and internationally. Section II focuses on the first-order consistency algorithm (1OCA) and D2OCA in EDoSG problems. Section III analyzes the convergence performance and accuracy of D2OCA. Section IV summarizes the research results and elaborates on the limitations and shortcomings of the study.

II. Related Works

Against the backdrop of the continuous development of new energy technologies, scholars in the field of smart grids have conducted extensive research on economic low-carbon scheduling. Guo R et al. established a stepped carbon trading model with different carbon emission ranges corresponding to different carbon trading prices. The goal of this model was to minimize the sum of power generation costs and carbon emissions, while considering safety constraints. Case studies have shown that analyzing the tiered carbon trading mechanism (TCTM) has great advantages in guiding the operation of low-carbon economy (LCE) in the system, providing necessary support for the LCE operation of smart grids [8]. Cui D's teams have proposed a peak shaving and valley filling model to regulate the LCE clean power system. It could preliminarily achieve LCE scheduling of integrated energy systems [9]. Scholars such as Zhu X have established an LCE scheduling model under TCTM, focusing on electrical and thermal integrated energy systems. Through comparative analysis of multiple scenarios, the proposed technology improved the economic benefits of the system by consuming wind power, thereby reducing the cost of the power grid [10]. Fu Y and researchers proposed a DED scheme that combines consensus theory and deep strong zeroing learning theory to solve the problems of low security and scheduling effectiveness of centralized algorithms in the optimization scheduling of smart grids. This scheme used Adam algorithm and consistency algorithm to obtain the optimal economic scheduling of unit output. This scheme was suitable for smart grids with complex network structures and could handle economic dispatch problems with large-scale data, reducing the impact of the objective function on economic dispatch results [11].

Ayalew F et al. summarized relevant literature reports on existing economic dispatch problems in smart grids, including economic dispatch, centralized and distributed algorithms, demand side management, etc. [12]. Ismi et al. analyzed the economic dispatch problem under assumed uncertainty and solved it through centralized methods under load or energy changes to maintain the stability of the power system [13]. Wang et al. proposed an economic scheduling algorithm for parallel computing in distributed power nodes, which has higher convergence performance compared to centralized methods [14]. Sadouni H et al. analyzed the current research status of smart grid DED problems, including efficient uninitialized processes, distributed power generation systems with practical constraints, and safety [15]. Liu H et al. proposed a finite time DED model suitable for smart grids. The simulation results obtained through DED algorithm had high robustness in time-varying communication networks [16]. Table I refers to the limitations of the relevant research work.

TABLE I. Limitations of Related Research Work

Reference	Achievement	Limit
Guo R [8]	Established a tiered carbon trading model with different carbon emission ranges corresponding to different carbon trading prices	Only considering carbon constraints and emissions
Cui D [9]	Proposed a peak shaving and valley filling model to regulate the economic, low-carbon, and clean power system	The applicability of scheduling models is limited
Zhu X [10]	Established a low-carbon economic dispatch model under a TCTM	Mainly aimed at minimizing economic operating costs
Fu Y [11]	Obtained the optimal economic dispatch of unit output through Adam algorithm and consistency algorithm	DED not considered
Ayalew F [12]	Analyzed relevant literature on existing economic dispatch problems, including economic dispatch, centralized and distributed algorithms, demand side management, etc.	No mention of D2OCA
Ismi [13]	Solved economic dispatch under load or energy changes through centralized methods	There are too many assumptions in the model
Wang S [14]	Proposed an economic scheduling algorithm for parallel computing in distributed power generation nodes, which has high convergence performance	But compared to the latest scheduling algorithms, the convergence performance is average
Sadouni H [15]	Analyzed the current situation of distributed power generation systems	Failure to analyze the algorithm for solving the DED model of the smart grid
Liu H [16]	Distributed economic scheduling algorithms have extremely high robustness in time-varying communication networks	Model solving without considering consistency algorithms

Based on the current situation of centralized smart grid and DED, current consistency algorithms have a positive role in EDoSG optimization problems, but EDoSG also has prominent problems. In economic dispatch, few scholars analyze energy storage equipment, renewable energy, and power generation constraints. Based on this, this study proposes D2OCA to achieve EDoSG on the basis of multi-agent consensus algorithms, providing new development directions for the sustainable development of smart grids.

III. EDoSG Model of D2OCA

The goal of EDoSG is to find the optimal power generation with the minimum economic cost while ensuring that the system constraints are met. The economic scheduling method commonly used in the past for generator scheduling was centralized, but the optimal scheduling solution obtained from this method cannot meet the real-time requirements of distributed power consumption and power outage. DED has

advantages such as simple protocol, strong scalability, and low complexity, which can achieve safe and stable economic operation of smart grids. The study examines different limitations, including SDB and climb constraints. Using the unified consensus algorithm of multiple intelligent systems, it transforms the optimization problem of smart grid economic dispatch into an unconstrained optimization problem through LDT, IPFM, and the alternating direction multiplier method (ADMM). At the same time, a D2OCA is proposed to solve the optimization model problem of smart grid economic dispatch.

A. EDoSG and Multi-Intelligent 1OCA

The research content of DED problem in smart grid is to maximize the economic effect of power generation under the constraint of power generation unit, that is, to find the optimal power generation required at the lowest cost. The research on DED problems can be divided into three parts: problem modeling, algorithm design, algorithm analysis, and validation [17-18]. Problem modeling is a convex optimization problem, but it involves constraints such as SDB and capacity constraints in economic scheduling problems. Therefore, this study utilizes IPFM to remove capacity constraints, while utilizing LDT to address SDB constraints and climb constraints. If the set is a convex set, then all points on the line connecting any two points x_1 and x_2 in set $C \in R^n$ are in set C, then it can be considered a convex set, that is, Eq. (1).

$$\beta x_1 + (1-\beta) x_2 \in C \quad (1)$$

In Eq. (1), β refers to any real number within 0-1, and the convex function (CF) f of C on the convex set must satisfy Eq. (2).

$$f\left(\beta x_1 + (1-\beta) x_2\right) \le \beta f\left(x_1\right) + (1-\beta) f\left(x_2\right) \quad (2)$$

When the coordinates of points x_1 and x_2 are the same. Eq. (2) takes equal sign. At this point, f is a strictly CF on the convex set C. The optimization problem with constraints can be referred to by Eq. (3).

$$\min_x f(x) \quad s.t. g_i(x) \le 0, h_j(x) \le 0 \quad (3)$$

In Eq. (3), $f(x)$ and $g_i(x)$ are different CFs, $h_j(x)$ is an affine function, $i = 1, \cdots, n$, $m = 1, \cdots, m$, $j = 1, \cdots, j$. Fig. 1(a) is a schematic diagram of a CF.

The methods for solving convex optimization problems include Newton's method, Lagrangian dual function method, IPFM, etc. The solving principle of IPFM is shown in Fig. 1 (b). IPFM converts constraint conditions into obstacle terms that constrain the objective, and the iteration point needs to be far away from the boundary of the feasible domain to find the optimal solution. When the iteration point approaches the boundary of the feasible domain, the value of the obstacle term tends to infinity. The augmented objective function $L(x, \gamma)$ constructed by this method is represented by Eq. (4).

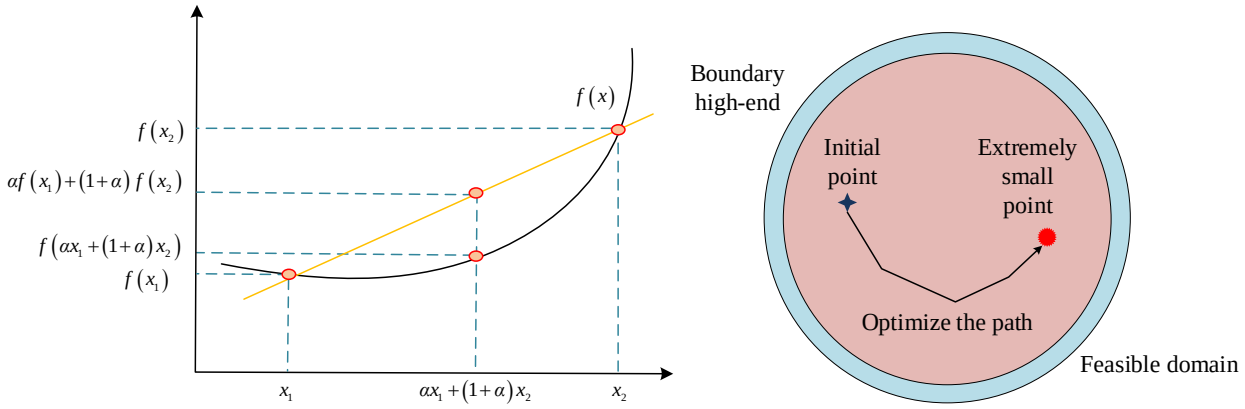
$$L(x, \gamma) = f(x) + \gamma b(x) \quad (4)$$

In Eq. (4), the penalty factor is γ. To reduce the impact of this parameter on the function value, it is defined as a first-order jump function, and the value increases with time. The obstacle function is $b(x)$, characterized by continuous numerical values within the feasible domain. If the constraint conditions are met, its numerical value is a finite positive number. LDT is suitable for raw optimization problems that are difficult to handle. A generalized Lagrangian function based on Eq. (3) is built and the Eq. (5) is used to refer to it.

$$L(x, a, b) = f(x) + \sum_{i=1}^{n} a_i g_i(x) + \sum_{j=1}^{m} b_j h_j(x) \quad (5)$$

In Eq. (5), the Lagrange multiplier is represented by b, and the dual variable is a. The dual problem of the original problem can be represented by Eq. (6).

$$\max_{a,b,a_i \ge 0} L_D(a, b) = \max_{a,b,a_i \ge 0} \min_x L(x, a, b) \quad (6)$$



(a) Schematic diagram of convex functions

(b) The Principle of Solving Internal Penalty Function Method

Fig. 1. The schematic diagram of CFs and the principle of solving IPFM.

In Eq. (6), $D=\{x\in R^n : k_i(x)\geq 0\}$ refers to the feasible region and $k_i(x)$ refers to the boundary function of the feasible region. The optimal solutions for the original problem and the dual problem are p^* and d^*, respectively, as shown in Eq. (7).

$$d^* = \max_{a,b,a_i\geq 0}\min_{x} L(x,a,b) \leq \min_{x}\max_{a,b,a_i\geq 0} L(x,a,b) = p^* \quad (7)$$

The ADMM, as an extension of augmented Lagrangian, is a framework for solving large-scale data in machine learning. It can transform large-scale image problems into relatively simple local sub-problems, and obtain global solutions by calculating the solutions of local sub-problems. ADMM solves constrained local problems by introducing auxiliary variables, decomposing the objective function containing the original problem into multiple easily solvable local sub-problems. ADMM is related to iterative algorithms such as splitting, multiplier methods, and dual decomposition methods, and is very suitable for solving distributed convex optimization problems. On the basis of augmenting the Lagrangian function, ADMM has multiple advantages in simplicity, efficiency, and convex optimization solving. It can solve the minimization problem with equality constraints on two variables and the objective function, as shown in Eq. (8).

$$\min_{x,z} \; f(x)+g(z) \quad s.t. Wx+Bz=c \quad (8)$$

In Eq. (8), x, z, and c refer to vectors, W, and B matrices. x and z are the optimization variables for the demand solution. $f(x)+g(z)$ refers to minimizing the objective function, which can be composed of the function of variable x and z. They can handle regularization terms in optimization objectives of statistical learning problems, consisting of equality constraints. The specific process of minimizing iterative solutions and updates is as follows. Combining the linear part with the quadratic term yields a concise scaling form, with the specific iteration process as follows. One is to calculate and minimize related problems, and solve variables. The second is the calculation and related minimization problem. The third is to update the dual variables until the algorithm reaches the convergence condition. The multiplier method in ADMM refers to the dual ascent method of augmented Lagrangian functions, while the alternating direction refers to the alternating updates between the original variable and the dual variable. Fig. 2 is a schematic diagram of ADMM.

B. EDoSG Combined with D2OCA

The EDoSG problem considers ESDs, renewable energy, and generators, due to differences in ideal models and power generation equipment. Therefore, the generator set needs to consider capacity constraints, climb constraints, and SDB on both sides, and based on this, construct D2OCA to solve the EDoSG problem. The MAS is a system that places individual agents to achieve overall optimization goals. According to different control strategies, MASs can be divided into three structural systems: hybrid, distributed, and centralized [19-20]. Fig. 3 is a diagram of a distributed system.

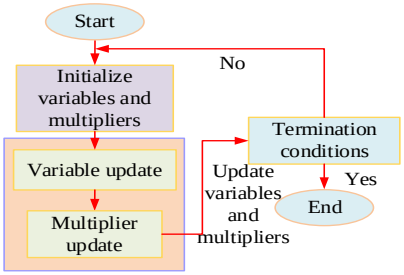


Fig. 2. Schematic diagram of alternating direction multiplier method.

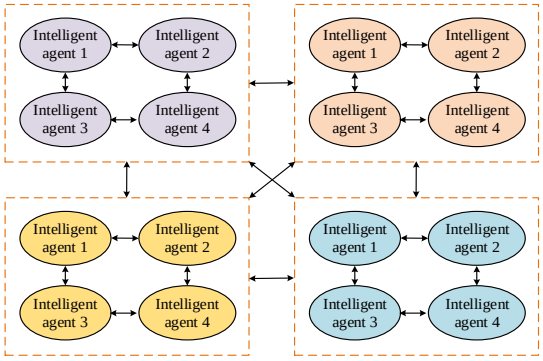

Fig. 3. Schematic diagram of a distributed system.

In a distributed architecture system, the task of each agent is to collect local information, exchange and update information with neighboring agents, with the aim of achieving task objectives. The consistency problem of MASs has been applied in EDoSG and state estimation of power networks, which can be described through graph theory. The communication topology relationships of various generator units in EDoSG can be represented through graph theory. Fig. 4(a) and 4(b) are directed and undirected graphs, respectively. The difference between the two graphs is that directed graphs have directions, while undirected graphs have no directions.

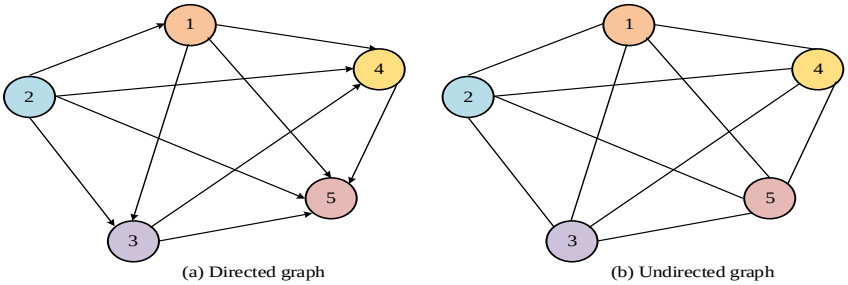

Fig. 4. Schematic diagrams of directed and undirected graphs.

The topology of multi-agent networks is represented by an undirected graph $G=(V,E,A)$. The state information of the i-th agent in a MAS at time t is $x_i(t)$. The model of a MAS with first-order continuous time is Eq. (9).

$$\dot{x}_i(t)=u_i(t) \tag{9}$$

In Eq. (9), the control input at time t is $u_i(t)$. The classic 1OCA under continuous time is expressed as Eq. (10).

$$\dot{x}_i(t)=u_i(t)=\sum_{j=1}^{n}a_{ij}\left(x_j(t)-x_i(t)\right) \tag{10}$$

The matrix form of Eq. (10) indicates that the states of each agent gradually reach homogeneity, i.e. $x_j(t)-x_i(t)\to 0$. The first-order consistent dynamic model of MASs in discrete-time is Eq. (11).

$$x_i(k+1)=x_i(k)+u_i(k) \tag{11}$$

The distributed consistency algorithm achieves the same value of state variables through a consistency mechanism, including average consistency, arithmetic consistency, geometric consistency, and harmonic consistency. The daily economic dispatch period can be divided into flat peak, low valley, and peak. The total demand during the corresponding time period is 128MW, 96MW, and 148MW, respectively. The total output of ESU and renewable energy is 20MW, 10MW, and 13MW, respectively. Eq. (12) is the mathematical expression for the EDoSG problem.

$$\begin{cases}\min\sum_{h=1}^{H}\sum_{i=1}^{N}\left(f_{i.h}\left(P_{i,h}\right)+g_{i,h}\left(S_{i,h}\right)\right)\\ \sum_{i=1}^{N}\left(P_{i,h}+R_{i,h}+S_{i,h}\right)=D_h\\ -P_i^R\le P_{i,h}-P_{i,h-1}\le P_i^R\\ P_i^m\le P_{i,h}\le P_i^M\\ S_i^m\le S_{i,h}\le S_i^M\end{cases} \tag{12}$$

In Eq. (12), the different time periods in the daily schedule are $h=[1,2,\cdots,H]$. The output power of the i-th generator during time period h is $P_{i,h}$. The output power of the i-th ESU is $S_{i,h}$. The output power of the i-th renewable power generation unit is $R_{i,h}$. The expected electricity demand during time period h is D_h. The ramp rate limit for the i-th generator is P_i^R. The min-output and max-output of the i-th generator are P_i^m and P_i^M, respectively. The min-output and max-output of the i-th ESU are S_i^m and S_i^M, respectively. The cost functions for the i-th ESD and the i-th generator during time period h are $g_{i,h}\left(S_{i,h}\right)$ and $f_{i.h}\left(P_{i,h}\right)$, respectively, and the calculation formula is Eq. (13).

$$\begin{cases}f_{i.h}\left(P_{i,h}\right)=a1_{i,h}P_{i,h}^2+a2_{i,h}P_{i,h}+a3_{i,h}\\ g_{i,h}\left(S_{i,h}\right)=b1_{i,h}S_{i,h}^2+b2_{i,h}S_{i,h}+b3_{i,h}\end{cases} \tag{13}$$

In Eq. (13), the cost parameters of the generator cost function are $a1_{i,h}$, $a2_{i,h}$, and $a3_{i,h}$, and the cost parameters of the ESU cost function are $b1_{i,h}$, $b2_{i,h}$, and $b3_{i,h}$. Table II shows the cost parameters of the generator in the communication topology diagram of three nodes. Each vertex in the communication topology diagram is connected to a generator, ESD, renewable energy, $i=3$, $h=3$. The Laplace matrix can be expressed as $W=\begin{bmatrix}2&-1&-1\\-1&2&-1\\-1&-1&2\end{bmatrix}$.

TABLE II. COST PARAMETERS OF GENERATORS IN THE COMMUNICATION TOPOLOGY DIAGRAM OF THREE NODES

Alternator	$a1$	$a2$	$a3$	P^m	P^M	P^R
$P_{1,1},P_{1,2},P_{1,3}$	0.0075	-1	0	34	78	28
$P_{2,1},P_{2,2},P_{2,3}$	0.2500	-4	0	9	32	17
$P_{3,1},P_{3,2},P_{3,3}$	0.1000	2	0	17	49	18

Before solving the optimal solution, the EDoSG model needs to propose the following assumptions: the communication topology of the smart grid is connected and undirected, and the capacity constraints of the generator and ESU can be found internally. The direct solution of the EDoSG model is computationally challenging, and research is needed to transform the problem into an unconstrained optimization problem before solving it. Based on the assumptions and IPFM, the EDoSG problem can be described again using Eq. (14).

$$\begin{cases}\min\sum_{h=1}^{H}\sum_{i=1}^{N}\left(f_{i.h}^{\gamma}\left(P_{i,h}\right)+g_{i,h}^{\lambda}\left(S_{i,h}\right)\right)\\ \sum_{i=1}^{N}\left(P_{i,h}+R_{i,h}+S_{i,h}\right)=D_h\\ -P_i^R\le P_{i,h}-P_{i,h-1}\le P_i^R\end{cases} \tag{14}$$

According to LDT, the EDoSG problem can be transformed into an optimal solution of $(P^*,S^*,\mu^*,\lambda^*)$. Renewable energy has characteristics such as intermittency, volatility, and randomness, making it difficult for smart grids to control output power. To ensure the stability of the renewable energy generation grid, the smart grid is set to maintain a fixed value of renewable energy and ESUs through the output of ESUs during the time period, and the SDB can be regarded as unchanged. Based on assumptions and the expression of D2OCA, this study proposes D2OCA in the EDoSG problem. The new variables for P_i and S_i in this method are B_i and U_i, respectively, and the convergence parameters are η_P and η_S. This D2OCA has high convergence performance, which can be confirmed by the research conclusions of scholars in the supply and demand balance of smart grids. The ESU does not change with the fluctuation of renewable energy supply at the beginning of each time slot, but it can still reach the optimal solution through the convergence process within each time slot.

IV. Analysis of D2OCA Simulation Results in EDoSG

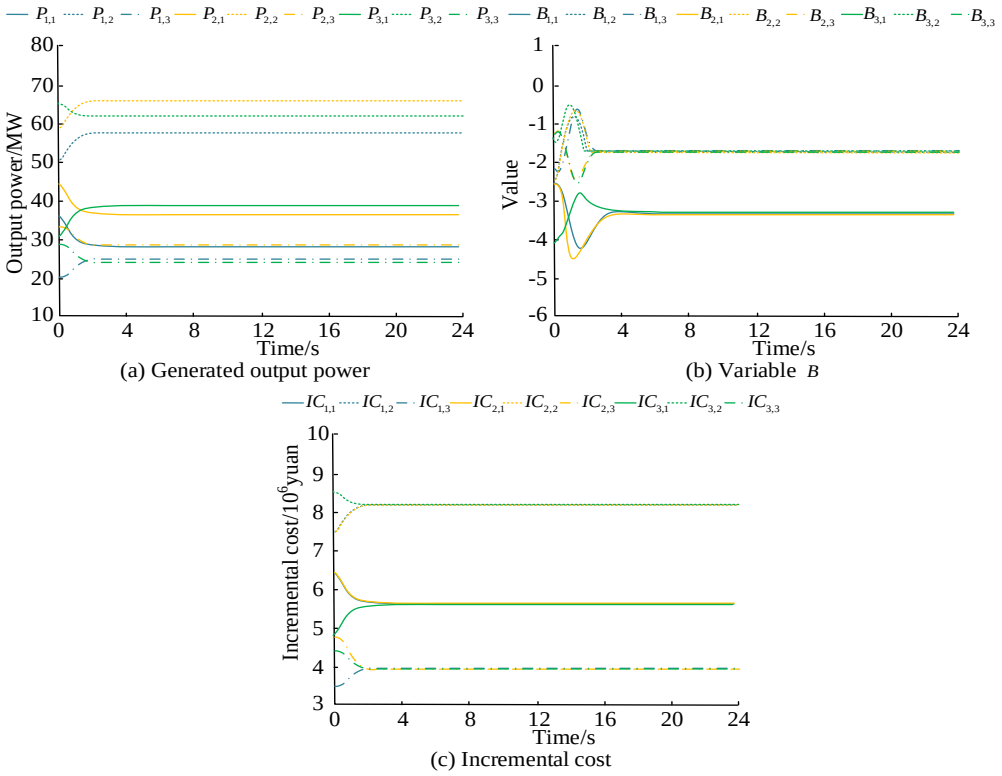
The performance of the D2OCA for smart grids is analyzed, including convergence performance and output power. The used testing system is the IEEE6 bus system, and the communication topology of the smart grid is represented by an undirected graph with three vertices. The cost function of generators and energy storage can be represented by a quadratic function. The classic economic scheduling algorithm, 1OCA, is known for its ideal convergence accuracy and speed. The D2OCA, optimized from 1OCA, is used as a comparative algorithm. Both algorithms are reasonable. The operating system is Windows 7, the storage is solid-state drives, the central processing unit is Intel Core i7, and the operating memory is 16GB. Table III shows the power generation cost parameters of the ESU. The time slot is set to 24 seconds, and the starting output power of the generator is (47, 15, 25, 72, 28, 31, 50, 23, 35) MW. The starting output power of the ESU is (5, 3, 3, 6, 3, 4, 8, 8, 4) MW. The initial values of B_i and U_i are 0, and the η_P values during low, peak, and off peak periods are 2.54, 3.95, and 2.20, respectively. The η_S value for all three time periods is 2.14, and the initial values for a and b are all 10.

This study first conducts economic dispatch simulation analysis on the output power of the generator and variable B_i. Fig. 5(a) to 5(c) show the economic dispatch results of the output power P_i, variable B_i, and incremental cost IC_i of the smart grid D2OCA. In Fig. 5(a), different generators can converge to stable values in a short period of time at different time periods. The output power of each generator during low, peak, and off peak periods is consistent with the actual electricity consumption. There are significant differences in the output power of different generators. In Fig. 5(b), the stable values of variable B_i for different generators during the same time period are the same, which are (-2.3816, -2.3715, -3.5029). In Fig. 5(c), the incremental cost of the generator gradually converges with the output power, and the incremental cost of power generation during the low, peak, and flat peak periods is consistent, with values of 6.0874, 9.4528, and 7.7068, respectively.

TABLE III. Power Generation Cost Parameters of Energy Storage Units

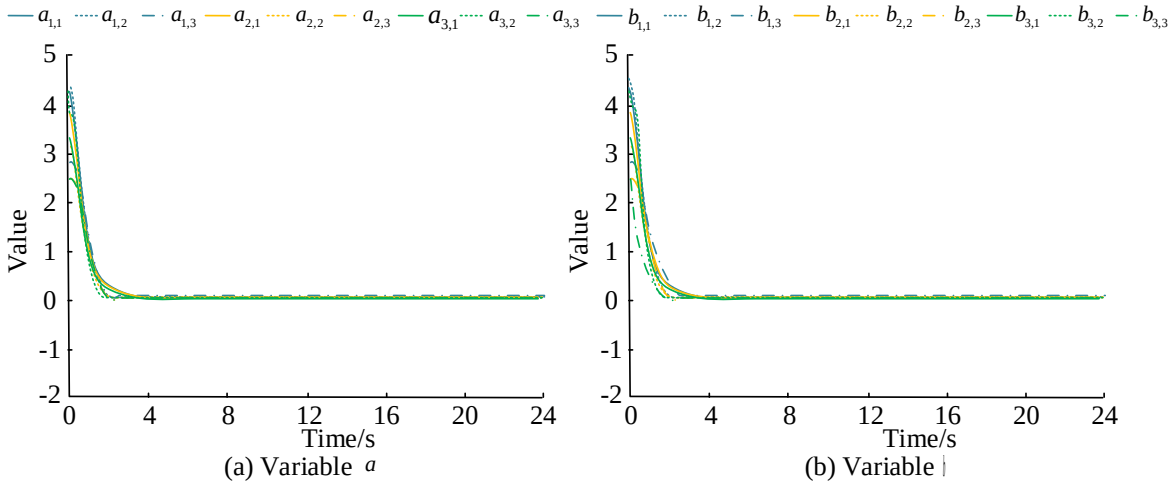
Energy storage unit	$b1$	$b2$	$b3$	S^m	S^M
$S_{1,1}, S_{1,2}, S_{1,3}$	0.7	-1	0	0	30
$S_{2,1}, S_{2,2}, S_{2,3}$	0.5	-2	0	0	20
$P_{3,1}, P_{3,2}, P_{3,3}$	0.2	1	0	0	20

Fig. 6(a) to 6(b) respectively refer to the iterative results of variables a and b. Both variables a and b converge to a value of 0 in a relatively short period of time. The convergence speed during low valley periods is moderate, the convergence speed during peak periods is the slowest, and the convergence speed during off peak periods is the fastest. Based on Fig. 5, when the two variables a and b reach convergence values, the output power of the generator gradually tends towards the optimal economic dispatch result.



(a) Generated output power (b) Variable B (c) Incremental cost

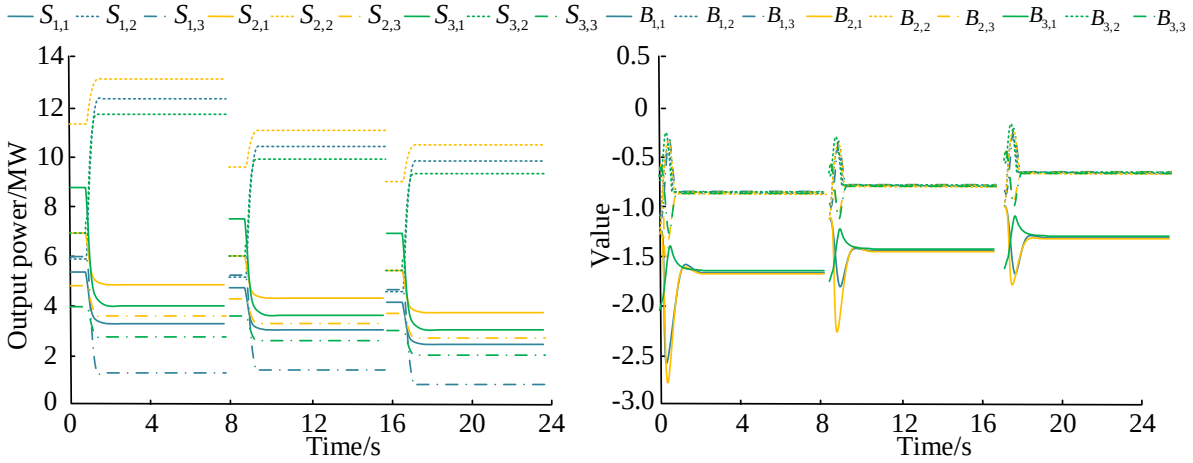
Fig. 5. Economic dispatch results of D2OCA for smart grid.



(a) Variable a (b) Variable b

Fig. 6. Iteration results of two variables.

This study then conducts economic dispatch simulation analysis on the output power and variable U_i of the ESU. Fig. 7(a) and 7(b) respectively refer to the optimal scheduling results of the output power and variables of the ESU. In Fig. 7 (a), at the beginning of each gap, the output of renewable energy leads to the output power of the ESU, and reaches the optimal value at each time slot. There is no significant variation pattern between the output power of the ESU and the electricity consumption period and the type of ESU. The optimal scheduling results for ESUs in the first time slot are (0.747, 2.0424, 5.2028, 0.8419, 2.1896, 5.9849, 1.5867, 3.2635, 10.968). In the second time slot, the optimal scheduling result of the ESU decreases, with values of (0.6279, 1.8568, 4.4679, 0.7356, 2.0356, 5.2132, 1.3758, 2.8965, 9.5689). When the time increases to the third time slot, the optimal scheduling result of the ESU is lower than that of the second gap, but the magnitude of the decrease does not show a clear pattern of change. In Fig. 7(b), the variable U_i for each time slot reaches a convergence value. As the time slot increases, the numerical value of convergence also gradually increases. In the third time slot, the convergence values of variable U_i are (0.1087, 0.1087, 0.1185, -0.1582, -0.1582, -0.1583, -0.3660, -0.3659, -0.3660).



(a) Energy storage unit output power (b) Variable B

Fig. 7. Optimal scheduling results for output power and variables of ESUs.

Fig. 8 shows the simulation results of the actual total output at different time periods. The actual total output reaches SDB in a short period of time with changes in renewable energy, while remaining in SDB during the scheduling process. The actual total output during low, peak, and off peak periods is 99MW, 147MW, and 120MW, respectively.

Finally, this study validates the results of D2OCA in EDoSG by comparing it with the classic 1OCA. Fig. 9(a) and 9(b) respectively refer to the output power and incremental cost of each generator. In Fig. 9(a), the variation pattern is similar to that in Fig. 5(a), but there are still differences, mainly reflected in the convergence speed and stable values. Different generators can converge to stable values in a short period of time at different time periods. There are certain differences between the output power and actual electricity consumption of each generator during low, peak, and off peak periods, and there are also significant differences in the output power of different generators during the same electricity

consumption period. The optimal scheduling result for output power is (46.5, 29.4, 17.4, 69.5, 28.1, 37.6, 58.0, 24.6, 28.5) MW. In Fig. 9(b), the incremental cost of the generator gradually converges with the output power, and the incremental cost of power generation during the low, peak, and flat peak periods is consistent, with values of (7.456, 9.251, 5.621).

Table IV shows the total cost of two consistency algorithms in EDoSG. Compared to 1OCA, D2OCA has better optimal scheduling results. The generator costs of D2OCA in the first, second, and third time periods are 2.2475 million yuan, 5.8236 million yuan, and 3.7932 million yuan, respectively, which increases by 10.23%, 11.36%, and 13.36% compared to the corresponding time periods of 1OCA. Therefore, the proposed D2OCA application in the EDoSG problem model solving process can reduce the total cost of the generator. Therefore, D2OCA is effective and has higher convergence accuracy and speed compared to 1OCA.

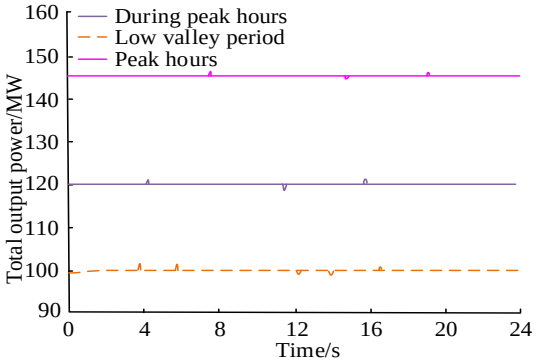


Fig. 8. Simulation results of actual total output in different time periods.

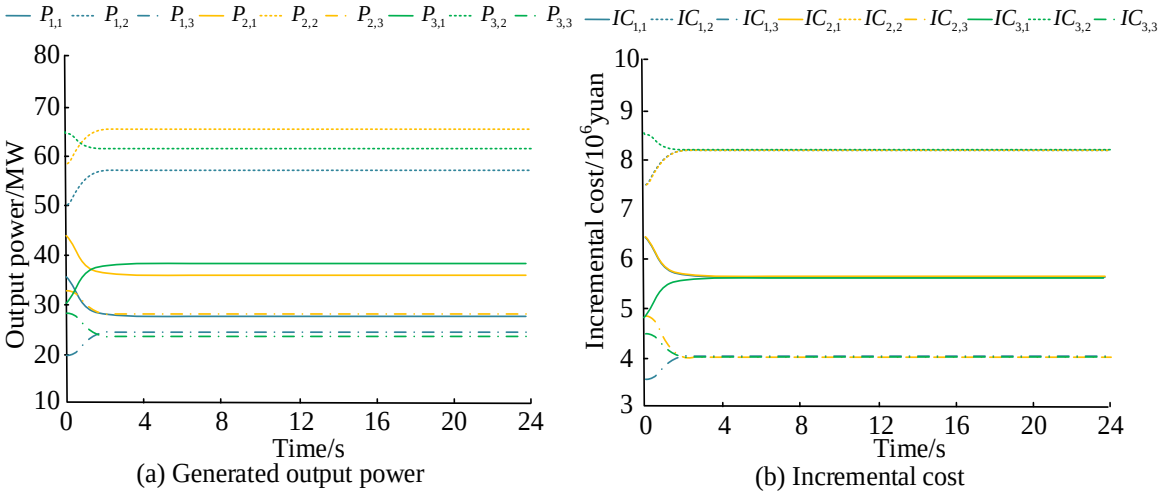

(a) Generated output power (b) Incremental cost

Fig. 9. Output power and incremental cost of each generator.

TABLE IV. THE TOTAL COST OF TWO CONSISTENCY ALGORITHMS IN SMART GRID ECONOMIC DISPATCH (106YUAN)

algorithm	varIable	Period 1	Period 2	Period 3	Total
1OCA	P_1	75.362	185.368	126.375	387.105
	P_2	76.465	176.341	119.351	372.157
	P_3	81.268	191.361	119.829	392.458
D2OCA	P_1	75.359	185.363	126.372	387.094
	P_2	76.463	176.337	119.349	372.149
	P_3	81.265	191.357	119.826	392.448

V. CONCLUSION

To achieve low-cost control of generators in EDoSG problems, this study innovatively proposed D2OCA based on the introduction of multi-agent consensus algorithms. The simulation of D2OCA showed that different generators could converge to a stable value in a short period of time at different time periods, and there were significant differences in the output power of different generators. The stable values of variable B_i for different generators during the same time period were the same, which were (-2.3816, -2.3715, -3.5029). The incremental cost of generators was consistent in the three time periods of low valley, high peak, and off peak, with a total cost of 6.0874, 9.4528, and 7.7068, respectively. Both a and b variables converged to a value of 0 in a relatively short period of time. The convergence speed during low valley periods was moderate, the convergence speed during peak periods was the slowest, and the convergence speed during off peak periods was the fastest. 1OCA could converge to a stable value in a short period of time for different generators at different time periods. There was a certain difference between the output power and actual electricity consumption of each generator during low, peak, and off peak periods. The application of D2OCA in the EDoSG problem model solving process could reduce the total cost of generators. The proposed EDoSG model still has limitations, such as the communication topology of the smart grid being connected and undirected, and the capacity constraints of the generator and ESU being able to find the optimal solution internally. The study did not take into account the charging and discharging limitations of the energy storage device. Instead, it was treated as a regular power source, which is not consistent with the actual system. Subsequent research on the economic scheduling problem of non-convex smart grids with energy

storage device charging and discharging restrictions has certain practical significance.

***Abstract*—The use of 3D Human Pose Estimation (HPE) has become increasingly popular in the field of computer vision due to its various applications in human-computer interaction, animation, surveillance, virtual reality, video interpretation, and gesture recognition. However, traditional sensor-based motion capture systems are limited by their high cost and the need for multiple cameras and physical markers. To address these limitations, cloud-based HPE tools, such as DeepMotion and MOTiON by RADiCAL, have been developed. This study presents the first scientific evaluation of MOTiON by RADiCAL, a cloud-based 3D HPE tool based on deep learning and cloud computing. The evaluation was conducted using the CMU dataset, which was filtered and cleaned for this purpose. The results were compared to the ground truth using two metrics, the Mean per Joint Error (MPJPE) and the Percentage of Correct Keypoints (PCK). The results showed an accuracy of 98 mm MPJPE and 96% PCK for most scenarios and genders. This study suggests that cloud-based HPE tools such as MOTiON by RADiCAL can be a suitable alternative to traditional sensor-based motion capture systems for simple scenarios with slow movements and little occlusion.**

***Keywords*—3D; human pose estimation; animation; evaluation; motion tracking**

I. Introduction

Due to its crucial applications in human-computer interaction, surveillance, virtual reality [36], video interpretation, gesture recognition, and many other fields, as depicted in Fig. 1, 3D human body pose estimation (3D HPE) has attracted substantial interest in computer vision. Nevertheless, despite recent advancements, motion capture (MoCap) systems still rely on costly sensor-based systems consisting of multiple-camera setups and heavy motion capture suits with physical markers that allow position estimation. A considerable number of studies have been conducted using several approaches. However, the most significant advances in that field have been made in recent years thanks to breakthroughs in deep learning and convolutional neural networks.

Recently, cloud-based 3D HPE tools, such as MOTiON by RADiCAL and DeepMotion, have become more popular for a variety of reasons, including the needless for a powerful computer since processing is done in the cloud, the intuitive graphical user interface, and the ready-to-use outputs by almost all 3D computer graphics software. These tools are generally based on deep learning techniques and offer the ability to directly convert 2D videos to 3D coordinate files through FBX motion frames in a short time. Despite the widespread adoption of those tools, scientific evaluation of their accuracy has yet to be published to determine whether they can serve as an alternative to conventional sensor-based motion capture systems.

In this research, we are especially interested in evaluating the accuracy and suitability of 3D HPE tools based on deep learning and cloud computing. We aim to address the following research questions:

- How accurate are cloud-based 3D HPE tools in estimating human poses compared to ground truth data?
- Can cloud-based 3D HPE tools serve as a feasible alternative to traditional motion capture systems in various scenarios?

Therefore, MOTiON by RADiCAL 3D HPE tool was chosen as a case study. To achieve this goal, we now go over how the CMU dataset was cleaned and filtered for use in this study. The dataset contains multiple scenarios, each of which includes a range of actions seen in videos and the resulting 3D human poses. These videos were used to obtain 3D coordinates for each human joint. For quantitative evaluation, the results were compared to the ground truth after Procrustes alignment [1]. Several metrics, including Mean per Joint Position Error (MPJPE) and Percentage of Correct Keypoints (PCK), were used to evaluate the results of each scenario and both genders. The second sort of evaluation is qualitative, in which one frame from each situation is selected and visually evaluated.

Quantitative results revealed that the MOTiON by RADiCAL tool is adequate for most scenarios and genders. However, it has several limitations, particularly for occlusion and dynamic motions. After data analysis, it is considered that these cloud-based tools could advantageously replace the expensive traditional tools for simple scenarios with slow movements and little occlusion. As for qualitative results, nine scenarios have been accurately estimated, whereas the skeleton or some of its components were misaligned in the other scenarios.

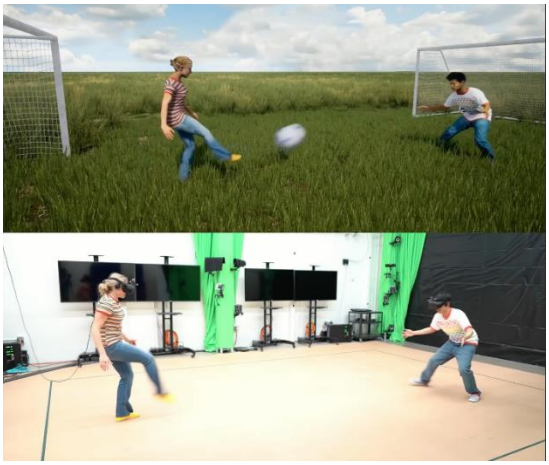

Fig. 1. Facebook's markerless body tracking for VR from a single sensor.

This study is structured to provide a comprehensive evaluation of cloud-based 3D HPE tools, with a specific focus on the MOTiON by RADiCAL system. The structure and goals of this research are aligned to achieve several key contributions:

1) Presents the first comprehensive scientific evaluation of a case study of cloud-based 3D HPE, assessing its accuracy using robust metrics.

2) It contributes to the broader understanding of the potential and limitations of cloud-based 3D HPE tools in various realistic scenarios.

3) The findings could potentially influence future developments in 3D HPE technology, enhancing the accessibility and applicability of cloud-based motion capture solutions.

The organization of the paper is as follows: the related works in Section II reviews prior studies and developments within the field, detailing advancements and challenges in 3D HPE, setting the stage for the current research. The methodology in Section III details the datasets employed in the study, the evaluation metrics used specifically MPJPE and PCK and the experimental setup designed to test the efficacy of the 3D HPE tool. Results in Section IV, presents both quantitative and qualitative analyses that compare the performance of MOTiON by RADiCAL against established ground truth data, highlighting the tool's accuracy and operational characteristics in various scenarios. The discussion in Section V interprets these results, exploring their implications for the field of 3D HPE and discussing potential limitations of the study. Finally, the conclusion in Section VI summarizes the key findings and proposes directions for future research, suggesting how improvements could enhance the utility and accuracy of cloud-based 3D HPE tools.

II. Related Works

A. 3D Human Pose Estimation

Over the past few years, there has been a growing interest in 3D HPE due to its ability to provide accurate information about the 3D structure of the human body. 3D HPE seeks to predict the location of body joints in 3D space. It can be applied to a variety of situations (e.g., 3D animation movies, extended realities, and cloud-based 3D action estimation). Even though 2D HPE has recently seen significant advancements, 3D HPE is still a challenging task to complete. Recent research in the field of computer vision has been focused on the extraction of 3D human pose estimation (HPE) from monocular images or videos. Those are a 2D representation of a 3D scene, resulting in the loss of one dimension. As a result, researchers have been working on developing algorithms and techniques to accurately estimate the 3D pose of human subjects from these 2D images. 3D human pose estimation can be a well-defined problem that is solvable using information fusion methods if there are multiple perspectives or additional sensors such as IMU and LiDAR available. However, one drawback of using deep learning models for this task is their high data dependence and sensitivity to data collection circumstances. Extensive amounts of annotated data are necessary for these models to learn accurate representations of input and output spaces, and factors such as lighting conditions, camera positions, and background can influence their performance negatively.

While obtaining accurate two-dimensional posture annotations for human datasets is relatively straightforward, obtaining accurate three-dimensional pose annotations is considerably more challenging and cannot be done manually. Furthermore, datasets are often collected in controlled indoor settings that focus on specific activities, making them biased towards these scenarios. Recent studies have shown that models trained on such biased datasets tend to perform poorly when applied to other datasets, as demonstrated by cross-dataset inference [2], [3].

1) Single-person 3D HPE: The strategies of Single-person 3D HPE can be categorized as model-free or model-based methods. The first one can be divided into two categories:

a) Direct estimate techniques: instead of first estimating the 2D pose representation, some algorithms in 3D human pose estimation employ direct estimation techniques, as seen in [4], [5], to directly infer the 3D human position from 2D images. Recent advancements include the study by H Ye et al., which enhances real-time 3D pose estimation efficiency through orthographic projection techniques, simplifying the direct estimation process from images without intermediate 2D pose estimation [33].

b) 2D to 3D lifting techniques: The process of inferring 3D poses from intermediate 2D pose pairings is inefficient because it requires multiple network inferences. Human body models are not used in the model-free approaches for recreating 3D human representations. Standard 2D HPE models are used in the first stage to estimate the 2D posture, and 2D to 3D lifting is used in the second stage to construct the 3D pose, such as [6], [7], and [5]. 2D heatmaps rather than 2D poses were used as intermediate representations to estimate 3D posture ([8] and [9]). Through distance matrix regression, Moreno-Noguer [10] deduced the 3D human position from the distances between the joints in the 2D and 3D body (EDMs). When normalization techniques are used, EDMs are invariant to scaling invariance as well as in-plane

image rotations and translations. A Paired Ranking Convolutional Neural Network (PRCNN) was created by Wang et al. [11] to predict the depth ranking of pairwise human joints. The 3D pose was then regressed from the 2D joints and the depth ranking matrix using a coarse-to-fine pose estimator. Li and Lee [12], Sharma et al. [13], and Jahangiri and Yuille [14] were the first to develop numerous, different 3D pose hypotheses. Recent work by C Han et al. introduces uncertainty learning to improve the accuracy and robustness of 3D pose estimations from single images, effectively enhancing this lifting process [34].

Parametric body models, such as kinematic and volumetric models, are utilized by model-based methods to estimate human position, as illustrated in Fig. 2.

The kinematic model represents the body as a series of joints and articulating bones, and in recent years, it has garnered increasing attention in the field of 3D human pose estimation. Pavllo et al. [15] suggested a temporal convolution network for estimating 3D posture from sequential 2D sequences using 2D keypoints. A Short-Term Long Memory (LSTM) unit and shortcut connections were employed in a recurrent neural network to leverage temporal information from human pose data [16].

The Skinned Multi-Person Linear (SMPL) model is among the most commonly utilized volumetric models in the field of 3D HPE, as evidenced by its implementation in works such as [17], [18].

2) Multi-person 3D HPE: There are two approaches for 3D multi-person human pose estimation from monocular RGB images or videos, which are classified into top-down and bottom-up categories. These approaches are illustrated in Fig. 3.

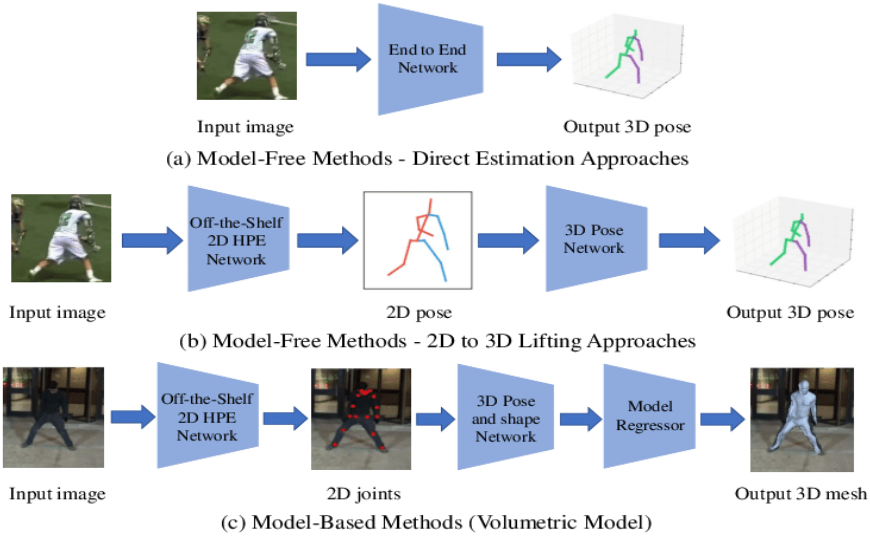

Fig. 2. Frameworks of 3D single-person pose estimation [19] (a) This method is done in one stage, i.e., directly from RGB image to 3D pose. (b) The approaches perform 3D HPE using a two-stage approach, i.e., it performs 2D HPE first and then uses the 2D keypoints to get 3D ones. (c) The 3D mesh is obtained using a regression stage on the 3D HPE outputs.

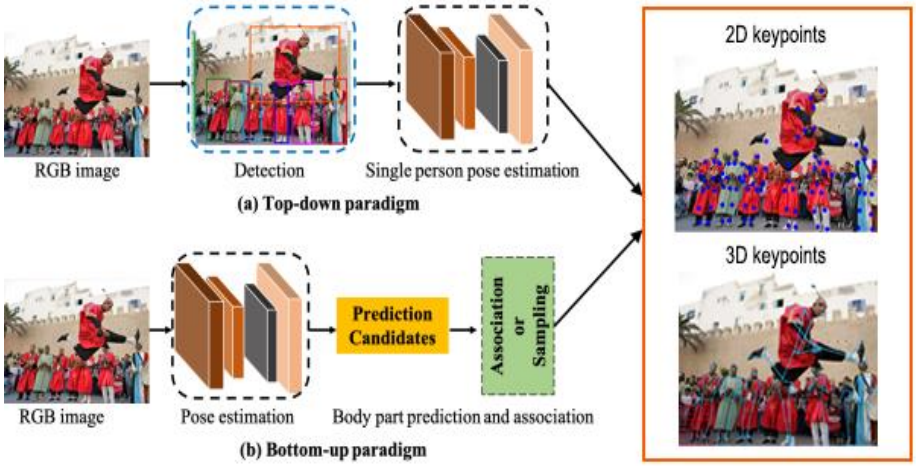

Fig. 3. Frameworks of 2D and 3D multi-person pose estimation [27] (edited). (a) The top-down approach uses person detection techniques to determine the number of persons detected in the frame, and then it applies a 2D single-person estimation framework. (b) The bottom-up approach identifies each joint in the image and then associates each one with individuals.

a) Top-down approaches: They use human detection to estimate each person's position. Each time a person is identified, 3D pose networks estimate their root (the human body's central joint) coordinate and their 3D root-relative posture. Rogez et al. [20] targeted candidate areas of each individual to produce prospective postures and then utilized a regressor to improve the pose suggestions jointly. The LCR-Net technique, which involves localization, classification, and regression, performed well on datasets collected in controlled environments, but not on images captured in natural settings. To address this limitation, LCR-Net++ was introduced, which utilizes synthetic data augmentation during training to improve performance. [21]. The 3D multi-person HPE module was enhanced with scene constraints and semantic segmentation [22]. The 3D temporal assignment problem was also tackled by the Hungarian matching approach for video-based multi-person 3D HPE, which achieved impressive results in [23], [24]. L Jin et al. introduced a single-stage method that integrates human detection and pose estimation, simplifying the process and enhancing efficiency by directly estimating 3D poses from detected individuals in a single network pass, demonstrating significant improvements over traditional multi-stage methods [35].

b) Bottom-up approaches: First, generate joint positions and depth maps for all body joints. They then assign body parts to each individual based on the root depth and relative depth of the body component [25], [26]. How to categorize human body joints is a fundamental difficulty for these techniques. Methods at a lower level exploit the common latent space between two distinct modalities.

B. Datasets for 3D HPE

Obtaining precise 3D labeling for 3D human pose estimation datasets is a difficult endeavor that necessitates the use of motion capture techniques such as MoCap and wearable IMUs. Since the 3D HPE deep learning-based needs larges datasets to train, validate, and test their models, several 3D posture datasets are created due to this need.

1) HumanEva Dataset [28]: It includes seven calibrated video sequences (4 grayscale and three colors) with ground truth 3D annotation taken by a ViconPeak commercial MoCap system. The database comprises four scenarios executing six common actions in a 3m × 2m area: walking, jogging, pointing, throwing and catching a ball, boxing, and combination.

2) Human3.6M [29]: One of the most commonly used datasets for indoor 3D human pose estimation from monocular images and videos. The dataset features 11 professional actors (six males and five females) performing 17 actions (such as smoking, taking photos, and talking on the phone) in a laboratory environment captured from four different perspectives.

3) The CMU Graphics Lab Motion Capture Database (CMU) [30]: CMU is one of the most publicly large databases of motion capture data. Numerous researchers within the scientific world have utilized it to develop previous models of human motion. However, the dataset is poorly synced and contains some films unsuitable for HPE due to multiple actors in each scene. The database comprises more than 100 scenarios executing several actions in a 3m × 8m area.

III. Methodology

After extracting videos from CMU and their associated BVH pose files, a preprocessing stage comprising: cleaning (i.e., avoid corrupted sequences or those that do not verify the necessary conditions), reorganization (i.e., reclassifying all sequences into 12 scenarios), and synchronization (because the BVH poses files are not synchronized with the associated videos) was performed. The sequences in video format were then processed in the cloud with RADiCAL. Both BVH poses of CMU and RADiCAL were rendered using a virtual camera to get the 3D coordinates of each joint. Then two evaluation types were performed; the first one was quantitative, which compared both poses of RADiCAL (as predicted results) and those of CMU (as a ground-truth one). The other evaluation type is a qualitative one based on visual analysis of the predicted 3D human pose scenario according to the ground truth. The workflow was summarized in Fig. 4.

A. Data Preprocessing

The CMU Graphics Lab Motion Capture Database (CMU) was obtained using 12 Vicon MX-40 infrared cameras, each capable of collecting 4-megapixel pictures at 120 Hz. The cameras are positioned around a 3m x 8m rectangle area in the center of the room. The actor wears a black jumpsuit with 41 markers affixed to it while infrared Vicon cameras detect the markings. The pictures captured by the numerous cameras are triangulated to provide three-dimensional data.

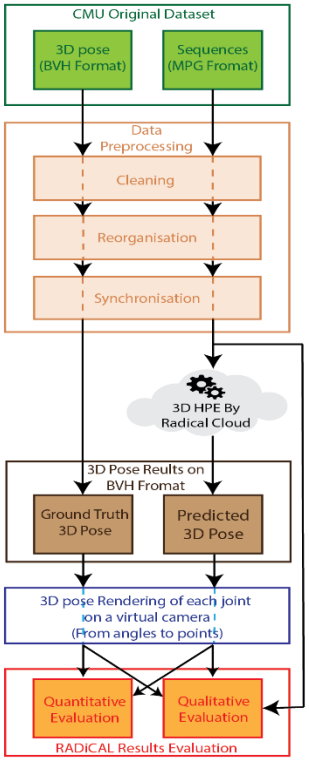

Fig. 4. Overview of the suggested approach.

Despite the dataset covering many scenarios (more than 100), several sequences are without their corresponding videos. Many videos are corrupted, contain more than one actor, or do not contain all body parts. In addition, all files, including BVH and Videos, need to be synced. Therefore the dataset was edited following the three steps below:

1) Cleaning: some corrupted videos were eliminated, and the rest were repaired by hiding the second actor, if that is possible.

2) Reorganization: the sequences were classified into 12 essential scenarios, as shown in Table I.

3) Synchronization: since all BVH frames are not synced with videos, a manual process was manually done using Blender. Also, the sequences captured with 120 or 60 FPS were decreased to 30 FPS since the RADiCAL support only motion capturing with 30 FPS.

B. MOTiON by RADiCAL

MOTiON by RADiCAL is a model-based 3D HPE AI-driven and cloud-based software that converts 2D movies into complete 3D animation with 6 degrees of freedom. The animation data is stored with 30 FPS into FBX (Filmbox), a format that allows the exchange of geometric and animation data between 3D animation software, such as Blender.

For the study, the sequences in MPG format were imported to the RADiCAL cloud then the HPE was processed using the RADiCAL model. After a few moments, the FBX files were done. In order to compare those results to CMU's ground truth, the FBX output files were converted to BVH format using Blender. The output skeleton and the joints are shown in Fig. 5.

C. BVH Projecting to 3D Coordinates

The motion capture of videos from the RADiCAL and CMU datasets is stored in BVH format, including the root transaction coordinates and Euler angles for each joint. As illustrated in Fig. 6, all the coordinates, including those in the BVH files, were projected to a 3D virtual camera to obtain the 3D coordinates of each joint.

Algorithm 1 computes the joint coordinates in camera space from a BVH file containing joint hierarchy and motion data. The algorithm starts by defining the camera intrinsic matrix K, which represents the camera's internal parameters such as focal length and principal point. The camera extrinsic matrix C is also defined, which represents the camera's external parameters such as position and orientation in global space.

$$K = \begin{pmatrix} f_x & 0 & c_x \\ 0 & f_y & c_y \\ 0 & 0 & 1 \end{pmatrix} \quad (1)$$

Algorithm 1: Extract 3D Joint Coordinates from BVH File.

***Algorithm**: Compute Joint Coordinates in Camera Space from BVH File*

Input: BVH file with joint hierarchy and motion data
Output: 3D joint coordinates in camera space for each frame of motion data

1) Load BVH file and extract joint hierarchy and motion data.
2) Define camera intrinsic matrix K with focal lengths f_x and f_y and principal point coordinates c_x and c_y.
3) Define camera extrinsic matrix C with rotation matrix R and position vector P.
4) For each frame of motion data, traverse the joint hierarchy in forward kinematics to compute global joint positions.
5) Transform global joint positions to camera coordinates using K and C.
6) Output the 3D joint coordinates in camera space for each frame of motion data.

End algorithm.

TABLE I. CMU DATASET COMPONENT AFTER CLEANING, FILTERING, AND CLASSIFICATION

Number of scenarios	Number of sequences	Number of views	Frequency	Scenarios	Number of frames
12	279	1	30 FPS	Animal behaviors	62 454
				Climbing	981
				Daily activities	6 306
				Dancing	1 122
				Home activities	56 359
				Jumping	1 553
				Reactions	12 852
				Running	332
				Sitting	4 548
				Sport	9 714
				Walking	16 493
				Working	11 952
				Female	71 759
				Male	112 907
				All	184 667

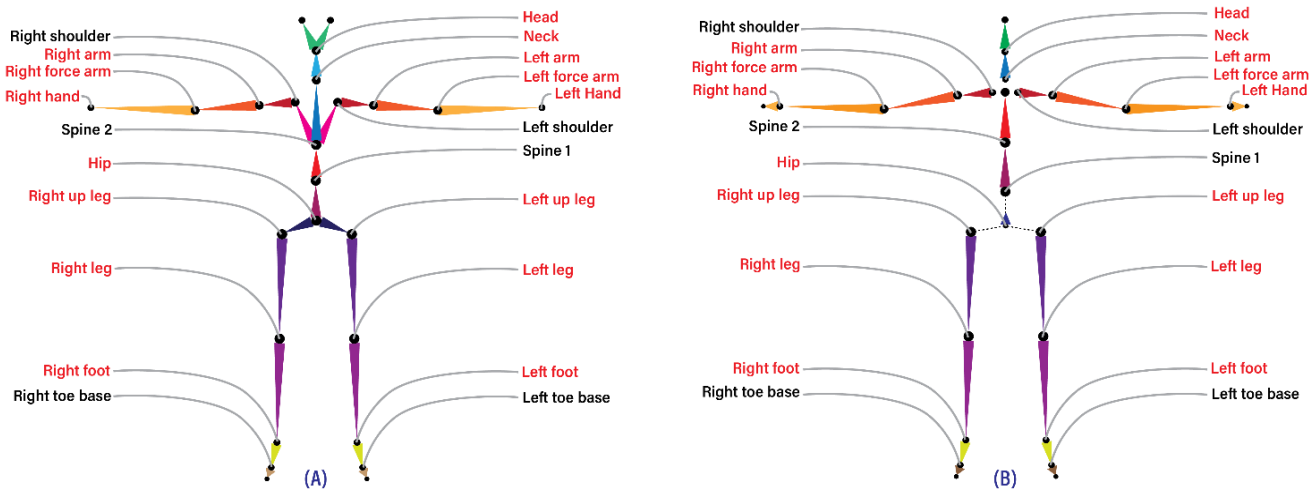

Fig. 5. Skeleton model hierarchy of CMU. (B): Skeleton model hierarchy of RADiCAL. The red ones are the chosen joints to perform the quantitative evaluation.

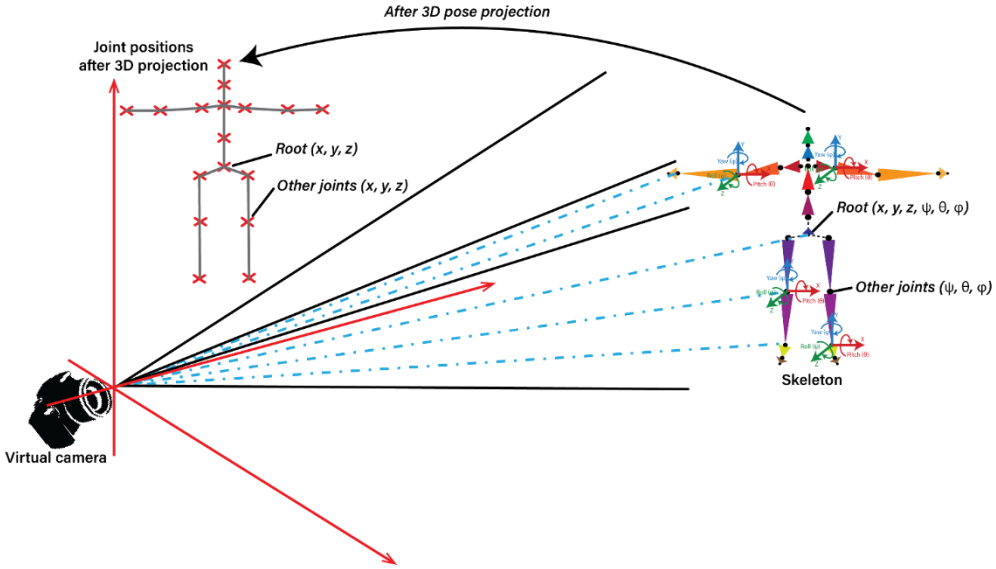

Fig. 6. Rendering process of CMU and RADiCAL skeletons. The purpose is to obtain the 3D pose coordinate of joints from angles.

where, f_x and f_y are the focal lengths of the camera in x and y directions, and c_x and c_y are the coordinates of the principal point of the camera.

$$C = \begin{pmatrix} r_{11} & r_{12} & r_{13} & t_1 \\ r_{21} & r_{22} & r_{23} & t_2 \\ r_{31} & r_{32} & r_{33} & t_3 \end{pmatrix} \quad (2)$$

where, r_{ij} is the rotation matrix that describe the camera's orientation in global space, and t_i is translation offset. The joint positions and orientations for each frame in the motion data are then computed using forward kinematics, with the root joint's global position and orientation serving as the initial values. The global positions and orientations of child joints are then computed by traversing the joint hierarchy, and the resulting global joint positions are transformed to camera coordinates using the intrinsic and extrinsic matrices. This transformation can be represented mathematically as:

$$\begin{pmatrix} X_{position\_camera} \\ Y_{position\_camera} \\ Z_{position\_camera} \end{pmatrix} = K \times C \times \begin{pmatrix} X_{position\_global} \\ Y_{position\_global} \\ Z_{position\_global} \\ 1 \end{pmatrix} \quad (3)$$

where, $(X_{position\_global}, Y_{position\_global}, Z_{position\_global})$ the global joint position in 3D space, and the resulting is $(X_{position\_camera}, Y_{position\_camera}, Z_{position\_camera})$ is the joint position in camera coordinates. This algorithm provides the way to extract joint positions in camera space from a BVH file.

D. Skeleton Scaling and Evaluation Metrics

1) Skeleton scaling: Since the skeletons of CMU and Radical are not similar, the Procrustes analysis was used to determine the scale [1], rotation, and translation. Given correspondences of points $A_j \in R^3$ and $B_j \in R^3$ of the joint j find scaling, rotation, and translation transformation, called similitude transformation that satisfies:

$$A_j = sRB_j + T \quad (4)$$

For $R \in SO(3), T \in R, and\ s\ \in R^+$

2) Evaluation metrics: Our experiments use two metrics. The first is the mean per-joint position error (MPJPE [29]) between the ground-truth 3D pose and the predicted 3D pose, which is calculated using the Eq. (5): Then, we calculate the mean error across all poses and actions in the dataset.

$$MPJPE = \frac{1}{m}\sum_{i=1}^{m}\left\|p_i^3 + \overline{p_i^3}\right\|_2 \quad (5)$$

For a given skeleton comprising m joints, p_i^3 denotes the actual 3D pose of joint i, whereas $\overline{p_i^3}$ signifies the predicted 3D pose of the same joint.

The second metric is the Percentage of Correct Keypoints for 3D Pose Estimation (PCK3D) [31], a 3D version of the PCK utilized for 2D pose estimation [32]. If the estimated joint location is within a reasonable distance of the ground-truth joint, it is considered to be accurately estimated. Then, the proportion of accurately calculated joints is computed. As in earlier research, the neighborhood threshold is chosen at 150mm [31], corresponding to about half the head size. This statistic is more expressive and robust than MPJPE, highlighting joint mispredictions more clearly. A 15 keypoints were examined, which are indicated in red in Fig. 5.

IV. Results

As stated previously, qualitative and quantitative evaluations were performed. With the restructured CMU dataset, the initial step was to obtain the MPJPE and the PCK by scenario and gender. The second sort of evaluation consisted of picking 3D postures of various scenarios and visually analyzing the results' accuracy.

A. Quantitative Evaluation

The results obtained using MOTiON by RADiCAL cloud-based were compared with the ground-truth 3D poses from the reconstructed CMU dataset using two metrics measurements (MPJPE and PCK). The 3D poses were classified by gender and scenario to assess the accuracy of each one. Then the accuracy of each joint was discussed.

1) Comparing by joints: In this evaluation, 15 crucial joints were analyzed, as depicted in Fig. 5 where the red joints are highlighted. The results are presented in Table II and Fig. 7, displaying the highest mean error values of the Middle Hip, Left Wrist, and Right Wrist joints. While, the lowest mean error values were obtained for the Shoulders, Knees, Nose, and Nick.

2) Comparing by scenarios: Fig. 8 and Table III show that the MPJPE varied from 90,7 mm to 119,1 mm, depending on the scenario. The walking scenario was the most accurate, with an MPJPE of 90.7 mm, whereas the running scenario was the least accurate.

Each scenario's MPJPE (walking, jumping, dancing, reaction, and animal behavior) was under 100 mm while they were near one another, except for home activities, who's MPJPE was just under 100 mm. The MPJPE is more than 100 mm for the remaining scenarios (daily activities, working, climbing, sitting, sports, and running). Expect "Running," "Sitting," and "Sport"; all the scenarios were accurate with higher than 90% of correct joints according to the PCK values of each one. The scenarios: "Home activities," "Jumping," "Reactions," and "Walking" had a PCK near 100%. Expect running and sports scenarios with a standard deviation of around 70 mm. Every other scenario was within 50 mm.

TABLE II. Mean Error by Joints

Joints	Mean (mm)	Standard deviation (mm)
Nose	85.28	36.11
Neck	87.15	27.30
Right Shoulder	77.96	33.85
Right Elbow	99	41.29
Right Wrist	116.96	77.72
Left Shoulder	70.52	30.86
Left Elbow	103.61	49.12
Left Wrist	122.73	85.58
Middle Hip	170.49	20.33
Right Hip	94.78	24.28
Right Knee	80.91	37.07
Right Ankle	92.17	59.06
Left Hip	91.13	25.73
Left Knee	89.61	42.77
Left Ankle	99.07	50.24

TABLE III. MPJPE by Scenarios

Scenarios	MPJPE (mm)	Standard deviation (mm)	PCK (%)
Animal behaviours	92.14	52.33	96.5
Climbing	112.65	54.48	95.62
Daily activities	101.92	53.56	95.8
Dancing	92.14	63.09	94.55
Home activities	99.44	47.66	97.3
Jumping	91.30	40.58	99.03
Reactions	92.97	47.67	98.63
Running	119.10	72.22	83.68
Sitting	116.75	59.32	87.28
Sport	118.31	68.82	83.75
Walking	90.71	45.39	98.13
Working	104.79	56.47	91.57
All	98.76	52.06	95.8

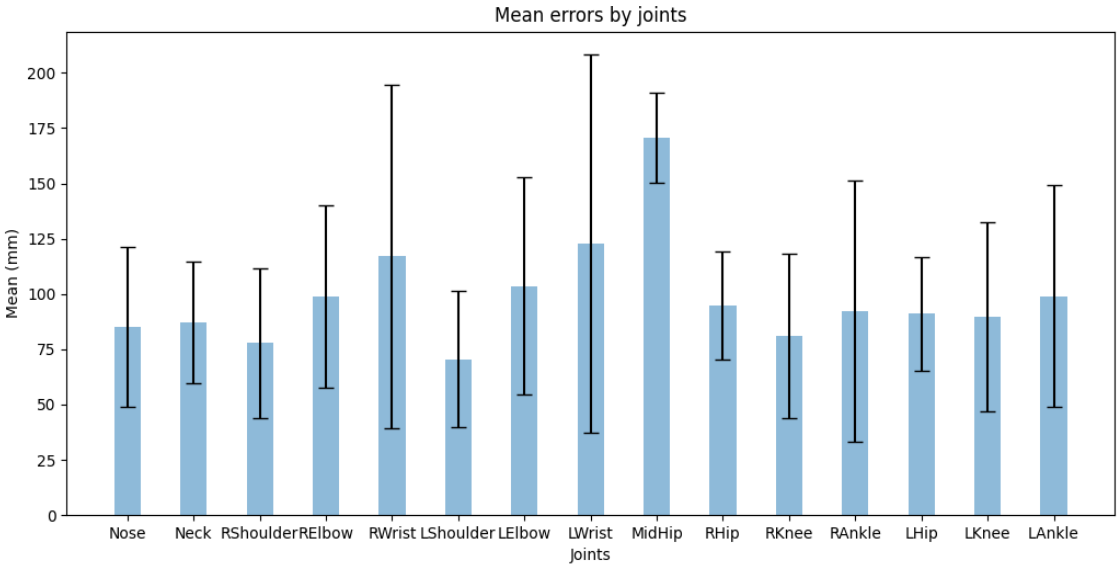

Fig. 7. The results of MPJPE by joints.

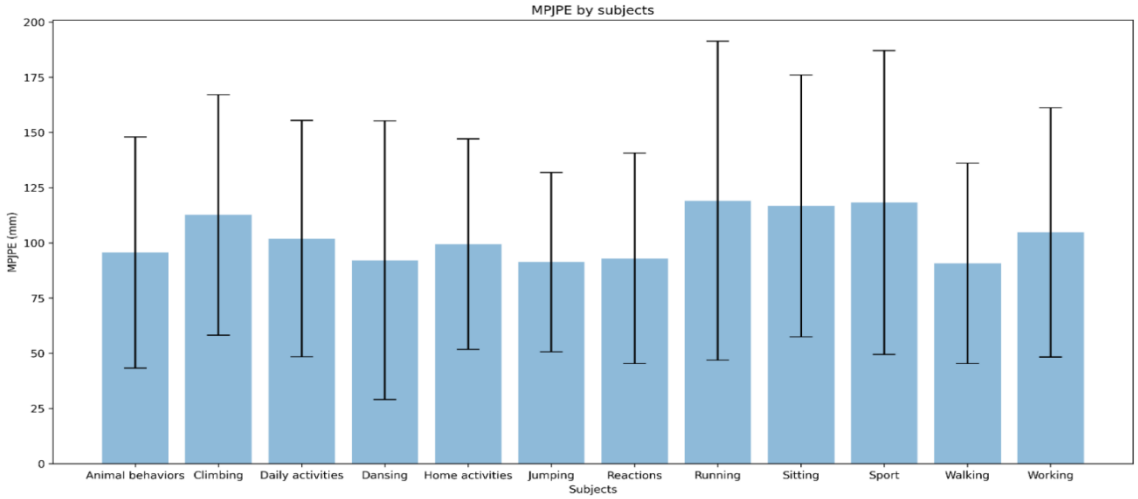

Fig. 8. The results of MPJPE by scenarios.

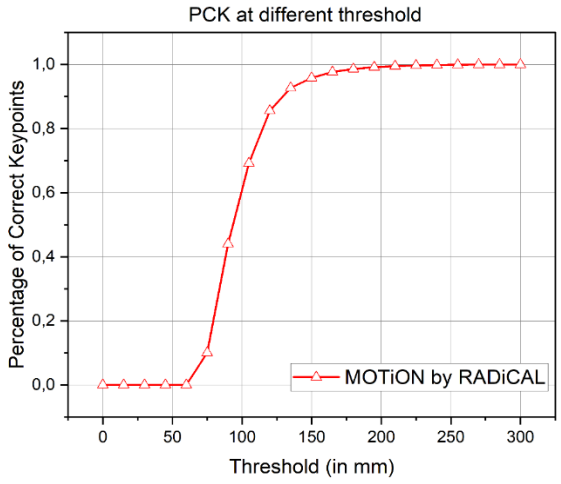

Fig. 9. The thresholds and the corresponding PCK.

Fig. 9 shows a clear progression of the Percentage of Correct Keypoints (PCK) in response to the changing Mean Per Joint Error (MPJPE) threshold. As the MPJPE threshold increases, the PCK also follows suit. Notably, at a relatively stringent threshold of 75 mm, the PCK already reaches about 44%, almost half of the keypoints estimated correctly within this error range. This trend continues and the PCK grows to about 96% when the MPJPE threshold is relaxed to 150 mm, indicating a substantial portion of the estimated keypoints are accurately detected within this margin of error. As we further expand the MPJPE threshold beyond 150 mm, the PCK continues to increase, albeit at a slower rate. The curve eventually approaches a saturation point near 100%, indicating that practically all keypoints are accurately estimated within these larger margins of error.

3) Comparing by gender: The findings of gender-based evaluations are depicted in Table IV and Fig. 10. Male and female MPJPEs were comparable, with the female MPJPE (95

mm) being 5 mm better than the male MPJPE (100 mm). The same holds for the standard deviation, which was almost identical. The PCK of both genders was almost the same, with 95.7%. As shown in Fig. 11, comparing all joints by gender reveals a lower mean error for eight male joints.

TABLE IV. MPJPE BY GENDER

	Female	Male
MPJPE (mm)	95.7	100.71
Standard deviation (mm)	53.06	51.31
PCK (%)	95.9	95.7

B. Qualitative Evaluation

One challenging frame from each scenario was selected, and RADiCAL output was visually compared to the ground-truth frame. As demonstrated in Fig. 12, the scenarios such as "Animal Behaviors," "Daily Activities," "Reactions," "Dancing," "Jumping," "Home Activities," and "Walking" imitate the ground-truth quite accurately. In addition, all skeletal parts are in their proper locations. In the remaining instances, RADiCAL correctly estimated all skeleton parts. However, its orientation was incorrect. The "Working" scenario was estimated correctly, except for the head in several frames. Some parts of the "Sports" scenario, such as the hand, were not precisely estimated.

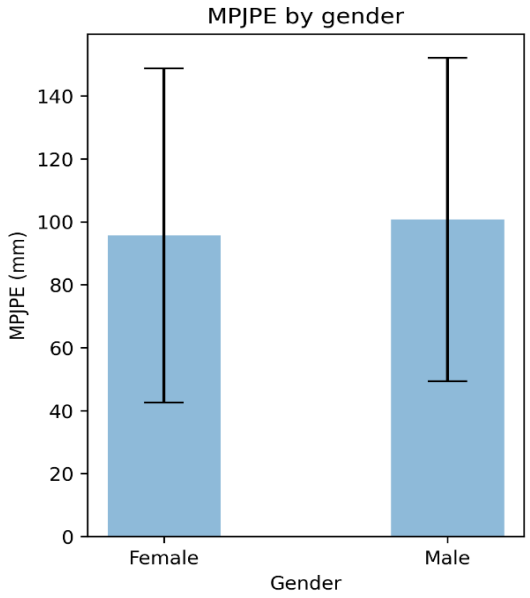

Fig. 10. The results of MPJPE by gender.

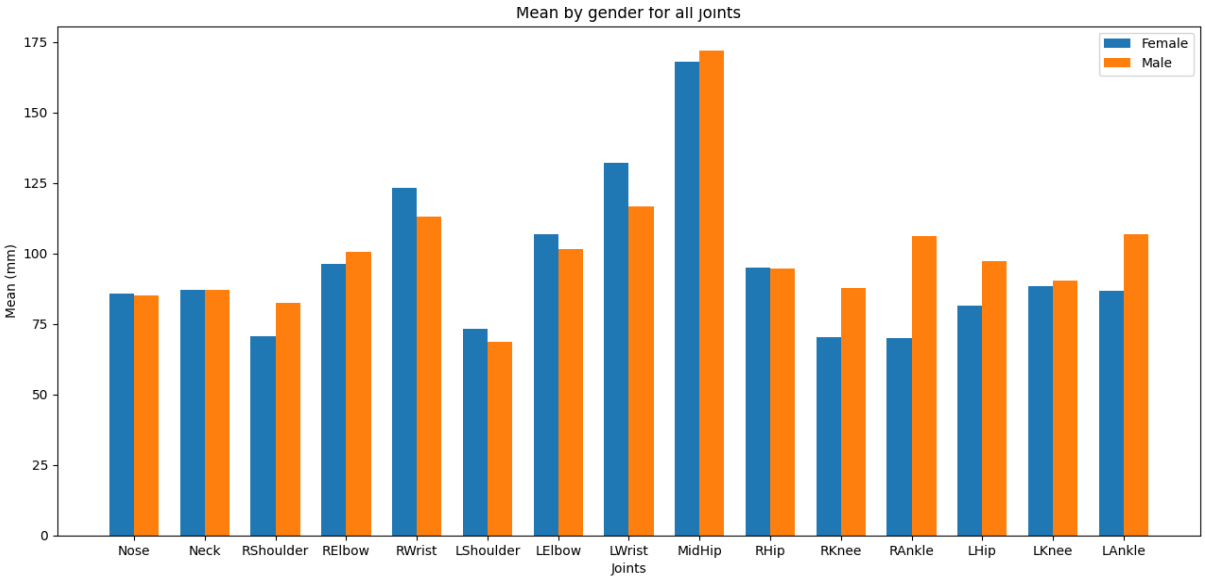

Fig. 11. The MPJPE results of comparison of joints by gender.

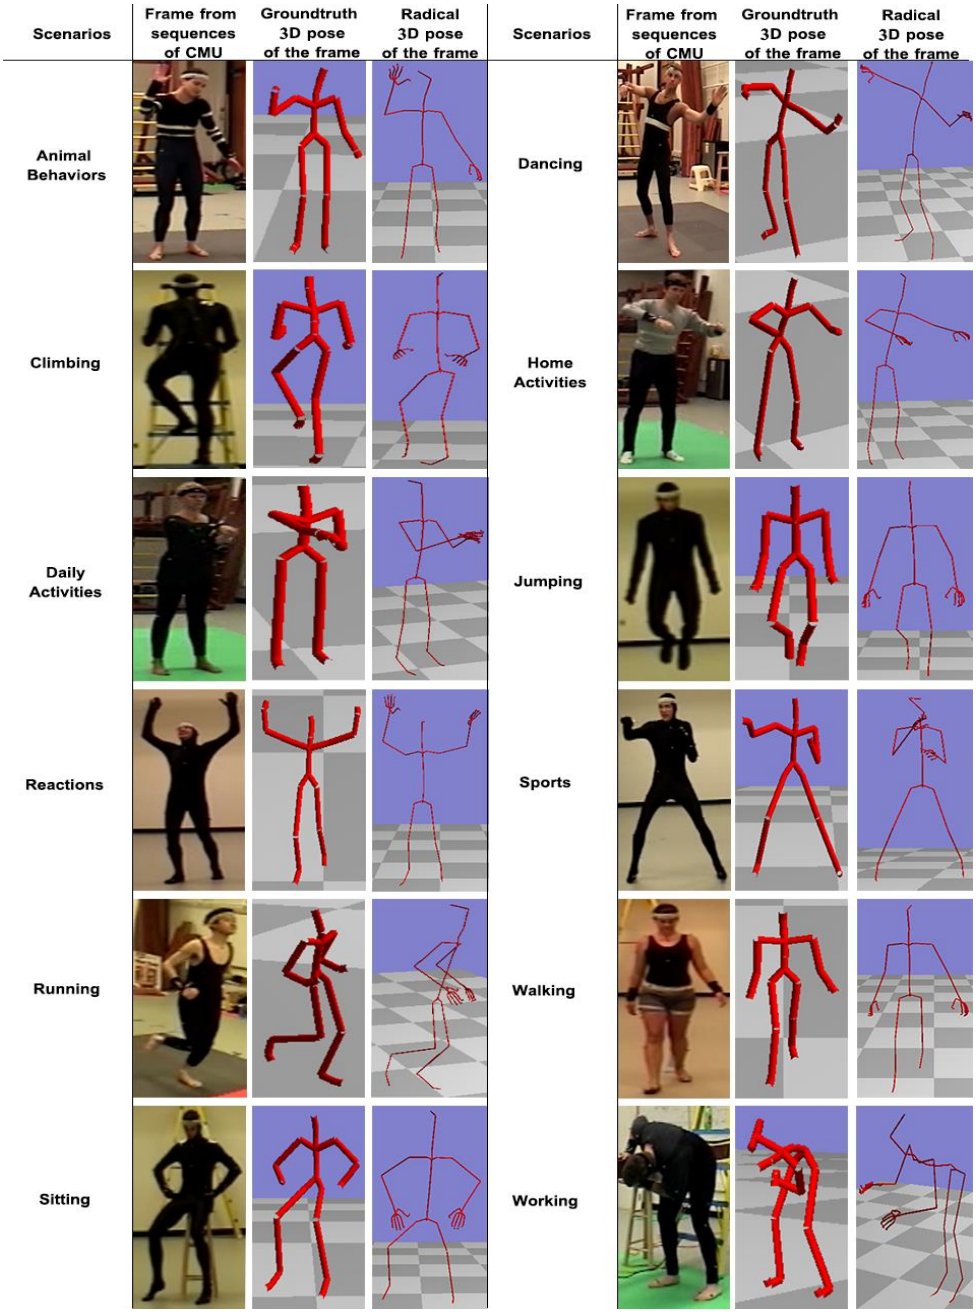

Fig. 12. The qualitative results of each scenario.

V. Discussion and Limitations

This study provides the first comprehensive evaluation of MOTiON by RADiCAL, a cloud-based 3D human motion estimation tool, revealing both its potential advantages and inherent limitations. In scenarios involving less complex actions or slower movements, such as walking or light exercise routines, our evaluation demonstrated a relatively low Mean Per Joint Position Error (MPJPE) and a high Percentage of Correct Keypoints (PCK), signaling promising performance. However, the tool's performance diminished in complex, dynamic scenarios, including sports movements, actions involving occlusion, or tasks requiring significant height variation like climbing.

The distinction in performance directly influences the range of applications suitable for MOTiON by RADiCAL. In digital content creation fields such as simple animation for games or films, or casual fitness tracking where millimeter-level precision may not be paramount, the tool's cost-effectiveness and accessibility offer substantial benefits.

However, for applications demanding high-precision motion capture, such as advanced biomechanical analysis, sports performance analysis, or precise virtual reality interaction, the current version of MOTiON by RADiCAL may not provide the necessary accuracy. The MPJPE of 98mm found in our study, while acceptable in some contexts, could

lead to significant errors in these precision-demanding applications.

VI. Conclusion

MOTiON by RADiCAL, as evaluated in this study, shows promise as a cost-effective, user-friendly alternative to traditional sensor-based motion capture systems. However, the tool's current performance suggests its best fit for applications where absolute precision is not a critical requirement.

In realms like basic animation for gaming, motion-guided user interface design, or casual fitness tracking, the tool's slight inaccuracies are unlikely to substantially impact the end result, making it a beneficial tool. Its cost and usability advantages are particularly beneficial for independent creators, small studios, or hobbyists in these fields.

However, in precision-critical applications, such as advanced biomechanical research, sports performance analysis, or high-end virtual reality systems that require nuanced interaction, the existing error levels in MOTiON by RADiCAL may be prohibitive. For these applications, traditional sensor-based systems, despite their higher cost and complexity, may remain the gold standard.

In summary, MOTiON by RADiCAL represents a significant step forward in democratizing access to 3D human motion estimation. However, its current performance limitations suggest that it is not a one-size-fits-all solution. Future research should explore ways to improve the precision of such tools to extend their applicability to a broader range of scenarios.

Conflicts of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors would like to thank MOTiON by RADiCAL for providing a discount to use their cloud to get the results.

***Abstract*—Given the information stored in educational databases, automated achievement of the learner's prediction is essential. The field of educational data mining (EDM) is handling this task. EDM creates techniques for locating data gathered from educational settings. These techniques are applied to comprehend students and the environment in which they learn. Institutions of higher learning are frequently interested in finding how many students will pass or fail required courses. Prior research has shown that many researchers focus only on selecting the right algorithm for classification, ignoring issues that arise throughout the data mining stage, such as classification error, class imbalance, and high dimensionality data, among other issues. These kinds of issues decreased the model's accuracy. This study emphasizes the application of the Multilayer Perceptron Classification (MLPC) for supervised learning to predict student performance, with various popular classification methods being employed in this field. Furthermore, an ensemble technique is utilized to enhance the accuracy of the classifier. The goal of the collaborative approach is to address forecasting and categorization issues. This study demonstrates how crucial it is to do algorithm fine-tuning activities and data pretreatment to address the quality of data concerns. The exploratory dataset utilized in this study comes from the Pelican Optimization Algorithm (POA) and Crystal Structure Algorithm (CSA). In this research, a hybrid approach is embraced, integrating the mentioned optimizers to facilitate the development of MLPO and MLCS. Based on the findings, MLPO2 demonstrated superior efficiency compared to the other methods, achieving an impressive 95.78% success rate.**

Keywords*—Educational data mining; multilayer perceptron classification; pelican optimization algorithm; crystal structure algorithm; student performance

I. Introduction

A. Background

Providing high-quality education to students is the primary goal of higher education establishments [1]. One strategy for achieving a better quality standard in a higher education program is to forecast pupils' academic success and intervene soon to raise pupil achievement and teacher quality [2]. Data mining techniques may be used to retrieve the useful knowledge concealed inside the educational data collection [3]. Against the backdrop of higher education, the current research aims to evaluate the potential of data-mining approaches by providing a data-mining model [4]. This activity aims to assess pupils' performance through categorization [5]. It is necessary to continuously assess how well pupils do in every topic. to pinpoint where the learner lost their grade [6]. This makes it easier for the educator to take the required steps, such as giving the student greater focus on that specific topic, teaching in a way that the student can understand quickly, giving tests, etc., all of which eventually raise the student's academic standing and quality [7]. Educational Data Mining (EDM) is the term for data mining within the education framework. Analytics has been used more in the previous few decades in educational settings [8], [9].

B. Related Works

On the provided dataset, six classifiers were used. At 79.23%, the ID3 had the highest accuracy [10]. The class mismatch challenge was beyond the model's ability to solve. To identify weak pupils, a model of ensembles such as classifiers (NB, SVM, and KNN) was suggested [11]. In addition to the common score-based evaluation, the data collection includes a characteristic referred to as standard-based grading evaluation. Comparing the outcomes of the suggested approach via six independent classifiers led to the conclusion that the ensemble model's accuracy was greater than the others at 85%. A multilayer classification model was put forth to overcome the multiple classifications issue regarding student performance prediction [12]. A methodology to give an early categorization of first-year students with poor educational outcomes was suggested by Dech Thammasiri et al. [13]. The class imbalance challenge was solved by applying four classifications and three balancing techniques. According to the results, the combination of SMOTE and support vector machines produced a maximum general precision of 90.24%. Students' performance in an online class may be predicted using information from their learning portfolios, according to one proposed early warning system [14]. The results showed that approaches based on time were more precise than those independent of time. Test the framework did not in offline mode. Using time-dependent properties, functioning might be reduced in offline mode.

Earlier research suggested that data mining algorithms only worked effectively with huge data sets; however, this study provided evidence that data mining may also be used for smaller datasets [15]. A model for predicting learner achievement was presented in this study. Several decision tree techniques were used for a small dataset containing students'

academic data (Reptree, J48, M5P). According to the results, the Reptree had the best accuracy, exceeding 90 percent. The suggested model does not support class balance issues and data with large complexity. By grouping students into binary classes (successful/unsuccessful), Dorina et al. [16] presented a prediction model for students' performance. The suggested model was built using the research methodology of the Cross-Industry Standard Procedure for Data Mining, or CRISP-DM [17]. The provided dataset was subjected to the categorization methods OneR [18], MLP, J48, and IBK. The results showed that the MPL model was the most accurate at 73.59 percent in determining which students passed, while the other three models did a better job of determining which students failed. Issues with class balance and large complexity data were unsolvable for the model.

To overcome issues with disparities in classes and data complexity, Carlos et al. [19] focused on a machine learning-based failure of students' prognosis model. The dataset was utilized to execute ten classifiers. The accuracy of the ICRM classifier was found to be 92.7%, surpassing the performance of the other classifiers. The evaluation of the proposed model's performance was not conducted across various educational levels due to the distinct student characteristics associated with each level of education. Another EDM challenge is predicting which students will drop out of their classes [20]. Four data mining techniques with six characteristic pairings were employed in this study. The outcome reveals that, in data classification, superior performance was achieved when utilizing the support vector machine model that combined the variables. Adding a characteristic, achieved scores of prerequisite courses, in a data set was the study's restriction since it was feasible that the student had become more knowledgeable about the prerequisites for any course while studying for any other course. Research on pupil achievement prediction was carried out by Ajay et al. [21]. The main importance of the study was the introduction of a new social element, known as the CAT. The text elucidates the first categorization of Indians into four distinct groups based on their social standing and other variables that influenced student admission. The dataset underwent classification using four methods, namely R, MLP, J48, and IB1. Based on the available data, it can be shown that the IBI model has the highest level of accuracy, reaching 82%. Create an enhanced iteration of the ID3 method, which forecasts academic achievement in students [22]. The ID3 model's intention to choose those qualities as a node with additional values was one of its weaknesses. Consequently, the produced tree lacked efficiency. The suggested model resolves such an issue. This model generated the Pass and Failure output types. J48, wID3, and Naïve Bayes classifiers were used, and the outcomes were contrasted. An accuracy rate of 93% was attained with the wID3A model to forecast student achievement in courses presented in [23]. This study used three decision tree classifiers: Reptree, Hoeding tree, and J48. Reptree obtained the greatest accuracy of 91.47%. Problems with class balance and large dimensionality data were unsolvable for the model.

Through solving the data complexity issue, Edin Osmanbegovic et al. [24] was created a model to estimate the academic progress of students in a given course. This study evaluated many machine learning classifiers, such as NB, MLP, and j48. Based on the results, it can be observed that the Naïve Bayes model achieved the highest level of accuracy, reaching 76.65%. The issue of class imbalance is not addressed by the suggested model. In this paper, a model for predicting students' academic success was presented [25]. This study examined the classification methods with three different feature arrangements: J48, Decision Stump, Reptree, NB, and ANN. A high accuracy of 90.51% was attained with the J48 classifier. To forecast student abandonment, the suggested method took into account three numbers of courses that were assessed: dropout, persisting, and completing. Ten models of categorization were evaluated. According to the research's findings, for all three student classes, the Naïve Bayes algorithm achieved the greatest prediction values.

C. Objective

The fundamental aim of this research was to develop a robust machine-learning framework tailored to forecast student performance in Portuguese language courses, leveraging dependable data reservoirs. Through the strategic utilization of the Multilayer Perceptron Classification (MLPC) methodology, this study embarked on a path of innovation, ingeniously amalgamating two optimization algorithms: the Pelican Optimization Algorithm (POA) and the Crystal Structure Algorithm (CSA). This unique integration sought to improve both the accuracy and precision of the estimative model, thereby enriching the efficacy of prognostications regarding student performance. MLPC is chosen for predicting and classifying student performance in Portuguese language learning due to its ability to capture complex patterns inherent in language acquisition processes. By accommodating non-linear relationships between various factors influencing language proficiency and automatically learning feature representations from diverse datasets, MLPC offers scalability and robust generalization to unseen data. Moreover, its capacity for fine-tuning and potential for interpretability allows for continuous model improvement and insights into the determinants of student performance. Consequently, MLPC is a valuable tool for educators and stakeholders in effectively assessing and addressing student needs in Portuguese language education.

II. Materials and Methods

A. Data Gathering

As previously elucidated, the prognostication of students' academic performance is shaped not only by their quiz outcomes, fulfilment of homework assignments, and engagement in class activities but also by the external circumstances they encounter outside the confines of the educational institution. For example, their family situation, the size of their family ($famsize$), family support ($famsup$), their health status, the amount of time spent on social media, their parents' occupation ($Fjob/Mjob$), and other relevant factors. Each of these terms influences the students' conditions in the classroom. However, the educational system's responsibility is to diagnose these factors, treat students according to their situations, act according to their talents, address their weaknesses, and capitalize on their strengths. The following diagram delineates the interplay between input and

output variables. Notably, the school manifests a direct correlation with sex, suggesting the insignificance of students' gender. Likewise, while travel time lacks a direct association with students' failure, it does exert a marginal effect.

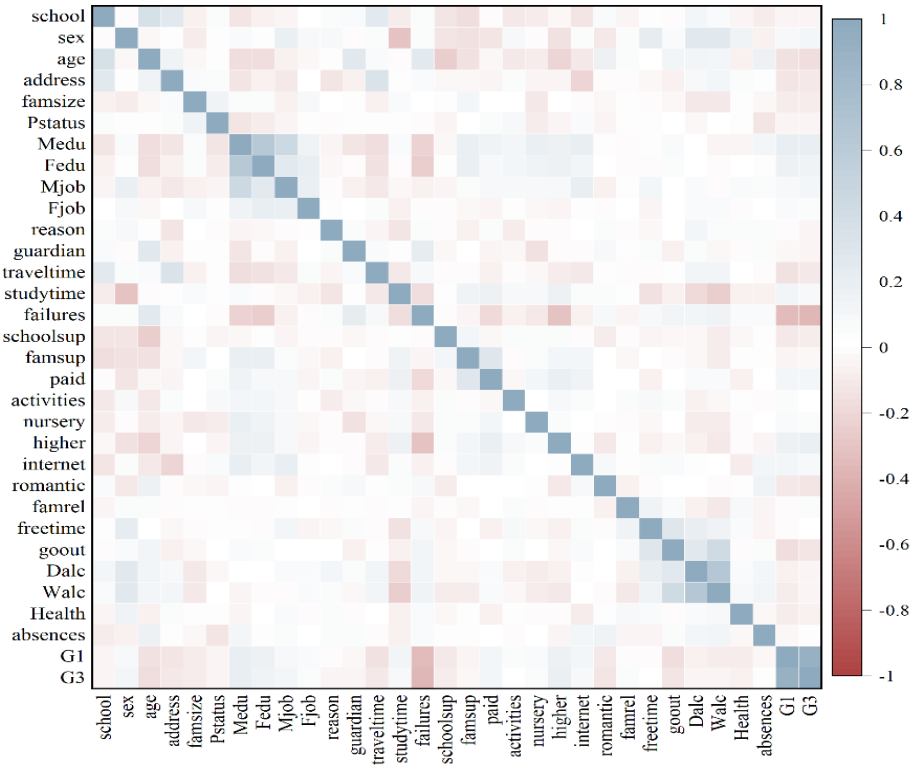

Fig. 1. Correlation matrix for the input and output variables.

Furthermore, study time exhibits no correlation with gender or school. In conclusion, although the diagnosis of these elements initially influences the prediction of students' performance, it is crucial to emphasize that none of these factors operates in isolation; instead, their effectiveness relies on the collaborative engagement of each student. Fig. 1 exhibits the correlation matrix for the in/output variables.

B. Multilayer Perceptron Classifier (MLPC)

Based on the concepts of neural network design, the Multilayer Perceptron Classifier (MLPC) is a particular kind of feed-forward artificial neural network (ANN) classifier. The MLPC in this configuration is made up of several layers of nodes, each of which is intimately linked to the network's next layer. Because of its architecture, the network can analyze and alter incoming data over a series of layers, which makes it possible for the MLPC to identify intricate patterns and correlations in the data. The nodes in the input layer of the MLPC represent the input data. Every node after it in the network uses its weight (shorthand for w) and an offset b to conduct a linear selection of the input as the data moves through the network. After this combination, an activation function transfers the input to the output. For improved clarity and illustration, this procedure may be concisely described in matrix form in the case of an MLPC with $K + 1$ layers [26].

$$y(x) = f_k(\dots f_2(w_2^T f_1(w_1^T + b_1) + b_2) \dots + b_k) \quad (1)$$

Nodes inside the middle layer use the logistic or stochastic algorithm:

$$f(z_i) = \frac{1}{1 + e^{-z_i}} \quad (2)$$

The results of the layer's nodes use the $softmax$ feature:

$$f(z_i) = \frac{e_{z^i}}{\sum_{K-1}^{N} e^{z_k}} \quad (3)$$

The number of classes and nodes in the output layer has the matches.

C. Crystal Structure Algorithm (CSA)

Crystals are minerals with a structured composition that exhibit three regularly repeating or ordered crystalline dimensions. Crystalline solids can take on various sizes and shapes, and their properties may be either isotropic or anisotropic [27]. Crystals consist of small particles with well-defined shapes. Numerous physical and chemical compositions have been explored and suggested through experimentation. Moreover, crystals' complex symmetries and characteristics have profoundly influenced diverse human creations, including mechanisms, structures, and artworks. This article employs the Bravais model to explain the crystal structure. In this model, infinite lattice geometry is examined, and the periodic arrangement described by the lattice geometry, along with the vector of the lattice positions, is defined as follows:

$$l = \sum m_i e_i \quad (4)$$

where e_i is the minimum vector of the principal crystal directions, m_i is the and i is the angular number of the

$crystal$. Here, the basic idea of $Crystal$ is presented with appropriate modifications for the $CryStAl$ mathematical model. In this model, every candidate solution of the optimization method is likened to a distinct crystal space. To initiate the $cycle$, an arbitrary number of precious stones is selected.

$$\begin{bmatrix} cl_1 \\ cl_2 \\ \vdots \\ cl_i \\ \vdots \\ cl_m \end{bmatrix} = \begin{bmatrix} x_1^1 \dots & x_1^j \dots & x_1^p \\ x_2^1 \dots & x_2^2 \dots & x_2^p \\ \vdots & \vdots & \vdots \\ x_i^1 \dots & x_i^2 \dots & x_i^p \\ \vdots & \vdots & \vdots \\ x_m^1 \dots & x_m^2 \dots & x_m^p \end{bmatrix}, \begin{cases} i = 1,2,3, \dots, m \\ j = 1,2,3, \dots, p \end{cases} \quad (5)$$

where m is the candidate solution, and p is the dimension of the problem. Within the search space, the initial positions of these crystals are determined randomly by:

$$x_i^j(0) = x_{i,min}^j + \delta\left(x_{i,max}^j - x_{i,min}^j\right), \begin{cases} i = 1,2,3, \dots, m \\ j = 1,2,3, \dots, p \end{cases} \quad (6)$$

where, $x_i^j(0)$ characterizes the starting gem position, the least and greatest permitted values are characterized as $x_{i,max}^j$ and $x_{i,min}^j$ separately, the jth choice variable of the ith candidate arrangement is within the indicated ς. Based on the crystallographic concept of the $base$, the primary crystals are all corner crystals. cl_{main} randomly determined considering the first generated crystal. In addition, the c_l the current value is ignored, and a random extraction method is set for each tread. $Crystals$ with optimal configuration determined by cl_z. S_u represents the mean of randomly selected crystals. To monitor the position of a candidate solution in the search space, four types of update procedures are established based on fundamental network principles:

Simple cubic;

$$cl_{new} = cl_{main} + cl_{old} \quad (7)$$

Best crystal cubicle;

$$cl_{new} = l_1 cl_{lmain} + l_2 cl_z + cl_{old} \quad (8)$$

Mean crystal cubicle;

$$cl_{new} = l_1 cl_{lmain} + l_2 S_u + cl_{old} \quad (9)$$

M&B crystal cubicle;

$$cl_{new} = cl_{old} + l_1 cl_{lmain} + l_2 cl_z + l_3 S_u \quad (10)$$

In the above formula, the old position is given by cl_{old} and the new position is denoted by cl_{new} and the random numbers are denoted by $l, l_1, l_2, and\ l_3$. Mining and exploration are the two main elements of metaheuristics, and it is worth mentioning that they have beesn tested in Eq. (7) to (10), where global and local searches are performed simultaneously. To deal with variable solutions x_i^j that violate the variable limit requirements, a mathematical flag is created that requires adjustment of the variable limits, causing problems with x_i^j they are exceeding the variable range. The termination criteria depend on the maximum number of iterations, which determines when the optimization process concludes after a fixed number of iterations [28], [29].

D. Pelican Optimization Algorithm (POA)

The researchers identified a population-based optimization method, known as the POA, which draws inspiration from pelicans [30]. The method employs a simulation of evolutionary processes within an ecological system, wherein pelicans are seen as single entities within a larger population. Every person represents a possible solution and provides optimization recommendations, which arise from adjusting the issue variable according to the position of each person in the search area. In order to ensure the variety of the population and improve the global search capacity, each member is randomly initialized within the stated upper and lower limits of the issue during the population initialization procedure, as illustrated in Eq. (11).

$$x_{i,j} = l_j + rand.\left(u_j - l_j\right), i = 1,2, \dots, N, \quad j = 1,2, \dots, m \quad (11)$$

Where N is the number of population members, m is the number of issue variables, $rand$ is a random integer in the interval $[0, 1]$, l_j is the jth lower bound, and u_j is the jth upper limit of problem variables. The values of the variables indicated by the ith candidate solution are represented by the variables $x_{i,j}$. Eq. (12) uses a matrix known as the population matrix to identify the pelican population members in the proposed POA. The columns of this matrix show the suggested values for the issue variables, and each row indicates a potential solution.

$$X = \begin{bmatrix} X_1 \\ \vdots \\ X_i \\ \vdots \\ X_N \end{bmatrix}_{N \times m} = \begin{bmatrix} x_{1,1} & \cdots & x_{1,j} & \cdots & x_{1,m} \\ \vdots & \ddots & \vdots & & \vdots \\ x_{i,1} & \dots & x_{i,j} & \cdots & x_{i,m} \\ \vdots & & \vdots & \ddots & \vdots \\ x_{N,1} & \dots & x_{N,j} & \cdots & x_{N,m} \end{bmatrix}_{N \times m} \quad (12)$$

If X_i is the ith pelican, and X is the pelican population matrix. A potential fix for the stated issue is the planned POA, in which every member of the population is a pelican. Thus, assessing the given issue's objective function is possible by considering each potential solution. The objective function vector in Eq. (13) is used to derive the values obtained for the objective function.

$$F = \begin{bmatrix} F_1 \\ \vdots \\ F_i \\ \vdots \\ F_N \end{bmatrix}_{N \times 1} = \begin{bmatrix} F(X_1) \\ \vdots \\ F(X_i) \\ \vdots \\ F(X_N) \end{bmatrix}_{N \times 1} \quad (13)$$

where, F_i is the objective function value of the ith candidate solution, and F is the objective function vector. To update potential answers, the suggested POA mimics the tactics and behaviour of pelicans during hunting and assault. There are two phases to simulating this hunting strategy: i Approaching the prey (the period of exploration). ii Winging during the exploitation phase on the water's surface.

1) Phase 1 (exploration phase): approaching the prey: The initial stage of the process involves the pelicans locating

the prey and then approaching it. Search space scanning and the exploration capability of the suggested POA in locating various search space regions are made possible by modelling this pelican approach. The fact that the prey's position is produced is crucial to POA.

$$x_{i,j}^{P_1} = \begin{cases} x_{i,j} + rand.(p_j - I.x_{i,j}), & F_P < F_i; \\ x_{i,j} + rand.(x_{i,j} - p_j), & else, \end{cases} \quad (14)$$

Where x^{P1}. In the context of Eq. (14), the importance of the variable can be observed $x_{i,j}^{P_1}$, an updated state of the pelican in the jth dimension is represented by the result of stage 1, and this can be the ith pelican. To introduce additional diversity and exploration, the value of I is introduced as a random number ranging between one and two. Also, the parameter pj, the position of the prey, is employed to be denoted jth dimension, while F_P the objective function value of the prey is represented. By incorporating Eq. (15), the process can be effectively simulated and modelled.

$$X_i = \begin{cases} X_i^{P_1}, F_i^{P_1} < F_i; \\ X_i \quad else, \end{cases} \quad (15)$$

Where X^{P_1}. This is the updated status for the F^{P_1} and ith pelican. The goal function is based on values pertaining to the phase.

2) Phase 2: winging on the water surface (exploitation phase): In the subsequent stage, the pelicans gather their meal in their throat pouches after reaching the water's surface and spreading their wings to push the fish upward. This tactic helps pelicans catch more fish in the assaulted region. As a result of simulating this pelican behaviour, the suggested POA converges to more advantageous locations inside the hunting region. The exploitation potential and local search power of POA are enhanced by this method. From a mathematical perspective, the algorithm must look at the points surrounding the pelican position to converge to an optimal solution. Eq. (16) simulates the hunting behaviour of pelicans mathematically.

$$x_{i,j}^{P_2} = x_{i,j} + R\left(1 - \frac{t}{T}\right).(2.rand - 1).x_{,j} \quad (16)$$

Where X^{P_2}, based on phase 2, i,j represents the ith pelican's new state in the jth dimension. $x_{i,j}, s$ neighbourhood radius is given by $R\left(1 - \frac{t}{T}\right)$, which is equal to 0.2 . T represents the maximum number of iterations and iteration counter. The exponent $R\left(1 - \frac{t}{T}\right)$ reflects the local search radius for the population members' neighbourhoods. Close to every participant to arrive at an improved answer. This coefficient works well on the POA exploitation power to reach the ideal global solution. Since this coefficient is highly valued in the first iterations, a bigger region is considered around each member. The $R\left(1 - \frac{t}{T}\right)$ The coefficient falls as the method replicates more, resulting in smaller radii for each neighbourhood member. For the POA to converge to solutions that are closer to the global (and even precisely global) ideal based on the utilization notion, this enables us to scan the region surrounding each member of the population in smaller and more precise stages. Eq. (17) models the new pelican posture, which has also been accepted or rejected at this stage by successful updating.

$$X_i = \begin{cases} X_i^{P_2}, F_i^{P_2} < F_i; \\ X_i, \quad else, \end{cases} \quad (17)$$

where X^{P_2}. This is the updated status for the F^{P_2} and ith pelican. Its goal function is value-based, and i on stage 2.

3) Steps repetition, pseudo-code, and flowchart of the proposed POA: The best candidate solution up to this point will be updated after all population members have been updated based on the first and second phases, the population's new status, and the values of the goal function. When the algorithm reaches the next iteration, the stages of the suggested POA are based on Eq. (15) to (17) are repeated until the execution is finished. Lastly, a quasi-optimal solution to the given issue is offered using the best candidate solution found throughout the algorithm rounds.

E. Performance Evaluators

When evaluating a classifier's performance, it is essential to consider multiple criteria to obtain a thorough insight into its effectiveness. These criteria function as metrics, providing insights into various aspects of the classifier's performance and enabling a nuanced assessment. Here are some crucial factors to consider:

- Accuracy: A frequently employed metric measures the classifier's efficiency by determining the percentage of accurately predicted samples.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (18)$$

- Recall: Recall quantifies the proportion of correctly predicted positive instances in relation to all actual positive instances.

$$Recall = TPR = \frac{TP}{P} = \frac{TP}{TP + FN} \quad (19)$$

- Precision: Precision centres on the precision of positive predictions, evaluating the probability that instances identified as positive are indeed accurate. This metric is particularly valuable when the cost of false positives is significant.

$$Precision = \frac{TP}{TP + FP} \quad (20)$$

- F1-score: The combination of Precision and Recall yields a composite measure recognized as the f1-score.

$$F1\ score = \frac{2 \times Recall \times Precision}{Recall + Precision} \quad (21)$$

In Eq. (18) to (21), TP represents a positive prediction that correctly corresponds to the actual positive outcome. FP denotes a positive prediction when the actual outcome is negative. FN is used to indicate a negative prediction when the

actual outcome is positive, while TN represents a negative prediction that accurately aligns with the actual negative outcome.

III. RESULT

A. Hyperparameters and Convergence Curve Results

Hyperparameters are external settings that encompass vital factors like learning rates and regularization strengths, exerting significant influence over a behavior of model. They are predetermined values and are not directly inferred from the dataset itself. Maximizing model performance relies heavily on the indispensable task of fine-tuning hyperparameters, which necessitates rigorous experimentation and the adept application of optimization methodologies. The results of the hyperparameters for MLPC-based hybrid models (MLPO and MLCS) are represented in Table I for G2 and Table II for G3 values. The hyperparameter of the MLPC-based models is Layer_size. This comprehensive exposition substantially enhances the transparency and reproducibility of models within the field of machine learning research, furnishing invaluable insights that deepen understanding and facilitate precise replication of model configurations.

This study aims to forecast learners' academic achievement throughout the educational program to improve their skills and increase their chances of success. The MLPC model, which combines the two optimizers known as POA optimization and CSA, is presented to achieve this aim. The model has a favourable impact on the prediction of pupil achievement. In this study, two novel models, MLCS and MLPO, are generated by integrating the foundational model, MLPC, with optimizers to enhance prognostic capabilities further. This section encompasses a comparative analysis to determine the relative effectiveness of each model over the others. A hybrid model's convergence is typically understood to signify that it has reached its peak throughout the training process. When a machine learning algorithm gets to a point where more iterations of training do not significantly improve the model's performance on the training set, it stabilizes its parameters and becomes a convergent state. This is especially true for complex models like hybrid models. In the context of hybrid models, characterized by incorporating multiple model or technique types, achieving convergence necessitates verification that each constituent functions as intended and that the model achieves overall prediction consistency. The monitoring of convergence during the training phase commonly involves observing effectiveness indicators or examining loss functions on a validated dataset. Rapid convergence is imperative for a hybrid model to comprehend knowledge structures and effectively generalize its findings to novel, unseen data. Fig. 2 and 3 comprehensively compare models across two distinct targets, G2 and G3, encompassing three layers. In the initial layer of the G2 target, the MLCS model achieves stability at a core value of 0.889 within 90 iterations, in contrast to the MLPO model, which attains stability at a point of 0.899 in 120 iterations.

Although the MLPO model maintains a higher accuracy than the MLCS model in the second layer, achieving stability at 0.939 within 130 iterations, compared to the MLCS model's accuracy of 0.927 measured in 128 iterations. Examination of the third layer underscores the MLPO model's superior accuracy in the G2 target, reaching an estimated value of 0.919 within 130 iterations, in contrast to the MLCS model, with a measured value of 0.904 in 150 iterations. Incidentally, in the first layer of the G3 target, the MLCS model, with an accuracy of 0.861 measured in 148 iterations, is surpassed by the MLPO model, which achieves a higher accuracy of 0.878 within 150 iterations. Subsequently, in the second layer, the MLCS model reaches a level of 0.901 in the 90th iteration; however, the MLPO model outperforms it with an accuracy of 0.914 measured in the 148th iteration. Ultimately, in the third layer, the MLPO model attains an accuracy of 0.891 after 150 iterations. Conversely, the MLCS model exhibits weaker performance with a lower accuracy measurement than the MLPO model. Ultimately, the current line plot reveals that higher accuracy is achieved by the POA optimizer when combined with the base model across three layers of two targets.

B. Results of Predictive Models

Table III delineates measured values of accuracy, precision, recall, and F1 score across three phases—namely, train, test, and all—within the G2 and G3 targets, each comprising three layers. For instance, during the training phase, the MLPO model exhibits values of 0.910, 0.913, 0.910, and 0.909 for accuracy, precision, recall, and F1-score, respectively. In contrast, the MLCS model in the training phase records values of 0.906, 0.910, 0.906, and 0.905 for the corresponding metrics. This comparative analysis underscores that the MLPO model consistently attains higher accuracy in each of the four metrics than the MLCS model in the same phase. However, during the test phase for both models, precision emerged as the metric with the highest value, specifically registering at 0.888 for the MLPO model and 0.863 for the MLCS model.

Incidentally, in the second layer, the aggregate precision value in the MLPO model is 0.940, surpassing the corresponding value of 0.927 in the opposing model. Notably, the MLCS model maintains uniform values across all phases for three metrics—accuracy, precision, and recall—except for the F1-score, where it records a lower value of 0.926, indicating inferior accuracy compared to other metrics. In the final layer, the MLPO model achieves accuracy values of 0.931 and 0.890 in the train and test phases, respectively.

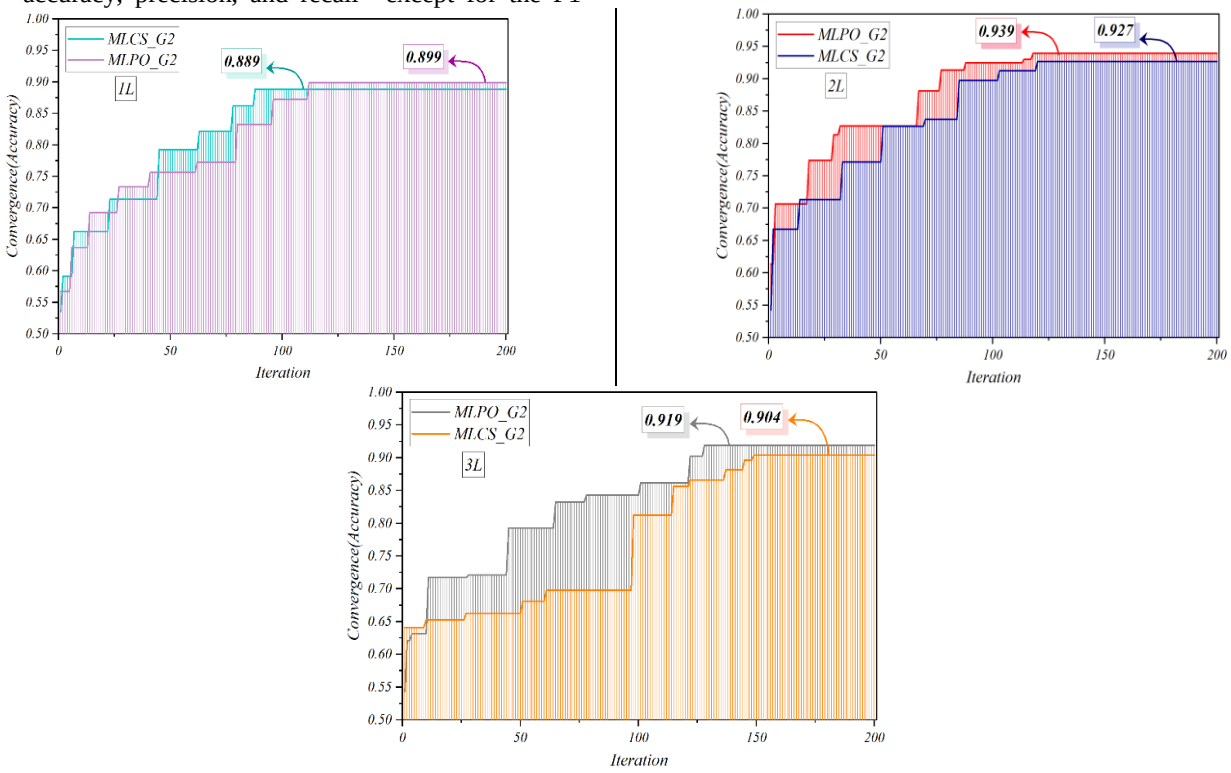

Fig. 2. Line plot for convergence of hybrid models for G2 values.

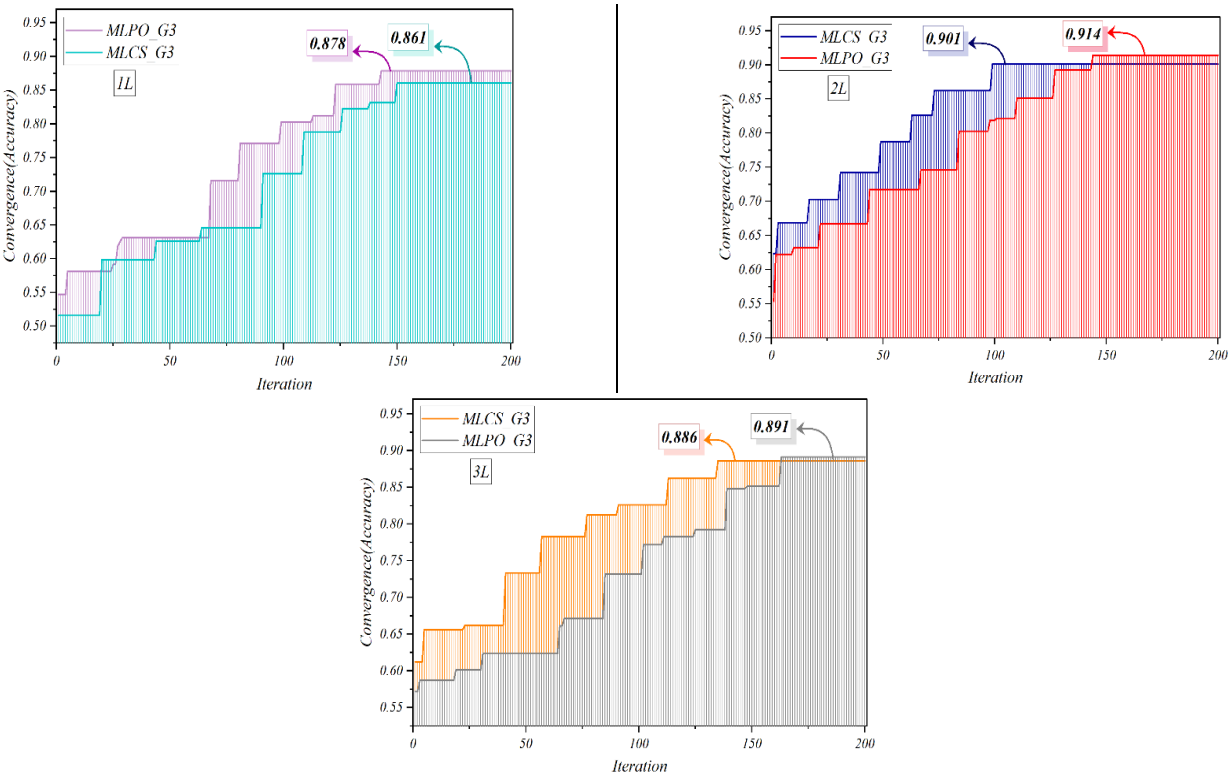

Fig. 3. Line plot for convergence of hybrid models for G3 values.

TABLE III. RESULT OF PRESENTED MODEL FOR G2

Model	Section	Index values			
		Accuracy	*Precision*	*Recall*	*F1_score*
MLPO (1)	Train	0.910	0.913	0.910	0.909
	Test	0.873	0.888	0.873	0.870
	All	0.899	0.905	0.899	0.898
MLCS (1)	Train	0.906	0.910	0.906	0.905
	Test	0.847	0.863	0.848	0.846
	All	0.889	0.892	0.889	0.888
MLPO (2)	Train	0.953	0.954	0.953	0.953
	Test	0.907	0.9079	0.907	0.903
	All	0.939	0.940	0.939	0.939
MLCS (2)	Train	0.946	0.949	0.946	0.945
	Test	0.881	0.891	0.881	0.878
	All	0.927	0.927	0.927	0.926
MLPO(3)	Train	0.931	0.934	0.931	0.932
	Test	0.890	0.893	0.890	0.886
	All	0.919	0.921	0.919	0.919
MLCS (3)	Train	0.921	0.921	0.921	0.920
	Test	0.864	0.873	0.864	0.865
	All	0.904	0.905	0.904	0.904

In contrast, the MLCS model exhibits values of 0.921 and 0.864 for the corresponding terms in the train and test phases, illustrating that, in both terms and phases, the MLPO model consistently outperforms the MLCS model in accuracy. In summary, it is noteworthy that the MLPO model demonstrates superior performance compared to the MLCS model. Examining two models within the G3 target across three layers reveals that the MLPO model consistently maintains higher accuracy than its counterpart. For instance, in the recall term during the training phase, the MLPO model achieves a value of 0.892, whereas the MLCS model records a slightly lower value of 0.888. Similarly, in the F1-score metric, the MLPO model attains a value of 0.890, surpassing the MLCS model's F1-score of 0.886. This subtle comparison unequivocally underscores the MLPO model's superior accuracy compared to the MLCS model. Concerning the second layer, the accuracy values in the test phase for the MLPO and MLCS models are 0.864 and 0.856, respectively. Additionally, the precision values of the MLPO and MLCS models are 0.873 and 0.866, respectively. This observation signifies that the accuracy of the MLPO model surpasses that of the opposing model. Moreover, the MLPO model exhibits superior performance in the third layer. For a more thorough comprehension, it is noteworthy that the accuracy and precision values of the MLPO model across all phases are higher than the corresponding values of the MLCS model, with the accuracy comparison being 0.891 > 0.886. Ultimately, the accuracy of the MLPO model surpasses that of the MLCS model in each layer of both targets. This comparison is presented in Table IV for further examination.

C. Results of Classification Processes

The comparison between the MLPO and MLCS models in two targets is illustrated in Tables V and VI, elucidating the layer-wise accuracy of each model. Analogous to the preceding tables, these tables contrast grades instead of phases. Notably, the precision values of the MLPO model in the excellent grade across the first, second, and third layers are recorded as 0.77, 0.88, and 0.84, respectively. This observation suggests that the model's optimal performance is evident in the second layer, outperforming the other layers. The recall values for the good and acceptable grades in the MLPO model are 0.64 and 0.88 in the first layer, 0.76 and 0.88 in the second layer, and 0.76 and 0.88 in the third layer. This implies that the performance of the MLPO model is consistent in the second and third layers, while it is comparatively lower in the first layer. In the first layer, MLCS exhibits precision values of 0.74 and 0.96 for the acceptable and poor grades, respectively. In the second layer, the corresponding precision values are 0.85 and 0.96; in the third layer, they are 0.86 and 0.94, respectively. This analysis indicates that the model achieves higher accuracy in the third layer for the acceptable grade, surpassing the accuracy in the first and second layers. However, in the case of poor grades, the functionality is optimal in the first and second layers, contrasting with the third. It is pertinent to note that this comparison pertains to the G2 target. Contrastingly, within the G3 target, the recall values for the MLPO model in the first layer are 0.76 for excellent grade and 0.65 for good grade; in the second layer, they are 0.87 for excellent grade and 0.78 for good grade, and in the last layer, they are 0.81 for excellent grade and 0.83 for good grade. These statistics reveal that the model demonstrates heightened accuracy in the excellent grade of the second layer compared to the other layers. However, in the context of the good grade, the second layer exhibits superior functionality compared to the first and third layers.

	Acceptable	0.79	0.87	0.83
	Poor	0.95	0.95	0.95

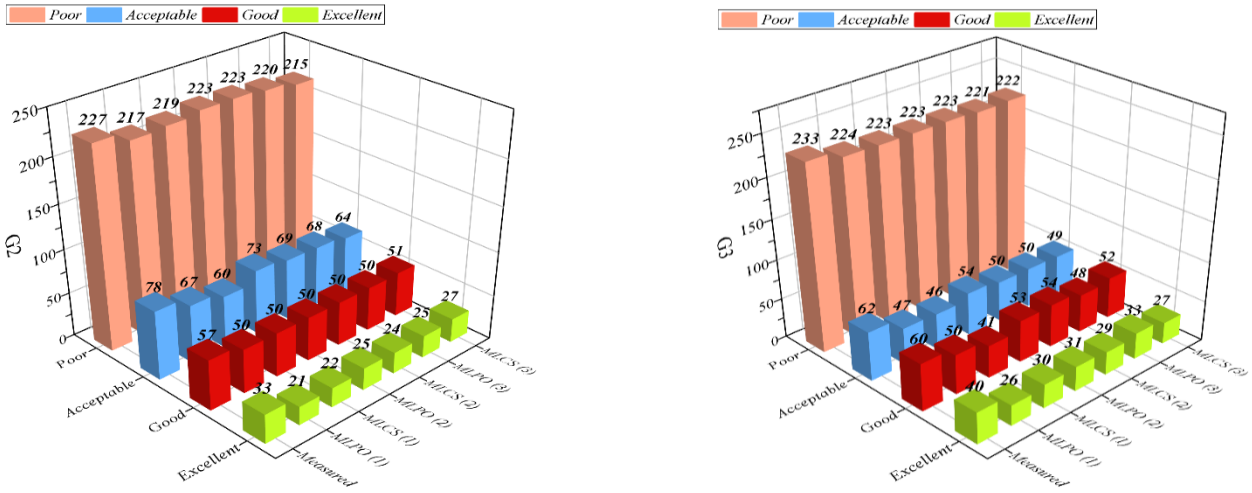

Fig. 4. 3D Bars plot for comparing the measured and predicted values.

Conversely, the recall values of the MLCS model in the first layer are 0.74 for excellent grade and 0.75 for good grade; in the second layer, they are 0.81 for excellent grade and 0.73 for good grade, and in the last layer, they are 0.79 for excellent grade and 0.68 for good grade. These figures suggest that the MLCS model exhibits enhanced functionality in the excellent grade of the second layer. However, concerning the good grade, it is noteworthy to emphasize that this model in the first layer attains higher accuracy than the second and third layers.

Fig. 4 delineates the comparison between each layer's measured and predicted values for the MLPO and MLCS models in the G2 and G3 targets. The illustration of this plot reveals that the accuracy of the MLPO model in the first layer attains 21 out of 33 measured values. In the second layer, it

achieves 25 out of 33 measured values; in the last layer, it similarly attains 25 out of 33 measured values. This observation underscores that the MLPO model demonstrates the highest accuracy in the excellent grade for the second and third layers, surpassing the accuracy observed in the first layer. Nevertheless, in the good grade, the accuracy of the MLPO and MLCS models across all three layers is recorded at 50 out of 57 measured values, except for MLCS in the third layer, which achieves a measured value of 51 out of 57. It is discernible that this model exhibits superior functionality in the third layer compared to other models across all three layers.

Regarding the acceptable grade, the MLPO model attains the highest accuracy in the second layer, with 73 out of 78 measured values. The second-highest accuracy in the same layer is observed for the MLCS model, recording 69 out of 78 measured values. In contrast, the third-highest accuracy is attributed to the MLPO model in the first layer, achieving a measured value of 67 out of 78. The comparative analysis elucidates that superior performance is evident in both models within the second layer when contrasted with other models in different layers. Nevertheless, within the same target, the measured value of the MLCS model in the third layer amounts to 215 out of 227, indicative of the lowest measured value across all layers among the models. The second-highest performance is attributed to the MLPO model in the first layer, achieving a measured value of 217 out of 227, while the third-highest performance is observed for the MLCS model in the same layer.

On the contrary, ascendancy is asserted by both the MLPO and MLCS models in the second layer, attaining 223 out of 227 measured values. In the subsequent target, parity is observed between the MLCS and MLPO models in the second layer and the MLCS model in the first layer, registering 223 out of 233 measured values. However, the MLPO model in the first layer stands out with the highest accuracy, recording 224 out of 233 measured values, particularly notable in the context of the poor grade. For the acceptable grade, equivalence is noted as both models in the third and second layers exhibit identical measured values of 50 out of 62, representing the maximum accuracy among models across all three layers. The MLCS model in the third layer achieves the second-highest performance, recording 49 out of 62 measured values.

Conversely, the least favourable measured value is attributed to the MLCS model in the first layer. Notably, in the good grade, optimal performance is observed in the MLCS model within the second layer, achieving the highest measured value of 54 out of 60. In contrast, the least favourable performance in this grade is associated with the same model but in the first layer, registering 41 out of 60 measured values. In the highest grade, excellent, the highest accuracy is attained by the MLPO model in the third layer, achieving 33 out of 40 measured values. The second-highest performance in this grade is noted for the MLPO model in the second layer, with a measured value of 31 out of 40. In contrast, the third-highest performance is attributed to the MLCS model in the first layer, recording 30 out of 40 measured values. The lowest performance in the excellent grade is associated with the MLPO model in the first layer, registering 26 out of 40 measured values.

The accuracy of the models in the confusion matrix across all three layers for two targets is depicted in Fig. 5 and 6. The performance of the MLPO models in the G2 target, specifically in layer one, is observed. In instances characterized by a suboptimal grade, the recorded value is 217 out of 227, reflecting a difference of 4.5%. Additionally, nine students are misclassified in an acceptable grade and one in a good grade. Similarly, within the same layer, the value for acceptable grades is 67 out of 78, indicating a difference of 15.17%. In this context, ten students are misclassified as having a poor grade and one as having a good grade. The MLCS model's measured value in the second layer of a suboptimal grade is 219 out of 223, reflecting a marginal difference of 1.81%. This outcome entails misclassifying five students in an acceptable grade, two in a good grade, and one in an excellent grade.

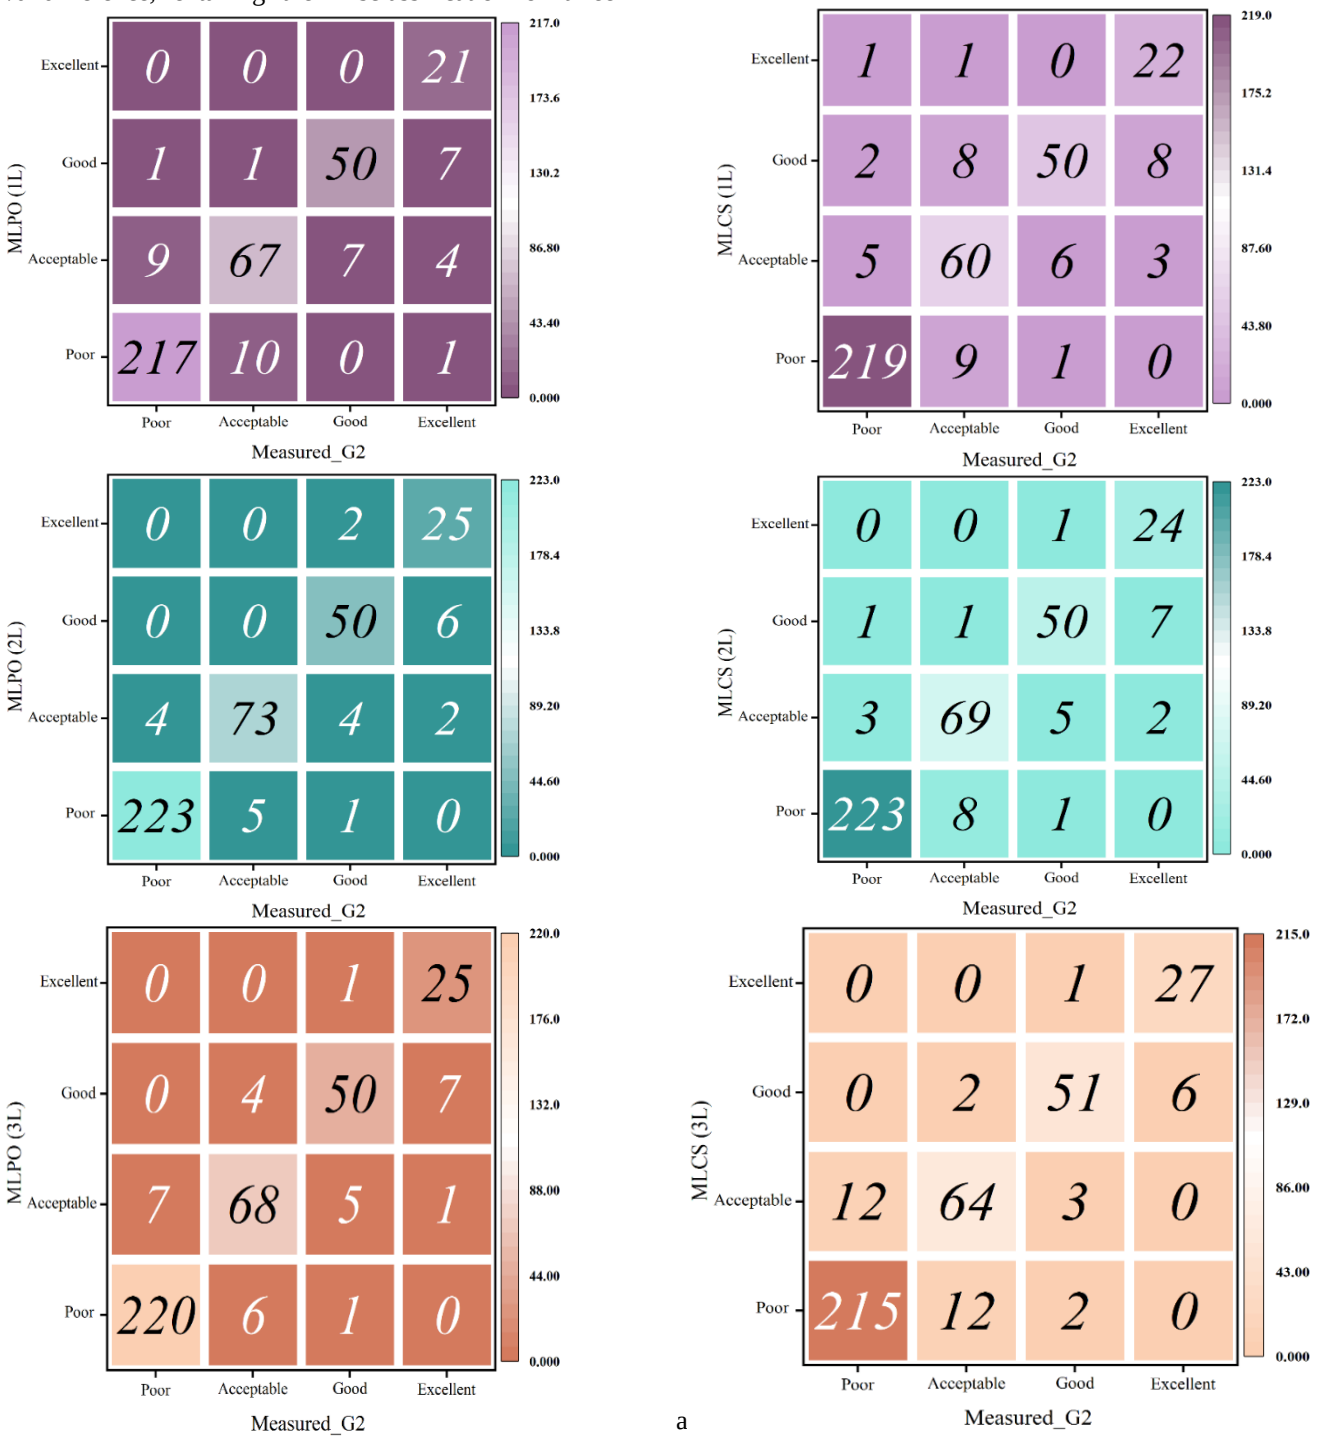
Conversely, the measured value for acceptable grades in the first layer is 60 out of 62, with a difference of 3.28%, accompanied by the misclassification of nine students with poor grades, eight with good grades, and one with excellent grades. Furthermore, in the second layer, the measured value of the MLPO model in a good grade is 50 out of 60, demonstrating an 18.18% difference and involving the misclassification of two students in an excellent grade, four in an acceptable grade, and one in a good grade. Incidentally, within the G2 target of an excellent grade, the MLPO model exhibits a difference of 27.59% in the second layer, entailing the misclassification of six students in a good grade and two students in an acceptable grade. Conversely, the MLCS model in the G3 target of the current grade manifests a 50% difference, accompanied by the misclassification of seven students in a good grade and two in an acceptable grade. Additionally, in the G2 target, the MLPO model in a poor grade of the second layer demonstrates a 5.74% difference, resulting in the misclassification of seven students in an acceptable grade. Simultaneously, within an acceptable grade, it showcases a 6.62% difference, leading to the misclassification of five students with poor grades.

Regarding the good grade, it is imperative to note that it exhibits a 13.8% difference, resulting in the misclassification of four students in an acceptable grade, one in a poor grade, and two in an excellent grade. In the same target and layer, the MLCS model demonstrates a 1.78% difference in the poor grade category, leading to the misclassification of three students in an acceptable grade and one in a good grade. Meanwhile, a 12.24% difference is observed for the acceptable grade, entailing the misclassification of one student in a good grade and eight students in a poor grade. In the third layer of the G2 target, the MLPO model is observed to misclassify seven students with a good grade and one student with an acceptable grade, reflecting a 27.59% difference. This denotes the performance of the current model in an excellent grade.

Conversely, the MLCS model in the same target, layer, and grade exhibits a 20% difference, accompanied by the misclassification of six students with good grades. Upon reaching the G3 target and assessing the models' performance in the first layer, a discernible discrepancy is observed between the MLCS model and the MLPO model in the context of an excellent grade. Specifically, the MLPO model manifests a substantial 42.4% difference in an excellent grade,

accompanied by the misclassification of eleven students in a good grade, one in an acceptable grade, and two in a poor grade. In contrast, the MLCS model exhibits a 28.57% difference, misclassifying eight students with good grades and two with acceptable grades. In the second layer, the MLPO model demonstrates a 12.39% difference, with the misclassification of two students in an excellent grade, two in an acceptable grade, and one in a poor grade.

Conversely, the MLCS model in the same layer features a 10.53% difference, entailing the misclassification of three students with excellent grades and three with acceptable grades. Nevertheless, a singular examination of one stage for each model might suggest that the MLCS model exhibits superior accuracy compared to the alternative model. However, when considering the comprehensive assessment across all layers, it becomes apparent that the functionality of the MLPO model surpasses that of the MLCS model in each respective layer.



a

Fig. 5. Confusion matrix for accuracy of each model for G2 values.

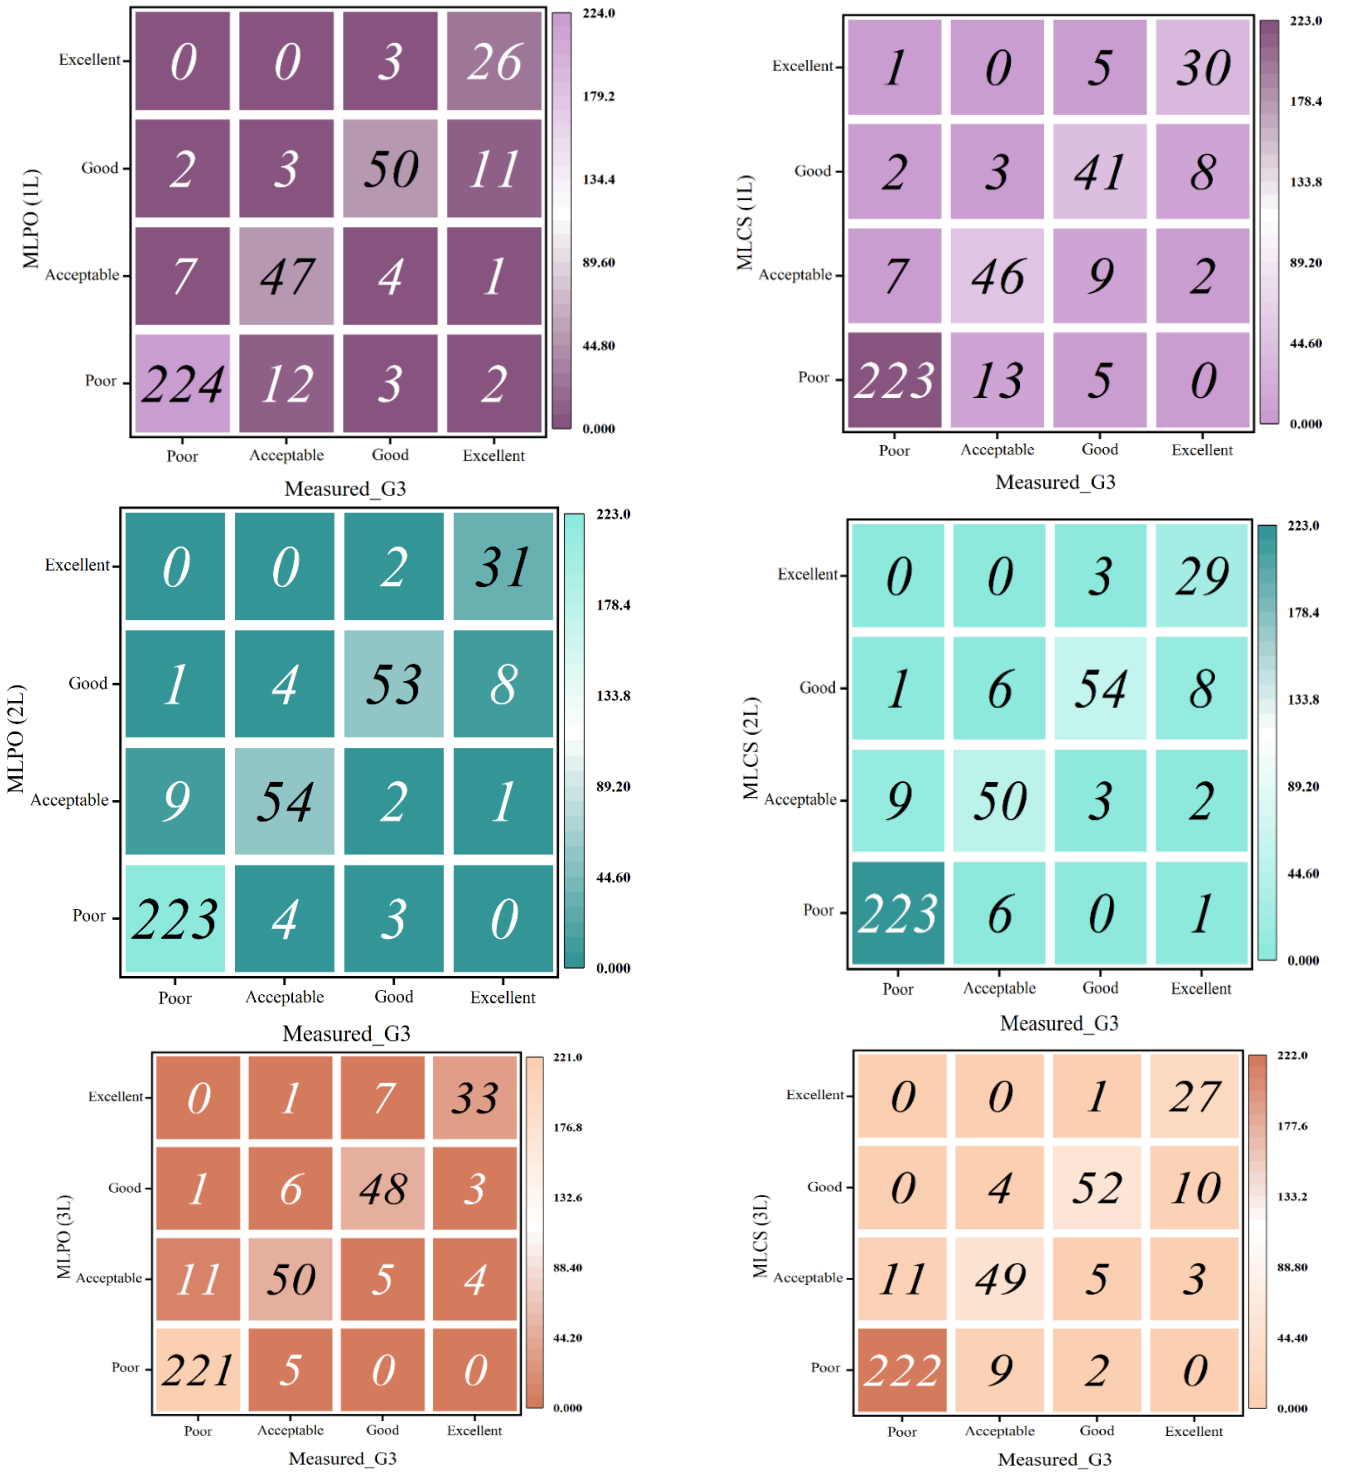


Fig. 6. Confusion matrix for accuracy of each model accuracy for G3 values.

The subsequent column plot illustrates the percentage achievements of the developed models. Specifically, within the G2 target, the MLPO model in the second layer attains the highest accuracy at 0.93924, followed by the MLCS model in the same layer with a percentage of 0.92658, securing the second rank. The MLPO model in the third layer holds the third rank with a percentage of 0.91899. This concise comparison indicates that the MLPO model in the second layer exhibits superior functionality compared to the other layers. Nevertheless, the MLPO model in the second layer is characterized by superior precision relative to the other models, achieving a percentage of 0.9395. The MLCS model in the second layer and the MLPO model in the third layer secure the second and third ranks, respectively, with percentages of 0.9274 and 0.9214, respectively.

Additionally, the recall and F1-score values of the MLPO model, standing at 0.9392 and 0.9385, surpass those of the alternative models. In summary, the performance of MLPO L2 not only outperforms the MLCS model but also exceeds its performance in other layers. Upon a cursory examination, it becomes evident that MLPO L2 in the G3 target attains elevated accuracy, precision, recall, and F1-score values. The column plots in Fig. 7 and 8 illustrate the achievement percentage for developed models as assessed by evaluators.

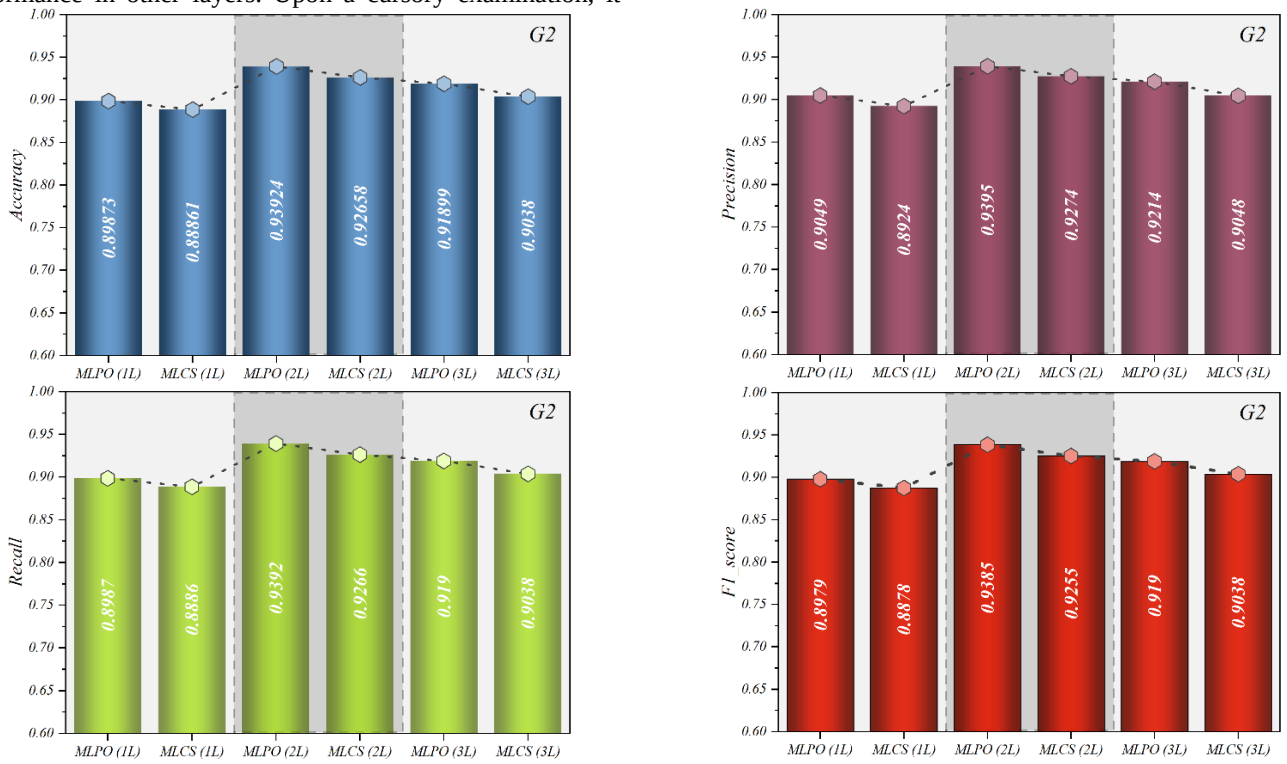

Fig. 7. Column plots the achievement percentage for developed models of G2 prediction values based on evaluators.

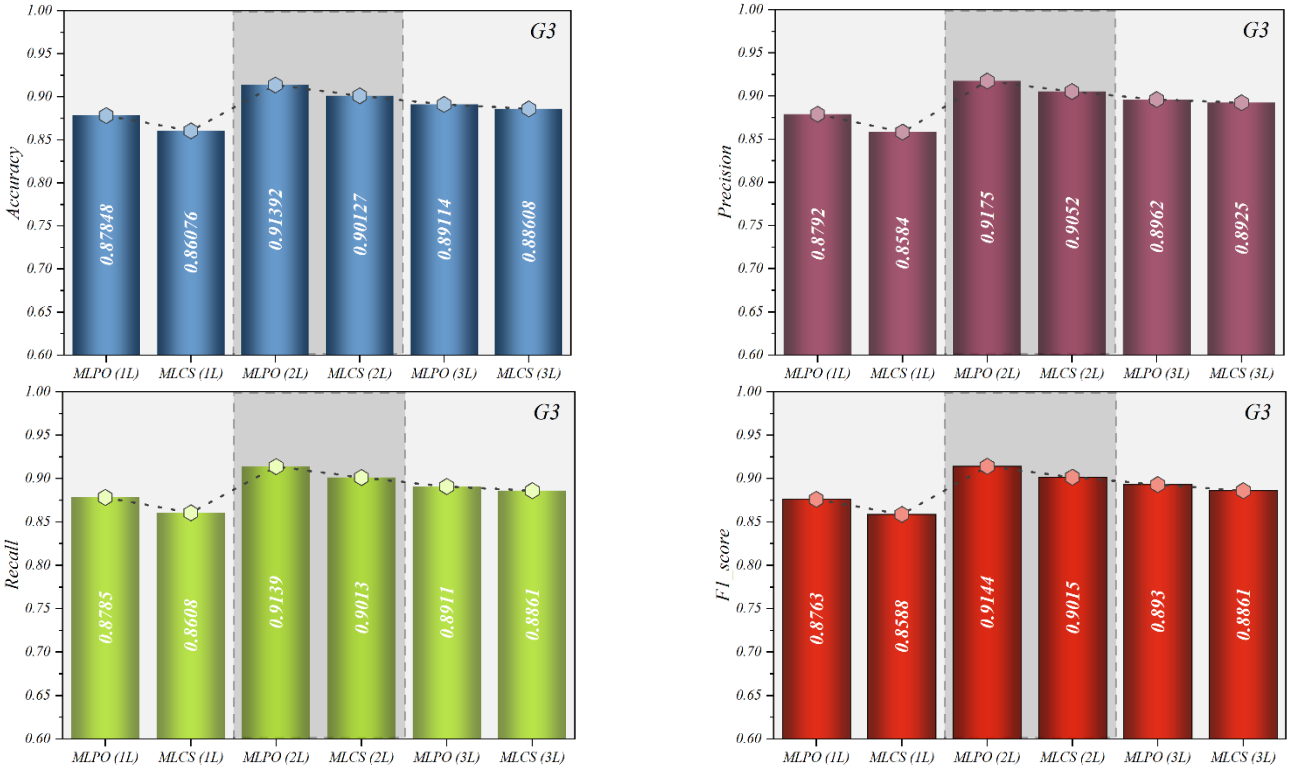

Fig. 8. Column plots the achievement percentage for developed models of G3 prediction values based on evaluators.

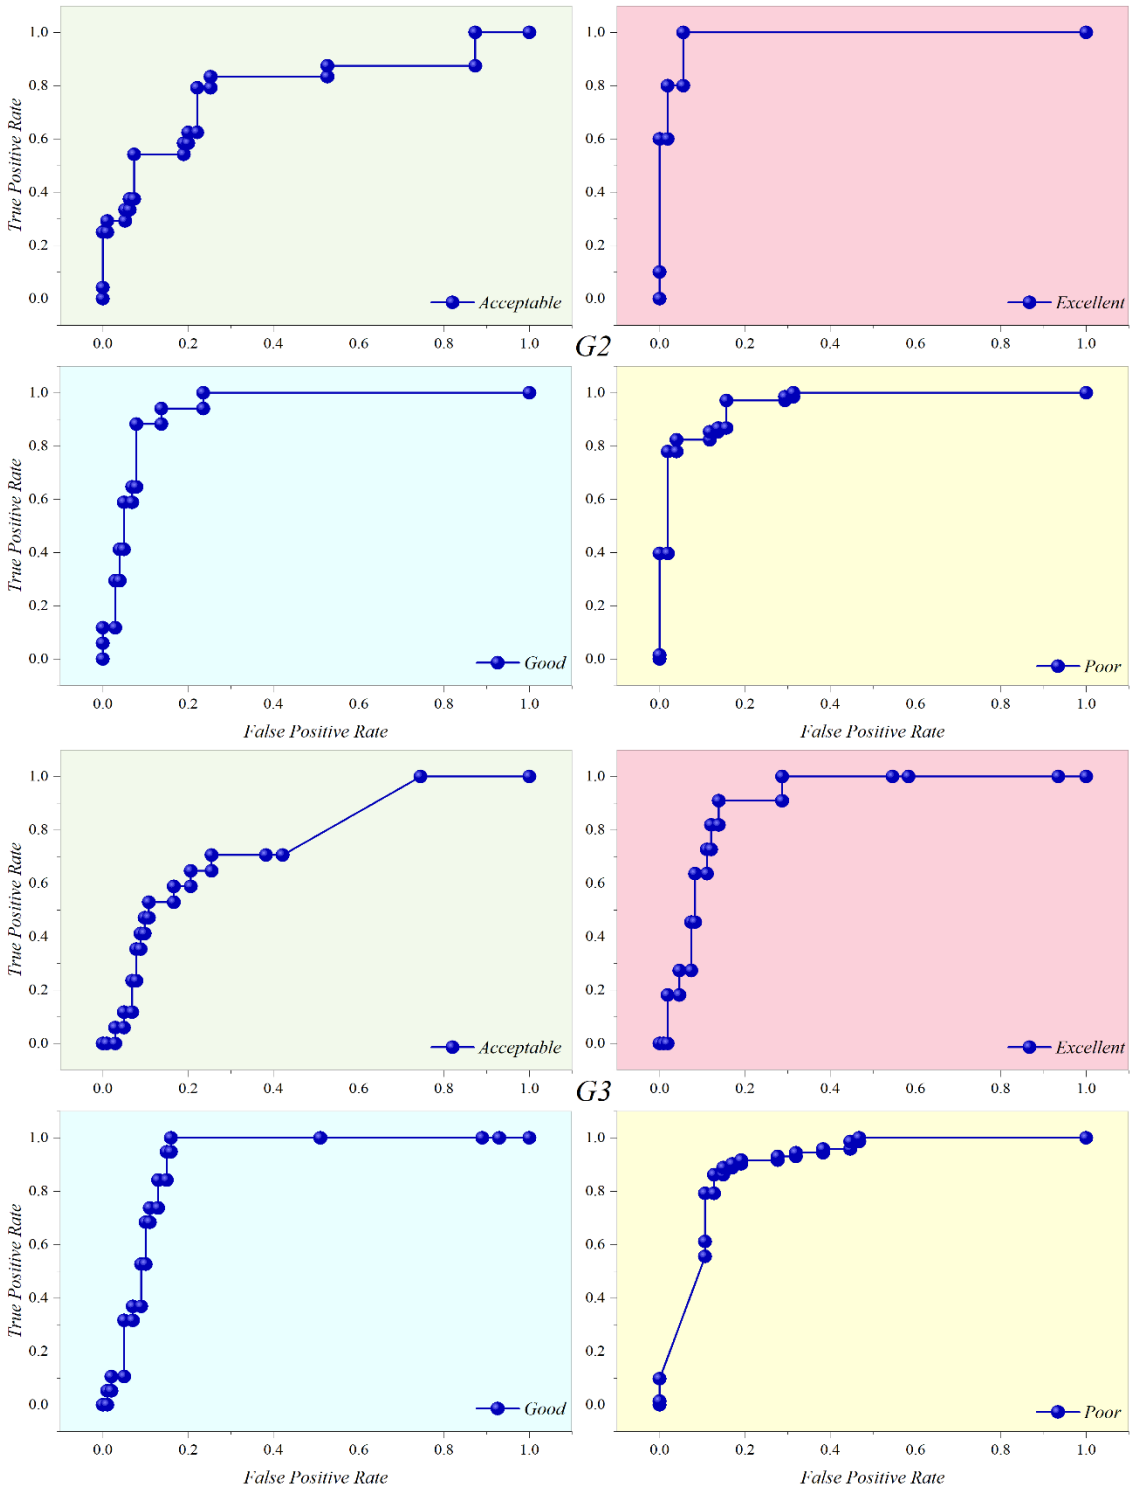

Fig. 9. The result of the ROC curve.

A binary classification model's performance at different classification thresholds is represented graphically by the Receiver Operation Characteristic (ROC) curve presented in Fig. 9. It shows how different threshold values affect the trade-off between the genuine positive rate (sensitivity) and the false positive rate (1-specificity). The following are important ideas about ROC curves: True Positive Rate (Sensitivity): The percentage of real positive cases the model accurately predicts is the true positive rate. To compute it, divide the number of true positives (TP) by the quantity of false negatives (FN), or TP / (TP + FN). False Positive Rate (1-Specificity): This refers to the percentage of real negative cases the model mispredicts as positive. The formula for calculating it is FP / (FP + TN), where FP stands for false positives and TN for true negatives.

Threshold: Predictions in binary classification models are frequently predicated on a probability threshold. Positive observations are those whose estimated probability falls above the threshold; negative observations fall below it.

By changing this threshold and seeing how the true positive rate and false positive rate change in tandem, ROC curves are produced. Area Under the ROC AUC-ROC curve: This concisely indicates the classifier's overall effectiveness and potential classification levels. It offers a solitary scalar value that symbolizes the model's overall performance. On the other hand, AUC-ROC values of 1.0 and 0.5 suggest models with performance comparable to random chance and are regarded as ideal, respectively. On the other hand, the following convergence curve shows the optimal model (MLPO 2), whose grade has the highest accuracy and a rank of false positive rate that approaches 1.0. The current plot demonstrates that the performance of the best model within an acceptable range is deemed unsatisfactory, as evidenced by its attainment of a true positive rate of 1.0 after a false positive rate of 0.8. The best model exhibits improvement in both poor and good performance categories, yet it remains insufficient. An examination of the excellent performance category reveals that the vector achieves a true positive rate of 1.0 before a false positive rate of 0.2.

Consequently, the optimal performance of MLPO 2 is realized in the excellent grade of the G2 target. On the contrary target, superior performance is observed in the good grade by the best model, with a true positive rate of 1.0 occurring before a false positive rate of 0.2. Following the good grade, the subsequent rank is assigned to the excellent grade, while the poor and acceptable grades occupy the third and fourth ranks, respectively.

IV. Discussion

A. Comparing Previous Studies vs. Present Study

The findings from three articles investigating student performance in the literature—specifically, one by Bichkar and R. R. Kabra [31], another by Edin Osmanbegovic et al. [32], and a third by Nguyen and Peter [33] —are succinctly summarized in Table VII. Notably, the research conducted by Nguyen and Peter, employing the DTC model, demonstrated the highest accuracy rate of 82%. In contrast, within this particular present study, which endeavors to forecast and classify students' performance in Portuguese language based on their G2 and G3 scores, the combination of the MLPC model and POA optimization algorithm yielded remarkable results. The accuracy metrics recorded were 95.3% for G2 and 93.5% for G3. Consequently, the proposed methodology achieved notably more reliable outcomes compared to prior studies, underscoring its efficacy in enhancing predictive accuracy and classification precision.

TABLE VII. Result of Presented and Published Studies

Author (s)	Model	Accuracy
Bichkar and R. R. Kabra [31]	DTC	69.94%
Edin Osmanbegovic et al. [32]	NBC	76.65%
Nguyen and Peter [33]	DTC	82%
Present study for G2	MLPC+POA (2)	95.3%
Present study for G3	MLPC+POA (2)	93.5%

V. Conclusion

To sum up, utilizing the MLPC model in conjunction with the Pelican Optimization and Crystal Structure Algorithm optimizers presents a viable method for predicting achievement among learners. Using these sophisticated methodologies enhances the precision and efficacy of evaluating learning objectives. This study highlights the possibilities for subsequent breakthroughs in educational analytics while also improving the accuracy of achievement prediction using complex machine learning algorithms and optimization techniques. The combined use of Crystal Structure Algorithm Optimizers, Pelican Optimization, and MLPC demonstrates a strong foundation for forecasting and comprehending students' academic performance. This opens the door for more knowledgeable and focused interventions in educational settings.

Nevertheless, within the scope of this study, an evaluation of the performance of MLPO and MLCS models is conducted across three distinct layers of the G2 and G3 targets. The findings reveal that the MLPO model in the second layer of both targets demonstrates superior accuracy, precision, recall, and F1-score, registering percentages of 0.9324 and 0.91392 for accuracy, 0.9395 and 0.9139 for precision, 0.9393 and 0.9139 for recall, and 0.9385 and 0.9144 for F1-score, respectively. Conversely, MLPO L2 achieves the highest accuracy in the G3 target, specifically in the acceptable grade, with a measured value of 54 out of 62, in contrast to MLCS L1, which records the lowest accuracy in the same grade and target, with a measured value of 46 out of 62. This comparison suggests that the MLPO model L2, given its elevated accuracy, can predict student performance with a high degree of precision. There is substantial potential for the educational system to utilize this model for advancements in this domain. Notably, the outcomes of this predictive process can be applied in real-world scenarios, yielding consistent results.

***Abstract*—Assisted evaluation through retinal vessel segmentation facilitates the early prevention and diagnosis of retinal lesions. To address the scarcity of medical samples, current research commonly employs image patching techniques to augment the training dataset. However, the vascular features in fundus images exhibit complex distribution, patch-based methods frequently encounter the challenge of isolated patches lacking contextual information, consequently resulting in issues such as vessel discontinuity and loss. Additionally, there are a higher number of samples with strong contrast vessels compared to those with weak contrast vessels in retinal images. Moreover, within individual patches, there are more pixels of strong contrast vessels compared to weak contrast vessels, leading to lower segmentation accuracy for small vessels. Hence, this study introduces a patch-based deep neural network method for retinal vessel segmentation to address the issues. Firstly, a novel architecture, termed Double U-Net with a Feature Fusion Module (DUF-Net), is proposed. This network structure effectively supplements missing contextual information and improves the problem of vessel discontinuity. Furthermore, an algorithm is introduced to classify vascular patches based on their contrast levels. Subsequently, conventional data augmentation methods were employed to achieve a balance in the number of samples with strong and weak contrast vessels. Additionally, method with skeleton fitting assistance is introduced to improve the segmentation of vessels with weak contrast. Finally, the proposed method is evaluated across four publicly available datasets: DRIVE, CHASE_DB1, STARE, and HRF. The results demonstrate that the proposed method effectively ensures the continuity of segmented blood vessels while maintaining accuracy.**

***Keywords*—Fundus image; vessel segmentation; skeleton fitting; data augmentation; patch classification**

I. INTRODUCTION

The eye stands as one of the paramount sensory organs in the human body, serving as the primary conduit for external stimuli reception. Presently, propelled by societal advancements and the proliferation of electronic devices, there is a sustained escalation in the prevalence of ophthalmic diseases among patients. Today, with the development of society and the widespread use of electronic devices, the number of patients with ophthalmic diseases continues to increase. Ophthalmic diseases are closely associated with retinal lesions, with glaucoma, diabetic retinopathy, and diabetic macular degeneration being major causes of global blindness [1]. Retinal fundus images represent the singular non-invasive modality for observing the deep microvascular system, encompassing a diverse array of retinal structures such as the retinal vascular tree, optic disc, fovea centralis, and macula [2]. The early clinical characteristics of diabetic retinopathy encompass microaneurysms, dot and blot hemorrhages, cotton wool spots, and intraretinal microvascular abnormalities [3]. The characteristic sign of glaucoma is optic disc cupping, and the ratio of the cup to disc area in fundus images, referred to as the cup-to-disc ratio (CDR), serves as a vital structural metric for evaluating the presence and advancement of glaucoma [4]. The hallmark of age-related macular degeneration (AMD) is the infiltration of choroidal vasculature into the macular region, accompanied by heightened vascular permeability [4]. Variations in retinal structure are pivotal for diagnosing diabetic retinopathy, glaucoma, and AMD. Given that retinal vessel segmentation is essential for visualizing and quantifying retinal pathology, it is an indispensable component in the analysis of retinal diseases [5]. The conventional method for retinal vessel segmentation is characterized by its costly, intricate, and time-intensive nature. Furthermore, challenges such as uneven illumination, complex vascular structures, and low vessel-background contrast in images contribute to inconsistencies in vessel segmentation across different experts [6]. This has spurred the advancement of automated retinal vessel segmentation technology.

Traditional segmentation methods mainly include line detection [7], edge detection [8], matched filtering [9] [10], and shape-based methods [11] [12]. These methods perform vessel segmentation based on vessel edge pixels or shape features. The main reason is that, compared to the background, the edge and shape information of vessels with strong contrast are more prominent, making their features easier to learn. In recent years, deep learning methods have propelled the progress of retinal vessel segmentation techniques, surpassing traditional machine learning methods [13]. Deep learning methods do not require manual feature design and can effectively extract key features from data while achieving good accuracy and generalization capabilities, thus promoting the development of retinal vessel segmentation methods [14] [15]. Currently, there are generally two types of retinal vessel segmentation methods based on deep learning [16]. End-to-end methods are one of the types, sacrificing spatial resolution to ease memory constraints during

*Corresponding Author.

training. However, these methods lead to in the loss of spatial information in retinal vessel images. On the other hand, patch-based segmentation methods are another type. Although these methods enhance data samples, it may lead to a lack of contextual information between independent patches. Through observation, we notice that there are more samples of vessel patches with strong contrast compared to those with weak contrast, and within individual patches, there are more pixels of vessels with strong contrast compared to those with weak contrast. These issues may result in problems such as vessel discontinuity and poor segmentation of small vessels when restoring segmented blocks to the original image size.

Therefore, in this paper, we first compare the pixel values of vessels and background within vessel patches. If a patch contains a higher proportion of pixels with strong vessel contrast, it is classified as a Contrast Strong Vessel Patch (CSVP); otherwise, it is classified as a Contrast Weak Vessel Patch (CWVP). Next, we introduce a novel network structure named DUF-Net, which is capable of learning both global and local information, effectively supplementing missing contextual information between patches. Additionally, we design a patch classification algorithm to perform patch classification and quantity statistics. Data augmentation is utilized to augment deficient image patches, aiming to balance the number of samples for various types of retinal vessel pathology, including CSVP and CWVP. Additionally, a training method integrating skeleton fitting assistance is introduced to enhance the model's segmentation capability for CWVP within individual samples. In summary, the principal contributions of this paper can be outlined as follows:

- In order to compensate for the absence of contextual information between patches, We introduce a novel network structure named DUF-Net. It is capable of simultaneously learning both global and local features, guiding the model to capture contextual information surrounding the patches and thereby improving the completeness of vessel segmentation.
- To improve the segmentation capability of CWVP, a patch classification algorithm was designed to balance the quantity of CSVP and CWVP samples. Additionally, during training, prior knowledge of vessel skeletons and corresponding loss functions were introduced to guide the model in learning CWVP features and address the issue of pixel imbalance within individual patches.
- We assessed the proposed method across four publicly available datasets and conducted comparisons with six latest methods. Experimental findings affirm the efficacy and robustness of the proposed approach.

The remaining sections of this paper are organized as follows. Section II provides a review of traditional and deep learning methods in retinal vessel segmentation. Section III provides a detailed explanation of the proposed method. Section IV showcases the implementation details of the experiments. Section V presents the experimental results. Section VI and VII respectively discuss and summarize the proposed method.

II. Related Work

Research on retinal vessel segmentation can be categorized into traditional methods and deep learning methods.

A. Traditional Methods

Traditional methods involve direct detection of features or edge pixels in retinal vessel images. Sheng et al. [17] combined geometric structures, texture, color, and spatial information in the image while simultaneously refining the segmentation results using a minimum spanning superpixel tree to refine segmentation results. Lam et al. [18] proposed a novel multi-concave modeling approach for handling bright lesions in the perceptual space and removing dark lesions that differ from the retinal vascular structure. To improve vessel segmentation efficiency, Rezaee and Haddadnia [19]employed a skeletonization and fuzzy entropy thresholding segmentation algorithm. They differentiated retinal main vessels from other tissue components through adaptive filtering and fuzzy entropy thresholding. In summary, although the aforementioned methods do not require training and have lower complexity, they heavily rely on filter design and often exhibit lower accuracy.

In machine learning, manual feature extraction is utilized for retinal fundus image analysis, followed by classification using common classifiers such as k-nearest neighbors (KNN) [20], support vector machine (SVM) [21], and Bayesian methods [22] [23]. Orlando et al. [24] utilized conditional random fields and support vector machines for retinal fundus image vessel segmentation. Zhu et al. [25] presented a supervised approach employing Extreme Learning Machine (ELM). This method involved constructing matrices by extracting features from each pixel of each retinal image and the manually labeled pixels, which were then input into ELM. These approaches heavily depend on prior knowledge or necessitate a series of complex operations for extracting discriminative features, thereby lacking generalization ability [26].

The segmentation performance of traditional methods needs improvement, especially when facing environments with retinal lesion features and low brightness. Traditional methods lack generalization capabilities in such scenarios. As a result, deep neural networks have found extensive applications in the field of retinal imaging.

B. Deep Learning Methods

Deep learning approaches equipped with automatic feature recognition capabilities exhibit superior performance in the field of retinal vessel segmentation compared to traditional methods. Overall, these methods can be categorized into two main types [16]. An end-to-end training approach is one of the types, because of its simple and stable performance has attracted the attention of many researchers. Hu et al. [27] incorporate a saliency mechanism to leverage features from one block as attention cues for the features of the subsequent block, effectively mitigating the problem of data imbalance. Moreover, o enhance the integrity and continuity of vessels after segmentation, Mou et al. [28] utilize a dense dilated model to integrate the newly proposed dense dilated feature extraction blocks, with the goal of extracting and accumulating

features across various scales. For improving the segmentation of fine vessels, Mishra et al. [29] employ the mean retinal vessel width and align it with the effective receptive field to identify the location of auxiliary supervision, thereby directing the model's attention towards fine vessels. The consecutive downsampling leads to the loss of a considerable amount of spatial feature information. To mitigate this challenge, Wang et al. [30] introduced two paths separately in the encoder and decoder, enhancing the model's capability for detailed representation and discrimination.

Patch-based segmentation methods are another type. In recent years, patch-based segmentation methods, which reduce computational pressure while minimizing the impact on vessel morphology, have been extensively investigated by many scholars. Dasgupta et al. [31] extracted 28 × 28 patches from preprocessed images and fed them into a CNN network for vessel segmentation. To ameliorate the problem of pixel imbalance between contrast strong vessels and contrast weak vessels in retinal images, Yan et al. [32] cropped retinal images into small 128 × 128 patches and proposed a loss function to balance contrast strong vessel and contrast weak vessel, enabling the model to learn more effective vessel segmentation features. Wu et al. [33] link two identical multi-scale backbone networks to facilitate the direct propagation of useful multi-scale features from shallow layers to deep layers. Wang et al. [34] designed three decoder networks: the first network dynamically localized image segmentation difficulty areas, while the other two networks are utilized for segmenting difficult and easy regions, respectively. Meanwhile, attention mechanisms were introduced in the network to enhance the focus on features of difficult areas in images. Yang et al. [35] designed an effective loss function to accommodate the two distinct vessel segmentation tasks, thereby improving the imbalance issue between thick and thin vessel segmentation ratios. Tan et al. [36] addressed the issue of having more pixels of strong contrast vessels than weak contrast vessels within individual patches by introducing skeleton priors and contrast losses. However, this method utilized maximum pooling on all extracted features before introducing skeleton-assisted vessel segmentation, leading to some contrast weak vessel missing and insufficient guidance for the model to learn contrast weak vessel. Therefore, we design a retinal vessel segmentation method that incorporates skeleton fitting assistance and fusion of global and local features to address vessel discontinuity and improve contrast weak vessel segmentation effectiveness.

III. METHODOLOGY

Firstly, we preprocess the original images by cropping them into several small patches. We balance the number of different class image patches through sample correction, and then perform image enhancement on CWVP. Secondly, the preprocessed patch samples are fed into the proposed Double U-Net with a Feature Fusion Module Networks (DUF-Net) to obtain corresponding segmentation maps. The DUF-Net architecture consists of green and blue Base-Nets, along with a Feature Fusion Module (FFM) designed to learn and fuse global and local information from the patches. Additionally, the feature maps outputted by the two Base-Net models are fed into the Skeleton Fitting Assistance (SFA) section. Finally, the segmented patches are restored to the original image size. The specific workflow is illustrated in Fig. 1.

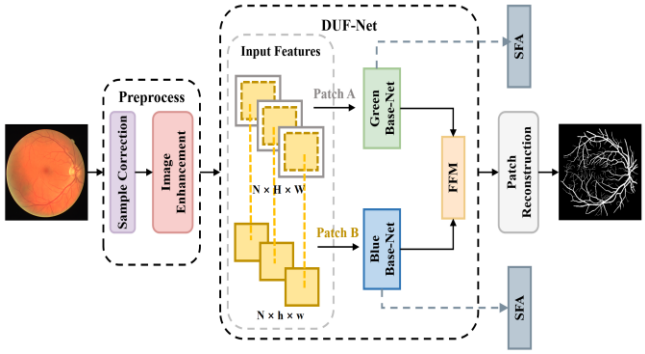

Fig. 1. Workflow of the proposed a retinal vessel segmentation method integrating global and local features with skeleton fitting assistance.

A. Preprocessing

Due to the limited quantity of existing retinal vessel datasets and the difficulty for models to learn contrast weak vessel features, we propose a preprocessing method consisting of two main stages: sample correction and image enhancement, as illustrated in Fig. 2.

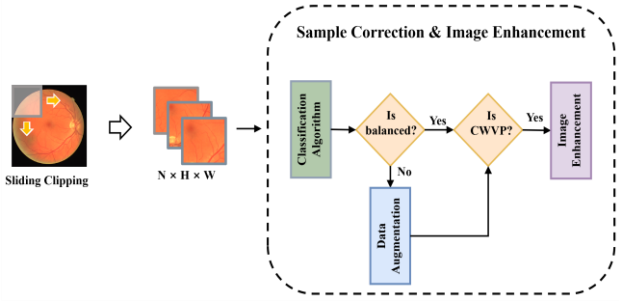

Fig. 2. The preprocessing steps.

1) Sample correction: This paper employs a patch-based approach for image segmentation. Firstly, patches are extracted from the original image using a sliding window approach to augment the model's training samples. Within these samples, patches are categorized into CSVP and CWVP. Typically, CSVP samples outnumber CWVP samples, resulting in suboptimal segmentation performance for CWVP samples. To address the issue of imbalanced CSVP and CWVP sample quantities, this paper designs a patch classification algorithm, as shown in Algorithm 1. This algorithm aims to achieve a balanced state with a nearly 1:1 ratio of samples for different classes in the training set. Data augmentation techniques are applied to CWVP; including random flipping, rotation, and Gaussian noise addition, to bring its quantity closer to that of CSVP.

Algorithm 1: patch classification Algorithm

Require: The Ground Truth *Gt* of the patch.

Ensure: The class of the patch.

Set *Gt_temp* = *Gt* / 255.
Set *first_eroded* = the erosion of *Gt_temp*.
Set *dilated* = the dilation of *first_eroded*.
Set T1 = Gt_temp - dilated_image.
Set *second_eroded* = the erosion of *first_eroded*.
Set T2 = first_eroded - second_eroded.
Calculate the sum of pixels with a value of 1 in images *T1* and *T2* to obtain *S1* and *S2*, respectively.
If *S1* > *S2*
    c = CWVP
else
    c = CSVP
Output the class *c* of the patch

2) The details of Algorithm 1 are described as follows:

a) Step 1: Perform the first erosion operation on the ground truth, followed by a dilation operation, to obtain an image representing contrast strong vessel pixels.

b) Step 2: The ground truth is subtracted from the result of dilation in Step 1 to obtain the image T1, which represents contrast weak vessel pixels that are deleted after the first erosion.

c) Step 3: Perform second erosion on the result obtained after the first erosion in Step 1.

d) Step 4: Subtract the result obtained after the second erosion in Step 3 from the result obtained after the first erosion in Step 1 to obtain the image T2, representing contrast weak vessel pixels that are deleted after the second erosion.

e) Step 5: Calculate the pixel sum for both T1 and T2 images to obtain S1 and S2, respectively. If S1 is greater than S2, the patch is classified as CWVP; otherwise, it is classified as CSVP.

3) Image enhancement: This paper employs a sliding window cropping approach to increase training samples; however, the background of fundus images exhibits relatively uniform brightness and weak lighting compared to blood vessels. In scenarios with low brightness and weak lighting, the model lacks generalization ability and struggles to achieve satisfactory segmentation results in complex environments. Moreover, In CWVP, the vessels exhibit lower contrast with the background, leading to increased learning difficulty and the introduction of noise during the segmentation process, affecting accuracy. The basic idea is to enhance the contrast of randomly selected CWVP samples, considering that different contrasts typically highlight different details.The main concept of this method is outlined in Eq. (1). Specifically, a probability factor p is randomly generated from the range [0, 1]. When p falls within the range [0, 0.5] and the patch corresponds to CWVP, contrast enhancement is applied. Otherwise, the image remains unaltered, without contrast enhancement.

$$X_{new} = \begin{cases} \partial \cdot T(X), & X \in CWVP \text{ and } p \in [0, 0.5] \\ X, & otherwise \end{cases} \quad (1)$$

where, X represents the original fundus image, X_{new} denotes the obtained new image sample, T signifies contrast enhancement applied to the image, and ∂ represents a randomly generated contrast factor within the range [0.5, 1.5].

B. DUF-Net

The architecture of the DUF-Net is depicted in Fig. 3, consisting of green and blue Base-Nets and a Feature Fusion Module (FFM). Patch A corresponds to the output obtained in Fig. 2, with lengths and widths denoted as H and W, respectively. Due to the patch segmentation approach, there is a loss of contextual information around the patch, leading to the issue of vessel discontinuity after segmentation. Therefore, while feeding Patch A into the model, it is simultaneously center-cropped to obtain Patch B, with lengths and widths represented as h and w, respectively. The final segmentation map outputted by the model has the same dimensions as Patch B. Patch A is inputted into the green Base-Net for learning global features, while Patch B is inputted into the blue Base-Net to capture local features. Subsequently, the Feature Fusion Module (FFM) is employed to integrate global and local features, completing the supplementation of missing contextual information to prevent vessel discontinuity issues after segmentation.

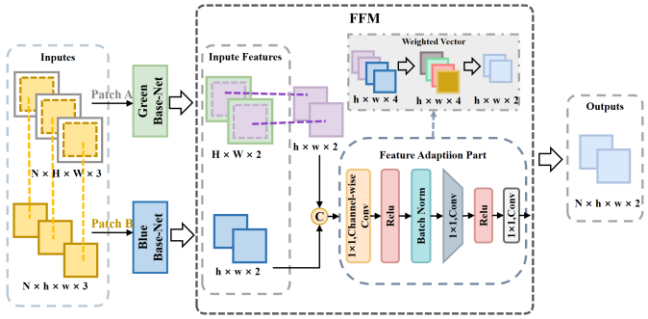

Fig. 3. DUF-Net architecture.

In Fig. 3, the Base-Net utilizes the U-Net model, which typically employs a downsampling structure to achieve a larger receptive field for capturing more semantic information. It utilizes upsampling to restore the original image, and spatial information recovery is achieved through skip connections, resulting in improved accuracy [37]. In order to reduce model parameters and minimize the loss of spatial structural information during the model downsampling process, an enhanced U-Net is designed, as illustrated in Fig. 4. The number of downsampling steps is reduced from four to three, and the channel count is halved from [64, 128, 256, 512] to [32, 64, 128, 256].The DUF-Net model employs the Base-Net as a feature generator for producing global and local information features. Subsequently, Patch A and Patch B are separately input into the green and blue Base-Nets, resulting in corresponding features *Fa* and *Fb*. Fa represents features obtained from Patch A, incorporating contextual information around the patch, while *Fb* represents local information features derived from Patch B.

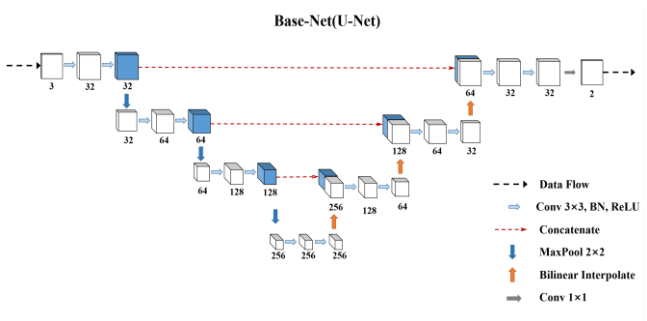

Fig. 4. Base-Net architecture.

Furthermore, we introduce a Feature Fusion Module (FFM) designed to merge feature information of varying scales generated by different Base-Net. As depicted in Fig. 3, this module is primarily composed of three components: the dimension adaptation stage, the feature concatenation stage, and the feature adaptation stage. *Fa* and *Fb* represent the features generated from the Base-Net model. Due to the disparate patch sizes of Patch A and Patch B, the corresponding feature sizes differ. To facilitate effective fusion, *Fa*'s feature is centrally cropped, resizing it from H × W to h×w, yielding the feature Fa^c. This cropping ensures consistency in size with *Fb* while retaining contextual features around the patch. The next step involves concatenating the two input features. As outputs from different-sized input images yield distinct features, a simple concatenation might not effectively integrate global and local features, potentially leading to the loss of edge information during learning. Thus, for effective feature fusion, the feature adaptation stage employs a 1×1 channel-wise convolution to adjust the weights of the concatenated features. This convolution can be considered a weight vector that highlights important channel information. Subsequently, two 1×1 convolutions are used to learn the adjusted features' weights, reducing the channel count by half. Y_{out} denotes the output of the fusion module and can be computed as given in Eq. (2):

$$Y_{out} = \gamma(\gamma([Fa^C, Fb] \otimes k_1) * k_2) * k_3 \quad (2)$$

where, *k1*, *k2*, and *k3* represent 1×1×4, 1×1×2, and 1×1×2 convolutional filter kernels, respectively. γ represents the ReLU activation function.⊗signifies channel-wise convolution and * signifies the regular convolution operation. To enhance the fusion of concatenated feature information and reduce model parameters, channel-wise convolution is utilized to redistribute the weights of the concatenated features. Finally, *k2* and *k3* are employed to downscale the concatenated features. This design ensures the effective integration of features at different scales, incorporating both global and local information.

C. Loss Mapping with Skeleton Fitting Assistance

On the DRIVE dataset [39], approximately 77% of the vessel pixels belong to contrast strong vessels, while only 23% are contrast weak vessels [38]. Therefore, this paper introduces SFA to enhance the segmentation capability of contrast weak vessels. Three feature maps are generated in this study: one from the green Base-Net, another from the blue Base-Net, and the third from the Feature Fusion Module (FFM). Specifically, the feature maps outputted by the two Base-Nets undergo skeleton fitting assisted loss mapping, while the output segmentation image from the FFM is combined with the ground truth for loss calculation. The specific workflow is depicted in Fig. 5.

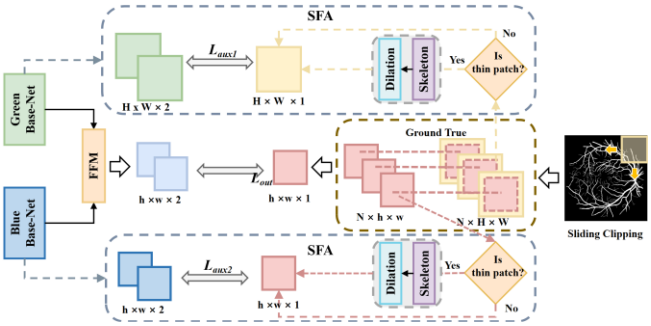

Fig. 5. The process workflow of loss mapping with skeleton fitting assistance.

The original segmentation map is cropped into N patches of size H×W using a sliding window approach. As the output segmentation map from the Feature Fusion Module (FFM) has dimensions h×w, central cropping is performed to obtain h×w patches. Subsequently, the cross-entropy loss function is applied for loss calculation, and it is given in Eq. (3):

$$L_{out} = -\frac{1}{N}\sum_{i=1}^{N}\left[y_i \log(p_i) + (1-y_i)\log(1-p_i)\right] \quad (2)$$

where, *N* represents the total number of pixels in the patch, p_i denotes the model's predicted probability for pixel , y_i represents the true label of pixel *i*.

In Algorithm 1, we propose an algorithm for the classification of vessel patches. In the SFA, we adopt a similar approach for vessel patch classification. To enhance the model's learning capability for CWV, skeleton prior knowledge is employed to dilate vessel pixels within CWVP. Through the classification algorithm, H×W patches of the ground truth, as well as the center-cropped h×w patches, are classified. When a patch is identified as CSVP, no additional processing is performed, and the Dice loss is directly computed with the corresponding Base-Net output feature map. In the case of a patch classified as CWVP, the patch undergoes skeleton extraction and dilation operations to generate a new ground truth. The Dice loss is then calculated by comparing the outputs of the two Base-Nets with the new ground truth. The Dice loss function is given by Eq. (4):

$$L_{aux} = \begin{cases} 1 - \dfrac{2\left|P \cap D(S(Y))\right|}{\left|P\right| + \left|D(S(Y))\right|}, & Y \in CWVP \\ 1 - \dfrac{2\left|P \cap (Y)\right|}{\left|P\right| + \left|Y\right|}, & Y \in CSVP \end{cases} \quad (3)$$

where, *P* represents the model's prediction result, *Y* is the corresponding ground truth, $S(\cdot)$ denotes the skeleton extraction operation, $D(\cdot)$ represents the dilation operation.

The final loss function is given in Eq. (5):

$$L_{all} = \begin{cases} L_{out} + \frac{L_{out}}{L_{aux1}} L_{aux1} + \frac{L_{out}}{L_{aux2}} L_{aux2}, & Y \in CWVP \\ L_{out} + L_{aux1} + L_{aux2}, & Y \in CSVP \end{cases} \quad (4)$$

where, L_{aux1} and L_{aux2} are the corresponding loss functions for the two SFA components.

IV. Experiments

A. Fundus Datasets

The existing widely used datasets include DRIVE [39], STARE [40], CHASE_DB1 [41], and HRF [42].

1) DRIVE dataset: The dataset comprises 40 retinal images, each measuring 565 × 584 pixels, with 20 images allocated for training. Additionally, the dataset has been pre-divided into training and testing sets. In the experiments, we utilize the first set of labels to evaluate the proposed method.

2) STARE dataset: The dataset consists of 20 images, each with dimensions of 700 × 605 pixels, with half of them representing pathological cases and the other half representing normal cases. We choose 10 images for training and another 10 images for testing.

3) CHASE_DB1 dataset: The dataset comprises 28 retinal images from various children, each with dimensions of 999 × 960 pixels for both left and right eyes. Annotations in CHASE_DB1 are provided by two different observers. In our experiments, we utilize first set of labels as the ground truth for evaluation. Specifically, we designate 8 images as test samples and allocate the remaining images for training samples.

4) HRF dataset: The dataset consists of 45 high-resolution color retinal images. These images are categorized into three classes: healthy, diabetic retinopathy, and glaucoma, each comprising 15 images. For training, we select 15 images from each category: healthy children, diabetic retinopathy patients, and glaucoma patients. The remaining 30 images are allocated for testing.

B. Evaluation Metrics

In retinal images, binary pixel values typically classify pixels into vessel (positive) and non-vessel (negative) categories. Based on this comparison, there are four fundamental pixel metrics: pixels labeled as vessels and correctly predicted as vessels are defined as True Positives (TP); pixels labeled as backgrounds but incorrectly predicted as vessels are False Positives (FP); similarly, False Negatives (FN) represent pixels labeled as vessels but incorrectly predicted as backgrounds, while True Negatives (TN) denote pixels labeled as backgrounds and correctly predicted as backgrounds. Furthermore, we employed eight metrics for evaluation, including Accuracy (Acc), Sensitivity (Sen), Specificity (Spe), Precision (Pre), F1 score (F1), G-mean (G), Matthews Correlation Coefficient (MCC), and Area Under the ROC Curve (AUC). all metrics are defined as follows:

$$Acc = \frac{TP + TN}{TP + FN + TN + FP}, \quad (5)$$

$$Sen = \frac{TP}{TP + FN}, \quad (6)$$

$$Spe = \frac{TN}{TN + FP}, \quad (7)$$

$$Pre = \frac{TP}{TP + FP}, \quad (8)$$

$$F1 = \frac{2 \cdot Pre \cdot Sen}{Pre + Sen}, \quad (9)$$

$$G = \sqrt{Sen \cdot Spe}, \quad (10)$$

$$MCC = \frac{(TP \times TN) - (FP \times FN)}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}}, \quad (11)$$

C. Implementation Details

The proposed model was implemented using PyTorch 1.12.1 on an RTX 3060 GPU with 12GB of memory. Stochastic gradient descent (SGD) was utilized for parameter optimization. Additionally, a "poly" learning rate policy was applied, where the learning rate was multiplied by $(1 - \frac{\text{iter}}{\text{Max\_iter}})^{\text{power}}$ and the power was set to 0.9, with a base learning rate of 0.01 in training. Furthermore, the batch size was set to 1 and each experiment was conducted for 100 epochs. During testing, the test images were partitioned into overlapping small patches. Subsequently, the segmented samples generated by the model were reconstructed into complete segmentation results.

V. Results

A. Comparison with Other Methods

1) Comparison of composite metrics: We initially compared it with six methods on four datasets, including FANet[43], Convmixer[44], BFMD[45], GT-U-Net[46], SA-Unet[47], and CFPNetM[48], with quantitative metrics shown in Table I to Table IV.. Overall, the proposed method showed improvements in metrics,especially Acc and Pre. As illustrated in Table I, across the DRIVE dataset, Sen, G, and AUC metrics outperformed the six methods, reflecting superior segmentation results. F1 and MCC metrics were also close to the optimal values. Among them, G, AUC, F1, and MCC metrics are more comprehensive, indicating that the proposed method has better vascular segmentation capabilities.As depicted in Table III, on the STARE dataset, Acc, Spe, Pre, and F1 metrics achieved optimal results, and the other four metrics ranked second among the seven methods, showing results close to the optimal values.

Particularly, the F1 metric, reflecting the connectivity and accuracy of vascular segmentation, indicated the good segmentation demonstrated by the proposed method on this dataset indicate its excellent segmentation performance. As shown in Table IV, the HRF dataset includes high-resolution images of patients afflicted with diabetic retinopathy and glaucoma, posing challenges for vessel segmentation. Experimental results demonstrate that the proposed method for retinal vessel segmentation outperforms others, achieving the highest accuracy metric (Acc), while also securing the second or third position in the comparison of comprehensive metrics. These results suggest that the devised approach demonstrates promising segmentation capabilities for high-resolution and pathological images. The examples provided in 0 demonstrate the favorable segmentation performance of the proposed method. In the first and last rows of 0, DUF-Net exhibits more complete segmentation of thin blood vessels with fewer vessel interruptions. The features of DUF-Net contribute to preserving the continuity and accuracy of thin blood vessels in datasets like HRF, which include images with diabetic retinopathy and glaucoma. This capability is crucial for supporting the prevention and treatment of retinal pathologies.

TABLE I. COMPREHENSIVELY COMPARING PERFORMANCE ON DRIVE DATASET (UNIT: %)

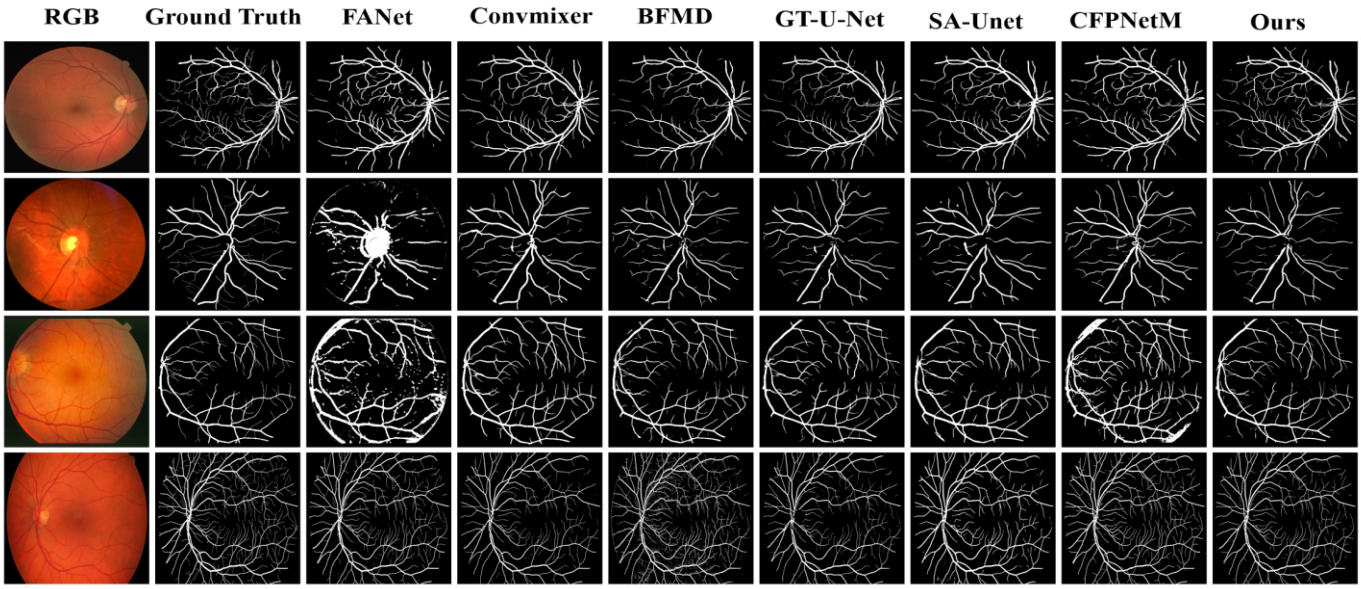

Fig. 6. The segmentation outcomes from the DRIVE, CHASE_DB1, STARE, and HRF datasets are juxtaposed in the figures below (from top to bottom).

2) Segmentation of optic disc and pathological vessel regions: Detailed comparisons of the optic disc and pathological vessel regions are illustrated in Fig. 7 demonstrating the magnified views of these areas. The first and second rows of Fig. 7 compare the optic disc regions with state-of-the-art methods from recent years. Due to challenges such as low contrast and uneven brightness, blood vessels around the optic disc region are often overlooked by other methods. In contrast, the proposed approach effectively identifies the vessels around the optic disc. Furthermore, the presence of bleeding around the lesions, which closely resembles vascular features, significantly increases the difficulty of vessel segmentation in lesion images. As evident in the third rows of Fig. 7, the proposed method accurately segments vessels in the pathological regions. This is primarily attributed to the integration of skeletal prior knowledge to augment the model's comprehension of fine vessels and enhance its discrimination between vessel and background pixels .In the fourth row of Fig. 7, a substantial amount of noise is evident in the segmentation image due to BFMD misclassifying numerous lesions and surrounding hemorrhagic areas as vessels. This could potentially compromise subsequent auxiliary diagnostics.

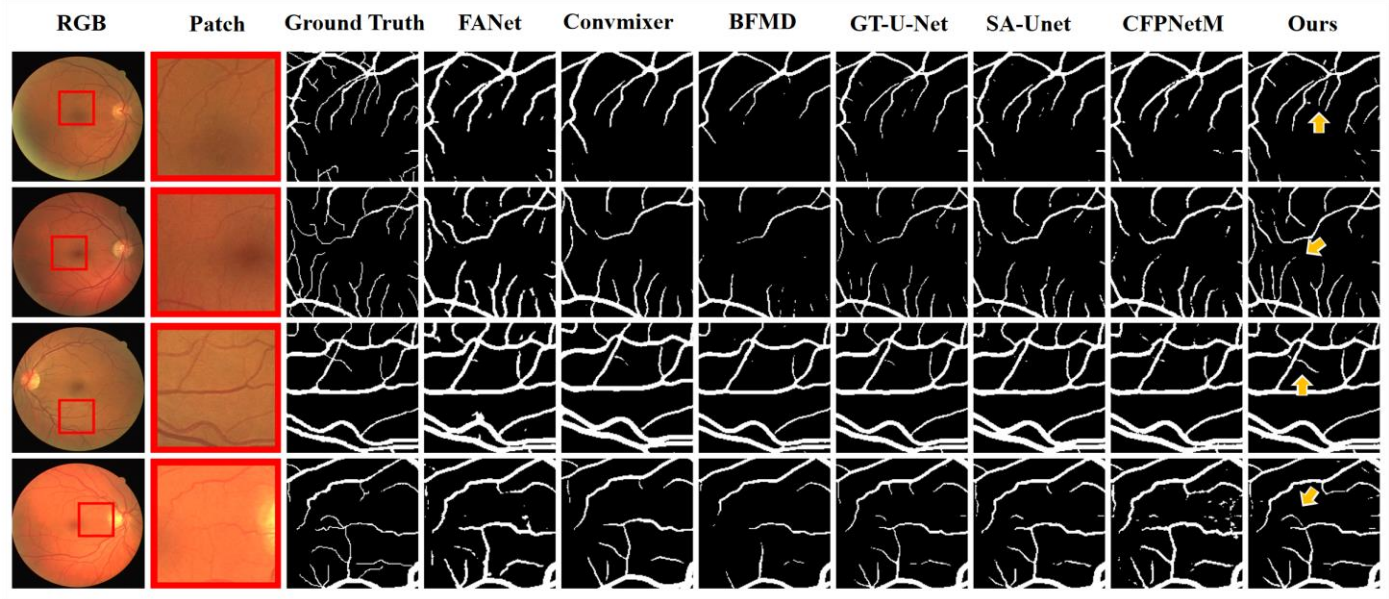

Fig. 7. Comparison of vessel segmentation results in the optic disc region (first two rows) and the lesion region (last two rows).

3) Segmentation of contrast weak vessels: The proposed method accurately segments contrast weak vessels, as illustrated in 0. When compared with other methods, it is evident that DUF-Net extracts more complete contrast weak vessels. This improvement can be attributed to the model's ability to learn both local and global features, effectively addressing the missing contextual information. This results in superior performance in detecting thin vessels, reflected in a higher accuracy (Acc) score.

B. Experiment for Algorithm Involves Categorizing CSVP and CWVP

In Algorithm 1, introduces a patch classification algorithm designed to categorize CSVP and CWVP. 0 illustrates the classification results of the patch classification algorithm on the DRIVE dataset. The first and second rows show the patches classified as CWVP by the algorithm and their corresponding ground truth. In this classification result, all vessels are characterized by low contrast. The third and fourth rows display the patches classified as CSVP by the algorithm and their corresponding ground truth. Here, it is evident that vessels with strong contrast are prominent.

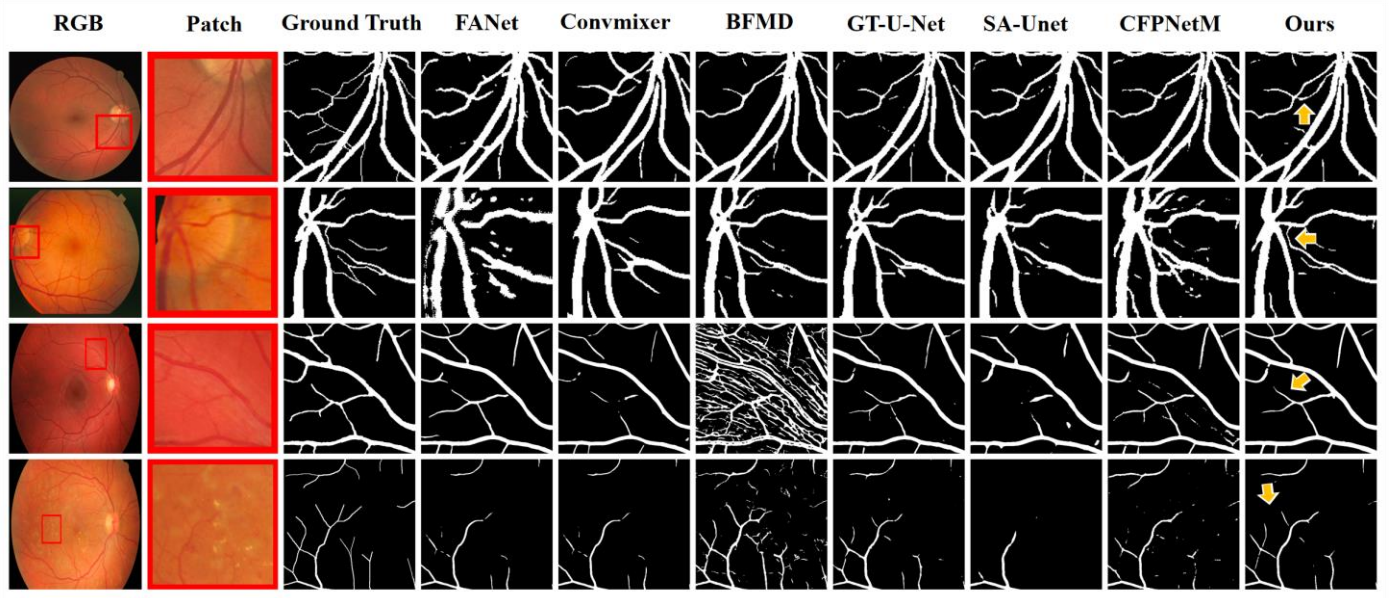

Fig. 8. Comparison of contrast weak vessel segmentation results.

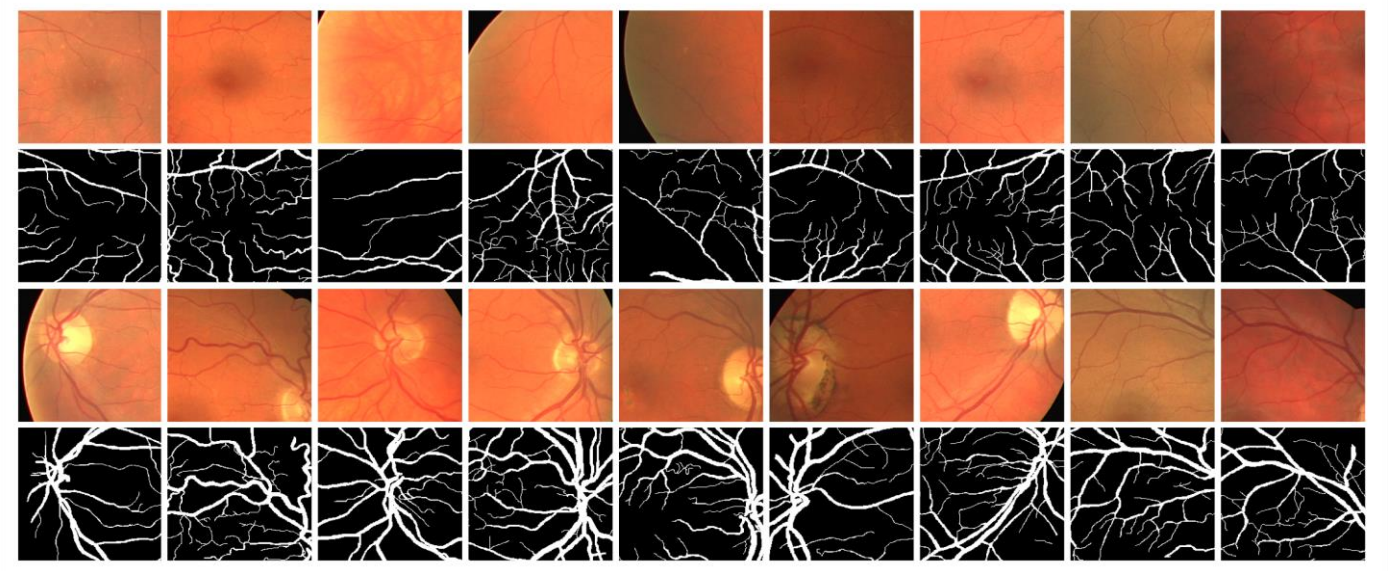

Fig. 9. The outcomes of patch classification into CSVP (first two rows) and CWVP (last two rows) on the DRIVE dataset are juxtaposed with their respective ground truth.

C. Experiment for Loss Mapping with Skeleton Fitting Assistance

In Fig. 5, we proposed a loss mapping with skeleton fitting assistance composed of three loss functions: L_{aux1}, L_{aux2}, and L_{out}. The evolution of these three loss functions during training for 100 epochs on the DRIVE dataset is illustrated in 0 . The values of L_{aux1} and L_{aux2} are greater than the value of L_{out}. When the patch represents CSVP, the coefficient weights of the three loss functions are configured as 1, and the values of the three loss functions show a synchronous decreasing trend in 0(a). However, when the patch represents CWVP, the skeleton fitting assistance part involves computing losses using the feature map and the newly generated ground truth after skeleton extraction. This may bias the model towards learning the new ground truth, leading to suboptimal segmentation results. Therefore, an adaptive weight assignment method is designed in this paper. It uses L_{aux1}/L_{out} as the weight for L_{aux1} and L_{aux2}/L_{out} as the weight for L_{aux2} to balance the loss functions. In 0(b), it can be observed that with the adaptive weight assignment, L_{out} shows a decreasing trend, while L_{aux1} and L_{aux2} remains within a certain range of variation.

D. Ablation Analysis

The ablation analysis presents the performance of each proposed method, as demonstrated in TABLE V. . For comparison, we refer to DUF-Net without contextual information as DU-Net. DU-Net does not undergo central cropping when fed into the model, employs blocks of the same size, and omits the use of the Feature Fusion Module (FFM). Additionally, DU-Net does not undergo the proposed preprocessing methods and the loss calculation of Skeleton Fitting Assist (SFA). By incorporating preprocessing methods, enhancing contextual information supplementation, and integrating FFM and SFA loss calculation, all metrics show corresponding improvements, as depicted in TABLE V. .

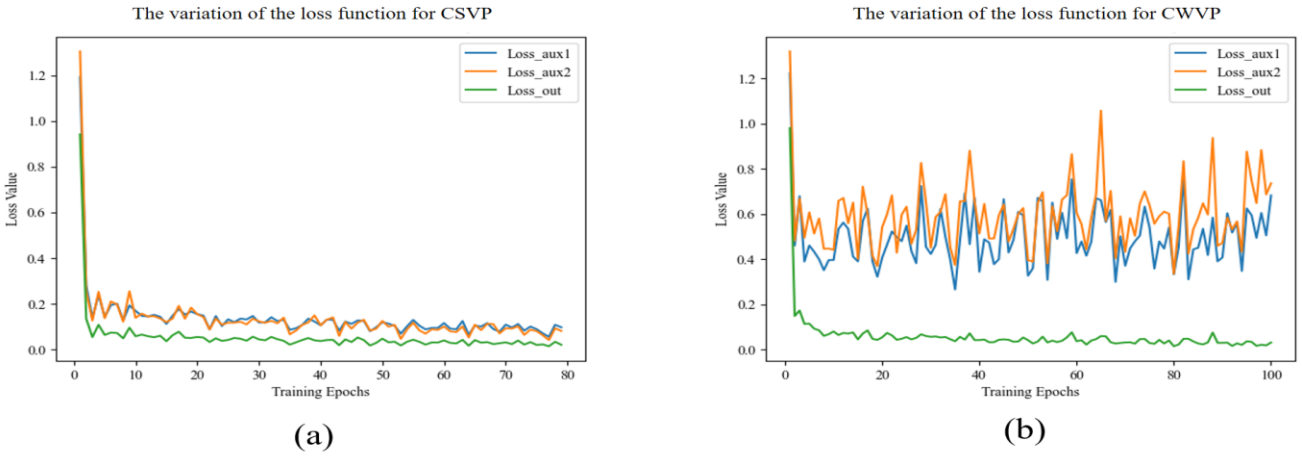

Fig. 10. The variation of the loss functions on the DRIVE dataset (a) The variation of the loss function for CSVP (b) The variation of the loss function for CWV.

TABLE V. THE RESULTS OF THE ABLATION ANALYSIS ON THE DRIVE DATASET (UNIT: %)

Method	Accurary	Sensitivity	Specificity	Precision	F1-score	G-mean	MCC	AUC
DU-Net	96.62	77.19	98.52	83.55	79.76	87.05	78.28	87.85
+Preprocess	96.65	81.97	97.94	79.47	80.22	87.39	77.98	88.27
+FFM	96.68	81.68	97.98	78.28	79.98	88.50	78.51	89.18
+SFA	96.70	82.18	98.00	78.68	80.39	89.74	78.61	90.09

VI. DISCUSSION

Compared to end-to-end segmentation, patch-based segmentation methods can significantly alleviate computational hardware pressure while increasing the training samples in datasets, thereby enhancing vessel segmentation capability, which has gradually attracted attention from many scholars [49]. However, when restoring the segmented patch results to the original size, issues such as vessel discontinuity and poor segmentation of small vessels may arise. Therefore, this paper designs a preprocessing method tailored for fundus images, a novel network architecture, and a training approach with skeleton fitting assistance to address the aforementioned issues.

Due to the difficulty in segmenting small vessels, datasets with a higher density of small vessels often exhibit lower performance metrics compared to datasets with fewer small vessels, such as DRIVE [39] and HRF [42] datasets containing more small vessels than STARE [40] and CHASE_DB1 [41] datasets. Consequently, the performance of six vessel segmentation methods is significantly reduced. Additionally, existing fundus segmentation methods are primarily evaluated based on pixel measurements, where the contribution of small vessel pixels is relatively minor, limiting the potential improvement in performance metrics. The proposed method shows limited improvement on the HRF dataset. This is partly due to the high resolution of this dataset leads our classification algorithm to misclassify some CWVP samples as CSVP, resulting in incomplete feature capture of CWVP. Thus, there remains considerable room for improvement in our method.

VII. CONCLUSION

This paper proposes a novel segmentation method by addressing the limitations of patch-based retinal vessel segmentation. Firstly, the patch-based segmentation approach often overlooks the issue of imbalanced contrast between strong and weak vessel samples in the dataset. Therefore, this paper designs a vessel patch classification algorithm to balance the training data samples by augmenting contrast weak vessel samples based on the computed quantities. To address the missing contextual information around the patches, new network architecture, DUF-Net, is proposed. By feeding features of different scales into the network model, both global and local information are learned separately and then fused to complement the missing features. Lastly, skeleton prior knowledge is introduced to alleviate vessel discontinuity issues after segmentation, and the adaptive weight allocation mechanism is employed to adjust the imbalanced pixel distribution within blocks, thereby enhancing the model's segmentation capability for contrast weak vessels.

In the experimental results, the proposed method demonstrates promising performance. As retinal lesions significantly affect vessel segmentation results, future work will focus on enhancing lesioned retinal images using image enhancement techniques and loss functions to improve the performance of segmentation. Moreover, extending this method to other segmentation tasks in medicine, such as neuron segmentation and cell segmentation, will also be considered.

Novel Approaches for Access Level Modelling of Employees in an Organization Through Machine Learning

Priyanka C Hiremath, Raju G T
Department of Computer Science and Engineering, SJC Institute of Technology, Chickballapur, India

***Abstract*—In the contemporary business landscape, organizational trustworthiness is of utmost importance. Employee behavior, a pivotal aspect of trustworthiness, undergoes analysis and prediction through data science methodologies. Simultaneously, effective control over employee access within an organization is imperative for security and privacy assurance. This research proposes an innovative approach to model employee access levels using Geo-Social data and machine learning techniques like Linear Regression, K-Nearest Neighbours, Decision Tree, Random Forest, XGBoost, and Multi-Layered Perceptron. The data, sourced from social and geographical realms, encompasses details on employee geography, navigation preferences, spatial exploration, and choice set formations. Utilizing this information, a behavioral model is constructed to assess employee trustworthiness, categorizing them into access levels: low, moderate, high, and very high. The model's periodic review ensures adaptive access level adjustments based on evolving behavioral patterns. The proposed approach not only cultivates a more trustworthy organizational network but also furnishes a precise and reliable trustworthiness evaluation. This refinement contributes to heightened organizational coherence, increased employee commitment, and reduced turnover. Additionally, the approach ensures enhanced control over employee access, mitigating the risks of data breaches and information leaks by restricting the access of employees with lower trustworthiness.**

Keywords*—Access control; machine learning; employee behavior modeling; data analysis; organizational performance

I. Introduction

Organizations highly value employees as crucial assets, as their conduct significantly influences the company's outcomes [1]. Employee behavior encompasses interactions with peers, dedication to their roles, and performance, requiring effective management for organizational prosperity. Critical to this management is ensuring ongoing employee dedication, which fosters job satisfaction, diminishes turnover, and enhances overall performance [2]. Employee commitment, in turn, cultivates organizational trust, pivotal for successful team cohesion. Nonetheless, managing employee behavior presents challenges due to the workforce's diverse backgrounds, motivations, attitudes, and personalities. Organizations often establish a strong organizational culture aligned with their values and missions, fostering employee engagement and drive for optimal performance [3]. Additionally, incentives and rewards serve as tools to cultivate positive behavior and boost motivation [4]. Understanding employee behavior entails utilizing various methods such as surveys, performance assessments, and data analysis. Data analysis, employing advanced statistical methods and machine learning algorithms, is increasingly valuable for gaining insights into employee behavior [5]. Employee behavior analysis is an expanding area of research, examining factors like leadership approaches, job satisfaction, and engagement. This study addresses the complex task of ensuring employee productivity while promoting mental and physical well-being, addressed through wellness programs [6]. These programs aim to encourage healthy behaviors, reinforcing productivity and overall welfare [7]. Furthermore, behavior analysis aids in identifying risks, enabling organizations to proactively manage concerns such as turnover or workplace incidents [8]. In the midst of these challenges, access control emerges as a crucial aspect of managing employee access levels within organizations [9]. Ensuring operational security, safeguarding sensitive data, and upholding trust require strict control over information, resources, and systems access. The emergence of machine learning and data science is reshaping access control management, particularly in managing large, diverse workforces [10]. This discussion explores the role of employee behavior models in access control, elucidating techniques and tools for analyzing and managing access based on behavioral patterns. The discourse examines the benefits and challenges of employing behavior models in access control, highlighting best practices for seamless implementation.

Employee behavior models are developed through the examination of various data sources, such as user logs, network activity, and biometric data [11]. Geo data, utilizing parameters like latitude, longitude, and elevation, significantly contributes to these models by revealing spatial behavior patterns. Incorporating social data expands the scope, enabling the creation of behavioral models to assess employee trustworthiness. Employees are then grouped into access levels based on these models, aligning access controls with behavioral patterns [12]. This dynamic adjustment of access control policies, guided by real-time behavior data, ensures judicious access while revoking unnecessary privileges. Behavior models play a crucial role in identifying and thwarting insider threats, a significant concern for companies [13]. Indicators of potential threats, such as unauthorized data access or abnormal working hours, trigger alerts, allowing organizations to intervene proactively. Furthermore, behavior models streamline user experience by automating access control processes, reducing reliance on manual approval

procedures [14]. Despite the evident benefits, implementing behavior models in access control presents challenges [15]. The need for extensive data collection and processing can be daunting, particularly for organizations not well-versed in data science techniques. Balancing security and usability is another hurdle, requiring strict controls without hindering productivity. Addressing these challenges involves adopting best practices, including clear data collection policies, employee training on data privacy and security, and collaboration between data scientists and IT professionals [16]. Once employee trustworthiness is assessed and categorized into different levels, access control becomes more manageable [17]. Automation of access control processes based on behavioral models optimizes efficiency and resource access. Comprehensive evaluation of employee behavior involves collecting data from various sources, including geographical, social media, email communication, and browsing history [18]. Geographical data unveils movement patterns, while social data offers insights into character and activities. Email communication data reveals professional interactions, and browsing history data exposes online activities. Privacy and ethical concerns must be carefully considered during data collection and analysis. Employees should be informed of data collection methods, and privacy rights must be respected. Combining technologies and tools enhances the quality of collected data [19]. Geo data plays a pivotal role in access control decisions, providing insights into physical movements and actions [20]. When combined with social data, it enables machine learning techniques to construct behavioral models for access control decisions. Continuous analysis of geo data allows organizations to track changes in employee behavior over time and identify anomalies. Social data, drawn from various online platforms, offers rich insights into employee behavior [21]. Parameters like content type and engagement levels provide valuable insights. Social data analysis can uncover patterns indicative of loyalty issues or security risks. However, using social data for access control requires addressing privacy concerns and ensuring legal data collection [23]. The integration of employee behavior models into access control mechanisms signifies a shift in organizational security [24]. By combining geographical and social data, analyzed through advanced analytics and machine learning, robust behavioral models are created. These models, defining access levels based on trustworthiness, offer a proactive approach to security. Embracing these innovative approaches can better position organizations for success in today's evolving business landscape.

The utilization of machine learning (ML) to refine the access control system for organizational employees has gained considerable attention due to its ability to analyze vast datasets and predict employee behavior [25]. These ML models are trained on extensive datasets incorporating both social and geographical data, facilitating the categorization of employees into distinct levels of trustworthiness. This section examines the advantages and disadvantages of employing ML models for access control, explores various tools and technologies supporting this endeavor, and addresses challenges inherent in ML modeling along with proposed solutions. Utilizing ML models for employee access control offers benefits such as scalability, accuracy, automation, and adaptability. However, challenges such as bias, interpretability issues, complexity, and concerns regarding data quality also accompany this approach. Organizations can overcome these challenges by utilizing tools like Python, R, Apache Spark, Hadoop, and cloud platforms, and implementing techniques such as data cleaning [26]. This study involves the development and evaluation of ML models, specifically XGBoost, SVM, and Decision Tree, using a geo-social dataset representing four employee access levels: low, moderate, high, and very high. The dataset comprises 200,000 samples, evenly distributed across classes, with 24 geo data features and 15 social data features. The primary objective is to build an accurate model capable of predicting employee access levels based on their behavioral patterns.

II. Literature Review

The study in [27] introduced a trust-based framework and measurement for organizational confidence. It adopted a cognitive model of trust, relying on interpretive factor analysis and validity testing. Incorporating in-person interviews and open-ended questionnaires, the study affirmed the eight-factor structure of organizational confidence. Table I provides a summary of the corporate confidence study results.

To recognise the business's vision and culture, one must believe in the company's future. Fig. 1 shows the whole plan to enhance workers' self-confidence.

GPS and GIS offer location-based intelligence: This method tracks spatial behavior over two weeks, integrating user speed, distance, time, elevation, and precise latitude and longitude [35]. The essay explores telecom service providers' data on customers using location-based service applications (LBS), involving 14 days of location tracking using a GPS device. Safety measures were in place to avoid disrupting the member's routine. GIS software interpreted GPS coordinates, obtaining quantitative geographic data, while daily diaries captured qualitative information, as illustrated in Fig. 2.

Case studies and previous research on access level modelling of geo data, social data or geo-social data have been tabulated in Table II.

TABLE I. Investigations on Factors Affecting Company's Confidence on Employees

Reference	Contents in an organisation confidence
[28]	Confidence is classified into two categories: cognitive and affective.
[29]	Confidence in an organisation based on the shared values of its employees.
[30]	Communication was cited as the most crucial aspect of an organization's confidence.
[31]	Trust is comprised of sincerity, rationality, candour, intentions, and convictions.
[32]	Trust in an organisation can be subdivided into a sense of belonging and information sharing.
[33]	A confidence in an organisation consisted of virtue, capabilities, transparency, and sincerity.
[34]	Distribution justice, job security, procedure justice, and organisational support are all parts of organisational trust.

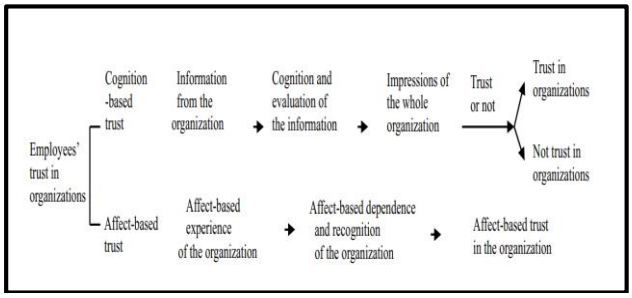

Fig. 1. Trust of employees in an organisation.

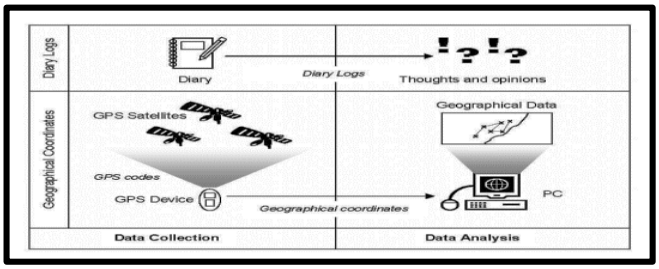

Fig. 2. Observational instruments used for data collection and analysis.

TABLE II. PAST RESEARCH WORKS

Reference	Objective Of Research	Dataset Used	Algorithm	Metric	Advantages
[36]	Developing an access control model for mobile social networks based on user behaviour	Twitter dataset	Fuzzy logic	Accuracy: 85.6%	High accuracy and reduced risk of unauthorized access
[37]	Investigating the effectiveness of location-based access control for online social networks	Facebook dataset	Probabilistic graphical models	Precision: 93.2%	Improved privacy and security for social network users
[38]	Proposing a framework for access control in geo-social networks	Geo-tagged tweets dataset	Deep learning	F1-score: 0.89	High accuracy and scalability
[39]	Evaluating the performance of different machine learning algorithms for access control in social media	Twitter and Facebook datasets	Decision trees, SVM, Naive Bayes	Accuracy: 91.4%	Comparative analysis of different algorithms
[40]	Investigating the privacy risks of social media check-ins and proposing a privacy-preserving access control mechanism	Foursquare dataset	Differential privacy	Privacy guarantee: ε=0.5	Improved privacy protection for users
[41]	Developing an access control model for online social networks based on user location and activity	Facebook dataset	Rule-based system	Precision: 92.8%	Simple and easy-to-understand rules
[42]	Proposing a hybrid access control mechanism for geo-social networks based on fuzzy logic and reinforcement learning	Geo-tagged tweets dataset	Fuzzy logic, Reinforcement learning	Accuracy: 89.3%	Improved accuracy and adaptability
[43]	Investigating the impact of social network structure on access control policies	Synthetic network dataset	Network analysis	Network density: 0.35	Improved understanding of the relationship between network structure and access control
[44]	Developing a privacy-preserving access control model for social media based on secure multi-party computation	Twitter dataset	Secure multi-party computation	Accuracy: 87.2%	Improved privacy protection and reduced risk of data breaches
[45]	Investigating the impact of temporal dynamics on access control policies in social media	Facebook dataset	Temporal analysis	Average access frequency: 3.8/day	Improved understanding of the temporal behaviour of social media users
[46]	Developing a context-aware access control model for social media based on user location and activity	Twitter dataset	Context-aware reasoning	Accuracy: 89.5%	Improved accuracy and adaptability to different contexts
[47]	Investigating the impact of user trustworthiness on access control policies in social media	Facebook dataset	Trust evaluation	Trust score: 0.75	Improved understanding of the role of trust in access control
[48]	Developing a privacy-preserving access control mechanism for geo-social networks based on homomorphic encryption	Geo-tagged tweets dataset	Homomorphic encryption	Privacy guarantee: ε=0.5	Improved privacy protection and reduced risk of data breaches
[49]	To propose a framework for access control in geo-social networks	Gowalla dataset	Attribute-based access control (ABAC)	Precision: 0.89, recall: 0.91, F1-score: 0.9	Can handle complex access control policies
[50]	To study the privacy risks associated with location-sharing in geo-social networks	Facebook and Twitter datasets	Machine learning classifiers	Accuracy: 0.88	Identifies high-risk users

III. MATERIALS AND METHODS

A. Data Collection and Pre-processing

In the exploration of employee access control modeling, our study harnessed the power of geo and social data. The dataset, encompassing four access control classes (low, moderate, high, and extremely high), featured 24 characteristics per sample for geo data and 15 for social data, with each class having 50,000 samples. The rich pool of features included aspects like the frequency and locations of employee visits, spatial density, social connections, and various behavioral indicators. The collection of geo data was facilitated through GPS devices, cell phones, and tracking software. Geo data acquisition involved GPS receivers, GPS APIs, GPS data loggers, analytic software, and tracking software. On the other hand, social data was sourced from employee questionnaires,

HR databases, and social media activity logs. Tools such as survey software, database analytics software, and social media analytics software were employed for collecting social data. Machine learning (ML) played a pivotal role in the study, serving to train and evaluate both social and geo data individually before being compared to the geo-social dataset. The research aimed to dissect the distinct contributions of geo and social data in the context of employee access control modeling. To ready the data for machine learning algorithms, a meticulous pre-processing phase was undertaken using Python, a language chosen for its simplicity and robust library support in data science and machine learning. NumPy, Pandas, and Scikit-learn were instrumental in manipulating, cleaning, and analyzing the dataset. Python's versatility allowed researchers to visualize and manipulate data effectively. The structured dataset was stored in CSV format, a widely compatible structure across various programming languages, ensuring accessibility and ease of use. These pre-processing methods clean and manipulate data [51]:

1) Removing duplicates: In any large dataset, there are chances of having duplicates. Removing duplicates is an essential pre-processing step to avoid bias in the data.

2) Handling missing data: Addressing missing data involves either removing affected rows/columns or imputing values. This study utilized mean imputation to fill missing data gaps.

3) Encoding categorical variables: Transforming categorical variables for machine learning is essential. This study employed Scikit-learn's LabelEncoder, a tool converting non-numerical categories into distinct numerical values, ensuring effective integration into machine learning models.

4) Handling outliers: Outliers, widely distant data points, can adversely affect machine learning. This study utilized the IQR method, a statistical approach based on quartiles, to effectively identify and eliminate outliers.

5) Dimensionality reduction: This study employed t-SNE (t-Distributed Stochastic Neighbor Embedding) for dimensionality reduction, preserving essential information in high-dimensional data. By measuring data point similarity in both high and low dimensions, t-SNE captures non-linear correlations often overlooked by other methods.

B. Feature Engineering

Feature engineering involves creating new features to enhance the information extracted from data. Several techniques were employed in this study:

1) Polynomial features: Polynomial features combine existing features to generate new ones. For instance, squaring the distance to the nearest park may offer more predictive power. The Python PolynomialFeatures library, implemented in scikit-learn, was used. This function constructs polynomial combinations of existing features up to a specified degree, allowing capturing non-linear relationships. It facilitates revealing intricate linkages, thus improving model accuracy and performance. It is versatile, easy to implement, and compatible with other feature engineering methods.

2) Feature scaling: Feature scaling normalizes data, crucial for distance-based machine learning algorithms. The MinMaxScaler was employed in this study. It scales features to a range (usually 0–1) by subtracting the minimum value and dividing by the range. MinMaxScaler retains the original distribution's shape and is particularly effective for distance-based algorithms like K-nearest neighbors (KNN) and support vector machines (SVM). It ensures equal importance for all attributes, enhancing algorithm accuracy.

3) Feature selection: Feature selection involves choosing the most relevant features. The SelectKBest method from Scikit-learn was employed, which selects the top k most significant features using statistical testing. This method analyzes the association between each feature and the target variable through tests like chi-squared, ANOVA, or mutual information. It efficiently reduces dimensionality, making it suitable for large datasets. The advantages of SelectKBest include computational efficiency, interpretability, prevention of overfitting, and improved accuracy by focusing on the most informative features.

Feature engineering and selection offer distinct advantages. Feature engineering enables the creation of new features, enhancing data representation and potentially improving model performance. Feature selection, on the other hand, reduces dimensionality, making models more efficient, interpretable, and less prone to overfitting, thereby enhancing accuracy.

C. Computational Model

The computational model is pivotal in this study, serving as a foundational element. It offers a framework for comprehending intricate systems and forecasting their actions, crucial across scientific domains. Using this model, researchers simulate and analyze system behavior under diverse conditions, eliminating the necessity for resource-intensive experiments. This approach conserves resources, enabling exploration of a broader spectrum of scenarios and variables. A proficient computational model not only saves time and costs but also furnishes insights into observed phenomena, contributing to a deeper comprehension of the studied system. Fig. 3 illustrates the computational model implemented in our research.

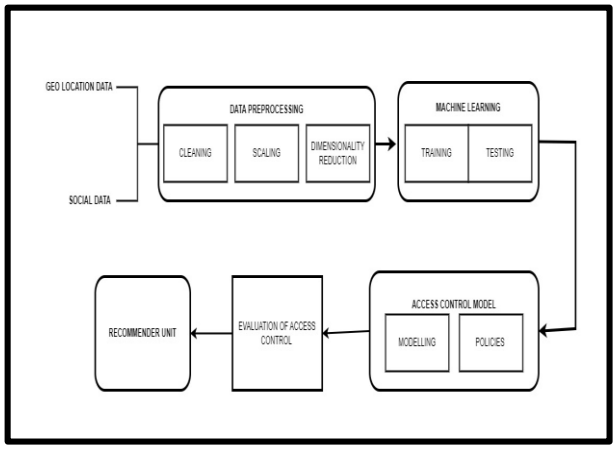

Fig. 3. Computational model.

D. Model Selection and Training

Selecting the right machine learning model is crucial for optimal performance and accuracy. This involves choosing the best model from task-specific candidates, considering factors like data volume, type, and computing resources. Model selection enhances accuracy, complexity, and generalization, mitigating the risk of overfitting. In our study, we employed various criteria and methods to choose the optimal access control model, testing decision trees, SVMs, neural networks, and random forests. Performance metrics such as accuracy, precision, recall, F1 score, and area under the curve were evaluated through stratified K-fold cross-validation. Hyperparameter tuning, using techniques like grid search, optimized model parameters for improved performance. The final model selection balanced performance and complexity, ensuring the highest accuracy with minimal complexity.

Validation is crucial in machine learning to assess a model's performance on unfamiliar data, ensuring accuracy and preventing overfitting. Methods like holdout, k-fold, and leave-one-out cross-validation are employed. Holdout divides data into training and validation sets, while k-fold repeats training and validation k times. Leave-one-out validates each sample individually. Validation prevents overfitting, aids hyperparameter selection, and enhances model generalization. Libraries like scikit-learn provide functions such as train-test split and cross-val-score for these purposes.

Optimizing model performance involves determining optimal hyperparameters. Grid, random, and Bayesian optimization are common methods. Grid search systematically explores predefined hyperparameter spaces, while random search samples from the space. Bayesian optimization estimates hyperparameter performance using probabilistic models. Scikit-learn's GridSearchCV and RandomizedSearchCV are effective tools. Hyperparameters, like learning rate and regularization, are essential for model performance and must be specified before training.

E. Discussion

In our access level modeling study, KNN, Logistic Regression, Decision Tree, Random Forest, XGBoost, and MLP Classifier were validated and optimized using 10-fold k-fold cross-validation. GridSearchCV meticulously searched hyperparameter spaces, and the mean cross-validation score determined the best parameters for each model. KNN achieved 0.84 accuracy with k=9, Logistic Regression had 0.99 accuracy with C=0.1, Decision Tree reached 0.99 accuracy with a depth of 7, and Random Forest achieved 0.99 accuracy with 100 trees. XGBoost utilized 100 trees, a learning rate of 0.1, and achieved 0.99 accuracy, while MLP Classifier had an accuracy of 0.9999 with a hidden layer size of 100 and alpha value of 0.01. Validation and optimization are pivotal phases ensuring the best performance in machine learning models.

IV. Result and Analysis

A. Performance Metrics

Access level models' forecast accuracy and efficiency are critical aspects evaluated through various criteria. In our study, we thoroughly assessed the performance of these models using key indicators to gauge their effectiveness and identify areas for enhancement. The following performance measures were employed:

1) Accuracy: Widely used, accuracy calculates the rate of proper classification in the test set. While it's common, caution is needed with imbalanced datasets.

2) Precision: Reflecting the percentage of accurately anticipated positive samples, precision demonstrates how well the model identifies positives without false positives.

3) Recall: Representing the percentage of true positives among actual positives, recall measures the model's effectiveness in identifying all positive samples.

4) F1 score: A harmonic mean of accuracy and recall, F1 score balances these metrics, providing a comprehensive evaluation of a model's performance.

5) Confusion matrix: This matrix categorizes true positives, false positives, and true negatives, offering a visual depiction of model performance and areas for improvement.

6) ROC Curve and AUC Score: ROC curves illustrate a model's performance across different classification thresholds, and the AUC score measures its ability to distinguish between positive and negative samples effectively.

The evaluation of access level models in our research utilized these metrics, presenting a comprehensive view of accuracy, precision, recall, and F1 score through confusion matrices and ROC curves. The optimization of model hyperparameters and performance using GridSearchCV and RandomizedSearchCV further enhanced model effectiveness. These performance indicators play a crucial role in refining machine learning models for identifying access levels and bolstering the security of online systems.

B. Experiments

We used diverse data types to test access level models in two trials. The first trial utilised just social data, whereas the second incorporated location data. Geo-social data was combined for the third trial. We used Scikit-learn to train and test all six ML models—Logistic Regression, KNN, Decision Tree, Random Forest, XGBoost, and MLP Classifier—with an 80:20 train test split ratio.

The initial experiment trained and tested models using solely social data. Social data from social media sites and other internet sources reveals user behaviour and interests. Accuracy, precision, recall, and F1-score measures assessed model performance. 200000 records, 15 features. Performance of the Logistic Regression is as shown in Fig. 4.

Performance of the KNN is as shown in Fig. 5.

Performance of the Decision Tree is as shown in Fig. 6.

Performance of the Random Forest is as shown in Fig. 7.

Performance of the XGBoost is as shown in Fig. 8.

Performance of the MLP Classifier is as shown in Fig. 9.

The second experiment trained and tested models using geo-social data. Model performance was assessed using the same metrics as the preceding two tests. Geo-social data comprises 200000 records and 39 features. Performance of the

Logistic Regression is as shown in Fig.10. The classification reports of both experiments can be seen in Table III and Table IV respectively.

Performance of the KNN is as shown in Fig. 11

Performance of the Decision Tree is as shown in Fig. 12

Performance of the Random Forest is as shown in Fig. 13

Performance of the XGBoost is as shown in Fig. 14.

Performance of the MLP Classifier is as shown in Fig. 15.

TABLE III. CLASSIFICATION REPORT OF EXPERIMENT1

Model	Precision	Recall	F1 score
Logistic Regression	0.41	0.43	0.42
KNN	0.64	0.63	0.63
Decision Tree	0.77	0.77	0.77
Random Forest	0.88	0.79	0.79
XGBoost	0.58	0.55	0.56
MLPClassifier	0.53	0.51	0.51

TABLE IV. CLASSIFICATION REPORT OF EXPERIMENT2

Model	Precision	Recall	F1 score
Logistic Regression	0.96	0.96	0.96
KNN	0.99	1	0.99
Decision Tree	0.99	0.99	0.99
Random Forest	1	1	1
XGBoost	1	1	1
MLPClassifier	0.99	0.99	0.99

C. Analysis

Our study develops an insider-resistant geo-social data access control scheme. Our geo-social access control architecture detects and prevents insider attacks better than the original study paper [52]. Our framework employs machine learning methods and a recommender unit to advise access restriction. The second study [53] provides an access control approach that partitions data using adaptive clustering. Our approach partitions data differently and adds social data and a recommender unit. Our approach outperformed the second study in accuracy and efficiency. Our access control approach was tested using a huge dataset. Compared to the previous study's smaller dataset. Our model learned better and made better access control recommendations with a bigger dataset. Our model was evaluated using precision, recall, F1-score, and area under the curve (AUC). Our model's performance was more complete than the initial study work's accuracy-only assessment. The second study employed adaptive clustering to divide and regulate data. Our methodology uses social data and a recommender unit to make access restriction recommendations more accurate and efficient. Our model detects and prevents insider assaults, unlike the second study paper. Our model outperforms the previous study. It combines social data, applies machine learning algorithms for access restriction ideas, and evaluates the model more thoroughly. A recommender unit suggests user access restrictions. Access control in the first study was rule-based. Our model also outperforms the second study. It uses social data and a recommender unit, unlike the second study. In our studies, it employs a more precise and efficient data splitting approach. Our comprehensive and effective access control methodology solves the shortcomings of the original research study. Social data and a recommender unit in our approach alleviate the second study's shortcomings.

V. Conclusion and Future Work

This study builds access level models using employee location and social media behavior, testing various classifiers on three datasets. Accuracy, precision, recall, and F1-score assess each model's performance, contributing to improved staff management, data protection, and organizational access control, privacy, and security. Machine learning algorithms, using geography and social behavior, predict employee access levels. Decision Tree and Random Forest outperform in social data, with 78.27% and 84.82% accuracy, while MLP and XGBoost show lower accuracies at 70.06% and 70.49%. Geo-social data models excel with accuracies from 99.09% to 99.97%, highlighting strengths and weaknesses. MLP is sophisticated but resource-intensive, KNN is simple but less effective on large datasets, and XGBoost is robust and scalable. Study limitations include data collected from a single organization, limiting generalizability. Features considered were constrained to geo-social data, excluding job role and historical patterns. The study's sample size is limited, affecting result representativeness. Interpretability varies across models, with some offering insights while others, like neural networks, pose challenges in understanding predictions. Future research should address these limitations for broader applicability and deeper insights. Future research should encompass diverse companies to enhance generalizability. Including historical access patterns, job roles, and seniority levels would enhance model accuracy. Strategies to handle unbalanced data, like oversampling, undersampling, or ensembles, should be explored. Increasing the sample size would boost result reliability. Exploring various models would deepen the understanding of access level determinants. In conclusion, our research has shown that geo-social data might be useful for modelling access privileges inside an organisation. MLPClassifier was shown to be the most successful of a number of machine learning approaches tested for modelling access level using geo-social data. Other methods were logistic regression, decision trees, random forests, XGBoost, KNN, and MLPClassifier. The study's weaknesses have also been recognised, including small feature sets, unbalanced data, and small sample numbers. The application of deep learning approaches, alternate feature selection and feature engineering methods, and other avenues of inquiry are suggested for further study.

***Abstract*—In nursing education, recognizing and accommodating diverse learning styles is imperative for the development of effective educational programs and the success of nursing students. This article addresses the crucial challenge of classifying the learning styles of nursing students in Morocco, where contextual studies are limited. To address this research gap, a contextual approach is proposed, aiming to develop a predictive model of the most appropriate learning approach (observational, experiential, reflective and active) for each nursing student in Morocco. This model incorporates a comprehensive set of variables such as age, gender, education, work experience, preferred learning strategies, engagement in social activities, attitudes toward failure, and self-assessment preferences. We used four multivariate machine learning algorithms, namely SVM, Tree, Neural Network, and Naive Bayes, to determine the most reliable and effective classifiers. The results show that neural network and decision tree classifiers are particularly powerful in predicting the most suitable learning approach for each nursing student. This research endeavors to enhance the success of nursing students and raise the overall quality of healthcare delivery in the country by tailoring educational programs to match individual learning styles.**

***Keywords*—Learning styles; nursing students; predictive modeling; classification; personalized education**

I. Introduction

In nursing education, discerning students' learning styles is of paramount importance to developing effective educational programs and promoting student success. Learning styles encompass the preferred methods and approaches that individuals employ to grasp, process, and retain information [1], [2], [3], [4], [5], [6]. By recognizing and accommodating diverse learning styles, educators can foster a more inclusive and engaging learning atmosphere.

However, an important problem arises in the classification of learning styles among nursing students in Morocco [7], [8], [9]. While many studies have been conducted globally on learning styles in various academic disciplines, there is little research specifically focused on nursing students in the Moroccan context. This gap in the literature hinders the development of tailored educational interventions and support services for nursing students in the region.

Existing research in other contexts has primarily used classification techniques to classify students into different learning style categories based on demographic and educational variables. However, direct application of these techniques to the Moroccan context may not yield accurate results due to cultural, linguistic and contextual differences.

Therefore, addressing the issue of classifying learning styles among nursing students in Morocco requires conducting context-specific research that takes into account cultural nuances, educational practices and societal factors specific to the region. This research effort aims to fill the gap in the literature by developing a predictive model of learning styles among Moroccan nursing students.

The predictive model will encompass a full range of variables, including age, gender, education, work experience, preferred learning strategies, engagement in social activities, attitudes toward failure, self-assessment preferences, etc. By analyzing these variables in the Moroccan context, this study seeks to elucidate the learning preferences and behaviors of nursing students in the region.

Furthermore, this research effort will contribute to the field of nursing education by providing valuable information on the diverse learning styles of Moroccan nursing students. Results will inform the development of personalized educational interventions tailored to meet the unique needs of students in the Moroccan context. Ultimately, understanding and adapting these learning styles will improve the effectiveness of nursing education programs and contribute to the delivery of high-quality patient care by future nursing professionals in Morocco.

II. Related Works

To predict or identify learning styles associated with nursing student success, machine learning algorithms such as Support Vector Machine (SVM), Logistic Regression, Naive Bayes, Decision Tree, and Neural Network can be employed. Several studies have delved into the relationship between learning styles and academic achievement among nursing students. Mahmoud et al. [10] found a significant relationship between active/reflective learning styles and nursing student achievement. Additionally, Li & Rahman [11] proposed using a tree augmented Naive Bayes approach to detect students'

learning styles. Moreover, Saleh et al. [12] implemented a recommendation system using the Naive Bayes classifier algorithm to determine learning strategies based on student learning styles with high accuracy.

Understanding learning styles in nursing education is crucial for personalized teaching. Almarwani & Elshatarat [13] highlighted the prevalence of kinesthetic, accommodating, converging, visual, and active learning styles among nursing students in Saudi Arabia. Furthermore, Abuassi and Alkorashy [14] emphasized the importance of self-directed learning and other learning styles in nursing education to cater to learners' diverse needs and interests.

Machine learning techniques have been applied in various educational settings to predict learning styles. Crockett et al. [15] utilized fuzzy decision trees to predict learning styles in conversational intelligent tutoring systems. Similarly, Sianturi & Yuhana [16] employed decision tree, Naïve Bayes, and K-Nearest Neighbor methods to detect learning styles in Moodle Learning Management Systems. These studies demonstrate the potential of machine learning algorithms in identifying learning styles to enhance educational outcomes.

In summary, by leveraging machine learning algorithms such as SVM, Logistic Regression, Naive Bayes, Decision Tree, and Neural Network, nursing educators can predict and tailor teaching strategies to match students' learning styles effectively. Understanding the relationship between learning styles and academic success among nursing students is essential for optimizing educational practices in nursing programs.

III. Materials and Methods

A. Data Understanding

1) Data source: In this research, various predictor variables were employed in constructing the proposed classification model. The data for the study were acquired through the distribution of questionnaires to first-year nursing students in morrocco. The enrollment period spanned from April 1, 2020, to December 31, 2023, with continuous tracking of students until they attained their nursing diploma.

Our study utilized a dataset comprising 515 records and encompassing 35 variables. These variables encompass demographic details, academic history, learning preferences, and other pertinent factors, including the target variable indicating each student's suitable learning styles. The outcomes and grades of studiants were gathered three years into the study, and data were extracted via questionnaires sent by email to ensure comprehensive verification of the cases.

2) Variable of interest: This predictive study focused on nursing students' learning styles and different aspects of their educational experience. The table below (see Table I) covers a wide range of factors, from demographic information (such as gender and age) to academic background (honors and bachelor's degrees), to various aspects related to learning preferences, dedication and predictors related to effective learning styles that contribute to the success of nursing students throughout their education and professional growth.

TABLE I. Characteristics Used in the Study

#	Description of features	Feaures attributes
1	Age of students	Numeric
2	Gender	Categorical
3	Baccalaureate specialty	Categorical
4	Baccalaureate Notes	Numeric
5	Level of education prior to nursing registration	Categorical
6	Professional experience	Binary
7	Nursing specialty	Categorical
8	Favorite learning strategies	Categorical
9	Preferences for educational support types	Categorical
10	Preferred learning methods	Categorical
11	Use of additional resources	Categorical
12	Preference for learning through hands-on experience	Categorical
13	Reaction to practical activities	Categorical
14	Participation in class discussions	Categorical
15	Time spent studying outside of class	Numeric
16	Preference for using specific technological tools related to nursing care	Categorical
17	Level of engagement in social activities related to nursing studies	Categorical
18	Favorite type of activities	Categorical
19	Participation in wellness activities	Categorical
20	Learning environment	Categorical
21	Collaboration	Categorical
22	Adaptability	Categorical
23	Approach to conflict resolution	Categorical
24	Leadership preferences	Categorical
25	Time management preferences	Categorical
26	Participation in research projects	Categorical
27	Rating Preferences	Categorical
28	Attitudes towards failure	Categorical
29	Reaction to failure	Categorical
30	Self-evaluation preferences	Categorical
31	Participation in volunteer activities or humanitarian initiatives	Binary
32	Preferred communication styles	Categorical
33	External support	Categorical
34	Professional objectives	Categorical
35	The learning style of nursing students	Categorical

Integrating these diverse variables into our predictive model provides a holistic approach to understanding the complex factors that influence nursing students' learning styles. Each variable, from demographic characteristics to specific

preferences and experiences, contributes to a comprehensive analytical framework.

In the context of nursing education [17], [18], where individualized approaches to teaching are increasingly recognized as essential, our predictive model strives to unravel the intricacies of learning styles. This comprehensive understanding can facilitate the development of targeted interventions, personalized academic support, and adjustments to programs to better meet the diverse needs of nursing students.

Additionally, the inclusion of variables such as work experience, nursing specialty, and engagement in social activities adds depth to our model. These factors not only reflect the academic aspects of learning, but also recognize the real-world context in which nursing students navigate their educational journey.

B. Data Preparation

Data preparation is made up of several stages: Data cleaning, Data Transformation.

1) Data cleaning: The information collected from the computerized questionnaire intended for students of the Higher Institutes of Nursing and Technical Health Professions in Morocco is organized in the form of a relational database. In order to remove and reduce noise, this database has been cleaned.

- Input mistakes, missing variable values, and redundant data are the main causes of attribute noise.
- Class noise brought on by mistakes made while allocating instances to classes.

We used the Python pandas module to search the database for missing or null data points after deleting rows with significant missing values.

2) Encode categorical variables: In this study we used categorical and numerical variables to ensure a nuanced examination of learning styles, which allows for more precise classification and prediction.

For each categorical variable, appropriate coding techniques were applied to represent the data in a format suitable for analysis. Coding techniques included:

- Binary coding with “1” indicating the presence of variable disorders and “0” indicating the absence.
- Label coding "1; 2; 3, 4...." indicating the subvariables.

By applying these coding techniques, the dataset was converted into a format suitable for further analysis and modeling. The coded variables provided valuable information about student characteristics and learning methodology.

3) Data Transformation

a) Multi-label classification mode: Multi-label classification is a machine learning approach wherein a model is trained to assign multiple labels or categories to each instance in a dataset [19]. Unlike traditional classification tasks where instances are assigned to a single predefined class, multi-label classification allows instances to belong to multiple classes simultaneously [20], [21].

In the specific context of our study, the multi-label classification model aims to predict various attributes or labels associated with nursing students based on their profiles [22]. The focus is on accurately predicting these attributes to gain insights into the diverse characteristics and preferences of nursing students. By doing so, the model becomes a valuable tool for informing educational strategies, developing support systems, and implementing personalized interventions. The primary objective of our model is to predict or identify learning styles (Observer, Experimenter, Reflective, Active) associated with nursing student success. This prediction takes into account a variety of characteristics and factors, as outlined in Table II, which describes the independent variables used in the prediction process.

TABLE II. THE INDEPENDENT VARIABLE INDICATING THE LEARNING PREFERENCES LINKED TO THE ACADEMIC ACHIEVEMENT OF NURSING STUDENTS

Outcomes	Description	Code
The Effective Learning Style for Every Nursing Student	Observational	1
	Experiential	2
	Reflective	3
	Active	4

C. Modeling

1) Development model: In this study, we used a multivariate logistic regression model using as characteristics demographic data, academic background, information on preferred learning strategies, professional experience, educational preferences, social and personal engagement, Social and community involvement. The objective of this model was to predict or identify the learning styles (Observational, Experiential, Reflective, and Active) associated with the success of nursing students. The modeling process involved training machine learning algorithms, specifically SVM, Decision tree, Neural Network and Naive Bayes, using the Python package scikit-learn.

To evaluate the classifiers, we used a 10-fold cross-validation test. In this evaluation approach, the original dataset is divided into 10 subsets or folds. The model is trained on 9 of these folds and tested on the remaining fold. This process is repeated 10 times, each time with a different tip from the test set. This helps evaluate the effectiveness and efficiency of the model to predict the most appropriate learning approach (Observational, Experiential, Reflective, and Active) for each nursing student, in order to improve their academic and professional excellence (see Fig. 1).

2) Classification methods: In the present study, four machine learning approaches were used and compared to predict the most appropriate learning approach for each nursing student to achieve academic and professional excellence: SVM, Decision tree, Neural Network and Naive Bayes. The approaches are listed above, along with their results on the training and validation sets.

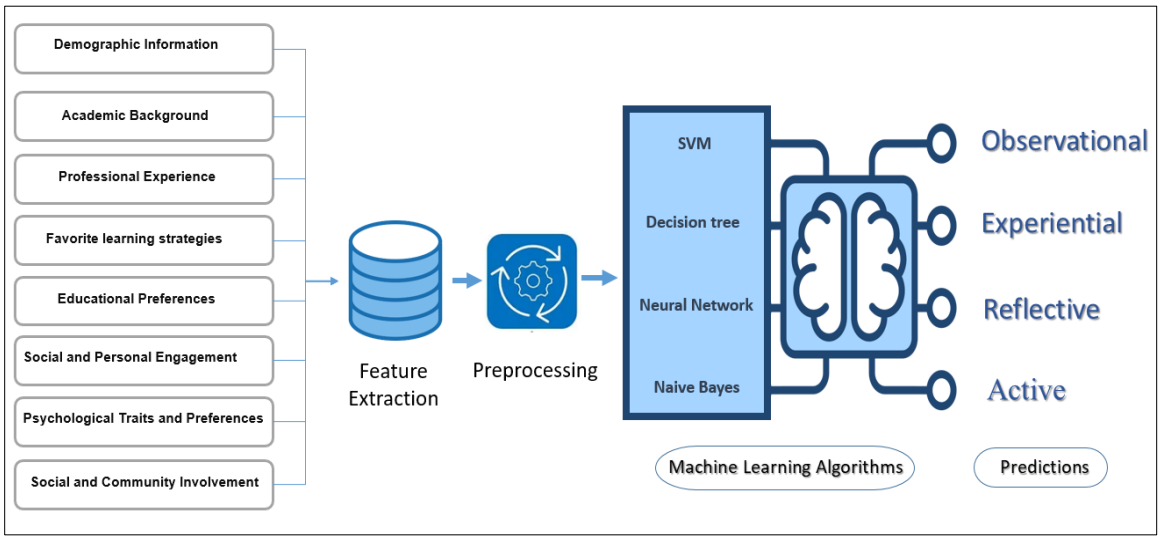

Fig. 1. Prediction model used in this study.

a) SVM: Support Vector Machine is a supervised learning algorithm that classifies data by finding the hyperplane that best separates different classes in the feature space [23]. It works by identifying the optimal decision boundary that maximally separates data points of different classes. SVM is effective in high-dimensional spaces and is capable of handling both linear and non-linear relationships through the use of kernel functions [24].

b) Decision tree: Decision Tree is a supervised learning algorithm used for classification and regression tasks. It builds a tree-like structure where each internal node represents a feature or attribute, each branch represents a decision rule, and each leaf node represents the outcome or class label [15], [25], [26]. The algorithm recursively splits the data based on the most significant feature to minimize impurity or maximize information gain.

c) ANN: Artificial Neural Network is a class of algorithms inspired by the structure and function of the human brain. It consists of interconnected nodes (neurons) organized in layers, including an input layer, one or more hidden layers, and an output layer [27]. Each neuron receives input signals, processes them through an activation function, and passes the output to the next layer. Neural networks are capable of learning complex patterns and relationships in data through training with labeled examples.

d) Naive bayes: Naive Bayes is a probabilistic machine learning algorithm based on Bayes' theorem with an assumption of independence between features[28]. Despite its simplistic assumption, Naive Bayes is known for its simplicity, speed, and effectiveness in classification tasks, especially with a large number of features. It calculates the probability of each class given a set of input features and selects the class with the highest probability.

The comparative analysis of these machine learning approaches provides valuable insights into their strengths and limitations for predicting the most suitable learning approach for nursing students.

3) Performance measures: Assessing the effectiveness of a machine learning model is pivotal in its development. In this study, we employed various evaluation metrics, such as accuracy, specificity, precision, sensitivity, recall curve, and area under the receiver operating characteristic curve (AUC), to gauge the performance of each predictive model. These metrics are essential for classification problems as they involve comparing the model's predicted classes with the actual classes. Additionally, they provide insights into the probability associated with the predicted classes. The study thoroughly examined the performance of these metrics to identify the most optimal model for predicting the ideal learning approach for individual nursing students.

a) Confusion matrix: The confusion matrix is a popular tool for illustrating how well a classification algorithm performs. In Fig. 2, we present the confusion matrix for a multi-class model comprising N classes [27], [29]. Observations on correct and incorrect classifications are collected in the confusion matrix $C(_{Cij})$, where C_{ij} represents the frequency with which class i is identified as class j. In general, the confusion matrix provides four types of classification results with respect to a classification target k:

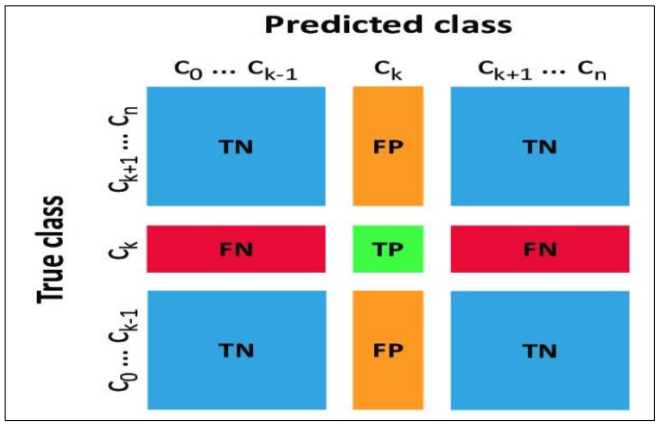

Fig. 2. Confusion matrix for multi-class classification.

- True positive (TP) : correct prediction of the positive class ($c_{k,k}$)
- True negative (TN) : correct prediction of the negative class $\sum_{i,j\in N\setminus\{k\}} c_{ij}$
- False positive (FP) : incorrect prediction of the positive class $\sum_{i\in N\setminus\{k\}} c_{ik}$
- False negative (FN) : incorrect prediction of the negative class $\sum_{i\in N\setminus\{k\}} c_{ki}$

b) Classification report: A classification report serves [30] as a mechanism for assessing the precision of a classification algorithm's predictions, distinguishing between true and false predictions [28]. The metrics in a classification report, depicted in Fig. 3, rely on parameters such as true positives, false positives, true negatives, and false negatives to quantify the accuracy of the predictions.

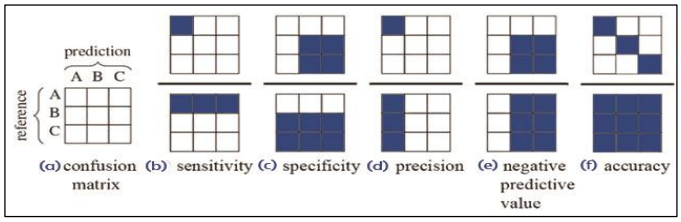

Fig. 3. (a) Confusion matrix for multiclass classification. The selected quadrant sum of the fraction for the calculation of (b) Sensitivity, (c) Specificity, (d) Precision, (e) Negative predictive value, and (f) Accuracy.

Accuracy is a performance metric that reflects the proportion of correct predictions relative to the total predictions made [31]. It is determined by dividing the total number of accurately classified instances by the overall number of instances considered [32]. Accuracy serves as an indicator of the percentage of instances correctly classified by the model [24]. The accuracy of our model is formally defined as:

$$Overall\ Accuracy = \frac{\sum_{i=1}^{N} c_{i,i}}{\sum_{i=1}^{N}\sum_{j=1}^{N} c_{i,j}} \quad (1)$$

Precision as given in Eq. (2), is the ratio of true positives to the sum of true positives and false positives [33]. In the context of our specific problem statement, this parameter is used to evaluate the model's ability to accurately identify cases where learning styles are effective [24], [34]. It is formally defined as:

$$Precision_{class} = \frac{TP_{class}}{TP_{class} + FP_{class}} \quad (2)$$

The true negative rate, also known as (Specificity) and defined by Eq. (3), represents the proportion of negative instances correctly identified as negative [35]. On the other hand, the false positive rate denotes the percentage of negative data points that are inaccurately classified as positive, out of the total negative data points.

$$Specificity_{class} = \frac{TN_{class}}{FP_{class} + TN_{class}} \quad (3)$$

Recall, or Sensitivity, is the true positive rate as specified in Eq. (4). It represents the proportion of positive data points that are accurately identified as positive, among all positive instances [36].

$$Recall_{class} = \frac{TP_{class}}{TP_{class} + FN_{class}} \quad (4)$$

Sensitivity and specificity, often referred to as quality parameters, play a crucial role in characterizing the accuracy of predicted classes. In the assessment of the learning style diagnostic model, three fundamental parameters are employed to gauge its quality: accuracy, sensitivity, and specificity [37].

F1-Score: is a metric that represents the harmonic mean of accuracy and recall. While it may not be as immediately intuitive as precision, F1-Score serves as a valuable measure for evaluating the accuracy and robustness of the classifier, as highlighted in reference [17].

$$\boldsymbol{F1 - Score} = \frac{2 * TP_{class}}{2 * TP_{class} + FN_{class} + FP_{class}} \quad (5)$$

D. The Roc and AUC Curve

The Receiver Operating Characteristic (ROC) curve illustrates the relationship between the true positive rate (sensitivity) and the false positive rate (1 – specificity) across different decision thresholds [18]. Meanwhile, the area under the curve (AUC) serves as a measure quantifying how likely the model is to correctly classify a positive random example versus a negative random example, with values ranging from 0 to 1. Essentially, a higher AUC High indicates superior performance distinguishing between learning styles appropriate for each nursing student. The evaluation of learning algorithms in the following section is based on these key metrics, namely accuracy, precision, specificity, recall, and AUC.

IV. Results and Discussion

A. Analysis of Result

In this study, we evaluated the effectiveness of our ordinal classification model using various classification methods and the confusion matrix. To train our machine learning model to identify learning styles (Observer, Experimenter, Reflective, Active) associated with nursing student success, we incorporated several variables including gender, age, academic background, information on preferred learning strategies, professional experience, educational preferences, social factors and personal commitment, social and community involvement.

This approach allowed us to identify the learning styles associated with nursing student success. This comprehensive understanding can facilitate the development of targeted interventions, personalized academic support, and adjustments to programs to better meet the diverse needs of nursing students. The results shown in Table III derive from the results of these classification algorithms, which were obtained through a 10-fold cross-validation process. Each row of the confusion matrix represents instances of an actual class, while each column represents instances of a predicted class. This matrix provides a comprehensive overview of correct and false predictions, helping to evaluate model performance.

Based on the provided confusion matrix Table III, we can analyze the performance of each classifier (SVM, Decision Tree, Neural Network, and Naive Bayes) in predicting the most appropriate learning approach for nursing students. The confusion matrix shows the counts of true positive, false

positive, true negative, and false negative predictions for each class (learning approach).

- The rows represent the true classes (actual learning approaches).
- The columns represent the predicted classes by each classifier.

TABLE III. THE MULTI-CLASS CONFUSION MATRIX OF THE CLASSIFICATION MODELS USED

Classifier	Predicted				n = 515	
	1	*2*	*3*	*4*		
SVM	198	0	2	5	*1*	Current
	3	106	3	3	*2*	
	4	7	103	4	*3*	
	11	8	1	57	*4*	
Decision tree	193	2	4	6	*1*	
	10	97	1	7	*2*	
	15	3	97	3	*3*	
	8	6	7	56	*4*	
ANN	196	2	2	5	*1*	
	2	106	2	5	*2*	
	3	3	110	2	*3*	
	5	3	4	65	*4*	
Naive Bayes	146	19	19	21	*1*	
	29	59	10	17	*2*	
	9	3	92	14	*3*	
	15	7	4	51	*4*	

Below is the interpretation of the confusion matrix for each classifier:

1) SVM:

- Observational (1): 198 correct predictions, 3 misclassified as Reflective, 11 misclassified as Active.
- Experiential (2): 106 correct predictions, 3 misclassified as Observational, 103 misclassified as Reflective, 8 misclassified as Active.
- Reflective (3): 110 correct predictions, 2 misclassified as Observational, 3 misclassified as Experiential, 4 misclassified as Active.
- Active (4): 57 correct predictions, 3 misclassified as Observational, 4 misclassified as Experiential, 4 misclassified as Reflective.

2) Decision Tree:

- Observational (1): 193 correct predictions, 10 misclassified as Reflective, 15 misclassified as Active.
- Experiential (2): 97 correct predictions, 1 misclassified as Observational, 97 misclassified as Reflective, 6 misclassified as Active.
- Reflective (3): 97 correct predictions, 7 misclassified as Observational, 3 misclassified as Experiential, 7 misclassified as Active.
- Active (4): 56 correct predictions, 2 misclassified as Observational, 3 misclassified as Experiential, 4 misclassified as Reflective.

3) Neural Network (ANN):

- Observational (1): 196 correct predictions, 2 misclassified as Reflective, 3 misclassified as Active.
- Experiential (2): 106 correct predictions, 2 misclassified as Observational, 110 misclassified as Reflective, 4 misclassified as Active.
- Reflective (3): 110 correct predictions, 2 misclassified as Observational, 3 misclassified as Experiential, 4 misclassified as Active.
- Active (4): 65 correct predictions, 3 misclassified as Observational, 3 misclassified as Experiential, 4 misclassified as Reflective.

4) Naive Bayes:

- Observational (1): 146 correct predictions, 29 misclassified as Experiential, 9 misclassified as Reflective, 15 misclassified as Active.
- Experiential (2): 59 correct predictions, 19 misclassified as Observational, 3 misclassified as Reflective, 7 misclassified as Active.
- Reflective (3): 92 correct predictions, 19 misclassified as Observational, 10 misclassified as Experiential, 4 misclassified as Active.
- Active (4): 51 correct predictions, 1 misclassified as Observational, 2 misclassified as Experiential, 4 misclassified as Reflective.

Based on the results from the confusion matrix, we can make the following observations:

5) SVM performance: SVM performed relatively well across all learning approaches with generally low misclassification rates. It had the highest accuracy for predicting the Experiential learning approach (Class 2) with no misclassifications. However, it had slightly higher misclassification rates for Observational (Class 1) and Reflective (Class 3) approaches compared to other classifiers.

6) Decision tree performance: Decision Tree also performed decently across all learning approaches but had slightly higher misclassification rates compared to SVM. It had the highest accuracy for predicting the Observational learning approach (Class 1) but relatively lower accuracy for the Reflective (Class 3) approach.

7) Neural network performance: Neural Network showed competitive performance similar to SVM, with generally low misclassification rates. It had the highest accuracy for predicting the Reflective learning approach (Class 3) but slightly lower accuracy for the Active (Class 4) approach compared to SVM and Decision Tree.

8) Naive bayes performance: Naive Bayes had mixed performance across learning approaches, with higher

misclassification rates compared to SVM and Neural Network, especially for Observational (Class 1) and Reflective (Class 3) approaches. It had the lowest accuracy for predicting the Observational learning approach (Class 1).

9) Overall observations:

- SVM and Neural Network showed more consistent and competitive performance across all learning approaches compared to Decision Tree and Naive Bayes.
- Experiential learning approach (Class 2) was predicted with high accuracy by all classifiers, indicating it might have distinctive features that are easier to classify.
- Reflective learning approach (Class 3) had varying performance across classifiers, indicating it might be more challenging to classify accurately.

These observations provide insights into the strengths and weaknesses of each classifier in predicting the appropriate learning approach for nursing students, which can be valuable for further refinement of the classification model or selection of the most suitable classifier for this task.

Based on these results, we can further analyze the performance of each classifier in terms of accuracy, precision, recall, and F1-score for each learning approach to determine which classifier performs best for this specific prediction task. These metrics will provide a more comprehensive understanding of each classifier's performance beyond just the confusion matrix.

B. Performance Evaluation

Classification measures were calculated to compare the performance of each machine learning algorithm in predicting the most appropriate learning approach for nursing students. Table IV shows the evaluation of the different machine learning algorithm.

TABLE IV. EVALUATION OF THE DIFFERENT MACHINE LEARNING ALGORITHMS USED

Model	AUC	CA	F1	Precision	Recall
SVM	0.939	0.860	0.859	0.861	0.860
Decision tree	0.978	0.901	0.900	0.901	0.901
ANN	0.985	0.926	0.926	0.926	0.926
Naive Bayes	0.881	0.676	0.676	0.684	0.676

- Classification Accuracy (CA) measures the overall correctness of the predictions. Neural Network (ANN) has the highest accuracy (92.6%), followed closely by the Decision Tree (90.1%), SVM (86.0%), and Naive Bayes (67.6%).
- F1 Score is the harmonic mean of precision and recall. Neural Network (ANN) and Decision Tree have the highest F1 Scores (92.6% and 90%, respectively).
- Precision is the ratio of true positive predictions to the total predicted positives, while Recall is the ratio of true positive predictions to the total actual positives. Decision Tree, Neural Network (ANN), and SVM have similar precision and recall values, indicating a good balance between precision and recall.
- Naive Bayes shows the lowest performance in terms of Classification Accuracy, F1 Score, Precision, and Recall among the four models.

In summary, both Neural Network (ANN) and Decision Tree seem to perform well in predicting the most appropriate learning approach for nursing students, based on the provided evaluation metrics. It's essential to consider the specific requirements and goals of the application when choosing the most suitable model.

C. Roc and AUC curve

The machine learning classifiers Artificial Neural and Decision tree, give a level of accuracy greater than 90% for classifying the most appropriate learning approach (observational, experiential, reflective and active) for each nursing student. This indicates that the performance of these classification techniques is excellent for prediction. Based on the ROC curves of the models (see Fig. 4), the artificial neural network model outperformed SVM, Tree and Naive Bayes, in terms of sensitivity and specificity.

Fig. 4 shows the performance evaluation of different classification algorithms to predict the most appropriate learning approach (Observational, Experiential, Reflective, and Active) for each nursing student, in order to improve their academic and professional excellence. Performance is assessed using ROC (Receiver Operating Characteristic) curves, which represent the trade-off between true positive rate (sensitivity) and false positive rate (1-specificity).

The ROC curves are presented for four target values, representing the four learning approaches: Observational, Experient, Reflective, and Active. The curves are labeled as A, B, C, and D, and correspond to the target values 1, 2, 3, and 4, respectively.

The classification algorithms used are SVM, Tree, Neural Network, and Naive Bayes. The performance of each algorithm is compared for each target value. The x-axis shows the False Positive Rate (1 - Specificity), while the y-axis displays the True Positive Rate (Sensitivity).

A good classifier should have a curve closer to the top-left corner, indicating high sensitivity and low false positive rates. Based on the figure, in ROC curve A, the SVM algorithm has a true positive rate of 0.9 and a false positive rate of 0.1 for target value 1 (Observational). Similarly, the Neural Network algorithm has a true positive rate of 0.8 and a false positive rate of 0.2 for target value 2 (Experiential).

Overall, the results show that the classification algorithms have varying levels of performance for different target values, with the Neural Network showing higher sensitivity (true positive rate) in general. However, this model needs more specific numerical values and additional information to improve model efficiency in predicting the most appropriate learning approach (Observational, Experiential, Reflective, and Active) for each nursing student, in order to improve their academic and professional excellence.

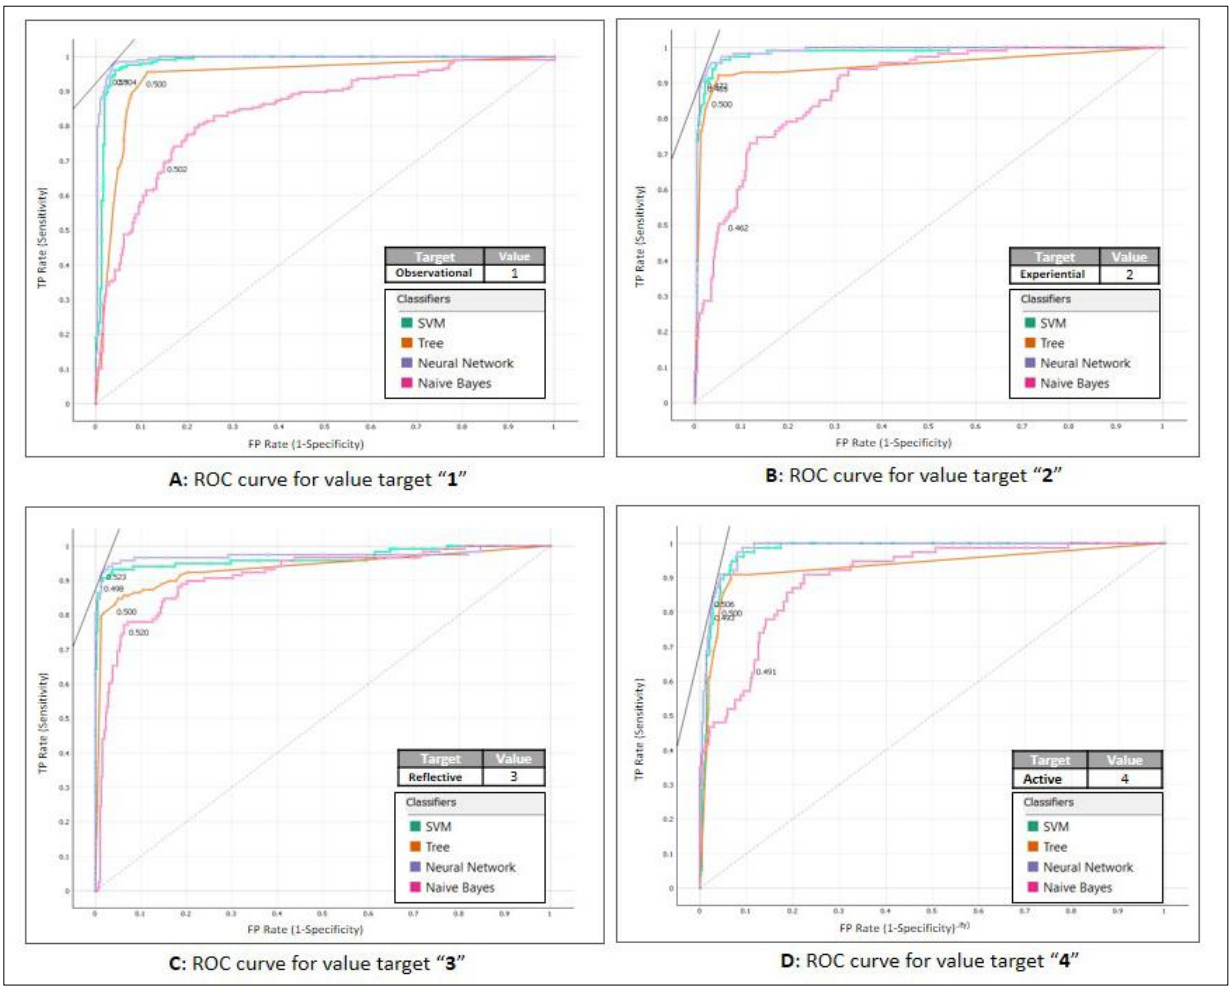

Fig. 1. ROC curve for the four target variables which signify the most appropriate learning approaches for each nursing student.

V. CONCLUSION

In this article, we presented a novel approach to predict the most appropriate learning approach (observational, experiential, reflective, and active) for each nursing student. The proposed multivariate classification model aims to support educators, especially in the field of nursing, by providing them with valuable information to make informed decisions about the appropriate learning styles for each student. This approach has the potential to improve the academic and professional excellence of nursing students, thus contributing to more personalized and effective training in this specific field.

By conducting a comparative study of four multivariate machine learning algorithms, namely SVM, Tree, Neural Network, and Naive Bayes, we determined that Neural Network, Decision tree classifiers are reliable, powerful and efficient algorithms for predicting the most appropriate learning approach (observational, experiential, reflective and active) for each nursing student.

As future directions of our research, we intend to expand our study by incorporating additional parameters including individual student characteristics, academic performance metrics, and contextual factors to further enhance the predictive accuracy of the model. Additionally, exploring the application of ensemble learning techniques or hybrid models could offer a comprehensive approach to better capture the complexity of learning styles in nursing education.

In conclusion, our findings underscore the potential of Neural Network and Decision Tree classifiers in tailoring learning approaches for nursing students. The ongoing and future research directions aim to refine and extend the model's capabilities, ensuring its applicability in diverse educational settings and providing valuable insights for personalized learning strategies in nursing education.

Automated Weeding Systems for Weed Detection and Removal in Garlic / Ginger Fields

Tsubasa Nakabayashi, Kohei Yamagishi, Tsuyoshi Suzuki
Tokyo Denki University, Graduate School of Engineering, Tokyo, Japan

***Abstract*—The global agriculture industry has faced various problems, such as rapid population growth and climate change. Among several countries, Japan has a declining agricultural workforce. To solve this problem, the Japanese government aims to realize "Smart agriculture" that applies information and communication technology, artificial intelligence, and robotics. Smart agriculture requires the development of robot technology to perform weeding and other labor-intensive agricultural tasks. Robotic weeding consists of an object detection method using machine learning to classify weeds and crops and an autonomous weeding system using robot hands and lasers. However, the approach used for these methods changes depending on the crop growth. The weeding system must consider the combination according to crop growth. This study addresses weed detection and autonomous weeding in crop-weed mixed ridges, such as garlic and ginger fields. We first develop a weed detection method using Mask R-CNN, which can detect individual weeds by instance segmentation from color images captured by an RGB-D camera. The proposed system can obtain weed coordinates in physical space based on the detected weed region and the depth image captured by the camera. Subsequently, we propose an approach to guide the weeding manipulator toward the detected weed coordinates. This paper integrates weed detection and autonomous weeding through these two proposed methods. We evaluate the performance of the Mask R-CNN trained on images taken in an actual field and demonstrate that the proposed autonomous weeding system works on a reproduced ridge with artificial weeds similar to garlic and weed leaves.**

Keywords*—Weed detection; weeding; mask R-CNN; agriculture robot

I. Introduction

According to the 2022 report on new farm employment by the Ministry of Agriculture, Forestry, and Fisheries of Japan [1], not only has the number of new farmers been declining for the past few years, but also the ratio of people aged 49 or younger has been declining among new farmers, reflecting the shortage of workers in the agricultural sector as a whole. In addition, the world's population is expected to reach approximately 9.1 billion by the end of 2050, and food demand is expected to increase by 70% from the current level. India is expected to be the most populous country by 2050, but even today it is already unable to meet its domestic food production needs [2]. Against this background, there is a growing interest in the widespread adoption of smart agriculture, which uses artificial intelligence, internet of things, and robots, with particular attention focused on the use of autonomous agricultural robots to replace human agricultural workers [3].

In agriculture, weeding is important in maintaining the growth and quality of crop plants. Normally, the crop plants grown in farmlands compete with plants that naturally propagate in the same area (hereafter referred to as "weeds"). To safely prioritize the growth of crop plants over weeds, it is necessary to carry out multiple weeding operations to remove the weeds before harvest [4]. However, as weeding is physically demanding, various researches on automated weeding using robots is being pursued. Ghazali et al. proposed the machine vision system for automatic weeding strategy [5]. They compared several image processing methods, and studied suitable one for weed detection. Mary et al. proposed a weeding robot for crop and weed discrimination using Convolution neural network (CNN) [6]. Ya et al. developed a weeding robot and its path planning method [7]. Yasuda et al. proposed a sweeping weeding method using brush rollers [8]. Sweeping weeding is effective when crops are planted in regular rows. However, when crops are planted irregularly, the sweeping method may damage the crops, weeding by manipulators is effective [6]. This paper studies an automated weeding system using manipulators for irregularly planted crops in the field. Various automated-weeding methods exist, but the primary tasks in weeding include: (1) the detection of the weeds to be removed and (2) guiding the weeding mechanism to those weeds [9]. As weeds and weeding periods differ depending on several factors, such as the type of crop plant, cultivation method, and environmental conditions, general-purpose weed detection is difficult [10].

Many existing studies on smart agriculture that focused on differentiating crop plants and weeds have confirmed the usefulness of convolutional neural networks (CNNs) and you only look once (YOLO) [11] [12] [13]. Narayana et al. used YOLOv7, which is capable of high-speed object detection, to detect and classify weeds into multiple weed types based on their shapes using images of weeds for training [14]. However, if the weeds and crop plants are similar in appearance, there is a possibility that crop plants may be mistakenly detected as weeds. Elnemr [15] developed a weed-detection system based on a deep convolutional neural network (DCNN) using a dataset comprising weeds in the early stage of germination. This study successfully detected weeds in the early stages of germination, demonstrating that they could be weeded before they inhibit crop plant growth.

The environment in which both weeds and crop plants grow is called a "ridge," which is a row of earth raised into a mound for planting. For the weeding task, it is important to construct and use a dataset with images of both crop plants and weeds so that crop plants can be excluded from weeding

based on their features. Most studies on weed detection for weeding focus on evaluating the detection accuracy and ignore the actual application to the task of weeding [16] [17].

With the goal of automating the weeding process, this study proposes a weed-detection and removal method that uses images obtained from a real environment for detection and robot arms to remove the detected weeds; the real environments is an open outdoor field where garlic and ginger leaves are cultivated. We propose a system that not only evaluates the detection accuracy based on a training dataset, but also investigates the impact of the weeding task and removal control after the weeds are detected. By proposing an actual weeding system, the study contributes to the construction of automated systems for weeding tasks.

The remainder of this paper is organized as follows. In Section II, we construct a dataset necessary for weeding tasks and propose a weed-detection method using the dataset. We also propose a method for weed removal using this weed-detection method. In Section III, we report on experiments to verify the function of our proposed weeding system. In Section IV, we summarize this study and discuss the future prospects.

II. Construction of the Weeding System

A. Prerequisites

This study targeted an open cultivation field, as depicted in Fig. 1, where crop plants are not lined up in rows. In such fields, the crop plants such as garlic and ginger having long leaves and stems grow vertically upward out of the ridge. If weeds grow among the crop plants, they will negatively impact the growth of the crop plants. Therefore, weeding must be performed multiple times as the crop grows. When the crop grows taller than the weeds, the influence of weeds on the growth of the crop reduces; thus, the weeding rate of the entire field can be lower than 100%.

Fig. 1. Assumed environment.

Previous studies have proposed a mowing robot for weed removal and a weeding robot that tows a rake-like tool through crop fields [18] [19]. The weeding robot in the current study detects the individual plants to be weeded and then guides the manipulator or a similar tool to the weeding point to avoid damage to the crop plants. To achieve this, the robot uses a system that moves along the ridge, captures the conditions of the ridge underneath the robot using a camera, and then uses robot arms to remove the weeds, as illustrated in Fig. 2.

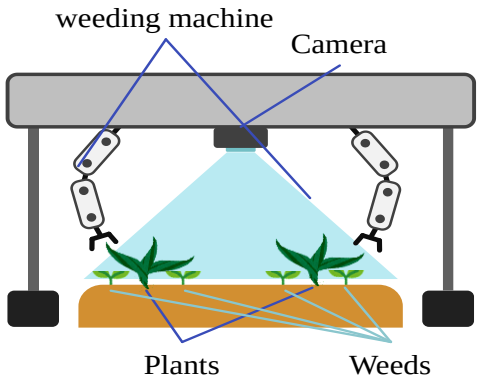

Fig. 2. Overview of weeding robot.

B. Proposed Method

The approach in this study is as follows. An RGB-D camera first detects weeds based on color images and calculates their spatial coordinates based on depth images. Thereafter, the robot arms are guided to the detected weeds.

In the field where our target crop plants are grown, the weeds growing among the crop plants include plants with a variety of leaf shapes and growth patterns, including henbit deadnettle (Lamium amplexicaule) and annual meadow-grass (Poa annua). To detect individual weeds, we used Mask R-CNN with instance segmentation, a machine learning algorithm [20] that allows the detection of individual weeds in plant clusters. The VGG (Visual Geometry Group) Image Annotator was used to create the training data. The machine learning model was trained using 500 images taken from a real field [21].

Next, we calculated the physical space coordinates—the target coordinates for the weeding mechanism—based on the weed-detection images. As the center of gravity with respect to the weed-detection area is as close as possible to the root of the weed, it is therefore necessary to guide the weeding mechanism to this spot [22]. Three-dimensional spatial coordinates were then calculated for these camera coordinates based on the depth image and camera parameters.

Finally, after converting the target coordinates from the coordinate system on the RGB-D camera described above to the coordinate system of the manipulator, the position of the end effector that grips the weed was guided to the coordinates of the root of the weed as follows:

1) The robot arm was moved so that the horizontal plane coordinates of the end effector aligned with the target coordinates.

2) Based on the depth information obtained by the RGB-D camera, the end effector was lowered to the weed surface.

3) To remove the weed, it was grasped by the end effector and pulled up.

4) The manipulator was moved to its home position and the gripped weed was released.

III. VERIFICATION OF THE WEEDING SYSTEM FUNCTIONS

A. Evaluation of Detection Accuracy by Annotation Shape

The training parameters are shown in Table I. The PC used for training was configured as shown in Table II, and the training was performed using detectron2 provided by META. Training time required to build the machine learning model using 500 images on this PC was approximately fifteen minutes. Object detection using Mask R-CNN depends on the accuracy with which the annotation task is performed. Therefore, we trained the detection model on two types of weed datasets: rectangular (in which the weeds were annotated as rectangles) and polygonal (in which the weeds were annotated as polygons), and their detection accuracies were compared. As target-coordinate detection for weed removal is important in this study, we counted the number of annotation labels in which the center of gravity of the detected weed is contained in the weed area in 20 test images. The results are shown in Table III. Fig. 3 shows examples of weed detection using each annotation shape, and Fig. 4 shows examples of the weed centers of gravity.

TABLE I. THE TRAINING PARAMETERS

Batch size	128
Iterations	1000
Learning Rate	0.0003

TABLE II. THE PC CONFIGURATION USED FOR TRAINING

CPU	Intel Core i5
GPU	Geforce RTX3050Ti
OS	Ubuntu 18.04
Training Time	15 min / 500 images

TABLE III. COMPARISON OF RESULTS BY ANNOTATION SHAPE

Annotation	Total weeds	Total detections	Total off the top of weeds	Accuracy
Rectangle	214	199	8	0.851
Polygon	214	278	5	0.852

(a) Rectangle result.

(b) Polygon result.

Fig. 3. Comparison of results by annotation method.

(a) Rectangle.

(b) Polygon.

Fig. 4. Results of each weeding-point drawing.

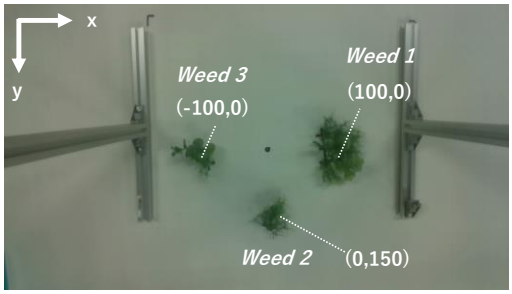
Fig. 4 shows that the center of gravity is positioned on the top of the weed for both the rectangle and polygon annotation shapes. However, when we compared the results on the same 50 test images, we found that the total number of detections was higher in the system trained on polygonal annotations. The fact that the training results were more accurate for

polygon annotation suggests that the polygonal annotation was more effective for training the weed detector of the weeding robot.

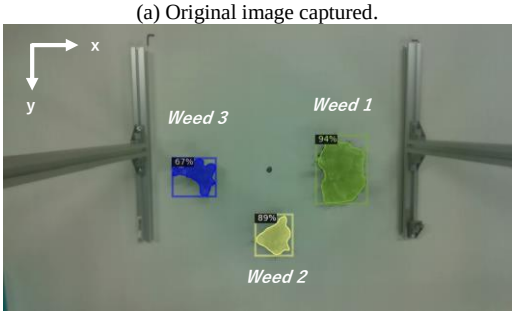
B. Experiment to Calculate Spatial Coordinates for Weeding

The accuracy of spatial coordinates is important to properly guide the weeding mechanism to the target weeds. Therefore, in an experiment, we placed artificial flowers on a sheet of imitation Japanese vellum to confirm whether the coordinates obtained using our weed-detection method and coordinate transformation were appropriate. The RGB-D camera used in this experiment was the Intel RealSense D435i.

In the experiment, we arranged the artificial flowers as "weeds" on a square paper as shown in Fig. 5 such that three "weeds" of different sizes were in the field of view of the camera, and then verified the accuracy of the two-dimensional coordinates after object detection by comparing them with actual measured values. The weed sizes and labels from right to left are—large (Weed 1), medium (Weed 2), and small (Weed 3).



(a) Original image captured.



(b) Masked image.

Fig. 5. Results of weed-location detection experiment.

Table IV shows the coordinates where the weeds were placed, Table V shows the calculated coordinates, and Table VI shows the difference between the results in Table IV and Table V. It was confirmed that there was a maximum difference of 30.0 mm in the x-direction. Weed 3, which was the smallest, had a difference of 8.30 mm, while Weed 1 and Weed 2 had a difference of 30.0 mm. This is probably because as the size of the detection target increases, the center of gravity of the generated mask region moves away from the center of the weed. However, even with a maximum error of 30.0 mm, the weeding point was within the weed-detection area, thus the results of this experiment were considered acceptable. In future, we plan to confirm the effectiveness of our approach when performing manipulation control in actual fields.

TABLE IV. THEORETICAL VALUES OF TWO-DIMENSIONAL COORDINATES

	Actual Arrangement	
Index	**X [mm]**	**Y [mm]**
Weed 1	100	0
Weed 2	0	-100
Weed 3	-100	0

TABLE V. MEASURED VALUES OF TWO-DIMENSIONAL COORDINATES

	Measurements	
Index	**X [mm]**	**Y [mm]**
Weed 1	130	1.48
Weed 2	30.0	-108.2
Weed 3	-91.7	6.98

C. Manipulation Control Experiment

Further, we confirmed the ability of the system to guide the robot arms to the weeds based on the proposed method. In this experiment, we conducted an evaluation in an artificial environment in which soil was placed in a shallow tray, and artificial flowers were placed on top of the soil as weeds. The manipulation control was performed using the spatial coordinates of the weeds obtained by the weed detection and coordinate transformation evaluated above. The manipulator used in this experiment was a Dobot Magician, a tabletop 4-axis manipulator manufactured by Dobot Robotics. Fig. 6 shows the experimental setup. The control flow implemented for the manipulation is shown in Fig. 7.

TABLE VI. ERROR BETWEEN THEORETICAL AND MEASURED VALUES

	Error	
Index	**X [mm]**	**Y [mm]**
Weed 1	30.0	-1.48
Weed 2	30.0	-8.20
Weed 3	8.30	6.98

Fig. 6. Experimental environment.

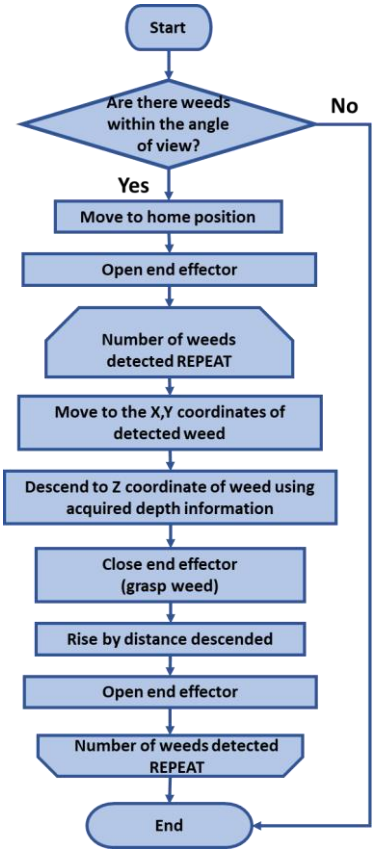


Fig. 7. Flowchart of manipulation control.

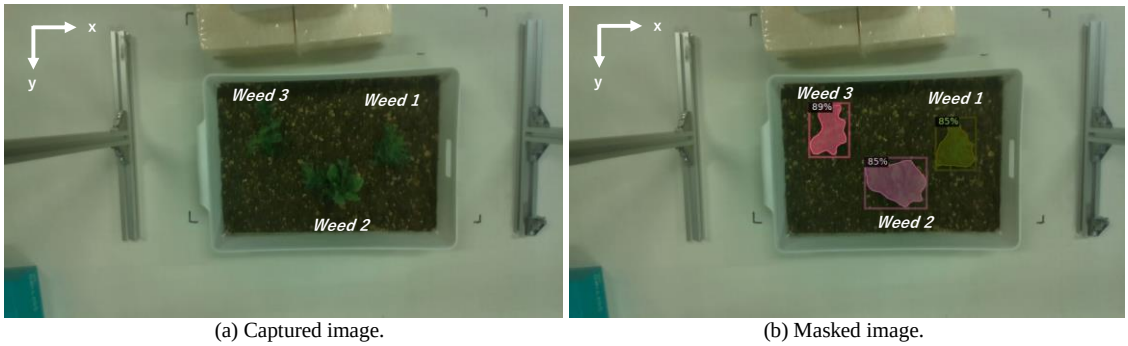
We calculated the three-dimensional coordinates as described in the previous section. The calculated three-dimensional coordinates are shown in Table VII.

We assigned the weed numbers, starting with Weed 1 in the lower right corner. An example of the original captured image is shown in Fig. 8(a) and the same image with the corresponding masked areas that were generated as shown in Fig. 8(b). The manipulation control was applied to the three coordinates shown in Table VII, and all the three weeds were successfully grasped. Fig. 9 shows an example of the weeding process using the proposed weeding system.



(a) Captured image. (b) Masked image.

Fig. 8. Experimental results in a simple field

TABLE VII. THREE-DIMENSIONAL COORDINATES

	Actual Arrangement		
Index	**X [mm]**	**Y [mm]**	**Z [mm]**
Weed 1	-24.8	-49.2	562.0
Weed 2	69.9	22.8	564.9
Weed 3	151.8	24.1	558.0

Fig. 9. Weeding Scene. (a) Initially, the robot arm is in the home position. (b) The end-effector is moved by the robot arm so that its horizontal plane coordinates match the target coordinates. (c) Based on depth information, the end-effector is lowered to the surface of the weed. (d) The end-effector grasps the weed. (e) The robot arm moves and pulls the weed out with the end-effector. (f) After releasing the grasped weed, the robot arm moves to the home position.

D. Discussion

From the above functional verification, the following results were obtained for the weeding system functions.

- The polygonal annotation was more effective than rectangular annotation for training the weed detector of the weeding robot.
- The center-of-gravity position was within an acceptable range for the maximum error in the weeding position calculation.
- The manipulation control was applied to the calculated three-dimensional coordinates of weeding points, and the weeds were successfully grasped.

Fig. 10. Example of weeds that are difficult to detect center-of-gravity position.

By setting the manipulation control point at the center of gravity of the segmentation mask, rather than at the center of the bounty box, the weeds could be approached correctly in many cases. However, depending on the shape of the weeds, as shown in Fig. 10, weeding could not be performed correctly. We believe that the construction of a network to predict weed roots after weed detection is one of an important issue to be addressed in the future.

IV. CONCLUSION

We believe that smart agriculture is an effective way to address the labor challenges facing the agricultural sector of Japan. Focusing on the weeding task, which is one of the most burdensome agricultural tasks because it must be done multiple times before harvesting, we investigated weed detection and removal to implement an automatic weeding robot.

To realize the automatic weeding robot, we built a series of functions—including weed detection using Mask R-CNN, calculation of the three-dimensional coordinates of detected weeds, and manipulation control to the detected coordinates—and confirmed the effectiveness of these functions through operational verification.

In future work, we plan to experimentally verify these functions in an actual field. In addition, as it is necessary to distinguish between crop plants and weeds more accurately in actual operation, we also plan to study ways to improve detection accuracy, for example, by enlarging the dataset and investigating other training techniques. Moreover, since not only a single robot but also a multi-robot system with multiple robots is effective for actual operation in the field [23], a multi-robot system version of the system in this paper will also be considered.

ACKNOWLEDGMENT

This work was supported by a grant from "Development of Weeding Robot with Autonomous Navigation Capability for Agricultural Fields" in collaboration with KOGANEI CORPORATION. We are grateful to project members for useful discussion. We would like to thank Editage (www.editage.com) for English language editing.

***Abstract*—The research tackles the complex problem of accurately predicting cooling loads in the context of energy efficiency and building management. It presents a novel approach that increases the precision of cooling load forecasts by utilizing machine learning (ML). The main objective is to incorporate a hybridization strategy into Radial Basis Function (RBF) models, a commonly used method for cooling load prediction, to improve their effectiveness. This new method significantly increases accuracy and reliability. The resulting hybrid models, which combine two powerful optimization techniques, outperform the state-of-the-art approaches and mark a major advancement in predictive modelling. The study performs in-depth analyses to compare standalone and hybrid model configurations, guaranteeing an unbiased and thorough performance evaluation. The deliberate choice of incorporating the Self-adaptive Bonobo Optimizer (SABO) and Differential Squirrel Search Algorithm (DSSA) underscores the significance of leveraging the distinctive strengths of each optimizer. The study delves into three variations of the RBF model: RBF, RBDS, and RRBSA. Among these, the RBF model, integrating the SABO optimizer (RBSA), distinguishes itself with an impressive R^2 value of 0.995, denoting an exceptionally close alignment with the data. Furthermore, a low Root Mean Square Error (RMSE) value of 0.700 underscores the model's remarkable precision. The research showcases the effectiveness of fusing ML techniques in the RBSA model for precise cooling load predictions. This hybrid model furnishes more dependable insights for energy conservation and sustainable building operations, thereby contributing to a more environmentally conscious and sustainable future.**

Keywords*—Building energy; cooling load; machine learning; radial basis function; self-adaptive bonobo optimizer; differential squirrel search algorithm

I. Introduction

In the contemporary discourse surrounding global energy challenges, there exists an escalating emphasis on imperative energy conservation measures. This urgency is particularly salient within the purview of the global building sector, constituting a substantial fraction of overall energy consumption. Within this context, the imperative to optimize energy efficiency has prompted a meticulous examination of key metrics, where Cooling Load (CL) and Dynamic Air-Conditioning Load assume pivotal roles in the paradigm of building design and operation [1], [2]. Of particular significance is the latter, as it intricately interfaces with the orchestration of heating, ventilation, and air conditioning (HVAC) systems, endowing a spectrum of advantages including expeditious cooling startups, precise management of peak demand, cost optimization, and heightened energy efficiency within cooling storage systems [3]. The Dynamic Air-Conditioning Load, as a multifaceted entity, stands as the linchpin for realizing energy and cost efficiency objectives across a diverse array of HVAC systems. It functions as a discerning orchestrator, facilitating seamless coordination and adjustment of HVAC operations in response to the dynamically evolving thermal requisites of a given structure [4]. This adaptability becomes instrumental in meeting the heterogeneous and evolving demands posed by residential, commercial, and industrial structures alike. Nevertheless, the realization of these efficiency goals is not bereft of challenges. The accurate prediction of building cooling loads remains a formidable task, characterized by the intricate interplay between the optical and thermal properties of the building and meteorological data [5]. The integration of these factors into the cooling load prediction process engenders a complex network that necessitates innovative solutions. The scientific pursuit of building cooling load prediction has endured for several years, embodying an enduring commitment to surmounting these challenges [6].

In the quest for precision, diverse methodological avenues have been explored. Engineering-based feature extraction techniques have surfaced as a valuable approach, probing into the intrinsic thermal properties of diverse building materials. By eliciting domain-specific insights from data, these techniques shed light on the nuanced ways in which distinct materials exert influence on the cooling load [7]. From concrete to glass, each material introduces a unique set of thermal dynamics that contributes to the overall cooling load profile. These insights not only enrich the comprehension of thermal intricacies but also facilitate the development of tailored solutions for augmented energy efficiency. Beyond engineering-based techniques, statistical feature extraction methods have assumed an integral role in the predictive arsenal. Employing mathematical approaches, these methods unearth pertinent information from the data, revealing patterns and relationships that may elude conventional scrutiny [8].

This data-driven approach affords a comprehensive exploration of the intricate factors influencing cooling loads, offering a holistic perspective that transcends traditional analytical confines. Advancing the pursuit of precision, structural feature extraction methods have evolved to scrutinize the underlying data structure itself. These methods endeavour to uncover latent dependencies and patterns that might elude conventional analyses. By delving into the depths of data intricacies, structural feature extraction unveils critical insights that can significantly enhance the precision of cooling load predictions [9].

A multitude of techniques has been devised for optimizing HVAC systems, which can be broadly classified into three categories: artificial intelligence (AI), simulation, and regression analysis. Simulation tools like DOE-2, ESP-r [10], TRNSYS [11], EnergyPlus and ACO [12] are used to estimate CL when complete building data is accessible. Accurately measuring different building parameters, however, presents practical challenges [13]. There are different ways to simplify the process of building models, but it still takes a lot of time and labour to complete. Furthermore, the accuracy of simulated load results depends on the model's precision and the quality of the weather data. In real-time applications like online prediction or optimal operational control, the usefulness of simulation software is constrained [14].

Against this backdrop, recent scholarship has spotlighted the substantial potential of cutting-edge Machine Learning (ML) techniques in transforming the landscape of cooling load predictions [15]. ML, with its adeptness in discerning complex patterns and adapting to evolving data dynamics, emerges as a potent ally in the pursuit of precision and efficiency. The infusion of ML not only refines extant models but also engenders novel approaches capable of navigating the intricate terrain of cooling load prediction with unprecedented precision. Concurrently, feature extraction methods have risen to prominence as indispensable tools within the ML-driven paradigm [16], [17]. These methods assume a pivotal role in harnessing historical data, ensuring that predictions remain not only precise but also computationally manageable. As the volume and intricacy of data burgeon, the symbiosis between ML techniques and feature extraction methods becomes increasingly critical, providing a robust framework to address the evolving challenges of building cooling load prediction [18]. Envisaging the trajectory ahead, these technological strides hold promise in ushering forth a new era of sustainability and energy efficiency in buildings. The amalgamation of ML techniques and feature extraction methods is poised not merely to refine predictive accuracy but also to lay the groundwork for more intelligent and adaptive HVAC systems. By bridging the lacuna between data insights and operational efficiency, these advancements contribute to a future where sustainable practices are not merely aspirational but intrinsic characteristics of contemporary infrastructure [19].

The study introduces a new method for improving cooling load predictions by integrating ML. It uses a hybridization technique to enhance the performance of Radial Basis Function (RBF) models, ensuring greater accuracy and reliability. The hybrid models, which combine two optimization techniques, show superior performance compared to conventional methods. A thorough evaluation was conducted to mitigate potential biases and provide a transparent assessment of the models' performance. The strategic choice of merging Self-adaptive Bonobo Optimizer (SABO) and Differential Squirrel Search Algorithm (DSSA) highlights the importance of each optimizer's strengths. This study demonstrates the effectiveness of ML and the benefits of using tailored hybrid models for improved cooling load predictions. The following section includes the methodology section, which details the study's approach, covering data collection, preprocessing, model development (including machine learning integration), and validation. Results present findings, including performance compared to existing methods, with quantitative data and visualizations. Discussion interprets results within the study's context, evaluating methodology strengths and limitations. The conclusion summarizes key findings, emphasizes research significance, and suggests future research directions.

II. Materials and Methods

A. Data Gathering

Table I provides a comprehensive overview of the statistical properties of the input variables contributing to the cooling load prediction models, as well as the resultant cooling load output. The variables under scrutiny encompass a range of crucial factors influencing building energy dynamics. The Relative Compactness category, denoting the building's surface area-to-volume ratio, exhibits a minimum value of 0.62 and a maximum value of 0.98. The average and standard deviation are reported as 0.76 and 0.105, respectively. Surface area, a pivotal input parameter, ranges from 514.5 to 808.5, with an average of 671.70 and a standard deviation of 88.086. Wall area, roof area, overall height, orientation, glazing area, and glazing area distribution, each with distinct roles in the prediction models, are similarly characterized by their minimum, maximum, average, and standard deviation values. Of particular significance is the Cooling output variable, which represents the anticipated cooling load. The reported statistics for this variable delineate its minimum, maximum, average, and standard deviation as 10.9, 48.03, 24.58, and 9.513, respectively. These values encapsulate the variability in cooling loads expected from the developed prediction models. The statistical summary provides insights into the range and central tendency of each input variable and the variability in cooling load output, which is crucial for understanding data distribution and ensuring the accuracy and reliability of cooling load predictions generated by developed models [20], [21].

TABLE I. STATISTICAL PROPERTIES OF THE INPUT VARIABLE OF COOLING

Variables		Indicators			
	Category	*Min*	*Max*	*Avg*	*St.Dev.*
Relative Compactness	Input	0.62	0.98	0.764	0.105
Surface Area	Input	514.5	808.5	671.708	88.086
Wall Area	Input	245	416.5	318.5	43.626
Roof Area	Input	110.25	220.5	176.60	45.165
Overall Height	Input	3.5	7	5.25	1.751
Orientation	Input	2	5	3.5	1.118
Glazing Area	Input	0	0.4	0.234	0.133
Glazing Area Distribution	Input	0	5	2.812	1.550
Cooling	Output	10.9	48.03	24.58	9.513

B. Radial Basis Function (RBF)

Ojo et al. [22] discusses the challenges associated with traditional path loss prediction models in wireless signal propagation and proposes the use of machine learning algorithms to address these issues. It highlights the trade-off between simplicity and accuracy in deterministic and empirical models. The paper introduces two machine learning-based path loss prediction models, namely the radial basis function neural network (RBFNN) and the multilayer perception neural network (MLPNN), developed using experimental data collected from drive tests in multi-transmitter scenarios. The RBFNN model is found to be more accurate than the MLPNN, exhibiting lower root mean squared errors (RMSEs) when compared to measured path loss. Furthermore, the proposed machine learning-based models are compared against five existing empirical models, with the RBFNN showing the most accurate results. Elansari et al .[23] presents a novel approach called Mixed Radial Basis Function Neural Network (MRBFNN) training using Genetic Algorithm (GA). This study focuses on optimizing the choice of radial basis functions, centers, radius, and weights of the output layer in RBFNNs. They formulate the optimization problem as a mixed-variable problem with linear constraints and employ a genetic algorithm-based approach to solve it. The numerical results validate the theoretical findings and demonstrate improved generalization compared to existing methods. Alitasb et al. [24] discuss the application of RBFNNs in model predictive control for a 4 × 3 Multiple-Input Multiple-Output (MIMO) biomass control system. The study aims to enhance the control performance of a biomass boiler by utilizing RBFNNs to improve the accuracy of the model. They develop a biomass boiler model using system identification techniques and implement the RBFNN model using MATLAB. Simulation results show that the RBFNN-based model predictive controller achieves shorter settling times and tolerable overshoots compared to a state space model-based controller, indicating superior performance in controlling boiler dynamics. Overall, these references demonstrate the versatility and effectiveness of RBFNNs in various applications, including pattern recognition and control systems, showcasing their potential to address complex problems in different domains.

1) Network architecture for RBF: A RBF neural network consists of three distinct layers: the input layer, hidden layer, and output layer, as its fundamental structure. The input vector x in the hidden layer, which is made up of each unique input, $x_1, x_2, x_3, \ldots, x_n$ is practical to all neurons. The hidden layer of an RBF network consists of n RBF that have direct connections to each component of the output layer. More information about RBF networks can be found in academic sources, including references. An RBF network's hidden layer nodes increase their output as the input pattern they represent approaches each node's centre. The output of these nodes decreases with increasing distance from the middle if symmetric basis functions are applied. Therefore, neurons with centres near a given input pattern will produce non-zero activation values when that pattern is present, amplifying the input. The neurons' receptive field function, which controls how they react to outside stimuli, is what causes this behavior [23], [25], [26]. The jth covered−up hub's theoretical basis is often represented by a Gaussian exponential function, which can be written as follows:

$$p_j = p(\omega_j) = e\left(-\frac{\omega_j^2}{2\varphi_j^2}\right) \quad (1)$$

The thickness of the jth neuron, signified by φ_j, and ω_j, this is typically computed as the Euclidean distance between the input vector and the neuron center.

$$\omega_j(x) = \|x - c_j\| = \sqrt{\sum_{i=1}^{w}(x_i - c_{i,j})^2} \quad , i = 1,2,\ldots,w \quad (2)$$

Let and $x = [x_1, \ldots, x_w]^F$ c_j be the centres of the jth RBF parts, which are vectors having the same dimensions as the jth neuron's input [27]. The network's output, represented by the letter M, is the sum of the weights of all the premise capacities in the hidden layer. The following formula can be used to determine the output node value:

$$M_r = \sum_{j=1}^{u} s_{js} p_j \quad (3)$$

A weighted sum of the output signals from the nodes in the hidden layer yields the output of the r th node in the output layer, which is denoted by M_r as the kth component of M. s_{js} is a representation of the weights connected to the link between

the jth neuron in the hidden $layer$ and the sth neuron in the $output$ layer. The algorithm additionally takes into account the output p_j of the jth node in the hidden layer. In essence, the hidden layer nodes calculate a linear combination of basic functions that define the network's output.

2) RBF network training and testing principles neural system RBF operates in two distinct modes: testing and training. The network necessity calculates the ideal number of her RBFs, identifies the centres for each, and constructs the output layer weight matrix during the training phase. Minimizing the total squared error, or (R), is the goal [28] al [28]:

$$R = \frac{1}{2}\sum_{I=1}^{r}\sum_{F}^{n}\{q_f^i - m_f^i(X^i)\}^2 \quad (4)$$

Here q_f^i is the apparent framework control in the event that an input vector X^i is R is the number of cases under preparation that is shown to the organizer. In RBF networks, node centers are positioned during training, and the network's capacity to generalize is greatly influenced by the output of the kernel function. Numerous methods may be used to determine the center of the RBF node in the hidden layer; the most popular method utilized in this research was $p-$ means clustering. The algorithm's objective is to find a set of F cluster centers that minimizes E, which is the sum of the Euclidean distances between each cluster center (yj) and the train points assigned to that cluster.

$$E = \sum_{j=1}^{N}\sum_{I=1}^{N} G_{ij}\|y_j - X_i\| \quad (5)$$

The membership matrix was given to the network, signified as G_{ij} with dimensions of $m \times N$, where N represents how many training examples there are. There is only one 1 in each column of this binary matrix; all other values are $0s$. After establishing the RBF unit centre, each RBF unit width is calculated with a parameter named z, which regulates the amount of overlap between adjacent nodes and the $Root - Mean - Square$ distance to the closest RBF node. The $S-$fold cross-validation approach may be used to find the value of z. Eq. (6) provides the breadth of the $j - th\ RBF$ unit, which is represented as ς_j.

$$\varsigma_j = \left(\frac{1}{z}\sum_{o=1}^{z}\|c_j - c_o\|^2\right)^{1/2} \quad (6)$$

After the centers of the nodes near node j are determined as $(c_1, \ldots . c_z)$ the RBF neural network is considered fully determined. Afterwards, Eq. (1) through Eq. (3) can be used to represent a newly provided, easily navigable input vector. The RBF flowchart is displayed in Fig. 1 [29].

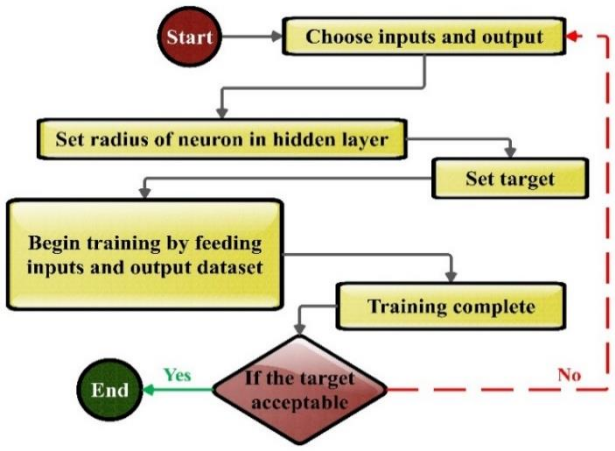

Fig. 1. Flowchart of RBF.

C. Self-adaptive Bonobo Optimizer (SABO)

A detailed argument is presented regarding an improved version of Bonobo Optimizer (BO), acknowledged as SABO with repulsion and a memory-based learning strategy for parameter upgrading. There are four types of mating behaviors found in it: consort ship, extra-group mating, promiscuous mating, and restrictive mating. A few changes have been made to this optimizer to improve performance. In addition, SABO has three additional memorized populations that are distinct from the current population, and the members of these populations mate to give birth to modern bonobos. The SABO's controlling criteria are based on a repulsion-based learning approach [30]. Other than these, p^{th}-bonobo choice in SABO is planned extraordinarily. In this case, the estimate of the subgroup is determined by the calculation taking into account the input obtained during the search procedure. To improve the efficiency of the search process, boundary control technology has also been modified in SABO as opposed to BO. Below is a detailed explanation of each of these key components of the suggested SABO.

1) Memory and its updates: The three populations that make up the proposed SABO are $oldpop$, $worsepop$, and $badpop$, as was previously mentioned. These populations initially match the $SABO's$ the original population. Later, with every iteration, these are revised and updated. Consider that N and d, respectively, are population size and number of decision variables.

a) Oldpop: At any time, i^{th}-new bonobo found superior to the i^{th}-parent bonobo is accepted in the current population position. Furthermore, the i^{th}-parent bonobo is remembered within the i^{th}-position of oldpop.

b) Worsepop: If i^{th}-new bonobo turns out to be worse than i^{th}-parent bonobo in fitness value comparison; it is stored in i^{th}-worse position than the current population.

c) Badpop: The selection process of this N size population is choosing from mixed populace $worsepop$ and $badpop$ in size $2N$. The unique solutions named l, distinguished by objective values, display mixed populations.

If l realized that be less than N, then l number copied to the $badpop$. If l realized that be less than N, then l number copied to the $badpop$. Also, if l found to be greater than or equal to N, $babpop$ is chosen from $l1$ (l1≥N), and it is between N_2 and 1, Eq. (7) calculates N_1.

$$N_2 = ceil(df \times \mathrm{N}) \tag{7}$$

df, diversity factor, is in the range of $[(df_{min}, df_{max})$ = (1.2, 1.8)].

2) Repulsion-based learning: First, using repulsion-based learning, two controlling variables are identified: phase probability (pp) and sharing co-efficient (sc). Both of this parameter's range are between 0 and 1. If a good solution's number appears superior to predetermined solutions (called N_1) then N_1 solution with the highest change in fitness value will be considered. Eq. (8) calculates the N_1.

$$N_1 = maximum\ of(5, ceil(N \times 0.08)) \tag{8}$$

By taking after a comparative strategy, one can get a worse value that is not upgraded fitness-wise, named pp_{worse} . Considering pp_{worse} and pp_{better} repulsion; their value directions shift in the reverse direction. $pp_{bettter}^{modified}$ determined by Eq. (9).

$$PP_{better}^{modified} = PP_{better} \pm \frac{\sigma \times PP_{better} \times PP_{worse}}{e^{(PP_{better} - PP_{worse})^2}} \tag{9}$$

3) Mating strategies: There are four mating strategies in the proposed $SABO$. There are also conceptions of the positive phase (pp) and negative phase (NP). Phase probabilities (pp) are probabilities that PP or NP use to update the solution at each iteration. Furthermore, in PP, applying a promiscuous or restrictive mating strategy will generate a new bonobo with a probability of 0.5. The probability of mating outside the group is called p_{xgm} which is in the range of $(p_{xgm}^{min}, p_{xgm}^{max})$ and calculates as follows:

$$I_0 = \frac{\sum_{j=1}^{d} \frac{SD_j}{(V_{max_j} - V_{min_j})}}{d} \tag{10}$$

$$I_1 = 0.1 \times I_0 \tag{11}$$

$$P_{xgm}^{min} = minimum\ of\ (I_1, \frac{1}{d}) \tag{12}$$

$$p_{xgm}^{max} = 2 \times I_1 \tag{13}$$

In initial population, SD_j represents the standard deviation of j^{th}-variable; j is in the range of 1 to d, and d is the decision variable number in the problem. The maximum and minimum merits of j^{th}-variable called v_{max_j} and v_{min_j}. p_{xgm}^{min} and p_{xgm}^{max} are determined by I_0 and I_1. Fig. 2 shows a detailed flowchart of the suggested SABO.

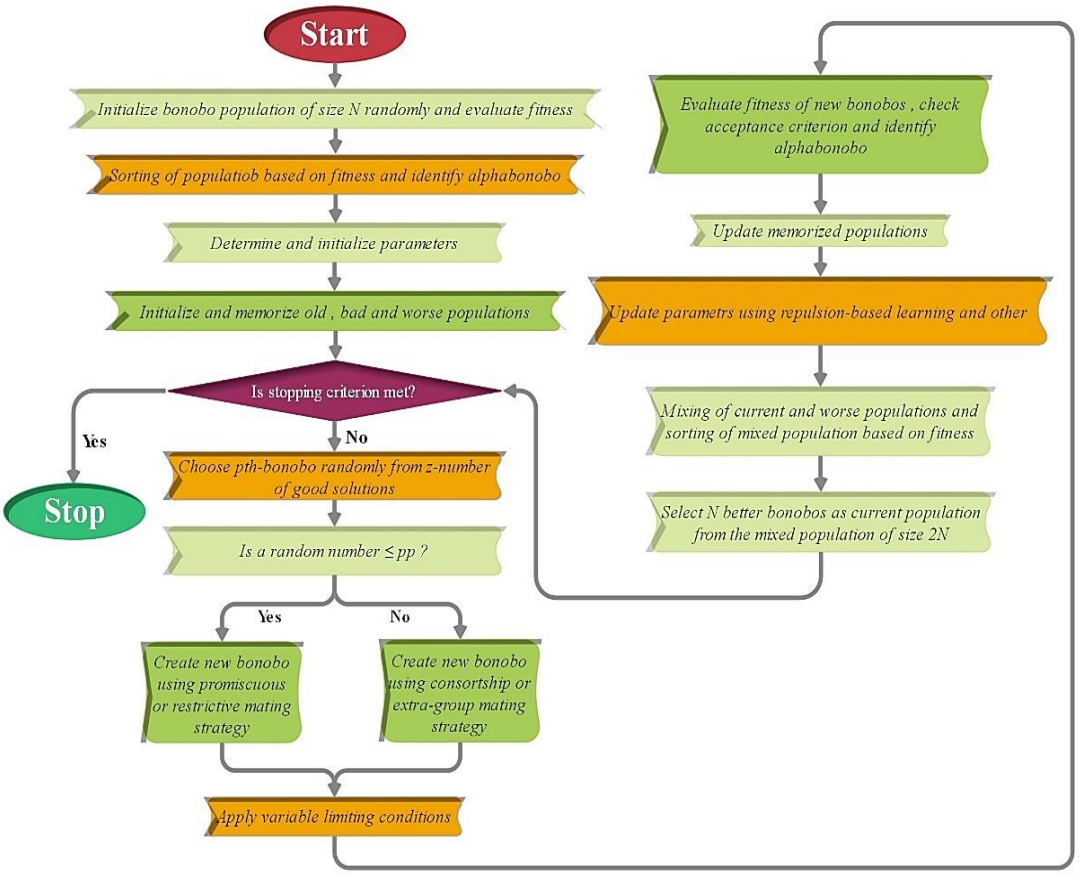

Fig. 2. Flowchart of suggested SABO.

D. Differential Squirrel Search Algorithm (DSSA)

Manoj et ao et al. introduced an innovative optimization approach referred to as DSSA, which integrates two distinct algorithms, namely the squirrel search algorithm (SSA) and differential evolution algorithm (DE). Squirrels are observed to update their location in the context of the Simulated Squirrel Algorithm (SSA) by closely monitoring the positions of other squirrels living in the hickory or acorn tree. That means that to improve their search strategies, the top squirrels have modified their updating mechanisms. Adding a crossover operation that draws inspiration from Differential Evolution (DE) improves exploration potential. This exposition provides a mathematical model of the various foraging strategies that are included in the Decision Support System for Agriculture (DSSA).

1) Initialization of position and the evaluation of fitness: Initially, the squirrels are arranged at random within the exploratory domain. Following the squirrels' positions, the fitness levels of each are evaluated by inserting the position mentioned earlier into the fitness function. This indicates the nutritional value of the food source that each squirrel obtained within its position. The values of fitness are subsequently subjected to a sorting process to obtain the most optimal squirrel, denoted as PS_{ht}, that currently inhabits the hickory tree. The subsequent 3 optimal function values signify the locations of the squirrels inhabiting the acorn tree PS_{at} (1:3). In addition, they are deemed to be a step towards achieving an optimal location in the next iteration. Thus far, the remaining individuals belonging to the squirrel population are denoted as PS_{nt}^{p1} have yet to discover a viable nourishment source occupying typical locations within the tree habitat.

2) Update of the position: When a squirrel colonizes a tree that provides acorns, it updates its position and moves towards the best source by following the current best path or PS_{ht} in the absence of a predator. By mimicking the movements of the squirrels living in the hickory or acorn tree, the squirrels in the regular tree can track where they are. The observed phenomenon is that when faced with the possibility of predation, squirrels tend to change their foraging route randomly. The following can be used to express the mathematical models that were used to update the squirrel's position. Now, as the others adjust their position, the squirrels in the acorn trees do the following:

$$PS_{at}^{new} = \begin{cases} PS_{at}^{old} + d_g . G_c\left(PS_{ht}^{old} - PS_{at}^{old} - P_{avg}\right), & r_1 \geq P_{dp} \\ random\ position, \quad otherwise \end{cases} \quad (14)$$

P_{avg} is the mean of whole squirrels' positions in the available population.

The crossover mechanism is incorporated into the DE algorithm to reduce the likelihood of local minima, thereby increasing the diversity of the squirrel population being evaluated. The crossover operation, which was derived from Eq. (15), was applied to the current position and its corresponding new position.

$$PS_{at,i,j}^{cr} = \begin{matrix} PS_{at,i,j}^{new}, \ if\ \left(rand_j \leq Cr\right)\ or\ j = j_{rand} \\ PS_{at,i,j}^{old}, \ if\ \left(rand_j > Cr\right)\ or\ j \neq j_{rand} \\ j = 1,2,3,\dots,D \end{matrix}, \quad (15)$$

$$i = 1, 2, 3, \dots, NP$$

$PS_{at,i,j}^{new}$ and $PS_{at,i,j}^{old}$ are new and old squirrels' locations normal, or are acorn trees.

$PS_{at,i,j}^{cr}$ are the squirrels' positions after the operation of the crossover.

NP shows the population size.

Cr indicates the rate of crossover, and it is equal to 0.5.

D shows the dimension of the problem.

$j_{rand} \in [1, D]$ is a randomly generated index

$rand_j \in [1, D]$ is the $j - th$ random numbers' assessment uniformly developed in the distinct range.

According to Eq. (16), some of the squirrels that live in typical trees move to new areas by following the squirrels that live in acorn trees.

$$PS_{nt}^{new} = \begin{cases} PS_{nt}^{old} + d_g . G_c(PS_{at}^{old} - PS_{nt}^{old}), & r_2 \geq P_{dp} \\ random\ position, \quad otherwise \end{cases} \quad (16)$$

r_2 conforms to a uniform distribution across the interval of $[0, 1]$.

The squirrels that are still in traditional trees align with the current optimal location, and their updated locations are expressed as follows:

$$PS_{nt}^{new} = \begin{cases} PS_{nt}^{old} + d_g . G_c\left(PS_{ht}^{old} - PS_{nt}^{old}\right), & r_3 \geq P_{dp} \\ random\ position, \quad otherwise \end{cases} \quad (17)$$

The application of a crossover operation on squirrels residing in ordinary trees is as follows:

$$PS_{nt,i,j}^{cr} = \begin{matrix} PS_{nt,i,j}^{new}, \ if\ \left(rand_j \leq Cr\right)\ or\ j = j_{rand} \\ PS_{nt,i,j}^{old}, \ if\ \left(rand_j > Cr\right)\ or\ j \neq j_{rand} \\ j = 1,2,3,\dots,D \end{matrix}, \quad (18)$$

One way to speed up the convergence rate is to allow the squirrel in the hickory tree to move about the average of the squirrels' positions inside the tree, as shown by Eq. (19):

$$PS_{ht}^{new} = PS_{ht}^{old} + d_g . G_c\left(PS_{ht}^{old} - PS_{at}^{avg}\right) \quad (19)$$

PS_{at}^{avg} represents the average of whole squirrel's locations in the acorn trees.

To determine who gets to participate in the next development population, the best hybrid positions and their unused positions are compared with the historical positions in the determination handle. Algorithm 1 explains the procedural instructions involved in DSSA.

Algorithm 1: DSSA Pseudocode

Input $Itermax, NP, Pdp, sf, Gc, ub, and\ lb$
Initialize *the flying squirrels^' location haphazardly using Eq.(14)*
Compute *the fitness value utilizing the represented fitness function employing Eq.(15)*
While $itr \leq itermax$ ***do***
Sort of all functions of squirrels^' fitness and recognize the current best, $〚PS〛\_ht$*,positions of squirrels in acorn tree,* $〚PS〛\_at\ (1:3)$
and the position of squirrel in the normal tree, $〚PS〛\_nt\ (1:NP-4)$
$Develop\ the\ new\ position\ of\ squirrels\ by\ comparing\ the\ new\ locations\ in\ acorn\ trees\ achieved\ via\ utilizing\ Eq.(14)\ and\ Eq.(15)$
$Develop\ the\ new\ location\ of\ squirrels\ by\ comparing\ the\ new\ positions\ in\ normal\ trees\ achieved\ via\ utilizing\ Eqs.(16)-(18)$
$Generate\ the\ new\ location\ of\ squirrels\ by\ comparing\ the\ new\ positions\ in$
hickory trees achieved via utilizing Eq.(19) and old positions.
Update the population with the best position achieved so far
End While
Return PS_{ht}

E. Performance Evaluation Methods

The models are evaluated in this article using some metrics, such as the BIAS mentioned earlier, the correlation coefficient (R^2), the Mean Square Error (MSE), the Symmetric Mean Absolute Percentage Error ($SMAPE$), and the root mean square error (RMSE). A high R^2 value indicates that the algorithm performed exceptionally well during the training, validation, and testing phases. Lower RMSE and MAE values, on the other hand, are preferred because they demonstrate less model error. Eq. $(20-24)$ are used to calculate these metrics.

Coefficient of Correlation.

$$R^2 = \left(\frac{\sum_{i=1}^{W}(h_i-\bar{h})(l_i-\bar{l})}{\sqrt{[\sum_{i=1}^{W}(h_i-h)^2][\sum_{i=1}^{W}(l_i-\bar{l})^2]}} \right)^2 \quad (20)$$

Root Mean Square Error.

$$RMSE = \sqrt{\frac{1}{W}\sum_{i=1}^{W}(l_i-h_i)^2} \quad (21)$$

Mean Square Error.

$$MSE = \frac{1}{W}\sum_{i=1}^{w}(l_i-h_i)^2 \quad (22)$$

Symmetric Mean Absolute Percentage Error.

$$SMAPE = \frac{100}{W}\sum_{I}^{W}\frac{2\times|l_i-h_i|}{|l_i|+|h_i|} \quad (23)$$

BIAS.

$$BIAS = \frac{\bar{l}}{\bar{h}} \quad (24)$$

- In these equations, h_i and l_i refer to the predicted and experimental values, respectively.
- The mean values of the experimental samples and predicted are represented by $\bar{h}$ and $\bar{l}$.
- Otherwise, W denotes the number of samples being considered.

III. RESULTS

The results of the created RBF models are shown in Table II. It includes an aggregate evaluation that covers all phases and a detailed summary of performance metrics for each of the three phases: training, validation, and testing. Based on RMSE, R^2, MSE, SMAPE, and BIAS, the RBF models RBSA, RBDS, and the generic RBF are assessed. The RBSA model performs well during the training phase, as evidenced by its low RMSE of 1.007, high R^2 of 0.989, and minimized MSE of 1.040. The accuracy of the model in capturing the subtleties of the training dataset is demonstrated by the SMAPE value of 0.00005 and the insignificant BIAS of -0.020. In the same way, RBDS performs admirably during training, showing an RMSE of 1.343, an R^2 of 0.980, and an MSE of 1.844. When the models move on to the validation stage, RBSA continues to perform well, with a lower RMSE (0.800) and a higher R^2 (0.994), indicating that it can generalize far beyond the training set. The RBDS model, on the other hand, shows a little increase in RMSE (1.172) and a lower R^2 (0.987), but it still retains a respectable degree of accuracy during validation. The generic RBF model, on the other hand, shows higher RMSE (1.410) and lower R^2 (0.981) values, indicating a relatively lower fit during the validation phase. When the models are tested, the models' performance is evaluated once more, and RBSA continues to perform well, with a minimum RMSE of 0.700, a high R^2 of 0.995, and an MSE of 0.489. During testing, both the generic RBF model and RBDS perform satisfactorily, with R^2 values of 0.984 and 0.976 and $RMSE$ values of 1.208 and 1.486, respectively. With an overall RMSE of 0.938 and an R^2 of 0.990 when all phases are considered, RBSA performs remarkably well, proving its dependability across a range of datasets. In contrast, the generic RBF model and the RBDS model have higher overall RMSE values of 1.623 and 1.299, respectively. In Fig. 3, the metrics' radar plot is displayed.

These findings show how the RBF models' effectiveness varies depending on the phase, with RBSA constantly showing higher predictive accuracy. The extensive assessment metrics highlight the potential of the RBSA model in producing accurate and trustworthy predictions for cooling loads and offer insightful information about the models' generalization ability.

In Fig. 4, a scatter plot is used to compare the hybrid models' performance over the 3 train, validation, and test phases. R^2 quantifies the degree of agreement between observed and expected values, whereas RMSE shows the prediction error or dispersal. The data points are closely clustered around the centerline of the RBSA model, which shows exceptional accuracy across all three phases. There is little variation between the expected and actual values and a high degree of agreement. The RBF and RBDS models, on the other hand, featured data points that were further from the centerline and comparable performance levels. In comparison to the RBSA model, this broader dispersion predicts a slightly lower precision and a higher inaccuracy.

TABLE III. THE OUTCOME OF THE DEVELOPED *RBF* MODELS

Model	Phase	Index values				
		RMSE	R^2	MSE	SMAPE	BIAS
RBSA	Train	1.007	0.989	1.040	0.00005	-0.020
	Validation	0.800	0.994	0.640	0.00019	0.044
	Test	0.700	0.995	0.489	0.00018	0.038
	All	0.938	0.990	0.896	0.00003	-0.001
RBDS	Train	1.343	0.980	1.844	0.00007	0.002
	Validation	1.172	0.987	1.373	0.00027	0.073
	Test	1.208	0.984	1.460	0.00026	-0.077
	All	1.299	0.981	1.716	0.00004	0.001
RBF	Train	1.692	0.970	2.863	0.00011	-0.093
	Validation	1.410	0.981	1.989	0.00043	0.134
	Test	1.486	0.976	2.209	0.00047	0.174
	All	1.623	0.972	2.634	0.00007	-0.019

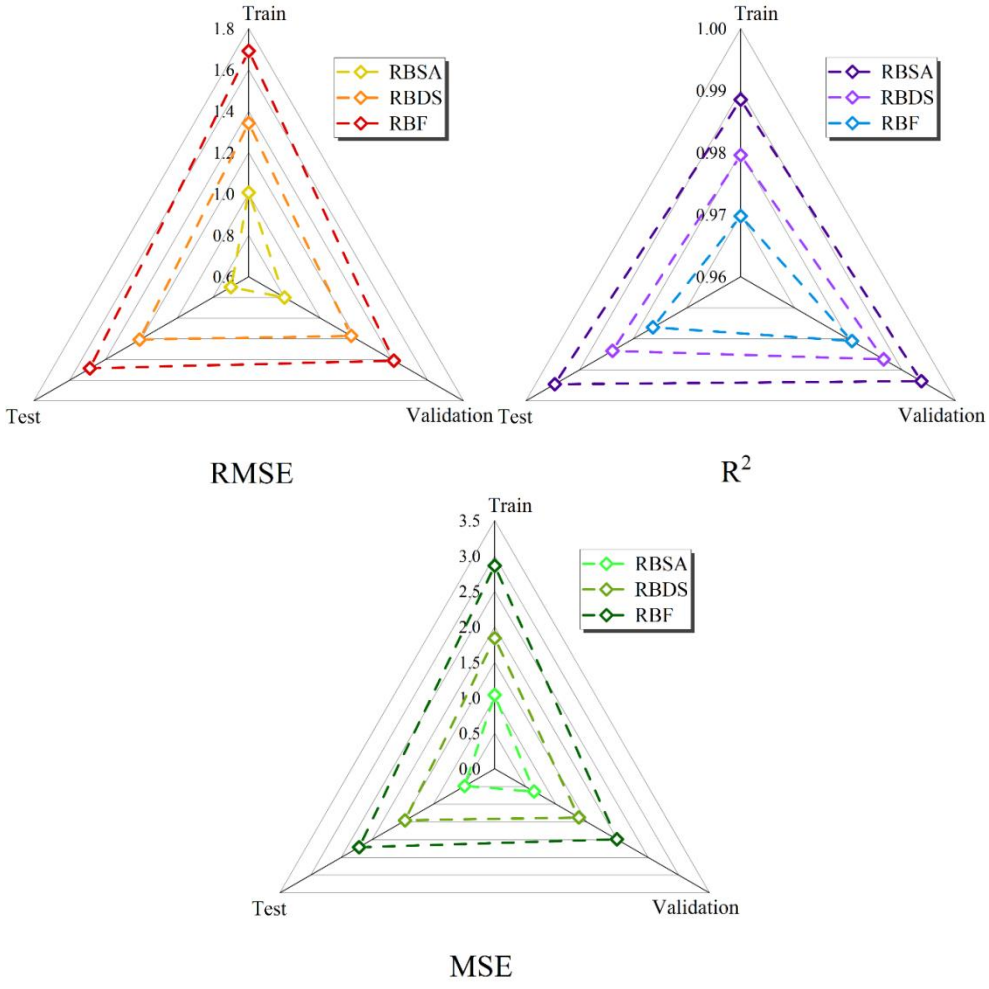

Fig. 3. Radar plot for comparison between the developed models based on metrics.

The study's line plot in Fig. 5 shows the error percentages associated with the models, with the RBSA model being the most prominent due to its low error rate. The majority of error values cluster within the 12.08% range. The RBF and RBDS models show greater variability, with a higher frequency of values exceeding the 23.66% and 17.35% thresholds. Both models display a right-skewed distribution, indicating the presence of specific data points with greater proportions of errors.

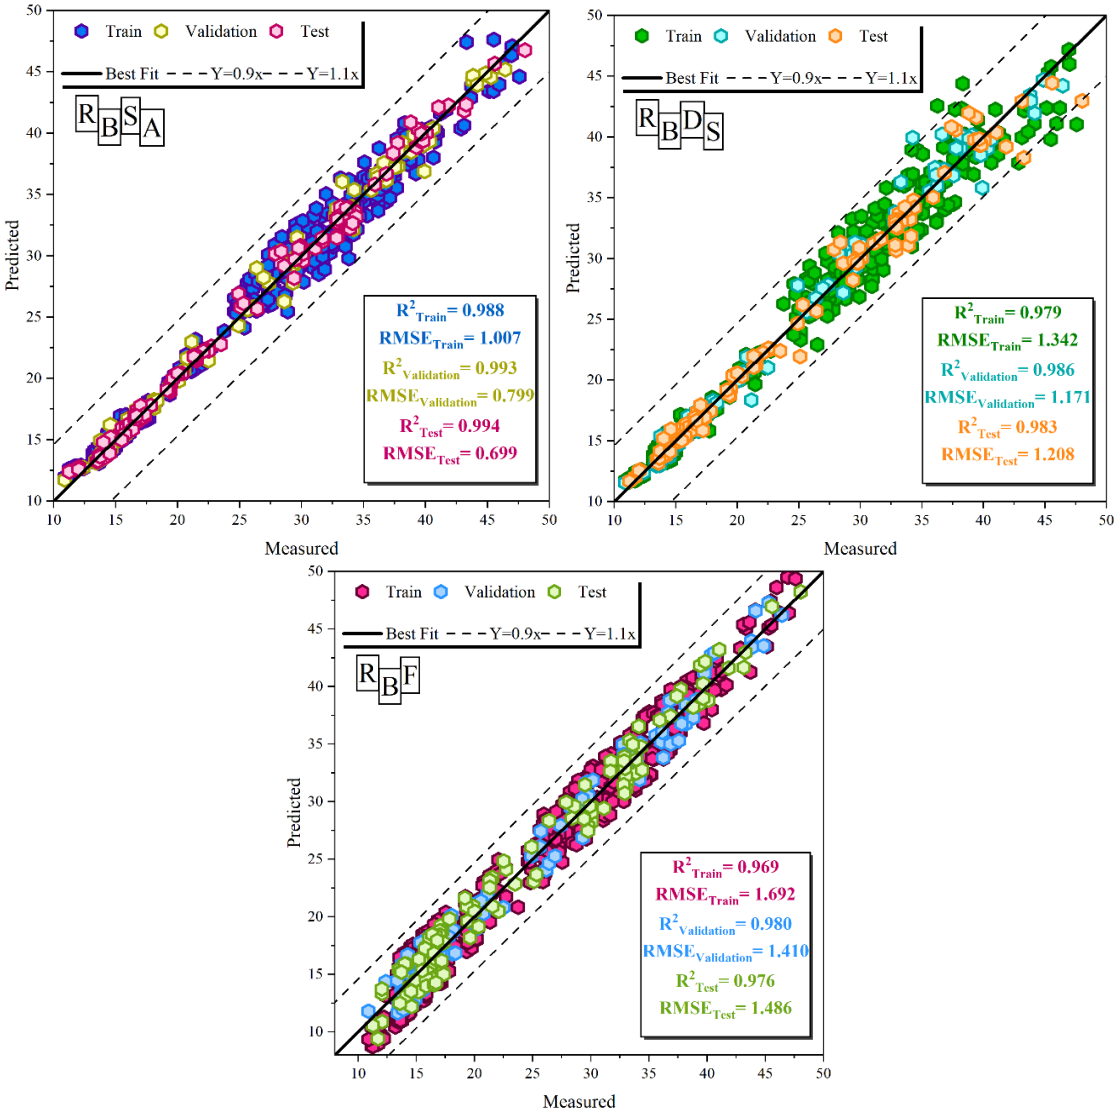

Fig. 4. Scatter plot of the dispersion of evolved hybrid models.

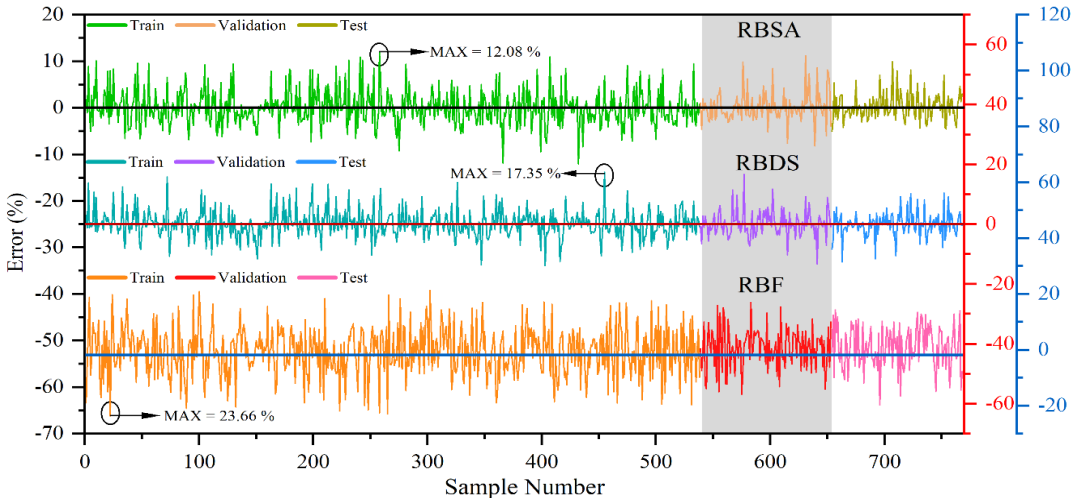

Fig. 5. Error percentage of the models based on the line plot.

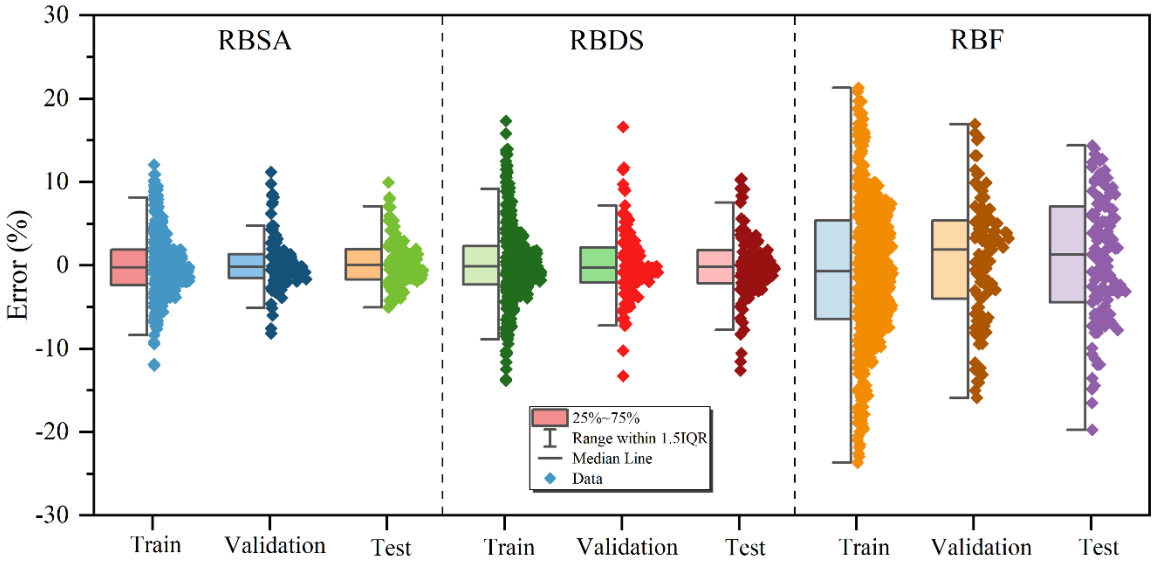

Fig. 6. Half-box plot errors of proposed models.

In Fig. 6, the study displays a half-box plot that shows the three models' respective error percentages. The RBSA model performed remarkably well, with errors kept below 10% and little dispersion. Dispersion was seen in all phases of the RBF model, with a uniform normal distribution and a maximum of 25%. During the assessment stage, the RBDS model exhibited the highest degree of discrepancy among the models, with one outlier data point representing more than 18% of the dataset. The RBF model's Gaussian distribution revealed more dispersion and fewer instances of near-zero frequency.

IV. Discussion

A. Advantages of the Present Study

The novel approach introduced in the study aims to revolutionize the prediction of cooling loads, offering fresh insights and innovative solutions to longstanding challenges in energy efficiency and building management. By harnessing the power of machine learning techniques and hybridization strategies, the proposed methodology endeavors to elevate the accuracy and dependability of cooling load predictions beyond the capabilities of conventional methods. Through rigorous comparative analyses, the research delves into intricate examinations, juxtaposing the proposed methodology with state-of-the-art approaches. These comparisons yield invaluable insights into the efficacy and superiority of the novel methodology, shedding light on its potential to outperform existing techniques in predicting cooling loads with precision and reliability. The practical implications of successfully implementing the study's findings are substantial, encompassing a wide array of benefits ranging from optimized energy consumption in buildings to tangible cost reductions and advancements in sustainability initiatives. Furthermore, the study's contribution to the academic literature is profound, marking a significant advancement in predictive modeling techniques within the realm of cooling load prediction. By pushing the boundaries of knowledge and innovation, the study paves the way for future research endeavors and opens new avenues for exploration in the pursuit of energy-efficient building management practices.

B. Limitations

The effectiveness of the proposed methodology could face constraints due to data availability and quality, which might hinder the reliability of predictions if the data is insufficient or inaccurate. Moreover, the implementation of machine learning algorithms and hybridization strategies adds complexity to the modeling process, potentially necessitating specialized expertise for development and interpretation. Additionally, the study's findings might have limited generalizability to various contexts or building types, as factors like geographical location, building design, and occupancy patterns could influence the applicability of the methodology. Validating the proposed approach poses challenges, particularly in ensuring robustness and reliability across diverse scenarios and conditions. Furthermore, ethical considerations surrounding data privacy, bias, and transparency must be meticulously addressed due to the use of machine learning techniques and optimization algorithms. These ethical concerns underscore the need for responsible and transparent research practices throughout the study.

C. Future Study

For future studies, researchers may explore refining the methodology, analyzing long-term performance, integrating advanced technologies, validating in real-world settings, considering external factors' impact, conducting sensitivity analysis, integrating with building automation systems, and engaging users for feedback. These avenues aim to advance cooling load prediction, enhance energy efficiency, and promote sustainable building management practices.

D. Comparison with Published Papers

Table III shows the comparison between the presented and published papers. From the comparison, it can be observed that the presented study falls within the range of RMSE and R^2 values reported in the published articles. While the RMSE value of the present study (0.938) is higher than that of Roy et al. (0.059) and Gong et al. (0.1929), it is lower than that of Afzal et al. (1.4122). Similarly, the R^2 value of the present study (0.990) is slightly lower than that of Moradzadeh et al. (0.9993) but higher than that of Gong et al. (0.9882) and Afzal et al. (0.9806). Overall, the presented study demonstrates competitive performance in terms of both RMSE and R^2 compared to the published articles, indicating its effectiveness in predicting cooling loads.

TABLE IV. COMPARISON BETWEEN THE PRESENTED AND PUBLISHED ARTICLES

Articles	Index values	
	RMSE	**R^2**
Moradzadeh et al. [31]	0.4832	0.9993
Roy et al. [9]	0.059	0.99
Gong et al. [32]	0.1929	0.9882
Afzal et al. [14]	1.4122	0.9806
Present Study	0.938	0.990

V. CONCLUSION

As a result of the significant influence that the global building industry has on total energy consumption, efforts must be made to precisely forecast cooling loads in the context of energy conservation and building operations. The study established a multimodal investigation to improve cooling load prediction models by applying cutting-edge techniques and creative ideas. Initially, the emphasis was on important metrics like Dynamic Air-Conditioning Load (DACL) and Cooling Load (CL), which highlighted the critical role these parameters play in HVAC system optimization. Several different approaches have been adopted to improve prediction accuracy because of the complex interactions that have been identified between the optical and thermal properties of buildings and meteorological data. The process of extracting detailed insights from the data required the application of feature extraction techniques, such as engineering-based, statistical, and structural methods. These techniques, which combined mathematical and domain-specific viewpoints, made it easier to comprehend the thermal dynamics present in different types of construction materials. The rapidly changing field of machine learning (ML) has the potential to transform the precision and effectiveness of cooling load forecasts completely. The combination of machine learning and feature extraction techniques demonstrated the potential to improve current models and introduce new ones that can more accurately predict cooling load with never-before-seen levels of detail. The development and assessment of the RBF models RBSA, RBDS, and generic RBF represented the culmination of these efforts. The thorough statistical characteristics of the input variables served as a fundamental point of reference, allowing for an in-depth analysis of the models' performance during the training, validation, and testing stages. With the Self-adaptive Bonobo Optimizer (SABO) integrated, RBSA proved to be an exceptional performer, exhibiting superior accuracy in every phase. RBSA is a strong and dependable model for cooling load prediction because of its exceptional performance during testing, reduced RMSE and increased R^2, and ability to generalize far beyond the training set. These findings have wider ramifications that go beyond the immediate setting and provide a promising path towards more environmentally friendly and energy-efficient structures. By incorporating advanced modelling techniques, predictive accuracy is improved, and the foundation for intelligent, adaptive HVAC systems is laid. The combination of state-of-the-art machine learning, research methodologies, and feature extraction techniques could lead to the intelligent response of buildings to environmental demands in the future, resulting in a more sustainable and environmentally conscious global infrastructure.

Securing IoT Environment by Deploying Federated Deep Learning Models

Saleh Alghamdi, Aiiad Albeshri
Faculty of Computer Sciences, King Abdulaziz University, Jeddah, Saudi Arabia

***Abstract*—The vast network of interconnected devices, known as the Internet of Things (IoT), produces significant volumes of data and is vulnerable to security threats. The proliferation of IoT protocols has resulted in numerous zero-day attacks, which traditional machine learning systems struggle to detect due to IoT networks' complexity and the sheer volume of these attacks. This situation highlights the urgent need for developing more advanced and effective attack detection methods to address the growing security challenges in IoT environments. In this research, we propose an attack detection mechanism based on deep learning for federated learning in IoT. Specifically, we aim to detect and prevent malicious attacks in the form of model poisoning and Byzantine attacks that can compromise the accuracy and integrity of the trained model. The objective is to compare the performance of a distributed attack detection system using a DL model against a centralized detection system that uses shallow machine learning models. The proposed approach uses a distributed attack detection system that consists of multiple nodes, each with its own DL model for detecting attacks. The DL model is trained using a large dataset of network traffic to learn high-level features that can distinguish between normal and malicious traffic. The distributed system allows for efficient and scalable detection of attacks in a federated learning network within the IoT. The experiments show that the distributed attack detection system using DL outperforms centralized detection systems that use shallow machine learning models. The proposed approach has the potential to improve the security of the IoT by detecting attacks more effectively than traditional machine learning systems. However, there are limitations to the approach, such as the need for a large dataset for training the DL model and the computational resources required for the distributed system.**

***Keywords*—Internet of Things (IoT); security breaches; machine learning; Deep Learning (DL)**

I. Introduction

IoT security has attracted more attention as a result of the Internet of Things (IoT) technologies' quick growth and wide use. IoT is a network system comprising numerous IoT devices that can be accessible to cyber-attacks because they are typically found in unsupervised locations. One of the most difficult study areas in information technology is cyber security. It is especially challenging to do when new technologies are involved, such as the IoT, because of its common use in numerous technological fields, the internet of things is predicted to reach 50 billion devices by the year 2020 [1]. The privacy, integrity, and availability of data are seriously threatened by this growth, which malevolent actors may use against them. In addition to preventing illegal access to networks and systems, cyber security also involves protecting data and personal information. As more and more new applications depending on connected devices are created, there has been an increased focus on IoT security in recent years. In comparison to computer networks, attacks on the Internet of Things could make things worse and result in significant, extremely expensive damage. IoT is so strongly dependent on the reduction of end security setup, and all IoT strategies and components should completely address security threats. In light of research into IoT risk categories and security architecture, the detection methods need to be improved [2].

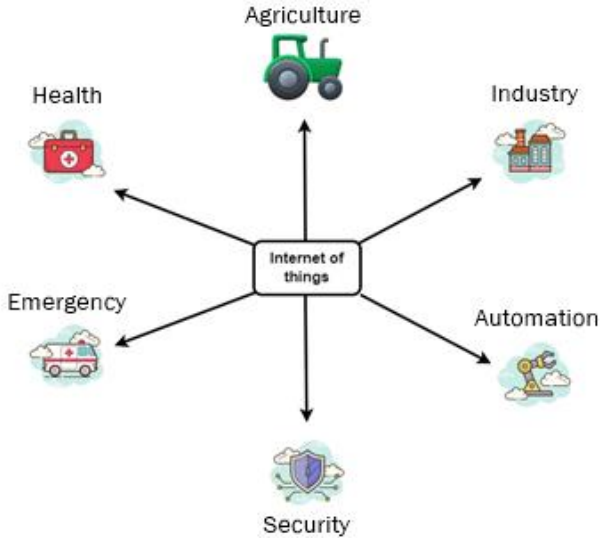

Fig. 1. Internet of things.

Attacks on linked devices have become a serious issue as IoT has gained popularity as shown in Fig. 1. IoT devices are sensitive to a variety of attacks, including denial of service, monitoring of communications, and password cracking. As the number and variety of Internet of Things (IoT) devices continue to grow, safeguarding these devices against cyber-attacks is becoming increasingly critical. Study [3-6] highlight the growing concern for the security of IoT devices, underscoring the urgency of implementing effective protective measures. Moreover, the complex nature of these interconnected systems, which often depend on wireless networks for the transmission of real-time, sensitive data, further elevates the risk of cyber threats. Such vulnerabilities can be exploited through attacks like web insertion, potentially resulting in the unauthorized access and exposure of private data, as well as the alteration or tampering of critical information. This exposure not only compromises the privacy of individuals and organizations but also threatens the integrity

and reliability of the system as a whole [7]. For IoT devices, improved, more reliable intrusion detection systems are required. For threat detection, deep learning-based security systems do not require a network connection and work with all types of devices, operating systems, and data [8].

Attack detection methods include anomaly-based and signature-based methods. The signature-based method analyzes the incoming traffic to the database's list of known attack types, whereas the anomaly-based method detects attacks as behavioural anomalies from normal traffic. The earlier method has received criticism for not being able to detect fresh attacks despite having high detection accuracy and a low false alarm rate. On the other hand, anomaly detection does not have high accuracy, but it does detect new attacks. Classical machine learning has been heavily employed in both strategies [9]. Traditional machine learning algorithms are unable to identify advanced cyber-attacks due to the attackers' continuous increase in strength and resources. The majority of these attacks are minor variations of cyber-attacks that have been seen before. It is noticeable that even the as such unique attacks (1% of all attacks) depend on earlier concepts and logic [10-11].

Unlike traditional machine learning methods that struggle with abstract feature extraction, DL can develop high-level, stable representations of training data, making it sensitive to slight variations or modifications. This sensitivity is particularly useful in fields like pattern recognition, computer vision, and image processing, where DL has significantly improved classification and prediction accuracy. The passage highlights recent findings that suggest DL's effectiveness in traffic classification and intrusion detection systems, indicating its novel application in cyber security attack detection, even within resource-constrained networks. The research aims to develop a distributed attack detection mechanism based on DL for the IoT, leveraging DL's self-learning capability to enhance accuracy and processing speed.

This research makes the following contributions:

- Develop and deploy an attack detection mechanism based on federated learning and deep learning that captures the distribution patterns of IoT networks.
- The proposed system can identify attacks as soon as they occur and respond swiftly to mitigate future damage.
- The proposed system can reduce the probability of false positives by learning and adapting to new attack patterns.

The Section II provides a background study; Section III outlines the proposed methodology, followed by the results in Section IV. Finally, the paper is concluded in Section V.

II. Literature Review

Many researchers have used different techniques on different types of data for user behaviour. Each researcher explores different aspects of user behaviour analysis. Here the study discusses a few of them, especially for Anomaly Detection in the Internet of Things.

In study [14], author discusses the rapid growth of the Internet of Things (IoT) industry, projected to reach 30.9 billion devices by 2025, and the associated security risks due to manufacturers prioritizing service quality over security. In response to the significant challenge posed by detecting intrusions within the extensive and diverse networks of the Internet of Things (IoT), the authors propose a sophisticated solution. They have developed an intrusion detection system that utilizes the capabilities of deep learning to effectively address this issue. This system is uniquely designed to be highly adaptable, enabling it to learn from and adjust to the intricacies of any IoT network it encounters. One of the most notable achievements of this system is its exceptional accuracy rate, which stands at 93.74%. This level of precision underscores the system's effectiveness in identifying and responding to security breaches across the varied landscape of IoT environments. In study [15], the authors address the security vulnerabilities of the Industrial Internet of Things (IIoT) to protect against sophisticated multi-variant botnet attacks. This approach utilizes a combination of supervised and unsupervised machine learning algorithms to develop an Intrusion Detection System (IDS) that outperforms existing methods in speed and accuracy of bot attack detection, showcasing its effectiveness through comprehensive evaluations using the latest datasets and performance metrics. In study [16], the paper explores the implementation of machine learning-based Intrusion Detection Systems (IDS) in IoT environments with limited resources. The proposed IDS combines Principal Component Analysis (PCA) for feature reduction with various machine learning models, achieving high detection accuracy against contemporary attacks as demonstrated using the UNSW-NB15 datasets. The approach prioritizes reducing communication overhead and avoiding the complexities of encryption methods, with future work aimed at enhancing this model with deep learning techniques and novel datasets for broader IoT applications.

In this study, [17] researchers tackle the challenge of safeguarding Industrial Internet of Things (IIoT) edge devices from cyber-threats and anomalies to enhance threat detection. Their method demonstrates a high accuracy of 99.5% on an IIoT-specific dataset, surpassing traditional ML-based classifiers in metrics like precision, F1-score, and recall. In [19], a novel intrusion detection architecture named DRaNN is introduced for improving security in IIoT settings, employing a hybrid approach of particle swarm optimization (PSO) and sequential quadratic programming (SQP) for optimizing hyperparameters for enhanced attack detection. The study in [20] explores a DL-based method for bolstering blockchain data security, focusing on the identification and deployment of secure smart contracts within public blockchain networks. This approach achieves notable results in vulnerability detection accuracy (99.083%), precision (91.935%), and recall (87.692%).

TABLE I. LITERATURE REVIEW

Paper Title	Dataset	Methodology	Domain	Limitations
[23]	KDD Cup 1999 datasets	deep neural network	IoT security	Benchmark dataset not used
[24]	UNSW-NB15 datasets	CNN+RNN	IoT security	The system may not be effective against attacks that do not generate anomalous traffic patterns
[25]	CICIDS2017 dataset	BiLSTM	IoT security	Low performance in some type of attacks
[26]	Various IoT datasets	CNN	IoT security	Small datasets
[27]	UNSW-NB15 dataset	RNN+Blockchain	IoT security	The proposed approach may not be effective against attacks that do not generate anomalous network traffic patterns.

In study [21], researchers propose a unique pairing structure and algorithm to verify the authenticity of sensor data within the IoT framework. Their method is validated through case studies and experiments on two real-world datasets, applying CART, SVM, and KNN algorithms. Lastly, [22] presents an innovative architecture designed to detect and counteract DoS/DDoS attacks in IoT environments, offering precise detection capabilities that identify both the attack type and the packet type involved. Some studies are detailed in Table I, showcasing advancements in IoT security through various approaches.

III. PROPOSED MODEL

The proposed system used a Federated Learning (FL) approach to overcome the challenges of anomaly detection in the Industrial Internet of Things (IIoT) ecosystem, where devices often have limited capabilities and generate minimal data. This method involves aggregating training data from multiple users to quickly develop a robust model, with local FL clients training models on available data and a global server aggregating these insights to improve both global and local models. This strategy enhances the ability to differentiate between malicious and benign traffic within an IIoT network. In Fig. 2, the configuration of the proposed FL approach for IIoT intrusion detection is depicted, with several installed and network-connected devices spread across various places [28].

A. Learnings and Intelligence at the Local Level

In this component of the framework, each client (ranging from k=1 to K) locally trains the data collected from their respective Industrial Internet of Things (IIoT) devices using the models provided by the server. Concurrently, an Intrusion Detection System (IDS) at the client's site identifies any potential attacks. Additionally, a network data analyzer is employed to log data for subsequent analysis. This approach of enabling local training, adjusting parameters, and refining the inference mechanisms, ensures the autonomy of local intrusion detection systems through intelligent, device-level learning.

B. Distribution of Learnings

To enhance the intrusion detection system by optimizing its parameters, clients share their individually trained models with a centralized server for aggregation. This process of model exchange is managed by an intelligent communication administrator, such as a security gateway. This collaborative approach aims to refine and improve the system's ability to detect intrusions effectively.

C. Model and Assumptions

In an Industrial Internet of Things (IIoT) network, a threat or adversary, referred to as M, can originate from either inside or outside the network. This includes insiders, such as compromised IIoT devices or other connected devices that remain within the network's confines, as well as external attackers who exploit the Internet to conduct cyberattacks. These attacks may involve manipulating digitally connected systems, inserting harmful content into databases, or pilfering sensitive information. IIoT malware often seeks out devices with lax security measures to serve as a foothold for launching attacks, aiming to identify and exploit weaknesses in IIoT systems and devices. We also made a few more assumptions during our analysis. These are what they are:

- A reliable FL aggregator is vital because aggregation servers play a crucial role in the learning process. For this reason, there must always be some level of faith in the system that organizes learning.
- No nefarious IIoT Device by Design: In some circumstances, newly introduced IIoT products may already have security issues. However, before being used for their intended function, these gadgets must not be contaminated or diseased.
- Secure Clients: Assuming that secure clients are essential for Federated Learning (FL) in IIoT systems, we proceed under the presumption that they exist.

D. Intrusion Detection for FL

In the Federated Learning (FL) model, each of the K clients independently trains a local model based on a common global model distributed by the server, utilizing their unique local datasets instead of relying on a centralized data repository. These clients then securely transmit the insights gained from local training sessions to an aggregation server via an SSL/TLS secured connection. The aggregation server merges these individual contributions to update the global model, optimizing it with the best possible parameters. This process is iterated through several rounds of federated learning, denoted by R, starting from initial weights represented by w, until the model converges to an optimal state. The model weights update during each communication round is guided by a formula derived from the FedAvg algorithm, ensuring efficient and effective learning from each local client's data.

$$w_{t+1} = \sum_{k+1}^{k} \frac{n_k}{n} w_{t+1}^{k} \quad (1)$$

In this context, n_k represents the dataset size for each individual client, while n signifies the total dataset size across all clients. After the iteration process, the updated global model is denoted as w_{t+1}^k. Fig. 3 illustrates the connections between various participants in the Federated Learning (FL) IIoT intrusion detection system. For inclusion in the FL cycle, the server selects clients that are connected to operational IIoT devices, which must be turned on, plugged into a power source, and linked to an unmetered Wi-Fi connection. The interaction among the system's components to facilitate the FL process is outlined as follows:

1) The server initializes a NN model based on a global intrusion detection framework, specifying parameters such as the number of neurons, epochs, and hidden layers. The initial weights of this model are symbolized by w.

2) Clients maintain the confidentiality of their local data while leveraging it to refine the model using information from the IIoT devices they manage.

3) To safeguard client privacy, only the parameters of the updated model, which contribute to the enhanced intrusion detection capabilities, are shared with the central server.

4) Upon collecting all the updates, the server aggregates the weights from each client's model to form an updated, improved global model using the FedAvg algorithm. This aggregation takes into account the dataset size at each client node.

5) The central server pushes the modified model parameters back to the clients.

6) Every client applies the updated model parameters and modifies them in light of the fresh information.

7) Repeat steps 4, 5, 6, and 7 to continue refining and improving the model.

E. Machine Learning Classifiers for Intrusion Detection

The rapid development of ML methods and applications has given the intelligent IDS solution an altogether novel avenue for development. To extract better data representations for powerful model construction, neural network methods have proven to be highly helpful. Neurons, weights, biases, and functions are the essential elements that all neural networks share, even though there are many different types of neural networks. For intrusion detection, we have maintained a minimal number of classifiers at a central location, utilizing the following two:

CNNs are designed to process data represented in multiple arrays. At the core of this approach are the initial layers, which consist of a set of learnable filters applied via convolutional feature extractors. These filters are employed across the input data using a sliding window mechanism. The term "stride" denoting the extent of overlap between these filters' applications. Convolutional kernels, essential elements of a CNN layer, are utilized to create unique feature maps by connecting neurons to local regions in the preceding layer's feature map. To form a feature map, the kernel is systematically applied across all spatial positions of the input. After constructing convolutional and pooling layers, classification is achieved through one or more densely connected layers.

$$h_j^{(n)} = \sum_{k=1}^{k} h_k^{(\cap-1)} * w_{k_j}^{(n)} + b_{k_j}^{(n)} \qquad (2)$$

Recurrent Neural Networks (RNNs) are advanced models of feed-forward neural networks, designed to retain information at each stage for future outputs. In an RNN, the output from neurons is fed not only to their own input but also to the input of other neurons. This design allows RNNs to process sequences of data and time series effectively by leveraging their internal memory.

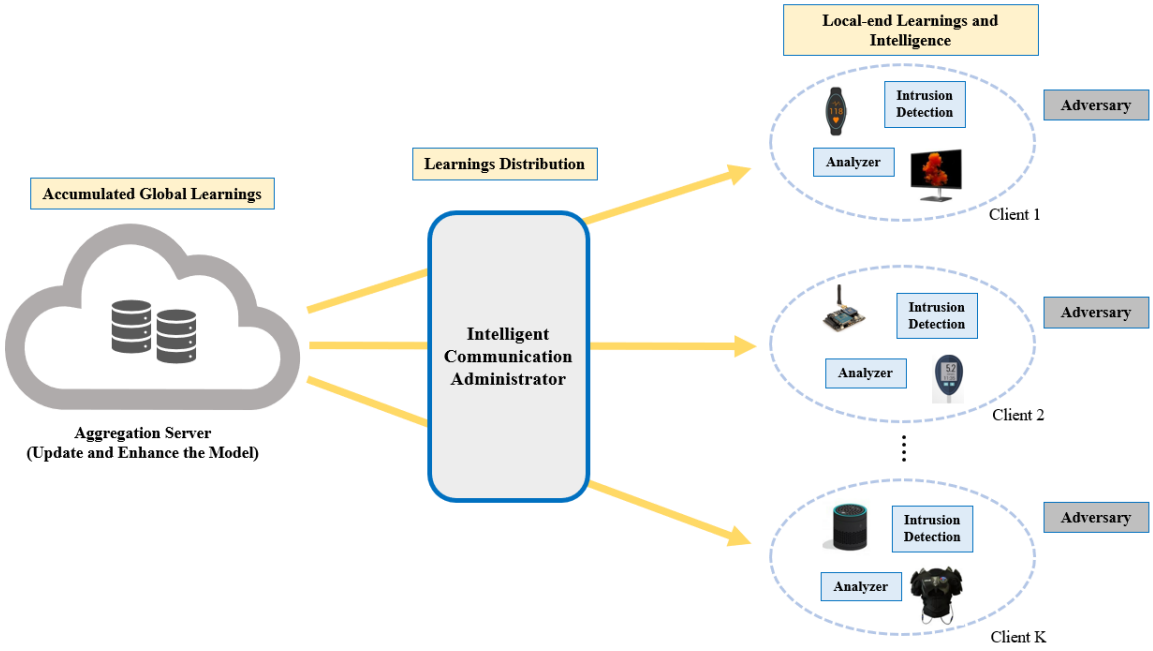

Fig. 2. Proposed approach.

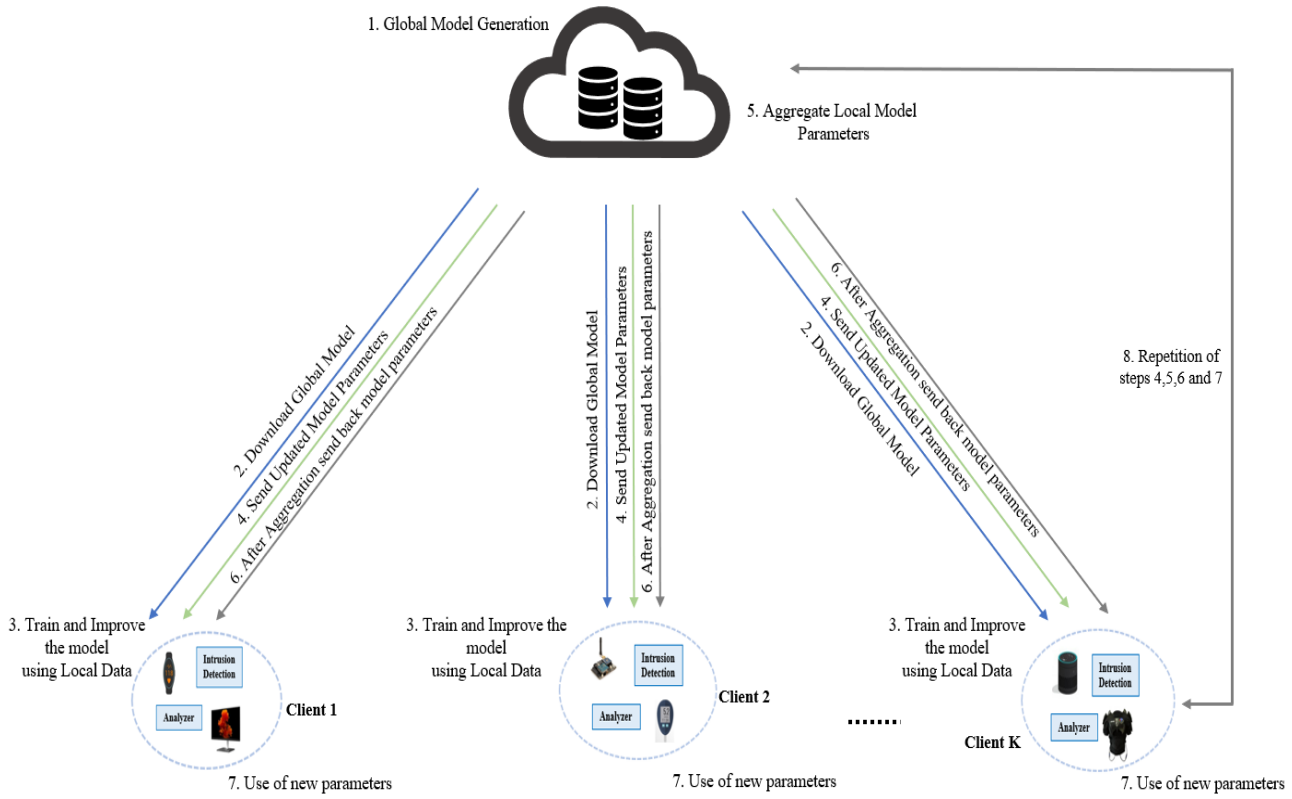

Fig. 3. Interactions among FL-based IDS clients' participants.

VI. Experimental Results

For training and evaluating Intrusion Detection Systems (IDSs) in IIoT networks, selecting an appropriate dataset is crucial. To address this need in IIoT and IoT contexts, a novel cybersecurity dataset named Edge-IIoTset has been introduced. The dataset includes data from a wide range of IoT devices, including heart rate monitors, flame detectors, and sensors for temperature and humidity. For Federated Learning (FL) projects, it's crucial that the dataset showcases a distribution that is both imbalanced and non-independently and identically distributed (Non-IID), reflecting the complexity of real-world situations accurately. Our dataset (Edge-IIoTset) has been partitioned for experimental purposes into several local datasets so that they can be trained to meet FL's requirements. Due to the lack of FL-specific datasets, this was necessary. The dataset breakdown is shown in Table II.

TABLE II. Training and Testing Distributed Data

Dataset	Total	Training	Testing
Normal	25,320	21,112	5933
DDoS-UDP Attack	15498	12540	3033
DDoS-ICMP Attack	13090	10179	2899
Uploading Attacks	10,147	8261	2017
DDoS-TCP Attack	10,380	9045	2302

To assess the effectiveness of FL, we ran several tests with 3 to 15 clients contributing to model training. Before achieving the best results, our model was trained for a total of 50 epochs. While creating the federated model, we looked at how effective the system was for various client counts. The deployment dataset's training data was distributed to each client, a random selection from which was made. We created three federated models and compared them to a centralised model to investigate this potential loss in accuracy. The training dataset was distributed among 3, 9, and 15 clients.

A. Performance Metrics

When evaluating the model using test data, the following performance metrics were considered:

$$ACC = \frac{TP+TN}{TP+TN+FP+FN} \quad (3)$$

$$Pre = \frac{TP}{TP+FP} \quad (4)$$

$$Rec = \frac{TP}{TP+FN} \quad (5)$$

$$F1 = 2 . \frac{Precision.Recall}{Precision+Recall} \quad (6)$$

B. Evaluation of Performance

This section covers the results of the experiment employing centralised learning and the performance of our suggested FL-based model for incursion detection using the Edge IIoT set dataset.

1) Using centralised method for intrusion detection: We first employed two conventional centralised ML methods, namely CNN and RNN, to assess the performance of the new model. In the method we propose, Table III lists the values assigned to the parameters of various classifiers.

TABLE III. ML CLASSIFIER SETTINGS

Classifier	Parameters
CNN	Filters Pooling layer Hidden notes Hidden layers
RNN	Batch size Local epochs Loss function Activation function

Table IV presents the performance metrics of machine learning techniques for a centralized model, focusing on their ability to differentiate between benign and attack classes within the dataset. According to the table, both RNN and CNN methods exhibit high effectiveness, with Accuracy and F1-Score reaching up to 94% and 93%, respectively. Furthermore, these techniques demonstrate excellent capability in distinguishing between benign and malicious activities, achieving Precision and Recall rates as high as 95% for RNN and 94% for CNN.

2) Using federated method for intrusion detection: We conducted Federated Learning (FL) experiments using our model with three different sets of clients, denoted as K, where K equals 3 for the first set, 9 for the second set, and 15 for the third set. To address our varied client base, we employed two scenarios:

- Independent and Identically Distributed (IID): In this scenario, each client's data distribution is uniform across the dataset.
- Non-Independent Identically Distributed (Non-IID): In this scenario, the overall dataset's data distribution varies from that of each individual client.

C. Comparison to Related Works

Table V outlines a comparative analysis against similar methodologies encompassing various dimensions such as deployment year, datasets utilized, machine learning classifiers, number of clients, and data distribution strategies. This comparison reveals that our proposed model uniquely tackles both IID and Non-IID data issues, demonstrating effective performance across these data types as discussed in the preceding section.

D. Discussion

Utilizing Federated Learning (FL) instead of traditional Machine Learning (ML) techniques offers significant advantages for Industrial Internet of Things (IIoT) devices in terms of data security and bandwidth efficiency. By adopting FL, IIoT devices can transmit data that is not only more secure but also requires less bandwidth. This is because, in an FL setup, the vast amounts of private and sensitive information are not centralized on a single server. Instead, clients only share the outcomes of their individual local model trainings, substantially reducing bandwidth needs [13] [18]. This approach not only ensures the security of the data but also upholds the privacy of the users since the raw data remains on the device. Additionally, FL enables devices to autonomously predict and detect network anomalies, even when offline, by leveraging the local representations of the models [30]. This implies that local clients are able to persist with their model training and intrusion detection efforts, irrespective of their connectivity status. Furthermore, with an increase in the number of Federated Learning (FL) rounds, the precision of intrusion detection nears that of centralized Machine Learning (ML) models. This improvement in performance is attributed to the cumulative enhancements from client-end learnings, allowing the models to operate with the same efficacy as centralized models after each FL round.

TABLE IV. ASSESSMENT OF THE CENTRAL INTRUSION DETECTION MODEL

Class	Accuracy		Precision		Recall		F1-Score	
	CNN	**RNN**	**CNN**	**RNN**	**CNN**	**RNN**	**CNN**	**RNN**
Normal	0.94	0.95	0.93	0.91	0.91	0.91	0.92	0.91
DDoS-UDP Attack	0.89	0.90	0.95	0.96	0.89	0.88	0.90	0.91
DDoS-ICMP Attack	0.83	0.81	0.80	0.78	0.88	0.87	0.83	0.81
Uploading Attacks	0.74	0.79	0.78	0.83	0.63	0.78	0.71	0.80
DDoS-TCP Attack	0.91	0.92	0.91	0.93	0.91	0.93	0.93	0.92
Proposed model	0.94	0.96	0.93	0.92	0.93	0.95	0.94	0.95

TABLE V. COMPARSION OF PROPOSED MODEL WITH BASELINES

IoT IDS	Year	Dataset	Classifier	IID	Non-IID
Nguyen et al [27]	2020	Private Dataset	RNN-GRU	No	Yes
Li et al [28]	2021	Gas Pipeline	CNN-GRU	Yes	Yes
Huong et al [29]	2022	Bot-IoT	LocKedge	No	Yes
Proposed model	2022	Edge-IIoTSet	CNN RNN	Yes	Yes

V. CONCLUSION

This study introduces an innovative intrusion detection system that leverages federated machine learning (ML) to tackle the vital concerns of security and privacy within IoT networks. Our key goal was to identify and stop unauthorized intrusions, which would ultimately ensure the security of IoT networks. We carried out extensive experiments with a freshly created dataset called Edge-IIoTset to verify the efficacy of our strategy. These tests were conducted using two well-known ML models: CNN and RNN, on both centralised and federated systems. The experimental results showed that our suggested federated learning (FL) approach can produce competitive results in the area of intrusion detection, which was quite encouraging. Our technology demonstrated its capacity to successfully identify intrusions in IoT networks by utilizing the power of collaborative learning while protecting data privacy. We also performed a thorough comparative analysis, comparing our method to previous FL-based intrusion detection systems in independent and non-independent, identically distributed (IID and non-IID) scenarios. The studies in our research help to demonstrate the viability, applicability, and utility of our suggested approach. They greatly advance our knowledge of and ability to use federated learning in the context of IoT networks. The results of our study highlight FL's potential as a workable option for boosting the security and privacy of IoT systems.

Review and Analysis of Financial Market Movements: Google Stock Case Study

Yiming LU
School of Continuing Education, Shijiazhuang College of Applied Technology, Shijiazhuang, 050081, China

***Abstract*—A financial marketplace where shares of companies with public listings are bought and sold is called the stock market. It serves as a gauge of a nation's economic health by taking into account the operations of individual businesses as well as the general business climate. The relationship between supply and demand affects stock prices. Though it might be dangerous, stock market investing has the potential to provide large rewards in the long run. Together with increased prediction accuracy, optimization techniques such as Biogeography-based optimization (BBO), Artificial bee colony algorithm (ABC) and Aquila Optimization (AO) Algorithm further enhance the Extreme gradient boosting (XGBoost) ability to adapt to changing market conditions. The results were 0.955, 0.966, 0.972, and 0.982 for XGBoost, BBO-XGBoost, ABC-XGBoost, and AO-XGBoost, in that order. The performance difference between AO-XGBoost and XGBoost shows how combining with the optimizer may enhance the model's performance. By comparing the output of many optimizers, the most accurate optimization has been determined to be the model's main optimizer.**

***Keywords*—Stock future trend; financial market; investment; machine learning algorithms; Google stock**

I. INTRODUCTION

A. Background knowledge

The task of forecasting stock prices is difficult [1], [2], [3], [4]. The long-term unpredictability in the market presents a significant challenge. The conventional theory of markets posits that stock valuations are inherently random and lack any discernible pattern. Nevertheless, contemporary technical analysis has provided evidence to support the notion that historical data largely influences stock prices, hence emphasizing the importance of understanding patterns of movement in order to make accurate projections [5]. Various economic factors, including political events, general economic circumstances, commodity price indicators, investor sentiment, movements in other stock markets, and investor behavior, also exert an influence on the categorization and fluctuations of stock market entities [6]. Stock values are determined through the assessment of market capitalization, which is the total worth of a company's outstanding shares. Additionally, statistical data can be derived by employing a range of technical variables [7]. Stock indexes are often constructed using the prices of equities with significant market investments, serving as a means to assess the economic conditions of various nations. Empirical evidence suggests that stock market capitalization exerts a positive impact on a country's economic growth [8]. Investments pose inherent risks due to the volatile nature of stock price fluctuations. Furthermore, ascertaining the market standing of governments is sometimes a complex task. Due to the inherent characteristics of stock values, namely their dynamic, non-parametric, and non-linear nature, statistical models often encounter challenges in accurately predicting precise values and trends, hence diminishing their efficacy [9], [10]. Machine learning (ML) is often regarded as the most powerful technology due to its ability to leverage diverse algorithms to improve performance in specific case studies. ML is commonly acknowledged for its significant capability to identify trustworthy data and detect patterns within datasets [11], [12], [13], [14], [15]. It is imperative to acknowledge the challenging and intricate nature of projecting stock prices. Although machine learning algorithms cannot be deemed as reliable sources for generating precise forecasts, they have significantly impacted stock prediction and financial markets through many means. This paper examines the effects and contributions of ML techniques in the domain of stock prediction. ML algorithms possess the capability to analyze historical stock price data in order to identify patterns and trends that may not be readily discernible to human analysts. The individuals possess the capability to discern complex patterns inside the dataset and employ them in order to predict forthcoming fluctuations in prices [16]. Various techniques of machine learning are employed for the purpose of prediction. The model employed in this study is an Extreme gradient boosting (XGBoost). Chen et al. (2015) [17] developed XGBoost, which is effective at building boosted trees, performing parallel operations, and resolving issues related to both regression and classification. The primary aim of the method is to optimize the value of the objective function by the repeated combination of weak base learning models into a stronger learner [18]. The residual is utilized to adjust the preceding prediction so that the designated loss function may be optimized at each gradient boosting cycle. The optimizers provided for the hyperparameters optimizer of the model are Biogeography-based optimization (BBO) [19], [20], [21], Artificial bee colony algorithm (ABC) [22], [23], and Aquila Optimizer (AO) [24]. The concept of species movement based on habitat appropriateness is the foundation of biogeography-based optimization or BBO. Therefore, a solution is like a habitat for an optimization issue. A crowded environment, where the circumstances for living species are better than in other habitats, is a better answer for the population. The environment where living things struggle is the worst answer for the people. Because they share properties, the superior solutions draw in the inferior ones. Another optimization method used is ABC; three groups of bees make up the artificial bee colony in the ABC algorithm: employed bees, bystanders, and scouts. In the first half of the colony are the working artificial bees, while in

the second half are the observers. There is one working bee for each food source. Stated differently, the quantity of food sources and the number of bees engaged are the same. An employed food source bee transforms into a scout. Another optimization method which has the best result, Aquila has a dark brown plumage, with a distinct golden-brown hue seen on the posterior region of its neck. Aquila has outstanding velocity and dexterity. Furthermore, the Aquila has robust lower extremities and formidable talons. This feature facilitates the capture of diverse prey. Aquila has been identified as an adult deer assailant. Aquila builds huge nests in elevated locations like as mountains or other elevated terrains. Aquila has exceptional cognitive abilities and demonstrates remarkable proficiency in hunting people.

B. Contributions and Novelties

This study offers valuable insights into the field of stock market prediction by seeking to enhance prediction accuracy through the integration of machine learning methodologies, specifically XGBoost. The model showcases improved flexibility in response to dynamic market conditions by integrating optimization techniques such as BBO, ABC, and AO. By conducting a thorough comparison of these optimization techniques, the study systematically determines that AO-XGBoost is the most effective model, demonstrating exceptional performance in predicting stock market values. This advantageous model shows potential for incorporation into dynamic trading systems, offering lucrative suggestions for traders and investors. The effectiveness of the proposed model is further confirmed through empirical validation using real-world data from Google stock prices, which shows minimal inaccuracies in forecasting stock prices. The study's well-defined performance evaluation highlights the dependability and resilience of the AO-XGBoost model, providing practical implications for decision-making in financial markets.

II. Literature Review

A. Related Works

Agrawal [25] focuses on stock market forecasting using machine learning algorithms, aiming to accurately estimate future stock values. The efficient market hypothesis suggests that stock prices depend on available information, making accurate prediction crucial for investor decision-making. The paper introduces a deep learning-based non-linear regression method for stock price prediction, evaluated on Tesla and New York Stock Exchange datasets from 2010 to 2020. The results indicate superior performance compared to existing machine learning approaches [25].

Hong et al. [26] employs Bidirectional Long Short-Term Memory (BLSTM), considered more accurate than unidirectional LSTM, to forecast near-future stock prices. The dynamic nature of the stock market is likened to a living creature, requiring continuous input and analysis of data for accurate predictions through consistent monitoring with BLSTM.

Wen et al. [27] presents a stock price forecasting model using Principal Component Analysis (PCA) and Long Short-Term Memory (LSTM). PCA reduces data correlation and dimensionality, while LSTM accurately forecasts stock prices. Experimental results on Pingan Bank data show improved accuracy compared to traditional models.

Simon et al. [28] focuses on using Artificial Neural Networks (ANN) as a dominant technique for accurate predictions. It reviews various ANN models and enhancement techniques, exploring research strategies to improve accuracy in stock market prediction.

Krollner et al. [29] interest in using machine learning for stock market prediction stems from its profit potential. Krollner et al. explores a less-explored aspect by applying ANNs in financial data mining for risk management. The goal is to leverage advances in stock market forecasting to develop hedging strategies safeguarding portfolios during market downturns. Simulation results demonstrate that ANNs offer a flexible and effective decision support tool for risk management in the Australian stock market.

B. Gaps and Fulfillment

Insufficient attention has been given to the examination of optimization techniques aimed at improving the efficacy of ML models in the context of stock price prediction within the current body of research. Many studies have primarily concentrated on experimental findings derived from specific datasets. However, there exists a dearth of comprehensive assessments encompassing diverse datasets that encompass various market conditions. To improve the performance of ML models, this research suggests integrating optimization techniques such as ABC, BBO, and AO. These techniques enhance the configuration of model parameters and enhance the precision of predictions. In order to make up for the insufficient assessment of real-world data, we conduct thorough testing on datasets that represent Google stock. The proposed model's generalizability and robustness can be guaranteed through this.

III. Methodology

A. Extreme Gradient Boosting Regression Method

A method of machine learning that uses gradient-boosting decision trees to provide regression and classification, which has been demonstrated in Fig. 1. To guarantee thorough coverage, the approach generates a sequence of weak learners, often in the form of classification regression trees. The model generates the final iteration of the regression model by averaging the weighted summation of the learners once the training procedure is complete. Regression trees are produced using the regularized and improved XGBoost regression algorithm, which helps predict continuous numerical target variables with accuracy. This approach follows the guidelines of gradient boosting, in which a new learner is introduced at construction time depending on the weak learner iteration's residual error. To reduce the overall model error, a gradient is used to generate the new learner. The XGBoost method is well known for its low computational complexity, fast speed, and great accuracy. Assume that the training sample data set D's class labels $\boldsymbol{y_i}$ and samples $\boldsymbol{x_i}$ are represented as follows:

$$D = \{(X_1, Y_1), (X_2, Y_2) \dots (X_N, Y_N)\} \quad (1)$$

Consequently, the i^{th} sample's prediction function may be shown as follows:

$$\hat{y}_i = \sum_{k=1}^{k} f_k(x_i), f_k \in F \quad (2)$$

Here, $f_k(xi)$ is the discriminating function of the $\boldsymbol{K}$th tree for the ith data, and $\boldsymbol{F}$ is the resilient structure for the $\boldsymbol{k}$ choice tree model integrating. The enhanced tree model that XGBoost uses anticipates a value using a starting tree, calculates the value's deviation from the real value, and then inserts a tree to get the deviation.

when $k = 0, \hat{y}_i^{(0)} = 0$; when $k = 1, \hat{y}_i^{(1)} = f_1(x_i) = \hat{y}_i^{(0)} + f_1(x_i)$; when we add t trees, then

$$\hat{y}_i^{(t)} = \sum_{k=1}^{t} f_k(x_i) = \hat{y}_i^{(t-1)} + \eta f_t(x_i), 0 < \eta < 1 \quad (3)$$

where, η is the learning rate.

The calculation of the objective function for XGBoost with the Mean Squared Error (MSE) loss function is as follows:

$$\text{Objective} = \sum_{i=1}^{n} (y_i - \hat{y}_i)^2 + \sum_{t=1}^{T} \Omega(f_t) \quad (4)$$

Preventing overfitting is achieved by regularizing the second term, which is the mean squared error between the true labels y_i and the predictions $\hat{y}_i$.

B. Biogeography-Based Optimization

The BBO algorithm works by modeling the movement of various species, which depends on how well-suited their specific surroundings are, as Fig. 2 illustrates. This process makes it easier to examine the complex relationships that exist between different species and their environments, which in turn leads to more accurate and trustworthy predictions about ecological patterns. Within the framework of an optimization issue, it is possible to argue that a solution resembles a habitat. Creating densely populated habitats that offer more favorable living circumstances for a wider variety of species than other habitats is a useful tactic for handling population issues. The least desirable situation for a population is one in which living things must deal with significant issues. Because of this, the better solutions have the capacity to make the worse solutions pay attention by virtue of their shared characteristics. The sharing of attributes is accomplished by the application of the defined operators. Emigration rates show that migration is the process by which people move from a less favorable environment to a more favorable one. The assessment of a species' entrance into a certain geographic area is known as the immigration rate. When comparing a less favorable option to a more favorable one, the expected rate of migration is predicted to be higher.

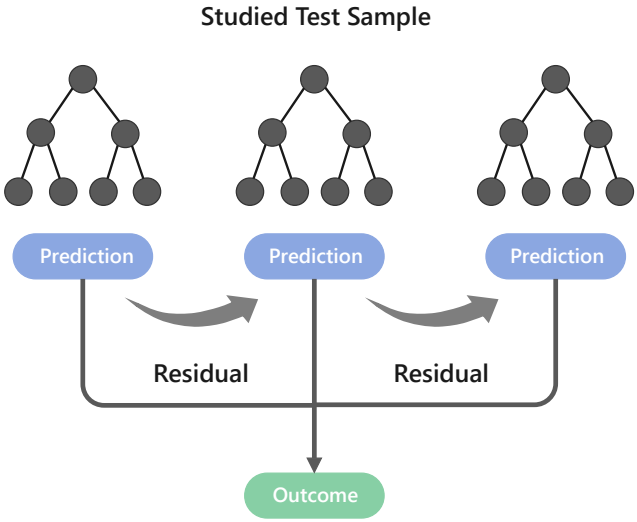

Fig. 1. The overall structure of the XGBoost.

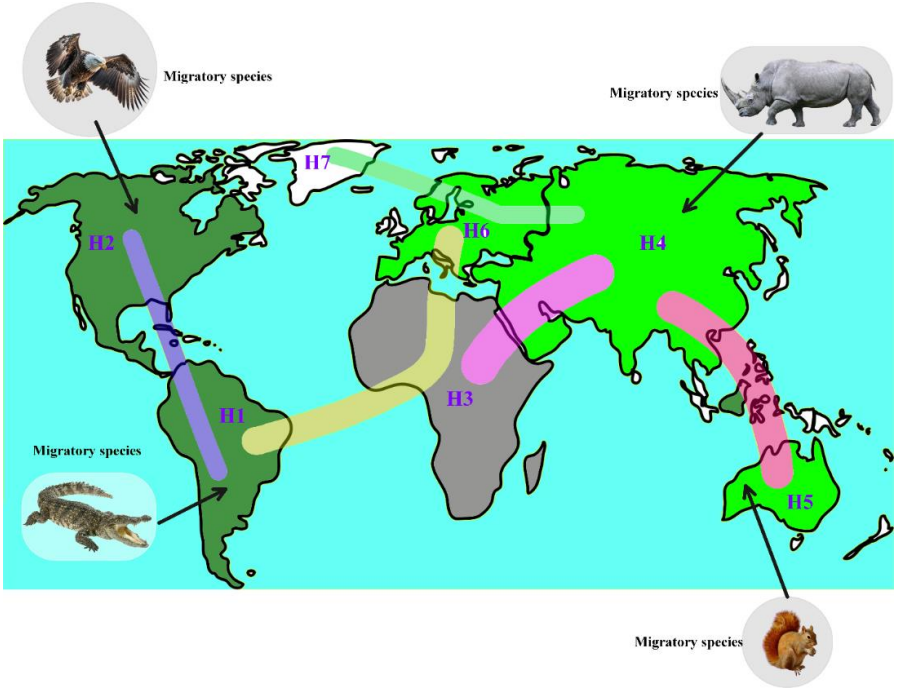

Fig. 2. Visual representation of the structure of BBO, habitats and migrations of species.

Conversely, the rate of migration pertains to the quantitative evaluation of the population size of individuals within a particular species who relocate from their habitat. As a result, it is anticipated that the rate of immigration will be higher when considering a poor solution in comparison to an optimal one. The BBO has employed the straight paths described by Eq. (5). The population size has been determined to be 100, and the epoch has been set to 500.

$$\mu_k = \frac{E \times k}{n}\lambda_k = I\left(1 - \frac{k}{n}\right) \quad (5)$$

where, μ_k is the migration amount of k[th] habitat, λ_k represents migration amount of k[th] habitat, I donates the maximum immigration amount, E is the maximum emigration rate, and n is the maximum amount of species that a habitat can support.

K: Number of species count.

C. Artificial Bee Colony

The ABC method is an optimization technique that draws inspiration from the intricate search and foraging activity of honey bees. It is commonly employed to address complicated issues with multiple dimensions and several modes in various domains of life. The ABC algorithm incorporates a nectar collection system within the honey bee colony, comprising nectar sources, employed bees, and unemployed bees. The unemployed bees are further categorized as bystanders and scouts. The task of the employed bees is to locate new food sources close to established ones. The observers must wait in the dance area and make a probabilistic decision regarding whether to select the food sources discovered by the employed bees, and the scouts must locate new food sources randomly [30]. During the process of nectar collection, certain workers within the beehive exhibit scouting behavior by engaging in continuous and indiscriminate search activities for food sources in close proximity to the hive. Subsequently, the researchers discovered two distinct food sources, labeled A and B. Following the observation of the waggle dance, a subset of the prospective worker bees transitioned into the role of hired bees and commenced their exploration of the aforementioned food sources. When a scout bee discovers a food source that surpasses a specific nectar threshold, it transitions into an employed bee. This bee subsequently engages in nectar collection and afterward returns to the beehive to deposit the gathered honey into the nectar store. When a scout bee discovers a food source that surpasses a specific nectar threshold, it transitions into an employed bee. This bee subsequently engages in nectar collection and afterward returns to the beehive to deposit the gathered honey into the nectar store. When a food supply isn't replenished many times, the worker bee transforms into a scout in search of fresh food. A detailed explanation of the mathematical models related to the several stages of the ABC algorithm can be found in the following section, and the visual representation of bees are shown in Fig. 3.

For starting food sources, the following equation is shown using a random solution vector boundary value. The population size is determined to be 100 and the epoch is 500.

$$x_{i,j} = x_j^{min} + rand(0,1)\left(x_j^{max} - x_j^{min}\right) \quad (6)$$

where, $i = 1, \ldots SN, j = 1, \ldots D, SN$ represents the number of solutions to be optimized, and D signifies the parameters to be optimized, where $x_j^{\min}$ and $x_j^{\max}$ signify the lower and upper limits of the $j\ th$ parameter, respectively. The aforementioned formula must be employed to ascertain the fitness value of each food source subsequent to the initiation of said food sources.

$$\text{fit}_{\ i} = \frac{1}{1 + obj \cdot fun_i} \quad (7)$$

$obj \cdot fun_i$, in this context, pertains to the intentional conduct.

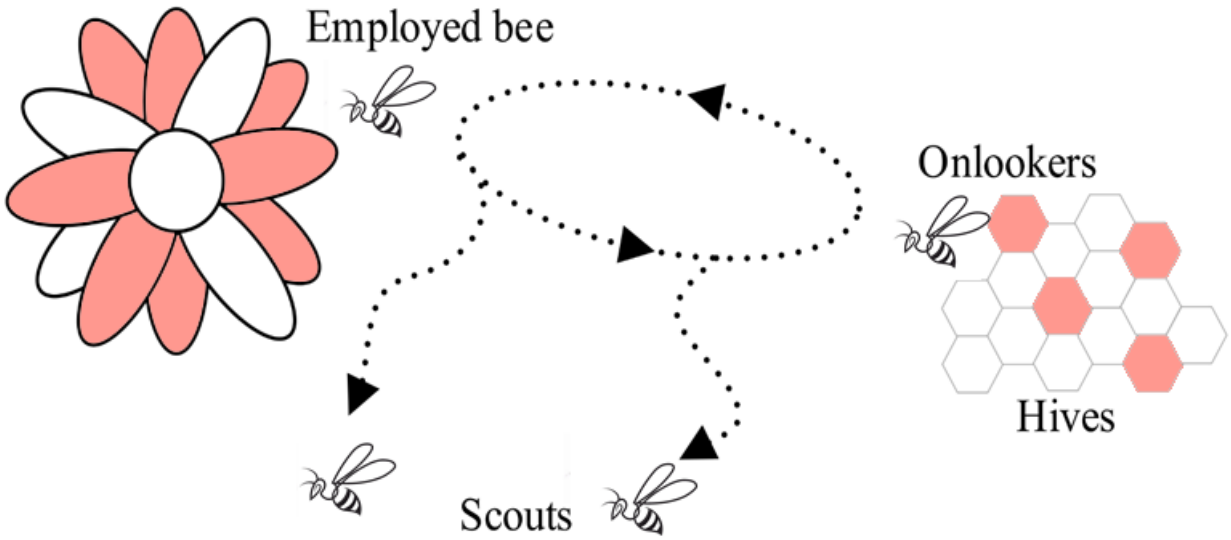

Fig. 3. The visual representation of the bees.

1) Employed bee stage: The quantity of responses matches the quantity of working bees and observers that SN has provided. Each active bee is supported by a single food source. By using Eq. (8) as a means to generate novel solutions, both observers and working bees engage in the exploration of proximate food sources and subsequently adjust their respective locations.

$$v_{ij} = x_{ij} + r_{ij}(x_{ij} - x_{kj}) \tag{8}$$

where, $k \neq i; r_{ij}$ is a randomly generated integer between [-1,1] and $j \in \{1,2,\dots,D\}$ and $k \in \{1,2,\dots,S\}$ are chosen at random. It is used to police a variety of communities. The fitness value of the new solution should be recalculated; subsequently, a comparison between the fitness values of $\boldsymbol{v_{ij}}$ and $\boldsymbol{x_{ij}}$ should be conducted, and the greater value should be selected.

2) Onlooker bee stage: As indicated by Eq. (9), observer bees evaluate a specific probability and measure of fitness while selecting food sources.

$$p_i = \frac{f_{it_i}}{\sum_{n=1}^{SN} fit_n} \tag{9}$$

where, fit_i is the solution's fitness value, which is connected to the food source's relevant nectar level. Eq. (7) illustrates that when sources of food are more appropriate, people are more inclined to choose them. The employed step goes to each food location and examines it, but the observer stage only applies Eq. (8) to the food sources chosen to produce fresh results. The spectator stage and the engaged stage are the same.

3) State – Scout: If the current food supply has been seen for a duration beyond the predetermined threshold, the employed bees will undergo a transformation into scout bees and start a stochastic exploration, as outlined in Eq. (6).

D. Aquila Optimization Algorithm

The AO was introduced in the year 2021 [24], as illustrated in Fig. 4, and the structure of the method is shown in Fig. 5. The following are the stages of the AO algorithm for establishing:

1) First-class vertical dives include: The Aquila species employs a strategic approach in identifying its prey area. It first undertakes a high-altitude flight to ascertain the optimal hunting region within the global context. This enables Aquila to effectively narrow down its search space and seek the most favorable solution. The procedure is seen in Eq. (10). The population size has been determined to be 100 individuals and the epoch has been set to 500.

$$\begin{cases} Z_1(t+1) = Z_{best}(t) \times \left(1 - \frac{t}{T}\right) \\ +\left(Z_M(t) - Z_{best}(t) \times rand\right) \\ Z_M(t) = \frac{1}{N}\sum_{i=1}^{N} Z_i(t), \\ \forall j = 1,2,\dots\dots, Dim \end{cases} \tag{10}$$

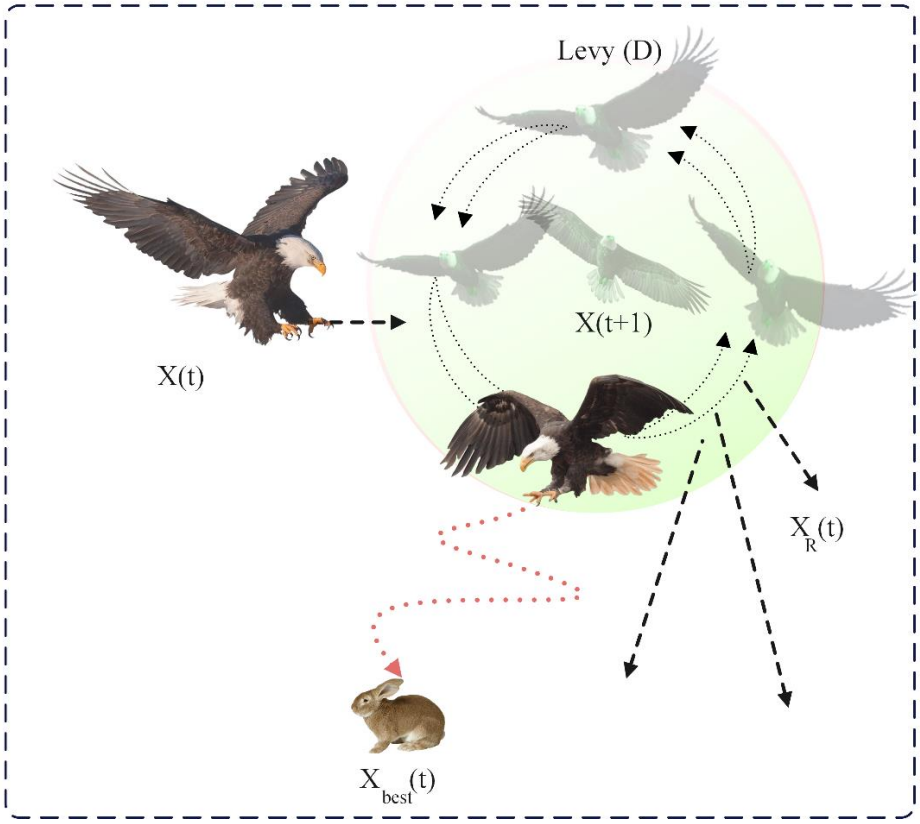

Fig. 4. Aquila optimization algorithm.

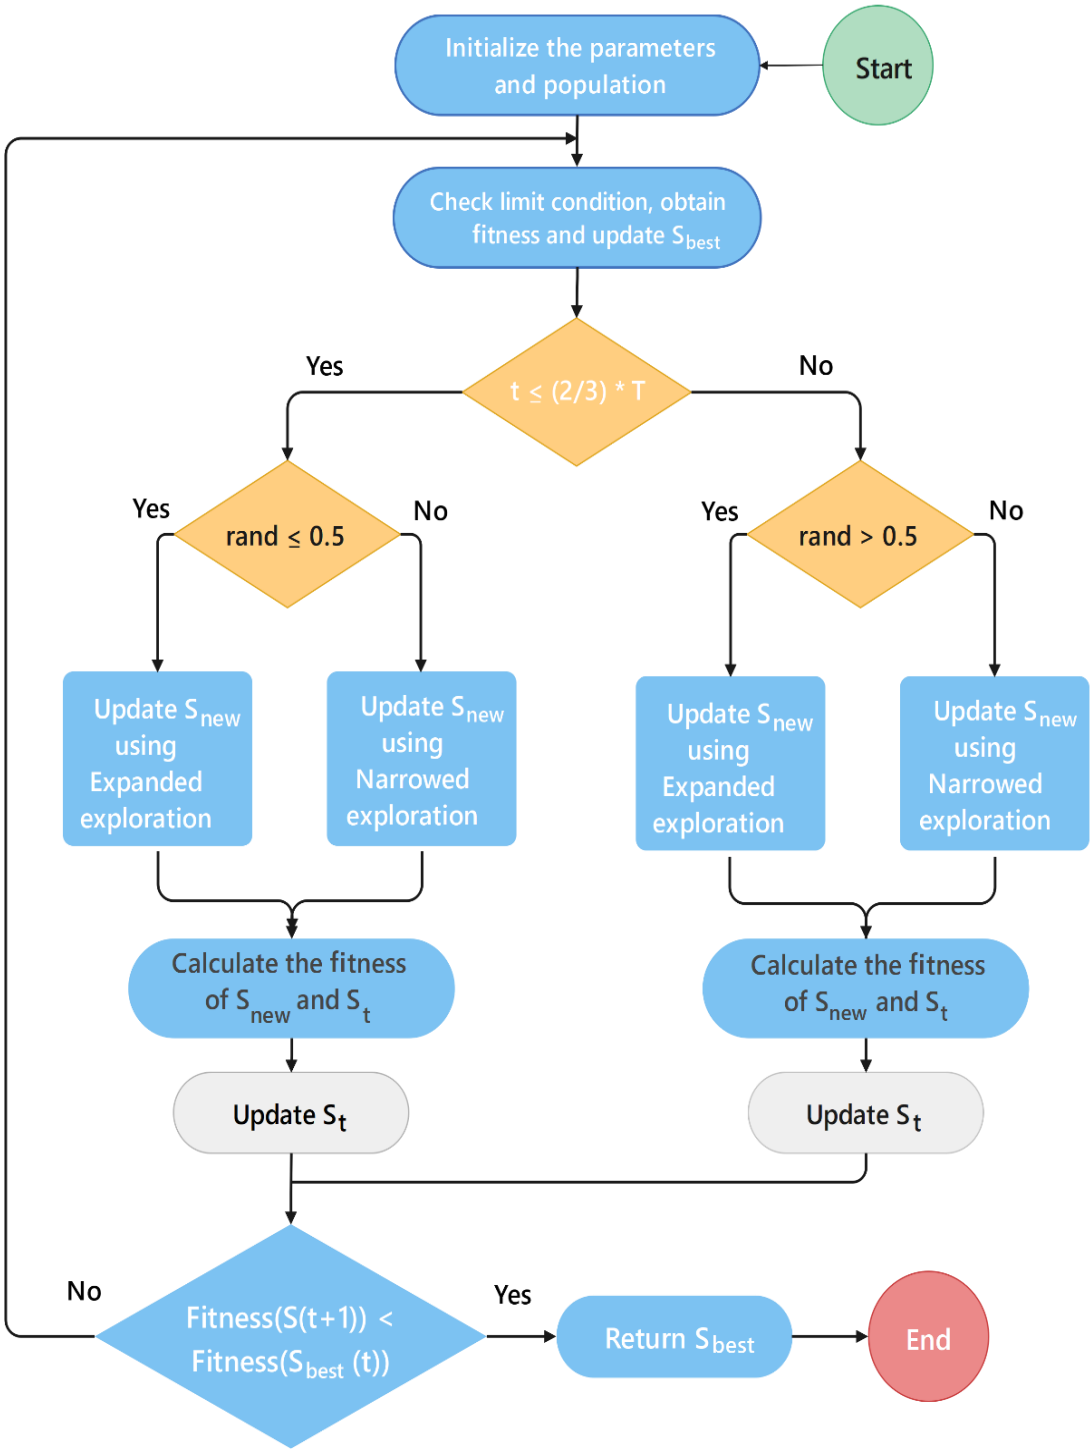

Fig. 5. Flowchart of the aquila optimization algorithm.

$Z(t+1)$ is the formula's generation $t+1$ solution, which was produced using the search procedure. The best strategy is Z_1, $Z_{\text{best}}(t)$, showing the position of the nearby prey target. Number t denotes the current iteration. T stands for the maximum number of iterations that may be carried out. Z(t) indicates the current solution's mean location at the t-th iteration. An integer between 0 and 1 is referred to as a rand. The subsequent swift glide attack: The eagle descends to a height where it can detect the prey region. It then hovers above the area it plans to hunt or investigate in search of the best solution.

2) Using formula (11):

$$\begin{cases} Z_2(t+1) = Z_{best}(t) \times Z(D) \\ +Z_R(t) + (y-z) \times rand \\ L(D) = s \times \dfrac{\mu \times \sigma}{|\nu|^{\frac{1}{\beta}}} \end{cases} \quad (11)$$

The random solution, denoted as $\boldsymbol{Z_R(t)}$, is a variable that takes on values between 1 and N, D represents the dimensional space, while L(D) refers to the hunting flight distribution function.

3) The third category of flights at low altitudes: Once the prey region has been precisely identified and the Aquila is prepared for landing and initiating an assault, it will assess the response of the prey inside the designated target area using a low-altitude and gradual descending approach, gradually closing in on the intended target. The procedure is demonstrated in Eq. (12).

$$\begin{aligned} Z_3(t+1) = &\left(Z_{best}(t) - Z_M(T)\right) \times \alpha \\ &- rand + \Big((U_b - L_b) \\ &\times rand + L_b\Big) \times \delta \end{aligned} \quad (12)$$

The adjustment parameters $\boldsymbol{\alpha}$ and $\boldsymbol{\delta}$ are set at a lesser value of 0.1. The variables $\boldsymbol{L_b}$ and $\boldsymbol{U_b}$ denote the bottom and upper limits, correspondingly, of the given issue.

4) The fourth kind of walking capture: Upon the Aquila's approach to the designated target during the same day, it engages in an aerial assault on the prey, using its superior positioning and swiftly converging on its intended objective. The procedure is shown in Eq. (13).

$$\begin{cases} Z_4(t+1) = Q_F \times Z_{best}(t) - \\ \left(G_1 \times Z(t) \times rand\right) - \\ -G_2 \times L(D) + rand \times G_1 \\ Q_F(t) = \dfrac{2 \times rand - 1}{t^{(1-T)2}} \\ G_1 = 2 \times rand - 1 \\ G_2 = 2 \times \left(1 - \dfrac{t}{T}\right) \end{cases} \quad (13)$$

In this context, $\boldsymbol{c_F}$ denotes the quality function used to optimize the search strategy. $\boldsymbol{p_1}$ corresponds to the diverse movements executed by the Aquila throughout its prey-hunting activities, while $\boldsymbol{p_2}$ represents the flight slope of the Aquila during the hunting process. $\boldsymbol{Z(t)}$ denotes the current solution at the $\boldsymbol{t}$th iteration.

E. Dataset Description

Ensuring that the raw data is of exceptional quality is an essential first step towards gaining meaningful information. Data preparation is a necessary first step in order to do this. It involves many activities, including deleting irrelevant data, standardizing it for shared use, and organizing it to make it simple to retrieve important information. This is particularly relevant for large-scale data efforts when data quality is more important than quantity. Tasks related to data preparation may also involve encoding categorical data and scaling, standardizing, normalizing, and cleaning data in compliance with industry standards. By completing these procedures, analysts may improve the accuracy and reliability of the insights they get from the data. Min-Max scalers were used to scale and normalize the data, remove any possible inconsistencies, and measure the null, missing, and unknown values as part of the project's data pre-processing step. This method is shown using data from the Google stock. This data covers the period from 2015 to the middle of 2023 and goes through a number of preliminary procedures, including normalization.

Google stock data spanning a substantial timeframe is easily accessible and frequently examined, guaranteeing the dataset's resilience and superior quality. The availability of the hybrid AO-XGBoost model enables the training and testing processes. Google is widely recognized as a prominent technology corporation, and its stock performance serves as a reliable indicator of prevailing patterns within the technology industry. The examination of Google stock can yield significant insights into the intricacies of the technology market, thereby facilitating the development of a hybrid model centered on the prediction of stock market trends. Technology stocks, such as Google, frequently demonstrate elevated levels of volatility and substantial prospects for growth. Through the examination of Google stock data, the hybrid model is capable of capturing and acquiring knowledge from the intricate patterns and trends that are inherent in unpredictable markets. This is essential for improving the model's ability to make accurate predictions. Investors and analysts show significant interest in Google's stock performance due to its widespread recognition and following. Utilizing Google stock data to develop a hybrid AO-XGBoost model can effectively engage stakeholders who possess knowledge and interest in the company, thereby enhancing the model's attractiveness and pertinence. The prominent position of Google as a dominant player in the technology industry presents a valuable occasion to evaluate the efficacy of the hybrid AO-XGBoost model in comparison to a widely recognized stock. The validation of the model's efficacy and dependability in forecasting stock market fluctuations can be achieved by juxtaposing its predictions with the actual stock performance of Google. The hybrid AO-XGBoost model for stock market prediction can benefit from utilizing Google stock data for analysis and model development.

Several charts in Fig. 6 depict histograms illustrating the distribution of data points in specific bins. These bins are evenly distributed along the x-axis, with each bar's height indicating the number of data points in the corresponding bin. Employing histograms proves valuable for scrutinizing data distribution and recognizing patterns. Examining the frequency of each variable over time aids in understanding how the data changes and responds to external factors. The graphical representation of the data in these charts is easily interpretable, helping users make informed decisions based on the presented information.

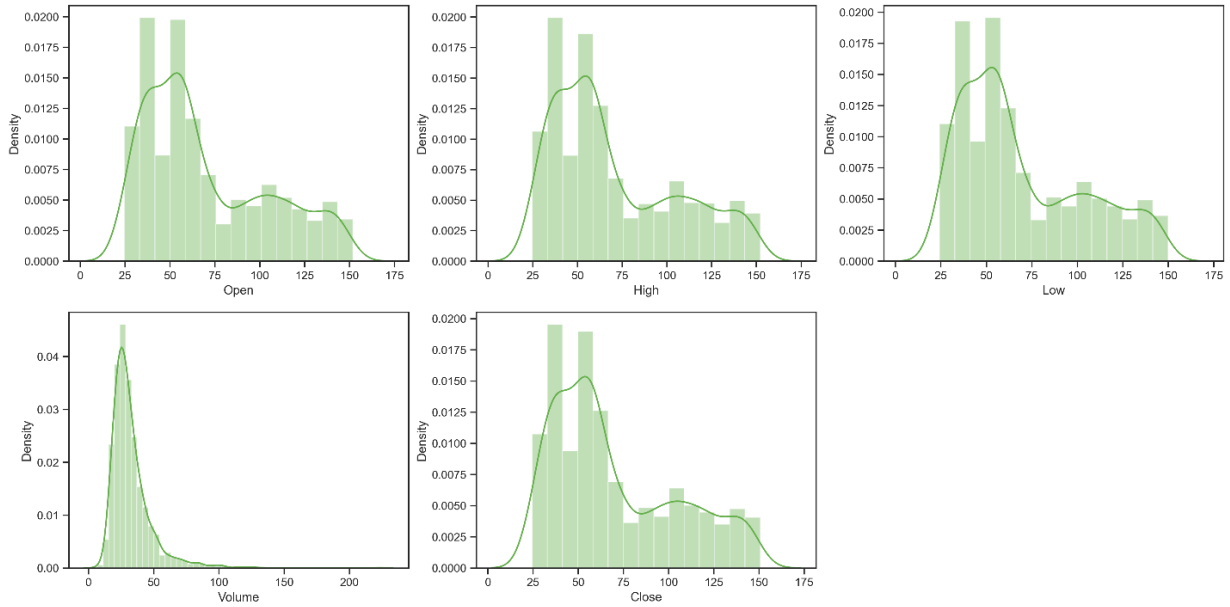

Fig. 6. Display density of variables.

Feature scaling is the process of rescaling numerical features in a dataset to a specified range, usually between zero and one. It is sometimes referred to as data preparation or Min-Max normalization. As all the characteristics are brought to the same scale, the goal is to preserve the relative relationships between the values. This could be especially important for ML algorithms that depend on the amount of input data.

$$\text{XScaled} = \frac{(X - Xmin)}{(Xmax - Xmin)} \quad (14)$$

where, X denotes the feature's initial value that you wish to normalize, X_{min} denotes the feature's lowest value in the dataset, and X_{max} denotes the feature's maximum value in the dataset.

1) Candlestick description: The Candlestick chart originated in the 16th century and was created by a Japanese rice merchant who dealt with financial instruments. The chart is a hybrid of a line chart and a bar chart, where each bar visually reflects the price range within a certain time period. It is mostly used in the technical analysis of patterns in stock and currency prices. A candlestick is constructed using the open, high, low, and closing prices of the day as Fig. 7 describes the overall structure. A full candlestick is drawn when the open price is higher than the closing price.

2) Statistical result: The statistical properties are shown in Table I and include variance, skewness, kurtosis, mean, minimum, maximum, and standard deviation (Std.).

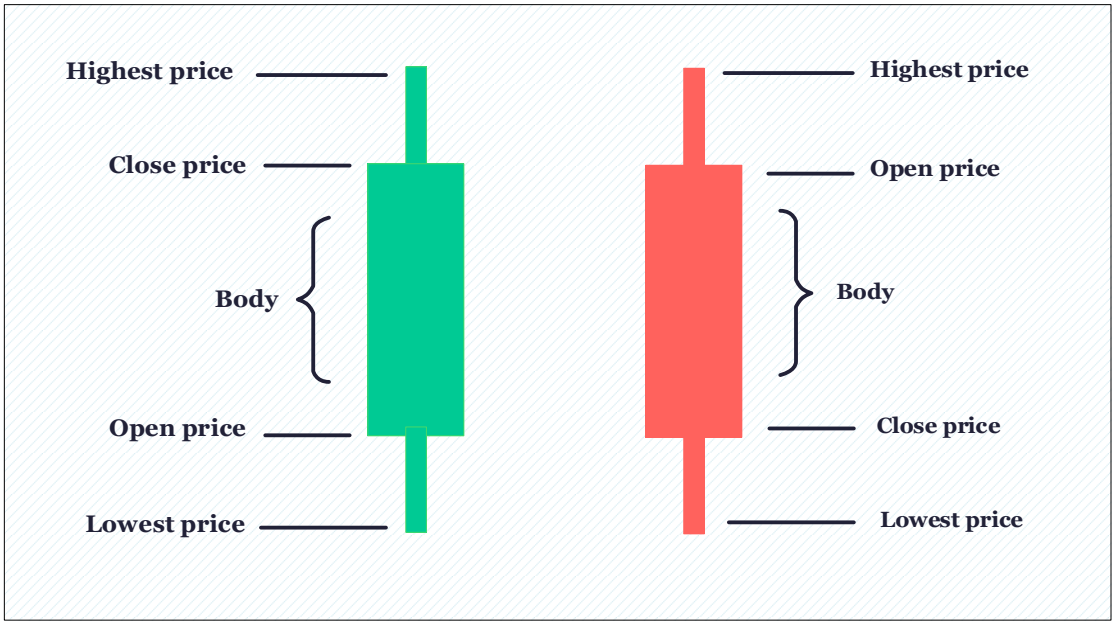

Fig. 7. Candlestick description.

TABLE I. STATISTICAL RESULTS OF THE PRESENTED DATASET

	Open	High	Low	Volume	Close
Mean	70.04	70.80	69.33	32.59	70.09
Std.	34.54	34.97	34.15	15.60	34.55
Minimum	24.65	24.72	24.31	6.93	24.55
Maximum	151.85	152.10	149.88	223.29	150.70
Skewness	0.74	0.73	0.74	2.87	0.73
kurtosis	-0.62	-0.65	-0.61	16.57	-0.63
variance	1193.42	1223.37	1165.98	243.54	1194.32

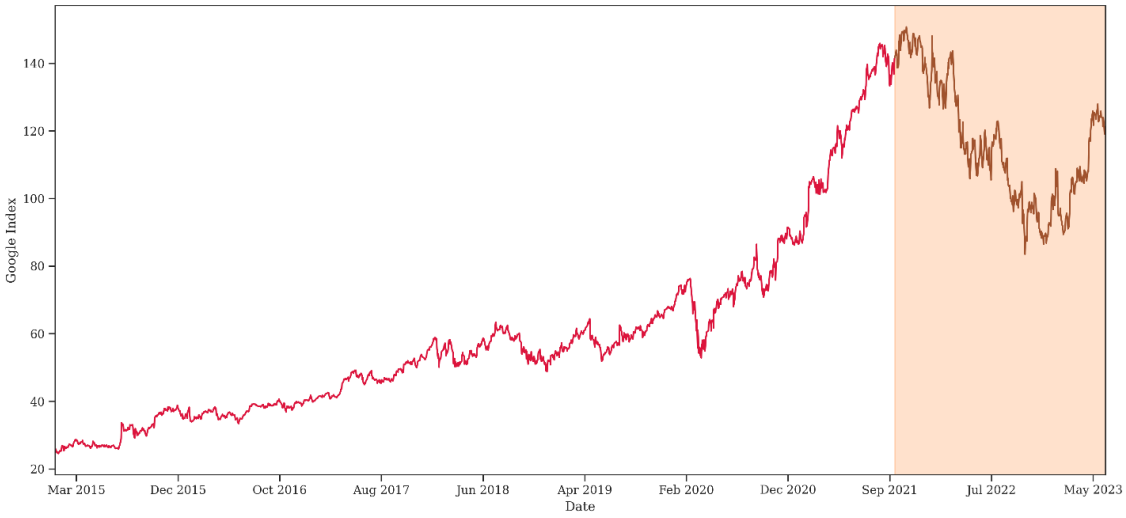

Fig. 8. Separation of the dataset into train and test.

The closing price data, which has been split into training and testing zones, is shown in Fig. 8. This approach guarantees data accuracy while assisting customers in getting accurate insights.

F. Evaluation Metrics

The following mathematical formulae were used to determine the performance metrics used in the current work: mean absolute error (MAE), mean absolute percentage error (MAPE), mean squared error (MSE), and coefficient of determination (R^2).

$$MAE = \frac{\sum_{i=1}^{n}|y_i - \hat{y}_i|}{n} \quad (16)$$

$$MAPE = \frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right| \quad (17)$$

$$\text{MSE} = \frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2 \quad (18)$$

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2} \quad (19)$$

In which, $\bar{y}$ is the mean value, y_i indicates the true value, and $\hat{y}_i$ provides the projected value. n denotes the stock series data length.

G. Detailed Description

The data is gathered from 2015 to 2023. The unprocessed data is standardized to ensure that all characteristics are on a same scale. This aids in mitigating the algorithm's inclination towards favoring a certain trait. The normalized data is partitioned into two distinct sets: an 80% training set and a 20% test set. The training set is used to instruct the machine learning model, whilst the test set is employed to assess its performance. The XGBoost method is selected as the ML model for forecasting the closing price. XGBoost is a robust ensemble approach based on trees that has shown effectiveness in a wide range of prediction applications. The hyperparameters of the XGBoost model are fine-tuned to enhance its performance. Hyperparameters are the configuration options that govern the behavior of a model, and identifying the optimal combination of hyperparameters may have a substantial influence on the accuracy of the model. The performance of the trained AO-XGBoost model is assessed using four assessment measures. The AO-XGBoost model, which has been trained, is used to forecast the future closing price of Google stock. The forecast is derived from the analysis of past data and the acquired trends.

IV. RESULT AND DISCUSSION

A. Tuning of the Hyperparameters

Table II provides a comprehensive overview of the hyperparameter configurations for XGBoost, utilizing three distinct optimization algorithms: AO, ABC, and BBO. Each

row in the table represents a distinct hyperparameter, while each column corresponds to a particular optimizer. This hyperparameter specifies the quantity of boosting rounds or trees to construct. The range for all three optimizers (AO, ABC, BBO) is 100 to 5000. Each optimizer employs a distinct value within this range: 500 for AO, 500 for ABC, and 300 for BBO. Gamma serves as a regularization parameter that governs the level of complexity exhibited by the trees. To establish a new partition on a leaf node, the smallest loss reduction is required. The gamma values range from 0 to 10. The chosen values for each optimizer are 4.967375 for AO, 7.071759 for ABC, and 5.612515 for BBO. The L1 regularization term on weights is referred to as a hyperparameter. It promotes the reduction of weight vectors. The range of values for the variable "reg alpha" is between 0 and 5. The chosen values for each optimizer are as follows: 0.457479 for AO, 0.646517 for ABC, and 0.541563 for BBO. The term "Reg lambda" refers to the L2 regularization term applied to the weights. The term is also referred to as the Ridge regularization term. The permissible values for the regularization parameter lambda range from 0 to 1. The chosen values for each optimizer are as follows: 0.799153 for AO, 0.677998 for ABC, and 0.87415 for BBO. This hyperparameter adjusts the weight or influence of each tree in the model. It is alternatively referred to as eta. The learning rate is bounded between 0.0001 and 1. The selected values for each optimizer are 0.001 for AO, 0.0001 for ABC, and 0.01 for BBO.

B. Comparative Analysis

To assess the effectiveness of the presented models, a range of common measures was employed. These measures included MSE , MAPE , R^2 , and MAE . These metrics offer a comprehensive overview of the prediction precision of the methods. A detailed summary of the performance metrics for four models, namely XGBoost, BBO-XGBoost, ABC-XGBoost, and AO-XGBoost, is presented in Table III. The development and evaluation of these models were based on historical stock price data for a Google stock market, spanning from the start of 2015 to the middle of 2023. This dataset was chosen to provide a comprehensive evaluation of the model's performance over a period of several years.

The results shown in Table III indicate that the AO-XGBoost model outperforms the other models in terms of forecasting accuracy; the model's success can be seen in the relatively low values for MSE, MAPE, and MAE, which show that the model was able to capture the complex temporal patterns and correlations found in stock price data. These outcomes imply that the AO-XGBoost model is a potentially useful tool for forecasting future market trends and helping investors make well-informed decisions, as it has the closest estimation curve to the actual index shown in Fig. 9 and Fig. 10. Through a comparative analysis of the four models represented by Table III, it is evident that the AO approach yielded the greatest results when it came to optimizing the model's hyperparameters among the optimization techniques utilized. BBO and ABC were the next top-performing techniques. The classification of the BBO-XGBoost, ABC-XGBoost, and AO-XGBoost models' findings is 0.966, 0.972, and 0.982, indicating an improvement in the model's performance.

These results have many practical implications for investors and financial institutions. Owing to its improved performance, AO-XGBoost could be a helpful tool for short-term stock price prediction, empowering traders to make more informed trading choices. The feature importance study also emphasizes how important it is to include historical data and sentiment analysis in prediction models. Given that these models rely on previous data, stock markets may be impacted by a variety of unanticipated events. Future research may look at using real-time data and external factors, including economic indicators and current events, to further increase prediction accuracy.

In conclusion, our research demonstrates the usefulness of machine learning models, specifically XGBoost, for stock market forecasting. Investors who understand the importance of certain features and model performance metrics might lower their risks in the erratic world of stock trading. Fig. 11 and Fig. 12 show the models' training and testing outcomes for each model.

TABLE II. SETTING OF THE HYPERPARAMETERS

XGBoost		AO	ABC	BBO
Numbers of estimators	[100, 5000]	500	500	300
gamma	[0,10]	4.967375	7.071759	5.612515
Reg alpha	[0, 5]	0.457479	0.646517	0.541563
Reg lambda	[0, 1]	0.799153	0.677998	0.87415
Learning rate	[0.0001, 1]	0.001	0.0001	0.01

TABLE III. THE OUTCOMES OF THE PERFORMANCE CRITERIA FOR MODELS

MODEL/Metrics	**TRAIN SET**				**TEST SET**			
	R^2	*MAPE*	*MAE*	*MSE*	R^2	*MAPE*	*MAE*	*MSE*
XGBoost	0.960	3.225	2.729	29.045	0.955	2.719	3.182	14.877
BBO-XGBoost	0.982	3.748	2.427	13.105	0.966	2.314	2.679	11.166
ABC-XGBoost	0.985	2.054	1.702	11.161	0.972	2.150	2.438	9.213
AO-XGBoost	0.990	3.007	1.803	7.250	0.982	1.721	1.994	5.946

TABLE IV. THE MODEL COMPARISON ANALYSIS TO PRIOR STUDIES

References	**Method**	R^2
[31]	CEEMDAN-LSTM	0.9031
	LSTM	0.6896
	EMD-SC-LSTM	0.9111
	EMD-LSTM	0.8703
	SC-LSTM	0.6871
	CEEMDAN-SC-LSTM	0.9206
[32]	MLS-LSTM	0.95
	SVM	0.93
	Linear regression	0.73
Present work		0.982

The results presented in Table IV indicate that the AO-XGBoost model exhibits superior performance in the field of stock price prediction when compared to other evaluated models. Our study revealed a remarkable R^2 value of 0.982, which outperformed other evaluated models including CEEMDAN-LSTM, LSTM, EMD-SC-LSTM, EMD-LSTM, SC-LSTM, CEEMDAN-SC-LSTM, SVM, Linear Regression, and MLS-LSTM. This observation suggests a higher degree of correlation between the projected and observed stock prices, implying that the model exhibits greater efficacy in capturing the fundamental patterns within the data. The AO-XGBoost model acquires the ability to dynamically modify its parameters during training by incorporating adaptive optimization techniques. This capability enables the system to adjust to the intricacies of the data and enhance its capacity to manage fluctuations and intricacies within the stock market. The utilization of the XGBoost ensemble learning algorithm is effective in capturing nonlinear relationships and interactions within the data. This algorithm combines the strengths of gradient boosting with tree-based models. The utilization of ensemble learning in XGBoost, wherein multiple weak learners are combined to form a strong learner, serves to augment the predictive accuracy and robustness of the model. Furthermore, the regularization techniques employed by XGBoost serve to mitigate the issue of overfitting and enhance the overall generalization performance. The inclusion of this feature guarantees the model's ability to generalize to unfamiliar data, which is a critical factor in predicting stock market trends where data distributions may vary over time. In addition, the scalability and efficiency of XGBoost render it well-suited for the management of extensive datasets and the execution of real-time prediction tasks. Due to its distributed computing capabilities, parallel processing is facilitated, leading to enhanced efficiency in both training and inference processes. The AO-XGBoost model is highly suitable for real-time applications that require prompt predictions. Furthermore, the accessibility of the model is improved by the clarity of XGBoost's decision-making process.

The AO-XGBoost model has demonstrated promising accuracy in predicting short-term stock prices. These forecasts can assist investors in maximizing profits and mitigating risks in the stock market. It may be advantageous to incorporate high-performing XGBoost models such as BBO-XGBoost or ABC-XGBoost into algorithmic trading systems. These systems can autonomously execute buy or sell orders on the predictions made by the model, thereby enabling traders to take advantage of short-term market fluctuations. It may be worthwhile to investigate risk management solutions for financial institutions that utilize XGBoost models to forecast market trends. Accurate forecasts of stock prices and market volatility have the potential to assist institutions in evaluating and mitigating risks associated with their investment portfolios. It is advisable to develop investor portfolio management tools that utilize XGBoost models to enhance asset allocation and diversification. XGBoost stock price forecasts can be utilized by investors to construct portfolios that optimize returns and mitigate market risk. An alternative approach entails the utilization of XGBoost models in financial advisory services to generate tailored investment recommendations. Financial advisors can customize guidance based on individual client's investment objectives and risk tolerance through the examination of past stock market data and the utilization of sophisticated machine learning techniques. It may be intriguing to develop trading signal platforms that offer real-time buy or sell signals using XGBoost models. Traders can subscribe to these platforms to receive timely notifications and alerts, enabling them to make well-informed trading decisions in rapidly changing markets. Enhancing the accuracy, robustness, and scalability of XGBoost stock market forecasting models through research and development could yield advantageous outcomes. Enhancing machine learning methods enables researchers to enhance predictive models for intricate market dynamics and patterns. These illustrations indicate that XGBoost models have the potential to be employed in various domains such as stock market prediction, investment tactics, algorithmic trading, risk mitigation, and financial advisory consulting. The predictive capabilities of XGBoost models can assist stakeholders in making more informed decisions and effectively navigating the stock market.

V. CONCLUSION

The trading system may provide profitable buy, sell, and hold recommendations. Traders and investors may benefit from the forecasts. The successful model from this study is intended to be applied to the dynamic trading system. Either an automated stock market system or a dynamic trading system may include this method. Thus, it is possible to forecast stock prices in the future with little inaccuracy. In this study, a novel

model XGBoost network optimized using the AO is proposed. The AO-XGBoost is the suggested model. The suggested model seeks to forecast stock market values. Stock market prices are predicted using data from Google stock prices. The dataset covers the months of 2015 to mid-2023. The data is separated into 80% train data and 20% test data after normalization. With parameters, a new XGBoost network is constructed. The AO algorithm variables are linked to the parameters. The design of the XGBoost adapts to changes in the variables. To get the best outcomes, AO selects the optimal design. The newly suggested model is compared to the XGBoost, ABC-XGBoost, and BBO-XGBoost networks in order to assess its quality. The results unequivocally demonstrate that, out of all the models, the AO-XGBoost model is the best. It also provides very accurate forecasts.

Although the proposed AO-XGBoost model has demonstrated impressive performance in predicting stock prices, it is important to take into account several limitations. The utilization of historical data derived from Google stock prices within a designated time period may not comprehensively capture the complexities and fluctuations inherent in the wider stock market. Furthermore, although optimization techniques such as BBO, ABC, and AO strive to improve the model's ability to adjust, there is a possibility of overfitting the training data, which could undermine its ability to apply the model to new market conditions. Furthermore, the model's susceptibility to parameter selection and the computational burden involved in determining optimal values present practical obstacles. Moreover, the model's forecasting accuracy is limited by the inherent unpredictability of market dynamics, which is influenced by various factors including geopolitical events and investor sentiments. The implementation and interpretation of the AO-XGBOOST model in real-world trading environments may be impeded by its complexity, thereby restricting its applicability for practitioners with diverse levels of technical proficiency. Therefore, it is imperative to recognize and tackle the limitations of the AO-XGBoost model in order to ensure its successful implementation in dynamic financial markets, despite the promising insights it provides.

Prediction of Financial Markets Utilizing an Innovatively Optimized Hybrid Model: A Case Study of the Hang Seng Index

Xiaopeng YANG
School of Economics and Management, Weifang University, Weifang 261061, Shandong, China

***Abstract*—Stock trading is a highly consequential and frequently discussed subject in the realm of financial markets. Due to the volatile and unpredictable nature of stock prices, investors are perpetually seeking methods to forecast future trends in order to minimize losses and maximize profits. Nevertheless, despite the ongoing investigation of various approaches to optimize the predictive efficacy of models, it is indisputable that a method for accurately forecasting forthcoming market trends does not yet exist. A multitude of algorithms are currently being employed to forecast stock prices due to significant developments that have occurred in recent years. An innovative algorithm for predicting stock prices are examined in this paper which is a Gated Recurrent Unit combined with the Aquila optimizer. A comprehensive data implementation utilizing the Hang Seng Index stock price was executed as a dataset of this research which was collected between the years of 2015 and the end of June 2023. In the study, several additional methods for predicting stock market movements are also detailed. A comprehensive comparative analysis of the stock price prediction performances of the aforementioned algorithms has also been carried out to offer a more in-depth analysis and then the results are displayed in an understandable tabular and graphical manner. The proposed model obtained the values of 0.9934, 0.71, 143.62, and 36530.58, for R^2, MAPE, MAE, and MSE, respectively. These results proved the efficiency and accuracy of the suggested method and it was determined that the proposed model algorithm produces results with a high degree of accuracy and performs the best when it comes to forecasting a time series or stock price.**

I. INTRODUCTION

The stock market, as defined, is a marketplace wherein individuals engage in the buying and selling of stocks associated with certain companies. Over time, the values of these stocks exhibit significant fluctuations. Nevertheless, it would be unwise to disregard the factors contributing to the significant fluctuations in the stock market, which may include political influences, brand perception, and the prevailing global conditions. The aforementioned elements have the ability to significantly influence the perspectives and convictions of prospective investors, hence contributing to fluctuating patterns in the stock market. Hence, while it is crucial to comprehend the potential variables contributing to these fluctuations, it remains insufficient to devise a methodology that can reliably forecast trends in light of perpetual worldwide transformations and uncertainties [1]. Given the inherent unpredictability and significant market volatility, a considerable number of individuals interested in the stock market want to acquire a tool or method that can dependably forecast market trends, so enabling them to achieve more profitability [1]. Nonetheless, persistent endeavors are being undertaken to construct a model or algorithm that can assist investors in forecasting changes with more precision than previously achieved. The utilization of machine learning (ML) algorithms is a prevalent and well-accepted approach for constructing predictive models [2]. ML is a computational paradigm in which computers acquire information and make predictions based on previous experiences and training, without relying on external programming [2]. A few approaches and algorithms linked to ML have been investigated and addressed in [3-5]. Many advancements in data science and ML have occurred in the last few years, which have led to the creation of certain specific algorithms that are highly effective for predictive analytics across all sectors. Among the models examined in this article is GRU, a subfield of machine learning.

Recurrent neural networks (RNNs), such as Gated Recurrent Units (GRUs) [5], are used to handle sequential data, including time series. It was presented as an abridged form of the long short-term memory (LSTM) architecture. GRU is intended to address the vanishing gradient issue in RNNs and allow the network to store data over extended sequences, much like LSTM. The GRU model has one fewer gate structure than the LSTM; it consists of an update gate and a reset gate. It has been demonstrated that GRU performs comparably to LSTM while processing time series data, therefore this difference in operation impact is not very important. Compared to LSTM, GRU can converge more quickly because of its streamlined structure, which also speeds up training. Applications for the GRU model include speech recognition, video analysis, and natural language processing [5]. GRU was utilized by Ya Gao et al. [6] to predict stocks. GRU Neural Network Based on CEEMDAN-Wavelet was utilized by Chenyang Qi et al. [7] to predict stock prices.

The accuracy of predicting the value of the stock market rose as optimizers were developed and combined with a range of models to provide better outcomes in the predictions. Among the optimizers that were demonstrated were the whale optimization algorithm (WOA) [8], biogeography-based optimization (BBO) [9], genetic algorithm (GA) [10], moth–flame optimization (MFO) [11], ant lion optimization (ALO) [12], grey wolf optimization (GWO) [13], and Aquila

optimizer (AO) [14]. The most recent method to replicate the four distinct stages of Aquila hunting behavior is the AO, which was put out by Abualigah et al. [14]. Aquila employs four main hunting techniques: strolling and capturing prey, contour flying with a brief glide, low flying with a slow drop, and high soar with a vertical stoop [15]. These four core Aquila hunt processes served as the inspiration for the creation of the AO, a nature-inspired optimization algorithm that fundamentally clarifies the actions of each hunt stage. Initialization, Expanded Exploration, Narrowed Exploration, Expanded Exploitation, and Narrowed Exploitation are the five main processes that the traditional AO concentrates on. One of the most important aspects of the algorithm, the current iteration maximum iteration, usually guides the AO algorithm from the exploration to the exploitation stage. The exploration phase will be activated if the condition mentioned is true; otherwise, the exploitation step will be carried out [15].

From the commencement of 2015 until the conclusion of June 2023, daily transaction data from the Hang Seng Index (HSI) was collected, encompassing the following metrics: opening price, closing price, highest price, lowest price, and trading volume. To assess the reliability of each model, the research looked at a variety of models, including GRU, ALO-GRU, GWO-GRU, and AO-GRU. For this post, the AO-GRU model was selected since it has the best performance. The rest of the paper is structured as follows. The literature review is given in the Section II. Numerous analytical methods, including optimizer approaches, and the GRU model along with the dataset were provided in Section III. The study's findings are provided in Section IV and their discussions are demonstrated in Section V. Section VI provides a quick summary of the research's findings.

II. Literature Review

In recent years, there has been a significant increase in the utilization of machine learning algorithms for the purpose of forecasting the stock market. A comparative study of fundamental analysis, technical analysis, and machine learning (ML) approaches was what Christanto et al. [16] proposed as an investigation into methodologies utilized in the capital market to forecast stock prices. For predicting stock prices, they employed Support Vector Regression (SVR) and Support Vector Machine (SVM) as ML techniques. Technical-only (TEC), financial statement-only (FIN), and a combination of the two (COM) parameter groups are assessed. Financial statement integration had a neutral effect on SVR predictions but a positive effected on SVM predictions, according to their experiments. The model achieved an accuracy rate of 83% in the conducted study. Chen et al. [17] examined the historical backdrop of economic recessions, highlighting the sudden and catastrophic consequences of occurrences such as the 2008 financial crisis, characterized by a substantial decrease in the SP 500. Driven by the prospective advantages of timely crisis detection, they implemented sophisticated machine learning methodologies, including Random Forest and Extreme Gradient Boosting, to forecast possible market downturns in the United States. Comparing the performance of these approaches, their research seeks to ascertain which model is more accurate at predicting US stock market crashes. Market indicators for crisis prediction were analyzed by employing daily financial market data and 75 explanatory variables, which encompass general US stock market indexes as well as sector indexes. By employing particular classification metrics, they derived conclusions concerning the efficacy of their predictive models. Tsai et al. [18] discussed investors' interest in stock prediction, especially with the recent use of machine learning to improve accuracy. Machine learning works in technical, fundamental, and sentiment analysis, according to prior research. They discussed fiscal year-end selection and how misaligned reporting periods affect comparability and investment decisions. They emphasized synchronized fiscal years and use machine learning models for fundamental analysis to forecast Taiwan (TW) stock market returns. They created stock portfolios with higher predicted returns using Random Forest (RF), Feedforward Neural Network (FNN), Gated Recurrent Unit (GRU), and Financial Graph Attention Network (FinGAT) models. These portfolios outperformed TW50 index benchmarks in returns and portfolio scores, according to their study. Machine learning models were beneficial for stock market analysis and investment decision-making, according to Tsai et al [18]. Ardakani et al. [19] proposed a federated learning framework for stock market prediction using Random Forest, Support Vector Machine, and Linear Regression models. They compared federated learning to centralized and decentralized frameworks to find the best approach. Federated learning outperformed centralized and decentralized frameworks in Mean Square Error (MSE) using Random Forest (0.021) and Support Vector Machine (37.596). Linear regression model-based centralized learning (MSE = 0.011) outperformed federated and decentralized frameworks. Federated learning had a lower model training delay than benchmarks for Linear Regression (9.7 s) and Random Forest (515 s), while decentralized learning saves time for Support Vector Machine (3847 s). Their findings illuminated stock market prediction learning framework strategies [19]. A novel stock price prediction method by Mamluatul et al. [20] uses machine learning, stock price data, technical indicators, and Google trends. SVR, MLP, and Multiple Linear Regression were used to predict stock prices. SVR predicts Indonesian stock prices better than MLP and Multiple Linear Regression with a MAPE of 0.50%. They found that SVR predicts stock prices accurately, helping investors make informed stock market decisions [20]. The importance of stock market forecasts in financial market profits was stressed by Juare et al. [21] Their research used Random Forest, Support Vector Machine, KNN, and Logistic Regression to predict stock market trends. These algorithms are evaluated using accuracy, recall, precision, and F-Score. The main goal was to find the best stock market prediction algorithm. Effective forecasts can benefit stock exchanges and investors, highlighting the importance of predictive models in financial decision-making [21]. Swathi et al. [22] emphasized the need for investors to use stock price prediction (SPP) models in the global financial market for profit. Earlier SPP models used statistical and machine learning (ML) methods. In their study, the authors introduced SCODL-SPP, a stock price prediction method using Sine Cosine Optimization (SCO) and deep learning. The SCODL-SPP model forecasts share closing prices using deep learning and a stacked long short-term memory (SLSTM) model. The SLSTM model hyperparameters are optimized

using the SCO algorithm after the min-max normalization of primary data. The SCODL-SPP model outperformed other models in stock price prediction accuracy, according to experiments [22]. Su et al. [23] proposed a stack framework using LGBM to predict the Taiwan stock market index. Their study created a comprehensive feature set to account for political events, economic conditions, investor psychology, and global market trends that affect stock market predictions. They introduced a feature selection algorithm to identify important features and improve training performance. A stacking strategy integrates multiple classifiers to improve prediction accuracy. The proposed model is tested using a 10-year Taiwan Stock Exchange Capitalization Weighted Stock Index dataset. Both the prediction model and feature selection method performed well in experiments, indicating that the proposed approach is effective in stock market index prediction [23]. Ryan Chipwanya's study examined how stock market prediction tools and data have improved, making market predictions possible [24]. Logistic regression, decision trees, and random forest algorithms were compared for predicting Japanese stock market asset movements using machine learning models for time-series forecasting. The models were also compared to feedforward deep neural networks. Overall, all models achieved directional bias forecasting accuracy above 50% [24]. Pardeshi et al. [25] emphasized the importance of stock market prediction for profitable investing. To address complex financial market dynamics, they emphasized deep learning. Geopolitical events and historical price trends affect stock market volatility. They introduced Long Short-Term Memory with a Sequential Self-Attention Mechanism (LSTM-SSAM) to predict stock prices with low error. Their proposed model was tested using SBIN, HDFCBANK, and BANKBARODA stock datasets. Their study showed that LSTM-SSAM improves stock price prediction accuracy through extensive experimentation [25].

The literature review on stock market prediction effectively addresses several identified gaps. The inclusion of the Hang Seng Index as a focal point allows for the provision of market-specific insights pertaining to Hong Kong, thereby expanding the geographical scope of research within this field. Moreover, through the transparent elucidation of data preprocessing procedures, the assurance of data quality and reproducibility is achieved, thereby addressing the existing gap in the literature regarding the evaluation of data quality and preprocessing methodologies. Furthermore, the enhancement of predictive accuracy through domain knowledge is exemplified by the integration of domain-specific insights into the AO-GRU model, thereby addressing the limitation of limited domain knowledge integration. Moreover, the comparison between the AO-GRU model and ensemble techniques offers valuable insights into the efficacy of ensemble methods, thus filling the void in the limited investigation of these methods. Finally, a more thorough evaluation of model performance can be achieved by integrating supplementary evaluation metrics or examining the constraints of current ones, thereby addressing the deficiency in insufficient evaluation metrics. These contributions have made significant advancements in the field of stock market prediction, resulting in improved robustness, accuracy, and applicability of predictive models in financial markets.

III. Methods and Materials

A. Data Gathering and Preparation

The Hang Seng Index is a prominent stock market index in Hong Kong that tracks the performance of several notable companies listed on the Hong Kong Stock Exchange. The Hong Seng Index is composed of a diverse group of companies that lead their respective industries in many sectors of the Hong Kong economy. These sectors include, among others, the manufacturing, banking, real estate, and telecommunications sectors. Like other notable stock indices, the Hang Seng Index is weighted by market capitalization. Each company's weight in the index is based on its share market value; larger companies have a greater impact on the index's movements. Many factors, including trading volume and the Open, High, Low, and Close (OHLC) prices during a specific time period, should be included in a comprehensive study. The Hong Kong Stock Exchange provided hundreds of stocks from various industries that were used as the source of stock data for this study. Raw transaction data, comprising the opening price, closing price, highest price, lowest price, and trading volume, was gathered for every day from the start of 2015 to the end of June 2023. The gathered data was divided into two groups in order to maximize the performance of the models. As shown in Fig. 1, a partitioning approach was used in this experiment. In particular, twenty percent of the data was reserved for testing, while the remaining eighty percent was used for training. This division's main objective was to determine the most workable solution that balanced the need for a sizable amount of data for model training with the demands of a large, untested dataset for thorough testing and validation.

B. Gated Recurrent Unit

The GRU network was first introduced by Cho et al. [26]. The basic RNN concept [27] is to determine outputs by taking into account inputs and the hidden state, which is determined by squaring up past outputs or hidden states. With an update gate and a reset gate, the GRU offers sophisticated control over the data in a concealed state. In general, it can determine which data adding from the existing inputs is necessary (because it may be crucial to the future) and which data from the past may be eliminated from the hidden state (because it is unrelated to the present state). Compared to long short-term memory [28], which features a unit made up of three gates and a cell structure, the GRU has fewer parameters. A single GRU's construction is seen in Fig. 2, h, in which z is the update gate and r is the reset gate. Several of these units, designated h_j (along with associated r_j and z_j) in a GRU network, are updated using the following equations:

$$r_j = \sigma\left([V_r x]_j + \left[U_r h_{\langle t-1\rangle}\right]_j\right) \quad (1)$$

$$z_j = \sigma\left([V_z x]_j + \left[U_z h_{\langle t-1\rangle}\right]_j\right) \quad (2)$$

$$h_j^{\langle t\rangle} = z_j h_j^{\langle t-1\rangle} + \left(1 - z_j\right)\tilde{h}_j^{\langle t\rangle} \quad (3)$$

$$\tilde{h}_j^{\langle t\rangle} = \phi\left([Vx]_j + \left[U\left(r \odot h_{\langle t-1\rangle}\right)\right]_j\right) \quad (4)$$

Let $\mathrm{x}^{(t)}$ be the vector that is input at a time t. The bias parameter is a part of V, which stands for parameter matrices.

To take the j-th element of a vector, use the boldface notation h and r, which represent the vectors with all of the values h_j and r_j. When first introduced, σ represents a hyperbolic tangent function and σ is a logistic function. In the beginning, for every j, $h_j^{(0)} = 0$.

C. Ant Lion Optimizer

The predatory behavior of ant lions in the wild, which primarily consists of ants, ant lions, and elite ant lions, served as the primary inspiration for the creation of ALO in 2015 [12]. The structure of the ALO algorithm is as follows: Using the roulette and random walk techniques, the ant colony and ant placements are first established at random. After an ant has completed its journey, their fitness is assessed using a fitness function. If the ant's location outperforms that of the ant lions around it, then it is deemed the best option available at this time. Furthermore, the position of the ant lion becomes the best option if it manages to capture an ant. In every cycle, the elite antlion stands in for the best possible outcome within the ant lion population. In contrast, the elite antlion is updated if the optimal antlion outperforms it; if not, it stays the same until the end of the iteration, at which point it overcomes the elite antlion [12].

The random walk, which is used to show how ants travel, is stated as follows by Eq. (5):

$$X(t) = [0, \mathrm{cs}(2r(t_1) - 1)], \ldots, \mathrm{cs}(2r(t_n) - 1) \quad (5)$$

where, $r(t_n)$ is the random walk function of the n-th iteration and cs is the cumulative sum.

Moreover, Eq. (6) illustrates how Eq. (5) is further standardized.

$$X_i^{(t)} = \frac{\left(X_i^{(t)} - a_i\right) \times \left(d_i - c_i^{(t)}\right)}{\left(d_i^{(t)} - a_i\right)} \quad (6)$$

The i-th individual's min and max values are denoted by a_i and d_i, respectively, while the t-th iteration of the i-th variable maximum value is represented by $c_i^{(t)}$ and $d_i^{(t)}$, respectively.

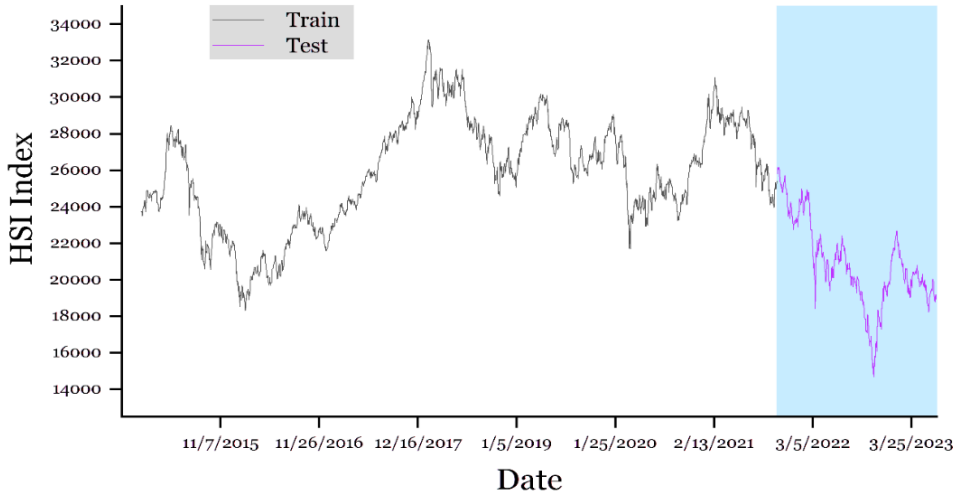

Fig. 1. Creating a separate train and test set of data.

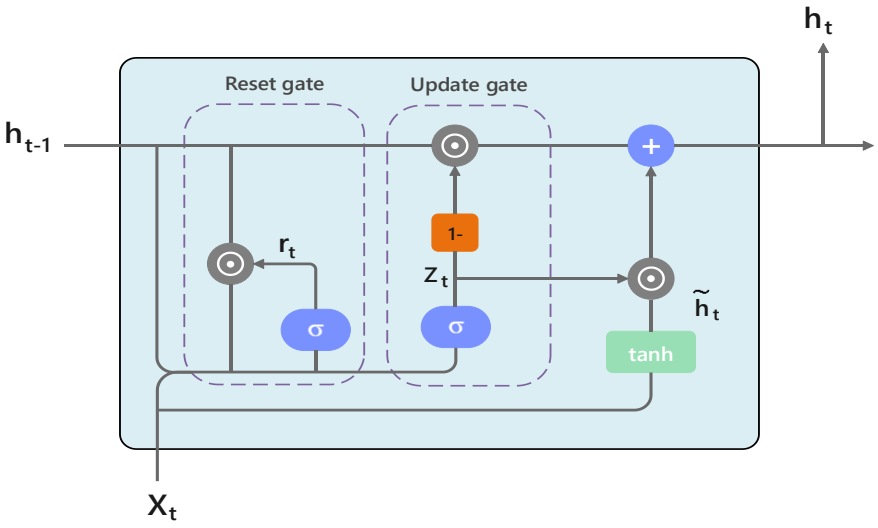

Fig. 2. The GRU model's structure.

Antlion traps have an impact on the random movement of ants, as demonstrated by Eq. (7) and Eq. (8):

$$c_i^{(t)} = \text{Antlion}_j^{(t)} + c^{(t)} \quad (7)$$

$$d_i^{(t)} = \text{Antlion}_j^{(t)} + d^{(t)} \quad (8)$$

In the t-th iteration, the individual's minimum and maximum values are denoted by $c^{(t)}$ and $d^{(t)}$, respectively, whereas $Antlion_j^{(t)}$ signifies the location of the j-th ant-lion.

Ants move randomly or in a roulette pattern around the antlion, as seen by Eq. (9):

$$Ant_i^{(t)} = \frac{R_A^{(t)} + R_E^{(t)}}{2} \quad (9)$$

The positions of the i-th ant at the t-th iteration are indicated by $Ant_i^{(t)}$, and $R_A^{(t)}$ and $R_E^{(t)}$ are the random walks around the elite or the roulette wheel on the second day of the, respectively.

As the number of iterations increases, antlion will get closer to the approximate optimal solution by reducing the boundaries in the manner described by Eq. (10) and Eq. (11):

$$c^i = \frac{c^{(t)}}{I} \quad (10)$$

$$d^i = \frac{d^{(t)}}{I} \quad (11)$$

where the lowest and maximum values of all variables at the t-th iteration are denoted by I, and $c^{(t)}$ and $d^{(t)}$ accordingly. Eq. (12) displays the location update formula, which the ant lion will use to feed on the ants after the iteration.

$$\text{Antlion}_j^{(t)} = Ant_i^{(t)}, \text{ if } f\left(\text{Ant}_i^{(t)}\right) > f\left(Ant_j^{(t)}\right) \quad (12)$$

Where the locations of the i-th and j-th ant-lions of the t-th iteration are represented by $\text{Antlion}_j^{(t)}$ and $Ant_i^{(t)}$.

D. Grey Wolf Optimization

A novel swarm intelligence algorithm called the GWO makes use of the capabilities that Mirjalili et al. [29] discovered. Accurate stability is achieved between exploration and development, and it is expandable and adaptable. Following the wolf cooperation mechanism, the GWO imitates the actions of a population of grey wolves that are predators. Following natural law and rigid social structures, every wolf in the population has a certain role to fulfill [29]. Wolf populations in a GWO are arranged based on fitness levels.

The wolf with the lowest health, ω, is regarded as the lowest-ranking person. A wolf within the wolf pack can be considered a feasible response, and the wolves corresponding to the finest solution, superior answer, and suboptimal answer of the present day may be designated as the α, β, and γ Wolf, respectively. The following sums up the grey wolf population's predatory behavior during the search:

$$D = \left|C \times X_p(t) - X(t)\right| \quad (13)$$

$$X(t+1) = X_p(t) - A \times D \quad (14)$$

The distance D between the wolf and the target is given in Eq. (13). The coordinate transformation of a wolf is represented by Eq. (14), where $X_P(t)$ represents the target's location in the t-generation, X(t) represents the position of a lone wolf inside the t-generation wolf pack, A and C are coefficients, and the calculation formula is as follows:

$$a = 2 - 2 * \frac{\text{iter}}{\text{Max}_{\text{iter}}} \quad (15)$$

$$A = 2a * r_1 \quad (16)$$

$$C = 2r_1 \quad (17)$$

where, $r_1, r_2 \in [0,1]$, iter is the population of iterations, and Max $iter$ is the maximum number of iterations. The three different sorts of wolves choose which gray wolf will replace which when the wolf assaults its prey, or when it catches quarry. The paradigm for this decision is as follows:

$$D_i^j(t) = \left|C \times X_i^j(t) - X^j(t)\right| \quad (18)$$

$$X_i^j(t+1) = X_i^j(t) - A \times D_i^j(t) \quad (19)$$

$$X(t+1) = \frac{1}{3} \times \sum X_m(t+1) \quad (20)$$

The difference between the t-generation and i($i = \alpha, \beta, \gamma$) wolves are denoted by $D_i^j(t)$. In accordance with α, β, and γ stride length and the wolf's motion direction, in that order, Eq. (18)-(20) determine the ω wolf. The new period of grey wolves formed following a location update is represented by Eq. (20).

E. Aquila Optimizer

The AO is a recently introduced algorithm that aligns with the inherent hunting behavior of the Aquila species [14]. The hunting process has four distinct stages: an initial phase of extensive exploration achieved via soaring at high altitudes followed by a rapid vertical drop, a subsequent phase of focused exploration accomplished through gliding with precise contour flight, a subsequent phase of extensive exploitation achieved through a low-flying descending attack, and a final phase of focused exploitation accomplished through walking and capturing prey as seen in Fig. 3. The AO algorithm employs a range of characteristics to facilitate the transition from the exploration stage to the exploitation stage [14]. The initial two-thirds of iterations are dedicated to simulating the exploration stage, while the remaining one-third of iterations is allocated for imitating the exploitation stage [14] as the summary of AO optimizer performance is shown in Fig. 4.

The eagle starts the initial form of vertical descent when it identifies a potential area for prey and promptly determines the optimal hunting spot on the planet by ascending to significantly high elevations and identifying the region of investigation where the most efficient approach is determined using the subsequent formula:

$$\begin{cases} Z_1(t+1) = Z_{\text{best}}(t) \times \left(1 - \frac{t}{T}\right) + \left(Z_M(t) - Z_{\text{best}}(t) \times \text{ rand }\right) \\ Z_M(t) = \frac{1}{N}\sum_{i=1}^{N} Z_i(t), \forall j = 1,2, \ldots \ldots, \text{Dim} \end{cases} \quad (21)$$

The generation $t+1$ solution is represented by $Z(t+1)$, which is the result of the search strategy $Z_1 \cdot Z_{\text{best}}(t)$, where (t) is the ideal approach that indicates the position of the closest target prey. This loop has t iterations remaining. T is the highest possible number of iterations. The location means of the current solution at the t-th iteration is denoted by $Z(t)$. A random number between 0 and 1 is referred to as a Rand. The subsequent swift-gliding assault: The eagle soars to a height to discover the prey region in order to reduce the hunting area or search space in line with the following equation for the best reaction:

$$\begin{cases} Z_2(t+1) = Z_{\text{best}}(t) \times Z(D) + Z_R(t) + (y - z) \times \text{ ra} \\ L(D) = s \times \dfrac{\mu \times \sigma}{|\nu|^{\frac{1}{\beta}}} \end{cases} \quad (22)$$

The Aquila enters the low-flying, slow-falling assault mode at the chosen target point when the prey zone has been carefully located and it is ready to land and attack. This is the third pattern of low-altitude flying; by using this tactic, the bird could see how its prey would respond and gradually approach it, as in the formula below: with D representing the dimensional space, $Z_R(t)$ representing the random solution between $[1, N]$, and $L(D)$ representing the hunting flight distribution function.

$$Z_3(t+1) = \left(Z_{\text{best}}(t) - Z_M(T)\right) \times \alpha - \text{ rand } + \left((U_b - L_b) \times \text{ rand } + L_b\right) \times \delta \quad (23)$$

α and δ are the two moderating elements in this case. U_b is upper bound on the issue. L_b is the lower bound of the issue. Walking capture is the fourth method when the eagle uses the following equation to rapidly converge and attack the target from above.

$$\begin{cases} Z_4(t+1) = Q_F \times Z_{\text{best}}(t) - \left(G_1 \times Z(t) \times \text{ rand }\right) - G_2 \times L(D) + \text{ rand } \times G_1 \\ Q_F(t) = \dfrac{2 \times \text{ rand } - 1}{t^{(1-T)2}} \\ G_1 = 2 \times \text{ rand } - 1 \\ G_2 = 2 \times \left(1 - \dfrac{t}{T}\right) \end{cases} \quad (24)$$

The quality function, or Q_F, and the search technique is balanced. The Aquila's motions as it searches for its food are seen on G_1. The hunting flying slope of Aquila is represented by G_2 . $Z(t)$ is the solution for this iteration.

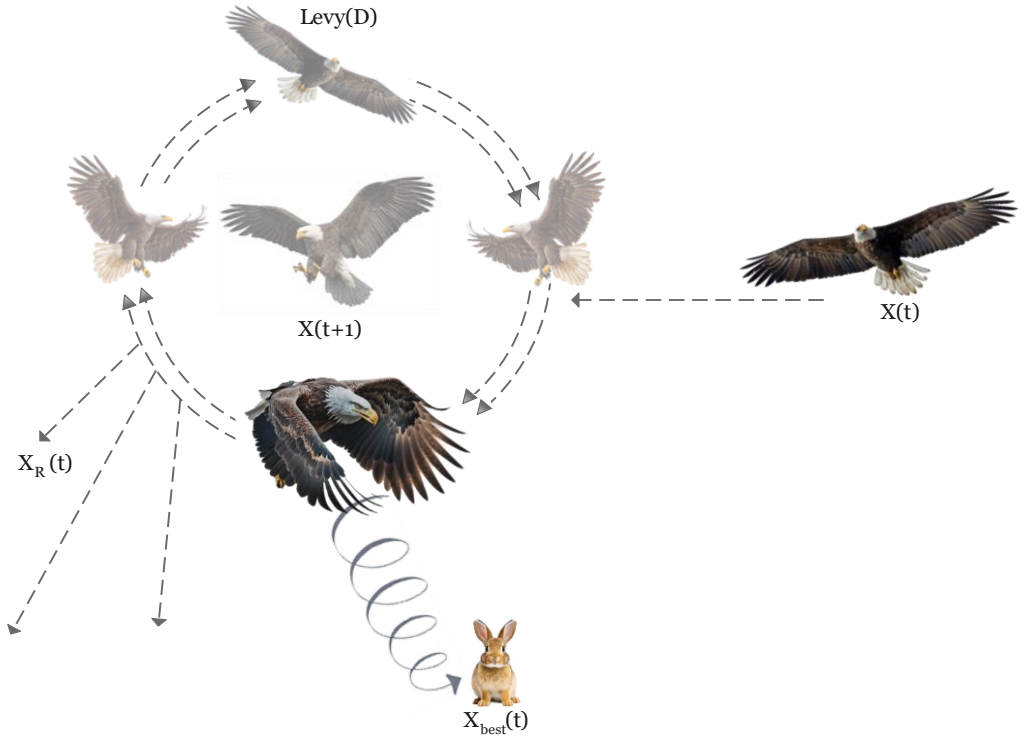

Fig. 3. An illustration of the Aquila hunting.

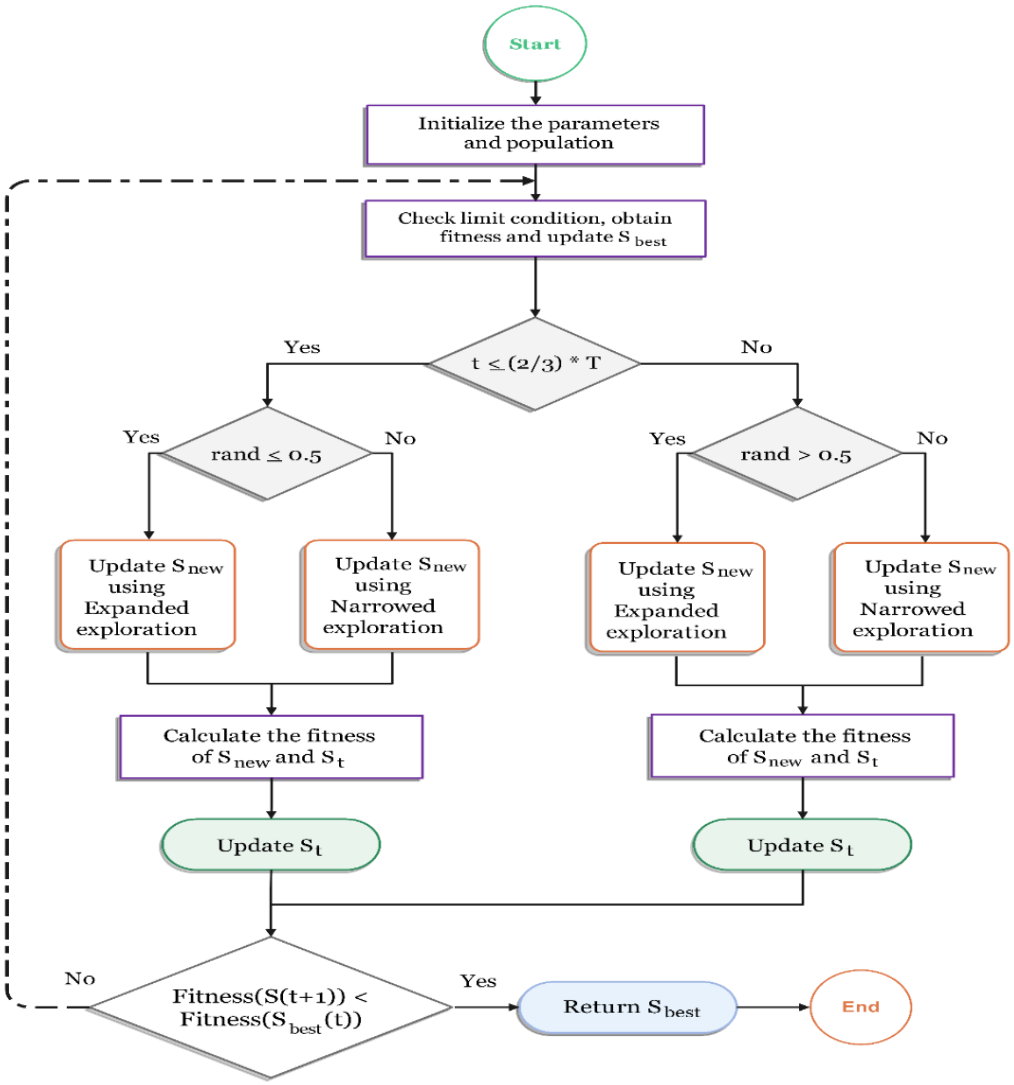

Fig. 4. The selective AO optimizer's graphical flowchart.

IV. RESULTS

A. Evaluation Metrics

The evaluation of the accuracy of the future forecast was conducted by employing a variety of performance measures. The carefully chosen metrics provide a thorough evaluation of the reliability and precision of the predictions. The assessment criteria employed in this article encompass:

- Coefficient of determination (R^2):

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2} \quad (25)$$

- Mean absolute error (MAE):

$$MAE = \frac{\sum_{i=1}^{n}|y_i - \hat{y}_i|}{n} \quad (26)$$

- Mean squared error (MSE):

$$\text{MSE} = \frac{1}{N}\sum_{i=1}^{N}(\hat{y}_i - y_i)^2, \quad (27)$$

- Mean absolute percentage error (MAPE):

$$MAPE = \left(\frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right|\right) \times 100 \quad (28)$$

B. Statistic Values

The dataset encompassed a significant temporal range, commencing on January 1, 2015, and concluding at the termination of June 2023. This section presents tabular representations of the project's outcomes subsequent to its effective implementation. The inclusion of OHLC price and volume statistics in Table I enhances the comprehensibility of the information. The utilization of statistical metrics such as count, mean, minimum (min), maximum (max), standard deviation (Std.), 25%, 50%, 75%, and variance enables a thorough and precise examination of the data.

TABLE I. A COLLECTION OF STATISTICAL VALUE SUMMARIES

	Open	High	Low	Volume	Close
count	2090	2090	2090	2090	2090
mean	24877.8	25026.72	24689.52	4013.656	24862.03
Std.	3492.279	3486.289	3484.234	1462.996	3486.437
min	14830.69	15113.15	14597.31	0	14687.02
25%	22194.44	22350.36	21998.24	3068.985	22151.32
50%	25002.49	25118.69	24755.93	3679.685	24973
75%	27716.1	27860.96	27525.43	4594.719	27693.23
max	33335.48	33484.08	32897.04	12025.52	33154.12
variance	12196013	12154214	12139887	2140358	12155245

C. Compare and Analysis

The successful completion of the project has yielded the results, which are displayed in this section as Table II and Fig. 5, 6. For this study, four algorithms were used to predict HSI stock values: GRU, ALO-GRU, GWO-GRU, and AO-GRU. The dataset was massive, spanning from the beginning of 2015 to the end of June 2023. The models were evaluated using four important performance indicators: R^2, MAPE, MAE, and MSE.

TABLE II. A PREDICTION OF THE EVALUATION OUTCOMES OF THE MODELS

MODEL/Metrics	TRAIN SET				TEST SET			
	R^2	*MAPE*	*MAE*	*MSE*	R^2	*MAPE*	*MAE*	*MSE*
GRU	0.9894	1.09	280.91	92243.40	0.9875	1.01	202.16	69134.21
ALO-GRU	0.9923	0.83	213.74	67466.58	0.9906	0.97	198.26	51900.77
GWO-GRU	0.9941	0.77	197.79	51335.10	0.9921	0.78	161.26	43986.23
AO-GRU	0.9952	0.60	154.69	41515.24	0.9934	0.71	143.62	36530.58

V. DISCUSSIONS

The tabulated results for the GRU obtained during the testing of a specific model on the dataset of that firm are shown in Table II. The AO-GRU method has produced the greatest predictive performance out of all four models, with an MSE of 36530.58, the lowest of all four. This is because the optimum MSE value is near zero. The results of the R^2 calculations for several models evaluated on a certain dataset are listed in Table II. The model fit is better when the value of R^2 is nearer 1. The obtained results demonstrate that the AO-GRU has yielded the most encouraging outcomes among the four computational models that were examined. Because its R^2 score of 0.9934 is the closest to 1, which suggests that the accuracy rate of the model is high. This table offers a thorough summary of the MAPE that a given model obtained during testing on the dataset. A lower number in the MAPE indicates greater performance. With a MAPE of 0.71, Table II analysis reveals that AO-GRU performed the best out of the three algorithmic models examined. Because it produces the most accurate predictions, it can be concluded that the AO-GRU algorithm is the best computational model to apply when working with comparable datasets. Regarding the MAE report, it should be noted that the more accurate the prediction, the closer the reported value is to zero. This is supported by the reported table, which indicates that the reported number for the AO-GRU model's test phase is 143.62, indicating that the model in question is more accurate at forecasting and is the one used in this article. The findings may be used in business and other domains where data analysis is essential for making well-informed choices and forecasts.

The GRU model's combination with the Aquila optimizer as seen in Fig. 7 and Fig. 8, it is clear from the analysis of the HSI index curves and their comparative assessment that the AO-GRU model performs better and is more effective than the other models investigated in this study.

TABLE III. A COMPARATIVE ANALYSIS OF THE MODEL IS PROVIDED IN RELATION TO PREVIOUS STUDIES

Authors	Method	R^2
Zhu et al. [30]	LSTM	0.6896
	EMD-LSTM	0.8703
	CEEMDAN-LSTM	0.9031
	SC-LSTM	0.6871
	EMD-SC-LSTM	0.9111
	CEEMDAN-SC-LSTM	0.9206
Abdul et al. [31]	Linear regression	0.73
	SVM	0.93
	MLS-LSTM	0.95
Current study		0.9934

Based on the findings presented in Table III, the AO-GRU model demonstrates superior performance when compared to other models evaluated in the domain of stock price prediction. In this study, the R^2 value of 0.9934 was found to be highly impressive, surpassing the performance of other evaluated models such as LSTM, SVM, and MLS-LSTM. This indicates a stronger correlation between the predicted and actual stock prices, suggesting that the model is more effective in capturing the underlying data patterns. By integrating adaptive optimization techniques, the AO-GRU model gains the capability to dynamically modify its parameters during training. This allows it to adapt to the subtleties of the data and improve its capacity to handle variations and complexities in the stock market. The model effectively utilizes the GRU architecture to capture long-range dependencies in sequential data, while also addressing challenges such as the vanishing gradient problem. The gating mechanisms of GRU control the flow of information within the network, enabling more effective learning, especially in situations where there is a scarcity of training data. Significantly, the efficiency of the GRU architecture, which necessitates fewer parameters and computations in comparison to more intricate models such as LSTM, results in expedited training durations and reduced computational expenses. Consequently, the AO-GRU model becomes more viable for real-time or extensive applications. Moreover, the model's architecture, which is relatively uncomplicated, improves its interpretability, offering stakeholders valuable insights into the determinants of stock price fluctuations and the underlying reasoning behind the model's predictions, as opposed to certain intricate black-box models.

VI. Conclusion

This study aimed to develop machine learning models with improved stock price prediction accuracy. By making the appropriate sort of investment at the appropriate moment, traders and investors would be able to take advantage of these strategies and maximize their gains. This project included the effective implementation of four algorithms: GRU, ALO-GRU, GWO-GRU, and AO-GRU. A comprehensive comparative analysis of the algorithms' performances during stock price prediction was conducted after GRU algorithms were utilized to create accurate predictive models for use in the stock price prediction of HSI. The collected stock values 1st of January 2015 to the end of June 2023. The four assessment metrics MSE, R^2, MAPE, and MAE as well as the data gathered during the model testing are displayed in tabular and graphical form in the research study's results section.

- Following a comprehensive review and analysis of the data, the AO-GRU approach is shown to be the most error-free among the available strategies for time series prediction, with the lowest MSE (36530.58), MAPE (0.71), and MAE (143.62) errors and the highest value of R^2 (0.9934).

The study's findings present compelling evidence that suggests several promising avenues for future research in the field of stock price prediction. In order to enhance predictive accuracy and robustness, it is imperative to investigate alternative optimization techniques beyond Aquila, the optimizer employed in the AO-GRU model. The incorporation of supplementary datasets not limited to the Hang Seng Index has the potential to yield more profound insights and improve the generalizability of the model. This could involve the inclusion of macroeconomic indicators, industry-specific data, or sentiment analysis derived from diverse sources. Furthermore, the implementation of strategies such as attention mechanisms or feature importance analysis has the potential to improve the interpretability of models, thereby promoting increased trust and usability among various stakeholders. It is imperative to conduct thorough testing in various market conditions and economic cycles in order to evaluate the robustness and flexibility of models. Additionally, investigating the applicability of these models to different asset classes, such as commodities or currencies, may reveal novel opportunities for investment strategies. By directing attention towards these specific areas, forthcoming research endeavors possess the capacity to propel the domain of stock price prediction forward and effectively address the changing demands of investors and financial professionals.

Abstract—Knee diseases are common diseases in the elderly, and timely and effective diagnosis of knee diseases is essential for disease treatment and rehabilitation training. In this study, we construct a diagnostic model of common knee diseases based on subjective symptoms and random forest algorithm to realize patients' self-initial diagnosis. In this paper, we first constructed a questionnaire of subjective symptoms of knee, and set up a questionnaire system to guide users to fill out the questionnaire correctly. Then clinical data collection is carried out to obtain clinical questionnaire data. Finally, the diagnostic analysis of three common diseases of knee joint is carried out by random forest machine learning method. Through leave-one-out cross validation, the accuracy of meniscus injury, anterior cruciate ligament injury and knee osteoarthritis diseases are 0.79, 0.84, 0.81 respectively; the sensitivity is 0.79, 0.84, 0.88 respectively; and the specificity is 0.80, 0.84, 0.79 respectively. The results show that the method can achieve a good effect of self-diagnosis, and can provide a knee joint disease screening a convenient and effective approach.

Keywords—Knee diseases; subjective symptoms; random forest algorithm; self-diagnosis

I. INTRODUCTION

Knee disease is a highly prevalent condition that has a significant impact on the quality of life, particularly among older individuals. The knee is a complex structure, and as individuals age, the bones, cartilage, ligaments, and other functional components undergo degenerative changes. This gradual degeneration can lead to various knee conditions, including osteoarthritis, meniscus injuries, and ligament injuries [1-2]. Early detection of knee diseases is crucial for effective control and management. However, there is often a lack of awareness about knee diseases, and minor pain and dysfunction are frequently overlooked or attributed to old age or knee osteoarthritis. This delay in recognizing and treating knee diseases results in missed opportunities for prevention and early intervention [3-4].

Knee diseases encompass a wide range of symptoms and dysfunctions, underscoring the importance of recognizing abnormal subjective knee symptoms for early treatment and management. Researchers have explored multiple models and methods based on knee risk factors, symptoms, and etiology to develop diagnostic models for knee diseases and investigate symptom-based identification [5]. For example, Lim et al. employed deep learning algorithms to predict osteoarthritis using a Korean database [6], while Snoeker et al. designed a questionnaire for diagnosing meniscal injuries [7]. Wang Pei's team conducted ordered logistic regression analysis to identify factors influencing knee osteoarthritis grading, ultimately establishing a diagnostic model for grading knee osteoarthritis [8]. Bisson et al. designed a web-based symptom questionnaire with 26 questions and 126 entries to establish a differential diagnosis of knee disorders, providing patients with potential disorder types. However, the tool's sensitivity (58%) and specificity (48%) were found to be insufficient [9].

Despite the promise shown in clinical applications, these studies primarily focus on diagnosing specific types of knee diseases. The identification and diagnosis of different types of knee diseases and the provision of appropriate treatments present greater challenges. In summary, symptom-based screening and differential diagnosis of knee disorders currently face significant hurdles, resulting in low overall identification effectiveness. The subjective nature and ambiguity of symptom definition and acquisition, coupled with limitations in diagnostic models, pose significant difficulties in applying these models to the general population. Factors such as the subjective and variable nature of symptoms, the need for analyzing the relationship between diseases and symptoms, and the suitability of modeling methods all contribute to the complexity of diagnosing knee diseases based solely on subjective symptoms. Addressing these challenges is crucial for improving the performance of diagnostic models and enhancing the accuracy of knee disease identification.

To address the challenges mentioned above, this study proposes a diagnostic model for knee diseases based on subjective symptoms and random forests. The main research work is outlined as follows:

*Corresponding Author

Definition and screening of the knee subjective symptom questionnaire: The researchers define and screen a questionnaire for knee subjective symptoms through data collection, expert validation, and patient assessment methods. A questionnaire assistance system is designed to guide patients in accurately completing the questionnaire.

Data collection and statistical analysis: Clinical questionnaire experiments are conducted to gather research data on subjective knee symptoms. Statistical analysis is performed to examine the relationship between knee diseases and the distribution of major diseases and symptoms. Univariate logistic regression analysis is utilized to filter out irrelevant symptoms, reducing computational complexity and improving the accuracy of the diagnostic model.

Construction of a diagnostic model: A diagnostic model for knee diseases is built based on subjective symptoms, supplemented with the random forest algorithm. The researchers select optimal model parameters through grid search and explore optimal diagnostic thresholds to achieve the best diagnostic performance. The importance of diagnostically significant symptoms for each disease is further investigated to enhance the interpretability of the model.

The research framework for the diagnosis and screening of knee diseases based on subjective symptoms is illustrated in Fig. 1. By implementing this research framework, the aim is to improve the accuracy and interpretability of knee disease diagnosis, providing a valuable tool for early screening and management of knee diseases based on subjective symptoms.

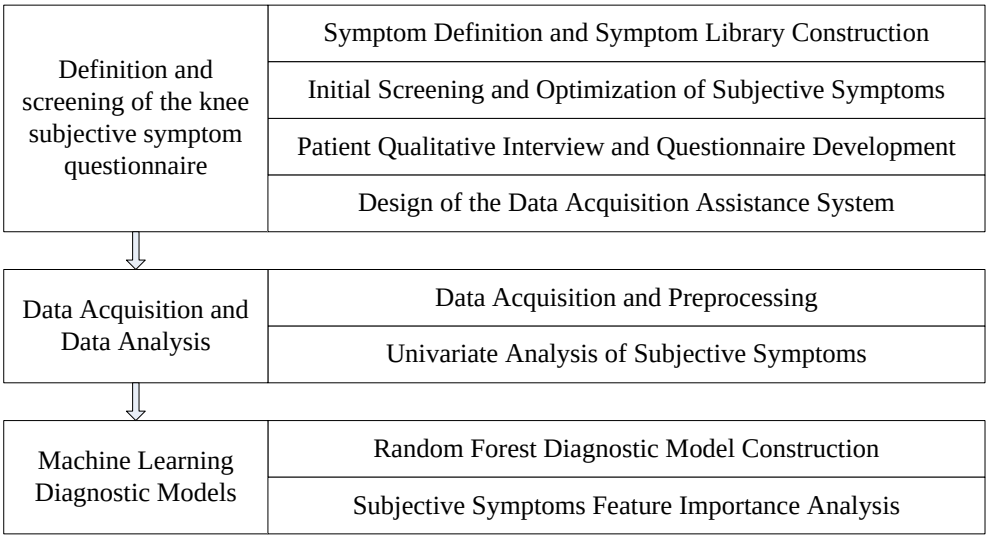

Fig. 1. Research framework for the diagnosis of knee diseases based on subjective symptoms and random forest algorithm.

II. Design of a Subjective Symptom Acquisition System

A. Subjective Symptom Definition

When designing the subjective symptom questionnaire, this study adhered to two core principles: firstly, ensuring that the items effectively reflect knee joint diseases and functional status, and secondly, ensuring that the items have clear and easily understandable meanings for the general public. To achieve these goals, the study employed various methods, including data surveys, expert consultations, and qualitative interviews, to construct a comprehensive library of subjective symptom questionnaires.

1) Preliminary definition of symptom item library: Constructing a symptom library that can comprehensively and effectively reflect the characteristics of various knee joint diseases is a challenge due to the subjective and ambiguous nature of symptoms. The research team initially conducted a data survey, gathering relevant literature and books on knee joint diseases to compile a list of possible symptoms. For example, knee osteoarthritis may cause symptoms such as joint pain, morning stiffness, and snapping, while meniscus injuries may result in joint tenderness. Based on this information and by referring to existing joint scales such as WOMAC and KSS, the team constructed a library of subjective symptoms for knee joints. Through discussions with knee-related experts and clinicians, as well as consideration of the clinical complaints of patients, the initial definition of knee joint subjective symptoms was established, and a symptom library was created. This library included medical history, etiology, subjective feelings, functional status, and various specific conditions and degrees, resulting in the design of 104 questionnaire items and 302 subjective symptom options.

2) Optimization of symptom item library Based on expert experience: The initial subjective symptom questionnaire contained a significant amount of redundant information, necessitating screening and optimization. The research team sought expert consultation by inviting 10 experienced doctors to analyze the feasibility, necessity, and comprehensibility of the questionnaire. The experts optimized the item selection and content of the questionnaire by removing redundant and difficult-to-understand symptoms, adding necessary symptoms, and modifying the definitions and explanations of certain symptoms. This process resulted in an optimized

screening questionnaire for subjective symptoms, incorporating the suggestions provided by the experts.

3) Further optimization of symptom item library Based on patient feedback: As patients are the ultimate users of the questionnaire, their understanding and applicability are of utmost importance. To address this, the study conducted qualitative interviews with 30 knee joint patients who had been diagnosed with knee joint diseases. Based on the feedback received from the patients, the symptom item library was further optimized. This iterative process led to the finalization of the subjective knee joint symptom questionnaire, which was refined and improved based on patient input. Table I shows the subjective symptoms and corresponding values included in the final questionnaire.

By following this design process, the subjective symptom acquisition system ensures that the knee disease-related symptoms are effectively represented and easily understood by the general population. This system plays a crucial role in accurately capturing subjective symptoms for further analysis and diagnosis of knee diseases.

TABLE I. DEFINITION OF SUBJECTIVE SYMPTOMS OF KNEE DISEASE

Number	Definition of subjective symptoms	value	Number	Definition of subjective symptoms	value
S1	Flexion Limit	False=0 True=1	S16	Pain Activity	False=0 True=1
S2	Extension Limit	False=0 True=1	S17	Pain Rest	False=0 True=1
S3	Snapping	False=0 True=1	S18	Pain Hyperalgesia	False=0 True=1
S4	Locking	False=0 True=1	S19	Pain Hyperflexion	False=0 True=1
S5	Instability	False=0 True=1	S20	Pain Wandering	False=0 True=1
S6	Knee Dislocation	False=0 True=1	S21	Tend Knee Space	False=0 True=1
S7	Patellar Dislocation	False=0 True=1	S22	Tend Above Patella	False=0 True=1
S8	Stiffness	False=0 True=1	S23	Tend Patella	False=0 True=1
S9	Injure	False=0 True=1	S24	Tend Blow Patella	False=0 True=1
S10	Injure Zip	False=0 True=1	S25	Tend Knee Eye	False=0 True=1
S11	Knee Varus	False=0 True=1	S26	Tend Tibial Tubercle	False=0 True=1
S12	Knee Knock	False=0 True=1	S27	Tend LCL	False=0 True=1
S13	Quadriceps Atrophy	False=0 True=1	S28	Tend Iliotibial Band	False=0 True=1
S14	Swelling	False=0 True=1	S29	Tend MCL	False=0 True=1
S15	Pain	False=0 True=1	S30	Tend Popliteal Fossa	False=0 True=1

B. Design of the Data Acquisition Assistance System

To improve the comprehensibility of symptoms and enhance the accuracy of data acquisition, a subjective symptom questionnaire assistance system was designed in this study. The system aims to assist patients in effectively completing the questionnaire. The main components of the system are outlined below:

1) Skip mechanism: The questionnaire incorporates a skip mechanism to reduce redundancy and enhance efficiency. For instance, if a user does not experience pain in the pain section, subsequent pain-related questions will be skipped, eliminating the need to answer irrelevant questions.

2) Tutorial system: The questionnaire incorporates a tutorial system to familiarize users with the questionnaire completion process.

- Overall Tutorial: A brief video, approximately 3 minutes in duration, introduces the questionnaire content to users. Digital media technology, including video animation and interactive media, is employed to help users grasp the questionnaire's content and guide them in providing accurate responses.
- Step-by-Step Tutorial: Complex questions within the questionnaire are accompanied by explanations. Users can click on the question title to access detailed explanations, facilitating their understanding and accurate completion of the questionnaire.

3) 3D Visualization for assisted answering: To address issues of ambiguity and improve the understanding of certain questions, the questionnaire system incorporates 3D visualization. For example, a 3D visualization model is designed for the pressure pain questionnaire. Users can interact with the model to indicate the location of their self-perceived pressure pain. The system automatically fills in the corresponding options based on the user's selection.

The subjective symptom questionnaire assistance system enhances the usability and accuracy of the subjective symptom questionnaire. The skip mechanism reduces redundancy, the tutorial system provides guidance, and the 3D visualization feature facilitates precise responses. These features collectively contribute to more effective and efficient data collection for knee diseases.

III. MATERIALS AND METHODS

A. Random Forest Algorithm

The random forest algorithm is an integrated machine learning algorithm that utilizes decision trees as its base learners. Each decision tree is constructed based on a different

subset of the training data and features. As a result, each decision tree is unique and independent, and the collective learning results of multiple decision trees are considered as the final output of the random forest algorithm. This algorithm helps to reduce the variance present in individual decision trees. Random forest is particularly effective in handling classification tasks with complex interactions among attributes. It can also adapt well to datasets with noise or missing values, and the training process is relatively fast. The random forest algorithm is versatile, capable of performing classification, regression, and outlier detection tasks [10-11].

The calculation steps of the random forest algorithm are outlined in Algorithm 1. This algorithm combines the predictions of multiple decision trees to arrive at the final prediction [12].

In the random forest algorithm, each decision tree is trained on a different subset of the data, promoting diversity and reducing overfitting. The final prediction is made by aggregating the predictions of all the decision trees in the ensemble model. This ensemble-based algorithm helps to improve the accuracy and robustness of the model.

Random forest has been widely used in various fields due to its effectiveness and versatility in handling complex datasets. In the context of the study, the random forest algorithm can be employed for tasks such as knee disease classification, regression analysis of symptom severity, or identifying outliers in the dataset.

The calculation steps of the random forest algorithm are shown in Algorithm 1.

Algorithm 1: Random forest algorithm steps

Input: Training set $D = \{(x_1, y_1), (x_2, y_2), \ldots, (x_N, y_N)\}$, $x_i = (x_i^1, x_i^2, \ldots, x_i^n)$, $x_i^1, x_i^2, \ldots, x_i^n$ is a characteristic of k:

Output: Classification result1

1: $for\ i = 1:K$

2: A subset is constructed by randomly selecting k samples from the training set $S_i, S_i \grave{I} D$

3: The features contained in each feature are randomly selected from each feature ($m £ n$)

4: $Gini(S_i) = 1- \mathring{a}_J (\frac{|y_J|}{|S_i|})^2$ J is the number of features contained in y

5: while(!Generate(T_i))

6: $for\ j = 1:m$

7: $Gini(S_i, x^j) = \frac{|S_{i1}|}{|S_i|} Gini(S_{i1}) + \frac{|S_{i2}|}{|S_i|} Gini(S_{i2})$

8: $\Delta \mathrm{Gini}(x^j) = \mathrm{Gini}(S_i) - \mathrm{Gini}(S_i, x)$

9: $endfor$

10: The smallest corresponding node is selected as the classification node;

11: end

12: $endfor$

13 : The generated individual trees constitute the random forest classifier, which is the final output classification result of the random forest through the voting strategy.

B. Performance Evaluation Indicators

The performance of a disease diagnostic model can be assessed using various indicators, including Accuracy, Sensitivity, Specificity, Receiver Operating Characteristic (ROC) curve, and the Area Under the Curve (AUC) [13]. These indicators provide valuable insights into the model's ability to correctly classify individuals with and without a specific knee disease.

To calculate these indicators, the following four parameters are defined:

True Positives (TP): The number of individuals correctly diagnosed with a particular knee disease.

True Negatives (TN): The number of individuals correctly diagnosed as not having the knee disease.

False Positives (FP): The number of individuals incorrectly diagnosed with the knee disease (false alarms).

False Negatives (FN): The number of individuals incorrectly diagnosed as not having the knee disease when they actually have it (missed diagnoses).

Taking meniscus injury as an example, the classification confusion matrix is shown in Table II:

TABLE II. CLASSIFICATION CONFUSION MATRIX

Diagnostic	Predicted Meniscus Injury	Predicted No Meniscus Injury
Actual Meniscus Injury	TP	FN
Actual No Meniscus Injury	FP	TN

The indicator parameters are defined as follows.

1) The accuracy rate is mainly used to measure the accuracy of the diagnosis of the total sample, i.e., the number of samples correctly diagnosed as a proportion of the total number of samples. The formula for calculating the accuracy rate is as follows:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

2) Sensitivity is the proportion of samples diagnosed as positive out of all positive samples, also known as the true positive rate (TPR), the recall rate. The formula for calculating sensitivity is as follows:

$$\mathrm{Sensitivity} = \frac{TP}{TP + FN} \quad (2)$$

3) Specificity is the proportion of samples with a negative diagnosis to all negative samples, and the formula for calculating specificity is as follows:

$$\text{Specificity} = \frac{TN}{TN + FP} \tag{3}$$

4) False-positive rate is the proportion of incorrectly diagnosed positive samples to all negative samples, and the formula for calculating the false-positive rate is as follows:

$$FPR = \frac{FP}{TN + FP} \tag{4}$$

5) AUC (Area Under Curve, AUC) indicates the area under the ROC (receiver operating characteristic curve, ROC) curve. The formula for calculating AUC is as follows:

$$\text{AUC} = \int_{x=0}^{1} TPR(FPR^{-1}(x))dx \tag{5}$$

where, TPR represents the true positive rate and FPR represents the false positive rate.

6) Youden index, also known as the correct index, is the sum of sensitivity and specificity minus 1. The larger the index, the better the screening test is, and the more truthful it is. The Youden index can be applied when it is assumed that the false-negative (missed diagnosis) and false-positive (misdiagnosis) rates are of equal significance. The method of evaluating the veracity of a screening test indicates the total ability of the screening method to detect true patients versus non-patients.

$$\text{Youden index} = \text{Sensitivity} + \text{Specificity} - 1 \tag{6}$$

C. Feature Importance

In order to improve the interpretability of the machine learning model, we calculated and ranked the importance of each symptom in the classification model. Random forest samples datasets from the sample set by bootstrap method with putback, and each dataset constitutes a decision tree. is the out-of-bag dataset, i.e., the dataset that was not sampled in when the dataset was generated. It is used as a test set to compute the importance of each feature using the Random Forest model, and the importance ranking of each feature is obtained by ranking the importance probability of each feature. For example, the steps of feature F importance calculation are as follows. The process of feature importance algorithm is shown in Algorithm 2:

Algorithm 2: Feature Importance Algorithm Steps

1: Using the random forest model based $\overline{D_i}$ calculating the error of each decision tree $\varepsilon = [\varepsilon_1, \varepsilon_2, \cdots, \varepsilon_n]$;

2: Randomly upset the order of the features in the sample set and again use the random forest model to calculate to get the error $\bar{\varepsilon} = [\overline{\varepsilon_1}, \overline{\varepsilon_2}, \cdots, \overline{\varepsilon_n}]$, The difference between the two calculation errors is $d = \varepsilon - \overline{\varepsilon}$;

3: Calculate the average of the differences $mean(d)$ *and* (statistics) standard deviation $\sigma(d)$;

4: The significance of a feature is the ratio of the mean to the standard deviation, i.e., $importance(F) = mean(d)/\sigma(d)$.

IV. Results

A. Data Collection

This study utilized the knee subjective symptom questionnaire assistance system for data collection and analysis of knee diseases and symptoms. The collection of clinical data was conducted in adherence to ethical guidelines and approved by the Ethics Committee Board of the Hefei Institute of Materials Research, Chinese Academy of Sciences, following the principles outlined in the Declaration of Helsinki. Informed consent forms were obtained from all participants after providing them with information about the study.

The gold standard for diagnosing knee diseases in the patients was based on assessments using MRI scans and comprehensive evaluations by physicians. The inclusion criteria for participants in the experiment were a definite diagnosis of a specific knee disease through MRI and other necessary examinations, the ability to provide complete clinical examination data and case information, and voluntary participation with an understanding of the nature of the experiment. Exclusion criteria included patients with myocardial infarction, serious infectious diseases, malignant diseases, or cognitive impairment.

The process of data collection and pre-processing involved the following steps: Firstly, patients independently completed the knee subjective symptom questionnaire through the questionnaire system. Subsequently, physicians reviewed each item of the questionnaire with the patients, verifying the diagnostic information related to the type of knee disease, which could include multiple disease types. This ensured the accuracy and validity of the questionnaire data. Finally, the data was exported from the questionnaire system for further analysis.

Data collection primarily took place from January 2021 to April 2021 at the orthopedic outpatient clinic of a tertiary hospital in Hefei, Anhui Province, China. Three orthopedic specialists were involved in acquiring and verifying the questionnaire data. A total of 157 valid data cases were obtained, comprising 76 male and 81 female participants, with no significant difference observed. The average age of the participants was 56±7, predominantly middle-aged and elderly patients.

B. Univariate Analysis

In this study, the subjective symptom questionnaire designed for knee disease symptoms is comprehensive, but not all symptoms are directly or strongly correlated with a specific disease. Therefore, it is crucial to filter and remove redundant symptom information to improve the efficiency of disease diagnosis. Symptom screening is an essential step in data

preprocessing for data mining and machine learning analysis. Effective symptom selection can significantly enhance the classification performance and overall robustness of the model. The primary objective of symptom selection is to eliminate features with weak or no relevance to the classification target and utilize only the most effective features to achieve accurate classification or prediction results.

For feature selection, we employed the logistic regression algorithm as the Univariate Analysis method. Univariate logistic regression analysis explores the potential correlation between the dependent variable and each independent variable by establishing a functional relationship between the value of the independent variable and the probability of the occurrence of the event defined by the dependent variable. In this paper, univariate regression analysis was utilized to identify multiple symptoms that can effectively characterize knee disorders. Table III presents the results of univariate logistic regression analyses for three specific diseases: meniscus injury, anterior cruciate ligament injury, and knee osteoarthritis.

Symptoms with a p-value of less than 0.05 were included as significant symptoms of the disease based on the variable inclusion criteria for statistical significance. As can be illustrated in Table III, the significant symptoms of meniscus injury disease include seven symptoms: Knee Dislocation, Patellar Dislocation, Quadriceps Atrophy, Pain Activity, Pain Hyperflexion, Tend Knee Space, and Tend Patella, and the significant symptoms of ACL injury disease include nine symptoms such as Snapping, Instability, Knee Dislocation, Injure, Injury Zip, Quadriceps Atrophy, Swelling, Pain, and Tend MCL. The notable symptoms of knee osteoarthritis include seven symptoms of Extension Limit, Snapping, Knee Dislocation, Stiffness, Injure, Injure Zip, and Swelling. These symptoms differed significantly in the incidence of knee disease, so these factors needed to be screened for inclusion in the subsequent diagnostic modeling index system.

C. Disease Diagnosis

The experiment aimed to build a diagnostic screening model for knee diseases based on the significant symptoms identified through univariate analysis of each illness. The performance of the classification model was evaluated using leave-one-out cross-validation, a technique where each data point is used as a test sample once while the remaining samples were used for training the model.

To assess the effectiveness of our proposed method, we compared the diagnostic performance of the optimized random forest-based model with other models, including support vector machine (SVM), logistic regression (LR), AdaBoost (AB), and MLP neural network (Multi-Layer Perceptron, MLP). We evaluated the diagnostic performance regarding various indicators such as AUC, accuracy, sensitivity, specificity, and

Yoden's index. To address data imbalance, we used the SMOTE (Synthetic Minority Over-sampling Technique) method for data augmentation, which helped achieve analyzable results.

Furthermore, to improve the interpretability of the model, we employed a variable importance calculation method specifically designed for the random forest-based model. This method allowed us to calculate and rank the importance of each variable in the model.

The specific results obtained from the experiment are as follows:

1) Model performance analysis: We evaluated the performance of the subjective symptom-based diagnostic model for knee diseases proposed in this study. The model, supplemented with the random forest algorithm, was used for diagnosing meniscus injury, anterior cruciate ligament (ACL) injury, and knee osteoarthritis. Table IV show the diagnostic results of the model for three diseases. The experimental results showed that the AUC values of the diagnostic model for all three diseases were more significant than 0.8. This indicates that the model constructed in this study is suitable for the diagnostic task of common knee diseases. ACL injury showed the highest diagnostic performance among the three diseases, with an AUC value of 0.92. Meniscus injury had an AUC of 0.87, and knee osteoarthritis, after excluding a large amount of concomitant disease data and using SMOTE data augmentation, achieved an AUC of 0.85. Additionally, this study evaluated the comprehensive performance and found that the AUC value showed the best performance among the comprehensive performance of the three disease diagnosis.

These findings demonstrate the effectiveness of the diagnostic screening model for knee diseases based on subjective symptoms. The optimized random forest-based model, along with the use of appropriate machine learning algorithms, showed promising performance in diagnosing common knee diseases. The evaluation metrics such as AUC, accuracy, sensitivity, specificity, and Yoden's index provided comprehensive insights into the model's diagnostic capabilities.

2) Comparison of model performance based on different models: We used support vector machines, logistic regression, AdaBoost algorithm, and MLP neural networks to construct prediction models for comparative analysis. The hyperparameter settings for these four models were carried out in the same manner as the Random Forest model.

A random forest algorithm was used to construct a diagnostic screening model for meniscus injury, anterior cruciate ligament (ACL) injury, and knee osteoarthritis. Four common machine-learning algorithms were used for comparative analysis. Table V presents the accuracy, sensitivity, specificity, and Youden's index for diagnosing the three common knee disorders. Fig. 2 to Fig. 4 display the AUC curves for diagnosing the three disorders.

TABLE IV. THE DIAGNOSTIC RESULTS OF THE MODEL FOR THREE DISEASES

Disease Types	AUC	Accuracy	Sensitivity	Specificity	Threshold	Jordon Index
Meniscus injury	0.87	0.79	0.79	0.80	0.53	0.61
Anterior Cruciate Ligament Injury	0.92	0.84	0.84	0.84	0.30	0.73
Knee osteoarthritis	0.85	0.81	0.88	0.79	0.19	0.68
comprehensive performance	0.88	0.81	0.84	0.81	0.34	0.67

TABLE V. PERFORMANCE OF A DIAGNOSTIC MODEL FOR COMMON KNEE DISEASES IN SELECTING OPTIMAL THRESHOLDS

Disease Types	AUC	Accuracy	Sensitivity	Specificity	Threshold	Jordon Index
Meniscus injury	0.87	0.79	0.79	0.80	0.53	0.61
Anterior Cruciate Ligament Injury	0.92	0.84	0.84	0.84	0.30	0.73
Knee osteoarthritis	0.85	0.81	0.88	0.79	0.19	0.68
comprehensive performance	0.88	0.81	0.84	0.81	0.34	0.67

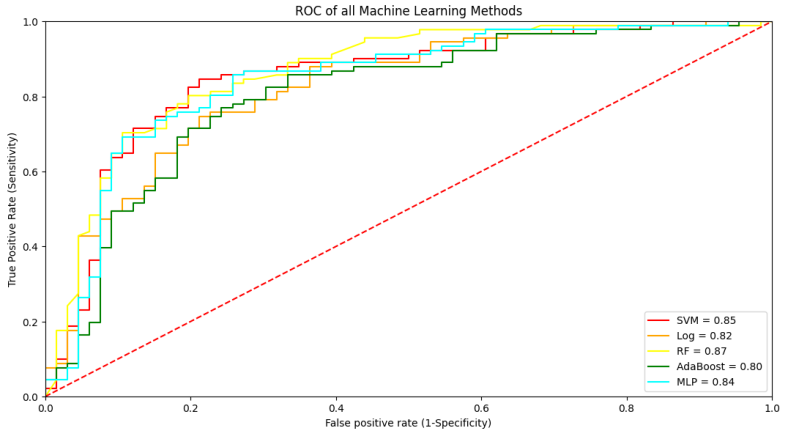

Fig. 2. Machine learning algorithm to meniscus injury disease AUC curve.

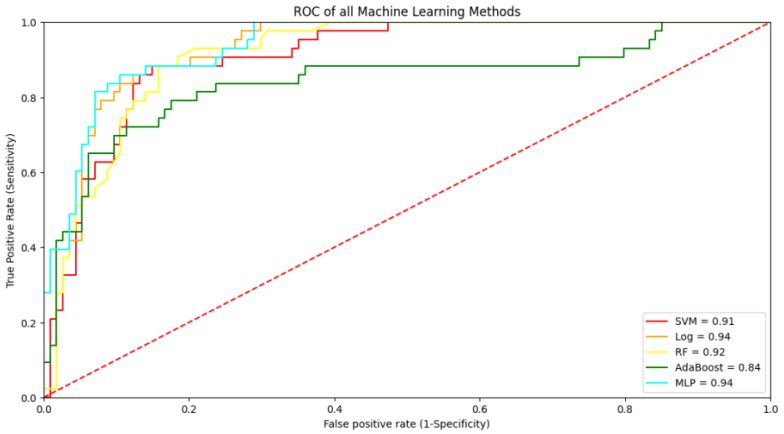

Fig. 3. Anterior cruciate ligament injury disease machine learning algorithm AUC curve.

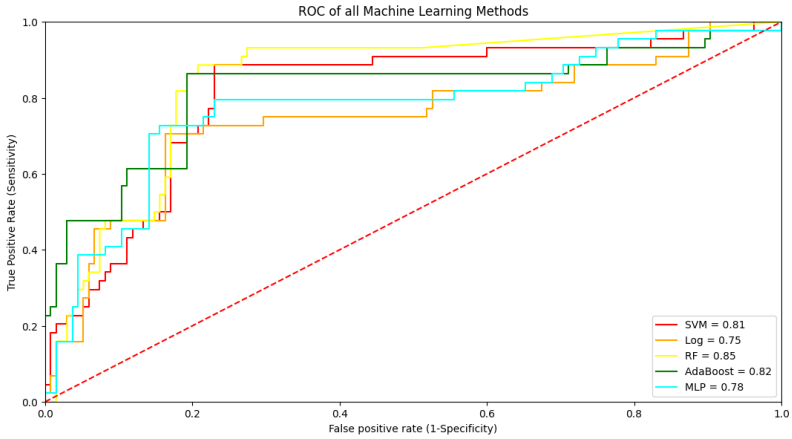

Fig. 4. Knee osteoarthritis disease machine learning methods AUC curve.

Specifically, for the diagnosis of meniscus injury disease, the Random Forest (RF) model achieved the highest AUC of 0.87, followed by the Support Vector Machine (SVM) model at 0.85, the MLP neural network model at 0.84, the Logistic Regression (Log) model at 0.82, and the AdaBoost model at 0.80.

For diagnosing ACL injury disease, the MLP neural network model and Log model performed the best with an AUC of 0.94, followed by the RF model at 0.92, the SVM model at 0.91, and the AdaBoost model at 0.84.

In the knee osteoarthritis disease diagnostic model, the RF model achieved the highest AUC of 0.74 on the test set, followed by the Log model at 0.73, the MLP neural network model and the AdaBoost model, both with an AUC of 0.72, and the SVM model performed slightly worse with an AUC of 0.63. The overall performance of the knee osteoarthritis disease diagnostic model was significantly improved by enhancing the model with SMOTE data, with an AUC of 0.80, accuracy of 0.80, sensitivity of 0.78, and specificity of 0.81.

Compared to the other four classifiers random forest model has higher AUC value and Yoden index, and better comprehensive performance for disease diagnosis. The random forest model has good ability to diagnose and screen common knee joint diseases, and therefore has some practical value, which further indicates that the disease diagnosis and screening based on subjective symptoms proposed in this study is feasible.

3) Symptom feature importance for random forest algorithms: The highest importance scores constructed for different knee diseases varied considerably. The feature importance scores of the random forest algorithm are shown in Fig. 5 to Fig. 7. The first four subjective symptoms were taken as follows: meniscus injury disease with the following order of significance: Tend Knee Space, Knee Dislocation, Pain Hyperflexion, Pain Activity, ACL injury disease with the following order of significance: Knee Dislocation, Instability, Injure Zip, Injure. Significant symptoms of osteoarthritis of the knee and their ranking are as follows: Injure, Stiffness, Snapping and Extension Limit. These are important references for disease analysis.

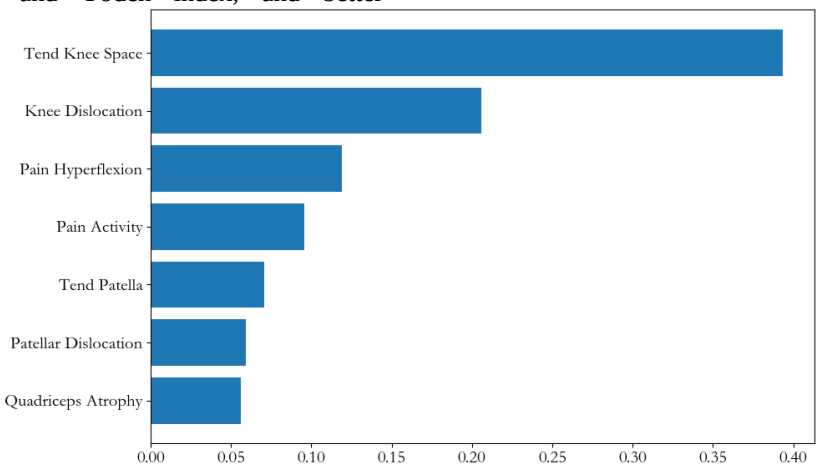

Fig. 5. Ranking the symptom feature importance of diagnostic model for MT injuries.

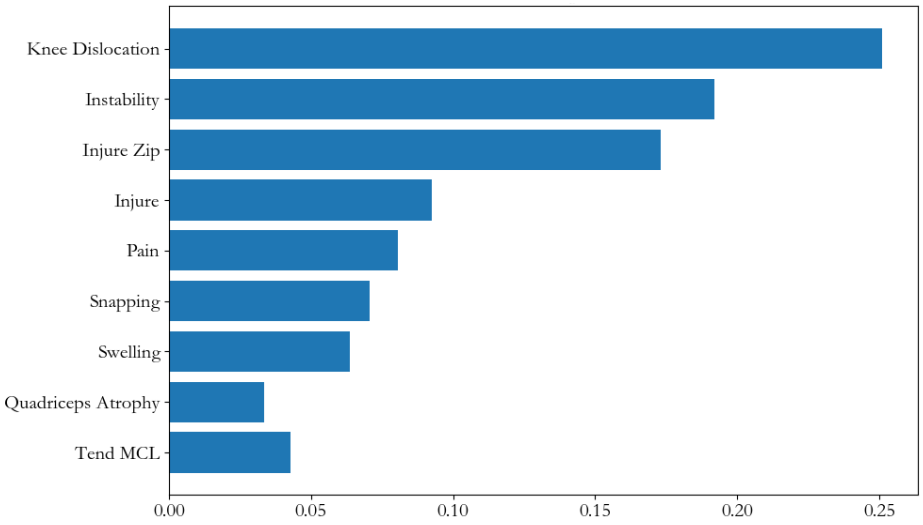

Fig. 6. Ranking the symptom feature importance of diagnostic model for ACL injuries.

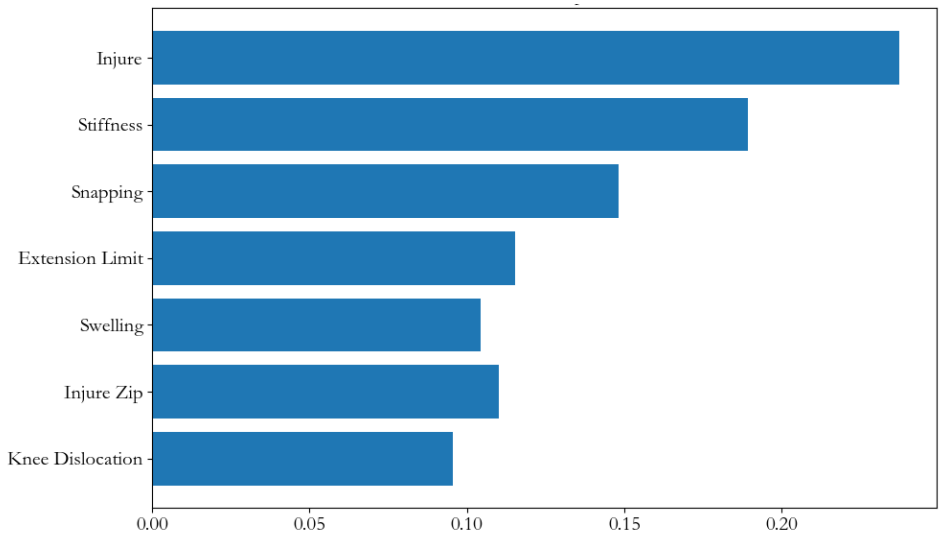

Fig. 7. Ranking the symptom feature importance of diagnostic model for KOA.

V. Dicussion

A. Disease Diagnosis Effectiveness Analysis

In this study, a diagnostic screening model for common knee diseases was constructed using a random forest algorithm. The results of the study revealed variations in the diagnostic accuracy for different diseases. ACL injuries were generally better identified, meniscal injuries had slightly lower accuracy, and knee osteoarthritis showed the lowest diagnostic effectiveness. One of the reasons behind the lower diagnostic effectiveness for meniscal injuries and knee osteoarthritis is their strong concurrency.

Pathologically, ACL injuries involving ligamentous structures tend to exhibit more distinct symptoms and a certain degree of specificity. On the other hand, meniscal injuries and knee osteoarthritis are both cartilage diseases and share similar symptoms, making it more challenging to differentiate between them.

When comparing different machine learning methods, the random forest model demonstrated advantages in this study. Random forest is an ensemble learning algorithm that combines multiple decision trees into a single predictive model. It mitigates overfitting issues and enables parallel operation since there are no dependencies between weak learners. Random forests have shown excellent performance in various classical problems, including disease diagnosis. Another integrated learning algorithm, AdaBoost, also performed well in this study. AdaBoost, based on boosting, is particularly effective in handling categorical variables. However, the MLP neural network algorithm, commonly used for unstructured and complex data, was not the most suitable choice for the structured data and categorical features of this study. The random forest andAdaBoost models were more appropriate and demonstrated good performance. Among the compared models, the random forest model generally outperformed the AdaBoost model in this study, supporting previous findings that highlighted the superior classification performance of random forests. Logistic regression, although widely used in the biomedical field due to its simplicity and interpretability, may not have been as effective in addressing the classification problem of this study.

This study achieved better results than the current symptom-based diagnosis of knee disorders. The diagnostic rate for meniscal injuries based on detailed history and clinical examination by doctors is typically around 80% to 85%. The developed diagnostic system in this study showed similar diagnostic accuracy to that of doctors' initial diagnoses, indicating its high clinical value. Table VI provides a comparison of the diagnosis of knee diseases based on symptoms and risk factors.

Overall, the random forest-based diagnostic screening model demonstrated superior performance in identifying knee disorders compared to other machine learning methods and the current symptom-based diagnosis. Removing the interference of concurrent diseases improved the diagnostic accuracy for knee osteoarthritis. These findings highlight the potential of machine learning algorithms in improving disease diagnosis and could have implications for clinical practice.

B. Analysis of Significant Symptoms of Disease

The subjective knee symptoms constructed in this paper can characterize knee disease states with good accuracy for diagnostic prediction through machine learning. Symptoms that characterize the functional state of knee diseases need to meet the needs of diagnosing the effectiveness of the disease, public comprehensibility, and other needs, and there are greater challenges. In this paper, through multiple rounds of research, collation and expert selection and optimization, 30 subjective knee symptoms are finally identified for characterizing knee diseases. Further diagnostic prediction through machine learning algorithms achieves a high correct rate and verifies the validity of symptom definition and selection.

TABLE VI. COMPARISON ON DIAGNOSIS OF KNEE DISEASES BASED ON SYMPTOMS AND RISK FACTORS

Establishment of a diagnostic grading model for osteoarthritis of the knee on the basis of data from pathogenic factors, symptoms, signs, physical examination and various scales using logistic regression methods.	Overall accuracy for knee osteoarthritis was 67%, sensitivity 50%, specificity 75%, and AUC of 0.88.
This paper	Differential diagnosis of meniscus injury, anterior cruciate ligament injury and osteoarthritis of the knee by self-developed subjective symptom questionnaire combined with random forest machine learning method for common knee diseases.	Diagnostic performance for MT: an AUC of 0.87, accuracy of 0.79, sensitivity of 0.79 and specificity of 0.80; ACL injury disease: 0.92, 0.84, 0.84 and 0.84; KOA: 0.85, 0.81, 0.88 and 0.79.

Through the clinical questionnaire data collection process, it can be found that patients are able to fill in the questionnaire by themselves through the questionnaire and its auxiliary system, and the detection error rate of the doctor's verification is low, which fully demonstrates that ordinary patients can understand the questionnaire content, and it can be applied to further clinical promotion.

Machine learning algorithms build models with better performance compared to statistical methods but have the disadvantage of poor model interpretability. Machine learning involves learning to train, construct a model and predict new input data. To increase the transparency of the model and provide health education for residents in practical applications, we calculated the impact of each symptom on the performance of the diagnostic model. Through the one-way analysis and diagnostic model importance analysis, significant symptoms can be filtered out for differential diagnosis of knee diseases, and further through the machine learning method and the importance of the calculation of the ranking, to obtain the more important symptoms for each disease, the specific analysis is as follows:

1) The notable symptoms of meniscus injury disease and their symptoms of high importance are compression Tend Knee Space, Knee Dislocation, Pain Hyperflexion and Pain Activity, which are important references for the analysis of the disease. Since the meniscus is present in the knee space, pressure pain in the knee space is a prominent symptom in the diagnosis of meniscus injury [16]. The meniscus is the role of the spacer for the knee activity to form a cushioning effect; once the injury lesion, the knee activity will be exacerbated by pain, so Pain Hyperflexion is increased, Pain Activity is increased, and other symptoms [17]. Generally, meniscal disease does not cause symptoms of dislocation sensation. In this study, there existed a large number of symptoms of meniscus in combination with ACL, and dislocation sensation was a significant symptom of ACL injury and thus was included among the significant symptoms of meniscus, which is a reflection of the complexity of knee disease.

2) The notable symptoms of ACL injury disease and its symptoms of higher importance are Knee Dislocation, Instability, Injure Zip, and Injure, respectively. ACL injury disease indicates the presence of damage and rupture of the ACL. The anterior cruciate ligament (ACL) is located in the knee, connecting the femur and tibia, and its main role is to limit the tibia's forward shift. It is an important static and kinetic anterior stabilizing structure of the knee, which prevents the tibia's anterior shift in flexion, prevents the knee from over-extending in extension, controls knee rotation, and controls knee internal and external rotation at different flexion angles, and has a proprioceptive function [18]. When an injury rupture of the ACL occurs, there is a noticeable sense of dislocation, which later develops into a sense of instability. The main cause of ACL rupture is injury, which accounts for more than 70% of the cases. Therefore, the presence of a history of trauma in the patient is the main causative factor in the development of the disease [19]. A tearing sound accompanies ligament tear injuries. Further intra-articular hemorrhage leads to swelling, pain, and, in most cases, inability to continue with the original sport or even limited extension and hyperflexion activities.

3) The prominent symptoms of osteoarthritis disease of the knee and their higher importance are Stiffness, Snapping, Injure, and Swelling, respectively. This is almost identical to the clinical diagnostic criteria for the knee. Clinical diagnostic criteria for knee osteoarthritis usually consider ① knee pain, ② snapping, ③ morning stiffness time≤30min, ④ age ≥38 years old, ⑤ bony enlargement, Osteoarthritis of the knee is

diagnosed if①②③④, or ①②⑤ or ①④⑤ are fulfilled [20]. From the perspective of subjective symptoms, pain was the basic symptom, while joint friction sound (sensation), morning stiffness and bony enlargement were important for clinical diagnosis, which verified the reliability of the subjective and significant symptom analysis in this study.

From the distribution of disease symptoms, it can be found that pain is the first complaint of knee diseases, and in this questionnaire case, different diseases caused pain symptoms almost 100%. Therefore, pain symptoms are the basic symptoms but are not significant for the differential diagnosis of the disease.

Stiffness is an important symptomatic feature of knee osteoarthritis. Patients may experience stiffness in the joints in the morning or after rest, which can be relieved by activity due to verification of cartilage or joint adhesions.

Snapping due to cartilage destruction and rough joint surface, bone friction sound (sense) occurs during joint movement.

Injure is an important symptom in the history of knee disease and an important factor in the development of Osteoarthritis of the knee. Everyday knee injuries are prone to cause cartilage damage or lesions, which gradually form Osteoarthritis of the knee.

Swelling symptoms in this study were generally compared to the difference in the knee compared to the healthy side or the previous one, so bony enlargement symptoms were included. As Osteoarthritis of the knee progresses, patients experience swelling and bony enlargement of the knee. Swelling is caused by fluid and cells collecting around the joint due to inflammation, resulting in swelling, pain, and warmth in the joint area. The swelling may get worse as the inflammation increases. On the other hand, bone enlargement is caused by damage to the cartilage in the knee. The cartilage loses its ability to protect the articular bones, causing them to be exposed to friction and wear and tear. Over time, the articular bones regrow, forming bone spurs and osteophytes. These bony protrusions cause pain and stiffness when the joint moves.

C. Research Limitations

This research also has some limitations.

Firstly, the sample size used for constructing the diagnostic model was relatively small, and the uneven distribution of positive and negative cases may have affected the model's training and analysis of the disease. Therefore, the model may not directly apply to clinical diagnosis, but it can still be valuable for self-screening common knee diseases.

Secondly, the data used in the study were collected from a specific region and population in Anhui province, which may limit the generalizability of the findings to other populations. Regional differences and variations in disease duration should be considered when applying the model to different populations.

Lastly, the subjective questionnaire employed in the study mainly utilized dichotomous data and lacked more detailed information regarding symptom typing and severity. Incorporating more comprehensive and detailed symptomatic details in future studies could enhance the diagnosis of a wider range of diseases and provide a better understanding of disease severity.

These limitations should be addressed in future research to improve the diagnostic accuracy and applicability of the model.

VI. Conclusion

In this study, we designed a subjective symptom questionnaire for knee diseases based on easily collected subjective symptoms. We collected clinical data to analyze the relationship between diseases and symptoms. By combining univariate logistic regression analysis and random forest, we developed a diagnostic screening method for common knee diseases using these subjective symptoms. The study demonstrated promising diagnostic performance for the examined common knee diseases.

The area under the curve value was 0.87 for meniscal disease. For ACL injury, the AUC value was 0.92; for knee osteoarthritis, the AUC value was 0.84. Additionally, accuracy, sensitivity, and specificity values were reported for each disease, indicating favorable performance compared to similar studies and proximity to the clinical diagnosis results of physicians. These findings suggest that the proposed method, which utilizes subjective symptoms, holds advantages in screening common knee diseases and may be applicable for self-diagnosing these conditions.

Furthermore, the study presents a general framework for utilizing machine learning methods to predict the risk of developing other chronic diseases. However, it is important to note that further research and validation are necessary to ensure the robustness and generalizability of the proposed diagnostic method.

Data Dynamic Prediction Algorithm in the Process of Entity Information Search for the Internet of Things

Tianqing Liu
College of Artificial Intelligence and Big Data, Zibo Vocational Institute, Zibo, 255000, China

***Abstract*—To address the issue of insufficient real-time capability in existing Internet search engines within the Internet of Things environment, this research investigates the architecture of Internet of Things search systems. It proposes a data dynamic prediction algorithm tailored for the process of entity information search in the Internet of Things. The study is based on the design of a data compression algorithm for the Internet of Things entity information search process using the Rotating Gate Compression Algorithm. The algorithm employs the Least Squares Support Vector Machine to dynamically predict changes in entity node states in the Internet of Things, aiming to reduce sensor node resource consumption and achieve real-time search. Finally, the research introduces an Internet of Things entity information search system based on the data dynamic algorithm. Performance test results indicate that the segmented compression algorithm designed in the study can enhance compression accuracy and compression rate. As compression accuracy increases, errors also correspondingly increase. The prediction algorithm designed in the study shows a decrease in node energy consumption as reporting cycles increase, reaching 0.2 at 5 cycles. At the 5-cycle point, the prediction errors on two research datasets are 0.5 and 7.8, respectively. The optimized data dynamic prediction algorithm in the study effectively reduces node data transmission, lowers node energy consumption, and accurately predicts node state changes to meet user search demands.**

Keywords*—Internet of Things; sensors; swinging door trending (SDT); support vector machine (SVM); data dynamic prediction

I. Introduction

In the era of the Internet of Things (IoT), massive devices continuously generate vast streams of data containing crucial insights for entity information search. With the rapid development of IoT technology, effectively processing and predicting this data to support real-time, accurate information search has become a significant research topic. The data dynamic prediction algorithm for entity information search in the IoT aims to predict dynamic changes in data in the IoT environment using advanced data analysis techniques to enhance search efficiency and accuracy [1-2]. The complexity of the IoT environment is mainly reflected in the high dynamism, large-scale, and heterogeneity of data. These characteristics make traditional data processing and prediction methods challenging to adapt. For example, IoT devices generate diverse data types with a fast update frequency, influenced by various factors such as environmental changes, device status, and user behavior. Therefore, developing an algorithm that can accurately predict these dynamic data changes is crucial for efficient IoT entity information search. Currently, IoT data processing and analysis rely mainly on traditional data processing techniques and algorithms. However, these methods face numerous challenges when handling large-scale, highly dynamic, and heterogeneous IoT data. On the one hand, unlike the traditional Internet, the object of IoT search is structured and highly dynamic, and traditional search engines cannot adapt to IoT information search. On the other hand, the Internet of Things has a large number of nodes, diverse data types, and fast update frequencies. Traditional search strategies have poor timeliness and waste a large amount of computing resources [3]. Based on this, research has been conducted on the architecture of IoT search systems, proposing a data dynamic prediction algorithm for IoT entity information search processes. The innovation of the research is mainly in two aspects, one of which introduces a lightweight data compression method to compress the original data and reduce the network communication pressure. The second introduces a minimized quadratic loss function to improve the support vector machine for real-time search. Additionally, the research considers the real-time and dynamic nature of data to ensure that the algorithm can adapt to the rapid changes in IoT data. This research is expected to provide new theoretical and practical references in the field of IoT data processing and analysis on the one hand; on the other hand, it promotes the development and innovation of IoT applications, and has great potential to provide richer and smarter services for people.

The research is divided in six sections. Section II delves into related. Section III presents an IoT entity information search system based on the data dynamic prediction algorithm. Section IV tests and analyzes the performance of the model and algorithm. Results and discussion is given in Section V. Section VI summarizes and concludes the above content.

II. Related Works

In the field of sensor networks, numerous studies focus on data transmission and application. Sreedharan et al. proposed a cluster head selection and hybrid routing protocol algorithm based on fuzzy multi-attribute decision-making to enhance the performance of wireless sensor networks. Subsequent experiments demonstrated the effectiveness of their algorithm [4]. Pattnaik et al. introduced an algorithm that combines fuzzy clustering and elephant herd optimization to achieve efficient routing assembly in wireless sensor networks, with simulation experiments validating its advantages in energy utilization and system lifespan [5]. Javaheri et al. conducted research on data fusion techniques in wearable sensors, comparing Kalman fusion and alpha-fine-tuned mean filtering. They designed an algorithm that switches between the two fusion methods based on Signal Quality Index, with

experimental results showing its superiority over baseline dual-channel RR interval averaging by approximately 54% and 21%, respectively [6]. The IoT, as a network connecting everything, involves processes where sensor-acquired data is uploaded to the network and then processed by artificial intelligence or corresponding algorithms to issue instructions for desired actions by executive devices. As an emerging concept, IoT has been widely studied in various fields. Turner et al. focused on reducing the environmental impact of the manufacturing industry by aligning with practices in digital computation and the automotive industry. They constructed an IoT network framework for the circular economy model in manufacturing based on Industry 4.0 computing and IoT interaction networks [7].

Zhang et al. addressed the issue of battery replacement in large-scale IoT deployments by employing wireless power transfer using radio frequencies. Based on DEIN technology, they developed a time allocation model to manage radio frequency energy and the transmission of uplink data in different time slots. Additionally, they proposed a joint time and power allocation algorithm to reduce the energy consumption per bit for uplink data transmission in the system [8]. Mabodi et al. focused on the ability of IoT nodes to provide general intelligent predictions and used a method to reduce gray hole attacks by inspecting node information. The approach involved validating trust in IoT nodes, testing routes, detecting gray hole attacks, and eliminating malicious attacks in the MTISS-IoT process. Experimental results demonstrated a high detection rate [9]. Dynamic data prediction algorithms have been studied in various fields, and Huang et al. conducted research on the numerical simulation process of Steam-Assisted Gravity Drainage (SAGD). They developed and tested a workflow based on a data-driven model for predicting SAGD production performance. A comparison of different machine learning algorithms indicated that a model based on Gated Recurrent Units (GRU) exhibited the best predictive capability [10]. Xiao et al. considered the spatiotemporal dynamic characteristics for air quality prediction and proposed a Dual-Path Dynamic Directed Graph Convolutional Network (DP-DDGCN) for air quality prediction. The model aimed to comprehensively capture dynamic spatial dependencies, and experimental results showed its superior performance in predicting PM2.5 concentration [11].

In summary, although scholars have conducted extensive research on algorithms and functional optimizations to enhance IoT performance, more research has been done on application improvement, node prediction, and performance enhancement for IoT only. There has been limited optimization of the entity information search process. However, the search optimization for dynamic data content of sensor nodes has important potential application value in IoT performance transmission. Therefore, the research started from three aspects: compression of data resources, dynamic prediction, and real-time search, and designed an IoT entity information search system based on data dynamic algorithms, which to a certain extent fills the research gap of entity information search.

III. Design of Data Dynamic Prediction Algorithms for Entity Information Search in IoT

Traditional IoT search methods involve broadcasting search requests to each sensor node, enabling real-time acquisition of dynamically changing node status information. However, this approach leads to high communication overhead, bandwidth consumption, and consequently, a reduction in the lifespan of nodes. To address this challenge, research has been conducted on data dynamic prediction algorithms, proposing a novel architecture for an IoT search system to overcome the inadequacy of existing internet search engines in providing real-time results within the IoT environment.

A. Design of IoT Entity Information Search System Based on Data Dynamic Prediction Algorithms

The study focused on researching data dynamic prediction algorithms for IoT entity information search processes, integrating web technologies into the IoT domain. They proposed a Web of Things (WoT) search system based on data dynamic prediction algorithms. The architecture of this search system is illustrated in Fig. 1.

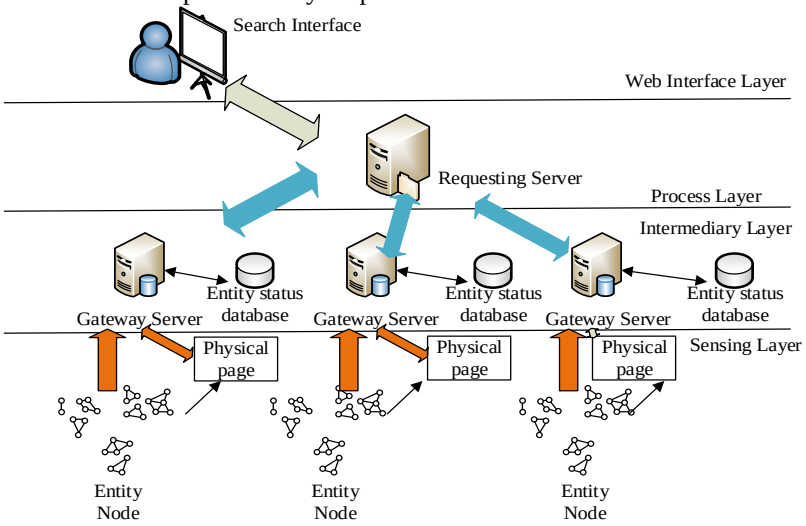

Fig. 1. WoT search system.

As shown in Fig. 1, the WoT Search System is primarily divided into four layers, each serving different functions to achieve efficient, flexible data processing, and user interaction. The Sensing Layer constitutes the core of the system's data source, consisting of numerous sensor nodes responsible for collecting environmental data. These data undergo initial compression processing within the nodes themselves to reduce transmission burdens. The Mediation Layer (Gateway Service Layer) acts as the hub for data processing and forwarding, collecting data from the Sensing Layer for further analysis and prediction, ensuring real-time and accurate data. Simultaneously, this layer responds to external query requests, retrieving and filtering relevant data. The Processing Layer (Request Service Layer) serves as the direct processing center for user requests, analyzing user queries, interacting with the Mediation Layer, integrating acquired data, and optimizing the presentation order of results. The User Interface Layer provides users with an intuitive, user-friendly interface, presenting complex backend data processing results in a clear and concise manner to meet specific user query requirements. This search system is based on existing search technology and optimized for the characteristics of IoT network architecture.

B. *Data Compression Algorithm based on SDT Compression Algorithm*

In order to enhance the efficiency and accuracy of network searches, data compression technology is employed to reduce data transmission volume and enable accurate querying of IoT node statuses through efficient prediction of sensor data. This approach effectively improves the utilization of network and server resources, ensuring users obtain satisfactory search results. Among various compression algorithms, the study compared lossy and lossless compression algorithms, and the Swinging Door Trending (SDT) algorithm, characterized by lower compression rates, lower time complexity, simplicity, and minimal system resource usage, emerged as a suitable choice for compressing sensor data in IoT sensor networks [12]. Refer to Fig. 2 for an illustrative diagram of the SDT algorithm.

The SDT algorithm is a compression algorithm designed for time series data. It introduces the concept of a "swinging door" that allows data to fluctuate within a preset error range. When data points deviate from the set threshold, the algorithm creates a new data segment. The core of SDT lies in balancing data fidelity and compression rate, maintaining sufficient data information while eliminating redundant data. This method is particularly effective in industrial process control and real-time data monitoring systems, significantly reducing data storage and transmission requirements while ensuring critical information is not lost. The SDT algorithm's implementation process selects the first sampled data point of the sensor as the starting point, and the sampled value sequence is as shown in Eq. (1).

$$P = \{t_i, p(t_i)\} \quad i = 1, 2, \cdots, n \tag{1}$$

In Eq. (1), where i represents the sampling time point and $p(t_i)$ is the corresponding sensor value at time t_i, as shown in Fig. 2, A is the starting point of a data segment, and the sampled value is denoted as $p(t_A)$. B is a sampling point after A, with a sensor data compression precision Δe, and the trend line calculation Equations are given by Eq. (2) and Eq. (3).

$$K_{AB}^{1} = \frac{p(t_B) + \Delta e - p(t_A)}{t_B - t_A} \tag{2}$$

Eq. (2) represents the upper limit of the trend line, where $p(t_B)$ represents the sampled value of B, and the calculation Equation for the lower limit of the trend line is given by Eq. (3).

$$K_{AB}^{2} = \frac{p(t_B) - \Delta e - p(t_A)}{t_B - t_A} \tag{3}$$

Eq. (3) is the calculation Equation for the lower limit of the trend line. After adding C to the samples, the slope K_{AC} of the line segment AC is calculated using Eq. (4).

$$K_{AC} = \frac{p(t_C) - p(t_A)}{t_C - t_A} \tag{4}$$

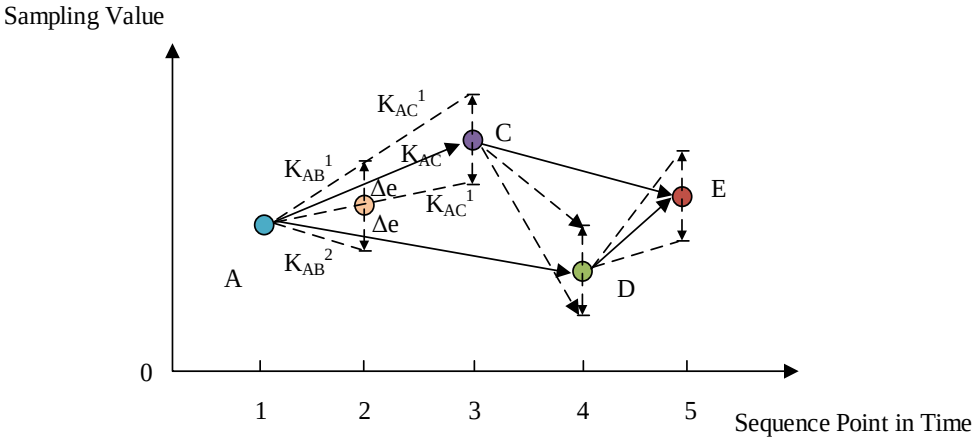

Fig. 2. SDT algorithm.

In Eq. (4), if $K_{AB}^1 \le K_{AC} \le K_{AB}^2$, it indicates that the segmentation compression condition is satisfied. Compression is performed on point C, and trend lines K_{AC}^2 and K_{AC}^1 are calculated following Eq. (2) and Eq. (3) for further assessment. Otherwise, if K is not equal to A, it indicates that the condition is not satisfied. The data at point B is saved, and the slope of the trend line BC is recalculated for further assessment. This operation is repeated for different data points until all data points are compressed, ensuring that the compression precision loss for each sampling point is less than Δe. For decompression, the first step is to extract the sensor data set UT that needs to be decompressed. All the data in $U\{t_i, p(t_i)\}$ are restored, assuming adjacent data points $\{t_i, p(t_i)\}$ and $\{t_j, p(t_j)\}$ have a difference expression as given in Eq. (5).

$$diff = (t_j - t_i)/t_s \quad (5)$$

In Eq. (5), $t_s = t_i - t_{i-1}$, representing the sampling time interval. When $diff = 1$, there are no sampling points between the two points, and the process moves on. If $diff > 1$, the restoration is performed, and the calculation is given by Eq. (6).

$$p(t_x) = \frac{p(t_j) - p(t_i)}{t_j - t_i}(t_x - t_i) + p(t_i), \quad x = i, i+1, \cdots, j \quad (6)$$

This operation is repeated until all data points are restored. To address the slowly varying characteristics of sensor data, an improved rotating gate algorithm is proposed. When the sensor state is stable for a long time, only the initial state is stored to reduce data redundancy. When a significant change in state occurs, the rotating gate algorithm is activated for compression. The algorithm takes the first data point as a reference, sets a threshold, and judge's subsequent points: if the change is less than the threshold, it is ignored; if it exceeds the threshold, it is recorded, and the new point becomes the reference for continued processing. This method effectively reduces data volume while retaining key changes. The flowchart of the segmentation compression algorithm is shown in Fig. 3.

As illustrated in Fig. 3, the decompression process begins by assessing whether the difference between two consecutive sampled points is less than a predefined threshold. If the difference is small, the value of the first point is directly used as the intermediate point value. If the difference is large, the standard decompression method of the rotation gate algorithm is employed. The key advantage of this algorithm lies in its handling of stable time periods. In time ranges where node states change minimally, only one state value needs to be stored, significantly improving compression efficiency. This strategy outperforms traditional rotation gate algorithms in time periods with minimal state changes. While the improved algorithm and the original algorithm perform similarly in data segments with frequent changes, considering that IoT nodes often experience stable states, the improved algorithm effectively reduces compression ratios and errors overall, despite a slight increase in compression time. Experimental results demonstrate that this enhanced algorithm is particularly suitable for scenarios with minimal state changes in IoT search systems, effectively reducing data storage requirements within an acceptable time increase range.

C. IoT Entity Information Prediction Algorithm Design Based on LS-SVM

The study employs the Least Squares Support Vector Machine (LS-SVM) to dynamically predict changes in entity node states in IoT, aiming to reduce sensor node resource consumption and achieve real-time search [13-15]. The schematic diagram of the LS-SVM model is shown in Fig. 4.

LS-SVM is a supervised learning method based on statistical learning theory and is a variant of the traditional Support Vector Machine (SVM). It addresses classification and regression problems by minimizing a quadratic loss function, as opposed to the hinge loss function in traditional SVM, simplifying the problem-solving process. The parameters of the predictive model established in the research are presented in the figure and outlined in Table I.

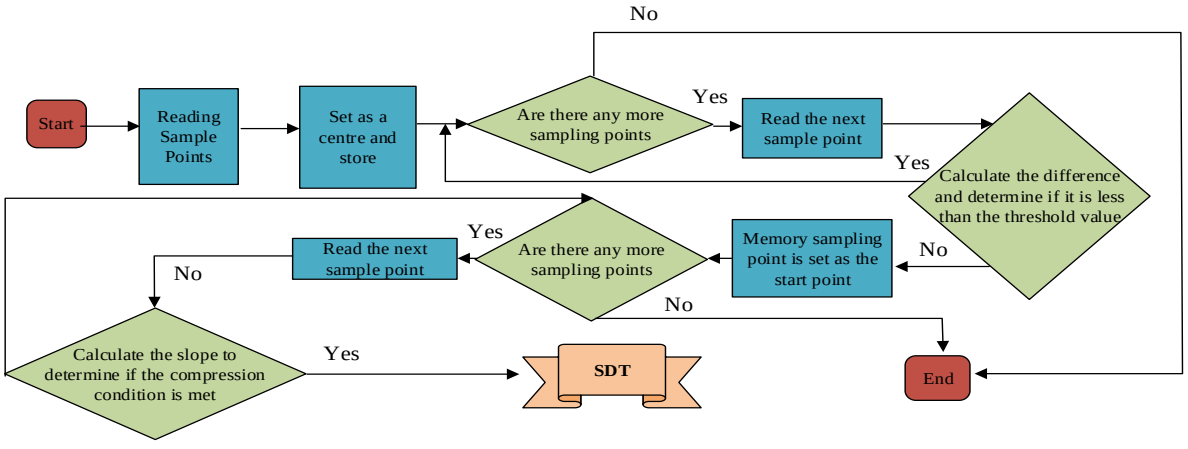

Fig. 3. Segmented compression algorithm flowchart.

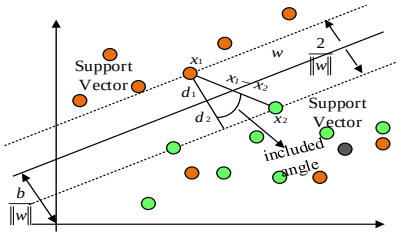

Fig. 4. LS-SVM Model schematic diagram.

TABLE I. MODEL PARAMETERS AND PROCESS

Input Parameter	✧Sensor History Sampling Value List X_{tr} ✧parametric *sigma* ✧parametric *gamma* ✧Projected point in time *time*
Output Parameter	✧Predicted sensor values *result*
Algorithm steps	
Step 1	Construct the historical data input matrix X and output matrix Y from X_{tr}
Step 2	Compute the *omega* value of the kernel function matrix from X
Step 3	Compute the value of the symmetric semipositive definite matrix A from X *omega*, *gamma*
Step 4	Compute the value of the intermediate variable b from the semipositive definite matrix A and the output matrix Y
Step 5	The value of the Lagrange factor a is obtained from the values of A, Y and b
Step 6	According to the intermediate variables and related parameters obtained from the calculation to obtain the final prediction function $f(x)$, input the predicted time point *time*, so as to obtain the predicted value of the moment *result*

Firstly, the input-output matrices X and Y are constructed based on sampled data. Following the principle of minimizing structural risk, the optimal nonlinear regression function is transformed into an optimization problem, as shown in Eq. (7).

$$\min J(w,e) = \frac{1}{2} w^T w + \frac{1}{2} \gamma \sum_{i=1}^{n} e_i^2 \tag{7}$$

In Eq. (7), w^T represents the transpose of the weight vector w, γ is a tunable parameter controlling the penalty for samples outside the error range of the function, n denotes the matrix dimension, and e_i represents the deviation between predicted and actual values. By applying the Lagrangian method to solve this function, it is transformed into a constrained problem, as illustrated in Eq. (8).

$$L(w,b,e,a) = J(w,e) - \sum_{i=1}^{n} a_i (w^T \varphi(x_i) + b + e_i - y_i) \tag{8}$$

In Eq. (8), a_i represents the Lagrange multiplier, $\varphi(x_i)$ denotes the non-linear mapping of x_i, b signifies the bias term, and x_i and y_i belong to the matrix X and the matrix Y. Employing the partial derivative method to eliminate w and e yields a set of Equations as shown in Eq. (9).

$$\begin{bmatrix} 0 & 1 & \cdots & 1 \\ 1 & \varphi(x_1)^T \varphi(x_1) + \frac{1}{\gamma} & \cdots & \varphi(x_1)^T \varphi(x_n) \\ \vdots & \vdots & \ddots & \vdots \\ 1 & \varphi(x_n)^T \varphi(x_1) & \cdots & \varphi(x_1)^T \varphi(x_n) + \frac{1}{\gamma} \end{bmatrix} \begin{bmatrix} b \\ a_1 \\ \vdots \\ a_n \end{bmatrix} = \begin{bmatrix} 0 \\ y_1 \\ \vdots \\ y_n \end{bmatrix} \tag{9}$$

Solving Eq. (9) allows us to determine the values of a and b, leading to the construction of Eq. (10).

$$f(x) = \sum_{i=1}^{n} a_i \varphi(x_i)^T \varphi(x) + b \tag{10}$$

Utilizing Mercer's transformation on Eq. (10), we derive the kernel function as depicted in Eq. (11).

$$K(x_i, x_j) = \varphi(x_i)^T \varphi(x_j) \tag{11}$$

Within Eq. (11), $K(x_i, x_j)$ represents the kernel function. Based on this kernel function, the calculation Equation for the non-linear predictive model is shown in Eq. (12).

$$f(x) = \sum_{i=1}^{n} a_i K(x, x_i) + b \tag{12}$$

The selected kernel function for study is the Gaussian radial basis kernel function, with the final predictive function depicted in Eq. (13).

$$f(x) \approx \sum_{i=1}^{n} a_i e^{\frac{\|x - x_i\|^2}{2\sigma^2}} + b \tag{13}$$

In Eq. (13), σ denotes the kernel width, and $\|x - x_i\|^2$ represents the norm between vectors. LS-SVM commonly utilizes a grid-search method in conjunction with cross-validation to determine parameters and find the combination that minimizes prediction error. This method involves constructing a grid within the parameter space to conduct a global search. Throughout the computation, a sparse grid reduces computational load but might miss the optimal parameters, while a dense grid enhances precision but increases computational complexity. This research adopts a multi-grid approach, initially defining a parameter range, selecting a set of parameter points within this range for training, adjusting the grid based on error results, gradually narrowing the search scope until finding the optimal parameter pair. This method enhances parameter optimization efficiency while controlling computational load. The system's functional module design based on the above algorithm is illustrated in Fig. 5.

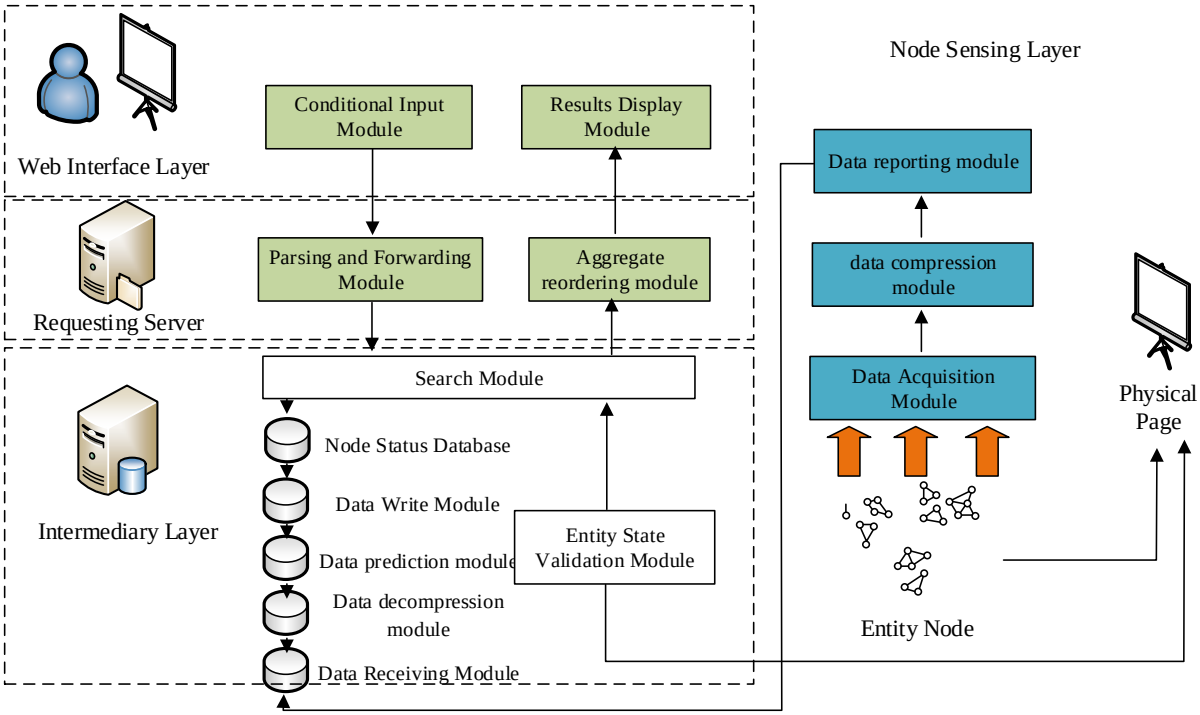

Fig. 5. WOT system functional module design.

The constructed WOT search system comprises three core layers: the node perception layer, the gateway service layer, and the frontend interface layer, developed using Python and Java. In the node perception layer, multiple simulated sensor nodes run as independent threads, periodically collecting and compressing data, then transmitting it to the gateway service layer through a data reporting module. Additionally, each node maintains a web page, recording real-time status. The server in the gateway service layer queues the received data, sequentially decompresses and restores it, utilizes the prediction module to forecast future states, and updates them in the status database. The frontend web interface layer serves as the user interaction point, receiving search requests via a browser. These requests, once parsed, are forwarded to the gateway server. The search module within the gateway server retrieves nodes meeting the criteria from the database, conducts relevance scoring and status validation, and ultimately feeds back the sorted results to the frontend for display. Despite sharing the same hardware platform in actual deployment, the request server and gateway server are logically independent, ensuring seamless system functionality. The entire search system, customized based on an open-source search engine, effectively implements the required search flow.

IV. Performance Testing of WoT System Based on Data Dynamic Prediction Algorithm

The simulated testing in this study focuses on an IoT search platform utilizing a data dynamic prediction algorithm. The testing process involves collecting multi-dimensional time series data from various physical entities, such as car engines and study room environmental data. The collected data is classified, cleaned, and ensured of its validity. After processing, the data is stored as text, with each text representing a node for testing purposes. The platform employs compression techniques to reduce data transmission, saving energy. Additionally, a prediction mechanism forecasts the future state of nodes, providing accurate search results. The main focus of the testing lies in evaluating the platform's capabilities in scenarios like fault detection and resource retrieval. The dataset used in the research is presented in Table II.

Due to limited sources for simulated testing data, the research concentrates on scenarios such as searching for a suitable study room and finding an appropriate exercise location. The first simulation scenario involves students looking for study rooms, considering factors like temperature, humidity, and light intensity. The system calculates relevance scores for study rooms, ranks them, and helps users find the most suitable place to study. The second scenario involves searching for exercise locations based on user-specified conditions like temperature, PM2.5 levels, and wind speed. The system provides a list of parks sorted according to the specified conditions, assisting users in choosing the best exercise location. The original data used in the testing follows a specific format. The research selects compression accuracy as a measurement parameter for compression algorithms. By setting different levels of accuracy, the compression effects are compared, as shown in Fig. 6.

TABLE II. RESEARCH-CONSTRUCTED DATASET

Causality	Corridor	Data format	Unit (of measure)	Example
Dates	/	Year-Month-Day	/	2004/2/28
Times	/	Hours:Minutes:Seconds. Milliseconds	/	39:46.2
Serial number	/	Integers	/	84
Node number	/	Integers	/	18.9594
Temperature value	Variation interval	Floating point type	Degrees centigrade	38.8039
Humidity value	[0,100]	Floating point type	Per cent	43.24
Light intensity	Positive number	Floating point type	Lux	2.68742
Voltage level	[0,4]	Floating point type	Vodka	/
PM2.5 data set				
Causality	Corridor	Data format	Unit (of measure)	Example
Point in time	/	"Year-Month-Day Hour:Minute:Second"	/	"2010/1/2 0:00:00"
PM2.5 concentration	Positive number	Floating point type	Micrograms per cubic metre	129
Temperatures	Float range	Floating point type	Degrees	-4
Barometric Pressure Indicator	Float range	Floating point type	Megapascal	1020
Wind speed	Positive number	Floating point type	metres/second	1.79

Fig. 6(a), Fig. 6(b), Fig. 6(c), and Fig. 6(d) present the compression test results for the segmented compression algorithm designed in the study on temperature, humidity, light intensity, and voltage data from the IntelLab dataset. Overall, it is observed that increasing compression accuracy leads to higher compression rates, as higher accuracy allows for more data loss. However, different sensor types exhibit varying sensitivities to changes in compression accuracy; humidity sensors show lower sensitivity, while temperature sensors demonstrate a more significant response. This suggests that different sensor types have unique compression behaviors. With the growth of compression accuracy, errors also increase accordingly, aligning with compression logic. Therefore, selecting an appropriate compression accuracy based on sensor data characteristics is crucial for balancing errors and reducing data volume. After testing, the research selects compression accuracies as follows: 0.5 for temperature, 1.0 for humidity, 1.0 for light intensity, 0.2 for voltage, 3.0 for PM2.5, 0.7 for humidity, 3.0 for air pressure, and 0.5 for wind speed. The study compares the proposed segmented compression algorithm with the rotation gate algorithm using the IntelLab dataset, and the results are shown in Fig. 7.

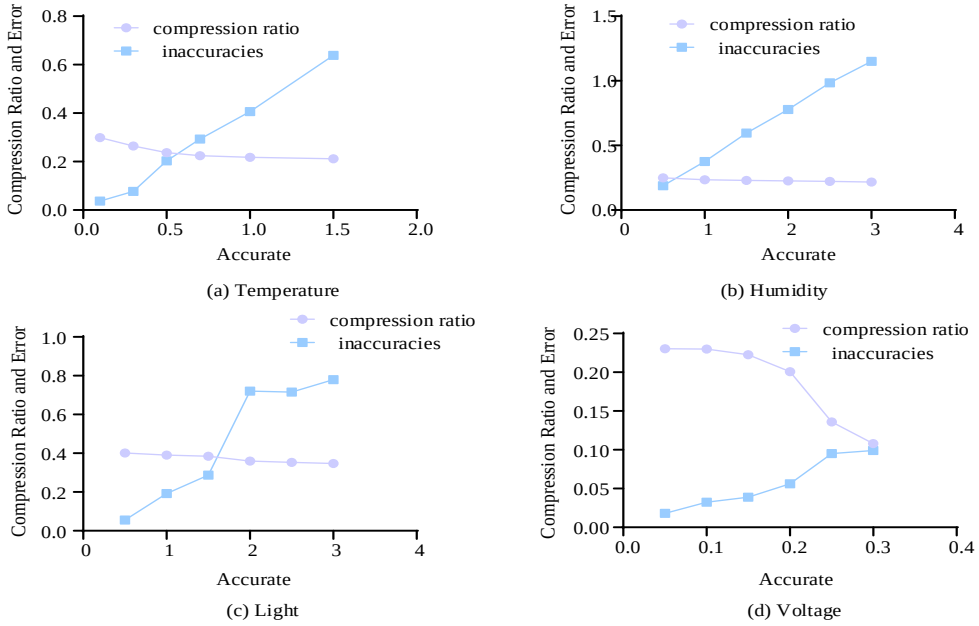

Fig. 6. Compression algorithm test results.

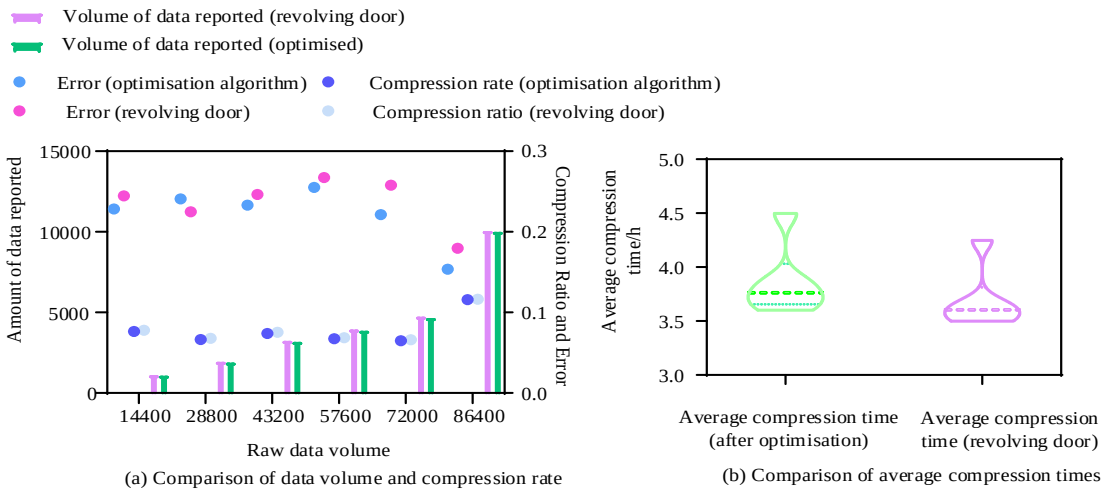

(a) Comparison of data volume and compression rate

(b) Comparison of average compression times

Fig. 7. Comparison of segmental compression algorithm and rotation gate algorithm test results.

The results of the comparison test between the proposed Segmental Compression Algorithm and the Rotation Gate Algorithm are illustrated in Fig. 7. Due to the regularity of the dataset, both the original Rotation Gate Algorithm and the Segmental Compression Algorithm exhibit stable performance in terms of compression rate and error. As seen in Fig. 7(a), the improved algorithm shows a 6.14% reduction in compression rate, a 5.95% decrease in error. However, as seen in Fig. 7(b), an increase in compression time by 13.12%. This performance improvement is attributed to the improved algorithm using initial points instead of the stable interval, optimizing the compression effect despite increased complexity and processing time. In order to achieve the goal of reducing node energy consumption, the study proposes the Segmental Compression Algorithm based on the Rotation Gate Algorithm to reduce the amount of data reported by sensor nodes. To verify its energy-saving performance, the study tests its energy savings and time relationship on two datasets, as shown in Fig. 8.

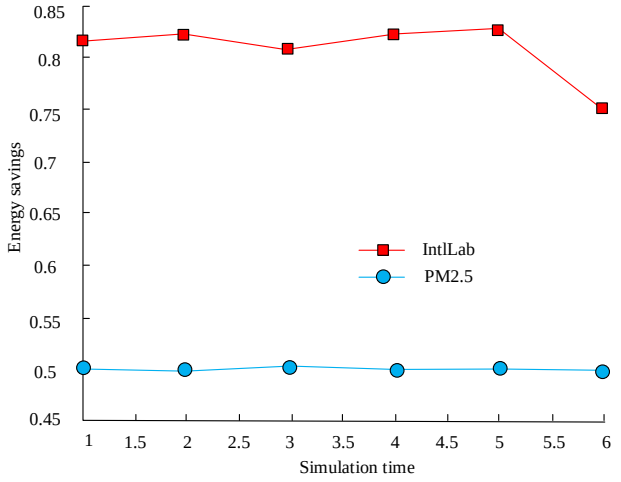

Fig. 8. Energy savings and time relationship of the segmental compression algorithm.

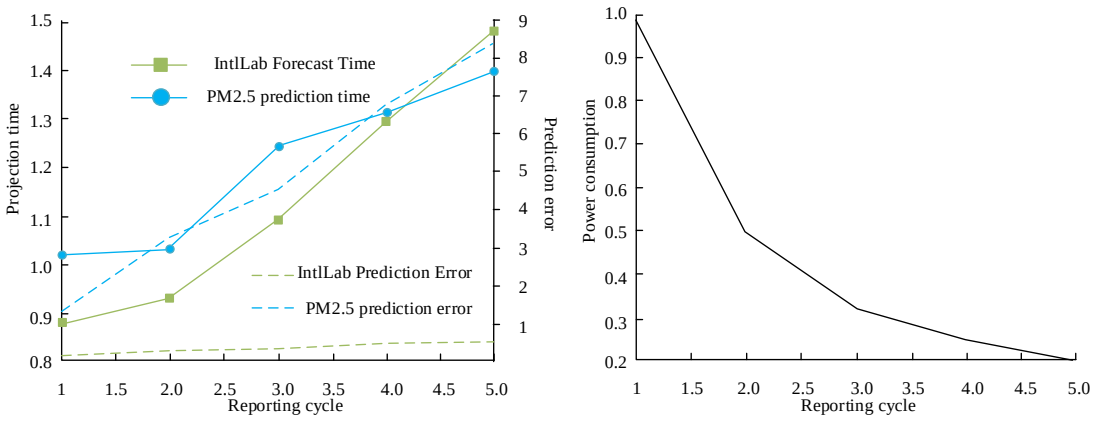
Fig. 8 presents the experimental results of the energy savings of the Segmental Compression Algorithm on the IntelLab and PM2.5 datasets over time. By applying the data compression module, energy consumption decreases by approximately 82% and 50%, respectively. This significant reduction in energy consumption is attributed to the decrease in the amount of data uploaded by nodes, reducing frequent data reporting and saving network bandwidth. Moreover, this method effectively extends the running time of nodes and the overall lifespan of the network. The training results of the prediction algorithm are shown in Table III.

TABLE III. PREDICTION ALGORITHM TRAINING RESULTS

IntelLab dataset				
Causality	Training time	Best *sigma*	Best *gamma*	Prediction error
Temp	7.417	1.537	0.927	0.516
Humidity level	15.026	2.04	0.939	0.274
Sunlight	15.058	3.941	0.902	0.086
Input voltage	14.54	8.264	-0.05	0.355
PM2.5 data set				
Causality	Training time	Best *sigma*	Best *gamma*	Prediction error
PM2.5	7.594	1.202	0.996	3.809
Temp	15.48	0.641	1.021	0.342
Pneumatic	16.017	1.819	0.895	0.238
Air velocity	15.21	1.029	0.997	2.043

As shown in Table III, setting a certain reporting period and reducing the frequency of terminal node data reporting can effectively reduce energy consumption. However, this may lead to users searching for historical data, affecting accuracy. To address this issue, a prediction module is introduced to predict the next cycle state of nodes, balancing energy consumption and search accuracy. The impact of different reporting periods on the system is analyzed using the energy consumption formula, with mean square error and prediction time as evaluation indicators. Simulation results of the prediction algorithm are shown in Fig. 9.



(a) Impact of different reporting cycles on forecasting time and error

(b) Impact of different reporting cycles on energy consumption

Fig. 9. Simulation results of the prediction algorithm.

Fig. 9 presents the comparative results of energy consumption, prediction error, and prediction time of the proposed prediction algorithm at different reporting intervals on the IntelLab and PM2.5 datasets. As seen in Fig. 9 (b), as the reporting interval increases, the energy consumption of nodes decreases, reaching 0.2 at a 5-cycle interval. However, the extension of the reporting interval means an increase in the prediction step, leading to a decrease in prediction accuracy and an increase in the uncertainty of search results. As seen in Fig. 9 (a), at a 5-cycle interval, the prediction error on the IntelLab dataset is around 0.5, while on the PM2.5 dataset, the error is 7.8. Additionally, a longer step length requires more computational resources and time, necessitating a balance between energy consumption, prediction accuracy, and computational costs. The prediction error on the IntelLab dataset is smaller than that on the PM2.5 dataset, as the former exhibits stronger data regularity with a smoother and more predictable variation. In contrast, the PM2.5 dataset has significant data variations, making predictions more challenging and resulting in higher errors. The model designed by the research has more predictive advantages on the data with strong regularity, is more applicable to this type of data. The setting of the reporting interval effectively influences the energy consumption, computational burden, and search performance of sensors.

V. Results and Discussion

IoT is a network system that realizes information interaction and interaction between devices by connecting various sensing devices to the Internet. As the expansion of the Internet in the physical world, IoT is widely used in smart home, intelligent transportation, health care and industrial and agricultural Internet of Things and it has become an important helper for people's production and life as well as an important technological means for the development of intelligence. Various industries at home and abroad have carried out extensive research and analysis on IoT, mainly focusing on exploring the network architecture and protocol design of IoT, data security and privacy protection, as well as big data analysis and intelligent decision-making. At the same time, a series of IoT-related industry standards and specifications have been formulated. Overall, IoT, as an important part of the future information society, has been highly valued by all walks of life, and its application and research fields are still developing and expanding.

Under the environment of IoT, the amount of data produced by numerous devices and sensors in real time is very large, and the Internet search engine is unable to efficiently process and index large-scale data, and the search capability of the existing Internet search engine does not satisfy the search demand of IoT. And the Internet search engine is usually based on batch indexing and offline processing, which is unable to obtain and process a large amount of real-time data produced by IoT devices in real time. At the same time, the data collected by IoT devices are usually structured or semi-structured data, and the existing search engines are difficult to deal with the semantic relationship between the data and the user, resulting in low accuracy and precision of the search results. In this regard, the research firstly adopts data compression technology to reduce the amount of sensor data to improve the storage and transmission efficiency, and then analyzes and predicts the future state of entity nodes using historical state information to improve the search accuracy and efficiency. The research-designed method reduces the compression rate by 6.14%, reduces the error by 5.95%, increases the compression time by 13.12%, and reduces the energy consumption by up to 82% on different public datasets. Moreover, the method can accurately predict the node state changes to satisfy the user's search needs.

Based on the work progress achieved in the research, future research can continue to focus on data compression and indexing technology, introduce intelligent optimization search algorithms to further improve the efficiency and accuracy of search algorithms, or carry out the exploration of distributed search engine technology, combining the technology of multiple fields to further achieve efficient, accurate, secure and personalized search services.

VI. Conclusion

The study addresses the insufficient real-time search capabilities of existing Internet search engines in the IoT environment. It investigates the architecture of an IoT search system and proposes a data dynamic prediction algorithm

tailored for searching IoT entity information. The research begins by employing data compression techniques to reduce sensor data volume, thereby enhancing storage and transmission efficiency. Subsequently, it utilizes historical state information analysis to predict the future states of entity nodes, aiming to improve search accuracy and efficiency. Performance test results indicate that the segmented compression algorithm designed in the study enhances compression accuracy and rates. As compression accuracy increases, errors correspondingly rise, aligning with compression logic. After testing, the research selects compression accuracies for various parameters, such as temperature (0.5), humidity (1.0), illumination (1.0), voltage (0.2), PM2.5 (3.0), humidity (0.7), atmospheric pressure (3.0), and wind speed (0.5). The improved algorithm reduces compression rates by 6.14%, decreases errors by 5.95%, but increases compression time by 13.12%. Application of the data compression module results in energy consumption reductions of approximately 82% and 50%, respectively. By setting specific reporting intervals to reduce frequent data reporting by terminal nodes, energy consumption can be effectively lowered. The designed prediction algorithm demonstrates that, with an increasing reporting interval, node energy consumption decreases, reaching 0.2 at a 5-cycle interval. At this point, the prediction error is around 0.5 for the IntelLab dataset and 7.8 for the PM2.5 dataset. Experimental results show that the optimized data dynamic prediction algorithm effectively reduces node data transmission, lowers node energy consumption, and accurately predicts node state changes, meeting user search requirements. However, the study has some limitations. The testing scale for compression and prediction algorithms is relatively small, lacking large-scale practical implementation, and the robustness is insufficient. Subsequent research could consider increasing the test data for experimentation.

***Abstract*—Currently, lung cancer poses a significant global threat, ranking among the most perilous and lethal ailments. Accurate early detection and effective treatments play pivotal roles in mitigating its mortality rates. Utilizing deep learning techniques, CT scans offer a highly advantageous imaging modality for diagnosing lung cancer. In this study, we introduce an innovative approach employing a hybrid Deep Convolutional Neural Network (DCNN), trained on both CT scan images and medical data retrieved from IoT wearable sensors. Our method encompasses a CNN comprising 22 layers, amalgamating latent features extracted from CT scan images and IoT sensor data to enhance the detection accuracy of our model. Training our model on a balanced dataset, we evaluate its performance based on metrics including accuracy, Area under the Curve (AUC) score, loss, and recall. Upon assessment, our method surpasses comparable approaches, exhibiting promising prospects for lung cancer diagnosis compared to alternative models.**

***Keywords*—Diagnosis; CT images; deep learning; convolutional neural network; lung cancer**

I. Introduction

The rising incidence of pulmonary ailments in contemporary industrialized societies underscores the urgent requirement for innovative models facilitating early and precise detection. Lung cancer, among these maladies, stands out as one of the most formidable cancers, contributing to a third of all cancer-related fatalities [1]. Consequently, it holds the grim distinction of being the deadliest and most hazardous cancer. Following diagnosis, approximately 80% of patients face a five-year survival prognosis, highlighting the severity of this disease. Air pollution ranks among the primary catalysts for lung cancer development [2]. Early detection of lung diseases significantly impacts the likelihood of successful treatment. Diagnosis typically involves a range of methods, including imaging modalities such as radiography, CT scans, biopsy, chest mucosa tests, and bronchoscopy. Lung nodules, characterized as small, round, and hazy masses within lung tissue, are radiographic opacities with diameters less than 30 millimeters [3, 4].

Enhancing the performance of CNNs involves incorporating task-specific layers tailored to the desired application. CNN models mimic certain aspects of human visual processing, thus enabling effective image analysis akin to human brain functions [5]. Consequently, extensive research has focused on utilizing CNNs for the automatic classification of lung cancer nodules from CT images. However, traditional CNN architectures typically rely solely on CT image features, neglecting potential contributions from physiological data that could enhance lung cancer diagnosis [3]. Conversely, advancements in medical IoT methodologies have facilitated remote patient monitoring, leveraging wearable health sensors. These sensors monitor various vital signs including blood pressure, body temperature, heart rate, respiratory patterns, weight fluctuations, and sleep behaviors [6, 7]. Notably, certain indicators such as anorexia, anxiety, constipation, depression, and fatigue pose challenges for direct tracking via wearable sensors [8].

However, there are alternative approaches that utilize textual and graphical interactions through mobile applications, offering symptom-based data that can aid in diagnosing lung cancer [9, 10]. This study introduces a medical body area network integrating medical IoT technologies and mobile applications. A data normalization technique, facilitated by the application programming interface, is employed to receive and process the data. Subsequently, the processed data is stored in a database using a relational schema.

Various studies have been conducted to identify and characterize lung diseases. Due to the abundance and complexity of lung radiographic images, distinguishing nodules from veins, wounds, and other structures poses a significant challenge for medical practitioners [4]. Computer-aided diagnosis systems serve as valuable tools to assist physicians in disease diagnosis. This paper introduces a novel approach based on a hybrid Deep Convolutional Neural Network (DCNN), trained on CT scans and medical data obtained from wearable IoT sensors. Our method incorporates a CNN with 22 layers, leveraging hidden features extracted from both CT images and IoT sensor data to enhance detection accuracy. Training our model on a balanced dataset, we evaluate its performance based on accuracy, Area Under the Curve (AUC) score, loss, and recall metrics.

The motivation behind this study stems from the pressing need for improved methods of early detection and precise diagnosis of lung cancer, given its significant impact on public health. With lung cancer accounting for a substantial portion of cancer-related deaths globally, there is an urgent requirement for innovative models that can aid in early detection, thereby improving treatment outcomes and patient survival rates. Traditional diagnostic methods, while effective to some extent, often rely solely on imaging modalities and may overlook valuable physiological data that could enhance diagnostic accuracy. Moreover, advancements in medical IoT technologies offer opportunities for remote patient monitoring, presenting a wealth of physiological data that could be leveraged for improved lung cancer diagnosis. By integrating

these disparate data sources and utilizing advanced machine learning techniques, using the DCNN, this study seeks to develop a novel approach that enhances the accuracy and efficiency of lung cancer detection, ultimately contributing to improved patient care and outcomes.

The subsequent sections of this article are structured as follows: Section II presents a literature review. Section III provides a detailed description of our proposed method. Section IV outlines the dataset used, tests performed, and results obtained. Finally, Section V offers conclusions and recommendations.

II. Related Works

Considerable progress has been made in lung cancer diagnosis, with numerous studies contributing to this field. In this section, we provide an overview of some notable research endeavors.

In study [11], researchers utilized Artificial Neural Network (ANN) techniques to analyze chest radiograph images for lung cancer detection. Their approach involved a novel method for identifying lung cancer from raw X-ray images sourced from the JSRT database. Initially, conventional image processing techniques were employed to reduce noise and differentiate lung structures from other anatomical features present in chest X-rays. Subsequently, regions displaying characteristics indicative of pulmonary nodules were isolated from the images. These areas were then subjected to statistical analysis, with the first and second categories of tissue statistical characteristics serving as input for ANN training. This process aimed to ascertain whether the identified regions represented nodules in the initial stage of diagnosis.

In study [12], the authors explored the use of CNN with transfer learning for the diagnosis of non-nodules, benign nodules, and malignant nodules, along with determining nodule locations. The experiments have shown that this proposed model has less ability in the characterization of the nodules of the benign and the nodules of malignant, and it is also unable to determine the exact location of the nodule. In study [13], the authors have used the K-nearest neighbor classifier in their proposed system. This classification identifies the K-nearest neighbor among all nodule candidates by searching in the feature space. Finally, the probability of nodule detection will be $\frac{n}{K}$, where n displays the number of the real nodules between K adjacent neighbors. They have stated in their article that the classification results are largely independent of the number of neighbors.

In study [14], a method combining features derived from wavelet transform and morphological characteristics was employed as input for Multilayer Perceptron (MLP). The number of neurons in the first layer of MLP depended on the input feature count, with neuron outputs determining whether a candidate region represented a nodule or normal tissue while neural networks excel in training based on explicit error criteria such as mean square error, direct comparison of network efficiency remains challenging. Neural networks suffer from the time-intensive nature of their training phase, exacerbated by the random selection of initial weights that are adjusted during learning, leading to varying separation thresholds. Thus, achieving an optimal configuration necessitates running the network multiple times with different initial weights and evaluating efficiency criteria.

In study [15], a combination of Artificial Neural Networks (ANN) and fuzzy clustering was employed for lung cancer diagnosis using CT scan images. Their model comprised four stages: pre-processing, target area evaluation, feature extraction, and final classification using ANN. Pre-processing involved various image enhancement techniques to enhance tumor observations in CT scan images. Subsequently, the target area was identified, and its features were input into the classification phase for diagnosis.

In study [16], the authors have presented a model based on the automata of cellular learning to detect cancer of the lung by using CT scan images. Their images contain both undesirable and significant features crucial for processing. In this framework, they employed pre-processing techniques, such as Gabor filtering, to enhance CT scan images. Images from prior stages were fed into the cellular learning automata for training, followed by extraction of automata rules. In study [17], the classification of the tumor tissue by using recurrent networks along with short-term memory is presented. The training samples are obtained from the real soft tissue samples through the tomography, and they are given as the input to the network. Their tests show that this classifier is a good choice for the classification. In study [18], authors utilized a combination of two-dimensional and three-dimensional models for pulmonary nodule detection, resulting in reduced false positive errors.

In study [19], the authors have used the model of ANN and the clustering of the fuzzy to detect the cancer of the lung. They have used two methods of the Hopfield neural networks and the clustering fuzzy algorithm to segment the color images. The experiments have displayed which ANN of Hopfield outperforms for the classification from the fuzzy clustering. In [20], the convolutional neural network with a cut has been used to diagnose the nodules of the pulmonary by the images of CT. The difference between their model and the traditional CNN model is in the use of a creative aggregation function. In [21], the main focus was on the feature extraction from the 3D CT images, and for this purpose, the morphological operators were used to thin the images. The classifier used in study [21] was the support vector machine. In study [22], to extract the feature, the embedded linear local maps have been used and correlation coefficients have been used to adjust the distance criterion in LLE.

The existing research landscape in lung cancer diagnosis reveals a plethora of methodologies, each with its strengths and limitations. However, a critical gap exists in the current literature, prompting the need for further investigation. While previous studies have explored various techniques, including ANN, CNN, and hybrid models, each approach has encountered challenges in accurately diagnosing lung cancer nodules. For instance, while ANN methods have shown promise in analyzing chest radiograph images, they may struggle with the precise identification of nodules due to limitations in feature extraction. Similarly, CNN models, despite their success in image classification tasks, may lack the ability to accurately determine nodule locations or characterize

benign versus malignant nodules. Moreover, techniques such as fuzzy clustering and cellular learning automata have demonstrated potential, yet their effectiveness in addressing the complexities of lung cancer diagnosis remains uncertain. Thus, there is a pressing need for novel methodologies that address these limitations, offering improved accuracy, robustness, and efficiency in lung cancer detection. This research gap underscores the motivation for the present study, which seeks to develop an innovative approach leveraging medical IoT data and advanced CNN architectures to enhance the accuracy and reliability of lung cancer diagnosis.

III. Our Presented Approach

Our method integrates CNN with medical IoT sensors, establishing a medical body area network that furnishes vital data for classification purposes. This approach significantly bolsters the reliability and precision of diagnosis. Following initial classification, identified nodules undergo segmentation, with subsequent sub-classification based on nodule size. This method typically unfolds in four sequential steps. Firstly, data collection entails transmitting sensor data from wearables and CT scanners to a central server. Next, data undergoes processing to train the network, encompassing numerical data processing and image data processing. In numerical data processing, data are condensed and outliers are identified and removed. Meanwhile, image preprocessing is performed to enhance features by minimizing the feature distance between cancerous and non-cancerous nodules. Subsequently, sub-classification based on nodule size ensues. The final step entails detection and decision-making based on predictions generated by our trained model.

It should be noted that the last conformity of the 5G technology in mobile has enabled advanced functionality of medical IoT sensors for the monitoring and the transmission of related data in real-time. These sensors can identify patient symptomatic information and send it to specified servers in real-time via the Internet. In the following and each of the below sub-sections, more details of our presented approach are provided.

A. First Step: Data Collection

As described, the medical IoT sensors form a network, depicted in Fig. 1(a). This network comprises sensors responsible for collecting physiological data. Communication within the network is structured into three levels, as illustrated in Fig. 1. Level 1 encompasses communication between sensors. Level 2 involves final devices utilized by patients for monitoring, accessing, and transmitting data to our proposed method. Level 3 manages the secure transmission of physiological data and CT images to the proposed method's server. Data collection occurs through two methods: active monitoring and passive monitoring. Active monitoring involves data collection via wearable IoT sensors, while passive monitoring involves patient interaction with sensors to generate data. This includes physiological data obtained through a mobile app and CT images. Level 2 networks comprise final devices utilized by patients, where physiological data is stored. Patients can access CT images through client-server communication. The server used in our proposed method receives data sent from the network at this stage.

In addition, the communication of the point of the access is maintained via the key of PreShared, it is applied as the main key of the pairwise in the 4 method-method handshakes [23]. Four thousand ninety-six iterations create PMK with 256 bits. The mentioned procedure exploits the function of the derivation of the key basis on the password, which is described in the relation as shown in Eq. (1):

$$PSK = PBKDF2\ (HMAC - SHA1.Password.SSID.4096.256) \quad (1)$$

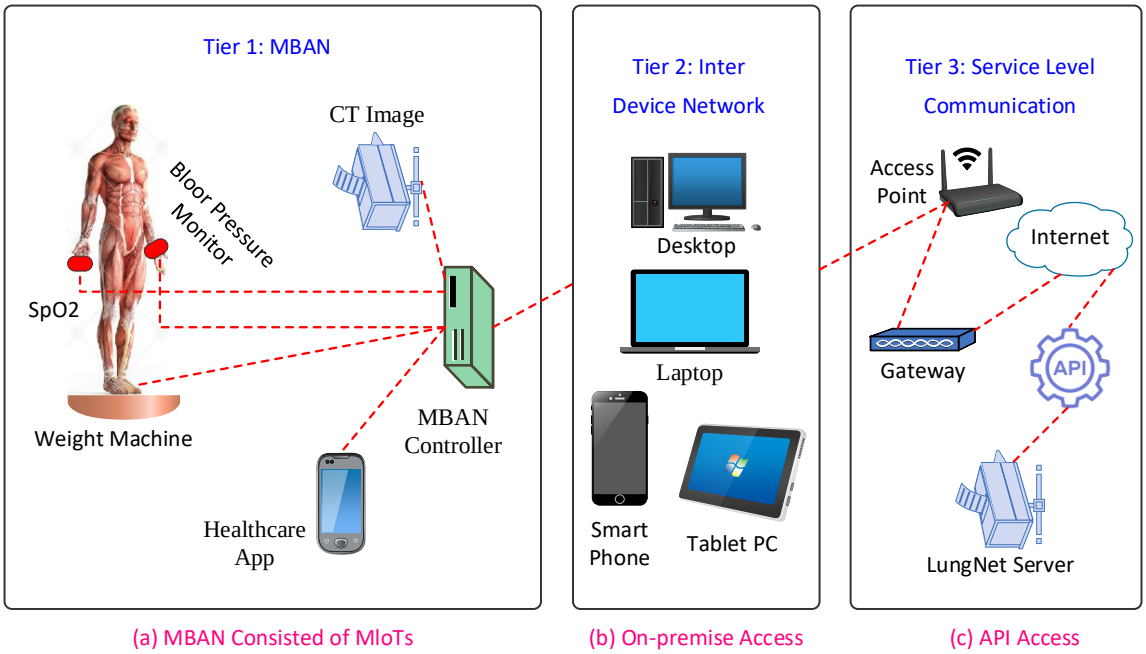

Fig. 1. The framework of the medical body area networkCT image.

A function of the Hash-based Message Authentication Code (HMAC) is applied for the generation of the hash of the password. On the mentioned test, the password has 16 characters, which are codified with the use of the ASCII of the printable. The counter of the packet and the service set identifier (SSID) are applied as the salt of the password. Then, the data is transmitted to the server with the patient's approval. The task manager checks the type of the data of the input. Next, the method schedules the tasks. Once data is placed in the database, the next stage is started. In these stages, the data is processed for the training, the validation, and the test of the model based on DNN. The data that is displayed by the portal of the patient doctor is also processed from this data.

B. Second Step: Pre-processing of Collected Data

The performance of Deep Neural Network (DNN)-based models relies heavily on both the quantity and quality of the data, emphasizing the importance of data preprocessing. Particularly, the focus lies on preprocessing imaging data related to lung cancer nodules, which often requires several stages of refinement. In this section, we outline the methods applied for preprocessing both non-image and image data.

Firstly, let's discuss non-image data preprocessing. Non-image data is typically gathered from sensor responses or patient interactions with healthcare applications. Wearable sensors capture various data such as temperature, irregular heartbeat, breathing patterns, and blood pressure. Additionally, non-wearable sensors are utilized for measuring weight loss and managing CT image data. Patient interactions also provide valuable data, including reports of anorexia, anxiety, depression, pain, insomnia, fatigue, and constipation. These signals and the relevant sensor values are normalized with the use of the defined linear normalization by relation as shown in Eq. (2). The lack of the related data is exchanged by NA. But, in the numerical calculations, these values are considered as 0. s' displays the normalized data, and s displays the real data.

$$s' = \frac{s - \min(s)}{\max(s) - \min(s)} \tag{2}$$

However, when dealing with image data, a distinct preprocessing approach becomes necessary. Image data processing comprises three main stages: 1) resizing and transforming the images; 2) validating candidate images; and 3) segmenting symmetrically with feature enhancement. Each Convolutional Neural Network (CNN) has a fixed input layer size, but there's no assurance that the input image size will align perfectly with the input layer size. Additionally, CNN input layers can only process a certain number of channels at a time. Hence, it's crucial to resize images and adjust color spaces according to network specifications. Certain CT scans may include regions with minimal lung tissue or even areas devoid of lung tissue entirely. Removing these sections improves the quality of training data.

Moreover, the ambiguous characteristics of lung cancer nodules pose challenges to the efficacy of feature learning layers. Consequently, it becomes imperative to augment the features of lung cancer nodules. The initial preprocessing step involves resizing images and transforming color spaces. The input layer size of our proposed model is set at 224×224×3. The collected data for this experiment includes both three-channel and one-channel images. All images are resized to 224×224 while maintaining the aspect ratio to streamline training duration. Furthermore, one-channel images are converted to RGB three-channel images using Eq. (3).

$$I_{RGB} = I_{(Gray.R)} + I_{(Gray.G)} + I_{(Gray.B)} \tag{3}$$

I_{RGB} represents our created RGB image from the grayscale image. Also, $I_{(Gray.R)}$, $I_{(Gray.G)}$ and $I_{(Gray.B)}$ represent, respectively, the equivalent value of the gray for the red channel, the equivalent value of the gray for the green channel, and the equivalent value of the gray for the blue channel. The size resizing of the image does not modify the data inside it due to the logical change. Even after the transformation of it into an image of 3-channel, our essential features stay without change. Our second processing of the image data is the candidate image validation. In this stage, the function of the validation takes the images. Then, it validates whether the image displays a candidate valid or not. The candidate's set of valid and set of invalids are shown in Fig. 2. If the image of the input does not include a part of the effective lung, which the nodules can be recognized, then the function ignores this image. Differently, this function rebounds the pre-processed copy of the image, and then, the algorithm exploits it for more pre-processing. This function takes the images of RGB (I_{Color}) which it is described as below:

$$I_{Color} = \sum_{n=1}^{N}\sum_{m=1}^{M} I(n.m.g) + \sum_{n=1}^{N}\sum_{m=1}^{M} I(n.m.r) + \sum_{n=1}^{N}\sum_{m=1}^{M} I(n.m.b) \tag{4}$$

Also, the image of RGB is transformed into an image of the grayscale by using relation, as shown in Eq. (5).

$$I_{gray}(n.m) = \alpha I_{Color}(n.m.r) + \beta I_{Color}(n.m.g) + \gamma I_{Color}(n.m.b) \tag{5}$$

α, β, and γ denote the constants for the red, green, and blue channels, respectively. It is essential to calculate the part area of the lung in the image because it is necessary to check whether I_{Color} is a valid candidate or not. It is easier and faster to measure the lung area in the binary image. The threshold of the gray conversion I_{gray} into the binary image is calculated by using the Otsu method, which is shown in the relation (6):

$$\sigma_b^2(t) = \sigma^2 - \sigma_w^2(t) = \omega_0(\mu_0 - \mu_T)^2 + \omega_0(\mu_1 - \mu_T)^2 \tag{6}$$

where, $\sigma_b^2(t)$ is the maximum threshold and σ^2 represents the variance and μ_0 represents the mean. Also, ω_0 is the weighted probability. The obtained threshold from the relation (6) is used to transform $I_{gray}(n.m)$ into a binary image $I_{bin}(n.m)$ by using the relation (7).

$$X = \begin{cases} 1 & I_{gray}(n.m) \geq \sigma_b^2(t) \\ 0 & otherwise \end{cases} \tag{7}$$

A binary image contains small noise objects that these objects have areas of about 450 -5000 pixels. The obtained

objects influence the accuracy of the learning of the layers of the learning of the feature. Thus, that is why it is essential to discard these cases. The opening of the region of the morphological is applied for the removal of the objects by a value of the threshold equal to 5000. The series of little holes remain in the foreground after the region opens. To remove the holes, the operation of the flood filling by the four-way connection is applied.

$$I_{fill}(n.m) = Flood_{filling}(area_{opening}(I_{bin}(n.m))) \quad (8)$$

where, $I_{fill}(n.m)$ displays the image after filling the holes and $I_{bin}(n.m)$ is the binary image. Next, the image of the binary is deduced by the filled image. Finally, it renders the lung form as an object in the foreground.

$$I_{sub}(n.m) = I_{fill}(n.m) - I_{bin}(n.m) \quad (9)$$

where, $I_{sub}(n.m)$ displays the image after the deduction of the image of the binary by the filled image. Then, the area is computed with the implementation of a logical operation of AND among $I_{sub}(n.m)$ and the logical 1, which is shown in the relation (10).

$$Area = \sum_{n=1}^{N}\sum_{m=1}^{M} I_{sub}(n.m) \wedge Logical(1) \quad (10)$$

Assuming the area exceeds 20,000, we consider the image to represent a valid candidate for lung cancer nodule diagnosis. Conversely, if the area falls below 20,000, the image is deemed invalid. Validating the candidate confirms the efficacy of the feature learning layer and captures key features crucial for lung cancer nodule classification. Thus, this method serves to enhance the quality of lung cancer image datasets.

Lastly, the third step in image data processing involves segmenting the lungs symmetrically and enhancing features. Following validation, symmetric segmentation is performed. The segmented lungs, enhanced by improved features, are illustrated in Fig. 3. The lung separation function operates on the pre-processed binary image copies of valid candidate images (I_sub(n.m)). At this stage, both the left and right lungs are presented in a composite image. To separate the left and right lungs, two separate masks need to be generated. This process initiates by convolving an image of zeros with the grayscale image and saving the results as left and right masks, as described in Eq. (11) and Eq. (12).

$$L_{mask} = \sum_{n=1}^{N}\sum_{m=1}^{M} I_{gray}(n.m) \otimes I_{zero}(n.m) \quad (11)$$

$$R_{mask} = \sum_{n=1}^{N}\sum_{m=1}^{M} I_{gray}(n.m) \otimes I_{zero}(n.m) \quad (12)$$

L_{mask} and R_{mask} indicate the mask of the left and the mask of the right. $I_{sub}(n.m)$ contains more than one area with the values of the pixel of the binary. For the segmentation of the obtained areas, it is necessary to label them. The labeling is performed with the use of the relation (13) where $K = \{x | x \in N\}$ and I_{str} is an 8-connection morphological structure with the pixel values equal to 1.

$$L_K = (L_{K-1} \otimes I_{str}) \cup I_{sub} \quad (13)$$

where, L_K is the label of the region K. Also, $I_{sub}(n.m)$ can have a maximum of two regions. That is why, $L_K = \{x \mid x \in N. x \leq 2\}$. In L_{mask} where $L_K = 1$, the values of the pixel are filled. In the same way, in R_{mask} where, $L_K = 2$, the values of the pixel are also filled. Finally, L_{mask} and R_{mask} are deduced by the main image to fill masks further. Next, the opening of the morphological with the ellipse has a main axis equal to 90 pixels and a height equal to 10 pixels. This case is used in 2 masks and the other complementary action, which is described by the relation (14). M_o displays the opening of the morphological and M_{mask} represents the mask of the left and the mask of the right.

$$X_{mask} = 1 - M_o((1 - X_{mask}).\frac{n^2}{90^2} + \frac{m^2}{10^2} \quad (14)$$

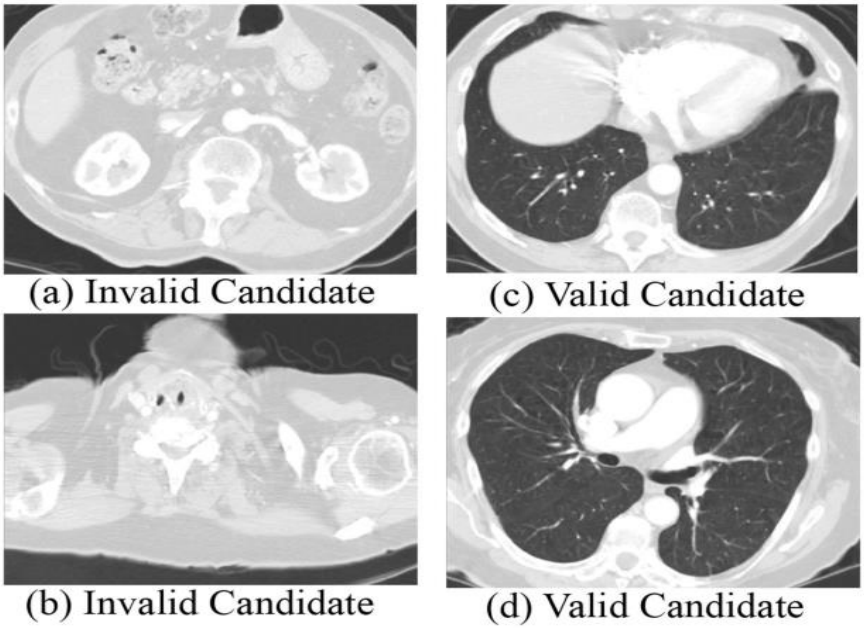

Fig. 2. (a,b) the candidates of the invalid; (c,d) the candidates of the valid.

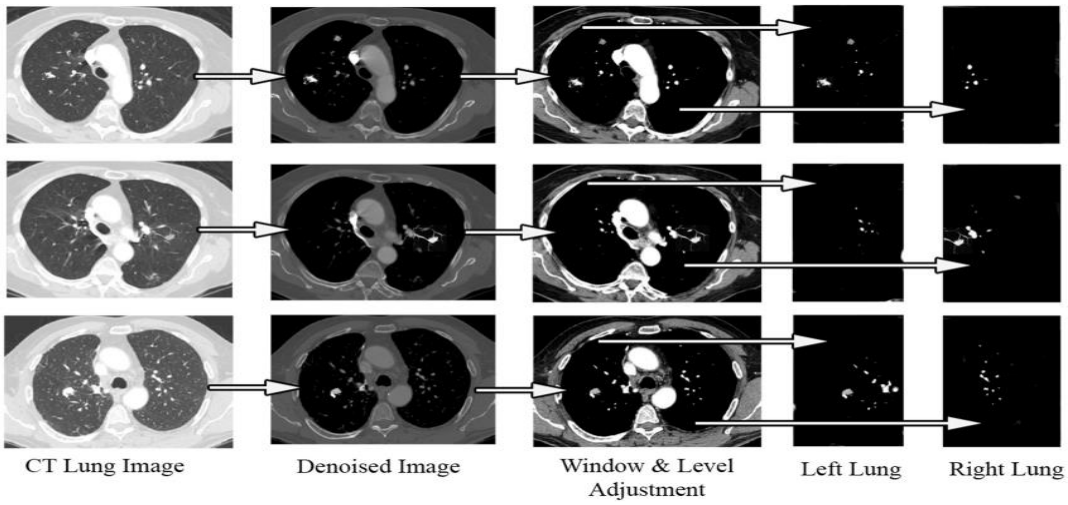

Fig. 3. The segmentation of the symmetric and the enhancement of the feature in the image data processing stage.

The obtained masks from the relation (14) include a blurred gradient. Binarization for X_{12} in the value of the threshold equal to 0.5 returns the severe discontinuities.

$$X_{mask} = \begin{cases} 1 & X_{mask} \geq 0.5 \\ 0 & otherwise \end{cases} \quad (15)$$

Finally, the masks are connected with $I_{sub}(n.m)$ as separately and then, it separates the lung of the left and the lung of the right from the image of the source.

$$I_{lung} = \sum_{n=1}^{N} \sum_{m=1}^{M} I_{gray}(n.m) \otimes X_{mask}(n.m) \quad (16)$$

Here, I_{lung} represents the lung of the left and the lung of the right separately. If $I_{gray}(n.m)$ is convolved by the mask of the left, relation (16) creates the left lung. Similarly, when $I_{gray}(n.m)$ is convolved with the right mask, the relation (16) creates the lung of the right. Finally, the lung of the left and the lung of the right are elided together.

The enhancement of the feature is a successive procedure that this procedure begins with noise removal. The non-local average methods, under the control of the relation (17), have been applied to the current test for the removal of the noise from the image, which in it, $\nu(I_f)$ displays the pixel of the filtered, $\nu(I_s)$ displays the pixel of the target and $\upsilon(I_s)$ represents the value of the unfiltered in $\nu(I_f)$. Also, $f(I_f.I_s)$ is the weighting function [24].

$$\nu(I_f) = \frac{1}{c(I_f)} \int_{n \times m} \upsilon(I_s) f(I_f.I_s) dI_f \quad (17)$$

Following noise removal, the adaptive histogram equalization algorithm, leveraging genetic algorithms [25], is applied. Subsequently, a surface contrast enhancement window is utilized to eliminate irrelevant features unrelated to lung cancer nodules. The segmentation result of the symmetric and the outcome of the feature enhancement process are depicted in Fig. 3. Augmenting data is one strategy employed to address overfitting challenges. However, the annotated dataset, even with input from radiologists, proves insufficient for achieving optimal classification efficiency in our model. Moreover, a significant disparity exists between the number of positive and negative training images, leading to imbalanced data in predictive modeling. To address this, we employ data augmentation techniques to generate additional relevant data from the existing dataset, thereby balancing the number of positive and negative images. Sufficient training samples are created through random spatial transformations and data augmentation methods.

C. Third Step and Fourth Step: Proposed Network, Training, and Classification

The proposed method introduces a unique network structure and a combined classification approach. This method employs a deep network with 22 layers, enabling it to learn distinctive features of lung cancer nodules. Additionally, the combined classifier enhances efficiency and provides more reliable predictions by leveraging data from the medical body area network. The CNN architecture used in our method is illustrated in Fig. 4, featuring a convolutional neural network with 22 layers and an input layer size of 224×224×3. Rectified Linear Unit (ReLU) functions are applied as activation functions for each convolution operation in the network.

Given the centralized server used by the network, reducing operational costs and maintaining accuracy presents a challenge. To address this, we adopt an alternative method compared to advanced CNN models, which typically utilize convolution operations of size n×n. Instead, our proposed model employs convolution operations of size 1×1, resulting in reduced weights and biases. However, this deepens the network model, leading to a performance reduction of 46%. It's worth noting that fully connected CNNs are popular among researchers in lung cancer diagnosis due to their satisfactory efficiency [26].

Nevertheless, a model of the fully connected needs further resources of computational from the models of the sparsely connected [27]. That is why, thus, in our proposed method, a model of the non-fully-connected is applied. In addition, a global layer of the average-pooling averages the signals; it decreases the 7×7 feature maps to the 1×1 feature maps to reduce the number of non-cooperative features.

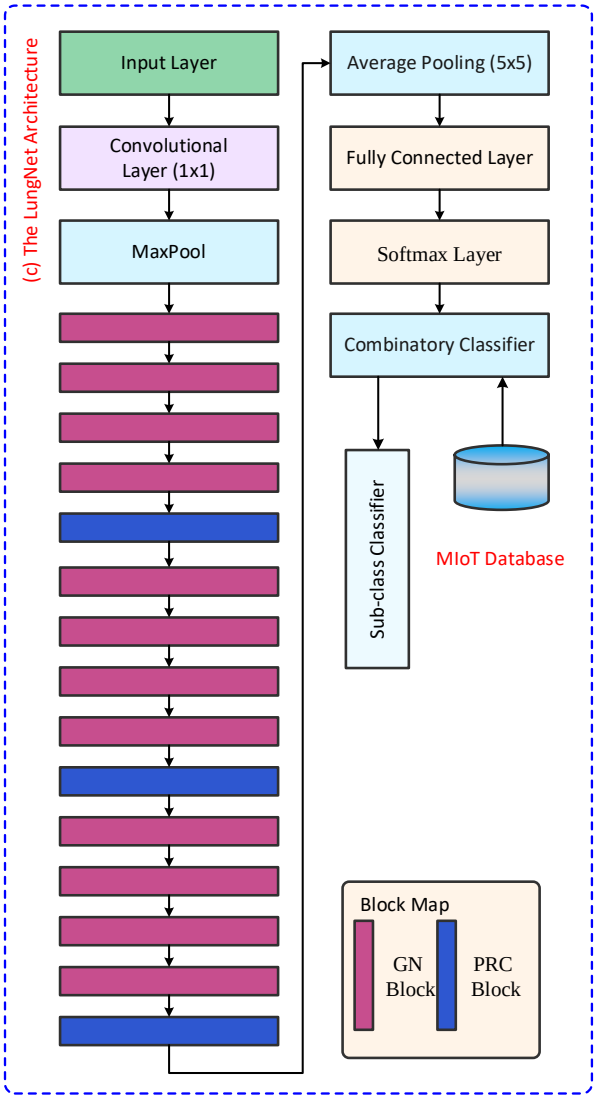

Fig. 4. Structure of the presented method.

It has been observed that employing a diverse range of convolutional matrices instead of a constant matrix enhances network performance. In our proposed method, convolutional matrices of sizes 1×1, 3×3, 5×5, and 7×7 are aggregated together by a max-pooling layer of size 3×3, which operates in parallel with this stack. The ability of the convolutional layer to investigate objects of varying sizes is crucial, and the use of multiple convolution matrices ensures this capability.

These separate layers are then combined into a deep concatenation layer, which transmits signals to the subsequent layer. In contrast to fully connected layers, our proposed method includes several intermediate pre-classification layers to mitigate the impact of the vanishing gradient problem. These branches are only activated during the training process. The purpose of these pre-classification layers is to perform classification before reaching the final classifier. Each of these layers comprises a 5×5 average pooling layer with a stride of 3, performing convolutions with 1×1 filters totaling 128 filters. The proposed method features 5 output nodes, processed through a softmax classification layer and aided by dataset data. The 2nd and 3rd nodes are combined for sub-classification.

In terms of the learning algorithm, it's worth noting that most CNNs initialize the weights of the classification layer randomly. However, for our proposed method, we've adopted various techniques to achieve better efficiency. Empirical results indicate that employing the modified Nguyen-Widrow initial weighting approach [28] improves validation accuracy and reduces validation loss more quickly.

We utilize the Levenberg-Marquardt backpropagation algorithm as the learning rule [29]. This choice is validated by the computational expense of calculating the Hessian matrix [30]. Given that our proposed method is intended to operate from a centralized server, multiple instances could degrade service quality. The Levenberg-Marquardt backpropagation algorithm estimates the Hessian matrix using the Jacobian matrix, which is computationally cheaper and faster [31]. Consequently, we update weights using the Levenberg-Marquardt backpropagation algorithm.

Furthermore, employing a dynamic learning rate, as opposed to a fixed learning rate, enhances validation accuracy [32]. Therefore, our proposed method adopts an adaptive learning rate during training, where the rate starts at 0.01 and gradually decreases to 0.0003.

After the training step, the classification step is done. A new hybrid classifier is designed and is used in the proposed method. The network classifier is considered for cancer classification. The data of the feature of the image of the high level and the data of the feature of the image of the low level are the features of the node based on the classification of the network. Commonly, the data of the probabilistic network is applied for the classification. Our proposed method incorporated an extra system of support for the decision-making of the weighted with the classifier of the convolution. The normalized data are the parameters of the step of the classification. The sum of the weighted of the prediction for our proposed method (P_L) and also prediction based on the normalized data (P_S), which is defined by the relation (18), form the final output of the proposed method.

$$P_{stage_n} = 0.6P_L + 0.4P_s \quad (18)$$

By using the value of P_{stage_n}, where $n = \{n \mid n \subset Z. 0 \leq n \leq 4\}$, the classification of the final (based on the medical thresholds) is performed. The lung cancer is further classified based on the size of the nodule. After the classification, the test image is sent to the sub-classifier. This module includes a module for the processing of the image and also a module for decision-making. The module of the processing of the image separates the nodule of the lung from the image. Next, the module of decision-making computes the nodule size. Based on the medical thresholds, this module classifies the nodules (see Fig. 5).

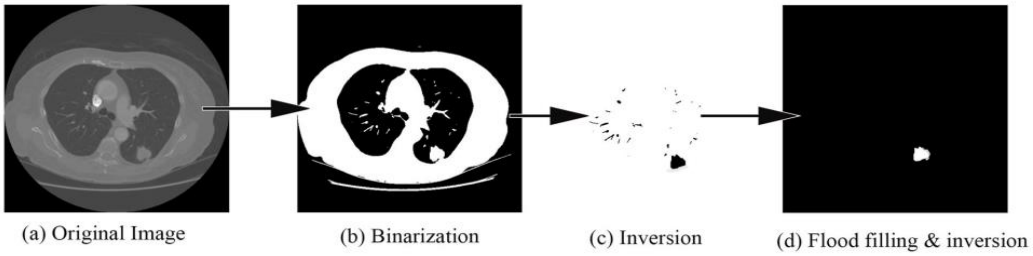

Fig. 5. An example of the separation of the lung nodule from the sub-classified image.

IV. Tests and Evaluation of Results

In this section, the details of the evaluation criteria, the used datasets, our performed tests, and the gained outcomes are provided. The language of the programming of Python has been applied to implement these experiments. Our proposed approach is done in a computer with 8G RAM and Core (TM) i7 CPU 3.0 GHz Intel(R). The network of the convolutional is implemented on GPU and the used card of the graphics in our approach is GEFORCE 840M for NVIDIA.

A. Applied Datasets and Evaluation Criteria

The performance evaluation criteria in this paper include accuracy, false positive rate, and false negative rate, which are utilized to calculate the Area Under the Curve (AUC) score and Recall. The LIDC-IDRI dataset [33] and the LUNGx dataset [34] are employed to evaluate the effectiveness of our proposed approach and to compare it with similar approaches. These two datasets are combined into a single dataset for evaluating our approach. Additionally, data obtained from the medical body area network are incorporated into this evaluation process.

Within this dataset, image scans containing lung regions are considered non-candidates and are consequently excluded from the datasets.

Furthermore, the datasets contain scans both with and without nodules. These cases are identified and separated based on existing metadata within the dataset, with annotations performed by radiologists. However, there is no inherent distribution logic between these two classes. Following partitioning, the number of images available for training, testing, and validation is insufficient. The scarcity of images poses a challenge in achieving satisfactory validation accuracy for CNNs. To overcome this challenge, we employ two-dimensional spatial image enhancement and generate features to preserve enhanced images using the existing dataset [35]. As a result, each CT scan is represented as a 3-channel image with dimensions of 224×224. The statistics of our utilized datasets are presented in Table I.

B. Obtained Results

In this section, we examine and also, we analyze the obtained results from the different experiments. Before the presentation of the results, we should mention that we compare the obtained outcomes by our presented approach with the obtained outcomes by the ResNet-50 network [36], the Inception V3 network [37], and the Xception network [38]. The results of our presented approach and other deep learning-based networks in our used dataset and the obtained data are provided in Tables II, III, and IV. Also, Fig. 6 displays the efficiency of deep learning models and the efficiency of our presented model according to accuracy, score of AUC, and loss. Note that in Tables II, III, and IV, results are presented for training, validation, and testing, respectively.

TABLE I. The Statistics of used Datasets and their Combination for the Evaluation of the Proposed Method

Dataset	CT Cases	Candidate Cases	Cases with Nodules	Augmented Cases
LUNGx	70	3280	1822	160000
LIDC-IDRI	1018	8252	5249	365000

TABLE II. Outcomes of Training of the Different Deep Learning Approaches and Our Presented Approach

Model	Accuracy	AUC Score	Recall	Loss
ResNet-50	99.56	99.99	99.60	0.045
InceptionV3	94.25	96.40	94.23	1.960
Xception	94.10	96.70	94.08	1.450
Proposed Model	99.85	100	99.76	0.0018

TABLE III. Outcomes of Validation of the Different Deep Learning Approaches and Our Presented Approach

Model	Accuracy	AUC Score	Recall	Loss
ResNet-50	84.20	94.90	83.50	0.598
InceptionV3	82.07	88.50	82.10	15.70
Xception	82.10	90.00	82.06	8.270
Proposed Model	92.25	98.12	91.54	0.324

TABLE IV. OUTCOMES OF TEST OF THE DIFFERENT DEEP LEARNING APPROACHES AND OUR PRESENTED APPROACH

Model	Accuracy	AUC Score	Recall	Loss
ResNet-50	84.13	94.85	83.45	0.604
InceptionV3	82.09	88.65	82.06	15.64
Xception	82.12	90.13	82.07	8.301
Proposed Model	92.78	98.46	92.01	0.321

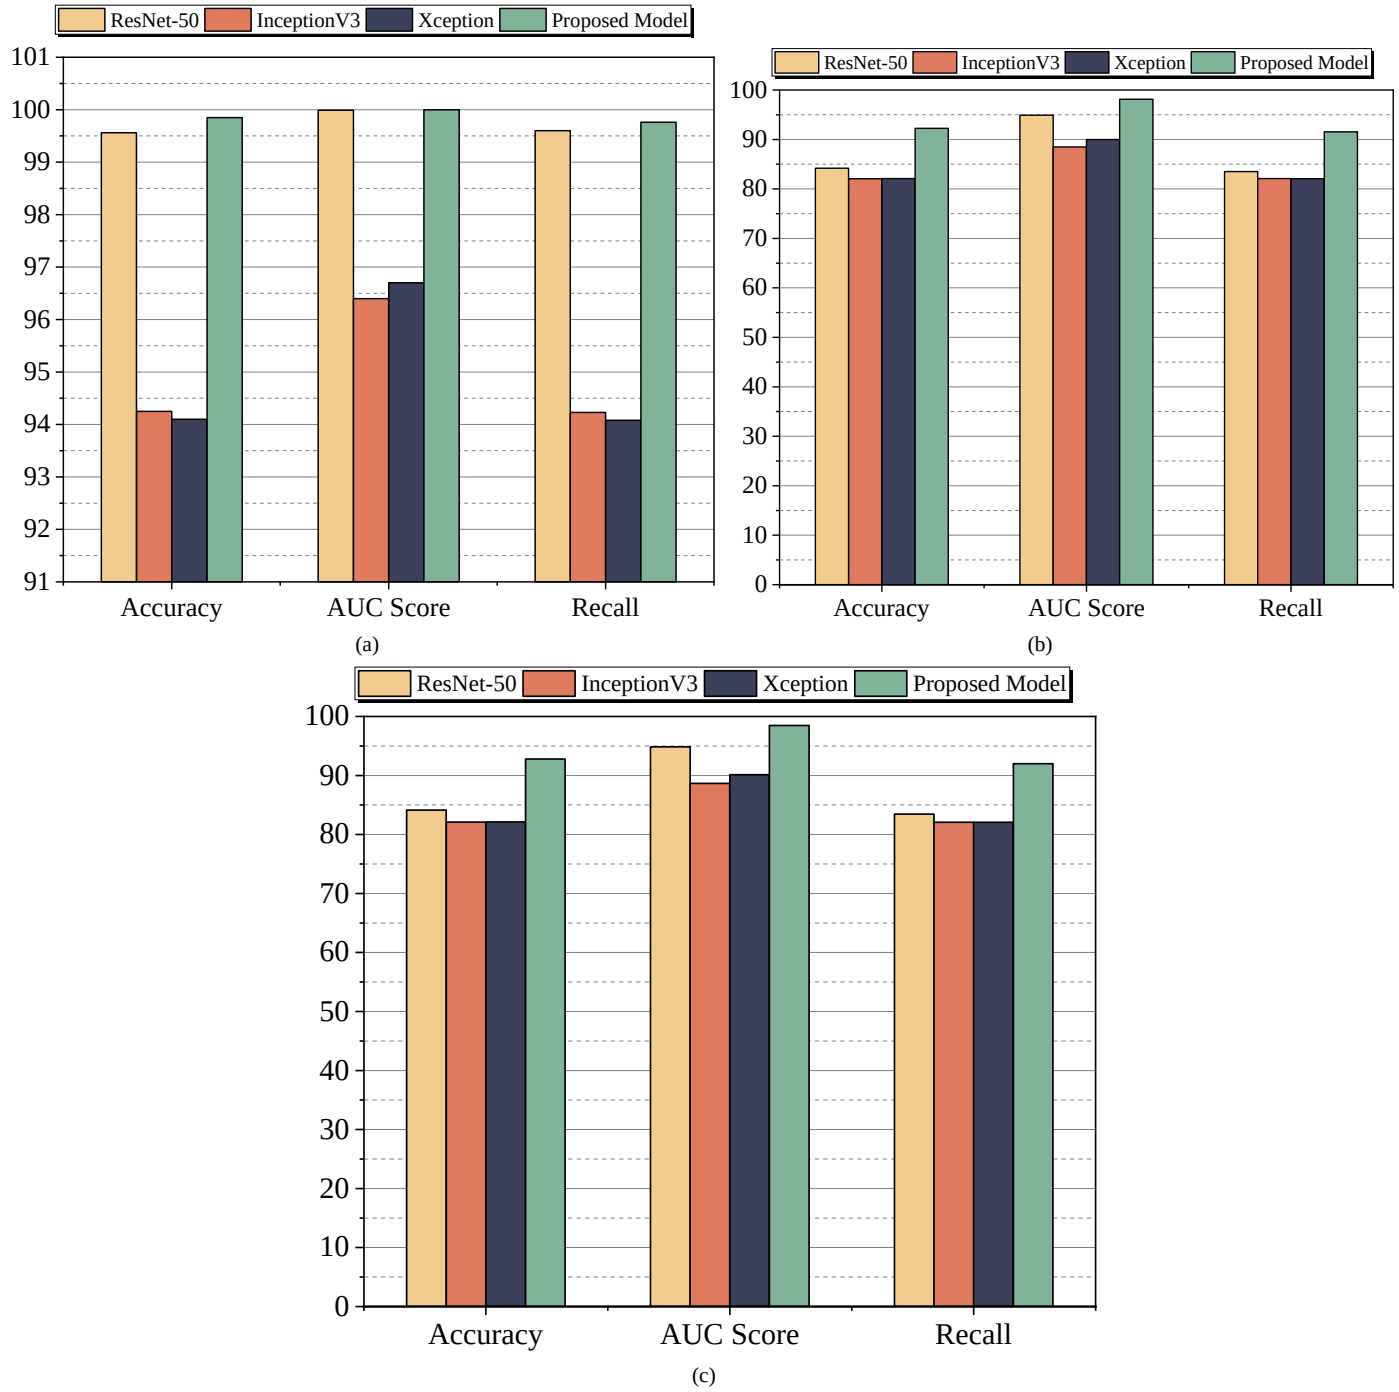

Fig. 6. Illustration of performance evaluation results for different methods, (a) Result of training process, (b) Result of validation process, (c) Result of test process.

After analyzing the outcomes of our proposed model and comparing them with ResNet-50, Inception V3, and Xception, it is evident that our model outperforms similar deep learning models, as shown in Tables II, III, and IV, as well as Fig. 6. Our proposed method achieved a test accuracy of 92.78%, a test AUC score of 98.46%, a test recall of 92.01%, and a test loss of 0.321.

In Fig. 6, the accuracy, AUC score, and loss values of different models are depicted. These metrics are crucial for evaluating model performance. Notably, our proposed model exhibits the highest test accuracy compared to other models. The AUC score is a key measure for assessing method efficiency and its ability to discriminate between positive and negative classes. A higher AUC score indicates superior performance. A score between 0.7 and 0.8 is considered acceptable, between 0.8 and 0.9 is excellent, and above 0.9 is considered outstanding [39]. As shown in Fig. 6, the proposed method not only achieved the highest test accuracy but also attained the highest test AUC score, indicating its excellent discriminatory ability between positive and negative classes.

Indeed, the loss value is another crucial criterion in assessing model performance. It represents the degree of inaccuracy in the model's predictions at each iteration. A loss value of 0 indicates perfect model predictions, whereas higher loss values indicate poorer performance. In our detection process, we use the cross-entropy loss function, commonly employed for multi-class classification tasks [38]. The proposed method achieves the lowest loss value, indicating superior predictive accuracy. Conversely, models such as Xception and Inception V3 exhibit significantly higher loss values [40, 41]. This evaluation demonstrates that our approach outperforms other deep learning models in diagnosing various types of lung cancer using the datasets and collected data.

C. Discussion and Limitations

Despite the promising results observed in various tests, the proposed method has several limitations, most of which are typical of CNN-based models. These limitations are outlined below.

Firstly, the efficacy of our approach, which surpasses that of similar methods, heavily relies on hybridization. The integration of data from the medical body area network contributes to the combined layer. However, any erroneous measurements by faulty IoT sensors could significantly compromise the overall integrity of the model. Although such occurrences are rare, the absence of a fault detection mechanism for medical sensors poses a potential risk.

Moreover, like any lung cancer classifier based on CNN, our proposed method requires image processing to enhance features. This image processing involves a series of computationally expensive processes. Each image must be processed and segmented individually, resulting in significant time consumption. Additionally, it is beyond the scope of this paper to dissect each module of image processing separately and evaluate its impact on the overall efficiency of the network.

However, this also underscores the need for further research. The validation performance of our proposed approach sees a significant decline when image enhancement is not employed. This implies that the overall efficacy of the model is reliant on image enhancement. However, it's important to note that this limitation isn't exclusive to our proposed method. To date, no efforts have been made to determine the optimal number of enhanced images. This aspect leaves room for future optimization of the efficiency of our proposed method.

V. Conclusions and Suggestions

The mortality rate associated with lung cancer remains alarmingly high, underscoring its status as one of the most prevalent and aggressive forms of cancer worldwide. While its occurrence cannot be prevented, early diagnosis can significantly improve patient outcomes, prolonging lives. Notably, in North America and other industrialized nations, lung cancer ranks as the leading cause of cancer-related deaths. Despite significant strides in recent years, early diagnosis remains challenging and lacks reliability.

In this study, we departed from current research trends to explore specialized layers within our CNN model. By integrating physiological data into our CNN model specifically designed for lung nodule classification, we achieved promising results. Our combined classifier attained an accuracy of 92.78%, surpassing similar models according to our literature review. Even in scenarios where feature learning layers may suffer from mistraining due to the absence of beneficial features, the classification accuracy of our proposed method remains reliable, thanks to the weighted aggregation of data collected from the medical body area network.

This study extends the development of one of the most precise automated models for lung cancer detection, emphasizing its comprehensive service availability. In summary, our proposed method represents a significant advancement in CNN-based automated models for lung cancer detection. We anticipate that our approach will pave the way for the development of more reliable computer-aided detection systems.

The proposed approach addresses the critical problem of early and accurate detection of lung cancer through the integration of data from CT scans and wearable IoT sensors, leveraging the DCNN for analysis. By combining information from both sources, the approach enhances diagnostic accuracy by capturing a comprehensive range of patient data. The hybrid model trained on a balanced dataset ensures robust learning and classification of lung nodules, while rigorous evaluation metrics such as accuracy, AUC score, loss, and recall provide thorough assessment of performance. Overall, the proposed approach offers a holistic and reliable solution to the challenge of lung cancer diagnosis, leveraging advanced machine learning techniques and diverse data sources to improve patient outcomes.

Future research could focus on integrating multi-modal data, including medical imaging, physiological data from wearable sensors, and patient history, into a comprehensive diagnostic model. By leveraging a wider range of data sources, such as genetic information, lifestyle factors, and environmental exposures, researchers can develop a more holistic understanding of lung cancer risk and improve the

accuracy of early detection models. This approach would require advanced data fusion techniques and machine learning algorithms capable of processing diverse data types and extracting meaningful patterns for accurate diagnosis and prognosis.

Another potential avenue for future research is the development of explainable artificial intelligence (XAI) models for lung cancer diagnosis. While deep learning models like CNNs have demonstrated impressive performance, their inner workings can be opaque, making it challenging to understand the factors driving their decisions. By incorporating explainability into the model architecture, researchers can provide clinicians with insights into how specific features contribute to the diagnostic process, enhancing trust and facilitating clinical decision-making. This research could involve exploring interpretable machine learning techniques, such as attention mechanisms, feature visualization, and decision trees, to create transparent and clinically actionable diagnostic models for lung cancer detection.

***Abstract*—Given wireless sensor networks' significant data transmission requirements, conventional direct transmission often leads to bandwidth constraints and excessive network energy consumption. This paper proposes a transmission line monitoring technology based on compressed sensing wireless sensor networks to achieve real-time monitoring of ice-covered power lines. Grounded in compressed sensing theory, this method utilizes dual orthogonal wavelet transform sparse matrices for sparse representation of sensor data. Considering the practical requirements of power line monitoring, a data transmission model is established to implement compressed sampling transmission. The regularization orthogonal matching pursuit algorithm is employed for high-precision reconstruction of compressed data. The software and hardware components of the power line monitoring system are designed, and experiments are conducted under real-world conditions. The results demonstrate that: 1) the system operates stably with an ideal data compression effect, achieving a compression ratio of 93.191%. The absolute reconstruction errors for temperature, humidity, and wind speed sensor data are 0.064°C, 0.052%, and 0.128 m/s, respectively, indicating high reconstruction accuracy and effectively avoiding transmission impacts caused by bandwidth issues. 2) In a 36-hour energy consumption loss test, compared to direct transmission, the compressed transmission mode exhibits a lower rate of battery voltage decay, with a decrease of approximately 11.18%, effectively extending the network's lifespan.**

Keywords*—Compressed sensing; transmission line; wireless sensor network; orthogonal wavelet transform; data reconstruction

I. Introduction

As a crucial component of the power system, transmission lines are responsible for conveying the electrical energy generated by power stations to various distribution points and ultimate consumers. The stable operation of these infrastructures is vital to the reliability and security of the entire power system, and it also directly affects the continuity and quality of power supply [1]. In view of the uneven geographical distribution of China's power resources, transmission lines often have to traverse regions with complex geographical environments and adverse climatic conditions. Particularly in environments characterized by low temperatures, high humidity, and strong winds, the surfaces of transmission lines are highly susceptible to ice accretion, which increases the risks of galloping, breakage, overloading, and flashovers on insulator strings, severely threatening the stability and safe operation of transmission lines [2-4]. In response to these risk factors, it is particularly important to implement real-time monitoring and develop efficient transmission line operational status monitoring systems. By employing advanced sensing technologies, image processing techniques and big data analytics, comprehensive condition monitoring of transmission lines can be achieved, enabling timely identification and response to existing or potential issues and effectively reducing the probability and impact of failures. Such monitoring systems not only provide early warnings of possible line failures but also offer real-time data support to operations and maintenance personnel, assisting them in making rapid and accurate decisions. Therefore, strengthening the real-time monitoring capabilities of transmission lines plays a crucial role in enhancing the levels of fault prevention and control, improving the system's emergency response and early warning capabilities, and ensuring the safe and stable operation of the power grid.

Currently, transmission line monitoring methods primarily include manual inspection, unmanned aerial vehicle (UAV) surveillance, infrared thermal imaging, and fiber optic sensing technologies. Tang [5] proposed a technical approach utilizing video surveillance systems for vibration analysis of transmission lines. This method involves the collection of video image data from transmission lines and the establishment of a relative coordinate system between the power tower and the transmission line, thereby enabling the tracking of vibration frequency and amplitude at specific line positions. Through such tracking, the dynamic characteristics and operational status of the transmission lines can be assessed. Although this technology has demonstrated certain effectiveness in vibration monitoring of transmission lines, its implementation relies on various equipment, and the operational process is complex with insufficient real-time capabilities, making it unsuitable for widespread deployment in large-scale transmission line systems. He [6] addressed the requirements of the sensor layer in the power Internet of Things by combining fiber optic sensing technology with big data and artificial intelligence for multi-risk monitoring of transmission lines. The monitoring system was deployed, and experiments were conducted using different monitoring scenarios, yielding good performance. However, the scheme is costly to implement, complex to install, and susceptible to temperature effects, leading to less-than-ideal practical application outcomes. Wireless Sensor Networks (WSN), which integrate microsensors, embedded computing, wireless communication, and information processing, coordinate among network nodes to monitor, sense, collect, and process information about the objects of interest, transmitting data wirelessly [7,8]. Sensors in WSN are less

affected by time, space, and environmental conditions during data collection and are widely used in various monitoring fields. However, the transmission of large volumes of data in WSN, when using traditional transmission methods, can lead to congestion in limited bandwidth, reducing the efficiency of data collection and increasing the energy consumption of nodes, thus affecting the network's lifespan. Consequently, some scholars have adopted compressed sensing technology to address the shortcomings of traditional WSN transmission methods. Compressed sensing is a novel signal acquisition theory that enables the reconstruction of sparse or compressible signals from sampling frequencies far below the Nyquist rate, offering advantages such as low sampling rates, strong anti-noise capabilities, efficient signal recovery, low energy consumption, and ease of implementation, and it is widely applied in various monitoring scenarios. Yang et al. [9] used a distributed wavelet transform theory based on hybrid decomposition, leveraging the computational capabilities of nodes to reduce communication overhead from inter-node exchange of wavelet coefficients, and employed adaptive wavelet transform to determine network overhead, resulting in significant improvements in network performance. Fute [10] utilized distributed data compression algorithms to reduce the total amount of data within WSN, decreasing the likelihood of data packet collisions on wireless media to enhance data transmission efficiency, reduce resource consumption within the network, and extend network lifespan. Jiang [11] proposed a compressed sensing algorithm with dynamic retransmission to address data packet loss due to unreliable wireless communication, achieving high-precision signal reconstruction to improve network energy utilization and lifespan, with the normalized mean absolute error (NMAE) reduced by 64.5%, and energy efficiency also correspondingly enhanced. Yang [12] estimated the signal's sparsity through an adaptive subspace pursuit algorithm, selected atoms using an approximate matching principle, and completed signal residual updates after multiple iterations to achieve signal reconstruction.

The aforementioned research has provided valuable guidance for the study of Wireless Sensor Networks (WSN); however, due to the complexity of the algorithms, their adaptability in the transmission line monitoring networks with parallel transmission of large volumes of data is not optimal. In light of this, this paper draws on the theory of Compressed Sensing (CS) as the design cornerstone and designs a transmission line monitoring network based on real-world scenarios. The biorthogonal wavelet transform algorithm is utilized to construct a sparse sampling model for signal compression, while the Regularized Orthogonal Matching Pursuit (ROMP) algorithm is employed for high-precision signal reconstruction. Based on this, a transmission line monitoring system is designed to ensure the real-time and stable monitoring of lines, which holds positive implications for the secure operation of power systems and the extension of the service life of monitoring networks.

The remainder of the paper has been organized as follows. The compressed sensing theory in Section II introduces an innovative method for transmission line monitoring using Compressed Sensing (CS) theory. It discusses CS's ability to reconstruct sparse signals from low-frequency samples, crucial for dense wireless sensor networks (WSNs). To tackle non-sparse signal transmission challenges, the paper proposes a method in Section III utilizing biorthogonal wavelet transform for signal sparsity and the ROMP algorithm for efficient reconstruction. It details network architecture and sparse sampling model, emphasizing adaptive signal analysis via wavelet transformation. Additionally, it explains the ROMP algorithm's iterative process, highlighting its role in enhancing accuracy and handling noise. The paper also discusses the system design, including hardware components and data transmission mechanisms in the design and implementation of the monitoring system in Section IV. The experimental results and analysis in Section V validate the proposed method's efficacy, showcasing high compression ratios, low reconstruction errors, and reduced energy consumption compared to existing algorithms. Finally, conclusions emphasize the significance of the proposed scheme in enhancing transmission line monitoring efficiency and extending network lifespan, offering practical value for energy-efficient management of monitoring systems in Section VI.

II. Compressed Sensing Theory

Compressed Sensing (CS) is a novel signal sampling method proposed by Candès et al. in 2004, aiming to address the shortcomings of traditional signal acquisition and processing [13]. This theory indicates that if the original signal exhibits sparsity and orthogonality, it can be reconstructed from observation values at a sampling frequency much lower than the Nyquist theorem requires. In other words, it is possible to reconstruct the signal using a much lower sampling frequency and an appropriate reconstruction algorithm. Fig. 1 illustrates the concept of compressed sensing data collection.

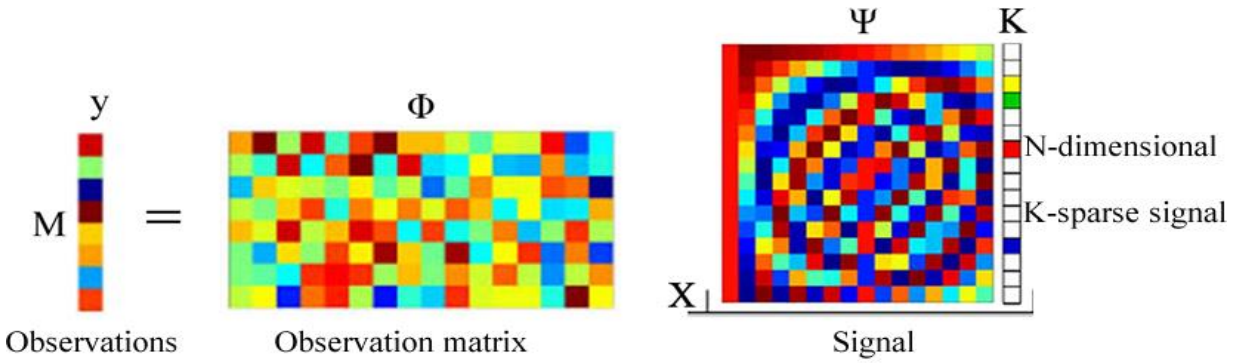

Fig. 1. Schematic diagram of compressed sensing data collection.

Wireless sensor networks are characterized by dense sensor node deployment and high signal sampling frequencies, making the original signals compressible [14]. However, in most cases of transmission line monitoring networks, signal values are not zero, indicating a lack of sparsity [15]. Therefore, it is necessary to employ methods for transforming continuous-time domain signals into sparse signals. If X is an N -dimensional column vector representing the original signal and, α is the coefficient vector under the basis Ψ, the sparse processing can be expressed as follows:

$$X = \Psi\alpha \tag{1}$$

Assuming the sparsity level K represents the number of non-zero points in the sparse domain. If $K = n$ $(n << N)$ is satisfied, the data can be sampled using the observation matrix Φ $(M \times N)$ to obtain the observation values y. The observation matrix Φ is randomly generated from a Gaussian matrix with a mean of zero and a variance of $1/M$. If the performance meets the requirements, the observation values y contain the essential information from the original signal X.

The signal reconstruction can be solved through non-deterministic polynomial (NP) optimization problems, expressed as follows:

$$y = \Phi X \tag{2}$$

$$\begin{cases} \alpha^{(0)} = arg\min\limits_{\partial \in R^N} \|\alpha\|_0 \\ y = \Phi X = A\alpha \end{cases} \tag{3}$$

Since the term $A = \Phi\Psi$ belongs to a non-convex combinatorial optimization problem, convex relaxation approximation methods can be employed for solving:

$$\begin{cases} \alpha^{(1)} = arg\min\limits_{\partial \in R^N} \|\alpha\|_1 \\ y = \Phi X = A\alpha \end{cases} \tag{4}$$

III. Model Construction

A. Network Structure and Sparse Sampling Model for Signal

The transmission line monitoring network adopts a tree structure, as illustrated in Fig. 2. Sensor nodes transmit collected information through long-distance communication modules. After convergence nodes compress the observations, the information is transmitted to the remote monitoring platform through GPRS and the Internet. The monitoring platform utilizes corresponding algorithms to reconstruct the data information, thereby achieving the identification of the original signal for monitoring and early warning purposes.

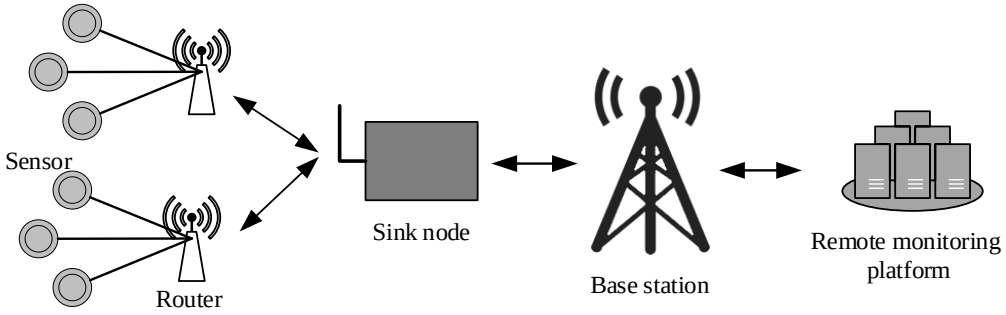

Fig. 2. Transmission line monitoring network structure.

Various sensor nodes exchange information with convergence nodes through a wireless network in the perception area. The temporal characteristics of signals collected by various sensors exhibit continuity and piecewise smoothness, and they have approximate spatial regularity. Based on spatiotemporal characteristics, the biorthogonal wavelet transform can locally transform the signal in both time and frequency. Using translation and scaling operations, it achieves multi-scale refinement of signals, meeting the adaptive analysis requirements of time-frequency signals. This makes it suitable for sparse representation of signals in monitoring sensor networks [16]. Therefore, based on the characteristics of the transmission line monitoring signals, a sparse sampling model is constructed using the biorthogonal wavelet transform algorithm to achieve signal compression. The detailed signal transmission steps are shown in Fig. 3, where the dashed box represents the sparse sampling process.

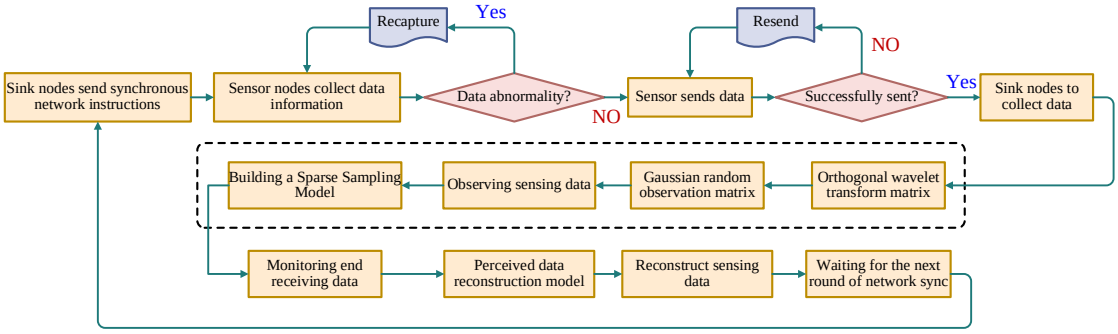

Fig. 3. Compressed sensing-based signal transmission process.

B. Data Information Reconstruction

The Regularized Orthogonal Matching Pursuit (ROMP) algorithm represents an improvement over the classical Orthogonal Matching Pursuit algorithm. The ROMP algorithm enhances signal reconstruction accuracy and stability by incorporating greedy algorithm principles, convex optimization methods, and regularization conditions during iterations [17].

In this algorithm, atoms in the sparse representation are systematically selected through iterations, considering both the sparsity of the signal and regularization conditions. This approach efficiently achieves the reconstruction of the original signal, contributing not only to improved reconstruction accuracy but also enhanced capability in handling noise and complex signal structures, showcasing excellent performance in practical applications.

The ROMP algorithm plays a crucial role in signal reconstruction and is well-suited for handling large-scale sensor data generated in transmission line monitoring. Through meticulous and robust signal reconstruction, the ROMP algorithm provides an effective mathematical tool for accurately restoring the transmission line monitoring signal. This not only aids in reducing data transmission volume and improving network efficiency but also effectively addresses complex environmental conditions and multi-source interference, offering robust support for the reliability and robustness of monitoring systems.

Assumption: r_t represents the residual of the observed data, Φ represents the empty set, λ_t represents the column indices obtained after the t -th iteration, A_t represents the set of columns of matrix A selected according to the index Λ_t, a_j represents the j -th column of the matrix, Λ_t represents the index set for the t -th iteration, $<\bullet, \bullet>$ represents the inner product of vectors, $\cup$ represents the set union operation, θ_t represents the column vector after the t -th iteration, $abs[\bullet]$ represents the absolute value operation. The algorithmic process can be described as follows:

Input: N -dimensional observation vector y, sensing matrix A, sparsity level K

Output: Estimated sparse representation coefficients $\hat{\theta}$, N -dimensional residual $r_K = y - A_K\hat{\theta}_K$

Initialization:

Iteration: $\Lambda_0 = \phi,\ A_0 = \phi,\ r_0 = y,\ t = 1$

1) Compute $u = abs[A^T r_{t-1}]$ by obtaining K largest values and corresponding column indices set J of matrix A.

2) Regularization: Search for a subset J_0 within J satisfying the condition of $|u(i)| \le 2|u(j)|\ \ i,j \in J_0$, and select J_0 with the maximum correlation.

3) Set $\Lambda_t = \Lambda_{t-1} \cup J_0$), $A_t = A_{t-1} \cup \alpha_j (j \in J_0)$

4) Solve for $y = A_t\theta_t$ by finding the least squares solution: $\theta t = arg\ \min_{\theta}\|y - A_t\theta_t\| = (A_t^T A_t)^{-1}A_t^T y$.

5) Update the residual $\theta t = arg\ \min_{\theta}\|y - A_t\theta_t\| = (A_t^T A_t)^{-1}A_t^T y$.

6) $t = t + 1$. If $t \le K$, return to step 3; if $t > K$ or $r_t = 0$ or $\|\Lambda_t\|_0 \ge 2K$, stop the iteration, and reconstruct θ by placing all non-zero elements at the positions Λ_t.

After iterations, perform wavelet inverse transform on the obtained high-frequency signal and low-frequency part to complete the data reconstruction.

C. Key Model Parameters

The determination of key model parameters not only affects the efficiency of signal compression sensing and the quality of reconstruction but also governs the learning efficiency and accuracy of the model. Therefore, a comprehensive list of key parameters for the model has been constructed, taking into account the actual requirements of the model and the need for real-time and stable monitoring. The list is presented in Table I.

TABLE I. KEY PARAMETERS OF THE MODEL AND DETERMINATION

Parameter	Description
Wavelet Basis	In the realm of compressed sensing, the selection of an appropriate wavelet basis is of paramount importance, as it directly influences the sparsity representation and the quality of signal reconstruction. This study employs the Morlet wavelet to construct a sparse sampling model through experimental comparison, aiming to achieve signal compression. The Morlet wavelet, which combines a Gaussian function with a sine wave, aids in the identification of abrupt changes within signals, thereby facilitating line monitoring.
Regularization Parameter	The regularization parameter λ is utilized to control the degree of sparsity in the Regularized Orthogonal Matching Pursuit (ROMP) algorithm, striking a balance between data fidelity and sparsity to better capture the signal's sparse structure and enhance the quality of the reconstructed signal. This paper determines λ based on the minimum reconstruction error derived from leave-one-out cross-validation experiments, with the Mean Squared Error (MSE) serving as the evaluation metric for signal reconstruction error.
Sparsity	Sparsity is employed to regulate the balance between the greedy search and regularization in the ROMP algorithm, constraining the number of non-zero elements in the solution vector of the algorithm to prevent overfitting and underfitting phenomena. This study estimates sparsity by integrating the characteristics of the signal with prior knowledge and applying threshold processing.
Atom Dictionary	The Atom Dictionary dictates the representational capacity of the signal during the reconstruction process, reducing the number of atoms that need to be processed, lowering computational complexity, and enhancing computational efficiency. In this paper, the optimal Atom Dictionary is assessed, adjusted, and determined through cross-validation, based on the signal's characteristics and the degree of matching.
Initial Estimate	The Initial Estimate significantly impacts the convergence rate of the algorithm and the quality of the final solution. An appropriate Initial Estimate can effectively reduce computational complexity and minimize the influence of noise and outliers on the reconstructed signal. This research utilizes the Iterative Soft Thresholding Algorithm (ISTA) for sparse reconstruction as the Initial Estimate for the ROMP algorithm.

IV. Design and Implementation of Monitoring System

Conditions for the formation of ice on transmission lines include environmental temperature ≤ 0°C, air relative humidity ≥ 85%, and wind speed > 1m/s, among others [18]. Therefore, temperature, humidity, and wind speed sensors were chosen as monitoring nodes. The hardware and software components of the transmission line monitoring system were designed by combining the network structure mentioned above and the algorithmic model. These components underwent detailed analysis and testing to ensure that, under stable system operation, the comprehensive performance indicators met the design requirements. The hardware structure of the system is illustrated in Fig. 4.

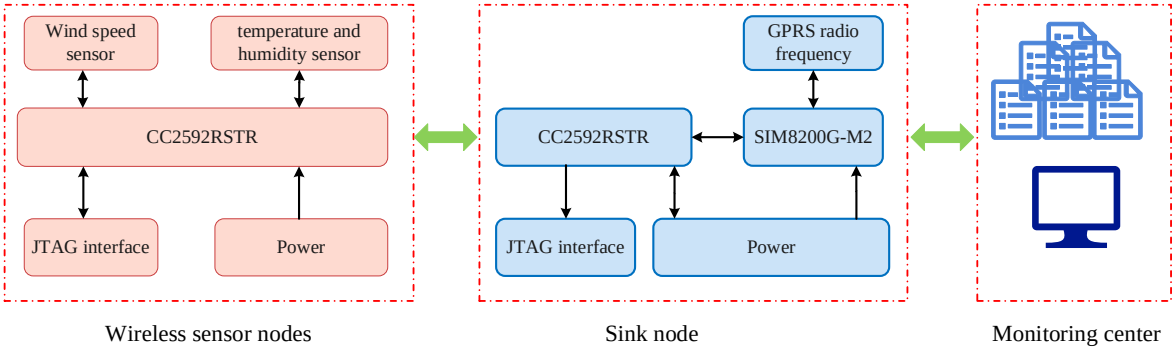

Fig. 4. System hardware structure.

The monitoring system utilizes the convergence node as the time reference point to send clock synchronization control signals to sensor nodes. Each node estimates its delay and makes corrections. Due to timing differences between sensor timers [19], each node is set with a 2.5s lead time to ensure timely responses. When receiving commands from the superior node, nodes exit sleep mode, correct their clocks, and collect and upload data. Upon receiving an ACK message from the convergence node, sensors transition to sleep mode to reduce power consumption. If a sensor node does not receive an ACK message, it continues data collection and uploads until receiving one. Once all nodes have received ACK messages, the convergence node performs data compression and observation processing.

The SHT31 sensor from Sensirion AG is employed for temperature and humidity sensing, with a temperature range of -40 °C to 125 °C and a humidity range of 0-100% RH, suitable for harsh weather conditions. The compact dimensions (2.5 x 2.5 x 0.9 mm) facilitate lightweight sensor node design. Wind speed measurement is achieved using the FS4G wind speed sensor from Renke Corporation, with a range of 0-60m/s.

The convergence node must perform data observation compression, remote transmission, and network management tasks. It is significantly affected by outdoor environmental factors. Overall, the convergence node should possess fast response, low power consumption, good sealing, and anti-interference capabilities. The SmartRF04-CC2592 chip from Texas Instruments, which integrates a 2.4GHz multi-channel RF transceiver supporting various standard protocols such as IEEE802.15 and ZigBee, is used. It has advantages such as small volume (QFP 4×4mm package), low current consumption (21.8mA when TX at 0dBm output, 12.2mA when TX at -12dBm output), programmable high output power, and strong anti-interference capabilities, making it suitable for the development and application of small wireless nodes. Based on this, the CC2592 chip is used for communication between network nodes and data observation compression. It is connected to the SIM8200G-M2 wireless communication module via a serial bus, enabling communication with the monitoring center to ensure reliable and stable data transmission.

V. Experimental Results and Analysis

A. Experimental Environment and Parameters

Experiments were conducted in the simulation laboratory of the State Grid Corporation of China (SGCC) Henan Province Power Grid Simulation Center to validate the feasibility of the proposed method. The span of the transmission line is 42.5m, and sensor nodes are deployed at positions 1, 2, 3, 4, 5, and 6. The convergence node is placed in the tower control box. The monitoring center is located in the simulation center building, 1.2km from the convergence node, and is responsible for receiving reconstructed convergence node data. The deployment of nodes is shown in Fig.5. LG18650 lithium batteries power all nodes with a nominal voltage of 3.7V and a capacity of 3200 mAh.

Data collection spanned five days from November 26 to 30 during the experimental period. Different time intervals (00:00-03:00, 8:00-10:30, 12:00-14:00, 17:30-19:30, 22:00-00:00) were selected to cover various working and environmental conditions, totaling 3450 minutes of sensor data collection. The analysis of diverse data aimed to ensure the reasonability and effectiveness of the experimental results.

Each sensor node's sampling and transmission intervals were set at 30 and 120 seconds, respectively. The observed temperature, humidity, and wind speed values were all 256. After compression by the convergence node, the final quantity was reduced to 768.

B. Reconstruction Error Performance Analysis

Sensor nodes collected environmental information using the parameters designed in the previous section as the basis for the experiment. The convergence node then compressed and

uploaded the data, ultimately achieving the reconstruction of compressed data in the monitoring center. Throughout the data compression and transmission process, the nodes operated collaboratively, meeting the requirements for system stability.

Taking the data collected during the time interval of 8:00-10:30 on November 28 as an example, the reconstructed temperature, relative humidity, and wind speed were compared with the original data, as illustrated in Fig. 6, Fig. 7, and Fig. 8.

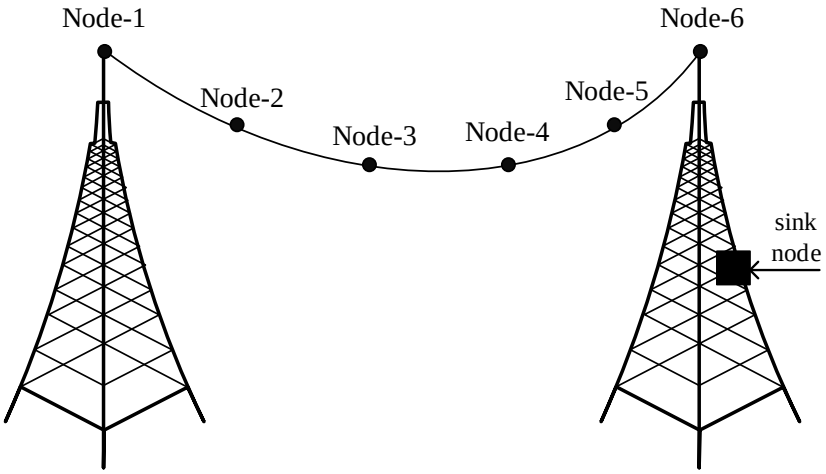

Fig. 5. Node deployment diagram.

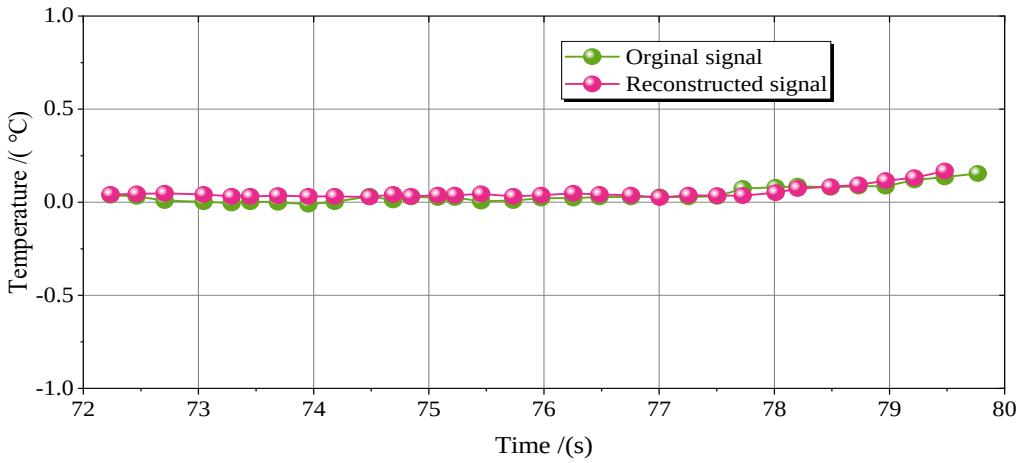

Fig. 6. Temperature comparison curve before and after reconstruction.

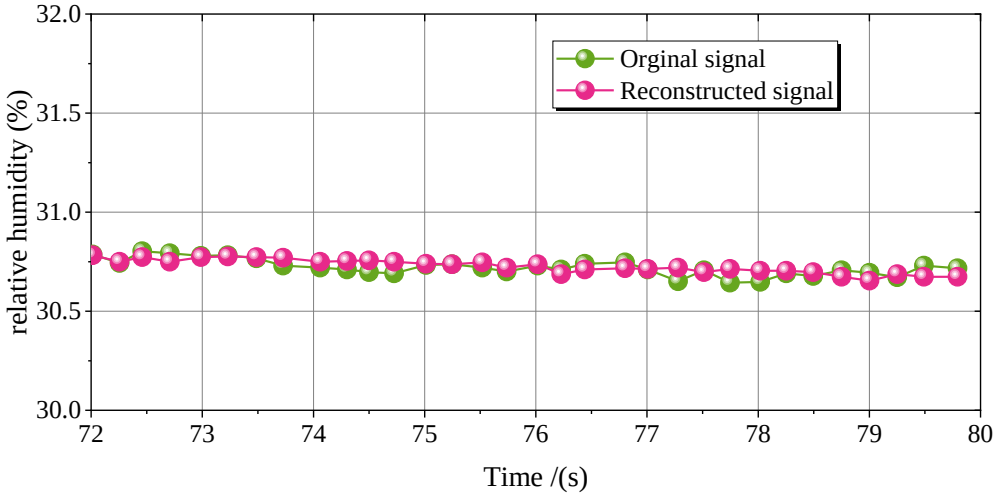

Fig. 7. Comparison curve of relative humidity before and after reconstruction.

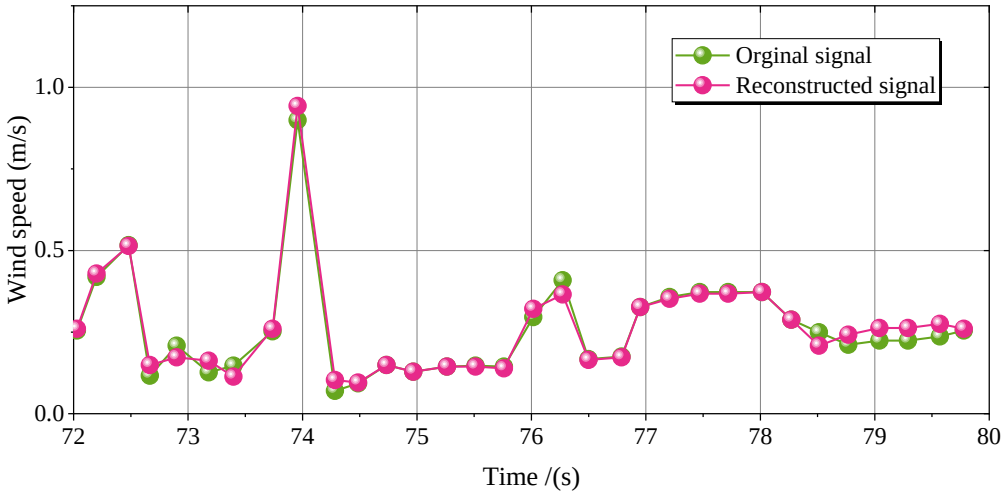

Fig. 8. Wind speed comparison curve before and after reconstruction.

The performance of the reconstruction algorithm is assessed by employing the Normalized Mean Square Error (NMSE) to calculate the mean square values of elements in the vector, thus evaluating the reconstruction error. Simultaneously, the data compression ratio ρ is used to measure the efficiency of data compression to obtain the maximum absolute and relative errors before and after reconstruction. The formulas for NMSE and ρ are expressed as Eq. (5) and Eq. (6), respectively:

$$NMSE = \frac{\left\| \hat{X}_j(n) - X_j(n) \right\|_p}{\left\| X_j(n) \right\|_p} \quad (5)$$

In the equations, $X_j(n)$ and $\hat{X}_j(n)$ represent the j -th values corresponding to the data before and after reconstruction, and the norm p takes a value of 2.

$$\rho = \frac{N-M}{N} \times 100\% \quad (6)$$

In the equations, M and N represent the quantities of observed data and original data, respectively. Table II presents the error situation of the reconstructed data.

TABLE II. RECONSTRUCTION DATA ERROR SUMMARY (N=3760)

Project	Data Compression Ratio ρ (%)	Mean Square Error NMSE (%)	Relative Error (%)	Absolute Error
Temperature	93.191	3.741	13.346	0.064℃
Relative Humidity	93.191	0.184	0.077	0.052%
Wind Speed	93.191	2.752	16.454	0.128m/s

As shown in Table II, the data sampling reconstruction method based on the joint use of the biorthogonal Wavelet algorithm and the ROMP algorithm achieves a high compression ratio, demonstrating excellent compression results and the ability to achieve the high-precision reconstruction of compressed data. Due to the relatively stable changes in relative humidity compared to temperature and wind speed, the sparsity after wavelet transformation is greater, resulting in higher data reconstruction accuracy. The mean square error accuracy of wind speed reconstruction is relatively ideal, but the relative and absolute errors are higher. This is because the wind speed signal exhibits significant fluctuations, and the sparse sampling process did not adequately adapt to the changing characteristics of the signal.

C. Energy Consumption Analysis

This section analyzes the power consumption of the compressed sensing wireless sensor network. Considering that the convergence node mainly completes the compression observation of data, experiments were conducted in direct and compressed transmission modes to ensure the comparability of experimental results. The lithium battery was fully charged to the nominal value, and the system was set to run for 36 hours in both modes to measure the voltage decay. The experimental results are shown in Fig. 9.

From the power consumption decay curves in Fig. 9, it can be observed that the convergence node using compressed sampling transmission has a slower voltage decay rate. In a relatively short experiment period, the nominal battery voltage (3.7v) dropped to approximately 3.565v and 3.548v under direct and compressed transmission modes, respectively, with a decrease of about 11.18%. Therefore, the use of compressed sampling transmission can effectively extend the service life of the sensor network.

D. Comparative Experiments

To further corroborate the validity of the method proposed in this paper, experiments were conducted using the respective algorithms from study [9-11] under the premise of the same data transmission volume. A comparison was made between the reconstruction errors, computational efficiency, and energy consumption of each algorithm. Fig. 10 presents the results of the comparative experiments.

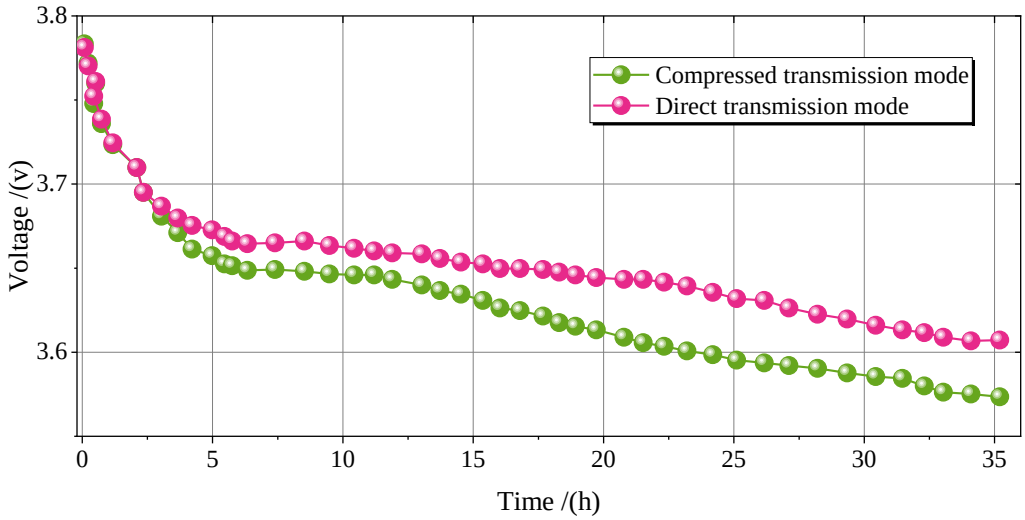

Fig. 9. Convergence node power consumption decay curve under different transmission modes.

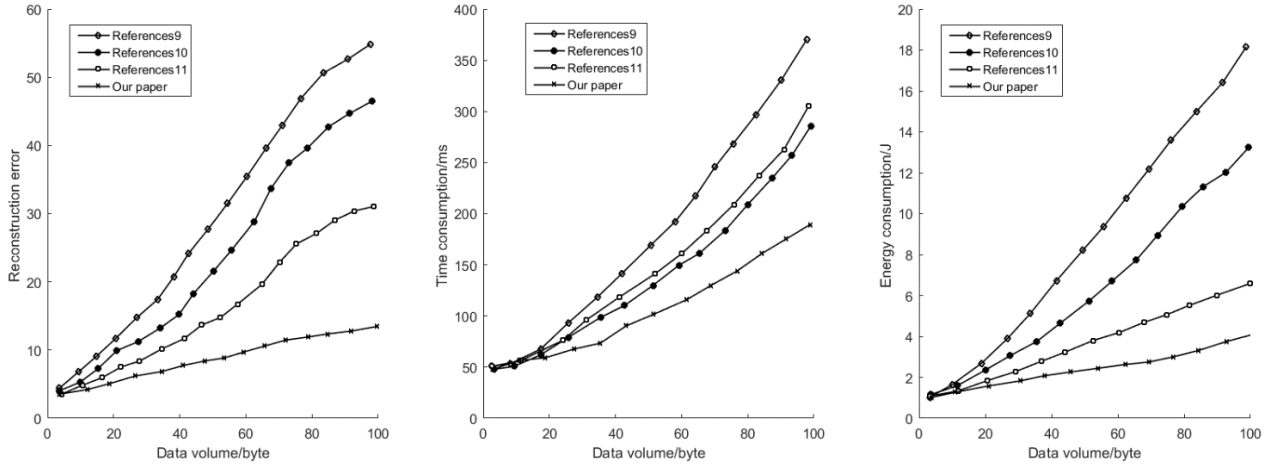

(a) Signal reconstruction error (b) Calculation time (c) Energy consumption

Fig. 10. Comparison of performance indicators of different algorithms.

Fig. 10(a) illustrates that with the increase in data volume, the reconstruction error of different algorithms escalates progressively. The signal reconstruction errors for the distributed optimal wavelet compression algorithm from reference 9, the distributed data compression algorithm from reference 10, and the dynamic retransmission-based compressed sensing algorithm from study [11] are notably higher. In contrast, the method proposed in this paper exhibits a relatively lower reconstruction error and superior stability, which can be attributed to the incorporation of a regularization condition within the iterative process. As observed in Fig. 10(b), when the data volume reaches 100 bytes, the data processing time for the methods described in references [9], [10], and [11] all exceed 250 ms, whereas the processing time for the method introduced in this paper is reduced to only 163 ms, fulfilling the requirements for real-time monitoring and rapid response of transmission lines. According to Fig. 10(c), the energy consumption of the method designed in this paper is significantly reduced to 2.7 J, which is considerably lower than that of the other three algorithms. This indicates a higher energy utilization rate for sensor nodes, which is conducive to extending the operational lifespan of the transmission line monitoring network and reducing maintenance costs.

VI. Conclusion

Focusing on addressing the technical challenges in transmission line monitoring, this paper proposes an innovative wireless sensor network monitoring scheme based on compressed sensing theory. The scheme leverages the combination of compressed sensing technology and orthogonal wavelet transform to achieve sparse representation and efficient compressed sampling transmission of sensor data. By employing the Regularized Orthogonal Matching Pursuit (ROMP) algorithm, the rapid and accurate reconstruction of compressed data is successfully realized. In terms of hardware and software co-design, system architecture suitable for transmission line monitoring is constructed according to the proposed algorithm model. Rigorous experimental validation has demonstrated that the designed monitoring method achieves a high compression ratio of 93.191%, with low signal reconstruction error and superior stability. Moreover, the method features reduced data processing time, meeting the

requirements for real-time monitoring and rapid response. Additionally, by introducing a compressed transmission mechanism at the sink node, the energy consumption of the system operation is significantly reduced, slowing down the rate of energy decay, and effectively prolonging the service life of the wireless sensor network. This scheme holds important practical value and long-term significance for optimizing the energy efficiency management of transmission line monitoring systems and enhancing the system's sustained operational capability.

Implementation of Cosine Similarity Algorithm on Omnibus Law Drafting

Aristoteles*, Muhammad Umaruddin Syam, Tristiyanto, Bambang Hermanto
Department of Computer Science, Faculty of Mathematics and Natural Sciences, Lampung University, Indonesia

***Abstract*—Drafting of Omnibus Laws presents a complex challenge in legal governance, often involving the integration and consolidation of disparate legal provisions into a unified framework. In this context, the application of advanced computational techniques becomes crucial for streamlining the drafting process and ensuring coherence across the law's various components. Cosine similarity, a widely used measure in natural language processing and document analysis, offers a quantitative means to assess the similarity between different sections or articles within the Omnibus Law draft. By representing legal texts as high-dimensional vectors in a vector space model, cosine similarity enables the comparison of textual similarity based on the cosine of the angle between these vectors. Implementing cosine similarity in the context of omnibus law using FastAPI and Laravel can be a valuable tool for analyzing similarity between legal documents, especially in the context of omnibus law. Legal practitioners and researchers can use the cosine similarity measure to compare the textual content of different legal documents and identify similarities. This can aid in tasks such as legal document retrieval, clustering similar provisions, and detecting potential inconsistencies. The combination of FastAPI and Laravel provides a potent and efficient way to develop and deploy this functionality, contributing to the advancement of legal informatics and analysis. The dataset used is Undang-Undang (UU) which used Bahasa from 1945 to 2022, comprising a total of 1705 UU. The implemented cosine similarity yielded a recall rate of 90.10% on the law.**

***Keywords*—Cosine similarity; FastAPI; Laravel; Omnibus Law**

I. Introduction

Indonesia is a country of law with numerous regulations. President Jokowi has acknowledged that there are too many regulations in Indonesia and that it is not ideal for the country to be known as a 'country of regulations'. President Jokowi has acknowledged that there are too many regulations in Indonesia and that it is not ideal for the country to be known as a 'country of regulations" [1]. According to the website peraturan.go.id, as of May 19, 2022, Indonesia has 50,538 regulations. When considering the median growth for the top five hierarchies outlined in Article 7, Paragraph 1 of Undang-Undang (UU) Number 12 of 2011, the Constitution has a median of 0, the MPR Tap has a median of 0, the UU has a median of 16, the PP has a median of 55, and the Perpres has a median of 0. Regulations are implemented to organize and regulate people's lives within a nation or state. The large number of regulations can have a negative impact, which is grouped into four categories: (1) Regulatory conflict, which occurs when some regulations or articles conflict with existing regulations, (2) Inconsistent regulatory consistency, which occurs when there are inconsistent regulations or provisions in one legislation and its derivatives, (3) Diverse regulatory interpretations, which occurs when the objectives and subjects of regulation are unclear. This results in unclear language that is difficult to understand and an inappropriate system. Additionally, there may be non-operational regulations, which are regulations that are inconsistent with one law and its derivatives or have no effect, but are still valid or lack enforcement regulations [2].

The government aims to reduce the growth of regulations, particularly UU, by simplifying or shortening them. This is achieved through the implementation of the omnibus law approach, which is an appropriate way to develop a legal framework for licensing Indonesia's business processes. This method allows the creation of regulations that cover several substantive materials or several smaller ones in one rule, promoting order, legal certainty, and expediency [3]. The omnibus law is a method or concept of rule-making that aims to solve problems related to licensing by creating a new UU that revises articles in several existing UU [4].

According to Article 64 paragraph 1b of UU No. 13 of 2022, one of the omnibus methods is to revoke laws and regulations of the same type and hierarchy. To avoid overlap between rules, legal drafters must identify the source of the revoked rules. This requires an understanding of similar regulations and their hierarchy. A database of UU, including articles and paragraphs, can aid legal drafters. Additionally, it is important to check for similarities between norms and UU to minimize language differences.

Algorithms that can be used to check for similarity include cosine similarity. Cosine similarity measures vector similarity by calculating the angle between them [5]. Calculating similarity using two angles has the advantage of being language-independent. It can be used even when no corpus is available. Unfortunately, cosine similarity is not sensitive to differences in size, which means that two patterns with very different attribute values can have high similarity scores [5]. Using Term Frequency and Inverse Document Frequency (TF-IDF) can solve the problem of cosine similarity, which is insensitive to vector magnitude [6].

Cosine similarity is a technique used in legal document retrieval to assess the similarity of several legal documents. To guarantee that cases with comparable circumstances are handled uniformly in each instance, it is employed to obtain previous case records of a particular case [7]. It has been demonstrated through experimentation that cosine similarity and the doc2vec approach may automatically obtain court rulings of comparable legal issues [8]. When it comes to legal aid, cosine similarity is used to compare legal document

*Corresponding Author.

embeddings, which are texts represented in a semantic vector space [9]. Cosine similarity is another method that uses unsupervised learning techniques like Word2Vec CBoW, Word2Vec Skip-gram, and TF-IDF to determine how similar court documents are to one another [10]. Cosine similarity is employed to group lawful [11].

This research aims to confidently assist lawmakers and legal writers in thoroughly searching for keywords (norms) in UU using Bahasa and implementing them in lawmaking with the aid of a search engine, this approach will significantly save time in understanding each existing law.

II. METHODS

The research was conducted using the waterfall model, one of the software development models. Waterfall model is divided into four stages, namely analysis, design, implementation and testing. Fig. 1 illustrates the research design using the waterfall model.

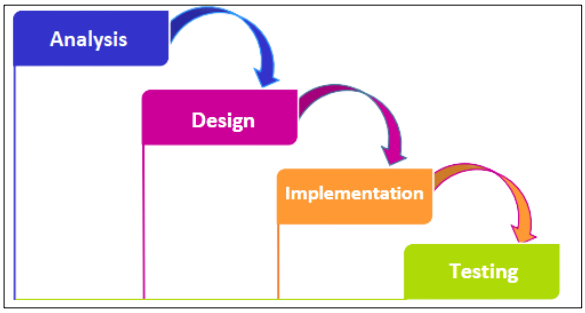

Fig. 1. Research design.

A. Analysis Phase

The analysis stage, also known as software requirements specification (SRS), is a thorough and comprehensive description of the software to be developed. Analysis includes system and business analysis to define both functional and non-functional requirements. The task for the analysis stage is to identify functional and data requirements for the software. Requirements gathering can be done by conducting observations, interviews, and document analysis. Function and data requirements that are complete can facilitate the next stage in the waterfall model. Raw data collection is transformed or pre-processed into mature, processable data. Preprocessing is the stage of converting data into a form that can be understood by machines [12]. Preprocessing aims to standardize data to facilitate processing [13]. This process involves four steps.

1) Case folding: Case folding is the process of equalizing cases in a document [14]. Phase of case folding aims to make all characters in the law lower case, remove numbers, remove punctuation marks, and remove spaces.

2) Tokenizing: Tokenization is the process of dividing a document into smaller parts, known as tokens [14].

3) Filtering: Filtering involves removing words deemed unnecessary or unimportant, based on stop words [15].

4) Stemming: Stemming is the process of removing all of the affixes and suffixes from the words, and this process is used to filter the results [9].

B. Design Phase

The design stage involves planning and problem-solving for a software solution. It requires the software developer to define the plan of the solution, including algorithm design, software architecture design, database conceptual schema and logic diagram design, concept design, graphical interface, and data structure definition.

Algorithm and architecture design can be aided by image processing software such as Paint, Adobe Photoshop, or Corel Draw. Conceptual schemes and data structure definitions can be created using ERD diagrams or other charting software. For interface design, Balsamiq or Figma can be used.

C. Implementation Phase

The implementation stage is when business requirements and design specifications are transformed into executable programs, databases, websites, or software components through programming. During the implementation phase, real code is written and compiled into a working application where the database and text have been created; in other words, the implementation phase is the process of converting all the requirements and blue ink into a production environment.

The research implementation utilizes information systems to enhance user comprehension. Information systems are organizational systems that summarize management functions and daily transaction processing requirements. These systems support the strategic activities of the organization in order to provide certain external parties with the information needed to facilitate decision making [16]. The information system is referred to as Omnibus Law Information System for the purpose of this research. The architecture is structured using FastAPI, Laravel, and MariaDB. FastAPI was chosen due to its superior performance compared to NodeJS and Go [17].

D. Testing Phase

The testing phase is commonly referred to as verification and validation. Verification is the process of verifying that the software meets the requirements and specifications to achieve the goals of software development. The purpose of verification is to evaluate the software to determine whether the product of the development phase meets the conditions imposed at the beginning of the stages of the waterfall model. Validation is the process of evaluating software during or at the end of the development process to determine if it meets the specified requirements.

III. RESULT AND DISCUSSION

The results include the research process on the case study that is the Omnibus Law and the data which are the UU. The Discussion includes the implementation process of each research methodology in the research, which consists of analysis, design, implementation, and testing.

A. Research Results

The Omnibus Law is a means of reducing the number of laws in Indonesia, which is considered an effective way to consolidate numerous regulations into a single unit [18]. Another potential benefit of the Omnibus Law is the ability to modify laws that have overlapping or other issues. However,

the challenge of the Omnibus Law is to modify the content without creating problems such as overlap or multiple interpretations. This study aimed to address the challenge of identifying similarities between legal content and the normative vocabulary to be established.

This research utilizes cosine similarity through the Python programming language and the FastAPI framework as the backend for calculations. The frontend uses the Laravel framework with PHP as the primary language. The FastAPI framework is employed to implement the cosine similarity model, and the final result is the API requested by the Laravel framework.

B. Discussion

The discussion is structured according to the research design presented in Fig. 1. The research process begins with the analysis stage, followed by the design, implementation, and testing stages.

1) Analysis phase: The author designs the function and data requirements based on the analysis and observation of the Law. The following are the function and data requirements.

a) Function requirements: Functional requirements define the software's necessary functions. The intended user is a legal drafter or lawmaker.

- Users can calculate the similarity of the vocabulary (norms) with the law as a whole.
- Users can perform vocabulary (norm) search on any article of the law.
- Users can see the highlight of the vocabulary (norm) in each article.
- Users can select the article to be printed in pdf or docx.

b) Data requirements: The study's data requirements are focused on preprocessed UU data. Preprocessing is accomplished using regular expressions and natural language toolkits (NLTK) in the Python programming language. The preprocessing process generated 60,186 data points, which is 15,595 fewer than the extraction process.

2) Design phase: The design stage is the implementation phase of the analysis stage. The draft module development design phase includes algorithm design, use case diagram, and user interface design.

a) Algorithm design: The drafting module was developed using the cosine similarity algorithm to calculate the distance between two angles. Converting words into vectors is essential for accurately measuring the distance between two vectors projected onto the X and Y axes. The angle is obtained from the TF-IDF results formula can be seen at Eq. (1) and Eq. (2), which are calculated using the cosine similarity formula [19]. The cosine similarity, as a method of measuring the similarity between the documents, varies between positive values from 0 to 1 [20]. Two texts are virtually identical, as evidenced by a cosine similarity close to 1, indicating a small angle between them. Cosine similarity method enables us to identify similarities between vectors as long as these words are present in the document. The formula can be seen in Eq. (3) and an overview of the cosine similarity algorithm process is described in Fig. 2.

$$idf_i \tag{1}$$

$$w_{i,j} = tf_{i,j} \times idf_i \tag{2}$$

$$cos(A,B) = \frac{A \cdot B}{|A||B|} = \frac{\sum_{i=1}^{n} A_i \, x \, B_i}{\sqrt{\sum_{i=1}^{n}(A_i)^2} \, x \, \sqrt{\sum_{i=1}^{n}(AB_i)^2}} \tag{3}$$

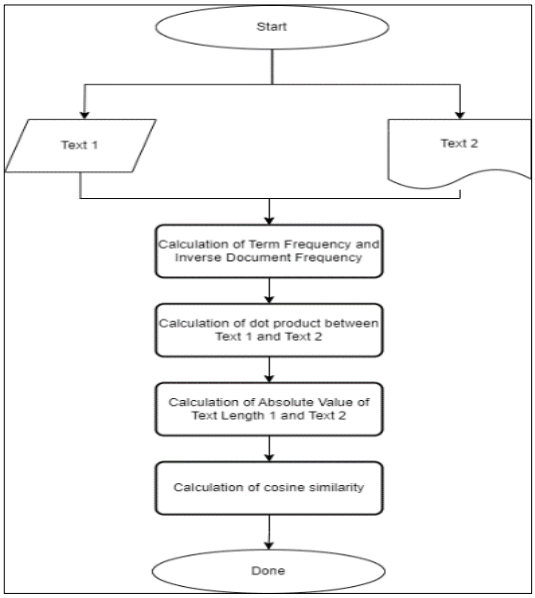

Fig. 2. Cosine similarity process.

b) Use case diagram: The Use Case diagram is a design tool used to address business problems in research. Fig. 3 displays the Use Case Diagram for the drafting module in the Omnibus Law Information System.

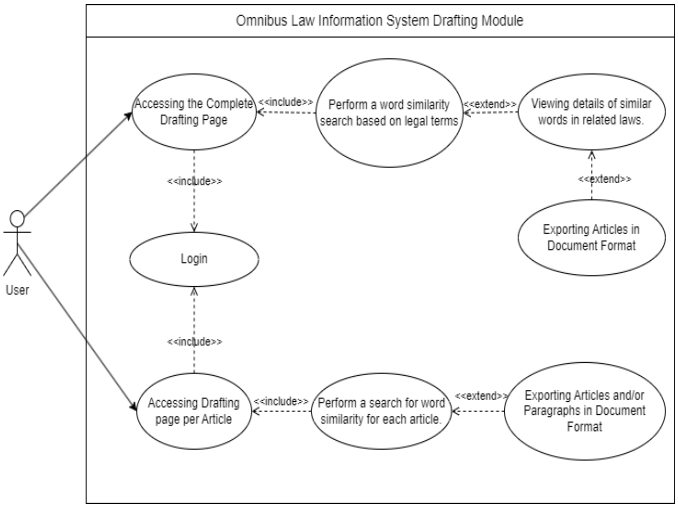

Fig. 3. Use case diagram of the drafting module of the omnibus law information system.

Legal drafters are the users of the Omnibus Law Information System. Explanation of Fig. 3 regarding use of use cases can be shown in Table I.

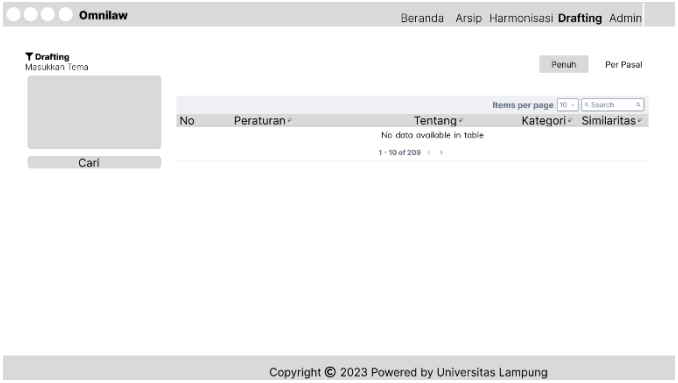
TABLE I. DESCRIPTION OF USE CASE DIAGRAM

Actor	Use Case	Description
User	Accessing the complete drafting page	User can view the full design page
	Perform a word similarity search base on legal terms	Users can search for similarities between words based on legal terms.
	Viewing details of similar word in related laws.	Users can view details of word similarities in related laws.
	Exporting articles in document format	Users can export articles in document format
	Accessing drafting page per article	Users can view the draft page per article
	Perform a search for word similarity for each article	Users can search for word similarities per article
	Exporting articles and/or paragraphs in document format	Users can export articles and/or paragraphs in document format

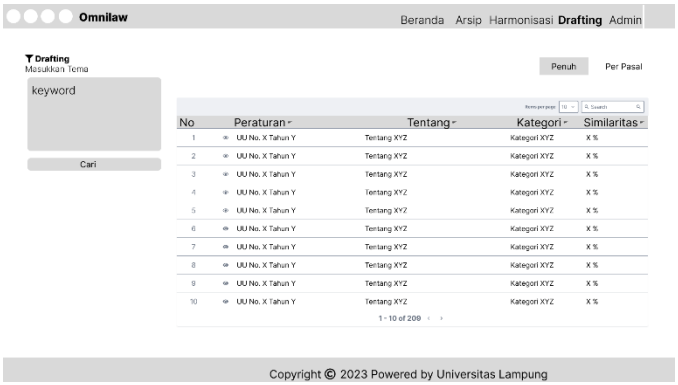
c) User interface design: User interface design is carried out as a reference for system display design. Fig. 4 shows the display design consists of five display pages that follow the design of each display.

3) Implementation phase: The implementation phase is the phase in which the results of the analysis and design are applied. This stage involves implementing algorithm, activity diagram and user interface design.

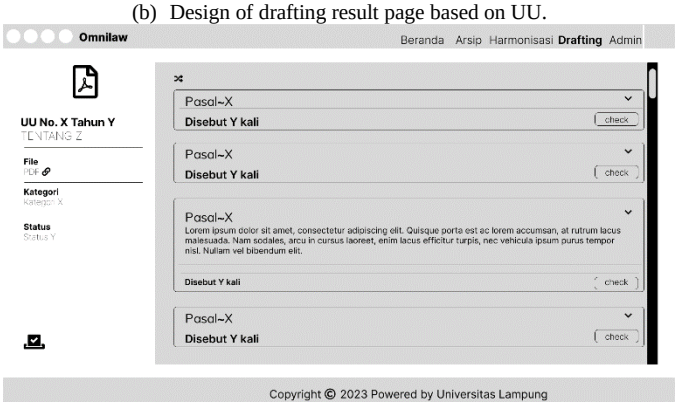
a) Algorithm: Cosine similarity is the algorithm used in the development of the Drafting module. Cosine similarity uses the cosine as the basis for calculation, which means that if this means that if two words or documents have a calculation result with an angle of 0 degrees, they have 100% similarity. FastAPI is used to implement the algorithm. Construction of FastAPI uses standards from OpenAPI known as Swagger and JSON Schema [21]. Interactive documentation can be used to test the response of any feature provided by Swagger UI. Fig. 5 shows the documentation page provided by Swagger UI.



(a) Design of drafting home page based on UU.

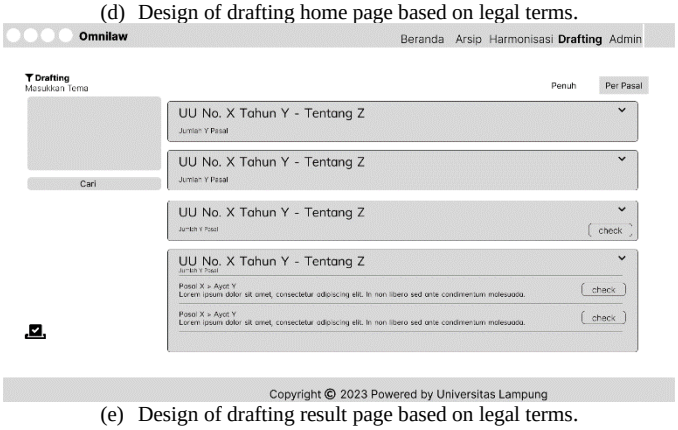


(b) Design of drafting result page based on UU.



(c) Design of drafting result detail page based on UU.

(d) Design of drafting home page based on legal terms.



(e) Design of drafting result page based on legal terms.

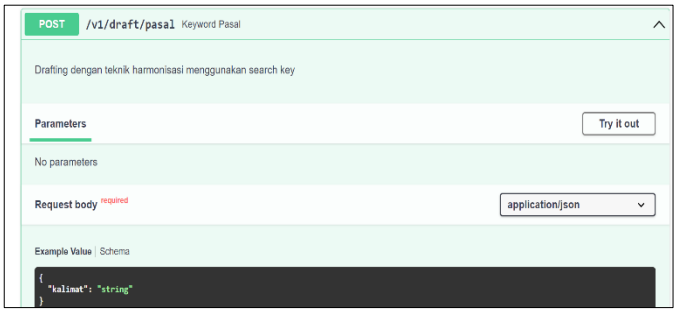

Fig. 5. Swagger UI documentation.

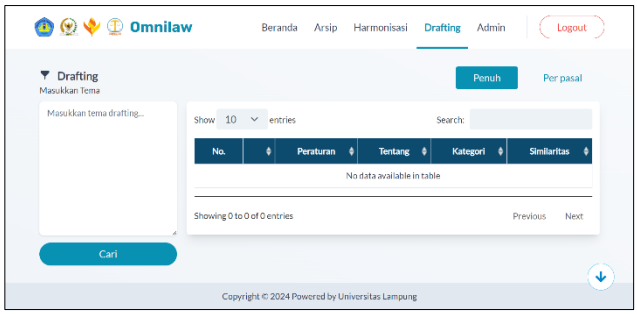
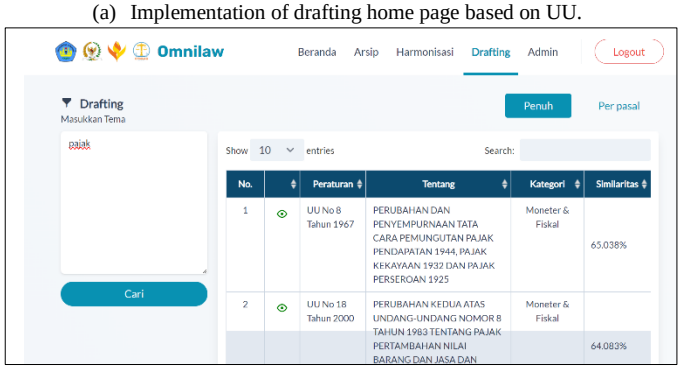
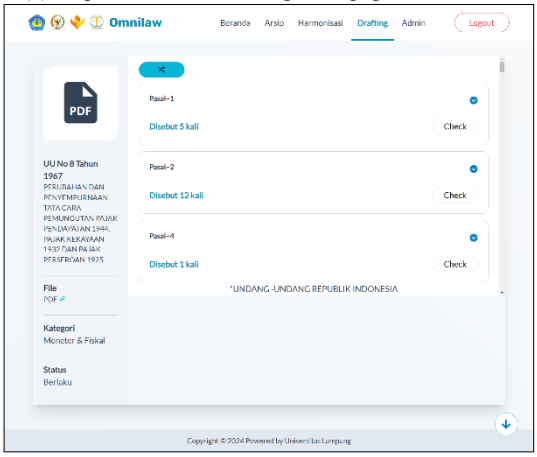
b) Laravel: Laravel is a PHP framework used as a front end that adheres to the Model - View - Controller (MVC) concept [22]. The functions included in Laravel are the implementation of use cases, activity diagrams and user interfaces. There are seven use cases implemented with Laravel as shown in Fig. 6.



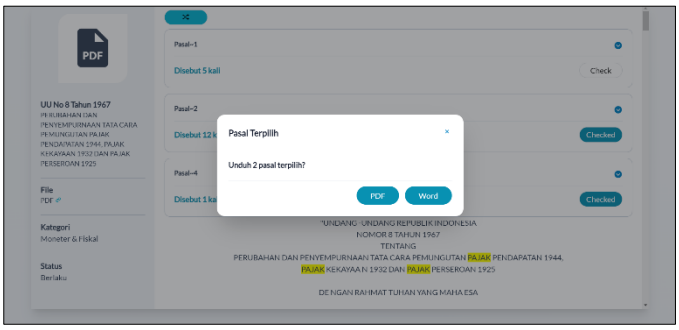
(a) Implementation of drafting home page based on UU.



(b) Implementation of drafting result page based on UU.



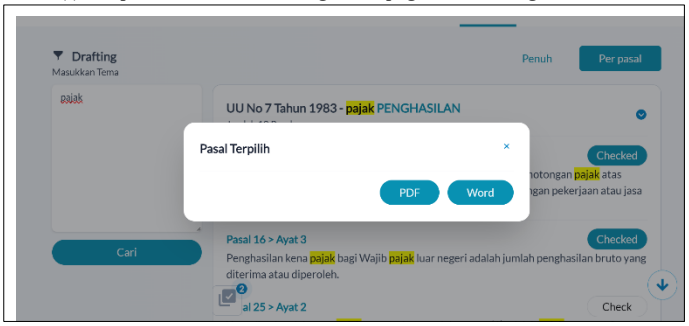
(c) Implementation of drafting result detail based on UU.



(d) Implementation of exporting result in document format based on UU.

(e) Implementation of drafting home page based on legal terms.

(f) Implementation of drafting result page based on legal terms.



(g) Implementation of exporting result in document format based on legal terms.

Fig. 6. Implementation of (a) Drafting home page based on UU (b) Drafting result page based on UU (c) Drafting result detail based on UU (d) Exporting result based on UU (e) Drafting home page based on legal terms (f) Drafting result page based on legal terms (g) Exporting result in based on legal terms.

c) Information systems architecture: The Omnibus Law information system architecture uses a full stack architecture. Full stack architecture divides an information system into two parts, namely the front-end or user display and the back-end or screen behind the process. Fig. 7 shows the omnibus law information system architecture.

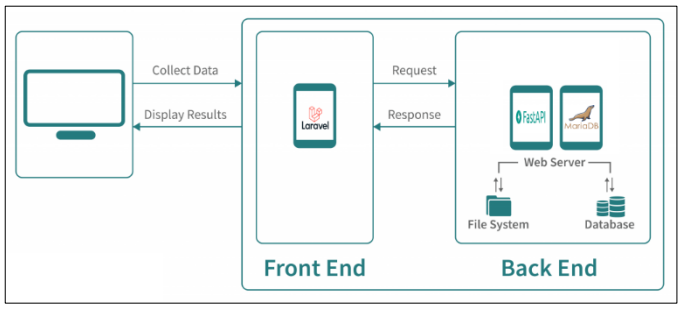


Fig. 7. Information system architecture.

4) Testing phase: Testing is the stage of validation and verification of each function included in the information system to ensure that it works correctly. Testing the algorithm using the confusion matrix. Confusion Matrix is used to see the predictive ability of the algorithm. Confusion matrix is a predictive analysis tool that compares actual values with predicted model values [23]. From the results of the confusion matrix calculation performed, a recall of 90.10%, accuracy of 56%, precision of 30% and F1 score of 45% was obtained.

IV. Conclusion

Based on the results of research on the implementation of cosine similarity in the Omnibus Law Information System, the authors draw the following conclusions: (1) The degree of similarity between keywords for drafting laws and existing laws can be measured using the cosine similarity algorithm and TF-IDF, with recall 90.10%. (2) Implementation of the similarity model between keywords and existing UU so that it can be used by users (legal drafters) using FastAPI as a back-end and Laravel as a front-end, so that it speeds up user work in seeing the similarity between keywords and existing UU.

For future works, Inclusion of datasets containing regulations with a different hierarchy from UU, such as Perpres and others, would be more beneficial for lawmakers. This would aid in determining which parts are attached to the new laws, without causing any overlap in Indonesian regulations.

Enhancing Particle Swarm Optimization Performance Through CUDA and Tree Reduction Algorithm

Hussein Younis, Mujahed Eleyat
Department of Computer Systems Engineering, Arab American University, Palestine

***Abstract*—In this paper, we present an enhancement for Particle Swarm Optimization performance by utilizing CUDA and a Tree Reduction Algorithm. PSO is a widely used metaheuristic algorithm that has been adapted into a CUDA version known as CPSO. The tree reduction algorithm is employed to efficiently compute the global best position. To evaluate our approach, we compared the speedup achieved by our CUDA version against the standard version of PSO, observing a maximum speedup of 37x. Additionally, we identified a linear relationship between the size of swarm particles and execution time; as the number of particles increases, so does computational load – highlighting the efficiency of parallel implementations in reducing execution time. Our proposed parallel PSOs have demonstrated significant reductions in execution time along with improvements in convergence speed and local optimization performance - particularly beneficial for solving large-scale problems with high computational loads.**

***Keywords*—Particle swarm optimization; tree reduction algorithm; parallel implementations; CUDA; GPU**

I. Introduction

Optimization techniques are crucial in various domains for finding optimal solutions to complex problems. However, Particle Swarm Optimization, a widely used metaheuristic algorithm, has demonstrated limitations in terms of convergence speed and local optimization performance [1] [2]. As a result, researchers have turned to parallel computing techniques like Compute Unified Device Architecture (CUDA) a parallel computing platform and application programming interface (API) developed by NVIDIA, to enhance the performance of PSO by implementing it on a parallel architecture. Significant reductions in computing time compared to traditional implementations using different programming languages have been observed by researchers.

In the field of parallel computing, practitioners often employ various techniques to break down a computational task into smaller subtasks that can be executed simultaneously on multiple processors. These subtasks, commonly known as threads, are vital in this approach and are managed for execution by an operating system. CUDA supports shared memory parallel programming, which enables multiple processors or cores to access a shared memory space efficiently [3].

The integration of CUDA technology plays a pivotal role in enabling the seamless implementation of Particle Swarm Optimization (PSO) within a parallel architecture. This cutting-edge approach harnesses the power of GPUs to efficiently distribute workloads into smaller tasks, allowing for concurrent processing on the Graphics Processing Units. By utilizing CUDA for the parallel execution of PSO on GPUs, computational tasks benefit from enhanced efficiency and performance through the utilization of parallel processing capabilities, ultimately leading to accelerated computations and improved results in various applications such as optimization, machine learning, and scientific simulations [4].

This parallel method empowers each particle to autonomously execute a designated number of iterations before resynchronization occurs. Many researchers have successfully implemented PSO algorithms using CUDA for GPUs, and the outcomes from these endeavors unequivocally indicate that parallelization significantly enhances the performance capabilities of PSO [5].

This paper produces a CUDA version of the PSO algorithm called (CPSO). The tree reduction algorithm and the CUDA shared memory were used in CPSO to reduce the comparison operations to half and reduce the amount of time spent accessing global memory. The contributions of this work are summarized as follows:

1) Propose a CUDA version of the PSO algorithm.

2) Enhance the CUDA implementation of the PSO algorithm using the tree reduction algorithm and the CUDA shared memory.

3) Compare the proposed algorithms in terms of execution time and speedup to demonstrate the effectiveness and efficiency of our proposed algorithm.

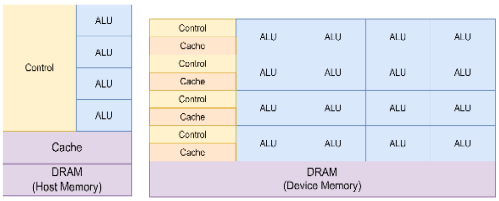
The structure of this paper is outlined as follows: Section II presents the background information, Section III discusses related work, Section IV details the implementation of PSO algorithms, Section V outlines the experimental setup, Section VI presents the results and discussions, and Section VII provides the conclusions and suggestions for future work.

II. Background

A. Graphics Processing Unit

The Graphics Processing Unit (GPU) was initially developed in the 1970s as an electronic circuit for displaying vector graphics [6]. Over the years, the GPU has undergone significant development and has evolved into a highly parallel processor capable of performing complex computations, providing significant performance boosts for graphics-intensive applications [7]. One of the main advantages of the GPU is its ability to provide higher instruction throughput and memory bandwidth than the Central Processing Unit (CPU) within the same power envelope. Unlike the CPU which is designed to

execute threads as fast as possible and execute only a few threads in parallel depending on the number of cores, the GPU is designed to execute thousands of sequences of operations, called “threads,” in parallel up to 1024 threads per block limit of the GPU [8]. The main architecture of the CPU and GPU is illustrated in Fig. 1, where the CPU (host) and GPU (device) work together and communicate via a PCI-express bus [9].



(a) (b)

Fig. 1. The architecture of (a) CPU; and (b) GPU.

B. Compute Unified Device Architecture

NVIDIA, a leading player in the field of visual computing and parallel processing, introduced the CUDA in 2007 as a parallel platform programming model [10]. CUDA provides a set of tools that enable the development of high-performance applications to be executed on GPUs. Typically, a CUDA program consists of two parts: the first part is executed on the host CPU, while the second part is executed on the device GPU, with the result being returned to the host CPU [11]. As shown in Fig. 2, the CUDA programming architecture consists of N number of grids which depends on the limitations of the GPU hardware. Each grid is composed of blocks, and each block contains multiple threads that can be executed concurrently. The thread blocks are organized into 1D, 2D, or 3D arrays of threads [12].

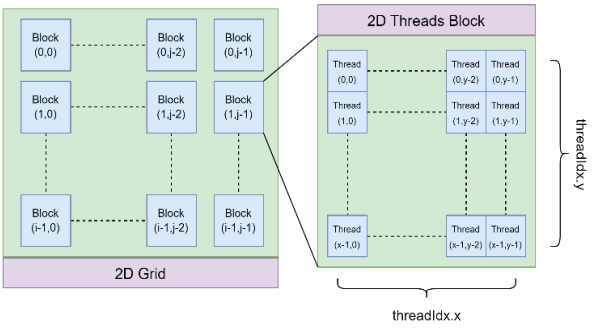


Fig. 2. CUDA 2D grid and thread block indexes presentation.

Each thread within a block has a specific index that is used to identify its location during the execution of the CUDA function, known as the 'kernel' function. The thread index for a 1D dimension is calculated using the following equation [13]:

$$thread\ index = (blockIDx.x \times blockDim.x) + threadIdx.x \quad (1)$$

Here, $blockIDx.x$ represents the x-dimension identifier of the thread block, $blockDim.x$ represents the x-dimension of the thread block, and $threadIdx.x$ represents the x-dimension identifier of the thread.

In GPUs, threads can be executed together in parallel in groups called "warps" which consist of 32 or 64 threads depending on the GPU architecture [14]. Within each warp, the threads execute the same instruction at the same time, a concept known as Single Instruction Multiple Threads (SIMT) which minimizes the amount of branching and divergence between threads which can result in performance penalties [15]. Each CUDA thread possesses its private local memory and can access data from multiple memory spaces. Furthermore, each block has shared memory that can be accessed by its threads or by other thread blocks as illustrated in Fig. 3. Local memory offers the fastest memory access speed for each thread, followed by shared memory. Global, static, and texture memory speeds are relatively slower [15].

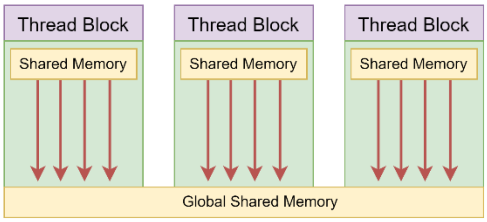

Fig. 3. Memory hierarchy in GPUs.

CUDA provides a function called “cudaMallocManaged” for unified memory management between CPU and GPU without explicit data transfers. It acts like a single memory space that can be accessed by both CPU and GPU. The overhead of explicit data transfer between CPU and GPU is reduced which improves the overall performance by providing a unified memory space [16]. Also, CUDA provides a function called “cudaMemPrefetchAsync” to prefetch data from the host or device memory to the device cache before it is needed. The main advantage of “cudaMemPrefetchAsync” is that data movement operation is performed asynchronously, optimizing memory access patterns and reducing data transfer latency in CUDA applications [17], [18]. Typically, a GPU program consists of one or more kernels which are collections of tasks executed sequentially by GPUs. These kernels are composed of blocks, separate groupings of Arithmetic Logic Units (ALUs). Each block contains multiple threads, representing various levels of computation. Usually, the threads within a block collaborate to calculate a specific value. It is important to note that threads within the same block can share memory, enabling efficient data interchange. In the context of CUDA, the most common computation involves transferring data from the CPU to the GPU [19] The main steps of the CUDA program flow, as depicted in Fig. 4, are: the data is loaded into the host CPU memory and then transferred to the GPU memory using a function called *"cudaMemcpy"*. Subsequently, the kernel is launched on the GPU using the syntax *"kernel<<<numBlocks, threadsPerBlock>>>"* [14]. The "<<<>>>" notation is employed to configure the execution of the kernel by specifying the number of thread blocks and the number of threads per block [20].

III. Related Work

PSO has been applied and extended in various studies. In this context, several works have focused on optimizing the performance of PSO algorithms, particularly by leveraging parallel computing techniques.

In study [21] the authors provide an overview of the PPSO algorithm which is commonly used in complex optimization problems requiring significant computational power. They discuss different parallelization options for PPSO, including programming languages and communication topologies. Also, they cover various models of parallelization, implementation, and uses of PPSO algorithms, making them a valuable resource for researchers and developers working with PPSO and other parallel optimization algorithms.

In study [22] the authors propose a novel algorithm called "cuPSO" that reduces the computation time of PSO-based algorithms with massive threads on GPUs. The proposed algorithm addresses excessive memory accesses and thread synchronization overheads faced by traditional reduction-based methods through the use of atomic functions. Experimental results show that cuPSO achieves over 200x speedups compared to the serial version running on the CPU and outperforms the state-of-the-art method by a factor of 2.2 in terms of computation time. Similarly, the authors focus on optimizing particle systems using CUDA-assisted multithreading. They aim to improve the performance of particle systems by enhancing a CUDA particle demo developed by Nvidia using a Python script. The experimental results in their work demonstrate the achievement of desired performance levels by adjusting the number of particles, grid size, and grid orientation. It also presents hypotheses regarding the impact of changing these parameters on processing time and provides experimental results to support these hypotheses [23]. Furthermore, another work introduces a new approach to running standard particle swarm optimization (SPSO) by utilizing GPU's parallel computing capability and NVIDIA's CUDA software platform. Experiments were conducted to optimize benchmark test functions using both GPU-SPSO and CPU-SPSO, results show that GPU-SPSO significantly reduces running time compared to CPU-SPSO more than 11 times faster than CPU-SPSO, especially for large swarm population applications and high dimensional problems [24].

The authors explore and evaluate two different ways of utilizing GPU parallelism in the implementation of particle swarm optimization (PSO) on graphics processing units (GPUs). The execution speed of these two parallel algorithms is compared with a standard sequential implementation of PSO, known as SPSO. The study also includes a comprehensive analysis of the computation efficiency of the parallel algorithms, considering speed-up and scale-up with SPSO. Also, the authors investigate the extent to which PSO can benefit from a parallel implementation using CUDA. The design of the two parallel versions of PSO considered in this study was influenced by the structure of CUDA and compatible GPUs. Additionally, the practical implications of the parallel algorithms resulted in two possible solutions that differentiate the potential use of each version [5].

Finally, another work introduces a parallel implementation of Cooperative Particle Swarm Optimization (CPSO) using CUDA. The work includes a comparison between CPSO implemented in C and C-CUDA, and tests were conducted on standard benchmark optimization functions. The results showed improvements in speed and convergence time, with CUDA's randomizing procedures contributing to better solutions. The paper emphasizes the utility of CUDA for complex and computationally intensive applications [25].

IV. PSO Algorithms Implementation

In general, the choice of data structure in the PSO algorithm is crucial for effectively representing and manipulating particles within the swarm. The main data structure used in proposed PSO algorithms is the Particle structure as illustrated in Fig. 5(a), which encapsulates the necessary information for each particle. This structure typically includes components such as the current position, best position, velocity, and best value. The current position represents the particle's location in the search space, while the best position stores the particle's personal best solution found so far. The velocity determines the particle's movement in the search space, and the best value represents the fitness or objective value associated with the best position. The struct position as illustrated in Fig. 6(b) represents a two-dimensional position in space, with x and y coordinates stored as floating-point values. It also includes two member functions and two overloaded operators. PSO algorithms can efficiently update and track the positions and velocities of particles, facilitating the exploration and exploitation of the search space by utilizing these data structures. The design and implementation of these data structures are critical for the success of PSO in finding optimal solutions to optimization problems.

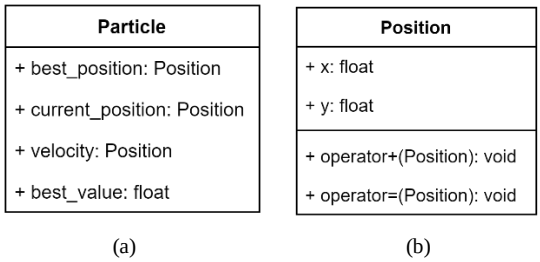

Fig. 5. Data structure for (a) The particle struct; and (b) The position struct.

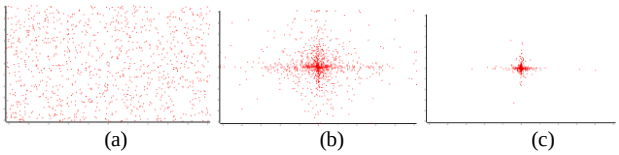

Fig. 6. A 2D visualization for PSO with 5000 particles: (a) The initial state of particles; (b) The particle's state after 100 iterations; (c) The particle's state after 200 iterations.

A. Standard PSO Algorithm

The Standard Particle Swarm Optimization (SPSO) algorithm is one such technique that draws inspiration from the social behavior of bird flocking or fish schooling. It is categorized as a population-based optimization technique and was first introduced in 1995 by Kennedy and Eberhart. In

SPSO, each solution is referred to as a "particle" that moves through the search space, seeking the optimal position as illustrated in Fig. 6. The search for the optimal position is guided by a "fitness function." Each particle has its position and velocity which are adjusted in each iteration based on its experience and the collaboration with its neighbors in the search space [26], [27].

This collaboration is demonstrated by the following equations [28]:

$$v_i^n = \omega v_i^n + c_1 r_1 (pbest_i^n - x_i^n) + c_2 r_2 (gbest^n - x_i^n) \quad (2)$$

$$x_i^{n+1} = x_i^n + v_i^{n+1} \quad (3)$$

where, the v_i^n *and* x_i^n present the current velocity and the position of the particle i at the nth iteration respectively, the ω presents the inertia weight, the c_1 *and* c_2 present the cognitive and social coefficients, respectively, the r_1 *and* r_2 are random numbers in the range $[0,1]$, the $pbest_i^n$ represents the best position of the particle i in the nth iteration and the $gbest^n$ represents the best position among all particles at the nth iteration.

Algorithm 1 demonstrates the pseudocode of the SPSO algorithm, with the following description of the SPSO parameters [26]:

- Population: It presents the total number of particles in the swarm space.
- T_{max} present the maximum number of iterations.
- x_i and v_i present the current position and the velocity, respectively, for the particle p_i.
- italicsfitness$_i$ and pbest_fitness$_i$: present the fitness value and the best fitness value, respectively, for the particle p_i.
- pbest$_i$ presents the best position for the particle p_i.
- gbest and gbest_fitness present the team best position and best fitness value, respectively, of the entire swarm space.
- Termination condition presents the criteria that determine when the SPSO will stop searching for the optimal solution.

Algorithm 1 Sequential SPSO algorithm

For every particle p_i in the swarm space, where $0 \leq i <$ population do:
  Initialize the x_i and v_i randomly
  Evaluate the fitness$_i$ by the x_i using the fitness function.
  Initialize the pbest_fitness$_i$ and $pbest_i$.
  Update the $gbest$ and the $gbest\_fitness$.
End
For every iteration $t = 0,1,2, \dots, T_{max}$, do:
  For every particle p_i in the swarm space, where $0 \leq i <$ population do:
    Update the position x_i and the velocity v_i for particle p_i by the Eq. (4) and (5).
    Evaluate the new fitness$_i$ by the x_i using the fitness function.
    If the new fitness$_i$ > pbest_fitness$_i$ then update pbest_fitness$_i$ by new fitness$_i$ and $pbest_i$ by x_i.
    If the new fitness$_i$ > $gbest\_fitness$ then update $gbest\_fitness$ by new fitness$_i$ and $gbest$ by $pbest_i$.
    If the $gbest\_fitness$ met the termination condition, then exit from main and secondary loops.
  End
End

The time complexity of the SPSO algorithm is typically$O(T \times P)$, where the T is the number of iterations and the P is the number of particles in the swarm space.

B. CUDA PSO Algorithm

The SPSO algorithm is one such technique to leverage the power of parallel computing of GPU, to introduce the CUDA Particle Swarm Optimization (CPSO). The CPSO involves parallelizing by assigning each particle to a separate thread on the GPU to update its position and velocity based on its own best position ($pbest$) and the best position ($gbest$) founded by any particle in the swarm space. Also, the unified memory management and shared memory within each block have been utilized since the SPSO is a memory-bound problem. The CPSO consists of three kernels update particle velocity, update particle position, and compute the best position ($gbest$). The pseudocode of the CPSO is demonstrated in Algorithm 2.

Algorithm 2 CUDA PSO Algorithm (CPSO)

Set the blockSize equal to 32 and determine the grid size by the Eq. (3).
Allocate memory for particles, $gbest$ and the $gbest\_fitness$ using *cudaMallocManaged*.
Initialize the particles with random starting positions, velocities, and $pbest$.
compute $gbest$ and the $gbest\_fitness$ using *ComputeGlobalBestPosition* kernel.
Prefetch the particles array to the GPU.
For every iteration $t = 0,1,2, \dots, T_{max}$, do:
  Update the velocity of each particle using the kernel *updateParticleVelocity*.
  Update the position of each particle using the kernel *updateParticlePosition*.
  Update the $gbest$ and the $gbest\_fitness$ using the kernel *ComputeGlobalBestPosition*.
  If the $gbest\_fitness$ met the termination condition, then terminate.
  End
End
Wait for GPU to finish the computation.
Free allocated memory.

The kernel “ComputeGlobalBestPosition” is implemented by applying the "tree" reduction algorithm where each block

calculates its bbest within its shared memory where the bbest presents the best position within each block. This means that each block independently determines the bbest among the particles it is responsible for. The resulting minimum bbest is stored in shared memory and then reduced across all blocks to find the overall minimum value to obtain gbest. The following Fig. 7 illustrates a chart that shows how this works for a block of eight threads.

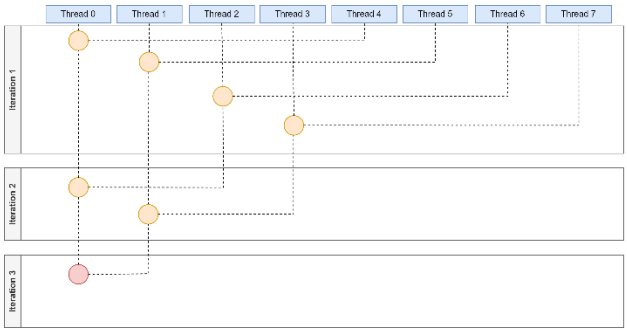

Fig. 7. Tree reduction algorithm workflow for eight threads.

For the first iteration, Thread 0 compares the best fitness value at index 0 with value at index 4, Thread 1 compares value at index 1 with value at index 5, Thread 2 compares value at index 2 with value at index 6, Thread 3 compares value at index 3 with value at index 7 and Threads 4-7 do nothing. For the second iteration, Thread 0 compares value at index 0 with value at index 2, Thread 1 compares value at index 1 with value at index 3 and Threads 2-3 do nothing. For the third iteration, Thread 0 compares value at index 0 with value at index 1 to obtain the final minimum value.

In each iteration of the loop, the number of threads that perform a comparison is halved. This means that the number of iterations required to reduce all values to a single minimum value is $log_2(N)$, where N is the number of threads in the block. After the parallel reduction loop completes, each thread block has found its own minimum value and corresponding index. These values are stored in shared memory. The final step is to reduce across all thread blocks to find the overall minimum value and corresponding index. This is done on the CPU after all threads have completed their computations.

The pseudocode of the "ComputeGlobalBestPosition" is illustrated in Algorithm 3.

Algorithm 3 *ComputeGlobalBestPosition kernel*

Declares a shared memory array *blockBestValueArray* with a size of 32 that will be used for the parallel reduction within each block.
Compute the thread ID within the block t_{id} for the current thread by threadIdx.x and the idx for the current thread by Eq. (1). where idx is the global index of the particle that this thread is responsible for.
Initialize $blockBestValueArray[t_{id}]$ with $pbest$ value of $idx's$ particle.
Synchronize all threads within the block using *__syncthreads ()* to ensure that all threads have finished updating the shared memory variables.
loop i= $\frac{blockDim.x}{2}, i < 0, i >>= 1$ do the following:
    If the $t_{id} < i$ then
        If $blockBestValueArray[t_{id}] > blockBestValueArray[t_{id} + i]$, then update $blockBestValueArray[t_{id}]$ with $blockBestValueArray[t_{id} + i]$.
        End
    End
End
Synchronize all threads within the block using *__syncthreads ()* to ensure that all threads have finished updating the shared memory variables.
If the $t_{id} = 0$ then
    Update the $gbest$ value by the first element of *blockBestValueArray*.
End

The kernel "updateParticleVelocity" is implemented where each thread is responsible for a particle update their velocity based on Eq. (4). The pseudocode of the "updateParticleVelocity" is illustrated in Algorithm 4.

Algorithm 4 *updateParticleVelocity kernel*

Compute the idx for the current thread by Eq. (1) where idx is the global index of the particle that this thread is responsible for.
Declares a shared memory variable $gbest$ to access by all threads within each block.
Synchronize all threads within the block using *__syncthreads ()* to ensure that all threads have finished loading the shared memory variable.
If the idx < population then
    Update the velocity for particle p_{idx} by the Eq. (4).
End

The kernel "updateParticlePosition" is implemented where each thread is responsible for a particle updating its position based on Eq. (5) and updating its pbest. The pseudocode of the "updateParticlePosition" is illustrated in Algorithm 5.

Algorithm 5 *updateParticlePosition kernel*

Compute the idx for the current thread by Eq. (1) where idx is the global index of the particle that this thread is responsible for.
If the idx < population then
    Update the position for particle p_{idx} by the Eq. (5).
    Evaluate the new $fitness_{idx}$ by the x_{idx} using the fitness function.
    If the new $fitness_{idx}$ > $pbest\_fitness_{idx}$ then update $pbest\_fitness_{idx}$ by new $fitness_{idx}$ and $pbest_{idx}$ by x_{idx}.
End

V. EXPERIMENTAL SETUP

The software and hardware specifications for the computer used to implement and test the PSO and CPSO algorithms are listed in Table I and Table II respectively. The details specification of the Graphics Card is listed in Table III.

TABLE I. SOFTWARE SPECIFICATION

Name	Version
Microsoft Windows 11	22H2
Visual Studio	2022
Nsight Systems	2023.2.3
CUDA	12020
OpenMP	2.0

TABLE II. HARDWARE SPECIFICATION

Specification	Properties
Processor	AMD Ryzen 9 5900HX, 3301 MHz, 8 Core(s), 16 Logical Processor(s)
Physical Memory (RAM)	32.0 GB
Graphics Card	NVIDIA GeForce RTX 3080 Laptop GPU

TABLE III. THE DETAILS SPECIFICATIONS OF THE GRAPHICS CARD

Specification	Properties
Global memory	16,383 MB
Shared memory	48 kb
Block registers	65,536
Max threads per block	1024
Max dimensions of a block	(1024, 1024, 64)
Max dimensions of a grid	$(2^{31} - 1, 65535, 65535)$
Warp size	32 threads
CUDA core	6,144 cores
Memory bandwidth	760.3 GB/sec
Memory channels	8
memory bus width	256-bit
Memory clock	1750 MHz

An important design parameter of the PSO algorithm is the fitness function. We choose the Euclidean distance function as the fitness function for all the experiments, as shown in Eq. (4). The parameter w used by the fitness function is set as 1 and learning factor $c1$ and $c2$ as 2, which are commonly seen settings [29].

$$f(x, y) = \sqrt{x^2 + y^2} \quad (4)$$

VI. RESULTS AND DISCUSSION

The experiments were conducted ten times per particle number to calculate the minimum, maximum, and average execution time to ensure the reliability of results. Also, the median execution time and standard deviation were calculated. Table IV provides execution time data of the SPSO algorithm on CPU for different numbers of particles. The data shows that as the number of particles increases, the median execution time also increases. For example, the median execution time for 32 particles is 328 (ms), while the median execution time for 65,536 particles is 793,717 (ms). This indicates that the SPSO algorithm on the CPU becomes slower as the number of particles increases. In addition, the standard deviation also increases as the number of particles increases. This indicates that there is more variation in the execution times for larger numbers of particles which may be due to increased memory usage and/or contention for system resources.

TABLE IV. SPSO ALGORITHM EXECUTION TIME ANALYSIS

Particles	Iteration	SPSO CPU				
		Execution Time (MS)			Median Execution Time (MS)	Standard Deviation (MS)
		MIN	**MAX**	**AVG**		
32	100,000	309	387	335.90	328	23.31
64	100,000	604	693	634.30	622.50	28.35
128	100,000	1,222	1,401	1,259.30	1,243	48.38
256	100,000	2,676	2,813	2,735.10	2,731.50	40.05
512	100,000	5,378	5,664	5,489.90	5,482	81.48
1,024	100,000	11,189	12,237	11,496.10	11,360.50	309.38
2,048	100,000	24,548	25,640	4,865.50	24,812	296.38
4,096	100,000	45,907	47,328	46,369.80	46,248.50	387.45
8,192	100,000	101,203	103,771	102,598	102,670	703.28
16,384	100,000	199,465	201,425	200,503	200,560	796.56
32,768	100,000	93,643	402,628	398,791	399,447	3,717.68
65,536	100,000	788,879	798,531	793,711	793,717	4,784.19

TABLE V. CPSO ALGORITHM EXECUTION TIME ANALYSIS

Particles	Iteration	CPSO CPU				
		Execution Time (MS)			Median Execution Time (MS)	Standard Deviation (MS)
		MIN	**MAX**	**AVG**		
32	100,000	5,405	5,432	5,422.33	5,430	15.04
64	100,000	5,478	5,617	5,537	5,516	71.84
128	100,000	5,703	5,823	5,752.33	5,731	62.78
256	100,000	5,783	5,902	5,824	5,787	67.58
512	100,000	5,769	5,882	5,829.67	5,838	56.96
1,024	100,000	5,797	5,893	5,841.33	5,834	48.42
2,048	100,000	5,806	5,939	5,864	5,847	68.11
4,096	100,000	5,931	6,027	5,988	6,006	50.47
8,192	100,000	6,179	6,268	6,221	6,216	44.71
16,384	100,000	6,828	6,904	6,869.67	6,877	38.53
32,768	100,000	13,121	13,212	13,180.33	13,208	51.42
65,536	100,000	21,382	21,471	21,431	21,440	45.18

Table V shows the execution time data for the CPSO algorithm on a CUDA-enabled GPU for different numbers of particles. The data indicates that as the number of particles increased, the average and median execution times also increased. The minimum and maximum execution times were

also increased, with the highest execution time being 21,471 ms for 65,536 particles and 100,000 iterations. However, the standard deviation shows that there is relatively little variation in the execution times across the different numbers of particles.

As shown in Fig. 8 the execution times for SPSO increase significantly as the number of particles increases. For example, the execution time for 65,536 particles is 793,711 (ms). The execution times for CPSO are much lower than SPSO and show much more consistent execution times across different numbers of particles. For example, the execution time for 65,536 particles is 21,431 (ms), and the percentage of the decrease in execution time is approximately 97.308% by CPSO compared to SPSO.

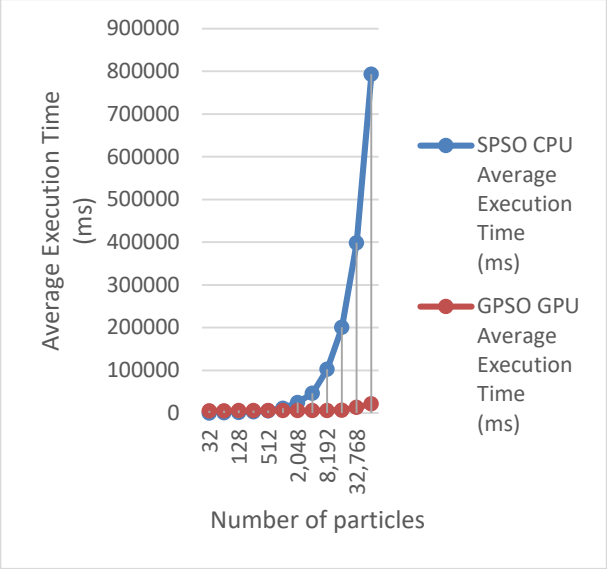

Fig. 8. Comparison of average execution time (ms) between SPSO on CPU and GPSO on GPU with respect to number of particles.

To compare the performance of these implementations, we calculated the speedup for CPSO relative to SPSO using the execution time for SPSO as a baseline. The speedup for CPSO was calculated using the following formula [30]:

$$Speedup = \frac{Execution\ Time(SPSO)}{Execution\ Time(Parallel\ Implementation)} \quad (5)$$

Table VI shows the speedup for CPSO relative to SPSO using the execution time for SPSO as a baseline. Based on the provided data for SPSO and CPSO with different particle counts and iterations, here is a summary of the key findings:

1) Execution time trends: The execution time increases as the number of particles and iterations increase. Also, for both Standard PSO (SPSO) and Constricted PSO (CPSO), the execution time generally follows an increasing trend with higher particle counts.

2) Speedup comparison: The speedup values for SPSO and CPSO range from 0.1 to 37.0 across different particle counts. These values indicate the parallelization efficiency, with higher values indicating better performance improvement with parallel processing.

3) Comparison between SPSO and CPSO: In most cases, CPSO shows lower execution times compared to SPSO for the same particle count and number of iterations. This difference suggests that the constriction factor used in CPSO may contribute to faster convergence and better optimization performance.

4) Impact of particle count: Increasing the number of particles has a significant impact on execution time, with higher particle counts leading to longer execution times. The data shows a clear trend of increasing execution time as the number of particles grows exponentially.

5) Optimal performance considerations: The choice between SPSO and CPSO should be based on the specific optimization problem and the desired trade-off between execution time and convergence speed. It is essential to consider the balance between speedup, execution time, and convergence efficiency when selecting the appropriate PSO variant.

TABLE VI. THE SPEEDUP FOR CPSO RELATIVE TO SPSO

Particles	Iteration	Execution Time (MS)		speedup
		SPSO	CPSO	
32	100,000	335.90	5,422.33	0.1
64	100,000	634.30	5,537	0.1
128	100,000	1,259.30	5,752.33	0.2
256	100,000	2,735.10	5,824	0.5
512	100,000	5,489.90	5,829.67	0.9
1,024	100,000	11,496.10	5,841.33	2.0
2,048	100,000	4,865.50	5,864	4.2
4,096	100,000	46,369.80	5,988	7.7
8,192	100,000	102,598	6,221	16.5
16,384	100,000	200,503	6,869.67	29.2
32,768	100,000	398,791	13,180.33	30.3
65,536	100,000	793,711	21,431	37.0

VII. CONCLUSIONS

In this work, we propose a CUDA version of the standard PSO algorithm to shorten the execution time for solving the PSO problem. We have shown the key ideas of the parallelizing algorithms for CUDA. Many experiments were conducted to improve the execution efficiency of the proposed algorithm by leveraging the power of parallel computing of GPU with the tree reduction algorithm, the CPSO achieving 37x speedup compared with the serial version SPSO and outperforming SPSO in terms of speedup. The result obtained shows that the relationship between swarm particle size and execution time is linear as the number of particles increased, the computational load also increased, making parallel implementations more effective at reducing the execution time. However, CPSO performed faster than SPSO for a high dimensional population, there was no significant improvement for the small number of particles. So, CPSO can especially benefit from optimizing with a large swarm population. For

future work, further optimization and fine-tuning of the CPSO algorithm could be explored to enhance its performance with smaller particle numbers. Additionally, investigating the scalability and adaptability of the proposed CUDA-based PSO algorithm to handle even larger swarm populations and more complex optimization problems would be a valuable direction for future research. Integration with advanced parallel computing techniques and exploring hybrid approaches could also be considered to push the boundaries of speed and efficiency in solving PSO problems.

Underwater Video Image Restoration and Visual Communication Optimization Based on Improved Non Local Prior Algorithm

Tian Xia
School of Arts and Design, Qingdao University of Technology, Qingdao, 266033, China

***Abstract*—Underwater image processing should balance image clarity restoration and comprehensive display of underwater scenes, requiring image fusion and stitching techniques. The pixel level fusion method is based on pixels, and by fusing different image data, it eliminates stitching gaps and sudden changes in lighting intensity, preserves detailed information, and thus improves the accuracy of stitching images. In the process of restoring underwater video images without local priors, there is still room for optimization in steps such as removing atmospheric light values, estimating transmittance, and calculating dehazing images through regularization. Based on the characteristics of Jerlov water types, water quality is classified according to the properties of suspended solids, and each channel is adjusted to the compensation space to improve the restoration algorithm. Background light estimation is used to determine the degree of image degradation, select the optimal attenuation coefficient ratio, and restore the image. The experimental results show that it is crucial to choose a ratio of attenuation coefficients that is close to the actual water quality environment being photographed. Both this model and traditional algorithms have an accuracy rate of over 99.0%, with the accuracy of this model sometimes reaching 99.9%. Pixel level fusion and background light estimation technology optimize underwater images, improve stitching accuracy and clarity, enhance target detection and recognition, and have important value for marine exploration rigs.**

I. Introduction

A. Current Research Fields and Hotspots

In today's scientific field, underwater video image restoration and visual communication optimization have become hot research areas [1-2]. Due to the complex and variable optical characteristics in underwater environments, such as scattering and absorption phenomena in water bodies, the quality of underwater images is often very poor and filled with various noises and distortions [3-4]. This greatly limits the application and research of underwater images.

B. Issues and challenges

Underwater videos provide intuitive information about the underwater world, which is crucial for marine ecological research, underwater facility maintenance, and seabed resource exploration. However, harsh visual environments and unstable lighting conditions often lead to low quality underwater videos, affecting information extraction and analysis. Developing effective image restoration techniques to improve the quality of underwater videos is of great significance for expanding research on the understanding and utilization of the marine world. In response to these challenges, researchers are committed to finding more precise and efficient algorithms to improve the clarity and overall visual effects of underwater images, to better utilize these valuable underwater visual resources.

C. Gap with Previous Research

Although numerous studies are currently focused on underwater image restoration and visual effect optimization, these methods are often limited by the accuracy and efficiency of processing algorithms. The previous methods have not yet achieved complete satisfaction for researchers and practical applications in removing noise and distortion from underwater images, improving image contrast and clarity [5-6]. Therefore, there is an urgent need to further improve underwater image processing technology to enable observers to see underwater details more clearly.

D. The Necessity and purpose of research

This study proposes an underwater video image restoration and visual effect optimization method on the grounds of an improved non local prior (NLP) algorithm. It optimizes the processing flow to remove noise and distortion in underwater images. It enhances image contrast and clarity, allowing observers to see underwater details more clearly. This will further promote the development of underwater image processing technology and provide stronger support for related applications. It is expected that this research can play its due role in future scientific research and practical applications.

E. Research progress

The research will be conducted in five sections. Section I gives the introduction and Section II delves into related works. Section III is the research on underwater video image restoration and visual communication optimization on the grounds of improved NLP algorithms. Section IV is the experimental verification of the Section III. Section V is a summary of the research content and points out the shortcomings.

II. Related Works

Underwater video image processing has always been a key research area in the field of computer vision, as the

complexity and variability of underwater environments make image restoration a major challenge. Glassman et al. compared the effectiveness of three types of bait and two types of bait containers on bait free systems. The results indicate that BRUVS is effective in observing species richness in shallow and low visibility freshwater environments, but there is almost no evidence to suggest that the use of bait improves the effectiveness compared to non-bait RUVS [7]. Zhang et al. proposed an end-to-end dual generator model DuGAN on the grounds of generative adversarial networks for enhancing underwater images. Two discriminators are used to perform adversarial training on different regions of the image using different training strategies. This framework is easy to use, and both subjective and objective experiments have shown that it has achieved excellent results in the methods mentioned in the article [8]. Davies et al. conducted annual evaluations by comparing captured and uncaught populations inside and outside the MPA, as well as using bait based remote underwater video systems. The results indicate that comprehensive protection of the entire region with different benthic habitats is of great significance for the protection of fixed organisms that make significant contributions to fish habitats, as well as for maintaining sustainable fisheries and the interests of important protected species [9]. Zhu et al. proposed an image enhancement algorithm to improve the problem of image degradation caused by light absorption. The results indicate that the enhanced image has higher visibility, more details, and edge information [10]. Park et al. proposed a visibility enhancement technology for underwater cutting environments on the grounds of artificial neural networks to address the problem of deteriorating visibility in underwater construction environments. It uses two types of real image training on the grounds of GAN models, corresponding to cloudy input images. Experiments have shown that compared to traditional improvement techniques, trained neural networks can significantly improve the clarity of cloudy images [11].

NLP algorithms have been widely applied in image restoration, however, this algorithm still has some limitations for underwater video image restoration. Liang et al. proposed a color image restoration method that adaptively determines the size of dictionary atoms and discussed a model on the grounds of partial differential equation restoration methods. The results show that the algorithm can effectively overcome the shortcomings of fuzzy details and region expansion in fixed dictionary repair, and the repair effect is significantly improved [12]. Yang et al. proposed a modified DCP method that utilizes locally variable weighted 4-direction L-1 regularization and corresponding parallel algorithms to optimize transmission, further training deep neural networks, 4DL (1) R-net, to improve processing speed. The results have shown that this method is effective, can obtain clear details, maintain the natural clarity of the image, and significantly outperform the current state-of-the-art methods [13]. Wang et al. proposed a novel restoration algorithm that utilizes regional extremum and kernel optimization to address the issue of system blur in high-energy flash X-ray images. The results indicate that the algorithm can more accurately estimate the blur kernel, making the edges of the restored high-energy flash X-ray images clearer [14]. Lyu et al. proposed an ultrasound C-scan image restoration method that combines Richardson Lucy algorithm and defect measurement model to improve ultrasound image quality. The results show that the restoration method effectively improves the accuracy of ultrasound C-scan imaging, with a maximum error of only 10% and a minimum error of 2% for defect size [15]. Zhao et al. vectorized and grouped similar image segments, constructed a low rank noise matrix, and simultaneously processed the weighted minimization of all image segment groups through a new regularization term, accurately representing the sparsity and self-similarity of the image structure. The results show that the research method outperforms some existing optimization algorithms in both numerical and visual effects [16].

In summary, the widespread application of NLP algorithms in image restoration has laid the foundation for this field. However, facing the complex optical characteristics of underwater video images, existing algorithms have limited performance, and visual effect optimization also needs to be deepened. Faced with the complex optical characteristics of underwater video images, this study proposes a new underwater video image restoration and visual effect optimization scheme on the grounds of an improved NLP algorithm. It is expected that this improved method can more efficiently restore underwater images, enhance visual effects, and open up new possibilities for underwater video image research and application.

III. Underwater Video Image Restoration and Visual Communication Optimization Method on the Grounds of Improved NLP Algorithm

It elaborates on the implementation of underwater video image restoration on the grounds of NLPs, and explores the improvement strategy of underwater video image restoration on the grounds of this algorithm. It introduces the implementation strategy of underwater image fusion and stitching technology, and explores in depth how to improve visual communication effects through optimization strategies. It provides reference for underwater video image restoration and visual effect optimization, in order to promote the development of underwater vision research.

A. Implementation of Underwater Video Image Restoration on the Grounds of NLPs

Clustering in RGB color space (RGB) can approximate fogless images with hundreds of colors. The pixels of each cluster are derived from the entire image, non-local regions, forming a NLP [17]. This theory is on the grounds of an improved NLP algorithm for underwater video image restoration and visual effect optimization, which can achieve effective restoration of underwater video images. The flowchart of NLP restoration of images is shown in Fig. 1.

In Fig. 1, starting from an NLP, clustering is performed in a fog free image. Due to differences in depth and distance of field, there will be differences in transmittance. It clusters foggy images in RGB space, forming fog lines due to differences in transmittance. It uses clustering fog lines of foggy images to estimate transmittance, and then starts from the image degradation model to perform NL restoration of the

image. The estimation method of transmittance is different from the prior restoration of dark channels. Then it clusters the pixels of the foggy image into fog lines, estimates the initial transmittance $t(x)$, regularizes and refines the estimated transmittance, and finally performs image restoration. The image containing fog to be processed is shown in Eq. (1).

$$I_A(x) = I(x) - A \tag{1}$$

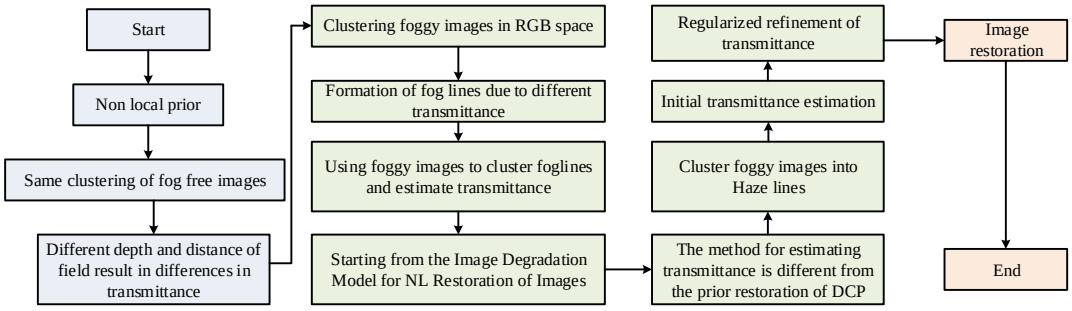

Fig. 1. Complex flowchart for NLP restoration of images.

In Eq. (1), $I(x)$ represents the image containing fog to be processed, and A represents the pre estimated atmospheric light value. A converts the RGB coordinate system of pixels in foggy images to point A as the coordinate origin [18-19]. The joint image degradation model is shown in Eq. (2).

$$I_A(x) = \left[r(x), \theta(x), \varphi(x) \right] \tag{2}$$

In Eq. (2), $r(x)$ is the distance from the origin A, $\theta(x)$ is longitude, and $\theta(x)$ is latitude. For each fog line in a foggy image, its two ends are a cluster of non-foggy image J and atmospheric light value A. The expression of transmittance with respect to the radius of the fog line is shown in Eq. (3).

$$r(x) = t(x) \times \left\| J(x) - A \right\|, 0 \le t(x) \le 1 \tag{3}$$

In Eq. (3), $t(x)$ is the transmittance and $r(x)$ is the radius of the fog line. The process of estimating transmittance from fog lines is shown in Fig. 2.

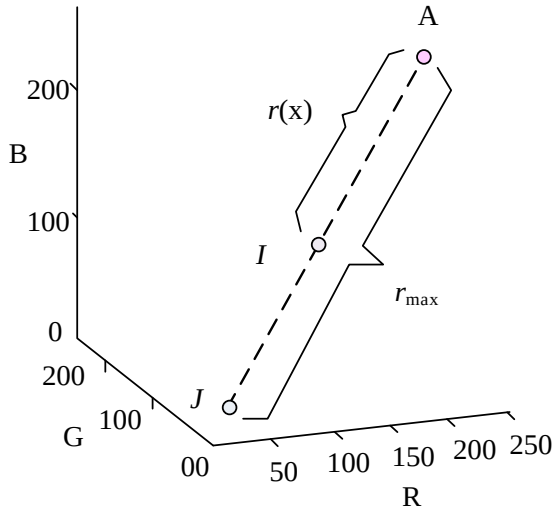

Fig. 2. The process of estimating transmittance from fog lines.

In Fig. 2, fog lines are formed by clustering foggy images to reveal differences in fog density. Then, the degradation model is used to initially estimate the transmittance, which directly affects the image clarity. It compares the estimated transmittance with the lower bound of transmittance, taking the larger one to ensure image authenticity, as real foggy images may not guarantee that each fog line contains fog free pixels. Finally, it smooths the transmittance map, suppresses noise, and enhances spatial continuity of the image. Its regularization refines the transmittance, as shown in Eq. (4).

$$\sum_x \frac{\left[\hat{t}(x) - \tilde{t}_{LB}(x) \right]^2}{\sigma^2(x)} + \lambda \sum_x \sum_{y \in N_x} \frac{\left[\hat{t}(x) - \tilde{t}(y) \right]^2}{\left\| I(x) - I(y) \right\|^2} \tag{4}$$

In Eq. (4), $\hat{t}(x)$ is the refined transmittance, N_x is the four neighborhoods centered on pixel N_x in the image, λ is the parameter used to balance the data and smoothing terms, and λ is the standard deviation of $\sigma^2(x)$. The restored image can be obtained from the degradation model, as shown in Eq. (5).

$$J(x) = \frac{\left\{ I(x) - \left[1 - \hat{t}(x) A \right] \right\}}{\hat{t}(x)} \tag{5}$$

B. Improvement of Underwater Video Image Restoration on the Grounds of NLP

The NLP underwater video image restoration process includes steps such as removing atmospheric light values, estimating transmittance, and calculating dehazing images through regularization. However, there is still room for optimization in improving the visibility of underwater images using this method, especially in transmittance estimation, where the R, G, and B channels are often uniformly processed [20]. This ignores the differences in underwater light wave attenuation and color distortion between channels. This study classifies water quality on the grounds of the characteristics of Jerlov water types and the properties of suspended solids, and adjusts each channel to the compensation space through the global attenuation coefficient ratio to improve the restoration algorithm. And it uses background light estimation to

determine the degree of image degradation, selects the optimal attenuation coefficient ratio, and restores the image. The transmittance is calculated and refined, as shown in Eq. (6) for different channels.

$$\begin{cases} A_R - I_R = e^{-\beta_R d} \cdot (A_R - J_R) \\ A_G - I_G = e^{-\beta_G d} \cdot (A_G - J_G) \\ A_B - I_B = e^{-\beta_B d} \cdot (A_B - J_B) \end{cases} \tag{6}$$

In Eq. (6), A is the background light and I is the type of water body. $e^{-\beta d}$ is the transmittance, $\beta(\lambda)$ is the attenuation coefficient, and $\beta(\lambda)$ is the depth of field. It performs power operations on the channel equations to obtain a moderate compensation space, as shown in Eq. (7).

$$\begin{bmatrix} (I_R(x) - A_R)^{\beta_{BR}} \\ (I_G(x) - A_G)^{\beta_{BG}} \\ (I_B(x) - A_B) \end{bmatrix} = t_B(x) \begin{bmatrix} (J_R(x) - A_R)^{\beta_{BR}} \\ (J_G(x) - A_G)^{\beta_{BG}} \\ (J_B(x) - A_B) \end{bmatrix} \tag{7}$$

In Eq. (7), β_{BR} is the blue red attenuation coefficient, and β_{BG} is the blue green attenuation coefficient. The smoothing factor is shown in Eq. (8).

$$\alpha(x) = \frac{D_M(I(x)) - \bar{D}_M - \sigma_M}{D_M^{\max} - \bar{D}_M} \tag{8}$$

In Eq. (8), $\alpha(x)$ is the smoothing factor, σ_M is the standard deviation, $D_M^{\max}$ is the maximum Mahalanobis distance, and $\bar{D}_M$ is the average Mahalanobis distance of the background light area. After estimating the transmittance, color attenuation compensation is performed to obtain the restored image. The scattering of light during its propagation in water can cause global color distortion. In order to make the image look like it is under white light, it can be corrected through white balance method after compensating for propagation loss. The implementation process of an improved underwater image restoration algorithm on the grounds of NLP prior is shown in Fig. 3.

In Fig. 3, edge detection is performed on the input image to determine the background light area and calculate the background light. On the grounds of the attenuation coefficient values under different water types, each channel is processed to estimate the initial transmittance. It performs soft cutout processing, uses enhanced images as guidance, and refines transmittance through filtering. It then restores the restored image and performs global white balance processing. Finally, its output refines the transmittance and restores the image.

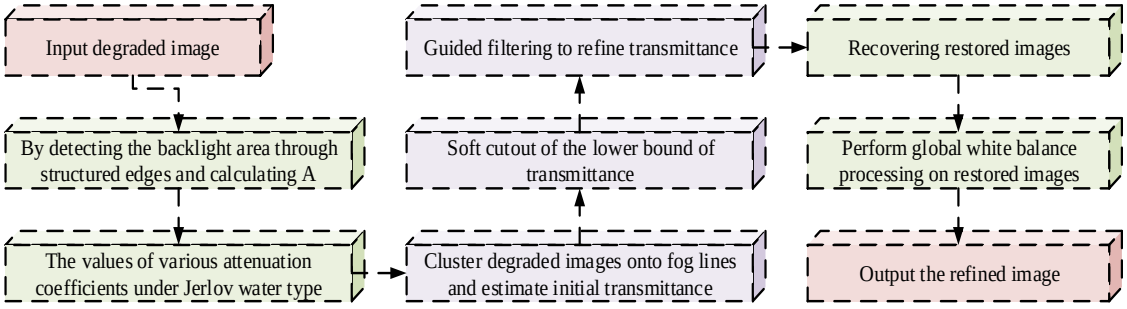

Fig. 3. Implementation of an improved underwater image restoration algorithm on the grounds of NLP prior.

C. Implementation Strategy for Underwater Image Fusion and Stitching Technology

In underwater image processing, in addition to clarity restoration, panoramic display of large-scale underwater scenes in complex environments is also required, which requires image fusion and stitching techniques. Image fusion is divided into pixel level, feature level, and decision level. Pixel level fusion has high accuracy but large data volume, feature level fusion reduces data volume but low accuracy, while decision level fusion has strong anti-interference ability, good real-time performance but low accuracy. In order to eliminate splicing gaps and sudden changes in lighting intensity, preserve detailed information and improve fusion accuracy, pixel level fusion is mainly used. Common methods include average value method, gradual in and out method, and multi band fusion method [21]. It takes the average of the pixel values of the corresponding points in two images within the overlapping area, and the average method is shown in Eq. (9).

$$I(x,y) = \begin{cases} I_1(x,y) & (x,y) \in R_1 \\ 0.5 \times [I_1(x,y) + I_1(x,y)] & (x,y) \in R_2 \\ I_2(x,y) & (x,y) \in R_3 \end{cases} \tag{9}$$

In Eq. (9), R_1 is the area that belongs only to the first image, R_2 is the area where the first and second images overlap, and R_2 is the area of the second image. The gradual in and out method assigns different weight values on the grounds of the distance between pixels and the overlapping boundary when processing regions of two overlapping images. Through this weighting method, the calculation of new pixel values can achieve a visual effect of smooth transition from one image to another. The pixel values corresponding to the fusion are shown in Eq. (10).

$$I(x,y)=\begin{cases} I_1(x,y) & (x,y)\in R_1 \\ d\times I_1(x,y)+(1-d)I_2(x,y) & (x,y)\in R_2 \\ I_2(x,y) & (x,y)\in R_3 \end{cases} \quad (10)$$

In Eq. (10), the meanings of R_1, R_2, and R_2 are the same as the average method. d is the gradient weight factor, and the image frames that are gradually approaching the middle are combined into the concatenated image. For a certain number of frame sets, a certain intermediate frame in the image set is selected as the initial reference image, and the image frames to be concatenated are selected from left to right in sequence. The image frame to concatenated image synthesis method on the grounds of intermediate frames is shown in Fig. 4.

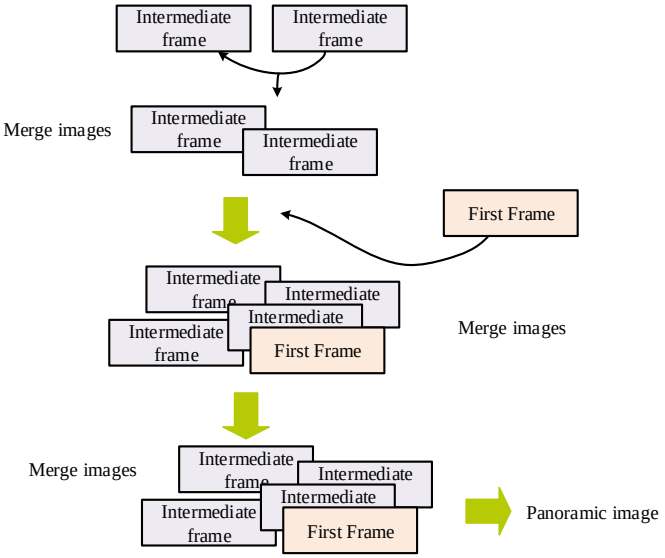

Fig. 4. Implementation of an improved underwater image restoration algorithm on the grounds of NLP prior.

In Fig. 4, it selects a frame in the middle as the initial reference image, registers it with the front and back frames through a projection transformation matrix, and fuses it using the gradual in and out method. It uses the fused image as a new reference image and sequentially selects the image to be stitched forward and backward for fusion. The advantage of this strategy is that it avoids the accumulation of transformation errors that may arise from frame by frame fusion. By using intermediate frames as the initial reference image, it can effectively consider the distance between all frames and the reference image, improve the overlap rate, and thus obtain a restored underwater panoramic image.

D. Optimization Strategies for Visual Communication Effects

The underwater image fusion and stitching technology optimizes visual effects, requiring comprehensive adjustments to image color, clarity, brightness, etc. Information graphical interaction technology also helps optimize visual effects, including two major elements: basic and interactive. The foundation ensures the accurate expression of information, provides a natural and convenient way for interaction, guides users to navigate, browse, filter, input, prompt and feedback, view conversion, etc. Macro to micro techniques handle complex graphics, allowing users to zoom in, scroll, jump, and move in the macro interface, observe details, and return to the macro interface to see the marked micro areas. Dynamic and interactive information prompts display hierarchical data information with organized structure, allowing users to see secondary information when browsing to a specified location. The comprehensive use of these technologies and strategies helps to improve underwater video image restoration and visual communication optimization methods on the grounds of NLP algorithms. In the underwater video image restoration and visual communication optimization method on the grounds of improved NLP algorithms, as shown in Fig. 5, interactive information prompt technology is an important strategy.

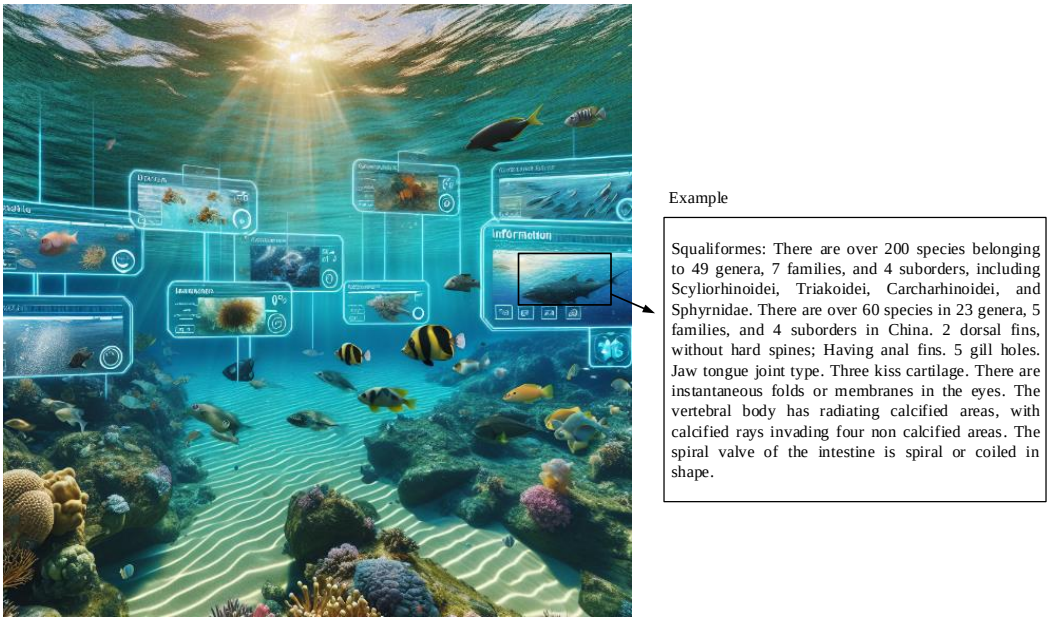

Fig. 5. Example of interactive information prompt technology.

This technology enables users to obtain relevant information by pointing to specific image elements, eliminating redundant operations. For underwater video images containing a large amount of information, interactive information prompt technology can provide dynamic display and concealment functions, and the content can change in real-time according to user operations. The dynamic prompt window provides users with real-time image information, improving the accessibility and usability of the information.

In the process of image restoration, dynamic query technology is the key to optimizing visual communication effects. It meets the needs of users for precise queries in a large amount of information. By using standard operating controls such as sliders, checkboxes, etc., users can define the display range of image information. For example, in video playback software, users can search for video information from a specific era on the grounds of the time of video release. The front-end logic of dynamic queries is clear, and the dominant power lies in the hands of users, ensuring efficient real-time interactive feedback. On the backend, the dynamic query engine processes user query requests, assembles query conditions, executes query instructions, parses parameters, searches for configurations, and determines query types. Finally, the search result data is objectified and formatted as a list of information that can be received by the control, which retrieves and renders the data, and returns it to the user interface. This achieves the precise query needs of users and improves the efficiency of information exploration. Fig. 6 shows interactive information prompts and dynamic query techniques. This combined application with interactive information prompt technology optimizes underwater video image restoration and visual communication effects on the grounds of NLP algorithms.

Fig. 6. Interactive information prompts and dynamic query techniques for optimizing visual communication effects.

IV. Analysis of Underwater Video Image Restoration and Visual Communication Optimization on the Grounds of Improved NLP Algorithm

Improving NLP algorithms can reduce noise and blur during image restoration and improve image quality. By combining interactive information prompts and dynamic query technology, the accessibility and usability of information can be enhanced, allowing users to accurately query a large amount of information, achieve efficient real-time interactive feedback, and improve information exploration efficiency.

A. Application Effect Analysis of Improved NLP Algorithm in Underwater Video Image Restoration

Improving the application effect of NLP algorithms is an important research direction in underwater video image restoration. This algorithm processes the local and non-local characteristics of the image, and the parameter settings of the model are shown in Table I. In the optimization analysis of visual communication effects, Sea rogman was selected to demonstrate the intermediate results of NL image restoration processing for underwater images. In this process, the parameter is set to 0.1. Table II shows the comparison results of the average gradient and information entropy after non local and dark channel prior restoration.

The improved NLP algorithm for restoring underwater video images can be observed through the SSIM index. For high-quality video frames such as Sea oral and Sea fish, this algorithm recovers SSIM values that surpass the Fast DCP algorithm. However, for low-quality video frames such as Underwater1_10, Underwater2_10, and Underwater2_340, their restored SSIM values are slightly lower. For specific effects, such as using Underwater1_10 as an example, it is necessary to refer to Fig. 7.

TABLE I. SYSTEM PARAMETER

Parameter Name	Description	Setting Value	Remarks
Operating System	Environment for running the software	Windows 10	64-bit
Processor	Hardware for executing the algorithm	Intel Core i7	2.6GHz
Memory	Temporary storage for algorithm and data	16GB	DDR4
Graphics Card	Hardware for processing images	NVIDIA GeForce GTX 1050	4GB
Algorithm Version	Executing algorithm	Improved Non-local Prior Algorithm	Latest version
Experiment Video	Testing data	Underwater video	1080p, 30fps
Experiment Environment	Place where the experiment is conducted	Laboratory	Temperature 25℃, Humidity 60%

TABLE II. COMPARISON OF AVERAGE GRADIENT AND INFORMATION ENTROPY AFTER NL AND DARK CHANNEL PRIOR RESTORATION

-	-	Original drawing				Information entropy E

Fig. 7. Image underwater1_10 results under different attenuation coefficient ratios.

In Fig. 7, the lower left grayscale image (d) shows the detected background light area, while Fig. 7(b), (c), (e), and (f) show the restored images obtained under different attenuation coefficient ratios. The attenuation coefficient ratio plays a crucial role in the process of image restoration. Using inaccurate ratios can lead to errors in the transmittance chart, resulting in color deviation in the reconstructed image. Therefore, it is crucial to choose a ratio of attenuation coefficients that is close to the actual water quality environment being photographed. The right choice can improve the restoration effect, while the wrong choice can lead to poor restoration effect.

B. Optimization Analysis of Visual Communication Effects

In the waters near the boundary island of Sanya, China, underwater videos were captured using the "Ocean Elf" sightseeing submarine. The experiment was conducted in the sea at a depth of 20-30 meters, with a submarine diving depth of 10-15 meters and visibility of 4-10 meters. The video was recorded using the iPhone 11 Pro rear camera. For detailed information on the video, please refer to Table III.

TABLE III. OPTIMIZATION ANALYSIS

Video file name	Duration (s)	Frame rate	Frame Image Size	Total Frames	Real keyframe rate
underwater1	6.0000	29.5357	544×980	232	8.0000
underwater2	8.0000	29.5357	980×544	247	9.0000
underwater3	10.0000	29.5357	640×480	296	10.0000
underwater4	12.0000	29.5357	1280×720	355	11.0000
underwater5	14.0000	29.5357	1920×1080	414	12.0000

To verify the superiority and accuracy of the model, experiments were conducted in underwater videos near the boundary island of Sanya, China. The sightseeing submarine takes photos in the sea area at a depth of 20-30 meters, with a diving depth of 10-15 meters and visibility of 4-10 meters. The experiment mainly used Underwater1 with a resolution of 544 * 960 and Underwater2 with a resolution of 980 * 544. The experiment first uses an improved keyframe extraction algorithm to obtain image frames, and then uses an improved algorithm for non-local underwater image restoration to process keyframes. After image registration and fusion, the matching results and fusion effects are displayed. For Underwater1 with poor image quality, the threshold T for new cluster partitioning is set to 18, and for good quality, it is set to 25. The experimental results are shown in Fig. 8.

In Fig. 8, the accuracy statistics of the model and traditional image restoration algorithms in 60 experiments are shown. Both the model and traditional algorithms have an accuracy rate of over 99.0%, and sometimes the accuracy of the model can even reach 99.9%, while the traditional model can only reach a maximum of 99.3%. In order to study the accuracy of the model in processing different underwater environments, 20 underwater videos were selected and 180 image data samples were collected for simulation of common underwater environments. The results are shown in Fig. 9.

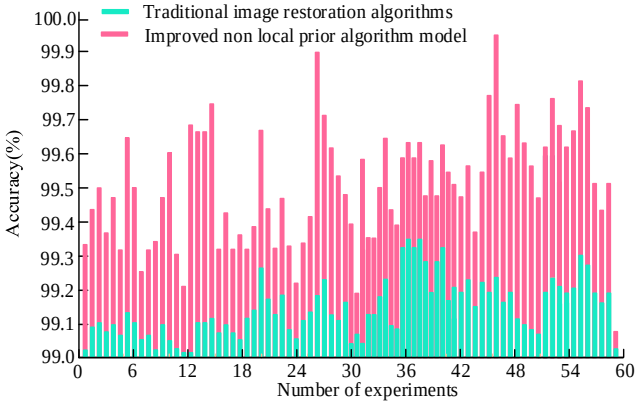

Fig. 8. Accuracy comparison chart.

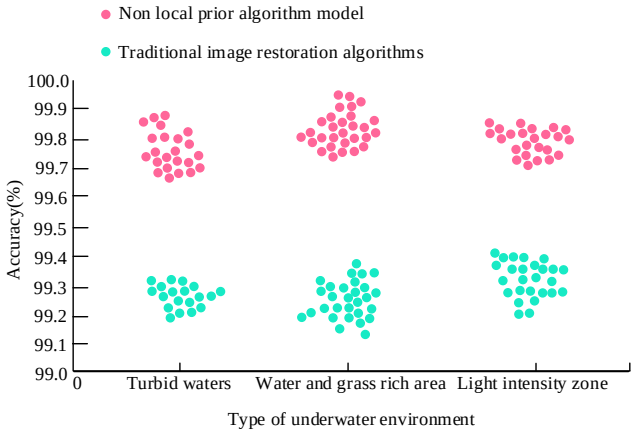

Fig. 9. Non-local prior model's accuracy in different underwater environments.

In Fig. 9, three types of seabed environments are covered: turbid waters, areas with abundant aquatic plants, and areas with strong sunlight. Regardless of the type of environment, the processing accuracy of NLP models exceeds 99.0%. The average accuracy of treating turbid water bodies is around 99.6%. This indicates that NLP models exhibit extremely high accuracy in restoring images of turbid water bodies. The average processing accuracy for areas with abundant water and grass is around 99.4%. This means that NLP models can effectively distinguish images in water grass rich areas and perform effective restoration processing, with an average accuracy of about 99.15% for areas with strong lighting.

V. CONCLUSION

Faced with the complexity of underwater environments and harsh lighting conditions, underwater image processing requires both restoration of image clarity and comprehensive display of underwater scenes, thus requiring the use of image fusion and stitching techniques. In this context, the research aims to optimize the NLP underwater video image restoration process and improve the accuracy of image processing. It classifies water quality on the grounds of Jerlov's water type characteristics, adjusts channel optimization restoration algorithms, and uses background light estimation to determine the degree of degradation. The results show that the attenuation coefficient ratio plays a crucial role in the image restoration process. The accuracy of this model can sometimes

even reach 99.9%, while traditional models only have a maximum of 99.3%. Not only that, NLP models can also effectively distinguish images in areas with abundant water and grass, and perform effective restoration processing. The average accuracy of processing in areas with strong lighting is about 99.15%. This study provides an effective method for improving the accuracy of underwater image processing. However, there are still shortcomings, such as the need to improve the accuracy of processing images in areas with strong lighting. Future research aims to further optimize the model, improve the accuracy of image processing for various complex underwater environments, and explore more image processing algorithms suitable for various complex underwater environments. This is to present the underwater scene more comprehensively while ensuring image clarity.

Integrated Ensemble Model for Diabetes Mellitus Detection

Abdulaziz A Alzubaidi, Sami M Halawani, Mutasem Jarrah
Faculty of Computing and Information Technology, King Abdulaziz University, Jeddah, Saudi Arabia

***Abstract*—Diabetes Mellitus, commonly referred to as (DM), is a chronic illness that affects populations worldwide, leading to more complications such as renal failure, visual impairment, and cardiovascular disease, thus significantly compromising the individual's well-being of life. Detecting DM at an early stage is both challenging and a critical procedure for healthcare professionals, given that delayed diagnosis can result to difficulties in managing the progression of the disease. This study seeks to introduce an innovative stacking ensemble model for early DM detection, utilizing an ensemble of machine learning and deep learning models. Our proposed stacking model integrates multiple prediction learners, including Random Forest (RF), Convolutional Neural Network (CNN) with Long Short-Term Memory networks (CNN-LSTM), and Sequential Dense Layers (SDLs) as base learner models, with the Extreme Gradient Boosting model (XGBoost) serving as the Meta-Learner model. Findings demonstrate that our proposed model achieves a 99% accuracy on the Pima dataset and 97% accuracy on the DPD dataset in detecting diabetes mellitus disease. In conclusion, our model holds promise for developing a diagnostic tool for DM disease, and it is recommended to conduct further testing on the types of diabetes mellitus to enhance and evaluate its performance comprehensively.**

Keywords*—Diabetes mellitus; machine learning; deep learning; stacking; ensemble learning; RF; CNN-LSTM; SDLs; XGBoost

I. Introduction

Diabetes mellitus carries a significant health risk and increases the likelihood of getting cardiovascular disease and more complications, which makes our lives suffer [1]. Insulin is essential for controlling blood glucose work, regulating the anabolism of carbohydrates, promoting physical growth, supervising cell division, and monitoring the anabolic activities of proteins and fats [2]. As a result, DM significantly impairs people's daily life and increases their risk of getting chronic illnesses such as cardiovascular disorders, renal failure, and sightlessness [3]. These disorders raise death rates [4]. In 2019, it was estimated that 463 million individuals worldwide suffered from diabetes [5].

There are two main types of diabetes mellitus (DM): Type-1 Diabetes, an autoimmune sickness that destroys the pancreatic beta cells that produce insulin, and the second type of Diabetes, a chronic that often raises blood sugar levels [6]. It can be challenging to differentiate between these kinds and choose the best course of action because doctors sometimes dispute about the best way to diagnose a patient [7]. Globally, diabetes is becoming more common, especially in countries with middle incomes [8]. Therefore, research on diabetes prediction through machine learning (ML) techniques is needed to help specialists build the best possible treatment plans. By 2030, the Global Sustainable Development Group wants to eradicate diabetes-related early death [8]. Consequently, scholars are consistently investigating various facets of diabetes mellitus. A range of machine learning methods, including the Random Forest and XGBoost algorithms, are utilized in this endeavor, each providing special benefits for classification procedures [9-10-11-12-13]. Convolutional Neural Networks (CNNs) with Long Short-Term Memory architecture and Multilayer perceptron's (MLPs) are two popular deep learning (DL) techniques that offer strong frameworks for managing sequential data and classification tasks [14–15–16].

In the healthcare sector, detecting DM at an early stage is challenging. Patient data is collected, including their ages, the mass of the body, the thickness of the skinfold in the triceps, insulin in the blood, plasma glucose level, the diastolic-blood-pressure, and other variables. Patients then turn to doctors for specialist care. The doctor's medicating process becomes harder because of the lengthy, weeks-long decision-making process that depends on the doctor's expertise and experience [17].

Healthcare science research is currently supported by a wide range of publicly available medical databases. But managing such massive volumes of data by humans is frequently difficult, if not infeasible. Deep learning techniques deliver a solution because they grow and mimic how humans thinking. That happens by providing data at several tiers and successfully resolves the selectivity-invariance issue [18]. In the discipline of medicine, deep learning algorithms have several uses, especially in the diagnosis sector. Much research continually demonstrates the superior performance of deep learning approaches over conventional machine learning techniques. These algorithms are superior to other methods in terms of performance and their ability to lower classification error rates [19].

Numerous deep-learning methods are promising in the medical field. The CNN-LSTM architecture is an effective structure suited for handling classification problems and time-series processing of data. Convolutional neural networks (CNNs) and long short-term memory (LSTM) networks are coupled in this design to make use of their respective advantages in processing sequential input and extracting pertinent information [14]. A crucial aspect of deep learning is the Multilayer Perceptron (MLP), a conventional neural network architecture. Because of its historical relevance and fundamental role in the evolution of neural networks, this

artificial neural network with feedforward algorithms is frequently regarded as a (classical) model [15]. Under deep learning techniques, the Keras framework is excellent at developing sequential stacking models, such as dense layered models, which are well-known for their ability to forecast time-series data. These thick layers are typically fully connected, with each node in one layer connecting to every node in the next, resulting in a chain-like structure [20].

Given the extensive information on diabetes mellitus and the diverse techniques employed for its prediction, we propose an enhanced stacking ensemble model that combines machine and deep learning models for DM prediction.

The contributions for this study are as follows:

- Developing an innovative stacking ensemble model for detecting Diabetes Mellitus by integrating machine learning and deep learning models, utilizing an ensemble of RF, CNN-LSTM, and SDLs models as base learners, with the XGBoost model serving as a meta-learner.
- Merging a combination of ML and DL techniques, including ADASYN, RFECV, GridSearchCV, and Optuna, aimed at refining the performance of the proposed stacking model in detecting DM.

The format of this document is as follows: Section II provides an overview of related work in the area. Section III details the materials and methods used in our research. Section IV presents the experimental setup for our ensemble model. In Section V, we discuss the performance measures. Our results and discussion are covered in Sections VI and VII respectively. In the end, the conclusions are addressed in Section VIII.

II. Related Work

Ensemble learning is a mathematical and analytical methodology that simulates human learning by combining diverse machine learning models to yield more accurate predictions [21-22]. Dutta et al. highlight the importance of ML-based ensemble models in diabetes prediction, advocating the exploration of deep learning techniques alongside ensemble learning, particularly through the stacking method [23]. Ganie and Malik [24] address ensemble methods for detecting Type-2 Diabetes Mellitus, including Bagging, which emphasizes aspects of lifestyle and uses the SMOTE technique that is; (artificial minority oversampling) for dataset rebalancing, validated using cross-validation techniques.

Laila and colleagues [25] investigated effective ensemble algorithms for early-stage prediction of diabetic risks, employing 17 features sourced from the UCI library encompassing diverse datasets. The study employed predictive models, like Ada-Boost, bootstrap aggregation, and RF, and evaluated the proposed model's accuracy and other performance measures. The Random Forest ensemble approach outperformed AdaBoost and Bagging concerning accuracy, scoring 97 percent.

Prasad and Geetha [26] propose an ensemble model utilizing ensemble approaches like bootstrap aggregation, RF, and Ada-boost, together with classification techniques such as (Naive Bayes). Joshi et al. [27] used the logistic regression model and the decision tree to predict diabetes type-2 in the Pima dataset, with an accuracy reaching 78%.

Javale and Desai [28] delved into elevating healthcare information analytics through the application of an ensemble methodology using machine learning, specifically addressing challenges posed by unbalanced datasets. Their approach incorporated SMOTE and adaptive ADASYN oversampling methods. Various performance evaluation approaches were employed, like train-test split and K-folding. The diabetes dataset underwent an ensemble strategy utilizing the average Stacking-C technique, encompassing classifiers such as K-Nearest Neighbors, Random Forest, and others.

Early DM detection can save human lives and help healthcare workers to control the illness. Many individuals diagnosed with diabetes are unaware of the risk aspects they may be exposed to before the diagnosis happens [25]. Patil et al. [29] introduced an approach for predicting Type-2 Diabetes Mellitus (T2DM) utilizing a stacking ensemble model. The primary aim is to minimize the period between diabetes disease detection and medical checkups. Proposed non-dominated sorting genetic algorithm (second version) stacking model compared against Boosting, bootstrap aggregation, RF, and Random Subspace techniques. Results demonstrate that the proposed ensemble model outperforms the traditional ensemble models, achieving an accuracy of 81 percent.

Zhou et al. [30] introduce an enhanced deep neural network algorithm for diabetes prediction, concentrating on type-1 & type-2 diabetes. Deep learning algorithms, such as Dense Layer Neural Networks [31], MLP models [32], and CNN-based architectures, have demonstrated success in various aspects of diabetes-related activities. Zhu et al.'s [33] comprehensive study emphasizes the superiority of deep learning over traditional machine learning in diabetes diagnosis, glucose management, and complication diagnosis. CNNs are particularly praised for clinical imaging issues, offering feature extraction capabilities. CNN-based architectures are employed to analyze clinical scans, diagnose complications, and assess food images for individuals with diabetes. The emerging field of AI and deep learning holds promising prospects for advancing diabetes applications [16].

Sainte et al. [34] explore new techniques for diabetes prediction, incorporating a wide range of DL methods. A CNN-LSTM model emerges as the most accurate, recording a 95% accuracy in predicting diabetes. The study compares the accuracy of DL models (95%) with that of ML models (68–74%), showcasing the superior performance of deep learning. Kim et al. [16] utilize various deep-learning models, including RNNs, for blood glucose predictions. Gupta et al. [31] offered a Deep Dense Layer Neural Network model for diabetes prediction utilizing the Pima dataset with 768 samples. It was getting an accuracy of 84%. Dense layers are densely connected, meaning each neuron acquires input from all the neurons in the previous layer (each neuron is linked to all neurons of the last layer [31]. The proposed DDLNN model was evaluated by the cross-validation technique to optimize the model performance. Majority voting was utilized to select the best outcomes among the models [31]. Deep learning

techniques have shown remarkable success in various fields, including disease prediction and diagnosis [31]. Table I summarizes the most notable research based on their limits and advantages, as well as the data sources.

III. MATERIALS AND METHODS

This research introduces an ensemble stacking for detecting DM disease, comprising two crucial construction levels. The first level, termed base learners, involves the preparation, training, and initial predictions by a combination of ML and DL models. Predictions from these initial learners are used as inputs for a new model called meta-learner located at the second level and train from the information provided to come up with the final prediction. For our base learners, we have chosen Random Forest, CNN-LSTM, and SDLs due to their distinctive capabilities in classification problems. The XGBoost model is employed at the second level (meta-learner), which assists significantly in managing unbalanced dataset classes' via lowering the loss function and boosting the weight of incorrectly categorized categories. To optimize our base learners, we apply GridSearchCV and Optuna technologies, aiming to achieve the best possible results for Random Forest, CNN-LSTM, and SDLs. Our proposed stacking model incorporates the cross-validation method with several iterations to obtain best findings. Additionally, an adaptive oversampling technique (ADASYN) is implemented to balance the classes of the Pima dataset investigated in our study and increase the size of the dataset in a way that does not include overfitting issues. Fig. 1 outlines the schema behind our suggested stacking model.

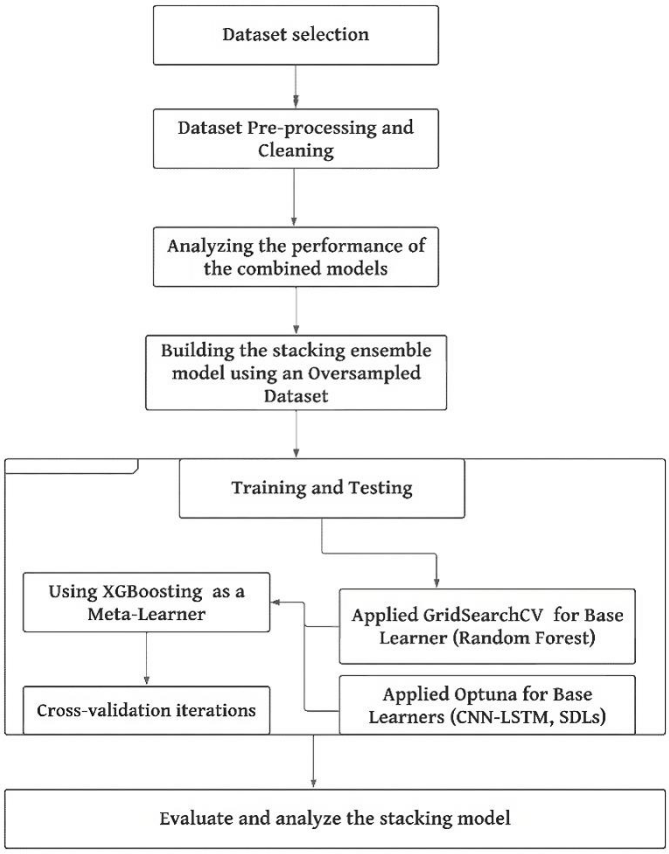

Fig. 1. Proposed stacking model.

A. Stacking

Stacking is an ensemble technique that leverages a "meta-model" to enhance predictive performance by integrating multiple base learners' predictions. In the stacking methodology, there are two distinct levels of model building. At level 1, a set of diverse base learners, each trained on a specific split from the dataset, then produces separated predictions. These predictions serve as input for the meta-learner at level 2 [35].

The goal of the second-level meta-learner is to produce predictions that are reliable and accurate by efficiently combining them [35]. Our proposed model is constructed using the stacking ensemble method, incorporating additional contributions, such as employing cross-validation techniques and leveraging the GridSearchCV hyperparameter tuning method for the Random Forest (RF) base learner. Additionally, Optuna is employed for the CNN-LSTM and SDLs deep learning learners.

The ensemble stacking methodology, as depicted in Fig. 2, involves multiple k-folds cross-validations (m*n) traversing the training dataset and each base learners models. Subsequently, the predictions (m*M) from multiple base learners are entered as inputs to the meta-learner, which learns

from this collective information to generate the final prediction. This approach enhances the model's efficiency for generalization and produces accurate predictions by leveraging the diverse insights from individual base learners and optimizing their combination through the meta-learner. It outperforms other ensemble models in prediction performance, so we have chosen to apply it in our study. The stacking approach aims to provide us with the concept of meta-learning, which can minimize ML model generalization errors [29].

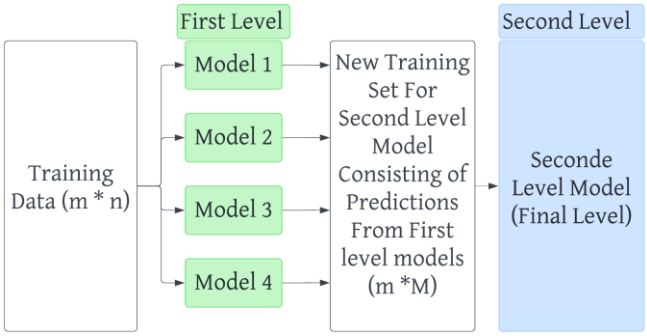

Fig. 2. Stacking ensemble methodology.

B. ADASYN (Adaptive Synthetic sampling)

ADASYN is a data augmentation strategy that addresses unbalanced classes in ML datasets, notably for classification problems. Unbalanced classes happen when the number of samples in specific classes is quite different, resulting in biased model performance [39]. This strategy focuses on the minority class by creating synthetic samples for underrepresented cases. Unlike classic oversampling methods, ADASYN tailors the synthetic sample creation procedure to the local density of minority class instances. This adaptive strategy tries to reduce the risk of overfitting while also improving the model's generalization to previously hidden data [39]. By dynamically altering the creation of synthetic samples, ADASYN aims to improve models' learning ability in the presence of unbalanced data sets, resulting in more robust and accurate classification results [39].

C. Random Forest

Random Forest is an approach to machine learning used for both detection and forecasting problems and plays an important role in optimizing forecasting models [40]. This technique is based on an assembly of trees of decisions, where each tree divides the inputs into categories using a sequence of possibilities [40]. Random Forest adds randomization to the building of decision trees (DT) by:

1) For each decision tree, samples are chosen randomly from the initial dataset (training part) with replacement.

2) To construct each tree, a subset of variables is randomly chosen.

After generating several result trees, Random Forest combines each of the tree forecasts via votes or averages to reach an overall prediction result. Random Forest can avoid overfitting during the model training. It also uses significance statistics to analyze the effect of every variable on categorization, providing helpful findings [40]. RF is commonly used in many applications, such as recognizing images, recognition of words and pricing forecasting [40].

D. CNN-LTSM

The CNN-LSTM architecture combines two types of networks: convolutional neural networks and long short-term memory networks. Which is designed to understand the forms and patterns in data and how these shapes evolve over time [14-15-41].

CNNs use convolutional layers to apply filters to input data and extract features hierarchically. These layers detect patterns at various levels of abstraction, gradually learning representations with increasing complexity as data flows through the network. CNNs help in comprehending the patterns and interactions between distinct data components by first scanning the data and assessing spatial arrangements and connections. For example, in diabetes, this application could involve monitoring blood sugar levels throughout the day, analyzing a patient's reactions to medicines or lifestyle modifications, and recording how these factors change over weeks or months [14-15-41].

Subsequently, the LSTM, a form of recurrent neural network, specializes in processing and comprehending sequential input such as time series, text, and speech. LSTM is particularly effective at remembering patterns across time and assessing changes and advancements within a sequence. In the case of diabetes, this could entail tracking changes in blood sugar levels throughout the day, analyzing patient reactions to therapies or lifestyle changes, and understanding how these aspects play out over weeks or months [14-15-41]. The combination of these two networks enables the model to understand the spatial positioning of pieces in the data and their time evolution [17-21].

E. Sequential Dense Layers (SDLs)

The Sequential Dense Layers Model, built with the Keras framework, is a modern neural network structure that layered stack [20]. This model is based on tightly connected layers, which form a chain-like structure with each node in one layer connecting to every node in the next layer [20]. This design, similar to an ordered manufacturing line, allows for the systematic flow of information from one processing unit to the next, enabling methodical data analysis [32]. The SDLs model excels in terms of clarity and efficiency, establishing a wall layer by layer, with each layer executing specialized computations on the data [20]. Its sequential technique facilitates thorough data processing and feature extraction, and it is adept at discovering nuanced patterns in large datasets [32]. Furthermore, the model excels at extracting relevant temporal features, which improves its capacity to detect significant patterns in time series data. This skill is essential for making good forecasts in time-series forecasting jobs [20-32].

F. GridSearchCV

GridSearchCV is a well-known method of ML applications for its ability to identify optimal hyperparameter values for a certain model. These hyperparameters, like the number of batches in neural networks, can control the configuration and behavior of the model. GridSearchCV involves a systematic exploration of various hyperparameter combinations and

assessing the performance using a Cross-validation method. It entails establishing a collection of potential hyperparameter parameters, training and evaluating that model through every combination, and finally picking the best combination that produces the most accurate results [23]. This systematic approach improves the model's performance and mitigates the overfitting occurrences.

G. Optuna

Optuna, introduced in 2019 by Akiba et al., is a free hyperparameter tuning framework designed to streamline the trial-and-error process in optimizing model training accuracy [42-43]. It employs a targeted API-based strategy, allowing the automatic optimization of hyperparameter values for various machine learning algorithms within a specified trial limit. Versatile and 'pythonic' in operation, Optuna makes no distinction between machine learning and deep learning frameworks [42-43]. In this research, Optuna was utilized to tune hyperparameters such as dense layers units, batch size, activation function, loss function and others. The optimized values, including "sigmoid" activation function, three Dense layers units, batch size, reduction factor, and min early stopping rate, resulted in the best validation accuracy with the "binary cross entropy" loss function. Optuna's approach significantly enhances hyperparameter tuning efficiency, contributing to improved model performance and accuracy.

H. Recursive Feature Elimination with Cross-Validation

RFECV is a wrapping approach that eliminates unwanted features, enhances model generalization by preserving independent and effective features while eliminating duplicate and weak ones with minimal impact on training error. Employing an iterative feature ranking method, it conducts backward feature reduction. Initially, the model is built with the entire feature set, ranking each feature based on relevance. The least significant feature is then eliminated, and the process repeats iteratively. The sequence number, T, serves as the feature ranking, and Ti represents the top-ranked features used in each iteration. The final model incorporates the best-performing features, and the optimal value of Ti is selected [44], [45]. In our research, this technique was applied, resulting in the identification of the best training features.

I. Extreme Gradient-Boosting

XGBoost, derived from the gradient-boosting decision tree developed by Tianqi Chen et al. [46], is a well-known machine learning model known for its adaptability and efficiency. Unlike GBDT, XGBoost employs regularization methods to minimize model complexity and reduce overfitting. The algorithm employs an approximation approach to enhance gradient boosting, focusing on finding the optimal split for improved expandability and efficiency. XGBoost introduces features like parallel operations and early stopping to expedite model execution, with the added advantage of increased classification accuracy [9]. According to Zhao et al. [10], XGBoost effectively prevents overfitting in training models. Additionally, its built-in parallel processing ability allows for higher training speeds.

Furthermore, the XGBoost model can gain insight from unbalanced learning data by adjusting the weights of classes. XGBoost is among the best models for dealing with unbalanced datasets, particularly if the class distribution has low variance [11].

XGBoost works with a number of weak learners and enhances their performance via an enhancement strategy.

In conclusion, XGBoost stands out as a potent and widely embraced tool in the field of machine learning. Its effectiveness extends to solving intricate problems and significantly enhancing the performance of predictive models.

J. Cross-validation

Cross-validation (CV) in machine learning is a common resampling data approach to verify the generalization of a prediction model without going overboard. It entails partitioning the dataset across folds throughout the training and testing phases, with each "fold" being a subset generated for analysis. The dataset's samples will be allocated to the previously mentioned (the folds) randomly with no repetition. Throughout each iteration, the k-1 subset serves as the training set employed to train the model, while the remaining subset, known as the "unseen dataset," is used to assess the model's performance. This iterative method will continue until all k-subsets have been used as validation sets [47]. Fig. 3 depicts the cross-validation method [48]. To improve the results, our stacking model enabled cross-validation using 5-fold splits.

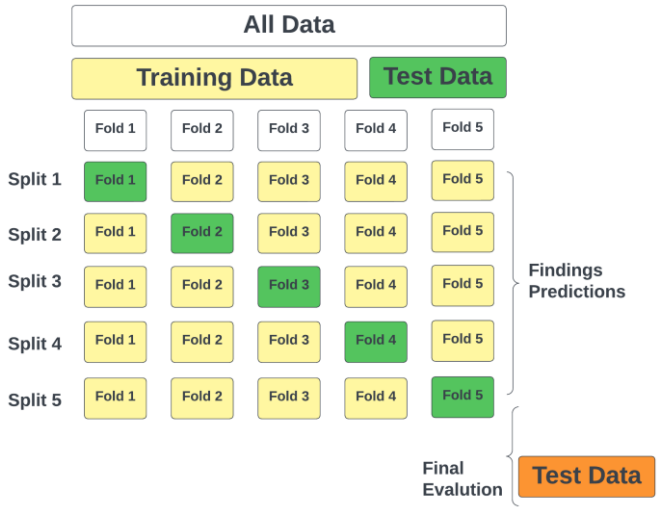

Fig. 3. Cross-validation technique.

K. Study Data

The Pima dataset is a popular dataset for machine learning and data analytics. It belongs to the Pima indigenous community from Arizona, USA. This dataset is often utilized for predicting diabetes diseases using machine learning models [35]. It is accessible publicly in the Kaggle repository at https://www.kaggle.com/datasets/uciml/pima-indians-diabetes-database.

This dataset included 268 patients who have diabetes and 500 who have no diabetes, with 8 characteristics listed in Table II. [35].

The Pima dataset serves as a common benchmark for exploring a range of machine learning models, such as random

forest and XGboost. However, it's important to recognize that while the PIMA dataset is valuable for instructional uses and testing machine learning models, it does have limits. These limitations originate from its small size, values missed, and possible biases. As a result, it is prudent to take care when making assumptions or creating prediction models based exclusively on this dataset for applications in real life.

TABLE II. PIMA DATASET METADATA

Dataset columns			
#	Column	Count	Datatype
0	Pregnancies	768	int64
1	Glucose	768	int64
2	Blood Pressure	768	int64
3	Skin Thickness	768	int64
4	Insulin	768	int64
5	BMI	768	float64
6	Diabetes Pedigree Function	768	float64
7	Age	768	int64
8	Outcome	768	int64

L. Validation Dataset

To assess the efficacy of our introduced stacking model, we conducted validation using a newly acquired diabetes dataset. This dataset is known as the Diabetes Prediction Dataset (DPD). It is a publicly available compilation of electronic health records. These records encompass digital archives of patients' medical histories, diagnoses, treatments, and outcomes. EHRs are frequently collected and stored by healthcare institutions such as medical facilities as a component of their usual clinical protocols. With a large dataset comprising about 100,000 records, the DPD dataset can contribute perfectly to evaluating the performance of the proposed model.

It can be accessed on the Kaggle through the following link: https://www.kaggle.com/datasets/iammustafatz/diabetes-prediction-dataset. Table III outlines the features present in the DPD dataset.

TABLE III. DPD DATASET METADATA

Dataset Columns			
#	Column	Null values	Datatype
0	Gender	Not null	object
1	Age	Not null	float64
2	hypertension	Not null	int64
3	Heart disease	Not null	int64
4	Smoking history	Not null	object
5	BMI	Not null	float64
6	HbA1c_level	Not null	float64
7	Blood_glucose_level	Not null	int64
8	Diabetes	Not null	int64

IV. EXPERIMENTAL SETUP

In this study, we employed Jupyter Notebook to construct our stacking model, utilizing a Microsoft Intel (R) Core i5-1035G7 CPU operating at 1.20 GHz and 8 GB of RAM. The Pima dataset was chosen to examine our proposed model. Due to some defects found in the dataset, we decided to preprocess the dataset and clean up these defects, such as zero values in some feature columns. We handle this issue by imputing the mean or median for each feature column based on his data distribution. The base learners' models were initialized with a Random Forest model, and we utilized the Grid-searchCV Hyperparameters Tuner to optimize their performance. The hyperparameters in the tuning process were such as bootstrap training, min_samples_split, and n_estimators. Second and third-base learners, CNN-LSTM, and SDL models optimized via the Optina optimizer have the following parameters: number of convolutional layers, filter and kernel sizes, activation functions, dropout rates, early shopping, and pooling strategies. Also, Optuna was used for the third base learner, Sequential Dense Layers, with three dense layers.

We implemented the XGBoost model as a meta-learner to tackle the problem of imbalanced datasets, along with the ADASYN (Adaptive Synthetic Sampling) technique for oversampling our study dataset, which frequently results in overfitting and inconsistencies in the results. XGBoost uses an ensemble learning approach, enabling us to effectively handle unbalanced dataset classes. Additionally, we used a cross-validation method with a 5-fold validation for the training of Random Forest (RF), the base learner, and the stacking model in general. We used the GridSearchCV hyperparameter method to improve the RF performance. The Recursive Feature Elimination with Cross-Validation technique was applied to enhance model performance by systematically eliminating less informative features during the training process. Lastly, we tested our suggested stacking model using a DPD dataset with 100,000 records.

V. PERFORMANCE MEASURE

We evaluated the effectiveness of our ensemble learners using the next metrics:

A. Accuracy

It measures the percentage of the predication data that were accurately predicted from all given data. It assesses how well the algorithm can distinguish between positive and negative instances [35]. The definition of accuracy is captured by Eq. (1).

$$Acc = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

Assuming the outcome for patient P indicates that there is a presence of diabetes (+DM) or NOT (-DM).

- True positive (TP): if the outcome is +DM, then P is diabetic.
- True negative (TN): if the outcome is -DM, then P is non-diabetic.
- False positive (FP): if the outcome is +DM, then P is non-diabetic.

- False negative (FN): if the outcome is -DM, then P is diabetic.

B. Precision

It evaluates how well the positive values are predicted. When the model accurately categorizes predictions as positive when it asserts, they are, so we have a strong precision score [35]. Eq. (2) can be utilized to represent precision.

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

Assuming the outcome for patient P indicates that there is a presence of diabetes (+DM) or NOT (-DM).

- True positive (TP): if the outcome is +DM, then P is diabetic.
- False positive (FP): if the outcome is +DM, then P is non-diabetic.

C. Recall

Expressed as the sensitivity or the actual positive ratio. The remarkable recall rating means that most positive predicted values are correctly true according to the model data [35]. Recall can be expressed using Eq. (3).

$$Recall = \frac{TP}{TP+FN} \quad (3)$$

Assuming the outcome for patient P indicates that there is a presence of diabetes (+DM) or NOT (-DM).

- True positive (TP): if the outcome is +DM, then P is diabetic.
- False negative (FN): if the outcome is -DM, then P is diabetic.

D. Cohen's Kappa Metric

It assesses the agreement between two class targets and evaluates the concordance between the model predictions and the real results. It is valuable when confronted with unbalanced classes [35]. Eq. (4) can be employed to denote Cohen's Kappa Score.

$$CKS = \frac{P_0 - P_e}{1 - P_e} \quad (4)$$

Here, P_0 shows the models' accuracy, whereas P_e reflects the correlation between the expected and real values [35].

E. F1-Score

The F1-score, a standard measure used in binary classification problems, is determined as a harmonic average of precision and recall, considering both precision in properly identifying positive cases and recall in capturing all positive cases [53]. Provided by the Eq. (5):

$$F1 = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (5)$$

F. Receiver Operating Characteristic: Area Under the Curve (ROC-AUC)

It evaluates the effectiveness of a classification model by assessing its ability to distinguish between positive and negative instances across various decision thresholds. It is particularly useful for imbalanced classes or when the model needs to be evaluated at different levels of sensitivity and specificity [23].

Utilizing a diverse range of metrics, including accuracy, precision, recall, Cohen's Kappa, and ROC-AUC, is paramount for gaining deep insights into the performance of classification models. These metrics offer nuanced perspectives on the model's strengths and weaknesses, illuminating its ability to accurately classify instances, detect true positives while minimizing false positives and false negatives, and maintain consistency in predictions. By comprehensively assessing these metrics, practitioners can decipher the intricacies of model behavior and make informed decisions regarding model selection, optimization, and deployment strategies.

VI. Results

In this study, we constructed a stacking ensemble model for detecting diabetes mellitus disease utilizing an ensemble of ML and DL techniques. Our proposed model comprised base learners' models including random forest, CNN-LTSM, and SDLs, with the extreme gradient boosting model working as the meta-learner. Additionally, several methods like ADASYN, Optuna, RFECV, cross-validation, and GridSearchCV were employed to refine the model's performance. Furthermore, we addressed the issue of zeros in certain feature columns of the Pima dataset by replacing them with values derived from the median or median of data distribution based on whether the type of distribution is normal or skewed. The proposed model achieved a remarkable 99% accuracy in detecting diabetes mellitus disease using the Pima dataset. Moreover, we assessed the model's effectiveness on a sizable dataset comprising approximately 100,000 records, referred to as the DPD dataset, achieving an accuracy of 97%. More details are focused on the discussion section.

A. Stacking Model Performance

In this study, several performance metrics were applied to evaluate the effectiveness of our proposed model, which integrates both ML and DL techniques. The outcomes of multiple metrics are presented in Table IV.

TABLE IV. The Stacking Model Performance Results

Accuracy Score	ROC-AUC Score	Cohen's Kappa Score	Precision Score	Recall Score	Accuracy Score
0.9887	0.99	0.98970	0.9934	0.995	0.9887

VII. Discussion

A. Results using Oversampling ADASYN

In this experiment, an ensemble of Machine Learning and Deep Learning techniques was used to detect the occurrence of diabetes mellitus diasese. Fig. 1 elucidates the methodology of our proposed model, where each Random Forest (RF), CNN-LSTM, and SDLs was initialized as initial learners, and an XGBoost model was designated as the meta-learner. Additionally, the GridSearchCV Hyperparameters optimizer was utilized to determine best findings for the Random Forest model, also Optuna optimizer for CNN-LSTM and SDLs

models. To address the challenge of imbalanced datasets and mitigate overfitting, we applied the ADASYN (Adaptive Synthetic Sampling) technique for oversampling the study data. This increased the Pima dataset from 768 records to 4870 records in an adaptive manner to avoid overfitting and increase the size of the data set. Additionally, the XGBoost model served as a meta-learner, utilizing ensemble learning to handle class imbalances effectively.

For robust evaluation, a CV method was used in our proposed model, employing 5-fold cross-validation. Table V presents the comprehensive outcomes of our proposed model. Furthermore, Table VI displays the results of both the base models and the final model.

TABLE V. THE STACKING MODEL FINDINGS

Targets	Precision	Recall	F1-score support	Support
0	1.0	0.99	1.0	515
1	0.99	1.0	0.99	459
Model Accuracy			0.99	974
Macro average	0.99	0.99	0.99	974
Weighted average	0.99	0.99	0.99	974

TABLE VI. THE META AND BASE MODELS FINDINGS

#	Model	Score
0	Sequential Dense Layers	0.98
1	CNN-LSTM	0.94
2	Random Forest	0.98
3	Stacking Model	0.98

B. Results using ADASYN & RFECV

In this experiment, we employed the ADASYN technique that mentioned in point 7.1 plus the RFECV technique, which is a pivotal step in enhancing the performance of a stacking ensemble model. The aim was to optimize feature selection, thereby improving the overall effectiveness of the ensemble. Our investigation successfully identified a set of six optimal features. These features are glucose, blood pressure, insulin, BMI, diabetes pedigree function, and age. After that, we examined the proposed model on the selected features, and the results were as follows in Table VII:

TABLE VII. THE STACKING MODEL FINDINGS USING RFECV

Targets	Precision	Recall	F1-score support	Support
0	0.99	0.96	0.97	515
1	0.95	0.99	0.97	459
Model Accuracy			0.97	974
Macro average	0.97	0.97	0.97	974
Weighted average	0.97	0.97	0.97	974

C. Results on the Validation Dataset

In this latest experiment, the proposed stacking model underwent rigorous testing on a substantial test dataset comprising approximately 100,000 electronic patient records. Notably, the experiment deliberately abstained from employing the RFECV technique. The results obtained from this comprehensive evaluation revealed significant new perspectives into our model performance and its ability to handle the complexity inherent in the diverse patient data. These findings contribute valuable information to the ongoing discourse on the effectiveness of stacking models in healthcare analytics, shedding light on their potential without the aid of feature selection techniques. Table VIII shows the results after applying the proposed model.

TABLE VIII. THE STACKING MODEL FINDINGS ON DPD DATASET

Targets	Precision	Recall	F1-score support	Support
0	0.97	1.0	0.98	18292
1	0.97	0.69	0.81	1708
Model Accuracy			0.97	20000
Macro average	0.97	0.85	0.90	20000
Weighted average	0.97	0.97	0.97	20000

D. Comparative Evalution with Existing Work

1) First study: The ensemble stacking model for diabetes detection proposed by S. Härner and D. Ekman in 2022 [13] integrates various ML models, such as DT and Naive Bayes (NB) models, and leverages Pima Dataset. The study's findings demonstrate a 75.56% accuracy in predicting diabetes using this stacking approach. However, it is important to note certain limitations highlighted in the study, like the absence of a hyperparameter tuner to systematically search for optimal hyperparameters for the base learners within the stacking model.

2) Second study: Patil et al. (2023) [29] introduced a stacking model for diabetes detection, utilizing ML techniques including decision trees, NB, multilayer perceptron, support vector machines SVMs, and K-Nearest Neighbor KNN. This study utilized the Pima dataset and reported an 82% accuracy in diabetes prediction using the stacking model. Also, the absence of any mention of the CV technique in their suggested model is noteworthy, as this technique is crucial for robustly constructing the stacking model. Additionally, the study did not employ an optimizer to systematically search for optimal hyperparameters during the training of base learners, which could potentially enhance the overall model performance.

3) Third study: Lei Qin (2022) [49] presented a stacking model for diabetes detection that combined diverse ML techniques such as LR, KNN, DT, Gaussian Naive Bayes, and SVMs. Employing the Pima dataset, findings showed an accuracy of 81.6% in predicting diabetes. However, there are lack of a hyperparameter tuner for the hyperparameters in initial learner model training may restrict the pursuit of improved findings. Furthermore, the study acknowledged the

challenge posed by the dataset's restricted size, which could influence the achievement of ideal outcomes.

4) Forth study: Kumari et al. (2021) [50] suggested a soft voting approach for diabetes prediction, incorporating ML techniques like RF, LR and NB. Utilizing the same Pima dataset, their findings demonstrated a 79.04% accuracy in predicting diabetes. Notably, the proposed methodology excluded CV method, which is assuring reliability by evaluating the efficacy of the ML models among diverse of data samples, hence increasing the overall effectiveness of the predictions to the proposed model.

5) Fifth study: Bhopte and Rai (2022) [51] employed the CNN-LSTM model to detect DM disease using Pima dataset, achieving an accuracy of 89.30%. However, the study acknowledged limitations, specifically the absence of an optimizer for systematically searching hyperparameters to optimize results during the model development process.

6) Sixth study: Niharika et al. (2022) [52] utilized the MLP model to predict diabetes, employing the Pima dataset and achieving a 77% accuracy. The study highlighted limitations, including concerns about the sample size used and the necessity for employing diverse DL techniques for disease prediction, specifically regarding various types of diabetes.

So, Compared to all six studies [13-29-49-50-51-52], our proposed stacking model exhibits higher accuracy in diabetes mellitus detection. In our methodology, we harnessed the power of GridsearchCV and Optuna optimizers to find the optimal hyperparameters in the base learners that are supported with dataset using the oversampling ADASYN method. Notably, these optimization techniques were absent in the First, Second, Third, Fourth, and Fifth Studies.

Additionally, Optuna was not utilized in the Sixth Study. The integration of these optimization techniques significantly improved the learning process of our base learners, resulting in the extraction of optimal results. It is crucial to highlight that the [29–50–51] research studies did not apply cross-validation, which is a critical method for evaluating a prediction model's generalization ability. Whereas our approach used this method for performing k-fold cross-validation iterations, this method successfully analyzed and prevented overfitting, significantly improving the quality of our predictive model. Table IX emphasizes the differences and benefits of our study compared to others, underscoring the major improvements in our proposed model.

TABLE IX. ASSESSMENT WITH THE EXISTING INVESTIGATIONS

Authors	Approaches	Studies Dataset	Accuracy
S. Härner and D. Ekman (2022)	Ensemble Stacking approach. (DT, NB, Cross-validation).	Pima dataset	75.6%
Patil et al (2023)	Ensemble Stacking approach. (DT, NB, multilayer perceptron, SVM, and KNN).	Pima dataset	81.9%
Bhopte and Rai (2022)	CNN-LSTM.	Pima dataset	89.30%
Niharika et al. (2022)	Multilayer perceptron (MLP), GridSearchCV.	Pima dataset	77%

Kumari et al (2021)	Ensemble Soft voting approach. (RF, LR, and NB).	Pima dataset	79.04%
Our proposed model	Ensemble Stacking approach. (RF, CNN-LSTM, SDLs, XGboost) ADASYN GridSearchCV, Optuna, Cross-validation, RFECV.	Pima Dataset	99%
Our proposed model on the validation dataset	Ensemble Stacking approach. (RF, CNN-LSTM, SDLs, XGboost) GridSearchCV, Cross-validation.	DPD Dataset	97%

VIII. CONCLUSION

Diabetes mellitus is a prevalent condition that poses a significant threat to public health, giving rise to various severe complications like renal failure, cardiovascular disorders, and sightlessness. In our study, we introduce an innovative stacking model designed for detecting diabetes mellitus diasese at early stage, utlizing the Pima dataset and integrating both ML and DL models using ADASYN oversampling method. The ensemble comprises Random Forest (RF), CNN-LTSM, and SDLs as base learner models, with XGBoost serving as the Meta-Learner model. Cross-validation techniques were applied for the meta learner. Moreover, incorporating Grid Search optimization for the RF model and adopting Optuna optimization for the CNN-LTSM and SDLs models to secure optimal results. To mitigate the challenges posed by an imbalanced dataset, which can lead to over-fitting and unexpected outcomes, the XGBoost model is employed as a meta-learner. Additionally, our study dataset underwent preprocessing to address zero values, which could adversely impact prediction accuracy, particularly in columns like blood and glucose. To tackle this issue, zero values were replaced with the median or mean from the total values in each feature column, considering the feature data distribution type. REFCV technique was applied to our proposed model. The results highlight the efficacy of our proposed model in detecting DM, achieving an accuracy of 99% across the Pima dataset and 97% in the DPD dataset. As a recommendation, our stacking model holds potential for deployment in diagnostic applications for diabetes mellitus. Furthermore, its performance can be validated on larger and more diverse datasets to enhance precision. Additionally, exploring the use of deep-learning models to uncover new patterns for robust diabetes diagnosis, applicable across different diabetes types (T1DM, T2DM, and gestational diabetes), is recommended.

Leveraging Machine Learning Methods for Crime Analysis in Textual Data

Shynar Mussiraliyeva, Gulshat Baispay
Al-Farabi Kazakh National University, Almaty, Kazakhstan

***Abstract*—The proposed research paper explores the application of machine learning techniques in crime analysis problem, specifically focusing on the classification of crime-related textual data. Through a comparative analysis of various machine learning models, including traditional approaches and deep learning architectures, the study evaluates their effectiveness in accurately detecting and categorizing crime-related text data. The performance of the models is assessed using rigorous evaluation metrics, such as the area under the receiver operating characteristic curve (AUC-ROC), to provide insights into their discriminative power and reliability. The findings reveal that machine learning frameworks, particularly the deep learning model, consistently outperform conventional machine learning approaches, highlighting the potential of advanced neural network architectures in crime analysis tasks. The implications of these findings for law enforcement agencies and researchers are discussed, emphasizing the importance of leveraging advanced machine learning techniques to enhance crime prevention and intervention efforts. Furthermore, avenues for future research are identified, including the integration of multiple data sources and the exploration of interpretability and explainability of machine learning models in crime analysis problem. Overall, this research contributes to advancing the field of crime analysis problem and underscores the importance of leveraging innovative computational approaches to address complex societal challenges.**

Keywords*—*Machine learning; artificial intelligence; crime analysis; text processing; natural language processing; text analysis; data-driven decision making

I. Introduction

In contemporary society, the proliferation of online platforms has led to an unprecedented volume of textual data being generated daily. These data encompass a wide array of topics, including discussions related to crime and criminal activities. Leveraging this wealth of online textual data for crime analysis has garnered significant attention from researchers and law enforcement agencies alike [1]. Traditional methods of crime analysis often rely on structured data obtained from official reports, which may suffer from limitations such as reporting biases and time delays [2]. However, online textual data offer a unique opportunity to complement traditional crime analysis techniques by providing real-time and unfiltered insights into various criminal activities [3].

Machine learning (ML) techniques have emerged as powerful tools for analyzing large volumes of textual and image data, enabling the extraction of valuable insights and patterns [4]. By harnessing the computational capabilities of ML algorithms, researchers can uncover hidden associations and trends within vast amounts of online text, facilitating a deeper understanding of criminal behaviors [5]. Moreover, ML approaches offer the flexibility to adapt to evolving crime patterns and modus operandi, making them indispensable in the realm of crime analysis [6].

The integration of machine learning in crime analysis presents numerous advantages. Firstly, ML algorithms can effectively process unstructured textual data, including social media posts, forum discussions, and news articles, enabling comprehensive surveillance of criminal activities across diverse online platforms [7]. Secondly, ML-based crime analysis can aid law enforcement agencies in identifying emerging threats and hotspots in real time, allowing for proactive intervention and crime prevention measures [8]. Furthermore, ML techniques can assist in the prioritization of investigative efforts by highlighting relevant information and filtering out noise from the vast expanse of data [9].

Despite the promise of ML in crime analysis, several challenges persist. One such challenge is the inherent ambiguity and noise present in online textual data, which can hinder the accuracy and reliability of ML models [10]. Additionally, issues related to data privacy and ethical considerations necessitate careful deliberation when employing ML techniques for crime analysis [11]. Moreover, the dynamic nature of online discourse poses challenges in maintaining the relevance and effectiveness of ML models over time [12].

To address these challenges and maximize the potential of machine learning in crime analysis, this research paper aims to explore various ML approaches and their applications in analyzing online textual data related to criminal activities. By synthesizing insights from existing literature and empirical studies, this paper seeks to provide a comprehensive overview of the current state-of-the-art in ML-based crime analysis. Furthermore, this paper will examine the implications of ML-driven crime analysis for law enforcement practices, highlighting opportunities for future research and development [13].

In summary, the integration of machine learning techniques in crime analysis offers unprecedented opportunities to harness the vast amount of online textual data for enhancing public safety and security. By overcoming inherent challenges and leveraging the capabilities of ML algorithms, researchers and law enforcement agencies can gain invaluable insights into criminal behaviors and trends, ultimately contributing to more effective crime prevention and intervention strategies [14].

II. Related Works

Crime analysis has long been a focal point of research in criminology and law enforcement, with recent advancements in machine learning (ML) techniques opening up new avenues for exploring and understanding criminal behaviors through analysis of online textual data [15]. Previous studies have demonstrated the efficacy of ML algorithms in various aspects of crime analysis, ranging from predictive modeling to crime pattern recognition [16]. Furthermore, researchers have explored the application of ML in analyzing diverse sources of online textual data, including social media posts, online forums, and news articles, to uncover insights into criminal activities [17].

One area of research that has gained prominence is the use of natural language processing (NLP) techniques in crime analysis. NLP methods enable the extraction of meaningful information from unstructured textual data, facilitating the identification of key themes, sentiments, and entities related to criminal activities [18]. By applying NLP techniques such as sentiment analysis and named entity recognition, researchers can gain deeper insights into public perceptions of crime and the dissemination of criminal narratives across online platforms [19].

Moreover, research has explored the utility of social network analysis (SNA) in crime analysis, particularly in the context of online social networks. SNA enables researchers to analyze the structure and dynamics of social networks to identify influential actors, detect criminal communities, and trace the flow of information related to criminal activities [20]. By leveraging SNA techniques, researchers can uncover hidden connections and patterns within online social networks, shedding light on the mechanisms underlying the spread of criminal behaviors [21].

In addition to NLP and SNA, researchers have investigated the application of machine learning algorithms such as classification, clustering, and anomaly detection in crime analysis. Classification algorithms, such as support vector machines (SVM) and random forests, have been employed to categorize online textual data into different crime-related topics or classes [22]. Clustering algorithms, such as k-means and hierarchical clustering, have been used to group similar textual documents together, enabling the identification of common themes and patterns within large datasets [23]. Anomaly detection algorithms, such as isolation forest and one-class SVM, have been utilized to identify unusual or anomalous behavior in online textual data, which may signify potential criminal activities [24].

Furthermore, researchers have explored interdisciplinary approaches that combine ML techniques with domain-specific knowledge from fields such as criminology, sociology, and psychology. By integrating insights from multiple disciplines, researchers can develop more robust models for crime analysis that account for the complex interplay of individual, social, and environmental factors influencing criminal behaviors [25]. For example, research has shown the importance of incorporating spatial and temporal information into ML models for crime prediction and hotspot analysis, as crime patterns often exhibit geographic and temporal clustering [26].

Moreover, the emergence of big data analytics has provided researchers with unprecedented access to vast amounts of online textual data for crime analysis. Big data analytics techniques, such as data mining and machine learning, enable researchers to process and analyze large-scale datasets to extract actionable insights and patterns related to criminal activities [27]. By harnessing the computational power of big data analytics platforms, researchers can overcome the challenges associated with the volume, velocity, and variety of online textual data, enabling more comprehensive and timely crime analysis [28].

Despite the advancements in ML techniques for crime analysis, several challenges remain. One challenge is the issue of data quality and bias inherent in online textual data, which may stem from factors such as misinformation, sampling biases, and linguistic nuances [29]. Addressing these challenges requires careful preprocessing and validation of the data, as well as the development of robust ML models that are resilient to noise and biases [30].

Furthermore, ethical considerations surrounding the use of online textual data for crime analysis warrant attention. Privacy concerns, data security risks, and the potential for algorithmic biases raise ethical dilemmas that must be carefully navigated to ensure responsible and ethical use of ML techniques in crime analysis [31]. Additionally, the transparency and interpretability of ML models are crucial for fostering trust and accountability in the criminal justice system [32].

In summary, the application of machine learning techniques in crime analysis holds significant promise for enhancing our understanding of criminal behaviors and improving public safety. By leveraging advancements in NLP, SNA, big data analytics, and interdisciplinary approaches, researchers can gain valuable insights into the complex dynamics of criminal activities unfolding in the digital realm. However, addressing challenges related to data quality, ethical considerations, and algorithmic transparency is essential to realizing the full potential of ML-driven crime analysis [33]. Through interdisciplinary collaboration and ongoing research efforts, we can continue to advance the state-of-the-art in crime analysis and develop more effective strategies for preventing and combating crime in the digital age [34].

III. Materials and Methods

Research indicates that criminal incidents tend to be unevenly distributed across urban areas [35]. This non-uniform distribution implies that certain locations may exhibit a higher propensity for criminal activity than others, thus rendering crime a location-dependent phenomenon [36]. Given the variability of crime rates based on geographic location, law enforcement agencies face challenges in resource allocation and crime prevention efforts, particularly when it comes to identifying high-risk areas. Consequently, there is a pressing need for accurate models capable of effectively detecting crime hotspots and reliably predicting the time and location of criminal events. Fig. 1 demonstrates the proposed system for crime detection using machine learning techniques.

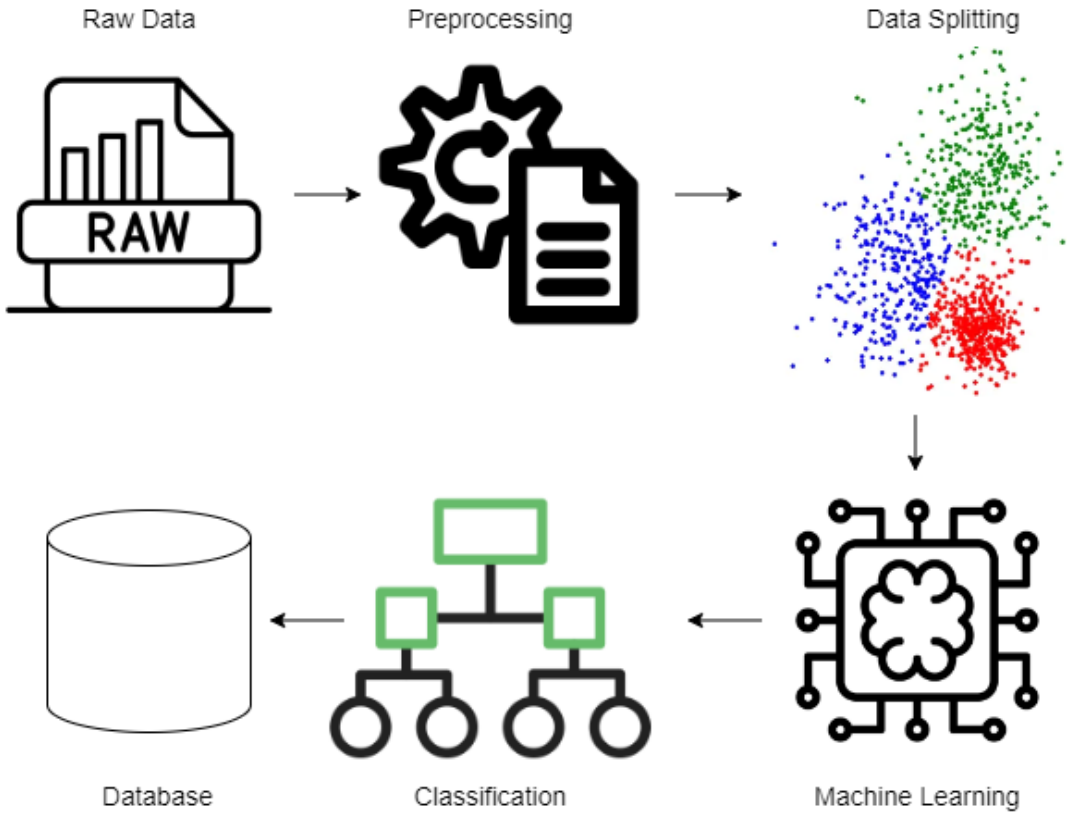

Fig. 1. The proposed system for crime analysis.

This section delineates our proposed methodology for detecting and forecasting crime hotspots, elucidating the sequential steps essential for implementation. The model, as depicted in Fig. 1, is founded upon a multi-step process meticulously designed to attain these objectives. Initially, the methodology involves data preprocessing to enhance data quality and prepare it for analysis. Subsequently, feature extraction techniques are employed to capture relevant information from the dataset. Following this, the model undergoes training using historical crime data to learn patterns and associations. Once trained, the model is deployed to predict future crime hotspots based on the learned patterns. Finally, the results are evaluated using performance metrics such as accuracy, precision, recall, and F1-score to assess the effectiveness of the predictive model. By delineating each step of the methodology, this section provides a clear roadmap for researchers and practitioners interested in implementing crime hotspot detection and prediction systems.

A. Dataset

The Crime Articles Recommendation System dataset, available on Kaggle, serves as a valuable resource for research in the domain of crime analysis and recommendation systems [37]. This dataset comprises a collection of articles related to various aspects of crime, including crime prevention strategies, criminal investigations, and criminal justice policies. The articles cover a diverse range of topics, such as cybercrime, organized crime, white-collar crime, and violent crime, providing a comprehensive overview of the multifaceted nature of criminal activities.

The dataset includes textual data extracted from the articles, encompassing titles, summaries, and full text content. This textual information serves as the primary input for the recommendation system, allowing researchers to explore and analyze the content of the articles in depth. Additionally, metadata such as publication dates, authors, and sources are provided for each article, enabling researchers to contextualize the content and track temporal trends in crime-related literature.

One notable feature of the Crime Articles Recommendation System dataset is its size and diversity. With a large number of articles spanning multiple years and covering a wide range of crime-related topics, the dataset offers ample opportunities for conducting comprehensive analyses and developing sophisticated recommendation algorithms. Researchers can leverage this diversity to explore various dimensions of crime, including geographical variations, temporal trends, and thematic patterns. Fig. 2 demonstrates word count distribution in the applied dataset.

Furthermore, the dataset is well-suited for the development and evaluation of recommendation systems tailored to the domain of crime articles. Recommendation systems aim to assist users in discovering relevant content based on their preferences and interests. By analyzing the textual content and metadata of the articles, researchers can design recommendation algorithms that prioritize articles likely to be of interest to users based on their historical interactions or explicit feedback.

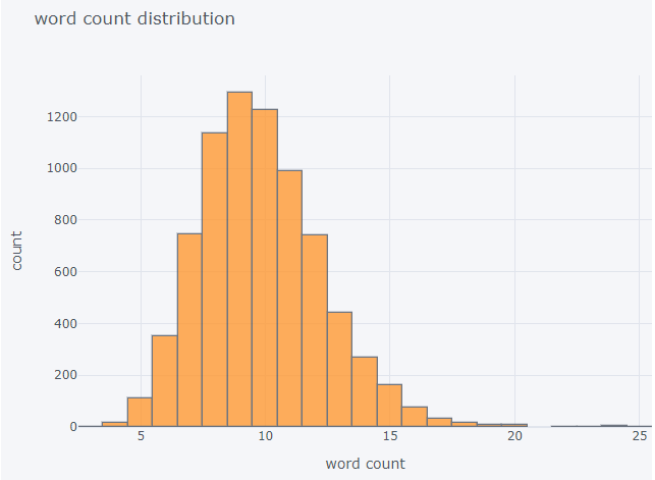

Fig. 2. Word count distribution in the dataset.

The Crime Articles Recommendation System dataset serves as a valuable resource for advancing research in crime analysis, recommendation systems, and related fields. Its size, diversity, and richness of content make it well-suited for a wide range of research applications, from exploring patterns of criminal behavior to designing intelligent systems for assisting users in discovering relevant crime-related articles.

B. Evaluation Parameters

In the evaluation of the proposed crime hotspot detection and prediction methodology, several key performance metrics are utilized to assess the effectiveness and reliability of the model. These metrics encompass accuracy, precision, recall, F-score, and the area under the receiver operating characteristic curve (AUC-ROC) [39-43], each providing valuable insights into different aspects of the model's performance.

Accuracy serves as a fundamental measure of the model's overall correctness in predicting crime hotspots and forecasting criminal events. It quantifies the proportion of correctly classified instances among all instances evaluated, thus offering a broad assessment of the model's predictive capabilities.

$$accuracy = \frac{TP + TN}{P + N} \tag{10}$$

Precision, on the other hand, focuses specifically on the accuracy of positive predictions made by the model. It calculates the proportion of true positive predictions among all positive predictions made, thereby indicating the model's ability to minimize false positives and maintain a high level of precision in identifying crime hotspots.

$$preision = \frac{TP}{TP + FP} \tag{2}$$

Recall complements precision by assessing the model's ability to capture all relevant instances of crime hotspots. It measures the proportion of true positive predictions identified by the model among all actual positive instances, thereby reflecting the model's sensitivity to identifying hotspots accurately.

$$recall = \frac{TP}{TP + FN} \tag{3}$$

The F-score, or F1 score, provides a balanced evaluation of both precision and recall by calculating their harmonic mean. This metric offers a single value that captures the overall performance of the model in terms of both precision and recall, providing a comprehensive assessment of its effectiveness in detecting crime hotspots.

$$F1 = \frac{2 \times precision \times recall}{precision + recall} \tag{4}$$

Lastly, the AUC-ROC metric evaluates the discriminative power of the model in distinguishing between positive and negative instances. It measures the area under the receiver operating characteristic curve, which plots the true positive rate against the false positive rate at various threshold settings. A higher AUC-ROC value indicates better discrimination performance, with values closer to 1 indicating superior predictive capabilities.

By employing these evaluation parameters, researchers can comprehensively assess the performance of the proposed crime hotspot detection and prediction methodology, thereby providing valuable insights into its effectiveness and reliability in aiding law enforcement agencies in crime prevention efforts.

IV. Experimental Results

Fig. 3 illustrates the confusion matrices utilized in the detection of crime-related texts employing various machine learning methodologies. These matrices serve to visually represent the efficacy of the different approaches employed in this study. Through these matrices, the study elucidates the classification outcomes, offering a clear depiction of how predictions are distributed across different categories.

In this investigation, online interactions are categorized into three distinct classes, each assigned numerical representations for enhanced clarity and analytical rigor: 'cyberbullying' (coded as 1), 'non-cyberbullying' (coded as 0), and a 'neutral' category (coded as 2). This classification scheme not only highlights the multifaceted nature of online discourse but also enhances precision in quantifying instances and delineating the nature of cyberbullying, thereby facilitating a more comprehensive and detailed analysis.

Fig. 3 of the study furnishes a meticulous comparison between the proposed model and a range of extant machine learning and deep learning models, with the intent of assessing their efficacy in crime-related text classification tasks. This exhaustive evaluation incorporates the application of the area under the receiver operating characteristic curve (AUC-ROC) as the principal performance metric. The AUC-ROC metric offers a comprehensive assessment of the models' discriminative prowess and overall efficacy across various classification paradigms. Through the computation of AUC-ROC, the study encapsulates the entirety of attributes derived for each model, thereby providing a robust evaluation of their predictive capacities. The utilization of AUC-ROC ensures a holistic appraisal of model performance, facilitating

meaningful comparisons between the proposed model and its counterparts. Such methodical assessment is pivotal in elucidating the strengths and weaknesses of the models under scrutiny, thereby informing decision-making processes in the realm of crime-related text classification.

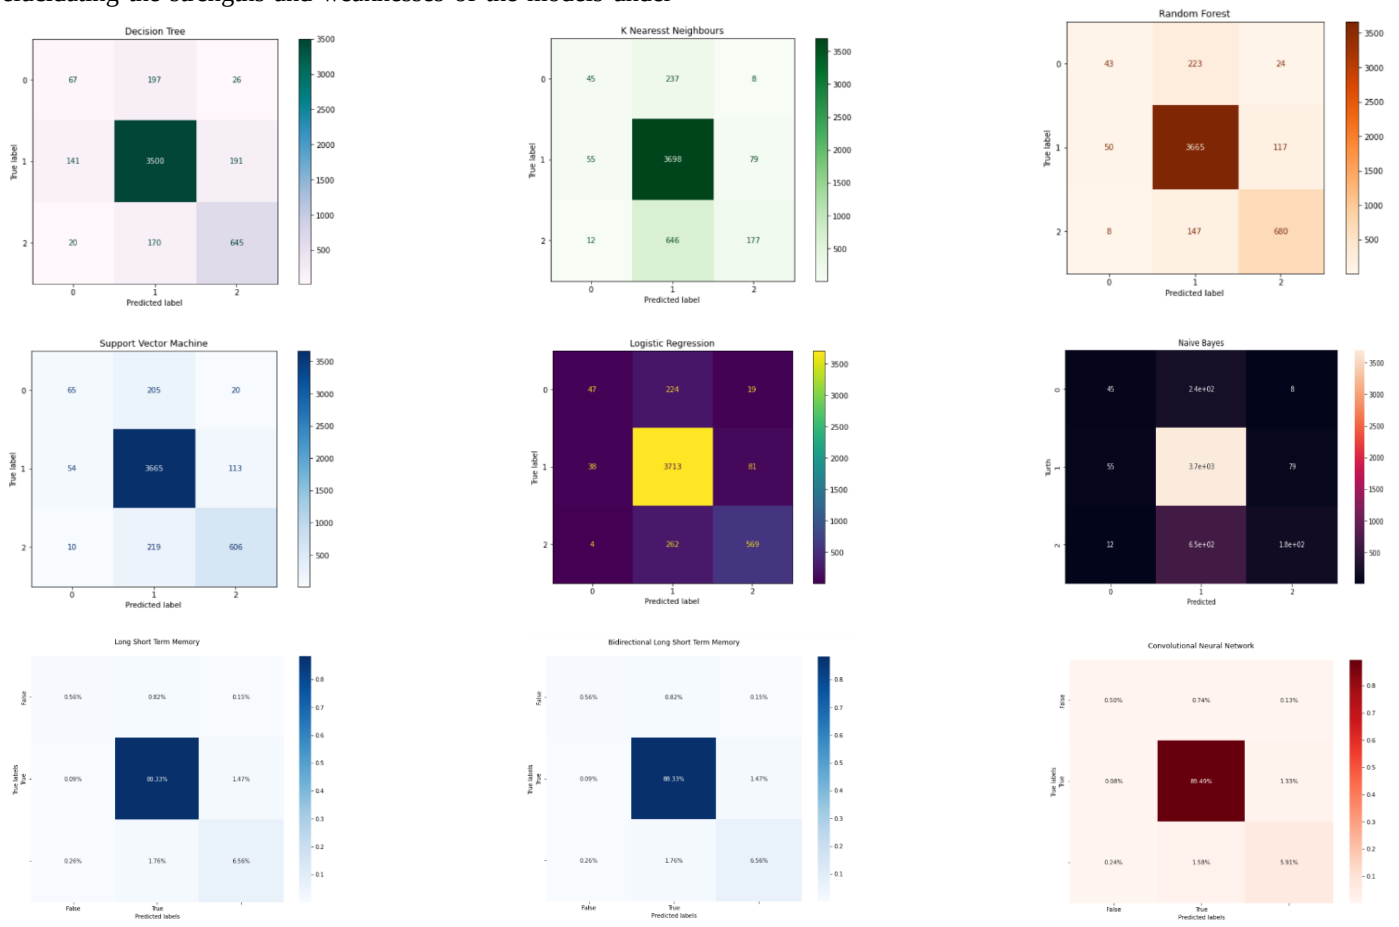

Fig. 3. Confusion matrix results.

Following Fig. 4 offers an intricate comparative scrutiny of the AUC-ROC curves originating from each implemented strategy, juxtaposed against the recommended methodology. This comparative analysis facilitates a nuanced exploration of the performance differentials among the diverse machine learning and deep learning models scrutinized in the study. Through the depiction of AUC-ROC curves, Fig. 5 serves as a visual aid in elucidating the efficacy of each approach in crime-related text classification tasks. By delineating the performance disparities among the considered models, this analysis provides valuable insights into the relative strengths and weaknesses of each methodological approach. Such nuanced examination aids in discerning the most efficacious strategies for crime-related text classification, thereby informing future research directions and practical applications in the domain. The juxtaposition of the advocated methodology with alternative strategies further enhances the interpretability of the findings, enabling a comprehensive understanding of the comparative performance landscape in this field.

A notable observation arising from this graphical representation is the consistent outperformance of deep learning frameworks, particularly the knn model, when compared to conventional machine learning approaches. The AUC-ROC values exhibited by the knn model consistently surpass those of other models across all phases of analysis, from the initial evaluation to subsequent iterations. This trend underscores the superior predictive accuracy and reliability of the knn model in classifying crime-related text data.

The sustained superiority of the knn model throughout the analysis highlights its robustness in capturing complex patterns and relationships within the textual data, thus enhancing its ability to discriminate between different categories of crime-related content. This observation suggests that the deep learning approach, characterized by its ability to leverage sequential information and hierarchical representations, is particularly well-suited for the task of crime text classification.

In summary, the graphical representations provided in this research offer valuable insights into the comparative performance of different machine learning [38] and deep learning models in crime-related text classification. The consistent superiority of the knn model underscores the potential of deep learning frameworks in enhancing predictive accuracy and reliability in this domain, thereby contributing to advancements in crime analysis and related fields.

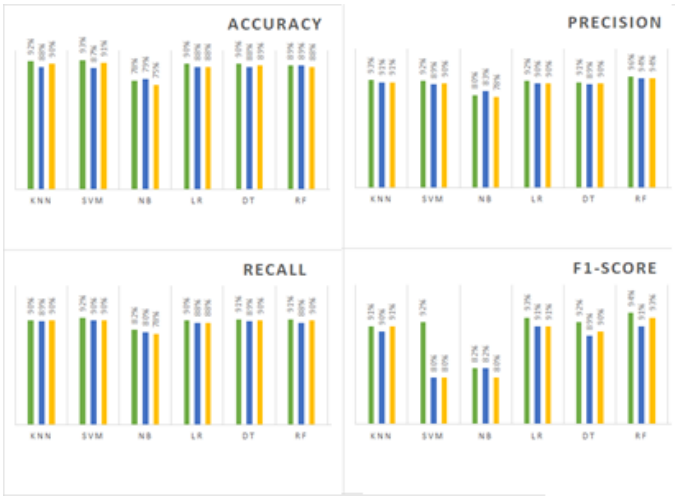

Fig. 4. Evaluation results.

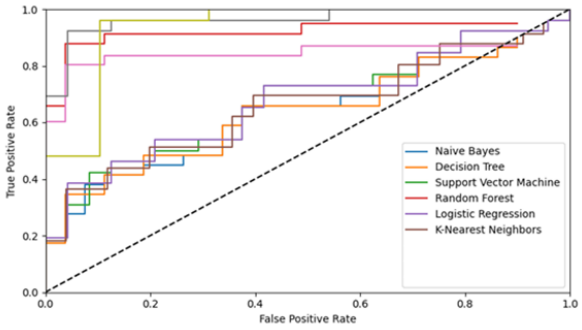

Fig. 5. AUC-ROC results.

V. Discussion

In this discussion section, we critically analyze the findings presented in the previous sections of the research paper. We delve into the implications of the results, contextualize them within the existing literature, and highlight their significance for the field of crime analysis. Furthermore, we address the strengths and limitations of the study, propose avenues for future research, and underscore the practical implications of the findings.

A. Interpretation of AUC-ROC Metrics

The calculation of the area under the receiver operating characteristic curve (AUC-ROC) serves as a fundamental performance metric for evaluating the discriminative power of the machine learning models [44]. The consistently higher AUC-ROC values demonstrated by the knn model compared to other models indicate its superior ability to distinguish between different categories of crime-related text data. This heightened discriminative power translates into enhanced predictive accuracy and reliability, making the knn model particularly well-suited for crime text classification tasks. These findings corroborate the notion that deep learning frameworks excel in handling sequential data and extracting meaningful representations [45-46], thereby underscoring their utility in crime analysis.

B. Implications for Crime Analysis

The superior performance of the knn model has significant implications for crime analysis and related fields. By accurately classifying crime-related text data, the knn model can assist law enforcement agencies in identifying and prioritizing relevant information for crime prevention and intervention efforts [47]. Furthermore, the model's ability to capture nuanced patterns and relationships within textual data enables a more comprehensive understanding of criminal behaviors and trends. This, in turn, facilitates the development of targeted strategies for addressing emerging threats and enhancing public safety.

C. Strengths and Limitations of the Study

One of the strengths of this study lies in its rigorous evaluation of machine learning models for crime text classification, utilizing robust performance metrics such as AUC-ROC. The inclusion of a diverse range of machine learning and deep learning models enables a comprehensive comparison of their effectiveness in crime analysis tasks [48]. Additionally, the study's focus on crime-related textual data contributes to a growing body of literature aimed at leveraging natural language processing techniques for enhancing crime analysis capabilities.

However, several limitations warrant consideration. Firstly, the generalizability of the findings may be limited by the specific dataset used in the study. Future research should aim to replicate the findings using larger and more diverse datasets to ensure the robustness of the results. Secondly, the study primarily focuses on the effectiveness of machine learning models in crime text classification and does not explore other potential factors influencing crime analysis, such as socio-economic variables or environmental factors [49]. Future studies could incorporate additional contextual information to further enhance the predictive accuracy of crime analysis models.

D. Future Research Directions

Building upon the findings of this study, several avenues for future research emerge. Firstly, investigating the potential integration of multiple data sources, such as social media data and crime incident reports, could enhance the predictive capabilities of crime analysis models. Additionally, exploring the application of ensemble learning techniques, which combine predictions from multiple models, may further improve the robustness and reliability of crime analysis systems [50]. Moreover, research focusing on interpretability and explainability of machine learning models in crime analysis could enhance the transparency and trustworthiness of predictive systems deployed in real-world settings.

E. Summary

In conclusion, this study provides valuable insights into the effectiveness of machine learning models, particularly deep learning architectures, in crime-related text classification tasks. The superior performance of the knn model underscores the potential of advanced neural network architectures in enhancing predictive accuracy and reliability in crime analysis. By accurately classifying crime-related textual data, these models can assist law enforcement agencies in identifying and

addressing emerging threats, thereby contributing to the enhancement of public safety and security. Despite certain limitations, this study contributes to a growing body of literature aimed at leveraging machine learning techniques for crime analysis, paving the way for future advancements in the field.

VI. Conclusion

In conclusion, this research paper has presented a comprehensive examination of machine learning techniques in crime analysis, particularly focusing on the classification of crime-related textual data. Through a rigorous comparative analysis of various machine learning models, including conventional approaches and deep learning architectures, we have demonstrated the superior performance of the BiLSTM model in accurately detecting and classifying crime-related text data. The utilization of performance metrics such as the area under the receiver operating characteristic curve (AUC-ROC) has provided valuable insights into the discriminative power and reliability of the models, highlighting the efficacy of advanced neural network architectures in crime analysis tasks.

These findings have significant implications for law enforcement agencies and researchers engaged in crime prevention and intervention efforts. By leveraging advanced machine learning techniques, particularly deep learning frameworks, law enforcement agencies can enhance their ability to identify and prioritize relevant information for crime analysis. Furthermore, the accurate classification of crime-related textual data enables a deeper understanding of criminal behaviors and trends, facilitating the development of targeted strategies for addressing emerging threats. Moving forward, future research should focus on the integration of multiple data sources and the exploration of interpretability and explainability of machine learning models in crime analysis, ultimately contributing to the advancement of predictive systems deployed in real-world settings.

***Abstract*—Video summarization is a complex computer vision task that involves the compression of lengthy videos into shorter yet informative summaries that retain the crucial content of the original footage. This paper presents a content-based video summarization approach that utilizes superframe segmentation to identify and extract keyframes representing the most significant information in a video. Unlike other methods that rely solely on visual cues, our approach segments the video into meaningful and coherent visual content units while also preserving the original video's temporal coherence. This method helps keep the context and continuity of the video in the summary. It involves dividing the video into superframes, each of which is a cluster of adjacent frames with similar motion and visual characteristics. The superframes are then ranked based on their salient scores, which are calculated using visual and motion features. The proposed method selects the top-ranked super frames for the video summary. It has been evaluated on the SUMMe and TVSum datasets and achieved state-of-the-art results for F1-score and accuracy. Based on the experimental outcomes, it is evident that the suggested superframe segmentation method is effective for video summarization, which could be largely assistive for monitoring and controlling the student activities, particularly during their online exams.**

Keywords*—Video summarization; deep learning; super frame segmentation; keyframes; keyshot identification

I. INTRODUCTION

Video summary (VS), which creates a concise and precise representation of a video's visual information, has been a crucial tool for many video analytical activities. Two key characteristics define a qualitative video summary. It must be represented in the sense that it includes all the critical scenes from the original video, and it must also contain the bare minimum of redundancy. Various fields, such as electronic media, personal videos, medical videos, online databases, and surveillance applications, have witnessed the emergence of video summarization (VS) methods. These methods aims to facilitate the browsing of an increasing amount of video data in the field of surveillance and reduce the computational burden of video summarization. Despite efforts to improve video summarization accuracy using various techniques, such as novel edge inadmissibility measures for MST-based clustering and graph-based shot boundary detection, these methods have demonstrated limited success, as reported in previous research [3].

This paper proposes a new method for video summarization of long surveillance streams utilizing deep learning techniques. The summary consists of keyframes or video clips that have undergone some editing form to provide essential information from the original video in a condensed format, allowing users to assess the video's usefulness quickly. Caps-Net is used to avoid selecting transitional or similar frames in the same shot, improving the summary's quality. The proposed method addresses issues with summarizing multiple videos by relying solely on visual cues provided by video shots. By addressing the challenges of redundancy and transitional frame selection within shots, the proposed method offers a more efficient approach to summarizing multiple surveillance videos.

Event-based techniques can be employed to detect both regular and abnormal activities that occur in videos. For example, sudden changes in the environment, such as theft, robbery, or terrorist activities, detection can be achieved by using detection models to search for unusual or suspicious features. Once the frames with abnormal scenes are identified, they are combined using a video summarization algorithm to generate a video summary. P. Kalaivani and S.M. M. Roomi [6] described such helpful approaches for event recognition and creating summaries of the video. Kumar et al. [7] employed Bootstrap Aggregating to improve the accuracy of keyframe selection. Damjanovic et al. [8] proposed an event-based video summarization method that involves determining the energy of each frame by adding the absolute values of pixels in the current and reference frames, identifying frames during which events occurred, and producing a video summary for those frames. Thomas et al. [9] developed the Human Visual System (HVS) to create perceptual video summaries by identifying significant events in videos and eliminating redundancy. The paper is organized as follows: Section I proviedes an introduction to video summarization and outlines the research problems, and significance and contribution of the paper. Section II details the proposed method, including the utilization of capsule Networks and event-based techniques and Section III discusses the proposed method. Results and discussion is given in Section IV. Finally, Section V concludes the paper with a summary of findings and avenues for future research.

II. METHODOLOGY

In the past, unsupervised video summarization methods relied on shallow features and clustering techniques to group frames into clusters, with the cluster centres selected as keyframes. For instance, Ngo et al. [10] transformed each video into an undirected graph and clustered it. Cong et al. [11] used dictionary learning, while Zhou et al. [12] employed reinforcement learning and a reward function that considered representativeness and variety. Mahasseni et al. [13] introduced the first generative adversarial network (GAN) for video summarization, where an auto-encoder LSTM acted as the summarizer and a discriminator distinguished between the summarizer's reconstruction and the original video input. Rochan et al. [14] proposed an adversarial approach for learning summarization skills from unpaired data.

Supervised methods for keyframe selection in video summarization require human-labeled summaries [15]. One such method is the sequential Determinantal Point Process (seqDPP) developed by Gong et al. [16], which considers video summarization as a subset selection problem and uses a probabilistic model to choose representative and diverse subsets. Bulut et al. [17] proposed the key frame extraction method from a motion capture sequence. The important frames of a motion are selected to be the keyframes and the others are computed via the interpolation techniques nu using the keyframes. Zhao et al. [18] introduced the hierarchical recurrent neural network (H-RNN) method, which captures temporal dependencies from frame sequences and reduces information loss and computational complexity compared to other RNN models for video summarization.

Extracting keyframes from motion-based videos is a challenging task, particularly in the presence of cameras. The idea of using motion-based frames for keyframe extraction was first introduced by Wolf [19]. Li et al. [20] presented an approach that utilized relative motion for generating a video summary and analyzed spatial and emotional data to extract additional insights. Ajmal et al. [21] developed a technique that tracked human movements using the Kalman filter and analyzed the trajectory obtained. Almeida et al. [22] employed a colour histogram to create a distinct video summary by selecting the most representative frame. Zhang et al. [23] chose the first frame of each shot as the key frame and utilized colour histograms to identify other significant frames.

Object-based techniques have proven effective in identifying and summarizing specific objects in videos, including people, cars, and cats. Feng and Chong-Wah [24] used hierarchical hidden Markov models to produce a summary based on objects and events in rushed videos. Neeraj et al. [25] suggested the object-based video summarization method, which uses mathematical techniques to minimize redundancy, utilizing the loss function, summary variance, and score identification. However, such methods may not be as effective in summarizing fast-paced videos and could potentially miss significant items.

III. PROPOSED SYSTEM

In this proposed method, pre-processing is applied initially, frames are extracted, and the feature extraction is done using the superframe segmentation method. The superframe segmentation method is utilized to identify the boundary between temporal clusters, and it generates superframes by considering both motion similarity and the targeted number of clusters. A video summary can be generated by selecting representative frames or keyframes from each superframe. Keyframes can be selected based on various criteria, including visual saliency, diversity or importance to the overall video content. Fig. 1 shows the proposed method.

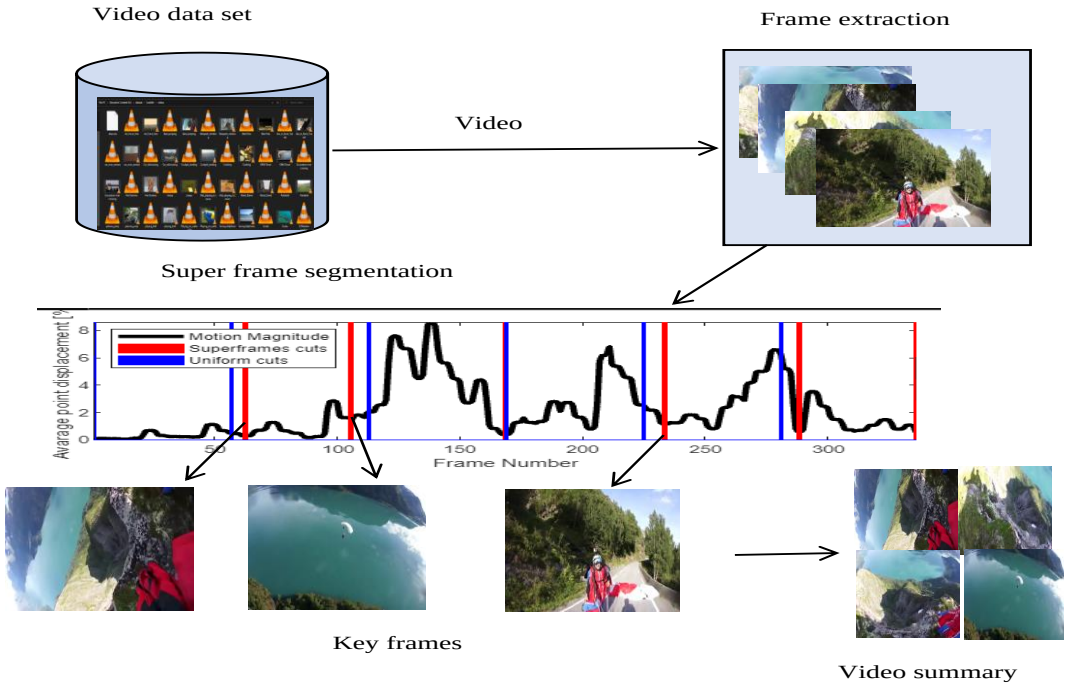

Fig. 1. Proposed system design.

A. Frame Extraction

Frame extraction involves capturing individual frames from a video, typically at a fixed rate or at specific points in time. This fact can be helpful for various applications, such as analyzing the contents of a video, detecting changes between frames, or creating a new video from selected frames. Algorithm 1 represents the frame extraction process from the video. The input for this module is a video data set which contains many user videos. Separate folder will be created for each video. Then, the frames are saved in the respective folder. Pre-processing refers to the techniques applied to data before the analysis to enhance its quality and suitability for downstream analysis. In this, we did rgbtohsi. Converting RGB to HSI can be a crucial step in image processing and computer vision tasks as it can help to separate the image information based on its colour properties. HSI colour model represents colours in terms of hue, saturation, and intensity, which are intuitive and perceptually meaningful to the human eye. The hue component can be used to segment objects based on their colour, the saturation component can be used to detect edges, and the intensity component can be used for brightness normalization. By converting an image from RGB to HSI, we can perform these operations more efficiently and accurately. It can provide a more meaningful and robust representation of colour information in an image.

ALGORITHM 1 Frame extraction(V)
//**Input:** Video V
//**Output:** Sequence of extracted frames
1.V←videoreader(videoname)
2. Initialize:
3. counter ← 0
4. while not at the end of V do:
5. read the frame
6. if not end of V:
7. break
8. else:
9. update the frames in the destined folder
10. counter← counter+1
11. end while

B. Super Frame Segmentation

For feature extraction, we use a superframe segmentation algorithm. Our superframe segmentation approach locates the boundary between temporal clusters in video frames. The superframe algorithm generates superframes based on the motion similarity and the required number of clusters. The following Algorithm 2 describes the superframe segmentation. At the beginning of the algorithm, cluster centres are initialized with a regular step size S and then adjusted to the position with the lowest gradient within a neighbourhood. This step aims to ensure that the clusters are initialized in a good position and to prevent them from getting stuck in local minima. The algorithm iteratively assigns frames to the nearest cluster centre using a distance measure as in Eq. (1). This could be any distance measure such as Euclidean distance, Manhattan distance or Cosine distance. After assigning frames to clusters, new cluster centres are computed using the L1 distance. The algorithm repeats this process until the error E falls below a threshold.

ALGORITHM 2 Video super frame clustering algorithm
//Inputs: Video Frames
1: **Initialize:**
a= 0.1 ∗ K.
Cluster centers $Cl_k = [x1 \ldots . xf]^T$ at regular step F
2: Perturb cluster centers in a neighborhood, to the lowest gradient position
3: repeat
4: $S_t \leftarrow S_t - 1$
5: for each Cl_k do
6: Assign best-matching frames from a 2S neighbourhood around Cl_k according to D_s
7: end for
8: Compute new cluster centres and error E (L1 distance)
9: until E ≤ threshold
10: Post-processing to remove very short clusters

Finally, post-processing is performed to remove very short clusters. This could be done by merging small clusters with neighbouring clusters or by removing them altogether. We employ D_s as a distance unit, which is denoted as follows: One way to measure the distance between cluster k and frame i is expressed by the following formula:

$$D_s = \sqrt{\Sigma}(X_k - X_i)^2 \quad (1)$$

where, X is the feature vector.

We might have a small number of clusters with very short lengths at the end of this operation. Fig. 2 shows the superframe cut during this segmentation process.

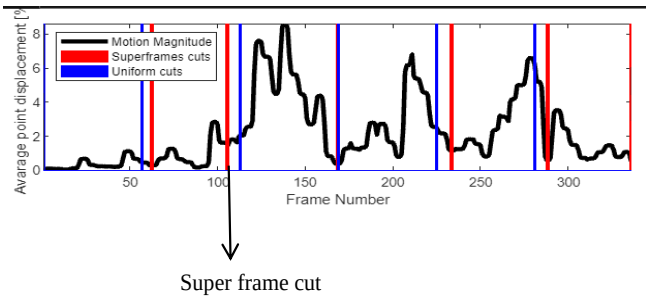

Fig. 2. Illustration of the superframe cut during the segmentation process.

C. Key Shot Identification

Based on characteristics, we will select n frames from the superframe segmentation. The key shots needed to create the summary were found in m frames. Conventional video summarization techniques primarily target edited videos, such as news reports, sports broadcasts, or movies that are composed of several short shots. Shot detection based on changes in the colour histogram is often adequate to segment such videos [25]. Such a technique cannot be applied in our case because we concentrate on user movies that are generally unedited and frequently only comprise one single shot. This issue was also addressed previously by [21], who offered to

partition egocentric films into shots by classifying the frames into static, in-transit, or head-movement categories.

This approach, however, is only appropriate for egocentric videos and produces shots that last for roughly 15 seconds, which is substantially longer than the average length of time for a video summary. Splitting a video into fixed-length segments is a commonly used technique, but it may not align with the meaningful units of the video. Furthermore, abrupt cuts caused by such randomly chosen shot boundaries are disliked by viewers due to the sudden changes in motion.

To achieve sub-shot segmentation, we propose a technique incorporating editing rules to identify moments of no motion or matching motion speed and direction between consecutive frames. These segments are then referred to as "superframes" and compared to superpixels. Additionally, we propose a method inspired by recent advances in image segmentation. The quality of super frames is measured using an energy function E(S_j) as,

$$E(S_j) = \frac{1}{1+\gamma C_{cut}(S_j)} \cdot P_l(|S_j|) \quad (2)$$

where, P_l is a length prior for the super frames and C_{cut} is the cut cost. The value of parameter γ determines how much weightage should be given to the cut cost versus the length prior in the energy function. By decreasing the value of the parameter, the superframes become more homogeneous. The cut cost is defined as,

$$C_{cut}(S_j) = m_{in}(S_j) + m_{out}(S_j) \quad (3)$$

The formula calculates the estimated motion magnitude of the first $m_{in}(S_j)$ and last frame $m_{out}(S_j)$ in a superframe as and, respectively. We obtain these estimates using the KLT technique to track points in the video and compute the mean magnitude of the translation. The cost incurred by a superframe is lower if its boundaries align with frames that have little or no motion. By applying a log-normal distribution to a histogram of segment lengths of the human-made summary selections, the length prior P_l is learned.

By using hill-climbing optimization, we locally maximize the energy of Eq. (2). First, using the segment length $|S_j|$ = argmax(P_l), the super frames are initialized and dispersed uniformly throughout the video/shot (P_l). Then, to improve Eq. (3), we iteratively update the borders between two superframes. This results in segments with boundaries that are aligned in places that are appropriate for cuts. The optimization process is performed in a step-by-step manner, starting with a coarse approach and gradually refining the results. The boundaries are adjusted by one frame at a time. If the adjustment improves the overall score of the energy function given by Eq. (1) for the two relevant superframes, the change is accepted. We begin at the initial value and update iteratively until the algorithm converges. The optimization is then carried out once again after it is reduced by one frame. Only a few iterations are required for this optimization to converge because it is local.

The super frame's interestingness rating S_i is just the total of the frames' degree of interest:

$$I(S_i) = \sum_{k=n}^{m} i_k \quad (4)$$

where the beginning and ending frames of the superframe are denoted as 'n' and 'm'. Although other scoring strategies were tested, including taking the maximum or considering the size of the cluster, it was found that the simple sum used in this method was the most effective. Fig. 3 illustrates the key shot identification process.

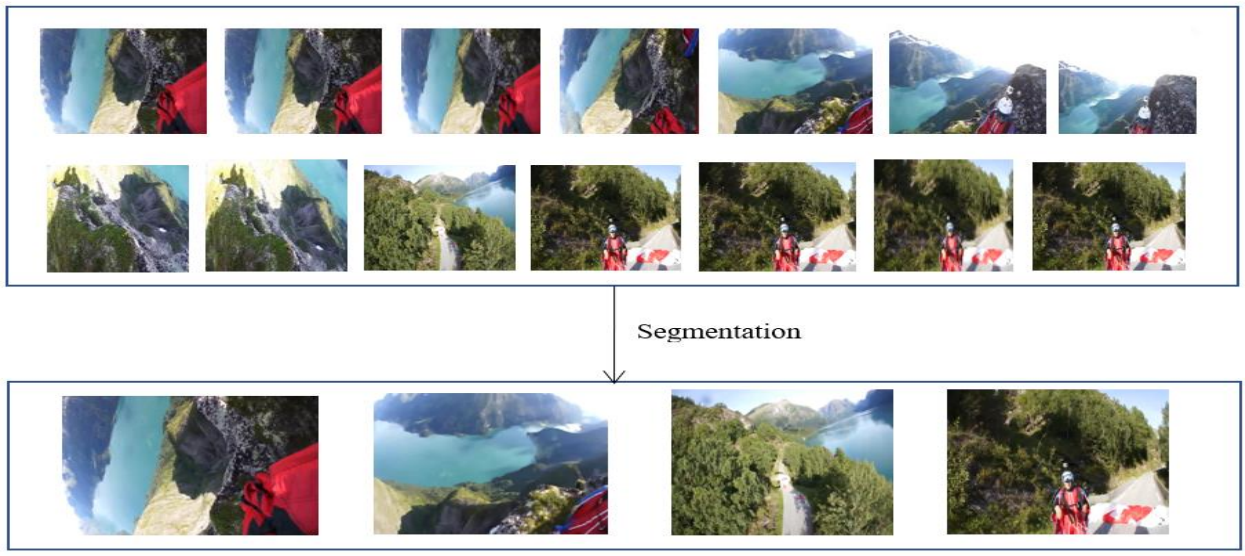

Fig. 3. Key shot identification of the video Base jumping in SUMMe dataset. The first row indicates the input video frame. The second row indicates the key shot identified from the input frames.

D. Key shot-based Summary Generation

Our objective is to find a subset of superframes, denoted as S, whose lengths are below a certain threshold (i.e., maximum), such that the sum of their interestingness scores is maximized.

$$\text{maximize} \sum_{i=1}^{n} x_i I(S_i) \quad (5)$$

X

$$\text{subject to} \sum_{i=1}^{n} x_i |S_i| \leq L_s \quad (6)$$

where, $x_i \in \{0, 1\}$ and $x_i = 1$ indicates that a super frame is selected. A summary is generated by combining the selected keyframes in a coherent and visually appealing way. The summary should provide an accurate representation of the original video's content while also being concise and easy to understand.

IV. Results and Discussion

A. Data Set

We evaluate our super frame segmentation on the most popular two datasets SUMMe and TVSum dataset. SUMMe (Summarization of Multiple Longer Videos) is a video summarization dataset that consists of 25 videos from YouTube. The videos are selected from different categories, such as sports, documentaries, and news. The TVSum dataset is a collection of 50 videos from various genres, such as news, documentaries, sports, and movies, suitable for video summarization research. This dataset, along with the SumMe dataset, includes multiple user annotations. To handle temporal redundancy and to comply with earlier efforts, we specifically downsampled all videos to 10 fps, initially shot at 30 fps, to minimize computation. The description of two video summarizing datasets is shown in Table I.

TABLE I. Description of Video Summarization Dataset Used

Dataset	Total videos	Content	Annotation	Duration(Min,Max,Average)
SumMe	25	User-generated Videos	Frame level score	38s, 324s, 146s
TVSum	50	Web videos	Frame level score	83s, 647s, 238s

B. Evaluation Metrics

For evaluation, we found F1-Score and Accuracy for the summarized video. The accuracy metric measures the percentage of correctly identified important frames or segments in the video summary compared to the ground truth summary. TP, TN, FP, and FN are employed in the context of binary picture segmentation. TP is the proportion of pixels in the expected binary picture and the ground truth that is properly classified as object pixels. The number of pixels in the anticipated binary picture as well as the ground truth that are properly classified as non-object pixels is known as TN. The number of pixels that are mistakenly classified as objects in the anticipated binary picture but are non-object pixels in the actual image is known as FP. FN is the number of pixels in the anticipated binary image that are mistakenly classified as non-object pixels but are object pixels in the actual picture. These metrics are used to determine how well a binary image segmentation algorithm performs, and they are frequently utilized to determine different evaluation criteria.

The formula for calculation accuracy, F1-score, precision and recall are discussed below.

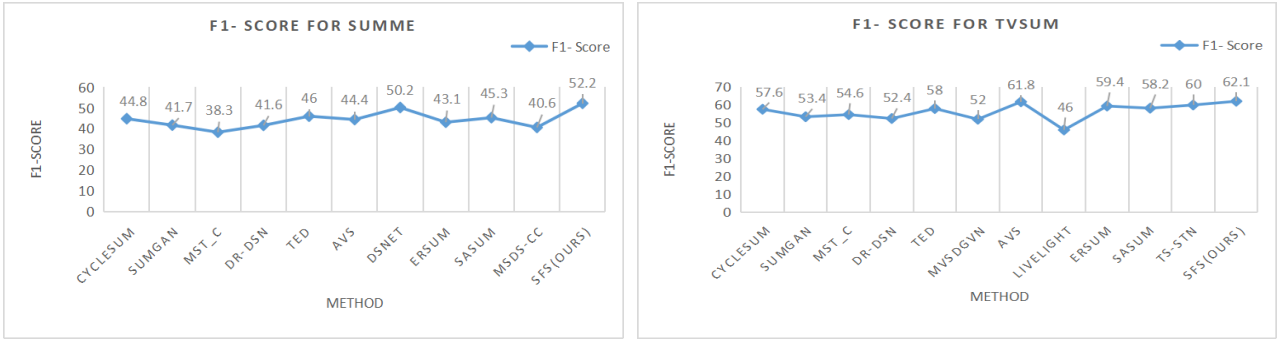
$$\text{Accuracy} = \frac{TP+TN}{FN+FP+TP+TN} \quad (7)$$

$$\text{Recall} = \frac{TP}{FN+TP} \quad (8)$$

$$\text{Precision} = \frac{TP}{FP+TP} \quad (9)$$

$$\text{F1- Score} = \frac{2*TP}{(2*TP+FP+FN)} \quad (10)$$

1) Our SFS approach was compared to other video summarization methods, including LiveLight [26], ERSUM [27], MSDS-CC [31], SUM-GAN[13], AVS [5], SASUM [28], DR-DSN [15], and TSSTN [29], on the SumMe and TVSum datasets. These methods were categorized into two groups: conventional and deep learning-based methods. The experimental results are presented in Table II under the canonical setting. The results show that the SFS approach outperforms all other methods, including state-of-the-art techniques, by at least 0.5% on both datasets. While methods such as MST_C, MSDS-CC, DR-DSN, and SUMGAN have the lowest F1-score, their performance lags behind that of the SFS approach by at least 4% on both SumMe and TVSum datasets. Fig. 4 shows the f1 score for each of the two datasets.



(a) (b)

Fig. 4. F1-Score (%) of both the datasets with other state-of-the-Art methods (a) TVSUM (b) SUMME.

TABLE II. PERFORMANCE MEASURE F1-SCORE(%) OF TVSUM AND SUMME DATASET WITH OTHER STATE-OF-THE-ART METHODS

Method	TVSUM	SUMME	Supervised/Unsupervised
CycleSum[13]	57.6	44.8	Unsupervised
SUMGAN[13]	53.4	41.7	Unsupervised
MST_C[4]	54.6	38.3	Unsupervised
DR-DSN[15]	52.4	41.6	Supervised
TED[2]	58	46	Supervised
mvsDGCN[3]	52.0	-	Supervised
AVS[5]	61.8	44.4	Supervised
LiveLight[27]	46.0	-	Unsupervised
ERSUM[28]	59.4	43.1	Supervised
SASUM[29]	58.2	45.3	Supervised
TS-STN[30]	60.0	-	Supervised
DSNet[31]	-	50.2	Supervised
MSDS-CC[32]	-	40.6	Unsupervised
SFS(ours)	62.1	52.2	Unsupervised

2) Comparison of Accuracy with other State-of-the-Art methods: We also use accuracy as the evaluation metric. The accuracy of a video summarization method is determined by calculating the percentage of significant frames or segments that are identified correctly in the generated summary compared to the ground truth summary. Table III and Fig. 5 present a comparison of the accuracy of our proposed method with other State-of-the-Art approaches. The experimental results demonstrate the superiority of our formulation.

TABLE III. COMPARISON OF ACCURACY METRIC WITH OTHER METHODS

Method	Methodology	Accuracy(%)	
		SUMME	TVSUM
CAVS [1]	The algorithm is developed to learn and update dictionaries of video features along with feature correlations	81.3	-
DR-DSN [15]	Dynamic graph node classification on videos is used to get the summary result.	89	90.6
SFS (ours)	Keyshot-based summary generation using superframe segmentation.	89.34	90.9852

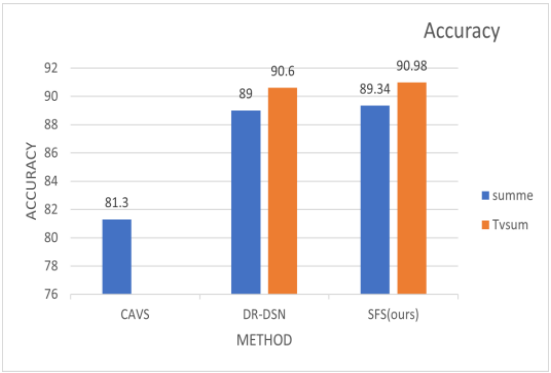


Fig. 5. Representative graph for the given dataset comparing with various methods.

3) We performed an investigation to assess the influence of long-range features, following a methodology comparable to the anchor-based approach. In this study, we analyzed the impact of using various feature extraction layers on performance metrics such as F-score, precision, and recall. The findings of this examination are illustrated in Table IV, indicating that our SFS technique surpasses the other temporal layers on both datasets, resulting in the most superior overall performance.

TABLE IV. COMPARISON OF F1-SCORE, PRECISION AND RECALL WITH ANOTHER STATE-OF-ART METHOD

Method	SUMME			TVSUM		
	F	P	R	F	P	R
LSTM	49.5	48.7	51.2	59.8	59.8	59.8
GCN[32]	50.5	50.0	51.3	59.8	59.8	59.8
Attention[33]	51.2	50.8	51.9	61.9	61.9	61.9

4) Exemplar key shot summaries: Exemplar key shot summaries are shown in Fig. 6. Video 47 discusses cleaning a dog's ears. We may observe that the key shot summaries of video 47 created by our SFS independently display the narrative details of washing a dog's ears. In the key shot summaries of video 47, our technique can skip a lot of unnecessary video shots. In comparison, DHAVS [34] and DR-DSN[15] key shots contain more frames that aren't significant. As a result, the suggested SFS can receive a higher F1 score.

Fig. 6. Generated summaries with F1-Score from video 47 in TVSum dataset.

C. Parameter Tuning

With varying γ values we found F1-Score for both the datasets. We set the initial data as γ=1 and then varied the values to get better performance evaluation for both datasets. The value sets of parameters γ are 0.4, 05, 0.7, 0.8. 1. 1.2 and 1.4 respectively. From Fig. 7, we observe that a rise in γ value leads to reduced performance.

Table V shows the varying F1-Score for SUMME and TVSUM datasets. The below table leads to the conclusion, for the value of 0.7 our model gives the highest F1-Score when compared with others for our datasets.

TABLE V. F1 SCORE FOR VARYING Γ VALUE (A) SUMME (B) TVSUM

Method	**Value**						
	0.4	**0.5**	**0.7**	**0.8**	**1**	**1.2**	**1.4**
LSTM	60.7	60.9	60.5	60	60.6	60.3	60.2

V. CONCLUSION

The proposed approach in this study introduces a technique for segmenting user videos using temporal superframes and a method for generating informative video summaries. The main goal of this paper is to provide a better summary of surveillance video, which is helpful for law enforcement officials. So, we use a superframe segmentation process in which dividing the video into short, visually consistent segments called superframes and select representative frames from each superframe to construct the summary. In contrast to other methods, our approach can handle variations in camera movements and scene changes, which makes it different visual characteristics. We choose Accuracy, F1-score, Precision, and Recall as the assessment measures to compare our method fairly to existing video summarizing techniques. Our experimental findings demonstrate that the SFS method we proposed performs competitively on the SumMe and TVSum datasets. Furthermore, we conducted additional experiments to investigate the effect of the final summary length (L) on the performance metrics, including F-score, precision, and recall. Our results suggest that the best performance of our method can be achieved when the final summary length is set to 15% of the original video length on both datasets. This framework could be largely assistive for observing the activities of the students during their online exams. It could be a better alternative for the officials conducting the assessment and monitoring the suspicious activities of the students.

Training Model of High-Rise Building Project Management Talent under Multi-Objective Evolutionary Algorithm

Pan QI
TianPIng College of Suzhou, University of Science and Technology, Jiangsu, 215000, China

***Abstract*—In order to meet the development needs of the construction engineering industry and further optimize and improve the talent training mode, this paper studies the talent training model of high-rise construction project management under the multi-objective evolutionary algorithm. The cognitive ability model of management talent is constructed, and the learning ability of management talent is analyzed. With the optimization objectives of minimizing the construction period, minimizing the project cost, and maximizing the benefit of skill growth in high-rise building projects, and taking the conditions of average proficiency and average duration of construction as constraints, the mixed immune genetic algorithm with the introduction of the double-island model is adopted to carry out multi-objective evolution of management talent training, so as to obtain the best training scheme for management talent in high-rise building projects. The experimental results show that after the optimization of this model, the skill proficiency of project management personnel can be effectively improved, construction time can be effectively reduced, construction efficiency can be improved, and construction costs can be improved.**

***Keywords*—Multi-objective evolution; high-rise building; engineering project; management personnel training; skill proficiency; project cost**

I. Introduction

High-rise buildings are one of the symbols of urban modernization. They can provide more office space, commercial space, and housing space for cities to meet the growing population and economic needs [1]. The construction of high-rise buildings can promote the development and urbanization of cities. Due to the limited land resources, high-rise buildings can create more functional space on the restricted land area and improve the efficiency of land use [2]. Compared with traditional low-rise buildings, high-rise buildings can provide more usable area under the same floor space, thus saving valuable land resources [3]. At the same time, high-rise building projects will drive a lot of investment and consumption in the construction process, thus promoting local economic development [4]. After the completion of high-rise buildings, it can also provide commercial rents and real estate sales income, bringing considerable financial benefits to investors. Moreover, high-rise buildings often become urban landmarks and landmark buildings, which can enhance the image and attractiveness of the city [5]. The design and construction level of high-rise buildings directly reflects the comprehensive strength and development level of a town, which can enhance the performance of the city's culture, art, and modernization and improve the competitiveness of the city on a global scale [6]; High-rise building projects also provide opportunities for promoting green buildings and sustainable development. Innovations in architectural design, building materials selection, energy conservation, and environmental protection can reduce energy consumption, reduce carbon emissions, and promote sustainable development.

The construction process of high-rise building projects is usually characterized by high complexity and risk, and these projects need to coordinate the work of multiple professional teams, such as architectural design, structural engineering, electromechanical engineering, decoration engineering, etc. [7]. Therefore, the current construction enterprises urgently need to cultivate high-level management talent. By developing talent with management skills, potential risks can be identified and evaluated in advance, and corresponding risk management measures can be formulated to reduce project risks and ensure the smooth implementation of the project [8]. Cultivating talent who can effectively coordinate and manage teamwork can improve the team's cooperation ability and efficiency and ensure the seamless connection between various majors [9]. At the same time, the cultivation of high-rise building engineering management talent can also promote engineering innovation and technological progress. They have a keen awareness of new technologies and innovative methods, can introduce new engineering management concepts and technical methods, improve work efficiency and quality, and promote the development of the high-rise building engineering industry [10]. However, there are some defects in the current training of construction engineering talent, and construction projects need to master a series of professional skills, including skills in design, construction, management, etc. However, the existing talent training pays insufficient attention to skills training and pays more attention to knowledge transmission, ignoring the cultivation of practical operation and practical skills [11] Due to the continuous development and changes in the construction engineering industry, the docking of talent training and industry demand is not close enough. To this end, many scholars have put forward different talent training programs. For example, Klipkova, O et al. [12] studied the optimization of personnel management mechanisms based on intergenerational theory. This method is based on the three-dimensional method of employees, enterprises, and external conditions, and applies certain leadership theories and team cooperation principles to effectively manage the personnel of the enterprise, thereby achieving talent cultivation in the

enterprise. However, this method cannot guarantee the improvement of enterprise operating costs, leading to excessive burden on the enterprise; for example, Nguyen, D. A et al. [13] studied the use of neural networks to model the labor productivity of high-rise building construction projects. Through the optimization of neural networks, the labor productivity of construction enterprises can be improved, thereby accelerating construction efficiency. However, this method cannot guarantee the cultivation of personal skills of employees; for example, Hudyakova, E et al. [14] studied the problems and solutions in the configuration of management personnel in agricultural and industrial complexes. This method deeply planned the responsibilities that enterprise management personnel should fulfill and cultivated the required skills for different responsibilities. However, the training plan of this method does not apply to multiple fields, and it focuses more on learning knowledge content in the process of talent cultivation, resulting in neglecting the cultivation of personal skills of employees. A multi-objective evolutionary algorithm is an algorithm used to solve multi-objective optimization problems. Different from the traditional single-objective optimization algorithm, a multi-objective evolutionary algorithm can simultaneously optimize multiple conflicting objective functions in a set of solutions [15]. To effectively realize the optimization of management personnel training, this paper puts forward a high-rise building project management personnel training model based on a multi-objective evolutionary algorithm. It recognizes the optimization of management personnel training schemes by using a multi-objective evolutionary algorithm.

II. High-Rise Building Project Management Personnel Training Optimization Model Design and Research

A. Overall Description of High-Rise Building Project

A large high-rise building construction project usually consists of several single projects. A single project can be decomposed into multiple unit projects, such as civil engineering water and electricity installation engineering [16]. Each unit project is further decomposed into several sub-projects, such as civil engineering, which can be divided into basic engineering, main engineering, roofing engineering, and decoration engineering [17]. Sub-projects can be subdivided into sub-projects, such as foundation projects, which can be divided into earthwork excavation, foundation treatment and testing, concrete foundation, and other sub-projects. A sub-project can be regarded as a relatively independent activity (or task) that is completed by a large number of technicians. It is a separate dispatching unit and also the basic activity of dispatching [18]. Therefore, the training of high-rise building project management talent can enhance the construction efficiency of building projects.

Human resources in high-rise building projects include managers at different levels and various workers involved. The management personnel of the construction project department mainly include the project director (project manager), technical director, production director, builder, machine controller, safety officer, quality inspector (sampler), material engineer, cost engineer, etc. At the same time, these personnel are also professional and technical management personnel. These personnel are the main managers of engineering construction, and their management ability will directly affect the safety, progress, quality, and cost of engineering construction, which is related to the survival and development of construction enterprises [19]. Therefore, effective ways must be adopted to train the project managers of high-rise buildings. Table I shows a comparison of the proposed work in experimental analyses with similar research works and state-of-the-art research studied as part of the literature review.

B. Modeling and Design of Employees' Cognitive Ability

In order to optimize the training scheme of high-rise building project management talent, this paper puts forward a model of employees' cognitive ability based on a learning-forgetting curve, which can fully consider the learning effect and forgetting degree of employees in the learning process so as to obtain the skill proficiency of a high-rise building project management talent.

1) Analysis of learning effect and learning curve: Before modeling employees' cognitive ability, it is necessary to analyze employees' learning effects and the change in the learning curve. Only by using this analysis result can the employees' mental ability model be effectively built based on a learning-forgetting curve. The learning effect, also known as the learning phenomenon, refers to the effect that the accumulated experience through long-term work leaves a memory in employees' minds, which helps employees improve the same or similar work efficiency [20]. Long-term research shows that the study of the learning effect basically needs to follow three hypotheses. (1) For repeated construction tasks, the time consumption of a single construction operation decreases with the increase of construction repetitions. (2) The learning effect can gradually reduce the time consumption of a single construction operation and the absolute efficiency. (3) The existence of the learning effect can be predicted and applied scientifically. Therefore, the learning curve can generally be expressed by Formula (1):

$$Y_x = Cx^b \tag{1}$$

In the Formula (1), $x$represents the cumulative completion of construction; Y_x represents the working hours or costs of the$x$construction task;Cindicates the operating hours or price of the first construction task;$b$represents the learning index, with a value less than or equal to zero,$b = log\ s\ /\ log\ 2$, S indicates the learning rate, which is an index used to describe the learning curve. When the learning effect is better, the learning efficiency is lower.

TABLE I. COMPARING THE PROPOSED WORK IN EXPERIMENTAL ANALYSES WITH SIMILAR RESEARCH WORKS AND STATE-OF-THE-ART RESEARCH STUDIED AS PART OF THE LITERATURE REVIEW

Aspect	Proposed Work	Similar Research Works
Scope and Focus	Training model for high-rise building project management talent under a multi-objective evolutionary algorithm	Optimization of personnel management mechanisms, labor productivity modeling, and configuration of management personnel in various industries
Objective Function	Balances project duration, cost, and skill growth rate	Varies based on research: personnel management mechanisms, labor productivity improvement, skill cultivation and task allocation
Methodology	Multi-objective evolutionary algorithm	Intergenerational theory, neural networks, management personnel configuration
Analysis Techniques	Learning and forgetting curves, cost optimization, human resource utilization	Various techniques including optimization algorithms, productivity modeling, skill proficiency analysis
Evaluation Metrics	Employee efficiency, construction cost, human resource utilization, skill proficiency	Employee proficiency, project cost, resource utilization, skill growth rate
Experimental Setup	Application to a specific high-rise building project	Not specified in the provided text
Results and Findings	Enhanced project efficiency, cost savings, improved human resource utilization	Varies based on research: potential improvements in management efficiency, productivity, and skill development
Conclusion	Provides a scientific and effective method for talent training in high-rise building project management	Varies based on research: suggests improvements in talent training methods and strategies

The learning effect can generally be expressed by describing the relationship between the cumulative construction quantity and the input factor quantity of unit construction quantity. The learning curve is also called the starting curve, experience curve, or improvement curve. The learning curve was first put forward by Wright in 1936. Through the learning curve, it is revealed that with continuous construction, the processing time of unit construction tasks will be gradually shortened, and the learning curve is widely used in industrial production. The learning curve can be expressed by Formula (2):

$$T_x = T_1 x^{-l} \tag{2}$$

In the Formula (2), T_x represents the time required for processing the construction of the $x$task, values of X are 0, 1, and 2,. T_1 indicates the time needed to handle the first construction task, and l indicates the learning efficiency of employees. With the continuous construction work, the time spent on the completion of unit construction tasks is decreasing, and with the constant learning of employees, the construction skills are also rising. At the same time, the processing time of unit construction tasks has a lower bound, which means that the processing time of unit construction tasks will not decrease indefinitely, which means that the skill value of employees is limited. Employees can continuously improve their skill value through construction work, but it will not increase excessively.

With the application of the learning curve in various fields and its development in different degrees, some scholars suggest that the longer employees use a skill, the higher the construction efficiency of the skill will be, and assume that employee p participates in construction tasks k, then the learning curve formula can be expressed by Formula (3):

$$\bar{E}_n = \bar{E}_1 n^b \tag{3}$$

In Formula (3), n represents the total time spent by employee$p$in the construction task$k$; $\bar{E}_1$represents the average efficiency of employee p on starting the construction task; $\bar{E}_n$ represents the accumulated average efficiency of employee p after spending n cycles in the construction task k; $b = -\frac{ln(r)}{ln\,2}, (0 < r \leq 1)$, b represents a learning factor, r represents the percentage of learning. The smaller the value of r, the greater the value of b, the higher the learning efficiency.

2) Modeling of employees' cognitive ability based on learning-forgetting curve model: In order to accurately understand the cognitive level of high-rise building project management talent, combined with the learning curve of the above research, the learning-forgetting curve model of employees' cognitive ability is constructed by using the LFCM (Learning and Forgetting Curve Model) model. This model is a perfect model based on the classic WLC learning curve model, which reveals the relationship between learning and forgetting degree and interruption time by comparing the forgetting effect with the learning effect [21]. Based on LFCM theory, the calculation method of skill proficiency considering learning-forgetting impact is shown in Formula (4):

$$\beta_{pki}^{f} = \beta_{pki}^{s} + L \cdot T^{a_k} - F \cdot T'^{b_k} \tag{4}$$

In Formula (4), β_{pki}^{f} indicates the proficiency of the employee p using the skill$k$before performing the construction task$i$; Tindicates the duration of the employee$p$using the skill k; T'indicates the difference between the initial moment of the employee$p$use skill$k$to perform the construction task$i$and the end moment of the last previous use skill$k$, that is, the time when the employee is idle; L represents the learning curve coefficient, F represents the coefficient of forgetting curve, which is related to the initial skill proficiency. Usually, the lower the skill level, the faster the level will improve because of the lower difficulty in learning basic knowledge, and the knowledge will not be easily forgotten. When the skill level is

high, the learning difficulty of deep expertise is relatively high, the speed of level improvement will slow down, and knowledge is easy to forget. Under normal circumstances, the forgetting rate of employees is less than the learning speed, and the article stipulates that $L = -ln(\beta_{pki}^{s}/2)/10$, $F - ln(3\beta_{pki}^{s})/15$. The greater the initial skill proficiency, the smaller the learning curve coefficient and the larger the forgetting curve coefficient;a_{pk}represents the learning factor of employee$p$for construction skills$k$,$a_{pk} = -ln(\lambda_{pk})/ln(2)$, $\lambda$is the learning rate,λ generally is between 75%~95%, the greater the learning factor, the stronger the learning effect; b_{pk} represents forgetting factor of employee p for skills k, $b_{pk} = ln(1-\mu_{pk})/ln(2)$, μ is the forgetting rate,μgenerally is between 3%~15%. The greater the forgetting factor, the weaker the forgetting effect. The learning rate and forgetting rate are closely related to employees' factors. Considering the limitations of people's physiological conditions, there is a learning upper limit $\hat{\beta}$ for skill proficiency, and ignoring the lower limit$\breve{\beta}$.$\Delta\beta(T) > \Delta\beta(T')$, $T = T'$means that the learning effect of employees is stronger than the forgetting effect at the same time. In addition, the learning effect and forgetting effects of employees change after each interruption. With the improvement of skill proficiency, the learning speed slows down, and the forgetting rate accelerates.

C. High-Rise Building Project Management Personnel Training Optimization Model Construction

1) Design of objective function: Combined with the employee as mentioned above cognitive ability modeling, this paper constructs a multi-objective function of the training model for project managers of high-rise buildings, aiming at minimizing the project duration, minimizing the project cost, and maximizing the benefit of skill growth, and constructs a multi-objective function model, as shown in Formula (5), Formula (6) and Formula (7):

$$min\ T = \sum_{i \in A} T_i \tag{5}$$

$$min\ C = m \cdot w + \sum_{i=1}^{n\sum} \sum_{k=1}^{r\sum} (\bar{\beta}_{ki} \cdot c_{ki}^{max}()) \tag{6}$$

$$max\ R = \sum_{i=1}^{n} \sum_{k=1}^{r} \sum_{p=1}^{m} \varepsilon_k \cdot (\beta_{pki}^{f} - \beta_{pki}^{s}) \tag{7}$$

Among the above formulas, Formula (5) represents the objective function of minimizing the project duration, and the total time is the sum of the durations of tasks on the critical path.T represents the project duration,Arepresents a collection of functions on a critical path,$A = \{a_1, a_2, \ldots, a_x\}, a_x \in [1, n]$, T_i represents the duration of the task i; Formula (6) represents the objective function of minimizing the project cost. The project cost is the sum of the salaries paid to all employees, including the basic salary and the commission. The basic salary is fixed and consistent for all employees, and the commission is positively related to the average efficiency of completing the work.Crepresents the project cost,$\bar{\beta}_{ki}$represents the average proficiency workJ_{ki}, describes the basic salary of employees, m represents the employee's commission salary,c_{ki}^{max} represents the highest commission for a job, which means the remuneration received by an employee with skill proficiency of 1 completes the jobJ_{ki}; Formula (7) represents the objective function of maximizing the benefit of skill growth, and the total benefit is equal to the sum of the skill proficiency appreciation of all employees after participating in various jobs. R indicates that benefit of skill growth, ε_k represents the development weight of skill k that refers to the importance of skills to enterprises.β_{pki}^{s} represents the skill proficiency of an employee$p$start workJ_{ki}, describes the skill proficiency of an employee$p$finish workJ_{ki}.

In order to ensure the optimization effect of the article on the talent training scheme, according to the above objective function, the following optimization constraints are constructed:

a) Average working proficiency: Formula (8) is used to express the average working proficiency of employees:

$$\bar{\beta}_{ki} = \frac{\sum_{p=1}^{m} \beta_{pki}^{s} \cdot X_{pki}}{d_{ki}} \tag{8}$$

In the Formula (8), X_{pki} is the number of employees required for workJ_{ki};$d_{ki}$is 1 if the employee$p$is involved in workJ_{ki}, otherwise, the value is 0.

b) Duration of construction task: the duration of the construction task is constrained by Formula (9):

$$T_i = max_{k \in K}\{T_{ki}\}, T_{ki} = \frac{T_{ki}^{min}}{\bar{\beta}_{ki}} \tag{9}$$

In the Formula (9),T_{ki}^{min}represents the minimum duration of workJ_{ki}that refers to the time required for employees with skill proficiency of 1 to complete the work;T_{ki}represents the duration of employmentJ_{ki}.

c) Formula (10) is used to express the logical constraint condition of the construction task, that is, the task can only be started after all the tasks immediately before it is finished:

$$B_i - B_j \geq T_j, \forall i \in I, \forall j \in PF_i \tag{10}$$

In the Formula (10),$B_i$represents the commencement time of the construction task$i$;B_j represents the end time of the construction task$i$;I represents the collection of a task$i$, $I = \{1,2,\ldots,n\}$; PF_i represents a set of immediate tasks of task$i$.

d) Formula (11) is used to express the calculation method of skill proficiency of employees at the beginning of work:

$$\beta_{pki}^{s} = \begin{cases} \beta_{pk}^{s}, \forall x_{pki'} \neq 1, i' \in PF_i \\ \beta_{pk}^{f}, argmin_{i' \in PF_i}\{B_{ki} - (B_{ki'} + T_{ki'})\}, \exists x_{pki'} = 1, i' \in PF_i \end{cases} \tag{11}$$

In the Formula (11), x_{pki} indicates that if employee p participates in work J_{ki}, the value is 1; if the employee$p$has skills$k$but does not participate in work J_{ki}, the value is 0; if the employee$p$does not have skills$k$, the value is -1;B_{ki} indicates the start time of work J_{ki};β_{pk}^{s} represents the proficiency of employee$p$using skill$k$at the beginning of the project, representing employee productivity, $\beta_{pk} \in [0,1]$, if

the employee$p$does not have skill$k$, the value is 0;β_{pk}^{f}indicates the ability of employee$p$using skill$k$at the end of the project.

e) Calculate the skill proficiency of employees at the end of work by Formula (12), and specify that the upper learning limit of skill proficiency is 1 and the lower forgetting limit is 0.3. If the calculated proficiency value is greater than 1 or less than 0.3, reset the value to the upper or lower limit:

$$\beta_{pki}^{f} = \begin{cases} \beta_{pki}^{s} + L \cdot T_{ki}^{a_{pk}}, \forall x_{pki'} \neq 1, i' \in PF_{i'} \\ \beta_{pki}^{s} + L \cdot T_{ki}^{a_{pk}} - F \cdot \left(\min\limits_{i' \in PF_{i'}} \{B_{ki} - (B_{ki} + T_{ki'})\} \right)^{b_{pk}} \\ , \exists x_{pki'} \neq 1, i' \in PF_{i'} \end{cases} \quad (12)$$

$$L = -\ln\left(\beta_{pki}^{s}/2\right)/10, F = \ln\left(3\beta_{pki}^{s}\right)/15$$

In the Formula (12), L represents the learning curve coefficient; b_{pk} represents the learning factors for an employee$p$to skills$k$,a_{pk} represents the learning efficiency of an employee$p$to skills$k$.

f) Formula (13) indicates that when there is a situation where the same employee is assigned to complete multiple tasks in parallel tasks, and there is a human resource conflict in job assignment, the employee is first given the job with a higher priority, that is, the position with higher priority starts first:

$$B_{ki} - B_{kj} \geq T_{bj}, \varphi_{kj} \geq \varphi_{ki}, PF_i = PF_j, S_{ki} \cap S_{kj} \neq \emptyset \quad (13)$$

In Formula (13), φ_{ki} represents the priority of work J_{ki} , $\varphi_{ki} \in [1, j]$; S_{ki} represents assignment to a job.J_{ki} represents a collection of employees; F represents the forgetting curve coefficient.

g) By Formula (14), the number of employees assigned to task$i$using skill$k$shall be equal to the number of employees required to complete task$i$using skill$k$:

$$\sum_{p=1}^{m} X_{pki} = d_{ki} \quad (14)$$

h) Restrict each employee to participate in only one job at any time by Formula (15):

$$\sum_{i=1}^{n} \sum_{k=1}^{r} y_{pkit} \leq 1 \quad (15)$$

In the Formula (15), y_{pkit} represents an employee$p$participates in the work J_{ki} at time$t$, the value is 1, otherwise the value is 0.

i) The range and relationship of the three decision variables are expressed by Formula (16), Formula (17) and Formula (18):

$$x_{pki} \in \{0,1,-1\}, y_{pkit} \in \{0,1\}, X_{pki} \in \{0,1\}; \forall p, k, i, t \quad (16)$$

$$x_{pki} = \begin{cases} 1, \forall t, y_{pkit=1} \\ 0, \forall t, y_{pkit=0}; \forall p, k, i \\ -1, \alpha_{ki} = 0 \end{cases} \quad (17)$$

$$X_{pki} = \begin{cases} 1, x_{pki} = 1 \\ 0, x_{pki} \neq 1 \end{cases}; \forall p, k, i \quad (18)$$

In the above formula,Krepresents a collection of skill$k$,$K = \{1,2,\ldots,r\}$; P represents a collection of employees p, $P = \{1,2,\ldots,m\}$; J_{ki} represents the work performed in a task i using skills$k$,$j = \sum_{i=1}^{n} \sum_{k=1}^{r} \alpha_{ki}$.

Through the above methods, the constraint conditions of the optimization goal of high-rise building project management personnel training are constructed, which provides a reliable guarantee for multi-objective optimization.

D. Optimization of Personnel Training Model based on Multi-Objective Genetic Algorithm

The Genetic algorithm is a highly parallel adaptive search algorithm based on the "survival of the fittest" mechanism. In 1967, some scholars applied genetic evolution to multi-objective optimization problems for the first time; thus, the research on multi-objective optimization problems entered a new era, and the search idea using genetic evolution later became the basis for a large number of scholars [22]. Because the article constructs a variety of objective functions of talent training optimization in the above chapters, in order to realize these multi-objective optimizations, this paper uses a multi-objective genetic algorithm to find out the best management talent training scheme through multi-objective optimization.

All genetic algorithms (GA) follow a similar basic framework, which was put forward by Holland and called a simple genetic algorithm [23]. The main flow of the algorithm is as follows:

- According to the modeling results of the above-mentioned objective function, the chromosome coding of the training target of management talent in high-rise building projects is carried out, and the initial population of management talent training targets is randomly generated.
- Judge whether the evolutionary algebra meets the requirements, if it meets the requirements, outputting the training target population of the last generation of management talent and ending the test; otherwise, enter step (3).
- Calculate the fitness value of the target population for training management talent, replace it with the "two-person competition" method (including male parent and female parent), and cross it with some rules to produce offspring; after the crossover is completed, the parent mutates with a certain probability to produce offspring (in order to preserve population diversity, the mutated parent is kept.) Merge the crossed and mutated offspring with the parent, and recalculate the individual fitness value of the target population of management talent training.

- Judge whether the number of the target population for training management talent is greater than the initial set value, and if it exceeds the set value, put forward the inferior solution through the "three-person championship" according to the fitness. Evolutionary algebra Gen+1, and return to step (2).

Because the above steps are only the basic framework of the genetic algorithm, the state of the actual management personnel training goal optimization is not considered. Therefore, the calculation process of chromosome coding, crossover, mutation, and fitness function is analyzed through the following contents.

1) Management personnel training target chromosome coding and decoding.

a) Chromosome Coding: Each individual in the target population of management personnel training represents a feasible optimization scheme. Because it is necessary to arrange the construction sequence and human resource allocation at the same time, each possible solution is set to contain two chromosomes, namely the construction task chromosome and the employee chromosome, and they should have the same number of genes. The construction task chromosome is the arrangement of all tasks in a high-rise building project under the immediate constraints, that is, each construction task must be located after all its quick activities; This chromosome shows the sequence of all construction tasks in a feasible optimization scheme of management personnel training objectives [24]. The gene of the employee chromosome indicates the employee's situation of construction task assignment. Let$list_r_{jk}$be the set of employees where the chromosome uses skill$k$in the$j$th construction task, andα_{jk}be the overall tacit understanding of the set of employees serving the construction task$j$skill$k$, so the forms of the chromosome and the construction task are shown in Fig. 1.

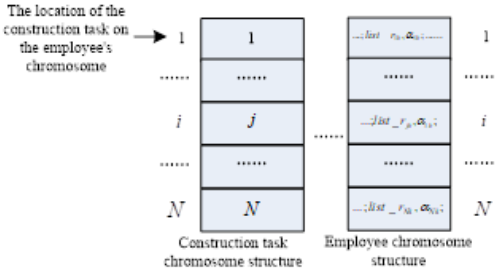

Fig. 1. Chromosome structure analysis diagram.

b) Population Initialization: Initializing the target population of management talent training is to initialize the construction task and employee chromosome, that is, to determine the completion order of the construction task first, and then assign the corresponding employees according to the construction order arranged on the chromosome of the construction task. The specific steps are as follows:

Inserting the construction tasks into the chromosome of the construction tasks one by one by adopting a serial scheduling method, and ensuring that the immediately preceding tasks are placed in the chromosome when each construction task is added; For parallel tasks, they are randomly arranged in chromosomes [25].

Assign employees to each construction task according to the gene sequence on the chromosome of the construction task, and the specific employee allocation steps are as follows:

- Set in time$t = 0$, the scheduled construction task set is$S = \phi$, the scheduling construction task set is$D = \phi$, the corresponding completion time of each construction task$j$in D ish_j, and the current scheduled set meeting the logical relationship is E_v. If set $E_v = \phi$, the employee assignment is over, the t at this time is makspan. The unoccupied employee collection is E_r, assigning the following steps for each of E_v of the construction tasks.
- If set $E_v = \phi$, then select in D the minimum$h_j$construction task ofj', update$t = h_{j'}$, the construction task $S = j' \cup S$ and return to step a; Otherwise from the collection$E_v$choose the construction task$j$, and conduct employee evaluation for each skill required for its implementation.
- Select the skill$k$without employee assessment in the construction task j, initialize the tacit understanding factor$factor = 1.0$, skill quantity$amount = 0.0$.
- If there is no employee with skill$k$inE_r, the employee does not meet the requirements of construction task, put the employee of each employee setb_{jk}in construction task$j$back toE_r, then empty the setb_{jk}, finally remove the construction task j from E_v and return to step b; otherwise randomly select the employee r with skill k in E_r, put it into the employee set S_{jk} of the skill k required in a construction task j, and remove from E_r, the corresponding skill quantity $amount = amount + a_{rk}$, update the collaboration factor$factor$.
- Judge whether$amount \times factor$is greater thanb_{jk}. If the conditions are not met, return to step d; otherwise, it indicates the constraint judgment is completed of the construction task j with skill k, and then determine whether the other skills of the construction task$j$have been judged, if not, return to step c, otherwise, explain the construction task$j$meet the staff constraints, will be assigned to the construction task$j$put all employees in the occupied state, and put the construction task$D = j \cup D$, and calculate the completion periodh_j, return to step b.

Because each step is selected in a randomized way, the diversity of the target population for initial management personnel training is ensured. Repeat the above steps until the number of the initial management personnel training target population isPOP.

c) Chromosome Coding: The serial schedule generation mechanism is used to decode the chromosome to generate the solution. The serial schedule generation mechanism needs to meet the task sequence constraint (forward scheduling) of the employee chromosome and the resource constraint of the

corresponding construction task in the employee chromosome [26]. Specifically, before the next construction task starts, all its immediate tasks must be completed, and the employees assigned to it are available. At this point, the earliest start time of the construction task can be obtained. It should be noted that only one feasible scheduling scheme can be obtained in the process of decoding the target chromosome of management personnel training. The project duration is received in the above initialization process. Then, the multi-objective solution can be used to calculate the objective function value of the remaining management talent training.

2) Design of fitness function for optimization of management personnel training objectives.

The main difference between a multi-objective evolutionary algorithm and a single-objective evolutionary algorithm lies in the fitness function, which is caused by the different number of solutions. Therefore, the relative non-dominance of solutions is usually used to measure the quality of solutions obtained by multi-objective evolutionary algorithm, that is, the Pareto solution or approximate Pareto solution is used as the solution set of multi-objectives. Pareto solution is a collection of non-dominant solutions, and the concept of a dominant solution is defined as follows:

Assume that X and Y are two feasible solutions of management talent training objectives, and each possible solution of management talent training objectives is a ternary vector $x = (x_1, x_2, x_3)$, x_1、x_2、x_3 are three target values (assuming that the bigger the better), then x dominant solution y can be defined as the following formula (19):

$$x \succ y \Leftrightarrow \forall x_i \geq y_i, \exists i\{1,2,3\}, x_i > y_i \tag{19}$$

In Formula (19), the non-dominant solution is defined as that any other individual does not dominate an individual, that is, for other management personnel training target individuals, the result of one goal of the management personnel training target individual is always better than other individuals (excluding duplicate individuals).

The fitness value of the target individual of management talent training is determined by the number of other individuals who dominate it and the number of individuals adjacent to it. Set $d(x)$ be the number of other individuals controlling the individual X, and $s(x)$ is the number of individuals adjacent to x, as defined in Formula (20) and Formula (21):

$$d(x) = |x' \in P: x' \succ x| \tag{20}$$

$$s(x) = \left|x' \in P, x' \neq x: \frac{|f_i(x) - f_i(x')|}{f_i(x')}\right|, i = 1,2,3 \tag{21}$$

In Formula (20) and Formula (21), P is the management of the population of target individuals, $f_i(x)(i = 1,2,3)$ represents the target individual X of management talent training of the i th target value, shared distance $\sigma_i(i = 1,2,3)$ is a constant.

The assignment process of individual fitness of management talent training target $\phi(x)$ is as follows:

- Calculate $d(x)$ and $s(x)$ for each management talent training target individual in population P.
- According to $d(x)$ to assign value to the target individuals of management talent training;

$$\phi(x) = d(x) + 1 \tag{22}$$

- To $d(x)$ with the same management talent training target individual set (that is, the unique set that does not dominate each other), according to the values of $s(x)$, sorted from small to large, and the serial number is n; The number of the same $d(x)$ management talent training target individuals is num, $\Delta = \frac{1}{num}$, then there is:

$$\phi(x) = \phi(x) + n * \Delta, n = 0,1,\ldots,num - 1 \tag{23}$$

According to the definition of fitness value, the smaller the fitness value, the better the solution is.

3) Management personnel training objectives optimization, crossover and mutation operation.

a) Parent selection: In this paper, the "two-person competition method" is used to select the father for pairing to produce offspring. Select two target chromosomes of management personnel training from the population, take the excellent target individuals of management personnel training as the male parent, and repeat this step to find the female parent until POP/2 pairs of fathers are produced. The advantage of this method is that it can combine relatively good parents to make better offspring and improve convergence.

b) Crossing: Cross operation refers to the process of exchanging and recombining the genes of the male parent and the female parent, and then producing offspring. Because crossover operation can combine and keep the best genes of parents, it plays a core role in genetic function. Given crossover probability P_c (generally 0.4~1), which means that parents P_c take the probability of crossing. Through the following contents, the detailed operation steps of crossing the construction task chromosome and the employee chromosome are given.

Cross operation of construction task chromosomes: The two-point cross method is adopted for the cross of construction task chromosomes. Firstly, two integers are randomly generated q_1、q_2, they meet $1 \leq q_1 \leq q_2 \leq J$. In the construction task sequence of the first generation $1 \sim q_1$ is up to the mother, $q_1 + 1 \sim q_2$ inherit from my father, $q_2 + 1 \sim J$ inherit from mother; Descendant 2 inherits in the opposite way to descendant 1.

Generate a random number v in the interval of [0,1] through a random number generator according to the construction task sequence on the chromosome of the offspring construction task obtained by crossing, if $v \leq 0.5$, then the daughter resource chromosome 1 inherits the employee chromosome gene of the construction task number corresponding to the daughter construction task chromosome 1 from the parent, and the daughter resource chromosome 2

inherits the employee chromosome gene of the construction task number corresponding to the daughter construction task chromosome 2 from the parent; if$v > 0.5$, the inheritance order is exchanged.

c) Mutation operation: Chromosome mutation operation of construction task: given mutation constant P_m , each individual has the probability of mutation occursP_m, and for the mutated individuals, the construction task i in the individual construction task chromosome is randomly selected and inserted into a new position (mutation occurs); The role of mutation is related to its immediate pre-task and immediate post-task, that is, the position of mutation must be between the immediate pre-task and immediate post-task; In order to ensure the feasibility of the employee chromosome, the resource chromosome corresponding to the mutation construction task is changed in the same position.

Mutation operation of employee chromosomes: each individual has the probability of mutationP_m, for the mutated individual, the simple way of randomly selecting a skill in the construction task and redistributing employees is used to complete the mutation of employee chromosomes. Considering the diversity of Pareto solutions, the parents of the mutated individuals are reserved.

d) Choose: After the crossover operation, a large number of offspring will be produced. In order to keep the target population number of management talent unchanged, the "three-person championship method" is adopted to eliminate the poor individuals. The selection method of three-person championship is random selection, proportional selection, and the expansion method of double competition. The specific process is to randomly select three chromosomes, namelyI_1、I_2、I_3. If Formula (23) is satisfied:

$$\phi(I_1) \geq \phi(I_2) 且 \phi(I_1) \geq \phi(I_3) \quad (24)$$

Then individual I_1 is eliminated from the population, and the operation is repeated until the population becomes the initial set value POP again; if the target population number of management talent training is not greater than POP before the substitution operation, the operation will not be carried out.

E. Optimization Process Design based on Hybrid Immune Genetic Algorithm

The multi-objective genetic algorithm (MOGA) is one of the adaptive heuristic algorithms used to solve multi-objective problems, but it has a great disadvantage: it is premature. Aiming at this problem, this paper proposes a hybrid immune genetic algorithm. Immunity is an important physiological behavior of living things. Its main function is to resist viruses, bacteria, etc., that may cause discomfort from the outside and maintain the homeostasis of the body. It recombines genes through complex and intense mechanisms to cope with invading antigens, produce antibodies, and eliminate antigens. The immune process can improve the diversity of the population, expand the search range of the population, and then improve the quality of people. Combining these two algorithms is of great significance to solve the problem of premature convergence of genetic algorithms in theory and improve the diversity of non-inferior solutions.

At the same time, some Japanese scholars put forward the double island model to improve the lethal chromosome in the process of evolution. In each generation of the evolutionary algorithm, many poor-quality chromosomes will be produced, and the double island model will separate the excellent and inferior chromosomes. In this model, the lethal chromosomes are put together (called "dead islands"). The chromosomes in the "dead island" are crossed and mutated, and finally, the excellent chromosomes are put back into the genetic process. However, in this process, only the lethal chromosomes in the "dead island" are manipulated, and the effect is not significant. Introducing the immune process is helpful in solving this problem, so this paper presents the immune process in the two-island model. By combining the two-island model with the immune process, a hybrid immune genetic algorithm is formed. The algorithm is actually carried out in two aspects: on the one hand, the "dead island" is immunized; on the other, the individuals on the "living island" are crossed and mutated. Before the evolution of each generation, it is necessary to inoculate the individuals in the "dead island" to produce excellent individuals, and then move these individuals into the "living island" for evolutionary operation, and perform this step circularly until the constraint conditions are met.

The specific flow of the algorithm is as follows:

1) Coding chromosomes according to the modeling result of the training objective function of high-rise building project management talent and randomly generating the initial population of the training objective of management talent.

2) Judging whether the evolutionary algebra meets the requirements, if it meets the requirements, outputting the training target population of the last generation of management talent, and ending the test; otherwise, entering step (3).

3) Calculate the fitness value and average fitness value of the target population for training management talent, and move the individuals with higher-than-average fitness into the "dead island" and those with lower-than-average fitness into the "living island." Inoculate the chromosomes in the "dead island" and put the excellent individuals into the "living island" after injection. For the crossover and variation of individuals in the "living island," the individual fitness value of the population is recalculated.

4) Judge whether the number of the target population for training management talent is greater than the initial set value, and if it exceeds the set value, reject the inferior solutions according to the fitness. Evolutionary algebra Gen+1, and return to step (2).

Steps (1), (2), and (4) in the above steps are the same as the basic genetic algorithm, and the selection rule of parents still adopts the "two-person economic law," and the "three-person championship" method is selected when the redundant individuals in the population are eliminated. The difference is that the "double island model" and inoculation process are added in step (3).

Through the optimization of this method, the best training scheme can be found for project management talent of high-rise buildings.

III. Experimental Analyses

In order to evaluate the application effect of the high-rise building project management talent training model designed in this paper, the model is applied to a high-rise building project. The total height of this high-rise project is 269.7m, and the entire construction area is 172,000 $m^{2,}$ with 57 floors above ground and three floors underground. The overall building structure is frame+facade support+tube structure. A total of 157 constructors+managers are employed in this project. The management talent used in the construction of this high-rise building project is trained, and whether the training model designed in this article has a certain use effect is analyzed.

Select an employee from the project managers of high-rise buildings and analyze the changes of the learning curve, forgetting curve, and learning forgetting curve of the employee at different times so as to verify the evaluation effect of the article on employees' cognitive ability. The results of the analysis are shown in Fig. 2.

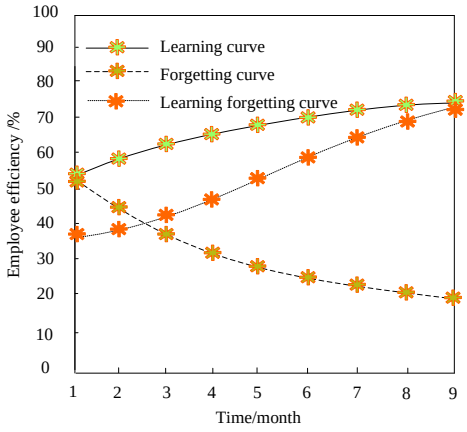

Fig. 2. Employee learning curve, forgetting curve, and learning forgetting curve.

According to Fig. 2, through the evaluation of employees' cognitive ability by this model, it can be seen that the employee's learning curve maintains about 50% employee efficiency in the initial stage, and with the continuous progress of the learning process, the employee efficiency increases to about 70%, but this curve does not consider the employee's forgetting degree; Through the analysis of forgetting curve, it can be seen that the employee efficiency has gradually decreased from the initial 50% to about 20%, which leads to the degree of forgetting obviously affecting the employee's work efficiency; Therefore, this model combines the learning and forgetting curve to analyze, and it is known that when employees' forgetting problem is considered, the employee efficiency gradually starts to rise from the initial 30%~40%, and can reach more than 60% with the continuous learning process. Through the analysis of this model, it is possible to accurately know the influence of employees' learning and forgetting methods on their efficiency.

This paper analyzes the changes in the total project construction cost before and after the optimization of the training of high-rise building project management talent by using this model so as to verify the optimization ability of this model to the cost target, and the analysis results are shown in Fig. 3.

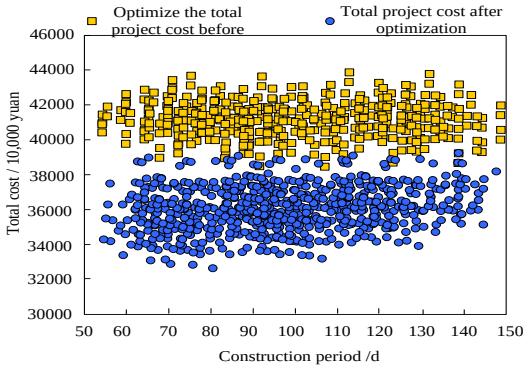

Fig. 3. Analysis of total cost optimization results.

According to Fig. 3, through comparison, it can be seen that the total cost of this high-rise building project has always remained at a high level before being optimized by this model, which leads to a large amount of expenses in the construction of this project. When this model optimizes the management talent, the construction strategy of this project has been improved, which makes the total construction cost of this project decline. It can be seen that when the model is optimized, the total cost of the project is no more than 400 million yuan, which can obviously save a lot of expenses. Therefore, the model has a good optimization effect.

Select different tasks from the overall project construction and analyze the human resource utilization ratio of other tasks before and after optimizing management talent so as to verify the effect of this model on different talent training. The analysis results are shown in Table II.

From the analysis in Table II, it can be seen that the utilization rate of human resources in this project is always at a low level for different construction tasks before the model is adopted for optimization. Among them, the utilization rate of human resources in foundation treatment construction, pile cap construction, and fence construction tasks can reach the highest, but it is only 57%. After the model is optimized in this paper, the management personnel are effectively trained, and the utilization rate of human resources in construction is also increased. Among them, the utilization rate of human resources in each task is above 85%, and the highest utilization rate is 92%, which shows that human resources can be fully utilized in the construction process, thus ensuring construction efficiency. Therefore, the model has excellent optimization ability.

Select an employee from different employees and analyze the changes in the employee's proficiency in technical ability, planning and organization ability, and cost control ability during the training process so as to verify the evolutionary power of the model. The results of the analysis are shown in Fig. 4.

TABLE II. ANALYSIS OF HUMAN RESOURCE UTILIZATION IN DIFFERENT TASKS

Serial number	Construction task	Human resource utilization before optimization /%	Human resource utilization rate /% after optimization in this paper
1	Construction preparation and temporary facilities	54	89
2	Foundation treatment	57	91
3	Cut earth	48	92
4	Pile driving	49	88
5	Backfill and lightning protection grounding works	53	87
6	Pile cap construction	57	93
7	Column reinforcement and lightning belt construction	55	86
8	Ground concrete cushion construction	46	91
9	Roof beam plate formwork construction	47	90
10	Concrete placement construction	52	89
11	Power threading construction	56	88
12	Plastering works	53	92
13	Ceiling works	54	87
14	Drainage engineering construction	55	89
15	Wall construction	57	90
16	Electrical installation and construction	48	87
17	Plastering of exterior walls	49	89
18	Exterior wall coating construction	50	87
19	Defect repair construction	52	89

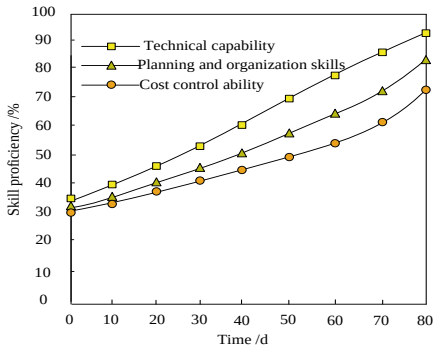

Fig. 4. Analysis of employee skill proficiency.

According to Fig. 4, with the continuous increase of time, the employee's proficiency in different skills began to increase. Among them, the employee's technical ability always maintained a high proficiency, while the employee's planning and, organization ability and cost control abilities were relatively weak. However, when the time reached 80 days, the employee's proficiency in different skills reached more than 70%, indicating that the employee had a high proficiency in skills at this time. Therefore, after the model was optimized,

Analyze the changes in skills growth benefits of the optimized talent training model under different project durations and project costs, and the analysis results are shown in Fig. 5.

The benefit of skill growth refers to all kinds of advantages and benefits brought by learning and developing new skills. According to Fig. 5, through the optimization of the model in this paper, the skills growth benefit can be maintained at different project duration and project costs. It can be seen that the model can improve the problem-solving ability of project management talent, stimulate employees' creativity and innovation ability, maximize employees' self-value, and thus enhance the overall benefits of enterprise construction projects.

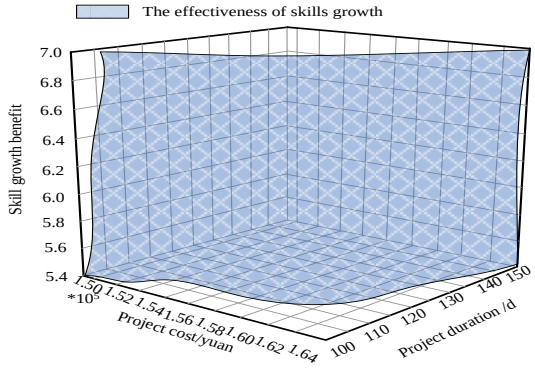

Fig. 5. Skill growth benefit analysis.

This paper analyzes the influence of traditional genetic algorithms, multi-objective genetic algorithms, and genetic algorithms based on mixed immunity on the construction period of the project under different optimization times so as to evaluate the optimization effect of the model on the construction period index and the analysis results are shown in Fig. 6.

According to Fig. 6, after the iterative evolution of different algorithms, the construction period of high-rise buildings has decreased. When the number of iterative developments reaches 800 times, the optimized construction period of the three algorithms has reached the lowest state. Among the three algorithms, the construction period optimized by the traditional genetic algorithm has remained above 670d, and it has maintained the highest level among the results optimized by the three algorithms. After the optimization by the multi-objective genetic algorithm, although the construction period has decreased, it is still higher than the result of optimization

based on the hybrid immune genetic algorithm in this paper. Under the optimization of this model, project management talent has been trained efficiently, thus effectively reducing the construction period. When the number of iterations reaches 800, the optimization result of this model only takes about 620d days to complete the project construction so that the total construction period can be effectively shortened after the optimization of this model.

After applying this model to optimize multi-objectives, the construction quality and actual construction duration of different project tasks are analyzed to verify the multi-objective optimization effect of this model. The analysis results are shown in Table III.

According to the analysis in Table III, after multi-objective optimization with this model, the construction can be completed within the specified time range when dealing with different construction tasks, and the actual construction time of most tasks is lower than the specified time. At the same time, when the construction is completed, it can be seen that the construction quality of different tasks meets the construction standards. Therefore, under the optimization of this optimization model, the technical level of high-rise building project management personnel can be effectively improved to ensure smooth construction.

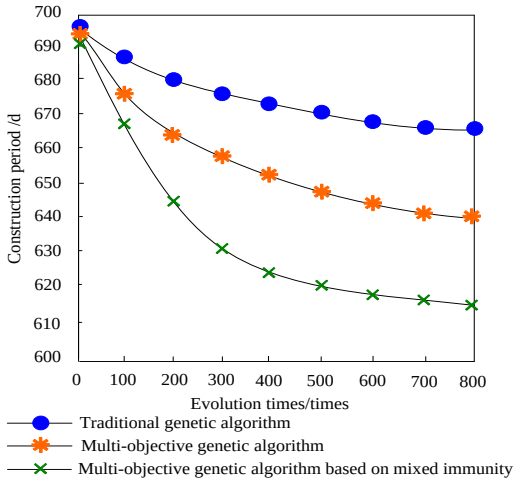

Fig. 6. Changes in the construction period after optimization.

TABLE III. ANALYSIS OF CONSTRUCTION QUALITY AND ACTUAL CONSTRUCTION TIME IN DIFFERENT TASKS

Serial number	Construction task	Estimated standard construction time /d	Actual completion time /d	Construction quality inspection
1	Temporary electricity construction	9	8	The quality meets the construction standard
2	Site clearing	14	12	The quality meets the construction standard
3	Erection test pile	4	3	The quality meets the construction standard
4	Erection column	18	14	The quality meets the construction standard
5	Site formation construction	5	5	The quality meets the construction standard
6	Pile head preparation	10	8	The quality meets the construction standard
7	Immersed pipe pouring concrete and pile cap construction	11	10	The quality meets the construction standard
8	Construction of the embedded underground pipeline	12	10	The quality meets the construction standard
9	Backfill construction	6	5	The quality meets the construction standard
10	Concrete bedding and waterproof construction	1	1	The quality meets the construction standard
11	Underground pillar construction	6	6	The quality meets the construction standard
12	Stairwell construction	10	9	The quality meets the construction standard
13	Ceiling plaster	8	7	The quality meets the construction standard
14	Plaster the walls	10	8	The quality meets the construction standard
15	Ground waterproof layer construction	5	5	The quality meets the construction standard
16	Cement mortar protective layer construction	10	8	The quality meets the construction standard
17	Wiring construction	15	13	The quality meets the construction standard
18	Water pipe installation	7	6	The quality meets the construction standard
19	Natural gas pipeline installation and construction	8	7	The quality meets the construction standard
20	Decoration and beautification construction	10	8	The quality meets the construction standard

IV. Conclusion

This paper studies the training model of high-rise building project management talent under a multi-objective evolutionary algorithm. The research results show that the model can effectively evaluate and optimize the training scheme of project management talent. In this paper, firstly, an objective function with multiple objectives is constructed, including project duration, project cost, and skill growth rate. By adopting a multi-objective evolutionary algorithm, these indexes can be optimized at the same time, and a balanced training scheme among different objectives can be obtained. Secondly, this model is used to optimize the training scheme of real high-rise building project management talent. The results show that by adopting a multi-objective evolutionary algorithm, a more practical training scheme can be achieved. At the same time, the feasibility and flexibility of the model were also verified through case analysis. Generally speaking, this research has developed and verified the talent training model of high-rise building project management, which provides a scientific and effective method for talent training. This model can not only help decision-makers formulate reasonable training strategies but also provide an innovative idea and plan for talent training in the field of high-rise building project management.

***Abstract*—This paper discusses the development of a new chaotic function (proposed chaotic map) as a keystream generator to be used to encrypt and decrypt the image. The proposed chaotic function is obtained through the composition process of two chaotic functions MS map and Tent map, with the aim of increasing data resistances to attacks. The randomness properties of the keystream generated by this function have been tested using Bifurcation diagrams, Lyapunov exponent, and NIST randomness analysis. All the analysis results indicate that the keystream passed the randomness tests and safe to be used for image encryption. The performance of the proposed chaotic function was measured by way of analysis of its initial value sensitivity, key space, and correlation coefficient of the encrypted image. This function can further increase the resilience against brute force attacks, minimizing the possibility of brute attacks, and has key combinations or key space of 1.05×10^{959} that is much greater than the key space generated by MS Map + Tent Map of 5.832×10^{958}. Finaly, quantitative measurements of encrypted image quality show an MSE value of 0 and a PSNR value of ∞. These values mean that the encrypted image data is the same as its original and both are also visually identical.**

I. Introduction

It is always easy for internet users to obtain various data and information from anywhere and at any time. The development of information technology in the form of text, images, audio and video (multimedia data) and communication is very rapid. Therefore, information security is an absolute matter that must be seriously considered by all users concerned. Information is a very valuable asset for an organization because it serves a strategic resource in increasing value. The information security here concerns policies, procedures, processes and activities to protect information from various types of threats against it that can cause harm to the survival of the organization. Based on this purpose, cryptography is implemented related to information security such as confidentiality, data integrity, entity authentication, and data origin authentication.

In general, cryptography is divided into two parts, namely classical and modern cryptography. Modern cryptography is the development of algorithms from classical cryptography which prioritizes bit mode operations, in contrast to classical cryptography which operates on characters. In one study, there was an encryption system which combined Logistic Map and Henon Map to produce an average PSNR value of less than 10 dB which indicated that the encrypted image had very high noise and an MSE value of more than 400, this means that there are still many signal errors from the original image and cipher image. The length of the process required carrying out the encryption and decryption process was greatly influenced by the size of the dimensions and the number of pixels in a digital image. The encryption system using a combination of Logistic Map and Henon Map took more than 15 seconds to encrypt images that had dimensions of 512×512; however image encryption results were not influenced by the dimensions of the encrypted image [1].

The chaos function has been developed for data encryption in the last decade because of its nature described in [2]. The nature of the chaos function, which is sensitive to the initial conditions, results in a significant difference in the image encryption results. Some of the chaotic functions used in image encryption are Logistic Maps and MS maps. The Logistic Map function has a key space of 10^{30} [3-4], the MS Map function has a key space of up to 3.24×10^{634}[5].

There is an algorithm technique that composes a sequential Logistic Map and Chebyshev Map [6], both of which are used to encrypt medical images. In the initial stage, the medical image is encrypted with a Logistics Map, then an encrypted image is formed, and the image is re-encrypted with a Chebyshev map. Besides that, there is also the Gauss-Circle Map algorithm which is a combination of Gauss Map and Circle Map by combining the two [7] by applying a composition function [8], then proposed a new image encryption algorithm by jointly exploiting overlapping random block partitioning, scanning, double spiral, Henon's chaotic map, and L ü' s chaotic map. Another study proposed a cryptosystem based on 4D Lorenz-type hyper-chaos and deoxyribonucleic acid (DNA) [9].

The MS Map and Tent Map algorithms are two well-known chaotic function algorithms that exhibit chaotic properties, which both have a high potential to generate random keys. Therefore, this paper proposes a new chaotic function which is a composition of the two chaotic functions of MS Map and Tent Map. The proposed function is also chaotic, so it can be used as a random number generator function. This chaotic system is useful for generating random numbers for chaos that has no period. This random number generator is created by compiling a Bifurcation Diagram, Lyapunov Exponent, and the NIST Randomness Test. The chaos system is used as the basis for secure cryptographic algorithms for communication because of the very close relationship between chaos and cryptography [10].

After generating random numbers by composing the MS Map and Tent Map functions, the algorithm performance analysis was carried out based on initial value sensitivity level analysis, key space size analysis, correlation coefficient analysis, and image quality testing (PSNR).

II. RESEARCH METHOD

Two chaotic functions that are often used for data encryption and decryption are MS Map and Tent Map. Both will be used to build a new chaotic function. MS Map is a modification of the Logistic map function as shown by Eq. (1), where $(x\ mod\ 1) = x - \lfloor x \rfloor$ according to the definition. This equation can be expressed recursively as shown in Eq. (2), with initial value $x_0 \in (0, 1)$ and $n = 1,2,3, \ldots$ [5].

$$f(x) = \left(\frac{r\lambda x}{1+\lambda(1-x)^2}\right)(mod\ 1) \quad (1)$$

$$x_{n+1} = \left(\frac{r\lambda x_n}{1+\lambda(1-x_n)^2}\right)(mod\ 1) \quad (2)$$

The modulo operation is applied as a congruent function. In a set of integers, congruence is a method or way of explaining the divisibility of an integer. Modulo arithmetic is used in cryptography because the modulo b arithmetic value is in a finite rounded set, namely 0 to $b - 1$. Calculations in the cryptographic process are not outside the set of integers, meaning that the decryption process will not produce a value that is different from the value of the original message. Thus, there is no need to worry about losing information because the rounding occurs as in real number operations.

In mathematics, the Tent map is an iteration chaotic function, which forms a dynamic system based on discrete time. It takes x_n points on a real line and then maps those points to other points [11]. This function can be expressed as in Eq. (3).

$$x_{n+1} = g(x) = \begin{cases} \mu x_n & for\ x_n < ½ \\ \mu(1 - x_n) & for\ x_n \geq ½ \end{cases} \quad (3)$$

Now suppose g is a function from set *A* to set *B* and *f* is a function from set *B* to set *C*. The composition between two functions *f* and *g*, denoted by $(f \circ g)$, is a function from *A* to *C* which is defined as $(f \circ g)(a) = f(g(a))$. Furthermore, if f represents the MS map function in Eq. (2) and g acts as the Tent map function in Eq. (3), so the proposed new chaotic function resulting from the composition of both is expressed in two domain partitions as shown in Eq. (4) and Eq. (5).

$$(f \circ g)(x) = \mu\left(\left(\frac{r\lambda x}{1+\lambda(1-x)^2}\right)(mod\ 1)\right)\ for\ x < ½ \quad (4)$$

Map function was generated from the composition of

$$(f \circ g)(x) = \mu\left(1 - \left(\frac{r\lambda x}{1+\lambda(1-x)^2}\right)(mod\ 1)\right) for\ x \geq ½ \quad (5)$$

Thus, based on Eq. (4) and Eq. (5), the proposed chaotic function can be expressed as in Eq. (6).

$$(f \circ g)(x) = \begin{cases} \mu\left(\left(\frac{r\lambda x}{1+\lambda(1-x)^2}\right)(mod\ 1)\right) & for\ x < ½ \\ \mu\left(1 - \left(\frac{r\lambda x}{1+\lambda(1-x)^2}\right)(mod\ 1)\right) for\ x \geq ½ \end{cases} \quad (6)$$

Furthermore, this equation is called the MS Tent map chaotic function and can be represented in recursive form as shown in Eq. (7), for $= 0,1,2,3, \ldots$.

$$(x_{n+1}) = \begin{cases} \mu\left(\left(\frac{r\lambda x_n}{1+\lambda(1-x_n)^2}\right)(mod\ 1)\right) & for\ x_n < ½ \\ \mu\left(1 - \left(\frac{r\lambda x_n}{1+\lambda(1-x_n)^2}\right)(mod\ 1)\right) for\ x_n \geq ½ \end{cases} \quad (7)$$

III. RESULT AND ANALYSIS

The chaotic behavior of the proposed MS Tent map can be evaluated using three types of analysis. First is bifurcation diagram analysis for density sensitivity test. Second is Lyapunov exponent diagram analysis for transitive test and the last one is NIST Randomness tests using 16 statistical tests. These three tests are carried out on the number sequence or keystream generated by the MS Tent map. Algorithm 1 shows how to generate a keystream using the MS Tent map.

After testing the chaotic properties has been completed, the next stage is to develop encryption and decryption algorithms as shown by Algorithms 2 and 3. To analyze the results of the encrypted image and decrypted image, the keystream generated by MS Tent map is used with the initial value of the variable $x_0 = 0.9$ and the parameters $\lambda = 30$, $\mu = 1.5$, and $r = 3.7$. All algorithms keystream generator, keystream testing, image encryption and decryption are implemented using Python programming language and runed on a computer with the specification Intel(R) Core (TM) i5-4200M CPU @ 2.50GHz and 10.00 GB of Memory (RAM).

Performance analysis of the proposed chaotic function is carried out on encrypted and decrypted images using 30 test images: 15 color images and 15 grayscale images. To test the resistance of an encrypted image to brute force attacks, several indicators are used:

1) Sensitivity analysis.
2) Key space measurement analysis.
3) Correlation analysis.
4) Image quality test.

Algorithm 1: Keystream Generator Algorithm

Input: x_0, λ, μ, r, t
Output: *Keystream* K_i
1. For $i = 1\ to\ t\ do$
2. calculate x_i using Eq. (7)
3. $K_i \leftarrow \lfloor x_i \times 10^6 \rfloor mod\ 256$
4. End For

Algorithm 2: Image encryption algorithm

Input:x_0, λ, μ, r, t, original image ($P_i: m \times n$)
Output: encrypted image ($C_i: m \times n$)
1. $N = m \times n$; $i = 1$
2. If $i \leq N$, do Step-3 to step-6
3. Calculate x_{i+t} using Eq. (7)
4. $K_{i+t} \leftarrow \lfloor x_{i+t} \times 10^6 \rfloor \, mod \, 256$
5. $C_i = P_i \oplus K_{i+t}$
6. $i = i + 1$; Back to Step-2
7. Else to step-8
8. Show matrix C_i in encrypted image display

Algorithm 3: Image decryption algorithm

Input: x_0,r,λ,μ, i, t, encrypted image ($C_i: m \times n$)
Output: decrypted image ($D_i: m \times n$)
1. $N = m \times n$; $i = 1$
2. If $i \leq N$, do Step-3 to step-6
3. Calculate x_{i+t} using Eq. (7)
4. $K_{i+t} \leftarrow \lfloor x_{i+t} \times 10^6 \rfloor \, mod \, 256$
5. $D_i = C_i \oplus K_{i+t}$
6. $i = i + 1$; Back to Step-2
7. Else to step-8
8. Show matrix D_i in decrypted image display

A. Bifurcation Diagram

A bifurcation diagram is a diagram that shows the asymptotically approximate values of a system as the function of the parameters. By looking at the bifurcation diagram, we can determine the chaotic nature of a function. If the periodic points on the bifurcation diagram are dense, then the function is chaotic [2].

Algorithm 4. Plotting Bifurcation Diagram

Input: x_0, λ, μ, r, t
Output: plotting x_i
1. For $i = 1$ to n
2. Calculate x_i using Eq. (7)
3. Plotting x_i
3. end for

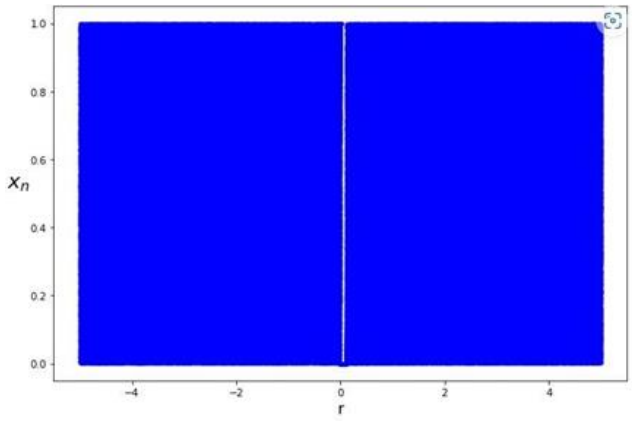

Fig. 1. MS Tent map bifurcation diagram, for $x_0 = 0.9$, $\lambda = 30$, $\mu = 1.5$, $r = 3.7$.

Based on Algorithm 4, with variable values of $x_0 = 0.9$, $\lambda = 30$, $\mu = 1.5$, $r = 3.7$, a diagram is obtained as seen in Fig. 1. The result of the bifurcation diagram is dense for every value of r except for $r = 0$. Thus, the MS Tent map has chaotic properties except for $r = 0$.

B. Lyapunov Exponent Diagram

According to Eq. (8), the Lyapunov exponent can measure the sensitivity of a chaotic system to initial conditions. The Lyapunov exponent is defined as the exponential difference in the divergence or convergence of two vectors in a plane starting from the area around the plane.

Definition: Let X be a set. The map $f : X \rightarrow X$ is chaotic on X, if f is sensitive on the initial value, f is topologically transitive, and the periodic points are dense on X [10].

A function f is said to be chaotic if its Lyapunov exponent is positive. The Lyapunov exponent equation is defined according to Eq. (8) and its implementation uses Algorithm 5. Fig. 2 is a plot result of the Lyapunov exponent diagram, which shows that the MS Tent map has positive Lyapunov exponents at $x_0 = 0.9$, $\lambda = 30$, and for every value of r except for $r = 0$. This proves that the MS Tent map has chaotic properties.

$$\mu = \lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} ln|f'(x)| \quad (8)$$

Algorithm 5. Lyapunov Exponent Diagram

Input: x_0, λ, μ, r
Output: plotting the value of μ
1. for $i = 1$ to n
2. Calculate μ using Eq. (8)
3. plotting μ
4. end for

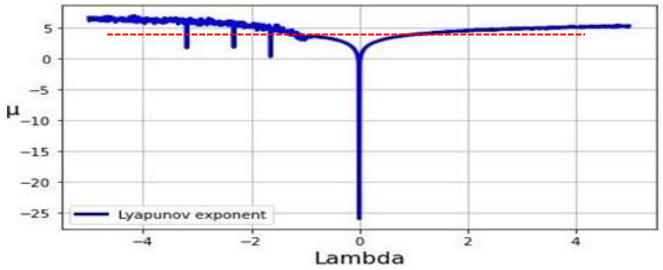

Fig. 2. Lyapunov exponent diagram of the MS Tent Map.

C. Key Stream Randomness Test

After conducting a chaotic test on the MS Tent map function using a bifurcation diagram and Lyapunov exponent, then a randomness test is carried out on the keystream or number sequence generated from this function. The keystream randomness test used is the NIST test suite which aims to evaluate the chaotic level of MS Tent map function [12]. The NIST test suite is a statistical package consisting of 16 tests [13] and their results are shown in the Table I. Based on these 16 statistical tests results, it can be concluded that the keystream generated by MS Tent map is random. This is because the statistical test process shows that the P-value is greater than the significance level (by default it is 0.01).

TABLE I. NIST RANDOMNESS TEST RESULTS OF THE MS TENT MAP

Type of Test	P-Value	Conclusion
Frequency (Monobit)	0.031555	Successful
Frequency within a Block	0.748768	Successful
Run Test	0.394557	Successful
Longest Run of Ones in a Block	0.229904	Successful
Binary Matrix Rank	0.168577	Successful
Discrete Fourier Transform (Spectral)	0.755036	Successful
Non-Overlapping Template Matching	0.425093	Successful
Overlapping Template Matching	0.904727	Successful
Maurer's Universal Statistical	0.803366	Successful
Linear Complexity	0.141618	Successful
Serial Test	0.356311	Successful
	0.490805	Successful
Approximate Entropy	0.083009	Successful
Cumulative Sums (Forward)	0.060013	Successful
Cumulative Sums (Reserve)	0.025765	Successful
Test Random Excursions	0.431326	Successful
Test Random Excursions Varian	0.641948	Successful

D. Sensitivity Analysis

Sensitivity analysis aims to find out how big the difference is between the key parameter values used in the encryption process and the key parameter values applied in the decryption process, so that they can be considered the same or different. Fig. 3 is two examples of color and grayscale face images used for sensitivity testing. In the image encryption process the parameters values employed are: $x_0 = 0.9$, $\lambda = 30$, $\mu = 1.5$, $r = 3.7$, and iteration $t = 100$.

The sensitivity test results are displayed in Table II. The tests are performed by varying the value of each parameter, as shown in the first and second columns. The third column displays the decrypted image results according to the parameter values used in the first and second columns. The last column represents the histogram pattern of each decrypted image in the third column.

The key variable x_0 has a sensitivity value of 10^{-17}. This is proven because for x_0 value with a difference of up to 10^{-17} the decrypted image has not returned to the original image and their histogram appears to have a uniform (flat) distribution. Visually from this histogram, one cannot predict what information is contained in the original image. The decrypted image will only return to the original if the difference between x_0 value in the encryption and decryption processes is 10^{-18}. The sensitivity levels of the other parameters are: $r = 10^{-17}$, $\lambda = 10^{-16}$, and $\mu = 10^{-17}$. Based on the sensitivity test results, it can be concluded that the encrypted image is safe against brute force attacks at the sensitivity level of each parameter: $x_0 = 10^{-17}$, $r = 10^{-16}$, $\lambda = 10^{-15}$, and $\mu = 10^{-16}$.

E. Key Space Measurement Analysis

Brute force attacks usually always try all possible keys to decrypt to get the actual facial image. To reduce the chance of a successful brute force attack, the algorithm must also have a large key space. The key space represents the number of different keys that can be used to perform encryption/decryption [14]. In Python, the maximum value of floating-point numbers is $1.7976931348623157\times10^{308} \approx 1.8\times10^{308}$. The natural numbers lie in the interval (0, 1), the precession rate reached $2^{52} \approx 10^{15}$ and the integer data had a possible value of $2^{64} \approx 1{,}8\times10^{19}$. The encryption and decryption algorithms based on MS Tent map chaotic function have five parameters: x_0, r, μ, λ, and iteration t with domains $x_n \in (0, 1)$, λ, μ, r, $\in$ R, and $t \in$ Z. Overall, these five parameters can produce a key space size of $1.8\times10^{308} \times 1.8\times10^{308} \times 1.8\times10^{308} \times 10^{15} \times 1.8\times10^{19} \approx 1.05\times10^{959}$. This key space is very large, so the encrypted image can be resistant to the brute force attacks.

Fig. 3. (a) Color face image. (b) Grayscale face image.

TABLE II. SENSITIVITY TEST RESULTS FOR DIFFERENCES IN PARAMETER VALUES x_0, μ, r, λ

Sensitivity Test Results		Face Image Decryption	Histogram
Initial value difference x_0 with $r = 3.7$, $\mu = 1.5$, and $\lambda = 30$	$x_0 = 0.9 + 10^{-6}$			$x_0 = 0.9 + 10^{-17}$			$x_0 = 0.9 + 10^{-18}$		Parameter value difference r with $x_0 = 0.9$, $\mu = 1.5$, and $\lambda = 30$	$r = 3.7 + 10^{-6}$			$r = 3.7 + 10^{-16}$			$r = 3.7 + 10^{-17}$		Parameter value difference λ with $x_0 = 0.9$, $r = 3.7$, and $\mu = 1.5$	$\lambda = 30 + 10^{-6}$			$\lambda = 30 + 10^{-15}$			$\lambda = 30 + 10^{-16}$		Parameter Value difference μ with $x_0 = 0.9$, $r = 3.7$, and $\lambda = 30$	$\mu = 1.5 + 10^{-6}$			$\mu = 1.5 + 10^{-16}$			$\mu = 1.5 + 10^{-17}$		
TABLE III. KEY SPACE COMPARISON OF CHAOTIC FUNCTIONS

Function	Parameters	Key Space
Tent Map [11]	$\boldsymbol{x}_n \in (0, 1)$, $\boldsymbol{\mu} \in \mathbb{R}$, and $t \in \mathbb{Z}$	1.8×10^{323}
MS Map [15]	$\boldsymbol{x}_n \in (0, 1)$, $\boldsymbol{\lambda}, \boldsymbol{r} \in \mathbb{R}$, $t \in \mathbb{Z}$	3.24×10^{635}
Tent + MS Map	$\boldsymbol{x}_n(t), \boldsymbol{x}_n(\mathbf{ms}) \in (0, 1)$, $\lambda, r \in \mathbb{R}$, $t \in \mathbb{Z}$	5.832×10^{958}
MS Tent Map	$\boldsymbol{x}_n \in (0, 1)$, $\boldsymbol{\lambda}, \boldsymbol{\mu}, r \in \mathbb{R}$, and $t \in \mathbb{Z}$	1.05×10^{959}
MS Circle Map [16]	$\boldsymbol{x}_n \in (0, 1)$, $\lambda, r, \Omega, K \in \mathbb{R}, t \in \mathbb{Z}$	1.889×10^{1267}

Table III displays the key space of chaotic functions, where the first and second rows represent the key space of the Tent map and MS map which are 1.8×10^{323} and 3.24×10^{635} respectively. The third row is a key space of 5.832×10^{958} which is produced when the encryption process is carried out twice serially by the Tent map and MS map. In the fourth row is a key space of 1.05×10^{959}, if the proposed MS Tent map is applied for the data encryption process. This shows that data encryption based on MS Tent Map is more secure against brute force attacks than when using MS Map, Tent Map and a serial combination of MS Map and Tent Map.

F. Correlation Analysis Test

Correlation analysis is a method used to determine the direction and strength of the relationship between two variables [17] or between pixels in an image. The correlation coefficient is usually a value without units which is located between 1 and -1. High correlation (close to 1) indicates a strong relationship between neighboring pixel values, so that it can describe the information contained therein. On the other hand, low correlation (close to 0) means that the relationship between neighboring pixels is weak, so that no information can be depicted by these pixels.

Table IV shows the results of the correlation coefficient test from color and grayscale images in Fig. 3. The correlation coefficient is calculated referring to the correlation between neighboring pixels vertically, horizontally, and diagonally. In the second, third and fourth columns, all correlation coefficient values are close to 1 for the original images. These values show a close correlation between pixels in the images, so that all information can be read visually. On the other hand, all the correlation coefficient values of the encrypted images in the fifth, sixth and seventh columns are close to 0. This indicates that there is no correlation between pixels in the encrypted images, so that no information can be read visually from these images. Likewise, this correlation coefficient results show that the encrypted images are secure against statistical attacks.

G. Encrypted Image Quality Test

Functional analysis of encryption and decryption algorithms based on the proposed MS Tent map aims to determine their success in securing data: from the original images to the cipher images (encrypted images) and then returned to the original images (decrypted images), as demonstrated in the Fig. 4. In column (a) are the original images, in column (b) are the results of the encryption algorithm, and the results of the decryption algorithm can be found in column (c). In this functional analysis, it will be determined whether the decrypted images, as the results of the decryption process of the encrypted images, are the same as the original images.

(a) (b) (c)

Fig. 4. (a) Original images. (b) Encrypted images. (c) Decrypted images.

Mean Square Error (MSE) in Eq. (9) and Peak Signal to Noise Ratio (PSNR) in Eq. (10) are employed to measure the quality of the decrypted image compared to the original image. Quality analysis was carried out using thirty test images consisting of fifteen color images and fifteen grayscale images. These images have various colors, shapes, and textures features, as well as different sizes. The images in Fig. 4 are two of thirty test images.

$$PSNR(x, y) = 10 \log \frac{255^2}{MSE(x,y)} \quad (9)$$

$$MSE(x, y) = \frac{1}{N} \sum_{i=1}^{N} (x_i - y_i)^2 \quad (10)$$

Table V shows the MSE and PSNR values calculated between the original image and the decrypted image on thirty test images. MSE has a value of 0 and PSNR equals to ∞, for all decrypted color images (test image 1 to 15) and decrypted grayscale images (test image 16 to 30). These MSE and PSNR values prove that there are no errors in the decrypted images, or it can be said that the decrypted images are the same as the original images.

TABLE IV. CORRELATION COEFFICIENT TEST RESULTS OF COLOR AND GRAYSCALE IMAGES IN FIG. 3 AND THEIR ENCRYPTION

Test Data	Original Image Correlation Coefficient			Encrypted Image Correlation Coefficient		
	Horizontal	Vertical	Diagonal	Horizontal	Vertical	Diagonal
Color faceimage	0.9885	0.9933	0.9827	0.00065	0.00019	0.0014
Grayscale face image	0.9525	0.9631	0.9246	0.0067	0.0017	0.0036

TABLE V. MSE AND PSNR VALUE BETWEEN THE ORIGINAL AND DECRYPTED IMAGES

Test Image	MSE	PSNR		Test Image	MSE	PSNR
1	0	∞		16	0	∞
2	0	∞		17	0	∞
3	0	∞		18	0	∞
4	0	∞		19	0	∞
5	0	∞		20	0	∞
6	0	∞		21	0	∞
7	0	∞		22	0	∞
8	0	∞		23	0	∞
9	0	∞		24	0	∞
10	0	∞		25	0	∞
11	0	∞		26	0	∞
12	0	∞		27	0	∞
13	0	∞		28	0	∞
14	0	∞		29	0	∞
15	0	∞		30	0	∞

IV. CONCLUSION

MS Tent map is a proposed chaotic function which is developed through the composition process of the two chaotic functions MS Map and Tent Map. Through sensitivity, transitivity, and randomness tests on the keystream generated by MS Tent map, it is proven that this function has chaotic properties. MS Tent map has four key parameters that can produce a key space of 1.05×10^{959}. This shows that data encryption based on MS Tent map is more secure against brute force attacks than when using MS map or Tent map or a serial combination of MS map and Tent map, which have key spaces of 1.8×10^{323}, 3.24×10^{635}, and 5.832×10^{958}, respectively. Likewise, based on the results of the correlation coefficient analysis, it shows that encrypted images are also secure against statistical attacks.

***Abstract*—Breast cancer can have significant emotional and physical repercussions for women and their families. The timely identification of potential breast cancer risks is crucial for prompt medical intervention and support. In this research, we introduce innovative methods for breast cancer detection, employing a Convolutional Neural Network (CNN) architecture and Transfer Learning (TL) technique. Our foundation is the ICAIR dataset, encompassing a diverse array of histopathological images. To harness the capabilities of deep learning and expand the model's knowledge base, we propose a TL model. The CNN component adeptly extracts spatial features from histopathological images, while the TL component incorporates pretrained weights into the model. To tackle challenges arising from limited labeled data and prevent overfitting, we employ ResNet152v2. Utilizing a pre-trained CNN model on extensive image datasets initializes our CNN component, enabling the network to learn pertinent features from histopathological images. The proposed model achieves commendable accuracy (96.47%), precision (96.24%), F1-score (97.18%), and recall (96.63%) in identifying potential breast cancer cases. This approach holds the potential to assist medical professionals in early breast cancer risk assessment and intervention, ultimately enhancing the quality of care for women's health.**

***Keywords*—Breast cancer; transfer learning; ResNet152v2; medical image analysis; ICAIR 2018 dataset**

I. Introduction

In our contemporary landscape, cancer has solidified its status as a ubiquitous threat, permeating global communities and emerging as a predominant cause of illness and mortality. A chilling statistic underscores the severity of its impact—over 14.5 million lives have succumbed to cancer worldwide, and an ominous prognosis emerge, suggesting an alarming surge to over 28 million by the year 2030. In the realm of oncology, breast cancer takes center stage, its diagnosis often initiated through the intricate dance of biopsy and subsequent microscopic image analysis [1]. Within the microscopic tapestry of breast tissue, pathologists wield their expertise, navigating the labyrinthine structures and components that hold the key to early detection. Histologically probing the microscopic realm, they unravel the intricate distinctions between normal tissue, benign formations, and the malignant lesions that herald a potential storm [2]. The insights harvested from these histological images are not merely observations; they serve as the bedrock for prognosis assessments, guiding the course of treatment in the relentless pursuit of increased curative outcomes with minimized morbidities.

As the medical landscape continues to evolve, the arrival of Deep Learning (DL) heralds a promising era, transcending traditional boundaries in recognition tasks. DL-based technologies, seamlessly integrated into the workflow of pathologists and clinicians, become instrumental in the perpetual quest for early cancer detection—a steadfast research focus in the expansive field of tumor oncology [3]. A beacon within this evolving narrative is the emergence of Computer-Aided Breast Cancer Diagnosis, an application of paramount importance. Yet, to maintain a grounded perspective on clinical applications, the imperative of multicategory diagnosis becomes evident, recognizing the intricate spectrum of breast cancer manifestations. Motivated by this imperative, the incorporation of deep learning approaches stands as a beacon, promising not just innovation but an elevation in the accuracy of classifiers, further fortifying the arsenal against cancer's relentless assault [4].

The intricate relation between microscopic analysis and biopsy marks the inception of the breast cancer diagnostic journey, unraveling the complex narrative within tissue samples. In the relentless pursuit of early cancer detection, the intersection of radiomics and histopathology emerges as a frontier, promising enhanced insights into tumor characteristics. Emerging technologies such as three-dimensional histopathological reconstruction redefine our approach, offering a holistic visualization of tissue architecture for comprehensive diagnosis. Beyond traditional image-based classification, molecular signatures and genomic profiling usher in a new era of precision medicine, tailoring treatments to individual patients. Ethical considerations in the use of artificial intelligence within pathology underscore the need for responsible and transparent integration into clinical workflows [5].

The integration of blockchain technology into histopathological data management ensures secure, traceable, and interoperable handling of sensitive medical information. The collaboration between pathologists and computational biologists becomes a cornerstone, fostering a symbiotic

relationship for refining algorithms and validating findings [6]. Virtual reality applications in medical education leverage histopathological images, providing immersive learning experiences for the next generation of pathologists. Novel contrast agents in histopathology imaging promise heightened sensitivity, enabling the detection of subtle cellular changes indicative of early-stage malignancies. The burgeoning field of exosome analysis in breast cancer pathology offers a promising avenue, unveiling the potential of liquid biopsy for non-invasive and real-time disease monitoring [7].

However, challenges persist in the current paradigm. The inadequacy of feature representation in existing methods poses a threat to classifier accuracy, highlighting a critical need for improvement [8]. Furthermore, the influence of the magnification factor in acquiring histopathology images introduces a variable that can lead to misclassification, amplifying the urgency for refinement. The deficiencies in accuracy and sensitivity within existing methods underscore the necessity for an overhaul, especially in applications demanding precise classification results [9]. In navigating this complex terrain, the existing classification algorithms grapple with singular features—be it spatial, morphological, or textural. The demand echoes for a comprehensive framework adept at handling multiple feature types, bridging the existing gaps and fortifying the foundation for a new era in cancer diagnosis [10]. As the quest for reliable and precise classification intensifies, the intersection of medical expertise and technological innovation emerges as the crucible where breakthroughs are forged and the relentless pursuit of conquering cancer unfolds.

Moreover, considering the limited availability of labeled data, the study leverages advanced Transfer Learning (TL) methods to enhance the model's adaptability to the specific task under consideration. Following this, the model undergoes a process of fine-tuning and adaptation tailored to the breast cancer detection task. This enables the model to autonomously acquire the ability to discern relevant spatial features from histopathological images. The integration of information from various sources, including disparate imaging and clinical data, into a unified model showcases commendable levels of accuracy, sensitivity, and specificity. In an age where healthcare increasingly embraces data-driven methodologies, this study contributes significantly to the expanding domain of medical image analysis. It underscores the importance of employing TL to overcome the limitations imposed by scarce labeled data. Subsequent sections of this manuscript will delve into the intricacies of the methodology, the careful design of the experimental framework, the presentation of results, and a thorough discussion of the findings.

By seamlessly combining the capabilities of hybrid neural network architectures with sophisticated TL techniques, this research aims to establish a more refined approach to breast cancer risk assessment. These pioneering efforts are expected to have a substantial impact on healthcare outcomes and usher in a new era of enhanced women's health. The major contribution of the research work includes:

- Enhancing the accuracy of breast cancer classification from histopathological images by leveraging transfer learning-based CNN models.
- Effectively extract relevant features for breast cancer classification, reducing the annotation burden and potentially speeding up the diagnostic process.
- Transfer learning-based CNN models offer increased generalizability across different datasets and scalability to handle larger volumes of data. This allows the developed model to be applicable across diverse clinical settings and potentially assist in automating the analysis of histopathological images on a larger scale, thus improving the efficiency of breast cancer diagnosis and treatment.

II. Literature Review

The emergence of Computer-Aided Breast Cancer diagnosis signifies a pivotal milestone in clinical applications, amplifying the need for a realistic perspective that incorporates multicategory diagnosis. The incorporation of DL approaches in breast cancer diagnosis holds the ability to enhance the accuracy of classifiers by delivering more robust foundation for clinicians and pathologists. Existing methods face challenges related to feature representation, affecting the overall accuracy of classifiers, thereby necessitating a drive for improved methodologies. The influence of the magnification factor in acquiring histopathology images introduces variability, potentially leading to misclassification—a factor that demands standardized protocols and careful consideration. Current breast cancer classification algorithms often focus on singular features, such as spatial, morphological, or textural characteristics, highlighting the need for a comprehensive framework capable of handling multiple feature types. Existing methodologies contribute uniquely to the evolving landscape of breast cancer detection, encompassing advancements in DL, challenges in feature representation, and the quest for a more comprehensive diagnostic framework.

Xie et al. [11] introduced a convolutional neural network (CNN) architecture tailored for breast cancer grading, demonstrating exceptional performance across diverse datasets and illustrating the model's adaptability to different staining techniques and tissue variations. The research elucidates the interpretability of the deep learning model, utilizing attention mechanisms to highlight regions crucial for accurate grading, fostering trust and understanding among clinicians. This work delves into the transferability of the trained model to different institutions, addressing concerns of model generalizability and promoting wider adoption in diverse clinical settings. Expanding on morphological features, Wei et al. [12] conducted an in-depth analysis of the discriminatory power of specific morphological descriptors, emphasizing the significance of nuclear shape, glandular arrangement, and stromal characteristics. This study explored the correlation between morphological features and clinical outcomes, establishing potential links between specific histopathological patterns and prognosis. The computational efficiency of morphological feature extraction methods is crucial for real-time applications in clinical settings.

Zewdie et al. [13] introduced texture analysis methods, including gray-level co-occurrence matrices and Gabor filters, evaluating their effectiveness in capturing subtle textural nuances indicative of different breast cancer subtypes. They

explored the impact of preprocessing techniques on texture analysis outcomes, shedding light on the importance of standardized image preparation for robust classification results. Moreover, the research investigates the reproducibility of texture features across multiple institutions, addressing concerns related to dataset variability and ensuring the reliability of the proposed classification approach. Aswathy et al. [14] introduced a novel spatial feature integration method, considering not only local but also global contextual information for improved classification accuracy. They explored the impact of spatial feature incorporation on the model's ability to differentiate between intertumoral heterogeneity and distinct tumor subtypes. They discussed the potential applications of spatial feature-based classification in guiding targeted therapies and predicting treatment response based on spatial tumor characteristics.

Building on ensemble learning model, Hameed et al. [15] systematically evaluated various ensemble strategies, including bagging and boosting, to discern their impact on breast cancer diagnosis accuracy. They investigated the robustness of ensemble models against noisy or imbalanced datasets, providing insights into the models' performance in real-world clinical scenarios. They discussed the scalability of ensemble learning approaches, exploring their feasibility for large-scale deployment in healthcare institutions. Yan et al. [16] introduced a multimodal fusion paradigm, which showcased the synergy between histopathological images and complementary data sources, such as gene expression profiles or clinical information. The added value of multimodal fusion helped in resolving ambiguous cases, demonstrating the potential for more confident and accurate breast cancer subtype classification. Challenges related to data integration, emphasizing the importance of harmonized datasets for meaningful fusion and collaboration across different domains were discussed.

Xue et al. [17] extended the application of transfer learning to histopathological image classification, leveraging pre-trained models on large datasets to enhance the efficiency and generalizability of classifiers. The impact of domain adaptation techniques in mitigating domain shift issues were addressed along with the challenges related to variations in staining techniques and image acquisition protocols. This work transferred knowledge from other medical imaging domains, offering insights into the broader applicability of histopathological image analysis. Hussain et al. [18] integrated explainable AI techniques and evaluated the effectiveness of explainability methods, such as saliency maps and attention mechanisms, in enhancing the transparency and trustworthiness of histopathological image classifiers. Hameed et al. [19] introduced and evaluated a suite of quantitative metrics specific to histopathological image classifiers, ensuring comprehensive and standardized performance assessment. The research addressed the limitations of traditional metrics, proposing novel measures tailored to the intricacies of histopathological images, including inter-observer agreement and sensitivity to rare subtypes. The importance of benchmark datasets with ground truth annotations is evaluated by facilitating fair and meaningful comparisons between different classification models.

III. Materials and Methods

This section serves as the foundation of our endeavor to advance breast cancer classification by combining state-of-the-art technologies. As we navigate through the intricate details of our approach, our goal is to elucidate the systematic framework that forms the foundation for the development and evaluation of our breast cancer detection model. Within this section, we delineate the essential steps, techniques, and tools utilized in our research, shedding light on the trajectory toward unlocking the full potential of transfer learning and CNN architectures. Breast cancer, posing a significant challenge to women's health globally, calls for innovative solutions in early detection [20]. Our methodology aims to bridge the gap between the intricacies of breast cancer diagnosis and the capabilities of artificial intelligence, specifically tailored for the ICIAR 2018 histopathological dataset—an invaluable repository of histopathological images and clinical data. In the subsequent sections, we will meticulously detail our data preprocessing strategies, the architectural framework of our transfer learning model and the intricacies of the training and validation procedures. The proposed methodology is crafted not only to make a meaningful contribution to the field of breast cancer classification but also to serve as a blueprint for future research endeavors focusing on unlocking the potential of artificial intelligence in healthcare diagnostics.

A. Dataset Description

Utilized in our experimental investigations, the ICIAR 2018 breast cancer histopathological dataset offers a comprehensive exploration of breast cancer pathology through Hematoxylin and Eosin (H&E) stained microscopy images [21]. These images, categorized as normal, benign, in situ carcinoma, or invasive carcinoma, present a diverse spectrum of breast cancer types. The dataset's credibility is ensured by the meticulous annotation conducted by doctors, with any annotation discrepancies leading to the exclusion. To provide visual context, Fig. 1 offers illustrative examples derived from the ICIAR 2018 dataset, granting a preview of the varied histopathological presentations contained within the dataset.

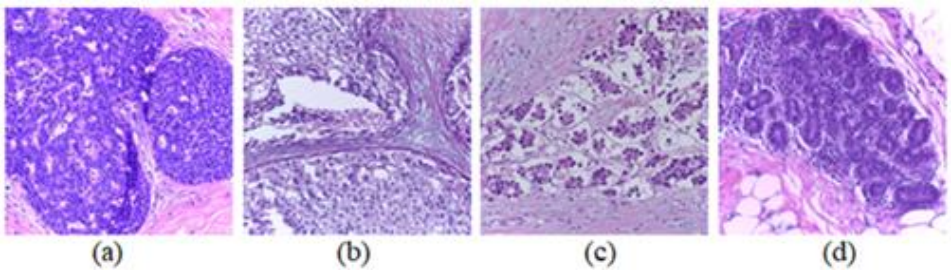

Fig. 1. Images from ICIAR 2018 dataset (a) Benign, (b) Carcinoma-in-situ, (c) Carcinoma-invasive, (d) Normal.

Employing the Red-Green-Blue (RGB) color model, the dataset captures intricate cellular details. Each image boasts a resolution of 2048 x 1536 pixels, enabling microscopic insights. With a memory space requirement of 10-20 MB per image, the dataset strikes a balance between richness of information and computational efficiency. The image-wise labeling approach contributes to a holistic understanding of breast cancer pathology, offering valuable insights for researchers and clinicians alike. Table I furnishes a thorough breakdown, shedding light on the distribution of different image classes within the given dataset. This classification facilitates the methodical analysis of breast cell properties, serving both research and diagnostic objectives.

TABLE I. IMAGES IN ICIAR 2018 DATASET

Sl. No	Image Class	Total	Train	Test
1	Benign	1000	800	200
2	Carcinoma-in-sit	1000	800	200
3	Carcinoma invasive	1000	800	200
4	Normal	1000	800	200

The strategic use of data augmentation is implemented to address overfitting concerns in CNNs while concurrently improving the accuracy of disease detection. Fig. 2 provides a visual depiction of images within the dataset and a comprehensive overview of the image distribution.

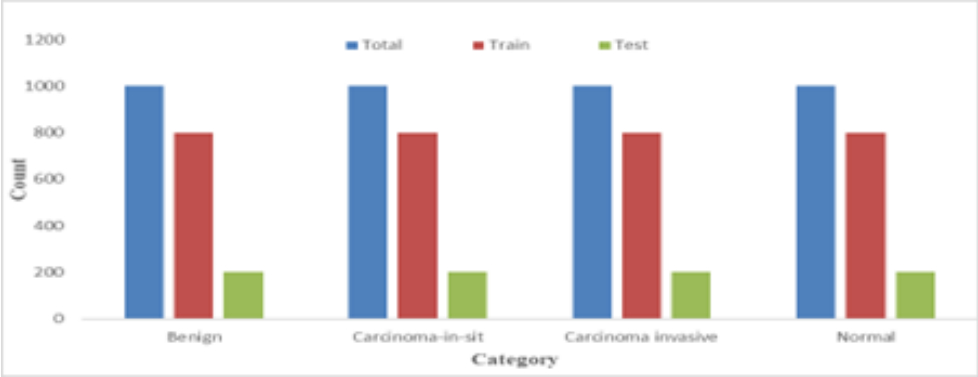

Fig. 2. Distribution of various categories in dataset.

B. Breast Cancer Classification using Transfer Learning

While dealing with histopathological images, the utilization of ResNet-152v2 stands as a pivotal advancement in leveraging deep learning for enhanced diagnostic accuracy. ResNet-152v2, renowned for its depth and skip-connection architecture, proves instrumental in capturing intricate patterns and subtle features crucial for discerning between cancer categories [22]. This classification model benefits from its ability to mitigate vanishing gradient issues, allowing for effective training of deep networks using TL technique. This approach facilitates a more nuanced understanding of the complex structures present in histopathological images, empowering the model to provide precise and reliable identification of breast cancer pathology. The proposed model incorporating ResNet-152v2 and TL is illustrated in Fig. 3.

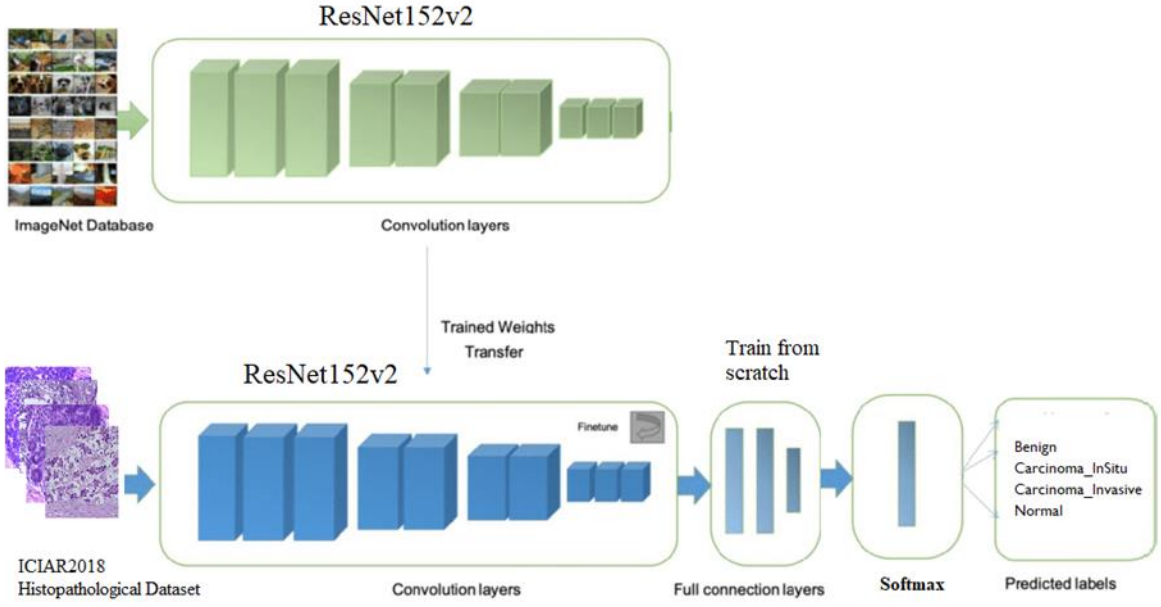

Fig. 3. Proposed transfer learning model.

To address the challenges associated with vanishing or exploding gradients during training, researchers introduced the concept of Residual Blocks. In the architecture of these Residual Networks (ResNets), a crucial technique called skip connections is employed. Skip connections establish links between the activations of one layer and subsequent layers by bypassing certain intermediary layers. This design creates what is known as a residual block, which is a fundamental building block of ResNets. The strength of ResNets lies in their ability to stack these residual blocks together, forming a deep and interconnected network. By incorporating skip connections, ResNets facilitate the flow of information across layers, mitigating the issues of vanishing gradients and enabling the training of exceptionally deep neural networks. This design principle has proven effective in improving the optimization process and fostering the successful training of deep model. The process flow and working of the skip connections is illustrated in Fig. 4.

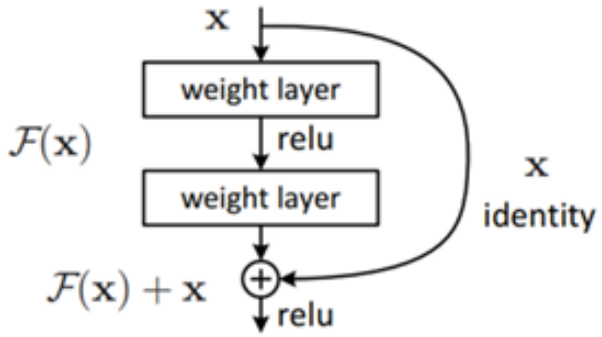

Fig. 4. Skip (Shortcut) connections.

The methodology employed in this network diverges from conventional layer-wise learning of the underlying mapping. Instead, we enable the network to adapt to the residual mapping. Thus, rather than expressing it as H(x), the initial mapping, we encourage the network to adjust according to Eq. (1) and Eq. (2).

$$F(x) = H(x) - x \tag{1}$$

$$H(x) = F(x) + x \tag{2}$$

The residual block in the proposed architecture is expressed using Eq. (3). This equation provides an insight about the output of the network. Here, x is the input to the block, Wi represents the learnable parameters, and F is a residual function implemented by a series of convolutional layers. The output y is the sum of the residual function and the input, allowing for the bypass of information is expressed as in Eq. (3).

$$y = F(x, \{W_i\}) + x \tag{3}$$

The inclusion of skip connections offers a notable benefit: if a particular layer negatively impacts the architecture's performance, regularization allows it to be bypassed. Consequently, this permits the training of extremely deep neural networks without encountering issues related to vanishing or exploding gradients. The ResNet architecture pioneered the concept of employing deeper networks [23]. The skip connection technique facilitates the training of highly deep networks, contributing to enhanced model performance. By preserving acquired knowledge during training, residual connections expedite the training process, effectively amplifying the network's capacity.

ResNet152V2 stands out as a residual network comprising an impressive 152 layers. Its primary function involves feature extraction from images by training input images based on pre-existing weights [24]. The architectural makeup of this model encompasses various layers, including reshape, flatten, the first dense layer, dropout, the second dense layer, and an activation layer dedicated to predicting image classes. Given its considerable depth and a multitude of parameters, ResNet152V2 proves particularly well-suited for intricate tasks, especially in scenarios where datasets are extensive and diverse. It's important to highlight that initiating training for ResNet152V2 from scratch demands a substantial amount of labeled data and significant computational resources. This proves especially beneficial when confronted with limited data or computational resources. The proposed architecture, as illustrated in Fig. 5, encapsulates the key components of this sophisticated model.

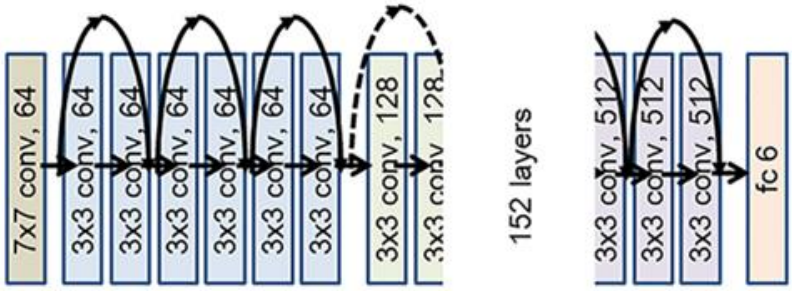

Fig. 5. ResNet152 V2 architecture.

The architecture of proposed classifier within the context of multi-classification comprises of two distinct components: the reduction path and the classifier head. The reduction path follows conventional convolutional network design principles, incorporating repeated convolutions and max-pooling operations to facilitate down sampling [25]. This process involves iteratively applying three stages, collectively termed a "block," multiple times, contributing depth to the network. The sequence concludes with fully connected layers that form the classifier. Critical to this architecture are the convolutional layers, pivotal in computing local weighted sums, commonly known as 'feature maps,' at each layer. These feature maps are generated by the repeated application of filters across the entire dataset, significantly enhancing training efficiency. The

iterative application of these processes contributes to the network's depth and its ability to capture intricate patterns in the data. In the concluding stage, an activation function, specifically the softmax function, is employed to categorize the outputs of the model into different classes, covering various aspects of breast cancer cases. This crucial step equips the model with the ability to make nuanced and precise predictions, ultimately enhancing its diagnostic capabilities. Table II provides a detailed examination of the network's structure, encompassing the arrangement of layers and corresponding parameters.

TABLE II. PROPOSED TRANSFER LEARNING MODEL SUMMARY

Layers	Type	Output Shape	Parameters
Input Layer	Dense	256 x 256 x 3	-
ResNet152v2	Feature Transfer	8 x 8 x 2048	58331648
Convolution Layer	Conv2D	8 x 8 x 64	131136
Max pooling layer	Maxpooling2D	4 x 4 x 64	0
Convolution Layer	Conv2D	4 x 4 x 32	2080
Convolution Layer	Conv2D	4 x 4 x 64	2112
Dense	Dense	4 x 4 x 32	4160
Dense	Dense	4 x 4 x 64	2080
Flatten	Flatten	512	0
Dense	Dense	4	2052
Total			58,475,268
Trainable			143,620
Non-Trainable			58,331,648

The initial step involves transferring features and weights from a pre-trained ResNet152v2 model, originally trained on the ImageNet dataset. Following this, the data undergoes a series of processing steps, including convolutional operations, max-pooling, dense layers, flattening, and hidden layers. These operations result in a final output comprising six distinct classes, facilitating individual class predictions. During the model's training and validation, a batch size of 128 and a total of 25 epochs were utilized. 25 epochs are the optimal value required for the TL model to converge. It was noted that at this epoch count, both the loss and accuracy metrics stabilize, yielding the most favorable and consistent results. Fig. 6 provides a visual representation of the proposed TL model tailored for the ICAIR 2018 dataset. This schematic diagram provides an overview of the model's architecture, initiating with six distinct classes and setting the stage for robust classification.

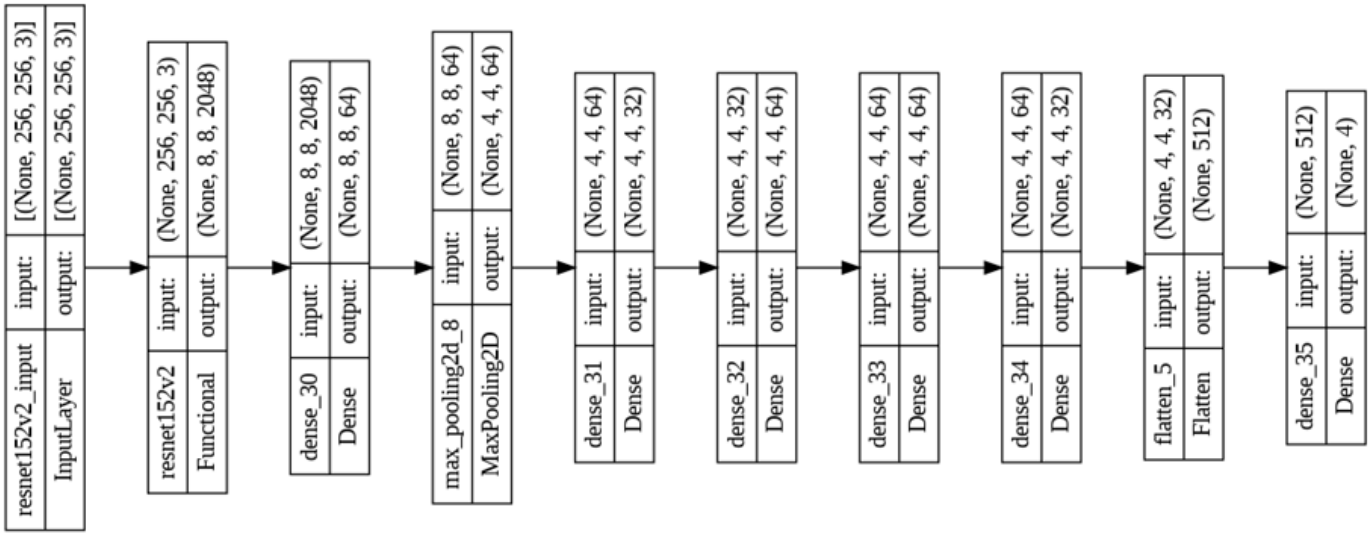

Fig. 6. Proposed transfer learning model.

IV. RESULTS AND DISCUSSION

The systematic investigation involves the extraction of features from various levels within the CNN, placing a specific focus on evaluating the granularity of these features in relation to their performance in classification tasks. This process includes utilizing different layers of the CNN to obtain these features. An integral part of the research revolves around

identifying the optimal CNN layer that produces the most distinctive features for the classification of histopathological images into distinct categories. This holds particular significance considering the training of the TL-CNN model on the ICAIR 2018 dataset. The primary objective of the study is to unveil the CNN layer that offers the most valuable insights for distinguishing between different classes of breast cell images, ultimately enhancing the overall efficiency of the model.

In our suggested methodology, our emphasis lies specifically on the profound layers of the model, leveraging their output features to train the classifier, while maintaining the immobility of the layers leading up to this depth. This approach effectively trims down the number of trainable components, although a considerable number of features remain viable. Our training approach involves an 80% allocation for training and a 20% allocation for testing. Furthermore, for result comparison with previous studies, we ensure consistency by employing the same parameters in cross-validation and fixed partitioning methodologies. The development of the proposed model is executed using Python on the Google Colab platform. We have implemented a learning rate of 1x10-4 for this work, accompanied by a minimized batch size of 128 and a total of 25 training epochs. The loss the model needs to be reduced after each epoch. The loss becomes low and constant after 7 epochs. The accuracy also turns out to be constant after 7 epochs. Fig. 7 provides a graphical representation of the training and validation performance of the proposed TL-CNN classifier.

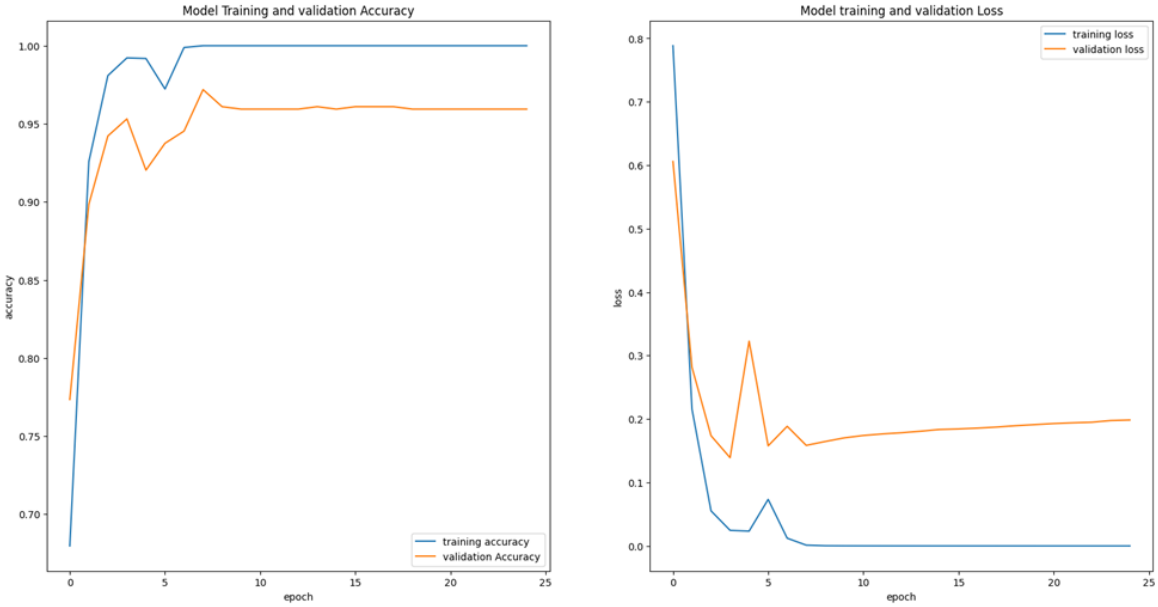

Fig. 7. Accuracy plot and loss plot of proposed model.

To comprehensively evaluate the effectiveness and operational efficiency of the model we suggest, we utilize a suite of four pivotal metrics: F1-score, accuracy, precision, and recall. In defining these metrics, we incorporate the terms False Positive (FP), False Negative (FN), True Negative (TN), and True Positive (TP), which are fundamental for evaluating model performance. These performance parameters are expressed mathematically as in Eq. (4), (5), (6) and (7).

$$Precision = \frac{TP}{TP+FP} \quad (4)$$

$$Recall = \frac{TP}{TP+FN} \quad (5)$$

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} \quad (6)$$

$$F1-Score = 2 \times \frac{Precision \times Recall}{Precision+Recall} \quad (7)$$

Beyond the 7th epoch in the proposed ResNet152v2 based CNN classifier, the performance metrics consistently display a commendable level of accuracy. This stability in performance can be credited to the effective application of TL techniques, addressing challenges inherent in categorization tasks. Within the training process, the consideration of errors, often referred to as loss, is crucial. In our case, the observed loss is merely 0.3, indicating an exceptionally low level of error. To comprehensively evaluate the model, the entire test image dataset was employed. The mean accuracy achieved by our suggested TL-CNN model reaches an impressive value of 96.47%. Additionally, the mean values for precision, recall, and F1-score showcase strong performance, measuring at 96.24%, 96.63%, and 97.18%, respectively. Table III provides the classification report for the proposed multiclass classification model.

TABLE III. CLASSIFICATION REPORT OF PROPOSED CLASSIFIER

Category	Precision (%)	Recall (%)	F1-Score	Accuracy (%)
Benign	96	96	96	95
Carcinoma-in-Situ	97	92	95	97
Carcinoma-Invasive	96	97	97	96
Normal	95	98	96	97

The effectiveness of the proposed model is notably impressive in accurately identifying the breast cancer classes. Moreover, it maintains a minimum accuracy of 95% with benign class. This model provides maximum accuracy of 97% with carcinoma-in-situ and normal classes. Precision analysis reveals that the model attains its peak value of 97% for carcinoma-in-situ class. The lowest precision, still notably high at 95%, is observed in the normal class. Moving on to recall, the model reaches a maximum value of 98%, for the normal class. The lowest recall of 92% is noted in carcinoma-in-situ class. F1-score achieves a maximum value of 97% for the carcinoma-invasive class and maintains a minimum value of 95% for the carcinoma-in-situ class. In summary, the classification report underscores the superior performance across all classes. The proposed model demonstrates particular proficiency in identifying various classes within the given dataset. For a detailed perspective on the performance of individual classes, (see Fig. 8). Additionally, Fig. 9 illustrates the confusion matrix generated for the proposed classifier, offering a comprehensive visualization of the classification performance across various breast cancer categories.

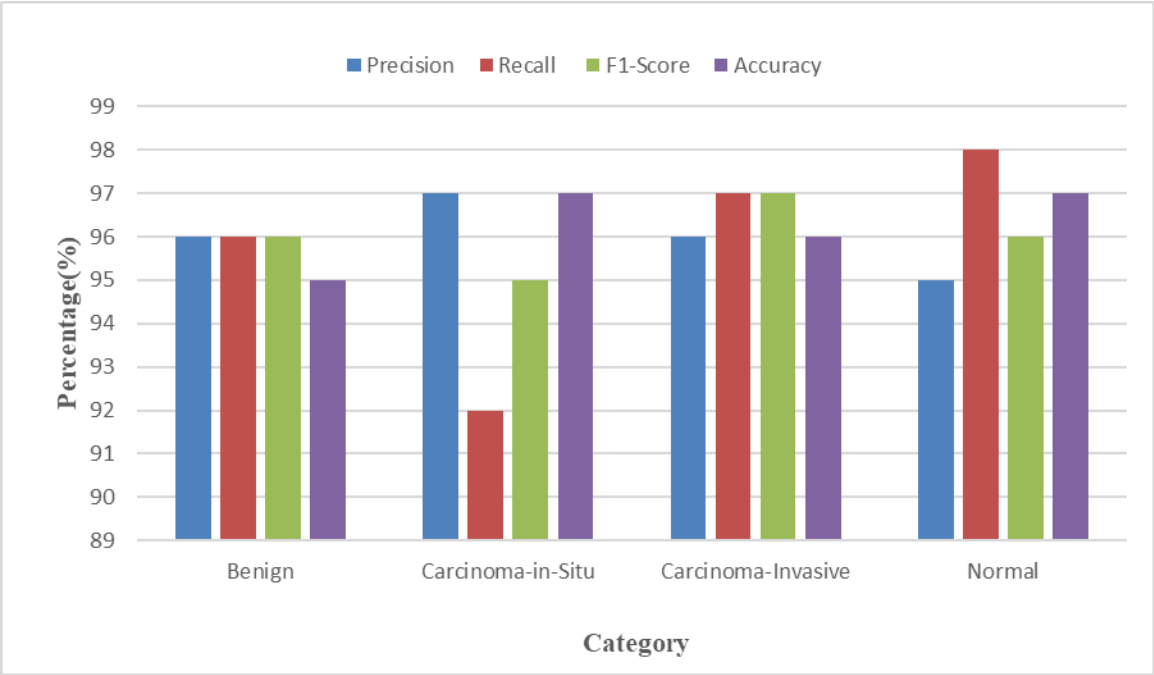

Fig. 8. Category wise classification performance of proposed classifier.

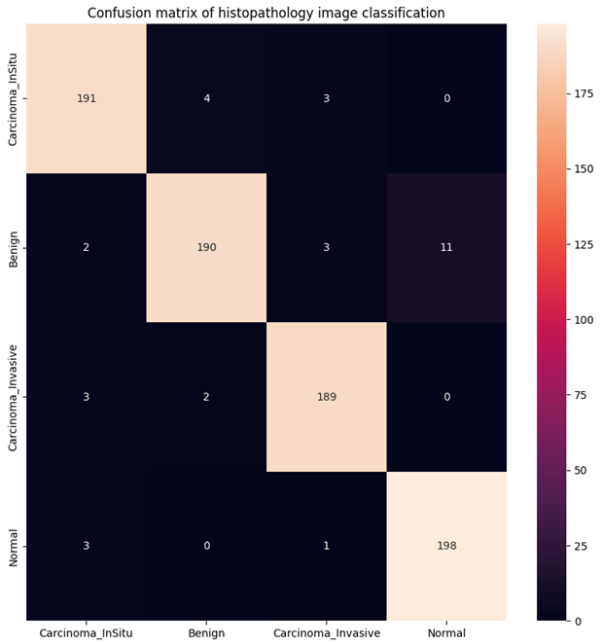

Fig. 9. Confusion matrix of proposed classifier.

In evaluating the effectiveness of the constructed model, it is imperative to conduct a thorough comparison of their classification performance. The assessment of the proposed TL models' classification performance is conducted across diverse datasets. Table IV analyzes of the efficiency of existing models using the selected performance metrics.

TABLE IV. PERFORMANCE COMPARISON

Model	Precision (%)	Recall (%)	F1-score (%)	Accuracy (%)
AlexNet	93.71	95.32	94.35	94.14
GoogleNet	88.44	89.45	86.65	89.42
ResNet 50	92.14	91.67	92.36	92.36
VGG16	93.86	93.83	94.12	93.15
Inception v3	89.31	87.61	88.38	86.11
ResNet152v2-CNN (Proposed)	96.24	96.63	97.18	96.47

In the assessment of classification accuracy, the proposed model distinguishes itself with the highest score of 96.47%. Noteworthy among the pre-trained models are VGG16 with an accuracy rate of 93.15%, ResNet50 at 92.36%, and AlexNet demonstrating a performance of 94.14%. Turning to precision, the proposed model excels with an impressive precision rate of 96.24%. In contrast, AlexNet achieved 93.71% precision, ResNet50 recorded 92.14%, and VGG16 obtained 93.86%. Proposed model attains an outstanding recall value of 96.63%, outperforming all other models in this metric. In comparison, VGG16 achieved a recall rate of 93.83%, ResNet 50 reached 91.67%, and AlexNet recorded 95.32% in recall. Remarkably, the proposed model's recall surpasses other TL models by a significant margin, demonstrating its superiority in capturing and correctly identifying relevant instances. Furthermore, in assessing the F1-score, the proposed model once again takes the lead with a score of 97.18%. There is a noticeable difference between the F1 score of proposed model and existing TL approaches, underscoring the proposed model's overall effectiveness in achieving a good balance between precision and recall. Overall, the proposed model not only exhibits the highest accuracy for breast cancer categorization but also emphasizes the crucial role of specific parameters, particularly TL, in mitigating overfitting and elevating classification accuracy. For a visual comparison of the proposed model with existing classifier (see Fig. 10).

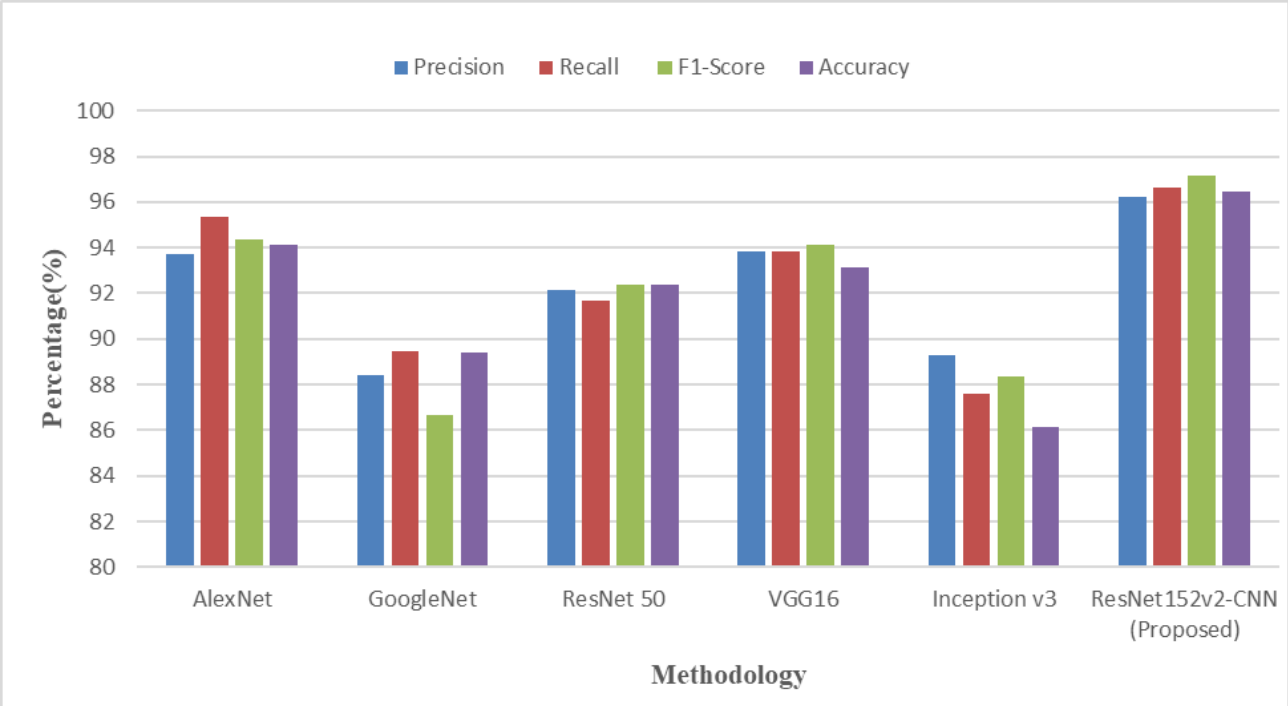

Fig. 10. Performance comparison.

Primary among the benefits is the complete automation of the classification process, eliminating the necessity for manual intervention. Tasks such as feature extraction, noise filtering, delineation of regions, and selection become obsolete. As a result, the predictions provided by the proposed model not only become automated but also consistently reproducible, free from any inherent bias. The prediction results generated by the proposed model along with the ground truth are provided in Fig. 11.

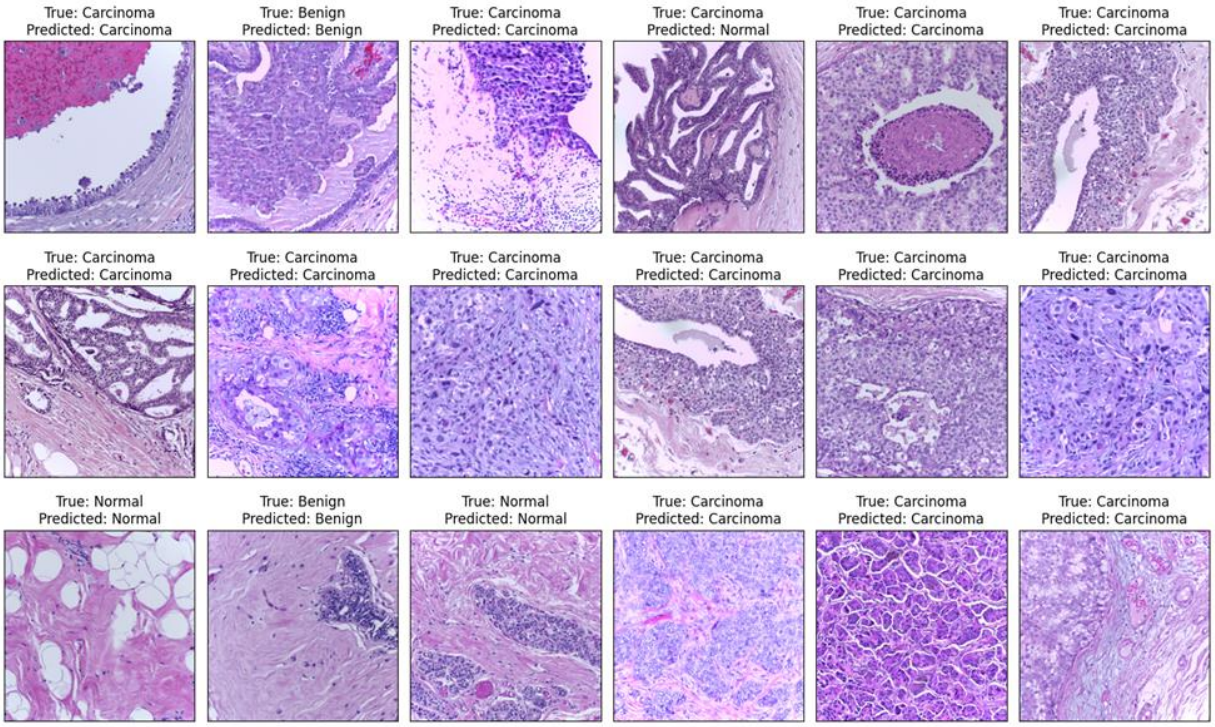

Fig. 11. Prediction outputs.

V. Conclusion

This study focused into the efficacy of TL in the classification of breast cancer through the analysis of histopathological images. The integration of TL with CNN structures proved to be an exceptionally efficient strategy, resulting in peak recognition rates. Notably, the ResNet152v2-CNN model proposed in this research achieved remarkable accuracy (96.47%), precision (96.24%), F1-score (97.18%), and recall (96.63%) in the identification of potential breast cancer cases. One notable advantage of the proposed model lies in their capacity to diminish or even eliminate the need for extensive pre-processing stages, surpassing existing techniques in this aspect. Interestingly, when contrasted with the proposed model, the pre-trained AlexNet classifier demonstrated inferior performance across various performance metrics. Future research endeavors will focus on optimizing the deployment of the proposed model on mobile platforms, addressing computing complexity issues. Additionally, there will be an exploration of further fine-tuning methods and strategies, promising ongoing advancements in histopathological image classification.

Acknowledgment

I would like to express my sincere gratitude to all those who contributed to the completion of this research paper. I extend my heartfelt thanks to my supervisor, my family, my colleagues and fellow researchers for their encouragement and understanding during the demanding phases of this work.

***Abstract*—Content-Based Medical Image Retrieval (CBMIR) is a widely adopted approach for retrieving related images by the comparison inherent features present in the input image to those stored in the database. However, the domain of CBMIR specific to multiclass medical images faces formidable challenges, primarily stemming from a lack of comprehensive research in this area. Existing methodologies in this field have demonstrated suboptimal performance and propagated misinformation, particularly during the crucial feature extraction process. In response, this investigation seeks to leverage deep learning, a subset of artificial intelligence for the extraction of features and elevate overall performance outcomes. The research focuses on multiclass medical images employing the ImageNet dataset, aiming to rectify the deficiencies observed in previous studies. The utilization of the CNN-based Autoencoder method manifests as a strategic choice to enhance the accuracy of feature extraction, thereby fostering improved retrieval results. In the ImageNet dataset, the results obtained from the proposed CBMIR model demonstrate notable average values for accuracy (95.87%), precision (96.03%) and recall (95.54%). This underscores the efficacy of the CNN-based autoencoder model in achieving good accuracy and underscores its potential as a transformative tool in advancing medical image retrieval.**

***Keywords*—Medical image retrieval; multiclass medical images; artificial intelligence; deep learning; convolutional neural network; autoencoder**

I. INTRODUCTION

Content Based Medical Image Retrieval (CBMIR) plays a pivotal part in modern healthcare, leveraging the developments in Deep Learning (DL) to enhance efficiency and accuracy of diagnosing and treating various medical conditions. As medical imaging technologies continue to evolve, the vast amount of digital medical images generated necessitates robust and intelligent retrieval systems. DL, a subset of Artificial Intelligence (AI), has emerged as a transformative force in the field, offering unprecedented capabilities in feature extraction and pattern recognition. This research delves into the area of CBMIR, exploring the application of DL techniques to navigate and retrieve relevant information from extensive medical image databases [1]. The integration of DL models not only streamlines the retrieval process but also contributes to the overall improvement of diagnostic accuracy and clinical decision-making. In this comprehensive examination, we delve into the key methodologies, challenges, and breakthroughs associated with CBMIR using DL, shedding light on the promising future it holds for the medical community [2].

The fusion of cutting-edge technology and healthcare exemplifies a synergy that has the potential to revolutionize patient care and medical research. Through an exploration of various DL architectures and their adaptations to the intricacies of medical images, this work provides implications for the future of CBMIR. In navigating the intricate landscape of medical data, DL proves to be an invaluable tool, offering a paradigm shift in how medical professionals access, analyze, and leverage the wealth of information embedded in medical images [3]. The integration of DL into CBMIR not only addresses the challenges posed by the sheer volume of data but also opens avenues for novel insights, early disease detection, and personalized treatment strategies. As we embark on this exploration, it is evident that the combination of medical imaging and DL is poised to redefine the landscape of healthcare, paving the way for more precise diagnoses, timely interventions, and improved patient outcomes [4].

DL can automatically obtain hierarchical representations from images and provide a compelling solution to the complex task of CBMIR. By leveraging Convolutional Neural Network (CNN) and other sophisticated architectures, DL models can discern subtle patterns and relationships within medical images that may elude traditional retrieval methods [5]. The synergy between the depth of neural networks and the intricacies of medical image content enables the extraction of high-level features crucial for accurate retrieval and analysis. Heterogeneity of imaging modalities, ranging from X-rays and MRIs to CT scans and beyond [6] is a serious issue. DL algorithms, through transfer learning and domain adaptation, demonstrate their adaptability to diverse imaging sources, promising a unified framework for efficient retrieval across modalities [7].

Autoencoders, with their capacity to learn compact and informative representations of input data, are examined for their utility in extracting latent features from medical images [8]. Whether applied to X-rays, MRIs, or CT scans, autoencoders demonstrate their versatility in capturing intrinsic features, thereby enhancing the robustness of CBMIR systems across a spectrum of medical image types. An in-depth discussion on the potential synergy between autoencoders and other DL architectures, such as CNN, is presented [9]. The combination of these models provides a comprehensive

framework for medical image retrieval, where autoencoders contribute to feature extraction and CNNs leverage these extracted features for accurate CBMIR. Furthermore, the paper addresses the interpretability of autoencoder-based models, highlighting how the encoded representations can be harnessed for visualizing and understanding the salient features within medical images [10]. This interpretative aspect not only fosters trust in the model's decision-making process but also facilitates the identification of clinically relevant patterns that may elude traditional CBMIR techniques. The major contribution of the proposed work includes:

- Integration of two powerful techniques, autoencoder and CNN, to tackle content-based retrieval of multimodal medical images.
- Provides a solution to efficiently search and retrieve images based on their content, enabling better diagnosis, treatment planning, and research in healthcare.
- Enhances retrieval accuracy and efficiency compared to traditional methods by leveraging deep learning techniques.

II. Literature Review

CBMIR witnessed transformative advancements with the integration of DL techniques. In the area of multimodal image representation, the effective retrieval of relevant medical images plays a pivotal role in ensuring accurate and timely diagnoses. This survey examines the recent developments and contributions of DL methods, specifically focusing on CBMIR for multimodal diagnosis images.

Ozturk [11] introduced an approach for radiological image retrieval by employing deep features extracted through CNN. The study demonstrates an enhancement in retrieval performance, showcasing the potential of DL in streamlining radiological diagnosis. The automated feature extraction process proves crucial in improving the efficiency of the diagnostic workflow, providing valuable insights for the integration of DL in medical imaging applications. Liu et al. [12] propose an innovative technique utilizing autoencoder architectures for feature extraction in cross-modality image retrieval. The research highlights the versatility of autoencoders in handling various medical imaging modalities, showcasing improved performance and robustness. By minimizing misinformation, this work contributes significantly to the reliability and accuracy of cross-modality image retrieval, offering potential advancements in diagnostic capabilities across diverse imaging technologies. Cai et al. [13] conducted a comprehensive comparative analysis of multiple CNN architectures for medical image retrieval. The findings reveal substantial variations in retrieval accuracy based on the selected network architecture, providing critical insights for practitioners in choosing optimal models for specific medical imaging applications. This study underscores the influence of network architecture on the performance of medical image retrieval systems, aiding informed decision-making for the development and implementation of DL technologies in clinical settings.

Li et al. [14] analyzed the robustness of CNN-based autoencoders in the realm of CBMIR. The study evaluates the performance of these models across various medical imaging modalities and assesses their ability to handle noisy or low-quality images. By investigating the robustness of CNN-based autoencoders, the research contributes valuable insights into the reliability of these models in real-world clinical scenarios. The findings provide guidance on the potential challenges and opportunities in deploying such models for CBMIR applications. Guan et al. [15] concentrate on improving the interpretability of features extracted by CNN in CBMIR. The study introduces methodologies for visualizing and understanding critical features, enhancing transparency in the decision-making process. This research marks a crucial step toward building trust in DL models and refining their interpretative capabilities for real-world medical applications. Shen et al. [16] explored the application of federated learning for privacy-preserving CBMIR. This research underscores the potential of federated learning in maintaining data security while advancing CBMIR capabilities.

Liu et al. [17] focused on investigating semi-supervised DL approach in CBMIR. This work demonstrates the potential of leveraging unlabeled data to enhance model performance, addressing challenges associated with limited labeled datasets. By incorporating semi-supervised learning, the study contributes to the adaptability of CBMIR systems across diverse clinical scenarios. Bouchareb et al. [18] delve into ethical considerations associated with AI-driven diagnostic imaging. The study emphasizes transparency, accountability, and the mitigation of biases in the deployment of DL models for diagnostic purposes. By addressing ethical concerns, this research contributes to responsible AI practices in the evolving landscape of CBMIR. Swati et al. [19] provide a broader perspective by exploring applications of DL in precision medicine for medical imaging. The study highlights the potential for personalized treatment strategies based on CBMIR results, showcasing the transformative impact of DL in tailoring medical interventions to individual patient needs. Jaiswal et al. [20] focused on exploring the applications of transfer learning in the context of CBMIR. By adapting knowledge learned from one domain to another, transfer learning proves to be a valuable strategy for addressing challenges associated with limited labeled medical image datasets. The study provides insights into the potential of transfer learning to improve the generalization capabilities of DL models in the medical imaging domain. This research contributes to the ongoing efforts in making medical image retrieval systems more adaptable and effective in diverse clinical settings.

This review showcased the evolution of CBMIR in multimodal diagnosis, emphasizing the transition from traditional CBMIR to sophisticated DL models. The integration of CNN-based Autoencoders presents a promising avenue for addressing challenges in feature extraction and enhancing overall performance. This research continues to explore innovative methodologies and datasets to advance the capabilities of DL in CBMIR for multimodal diagnosis.

III. Materials and Methods

In this research, we present a novel CBMIR system designed specifically for multimodal diagnosis images associated with various diseases. Our primary focus is to overcome limitations identified in previous studies, and to achieve this, we employ the CNN-based autoencoder methodology. The rationale behind adopting the CBMIR approach lies in its demonstrated efficacy in optimizing both the feature extraction process and the learning phase. This strategic utilization aims to rectify and minimize inaccuracies that may have been prevalent in earlier research endeavors. The CNN-based Autoencoder method plays a crucial role in amending misinformation issues that might have arisen in the feature extraction process during previous studies. By leveraging the power of DL, this approach not only refines the accuracy of feature extraction but also contributes to an overall improvement in the system's performance in essence; this research positions the CBMIR system, enhanced by the CNN-based autoencoder method, as a robust solution for retrieving multimodal diagnosis images. By addressing and mitigating misinformation concerns, we aim to contribute to the advancement of CBMIR methodologies, fostering precision and reliability in the context of subclass dataset categorization. The process flow of proposed methodology is depicted in Fig. 1.

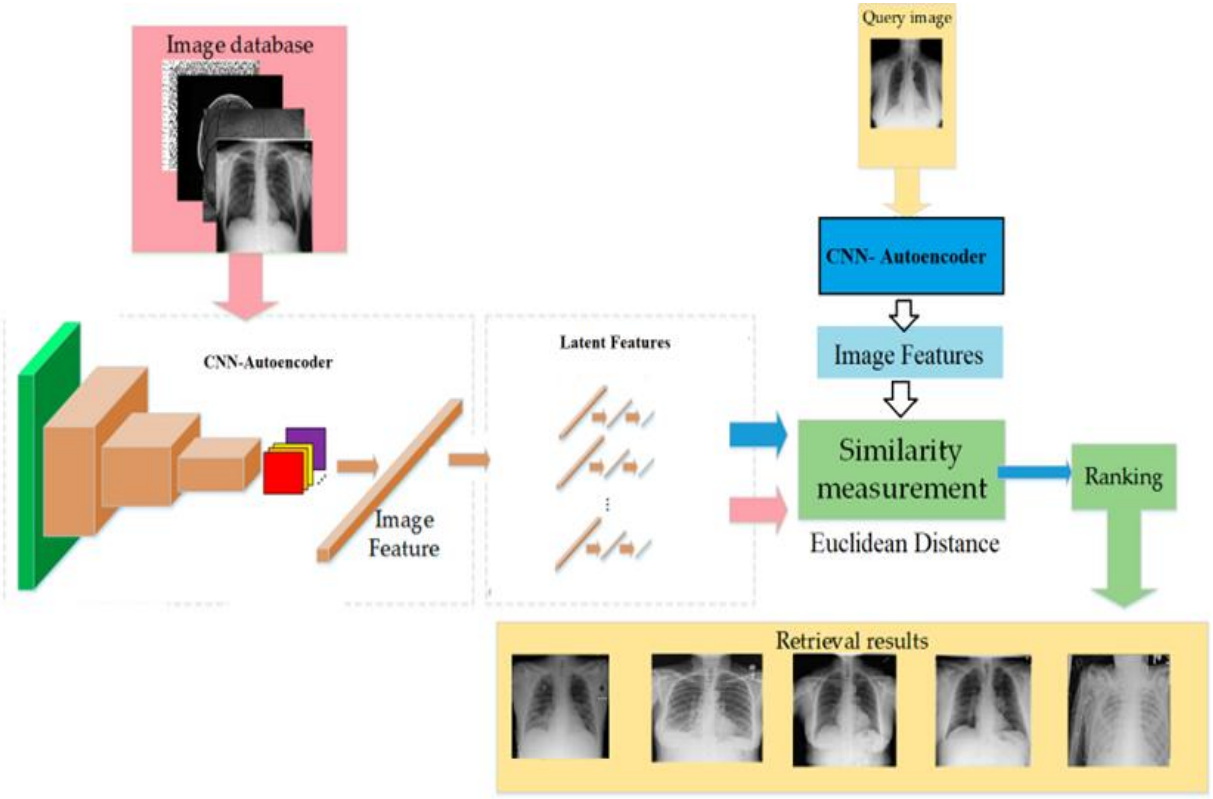

Fig. 1. Basic block diagram of proposed method.

A. Dataset Description

The dataset comprising around 50,000 2D images, sourced from diverse and easily accessible open-access medical databases like ImageNet. The primary objective of this compilation is to enable the differentiation among Magnetic Resonance Imaging (MRI), X-ray Electroencephalograph (EEG), and OCT. ImageNet stands as a vast image repository that has played a pivotal role in propelling forward the realms of computer vision and DL research. Notably, the dataset encompasses images of varying data sizes, providing a comprehensive and diverse set of examples for training and evaluation purposes in the context of multimodal medical image analysis. The dataset has been categorized into four primary classes, encompassing X-ray, MRI, OCT, and EEG modalities. A visual representation of a sample image from the dataset, utilized in the present study, is depicted in Fig. 2. This division into distinct classes serves as a foundational structure for the dataset, facilitating a nuanced exploration and analysis of varied medical imaging modalities.

B. Proposed Model Architecture

The Autoencoder process involves three key stages: Encoder, Decoder, and the computation of the Calculating Function and Optimization Errors. During the encoding phase, input data undergoes a transformation into smaller dimensions, often referred to as compression. Employing Conv2D (2D Convolution Layer), the input image is transformed to 48 nodes (latent dimension). This latent representation must then be converted back to initial state. Decoding process utilizes transpose operation to generate the reconstructed image. Loss calculation for each function is iteratively performed to determine the function with the lowest loss value. In this research, the selected loss function is Mean Square Error (MSE). Fig. 3 illustrates the structure of designed autoencoder.

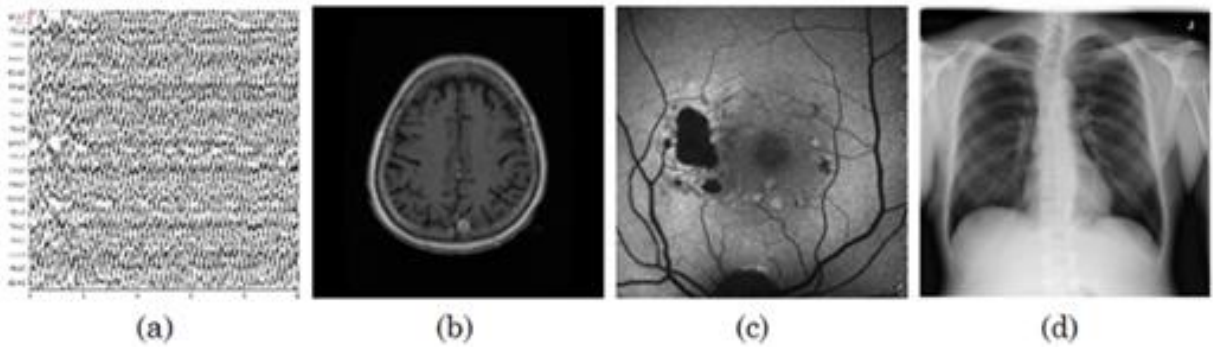

Fig. 2. Sample images from dataset (a) EEG, (b) MRI, (c) OCT, (d) X-Ray.

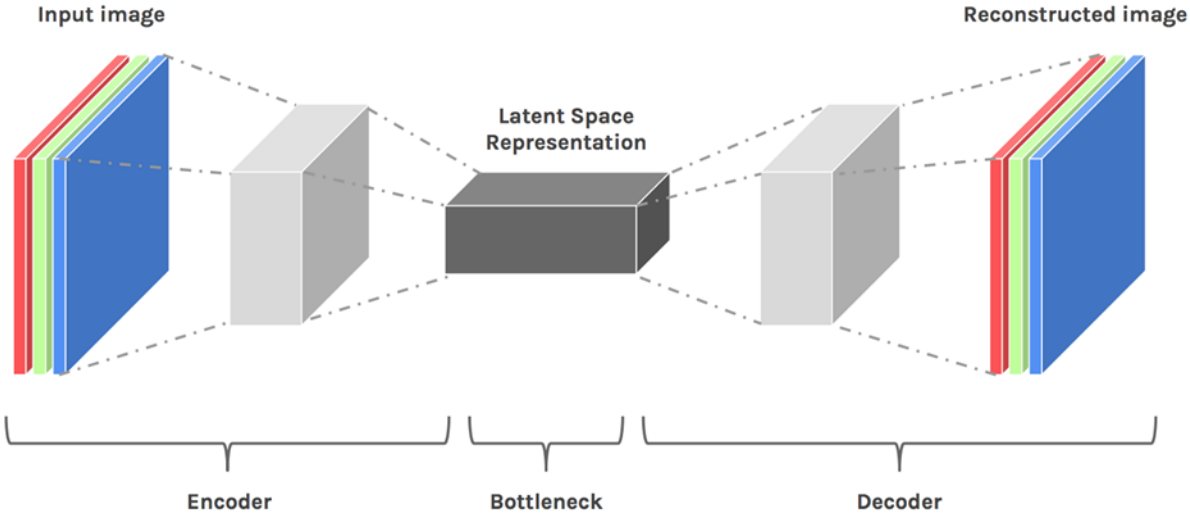

Fig. 3. Structure of the proposed autoencoder.

The commencement of the training process in this investigation involves segregating images into three subsets: training (80%), validation (10%), and testing (10%). Employing the CNN- Autoencoder model, the original image is transformed into a reconstructed image. The Autoencoder involve in the extraction of output image to reconstruct the input image, facilitating a comparison with the original input image [21]. Following this, the learning process initiates, and through numerous iterations, the optimal model is obtained and saved, featuring the lowest loss value in relation to the extraction and retrieval stages. The training data includes the segmented data for training, while the validation data evaluates the developed model. Additional explanation of phases in the training process is provided in Fig. 4.

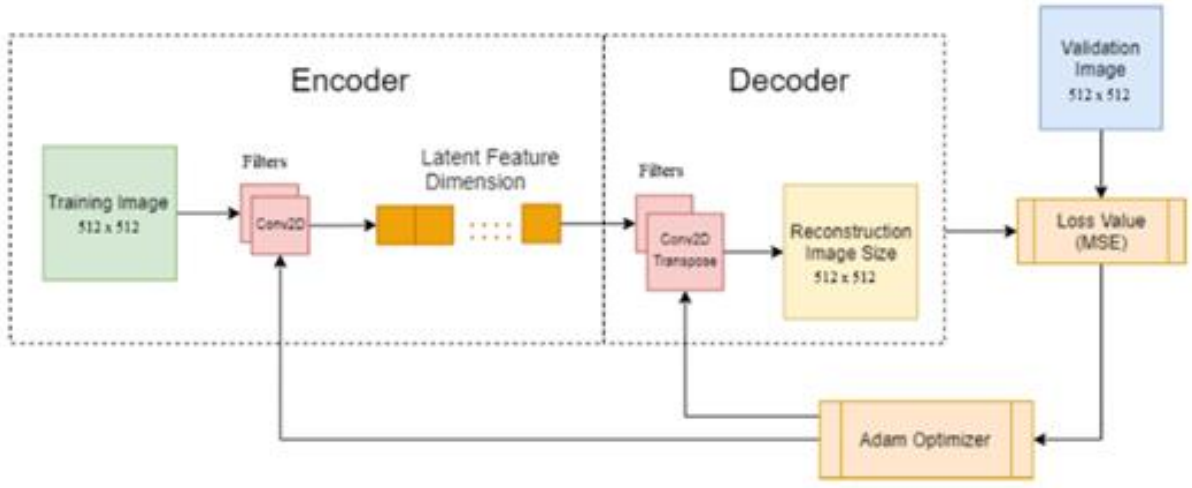

Fig. 4. Process flow of training.

During the encoder stage, the input data undergoes compression. Conv2D, with modified default parameters, employs a stride of 2 for convolution, along with "same" padding value. This ensures even distribution of zero-value padding convolution. With 128 filters having 3x3 kernels, Leaky Relu is applied, which is recognized for its effectiveness in overcoming gradient loss issues in DL. Leaky Relu is preferred over its predecessors, sigmoid and Tanh, for its simplicity and improved performance [22]. The Leaky Relu function is defined by the following equation.

$$f(x) = \begin{cases} x, x \geq 0 \\ ax, x < 0 \end{cases} \quad (1)$$

The LeakyRelu activation function incorporates a parameter known as alpha, representing the negative slope coefficient, and in this study, it is set to 0.2.

In a parallel arrangement to the encoder, the decoder employs a convolution method with 128 filters and a filter having 3x3 kernels, maintaining the same activation function but with a distinct approach to processing. The decoder employs transposed data from the latent dimension to produce the reconstructed image. Upon the conclusion of both the encoder and decoder stages, the procedure progresses to the error calculation and optimization phase. In this phase, iterative loss calculations are performed for each function, aiming to pinpoint the function with the minimum loss value [23]. The chosen loss function for this study is the Mean Square Error (MSE), calculated through Eq. (2). Here, pi is the predicted image and yi is the actual image.

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(p_i - y_i)^2 \quad (2)$$

In the process of optimizing CNNs, the weighted values and biases of the convolutional layers undergo updates through the utilization of the Adam's algorithm. This algorithm, known for its efficiency in optimization tasks, plays a crucial role in adjusting these parameters. To initiate the learning process, a standard learning rate of 1e-3 is employed, serving as a foundational value for the optimization algorithm. Moreover, a learning rate scheduler is integrated into the training procedure, incorporating a decay parameter set at a rate of 2e-5. This scheduler dynamically adjusts the learning rate during the training epochs, enabling a gradual decrease in the learning rate over time. This adaptive learning rate scheduling contributes to the model's stability and convergence during the optimization process. By leveraging these techniques, the convolutional layers continually adapt their weighted values and biases to improve its ability to obtain meaningful features. The thoughtful integration of optimization strategies, such as the Adam's optimization algorithm and learning rate scheduling, is essential for achieving robust and effective performance in CNN training.

Feature extraction involves the retrieval of distinctive attributes from an image, which are subsequently scrutinized for subsequent processes. Following this, the acquired features are recognized to establish distinctions between images [24]. As depicted in Fig. 5, extraction of features is executed by utilizing the stored optimal model.

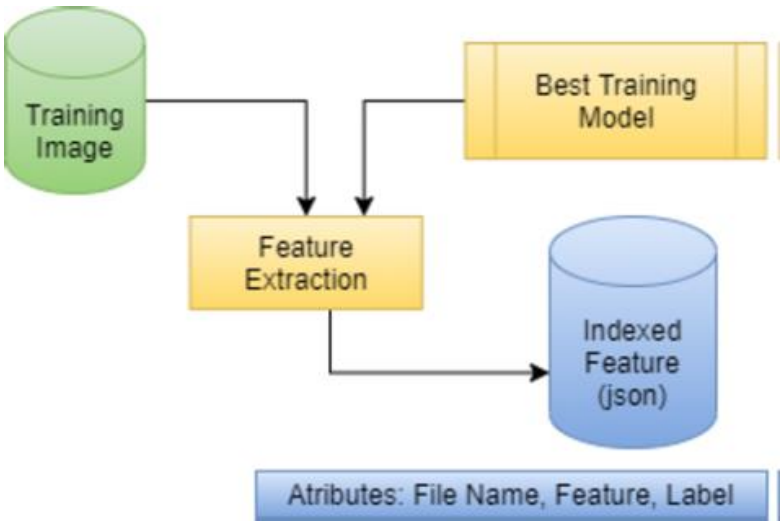

Fig. 5. Feature extraction process.

The outcomes of this feature extraction process are systematically cataloged to create a ".json" (JavaScript Object Notation) file. This file not only includes the extracted features but also incorporates the image file names and labels associated with each image. The compilation of annotated images serves as a comprehensive database, pivotal for subsequent comparisons during the retrieval stage.

C. Image Retrieval

The retrieval process involves seeking identical images with reference to query image. The data, previously segregated into test data, undergoes feature extraction, mirroring the procedure in the preceding stage. Following the successful extraction of images, calculations ensue to determine the resemblances of features in test images and those indexed in the training set, saved in the ".json" file. In this work, the Euclidean Distance is specifically applied to quantify the distance similarity between two image vectors. A detailed depiction of the retrieval process is provided in Fig. 6.

Euclidean Distance is utilized for efficiently calculating the similarity distance between two vectors, irrespective of

their dimensionality—be it two-dimensional, three-dimensional, or beyond [25]. The comparison of the two feature vectors extracted from the features involves calculating the distance between them. This meticulous process ensures a robust evaluation of the similarity between images, employing a widely recognized distance calculation method within the domain of image retrieval. The Euclidean Distance is expressed through the following equation, frequently employed for measuring the distance between vectors [26]. Here de is the Euclidean distance, qi is the vector query image and bi is the vector present in train data.

$$d_e = \sqrt{\sum_{i=1}^{n}(q_i - b_i)^2} \quad (3)$$

Following the computation of distances between each image in the test data and all images within the training data, the resulting distance values are subjected to comparison. A smaller Euclidean value indicates a higher degree of similarity between images. As a result, the image possessing the smallest distance value is included in the retrieval process. In essence, this retrieval methodology prioritizes images that exhibit the closest proximity in terms of features, as quantified by the Euclidean distance. The selection of the top five most similar images enhances the comprehensiveness and accuracy of the retrieval process, providing a nuanced understanding of image similarity.

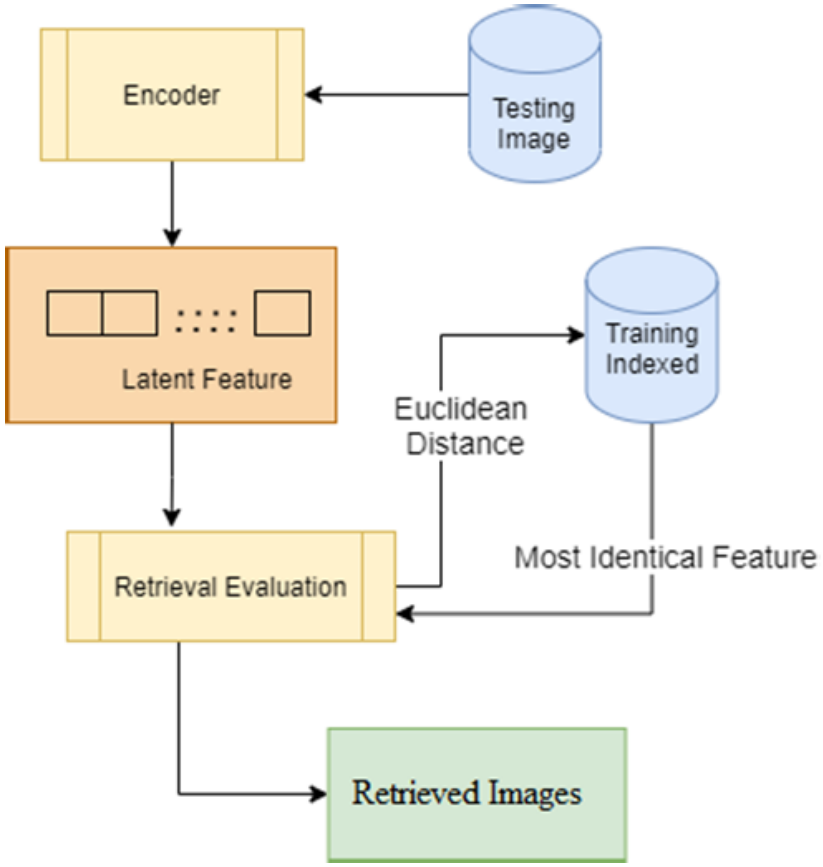

Fig. 6. Image retrieval process.

IV. Results and Discussion

The evaluation stage is crucial in assessing the effectiveness of the system developed within this research [27]. Precision and recall metrics are actively employed to gauge the success rate of the system, providing insightful measures of its performance. Initially, the retrieval process flow begins by taking an image from the test data as input. Utilizing the saved encoder model from the training phase, the system generates latent features and proceeds to the retrieval evaluation stage. In this stage, Euclidean distances are calculated based on the indexed .json file, employing information obtained from the previous feature extraction process flow. The ultimate output of this process includes precision and recall values, which serve as key indicators of the system's retrieval performance. Eq. (4) and (5) outline the formulas employed for calculating precision and recall in this context. Here Ir represents the count of retrieved images, n represents the count of images captured and M denotes relevant images present in the database.

$$Precision = \frac{I_r}{n} \quad (4)$$

$$Recall = \frac{I_r}{M} \quad (5)$$

As depicted in Fig. 7, the training phase during the testing of the dataset in all categories exhibits a gradual reduction in loss values up to epoch 35. The cumulative results across all categories yield loss values below 0.2, indicating a successful retrieval process. This signifies the efficacy of the training process in minimizing errors, enabling a robust and accurate retrieval of images across various imaging modalities.

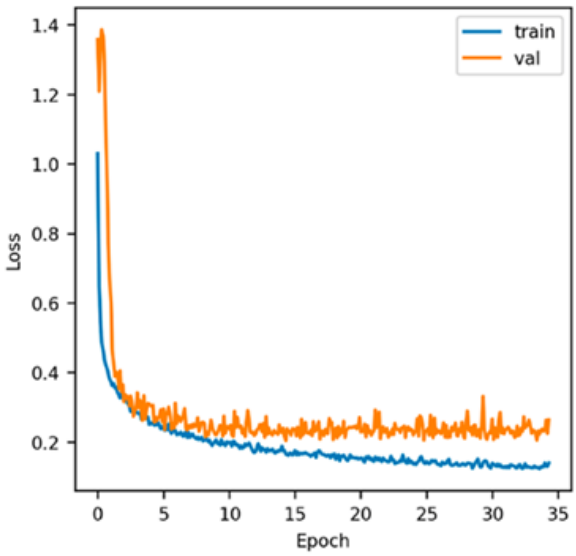

Fig. 7. Loss plot of proposed model.

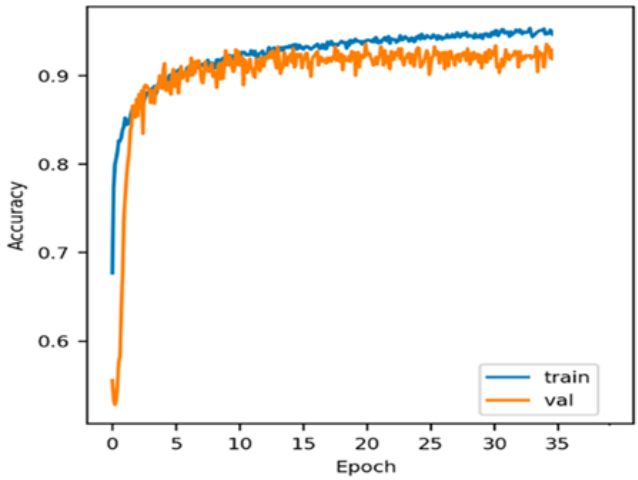

Fig. 8. Accuracy plot of proposed model.

As illustrated in Fig. 8, the training phase showcases a steady rise in accuracy values for all categories up to the 5th epoch, maintaining a consistent level thereafter. The collective outcomes across all categories yield an accuracy value surpassing 94%, underscoring the success of the retrieval process. This highlights the effectiveness of the training process in minimizing errors, facilitating a resilient and precise retrieval of images across diverse imaging modalities.

Upon conducting image retrieval using the implemented CBMIR model, the evaluation process provides crucial insights into the system's effectiveness, quantified through accuracy, precision and recall values. These metrics serve as key indicators of the system's ability to accurately retrieve relevant medical images based on content. The comparison of system performance involves assessing the proposed CBMIR system against varying number of retrieved images. This comparative analysis is conducted separately for each dataset category, with the results meticulously tabulated in Table I.

The evaluation results presented in Table I affirm that CNN-autoencoder based CBMIR model has achieved notable success in delivering suitable outcomes. The effectiveness of this model is demonstrated through its capability to enhance precision and recall values, signifying improvements in the accuracy and completeness of the image retrieval process. Overall, this evaluation adds empirical evidence to the merit of the proposed system in the context of CBMIR. Fig. 9 visually represents the performance of the CBMIR system proposed in this study.

TABLE I. PERFORMANCE EVALUATION

Retrieved Images (IR)	Accuracy (%)	Precision (%)	Recall (%)
20	98.34	97.84	98.42
40	97.56	97.15	97.15
60	96.11	95.48	94.87
80	94.35	95.66	94.24
100	93.00	94.00	93.00

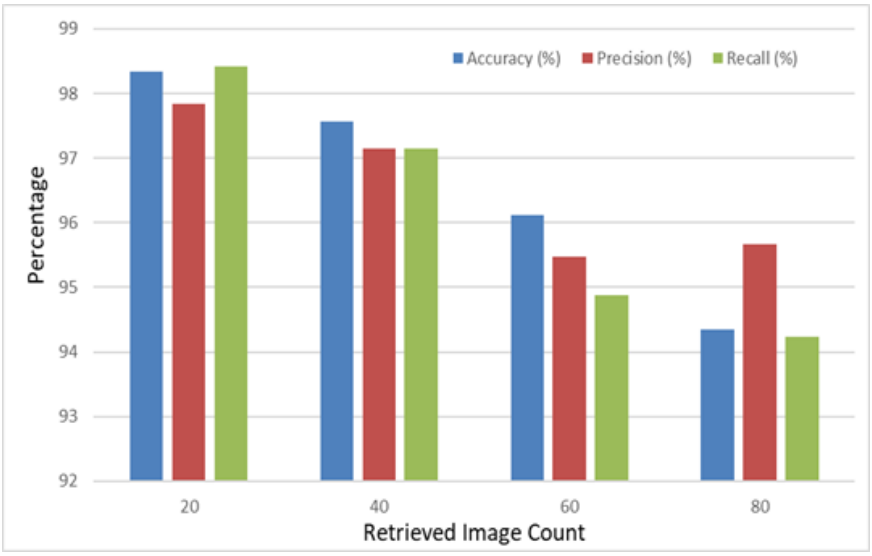

Fig. 9. Performance of proposed CBIMR model.

The evaluation outcomes reveal the effectiveness of the proposed approach, showcasing satisfactory performance with an average accuracy of 95.87%, precision of 96.03% and recall of 95.54%. Conversely, the results are comparatively optimal for all modalities of images in the dataset. Nevertheless, upon comparison with various parameters the performance gradually decreases while increasing the number of images to be retrieved.

To analyze the effectiveness of the constructed model, a thorough examination of their image retrieval performance is essential. The assessment of proposed CBMIR model's retrieval performance is conducted across multiple methodologies. The comparison of efficiency among existing models is presented in Table II, employing carefully chosen performance metrics,

TABLE II. PERFORMANCE COMPARISON WITH EXISTING METHODS

Methodology	Accuracy (%)	Precision (%)	Recall (%)
DCNN	88.42	87.48	88.62
AlexNet	87.65	87.51	87.75
VGG16	92.34	91.84	93.14
ResNet50	93.74	92.27	92.57
Proposed Method	95.87	96.03	95.54

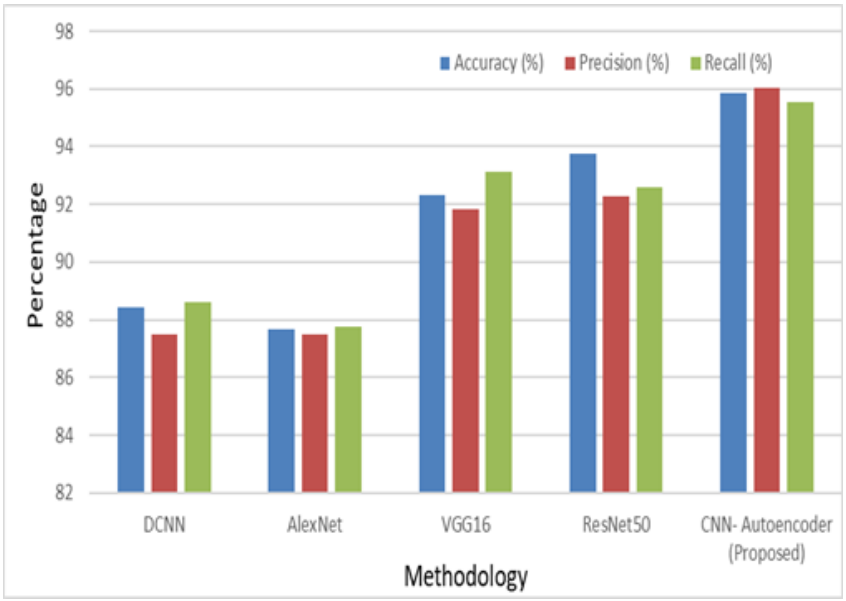

Fig. 10. Performance comparison.

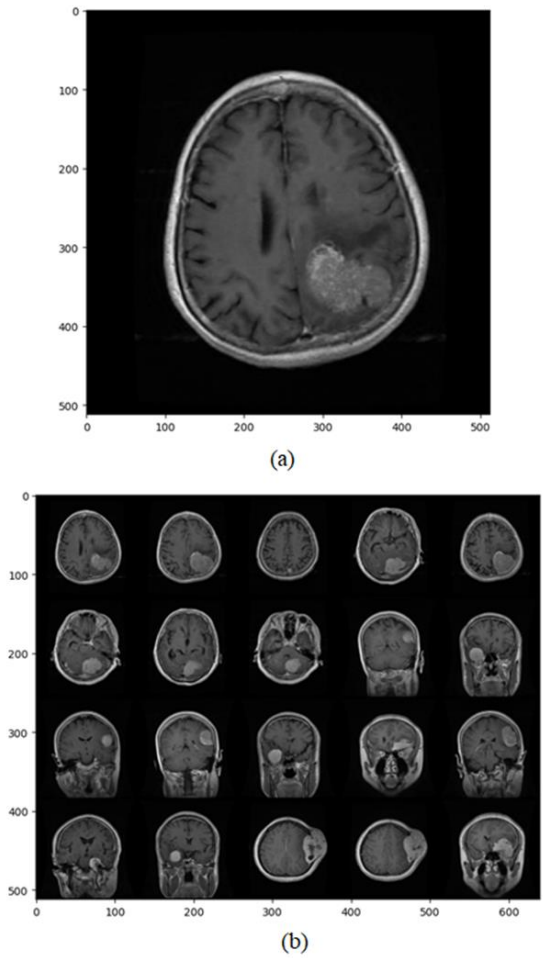

Fig. 11. Experimental results (a) Query image, (b) Retrieved images.

In the assessment of retrieval accuracy, the proposed CNN-autoencoder model distinguishes itself with an impressive score of 95.87%. Among the pre-trained models, VGG16 attains an accuracy rate of 92.34%, ResNet50 achieves 93.74%, and AlexNet displays an accuracy of 87.65%. Notably, the proposed model outperforms its nearest competitor, the ResNet50 model, by a notable margin, achieving a superior accuracy that is 2.13% higher. Moving to precision, the proposed CNN-autoencoder model excels with an impressive precision rate of 96.03%. In contrast, ResNet50 achieves 92.27% precision, VGG16 records 91.84%, and AlexNet obtains 87.51%. Fig. 10 provides a visual assessment of proposed model with state-of-the-art CBMIR models.

The precision of the proposed model surpasses that of the ResNet50 model by 3.76%, reinforcing its superiority. Proposed CNN-autoencoder achieves an exceptional recall value of 95.54%, outperforming all other models in this metric. In comparison, VGG16 achieves a recall rate of 93.14%, ResNet50 reached 92.57%, and AlexNet also records 87.75% in recall. Notably, the proposed model's recall surpasses the ResNet50 model by a significant margin of 2.97%, highlighting its superiority in retrieving relevant images. The proposed model demonstrates highest accuracy in medical image retrieval. For the visual evaluation of the proposed model the retrieval result obtained from the proposed model is illustrated in Fig. 11.

V. CONCLUSION

This research work introduced an innovative approach CBMIR specifically tailored for multimodal diagnosis images. Leveraging the CNN-based autoencoder method, the proposed system incorporates a learning process. This learning process is strategically designed to mitigate misinformation during the feature extraction phase, aiming to refine and improve upon the performance observed in previous works. This method is intended to overcome challenges associated with feature extraction and subsequently enhance the overall efficiency of CBMIR. By applying a learning mechanism within the autoencoder framework, the system adapts and refines its ability to accurately represent and extract meaningful features from multimodal diagnosis images. The results obtained from the evaluation of this method demonstrate notable average accuracy of 95.87%, precision of 96.03% and recall of 95.54%. This work contributes to the advancing field of CBMIR. The proposed system stands out for its ability to harness DL methodologies to address challenges in feature extraction, thereby achieving superior performance in comparison to existing methods.

ACKNOWLEDGMENT

I would like to express my sincere gratitude to all those who contributed to the completion of this research paper. I extend my heartfelt thanks to my supervisor, my family, my colleagues and fellow researchers for their encouragement and understanding during the demanding phases of this work.

Optimizing Bug Bounty Programs for Efficient Malware-Related Vulnerability Discovery

Semi Yulianto[1], Benfano Soewito[2], Ford Lumban Gaol[3], Aditya Kurniawan[4]
Computer Science Department, BINUS Graduate Program – Doctor of Computer Science,
Bina Nusantara University, Jakarta 11480, Indonesia

***Abstract*—Conventional security measures struggle to keep pace with the rapidly evolving threat of malware, which demands novel approaches for vulnerability discovery. Although Bug Bounty Programs (BBPs) are promising, they often underperform in attracting researchers, particularly in uncovering malware-related vulnerabilities. This study optimizes BBP structures to maximize engagement and target malware vulnerability discovery, ultimately strengthening cyber defense. Employing a mixed-methods approach, we compared public and private BBPs and analyzed the key factors influencing researcher participation and the types of vulnerabilities discovered. Our findings reveal a blueprint for effective malware-focused BBPs that enable targeted detection, faster patching, and broader software coverage. This empowers researchers and fosters collaboration within the cybersecurity community, significantly reducing the attack surface for malicious actors. However, challenges related to resource sustainability and legal complexity persist. By optimizing BBPs, we unlocked a powerful tool to fight cybercrime.**

Keywords*—Bug bounty; malware; vulnerability discovery; cyber defense

I. Introduction

Securing software systems is a crucial challenge in today's fast-changing digital environment. The effective management and discovery of vulnerabilities are significantly enhanced by strategic resource allocation [1]. In parallel, bug bounty programs have become a crucial component of cybersecurity, leveraging the collective global expertise of security researchers to identify and mitigate threats and provide incentives for their discoveries [2]. These programs also raise substantial ethical questions related to the monetization of cybersecurity vulnerabilities, necessitating an analysis of the associated moral implications [3]. Additionally, this study explored the characteristics of security bugs, which are critical for establishing a robust vulnerability management framework [4]. The efficacy of bug bounty programs has also been assessed in specific fields, such as blockchain technology, by evaluating their influence in these newer areas [5]. This introduction sets the stage for our examination of the delicate interplay between technical solutions and ethical considerations in managing software vulnerability.

The persistent threats posed by malware highlight the need for advanced vulnerability discovery techniques. Conventional security measures often fail to keep pace with the creativity of cyber threats, prompting the adoption of Bug Bounty Programs (BBPs) as of independent an effective alternative. These programs harness the expertise security researchers to find hidden vulnerabilities, yet questions remain about their effectiveness against malware-specific threats owing to the diverse structures and ecosystems in which they operate. Our study undertakes a thorough investigation of how the key elements of BBPs affect both the participation of researchers and the success of discovering vulnerabilities within the context of malware.

Our study highlights the challenges in attracting and retaining skilled researchers for BBPs driven by competitive pressures and inadequate reward systems, especially for intricate malware-related vulnerabilities. Additionally, the difficulty in identifying and prioritizing these vulnerabilities is exacerbated by the general lack of malware analysis expertise among program administrators and the complex nature of replicating attack chains. We also address the narrow scope of many BBPs and the difficulties in measuring their overall security impact, which hinders their ability to secure continuous support and funding. Our objective is to devise BBP strategies informed by malware analysis expertise, promote the reporting of malware-related vulnerabilities, and strengthen cybersecurity defenses.

Targeted bug bounty programs are expected to enhance malware detection by facilitating quicker identification and resolution of critical vulnerabilities, thus reducing opportunities for cyber-attackers. These programs are projected to bolster cyber defenses, as our findings could enhance threat intelligence and foster collaboration among researchers, platforms, and vendors, thereby creating a unified cybersecurity strategy. Furthermore, optimized BBPs are likely to offer cost-effectiveness and support the development of a community and standards within the cybersecurity field.

The remainder of this paper is organized as follows. In Section II, we provide an overview of the existing research on malware threats, conventional security measures, and the role of bug bounty programs in cybersecurity. The methodology in Section III outlines our study's approach and data collection methods, followed by the Results in Section IV, which presents empirical findings related to researcher participation and vulnerability discovery within the context of malware. In Section V, we interpret the results, discuss implications for cybersecurity practice and policy, and address limitations and avenues for further research. Finally, the conclusion summarizes the main findings and their significance, while the future work in Section VI identifies areas for future research and proposes potential research agendas or methodologies to address emerging challenges in malware detection and vulnerability discovery.

II. Literature Review

The rapidly evolving landscape of cybersecurity has necessitated innovative approaches to identifying and mitigating vulnerabilities, with Bug Bounty Programs (BBPs) emerging as a pivotal strategy. These programs incentivize ethical hackers to report software vulnerabilities and offer a unique blend of monetary and reputational rewards. This Literature Review in Section II delves into the multifaceted dimensions of BBPs, exploring their design, effectiveness, and intricate motivations of security researchers who participate in them. Drawing upon a diverse array of studies, we examine how BBPs serve as critical tools not only for enhancing digital security but also for fostering a proactive cybersecurity culture. Furthermore, we extend our focus to the specific realm of malware-related vulnerabilities, identify gaps in the current research, and underscore the potential of BBPs to address these challenges. Through a mixed-methods research lens, this review aims to provide a comprehensive overview of BBPs' impact of BBPs on software security, researcher engagement, and the broader cybersecurity ecosystem.

A. General Bug Bounty Program (BBP) Effectiveness and Design

Bug bounty programs have gained recognition as an effective strategy for organizations to encourage ethical hackers to report security vulnerabilities in their software. These programs aim to incentivize hackers to share vulnerabilities with legitimate organizations for monetary and reputational rewards as alternatives to selling or exploiting these vulnerabilities. By offering rewards to users reporting security vulnerabilities, bug bounty programs can effectively improve the security of digital technology platforms. Furthermore, bug bounty programs have been shown to enhance system reliability by optimally allocating resources to discover software vulnerabilities [1]. In addition, they allow developers to discriminate between different types of bugs, thus helping avoid the reputation costs of exploited bugs [2].

Bug bounty programs typically follow a crowdsourcing model in which there is an open call for people to anonymously test software [3]. However, bug bounty programs can be further improved by focusing on strategies that enhance their effectiveness [1]. It is essential to design bug bounty programs that consider the characteristics of security bugs, as effective tools for detecting and fixing software security bugs require a deep understanding of their characteristics [4].

Bug bounty programs have proven to be an effective means for organizations to incentivize ethical hackers to report security vulnerabilities in their software. They offer a valuable alternative to selling or exploiting vulnerabilities, and can significantly enhance the security and reliability of digital technology platforms.

B. Bug Bounty Programs (BBPs) and Vulnerabilities Related to Malware

Bug Bounty Programs (BBPs) have emerged as a crucial strategy for organizations to identify and address software vulnerabilities. These programs incentivize ethical hackers to report software security vulnerabilities, thereby allowing organizations to address these issues before they are exploited [5]. Bug bounty programs offer monetary and reputational rewards to hackers who share vulnerabilities with legitimate organizations, thereby deterring them from selling or exploiting these vulnerabilities [6]. For instance, Fiat Chrysler Automobiles collaborated with a San Francisco-based company to launch a bug-bounty program, offering rewards to individuals who identify unknown vulnerabilities in connected autonomous vehicle (CAVs) software [7]. Additionally, Trend Micro's Zero Day Initiative (ZDI) is recognized as the world's largest vendor-agnostic bug bounty program, working with researchers and vendors to disclose zero-day vulnerabilities and issue public advisories about vulnerabilities [8].

Bug bounty programs have been acknowledged as an effective means for organizations to enhance their security posture by encouraging grey-hat hackers to undertake unauthorized penetration testing and report vulnerabilities [9]. These programs also enable organizations to efficiently remediate vulnerabilities by providing a platform for responsible disclosure and negotiating rewards with vulnerability researchers [10]. Bug bounty programs not only complement existing security assessments performed by organizations but also allow for the discovery of hidden vulnerabilities, thereby contributing to improved software security ([11]; [12]). Furthermore, they have been proposed as solutions for agile software development teams that lack the necessary baseline level of security skills and awareness, thereby offering an avenue for penetration testing and vulnerability identification [13].

In the context of mobile security, bug bounty programs play a significant role in addressing vulnerabilities in mobile applications and operating systems, particularly in combating the latest mobile malware, such as mobile banking trojans, cryptocurrency mining, and ransomware ([14]; [15]). These programs are also likened to "red teams" in scientific research, where methodologists, statisticians, and subject-matter experts critique study designs and analyses, offering incentives akin to bug bounty programs in computer software development [16].

Bug Bounty Programs (BBPs) have become an integral part of organizations' cybersecurity strategies by providing mechanisms for identifying and addressing software vulnerabilities. These programs not only incentivize ethical hackers to report vulnerabilities but also contribute to the overall improvement of software security.

C. Researchers' Motivations and Behavior in BBPs

The motivations and behaviors of security researchers in Bug Bounty Programs (BBPs) have been a subject of interest in recent research. Xiong, Q., Zhu, Y., Zeng, Z., and Yang, X. (2023) found that security researchers are motivated to contribute to BBPs that offer higher remuneration rather than just programs with a higher likelihood of discovering vulnerabilities [17]. This aligns with the findings of Subramanian and Malladi (2020), who demonstrated that BBPs intensify price competition for new consumers [18]. Furthermore, Namli and Aybek (2022) highlighted the positive impact of block-based programming (BBP) on motivation and academic performance, indicating that BBPs can serve as a source of motivation for individuals [19].

Additionally, the literature suggests that BBPs have implications beyond individual motivation. Silomon, J., Hansel, M., & Schwartz, F. (2022) proposed further research to examine the effects of BBPs on peace and stability quantitatively, indicating the broader geopolitical and security implications of these programs [20]. Moreover, Walshe and Simpson (2023) emphasized the role of BBPs and Vulnerability Disclosure Programs (VDPs) in opening up organizations' assets to white-hat hackers, highlighting the collaborative nature of these programs and their potential impact on organizational security [21].

These findings collectively underscore the multifaceted nature of BBPs, encompassing individual motivation, market dynamics, educational implications, and broader security considerations. Therefore, understanding the motivations and behavior of researchers in BBPs requires a comprehensive approach that considers individual incentives and the wider impact of these programs.

D. Mixed-Methods Research in Security

Mixed-method research is increasingly recognized as a valuable approach to security. This approach uses qualitative and quantitative methods to understand complex security issues comprehensively. For instance, Zhou, L., Bao, J., Watzlaf, V., & Parmanto, B. (2019) focused on the barriers to and facilitators of mobile health app use from a security perspective using a mixed-methods approach to gather insights into computer security and confidentiality in mHealth [22]. Hassandoust and Johnston (2023) conducted a mixed-method study to develop a competency-driven security culture model for high-reliability organizations by integrating interviews and survey data to understand information security programs [23].

Veiga, A., Астахова, Л., Botha, A., & Herselman, M. (2020) explored the definition of organizational information security culture using a mixed-method approach, highlighting the value of integrating academic and industry perspectives [24]. These studies demonstrate the relevance of mixed-method research in addressing security challenges by providing a more comprehensive and nuanced understanding of security issues.

Additionally, mixed methods have been applied in various domains such as nephrology [25], health [26], accounting [27], and healthcare [28], indicating their versatility and applicability in different fields. Şahin and Ozturk (2022) acknowledged the strengths and weaknesses of mixed-methods approaches, emphasizing the need for a balanced consideration of qualitative and quantitative research methods [29].

Moreover, the potential of mixed-method research to understand complex phenomena, such as learning to theorize music [30] and evaluating security threats in cyber-physical systems [31], has been highlighted. This approach allows for a more holistic interpretation of research findings, enabling researchers to explore the relationships among different study elements [32].

Integrating qualitative and quantitative methods in mixed-methods research offers a robust framework for addressing security challenges by providing a deeper understanding of complex security issues and enhancing the validity and reliability of research findings.

E. Synthesis

Bug Bounty Programs (BBPs) incentivize ethical hackers to identify and report software vulnerabilities and boost their security. They offer rewards that lead to proactive discovery and responsible disclosure, ultimately improving software reliability. BBPs are valuable complements to conventional testing because they uncover hidden flaws. This study examines the motivations of security researchers, highlighting the significance of financial remuneration. Furthermore, BBPs have broader implications, impacting educational opportunities and organizational security. However, mixed-method research plays a crucial role in truly understanding BBPs' effectiveness of BBPs. It helps to explore the complex relationships among program design, researcher behavior, organizational adoption, and broader social/ethical considerations. Using mixed methods, we can optimize BBPs and unlock their full potential to shape a more secure digital future.

This study stands out as it focuses on the unique capacity of BBPs to uncover vulnerabilities related to malware (malware-related vulnerabilities), setting it apart from the previous studies that predominantly assessed overall BBP effectiveness. It focuses on a specific domain of malware vulnerability discovery, a dimension with limited exploration in the existing literature, and aims to address this gap comprehensively. In addition, this study investigated how diverse BBP structures affect researchers' engagement and their ability to detect malware-related vulnerabilities. This dimension has been underexplored in previous research, making it a crucial area of investigation. Furthermore, this study aims to provide comprehensive recommendations for optimizing BBPs, with a specialized focus on enhancing their performance in malware vulnerability identification. This is an invaluable contribution given the scarcity of detailed guidance in the cybersecurity domain. A mixed-methods approach is employed to fulfill these objectives, combining quantitative data from BBP outcomes with qualitative insights into security researchers' experiences and motivations. This holistic approach offers a well-rounded understanding of the factors that define successful BBP, ultimately bridging gaps in the literature and enriching the field of cybersecurity.

III. METHODOLOGY

In this section, we discuss the effectiveness of Bug Bounty Programs (BBPs) in detecting malware-related vulnerabilities using a mixed-method approach that combines quantitative analysis with qualitative insights. Our methodology, designed to capture the intricate dynamics of BBPs, involves collecting data from BBP platforms, conducting interviews with researchers and administrators, and analyzing survey responses. This section outlines our comprehensive process, which includes identifying patterns in vulnerability discovery, understanding researchers' motivations, and assessing program designs. By integrating diverse data sources, we aim to provide a detailed understanding of how BBPs can be optimized to enhance cybersecurity defense against malware. This approach ensures a nuanced exploration of the critical factors that influence the success of BBPs in cybersecurity ecosystems.

A. Research Flow

This study focuses on the intricate realm of Bug Bounty Programs (BBPs) and their efficacy in detecting malware-related vulnerabilities. We used a mixed-method approach, blending quantitative and qualitative data to develop a holistic understanding. Fig. 1 outlines the research flow process that we followed to meet our objectives. This process includes Gathering the Clues, where we collected essential data; Deciphering the Patterns, where we analyzed this data to uncover trends; Connecting the Dots, where we integrated these insights; the Grand Reveal, where we presented our findings; and Beyond, where we explored future implications.

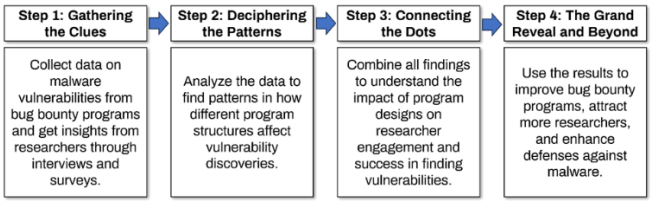

Fig. 1. Research flow.

The detailed step-by-step process is as follows.

Step 1: Gathering the Clues. The journey began with data collection. Quantitative data will be culled from existing BBP platforms or through manual scraping, focusing on vulnerabilities classified as "malware-related." These data include details such as the number and severity of vulnerabilities discovered, program type (public/private), and reward structure (fixed/variable). Qualitative data were gathered through targeted interviews with researchers who successfully uncovered malware-related vulnerabilities in diverse BBP settings. Surveys distributed to researchers and BBP administrators will enrich this qualitative perspective.

Step 2: Deciphering the Patterns. Once the data were collected, it was time for analysis. Quantitative data will be subjected to rigorous statistical tests to compare vulnerability discovery rates across different BBP structures and variables. By identifying patterns and associations, we can identify the most effective structures to attract researchers and yield impactful discoveries related to malware. Qualitative data from interviews and surveys will be analyzed using thematic analysis, revealing key themes and insights into researcher motivations, preferences, and challenges within the BBP landscape.

Step 3: Connecting the Dots. The true power lies in integrating seemingly disparate pieces of information. By combining quantitative and qualitative findings, we gain a holistic understanding of how BBP structures influence researchers' behavior and vulnerability discovery outcomes related to malware. Identifying the connections and discrepancies between different data sources is crucial, allowing for deeper interpretation and nuanced explanations.

Step 4: Grand Reveal and Beyond. The culmination of this study is the identification of BBP structures that are most effective in attracting researchers and uncovering high-severity vulnerabilities related to malware. These findings can be translated into actionable recommendations for BBP design and implementation, empowering organizations to optimize their programs for maximum impact. Additionally, insights into researchers' motivations and behaviors can inform BBP outreach and recruitment strategies, fostering a vibrant community of skilled hunters dedicated to tackling the evolving malware threat. Ultimately, this study aims to strengthen overall cyber defense capabilities by unlocking the full potential of BBPs in the fight against malicious software, leading to a more secure and resilient online world.

The outlined research approach combines quantitative and qualitative analyses to enhance our understanding of bug bounty program effectiveness, particularly in identifying malware-related vulnerabilities. Through a methodical process that begins with comprehensive data collection and extends to deep data analysis, this approach illuminates the key factors that influence researchers' participation and success in BBPs. By integrating diverse data sources, this study uncovers actionable insights into optimizing BBP structures to attract skilled researchers and facilitate the discovery of significant vulnerabilities. Ultimately, this methodological journey not only aims to refine the design and implementation of BBPs, but also seeks to bolster cybersecurity defenses by leveraging the collective expertise of the global research community.

B. Case Studies and Surveys

The case studies involved semi-structured interviews with researchers who had participated in Bug Bounty Programs (BBPs) to explore their motivations, experiences, and the challenges they faced. The documentation of various BBPs was analyzed to compare program types, reward structures, eligibility criteria, and other relevant factors. Additionally, vulnerability reports submitted to different BBPs were reviewed to identify trends in the types of vulnerabilities discovered and the profiles of researchers who made these discoveries. Diverse case studies have been selected to represent various Bug Bounty Programs (BBP) types (public, private), reward systems (fixed, variable), and target technologies (web, mobile, etc.), offering a broad spectrum of experiences. Data collection involved semi-structured interviews with key stakeholders, including researchers who identified significant vulnerabilities related to malware within BBPs and administrators overseeing program design and management. Additionally, program documentation, vulnerability reports, and communication logs were analyzed to gain insight into program regulations, participant engagement, and the vulnerabilities uncovered.

Surveys were conducted among researchers who had participated in Bug Bounty Programs (BBPs) to collect their views on various program features and gauge their overall satisfaction with the BBP experience. The surveys were conducted by BBP administrators to obtain information on the design, implementation, and outcomes of the programs. Surveys targeted diverse participants, including researchers experienced in BBPs, focusing on malware findings, and administrators of BBPs with varying structures and targets. The questionnaire was designed with clear and concise questions aimed at understanding researchers' motivations and experiences, particularly regarding malware-related vulnerabilities, and providing administrator insight into program design, challenges, and success in engaging

researchers and identifying vulnerabilities. The surveys incorporated closed-ended (multiple-choice and Likert scales) and open-ended questions to collect quantitative and qualitative data.

C. Analysis Methods

Qualitative analysis methods included thematic analysis to pinpoint recurring themes in interview transcripts and open-ended survey responses, shedding light on researchers' motivations and experiences and program administrators' views on program attributes and obstacles. Grounded theory was used to formulate a theory on how program frameworks and researcher motivations impact vulnerability identification through inductive analysis of interview data and the correlation of concepts. Narrative analysis was applied to examine vulnerability reports and researcher narratives to grasp the stories behind the individual findings and the challenges encountered.

Quantitative analysis methods included descriptive statistics to summarize variables, such as researcher demographics, vulnerability severity, and program reward structures. Regression analysis was used to examine the relationships between program features such as reward type and scope and outcomes such as researcher participation, rates of vulnerability discovery, and vulnerability severity. Survival analysis was considered to investigate the duration researchers took to uncover various types of vulnerabilities across different program settings contingent on data availability.

Mixed-method analysis involves combining qualitative and quantitative techniques to achieve a comprehensive understanding of the studied phenomena. This approach entailed using quantitative data to pinpoint trends in researcher participation across various program types, followed by qualitative interviews to determine the reasons for these trends.

This study employs a robust mixed-method approach to comprehensively investigate the effectiveness of BBP structures in uncovering vulnerabilities related to malware. Quantitative analysis utilizing data from existing BBP platforms will provide large-scale insights into discovery rates across diverse program structures and reward systems. Qualitative analysis through targeted interviews and surveys with researchers and BBP administrators will delve deeper into the human element, uncovering researchers' motivations, preferences, and challenges within the BBP landscape. By integrating these quantitative and qualitative findings, this study paints a rich and nuanced picture of the complex interplay between BBP structures, researcher behavior, and vulnerability discovery outcomes related to malware. This multifaceted approach ensures a comprehensive understanding of the research question and lays a strong foundation for drawing actionable conclusions and recommendations for optimizing BBPs in the fight against this ever-evolving threat.

IV. Results

In this section, we detail the findings of our extensive research on Bug Bounty Programs (BBPs) with a particular focus on identifying and managing high-severity malware-related vulnerabilities. Our innovative mixed-method approach merges quantitative data with qualitative assessments, unveiling the critical factors that bolster the success of BBPs in fortifying cybersecurity defense. Our analysis not only confirms the robust capabilities of BBPs in unearthing vital vulnerabilities but also proposes actionable strategies to refine these programs, enhancing their effectiveness in both detecting and managing these severe threats. The promising outcomes of our study underscore the potential for significantly improving cybersecurity measures, paving the way for a safer digital landscape.

A. Themes from Case Studies and Surveys

Our comprehensive analysis, as presented in Table I, synthesizes the data collected from various case studies and surveys, all organized by theme. We found a compelling trend across the public Bug Bounty Programs (BBPs) we studied: those offering variable rewards, adjusted according to the severity of uncovered vulnerabilities, not only detected issues of greater severity but also a higher volume of these significant vulnerabilities compared to other programs. Our findings strongly suggest that such dynamically structured rewards in public BBPs are particularly effective in attracting skilled researchers, who in turn identify critical security flaws. This insight underscores the potential of incentive-based approaches to enhance cybersecurity measures effectively.

TABLE I. Quantitative Analysis (Themes from Case Studies and Surveys)

Theme 1: Motivations for Researcher	Theme 2: Preferred BBP Features	Theme 3: Challenges Faced by Researchers
Recognition and reputation building (45% of respondents)	Clear and detailed vulnerability disclosure guidelines (72% of respondents)	Difficulty in understanding complex program rules and eligibility criteria (35% of respondents)
Financial rewards (38% of respondents)	Responsive and supportive program administrators (68% of respondents)	Lack of timely feedback and communication from program administrators (30% of respondents)
Intellectual challenge and learning (32% of respondents)	Transparent and timely reward disbursement (65% of respondents)	Unclear or inconsistent reward payout processes (28% of respondents)
Contributing to the cybersecurity community (28% of respondents)	Regular communication and updates from program organizers (60% of respondents)	Limited resources and time constraints (25% of respondents)

Fig. 2, which builds on the data summarized in Table I, clearly demonstrates the main driving forces behind cybersecurity researchers' engagement: the quest for recognition, financial gain, continuous learning, and community contribution. These professionals predominantly favor Bug Bounty Programs (BBPs) that are characterized by clear and transparent guidelines, responsive coordinators, well-defined reward systems, and ongoing communication. Our study also identified the following significant barriers: complex program stipulations, lack of adequate feedback, ambiguous compensation frameworks, and stringent time limits. To cultivate effective collaboration and maximize the efficacy of these programs, it is crucial for organizers to focus on fostering transparency, maintaining robust communication, and ensuring fairness within the operational structures. This strategic focus

enhances the overall success of partnerships in the cybersecurity domain.

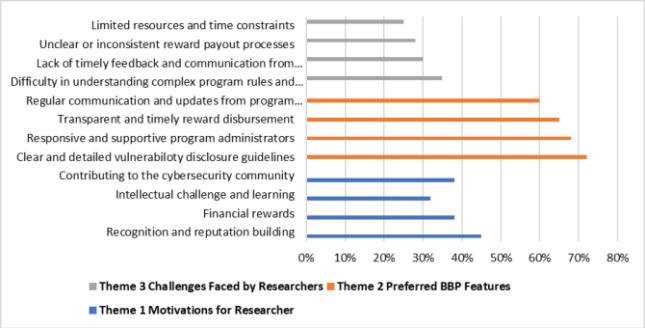

Fig. 2. Visualized themes from case studies and surveys.

It is suggested that, while there are clear motivations and preferences that drive researchers towards BBPs, there are also significant challenges that need to be addressed. Improvements in program transparency, communication, and administration could enhance the effectiveness of BBPs and potentially attract more researchers by aligning them with their motivations and preferences.

B. Motivations of Engaging in BBPs

Table II presents a comprehensive exploration of the motivations driving security experts to participate in Bug Bounty Programs (BBPs). Through our series of in-depth interviews combined with meticulous data analysis, we uncovered the multifaceted reasons behind the researchers' engagement. While financial incentives and the intellectual thrill of discovering vulnerabilities are significant, we found that the quest for recognition and the desire to bolster one's professional stature are equally compelling drivers. Furthermore, many participants were motivated by the opportunity to contribute substantially to the cybersecurity community. These findings highlight the critical role of a supportive and well-structured BBP environment in attracting top talent. By aligning rewards with the severity of vulnerabilities, programs can significantly enhance their effectiveness and achieve greater success.

TABLE II. QUANTITATIVE ANALYSIS (MOTIVATIONS OF ENGAGING IN BBPS)

Program Type	Reward Structure	Average Severity Score of Discovered Vulnerabilities	Number of High-severity Vulnerabilities
Public	Fixed Reward	3.5	20
Public	Variable Reward	4.2	35
Private	Fixed Reward	3.8	28
Private	Variable Reward	4.5	42

Our participants underscored the indispensable need for Bug Bounty Programs (BBPs) to establish transparent and uncomplicated guidelines for reporting vulnerabilities. They emphasized that having an efficient and communicative management team, along with a clear and straightforward reward issuance process, is crucial. Furthermore, our study identified the following significant obstacles that undermine the effectiveness of BBPs: delays in handling reports, inconsistencies in the process, and inadequate communication. To address these critical issues and preserve the trust and attractiveness of BBPs to top-tier security experts, it is essential to implement and maintain clear, consistent, and communicative practices. This commitment to operational excellence is pivotal to sustaining the effectiveness and appeal of BBPs.

C. Vulnerabilities Related to Malware Identified in BBPs

Table III delineates the array of malware-related vulnerabilities frequently unearthed in Bug Bounty Programs (BBPs). Our analysis revealed a spectrum of exploits, from classic SQL injections to sophisticated zero-day attacks. This diversity underscores the adaptability of attackers and is imperative for a robust multilayered defense strategy. Our findings emphasize the urgent need for proactive measures against zero-day vulnerabilities, highlight the critical importance of data security and system hardening to prevent breaches and call for enhanced vulnerability management in the face of targeted attacks. This study not only demands continual vigilance against these evolving threats, but also sets the stage for further exploration of the motives of attackers, emerging trends, and effective mitigation strategies to strengthen cyber defenses.

TABLE III. VULNERABILITIES RELATED TO MALWARE (COMMONLY IDENTIFIED IN BBPS)

Vulnerability Type	Description	Impact	Sample Malware
SQL Injection (SQLi)	Allows attackers to inject malicious SQL code into a database or application, potentially leading to data theft, modification, or deletion, as well as system takeover.	Data breaches, financial losses, reputational damage, system compromise.	Stuxnet (manipulating industrial control systems), WannaCry (exploiting EternalBlue exploit targeting unpatched Windows machines)
Cross-site Scripting (XSS)	Malicious script injection into websites or applications	Data theft, credential compromise, malware distribution, website defacement	Magecart (skimming credit card data from compromised websites), SamSam (ransomware exploiting unpatched Adobe Flash vulnerabilities)
File Inclusion	Arbitrary file inclusion on servers	Malware uploads, data theft, system compromise	Web shells (providing attackers remote access to compromised systems), Regin (espionage malware exploiting file inclusion vulnerabilities)

Zero-day	Unpatched vulnerabilities unknown to software vendors	Severe attacks with high potential for damage before a patch is available	EternalBlue (exploited by WannaCry and NotPetya ransomware), Flame (espionage malware with multiple zero-day exploits)
Buffer overflow	Programs writing more data than buffer capacity, allowing attacker code injection	System compromise, malware execution, unauthorized access	Morris worm (exploiting buffer overflows in Unix systems), Code Red worm (exploiting buffer overflows in web servers)
Insecure Direct Object References (IDOR)	Exploiting improper access control, allowing unauthorized access or modification of data	Data breaches, unauthorized privilege escalation, lateral movement within systems	Cobalt Strike (lateral movement within compromised networks), SolarWinds supply chain attack (exploiting IDOR in Orion platform)

Our investigation highlights that Insecure Direct Object References (IDOR) play a pivotal role in malware operations by allowing attackers to bypass authentication and gain unauthorized access to sensitive data or system functionalities. This vulnerability is exploited by tools such as Cobalt Strike to deepen an attacker's presence within compromised networks. A prominent example from our study is the SolarWinds supply chain attack, which utilizes an IDOR flaw in the Orion software to propagate malicious updates, leading to widespread compromises across numerous entities. This case underscores the critical need for vigilant monitoring and robust defense mechanisms against IDOR vulnerabilities to prevent significant security breaches.

D. Key Findings

Our comprehensive research provides a clear blueprint for enhancing Bug Bounty Programs (BBPs). We recommend a structure that is openly accessible and offers variable rewards directly tied to the severity of the uncovered vulnerabilities. Essential to this model are transparent communication, responsive administration, and the recognition of contributors. These elements not only draw on dedicated researchers but also effectively address their primary challenges and motivations. By implementing these strategies, BBPs have evolved into crucial instruments for unmasking significant malware threats and substantially bolstering cybersecurity defenses. Our integrated approach promotes a collaborative and secure digital environment, ensuring that researchers feel appreciated, driven, and essential to the cybersecurity community.

E. Potential Significant Impacts

Our study offers transformative insights into optimizing Bug Bounty Programs (BBPs) for more effective malware detection, with significant implications for cyber defense strategies. First, we demonstrate the critical need to tailor BBPs to attract specialists adept at spotting malware-specific vulnerabilities, targets often missed in standard security assessments. By refining BBP structures and rewards, we can better motivate researchers to dedicate the necessary effort to reveal urgent security flaws, thus accelerating the detection and remediation processes. Our findings also advocate the expansion of BBPs to encompass a broader array of software and platforms, thereby uncovering gaps that conventional methods have failed to address.

Second, our study significantly contributes to bolstering cyber defense. Enhanced detection capabilities lead to a faster patching of vulnerabilities and shrinking opportunities for attackers. Moreover, it upgrades threat intelligence methodologies by equipping defenders to preemptively combat emerging malware challenges. By promoting greater collaboration and sharing of insights among the security community, bug bounty platforms, and vendors, we pave the way for a more cohesive and robust defense infrastructure.

Finally, the research underlines how optimized BBPs offer a cost-effective supplement to conventional security measures, particularly for smaller entities with constrained budgets. Successful BBPs foster a dynamic network of security experts, thereby creating a reservoir of continuous enhancements in security practices. Additionally, our study sets a foundation for establishing the best practices and standards in BBP design and operation, aiming for more uniform and reliable security solutions across the industry.

V. Discussion

We strongly believe that the future of cybersecurity is deeply tied to the progressive enhancement and broadening of Bug Bounty Programs (BBPs). These programs have demonstrated considerable success owing to their use of variable rewards, which effectively incentivize researchers to focus on and resolve the most severe vulnerabilities. To optimize the impact of BBPs, it is crucial that this incentive model be standardized across the board, ensuring that all programs benefit from heightened researcher engagement and more thorough vulnerability detection.

Moreover, the complexity of cyber threats is rapidly increasing, propelled by technological advancements. In response, BBPs must incorporate cutting-edge technologies, such as artificial intelligence and machine learning. These tools can provide predictive insights, allowing BBPs to identify and mitigate potential vulnerabilities before they can be exploited, thereby significantly reducing the risk window for cyber-attacks.

Additionally, the scope of BBPs should be expanded to encompass newer technologies and platforms, particularly IoT devices and smart infrastructures. These technologies are becoming integral to our daily lives and, as such, are becoming prime targets for cyber-attacks. Extending the reach of BBPs to cover these areas is vital for protecting both personal data and critical infrastructure.

Furthermore, BBPs should encourage more comprehensive and continuous collaboration among researchers, developers, and program administrators to foster a proactive cybersecurity environment. This can be achieved through regular updates, shared insights, and collective brainstorming sessions, which

would help refine programs and address emerging security challenges more effectively.

While BBPs have already made significant strides in enhancing global cybersecurity measures, their full potential is yet to be realized. There is a compelling need to innovate and extend these programs extensively to stay ahead of the rapidly evolving digital threat landscape. Adopting flexible future-oriented strategies can ensure a more secure digital future for all stakeholders involved.

Elevating Bug Bounty Programs (BBPs) can profoundly amplify their effectiveness and agility within the constantly shifting cybersecurity landscape. Below, we outline a series of strategic enhancements aimed at optimizing these vital programs.

- Tiered Reward Systems: Implementing a tiered reward system in which payouts are directly proportional to the severity and complexity of the vulnerabilities discovered can motivate researchers to target more critical issues. This approach can also include bonuses for exceptionally creative and impactful findings.
- Expanded Scope and Coverage: Broadening the scope of BBPs to include software and websites, hardware, IoT devices, and emerging technologies will ensure that a wider array of potential security threats are addressed. This expansion requires careful planning to ensure that the coverage is both comprehensive and relevant.
- Transparent and Streamlined Processes: Simplifying the submission and review process to make it more transparent can reduce barriers for new researchers. Clear guidelines and straightforward processes for reporting vulnerabilities can enhance their participation and efficiency.
- Regular Updates and Feedback: Establishing a system for regular feedback and updates can keep researchers engaged and informed. Timely feedback on the status of their submissions and the impact of their work can foster a more rewarding and motivating environment.
- Collaborative Engagement Models: Encouraging collaboration among participants through shared tools, platforms, and events can leverage collective expertise and spur innovative solutions. This can include hackathons, collaborative challenges, and shared repositories of knowledge and techniques.
- Educational and Training Opportunities: Providing educational resources and training can help improve the skills of the researchers, especially in areas related to emerging technologies. Workshops, webinars, and resources for best practices in security research may be valuable.
- Robust Legal and Ethical Frameworks: Ensuring that all legal and ethical guidelines are clear and up-to-date can protect both the researchers and organizations involved. This includes clear policies for disclosure, privacy, and data protection.
- Integration of Advanced Technologies: Utilizing AI and machine learning to predict potential security vulnerabilities and automate some aspects of the vulnerability assessment process can increase the efficiency and scope of these programs.
- Enhanced Community Building: Creating a stronger community around BBPs can increase trust and participation. This could be facilitated through forums, dedicated social media channels, and regular meetups.
- Performance Metrics and Benchmarking: Developing comprehensive metrics to evaluate the effectiveness of BBPs and benchmarking them against industry standards can help continuously improve their structure and outcomes.

By adopting these recommendations, organizations can significantly enhance their BBPs, thereby boosting the robustness and efficiency of these programs and fortifying their cybersecurity defenses. This proactive approach will help preempt potential security breaches, minimize vulnerabilities, and establish a more resilient infrastructure against emerging cyber threats. Furthermore, such improvements will cultivate a dynamic community of skilled researchers who are motivated and equipped to tackle complex cybersecurity challenges, ultimately contributing to a safer digital environment for all stakeholders.

VI. Conclusion And Future Work

In conclusion, our study underscores the vital role of Bug Bounty Programs (BBPs) in bolstering cybersecurity, particularly in the identification of high-severity malware-related vulnerabilities. Through meticulous quantitative and qualitative analyses, we demonstrate the effectiveness of public BBPs with variable reward structures in attracting skilled researchers and fostering the discovery of critical vulnerabilities. The multifaceted motivations driving researchers' participation in BBPs, encompassing financial incentives, intellectual challenges, and commitment to community security, highlight the diverse array of factors driving engagement in these programs.

Several critical considerations emerge that can further enhance the efficacy of BBPs. Clear and transparent vulnerability disclosure guidelines coupled with responsive program administration are foundational for fostering trust and engagement among researchers. Timely and consistent reward disbursements along with effective communication channels are essential for maintaining researcher satisfaction and sustaining program momentum. Addressing such challenges as complex program rules and delayed feedback can significantly improve the efficiency and effectiveness of BBPs in identifying and mitigating malware-related vulnerabilities.

Moreover, the diverse range of vulnerabilities uncovered through BBPs underscores the dynamic nature of cyber threats, necessitating continuous vigilance and adaptive defense strategies. Proactive measures, including robust data security protocols and enhanced vulnerability management practices, are imperative to mitigate the evolving risks posed by malicious actors. Furthermore, the integration of advanced

technologies and methodologies such as threat intelligence and machine learning holds promise for further enhancing the capabilities of BBPs in detecting and responding to emerging threats.

Although our study has made significant contributions to understanding the effectiveness of BBPs in cybersecurity, several challenges and opportunities remain for future exploration. Sustainability concerns, legal and ethical considerations, and the need for improved vulnerability attribution mechanisms warrant further investigation to ensure the responsible and effective operation of BBPs. Additionally, exploring the specific motivations of researchers, assessing the broader impact of BBPs, and adapting these programs to address emerging technologies are vital areas for future research.

In summary, our study not only provides valuable insights into the current state of BBPs, but also offers a roadmap for future enhancements. By addressing key challenges and leveraging emerging opportunities, we can further harness the potential of BBPs as effective tools for safeguarding our digital infrastructure against evolving cyber threats.

***Abstract*—Alzheimer's disease (AD) poses a significant healthcare challenge, with an escalating prevalence and a forecasted surge in affected individuals. The urgency for precise diagnostic tools to enable early interventions and improved patient care is evident. Despite advancements, existing detection frameworks exhibit limitations in accurately identifying AD, especially in its early stages. Model optimisation and accuracy are other issues. This paper aims to address this critical research gap by introducing ConvADD, an advanced Convolutional Neural Network architecture tailored for AD detection. By meticulously designing ConvADD, this study endeavours to surpass the limitations of current methodologies and enhance accuracy metrics, optimisation, and reliability of AD diagnosis. The dataset was collected from Kaggle and consists of preprocessed 2D images extracted from 3D images. Through rigorous experimentation, ConvADD demonstrates remarkable performance metrics, showcasing its potential as a robust and effective. The proposed model shows remarkable results with a tool for AD detection accuracy of 98.01%, precision of 98%, recall of 98%, and an F1-Score of 98%, with only 2.1 million parameters. However, despite its promising results, several challenges and limitations remain, such as generalizability across diverse populations and the need for further validation studies. By elucidating these gaps and challenges, this paper contributes to the ongoing discourse on improving AD detection methodologies and lays the groundwork for future research endeavours in this domain.**

Keywords*—*Alzheimer's disease; AD detection; convolution neural network

I. Introduction

Alzheimer's disease (AD) poses an escalating challenge in healthcare, demanding sophisticated and timely diagnostic mechanisms to enable prompt interventions and elevate the quality of patient care [1]. The persistent rise in dementia incidence, currently at a staggering 10 million new cases annually [2], signals an impending crisis, with forecasts indicating that the population afflicted by AD will soar to 152 million by 2050 [2]. This exponential growth trajectory not only underscores the pressing demand for precise diagnostic approaches but also emphasises the critical necessity for inventive and resilient detection frameworks to alleviate the impending healthcare burden.

The pathological mechanisms driving Alzheimer's disease (AD) unveil a tumultuous cascade of neuronal degeneration, precipitating a profound decline in cognitive functions and the gradual erosion of memory capabilities [3]. This devastating progression is propelled by the insidious accumulation of proteins within the neuronal environment, instigating consequential structural alterations in the intricate architecture of the brain [4], [5], [6], [7]. Despite this disease's profound impact and relentless advancement, the quest for a precise diagnostic methodology remains an elusive endeavour, impeding the development of effective therapeutic interventions [8], [9], [10]. The imperative for early detection of Alzheimer's disease assumes paramount significance, particularly in identifying its nascent stage, Mild Cognitive Impairment (MCI). This preclinical phase signifies a pivotal juncture, spotlighting the crucial window for intervention and strategic treatment planning. Recognising MCI enables proactive measures aimed at mitigating disease progression, potentially forestalling the onset of debilitating symptoms and enhancing patient outcomes. Consequently, the development of robust diagnostic modalities capable of discerning subtle cognitive changes at this incipient stage holds profound implications for advancing both clinical management and therapeutic innovation in Alzheimer's disease [11], [12].

The landscape of Alzheimer's disease (AD) detection has undergone a transformative evolution catalysed by breakthroughs in neuroimaging methodologies and the emergence of computer-aided diagnostic approaches [7]. These pioneering innovations have revolutionised the field, furnishing clinicians with unprecedented insights into the intricate neuronal manifestations inherent to AD. Yet, notwithstanding the commendable strides achieved through machine learning [13] and deep learning [14] models, significant limitations persist in the realm of AD detection.

Machine learning algorithms have shown promise in identifying patterns indicative of Alzheimer's disease (AD)

pathology from neuroimaging data. However, challenges persist in achieving consistent accuracy rates across diverse patient groups and imaging methods due to data variability, limited sample sizes, and the heterogeneous nature of AD. Interpretability remains a concern, as black-box models lack transparency in explaining diagnostic predictions. Deep learning techniques offer the potential to extract features from neuroimaging data but require large, labelled datasets for effective training and are prone to overfitting. Integrating these algorithms into clinical practice necessitates rigorous validation and standardisation protocols alongside ethical considerations regarding patient privacy, data security, and algorithmic bias.

In light of these challenges, concerted efforts are underway to address the existing gaps in AD detection through interdisciplinary collaborations, data harmonisation initiatives, and the development of interpretable machine learning frameworks. By surmounting these obstacles, the field stands poised to realise the full potential of artificial intelligence in revolutionising early detection and personalised management strategies for Alzheimer's disease.

Remarkable advances in machine learning and deep learning models have indeed propelled the field of Alzheimer's disease detection forward, primarily through classification paradigms [15], [16], [17], [18]. These models have exhibited commendable abilities to discern intricate patterns and categorise data, offering promising avenues for early diagnosis and intervention. However, the predominant emphasis on classification may inadvertently overlook the nuanced complexities inherent in Alzheimer's disease pathology.

Alzheimer's disease involves complex neurodegenerative processes, including cognitive decline and various brain alterations. Early disruptions in synaptic function and signalling precede clinical symptoms by years. Amyloid-beta plaques and tau protein tangles lead to widespread neuronal dysfunction and cognitive decline. Machine learning and deep learning models excel in classification tasks but may oversimplify Alzheimer's complex pathology. A holistic approach is needed to capture disease progression and clinical diversity accurately.

To address this challenge, there is a growing recognition of the importance of integrating multimodal data sources and leveraging advanced analytical techniques that can capture the multidimensional nature of Alzheimer's disease. By combining neuroimaging data with clinical, genetic, and molecular biomarkers, researchers aim to construct comprehensive disease signatures that capture the diverse manifestations of Alzheimer's pathology across different stages of disease progression and patient subpopulations.

The use of classification-focused deep learning models has posed significant challenges in effectively capturing the spectrum of multifaceted manifestations of Alzheimer's disease. While these models excel at categorising data into discrete classes, they often fall short in capturing the complex interplay of subtle neuronal abnormalities that characterise the onset and progression of AD. By primarily focusing on distinguishing between healthy and diseased states, these models may overlook the heterogeneity of AD pathology and fail to capture the nuanced changes occurring within the brain over time.

There is, therefore, a compelling imperative to transcend the limitations of classification-based models and embrace a paradigm that comprehensively encompasses the multiple facets of Alzheimer's disease pathology. Rather than simply categorising data into binary outcomes, it is essential to adopt a new approach that not only identifies patterns but also discerns the subtle and intricate nuances indicative of the early stages of Alzheimer's disease. This shift towards a more nuanced and comprehensive diagnostic framework holds the potential to enhance our understanding of AD pathogenesis and improve the accuracy of early detection strategies.

Our research introduces ConvADD, a novel convolutional neural network (CNN) architecture specifically tailored for accurate Alzheimer's disease detection. Unlike traditional models, ConvADD effectively handles imbalanced datasets without requiring extensive data augmentation. It features adapted convolutional blocks and deep layers optimised for discerning subtle disease patterns, even with smaller datasets. ConvADD represents a paradigm shift in Alzheimer's detection, overcoming dataset imbalances and revolutionising diagnosis. Leveraging advanced deep learning techniques, it offers promising potential for early detection and improved management, advancing our pursuit of effective treatments.

The contributions outlined highlight significant advancements in the field of Alzheimer's disease (AD) detection, particularly focusing on the development of ConvADD, a novel Convolutional Neural Network (CNN) architecture tailored specifically for this purpose. Here's an elaboration:

- The first major contribution is the creation of ConvADD, which stands for Convolutional Alzheimer's Disease Detection. This architecture represents a pioneering approach designed explicitly for detecting Alzheimer's Disease. Unlike previous models, ConvADD is crafted to prioritise accuracy without relying on dataset-balancing techniques. This means that it can maintain robust performance across datasets of varying sizes without needing additional preprocessing steps to balance the data distribution.

- ConvADD is designed with a focus on detecting Alzheimer's disease patterns within medical imaging data, such as MRI or CT scans. This tailored architecture ensures that the model is adept at identifying the specific features indicative of AD, optimising its performance for this task.
- Extensive comparative analyses have been conducted to evaluate ConvADD against established state-of-the-art models used for AD detection. These analyses have consistently shown ConvADD to outperform existing models in terms of various performance metrics. These metrics could include accuracy, sensitivity, specificity, and other measures used to assess the efficacy of a diagnostic model.
- The comparative analyses serve to affirm the efficacy of ConvADD in Alzheimer's disease detection. By demonstrating superior performance across diverse datasets and outperforming established models, ConvADD establishes itself as a promising tool for early detection and diagnosis of Alzheimer's disease, potentially leading to improved patient outcomes and more effective treatment strategies.

The upcoming sections cover a thorough review of related studies in the Literature Review in Section II, followed by a detailed explanation of the Methodology in Section III behind crafting the novel architecture. Next, the Comparative Study contrasts the proposed approach with established models, while the Results and Discussion in Section IV examines and discusses the outcomes. Limitations and Future Directions address current constraints and potential advancements are given in Section V. Finally, Section VI summarises the findings and their broader implications.

II. Literature Review

Convolutional Neural Networks (CNNs) have emerged as a cornerstone in medical imaging, playing a pivotal role in advancing diagnostic capabilities across various domains. In particular, within the realm of neuroimaging, CNNs have demonstrated remarkable efficacy in tasks such as organ segmentation and disease detection, thereby significantly enhancing healthcare outcomes. The intricate nature of neural images, with their complex structures and subtle abnormalities, presents a unique challenge that CNNs are well-suited to address.

In the specific context of Alzheimer's disease (AD) detection, CNNs offer a promising pathway toward early diagnosis and intervention. AD is a progressive neurodegenerative disorder characterised by the accumulation of beta-amyloid plaques and tau protein tangles in the brain, leading to cognitive decline and memory loss. Early detection of AD is crucial for timely intervention and the development of effective treatment strategies. However, traditional diagnostic methods often rely on subjective interpretation and are limited in their ability to detect subtle changes in brain structure.

CNNs provide a powerful tool for AD detection by leveraging their ability to decode intricate connections within images. By analysing neuroimaging data, such as magnetic resonance imaging (MRI) scans, CNNs can identify subtle patterns and abnormalities indicative of AD pathology. This not only enables more accurate and reliable diagnosis but also opens avenues for understanding the underlying mechanisms of the disease.

The significance of CNNs in AD detection is underscored by a growing body of literature [15], [16], [17], [18], [19], [20]. These studies highlight the effectiveness of CNN-based approaches in identifying AD-related biomarkers and distinguishing between healthy and diseased brain tissue. By harnessing the vast amounts of data available in neuroimaging databases, CNNs offer a data-driven approach to AD diagnosis that is both objective and scalable.

In summary, CNNs represent a transformative technology in the field of neuroimaging, with profound implications for AD detection and diagnosis. Their ability to decode intricate connections within images offers a novel avenue for early intervention and personalised treatment strategies, ultimately enhancing the quality of care for patients affected by this devastating disease.

A. Traditional CNN Architectures in AD Analysis

While traditional CNN architectures like LeNet-5 [21] and AlexNet [22] have laid a solid foundation for AD analysis, their efficacy in capturing the intricate features relevant to AD pathology may be limited [23], [24], [25], [26]. Although successful in various image classification tasks, these architectures may struggle to capture the subtle and complex patterns present in neuroimaging data associated with AD progression.

The complexity of AD pathology necessitates a more nuanced approach to feature extraction and representation learning. While LeNet-5 and AlexNet excel in extracting basic features, they may fall short when faced with the intricate structural changes and spatial relationships within the brain that are indicative of AD [27]. As a result, there is a growing recognition of the need for more advanced models specifically tailored to address the unique challenges posed by AD detection.

The limitations of traditional CNN architectures underscore the need for more advanced models capable of capturing the nuanced features relevant to AD pathology [28]. These features may include subtle changes in brain morphology, alterations in

connectivity patterns, and the presence of specific biomarkers indicative of disease progression. By leveraging more sophisticated architectures and learning algorithms, researchers can enhance the sensitivity and specificity of AD detection models, thereby improving diagnostic accuracy and patient outcomes.

Advanced CNN architectures offer several advantages in the context of AD detection [29]. They can adaptively learn hierarchical representations of neuroimaging data, allowing for the extraction of features at multiple spatial and temporal scales. Additionally, advanced models can incorporate domain-specific knowledge and priors, enabling them to effectively capture the complex patterns associated with AD pathology [30].

Moving forward, there is significant potential for the development of advanced CNN architectures tailored specifically for AD detection. These architectures may incorporate innovative design elements such as attention mechanisms [31], recurrent connections [32], and graph-based representations [33] to better capture the spatial and temporal dynamics of AD pathology. Moreover, the integration of multimodal imaging data, including MRI, fMRI, PET, and sMRI, presents an exciting opportunity to enhance the performance of AD detection models further [34].

By leveraging the latest advancements in deep learning and neuroimaging, researchers can develop highly specialised CNN architectures optimised for AD detection. These architectures have the potential to revolutionise the field by enabling earlier and more accurate diagnoses of AD, facilitating timely intervention, and personalised treatment strategies. Overall, the development of advanced CNN architectures represents a critical step towards addressing the growing challenge of AD and improving outcomes for affected individuals and their families.

B. The Emergence of 3D CNNs in AD Analysis

The advent of 3D Convolutional Neural Networks (CNNs) represents a significant advancement in the analysis of neuroimaging data, particularly in the context of AD detection [35]. Unlike traditional 2D CNNs, which process images as two-dimensional grids of pixels, 3D CNNs operate directly on volumetric data, such as MRI scans, capturing spatial information across multiple slices and dimensions [23], [24], [25], [26]. This ability to analyse volumetric data enables 3D CNNs to capture nuanced features crucial for understanding AD's temporal progression, including changes in brain volume, morphology, and connectivity over time.

The use of 3D CNNs in AD analysis offers several distinct advantages. By considering the spatial context of neuroimaging data, 3D CNNs can better capture the complex three-dimensional structures of the brain and the subtle changes associated with AD pathology [35]. This allows for more accurate and robust detection of disease-related abnormalities, enhancing diagnostic accuracy and facilitating early intervention.

While 3D CNNs have shown promise in AD analysis, the interpretability of their predictions remains a significant challenge. Conventional performance metrics such as accuracy, sensitivity, and specificity provide valuable insights into model performance but offer a limited understanding of the underlying features driving predictions. In the context of AD detection, where the identification of subtle biomarkers is crucial, interpretability is essential for gaining insights into disease mechanisms and guiding clinical decision-making.

To address this challenge, ongoing research is focused on developing interpretability tools and techniques for 3D CNNs. One promising approach involves the use of attention mechanisms [31], which highlight regions of interest within neuroimaging data that are most relevant to the model's predictions. By visualising these attention maps, researchers can gain insights into the features driving the model's decisions and identify potential biomarkers of AD pathology.

Additionally, advances in visualisation techniques, such as heatmaps and saliency maps [36], provide intuitive representations of model predictions, enabling clinicians to interpret and validate the results more effectively. These visualisation tools not only enhance the interpretability of 3D CNNs but also facilitate communication and collaboration between researchers and clinicians, ultimately improving the translation of AI-driven findings into clinical practice.

Looking ahead, there is significant potential for further advancements in 3D CNNs for AD analysis. Future research efforts may focus on refining model architectures to improve both performance and interpretability, incorporating novel attention mechanisms and visualisation techniques. Moreover, the integration of multimodal neuroimaging data [37], including structural MRI, functional MRI, and positron emission tomography (PET), presents an exciting opportunity to enhance the sensitivity and specificity of AD detection models.

By leveraging the capabilities of 3D CNNs and addressing the challenges of interpretability, researchers can develop more accurate, reliable, and clinically relevant tools for AD diagnosis and monitoring. These advancements have the potential to revolutionise the field of neuroimaging and improve outcomes for individuals affected by AD, ultimately

leading to earlier diagnosis, personalised treatment strategies, and improved quality of life.

C. Transfer Learning Strategies in AD Detection

Transfer learning has emerged as a potent strategy in the field of Alzheimer's disease (AD) detection, offering a promising approach to leverage pre-trained models and enhance the accuracy of AD detection systems. One notable example of transfer learning involves the use of pre-trained models like VGG16, which are fine-tuned using AD-specific datasets to improve their performance in detecting AD-related biomarkers and abnormalities [23], [24], [25], [26]. By leveraging insights from extensive image datasets, pre-trained models can effectively capture complex patterns and features relevant to AD pathology, thereby enhancing the accuracy and reliability of AD detection systems.

Transfer learning offers several advantages in the context of AD detection [38]. By utilising pre-trained models trained on large-scale image datasets, researchers can leverage the knowledge and representations learned by these models to bootstrap the training process for AD-specific tasks. This not only accelerates the training process but also enables AD detection systems to benefit from the generalisation capabilities of pre-trained models, thereby improving their performance on new and unseen data.

In addition to transfer learning, the efficacy of 3D architectures in handling volumetric data underscores their relevance in capturing the temporal nuances critical for AD progression analysis. Unlike traditional 2D CNNs, which process images as two-dimensional grids of pixels, 3D CNNs operate directly on volumetric data, enabling them to capture spatial and temporal information across multiple dimensions [23], [24], [25], [26]. This allows 3D architectures to effectively analyse longitudinal neuroimaging data, such as MRI scans, and identify subtle changes indicative of AD progression over time.

The integration of transfer learning and 3D architectures represents a powerful approach to AD detection, combining the benefits of pre-trained models with the ability to analyse volumetric data. By fine-tuning pre-trained 3D CNNs using AD-specific datasets, researchers can develop highly specialised models optimised for detecting AD-related abnormalities and biomarkers [38]. This integrated approach not only improves the accuracy and reliability of AD detection systems but also facilitates the interpretation of results by capturing the temporal dynamics of AD progression.

Looking ahead, the combination of transfer learning and 3D architectures holds promise for advancing the field of AD detection. Future research efforts may focus on further optimising transfer learning techniques and developing more sophisticated 3D CNN architectures tailored specifically for AD progression analysis. Moreover, the integration of multimodal neuroimaging data, including structural MRI, functional MRI, and positron emission tomography (PET), presents an exciting opportunity to enhance the sensitivity and specificity of AD detection models. Ultimately, the integration of transfer learning and 3D architectures has the potential to revolutionise AD detection by providing clinicians with powerful and reliable tools for early diagnosis and intervention, ultimately improving patient outcomes and quality of life [39].

D. Recent Advancements in CNN for AD Detection

Recent studies have underscored the potential of Convolutional Neural Networks (CNNs) in various facets of Alzheimer's disease (AD) detection, ranging from hippocampal segmentation to disease stage classification and early prediction using diverse imaging modalities [8], [9], [10], [11], [12]. These studies have demonstrated the versatility and effectiveness of CNN-based approaches in analysing neuroimaging data and extracting relevant biomarkers indicative of AD pathology.

While CNNs have shown promise in AD detection, most existing models rely on transfer learning or access to larger datasets to enhance their performance. Transfer learning involves fine-tuning pre-trained models on AD-specific datasets to leverage knowledge learned from other domains. While effective, this approach often requires access to extensive computational resources and large, well-curated datasets, which may not be readily available in many clinical settings. Moreover, existing models may struggle to generalise to new datasets or clinical populations, limiting their utility in real-world applications.

In contrast to traditional approaches, ConvADD represents a pioneering approach to AD detection that directly addresses the dependency on transfer learning and large datasets. ConvADD prioritises accuracy without resorting to dataset balancing techniques, mitigating the need for exceptionally large datasets or extensive pre-training. By focusing on robust feature extraction and representation learning, ConvADD aims to enhance the reliability and generalizability of AD detection models across diverse datasets and clinical populations.

ConvADD offers several advantages over existing models in AD detection. By prioritising accuracy and robustness, ConvADD reduces the risk of model bias or overfitting, thereby improving the reliability of AD diagnosis. Additionally, ConvADD's ability to perform effectively without extensive pre-training or dataset balancing simplifies the implementation and deployment of AD detection systems

in clinical settings, making them more accessible to healthcare practitioners and researchers.

ConvADD's pioneering approach marks a promising direction in overcoming the challenges associated with AD detection. Moving forward, further research efforts may focus on refining ConvADD's architecture and training strategies to improve its performance and scalability. Additionally, the integration of multimodal neuroimaging data and advanced analysis techniques, such as attention mechanisms and graph-based representations, presents an exciting opportunity to enhance the sensitivity and specificity of AD detection models.

In conclusion, recent advances in CNNs have demonstrated their potential to transform AD detection by enabling accurate, reliable, and accessible diagnostic tools. ConvADD's pioneering approach represents a significant step forward in overcoming the challenges associated with AD detection, offering a promising direction for future research and clinical applications. By prioritising accuracy and robustness while minimising dependencies on transfer learning and large datasets, ConvADD holds promise for improving patient outcomes and advancing our understanding of AD.

E. Importance of novel CNN

In the area of Alzheimer's disease (AD) detection, the justification for the development of novel CNN architectures is imperative. Traditional methods often face challenges in accurately identifying AD, particularly in its early stages, due to the complexity and heterogeneity of the disease [40], [41]. Besides that, advanced approaches are too complex and take computational resources and as well as time [42], [43]. By introducing ConvADD, a tailored CNN architecture for AD detection and optimisation, this research endeavours to address these challenges and enhance diagnostic accuracy with effective memory management. Novel CNN architectures offer the potential for improved feature extraction and representation learning, enabling better discrimination between AD and non-AD brain images. Recent studies have shown the efficacy of deep learning approaches, such as CNNs, in various medical imaging tasks [44], [45], [46], [47], including AD classification. Moreover, advancements in deep learning techniques, coupled with the availability of large-scale medical imaging datasets, have forced the exploration of innovative CNN architectures for AD detection [48]. Therefore, the development and validation of ConvADD contribute to the ongoing efforts to enhance the accuracy and reliability of AD diagnosis, underscoring the necessity for novel CNN architectures in addressing the evolving challenges of AD detection.

III. METHODOLOGY

The methodology employed in this study amalgamates innovative architectural design with meticulous dataset curation to formulate a robust convolutional neural network (CNN) model tailored explicitly for Alzheimer's Disease (AD) detection. Fig. 1. depicts the overall methodology of the process. The ConvADD architecture stands as the cornerstone of this study, meticulously designed to encapsulate the intricate nuances of AD pathology. Comprising ConvADD convolutional blocks and novel design principles, this architecture addresses the imperative need for precise and nuanced AD detection methodologies.

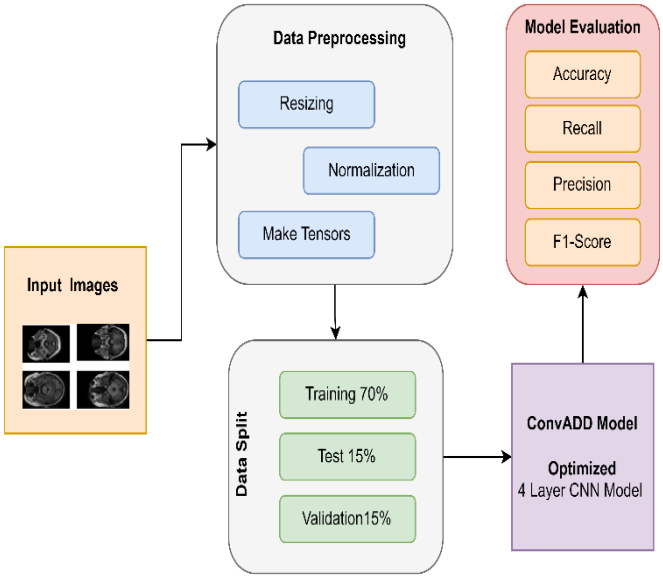

Fig. 1. Methodology diagram of ConvADD.

Fig. 2. outlines the schematic representation of the ConvADD architecture, elucidating its intricate layers and design principles. Subsequent subsections detail the dataset collection process, delineate the architectural design considerations and provide an in-depth analysis of the ConvADD convolutional blocks. These subsections elucidate the meticulous approach taken in crafting the ConvADD architecture, underscoring its robustness and efficacy in AD detection.

A. Dataset Collection

Several datasets available online for Alzheimer's Disease (AD) classification were considered for this research. However, many of these datasets were in CSV format, which was deemed unsuitable for the purposes of this study. Dedicated organisations such as the Alzheimer's Disease Neuroimaging Initiative (ADNI) and the Open Access Series of Imaging Studies (OASIS) offer extensive datasets for research and educational use. Nevertheless, both the OASIS

and ADNI datasets consist of voluminous 3-dimensional image files, with the OASIS dataset totalling 18 gigabytes and the ADNI dataset reaching 450 gigabytes in size.

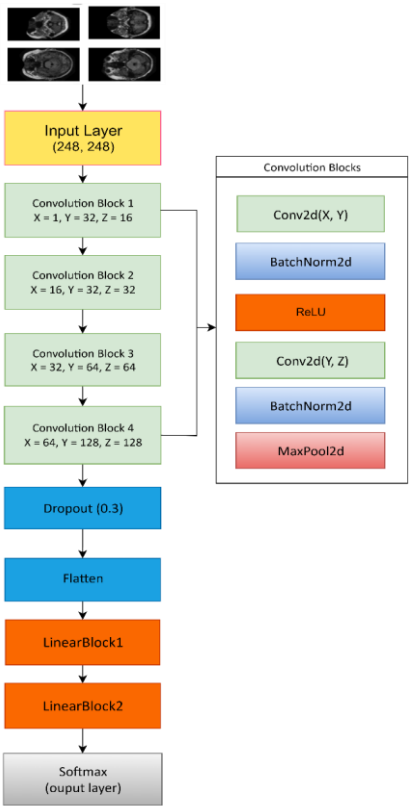

Fig. 2. ConvADD architecture.

To address these challenges, the Kaggle dataset was selected for this research. The Kaggle dataset (link) undergoes meticulous verification by the uploader, ensuring the reliability of each sample. Moreover, its manageability is enhanced by its reasonable size and meticulous preprocessing efforts, including resizing and organisation. The dataset comprises a total of 6400 samples, each represented as individual three-channel (RGB) images with dimensions of 176 x 208 pixels, which were resized to 248 x 248 pixels for uniformity. These samples are categorised into four distinct classes: Non-Demented (NOD), Very Mild-Demented (VMD), Mild-Demented (MD), and Moderate Demented (MOD). The NOD class, with 3200 samples, constitutes the majority, while the remaining classes comprise 2240, 896, and 64 images, respectively (see Table I).

TABLE I. CLASS DISTRIBUTION IN AD DATASET

Class label	Number of Images
Mild Demented (MD)	896
Moderate Demented (MOD)	64
Non-Demented (NOD)	3200
Very-Mild Demented (VMD)	2240

Furthermore, the dataset was strategically partitioned into training (70%), validation (15%), and test sets (15%) to ensure an equitable distribution for robust model training and evaluation. Fig. 3. provides a visual representation of some random samples from the dataset, along with their corresponding class labels. This comprehensive approach to dataset selection and preprocessing lays a strong foundation for the subsequent experimentation and evaluation of the proposed ConvADD model for AD detection.

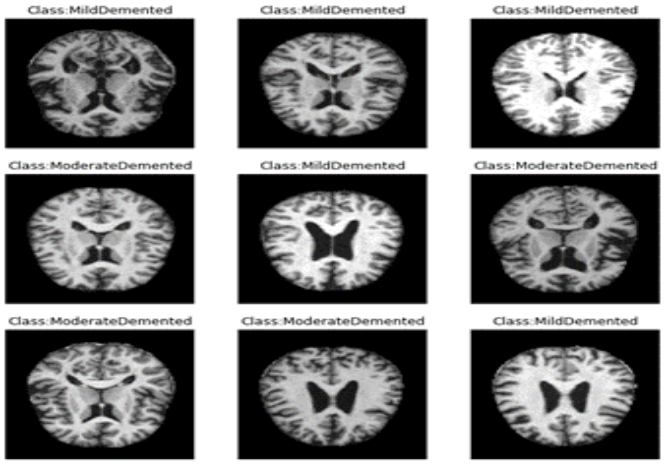

Fig. 3. Random sample from the dataset representing the MRI image with the corresponding class label.

B. *Architecture Design – ConvADD*

The ConvADD architecture, a Convolutional Neural Network (CNN), embodies a hierarchical structure that effectively processes input data through a series of distinct layers. Starting from the input layer, the network ingests grayscale images of size 176x208 pixels. These images are passed through the initial convolutional block, where the data traverses two consecutive convolutional layers. The first layer, a 3x3 kernel Conv2d operation with 32 output channels, extracts fundamental features from the input. Batch normalisation follows, ensuring standardised inputs to the rectified linear unit (ReLU) activation, introducing non-linearity and enhancing model convergence. Subsequently, the second convolutional layer with a similar kernel size further transforms these features, condensing them into 16 output channels. Another round of batch normalisation and ReLU activation precedes max pooling, downsampling the data by a factor of 2x2.

The subsequent convolutional blocks follow a similar pattern, progressively deepening the network's representation of intricate features. The second block takes the 16 output channels from the previous block, initiating another 3x3 kernel Conv2d operation to generate 32 output channels. Batch normalisation, ReLU activation, and max pooling are then

applied. This process continues through the third and fourth blocks, each enhancing the depth and complexity of feature extraction. The third block further transforms the 32 channels into 64 output channels, while the fourth block expands this to 128 output channels, thereby capturing increasingly sophisticated patterns.

The architecture integrates dropout regularisation to prevent overfitting, strategically removing a small fraction of nodes during training. Following the convolutional layers, a flattening operation converts the multidimensional data into a one-dimensional vector, preparing it for processing through fully connected layers. These layers, comprising linear transformations and batch normalisation, iteratively reduce the dimensions of the data to eventually output class probabilities via the softmax layer. ConvADD's design embodies this systematic progression, facilitating the extraction of hierarchical features, culminating in effective classification outputs for Alzheimer's disease stages.

C. ConvADD Convolutional Blocks

The ConvADD architecture introduces a novel approach to feature extraction through its meticulously designed convolutional blocks. These blocks, strategically structured to capture intricate patterns in Alzheimer's disease (AD) imaging data, mark a significant departure from traditional architectures.

1) Block 1: Initial Feature Extraction: The first convolutional block kickstarts the feature extraction process. It consists of two convolutional layers: the first layer operates with a 3x3 kernel size, transforming the input grayscale images into 32 fundamental features. Batch normalisation and ReLU activation layers ensure stabilised inputs and introduce non-linearity, respectively. Subsequent max-pooling downsamples the data, aiding in information condensation.

2) Block 2 to Block 4: Hierarchical Complexity: Blocks 2 through 4 follow a similar blueprint, progressively enhancing the network's feature representation. Block 2, building upon the output channels from the previous block, refines these features by employing 32 output channels. Successive blocks intensify the complexity of feature extraction, with Block 3 generating 64 output channels and Block 4 culminating in 128 output channels. Each block integrates batch normalisation, ReLU activation, and max pooling, contributing to a hierarchical refinement of extracted features.

3) Novelty of ConvADD's convolution blocks: The innovation within ConvADD's architecture lies in the precise orchestration of these convolutional blocks. Each block contributes to the nuanced extraction of hierarchical features, leveraging depth and width to capture AD-specific patterns in imaging data. This novel arrangement distinguishes ConvADD from conventional CNN architectures, enhancing its efficacy in AD stage classification.

D. Dense Blocks: Enabling Robust Classification in ConvADD

Following the convolutional layers, ConvADD employs dense blocks to refine the extracted features further before the final classification. These dense layers contribute to the network's ability to understand intricate patterns and make informed predictions regarding the stages of Alzheimer's disease (AD).

1) Linear Block 1: Feature Fusion and Transformation: After flattening the feature maps extracted by the convolutional layers, Linear Block 1 acts as a pivotal point for feature fusion and transformation. This block consists of a fully connected layer (Linear) that transforms the high-dimensional flattened features into a lower-dimensional space of 16 units. Batch normalisation enhances stability within the network, and ReLU activation introduces non-linearity, facilitating the network's capacity to learn complex mappings between features.

2) Linear Block 2: Stage Classification: The subsequent Linear Block 2 is designed explicitly for stage classification. This block employs another fully connected layer, reducing the feature space further to four units, aligning with the four distinct classes related to AD stages. Batch normalisation and ReLU activation continue to contribute to feature stability and non-linearity, respectively, preparing the features for the final Softmax activation.

3) Contribution of dense blocks in ConvADD: The inclusion of these dense blocks within ConvADD amplifies the network's capability to abstract and distil essential features learned from the convolutional layers. These blocks play a pivotal role in synthesising complex hierarchical features into a form that facilitates the precise classification of AD stages, marking a significant contribution to the architecture's efficacy.

E. Hyperparameters and Network Configuration

ConvADD architecture incorporates a set of meticulously chosen hyperparameters and specific network configurations that profoundly influence its performance and learning capabilities.

1) Learning rate and optimizer: The learning rate, set at a crucial 0.001, guides the step size during the network's weight updates, balancing between convergence speed and overshooting. The Adam optimiser, a variant of stochastic gradient descent (SGD), dynamically adjusts learning rates for each parameter, ensuring efficient convergence and optimal weight updates during training.

2) Dropout for regularization: To mitigate overfitting and enhance generalisation, ConvADD integrates dropout regularisation with a probability of 0.03. Implemented after the convolutional blocks, dropout randomly deactivates a fraction of neurons during each training iteration, preventing

the network from relying too heavily on specific features or connections and promoting more robust feature learning.

3) Activation function: ReLU: Rectified Linear Unit (ReLU) activation functions are employed throughout ConvADD. ReLU introduces non-linearity, allowing the network to model complex relationships within the data efficiently. By thresholding negative values to zero, ReLU accelerates convergence during training and prevents the vanishing gradient problem.

4) Batch normalization: Batch normalisation layers are strategically placed after convolutional and linear blocks. These layers standardise the input to a layer, reducing internal covariate shift and accelerating training by ensuring more stable gradients and facilitating faster convergence.

5) Weight initialization: ConvADD utilises appropriate weight initialisation strategies, such as Xavier or Him initialisation, enhancing the network's ability to learn and converge effectively by providing a suitable starting point for weights.

6) Grid search for optimal hyperparameters: The selection of these hyperparameters was meticulously curated through systematic grid search and cross-validation, optimising ConvADD's performance on the dataset used for training and validation.

7) Impact of parameter configuration: The careful selection and configuration of these parameters and techniques significantly contribute to ConvADD's stability, robustness, and capability to discern intricate patterns associated with AD stages.

IV. Results and Discussion

A. Performance Evaluation Metrics

1) Evaluation criteria: Evaluation metrics are pivotal in assessing the performance and efficacy of machine learning models. The ConvADD architecture's performance in Alzheimer's Disease classification using MRI images was rigorously evaluated employing a diverse set of metrics. These evaluation criteria allowed for a comprehensive understanding of the model's capabilities in different facets of classification accuracy and robustness.

a) Metrics Utilized

i) Accuracy: A fundamental metric indicating the proportion of correctly classified samples over the total number of samples. It provides an overall understanding of the model's correctness in predictions. The equation of accuracy [48], [49], [50], [51], [52] could be described as follows:

$$Accuracy = \frac{TP + TN}{TP + FN + FP + TN}$$

where, TP is true positive, TN is true negative, FN refers to false negative, and FP is false positive.

ii) Precision: Precision measures the model's accuracy concerning positive predictions. It denotes the ratio of correctly predicted positive observations to the total predicted positive observations. The formula is obtained as follows:

$$Precision = \frac{TP}{TP + FP}$$

iii) Recall (Sensitivity): This metric signifies the model's ability to identify all positive instances. It calculates the ratio of correctly predicted positive observations to the actual positives. The recall equation is:

$$Recall = \frac{TP}{TP + FN}$$

iv) F1-score: The F1 score conveys a balance between precision and recall. It's the harmonic mean of precision and recall, providing a consolidated measure of a model's accuracy. The F1-score formula is:

$$F1 = 2 * \frac{Precision * Recall}{Precision + Recall}$$

v) Confusion Matrix: The confusion matrix serves as a foundational tool for evaluating the performance of a classification model. It systematically presents the division of outcomes, encompassing all the predictions made by the model during its training or testing phase. This matrix provides a comprehensive breakdown of predicted versus actual class labels, offering insights into the model's accuracy and potential misclassifications.

vi) Loss Function: The loss function serves as a crucial guidepost in the training process of machine learning models. It quantifies the model's performance by calculating the inconsistency between predicted and actual values, ultimately indicating how well the model is learning the patterns within the data. This metric is pivotal in adjusting the model's parameters to minimise errors, leading to enhanced predictive accuracy and convergence towards optimal outcomes.

b) Significance: These evaluation criteria enable a comprehensive analysis of the ConvADD model's performance. Accuracy, precision, and recall provide insights into the model's correctness and its ability to classify different stages of Alzheimer's Disease correctly. The F1 score balances precision and recall, offering a consolidated performance measure. Furthermore, ROC-AUC quantifies the model's discriminatory capacity between different classes, contributing to a holistic understanding of its effectiveness.

The utilisation of these metrics contributes to a nuanced and comprehensive assessment of the ConvADD architecture's performance in Alzheimer's disease classification, facilitating a deeper understanding of its strengths and areas for potential improvement.

2) Comparative analysis: Table II provides a comprehensive comparison of various models employed in the classification of Alzheimer's disease utilising MRI images. Each model's performance is evaluated based on crucial metrics, including accuracy, precision, recall, and F1-score, elucidating their effectiveness in accurately diagnosing Alzheimer's disease. The comparison encompasses ConvADD

and ADD-Net with and without the SMOTETOMEK technique, as well as well-known architectures like AlexNet, ResNet-50, and Inception ResNet-50. This detailed analysis offers insights into the strengths and limitations of each model, highlighting ConvADD's exceptional performance across multiple evaluation metrics, signifying its potential as a pioneering diagnostic tool for Alzheimer's disease detection.

In our comparative analysis with existing methods for Alzheimer's disease classification using MRI images, ConvADD emerged as a standout performer, showcasing superior performance across multiple evaluation metrics. ConvADD achieved an accuracy of 98.01%, outperforming other models such as ADD-Net (97.05%), ADD-Net with the SMOTETOMEK technique (92.88%), AlexNet (92.20%), ResNet-50 (93.10%), and Inception ResNet-50 (79.12%).

TABLE II. COMPARISON OF ALZHEIMER'S DISEASE CLASSIFICATION MODELS USING MRI IMAGES

Reference	Accuracy	Precision	Recall	F1-score
ConvADD	98.01%	98%	98%	98 %
ADD-Net (SMOTETOMEK) [48]	97.05%	97%	97%	97.05%
ADD-Net [48]	92.88%	82%	89%	84.55%
AlexNet [22]	92.20%	-	94.50%	-
ResNet-50 [52]	93.10%	-	92.55%	-
Inception ResNet-50 [49]	79.12%	70.64%	28.22%	39.91%

When evaluating precision, ConvADD demonstrated a precision rate of 98%, surpassing ADD-Net (97%), ADD-Net with SMOTETOMEK (82%), AlexNet (N/A), ResNet-50 (N/A), and Inception ResNet-50 (70.64%). This superior precision illustrates ConvADD's capability to accurately identify true positive cases among the predicted positive results, highlighting its robustness in minimising false positives.

Regarding recall metrics, ConvADD exhibited a recall rate of 98%, outstripping ADD-Net (97%), ADD-Net with SMOTETOMEK (89%), AlexNet (94.50%), ResNet-50 (92.55%), and Inception ResNet-50 (28.22%). This high recall rate indicates ConvADD's effectiveness in identifying true positive cases from the actual positive cases in the dataset, showcasing its ability to detect relevant instances without missing many positive samples.

Analysing the F1 Score, ConvADD showcased an F1 Score of 98%, demonstrating a harmonious balance between precision and recall. This excelled against ADD-Net (84.55%), ADD-Net with SMOTETOMEK (97.05%), AlexNet (N/A), ResNet-50 (N/A), and Inception ResNet-50 (39.91%). ConvADD's high F1 score signifies its proficiency in correctly classifying positive instances while minimising false positives and negatives.

ConvADD's consistently superior performance across accuracy, precision, recall, and F1-score underscore its efficacy in Alzheimer's disease classification, showcasing its potential as an advanced diagnostic tool in healthcare settings.

B. Experimental Setup

1) Experimental environment: Utilising the robust computational resources of Google Colab Pro's GPU environment was pivotal in training and evaluating ConvADD, our novel architecture. This cloud-based platform provided scalable computational power, freeing us from hardware constraints and allowing a concentrated focus on model refinement.

Instead of relying on personal hardware configurations, Google Colab Pro offered a versatile environment, enabling a laser focus on ConvADD's architecture. We meticulously assessed the model's performance using a segregated test set derived from the original dataset, ensuring an unbiased evaluation of its generalizability and accuracy.

Recognising the limitations of singular metrics like accuracy, we took a multifaceted approach. Alongside accuracy, we examined diverse metrics encompassing loss, overfitting, and other relevant indicators. This comprehensive evaluation methodology presents a nuanced view of ConvADD's strengths and limitations, leading to a more robust and reliable model.

In adherence to open science principles, we are dedicated to sharing our work openly. The complete source code for ConvADD will be publicly accessible on GitHub [1]. This transparency fosters collaboration, allowing for replication, extension, and contribution to the advancement of Alzheimer's Disease research.

2) Training configuration: Table III represents a comprehensive breakdown of the ConvADD architecture, delineating the intricate details of each layer within this specialised neural network tailored for Alzheimer's Disease classification using MRI images. From ConvBlock1 to the final Softmax layer, the table provides a detailed account of the output shapes, number of parameters, and specific configurations of each layer, underscoring the complexity and depth of the ConvADD model. Additionally, it encapsulates the predefined hyperparameters and training configurations instrumental in optimising the ConvADD architecture's performance and robustness during the training and validation phases.

[1]https://github.com/MAlsubaie/ConvADD.git

The ConvADD architecture, tailored for Alzheimer's Disease classification utilising MRI images, comprises a sequence of convolutional blocks, fully connected layers, and a concluding Softmax output. Each convolutional block, ranging from ConvBlock1 to ConvBlock4, introduces distinct layers of complexity to the model's architecture.

TABLE III. CONVADD ARCHITECTURE: LAYER DETAILS AND TRAINING CONFIGURATIONS

Layer Type	Output Shape	Number of Parameters
ConvBlock1	(64, 32, 176, 208)	2,308
ConvBlock2	(64, 32, 88, 104)	34,976
ConvBlock3	(64, 64, 44, 52)	70,752
ConvBlock4	(64, 128, 22, 26)	1,895,104
Dropout	(64, 128, 22, 26)	0
Flatten	(64, 7056)	0
LinearBlock1	(64, 16)	113,008
LinearBlock4	(64, 4)	72
Softmax	(64, 4)	0
Total number of parameters		2,116,220

ConvBlock1 initiates MRI image processing with 32 filters of 3x3 dimensions, yielding 32 sets of learned features and an output shape of (64, 32, 176, 208), entailing 2,308 parameters. Following this, ConvBlock2, utilising 32 filters akin to its predecessor, downsizes spatial dimensions via pooling, yielding an output of (64, 32, 88, 104) while contributing 34,976 parameters.

Advancing further, ConvBlock3 heightens model intricacy by doubling filters to 64, refining the image to (64, 64, 44, 52), and infusing 70,752 parameters. Subsequently, ConvBlock4 amplifies complexity with 128 filters, refining image processing and reducing spatial dimensions to (64, 128, 22, and 26), significantly elevating parameters to 1,895,104.

The Dropout and Flatten layers, though not adding parameters, play pivotal roles. Dropout combats overfitting by randomly deactivating neurons, while Flatten reshapes output for fully connected layers.

Linear blocks, especially Linear Block 1, which has 113,080 parameters, and Linear Block 4, which has merely 72 parameters, progressively process the flattened output, ultimately shaping the final output. The Softmax layer, computing class probabilities, doesn't introduce additional parameters.

The ConvADD architecture encompasses over two million parameters (2,116,220), highlighting its depth, intricate processing capacity, and potential to discern complex features from MRI images for Alzheimer's Disease classification.

Additionally, the ConvADD architecture underwent training and validation using predefined hyperparameters and training configurations to optimise performance and gauge robustness:

- Train Batch Size: 64
- Test Batch Size: 64
- Learning Rate: 0.001
- Number of Epochs: 10
- Validation Split: 15%
- Test Split: 15%

C. Performance of ConvADD

The ConvADD model was meticulously trained and validated over ten epochs using meticulously designed architecture and a carefully curated dataset. Throughout the training process, the model demonstrated remarkable progress in both accuracy and loss reduction, indicative of its ability to discern complex patterns inherent in AD pathology.

1) Loss function: The loss function, a critical metric in assessing model convergence and optimisation, exhibited a consistent downward trend over ten epochs. Fig. 4. shows loss starting at 0.0184 in the initial epoch; the loss function steadily decreased to 0.013 in the final epoch, showcasing the model's ability to minimise errors and optimise its predictions with training progression.

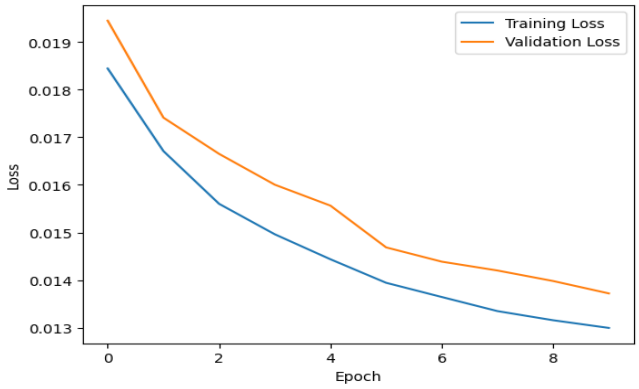

Fig. 4. Loss function trend over epochs.

2) Training accuracy: Simultaneously, ConvADD's accuracy increased remarkably during training, reflecting the model's enhanced proficiency in correctly classifying AD-related patterns within the dataset. Fig. 5. depicts starting accuracy at 68.5% in the initial epoch, ConvADD achieved an impressive 99.9% accuracy by the final epoch.

3) Confusion matrix: The confusion matrix, a comprehensive representation of the model's classification performance, revealed ConvADD's robustness in classifying AD-related categories, as shown in Fig. 6. The model demonstrated exceptional precision, recall, and F1-score

across MD, MOD, NOD, and VMD classes. With an accuracy of 98% and a macro average F1 score of 99%, ConvADD showcased its proficiency in discerning intricate nuances across various AD-related categories.

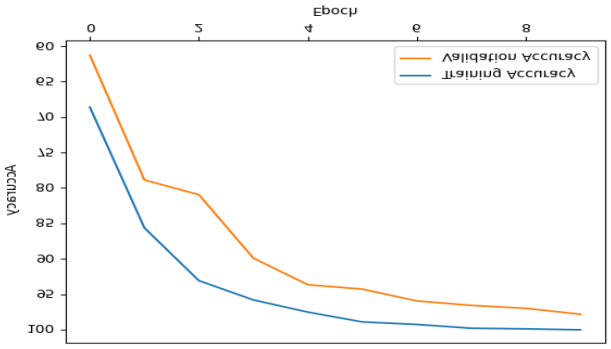

Fig. 5. Accuracy progression over training epochs.

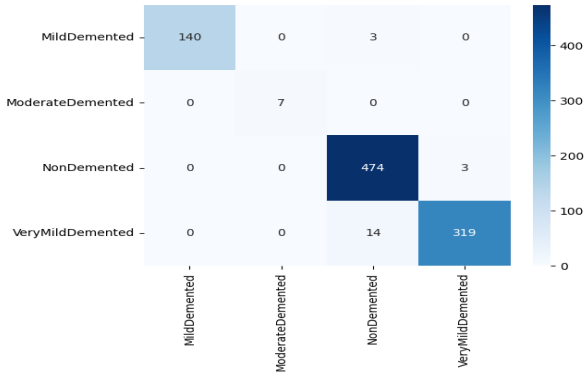

Fig. 6. Confusion matrix for ConvADD's classification performance.

The model's exceptional performance metrics across accuracy, loss function minimisation and confusion matrix analyses underscore its efficacy in precise AD detection without resorting to dataset balancing techniques. ConvADD's ability to capture intricate patterns indicative of AD pathology stands as a testament to its robustness and potential in clinical applications for AD diagnosis and prognosis.

D. Discussion

In evaluating various models for Alzheimer's Disease classification using MRI images, a thorough analysis emerges, highlighting ConvADD's noteworthy performance compared to established methodologies. ConvADD boasts superior accuracy at 98.01%, outshining the majority of models, including ADD-Net (97.05%), ADD-Net with SMOTETOMEK (92.88%), AlexNet (92.20%), ResNet-50 (93.10%), and Inception ResNet-50 (79.12%). This pronounced accuracy underscores ConvADD's efficacy in precisely discerning between different disease stages and healthy states. Moreover, ConvADD exhibits exceptional precision and recall at 98% across classes, indicative of its balanced identification of both positive and negative instances within the dataset. In contrast, models like Inception ResNet-50 display substantially lower recall scores, signifying their limitation in correctly identifying true positive instances, especially in classifying the mild cognitive impairment stage. ConvADD's robust performance across multiple metrics reaffirms its potential as a reliable diagnostic tool for Alzheimer's disease, transcending the limitations observed in other widely employed models.

V. Limitations and Future Directions

A. Model Limitations

Despite ConvADD's promising performance, several limitations warrant consideration. One notable aspect is the model's reliance on existing datasets, which may exhibit biases or inadequacies inherent in the data collection process. Dataset limitations, such as sample size, heterogeneity, or lack of diversity across demographics, may affect ConvADD's generalizability. Additionally, ConvADD's performance might vary when applied to datasets acquired from different imaging modalities or from varied scanning devices due to inherent variability in image quality and resolution.

Another limitation lies in the interpretability of ConvADD's decisions. Like many deep learning models, ConvADD operates as a complex, black-box system, making it challenging to discern the reasoning behind its classifications. This opacity could hinder its acceptance in clinical settings, where interpretability and explainability are critical.

Furthermore, ConvADD's performance might fluctuate when dealing with extremely noisy or ambiguous images, where identifying distinct pathological features becomes challenging. The model's ability to handle rare or atypical cases also needs careful consideration, as these instances might be underrepresented in training datasets, potentially affecting ConvADD's accuracy in such scenarios.

B. Future Prospects

Addressing the identified limitations opens avenues for future research in Alzheimer's Disease detection using ConvADD. One direction involves enhancing dataset quality and diversity, ensuring inclusivity across different demographic groups, disease stages, and imaging protocols. Augmenting datasets with more diverse samples, including rare and atypical cases, can further refine ConvADD's learning process, boosting its adaptability and robustness.

Another promising avenue involves advancing explainable AI techniques tailored for ConvADD, enabling the model to provide insights into its decision-making process. Methods such as attention mechanisms or saliency maps could elucidate the regions or features in the MRI images that significantly

influence ConvADD's classifications, enhancing its interpretability and fostering trust among clinicians and practitioners.

Additionally, fine-tuning ConvADD or integrating transfer learning approaches on larger, more varied datasets or multi-modal imaging data may fortify the model's capability to handle diverse image qualities and pathological manifestations. Exploring ensemble models or incorporating domain knowledge from neuroscience could further enrich ConvADD's understanding of complex disease patterns.

Moreover, deploying ConvADD in a real clinical setting for prospective validation studies could ascertain its performance, assess its practicality, and validate its utility as an auxiliary diagnostic tool. These studies could illuminate ConvADD's efficacy in aiding clinical decision-making and patient management, ensuring its seamless integration into the clinical workflow.

Continued research in these directions could not only surmount current limitations but also propel ConvADD toward becoming an indispensable, accurate, and clinically relevant tool for Alzheimer's disease diagnosis and monitoring.

VI. Conclusion

In conclusion, the ConvADD architecture stands as a pioneering convolutional neural network tailored explicitly for Alzheimer's Disease (AD) detection through MRI images. Its design, characterised by adapted conventional blocks and deep layers, exhibits superior discernment of AD pathology even with smaller datasets, marking a paradigm shift in AD detection frameworks.

Our contributions are substantial: the inception of ConvADD prioritises accuracy without relying on dataset balancing techniques, ensuring robust performance across varying dataset sizes. Comparative analyses underscore ConvADD's exceptional performance metrics against established state-of-the-art models, reaffirming its efficacy in AD detection.

The ConvADD model's performance, as depicted in the loss function, accuracy, and confusion matrix, demonstrates consistent advancements across epochs. With accuracy hovering around 98.01% and a robust F1-score of 98%, ConvADD showcases its reliability and proficiency in detecting different stages of AD, depicting precision in classifying distinct dementia types.

Comparison with existing models highlights ConvADD's superiority, particularly over ADD-Net with SMOTETOMEK and ADD-Net, showcasing its potential to outperform models leveraging data balancing techniques. The ConvADD architecture's strength lies in its ability to capture the multifaceted manifestations of AD, surpassing the limitations of classification-focused models.

While ConvADD exhibits promise, limitations in dataset biases, interpretability, and handling ambiguous images warrant further exploration. Future directions encompass refining dataset quality, enhancing interpretability, and integrating domain knowledge to fortify ConvADD's capabilities. Prospective validation studies in clinical settings will ascertain its utility and integration into clinical workflows.

In essence, ConvADD emerges as a transformative tool, poised to redefine AD detection. Its adaptability, accuracy, and potential to discern intricate disease features position it as a pivotal advancement in the realm of AD diagnostics, promising precision and early detection critical for effective therapeutic interventions and patient care.

A Cost-Effective IoT-based Transcutaneous Electrical Nerve Stimulation (TENS): Proof-of-Concept Design and Evaluation

Ahmad O. Alokaily*, Meshael J. Almansour*, Ahmed A. Aldohbeyb, Suhail S. Alshahrani
Department of Biomedical Technology, College of Applied Medical Sciences,
King Saud University, Riyadh 12372, Kingdom of Saudi Arabia

***Abstract*—Transcutaneous electrical nerve stimulation (TENS) systems have been extensively used as a noninvasive and non-pharmaceutical approach for pain management and rehabilitation programs. Moreover, recent advances in telemedicine applications and the Internet of Things (IoT) have led to an increased interest in developing affordable systems that facilitate the remote monitoring of home-based therapeutic programs that help quantify usage and adherence, especially in clinical trials and research. Therefore, this study introduces the design and proof of concept validation of an IoT-enabled, cost-effective, single-channel TENS for remote monitoring of stimulation parameters. The presented prototype features programmable software that supports manipulating the stimulation parameters such as stimulation patterns, pulse width, and frequency. This flexibility can help researchers substantially investigate the effect of different stimulation parameters and develop subject-specific stimulation protocols. The IoT-based TENS system was built using commercial-grade electronic components controlled with open-source software. The system was validated for generating low-frequency (10 Hz) and high-frequency TENS stimulation (100 Hz). The developed system could produce constant biphasic pulses with an adjustable compliance voltage of 5–32 V. The stimulation current corresponding to the applied voltage was quantified across a resistive load of 1 kΩ, resulting in a stimulation current of approximately 4.88–28.79 mA. Furthermore, synchronizing the TENS system with an IoT platform provided the advantage of monitoring the usage and important stimulation parameters, which could greatly benefit healthcare providers. Hence, the proposed system discussed herein has the potential to be used in education, research, and clinics to investigate the effect of TENS devices in a variety of applications outside of the clinical setup.**

I. Introduction

Chronic pain, lasting over three months, is considered one of the critical public health issues worldwide, with approximately 20% of the world's population estimated to suffer from chronic pain [1, 2]. Several studies have reported that the prevalence of chronic pain in adults is approximately 33% and 56% in the elderly in middle-income and low-income countries [3]. Moreover, pain and pain-related illnesses are the primary cause of disability worldwide [4]. Thus, there is a continuous need to develop and implement therapeutic interventions and medical technologies to enhance the quality of pain management.

Pain management is essentially managed via two main approaches: pharmacological and non-pharmacological interventions [5]. Pharmacological intervention has been shown to have some limitations and risks, such as opioid dependency, tolerance, and hyperalgesia [6, 7]. In comparison, non-pharmacological pain management strategies often refer to interventions and techniques used to reduce pain sensation without medicine. Non-pharmacological interventions such as physical and occupational therapy, psychological approaches, and neurostimulations have been previously shown to be effective in acute and chronic pain management [5].

One of the most widely used neurostimulation techniques for pain management is transcutaneous electrical nerve stimulation (TENS) [8]. TENS is a non-pharmacological, noninvasive, and inexpensive stimulation procedure in which pulses of electrical currents are delivered across the skin via pairs of electrodes that stimulate peripheral nerves to alleviate pain [9]. The analgesic effects of TENS have been shown to be effective in mediating pain sensation through peripheral and central neurological mechanisms [10]. Moreover, several studies have demonstrated the efficiency of various TENS protocols in alleviating neuropathic pain in multiple sclerosis [11], cancer [12], postherpetic [13], spinal cord injury [14], and stroke populations [15].

TENS devices can be configured with various stimulation parameters depending on the case. Therefore, the clinical settings for TENS can be classified into three main paradigms. In the conventional TENS protocol, low-intensity electrical pulses are delivered at a high frequency (50–100 Hz) with a pulse width adjustable between 50 and 200 µs, while in the intense TENS protocol, high-intensity electrical pulses are delivered at a low frequency (<10 Hz). Moreover, acupuncture-like TENS is configured to provide high-intensity electrical pulses at low frequencies (<10 Hz) with a more extended pulse width of 100–400 µs [16].

The physiological mechanism of conventional TENS is believed to be based on the Gate-Control theory of pain, where the activation of large-diameter mechanoreceptive nerve fibers with a low threshold level leads to impeding the transmission of action potentials generated by small-diameter nociceptive fibers [8, 9]. Essentially, the touch-related nerves can prevent the pain-related nerves from sending signals to the brain by

blocking their transmission through the spinal cord. Moreover, an acupuncture-like TENS paradigm is intended to cause muscle twitches by engaging the motor afferents with a small diameter to induce extrasegmental analgesia, whereas the intense TENS paradigm causes extrasegmental analgesia and peripheral nerve blockade via the activation of small-diameter noxious afferents [17].

Several previous studies have investigated the feasibility of developing nerve and muscle microcontroller-based stimulation systems that can be used in educational, clinical, or research setups. For instance, Cornman et al. [18] proposed a portable, inexpensive, low-power consumption stimulation apparatus capable of producing ±150 V monophasic or biphasic pulses. Additionally, Trout et al. [19], implemented and further developed a proposed TENS electrical design of the stimulator proposed in [18] and validated its use for cutaneous and transcutaneous nerve stimulation. The results of Trout et al. show that nerve and muscle stimulation generated comparable forces with no significant effect of stimulation timing when applied to nerves or hand muscles.

Advances in smart technology applications in healthcare have gained attention in recent years as they provide the benefit of remote monitoring of patients' conditions and can be utilized as a tool to monitor patients' adherence, particularly for self-administered therapeutic interventions. Therefore, various medical applications have been developed to support the integration of IoT technology to support remote monitoring and reduce the daily time clinicians need for patient follow-ups. For instance, Ursache et al. [20] developed a low-cost smart TENS system that can be programmed and controlled via an Android application that can digitally adjust the stimulation parameters. Their proposed system was developed from commercial, low-cost electronic hardware and could deliver up to 100 V of monophasic pulses with an adjustable pulse duration. Additionally, Ortiz et al. [21] designed a knee orthosis with an embedded Bluetooth-connected TENS system controlled by a mobile application with customizable electrical muscle stimulation parameters suitable for osteoarthritis treatment.

To the best of our knowledge, no study has investigated the ability to develop an open-access, programable, and inexpensive TENS system incorporating the IoT application and its importance in enhancing the remote monitoring of systems designed to be operated by end users out of clinical setups with minimal training. Therefore, this paper presents and discusses the design and development of a low-cost and Internet of Things (IoT)-based TENS system. The use of an IoT-enabled neurostimulation system could facilitate the remote monitoring of patients' use of the TENS system and provide accurate information regarding adherence to prescribed daily usage.

The rest of this study is structured as follows: Section II provides an overview of the primary hardware elements of the proposed IoT-based TENS system along with details about the software structure and interface. Section III presents the proposed system's integration and validation. Lastly, Section IV discusses the study's conclusions, outlining its objectives and offering suggestions for future advancements.

II. Materials and Methods

The development of the IoT-based TENS system consists of identifying effective and inexpensive low-power consumption electronic hardware and tailored software to control the stimulation parameters. An IoT platform containing individual channels is also needed to record and monitor patient usage and the most critical protocol parameters, such as stimulation frequency and duration. The block diagram of the IoT-TENS system is shown in Fig. 1.

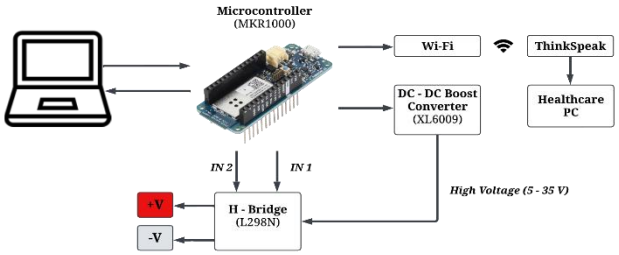

Fig. 1. Block diagram of the proposed IoT-based TENS unit.

A. Hardware Design

The electrical hardware components used in the study were selected based on their efficiency to provide an effective compliance voltage and the required amount of direct current stimulation. Hence, the IoT-based TENS was constructed using the following main consumer-grade components:

1) Microcontroller: A low-cost consumer-grade microcontroller (MKR 1000, Arduino LLC, Boston, MA) with internet connectivity via the integrated Wi-Fi shield. The IoT-enabled microprocessor is crucial for transmitting session information to the cloud.

2) Notebook: The proposed TENS system must be connected to a computer or notebook to power the system via the universal serial bus and establish serial communication with the microcontroller to send commands through a simple, user-friendly interface.

3) DC-DC step-up voltage transformer: A voltage boost converter was used to increase the output voltage of the microcontroller. The DC-DC voltage boost converter (XL 6009) used in this study can increase the essential 5-V-supplied input voltage to an output voltage between 5 and 32 V. The desired output voltage can be adjusted via an incorporated potentiometer.

4) Full H-Bridge module: TENS protocols could be administered through mono- or biphasic pulses. However, biphasic symmetrical TENS was found to achieve better clinical results [22]. Therefore, a dual H-Bridge (L298N) driver module was used in this prototype to switch the polarity of the monopolar pulses generated by the microcontroller and amplified by the boost converter. The H Bridge allows for generating positive and negative pulses with a maximum voltage of 5–35 V and a maximum current of 1 mA per channel.

5) Surface electrodes: A pair of adhesive 5 × 5-cm reusable surface electrodes were used.

B. Internet of Things Platform

The ThingSpeak platform was used in the IoT-based TENS device. A private channel was established to capture, track, and retrieve real-time information on the chosen stimulation type and duration. This information is critical for healthcare providers to track the patient's adherence to protocol and frequency of use [23].

C. Software Architecture

An open-access C++-based Arduino Integrated Development Environment (IDE; Version 2.1.1) was used to design custom-made software to control and activate the IoT-based TENS system. The software initiated the connection to the wireless network to feed the session's information to the IoT cloud at the start and finish of the stimulation. In addition, the healthcare provider could adjust the stimulation parameters, such as pulse width, frequency, and interpulse interval, to suit patients' needs. The stimulation pattern can be modified to be mono- or biphasic as needed. However, the work presented here was based on symmetric biphasic stimulation pulses as monophasic stimulation may lead to adverse effects such as excessive accumulation of charge and skin irritation [24, 25].

Therefore, various settings were implemented as a proof of concept for the IoT-based TENS system demonstrated in this study. Two distinct biphasic stimulation montages were programmed. First, the low-frequency stimulation, which has a stimulation frequency of 10 Hz and a pulse width of 400 µs, and the high-frequency stimulation protocol, where the stimulation was delivered at 100 Hz with a pulse width of 200 µs. The custom-made algorithm was designed based on the switch statement approach, where a set of discrete stimulation options are preconfigured based on the two types of stimulation (low frequency or high frequency) and the stimulation duration (5, 10, 15, 20, and 30 min).

The flowchart of the proposed algorithm is shown in Fig. 2. Users are prompted to enter a predefined code of the required stimulation frequency and duration, as shown in Table I. Upon entering the correct session code, the stimulation would begin by sending activation pulses from the microcontroller digital pins to produce the amplified biphasic stimulation pulses (pin 6 for the positive phase and pin 11 for the negative phase). Furthermore, the session information (frequency and duration) would be fed to the IoT Thinkspeak cloud at the beginning and end of each session.

TABLE I. STIMULATION SETTINGS

[a]. adjustable parameters.

Stimulation type	Predefined session code	Duration [a] (minutes)	Pulse width [a]
Low Frequency (default: 10 Hz[a])	a	5	400µs
	b	10	
	c	15	
	d	20	
	e	30	
High Frequency (default: 100 Hz[a])	f	5	200µs
	g	10	
	h	15	
	i	20	
	j	30	

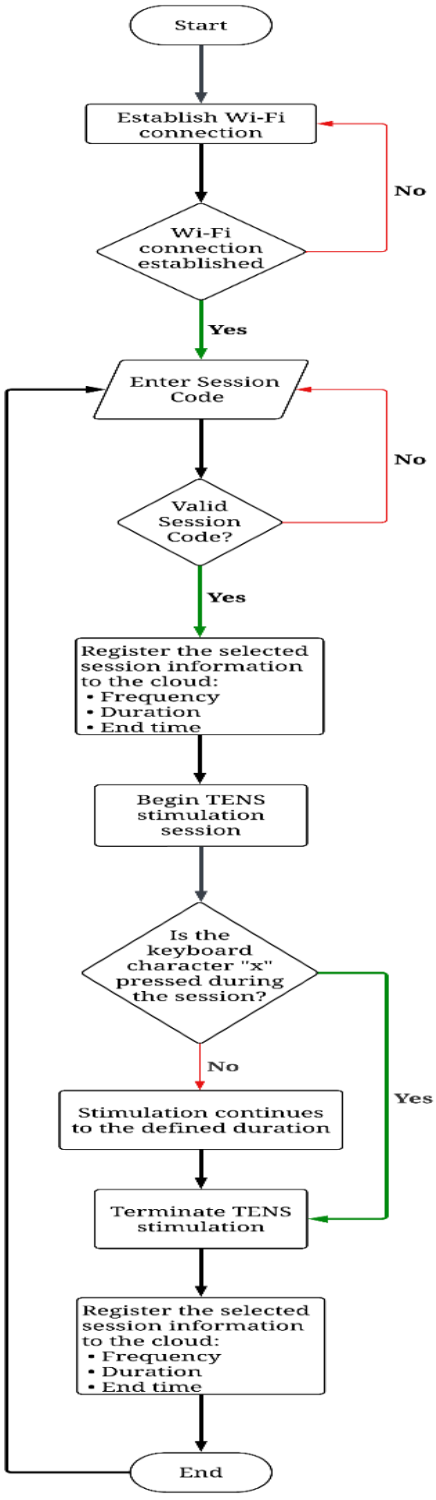

Fig. 2. Flowchart of the IoT-based TENS software.

D. System Functionality Testing

To evaluate the performance of the IoT-based TENS, the generated biphasic square pulses were monitored via an oscilloscope. The resulting frequency, current, and voltage range were recorded using a digital multimeter (GDM-451,

GW Instek) across a resistor with a resistance of 1000 Ω to represent human skin resistance [26]. The stimulation durations were also monitored and recorded to confirm the accuracy of each selected duration option. Moreover, the successful real-time synchronization of the session information was validated, including the stimulation type and the duration of the session between the proposed IoT-TENS system and the Thinkspeak cloud.

III. Results

A. System Integration

The prototype of the constructed IoT-based TENS system is shown in Fig. 3. The system components can be secured in a compact portable box with approximate dimensions of 16 × 10 × 8 cm. The proposed system successfully generated square pulses originating from the pulse-width modulation pins of the microcontroller and amplified by the DC-DC converter. The monophasic pulses were then converted into biphasic pulses via the H-bridge module (see Fig. 4). The resulting output peak-to-peak voltage of the system is adjustable between approximately 10–60 V (peak-to-peak) via the DC-DC converter voltage adjust potentiometer. The potentiometer allows users to alter the current intensity of the stimulation by increasing or decreasing the compliance stimulation voltage. Notably, the cost of developing the single-channel IoT-based TENS system was $58.72.

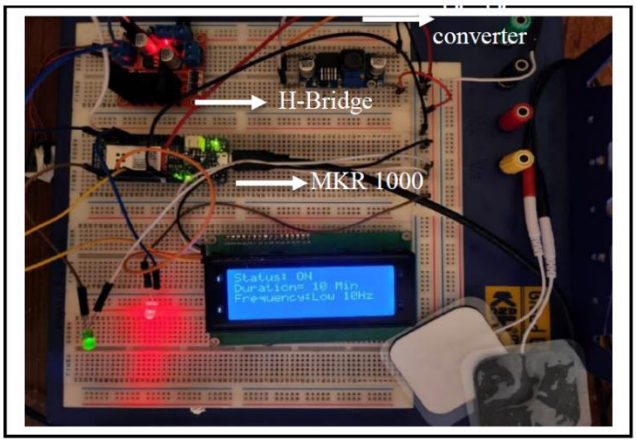

Fig. 3. Photograph of the proposed IoT-based TENS circuit.

B. System Validation

The noninvasive IoT-based TENS system operation was validated by visualizing the output waveform across the electrode leads. The low-frequency stimulation program generated biphasic stimulation waveforms, as shown in Fig. 4. Using a load of 1 kΩ, the stimulation current amplitude can be changed between 4.88 mA and 28.79 mA for compliance voltage between 5 and 30 V, respectively, with a variation of stimulation current between −0.90 % and −4.03% (see Table II). Moreover, testing the system's internet connectivity revealed that maintaining connectivity was achievable with a mobile hotspot. Two data points recorded the selected session's information on start time, stimulation duration and frequency, and the end time, upon which the stimulation was completed across all the predefined settings and uploaded to the system's private channel, accordingly (see Fig. 5).

TABLE II. Comparison Between Calculated and Measured Current Intensity

Applied peak voltage (V_p)	Calculated current across a resistive load of 1kΩ ($I_p = V_{IN}/R_L$)	Measured Current	Error
5 V	5 mA3	4.88 mA	−2.4 %
10 V	10 mA	9.91 mA	−0.90 %
20 V	20 mA	19.23 mA	−3.85%
30 V	30 mA	28.79	−4.03 %

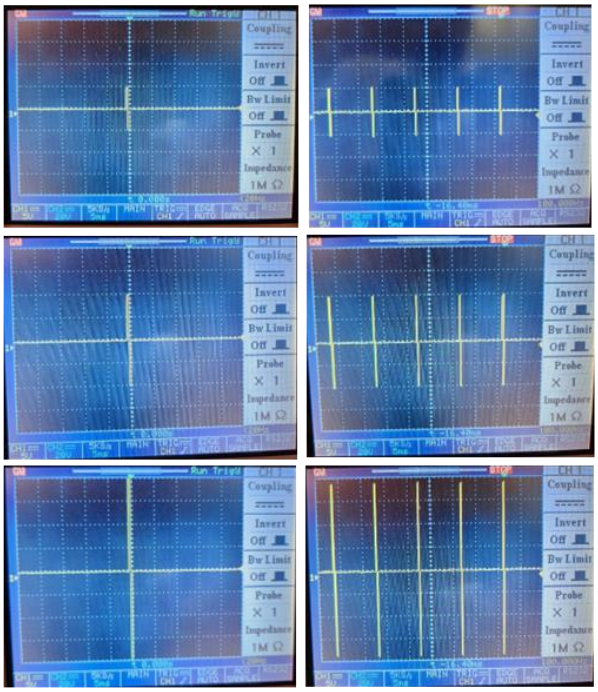

Fig. 4. Demonstrates the testing of the IoT-based biphasic output voltage with an oscilloscope, showcasing different compliance voltages and stimulation frequencies. The left column shows low-frequency stimulation. pulses (10 Hz) with 10, 20, and 40 V peak-to-peak voltage amplitudes, respectively. The right column displays high-frequency stimulation pulses (100 Hz) with 10, 20, and 40 V peak-to-peak voltage amplitudes, respectively.

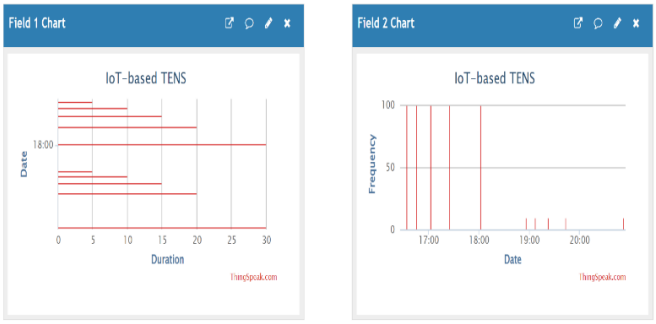

Fig. 5. ThinkSpeak private channel information in which the session duration in minutes (left) and frequency in Hertz (right) were updated and validated for each predefined setting.

IV. Conclusion

The IoT-based TENS system presented in this study demonstrates the feasibility of constructing an affordable single-channel TENS system with IoT capabilities that can be used in research laboratories and studies requiring users' adherence to the stimulation protocols. Moreover, the data

derived from the IoT-based TENS can be critical in evaluating the effect of the TENS system, especially in cases where users are instructed to employ the stimulation system as a treatment for pain. Additionally, the stimulation waveforms and properties of most of the available TENS systems in the market cannot be customized [19]. Thus, using a microcontroller-based system and the associated software has the advantage of designing tailored stimulation patterns, durations, and frequencies to target different clinical or research purposes and facilitate the customization of stimulation parameters for each end user.

The proposed system has an additive value of incorporating the IoT feature that can automatically save vital information regarding system usage compared with the previously developed TENS systems [19-21]. Although the IoT-based TENS system incorporated a single stimulation channel and biphasic stimulation patterns were presented, this can be expanded to two or more channels, and monophasic or biphasic stimulation can be generated, as in [18, 19]. Furthermore, although the generated compliance voltage capabilities of the presented system (±30 V) are commonly used in battery-powered TENS systems, this can be further enhanced and upgraded directly by replacing the DC-DC boost converter and the H-bridge modules with other models that have higher power ratings as used in [18, 19]. However, as TENS systems are often available as over-the-counter options, operating high-voltage instruments of ±300V is hazardous and requires those systems to be only used in a well-controlled environment.

Further studies are required to validate the efficacy of the proposed IoT-based TENS systems on the human population to evaluate their ability to stimulate nerves and muscles. Additional research can discern whether the proposed system has the potential to be used in clinical treatment programs to reduce the sensation of pain.

An Intelligent Learning Approach for Improving ECG Signal Classification and Arrhythmia Analysis

Sarah Allabun
Department of Medical Education, College of Medicine,
Princess Nourah bint Abdulrahman University, P.O.Box 84428, Riyadh 11671, Saudi Arabia

***Abstract*—The development of deep learning algorithms in recent years has shown promise in interpreting ECGs, as these algorithms can be trained on large datasets and can learn to identify patterns associated with different heart conditions. The advantage of these algorithms is their ability to process large amounts of data quickly and accurately, which can help improve the speed and accuracy of diagnoses, especially for patients with heart conditions. Our proposed work provides performant models based on residual neural networks to automate the diagnosis of 12-lead ECG signals with more than 25 classes comprising different cardiovascular diseases (CVDs) and a healthy sinus rhythm. We conducted an experimental study using public datasets from Germany, the USA, and China and trained two models based on Residual Neural Net-works-50 (ResNet-50) and Xception from CNN techniques, which is one of the most effective classification models. Our models achieved high performances for both training and test tasks in terms of accuracy, precision, recall, and loss, with accuracy, recall, and precision exceeding 99.87% for the two proposed models during the training and validation. The loss obtained by the end of these two phases was 3.38.10-4. With these promising results, our suggested models can serve as diagnostic aids for cardiologists to evaluate ECG signals more quickly and objectively. Further quantitative and qualitative evaluations are presented and discussed in the study, and our work can be extended to other multi-modal big biological data tied with ECG for similar sets of patients to obtain a better understanding of the proposed approach for the benefit of the medical world.**

Keywords*—*Electrocardiogram; cardiovascular diseases; classification; ResNet-50; Xception

I. Introduction

Globally, one of the major causes of death is cardiovascular disease (CVD) as it represents about greater than 30% which 85% of it is a heart attack, it is expected that more than 130 million people will be suffering by 2035 [1]. CVD has caught the attention of many researchers as they have been studying to elaborate solutions for the prevention and detection of these diseases regarding their impact economically [2]. Every year, studies have shown that the impact of CVD on the American and European economies is estimated at $555M and €210M, respectively. Understanding how the heart's electrical system works is crucial before examining [20] the electrocardiogram (ECG). The heart is an organ that periodically contracts and relaxes. Its cells play a role in the propagation of electrical impulses to nearby cardiac cells [3].

The principle of the ECG is to record the electrical impulses at the origin of cardiac contractions. The electrical impulses are recorded away from the heart, through the skin, using electrodes [4]. There are two types of electrodes: six precordial electrodes implanted on the chest and three frontal electrodes (or four, to refine the signal) placed on the limbs. The accuracy of the diagnosis is influenced by the number of electrodes. In fact, the more there are, the more accurate and precise the diagnosis will be. The accuracy of an electrocardiograph with 4 leads will be less than one with 12 leads. the most common clinical use is with 12 leads [5]. If the electrical impulse moves toward one of these electrodes, it registers a positive signal; if it moves away, it registers a negative signal. The wrists and ankles of the patient are where the frontal electrodes are placed [6]. They enable the reconstruction of the patient's heart's electrical axis; the ECG is the tracing obtained. Numerous cardiac issues are highlighted by this diagram, including atrioventricular blocks (poor electrical impulse conduction), bradycardias, and tachycardias with a slowing or accelerating of these complexes on the drawing [7].

The interpretation of this schema enables the doctor to confirm whether the heart is functioning properly. The responsibilities of cardiologists are expanding along with the rise of cardiac problems. Cardiology variation both within and across radiologists affects the manual interpretation [8]. The result of the manual interpretation will also be influenced by other factors such as mood, exhaustion, and others. Doctors regularly analyze and interpret ECGs, the diagnoses are greatly influenced by the doctor's training, qualifications, expertise, and experience. However, even experts and specialists are unable to fully identify all ECG signals information. In actuality, the analysis of lengthy recordings, such as Holter examinations and ambulatory cases of continuous monitoring in intensive care and intensive care and resuscitation units, is difficult and time-consuming, particularly for the detection of characteristic waves of the ECG signal and the classification of heartbeats [9].

Nowadays, innovative technologies such as Artificial intelligence have been helpful in a revolutionary way. Computer-aided medical diagnostics (CAMD) are now crucial for the diagnosis of CVD due to developments in hardware and algorithms. Cardiologists can consult CAMDs based on ECG signals for guidance and interpret results within a few seconds by checking CVD-specific characteristics. Due to the enormous number of patients in critical care units and the requirement for ongoing surveillance, they can assist doctors in making the diagnosis in a simpler and quicker way, which appears to be essential [10]. This is how it appeared that DMAOs helped with the ECG signal-based cardiac diagnosis. These systems

should be simple to use, scalable, precise, reliable, and solid. Several techniques have been suggested in the latest decades for the evaluation of CVD. Various approaches, such as Deep Learning (DL) techniques have lately become useful tools in complex applications such as computerized machine vision and natural language processing. Among DL technics, a convolutional neural network (CNN) is by far one of the most effective [11].

Many researchers have shown interest in this topic and numerous approaches have been put out by various researchers to address it. There are several types of CVDs surpassing 100 types. This study aims to classify 27 heart rhythm types using ECG data including 26 different varieties of CVDs and normal sinus rhythm. The four merged used datasets to train, validate, and assess models in this classification, which comprises 42511 ECG records. The dataset utilized comprises 12-lead ECG signals, which is a common ECG category used in hospitals and clinical situations. It is trained with two models based on Residual Neural Networks-50 (ResNet-50) and Xception from CNN techniques, which is one of the most effective classification models.

The remainder of this investigation is organized as follows. Section II provides a review of comparable publications in the literature, while Section III described the suggested model and the simulation methodologies. A discussion and evaluation of the proposed ECG classification models' findings are provided in Section IV. Test phases are given in Section VI. Finally, Section VI discusses the conclusion and future projects.

II. Related Works

For ECG diagnosis, the Uni-G analysis tool, developed by the University of Glasgow, used rule-based criteria on signal processing and medical characteristics [3]. Datta et al obtained the best score in the Physionet/CinC Challenge 2017 [4] that have as its objective the single-leads ECGs classification. They applied a feature-oriented technique that includes a two-layer cascaded binary classifier. Another SP was employed in [6], Aziz et al used a Discrete Wavelet Transform (DWT) and SVM to detect R peaks and classify ECG signals.

Lately, DL models have been used on ECG data for a variety of applications such as denoising signals, pathology diagnosis [12], annotation or detection, and so on. The application of Deep Neural Network (DNN) in the classification of single or multiple ECG leads had shown a wonderful outcome [13]. Moreover, the results obtained by the em-ployment of a DNN on 91,232 ECG records are more performant than cardiologists when trying to diagnose 11 types of CVDs [14].

There are a variety of datasets used to train DL models. Most publications employ public databases such as MIT-BIH Databases and the Phsysionet/CinC Challenges da-taset. For example, the first dataset is MIT-BIH Arrhythmia Database [15] which comprises 48 2-leads ambulatory ECG recordings. Each one has a duration of 30 min. These were acquired from the BIH Arrhythmia Laboratory's 47 patients investigated between 1975 and 1979. This dataset includes five classes. In addition, MIT-BIH Atrial Fibrilla-tion Database [16] contains 25 ECG records. The duration of all the recordings is 10 hours. Most of the investigation dedicated to the Atrial Fibrillation (AFib) automated detection used this dataset. In addition, PTB is a widely used dataset that includes 54912-leads ECG signals from 290 subjects. This contains nine various diagnostic classes. Also, Ones of the most utilized dataset in the task of ECG classification are China Physiological Signal Challenge datasets [17]. Actually, the CPSC 2017, includes 8528 single lead ECG recordings. Their duration varies from 9s to 61s, and this comprises four classes: AFib, Normal, Noise and other MCVs. Whereas the CPSC 2018, it is a series of 6877 10s 12-leads ECG records. This comprises 9 diagnostic classes [18].

Ribeiro et al [19] used 2,322,513 ECG recordings, collected from 1,676,384 various patients, containing 6 types of CVDs as the training and the validation set. Their model is based on a Deep Neural Network (DNN) Architecture. DNNs outperformed cardiology resident clinicians in detecting six categories of anomalies in 12-lead ECG recordings, with F1-score over 80% and specificity exceeding 99%. These findings show that ECG diagnosis using DNNs, which was before examined in a single-lead scenario, generalizes effectively to 12-lead tests, bringing the technique closer to mainstream clinical practice. Besides, Zhu et al. [23] established their work on private dataset counting 180,112 12-leads ECG from 70,692 patients, including 21 classes. To classify these CVDs, they employed a CNN. The suggested CNN model consists of fifteen alternating layers for multilabel classification of the 21 heartbeats varieties. Shortcut connections in residual blocks were utilized to skip intermediate layers to avoid gradient vanishing difficulties. Rectified linear unit (ReLU) nonlinearity with dropout was utilized in the network to improve the performance and avoid the overfitting of the model. Similar to Zhu et al., Zhang et al. [21] used CNN to classify 6877 12-leads ECG provided by the CPSC 2018 to nine heart rhythm types. The suggested 1D-CNN has a similar overview to the original residual neural network for image recognition with 2D CNNs [22]. Actually, the proposed model has 34 layers. To capture deep characteristics, four residual blocks are stacked, then employed. Moreover, they used SHapley Additive exPlanations (SHAP) [23] to interpret the prediction of the model. This was used to interpret the patient level and the population level. Otherwise, this clarifies the attitude of the model against the single input, 12-lead ECG, and the whole used dataset. The SHAP method is based on game theory. In simple terms, it measures the impact on the prediction of adding a variable (all else being equal) by permuting all possible options.

In other papers, researchers opted to combine Neural Networks to boost models' performance. Zheng et al. [24] developed model formed by a combination of CNN and long short-term memory (LSTM) which belong to the Recurrent Neural Network (RNN) and trained it on the MIT-BIH databases. CNN is best suited for analyzing spatial or locally linked data, whereas LSTM excels at collecting time series data properties. Concerning the CNN, they used two models. The first is a simple CNN. The model's layers 1-9 are convolutional layers connected to the highest collection layer, while layer 10 is the LSTM layer. To predict the output, the network's end employs a fully - connected layer. Whereas the second is VGGNet belonging to the deep CNN. By combining

convolution and pooling layers, the model can successfully collect ECG deep information.

To enhance the robustness of models, investigators used data augmentation technics which are usually figured when there is an imbalance in training data. Wu et al. [25] utilized shifting test data. Moreover, Nonaka et al. [26] applied 13 data augmentation method on ECG signals to improve the efficiency of their DNN model. For example, they used erasing, scaling, squaring and so on.

III. METHODS

Fig. 1 depicts the process of the proposed methods, which were used in this investigation. The next subsections will discuss each phase of this workflow. Actually, this starts with the fundamental steps which is data preparation. This step comprises data cleaning, data preprocessing, data partition and data augmentation. The next step is the training and validation of the proposed models using the training and validation data already split. Lastly, the test of the trained and validated model. This requires the test data.

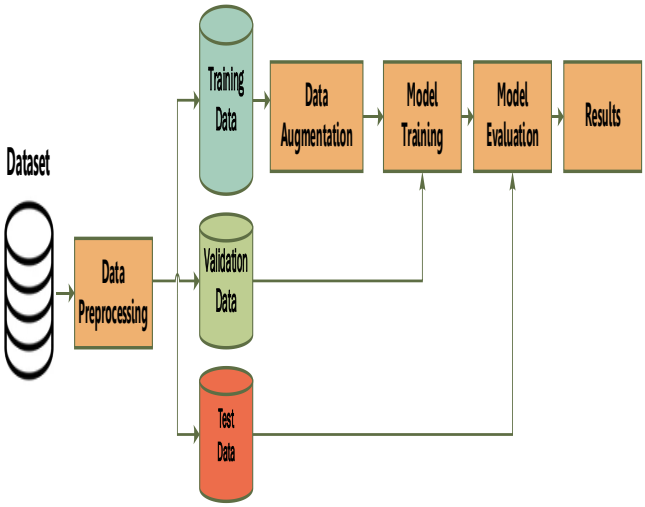

Fig. 1. Workflow of the proposed methods.

A. Dataset

The utilized dataset in this study contains four combined open source and free databases from George B. Moody PhysioNet Challenges which aims to classify 12-leads ECGs. This dataset contains 42 511 ECGs, 500 Hz-sampled, recorded from patients for a duration of 10 seconds. They come from three various countries, the USA, China, and Germany. Table I details the characteristics of these databases.

TABLE I. CHARACTERISTICS OF THE USED DATABASES

Database	Source	Records	Length
CPSC [21]	China Physiological Signal Challenge in 2018	6877 M: 3699 |F: 3178	6 s ~60 s
CPSC EXTRA [21]		3453 M: 1843 |F: 1610	6 s ~60 s
PTB-XL [26]	Physikalisch Technische Bundesanstalt	21837 M: 11379 |F: 10458	10s
Georgia [27]	Georgia	10344 M: 5551 |F: 4793	10s

The database is annotated with more than 110 diagnostics. In this study, due to the delimited annotations scored by the SNOMED-CT organization, which is a standardized multilingual clinical terminology vocabulary, only 27 classes will be considered, divided into normal sinus rhythm (NSR) and 26 categories of CVDs. Fig. 2 presents these classes.

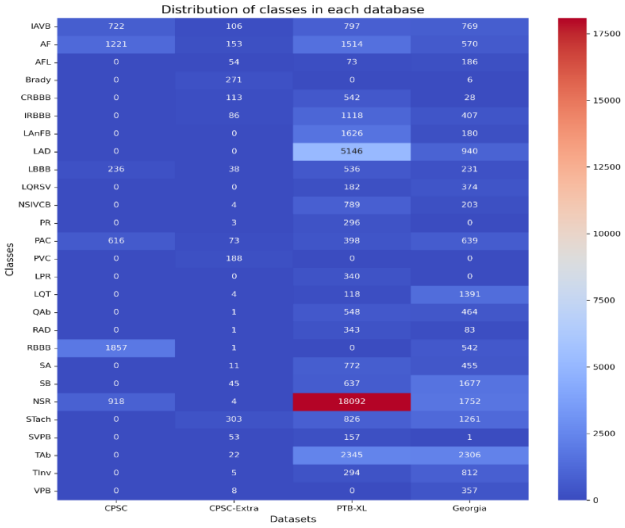

Fig. 2. Distribution of classes in each database.

B. Data Preparation

The data preparation starts with the extraction of the patient's personal information from the header files such as ID, age, gender, and anomalies codes. The following paragraphs detail the rest of the data preparation steps of training, validation, and testing. As indicated in paragraph 3, this work focuses on the 27 scored classes. For that, any annotated signal from the unscored classes will be removed. As a result, the number of ECGs will decrease from 42511 to 21724. The final distribution of the classes is presented in Fig. 3.

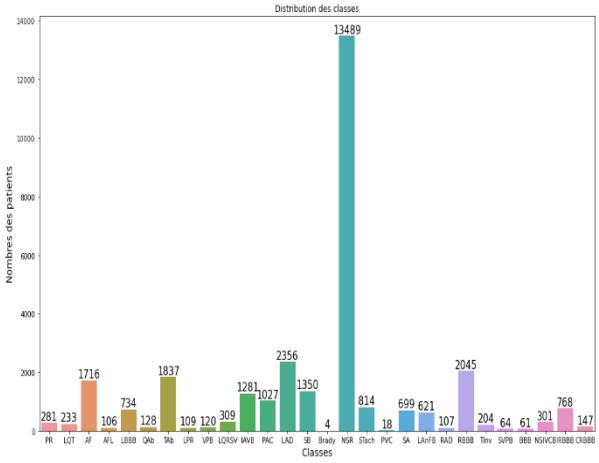

Fig. 3. Dataset classes distribution.

C. Data Preprocessing

The dataset includes 12-lead multi-label ECGs with diverse lengths between 6 s and 60 s. Considering DL needs inputs to be the same length, the dataset has been preprocessed to

guarantee that all inputs have the same length. A variety of lengths were tried, and it was discovered that proceeding with lengths equal to 5000 (10 s duration, 500 Hz sampling rate) gave the best performance. Regarding ECGs with full length longer than 10 s, they will be shortened, and the first 10 seconds of the ECG signal will be kept. Otherwise, they are padded with zeros until they have 10 seconds of recording. Fig. 4 shows the techniques used in the preprocessing of the data.

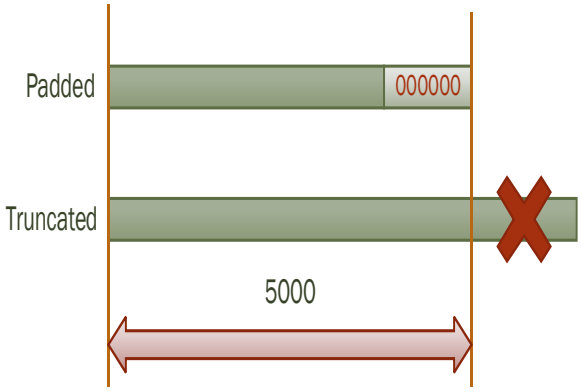

Fig. 4. Data preprocessing techniques.

D. Data-Split

To start with, the dataset is partitioned into two sets with a 0.75/0.25 ratio: the Training and Validation (TV) set and the test set. After that, the K-Fold stratified multi-class cross-validation technique was used, with 10 folds for the training and validation sets. As a result, ten stratified folds were generated by keeping each class samples rate constant. This ensures its existence at all stages. The training set is used to ensure the training of the model. The validation set is set aside for model optimization. As a result, a search for the appropriate parameterization is done without utilizing test data. This aims to determine the model's performance and evaluate its generalization potential. To resume this step explained in Fig. 5, the data was split into a TV set and a test set containing 16293 and 5431 ECG records, respectively. For the TV set, each training and validation fold includes 14655 and 1638 ECG recordings, respectively.

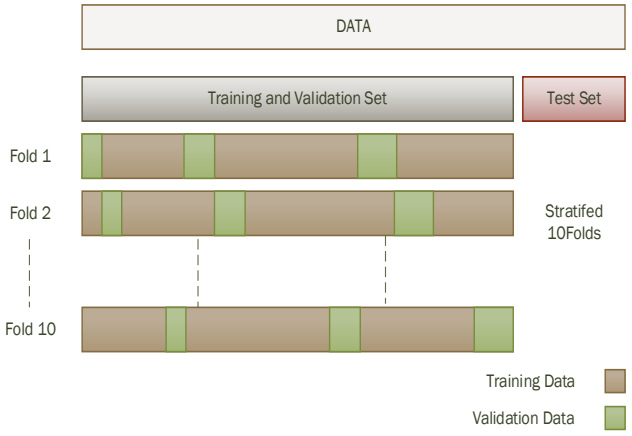

Fig. 5. 10-Folds stratified used in data split.

E. Data-Augmentation

As shown in Fig. 3, the problem of imbalance and insufficient data is very severe for the diagnosis of these cardiac arrhythmias. To solve this problem, Amplitude Scaling was applied to augment the data during the training phase. Data augmentation consists in generating realistic data to avoid data insufficiency. To extend or compress the amplitude, amplitude scaling method amplifies ECG signals by a random coefficient generated from a normal distribution N (1, 0,1). Although this da-ta augmentation technique introduces noise, it can assist prevent model overfitting and enhance resilience against bad cases [30].

IV. Models Architectures

After the text edit has been completed, the paper is ready for the template. Duplicate the template file by using the Save As command and use the naming convention prescribed by your conference for the name of your paper. In this newly created file, highlight all of the contents and import your prepared text file. You are now ready to style your paper; use the scroll down window on the left of the MS Word Formatting toolbar. This section is reserved for the presentation of the two models' architectures. Actually, in this work, the proposed models are model 1 and model 2 which refers to ResNet-50 and Xception respectively.

A. Model 1

The first proposed model is ResNet-50 which belongs to the residual neural networks. At the conclusion of its layers, this network learns numerous low/medium/high level characteristics. Instead of trying to train features, residuals are trained in residual training. The residual may be easily defined as input for that layer minus the trained features. ResNet employs shortcut connections for this purpose (directly linking the nth layer's input to the (n+i)th layer). The training of the model is made possible thanks to the residual blocks with shortcut connections. The input of the models is a patient ECG recording $x \in \mathbb{R}_n$samples×12, and the output is $\hat{y} \in \mathbb{R}_1$x27 which represents the multi-label classification outcome. These inputs were subjected to a 1D convolution layer (Conv1D), a batch normalization layer (BN1D), a rectified linear unit (ReLU) activation layer, and a Max Pooling layer. As well as, for the extraction of wide features, 16 residual blocks were used. In this model, there are two types of residual blocks:

1) Res_Block_1 consists of 3 Conv1D layers, 3 BN1D layers, 2 activation layers ReLU, 1 Conv1D layer and 1 BN1D layer, while it is utilized to adjust dimensions and skip connections. Res Block 2 is just 3 Conv1D layers, 3 BN1D layers and 2 ReLU activation layers.

2) The Conv1D layers extract features, the BatchNorm1D layers speed up and stabilize the model, and the ReLU layers do non-linear activation. The residual blocks' extracted characteristics are pooled by Average Pooling. The findings are gathered and transferred to the output layer (dense layer) for prediction utilizing the sigmoid activation function.

Fig. 6 presents the architecture of the first proposed model is presented.

B. Model 2

The second proposed model is Xception. It is a deep convolutional neural network architecture incorporating depth-separable convolutions [31]. This is a powerful architecture that relies on its two main points of: Depth-separable convolution and Shortcuts between convolution blocks as in ResNet. Depth-separable convolution is said to be an alternative to classical convolution and much more computationally time efficient [32]. As in the first model, the Xception model has the same input and output. Xception comprises 36 layers of convolutions that form the basis for extracting network features. They are divided into 14 modules with linear residual connections around all but the last and first modules. The Xception architecture is essentially a linear stack of depth-separable convolution layers with residual connections. Data is routed via the Entry flow first, then via intermediate flow 8 times, and lastly the Exit flow. A batch normalization layer follows all convolution (Conv1D) and separable convolution (Sep-Conv1D) layers (BN1D). These modules' collected characteristics are pooled using Global Average Pooling. The pooling results are gathered and forwarded to the dense layer, which uses the sigmoid activation function to make predictions. Fig. 7 details the architecture of proposed model 2.

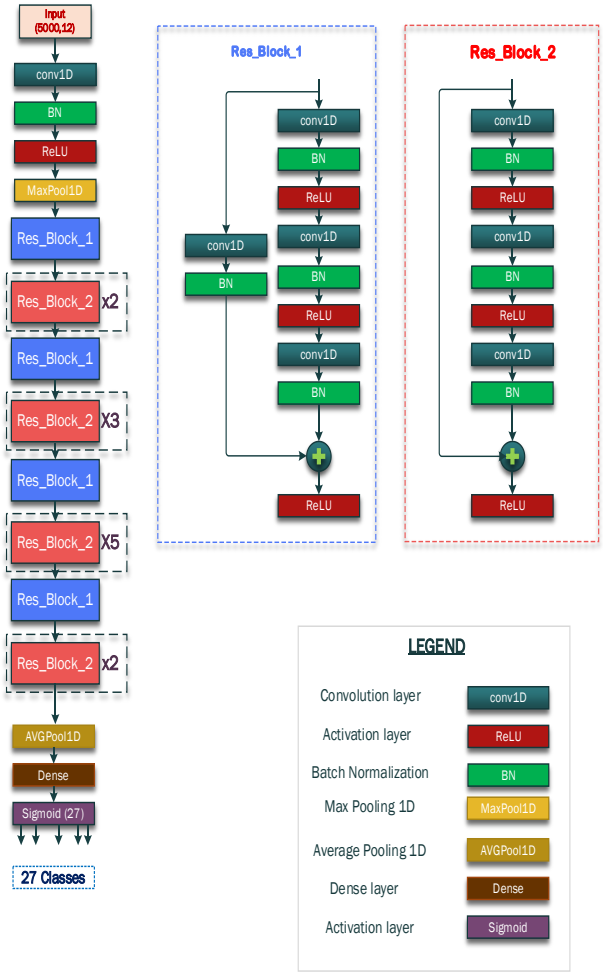

Fig. 6. Architecture of the proposed model 1.

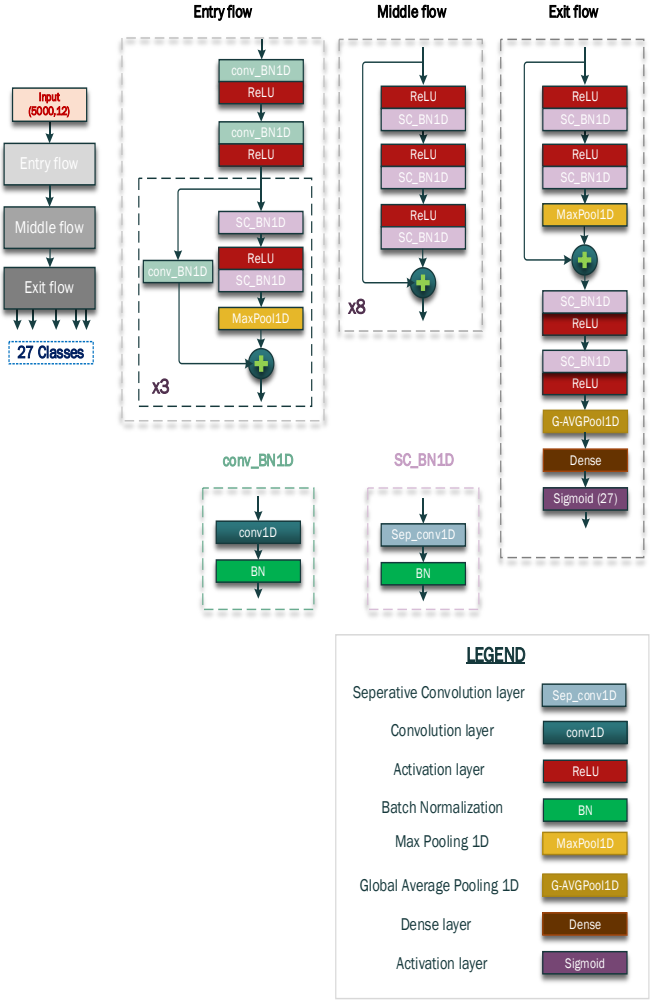

Fig. 7. Architecture of the proposed model 2.

V. Results & Discussions

In the Training and Validation phase, there are many introduced metrics. In fact, this paragraph details the evolution of the accuracy, recall, precision, and loss during these two phases for the two proposed models.

A. Accuracy

At the end of the training and validation, for the model N°1, ResNet-50, the accuracy obtained is 99.99% and 99.98% respectively. For the model N°2, Xception, it reached 100% in both phases. Fig. 8 and 9 represent the development of the accuracy during the two phases for the ResNet-50 and Xception respectively.

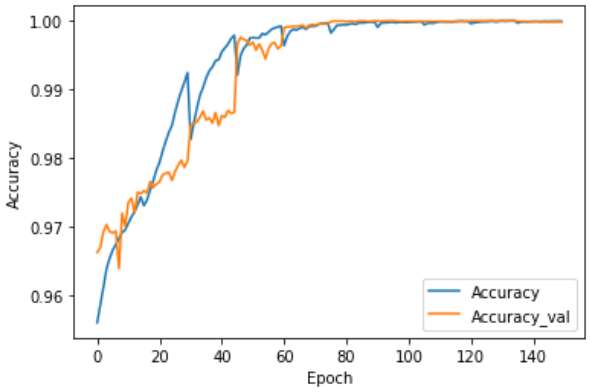

Fig. 8. Evolution of accuracy during the training of two models.

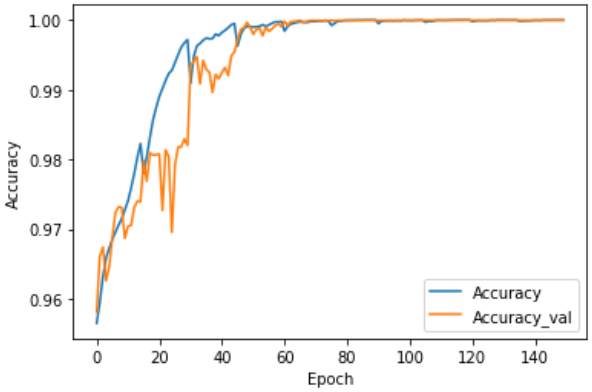

Fig. 9. Evolution of accuracy during the validation of two models.

B. Precision

Fig. 10 and 11 illustrate the evolution of the precision in the two steps for the two proposed models. Indeed, for model 1, it reached 99.99% in the training and 99.87% in the validation. Concerning the model N°2, the precision obtained in the two phases is 100% and 99.96%.

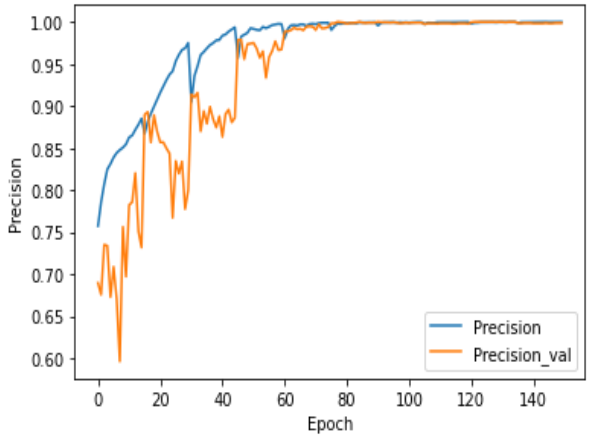

Fig. 10. Evolution of the precision during the training of two models.

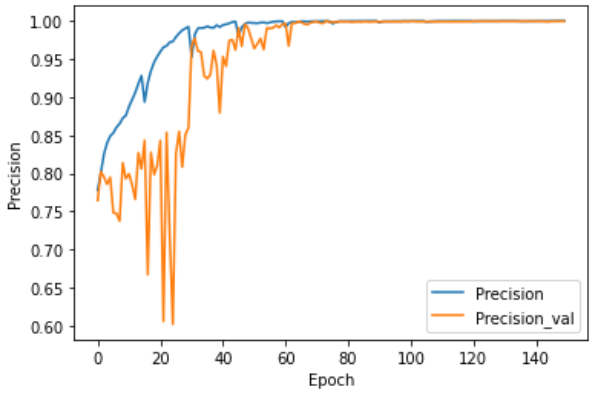

Fig. 11. Evolution of the precision during the validation of two models.

C. Recall

Concerning the recall parameter, at the end of the training and validation of ResnNet-50 model, it reached 100% and 99.87%. For the Xception model, it is 100% in both phases. Fig. 12 and 13 show the evolution of recall for the two models.

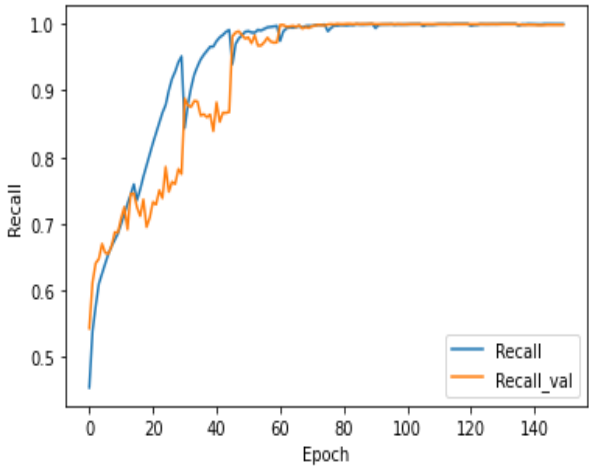

Fig. 12. Evolution of the recall during the training of two models.

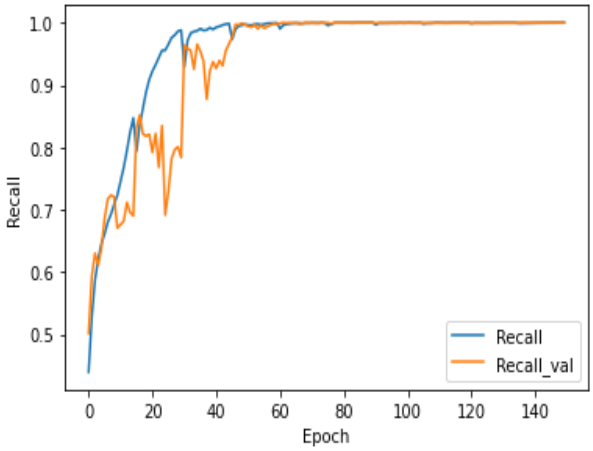

Fig. 13. Evolution of the recall during the validation of two models.

D. Loss

In terms of loss, the first model reached $7{,}89.10^{-05}$ and $3{,}83.10^{-04}$ in the two phases. For the second model, at the end of learning and validation, it reaches $4{,}37.10^{-05}$ and $2{,}05.10^{-04}$, respectively. Fig. 14 and 15 present the declination of the Loss function for the two models.

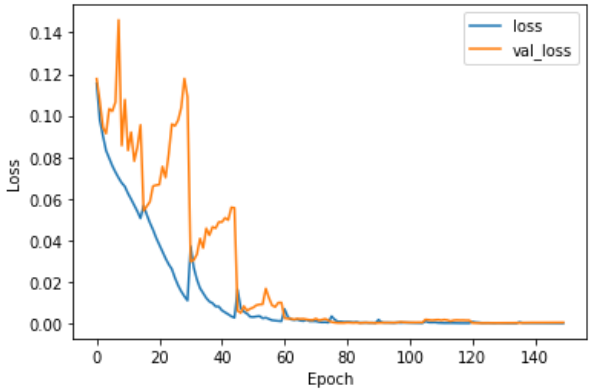

Fig. 14. Evolution of the loss during the training of two models.

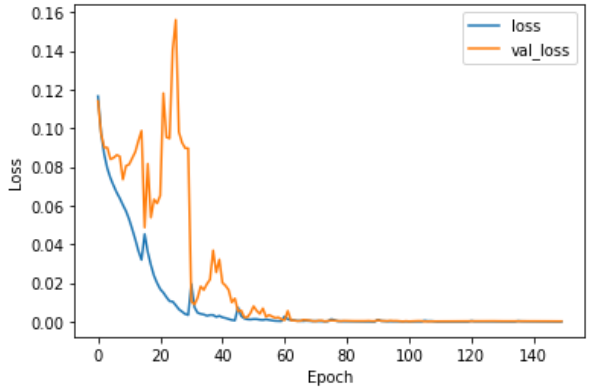

Fig. 15. Evolution of the loss during the validation of two models.

Globally, for both models, the evolution of the performance parameters is generally similar to a faster stabilization of the Xception model. Indeed, the model N°2 has converged since the 60th epoch (beginning of fold N°5) whereas the model N°1 has converged only after the 90th epoch (beginning of fold N°7). Also, the evolution of the validation curves of the performance parameters for the ResNet-50 model is more stable than that of the Xception model. Moreover, the saw teeth noticed in these curves are less severe for the model N°1.

VI. Test Phases

In the test phase, the metrics presented are the confusion matrices of the proposed two models as well as their classification reports. Fig. 16 presents the normalized confusion matrix obtained. The model N°1 is performing for the classes CRBBB, RAD, Brady, PR, NSR, RBBB, AF, IRBBB, STach, IAVB, PAC, LBBB. Indeed, their percentages of correct determinations are greater than 80%. Moreover, its performance is moderate for the PVC, SA, TInv, SB, and AFL classes where their percentages of correct predictions are higher than 60%. For lasting classes, such as QAb, LPR, and LAD, ResNet-50 has a bad performance.

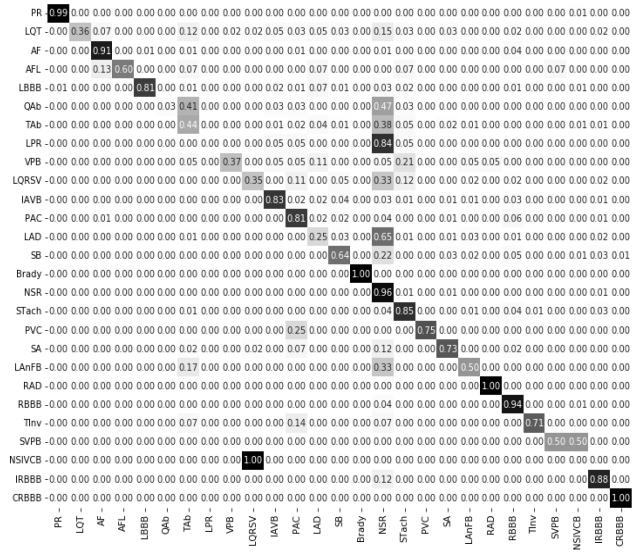

Fig. 16. Confusion matrix of the proposed model 1.

Fig. 17 illustrates the normalized confusion matrix obtained from model N°2. It performs well for the classes NSIVCB, CRBBB, SVPB, NSR, RBBB, PR, IRBBB, AF, AFL, IAVB, STach. Moreover, their percentages of correct predictions exceed 80%. Moreover, its performance is moderate for the classes PAC, SB, SA, TInv, and LQRSV where their percentages of correct predictions are above 60%. For the remaining classes, like LPR, QAb, Brady and RAD..., Xception has a bad performance.

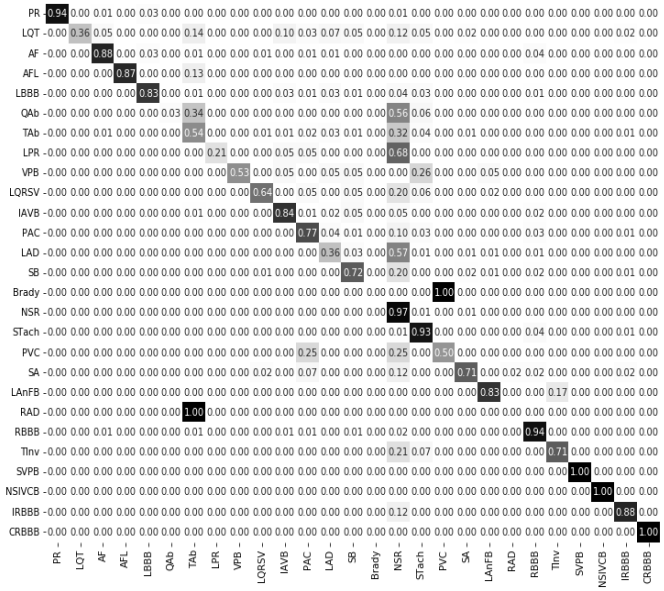

Fig. 17. Confusion matrix of the proposed model 2.

VII. Conclusion

This study showcases a successful application of deep learning (DL) techniques for the accurate diagnosis of cardiovascular diseases (CVDs) using ResNet-50 and Xception models. The study considered 27 heartbeat rhythms, where one belongs to normal sinus rhythm (NSR), and the remaining 26

belong to cardiac abnormalities. The dataset utilized in this research was created by aggregating four distinct datasets from three different nations, providing a diverse range of cardiac conditions. The results demonstrate the effectiveness and high performance of the proposed methods, which were also validated against recent literature. However, it is essential to acknowledge the limitations of the suggested methods. Firstly, the high complexity of computation required for the deep learning models may hinder their implementation in some medical settings. Additionally, the limited interpretability of some of the classes in the global dataset used may pose challenges in diagnosing and treating certain cardiac conditions. To address these challenges, future studies will focus on enhancing the proposed techniques to make them more accessible and interpretable for a broader range of medical applications. Overall, this research provides promising insights into the potential of deep learning models for CVD diagnosis, and with further development, they have the potential to revolutionize the field of cardiac medicine.

Multi-Discriminator Image Restoration Algorithm Based on Hybrid Dilated Convolution Networks

Chunming Wu, Fengshuo Qi
Northeast Power University, College of Electrical Engineering, Ji lin, China

***Abstract*—With the continuous development of generative adversarial networks (GAN), many image restoration problems that are difficult to solve based on traditional methods have been given new research avenues. Nevertheless, there are still problems such as structural distortion and texture blurring of the complemented image in the face of irregular missing. In order to overcome these problems and retrieve the lost critical data of the image, a two-stage image restoration complementation network is proposed in this paper. While introducing hybrid dilation convolution, two attention mechanisms are added to the network and optimized using multiple loss functions. This not only results in better image quality metrics, but also clearer and more coherent image details. In this paper, we tested the network on CelebA-HQ, Places2 and The Paris datasets and compared it with several classical image restoration models, such as GLC, Gconv, Musical and RFR, and the results proved that the complementary images in this paper are improved compared to the others.**

***Keywords*—GAN; image restoration; hybrid dilated convolution; attention mechanism; two-stage network**

I. Introduction

Image Completion is a long-standing and critical problem in the field of computer vision, aiming at completing the missing pixels and semantic parts among a given image. It is widely used in the fields of object removal, photo restoration, and image processing [1-3], where the naked eye can easily notice if the complementary image is not plausible or lacks critical information.

Early work [3-5] was an attempt to perform complementary filling at the image level using methods similar to texture synthesis. While these methods can achieve good results in complementing the background, they fail to produce a new image when non-repetitive structures are encountered. In addition, such methods lack semantic support and high-level understanding.

With the rapid development of deep learning (e.g., generative adversarial networks [6]), image complementation has evolved to new heights. Deep learning based image complementation is broadly categorized into single-stage [7-11], two-stage [12-15] and multi-stage [16-19]. All these methods can generate new content such as faces, objects and scenes. However, artifacts tend to arise when using these methods, making the complementary image inconsistent with the surrounding region.

To address this problem, we introduce hybrid dilated convolution, gated convolution, and attention mechanism to improve on the generative adversarial network, and use multiple loss functions to optimize the process and train the generator more efficiently. Meanwhile, the VGG-16 feature extractor is introduced into the discriminative network, which can obtain more feature information and increase the sensory field.

Experiments on three datasets, including CelebA-HQ [20], Places2 [21] and The Paris dataset [22], and comparisons with several classical methods demonstrate that our method can generate better image results.

Our main contributions are as follows:

1) A two-stage image complementation network model from coarse to fine is proposed, where the generator consists of gated convolution, hybrid dilated convolution and two attention mechanism modules. The input to the generator network is a missing image with mask and the complemented image is input to the second order network. And then the coarse complemented image is refined and then fed into the discriminator and so on to the final result.

2) An attentional mechanism is incorporated in both stages of the generative network. In the coarse network the first attention mechanism is used to extract the missing and intact regions of the image and calculate the attention scores for both regions. The second attention mechanism is used in the refinement network to optimize the complementary part of the image by calculating the similarity of any two pixel points in the feature map to obtain the feature information of the whole image while preserving the original information.

3) Improve the existing dilated convolution using hybrid dilated convolution to make the sampling information more accurate.

4) Use three different loss functions in combination with each other for better training of generator model.

This paper is categorized as follows: Section II describes the work related to image complementation techniques; Section III describes the components of the network structure. Section IV analyzes the experimental complementation results. Section V is used for discussion and comparison. Section VI concludes the study.

II. Related Works

Today, image complementation is broadly categorized into two types: the previous traditional complementation methods and the now popular deep learning based image complementation methods.

There are two types of traditional image complementation methods. One is based on diffusion [23-24], which diffuses neighboring information to the missing regions, but these methods are limited to locally available information for complementary reconstruction, and cannot recover the semantic structure of the missing parts or complement larger missing regions. Another approach is based on PATCH [25-27], in which pixel-level patches of the original image are used to fill in the missing regions, e.g., by mixing the copied original regions with the target regions to ensure their similarity [28]. However, these methods are computationally expensive and the patch computation must be performed for each target to obtain its similarity score. Patch Match [29] achieves fast matching by using local correlations of the image, but the patched portion can also be found in other locations and cannot produce a new image. These methods can recover image regions with high graphical similarity, such as background complementation, but have difficulty repairing complex, low-similarity images.

In recent years, with the development of deep learning ground, deep learning methods for image complementation have been proposed. The initial study was the context encoder [8], which uses an encoder-decoder architecture. The encoder maps the image of the missing region into a low-dimensional feature space, and the decoder utilizes its feature space to construct the complementary image. The progression is performed by a combination of pixel-level reconstruction losses [6]. However, the complementary image usually contains blurry visual artifacts due to the information width of the channel fully connected layers.Lizuka et al. [7] introduced global and local contextual discriminators to train a complete convolutional complementary network to solve this problem. However, the training time increases significantly due to the use of extremely sparse filters.Zhang et al. [10] proposed a pixel-by-pixel localization of the complementary method and inserted the missing region location information into the reconstruction loss to better train the complementary network.

In multi-stage, Yu et al. [13] proposed an image complementation method consisting of a coarse network and a refinement network. In the refinement network, a contextual attention module was introduced. Later, Yu et al. [30] introduced gated convolution while using an attention mechanism to further optimize the network.Zhang et al[16] divided the image complementation process into four different stages and used the LSTM architecture [31] to control the information of the recursive process. However, it cannot handle irregular defects in practical applications. On the other hand, Guo et al. [17] proposed a fully parsed network with multiple extension modules to solve this problem. Pawar et al [32] proposed recurrent neural networks based on multiscale deep learning to deal with the problem of missing images using a multiscale approach. Mansur [33] used StyleGAN framework with VGG19 and CatBoost gradient to improve the accuracy of predicting images.

III. Introduction to Network Architecture

A. Overall Network Structure

The overall network structure model proposed in this paper is shown in Fig. 1. The generator model proposed in this paper has two final outputs, the rough processing result of the first stage will be used to perform the inputs of the second stage, and the result of the second stage of fine processing as the final output of the network. It will be used as an input along with the real image and the input will be sent to VGG-16 and modeled pairwise discriminative network for judgment.

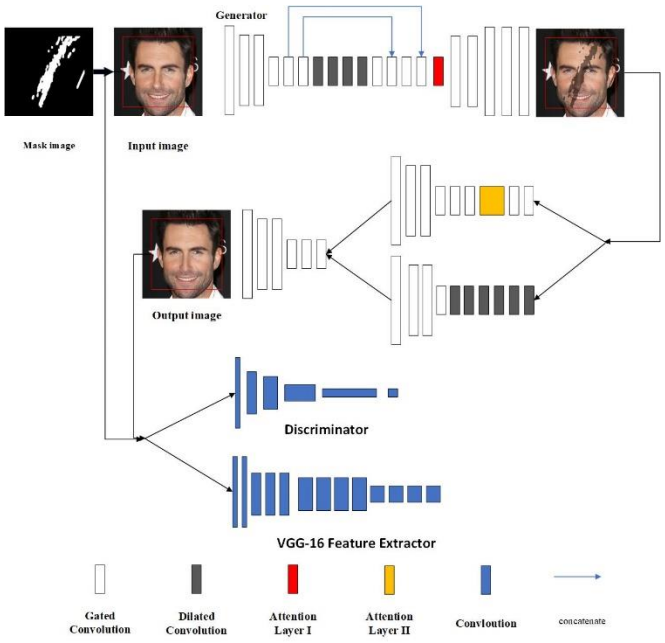

Fig. 1. Overall network structure.

B. Introducing Hybrid Dilated Convolution

Hybrid dilated convolution can solve the problem of missing continuity of image information due to cavity convolution. In order to solve the problem of the loss of image information after the merging of traditional convolutional layers, literature [7] proposes the use of cavity convolutional layers for image complementation. However, the increase of sensory field is accompanied by the problem of loss of continuity of image information.

Feeling wild is defined as:

$$r_n = r_{n-1} + (k-1) * \prod_{I=1}^{n-1} s_i \quad (1)$$

where, r_n denotes the receptive field of the layer, s_i denotes the convolution or pooling step of the layer , and k is the convolution kernel size.

Fig. 2 shows the cavity convolution with convolution kernel 3×3 and dilated rate 2. It can be seen that although the dilated convolution increases the receptive field, the convolution kernel is discontinuous and the continuity of the image information is inevitably lost. To address this problem, we introduce the hybrid dilated convolution. As shown in Fig. 3, the hybrid cavity convolution retains the continuity of the region completely, while still maintaining its coherence after superposition. The hybrid hole convolution not only can effectively solve the problem of large-scale missing, but also will not lose its continuity in the face of detailed processing. The maximum void rate of its i-th layer is satisfied:

$$N_i = \max[N_{i+1} - 2R_i, N_{i+1} - 2(N_{i+1} - R_i), R_i] \quad (2)$$

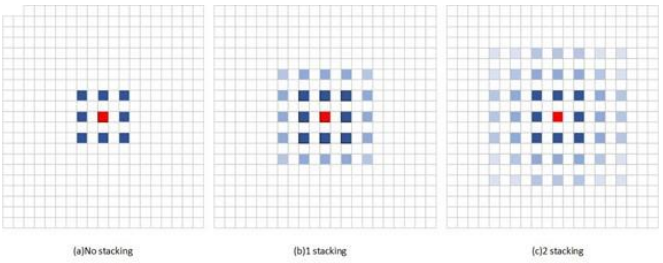

Fig. 2. Dilated convolution superposition with a void rate of 2.

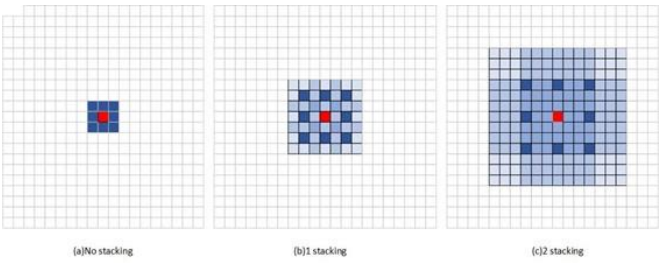

Fig. 3. Convolutional superposition of mixed voids with a void rate of 2.

Where the voiding rate of layer i is R_i, and N_i and N_{i+1} are the maximum voiding rates of layers i and i+1, respectively.

We apply the hybrid dilated convolution structure to the refinement network stage with a jagged dilated rate, which should satisfy the following conditions:

1) The convention of the cascaded dilated convolution rates is should be 1. e.g., [1, 2, 3] satisfy this requirement; although [2, 4, 8] do not satisfy this requirement, they have the conventions 1 and 2.

2) have cyclic jagged dilated rates, e.g., [1, 2, 3, 1, 2, 3].

3) Satisfy the verification formula

$$H_i = \max[H_{i+1} - 2r_i, H_{i+1} - 2(H_{i+1} - r_i), r_i] \quad (3)$$

where, $H_i = r_i$, r_i is the dilated rate of the ith layer. Take the cascade convolutional layers of [1, 2, 9, 1, 2, 9] and [1, 2, 3, 1, 2, 3] with a void rate of r as an example. The former satisfies the first two of the conditions, which leads to $H_2 = 5 > K = 3$ according to Eq. (3), and does not satisfy condition three. And [1, 2, 3, 1, 2, 3] both satisfy the above three conditions.

In this paper, the hybrid cavity convolution with sawtooth structure of cavity rate of [1, 2, 3, 1, 2, 3] is chosen to replace the cavity convolution. The hybrid cavity convolution not only solves the problem of information loss of cavity convolution, but also makes full use of the pixel information between images and increases the sensory field.

C. Introduction of Attention Mechanisms

The attention mechanism I is shown in Fig. 4. For the input feature map X_{in}, we specifically refer to the foreground of the missing region instead of the background of the image. As can be seen from Fig. 4, the missing region of the feature map is white, and the corresponding RGB is (255, 255, 255). If the RGB of the complementary part is (255, 255, 255), all input features are foreground, otherwise they are background. We extract the pixel information from the foreground and background of the image separately, labeling the foreground as $\{a_{x,y}\}$ and the background as $\{b_{m,n}\}$. The similarity between them is calculated by normalization:

$$S_{x,y,m,n} = \left\langle \frac{a_{x,y}}{\|a_{x,y}\|}, \frac{b_{m,n}}{\|b_{m,n}\|} \right\rangle \quad (4)$$

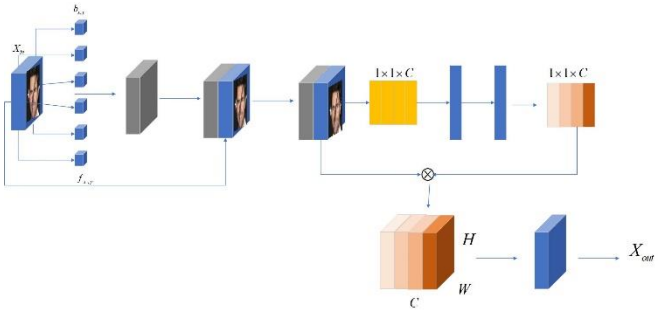

Fig. 4. Attention mechanism I.

The result of the computation is obtained by softmax to get the attention score. The input image is then inversely convolved to obtain the feature map X_{mid}. We input X_{in} and X_{mid} into the SE module as a way to increase the weight value of the useful features. The final output of the attention mechanism I is denoted as:

$$X_{out} = f_{conv}\left(f_{SE}\left(\left(X_{in,} X_{mid}\right)\right)\right) \quad (5)$$

where, f_{SE} is the SE module and f_{conv} is the convolution operation that ensures that X_{in} is the same as the input image channel.

The SE module first maps the input image into the dimension tensor of $1\times1\times C$ and then takes the global average:

$$z_c = \frac{1}{H \times W} \sum_{i}^{H} \sum_{j}^{W} x_{i,j}, x_{i,j} \in X \quad (6)$$

z_c is then converted to a weight tensor of [0, 1]. In turn, the weight values for each channel are calculated:

$$w_c = \sigma\left(W_2\left(\phi\left(W_1, z_c\right)\right)\right) \quad (7)$$

where, W_1 and W_2 are fully connected operations and σ and ϕ refer to sigmoid function and ReLU function. The weights of the final output image are:

$$X_{out} = X \otimes w_c \quad (8)$$

Attention Mechanism II is shown in Fig. 5. For the input feature map, Attention Mechanism II makes three copies of it and uses the convolution kernel of 1×1 to perform the convolution operation. The feature map is first stretched by channel into vectors with a total number of N pixels to obtain $f(x)$, $g(x)$ and $h(x)$.Then $f(x)$ is subjected to transpose operation and $g(x)$ is subjected to vector dot product, and the result obtained is normalized to obtain the matrix:

$$\beta_{i,j} = \exp\left(f(x)^T * g(x)\right) / \sum_{i=1}^{N} f(x)^T * g(x) \quad (9)$$

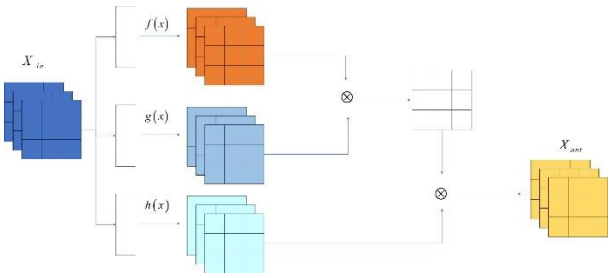

Fig. 5. Attention mechanism II.

$\beta_{i,j}$ is the attention score at the j th pixel i . The transposed $\beta_{i,j}$ and $h(x)$ are then multiplied to obtain the final attention feature result $o(x)$. The input features are weighted to obtain the output:

$$out = \gamma o_i + x_i \quad (10)$$

where, γ is the weights that are constantly updated by training.

D. Coarse Network Structure

Coarse network is the first stage of generative network, the whole network is encoding-decoding structure, coarse network structure as shown in Fig. 6, encoding stage the first phase of the input image through the convolution kernel for convolution, to increase the sensory field. Then three convolution kernels are used for feature extraction. In this paper, multiple downsampling is used to compress and encode the input image, and useful local feature information is extracted to recover the image. The input image is then passed through eight convolutional layers (including four hybrid dilated convolutional layers) and the attention mechanism I module to enhance the feature transfer and obtain a larger receptive field. The decoding stage up-samples the high-level feature information previously removed through a structure symmetric to the decoding to obtain the restored image of the coarse network. The specific parameters of the coarse network are shown in Table I:

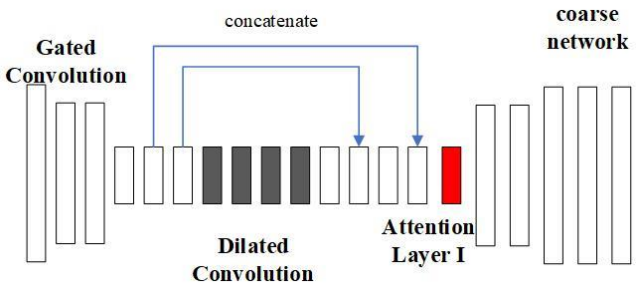

Fig. 6. Coarse network structure.

E. Refined Network Structure

After the first stage of the coarse network repair, this paper takes the result as the input of the refinement network. Compared with the coarse network, the refinement network is more complete in extracting feature information, and the feature extraction through the double parallel network can output the image ground diversity more effectively. The structure of the refinement network is shown in Fig. 7:

As shown in Fig. 7, the refinement network consists of a parallel network structure containing a hybrid dilated convolutional branch and a branch containing the attention mechanism II. The two branches perform feature extraction on the input image by different methods, and then the results are combined and decoded by a decoder to obtain the output result.

Table II represents the parameters of the Attention Mechanism II branch in parallel networks.

F. Discriminator and Feature Extractor

In this paper, both the discriminator and the VGG-16 feature extractor are ordinary convolutional full convolutional neural networks, which can be effectively applied in GANs with large missing fields. The discriminator and feature extractor are shown in Fig. 8. The discriminator needs to judge the quality of the output image as a whole, while the full convolutional neural network can effectively extract the global contextual information through a large sensory field.

VGG-16 is a pre-trained model trained using the large-scale ImageNet dataset, which contains more than 1 million images of over 1,000 different categories. Because of this, VGG-16 can be easily and quickly applied to generate new images. Its convolutional layers are arranged in a stepwise manner, which not only increases the sensory field, but also extracts different feature information of the image.

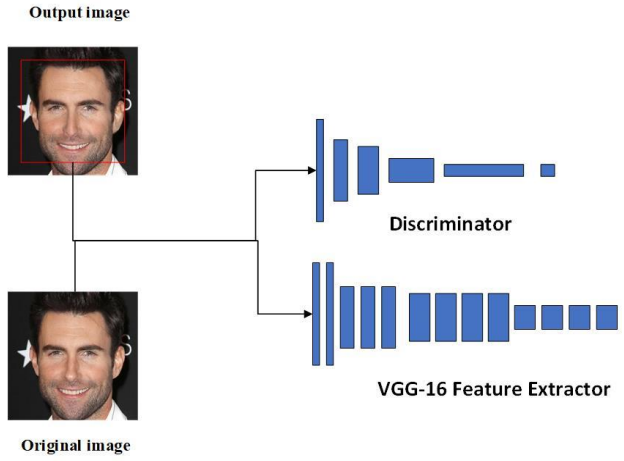

Fig. 8. Discriminators and feature extractors.

G. Loss Functions

In image complementation, the use of a single loss function may cause problems such as blurring and loss of semantic information in the restored image. To address this problem, this paper uses a combination of three different loss functions, which not only improves the network model's ability to perceive the details of the image, but also helps the network model to retain the texture structure of the original image and improves the model's generalization ability for image processing.

The loss function in this paper is:

$$L = \lambda_1 L_1 + \lambda_2 L_2 + \lambda_p L_{perceptual} + \lambda_G L_G \quad (11)$$

where, λ_1, λ_2, λ_p and λ_G are hyperparameters with loss function weights $\lambda_1 = \lambda_2 = 100$, $\lambda_p = 10$ and $\lambda_G = 1$.

H. MAE loss

Mean Absolute Error (MAE) loss is less sensitive and more robust to anomalies and noise in the data. In image restoration, the pixels in the missing region are very different from the surrounding pixels, and a robust MAE can restore the image more efficiently.The MAE loss helps to compensate for the sparsity of the output image, and can be used to generate images with fewer non-zero pixel points and sharper and more lifelike images by minimizing the absolute difference between the predicted pixels and the real image.

For the output of coarse and refined networks, this paper uses pixel level reconstruction loss to make the complementary image close to the true image with the following formula:

$$L_1 = \left\| I_{gt} - I_1 \right\|_1 \quad (12)$$

$$L_2 = \left\| I_{gt} - I_{out} \right\|_1 \quad (13)$$

where, I_1 is the complementary image of the coarse network, I_{out} is the refined network output image, and I_{gt} is the real image.

I. Perceived Loss

The perceptual loss is calculated by inputting the real image and the generated image into the pre-trained model VGG-16, mapping the image to the feature space, and calculating the comparisons using the vanity L_1. This calculates the perceptual loss and preserves the structural and content information of the image more efficiently. The formula is as follows:

$$L_{perceptual} = \sum_{i=1}^{N} \frac{1}{C_i H_i W_i} \left\| \phi_i \left(I_{gt} \right) - \phi_i \left(I_{pred} \right) \right\|_1 \quad (14)$$

where $\phi_i \left(X \right)$ denotes the feature information extracted by VGG-16 in layer i of the input image, and C, H, and W are the number of channels, height, and width dimensions of the layer, respectively.

J. SN-PatchGAN

The SN-PatchGAN loss function can solve the problem of irregular image complementation more effectively. The discriminator trained using this loss function divides the generated complementary image into several pieces, then maps each piece to an output value and calculates the loss for each output result, thus effectively solving the problem of irregular missing. The specific formula is as follows:

$$L_D = E_{x \sim p}[\mathrm{Re}LU(1 - D(x))] + E_{z \sim p_z}[\mathrm{Re}LU(1 + D(G(z)))] \quad (15)$$

$$L_G = -E_{z \sim p_z}[D(G(z))] \quad (16)$$

where, D denotes the discriminator network, G denotes the generator network, x denotes the true image I_{gt}, and z denotes the to-be-complemented image I_{in}.

IV. Experimental Results and Analysis

A. Introduction to the Datasets

In this paper, we conduct experiments on three public datasets, CelebA-HQ, Places2 and The Paris, with the specific parameters shown in Table V.

1) CelebA-HQ: In this paper, 27,000 images are randomly selected for training and 3,000 images for testing, totaling 30,000 images.

2) Places2: In this paper, 10 of the classes are selected as the experimental dataset, and 4000 images are selected in each class, totaling 40000 images. Among them, 38000 are used for training and 2000 are used for testing.

3) The Paris: This paper randomly selects 15000 of them as the experimental dataset, 14900 as the training samples and 100 as the test samples.

In order to train the network model, this paper uses the QD-IMD mask dataset for the construction of irregular masks. Meanwhile, we use the publicly available irregular data provided by Liu et al. [34] as the test mask to evaluate the training model.

TABLE V. Dataset Parameters

	Training	***Testing***	***Total***
CelebA-HQ	27000	3000	30000
Places2	38000	2000	40000
The Paris Dataset	14900	100	15000

B. Experimental Environment Construction

The parameters of the training device in this paper are CPU Intel i7-10750H, GPU RTX3060-6G, and memory DDR4-2399-32G.The training environment in this paper is realized on TensorFlow v1.3, CUDNN v8.1.1, and CUDA v11.1. All images and masks in the experiment are of size 256×256.

C. Analysis of Experimental Results

The performance of the model in this paper is evaluated by comparing the method in this paper with a variety of other classical complementation methods.

1) GLC [7]: A complementation method that combines an inflated convolution and a global context discriminator for maintaining the consistency of the generated images.

2) Gconv [30]: A coarse-to-fine two-stage network with the addition of gated convolution, an improvement on previous work [13].

3) MUSCIAL [35]: A complementary method that introduces a multiscale attention module.

4) RFR [18]: A progressive inference image complementation method that introduces cyclic feature inference for complementation.

The complementary results for CelebA-HQ dataset are shown in Fig. 9, the images generated by the model in this paper are visually closer to the original images. From the data, it can be seen that the structural similarity index (SSIM), average loss and peak signal-to-noise ratio (PSNR) are higher than several other methods.

The complementary results for Places2 dataset are shown in Fig. 10, this paper produces better complementary images compared to other methods, but also has a few artifacts. From the data, the method in this paper has the same PSNR as RFR, but the SSIM and average loss are better than RFR.

The complementary results for The Paris dataset are shown in Fig. 11, and the method in this paper is very similar to RFR's complementary naked eye. However, as can be seen from the data, this paper outperforms RFR in terms of average loss, but slightly underperforms RFR in terms of SSIM and PSNR.

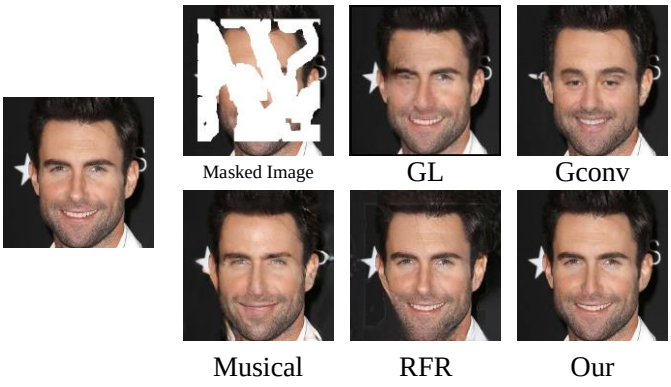

Fig. 9. Complementary images of CelebA-HQ dataset.

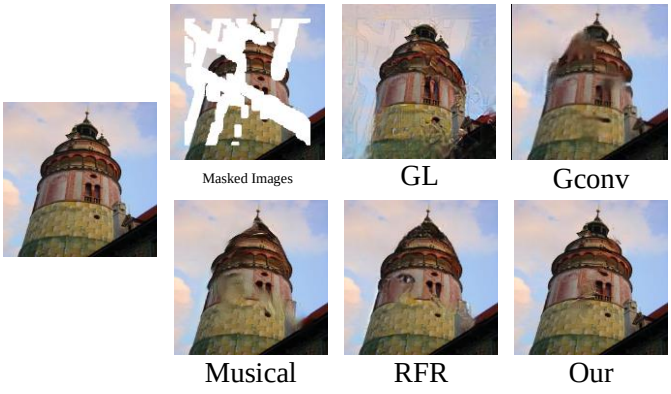

Fig. 10. Complementary images of Places2 dataset.

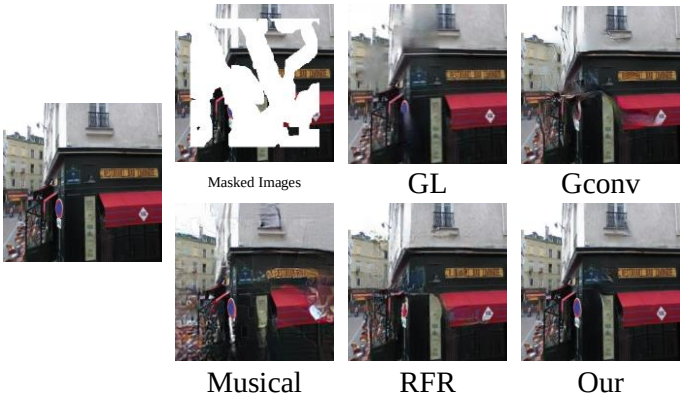

Fig. 11. Complementary images of the Paris dataset.

D. Ablation Experiments

In order to be able to demonstrate the effectiveness of the method in this paper more intuitively, the following experiments are conducted on the CelebA-HQ dataset.

1) Experiment 1: Retain the gated convolution and hybrid dilated convolution, but remove the attention mechanism module.

2) Experiment 2: Replace all convolutions with ordinary convolutions and keep the attention mechanism module.

The results of the experiments are shown in Fig. 12. From the results, it can be seen that compared to the method in this paper, Experiment 1 generates more complementary images containing artifacts and texture blurring, while the introduction of the attention mechanism module can more effectively reduce the loss of image information. The results of Experiment 2 show that the addition of gated convolution and hybrid dilated convolution can obtain more information when generating images and generate complementary images that are more in line with the real situation.

(a) (b) (c) (d) (e)

Fig. 12. (a) Input image, (b) Original image, (c) Experiment 1, (d) Experiment 2, and (e) Our.

V. Results and Discussion

Compared with several classical algorithms such as GLC, Gconv, Musical and RFR, the method in this paper complements to better results. The comparison parameters on the three datasets are shown in Table VI, Table VII and Table VIII, the complementation results of this paper's method are better than the other methods in SSIM, PSNR and Mean loss, which shows that this paper's method can reasonably complement the irregular missing images.

Meanwhile, the ablation experiments can prove that the hybrid null convolution structure and the attention mechanism module cited in this paper effectively enhance the model. Therefore, the method in this paper can be applied to the frequently occurring missing problems in reality, to complement the problem of criminal's facial occlusion; to fill in the problem of missing details in old photos; and to predict the key contents of medical images.

TABLE VI. PERFORMANCE OF DIFFERENT MODELS ON CELEBA-HQ DATASET

Method	Parameter		
	SSIM	***PSNR***	***Mean l_1 Loss***
GLC	0.693	19.62	6.91%
Gconv	0.768	21.74	5.42%
Musical	0.771	21.95	5.31%
RFR	0.809	22.16	4.54%
Our Method	**0.811**	**22.53**	**4.56%**

TABLE VII. PERFORMANCE OF DIFFERENT MODELS ON THE PLACES2 DATASET

Method	Parameter		
	SSIM	***PSNR***	***Mean l_1 Loss***
GLC	0.453	17.79	9.22%
Gconv	0.574	18.31	8.22%
Musical	0.583	18.76	7.91%
RFR	0.594	**18.90**	7.63%
Our Method	**0.607**	**18.90**	**7.32%**

TABLE VIII. PERFORMANCE OF DIFFERENT MODELS ON THE PARIS DATASET

Method	Parameter		
	SSIM	***PSNR***	***Mean l_1 Loss***
GLC	0.531	19.93	7.21%
Gconv	0.628	20.72	6.61%
Musical	0.631	21.65	6.72%
RFR	**0.674**	**22.79**	5.58%
Our Method	0.673	22.76	**5.44%**

VI. CONCLUSION

The field of image restoration dates back to the 1950s. Most traditional image restoration methods use techniques such as texture synthesis, and although they can complement images, these methods have their own limitations. In recent years, with the advancement of deep learning techniques, image complementation has developed rapidly. Deep learning methods are trained with a large amount of data, constantly learning and updating, and excel in computer vision tasks, natural language processing and speech recognition. In the field of deep learning, Generative Adversarial Networks (GANs) are popular for their ability to generate images. Compared with other models, GAN-based image complementation methods have excellent performance when targeting complex texture image restoration.

In this paper, we propose a two-stage GAN image-completion model with generative adversarial network as the underlying architectural model, i.e., a coarse-completion stage and a refinement-completion stage. The model mainly consists of gated convolution, hybrid dilated convolution and two attention mechanism modules, etc., while three different loss functions are used to train the generator more efficiently. The discriminative part introduces the VGG-16 feature extractor, which increases the sensory field and at the same time can extract more feature information from the image.

In this paper, the proposed model is experimentally compared with GLC, Gconv, MUSCIAL and RFR on three different datasets (CelebA-HQ, Place2, and The Paris dataset).GLC produces complementary images with blurred texture and confusing structure when complementing a wide range of deletions while Gconv and Musical produce less results when faced with a wide range of deletions, and GLC produces less results when faced with a wide range of deletions. Deletions produce less realistic or unrecognizable results. Similarly, the training results of RFR are similar to those of this paper, but the method in this paper generates results with fewer artifacts and better results. In terms of data, on the CelebA-HQ and Places2 datasets, this paper's method outperforms the other methods in terms of SSIM, PSNR and average loss. While on The Paris dataset, although the average loss is better than other methods, both SSIM and PSNR are slightly inferior to RFR.

The experimental results prove that the method in this paper has good progress and can recover the image details better while complementing the image.

Research on Resource Sharing Method of Library and Document Center Under the Multimedia Background

Jianhui Zhang[1]*
Jiangsu College Nursing, Library, Jiangsu Huaian 223005

***Abstract*—In order to improve the utilization effect of the resources of the book and document center and ensure the security of its resource sharing, the resource sharing methods of the book and document center under the multimedia background are studied. The resource layer of this method is based on multimedia technology and combined with virtual technology to build a multimedia document cloud resource pool; At the same time, the adaptive clustering algorithm of empirical mode feature decomposition is used to obtain the number of document resources clustering and resource category labels, complete the resource clustering of the book and document center, and store it in the constructed resource pool; Users log in directly through the document resource sharing service of the service layer, and enter the resource center after authentication by the management layer. The service layer uses the regional document information resource co-construction and sharing mechanism based on blockchain to encrypt, co-identify and decrypt the clustered resources in the resource pool and then share the resources of the book and document center. The test results show that the clustering purity and contour coefficient of the method is above 0.970, and the clustering quality is good; The security of resource sharing is good, and the sensitivity result is 10.11% when the resource sharing ratio is 100%; It can effectively complete the resource sharing in the book and document center, and meet the sharing needs of book and document resources.**

Keywords*—Multimedia background; library and reference center; resource sharing; virtual technology; multimedia technology

I. INTRODUCTION

The Library and Reference Center is a virtual scientific and technological document information service institution [1, 2]. It is to provide scientific and technological document information services to the whole country according to the needs of national scientific and technological development and the collection, store, and development of scientific and technological document resources in various disciplines of science, engineering, agriculture, and medicine [3, 4]. Document service is a major service item in the book and document center. The specific contents include document retrieval, full-text provision, online full-text, catalog browsing, catalog query, etc. Non-registered users can obtain services other than full-text services for free, and registered users can also obtain full-text services [5, 6]. The document retrieval column provides users with query and sharing services for various scientific and technological document titles or abstracts [7]. The reference types include journals, conference proceedings, dissertations, scientific and technological reports, patent standards and books, etc., the types of reference involve China, West, Japan, Russia, etc., and the fields involve medicine, architecture, chemical engineering, etc. [8]. It provides common search, advanced search, periodical search, classified search, natural language search, and other search methods. Resource sharing refers to using information technology resources to integrate and optimize, avoid repeated construction of resources, improve the utilization of resources, and meet users' resource service needs while meeting users' interactive communication needs and complete personalized push of resources [9].

When the resources of the book and document center are shared, there are still some deficiencies in the interaction between multiple users. Therefore, to better realize the sharing of such resources, reference [10] focused on the FULink platform to carry out the research on the resource-sharing process. Through this platform, all libraries could adhere to the common concept, abide by the unified standards, establish a scientifically coordinated operation mechanism and a perfect incentive mechanism, and promote the effective sharing of books and reference resources. This method can effectively coordinate sharing of reference resources among all participating libraries. It mainly focuses on the information exchange and control between participating libraries, but the security protection for the resources of the document center is poor. In reference [11], based on information sharing needs, after carrying out relevant research, an Internet information resource model of hierarchical information resource sharing for cloud computing was proposed. This method used specific constraints, trust gradient function, cloud trust evaluation criteria, and trust constraint coefficient to establish a hierarchical information resource sharing model and complete information sharing through this model. This method has good integrity in the application process. Still, it cannot cluster information resources, so it takes a long time in the sharing process, and the sharing effect of high-level resource information still needs further verification. Reference [12] took the remote sharing of resources as the research core. It proposed a blockchain-based resource-sharing method to protect the privacy and security of the experimental platform resources during the remote sharing of resources. However, this method cannot automatically push resources during application. Reference [13] puts forward a method of sharing digital English teaching resources based on artificial intelligence. Through the collection and management of English digital teaching resources, an evaluation index system of teaching resources is constructed, so as to comprehensively and objectively evaluate digital teaching resources, promote the construction and development of digital teaching resources, effectively promote and improve teaching effect, and realize the research requirements of effective sharing of massive

teaching resources in complex environment. However, this method has poor sensitivity to resource sharing. Reference [14] puts forward a resource sharing method of state update freshness. In the automatic driving system, the traffic situation and the vehicle position must be as close as possible. The information age is a relatively new indicator, which is used to measure the freshness of our understanding of the status of remote systems in order to better share resources. However, this method is not effective for the resource sharing of library and literature center.

At present, the rapid development of media technology has greatly changed the way of communication of information resources, and the dissemination of information resources also has gradually diversified with the integration of various media into the information age. Multimedia technology is the product of this information age. It is a technology that uses computers to store and manage various kinds of information, such as language, data, audio, video, etc. so that users can communicate real-time information through multiple senses and computers. The content displayed and carried by multimedia technology is actually the product of computer technology, with the characteristics of integration, control, interactivity, nonlinearity, synchronization, and dynamic information structure. Therefore, in order to meet the resource sharing of the book and document center in the information era, this paper studies the relevant resource-sharing methods of the book and document center based on the multimedia background. This method combines cloud services to complete the clustering and storage of reference resources and constructs resource pools through virtual technology to achieve efficient management of resources; Combined with the advantages of blockchain technology, the sharing mechanism is built to realize the safe sharing of resources. The feasibility of the proposed method and the effect of resource management and sharing are verified by the relevant analysis of the method.

The research motivation of this method is:

First of all, with the rapid development of information technology and the increasing richness of multimedia resources, the form and content of books and literature resources are undergoing profound changes. How to realize the effective sharing of books and literature resources under the multimedia background and ensure the full utilization and efficient management of resources has become an urgent problem. Therefore, studying the methods of resource sharing in the library and literature center under the background of multimedia is helpful to promote the digitalization, networking and intelligent development of library and literature resources, and improve the utilization efficiency and management level of resources.

Secondly, with the increasingly obvious trend of interdisciplinary integration, the demand for books and literature resources is also diversified and cross-disciplinary, and the exchanges and cooperation between different disciplines need to share rich literature resources as support.

Finally, from the perspective of users' demand, with the diversification of information acquisition methods and the increase of personalized demand, users' demand for books and literature resources also presents the characteristics of diversification and personalization. Studying the resource sharing method of library and document center under the multimedia background is helpful to better meet the needs of users and provide more convenient and efficient services.

II. Resource Sharing of Book and Document Center

A. Resource Sharing Method Framework of the Book and Document Center

The functional services are designed from two aspects, namely, common functions and spatial functions. The former meets the basic needs of users for resource services, and the latter meets the basic needs of users for resource services. At the same time, users can get more communication and personalized experience. The functional design of common functions includes resource browsing, resource retrieval, resource download, resource upload, resource evaluation, and other functions. Users can search resources in the platform according to keywords or platform navigation classification. The space function is used to meet the communication and cooperation between users and realize sharing. The overall framework of this method consists of three layers: the service, the management, and the resource. The overall framework is shown in Fig. 1.

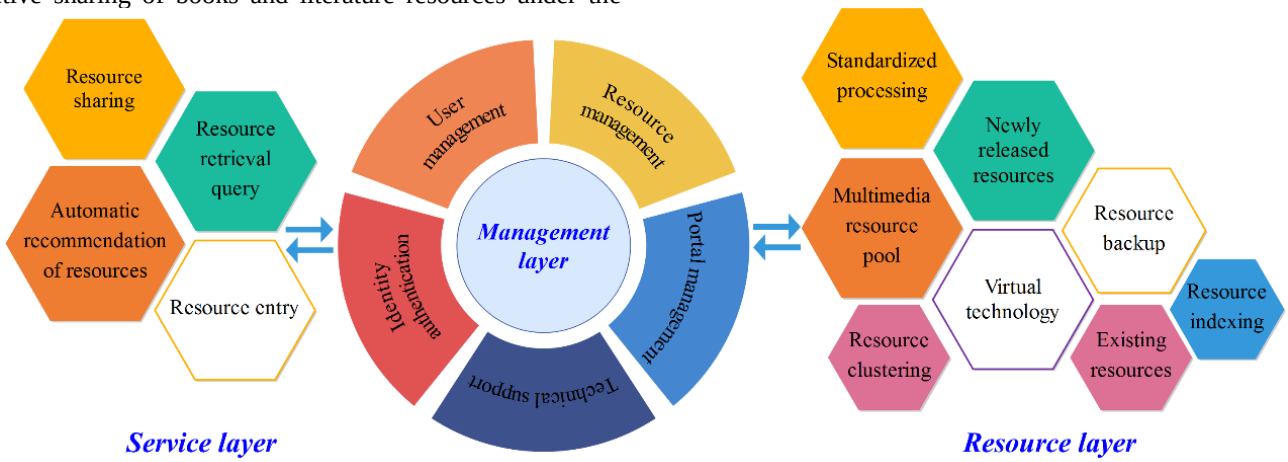

Fig. 1. Resource sharing method framework of the book and document center under the multimedia background.

The basic function of this method is to accept resource service requests from cloud computing users, deliver specific resources and services to the requester according to user needs, and reasonably schedule the corresponding resources so that users can request resources and services to run.

Service layer: The service layer is located at the top of the system platform and is also the realization part of the method of sharing. At the same time, this layer is the direct entrance to the document resource-sharing service presented to users. Users can access the multimedia resource-sharing platform through computers, mobile phones, panel computer, and other mobile devices, and can browse and download resources at any time, obtain resource services, improve user experience, and promote the sharing of document resources; In addition, the resource search method in the multimedia teaching resource sharing portal uses the classified navigation plus keyword search method to search, which can greatly improve the efficiency and accuracy of document retrieval. While meeting the user's resource demand, this layer can also provide more personalized and intelligent services. The platform can actively push information according to the user's usage habits to keep abreast of the latest developments of the resources concerned.

Management layer: As the management part of the overall framework of the method, the main role of this layer is to achieve comprehensive management of users, resources, etc. Because books and reference resources are stored in the form of a cloud resource pool and related services are provided through cloud service, the cloud service provider should be responsible for providing and managing the relevant cloud technology hardware equipment, storage, computing, and other functions while managing resource services, user accounts, resources, platform portals, etc. Account management is mainly to assign a unified authentication ID to users. It can access the resource pool and obtain relevant resource services only after applying for a unified ID number. Portal management is mainly used to manage the service items of the resource cloud-sharing platform. It can update the website layout and columns in a timely manner so as to provide users with a better service experience and complete the timely release of website-related information and resources.

Resource layer: As the key layer to realize sharing, this layer mainly consists of two parts, namely, resource co-construction and resource storage. Resource co-construction is to summarize the original book and reference resources through a unified interface according to the specified standards through the integration method, and then filter index, clean the collected resources and store them in the document resource cloud resource pool to provide resource service support for the platform. In this paper, when storing resources, it can use virtual technology to build resource pools, which have storage space disaster tolerance technology, data encryption technology, and often backup resources to ensure the security of resource storage and avoid the loss of resources caused by Internet attacks. Redundant storage technology is adopted to make the storage of resources safer and more environmentally friendly.

B. Design of Resource Layer

1) Structure of the reference resource pool: The resource layer is the support for the realization of document sharing. In order to achieve better resource services, the storage of resources is particularly important. In this paper, multimedia technology is used to build a multimedia document cloud resource pool to achieve efficient resource integration; In addition, in order to ensure the cloud storage effect of resources, the virtualization of the resource pool is completed in combination with virtual technology to achieve efficient storage of resources. The structure of the multimedia reference cloud resource pool is shown in Fig. 2.

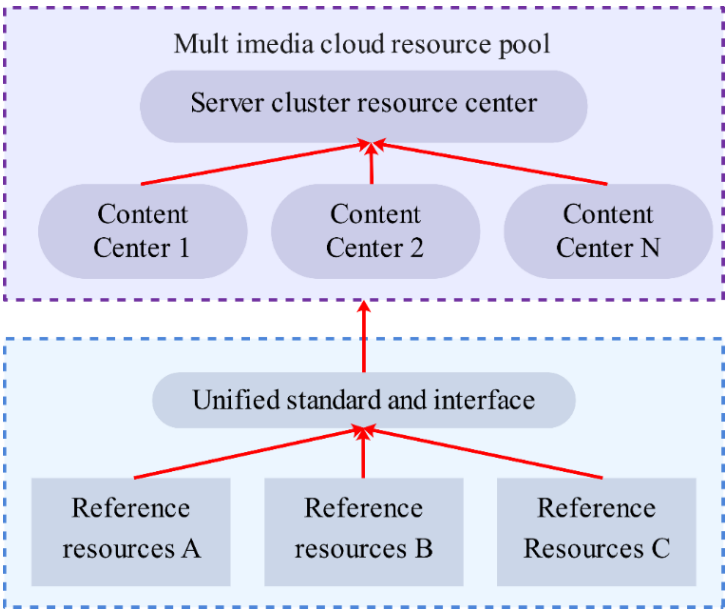

Fig. 2. Cloud resource pool structure of multimedia reference.

During resource integration, the resource layer uses the resource clustering algorithm to cluster and upload resources to cloud storage through the unified platform interface. All colleges and universities can access the resources uploaded to the cloud, further improving the efficiency of resource sharing. The resource storage method cloud service providers adopt centralized storage and multiple redundant backups, which is more secure. Even if one of the data analysis servers loses data due to natural disasters or other reasons, the data control center can recover data from other backups in time to ensure normal service delivery.

2) Document resource clustering: Before resource sharing, it is necessary to cluster the document resources. Due to the differences in the category and attribute of resources, in order to efficiently cluster the document resources, the adaptive clustering algorithm of empirical mode feature decomposition is used to complete the clustering, and the concept of cosine similarity is introduced to ensure the clustering effect.

Before clustering the reference resources, it should normalize the resources to limit them to a certain range, to eliminate the impact of resource structure differences on the clustering effect [15]. Assuming that the parameters of the adaptive clustering algorithm are represented by K, if the multi-source heterogeneous document resource set is represented by $X = \{x_1, x_2, \ldots, x_n\}$, the number of resource categories contained therein is k, and the attributes of different resources are represented by S_k, and k is the maximum number of attributes. Based on this, the equation for calculating the confidence distance between samples of different reference resources is:

$$d(x_1, x_2) = K \times \sum_{k=1}^{n} S_k X_k \frac{1}{n \times u(x_1, x_2)} \quad (1)$$

In the formula: $u(x_1, x_2)$ represents confidence; n represents the number of reference resource samples. The normalization result of $X = \{x_1, x_2, \ldots, x_n\}$ can be obtained after compression processing, and the equation is:

$$x_n = d(x_1, x_2) \times \left(1 + \frac{S_k}{\eta}\right) \quad (2)$$

In the formula: η represents the normalization factor.

After the normalization of reference resources is completed according to the above steps [16], the initial clustering center C_i is determined, and its calculation equation is:

$$C_i = \frac{x_n}{\sum_{i,k=1}^{n} y_{ik}} \quad (3)$$

In the formula: y_{ik} represents the degree of membership. After determining C_i, the document resources are clustered. In order to ensure a more reliable clustering effect, the concept of weighted cosine distance d_{ij} is introduced in the clustering process to ensure the reliable clustering of resources of the same category. The calculation equation of d_{ij} is:

$$d_{ij} = 1 - \frac{\sum_{g=1}^{G} \sum_{k=1}^{K} (w_{gk} \times z_{igk})(w_{gk} \times z_{jgk})}{\sqrt{\sum_{g=1}^{G} \sum_{k=1}^{K} (w_{gk} \times z_{igk})^2} \sqrt{\sum_{g=1}^{G} \sum_{k=1}^{K} (w_{gk} \times z_{jgk})^2}} \quad (4)$$

In the formula: $g = 1,2,\ldots,G$; $k = 1,2,\ldots,K$; $i,j \in 1,2,\ldots,n$; w_{gk} represents the weight, corresponding to the g -th resource in the k -th category; z_{igk} and z_{jgk} represent the standardization results respectively. The former corresponds to the i -th resource, and the latter corresponds to the j -th resource.

On the basis of cosine similarity, the weighted cosine distance is used to objectively weight the different characteristics of the document resource samples, and the characteristic that the angle cosine measures the difference between any two individuals of different resource samples is retained, which can provide reliable guarantee for resource clustering [17].

If each resource is a category, the initial category and the distance between categories are expressed by $D_{i,j}$, and $D_{i,j} = d_{ij}$, then the initial category and the distance matrix between categories are expressed by $D^{(1)} = \left(d_{ij}\right)_{N \times N}$. On this basis, after determining the distance $D_{k,r}$ between the merged class and other classes, the number of clusters is determined; If the given threshold of the number of clusters is Ψ, the relationship between it and any classes X_i and X_j is:

$$D_{k,r} = \Psi \times \left(X_i, X_j\right) \quad (5)$$

According to the calculation results of this equation, it can compare the distance and threshold results between different classes and classes of resources [18]. If Equation (5) is satisfied, that is, the distance between classes is less than or equal to the threshold, X_i and X_j are combined into one class. And one resource category is reduced according to the calculation result of $D_{k,r}$. The above contents are processed circularly. When the distance between all resource categories and categories is less than Ψ, the final document resource cluster quantity and resource category label can be obtained, and the book and document center resource cluster can be completed [19].

C. Realization of Resource Sharing

1) Structure of resource sharing mechanism: After completing the resource clustering of the book and document center through the above sections, the service layer will share the resources after clustering. To ensure security in the sharing process, the regional document information resource co-construction and sharing mechanism based on blockchain is adopted for resource sharing. The sharing structure of this mechanism is shown in Fig. 3.

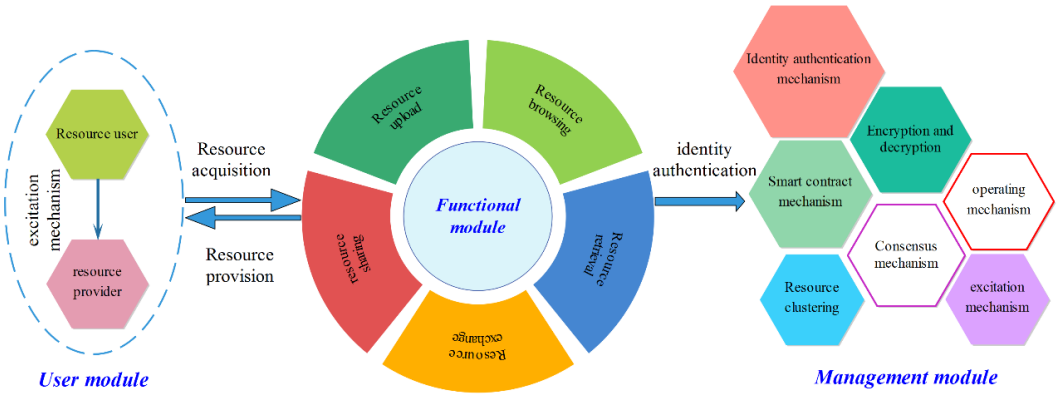

Fig. 3. Structure of regional document information resources co-construction and sharing mechanism based on blockchain.

The sharing mechanism proposed in this paper includes three modules, namely the user, function, and management modules. Through the mutual assistance of the three modules, a resource-sharing alliance chain is formed to realize the safe sharing of resources.

- User module: This module is based on the private chain of user behavior, which includes all service objects of the Alliance, namely users of information resources, as well as alliance resource providers, such as various types of databases, publishers, and libraries. Therefore, users can become both providers and users of the Alliance's reference and information resources, thus expanding the types and service scope of regional reference and information resources co-construction and sharing.
- Function module: The service layer includes a data sub-module and function sub-module, which are used for uploading, browsing, searching, downloading, and other functions of information resources. Users can upload data resources within certain rules through the data sub-module. They can select corresponding functions to download information resources according to their own needs through the function sub-module.
- Management module: The management layer uses the blockchain-based distributed ledger technology [20], and the member libraries of the Alliance store their reference data resources in different blocks in a distributed manner. They use point-to-point communication to achieve efficient use of resources, solve the problem of resource islands, promote the free circulation and safe sharing of information resources among university libraries in the Alliance, and improve the sharing efficiency. The member libraries of the Alliance are interrelated and independent of each other. Through identity authentication mechanism, consensus mechanism, incentive mechanism, and smart contract mechanism, they are jointly built in the framework of the Alliance to identify the rights and responsibilities of document resource allocation within the Alliance and to standardize the behavior of the member libraries of the Alliance.

2) Implementation method of resource sharing: When using the regional reference information resource co-construction and sharing mechanism based on blockchain to share the resource, in order to ensure the sharing effect, ensure the stability in the sharing process, and complete the sharing among multiple nodes, this mechanism uses consensus algorithm to maintain the resource sharing, with good decentralized characteristics [21]. According to different principles, the algorithm can be divided into a verification pool mechanism, proof of rights and interests' mechanism, and proof of workload mechanism. The practical Byzantine fault-tolerant algorithm, system fault-tolerant performance [22], response time, and throughput are the main factors in judging the performance of the consensus algorithm. The parameter of consensus algorithm is fault tolerance, the calculation equation of fault-tolerant performance f during resource sharing is as follows:

$$f = \left|\frac{m-1}{3}\right| \tag{6}$$

In the formula: m represents the number of shared user nodes.

If the time of the consensus node of the algorithm for resource reception and consensus is t' and $\tilde{t}$ respectively, the calculation equation for the response time t of resource sharing is:

$$t = t' + \tilde{t} \tag{7}$$

In unit time, the total amount of resources shared on the blockchain $T_{PS_{\Delta t}}$ is calculated as follows:

$$T_{PS_{\Delta t}} = \frac{T_{otal} \times T_{\Delta t}}{\Delta t} \tag{8}$$

In the formula: $T_{PS_{\Delta t}}$ represents the total amount of resources shared on the blockchain per unit of time, which also represents throughput; Δt represents the response time change of resource sharing, $T_{\Delta t}$ represents the amount of resources shared on the blockchain. T_{otal} represents the total amount of resources shared on all blockchains.

3) Privacy protection of shared resources: The decentralization of the blockchain makes every node contain

all the information of the system, so the link's capacity restricts the further improvement of the blockchain and how to protect data privacy. At the same time, not affecting blockchain performance is the main problem to be solved. Privacy protection mainly adopts password technology, mixed currency technology, etc. This paper uses the aggregate signature method in encryption technology. The aggregate is superimposed into a single data through the input and output of multiple signature information. This algorithm has a high-security factor and can provide block transaction information without increasing the system burden. The specific process is as follows:

In the case of resource sharing transaction, input and output resources are represented by x and y respectively, and the relationship between them is shown in Equation (9):

$$\sum_{i=1}^{x} ix_i = \sum_{j=1}^{y} out_j \tag{9}$$

In the formula: x_i and out_j both indicate that resources need to be hidden; $i \in [0, x]$; $j \in [0, y]$.

If the resource sharing transaction generator is represented by z, the conversion equation of the resource sharing transaction mode of x_i and out_j is:

$$\begin{cases} I_i = x_i \times z \\ O_i = out_j \times z \end{cases} \tag{10}$$

According to Equation (10), if the results of x_i and out_j cannot be obtained through I_i and O_i during resource sharing, it means that the shared resource cannot be found, which can greatly ensure the security of the resource and realize safe sharing.

4) Shared resource decryption: After the shared resource encryption is completed in the above section, users need to decrypt before sharing resources [23]. If the random number received by the resource provider is X_i, its ID is I_x, and the ID of the resource receiver is I_y, the expression of the harvest factor S_{x*y} of the decoding work can be obtained as follows:

$$S_{x*y} = (e^x, e^y) \tag{11}$$

In the formula: e^x and e^y both refer to the shared secret key, the former corresponds to the resource provider, and the latter corresponds to the resource receiver. To obtain the decryption parameter H_{x*y}, its calculation equation is:

$$H_{x*y} = \prod_{i=1}^{n} h^{R_x} + h^{R_y} \tag{12}$$

In the formula: h^{R_x} and h^{R_y} both represent encrypted resource parameters. The former corresponds to the resource center and is transmitted to the processor, while the latter corresponds to the processor and is transmitted to the resource receiver.

On the basis of the above steps, the resource receiver needs to decrypt the secret text resources [24]. The equation for decrypting the plaintext resources is:

$$\xi_{xu} = \frac{b_{2xj}}{W^{-\mu}} \tag{13}$$

In the formula: the resource receiver I_y decrypts and obtains the plaintext resource, which is expressed as ξ_{xu}; b_{2xj} indicates the location of the private key; $W^{-\mu}$ represents the weight attribute.

D. Shared Resource Push

After the decryption of resources is completed in the above section, the service layer will share and push the decrypted resources. During the implementation of this push, users can easily obtain the rich required resource content. With this automatic push function, users can easily obtain a certain type of frequently updated resource information without having to search on the resource platform. The automatic push process of shared resources is shown in Fig. 4.

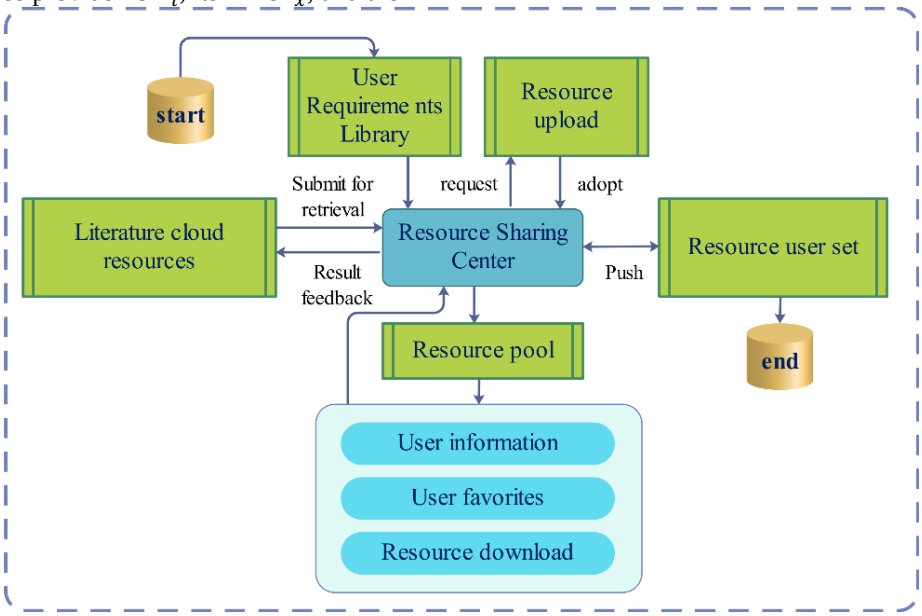

Fig. 4. Push process of resource sharing resources in the book and document center.

As shown in Fig. 4, the active resource push process shows that the cloud-sharing platform will push the decrypted shared resources and can build a user demand library; when the user is on the next visit, the document center can understand the user's preference for resources through the user demand database. According to this user demand database, the resource information matching the user demand database in the relevant resource pool is searched. Then the searched resource blockchain is encrypted and pushed to the user. After the user decrypts the information, the automatic push of the information is realized to complete the resource sharing.

III. TEST ANALYSIS

In order to verify the application effect of the method in this paper, it takes a university's book and document center as an example research object. It applies this method to the document resource sharing and exchange platform management center. 2000 medical resources in the center are selected as the document resource data for testing. The resources are divided into three categories according to the publishing form: books, special documents, and continuous publications. The test document resources include 1000 traditional Chinese and 1000 western medicine document resources. The method in this paper is used to share the document resources and obtain the sharing results to analyze the application effect of the method in this paper.

During the test, users are all high school students and distributed in the same base station. The MEC computing capacity deployed in the base station is 20GHz/s, and the computing resources of other devices are randomly distributed in the range of [2,4] GHz/s. Other relevant parameters of network communication are shown in Table I.

TABLE I. DETAILS OF COMMUNICATION PARAMETERS

Parameter Name	Numerical Value
Cellular channel bandwidth /MHz	12
Uplink transmission power /mW	200
D2D bandwidth /MHz	12
D2D transmit power /mW	100
noise power /dBm	-100
Channel gain	0.00006
Number of cellular orthogonal channels	20
Number of D2D orthogonal channels	20

In order to verify the clustering effect of the method in this paper on different document resources, the paper uses the clustering purity ρ and the contour coefficient φ as the evaluation indicators, ρ is to measure the clustering quality of the method, and φ is to measure the advantages and disadvantages of clustering. The value range of the two indicators is between [0~1] and [- 1~1], respectively. The closer the value is to 1, the better the clustering quality and the better the clustering effect. The calculation equations are as follows:

$$\rho = \frac{1}{N}\sum_{k=1}^{K} n_k \tag{14}$$

$$\varphi = b\frac{d'}{max\{d', b_{min}\{\}\}_{min}} \tag{15}$$

In the formula: N represents the total number of resource samples; n_k is the sample number of most classes in the k -th cluster; b_{min} represents the minimum vector, and represents the average distance between the point i and points in different classes; d' represents the average distance between resource i and other resources in its same category.

According to Eq. (14) and Eq. (15) above, it can calculate the results of the two indicators with the gradual increase of the number of resource samples when clustering the three reference resources using this paper's method, as shown in Table II.

TABLE II. TEST RESULTS OF THE CLUSTERING EFFECT OF DIFFERENT REFERENCE RESOURCES

Number of Clusters/Piece	Reference Category					
	Books		*Special reference*		*Series publications*	
	Cluster Purity	*Profile Factor*	*Cluster Purity*	*Profile Factor*	*Cluster Purity*	*Profile Factor*
100	0.954	0.943	0.922	0.952	0.955	0.952
200	0.963	0.951	0.941	0.949	0.947	0.936
300	0.948	0.946	0.928	0.962	0.944	0.939
400	0.939	0.955	0.931	0.954	0.952	0.944
500	0.954	0.933	0.956	0.986	0.971	0.967
600	0.966	0.926	0.947	0.971	0.968	0.935
700	0.978	0.947	0.962	0.983	0.949	0.974

800	0.972	0.952	0.958	0.966	0.933	0.987
900	0.959	0.946	0.934	0.924	0.945	0.958
1000	0.977	0.977	0.977	0.936	0.962	0.962
1100	0.954	0.979	0.961	0.958	0.957	0.984
1200	0.928	0.959	0.958	0.966	0.981	0.967
1300	0.936	0.928	0.969	0.927	0.975	0.986
1400	0.941	0.981	0.972	0.958	0.982	0.981
1500	0.952	0.982	0.958	0.986	0.985	0.964
1600	0.953	0.963	0.974	0.977	0.956	0.959
1700	0.964	0.957	0.947	0.985	0.986	0.937
1800	0.956	0.924	0.955	0.965	0.928	0.962
1900	0.944	0.932	0.928	0.972	0.974	0.955
2000	0.922	0.944	0.931	0.982	0.979	0.978

According to the test results in Table II, after clustering the three kinds of reference resources using the method in this paper, with the gradual increase of the number of samples, the results of the clustering purity ρ and the contour coefficient φ of the book resources are very close to 1, the maximum value of ρ is 0.978, and the maximum value of φ is 0.982; The maximum results of clustering purity ρ and profile coefficient φ of special reference are 0.977 and 0.986 respectively; The maximum results of cluster purity ρ and contour coefficient φ of the continuous publications are 0.986 and 0.987, respectively. Therefore, the method in this paper has a good clustering effect on document resources, can effectively complete the clustering of different categories of document resources, and provide a reliable basis for resource sharing.

In order to verify the security of resources in the method of this paper when sharing resources, resource sharing sensitivity ψ is used as the measurement uncertainty. ψ can measure the security degree of resources in the process of sharing, and its value range is between 0% and 100%. The larger the value is, the higher the sensitivity of sharing is, and the worse the security of information sharing is. The calculation equation of this indicator is:

$$\psi = \frac{\sum_{i=1}^{B_n} \left| \frac{\alpha_i - \beta_i}{\alpha_i} \right|}{B_n} \tag{16}$$

In the formula: B_n represents the sensitive category threshold of resource sharing, α_i represents the frequency efficiency of document resource i sharing, β_i refers to the efficiency of frequency estimation of shared resources.

In order to intuitively reflect the security of resource sharing of the method in this paper, the three methods in reference [10], reference [11], and reference [12] are used as the comparison methods for the method in this paper. According to Eq. (16), the calculation results of ψ are shown in Table III, with the increasing proportion of total resources successfully shared when the above algorithms share different amounts of resources.

TABLE III. RESOURCE SHARING SECURITY TEST RESULTS OF FOUR METHODS

Method category		**Successful share ratio /%**		
		10	50	100
Reference [10]method	Number of shared resources 500/ strip	14.32	17.66	22.76
	Number of shared resources 1000/ strip	20.17	26.62	31.46
Reference [11]method	Number of shared resources 500/ strip	15.33	18.47	20.86
	Number of shared resources 1000/ strip	22.33	27.45	30.22
Reference [12]method	Number of shared resources 500/ strip	16.26	19.44	23.76
	Number of shared resources 1000/ strip	21.82	26.36	29.97
Method in this paper	Number of shared resources 500/ strip	4.36	5.96	7.44
	Number of shared resources 1000/ strip	5.82	7.68	10.11

According to the test results in Table III, with the gradual increase of the number of shared resources under different successful sharing ratios, the sensitivity results of the method in Reference [10], [11], [12] and the method in this paper for resource sharing also have different changes. Among them, the method in reference [10], the method in reference [11], and the method in reference [12] have different results when the number of shared resources is 1000. The sharing success ratio reaches 100%, and the highest results of them of ψ are 31.46%, 30.22% and 29.97%, respectively, while the results of ψ in this paper's method are 10.11%. The reason is that in the process of sharing, the method in this paper introduces the regional document information resources co-construction and sharing mechanism based on blockchain, which can encrypt the shared

resources and combine the consensus algorithm to process the shared resources. The resource receiver can obtain the resources of the resource center after decryption, so the security of resource sharing can be greatly guaranteed.

In order to verify the applicability of document resource sharing in the system of this paper, after obtaining the application of the method in this paper, the management results of the university's document resource sharing and exchange platform management center for book and document resources are shown in Fig. 5.

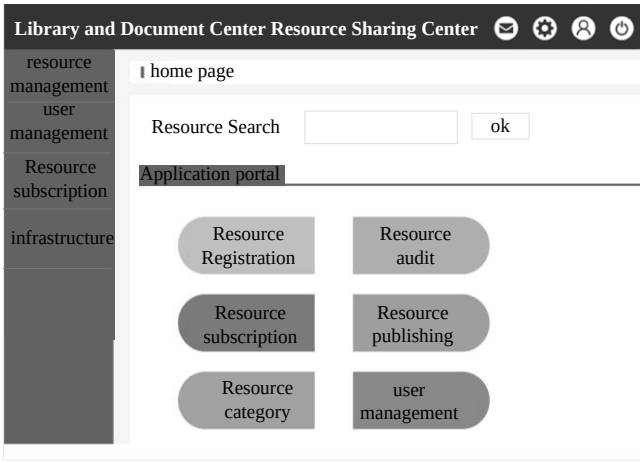

Fig. 5. Management results of book and document resources.

According to the test results in Fig. 5, after the application of the method in this paper, the university's document resource sharing and exchange platform management center can view the details of different types of resources through resource clustering. At the same time, it can view the release of users, the review of resources, the subscription of users, and master users' browsing and needs for document resources. Because this method has good applicability, it can complete the unified storage and management of different types of document resources after application and provide a resource guarantee for resource sharing.

In an ideal state, the maximum coverage of resource sharing in the library and literature center is 100%. Based on this data standard, if the actual coverage of the research method is closer to this value, it means that the wider the coverage of resource sharing is, the more it meets the resource sharing requirements of the library and literature center. According to the above discussion, calculate the coverage rate of the shared range, and the formula is:

$$\lambda_{\alpha\beta} = \frac{\sum_{i=1}^{n} N_i}{M_i} \times 100\% \quad (17)$$

In the formula: $\lambda_{\alpha\beta}$ represents the coverage rate of the shared range; N_i represents the amount of shared resources in a certain link; M_i represents the total resources of this link. Based on the above formula, the coverage results of resource sharing range of the four methods are calculated respectively, as shown in Table IV.

From the experimental results recorded in Table IV, it can be seen that method in this paper has a sharing coverage rate of over 98% each time, while the other three reference methods can only reach 85.47% at the highest, and the sharing coverage rate is small. Therefore, through the above experimental results, it can be proved that the research on the resource sharing method of book and document center proposed in this paper has a higher coverage of sharing scope in practical application, which can fully meet the sharing needs of book and document center resources.

TABLE IV. COMPARISON TABLE OF SHARING SCOPE COVERAGE OF FOUR METHODS

Sharing times	Method in this paper/%	Reference [10] method/%	Reference [11] method/%	Reference [12] method/%
The first time	98.25	54.21	55.26	56.25
The second time	98.36	53.36	64.52	62.15
Third time	98.52	61.36	71.41	64.58
The fourth time	98.95	68.20	84.25	71.25
The fifth time	99.61	73.35	85.47	75.69

IV. DISCUSSION

Under the background of the rapid development of multimedia, it is particularly important to study the resource sharing method of library and document center. This research is not only an innovation of the traditional management of books and documents, but also a deep exploration of the knowledge dissemination and sharing mechanism in the information age.

First of all, the application of multimedia technology has brought unprecedented development opportunities for the library and documentation center. Through digitalization, networking and other means, books and literature resources can be spread and utilized more conveniently and efficiently. However, how to effectively share the resources of the library and literature center under the multimedia background is an urgent problem to be solved. The importance of this research lies in that it can provide a set of scientific and reasonable resource sharing methods for the library and literature center, thus promoting the maximum utilization of library and literature resources and improving the efficiency of knowledge dissemination.

Secondly, the research on the resource sharing method of library and documentation center is helpful to promote the interdisciplinary and integration. Under the background of multimedia, books and literature resources are no longer limited to a certain discipline or field, but show an interdisciplinary and cross-disciplinary trend. Therefore, how to build a shared platform that can accommodate diversified resources and promote exchanges and integration between different disciplines has become an important research direction. This research can not only promote the intersection and integration of disciplines, but also provide fertile soil for the generation of new knowledge.

Finally, the research on the resource sharing method of library and document center is of great significance for acquiring new knowledge. Through the research and practice of sharing methods, we can dig deeper into the value of books and literature resources and discover the new knowledge contained in them. At the same time, the optimization and innovation of sharing methods can also provide strong support for knowledge innovation and promote the in-depth development of academic research.

To sum up, the research on the resource sharing method of library and literature center under the multimedia background has important theoretical value and practical significance. It not only helps to promote the maximum utilization of books and literature resources and the intersection and integration of disciplines, but also provides strong support for the generation of new knowledge. Therefore, we should strengthen the research investment in this field and constantly promote the innovation and development of resource sharing methods in book and document centers.

V. Conclusion

The application field of multimedia technology has gradually expanded, and people's demand for resources in the field of multimedia has also increased significantly. For the book and document center, it is of great significance to maximize the utilization of its resources and expand its capabilities. However, in the current book and document center, there are many types of resources and a large amount of information, which leads to low processing efficiency in the process of using or sharing resources, and there are certain security risks. Therefore, this paper starts from the human problem in the resource sharing of the book and document center and combines several major problems in the resource sharing under the current multimedia background, including the storage, security sharing, and overall management of resources, and puts forward the resource sharing method of the book and document center under the multimedia background. This method makes use of the advantages of multimedia technology to uniformly store the scattered resources in different data sources and realize the sharing of data resources in different servers, which can expand the sharing range of information resources and effectively meet the personalized needs of users for resources.

With the continuous development and popularization of multimedia technology, the research on resource sharing methods in book and document centers is facing broader prospects and higher requirements. In the future, the following aspects can be further studied:

1) The future research work will pay more attention to the intelligence and personalization of the resource sharing platform. By applying advanced technologies such as artificial intelligence and big data, the platform will be able to understand users' needs more accurately and provide more accurate resource recommendation and personalized services.

2) Future research work will be devoted to promoting cross-domain and cross-regional cooperation of resource sharing platforms. In the future, the sharing platform will pay more attention to cross-disciplinary resource integration and sharing, and promote exchanges and integration between different disciplines.

3) Future research work will also be devoted to promoting the openness and sharing of the resource sharing platform. By opening API and providing data interface, the platform will be able to realize seamless docking and data sharing with other systems and platforms, and further promote the sharing and utilization of books and literature resources.

Data Availability

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

Conflicts of Interest

The authors declared that they have no conflicts of interest regarding this work.

A Hybrid MCDM Model for Service Composition in Cloud Manufacturing using O-TOPSIS

Syed Omer Farooq Ahmed[1], Adapa Gopi[2]
Research Scholar[1], Associate Professor[2]
Koneru Lakshmaiah Education Foundation, Guntur, India

***Abstract*—The purpose of this research article was to define the current or future usage of Industry 4.0 technologies (Cloud Computing, IoT, etc.) to improve industrial manufacturing. The goal of this study is to rate the options using a hybrid CRITIC - O-TOPSIS Multi Criteria Decision Making model. The CRITIC technique is used to calculate Objective Weights. Also, when comparing the findings to TOPSIS, A thorough Systematic Literature Review comes first. Secondly, a theoretical approach to recognizing the Index System of Criteria. Third, Creating a Hybrid Model of CRITIC and O-TOPSIS for Decision Making. Lastly, Comparing and Ordering Options. The proposed technique successfully addresses the ambiguity and uncertainty of heterogeneous information while maintaining assessment data accuracy. Also, because objective weights are more grounded in reality than subjective weights, the result is more precise. CRITIC approach results reveals that Ease of Opting has the most weight and Ease of Implementation has the least weight O-TOPSIS method ranks alternatives in the following order: A4>A5>A3>A1>A2. This paper ranks alternatives based on extensive 22 criteria in Service Composition in Cloud Manufacturing using the hybrid model CRITIC - O-TOPSIS**

***Keywords*—Cloud manufacturing (CMFg); CRITIC method; O-TOPSIS method; service composition**

I. Introduction

In tech-based manufacturing, the most cutting-edge technological techniques can be employed to govern service composition. To be more specific, the concept of Industry 4.0 emerges first in this context. The Internet of Things (IoT) and cloud manufacturing (CM) are two examples of modern digital technologies.

An optimization-based strategy is not used in the fuzzy TOPSIS technique [1]. It is suggestible to consider objectivity arising due to human intervention. In order to solve this, O-TOPSIS with Objective Weights is used in this study's ranking of the alternatives. An advanced manufacturing system selection problem with six evaluation criteria and four alternatives is given the framework [2]. It is discovered that spherical fuzzy AHP-TOPSIS works well for managing decision-making uncertainty. Making decisions in real-time scenarios requires a wide range of criteria in order to take into account several factors that could influence the process. This paper uses 22 criteria to make up for that. Most scholars believe that this phenomenon is not conducive to decision-making. Rank reversal in MCDM that may cause decision makers to ignore the differences among alternatives. Also, the rank reversal phenomenon in the TOPSIS affects the credibility of the decision results as well as the universality of its decision method [3]. The process [4] increases the effectiveness of decision-making and empowers decision-makers to choose solutions according to their significance and impact on the business. The Service Composition in Cloud Manufacturing should constantly use relevant and updated technology to avoid competition and crises in the future. This work (O-TOPSIS) attempt to extend the usability of TOPSIS.

Since rough numbers are objective in information evaluation, most other models—such as fuzzy numbers, interval numbers, the 2tL model, and the CM theory—are employed in conjunction with rough numbers to handle information aggregation in DM scenarios [5]. Although this method is objective, the rough numbers are ill-suited to handle quantitative data. The paper [6] used the Simple-normalization, Entropy-based TOPSIS, and K-means methods to improve the energy performance evaluation and ranking strategy for office buildings. This technique requires additional criteria in most cases since it is not suitable for multi-type and multi-size buildings and is not ideal for building energy efficiency dynamic evaluation. Our approach focuses on selecting a broad set of criteria that can be used to a wide range of cases.

A MCDM examination consists of four essential parts. The Decision Makers (DM) choose all of the important factors that will be used to assess the other alternatives in the Underlying Stage. An ID of this kind can be obtained by looking at the writing, based on the information on the DMs, or by asking assistance from skilled people. DMs should devote appropriate time to this step since failing to meet any important criterion may result in a futile probe.

The Subsequent Stage, decision-makers should accumulate data about every other option or a nearby score for every rule characterized in the primary stage to make the decision network. Consider a MCDM issue where the arrangement of options viable is indicated by the letters computer based intelligence = $\{a_1, a_2, \ldots, a_m\}$ and the arrangement of assessment standards is addressed by the letters $c_j = = \{c_1, c_2, \ldots, c_n\}$. The underneath referenced grid structure can subsequently be utilized to address the choice framework's general structure, where x_{mn} represents the choice m's score according to standards n.

Alternatives/Criteria	c_1	c_2	…	c_n
a_1	x_{11}	x_{12}	x_{13}	x_{1n}
a_2	x_{21}	x_{22}	x_{23}	x_{2n}
.	.	.	.	.
.	.	.	.	.
a_m	x_{m1}	x_{m2}	x_{m3}	x_{mn}

The Last Stage includes ascertaining every basis' weight. It is critical to take note of that assessing every one of the variables similarly isn't prudent in light of the fact that, by and by, they might have fluctuating levels of importance in a dynamic cycle. These rules loads and the neighborhood scores related with every option are consolidated into a worldwide score in the last stage. The decisions can then be positioned from most to least preferred in light of these general scores.

This article is arranged as follows: Section II covers the related work. Section III delves into problem statement and objectives of O-TOPSIS. Results and discussion is given in Section IV. Finally, the conclusion and Future directions for this research are discussed in Section V.

II. Related Work

The research map includes the following steps

Step # 1 : Systematic Literature Review

Step # 2 : Identifying Index System of Criteria

Step # 3 : Designing CRITIC - O-TOPSIS hybrid Model for decision making

Step # 4 : Ranking Alternatives

A. Systematic Literature Review

A systematic Literature Review was conducted to understand the implementation of TOPSIS with respect to various specializations. Also, to identify the index system of criteria for service composition in Cloud Manufacturing. This paper evaluates the different perceptions involved to find answer to the research question

Research Question: Determining the ranking to the alternatives using O-TOPSIS

The following steps followed after formulation of research question.

1. **Locating Articles** : We used Scopus Database
2. **Inclusion Criteria** :
   - A. Papers that worked with TOPSIS in Cloud Manufacturing and in also areas
   - B. Peer reviewed journal, reviews, and international conferences
   - C. Paper title
3. **Search Strings**:
   - A. Cloud Manufacturing
   - B. TOPSIS
4. **Exclusion Criteria**:
   - A. Papers in languages other than “English”
   - B. Initial selection after reading the paper title- final selection after reading the paper abstract/ full text
5. **Analysis**
6. **Findings**

B. Identifying Index System of Criteria

O-TOPSIS implemented on seven criteria and in all 22 criteria including sub-criteria. These are mentioned in Table # 2

C. Desinging Critic - O-Topsis Hybrid Model for Decision Making

CRITIC method used to find Objective Weightgs and there by using them to implement O-TOPSIS

D. Ranking Alternatives

Finally ranking the alternatives

III. Proposed Approach

Extended TOPSIS [7] is used to determine sustainable supplier using. Triangle fuzzy numbers, which are used to express the linguistic data obtained from industry experts, are used to gauge the degree of ambiguity that the experts have while assessing Parameter Influencing Testing (PITs) with respect to the selection criteria. In addition, the fuzzy set is included into the AHP in order to calculate the selection criterion weights. Lastly, a fuzzy TOPSIS is used to PIT ranking [8], Geometric Mean method is used in this work. The Decision System [9] applied to large food firm for validation. The technique rated Cloud and Internet of Things (IoT) as most important 4.0 industry technologies. The developed Green low-carbon port (GLCP) evaluation index system [10] uses the FFIWAD-TOPSIS technique, applied to five major Chinese ports.

The proposed approach [11] might be applied to other economic sectors that are considered networks, such as energy or communications transmission lines, passenger and freight rail systems, and so on. "Cloud-based customization environment" and "migrating legacy system to CMfg services" were the most and least chosen CMfg applications, respectively, based on the trial results in the research paper [12]. The results [13] show that when sensor data is fused in the input vector, the NN models perform better. Validation trials confirmed the TOPSIS optimum parameters, which proved to be correct. Novel concepts have been developed, including positive and negative risks, tolerable positive and negative risks, and the risk-based TOPSIS technique for multi-period preventive maintenance scheduling [14].

To further explain and validate the created model, a case study, sensitivity analysis on two parameters, a normalization procedure, and multiple comparisons are carried out in the paper [15]. The contribution of the paper [16] is highlighting the benefits and drawbacks of various cloud services selection methodologies and their future directions, providing a taxonomy based on an extensive literature review, focusing on cutting-edge approaches to cloud services selection, and identifying nine critical challenges in cloud services selection that require additional research. The case study in [17] looks

at the risk assessment of failure modes in a steam valve system to show how beneficial the recommended method is.

A. Service Composition in Cloud Manufacturing

All items, characteristics, and resources that depict a product's states, information, and mode of operation are regarded as services in the cloud manufacturing environment. These services, whose objective is to carry out actions as responses to requests between service customers and providers, can be specified, published, identified, and called through a network. Services could be delivered using cloud-based technologies and on a single server or several servers. Such services may find it more challenging to carry out the required actions when operating alone. As a result, service composition—a combination of already offered and available services from various businesses—can carry out both straightforward and difficult tasks.

B. Critic Calculation of Criteria Weights

The main steps in this procedure are

Step # 1 – Normalizing the Decision Matrix

The scores of different criteria are incommensurable as they are expressed in different measurement units or scales. Normalization is a process of transforming the scores into standard scales, which range between 0 and 1. In the proposed method, as a first step, we use the following Eq. (1) for normalizing the scores available in the decision matrix.

$$\bar{x}_{ij} = \frac{x_j - x_j^{worst}}{x_j^{best} - x_j^{worst}} \quad (1)$$

where, $\bar{x}_{ij}$ is the normalized score of alternative i with respect to criterion j, x_{ij} is the actual score of alternative i with respect to criterion j, x_j^{best} is the best score of criterion j, and x_j^{worst} is the worst score of criterion j.

Step # 2 - Calculate standard deviation, σj for each criterion.

Step # 3 - Determine the symmetric matrix of n x n with element rjk, which is the linear correlation coefficient between the vectors xj and xk.

Step # 4 - Calculate the measure of the conflict created by criterion j with respect to the decision situation defined by the rest of the criteria by using the following formula,

$$\sum_{k=1}^{m}(1 - r_{jk}) \quad (2)$$

Step # 5 - Determine the quantity of the information, Cj, in relation to each criterion by using the following,

$$C_j = \sigma_j * \sum_{k=1}^{m}(1 - r_{jk}) \quad (3)$$

Step # 6 - Determine the objective weights, Woj, by using the following

$$W_{oj} = \frac{c_j}{\sum_{k=1}^{m} c_j} \quad (4)$$

Step # 7 - Compute the integrated weights by combining the subjective and objective weights

$$Wj = \frac{W_{sj} * W_{oj}}{\sum_{t=1}^{n} W_{st} * W_{ot}} \quad (5)$$

Where, Wj represents the comprehensive weight of each criterion, Wsj represents the subjective weight, and Woj represents the objective weight

C. O-TOPSIS

The O-TOPSIS method is a multi-criteria decision-making method that ranks the available alternatives based on the closeness of alternatives to the ideal scenario considering the objective weights into account. The ideal scenario is a hypothetical ideal and best alternative. The specific steps for O-TOPSIS are:

Step # 1 – Establish the Initial Decision Matrix, A

The original data for the alternative criteria are subjected to vector standardization processing to obtain the initial decision matrix A with $m \times n$ as follows

$$A = (a_{ij})_{mxn} = \begin{pmatrix} a_{11} & \dots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{m1} & \dots & a_{mn} \end{pmatrix} \quad (6)$$

$\forall$ i = 1, 2, 3, …..m & j = 1, 2, 3, …..n

For the unification and facilitating the calculations, the low-optimal criteria must be standardized into high optimal criteria.

Step # 2 – Constructing the Normalized Decision Matrix, B

In the normalized matrix, each element in B, bij is obtained using the following equation,

$$b_{ij} = \frac{a_{ij}}{\sqrt{\sum a_{ij}^2}} \quad (7)$$

After normalization, the decision matrix is,

$$B = (b_{ij})_{mxn} = \begin{pmatrix} b_{11} & \dots & b_{1n} \\ \vdots & \ddots & \vdots \\ b_{m1} & \dots & b_{mn} \end{pmatrix} \quad (8)$$

$\forall$ i = 1, 2, 3, …..m & j = 1, 2, 3, …..n

Step # 3: Construct a weighted normalized Decision Matrix , C

The weight of the normalized decision matrix C is obtained by multiplying the values of the index weights determined using the BWM by the values of each column of the corresponding normalized decision matrix. i.e.

$$C = (c_{ij})_{mxn} = \begin{pmatrix} c_{11} & \dots & c_{1n} \\ \vdots & \ddots & \vdots \\ c_{m1} & \dots & c_{mn} \end{pmatrix} \quad (9)$$

where, $c_{ij} = w_j * b_{ij}$, i = 1, 2, 3, …..m & j = 1, 2, 3, …..n

Step # 4: Calculate the positive and negative ideal solution

The maximum and minimum values in each column of matric C are selected. All the maximum values are elements of positive ideal set C+ and all minimum values are elements of negative ideal set C-

$$\begin{cases} \{C^+ = (c_j^+) = \{\max_i c_{ij} \mid j = 1,2,3,\dots,n\} \\ \{C^- = (c_j^-) = \{\min_i c_{ij} \mid j = 1,2,3,\dots,n\} \end{cases} \quad (10)$$

Step # 5: Calculate the Euclidean Distance

The Euclidean Distance is calculated from each alternative to the positive and negative ideal solutions using the following equations,

$$\begin{cases} D_i^+ = \sqrt{\sum_{j=1}^{n}(c_{ij} - c_j^+)^2} \\ D_i^- = \sqrt{\sum_{j=1}^{n}(c_{ij} - c_j^-)^2} \end{cases} \quad (11)$$

where,

D_i^+ represents the distance from alternative i to the positive ideal solution.

D_i^- represents the distance from alternative i to the negative ideal solution.

Step # 6: Calculate the Relative Ideal Solution

The relative ideal solution is the value closest to the positive ideal solution and farthest from the negative ideal solution and is calculated using the equation,

$$CC_i = \frac{D_i^-}{D_i^+ + D_i^-} \quad (12)$$

where, CC_i represents the relative ideal solution for the ith alternative.

Step # 7: Rank the Alternatives

The alternatives are ranked based on the CC_i values, with the alternative having a maximum or minimum being the optimal solution.

1) Problem statement: Implementation of Multi-Criteria Decision Making (MCDM) method, the data collected and the techniques chosen for decision plays a major role.

a) Preparing the index system of criteria of service composition in Cloud Manufacturing.

b) Calculation of Objective Weights using appropriate method

c) Selecting the relevant method for ranking

d) Assigning of Ranking to the Alternatives

2) Objectives: For rating options, criteria, and sub-criteria, this article provides a hybrid multi-criteria decision technique.

a) A detailed analysis of the MCDM methods to rank the alternatives using objective weights.

b) A detailed analysis of service composition in Cloud Manufacturing

c) The objective weights of the criterion are calculated using CRITIC method.

d) To rank the various options, the Objective Weight -Technique for Order Preference by Similarity to Ideal Solution (O-TOPSIS) is used.

e) The results were compared with the conventional TOPSIS method.

IV. Results And Discussions

The initial criteria data were processed using vector standardization and the low-optimal criteria were converted to high-optimal criteria. Eq. (1) is used to obtain normalized decision matrix (it is represented in 22X5 Table, where 22 represents total criteria number and 5 represents the available alternatives). Table I represents the determined Objective Values.

A. Objective Weights using Critic

TABLE I. Objective Weights using CRITIC

We determine D^+ and D^- values and then finally calculate the ranking of all alternatives and these results are shown in Table V.

TABLE V. THE RANKING OF ALTERNATIVES -TOPSIS

Alternative	D^+	D^-	CC_i	Ranking
A_1	0.200499	0.182409	0.476377	4
A_2	0.236396	0.183752	0.437351	5
A_3	0.162992	0.207296	0.559823	3
A_4	0.164110	0.255312	0.608724	1
A_5	0.174182	0.235665	0.575006	2

C. TOPSIS vs. O-TOPSIS

From the Table VI, we can observe that the ranking using Objective Weights and Subjective weights is not similar. This work can be extended using comprehensive weights to rank the alternatives in the best possible way. The comprehensive weights can be calculated using both subjective and objective weights.

TABLE VI. THE RANKING OF ALTERNATIVES - TOPSIS VS O-TOPSIS

Alternative	TOPSIS		O-TOPSIS	
	CC_i	Ranking	CC_i	Ranking
A_1	0.599674	2	0.476377	4
A_2	0.499557	3	0.437351	5
A_3	0.642782	1	0.559823	3
A_4	0.449796	4	0.608724	1
A_5	0.355450	5	0.575006	2

V. CONCLUSIONS AND FUTURE DIRECTIONS

The prime purpose of this study was to define the current or future usage of Industry 4.0 technologies (Cloud Computing, IoT etc) to improve industrial manufacturing through a thorough review. It also established critical benchmarks for assessing the specific implications of various technologies. We examined forty-five papers published between 2019 and 2023. Later, 17 papers from the Scopus database were considered. Throughout the examination,

information from each publication was compiled into a large database that would be used for further research. A decision-making system will need to be constructed in the future to select the best cloud manufacturing technology within a specific firm domain.

Finally, utilising Objective Weights, this study includes a TOPSIS-based procedure for ranking and quantifying the application of the criteria using objective weights determined using CRITIC method. This technique was quite helpful in finding the most important technology.

A corporation employing a cloud manufacturing platform can use a valid selection model to pick the best cloud service provider (alternative) to improve the quality of its production and its capacity for sustained development. The following elements were considered in the model's implementation.

1) According to the CRITIC approach results, Ease of Opting has the most weight and Ease of Implementation has the least weight.

2) TOPSIS method rates options in the following order: A3>A1>A2>A4>A5.

3) The objective weights determined by using CRITIC method contribute to O-TOPSIS to obtain the desired ranking of the all the alternatives. O-TOPSIS method ranks alternatives in the following order: A4>A5>A3>A1>A2.

4) Quantitative data, including cost, is combined with linguistic assessment information when assessing cloud service providers. Moreover, DMs believe that they can communicate their preferences more clearly when they use a probabilistic word set. Consequently, the proposed method not only retains the correctness of assessment data but also effectively manages the ambiguity and uncertainty of heterogeneous information.

5) As the objective weights are more practical than the subjective weights, the result is more accurate.

***Abstract*—The analysis of sentiments expressed on social media platforms is a crucial tool for understanding user opinions and preferences. The large amount of the texts found on social media are mostly in different languages. However, the accuracy of sentiment analysis in these systems faces different challenges in multilingual low-resource settings. Recent advancements in deep learning transformer models have demonstrated superior performance compared to traditional machine learning techniques. The majority of preceding works are predominantly constructed on the foundation of monolingual languages. This study presents a comparative analysis that assesses the effectiveness of transformer models, for multilingual low-resource languages sentiment analysis. The study aims to improve the accuracy of the existing baseline performance in analyzing tweets written in 12 low-resource African languages. Four widely used start-of-the-art transformer models were employed. The experiment was carried out using standard datasets of tweets. The study showcases AfriBERTa as a robust performer, exhibiting superior sentiment analysis capabilities across diverse linguistic contexts. It outperformed the established benchmarks in both SemEval-2023 Task 12 and AfriSenti baseline. Our framework achieves remarkable results with an F1-score of 81% and an accuracy rate of 80.9%. This study provides validation of the framework's robustness in the domain of sentiment analysis across a low-resource linguistics context. our research not only contributes a comprehensive sentiment analysis framework for low-resource African languages but also charts a roadmap for future enhancements. Emphasize the ongoing pursuit of adaptability and robustness in sentiment analysis models for diverse linguistic landscapes.**

Keywords*—*Sentiment analysis; low-resource languages; multilingual, word-embedding, transformer

I. Introduction

In recent years, sentiment analysis has emerged as a pivotal research area in natural language processing [1]. It finds varied applications across various domains, including social media monitoring, customer feedback analysis, market research, and others [2] [3]. Sentiment analysis has been commonly classified into three levels based on various studies [4] [5] [3]. Thus, document-level sentiment classification focuses on discerning the overall sentiment expressed by an author in an opinionated text [6]. Sentence-level analysis, concentrating on individual sentences or arguments within a text. This is particularly valuable in subjectivity classification which assesses whether a sentence conveys an opinion [6] and lastly, the aspect level, is a more complex examination that aims to identify sentiments related to specific aspects of entities [7]. However, given the dynamic nature of social media. Sentence-level sentiment analysis finds particular significance in these platforms. It offers insights into user opinions and emotions on diverse topics. Moreover, X app formerly known as Twitter, has been a dynamic social media platform. It is a platform where users share a wide array of information in real-time [8]. It is considered one of the most vital sources for opinion mining and sentiment analysis [9]. Additionally, the X app contains a widespread multilingual text as individuals express their opinions in tweets spanning different languages, covering a variety of topics [10], [11].

The diversity in languages and cultures among users in the X app is evident in the multilingual nature of tweet texts [12]. This diversity opens up opportunities for businesses, governments, institutions, and other entities to find inferences about their entity for proper decision-making. Consequently, depending solely on sentiment analysis conducted in the English language carries a significant risk of missing crucial insights within written texts [13]. However, the increasing importance of multilingual sentiment analysis goes beyond high language limitations and becomes particularly relevant in low-resource languages.

The concept of low-resource languages encompasses various interpretations, including languages with limited research, facing resource scarcity, lacking computational support, being less commonly taught, or exhibiting low linguistic density [14]. In recent years, there has been a notable increase in the utilization of these languages on social media platforms, with a considerable proportion of users choosing to engage in communication through them [15]. Many languages in Africa and Asia fall into the low-resource category. They remain relatively unexplored in the realm of Natural Language Processing (NLP) research [16]. The underrepresentation of these languages in global economic, social, and political domains can potentially hinder economic and social progress. Nevertheless, advancing technology for low-resource languages can contribute to the increased participation of these language-speaking communities in the digital sphere [17]. Therefore, the abundance of multilingual content online underscores the necessity for sentiment analysis across various low-resource languages and cultures. Similarly, English remains the most extensively studied language [17], [18], [19], [20], [21]. Despite the linguistic diversity present in low-resource languages. The African languages with a substantial population received limited attention. Particularly in the context of sentiment analysis [22]. Low-resource languages pose unique challenges, including scarcity of labelled datasets [23], linguistic diversity, and limited computational resources.

Addressing sentiment analysis in such linguistic contexts necessitates a nuanced exploration of the capabilities and adaptability of transformer models.

The advent of transformer models, exemplified by architectures like BERT [24] (Bidirectional Encoder Representations from Transformers) and GPT (Generative Pre-trained Transformer), has considerably pushed the boundaries of sentiment analysis for diverse languages.

The study aims to enhance the accuracy performance of the current based-line performance on 12 African low-resource language tweets through rigorous hyper-parameter tuning and transformer comparison.

The paper is organized as follows: Section II gives a summary of related studies. Section III explores the proposed methodology for multilingual sentiment analysis within the framework. Section IV details the experiment and hyperparameter tuning. Section V showcases results and facilitates a discussion of the findings. Lastly, Section VI provides conclusions and outlines future directions for work.

II. Related Work

Sentiment analysis classification has different techniques, which are classified into three categories or classes lexicon-based, machine learning-based, and hybrid-based [9], [25], [26], [27], [28]. The machine learning techniques leverage well-known ML algorithms or models to address sentiment analysis. The models treat it as a typical text classification problem that incorporates syntactic and/or linguistic attributes [20]. Additionally, deep learning is a subset of the machine learning techniques [11], [29], based on the artificial neural network [7], [30]. The neural networks offer the most effective solutions for numerous challenges in image and speech recognition. As well as in the domain of natural language processing [31]. In recent years, deep learning models have shown remarkable performance in the field of sentiment analysis [28]. Especially transformer models. They are multilingual pre-trained based on transfer learning approaches that are trained on large various language text data [32], [33]. Moreover, the success of NLP has been primarily ascribed to transformers' capacity for learning broad language representations from enormous volumes of text input. Additionally, they have advanced to become the leading models in understanding and generating language [34] and It apply that knowledge learned to related tasks, producing astounding results [35]. However, prior studies utilized one or more of the above techniques for sentiment classification in one or more languages as:

The study of [13] performed sentiment analysis on English and Hausa tweets using an improved feature acquisition approach. They employed SVM, NB, and Maximum Entropy (MaxEnt) for classification. The experiment indicates that the classification models, when utilizing the aspect set, achieve a modest accuracy of 56% with the SVM classifier. In the case of the pure Hausa dataset SVM yields the best result. Similarly, [36] observed a scarcity of publicly accessible sentiment lexicons for low-resource languages, particularly notable in the Igbo language. In response, they advocated for the development of a comprehensive sentiment lexicon tailored for Igbo, designed to serve as a foundational resource for sentiment analysis in this linguistically underrepresented context. Another work by [37], performs feature learning and categorization using convolutional neural networks (CNN). They demonstrated the model's linguistic independence using the languages of English, French, and Greek with significant accuracy; however, it is highly domain-dependent as with only consists of a restaurant data set. So also, the authors [38], conduct a study that compares monolingual and cross-lingual sentiment analysis approaches utilizing the Hausa-English dataset. They translate most of the data using Google Translate before applying machine models. A similar approach was utilized by [39], the authors investigated the impact of translating from a language with ample resources to one with limited resources on emotion classification. They aim to address the observed gap leading to polarity changes and increase sentiment performance accuracy. Utilizing Google machine translation, they translate an English movie reviews dataset from IMDB into Urdu, Hindi, and German. Deep learning models with randomized parameters are employed and systematically adjusted to optimize results. The experimentation reveals varying accuracies, with English achieving the highest (88.37% via DNN), followed by Hindi (85.99% via Bi-LSTM), and Urdu (80.78%). Another work by [40] proposed a model that is independent of language for multi-class sentiment analysis, employing a straightforward neural network architecture. This is done on GenEval, Deutsche Bahn, and Arabic data sets with topic modelling. Their result shows that the deep neural network model can outperform traditional ML models when evaluated. In a different study presented by [41], find out that, there is a critique of the prevailing practice of constructing language models, particularly in low-resource scenarios. The inquiry revolves around the feasibility of translating data into English as an alternative, facilitating the use of pre-trained, comprehensive English language models. The researchers employ a contemporary machine translation approach to translate data into English that could potentially offer a solution to the challenges in multilingual sentiment analysis. Furthermore, their empirical experiment provides evidence that utilizing current baseline models on a huge scale does not result in a performance decrease, supporting the viability of this translation approach.

The work of [22] tries to bridge a gap of scarcity of data in low-resource language. They generated the inaugural extensive human-annotated Twitter sentiment dataset for four commonly spoken Nigerian languages, namely Hausa, Igbo, Pidgin, and Yoruba. In another research by [42], proposed a novel approach named AgglutiFiT, presenting an efficient fine-tuning strategy for pre-trained language models tailored for sentiment analysis and text classification. The fine-tuning process involves utilizing a low-noise dataset created through morphological analysis and stem extraction. The authors contend that this method excels in selecting pertinent semantic and syntactic information for low-resource languages like Kazakh, Kyrgyz, and Uyghur. Notably, the sentiment analysis task in Kazakh yielded an accuracy of approximately 92.87%. However, in research conducted by [43], analysed sentiment in code-mixed texts from users. They underscore the constrained predictability of conventional machine learning models

compared to deep learning counterparts using LSTM, CNN, and BiLSTM. Utilizing code-mixed data from Hindi-English and Bengali English, the experiment indicated that attention-based models outperformed traditional methods in accuracy by a margin of 20–60%. Additionally, when compared with monolingual English data, the accuracy reached 72.6% on the English monolingual dataset. In the study conducted by [44], the focus is on sentiment analysis of code-mixed Malaysian COVID-19-related news disseminated on Twitter. The researchers compile a multilingual Twitter dataset for COVID-19 encompassing tweets in Malay, English, and Chinese. Employing Byte-Pair Encoding (BPE) as a data compression technique, they apply two deep learning approaches: CNN and mBERT models. Results show that the BPE-M-BERT model exhibits a marginal performance advantage over the CNN model, emphasizing the advantageous adaptability of the pre-trained M-BERT network for a multilingual dataset. The researcher in study [45] investigates transformer fine-tuning methods for Hausa sentiment classification. Three pre-trained transformer multilingual language models, namely Roberta, XLM-R, and mBERT, are employed. The outcomes indicate that the mBERT-base-cased model achieves the best accuracy and F1-score, both reaching 0.73%.

The collective evidence from the diverse studies presented underscores the crucial importance of fine-tuning sentiment analysis models across multiple languages. Each study addresses specific linguistic nuances, cultural contexts, use of traditional ML models, and domain-specific challenges, emphasizing the need for a comprehensive approach to language diversity in sentiment analysis. From the creation of sentiment lexicons for underrepresented languages like Igbo, Hausa, Pidgin, and Yoruba to the exploration of code-switched data and the utilization of models such as XLM-R and mBERT across languages like Kazakh, Kyrgyz, Uyghur, Malay, Indian, and Chinese, these works collectively advocate for a nuanced understanding of sentiment in multilingual settings. Fine-tuning models across various languages allows for a more inclusive and accurate representation of sentiment expressions, reflecting the complex inherent in diverse linguistic structures and cultural contexts.

To address these limitations, the proposed framework emphasizes efficient parameter tuning to enhance model accuracy and performance. By optimizing model parameters, such as learning rates, batch sizes, and regularization techniques, the proposed framework aims to mitigate the shortcomings encountered in previous studies. Efficient parameter tuning enables the models to better capture the nuances of different languages and domains, thereby improving their overall effectiveness in sentiment analysis tasks. Table I present the summary of the related literature.

TABLE I. SUMMARY OF THE RELATED WORK

Study	Models/method	Language	limitation
[13]	SVM, MaxEn and NB	Hausa and English	Uses only traditional ML and the accuracy is below the benchmarking.
[36]	Manual data anotation	Igbo	Limited to Copus creation
[37]	CNN	English, French, and Greek	It highly domain dependent as with only consist of restaurant data set
[38]	NB, LSTM,BiLSTM, BERT, and Roberta.	Hausa	Depend on Google translator and domain specific
[39]	DNN, LSTM, Bi-LSTM and Conv1D	Urdu, Hindi, and German	Domain specific data, the model cannot be generalize to the domain.
[40]	ANN	Deutsche Bahn, and Arabic	The work is domain specific which rally on product data set
[22]	mBERT, Roberta,remBerta, XLR-R, and AfriBerta	Hausa, Igob, Yaruba, and Pidgen	Corpus creation for research progress and based-line evaluation. Need accuracy improvement
[41]	BERT, XLM-R	Scandinavian, Swedish, Norwegian Danish, Finnish	Depend on Machine translation which may not always be accurate.
[42]	XLM-R	Kazakh, Kyrgyz, and Uyghur	Different models may be explore for better performance.
[43]	BiLSTM, CNN, BERT	Hindi and Bengali	Different transformer models may be explore for evaluation.
[44]	CNN and mBERT	Malay, Indian, Chinese	Different transformer models may be explore for evaluation.
[45]	mBERT, Roberta and XLM-r	Hausa-English	Fine tuning specific to Hausa. It may not be generalize to other low resource language

III. METHODOLOGY

In this section, we provide an overview of the methodology framework for conducting sentiment analysis on tweets in low-resource multilingual settings. The pursuit of a better sentiment analysis framework tailored for multiple African languages tweets. This work adopts a distinctive approach that merges the strengths of transformer models through hyperparameter tuning. Specifically, use mBERT, Roberta, XLM-R, and AfriBERT from transformers. These models leverage the abundant semantic information present in tweets, offering a fundamental comprehension of word relationships through pre-trained embeddings. This approach facilitates the fine-tuning of models, thereby improving their adaptability to the distinctive linguistic nuances across various languages.

The core of our methodology involves the tweet datasets undergoing tokenization, feature detection, feature with model presentation, fine-tuning, training, and validating. To anticipate significant differences between these models, we conduct a rigorous statistical experiment. The decision-making process leads to the evaluation of model outputs using carefully chosen metrics. Fig. 1 serves as a visual guide, illustrating the proposed framework.

Through this framework, the objective is to contribute to a nuanced comprehension of sentiment in low-resource

languages and improve sentiment analysis accuracy. The development process of the sentiment classification models involves several distinct steps, commencing with the data description.

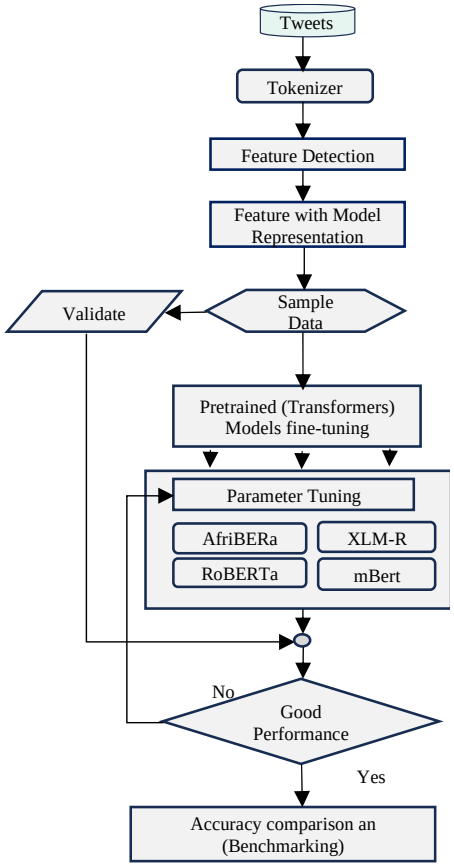

Fig. 1. Methodology framework workflow.

A. Multilingual Dataset

This stud utilized the Tweet data obtained from [46]. The data collection encompasses 12 distinct African languages, each characterized by unique linguistic features, writing systems, and language families, as outlined in Table II with their respective class label distribution. Spanning from Algerian Arabic, Moroccan Arabic/Darija, Hausa, Yoruba, Igbo, Nigerian Pidgin, Amharic, Swahili, Kinyarwanda, Twi, Mozambican Portuguese, and Xitsonga. The language and the class label distribution of the tweets are illustrated in Table II.

TABLE II. LANGUAGES AND THEIR RESPECTIVE CLASS DISTRIBUTION OF THE DATASETS

Language	Class label (distribution)		
	Positive	Neutral	Negative
Hausa	4687	4912	4573
Amharic	1332	3104	1548
Algerian Arabic	417	342	892
Darija Moroccan Arabic	1758	2161	1664
Swahili	1072	191	547
Yoruba	3542	3108	1872
Igbo	3084	4508	2600
Nigerian Pidgin	1808	72	3241
Xitsonga	384	136	284
Kinyarwanda	899	1257	1146
Twi	1644	522	1315
Mozambican Portuguese	681	1600	782

The datasets are provided as open-source resources explicitly crafted for research purposes, and they come pre-labelled. However, the training data comprises 63,685 instances of tweets, with 20,783 instances categorized as Positive, 20,108 as Negative, and 22,794 as Neutral. This distribution illustrates a fairly even representation of the three sentiment categories, reducing the potential for biased predictions towards any particular label. Fig. 2 provides a visual representation of the dataset distribution for additional reference. These datasets are subsequently employed to train feature detection and representation.

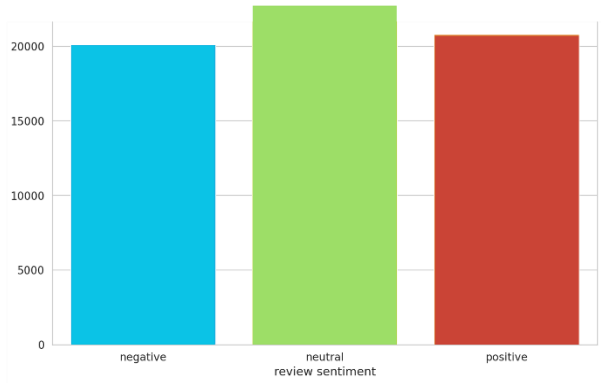

Fig. 2. Tweet class distribution.

B. Feature Detection

During the feature detection and extraction stage, textual data transforms into numerical form through tokenization. The Word Piece tokenizer is utilized in this procedure, fragmenting unfamiliar vocabulary words into sub-words, and consequently minimizing the occurrence of out-of-vocabulary words. This is accomplished through a greedy algorithm that prioritizes the longest possible match, thereby improving text-processing capabilities for transformers. Considering a tweet composed of N words, denoted as $T = \{w_1, w_2, w_3 \dots w_n\}$, each word w_i is processed and transformed into a numerical vector represented as e_i. Concurrently, the designated class y is converted into its vector, denoted as v_a.

$$e_i = E(w_i) \quad (1)$$

$$v_a = E(y) \quad (2)$$

The initialization of context embedding vectors, e_i, and class vectors, v_a, is described by Eq. (1) and Eq. (2). Eq. (1) denotes the transformation of each word, w_i, into a numerical vector, e_i, while Eq. (2) represents the conversion of class y into its vector v_a. In these equations, $E \in \mathbb{R}^{v \times d}$ denotes the embeddings, where d represents the dimension of the word embedding vectors. The vocabulary size is denoted as v, and N

represents the number of words in the tweet. Subsequently, the input vectors are passed into the transformers for fine-tuning.

C. Fine-turning

The fine-tuning process begins with the mBERT model transformer for sentiment classification, incorporating its pre-trained weights. Tokenized input sequences are enriched with a special classification token ([CLS]) at the beginning and a separation token ([SEP]) at the end. Token embeddings for each sub-word are generated using the embedding matrix and are combined with segment embeddings to differentiate between tokens from the first and second sentences. Position embeddings are employed to denote the position of each token in the input sequence. The BERT input representation, consisting of token embeddings, segment embeddings, and position embeddings, is then inputted into a SoftMax layer for classification aggregation. Fig. 3 depicts the visual representation of transformer architecture for the classification task.

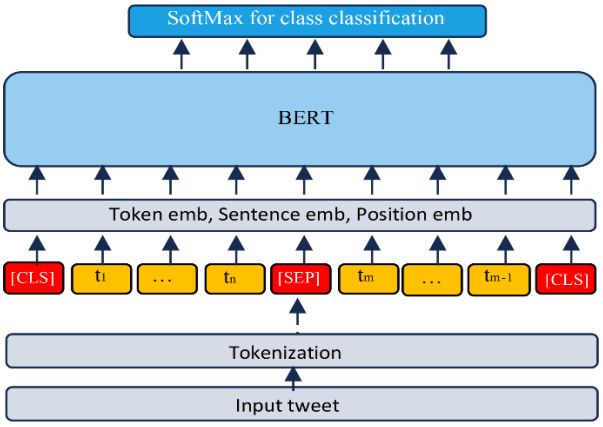

Fig. 3. Transformer model for classification.

Similarly, in the case of the Roberta model, we followed the same comparable fine-tuning approach, customizing the pre-trained weights specifically for sentiment analysis in low-resource contexts. The tokenization procedure, utilizing the Transformer tokenizer, and the creation of the input representation, which includes token embeddings, segment embeddings, and position embeddings, remained consistent with the models described earlier. In the end, a SoftMax layer was utilized for sentiment classification.

In addition to mBERT and Roberta, we included the XLM-R and afriBERTa models in the framework. These models adhered to a comparable methodology as the pre-trained mBERT models. The tokenized input sequences were converted into the input representation, which included token embeddings, segment embeddings, and position embeddings. Following this, the input representation underwent processing through a SoftMax layer for sentiment classification. The components of the model play a crucial role in the effective representation of language by transformers [24].

Furthermore, the models often require fixed-length input sequences for effective processing, a concept known as padding. The special token used for padding in transformers is generally the [PAD] token, which is inserted into the input sequence to fill the remaining empty spaces until the sequence reaches the desired fixed length. Additionally, any unknown token is represented as [UNK]. Tokens from the first sentence are assigned the label "0," while those from the second sentence are labelled "1". Position embeddings indicate the position of each token in the input sequence.

The selection of the aforementioned models was influenced by their proficiency in multilingualism, as discussed in the work by [47]. They are encompassed with some African languages. These chosen pre-trained language models were specifically designed to tackle this challenge and have demonstrated strong performance in multilingual settings, as highlighted by [48]. Given their robust nature, various hyperparameter combinations were employed to optimize their effectiveness in comprehending the complexities of different languages.

D. Hyperparameter Tuning

To determine optimal parameters, a series of experiments were conducted, employing different batch sizes, and assessing the performance of mBERT on a validation set. Table III provides a detailed presentation of results obtained from hyperparameter tuning. These values play a crucial role in the model optimization process. Each row in the table represents a unique combination of learning rates and batch sizes, depicting the mBERT model's performance in relation to the F1-score.

TABLE III. HYPERPARAMETER COMBINATION AND PERFORMANCE

Parameter						
	Learning rate	Batch size				Metric
sn		8	16	32	64	
1	5e-5	0.32	0.43	0.48	0.38	F1-score
2	3e-5	0.31	0.52	0.60	0.41	F1-score
3	2e-5	0.51	0.53	0.58	0.54	F1-score
5	1e-6	0.58	0.56	0.62	0.60	F1-score

The chosen hyperparameter values were systematically selected to assess their influence on the sentiment analysis tasks. Striving to pinpoint combinations that achieve an ideal equilibrium between model convergence and computational efficiency. The primary objective was to finds a configuration that strike a favorable equilibrium for the task. A detailed analysis of the table exposes discernible patterns. Particularly in terms of F1-score variations across different learning rates and batch sizes. The experiments were carefully carried out to measure the influence of hyperparameter selections on the overall performance of the model. Remarkably, it was observed that employing a learning rate of 1e-6 in conjunction with a batch size of 32 yielded the highest f1-score. This finding validated the model's ability to find a balance between efficient computation and robust model convergence. Subsequently, these values were adopted for the remaining experiments involving other models in the study. The moderate batch size has an advantage over the smaller batch which exhibits more variability in their performance as in the f1-score validation in Table III. On the other hand, a bigger batch size led to slower convergence of the training process which caused the model to overfit on the validation data. Therefore, utilizing moderate batch sizes offers several advantages, including

enhanced memory efficiency, accelerated convergence, and improved regularization effects by introducing sufficient noise to mitigate overfitting. Additionally, training with moderate batch sizes is observed to contribute to heightened stability in selecting an optimal learning rate as in Table III.

The selection of the maximum sequence length parameter is set at 150. As a result of an analysis of the tweet distribution within the datasets. This choice was made precisely to minimize the requirement for unnecessary padding during the training. This aims to capture the primary concepts conveyed in the tweets effectively. Fig. 4 visually depicts the maximum token length observed in tweets, illustrating the determined maximum sequence length for better context. The choice of a learning rate of 1e-6 was arrived at after a comprehensive examination of diverse parameter combinations throughout the training process, as outlined in Table III. This is a lower learning rate. A lower learning rate has demonstrated effectiveness across multiple Natural Language Processing. (NLP) tasks. Additionally, a systematic dropout tuning process was conducted, exploring a range of dropout rates from 0.5 to 0.3. This iterative experimentation aimed to pinpoint the dropout rate that strikes the best balance between mitigating overfitting and enhancing model generalization.

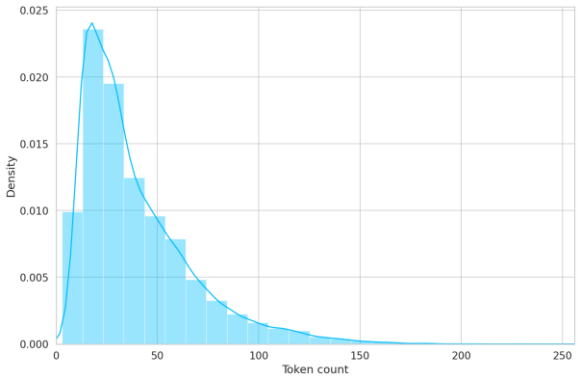

Fig. 4. Tweets token maximum sequence length.

Through this process, it was observed that a dropout rate of 0.3 consistently resulted in improved accuracy in this task compared to higher dropout rates. This careful tuning ensures that the chosen value aligns with best practices and is empirically grounded in its positive impact on model performance. For optimization, the widely employed Adam optimizer was utilized, known for its efficiency and effectiveness in training deep learning models. The same set of hyperparameter values was consistently applied across other models, as depicted in Table IV, outlining the chosen hyperparameters.

TABLE IV. HYPERPARAMETER USED

Sn	*Parameter*	*Value*
1	Max Sequence length	150
2	Batch size	32
3	Learning rate	1e-6
4	Optimizer	Adam
5	Dropout	0.3

IV. EXPERIMENT

This research explores the utilization of transformers' fine-tuning techniques for sentiment classification tasks in multilingual tweets. Specifically, it delves into the application of the Roberta, XLM-R, mBERT, and AfriBERT models in this context.

A. System Implementation

This research conducted experiments using the Python programming language, TensorFlow version 1.13.1, and the torch library version 2.0.1+cu118 for multilabel classification. The implementation took place on Google Collaboratory, utilizing a GPU hardware accelerator to enhance computational efficiency. Various tools, including NumPy, Pandas, sci-kit-learn, transformers, and seaborn libraries, among others, were employed to facilitate the analysis of tweets. The obtained results highlight the effectiveness of the implemented framework and emphasize the importance of adapting the code to specific requirements. The experiment notebook is accessible at: https://github.com/yusuf-003/Multilingual_experiment

B. Data Description

In this study, a dataset consisting of 63,685 tweets in 12 low-resource African languages was utilized. The dataset comprises three columns: id, tweet, and labels. The class labels are multiclass categorical data named as positive, negative, and neutral. To prepare the data for machine learning algorithms, the class labels were converted to numerical data using a dictionary-based class mapping function. This preprocessing step was conducted before feeding the data into the machine learning algorithm. Table V provides a sample of the dataset. The datasets are available at https://github.com/afrisenti-semeval/afrisent-semeval-2023/tree/main/SubtaskB

TABLE V. TWEETS SAMPLE

The dataset was randomly partitioned into three subsets for training purposes. These subsets were designated as train, validation, and test sets. 90% of the data was allocated for training, amounting to a finalized set of 57,316 tweets, while the validation set for 5% accounted for 3184. Lastly, 5% was separated for testing, resulting in 3185 tweets data. The importance of splitting the data into three parts is that it allows for a more robust evaluation of the model. The models were trained on the training data, and their performance are evaluated on the validation set. The hyperparameters of the model are tuned based on the performance of the validation set. Finally, the model was evaluated on the test set to estimate its performance on unseen data. Splitting the data into three parts helps to avoid overfitting and to have a better estimate of the model's generalization performance. The models are evaluated using the standard machine learning evaluation metric.

C. Evaluation Metric

Evaluation metrics are crucial instruments for assessing the performance of machine learning models. Through comparison of the predicted outcomes to actual results. Higher scores indicate superior predictive capabilities. It is a guiding parameter optimization for optimal performance during the tuning phase. Understanding the fundamental definition of metrics is crucial for alignment with system goals. Inaccurate evaluation using diverse metrics can lead to challenges in deploying systems on unobserved datasets. This may result in suboptimal predictions. The emphasis of this study is on Natural Language Processing metrics, which encompass precision, recall, F1-Score, and Accuracy. These metrics are derived from the confusion matrix, incorporating elements like true positives (TP), false positives (FP), true negatives (TN), and false negatives (FN) values.

1) Accuracy metric: To Accuracy is a metric that measures the frequency of correct sentiment ratings. The goal of accuracy testing is to showcase the efficiency of the suggested framework in predicting data. The accuracy formula is given as in Eq. (3):

$$Accuracy = \frac{TP+TN}{TP+FP+FN+TN} \quad (3)$$

2) Recall metric: Recall, essentially, assesses the outcome by determining how many of the genuinely relevant results are retrieved. The goal of recall testing is to appraise the proposed framework's ability to appropriately recall correctly classified data. The recall formula is given as in Eq. (4):

$$Recall = \frac{TP}{TP+FN} \quad (4)$$

3) Precision metric: Precision signifies the precision of the proposed framework in forecasting the accurate class for a particular tweet. This aspect underscores the model's capability to minimize false positives and ensure the correctness of predicted values corresponding to the designated class. Eq. (5) provides the formula:

$$Precision = \frac{TP}{TP+FP} \quad (5)$$

4) F1-score metric: The f1-score represents the interplay between precision and recall, and it is inversely proportional to strike a balance between the two. Additionally, the f1 score serves as a harmonic mean [39]. It effectively mitigates the imbalance between precision and recall in the evaluation of a model's performance. The formula is given as in Eq. (6):

$$F1 - score = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (6)$$

V. Result and Discussion

This section reveals the results of the experiment. It is rigorously analyzed, and thoughtfully presented. It involves a thorough investigation of the evaluation results, comparative metrics and conclusions drawn from the study. The comparison of performance evolution is grounded in results obtained from training and testing the unseen data. Initially, the training epoch is set at a maximum of 20 epochs. The experiment delves into various transformers, including mBERT, RoBERTa, XLM-R, and AfrBERTa.

A. Performance Evaluation

The effective evaluation of the proposed method in classifying tweets test data into sentiment categories: Positive, Negative, and Neutral. It encompassed several key models of varying multilingualism complexities. Table VI illustrates the results obtained from the experiment.

TABLE VI. Sentiment Analysis Model Performance Comparison and Evaluation Performance

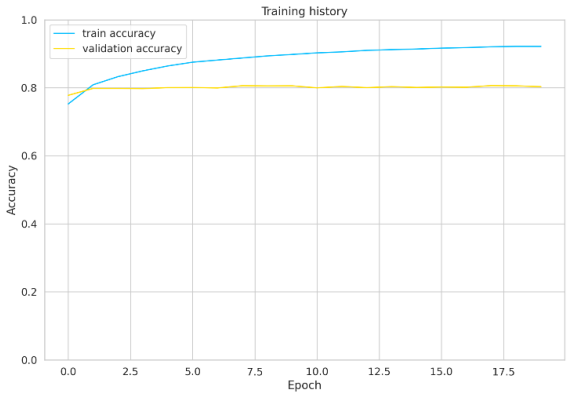
Model	Evaluation Metric			
	Accuracy	***Recall$_{ma}$***	***Precision$_{ma}$***	***F1-score***
mBERT	0.6229	0.62	0.63	0.62
RoBERTa	0.6556	0.75	0.75	**0.74**
XLM-R	0.6411	0.64	0.64	0.64
AfriBERTa	0.8088	0.81	0.81	**0.81***

The results of the experiment in Table VI offer a comprehensive insight into the performance of multilingual sentiment analysis models. The experiment was done across a diverse range of low-resource African languages. The evaluation metric. Thus accuracy, recall (macro-average), precision (macro-average), and F1-score offer a nuanced comprehension of the capabilities and constraints of each model.

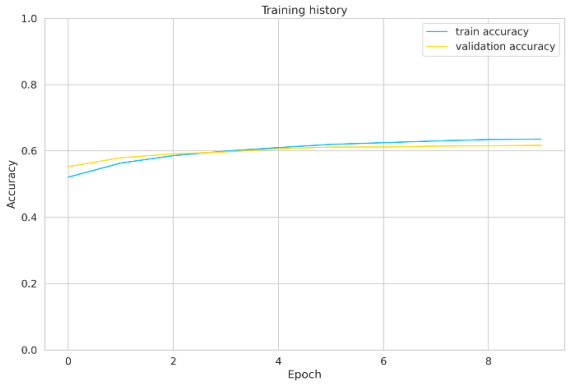
AfriBERTa stands out as the most effective model, achieving an impressive accuracy of 0.8088 and a balanced F1-score of 0.81. The model's specialization for African languages, coupled with fine-tuning on a diverse linguistic dataset, appears to be a key factor in its superior performance. This allows AfriBERTa to capture complex linguistic patterns and cultural context, essential for accurate sentiment analysis in this context. RoBERTa demonstrates commendable performance, securing the second-highest accuracy (0.6556) and a competitive F1-score of 0.74. Its general-purpose nature enables adaptability across different languages, outperforming mBERT and XLM-R. Although RoBERTa doesn't surpass AfriBERTa, recall and precision values of 0.75 indicate robustness, albeit slightly below the specialized model.

The decision to fine-tune models across multiple languages proves advantageous, particularly evident in the success of AfriBERTa. This approach enhances the model's robustness, allowing it to effectively handle the linguistic diversity present in African tweets. The contrast in performance metrics underlines the importance of considering regional linguistic variations when developing sentiment analysis models. AfriBERTa not only achieves high accuracy but also strikes a balance between precision and recall. A precision of 0.81 indicates that when AfriBERTa predicts a sentiment, it is highly likely to be correct. Simultaneously, a recall of 0.81 suggests the model captures a substantial portion of positive, negative, and neutral sentiments, crucial for an understanding of sentiment distribution.

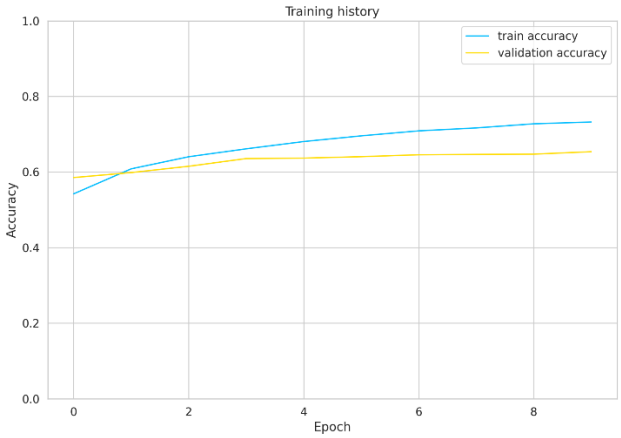
Fig. 5 illustrates the graphical representations of the model's train and validation accuracy curve of the experiment. However, the models' curves, indicate a steady improvement in accuracy as training progresses. This suggests that all the models effectively learned from the data. Moreover, an observation is the noticeable difference between the accuracy scores on the training and validation datasets, especially in the first to third training epoch in Fig. 5(a) and Fig. 5(c). This discrepancy implies the possibility of overfitting in the Afribarta and Robarta models, where the model may be overly tailored to the training data. This may be course due to variations in data distribution across languages. Although, the Afriberta model in Fig. 5(a), exhibits substantial overfitting despite its effectiveness in performance. While Fig. 5(b) mBart and Fig. 5(d) XLM-r control, this issue suggests that its pretraining on a diverse dataset might have played a crucial role in enhancing its ability to generalize effectively.



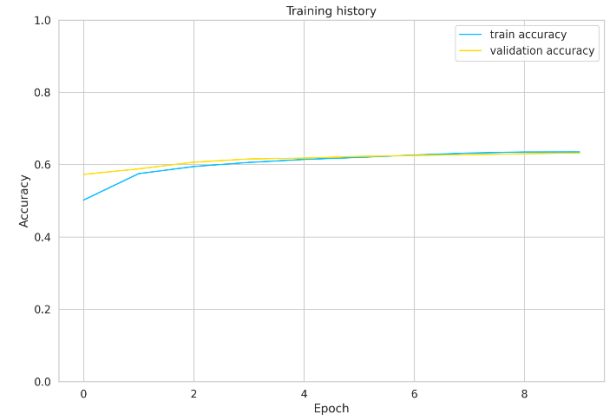
(a)



(b)



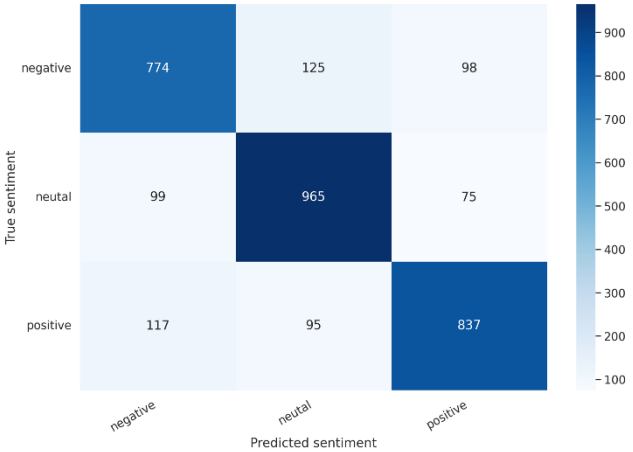
(c)



(d)

Fig. 5. (a) AfriBerta. (b) mBert. (c) Roberta. (d) XLM-r.

Similarly, Fig. 6 illustrates the confusion matrices, depicting correct and incorrect predictions by the models. Thus, a noticeable disparity is observed, with the Fig. 6(b) mBart, Fig. 6(c) RoBERTa, and Fig. 6(d) XLM-r exhibiting a higher rate of misclassifications compared to Fig. 6(a) Afriberta, which demonstrates a small number of incorrect predictions. Afriberta displays exceptional performance in accurately classifying each distinct category.



(a)

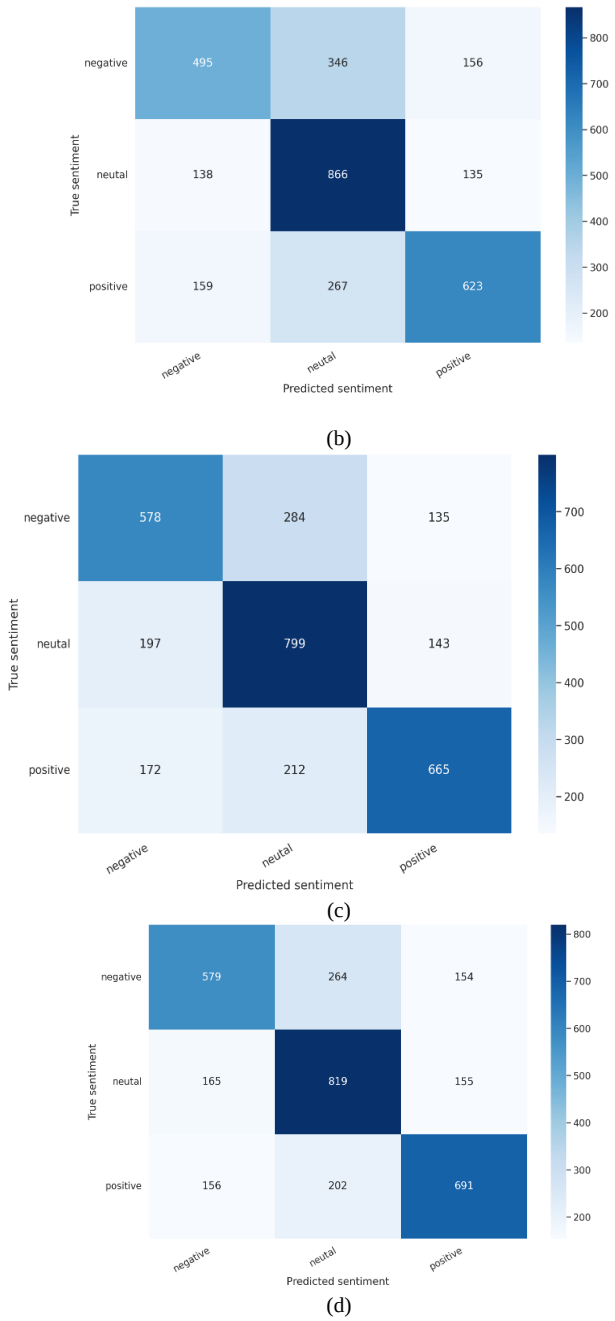


Fig. 6. (a) Afriberta. (b) mBert. (c) Robarta, (d) XLM-r.

B. Error analysis Evaluation

The training and validation metrics presented in Table VII provide a detailed view of the performance of each model during the training process.

TABLE VII. : SENTIMENT ANALYSIS MODEL PERFORMANCE COMPARISON AND EVALUATION PERFORMANCE

Model	Training metric			
	$Training_{loss}$	*Acc*	$Validation_{loss}$	*Acc*
mBERT	0.9037	0.6354	0.9189	0.6165
RoBERTa	0.8137	0.7322	0.8907	0.6536
XLM-R	0.9023	0.6349	0.9078	0.6319
AfriBERTa	0.6619	0.8874	0.7429	0.8059

Analyzing the values offers insights into potential sources of errors and the model's capacity to generalize to unfamiliar data. mBERT and XLM-r, relatively shows low training loss and exhibit a noticeable drop in accuracy during validation. The validation accuracy suggests that the model struggles to generalize to new data, possibly due to an excessive focus on training data specifics.

AfriBerta and RoBERTa demonstrate a more balanced performance with training and validation accuracy. The Roberta model exhibits a slightly higher training loss (0.8137), suggesting a degree of complexity in the learned representations. The marginal decrease in accuracy during validation might be attributed to the model's challenge in capturing subtle patterns in the validation set. The AfriBERTa exhibits impressive training accuracy (0.8874) and validation accuracy (0.8059), indicating robust learning and generalization capabilities. The comparatively low training loss (0.6619) further supports the model's capability to identify complex patterns within the data. AfriBERTa's performance suggests effective fine-tuning across multiple languages. It contributing to its superior performance in sentiment analysis as observed in the earlier sections. Fig. 7 illustrates the visual model train/accuracy and loss comparison.

C. State-of-the-art Benchmarking

To evaluate the efficiency of the proposed framework, a comprehensive evaluation was undertaken, where in the performance was compared against the best-reported results within the realm of sentiment analysis for low-resource languages. Notably, the framework demonstrates superior performance across multiple benchmarks, surpassing models that currently lead in the domain.

In the SemEval-2023 Task 12: Sentiment Analysis for African Language [46] a renowned competition in the field, the best-reported F1-score for multilingual task was 75.06%. Remarkably, the proposed framework surpasses this benchmark, achieving an impressive F1 score of 80.6%, showcasing its robustness in capturing sentiment in multilingual tweets.

Furthermore, the framework was compared against the AfriSenti benchmark [49]. A Twitter Sentiment Analysis benchmark for African Languages, where the reported best F1 score stands at 71.2%. In comparison, the framework exceeds this benchmark, highlighting its ability to handle the complexities of sentiment analysis in a multilingual context.

The model also outperforms NaijaSenti [22], a Nigerian Twitter Sentiment Corpus, including four languages in our training data. It achieved an average F1-score of 78.3%. The robustness of the framework is further emphasized by its ability to surpass these benchmarks, achieving an outstanding F1 score of 80.6%.

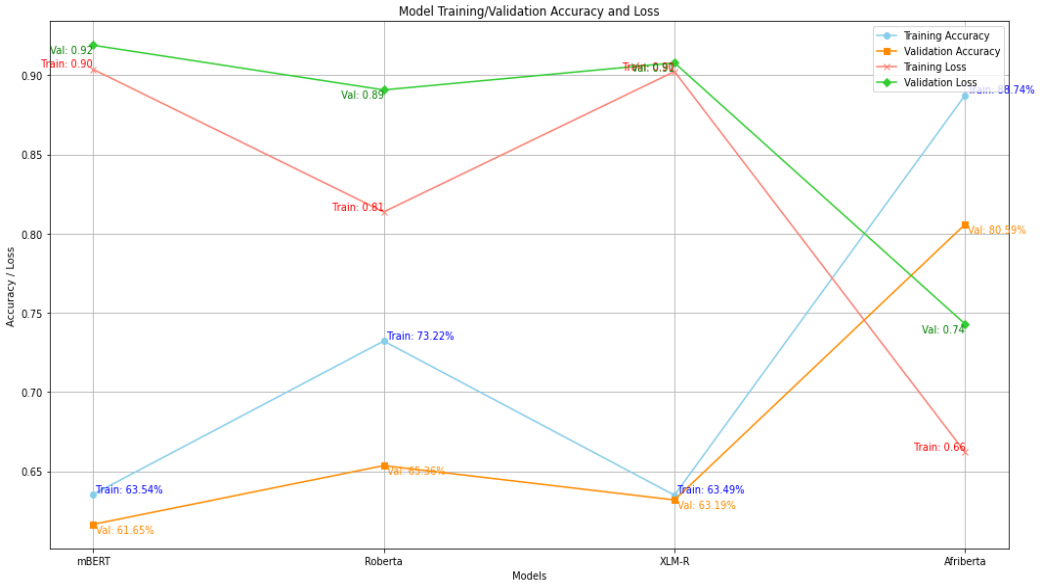

Fig. 7. Training / validation accuracy and loss (learning curve).

Table VIII provides a comprehensive comparison of the performance metrics benchmarking. It further illustrates the superiority of the proposed framework. These results signify the effectiveness framework. It demonstrated improvements over existing benchmarks underscore the novel contributions and practical utility of the framework through parameter tuning in low-resource language sentiment analysis.

TABLE VIII. PERFORMANCE BENCHMARKING COMPARISON

Reference	***F1-score***
[46]	75.1%.
[49]	71.2%.
[22]	78.3%
Ours	**80.6%**

VI. CONCLUSION AND FUTURE WORK

In conclusion, our comprehensive analysis of multilingual sentiment analysis models across a range of low-resource African languages provides valuable insights into their strengths and limitations. While AfriBERTa emerges as a robust performer, demonstrating effectiveness in capturing sentiment complexity the evaluation of mBERT, RoBERTa, and XLM-R reveals nuances in their training and validation metrics.

Despite the effective performance of the framework, a notable concern is the presence of overfitting. Most especially in on the AfriBerta suggests a need for addressing overfitting issues. To mitigate this, future work will incorporate data augmentation techniques during training, striving to improve the model's generalization to new data and enhance its performance on validation sets.

Furthermore, the study aims to expand its language coverage by experimenting with additional languages. While our current framework focuses on a diverse set of African languages, the inclusion of more languages will contribute to a more comprehensive understanding of the model's adaptability across different linguistic contexts. This expansion will involve fine-tuning the models on datasets specific to the additional languages, ensuring broader applicability of the sentiment analysis framework.

It is essential to acknowledge certain limitations in our study. One notable challenge is the prevalence of code-mixing in the tweets, where phrases of the English language are inserted within a single sentence or tweet. This linguistic phenomenon can impact the model's performance, and as such, future work will delve into addressing code-mixing challenges. Strategies such as incorporating code-switching-aware models or developing methods to handle mixed-language expressions will be explored to enhance the framework's efficacy.

The study provides valuable insights, but inherent challenges such as varying data quality across languages and potential overfitting in the training data must be acknowledged. Future research should address these limitations, explore additional low-resource languages, and enhance model interpretability. In conclusion, our comparative analysis adds to the expanding body of knowledge on sentiment analysis in low-resource languages, emphasizing the importance of linguistic diversity for model development in the African context.

ACKNOWLEDGMENT

We express our sincere appreciation to PTDF (Petroleum Technology Development Fund for their invaluable support in financing the scholarship. Additionally, we would like to appreciate the support received from the Universiti Teknologi PETRONAS (UTP) research grant: YUTP-FRG (015L0-312). Their involvement, financial assistance, and contributions to knowledge have played a pivotal role in facilitating the dissemination of our research findings, fostering engagement with emerging developments, and establishing meaningful professional connections within our field. We deeply value the investment made in our academic and practical development.

Influence of a Serious Video Game on the Behavior of Drivers in the Face of Automobile Incidents

Bryan S. Diaz-Sipiran, Segundo E. Cieza-Mostacero
Research Group Trend and Innovation in Systems Engineering -Trujillo, Cesar Vallejo University, Perú

***Abstract*—The primary objective of this research was to enhance driver behavior during incidents through the use of a serious video game. The study employed a true experimental design. The research population consisted of an unspecified number of drivers from the city of Trujillo. Sixty drivers from Trujillo were randomly selected, with 30 assigned to the control group and 30 to the experimental group. The experimental group utilized a video game developed in Unreal Engine 5.2.1., observation forms were used to gather information, and the collected data were subsequently analyzed and processed using the statistical software Jamovi v2.4.11. The results revealed a decrease equivalent to a 43.75% reduction in the number of action mistakes, a 51.14% reduction in the number of intention mistakes, a 31.4% decrease in the number of traffic law violations, and a 42.92% reduction in the number of aggressive attitudes. In conclusion, the use of a serious video game significantly improved driver behavior during incidents.**

***Keywords*—Videogame; serious; behavior; driving; incidents**

I. Introduction

Mobility is an essential need for human beings, which requires transportation systems to make it possible. The arrival of the pandemic presented new and additional challenges in addition to existing ones, for example, inappropriate driver behavior. Since December 31, 2019, when the first case of COVID-19 was reported in Wuhan, the world has fought against the spread of this disease, which reached Latin America and the Caribbean at the end of February 2020. Since then and until 2023, the governments of the region have taken various measures that have directly or indirectly affected mobility and its characteristics [1].

The World Health Organization [2] stated that worldwide, road traffic accidents caused almost 1.3 million preventable deaths and an estimated 50 million injuries per year. Similarly, the Andean Community (2020) mentioned that, in 2020, the number of road traffic accidents in the community constituted by Bolivia, Colombia, Ecuador and Peru decreased by 32.3% compared to 2019, from 328,418 to 222,340. It also mentioned that, in Peru, traffic accidents decreased by 40.2% compared to 2019, going from 95 800 to 57 335.

In addition, the Road Safety Directorate [3] indicated that in the last four years, a total of 12079 traffic accidents were registered in the province of Trujillo, which generated 137 deaths and 13961 injuries. During that period, the accident rate was increasing, in contrast to 2020, where a decrease of 50.6% was observed compared to 2019. It is important to note that although the COVID-19 pandemic contributed to the decrease in traffic accidents in 2020, the trend in the province of Trujillo has been increasing in recent years, which requires more effective measures to improve road safety and driver behavior. The measure that was proposed is a serious video game.

Video games have become a very useful tool due to their capacity to provide interactive content and to transmit audiovisuals in real time, and their global interactivity capacity allows them to be used in various fields, such as education, medicine, advertising, collective communication and art, among others. In Latin America, Mexico and Brazil were the main generators of video game revenues, while Peru ranked sixth in the list with a figure of US$152 million [4].

A serious video game is distinguished from entertainment games, because its main purpose is educational or informative. These games have a great influence on the way players interact cognitively, emotionally and socially, which increases their motivation and commitment. Gamification of an environment can encourage people to engage in tasks that might otherwise seem repetitive, to experience failure, and to try again despite the risk. Furthermore, in the workplace, the incorporation of serious games can provide many benefits for companies, such as improved employee retention and recruitment, increased program adoption, and better overall job performance [5]. Given the aforementioned arguments, the following general research question was asked: How did the use of a serious video game improve drivers' incident behavior in Trujillo, 2023?

The theoretical justification for this research is based on [6] who mentioned that serious games are simulated representations of reality, in which a fictitious scenario is constructed based on real problems. Since it is a game environment, there is the ability to adjust variables and explore different scenarios without causing any harm in real life. And in study [7] who stated that safe driving involves carefully examining the visual environment in order to identify and differentiate relevant stimuli for smooth performance.

The methodology used in this research was justified for several reasons. Random sampling made it possible to obtain a representative sample of drivers in the city of Trujillo, which guaranteed generalizable and applicable results in broader contexts. The use of observation cards captured drivers' behavior in real time while driving, providing objective information on the indicators, number of action errors, number of intention errors, number of traffic law violations, and number of aggressive actions. In addition, the face-to-face evaluation during actual driving ensures greater ecological validity when confronted with real-life situations.

This research was relevant in practice, since it sought to address an important problem in road safety. The development of the serious video game aimed to improve the behavior of drivers in the city of Trujillo and contribute to the reduction of accidents and reckless behaviors on the roads. The implementation of experimental and control groups allowed us to rigorously evaluate the effectiveness of the video game in modifying the behavior of drivers. These results were useful in designing interventions and training programs aimed at improving road safety and reducing driving risks.

The research on improving driver behavior in Trujillo through a serious video game was socially relevant. Since road safety is a major concern, and it is essential to implement effective strategies to encourage responsible driving behaviors, the proposed video game has the potential to educate drivers and raise awareness about the consequences of their actions behind the wheel, promoting safer behaviors. This can have a positive impact on reducing accidents, injuries and human losses, improving the quality of life in the Trujillo driving community.

Therefore, the research "Serious video game to improve the behavior of drivers in the event of incidents in Trujillo, 2023" was undertaken. The main objective was to improve the behavior of drivers in the event of incidents through the use of a serious video game in Trujillo in 2023, with the specific objectives of reducing the number of action errors, reducing the number of intention errors, reducing the number of traffic law violations, and reducing the number of aggressive attitudes.

The main hypothesis was: if a serious video game was used, then the behavior of drivers in Trujillo in the year 2023 would be significantly improved; and the specific hypotheses were: if a serious video game was used, then the number of action errors in Trujillo in the year 2023 would be decreased, if a serious video game was used, then the number of action errors in Trujillo in the year 2023 would be decreased; then the number of intention errors decreased in Trujillo in the year 2023, if a serious video game was used; then the number of traffic law violations decreased in Trujillo in the year 2023 and if a serious video game was used; then the number of aggressive attitudes decreased in Trujillo in 2023.

II. Related Work

As background, the research [8] titled "The impact of gamification and serious games on driving under unknown traffic rules", aimed to evaluate the impact of gamification elements in driving simulators on road safety in unknown traffic situations. A quantitative and qualitative experimental approach was used, with a sample of 14 people. The results showed that, when driving without a gamification element, there were 13 cases of driving against the flow of traffic and 15 cases of misuse of the signal indicator. However, when driving with the gamification element, these errors were reduced to 1 case of driving against the flow of traffic and 6 cases of signal indicator misuse. In conclusion, serious games and gamification were effective in decreasing driving errors in unfamiliar traffic situations.

III. Theoretical Framework

A. Serious Video Game

Type of game designed for a purpose other than simple entertainment; their focus is usually educational or goal-oriented. The serious ones share similarities with simulation genres, since they seek to offer more realistic representations and provide teachings about real-life situations [9].

In addition, the serious game incorporates, in this way, a specific purpose that transcends mere entertainment, and this objective may be related to education, the generation of changes in attitude, the development of new competencies or skills in the player in a specific context, among other things History, Geography, Mathematics or the understanding of social issues. What is essential is that, at the end of the experience, the player has acquired a new knowledge, skill or attitude that he or she did not have before [10].

B. Driver Behavior

The analysis of human behavior in driving is essential to achieve a deeper understanding of the traffic phenomenon, since it is people who make crucial decisions, among them the choice of route, type of vehicle, vehicle maintenance, and traffic regulations, besides being the direct performers of actions when driving a vehicle in different situations. The human factor involves several aspects of the human psyche, considering the relevance of each one of them in the performance as drivers. Although the observable manifestations are usually gestural, movement or linguistic, their cause is due to the complex interaction of multiple factors, among them psychophysical, emotional and cognitive aspects, which complicates the study of the roots of human driving behavior [11].

C. SUM Methodology

The SUM methodology is a derivative of SCRUM, taking advantage of the popularity of agile methodologies, especially in contexts of fast, precise and optimized programming, as is the case of video game development. Its central purpose is to achieve efficient and cost-effective development of high-quality software, with a constant focus on continuous process improvement to optimize its efficiency and effectiveness [12].

IV. Material and Methods

A. Research Typology

Applied: The essence of applied methodology is problem-solving, focus on applying specialized knowledge from one or several areas to specific contexts. Its primary goal is to provide practical solutions to specific needs in social or productive fields. This methodology is centered on identifying and resolving a particular problem or question, dedicating itself to the research and consolidation of knowledge for practical application [13].

B. Research Design

Pure experimental, the key feature is evaluating the effects of an intervention, whether preventive or corrective. This involves carefully selecting a group of individuals and obtaining their prior consent. Participants are then randomly divided into two or more groups, including control and

experimental groups. This design is fundamental in understanding the impacts of various interventions [14].

C. Variables and Operationalization

1) Independent variable: Serious video games are a virtual representation of reality, in which a fictitious scenario based on real situations is recreated. In these games, the player assumes a specific role within the situation and is responsible for solving the challenges present in the scenario. Through interaction and decision-making, the player seeks to find effective solutions to the problems posed. These games allow users to develop skills and acquire practical knowledge by facing situations similar to those they would encounter in the real world [6]. A driving simulation video game will be used by the experimental group of 30 people. A nominal scale will be used.

2) Dependent variable: Driver behavior is safe driving that requires a detailed examination of the visual environment to identify and distinguish stimuli that are relevant to smooth driving. In addition, the driver must be able to select relevant stimuli from the context in a specific traffic situation, even when such stimuli are hidden or disguised in a complex visual field. In summary, safe driving involves the ability to interpret and respond appropriately to visual stimuli in different traffic scenarios. [7]. The driver behavior variable was measured through four indicators, which are: Number of action errors, the number of intention errors, Number of traffic law violations, and the number of aggressive attitudes, which shall use the ratio scale.

D. Population, Sample and Sampling

1) Population: The target population refers to the set of individuals who are relevant to the main problem or objective of the study; these individuals represent the group to which the results are intended to be generalized. The target population is characterized by its general demographic and clinical features. The study population is a specific group within the target population that is chosen according to the criteria defined in the research protocol. This selection is made with the purpose of carrying out the study in a more accessible and controlled manner. It is important to keep in mind that the study population may have particular geographical and temporal characteristics that make it suitable for the purposes of the research [15]. In this case, the study population consists of all drivers residing in the city of Trujillo.

A sample is defined as a portion or subset of representative elements extracted from a larger set, known as the population or universe. This selection is made randomly and is meant for scientific observation, with the goal of obtaining results that are applicable to the entire universe under investigation within established limits of error and probability specific to each situation [16]. In the context of the research mentioned, the sample consists of 60 drivers randomly selected from the city of Trujillo, divided into control and experimental groups, each comprising 30 drivers. Biases were prevented, and representative results for the population were guaranteed with randomized sampling.

E. Data Collection Techniques and Instruments

In terms of data collection techniques and instruments, non-participant observation is a method where no direct contact is established between the researcher and the subjects under study. This technique is particularly utilized in administrative fields to observe employees in a company, ensuring that their tasks are carried out without impacting their productivity or performance [14]. This research employs observation as its primary data collection technique.

The observation sheet, facilitates the systematic recording of behaviors, enabling an accurate assessment of the information collected. This tool allows the observed behaviors to be documented in an organized manner, which is essential for an adequate and comprehensive assessment of the information collected [17]. For this research, four observation sheets were made for the indicators: the number of action errors, the number of attention errors, the number of traffic law violations, and the number of aggressive attitudes.

F. Procedures

In this study, random sampling was utilized to select participants. A total of 60 drivers from the city of Trujillo were chosen through a random process to be part of the study. Once selected, these drivers were further randomly divided into two groups: a control group and an experimental group, with each group comprising 30 drivers. The assignment of drivers to each group was carried out using a random assignment process in Excel. This approach was chosen to ensure that both groups were comparable in terms of demographic characteristics and driving experience. The research flowchart presented in Fig. 1.

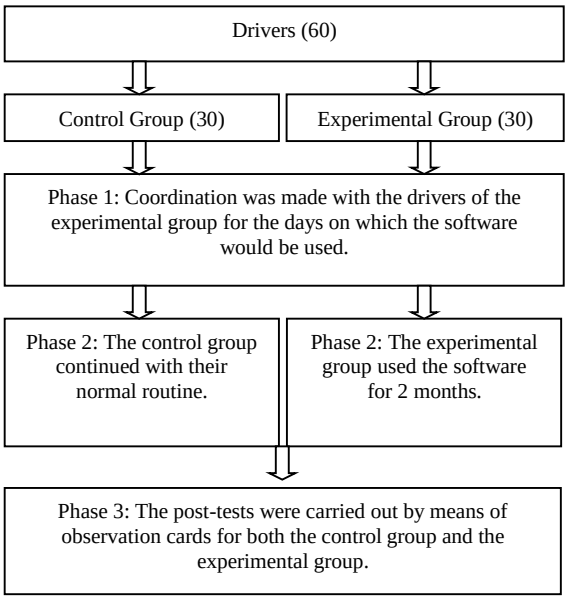

Fig. 1. Research flowchart.

The focus of the study was on a serious video game designed specifically to improve driver behavior in Trujillo. The experimental group was given access to this video game and received instructions on its proper use. They were also allowed a certain period to practice with the game before undergoing evaluations. In contrast, the control group did not receive any additional intervention; they continued their

regular driving routines without access to the video game. This setup allowed for a comparison between the two groups, aiming to evaluate the specific impact of the video game on the drivers' behavior.

For the study, observation sheets were developed containing several specific indicators to evaluate the behavior of drivers in Trujillo during incidents. These indicators included the number of action errors, which recorded the mistakes drivers made while executing specific actions. Another indicator was the number of intention errors, capturing errors in decision-making and action planning while driving. The sheets also tracked the number of traffic law violations, noting any infractions drivers committed relative to current traffic rules and regulations. Additionally, the number of aggressive attitudes was evaluated by observing behaviors. The evaluation of driver behavior was conducted in person while driving in real traffic conditions. The evaluators used observation sheets for data recording, and then a descriptive and inferential analysis was performed between the experimental and control groups, using statistical techniques to identify significant differences in the indicators assessed. A detailed analysis of each indicator was conducted to identify patterns and trends in driver behavior. This process evaluated the effectiveness of the video game in improving driver behavior in Trujillo. The results helped to understand the impact of the video game and could inform strategies to promote safer driving in the city.

To carry out this study, random sampling was applied to select the research participants. Since 60 drivers were randomly selected to participate in the study, once they were selected, they were randomly divided into two groups: a control group and an experimental group. Each group was composed of 30 drivers. Then, the assignment of drivers to each group was done through a random assignment process in Excel to ensure that the groups were comparable in terms of demographic characteristics and driving experience.

The experimental group used a serious video game designed specifically to improve driver behavior in the city of Trujillo. The drivers in the experimental group were given access to the video game and were instructed on its proper use; they were allowed to practice with the video game for a certain period of time before performing the evaluations. The control group did not receive any additional intervention and continued with their normal driving routine without access to the video game. This allowed comparison of the results between the experimental group and the control group, thus evaluating the specific impact of the video game on the drivers' behavior.

G. Development through SUM Methodology

1) Concept phase: During this period, the conceptual document was drafted, which provides a detailed description of the video game, addressing aspects such as its distinctive attributes, genre, game mechanics, setting, narrative, target audience, and the sources that served as inspiration. A detailed explanation of some of the aforementioned features is provided below.

2) Game vision: A driving video game will be developed, that allows the user to learn how to behave while driving, in a 3D environment, focusing on the educational and driving simulation video game genres.

3) Technologies: Visual Studio IDE, C++ programming language, Unreal Engine, and Blender.

4) Architecture: The architecture used in this research consists of a logic module, animation module, player module, game objects and resources module and finally a graphical interface as shown in Fig. 2.

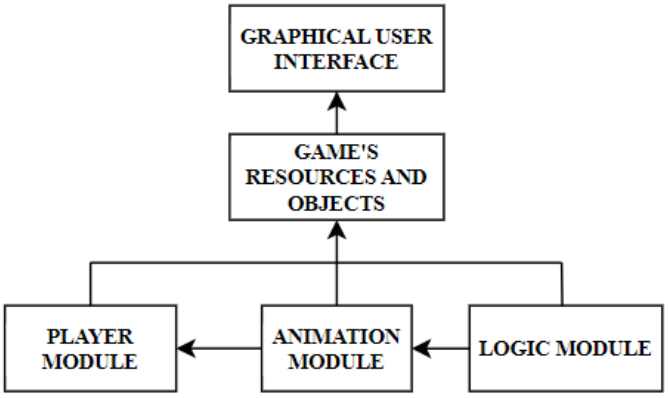

Fig. 2. Video game architecture diagram.

5) Planning phase: In this stage, the fundamental document of the project is prepared. This includes a detailed explanation of the work performed, the rationale of the project, the parties involved, quantifiable goals, functional requirements in Table I, and non-functional requirements in Table II. It also includes assumptions and other relevant components. In addition, both the activity plan and the project budget are detailed in this document.

6) Functional Requirements.

Code	Description
RF01	Interactive scene with situations of action errors.
RF02	Interactive scene with situations of intention errors.
RF03	Interactive scene with situations of traffic law violations.
RF04	Interactive scene with situations of aggressive actions.
RF05	Show the correct actions or decisions for each situation.

[a] Source: Own work

TABLE I. NON-FUNCTIONAL REQUIREMENTS

Code	Description
RNF01	Compatibility with the largest number of devices, whether laptop or desktop pc.
RNF02	Spanish language.
RNF03	Simple gameplay.

TABLE II. VIDEOGAME SCREENSHOTS

Videogame	Remarks
	Main start view
	Main scenario in which the player can freely roam the city.
	Decision making interface in which the user is suggested a situation.
	Action error interface, when the user makes a mistake when interacting with the scenario, 1 point will be automatically deducted.

[c.] Source: Own work.

7) Elaboration phase: The aim of this stage is to carry out the implementation of the video game. This involves adopting an iterative and incremental approach, ensuring the development of a functional version of the video game at the conclusion of each iteration.

a) Iteration 1: As can be seen in Fig. 3, it started with small scenery: one vehicle and six buildings, the road, and boundary markers; the vehicle can be controlled in any direction. The third-person camera follows the vehicle and performs the necessary movements when the player turns.

b) Iteration 2: As shown in Fig. 4, actors were implemented in the scenario to be used as collisions that activate the messages on the screen; each one will disappear as soon as the driver finishes interacting with the interface. In Fig. 5, control of the vehicle will be returned, and the driver will be able to continue.

c) Iteration 3: As shown in Fig. 6, a new vehicle was implemented, which will be an extra that will fulfill the function of generating traffic in the scene. Several functionalities were programmed, including stopping at the traffic light when it is red or following a specific route.

d) Iteration 4: As shown in Fig. 7, the scenario was completed with 4 blocks, 2 extra vehicles, 4 traffic lights with their logic of lights and interactions presented in Fig. 8, and a coordinated building aesthetics. All interaction points were placed, sound to the main vehicle, and the corresponding messages on screen.

Fig. 3. Progress of the first iteration.

Fig. 4. Progress of the second iteration.

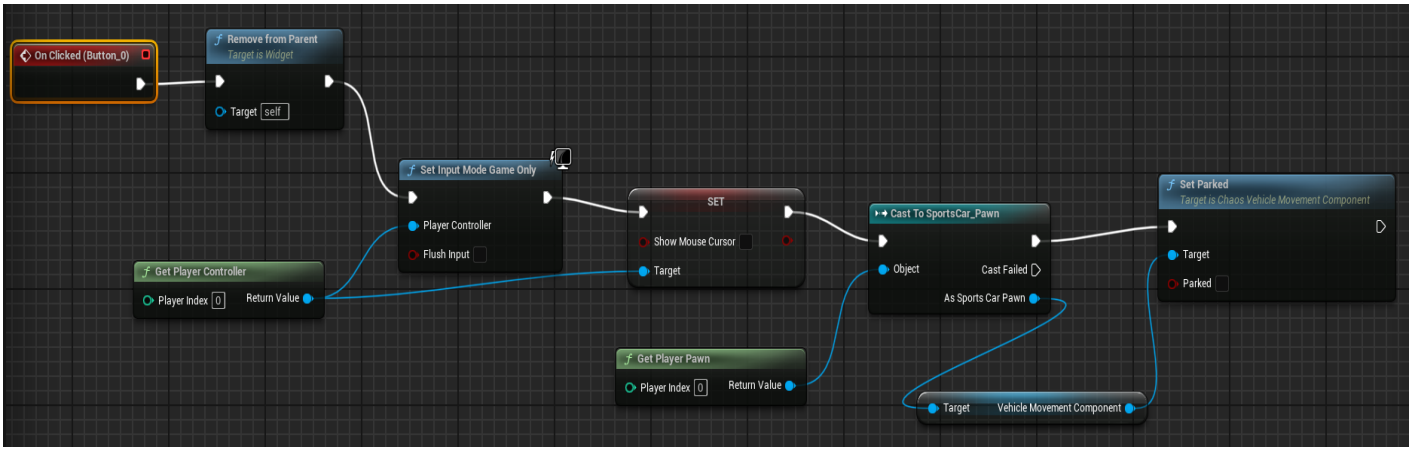

Fig. 5. Programming (Blueprints) interface in unreal engine 5.2

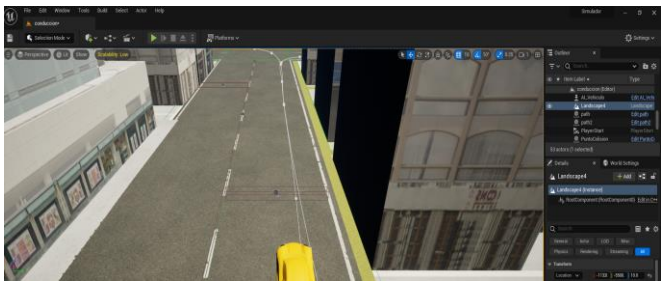

Fig. 6. Progress of the third iteration.

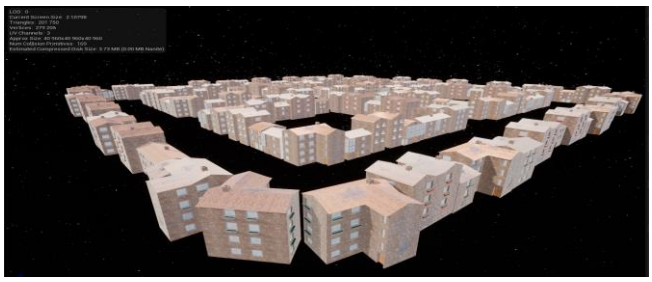

Fig. 7. Progress of the fourth iteration.

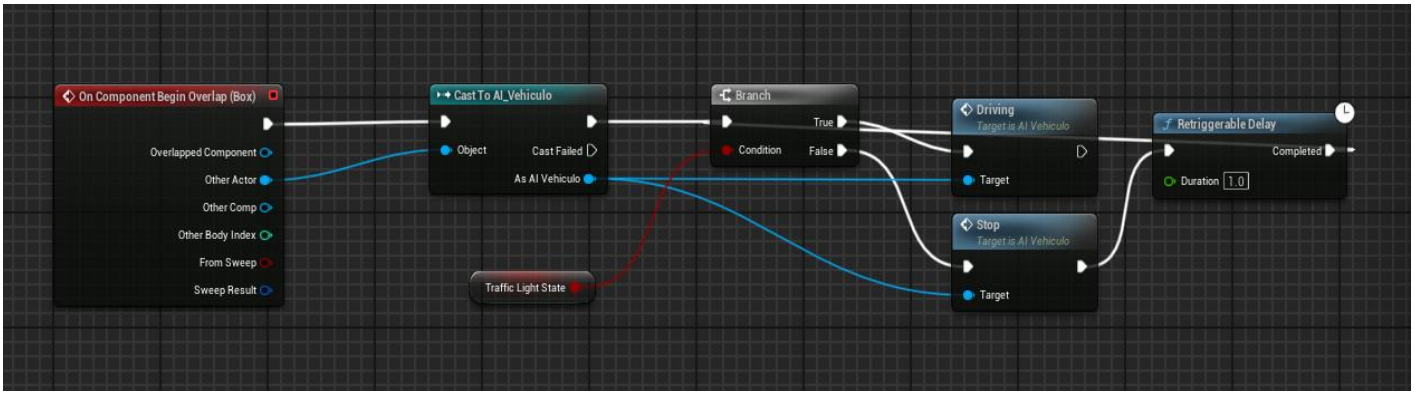

Fig. 8. Programming (Blueprints) traffic light interaction in unreal engine 5.2.

8) Beta phase: At the end of the development, we proceeded to package and install the video game on different computers with the Windows operating system. Several failures were found at the time of packaging the software, which generated a time of verification and error correction. After doing so, we proceeded to the packaging.

Performance and playability tests were started, which were correct in mid-range devices (GTX 1060 dedicated graphics card, 16GB RAM).

Performance and playability tests on low-end devices (no dedicated graphics card), failed.

a) Errors: When running the video game, the textures failed and the scenery was not displayed completely. At the moment of joining the player and an extra vehicle at a traffic light, the extra vehicle did not move again.

b) Fixes: Faulty textures were changed and the error of the extra vehicles was corrected.

9) Closing Phase: In this phase, we proceeded to launch the final version of the video game using Unreal Engine 5.2, accompanied by the enumeration of the lessons learned throughout the process. Some of these lessons include:

a) When working with Unreal Engine, it's crucial to carefully choose the version for development due to the potential for significant changes between different versions. It is advisable to consult the official documentation thoroughly before selecting a specific version, as this can affect various aspects of game development.

b) Creating a video game from scratch is a complex and challenging task that requires a considerable amount of information and practice for optimal development. Each aspect, from game mechanics to interactions within the game environment, needs careful planning and execution, as shown in Table III. Game executable can be found at https://acortar.link/wgI7ba

TABLE III. DESCRIPTIVE ANALYSIS FOR ALL INDICATORS

Research Indicator	Average		P	N < Average			% < Average		
	GC	*GE*		*GE*	*MP*	*GC*	*GE*	*MP*	*GC*
NEA	3.2	1.8	2	11	11	30	36.67	36.67	100
CEI	4.83	2.47	2	16	8	29	53.33	26.67	96.67
NVLT	2.23	1.53	2	16	16	28	53.33	53.33	93.33
CAA	4.73	2.7	2	17	7	26	56.67	23.33	86.67

[d] Source: Own work

H. Data Analysis Methodology

In this section, the specific hypotheses for the indicators of the dependent variable were established. For the indicator of the number of action errors, the alternate hypothesis (Ha) was that if a serious video game is used, it will decrease the number of action errors in the post-test of the experimental group (CEAGE). This was compared to the post-test sample of the control group (CEAGC). Regarding the indicator of the number of intention errors, the alternative hypothesis (Ha) was that the use of a serious video game would decrease the number of intention errors in the post-test of the experimental group (CEIGE). Compared to the post-test sample of the control group (CEIGC). For the indicator of the number of traffic law violations, the alternative hypothesis (Ha) stated that using a serious video game will reduce the number of traffic law violations in the post-test of the experimental group (CVLTGE). This is compared to the control group post-test sample (CVLTGC). Lastly, for the indicator of the number of aggressive attitudes, the alternative hypothesis (Ha) is that if a serious video game is used, the number of aggressive attitudes in the post-test of the experimental group (CAAGE) will decrease. This is compared to the control group post-test sample (CAAGC).

Descriptive analysis: An analysis of the data collected in this research was carried out. The data obtained in the experimental group were tripled to perform the calculations, and the average of the data collected for each indicator was obtained, both from the control group and the experimental group. An acceptable goal was then established based on the background or the goal expected by the entity. The amount of data that exceeded the average of the control group was counted, as well as the average of the experimental group and those data that exceeded the established goal, and the corresponding percentage was calculated for these results. In addition, a table of descriptive statistics was generated using the software Jamovi for each indicator.

Inferential analysis: At this point, normality tests (Shapiro-Wilk) and histograms were performed for each indicator using Jamovi software. As a result of the normality tests, if both variables were normally distributed, then parametric tests were

Applied (T-Student), and if any of the variables were abnormally distributed, nonparametric tests were applied (Mann-Whitney U). And it was defined whether the null hypotheses were accepted, or if otherwise the alternative hypotheses were accepted.

V. RESULTS

In this section, the main point was the descriptive analysis, with which the results were interpreted. The corresponding mean values were obtained using the Jamovi statistical software, and the decrease in the data of the experimental group compared to those of the control group was identified and presented. The second point was the inferential analysis, in which normality tests and hypothesis testing were performed for each indicator. You can access the database at the following link: https://figshare.com/s/1fa9139817410ca889c7

A. Descriptive Analysis

Table IV provides data on the average number of errors and violations committed by drivers in the control group (CG) and the experimental group (GE) in their respective post-tests. For action errors in the CG post-test, 36.67% were lower than their average, another 36.67% were lower than the target, and all 100% were lower than the CG's average.

TABLE IV. NORMALITY TEST STATISTIC SHAPIRO-WILK BY INDICATOR

Nº	Research Indicators	Statistic		p	
		GC	*GE*	*GC*	*GE*
1	Number of Action Errors	0.943	0.798	0.112	<.001
2	Number of Intent Errors	0.962	0.923	0.345	0.035
3	Number of Traffic Law Violations	0.852	0.732	<.001	<.001
4	Number of Aggressive Attitudes	0.947	0.861	0.145	0.001

[e] Source: Own work

In terms of intention errors in the CG post-test, 53.33% were lower than their average, 26.67% were lower than the target, and 96.67% were lower than the CG's average

Regarding traffic law violations in the GE post-test, 53.33% were lower than their average, another 53.33% were lower than the target, and 93.33% were lower than the CG's average. This data suggests a significant variation in the performance of drivers in both groups across different types of errors and violations.

B. Inferential Analysis

According to the data in Table V, for the indicator Number of Action Errors (NEA) in the Control Group (CG), the p-value was 0.112. This indicates that the data were normally distributed, as the p-value was greater than 0.05. In contrast, in the Study Group (SG), the p-value for NEA was less than .001, showing that the data were non-normally distributed, as the p-value was less than 0.05. This led to the application of a non-parametric test when one of the groups showed a non-normal distribution.

TABLE V. HYPOTHESIS TESTING STATISTICS U DE MANN-WHITNEY BY POSTTEST INDICATOR

Nº	Research Indicators	Statistics	p
1	Number of Action Errors	290	0.007
2	Number of Intent Errors	147	< .001
3	Number of Traffic Law Violations	277	0.003
4	Number of Aggressive Attitudes	190	< .001

[f.] Source: Own work.

For the Quantity of Intention Errors (CEI) indicator, the p-value for the CG was 0.345, indicating that its data were normally distributed, as the p-value was greater than 0.05. However, for the SG, the p-value was 0.035, which indicated non-normal distribution of data since the p-value was less than 0.05. Again, this necessitated the use of a non-parametric test when data in one of the groups were non-normally distributed.

Similarly, for the indicator Number of Traffic Law Violations (NVLT), its p-value was <.001 for the CG, which proved that its data were non-normally distributed, and for the SG, its p-value was <.001, which proved that its data were non-normally distributed, which allowed identifying that since both groups were non-normally distributed, a non-parametric test would be used.

Similarly, for the indicator Number of Aggressive Attitudes (CAA), the p-value for the CG was 0.145 greater than 0.05, which established that its data were normally distributed, and for the EG the p-value was 0.001 less than 0.05, which determined that its data were non-normally distributed, which allowed us to identify that when one of its groups was non-normally distributed, a non-parametric test was used.

According to the data obtained in Table VI for the Number of Errors of Action Indicator (NEA) its p-value was 0.007 less than 0.05, there was sufficient statistical evidence to reject the null hypothesis (Ho) and accept the alternative hypothesis (Ha); for the Number of Intention Errors Indicator (CEI) its p-value was <. 001 less than 0.05, there was sufficient statistical evidence to reject the null hypothesis (Ho) and accept the alternative hypothesis (Ha); for the Number of Traffic Law Violations Indicator (NVLT) its p-value was 0. 003 less than 0.05, there was sufficient statistical evidence to reject the null hypothesis (Ho) and accept the alternative hypothesis (Ha); for the Number of Aggressive Attitudes Indicator (CAA) its p-value was <.001 less than 0.05, there was sufficient statistical evidence to reject the null hypothesis (Ho) and accept the alternative hypothesis (Ha).

VI. DISCUSSION

From the results obtained, it was evident that with the use of a serious video game. The number of errors of action, the number of errors of intention, the number of traffic law violations, and the number of aggressive attitudes were reduced. This demonstrates that the use of a serious video game significantly improved the driver's behavior.

Regarding the main goal, which sought to improve the behavior of drivers in the event of incidents through the use of a serious video game in Trujillo in 2023, it was determined that it did indeed improve the behavior of drivers. This was evidenced by the decrease in the average of all indicators measured; the results are similar to the research [8], in which the effectiveness of gamification elements in driving simulators on road safety in unknown traffic situations was assessed and proven.

Regarding the first indicator, which is the number of action errors (CEA), the total average was 3.2 in the control group and 1.8 in the experimental group, which showed a reduction of 1.4 action errors. In addition, it was evident that of the 100% average action errors of the control group, the average of the experimental group equals 56.25%; this proved a 43.75% reduction of action errors after implementation. The results were generally comparable with the research [8], which presented a 13–1 decrease in the number of action errors. It should be noted that the author Useche [18] defines action errors as errors in the execution planned by the driver, which can manifest themselves in terms of observation, execution, or incorrect judgments and do not involve intentional actions.

Regarding the second indicator, which is the number of intention errors (CEI), there was a total average of 4.83 in the control group and 2.47 in the experimental group, which showed a reduction of 2.36 in intention errors. In addition, it was evidenced that of the 100% average intention errors in the control group, the average in the experimental group equaled 48.86%; this proved a 51.14% reduction in intention errors after implementation. The results were generally comparable with the research [19], which presented a decrease of 40%, 30%, 25%, and 30% in the number of errors. It should be noted that the author Useche [18] defines intention error as errors in the attention or memory processes that hinder the proper execution of the driving task.

Regarding the third indicator, which is the number of traffic law violations (NVLT), a total average of 2.23 was obtained in the control group and 1.53 in the experimental group, which showed a reduction of 0.7 traffic law violations. In addition, it was evidenced that of the 100% of the average traffic law violations in the control group, the average in the experimental

group equals 68.60%, which proved a 31.4% reduction of traffic law violations after implementation. The results are generally comparable with the research [20], who obtained that a video game can help in the understanding of laws by up to 90%. It should be noted that the author Useche [18] defines traffic law violations as intentional violations of traffic rules, laws, or codes, which are deliberate actions.

Regarding the fourth indicator, which is the number of aggressive attitudes (CAA), a total average of 4.73 was obtained in the control group and 2.7 in the experimental group, which showed a reduction of 2.03 aggressive attitudes. In addition, it was evidenced that of the 100% average aggressive attitudes of the control group, the average of the experimental group equals 57.08%; this proved a reduction of 42.92% aggressive attitudes after implementation. The results are generally comparable with the research [21], which found that cab drivers are more likely to commit aggressive attitudes, with a 98% chance during the year. It should be noted that the author Useche [18] defines aggressive attitudes as manifestations of hostility directed towards other road users or driving patterns strongly linked to aggressive behavior by the driver.

Finally, it was concluded that with the use of a serious video game, the behavior of drivers in the city of Trujillo 2023 was improved.

VII. LIMITATIONS

During the development of the research, several limitations arose that influenced the process and the obtaining of comprehensive results. Among the most prominent limitations was the availability of the drivers, whose work schedules sometimes made it challenging to coordinate the tests efficiently. This variable, in turn, was affected by traffic variability at specific times when post-tests were conducted, introducing an unpredictable element that could have influenced the consistency of the data collected.

Another significant limitation was the time constraint for data collection. The need to collect relevant information in a limited period of time may have impacted the completeness of the research, limiting the amount of data that could be collected and analyzed in detail.

In addition, the need on the part of the researcher to acquire knowledge of new video game development software was identified. This limitation not only added a learning curve to the project but also implied dedicating additional time to becoming familiar with the necessary tools. This factor may have impacted the efficiency of the implementation of certain parts of the study.

Finally, limitations were found related to the hardware used for the execution of the video game. These constraints could have affected the quality and accuracy of the results obtained, since the performance of the hardware can directly influence the execution of the software and thus the user experience and the data collected.

Taken together, these limitations underscore the inherent complexity of the research and highlight the importance of addressing these challenges strategically to mitigate their impact on the validity and reliability of the findings.

ACKNOWLEDGMENT

The research was not externally funded. We would like to express our sincere gratitude to all those who have contributed to this research.

CONFLICT OF INTEREST

The authors declare no conflict of interest.

A Genetic Artificial Bee Colony Algorithm for Investigating Job Creation and Economic Enhancement in Medical Waste Recycling

El Liazidi Sara, Dkhissi Btissam
National school of applied sciences Tetuan, Morocco

***Abstract*—The effective management of end-of-life products, whether through recycling or incineration for electricity generation, holds pivotal significance amidst escalating concerns over economic, environmental, and social ramifications. While the economic and environmental dimensions often receive primary focus, the social aspect remains comparatively neglected within sustainability discourse. This paper undertakes a comprehensive exploration of the positive social impacts engendered by medical waste recycling, with a specific focus on job creation and economic value enhancement. The principal aim of this research is to highlight the social benefits derived from medical waste recycling, elucidating its role in fostering employment opportunities, and augmenting economic prosperity. By employing a Genetic Artificial Bee Colony algorithm, this study addresses two mathematical problems pertinent to optimizing recycling processes, thereby contributing to the advancement of sustainable waste management practices. Additionally, the proposed algorithm exhibits superior performance, highlighting its potential in addressing sustainability challenges. Ultimately, integrating the social dimension into end-of-life product management discussions can lead to a more comprehensive approach to sustainability, balancing environmental preservation with socio-economic progress.**

***Keywords*—Medical waste recycling; social impacts; genetic artificial bee colony algorithm; job creation; economic value**

I. INTRODUCTION

The growth of the population and their increasing demand for consumable products necessitate a concerted effort to reduce the amount of waste generated by these products after use, the management of products extends far beyond their initial creation and use. The footprint left by this waste has become a critical concern, urging a transition from the traditional "cradle-to-grave" model, to the more encompassing and sustainable "cradle to cradle". The increase in waste in landfill sites becomes a crucial challenge for decision-makers, researchers, and consumers, considering the dangers effects that can be caused by the poor management of these wastes, whether at the economic, environmental, or social dimensions. Addressing these three challenges in the design of a closed-loop supply chain (CLSC) forms the three pillars of sustainability [1]. The complexity of the intersection between environmental, economic, and social considerations finds its explanation in the model of designing a CLSC. This represents a systematic departure from the "cradle to grave" model, emphasizing a circular economy, environmental concerns, and social indicators.

Recently, in the discourse on sustainable development, one of the sectors that attracts the attention of researchers and decision-makers is the healthcare sector. This sector is subject to increased scrutiny, especially after the Covid-19 pandemic, wars, and natural disasters that have generated substantial amount of medical waste in recent years. According to the World Health Organization report [2], the COVID-19 pandemic generated tens of thousands of tons of medical waste between March 2020 and November 2021. These wastes are disposed of in landfill sites without any treatment. This situation highlights the importance of adopting a strategy to implement the principles of reverse logistics in traditional supply chain management and integrating environmental concerns and social indicators.

It is evident that in recent times, the focus of decision-makers and researchers has pivoted towards the environmental impact resulting from supply chain. While there is an increasing recognition of the importance of reducing the environmental footprint to attain the second dimension of a sustainable CLSC network, there remains a noticeable gap in the existing literature concerning the third dimension of sustainability, namely, social impacts[3]. This study aims to highlight the importance of integrating social indicators into sustainable CLSD. Recycling medical waste can have several positive social impacts contributing to the well-being of societies and individuals, including the community, workplace safety, education and awareness, and job creation. This study focuses on two social indicators: the first is job creation, which plays a significant role in reducing unemployment rates, and the second is balancing economic development.

The rest of this article is outlined as follows: Section II provides a review of the literature. In Section III, we delve into a detailed description of the problem and the corresponding mathematical model. Section IV introduces the Genetic Artificial Bee Colony (GABC) algorithm proposed in this study. The practical implementation of GABC and a comparative analysis between the results obtained by GABC and the original ABC are presented in Section V. Finally, Section VI offers concluding remarks.

II. LITERATURE REVIEWS

For decades, the main objective of supply chains has been the maximization of profit or the minimization of costs throughout the network. This goal has been the focus of many research works and studies [4], [5], [6], [7], [8]. The efforts made by researchers to increase the profit of the logistics chain undeniably contributed to enhancing its efficiency and profitability.

In order to reduce total supply chain operating costs, A bi-objective optimization approach is presented by [9], which aims to minimize total expenditures and decrease cycle time delay overall. They use a solution strategy that combines the dual simplex method, the constraint method, and scatter search when taking discrete facility capacity alternatives into consideration. A trade-off between the two goals is shown by computational analyses, which show that decreasing cycle time produces a decentralized network structure while optimizing for cost produces a centralized network structure. The author in [10] present a novel model for designing a reliable network in a closed-loop supply chain, minimizing total and post-failure transportation costs under uncertainty. Their solution approach, combining robust optimization, queuing theory, and fuzzy multi-objective programming, proves effective in addressing uncertainty and optimizing facility design. The author in [11] provide a mixed-integer linear programming model for a closed-loop supply chain network that uses stochastic programming to minimize overall costs and account for uncertainties. To solve the complex problem of creating cost-effective closed-loop supply chains, [12] provide a novel approach that uses a deterministic multi-product, multi-echelon, multi-period model. The author in [13] proposes a novel Genetic Artificial Bee Colony (GABC) algorithm for optimizing closed-loop supply chain networks, addressing uncertainties in demand, and returned product quantities. Their GABC algorithm surpasses standard Artificial Bee Colony (ABC) and Genetic Algorithm (GA) methods in minimizing total network cost across diverse scenarios. The author in [14] uses an integer-programming approach to address a two-stage supply chain distribution-allocation problem. They proposed heuristic, based on Ant Colony Optimization, exhibits computational efficiency, and produces solutions in a fair amount of time with an average deviation from optimal solutions of about 10%. The author in [15] propose a mobile Waste Heat Recovery (WHR) supply chain, minimizing distribution costs compared to traditional WHR. Their optimization model, integrating life cycle assessment, ensures energy supply stability and cost savings, presenting an efficient alternative to conventional WHR and fossil fuel heating, especially under stochastic demand conditions. The author in [16] explores the economic advantages of new product formulations, specifically through concentration, in formulated product supply chain networks. They reduce overall costs by optimizing facility locations, capacities, and production planning through the use of mixed-integer linear programming, which has major advantages in a supply chain for fast-moving consumer goods.

Recently, the challenge of implementing a sustainable CLSC that adheres to the three dimensions of sustainability has become a task facing the researchers and the decision-makers. It is noted that several studies are beginning to incorporate environmental and / or social impacts as additional objectives in their multi-objective CLSC. The literature on the sustainable CLSC can be categorized into two primary groups: Economic and environmental dimensions in CLSC and sustainable CLSC.

A. Economic and Environmental Dimensions in CLSC

Over the past two decades, the challenge of environmental impacts generated by industries and end-of-life waste, leading to an increase in greenhouse gas (GHG) emissions and loss of natural resources, has become a major focus for researchers. The author in [17] introduce a conceptual framework for designing a sustainable food packaging and distribution network, comparing the environmental and economic impacts of reusable plastic containers (RPC) with traditional single-use options in the fresh food supply chain. Using life cycle assessment (LCA), the study evaluates the carbon footprint and explores sensitivity to key parameters, offering insights into the sustainability of packaging approaches in the food catering chain. The author in [18] presents a multi-objective model for the logistics of the gold industry that gives cost and CO2 emissions priority. Their work effectively addresses a case study of a 7-layer network using an ant colony optimization technique, demonstrating usefulness. The algorithm performs better when the parameters are set Taguchi-based, and the results highlight managerial insights for supply chain optimization. The author in [19] addresses environmental concerns by proposing a green supply chain model that optimizes transportation and waiting times for fleets in both forward and reverse logistics. The model aims to minimize environmental impacts and energy consumption through strategic determinations of loading, unloading, and production rates. The author in [20] explores how producing power from wood pellets might help achieve climate objectives. They focus on how supply chain costs can be reduced by using techno-economic analysis and a study of relevant research. The analysis highlights the impact of variables such as plant size on costs by revealing trade-offs in cost components across various supply chain configurations. [21]propose novel mathematical models for inventory management in reverse logistics systems, extending [22] model by considering different demands for newly produced and remanufactured products. The study also extends into sustainability, presenting a three-objective mathematical model and an algorithm to achieve Pareto solutions, addressing greenhouse gas emissions and energy consumption in production and remanufacturing processes. The author in [23] innovate a methodology for plastic footprint analysis at the enterprise and supply chain levels, focusing on a clothing industry case. Their study identifies key strategies, such as lightweight plastic promotion and increased use of recycled materials, offering practical solutions for substantial environmental benefits in reducing plastic impact.

B. Social Dimension

The concept of sustainability was introduced by [24] report, emphasizing the importance of integrating environmental and social concerns to ensure a viable future. Unfortunately, in the literature, the social dimension has rarely been addressed. The author in [25] aims to improve reverse

logistics decision-making by integrating economic, environmental, and social objectives. Using a recyclable waste collection system as a case study, they model the problem as a multi-objective, multi-depot periodic vehicle routing challenge, proposing a compromise solution for a sustainable reverse logistics plan that considers trade-offs and achieves balance. The author in [26] introduces a multi-objective possibilistic programming model for designing a sustainable medical supply chain network under uncertainty, addressing conflicting economic, environmental, and social objectives. The model employs effective social and environmental life cycle assessment methods, and an accelerated Benders decomposition algorithm is introduced to handle computational complexity, demonstrated through a medical industrial case study. The authors in [27] have introduced an innovative sustainable closed-loop location-routing-inventory model. This model considers economic, environmental, and social impacts, particularly in the context of mixed uncertainty. The author in [28] address the need for supply chain designs considering environmental, social, and economic objectives, specifically focusing on sustainable closed-loop supply chain networks for recycled tires. They develop a multi-objective mixed-integer linear programming model to optimize total cost, environmental impacts, and social factors. To efficiently handle large-scale networks, four new hybrid metaheuristic algorithms are introduced and demonstrated to be effective through extensive computational experiments and analyses. The author in [29] develops a multi-objective linear mathematical model to optimize a steel sustainable closed-loop supply chain, addressing uncertainties and applying fuzzy goal programming. Validated through a real case study in an active steel supply chain in Iran, the model aims to optimize total profit, energy and water consumption, CO2 emissions, job opportunities, and lost working days. Results highlight the significant environmental benefits achievable even with a minor profit decrease, providing essential managerial insights for industry leaders navigating the balance between profits and environmental/social considerations. The author in [30] highlights the impact of decisions related to facility locations and industrial activities on initial pollution levels and unemployment rates in various regions. Through numerical experiments, the research demonstrates that intentional objectives focused on reducing environmental and social inequities lead to a decrease in disparities among regions. The paper concludes by providing managerial insights and suggesting future research directions within the context of supply chain networks and sustainable development.

Due to the diverse nature of social responsibility aspects, integrating all of them into the design of a sustainable closed-loop supply chain would lead to a non-optimal network. Our primary objective in this paper is to maximize positive social indicators in recycling three types of medical waste: glass, plastic, and steel. To achieve this, we propose a programming model with two objective functions that aims to maximize job creation and balance economic development. The study introduces a Genetic Artificial Bee Colony (GABC) algorithm, and its performance is compared with the original Artificial Bee Colony algorithm. This work builds upon our previous research [31], which focuses on minimizing the total cost of reverse logistics and reducing CO2 emissions in the network.

III. Problem Modeling

This model aims to develop a programming model for two objective functions to maximize job opportunities creation and balance economic value within a reverse supply chain network. The network encompasses hospitals, collecting centers, recyclers, and disposal centers. Fig. 1 illustrates the network schematic, emphasizing the reverse logistics aspect. The medical waste generated by the hospitals is shipped to collecting centers where the waste is disinfected and sorted. In this study, three types of waste are addressed: plastic (Polyethylene (PET), Polypropylene (PP)), glass (clear or white glass and brown glass), and stainless steel. The non-recyclable waste is transported to disposal centers, while the remaining medical waste is directed to recycling centers where it is processed and recycled to be used as new products. The unrecovered waste is shipped to the disposal center for safe landfill.

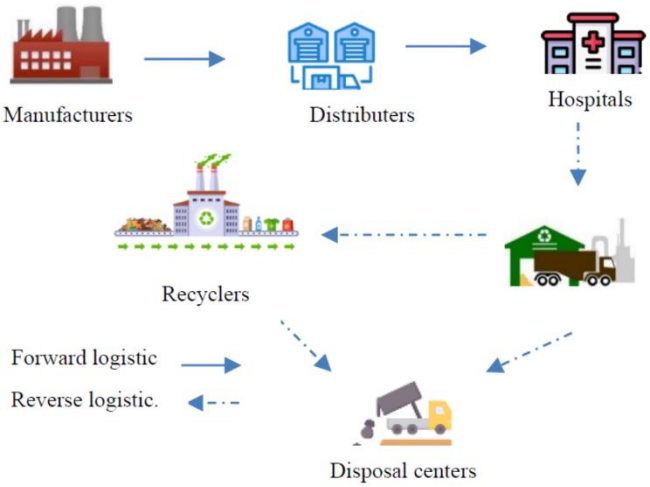

Fig. 1. Medical product for forward / reverse logistics network.

A. Assumptions

To formulate our model, we have based our analysis on the following assumptions and simplifications:

- There are no exchanges of products among facilities at the same level.
- The locations for the opening of recyclers and collecting centers are predetermined.
- The capability of each facility is constrained.
- The quality of recycled products and manufactured products is the same.
- The unrecovered waste is transported to a disposal center for safe landfilling.

B. Notation

- Indices

l : Index of hospitals, $l \in \{1, \dots, L\}$.

n : Index of collecting centers, $n \in \{1, \dots, N\}$.

m : Index of recyclers, $m \in \{1, \dots, M\}$.

o : Index of disposal centers, $o \in \{1, \dots, O\}$.

k : Index of plastic waste, $k \in \{1, \dots, K\}$.

r : Index of glass waste, $r \in \{1, \dots, R\}$.

v : Index of plastic waste, $v \in \{1, \dots, V\}$.

- Parameters

DJ_{km} : Number of fixed job opportunities created by establishing plastic recycler m.

DJ_{rm} : Number of fixed job opportunities created by establishing glass recycler m.

DJ_{vm} : Number of fixed job opportunities created by establishing steel recycler m.

DJ_n : Number of fixed job opportunities created by establishing collecting center n.

IDJ_n : Number of variable job opportunities created at collecting center c (depends on amount of waste and capacity of collecting center).

IDJ_{km} : Number of variable job opportunities created at plastic recycler m.

IDJ_{rm} : Number of variable job opportunities created at glass recycler m.

IDJ_{vm}: Number of variable job opportunities created at steel recycler m.

μ_n : Unemployment rate at collecting center n.

μ_{km} : Unemployment rate at plastic recycling center m.

μ_{rm} : Unemployment rate at glass recycling center m.

μ_{vm} : Unemployment rate at steel recycling center m.

V_{km} : Economic Value of recycling waste at plastic recycler m.

V_{rm} : Economic Value of recycling waste at glass recycler m.

V_{vm} : Economic Value of recycling waste at steel recycler m.

V_n : Economic Value at collecting center n.

rd_{km} : Regional development at plastic recycler m.

rd_{rm} : Regional development at glass recycler m.

rd_{vm} : Regional development at steel recycler m.

rd_n : Regional development at collecting center n.

δ_k : The percentage of non-recyclable plastic waste being transported from the collection center to the disposal center.

δ_r : The percentage of non-recyclable glass waste being transported from the collection center to the disposal center.

δ_v : The percentage of non-recyclable steel waste being transported from the collection center to the disposal center.

β_k : The percentage of unrecovered plastic waste being transported from the recycler to the disposal center.

β_r : The percentage of unrecovered glass waste being transported from the recycler to the disposal center.

β_v : The percentage of unrecovered steel waste being transported from the recycler to the disposal center.

- Capacities

F_l : Quantity of medical waste generated by hospital l.

$Mcap_n$: Capacity of collecting center n.

MPW_m : Capacity of plastic recycler m.

MGW_m : Capacity of glass recycler m.

MSW_m : Capacity of steel recycler m.

$Mcap_o$: Capacity of disposal center o.

UP_n : The upper limit for establishing collecting center n.

UP_{km} : The upper limit for establishing plastic recycler m.

UP_{rm} : The upper limit for establishing glass recycler m.

UP_{vm} : The upper limit for establishing steel recycler m.

- Decision variables

AM_{ln} : The quantity of waste transported from hospital l to collection center n.

AM_{nkm} : The quantity of plastic waste transported from collection center n to recycler m.

AM_{nrm} : The quantity of glass waste transported from collection center n to recycler m.

AM_{nvm} : The quantity of steel waste transported from collection center n to recycler m.

Y_n : 1 if the collecting center n is opened, 0 otherwise.

Y_{km} : 1 if the plastic recycler center m is opened, 0 otherwise.

Y_{rm} : 1 if the glass recycler center m is opened, 0 otherwise.

Y_{vm} : 1 if the steel recycler center m is opened, 0 otherwise.

C. Social Objective Functions

- Job Creation Opportunities

Employment is a key driver of social sustainability, significantly influencing the well-being and socio-economic status of individuals [32]. A study by the [33] projects a potential net job creation of up to 700,000 jobs in the EU. Specifically, employment in waste management is anticipated to witness a substantial increase, with a potential addition of 660,000 jobs. This increase is attributed to the labor-intensive nature of recycling, which is replacing less labor-intensive landfilling practices.

$$\textbf{Max Job Creation} = Fixed\ job\ creation(FJC) + Variable\ Job\ Creation\ (VJC) \quad (1)$$

$$\textbf{FJC} = \sum_{n=1}^{N} DJ_n \times Y_n \times \mu_n + \sum_{m=1}^{M}\sum_{k=1}^{K} DJ_{km} \times Y_{km} \times \mu_{km} + \sum_{r=1}^{R}\sum_{m=1}^{M} DJ_{rm} \times Y_{rm} \times \mu_{rm} + \sum_{v=1}^{V}\sum_{m=1}^{M} DJ_{vm} \times Y_{vm} \times \mu_{vm} \quad (1\text{-}1)$$

$$\textbf{VJC} = \sum_{l=1}^{L}\sum_{n=1}^{N} IDJ_n \times \frac{AM_{ln}}{Mcap_n} \times \mu_n + \sum_{n=1}^{N}\sum_{k=1}^{K}\sum_{m=1}^{M} IDJ_{km} \times \frac{AM_{nkm}}{MPW_{km}} \times \mu_{km} + \sum_{n=1}^{N}\sum_{r=1}^{R}\sum_{m=1}^{M} IDJ_{rm} \times \frac{AM_{nrm}}{MGW_m} \times \mu_{rm} + \sum_{n=1}^{N}\sum_{v=1}^{V}\sum_{m=1}^{M} IDJ_{vm} \times \frac{AM_{nvm}}{MSW_m} \times \mu_{vm} \quad (1\text{-}2)$$

The objective function (1) is designed to maximize both fixed and variable job creation opportunities within the network. Eq. (1-1) specifically represents the fixed job creation in the collecting and recycling centers. The inclusion of unemployment rates μ_n, μ_{km}, μ_{rm}, μ_{vm} in the objective function allows the model to adapt its assessment of job creation based on the prevailing employment conditions, making the optimization more realistic and reflective of the socio-economic context. When the unemployment rate is high, indicating a substantial pool of unemployed individuals in the considered region or sector, the model recognizes that the potential for job creation through the recycling process could have a more substantial positive impact on the local workforce. Conversely, in the case of a low unemployment rate, signifying a smaller proportion of unemployed individuals, the model exerts less influence, as the employment market is presumed to be more saturated. Equation (1-2) defines the variable job creation in the collecting and recycling centers. The utilization of the ratios, including $\frac{AM_{ln}}{Mcap_n}$, $\frac{AM_{nkm}}{MPW_m}$, $\frac{AM_{nrm}}{MGW_m}$, $\frac{AM_{nvm}}{MSW_m}$ serves as a measure of how much of the capacity of collecting center n and recycler center m is being utilized. A ratio close to 1 indicates that there is potential for additional job opportunities.

- Balanced Economic Development

Balanced economic development serves as a positive social indicator, emphasizing a fair and inclusive distribution of economic benefits. This approach aims to mitigate income inequality by creating job opportunities across diverse sectors and regions, ultimately elevating overall living standards. The ripple effect of this strategy extends to an enhanced quality of life, fostering social cohesion, and empowering communities. In essence, a commitment to balanced economic development reflects a dedication to creating a more equitable and thriving society.

$$Max\ ED = \sum_{n=1}^{N} V_n \times Y_n \times (1 - rd_n) + \sum_{m=1}^{M}\sum_{k=1}^{k} V_{km} \times Y_{km} \times (1 - rd_{km}) + \sum_{m=1}^{M}\sum_{r=1}^{R} V_{rm} \times Y_{rm} \times (1 - rd_{rm}) + \sum_{v=1}^{V}\sum_{m=1}^{M} V_{vm} \times Y_{vm} \times (1 - rd_{vm}) \quad (2)$$

The objective function (2) represents the economic development associated with each collection center and recycling center. The terms rd_n , rd_{km}, rd_{rm} , rd_{vm} in the objective function serve as adjusters, strategically considering the impact of regional development on the economic value associated with the proposed model. These adjusters play a crucial role in accounting for the varying degrees of regional development and tailor the objective function to reflect the nuanced economic landscape, ensuring a more accurate representation of the model's objectives in the context of different regions.

D. Constraints

- Supply Constraints

$$\sum_{l=1}^{L} AM_{ln} \leq F_l \ \forall n \quad (3)$$

This constraint guarantees that the amount of waste collected from each hospital is limited to the quantity of waste generated by that specific hospital.

- Flow Balance Constraints

$$\sum_{l=1}^{N} AM_{nkm} = \sum_{l=1}^{N} AM_{ln}\ (1 - \delta_k)\ \forall \text{ l, m, k} \quad (4)$$

$$\sum_{l=1}^{N} AM_{nrm} = \sum_{l=1}^{N} AM_{ln}\ (1 - \delta_r)\ \forall \text{ l, m, r} \quad (5)$$

$$\sum_{l=1}^{N} AM_{nvm} = \sum_{l=1}^{N} AM_{ln}\ (1 - \delta_v)\ \forall \text{ l, m, v} \quad (6)$$

Eq. (4), (5) and (6) Ensure that the total waste received at collection centers is equivalent to the total waste forwarded to recycling centers, considering potential damage.

- Capacity Constraints

Maximum capacity can be allocated to collecting center n.

$$\sum_{n=1}^{N} AM_{ln} \leq Mcap_n \times\ Y_n\ \forall \text{l} \quad (7)$$

Maximum capacity can be allocated to recycling center r.

$$\sum_{m=1}^{M} AM_{nkm} \leq MPW_m \times\ Y_{mk}\ \forall \text{ n, k} \quad (8)$$

$$\sum_{m=1}^{M} AM_{nrm} \leq MGW_m \times\ Y_{mr}\ \forall \text{ n, r} \quad (9)$$

$$\sum_{m=1}^{M} AM_{nvm} \leq MSW_m \times\ Y_{mv}\ \forall \text{ n, v} \quad (9)$$

Constraints (11), (12), (13), and (14) determine the upper limit on the number of collecting centers and recycling centers that can be opened.

$$\sum_{n=1}^{N} Y_n\ \leq\ UP_n \quad (11)$$

$$\sum_{m=1}^{M} Y_{mk}\ \leq\ UP_{mk}\ \ \forall \text{ k} \quad (12)$$

$$\sum_{m=1}^{M} Y_{mr}\ \leq\ UP_{mr}\ \forall \text{ r} \quad (13)$$

$$\sum_{m=1}^{M} Y_{mv}\ \leq\ UP_{mv}\ \forall \text{ v} \quad (14)$$

Finally, Constraint (15) and (16) enforce the binary and no negativity restrictions on corresponding decision variables.

$$Y_n, Y_{mk}, Y_{mr}, Y_{mv} \in \{0,1\} \quad (15)$$

$$AM_{ln}, AM_{nkm}, AM_{nrm}, AM_{nvm} \geq 0 \quad (16)$$

IV. Solution Approach

A. Artificial bee Colony Algorithm

The optimization algorithms based on swarm intelligence have come to be considered as one of the best methods for handling difficult real-world problems. The Artificial bee colony (ABC) is one of such optimization algorithms based on swarm intelligence, The ABC algorithm, introduced by [34], is an optimization algorithm inspired by the foraging behavior of honeybees. This algorithm is specifically designed to systematically explore and exploit potential solutions in the context of optimization problems. The ABC algorithm comprises as shown in Fig. 2, three distinct categories of bees: employees, onlookers, and scouts. First, employee bees are dispatched to diverse food sources, each with a designated location. These employees assess the nectar quantity associated with their designated food sources. At the same time, onlooker bees stay within the hive, systematically collecting crucial information about food sources with superior nectar levels, as communicated by the employee bees. Subsequently, onlooker bees influence the directional shifts for employee bees to explore further, based on the observed nectar quantity of each food source. Employee bees encountering stagnation in nectar accumulation may transform into scout bees, responsible for the stochastic discovery of new food sources. This dynamic interplay between exploration and exploitation is a core aspect of the ABC algorithm, reflecting the collaborative and adaptive dynamics inherent in natural honeybee colonies.

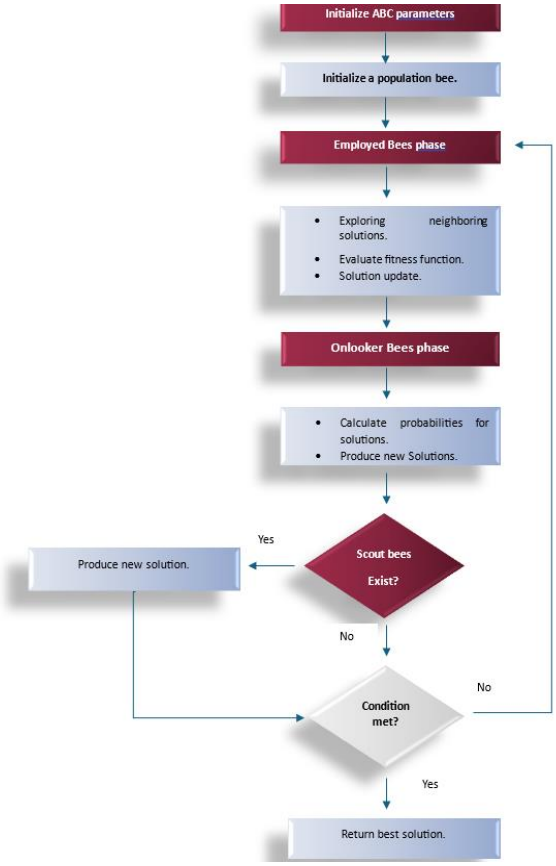

Fig. 2. Flowchart of artificial bee colony.

B. Genetic Artificial bee Colony Algorithmthe

In order to improve the exploration and exploitation capabilities of the ABC algorithm, a genetic algorithm is incorporated. This integration, specifically introduced into the employed phase of an Artificial Bee Colony (ABC), brings forth genetic operations like crossover and mutation. These genetic operations play a pivotal role in broadening the exploration of the solution space. The refined solutions produced by employed bees, through the application of genetic operations, contribute to a more thorough exploration, ultimately improving the overall performance of the algorithm. A comprehensive explanation of the hybridization process is presented below.

1) Initialization of prameters: In this initialization phase of the algorithm, critical parameters are defined to shape its behavior. The population size (PS) is determined, outlining the number of individuals constituting the population. Simultaneously, the number of food sources is established, each representing a potential solution within the optimization problem. The symmetry between employed and onlooker bees is emphasized, ensuring an equal distribution of roles in the algorithm. The maximum number of iterations is specified, delineating the extent of the algorithm's exploration and refinement cycles. A cycle limit is also set. Finally, the algorithm's initial population is initialized with bees, each carrying random solutions that signify quantities of waste transported between facilities. These defined parameters and the initial population collectively lay the foundation for subsequent algorithmic phases, guiding its systematic approach to solution exploration and optimization.

2) Employed bee phase: In the Artificial Bee Colony Algorithm, employed bees actively explore their surroundings in search of alternative food sources that offer higher nectar content than their current location.

- Exploring neighboring solutions: Employed bees explore neighboring solutions, conducting a systematic search for alternative options that reside in close proximity within the solution space.
- The fitness: To compute the fitness value for the current solution based on the objective function. The fitness is determined through the following Eq. (18):

$$fitness_i = \frac{1}{1+Gi} \tag{18}$$

Where $fitness_i$ is the fitness of the associated solution. Gj represents the objective function for the jth Solution.

- Solution Update: When the newly explored solution surpasses the previous one in terms of both job creation and economic development, the employed bee proceeds to update its solution.

3) Genetic operators phase: In this part the algorithm executes genetic operators, such as crossover and mutation, to introduce genetic variation and improve the solutions.

To choose a pair of parents from the solutions acquired through employed bees, it is essential to establish an encoding

scheme for this problem. As shown in Fig. 3 and Fig. 4, this model employs a hybrid encoding, integrating both binary and floating encodings to represent the chromosome. For example, considering five hospitals, two collecting centers, three plastic recyclers, two glass recyclers, and two steel recyclers, each chromosome can be represented by (2+3+2+2+5*2+2*3+2*2+2*2+3*2+2*2+2*2) array. The initial (2+3+2+2) genes denote whether the two collecting centers are open (1) or closed (0). The same logic applies to plastic recyclers, glass recyclers, and steel recyclers. Following this, the next set of genes (5*2) represents the quantity of waste generated by the five hospitals and transported to the collecting centers. Subsequently, the sequences (2*3), (2*2), and (2*2) signify the amounts of waste transported from collecting centers to plastic recyclers, glass recyclers, and steel recyclers, respectively. Finally, the last set of genes (3*2), (2*2), and (2*2) represent the unrecovered waste transported from plastic recyclers, glass recyclers, and steel recyclers.

As illustrated in Fig. 3, the first row comprises two elements representing the collecting centers, followed by three elements for plastic recyclers, two for glass recyclers, and the last two elements for steel recyclers. Meanwhile, the second row defines an example of the binary encoding scheme.

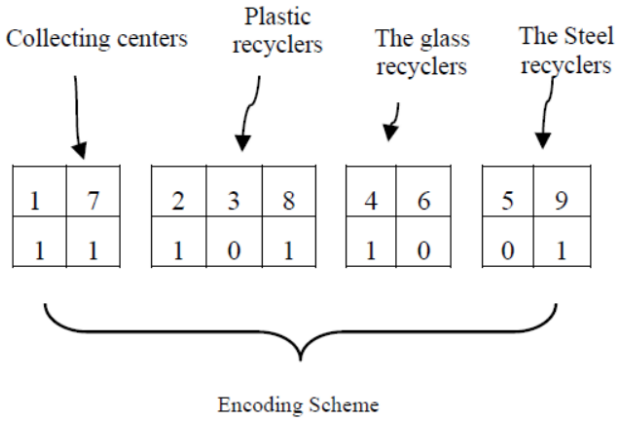

Fig. 3. Example of the binary representation.

In Fig. 4 an example of the floating encoding scheme is defined, the first table represents the Amount N_{ij} of waste generated by the hospital i and shipped to the collecting center j. The subsequent table defines the quantity M_{ijk} of plastic waste k transported from the collecting center i to plastic recycler j. The following table represent defines the quantity P_{ijk} of glass waste k transported from the collecting center i to glass recycler j. The last table represents the quantity R_{ij} of steel waste transported from the collecting center i to steel recycler j.

Quantities of generated waste in hospitals shipped to collecting centers					
N_{11}	N_{ij}	N_{51}	N_{12}	…	N_{52}
6356	…	5438	7685	…	3574

Quantities of waste shipped from collecting centers to plastic recyclers					
M_{111}	M_{ij1}	M_{231}	M_{112}	M_{ij2}	M_{232}
3452	…	1342	5432	…	3572

Quantities of waste shipped from collecting centers to glass recyclers					
P_{111}	…	P_{221}	P_{112}	…	P_{222}
2314	…	1931	3285	…	4362

Quantities of waste shipped from collecting centers to steel recyclers			
R_{11}	R_{21}	R_{11}	R_{22}
1462	965	2563	4362

Fig. 4. Example of floating encoding scheme of solution.

- Select Parent food source

Before testing the performance of integrating the genetic algorithm into the ABC algorithm by applying genetic operators, we need to select two of the best parents obtained by the employed bees solutions using the Tournament selection. These parents contribute to the creation of offspring through crossover and mutation operations.

- The Crossover Operator

After selecting the two best solutions obtained from employed bees as parents, the crossover is applied. Crossover is a genetic operator that combines the genetic material of the two selected parents to generate two new offspring.There are various types types of mutation exist, such as bit-flip mutation, of cross over one-point crossover, multi-point crossover, and uniform crossover in this study we use one-point crossover. A one-point crossover point is randomly chosen along the length of the parent chromosomes, this procedure involves cutting a chromosome at a specific position and switching the ends between the two parents.

- The mutation Operator

After the crossover operation, we apply the mutation operator to the two new offspring obtained. The mutation operator is another genetic operator that involves introducing

small changes to one or more genes in chromosomes. Differents random mutation, inversion mutation, displacement mutation, and swap mutation. In this paper, we apply the swap mutation, where two positions within the permutation are randomly chosen, and the elements at those positions are swapped.This operation helps to improve the exploration of new solotions.

- The new solution update

In this step, we substitute the worst solution acquired from the employed bees with the new offspring. The updated solutions with the information about the quality and location of their food sources are then communicated to the onlooker bees.

4) Onlooker bee phase

- The Probability

In this phase, onlookers utilize the information shared by the employed bees to determine whether the food source should be further explored in search of better solutions or if the food source should be sent to scout bees. The probability of selecting a specific food source for exploration is presented in Eq. (19), where the higher fitness has a higher probability to be chosen.

$$Pi = \left(\frac{fitness_i}{\sum fitness_i}\right) \quad (19)$$

The onlooker bees use the probability Pi to guide the employed bees toward the higher quality areas of solution space.

- Produce new solutions

Following the exploration of solution spaces, we assess the newfound fitness in comparison to the previous fitness. If the new solution provides better fitness, we substitute the previous solution; otherwise, we maintain the previous solution. This iterative process continues until the maximum number of iterations is achieved.

5) Scout bee phase: The bees that fail to demonstrate improvement in their associated food source transition into scout bees. This is because employed bees repeatedly exploring the same food source are no longer discovering useful information.

V. Computational Results

A. GABC Algorithm Parameters

To assess the effectiveness of the proposed GABC algorithm, we applied the Taguchi method [35]. This method is used to determine the optimal combination of GABC algorithm parameters by identifying the factors that influence the performance and effectiveness of GABC algorithm. In this paper, we considered three factors Table I: population size, iteration number, and limit cycle which represents the maximum number of times an employed bee can revisit the same food sources without improvement. Each factor was explored at three levels: 1 for low, 2 for medium, and 3 for high. The next step is to apply the Taguchi orthogonal array (OA) to design a set of experiments covering all combinations of the selected factors. In the proposed model, Table II shows that each parameter is tested across three levels, with three experiments for each level, resulting in a total of 9 tests.

TABLE I. Presentation of Different Factors and Levels

Levels	Population Size	Iterations	Limit cycles
1	60	100	15
2	120	200	20
3	180	300	25

The experiments presented in Table II, using the orthogonal array (OA), generate a series of combinations that aid in identifying the best combination providing the optimal performance for the proposed model among all the obtained combinations.

TABLE II. The Taguchi Orthogonal Array

Experiment	Levels		
	Population Size	**Iterations**	**Limit cycles**
1	1	2	2
2	1	3	3
3	1	1	1
4	2	1	2
5	2	2	1
6	2	3	3
7	3	3	3
8	3	2	2
9	3	1	1

After using orthogonal arrays and conducting experiments at different factor levels, The Signal-to-Noise (S/N) is calculated for each experimental using Eq. (20).

$$S/_N = 10 \log\left(\frac{(mean)^2}{(Variance)^2}\right) \quad (20)$$

Where the meanor signal represents the average performance of the objective function, Variance measures the extent to which each individual number in a set deviate from the mean, or average, of those numbers. In the following section, we will present the best combination obtained by utilizing the orthogonal array (OA) and Signal-to-Noise (S/N) ratio.

B. Numerical Result

The provided problem was implemented in python and executed in an Intel (R) Core (TM) i5-6300U Processor 2.67GHz with 8 GB of RAM.

To proceed with the numerical testing and confirm the efficacy and validity of the proposed model, we are addressing both small and large problems. To account for the uncertainties in the proposed model, we take into consideration different scenarios for each size. As mentioned earlier, studies conducted in the field of medical waste are limited, and most countries prefer not to disclose the actual

situation of generated medical waste. This makes obtaining data somewhat challenging. As mentioned earlier, studies conducted in the field of medical waste are limited, and most countries prefer not to disclose the actual situation of generated medical waste. This makes obtaining data somewhat challenging. To address this challenge, we have reviewed various existing studies in the literature and non-government reports that address the problem of medical waste to collect data. Specifically, we are concentrating on these two studies [36], [37] to gain an idea of the average amount of waste generated by hospitals. In this paper, as illustrated in Table III, we address three types, and for each type, we focus on a specific product.

1) Small problem: For a small problem size, we examined a network comprising 10 nodes. These nodes include four hospitals, two collecting centers (with a requirement for one collecting center to be opened), two plastic, one glass recycler, and one steel recycler, as shown in Table III. To tackle the uncertainties of the waste generated by the hospitals, we considered six scenarios, as illustrated in Table *IV*. The best combination for the different levels of the Taguchi method presented in the last section for the small size plus the genetic parameters are presented in Table V.

2) Large problem: In this part of the problem, we considered a network with 17 nodes, including 8 hospitals, 3 collecting centers (with one required to be opened), 3 plastic recyclers (with one plastic recycler required to be opened), 2 glass recyclers (one of which is required to be opened), and a steel recycler, as shown in Table VII. We considered six scenarios for the quantities of waste generated by hospitals in Table VIII. The Table IX presents the optimal combination for the proposed model using the Taguchi method.

TABLE III. TYPES OF MEDICAL WASTES

Waste types	Characteristic	
Plastic	• Polyethylene (PET) • Polypropylene (PP)	- Some medical containers, - Syringes, medical vials, and other medical containers.
Glass	• White glass • Brown glass	- -
Steel	• Stainless Steel	-

TABLE IV. THE VALUE OF THE PROPOSED MODEL

Set	Value
Hospitals	4
Collection centers	2
Plastic recyclers	2
Glass recyclers	1
Steel recyclers	1
$\boldsymbol{\delta_k}$	5%
$\boldsymbol{\delta_r}$	7,5%

C. Results

In this section, we compare the results obtained by the proposed GABC algorithm and the Artificial Bee Colony algorithm using optimal parameters derived through the application of the Taguchi method. Table VI shows optimal Taguchi method. The primary objective is to maximize positive social indicators in the proposed model, emphasizing the creation of job opportunities while maintaining a balance in economic development. We employed a weighted sum formulation approach, assigning equal weights (0.5, 0.5) to two objective functions, signifying an equal contribution of both objectives to the overall objective function.

For the unemployment rate and region development rate, we explore three different values for both small and large problems, as outlined in Table X and Table XI. Additionally, the assumption is made that all facilities are located within the same region. The economic value is centered on two aspects: cost savings achieved through the recycling of medical waste and revenue generated by purchasing recovered waste for use in creating new products.

1) Results for small problem: To calculate our second objective function, as shown in Table X, it is imperative to quantify the regional development rate. The term 'regional development' includes economic it is imperative to quantify the regional development rate. The term 'regional development' includes economic, environmental, it is imperative to quantify the regional development rate. The term 'regional development' includes economic, environmental, and social progress within a specific region.

The primary goal of regional development is to enhance the overall well-being of the population in that region by addressing economic disparities, improving infrastructure, and promoting address multidimensional poverty rates, where we will examine three different rates of multidimensional poverty.

TABLE X. THE RESULTS FOR SMALL PROBLEM

Unemployment rate	Multidimensional poverty rate	Scenario	GABC			ABC

The results from Table X and Table XI indicate that the solutions obtained by the proposed GABC algorithm are better than the solutions obtained by the original ABC algorithm for the two objective functions. Additionally, the time required to execute the GABC code is longer than that of the ABC, attributed to the hybrid nature of the GABC algorithm, which combines two algorithms. The increased computational time is expected due to this hybridization.

Regarding job creation opportunities, is illustrated in Fig. 5, the value increases as the unemployment rate rises.

In Fig. 6, depicting economic development, we observe the opposite trend: the economic value decreases as the multidimensional poverty rate increases.

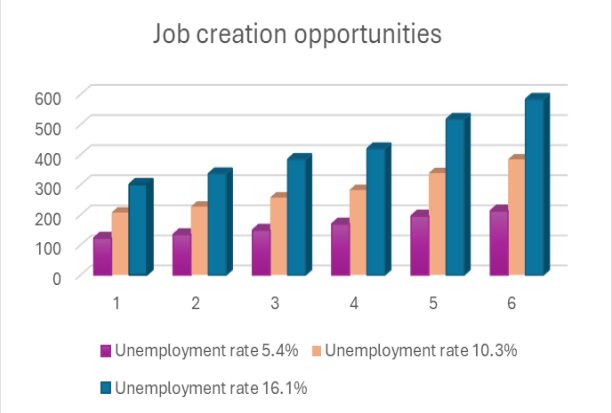

Fig. 5. Small problem comparison for different multidimensional poverty rates.

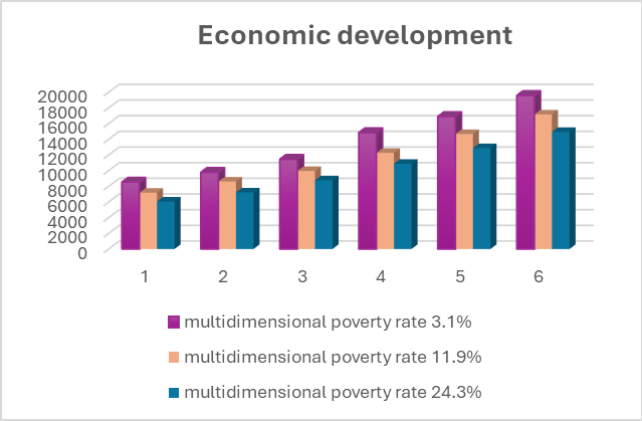

Fig. 6. Small problem comparison for different unemployment rates.

1) Results for large problem: Same as the small problem, for the large problem, the proposed GABC algorithm exhibits better results than those obtained by the ABC algorithm. In the job creation opportunities function for the large problem, there is an increase in regions with rising unemployment rates Fig. 7. This highlights the need for establishing more facilities in regions with high unemployment rates to address the issue. For the balanced economic development function Fig. 8, we observe that the region with higher multidimensional poverty experiences a decrease in economic development.

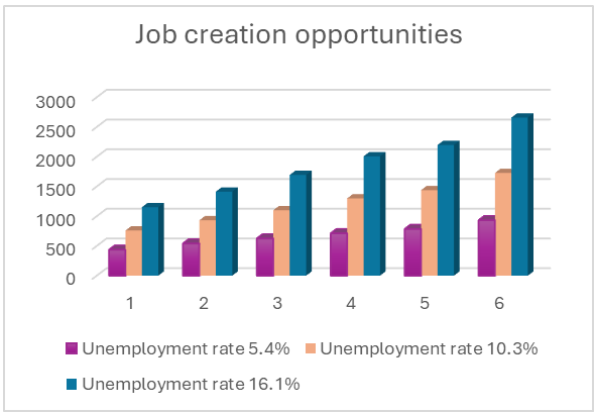

Fig. 7. Large problem comparison for different unemployment rates.

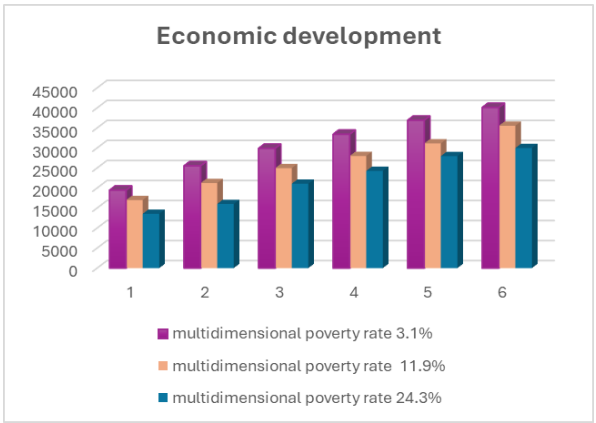

Fig. 8. Large problem comparison for different multidimensional poverty rates.

D. Discussion

In this paper, our objective is to maximize positive social indicators by focusing on job creation and balancing economic value. The results indicate that through the recycling of medical waste, we can generate more job opportunities and promote balanced economic development, thereby reducing social disparities and enhancing overall well-being.

Our research into the literature indicates a scarcity of studies focusing on the social impact of recycling end-of-life products. Specifically, few studies delve into issues such as job creation indicator or the number of days lost due to occupational accidents resulting from the construction of waste processing centers [25], [30], [38]. In light of this gap, our study aims to address the issue of multidimensional poverty, considering it as one of the positive indicators being investigated. Our examination of the existing literature highlights that this study marks the inception of discourse on this topic. The numerical results demonstrate that adopting sustainable practices to preserve natural resources and reuse them, using recycling principles, helps to create more job opportunities. This means decreasing the unemployment rate and multidimensional poverty, ultimately improving the quality of life for people.

VI. Conclusion

In this paper, we illuminate the often overlooked third dimension of sustainability in research, highlighting the significance of maximizing positive social indicators. Our hybrid approach, employing the Artificial Bee Colony (ABC) algorithm and Genetic Algorithm (GA) to tackle two objective functions: enhancing job creation opportunities and promoting balanced economic development. The paper focuses on the reverse supply chain for recycling medical waste, encompassing various stakeholders such as hospitals, collection centers, plastic recyclers, glass recyclers, and steel recyclers. To assess the performance and effectiveness of the proposed GABC algorithm, we conducted a comparative analysis with the ABC algorithm. We subjected the proposed approach to testing in diverse scenarios to simulate real-life situations.

The comparison between the proposed GABC and the original ABC indicates that the suggested approach consistently outperforms in various scenarios studied, providing superior solutions for both job creation opportunities and economic development. This success can be attributed to the nature of the proposed approach, which integrates two algorithms: ABC and GA.

Multimodal Feature Fusion Video Description Model Integrating Attention Mechanisms and Contrastive Learning

Wang Zhihao*, Che Zhanbin
School of Computer Science, Zhongyuan University of Technology, Zhengzhou, China

***Abstract*—To avoid the issue of significant redundancy in the spatiotemporal features extracted from multimodal video description methods and the substantial semantic gaps between different modalities within video data. Building upon the TimeSformer model, this paper proposes a two-stage video description approach (Multimodal Feature Fusion Video Description Model Integrating Attention Mechanism and Contrastive Learning, MFFCL). The TimeSformer encoder extracts spatiotemporal attention features from the input video and performs feature selection. Contrastive learning is employed to establish semantic associations between the spatiotemporal attention features and textual descriptions. Finally, GPT2 is employed to generate descriptive text. Experimental validations on the MAVD, MSR-VTT, and VATEX datasets were conducted against several typical benchmark methods, including Swin-BERT and GIT. The results indicate that the proposed method achieves outstanding performance on metrics such as Bleu-4, METEOR, ROUGE-L, and CIDEr. The spatiotemporal attention features extracted by the model can fully express the video content and that the language model can generate complete video description text.**

Keywords*—Multimodal feature fusion; video description; spatiotemporal attention; comparative learning

I. INTRODUCTION

Video description is a field of deep learning with practical value, and it has application value in areas such as assisting visually impaired individuals in accessing video content and video content analysis. When dealing with video content from real life, video description models require complex preprocessing steps, such as frame extraction and normalization operations, followed by feature extraction, and finally, the transformation of these features into linguistic descriptions. In this process, the model must not only delve into the semantic content of the video but also establish precise correspondences between visual and textual information to generate accurate descriptions [1]. However, due to the excessive redundancy in video data and the vast semantic gap between modalities, it is challenging for models to establish a unified representation of these modalities and to capture key information accurately for detailed descriptions.

To address the aforementioned issues, this paper proposes a two-stage multimodal feature fusion method. In the first stage, the TimeSformer encoder [2] is employed to extract spatiotemporal features from the input video. The TimeSformer is a transformer-based model for video action recognition that effectively captures spatiotemporal features within videos. The model generates video vectors rich in semantic features by dividing video frames into non-overlapping blocks and applying attention mechanisms in both temporal and spatial dimensions. After spatiotemporal feature extraction, these vectors undergo feature selection and are used as visual cues input into the GPT-2 model to generate video descriptions. This paper employs a contrastive learning approach in the second stage to align video embeddings with text embeddings in the latent space. Video-text contrastive learning is an effective training method that minimizes the semantic differences between different modalities by pulling closer the representations of the same entity across modalities and pushing apart the representations of different entities. This method enhances the similarity between the features output by TimeSformer and the corresponding textual descriptions. Experimental evidence suggests that the scheme incorporating contrastive learning is easier to train than the one that fine-tunes TimeSformer directly with video descriptions without contrastive learning. This ease of training may be attributed to the reduced involvement of generative methods, which typically require more extensive training time when contrastive learning is not employed.

This paper conducts comparative experiments to validate the effectiveness of the proposed model, and the results indicate that the proposed model achieves state-of-the-art results on the MSVD, MSR-VTT, and VATEX datasets. Compared to existing models, the text generated by this model is capable of providing a comprehensive description of video content and is straightforward to train. The contributions of this paper are as follows:

1) This paper proposes a two-stage multimodal feature fusion method that combines spatiotemporal attention with contrastive learning, efficiently integrating and utilizing temporal, visual, and textual features.

2) Within the training process, this paper conducts feature selection on spatiotemporal features to prevent redundant information from entering the language model, which could otherwise interfere with text generation.

3) Experimental evidence demonstrates that our method can effectively comprehend and describe the rich multimodal information within videos, achieving advanced results compared to similar models in the field.

This research was funded by Key Technology Research and Demonstration Application of News Intelligent Production (212102210417), Science and Technology Plan of Henan Province in 2021.

II. Related Work

When processing videos, video descriptions require the extraction of temporal information, image information, and other modal information from the video. These data are then multimodal fused to build a joint representation between modalities. The resulting representation serves as visual cues input into a text model to generate textual descriptions. This section discusses related work from spatiotemporal feature extraction and multimodal feature fusion perspectives.

A. Spatiotemporal Feature Extraction

In video description tasks, models must be capable of extracting temporal and spatial features from the video content. For temporal feature extraction, common methods include 3D Convolutional Neural Networks (CNN) and optical flow-based networks. As for spatial features that pertain to image characteristics, one can utilize popular pre-trained image feature extraction networks such as ResNet [3] and Vision Transformer [4].

DC-RL [5] employs a 3D CNN to model temporal features and concatenates these features with image features obtained from a pre-trained image encoder using an LSTM. However, this approach may yield little improvements over previous methods. This is because of the inherent locality of 3D neural networks, which limits their ability to learn long-term temporal dependencies. Moreover, LSTM are prone to vanishing or exploding gradients when dealing with long sequences of input temporal information, making them difficult to train effectively.

MA-Net [6] employs the Inflated 3D (I3D) [7] network to model temporal relationships and constructs semantic feature vectors from the textual descriptions of the video. These semantic feature vectors are then used alongside the video feature vectors for semantic detection, aiming to bridge the gap between the semantic video features and the actual semantic content of the video. I3D expands pre-trained 2D CNN into 3D CNN by "inflating" their 2D filters into 3D filters, allowing the network to capture spatiotemporal information in video data. Experimental results have shown improvements compared to DC-RL. However, it does not overcome the drawbacks of CNN, which fails to model long-range temporal information, and the extracted video features cannot fully represent the content of the video.

This paper addresses the issues above by employing TimeSformer. TimeSformer divides the video into non-overlapping spatial and temporal patches. It then applies attention mechanisms between patches that belong to the same spatial location but different time points and between patches from different spatial locations but the same time point. This approach enables efficient extraction of temporal and spatial features across the entire video, making it highly suitable for video description models.

B. Multimodal Feature Fusion

Videos are composed of multimodal data, including visual, audio, and textual components, each containing a vast amount of information accompanied by noise and uncertainty. To accurately describe the content of videos, it is necessary to employ multimodal feature fusion techniques to achieve complementarity and verification between different modalities. This approach facilitates a comprehensive understanding and analysis of video content, enhancing the accuracy and reliability of information processing. When performing multimodal feature fusion, common strategies include the following: (1) Data Fusion: This strategy involves combining information from multiple modalities through operations such as concatenation, addition, and multiplication and then passing the integrated data to subsequent processes. The advantages of this approach are its simplicity and the absence of the need for additional training methods. However, it may also lead to information redundancy or the inability to leverage complex modality information. (2) Neural Network Fusion: This strategy involves using neural network methods to jointly encode multimodal information based on data fusion or directly accepting multimodal inputs. For instance, the cross-attention mechanism in Transformer[8] utilizes self-attention to relate and fuse information from different modalities. The Feature Pyramid Network (FPN)[9] achieves fusion by constructing feature maps at different scales, which allows for information integration at various levels, thereby enhancing the performance of object detection tasks.

Fu et al. [10] have utilized the attention mechanism to query the relationship between object detection and action features, establishing a subject-verb relationship from a grammatical perspective and generating text accordingly. The primary benefit of this approach lies in the generation of coherent textual output. However, this grammar-based method has limitations in terms of text generation diversity. Since it focuses on establishing accurate grammatical structures, the generated text often follows similar sentence templates, which can lead to stiff and repetitive expressions in language. Moreover, in Fu's work, action features extracted by 3D neural networks fail to capture long-distance temporal information, which can lead to the model that is incapable of fully describing the semantics of the video.

The work by Ren et al. [11] is similar to the present study, as it also employs an attention mechanism to integrate spatiotemporal features. Additionally, they designed a semantic enhancement network to learn the latent semantic information of object features. However, in fusing visual-textual features, they utilized Long Short-Term Memory networks (LSTM). LSTM is a type of recurrent neural network (RNN) that is capable of handling sequence data and can remember long-term dependencies. In their work, LSTM networks were employed to process textual information, obviating the need to add position vectors within the attention mechanism. Position vectors are commonly used in attention mechanisms to ensure the model can understand the order of elements in the input sequence. Although LSTM networks have certain advantages in processing sequence data, it also have limitations, particularly when dealing with long-distance dependencies. LSTM networks may encounter issues with vanishing or exploding gradients, limiting its effectiveness in modeling long-distance dependencies between elements in long sequences.

To address the aforementioned issues, this paper employs a Visual-Text Contrastive (VTC) learning method to align the spatiotemporal features output by TimeSformer with textual

features. By analyzing the similarities and differences between data samples, VTC can discern the relationships and discrepancies between spatiotemporal and textual features, ensuring that semantically similar spatiotemporal features remain close to their corresponding textual features in the latent space. This facilitates the ability of feature mapping module to map spatiotemporal features to textual laten spaces and makes it possible to generate textual descriptions via GPT2[12]. This approach allows the model to learn a complete representation of spatiotemporal features and generates accurate textual descriptions.

III. METHODOLOGY

When processing videos, TimeSformer first applies an attention mechanism in both temporal and spatial dimensions to extract spatiotemporal features of videos. Subsequently, this paper utilizes a fully connected network to map the spatiotemporal features into a feature sequence, adapting them for input into the Transformer Encoder, the mapping network. In preparation for the input to the Transformer Encoder, a learnable vector of length τ was concatenated to the video feature sequence to screen the sequence and prevent the inclusion of redundant information. The learnable vector, which can be referred to as a visual prompt, is then input into the language model for decoding, yielding a textual description of the video. During the training process, the semantic gap between video and text features poses a significant challenge. To address this issue, the paper introduces a Video-Text Contrastive Learning module, which aligns video and text features in the semantic space. Fig. 1 depicts the structure of the entire model.

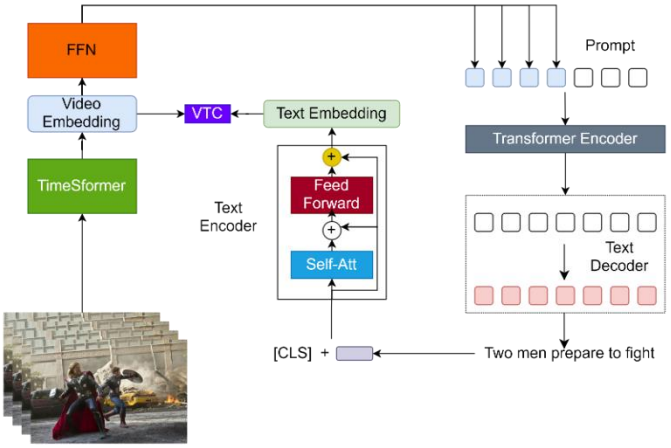

Fig. 1. Overall structure diagram.

A. Spatiotemporal Attention-based Feature Fusion

To fully comprehend video content, it is necessary to integrate both spatial and temporal information. In traditional 3D CNN, convolution operations are performed simultaneously across both temporal and spatial dimensions, allowing the model to capture spatiotemporal features within the video. However, 3D convolution operations are computationally intensive, leading to slower training and inference speeds for the model. To overcome this limitation, TimeSformer organizes the temporal and spatial dimensions into multiple video patches and performs attentional interactions on them separately, incorporating attention mechanisms into video understanding tasks. This approach has achieved outstanding results in the field of action recognition.

This paper employs TimeSformer to extract spatiotemporal features from videos. After preprocessing, a video is mapped into multiple non-overlapping patches through a linear layer, which is then input into the spatiotemporal feature extraction network, as illustrated in Fig. 2.

The output can be represented as $\{v_1, v_2, \ldots, v_\phi\}$, where $v_i \in R^{H_{video}}$ and ϕ denote the number of video patches. During the training of TimeSformer, the learnable vector CLS^{video} at the head of the video patch sequence is randomly initialized and incorporates the embedding representation of the entire video throughout the training process. In subsequent modules, the paper primarily uses CLS^{video} as the video feature for computation.

B. Visual Prompt Based on Contrastive Learning and Feature Selection

In the training process, the input video is first mapped using a linear layer to extract the embedded representation of the video. These representations capture the temporal and visual features between video frames. Subsequently, these video embeddings are concatenated with a learnable query vector of length τ and jointly input into a Transformer Encoder. The role of the query vector is to select the relevant features of the video that need to be described and filter out irrelevant information. Next, the query vector is used as a prompt and input into the GPT2 model.

Since the prompt already contains the necessary semantic information, the language model can generate readable text based on this prompt vector. This approach has been applied in

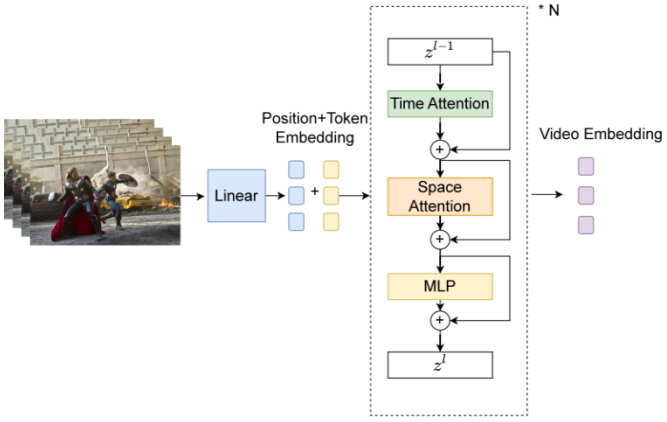

Fig. 2. TimeSformer architecture diagram.

the work by Zhou et al. [13]. However, a significant gap often exists between the vector spaces of video and text embeddings, even when they may be semantically related. This discrepancy makes it challenging to train directly using these embeddings. To address this issue, the paper introduces a contrastive learning approach. Contrastive learning aims to bridge the gap between visual and text embeddings in the

semantic space, even if they are far apart in the original space. By doing so, the model can learn how to map video content to relevant textual descriptions more easily, facilitating the training process.

Suppose the data consists of a dataset $\{V_i, T_i\}_{i=1}^{N}$ of N video-text pairs, where V represents the video and T corresponds to the associated textual description. Since GPT2 accepts input as a sequence of tokens, the paper maps the CLS^{video} obtained from TimeSformer to a sequence of video patches. Its formal representation is given in Eq. (1).

$$p_1, p_2, p_3, \ldots p_L = FFN(TimeSformer(CLS_{video})) \tag{1}$$

where, p_i is a one-dimensional vector of length H. In this paper, the hidden layer vectors for video and text are the same, set to 768.

During training, the paper concatenates the video patch vectors $\{p_1, p_2, p_3, \ldots p_L\}$ with randomly initialized learnable vectors $\{q_1, \ldots q_\tau\}$. It is then fed into the Transformer Encoder to obtain $\{p_1`, p_2`, p_3`, \ldots p_L`, q`_1, \ldots q`_\tau\}$, where L and τ are hyperparameters, with τ representing the length of the prefix.

The training objective is to predict the tokens autoregressively conditional on the prompt. The generation of the text loss objective can be described by the Eq. (2). The true distribution I_l is an indicator distribution that takes the value of 1 for the correct token t_l and 0 for all other tokens.

$$loss_{token} = -\sum_{i=1}^{L} \log p_\theta(t_1, \ldots, t_L \mid q`_1, \ldots q`_\tau) \tag{2}$$

In contrastive learning, the paper uses the CLS token as the video representation directly, which is paired with the text features extracted by BERT for contrastive learning. Similarly, the text feature utilizes BERT's CLS token, CLS^{text}, with the shape of R^H. The loss function is as follows in Eq. (3), where γ is the temperature parameter, taking the value of 0.07.

$$loss_c = -\log \frac{exp(CLS^{video} \cdot CLS^{text}{}_{+} / \gamma)}{\sum_{i=0}^{k} exp(CLS^{video} \cdot CLS^{text}{}_{i} / \gamma)} \tag{3}$$

IV. Experimental Verification

A. Dataset

In this paper, the experimental verification is carried out on three public datasets: MSVD, MSR-VTT, and VATEX

The Microsoft Research Video Description Corpus (MSVD) dataset [14] is widely used in video understanding models. Introduced by Microsoft Research in 2016, it is designed for video description generation, which automatically produces natural language descriptions for video clips. The dataset comprises 1,970 video segments, each accompanied by multiple English descriptions written by different individuals. The videos in the MSVD dataset are primarily sourced from YouTube and cover a variety of genres, including music videos, movie trailers, television shows, and more.

The Microsoft Research Video to Text [15] (MSR-VTT) dataset is another widely used dataset in video understanding models. Proposed by Microsoft Research in 2016 is also designed for video description generation, where the goal is to produce natural language descriptions for video clips automatically. This dataset comprises over 10,000 video segments, each with at least one English description. The videos in the MSR-VTT dataset are primarily sourced from YouTube and encompass a variety of genres, such as music videos, movie trailers, television shows, and more.

The Video-and-Text EXchange (VATEX) dataset[16] is a large-scale video description and subtitle dataset that contains multimodal information including video, audio, and text data. It is characterized by its vast scale, comprising over 250,000 pairs of videos and subtitle descriptions, covering multiple languages, with a particular focus on Chinese and English. The data is sourced from various scenes, including movies, TV series, news broadcasts, variety shows, and more, which results in a highly diverse dataset in both content and language.

B. Experimental Setup

All experiments were conducted using the PyTorch deep learning framework on two GTX-3090 GPUs. The model employed Adaptive Moment Estimation (Adam) as the optimization strategy and used the cross-entropy function as the loss function for back propagating gradients. The weight decay parameter was set to 0.009. The learning rate was scheduled using an inverse time scheme, as shown in the Eq. (4), where ò was set to 0.5, and the initial learning rate r was set to 0.01.

$$r_{new} = \frac{r}{1 + ò * step} \tag{4}$$

In the MSVD dataset, a total of 14,910 steps were trained with a batch size of 16; in the MSR-VTT dataset, a total of 25,320 steps were trained with a batch size of 8; and in the VATEX dataset, a total of 113,350 steps were trained with a batch size of 6.

C. Comparative Experiments

The proposed model is compared with state-of-the-art methods. MA-Net[6] attempts to construct semantic feature vectors from the textual description of videos, which are then used in conjunction with video feature vectors for semantic detection, to bridge the gap between semantic video features and the actual semantics of the video. However, the I3D network employed by the authors cannot model long-range temporal relationships.

MGRMP [17] proposes a recurrent regional attention module to extract diverse spatial features better and establish higher-order relationships between different regions across frames through motion-guided cross-frame message passing.

Uni-perceiver [18] attempts to create a unified model architecture that can flexibly handle multiple modalities of data without training separate models for each modality or task.

Fu Yan et al. [10] proposed a video description method based on the syntactic analysis of object features in scene representation. This method utilizes an object feature detector and constructs a grammar to generate textual descriptions.

Swin-BERT [19] successfully adapted the Swin Transformer [20] to the video description field and achieved promising results. However, it needed to address the significant semantic gap between video and text representations, leading to the protracted training process and failing to yield satisfactory results.

GIT [21] also attempted to model images, videos, and text using a unified network. However, video content merely relied on concatenating video frames without adequately learning the temporal features.

The evaluation metrics used are Bleu-4, METEOR, ROUGE-L, and CIDEr.

The performance of MFFCL on the MSVD dataset is presented in Table ITABLE I. In this work, we introduce a contrastive learning method in addition to Swin-BERT [16], which enables semantic alignment between videos and text. This method is easier to train than text generation tasks and has achieved promising results. Our approach outperforms Swin-BERT with 17%, 6%, and 18% improvements in Bleu-4, ROUGE-L, and CIDEr scores, respectively.

Unlike the MSVD dataset, the MSR-VTT dataset contains a richer set of scene information. TimeSformer is trained on human action recognition datasets. When the video has a lot of non-human behavior information, such as camera movements or birds flying, these details may act as noise for the MFFCL model, potentially leading to a degradation in performance. However, TimeSformer not only extracts features along the temporal dimension but also thoroughly learns video representations in the spatial dimension. Consequently, even in complex video scenes, MFFCL still achieves commendable results. In the work by Wang [22] et al. LSTM were employed for text generation. A limitation of this approach is that the length and coherence of the generated text are constrained. In contrast, our work utilizes GPT2 as the text generation model. During the text generation process, we randomly select from a set of p high-probability words, which allows for the generation of diverse and coherent texts. Compared to the method proposed by Wang et al., our approach demonstrates improvements of 4%, 3%, 9%, and 5% in Bleu-4, METEOR,

TABLE I. PERFORMANCE OF MFFCL ON THE MSVD DATASET

Model	Year	Bleu-4	METEOR	ROUGE-L	CIDEr

TABLE III. PERFORMANCE OF MFFCL ON THE VATEX DATASET

Model	Year	Bleu-4	METEOR	ROUGE-L	CIDEr
GIT[21]	2021	41.6	28.1	55.4	91.5
Swin-BERT[19]	2022	38.7	26.2	53.2	73.0
MFFCL	2024	**50.2**	**35.3**	**65.6**	**100.2**

ROUGE-L, and CIDEr scores, respectively. The specific data are shown in Table II.

While constructing the VATEX dataset, the authors extensively reused videos from the Kinetics-600 dataset[7], resulting in a rich presence of human actions. TimeSformer can fully model spatiotemporal features and accurately recognize action information, thus achieving significant results on VATEX. As mentioned earlier, Swin-BERT lacks the contrastive learning module used in this paper, which may lead to insufficient training. The GIT model, which is not specialized for video data, is less effective in temporal feature extraction than ours. Compared to GIT, our approach shows improvements of 20%, 25%, 18%, and 9% in Bleu-4, METEOR, ROUGE-L, and CIDEr scores, respectively. The specific data are given in Table III.

D. Ablation Experiments

To validate the effectiveness of the modules, this paper conducts ablation studies on the model from three aspects: the contrastive learning module, the mapping module, and the prompt length.

In the learning process of the contrastive learning module, the TimeSformer was fine-tuned using only textual descriptions. During the experiment, it was observed that the improvement in evaluation metrics was very slow. Even doubling the training time on the MSVD dataset did not yield satisfactory results. This could be due to the fact that the text generation task, which relies on contrastive learning, requires more advanced GPUs, and our experimental setup may not meet the training requirements.

TABLE IV. ABLATION EXPERIMENTS WITH CONTRASTIVE LEARNING

Contrastive Learning	Prompt Length	Bleu-4	METEOR	ROUGE-L	CIDEr
√	10	32.6	19.6	39.3	52.6
√	30	60.8	36.6	42.1	82.3
√	50	68.4	40.2	82.6	142.3
×	30	52.3	34.1	69.8	80.3
×	50	52.3	34.1	69.8	80.3

The results of the ablation study are presented in Table IV, the contrastive learning module structure is shown in Fig. 4. The model structure without the contrastive learning module is shown in Fig. 3.

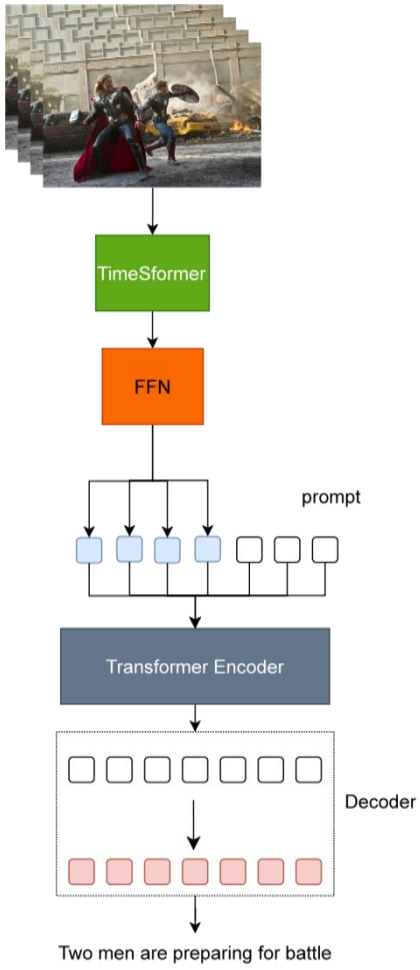

Fig. 3. Overall structure diagram without contrastive learning.

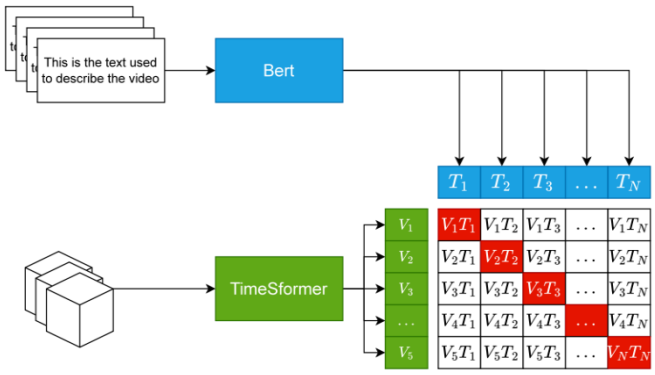

Fig. 4. Contrastive learning module structure.

Regarding the prompt length, it was noted that as the prompt length increased, the amount of information the model could accommodate increased, thereby enhancing its descriptive capabilities. It is believed that longer prompts can fully extract video representation information, which helps the model to understand and describe video content more accurately. However, excessively long prompts may complicate the training process and be limited by device performance and computational resources in practical applications. Experiments have demonstrated that the model can learn the correspondence between videos and texts through contrastive learning, bringing the representations of videos and texts closer in the feature space. This alignment aids the model in better understanding the video content and generates accurate descriptions based on the video embeddings.

To investigate the importance of the understanding mapping module, this paper replaces the Transformer Encoder with a Feedforward neural networks (FFN) to observe changes in the model's performance. Global Linguistic Evaluation Understudy (GLEU) was chosen as the activation function for this setup. Since feedforward neural networks do not contain attention mechanisms, the query vector is removed from the input, and the video block sequence is fed directly into the FFN.

The experimental results indicate that the model's performance decreases when the query vector is absent. This suggests that the query vector has learned a proficient video representation, which aids the model in focusing on the most relevant parts of the video and generates more accurate and coherent text descriptions. Furthermore, experimental results indicate that although feedforward neural networks can learn the mapping between video and text to some extent, their performance does not match that of the Transformer Encoder. The experimental results are presented in Table V.

TABLE V. ABLATION EXPERIMENTS OF THE MAPPING MODULE

Mapping Module	Bleu-4	METEOR	ROUGE-L	CIDEr
Transformer Encode	68.4	40.2	82.6	142.3
FFN	52.3	34.1	69.8	80.3

E. Qualitative Analysis

In this paper, a qualitative analysis of TimeSformer was conducted from the perspective of attention weights. During the execution of TimeSformer, the spatial attention weights were obtained and visualized after being weighted with the original images. The results are shown in Fig. 5. It can be observed that TimeSformer effectively extracts the spatiotemporal representation of the video and adjusts its focus to be similar to human visual attention through the two-stage learning tasks of video-text learning and text generation learning.

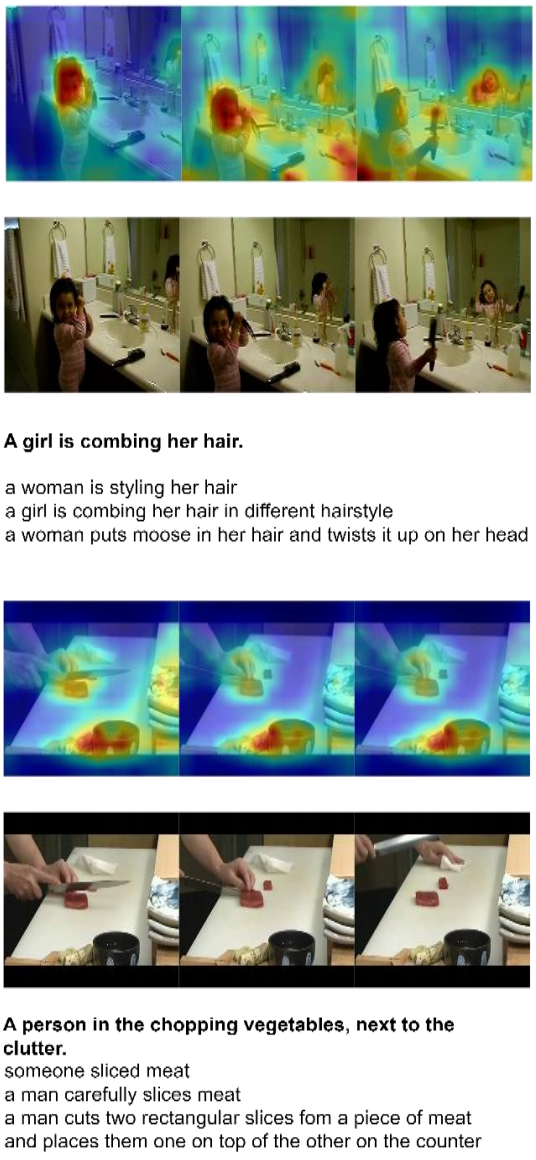

Fig. 5. The image illustrates the ablation results from the MSVD dataset. In each example, the top image represents a schematic of the attention weights, with darker colors indicate higher attention weights. The bottom image shows the original image. The bold part in the text corresponds to the model's output, while the non-bold part represents the dataset labels.

V. CONCLUSION

In the field of multimodal video description, effectively integrating temporal sequence information, visual imagery, and textual descriptions from videos is a worthwhile area of research. To address this challenge, this paper proposes a novel two-step fusion strategy designed to achieve a more precise and coherent understanding and description of video content through an efficient model architecture and training mechanism.

This paper employs TimeSformer, an advanced spatiotemporal feature extractor, in the first stage. Its unique network design for spatiotemporal feature extraction enables it to capture long-range temporal dependencies while preserving spatial details. In the second phase, the focus is on aligning video representations with text representations through contrastive learning. The core principle of contrastive learning is to minimize the distance between positive samples and maximize the distance between negative samples, thereby fostering similarity between video and text representations in the latent space. This study fine-tunes the TimeSformer through carefully designed contrastive tasks to produce video features that are more similar to textual features, prompt the model to generate more accurate video descriptions.

Compared to the Swin-BERT model on the MSVD dataset, our method achieves substantial improvements of 17%, 6%, and 18% on the critical evaluation metrics Bleu-4, ROUGE-L, and CIDEr, respectively. Experimental results confirm the efficacy of the method presented in this paper. TimeSformer is capable of fully representing video content in both temporal and spatial dimensions. The visual prompt also serve to filter out redundant features, while the contrastive learning module accelerates the training process of the TimeSformer.

Future researchers can focus on developing more advanced multimodal fusion techniques to enhance the model's understanding of context and long-term dependencies. Utilizing large-scale, diverse datasets and weak supervision learning can also be explored. Additionally, researching the field of dense video description are potential avenues for advancement.

Permanent Magnet Motor Control System Based on Fuzzy PID Control

Yin Sha*, Huwei Chen
Industrial Motor-Driving Center of Intelligent Network-Connection, Jiangyin Polytechnic College, Jiangyin, 214400, China

***Abstract*—Although the traditional permanent magnet synchronous motor control system is simple and convenient, the control of speed and accuracy is often affected by external interference, which impacts the dynamic and static performance requirements. Therefore, this study attempts to introduce fuzzy rules to improve the proportional integral differential control method, and further integrate intelligent optimization algorithms into the fuzzy proportional integral differential control method to construct an efficient and feasible permanent magnet synchronous motor control method. The simulation experiment demonstrates that under fuzzy proportional integral differential control, there is no overshoot in the waveform when facing changes in load, and the tuning time increases from 0.01 seconds to 0.12 seconds. The steady-state error of speed control is small, and there is no obvious oscillation in the waveform. Fuzzy control enhances the control system. After the optimization of the artificial bee colony algorithm, the control system has a faster speed response, with the overshoot diminished from 11.2% to 3.1%, and the adjustment time reduced from 0.27 seconds to 0.19 seconds, enhancing its adaptability. Under load regulation, the optimized control system speed response curve responds in a timely manner without obvious overshooting and oscillating changes. Optimizing variable universe fuzzy proportional integral differential control enables the control system for having better static and dynamic performance, and enhances the adaptability and follow-up of the control system. The current curve starts to stabilize at 0.04s, overcoming the control system oscillations early. The speed response curve and the motor torque curve are improved by the optimized variable domain theory, and the amount of overshoot is significantly reduced. The research and design of a permanent magnet motor control system has practical significance for improving the application performance and adaptability of permanent magnet motors.**

Keywords*—*Permanent magnet motor; fuzzy PID; fuzzy control; automatic control system; artificial bee colony

I. Introduction

Permanent magnet motors (PMM) are a product of the integration of multiple disciplines such as materials science, electronic science, and power control technology. Their development is closely related to the emergence of permanent magnet materials, especially the efficient and energy-saving rare earth permanent magnet materials, which have greatly promoted the development process of PMM. Permanent magnet materials replace electromagnetic induction to generate a working magnetic field, and the initial application of PMM was mainly concentrated in high-end special fields such as aerospace; With the emergence of neodymium iron boron permanent magnet materials and the promotion of power electronics technology, PMM are developing towards high speed, high energy, and miniaturization; PMM have significant characteristics such as simple structure, reliable operation, lightweight volume, low loss and high efficiency. The application of PMM has gradually expanded to industrial, agricultural, and civilian fields, becoming the preferred motor for driving systems, penetrating into the production of home appliance systems, medical devices, CNC machine tools, new energy vehicles, and even the military industry [1-2]. Under the background of vigorously advocating the transformation and upgrading of manufacturing industry, energy conservation and emission reduction, and Low-carbon economy, PMM have prominent energy-saving characteristics and become a research hotspot.

Permanent Magnet Synchronous Motor (PMSM) is a category of PMM. It has obvious advantages. It is the first motor of AC servo system. The research on PMSM control technology is very important. The traditional control method of PMSM control system (CS) adopts Proportional Integral Derivative Control (PID). PID control is a kind of earlier control strategy, with simple control algorithms and high reliability. Therefore, it is extensively utilized in industrial process control [3-4]. However, for the production of actual industrial processes, the modeling accuracy of PID control is low, the stability of control parameters is poor, and the adaptability to actual operating conditions is insufficient [5].

In view of this, to meet the more effective control strategy requirements of PMSM systems, this study first introduces fuzzy algorithms and uses fuzzy rules to adjust the PID control process; Secondly, on the basis of fuzzy PID control, further incorporating the Artificial Bee Colony Algorithm (ABC) to improve fuzzy PID control; This control algorithm is expected for further enhancing the control performance of PMSM and adjust the speed CS of PMSM. The study introduces the variable domain fuzzy control theory and intelligent optimization algorithm to improve the control accuracy of fuzzy PID control, which enriches the theoretical study of fuzzy PID control, fuzzy algorithm and intelligent optimization algorithm, and improves the research and application level of the corresponding technology; meanwhile, this control algorithm can further enhancing the control performance of the PMSM, and adjust the speed control system of the PMSM.

The research is separated into five. The first is a review of the late research status in the field of control both domestically and internationally; The second proposes a PMSM CS control algorithm in view of fuzzy PID and an improved fuzzy PID control model in view of ABC algorithm; The third tested and simulated the function; the fourth section discusses the

research work and future research directions. The fifth summarizes and summarizes the experimental outcomes of the study.

II. Related Works

The research on PMM mainly focuses on the optimization design of permanent magnet materials, control algorithms, and motor structures. With the rapid development of more intelligent tools and applications, the control requirements for PMM are also increasing. To achieve higher control accuracy, faster response, and better stability, lots of researchers have carried study about the control algorithms of PMM and general control algorithm problems. The uncertainty, time-varying, and nonlinearity of the PMSM AC servo system make the control effect of traditional control methods not ideal; To solve this problem, Zhong CQ et al. utilized the strong adaptability of fuzzy control (FCO) to the controlled object and designed a PMSM three closed-loop system. Fuzzy logic algorithm was introduced to adjust the parameters of the fractional order proportional integral differential controller, and the complementary advantages of the two algorithms were reasonably achieved; The experiment demonstrates that the control algorithm can effectively satisfy the trajectory tracking needs of PMSM servo control, and the control algorithm is effective [6]. Jakovljevi ć B et al. studied fractional order and distributed order PID controllers of PMSM, and introduced parameter setting and tuning of generalized Particle swarm optimization (PSO) controller. Then they proposed a new dual loop control method for controlling PMSM drivers; The experiment showcases that this control scheme can effectively suppress interference compared to traditional control methods [7]. Zeng X et al. designed a current control method for PMSM drivers, which includes decoupling term, adaptive proportional integral term, supervision term, and radial basis function neural network PID term. This adaptive controller in view of gradient descent strategy can adjust the parameter uncertainty of any system, ensuring the accuracy and efficiency of PMSM tracking speed. The comparative experiment outcomes showcase that relative to traditional proportional integral differential control methods, it achieves better control stability [8]. To realize the tradeoff between the performance of the uncertain model and the robust performance, Amieur T et al. designed a tilted PID controller. The controller introduced an optimization tool - genetic algorithm to solve the sensitive problem of controller weighting mixing, and optimized the parameters. For testing the controller, the tilted PID controller was applied to PMSM, and its performance and robustness were made a comparison with traditional PID control. The experiment showcases that the robustness and reduction of control energy of this control method are excellent [9].

Ghadiri H et al. combined fuzzy Evolutionary algorithm with PID controller for controlling the speed of PMSM. And PSO algorithm is utilized for optimizing the member function parameters and the relevant rule basis. Compared with the optimized controller, the controller in view of PSO algorithm shows greater advantages in speed control [10]. Lazim M H et al. used proportional integral differential control with two internal and one external feedback loops for optimizing the design performance of PMSM in speed control, and used genetic algorithms to optimize the controller parameters. The results of MATLAB simulation experiments indicate that this control method has good dynamic and static quality [11]. Abdulhussein K G et al. used butterfly optimization algorithm and PSO algorithm to calculate the gain value of cascade proportional integral differential control method. The controller mainly controls the position, speed, current and tracking trajectory of permanent magnet DC motor. The simulation outcomes of MATLAB showcase that the optimization performance of butterfly optimization algorithm is better than that of PSO [12]. Zhang R designed a design method of anti-saturation PID current controller for enhancing the dynamic current response speed of PMSM. The experiment illustrates that this control method is more accurate in controlling current than traditional controllers, and the dynamic current response performance has been improved [13].

In summary, although research on the CS of PMSM has made certain progress, the control efficiency and accuracy of PMSM in different fields still need to be improved, and the research on PID CSs combined with intelligent algorithms still needs further deepening; This is to design a CS for PMSM with more adaptability.

III. Design of PMM CS in View of Improved Fuzzy PID

PMSM is composed of three basic parts: rotor, stator, and permanent magnet. It relies on the interaction between the rotating magnetic field generated by the stator and the spindle magnetic field for generating electromagnetic torque for deriving the rotor to rotate, achieving the conversion of electrical energy. To ensure the normal operation of PMSM in the servo system, the speed index is an important indicator for evaluating the performance of PMSM. Therefore, it is essential for conducting research on the adaptive control of the PMSM speed CS. This study introduces the ABC algorithm into the fuzzy PID CS and conducts a series of studies on the PMSM CS.

A. Fuzzy PID Control in View of ABC Algorithm Optimization

FCO is a comprehensive intelligent control mode. It draws lessons from the principles of fuzzy reasoning and decision-making. Utilizing the experience of industry experts to develop fuzzy rules, the real-time signals transmitted by sensors are fuzzified and used as input to the fuzzy rules, and the completed fuzzy reasoning is then transmitted to the actuator [14-15].

Fuzzy Controller (FC) uses fuzzy conditional statements of fuzzy theory to describe fuzzy rules. The structure of fuzzy controller is demonstrated in Fig. 1. Among them, the fuzzy Inference engine is the core of the algorithm. According to the knowledge base to solve the fuzzy relationship, the solution method used in the study is the Mamdani method. The database contains membership vector values of fuzzy subsets of input and output variables. The rule base summarizes the control statements of fuzzy rules in view of the experience of experts, and continuously summarizes the control laws during the control process before adding them to historical experience. Finally, the weighted average method is used to convert the

inference fuzzy quantity into an accurate quantity.

The actual CS does not meet linear invariance and requires dynamic adjustment of PID control parameters. This study introduces FCO and its combination, taking deviation and changes in deviation as inputs, and uses fuzzy rules to adjust the parameters of PID to meet the different needs of deviation for PID parameters. Fig. 2 indicates the control principle of fuzzy PID.

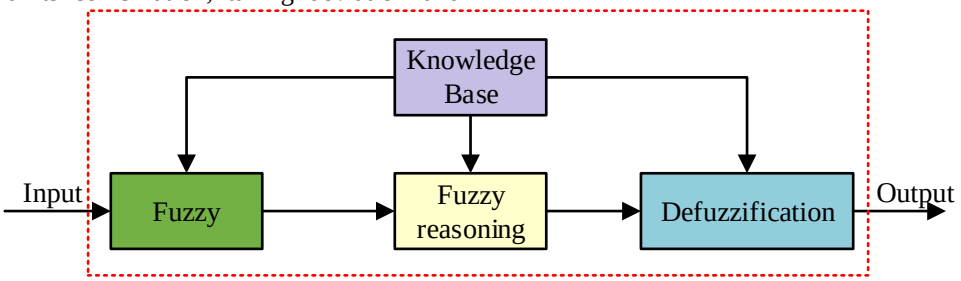

Fig. 1. Fuzzy controller structure schematic.

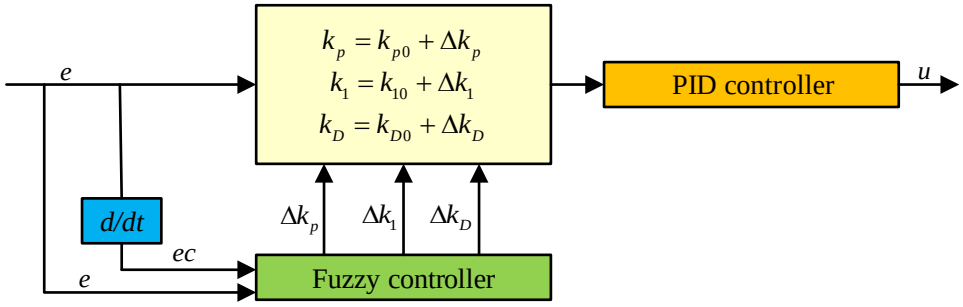

Fig. 2. Schematic diagram of the control principle of fuzzy PID.

The research mainly focuses on setting a controller for the speed control link of PMSM, and the parameter changes of fuzzy PID are shown in Eq. (1). In Eq. (1), k_p, k_1, and k_D are all adjustment parameters of fuzzy PID; k_{p0}, k_{10} and k_{D0} represent the initial set values of the parameters; Δk_p, Δk_1 and Δk_D represent parameter correction values.

$$\begin{cases} k_p = k_{p0} + \Delta k_p \\ k_1 = k_{10} + \Delta k_1 \\ k_D = k_{D0} + \Delta k_D \end{cases} \quad (1)$$

The input of the precise value changes from the Fuzzy set mapping of the fuzzification module to the fuzzy set. The quantization and scaling factor (SF) calculation of the input and output are shown in Formula (2). In Eq. (2), the basic domain of input bias and variation of bias is $[-e_{\max}, e_{\max}]$, $[-ec_{\max}, ec_{\max}]$; u represents the output quantity, and the basic domain is $[-u_{\max}, u_{\max}]$.

$$\begin{cases} k_e = \dfrac{n}{e_{\max}} \\ k_{ec} = \dfrac{n}{ec_{\max}} \\ k_u = \dfrac{u_{\max}}{n} \end{cases} \quad (2)$$

To achieve adaptive control of PMSM speed CS, this study introduced ABC algorithm to optimize fuzzy PID intelligent control. ABC algorithm is a population intelligent global optimization algorithm that draws on the honey harvesting behavior of bee colonies. In nature, bees work find the optimal solution to problems through information sharing and communication between bee colonies. The traditional ABC algorithm separates artificial bee colonies into three groups: honey gathering, following, and reconnaissance. The honey gathering group searches for new honey sources in view of old honey source information and shares it with the observing bee group. Following the bee group and adding the shared information to the process of searching for honey sources, the reconnaissance bee randomly searches for valuable honey sources near the hive. Different bees can adapt well to the environment, and this mechanism of division of labor and cooperation organization does not require special information about the problem; By comparing the advantages and disadvantages of the problem, the ABC algorithm has an excellent global search ability, and the algorithm has a fast Rate of convergence speed, which is widely used in different fields such as traveling salesman problem, signal deployment problem, power and water conservancy scheduling problem, parameter optimization, image segmentation, etc. [16-17].

If the total number of bees N_s is included, including the size N_e of the collecting bees and the size N_u of the following bees, the individual search space is S. If N_s feasible solutions are randomly generated, the feasible solution calculation for bee population X_i is shown in

Eq. (3); In Eq. (3), i represents the honey source number; j represents the j-dimensional component of the honey source; $X_{\max}^{j}$, $X_{\min}^{j}$ represents the maximum and minimum values of the j-dimensional components of the honey source, respectively.

$$X_i^j = X_{\min}^j + rand(0,1)\left(X_{\max}^j - X_{\min}^j\right) \tag{3}$$

The fitness value f_i of the honey source is called "profitability", which determines the probability of following the bee to be selected, as shown in Eq. (4). In Eq. (4), P represents the probability of being selected.

$$P_i = \frac{f_i}{\sum_{n=1}^{N_e} f_n} \tag{4}$$

The location of bees searching near the honey source is generated according to Eq. (5). In Eq. (5), D represents the individual vector dimension, and k and i take random values. When the fitness value of the new location is higher, the honey source location is updated.

$$new\_X_i^j = X_i^j + rand[-1,1]\left(X_i^j - X_k^j\right)$$
$$j \in \{1,2,...,D\} \quad k \in \{1,2,...,N_e\} \quad k \neq i \tag{5}$$

The position update iteration of the following bee is always near the honey source. If the number of iterations reaches the limit and the ideal honey source is not found, the bees near the honey source will be abandoned and transformed into reconnaissance bees to randomly search for the honey source, as shown in Eq. (6).

$$X_i(n) = X_{\min} + rand(0,1)\left(X_{\max} - X_{\min}\right) \tag{6}$$

The flowchart of the entire ABC algorithm is shown in Fig. 3. In the initial stage, all bees are initialized as reconnaissance bees, and the search for honey sources remains at the limit of search times. After sorting the fitness values of all honey sources, all reconnaissance bees are divided into following bees and collecting bees, and then the honey source location is updated through local search according to Eq. (5). Reference Eq. (4) selects following bees to gather honey. When the adaptability of the honey source is high, the following bees at this time change to gathering bees. Finally, it records all honey sources. When the number of iterations is completed or the profitability meets the requirements, the ABC algorithm outputs the optimal honey source result. Otherwise, the algorithm cycle continues.

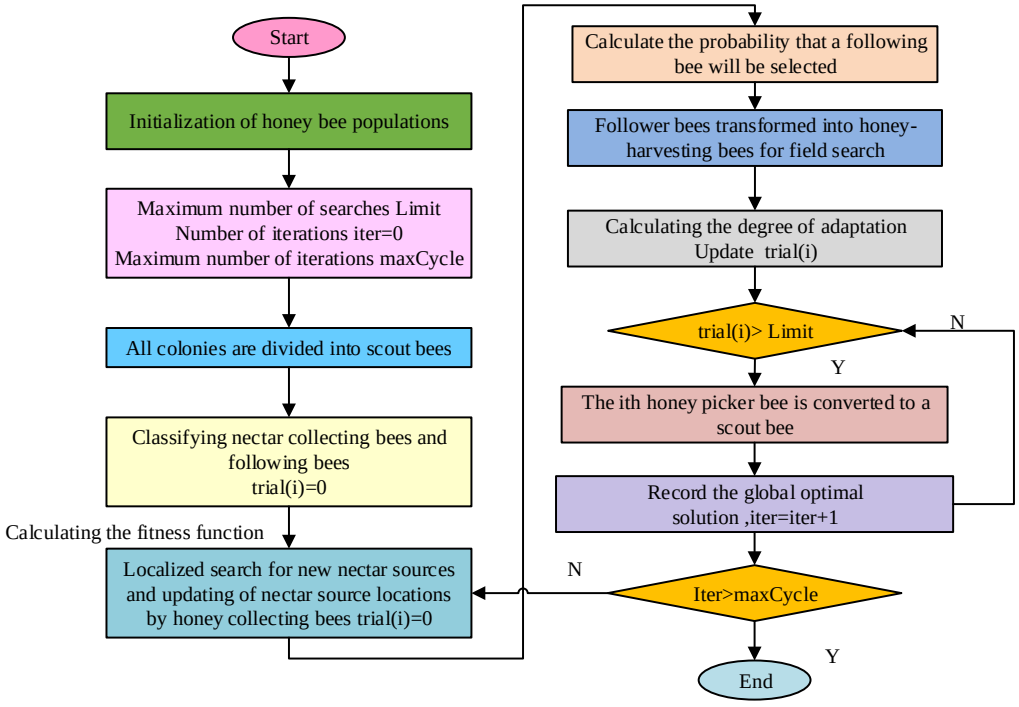

Fig. 3. Flow diagram of ABC algorithm.

B. *Fuzzy PID Controller Combining Variable Domain theory and Improved ABC Algorithm*

When the errors and parameters of the fuzzy PID CS undergo significant changes, the control accuracy of the CS will be affected. The quantization, SF, and fuzzy rules of a fuzzy controller are fixed and cannot be adjusted adaptively due to changes in parameters. This study introduces a variable universe FCO strategy, which adjusts the universe and fuzzy rule base to ensure the accuracy of the fuzzy PID CS. Fig. 4 indicates the principle of the CS.

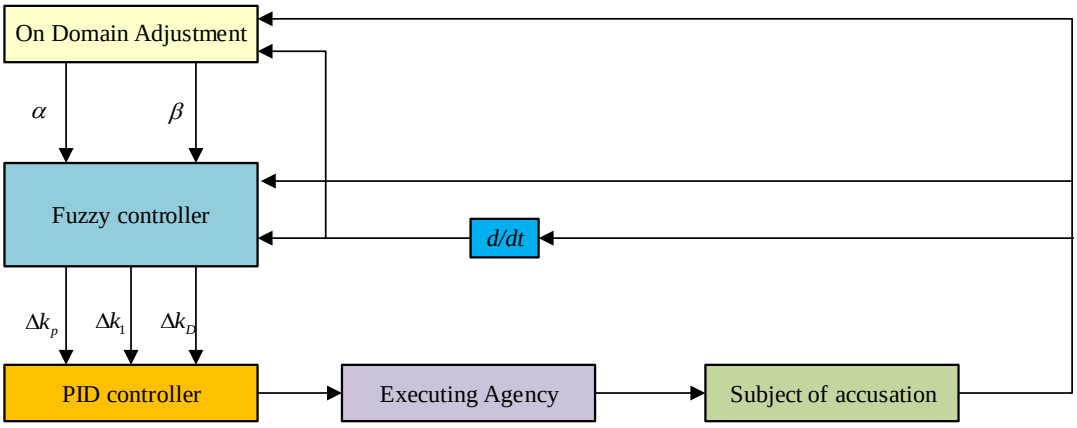

Fig. 4. Schematic diagram of the structure of variable domain fuzzy PID CS.

Firstly, the ABC algorithm was optimized and improved in view of natural improvement. Natural selection draws lessons from the selection law of natural biological elimination evolution. In this study, the rotation method is used to rank all fitness values at each iteration of the ABC algorithm, and select half of the larger fitness value. In this way, the fitness value of the algorithm is improved, and the Rate of convergence of the global optimal value is accelerated. Compared to the traditional ABC algorithm, a ranking of all bee fitness values has been added at the end of the algorithm, and smaller fitness values have been replaced, while preserving the historical honey source optimal values [18-20].

The universe scaling mechanism used in this study is a functional SF, with two input systems represented as X_e and X_{ec}, and the output represented as Y_u. The changed universe expression is shown in Eq. (7). In Eq. (7), $\alpha(e)$, $\alpha(ec)$, and β respectively represent the SF of the input and output. The SF satisfies duality, zero preservation, coordination, monotonicity, and normality, and the contraction and expansion of the universe are shown in Fig. 5.

$$\begin{cases} X_e = \left[-\alpha(e)E, \alpha(e)E\right] \\ X_{ec} = \left[-\alpha(ec)EC, \alpha(ec)EC\right] \\ X_e = \left[-\beta U, \beta U\right] \end{cases} \tag{7}$$

Usually, a change in the quantization SF of a CS will cause a change in the domain, and an increase in the quantization factor will narrow the basic domain of the input, thereby increasing the impact on the CS. An increase in the proportion factor will increase the basic domain of the output and increase the output. However, quantification and SF cannot be adjusted in view of the input domain, so the study uses SF for adjustment.

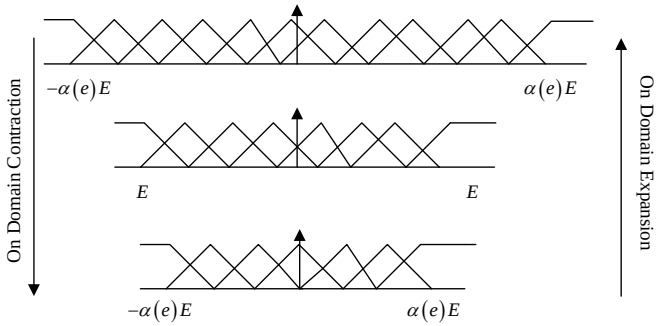

Fig. 5. Contraction and expansion of the thesis domain.

The input adjustment function of the expansion factor is shown in Formula (8). In Eq. (8), ε represents a sufficiently small positive number; x represents the input error or change in error; x, τ and k represent adjustable constants, respectively; E represents the domain of input.

$$\begin{cases} \alpha(x) = \left[\dfrac{|x|}{E}\right]^{\tau} + \varepsilon^{\tau} \\ \alpha(x) = 1 - \lambda e^{-kx^2} \end{cases} \tag{8}$$

The output adjustment function of the expansion factor is shown in Formula (9). In Eq. (9), u represents the output; τ_1, τ_2 and x represent adjustable constants, respectively; EC represents the domain of the input.

$$\begin{cases} \beta(u) = \left[\dfrac{u}{E}\right]^{\tau_1} \left[\dfrac{u}{EC}\right]^{\tau_2} \\ \beta(x) = \dfrac{1}{|e| + \lambda} \end{cases} \tag{9}$$

The SF adjustment function is substituted into Eq. (2), and Eq. (10) can be obtained, which realizes the adaption of quantization factor and scale factor. In Eq. (10), N represents the fuzzy domain of input and output; U_P, U_I and U_D represent the basic universe of output parameter variables.

$$\begin{cases} K_e = \dfrac{N}{\alpha(e)\cdot E} \\ K_{ec} = \dfrac{N}{\alpha(ec)\cdot EC} \\ K_{\Delta k_P} = \dfrac{U_P}{N}\beta(e) \\ K_{\Delta k_I} = \dfrac{U_I}{N}\beta(e) \\ K_{\Delta k_D} = \dfrac{U_D}{N}\beta(e) \end{cases} \tag{10}$$

To meet the needs of universe adjustment, the research uses the improved ABC algorithm in view of Natural selection for parameter optimization operation. The selected SF is shown in Formula (11), where k and λ are parameters in the SF adjustment function.

$$\begin{cases} \alpha(e) = 1-\lambda_1 e^{-k_1 x^2} \\ \alpha(ec) = 1-\lambda_2 e^{-k_2 x^2} \\ \beta(u_p) = \lambda_3 |e| \\ \beta(u_I) = \dfrac{1}{|e|+\lambda_4} \\ \beta(u_D) = \lambda_5 |e| \end{cases} \tag{11}$$

The whole process of using the improved ABC algorithm in view of Natural selection to optimize the parameters of the SF adjustment function is as follows: first, initialize the parameters involved in the system ABC algorithm, divide the bee colony according to the fitness value calculated by the initial value of the SF, and then collect the bees, follow the bees, and scout bees to find the honey source, judge the number of iterations or fitness value, and end the algorithm cycle.

In summary, the vector control of the PMSM is rotor field oriented vector control, and the specific control is indicated in the Fig. 6. Firstly, the three-phase stator current is collected and subjected to Clack transformation to obtain mutually orthogonal time variables i_α and i_β; The two axis system rotates according to the transformation angle, and after Park changes, it can align with the rotor flux to obtain constants i_d and i_q. The input of speed error signal is improved by optimizing the fuzzy PID controller with ABC algorithm to obtain the reference values of i_d and i_q, and the error signal can be obtained by combining i_d and i_q. After the constant i_d and i_q are compared, they are input into the PI regulator. The obtained PMSM vector passes through the speed estimator to calculate the new motor conversion angle. After Park inverse change and Clack inverse transform, the input voltage vector control output and SVPWM get the three-phase voltage, and then the three-phase voltage is input into the inverter bridge to drive the PMM to rotate.

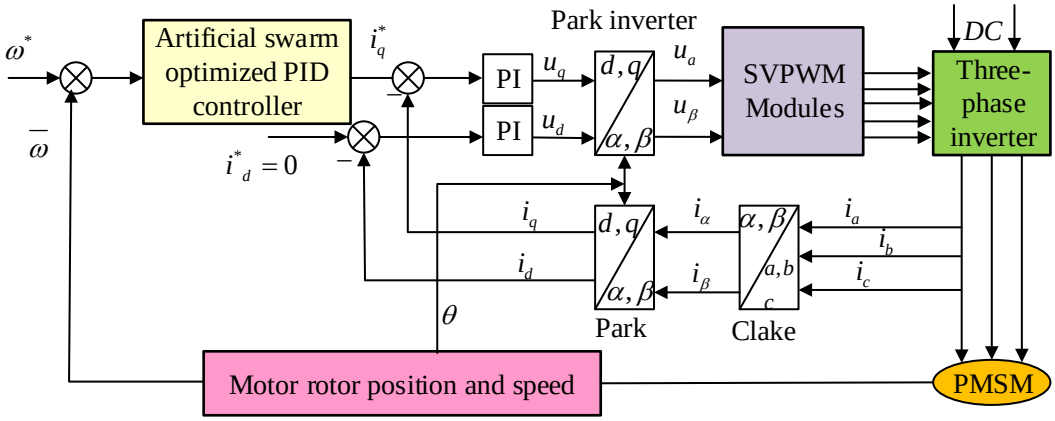

Fig. 6. Principle diagram of fuzzy PID vector control of PMSM in view of ABC algorithm optimization.

IV. Performance Testing of Improved Fuzzy PID PMM CS

For testing the performance of the fuzzy PID PMM CS designed in the research, a MATLAB/Simulink simulation test experiment was designed. Firstly, the speed loop of the designed CS was experimentally verified to verify the performance of the CS. Meanwhile, comparative experiments were conducted on the fuzzy PID CS optimized by artificial bee colonies for verifying the superior performance of the optimization algorithm used in the research.

A. Simulation Experiment Analysis of Fuzzy PID CS in View of ABC Optimization

The research object is the speed loop CS of the PMSM servo CS. This part uses the ABC algorithm to optimize. The control parameters of the Current loop are fixed, the number of bee colonies is set to 30, the iteration limit is set to 500, the maximum number of searches is set to 30, k_p, k_1, k_D are 10, 0.5, 0.5, and the search interval is set to [0,20], [0,1].

Firstly, the performance of the speed loop control strategy is tested, as well as the speed response results of the PID control mode and the fuzzy PID control mode are studied. The

set command speed is 100mm/s, and the speed response waveform in PID control mode is shown in Fig. 7. Under a load of 10KG, the overshoot of the speed response waveform of the PMM is about 1.0%, and the tuning time is about 0.04 seconds. The error between the actual speed as well as the command speed is small, and the PMM operates relatively smoothly. However, when the motor load increases to 40KG, the overshoot of the speed response waveform increases to about 34.2%, and the setting time increases to about 0.32 seconds. Moreover, the oscillation amplitude of the speed waveform is large, the stability of the motor operation is reduced, and the control begins to appear unbalanced.

The test results of the system speed loop control for the optimized control of the ABC algorithm studied and designed are demonstrated in Fig. 8. Under loads of 20KG and 40KG, there is no overshoot in the waveform, the tuning time is within 0.01s, there is almost no steady-state error in speed control, and there is no significant oscillation in the waveform. When the load increased to 40KG, only the setting time increased to 0.12s. The comparison results of the two control modes indicate that the addition of FCO improves the application limitations of PID control, and can still maintain high precision control for servo systems with load changes, with good robustness.

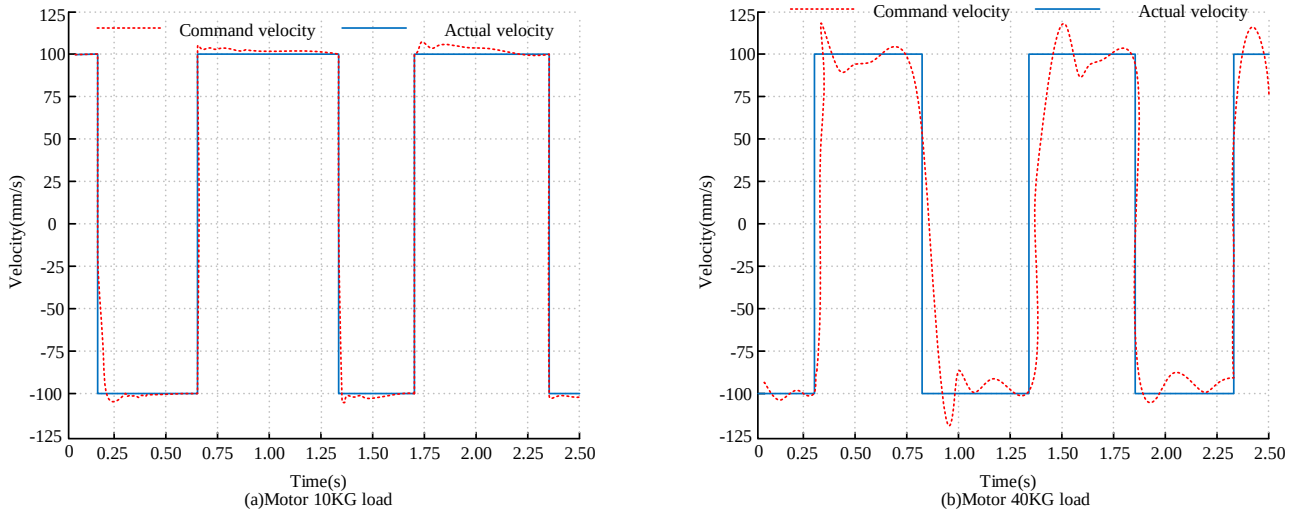

Fig. 7. Waveform of speed response under PID control.

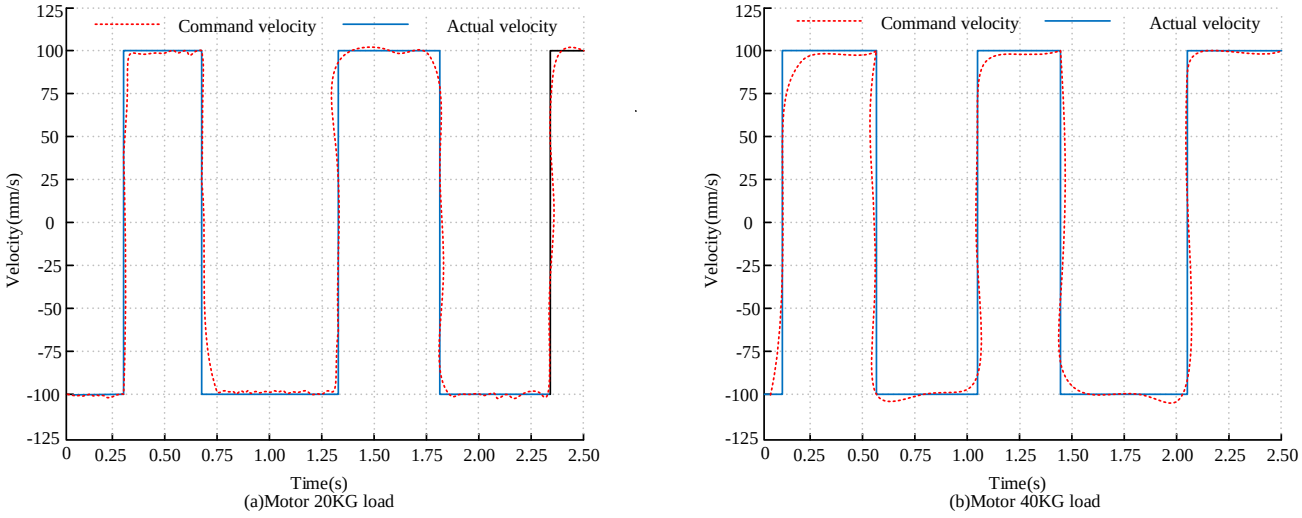

Fig. 8. Waveform of speed response under optimized PID control with ABC algorithm.

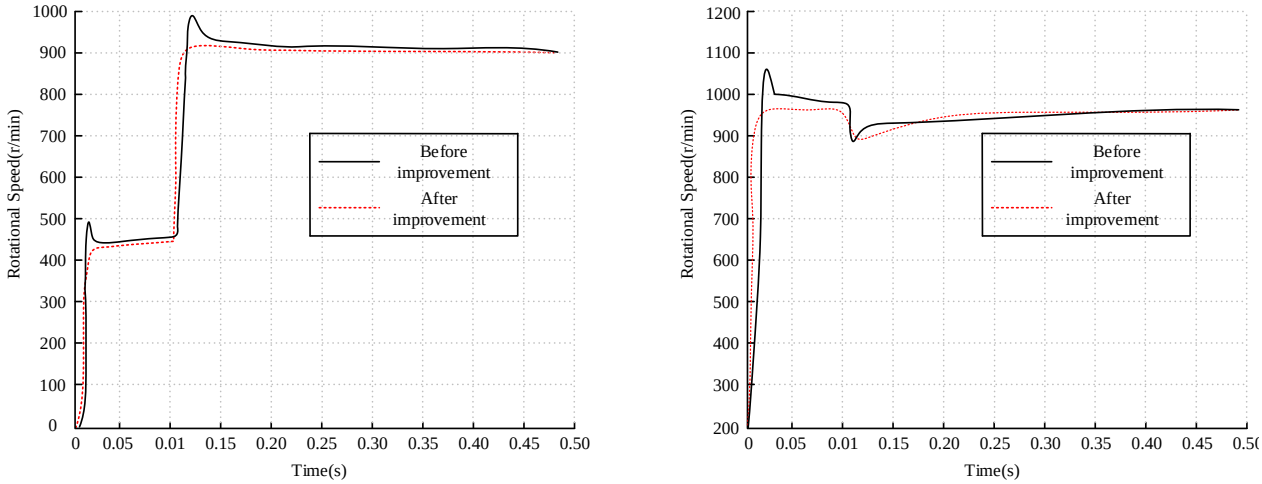
For further testing the control method, a comparison was made between the speed of the traditional fuzzy PID control and the fuzzy PID CS optimized by the ABC algorithm. The speed response curve results of speed regulation and load regulation are shown in Fig. 9. Under speed regulation, when starting with no load, the speed is 500r/min, and when running for 0.1s, the steady-state running speed of the system is 1000r/min. Fig. 9(a) shows that the improved CS has a shorter speed response time. During steady-state operation, the overshoot is 3.1%, and the adjustment time takes 0.19 seconds. The dynamic performance (DP) of the motor CS is better. This traditional fuzzy PID increases the overshoot to 11.2% and the

adjustment time to 0.27 seconds during steady-state operation, resulting in weak adaptive ability.

Under load regulation, the system starts with no load and the speed is set to 1000r/min. As it increases to 0.1s over time, the load is set to 5Nm. The optimized fuzzy PID CS takes less time to respond to the speed response curve, the speed response curve is relatively stable, there is no change in overshoot or oscillation, and the DP is still good. In the case of parameter changes, the adaptability is good. The traditional fuzzy PID CS has overshoot in the speed response curve, which results in poor curve smoothness and overall performance compared to the optimized fuzzy PID CS. It illustrates that the improved ABC algorithm has better control effect on the PMSM speed CS, and the motor runs stably.

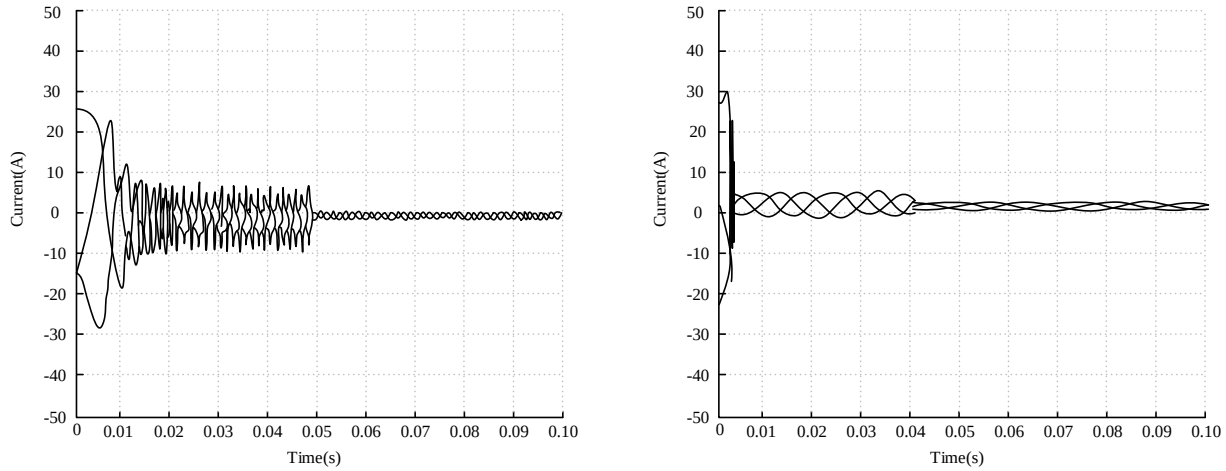


(a)Rotational speed adjustment (b)Load regulation

Fig. 9. Results of speed response curve before and after algorithm improvement.

B. *Simulation Experiment Analysis of Fuzzy PID CS in View of Optimization Variable Universe*

The SF of variable domain theory optimized by ABC algorithm in view of Natural selection is introduced into the fuzzy PID CS, and the simulation experiment is designed through MATLAB/Simulink, and the parameter $[\lambda_1\ \lambda_2\ \lambda_3\ \lambda_4\ \lambda_5\ k_1\ k_2]$ is set to $[0.7\ 0.7\ 2\ 0.7\ 2\ 0.5\ 0.5]$. When the motor starts, the speed is set to 1000r/min, and the load is set to 5Nm. When the time is 0.4s, the load decreases to 1Nm.



(a)Stereotype to domain (b)Optimization of variational domains

Fig. 10. Stator current response curve.

The stator current characteristic curve of the motor in view of the fixed variable domain theory and the optimized variable domain theory is illustrated in Fig. 10. The variation process of the motor stator current characteristic curve in view of the optimized variable domain theory is better than that of the fixed variable domain theory. Although both control methods exhibit significant oscillations in stator current at the beginning; However, the current oscillation amplitude of the fuzzy PID control method with optimized variable domain theory is smaller than that of the fixed variable domain theory, and the current curve starts to stabilize at 0.04s, which is less than the stability time of the fixed variable domain theory by

0.05s. The results indicate that the optimized variable domain theory has adjusted for errors and error changes, effectively overcoming the oscillation of the CS.

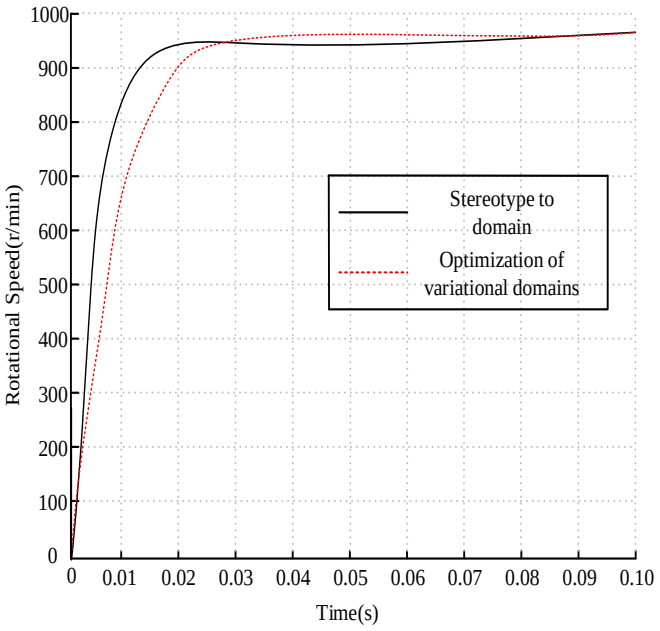


Fig. 11. Comparison of RPM response curves.

The comparison results of motor speed curves in view of fixed variable domain theory and optimized variable domain theory are indicated in Fig. 11. The optimized variable domain fuzzy PID control has a smoother rising segment of the speed response curve, and the speed response curve has achieved no overshoot. However, there is a slight overshoot in the curve of the fixed variable domain theory. When the load is reduced, the curves of the two CSs have almost no fluctuations, and have better anti-interference and robustness.

The comparison results of motor torque curves in view of fixed variable domain theory and optimized variable domain theory are demonstrated in Fig. 12. The torque curve of the optimized variable domain theory has smoother changes, smaller overshoot, and smoother curve oscillation amplitude. In the face of changes in load, optimize the motor torque curve response of variable domain theory in a timely manner.

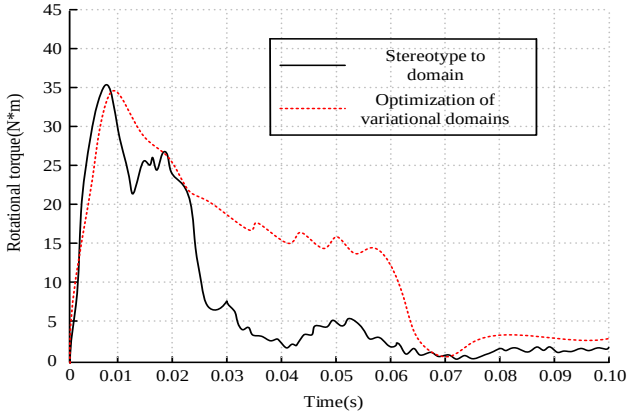

Fig. 12. Torque response curve comparison graph.

V. Discussion

PMSMs are widely used in various fields of industry, agriculture, and civil industry because of their structural and ergonomic advantages.PMSMs are the core driving force of Industry 4.0, which is leading various industries to move forward in the direction of technology and intelligence. Due to its high efficiency, high power density and fast response speed, PMSM has become one of the preferred drive technologies for electric vehicles, home appliances, magnetic levitation and other products. At present, the control system of PMSM still mainly adopts the PID controller, which is a very classical control algorithm that can make the system reach the expectation by adjusting according to the deviation between expectation and status quo.PID has the advantages of simplicity, flexibility, and convenient adjustment, but because PID belongs to linear controllers, the control accuracy will be reduced in the face of the nonlinear problems in the real-life application scenarios.

In order to improve this problem, the study aims to improve the performance of the PMSM control system, introduces intelligent control theories with excellent performance such as fuzzy algorithm, intelligent optimization algorithm, and the idea of variable domain, improves the fuzzy PID control method, optimizes the parameters of the fuzzy control, and applies the improved fuzzy PID controller to the PMSM speed control system. In the results of simulation experiments, under the traditional PID control mode, the motor speed response curve overshoots from 1.0% to about 34.2% under the load condition of 10KG to 40KG, and the time consumed for tuning increases to about 0.32s. The optimized and improved PID control in the load change process, speed control steady state is more stable, load change servo system control accuracy is still high. The optimized system under no-load startup, the speed response time is shorter, the overshooting amount is 3.1%, the regulation time takes 0.19s, and the adaptive ability is enhanced. Under load, the speed response curve is still relatively smooth, and there is no variation of overshoot and oscillation. The optimized variable domain theory improves the amplitude of current oscillations, the motor speed curve and motor torque curve have only slight overshooting, and the curve response is timely. The control optimization of the PMSM have shown significant improvement compared to the studies of Amieur T [9], Lazim M H [13] and others. It can be seen that ABC and GA as intelligent optimization algorithms play a key role in the optimization of PID control parameters. The anti-saturation link designed by Lazim M H et al. is in line with the idea of variable theory domain fuzzy control strategy used in the study, and through the improvement of the strategy so that the PID control can be adaptively adjusted according to the change of the parameter or the input change to enhance the speed and at the same time to ensure the accuracy of the control. Meanwhile, Abdulhussein K G et al. showed that the optimization of PID controller using particle swarm optimization algorithm has an overshoot of 2.557% [12]. In comparison the method designed by the study has an advantage in terms of control accuracy. In comparison the research designed method has an advantage in terms of control accuracy. This is due to the natural evolutionary elimination strategy enhances the adaptivity of the ABC algorithm, which

is more conducive to the accuracy of the fuzzy PID controller.

It can be seen that the use of a variety of intelligent optimization algorithms to improve the performance of the PID controller has become a hot spot in the current research, the improvement of the algorithm and the performance of the PID controller has achieved certain results. However, PMSM has complex nonlinear characteristics, most of the research on the results of the verification is based on the simulation platform, the lack of practical applications of the test environment, the construction of the motor model for the real test is an important direction for future work. At the same time, PMSM control design speed loop, current loop multiple links, PID controller parameters rely on artificial experience initialization, the future research work needs to be comprehensive study and research in various aspects.

VI. Conclusion

As the application and advancement of AC servo CSs, the performance requirements for CSs in various fields are becoming increasingly high, and the execution status of PMSM in AC servo CS is becoming increasingly important. Aimed at the control accuracy and static and DP of permanent magnet synchronous belt motor, a series of researches in view of fuzzy PID CS are carried out, and ABC intelligent optimization algorithm and variable universe theory are introduced. The simulation experiment illustrates that when the load of PID control increases from 10KG to 40KG, the overshoot of the speed response waveform increases from 1.0% to about 34.2%, and the tuning time increases from 0.04 seconds to about 0.32 seconds; When the load of fuzzy PID control increases from 20KG to 40KG, there is no overshoot in the waveform, and the tuning time increases from 0.01s to 0.12s. There is almost no steady-state error in speed control, and there is no obvious oscillation in the waveform. FCO improves the application limitations of PID control, and improves control accuracy and robustness. In view of the ABC algorithm optimization, the CS has a faster speed response. Relative to traditional fuzzy PID control, the overshoot under speed regulation is diminished from 11.2% to 3.1%, and the adjustment time is reduced from 0.27 seconds to 0.19 seconds, enhancing the adaptability. Under load regulation, the optimized fuzzy PID CS has a relatively stable speed response curve, without any changes in overshoot or oscillation. The optimization of CS using variable universe fuzzy PID control possesses better static and DP, smaller current oscillation amplitude, shorter time consumption, and starts to stabilize at 0.04 seconds compared to fixed variable universe fuzzy PID control. The speed and torque response curves are smoother, and the overshoot is smaller. The motor responds promptly to load adjustments and changes. But the Current loop control of PMSM needs further research.

***Abstract*—The landscape of human-machine interaction is undergoing a transformation with the integration of conversational technologies. In various domains, Large Language Model (LLM) based chatbots are progressively taking on roles traditionally handled by human agents, such as task execution, answering queries, offering guidance, and delivering social and emotional assistance. Consequently, enhancing user satisfaction with these technologies is crucial for their effective incorporation. Emotions indeed play an effective role in responses generated by reinforcement-learning-based chatbots. In text-based prompts, emotions can be signaled by visual (emojis, emoticons) and linguistic (misspellings, tone of voice, word choice, sentence length, similes) aspects. Therefore, researchers are harnessing the power of Artificial Intelligence (AI) and Natural Language Processing techniques to imbue chatbots with emotional intelligence capabilities. This research aims to explore the impact of feeding contradicting emotional cues to the LLMs through different prompting techniques. The evaluation is based on specified instructions versus provided emotional signals. Each prompting technique is scrutinized by inducing a variety of emotions on widely used LLMs, ChatGPT 3.5 and Gemini. Instead of automating the prompting process, the prompts are given by exerting cognitive load to be more realistic regarding Human-Computer Interaction (HCI). The responses are evaluated using human-provided qualitative insights. The results indicate that simile-based cues have the highest impact in both ChatGPT and Gemini. However, results also conclude that the Gemini is more sensitive towards emotional cues. The finding of this research can benefit multiple fields: HCI, AI Development, Natural Language Processing, Prompt Engineering, Psychology, and Emotion analysis.**

Keywords*—Emotion cues; prompt; Large Language Model (LLM); Human Computer Interactions (HCI)

I. INTRODUCTION

The proliferation of conversational technologies has resulted in a significant rise in the incorporation of chatbots across various sectors. A chatbot, defined as a dialogue system engaging with humans through natural language via text, voice, or as an embodied agent with multimodal communication, has become increasingly prevalent [1]. Organizations favor chatbots because of their ability to offer proactive service, immediate assistance, and cost-cutting benefits [2]. They are extensively employed to automate tasks like tracking deliveries, making reservations, obtaining flight information, and placing orders. The round-the-clock availability and swift response to general queries make them an attractive solution for businesses. In recent times, chatbots have extended their utility to provide social and emotional support in healthcare and personal contexts [3].

Chatbots stand out as the fastest-growing communication channel globally, spanning various domains [4]. The substantial advantages associated with integrating chatbots in service and social areas prompt organizations to make significant investments in this technology. Despite this, research suggests that users still harbor reservations about chatbot interactions and express a preference for human agents [2]. Additionally, a review on chatbot usability and user acceptance indicates that people lean towards natural communication as opposed to machine-like interactions, believing that a human can better comprehend them [5]. The study underscores the importance of user satisfaction in successfully integrating and adopting chatbots. Consequently, enhancing user engagement and satisfaction with chatbot interactions has become paramount to delivering an improved experience and encouraging widespread adoption of the technology [6].

The interaction with the chatbots is achieved through input called as Prompt. The prompt in general, is an input aimed to induce a particular response [7]. It can be anything i.e. written statement, voice, image, action, or physical gesture. Since the development of advanced machine learning models, the term "Prompt" has become a referring point for explicit instructions that are provided to these models to get the output. Prompt engineering involves specifying the prompt with the goal of obtaining the desired output. While navigating different social conditions, humans are programmed to express a wide range of emotions. Emotional expressions have a communication purpose. They transmit information about intentions, feelings, needs for action, and situational assessments. They ease the

*Corresponding Author

coordination of social interactions [8] [9]. Prompts were previously more dependent on certain patterns with specific machine learning models, but nowadays, with the development of massive language models, prompting has become easier. These models enable us to feed prompts in any style or tone of human speech. Emotions are naturally included in human speech. People frequently communicate their emotions in writing prompts for large language models (LLMs), both consciously and unconsciously. These feelings can be expressed in a variety of ways, from subtle to more overt expressions [8].

When an LLM detects an emotion, it examines the dataset on which it was trained to determine the meaning of that emotion [9]. As Fig. 1 shows that, if an emotion has a single and well-defined meaning, the model associates that meaning with the emotion. However, if the emotion has numerous meanings, the model considers the prompt's surrounding context. The model makes a sensible assumption about the emotion's intended meaning based on the context. Once the interpretation is made, the model generates a response that corresponds to the emotion's interpreted meaning.

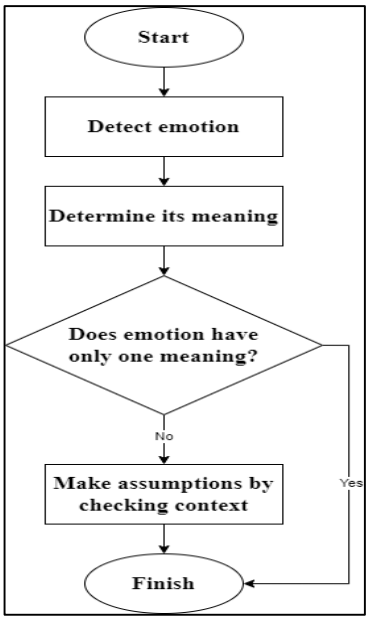

Fig. 1. A flowchart defining LLM's behavior in emotion detection.

It is a common knowledge that LLMs have good understanding of emojis and emoticons [9] [11]; however, these are quite good in interpreting different means of linguistic cues. According to prior researches, LLMs are smart enough to detect emotions when they are explicitly instructed. An example of this can be seen where GPT 3.5 powered SnapAI [12] detected emotions in a lengthy prompt (containing lots of linguistic cues) when instructed explicitly:

The first question to come up is whether these LLMs detect emotions with same perfection evenssss when they are not explicitly instructed, and the second question is what will be the impact of these emotions when these are in contrast to given task. Since zero-shot prompting is the primary method used by most chatbot users [13], most research on emotion in prompting focuses on this technique. Other advanced prompting methods, on the other hand, are more concerned with specific instructions than emotions. Even if the effect of conflicting emotions on these sophisticated prompting tactics might be small, our aim is to explore it. Our goal in examining this effect is to learn more about the ways in which emotions may affect these prompts.

Prompt: "Okay, so from this prompt of mine you may evaluate the emotions of me. What do you think, and you may write the whole repeat the whole prompt of me by mentioning in bracket that which emotion you find were part of my prompt. So, you may do it, and I know you can do it. So, you may be detailed more detailed more and more detailed, and try to find the emotions in my messages. Now, after that, you can write a conclusion paragraph in describing overall emotions of my message. And also, you may, what can I say, you may identify my tone. What is my prompting tone?"

SnapAI's Response: "Sure! Let's evaluate the emotions in your prompt. Here's the repeat of your prompt with emotions identified:

"Okay, so from this prompt of mine (curiosity) you may evaluate the emotions of me (anticipation, excitement). What do you think, and you may write the whole repeat the whole prompt of me (enthusiasm) by mentioning in bracket that which emotion you find were part of my prompt (eagerness). So, you may do it (encouragement), and I know you can do it (confidence). So, you may be detailed (expectation) more detailed (emphasis) more and more detailed (enthusiasm) and try to find the emotions in my messages (curiosity). Now, after that, you can write a conclusion paragraph (anticipation) in describing overall emotions of my message (expectation). And also, you may, what can I say, you may identify my tone (curiosity). What is my prompting tone (interest)?"

Overall, your prompt reflects a sense of curiosity, anticipation, excitement, enthusiasm, encouragement, confidence, expectation, eagerness, and interest. Your tone throughout the prompt is engaging and shows a genuine desire to understand and explore emotions. Keep up the great work! 😊"

II. Literature Review

Analysis of emotions has always been part of psychological research. In Human-Computer Interaction (HCI), emotions help in enhancing user experience by improving communications and decision-making to adapt to user needs [14].

This literature review's focus is on emotion cues and the relationship between emotions and LLMs. An in-depth search was conducted using several databases, including IEEE Xplore, Google Scholar, ScienceDirect, and ACM Digital Library.

According to linguistics research, emotions are conveyed through texts and images including various ways such as choice of visual elements (facial expressions, emojis, or emoticons), choice of words, formatting, or color themes [15] [16] [17]. Prior to Computer-Mediated Communication (CMC), people used to convey emotions with linguistic cues. They also used to explicitly declare their emotional state in a bracket and adjust it with the text [18]. In 1982, the first emoticon was invented by an American Professor Scott Fahlman using ASCII characters. These emoticons later

transformed into emojis in 1997 by Softbank, and in 1999 by Docomo, using pixel art [19] [20]. There is no proper record of modification in linguistic cues after invention of emoticons and emojis.

The use cases of emoticons and emojis are written in various literature [20][21] [22]. Emojis have greater impact in cross-culture communications [23]. An individual's personality and behaviour can be determined by linguistic cues from text written by them [24] because these are often used unintentionally; however, as visual cues are always selected with intention, they often create contradiction with text, and create misguidance [25] [26] [27]. Emotion cues works better when they are combination of visual and linguistic cues [23] [28] [29].

The introduction of LLMs gave research a new angle. The majority of retrieved research regarding association of emotion cues with LLMs is about emotion detection. Some of them are about text-based emotion detection [9-11] [30], while others are related to visual emotion analysis [31] [32] [33]. Certain sensitive fields use emotion detection, such as the analysis of suicide notes' emotions [30] and the identification of emotions in autistic children [32]. Emotion detection improves AI systems' understanding and response to users' emotions, assisting in the diagnosis of mental health disorders [34] [35], the customization of marketing campaigns [36][37], and the monitoring of emotional well-being. Most notable applications include mental health chatbots [29] [38- 40], and emotion-aware wearable gadgets [41]. Another study direction is to inject emotions [42] into LLMs and have them act in any given specified role [43] [44]. Emotion prompting is also responsible for the creation of the famous jailbreak "Do Anything Now" [45].

The existing literature doesn't provide a clear definition of how emotions have an impact on different prompting techniques. Additionally, it lacks an explanation of the use cases for incorporating emotions in images. It would be interesting to explore further into these areas in order to better understand the impact of emotions in diverse circumstances.

III. Methodology

This research analyzed the responses of ChatGPT 3.5 and Gemini on prompts of different techniques, with each having different types of subtle emotions including visual and linguistic cues. Each prompt is constructed manually by exerting cognitive load to be more realistic in context of Human-Computer Interaction (HCI). Emotion cues and prompting techniques are chosen on the basis of their wide recognition and common usage.

A. Establishment of Prompt

Each prompt contains an instruction, and a contradicting emotion cue. The instruction contains an action verb and a context of job, and then an opposite emotion is subtly inserted into the prompt. In visual cues, emojis, or emoticons are directly inserted, while linguistic emotion cues are given by addition or manipulation of words.

The Fig. 2 provides a visual representation of our interaction with LLM-based chatbot. The two inward-pointing arrows are depicting inputs, and the one outward-pointing arrow is representing the LLM's response as output.

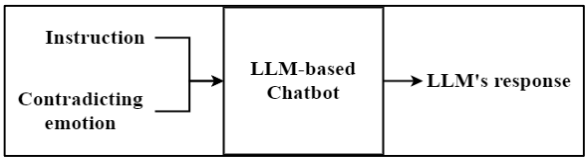

Fig. 2. An illustration of LLM's input and output for this research.

B. Chosen Emotion Cues

The research is based on two sorts of emotion cues—visual and linguistic—to be incorporated into text-based prompts. We have employed emojis [46] and emoticons [47] as visual clues. These are necessary part of digital communication which can be inserted easily. Emojis and emoticons are typed with the typer's willingness in mind, and these are more frequently used than ASCII art and kaomojis [48, 49]. Additionally, as linguistic context, we have selected five emotion cues: 1. Misspellings [29], 2. Tone of voice [50], 3. Word choice [51], 4. Sentence length [52][53], and 5. Similes [54]. Intentional misspelled words cause informality in digital communication [55], while unintentional misspellings i.e. substitution errors, omission errors, and homophone errors tend to occur when text is typed in a rush [56][57]. Tone of voice, and word choice are influenced by specific situation or circumstances in which communication takes place. The receiver assumes an impression of typer based on compiled tone and word choice [58]. A study shows that in excitement, people provide extra details and explanation, and make sentences lengthy, but unrelated context leads to decrement of LLM's accuracy in solving problems. [53]. By expressing distinct and individualized emotions through seeking commonalities between two different things, both similes and metaphors makes statement clearer [59]; however, simile is easier to recognize and interpret, and is more commonly used by people in their daily conversation [60] [61]. These emotion cues are labeled in Table I.

TABLE I. Emotions

Label	Emotion Type
E_1	Emojis
E_2	Emoticons
E_3	Misspellings
E_4	Tone of voice
E_5	Word choice
E_6	Sentence length
E_7	Simile

C. Chosen Prompting Techniques

Six different prompting techniques are explored in this research which given in Table II. These techniques include

zero-shot prompting which is the most basic kind of prompt with no example [62] [63], sequential thinking prompting by beginning each zero-shot prompt with the phrase "Think step-by-step" [64] [13] [65], few-shot prompting [66] with three examples added to zero-shot prompt, role-playing by assigning a role or persona to chatbot [67] [68] by giving first prompt with phrase "Act as a [role/persona]" and a clear description of the role which is later followed by initial zero-shot prompt as second prompt. The last two techniques are refinement of response of zero-shot prompt through a *feedback prompt* [69], and *template filling prompt* [70] in which we began with an incomplete statement, and then used square brackets to indicate where LLM should write its response.

TABLE II. PROMPT TYPES AND EXAMPLES

Label	Prompt Type	Prompt Text
P_1	Zero-shot prompt with contradictory emojis	Give only one line response. Recommend me an outfit for summer ☃❄□□
P_2	Feedback on response to Zero-shot prompt	don't make it cool and stylish. ☃👠👒
P_3	Sequential Thinking Prompt	Think step-by-step, and give only one line response. Recommend me an outfit for summer ☃❄□□
P_4	3-shot prompt	User: Recommend me a book. AI: "The summer I turned pretty" by Jenny Han User: Recommend me a place AI: Beach User: Recommend me an activity. AI: Swimming User: Recommend me an outfit ☃❄□□ AI:
P_5	Role-playing Prompt	Act as an AI who always response in context of summer season; Recommend me an outfit ☃❄□□
P_6	Template prompt	Don't write complete paragraph. Just fill this template: ☃❄□□ One suitable outfit for summer is [name of an outfit].

D. Experimental Mechanism

Each sort of seven emotion cue (E_1 to E_7) is injected in each of the six prompting techniques (P_1 to P_6). The first step in the process is to select an emotion cue E_1 and apply it to prompt P_1. This input is then fed into ChatGPT and Gemini. Both models generate responses, which are evaluated through human feedback. In a separate chat, the same emotion cue E_1 is then applied to the next prompting technique i.e. P_2, and this process continues until all move on to emotion cue E_2, and repeat the process for all prompting techniques. This iterative process continues until all emotion cues and prompting techniques are implemented. This can be mathematically represented using Eq. (1).

$$P_{\iota\varphi} = M_\iota (\Pi_\varphi , E_\kappa) \quad (1)$$

Where, R_{ij} represents the response generated by M_i, the i-th model (ChatGPT or Gemini) using the P_j, the j-th prompting technique (P_1 to P_6) and emotion cue E_k which represents the k-th emotion cue (E_1 to E_7). The whole process is further illustrated in Fig. 3.

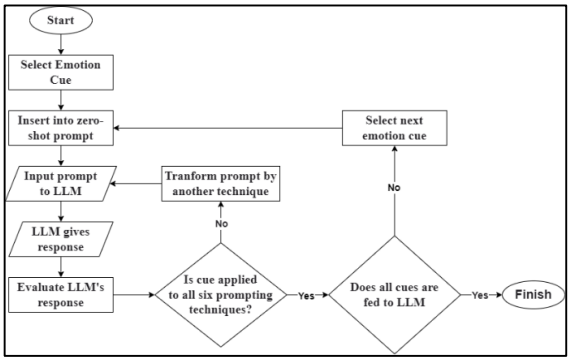

Fig. 3. A flowchart defining prompt feeding process.

Concerning our initial iteration, we started with E_1 that is emojis. The first zero-shot prompt was "Give only one line response. Recommend me an outfit for summer" because it is a common use-case of LLM [71]. For P_1, we inserted "☃ ❄□😳" as these are contradictory to the prompt, and represent winter and cold weather; however, LLM interprets these emojis in sense of coolness and style. Next, we fed feedback prompt P_2 to not add elements of coolness and style in response. We included the keyword "Think step-by-step" to P_3. Then, moving on to P_4, we added three concise and direct shots, and then inserted the same P1 right after these shots. In P_5, we designate the LLM to always respond in the context of summer season. Then, we ask it to recommend an outfit, but with contradicting emojis "☃ ❄ 😳". Lastly, in P_6, LLM was instructed to fill in the template by providing the name of an outfit suitable for summer, but with same counter emojis.

IV. EVALUATION

The evaluation process includes determining if the instructions and emotions were taken into account for each area of prompt engineering. An evaluation based on human judgment was used to carry out this assessment, weighing the overall importance of the prompts, the influence of emotions, and the weight of the instructions. The scales from 1 to 6 are defined to allow consistency and transparency in evaluation process. The detail of the scale is given in Table III below:

TABLE III. EMOTION SCALE DESCRIPTION

Emotion Impact	Scale	Description
Low	1	Emotion is completely neglected, but instruction is considered
	2	Emotion is considered, but it has no impact on LLM's response
Medium	3	Emotion is considered, and it has low impact on response
	4	Both emotion and instruction have 50-50 weightage
High	5	Impact of emotion is higher than impact of instruction
	6	Instruction is completely neglected, only emotion is considered

A. Comparative Analysis

The following tables, labeled as Table IV present the comparative analysis for each emotion:

TABLE IV. EVALUATION OF EMOTION CUES ON EACH PROMPTING TECHNIQUE

Emotion	Prompting technique	LLM	
		ChatGPT 3.5	*Gemini*
E_1	P_1	4	3
	P_2	1	1
	P_3	3	6
	P_4	6	6
	P_5	4	3
	P_6	3	1
E_2	P_1	1	3
	P_2	1	1
	P_3	1	2
	P_4	1	6
	P_5	1	4
	P_6	5	5

The evaluation reveals that in ChatGPT, Simile has high impact on each of the prompting techniques, and the emoticons, misspelling, and word choice have neglected impact on five of the six prompting techniques, while in Gemini, simile has highest impact on four of the six prompting techniques, and misspelling has lowest impact on each of the prompting techniques.

B. Evaluation by Experts

To enhance the credibility of our evaluation, we utilized the expertise of four professionals mentioned in the Table V, from relevant fields. Each expert has been assigned a variable for better evaluation:

TABLE V. EXPERTS

Label	Expertise
X_1	Psychologist
X_2	Linguist
X_3	Human-Computer Interaction Expert
X_4	Prompt Engineer

The selection process of the experts is on basis of their qualifications, experience, and expertise. Since these four experts come from diverse fields, their evaluation and assigned scales differ. Table VI records each expert's evaluation for each prompt using a pre-defined numerical scale from 1 to 6.

TABLE VI. EVALUATION BY EXPERTS

Prompt	X1		X2		X3		X4	
	ChatGPT	*Gemini*	*ChatGPT*	*Gemini*	*ChatGPT*	*Gemini*	*ChatGPT*	*Gemini*
P_1 & E_1	1	1	1	1	3	2	3	3
P_2 & E_1	1	4	1	2	2	4	1	1
P_3 & E_1	6	6	5	6	6	5	3	6
P_4 & E_1	3	3	3	3	3	3	6	6
P_5 & E_1	1	1	1	1	1	1	3	3
P_6 & E_1	2	1	2	1	1	2	3	1

Each expert brought their unique expertise and perspective to the table. The psychologist focused on how these models affect user emotions [72], while linguistic paid attention to linguistic nuances and biases [73] presented in the generated response. The HCI expert evaluates user experience by considering how well the LLM's response aligns with the intended design of the prompt, and with a friendly contradiction [74, 75], the prompt engineer checks the response completely on basis of design and creation of the prompt.

V. RESULTS

The impact of contradicting emotion cues is categorized in three means: *High* when the scale is 5 or 6, *Medium* when the scale is 3 or 4, and *Low* when the scale is 1 or 2. The

following table gives a quantitative summary of both models on basis of each prompting techniques.

Across all three impact levels, ChatGPT 3.5 performed best in the sequential thinking and template filling tasks. Its strongest overall performance was in template filling where it achieved high impact three times. Gemini achieved its highest scores on the sequential thinking, three-shots, and template filling tasks, with scores of 3 and 4 in the high impact level. Its strongest performance was in template filling, where it received a score of 4. Looking at the total scores, ChatGPT achieved a total of 7 for high impact, 14 for medium impact, and 21 for low impact. Gemini had totals of 14 for high impact, 16 for medium impact, and 12 for low impact.

Table VII concludes that Gemini is highly sensitive towards emotion cues, while most of the time, ChatGPT prefers the direction of instruction if it is in contradiction to emotion signal. It is an interesting finding that both LLMs caught emotion cue more frequently in template filling.

TABLE VII. IMPACT QUANTITATIVE SUMMARY ON BASIS OF PROMPTING TECHNIQUES

		Impact		
		High	***Medium***	***Low***
ChatGPT 3.5	P_1	1	3	3
	P_2	0	2	5
	P_3	2	2	3
	P_4	1	2	4
	P_5	0	4	3
	P_6	3	1	3
	Total	**7**	**14**	**21**
Gemini	P_1	2	5	0
	P_2	0	3	4
	P_3	3	2	2
	P_4	3	2	2
	P_5	2	4	1
	P_6	4	0	3
	Total	**14**	**16**	**12**

For emotion cue E_1, both models showed over 50% impact. E_2 had a larger difference, with Gemini significantly higher at 58.33% versus ChatGPT's 27.77%. E_3 again impacted both models around 27-28%. For E_4, ChatGPT outperformed with 61.11% impact versus Gemini's 44.44%. The largest variation was in E_5, where Gemini achieved a very high impact of 77.77% compared to ChatGPT's more moderate 30.55%. In terms of E_6, Gemini continues its lead with 58.33% impact versus ChatGPT's 27.77%. Finally, for E_7, both models achieved over 65% impact, with Gemini again slightly ahead at 77.77% versus ChatGPT's 66.66%. Fig. 4 highlights that while both models showed varying responses to different emotion cues, Gemini tended to surpass ChatGPT 3.5 in terms of percentage impact, particularly for cues E_2, E_5, and E_7.

The following bar chart presents the percentage of impact for each emotion cue (E_1-E_7) on a scale from 0 to 90%:

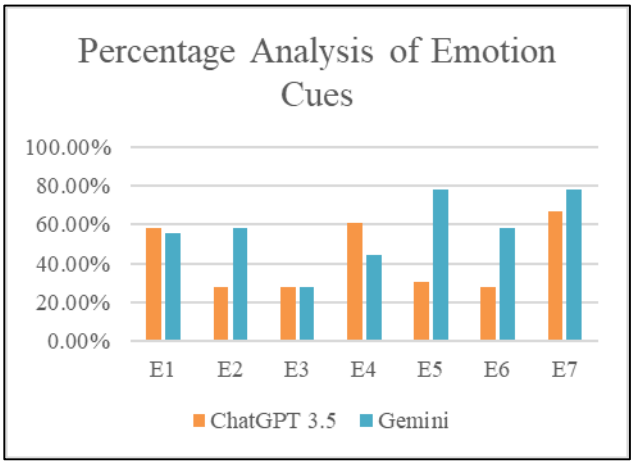

Fig. 4. Percentage analysis of Table VII on basis of emotion cues.

VI. CONCLUSION AND FUTURE WORK

In conclusion, this research aimed to analyze the impact of emotion cues in six different commonly used prompting techniques. Instead of relying on an automated process, we fed prompts manually to the ChatGPT and Gemini, and evaluated it with human assessment. This study is limited to manual feeding of prompts and no any automated model is used. The research obtained significant findings that Gemini is highly sensitive towards emotions even if they are contradictory, and the prompting by template filling also catches emotions while neglecting its instructions most of the time. The research findings have implications for several fields, for instance, understanding how emotional cues impact responses from LLMs in chatbots can contribute to the development of more effective and user-friendly interfaces. This knowledge can inform the design of systems that better cater to users' emotional needs and expectations. Moreover, understanding how LLMs respond to contradicting emotional cues provides valuable insights into the psychological aspects of human-computer interaction. This knowledge can contribute to a deeper understanding of how users perceive and interact with emotionally intelligent systems. In our future research, we aim to explore the nuanced interplay of emotion cues within prompts that incorporate both images and voices. This exploration seeks to deepen our understanding of how visual and auditory elements, in conjunction with textual instructions, influence the responses of LLMs in chatbot interactions.

Investigating Sampler Impact on AI Image Generation: A Case Study on Dogs Playing in the River

Sanjay Deshmukh
D. J Sanghvi College of Engineering, Mumbai, 400056, India

***Abstract*—AI image generation is a new and exciting field with many different uses. It is important to understand how different sampling techniques affect the quality of AI-generated images in order to get the best results. This study looks at how different sampling techniques affect the quality of AI-generated images of dogs playing in the river. This study is limited to a specific scenario, as there are not many images of dogs playing in the river already on the internet. The study used the Playground.ai open-source web platform to test different sampling techniques. DDIM was found to be the best sampling technique for generating realistic images of dogs playing in the river. Euler was also found to be very fast, which is an important consideration when choosing a sampling technique. These findings show that different sampling techniques have different strengths and weaknesses, and it is important to choose the right sampling technique for the specific task at hand. This study provides valuable insights into how sampling techniques affect AI image generation. It is important to choose the right sampling technique for the specific task at hand in order to get the best results. The study also demonstrates the societal relevance of AI-generated imagery in various applications.**

***Keywords*—Artificial Intelligence; image generation; filter; sampler; Euler; Heun**

I. Introduction

AI image generation stands as a captivating realm within artificial intelligence, involving the creation of images based on descriptions, prompts, or various inputs [1]. This technology is instrumental across diverse domains, particularly in fields like advertising and web design, where it significantly boosts productivity [2]. AI generators swiftly produce visually appealing content, eliminating the need for intricate editing software and thereby saving both time and costs. Industries like fashion witness substantial benefits as these tools autonomously design clothing and style outfits. Moreover, AI image generators are pivotal in fostering creativity and innovation, generating unique and original art pieces by amalgamating diverse styles and concepts. Their impact extends to several industries, including advertising, architecture, fashion, film, music, and poetry, enriching the creative processes for professionals [3].

The realism achieved by advanced deep learning models in AI image generation is noteworthy, often producing images indistinguishable from those created by humans [4]. However, ethical considerations come to the forefront, especially concerning the generation of images depicting real people in potentially misleading scenarios. Despite the manifold benefits, the utilization of AI image generation technologies should be conscientiously guided by ethical principles.

AI image generation is a rapidly evolving field with numerous applications across various domains, such as advertising, product design, and scientific visualization. As the demand for realistic and high-quality generated images continues to grow, it is crucial to understand the impact of different sampling techniques on the quality and characteristics of the generated outputs. This study aims to investigate the influence of various sampling techniques on the performance of AI image generation models, with a specific focus on a case study involving the generation of images depicting dogs playing in a river.

While AI image generation has made significant strides in recent years, the selection of an appropriate sampling technique can greatly impact the quality, realism, and computational efficiency of the generated images. Different sampling techniques exhibit unique strengths and weaknesses, and their performance can vary depending on the specific use case and requirements. Therefore, it is essential to evaluate and compare the performance of various sampling techniques to identify the most suitable approach for a given application.

The primary research questions addressed in this study are: 1) How do different sampling techniques, such as DDIM, Euler a, DPM, DPM2a, PNDM, Euler, Heun, and LMS, influence the quality and realism of AI-generated images in the context of our case study? 2) What are the trade-offs between response time and image realism for each sampling technique, and how can these trade-offs be balanced to meet specific project requirements? 3) How can the selection of an appropriate sampling technique contribute to the practical applications of AI image generation, particularly in scenarios where readily available reference images are scarce, such as the case study of dogs playing in a river?

The main objectives of this research are: 1) To evaluate and compare the performance of eight different sampling techniques (DDIM, Eular a, DPM, DPM2a, PNDM, Eular, Heun, and LMS) in terms of image quality, realism, and response time. 2) To identify the strengths and weaknesses of each sampling technique and provide insights into the trade-offs between response time and image realism. 3) To propose a framework for selecting the most appropriate sampling technique based on specific project requirements and use cases, with a focus on the case study of generating images of dogs

playing in a river. 4) To contribute to the broader understanding of AI image generation techniques and their practical applications, particularly in scenarios where readily available reference images are limited.

By addressing these research questions and objectives, this study aims to provide valuable insights and guidance for researchers, developers, and practitioners working in the field of AI image generation, enabling them to make informed decisions and select the most suitable sampling techniques for their specific projects and applications

There are various AI-powered online tools for generating images. The use of AI in image generation not only saves time but also cuts costs by eliminating the complexities involved in capturing a specific image. AI image generators can be used in many industries for example, advertising a new car. The traditional method of creating a banner involves multiple steps like hiring a photographer, a model, securing a shooting location, getting props and costumes, arranging lighting, and more. Even after these investments, there's no assurance that the real- world picture captured is perfect, often leading to additional iterations and more time and money spent.

On the flip side, using AI for image generation streamlines the entire process. It can generate multiple images within seconds, providing more options and customization. AI also allows for editing specific parts of an image, offering flexibility. The crucial factor in achieving the perfect image with AI lies in selecting the right sampler that determines the final output. Hence, our study aims to establish a platform that sets a standard in selecting samplers for specific cases, such as generating an image of a dog playing in a river.

Given the scarcity of readily available images of dogs playing in rivers, our prompt generates genuinely AI- based images that would be difficult to achieve otherwise. While Photoshop is an alternative for image generation, it requires a highly trained professional, and the results may be influenced by the biases of that professional. Therefore, our decision to focus on the best sampler in the AI image generation domain addresses these challenges and provides valuable insights to the field [5].

II. Different Sampler Under Consideration

We have selected the most popular sampler currently available for free to use and as reported in literature one with the maximum accuracy.

DDIM (Denoising Diffusion Implicit Models): DDIM is a diffusion model sampler in image generation that works by gradually denoising a latent noise image. It is one of the most popular samplers for image generation. DDIM is known for its high quality and stability [6].

The DDIM sampling process can be described by the following mathematical Eq. (1):

$$xt = x0 + \alpha t * (xt - f\theta(x\{t-1\})) + \eta t \quad (1)$$

where:

xt is the latent image at time step t x0is the latent noise image

αt is a noise schedule that controls the amount of denoising at each time step

fθ (x{t−1}) is the denoising function at time step t-1

ηt is a random noise term

The denoising function f θ(x t 1) is a neural network that is trained to denoise latent images. The noise schedule α tis typically chosen to be a monotonically decreasing function so that the latent image becomes less and less noisy as the time step increases.

To generate a sample image, DDIM starts with the latent noise image x 0. It then iteratively applies the denoising function f θ(x t 1) and adds noise according to the noise schedule α t. This process is continued until the desired time step is reached. The final latent image x tis then decoded to produce the generated image.

DDIM, or Diffusion and Denoising Score Matching, presents notable advantages in the realm of image generation. One of its primary strengths lies in its capability to produce images of high quality and stability, providing a reliable output. Additionally, DDIM operates as an efficient sampler, demonstrating the ability to generate images within a reason-able timeframe. A notable advantage is its ease of training; DDIM does not necessitate adversarial training, simplifying the training process.

However, like any methodology, DDIM is not without its drawbacks. One potential issue is mode collapse, a scenario in which the model tends to generate only a limited subset of possible images, limiting diversity. Another challenge is over-smoothing, wherein DDIM may excessively smooth images, leading to a blurred or unrealistic appearance. In summary, DDIM stands out as a powerful and versatile sampler in the domain of image generation, excelling in quality, stability, and training efficiency. Nevertheless, users must be mindful of its potential limitations, specifically the risk of mode collapse and over-smoothing, to make informed decisions in its application.

LMS (Langevin Monte Carlo Sampler): LMS is a sampler that is based on the Langevin equation, which is a stochastic differential equation that describes the motion of a Brownian particle [7]. LMS is known for its ability to generate high-quality images, but it can be slow and computationally expensive.

The mathematical equation for LMS is as follows:

$$dxt = -\nabla U(xt)dt + \sqrt{2D}dt \quad (2)$$

where:

xt is the latent noise image at time step t

U(xt) is the potential energy function.

D is the diffusion coefficient

The potential energy function in the LMS serves as a metric for gauging the probability of the latent noise image, with LMS employing distinct potential energy functions tailored to specific image generation tasks. This adaptability enables LMS to excel in producing high-quality images across a spectrum of tasks.

Highlighting its strengths, LMS exhibits the ability to generate not only high-quality but also diverse images. However, these advantages come with trade-offs. LMS can be slow and computationally expensive, and its effectiveness relies on a trained potential energy function for each image generation task.

In the broader context, LMS emerges as a robust sampler for image generation, finding applications in tasks like image synthesis, inpainting, denoising, and super-resolution. Beyond image-related tasks, LMS extends its utility to other domains within machine learning, including natural language processing, computer vision, and reinforcement learning.

PNDM (Progressive Noise Diffusion Model): PNDM is a diffusion model sampler that is similar to DDIM, but it is more efficient and can generate higher-quality images at higher resolutions [8]. PNDM works by gradually a latent noise image, just like DDIM. However, PNDM uses a progressive approach, where it starts with the image at a low resolution and then gradually increases the resolution. This approach allows PNDM to generate high-quality images at higher resolutions without sacrificing efficiency.

The mathematical equation for PNDM is as follows:

$$xt+1 = xt + \alpha(xt - f(xt)) \quad (3)$$

xt is the latent noise image at time step t

α is the learning rate

f(xt) is the denoising function

The denoising function is a neural network that is trained to denoise images. PNDM uses a different denoising function for each resolution level. This allows PNDM to generate high-quality images at higher resolutions without sacrificing efficiency.

Here is a more detailed explanation of the PNDM algorithm: Start with a latent noise image, x0.

Select a resolution level, r.

Compute the denoising function, f(x0), at the selected resolution level.

Update the latent noise image, x0, using Eq. (4):

$$x1 = x0 + \alpha(x0 - f(x0)) \quad (4)$$

Repeat the steps until the latent noise image is sufficiently denoised. Increase the resolution level, r, and repeat the steps. Once the latent noise image is sufficiently denoised at the highest resolution level, stop the algorithm. The output of the PNDM algorithm is a denoised image, which can then be decoded into a final image.

PNDM can be slower than other samplers, such as Euler and Heun, especially at high resolutions. PNDM requires a trained denoising function for each resolution level. Overall, PNDM is a powerful sampler for image generation that can produce high-quality and diverse images at high resolutions.

Euler: Euler is a simple and efficient sampler that is often used as a baseline for other samplers. It is known for its speed, but it can produce less realistic images than other samplers [9]. The Euler method works by approximating the solution of the ordinary differential equations (ODE) at a given time step using the following Eq. (5):

$$xt+1 = xt + h * f(xt) \quad (5)$$

xt is the solution of the ODE at the time step t,

h is the step size,

f(xt) is the right-hand side of the ODE,

The Euler method is a first-order method, which means that it is not very accurate. However, it is very fast and efficient, and it can be used to generate approximate solutions to ODEs. To apply the Euler method to image generation, we can use it to sample from the latent space of a diffusion model. The latent space of a diffusion model is a space of high- dimensional vectors that represent images. Diffusion models work by gradually denoising latent noise images. To sample from the latent space using the Euler method, we can start with a random latent noise image and then iteratively update the image using the following equation:

$$xt+1 = xt + h * \nabla x \log p(xt) \quad (6)$$

Start with a latent noise image, x0 the function, f(x0). a noise term “epsilon” from a random distribution. the latent noise image x0. Repeat the steps until the latent noise image is sufficient. The output of the Euler A algorithm is an image, which can then be decoded into a final image.

Euler A: Euler A also known as Ancestral Euler, is a diffusion model sampler that is similar to Euler, but it is more efficient and can generate more diverse images [10]. It works by gradually a latent noise image, but it uses an ancestral sampling scheme that allows it to explore a wider range of possible image configurations. The mathematical Eq. (7) for Euler A is as follows:

$$xt+1 = xt + \alpha(xt - f(xt) + \epsilon) \quad (7)$$

xt is the solution of the ODE at time step t f (x) is the right-hand side of the ODE

h is the step size

Euler A is more efficient than Euler and can generate more diverse images. Euler a is more stable than other samplers, such as the Langevin Monte Carlo Sampler (LMS). Euler a stable to generate high-quality images. Euler a can be slower than other samplers, such as Euler, especially at high resolutions Euler A requires a trained function. Overall, Euler is a powerful sampler for image generation that can produce high-quality and diverse images.

Heun: Heun is a numerical method used for approximating the solutions of ordinary differential equations (ODEs) [11]. It is an advancement over Euler’s method, providing more realistic images at the cost of increased computational complexity. Represented as a second-order method, Heun’s approach involves predicting the solution at the next time step using Euler’s method and refining this prediction with the midpoint method. The iterative process continues until the desired accuracy is achieved. The mathematical equation for Heun’s method is as follows:

$$k1 = f(xt) \quad (8)$$

$$k2 = f(xt + hk1) \quad (9)$$

where:

xt is the latent noise image at time step t h is the step size

∇xlogp(xt) is the gradient of the log-probability of the latent noise image at time step t

where:

$$xt+1 = xt + 0.5h(k1 + k2) \quad (10)$$

The gradient of the log probability of the latent noise image can be computed using the diffusion model. By iteratively updating the latent noise image using the Euler method, we can generate a variety of different images. The quality and diversity of the generated images will depend on the step size and the number of iterations. The Euler method is very fast and efficient. The Euler method is easy to implement. The Euler method is not very accurate. The Euler method can be unstable for large step sizes. Overall, the Euler method is a simple and efficient sampler for image generation. It is not the most accurate sampler, but it is very fast and easy to implement.

While Heun is more accurate and stable than Euler, it comes at the expense of higher computational demands. The method is relatively straightforward to implement and remains stable across a broad range of step sizes. Despite being surpassed by more sophisticated numerical techniques in terms of accuracy, Heun serves as a reliable baseline method for scenarios where computational resources are limited, making it a pragmatic choice for approximating ODE solutions when striking a balance between accuracy and efficiency is crucial.

DPM2 (Denoising Diffusion Probabilistic Model 2):

Denoising Diffusion Probabilistic Model 2 (DPM2) stands out as a diffusion model sampler celebrated for its stability and capacity to yield high-quality images [12]. While sharing similarities with DDIM, DPM2 excels in efficiency and the generation of superior images, particularly at higher resolutions. The underlying mechanism involves iteratively denoising a latent noise image using a distinct denoising function. The core equation of DPM2 integrates this denoising process with guidance, encompassing the learning rate (α), denoising function (f(xt)), and guidance function (g(xt)).

$$xt+1 = xt + \alpha(xt - f(xt) + g(xt)) \quad (11)$$

where:

xt is the latent noise image at time step t

α is the learning rate

f (xt) is the denoising function

g(xt) is the guidance function.

These neural networks are crucial components, where the former refines image denoising, and the latter guides the process toward an intended output image. DPM2's algorithm unfolds in steps, initiating with a latent noise image and progressing through resolution levels, applying denoising and guidance functions. This process iterates until the latent noise image achieves sufficient denoising, and the algorithm progressively increases the resolution level until the highest is reached, concluding the generation of a denoised image. The decoded result becomes the final image.

DPM2's merits include its enhanced stability compared to other samplers like Euler and Heun, its prowess in generating high-quality images, and its ability to align generated images with a specified guidance image. However, there are drawbacks; DPM2 might be slower than alternative samplers, especially at high resolutions, and necessitates trained denoising and guidance functions for each resolution level.

DPM2a (Denoising Diffusion Probabilistic Model 2 ancestral): DPM2a (Denoising Diffusion Probabilistic Model 2 ances- tral) emerges as a noteworthy variant of the DPM2 diffusion model sampler, renowned for its capacity to generate more diverse images [13]. While sharing a fundamental resemblance with DPM2, DPM2a distinguishes itself through an ancestral sampling scheme, enabling exploration of a broader spectrum of potential image configurations.

$$xt+1 = xt + \alpha(xt - f(xt)) + \beta(xt - xt-1) \quad (12)$$

where:

xt is the latent noise image at time step t

α is the learning rate

β is the ancestral sampling rate

f (xt) is the denoising function

The mathematical formulation for DPM2a involves the latent noise image (xt), learning rate (α), ancestral sampling rate (β), and the denoising function (f(xt)), shared with DPM2. The ancestral sampling rate governs the influence of the latent noise image's previous state, with higher values enhancing image diversity but potentially slowing down the algorithm and introducing instability.

The DPM2a algorithm commences with a latent noise image, progresses through the selection of an ancestral sampling rate, computes the denoising function, and iteratively updates the latent noise image. This process repeats until the image achieves sufficient denoising, concluding the algorithm. Advantages of DPM2a include its capacity to generate more diverse images than DPM2 while still maintaining high-quality and relative stability. However, drawbacks include potential slowness compared to DPM2 and the requisite of a trained denoising function.

Fig. 1 illustrates the conceptual framework of our proposed system designed to investigate the impact of different samplers on a case study prompt—"a dog playing in a river." Utilizing a range of sampler filters, including DPM2a, DDIM, PNDM (PMS), Euler, Euler a, Heun, and LMS, our system incorporates a dedicated validation unit. This unit assesses both response time and reality score, with the aim of minimizing response time and maximizing realization score. In our study, an ideal realization score is defined as 1, a benchmark only achieved by the DDIM sampler. Furthermore, the generated images corresponding to the specified text prompt are systematically archived for potential future investigations.

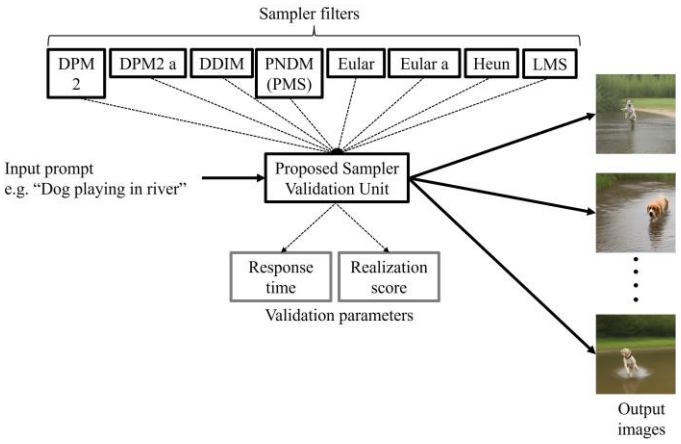

Fig. 1. Concept diagram of the proposed system for exploring sampler impact.

III. Literature Review

The field of artificial intelligence (AI) has seen significant contributions from various researchers across different domains. In (Hosny et al., 2018), a comprehensive understanding of AI methods, especially those related to image-based tasks, is established [14]. Moving from general AI to more specific applications, (Pereira et al., 2020) aims to conduct a thorough analysis of the necessity to integrate tumor information with other lung structures for the advancement of Computer-Aided Diagnosis (CADs), anticipating an impact on targeted therapies and personalized medicine [15]. The study by (Ibrahim et al., 2021) introduces a novel methodology for developing a detailed performance understanding of machine learning benchmarks [16]. While AI's benefits in marketing and advertising are well-documented, (Jeffrey, 2022) investigates the perceptions of Generation Z regarding AI in marketing. This research delves into levels of awareness, understanding, concerns about data privacy, and worries about psychological profiling, stereotyping, and manipulation [17].

(Nasari et al., 2022) undertake a performance comparison between Graphical Processing Units (GPUs) and Intelligence Processing Units (IPUs) by running training benchmarks of common AI/ML models [18]. In another exploration, (Cheng et al., 2023) assess the potential of GPT-4 in various branches of biomedical engineering, addressing challenges like ethical concerns and algorithmic biases [19]. (Alqahtani et al., 2023) contribute to the ongoing discussion about AI's role in education and research, emphasizing its potential to enhance outcomes for students, educators, and researchers [20]. Shifting focus to the realm of 3D object generation, (Sun et al., 2023) present UniG3D, a dataset addressing the limitations of existing 3D object datasets [21]. Lastly, (Tan et al., 2023) introduce DifFSS, the first work leveraging the diffusion model for Few-Shot Segmentation (FSS) tasks [22]. The landscape of AI research is dynamic and encompasses a wide array of applications, from medical diagnosis to marketing perceptions and educational enhancements, highlighting the need for interdisciplinary considerations and ethical frameworks, as underlined by influential works like (Joyce, 2010) [23].

While previous studies have made significant contributions to the field of AI image generation, there are certain limitations that our proposed approach aims to address. One notable limitation is the lack of comprehensive analysis on the impact of different sampling techniques on image quality and realism, particularly for specific use cases or prompts. Additionally, most studies focus on general image generation tasks, overlooking the unique challenges and requirements of generating images for specific scenarios, such as dogs playing in the river. Our proposed approach tackles these limitations by conducting a thorough investigation of various sampling techniques and their effects on image quality and realism, specifically for the case study of generating images of dogs playing in the river. Furthermore, we provide a systematic framework for selecting the most appropriate sampler based on project requirements, enabling more informed decision-making in AI image generation tasks.

IV. Methods

Eight distinct sampling filters constituted the crux of our experimentation, including DDIM (Denoising Diffusion Implicit Models), Euler a, DPM, DPM2a, PNDM (PMS), Euler, Heun, and LMS. Parameters for evaluation encompassed execution time (t) and the generation of realistic images. To maintain consistency, we employed specific experimental settings random seed "137927237," 25 iterations, prompt guidance set to 7, and fixed image size at 512x512 pixels. Each generative operation yielded four images, and our analysis focused on the realism of these images and the time investment for their creation.

Beyond performance metrics, our study concentrated on the utility of the generated images. We aimed to pinpoint the optimal sampler for the specific scenario of dogs playing in a river, a relatively unconventional but visually engaging context. The versatility of these images was considered for applications ranging from advertising dog-related products to enhancing the appeal of websites and desktop backgrounds. The proposed system, inclusive of the eight distinct filters, underwent rigorous validation using the Proposed Sampler Validation Unit, comparing the output against ground truth images. Evaluation metrics included response time, realization score, and validation parameters tailored to each filter.

The calculated realization score offered a comprehensive measure of system performance, considering the diverse set of filters. Output analysis involved the generation of eight distinct images corresponding to each filter, exemplifying how different filters processed the input prompt. This realization score facilitated nuanced comparisons of performance.

The system, designed to address a spectrum of image processing tasks, from classification to segmentation and denoising, demonstrated versatility. Beyond its immediate applications, the proposed system hinted at the potential for future developments in image processing filters and algorithms. In essence, our methodology ensured a meticulous exploration of samplers, combining performance evaluation with practical considerations in the realm of image generation.

The screenshot in Fig. 2 provides an overview of the Playground AI interface, showcasing a range of accessible options. These include the ability to rate generated images, engage with the community feed featuring images from other

users, and utilize the canvas-like Board for image generation and editing. Users can import existing images for further editing, organize their Board using columns, and experiment with different styles of image generation such as Euler, Heun, DPM2, and more. The interface incorporates features like DOIM for diffusion model image generation, PNDM (PLMS) for probabilistic neural diffusion model generation, and Euler as a method for solving differential equations. Filters can be applied, and users can exclude specific details from images. The text prompt, an integral component, guides image generation, while the Generate option brings the vision to life. A Private Session feature ensures the privacy of generated images. Playground AI emerges as a versatile tool, offering a spectrum of options for users to create images ranging from realistic to abstract, thereby establishing itself as a potent resource for image generation and editing.

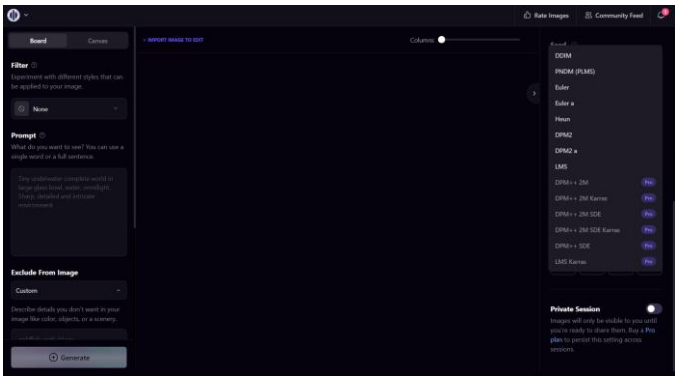

Fig. 2. Screenshot of the playground AI interface with all options visible.

The proposed system, inclusive of the eight distinct filters, each filter underwent rigorous validation using the Proposed Sampler Validation Unit, comparing the output against ground truth images. Evaluation metrics included response time, realization score, and validation parameters tailored to each filter. The calculated realization score offered a comprehensive measure of system performance, considering the diverse set of filters. Output analysis involved the generation of eight distinct images corresponding to each filter, exemplifying how different filters processed the input prompt. This realization score facilitated nuanced comparisons of performance.

In Fig. 3, the input command, exemplified by"Dog playing in River," is provided as the initial input. The subsequent step involves the selection of a sampler filter from a set of eight options using the algorithm"Select sampler filter." Once the sampler is chosen, the DiffusionNet CGAN (Conditional Generative Adversarial Network) is employed. The resulting output image is stored to facilitate validation. A check is implemented to verify whether all filters have been adequately tested; otherwise, the operation is halted. This process ensures a systematic approach to testing various sampler filters and capturing their output for thorough validation.

The ability to exclude specific details from images during the filtering process is a powerful feature of our proposed system. This capability is grounded in the principle of selective attention, which allows the model to focus on the most relevant aspects of the input prompt while disregarding unnecessary or distracting elements. By excluding specific details, the system can generate images that are more aligned with the intended subject matter, reducing visual clutter and enhancing the overall coherence and clarity of the output. The exclusion of specific details is particularly useful in scenarios where the input prompt may contain extraneous information or when the desired output requires a certain level of abstraction or stylization. For instance, in our case study of generating images of dogs playing in a river, excluding irrelevant background details could result in a more focused and visually appealing representation of the subject matter. Furthermore, the ability to exclude specific details can be leveraged to mitigate potential biases or undesirable elements that may be present in the training data or the input prompt. By carefully filtering out such elements, the generated images can better reflect the intended message or concept.

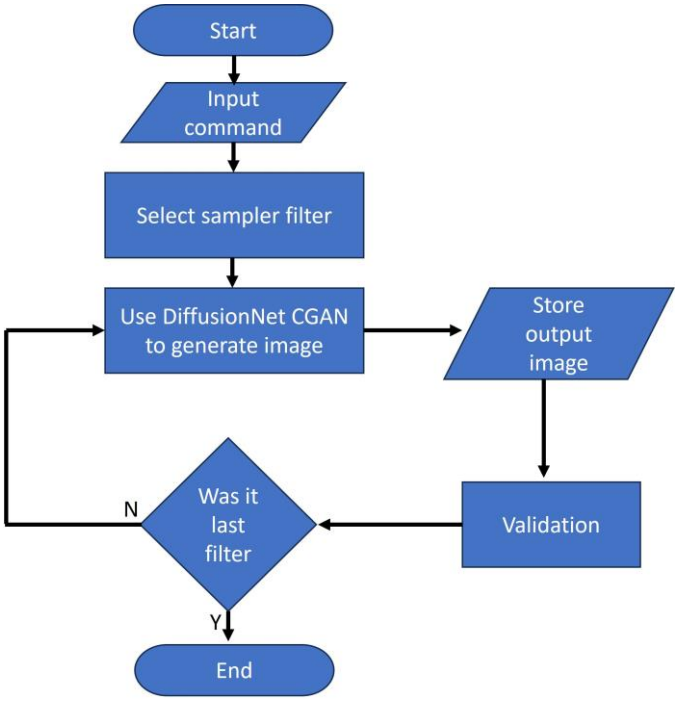

Fig. 3. Flowchart depicting the proposed mechanism for investigating the influence of samplers on AI generation.

Fig. 4(a) shows the effect of the sampler (filter) type used for AI-based image generation and the corresponding response time. The response time is the amount of time it takes for the model to generate an image from a given text prompt. The sampler type has a significant impact on the response time. The 'PNDM' and 'Euler a' samplers are the fastest, followed by the DPM, LMS, and Heun filters. The slowest sampler is the Euler type. Fig. 4(b) shows the sampler type used in AI image generation versus reality score of the generated images. The reality score is a measure of how realistic the generated images are. The sampler type also has a significant impact on the reality score. The DDIM sampler generates the most realistic images, followed by other samplers. The DPM2 and Euler sampler generate the least realistic images.

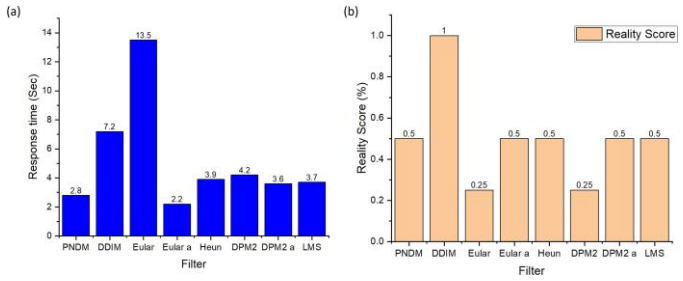

Fig. 4. Results obtained with proposed method (a) Filter type in AI image generation vs response time. (b) Filter type in AI image generation vs reality score in (%).

In general, there is a trade-off between response time and reality score. If you need to generate images quickly, you should use a faster sampler, such as Euler a. However, if you need to generate realistic images, you should use a slower filter, such as DDIM. If you need to generate realistic images at a moderate speed, you could use the PNDM sampler. Ultimately, the best sampler type for the project will depend on specific needs and requirements.

The images in Fig. 5 show a clear difference in the quality and realism of the generated images, depending on the sampler used. The PNDM and Euler a samplers produce the fastest results, but the images are also the least realistic. The DDIM and Euler samplers produce more realistic images, but they are also slower. The PNDM sampler strikes a balance between speed and realism. The dog in the PNDM image is blurry and the details are not very sharp. The water also looks unrealistic. The DPM image is sharper than the PNDM image, but the dog is still blurry in some places. The water looks more realistic, but it is still not perfect. The DPM2a image is sharper than the DPM image and the dog is no longer blurry. The water looks even more realistic. The DDIM image is the sharpest and most realistic image of all. The dog and the water are both very well-rendered. The Euler image is also very blurry and less realistic. The dog is poorly-rendered, and the water looks unnatural. The 'Euler a' image is much better than the Euler image, but it is slightly less sharp. The Heun image is not as sharp as the Euler a or DDIM images, but it is still more realistic than the DPM images. The LMS image is the blurry and least realistic image of all.

Fig. 5. Output images from each type of sampler for the prompt "dog playing in the river".

V. Results

The research underscores the significance of sampler selection in shaping the outcomes of AI image generation projects. The contextual analysis of a case study, where different samplers were evaluated for generating images of dogs playing in the river, illustrates the project-specific nature of this decision-making process. In this section, we discuss implications and findings that arise from the exploration of different samplers in the context of AI image generation. This study involved eight distinct sampling filters, each contributing unique characteristics to the generated images. The key factors evaluated were response time and the realism of the images, providing a nuanced understanding of the trade-offs involved in selecting a sampler for specific projects.

The DDIM sampler emerged as a consistent frontrunner in terms of image realism for this particular case study of dog image generation that plays in the river. This could be because of the iterative refinement approach of DDIM that sets it apart, enabling the generation of highly realistic images. This makes DDIM a compelling choice for projects where authenticity and visual fidelity are paramount, such as scientific studies or applications demanding a high level of image realism. On the other end of the spectrum, the PNDM sampler demonstrated a remarkable balance between response time and image realism. Its efficiency, coupled with the ability to produce realistic images, positions it as a versatile option suitable for a broad range of projects. The findings emphasize the importance of considering project requirements and objectives when selecting a sampler.

For instance, the Euler a sampler, with its combination of speed and reasonable realism, might be ideal for a marketing campaign requiring quick generation of high-quality images. The nuanced understanding of each sampler's strengths and weaknesses provides a practical guide for selecting the most appropriate sampler based on the specific requirements of a given project. This research lays the foundation for informed decision-making in the rapidly evolving field of AI image generation.

Our research has the potential to impact a diverse range of fields, including advertising, product design, and even dog training. For example, advertisers could leverage our findings to generate more engaging and effective marketing campaigns. Product designers could use our insights to create more realistic and appealing product prototypes. Additionally, dog trainers could utilize our research to develop more effective training methods.

Table I presents a comparison of different filters used in image processing along with their corresponding validation parameters and the number of images processed. The validation parameters include response time, realization score, and a calculated validation parameter. Response time indicates the time taken by each filter to process the images, with lower values being preferable as they indicate faster processing times. Realization score measures the effectiveness of each filter in achieving the desired outcome, with higher scores indicating better performance. The validation parameter is calculated using a formula based on the realization score and response time, providing an overall assessment of filter performance. The table enables the evaluation and comparison of filters based on these parameters, facilitating the selection of the most suitable filter for image processing tasks.

TABLE I. FILTER AND CORROSPONDING VALIDATION PARAMETERS

Filter	Validation parameter			Number of images
	Response time	*Realization score*	*Validation Parameter*	
PNDM	2.8	22	50.4	250
DDIM	7.2	39	7.2	250
Eular	13.5	11	391.5	250
Eular a	2.2	23	37.4	250
Heun	3.9	21	74.1	250
DPM2	4.2	12	117.6	250
DPM2 a	3.6	22	64.8	250
LMS	3.7	21	70.3	250

There is a clear difference in the quality and realism of the generated images, depending on the sampler used. The PNDM and Euler a samplers produce the fastest results, but the images are also the least realistic. The DDIM and Euler samplers produce more realistic images, but they are also slower. The PNDM sampler strikes a balance between speed and realism. The dog in the PNDM image is blurry, and the details are not very sharp. The water in the images generated also looks unrealistic. The DPM image is sharper than the PNDM image, but the dog is still blurry in some places. The water looks more realistic, but it is still not perfect. The DPM2a image is sharper than the DPM image, and the dog is no longer blurry. The water looks even more realistic. The DDIM image is the sharpest and most realistic image of all. The dog and the water are both very well-rendered. The Euler image is also very blurry and less realistic. The dog is poorly rendered, and the water looks unnatural. The 'Euler a' image is much better than the Euler image, but it is slightly less sharp. The Heun image is not as sharp as the Euler a or DDIM images, but it is still more realistic than the DPM images. The LMS image is the blurriest and least realistic image of all.

Our research has several potential future implications. First, it could inspire the development of new samplers that offer even better performance in terms of response time, image realism, or both. Second, it could lead to the development of new AI image generation tools that incorporate our findings to make them more user-friendly and effective. Third, it could inform the development of new applications for AI image generation in a wider range of fields.

We are excited to see how our research is used to advance the field of AI image generation and its applications in the future. PNDM is more efficient than DDIM and can generate higher- quality images at higher resolutions. PNDM is more stable than other samplers, such as Euler and PNDM is able to generate diverse images.

Our proposed model introduces several innovative contributions to the field of AI image generation, particularly in the context of evaluating and selecting appropriate samplers for specific use cases:

1) Comprehensive Sampler Evaluation Framework: Our study presents a systematic and holistic framework for evaluating the performance of various samplers in AI image generation. By considering a diverse set of eight samplers, including DDIM, Euler a, DPM, DPM2a, PNDM, Euler, Heun, and LMS, we provide a comprehensive understanding of their strengths, weaknesses, and trade-offs in terms of response time and image realism.

2) Case Study-Driven Approach: Our research adopts a novel case study-driven approach, focusing on the specific scenario of generating images of dogs playing in a river. This unconventional yet visually engaging context allows us to evaluate the samplers' performance in a real-world setting, providing practical insights that can inform decision-making processes for diverse applications.

3) Proposed Sampler Validation Unit: A key innovative aspect of our work is the introduction of the Proposed Sampler Validation Unit. This unit systematically validates the output of different samplers against ground truth images, employing a combination of quantitative metrics (response time and realization score) and qualitative analyses. This robust validation approach ensures a thorough assessment of the generated images, enabling informed selection of the most suitable sampler for a given task.

4) Versatile and Extensible Framework: Our proposed model is designed to be versatile and extensible, capable of addressing a wide range of image processing tasks, from classification and segmentation to denoising. Additionally, the framework lays the foundation for future developments in image processing filters and algorithms, fostering continued innovation and improvement in the field of AI image generation.

By presenting these innovative contributions, our research not only advances the understanding of sampler impact on AI image generation but also provides a practical and adaptable framework for researchers, developers, and practitioners to leverage in their respective domains.

VI. CONCLUSIONS

AI image generation is a rapidly evolving field with a wide range of potential applications. However, the quality and realism of generated images are highly dependent on the sampler type used. This paper presents a comprehensive study on the impact of eight distinct samplers on AI image generation, namely DPM, DPM2a, DDIM, PNDM, Euler, Euler a, Heun, and LMS.

Our findings reveal a nuanced landscape where response time and image realism form a delicate balance. Samplers such as PNDM and Euler a offer the fastest response times, making them ideal for projects where expeditious output is essential. Conversely, the Euler sampler, albeit slower, demonstrates superior performance in terms of image realism. In terms of image realism, the DDIM sampler consistently outperforms all others. This is attributed to its unique sampling approach, which iteratively refines the generated image to achieve greater realism. As such, the DDIM sampler is the best choice for projects where image authenticity is paramount.

The PNDM sampler strikes a balance between response time and image realism. It is faster than the DDIM sampler but still produces realistic images. This makes it a versatile option for a wide range of projects. Our research underscores the

importance of carefully selecting the appropriate sampler for each project. For instance, in the context of our case study on images of dogs playing in the river, we identified that the Euler a sampler would be the best choice for a marketing campaign that requires quick generation of high-quality images. Conversely, the DDIM sampler would be the better choice for a scientific study that requires highly realistic images of dogs playing in the river.

DECLARATIONS

A. Ethics Statements

All authors ensure that the manuscript fulfills the following statements:

1) This material is the author's original work, which has not been previously published elsewhere.

2) The paper is not currently being considered for publication elsewhere.

3) The paper reflects the author's own research and analysis truthfully and completely.

4) The paper properly credits the meaningful contributions of co-authors and researchers.

B. Availability of Data and Materials

Data and code will be made available, on reasonable request, to the corresponding author.

C. Funding Statement

This research has no funding associated with it.

D. Data Availability

Data will be made available at reasonable request to the authors.

E. Supplementary Information

Not applicable.

F. Ethical Approval

All the ethics approval was taken by an institutional review board or equivalent ethics committee.

G. Author Contributions

Conceptualization was done by Sanjay Deshmukh (SD). The experimental design was done by SD. All the experiments were performed by SD. The manuscript draft was prepared by SD. Data analysis and graphics designing were done by SD.

H. Conflicts of Interest or Competing Interests

The authors declare that there is no conflict of interest or competing interests.

Enhancing Ultimate Bearing Capacity Assessment of Rock Foundations using a Hybrid Decision Tree Approach

Mei Guo, Ren-an Jiang
College of Road and Bridge Engineering, Jilin Communications Polytechnic, Changchun Jilin, 130012, China

***Abstract*—Accurately estimating the ultimate bearing capacity of piles embedded in rock is of paramount importance in the domains of civil engineering, construction, and foundation design. This research introduces an innovative solution to tackle this issue, leveraging a fusion of the Decision Tree method with two state-of-the-art optimization algorithms: the Zebra Optimization Algorithm and the Coronavirus Herd Immunity Optimizer. The research approach encompassed the creation of a hybridized model, unifying the DT with the Zebra Optimization Algorithm and Coronavirus Herd Immunity Optimizer. The primary objective was to augment the precision of the ultimate bearing capacity of prediction for piles embedded in rock. This hybridization strategy harnessed the capabilities of DT along with the two pioneering optimizers to address the inherent uncertainty stemming from diverse factors impacting bearing capacity. The Zebra Optimization Algorithm and Coronavirus Herd Immunity Optimizer showcased their efficacy in refining the base model, leading to substantial enhancements in predictive performance. This study's discoveries make a significant stride in the realm of geotechnical engineering by furnishing a sturdy approach to forecasting ultimate bearing capacity in rock-socketed piles. The hybridization method is a hopeful path for future research endeavors and practical implementations. Specifically, the DT + Zebra Optimization Algorithm model yielded dependable outcomes, as evidenced by their impressive R-squared value of 0.9981 and a low Root mean squared error value of 629.78. The attained outcomes empower engineers and designers to make well-informed choices concerning structural foundations in soft soil settings. Ultimately, this research advocates for safer and more efficient construction methodologies, mitigating the hazards linked to foundation failures.**

Keywords*—Ultimate bearing capacity; decision tree; zebra optimization algorithm; coronavirus herd immunity optimizer

I. Introduction

A. Background

Pile foundations are essential for the structural load transmission into the ground, guaranteeing the stability of the structure. Precisely assessing the load-bearing capacity of piles holds paramount importance in planning geotechnical structures [1]. Numerous experimental and theoretical approaches established in the past for predicting pile capacity rely on assumptions related to the factors governing the ultimate bearing capacity (Q_u) [2]. Nevertheless, owing to the intricate behavior of piles, nearly all of the existing methods and models fall short of delivering precise predictions, and a considerable number of them are tailored to specific construction sites [3].

While the static load test (SLT) remains the most reliable approach for evaluating pile-bearing capacity, its implementation can be a time-consuming, expensive, and demanding process [4]. An advanced method for forecasting the bearing capacity of piles is high-strain dynamic testing ($HSDT$). This method relies on wave propagation theory and is executed by utilizing a pile-driving analyzer (PDA). The HSDT process is usually standardized according to American Standard Test Methods [5]. Previous studies have revealed a strong correlation between the bearing capacity projected through PDA and values anticipated through SLT.

Moreover, PDA (HSDT) offers the advantages of enhanced speed and cost-effectiveness when compared to SLT. However, the attainment of trustworthy results mandates the execution of multiple PDA tests for every construction project. Hence, the aim to reduce the necessary number of PDA tests is of great significance, as it would reduce overall project costs. In pursuit of this goal, novel techniques such as artificial intelligence (AI) have surfaced, demonstrating the ability to provide more accurate forecasts of pile-bearing capacity and expedite solutions for complex engineering problems compared to traditional methods [6].

B. Literature Review

Machine learning (ML) methods have recently become pivotal in civil engineering and geotechnical projects. They streamline labor-intensive engineering procedures and substantially contribute to these projects' cost efficiency. Additionally, numerous research studies utilize ML techniques to estimate the Q_u (ultimate bearing capacity) of rocks [7,8]. Yagiz et al. [9] presented ANN models, whereas Jahed Armaghani et al. [10] introduced adaptive neuro-fuzzy inference system ($ANFIS$) models to forecast rock strength. Concurrently, Singh et al. [11] recorded the effective application of an $ANFIS$ estimation model to estimate the Young's modulus of rock. In another study, Shirani Faradonbeh et al. [12] conducted research focused on developing a genetic programming (GP) technique for predicting backbreak caused by blasting. Monjezi et al. [13] applied ANN models to forecast ground vibration, whereas Marto et al. [14] utilized imperial competitive algorithm (ICA)-ANN models to predict fly rock incidents in their studies. Azimi et al. [15] also proposed a new control method, called Swarm-Based Parallel Control (SPC), inspired by the intelligence of swarms in

nature. In this study, sharing the response data among adjacent buildings using a wireless sensor network (WSN) at each floor is proposed to improve the seismic performance and minimize the risks of knocking.

In foundation design and analysis, these methodologies have garnered extensive usage. For example, Chan et al. [13] introduced an ANN model as a substitute for developing pile-driving formulas. In this scenario, the neural network was trained to employ data associated with the pile configuration, the energy employed during pile driving, and the elastic compression of the pile and the soil, with the ultimate bearing capacity (Q_u) of the pile as the network's output. In a separate investigation by Pal and Deswal [16], they developed two soft computing approaches, namely ANN and support vector machine (SVM), to evaluate the Q_u of concrete spun pipe piles. Their results demonstrated that among the models examined, ANN delivered the highest level of predictive accuracy. Shahin et al. [17] designed an ANN predictive model for foreseeing the bearing capacity of drilled shafts. In a distinct study, Jianbin et al. [18] evidenced the effectiveness of ANN in forcating the axial bearing capacity (ABC) of pipe piles in sandy soil. They included significant factors like the effective length and diameter of the pile, soil cohesion, unit weight, internal friction angle, and results from the standard penetration test (SPT) in the development of the network. In another research endeavor, Yu Lei et al. [19] conducted a comparative study involving six hybrid models that incorporated neural networks in conjunction with six different swarm intelligence optimization algorithms, including the innovative Seagull Optimization Algorithm (SOA). These hybrid models were evaluated against the predictive capabilities of two single models without any optimization techniques in forecasting Uniaxial Compressive Strength. Moreover, other researchers have contributed to the advancement of meta-heuristic algorithms. For instance, Agushaka [20] conducted studies aimed at enhancing arithmetic optimization, while Gaurav Dhiman et al. [21] focused on refining the Seagull Optimization Algorithm. These efforts collectively contribute to developing and improving hybrid models that leverage both ML techniques and advanced optimization methods for enhanced predictive accuracy.

C. Objective

This research introduces a novel ML approach to attain precise and optimal predictions. The hybridization method employed in this study is custom-tailored to enhance the performance of DT models, guaranteeing reliable outcomes. Through the combination of 2 cutting-edge and effective optimization techniques, namely the Zebra Optimization Algorithm (ZOA) and the Coronavirus Herd Immunity Optimizer (CHIO, the creation of these innovative hybrid models exceeded the capabilities of traditional methods, marking a substantial leap forward. A thorough assessment was carried out on these models, individually and in hybrid setups, to guarantee a fair and unbiased evaluation of their performance. To ensure the trustworthiness of the outcomes, the evaluation of model outputs included well-recognized performance metrics such as R^2 and RMSE. This approach played a crucial role in mitigating any possible bias in the results, offering a more precise understanding of the models' effectiveness. In addition to the technical aspects, this study acknowledged the practical importance of these discoveries. The increased precision achieved with the hybrid models holds the promise of improving decision-making in real-world geotechnical engineering projects, thus reducing the risks associated with inaccurate Q_u estimations. The ability of the DT model to provide dependable predictions, whether applied individually or in hybrid configurations, highlights their flexibility and appropriateness for various project needs.

II. Materials and Methodology

A. Data Gathering

In ML projects, the careful choice of input variables and the precise definition of desired outputs are crucial for attaining optimal model performance. An extensive set of input variables is systematically gathered from published literature [22]. It is important to reiterate, as highlighted in multiple references, including [23], that the pile's dimensions, particularly its length and diameter, play a paramount role in determining the Q_u. Therefore, to consider the impact of rock and soil layers, 2 ratios associated with pile geometry were chosen: the ratio of length within the soil layer (Ls) to socket length (Lr), and the ratio of total length (Lt) to diameter (D).

In summary, the model inputs for estimating the Q_u of rock-socketed piles consisted of $Ls/Lr, Lt/D, UCS,$ and $SPT\ N$ −value. In addition, Hr is the height of the layer. These inputs were chosen to simplify the predictive model using smaller parameters. Table I indicates the statistical properties of these inputs and Q_u. Fig. 1 presents a column plot for determining the input frequency in correlation with Q_u.

TABLE I. The Statistical Properties of the Input Variable of Q_u

Variables		Indicators			
	Category	***Min***	***Max***	***Avg***	***St. Div***
Lp/D	Input	4.331	96.30	31.39	22.57
Ls/Lr	Input	0.29	31.71	4.86	5.66
N_SPT	Input	0.00	166.42	44.67	59.57
UCS	Input	0.00	68.49	24.23	23.55
Hr	Input	0.00	8.36	0.79	1.50
Qu	Output	1449.00	42700.73	17421.79	10230.86

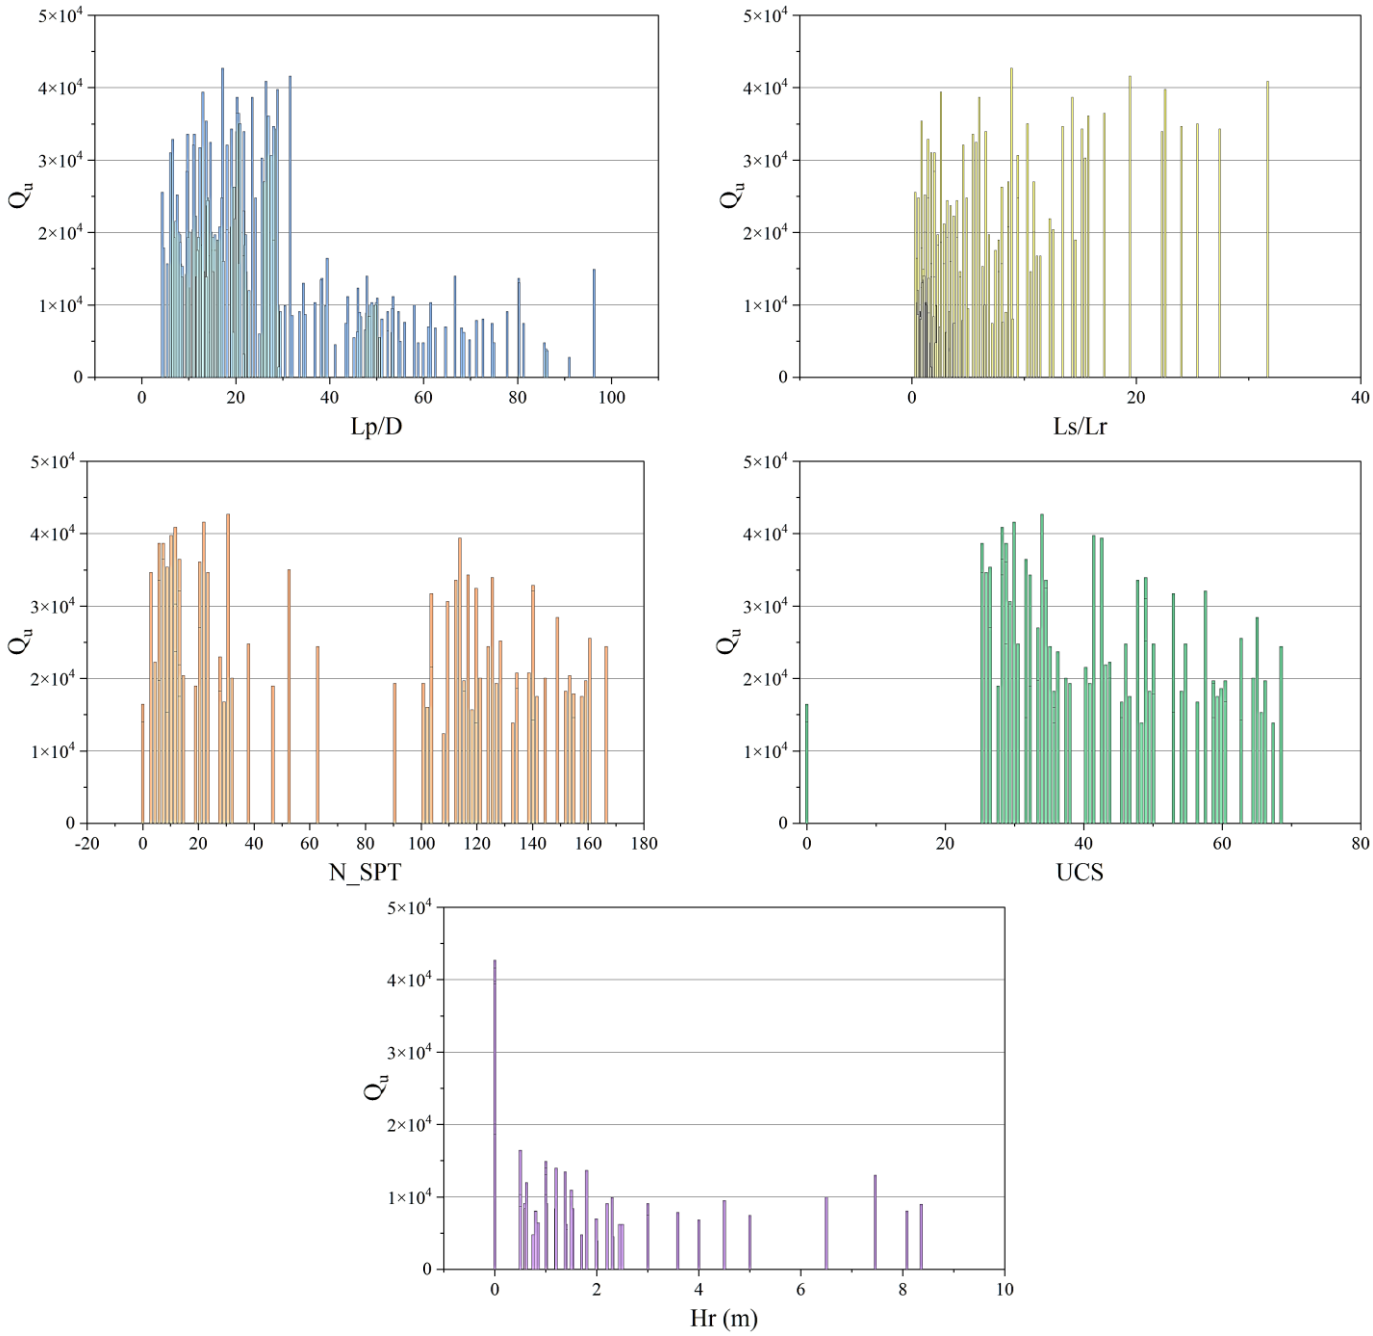

Fig. 1. The column plot between input and output.

B. DT

Derived from ML theory, a DT functions as a potent instrument for proficiently tackling regression and classification challenges. In contrast to other classification techniques that rely on a combined set of features for one-step classification, the DT employs a multi-stage or hierarchical decision approach, displaying a structure resembling a tree [24]. In contrast to other classification methods that depend on a unified set of features for immediate classification, the DT employs a multi-stage or hierarchical decision approach, showcasing a structure that resembles a tree. This tree includes a root node housing all the data, a sequence of splits (*internal nodes*) , and an assortment of leaves (*terminal nodes*) [25]. Within the DT structure, each node performs a binary decision, separating either a singular class or a subset of classes from the remaining ones. Typically, the process entails traversing the tree from the top to the bottom, following a top-down methodology [26].

1) Decision tree regression (DTR): As shown in Fig. 2, a distinct regression tree is built for every class to enable soft classification. Within the context of regression trees, the target vector is the defined class proportions of a pixel, also known as soft reference data, whilst the pixel intensity values from

various bands function as estimator feature vectors or variables. The technique generates predicted class proportions as an output by using the intensity values as input for each individual regression tree [27]. The steps involved in creating regression trees using the training dataset are as follows:

a) Employ the pixel intensity values from different bands as the variables that predict.

b) Employ the known class fraction of class i within the target variable, a pixel.

c) Create the regression tree specific to class i.

d) Iterate through the process for class i, varying from 1 to M.

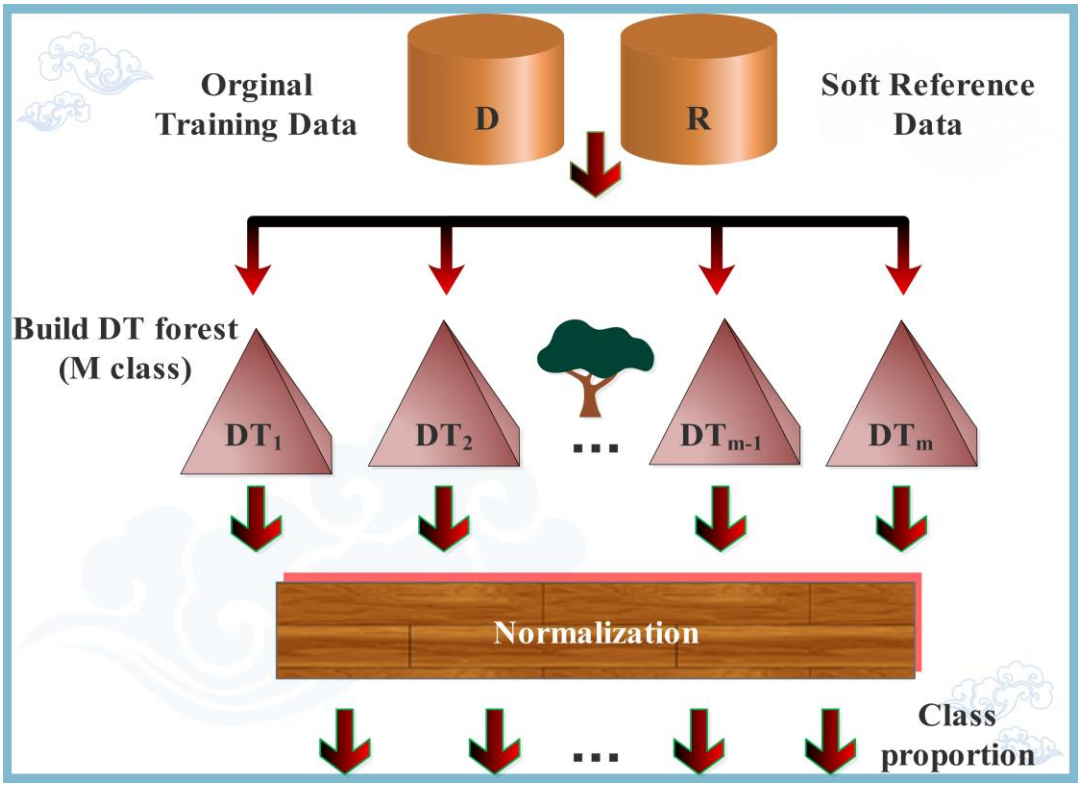

Fig. 2. The DT regression technique facilitates the soft classification of remote sensing data.

The regression tree algorithm for soft categorization is as follows:

1) Input the pixel intensity values from various bands.

2) Execute the regression tree for class i.

3) Retrieve the output of regression tree i, which represents the fraction of class i in a pixel.

4) Repeat the process for class i, ranging from 1 to M.

It is common practice to rescale the soft classification outputs to a range of 0 to 1 for each pixel, indicating the class fractions within the ground pixel area. Thus, the estimated class proportions from each tree, denoted as $DT(i)\ for\ i = 1,\dots,M$, undergo normalization through the following process:

$$P(i) = \frac{DT(i)}{\sum DT(i)}, i = 1, \dots, M \quad (1)$$

C. Zebra Optimization Algorithm (ZOA)

Zebras are included in the cohort population of ZOA, a population-based optimization method. It updates its members by utilizing 2 innate behaviors seen in wild zebras. These include hunting and gathering food as well as protecting oneself from predators. Therefore, the ZOA population members receive updates in 2 distinct stages for each iteration [28].

1) Foraging behavior: Zebras predominantly graze on grasses and sedges; however, they might turn to buds, bark, fruits, roots, and leaves when their preferred food is scarce. During the initial stage, updates to the population members are executed by simulating zebra behavior while searching for food. The amount of time zebras dedicate to eating can vary between 60-80 percent, contingent on the quality and accessibility of vegetation. Among zebras, the plains zebra stands out as a primary grazer. It consumes the upper canopy of grass, which is often less nutritious, creating an environment conducive for other species that rely on Shorter and more nutrient-rich grasses. In ZOA [29], the lead zebra is regarded as the top-performing member of the population and directs other members toward its location in the search area. Consequently, the adjustment of zebra positions during the foraging stage can be expressed mathematically utilizing Eq. (2) and (3).

$$x_{i,j}^{new,p_1} = x_{i,j} + e \times (BM_j - I \times x_{i,j}) \quad (2)$$

$$x_i = \begin{cases} x_i^{new,p_1}, F_i^{new,p_1} < f_i \\ x_i \qquad otherwise \end{cases} \quad (3)$$

In this context, x_i^{new,p_1} represents the updated state of the ith zebra, with $x_{i,j}^{new,p_1}$ denoting its value in the jth dimension and F_i^{new,p_1} indicating its updated objective function value. The lead zebra, referred to as BM, stands as the top-performing member, and BM_j signifies its value in the jth dimension [30]. The value of i is determined using a random number e, which can be any value between 0 and 1. The round function $(1 + rand)$ is then used to round the value of i to the closest integer. The parameter i has 2 possible values: 1 and 2. Setting i to 2 results in more significant changes in population mobility.

2) Defense strategies against predators: Updates to the positions of ZOA residents in the search area are made in the second stage by using simulations of a zebra's defensive maneuvers against predator attacks. Not only do lions pose a threat to zebras, but wild dogs, leopards, brown hyenas, and cheetahs also pose a hazard, each of which calls for a different approach to defense. Zebras defend themselves against lion attacks by using zigzag patterns and occasional sideways spins as evasive maneuvers. Zebras usually react more aggressively to smaller predators such as hyenas and dogs. They regroup and cause chaos to make their enemies more difficult to deal with. In the context of ZOA, the assumption is that lions or other predators may initiate an attack, prompting zebras to decide between an escape strategy when facing lions or an offensive approach against other predators [31]. The escape strategy is represented by mode S1, while the defensive strategy, where the herd forms a protective structure, is represented by mode S2. A zebra's new position is valid if it results in an improved objective function value.

$$x_{i,j}^{new,p_2} = \begin{cases} S1: x_{i,j} + E \times (2e-1) \times \left(1 - \frac{t}{T}\right) \times x_{i,j}, P_s \leq 0.5 \\ S2: x_{i,j} + e \times \left(BM_j - I \times x_{i,j}\right), \qquad otherwise \end{cases} \quad (4)$$

$$x_i = \begin{cases} x_i^{new,p_2}, F_i^{new,p_2} < f_i \\ x_i \qquad otherwise \end{cases} \quad (5)$$

In this context, the constant E is fixed at 0.01, and P_s represents the likelihood of selecting one of two methods at random from the range [0,1]. BM refers to the condition of the zebra under attack, where BM_j signifies its value in the jth dimension.

D. Coronavirus Herd Immunity Optimizer (CHIO)

The algorithm for optimization introduced in this study integrates the concept of herd immunity, drawing parallels between the principles of $COVID-19$ and the optimization process [32]. The steps that make up the $CHIO$ are listed below, with a detailed explanation of each. The algorithm explores each of the 6 primary phases in the parts that follow [33, 34].

Phase 1: To fit the optimization difficulty's context, the objective function is formulated as follows during the $CHIO$ and optimization problem's initialization phase:

$$minO(x) \quad x \in [lb, ub] \quad (6)$$
